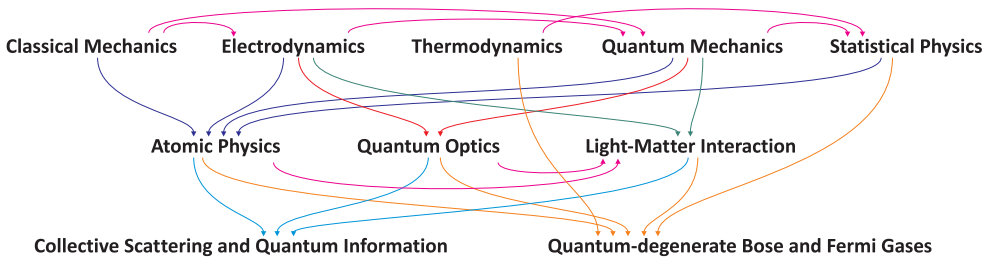
Preface

This script is a synthesis of several lectures for graduate students in physics given at São Carlos Physics Institute of the University of São Paulo in the years between 2010 and 2025.

It is organized into parts. Parts I to V review the fundamental theories edifying the framework of physics: classical mechanics, electrodynamics, thermodynamics, quantum mechanics, and statistical physics. Despite the existence of deep connections between these theories, each one of these parts can be studied separately without knowledge of the others. On the other hand, while parts VI to VIII can be studied separately from each other, they apply the notions of all previous parts I to V to the fields of atomic and molecular physics, quantum optics, and light-matter interaction and deepen the theoretical toolbox mainly of quantum mechanics. Parts IX to X on collective effects and quantum degenerate matter can, again, be studied separately, but require knowledge from all previous parts I to VIII. Finally, part XI is a lab course, which can be studied independently from all other parts.



The targeted audience of the script, particularly of the parts VI to XI, are mainly experimental and applied physicists working in the area of quantum optics and atomic physics. While many notions might prove useful for other areas of physics, the examples and exercises are mostly taken from the fields of laser physics and cold gases.

The pdf version of the script stands out by the fact that it features many cross-links between sections, equations, figures, examples, and exercises that can be directly accessed by mouse clicks. It also provides many links to supplementary information. For instance, references to literature are linked via the DOI of the publication. Solutions of exercises can be downloaded by clicking on the title of the exercise in the script. Numerical codes used to prepare the figures (generally written in Matlab or Julia) are available by clicking on the figure captions. Didactic movies and presentations can be accessed from web repositories. At the end of each chapter a list of references for further reading is linked to DOI or ISBN repositories.

The purpose of the script is to provide a synthesis of existing knowledge, not to relate novel results. I tried to consistently mark passages or sections borrowed from other scripts or adapted from internet resources, such as Wikipedia.

In order to increase the visibility of important messages some definitions, fundamental laws, and essential results are emphasized by colored boxes.

The script is still under elaboration and being updated on a monthly basis. Critical comments and suggestions for improvements or corrections are very welcome.

Philippe W. Courteille, São Carlos, March 2025

Content

I Classical Mechanics **1**

1 Foundations and mathematical formalism **5**
1.1 General considerations on physics . . . 5
1.1.1 What is physics . . . 5
1.1.2 Structure of physics . . . 7
1.1.3 Exercises . . . 12
1.2 Infinitesimal calculus . . . 13
1.2.1 Derivation . . . 13
1.2.2 Integration . . . 14
1.2.3 Exercises . . . 14
1.3 Complex numbers . . . 16
1.3.1 Basic rules . . . 16
1.3.2 Exercises . . . 17
1.4 Differential equations . . . 18
1.4.1 First order differential equations . . . 18
1.4.2 Second order differential equations . . . 18
1.4.3 Exercises . . . 19
1.5 Scalars, vectors and matrices . . . 20
1.5.1 Vector algebra . . . 20
1.5.2 Matrices . . . 22
1.5.3 Transformation of vectors . . . 23
1.5.4 Exercises . . . 25
1.6 Further reading . . . 28

2 Dynamics of point masses **29**
2.1 Motion of point masses . . . 29
2.1.1 One-dimensional motion . . . 29
2.1.2 Motion in two and three dimensions . . . 31
2.1.3 Newton's laws . . . 33
2.1.4 Exercises . . . 34
2.2 Kinetic and potential energy . . . 38
2.2.1 Conservative potentials . . . 38
2.2.2 Conservation of energy . . . 39
2.2.3 Translations and rotations of point masses, Galilei boost . . . 39
2.2.4 Exercises . . . 40
2.3 Friction . . . 47
2.3.1 Exercises . . . 47
2.4 Many-body systems . . . 51
2.4.1 Balance of forces . . . 51
2.4.2 Center-of-mass . . . 51

2.4.3 Collisions and conservation of linear momentum 52
2.4.4 Exercises 53
2.5 Further reading 61

3 Rotations and dynamics of rigid bodies 63
3.1 Rotation about a fixed axis 63
3.1.1 Transformation into a rotating system 65
3.1.2 Exercises 65
3.2 The rigid body 68
3.2.1 Translations and rotations: linear and angular momentum . . . 69
3.2.2 Rotational energy and moment of inertia 70
3.2.3 Rotation dynamics about a fixed axis 71
3.2.4 Static equilibrium of a rigid body 71
3.2.5 Constant acceleration 71
3.2.6 Exercises 71
3.3 Angular momentum 77
3.3.1 Torque and angular momentum of a particle system 77
3.3.2 Rotational work-energy relation 78
3.3.3 Conservation of angular momentum 78
3.3.4 Combination of translation and rotation 78
3.3.5 Exercises 80
3.4 Further reading 86

4 Vibrations 87
4.1 Free periodic motion 87
4.1.1 Clocks 87
4.1.2 Periodic trajectories 88
4.1.3 Simple harmonic motion 89
4.1.4 The spring-mass system 90
4.1.5 Energy conservation 90
4.1.6 The spring-mass system with gravity 92
4.1.7 The pendulum 92
4.1.8 The spring-cylinder system 95
4.1.9 Two-body oscillation 95
4.1.10 Exercises 96
4.2 Superposition of periodic movements 104
4.2.1 Rotations and complex notation 104
4.2.2 Lissajous figures 104
4.2.3 Vibrations with equal frequencies superposed in one dimension 106
4.2.4 Frequency beat 106
4.2.5 Amplitude and frequency modulation 107
4.2.6 Exercises 108
4.3 Damped and forced vibrations 109
4.3.1 Damped vibration and friction 109
4.3.2 Forced vibration and resonance 112
4.3.3 Exercises 114
4.4 Coupled oscillations and normal modes 118

4.4.1 Two coupled oscillators . . . 119
4.4.2 Normal modes . . . 119
4.4.3 Normal modes in large systems . . . 120
4.4.4 Dissipation in coupled oscillator systems . . . 121
4.4.5 Exercises . . . 122
4.5 Further reading . . . 123

5 Waves 125
5.1 Propagation of waves . . . 125
5.1.1 Transverse waves, propagation of pulses on a rope . . . 126
5.1.2 Longitudinal waves, propagation of sonar pulses in a tube . . . 127
5.1.3 Electromagnetic waves . . . 129
5.1.4 Harmonic waves . . . 131
5.1.5 Wave packets . . . 131
5.1.6 Dispersion . . . 132
5.1.7 Exercises . . . 135
5.2 The Doppler effect . . . 136
5.2.1 Sonic Doppler effect . . . 136
5.2.2 Wave equation under Galilei transformation . . . 138
5.2.3 Wave equation under Lorentz transformation . . . 140
5.2.4 Relativistic Doppler effect . . . 141
5.2.5 Exercises . . . 142
5.3 Interference . . . 144
5.3.1 Standing waves . . . 144
5.3.2 Interferometry . . . 146
5.3.3 Diffraction . . . 147
5.3.4 Plane and spherical waves . . . 148
5.3.5 Formation of light beams . . . 149
5.3.6 Exercises . . . 155
5.4 Fourier analysis . . . 159
5.4.1 Expansion of vibrations . . . 160
5.4.2 Theory of harmony . . . 161
5.4.3 Expansion of waves . . . 162
5.4.4 Normal modes in continuous systems at the example of a string 162
5.4.5 Waves in crystalline lattices . . . 163
5.4.6 Exercises . . . 166
5.5 Matter waves . . . 169
5.5.1 Dispersion relation and Schrödinger's equation . . . 169
5.5.2 Matter waves . . . 170
5.5.3 Exercises . . . 171
5.6 Further reading . . . 171

6 Gravitation 173
6.1 Planetary orbits . . . 173
6.1.1 Kopernicus' laws . . . 173
6.1.2 Kepler's laws . . . 174
6.1.3 Exercises . . . 174

6.2 Newton's law . . . 176
6.2.1 Cosmic velocities . . . 176
6.2.2 Deriving Kepler's laws from Newton's laws . . . 177
6.2.3 Exercises . . . 178
6.3 Gravitational potential . . . 178
6.3.1 Rotation and divergence of gravitational force fields . . . 181
6.3.2 Gravity gradients . . . 181
6.3.3 Constants of motion . . . 183
6.3.4 The virial law . . . 183
6.3.5 Exercises . . . 184
6.4 Outlook on general relativity . . . 190
6.4.1 Gravitational red-shift . . . 190
6.4.2 Exercises . . . 191
6.5 Further reading . . . 191

7 Hydrodynamics 193
7.1 Hydrostatics . . . 193
7.1.1 Buoyancy and Archimedes' principle . . . 193
7.1.2 Exercises . . . 194
7.2 Hydrodynamics . . . 196
7.2.1 Continuity and Navier-Stokes equations . . . 196
7.2.2 Exercises . . . 196
7.3 Further reading . . . 198

8 Appendices to 'Classical Mechanics' 199
8.1 Constants and units in classical physics . . . 199
8.1.1 Constants . . . 199
8.1.2 Units . . . 201
8.2 Quantities and formulas in classical mechanics . . . 202
8.2.1 Particular forces . . . 202
8.2.2 Inertial momentum . . . 203
8.2.3 Inertial forces due to transitions to translated and rotated systems 203
8.2.4 Conservation laws . . . 203
8.2.5 Rigid bodies, minimum required number of equations of motion 203
8.2.6 Gravitational laws . . . 203
8.2.7 Volume elements . . . 204
8.2.8 Oscillations $ma + bv + kx = F_0 \cos \omega t$ . . . 204
8.3 Probability distributions . . . 204
8.3.1 Binomial distribution . . . 204
8.3.2 Poisson distribution . . . 204
8.3.3 Gaussian distribution . . . 205
8.3.4 Some useful formulae . . . 205

II Electrodynamics 207

9 Foundations and mathematical formalism 211
9.1 Differential calculus . . . 212

9.1.1 Scalar and vector fields . . . 212
9.1.2 The gradient . . . 212
9.1.3 The divergence . . . 214
9.1.4 The rotation . . . 215
9.1.5 Taylor expansion of scalar and vector fields . . . 215
9.1.6 Rules for calculation with derivatives . . . 216
9.1.7 Exercises . . . 217
9.2 Integral calculus . . . 219
9.2.1 Path integral . . . 219
9.2.2 Surface integral . . . 220
9.2.3 Volume integral . . . 221
9.2.4 Fundamental theorem for gradients . . . 221
9.2.5 Stokes' theorem . . . 222
9.2.6 Gauß' theorem . . . 223
9.2.7 Exercises . . . 224
9.3 Curvilinear coordinates . . . 227
9.3.1 Differential elements in curvilinear coordinates . . . 227
9.3.2 Gradient in curvilinear coordinates . . . 228
9.3.3 Divergence in curvilinear coordinates . . . 228
9.3.4 Rotation in curvilinear coordinates . . . 229
9.3.5 Cylindrical coordinates . . . 230
9.3.6 Spherical coordinates . . . 231
9.3.7 Differential operators for tensor fields . . . 232
9.3.8 Exercises . . . 233
9.4 Differential geometry in curved space . . . 237
9.4.1 Co- and contravariant tensors . . . 237
9.4.2 Jacobian for coordinate transformations . . . 237
9.4.3 Metric and geodesic equation in Euclidean space . . . 239
9.4.4 Exercises . . . 241
9.5 Dirac's δ-function . . . 242
9.5.1 The Dirac function in 1 dimension . . . 243
9.5.2 The Dirac function in 2 and 3 dimensions . . . 244
9.5.3 Analytical signals . . . 244
9.5.4 Exercises . . . 247
9.6 Further reading . . . 249

10 Electrostatics **251**
10.1 The electric charge and the Coulomb force . . . 251
10.1.1 Quantization and conservation of the charge . . . 251
10.1.2 Coulomb's law . . . 252
10.1.3 Exercises . . . 253
10.2 Properties of the electric field . . . 257
10.2.1 Field lines and the electric flux . . . 258
10.2.2 Divergence of the electric field and Gauß' law . . . 259
10.2.3 Rotation of the electric field and Stokes' law . . . 260
10.2.4 Exercises . . . 261
10.3 The scalar electrical potential . . . 268

10.3.1 The equations of Laplace and Poisson 269
10.3.2 Potential generated by localized charge distributions 270
10.3.3 Electrostatic boundary conditions 270
10.3.4 Exercises 271
10.4 Electrostatic energy 275
10.4.1 Energy of a charge distribution 275
10.4.2 Energy density of an electrostatic field 276
10.4.3 Dielectrics and conductors 277
10.4.4 Induction of charges (influence) 278
10.4.5 Electrostatic pressure 279
10.4.6 Exercises 280
10.5 Treatment of boundary conditions and the uniqueness theorem 281
10.5.1 The method of images charges 282
10.5.2 Formal solution of the electrostatic problem 283
10.5.3 Green's Function 284
10.5.4 Poisson equation with Dirichlet's boundary conditions 285
10.5.5 Poisson equation with von Neumann's boundary conditions . . 286
10.5.6 Exercises 286
10.6 Solution of the Laplace equation in situations of high symmetry 290
10.6.1 Variable separation in Cartesian coordinates 290
10.6.2 Variable separation in cylindrical coordinates 291
10.6.3 Variable separation in spherical coordinates 291
10.6.4 Exercises 293
10.7 Multipolar expansion 294
10.7.1 The monopole 295
10.7.2 The dipole 296
10.7.3 The quadrupole 296
10.7.4 Expansion into Cartesian coordinates 297
10.7.5 Exercises 298
10.8 Further reading 303

11 Electrical properties of matter 305
11.1 Polarization of dielectrics 305
11.1.1 Energy of permanent dipoles 305
11.1.2 Induction of dipoles in dielectrics 307
11.1.3 Macroscopic polarization 308
11.1.4 Electrostatic field on a polarized or dielectric medium 308
11.1.5 Electric displacement 310
11.1.6 Electrical susceptibility and permittivity 311
11.1.7 Exercises 312
11.2 Influence of charges and capacitance 313
11.2.1 Capacitors and storage of electric energy 313
11.2.2 Exercises 315
11.3 Conduction of current and resistance 323
11.3.1 Motion of charges in dielectrics and conductors 324
11.3.2 Ohm's law, stationary currents in continuous media 324
11.3.3 Exercises 326

11.4 The electric circuit . . . 327
11.4.1 Kirchhoff's rules . . . 328
11.4.2 Measuring instruments . . . 329
11.4.3 Exercises . . . 329
11.5 Further reading . . . 336

12 Magnetostatics 339
12.1 Electric current and the Lorentz force . . . 339
12.1.1 The Hall effect . . . 341
12.1.2 Biot-Savart's law . . . 342
12.1.3 Exercises . . . 344
12.2 Properties of the magnetic field . . . 348
12.2.1 Field lines and magnetic flux . . . 348
12.2.2 Divergence of the magnetic field and Gauß's law . . . 348
12.2.3 Rotation of the magnetic field and Ampère's law . . . 349
12.2.4 Exercises . . . 351
12.3 The magnetic vector potential . . . 354
12.3.1 The Laplace and Poisson equations . . . 354
12.3.2 Magnetostatic boundary conditions . . . 356
12.3.3 Exercises . . . 357
12.4 Multipolar expansion . . . 360
12.4.1 Multipolar magnetic moments . . . 360
12.4.2 Exercises . . . 361
12.5 Further reading . . . 366

13 Magnetic properties of matter 367
13.1 Magnetization . . . 367
13.1.1 Energy of permanent dipoles and paramagnetism . . . 367
13.1.2 Impact of magnetic fields on electronic orbits and diamagnetism 368
13.1.3 Macroscopic magnetization . . . 371
13.1.4 Magnetostatic field of a magnetized material . . . 371
13.1.5 The H-field . . . 372
13.1.6 Magnetic susceptibility and permeability . . . 373
13.1.7 Exercises . . . 376
13.2 Induction of currents and inductance . . . 379
13.2.1 The electromotive force . . . 379
13.2.2 The Faraday-Lenz law . . . 381
13.2.3 Exercises . . . 383
13.3 Magnetostatic energy . . . 391
13.3.1 Energy density of a magnetostatic field . . . 391
13.3.2 Inductors and storage of magnetostatic energy . . . 392
13.3.3 Exercises . . . 392
13.4 Alternating current . . . 395
13.4.1 Electromagnetic oscillations . . . 395
13.4.2 Alternating current circuits . . . 396
13.4.3 Exercises . . . 397
13.5 Further reading . . . 402

14 Maxwell's equations **405**
14.1 The fundamental laws of electrodynamics . . . 406
14.1.1 Helmholtz's theorem . . . 408
14.1.2 Potentials in electrodynamics . . . 408
14.1.3 The macroscopic Maxwell equations . . . 409
14.1.4 The fundamental laws in polarizable and magnetizable materials 416
14.1.5 Exercises . . . 417
14.2 Conservation laws in electromagnetism . . . 420
14.2.1 Charge conservation and continuity equation . . . 421
14.2.2 Energy conservation and Poynting's theorem . . . 421
14.2.3 Conservation of linear momentum and Maxwell's stress tensor . 422
14.2.4 Conservation of angular momentum of the electromagnetic field 428
14.2.5 Exercises . . . 429
14.3 Potential formulation of electrodynamics . . . 431
14.3.1 The vector and the scalar potential . . . 431
14.3.2 Gauge transformation . . . 432
14.3.3 Green's function . . . 435
14.3.4 Retarded potentials of continuous charge distributions . . . 436
14.3.5 Retarded fields in electrodynamics and Jefimenko's equations . 440
14.3.6 The Liénard-Wiechert potentials . . . 441
14.3.7 The fields of a moving point charge . . . 443
14.3.8 Exercises . . . 447
14.4 Further reading . . . 449

15 Electromagnetic waves **451**
15.1 Wave propagation . . . 451
15.1.1 Helmholtz's equation . . . 453
15.1.2 The polarization of light . . . 454
15.1.3 The energy density and flow in plane waves . . . 458
15.1.4 Slowly varying envelope approximation . . . 459
15.1.5 Plane waves in linear dielectrics and the refractive index . . . 460
15.1.6 Reflection and transmission by interfaces and Fresnel's formulas 460
15.1.7 Transfer matrix formalism . . . 467
15.1.8 Exercises . . . 470
15.2 Optical dispersion in material media . . . 476
15.2.1 Plane waves in conductive media . . . 476
15.2.2 Linear and quadratic dispersion . . . 479
15.2.3 Microscopic dispersion and the Lorentz model . . . 482
15.2.4 Classical theory of radiative forces . . . 486
15.2.5 Light interaction with metals and the Drude model . . . 492
15.2.6 Causality connecting $\vec{\mathcal{D}}$ with $\vec{\mathcal{E}}$ and the Kramers-Kronig relations 494
15.2.7 Exercises . . . 498
15.3 Plasmons, waveguides and resonant cavities . . . 501
15.3.1 Green's tensor for wave propagation in dielectric media . . . 501
15.3.2 Plasmons at metal-dielectric interfaces . . . 506
15.3.3 Negative refraction and metamaterials . . . 509
15.3.4 Wave guides . . . 513

15.3.5 The coaxial line . . . 515
15.3.6 Cavities . . . 516
15.3.7 Exercises . . . 519
15.4 Beam and wave optics . . . 523
15.4.1 Gaussian optics . . . 523
15.4.2 Non-Gaussian beams . . . 530
15.4.3 Fourier optics . . . 531
15.4.4 Exercises . . . 535
15.5 Further reading . . . 537
15.5.1 on optics . . . 537
15.5.2 on metamaterials . . . 537

16 Radiation 539
16.1 Multipolar expansion of the radiation . . . 539
16.1.1 The radiation of an arbitrary charge distribution . . . 539
16.1.2 Multipolar expansion of retarded potentials . . . 542
16.1.3 Radiation of an oscillating electric dipole . . . 545
16.1.4 Magnetic dipole and electric quadrupole radiation . . . 548
16.1.5 Multipolar expansion of the wave equation . . . 550
16.1.6 Exercises . . . 555
16.2 Radiation of point charges . . . 557
16.2.1 Power radiated by an accelerated point charge . . . 558
16.2.2 Radiation reaction . . . 561
16.2.3 Exercises . . . 565
16.3 Diffraction and scattering . . . 568
16.3.1 Coupled dipoles model . . . 569
16.3.2 The limit of the Mie scattering and the role of the refractive index 572
16.3.3 Exercises . . . 575
16.4 Further reading . . . 575

17 Theory of special relativity 577
17.1 Relativistic metric and Lorentz transform . . . 578
17.1.1 Ricci's calculus, Minkowski's metric, and space-time tensors . . . 578
17.1.2 Lorentz transform . . . 580
17.1.3 Contraction of space . . . 582
17.1.4 Dilatation of time . . . 582
17.1.5 Transformational behavior of the wave equation . . . 583
17.1.6 The Lorentz boost . . . 587
17.1.7 Exercises . . . 591
17.2 Relativistic mechanics . . . 592
17.2.1 The inherent time of an inertial system . . . 592
17.2.2 Adding velocities . . . 594
17.2.3 Relativistic momentum and rest energy . . . 594
17.2.4 Relativistic Doppler effect . . . 596
17.2.5 Relativistic Newton's law . . . 597
17.2.6 Uniform acceleration . . . 598
17.2.7 Exercises . . . 598

17.3 Relativistic electrodynamics . . . 600
17.3.1 Relativistic current and magnetism . . . 600
17.3.2 Electromagnetic potential and tensor . . . 603
17.3.3 Lorentz transformation of electromagnetic fields . . . 604
17.3.4 Energy and momentum tensor . . . 606
17.3.5 Solution of the covariant wave equation . . . 608
17.3.6 Emission of radiation by a charged particle in gravity . . . 609
17.3.7 Exercises . . . 609
17.4 Lagrangian formulation of electrodynamics . . . 610
17.4.1 Relation with quantum mechanics . . . 610
17.4.2 Classical mechanics of a point particle in a field . . . 611
17.4.3 Generalization to relativistic mechanics . . . 614
17.4.4 Symmetries and conservation laws . . . 616
17.4.5 Exercises . . . 617
17.5 Relativistic gravity . . . 618
17.5.1 Metric and geodesic equation in curved space-time . . . 618
17.5.2 Schwarzschild metric . . . 619
17.5.3 Christoffel symbols for relativistic space-time, geodesic equation 620
17.5.4 Exercises . . . 620
17.6 Further reading . . . 621

18 Appendices to 'Electrodynamics' 623
18.1 Special topic: Goos-Hänchen shift with light and matter waves . . . 623
18.1.1 Evanescent wave potentials . . . 623
18.1.2 Energy flux in the evanescent wave . . . 624
18.1.3 Imbert-Fedorov shift . . . 626
18.1.4 Matter wave Goos-Hänchen shift at a potential step . . . 626
18.2 Special topic: The dilemma of Abraham and Minkowski . . . 627
18.2.1 Calculation of the momentum of light in a dielectric medium . 628
18.2.2 Exercises . . . 629
18.3 Special topic: Advanced Gaussian optics . . . 629
18.3.1 Laguerre-Gaussian beams . . . 629
18.3.2 Exercises . . . 634
18.4 Special topic: Superconductivity . . . 635
18.4.1 London model of superconductivity and the Meissner effect . . 635
18.4.2 BCS theory . . . 637
18.4.3 Josephson junctions . . . 639
18.4.4 Synchronization of coupled Josephson junctions . . . 640
18.4.5 Exercises . . . 643
18.5 Quantities and formulas in electromagnetism . . . 645
18.5.1 Electromagnetic quantities . . . 645
18.5.2 Formulas of special relativity . . . 647
18.5.3 CGS units . . . 647
18.6 Rules of vector analysis . . . 648
18.6.1 Basic rules . . . 648
18.6.2 Deduced rules . . . 649
18.6.3 Integral rules . . . 650

18.7 Rules for Laplace and Fourier transforms 651
18.7.1 Laplace transform 651
18.7.2 Correlation 651
18.7.3 Fourier transform 652
18.7.4 Convolution 654
18.7.5 Green's functions 655
18.8 Further reading 656
18.8.1 on the Abraham-Minkowski dilemma 656

III Thermodynamics 659

19 Foundations and mathematical formalism 663
19.1 Phenomenological thermodynamics at equilibrium 663
19.1.1 Temperature 665
19.1.2 Kinetic theory and microscopic interpretation of temperature . 667
19.1.3 Heat and work 670
19.1.4 Exercises 675
19.2 Canonical formulation of thermodynamics 681
19.2.1 Tackling thermodynamic systems 681
19.2.2 The laws of thermodynamics 684
19.2.3 Thermodynamic potentials 688
19.2.4 Strategy for deriving thermodynamic relations 694
19.2.5 Ideal gases 696
19.2.6 Cyclic processes 702
19.2.7 Real gases, liquids and solids 706
19.2.8 Exercises 709
19.3 Thermodynamic equilibrium 720
19.3.1 Conditions for equilibrium 721
19.3.2 Entropy maximization in two-phase systems, chemical potential 722
19.3.3 Exercises 723
19.4 Thermodynamic ensembles 723
19.4.1 Coupling of thermodynamic ensembles to reservoirs 725
19.4.2 Thermodynamic potentials associated to specific ensembles . . 725
19.4.3 Exercises 727
19.5 Further reading 727

20 Thermodynamics applied to fluids and solids 729
20.1 Unary heterogeneous systems 729
20.1.1 Unary phase diagrams in PT-space 729
20.1.2 The Clausius-Clapeyron equation, latent heat 733
20.1.3 Vacuum technology 737
20.1.4 Exercises 740
20.2 Multi-component, homogeneous, non-reacting systems 742
20.2.1 The Gibbs-Duhem equation 742
20.2.2 Partial molal properties 743
20.2.3 Chemical potential in solutions 748
20.2.4 Models of real solutions 752

20.2.5 Osmotic pressure . . . 753
20.2.6 Exercises . . . 755
20.3 Multi-component, heterogeneous, non-reacting systems . . . 756
20.3.1 Equilibrium conditions . . . 756
20.3.2 Structure of phase diagrams . . . 758
20.3.3 Exercises . . . 758
20.4 Continuous, non-uniform systems exposed to external forces . . . 759
20.4.1 Thermodynamic densities . . . 759
20.4.2 Equilibrium conditions . . . 760
20.4.3 Exercises . . . 765
20.5 Reacting systems . . . 765
20.5.1 Univariant chemical reactions in the gas phase . . . 766
20.5.2 Multi-variant chemical reactions in the gas phase . . . 768
20.5.3 Exercises . . . 771
20.6 Classification of thermodynamic phase transitions . . . 771
20.6.1 Solid-liquid-vapor . . . 772
20.6.2 Bose-Einstein condensation . . . 772
20.7 Materials . . . 772
20.7.1 Electrons in solids . . . 772
20.7.2 Plasmas . . . 774
20.7.3 Exercises . . . 776
20.8 Further reading . . . 776

21 Out-of-equilibrium thermodynamics 777
21.1 Out-of-equilibrium statistics . . . 777
21.1.1 Boltzmann's transport equation . . . 777
21.1.2 Stoßzahlansatz . . . 778
21.1.3 H theorem and Fokker-Planck equation . . . 779
21.2 Thermodynamic approaches to out-of-equilibrium systems . . . 779
21.2.1 Irreversibility . . . 779
21.2.2 Dissipative structures and synergetics . . . 781
21.2.3 Friction and diffusion . . . 787
21.2.4 Non-equilibrium quantum phase transitions . . . 787
21.2.5 Fluctuation-dissipation theorem . . . 787
21.2.6 Long-range interactions . . . 788
21.3 Further reading . . . 789

22 Appendices to 'Thermodynamics' 791
22.1 Data tables . . . 791
22.1.1 Material data . . . 791
22.1.2 Vacuum technology . . . 791

IV Quantum Mechanics 795

23 Foundations and mathematical formalism 799
23.1 The discovery of the atom . . . 801
23.1.1 Democrit's model . . . 801

23.1.2 Thomson's model and Rutherford's experiment 802
23.1.3 Emission of radiation in the planetary model 806
23.1.4 Zeeman effect in the planetary model 808
23.1.5 Bohr's theory and its limitations 809
23.1.6 Exercises 810
23.2 The discovery of the photon 812
23.2.1 Radiation in a conductive cavity 812
23.2.2 Black body radiation 814
23.2.3 Planck's distribution of modes 816
23.2.4 The corpuscular nature of the photon 817
23.2.5 Einstein's transitions rates 819
23.2.6 Absorption spectrum for a single atom 820
23.2.7 Absorption in a gas 823
23.2.8 Saturation 824
23.2.9 Exercises 826
23.3 Basic notions 828
23.3.1 Dispersion relation and Schrödinger equation 829
23.3.2 Relativistic particle waves 830
23.3.3 Born's interpretation 832
23.3.4 Continuity equation 832
23.3.5 Distributions in space and time 833
23.3.6 Eigenvalues 834
23.3.7 Temporal evolution of eigenvalues 834
23.3.8 Exercises 835
23.4 Postulates of quantum mechanics 835
23.4.1 Superposition principle (1. postulate) 836
23.4.2 Interpretation of the wavefunction (2. postulate) 836
23.4.3 Dirac bra-ket notation and vector representation 836
23.4.4 Observables (3. postulate) 837
23.4.5 Representation of operators as matrices 838
23.4.6 Correspondence principle (4. postulate) 840
23.4.7 Schrödinger equation and quantum measurements (5. postulate) 840
23.4.8 Stationary Schrödinger equation 841
23.4.9 Exercises 842
23.5 Abstract formalism of quantum mechanics 843
23.5.1 Lie algebra 843
23.5.2 Complete bases 844
23.5.3 Degeneracy 845
23.5.4 Bases as unitary operators 846
23.5.5 Complete set of commuting operators 847
23.5.6 Uncertainty relation 848
23.5.7 Representations 848
23.5.8 Spanning a Hilbert space with several degrees of freedom . . . 850
23.5.9 Exercises 858
23.6 Time evolutions 860
23.6.1 Unitary transformations 860
23.6.2 Schrödinger picture 860

23.6.3 Heisenberg picture 861
23.6.4 Interaction picture 863
23.6.5 Hamiltonian under arbitrary unitary transformation 864
23.6.6 Ehrenfest's theorem 865
23.6.7 Exercises 866
23.7 Symmetries in quantum mechanics 867
23.7.1 Translation, rotation and momentum kick 867
23.7.2 Transformation to accelerated and rotating frames 871
23.7.3 Composite transformations, Galilei boost 872
23.7.4 Gauge transformations 874
23.7.5 Noether's theorem and conservation laws 875
23.7.6 Exercises 878
23.8 Further reading 879

24 Linear motion / Separable potentials 881
24.1 Translational motion 881
24.1.1 Quadratic integrability 881
24.1.2 Separation of dimensions 882
24.1.3 Homogeneous force fields, gravity 882
24.1.4 Exercises 882
24.2 Rectangular potentials 883
24.2.1 Box potential 883
24.2.2 Multidimensional box potential 884
24.2.3 Potentials with several sections of constant depths 884
24.2.4 Potential well 885
24.2.5 Exercises 887
24.3 Potential barrier 887
24.3.1 $\mathcal{T}$-scattering matrix 888
24.3.2 $\mathcal{S}$-scattering matrix 888
24.3.3 Quantum reflection at a potential step 889
24.3.4 Continuity of probability flow 890
24.3.5 Tunneling and quantum reflection at a potential well 890
24.3.6 The delta-potential 891
24.3.7 Exercises 896
24.4 Numerical approaches for arbitrary potentials 897
24.4.1 Calculation of free and bound states wavefunctions 897
24.4.2 The Fourier grid method for bound states 897
24.4.3 Steepest descent ot the ground state 901
24.4.4 Exercises 902
24.5 Harmonic oscillator 903
24.5.1 Factorization of the Hamiltonian and Fock states 904
24.5.2 Harmonic oscillator in spatial representation 906
24.5.3 Properties of the harmonic oscillator 908
24.5.4 Time evolution of the unperturbed harmonic oscillator 909
24.5.5 Multidimensional harmonic oscillator 910
24.5.6 Exercises 910
24.6 Superposition states of a harmonic oscillator 911

24.6.1 Coherent states . . . 911
24.6.2 Kicking a harmonic oscillator . . . 915
24.6.3 Shaking a harmonic oscillator . . . 921
24.6.4 Forcing a harmonic oscillator . . . 922
24.6.5 Quantization of the electromagnetic field . . . 927
24.6.6 Exercises . . . 928
24.7 Further reading . . . 930
24.7.1 on the Fourier grid method . . . 931
24.7.2 on the harmonic oscillator . . . 931

25 Rotations / Central potentials 933
25.1 Particle in a central potential . . . 933
25.1.1 Transformation to relative coordinates . . . 933
25.1.2 Particle in a cylindrical potential . . . 934
25.1.3 Hamiltonian in spherical coordinates . . . 936
25.1.4 Separation of radial motion . . . 938
25.1.5 Exercises . . . 939
25.2 Quantum treatment of hydrogen . . . 940
25.2.1 Bohr's model . . . 941
25.2.2 The virial theorem . . . 946
25.2.3 Exercises . . . 946
25.3 Angular momentum . . . 948
25.3.1 The orbital angular momentum operator . . . 948
25.3.2 SU(2) algebra of angular momentum and spin . . . 949
25.3.3 The electron spin . . . 950
25.3.4 Exercises . . . 950
25.4 Coupling of angular momenta . . . 952
25.4.1 Singlet and triplet states with two electrons . . . 952
25.4.2 Coupling two spins . . . 954
25.4.3 Decoupled and coupled bases . . . 955
25.4.4 Clebsch-Gordan coefficients . . . 958
25.4.5 Exercises . . . 960
25.5 Further reading . . . 963

26 Periodic systems 965
26.1 The Bloch model for electrons . . . 965
26.1.1 Tight binding approximation for quasi-bound electrons . . . 967
26.1.2 Approximation for quasi-free electrons . . . 969
26.1.3 The Kronig-Penney model . . . 971
26.1.4 Bloch oscillations . . . 972
26.1.5 Exercises . . . 973
26.2 One-dimensional optical lattices . . . 973
26.2.1 Translations and accelerations in periodic potentials . . . 974
26.2.2 Band structure in the Bloch state basis . . . 977
26.2.3 Localization and tunneling in the Wannier state basis . . . 982
26.3 Bloch oscillations . . . 991
26.3.1 Bloch oscillations in shallow lattices in momentum space . . . 991

26.3.2 Bloch oscillations in the tight binding regime in position space 995
26.3.3 Extensions of the Bloch-Wannier model 999
26.3.4 Exercises 1000
26.4 Further reading 1002

27 Approximation methods 1005
27.1 Stationary perturbations 1005
27.1.1 Time-independent perturbation theory 1005
27.1.2 TIPT with degenerate states 1007
27.1.3 Exercises 1010
27.2 Variational method 1013
27.2.1 The Rayleigh fraction 1013
27.2.2 Rayleigh-Ritz method 1014
27.2.3 Exercises 1015
27.3 WKB approximation 1015
27.3.1 WKB approximation applied to the Schrödinger equation . . . 1016
27.3.2 Connection formulas 1017
27.3.3 Exercises 1022
27.4 Time-dependent perturbations 1022
27.4.1 Two-level systems 1022
27.4.2 The time-dependent perturbation method 1023
27.4.3 Specific perturbations 1025
27.4.4 Transition rates for higher-order perturbations 1029
27.4.5 Exercises 1032
27.5 Further reading 1034

28 Appendices to 'Quantum Mechanics' 1035
28.1 Quantities and formulas in quantum mechanics 1035
28.1.1 Notations and conventions 1035
28.1.2 Atomic units 1036
28.2 Clebsch-Gordan and Wigner symbols 1036
28.2.1 Clebsch-Gordan symbols 1036
28.2.2 $\{3j\}$-symbols 1037
28.2.3 $\{6j\}$-symbols 1037
28.2.4 $\{9j\}$-symbols 1037
28.3 Functions and polynomials 1038
28.3.1 The Gauss function 1038
28.3.2 Bessel functions 1038
28.3.3 Hermite polynomials 1039
28.3.4 Laguerre polynomials 1039
28.3.5 Legendre polynomials 1040
28.3.6 Spherical harmonics 1040
28.3.7 Vector spherical harmonics 1041
28.4 Further reading 1041

V Statistical Physics and Atomic Quantum Fields 1043

29 Statistical thermodynamics 1047
29.1 Microstates, macrostates, and entropy . . . 1047
29.1.1 Probabilities of microstates and the partition function . . . 1047
29.1.2 Equilibrium in statistical thermodynamics . . . 1049
29.1.3 Thermodynamic potentials in canonical ensembles . . . 1051
29.1.4 Two-level systems . . . 1052
29.1.5 Einstein-Debye model of solids . . . 1052
29.1.6 Maxwell-Boltzmann distribution of ideal gases . . . 1054
29.1.7 Exercises . . . 1055
29.2 Quantum statistics . . . 1059
29.2.1 Wavefunction symmetrization and detailed balance . . . 1059
29.2.2 Microcanonical ensembles of indistinguishable particles . . . 1060
29.2.3 Density-of-states in a trapping potential . . . 1065
29.2.4 Grand canonical ensembles of ideal quantum gases . . . 1067
29.2.5 Thermodynamic limit and Riemann's zeta function . . . 1077
29.2.6 Exercises . . . 1079
29.3 Condensation of an ideal Bose gas . . . 1080
29.3.1 Condensation of a gas confined in a box potential . . . 1080
29.3.2 Condensation of a harmonically confined gas . . . 1084
29.3.3 Density and momentum distribution for a Bose gas . . . 1087
29.3.4 Exercises . . . 1090
29.4 Quantum degeneracy of an ideal Fermi gas . . . 1092
29.4.1 Chemical potential and Fermi radius for a harmonic trap . . . 1092
29.4.2 Energy . . . 1093
29.4.3 Entropy and heat capacity . . . 1094
29.4.4 Density and momentum distribution for a Fermi gas . . . 1095
29.4.5 Density and momentum distribution for anharmonic potentials 1100
29.4.6 Signatures for quantum degeneracy of a Fermi gas . . . 1102
29.4.7 Fermi gas in reduced dimensions . . . 1104
29.4.8 Exercises . . . 1106
29.5 Further reading . . . 1106
29.5.1 on quantum statistics . . . 1106
29.5.2 on ideal quantum gases . . . 1106

30 Quantum theory of non-relativistic scalar ... 1107
30.1 Quantizing scalar fields . . . 1108
30.1.1 Wavefunction (anti-)symmetrization for atom pairs . . . 1108
30.1.2 Identical particles and exchange operator . . . 1110
30.1.3 Exercises . . . 1115
30.2 Occupation number representation . . . 1115
30.2.1 Number states in the N-body Hilbert space . . . 1115
30.2.2 Field operators . . . 1116
30.2.3 Correlations . . . 1118
30.2.4 Exercises . . . 1118
30.3 Quantum statistics . . . 1121

30.3.1 Exercises 1121

31 Appendices to 'Statistical Physics' 1123
31.1 Quantities and formulas in statistical physics 1123
31.1.1 Statistical formulas 1123
31.1.2 Polylogarithm 1123
31.2 Special topic: Microcanonical ensembles 1124
31.2.1 Density of states 1125
31.2.2 Entropy 1126
31.2.3 Calculating with the microcanonical ensemble 1130
31.2.4 Classical ideal gas 1132
31.2.5 Quantum statistics 1133
31.2.6 Exercises 1135

VI Atomic and Molecular Physics 1137

32 Electron spin and the atomic fine structure 1141
32.1 The Dirac equation 1141
32.1.1 The Klein-Gordon equation for bosons 1141
32.1.2 The Dirac equation for fermions 1142
32.1.3 The relativistic electron in a central Coulomb field 1147
32.1.4 The Pauli equation 1154
32.1.5 Exercises 1156
32.2 Fine structure of hydrogen-like atoms via TIPT 1158
32.2.1 Correction for relativistic velocities 1158
32.2.2 Correction due to spin-orbit coupling 1159
32.2.3 Non-local electron-core interaction 1162
32.2.4 Summary of the corrections 1163
32.2.5 Lamb shift 1164
32.2.6 Exercises 1164
32.3 Hyperfine structure 1164
32.3.1 Coupling to the nuclear spin 1165
32.3.2 Electric quadrupole interaction 1169
32.3.3 Exercises 1170
32.4 Exotic atoms 1171
32.4.1 Positronium and muonium 1172
32.4.2 Hadronic atoms 1172
32.4.3 Muonic hydrogen 1173
32.4.4 Rydberg atoms 1173
32.4.5 Exercises 1176
32.5 Further reading 1176

33 Atoms with spin in external fields 1177
33.1 Charged particles in electromagnetic fields 1177
33.1.1 Lagrangian and Hamiltonian of charged particles 1177
33.1.2 Minimal coupling 1178
33.1.3 Exercises 1179

33.2 Interaction with magnetic fields 1180
33.2.1 Normal Zeeman effect of the fine structure 1180
33.2.2 Anomalous Zeeman effect 1180
33.2.3 Paschen-Back effect and intermediate magnetic fields 1181
33.2.4 Zeeman effect of the hyperfine structure 1183
33.2.5 Paschen-Back effect of the hyperfine structure 1184
33.2.6 Landau levels in 2D systems subject to magnetic fields 1187
33.2.7 Exercises 1190
33.3 Interaction with electric fields 1192
33.3.1 Stark Effect 1192
33.3.2 Exercises 1193
33.4 Further reading 1194

34 Atoms with many electrons 1195
34.1 Symmetrization of bosons and fermions 1195
34.1.1 Pauli's Principle 1197
34.1.2 Consequences for quantum statistics 1198
34.1.3 Exercises 1199
34.2 Helium 1199
34.2.1 The ground state 1200
34.2.2 Excited states 1201
34.2.3 Exercises 1205
34.3 Electronic shell structure 1205
34.3.1 TIPT method 1206
34.3.2 Thomas-Fermi model for an electron gas 1206
34.3.3 Hartree method 1211
34.3.4 Hartree-Fock method 1212
34.3.5 Exercises 1214
34.4 The periodic system of elements 1214
34.4.1 Electronic shell model 1215
34.4.2 LS and jj-coupling 1217
34.4.3 Summary of contributions to the atomic energy levels 1219
34.4.4 Exercises 1221
34.5 Further reading 1222

35 Molecular dimers 1225
35.1 Molecular binding 1226
35.1.1 Ionic and covalent binding 1226
35.1.2 Born-Oppenheimer approximation and the $H_2{}^+$ molecule . . . 1227
35.1.3 Linear combination of orbitals and the H_2 molecule 1230
35.1.4 Molecular orbital theory 1230
35.1.5 Valence binding 1234
35.1.6 Exercises 1236
35.2 Rovibrational structure of molecular potentials 1238
35.2.1 The radial and angular equations 1238
35.2.2 Vibrational molecular states 1239
35.2.3 The Franck-Condon principle 1243

35.2.4 Rotational progression 1246
35.2.5 Computation of vibrational states 1247
35.2.6 Exercises 1252
35.3 Van der Waals forces and spin coupling 1253
35.3.1 Analytical models for short and long-range potentials 1254
35.3.2 Spin coupling in dimers, molecular quantum numbers 1255
35.3.3 Hund's coupling cases 1256
35.3.4 Molecular hyperfine structure 1257
35.3.5 Exercises 1257
35.4 Further reading 1258

36 Collisions 1259
36.1 Motion of interacting neutral atoms 1259
36.1.1 The collisional phase shift 1261
36.1.2 Hard-sphere potentials 1264
36.1.3 Spherical wells with a flat bottom 1265
36.1.4 Other types of potentials 1275
36.1.5 Exercises 1282
36.2 Scattering theory 1283
36.2.1 Lippmann-Schwinger equation 1283
36.2.2 Wave packets 1285
36.2.3 Born approximation 1287
36.2.4 Spherical potentials 1288
36.2.5 Scattering phase and length 1289
36.2.6 Optical theorem 1290
36.2.7 Exercises 1293
36.3 Cold atomic collisions 1294
36.3.1 Collision cross section, unitarity regime 1295
36.3.2 Collisions between identical particles 1296
36.3.3 Collisions between hot atoms 1299
36.3.4 Ground state collisions 1300
36.3.5 Hyperfine structure 1300
36.3.6 Scattering length in specific channels 1300
36.3.7 Hyperfine coupling in magnetic fields 1301
36.3.8 Inelastic collisions 1302
36.3.9 Excited states collisions 1304
36.3.10 Heteronuclear collisions 1306
36.3.11 Heteronuclear electric dipole moment 1309
36.3.12 Exercises 1310
36.4 Resonances in cold collisions 1310
36.4.1 Shape resonances 1310
36.4.2 Feshbach resonances 1310
36.4.3 Exercises 1312
36.5 Light-assisted collisions 1312
36.5.1 Optical shielding 1312
36.5.2 Photoassociation during cold collisions 1313
36.5.3 Two-color photoassociation 1317

36.5.4 Exercises . . . 1318
36.6 Further reading . . . 1318
36.6.1 on cold collisions . . . 1318
36.6.2 on Feshbach resonances . . . 1318

VII Quantum Optics 1319

37 Quantized radiation fields 1323
37.1 Quantization of the electromagnetic field . . . 1323
37.1.1 Field operators . . . 1323
37.1.2 Exercises . . . 1325
37.2 Density matrix . . . 1325
37.2.1 The density operator . . . 1326
37.2.2 Matrix formalism . . . 1327
37.2.3 Measurement and trace . . . 1328
37.2.4 Exercises . . . 1332
37.3 (Quasi-)probability distribution functions of the coherent state basis . 1333
37.3.1 The density operator and distribution functions . . . 1334
37.3.2 Relation between the P, Q, and Wigner distributions . . . 1338
37.3.3 Characteristic functions for arbitrary HO states in the Fock basis 1340
37.3.4 Representation of particular states in the Fock and Glauber basis 1342
37.3.5 Exercises . . . 1346
37.4 Squeezed states of the harmonic oscillator . . . 1349
37.4.1 The squeezing operator . . . 1349
37.4.2 Squeezed state in the Fock basis . . . 1351
37.4.3 Squeezed state in the Glauber basis . . . 1352
37.4.4 Exercises . . . 1353
37.5 Beam splitting, quantum amplification, and non-linear 1354
37.5.1 The beam splitter in various representations . . . 1354
37.5.2 Fock and Glauber states at a beam splitter . . . 1358
37.5.3 Ordinary and balanced homodyne detection . . . 1360
37.5.4 Quantum amplifier . . . 1364
37.5.5 Coupled quantum oscillators with/out counter-rotating terms . 1366
37.5.6 Backaction on the splitting device . . . 1368
37.5.7 Multimode squeezing . . . 1369
37.5.8 Exercises . . . 1369
37.6 Further reading . . . 1372
37.6.1 on second quantization . . . 1373
37.6.2 on beam splitters . . . 1374

38 Optical cavities 1375
38.1 Open systems and the master equation . . . 1376
38.1.1 Temporal evolution of the density operator . . . 1376
38.1.2 Born approximation for weak coupling . . . 1377
38.1.3 Assumption of an initial product state . . . 1378
38.1.4 Markov approximation for short memory . . . 1378
38.1.5 Example: Damped harmonic quantum oscillator . . . 1378

38.1.6 Deriving the Heisenberg-Langevin from the master equation . . 1380
38.1.7 Exercises 1380
38.2 Dynamics of light fields in empty cavities 1381
38.2.1 Master equation 1381
38.2.2 Mean field dynamics of an empty ring cavity 1384
38.2.3 Formal solutions of the master equation for a bosonic channel . 1386
38.2.4 Exercises 1389
38.3 Mode structure and density-of-states of cavities 1390
38.3.1 Characterization of the bare cavity 1390
38.3.2 Calculation of the density of states 1392
38.3.3 Cumulant expansion of correlation functions and power spectra 1394
38.3.4 Exercises 1396
38.4 Further reading 1396
38.4.1 on cavities 1397

VIII Light-Matter Interaction 1399

39 Semiclassical theory of light-atom interaction 1403
39.1 Perturbative approach to atomic excitation 1404
39.1.1 Time-dependent perturbation by a plane wave 1404
39.1.2 Absorption and stimulated emission 1405
39.1.3 Spontaneous emission 1406
39.1.4 Exercises 1408
39.2 The dipolar approximation and beyond 1408
39.2.1 Dipolar transitions 1408
39.2.2 Einstein transition rates 1410
39.2.3 Selection rules and electronic transitions 1413
39.2.4 Reduction of the fine and hyperfine structure 1416
39.2.5 Irreducible tensor operators 1418
39.2.6 Exercises 1420
39.3 Bloch equations for two-level atoms 1421
39.3.1 Liouville equation 1421
39.3.2 The matrix elements of the density operator 1424
39.3.3 Solution of the optical Bloch equations 1426
39.3.4 Pauli matrices and the atomic Bloch vector 1427
39.3.5 State manipulations by sequences of radiation pulses 1428
39.3.6 Nuclear magnetic resonance 1430
39.3.7 Exercises 1433
39.4 Bloch equations with spontaneous emission 1435
39.4.1 Phenomenological inclusion of spontaneous emission 1435
39.4.2 Liouville equation for two levels 1441
39.4.3 The effective Hamiltonian approach 1441
39.4.4 Exercises 1442
39.5 Line broadening mechanisms 1444
39.5.1 Saturation broadening 1445
39.5.2 Collision broadening 1446

39.5.3 Doppler broadening . . . 1447
39.5.4 Voigt profile . . . 1449
39.5.5 Bloch equations with phase modulation . . . 1449
39.5.6 Exercises . . . 1450
39.6 Bloch equations for multi-level systems . . . 1453
39.6.1 Liouville equation for many levels . . . 1454
39.6.2 Bloch equations for three levels . . . 1456
39.6.3 Numerical treatment of Bloch equations . . . 1457
39.6.4 General rules for setting up multilevel Bloch equations . . . 1458
39.6.5 Exercises . . . 1463
39.7 Multi-level phenomena . . . 1463
39.7.1 Electromagnetically induced transparency . . . 1464
39.7.2 Polarization, alignment, and orientation . . . 1466
39.7.3 Exercises . . . 1467
39.8 Further reading . . . 1474
39.8.1 on negative refraction . . . 1474

40 Atoms in quantized radiation fields 1477
40.1 Interaction of quantized fields with atoms . . . 1477
40.1.1 Hamiltonian for interaction of quantized fields with atoms . . . 1477
40.1.2 Dressed states . . . 1480
40.1.3 Dipole moments for vector transitions . . . 1481
40.1.4 Exercises . . . 1482
40.2 The Jaynes-Cummings model . . . 1482
40.2.1 Dressed states representation . . . 1484
40.2.2 Classical and quantum limits . . . 1485
40.2.3 Observables and correlations of the Jaynes-Cummings dynamics 1488
40.2.4 Jaynes-Cummings model with dissipation . . . 1493
40.2.5 Exercises . . . 1494
40.3 Correlation functions . . . 1495
40.3.1 Classical first and second order coherence . . . 1496
40.3.2 The Wiener-Khintchine theorem . . . 1496
40.3.3 Coherent and chaotic light . . . 1497
40.3.4 Quantum signatures in first and second order coherence . . . 1503
40.3.5 Photon counting statistics . . . 1503
40.3.6 Exercises . . . 1503
40.4 Spontaneous emission and light scattering . . . 1504
40.4.1 Interaction of atoms with vacuum modes . . . 1504
40.4.2 Resonance fluorescence and (in-)coherent light scattering . . . 1508
40.4.3 The spectrum of resonance fluorescence . . . 1511
40.4.4 Exercises . . . 1517
40.5 Light scattering from multi-level atoms . . . 1518
40.5.1 Quantum beats . . . 1518
40.5.2 Two-photon transitions . . . 1520
40.5.3 Exercises . . . 1524
40.6 Further reading . . . 1525
40.6.1 on the Jaynes-Cummings model . . . 1526

41 Quantum measurement **1527**
41.1 The reality and the observer . . . 1527
41.1.1 Schrödinger's cat . . . 1527
41.1.2 The quantum jump . . . 1531
41.1.3 *Welcher Weg* information . . . 1538
41.1.4 Exercises . . . 1538
41.2 Repeated measurements . . . 1539
41.2.1 The quantum Zeno effect . . . 1539
41.2.2 Quantum projection noise . . . 1542
41.2.3 Quantum non-demolition measurements . . . 1546
41.2.4 Exercises . . . 1546
41.3 Geometric and topological phases . . . 1547
41.3.1 Properties of the Berry phase . . . 1548
41.3.2 Aharonov-Bohm effect . . . 1551
41.3.3 Exercises . . . 1554
41.4 Further reading . . . 1555
41.4.1 on quantum jumps . . . 1555
41.4.2 on projection noise . . . 1556
41.4.3 on geometric phases . . . 1556

42 Nonlinear optics **1557**
42.1 The nonlinear optical susceptibility . . . 1558
42.1.1 Exercises . . . 1559
42.2 Quantum interference . . . 1559
42.2.1 Lasing without inversion . . . 1559
42.2.2 Brillouin scattering . . . 1559
42.2.3 Exercises . . . 1561
42.3 Further reading . . . 1561

43 Atomic motion in force fields **1563**
43.1 Electromagnetic forces . . . 1564
43.1.1 Forces on charges and electric dipole moments . . . 1565
43.1.2 Forces on magnetic dipole moments . . . 1566
43.1.3 Adiabatic potentials . . . 1566
43.1.4 Exercises . . . 1568
43.2 Optical forces . . . 1568
43.2.1 The dipolar gradient force and the radiation pressure force . . 1570
43.2.2 Semiclassical calculation of dipole force and radiative pressure 1572
43.2.3 Force exerted by a quantized radiation field . . . 1573
43.2.4 Refraction of atoms by light and of light by atoms . . . 1573
43.2.5 Exercises . . . 1575
43.3 Photonic recoil on free and confined atoms . . . 1576
43.3.1 Recoil- and Doppler-shift in classical mechanics . . . 1576
43.3.2 Kicking a free atom . . . 1578
43.3.3 (In-)elastic light scattering from a single confined atom . . . 1578
43.3.4 Exercises . . . 1585
43.4 Further reading . . . 1585

43.4.1 on optical forces 1585

IX Collective Scattering of Light and Correlations 1587

44 Cooperativity in light scattering 1591
44.1 Theoretical tools and models 1591
44.1.1 The structure factor and definition of cooperativity 1592
44.1.2 The scalar coupled dipoles model 1593
44.1.3 The Markov approximation 1597
44.1.4 General solution with exponential kernel, validity of the RWA . 1598
44.1.5 Calculation of light scattering in steady-state 1602
44.1.6 Calculation of the steady-state radiation pressure force 1603
44.1.7 The structure coefficient of the 'timed' Dicke state 1606
44.1.8 Exercises 1615
44.2 Coupled dipoles model with real atoms 1616
44.2.1 Limitations of the classical vectorial Green function 1616
44.2.2 Molecular level structure 1618
44.2.3 Photoassociation 1619
44.2.4 Generalization of the CDM 1621
44.2.5 Green tensor for parallel classical dipoles 1622
44.2.6 Exercises 1625
44.3 Continuous density distributions and Mie scattering 1625
44.3.1 Continuous density approximation 1626
44.3.2 Simulations of the time evolution 1627
44.3.3 Radiation pressure force in macro- and microscopic scattering . 1631
44.3.4 Spherical harmonics expansion and generalized timed Dicke state1637
44.3.5 Exercises 1640
44.4 Scattering from disordered and dense clouds 1640
44.4.1 Exercises 1641
44.5 Scattering from periodic structures and photonic bands 1642
44.5.1 Bragg scattering 1643
44.5.2 Scattering and transfer matrices 1647
44.5.3 Transfer matrices for optical lattices 1651
44.5.4 Photonic bands in the Bloch and the coupled dipoles models . 1656
44.5.5 Exercises 1658
44.6 Further reading 1659
44.6.1 on the coupled dipoles model 1659
44.6.2 on Bragg scattering 1661
44.6.3 on photonic bands 1662
44.6.4 on noise analysis of Bragg scattering 1663

45 Individual atoms in optical cavities 1665
45.1 Interaction of a cavity with one atom 1665
45.1.1 Spontaneous emission in a cooperative environment 1666
45.1.2 Characterization of the atom-field coupling 1672
45.1.3 Jaynes-Cummings model for one or two radiation modes 1676
45.1.4 Normal-mode splitting in linear and ring cavities 1679

45.1.5 Adiabatic elimination of internal states 1684
45.1.6 Normal mode splitting induced by beam splitting 1687
45.1.7 Time-dependent solutions 1691
45.1.8 Forced atomic vibration in a ring cavity 1692
45.1.9 Input-output theory for a single-ended linear cavity 1695
45.1.10 Emission spectra of cavities interacting with atoms 1695
45.1.11 Exercises 1696
45.2 Interaction of atoms with surfaces 1699
45.2.1 Local density of states for atoms near surfaces 1699
45.2.2 Interaction between atomic dipoles 1703
45.2.3 Exercises 1705
45.3 Further reading 1705

46 Dicke model and spin squeezing 1707
46.1 The Dicke model in the mean-field approximation 1708
46.1.1 Dicke states 1708
46.1.2 Coherent spin states 1714
46.1.3 Rotations, spin excitation and precession 1715
46.1.4 Uncertainties, quantum projection noise and spin squeezing . . 1717
46.1.5 Bosonic modes: Harmonic oscillators and collective spin states 1722
46.1.6 The Holstein-Primakoff prescription 1723
46.1.7 Quasi-probability distributions on the Bloch sphere 1726
46.1.8 Exercises 1729
46.2 Super- and subradiance in open systems 1732
46.2.1 Models for open systems and phase transitions 1733
46.2.2 Superradiant Dicke phase transition 1736
46.2.3 Beyond mean-field 1737
46.2.4 Exercises 1740
46.3 Atoms interacting in free space 1743
46.3.1 Rydberg blockade 1743
46.3.2 Dipole-dipole interactions in the non-linear optics regime . . . 1744
46.3.3 Interacting atoms in a cooperative environment 1749
46.3.4 Exercises 1750
46.4 Cavity-mediated spin-exchange interactions 1751
46.4.1 Adiabatic elimination of the modes of a bad high-finesse cavity 1752
46.4.2 Spin squeezing in the XX-Heisenberg model 1756
46.4.3 Cumulant expansion of the open Dicke model 1760
46.4.4 Exercises 1762
46.5 Driven-dissipative Dicke model 1762
46.5.1 Cooperative resonance fluorescence in mean field approximation 1763
46.5.2 Driven-dissipative spin squeezing beyond mean field 1768
46.5.3 Exercises 1780
46.6 Three-level atoms in a cavity 1780
46.6.1 Open Tavis-Cummings model for the three-level system 1781
46.6.2 Adiabatic elimination of excited state 1783
46.6.3 Open Dicke model for the two-level system 1787
46.6.4 Cavity at steady-state and small signal approximation 1787

46.6.5 Cumulant expansion for many atoms, the role of cooperativity 1790
46.6.6 Exercises . . . 1792
46.7 Further reading . . . 1793
46.7.1 on collective spin states . . . 1793
46.7.2 on spin squeezing . . . 1793
46.7.3 on superradiant lasing . . . 1794
46.7.4 on driven-dissipative spin squeezing . . . 1795

47 Quantum information science 1797
47.1 Quantum correlations and entanglement . . . 1797
47.1.1 The EPR paradox and GHZ states . . . 1797
47.1.2 Information entropy . . . 1803
47.1.3 Exercises . . . 1804
47.2 Creating quantum correlations . . . 1806
47.2.1 Correlating atoms in the Jaynes-Cummings model . . . 1807
47.2.2 Phononic quantum gate . . . 1813
47.2.3 Quantum gates via controlled collisions . . . 1814
47.2.4 Exercises . . . 1815
47.3 Quantum gates . . . 1815
47.3.1 The qubit . . . 1816
47.3.2 Quantum gates of 2 qubits . . . 1817
47.3.3 Boolean versus linear algebra . . . 1819
47.3.4 Fundamental and universal quantum gates of 3 qubits and more 1821
47.3.5 State propagation and projective measurements . . . 1823
47.3.6 The field of quantum information . . . 1828
47.3.7 Exercises . . . 1833
47.4 Metrology and quantum sensing . . . 1837
47.4.1 Atomic clocks . . . 1837
47.4.2 Quantum sensing . . . 1840
47.4.3 Parameter estimation from measurements . . . 1845
47.4.4 Quantum Fisher information . . . 1849
47.4.5 Quantum Fisher information for coupled systems . . . 1857
47.4.6 Exercises . . . 1860
47.5 Further reading . . . 1862
47.5.1 on entanglement . . . 1862
47.5.2 on quantum information . . . 1862
47.5.3 on quantum computing . . . 1863
47.5.4 on quantum sensing . . . 1863
47.5.5 on Fisher information . . . 1863

48 Atomic motion in optical cavities 1865
48.1 Cavity interacting with a single atom . . . 1865
48.1.1 Linear and ring cavities . . . 1866
48.1.2 Eliminating spontaneous emission and cavity decay . . . 1868
48.1.3 Adiabatic elimination of the excited state . . . 1870
48.1.4 Adiabatic elimination of the cavity modes . . . 1872
48.1.5 General rules for deriving equations of motion . . . 1873

48.1.6 Cumulant expansion for CARL 1877
48.1.7 Exercises 1878
48.2 CARL: The collective atomic recoil laser 1879
48.2.1 Classical CARL equations for many mobile atoms 1879
48.2.2 Observation of CARL in ring cavities 1884
48.2.3 Optical instability in ring cavities 1887
48.2.4 Phononic coupling of atoms mediated by a ring cavity 1888
48.2.5 Exercises 1890
48.3 Phenomena related to CARL 1892
48.3.1 Recoil-induced resonances 1892
48.3.2 FEL: the free electron laser 1895
48.3.3 CARL in an ion storage ring 1896
48.3.4 Matter wave superradiance 1897
48.3.5 Exercises 1898
48.4 Quantization of the atomic motion in cavities 1898
48.4.1 Quantum description of the motion 1898
48.4.2 Discretization of the momentum states 1901
48.4.3 Quantization of atomic motion without adiabatic elimination . 1902
48.4.4 Quantized motion with many particles 1905
48.4.5 Approximation for a bimodal momentum distribution 1908
48.4.6 Simulation of random quantum trajectories 1912
48.4.7 Exercises 1914
48.5 Quantized light interacting with atoms moving in cavities 1914
48.5.1 QED in ring cavities 1915
48.5.2 Description of quantized light fields in cavities 1915
48.5.3 Photon backscattering for fixed atomic position 1917
48.5.4 Quantized light fields and quantized recoil 1918
48.5.5 Kicking and forcing an atom in a ring cavity 1921
48.5.6 Quantum correlations 1923
48.5.7 Exercises 1925
48.6 Atomic self-organization in light fields 1926
48.6.1 The Langevin model 1926
48.6.2 The Fokker-Planck and the Vlasov model 1930
48.6.3 Thermalization in the Vlasov equation 1933
48.6.4 The Kuramoto model 1936
48.6.5 Thermodynamics of the CARL process 1941
48.6.6 CARL as a laser 1942
48.6.7 Exercises 1946
48.7 Coherent properties of CARL 1946
48.7.1 Analytical derivation of the coherence 1946
48.7.2 Measuring the coherence properties 1952
48.7.3 Exercises 1954
48.8 Further reading 1954
48.8.1 on CARL 1956
48.8.2 on self-organization 1956

X Degenerate Interacting Bose and Fermi Gases 1957

49 Manipulation of atomic gases 1961
49.1 The atomic motion . . . 1962
49.1.1 The atom as a matter wave . . . 1962
49.1.2 Bose-Einstein condensation . . . 1965
49.1.3 Exercises . . . 1967
49.2 Optical cooling . . . 1967
49.2.1 Optical molasses . . . 1967
49.2.2 Sub-Doppler cooling . . . 1968
49.2.3 Raman cooling . . . 1974
49.2.4 Adiabatic cooling of an optical lattice . . . 1976
49.2.5 Exercises . . . 1976
49.3 Optical and magneto-optical traps . . . 1977
49.3.1 The magneto-optical trap . . . 1977
49.3.2 Optical dipole traps . . . 1981
49.3.3 Exercises . . . 1985
49.4 Magnetic traps . . . 1987
49.4.1 Quadrupolar traps and Majorana spin-flips . . . 1987
49.4.2 Magnetic Ioffe-type traps . . . 1990
49.4.3 Radiative coupling and evaporative cooling . . . 1992
49.4.4 Sympathetic cooling . . . 1999
49.4.5 Exercises . . . 2000
49.5 Other traps . . . 2002
49.5.1 Ion traps . . . 2002
49.5.2 Micromotion . . . 2005
49.5.3 QUEST . . . 2007
49.5.4 Exercises . . . 2008

Part I

Classical Mechanics

Preface to the part *Classical Mechanics*

Classical mechanics is the oldest and, until the discovery of electricity and magnetism and the unraveling of the structure of matter, the only discipline of physics. Since, ancient Greece powerful mathematical tools have been developed to describe the motion of bodies and stars. The successful application of these tools to new areas in recent centuries lead to the extension of physics to many other fields of research, such as electrodynamics, atomic physics, or econophysics. Nowadays, physics is better defined by the methods employed than by the subject of the studies.

Although the mathematical methods are introduced step by step along with the lecture, a first chapter 1 recapitulates the most basic notions of infinitesimal calculus, complex numbers, differential equations, and vector algebra. The subsequent chapters on the dynamics of point masses Chp. 2, on rigid bodies Chp. 3, on gravity Chp. 6, and on hydrodynamics Chp. 7 are not yet elaborated in detail. They are nevertheless included in the script because of nice exercises taken and adapted from various sources. On the other hand, the chapters on vibrations Chp. 4 and on waves Chp. 5 are ready for use.

Chapter 1

Foundations and mathematical formalism

Before starting the physics course let us make some general comments on physics [1].

1.1 General considerations on physics

1.1.1 What is physics

1.1.1.1 Why to study physics?

The best motivation to study physics is certainly the desire to unravel the mysteries of the universe. The desire may be driven by curiosity (where are we coming from and where are we going) or by necessity, to improve our living conditions or to survive critical situations ('we gonna have to science the shit out of this' [2].)

Even if, during the studies or practicing research, curiosity is not always satisfied and many questions remain open, physicists are often confronted with questions of the very fundamental kind. Some of the questions may even have philosophical relevance (is there a master plan of the universe, is the future predetermined by the past?).

1.1.1.2 Physics and technology

Physics is the Greek word for *nature*. 'Doing physics' means setting up a *thought structure* with a proper language. The physical thought structure not only classifies observed phenomena and puts them into relation, but also allows us to predict new phenomena. The reward for this endeavor is a greater appreciation of the simplicity, beauty, and harmony of the laws of nature. But the impression to understand the world also gives us a feeling of power and supremacy, which is also alimented by the fact that physical discoveries often lead to technological applications, even though they may be sometimes unexpected.

1.1.1.3 Theory and reality

Since ancient Greece philosophers and scientists have been wondering about what is out there and how much of it human mind can grasp. How trustworthy is our

[1] See [697], Cap. 1.
[2] Matt Damon in 'The Martian'

physical thought structure? How does our image of the universe connect to reality? How much of reality can we learn through observation? After all 'it doesn't matter how beautiful your theory is, it doesn't matter how smart you are. If it doesn't agree with experiment, it's wrong' [3]. These questions have come up again with the advent quantum mechanics and its Copenhagen interpretation, which tells us what exactly we are allowed to know about nature and what features will forever be hidden in an abstract theoretical description of it. Nevertheless, 'quantum phenomena do not occur in a Hilbert space, they occur in a laboratory' [4].

1.1.1.4 The scientific method

The scientific method is characterized by an interplay between *observation and experimentation* and *abstraction and induction*. Natural phenomena are complicated and often occur as a combination or superposition of many different effects. In order to isolate particular dependencies, it is generally necessary to make an a *abstraction of inessential effects*. The isolation of pure and simple dependencies may lead to the identification of *physical laws*, which may be combined to *physical theories*.

Different physical theories describing the same phenomena may coexist. The quality of a theory is judged based on esthetics (how many laws and how many presumptions does it require? how simple is it to use?), consistency and completeness (how many phenomena does it handle and how many does it not?), and last not least, predictive power (how useful is it in practice?).

Every new theory should be better than the old ones. Nevertheless, it is important to try to determine the range of validity of the new theory. Of course, the a theory should contain the old ones in some limit, even if the basic concepts may differ radically. Indeed, old theories have their right to be (e.g. because they are more simple under certain circumstances). But it must be possible to be derived them from the newer more general theory following well-defined procedures.

1.1.1.5 Relationship between physics and mathematics

Although mathematics is the most important tool in physics, these two sciences are fundamentally different. According to *Carl Friedrich von Weizsäcker* mathematics is a *structural science* while physics is a *natural science* [945, 946]. The mathematical method is deductive. A mathematical theory is good when it is complete and intrinsically without controversy, it cannot be *correct*. It is nothing more than a tool and does not contain *reality*. For instance, axiomatic geometry remains valid, when the words 'point, straight, plane' are replaced by 'table, cup, chair'. The method of mathematics is deductive.

In contrast, physics is a *natural science*. A physical theory is good when it is *true*, which means that it describes the universe as correctly as possible. The central activity of a physicist is to *measure*. The physicist makes hypotheses that he formulates as theories, but he must verify their correctness experimentally, otherwise the theory is of no use. The physicist already has in his mind an image of how the universe works (which may or may not be correct), and this image guides his intuition in the

[3] Richard P. Feynman
[4] Asher Peres

formulation of new better theories or improved measurement techniques. According to *Karl Popper*, in contrast to pseudo-science and religious beliefs, a physical theory or model must be *falsifiable*, i.e. its correctness must be verifiable through experimentation. It is good practice to incorporate into a scientific model conjectures about its range of validity (e.g. sufficiently low velocities, small masses, or high energies). Within its range of validity the model should be universal, i.e. always and everywhere make correct predictions in the outcome of experiments. A single negative experiment is sufficient to falsify the model. A scientific model must provide recipes allowing for its falsification by experiment or at least allow for them to be formulated. An good example is Einstein's hidden variables assumption. At the beginning the debate appeared as purely metaphysical. Only Bell's proposal how to test the assumption by measurement turned it into a scientific theory, which finally was falsified experimentally. This shows that the whole art of a physicist consists in constructing meaningful experiments. The biggest task of theory is to allow questions to be asked. Measuring means: asking the *right question*. A right question is a question with possible answers, called *observables*.

1.1.1.6 Relationship between physics and other sciences

For being the most fundamental of all natural sciences, physics sets the basis for them, which is to say that any science must be compatible with physics. On the other hand, physics is very much characterized by the methods is employs, which are often reductionist in order to allow for exact calculations. Other sciences, for example chemistry and molecular biology, live from complexity, and any attempt to reduce it must lead to loss of essential information.

1.1.2 Structure of physics

1.1.2.1 Orders of magnitude, significant number of digits

The objects of physical science are measurable quantities or *observables*, which (at least in classical physics) correspond to *real* numbers. Even though complex numbers are sometimes used to represent physical quantities, only their real parts are associated with physical reality.

Many physical quantities have wide ranges of possible values (time, distances, ..), and many values are little known (for example, the number of stars in the universe. No physical quantity can be measured with absolute certainty. That is, when presenting the result of measurements, we always need to specify the estimated uncertainty or error. For example, a measurement of a mathematical constant may yield $\pi = 3.14159 \pm 0.00002$. Obviously, it is meaningless to specify a value with a higher precision as the uncertainty or to specify the uncertainty itself by more than 1 (or at most 2) digits. Hence, we always use the same number of *significant digits* for the value and its uncertainty, that is, the same number of digits behind the decimal point. If the quantity depends on several quantities, the significant digit is given by the quantity with the smallest precision.

The uncertainty of a measurement of a quantity m is a complicated issue because, in order to quantify it, in principle we would need a more precise measurement to compare with. However, what we always can do is repeat the measurement N times

(if possible varying the conditions) and to calculate the mean value,

$$\bar{m} = \tfrac{1}{N} \sum_k m_k \tag{1.1}$$

of the individual measurement outcomes m_k, as well as the standard deviation,

$$\Delta m = \sqrt{\frac{1}{N-1} \sum_k (m_k - \bar{m})^2} \ . \tag{1.2}$$

The physical quantity is then specified as,

$$m = \bar{m} \pm \Delta m \ . \tag{1.3}$$

This uncertainty grasps *stochastic (or random) errors* due to an imperfect realization of the measurement limiting the *precision*. On the other hand, a conceptual flaw of the design of the measurement apparatus can lead to deviations, which often are unknown. These are called *systematic errors* and limit the *accuracy* of the apparatus, as illustrated in Fig. 1.1.

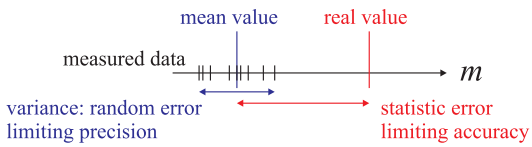

Figure 1.1: Illustration of stochastic and systematic errors in a measurement of a quantity m.

1.1.2.2 Units

Physical quantities *always* consist of a number and a unit forming an inseparable entity. For example, a mass can be specified by the assertion,

$$m = 2\,\mathrm{kg} \ , \tag{1.4}$$

stating that a particular object I have in mind and that I will call henceforward by the name m has a mass of 2 kg. Note that every equation represents an assertion, that is either a *definition* or a *verifiable statement*, which we assume to be true if not otherwise stated. For example, the sentence

$$2\,\mathrm{kg} \cdot 2\,\mathrm{m/s}^2 = 4\,\mathrm{N} \tag{1.5}$$

is a verifiable statement that we find to be correct [5]. In contrast, the statement

$$2 \ \cdot 2 = 4\,\mathrm{N} \tag{1.6}$$

[5] A practical issue of consequently using units is that they allow us to quickly check whether a formula is false. If a formula represented by an equation exhibits different units on both sides, it must obviously be wrong.

is false and the statement

$$2 \cdot 2 = 4 \tag{1.7}$$

is physically meaningless.

Measuring means determining the numerical value of a physical quantity, but this is only possible with respect to a reference value. For example, distances are compared to the circumference of the Earth, times with the duration of the day. In practice, it is more convenient to choose as reference value the unitary value. For example, we will consider the distance

$$d = 1\,\mathrm{m} \ , \tag{1.8}$$

as our reference distance, which in turn is related to a (previously determined) Earth circumference by a fixed numerical factor of 1:40 000 000. In this sense, measurement always means comparison with a reference that we will call *standard*.

1.1.2.3 Linearization of functions, graphical representation

The linearization of exponential, logarithmic and polynomial functions facilitates their graphical representation and the determination of constants,

$$\begin{aligned} y &= ax + b \\ \lg y &= ax + b \quad \Longrightarrow \quad y = 10^{ax+b} = BA^x \\ y &= a \lg x + b \\ \lg y &= a \lg x + b \quad \Longrightarrow \quad y = 10^{a \lg x + b} = Bx^a \end{aligned} \tag{1.9}$$

where we defined $B \equiv 10^b$ and $A \equiv 10^a$. See Fig. 1.2.

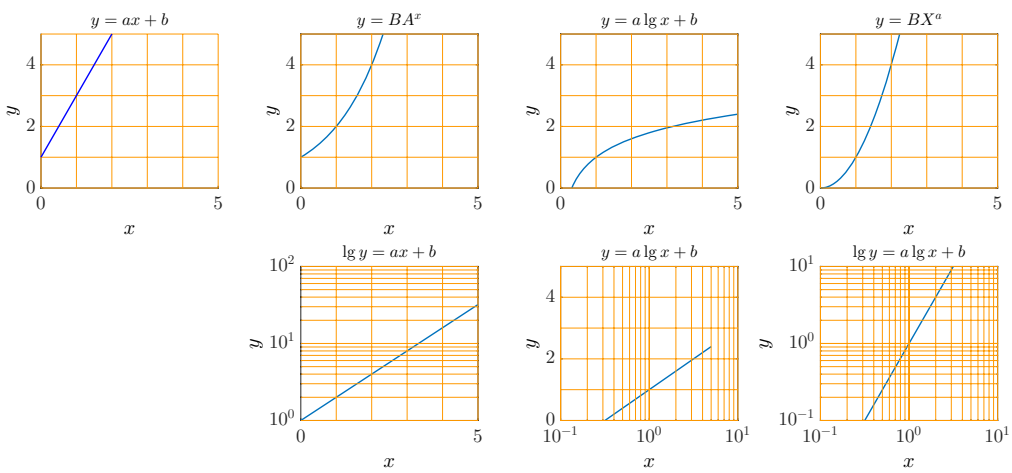

Figure 1.2: Original and linearized curved.

1.1.2.4 Length measurements

Length is the distance between two points in space and one of the 5 basic physical quantities. Its unit, the 'meter', has been introduced during the French revolution as the 40 000-th fraction of the Earth's circumference according to measurements performed at that time. The first measurement of the Earth's circumference was done by Eratosthenes 300 AC using a method explored in Exc. 1.1.3.1.

Because the original definition of the meter is not quite practical and not very precise (the Earth is not perfectly spherical and its circumference may vary over time), a physical standard meter was built out of a platinum-iridium alloy and stored at the Bureau International des Poids et Mesures (BIPM) in Paris. Its length was adjusted to fit the original definition as good as possible before it was declared the new standard.

Still, a unique physical standard is not practical, and so more abstract definitions were introduced later, such as the one using the wavelength of light emitted by a ^{86}Kr gas, according to which $1\,\mathrm{m} = 1\,650\,763.73\lambda_{\mathrm{Kr}_{86}}$. Nowadays the meter is defined via the speed of light. It is the 299 792 458-th fraction of the distance that light travels in 1 second. Of course we still need to define what a second is, which we will do later.

1.1.2.5 Coordinate systems

With the meter at hand we may subdivide a straight line in equal units marked ticks labeled by integer numbers. We may now locate a point on that line by telling how many ticks away it is from a reference point. The number of ticks is called the *coordinate* of the point. Sometimes, however, we want to localize a point on a two-dimensional plane or even three-dimensional space, which means that we need two, respectively, three coordinates.

The simplest coordinate system is constructed with three orthogonal lines crossing in one point, called *origin*. Such a coordinate system is called *Cartesian*. But other coordinate systems are possible, like *polar coordinates* in two dimensions or spherical or cylindrical coordinates in three dimensions. We will study them extensively in Sec. 9.3.

The reason why curvilinear coordinate systems are interesting is, that the equations describing the motion of objects confined to sub-spaces may adopt a simpler form. For example, although our Earth is embedded in 3D space, we are confined by gravity to evolve on the Earth's surface, which is a 2D curved space. Our location on Earth is thus sufficiently specified by only two numbers. The *latitude* is easy to measure, because the sun marks the location of the equator, $\lambda = 90° - \angle(\text{norte-zenit})$. On the other hand, the *longitude* is more difficult to measure and in fact needs very precise clocks.

1.1.2.6 Time measurements

Absolute space and time do not exist. According to the restricted and the general theory of relativity they are interconnected by velocity and they depend on the presence of mass. But even in a more metaphysical sense one may wonder with Gottfried Leibniz about the meaning of space with nothing inside and of time with nothing happening. Indeed, our practical approach to the measurement of time is based on

the observation of recurrent phenomena that we think of being periodic, such as a day on Earth, the dripping of a water pipe, or the oscillation of a pendulum or of an atomic excitation. Assuming the time intervals separating the recurrent phenomena as being all the same, we build a ruler for time which we call clock (see Sec. 47.4).

Historically, the development of ever precise clocks has been motivated by navigation. Indeed, 1 minute of inaccuracy in the clock generates an uncertainty of 28 km in global positioning. And this motivation still prevails nowadays although, meanwhile, atomic clocks have uncertainties of below 10^{-16}.

Apart from periodic processes, time measurement can also be done by exponential processes, such as radioactive decay. This method is commonly used in radioactive dating. Do the Excs. 1.1.3.1 to 1.1.3.5.

1.1.2.7 The international system of units

Not every physical quantity needs to have its own standard. Often it is easier to quantify this quantity by measuring other physical quantities to which it is related in a simple way. For example, instead of measuring a *distance* by comparing it to the Earth circumference it may be easier to measure the *time* needed by a beam of light to cover this distance. In this sense, all physical quantities have been traced back by simple relationships to a small number of so-called *basic units*. Today, seven basic units are officially recognized as such by the international Conférence Générale des Poids et mesures (CGPM): the second (unit symbol 's') as a measure of time, the meter (unit symbol 'm') as a measure of distance, the kilogram (unit symbol 'kg') as a measure of mass, the Ampère (unit symbol 'A') as a measure of electrical current, the Kelvin (unit symbol 'K') as a measure of temperature, the mol (unit symbol 'mol') as a measure of molar mass, and the candela (unit symbol 'cd') as a measure of luminosity [6].

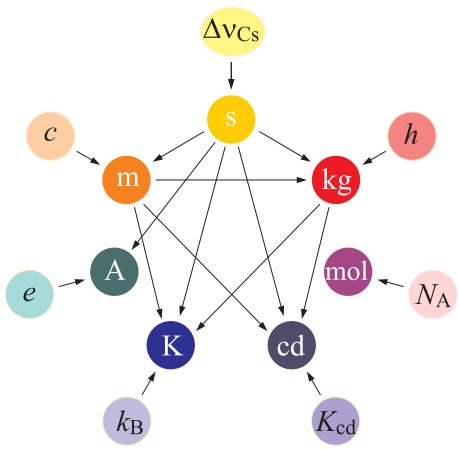

Figure 1.3: SI unit system.

[6] Note that, the molar mass and the luminosity are not fundamental in a strict sense, and only appear in the SI-system, because they are convenient for the communities of chemistry and illumination industry. After all, industrial and practical life applications are a main motivation for standardization (see Quantum Science Seminar talk by William Phillips).

By decision of the 26^e CPGM in 2018 [7], all basic units are related to the most fundamental unit, the second, for which the most precise measurement tools are available. Measurements of all other units are traced back to time measurements using simple relationships and *natural constants* [8]:

base unit	relationship	definition
time	t	$1\,\mathrm{s} = \frac{9\,192\,631\,770}{\Delta\nu_{Cs}}$
distance	$d = ct$	$1\,\mathrm{m} = \frac{c}{299\,792\,458}\,1\,\mathrm{s}$
mass	$m = \frac{h\nu}{c^2}$	$1\,\mathrm{kg} = \frac{(299\,792\,458)^2}{c^2}\,\frac{h}{6.626\,070\,15\times10^{-34}}\,\frac{1}{1\,\mathrm{s}}$
electric current	$I = \dot{Q}$	$1\,\mathrm{A} = \frac{e}{1.602\,176\,634\times10^{-19}}\,\frac{1}{1\,\mathrm{s}}$
temperature	$T = \frac{h\nu}{k_\mathrm{B}}$	$1\,\mathrm{K} = \frac{c^2}{(299\,792\,458)^2}\,\frac{1.308\,649\times10^{-23}}{k_\mathrm{B}}\,1\,\mathrm{kg}$
molar mass	$T = \frac{mc^2}{k_\mathrm{B}}$	$1\,\mathrm{mol} = \frac{6.022\,140\,76\times10^{23}}{N_\mathrm{A}}$
luminosity		$1\,\mathrm{cd}$

These natural constants are the transition frequency of cesium atoms Δ_{Cs}, the velocity of light c, Planck's constant h, the elementary charge e, Boltzmann's constant k_B, and Avogadro's constant N_A. The natural constants are considered as fixed and exact. Hence, any improved measurement of the velocity of light will not result in a more precise value of c, but in an improved definition of the meter.

1.1.3 Exercises

1.1.3.1 Ex: Circumference of the Earth

In the 3rd century BC, the Greek Eratosthenes measured the circumference of the Earth by comparing the angles between the sun's rays and the vertical at noon in two different places. In Siena he measured 0° and in Alexandria, which is 785 km north of Siena, he measured 7.2°. What is the circumference he found?

1.1.3.2 Ex: Mean value and standard deviation

The surface area of a house plant is measured by 10 people finding different values. Determine the mean and standard deviation of the measurement. How many measurements are in the confidence interval, that is, within the standard deviation?

[7] SI-Brochure.
[8] So, in a sense, 'time' is the only remaining fundamental quantity.

10	101.6

1.1.3.3 Ex: Radioactive dating with ^{40}K

A chemical analysis of a 1 g rock sample reveals the presence of $m_K = 4.21 \cdot 10^{-2}$ g potassium (^{39}K$^{+\,40}$K) and $m_A = 9.02 \cdot 10^{-7}$ g argon (^{40}Ar). How old is the rock? **Help:** The current relative abundance is 1 atom of ^{40}K for every 8400 atoms of ^{39}K. Only 12% of ^{40}K desintegrate into ^{40}Ar, the rest into ^{40}Ca. The decay time of ^{40}K is $t_{1/2} = 1.3 \cdot 10^9$ a.

1.1.3.4 Ex: Paramecia

A biologist analyzes the behavior of a paramecium. Make a position versus time diagram and determine the average speed.

tempo [s]	posição [cm]
0	2
10.5	2.1
12	96.0
23	100
40	101.6

1.1.3.5 Ex: Spirograph

Find the parametrization of the curves produced by a spirograph.

1.2 Infinitesimal calculus

Several physical quantities are related by derivatives or integrals.

1.2.1 Derivation

Do the Excs. 1.2.3.1 to 1.2.3.4.

1.2.2 Integration

Do the Excs. 1.2.3.5 to 1.2.3.7.

1.2.3 Exercises

1.2.3.1 Ex: Derivatives

We know that $(\sin x)' = \cos x$ and $(\cos x)' = -\sin x$. Use this notion to calculate:

$$\begin{aligned} &\text{a.} \quad (\arccos x)' \ , \\ &\text{b.} \quad (\arctan x)' \ . \end{aligned}$$

Derive by x:

$$\begin{aligned} &\text{c.} \quad y = (x^3 + 2)\cos x^2 \ , \\ &\text{d.} \quad y = \frac{x^2+1}{\sin \ \ln x} \ . \end{aligned}$$

Calculate the derivatives of,

$$\begin{aligned} &\text{e.} \quad f(x) = 5 \ x \ e^{ax} \ \sin x \ , \\ &\text{f.} \quad f(t) = \frac{a^t}{\sin t} \ , \\ &\text{g.} \quad f(z) = \ln \frac{1-z^2}{1+z^2} \ . \end{aligned}$$

1.2.3.2 Ex: Curves discussion

Consider the parable $y = 2x^2 + x - 3$.
a. Using the concept of the derivative, find the position x_0 that corresponds to the extreme (maximum or minimum);
b. Substitute the value of x_0 in the parabola equation to find the value of y_0;
c. Calculate the squares to find the vertex points x_0 and y_0;
d. Find the points at which the parable crosses the axis x;
e. Sketch the parable (graphic with few details);
f. Using integration, find the area under the parable between the points 1 and 2.

1.2.3.3 Ex: Taylor series

Expand the function

$$f(x) = \frac{1}{\sqrt{1+x}}$$

in a Taylor series around the position $x = 0$. To do this, calculate the derivatives at least until third order and try to find the general law indicating how to find the series coefficients. Draw the function and the Taylor approximations.

1.2.3.4 Ex: Partial derivatives

Be $r(x_1, x_2, x_3) = \sqrt{x_1^2 + x_2^2 + x_3^2}$. Find the first two partial derivatives and show by explicit calculation, that

$$\text{a.} \quad \frac{\partial^2 r}{\partial x_i \partial x_j} = \frac{\partial^2 r}{\partial x_j \partial x_i} \qquad \text{and} \qquad \text{b.} \quad \sum_{i=1}^{3} \frac{\partial^2}{\partial x_i^2} \left(\frac{1}{r} \right) = 0 \ .$$

1.2.3.5 Ex: Integrals

Calculate the following indefinite integrals,

$$\text{a.} \quad \int 3x \, dx \ ,$$

$$\text{b.} \quad \int (7x^2 + 4x^3 - 2) \, dx \ ,$$

and the definite integrals,

$$\text{c.} \quad \int_0^{\pi} (3 \sin x + \cos x) \, dx \ ,$$

$$\text{d.} \quad \int_{-1}^{1} (5 + 2x^2) \, dx \ ,$$

$$\text{e.} \quad \int_0^{1} e^{2x} \, dx \ ,$$

$$\text{f.} \quad \int_0^{\pi/4} \sin x \cos x \, dx \ .$$

1.2.3.6 Ex: Integrals

Find a suitable substitution to solve the following integrals,

$$\text{a.} \quad \int dt \ \sin(\omega t + \alpha) \qquad \text{b.} \quad \int dx \ \tfrac{2x}{\sqrt{1+x^2}}$$

$$\text{c.} \quad \int dx \ x^2 \ln x \qquad \text{d.} \quad \int_0^{\pi/3} d\phi \ \tfrac{\sin \phi}{\sqrt{1+\cos \phi}}$$

Calculate by partial integration,

$$\text{e.} \quad \int dx \ (x+2)^2 \ln x \qquad \text{f.} \quad \int dx \ x e^{-x}$$

$$\text{g.} \quad \int dx \ x^2 \ln x \qquad \text{h.} \quad \int_0^1 dx \ x\sqrt{1+x}$$

Calculate,

$$\text{i.} \quad \int \tfrac{dx}{x(\ln x)^3} \qquad \text{j.} \quad \int dx \ \tfrac{\sin 2x}{1-\cos 2x}$$

Find a serial expansion around the position $x = 0$ for,

$$\text{k.} \quad \int_0^1 dx \ e^{-x^2} \qquad \text{l.} \quad \int_0^{\pi} dx \ \tfrac{\sin x}{x}$$

1.2.3.7 Ex: Numerical integration for pedestrians

Consider the differential equation for the mass-spring system $\ddot{x} = -\omega^2 x$ with $\omega = 2\pi \cdot 1\ \mathrm{s}^{-1}$.
a. Determine the equivalent system of coupled first-order differential equations.
b. Calculate using the Euler procedure the numerical solution of this system for the initial conditions, $x(t = 0) = 1$ m and $v(t = 0) = 0$ for the two time intervals of $\Delta t = 0.1\,\mathrm{s}$. Compare the result with the exact solution.
c. Repeat the calculation of (b) with four time intervals of $\Delta t = 0.05\,\mathrm{s}$.
d. Use the second-order Runge-Kutta procedure with two time intervals of $\Delta t = 0.1\,\mathrm{s}$.

Figure 1.4: Runge-Kutta procedure.

1.3 Complex numbers

The imaginary unit is defined as,

$$\boxed{\imath \equiv \sqrt{-1}}\ . \tag{1.10}$$

From this follows a number of arithmetic rules that are studied in the following exercises.

1.3.1 Basic rules

Any complex number can be separated into a real and an imaginary part,

$$z = \mathfrak{Re}\, z + \imath \mathfrak{Im}\, z\ . \tag{1.11}$$

Both $\mathfrak{Re}\, z$ and $\mathfrak{Im}\, z$ are real numbers and may be represented graphically on a two-dimensional complex plane shown in Fig. 1.5. The complex conjugate is obtained by simply changing the sign of the imaginary part,

$$z = \mathfrak{Re}\, z - \imath \mathfrak{Im}\, z\ , \tag{1.12}$$

of more generally,

$$\bar{f}(z) = f(\bar{z})\ . \tag{1.13}$$

The absolute value of a complex number can be calculated as,

$$|z|^2 = z\bar{z} = \mathfrak{Re}^{\,2} z + \mathfrak{Im}^{\,2} z\ . \tag{1.14}$$

With this and defining the phase angle,

$$\varphi = \frac{\mathfrak{Im}\, z}{\mathfrak{Re}\, z} \tag{1.15}$$

We can also represent a complex number as,

$$z = |z|e^{\imath\varphi} = \cos\varphi + \imath\sin\varphi \ , \tag{1.16}$$

which is known as Euler's formula. Do the Excs. 1.3.2.1 to 1.3.2.5.

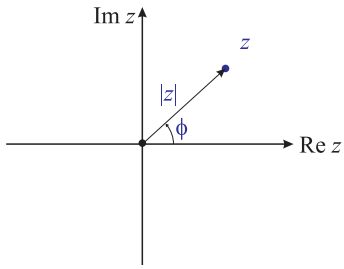

Figure 1.5: Complex plane.

1.3.2 Exercises

1.3.2.1 Ex: Complex numbers

Solve the following equations,

$$\frac{z}{1+\imath} - \frac{z}{1-\imath} = 1 + (z-\bar{z})\sin(\pi + \imath\ln 3) \quad , \quad -2\imath z = \frac{1+\bar{z}}{1+\imath} \ .$$

Calculate the absolute value, the real part and the imaginary part of,

$$\frac{2\imath - 1}{\imath - 2} \quad , \quad (1+2\imath)^3 \quad , \quad \frac{3\imath}{\imath - \sqrt{3}} \ .$$

1.3.2.2 Ex: Complex numbers

Let $z = a + \imath b$ be a complex number. Calculate the real part and the imaginary part of the following expressions: $\sin z$, $z^2 - \bar{z}^2$, $\frac{z+\imath}{\bar{z}-\imath}$.

1.3.2.3 Ex: Complex numbers

Solves the following equation by $z \in \mathbb{C}$:

$$-\bar{z} = \frac{1-z}{\imath - 1} + \ln(43)\cdot\sin\left(\frac{\pi}{\imath+1} + \frac{\pi}{\imath-1}\right) - \frac{e^{-\imath\frac{5}{4}\pi}}{\sqrt{2}} \ .$$

1.3.2.4 Ex: Complex numbers

Be $z_1 = 4 + 7\imath,\ z_2 = 3 - 9\imath$. Calculate

a. $z_1 + z_2$ e $z_1 - z_2$
b. $z_1 \cdot z_2$
c. z_1^2 e z_2^3
d. $|z_1|$ e $|z_2|$
e. z_1/z_2 .

Now be $z = x + \imath y$. Calculate the real and imaginary part of the expression,

$$\frac{z}{1+2z} \ .$$

Finally, we consider two complex numbers z_1 and z_2. Show that $(z_1 z_2)^* = z_1^* z_2^*$, where z^* is the conjugate complex number of z.

1.3.2.5 Ex: Complex numbers

Be

$$z_1 = 1 - \imath\sqrt{3} \quad , \quad z_2 = \frac{1}{2\sqrt{2}} + \imath\frac{\sqrt{2}}{4} \quad , \quad z_3 = -\imath \ ,$$

a. Represent $z_{1,2,3}$ in a polar form $z_{1,2,3} = r_{1,2,3} e^{\imath\phi_{1,2,3}}$.
b. Are the angles $\phi_{1,2,3}$ determined unambiguous? What values are possible?
c. Now, calculate,

$$\sqrt{z_1} \quad , \quad \sqrt[3]{z_2} \quad , \quad \sqrt[4]{z_3} \ .$$

Show how the different possible values of ϕ lead to an ambiguity of the roots.

1.4 Differential equations

1.4.1 First order differential equations

The solution is usually an exponential function. Do the Excs. 1.4.3.1 to 1.4.3.5.

1.4.2 Second order differential equations

Oscillations are processes described by second-order differential equations. We now consider the second-order linear differential equation with constant coefficients:

$$z''(x) + \alpha z'(x) + \beta z(x) = f(x) \ , \tag{1.17}$$

where $z, f : \mathcal{R} \to \mathcal{C}$, com $\alpha, \beta \in \mathcal{C}$.

The homogeneous equation $f \equiv 0$ is always solved by a linear combination of two solutions of the form $z_{1,2}(x) = e^{\lambda_{1,2}x}$ or $z_1(x) = e^{\lambda_1 x}$, $z_2(x) = xe^{\lambda_1 x}$. To show this, we consider two solutions z_1 and z_2 of the homogeneous differential equation, i.e. for

$f = 0$, then $z''_{1,2}(x) + \alpha z'_{1,2}(x) + \beta z_{1,2}(x) = 0$. Now we insert the linear combination $Az_1 + Bz_2$ into the differential equation:

$$(Az_1 + Bz_2)'' + \alpha(Az_1 + Bz_2)' + \beta(Az_1 + Bz_2) = 0 \ . \tag{1.18}$$

Arranging,

$$(Az_1'' + \alpha Az_1' + \beta Az_1) + (Bz_2'' + \alpha Bz_2' + \beta Bz_2) = 0 \ . \tag{1.19}$$

The two parentheses must disappear separately. By inserting the ansatz $e^{\lambda x}$ into the homogeneous differential equation, we get,

$$\begin{aligned}(e^{\lambda x})'' + \alpha(e^{\lambda x})' + \beta(e^{\lambda x}) &= 0\\ \lambda^2 e^{\lambda x''} + \lambda\alpha e^{\lambda x} + \beta e^{\lambda x} &= 0\\ \lambda^2 + \lambda\alpha + \beta &= 0 \ .\end{aligned}$$

The characteristic polynomial has two solutions,

$$\lambda_{1,2} = -\frac{\alpha}{2} \pm \sqrt{\frac{\alpha^2}{4} - \beta} \ .$$

Depending on the values of the coefficients α and β the root can be real, zero, or imaginary. For real $\lambda_{1,2}$, the solutions $e^{\lambda x}$ describe an exponential increase or a decay. For zero roots we obtain the aperiodic limit case. For imaginary $\lambda_{1,2}$ we get a vibration.

The inhomogeneous equation, $f \neq 0$, can always be solved by the solutions mentioned above plus a particular solution $z_f(x)$. Do the Excs. 1.4.3.6 to 1.4.3.6.

1.4.3 Exercises

1.4.3.1 Ex: Exponential law

The value of a coin is divided by two each day. Derive the exponential law allowing to predict the value of the currency at any future date.

1.4.3.2 Ex: First order differential equation

A differential equation of order n is usually an equation between the first n derivatives from a function, the function itself, and its independent variables with the form $F(x, y(x), y'(x), ..., y^{(n)}(x)) = 0$. The initial conditions $(y^{(n-1)}(x_0) = y_0^{(n-1)}, ..., y(x_0) = y_0)$ must be specified to obtain an unambiguous solution. A particular case are first-order equations of the form $y'(x) + f(x)g(y(x)) = 0$ with $y(x_0) = y_0$.
a. Show that the general solution of this equation is given by $\int_{y_0}^{y} \frac{d\tilde{y}}{g(\tilde{y})} = -\int_{x_0}^{x} f(\tilde{x})d\tilde{x}$.
b. Solve the following equations:

$$\begin{aligned} y'(x) + \cos 2y \cos x = 0 \qquad &\text{with} \qquad y(0) = \pi/4\\ \log y'(x)x + y + x^2 = 0 \qquad &\text{with} \qquad y(\infty) = 0 \ .\end{aligned}$$

Does each initial condition make sense?
c. Show that homogeneous linear first-order differential equations $y'(x)+f(x)y(x) = 0$ (with $y(x_0) = y_0$) belong to the class specified above. Find the general solution. $\left(y(x) = y_0 e^{-\int_{x_0}^{x} f(x)dx}\right)$.

1.4.3.3 Ex: Bernoulli's differential equation

Consider the equation,

$$y' = ay + by^{\alpha} \ ,$$

with $a, b \in \mathbb{R}$, $\alpha \neq 0, 1$ and the initial conditions $x_0 = 0$ and $y_0 = \left(\frac{1-b}{a}\right)^{1/(1-\alpha)}$. Find the solution $y(x)$.
Help: Transform the nonlinear differential equation into a first order linear differential equation by the substitution $y = z^{1/(1-\alpha)}$.

1.4.3.4 Ex: Population explosion

Develop a model for population explosion.

1.4.3.5 Ex: Population explosion

Develop a model for the Wuhan virus pandemia.

1.4.3.6 Ex: Second order differential equations

Find the general solutions $z(x)$ of the following equations:
a. $7z'' - 2\imath\sqrt{3}z' - 3z = 6$
b. $z'' - 10z' + 9z = 9x$.

1.4.3.7 Ex: Second order differential equations

Given is a second order linear differential equation with constant coefficients: $z''(x) + \alpha z'(x) + \beta z(x) = f(x)$, where z, f: $\mathbb{R} \to \mathbb{C}$, α, $\beta \in \mathbb{C}$. Show that
a. for the case $f(x) = \gamma x^n$ an ansatz $z_f(x) = \sum_{k=0}^{n} a_k x^k$ solves the inhomogeneous equation, where $\gamma, a_k \in \mathbb{C}$;
b. for the case, that $f(x)$ can be expanded in a Taylor series around the point x_0, the ansatz $z_f(x) = \sum_{k=0}^{\infty} a_k (x - x_0)^k$, $\gamma, a_k \in \mathbb{C}$, solves the inhomogeneous equation. Use linearity and the result of (a).
c. for the case $f(x) = \gamma x^n e^{\delta x}$ an ansatz $z_f(x) = e^{\delta x} \sum_{k=0}^{n} a_k x^k$ solves the inhomogeneous equation, where γ , δ , $a_k \in \mathbb{C}$.

1.5 Scalars, vectors and matrices

All physical quantities are represented by a conjunction of a *tensor* with numerical component and a *unit*. The tensor a by a scalar, a vector, or a matrix. Do the Excs. 1.5.4.1 to 1.5.4.8.

1.5.1 Vector algebra

Let us start with a little revision of vector algebra. A vector is a physical quantity composed of a value, a direction and a unit. For example, $\mathbf{v}$ could be the velocity of a body measured in meters per second traveling in northbound direction. Mathematically, vectors form a *vector space*, that is, an algebraic construct characterized by the existence of several operations defined by the following laws.

The addition of vectors is a *commutative* and *associative* operation, that is,

$$\mathbf{a}+\mathbf{b}=\mathbf{b}+\mathbf{a} \qquad \text{and} \qquad (\mathbf{a}+\mathbf{b})+\mathbf{c}=\mathbf{a}+(\mathbf{b}+\mathbf{c}) \ . \tag{1.20}$$

The multiplication with a scalar is *commutative* and *distributive*,

$$\lambda\mathbf{a}=\mathbf{a}\lambda \qquad \text{and} \qquad \lambda(\mathbf{a}+\mathbf{b})=\lambda\mathbf{a}+\lambda\mathbf{b} \ . \tag{1.21}$$

The scalar product of two vectors defined by,

$$\boxed{\mathbf{a}\cdot\mathbf{b}\equiv ab\cos\theta} \ , \tag{1.22}$$

where θ is the angle between the two vectors, is *commutative* and *distributive*, but not *associative*,

$$\mathbf{a}\cdot\mathbf{b}=\mathbf{b}\cdot\mathbf{a} \qquad \text{and} \qquad \mathbf{a}\cdot(\mathbf{b}+\mathbf{c})=\mathbf{a}\cdot\mathbf{b}+\mathbf{a}\cdot\mathbf{c} \qquad \text{and} \qquad (\mathbf{a}\cdot\mathbf{b})\mathbf{b}\neq\mathbf{a}(\mathbf{b}\cdot\mathbf{c}) \ . \tag{1.23}$$

Finally, the vector product defined by,

$$\boxed{\mathbf{a}\times\mathbf{b}\equiv ab\hat{\mathbf{e}}_n\sin\theta} \ , \tag{1.24}$$

where θ is the angle between the two vectors and $\hat{\mathbf{e}}_n$ a unit vector pointing in the direction perpendicular to $\mathbf{a}$ and $\mathbf{b}$, is *distributive*, but neither *commutative* nor *associative*,

$$\begin{aligned} \mathbf{a}\times\mathbf{b}=-\mathbf{b}\times\mathbf{a}\neq\mathbf{b}\times\mathbf{a} \qquad &\text{and} \qquad \mathbf{a}\times(\mathbf{b}+\mathbf{c})=\mathbf{a}\times\mathbf{b}+\mathbf{a}\times\mathbf{c} \\ &\text{and} \qquad (\mathbf{a}\times\mathbf{b})\times\mathbf{c}\neq\mathbf{a}\times(\mathbf{b}\times\mathbf{c}) \ . \end{aligned} \tag{1.25}$$

Once we have chosen a basis, that is, a set of three linearly independent vectors, we can also express the vectors in terms of their components in this basis. The most common basis is the Cartesian coordinate system characterized by three fixed and orthogonal vectors, $\hat{\mathbf{e}}_x$, $\hat{\mathbf{e}}_y$, and $\hat{\mathbf{e}}_z$, such that each vector can be decomposed as,

$$\mathbf{a}=a_x\hat{\mathbf{e}}_x+a_y\hat{\mathbf{e}}_y+a_z\hat{\mathbf{e}}_z \ . \tag{1.26}$$

In this representation the operations on the vector space defined above read,

$$\begin{aligned} \mathbf{a}+\mathbf{b} &= (a_x+b_x)\hat{\mathbf{e}}_x+(a_y+b_y)\hat{\mathbf{e}}_y+(a_z+b_z)\hat{\mathbf{e}}_z \\ \lambda\mathbf{a} &= \lambda a_x\hat{\mathbf{e}}_x+\lambda a_y\hat{\mathbf{e}}_y+\lambda a_z\hat{\mathbf{e}}_z \\ \mathbf{a}\cdot\mathbf{b} &= a_xb_x+a_yb_y+a_zb_z \\ \mathbf{a}\times\mathbf{b} &= \begin{pmatrix} a_yb_z-a_zb_y \\ a_zb_x-a_xb_z \\ a_xb_y-a_yb_z \end{pmatrix} \ . \end{aligned} \tag{1.27}$$

Combinations of scalar and vector products can be used to calculate other geometric quantities. An example is the *scalar triple product* defined by $\mathbf{a}\cdot(\mathbf{b}\times\mathbf{c})$ and satisfying the following permutation rules,

$$\mathbf{a}\cdot(\mathbf{b}\times\mathbf{c})=\mathbf{c}\cdot(\mathbf{a}\times\mathbf{b})=-\mathbf{c}\cdot(\mathbf{b}\times\mathbf{a})=(\mathbf{a}\times\mathbf{b})\cdot\mathbf{c} \ . \tag{1.28}$$

Its absolute value $|\mathbf{a}\cdot(\mathbf{b}\times\mathbf{c})|$ has the meaning of the volume of the parallelepiped spanned by the three vectors. The *vector triple product* defined by $\mathbf{a}\times(\mathbf{b}\times\mathbf{c})$ can be simplified,

$$\mathbf{a}\times(\mathbf{b}\times\mathbf{c})=\mathbf{b}(\mathbf{a}\cdot\mathbf{c})-\mathbf{c}(\mathbf{a}\cdot\mathbf{b}) \ . \tag{1.29}$$

We verify the commutativity and the distributivity of the scalar and vector triple products in Exc. 1.5.4.9, and we train them more in Excs. 1.5.4.10 to 1.5.4.12.

1.5.2 Matrices

Matrices are two-dimensional arrays of scalars.

1.5.2.1 Properties of matrices

Important properties of matrices are the *trace*,

$$\mathrm{Tr}\, A = \sum_{ij} A_{ij} \tag{1.30}$$

and the *determinant*,

$$\det A \equiv \quad . \tag{1.31}$$

Rules for determinants,

$$\begin{aligned} \det A^\top = \det A = \frac{1}{\det A^{-1}} \quad , \quad \det(AB) = \det A \det B \\ \det(cA) = c^{\dim A} \det A \ . \end{aligned} \tag{1.32}$$

1.5.2.2 Partial inversion of a matrix

It is sometimes useful to invert a matrix only partially. An example is the interconversion between scattering $\mathcal{S}$ matrices and transfer $\mathcal{T}$-matrices. Mathematically, the task consists in converting into each other two systems of linear equations [968],

$$\begin{pmatrix} Y_1 \\ Y_2 \end{pmatrix} = \mathcal{T} \begin{pmatrix} X_1 \\ X_2 \end{pmatrix} \quad \Longleftrightarrow \quad \begin{pmatrix} X_1 \\ Y_2 \end{pmatrix} = \mathcal{S} \begin{pmatrix} Y_1 \\ X_2 \end{pmatrix} \tag{1.33}$$

with

$$\mathcal{T} = \begin{pmatrix} M_{11} & M_{12} \\ M_{21} & M_{22} \end{pmatrix} \tag{1.34}$$

and

$$\mathcal{S} = \mathrm{inv}_1 T = \begin{pmatrix} M_{11}^{-1} & -M_{11}^{-1} M_{12} \\ M_{21} M_{11}^{-1} & M_{22} - M_{21} M_{11}^{-1} M_{12} \end{pmatrix} \ . \tag{1.35}$$

As an example, we would like to invert the second and third row,

$$\begin{pmatrix} y_1 \\ y_2 \\ y_3 \\ y_4 \end{pmatrix} = \mathcal{T} \begin{pmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \end{pmatrix} \Longleftrightarrow \begin{pmatrix} y_1 \\ x_2 \\ x_3 \\ y_4 \end{pmatrix} = \mathcal{S} \begin{pmatrix} x_1 \\ y_2 \\ y_3 \\ x_4 \end{pmatrix} \ . \tag{1.36}$$

In order to apply the above formula, we switch the rows and columns of the $\mathcal{T}$-matrix via a unitary transform,

$$\mathcal{U} = \begin{pmatrix} 0 & 0 & 1 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix} \tag{1.37}$$

so that

$$\tilde{\mathcal{T}} = \mathcal{U}^{-1}\mathcal{T}\mathcal{U} = \mathcal{U}^{-1}\begin{pmatrix} M^{11}_{22} & M^{13}_{24} \\ M^{31}_{42} & M^{33}_{44} \end{pmatrix}\mathcal{U} \equiv \begin{pmatrix} M^{22}_{33} & M^{21}_{34} \\ M^{12}_{43} & M^{11}_{44} \end{pmatrix} . \tag{1.38}$$

with

$$M^{ab}_{cd} = \begin{pmatrix} T^{ab} & T^{ad} \\ T^{cb} & T^{cd} \end{pmatrix} . \tag{1.39}$$

Now, we can apply the partial inversion formula,

$$\tilde{\mathcal{S}} = \mathrm{inv}_1\tilde{\mathcal{T}} = \begin{pmatrix} (M^{22}_{33})^{-1} & -(M^{22}_{33})^{-1}\ M^{21}_{34} \\ M^{12}_{43}\ (M^{22}_{33})^{-1} & M^{11}_{44} - M^{12}_{43}\ (M^{22}_{33})^{-1}\ M^{21}_{34} \end{pmatrix} . \tag{1.40}$$

Finally,

$$\mathcal{S} = \mathcal{U}\tilde{\mathcal{S}}\mathcal{U}^{-1} = \mathcal{U}\,\mathrm{inv}_1(\tilde{\mathcal{T}})\,\mathcal{U}^{-1} = \mathcal{U}\,\mathrm{inv}_1(\mathcal{U}^{-1}\mathcal{T}\mathcal{U})\,\mathcal{U}^{-1} . \tag{1.41}$$

The explicit solution can be written as,

$$\mathcal{S} = \frac{1}{\Delta^{22}_{33}}\begin{pmatrix} T^{11}\Delta^{22}_{33} + T^{12}\Delta^{23}_{31} + T^{13}\Delta^{21}_{32} & \Delta^{12}_{33} & \Delta^{13}_{22} & T^{12}\Delta^{23}_{34} + T^{13}\Delta^{24}_{32} + T^{14}\Delta^{22}_{33} \\ \Delta^{23}_{31} & T^{33} & -T^{23} & \Delta^{23}_{34} \\ \Delta^{21}_{32} & -T^{32} & T^{22} & \Delta^{24}_{32} \\ T^{41}\Delta^{22}_{33} + T^{42}\Delta^{23}_{31} + T^{43}\Delta^{21}_{32} & \Delta^{33}_{42} & \Delta^{22}_{43} & T^{42}\Delta^{23}_{34} + T^{43}\Delta^{24}_{32} + T^{44}\Delta^{22}_{33} \end{pmatrix} , \tag{1.42}$$

with the abbreviation

$$\Delta^{ab}_{cd} = \det\begin{pmatrix} T^{ab} & T^{ad} \\ T^{cb} & T^{cd} \end{pmatrix} . \tag{1.43}$$

Example 1 (*A particular case*): In particular for the case $y_2 = 0 = y_3$, the formula simplifies to,

$$\begin{pmatrix} y_1 \\ x_2 \\ x_3 \\ y_4 \end{pmatrix} = \frac{1}{\Delta^{22}_{33}}\begin{pmatrix} (T^{11}\Delta^{22}_{33} + T^{12}\Delta^{23}_{31} + T^{13}\Delta^{21}_{32})x_1 + (T^{12}\Delta^{23}_{34} + T^{13}\Delta^{24}_{32} + T^{14}\Delta^{22}_{33})x_4 \\ \Delta^{23}_{31}y_1 + \Delta^{23}_{34}y_2 \\ \Delta^{21}_{32}y_1 + \Delta^{24}_{32}y_2 \\ (T^{41}\Delta^{22}_{33} + T^{42}\Delta^{23}_{31} + T^{43}\Delta^{21}_{32})x_1 + (T^{42}\Delta^{23}_{34} + T^{43}\Delta^{24}_{32} + T^{44}\Delta^{22}_{33})x_4 \end{pmatrix} . \tag{1.44}$$

The solution for x_2 and x_3 can then we used to solve the $\mathcal{T}$-matrix equation in (1.43) directly. Do the Exc. 1.5.4.13.

1.5.3 Transformation of vectors

Of course, the definition of the vector as quantity characterized by a magnitude and a direction is unequivocal, for example, the speed $\mathbf{v}$ of a car on a road. Nevertheless, the representation of the vector depends on the orientation of the Cartesian coordinate system, which is totally arbitrary. For example, a vector given by $\mathbf{r} = x\hat{\mathbf{e}}_x + y\hat{\mathbf{e}}_r + z\hat{\mathbf{e}}_z$ in one system will be described by $\mathbf{r} = x'\hat{\mathbf{e}}'_x + y'\hat{\mathbf{e}}'_y + z'\hat{\mathbf{e}}'_z$ in another system.

The behavior of vectors under transformations of coordinate systems is a very important characteristic of physical quantities and of theories governing their dynamics. For example, while classical mechanics is defined by the Galilei transform, relativistic

mechanics is defined by the Lorentz transform, and we will see later that electrodynamics is incompatible with the Galilei transform. In Excs. 1.5.4.14 to 1.5.4.21 we practice the calculus with rotation matrices [9].

There are basically two things that can be done with vectors in space: *translations* and *rotations*. Both will be discussed in the following.

1.5.3.1 Translations

Translations are simply performed by adding a vector to all position vectors,

$$\mathbf{r}' = \mathcal{T}_{\mathrm{tr}}\mathbf{r} = \mathbf{r} + \mathbf{a} \ . \tag{1.45}$$

1.5.3.2 Rotations

If the two systems are simply rotated with respect to each other, we have [10],

$$\mathbf{r}' = \begin{pmatrix} x' \\ y' \\ z' \end{pmatrix} = \mathcal{T}_{\mathrm{rt}}\mathbf{r} = \begin{pmatrix} R_{xx} & R_{xy} & R_{xz} \\ R_{yx} & R_{yy} & R_{yz} \\ R_{zx} & R_{zy} & R_{zz} \end{pmatrix} \begin{pmatrix} x \\ y \\ z \end{pmatrix} = \mathcal{R}\mathbf{r} \ , \tag{1.46}$$

or [11],

$$\boxed{r'_k = \sum_l R_{kl} r_l} \ . \tag{1.47}$$

Example 2 (*Rotation about the z-axis*): For example, for a rotation around the z-axis by an angle of ϕ we get,

$$\begin{pmatrix} x' \\ y' \\ z' \end{pmatrix} = \begin{pmatrix} \cos\phi & \sin\phi & 0 \\ -\sin\phi & \cos\phi & 0 \\ 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} x \\ y \\ z \end{pmatrix} \ .$$

Rotation matrices $\mathcal{R}$ must satisfy the following requirements:

- The transformation preserves the lengths and orientations of vectors and the angles between vectors. That is, the scalar product satisfies $\mathcal{R}\mathbf{r}_2 \cdot \mathcal{R}\mathbf{r}_2 = \mathbf{r}_1 \cdot \mathbf{r}_2$.
- The transformation is orthogonal, $\mathcal{R}^{-1} = \mathcal{R}^\dagger$, and unitary, $\det \mathcal{R} = 1$.

[9] Note that the procedure is different from the one used in quantum mechanics, where any transformation needs to be described by unitary operations.

[10] By $\mathcal{T}$ we denote operations or prescriptions, while $\mathcal{R}$ is a rotation matrix.

[11] We note here that a tensor of two dimensions transforms like,

$$T'_{kl} = \sum_{l,k} R_{km} R_{ln} T_{mn} \ .$$

1.5.4 Exercises

1.5.4.1 Ex: Vectors

A room has the dimensions $3 \times 4 \times 5\,\mathrm{m}^3$. A fly departs from one of its corners and flies to the diametrically opposite corner. What is the absolute value of the displacement? Could its trajectory be less than this displacement? Choose a convenient coordinate system and express the displacement in vector form.

1.5.4.2 Ex: Vectors

Consider the vectors $\mathbf{x} = x_1\hat{\mathbf{e}}_1 + x_2\hat{\mathbf{e}}_2 + x_3\hat{\mathbf{e}}_3$ and $\mathbf{y} = y_1\hat{\mathbf{e}}_1 + y_2\hat{\mathbf{e}}_2 + y_3\hat{\mathbf{e}}_3$. Calculate $|\mathbf{x}|$, $\mathbf{x} \cdot \mathbf{y}$ and $\mathbf{x} \times \mathbf{y}$.

1.5.4.3 Ex: Vectors

Can we combine two vectors with different absolute values and have a resulting vector with zero length? How about 3 vectors?

1.5.4.4 Ex: Vectors

Consider a moving body whose position vector is given (in cm) by $\mathbf{r} = 3\hat{\mathbf{e}}_x \cos\omega t + 4\hat{\mathbf{e}}_y \sin\omega t$.
a. Display in a scaled graph $\mathbf{r}$ at a given time t;
b. after a small time interval Δt show the new vector $\mathbf{r}$ on the same graph;
c. calculate the displacement $\Delta\mathbf{s} = \mathbf{r}(t + \Delta t) - \mathbf{r}(t)$ suffered by the body during the interval Δt;
d. calculate $\mathbf{v} = \Delta\mathbf{s}/\Delta t$ and check its orientation for $\omega t = 0,\ \pi/2,\ \pi,\ 3\pi/2$;
e. calculate $\mathbf{r} \cdot \mathbf{v}$ and discuss the result;
f. calculate $\mathbf{r} \times \mathbf{v}$ and discuss the result.

1.5.4.5 Ex: Vectors

Show that the magnitude of the sum of two vectors $\mathbf{a}$ and $\mathbf{b}$ is always within the limits,

$$||\mathbf{a}| - |\mathbf{b}|| \leq |\mathbf{a} + \mathbf{b}| \leq |\mathbf{a}| + |\mathbf{b}| \ .$$

1.5.4.6 Ex: Vector product

Invent a method based on the cross product to calculate the area enclosed by a path delimited by the points $A \to B \to C$....

1.5.4.7 Ex: Matrix multiplication

Determine the products of the following matrices,

$$\begin{pmatrix} 1 & a \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ b & 1 \end{pmatrix} \quad , \quad \begin{pmatrix} 1 & 0 \\ b & 1 \end{pmatrix} \begin{pmatrix} 1 & a \\ 0 & 1 \end{pmatrix} \quad , \quad \begin{pmatrix} 4 & 3 \\ 2 & 2 \\ 7 & -5 \end{pmatrix} \begin{pmatrix} 1 & 2 & 3 & 4 \\ 5 & 6 & 7 & 8 \end{pmatrix} \ .$$

1.5.4.8 Ex: Matrix multiplication

Consider the matrices A and B and the column vector $\mathbf{x}$ given by,

$$A = \begin{pmatrix} 0 & 1 & 0 \\ 1 & 1 & 0 \\ 0 & 1 & 1 \end{pmatrix} \quad , \quad B = \begin{pmatrix} -1 & -5 & 8 \\ 2 & 1 & 0 \\ 1 & 4 & 6 \end{pmatrix} \quad , \quad \mathbf{x} = \begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix} \ .$$

a. Calculate the vector $\mathbf{y} = A(B\mathbf{x})$.
b. Show that for arbitrary matrices A and B and vectors $\mathbf{x}$ holds $A(B\mathbf{x}) = (AB)\mathbf{x}$.
c. Let A be an arbitrary matrix with A_{ij} elements. The conjugate matrix of A^t is defined by $(A^t)_{ij} = A_{ji}$; that is, the column indexes i and those of the row j are exchanged. Show,

$$(AB)^t = B^t A^t \ .$$

1.5.4.9 Ex: Vector algebra

a. Show that scalar and vector products are distributive.
b. Find out whether the vector product is associative.

1.5.4.10 Ex: Vector algebra

a. Consider a unit cube with one corner fixed at the origin and generated by the vectors, $\mathbf{a} = (1, 0, 0)$, $\mathbf{b} = (0, 1, 0)$ and $\mathbf{c} = (0, 0, 1)$. Determine the angle between the diagonals passing through the center of the cube.
b. Consider the plane containing the points $\mathbf{a}$, $\mathbf{b}$, and $\mathbf{c}$ giving in (a). Use the vector product to calculate the normal vector of this plane.

1.5.4.11 Ex: Vector algebra

a. Prove the rule $\mathbf{a} \times (\mathbf{b} \times \mathbf{c}) = \mathbf{b}(\mathbf{a} \cdot \mathbf{c}) - \mathbf{c}(\mathbf{a} \cdot \mathbf{b})$ writing both sides in component form.
b. Prove $\mathbf{a} \times (\mathbf{b} \times \mathbf{c}) + \mathbf{b} \times (\mathbf{c} \times \mathbf{a}) + \mathbf{c} \times (\mathbf{a} \times \mathbf{b})$. Under what conditions holds $\mathbf{a} \times (\mathbf{b} \times \mathbf{c}) = (\mathbf{a} \times \mathbf{b}) \times \mathbf{c}$?

1.5.4.12 Ex: Vector algebra

a. Two vectors point from the origin to points $\mathbf{r} = (2, 8, 7)$ and $\mathbf{r}' = (4, 6, 8)$. Determine the distance between the points.

1.5.4.13 Ex: Partial inversion of a matrix

Consider the transformation,

$$\begin{pmatrix} y_1 \\ y_2 \\ y_3 \\ y_4 \end{pmatrix} = \mathcal{T} \begin{pmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \end{pmatrix} \qquad \text{with} \qquad \mathcal{T} = \begin{pmatrix} t & & -r & \\ & t & & -r \\ -r & & t & \\ & -r & & t \end{pmatrix}$$

and invert is partially with respect to the second and third coordinate.

1.5.4.14 Ex: Rotation of the coordinate system

a. Show that the two-dimensional rotation matrix

$$\begin{pmatrix} \cos\phi & \sin\phi \\ -\sin\phi & \cos\phi \end{pmatrix}$$

preserves the scalar product, that is, $a'_x b'_x + a'_y b'_y = a_x b_x + a_y b_y$.
b. What are the constraints for the elements R_{ij} of the three-dimensional rotation matrix to preserve the length of an arbitrary vector under transformation?

1.5.4.15 Ex: Rotation of the coordinate system

Find the matrix describing a rotation of 120° around the axis $\vec{\omega} = (1, 1, 1)$.

1.5.4.16 Ex: Rotation of the coordinate system

Consider the transformation that corresponds to an inversion of the components of the vector $\mathbf{r} \to -\mathbf{r}$ and find out, how the vector product and the triple scalar product transform under inversion.

1.5.4.17 Ex: Rotation matrices

Show that the scalar product $\mathbf{a} \cdot \mathbf{b}$ and the angle α between the two vectors are preserved when we rotate the two vectors by an angle θ around any axis.

1.5.4.18 Ex: Rotation matrices

Consider the matrix,

$$\mathcal{R} = \frac{1}{2} \begin{pmatrix} \sqrt{2} & \sqrt{2} & 0 \\ -1 & 1 & \sqrt{2} \\ 1 & -1 & \sqrt{2} \end{pmatrix} .$$

a. Show that $\mathcal{R}$ is a rotation matrix.
b. Determine the axis of rotation.
Help: The rotation axis $\mathbf{a}$ stays invariant under rotation: $\mathcal{R}\mathbf{a} = \mathbf{a}$. Use this condition.
c. Determine the rotation angle.
Help: Consider for this a vector that is perpendicular to $\mathbf{a}$.

1.5.4.19 Ex: Rotation matrices

A rotation by an angle ϕ around the z-axis is described by the rotation matrix $\mathcal{R}_z(\phi)$ with,

$$\mathcal{R}_z(\phi) = \begin{pmatrix} \cos\phi & \sin\phi & 0 \\ -\sin\phi & \cos\phi & 0 \\ 0 & 0 & 1 \end{pmatrix} .$$

a. Show by an explicit calculation that inverse matrix satisfies, $\mathcal{R}_z^{-1}(\phi) = \mathcal{R}_z(-\phi) = \mathcal{R}_z^t(\phi)$.
b. Show, $\mathcal{R}_z(\phi_1)\mathcal{R}_z(\phi_2) = \mathcal{R}_z(\phi_1 + \phi_2) = \mathcal{R}_z(\phi_2)\mathcal{R}_z(\phi_1)$.
c. Show, $[\mathcal{R}_z(\phi_1)\mathcal{R}_z(\phi_2)]^t = \mathcal{R}_z^t(\phi_2)\mathcal{R}_z^t(\phi_1)$.

1.5.4.20 Ex: Rotation matrices

a. Be given the basis ($\hat{\mathbf{e}}_x$, $\hat{\mathbf{e}}_y$, $\hat{\mathbf{e}}_z$) in Cartesian coordinates. Determine the transformation matrices for cylindrical basis ($\hat{\mathbf{e}}_\rho$, $\hat{\mathbf{e}}_\varphi$, $\hat{\mathbf{e}}_z$) and the spherical basis ($\hat{\mathbf{e}}_r$, $\hat{\mathbf{e}}_\theta$, $\hat{\mathbf{e}}_\varphi$) and their inverse matrices.
b. For both cases transform the force fields,

$$\mathbf{F}_1 = -\kappa \begin{pmatrix} x \\ y \\ z \end{pmatrix} \qquad \mathbf{F}_2 = \gamma \begin{pmatrix} y \\ -x \\ 0 \end{pmatrix} \qquad \mathbf{F}_3 = \delta \begin{pmatrix} -\frac{xz}{\sqrt{x^2+y^2}} \\ -\frac{y\ z}{\sqrt{x^2+y^2}} \\ \sqrt{x^2+y^2} \end{pmatrix} .$$

c. Show generally that for rotation matrices, the vectors that correspond to the columns of the matrices are mutually orthogonal. The same holds for rows of the matrices. Use the relationship, $A^t A = AA^t = 1$.

1.5.4.21 Ex: Rotation of the coordinate system

Here, we want to rotate a rod around several axes and determine, whether its final orientation depends on the rotation path. We know that the matrix

$$\mathcal{R}_z(\alpha) = \begin{pmatrix} \cos\alpha & \sin\alpha & 0 \\ -\sin\alpha & \cos\alpha & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

describes the transformation of a vector under rotation of the coordinate system by an angle α around the axis z.
a. Show that corresponding rotations around the x-axis, respectively, the y-axis are given by,

$$\mathcal{R}_x(\alpha) = \begin{pmatrix} 1 & 0 & 0 \\ 0 & \cos\alpha & \sin\alpha \\ 0 & -\sin\alpha & \cos\alpha \end{pmatrix} \quad , \quad \mathcal{R}_y(\alpha) = \begin{pmatrix} \cos\alpha & 0 & -\sin\alpha \\ 0 & 1 & 0 \\ \sin\alpha & 0 & \cos\alpha \end{pmatrix} .$$

b. Show that a rotation of the coordinate system around the y-axis by an angle $\alpha = \pi/2$ leads to the same result as a rotation around the z-axis by the angle $\pi/2$ followed by a rotation around x by the angle $\pi/2$ followed by a rotation around z by the angle $3\pi/2$.

Chapter 2

Dynamics of point masses

2.1 Motion of point masses

2.1.1 One-dimensional motion

Among the various movements that we will study, the one-dimensional motion is the simplest, because all vector quantities that describe the motion are parallel. Since the motion occurs in only one dimension, only one coordinate is required to specify the position of a body at each instant of time [1].

2.1.1.1 Velocity

The rate of change of the spatial coordinates of a body is called *velocity*. It can be characterized by specifying the body's position in a time table, as shown below (stroboscopic measurement) or by a graph, as shown in Fig. 2.1.

t [s]	x [m]	v [m/s]
0	0	-
1	0.4	0.4
2	0.6	0.1
3	0.7	0.06
4	0.8	0.07

The velocity averaged over a time interval $[t_1, t_2]$,

$$\bar{v} = \frac{x(t_2) - x(t_1)}{t_2 - t_1} \ , \tag{2.1}$$

is the angular coefficient of the slope connecting the points $(x(t_1), t_1)$ and $(x(t_2), t_2)$ of the curve (see Fig. 2.1).

A motion is called *uniform* when the velocity is constant,

$$x(t) = x_0 + v(t - t_0) \ . \tag{2.2}$$

For non-uniform (e.g. accelerated) motion the instantaneous velocity is calculated via,

$$\boxed{v(t) = \lim_{\Delta t \to 0} \frac{x(t + \Delta t) - x(t)}{\Delta t} \equiv \frac{dx(t)}{dt} \equiv \dot{x}(t)} \ . \tag{2.3}$$

[1] See [Cap. 2, Moyses] [Cap. 2, Zilio & Bagnato].

For example, the function $y(t) = -10\,\mathrm{m/s^2}\cdot t^2 + 5\,\mathrm{m/s}\cdot t + 2\,\mathrm{m}$ parametrizes a trajectory taken by a uniform motion [2].

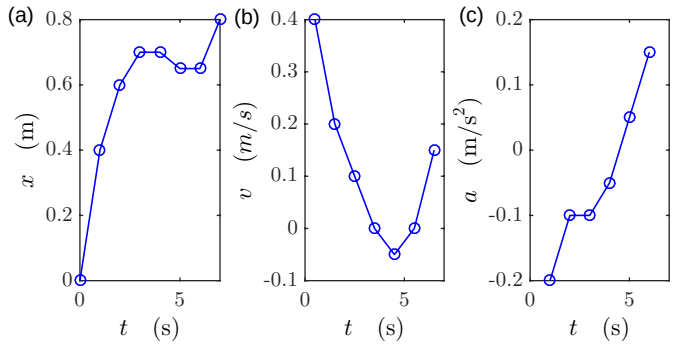

Figure 2.1: Graphical representation of the motion specified in the table. (a) Instantaneous position, (b) velocity, and (c) acceleration.

Inverse problem: Draw a graph $t \mapsto v$ and measure the area underneath:

$$x(t_2) - x(t_1) = \int_{t_1}^{t_2} v(t)dt \ . \tag{2.4}$$

2.1.1.2 Acceleration

The rate of change of the instantaneous velocity of a body is called *acceleration*. Analogous to the velocity it can be characterized by specifying the body's velocity in a time table or a graph.

Acceleration can be progressive or backward, leading to deceleration. The instantaneous acceleration is calculated via,

$$\boxed{a(t) = \lim_{\Delta t \to 0} \frac{v(t+\Delta t) - v(t)}{\Delta t} \equiv \frac{dv(t)}{dt} \equiv \dot{v}(t)} \ . \tag{2.5}$$

Inverse problem: Draw a graph $t \mapsto a$ and measure the area underneath:

$$v(t_2) - v(t_1) = \int_{t_1}^{t_2} a(t)dt \ , \tag{2.6}$$

yielding [3],

$$x(t) = x(t_0) + \int_{t_0}^{t} v(t')dt' = x(t_0) + \int_{t_0}^{t} \left[v(t_0) + \int_{t_0}^{t'} a(t'')dt'' \right] dt' \tag{2.7}$$

$$= x(t_0) + v(t_0)(t - t_0) + \int_{t_0}^{t} \int_{t_0}^{t'} a(t'')dt''dt' \ . \tag{2.8}$$

One-dimensional motion will be studied in Excs. 2.1.4.1 to 2.1.4.11.

[2] Why do we have to write the units?
[3] Galileo.

2.1.2 Motion in two and three dimensions

2.1.2.1 Description in terms of coordinates

Under normal circumstances, space is three-dimensional, and so is the motion of a body through it. Hence, we need three coordinates to specify the position of a body at a given time, and knowing the time-dependence of the three coordinates we can parametrized the body's motion through space. Luckily, specifying a coordinate system we can reduce a bi- or (tri-)dimensional motion into two (three) one-dimensional motions.

That is to say, the physical quantities position, velocity, and force are vector quantities consistent, in fact, of three values. In this sense, they are fundamentally different from scalar quantities, such as time, temperature, or volume [4]. Using the basis,

$$\hat{\mathbf{e}}_x \equiv \begin{pmatrix} 1 \\ 0 \end{pmatrix} \qquad \text{and} \qquad \hat{\mathbf{e}}_y \equiv \begin{pmatrix} 0 \\ 1 \end{pmatrix} \ , \tag{2.9}$$

called *Cartesian basis*, we write the vector velocity,

$$\mathbf{v}(t) = \frac{d\mathbf{r}(t)}{dt} = \dot{x}(t)\hat{\mathbf{e}}_x + \dot{y}(t)\hat{\mathbf{e}}_y = \begin{pmatrix} v_x(t) \\ v_y(t) \end{pmatrix} \ , \tag{2.10}$$

and the vector acceleration,

$$\mathbf{a}(t) = \frac{d\mathbf{v}(t)}{dt} = \dot{v}_x(t)\hat{\mathbf{e}}_x + \dot{v}_y(t)\hat{\mathbf{e}}_y = \begin{pmatrix} a_x(t) \\ a_y(t) \end{pmatrix} \ . \tag{2.11}$$

2.1.2.2 Uniformly accelerated movement by gravitation

The differential equations (2.3) or (2.5) are insufficient to determine the trajectory of a body. We additionally need to specify initial conditions. For a n-dimensional motion, we need $2n$ initial conditions.

Example 3 (*Motion due to terrestrial gravitation*): The acceleration of a body in the Earth's gravitational field is,

$$\mathbf{a}(t) = const = \Big(0, -g\Big) \ . \tag{2.12}$$

With arbitrary initial conditions, $\mathbf{r}(t_0) = \mathbf{r}_0$ and $\mathbf{v}(t_0) = \mathbf{v}_0$ we find,

$$\mathbf{v}(t) = \mathbf{v}_0 + \mathbf{a}(t - t_0) \tag{2.13}$$

and,

$$\mathbf{v}(t) = \mathbf{v}_0 + \mathbf{a}(t - t_0) \qquad \text{and} \qquad \mathbf{r}(t) = \mathbf{r}_0 + \mathbf{v}_0(t - t_0) + \tfrac{1}{2}\mathbf{a}(t - t_0)^2 \ . \tag{2.14}$$

Elimination time in these two equations,

$$y - y_0 = \frac{v_{0y}}{v_{0x}}(x - x_0) + \frac{a}{2}(x - x_0)^2 \ . \tag{2.15}$$

[4] Rules of how to use vectors (length, scalar product, and vector product.

Example 4 (*Motion of a projectile subject to gravity*): We identify the motion as being two-dimensional. Hence, an appropriate choice of the coordinate system allows us to eliminate one coordinate and to restrict to two coordinates that we will call $\hat{\mathbf{e}}_x$ and $\hat{\mathbf{e}}_y$. We choose the initial conditions as $\mathbf{r}(t_0) = (0, 0)$ and $\mathbf{v}(t_0) = v_0 \begin{pmatrix} \cos\theta \\ \sin\theta \end{pmatrix}$. The equations of motion are then,

$$\mathbf{r}(t) = \begin{pmatrix} v_0 t \cos\theta \\ v_0 t \sin\theta - \frac{1}{2} g t^2 \end{pmatrix} . \tag{2.16}$$

Elimination time in the two equations (2.16),

$$y = x \tan\theta - \frac{g x^2}{2 v_0^2 \cos^2\theta} . \tag{2.17}$$

We my now use this equation to calculate the maximum height and the maximum range of the throw.

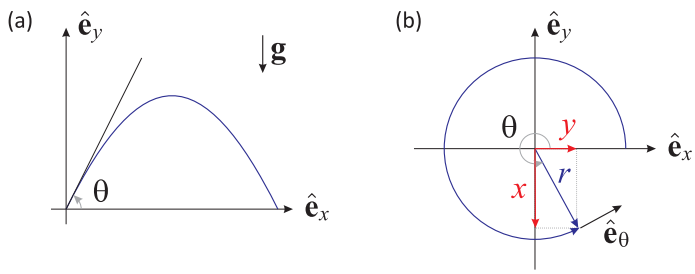

Figure 2.2: (a) Ballistic trajectory in the field of gravity. (b) Circular motion in Cartesian and polar coordinates.

Note that two movements $x(t)$ and $y(t)$ can be coupled by other physical effect, such as via the friction exerted by air.

2.1.2.3 Circular motion and polar coordinates

When we called a movement one, two, or three-dimensional, what we really meant is the number of scalar differential equations needed to describe it. Strictly speaking, however, any movement of a point mass is described by a curve in space, which is a one-dimensional object. Consequently, in the examples 3 and 4 we were able to replace the two differential equations parametrized in time $\{x(t), y(t)\}$ by a single one for $y(x)$ by eliminating time [5].

Sometimes the number of differential equations needed to describe a motion can be reduced without having to eliminate time by a proper choice of the coordinate system, which is better adapted to the symmetry of the motion. Until now we only used Cartesian coordinates (2.9). A nice example for this is the *circular motion*

[5] Note that time is automatically reintroduced in the equations once we calculate velocities by derivating coordinates.

defined by $|\mathbf{r}| = r = const$. Let us define two new coordinates oriented along the instantaneous position and the instantaneous velocity of the body,

$$\boxed{\hat{\mathbf{e}}_r(t) \equiv \frac{\mathbf{r}(t)}{r} \qquad \text{and} \qquad \hat{\mathbf{e}}_\theta(t) \equiv \frac{\mathbf{v}(t)}{v(t)}} \ . \tag{2.18}$$

We note that (for a circular motion) the new coordinates, called *polar coordinates*, are orthogonal but not fixed in space: they rotate along the circle together with the body.

The constancy of the radius $r^2 = x(t)^2 + y(t)^2$, however, implies that we may, choosing the Cartesian coordinate system such as to satisfy the initial condition $x(0) = r$, define two new variables $\{r, \theta(t)\}$ one of which is constant and the other time-dependent, such that,

$$\mathbf{r}(t) = \begin{pmatrix} x(t) \\ y(t) \end{pmatrix} = r \begin{pmatrix} \cos\theta(t) \\ \sin\theta(t) \end{pmatrix} = r\hat{\mathbf{e}}_r(t) \ , \tag{2.19}$$

for the velocity,

$$\mathbf{v}(t) = \frac{d\mathbf{r}(t)}{dt} = \begin{pmatrix} v_x(t) \\ v_y(t) \end{pmatrix} = r \begin{pmatrix} -\dot{\theta}(t)\sin\theta(t) \\ \dot{\theta}(t)\cos\theta(t) \end{pmatrix} = \dot{\theta}(t) \begin{pmatrix} -y(t) \\ x(t) \end{pmatrix} = v(t)\hat{\mathbf{e}}_\theta(t) \ , \tag{2.20}$$

and for the acceleration,

$$\mathbf{a}(t) = \frac{d\mathbf{v}(t)}{dt} = r \begin{pmatrix} -\ddot{\theta}(t)\sin\theta(t) - \dot{\theta}(t)^2\cos\theta(t) \\ \ddot{\theta}(t)\cos\theta(t) - \dot{\theta}(t)^2\sin\theta(t) \end{pmatrix} = -r\dot{\theta}(t)^2\hat{\mathbf{e}}_r + r\ddot{\theta}(t)\hat{\mathbf{e}}_\theta(t) \ . \tag{2.21}$$

That is, the acceleration is composed of a tangential and a normal component,

$$\mathbf{a}(t) \cdot \hat{\mathbf{e}}_\theta(t) = r\ddot{\theta}(t) \qquad \text{and} \qquad \mathbf{a}(t) \cdot \hat{\mathbf{e}}_r = -r\dot{\theta}(t)^2 \ . \tag{2.22}$$

The circular motion is called *uniform* when $|\mathbf{v}| = v = const$. Then, $\ddot{\theta} = 0$ and $\dot{\theta} \equiv \omega = const$, and the above formulas simplify accordingly. Then $\theta = \theta_0 + \omega(t - t_0)$ and, using $\omega \equiv v/r$, we get for the arc traveled by the body,

$$s(t) = r\theta(t) = s_0 + v(t - t_0) \ . \tag{2.23}$$

Motion in one and two dimensions will be studied in Excs. 2.1.4.1 to 2.1.4.28.

2.1.3 Newton's laws

Newton formulated the following fundamental laws of classical mechanics:

i. Principle of inertia (without forces objects move with uniform velocity)

ii. $F = ma$

iii. Reaction principle (actio = reaction)

iv. Forces can be added (corollary)

Their interpretation is that: (i) In the absence of forces linear momentum is conserved; systems not subject to external forces (called *inertial systems*) are equivalent, e.g. there no way to decide an absolute speed from with in a system. (ii) Forces generate a change of linear momentum leading to an acceleration $\sum_k \mathbf{F}_k = m\dot{\mathbf{v}}$.

Newton's laws have a wide range of applications. Formulated for fixed masses, they can nevertheless be generalized to variable masses,

$$\boxed{\mathbf{F} = \dot{\mathbf{p}} = m\dot{\mathbf{v}} + \mathbf{v}\dot{m}} \,. \tag{2.24}$$

2.1.4 Exercises

2.1.4.1 Ex: Overtaking

A car travels at a constant safety distance of 40 m behind a truck (length: 25 m) at 80 km/h . To overtake, he accelerates with $a = 1.3\,\mathrm{m/s^2}$ to $v = 100\,\mathrm{km/h}$. How long is the overtaking time and the path length if the safety distance at the time of reentering the drive lane is 40 m?

2.1.4.2 Ex: Skater

A roller skater who moves at a constant speed of 10 m/s overtakes a jogger. After 5 minutes she passes a snack bar, where she takes a break for 2 minutes. Then she drives back at the same speed and meets the jogger after another 3 minutes. How fast does the jogger run?

2.1.4.3 Ex: Thieves

Two bank robbers on the run have to walk $s = 10\,\mathrm{km}$ to the rescue border, but only have one bike without luggage rack. They therefore decide to proceed as follows: Robber A drives 500 m ahead, leaves the bike and continues. Robber B goes up to the bike, sits on, drives past Robber A and continues 500 m. Then he in turn leaves the bike. In this way the robbers take turns up to the border. Assume the robbers are 6 km/h on foot and 20 km/h on bike.
a. Is this a good idea? Are the robbers really faster? If so, calculate the time saved.
b. How often do they have to change?

2.1.4.4 Ex: One-dimensional movement

A large jet plane must reach a speed of 500 km/h in order to take off, and has an acceleration of $4\,\mathrm{m/s^2}$. How long does it take for the plane to take off and how far does it have to run on the runway?

2.1.4.5 Ex: One-dimensional movement

A particle, initially at rest at the origin, moves for 10 s on a straight line, with increasing acceleration according to the law, $a = bt$, where t is time and $b = 0.5\,\mathrm{m/s^3}$. Plot the velocity v and the position x of the particle as a function of time. What is the analytical expression for $v(t)$?

2.1.4.6 Ex: One-dimensional movement

A projectile of mass m is ejected at the initial velocity v_0 vertically from a catapult.
a. Calculate the maximum height that the projectile reaches without considering the air resistance.
b. Now, we consider air resistance given by Stokes' friction law. Write down the equation of motion for this case.
c. Show that the equation of motion is solved by $v = e^{-\gamma t/m}\left(\frac{mg}{\gamma} + v_0\right) - \frac{mg}{\gamma}$.
d. Determine the time t_m when the projectile is at its maximum point from $v(t_m) = 0$.
e. What is the maximum height $s(t_m)$?

2.1.4.7 Ex: Acceleration

A possible method to measure the acceleration of gravity g is to launch a ball upwards in an evacuated tube and accurately measure the instants t_1 and t_2 of its passage (on its way up and down) across a given height z. Show that:

$$g = \frac{2z}{t_1 t_2} \ .$$

2.1.4.8 Ex: Acceleration

You want to train to be a juggler, keeping two balls in the air throwing them to a maximum height of 2 m. How often and how fast and how fast do you have to throw the balls up?

2.1.4.9 Ex: Acceleration

A racing car can be accelerated from 0 to 100 km/h in 4 s. Compare the corresponding mean acceleration with the acceleration of gravity. If the acceleration is constant, how far does the car travel until it reaches 100 km/h?

2.1.4.10 Ex: Optical cooling

Atoms of a gas (rubidium-87) are irradiated by a laser beam. Each photon transfers the moment $\Delta p = h/\lambda$, where $\lambda = 780\,\mathrm{nm}$ is the wavelength of the light and $h = 6.626 \cdot 10^{-34}\,\mathrm{Js}$. The mass of a rubidium atom is $m = 87 \cdot 1.66 \cdot 10^{-27}\,\mathrm{kg}$. The scattering rate is $\Gamma = 3.8 \cdot 10^{7}\,\mathrm{s}^{-1}$. What is the acceleration? Compare with the Earth's gravitational acceleration.

2.1.4.11 Ex: Free fall

A stone falls from a balloon vertically ascending at a speed of $v_0 = 20\,\mathrm{m/s}$.
a. Calculate the speed of the stone after 10 s.
b. Calculate the distance covered by the stone in 10 s.
c. Solve the same problem with a balloon descending at the same speed.

2.1.4.12 Ex: Bodies sliding down a slope

Two children are descending with an interval of 2 s a 4 m high frictionless slide ending in a horizontal plane. What is the final distance between them?

2.1.4.13 Ex: Two-dimensional movement

A hose, with the nozzle 1.5 m above ground, is pointed upwards at an angle of 30° with the floor. The water jet hits a flower bed 15 m away.
a. At what velocity does the jet come out of the hose?
b. What is its maximum height.

2.1.4.14 Ex: One-dimensional movement

The driver of a train moving with speed v_1, sees, at a distance d ahead of him, a freight train moving in the same direction with speed v_2. He applies the brakes, transmitting the acceleration $-a$ to the train. Show that if: $d > (v_1 - v_2)^2/2a$, there will be no collision and if $d < (v_1 - v_2)^2/2a$ there will be a collision.

2.1.4.15 Ex: One-dimensional movement

Drops of water fall from a shower onto the floor 2 m below. The drops fall at regular intervals and when the first one hits the ground, the fourth is starting to fall. Determine the position of all the drops at the instant when one of them hits the floor.

2.1.4.16 Ex: One-dimensional movement

The position of a particle that moves along the x-axis depends on time according to the equation: $x = at^2 - bt^3$, x in cm, t in s.
a. At what point is x maximum?
b. What is the speed and at what moment is it zero?
c. What is the acceleration and at what time is it zero?

2.1.4.17 Ex: One-dimensional movement

A plane with speed v_0 lands on an aircraft carrier with negative acceleration $a = -A\sqrt{t}$. What is the minimum required length of the runway?

2.1.4.18 Ex: One-dimensional movement

Two bodies are located at the origin of the x-axis when $t = 0$ s. Body A has a constant speed of 2 m/s. Body B is initially at rest but subject to a constant acceleration of 1 m/s^2.
a. Represent schematically, in the same graph, the positions of bodies A and B as a function of time.
b. What is the time of collision?
c. What is the position x when the collision will occur?
d. What is the speed of body B at the time of collision?
e. At what time will the velocities of the two bodies be equal?

2.1.4.19 Ex: Cylinder rolling without sliding

Consider a cylinder of radius R rolling without sliding on a horizontal plane. The center-of-mass of the cylinder is accelerated.
a. What is the angular acceleration of the cylinder?
b. What is the rotation angle β of the cylinder as a function of time?

2.1.4.20 Ex: Relative velocity of rotating bodies

Two bodies A and B are in uniform circular movements of concentric trajectories with radii r_a and r_b and angular velocities ω_a and ω_b. Determine the relative speed between the two bodies.

2.1.4.21 Ex: Acceleration of a sliding body

Determine the acceleration of a body that slides along the thread of a screw with step h and radius R. Disregard friction and consider the body to have started from rest.

2.1.4.22 Ex: Ballistics

To launch a ball from ground over a wall of height H located at a distance S (see figure), what is the lowest initial speed with which the ball has to be launched?

2.1.4.23 Ex: Ballistics

A bullet is fired from a cannon with speed v_0. Determine the geometric region where the bullet will certainly not hit the ground.

2.1.4.24 Ex: Ballistics

An inclined plane forms an angle α with the xy-plane, as shown in the figure. A body is launched with speed v_0, forming an angle with the y-axis. Disregarding friction calculate: $x_{\max}$, $z_{\max}$, and the time it takes for the projectile to return to the y-axis.

2.1.4.25 Ex: Ballistics

A stone is launched at an initial speed of 20 m/s. Knowing that it stayed for 2 s in the air, calculate:
a. the launch angle (with respect to the horizontal),
b. the maximum height reached,
c. the reach,
d. another launch angle for which the stone will have the same range. (In this case the time will be different from 2 s).

2.1.4.26 Ex: Translation with / without friction

A body is moved with speed $v = 5\,\mathrm{m/s}$ over a horizontal plane without friction. Suddenly he encounters another plane (also without friction) inclined by an angle $\theta = 30°$ and having a height of $H = 0.8\,\mathrm{m}$, as shown in Fig. 2.3.

a. At what distance d from the end of the inclined plane will the body fall?
b. What is the maximum height that the body will reach?

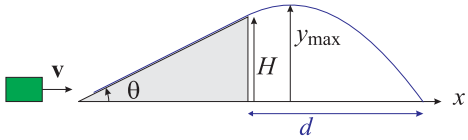

Figure 2.3:

2.1.4.27 Ex: Ballistics

A small body is launched from the origin with speed $v_0 = 100/\sqrt{3}\,\mathrm{m/s}$ under an angle $\theta = 60°$ with the horizontal. Another body is launched 1 second later, at the same speed v_0, but horizontally and from a height H, as shown in the figure. Suppose there is a collision between the two bodies and that $g = 10\,\mathrm{m/s^2}$.
a. At what time does the collision occur?
b. How high should H be for the collision to occur?
c. What are the x and y coordinates of the collision?

2.1.4.28 Ex: Ballistics

A small body is launched from the origin with speed v_0 under an angle θ with the horizontal. Another body is launched with the same speed v_0, but horizontally and from a height H. What should be the value of H such that they reach the same point on the x-axis?

2.1.4.29 Ex: Ballistics

a. Show that the movement of a projectile launched with v_0 and θ is described by the parabola: $y(x) = \frac{v_{0y}^2}{2g} - \frac{g}{2}\left(\frac{x}{v_{0x}} - \frac{v_{0y}}{g}\right)^2$, with $v_{0x} = v_0 \cos\theta$ and $v_{0y} = v_0 \sin\theta$.
b. Find the angle α that the trajectory forms with the horizontal for any x ($\tan\alpha = dy/dx$),
c. Find x_{max} corresponding to the top of the trajectory ($\tan\alpha = 0$).
d. Find the reach R by letting $\alpha = \pi - \theta$.

2.2 Kinetic and potential energy

2.2.1 Conservative potentials

Newton's axioms tell us that the reason for acceleration are forces, but they do not explain the origin of the forces. In our daily experience the forces seem to arise either from contact between bodies, i.e. collisions, or from action at a distance, as in the case of gravity or electromagnetism. In the latter case, the force exerted on a body may or may not depend on its position.

Newton realized the existence of a vertical force field called gravity, which appears to be homogeneous, that is, $F(y) = F = mgy$, where $g = 9.81\,\mathrm{m/s^2}$ is called *gravitational acceleration*.

Example 5 (*Ball rolling on a slope*): Throwing a mass into a rising slope, we experimentally notice that the height over ground Δy the mass reaches when coming to rest only depends on its initial velocity but not on the path. We also notice that this height satisfies,

$$\Delta y \propto v^2 \ . \tag{2.25}$$

Furthermore, we measure the proportionality factor to be $1/2g$.

Hence, in the homogeneous field of gravity,

$$F\Delta y = mg\Delta y = \frac{m}{2}v^2 \ . \tag{2.26}$$

We call the quantity on the right-hand side the *kinetic energy* of the mass while moving at a velocity v at ground height. The left-hand side quantity, attributed to the mass having climbed the slope to height Δy and been stopped to zero velocity, is termed *potential energy* of gravitation. Repeating the experiment for various types of slopes with various inclinations which may even vary along the slope, we verify that the final height does not depend on the trajectory of the mass, that we may parametrize as $t \to \mathbf{s}(\mathbf{t})$. That is,

$$\int_{\text{init}}^{\text{final}} \mathbf{F} \cdot d\mathbf{s} = const = V(y_{\text{final}}) - V(y_{\text{init}}) \ , \tag{2.27}$$

or for a closed path,

$$\oint \mathbf{F} \cdot d\mathbf{s} = 0 \ . \tag{2.28}$$

Only this fact allows us to attribute the potential energy solely to the mass and not to the force field. We will see later that this is only true for particular force fields (e.g. homogeneous or radial fields) and in the absence of friction. We will call force fields having this property *conservative*. The above integral equation can be cast into a differential version,

$$\boxed{\nabla \times \mathbf{F}(\mathbf{r}) = 0 \qquad \text{such that} \qquad \mathbf{F}(\mathbf{r}) = -\nabla V(\mathbf{r})} \ , \tag{2.29}$$

provided, of course, that such a unique conservative potential exists.

2.2.2 Conservation of energy

Do the Excs. 2.2.4.1 to 2.2.4.20.

2.2.3 Translations and rotations of point masses, Galilei boost

The *Galilei transform* to an inertial system moving with velocity $\mathbf{u}$ is defined by,

$$\begin{aligned} t &\to t' = t \\ \mathbf{x} &\to \mathbf{x}' = \mathbf{x} + \mathbf{u}t \ . \end{aligned} \tag{2.30}$$

2.2.3.1 Galilei invariance

Consider a set of interacting particles, $m\dot{v}_i = -\nabla_{\mathbf{x}_i}\sum_j V_{ij}(|\mathbf{x}_i - \mathbf{x}_j|)$. This equation has obviously a Galilei-invariant form. In contrast, the wave equation $\nabla_r^2\psi - \frac{1}{c^2}\frac{\partial^2\psi}{\partial t^2} = 0$ has not, because,

$$\left.\frac{\partial}{\partial t'}\right|_{r'=const} = \left.\frac{\partial}{\partial t}\right|_{r=const} - \mathbf{u}\cdot\nabla_r \ . \tag{2.31}$$

Do the Excs. 2.2.4.21 to 2.2.4.23.

2.2.4 Exercises

2.2.4.1 Ex: Potential

The following force field is given: $\mathbf{F}(\mathbf{r}) = \begin{pmatrix} -2axyz^2 + by^2 \\ -ax^2z^2 + 2bxy \\ -2ax^2yz \end{pmatrix}$. Determine the corresponding potential $V(\mathbf{r})$. Determine the work required to bring a point mass from $\begin{pmatrix} -1 \\ -1 \\ -1 \end{pmatrix}$ to $\begin{pmatrix} 1 \\ 1 \\ 1 \end{pmatrix}$.

2.2.4.2 Ex: Shot put

A shot put is able to throw a 7.257 kg ball at an initial speed of $v_0 = 15\,\mathrm{m/s}$. What is the maximum range w he can achieve with such a throw? How much further could he throw the ball (at the same initial speed) if it were half as heavy? How much further could he throw the ball if he were on the moon? **Note:** The lunar attraction is $g_M = 1.62\,\mathrm{m/s^2}$.

2.2.4.3 Ex: Shot put

In a shot put, a ball with the initial speed $v_0 = 10\,\mathrm{m/s}$ is thrown at a height of $h = 2\,\mathrm{m}$ above ground at an angle of 35°.
a. Calculate the throw distance of the ball.
b. At what speed and at what angle does the ball hit the ground?
c. Calculate the maximum throw height and the time when it is reached?
d. What condition must the throw angle fulfill for maximum throw range? At what angle is the maximum throw range reached in the special case $h = 0\,\mathrm{m}$?

2.2.4.4 Ex: Rocket in the homogeneous field of gravitation

A rocket moves in the homogeneous field of gravity vertically upwards. Reactor gas is ejected at a constant rate $\gamma = \left|\frac{dm}{dt}\right| = const$ and with the velocity v_g. Describe the recoil of the rocket exerted by the ejected gas using $\mathbf{F} = \frac{dm}{dt}\mathbf{v}_g$ or exploiting the momentum conservation law for infinitesimal changes of m (occurring with the velocity v_g) and of v_{rocket}.

2.2.4.5 Ex: Energy conservation in free fall

Consider the free fall of a mass m from the height h.
a. Write down the kinetic energy and the potential energy of the mass as functions of $z(t)$ respectively $\dot{z}(t)$.
b. Calculate $z(t)$ by integrating the energy conservation law for the initial conditions $\dot{z}(t = 0) = 0$. To do this, derive from $\dot{z}(t)$ an equation of the form $\dot{z} = f(z)$ and integrate this equation after separating the variables.

2.2.4.6 Ex: Ski jumping with salto

Two skiers go down a slope on different routes. Calculate the final speed and the arrival time for the two trajectories sketched on the graph by solid and dashed lines.

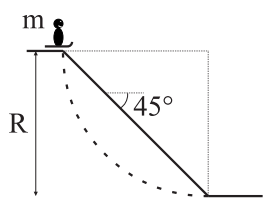

Figure 2.4: Scheme of the ramp.

2.2.4.7 Ex: Ski jumping with salto

A skier with a body weight of 75 kg descends an $L = 50$ m high ski jump with a -100% gradient. At the lower end the ski jump merges into a trough, the curvature of which is described by a circle with radius $R = 10$ m. At an inclination of 100%, the trough suddenly merges into a horizontal plane. Friction is neglected. What is the minimum weight the skis must bear before they break? How far does the skier fly over the plane D?

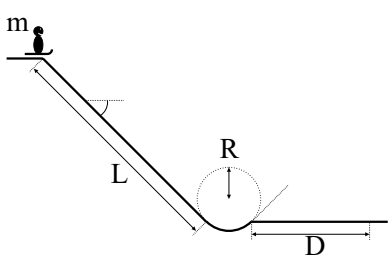

Figure 2.5: Scheme of the ramp.

2.2.4.8 Ex: Ski jumping with salto

A skier goes down a slide. The work exerted by the gravitational field on the skier is,

$$W = \int_{s_0}^{s_1} \mathbf{F} \cdot d\vec{s} = \int_0^x F_s \sqrt{1 + y''} dx \ .$$

Now we consider three different slides:
a. The slide is described by the function $y(x) = \sqrt{h^2 - x^2}$ with $dy/dx = -x/\sqrt{h^2 - x^2} = -x/y$. We also know,

$$F_s(x) = (-mg\hat{\mathbf{e}}_y) \cdot (-\hat{\mathbf{e}}_\theta) = mg\cos\theta \ .$$

Therefore, we can simplify the integral with $x = h\cos\theta$ and $y = h\sin\theta$,

$$\begin{aligned} W &= mg\cos\theta \int_0^x \frac{xdx}{\sqrt{h^2 - x^2}} = mg \int_0^x \frac{xdx}{y} = -mg \int_h^{\sqrt{h^2-x^2}} dy \\ &= mg(h - \sqrt{h^2 - x^2}) = mg(h - y) = \frac{m}{2}v^2 \ . \end{aligned}$$

b. The slide is described by the function $y(x) = (h - x)^2$ with $dy/dx = -2(h - x)$. We also know,

$$F_s(x) = -mg\sin\theta = -mg\frac{\tan\theta}{\sqrt{1 + \tan^2\theta}} = -mg\frac{y'}{\sqrt{1 + y'^2}} \ .$$

So we can simplify the integral,

$$W = -mg \int_0^x \frac{y'}{\sqrt{1 + y'^2}} \sqrt{1 + y'^2} dx = -mg \int_0^x y' dx = -mg \int_h^y dy = mg(h - y) = \frac{m}{2}v^2 \ .$$

c. The slide is described by the function $y(x) = h - \sqrt{h^2 - (x - h)^2}$. With $dy/dx = \frac{-(x-h)}{\sqrt{h^2-(x-h)^2}}$. We also know,

$$F_s(x) = -mg\sin\theta = -mg\frac{\tan\theta}{\sqrt{1 + \tan^2\theta}} = -mg\frac{y'}{\sqrt{1 + y''}} \ .$$

So we can simplify the integral,

$$W = -mg \int_0^x \frac{y'}{\sqrt{1 + y''}} \sqrt{1 + y'^2} dx = -mg \int_0^x y' dx = -mg \int_h^y dy = mg(h - y) = \frac{m}{2}v^2 \ .$$

2.2.4.9 Ex: Looping

A body starts at speed $v_0 = 0$ from point A and slides without friction on a slope (see figure). At point B the slope becomes a circle of radius R.
a. What is the speed at points B and C of the circle?
b. What is the maximum fraction R/h to prevent the body from falling at point B?
c. What is the minimum speed at point B to prevent the body from falling?

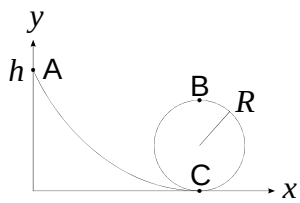

Figure 2.6: Looping.

2.2.4.10 Ex: Forces

A body of mass m moves under the influence of three forces:

$$\begin{aligned}
\mathbf{F}_1(\mathbf{r}) &= (\alpha\cos\omega(x+y), -\beta(y+y_0)^2, \gamma(z+z_0)^2) \\
\mathbf{F}_2(\mathbf{r}) &= (\alpha\sin\omega x\sin\omega y, \beta(y-y_0)^2, -\gamma(z-z_0)^2) \\
\mathbf{F}_3(\mathbf{r}) &= (\alpha\cos(\omega x+\pi)\cos\omega y, 3\beta y y_0, \gamma z_0(z_0-4z)) \ .
\end{aligned}$$

The body is at $t=0$ at the point $\mathbf{r}(0)$ with velocity $\mathbf{v}(0)$. What is the absolute value of the body's velocity $|\mathbf{v}(t)|$ after a time t when it is at the point $\mathbf{r}(t)$?

2.2.4.11 Ex: Pushed inclined plane

A 45° wedge is pushed over a table with constant acceleration a. A cuboid of mass m slides on the wedge without friction. At the time $t=0$ the cuboid is at a height h and, like the cuboid, at rest.
a. Give the acceleration $\mathbf{a}(t)$ and speed $\mathbf{v}(t)$ as a function of time.
b. Give kinetic and potential energy of the cuboid as a function of time. Does energy conservation hold?

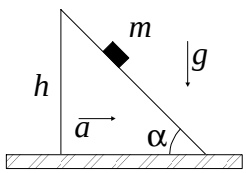

Figure 2.7: Pushed inclined plane.

2.2.4.12 Ex: Bungee jump

An organizer is offering bungee jumps from a bridge of height H. First of all, a student (body length h, mass m) wants to jump upside down from a standing position. The rope (spring constant C) is tied to him exactly in the middle of the body. Help the operator with his calculations.
a. By what length a_0 is the rope stretched when the student is hanging on the rope at rest?
b. How long is the rope to be dimensioned so that the student can just touch the

surface of the water flowing under the bridge with his head? Take into account (a) calculated pre-stretch of the rope. (Numerical values: $H = 100\,\mathrm{m}$, $h = 1.90\,\mathrm{m}$, $m = 50\,\mathrm{kg}$, $C = 50\,\mathrm{N/m}$)

2.2.4.13 Ex: Potential energy

A body is accelerated uniformly from rest until it reaches the speed v_f in time t_f. Show that the instantaneous power delivered to the body is:

$$P(t) = mv_f^2 \frac{t}{t_f^2} \ .$$

2.2.4.14 Ex: Lennard-Jones potential

Consider the Lennard-Jones potential commonly used as the interaction energy between two atoms forming a molecule:

$$U(r) = C\left[\left(\frac{r_0}{r}\right)^{12} - 2\left(\frac{r_0}{r}\right)^{6}\right] \ .$$

a. Draw $U(r)$ as a function of r.
b. Show that the minimum energy (equilibrium position) is at r_0.
c. Find the force between atoms as a function of r.
d. What is the energy required to separate the atoms that form the molecule?

2.2.4.15 Ex: Energy conservation at a pendulum

A pendulum of mass m and length l is released from the point $\theta = 60°$ from rest. Upon reaching the vertical position $\theta = 0°$, the pendulum string encounters a nail fixed at a distance d from the ceiling. Find the minimum distance d for the mass m to rotate around the nail.

2.2.4.16 Ex: Body in a circular truss

A body of mass m moves within a vertical circular rail of radius R (see figure). When m is at the lowest position its speed is v_0.
a. What is the minimum value of v_0 such that the body goes through the entire track?
b. If v_0 were 78% of the value determined in (a), the body would go up the rail up the point P, where it will lose contact with the rail. Find the coordinate θ of this point.

2.2.4.17 Ex: Body in a potential

A body of mass M, subject to a potential $U(x) = -U_0 \cos \pi x$, is released at the origin ($x = 0$) with speed v_0.
a. Sketch the potential in the region $-1 \leq x \leq 1$.
b. Find the force $F(x)$ acting on the body.
c. What is the maximum speed v_m that can be imparted to the body in such a way that it is confined to the region $-1 \leq x \leq 1$?

2.2.4.18 Ex: Roller coaster with looping

A mass m slides without friction along the roller coaster shown in the figure. The circular part has radius R and the mass departs from rest at point B, at the height h measured with respect to relation to the base of the tracks.
a. What is the kinetic energy of m at the point P?
b. What is the acceleration of m at point P assuming that the mass remains on the track?
c. What is the lowest value of h for m to perform the circular motion?
d. For a value of h greater than this minimum, write down the expression for the normal force exerted by the track on the mass.

2.2.4.19 Ex: Body on an inclined plane

A 2 kg body is released on an inclined plane from a point where it elongates by 4 m a spring having the constant spring constant of $k = 100\,\mathrm{N/m}$. The spring is fixed parallel to the plane, inclined by $\theta = 30°$ (see figure).
a. Calculate the maximum compression of the spring assuming that its mass be negligible;
b. Calculate the maximum compression of the spring when the inclined plane exerts friction, the friction coefficient between it and the body being equal to 0.2);
c. In the case (b), what is the height that the body reaches on its way back upward?

2.2.4.20 Ex: Bodies climbing a slope

Two bodies propagating at the same speed v on a horizontal plane have a distance of d. After having climbed a high slope h, what will be the distance between them?

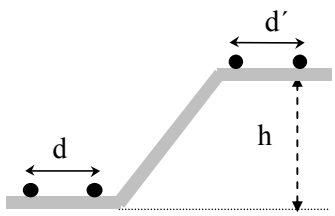

Figure 2.8: Bodies climbing a slope.

2.2.4.21 Ex: Galilei transform

A train runs at a constant speed v_0. Inside the train, from a height h_0 a ball of mass m is released.
a. Calculate the ball's trajectory as seen by an observer traveling on the train.
b. Calculate the ball's trajectory as seen by an observer outside the train.
c. Now, the train is uniformly decelerated from the moment on when the ball is released. Calculate the trajectory of the ball as seen by an observer i. traveling on the train and ii. outside the train.

2.2.4.22 Ex: Relative and center-of-mass coordinates

Consider two mass m_1 and m_2 at the positions $\mathbf{r}_1$ and $\mathbf{r}_2$.
a. Calculate the vector $\mathbf{r}$ of the center-of-mass and express the vectors $\mathbf{r}_1$ and $\mathbf{r}_2$ as a function of the vector $\mathbf{r}$ and the relative vector $\mathbf{r} \equiv= \mathbf{r}_2 - \mathbf{r}_1$.
b. Show that the vector is on the line connecting the masses m_1 and m_2. (**Help:** Parametrize the direct path from $\mathbf{r}_1$ to $\mathbf{r}_2$ and show, that $\mathbf{r}$ is a point on that path.)
c. Suppose that there are no external forces acting on the two masses and that only the gravitational force between them is present. Also suppose that each mass moves on a circle around the center-of-mass. Assume equilibrium between the gravitational attraction and the centripetal force for the two masses. Compare with the corresponding equation of motion for the relative coordinate (reduced mass).
d. Consider as an example the two-body system composed of the Earth and the Moon ($m_E = 5.974 \times 10^{24}\,\mathrm{kg}$, $m_M = 7.35 \times 10^{22}\,\mathrm{kg}$, $r = 384000\,\mathrm{km}$). What is the distance d from the center-of-mass of this system from the center of the Earth?
e. What is the error in calculating the period T of a revolution of the Moon around the Earth, when the Earth's movement is neglected, that is, when the origin of the coordinates is identified with the center of the Earth?

2.2.4.23 Ex: Mobile sports field

Two athletes play with a heavy medicine ball ($m = 4\,\mathrm{kg}$) on a moving platform without friction. They are at a distance of $L = 10\,\mathrm{m}$. In the middle between them there is an elastic net with spring constant $D = 800\,\mathrm{N/m}$. The left athlete throws the ball at a speed of $v_B = 8\,\mathrm{m/s}$ parallel to the Earth's surface.
a. What is the velocity of the platform together with the athletes (total mass $M =$

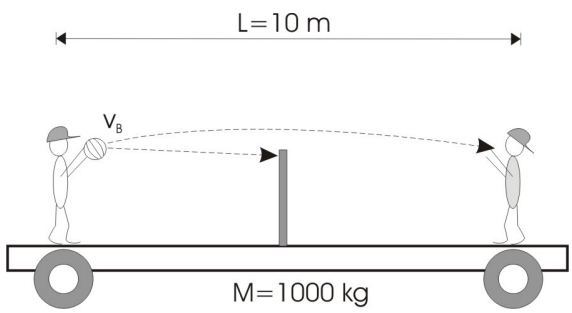

Figure 2.9: Scheme of the system.

$1000\,\mathrm{kg}$), after the moment when the ball leaves the athlete's hand? Suppose the athletes to be firmly connected to the ground.
b. The ball reaches the athlete to the right who catches it. What is the distance covered by the platform?
c. Now, suppose that the ball is blocked by the net. What is the maximum deflection

of the net? How is the speed profile of the platform from the moment on when the ball is released?

2.3 Friction

Stokes friction $F_{\text{fr}} \propto -v$ and *Newton friction* $F_{\text{fr}} \propto -v^2$. Do the Excs. 2.3.1.1 to 2.3.1.5, 2.3.1.6 to 2.3.1.16.

2.3.1 Exercises

2.3.1.1 Ex: Free flight with friction

A body of mass m starts to fall at time $t = 0$ and point $z = 0$ with the initial velocity $\mathbf{v} = v_0\hat{\mathbf{e}}_z$ in the homogeneous terrestrial field of gravity (the z-axis is directed downwards). Its movement in the atmosphere is subject to Newton's friction force, $\mathbf{F}_R = -\alpha v\mathbf{v}$. We are considering only the movement along the z-axis.
a. What is the equation of motion for the body?
b. How should v_0 be chosen to obtain a movement with constant speed? v
c. Now, let the initial velocity v_0 be zero. Calculate the relationship between the falling distance z and the maximum reached velocity. **Help:** Use the method of separating the variables and, for that, write the equation of motion in the form $dz = f(v)dv$. Use the following result: $\int \frac{x}{a^2-x^2}dx = -0.5\ln(a^2 - x^2)$.)
d. After which falling distance does the body reach 50 % of the maximum speed?

2.3.1.2 Ex: Free flight with friction numerically

Here, we want to solve Exc. 2.3.1.1 numerically. A body of mass $m = 1\,\text{kg}$ begins to fall at time $t = 0$ at point $z = 0$ with the initial velocity $\mathbf{v} = v_0\hat{\mathbf{e}}_z$ in the homogeneous gravitational field of the Earth (the z-axis is directed downwards). When moving in the atmosphere, it is subject to Newton's friction force $\mathbf{F}_R = -\alpha v\mathbf{v}$ with $\alpha = 0.01\,\text{kg/m}$. We are considering only the movement along the z-axis.
a. What is the equation of motion for the body?
b. Calculate the trajectory of the body by numerically integrating the equation of motion with the Euler method. Use different starting velocities v_0. Choose v_0 such that, at the beginning, the movement has constant v?

2.3.1.3 Ex: Parachutist with resistance (Möllemanns Rechenaufgabe)

A skydiver exits his plane in 2000 m. Unfortunately, he forgot to put on his parachute. Suppose that air resistance can be described by Stokes friction with the friction coefficient $k = 0.05\,\text{s}^{-1}$.
a. Calculate the parachutist's maximum speed.
b. What would be the total time T of the skydiver's flight if the friction was negligible?
c. What is the distance between the skydiver and the ground at time T in case the friction is not negligible.

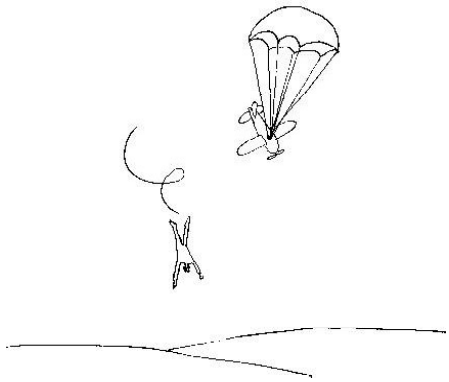

Figure 2.10: Parachutist with resistance.

2.3.1.4 Ex: Oblique throw with friction

You built a ski jumping tower, and now you have to create the associated slope. It

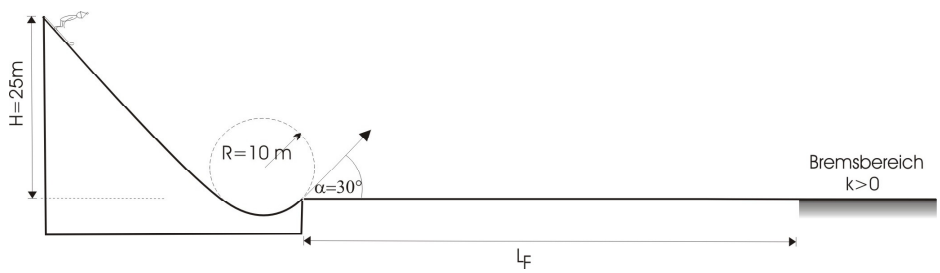

Figure 2.11: Oblique throw with friction.

consists of an inclined plane and a circular arc with radius $R = 10\,\mathrm{m}$ connected to it. The point of take-off is at ground level, and the tangent to the arc and the surface of the ground enclose an angle of $\alpha = 30°$. The ski ramp is frictionless and there is no friction by air resistance during the flight. Now, the braking area behind the desired flight path L_F, that causes a friction force $F_R = -k \cdot v$, needs to be engineered. The jumper has a mass of $m = 80\,\mathrm{kg}$.
a. At what distance L_F must the braking area begin so that the jumper arrives directly at the braking area for a height of the tower of $H = 25\,\mathrm{m}$?
b. What acceleration does the ski jumper experience in the lowest point of the tower (inside the circular path) in addition to the normal gravitational acceleration?
c. As soon as he arrives at the braking area, the frictional force acts and slows down the jumper. How large must the friction coefficient be chosen so that the ski jumper comes to a standstill in less than 6 s? A residual speed of less than 1 cm/s is defined as a standstill. To do this, set up the differential equation and solve it.

2.3.1.5 Ex: Oblique throw with friction

A soccer ball with a mass of 1 kg is shot at an initial speed v_0. In addition to the force of gravity, the Stokes force acts on the ball $\mathbf{F}_R = -km\mathbf{v}$.
a. Set up the equations of motion.
b. Solve the equations of motion for $x(t)$ and $y(t)$.
c. Show by a Taylor expansion of the solutions $x(t)$ and $y(t)$ that for $\beta \to 0$ follows the solution of the frictionless oblique throw.
d. Give an equation for the flight time T_{max} and determine the range x_{max}.
Note: Note that the general solution of the inhomogeneous differential equation consists of the general solution of the homogeneous and a particular solution of the inhomogeneous differential equation. Determine the constants from the boundary conditions.

2.3.1.6 Ex: Body sliding from a cylinder with friction

A body bound to move with friction on a cylinder of radius R is released at an angle θ_0 with zero velocity.
a. What is the maximum coefficient of static friction μ_e allowed for the body to slide?
b. Once the body starts to slide, the friction is dominated by the dynamic friction coefficient μ_d. What is the work done until the body reaches the horizontal position ($\theta = 0°$)?
c. What is the final velocity?

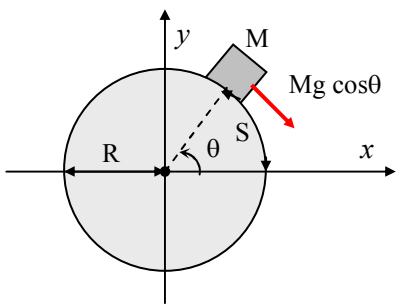

Figure 2.12: Body sliding from a cylinder with friction.

2.3.1.7 Ex: Mass sliding with friction

What is the energy expenditure for a body of mass m sliding over and decelerated by a horizontal plane with the dynamic friction coefficient μ_d.

2.3.1.8 Ex: Inclined plane with and without friction

a. Given the angle θ of an inclined plane without friction, what is the acceleration a_R such that the block of mass m shown in the figure does not slide?
b. If the inclined plane had a friction coefficient μ, what would be the maximum and minimum accelerations such that the block does not slide?

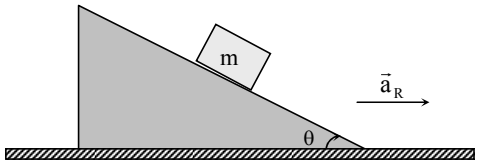

Figure 2.13: Inclined plane.

2.3.1.9 Ex: Static friction

a. The system shown in the figure is friction-free. Determine the value of the force F such that body A does not descend or rise.
b. If there were a static friction μ between the surfaces of the blocks, what would be the maximum and minimum values of forces such that body A does not fall or rise?

2.3.1.10 Ex: Inclined plane with friction

The system shown in the figure employs pulleys without mass. Find the acceleration of each block and the tension in the string.

2.3.1.11 Ex: Body subject to friction

A block of mass M rests on a table with a static friction coefficient μ_s. A force F is applied to the block so as to form an angle θ with the horizontal, as shown in the figure. Assuming that the block is always on the verge of sliding,
a. what is the angle θ that allows the applied force to be minimal, and
b. in this case, what will be the value of the force F_{min}?

2.3.1.12 Ex: Inclined plane with friction

A body of mass m is located on a triangular block of angle θ and mass M, as shown in the figure. There is no friction between the triangular block and the ground, and static friction coefficient between the two blocks is μ.
a. What is the maximum horizontal force F that can be applied to the block m such that it does not slide over the wedge?
b. What is the value of normal in this situation?

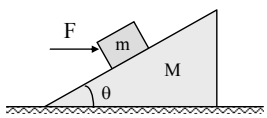

Figure 2.14: Inclined plane.

2.3.1.13 Ex: Stokes' friction

In viscous media (fluids, gases) a velocity-dependent force F_R acts opposite to the movement of a body. For laminar flows, $F_R = Cv$ with a constant C, which in the

case of a sphere of radius r has the value $C = 6\pi\eta r$, where η is the viscosity of the medium.
a. Emperor Charlemagne (year 742-814) is upset, because the Saxon Duke Widukind does let himself be subdued. Out of frustration, he threw his golden sphere, symbol of his kingdom (radius $r = 8\,\mathrm{cm}$, density $\rho = 3.19\,\mathrm{g/cm^3}$) into the Rhine. Establish the equation of motion for the sphere in the water and solve it with the initial values $x(t = 0) = 0\,\mathrm{m}$, $v(t = 0) = 0\,\mathrm{m/s}$. How fast does the golden sphere descend to the bottom? Despise buoyancy. The viscosity of water is $\eta_{H_2O} = 1.7 \cdot 10^{-3}\,\mathrm{Ns/m^2}$.
b. If Charlemagne had launched the sphere from the Lorelei rock (height 125 m above the Rhine), how big would the difference in velocity be due to Stokes friction at the moment of impact on the Rhine's surface compared to the frictionless case? Solve the equation of motion of the sphere with the viscosity of the air $\eta_{\mathrm{ar}} = 1.7 \cdot 10^{-5}\,\mathrm{Ns/m^2}$.

2.3.1.14 Ex: Viscous medium

A body with initial velocity v_0 penetrates a medium that produces a viscous force given by (a) $F = -b\sqrt{v}$ and (b) $F = -cv^2$. Determine the maximum distance that the body penetrates into this medium for both cases.

2.3.1.15 Ex: Newton's friction

A sports car feels air resistance of the form $F_R = -b \cdot v^2$ as well as a rolling frictional force independent on the velocity F_{rol}. Derive an equation for the power needed to maintain a high velocity v. Assume realistic values for the constants and the sports car's power, and calculate the maximum possible resulting speed. Justify your choice of values!

2.3.1.16 Ex: Body subject to friction

Consider the system sketched in the figure, where the force F is constant and the planes have a dynamic friction coefficient μ. Calculate the total work performed by the forces acting on the system when it moves an infinitesimal distance Δx.

2.4 Many-body systems

2.4.1 Balance of forces

Do the Excs. 2.4.4.1 to 2.4.4.17.

2.4.2 Center-of-mass

We have seen earlier that the choice of the coordinate system for the description of a movement is somewhat arbitrary. This implies that the point of origin can be chosen arbitrary. For instance, we all known that the Earth is orbiting around the sun. But it would not be practical to anchor geolocalization devices to a coordinate system having the sun at its origin. Obviously, some coordinate systems are special in the sense that they simplify the mathematical description of trajectories.

One such example, is the center-of-mass coordinate system, which has the potential of greatly simplifying the description of many-body systems, e.g. planetary systems, molecules, or colliding atoms. Let us first consider two bodies of masses m_1 and m_2 located at points $\mathbf{r}_1$ and $\mathbf{r}_2$. We define the center-of mass point and the relative distance by,

$$\mathbf{R} = \frac{m_1\mathbf{r}_1 + m_2\mathbf{r}_2}{m_1 + m_2} \qquad \text{and} \qquad \mathbf{r} = \mathbf{r}_2 - \mathbf{r}_1 \ . \tag{2.32}$$

Generalizing to many bodies,

$$\boxed{\mathbf{R} = \frac{\sum_n m_n\mathbf{r}_n}{\sum_n m_n} \qquad \text{and} \qquad \mathbf{r}_{nn'} = \mathbf{r}_n - \mathbf{r}'_n} \ . \tag{2.33}$$

The total momentum is zero in the center-of-mass coordinate system, since,

$$\mathbf{P} = \sum_n m_n\dot{\mathbf{r}}^{\text{cm}}_{\mathbf{n}} = \sum_n m_n \left(\dot{\mathbf{r}}_n - \frac{\sum_{n'} m_{n'}\dot{\mathbf{r}}_{n'}}{\sum_{n'} m_{n'}}\right) = 0 \ . \tag{2.34}$$

where $\mathbf{r}^{\text{cm}}_n = \mathbf{r}_n - \mathbf{R}$ are the positions of the masses with respect to the center-of-mass.

2.4.3 Collisions and conservation of linear momentum

The most universal laws of physics can be formulated as conservation laws. We have already discussed energy conservation in Sec. 2.2.2. Another conservation law holds for linear momentum. It states that for any system of many bodies not subject to external forces the total momentum cannot change,

$$\boxed{\sum_n \mathbf{p}_n = const} \ . \tag{2.35}$$

This holds if the bodies collide, even when the collisions are inelastic. Do the Excs. 2.4.4.18 to 2.4.4.32.

2.4.3.1 Binary elastic collisions and molecule formation

Binary collisions between atoms are always *elastic*. To see this, we set up the conservation laws for energy and momentum allowing for an inelastic lost of kinetic energy ΔE:

$$\boxed{\frac{p_{i1}^2}{2m} + \frac{p_{i2}^2}{2m} = \frac{p_{f1}^2}{2m} + \frac{p_{f2}^2}{2m} + \Delta E \qquad \text{and} \qquad \mathbf{p}_{i1} + \mathbf{p}_{i2} = \mathbf{p}_{f1} + \mathbf{p}_{f2}} \ . \tag{2.36}$$

Without loss of generality we may transform in to the center-of-mass system, where $\mathbf{p}'_{i1} + \mathbf{p}'_{i2} = 0 = \mathbf{p}'_{f1} + \mathbf{p}'_{f2}$. Inserting this into the law of energy conservation,

$$m\Delta E = p'^2_{i1} - p'^2_{f1} \ . \tag{2.37}$$

So, obviously, if no energy can be dissipated, e.g. into internal atomic excitations, the kinetic energy must remain unchanged.

Without loss of generality we may transform into the inertial system, where $\mathbf{p}''_{i2} = 0$. Inserting this into the conservation laws,

$$\frac{p''^2_{i1}}{2m} = \frac{p''^2_{f1}}{2m} + \frac{p''^2_{f2}}{2m} + \Delta E \qquad \text{and} \qquad \mathbf{p}''_{i1} = \mathbf{p}''_{f1} + \mathbf{p}''_{f2} \ . \tag{2.38}$$

Now substituting $\mathbf{p}_{i1}$ in the energy conservation law,

$$m\Delta E = \mathbf{p}''_{f1} \cdot \mathbf{p}''_{f2} \ . \tag{2.39}$$

So, if no energy can be dissipated, the atoms move in orthogonal directions after the collision.

Can two colliding atoms form a molecule? The laws of energy and momentum conservation require,

$$\frac{\mathbf{p}_1^2}{2m} + \frac{\mathbf{p}_2^2}{2m} = \frac{\mathbf{p}_{12}^2}{m} + \Delta E \qquad \text{and} \qquad \mathbf{p}_1 + \mathbf{p}_2 = \mathbf{p}_{12} \ . \tag{2.40}$$

In the center-of-mass inertial system, we have,

$$2\frac{\mathbf{p}''_1}{2m} = \Delta E \qquad \text{and} \qquad \mathbf{p}'_1 + \mathbf{p}'_2 = 0 = \mathbf{p}'_{12} \ . \tag{2.41}$$

That is, a molecule can only be formed if the collision is inelastic ($\Delta E \neq 0$), which is only possible if there is an excited internal state having exactly the energy ΔE.

2.4.4 Exercises

2.4.4.1 Ex: Mass hanging at a gallow

The mass M is hanging from a string attached to a vertical mast and attached to a boom, so that the angle becomes $\alpha = 90°$, as indicated in the figure. With $h = 1\,\mathrm{m}$, $l = 1\,\mathrm{m}$ and $m = 1\,\mathrm{kg}$, calculate the tension in the wire.

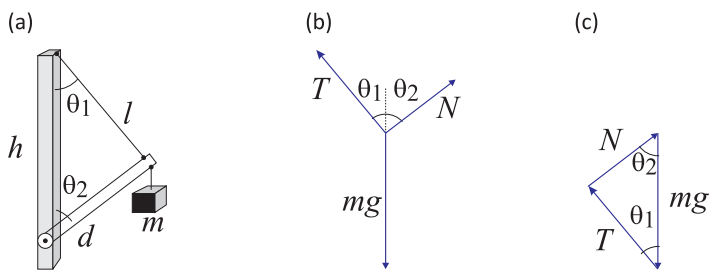

Figure 2.15: (a) Mass hanging at a gallow. (b,c) Alternative force diagrams.

2.4.4.2 Ex: Three blocks

Determine the equilibrium situation of the system sketched in the figure.

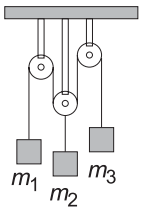

Figure 2.16: Scheme of the system.

2.4.4.3 Ex: Balance of forces on the inclined plane

One body with the mass 8 kg and a second body with the mass 10 kg connected by a wire slide without friction each one on an inclined plane. The wire runs without friction over a block, as shown in the diagram.
a. In which direction will the bodies move?
b. Calculate the acceleration of the bodies.
c. Now the two bodies are replaced by other bodies with the masses m_1 and m_2, such that there is no more acceleration, that is, the bodies are at rest. What should the ratio of the mass m_1 and m_2 be?

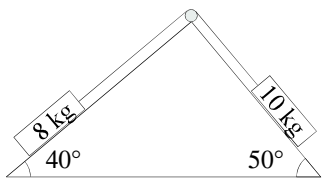

Figure 2.17: Inclined plane.

2.4.4.4 Ex: Balance of forces on the arc

Two spheres of mass m_1 and $m_2 = 2m_1$ connected by a rope of length L are located on both sides of a wall with a semicircular cross-sectional area (see figure). The diameter of the circular arc is $2R$.
a. At what horizontal distance x from the center of the wall must the spheres be in

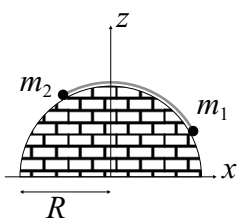

Figure 2.18: Balance of forces on the arc.

order to avoid acceleration? Assume $L = \pi R/2$.

b. Set up the equation of motion.
c. Now assume that the rope is so short that the sine expressions can be replaced by their first-order Taylor expansion. Solve the equation of motion in this approximation. Assume that at $t = 0$ the balls are the same height.

2.4.4.5 Ex: Why Paddy's Not at Work Today (Pat Cooksey)

Identify the movement described in the following song and calculate the total time of the event assuming that each floor is 3 m high, Paddy weighs 70 kg and the pile of bricks 100 kg.

Dear Sir I write this note to inform you of my plight
And at the time of writing I am not a pretty sight
My body is all black and blue, my face a deathly gray
I write this note to tell why Paddy's not at work today

While working on the fourteenth floor, some bricks I had to clear
And to throw them down from off the top seemed quite a good idea
But the gaffer wasn't very pleased, he was an awful sod
He said I had to cart them down the ladder in me hod.

Well clearing all those bricks by hand, it seemed so very slow
So I hoisted up a barrel and secured the rope below
But in my haste to do the job, I was too blind to see
That a barrel full of building bricks is heavier than me.

So when I had untied the rope, the barrel fell like lead
And clinging tightly to the rope I started up instead
I took off like a rocket and to my dismay I found
That half way up I met the bloody barrel coming down.

Well the barrel broke my shoulder as on to the ground it sped
And when I reached the top I banged the pulley with me head
I held on tight, though numb with shock from this almighty blow
And the barrel spilled out half its load fourteen floors below

Now when those building bricks fell from the barrel to the floor
I then outweighed the barrel so I started down once more
I held on tightly to the rope as I flew to the ground
And I landed on those building bricks that were scattered all around.

Now as I lay there on the deck I thought I'd passed the worst
But when the barrel reached the top, that's when the bottom burst
A shower of bricks came down on me, I knew I had no hope
In all of this confusion, I let go the bloody rope.

The barrel being heavier, it started down once more
And landed right on top of me as I lay on the floor

It broke three ribs and my left arm, and I can only say
That I hope you'll understand why Paddy's not at work today.

2.4.4.6 Ex: Superposition of forces

A climber wants to climb a mountain. He weighs with all its equipment 90 kg. He has a cable with a tensile strength of 100 kg. For safety reasons, he uses two ropes fixed at a distance of 10 m at the same height of the wall. He pulls upwards in a way to be always at an equal distance from the two fixing points. Will the ropes hold or will he fall? If so, at what point?

2.4.4.7 Ex: Coupled masses

a. Find the angle θ for the left figure so that the system remains at rest. Disregard friction.
b. Find the ratio between the masses M_1 and M_2 such that the system remains at rest in the right figure. Disregard friction.

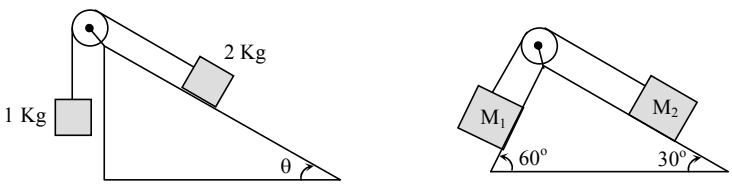

Figure 2.19: Coupled masses.

2.4.4.8 Ex: Coupled masses

a. Find the acceleration of the 2 kg body shown in the left figure.
b. Find the mass of body A such that the acceleration of body B in the right figure is zero.

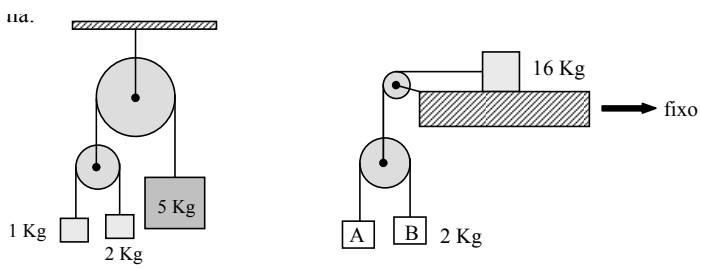

Figure 2.20: Coupled masses.

2.4.4.9 Ex: Coupled masses with friction

In the system exhibited in the figure body A slides on a surface with a friction coefficient μ. The ropes and pulleys have no mass.

a. find the accelerations of blocks A and B;
b. find the tension in the rope connected to body A.

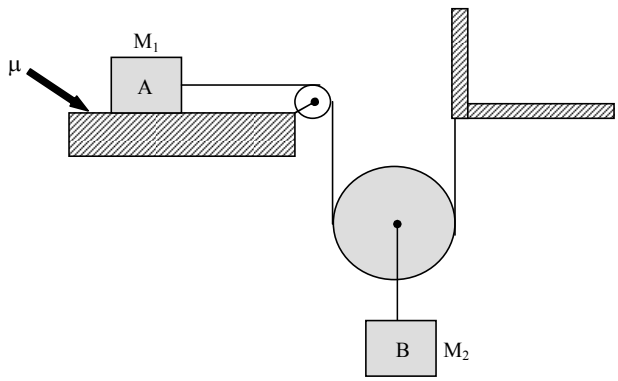

Figure 2.21: Coupled masses with friction.

2.4.4.10 Ex: Frictionless pulley

A string of length L and linear mass density λ passes through a pulley without friction. It is released from rest, with a length x pending on one side and $L - x$ on the other.
a. determine the acceleration as a function of x;
b. for which situation is the acceleration zero?

2.4.4.11 Ex: Coupled bodies

In the system shown in the figure, find:
a. the acceleration of the total system and
b. the force on the rope at point A.

2.4.4.12 Ex: Coupled bodies

N bodies connected to each other by massless strings are pulled on a ramp by means of a force F. Calculate the tension in the rope connected to the i-th body.

2.4.4.13 Ex: Coupled bodies

Consider the conical pendulum shown in the figure, where the string connecting the mass M to point O has no mass.
a. find the angle θ as a function of the velocity of mass M,
b. find the tension in the string at point O.

2.4.4.14 Ex: Coupled bodies without friction

A body of mass M is hung by an ideal string over a triangular block of angle θ, as shown in the figure. In the absence of friction between the blocks, we ask what is the maximum acceleration that can be given to the system such that the body M

remains in contact with the triangular block. In this case, what is the tension in the rope? If the system is moving at a constant speed, what is the value of the tension in the rope and of the normal?

2.4.4.15 Ex: Coupled bodies subject to friction

In the system shown in the figure, the block is in contact with the horizontal surface without friction and subject to a force F. There is a static friction μ between this block and block A in such a way that there is no relative movement between the three blocks forming the system. Calculate:
a. The angle,
b. the tension in the string, and
c. the minimum μ.

2.4.4.16 Ex: Coupled bodies with friction

A block of mass M_1 is on top of another block of mass M_2, which slides over the floor, as shown in the figure. The static friction between the two blocks is μ_e and the kinetic friction between block 2 and the ground is μ_c. a. Determine the maximum force F that can be applied to block 2 without block 1 sliding over it.
b. If the force is increased such that M_1 starts to slide, and the kinetic friction between the blocks is also μ_c, what will be the acceleration of each mass?

2.4.4.17 Ex: Coupled bodies with friction

A block of mass M is located on top of another block of the same mass, on a flat plane inclined by an angle θ, as shown in the figure. The static friction between the two blocks is μ, and between the lower block and the plane it is zero.
a. Determine the maximum force F that can be applied to the upper block without sliding over the lower block.
b. In this case, what will be the acceleration of the total system?

2.4.4.18 Ex: Firework rocket

A firework rocket is launched vertically up to a height of 50 m (along the z-axis). At the apex of the parabolic trajectory, the rocket explodes in three parts with masses $m_1 = 200\,\mathrm{g}$, $m_2 = 300\,\mathrm{g}$ and $m_3 = 400\,\mathrm{g}$. The energy liberated by the explosion (200 J) is converted into kinetic energy for the three fragments. Assume that the resulting momenta are on a single horizontal line (along the x-axis). How long after the explosion and at what positions do the fragments hit the ground in the case that the larger fragment receives the same energy than the sum of the energy of the smaller fragments?
How will the results change when the masses m_1 and m_2 stay the same, but the larger fragment has the mass $m_3 = 500\,\mathrm{g}$?

2.4.4.19 Ex: Ballistic pendulum

We measure the speed of a bullet by a ballistic pendulum. The pendulum, suspended on a wire (length $L = 2\,\mathrm{m}$, mass $M = 4\,\mathrm{kg}$) is moved due to the collision. Determine

from the maximum horizontal displacement ($y = 10\,\text{cm}$) the velocity of the pendulum after the collision and the velocity of the bullet (mass $m = 0.1\,\text{kg}$).

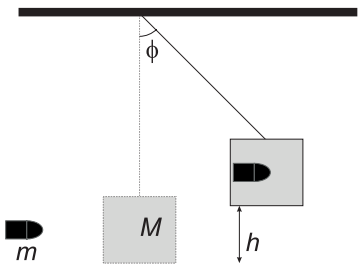

Figure 2.22: Ballistic pendulum.

2.4.4.20 Ex: Central collision in a train station

A wagon of mass m_1 collides elastically with another wagon at rest of mass m_2. What is the relation between the masses m_1 and m_2, if after the collision
a. the wagons have the same velocity in opposite directions,
b. m_2 is three times the velocity of m_1 in the same direction,
c. m_1 is repelled with a third of the initial velocity?

2.4.4.21 Ex: (In-) elastic collision

A billiard ball with the speed $\mathbf{v}_{1i} = v_0\hat{\mathbf{e}}_x$ hits a second one initially at rest. Due to the collision the first ball changes the speed to $\mathbf{v}_{1f} = \frac{2v_0}{3}(\hat{\mathbf{e}}_x \cos\theta + \hat{\mathbf{e}}_y \sin\theta)$, where $\theta = 45°$.
a. Determine the speed of the second ball, $\mathbf{v}_{2f}$, after the collision.
b. Calculate the dissipated energy and determine if shock whether elastic or inelastic.

2.4.4.22 Ex: Variable mass

A wagon of mass M initially at rest is filled with fuel representing half of its mass. The fuel is now horizontally ejected at a constant rate γ and a constant speed v_c, thus propelling the car in the opposite direction. What is the final speed of the wagon when the fuel is completely consumed?

2.4.4.23 Ex: Mass sliding down a movable wedge

A block of mass m rests on a wedge of mass M and angle θ, which is placed on a horizontal surface. Releasing the system from rest, with the body at a height h, determine the speed of the wedge when the block touches the ground. All surfaces are free from friction.

2.4.4.24 Ex: Vertical collision

A body of mass $M = 400\,\mathrm{g}$ is released from rest from a height of $h = 10\,\mathrm{m}$ with respect to the Earth's surface. Simultaneously, a bullet of mass $m = 100\,\mathrm{g}$ is fired vertically from the surface with the speed $v_0 = 10\,\mathrm{m/s}$. Knowing that somewhere in the trajectory the masses collide and merge, we ask how long it takes for the masses to fall from the moment when M is released.

2.4.4.25 Ex: Variable mass

An open freight car weighs 10 tons and is sliding on a frictionless track with a speed of 60 cm/s. Heavy rain suddenly starts and the drops fall vertically with a velocity v_0 with respect to the ground. How fast is the wagon after collecting 500 kg of water?

2.4.4.26 Ex: Variable mass

An hourglass is placed on a scale plate. Initially ($t = 0$), all the sand is at rest in the upper container of the hourglass. The sand falls into the lower container at a rate $\lambda = -dm/dt$. Prepare a graph of the reading on the scale for $t \geq 0$.

2.4.4.27 Ex: Variable mass

A raindrop of initial mass M_0 starts to fall from rest. Assuming that the drop gains mass as it passes through the clouds at a rate proportional to the product of mass by velocity ($dm/dt = Kmv$), calculate the velocity $v(t)$. Neglect air resistance.

2.4.4.28 Ex: Variable mass

A toy rocket has a carcass that weighs 100 g and an initial amount of fuel of 400 g. The velocity relative to the rocket with which the fuel comes out is 100 m/s and the rate at which it is burned is 100 m/s. Assuming it takes off from the Earth's surface ($g = 10\,\mathrm{m/s^2}$ constant) with zero initial velocity, what maximum velocity will it reach?

2.4.4.29 Ex: Variable mass

Calculate the power required to lift a rope vertically, initially completely wound on the ground, at a constant speed v_0. The linear mass density of the rope is λ.

2.4.4.30 Ex: Collision of two masses

Two trolleys with masses m_1 and m_2 and speeds v_1 and v_2 collide elastically (energy is conserved). Knowing that the momentum of the system is preserved during the collision, calculate the speeds of the cars after the crash.

2.4.4.31 Ex: Collision of two masses

Two balls A and B of different masses collide. A is initially at rest and B has the velocity v. After the shock, B has a speed of $v/2$ and moves perpendicular to the

direction of the initial movement. Determine the direction of A's movement after the collision. What is the change in energy due to the collision?

2.4.4.32 Ex: Collision of two masses

A bullet of mass m is fired with the velocity v against a ballistic pendulum of mass M. The bullet passes through the pendulum and emerges with the velocity $v/4$.
a. calculate the maximum height of the oscillating pendulum,
b. calculate the energy dissipated when the bullet passes through the pendulum.

Chapter 3

Rotations and dynamics of rigid bodies

So far we have considered the translation dynamics of point masses. Obviously, point masses, unlike extended rigid bodies, cannot rotate.

3.1 Rotation about a fixed axis

Summary of common transformations,

operation	action on position	on momentum
translation	$\mathcal{T}_{\rm tr}\mathbf{r} = \mathbf{r} + \mathbf{a}$	$\mathcal{T}_{\rm tr}\mathbf{p} = \mathbf{p}$
kick	$\mathcal{T}_{\rm kc}\mathbf{r} = \mathbf{r}$	$\mathcal{T}_{\rm kc}\mathbf{p} = \mathbf{p} + m\mathbf{v}$
rotation	$\mathcal{T}_{\rm rt}\mathbf{r} = e^{\vec{\alpha}\times}\mathbf{r}$	$\mathcal{T}_{\rm rt}\mathbf{p} = e^{\vec{\alpha}\times}\mathbf{p}$
Galilei boost	$\mathcal{T}_{\rm G}\mathbf{r} = \mathbf{r} + \mathbf{v}t$	$\mathcal{T}_{\rm G}\mathbf{p} = \mathbf{p} + m\mathbf{v}$
transform to accelerated frame	$\mathcal{T}_{\rm ac}\mathbf{r} = \mathbf{r}$	$\mathcal{T}_{\rm ac}\mathbf{p} = \mathbf{p} + m\mathbf{g}t$
transform to rotating frame	$\mathcal{T}_{\rm ar}\mathbf{r} = e^{\vec{\omega}t\times}\mathbf{r}$	$\mathcal{T}_{\rm ar}\mathbf{p} = e^{\vec{\omega}t\times}\mathbf{p}$

Let us have a closer look at the rotation operator defined by,

$$\boxed{\mathcal{T}_{\rm rt}\mathbf{r} = e^{\vec{\alpha}\times}\mathbf{r}} \ . \tag{3.1}$$

It can be expanded as,

$$\begin{aligned}\mathcal{T}_{\rm rt}\mathbf{r} &= \sum_n \frac{(\vec{\alpha}\times)^n}{n!}\mathbf{r} = \mathbf{r} + \vec{\alpha}\times\mathbf{r} + \tfrac{1}{2}\vec{\alpha}\times(\vec{\alpha}\times\mathbf{r}) + ... \\ &= \hat{\mathbf{e}}_\alpha(\hat{\mathbf{e}}_\alpha\cdot\mathbf{r}) + \hat{\mathbf{e}}_\alpha\times\mathbf{r}\sin\alpha - \hat{\mathbf{e}}_\alpha\times(\hat{\mathbf{e}}_\alpha\times\mathbf{r})\cos\alpha \ .\end{aligned} \tag{3.2}$$

Choosing the rotation angle along Cartesian coordinates, we find matrix representations of the rotations transformations. For, $\vec{\alpha} = \alpha\hat{\mathbf{e}}_x$,

$$\mathcal{T}_{\rm rt}\mathbf{r} = x\hat{\mathbf{e}}_x + (y\hat{\mathbf{e}}_z - z\hat{\mathbf{e}}_y)\sin\alpha + (y\hat{\mathbf{e}}_y + z\hat{\mathbf{e}}_z)\cos\alpha = R_x\mathbf{r} \tag{3.3}$$

$$\text{with} \qquad R_x = \begin{pmatrix} 1 & 0 & 0 \\ 0 & \cos\alpha & -\sin\alpha \\ 0 & \sin\alpha & \cos\alpha \end{pmatrix} \ ,$$

for, $\vec{\alpha} = \alpha\hat{\mathbf{e}}_y$,

$$\mathcal{T}_{\rm rt}\mathbf{r} = y\hat{\mathbf{e}}_y + (z\hat{\mathbf{e}}_x - x\hat{\mathbf{e}}_z)\sin\alpha + (x\hat{\mathbf{e}}_x + z\hat{\mathbf{e}}_z)\cos\alpha = R_y\mathbf{r} \tag{3.4}$$
$$\text{with} \qquad R_y = \begin{pmatrix} \cos\alpha & 0 & -\sin\alpha \\ 0 & 1 & 0 \\ \sin\alpha & 0 & \cos\alpha \end{pmatrix} ,$$

and for, $\vec{\alpha} = \alpha\hat{\mathbf{e}}_z$,

$$\mathcal{T}_{\rm rt}\mathbf{r} = z\hat{\mathbf{e}}_z + (x\hat{\mathbf{e}}_y - y\hat{\mathbf{e}}_x)\sin\alpha - \hat{\mathbf{e}}_z \times (\hat{\mathbf{e}}_z \times \mathbf{r})\cos\alpha = R_z\mathbf{r} \tag{3.5}$$
$$\text{with} \qquad R_z = \begin{pmatrix} \cos\alpha & -\sin\alpha & 0 \\ \sin\alpha & \cos\alpha & 0 \\ 0 & 0 & 1 \end{pmatrix} .$$

Furthermore, since the vectors $\hat{\mathbf{e}}_\alpha$, $\hat{\mathbf{e}}_\alpha \times \mathbf{p}$, and $\hat{\mathbf{e}}_\alpha \times (\hat{\mathbf{e}}_\alpha \times \mathbf{p})$ in Eq. (3.2) obviously form an orthogonal coordinate system, we find defining $\gamma \equiv \angle(\hat{\mathbf{e}}_\alpha, \mathbf{p})$,

$$\begin{aligned} \mathcal{T}_{\rm rt}(e^{\vec{\alpha}\times}\mathbf{p})^2 &= [\hat{\mathbf{e}}_\alpha(\hat{\mathbf{e}}_\alpha \cdot \mathbf{p}) + \hat{\mathbf{e}}_\alpha \times \mathbf{p}\sin\alpha\hat{\mathbf{e}}_\alpha \times (\hat{\mathbf{e}}_\alpha \times \mathbf{p})\cos\alpha]^2 \\ &= [\hat{\mathbf{e}}_\alpha(\hat{\mathbf{e}}_\alpha \cdot \mathbf{p})]^2 + [\hat{\mathbf{e}}_\alpha \times \mathbf{p}\sin\alpha]^2 + [\hat{\mathbf{e}}_\alpha \times (\hat{\mathbf{e}}_\alpha \times \mathbf{p})\cos\alpha]^2 \\ &= \mathbf{p}^2\cos^2\gamma + \mathbf{p}^2\sin^2\alpha\sin^2\gamma + \mathbf{p}^2\cos^2\alpha\sin^2\gamma = \mathbf{p}^2 , \end{aligned} \tag{3.6}$$

that the kinetic energy and the potential energy in radial potentials is invariant to rotation,

$$\mathcal{T}_{\rm rt}\left(\frac{\mathbf{p}^2}{2m} + V(|\mathbf{r}|)\right) = \frac{\mathbf{p}^2}{2m} + V(|\mathbf{r}|) . \tag{3.7}$$

3.1.0.1 Infinitesimal rotations

For small rotation angles $\delta\vec{\alpha}$ the expression (3.2) can be written as,

$$\begin{aligned} \mathcal{T}_{\rm rt}\mathbf{r} &\simeq \mathbf{r} + \delta\vec{\alpha} \times \mathbf{r} \\ &\simeq \hat{\mathbf{e}}_\alpha(\hat{\mathbf{e}}_\alpha \cdot \mathbf{r}) + \hat{\mathbf{e}}_\alpha \times \mathbf{r}\delta\alpha - \hat{\mathbf{e}}_\alpha \times (\hat{\mathbf{e}}_\alpha \times \mathbf{r}) = \mathbf{r} + \hat{\mathbf{e}}_\alpha \times \mathbf{r}\delta\alpha . \end{aligned} \tag{3.8}$$

For example, for $\delta\vec{\alpha} = \delta\alpha\hat{\mathbf{e}}_z$, the expression (3.5) can be decomposed into,

$$\begin{aligned} \mathcal{T}_{\rm rt}(z)\mathbf{r} = \left[\mathbb{I}_3 + \delta\alpha\begin{pmatrix} 0 & -1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}\right]\mathbf{r} &= \begin{pmatrix} x - y\delta\alpha \\ y + x\delta\alpha \\ z \end{pmatrix} \\ &= \mathbf{r} + \hat{\mathbf{e}}_z \times \mathbf{r}\delta\alpha = \mathbf{r} + \frac{\partial\mathbf{r}}{\partial\alpha}\delta\alpha . \end{aligned} \tag{3.9}$$

Expressing (3.9) as a Taylor expansion,

$$\frac{\partial\mathbf{r}}{\partial\alpha} = \begin{pmatrix} 0 & -1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix} . \tag{3.10}$$

3.1.1 Transformation into a rotating system

Transformation into a rotating system,

$$\frac{d}{dt}\mathcal{T}_{\rm ar}\mathbf{r} = e^{\vec{\omega}t\times}\frac{d}{dt}\mathbf{r} + \left(\frac{d}{dt}e^{\vec{\omega}t\times}\right)\mathbf{r} = \left(\frac{d}{dt} + \vec{\omega}\times\right)\mathcal{T}_{\rm ar}\mathbf{r}\ , \tag{3.11}$$

from which we deduce the rule,

$$\boxed{\left\{\frac{d}{dt}\right\}_{\rm lab} = \left\{\frac{d}{dt}\right\}_{\rm rot} + \vec{\omega}\times}\ . \tag{3.12}$$

Use this expression to resolve Exc. 3.1.2.1 to 3.1.2.4.

3.1.1.1 Inertial forces in the rotating system

Coriolis force, . Do the Excs. 3.1.2.5 to 3.1.2.14.

3.1.1.2 Inertial forces in the linearly accelerated system

3.1.2 Exercises

3.1.2.1 Ex: Rotating coordinate systems

A body of mass m is thrown horizontally at a velocity v_0 in the x-direction in the homogeneous gravitational field of the Earth. (Gravity towards $-z$). The rotation of the Earth is not taken into account.
a. Give the solution $\mathbf{r}(t)$ of the equation of motion.
b. Transform the solution into a coordinate system that rotates around the z-axis at the angular velocity ω.
c. Set up the equation of motion in the rotating system and show that the transformed path from (b) satisfies it.

3.1.2.2 Ex: Orbiting vulture

Consider two Cartesian coordinate systems that are identical at time $t = 0$. One rotates around the z-axis at a constant angular velocity ω, while the laboratory system is at rest. On the x-axis of this rotating system, a vulture moves from the coordinate origin (at time $t = 0$) at a constant speed v.
a. Calculate the vectors of the vulture's position and velocity in the rotating coordinate system.
b. Calculate the Cartesian coordinates of the vulture in the laboratory system and from this the velocity in the laboratory system.
c. Calculate directly the velocity observed in the laboratory system using the relationship (3.9).

3.1.2.3 Ex: Rotating system

Consider a rotating coordinate system, which at time $t = 0$ coincides with the lab system, but rotates relative to the lab system with angular velocity $\omega = 2\pi/T$, $T =$

10 s, around the z-axis. In this coordinate system the rotation of a mass point be given by the vector,

$$\mathbf{r}' = \begin{pmatrix} a \\ a \\ 0 \end{pmatrix} .$$

a. Determine the position vector of this point with respect to the laboratory coordinate system.
b. Consider the position vector at time $t = 5\,\mathrm{s}$ and determine its velocity measured in the rotating system and in the laboratory system.

3.1.2.4 Ex: Rotating system

Consider two coordinate systems, both with their origin at the center of the Earth and their z-axis parallel to the Earth's rotation axis. The rotating system rotates with the Earth, while the laboratory system is fixed to the solar system. An airplane moves at a constant velocity v relative to the Earth's surface on a direct trajectory from the north pole to the equator, where it arrives after a time $\tau = 12\,\mathrm{h}$. What is the velocity of the plane (as a function of time) seen by the lab system?

3.1.2.5 Ex: Inertial forces

A car travels at a speed $v = 100\,\mathrm{km/h}$ from São Carlos (latitude $\theta = -22°$) to Ribeirão Preto, which is north of São Carlos.
a. Calculate the value of the Coriolis acceleration. In which direction is the car deviated?
b. Calculate the centrifugal force knowing that the radius of the Earth is 6370 km.

3.1.2.6 Ex: Foucault's pendulum

A pendulum of mass $m = 7\,\mathrm{kg}$ and length $L = 6\,\mathrm{m}$ is deflected by the angle $\beta = 4°$ and then released. The experiment takes place at a latitude of $\Phi = 51°$ north.
a. How strong is the Coriolis force when passing through the rest position?
b. What is the radius of curvature r of the projection of the pendulum's path onto the horizontal base at the rest point?
c. How long is the oscillation period T of a full rotation of the pendulum plane in the lab frame?

3.1.2.7 Ex: Earth rotation

a. A car with the mass $m = 1000\,\mathrm{kg}$ stands on the equator of the Earth. What is the total force acting on the car, and in which direction does it point? Assume the Earth to be a sphere with radius $R_{♁} = 6370\,\mathrm{km}$. The angular velocity is $\omega_{♁} = 7.27 \cdot 10^{-5}\,\mathrm{s}^{-1}$.
b. Now the car is traveling eastwards at a speed $v = 100\,\mathrm{km/h}$ along the equator. What total force is acting on it, and which direction does this force have?
c. How fast would the car have to travel eastwards along the equator to lift off the surface of the Earth?

Figure 3.1: Earth rotation.

3.1.2.8 Ex: Spinning top in a horizontal plane

Discuss the spinning top on a horizontal plane. What happens when the plane is inclined?

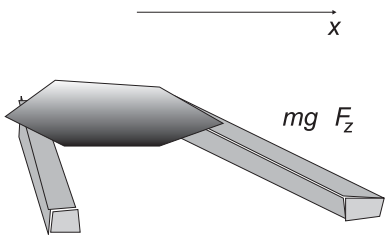

Figure 3.2: Spinning top.

3.1.2.9 Ex: Inertial forces

a. Calculate the correction for the weight of a mass m at rest at the equator due to centrifugal force. Does the centrifugal force modify the falling time for a mass released at a height above the Earth?
b. What are the value and orientation of the Coriolis acceleration acting on a body at the north pole moving with the speed $v = 100\,\mathrm{m/s}$ to the south?
c. Calculate the deviation due to the Coriolis force for a body falling at the equator from a height of $h = 100\,\mathrm{m}$.

3.1.2.10 Ex: Carousel

A vertical bar rotates around the z-axis at a constant angular velocity ω. A thread of length l is attached to the upper end of the rod, while a mass m is attached to the other end of the thread.
a. Find the tension that acts on the thread.
b. Find the angle between thread and bar in equilibrium.

3.1.2.11 Ex: Yo-yo

A yo-yo with radius R and thickness D is accelerated in the field of terrestrial attraction.
a. Determine the inertial moments with respect to the yo-yo's symmetry axis and to the instantaneous point of suspension on the string.
b. Calculate the torque and write down the equation for the rotational motion.
c. From the equation of motion, calculate the angular and linear accelerations, the angular and linear velocities, and the angular momentum.

3.1.2.12 Ex: Deviation to the east

An object is thrown up vertically at the initial speed v_0. Determine the east deflection based on the Earth's rotation as a function of latitude.

3.1.2.13 Ex: Coriolis force

A body falls in free fall at the equator of the Earth from a height of $h = 100\,\mathrm{m}$. At the beginning of the movement ($t = 0$) the body rests at the height h. Air friction is neglected. The centrifugal acceleration is already taken into account in the value of the gravitational acceleration $g = 9.81\,\mathrm{m/s^{-2}}$ relative to the Earth's surface.
a. Set up the equations of motion. Show that the path lies in a plane. What is its spatial location?
b. Solve the differential equations by combining the remaining components of $\mathbf{r}(t)$ into a complex variable $u(t)$. Pay attention to the initial conditions!
c. Give the solution $\mathbf{r}(t)$ and then approximate for small ωt (ω being the angular velocity of the Earth's rotation). Why is this approximation justified?
d. What is the distance from the real point of impact to the point that would be reached without the action of the Coriolis force? In which direction is the body deviated?

3.1.2.14 Ex: Coriolis force

A penguin with the mass m is located directly at the South Pole and begins to slide horizontally at the initial velocity v on the ice. The ice slows him down with the force $\mathbf{F} = -\gamma\mathbf{v}$.
a. Write down the equations of motion in a coordinate system originating at the south pole, which rotates with the Earth.
Note: Place the x-axis in the direction of the penguin's initial velocity and combine the variables x and y to a complex variable $z = x + \imath y$. Neglect the curvature of the Earth. b. Calculate the end position of the penguin on the assumption that the rotation speed of the earth ω is small enough to neglect quadratic terms $\propto \omega^2$ in the equations of motion or in their solution.

3.2 The rigid body

In mechanics a rigid body is defined as a system of masses whose mutual distances are kept fixed during any motion. The rigid bodies of practical interest are generally

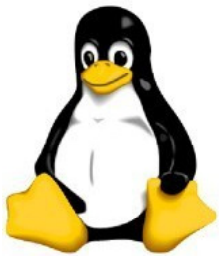

Figure 3.3: Coriolis force.

extended over macroscopic volumes and form a (quasi-)continuous mass distribution. The motion of large rigid bodies is more complicated than the motion of a point mass, since in addition to the translational motion, there may be rotations about one or more axes. The dynamics of both types of motion can clearly be separated in rigid bodies.

3.2.1 Translations and rotations: linear and angular momentum

The translational motion of a rigid body of mass M is fully described by the evolution of the coordinates and the velocity of its center-of-mass. In fact, one can assimilate the translation dynamics of the body with the whole mass M being concentrated in the center-of-mass. The total momentum $\mathbf{p}$ of the body is,

$$\mathbf{p} = m\mathbf{v} \ , \tag{3.13}$$

where $\mathbf{v}$ is the velocity of the center-of-mass. The equation that determines the translational dynamics is Newton's second law,

$$\mathbf{F}_{\text{ext}} = \frac{d\mathbf{p}}{dt} \ , \tag{3.14}$$

where $\mathbf{F}_{\text{ext}}$ is the vectorial sum of external forces acting on the body. When no external forces act, the amount of translational motion of the rigid body is conserved. Similarly, the translational kinetic and the gravitational potential energies of the rigid body can be evaluated by simply considering, respectively, the velocity and height H of the center-of-mass with respect to a reference level of potential energy:

$$E_{\text{kin}} = \frac{M}{2}v^2 \qquad \text{and} \qquad E_{\text{grv}} = MgH \ . \tag{3.15}$$

The (pure) rotation of a rigid body about its center-of-mass also contains kinetic energy. The quantity representing the amount of rotational motion of a rigid body is the rotational angular momentum. For simplicity, we will assume that the rotation occurs about an axis passing through the center-of-mass of the body, and that the body is symmetric around that axis. In this situation, the angular momentum reads,

$$\mathbf{L} = I\vec{\omega} \ , \tag{3.16}$$

where $\vec{\omega}$ is the angular velocity and I the moment of inertia of the rigid body with respect to the rotation axis. The moment of inertia is obtained by summing for the entire body over the contributions of the products between the elementary mass fragments δm_i and the square of their distances d_i^2 from the rotation axis,

$$I = \sum_i d_i^2 \delta m_i \ . \tag{3.17}$$

For an extensive body of volume V and density ρ, the sum in this equation is expressed as an integral along the infinitesimal mass elements $dm = \rho dV$,

$$I - \int_V d^2 \rho dV \ . \tag{3.18}$$

3.2.2 Rotational energy and moment of inertia

The equation that determines the dynamics of rotation is a consequence of Newton's second law, and results in,

$$\tau_{\text{ext}} = \frac{d\mathbf{L}}{dt} \ . \tag{3.19}$$

where τ_{ext} is the vectorial sum over the torques exerted by each external force acting on the body,

$$\tau_{\text{ext}} = \sum_i \mathbf{r}_i \times \mathbf{F}_{\text{ext},i} \ . \tag{3.20}$$

In this expression, $\mathbf{r}_i$ is the vector indicating the point of application of the force $\mathbf{F}_{\text{ext},i}$ on the body, measured with respect to the center-of-mass. When the total external torque is zero, the angular momentum of the rigid body is conserved. The kinetic energy associated with the rotation of the rigid body is given by the expression,

$$E_{\text{rot}} = \frac{I}{2}\omega^2 \ . \tag{3.21}$$

Do the Excs. 3.2.6.1 to 3.2.6.25.

Example 6 (*Cylinder on a slope*): A cylinder of radius R rolls down a slope of inclination θ. We have $h = z \sin\theta$ and $v = R\omega$. Energy conservation means, $mgh = \frac{m}{2}v^2 + \frac{I}{2}\omega^2$, hence,

$$v = \sqrt{\frac{2gh}{1 + I/mR^2}} \ . \tag{3.22}$$

For a plain cylinder we know $I = \frac{m}{2}R^2$ and for a hollow one we know $I = \frac{m}{2}(R^2 + r^2)$. This means, plain cylinders will always reach the same final velocity,

$$v = \sqrt{\frac{4gh}{3}} \ , \tag{3.23}$$

while hollow cylinders will be slower,

$$v = \sqrt{\frac{4gh}{3 + r^2/R^2}} \ . \tag{3.24}$$

3.2.3 Rotation dynamics about a fixed axis

3.2.4 Static equilibrium of a rigid body

3.2.5 Constant acceleration

3.2.6 Exercises

3.2.6.1 Ex: Center of mass

You have three rectangular blocks of same heights and depths, but with different lengths and different masses. You want to build an inclined tower with them. Determine experimentally or theoretically how to stack the blocks so that the top block overhangs as much as possible. What is the most favorable order in the case of same masses but different lengths? What is the most advantageous order in the case of same lengths but different masses?

3.2.6.2 Ex: Inclined pyramid

Five identical point masses m are arranged at the corners of an oblique pyramid with the height H and a square base area $F = a^2$, i.e. they are located at $(x, y, z) = (\pm a/2, \pm a/2, 0)$ and $(b, 0, H)$. What is the maximum lateral displacement b of the top of the pyramid so that the pyramid does not tip out of the horizontal xy-plane?

3.2.6.3 Ex: Inclined cone

A rigid cone with a homogeneous mass distribution has the height H and a base area with a radius R. How far can you tilt the cone before it falls over?

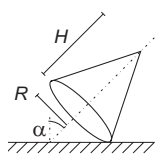

Figure 3.4: Inclined cone.

3.2.6.4 Ex: Angular momentum of the Earth

a. Calculate the angular momentum of the Earth's rotation around its center of mass (mass $M = 5.97 \times 10^{24}\,\mathrm{kg}$, radius $R = 6370\,\mathrm{km}$).
b. Compare this with the angular momentum of the Earth's rotation around the sun (distance between Sun and Earth $D = 150 \times 10^9\,\mathrm{km}$).

3.2.6.5 Ex: Inertial moment

a. Calculate the mass of a cone with homogeneous density (height H and a base radius R).
b. Calculate the cone's inertial moment with respect to the symmetry axis.

c. The cone now rotates with the frequency ω around an axis displaced by a distance R parallel to the symmetry axis. How to calculate the angular momentum?

3.2.6.6 Ex: Glass of beer

A cylindrical glass of beer (height $H = 18\,\mathrm{cm}$, diameter $D = 6\,\mathrm{cm}$, mass $m_\mathrm{G} = 0.5\,\mathrm{kg}$, the bottom is without mass) has, when empty, its center of mass exactly halfway up. Obviously, it is there too, when the glass is filled with beer (density $\rho = 1000\,\mathrm{kg/m^3}$) up to the upper limit. Down to which height h do you have to drink the beer for the center of mass to be at its lowest height?

3.2.6.7 Ex: Inertial moment

Consider a flat symmetrical triangle with surface density σ and corner length a. Fix the coordinate system such that the triangle is given by the corners $A = (0, \frac{a}{2})$, $B = (0, -\frac{a}{2})$ e $C = (\frac{a\sqrt{3}}{2}, 0)$.
a. Calculate the mass of the triangle.
b. Calculate the center of mass.
c. Calculate the inertial moment with respect to an axis normal to the surface through the center of mass of the triangle.

3.2.6.8 Ex: Inertial moment

Consider a flat arc segment with surface density σ, radius R, and angle ϕ. Fix the coordinate system at the center of the arc such that the axis of symmetry is x.
a. Calculate the mass of the segment.
b. Calculate the center of mass.
c. Calculate the inertial moment with respect to a normal axis at the surface through the center of mass of the segment.

3.2.6.9 Ex: Inertial tensor

Calculate the moment of inertia of a homogeneous hollow cylinder with mass m, length L, outer radius R, and inner radius r.

3.2.6.10 Ex: Inertial tensor

Determine the tensor of inertia for
a. a tetrahedron in which the mass is distributed equally between the corner points in a coordinate system in which the z-axis passes through the center of opposite edges;
b. of the tetrahedron in a coordinate system in which the z-axis passes through one of its corners and through its center of gravity.

3.2.6.11 Ex: Inertial tensor

Two balls of different radii $R_1 > R_2$ and same homogeneous mass density ρ are welded together at their point of contact. Derive the moment of inertia of each individual sphere (axis of rotation through the center).
a. Where is the center-of-mass of the total system?

b. Calculate the main moments of inertia of the total system with regard to its center of gravity. **Note:** Use Steiner's theorem.

3.2.6.12 Ex: Rolling movement

A cylinder of mass m with radius R rolls over the ski jump shown in the figure, which has a gradient of -173% (i.e. $\tan\alpha = -1.73$). After having left the ski jump at a height of $h = H/2$, he falls in the Earth's gravity field. Compare the flight distance with the case in which the cylinder does not roll, but slides smoothly over the hill.

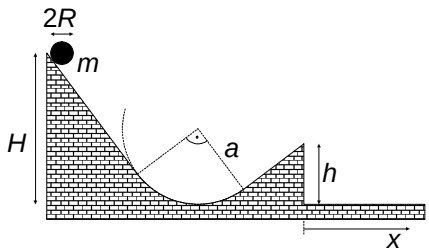

Figure 3.5: Rolling movement.

3.2.6.13 Ex: Accelerated rotational movement

A mass $m = 1\,\text{kg}$ is hanging on a light cord, which is wound on a $d = 2\,\text{cm}$ thick wheel with the radius $r = 10\,\text{cm}$. The wheel has a homogeneously distributed mass of $M = 10\,\text{kg}$ and rotates without friction.
a. Determine the tensile force in the cord.
b. Determine the acceleration of the mass.

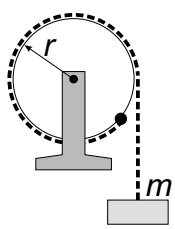

Figure 3.6: Accelerated rotational movement.

3.2.6.14 Ex: Hovering dumbbell

A dumbbell rotates at the angular velocity ω around a rotation axis that passes through its center of gravity and forms an angle α with the axis connecting the masses (see figure).
a. Calculate the angular momentum vector of the barbell in the co-rotating coordinate system.
b. How does the angular momentum behave in a non-rotating coordinate system?

c. Calculate the torque that must act so that the angular velocity remains constant.

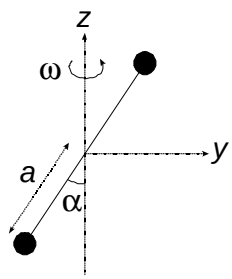

Figure 3.7: Hovering dumbbell.

3.2.6.15 Ex: Hovering cross

Four masses of equal weight m are connected to each other in the manner shown by a rigid cross. The mass of the connecting rods is negligible. The cross rotates at a constant angular velocity ω around an axis of rotation that lies in its plane, passes through its center of gravity and forms an angle α with its long axis.
a. Calculate the inertia tensor I of the body in the co-rotating system. b. First

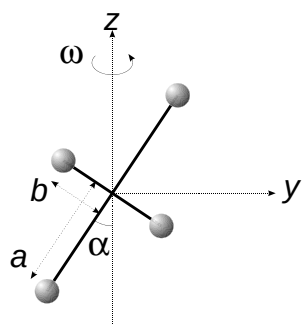

Figure 3.8: Hovering cross.

calculate the angular momentum $\mathbf{L}$ in the co-rotating system using the relationship $\mathbf{L} = I\vec{\omega}$, where $\vec{\omega} = (0, 0, \omega)$ is invariant under rotation around the z-axis. Then transform $\mathbf{L}$ back into the laboratory system.
c. Calculate the torque that must act so that the angular velocity remains constant.

3.2.6.16 Ex: A farmer on a ladder

A farmer of mass $M = 90\,\mathrm{kg}$ harvests apples climbing a ladder (length $L = 10\,\mathrm{m}$, mass $m = 30\,\mathrm{kg}$) leaning at an angle $\phi = 60°$ against a branch relative to the Earth's surface. While harvesting the highest apples at the top, the branch suddenly breaks away. In his fear, the farmer clings to the ladder. The system ladder-farmer now

falls down with the ladder base remaining fixed. Neglect the spatial expansion of the farmer. The ladder can be viewed as a one-dimensional rod.
a. Show that the moment of inertia I_{LB} of the ladder-farmer system for a rotation around the ladder base point can be given as $I_{\mathrm{LB}} = \left(\frac{m}{3} + M\right) L^2$.
b. At what speed v_1 does the farmer reach the surface of the Earth?
c. At the instant when the branches break, in his shock the farmer drops an apple. At what speed v_2 does the apple reach the surface of the Earth?
d. Would the farmer fall more slowly when letting the ladder go at the moment when the branch breaks?

3.2.6.17 Ex: Angular momentum

A thin bar of length L and mass M is suspended at one end thus forming a physical pendulum.
a. I calculate the inertial moment of the bar.
b. Now, the pendulum is tilted a little. Calculate the torque as a function of the angle of inclination.
c. For very small angles θ holds the approximation $\sin\theta \simeq \theta$. Use this approach to establish the equation of motion.

3.2.6.18 Ex: Accelerated pendulum

A pendulum of length R is suspended in a car which is uniformly accelerated with the acceleration a.
a. Calculate the angle of the pendulum's displacement.
b. Calculate the torque exerted by the accelerating force of the car.
c. What is the torque exerted by the weight in this situation?
d. Calculates the ratio of the torques. Justify the obtained result.

3.2.6.19 Ex: Rotating disc

A round disk of mass M with radius R is rotatably mounted about a vertical axis passing through its center. A spring of negligible mass with the spring constant κ is attached to the disc tangentially to the edge. The spring, which is initially fully compressed by the length d, represents a launching device for a ball of mass m. The disk rests until the ball is released being ejected horizontally by the spring. Calculate the angular velocity of the disk after the ejection.
Help: Use the angular momentum and energy conservation laws.

3.2.6.20 Ex: Billiard

A resting billiard ball with radius r is played with a horizontal queue, which gives it an impulse $\Delta p = F\Delta t$. The queue hits the ball at a height h above the table. How does the initial angular velocity ω of the sphere depend on Δp and h? **Help:** The ball rolls without slipping.

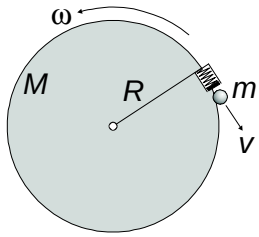

Figure 3.9: Rotating disc.

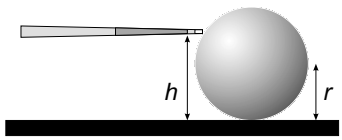

Figure 3.10: Billiard.

3.2.6.21 Ex: Rotating and propagating arc

Calculate the angular momentum of an arc (a) rotating around its center of mass, (b) rotating around a peripheral point, and (c) rolling without friction on a surface.

3.2.6.22 Ex: Inertial momentum

Calculate the moment of inertia of a quadrilateral of point masses in relation to the axes shown in the figure.

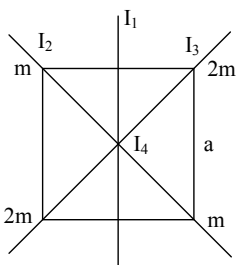

Figure 3.11: Inertial momentum.

3.2.6.23 Ex: Inertial momentum

A disc of radius R and surface mass density σ has a circular hole of radius r at a distance a from the center of the disc. Calculate the moments of inertia with respect to the axes 1, 2 and 3, as shown in the figure.

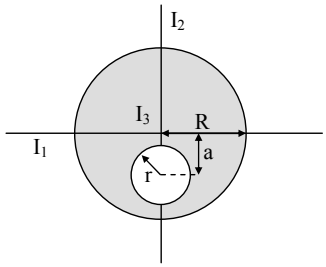

Figure 3.12: Inertial momentum.

3.2.6.24 Ex: Inertial momentum

Calculate the moment of inertia of a sphere of mass M and radius R with respect to an axis passing through the center of mass.

3.2.6.25 Ex: Inertial momentum of a slender bar

A thin bar of mass M and length L makes an angle θ with the y-axis, as shown in the figure.
a. Calculate the moment of inertia for rotation about the axis;
b. Calculate the moment of inertia for rotation around an axis parallel to y and passing through the center of mass.

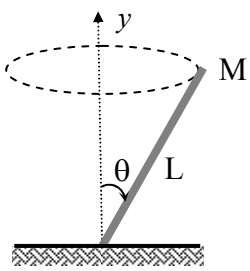

Figure 3.13: Slender bar.

3.3 Angular momentum

3.3.1 Torque and angular momentum of a particle system

3.3.1.1 Steiner's theorem

The angular momentum I_ω of a rigid body with respect to a rotation axis $\hat{\mathbf{e}}_\omega$ can be divided into $I_\omega = I_\omega^{\mathrm{SP}} + Mb^2$. Here, I_ω^{SP} is the inertial moment of the body with respect to the rotation axis $\hat{\mathbf{e}}_{0\omega}$, which is parallel to $\hat{\mathbf{e}}_\omega$ and traverses the center-of-mass of the body, M is the mass of the body, and b is the distance from the rotation axis. This is *Steiner's theorem*.

To demonstrate Steiner's theorem, we consider the vector of a mass point α of the rigid body a first time in the coordinate system, whose origin lies on the axis $\hat{\mathbf{e}}_\omega$, and which we call $\mathbf{r}_\alpha$. A second time we describe this mass point in the coordinate system, whose origin lies in the center-of-mass, and which we call $\mathbf{r}$. The vector of the position of the mass α in the center-of-mass system be described by ρ_α. With this nomenclature,

$$\mathbf{r}_\alpha = \mathbf{r} + \vec{\rho}_\alpha \ .$$

The moment of inertia with respect to the $\hat{\mathbf{e}}_\omega$-axis is then,

$$\begin{aligned}
I_\omega &= \sum_\alpha m_\alpha \left(\mathbf{r}_\alpha^2 - (\mathbf{r}_\alpha \cdot \hat{\mathbf{e}}_\omega)\right) \\
&= \sum_\alpha m_\alpha \left[(\mathbf{r} + \vec{\rho}_\alpha)^2 - ((\mathbf{r} + \vec{\rho}_\alpha) \cdot \hat{\mathbf{e}}_\omega)^2\right] \\
&= \sum_\alpha m_\alpha \left[(\mathbf{r}^2 + 2\mathbf{r}\vec{\rho}_\alpha + \vec{\rho}_\alpha^2 - (\mathbf{r} \cdot \hat{\mathbf{e}}_\omega)^2 - 2(\mathbf{r} \cdot \hat{\mathbf{e}}_\omega)(\vec{\rho}_\alpha \cdot \hat{\mathbf{e}}_\omega) - (\vec{\rho}_\alpha \cdot \hat{\mathbf{e}}_\omega)^2\right] \\
&= MR^2 + 0 + \sum_\alpha m_\alpha \vec{\rho}_\alpha^2 - M(\mathbf{r} \cdot \hat{\mathbf{e}}_\omega)^2 - 0 - \sum_\alpha m_\alpha \left(\vec{\rho}_\alpha \cdot \hat{\mathbf{e}}_\omega\right)^2 \\
&= I_\omega^{\mathrm{SP}} + Mb^2 \ .
\end{aligned}$$

The zeros of the fourth line come from $\sum_\alpha m_\alpha \vec{\rho}_\alpha = 0$, because the left side just corresponds to the center-of-mass vector multiplied with the total mass, but which has in the center-of-mass system the value $\mathbf{r} = 0$.

3.3.2 Rotational work-energy relation

3.3.3 Conservation of angular momentum

Like the conservation law for linear momentum, the conservation law for angular momentum is universal. It holds for a rotational collision,

$$(I_1 + I_2)\omega = I_1\omega_1 + I_2\omega_2 \ . \tag{3.25}$$

On the other side, non-rotational energy is not conserved in a rotational collision, $E_{\mathrm{rot}} < E_{\mathrm{rot},1} + E_{\mathrm{rot},2}$, because part of the energy can be dissipated:

$$E_{\mathrm{rot},1} + E_{\mathrm{rot},2} - E_{\mathrm{rot}} = \frac{I_1}{2}\omega_1^2 + \frac{I_2}{2}\omega_2^2 - \frac{I_1 + I_2}{2}\omega^2 = \frac{-I_1 I_2}{2(I_1 + I_2)}(\omega_1 - \omega_2)^2 \ . \tag{3.26}$$

3.3.4 Combination of translation and rotation

Do the Excs. 3.3.5.1 to 3.3.5.20.

Example 7 (*Gyroscope*): The angular momentum due to the rotation of a wheel is,

$$\mathbf{L}_\omega = I_\omega^{(cm)}\vec{\omega} \ .$$

for a disk-shaped wheel the inertial moment $I_\omega^{(cm)}$ about an axis of rotation $\vec{\omega}$ crossing the center-of-mass is,

$$I_\omega^{(cm)} = \frac{M}{2}R^2 \ .$$

The force of gravitation,

$$\mathbf{F}_g = m\mathbf{g}$$

produces a torque,

$$\vec{\tau}_g = \mathbf{D} \times \mathbf{F}_g = Dmg\hat{\mathbf{e}}_\phi \sin\theta \ .$$

Initially, the rotation axis of the disk is horizontal $\theta = 0$. Due to the torque the shaft tilts downward thus forcing the angular momentum to shift to $\mathbf{L}_\omega + d\mathbf{L}_\omega$ with the velocity,

$$\tfrac{d\mathbf{L}_\omega}{dt} = \vec{\tau}_g \ .$$

How can the system react to compensate for this change of $\mathbf{L}_\omega$?
The *total angular momentum in the direction* $\mathbf{g}$ *must be conserved*, as there is no external torque in it. Fortunately, there is another possible movement that can generate an angular momentum: the rotation around the point of support O with the angular velocity $\vec{\Omega}$:

$$const = \mathbf{L}_{\text{tot}} = \mathbf{L}_\omega + \mathbf{L}_\Omega \qquad \text{or} \qquad \frac{d\mathbf{L}_\omega}{dt} = -\frac{d\mathbf{L}_\Omega}{dt} \ .$$

That is, we have a torque $\vec{\tau}_\Omega = \frac{d\mathbf{L}_\Omega}{dt}$. Hence, $|\tau_\omega| = |\tau_\Omega|$, but since the orientation of $\mathbf{L}_\Omega$ is vertically fixed, the orientation of $\vec{\tau}_\Omega$ is also vertical, which corresponds to an azimuthal force. Thus, instead of an inclination of the rotation axis $\mathbf{L}_\omega$, we get an *azimuthal* shift by an angle,

$$d\vec{\phi} = \frac{d\mathbf{L}_\Omega}{L_\omega \sin\theta} = \frac{d\mathbf{L}_\omega}{L_\omega \sin\theta} = \frac{\vec{\tau}_g dt}{I_\omega^{(\text{cm})}\omega\sin\theta} = \frac{Dm(-\mathbf{g})\sin\theta dt}{I_\omega^{(\text{cm})}\omega\sin\theta} = -\frac{Dm\mathbf{g}dt}{I_\omega^{(\text{cm})}\omega} \ .$$

The frequency of this *precession* movement,

$$\vec{\Omega} = \frac{d\vec{\phi}}{dt} \ ,$$

produces an angular momentum,

$$\mathbf{L}_\Omega = M\mathbf{D} \times \mathbf{v}_\Omega = MD^2\vec{\Omega} = I_\Omega^{(\text{O})}\vec{\Omega} \ .$$

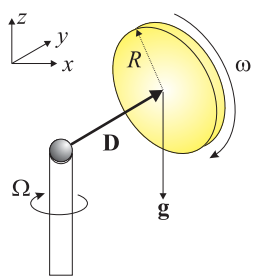

Figure 3.14: Rotating wheel supported on one end of its axis.

Now, the precession modifies the direction of the angular momentum in the plane,

$$\mathbf{L}_\omega = L_\omega \hat{\mathbf{e}}_\phi \ ,$$

with $\hat{\mathbf{e}}_\phi = \hat{\mathbf{e}}_x \cos\Omega t + \hat{\mathbf{e}}_y \sin\Omega t$. Hence,

$$\dot{\mathbf{L}} = L\vec{\Omega} = \vec{\tau}_\omega = L\frac{-Dm\mathbf{g}dt}{I_\omega^{(\text{cm})}\omega} = -Dm\mathbf{g} = \mathbf{D} \times \mathbf{F} \ .$$

Finally, we find a force exactly compensating gravity,

$$\mathbf{F} = -m\mathbf{g} \ .$$

3.3.5 Exercises

3.3.5.1 Ex: Statics of a ladder

A ladder of mass M and length L leans on a frictionless wall and and stands on a floor with friction μ (see figure). Knowing that the angle between the ladder and the wall is 45°, what should be the force on a rope tied in the middle of the stairs so that it does not fall?

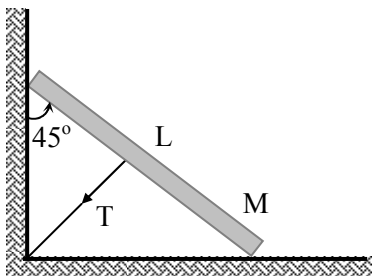

Figure 3.15: Statics of a ladder.

3.3.5.2 Ex: Statics of a ladder

A ladder of mass M and length L leans against wall and stands on the floor (both without friction) such as to form an angle θ with the wall, as shown in the figure. A rope tied at a height of H (parallel to the floor) keeps the ladder at rest. Calculate:
a. the tension in the rope;
b. the maximum height $H_{\max}$ at which equilibrium is possible;
c. the angular acceleration at the instant this rope is cut.

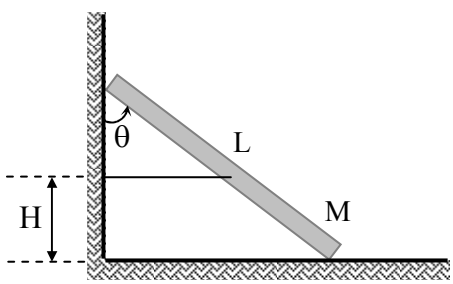

Figure 3.16: Statics of a ladder.

3.3.5.3 Ex: Statics of a ladder

A Λ-shaped ladder of mass $2M$ mass is opened to form an angle θ. What should be the coefficient of static friction with the floor so that it doesn't fall? (see figure).

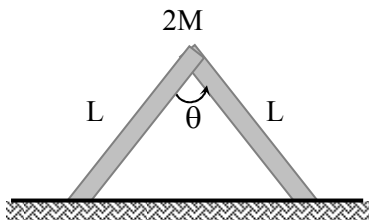

Figure 3.17: Statics of a ladder.

3.3.5.4 Ex: Statics of a ladder

A painter of mass M stands at the top of a Λ-shaped ladder of negligible weight (length of each side: L) that rests on an extremely smooth floor M. There is a crossbar at half height that prevents the ladder from opening. The vertex angle is θ. What is the force on the crossbar?

3.3.5.5 Ex: Statics of a ladder

A bar of length L and mass M is placed over a hole, as shown in the figure. What must be the friction coefficient for the bar to stay at rest?

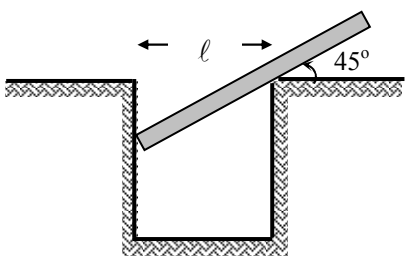

Figure 3.18: Statics of a ladder.

3.3.5.6 Ex: Torque on a block

On a smooth surface, a cubic block of size L and mass M slides with speed v (see figure). At a certain point, the cube hits a small obstacle. How fast should the velocity v of the block be in order to rotate around this point?

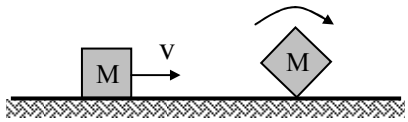

Figure 3.19: Torque on a block.

3.3.5.7 Ex: Falling rod

At the end of a rod of length L the negligible mass is placed a mass M. The system is released from vertical under the action of gravity. What is the equation that describes the angle $\theta(t)$ (see the figure)?

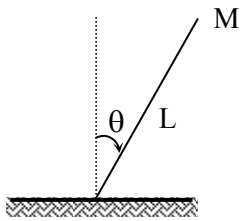

Figure 3.20: Falling rod.

3.3.5.8 Ex: Rotating arc

An arc of radius R, which rotates with angular velocity ω_0, is placed on a rough horizontal surface, as shown in the figure, the speed of its center of mass being zero. Determine the speed of the center of mass after slipping has ceased.

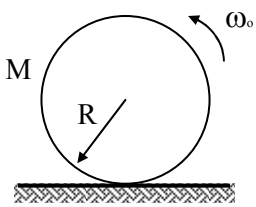

Figure 3.21: Rotating arc.

3.3.5.9 Ex: Angular momentum

The integral of the torque with respect to time is called the angular momentum. Starting from the relationship $\vec{\tau} = d\mathbf{L}/dt$, show that the impulse is the variation of the angular momentum.

3.3.5.10 Ex: Billiard

A billiard ball initially at rest receives an instant boost from a cue. The cue is kept horizontal at a distance h from the center. The ball leaves with speed v_0 and the final speed is $9v_0/7$. Show that $h = 4R/5$, where R is the radius of the sphere.

3.3.5.11 Ex: Bohr's atom

Niels Bohr postulated that a rotating mechanical system can only have angular momentum with multiple values of a constant $\hbar$, called Planck's constant $\hbar = h/2\pi = 1.054 \times 10^{-34}$ Js, that is: $L = I\omega = n\hbar$, being n a positive integer or zero.
a. Show that with this postulate, the energy of a rotor can only acquire discrete, that is, quantized values.
b. Consider a mass m forced to rotate on a circle of radius R (e.g. hydrogen atom). What are the possible values for the angular velocity considering Bohr's postulate?
c. What kinetic energy values can the atom adopt?

3.3.5.12 Ex: Earth rotation

Many of the great rivers flow into the equatorial region carrying sandy sediments. What effect does this have on the Earth's rotation?

3.3.5.13 Ex: Cylinder rolling on an inclined plane

A cylinder of mass M and radius R rotates without sliding on a horizontal plane. The speed of the center of mass is v. It encounters a plane with a tilt angle θ in front of it, as shown in the figure.
b. What were the linear and angular momenta when the cylinder meets the inclined plane?
c. How long does the cylinder take to reach the maximum height, and to what height does it rise on the inclined plane?
d. In this position, what was the change in angular momentum?

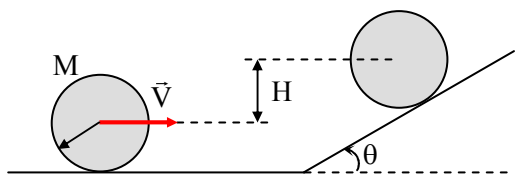

Figure 3.22: Cylinder rolling on an inclined plane.

3.3.5.14 Ex: Disc pushed by a mass

A disk of mass M and radius R can move around an axis passing through its center of mass, as shown in the figure. A particle of mass M as well follows a linear path with velocity v_i and impact parameter $d = R/2$ relative to the center-of-mass point. When it hits the disk it undergoes a deflection of 90° and has its velocity changed to

$v_f = v_i/2$.
a. What is the angular velocity of the disc after the collision?
b. What is the energy dissipated in the collision?

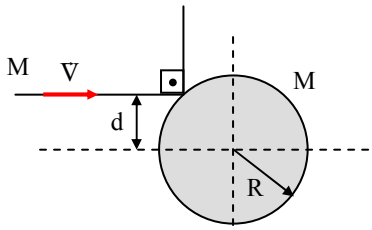

Figure 3.23: Disc pushed by a mass.

3.3.5.15 Ex: Disc pushed by a mass

A disc of mass $2m$ and radius R rests on an extremely smooth horizontal table. A bullet of mass m, speed v_0 and impact parameter R hits the disc and chokes it (see figure). Calculate:
a. The angular velocity of the system right after the collision;
b. The center-of-mass velocity after the collision;
c. The energy dissipated in the collision.

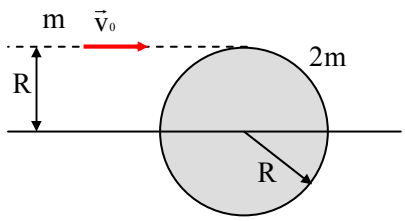

Figure 3.24: Disc pushed by a mass.

3.3.5.16 Ex: Billiard

A billiard ball initially at rest receives an sudden impulse from a cue, which forms an angle with the horizontal, as shown in the figure. The ball leaves with initial velocity v_0 and at the end of the movement it is at rest.
a. Determine the angle θ for this to happen.
b. What is the initial angular velocity of the ball?
c. What is the energy dissipated during the movement?

3.3.5.17 Ex: Horizontal pendulum with variable length

A particle of mass m is attached to the end of a wire and follows a circular path of radius r on a horizontal table without friction. The wire passes through a hole in the

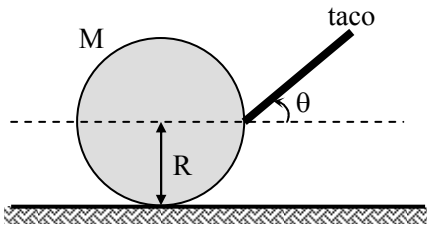

Figure 3.25: Billiard.

table and the other end is initially fixed. In this situation, the initial radius is r_0 and the initial angular velocity is ω_0. The wire is then slowly pulled in order to reduce the radius of the circular path, as shown in the figure.
a. How will the angular velocity vary as a function of r?
b. What work has to be done to bring the particle to the radius $r_0/2$?

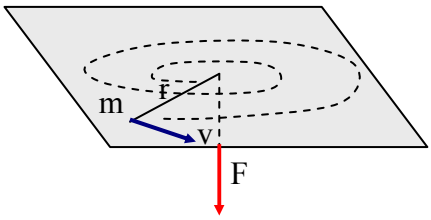

Figure 3.26: Horizontal pendulum with variable length.

3.3.5.18 Ex: Cylinder rolling on an inclined plane

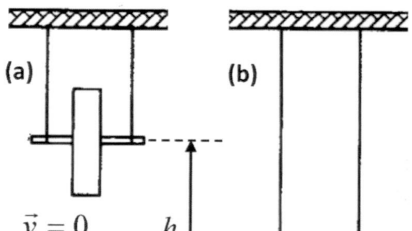
Consider a cylinder of mass M and radius R descending an inclined plane of angle θ without sliding. Calculate the acceleration of the center of mass and the friction force acting on the cylinder.

3.3.5.19 Ex: Billiard

A billiard ball of mass M and radius R ($I = \frac{2}{5}MR^2$ slides without rotating with speed v_0 on a frictionless table. Suddenly it encounters a part of table with friction and after some time is running without sliding.
a. Calculate the final speed of the ball.
b. What is the energy dissipated in the process?

3.3.5.20 Ex: Shock and conservation laws

In an experiment Maxwell's wheel was used to determine the moment of inertia I of a body of mass $m = 1490\,\mathrm{g}$. The axis of the body around



which it spins during the fall has a radius of $r = 0.6\,\text{cm}$ (the mass of the axis is included in the mass m of the body). See figure below. Measurements of the fall time t_b were made for various heights h, and the data are given in the table below. The moment of inertia I is given by the expression,

$$I = \left(\frac{gt_b^2}{2h} - 1\right) mr^2 \ ,$$

which implies the following relationship between h and t_b,

$$h = \alpha t_b^2 \qquad \text{where} \qquad \alpha = \frac{g}{2}\frac{mr^2}{I + mr^2} \ .$$

a. Using a double logarithmic paper draw the graph $\log h \times \log t_b$. Choose the line that best approximates the data and determine its angular and linear coefficients. From them determine (i) The power law of t_b in the expression $h = \alpha t_b^{\beta}$ and (ii) The value of α and from it the value of I.
b. Using a millimetric paper draw the graph $h \times t_b^2$, and from the slope α determine the value of I again. Compare the results.

h (cm)	t_b (s)

Chapter 4

Vibrations

Vibrations are periodic processes, that is, processes that repeat themselves after a given time interval. After a time called *period*, the system under consideration returns to the same state in which it was initially. There innumerable examples for periodic processes, such as the motion of a seesaw, oceanic tides, electronic $L - C$ circuits, alternating current or rotations like that of the Earth around the Sun. Thus, vibrations are among the most fundamental processes in all domains of physics. A lecture version of this chapter can be found at (watch talk).

4.1 Free periodic motion

A movement is considered as free, when apart from a *restoring force*, that is a force working to counteract the displacement, there are no other forces accelerating or slowing down the motion.

4.1.1 Clocks

Periodic motions are used to *measure time*. Assuming a given process to be truly periodic, we can inversely *postulate* that the time interval within which this process occurs is constant. This interval is used to define a *unit of time*. For example, the 'day' is defined as the interval that the Earth needs to complete a rotation about its axis. The 'second' is defined as the 86400-th fraction of this period. Taking the second inversely as the base unit, we can define the day as the time interval needed for a periodic process taking 1 s to occur 86400 times. That is, we count the number of times ν that this process occurs within a day and calculate the duration of a day through,

$$\Delta T = \frac{1}{\nu} \ . \tag{4.1}$$

In real life, vibrations are subject to perturbations, just like all physical processes. These perturbations may afflict the periodicity and falsify the measurement of time. For example, the oceanic tides, which depend on the rotation of the moon around the Earth, can influence the Earth's own rotation. One of the challenges of *metrology*, which is the science dealing with issues related to the measurement of time, is to identify processes in nature that are likely to be insensitive to external perturbations. Nowadays, the most stable known periodic processes are vibrations of electrons within atoms. Therefore, the international time is defined by an atomic clock based on

cesium: The 'official' second is the time interval in which the state of an electron oscillates 9192631770 times when the hyperfine structure of a cesium atom is excited by a microwave.

The unit of time is,

$$\text{unit}(T) = \text{s} \ . \tag{4.2}$$

A *frequency* is defined as the number of processes that occur within one second. We use the unit,

$$\text{unit}(\nu) = \text{Hz} \ . \tag{4.3}$$

Often, to simplify mathematical formulas, we will use the derived quantity of the *angular frequency* also called *angular velocity*,

$$\omega \equiv 2\pi\nu \ . \tag{4.4}$$

It has the unit,

$$\text{unit}(\omega) = \text{rad/s} \neq \text{Hz} \ . \tag{4.5}$$

It is important not to use the unit 'Hertz' for angular frequencies in order to avoid confusion.

4.1.2 Periodic trajectories

Many periodic processes are based on repetitive trajectories of particles or bodies. As an example, let us the movement of a body in a box shown in Fig. 4.1. When the body encounters a wall, it is elastically reflected thereby maintaining its velocity but reversing the direction of propagation. Clearly, the velocity is the derivative of the position,

$$v(t) = \dot{x}(t) \ . \tag{4.6}$$

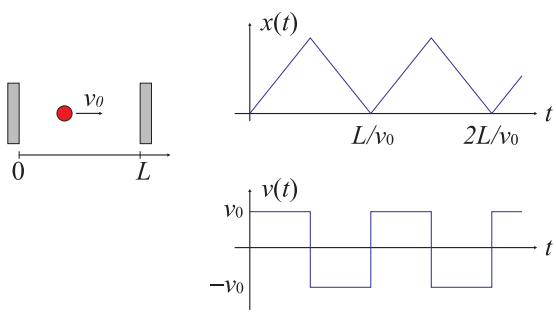

Figure 4.1: Trajectory of a body in a rectangular box. Upper trace: instantaneous position. Lower trace: instantaneous velocity.

To fully describe the trajectory of a body and to identify, when the trajectory repeats, two parameters are needed. Specifying, for example, the time evolution of position $x(t)$ and velocity $v(t)$, we can search for time intervals T after which,

$$x(t_0 + T) = x(t_0) \qquad \text{and} \qquad v(t_0 + T) = v(t_0) \ . \tag{4.7}$$

Obviously, as seen in Fig. 4.1, it is not enough just to look for the time when $x(t_0+T) = x(t_0)$.

4.1.3 Simple harmonic motion

The simplest motion imaginable is the harmonic oscillation described by,

$$x(t) = A\cos(\omega_0 t - \phi) \ , \tag{4.8}$$

and exhibit in Fig. 4.2. A is the *amplitude* of the motion, such that $2A$ is the distance between the two turning points. $T = 2\pi/\omega_0$ is the oscillation period, since,

$$\cos[\omega_0(t+T) - \phi] = \cos[\omega_0 t + 2\pi - \phi] = \cos[\omega_0 t - \phi] \ . \tag{4.9}$$

ϕ is a *phase shift* describing the time delay $t = \phi/\omega_0$ for the oscillation to reach the turning point.

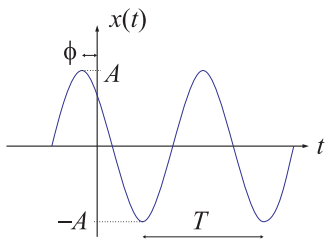

Figure 4.2: Illustration of the cosenus function with the amplitude A, the period T and the phase being negative for this graph $\phi < 0$.

The velocity and acceleration follow from,

$$v(t) = \dot{x}(t) = -\omega_0 A\sin(\omega_0 t - \phi) \qquad \text{and} \qquad a(t) = \dot{v}(t) = -\omega_0^2 A\cos(\omega_0 t - \phi) \ . \tag{4.10}$$

with this we can, using Newton's law, calculate the force necessary to sustain the oscillation of the body,

$$F(t) = ma(t) = -m\omega_0^2 A\cos(\omega_0 t - \phi) = -m\omega_0^2 x(t) \equiv kx(t) \ . \tag{4.11}$$

That is, in the presence of a force, which is proportional to the displacement but with the opposite direction, $F \propto -x$, we expect a sinusoidal solution. The proportionality constant k is called *spring constant*. Obviously the oscillation frequency is independent of amplitude and phase,

$$\omega_0 = \sqrt{k/m} \ . \tag{4.12}$$

Solve Exc. 4.1.10.1 and 4.1.10.2.

Example 8 (*Harmonic vibration*):

- Suspended spring-mass system, pendulums with various masses and lengths of wire, oscilloscope and function generator, water recipient with a floating body.

4.1.4 The spring-mass system

Let us now discuss a possible experimental realization of a sinusoidal vibration. Fig. 4.3 illustrates the spring-mass system consisting of a mass horizontally fixed to a spring. This system has a resting position, which we can set to the point $x = 0$, where no forces act on the mass. When elongated or compressed, the spring exerts a restoring force on the mass working to bring the mass back into its resting position,

$$F_{restore} = -kx \ . \tag{4.13}$$

This so-called *Hooke's law* holds for reasonably small elongations. The spring coefficient k is a characteristic of the spring.

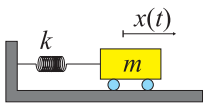

Figure 4.3: Illustration of the spring-mass system.

The oscillation frequency of the spring-mass system is determined by the spring coefficient and the mass, but the phase and the amplitude of the oscillation are parameters, that depend on the way the spring-mass is excited. Knowing the position and velocity of the oscillation at a given time, that is, the initial conditions of the motion, we can determine the amplitude and phase. To see this, we expand the general formula for a sinusoidal oscillation,

$$x(t) = A\cos(\omega_0 t - \phi) = A\cos(\omega_0 t)\cos\phi + A\sin(\omega_0 t)\sin\phi \tag{4.14}$$

and calculate the derivative,

$$v(t) = -A\omega_0\cos\phi\sin(\omega_0 t) + A\omega_0\sin\phi\cos(\omega_0 t) \ . \tag{4.15}$$

With the initial conditions $x(0) = x_0$ and $v(0) = v_0$ we get,

$$A\cos\phi = x_0 \qquad \text{and} \qquad A\omega_0\sin\phi = v_0 \ . \tag{4.16}$$

Hence,

$$x(t) = x_0\cos(\omega_0 t) + \frac{v_0}{\omega_0}\sin(\omega_0 t) \ . \tag{4.17}$$

Solve the Excs. 4.1.10.3, 4.1.10.4, 4.1.10.5, and 4.1.10.6.

4.1.5 Energy conservation

Considerations of *energy conservation* can often help solving mechanical problems. The kinetic energy due to the movement of the mass m is,

$$E_{kin} = \tfrac{m}{2}v^2 \ , \tag{4.18}$$

and the potential energy due to the restoring force is,

$$E_{pot} = -\int_0^x F dx' = -\int_0^x -kx' dx' = \tfrac{k}{2}x^2 \ . \tag{4.19}$$

The total energy must be conserved:

$$E = E_{kin} + E_{pot} = \tfrac{m}{2}v^2 + \tfrac{k}{2}x^2 = const \ , \tag{4.20}$$

but is continuously transformed between kinetic energy and potential energy. This is illustrated on the left-hand side of the Fig. 4.4.

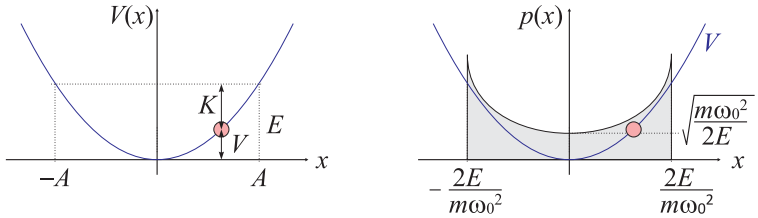

Figure 4.4: (Left) Energy conservation in the spring-mass system showing the kinetic energy K, the potential energy V, and the total energy E. (Right) Probability density of finding the oscillator in position x.

Example 9 (*Probability distribution in the harmonic oscillator*): Let us now use the principle of energy conservation to calculate the probability of finding the oscillating mass next to a given displacement x. For this, we solve the last equation by the velocity,

$$v = \frac{dx}{dt} = \sqrt{\frac{2}{m}E - \tfrac{k}{m}x^2} = \omega_0\sqrt{\frac{2E}{m\omega_0^2} - x^2} \ , \tag{4.21}$$

or

$$\frac{dx}{\sqrt{\frac{2E}{m\omega_0^2} - x^2}} = \omega_0 dt \ . \tag{4.22}$$

The probability of finding the mass within a given time interval dt is,

$$p(t)dt = \frac{dt}{T} = \frac{\omega_0}{2\pi}dt = \frac{dx}{2\pi\sqrt{\frac{2E}{m\omega_0^2} - x^2}} = \tilde{p}(x)dx \ . \tag{4.23}$$

Hence,

$$\tilde{p}(x) = \frac{1}{2\pi\sqrt{\frac{2E}{m\omega_0^2} - x^2}} \tag{4.24}$$

is the probability density of finding in the mass at the position $x(t)$. Using $\int \frac{dx}{\sqrt{a^2-x^2}} = \arcsin\frac{x}{a}$ with $x_0 = \sqrt{\frac{2E}{m\omega_0^2}}$ we verify,

$$2\int_{-x_0}^{x_0} \tilde{p}(x)dx = \frac{1}{\pi}\left[\arcsin\frac{x}{\sqrt{\frac{2E}{m\omega_0^2}}}\right]_{-x_0}^{x_0} = \frac{2}{\pi}\arcsin\frac{x_0}{\sqrt{\frac{2E}{m\omega_0^2}}} = \frac{2}{\pi}\arcsin 1 = 1 \ . \tag{4.25}$$

The probability density is shown on the right side of Fig. 4.4 [1].

[1] To understand the difference between the probability densities $p(t)$ and $\tilde{p}(x)$ we imagine the following experiments: We divide the period T into equal intervals dt and take a series of photos, all with the same exposure time dt. To understand the meaning of $p(t)$, we throw a random number to choose one of the photos. Each photo has the same probability dt/T to be chosen and, of course, $\int_0^T p(t)dt = 1$. To understand the meaning of $\tilde{p}(x)$, we identify the position of the oscillator in each photo and plot it in a histogram. This histogram is reproduced by $\tilde{p}(x)$.

4.1.6 The spring-mass system with gravity

When a mass is suspended vertically to a spring, as shown on the left-hand side of Fig. 4.5, the gravitational force acts on the mass in addition to the restoring force. This can be expressed by the following balance of forces,

$$ma = -ky - mg \ , \tag{4.26}$$

letting the y-axis be positive in the direction opposite to gravitation. Replacing $\tilde{y}' \equiv y - y_0$ with $y_0 \equiv -\frac{mg}{k}$, we obtain,

$$m\tilde{a} = -k\tilde{y} \ . \tag{4.27}$$

Therefore, the movement is the same as in the absence of gravitation, but around an equilibrium point shifted downward by y_0.

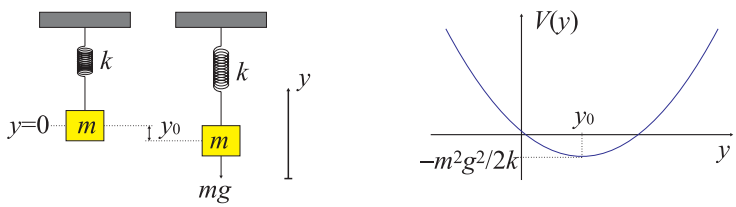

Figure 4.5: Left: Vertical spring-mass system. Right: Conservation of energy in the spring-mass system with gravity.

Energy conservation is now generalized to,

$$E = E_{kin} + E_{mol} + E_{grv} = \tfrac{m}{2}v^2 + \tfrac{k}{2}y^2 + mgy = const \ , \tag{4.28}$$

the potential energy being,

$$\begin{aligned} E_{pot} = E_{mol} + E_{grv} &= \tfrac{k}{2}y^2 + mgy \\ &= \tfrac{k}{2}(y-y_0)^2 + \tfrac{k}{2}2y_0y - \tfrac{k}{2}y_0^2 + mgy = \tfrac{k}{2}(y-y_0)^2 - \frac{m^2g^2}{2k} \ . \end{aligned} \tag{4.29}$$

The right-hand side of Fig. 4.5 illustrates the conservation of energy in the spring-mass system with gravity. See Excs. 4.1.10.7 to 4.1.10.9, 4.1.10.10, and 4.1.10.11.

4.1.7 The pendulum

The pendulum is another system which oscillates in the gravitational field. In the following, we will distinguish three different types of pendulums. In the *ideal pendulum* the mass of the oscillating body is all concentrated in one point and the oscillations have small amplitudes. In the *physical pendulum* the mass of the body is distributed over a finite spatial region. And *mathematical pendulum* is a point mass oscillating with a large amplitude and therefore subject to a nonlinear restoring force.

Figure 4.6: Physical pendulum.

4.1.7.1 The ideal pendulum

The *ideal pendulum* is schematized on the left side of Fig. 4.6. As the centrifugal force is compensated for by the traction of the wire supporting the mass, the acceleration force ma is solely due to the perpendicular projection $-mg\sin\theta$ on the wire. For small amplitudes, $\sin\theta \simeq \theta$, such that [2],

$$ma \simeq -mg\theta \ . \tag{4.30}$$

The tangential acceleration is now,

$$a = \dot{v} = \ddot{s} = \frac{d}{dt}\theta L = L\ddot{\theta} \ . \tag{4.31}$$

Thus,

$$\ddot{\theta} + \frac{g}{L}\theta \simeq 0 \ . \tag{4.32}$$

This equation has the same structure as that of the already studied spring-mass system $\ddot{x} + \frac{k}{m}x = 0$. Therefore, we can deduce that the ideal pendulum oscillates with the frequency,

$$\omega_0 = \sqrt{\frac{g}{L}} \ , \tag{4.33}$$

only that the oscillating degree of freedom is an angle rather than a spatial shift. It is interesting to note that the oscillation frequency is independent of the mass. See Exc. 4.1.10.12.

4.1.7.2 The physical pendulum

We consider an irregular body suspended at a point P as schematized on the right-hand side of Fig. 4.6. The center-of-mass be displaced from the suspension point by a distance D. This system represents the *physical pendulum*. Gravitation exerts a torque $\vec{\tau}$ on the center-of-mass,

$$\vec{\tau} = \mathbf{D} \times m\mathbf{g} \qquad \text{with} \qquad \tau = I\ddot{\theta} \ , \tag{4.34}$$

where I is the moment of inertia of the body for rotations about the suspension axis. Like this,

$$I\ddot{\theta} = -Dmg\sin\theta \ . \tag{4.35}$$

[2]The equation of motion can be derived from the Hamiltonian $H = \frac{L_\theta^2}{2ml^2} + mgl\cos\theta$ using $\dot{\theta} = \partial H/\partial L_\theta$ and $\dot{L_\theta} = -\partial H/\partial\theta$, where L_θ is the angular momentum.

Considering once more small angles, $\sin\theta \simeq \theta$, we obtain,

$$\ddot{\theta} + \omega_0^2\theta \simeq 0 \qquad \text{with} \qquad \omega_0 \equiv \sqrt{\frac{Dmg}{I}} \ . \tag{4.36}$$

It is worth mentioning that the inertial moment of a body whose mass is concentrated in a point at a distance D from the suspension point follows *Steiner's law*,

$$I = mD^2 \ . \tag{4.37}$$

With this we recover the expression of the ideal pendulum,

$$\omega_0 = \sqrt{\frac{Dmg}{mD^2}} = \sqrt{\frac{g}{D}} \ . \tag{4.38}$$

4.1.7.3 The mathematical pendulum

The equation describing the mathematical pendulum (see Fig. 4.6) has already been derived but, differently from what we did before, here we will not apply the small angle approximation,

$$\ddot{\theta} = -\frac{g}{L}\sin\theta = -\omega_0^2\sin\theta \ . \tag{4.39}$$

Energy conservation can be formulated as follows:

$$\begin{aligned} 0 = \frac{dE}{dt} &= \frac{d}{dt}(E_{rot} + E_{pot}) = \frac{d}{dt}\frac{I}{2}\dot{\theta}^2 + \frac{d}{dt}mgL(1-\cos\theta) \\ &= \frac{I}{2}2\dot{\theta}\ddot{\theta} + mgL\dot{\theta}\sin\theta \simeq \dot{\theta}(I\ddot{\theta} + mgL\theta) \ . \end{aligned} \tag{4.40}$$

Thus, we obtain the same differential equation,

$$\ddot{\theta} + \frac{mgL}{I}\theta = 0 \ . \tag{4.41}$$

Example 10 (*Simulation of an anharmonic pendulum*): When the anharmonicity is not negligible, it is impossible to solve the differential equation analytically. We must resort to numerical simulations. The simplest procedure is an iteration of the type,

$$\begin{aligned} \theta(t+dt) &= \theta(t) + dt\dot{\theta} = \theta(t) + dt\omega \\ \omega(t+dt) &= \omega(t) + dt\dot{\omega} = \omega(t) - dt\omega_0\sin\theta \ . \end{aligned}$$

Fig. 4.7(a) shows the temporal dephasing of the oscillation caused by the anharmonicity as compared to the harmonic oscillation. Fig. 4.7(b) shows the orbits $\theta(t) \longmapsto \omega(t)$ in the phase space.

Do the Excs. 4.1.10.17 to 4.1.10.18.

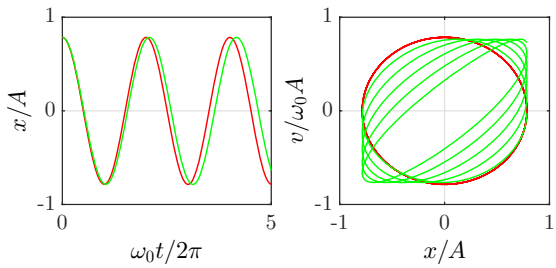

Figure 4.7: (code) Diffusion due to anharmonicities (a) in time and (b) in phase space. The red curves show the harmonic approximation.

4.1.8 The spring-cylinder system

Another example of an oscillating system is shown in Fig. 4.8. The inertial moment of the cylinder is $I = \frac{M}{2}R^2$. The spring exerts the force,

$$F_{mol} = -kx \ . \tag{4.42}$$

Therefore, we have the equations of motion,

$$\begin{aligned} M\ddot{x} &= F_{mol} - F_{at} \\ I\ddot{\theta} &= -RF_{at} \ . \end{aligned} \tag{4.43}$$

If the wheel does not slip, we can eliminate the friction using $x = R\omega$, and we obtain,

$$I\ddot{\theta} = I\frac{\ddot{x}}{R} = \frac{M}{2}R^2\frac{\ddot{x}}{R} = -RF_{at} = -R(-kx - M\ddot{x}) \ . \tag{4.44}$$

Resolving by $\ddot{x}$,

$$\ddot{x} + \frac{2k}{3M}x = 0 \ . \tag{4.45}$$

The frequency is,

$$\omega_0 = \sqrt{\frac{2k}{3M}} \ . \tag{4.46}$$

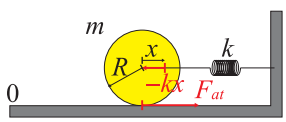

Figure 4.8: The spring-cylinder system.

4.1.9 Two-body oscillation

We now consider the oscillations of two bodies m_1 and m_2 located at the positions x_1 and x_2 and interconnected by a spring k, as shown in Fig. 4.9. The free length, that

is, the distance at which the spring exerts no forces on the masses, is ℓ. The forces grow with the stretch $x \equiv x_2 - x_1 - \ell$ of the spring, such that $x > 0$ when the spring is stretched and $x < 0$ when it is compressed. Thereby,

$$m_1\ddot{x}_1 = kx \qquad \text{and} \qquad m_2\ddot{x}_2 = -kx \ . \tag{4.47}$$

Adding these equations,

$$m_1\ddot{x}_1 + m_2\ddot{x}_2 \equiv (m_1 + m_2)\ddot{x}_{cm} = 0 \ . \tag{4.48}$$

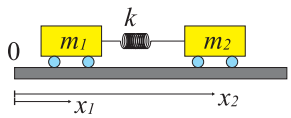

Figure 4.9: Two bodies in relative vibration.

Dividing the equations by the masses and subtracting them,

$$\ddot{x}_1 - \ddot{x}_2 = -k\left(\frac{1}{m_1} + \frac{1}{m_2}\right)x = \ddot{x}_{rel} = -\frac{k}{\mu}x = \omega_0 x \ , \tag{4.49}$$

where $\omega_0^2 = k/\mu$ and $\mu^{-1} \equiv m_1^{-1} + m_2^{-1}$ is called the *reduced mass*. The introduction of the reduced mass turns the oscillator consisting of two bodies equivalent to a system consisting of only one mass and one spring, but with an increased vibration frequency,

$$\omega_\mu = \sqrt{\frac{k}{\mu}} = \sqrt{2\frac{k}{m}} \ . \tag{4.50}$$

This system represents an important model for the description of *molecular vibration*. Note that for $m_1 \longrightarrow \infty$ we restore the known situation of a spring-mass system fixed to a wall.

4.1.10 Exercises

4.1.10.1 Ex: Zenith in São Carlos

Knowing that the latitude of the Sun in the tropics of Capricorn is $\alpha_{trop} = 23°$ calculate at what time of the year the sun is vertical at noon in São Carlos, SP, Brazil.

4.1.10.2 Ex: Length of days on Earth

Calculate the length of a day on Earth as a function of the location's longitude ϕ and latitude θ and of the season of the year.

4.1.10.3 Ex: Swing modes

In the systems shown in the figure there is no friction between the surfaces of the bodies and floor, and the springs have negligible mass. Find the natural oscillation frequencies.

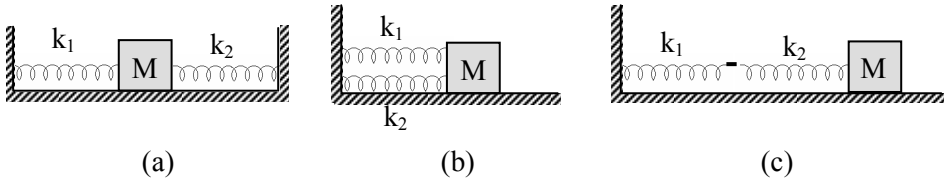

Figure 4.10: Swing modes.

4.1.10.4 Ex: Coupled springs

A mass m is suspended within a horizontal ring of radius $R = 1\,\mathrm{m}$ by three springs with the constants $D_1 = 0.1\,\mathrm{kg/m}$, $D_2 = 0.2\,\mathrm{N/m}$, and $D_3 = 0.3\,\mathrm{N/m}$. The suspension points of the springs on the ring have the same mutual distances. Determine the equilibrium position of the mass assuming that the springs' extensions at rest range is 0.

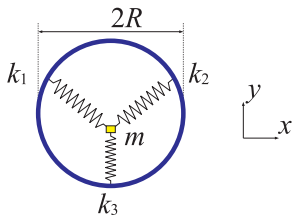

Figure 4.11: Coupled springs.

4.1.10.5 Ex: Coupled springs

A mass m is suspended by four springs with the constants k_n, as shown in the figure. Determine the equilibrium position of the mass. Assume the ideal case of ideally compressible springs.

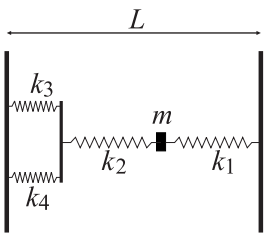

Figure 4.12: Coupled springs.

4.1.10.6 Ex: Coupled springs

Calculate the resulting spring constants for the constructions shown in the scheme. Individual springs are arbitrarily compressible with spring constants D_k.

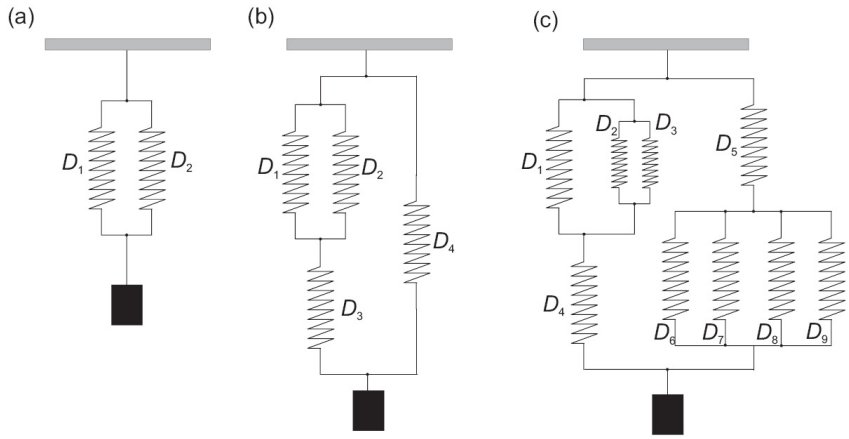

Figure 4.13: Coupled springs.

4.1.10.7 Ex: Spring-mass system

A body of unknown mass hangs at the end of a spring, which is neither stretched nor compressed, and is released from rest at a certain moment. The body drops a distance y_1 until it rests for the first time after the release. Calculate the period of oscillatory motion.

4.1.10.8 Ex: Spring-mass system

A body of $m = 1.5\,\mathrm{kg}$ stretches a spring by $y_0 = 2.8\,\mathrm{cm}$ from its natural length when being at rest. Now, we let it swing at this spring with an amplitude of $y_m = 2.2\,\mathrm{cm}$.
a. Calculate total energy of the system.
b. Calculate the gravitational potential energy at the body's lower turning point.
c. Calculate the potential energy of the spring at the body's lower turning point.
d. What is the maximum kinetic energy of the body (when $U = 0$ is the point where the spring is at equilibrium).

4.1.10.9 Ex: Energy conservation in the harmonic oscillator

Consider a mass of $m = 0.1\,\mathrm{kg}$ that vibrates on a spring with the spring constant $C = 10\,\mathrm{N/m}$. The maximum deflection A around the rest position of the spring is $10\,\mathrm{cm}$.
a. At what frequency does the mass vibrate?
b. Give the potential and the kinetic energy of the mass as a function of the displacement $x(t)$ resp. $\dot{x}(t)$.
c. Derive the equation of motion for the deflection from the energy theorem. The initial condition is chosen so that at time $t = 0$ the mass is at the zero crossing ($x(0) = 0$) and has maximum speed. **First help:** Integrate using the *variable separation* method. **Second help:** $\int \frac{dx}{\sqrt{a^2-x^2}} = \arcsin \frac{x}{a}$.

4.1.10.10 Ex: U-shaped water tube

Consider a U-shaped tube filled with water. The total length of the water column is L. Exerting pressure on one tube outlet the column is incited to perform oscillations. Calculate the period of the oscillation.

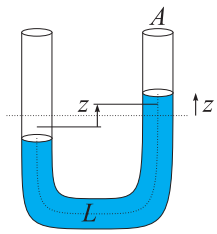

Figure 4.14: U-shaped water tube.

4.1.10.11 Ex: Buoy in the sea

A hollow cylindrical buoy with cross-sectional area A and mass M floats in the sea so that the axis of symmetry is aligned with gravitation. An albatross of mass m sitting on the buoy waits until time $t = 0$ and takes off. With which frequency and amplitude does the buoy oscillate if friction can be neglected? Derive the equation of motion and the complete solution.

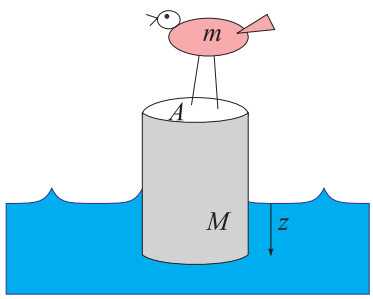

Figure 4.15: Fluctuating buoy.

4.1.10.12 Ex: Complicated pendulum oscillation

At a distance of $d = 30\,\text{cm}$ below the suspension point of a pendulum with the length $l_1 = 50\,\text{cm}$ there is a fixed pin S on which the wire suspending the pendulum temporarily bends during vibration. How many vibrations does the pendulum perform per minute?

4.1.10.13 Ex: Physical pendulum

Calculate the oscillation frequency of a thin bar of mass m and length L suspended at one end.

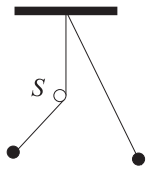

Figure 4.16: Mathematical pendulum.

4.1.10.14 Ex: Physical pendulum

An irregularly shaped flat body has the mass $m = 3.2\,\mathrm{kg}$ and is hung on a massless rod with adjustable length, which is free to swing in the plane of the body itself. When the rod's length is $L_1 = 1.0\,\mathrm{m}$, the period of the pendulum is $t_1 = 2.6\,\mathrm{s}$. When the rod is shortened to $L_2 = 0.8\,\mathrm{m}$, the period decreases to $t_2 = 2.5\,\mathrm{s}$. What is the period of the oscillation when the length is $L_3 = 0.5\,\mathrm{m}$?

4.1.10.15 Ex: Physical pendulum

A physical pendulum of mass M consists of a homogeneous cube with the edge length d. As shown in the figure, the pendulum is hung without friction on a horizontal rotation axis.
a. Determine the inertial momentum about the rotation axis using Steiner's theorem.
b. The pendulum now performs small oscillations around its resting position. Determine the angular momentum.
c. Give the equation of motion for small pendulum amplitudes ϕ around its resting position and the oscillation period.

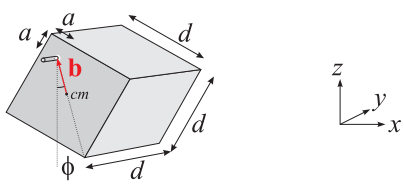

Figure 4.17: Physical pendulum.

4.1.10.16 Ex: Physical pendulum on a spiral spring

Consider a beam of mass $m = 1\,\mathrm{kg}$ with the dimensions $(a, b, c) = (3\,\mathrm{cm}, 3\,\mathrm{cm}, 8\,\mathrm{cm})$. The beam is rotatable about an axis through the point A. At point B, at a distance r from point A, the beam is fixed to a spiral spring exerting the retroactive force $\mathbf{F}_R = D\vec{\phi}$ with $D = 100\,\mathrm{N/m}$. Determine the differential equation of motion and solve it. Determine the period of the oscillation.

4.1.10.17 Ex: Anharmonic potential

A mass m moves in a potential $V(x)$, which has a minimum at $V(0) = 0$ for $x = 0$ and a first maximum at x_M. At time $t = 0$ the mass is at point $x = 0$. The initial speed

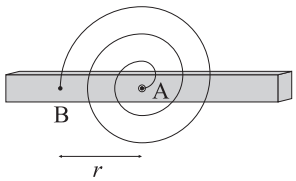

Figure 4.18: Physical pendulum on a spiral spring.

is chosen so that, when it reaches the maximum of the potential at x_M its velocity is zero. Calculate for the two cases $V(x) = \alpha x^2 - \beta x^4$ and $V(x) = \lambda(1 - \cos^2 \kappa x)$:
a. the coordinates of the maximum x_M and $V(x_M)$;
b. with the help of the energy conservation law the total energy E;
c. the implicit equation of motion $t = g(x)$ or, if possible, the explicit one $x = f(t)$;
How long does the mass take to reach the point x_M. Justify the result by physical arguments.

4.1.10.18 Ex: Anharmonic potential

A particle with the mass $m = 1.4 \times 10^{-25}$ kg moves along the positive x-axis. A constant force directed towards the origin of the coordinate system of $B = 10^{-23}$ N and a repulsive force of A/x^2 act on the particle, whereby $A = 10^{-35}$ Nm^2.
a. Calculate the potential energy function $V(x)$.
b. Sketch the energy as a function of the location x when the maximum kinetic energy is $T_0 = 10^{-28}$ J.
c. Determine the equilibrium position x_0 (force $F(x_0) = 0$) and the turning points (velocity $\dot{x} = 0$).
d. How large is the frequency of small vibrations around x_0?

4.1.10.19 Ex: Accelerated pendulum

A simple pendulum of length L is attached to a cart that slides without friction downward an plane inclined by an angle α with respect to the horizontal. Determine the oscillation period of the pendulum on the cart.

4.1.10.20 Ex: Accelerated pendulum

a. A pendulum of length L and mass M is suspended from the roof of a wagon horizontally accelerated with the acceleration a_{ext}. Find the equilibrium position of the pendulum. Determine the oscillation frequency for small oscillations and derive the differential equation of motion for an observer sitting in the wagon. (Note that you cannot assume small displacements, if the acceleration a_{ext} is large.)
b. In the same wagon there is a mass m connected to the front wall by a spring k. Find the equilibrium position of the mass. Determine the oscillation frequency and derive the differential motion equation for an observer sitting in the wagon.

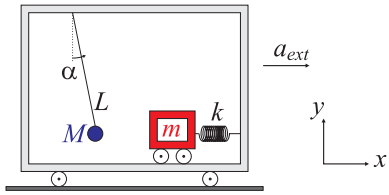

Figure 4.19: Accelerated pendulum.

4.1.10.21 Ex: Oscillation of a rolling cylinder

Consider a cylinder secured by two springs that rotates without sliding, as shown in the figure. Calculate the frequency for small oscillations of the system.

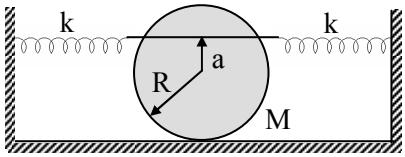

Figure 4.20: Rolling cylinder.

4.1.10.22 Ex: Rocking chair

Consider a thin rod of mass M and length $2L$ leaning on its center-of-mass, as shown in the figure. It is attached at both ends by springs of constants k. Calculate the angular frequency for small oscillations of the system.

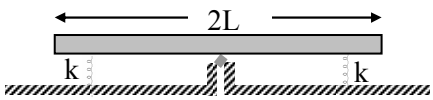

Figure 4.21: Rocking chair.

4.1.10.23 Ex: Rotational oscillation of a disk

Consider a disk of mass M and radius R ($I = \frac{1}{2}MR^2$) that can rotate around the polar axis. A body of mass $m$hangs at an ideal rope that runs through the disk (without slipping) and is attached to a wall by a spring of constant k, as shown in the figure. Calculate the natural oscillation frequency of the system.

4.1.10.24 Ex: Oscillation of a half cylinder

Consider a massive, homogeneous half-cylinder of mass M and radius R resting on a horizontal surface. If one side of this solid is slightly pushed down and released, it will swing around its equilibrium position. Determine the period of this oscillation.

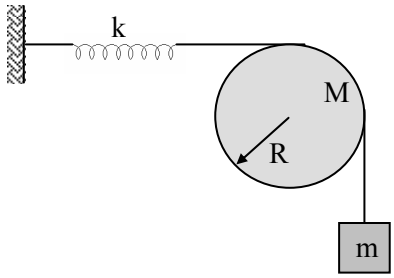

Figure 4.22: Rotational oscillation of a disk.

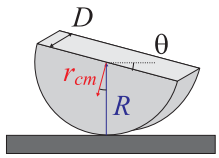

Figure 4.23: Oscillation of a half cylinder.

4.1.10.25 Ex: Pendulum coupled to a spring

Consider a simple pendulum of mass m and length L, connected to a spring of constant k, as shown in the figure. Calculate the frequency of the system for small oscillation amplitudes.

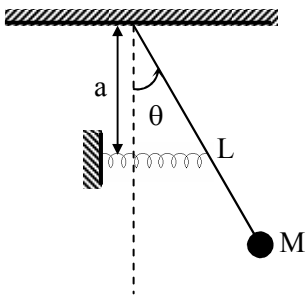

Figure 4.24: Pendulum coupled to a spring.

4.1.10.26 Ex: Pendulum carousel

A mass m is hung by a rope of length l on a carousel with the radius R. The pendulum performs small amplitude oscillations in the direction of the rotation axis of the carousel. How does the period of oscillation depend on the rotation speed of the carousel?

4.2 Superposition of periodic movements

Several movements that we already know can be understood as superpositions of periodic movements in different directions and, possibly, with different phases. Example are the circular or elliptical motion of a planet around the sun or the Lissajous figures. In these cases, the motion must be described by vectors, $\mathbf{r}(t) \equiv (x(t), y(t))$. It is also possible to imagine superpositions of periodic movements in the same degree of freedom. The movement of the membrane of a loudspeaker or musical instruments usually vibrates harmonically, but follows a *superposition* of harmonic oscillations. According to the *superposition principle*, we will take the resultant of several harmonic vibrations as the sum of the individual vibrations.

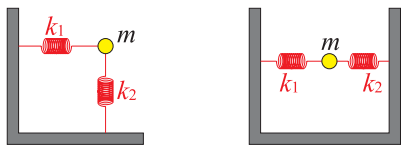

Figure 4.25: Superposition of vibrations in different (left) and equal (right) degrees of freedom.

4.2.1 Rotations and complex notation

We now consider a uniform circular motion. The radius of the circle being R, the motion is completely described by the angle $\theta(t)$ which grows uniformly,

$$\theta = \omega t + \alpha \ . \tag{4.51}$$

The projections of the movement in x and y are,

$$x(t) = A\cos\theta \qquad \text{and} \qquad y(t) = A\sin\theta \ . \tag{4.52}$$

Thus, we can affirm $x(t) = y(t + \pi/2)$, that is, the projections have a mutual phase shift of $\pi/2$.

The circular motion can be represented in the complex plane using the imaginary unit $i \equiv \sqrt{-1}$ and Euler's relationship $e^{\imath\theta} = \cos\theta + \imath\sin\theta$, as illustrated in Fig. 4.26.[3,4] With $r = Ae^{\imath\theta}$ we obtain $x = A\mathfrak{Re}\, e^{\imath\theta}$ and $\imath y = A\mathfrak{Im}\, e^{\imath\theta}$ and $r = x + \imath y$.

We will use the complex notation extensively, as it greatly facilitates the calculation.

4.2.2 Lissajous figures

Other periodic movements in the two-dimensional plane are possible, when the movements in x and y have different phases or frequencies. These are called *Lissajous figures*.

[3] The Euler relation can easily be derived by Taylor expansion.

[4] To check your notions on complex numbers do the exercises in Chp. 1 of the Book of A.P. French.

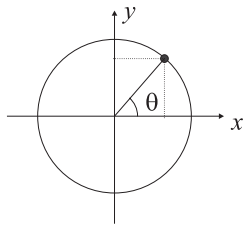

Figure 4.26: Circular motion in the complex plane.

We consider a body subject to two harmonic movements in orthogonal directions:

$$x(t) = A_x \cos(\omega_x t + \varphi_x) \qquad \text{and} \qquad y(t) = A_y \cos(\omega_y t + \varphi_y) \ . \tag{4.53}$$

When ω_x/ω_y is a rational number, the curve is closed and the motion repeats after equal time periods. The upper charts in Fig. 4.27 show trajectories of the body for $\omega_x/\omega_y = 1/2$, $1/3$, and $2/3$, letting $A_x = A_y$ and $\varphi_x = \varphi_y$. The lower charts in Fig. 4.27 show trajectories for $\omega_x/\omega_y = 1/2$, $1/3$, letting $\varphi_x - \varphi_y = 0$, $\pi/4$, and $\pi/2$.

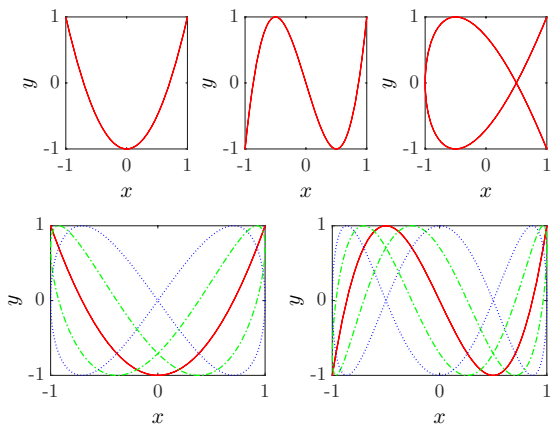

Figure 4.27: (code) Trajectories of a body oscillating with different frequencies in two dimensions.

Example 11 (*Lissajous figures*):

- Connect two function generators to the two channels of an oscilloscope in x-y.
- MATLAB simulation.

.

4.2.3 Vibrations with equal frequencies superposed in one dimension

Vibratory movements can overlap. The result can be described as a sum,

$$\begin{aligned} x(t) &= x_1(t) + x_2(t) = A_1 \cos(\omega t + \alpha_1) + A_2 \cos(\omega t + \alpha_2) \\ &= \mathrm{Re}[A_1 e^{\imath(\omega t + \alpha_1)} + A_2 e^{\imath(\omega t + \alpha_2)}] = \mathrm{Re} e^{\imath \omega t}[A_1 e^{\imath \alpha_1} + A_2 e^{\imath \alpha_2}] \ . \end{aligned} \tag{4.54}$$

That is, the new motion is a cosine vibration, $x(t) = A \cos \omega t$, with the phase,

$$\tan \alpha = \frac{\mathrm{Im}\ x(0)}{\mathrm{Re}\ x(0)} = \frac{\mathrm{Im}(A_1 e^{\imath \alpha_1} + A_2 e^{\imath \alpha_2})}{\mathrm{Re}(A_1 e^{\imath \alpha_1} + A_2 e^{\imath \alpha_2})} = \frac{A_1 \sin \alpha_1 + A_2 \sin \alpha_2}{A_1 \cos \alpha_1 + A_2 \cos \alpha_2} \ , \tag{4.55}$$

and the amplitude,

$$A = |A_1 e^{\imath \alpha_1} + A_2 e^{\imath \alpha_2}| = \sqrt{A_1^2 + A_2^2 + 2 A_1 A_2 \cos(\alpha_1 - \alpha_2)} \ . \tag{4.56}$$

We consider the case $A_1 = A_2$,

$$\tan \alpha = \frac{\sin \alpha_1 + \sin \alpha_2}{\cos \alpha_1 + \cos \alpha_2} \quad , \quad A = 2A \cos \frac{\alpha_1 - \alpha_2}{2} \ . \tag{4.57}$$

The cases $\alpha_1 = \alpha_2$ or $\alpha_2 = 0$ further simplify the result.

4.2.4 Frequency beat

Vibratory movements with different frequencies can overlap. The result can be described as a sum,

$$x(t) = x_1(t) + x_2(t) = A_1 \cos \omega_1 t + A_2 \cos \omega_2 t = \mathfrak{Re}\left[A_1 e^{\imath \omega_1 t} + A_2 e^{\imath \omega_2 t}\right] \ . \tag{4.58}$$

Considering the case $A_1 = A_2$ we obtain,

$$\begin{aligned} x(t) &= A \mathfrak{Re}\left[e^{\imath \omega_1 t} + e^{\imath \omega_2 t}\right] \\ &= A \mathfrak{Re}\left[e^{\imath(\omega_1 + \omega_2)t/2} e^{\imath(\omega_1 - \omega_2)t/2} + e^{\imath(\omega_1 + \omega_2)t/2} e^{-\imath(\omega_1 - \omega_2)t/2}\right] \\ &= A \mathfrak{Re}\, e^{\imath(\omega_1 + \omega_2)t/2} 2 \cos \frac{(\omega_1 - \omega_2)t}{2} \\ &= 2A \cos \frac{(\omega_1 + \omega_2)t}{2} \cos \frac{(\omega_1 - \omega_2)t}{2} \ . \end{aligned} \tag{4.59}$$

Example 12 (*Amplitude modulation*): An important example is the amplitude modulation of radiofrequency signals.

Example 13 (*Visualization of beat frequencies on an oscilloscope*):

- Connect two function generators to the two channels of an oscilloscope and add the channels.
- MATLAB simulation.
- Modulate one signal by another in a frequency mixer.

.

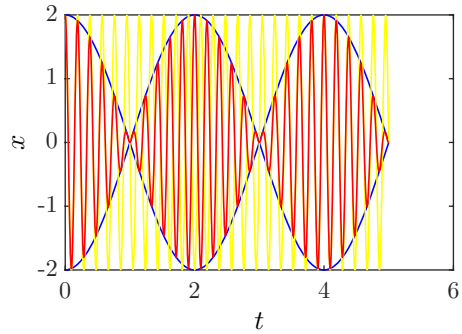

Figure 4.28: (code) Illustration of the beating of two frequencies $\nu_1 = 5.5\,\mathrm{Hz}$ and $\nu_2 = 5\,\mathrm{Hz}$ showing the perceived vibration (red), the vibration with the frequency $(\nu_1 + \nu_2)/2$ (blue), and the vibration with frequency $(\nu_1 - \nu_2)/2$ (yellow).

4.2.5 Amplitude and frequency modulation

Radio frequencies above 300 kHz can easily be emitted and received by antennas, while audio frequencies are below 20 kHz. However, radio frequencies can be used as carriers for audio frequencies. This can be done by modulating the audio signal on the *amplitude* of the carrier () before sending the carrier frequency. The receiver retrieves the audio signal by demodulating the carrier. Therefore, audio signals can be transmitted by electromagnetic waves. Another technique consists in modulating the *frequency* of these waves (). We will now calculate the spectrum of these two modulations using complex notation and show how to demodulate the encoded audio signals by multiplication with a local oscillator corresponding to the carrier wave.

4.2.5.1 AM

Let ω and Ω be the frequencies of the carrier wave and the modulation, respectively. We can describe the amplitude modulation by,

$$U(t) = (1 + S(t)) \cos \omega t \ . \tag{4.60}$$

After the receiver has registered this signal, we demodulate it by multiplying it with $\cos \omega t$:

$$U(t) \cos \omega t = (1 + S(t)) \cos^2 \omega t = (1 + S(t)) \left(\tfrac{1}{2} + \tfrac{1}{2} \cos 2\omega t \right) \ . \tag{4.61}$$

We purify this signal passing it through a low-pass filter eliminating the rapid oscillations:

$$U(t) \cos \omega t \longrightarrow \tfrac{1}{2}(1 + S(t)) \ . \tag{4.62}$$

We retrieve the original signal $S(t)$.

4.2.5.2 FM

We can describe the frequency modulation by,

$$U(t) = e^{\imath(\omega t + N \sin \Omega t)} = e^{\imath \omega t} \sum_{k=-\infty}^{\infty} \mathcal{J}_k(N) e^{\imath k \Omega t} \ . \tag{4.63}$$

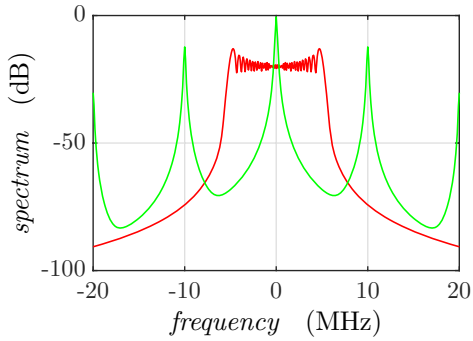

Figure 4.29: (code) Modulation signal.

The modulation of the carrier wave generates sidebands. This can be seen by expanding the signal carrying the phase modulation into a Fourier series,

$$e^{\imath\omega t}\sum_{k=-\infty}^{\infty}\mathcal{J}_k(\beta)e^{\imath k\Omega t}\simeq e^{\imath\omega t}+\mathcal{J}_1(N)e^{\imath\omega t+\imath\Omega t}+\mathcal{J}_{-1}(N)e^{\imath\omega t-\imath\Omega t} \tag{4.64}$$

when the *modulation index* N is small. Here, $J_{-k}(N)=(-1)^kJ_k(N)$ are the Bessel functions.

The spectrum of a signal with PM modulation consists of discrete lines, called sidebands, whose amplitudes are given by Bessel functions,

$$S(\omega)=\sum_{k=-\infty}^{\infty}|\mathcal{J}_k(N)|^2\delta(\omega+k\Omega)\ . \tag{4.65}$$

In real systems, the frequency bands have finite widths β due to frequency noise or to the finite resolution of the detectors,

$$S(\omega)=\sum_{k=-\infty}^{\infty}|\mathcal{J}_k(N)|^2\frac{N^2}{(\omega-k\Omega)^2+N^2}\ . \tag{4.66}$$

Example 14 (*Frequency spectrum*):

- Modulate the frequency of a VCO.
- Show in the spectrum analyzer the transition to sidebands.

.

4.2.6 Exercises

4.2.6.1 Ex: Amplitude modulation

Consider a carrier wave of $\omega/2\pi=1$ MHz frequency whose amplitude is modulated by an acoustic signal of $\Omega/2\pi=1\,\mathrm{kHz}$: $U(t)=A\cos\Omega t\cos\omega t$. To demodulate the signal, multiply the received wave $U(t)$ by the carrier radiofrequency. Interpret the result.

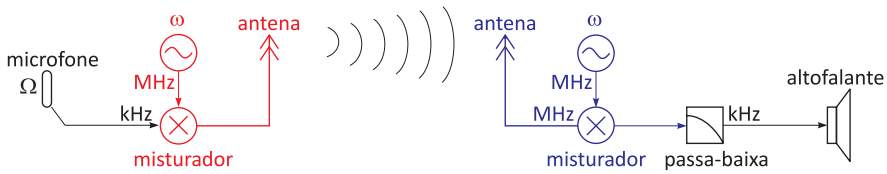

Figure 4.30: Illustration of radiofrequency signal transmission.

4.3 Damped and forced vibrations

Frequently, vibrations are exposed to external perturbations. For example, damping forces due to friction exerted by the medium in which vibration takes place work to waste and dissipate the energy of the oscillation and, therefore, to reduce the amplitude of the oscillation. In contrast, periodic forces can pump energy into the oscillator system and excite vibrations.

4.3.1 Damped vibration and friction

Let us first deal with damping by forces named *Stokes friction*, that is, forces which are proportional to the velocity of the oscillating mass and contrary to the direction of motion, $F_{frc} = -bv$, where b is the friction coefficient. With this additional term, the equation of motion is,

$$ma = -bv - kx \ . \tag{4.67}$$

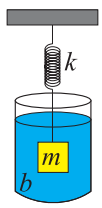

Figure 4.31: Oscillation damped by a viscous medium.

The calculation of the *damped oscillator* can be greatly simplified by the use of complex numbers by making the ansatz,

$$x(t) = Ae^{\lambda t} \ , \tag{4.68}$$

where λ is a complex number. We get,

$$m\lambda^2 + b\lambda + k = 0 \ , \tag{4.69}$$

giving the characteristic equation,

$$\lambda = -\gamma \pm \sqrt{\gamma^2 - \omega_0^2} \ , \tag{4.70}$$

with

$$\omega_0 = \sqrt{\frac{k}{m}} \qquad \text{and} \qquad \gamma = \frac{b}{2m} \ . \tag{4.71}$$

The friction determines the damping behavior. We distinguish three cases discussed in the following sections.

4.3.1.1 Overdamped case

In the overdamped case, for $\omega_0 < \gamma$, there are two real solutions $\lambda = -\gamma \pm \kappa$ with $\kappa \equiv \sqrt{\gamma^2 - \omega_0^2}$ for the characteristic equation, giving,

$$x(t) = e^{-\gamma t}(Ae^{-\kappa t} + Be^{\kappa t}) \ . \tag{4.72}$$

Choosing the initial conditions,

$$\begin{aligned} x_0 = x(0) &= e^{-\gamma t}(Ae^{-\kappa t} + Be^{\kappa t}) = A + B \\ 0 = v(0) &= -A(\gamma+\kappa)e^{-(\gamma+\kappa)t} - B(\gamma-\kappa)e^{-(\gamma-\kappa)t} = -A(\gamma+\kappa) - B(\gamma-\kappa) \ , \end{aligned} \tag{4.73}$$

we determine the amplitudes,

$$A = \frac{x_0}{2}\left(1 - \frac{\gamma}{\kappa}\right) \qquad \text{and} \qquad B = \frac{x_0}{2}\left(1 + \frac{\gamma}{\kappa}\right) \ . \tag{4.74}$$

Finally, the solution is [5],

$$x(t) = x_0 e^{-\gamma t}\left[\cosh \kappa t + \frac{\gamma}{\kappa}\sinh \kappa t\right] \ . \tag{4.75}$$

4.3.1.2 Underdamped case

In the underdamped case, for $\omega_0 > \gamma$, we have two complex solutions $\lambda = -\gamma \pm \imath\omega$ with $\omega \equiv \sqrt{\omega_0^2 - \gamma^2}$, giving,

$$x(t) = e^{-\gamma t}(Ae^{\imath\omega t} + Be^{-\imath\omega t}) \ . \tag{4.76}$$

Choosing the initial conditions,

$$\begin{aligned} x_0 = x(0) &= e^{-\gamma t}(Ae^{\imath\omega t} + Be^{-\imath\omega t}) = A + B \\ 0 = v(0) &= -A(\gamma-\imath\omega)e^{-(\gamma-\imath\omega)t} - B(\gamma+\imath\omega)e^{-(\gamma+\imath\omega)t} = -A(\gamma-\imath\omega) - B(\gamma+\imath\omega) \ , \end{aligned} \tag{4.77}$$

we determine the amplitudes,

$$A = \frac{x_0}{2}\left(1 + \frac{\gamma}{\imath\omega}\right) \qquad \text{and} \qquad B = \frac{x_0}{2}\left(1 - \frac{\gamma}{\imath\omega}\right) \ . \tag{4.78}$$

Finally, the solution is [6],

$$x(t) = x_0 e^{-\gamma t}\left[\cos \omega t + \frac{\gamma}{\omega}\sin \omega t\right] \ . \tag{4.79}$$

[5] Note that for super-strong damping, we have $\kappa \simeq \gamma$ and therefore,

$$x(t) = Ae^{-2\gamma t} + B \ .$$

, This is nothing more than the solution of the equation of motion without restoring force, $ma = -bv$.

[6] Note that, for very weak damping, we have $\gamma \simeq 0$ and $\omega \simeq \omega_0$ and hence,

$$x(t) = Ae^{\imath\omega_0 t} + Be^{-\imath\omega_0 t} \ .$$

This is nothing more than the solution of the frictionless equation of motion, $ma = -kx$.

4.3.1.3 Critically damped case

In the critically damped case, for $\omega_0 = \gamma$, there is only one solution $\lambda = -\gamma$, giving

$$x(t) = Ae^{-\gamma t} \ . \tag{4.80}$$

Since one solution is not sufficient to solve a second order differential equation, we need to look for another linearly independent solution. We can try another ansatz,

$$x(t) = Bte^{\lambda t} \ , \tag{4.81}$$

resulting in the characteristic equation,

$$m(\lambda^2 te^{\lambda t} + 2\lambda e^{\lambda t}) + b(\lambda te^{\lambda t} + e^{\lambda t}) + kte^{\lambda t} = 0 \ . \tag{4.82}$$

The terms in $e^{\lambda t}$ and $te^{\lambda t}$ should disappear separately, giving,

$$2m\lambda + b = 0 \quad \text{and} \quad m\lambda^2 t + b\lambda t + kt = 0 \quad \Longrightarrow \quad \lambda = -\frac{b}{2m} = -\gamma = -\omega_0 \ . \tag{4.83}$$

Finally, the solution is,

$$x(t) = (A + Bt)e^{-\gamma t} \ . \tag{4.84}$$

Choosing the initial conditions,

$$\begin{aligned} x_0 = x(0) &= (A + Bt)e^{-\gamma t} = A \\ 0 = v(0) &= (-\gamma A - \gamma Bt + B)e^{-\gamma t} = -\gamma A + B \ , \end{aligned} \tag{4.85}$$

we determine the amplitudes,

$$A = x_0 \quad \text{and} \quad B = \gamma x_0 \ . \tag{4.86}$$

Finally, the solution is,

$$x(t) = x_0(1 + \gamma t)e^{-\gamma t} \ . \tag{4.87}$$

Fig. 4.32 illustrates the damping of the oscillation for various friction rates γ.

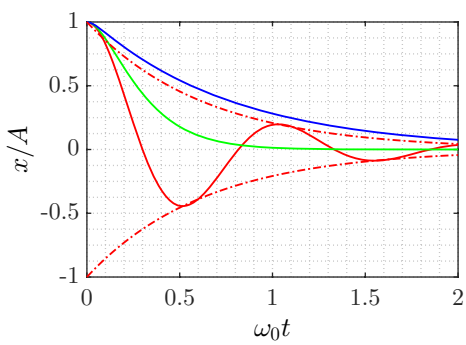

Figure 4.32: (code) Damped oscillation for $\omega_0 = 10\,\mathrm{s}^{-1}$ and $\gamma = 2.5\,\mathrm{s}^{-1}$ (red), $10\,\mathrm{s}^{-1}$ (green), and $25\,\mathrm{s}^{-1}$ (blue).

The critical friction coefficient generates a damped movement without any 'overshoot', since the velocity $\dot{x}(t)$ only disappears for $t = 0$.

4.3.1.4 Quality factor and energy loss

For a harmonic oscillation we establish the balance of energies,

$$\begin{aligned} E &= \frac{m}{2}v^2 + \frac{k}{2}x^2 \\ &= \frac{m}{2}\left(A\imath\omega_0 e^{\imath\omega_0 t} - B\imath\omega_0 e^{-\imath\omega_0 t}\right)^2 + \frac{m}{2}\omega_0^2\left(Ae^{\imath\omega_0 t} + Be^{-\imath\omega_0 t}\right)^2 = 2m\omega_0^2 AB \ . \end{aligned} \tag{4.88}$$

Now, for an underdamped oscillation we replace the amplitudes by $A \to Ae^{-\gamma t}$ and $B \to Be^{-\gamma t}$, such that,

$$E(t) = 2m\omega_0^2 ABe^{-2\gamma t} \ . \tag{4.89}$$

Obviously, the energy is decreasing at the rate 2γ.

We define the *quality factor* as the number of radians that the damped system oscillates before its energy falls to e^{-1},

$$Q = \frac{\omega}{2\gamma} = \frac{\omega m}{b} \simeq \frac{\omega_0 m}{b} \ . \tag{4.90}$$

Comparing the initial energy with the energy remaining after one cycle,

$$\frac{E}{\Delta E} = \frac{E(0)}{E(0) - E(2\pi/\omega)} = \frac{1}{1 - e^{-4\pi\gamma/\omega}} \simeq \frac{\omega}{4\pi\gamma} \ , \tag{4.91}$$

we find that the quantity,

$$\frac{Q}{2\pi} = \frac{E}{\Delta E} \tag{4.92}$$

represents a measure for the energy dissipation.

4.3.2 Forced vibration and resonance

We have seen that a damped oscillator loses its energy over time. To sustain the oscillation, it is necessary to provide energy. The simplest way to do this, is to force the oscillator to oscillate at a frequency ω by applying an external force $F_0 \cos\omega t$. The question now is, what will be the amplitude of the oscillation and its phase with respect to the phase of the applied force. We begin by establishing the equation of motion,

$$ma + bv + m\omega_0^2 x = F_0 \cos\omega t \ . \tag{4.93}$$

The calculation can be greatly simplified by the use of complex numbers. We write the differential equation as,

$$ma + bv + m\omega_0^2 x = F_0 e^{\imath\omega t} \ , \tag{4.94}$$

making the ansatz $x(t) = Ae^{\imath\omega t - \imath\delta}$, yielding

$$-\omega^2 Ae^{\imath\omega t - \imath\delta} m + \imath\omega b Ae^{\imath\omega t - \imath\delta} + m\omega_0^2 Ae^{\imath\omega t - \imath\delta} = F_0 e^{\imath\omega t} \ . \tag{4.95}$$

We rewrite this formula,

$$e^{\imath\delta} = A\frac{m(\omega_0^2 - \omega^2) + \imath b\omega}{F_0} \ . \tag{4.96}$$

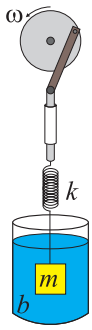

Figure 4.33: Forced oscillation damped by a viscous medium.

Immediately we get the solutions,

$$\tan\delta = \frac{\sin\delta}{\cos\delta} = \frac{\mathfrak{Im}\, e^{\imath\delta}}{\mathrm{Re} e^{\imath\delta}} = \frac{b\omega}{m(\omega_0^2-\omega^2)} \tag{4.97}$$

$$A = \left|Ae^{-\imath\delta}\right| = \left|\frac{F_0}{m(\omega_0^2-\omega^2)+\imath\omega b}\right| = \frac{F_0}{\sqrt{m^2(\omega_0^2-\omega^2)^2+b^2\omega^2}} \ .$$

The frequency response (spectrum) of the oscillator to the periodic excitation is illustrated in Fig. 4.34. We see that, when we increase the friction, we decrease the height and increase the width of the spectrum $|A(\omega)|$. Fig. 4.34(b) shows that, increasing the excitation frequency, the oscillation undergoes a phase shift of π.

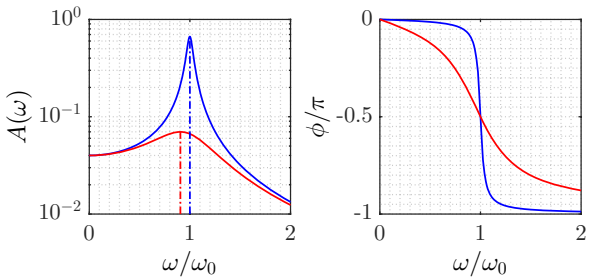

Figure 4.34: (code) Frequency response of the amplitude and phase of the oscillator for a force of $F_0 = 1\,\mathrm{N}$, a mass of $m = 1\,\mathrm{kg}$, a resonance frequency of $\omega_0 = (2\pi)\ 5\,\mathrm{Hz}$, and a friction coefficient of $b = 0.5$ (blue) or $b = 1$ (red).

We now ask, at what excitation frequency ω the oscillator responds with maximum amplitude,

$$0 = \frac{d}{d\omega_m}A(\omega_m) = F_0\omega_m\frac{2m^2\omega_0^2-2m^2\omega_m^2-b^2}{(m^2\omega_0^4-2m^2\omega_0^2\omega_m^2+m^2\omega_m^4+b^2\omega_m^2)^{\frac{3}{2}}} \ . \tag{4.98}$$

The numerator disappears for,

$$\omega_m = \sqrt{\omega_0^2-\frac{b^2}{2m^2}} \ , \tag{4.99}$$

and the amplitude becomes,

$$A_m = \frac{F_0}{b\sqrt{\omega_0^2 - \frac{b^2}{4m^2}}} \ . \tag{4.100}$$

4.3.2.1 Quality factor

For weak damping $\gamma \ll \omega_0$ and small detunings, $|\omega - \omega_0| \ll \omega_0$, we can approximate the expression for the spectrum by,

$$A(\omega) \simeq \left| \frac{F_0}{m} \frac{1}{2\omega_0(\omega_0 - \omega) + \imath\omega_0 \frac{b}{m}} \right| = \left| \frac{F_0}{2m\omega_0} \frac{1}{\omega - \omega_0 - \imath\gamma} \right| \ .$$

This function corresponds to a Lorentzian profile with the width FWHM $\Delta\omega = 2\gamma$. The *quality factor* defined in the section discussing the damped oscillator measures the quality of the resonance,

$$Q = \frac{\omega}{2\gamma} = \frac{\omega}{\Delta\omega} \ . \tag{4.101}$$

Example 15 (*Harmonic vibration*):

- Construct a L-C-circuit, excite it by a function generator by making a frequency ramp, and show the resonance on the oscilloscope. It works with a coil of $N = 12$ turns, of length $\ell = 6\,\mathrm{cm}$ and of radius $r = 1.4\,\mathrm{cm}$, giving $L = 1.4\,\mu\mathrm{H}$. We can also set $R = 2.2\,\Omega$ and $C = 100\,\mathrm{nF}$, giving $\omega_0 = 9.4\,\mathrm{MHz}$.

4.3.3 Exercises

4.3.3.1 Ex: Resolution of the damped oscillator equation

Solve the damped oscillator equation for $4km > b^2$ using the ansatz $x(t) = Ae^{-\gamma t}\cos\omega t$.

4.3.3.2 Ex: Damped oscillation

In a damped oscillation the oscillation period is $T = 1\,\mathrm{s}$. The ratio between two consecutive amplitudes is 2. Despite the large damping, the deviation of the period T_0 compared to the undamped oscillation is small. Calculate the deviation.

4.3.3.3 Ex: Damped physical pendulum

The physical pendulum shown in the figure consists of a disk of mass M and radius R suspended on an axes parallel to the symmetry axis of the disk and passing the edge of the disk.
a. Calculate the inertial momentum of the disk, $I = \int_V r^2 dm$, with respect to the suspension axes.
b. Derive the equation of motion by considering a weak Stokes damping due to friction proportional to the angular velocity and by approximating for small amplitude oscillations.

c. What is the natural oscillation frequency of the pendulum (without friction)? How to calculate the oscillation frequency considering friction?
d. Write down the solution of the equation of motion for the initial situation $\phi(0) = 0$ and $\dot{\phi}(0) = \dot{\phi}_0$.

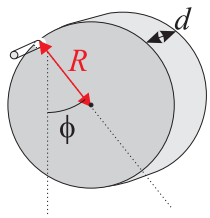

Figure 4.35: Damped physical pendulum.

4.3.3.4 Ex: Pendulum with friction

Jane has prepared dinner and Tarzan (80 kg) and Cheeta (40 kg) must return home. The house is in a tree at a height of 10 m, so that both must swing home on a (massless) rope hanging from $l = 100$ m high tree. Tarzan grabs the rope at the height of its center-of-mass $h = 1.2$ m above ground, Cheeta because of its height is smaller at 0.8 m above ground. With what initial speed both need to grab the rope to reach the platform of the house with their feet. Consider Stokes' friction force, $F_R = C \cdot v$ with $C = 4 \cdot 10^{-4}$ Ns/m (Tarzan) respectively, $C = 2 \cdot 10^{-4}$ Ns/m (Cheeta). Why is this force different for the two? Treat the oscillating motion as small displacement. Determine whether the vibration is weakly damped. Do you think Jane will have dinner alone?

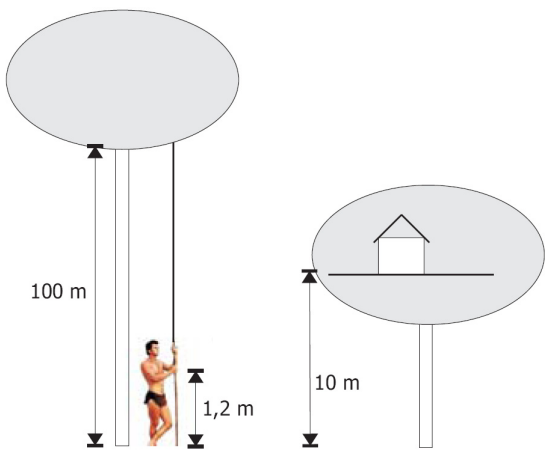

Figure 4.36: Pendulum with friction.

4.3.3.5 Ex: Oscillations and static friction

A wooden block vibrates smoothly on a horizontal spring with an oscillation period of $T = 1.2\,\mathrm{s}$. A second block of wood lies on top of the first, the coefficient of static friction between the two blocks being $\mu_H = 0.25$. The static friction is caused by the

Figure 4.37: Oscillations and static friction.

surface roughness of the two blocks and depends on the mass m of the upper block like $F_H = \mu_H mg$.
a. Will the wooden block slip, if the amplitude of the vibration is 1 cm?
b. Determine the largest allowable vibration amplitude for the wooden block not to slip.

4.3.3.6 Ex: Resolution of the forced oscillator equation

Solve the forced oscillator equation using the ansatz $x(t) = A\cos(\omega t - \delta)$.

4.3.3.7 Ex: Oscillation with coercive force

On a body of mass m along the x-axis act a force proportional to the displacement $F_h = -\kappa x$ and a Stokes friction force $F_R = -\gamma\dot{x}$. A time-dependent force is switched on at time $t = 0$, while the body rests at the position $x = 0$. The force increases linearly over time until it suddenly disappears at time $t = T$. Determine the work that the external force has done up this time. Consider the various solutions of the equation of motion resulting from the various combinations of κ and γ.

4.3.3.8 Ex: Oscillation with coercive force

You want to measure the friction coefficient γ of a sphere (mass $m = 10\,\mathrm{kg}$, diameter $d = 10\,\mathrm{cm}$) in water. To do this, you let the sphere oscillate on a spring (spring constant $k = 100\,\mathrm{N/m}$) in a water bath exciting the oscillation by a periodic force, $F(t) = F_0 \cos\omega t$. By varying the excitation frequency ω until observing the maximum oscillation amplitude, you measure the resonance frequency $\omega_w = 2\pi \cdot 1\,\mathrm{Hz}$. Now, you let the water out of the tub and repeat the measurement finding $\omega_0 = 2\pi \cdot 2\,\mathrm{Hz}$.
a. Determine the resting position of the mass in water and air.
b. Establish the differential equation of motion. Assume that the weight of the sphere in water is reduced by the buoyancy $V\rho_{wat}g$, where V is the volume of the sphere and ρ_{wat} the density of the water.
c. What is the value of γ?

4.3.3.9 Ex: Electronic oscillator circuit

The instantaneous current $I(t)$ in an L-R-C-circuit (inductance of a coil, ohmic resistance and capacitance in series) excited by an alternating voltage source $U(t) =$

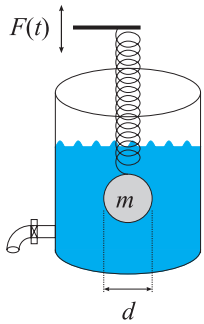

Figure 4.38: Driven pendulum.

$U_0 \cos \omega t$ satisfies the following differential equation,

$$L\dot{I} + RI + C^{-1} \int_0^t I dt' = U_0 \sin \omega t \ .$$

a. Derive the equation for the moving charge $\dot{Q} = I$, compare the obtained equation with that of the damped and forced spring-mass oscillator and determine the solution for the current.
b. Determine the resonance frequency ω_0 of the circuit.
c. Determine the quality factor Q of the circuit. How you can increase Q without changing the resonance frequency?

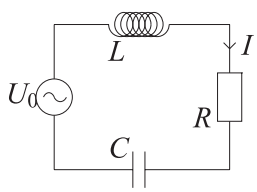

Figure 4.39: Line filter.

4.3.3.10 Ex: Electronic oscillator circuit

A voltage $U(t)$ is known to produce in an coil of inductance L the current $I_L = L^{-1} \int_0^{t'} U dt$, in an ohmic resistance R the current $I_R = R^{-1} U$, and in a capacitor of capacitance C the current $I = C\dot{U}$. In the parallel L-R-C circuit shown in the figure, at each instant of time the sum of the currents I_L, I_R and I_C must compensate the current $I_F(t) = I_0 e^{i\omega t}$ supplied by an alternating current source, while the voltage $U(t)$ is the same across all components.
a. Derive the differential equation for the derivative of the voltage $\dot{U}$.
b. What would be the oscillation frequency of the current without source ($I_0 = 0$) and without resistance ($R = \infty$)?
c. What would be the oscillation frequency of the current without source ($I_0 = 0$) but with resistance ($R \neq \infty$)?

d. Doing the ansatz $U(t) = U_0 e^{\imath\omega t + \imath\phi}$ derive the characteristic equation.
e. Use the characteristic equation to calculate the impedance defined by $Z \equiv |U_0/I_0|$ and the phase ϕ of the current oscillation as a function of the frequency ω. Prepare qualitative sketches of functions $Z(\omega)$ and $\phi(\omega)$.

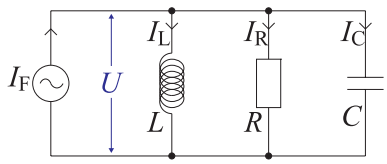

Figure 4.40: Notch filter.

4.3.3.11 Ex: Lorentz model of light-atom interaction

The Lorentz model describes the interaction of an electron attached to an atom with an incident light beam as a damped oscillator. The electron's binding to the nucleus is taken into account by a restoring force $-\omega_0^2 x$. The decay of the excited state with the rate Γ is the reason for the damping force $-m\Gamma\dot{x}$. And the excitation is produced by the Lorentz force exerted by the electrical component of the light beam, $e\mathcal{E}_0 e^{\imath\omega t}$, where e is the charge of the electron. Establish the differential equation and calculate the amplitude of electron's oscillation as a function of the excitation frequency.

4.3.3.12 Ex: Lorentz model of light-atom interaction

a. Electric fields $\mathcal{E}$ exert on electric charges q the Coulomb force $F = q\mathcal{E}$. Write the differential equation for the undamped motion of an electron (charge $-e$, mass m) harmonically bound to its nucleus under the influence of an alternating electric field, $\mathcal{E} = \mathcal{E}_0 \sin\omega t$.
b. Show that the general solution can be written as,

$$x(t) = \frac{-e\mathcal{E}_0 \sin\omega t}{m(\omega_0^2 - \omega^2)} + A\cos\omega_0 t + B\sin\omega_0 t \ .$$

c. Write the solution in terms of the initial conditions $x(0) = 0 = \dot{x}(0)$.

4.4 Coupled oscillations and normal modes

So far we have discussed the behavior of isolated oscillators. Energy losses or gains were described in a bulk way via a coupling to an external reservoir without structure of its own. However, the reservoir often has vibrational degrees of freedom, as well, and can dump (or supply) energy. This usually happens when neighboring oscillators share a rigid, massive, or sturdy medium. The transfer of energy to neighboring oscillators is the key ingredient for any oscillatory propagation of energy called *wave*.

4.4.1 Two coupled oscillators

To discuss the *coupling between oscillators* at the most fundamental level, we consider two ideal and identical pendulums (length L and mass m) coupled by a spring of constant k, as shown in Fig. 4.41. The differential equations of motion for the angles

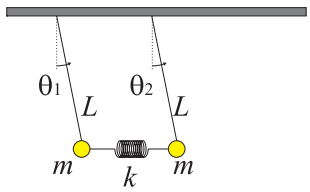

Figure 4.41: Two coupled pendulums.

θ_1 and θ_2 are,

$$\begin{aligned} mL\ddot{\theta}_1 &= -mg\sin\theta_1 - k(x_1 - x_2) \\ mL\ddot{\theta}_2 &= -mg\sin\theta_2 - k(x_2 - x_1)\ , \end{aligned} \tag{4.102}$$

with $x_j = L\sin\theta_j$. For small oscillations we have, therefore,

$$\begin{aligned} \ddot{\theta}_1 &= -\tfrac{g}{L}\sin\theta_1 - \tfrac{k}{m}(\sin\theta_1 - \sin\theta_2) \simeq -(\tfrac{g}{L} + \tfrac{k}{m})\theta_1 + \tfrac{k}{m}\theta_2 \\ \ddot{\theta}_2 &= -\tfrac{g}{L}\sin\theta_2 - \tfrac{k}{m}(\sin\theta_2 - \sin\theta_1) \simeq -(\tfrac{g}{L} + \tfrac{k}{m})\theta_2 + \tfrac{k}{m}\theta_1\ . \end{aligned} \tag{4.103}$$

We define the normal coordinates of the vibration $\aleph \equiv \frac{1}{\sqrt{2}}(\theta_1 - \theta_2)$ and $\Psi \equiv \frac{1}{\sqrt{2}}(\theta_1 + \theta_2)$. We find the differential equations for $\aleph$ and Ψ by adding and subtracting the equations of motion,

$$\ddot{\theta}_1 + \ddot{\theta}_2 \simeq -\tfrac{g}{L}(\theta_1 + \theta_2) \qquad \text{and} \qquad \ddot{\theta}_1 - \ddot{\theta}_2 \simeq -(\tfrac{g}{L} + \tfrac{2k}{m})(\theta_1 - \theta_2)\ ,$$

or,

$$\ddot{\Psi} + \omega_\Psi^2\Psi = 0 \qquad \text{and} \qquad \ddot{\aleph} + \omega_\aleph^2\aleph = 0$$

using the angular frequencies of the vibrational normal modes,

$$\omega_\Psi = \sqrt{\frac{g}{L}} \qquad \text{and} \qquad \omega_\aleph = \sqrt{\frac{g}{L} + \frac{2k}{m}}\ .$$

4.4.2 Normal modes

Thus, the normal coordinates Ψ and $\aleph$ allow a description of the motion by decoupled linear differential equations. A vibration involving only one *normal coordinate* is called *normal mode*. In this mode all the components participating in the oscillation oscillate at the same frequency.

The importance of the normal modes is they are totally independent, that is, they never exchange energy and they can be pumped separately. Therefore, the total energy of the system can be expressed as the sum of terms containing the squares of the normal coordinates (potential energy) and their first derivatives (kinetic energy).

Every independent path by which a system can gain energy is called *degree of freedom* and has an associated normal coordinate. For example, an isolated harmonic oscillator has two degrees of freedom, as it can gain potential or kinetic energy and two normal coordinates, x and v. And the coupled oscillator system,

$$E_\aleph = a\dot{\aleph}^2 + b\aleph^2 \qquad \text{and} \qquad E_\Psi = a\dot{\Psi}^2 + b\Psi^2 \ , \tag{4.104}$$

has four degrees of freedom.[7]

Every movement of the system can be represented by a superposition of normal modes,

$$\aleph = \tfrac{1}{\sqrt{2}}(\theta_1 - \theta_2) = \aleph_0 \cos(\omega_\aleph t + \phi_\aleph) \qquad \text{and} \qquad \Psi = \tfrac{1}{\sqrt{2}}(\theta_1 + \theta_2) = \Psi_0 \cos(\omega_\Psi t + \phi_\Psi) \ . \tag{4.105}$$

Choosing $\sqrt{2}A = \aleph_0 = \Psi_0$ and $\phi_\aleph = \phi_\Psi = 0$,

$$\begin{aligned} \theta_1 &= \tfrac{1}{\sqrt{2}}(\Psi + \aleph) = A\cos\omega_\aleph t + A\cos\omega_\Psi t = 2A\cos\tfrac{(\omega_\Psi - \omega_\aleph)t}{2}\cos\tfrac{(\omega_\Psi + \omega_\aleph)t}{2} \\ \theta_2 &= \tfrac{1}{\sqrt{2}}(\Psi - \aleph) = A\cos\omega_\aleph t - A\cos\omega_\Psi t = 2A\sin\tfrac{(\omega_\Psi - \omega_\aleph)t}{2}\sin\tfrac{(\omega_\Psi + \omega_\aleph)t}{2} \ . \end{aligned} \tag{4.106}$$

The oscillation shows the behavior of a frequency beat [8].

Example 16 (*Normal modes*):

- Two pendulums suspended on a movable horizontal bar which, in turn, is suspended by two wires to a rigid ceiling. Show (anti-)symmetric modes and their different exposure to damping of the motion of the bar.

4.4.3 Normal modes in large systems

There are techniques for solving systems many coupled oscillator. Let us consider, for example, a chain of $n = 1, ..., N$ oscillators coupled by springs. We have,

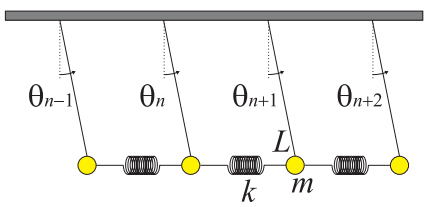

Figure 4.42: Array of coupled pendulums.

$$\ddot{\theta}_n = -\frac{g}{l}\theta_n - \frac{k}{m}(\theta_n - \theta_{n+1}) - \frac{k}{m}(\theta_n - \theta_{n-1}) \ . \tag{4.107}$$

Inserting the ansatz $\theta_n \equiv A_n e^{i\omega t}$, we obtain

$$\omega^2 A_n = \omega_0^2 A_n + \beta^2(A_n - A_{n+1}) + \beta^2(A_n - A_{n-1}) \ , \tag{4.108}$$

[7]Note that the motion of a single pendulum is a movement in two Cartesian dimensions and therefore would have four degrees of freedom. However, the joint action of gravity and the tension of the wire constrains the movement into one dimension thus freezing two degrees of freedom.

[8]Normal modes are observed in the molecular vibrations of H_2O and CO_2 (see Pain).

using the abbreviations $\omega_0^2 = g/l$ and $\beta^2 = k/m$. Defining the vector $\vec{A} \equiv (\cdots A_n \cdots)$ and the matrix,

$$\hat{M} \equiv \begin{pmatrix} \omega_0^2+\beta^2 & -\beta^2 & & & & \\ -\beta^2 & \ddots & \ddots & & & \\ & \ddots & \omega_0^2+2\beta^2 & -\beta^2 & & \\ & & -\beta^2 & \omega_0^2+2\beta^2 & \ddots & \\ & & & \ddots & \ddots & -\beta^2 \\ & & & & -\beta^2 & \omega_0^2+\beta^2 \end{pmatrix} , \tag{4.109}$$

we put the characteristic equation into a form called an eigenvalue equation,

$$\hat{M}\vec{A} = \omega^2 \vec{A} \ . \tag{4.110}$$

The matrix $\hat{M}$ is characterized by the fact that it contains on its diagonal the energy of each individual oscillator (that is, $\omega_0^2 + 2\beta^2$ when the oscillator is in the middle of the chain, and $\omega_0^2 + \beta^2$) at the two ends of the chain). On the secondary diagonals (that is, at the positions $M_{n,n\pm1}$) are the coupling energies between two oscillators n and $n \pm 1$. A normal mode of the system corresponds to an *eigenvector* of the matrix $\hat{M}$, and the natural frequency of this mode corresponds to the respective *eigenvalue*.

The equation (4.110) has non-trivial solutions only, when the determinant of the matrix $\hat{M} - \omega^2$ vanishes. The eigenvalues are those ω^2 which satisfy this requirement,

$$\det(\hat{M} - \omega^2 \mathbf{1}) = 0 \ . \tag{4.111}$$

4.4.4 Dissipation in coupled oscillator systems

We now extend the system of two coupled pendulums to include damping. Assuming that the movement of the pendulum is subject to damping,

$$\begin{aligned} \ddot{\theta}_1 &= -\Gamma\dot{\theta}_1 - \tfrac{g}{L}\theta_1 - \tfrac{k}{m}(\theta_1 - \theta_2) \\ \ddot{\theta}_2 &= -\Gamma\dot{\theta}_2 - \tfrac{g}{L}\theta_2 - \tfrac{k}{m}(\theta_2 - \theta_1) \ , \end{aligned} \tag{4.112}$$

giving the collective modes,

$$\begin{aligned} \ddot{\Psi} &= \ddot{\theta}_1 + \ddot{\theta}_2 = -\Gamma\dot{\Psi} - \tfrac{g}{L}\Psi \\ \ddot{\aleph} &= \ddot{\theta}_1 - \ddot{\theta}_2 = -\Gamma\dot{\aleph} - \left(\tfrac{g}{L} + \tfrac{2k}{m}\right)\aleph \ . \end{aligned} \tag{4.113}$$

Assuming that the movement of the spring (not the movement of the pendulums) is subject to damping,

$$\begin{aligned} \ddot{\theta}_1 &= -\tfrac{g}{L}\theta_1 - \tfrac{k}{m}(\theta_1 - \theta_2) - \Gamma(\dot{\theta}_1 - \dot{\theta}_2) \\ \ddot{\theta}_2 &= -\tfrac{g}{L}\theta_2 - \tfrac{k}{m}(\theta_2 - \theta_1) - \Gamma(\dot{\theta}_2 - \dot{\theta}_1) \ , \end{aligned} \tag{4.114}$$

giving the collective modes

$$\begin{aligned} \ddot{\Psi} &= \ddot{\theta}_1 + \ddot{\theta}_2 = -\tfrac{g}{L}\Psi \\ \ddot{\aleph} &= \ddot{\theta}_1 - \ddot{\theta}_2 = -\left(\tfrac{g}{L} + \tfrac{2k}{m}\right)\aleph - 2\Gamma\dot{\aleph} \ . \end{aligned} \tag{4.115}$$

Thus, the anti-symmetric mode Ψ is free from damping, while the symmetric mode $\aleph$ damps out twice as fast. Therefore, Ψ is called the *subradiant* mode and $\aleph$ the *superradiant* mode.

4.4.5 Exercises

4.4.5.1 Ex: Energy of normal modes

Verify that the total energy of a system of two coupled oscillators is equal to the sum of the energies of the normal modes.

4.4.5.2 Ex: Normal modes of two spring-coupled masses

Consider two different masses m_1 and m_2 coupled by a spring k.
a. Determine the equation of motion and the characteristic equation for each mass.
b. Write the characteristic equations in matrix form: $\hat{M}\vec{a} = \omega^2\vec{a}$, where $\vec{a} \equiv (a_1, a_2)$ and a_j are the amplitude of the oscillations and calculate the two eigenvalues of the matrix.
c. Calculate the normal modes, that is, the eigenvectors solving the equation $\hat{M}\vec{a} = \omega_k^2\vec{a}$ for each eigenvalue.
d. Derive the differential equations of the center-of-mass motion and the relative motion. Compare the result with the normal modes.

4.4.5.3 Ex: Spring-coupled chain of masses

Consider a chain of spring-coupled masses.
a. Determine the equation of motion and the characteristic equation for each mass.
b. Calculate the normal modes for a chain consisting of three masses.

4.4.5.4 Ex: Normal modes of CO_2

We consider the carbon dioxide molecule CO_2, for which we make a spring-mass model with three masses coupled by k springs in a linear chain. Calculate the frequencies of the normal modes and the eigenvectors of the vibrations.

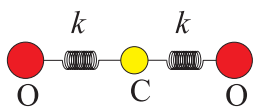

Figure 4.43: Normal modes of CO_2.

4.4.5.5 Ex: Three coupled pendulums

Determine the frequencies of the oscillation modes of a chain of three spring-coupled pendulums.

4.4.5.6 Ex: Super- and subradiance

We consider three carts attached by springs (spring constant k), as shown in the figure. The inner carts have mass m and are subject to damping by friction with the coefficient γ. The outer cart has mass M and friction Γ.
a. Establish the equations of motion of the three carts.
b. Discuss the case $M \to 0$.

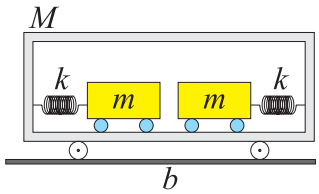

Figure 4.44: Super- and subradiant pendulums.

Chapter 5

Waves

While in *vibrating* bodies the motion and the energy are localized in space, *waves* do propagate and carry energy to other places. In fact, waves represent the most important mechanism for transporting and exchanging energy and information. We can understand a wave as a perturbation propagating through an elastic material medium. In some cases, however, e.g. for electromagnetic waves, the propagation of the wave is due to a self-sustained oscillation between two forms of energy (electric and magnetic) without the need of a material medium. Here, is a classification of the most common types of waves: A lecture version of this chapter can be found at

Table 5.1: *Types of waves.*

transform	Galilei	Galilei	Galilei	Galilei	Lorentz	Galilei
wave eq.	Helmholtz	Helmholtz	Helmholtz	Helmholtz	Helmholtz	Schrödinger

(watch talk).

5.1 Propagation of waves

There are several types of wave that we will classify according to the propagation medium and to the polarization, that is, we will distinguish longitudinal and transverse waves. There are media only supporting transverse waves (strings, water surfaces). Others only withstand longitudinal waves (sound in fluid media). Finally, there are media supporting both (sound in solids, electromagnetic waves).

The simplest example of a pulse is a local deformation of a string, as shown in Fig. 5.1. The pulse travels to one end of the string by a motion called *propagation*. The propagation is not conditioned to any transport of mass, but all the particles of the system go back to their original positions after the passage of the pulse. However, there is energy transport along the string, since each of its portions suffers an increase in kinetic and potential energy during the passage of the pulse.

In general, the pulse broadens during propagation, an effect called *dispersion*. To simplify the problem let us, as a first approximation neglect the dispersion and

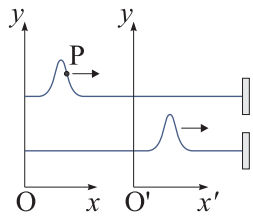

Figure 5.1: Pulse propagation along a rope.

suppose that the pulse does not change its shape,

$$Y(x,t) = f(x - vt) \ , \tag{5.1}$$

where the propagation velocity is positive when the pulse propagates in the direction of the positive x-axis.

The behavior of the pulse at the end of the rope depends on its fixation. Attached to a wall, the reflected pulse has opposite propagation amplitude and direction,

$$Y_{rfl}(x,t) = -f(x + vt) \ . \tag{5.2}$$

Fixed to another rope, the pulse will be partially reflected and partially transmitted.

5.1.1 Transverse waves, propagation of pulses on a rope

Pulses on a rope are examples for transverse waves. The speed at which the pulse propagates on a rope depends essentially on the properties of the string, that is, its mass density μ and the applied tension T, but not on the pulse amplitude. We take a small length element dx of the string with mass $dm = \mu dx$ and consider a pulse traveling with velocity v, as shown in Fig. 5.1.

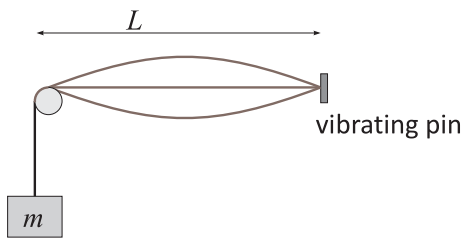

Figure 5.2: Mass element of a rope upon a passage of a pulse.

The vertical force due to the difference of tensions is,

$$F_y = T \sin\theta(x + dx) - T \sin\theta(x) \ . \tag{5.3}$$

Assuming $\theta(x)$ small, such that $\sin\theta(x) \simeq \tan\theta(x) = \frac{dY}{dx}$,

$$F_y = T \left(\frac{dY}{dx}\right)_{x+dx} - T \left(\frac{dY}{dx}\right)_x = T \frac{\partial^2 Y}{\partial x^2} dx \ . \tag{5.4}$$

On the other hand, applying Newton's second law to this string element, we find,

$$F_y = dm \frac{\partial^2 Y}{\partial t^2} \ . \tag{5.5}$$

Thus,

$$\frac{\partial^2 Y}{\partial x^2} = \frac{\mu}{T} \frac{\partial^2 Y}{\partial t^2} \ . \tag{5.6}$$

This equation is called *wave equation* and fully describes the propagation of the pulse on the string. Since $Y = f(x - vt)$ depends on both x and t, the derivatives that appear in the equation are partial, that is, one derives with respect to one variable keeping the other constant. To find the velocity, we write,

$$\frac{\partial^2 Y}{\partial t^2} = \frac{\partial}{\partial t}\left(\frac{\partial x}{\partial t}\frac{\partial Y}{\partial x}\right) = v\frac{\partial}{\partial t}\left(\frac{\partial Y}{\partial x}\right) = v\frac{\partial}{\partial x}\left(\frac{\partial Y}{\partial t}\right) = v\frac{\partial}{\partial x}\left(\frac{\partial x}{\partial t}\frac{\partial Y}{\partial x}\right) = v^2\frac{\partial Y^2}{\partial x^2} \ , \tag{5.7}$$

and compare the second relation with the wave equation, finding,

$$v = \sqrt{\frac{T}{\mu}} \ . \tag{5.8}$$

Example 17 (*Reflection of pulses on a rope*):

- Excite a pulse on a rope fixed to the wall (i) directly or (ii) through a thinner rope.

5.1.2 Longitudinal waves, propagation of sonar pulses in a tube

Acoustic pulses are examples for longitudinal waves. They are due to a process of compression and decompression of a gaseous medium (such as air), liquid or even solid. Let us consider an oscillating piston inside a tube (cross section A) filled with air of mass density ρ_0, as shown in Fig. 5.3. When the piston moves, it causes a local pressure increase. We want to find the velocity v at which the compression travels along the tube.

As shown in Fig. 5.3, the piston causes a negative pressure gradient along the tube giving rise to an unbalanced force which accelerates mass elements of air to the right. To simplify the situation let us assume that the piston is moved with velocity u within a time interval Δt compressing the volume of the tube by a value

$$\Delta V = -Au\Delta t \ . \tag{5.9}$$

During this time, the piston accelerates a mass $m = \rho_0 V$ of air within a volume V given by the propagation velocity v of the pulse along the tube,

$$V = Av\Delta t \ . \tag{5.10}$$

The mass within this volume receives a momentum,

$$F\Delta t = mu \ . \tag{5.11}$$

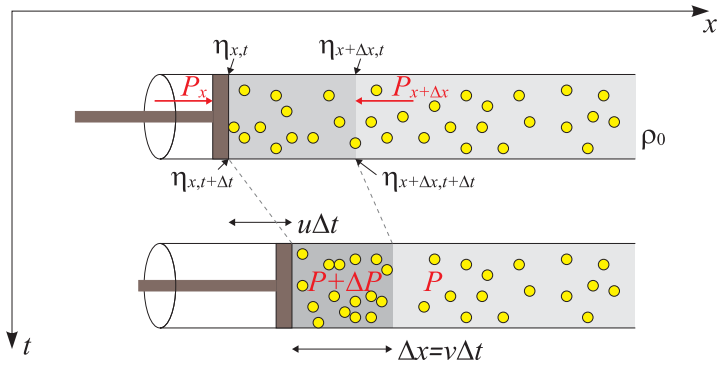

Figure 5.3: Sound waves produced by a swinging piston.

The pressure difference inside and outside the volume V causes a pressure imbalance,

$$F = A\Delta P \ . \tag{5.12}$$

With these relations we can calculate the *compressibility* of the gas,

$$\frac{1}{\kappa} \equiv -\frac{\Delta P}{\Delta V/V} = \frac{F/A}{u/v} = \frac{mu/A\Delta t}{u/v} = \frac{\rho_0 V v}{A\Delta t} = \rho_0 v^2 \ , \tag{5.13}$$

we obtain the propagation velocity of the pulse in the gas,

$$v = \sqrt{\frac{1}{\kappa\rho_0}} \ . \tag{5.14}$$

Thus, the velocity of sound propagation depends critically on the material medium. We have $v_{ar} = 331\,\mathrm{m/s}$, $v_{H_2} = 1286\,\mathrm{m/s}$, $v_{H_2O} = 331\,\mathrm{m/s}$, $v_{rubber} = 54\,\mathrm{m/s}$, and $v_{Al} = 5100\,\mathrm{m/s}$.

To derive the equation of motion, we consider a thin gas element with thickness Δx and mass $m = \rho_0 A\Delta x$ subject to a difference of pressure on both sides of,

$$P_x - P_{x+\Delta x} = -\frac{\partial P_x}{\partial x}\Delta x = -\frac{\partial}{\partial x}(P_0 + \Delta P)\Delta x = -\frac{\partial \Delta P}{\partial x}\Delta x \ , \tag{5.15}$$

where we subtracted the background pressure P_0 assumed to be constant. This pressure difference creates a force $F = A(P_x - P_{x+\Delta x})$ accelerating the gas element following Newton's law, $F = m\ddot{\eta}$, where $\eta(x)$ is the displacement of the element, such that,

$$\frac{\partial \eta}{\partial x} = \frac{\Delta V}{V} \tag{5.16}$$

and the compression (see Fig. 5.3). We therefore obtain,

$$\rho_0 \Delta x \frac{\partial^2 \eta}{\partial t^2} = \frac{F}{A} = -\frac{\partial \Delta P}{\partial x}\Delta x \ . \tag{5.17}$$

Substituting ΔP by the relationship (5.13),

$$\rho_0 \frac{\partial^2 \eta}{\partial t^2} = -\frac{\partial}{\partial x}\left(-\frac{1}{\kappa}\frac{\partial \eta}{\partial x}\right) = \frac{1}{\kappa}\frac{\partial^2 \eta}{\partial x^2} \ , \tag{5.18}$$

which gives the wave equation. Solve Excs. 5.1.7.1, 5.1.7.2, and 5.1.7.3.

5.1.3 Electromagnetic waves

Electromagnetic waves are in several aspects different from mechanical longitudinal or transverse waves. For example, they do not need a propagation medium, but move through the vacuum at an extremely high speed. The speed of light, $c = 299792458\,\mathrm{m/s}$ exactly, is so high, that the laws of classical mechanics are no longer valid, but must be replaced by relativistic laws. And since there is no propagation medium, with respect to vacuum all inertial systems are equivalent, which will have important consequences for the Doppler effect. We will show that the electromagnetic wave equation almost comes out as a corollary of the theory of special relativity.

Electromagnetic waves always arise when a charge changes position. In this way the theory of electromagnetic waves is also a consequence of the theory electromagnetism, which is contained in Maxwell's equations. We will introduce here, without derivation, the wave equation for the electric and magnetic fields.

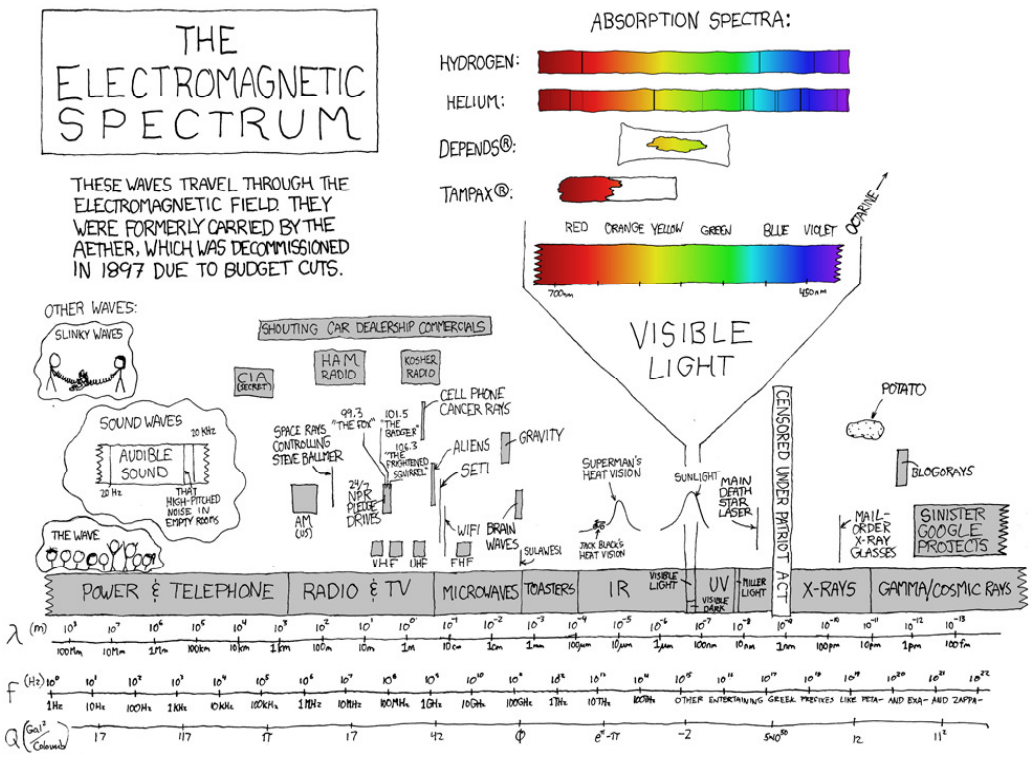

Figure 5.4: The electromagnetic spectrum.

5.1.3.1 Helmholtz equation

We have already seen how the periodic conversion between kinetic and potential energy in a pendulum can propagate in space when the pendulum is coupled to other pendulums attached to each other in a chain, and that this model explains the propagation of a pulse on the string. We also discussed how electrical and magnetic

energy can be interconverted in an electronic L-C-circuit with a capacitor storing electrical energy and an inductance (a coil) storing magnetic energy. The law of electrodynamics describing the transformation of electric field variations into magnetic energy is *Ampère's law*, and the law describing the transformation of magnetic field variations into electric energy is *Faraday's law*,

$$\frac{\partial \vec{\mathcal{E}}}{\partial t} \curvearrowright \vec{\mathcal{B}}(t) \quad , \quad \frac{\partial \vec{\mathcal{B}}}{\partial t} \curvearrowright -\vec{\mathcal{E}}(t) \ . \tag{5.19}$$

Extending the circuit L-C to a chain, it is possible to show that the electromagnetic oscillation propagates along the chain. This model describes well the propagation of electromagnetic energy along a coaxial cable or the propagation of light in free space.

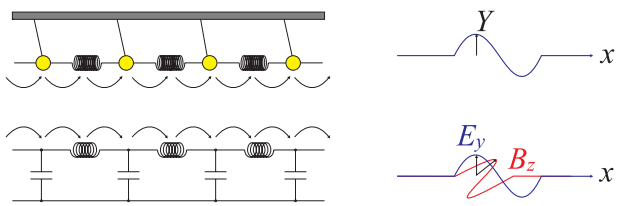

Figure 5.5: Analogy between the propagation of mechanical waves (above) and electromagnetic waves (below).

The *electrical energy* stored in the capacitor and the *magnetic energy* stored in the coil are given by,

$$E_{ele} = \tfrac{\varepsilon_0}{2}|\vec{\mathcal{E}}|^2 \quad , \quad E_{mag} = \tfrac{1}{2\mu_0}|\vec{\mathcal{B}}|^2 \ , \tag{5.20}$$

where the constants $\varepsilon_0 = 8.854 \cdot 10^{-12}$ As/Vm and $\mu_0 = 4\pi \cdot 10^{-7}$ Vs/Am are called *permittivity* and *permeability* of the vacuum. By analogy with the waves on a string, we can write the wave equations (called *Helmholtz equations*) for plane electromagnetic waves propagating along the x-axis,

$$\frac{\partial^2 \mathcal{E}_y}{\partial t^2} = \frac{1}{\varepsilon_0 \mu_0}\frac{\partial^2 \mathcal{E}_y}{\partial x^2} \quad , \quad \frac{\partial^2 \mathcal{B}_z}{\partial t^2} = \frac{1}{\varepsilon_0 \mu_0}\frac{\partial^2 \mathcal{B}_z}{\partial x^2} \ . \tag{5.21}$$

The formal derivation must be made from the *Maxwell equations*, which are the fundamental equations of the theory of electrodynamics. Here, we only note that,

- electromagnetic waves (in free space) are transverse;
- the electric field vector, the magnetic field vector, and the direction of propagation are orthogonal;
- the propagation velocity is the speed of light, because $c^2 = 1/\varepsilon_0\mu_0$.

5.1.3.2 Radiation intensity

In electrodynamic theory the energy flux is calculated by the *Poynting vector*,

$$\vec{S}(\mathbf{r},t) = \tfrac{1}{\mu_0}\vec{\mathcal{E}}(\mathbf{r},t) \times \vec{\mathcal{B}}(\mathbf{r},t) \ . \tag{5.22}$$

The absolute value is the intensity of the light field,

$$I(\mathbf{r}, t) = |\mathbf{S}(\mathbf{r}, t)| \ . \tag{5.23}$$

5.1.4 Harmonic waves

In general, a light field is a superposition of many waves with many different frequencies and polarizations and propagating in many directions. The laser is an exception. Being monochromatic, polarized, directional, and coherent, it is very close to the ideal of an *harmonic wave*, that is, a wave described by the function,

$$Y(x, t) = Y_0 \cos(kx - \omega_0 t) \ , \tag{5.24}$$

where $\omega_0 = 2\pi\nu$ is the angular frequency of the oscillation and $k = 2\pi/\lambda$ the wavevector. By inserting this function into the *wave equation*,

$$\frac{\partial^2 Y}{\partial t^2} = c^2 \frac{\partial Y^2}{\partial x^2} \ , \tag{5.25}$$

where we now call c the propagation velocity of the harmonic wave, we verify the *dispersion relation*,

$$\omega = ck \ . \tag{5.26}$$

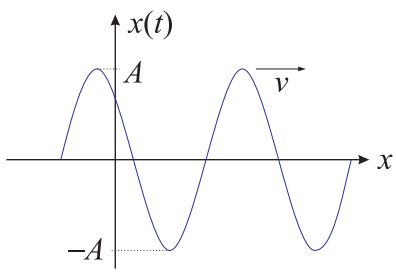

Figure 5.6: Illustration of a harmonic wave.

Often, the propagation velocity is independent of the wavelength, $c(k) = const$. In this case, a wave composed of several waves with different wavevectors k propagates without dispersing, that is, without changing its shape. In other cases, when $c(k) \neq const$, the wave deforms along its path.

5.1.5 Wave packets

Since the wave equation (5.25) is linear, the superposition principle is valid, that is, if Y_1 and Y_2 are solutions, then $\alpha Y_1 + \beta Y_2$ also is. More generally, we can say that, if $A(k)e^{\imath(kx-\omega t)}$ is a solution satisfying the wave equation for any k, then obviously,

$$Y(x, t) = \int_{-\infty}^{\infty} A(k) e^{\imath(kx-\omega t)} dk \ , \tag{5.27}$$

is. This means that the displacement $Y(x)$ and the distribution of amplitudes $A(k)$ are related by Fourier transform, $Y(x,t) = e^{-\imath\omega t}\mathcal{F}A(k)$.

Assuming a Gaussian distribution of wavevectors characterized by the width Δk, $A(k) = e^{-(k-k_0)^2/2\Delta k^2}$, we obtain as solution for the wave equation [1],

$$\begin{aligned} Y(x,t) &= \int_{-\infty}^{\infty} e^{-(k-k_0)^2/2\Delta k^2} e^{\imath(kx-\omega t)} dk \\ &= e^{\imath(k_0 x-\omega t)} \int_{-\infty}^{\infty} e^{-q^2/2\Delta k^2} e^{\imath q x} dq = \sqrt{2\pi k} e^{-\Delta k^2 x^2/2} e^{\imath(k_0 x-\omega t)} \ . \end{aligned} \tag{5.28}$$

This solution of the wave equation describes an *wave packet* with a Gaussian envelope [2], that is, a localized perturbation, as we discussed at the initial example of a pulse propagating on a string. Obviously, other distributions of wavevectors are possible.

Note that the width of the distribution of wavevectors, Δk, and that of the spatial distribution, $\Delta x \equiv 1/\Delta k$ satisfy a relation called *Fourier's theorem*,

$$\Delta x \Delta k = 1 \ , \tag{5.29}$$

which in quantum mechanics turns into *Heisenberg's uncertainty relation*: The broader a wavevector distribution, the narrower the spatial distribution, and vice versa. In the limit of a sinusoidal wave described by a single wavevector, we expect a infinite spatial extension of the wave.

5.1.6 Dispersion

We consider a superposition of two waves,

$$\begin{aligned} Y_1(x,t) + Y_2(x,t) &= a\cos(k_1 x - \omega_1 t) + a\cos(k_2 x - \omega_2 t) \\ &= 2a\cos\left[\tfrac{(k_1-k_2)x}{2} - \tfrac{(\omega_1-\omega_2)t}{2}\right]\cos\left[\tfrac{(k_1+k_2)x}{2} - \tfrac{(\omega_1+\omega_2)t}{2}\right] \ . \end{aligned} \tag{5.30}$$

The resulting wave can be regarded as a wave of frequency $\frac{1}{2}(\omega_1+\omega_2)t$ and wavelength $\frac{1}{2}(k_1+k_2)$, whose amplitude is modulated by an envelope of frequency $\frac{1}{2}(\omega_1-\omega_2)t$ and wavelength $\frac{1}{2}(k_1-k_2)x$.

In the absence of dispersion the *phase velocities* of the two waves and the propagation velocity of the envelope, called *group velocity*, are equal,

$$c = \frac{\omega_1}{k_1} = \frac{\omega_2}{k_2} = \frac{\omega_1-\omega_2}{k_1-k_2} = \frac{\Delta\omega}{\Delta k} = v_g \ . \tag{5.31}$$

[1] Δk is half the *total* Gaussian width at *rms* (root-mean-square) height, that is, at $1/\sqrt{e}$ of the maximum.

[2] The definition of the Fourier transform in one dimension is,

$$Y(x) = \mathcal{F}A(k) \equiv \tfrac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} A(k) e^{\imath kx} dk \ .$$

For the Gaussian function we have,

$$\begin{aligned} Y(x) &= \tfrac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} e^{-ak^2} e^{\imath kx} dk = \tfrac{1}{\sqrt{2\pi}} e^{-x^2/4a} \int_{-\infty}^{\infty} e^{-a(k-ix/2a)^2} dk \\ &= \tfrac{1}{\sqrt{2\pi}} e^{-x^2/4a} \int_{-\infty}^{\infty} e^{-aq^2} dq = \tfrac{1}{\sqrt{2a}} e^{-x^2/4a} \ . \end{aligned}$$

However, the phase velocities of the two harmonic waves can also be different, such that the frequency depends on the wavelength, $\omega = \omega(k)$. In this case, the phase velocity also varies with the wavelength,

$$v_g = \frac{d\omega}{dk} = \frac{d}{dk}(kc) = c + k\frac{dc}{dk} \ . \tag{5.32}$$

Often this variation is not very strong, such that it is possible to expand,

$$\omega(k) = \omega_0 + \left.\frac{d\omega}{dk}\right|_{k_0} \cdot (k-k_0) + \frac{1}{2}\left.\frac{d^2\omega}{dk^2}\right|_{k_0} \cdot (k-k_0)^2 \equiv \omega_0 + v_g(k-k_0) + \beta(k-k_0)^2 \ . \tag{5.33}$$

In general we have, $v_g < c$, a situation that is called *normal dispersion*. But there are examples of *abnormal dispersion*, where $v_g > c$, e.g. close to resonances or with matter waves characterized by a quadratic dispersion relation $\hbar\omega = (\hbar k)^2/2m$.

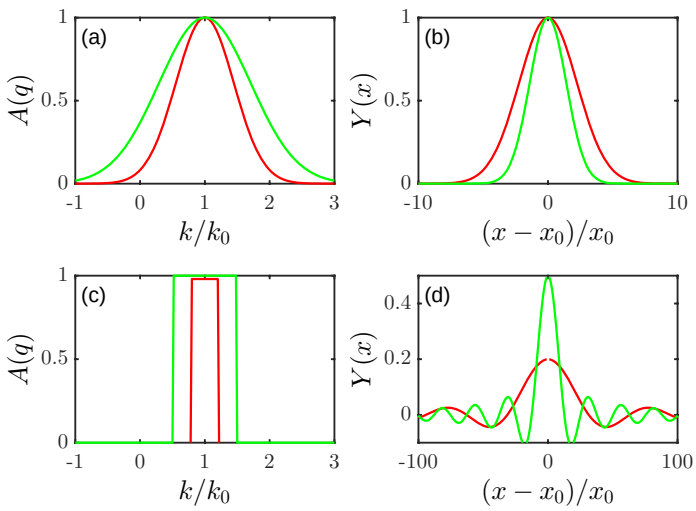

Figure 5.7: (code) Gaussian (upper graphs) and rectangular (lower graphs) distribution of amplitudes in momentum space (left) and in position space (right).

5.1.6.1 Rectangular wave packet with linear dispersion

As an example, we determine the shape of the wavepacket for a rectangular amplitude distribution, $A(k) = A_0\chi_{[k_0-\Delta k/2, k_0+\Delta k/2]}$, subject to linear dispersion (expansion up

to the linear term in Eq. (5.33)). By the Fourier theorem,

$$
\begin{aligned}
Y(x,t) &= \int_{-\infty}^{\infty} A(k) e^{\imath(kx-\omega t)} dk = A_0 \int_{k_0-\Delta k/2}^{k_0+\Delta k/2} e^{\imath(kx-\omega_0 t + \frac{d\omega}{dk}\big|_{k_0}(k-k_0)t)} dk \qquad (5.34)\\
&= A_0 e^{\imath(k_0 x-\omega_0 t)} \int_{k_0-\Delta k/2}^{k_0+\Delta k/2} e^{\imath(k-k_0)\left(x-\frac{d\omega}{dk}\big|_{k_0} t\right)} dk\\
&= A_0 e^{\imath(k_0 x-\omega_0 t)} \int_{-\Delta k/2}^{\Delta k/2} e^{\imath k\left(x-\frac{d\omega}{dk}\big|_{k_0} t\right)} dk = A_0 e^{\imath(k_0 x-\omega_0 t)} \int_{-\Delta k/2}^{\Delta k/2} e^{\imath k u} dk\\
&= A_0 e^{\imath(k_0 x-\omega_0 t)} \frac{e^{\imath \Delta k/2 u} - e^{-i\Delta k/2 u}}{\imath u} = 2A_0 e^{\imath(k_0 x-\omega_0 t)} \frac{\sin \frac{u\Delta k}{2}}{u} \equiv A(x,t) e^{\imath(k_0 x-\omega_0 t)} \ .
\end{aligned}
$$

With the abbreviation $u \equiv x - \frac{d\omega}{dk}\big|_{k_0} t = x - v_g t$ the interpretation of the group velocity becomes obvious,

$$
v_g \equiv \left.\frac{d\omega}{dk}\right|_{k_0} t \ . \qquad (5.35)
$$

The envelope has the shape of a 'sinc' function, such that the intensity of the wave is,

$$
|Y(x,t)|^2 = A_0 \Delta k \ \mathrm{sinc}\left[\tfrac{\Delta k}{2}(x - v_g t)\right] \ . \qquad (5.36)
$$

Obviously, the *wavepacket* is localized in space. It moves at group velocity, but does not diffuse.

5.1.6.2 Dispersion of a Gaussian wave packet subject to quadratic dispersion

Quadratic dispersion leads to a spreading of the wavepackets. We show this at the example of the Gaussian wavepacket $A(k) = e^{-\alpha(k-k_0)^2}$, expanding the dispersion relation (5.33) up to the quadratic term. By the Fourier theorem,

$$
\begin{aligned}
Y(x,t) &= \int_{-\infty}^{\infty} A(k) e^{\imath(kx-\omega t)} dk = A_0 e^{\imath(k_0 x-\omega_0 t)} \int_{-\infty}^{\infty} e^{\imath(k-k_0)(x-v_g t) - (\alpha+i\beta t)(k-k_0)^2} dk\\
&= A_0 e^{\imath(k_0 x-\omega_0 t)} \int_{-\infty}^{\infty} e^{\imath k(x-v_g t) - (\alpha+i\beta t)k^2} dk\\
&\equiv A_0 e^{\imath(k_0 x-\omega_0 t)} \int_{-\infty}^{\infty} e^{\imath k u - v k^2} dk = A_0 \sqrt{\tfrac{\pi}{v}} e^{\imath(k_0 x-\omega_0 t)} e^{-u^2/4v} \ . \qquad (5.37)
\end{aligned}
$$

The absolute square of this solution describes the spatial energy distribution of the wavepacket,

$$
|Y(x,t)|^2 = A_0^2 \frac{\pi}{\sqrt{vv^*}} e^{-u^2/4v - u^2/4v^*} = A_0^2 \frac{\pi}{x_0\sqrt{\alpha/2}} e^{-(x-v_g t)^2/x_0^2} \ , \qquad (5.38)
$$

with $x_0 \equiv \sqrt{2\alpha}\sqrt{1+\frac{\beta^2}{\alpha^2}t^2}$. Obviously, for long times the pulse spreads out at constant speed. Since the constant α gives the initial width of the pulse, we realize that an initially compressed pulse spreads faster. Therefore, the angular coefficient of the dispersion relation determines the group velocity, while the curvature determines the spreading speed (dispersion).

5.1.7 Exercises

5.1.7.1 Ex: Speed of sound

A person drops a stone from the top of a bridge and hears the sound of the stone hitting the water after $t = 4\,\mathrm{s}$.
a. Estimate the distance between the bridge and the water level, assuming that the propagation time of sound is negligible.
b. Improve the estimate by taking into account the finite speed of sound.

5.1.7.2 Ex: Distance of a lightning

An approximate method for estimating the distance of a lightning consists in starting to count the seconds when the lightning stroke and stop counting when the thunder arrives. The number of seconds counted divided by 3 gives the distance from the lightning in kilometers. Estimate accuracy of this procedure.

5.1.7.3 Ex: Speed of sound

A student in her room listens to the radio broadcasting a nearby football game. She is 1.6 km south of the field. On the radio, the student hears the noise generated by an electromagnetic pulse caused by a lightning strike. Two seconds later she hears the noise of thunder on the radio which was captured by the microphone of the football field. Four seconds after hearing the noise on the radio, she hears the noise of the thunder directly. Where did the lightning strike in relation to the soccer field?

5.1.7.4 Ex: Absence of dispersion in sound

Discuss the experimental evidence that leads us to assume that the speed of sound in the audible range must be the same at all wavelengths.

5.1.7.5 Ex: Optical dispersion

a. While vacuum is strictly dispersionless, the refractive index of air depends on the wavelength of light λ, on temperature T in $^\circ$ C and on the atmospheric pressure P in mbar like,

$$n_s = 1 + 10^{-8}\left(8342.13 + \frac{2406030}{130 - 10^{12}/\lambda^2} + \frac{15997}{38.9 - 10^{12}/\lambda^2}\right)$$
$$n = 1 + (n_s - 1)\frac{0.00185097P}{1 + 0.003661T}\ .$$

Calculate the dispersion of air within range $\lambda_1 = 400\,\mathrm{nm}$ and $\lambda_2 = 800\,\mathrm{nm}$.
b. Using Snell's law,

$$\frac{n_1}{n_2} = \frac{\sin\alpha_2}{\alpha_1}\ ,$$

calculate the angular dispersion $d\alpha_{ar}/d\lambda$ of a beam of light at the interface between vacuum and atmospheric air for $P = 1013\,\mathrm{mbar}$ and $T = 25^\circ$ C around $\lambda = 500\,\mathrm{nm}$.

5.1.7.6 Ex: Dispersion near an atomic resonance

Near an atomic resonance ω_0 the refractive index can be approximated by,

$$n = 1 - \frac{\alpha}{\omega^2 - \omega_0^2} \ ,$$

where the polarizability of the gas α is a constant. Calculate the group velocity $v_g(\omega_l)$ of a laser wave packet passing through a gas of these atoms as a function of the laser frequency ω_l. Approximate $|\omega - \omega_0| \ll \omega_0$. Make a qualitative chart of $n(\omega_l)$, $k(\omega_l)$, of the phase velocity $v_f(\omega_l)$, and of the group velocity $v_g(\omega_l)$.

5.1.7.7 Ex: Group velocity near a broad transition

The refractive index of a dilute gas (density ρ) of atoms excited by a light beam of frequency ω near a transition (resonant frequency ω_0 and width Γ) can be approximated by,

$$n = \sqrt{1 - \frac{4\pi\rho\Gamma}{k_0^3(2\Delta + \imath\Gamma)}} \simeq 1 - \frac{2\pi\rho\Gamma}{k_0^3(2\Delta + \imath\Gamma)} \ ,$$

where $ck_0 = \omega_0$ and $\Delta \equiv \omega - \omega_0$. Calculate the group velocity near resonance.

5.1.7.8 Ex: Dispersion in a metal

The dispersion ratio in metals can be approximated by,

$$n^2(\omega) = 1 + \omega_p^2 \left(\frac{f_e}{-\omega^2 - \imath\gamma_e\omega} + \sum_j \frac{f_j}{\omega_{0j}^2 - \omega^2 - \imath\gamma_j\omega} \right) \ ,$$

where ω_p is called the plasma frequency and f_e and f_j are constants. Calculate the group velocity $v_g(\omega)$.

5.2 The Doppler effect

5.2.1 Sonic Doppler effect

Waves propagate from a source to an listener within an elastic material medium with the propagation velocity v. So far, we assumed the source, the medium, and the listener at rest. The question now is, what happens when one of these three components gets in motion.

5.2.1.1 Source in motion

We imagine a source emitting signals at frequency f_0. Within the time of a period $T = \frac{1}{f_0}$ these pulses travel a distance,

$$\lambda = vT = \frac{v}{f_0} \ , \tag{5.39}$$

within the medium. While the source is at rest, the distance between the pulses is λ. However, when the source moves in the propagation direction of the pulses, a resting listener judges that the pulses are emitted within the medium at reduced distances Δx, as shown in Fig. 5.8,

$$\Delta x = \lambda - u_s T \ . \tag{5.40}$$

A listener now receives the pulses at the increased frequency of,

$$f = \frac{v}{\Delta x} = \frac{v}{\lambda - u_s T} = \frac{v f_0}{v - u_s} = \frac{f_0}{1 - u_s/v} \ . \tag{5.41}$$

This effect is called *sonic Doppler effect*. For small velocities we can expand,

$$f = \frac{f_0}{1 \mp u_s/v} \simeq f_0 \left(1 \pm \frac{u_s}{v}\right) \ , \tag{5.42}$$

where the upper (lower) signals apply, when the source approaches (moves away from) the listener.

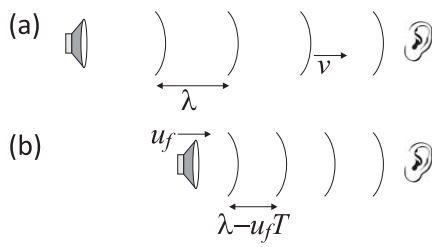

Figure 5.8: Doppler effect due to a motion of the source. In (a) the source is at rest, in (b) it moves toward the listener.

5.2.1.2 Listener in motion

Again, we consider the same source emitting signals at frequency f_0. While the source is at rest, the distance between the pulses is λ. However, when the listener is approaching the source, as shown in Fig. 5.9, pulses are recorded by the listener in a shorter time intervals,

$$T = \frac{\lambda}{v + u_r} = \frac{1}{f} \ . \tag{5.43}$$

That is, the listener measures a larger number of pulses,

$$f = f_0 \left(1 \pm \frac{u_r}{v}\right) \ , \tag{5.44}$$

where the upper (lower) signs apply, when the receiver approaches (moves away from) the source.

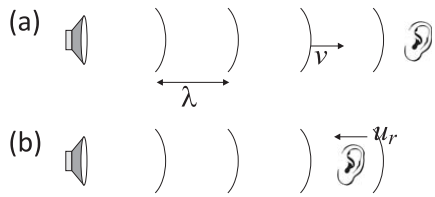

Figure 5.9: Doppler effect due to a motion of the listener. In (a) the listener is at rest, in (b) it moves toward the source.

5.2.1.3 Moving medium

We can combine the two Doppler effects into a single expression,

$$f = f_0 \frac{v^2 - \mathbf{v} \cdot \mathbf{u}_r}{v^2 - \mathbf{v} \cdot \mathbf{u}_s} \ . \tag{5.45}$$

The cases discussed above refer to the source or the listener being in motion *with respect to the medium carrying the wave* considered at rest. If the medium is moving at a velocity u_m, e.g. due to a wind moving the air, the velocities of the source and the listener with respect to the medium are modified, $u_s \to u_s - u_m$ and $u_r \to u_r - u_m$, such that,

$$f = f_0 \frac{1 - (u_r - u_m)/v}{1 - (u_s - u_m)/v} \ . \tag{5.46}$$

The same result is obtained by a transformation of the propagation velocity of the sound, $v \to v + u_m$.

5.2.2 Wave equation under Galilei transformation

The Galilei transformation says, that we obtain the function describing the motion in the system S' simply by substituting $x \to x'$ and $t \to t'$ with [3],

$$\begin{aligned} t' \equiv t \quad &\text{and} \quad x' \equiv x - ut \quad \text{or} \\ t \equiv t' \quad &\text{and} \quad x \equiv x' + ut \ , \end{aligned} \tag{5.47}$$

which implies,

$$v' = \frac{\partial x'}{\partial t'} = \frac{\partial x}{\partial t} - u = v - u \ . \tag{5.48}$$

Newton's classical mechanics is *Galilei invariant*, which means that fundamental equations of the type,

$$m\dot{v}_i = -\nabla_{x_i} \sum_j V_{ij}(|x_i - x_j|) \ , \tag{5.49}$$

[3]Note that the Galilei transform,

$$\begin{pmatrix} ct' \\ x' \end{pmatrix} = G \begin{pmatrix} ct \\ x \end{pmatrix} \qquad \text{with} \qquad G \equiv \begin{pmatrix} 1 & 0 \\ -\beta & 1 \end{pmatrix}$$

is unitary because $\det G = 1$.

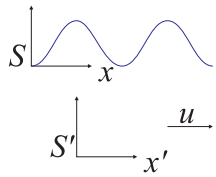

Figure 5.10: Wave in the inertial system S seen by an observer moving at the velocity u in the system S'.

do not change their form under *Galilei transform*. In contrast, the wave equation is not Galilei invariant. To see this, we consider a wave in the inertial system S being at rest with respect to the propagation medium. The wave is described by $Y(x,t)$ and satisfies the wave equation,

$$\frac{\partial^2 Y(x,t)}{\partial t^2} = c^2 \frac{\partial^2 Y(x,t)}{\partial x^2} \ . \tag{5.50}$$

An observer be in the inertial system S' moving with respect to S with velocity u, such that $x' = x - ut$. The question now is, what is the equation of motion for this wave described by $Y'(x',t')$, that is, we want to check the validity of,

$$\frac{\partial^2 Y'(x',t')}{\partial t'^2} \stackrel{?}{=} c^2 \frac{\partial^2 Y'(x',t')}{\partial x'^2} \ . \tag{5.51}$$

For example, the wave $Y(x,t) = \sin k(x - ct)$ traveling to the right is perceived in the system S', also traveling to the right, as $Y'(x',t') = \sin k[x' - (c-u)t'] = Y(x,t)$. Hence,

$$Y'(x',t') = Y(x,t) \ , \tag{5.52}$$

that is, we expect that the laws valid in S are also valid in S'. We calculate the partial derivatives,

$$\begin{aligned}
\frac{\partial Y'(x',t')}{\partial t'} &= \frac{\partial Y(x,t)}{\partial t'} = \frac{\partial t}{\partial t'} \left.\frac{\partial Y(x,t)}{\partial t}\right|_{x=const} + \frac{\partial x}{\partial t'} \left.\frac{\partial Y(x,t)}{\partial x}\right|_{t=const} = \frac{\partial Y(x,t)}{\partial t} + u \frac{\partial Y(x,t)}{\partial x} \\
\frac{\partial Y'(x',t')}{\partial x'} &= \frac{\partial Y(x,t)}{\partial x'} = \frac{\partial t}{\partial x'} \left.\frac{\partial Y(x,t)}{\partial t}\right|_{x=const} + \frac{\partial x}{\partial x'} \left.\frac{\partial Y(x,t)}{\partial x}\right|_{t=const} = \frac{\partial Y(x,t)}{\partial x} \ .
\end{aligned} \tag{5.53}$$

Therefore, we come to the conclusion that in the system propagating with the wave, the wave equation is modified,

$$\begin{aligned}
\frac{\partial^2 Y'(x',t')}{\partial t'^2} &= \frac{\partial^2 Y(x,t)}{\partial t^2} + 2u \frac{\partial^2 Y(x,t)}{\partial t \partial x} + u^2 \frac{\partial^2 Y(x,t)}{\partial x^2} \\
&= c^2 \frac{\partial^2 Y(x,t)}{\partial x^2} + 2u \frac{\partial^2 Y(x,t)}{\partial t \partial x} + u^2 \frac{\partial^2 Y(x,t)}{\partial x^2} \\
&= (c^2 + u^2) \frac{\partial^2 Y(x,t)}{\partial x^2} + 2u \frac{\partial^2 Y(x,t)}{\partial t \partial x} = (c^2 - u^2) \frac{\partial^2 Y'(x',t')}{\partial x'^2} + 2u \frac{\partial^2 Y'(x',t')}{\partial t' \partial x'} \ .
\end{aligned} \tag{5.54}$$

Only in cases, where the wavefunction can be written as $Y(x,t) = f(x - ct) = f(x' - (c-u)t') = f'(x' - ct') = Y'(x',t')$, do we obtain a wave equation similar to

the one of the system S, but with the modified propagation velocity,

$$\begin{aligned}\frac{\partial^2 f'(x'-ct')}{\partial t'^2} &= (c^2-u^2)\frac{\partial^2 f'(x'-ct')}{\partial x'^2} + 2u\frac{\partial^2 f'(x'-ct')}{\partial x'\partial t'} \\ &= (c^2-u^2)\frac{\partial^2 f'(x'-ct')}{\partial x'^2} + 2u\frac{\partial^2 f(x'-(c-u)t')}{\partial x'\partial t'} \\ &= (c^2-u^2)\frac{\partial^2 f'(x'-ct')}{\partial x'^2} - 2u(c-u)\frac{\partial^2 f'(x'-ct')}{\partial x'^2} = (c-u)^2\frac{\partial^2 f'(x'-ct')}{\partial x'^2} \ .\end{aligned} \tag{5.55}$$

The observation that the wave equation is not Galilei-invariant expresses the fact that there is a preferential system for the wave to propagate, which is simply the system in which the propagation medium is at rest. Only in this inertial system will a spherical wave propagate isotropically.

Example 18 (*Wave equation under Galilei transformation*): We now verify the validity of the wave equation in the propagating system S' using the example of a sine wave,

$$\begin{aligned}&(c^2-u^2)\frac{\partial^2 \sin k[x'-(c-u)t']}{\partial x'^2} + 2u\frac{\partial^2 \sin k[x'-(c-u)t']}{\partial x'\partial t'} \\ &= -k^2(c^2-u^2)\sin k[x'-(c-u)t'] + 2uk^2(c-u)\sin k[x'-(c-u)t'] \\ &= -k^2(c-u)^2\sin k[x'-(c-u)t'] = \frac{\partial^2 \sin k[x'-(c-u)t']}{\partial t'^2} \ .\end{aligned}$$

5.2.3 Wave equation under Lorentz transformation

The question now is, how about electromagnetic waves which, as we have already noted and as has been verified by the famous Michelson experiment, survive without any medium. If there is no propagation medium, all inertial systems should be equivalent and the wave equation should be the same in all systems, as well as the propagation velocity, i.e. the speed of light. These were the consideration of *Jules Henry Poincaré*. To resolve the problem we need another transformation than the one of *Galileo Galilei*. Who found it first was *Hendrik Antoon Lorentz*, however the biggest intellectual challenge was to accept all the consequences that this transformation bears. It was *Albert Einstein* who accepted the challenge and created a new mechanics called *relativistic mechanics*. As the wave equation for electromagnetic waves, called the *Helmholtz equation*, is a direct consequence of Maxwell's theory, it is not surprising that the relativistic theory is not only compatible with the electrodynamic theory, but provides a deeper understanding of it.

We begin by making the ansatz of a general transformation interconnecting the temporal and spatial coordinates by four unknown parameters, γ, $\tilde{\gamma}$, β, and $\tilde{\beta}$,

$$ct = \gamma(ct' + \beta x') \qquad \text{and} \qquad x = \tilde{\gamma}(x' + \tilde{\beta}ct') \ . \tag{5.56}$$

The same calculation made for the Galilei transform now gives the first derivatives,

$$\frac{\partial Y'(x',t')}{c\partial t'} = \frac{\partial Y(x,t)}{c\partial t'} = \frac{\partial t}{\partial t'}\left.\frac{\partial Y(x,t)}{c\partial t}\right|_{x=const} + \frac{\partial x}{c\partial t'}\left.\frac{\partial Y(x,t)}{\partial x}\right|_{t=const} = \gamma\frac{\partial Y(x,t)}{c\partial t} + \tilde{\gamma}\tilde{\beta}\frac{\partial Y(x,t)}{\partial x} \tag{5.57}$$

$$\frac{\partial Y'(x',t')}{\partial x'} = \frac{\partial Y(x,t)}{\partial x'} = \frac{\partial ct}{\partial x'}\left.\frac{\partial Y(x,t)}{c\partial t}\right|_{x=const} + \frac{\partial x}{\partial x'}\left.\frac{\partial Y(x,t)}{\partial x}\right|_{t=const} = \gamma\beta\frac{\partial Y(x,t)}{c\partial t} + \tilde{\gamma}\frac{\partial Y(x,t)}{\partial x} \ .$$

The second derivatives and the application of the wave equation in the system S give,

$$\begin{aligned}\frac{\partial^2 Y'(x',t')}{c^2\partial t'^2} &= \gamma^2\frac{\partial^2 Y(x,t)}{c^2\partial t^2} + 2\gamma\tilde{\gamma}\tilde{\beta}\frac{\partial^2 Y(x,t)}{c\partial t\partial x} + (\tilde{\gamma}\tilde{\beta})^2\frac{\partial^2 Y(x,t)}{\partial x^2} \\ &= \gamma^2\frac{\partial^2 Y(x,t)}{\partial x^2} + 2\gamma\tilde{\gamma}\tilde{\beta}\frac{\partial^2 Y(x,t)}{c\partial t\partial x} + (\tilde{\gamma}\tilde{\beta})^2\frac{\partial^2 Y(x,t)}{c^2\partial t^2} \\ &= (\gamma\beta)^2\frac{\partial^2 Y(x,t)}{c^2\partial t^2} + 2\gamma\tilde{\gamma}\beta\frac{\partial^2 Y(x,t)}{c\partial t\partial x} + \tilde{\gamma}^2\frac{\partial^2 Y(x,t)}{\partial x^2} = \frac{\partial^2 Y(x',t')}{\partial x'^2} \ .\end{aligned} \tag{5.58}$$

That is, the wave equation in the system S' has the same form [4]. Thus, the requirement of invariance of the wave equation allows to affirm,

$$\gamma = \tilde{\gamma} \quad \text{and} \quad (\gamma\beta)^2 = (\tilde{\gamma}\tilde{\beta})^2 \quad \text{and} \quad \beta = \tilde{\beta} \ . \tag{5.59}$$

In addition, the transformation

$$\begin{pmatrix} ct' \\ x' \end{pmatrix} = L\begin{pmatrix} ct \\ x \end{pmatrix} \quad \text{with} \quad L \equiv \begin{pmatrix} \gamma & \gamma\beta \\ \gamma\beta & \gamma \end{pmatrix} \tag{5.60}$$

has to be unitary, that is,

$$1 = \det L = \gamma\tilde{\gamma} - \gamma\tilde{\gamma}\beta\tilde{\beta} = \gamma^2(1-\beta^2) \ , \tag{5.61}$$

which allows to relate the parameters γ and β by,

$$\gamma = \frac{1}{\sqrt{1-\beta^2}} \ . \tag{5.62}$$

Finally and obviously, we expect to recover the Galilei transform at low velocities,

$$ct = \gamma(ct' + \beta x') \to ct \quad \text{and} \quad x = \gamma(x' + \beta ct') \to x + ut \ . \tag{5.63}$$

That is, the limit is obtained by $\gamma \to 1$ and $\gamma\beta c \to u$, such that,

$$\beta = \frac{u}{c} \ . \tag{5.64}$$

such that the *Lorentz transform* from one inertial system S to another system S' is,

$$\begin{aligned} t' &= \gamma\left(t - \tfrac{u}{c^2}x\right) \quad \text{and} \quad x' = \gamma(x - ut) \quad \text{or} \\ t &= \gamma\left(t' + \tfrac{u}{c^2}x'\right) \quad \text{and} \quad x = \gamma(x' + ut') \ . \end{aligned} \tag{5.65}$$

5.2.4 Relativistic Doppler effect

We have seen at the example of sonic waves, that the magnitude of the Doppler effect depends on who moves with respect to the medium, whether it is the source or the listener. Electromagnetic waves, however, propagate in empty space, hence there is no material medium or wind. According to Einstein's theory of relativity, there is no absolute motion and the propagation velocity of light is the same for all inertial systems. Therefore, the theory of the sonic Doppler effect can not apply to electromagnetic waves. To deal with the Doppler effect of light, we need to talk a little about time dilation.

[4] Note that the calculus is dramatically simplified using the covariant formalism of 4-dimensional *space-time vectors* introduced by *Hermann Minkowski* and *Gregory Ricci-Curbastro*.

5.2.4.1 Dilation of time

We consider a clock flying through the lab S with the velocity v. The clock produces regular time intervals for which we measure in the lab the duration $t_2 - t_1$. The spatio-temporal points are Lorentz-transformed to the system S' in which the clock is at rest by,

$$\begin{pmatrix} ct'_j \\ z'_j \end{pmatrix} = \begin{pmatrix} \gamma ct_j - \gamma\beta z_j \\ -\gamma\beta ct_j + \gamma z_j \end{pmatrix} . \tag{5.66}$$

Hence,

$$\begin{aligned} t'_2 - t'_1 &= \gamma t_2 - \gamma\beta\frac{z_2}{c} - \gamma t_1 + \gamma\beta\frac{z_1}{c} \\ &= \gamma t_2 - \beta\left(\frac{z'}{c} + \gamma\beta t_2\right) - \gamma t_1 + \beta\left(\frac{z'}{c} + \gamma\beta t_1\right) = \gamma^{-1}(t_2 - t_1) . \end{aligned} \tag{5.67}$$

Consequently, in the lab the time interval seems longer than in the resting system.

Example 19 (*Doppler effect on a moving laser*): Coming back to the Doppler effect we now consider a light source flying through the lab S, for example, a laser operating at a frequency ω', which is well defined by an atomic transition of the active medium. A spectrometer installed in the same resting system S' as the laser will measure just this frequency. Now we ask ourselves, what frequency would a spectrometer installed in the lab measure. The classical response has been derived for a moving sound source,

$$\omega = \omega' - ku = \omega' - \frac{\omega}{c}u = \frac{\omega'}{1 + \frac{u}{c}} , \tag{5.68}$$

with $k = \omega/c$. But now, because of time dilation, we need to multiply by γ,

$$\omega = \frac{\gamma^{-1}\omega'}{1 + \frac{u}{c}} = \sqrt{\frac{1-\beta}{1+\beta}}\omega' \simeq \omega'\left(1 \pm \frac{u}{c} + \frac{u^2}{2c^2}\right) . \tag{5.69}$$

5.2.5 Exercises

5.2.5.1 Ex: Sonic Doppler effect

A speaker hanging from a wire of length $L = 1\,\mathrm{m}$ oscillates with a maximum angle of $\theta_m = 10°$ and emits a sound of $\nu = 440\,\mathrm{Hz}$.
a. What is the frequency of oscillation of the pendulum?
b. What is the energy $E_{cin} + E_{pot}$ of the oscillation?
c. What is the maximum oscillation speed?
d. What are the minimum and maximum frequencies of the sound perceived by a stationary receiver.

5.2.5.2 Ex: Sonic Doppler effect

Two identical speakers uniformly emit sound waves of $f = 680\,\mathrm{Hz}$. The audio power of each speaker is $P = 1\,\mathrm{mW}$. A point P is $r_1 = 2.0\,\mathrm{m}$ away from one device and

$r_2 = 3.0\,\mathrm{m}$ from the other.
a. Calculate the intensities I_1 and I_2 of the sound from each speaker separately at the P.
b. If the emission of the speakers were coherent and in phase, what would be the sound intensity in P?
c. If the emission of the speakers were coherent with a phase difference of 180°, what would be the sound intensity in P?
d. If the speaker output were incoherent, what would be the sound intensity in P?

5.2.5.3 Ex: Sonic Doppler effect

Suppose that a source of sound and a listener are both at rest, but the medium is moving relative to this frame. Will there be any variation in the frequency heard by the observer?

5.2.5.4 Ex: Sonic Doppler effect

Consider a source that emits waves of frequency f_{fnt} moving at velocity v_{fnt} on the x-axis. Consider an observer moving with velocity v_{obs} also on the x-axis. What will be the frequency perceived by the observer? Call the wave propagation velocity of c.

5.2.5.5 Ex: Sonic Doppler effect

Two trains travel on rails in opposite directions at velocities of the same magnitude. One of them is whistling. The whistle frequency perceived by a passenger on the other train ranges from 348 Hz when approaching to 259 Hz when moving away.
a. What is the velocity of the trains.
b. What is the frequency of the whistle.

5.2.5.6 Ex: Sonic Doppler effect

On a mountain road, while approaching a vertical wall which the road will surround, a driver is honking his horn. The echo from the wall interferes with the sound of the horn, producing 5 beats per second. Knowing that the frequency of the horn is 200 Hz, what is the speed of the car?

5.2.5.7 Ex: Sonic Doppler effect

A fixed sound source emits a sound of frequency ν_0. The sound is reflected by a fast approaching object (velocity u). The reflected echo returns to the source, where it interferes with the emitted waves giving rise to frequent beats $\Delta\nu$. Show that it is possible to determine the amplitude of the velocity of the moving object $|u|$ as a function of $\Delta\nu$, of ν_0, and of the speed of sound c.

5.2.5.8 Ex: Sonic Doppler effect

Two cars (1 and 2) drive in opposite directions on a road, with velocities of amplitudes v_1 and v_2. Car 1 travels against the wind, whose velocity is V. At sight of car 2

the driver of car 1 presses his horn, whose frequency is ν_0. The speed of sound in motionless air is c. What is the frequency ν of the horn sound perceived by the driver of car 2? What is the frequency ν' heard by the driver of a car 3 traveling in the same direction as car 1 and at the same speed?

5.2.5.9 Ex: Sonic Doppler effect

A physicist is molested by a fly orbiting his head. Since he is also a musician, he realizes that the sound of the buzz varies by one pitch. Calculate the speed of the fly.

5.2.5.10 Ex: Doppler effect

a. In a storm with wind velocity v a speaker well attached to the ground makes a sound of frequency f_0. How do you calculate the frequency recorded by a microphone taken by the wind and driven away from the speaker at the speed u?
b. Verify your answer in (a) by comparing the three cases (i) $u = 0$, (ii) $u = v$, and (iii) $v = 0$ with the cases of a moving source or receiver.

5.2.5.11 Ex: Sonic Doppler effect

A citizen of São Carlos is molested by a Tucano airplane operated by the Academia das Forças Aéreas de Pirassununga. He notices that while the airplane realizes looping on top of his head, the emitted sounds varies by up to an octave. Estimate the airplane's velocity.

5.3 Interference

The superposition of two counterpropagating waves can generate a *standing wave*. In these waves the oscillation amplitude depends on the position, but there is no energy transport.

5.3.1 Standing waves

We consider two waves $Y_\pm(x,t) = A\cos(kx \mp \omega t + \phi)$ propagating in opposite directions. In the case of a string this situation can be realized, e.g. by exciting a wave $Y_-(x,t)$ propagating in $-x$ direction, reflecting it subsequently at the end of the string ($x = 0$), and letting the wave $Y_+(x,t)$ propagate back in x direction,

$$Y(x,t) = Y_-(x,t) + Y_-(x,t) = A\cos(kx + \omega t) \pm A\cos(kx - \omega t) \ . \tag{5.70}$$

The sign of the reflected wave depends on how the end of the string is attached. If the end is fixed, the reflected wave inverts its amplitude. If it is free to move, the amplitude remains unaltered.

Let L be the length of the rope. The boundary conditions can be formulated as follows: When one end is clamped, the oscillation amplitude must be zero at this end,

$$Y(0,t) = 0 \qquad \text{or} \qquad Y(L,t) = 0 \ . \tag{5.71}$$

When one end is loose, the amplitude of oscillation must be maximum,

$$Y(0,t) = A \qquad \text{or} \qquad Y(L,t) = A \ . \tag{5.72}$$

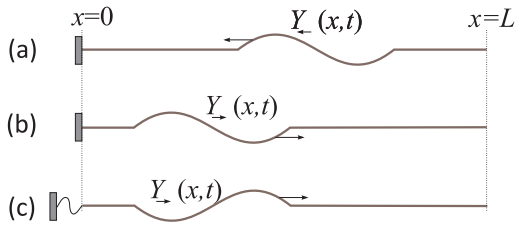

Figure 5.11: Superposition of a left-bound wave (a) with a wave reflected at a clamped end (b) or a loose end (c).

5.3.1.1 Rope with two ends fastened

In case that the two ends of the rope are clamped, we can simplify the superposition (5.70),

$$Y(x,t) = A\cos(kx + \omega t) - A\cos(kx - \omega t) = 2\sin kx \sin \omega t \ . \tag{5.73}$$

The boundary condition, $Y(L,t) = 0$, requires,

$$kL = \frac{2\pi L}{\lambda} = n\pi \ , \tag{5.74}$$

for a natural number n. This means that for a given length L and a given propagation velocity v, we can only excite oscillations satisfying,

$$\lambda = \frac{2L}{n} \qquad \text{and} \qquad \nu = \frac{v}{\lambda} = n\frac{v}{2L} \ . \tag{5.75}$$

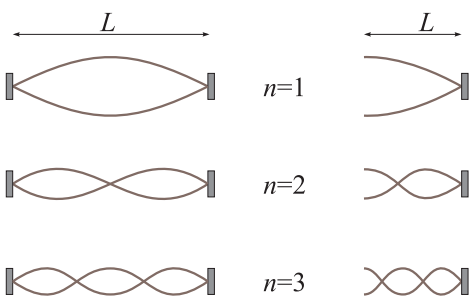

Figure 5.12: Vibration modes of a string fot (left) both ends tight up and (right) for one loose end.

5.3.1.2 Rope with one free end

In case that the end of the string at $x = 0$ is loose, we can simplify the superposition (5.70),

$$Y(x,t) = A\cos(kx + \omega t) + A\cos(kx - \omega t) = 2\cos kx \cos \omega t \ . \tag{5.76}$$

The boundary condition, $Y(L,t) = 0$, requires,

$$\phi = \tfrac{\pi}{2} \qquad \text{and} \qquad kL = \frac{2\pi L}{\lambda} = \left(n - \tfrac{1}{2}\right)\pi \ , \tag{5.77}$$

for a natural number n. This means that for a given length L and a given propagation velocity v, we can only excite oscillations satisfying,

$$\lambda = \frac{2L}{n - \frac{1}{2}} \qquad \text{and} \qquad \nu = \frac{v}{\lambda} = \left(n - \tfrac{1}{2}\right)\frac{v}{2L} \ . \tag{5.78}$$

Example 20 (*Stationary sound wave*):

- Exciting a stationary sound wave in a bottle.
- Exciting a standing sound wave on a guitar string.

5.3.2 Interferometry

5.3.2.1 Phase matching of two laser beams

When phase-matching two plane waves $\mathcal{E}_1 = Ae^{\imath\omega_1 t}$ and $\mathcal{E}_2 = Ae^{\imath\omega_2 t}$ on a photodiode, such that their wavevectors are parallel, the photodiode generates a *beat signal*,

$$I = |E_1 + E_2|^2 = AB[2 + 2\cos(\omega_1 - i\omega_2)t] \ . \tag{5.79}$$

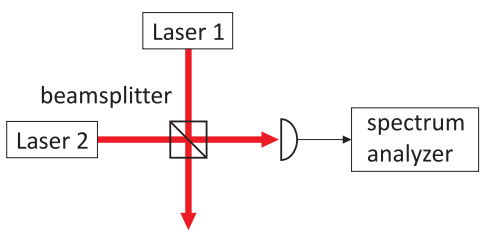

Figure 5.13: Principle of a beat frequency measurement.

In order to get a high signal contrast, a good phase-matching is important. It is particularly important to adjust the wavevectors to be absolutely parallel. In practice, however, this can be tricky, as the laser beams are frequently not plane waves, but have a finite diameter and radius of curvature.

Example 21 (*Laser interferometry*):

- Construct Michelson and Mach-Zehnder laser interferometers with one mirror mounted on a piezo. Show interference rings.

5.3.3 Diffraction

According to the Huygens principle, each point P_z within a slit emits a spherical wave reaching a given point P_k of the screen with a phase lag corresponding to the distance, as shown in Fig. 5.14,

$$r_{12} = \overline{P_\eta P_y} = \sqrt{(y-\eta)^2 + z^2} \ . \tag{5.80}$$

Thus, the phase difference between this ray and a ray coming out of the origin (which we place somewhere on the optical axis) is,

$$\phi = k\Delta r_{12} = k(\sqrt{(y-\eta)^2+z^2} - \sqrt{y^2+z^2}) \simeq -\frac{ky\eta}{\sqrt{y^2+z^2}} \simeq -\frac{ky\eta}{z} \equiv q\eta \ , \tag{5.81}$$

with $q = k\sin\alpha = ky/z$. If $A(\eta)$ is the amplitude of the excitation at the point η of the slit, then $B(y) = \frac{1}{z}e^{\imath\phi}$ is the amplitude at point y of the screen. Adding the contributions of all points,

$$B(q) = \sum_z e^{\imath\phi(y,z)} \to \int A(\eta)e^{\imath q\eta}d\eta \ . \tag{5.82}$$

We see that the amplitude distribution on the screen $B(y)$ is nothing more than the Fourier transform of the amplitude distribution $A(\eta)$ within the slit, regardless of the shape of the slit.

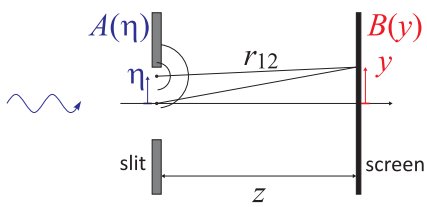

Figure 5.14: Fraunhofer diffraction at the slit.

The theory can be extended to 2D and 3D geometries, for example, a distribution of point-like scatterers within a given volume.

5.3.3.1 Single slit

As an example, we calculate the interference pattern behind a single slit. The Fourier transform of $A(\eta) = \chi_{[-d/2,d/2]}$ is,

$$B(q) = \int_{-d/2}^{d/2} e^{\imath q\eta}d\eta = \left.\frac{e^{\imath q\eta}}{\imath q}\right|_{-d/2}^{d/2} = d\frac{\sin\frac{1}{2}qd}{\frac{1}{2}qd} \ . \tag{5.83}$$

The intensity is $I(q) = c\varepsilon_0|B(q)|^2$.

5.3.3.2 Diffraction grating

We now calculate the interference pattern behind a diffraction grating with $N = 1000$ infinitely thin slits aligned within one millimeter. The Fourier transform of $A(\eta) =$

$\sum_{n=1}^{N} \chi_{[(n-1)d,(n-1)d+\Delta d]}$ is,

$$B(q) = \sum_{n=1}^{N} \int_{(n-1)d}^{(n-1)d+\Delta d} e^{\imath q\eta} d\eta = \frac{e^{\imath q\Delta d} - 1}{\imath q} \sum_{n=1}^{N} e^{\imath(n-1)qd} \tag{5.84}$$

$$\simeq \Delta d \sum_{n=0}^{N} e^{\imath nqd} = \Delta d \frac{1 - e^{\imath Nqd}}{1 - e^{\imath qd}} \ ,$$

where we approximated for $q\Delta d \ll 1$. For $N \to \infty$ we can approximate further,

$$B(q) = \frac{\Delta d}{1 - e^{\imath qd}} \ . \tag{5.85}$$

This is the *Airy function*, which is zero everywhere except at points where $qd = 2n\pi$. The intensity is,

$$I(q) = c\varepsilon_0 |B(q)|^2 = c\varepsilon_0 \frac{\Delta d^2}{2 - 2\cos qd} = c\varepsilon_0 \left(\frac{\Delta d}{2 \sin \frac{qd}{2}} \right)^2 \ . \tag{5.86}$$

The grating constant is $d = 0.001\,\mathrm{mm}$. The resulting pattern can be interpreted as

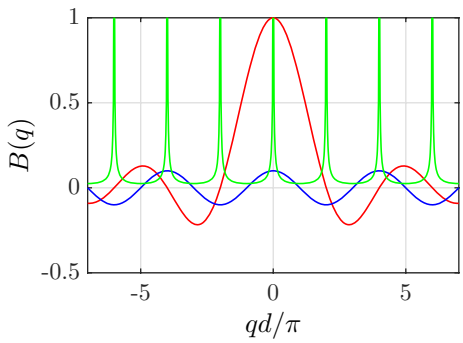

Figure 5.15: (code) Intensity distribution behind a diffraction grating for a single slit (red), a double slit (blue), and an infinite diffraction grating (green).

arising from a regular chain of antennas emitting synchronously. With a large number of point antennas, the chain emits in very well-defined directions. In addition, the direction can be controlled by arranging for a well-defined phase shift between the fields driving neighboring antennas.

5.3.4 Plane and spherical waves

In three dimensions the wave equation takes the form,

$$0 = \Box E \equiv \left(\frac{1}{c^2} \frac{\partial}{\partial t} - \nabla^2 \right) E \ . \tag{5.87}$$

In Cartesian coordinates, this gives,

$$0 = \left(\frac{1}{c^2} \frac{\partial^2}{\partial t^2} - \frac{\partial^2}{\partial x^2} - \frac{\partial^2}{\partial y^2} - \frac{\partial^2}{\partial z^2} \right) E \ . \tag{5.88}$$

Plane waves, that is, waves described by the function,

$$Y(\vec{r},t) = Y_0 \sin(\vec{k}\cdot\vec{r} - \omega t) \ , \tag{5.89}$$

satisfy the wave equation if,

$$0 = -\frac{\omega^2}{c^2} + k_x^2 + k_y^2 + k_z^2 = -\frac{\omega}{c^2} + \vec{k}^2 \ . \tag{5.90}$$

5.3.4.1 Spherical waves

Spherical waves, that is, waves described by the function,

$$Y(\mathbf{r},t) = f(r)\sin(kr - \omega t) \ , \tag{5.91}$$

also satisfy the wave equation, provided the function $f(r)$ satisfies certain conditions. To find these conditions we use the representation of the *Laplace operator* in spherical coordinates,

$$\nabla^2 = \frac{1}{r}\frac{\partial^2}{\partial r^2} r + \frac{1}{r^2 \sin\theta}\frac{\partial}{\partial\theta}\left(\sin\theta\frac{\partial}{\partial\theta}\right) + \frac{1}{r^2\sin^2\theta}\frac{\partial^2}{\partial\phi^2} \ , \tag{5.92}$$

and insert the ansatz for $Y(\mathbf{r},t)$ into the wave equation. We have on one hand,

$$\frac{1}{c^2}\frac{d^2}{dt^2}(f\sin) = -\frac{\omega^2}{c^2} f\sin \ . \tag{5.93}$$

On the other hand,

$$\begin{aligned}\frac{1}{r}\frac{d^2}{dr^2}(rf\sin) &= \frac{1}{r}\frac{d}{dr}[f\sin + rf'\sin + krf\cos] \\ &= f''\sin + \frac{2f'}{r}\sin - k^2 f\sin + \frac{2k}{r}f\cos + 2kf'\cos \ ,\end{aligned} \tag{5.94}$$

such that,

$$0 = \Box f\sin = -\left(f'' + \frac{2f'}{r}\right)\sin - 2k\left(f' + \frac{f}{r}\right)\cos \ . \tag{5.95}$$

Thus the function f must satisfy the radial differential equation,

$$rf' + f = 0 \ . \tag{5.96}$$

This equation can be easily solved with the result $f(r) = r^{-1}$.

5.3.5 Formation of light beams

We consider monochromatic waves with frequency ω. Other waveforms can be synthesized by superpositions of waves with different frequencies. We also restrict to scalar waves. In fact, electromagnetic light fields are vectorial, however, close to the axis of an optical beam the fields are practically uniformly polarized, and representing

the amplitude of the field by a scalar wave is an excellent approximation. The field amplitude $\psi(\mathbf{r}, t)$ is governed by the following scalar wave equation,

$$\nabla^2\psi = \frac{1}{c^2}\frac{\partial^2\psi}{\partial t^2} \ . \tag{5.97}$$

We let ψ be of the form,

$$\psi(\mathbf{r}, t) = A(\mathbf{r})e^{\imath[\phi(\mathbf{r})-\omega t]} \ , \tag{5.98}$$

where A and ϕ are real functions of space. A is the *amplitude*, and the exponent is called the *phase* of the wave. In this form, it is implied that abrupt spatial or temporal variations are contained in the phase. The surface obtained by fixing the phase equal to a constant,

$$\phi(\mathbf{r}) - \omega t = const \tag{5.99}$$

is called *wave front* or *phase front*. The fast motion associated with a wave can be followed through the propagation of a particular wavefront. The interference between two waves is formed by the fronts of the two waves. The speed at which a particular wavefront is moving is called *phase velocity*. Suppose we follow a particular wavefront at the moment t: At time $t + \Delta t$, the phase front will have moved to another surface. A point $\mathbf{r}$ on the original surface will have moved to another point $\mathbf{r} + \Delta\mathbf{r}$ [see Fig. 5.16(a)]:

$$\phi(\mathbf{r} + \Delta\mathbf{r}) - \omega(t + \Delta t) = \phi(\mathbf{r}) - \omega t = const \tag{5.100}$$

Expanding $\phi(\mathbf{r} + \Delta\mathbf{r}) \simeq \phi(\mathbf{r}) + \nabla\phi(\mathbf{r})\Delta\mathbf{r}$, we obtain,

$$\nabla\phi(\mathbf{r})\Delta\mathbf{r} = -\omega t \ . \tag{5.101}$$

$\nabla\phi(\mathbf{r})$ is orthogonal to the phase front and is called the *wavevector*. $\Delta\mathbf{r}$ is smallest in the direction $\nabla\phi$, and the wavefront propagates with the velocity,

$$\frac{|\Delta\mathbf{r}|}{\Delta t} = \frac{\omega}{|\nabla\phi(\mathbf{r})|} \ . \tag{5.102}$$

which is the *phase velocity*. The phase velocity can vary from point to point in space.

Example 22 (*Phase velocity of a superposition of two plane waves*): The superposition of two plane waves with wavevectors $\mathbf{k}_{1,2} = k\hat{\mathbf{e}}_z \cos\theta \pm k\hat{\mathbf{e}}_x \sin\theta$ is described by,

$$\psi(\mathbf{r}, t) = A_0 e^{\imath(\mathbf{k}_1\cdot\mathbf{r}-\omega t)} + A_0 e^{\imath(\mathbf{k}_2\cdot\mathbf{r}-\omega t)} = 2A_0\cos(kx\sin\theta)e^{\imath(kz\cos\theta-\omega t)} \ . \tag{5.103}$$

The phase front of this wave is a plane with normal vectors pointing along the z-axis, as illustrated in Fig. 5.16(b), and the phase velocity is now $\omega/k\cos\theta = c/\cos\theta > c$.

5.3.5.1 Beam formation by superposition of plane waves

Plane waves extend throughout the space and are uniform in transverse direction, whereas an *optical beam* is confined in transverse direction. However, as we saw in the last example, by superposing two plane waves, a resulting wave can be obtained

which varies sinusoidally in transverse direction. By extrapolating this concept to superpositions of many plane waves, it is possible to construct by interference arbitrary transverse amplitude distributions. The propagation of a confined wave is the essence of *diffraction theory*. A particular case is the Gaussian beam. For mathematical simplicity and ease of visualization let us restrict ourselves to waves in two dimensions in the x-z plane. Only in the final phase will we present the complete results for three-dimensional Gaussian beams.

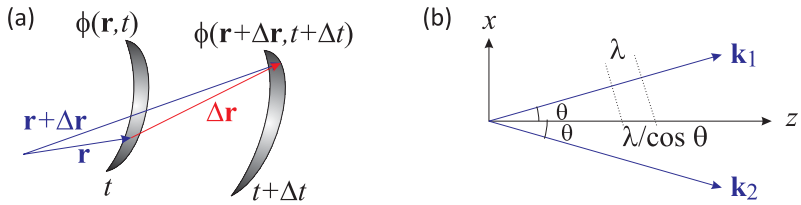

Figure 5.16: Superposition of two plane waves. The phase velocity along the direction z is higher than c, the speed of light, because in one period, the wavefront of each partial wave propagates over a distance λ, but along the z axis over a distance of $\lambda/\cos\theta$.

Before going into detailed calculations, we consider the last example again. The transverse standing wave resulting from the superposition of two plane waves, each one propagating at an angle θ with respect to the z-axis has a spatial frequency $k\sin\theta \simeq k\theta$ for small θ. We now come to a very important property of wave diffraction. Suppose that, in order to confine the wave in transverse direction, we continue adding plane waves, each one propagating at a different small angle θ, so that the amplitude adds constructively within the range $|x| < \Delta x$ and destructively out of it. By the uncertainty principle that results from the Fourier analysis and applies to this case,

$$\Delta(k\theta)\Delta x \gtrsim 1 \ . \tag{5.104}$$

That is, to confine a beam inside a width of Δx, it requires a distribution of plane waves in an angular spreading of at least $\lambda/2\pi\Delta x$. The angular spreading means that the beam will eventually diverge with an angle $\Delta\theta$.

5.3.5.2 Fresnel integrals and beam propagation

Let us now superpose plane waves in a way to form a beam. Each partial wave propagates under some angle θ with respect to the z-axis and has an amplitude $A(\theta)d\theta$, so that the resulting wave (omitting the harmonic temporal variation) is,

$$\psi(x,z) = \int d\theta A(\theta) e^{\imath kx\sin\theta + \imath kz\cos\theta} \ . \tag{5.105}$$

In the so-called *paraxial approximation*, $A(\theta)$ is significant only within a small angular interval close to zero. This means that, according to Eq. (5.104), the transverse dimension of the beam is large in comparison to the wavelength. Expanding the trigonometric functions up the order θ^2,

$$\psi(x,z) \simeq \int d\theta A(\theta) e^{\imath kx\theta + \imath kz(1-\theta^2/2)} = e^{\imath kz} \int d\theta A(\theta) e^{\imath kx\theta - ikz\theta^2/2} \ . \tag{5.106}$$

This wave can be considered as a plane wave, $e^{\imath kz}$, modulated by the integral of (5.106). The expression (5.106) completely describes the propagation of the wave, provided that the wave is known at some point, say $z = 0$. In fact, at $z = 0$, the expression (5.106) for $\psi_0(x) \equiv \psi(x, 0)$ is a Fourier transform, whose inverse yields the angular distribution,

$$A(\theta) = \frac{k}{2\pi} \int d\xi \psi_0(\xi) e^{-\imath k\xi\theta} \ . \tag{5.107}$$

Substitution of $A(\theta)$ back into Eq. (5.106) gives,

$$\psi_z(x) \equiv \psi(x, z) = \frac{k}{2\pi} e^{\imath kz} \int d\theta \int d\xi \psi_0(\xi) e^{\imath(k\theta x - k\theta\xi - kz\theta^2/2)} \ . \tag{5.108}$$

From here on, in order to emphasize the different roles played by the transverse coordinates x and y, we will label the axial position z as an index to the wave function.

We can first integrate over θ via a quadratic extension of the exponent. The result,

$$\frac{k}{2\pi} e^{\imath kz} \int d\theta e^{\imath(k\theta x - k\theta\xi - kz\theta^2/2)} = \sqrt{\frac{k}{2\pi\imath z}} e^{\imath k(z + (x-\xi)^2/2z} \equiv h_z(x - \xi) \ , \tag{5.109}$$

gives us the field at the position z as an integral over ξ of the field in $z = 0$, $\psi_0(\xi)$. The expression (5.109) is called *impulse response*, *kernel*, *propagator*, or *Green's function*, depending on the context. Carry out the integral (5.109) in Exc. 5.3.6.17.

The kernel has very simple physical interpretations: It is the field at point (x, z) generated by a point source with unitary amplitude located in $(\xi, 0)$. In the same time, it is a (two-dimensional) spherical wave in a paraxial form. To see this, we write the field of a two-dimensional spherical wave (i.e. a circular wave) with its center in $(\xi, 0)$ as,

$$\sqrt{\frac{1}{r}} e^{\imath kr} \ , \tag{5.110}$$

where $r = \sqrt{(x - \xi)^2 + z^2}$. (Instead of $1/r$ as in three dimensions, the amplitude decreases as $\sqrt{1/r}$ in two dimensions.) Near the z-axis, we approximate $r \simeq z + (x - \xi)^2/2z$, and the spherical wave becomes,

$$\sqrt{\frac{1}{z}} e^{\imath k[z + (x-\xi)^2/2z]} \ , \tag{5.111}$$

which is the same expression as $h_z(x - \xi)$ in Eq. (5.109). Note that the quadratic term in $x - \xi$ can become considerable in comparison with the wavelength. Eq. (5.106) now becomes,

$$\boxed{\psi_z(x) = \int h_z(x - \xi)\psi_0(\xi) d\xi = \sqrt{\frac{k}{2\pi\imath z}} e^{\imath kz} \int e^{\imath k(x-\xi)^2/2z} \psi_0(\xi) d\xi} \ . \tag{5.112}$$

We will call this integral the *Fresnel integral*. It is the mathematical expression of the *Huygens principle*: The field in (x, z) is the sum of all spherical waves centered on all previous points $(\xi, 0)$ weighed with the respective field amplitude $\psi_0(\xi)$ [848].

The expressions (5.106) and (5.112) represent two equivalent ways to calculate wave propagation. Eq. (5.106) calculates the wave from the angular distribution of

its plane wave components. When the angular distribution is of Hermite-Gaussian type, a Gaussian beam results. In contrast, Eq. (5.112) computes the wave at a point z from the field at an initial point $z = 0$. This is the traditional theory of Fresnel diffraction. Here, also a Gaussian beam results when ψ_0 is Hermite-Gaussian.

To deepen our understanding of beam propagation let us introduce the important concept of *near field* and *far field*. By 'near field' we mean a distance z sufficiently small to be allowed to neglect the quadratic term in the exponent of Eq. (5.106),

$$k\theta^2 z \ll 1 \ . \tag{5.113}$$

Then the near field, in zero-order approximation, is precisely the field at $z = 0$ multiplied with propagation phase factor $e^{\imath kz}$,

$$\psi_z(x) \simeq e^{\imath kz} \int d\theta A(\theta) e^{\imath kz\theta} = e^{\imath kz}\psi_0(x) \ , \tag{5.114}$$

where the second equation follows from Eq. (5.107). Let us now examine the first-order correction and define 'near' more precisely.

The question is, what is the maximum angle of θ allowed in (5.113)? It is not $\pi/2$, but rather, it is the range of angles over which $A(\theta)$ is significantly different from zero. This angular range $\Delta\theta$ is related to the range of transverse distance Δx via the Fourier transform (5.104), so that,

$$\frac{\pi\Delta x^2}{\lambda} \gg z/2 \ . \tag{5.115}$$

The quantity on the left side, called the *Rayleigh range*, is the demarcation between the near and far field regimes. A simple physical interpretation for this quantity will be given below.

Let us now investigate the 'far field' regime of large z having a closer look at Eq. (5.112). When ψ_0 is confined to Δx, and if z is sufficiently large for the quadratic factor to be,

$$k\xi^2/2z \ll 1 \ , \tag{5.116}$$

or

$$\frac{\pi\Delta x^2}{\lambda} \ll z \ , \tag{5.117}$$

then it can be ignored, and the integral becomes,

$$\psi(x,z) \simeq \sqrt{\frac{k}{\imath 2\pi z}} e^{\imath k(z+x^2/2z)} \int e^{-\imath kx\xi/z}\psi_0(\xi)d\xi \ . \tag{5.118}$$

We see that the amplitude of the far field is given by the amplitude of the Fourier transform of the field at $z = 0$ except for a quadratic phase factor $kx^2/(2z)$ [5]

Let us go back to the near field and calculate the first-order correction. For small $z = \Delta z$, we can expand the exponent in equation (5.106),

$$\begin{aligned}\psi_z(x) &\simeq e^{\imath k\Delta z} \int d\theta A(\theta) \left(1 - \imath k\frac{\theta^2}{2}\Delta z\right) e^{\imath k\theta x} \\ &= e^{\imath k\Delta z}\psi_0(x) - e^{\imath k\Delta z}\frac{\imath k\Delta z}{2} \int d\theta A(\theta)\theta^2 e^{\imath k\theta x} \ .\end{aligned} \tag{5.119}$$

[5] In fact, the phase factor can be circumvented by choosing z equal to a focal length f of a lens.

The last integral is,

$$\int d\theta A(\theta)\theta^2 e^{\imath k\theta x} = -\frac{1}{k^2}\frac{\partial^2}{\partial x^2}\int d\theta A(\theta)e^{\imath k\theta x} = -\frac{1}{k^2}\frac{\partial^2\psi_0(x)}{\partial x^2} \ , \tag{5.120}$$

Such that close to $z = 0$, we get,

$$\psi_z(x) \simeq e^{\imath k\Delta z}\left[\psi(x,0) + \frac{\imath\Delta z}{2k}\frac{\partial^2\psi(x,0)}{\partial x^2}\right] \ . \tag{5.121}$$

Note that the first-order correction is in quadrature with the zero-order term (5.114) (if ψ_0 is real), which means that the correction is in the phase, not in the amplitude. The second derivative can be seen as a diffusion operator [6], and it is this phase diffusion, which is the cause of phenomenon of *diffraction*.

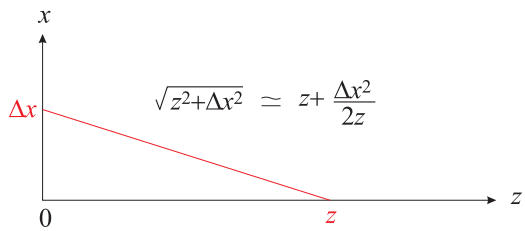

Figure 5.17: Illustration of the Rayleigh range: The distance from $(0,0)$ to $(0,z)$ is z. The distance from $(0,\Delta x)$ to $(0,z)$ is approximately $z + \Delta x^2/(2z)$. The difference is $\Delta x^2/(2z)$. Thus, a wave coming from $(0,0)$ and a wave coming from $(0,\Delta x)$ will acquire a phase difference of $k\Delta x^2/(2z)$ when they reach $(0,z)$. The phase difference is equal to 1 when z equals the Rayleigh range. The phase difference is insignificant in the far field, but significant in the near field.

We can generalize a little more: Suppose we write ψ as a plane wave $e^{\imath kz}$ modulated by a function with slow variation $u(x,z)$,

$$\psi_z(x) \equiv u_z(x)e^{\imath kz} \ , \tag{5.122}$$

then

$$u_{\Delta z}(x) - u_0(x) = \frac{\imath\Delta z}{2k}\frac{\partial^2 u_0(x)}{\partial x^2} \ . \tag{5.123}$$

We derived this relation for a particular point on the z-axis, $z = 0$. However, there is no particular need to choose this point, and the relationship applies to any z. Thus, letting $\Delta z \to 0$, we get,

$$2ik\frac{\partial u}{\partial z} + \frac{\partial^2 u}{\partial x^2} = 0 \ . \tag{5.124}$$

This equation is called *paraxial wave equation*. It is an approximate form of the scalar wave equation and has the same form as the Schrödinger equation for a free particle. The equation can be generalized to three dimensions by a similar derivation:

$$\boxed{2\imath k\frac{\partial u}{\partial z} + \frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} = 0} \ . \tag{5.125}$$

[6] This is because the second derivative of a Gaussian function is negative in the center and positive in the wings, so that when added to the original function, the distribution is reduced in the center and increased in the wings.

The *Fresnel integral is the solution of the paraxial wave equation* with a boundary condition for ψ at $z = 0$. We will show in Sec. 15.4.3 that a three-dimensional wave can be constructed from two-dimensional waves [963]. The resulting Fresnel integral in three dimensions is,

$$\boxed{\psi_z(x,y) = \frac{e^{\imath kz}}{\imath\lambda z}\int e^{\imath k(x-\xi)^2/2z} e^{\imath k(y-\eta)^2/2z}\psi_0(\xi,\eta)d\xi d\eta}\ , \tag{5.126}$$

where $\psi_0(x,y)$ is the distribution of the field amplitude at $z = 0$. Note that, as required by energy conservation, in three dimensions the field decays like $1/z$ and not like $\sqrt{1/z}$, as it does in two dimensions. Note also that the pulse response in three dimensions is essentially the product of two two-dimensional pulse responses.

5.3.5.3 Application of Fresnel diffraction theory

The Fresnel diffraction integral, Eq. (5.112), can be applied in various situations illustrating its use and the difference between wave optics and geometric optics. Examples are the diffraction through a slit, the pin-hole camera, the focusing of a thin lens, etc. [963].

Near-field diffraction (also called *Fresnel diffraction*) and far-field diffraction (also called *Fraunhofer diffraction*) are often distinguished by a quantity called the *Fresnel number*,

$$F \equiv \frac{a^2}{z\lambda}\ , \tag{5.127}$$

where a is the size of the beam (or *aperture*). The near field zone is defined by $F \gtrsim 1$, whereas in the far field zone, $F \ll 1$. For a Gaussian beam, letting $a = \sqrt{\pi}w_0$, we recover the Rayleigh length condition for Fresnel diffraction $z \lesssim z_R$, respectively Fraunhofer diffraction, $z \gg z_R$.

5.3.6 Exercises

5.3.6.1 Ex: Waves on a rope

A string with linear mass density μ is attached at two points distant by $L = 1\,\mathrm{m}$. A mass of $m = 1\,\mathrm{kg}$ is attached to one end of the string that goes over a pulley, as shown in the figure. Excited by a vibrating pin with frequency $f = 1\,\mathrm{kHz}$ the string performs transverse vibrations with the wavelength $\lambda = 2L$.
a. Calculate the sound velocity.
b. Now the mass is replaced by a mass $m' = 4m$. Calculate the new sound velocity.
c. Assuming the sound velocity, how often should the pin excite the string to observe the third oscillation mode (three anti-nodes)?

5.3.6.2 Ex: Optical cavity

Optical cavities consist of two light reflecting mirrors. Standing light waves must satisfy the condition that the electric and magnetic fields vanish on the mirror surfaces. What is the frequency difference between two consecutive modes of a of length $L = 10\,\mathrm{cm}$?

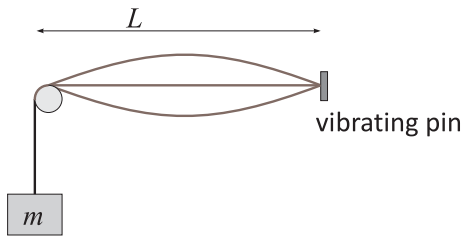

Figure 5.18: Waves on a rope.

5.3.6.3 Ex: Waves on a rope

A string vibrates according to the equation $y(x,t) = 15\,\sin\frac{\pi x}{4\,\mathrm{cm}}\cos(30\,\mathrm{s}^{-1}\,\pi t)$.
a. What is the velocity of a string element at the position $x = 2\,\mathrm{cm}$ at the instant of time $t = 2\,\mathrm{s}$?
b. What is the propagation speed of this wave?

5.3.6.4 Ex: Violin

The length of a violin string is $L = 50\,\mathrm{cm}$, and its mass is $m = 2.0\,\mathrm{g}$. When it is attached at the ends, the string can emit the a'-pitch ('la') corresponding to 440 Hz. Where should a finger be placed so that the emitted sound is the c"-pitch ('do') at 528 Hz?

5.3.6.5 Ex: Sound waves

The air column inside a closed tube, filled with a gas whose characteristic sound velocity is v_s, is excited by a speaker vibrating at the frequency f. Gradually increasing the frequency of the speaker one observes that the tube emits a sound at $f = 440\,\mathrm{Hz}$ and the next time at 660 Hz.
a. What is the length of the tube?
b. What is the speed of sound?

5.3.6.6 Ex: Sound in a bottle

An experimenter blows into a bottle partially filled with water producing a sound of 1000 Hz. After drinking some of the water until the level decreased by 5 cm he is able to produce a sound at 630 Hz. Determine the possible values for the speed of sound knowing that the vibration of the air column inside the bottle should have a node at the end which is in contact with water and an anti-node at the mouth of the bottle. Comparing the result to the known value for the speed of sound in air, what is the excited vibration mode?

5.3.6.7 Ex: Sonic waves in a tube

The figure shows a rod fixed at its center to a vibrator. A disc attached to the end of the rod penetrates a glass tube filled with a gas and where cork dust had been deposited. At the other end of the tube there is a movable piston. When producing

longitudinal vibrations at the rod, we note that for certain positions of the movable piston, the cork dust forms a pattern of node and anti-nodes. Knowing for one of the positions of the piston the distance d between the anti-nodes and the frequency f of the vibration, show that the speed of sound in the gas is $v = 2fd$. This is called Kundt's method for determining the speed of sound in a gas.

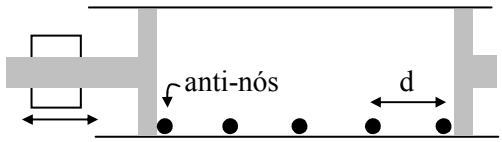

Figure 5.19: Sonic waves in a tube.

5.3.6.8 Ex: Sound filter

A tube can act as an acoustic filter discriminating various sound frequencies crossing it from its own frequencies. A car muffler is an application example.
a. Explain how this filter works.
b. Determine the 'cut-off' frequency below which sound is not transmitted.

5.3.6.9 Ex: Snell's law

Derive Snell's law from Huygens principle.

5.3.6.10 Ex: Surface gravitational waves, capillary waves

Dependence of the propagation velocity on the height of the water column.

5.3.6.11 Ex: Propagating standing wave

Consider two propagating waves $\mathcal{E}_{\pm}(x,t)$ with equal amplitudes and slightly different frequencies $\omega_{\pm}$ propagating in opposite directions along the x-axis.
a. Show that, approximating $k_+ \simeq k_-$, at each instant of time the interference pattern along the x-axis forms a standing wave.
b. Determine the group velocity of this wave.

5.3.6.12 Ex: Mach-Zehnder and Michelson-interferometer

Interferometers are devices that allow the comparison of distances via the propagation time of waves taking different paths. The interferometers outlined in the figures are based on beam splitters that divide and recombine a wave described by $I_n(x,t) = A_n \cos(kx - \omega t)$. Determine the amplitude of the signal at the position of the beam splitter recombining the waves as a function of a variation $\Delta x = 4\pi/k$ of the length of the second interferometer arm.

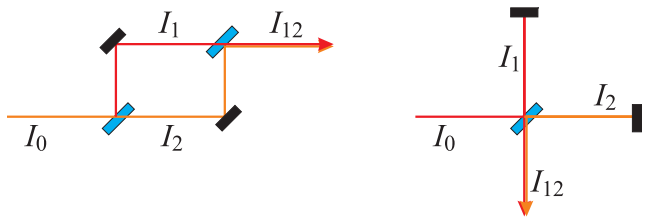

Figure 5.20: Mach-Zehnder and Michelson-interferometer.

5.3.6.13 Ex: Multiple interference in optical cavities

An optical beam splitter is a mirror with partial transmission and partial reflection,

$$\mathcal{E}_r(x,t) = \pm r\mathcal{E}_0(x,t) \quad , \quad \mathcal{E}_t(x,t) = t\mathcal{E}_0(x,t) \ .$$

The reflection signal depends on the direction of incidence, because reflection at a denser medium introduces a phase shift of π. Using this rules derive for a set of two mirrors r_1 and r_2 separated by a distance L the field $\mathcal{E}_{cav}$ between the mirrors as a function of the wave vector of the incident field $\mathcal{E}_{in}$. Also calculate the amplitudes of the transmitted and reflected light. Calculate the phase shifts between the transmitted (reflected) light and the incident light. Interpret the results.

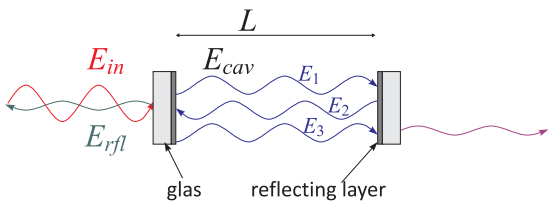

Figure 5.21: Optical cavity.

5.3.6.14 Ex: Double slit

Calculate the interference pattern behind a double slit.

5.3.6.15 Ex: Spherical waves

Show that spherical waves given by $Y(\mathbf{r},t) = \frac{Y_0}{kr}\sin(kr - \omega t)$ satisfy the 3D wave equation. Use Cartesian coordinates.

5.3.6.16 Ex: Interference in spherical waves

Two spherical waves are generated at positions $\mathbf{r}_\pm = \pm R\hat{\mathbf{e}}_z$. Determine surfaces of destructive interference for these waves.

5.3.6.17 Ex: Green's function

Calculate the integral Eq. (5.109).

5.4 Fourier analysis

Every periodic function $f(\xi) = f(\xi+2\pi)$ can be decomposed into a series of harmonic vibrations. This is the *Fourier theorem*,

$$\boxed{f(\xi) = \frac{a_0}{2} + \sum_{n=1}^{\infty}(a_n \cos n\xi + b_n \sin n\xi)} \ . \tag{5.128}$$

To determine the coefficients, we calculate,

$$\int_0^{2\pi} f(\xi)d\xi = \int_0^{2\pi} \left[\frac{a_0}{2} + \sum_{m=1}^{\infty} a_m \cos m\xi + b_m \sin m\xi\right] d\xi = \pi a_0 \tag{5.129}$$

$$\int_0^{2\pi} f(\xi)\cos k\xi d\xi = \int_0^{2\pi} \left[\frac{a_0}{2} + \sum_{m=1}^{\infty} a_m \cos m\xi + b_m \sin m\xi\right] \cos n\xi d\xi = \pi a_n$$

$$\int_0^{2\pi} f(\xi)\sin k\xi d\xi = \int_0^{2\pi} \left[\frac{a_0}{2} + \sum_{m=1}^{\infty} a_m \cos m\xi + b_m \sin m\xi\right] \sin n\xi d\xi = \pi b_n \ ,$$

using the rules,

$$\int_0^{2\pi} \cos n\xi \cos m\xi d\xi = \int_0^{2\pi} \sin n\xi \sin m\xi d\xi = \pi\delta_{n,m} \quad \text{and} \quad \int_0^{2\pi} \cos n\xi \sin m\xi dx = 0 \ . \tag{5.130}$$

We can use these equations to calculate the Fourier expansion. To simplify the calculations, it is useful to consider the symmetry of the periodic function, since if $f(\xi) = f(-\xi)$, we can neglect all the coefficients b_n, and if $f(\xi) = -f(-\xi)$, we can neglect the coefficients b_n [7]

Example 23 (*Frequency spectrum and low-pass filter*):

- Show the spectrum of a rectangular signal on an oscilloscope and on an spectrum analyzer.
- Show the same spectrum filtered by a low pass filter.

.

[7] Alternatively we can write the theorem as,

$$f(\xi) = \sum_{n=-\infty}^{\infty} d_n e^{\imath n\xi} \ ,$$

determining the coefficients as,

$$\int_{-\pi}^{\pi} f(\xi)e^{-\imath k\xi}d\xi = \int_{-\pi}^{\pi} f(\xi)e^{-\imath k\xi}d\xi \sum_{n=-\infty}^{\infty} d_n e^{\imath n\xi}d\xi = 2\pi d_n \ ,$$

with,

$$2d_n = a_n - \imath b_n \quad \text{for} \quad n \geq 0 \quad \text{and} \quad 2d_n = a_{-n} + \imath b_{-n} \quad \text{for} \quad n < 0 \ .$$

5.4.1 Expansion of vibrations

Interpreting $\xi \equiv \omega t$ as time, we can apply the Fourier theorem (5.128) on temporal signals, $S(t) = f(\omega t)$, where ω is the angular frequency,

$$S(t) = f(\omega t) = \frac{a_0}{2} + \sum_{n=1}^{\infty}(a_n \cos n\omega t + b_n \sin n\omega t) \ , \tag{5.131}$$

with,

$$a_0 = \frac{\omega}{\pi}\int_0^{2\pi/\omega} S(t)dt \quad \text{and} \quad a_n = \frac{\omega}{\pi}\int_0^{2\pi/\omega} S(t)\cos n\omega t dt \tag{5.132}$$
$$\text{and} \quad b_n = \frac{\omega}{\pi}\int_0^{2\pi/\omega} S(t)\sin n\omega t dt \ .$$

The representation of the coefficients a_n and b_n as functions of the number n is called *harmonic spectrum*. As we mentioned earlier, the spectrum of a sound is what determines the timbre. The total *harmonic distortion* is defined by,

$$k \equiv \frac{\sum_{n=2}^{\infty}(a_n + b_n)}{\sum_{n=1}^{\infty}(a_n + b_n)} \ . \tag{5.133}$$

Radiofrequency circuits such as HiFi amplifiers are characterized by their transmission fidelity, that is, the absence of harmonic distortion in the amplification of each harmonic coefficient.

5.4.1.1 Expansion of a triangular signal

We consider a *triangular signal* given by [8],

$$S(t) = \begin{cases} \omega t & \text{for} \quad 0 < \omega t < \frac{\pi}{2} \\ \pi - \omega t & \quad\quad \frac{\pi}{2} < \omega t < \pi \end{cases} \ . \tag{5.134}$$

We calculate the coefficients, $a_0 = 0$, because the signal is symmetric about the t-axis (it has no offset), and $a_n = 0$, because the signal has the symmetry $S(t) = -S(-t)$. Also,

$$b_n = \frac{2\omega}{\pi}\int_0^{\pi/2\omega} \omega t \sin n\omega t dt + \frac{2\omega}{\pi}\int_{\pi/2\omega}^{\pi/\omega}(\pi - \omega t)\sin n\omega t dt = \frac{4}{\pi}\frac{\sin\frac{1}{2}\pi n}{n^2} \ , \tag{5.135}$$

with the consequence,

$$S(t) = \frac{4}{\pi}\sum_{n=1,3,\ldots}\frac{(-1)^{(n-1)/2}}{n^2}\sin n\omega t \ . \tag{5.136}$$

[8] Note that the function $S(t) = \frac{\pi}{2} - \left(\frac{\pi}{2} - \omega t\right)\frac{\cos\omega t}{|\cos\omega t|}$, which describes the same triangular signal, it is easier to program in numerical softwares.

5.4.2 Theory of harmony

Non-linearities in oscillating systems can excite harmonic frequencies f_n, that is, multiples of the fundamental frequency $f_n = (n+1)f$. These are the components of the Fourier series.

All musical instruments produce harmonics. This is what makes the timbre of the instrument. When we play several notes together, we perceive the octave interval as pleasant. This is, because all the harmonics of a pitch and of its octave coincide.

- harmonic pitch, well-tempered chromatic scale, flat ♭, sharp ♯, ♮, musical clef, tuning fork $f_{a'} = 440\,\mathrm{Hz}$

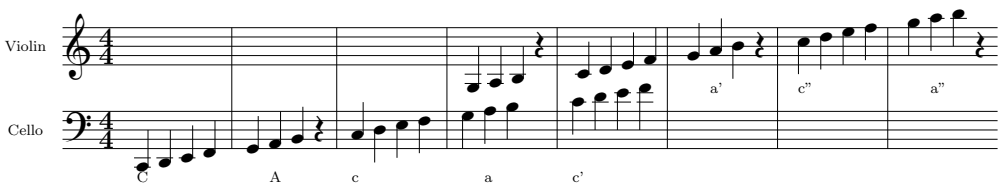

Figure 5.22: (code) Ladder of pitches over 3 octaves. Pitches can be generated in MATLAB. A sample program can be downloaded by clicking on the link.

In the *well-tempered* tonality the interval of a *octave* is divided into 12 intervals,

$$n \in [\text{a, a\#, h, c, c\#, d, d\#, e, f, f\#, g, g\#}] \ . \tag{5.137}$$

Defining *normal tuning* as,

$$f_a = 440\,\mathrm{Hz} \ , \tag{5.138}$$

the pitches correspond to the frequencies,

$$f_n = 2^{n/12} f_a \ . \tag{5.139}$$

For example, we calculate the frequency of the 'd',

$$f_d = 2^{-7/12} f_a = 391.9954\,\mathrm{Hz} \ . \tag{5.140}$$

Thus, all notes are logarithmically equidistant:

$$\mathrm{lb}\ f_{n+1} - \mathrm{lb}\ f_n = \mathrm{lb}\ (2^{(n+1)/12} f_{la}) - \mathrm{lb}\ (2^{n/12} f_{la}) = 1 \tag{5.141}$$

$$\frac{f_{n+1}}{f_n} = \frac{2^{(n+1)/12} f_{la}}{2^{n/12} f_{la}} = 2^{1/12} \ . \tag{5.142}$$

Why are there just 12 pitches? Several instruments have more than one resonator emitting sound, e.g. the violoncello has 4 strings, c, g, d', and a'. Each string is detuned by a *quint* from the next string, that is,

$$3f_c = 2f_g \quad \text{and} \quad 3f_g = 2f_{d'} \quad \text{and} \quad 3f_{d'} = 2f_{a'} \ . \tag{5.143}$$

Each string has its own series of harmonics. The timbre of the instrument appears more pleasant, when the harmonics of the various strings coincide. Let us now check, whether our definition of logarithmically equidistant pitches satisfies this condition,

$$3f_d = 3 \cdot 2^{-7/12} f_a = 2.0023 f_a \neq 2 f_a \ . \tag{5.144}$$

Thus, harmonic tuning is not perfect, but quite close to the well-tempered tuning. In Exc. 5.4.6.5 we show that, nevertheless, the discrepancy is able to produce nasty beat notes.

The guitar, which is tuned in *quart*s,

$$4f_c = 3f_{fa} \ , \tag{5.145}$$

has the same problem [9],

$$4f_c = 4 \cdot 2^{-5/12} f_f = 2.9966 f_f \neq 3 f_f \ . \tag{5.146}$$

Resolve the Excs. 5.4.6.6, 5.4.6.7 and 5.4.6.8.

5.4.3 Expansion of waves

Interpreting $\xi \equiv kx$ as position, we can apply the Fourier theorem (5.128) to standing waves, $Y(x) = f(kx)$, where $k = 2\pi/k$ is the wavevector.

5.4.4 Normal modes in continuous systems at the example of a string

We will now apply the Fourier expansion to calculate the normal modes of a vibrating string. Depending on which mode of oscillation is excited, the displacement of the string is given by,

$$Y_n(x,t) = (A_n \cos\omega_n t + B_n \sin\omega_n t) \sin\tfrac{\omega_n x}{c} \ , \tag{5.147}$$

where $\omega_n = n\pi c/l$ is the frequency of the *normal mode*. An arbitrary vibration can be decomposed as superpositions of these modes,

$$Y(x,t) = \sum_n Y_n(x,t) \ . \tag{5.148}$$

As an initial condition we assume that the string is at a position $Y(x,0) = Y_0(x)$ with the velocity $V(x,0) = V_0(x)$ at all points. Then,

$$\begin{aligned} Y_0(x) &= \sum_n Y_n(x,0) = \sum_n A_n \sin\tfrac{\omega_n x}{c} \\ \text{and} \qquad V_0(x) &= \sum_n \frac{d}{dt} Y_n(x,0) = \sum_n \omega_n B_n \sin\tfrac{\omega_n x}{c} \ . \end{aligned} \tag{5.149}$$

[9] Include Matlab sound examples here!

We find the amplitudes by calculating the integrals,

$$\frac{2}{l}\int_0^l Y_0(x)\sin\tfrac{\omega_n x}{c}dx = \frac{2}{l}\sum_m A_m\int_0^l \sin\tfrac{m\pi x}{l}\sin\tfrac{n\pi x}{l}dx = A_n \tag{5.150}$$
$$\frac{2}{l}\int_0^l V_0(x)\sin\tfrac{\omega_n x}{c}dx = \frac{2}{l}\int_0^l \sum_m \omega_n B_m \sin\tfrac{m\pi x}{l}\sin\tfrac{n\pi x}{l}dx = \omega_n B_n \ .$$

We now assume that the rope is initially excited by a triangular deformation, that is, we pull the rope in its middle up to a distance d and let go. That is, the initial conditions are given by,

$$V_0(x) = 0 \qquad \text{and} \qquad \frac{\pi}{2d}Y_0(x) = \begin{cases} \frac{\pi x}{l} & \text{for} \quad 0 < \frac{\pi x}{l} < \frac{\pi}{2} \\ \frac{\pi(l-x)}{l} & \phantom{\text{for}} \quad \frac{\pi}{2} < \frac{\pi x}{l} < \pi \end{cases} \ . \tag{5.151}$$

We can compare this function with the triangle function Eq. (5.134) and make the same Fourier expansion as in (5.136),

$$\frac{\pi}{2d}Y_0(x) = \frac{4}{\pi}\sum_{n=1,3,\ldots}\frac{(-1)^{(n-1)/2}}{n^2}\sin\tfrac{n\pi x}{l} \ . \tag{5.152}$$

Comparing this expansion with (5.149), we find $B_n = 0$ and,

$$\sum_m A_m \sin\tfrac{\omega_m x}{c} = Y_0(x) = \frac{2d}{\pi}\frac{4}{\pi}\sum_{n=1,3,\ldots}\frac{(-1)^{(n-1)/2}}{n^2}\sin\tfrac{n\pi x}{l} \ . \tag{5.153}$$

yielding for odd coefficients $m = 1, 3, ..,$

$$A_n = \frac{8d}{n^2\pi^2}(-1)^{(n-1)/2} \ . \tag{5.154}$$

Thus, the vibration of the string is completely described by,

$$Y(x,t) = \frac{8d}{\pi^2}\sum_{n=1,3,\ldots}\frac{(-1)^{(n-1)/2}}{n^2}\cos\omega_n t\sin\tfrac{\omega_n x}{c} \ . \tag{5.155}$$

The energy is the sum of the energies of all normal modes,

$$E = \sum_{n=1,3,\ldots}\frac{m}{4}\omega_n^2 A_n^2 = \sum_{n=1,3,\ldots}\tfrac{m}{4}\left(\frac{n\pi c}{l}\right)^2\left(\frac{8d}{n^2\pi^2}\right)^2 = \sum_{n=1,3,\ldots} m\frac{16d^2c^2}{n^2\pi^2 l^2} = \frac{2md^2c^2}{l^2} \ , \tag{5.156}$$

knowing $\sum_{n=1,3,\ldots}\frac{1}{n^2} = \frac{\pi^2}{8}$.

5.4.5 Waves in crystalline lattices

The sound may propagate in a crystalline lattice, for example a metal or a crystal, by means of longitudinal or transverse vibrations. To understand the propagation of longitudinal vibrations in a monoatomic lattice, we consider the model of a chain of

N masses coupled by springs. The treatment for transverse vibrations is analogous. As we have shown in previous sections, the movement of each mass is described by the differential equation,

$$\ddot{x}_n = \omega_0^2(x_n - x_{n-1}) + \omega_0^2(x_n - x_{n+1}) \ , \tag{5.157}$$

with $n = 1, .., N$. Making the ansatz $x_n = A_n e^{-\imath\omega t}$, we obtain the characteristic equation,

$$\omega^2 A_n = \omega_0^2(A_n - A_{n-1}) + \omega_0^2(A_n - A_{n+1}) \ . \tag{5.158}$$

When we hit one of the oscillators of a linear chain, we excite a wave that propagates along the chain. Therefore, it is reasonable to guess $A_n = Ae^{\imath nka}$ for the displacements of the oscillators, where $a \equiv x_{n+1} - x_n$ is the lattice constant. We obtain,

$$\omega^2 = \omega_0^2(1 - e^{-ika}) + \omega_0^2(1 - e^{\imath ka}) = 2\omega_0^2(1 - \cos ka) = 4\omega_0^2 \sin^2 \frac{ka}{2} \ . \tag{5.159}$$

The dispersion relation is shown in Fig. 5.23. Obviously, in the limit of long waves, $ka \ll 1$, the relation can be approximated by,

$$\omega = 2\omega_0 \left| \sin \frac{ka}{2} \right| \simeq \omega_0 ka \equiv ck \ , \tag{5.160}$$

where c is the propagation velocity of the wave. This relation is linear, thus reproducing the situation of acoustic waves.

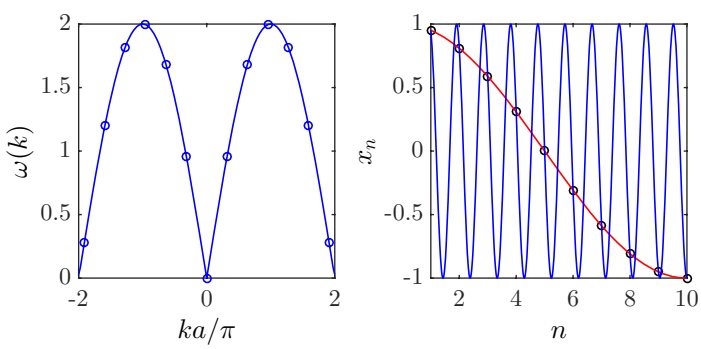

Figure 5.23: (code) Dispersion relation of a one-dimensional crystalline lattice consisting of 20 atoms.

The displacements of individual oscillators are now,

$$x_n(t) = na + Ae^{\imath nka - \imath\omega t} \ . \tag{5.161}$$

We need now to discuss, what are the possible values for k. First, since by adding 2π to the value ka we get the same result, we may concentrate on the region $-\pi < ka < \pi$, called the first *Brillouin zone*. And since the crystal is symmetric (we can reverse the

order of all oscillators), we can assume cyclic boundary conditions, $e^{\imath nka} = e^{\imath(N-n)ka}$, such that $(N-2n)ka/2\pi$ is an arbitrary integer number for any n, for example $n = 0$,

$$k = \frac{2\pi}{Na} \cdot \ell \ , \tag{5.162}$$

for $\ell \in \mathbb{N}$. To stay within the Brillouin zone, we set $\ell = -\frac{N}{2}, .., \frac{N}{2}$. That is, we have N possible values, which corresponds to just half the number of degrees of freedom.

Let us consider particular solutions. In the center of the Brillouin zone, $k = 0$ we have,

$$x_n(t) = na + Ae^{\imath\omega t} \ , \tag{5.163}$$

which corresponds to an in-phase oscillation of all oscillators. On the edge of the Brillouin zone, $k = \pm\pi/a$,

$$x_n(t) = na + A(-1)^n e^{\imath\omega t} \ , \tag{5.164}$$

which corresponds to a movement, where consecutive oscillators oscillate in anti-phase.

5.4.5.1 Waves in diatomic crystalline lattices

Many lattices are diatomic, that is, made of two species of atoms with different masses. For example, the NaCl salt crystal is a lattice alternating Na^+ and Cl^- ions. In analogy with the monoatomic lattice we establish the equations of motion,

$$\begin{aligned} \ddot{x}_n &= -\omega_x^2(x_n - y_{n-1}) - \omega_x^2(x_n - y_n) \\ \ddot{y}_n &= -\omega_y^2(y_n - x_{n+1}) - \omega_y^2(y_n - x_n) \ , \end{aligned} \tag{5.165}$$

with $\omega_{x,y} \equiv \sqrt{k/m_{x,y}}$. Inserting the ansätze $x_n = Ae^{\imath(nka-\omega t)}$ and $y_n = Be^{\imath(nka-\omega t)}$, we find the equations,

$$\begin{aligned} -\omega^2 A &= -\omega_x^2(2A - Be^{-\imath ka} - B) \\ -\omega^2 B &= -\omega_y^2(2B - Ae^{\imath ka} - A) \ , \end{aligned} \tag{5.166}$$

or,

$$\begin{pmatrix} 2\omega_x^2 - \omega^2 & -\omega_x^2(1 + e^{-ika}) \\ -\omega_y^2(1 + e^{\imath ka}) & 2\omega_y^2 - \omega^2 \end{pmatrix} \begin{pmatrix} A \\ B \end{pmatrix} = 0 \ . \tag{5.167}$$

The characteristic equation is,

$$0 = \det \hat{M} = (2\omega_x^2 - \omega^2)(2\omega_y^2 - \omega^2) - \omega_x^2(1 - e^{-\imath ka})\omega_y^2(1 - e^{\imath ka}) \ , \tag{5.168}$$

with the solution,

$$\omega^2 = \omega_x^2 + \omega_y^2 \pm \sqrt{\omega_x^4 + \omega_y^4 + 2\omega_x^2\omega_y^2 \cos ka} \ . \tag{5.169}$$

For $ka \ll 1$ we can approximate,

$$\begin{aligned} \omega^2 &\simeq \omega_x^2 + \omega_y^2 \pm \sqrt{(\omega_x^2 + \omega_y^2)^2 - \omega_x^2\omega_y^2 k^2 a^2} \\ &\simeq 2(\omega_x^2 + \omega_y^2) \ , \ \ \omega_x^2\omega_y^2 k^2 a^2 \ . \end{aligned} \tag{5.170}$$

The first eigenvalue is called the *optical branch* and the second the *acoustic branch*. The optical branch corresponds to an anti-phase motion of the atoms of the species x and y. This motion can be excited by light fields. The acoustic branch corresponds to an in-phase motion of the atoms.

In contrast, for $ka \simeq \pm\pi/a$ we obtain,

$$\omega^2 = \omega_x^2 \quad , \quad \omega_y^2 \ . \tag{5.171}$$

In these solutions either atom x oscillates while y stays at rest, or the opposite.

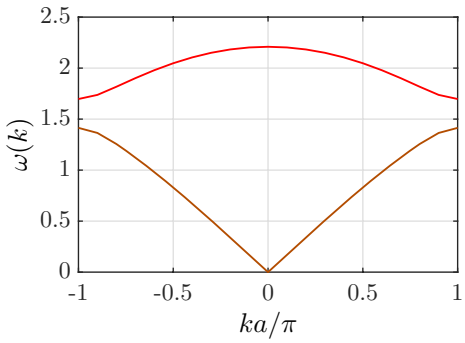

Figure 5.24: (code) Dispersion relation in a one-dimensional lattice showing in blue the optical branch and in green the acoustic branch.

5.4.6 Exercises

5.4.6.1 Ex: Fourier expansion

Expand the function $f(\xi) = \sin^3 \xi$ in a Fourier series.

5.4.6.2 Ex: Fourier expansion of sea waves

Surface waves on the sea are often better described by the function $f(x,t) = (kx - 2n\pi)^2$ inside the intervals $x \in [(2n-1)\pi/k, (2n+1)\pi/k]$ com $n \in \mathbb{N}$. Expands the wave in a spatial Fourier series. Use the formula $\int z^2 \cos(bz) dz = \frac{1}{b^3}[(b^2z^2 - 2)\sin bz + 2bz \cos bz]$.

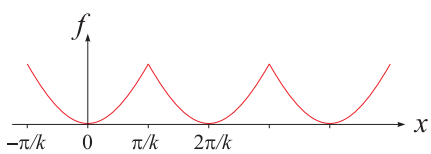

Figure 5.25: (code)

5.4.6.3 Ex: Fourier expansion of a rectified signal

An alternating electric current can be turned into a signal of half-cycles, $f(t) = |\cos\frac{\omega t}{2}|$, by a diode rectifier bridge. Expand this signal into a temporal Fourier series. Use the formula $\int \cos(az)\cos(bz)dz = \frac{\sin[(a-b)z]}{2(a-b)} + \frac{\sin[(a+b)z]}{2(a+b)}$.

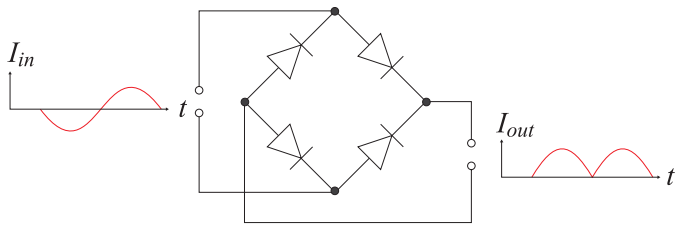

Figure 5.26: Fourier expansion of a rectified signal.

5.4.6.4 Ex: Action of a low pass filter on a spectrum

One method of creating a sinusoidal signal in electronics consist in first creating a rectangular signal via a switching circuit and then pass this signal through a low-pass filter by cutting off the harmonics. Simulate this procedure using the Fourier transform method starting from the rectangular signal $S(t) = \sin\omega t/|\sin\omega t|$ with $\omega/2\pi = 1\,\text{kHz}$ and using a low pass filter, such as $F(\omega) = 1/\left(1 + (\omega/\omega_g)^2\right)$, where the cut-off frequency is, $\omega_g/2\pi = 1\,\text{kHz}$. Evaluate the harmonic distortion of the rectangular signal and the filtered signal.

5.4.6.5 Ex: Tuning a violin

What would be the beat frequency between the pitches $3f_{c'}$ and $2f_{g'}$ if the strings were tuned logarithmically equidistant.

5.4.6.6 Ex: String instruments

Imagine a string instrument with 12 strings tuned in quints. How far would be the highest string from a harmonic of the lowest one.

5.4.6.7 Ex: String instruments

Prepare a list comparing the harmonics up to ninth order in the harmonic and in the tempered scale.

5.4.6.8 Ex: Frequency beating of sound waves

To tune a violin a musician first tunes the a-string ('la') at $f_a = 440\,\text{Hz}$ and then plays two neighboring strings, paying attention to the frequency beats. When playing the a- and the e-string ('mi'), the violinist hears a beat frequency of $3\,\text{Hz}$, and he notes that this frequency increases as the tension of the e-string increases. (The e-string is tuned to $f_e = 660\,\text{Hz}$.)

a. Why is there a beat when the two strings are played simultaneously?
b. What is the vibration frequency of the e-string when the beat frequency it generates together with the a-string is 3 Hz?
c. If the tension on the e-string is 80 N for a beat frequency of 3 Hz, what tension corresponds to a perfect tuning of the string?

5.4.6.9 Ex: Frequency beating of sound waves

A violinist tries to tune the strings of his instrument.
a. Comparing the a-string ('la') to a tuning fork ($\nu_{dia} = 440\,\text{Hz}$), he hears a beat with the frequency 1 Hz. By increasing the tension on the rope, the beat frequency increases. What was the frequency of the 'a'-string before the tension increased?
b. After having adjusted the a-string the violinist wants to tune the d-string ('re'). He realizes that the second harmonic $3\nu_d$ produces with the first harmonic of the a-string ($2\nu_a$) a beat of 1 Hz. Decreasing the tension of the d-string the beat disappears. What was the initial frequency of the d-string and by what percentage does the violinist need to decrease the tension of the string?

5.4.6.10 Ex: Normal modes on a string

A stretched wire of mass m, length L, and tension T is triggered by two sources, one at each end. Both sources have the same frequency ν and amplitude A, but are out of phase by exactly 180° with respect to each other. (At each end there is an anti-node.) What is the lowest possible value of ω consistent with the stationary vibrations of the wire?

5.4.6.11 Ex: Normal modes on a string

a. Find the total vibration energy of a wire of length L fixed at both ends and oscillating in its n-th characteristic mode with amplitude A. The tension on the wire is T, and its total mass is M. (**Suggestion:** Consider the integrated kinetic energy at the instant when the wire is straight.)
b. Calculate the total vibration energy of the same wire vibrating in the following superposition of normal modes:

$$Y(x,t) = A_1 \sin \tfrac{\pi x}{L} \cos \omega_1 t + A_3 \sin \tfrac{3\pi x}{L} \cos(\omega_3 t - \tfrac{\pi}{4}) \ .$$

You should be able to verify that it is the sum of the energies of the two modes taken separately.

5.4.6.12 Ex: Normal modes on a string

A wire of length L is attached at both ends under a tension T. The wire is pulled sideways by a distance h from its center, such that the rope adopts a triangular shape, and the it is released.
a. What is the energy of the subsequent oscillations. **Suggestion**: Consider the work that needs to be done against the tension to give the wire its initial deformation, and suppose that the tension remains unchanged upon a slight increase of its length caused by transverse the displacements.
b. How many times will the triangular shape reappear?

5.4.6.13 Ex: Waves on a rope

A string with linear mass density μ is attached at two points distant from each other by $L = 1\,\mathrm{m}$. A mass $m = 1\,\mathrm{kg}$ is now attached to one end of the rope that goes through a pulley, as shown in the figure. Excited by a vibrating pin with frequency $f = 1\,\mathrm{kHz}$ the string performs transverse vibrations with wavelength $\lambda = 2L$.
a. Calculate the propagation velocity of the wave.
b. At what frequency should the pin excite the rope to observe the third oscillation mode (three anti-nodes)?
c. Now the mass is doubled. Calculate the new speed of sound.
d. How should the mass be chosen to obtain a fundamental mode frequency equal to the frequency of the third mode calculated in (b)?

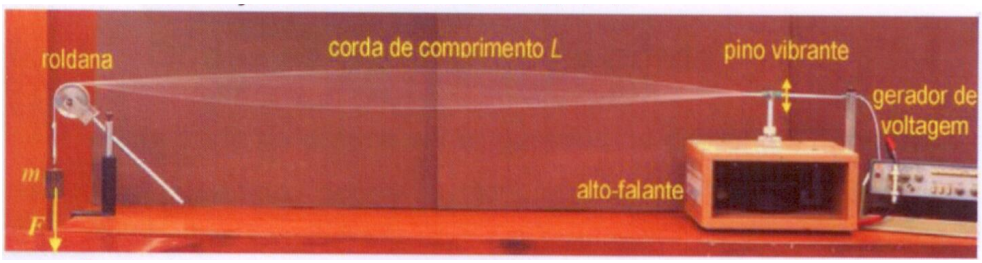

Figure 5.27: Waves on a rope.

5.5 Matter waves

Quantum mechanics tells us that light sometimes behaves like particles and matter like waves. Letting us guide by this analogy we will, in the following, guess the fundamental equations of motion for the propagation of matter waves from a comparison of the respective dispersion relations of light and massive particles.

5.5.1 Dispersion relation and Schrödinger's equation

On one hand, the propagation light is (in the vacuum) is described by the dispersion relation $\omega = ck$ or,

$$\omega^2 - c^2k^2 = 0 \ . \tag{5.172}$$

Since light is a wave it can, in the most general form, be described by a wavepacket, $A(\mathbf{r}, t) = \int e^{\imath(\mathbf{k}\cdot\mathbf{r}-\omega t)} a(\mathbf{k}) d^3k$. It is easy to verify that the *wave equation*,

$$\frac{\partial^2}{\partial t^2} A - c^2 \nabla^2 A = 0 \ , \tag{5.173}$$

reproduces the dispersion relation.

On the other hand, slow massive particles possess the kinetic energy,

$$E = \frac{p^2}{2m} \ . \tag{5.174}$$

With de Broglie's hypothesis that even a massive particle has wavelength, we can try an *ansatz* [10] for a wave equation satisfying the dispersion relation (5.174). From Planck's formula, $E = \hbar\omega$, and the formula of *Louis de Broglie*, $\mathbf{p} = \hbar\mathbf{k}$, describing the particle by a wavepacket not being subject to external forces $\psi(\mathbf{r}, t) = \int e^{\imath(\mathbf{k}\cdot\mathbf{r}-\omega t)}\phi(\mathbf{k})d^3k$, it is easy to verify that the differential equation,

$$\imath\hbar\frac{\partial}{\partial t}\psi = \left(-\frac{\hbar^2}{2m}\nabla^2\right)\psi \ , \tag{5.175}$$

reproduces the dispersion relation. If the particle is subject to a potential, its total energy is $E = \mathbf{p}^2/2m + V(\mathbf{r}, t)$. This dispersion relation corresponds to the famous *Schrödinger equation*,

$$\imath\hbar\frac{\partial}{\partial t}\psi = \left(-\frac{\hbar^2}{2m}\Delta + V(r, t)\right)\psi \ . \tag{5.176}$$

Since we accept that light particles and lenses behave like a wave, to calculate their trajectories, we must determine the potential landscape $V(\mathbf{r})$ in which this particle moves before solving the Schrödinger equation. This is the role of *wave mechanics*, which is one of the formulations of quantum mechanics.

5.5.1.1 Scalar waves and vectorial waves

The electromagnetic field is a *vector field*, since $\vec{\mathcal{E}}(\mathbf{r}, t)$ and $\vec{\mathcal{B}}(\mathbf{r}, t)$ are vectors. Therefore, it has a polarization. In contrast, the field of matter $\psi(\mathbf{r}, t)$ is a *scalar field* and therefore does not have the degree of freedom of polarization, in analogy with sound. This has important consequences, for example, the fact that two collinear light fields with orthogonal polarizations do not interfere has no analogue with matter wave fields.

5.5.2 Matter waves

Broglie's formula assigns a wave to each body, The wavelength decreases as the velocity of the particle grows. The necessity to describe a massive particle as a matter wave depends on the relationship between its Broglie wavelength and other characteristic quantities of the system under consideration. If the wavelength is large, we expect typical interference phenomena for waves; if the wavelength is small, the particle will behave like a mass, which is perfectly localized in space and incapable of interfering.

Characteristic features of the system may be, for example, the presence of a narrow slit diffracting the Broglie wave of an atom or an electron passing through it. Another characteristic feature is the average distance between several atoms. In fact, when an atomic gas is so cold, that is, composed of atoms so slow, that the Broglie wavelength of the atoms is longer than the average distance, then the atoms interfere with each other. In the case of bosonic atoms, the interference will be constructive, resulting in a matter wave of gigantic amplitude. This phenomenon is called Bose-Einstein condensation [11].

[10] Kick, work hypothesis, guess.
[11] See script on *Quantum mechanics* (2023).

Before calculating the temperature required for this phenomenon to happen, we need to inform the reader, that the interatomic distance can not be compressed arbitrarily, because below distances of typically $\bar{d} = 1\ \mu$m, the gas tends to form molecules. For the Broglie waves of different atoms to interfere, the wavelength must be longer. The average velocity of the atoms in a gas of temperature T is given by,

$$\frac{m}{2}\bar{v}^2 = \frac{k_B}{2}T\ .$$

Therefore, the temperature of the gas must be,

$$T = \frac{m\bar{v}^2}{k_B} = \frac{\bar{p}^2}{k_B m} = \frac{\hbar^2\bar{k}^2}{k_B m} = \frac{4\pi^2\hbar^2}{k_B m\lambda_{dB}^2} < \frac{h^2}{k_B m d^2}\ .$$

For rubidium atoms of mass $m = 87u$ we calculate $T < 200\,\text{nm}$.

The development of powerful experimental techniques allowed in 1995 the cooling of rubidium gases down to such low temperatures and the experimental realization of Bose-Einstein condensates, that is, matter waves made up of 10^6 atoms. See Exc. 5.5.3.1.

5.5.3 Exercises

5.5.3.1 Ex: Interference in Bose-Einstein condensates

Calculate the periodicity of the interference pattern of two Bose-Einstein condensates supposed to have intrinsic temperatures $T = 0$ interpenetrating at a relative velocity $v = 1\,\text{mm/s}$.

Chapter 6

Gravitation

Gravity is one of the four fundamental forces known in modern physics. Just like the electromagnetic force it has a long range, but differently from it, it is always attractive. For these reasons it rules the macroscopic behavior of our universe. When we studied the motion and dynamics of bodies, until now we either considered contact interaction without worrying about their microscopic nature and assuming the validity of conservation laws, or we tacitly supposed the presence of force fields without worrying where they came from.

There is, however, a force acting between distant bodies without them having to touch each other. Newton introduced gravity as an *action at a distance*, meaning that all bodies instantaneously sense the presence and eventually the motion of all other bodies. Einstein showed later, that this concept cannot be right.

We will in this chapter give an introduction into Newton's theory and a very brief outlook an Einstein's theory of gravity.

6.1 Planetary orbits

6.1.1 Kopernicus' laws

Nicolaus Copernicus published in 1543 his book *De revolutionibus orbium coelestium* in which he states:

1. The planetary orbit is a circle with epicycles.
2. The Sun is approximately at the center of the orbit.
3. The speed of the planet in the main orbit is constant.

Despite being correct in saying that the planets revolved around the Sun, Copernicus was incorrect in defining their orbits. It was Kepler who correctly defined the orbit of planets as follows:

1. The planetary orbit is not a circle with epicycles, but an ellipse.
2. The Sun is not at the center but at a focal point of the elliptical orbit.
3. Neither the linear speed nor the angular speed of the planet in the orbit is constant, but the area speed is constant.

6.1.2 Kepler's laws

Kepler's laws of planetary motion, published by *Johannes Kepler* between 1609 and 1619, describe the orbits of planets around the Sun:

1. The orbit of a planet is an ellipse with the Sun at one of the two foci.

2. A line segment joining a planet and the Sun sweeps out equal areas during equal intervals of time.

3. The square of a planet's orbital period is proportional to the cube of the length of the semi-major axis of its orbit.

The elliptical orbits of planets were indicated by calculations of the orbit of Mars. From this, Kepler inferred that other bodies in the Solar System, including those farther away from the Sun, also have elliptical orbits. The second law helps to establish that when a planet is closer to the Sun, it travels faster. The third law expresses that the farther a planet is from the Sun, the slower its orbital speed, and vice versa. *Isaac Newton* showed in 1687 that relationships like Kepler's would apply in the Solar System as a consequence of his own laws of motion and law of universal gravitation. Do the Excs. 6.1.3.1 to 6.1.3.4.

The eccentricity of the orbit of the Earth makes the time from the March equinox to the September equinox, around 186 days, unequal to the time from the September equinox to the March equinox, around 179 days. A diameter would cut the orbit into equal parts, but the plane through the Sun parallel to the equator of the Earth cuts the orbit into two parts with areas in a 186 to 179 ratio, so the eccentricity of the orbit of the Earth is approximately,

$$e \approx \frac{\pi}{4}\frac{186-179}{186+179} \approx 0.015 \ , \tag{6.1}$$

which is close to the correct value (0.016710218). The accuracy of this calculation requires that the two dates chosen be along the elliptical orbit's minor axis and that the midpoints of each half be along the major axis. As the two dates chosen here are equinoxes, this will be correct when perihelion, the date the Earth is closest to the Sun, falls on a solstice. The current perihelion, near January 4, is fairly close to the solstice of December 21 or 22.

6.1.3 Exercises

6.1.3.1 Ex: Kepler orbits

The moon moves in a good approximation on a circular path with radius $R = 384000\,\text{km}$ around the Earth. Assume that the Earth's mass would suddenly decrease.
a. How much would the mass have to decrease so that the moon could escape the Earth?
b. How would the moon's orbit change if the mass decreased by a factor of 3, 2 or 1.5?

6.1.3.2 Ex: Kepler orbits of missiles

Consider an object of mass $m \ll M_{\oplus}$ which is launched at an initial velocity $\mathbf{v}_0$ (at an angle θ relative to the Earth's surface). We neglects any friction.
a. What possible trajectories can the object move on? How does the type of trajectory depend on the conservation parameters?
b. Calculate the maximum speed that the object may have to move on a closed trajectory. Does this speed depend on θ? Does the projectile always fall back to Earth when the path is closed?
c. Neglecting the Earth's rotation calculate the flight distance of the projectile above the Earth's surface for velocities below the above-mentioned limit velocity.
Help: Set the center of the Earth in the focal point of the Kepler orbit.

6.1.3.3 Ex: Halley's Comet

The comet Haley moves like a planet on an elliptical orbit around the sun. Its orbital period is 75 years and the closest distance to the sun is 0.5 AE. (One astronomical unit is the distance from the Earth to the sun, assuming that the orbit of the Earth around the sun is a circular orbit.)
a. Use this information to calculate the value for the major semi-axis a and the minor semi-axis b of the comet's orbit in astronomical units. Use this to determine the eccentricity ε of the orbit.
b. What is the maximum distance of the comet from the sun?
c. Calculate the minimum and maximum speed of the comet on its orbit.

6.1.3.4 Ex: Ellipse

An ellipse is the set of all points C satisfying the condition $\overline{AC} + \overline{BC} = 2a$, where the two focal points A and B are at a given distance $2e$.
a. Show that this definition is equivalent to the ellipse equation of the form,

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1 \ ,$$

where a and b are the large and small half-axes. How does e depend on a de b?
b. Show that the ellipse equation is given in plane polar coordinates by,

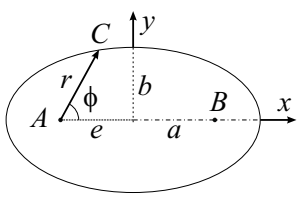

Figure 6.1: Ellipse.

$$r = \frac{P}{1 - \epsilon \cos \phi} \ .$$

Determine the eccentricity ϵ and the parameter P as a function of a and b.

6.2 Newton's law

Newton's law of *gravity* about the force between two massive bodies,

$$\mathbf{F} = -\nabla V(r) \ . \tag{6.2}$$

can be deduced from a conservative central potential,

$$\boxed{V(r) = \frac{\gamma_N M m}{r}} \ . \tag{6.3}$$

If $M = M_{\text{♁}}$ is the mass of the Earth, a test mass m close to the surface ($r_{\text{♁}} \approx 6378\,\text{km}$) will be accelerated by,

$$g = \frac{F}{m} = -\frac{\partial}{\partial r}\frac{\gamma_N M_{\text{♁}}}{r}\bigg|_{r=R_{\text{♁}}} = \frac{\gamma_N M_{\text{♁}}}{R_{\text{♁}}^2} = 9.81\,\text{m/s}^2 \ . \tag{6.4}$$

with Newton's constant,

$$\boxed{\gamma_N = 6.67 \cdot 10^{-11}\,\text{m}^3/\text{kg s}^2} \ . \tag{6.5}$$

6.2.1 Cosmic velocities

6.2.1.1 First cosmic velocity

The first *cosmic velocity* is defined as the velocity that a body must have in order to circle the center of the Earth on an orbit with the Earth's radius. We calculate this velocity from the condition that the centripetal force be equal to the centrifugal force,

$$\frac{m v_1^2}{r_{\text{♁}}} = \gamma_N \frac{m M_{\text{♁}}}{r_{\text{♁}}^2} \qquad \Rightarrow \qquad v_1 = \sqrt{\frac{\gamma_N M_{\text{♁}}}{r_{\text{♁}}}} \ , \tag{6.6}$$

yielding $v_1 \approx 7.91\,\text{km/s} = 2.84 \cdot 10^4\,\text{km/h}$. In Exc. 6.2.3.1 we estimate the mass of the milky way galaxy from the velocity of the sun and its distance from the galaxy's center. In Exc. 6.2.3.2 we compare the heights of stationary orbits around the Earth and the moon.

Example 24 (*Angular velocity of a satellite*): Here, we calculate the velocity of a satellite on a circular orbit at a height of 400 km above the Earth's surface,

$$v_1 = \sqrt{\frac{\gamma_N M_{\text{♁}}}{r_{\text{♁}} + h}} \ ,$$

yielding $v_1 \approx 7.66\,\text{km/s} = 2.76 \cdot 10^4\,\text{km/h}$.

6.2.1.2 Escape velocity

The *escape velocity* or second cosmic velocity is the velocity that a body must have to be able to leave the Earth's gravity field completely. We calculate the second cosmic speed for the Earth from,

$$E_{kin} = \frac{m}{2}v_2^2 = \text{final} - \text{initial energy in the limit final energy } \to 0 \ . \tag{6.7}$$

Hence,

$$E_{kin} = 0 - \left(-\gamma_N \frac{mM_{\text{♁}}}{r_{\text{♁}}}\right) \qquad \Rightarrow \qquad v_2 = \sqrt{\frac{2\gamma_N M_{\text{♁}}}{r_{\text{♁}}}} = v_1\sqrt{2} \ , \tag{6.8}$$

yielding $v_2 \approx 11.2\,\text{km/s} = 4.03 \cdot 10^4\,\text{km/h}$. Apparently, the cosmic velocities v_1 and v_2 are related. In Exc. 6.2.3.3 and 6.2.3.4 we calculate cosmic velocities for, respectively, Earth and the comet Tschurjumow-Gerasimenko.

Example 25 (*Escape velocity for a satellite*): The escape velocity for a satellite that is in a 400 km high orbit above the Earth's surface is $v_2 \approx 10.83\,\text{km/s} = 3.90 \cdot 10^4\,\text{km/h}$.

6.2.2 Deriving Kepler's laws from Newton's laws

6.2.2.1 Kepler's first law

The orbits are ellipses, with focal points F1 and F2 for the first planet and F1 and F3 for the second planet. The Sun is placed at focal point F1. The two shaded sectors A1 and A2 have the same surface area and the time for planet 1 to cover segment A1 is equal to the time to cover segment A2. The total orbit times for planet 1 and planet 2 have a ratio $(a_1/a_2)^{3/2}$.

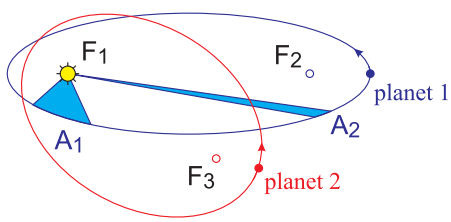

Figure 6.2: Illustration of Kepler's three laws with two planetary orbits.

6.2.2.2 Kepler's second law

The area swept by the planet's trajectory in infinitesimal time steps is,

$$A(t, t+dt) = \tfrac{1}{2}|\mathbf{r}(t) \times \dot{\mathbf{r}}(t)|dt = \tfrac{L}{2m}dt \ .$$

Since central potentials preserve angular momentum,

$$\dot{\mathbf{L}} = \frac{d}{dt}m\mathbf{r} \times \mathbf{p} = m(\dot{\mathbf{r}} \times \dot{\mathbf{r}} + \mathbf{r} \times \ddot{\mathbf{r}}) = m\mathbf{r} \times \ddot{\mathbf{r}} = -\mathbf{r} \times \nabla V(r) = -\mathbf{r} \times \frac{\partial V(r)}{\partial r}\hat{\mathbf{e}}_r = \mathbf{0} \ ,$$

for a given time difference $dt = t_1 - t_0$ the swept area is the same. Angular momentum is a constant of motion, $\dot{\mathbf{L}} = 0$, for central potentials.

6.2.2.3 Kepler's third law

6.2.3 Exercises

6.2.3.1 Ex: Mass of the Milky Way

Estimate the total mass of our galaxy (the milky way) using the parameters of the orbits of the sun (and the solar system) around the center of the galaxy. Assume that the major part of the mass of our galaxy is in the form of a uniform sphere (bulge). The speed of the sun on its way around the center of the galaxy is approximately $v = 250\,\mathrm{km/h}$, the distance of the sun from the center of the galaxy is approximately $r = 28000\,\mathrm{ly}$ (light years). To how many stars like our sun does this correspond to?

6.2.3.2 Ex: Gravitation on Earth and Moon

How high are the orbits of 'geo-stationary' and 'lunar-stationary' satellites?

6.2.3.3 Ex: Cosmic velocities

a. How long is the orbital period T of a 1 t satellite on a circular orbit at a height of 20 km around the Earth? How long is the orbital period T of the Earth around the sun (the mass of the sun is 3.334×10^5 times larger than that of the Earth)? At what distance from Earth is the orbit of a satellite geostationary?
b. Calculate the escape velocity from Earth (or cosmic speed) for a person weighing 75 kg.

6.2.3.4 Ex: Tschurjumow-Gerasimenko

The satellite Rosetta of the ESA ($m_{sat} = 3000\,\mathrm{kg}$) was placed on an orbit of the comet Tschurjumow-Gerasimenko (mass $m_{TG} = 3.14 \cdot 10^{12}\,\mathrm{kg}$, diameter $d_{TG} = 4\,\mathrm{km}$).
a. For the satellite to orbit the comet once a terrestrial day, what is the required height of the orbit?
b. What is the escape velocity from the comet's surface?

6.3 Gravitational potential

For an arbitrary mass distribution $\rho(\mathbf{r})$ the *gravitational potential* acting on a test mass m can be calculated from,

$$\boxed{V(\mathbf{r}) = -\gamma_N m \int_{\mathbb{R}^3} \frac{\rho(\mathbf{r}')}{|\mathbf{r} - \mathbf{r}'|} d^3 r'} \,. \tag{6.9}$$

For a point-mass with mass M located at the origin, $\mathbf{r}' = 0$, we parametrize $\rho(\mathbf{r}') = M\delta^3(\mathbf{r}')$, and recover Newton's law,

$$V(\mathbf{r}) = -\gamma_N \frac{Mm}{r} \,. \tag{6.10}$$

The gravitational potential being conservative, trajectories of test masses can simply be derived by solving the equation of motion,

$$\boxed{m\ddot{\mathbf{r}} = -\nabla V(\mathbf{r}) = \gamma_N m \int_{\mathbb{R}^3} \rho(\mathbf{r}') \frac{\mathbf{r}-\mathbf{r}'}{|\mathbf{r}-\mathbf{r}'|^3} d^3r'} \ . \tag{6.11}$$

If in practice analytic solution are beyond reach, numerical procedure are always possible.

Example 26 (*Gravitational potential in- and outside a homogeneous sphere*): In this example we will calculate the gravitational force that a particle of mass m is subjected to when placed inside a homogeneous sphere of radius R at a distance r from its center.
The potential exerted by a mass distribution with the density $\rho(\mathbf{r}')$ on a particle of mass m located at the position $\mathbf{r}$ is,

$$V(\mathbf{r}) = -\int \rho(\mathbf{r}') \frac{\gamma_N m}{|\mathbf{r}-\mathbf{r}'|} d^3r' = -\int_{sphere} \rho_0 \frac{\gamma_N m}{|\mathbf{r}-\mathbf{r}'|} r'^2 \sin\theta' dr' d\theta' d\phi' \ . \tag{6.12}$$

Substituting,

$$\xi \equiv |\mathbf{r}-\mathbf{r}'| = \sqrt{r^2 + r'^2 - 2rr'\cos\theta'} \tag{6.13}$$
$$\frac{d\xi}{d\theta'} = \frac{rr'\sin\theta'}{\xi} \ ,$$

we obtain,

$$V(\mathbf{r}) = -\int_{sphere} \rho_0 \frac{\gamma_N m r'}{r} d\xi dr' d\phi' = \frac{2\pi\rho_0\gamma_N m}{r} \int_0^R \int_{\xi_{\min}}^{\xi_{\max}} r' d\xi dr' \ . \tag{6.14}$$

The integration limits follow from the values adopted by ξ for $\theta = 0$ resp. $\theta = \pi$.
For $r \leq R$ we have that r' is always greater than r. Hence, $\xi = r' - r, .., r' + r$.
For $R \leq r$ we have that r' is always smaller than r. Hence, $\xi = r - r', .., r' + r$.

$$V(\mathbf{r}) = -\frac{2\pi\rho_0\gamma_N m}{r} \begin{cases} \int_r^R 2rr'dr' + \int_0^r 2r'^2 dr' \\ \int_0^R 2r'^2 dr' \end{cases} \quad \text{for} \quad \begin{cases} r \leq R \\ R \leq r \end{cases} \ . \tag{6.15}$$

With the sphere's mass,

$$M = \frac{4\pi\rho_0 R^3}{3} \ , \tag{6.16}$$

the potential becomes,

$$\begin{aligned} V(\mathbf{r}) &= -2\pi\rho_0\gamma_N m \left(R^2 - \frac{1}{3}r^2\right)\theta(R-r) - 2\pi\rho_0\gamma_N m \frac{2R^3}{3r}\theta(r-R) \\ &= -\gamma_N M m \left(\frac{3}{2R} - \frac{r^2}{2R^3}\right)\theta(R-r) - \gamma_N M m \frac{1}{r}\theta(r-R) \ . \end{aligned} \tag{6.17}$$

The force can be calculated using the gradient in spherical coordinates,

$$\begin{aligned} \mathbf{F} &= -\nabla V(\mathbf{r}) = -\hat{\mathbf{e}}_r \frac{\partial}{\partial r} V(\mathbf{r}) \\ &= -\hat{\mathbf{e}}_r \gamma_N M m \frac{r}{R^3}\theta(R-r) - \hat{\mathbf{e}}_r \gamma_N M m \frac{1}{r^2}\theta(r-R) \ . \end{aligned} \tag{6.18}$$

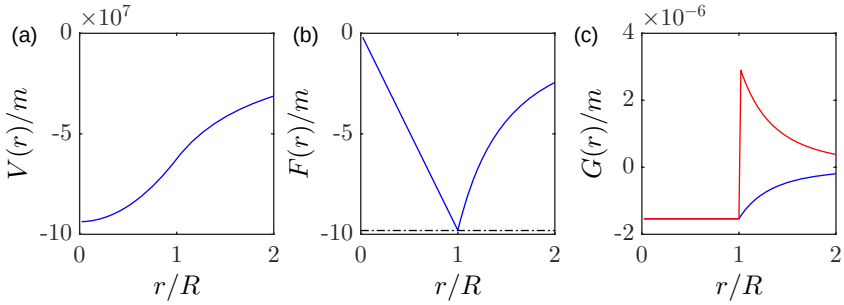

Figure 6.3: (code) Gravity in- and outside of Earth. (a) Gravitational potential, (b) gravitational force, and (c) radial (blue) and transverse (red) gravity gradient.

The gravitational acceleration is often specified in units of *Gal* after *Galilei*, where $1\,\mathrm{Gal} \equiv 1\,\mathrm{cm/s^2}$.

The above example shows that

1. outside a spherical mass distribution the gravitational potential can simply be replaced by that of a point mass sitting at the center of the mass distribution;

2. the superposition principle,

$$\boxed{V_{\rho_1+\rho_2}(\mathbf{r}) = V_{\rho_1}(\mathbf{r}) + V_{\rho_2}(\mathbf{r})}\ , \tag{6.19}$$

   allows us to described the impact of mass cavities via simple subtraction

In classical mechanics we often describe gravity as a homogenous force field, which can be derived from a potential scaling linearly with the height above normal ground,

$$V(h) = mgh\ . \tag{6.20}$$

Obviously, this is approximation obtained by linearizing the gravitational potential on the Earth's surface. From Newton's law,

$$V(\mathbf{r}) = -\frac{\gamma_N M m}{r}\ , \tag{6.21}$$

using the Taylor expansion:

$$V(\mathbf{r}+\mathbf{h}) = e^{\mathbf{h}\cdot\nabla_\mathbf{r}} V(\mathbf{r}) = \sum_{\nu=0}^{\infty} \frac{(\mathbf{h}\cdot\nabla_\mathbf{r})^\nu}{\nu!} V(\mathbf{r}) = V(\mathbf{r}) + (\mathbf{h}\cdot\nabla_\mathbf{r})V(\mathbf{r}) + \frac{1}{2}(\mathbf{h}\cdot\nabla_\mathbf{r})(\mathbf{h}\cdot\nabla_\mathbf{r})V(\mathbf{r})\ , \tag{6.22}$$

we get,

$$V(\mathbf{r}+\mathbf{h}) \simeq V(\mathbf{r}) + h\frac{\gamma_N M m}{r^2} = V(\mathbf{r}) + hgm\ . \tag{6.23}$$

In Exc. 6.3.5.1 we derive an expression generalizing Eq. (6.17) to arbitrary isotropic gravitational potentials. In Excs. 6.3.5.2, 6.3.5.3, 6.3.5.4, and 6.3.5.5 we calculate the potentials for other isotropic mass distributions. In Exc. 6.3.5.6 we use the superposition principle to calculate the potential generated by a spherical cavity inside a

homogeneous sphere. In Excs. 6.3.5.7, 6.3.5.8, and 6.3.5.9 we calculate potentials generated by non-spherical density distributions. In Excs. 6.3.5.10, 6.3.5.11, and 6.3.5.12 we apply the results derived for the Earth's inner gravitational potential to derive possible trajectories through boreholes traversing the Earth.

6.3.1 Rotation and divergence of gravitational force fields

The rotation and divergence of gravitational force fields are,

$$\begin{aligned} \nabla^2 V(\mathbf{r}) &= \nabla \cdot \mathbf{F}(\mathbf{r}) = -4\pi\gamma_N m\rho(\mathbf{r}) \\ \nabla \times \mathbf{F}(\mathbf{r}) &= 0 \ . \end{aligned} \tag{6.24}$$

The integral formulation of Eq. (6.24) reads,

$$\oint_{\partial V} \mathbf{F} \cdot d\mathbf{S} = -4\pi\gamma_N M m \ , \tag{6.25}$$

with $M = \oint_{\partial V} \rho(\mathbf{r}) d^3 r$.

The interpretation of these expressions are:

- The Poisson equation relates the divergence of the force field directly to the density distribution.
- The divergence is nothing else than the diagonal of gravity gradient defined in Sec. 6.3.2.
- For being conservative, gravitational potentials are rotation-free.
- The integral over a closed surface is proportional to the enclosed mass.

The Lagrangian density for Newtonian gravity is,

$$\mathcal{L}(\mathbf{r}, t) = -\rho(\mathbf{r}, t) - \tfrac{1}{8\pi\gamma_N}[\nabla V(\mathbf{r}, t)]^2 \ . \tag{6.26}$$

Applying the Hamitonian principle to this Lagrangian one recovers the Poisson equation for gravity.

6.3.2 Gravity gradients

The *gravity gradient* is a tensor defined as the second derivative of the potential,

$$\boxed{G_{kl}(\mathbf{r}) = G_{lk}(\mathbf{r}) = \frac{\partial g_l(\mathbf{r})}{\partial x_k} = \frac{1}{m}\frac{\partial F_l(\mathbf{r})}{\partial x_k} = -\frac{1}{m}\frac{\partial}{\partial x_k}\frac{\partial V(\mathbf{r})}{\partial x_l}} \ . \tag{6.27}$$

Inserting the potential (6.9) we obtain,

$$\begin{aligned} G_{kl}(\mathbf{r}) &= -\frac{1}{m}\frac{\partial}{\partial x_k}\frac{\partial V(\mathbf{r})}{\partial x_l} = \gamma_N \int_{R^3} \rho(\mathbf{r}')\frac{\partial}{\partial x_k}\frac{\partial}{\partial x_l}\frac{1}{|\mathbf{r}-\mathbf{r}'|} d^3 r' \\ &= \gamma_N \int_{R^3} \frac{\rho(\mathbf{r}')}{|\mathbf{r}-\mathbf{r}'|^5} \begin{pmatrix} 3(x-x')^2 - (\mathbf{r}-\mathbf{r}')^2 & 3(x-x')(y-y') & 3(x-x')(z-z') \\ 3(x-x')(y-y') & 3(y-y')^2 - (\mathbf{r}-\mathbf{r}')^2 & 3(y-y')(z-z') \\ 3(x-x')(z-z') & 3(y-y')(z-z') & 3(z-z')^2 - (\mathbf{r}-\mathbf{r}')^2 \end{pmatrix} d^3 r' \\ &= \gamma_N \int_{R^3} \frac{\rho(\mathbf{r}')}{|\mathbf{r}-\mathbf{r}'|^3} K_{kl}(\mathbf{r}-\mathbf{r}') d^3 r' \ , \end{aligned} \tag{6.28}$$

defining the kernel,

$$K_{kl}(\mathbf{r}-\mathbf{r}') \equiv \frac{3(x_k - x'_k)(x_l - x'_l) - \delta_{kl}(\mathbf{r}-\mathbf{r}')^2}{|\mathbf{r}-\mathbf{r}'|^2} \ . \tag{6.29}$$

For example, for the gravitational potential generated by a point mass,

$$V(r) = \gamma_N \frac{Mm}{r} = \gamma_N \frac{Mm}{\sqrt{x^2+y^2+z^2}} \ , \tag{6.30}$$

we find,

$$\begin{aligned} G_{kl}(\mathbf{r}) = -\frac{1}{m}\frac{\partial}{\partial x_k}\frac{\partial V(\mathbf{r})}{\partial x_l} &= \frac{\gamma_N M}{r^5}\begin{pmatrix} 3x^2-r^2 & 3xy & 3xz \\ 3xy & 3y^2-r^2 & 3yz \\ 3xz & 3yz & 3z^2-r^2 \end{pmatrix} \\ &= \frac{\gamma_N M}{r^5}(3x_k x_l - r^2\delta_{kl}) \ . \end{aligned} \tag{6.31}$$

Gravity gradients are often given in units of *Eotvos* after *Eötvös*, where 1 Eotvos = $10^{-9}\,\mathrm{s}^{-2}$. In Exc. 6.3.5.13 we calculate the gravity gradient tensor of Earth (modeled as an idealized sphere) at the north-pole.

Example 27 (*Gravitational curvature in- and outside a homogeneous sphere*): The gravitational potential an force in- and outside a homogeneous sphere have been calculated in the example 26. Using the result we derive the gravity gradient,

$$\begin{aligned} G_{kl}(\mathbf{r}) &= -\frac{1}{m}\frac{\partial}{\partial x_k}\frac{\partial}{\partial x_l}V(\mathbf{r}) \\ &= -\frac{\gamma_N M}{R^3}\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}\theta(R-r) + \frac{\gamma_N M}{r^5}\begin{pmatrix} 3x^2-r^2 & 3xy & 3xz \\ 3xy & 3y^2-r^2 & 3yz \\ 3xz & 3yz & 3z^2-r^2 \end{pmatrix}\theta(r-R) \\ &= -\frac{\gamma_N M}{R^3}\delta_{kl}\theta(R-r) - \frac{\gamma_N M}{r^3}\left(\delta_{kl} - \frac{3x_k x_l}{r^2}\right)\theta(r-R) \ . \end{aligned} \tag{6.32}$$

The example 26 revealed that neither the potential nor the force are discontinuous at the sphere's surface. In contrast, the radial component of the curvature $G_{k=l}(r=R)$ is discontinuous at the north pole, while the transverse components $G_{k\neq l}(r=R)$ stay continuous, which is obviously due to the isotropic symmetry of the potential. To see this better, let us move along the symmetry axis setting $\mathbf{r} = r\hat{\mathbf{e}}_z$,

$$G_{kl}(r\hat{\mathbf{e}}_z) = -\frac{\gamma_N M}{R^3}\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}\theta(R-r) - \frac{\gamma_N M}{r^3}\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & -2 \end{pmatrix}\theta(r-R) \ . \tag{6.33}$$

Applying this results to Earth, be find inside Earth a constant gravity gradient of $-\gamma_N M_{\text{♁}}/R^3_{\text{♁}} = 1.54\cdot 10^{-6}\,\mathrm{s}^{-2}$.

6.3.2.1 Gravimetry and gravity gradiometry

Gravity-gradiometers measure spatial variations of the gravitational acceleration. Being obtained as second derivatives of the gravitational potential, they are more sensitive to local mass variations, as nearly homogeneous large scale contributions to the acceleration are removed. For this reason, gravity-gradiometers need to be less accurate, provided they are sensitive enough. In Exc. 6.3.5.14 we estimate the sensitivity of modern gravimeters.

Example 28 (*Gravitation in- and outside a massive shell*): The calculations of examples 26 and 27 can be generalized for a homogenous massive shell with density ρ_1, inner radius R_i, and outer radius R_0. In Exc. 6.3.5.2 we show that the gravitational potential is,

$$V(\mathbf{r}) = -2\pi\rho_1\gamma_N m \left[(R_o^2 - R_i^2)\theta(R_i - r) + \left(R_o^2 - \frac{r^2}{3} - \frac{2R_o^3}{3r}\right)\theta(r - R_i)\theta(R_o - r) + \frac{2(R_o^3 - R_i^3)}{3r}\theta(r - R_o)\right] , \tag{6.34}$$

the gravitational force,

$$\begin{aligned}\mathbf{F}(\mathbf{r} = -\nabla V(\mathbf{r}) &= -\hat{\mathbf{e}}_r \frac{\partial}{\partial r} V(\mathbf{r}) \\ &= \hat{\mathbf{e}}_r \frac{4\pi\rho_1\gamma_N m}{3}\left[\left(-r + \frac{R_o^3}{r^2}\right)\theta(r - R_i)\theta(R_o - r) - \frac{R_o^3 - R_i^3}{r^2}\theta(r - R_o)\right] ,\end{aligned} \tag{6.35}$$

and the gravity gradient,

$$\begin{aligned}G_{kl}(\mathbf{r}) &= -\frac{1}{m}\frac{\partial}{\partial x_k}\frac{\partial}{\partial x_l} V(\mathbf{r}) \\ &= -\frac{4\pi\rho_1\gamma_N}{3}\left[\left(\delta_{kl} - \frac{R_i^3}{r^3}\left(\delta_{kl} - \frac{3x_k x_l}{r^2}\right)\right)\theta(r - R_i)\theta(R_o - r) \right. \\ &\quad \left. + \frac{R_o^3 - R_i^3}{r^3}\left(\delta_{kl} - \frac{3x_k x_l}{r^2}\right)\theta(r - R_o)\right] .\end{aligned} \tag{6.36}$$

For $R_i \to 0$ we recover the results of example 27. Particularly along the symmetry axis,

$$G_{zz}(\mathbf{r}) = -\frac{4\pi\rho_1\gamma_N}{3}\left[\left(1 + \frac{2R_i^3}{r^3}\right)\theta(r - R_i)\theta(R_o - r) - 2\frac{R_o^3 - R_i^3}{r^3}\theta(r - R_o)\right] . \tag{6.37}$$

6.3.3 Constants of motion

Trajectories can also be derive exploiting constants of motion. In Excs. 6.3.5.18 to 6.3.5.23 we calculate trajectories of bodies under the influence of gravity.

6.3.4 The virial law

The virial law states,

$$\boxed{\overline{T} = -\overline{\frac{1}{2}\sum_i \mathbf{F}_i \mathbf{r}_i}} . \tag{6.38}$$

For potentials of the form $V(r) = \alpha r^k$ we have,

$$\mathbf{F} = -\nabla V = -k\alpha r^{k-1}\hat{\mathbf{e}}_r \ . \tag{6.39}$$

Thus $\overline{T}$ and $\overline{V}$ related via,

$$\overline{T} = -\overline{\frac{1}{2}\sum_i \mathbf{F}_i\mathbf{r}_i} = \frac{k}{2}\overline{\sum_i \alpha r_i^{k-1}\hat{\mathbf{e}}_{r_i}\cdot\mathbf{r}_i} = \frac{k}{2}\overline{\sum_i \alpha r_i^k} = \frac{k}{2}\overline{V} \ . \tag{6.40}$$

In Exc. 6.3.5.24 we apply the virial law to a spring pendulum.

Example 29 (*The virial law for the harmonic potential and for* $1/r$-*potentials*): The special case $k = 2$ yields,

$$V(r) = \alpha r^2 \Rightarrow \overline{T} = \overline{V} \ , \tag{6.41}$$

and corresponds to a harmonic oscillator with $\alpha = \frac{1}{2}m\omega_0^2$.
The special case $k = -1$ yields,

$$V(r) = \frac{\alpha}{r} \Rightarrow \overline{T} = -\frac{1}{2}\overline{V} \ , \tag{6.42}$$

and corresponds to a Coulomb potential with $\alpha = \frac{q_1 q_2}{4\pi\epsilon_0}$, respectively a gravitational potential with $\alpha = -\gamma_N Mm$.
In the case of the gravitational potential, for positive total energy, we get,

$$E = \overline{T} + \overline{V} > 0 \qquad \overline{T} = -\frac{1}{2}\overline{V} \Rightarrow E = \frac{1}{2}\overline{V} > 0 \Rightarrow Mm < 0 \ . \tag{6.43}$$

Thus,

$$\overline{T} = \frac{1}{2}m\overline{v^2} = -\frac{1}{2}\overline{V} < 0 \Rightarrow m < 0 \tag{6.44}$$

This leads to the demand for negative masses, which is not sensible. The virial theorem can only apply to bound systems with $E < 0$.

6.3.5 Exercises

6.3.5.1 Ex: Arbitrary isotropic mass density distributions

a. Generalize the calculation of gravitational potentials and forces exhibited in example 25 to arbitrary, but isotropic mass density distributions $\rho(\mathbf{r}') = \rho(r')$.
b. Study the case of a sharp edge, $\rho(r') \equiv \rho(r')\theta(R - r')$.
c. Study the case of a homogeneous distribution, $\rho(r') \equiv \rho_0\theta(R - r')$, for a sphere with total mass M.
d. Study the case of a parabolic distribution, $\rho(r') \equiv \rho_0\left(1 - \frac{r'^2}{R^2}\right)\theta(R - r')$, for a sphere with total mass M.

6.3.5.2 Ex: Gravitational potential of a spherical shell

Consider a spherical shell with an inner radius a and an outer radius b.
a. Calculate the gravitational potential inside the sphere, inside the shell material and outside the sphere. (**Help:** Substitute the distance between the test particle m and a point of the mass distribution and make a case distinction for the integration limits for this distance variable.)
b. Calculate the force on a test particle.
c. Specify now for a massive sphere.
d. Specify for a very thin spherical shell.

6.3.5.3 Ex: Two concentric shells

Let us consider two concentric spherical shells of uniform density with masses M_1 and M_2. Calculate the force on a particle of mass m placed (a) inside the inner shell, (b) outside the inner but inside the outer shell, and (c) outside the outer sphere.

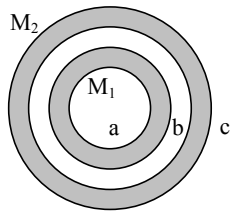

Figure 6.4:

6.3.5.4 Ex: Gravity influenced by a thin surface layer

Model the Earth as a homogeneous sphere of mass density ρ_0 isotropically covered by a $\Delta R = 1$m thick homogeneous layer with different density ρ_1. How does the gravitational potential depend on the ratio ρ_1/ρ_0?

6.3.5.5 Ex: Gravitational force inside a shell

Show through geometric arguments that a particle of mass m placed inside a spherical shell of uniform mass density is subject to zero force, regardless of the position of the particle. What would happen if the surface mass density was not constant?

6.3.5.6 Ex: Gravitational potential of a massive sphere with spherical cavity

A spherical cavity is machined into in a lead sphere of radius R such that its surface touches the outer surface of the massive sphere and passes through the its center. The primitive mass of the lead sphere is M. What will be the force that the sphere with the cavity will exert on a mass m at a distance z from the center of the outer sphere, when the mass and the centers of the sphere and the cavity are aligned?

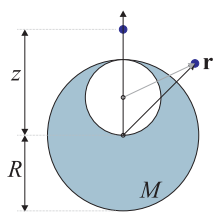

Figure 6.5: Scheme of the problem.

6.3.5.7 Ex: Gravitational potential of a disk

Calculate the potential of a homogeneous thin disc with the surface density $\sigma = M/\pi R^2 = \rho dz$ along the axis of symmetry and the gravitational force it exerts on a mass m.
Help: When integrating over the thickness a of the disk, use the relation: $\int_0^d zf(z')dz' = f(0)dz$.

6.3.5.8 Ex: Gravitational force of a ring

Calculate the gravitational force of a ring of linear mass density $\lambda = M/2\pi R = \rho dRdz$ on the symmetry axis.
Help: When integrating on the thickness of the ring, use the relations: $\int_0^{dz} f(z')dz' = f(0)dz$ and $\int_R^{R+dR} f(r')dr' = f(R)dR$.

6.3.5.9 Ex: Gravitational oscillation through a ring

Consider a heavy ring of mass M and radius R and a particle of mass m placed in its center. What is the frequency for small amplitude oscillations in the direction perpendicular to the plane of the ring?

6.3.5.10 Ex: Intraplanetary oscillation

A body of mass m is placed at a distance r_0 from the center of a planet of mass M and radius R.
a. Calculate the potential energy for $0 \leq r \leq \infty$. Suppose that the mass density of the planet is uniform and that the mass m can move within it through a tunnel. Consider $V(\infty) = 0$. Calculate the velocity as a function of r for $r < R$ knowing that $V(r_0) = 0$.

6.3.5.11 Ex: Shortcut avoiding the Earth's center

Show that in a tunnel dug through the Earth (not necessarily along a diameter) the movement of an object will be harmonic.

6.3.5.12 Ex: Shortcut through the Earth

a. Two innovative companies make suggestions on how to get mail to New Zealand as quickly as possible. One company suggests drilling a hole through the Earth, placing the mail in a fireproof box and allowing it to swing through the hole (smoothly) through the center of the Earth so that it can be easily received by the recipient in New Zealand. The other company wants to shoot the mail in a very low orbit of only 1 m above the surface of the Earth at the first cosmic speed (smoothly) to New Zealand, where it should then be caught by a correspondingly soft pillow. Which of these two suggestions (if they were feasible) would get the mail faster to destination?
b. Assume that the well was planned incorrectly and that the hole missed the center of the earth by 100 km. What does the equation of motion look like?
Help: The mass distribution of the earth can be assumed to be homogeneous. Earth rotation and friction effects are neglected.

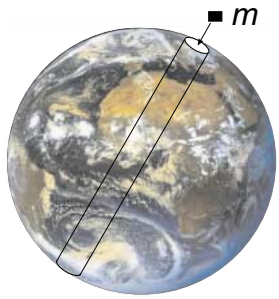

Figure 6.6:

6.3.5.13 Ex: Gravity gradient caused by underground cavities

In this exercise we discuss whether gravity gradiometry can identify the presence of underground cavities. We proceed in steps:
a. Assuming a homogeneous density distribution for Earth, calculate the gravity gradient tensor at the north-pole.
b. How does the tensor change in the presence of a point-like mass $M_1 = 10\,\text{tons}$ located at a distance $d = 1\,\text{m}$ in southern direction.
c. Describe the underground cavity by a spherical void centered at 1 m below the north-pole's surface at having a radius such that the missing mass corresponds to 10 tons of Earth material.

6.3.5.14 Ex: Gravity gradient upon horizontal density modulation

A gravimeter and a gravity gradiometer are hovering at a distance z over a flat surface infinitely extended in x and y. The surface has a thickness b and a horizontal density modulation in x-direction: $\rho_1(\mathbf{r}') = \rho_1(x')\theta(b+z')\theta(-z')$. Calculate the gravitational potential, force, and gradients. Consider the particular case of a localized density modulation: $\rho_1(x') = \rho_1\theta(x')\theta(a-x')$.

6.3.5.15 Ex: Gravity gradients

a. Modern commercial gravity gradiometers can measure acceleration gradients on the order of $|\nabla a| \approx 10^{-5}\,\text{s}^{-2}$. Compare with the gravity gradient on the Earth's surface. What is the smallest height difference detectable by a state of the art gradiometer?
b. Calculate the gravity gradient caused by a massive sphere of mass $m_{sphere} = 10\,\text{t}$ at $d = 1\,\text{m}$ distance?
c. The French company μQuans offers atomic quantum gravimeters with guaranteed sensitivities of $50\,\mu\text{Gal}/\sqrt{\text{Hz}}$ at a cycling frequency of 2 Hz. Assuming the Earth as a homogeneous sphere, for how long must the signal be integrated to be able to measure a 1 cm height variation over the Earth's surface.
d. For how long must the signal be integrated to be able to measure a gravity variation caused by a 10 t mass at 1 m distance.

6.3.5.16 Ex: Acceleration of a mass subject to a circular motion in an inhomogeneous force field

Commercial *Gravity Gradient Instruments* (GGI) are based on accelerometers mounted on the border of a disk of radius R rotating at a frequency ω. Let us suppose that the disk's rotation axis is the z-axis and that is located inside an inhomogeneous force field (e.g. gravity) characterized by its gradient tensor (assumed to be constant over time and over the length scale of R).
a. Calculate the time-dependent acceleration recorded by the accelerometer in radial direction.
b. The voltage signal delivered by the accelerometer is now added to one delivered by a second accelerometer sitting on the opposite side of the disk.
c. Finally, the signals are demodulated at 2ω and time-averaged over a period $2\pi/\omega$.

6.3.5.17 Ex: Angular momentum in spherical coordinates

a. Calculate the acceleration, the angular momentum, and its derivative in spherical coordinates using the result of Exc. 9.3.8.6.
b. Set $\theta = \frac{\pi}{2}$ in all expressions.
c. Derive the equation of motion for a central potential.

6.3.5.18 Ex: Scattering at a central force, angular momentum

Consider the scattering of a particle of mass M at an attractive central force field $\mathbf{F}(\mathbf{r}) = -\frac{\alpha}{r^2}\hat{\mathbf{e}}_r$ with $\alpha > 0$. Far from the force center the velocity of the particle is given by v_∞. The asymptotic distance perpendicular to the velocity for very large distances from the force center is called the impact parameter b.
a. Determine the relationship between the impact parameter b and the angular momentum L of the particle.
b. The path of the particle has the shape of a conic section, which in plane polar coordinates can be parametrized by $r = P/(1 - \epsilon\cos\phi)$. Find ϵ and P as a function of b, v_∞, M and α. c. Find an expression for $\sin(\theta/2)$. Here, θ is the scattering

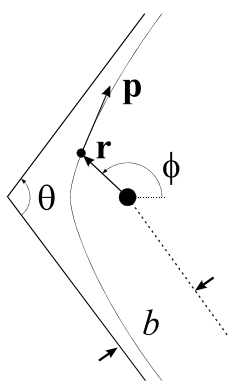

Figure 6.7:

angle between the asymptotic orbits of the particle, i.e. the paths of the incoming and

outgoing particles for large distances from the force center.
d. How does θ for constant v_∞ depend on the impact parameter b? Discuss the special cases $b = 0$ and $b \to \infty$.

6.3.5.19 Ex: Gravitational force, trajectory

The trajectory of the Kepler problem can be derived from the integral expression:

$$\varphi(r) = \varphi_0 + \int_{r_0}^{r} \frac{l\,dr}{r^2\sqrt{2m(E + \frac{\alpha}{r}) - \frac{l^2}{r^2}}} \ .$$

Here E is the total energy, $\alpha = \gamma_N mM$ and $l = mr^2\dot{\varphi}$. We also introduce the quantities:

$$p = \frac{l^2}{m\alpha} \qquad \text{and} \qquad \varepsilon = \sqrt{1 + \frac{2El^2}{m\alpha^2}} \ .$$

a. Convince yourself that, with the substitution $\xi = (p/r - 1)/\varepsilon$, the integral expression can be written in the form:

$$\varphi(r) = \varphi_0 - \int_{\frac{1}{\varepsilon}(\frac{p}{r_0}-1)}^{\frac{1}{\varepsilon}(\frac{p}{r}-1)} \frac{d\xi}{\sqrt{1-\xi^2}} \ .$$

b. Show with the help of energy conservation that the minimum distance from the force center is determined by $r_{\min} = \frac{p}{1+\varepsilon}$ for all values of E.
c. Show that the trajectories for $\varphi_0 = \pi$ and $r = r_{\min}$ are $r(\varphi) = \frac{p}{1-\varepsilon\,\cos\varphi}$, where $\int dx/\sqrt{1-x^2} = \arcsin x$.
d. Confirm that for elliptical trajectories ($0 \le \varepsilon < 1$ and $p = b^2/a^2$ where $a(b)$, the major semi-axis follows Kepler's 3rd law. Use the area theorem.

6.3.5.20 Ex: Central force, trajectory

Consider two masses m_1 and m_2 located at $\mathbf{r}_1$ and $\mathbf{r}_2$. There is an attractive force between them of the amount $F(\mathbf{r}_1, \mathbf{r}_2) = 2\lambda/|\mathbf{r}_1 - \mathbf{r}_2|^3$ ($\lambda > 0$).
a. Specify the angular momentum of the relative motion $\mathbf{l}$ and the energy conservation as a function of $\mathbf{r}$, $\mathbf{p}$ and the reduced mass μ, whereby we may designate by $E > 0$ the total energy of the system.
b. At the time $t = 0$ we let the relative distance of both particles be $r_{\min}$, the relative velocity in the direction of r be zero and $\varphi(r_{\min}) = 0$. Determine the relationship between $r_{\min}$, E, l, λ and μ. Is it possible to eliminate l and λ from the energy conservation law? Calculate the function $r(t)$.
c. Express $\frac{d}{d\varphi}r(\varphi) = \dot{r}/\dot{\varphi}$ as a function of E, l, r and $r_{\min}$ and calculate the trajectory $r(\varphi)$.

6.3.5.21 Ex: Ballistic movement

Consider the movement of an intercontinental missile launched at an inclination of θ_0, as shown in the figure, with speed v_0, in the indicated position. Calculate the body's trajectory.

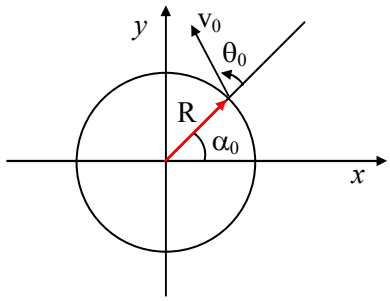

Figure 6.8:

6.3.5.22 Ex: Rotation of three bodies

Three identical bodies of mass M are located at the vertices of an equilateral triangle with border length L. How fast should they move, if they all rotate under the influence of mutual gravity, on a circular orbit that circumscribes the triangle always kept equilateral?

6.3.5.23 Ex: Rotation of two bodies

Consider two masses m and $2m$ with gravitational attraction. At what angular velocity should they rotate so that the distance d between them is constant?

6.3.5.24 Ex: The virial law

Consider a mathematical spring pendulum with $D = 100\,\mathrm{N/m}$ and an attached mass of $m = 100\,\mathrm{g}$. The average kinetic energy of the pendulum be $\overline{T} = 0.5\,\mathrm{J}$. What is the mean deflection $\overline{x}$ and the mean quadratic deflection $\overline{x^2}$?

6.4 Outlook on general relativity

The fundamental idea of *general relativity* is the *equivalence* of inert and heavy mass. While special relativity follows from Lorentz invariance, general relativity follows from Lorentz boost invariance, see also Secs. 9.4.3 and 17.5.

Example 30 (*Relativistic correction to Newton's law*): .

6.4.1 Gravitational red-shift

The *gravitational red-shift* $\Delta\omega$ suffered by a clock of mass m can be estimated from (see Sec.47.4.1),

$$\boxed{\hbar\Delta\omega = m\Delta\frac{V(\mathbf{r})}{m}}\,, \tag{6.45}$$

where $\Delta V(\mathbf{r})$ is the gravitational potential difference with and without a nearby heavy mass. The mass of the clock is a measure of its pace: $m = E/c^2 = \hbar\omega/c^2$. For

instance, on the surface of Earth we get,

$$\hbar\Delta\omega = mg\Delta z = \frac{E}{c^2}g\Delta z = \frac{\hbar\omega}{c^2}g\Delta z \ . \tag{6.46}$$

Hence,

$$\frac{\Delta\omega}{\omega} = \frac{g}{c^2}\Delta z \simeq \Delta z \cdot 10^{-16}\,\mathrm{m}^{-1} \ . \tag{6.47}$$

Chapter 7

Hydrodynamics

This chapter is not elaborated, yet. It is mainly included because of some nice exercises adapted from [1014].

7.1 Hydrostatics

7.1.1 Buoyancy and Archimedes' principle

The density of a substance is the quotient between its mass and its volume,

$$\rho \equiv \frac{m}{V} \ . \tag{7.1}$$

Archimedes' principle says that

> A body immersed in a liquid undergoes the action of an upward force, whose absolute value is equal to the weight of the volume of liquid displaced by the body.

Let us consider a liquid, with density $\rho_{\rm lq}$, in hydrostatic equilibrium inside a container and highlight a portion of it, with volume V, as shown in Fig. 7.1(a). In order to have hydrostatic equilibrium, it is necessary that the sum over all forces acting on the highlighted volume of liquid be zero. One of these forces is the weight,

$$\mathbf{G} = m\mathbf{g} = \rho V \mathbf{g} \ , \tag{7.2}$$

of the volume V. The other force is the sum $\mathbf{E}$ over all pressure forces that the remaining liquid exerts on the surface of the volume V, Fig. 7.1(b). That is,

$$\mathbf{G} + \mathbf{E} = 0 \ . \tag{7.3}$$

Thus, the force $\mathbf{E}$ which 'pushes' the highlighted portion of liquid, has a magnitude equal to its weight, $E = G = \rho_{\rm lq} V g$, and is called *buoyancy*.

In case that the highlighted volume V is filled with another body with density $\rho_{\rm bd}$ different from that of the liquid $\rho_{\rm lq}$, the buoyancy will not change. That is, the buoyancy E will always be the weight of the liquid displaced by the body that has been introduced in its interior.

On the other hand, the new weight of the volume is $G_{\rm bd} = \rho_{\rm bd} m V$. In the case $\rho_{\rm lq} > \rho_{\rm bd}$, the body submerged in the liquid will rise to the surface, since the buoyancy

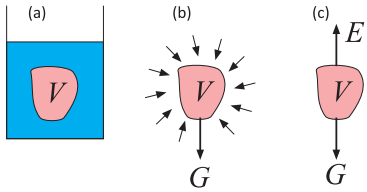

Figure 7.1: Representation of the forces acting on a body submerged in a liquid.

exerted by the liquid will be greater than the weight of the body. Otherwise, when $\rho_{\mathrm{lq}} < \rho_{\mathrm{bd}}$, the submerged body will sink to the bottom of the container. In both cases, the submerged body will not stay in hydrostatic equilibrium. Resolve the Excs. 7.1.2.1 to 7.1.2.8.

Example 31 (*Density Measurement exploiting Archimedes' principle*): We can exploit Archimedes' principle to determine the density of a material of unknown composition. To this end, we first measure the weight of the body in air,

$$G_{\mathrm{air}} = \rho_{\mathrm{bd}} V g \ . \tag{7.4}$$

We then fully immerse the body into a liquid of known density ρ_{lq} (assuming the body to be denser than that of a liquid), and measure the new weight,

$$G_{\mathrm{lq}} = G_{\mathrm{air}} - E = \rho_{\mathrm{bd}} V g - \rho_{\mathrm{lq}} V g \ . \tag{7.5}$$

The density of the body's material is then,

$$\rho_{\mathrm{bd}} = \frac{\rho_{\mathrm{lq}}}{1 - \frac{G_{\mathrm{lq}}}{G_{\mathrm{air}}}} \ . \tag{7.6}$$

7.1.2 Exercises

7.1.2.1 Ex: Critical buoyancy and Cartesian diver

A balloon is filled at atmospheric pressure with 1 liter of air. An aluminum weight of 1 kg is attached to it. The whole setup is now immersed into water. Calculate the total force acting on the setup as function of the depth of immersion.

7.1.2.2 Ex: Buoyancy of a wooden ball in a liquid

A wooden ball of mass m is trapped at depth h in a liquid of density ρ_{lq}. Having released the ball from its position, determine how high above the surface it will float.

7.1.2.3 Ex: Buoyancy of oil

Three containers with false bottoms (see Fig. 7.2) were placed in water at the same depth. Filling into the three bottles the same amount of oil, which one of the three bottoms will fall first? Justify!

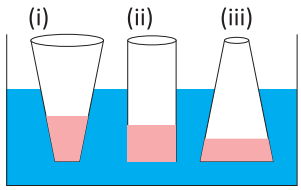

Figure 7.2: Buoyancy of oil.

7.1.2.4 Ex: A tank

A lidless rectangular tank, with the dimensions given in the figure, moves with an acceleration a and contains water up to a height of h (when $a = 0$). At what value of the acceleration will the water begin to flow out?

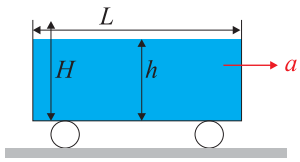

Figure 7.3: Scheme of the tank.

7.1.2.5 Ex: Buoyancy in mercury and water

A cube of a certain material floats in a container containing mercury ($\rho_{\text{Hg}} = 13.6\,\text{g/cm}^3$) such that 1/4 of its volume is submerged. Adding enough water to the system to cover the cube, what fraction of its volume will still remain immersed in mercury?

7.1.2.6 Ex: Immersion

A board of length L leans on a stone and is partially immersed in water. As the figure shows, a portion of length a is above the support point. Being ρ_{wd} is the density of the wood, what portion of the board is submerged?

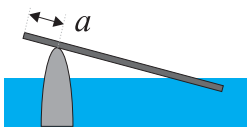

Figure 7.4: Immersion of a stone.

7.1.2.7 Ex: Conical container

Milk is placed in a conical container. Over time, occurs at the top the formation of cream, which is less dense. During this process there is no change in volume, that is, h remains constant (see Fig. 7.5). What happens to the pressure at the bottom of the container? Justify your answer.

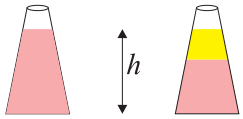

Figure 7.5: Conical container.

7.1.2.8 Ex: Rotating pipe

A water pipe rotates at a speed ω around a vertical axis, as shown in Fig. 7.6. Calculate the pressure as a function of r, using $P(r = 0) = P_0$.

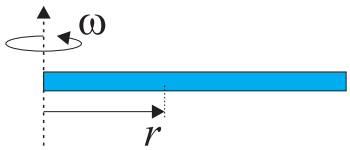

Figure 7.6: Water pipe.

7.2 Hydrodynamics

Resolve the Excs. 7.2.2.1 to 7.2.2.4.

7.2.1 Continuity and Navier-Stokes equations

7.2.1.1 Bernoulli's theorem

7.2.1.2 Viscosity

7.2.2 Exercises

7.2.2.1 Ex: Cylindrical can

a. Into a cylindrical can of area A water is poured up to a height of h. Determine the velocity v at which water flows out of a hole of area A_{hole} located at the bottom. How much water should be added to the can per unit of time such that v is constant?
b. In case that no water is added to the can and the height varies, calculate the flow rate θ as a function of time.

7.2.2.2 Ex: Siphon

Via a siphon, water is removed from a container, as shown in the figure. The area of the pipe is constant along its length and the velocity of the surface of the liquid is neglected.
a. What is the water speed at the outlet of the pipe?
b. What is the pressure at the highest point of the siphon?
c. What is the maximum height h at which it is still possible to siphon water?

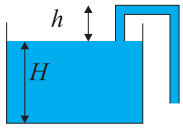

Figure 7.7: Siphon.

7.2.2.3 Ex: Water tank

A water tank is mounted on a wagon that can move horizontally without friction (see Fig. 7.8). In the wall of the box there is a hole of area A at a depth H, through which water flows parallel to the horizontal plane. The initial total mass of the system (box, water and wagon) is M_0 and the speed of the water surface is neglected. If the wagon is initially at rest when the hole is opened, what will be the initial acceleration of the system?

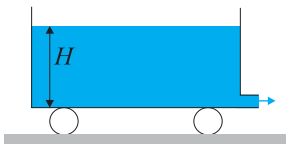

Figure 7.8: Water tank.

7.2.2.4 Ex: Flow meter

A flow meter consists of a conical, vertical glass tube with a metallic sphere of mass m and radius r fixed inside it, as shown in the figure. Calculate the flow of a gas with a given viscosity η as a function of the height h. Consider, very small α. **Note:** $F_{\text{Stokes}} = 6\pi\eta r v$.

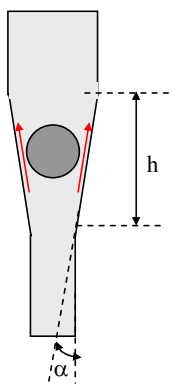

Figure 7.9: Flow meter.

Chapter 8

Appendices to 'Classical Mechanics'

8.1 Constants and units in classical physics

8.1.1 Constants

8.1.1.1 Mathematical constants

π constant	$\pi = 3.1415..$
Euler constant	$e = 2.71828..$

8.1.1.2 Constants of the SI unit system

These numbers of the special adjustment CODATA 2019 were proposed as *exact* values.

frequency of the hyperfine transition of Cs	$\nu = 9\ 192\ 631\ 770\,\mathrm{Hz}$
velocity of light	$c = 299\ 792\ 458\,\mathrm{m/s}$
Planck's constant	$h = 6.626\ 070\ 15 \times 10^{-34}\,\mathrm{Js}$
electronic charge	$e = 1.602\ 176\ 634 \times 10^{-19}\,\mathrm{C}$
Boltzmann's constant	$k_B = 1.380\ 649 \times 10^{-23}\,\mathrm{J/K}$
Avogadro's constant	$N_A = 6.022\ 14076 \times 10^{23}\,\mathrm{mol}^{-1}$
Luminous efficiency	$K_{cd} = 683\,\mathrm{lm}$

The main fundamental constants are each one representative for a ground braking physical theory: c for special relativity, e for electrodynamics, h for quantum mechanics, and k_B for statistical thermodynamics.

8.1.1.3 Derived constants

fine-structure constant	$\alpha = e^2/4\pi\varepsilon_0\hbar c \approx 1/137$
vacuum permittivity	$\varepsilon_0 = 1/\mu_0 c^2 = 8.8542 \times 10^{-12}\,\mathrm{As/Vm}$
vacuum permeability	$\mu_0 = 10^{-7}\,\mathrm{Vs/Am}$
Faraday's constant	$F = 96485.309\,\mathrm{C/mol}$
atomic mass unit	$u_A = 1/N_A \times 1\mathrm{g/mol} = 1.6605402 \times 10^{-27}\,\mathrm{kg}$
gas constant	$R = N_A k_B = 8.314510\,\mathrm{J/mol\ K}$
Bohr radius	$a_B = \alpha/4\pi R_\infty = 0.529 \times 10^{-10}\,\mathrm{m}$
Bohr magneton	$\mu_B = e\hbar/2m_e = 9.27 \times 10^{-24}\,\mathrm{J/T}$
classical electron radius	$r_e = \alpha^2 a_B$
Rydberg constant	$R_\infty = m_e c\alpha^2/2h = 13.7\,\mathrm{eV}$
Compton wavelength	$\lambda_C = h/m_e c$
Thomson cross section	$\sigma_e = (8\pi/3)r_e^2$
gravitational constant	$\gamma = 6.67259 \times 10^{-11}\,\mathrm{m^3kg^{-1}s^{-2}}$

8.1.1.4 Particle constants

electron mass	$m_e = 9.1096 \times 10^{-12}\,\mathrm{kg}$
g-factor of the electron	$g = 2.002\ 319\ 304\ 386$
muon mass	$m_\mu = 105.658389\,\mathrm{MeV}$
proton mass	$m_p = 938.27231\,\mathrm{MeV}$
g-factor of the proton	$g = 5.5858$
neutron mass	$m_p = 939.56563\,\mathrm{MeV}$
g-factor of the neutron	$g = -3.8261$
deuteron mass	$m_d = 1875.61339\,\mathrm{MeV}$

8.1.1.5 Astronomical constants

earth mass	$m_{\text{♁}} = 5.9736 \times 10^{24}\,\text{kg}$
earth radius	$R_{\text{♁}} = 6370\,\text{km}$
earth gravity	$g_{\text{♁}} = 9.80665\,\text{m/s}$
lunar mass	$m_{☾} = 7.348 \times 10^{22}\,\text{kg}$
lunar radius	$R_{☾} = 1740\,\text{km}$
lunar gravity	$g_{☾} = 1.62\,\text{m/s}$
distance earth-moon	$d_{ES} = 384000\,\text{km}$
sun massa	$m_{☼} = 1.99 \times 10^{30}\,\text{kg}$
sun radius	$R_{☼} = 695300\,\text{km}$
sun gravity	$g_{☼} = 273\,\text{m/s}$
distance earth-sun	$d_{ES} = 1.496 \times 10^{8}\,\text{km}$
sinodic day	$d_{syn} = 24\,\text{h}$
sideric day	$d_{syn} = 23.9345\,\text{h} = 23\,\text{h}\,56\,\text{min}\,4\,\text{s}$
sinodic month	$mon_{syn} = 29.530590\,\text{d}$
sideric month	$mon_{sid} = 27.321666\,\text{d}$
sideric year	$a_{syn} = 365.256365\,\text{h} = 365\,\text{d}\,6\,\text{h}\,9\,\text{min}\,10\,\text{s}$
lunar day	$d_{lunar} = 24.8412\,\text{h}$
$\frac{1}{mon_{sid}}$	$= \frac{1}{a_{sid}} + \frac{1}{mon_{syn}}$
$\frac{1}{d_{sid}}$	$= \frac{1}{a_{sid}} + \frac{1}{d_{syn}}$
$\frac{1}{d_{sid}}$	$= \frac{1}{mon_{sid}} + \frac{1}{d_{lunar}}$

8.1.2 Units

charge	Q	basic unit
current	I	A=C/s
voltage	U	V=N/As
polarizability	α_{pol}	Asm^2/V
susceptibility	χ	1
dipolar moment	1 Debye	$= 10^{-27}/2.998\ \text{Cm} = 10^{-19}/c\ \text{Cm}^2/\text{s} = 39.36\ ea_B$

8.2 Quantities and formulas in classical mechanics

time	t	basic unit
position	$\mathbf{r}$	basic unit
velocity	$\mathbf{v}$	$\mathbf{v} = \dot{\mathbf{r}}$
acceleration	$\mathbf{a}$	$\mathbf{a} = \dot{\mathbf{v}}$
mass	m	basic unit
linear momentum	$\mathbf{p}$	$\mathbf{p} = m\mathbf{v}$
force	$\mathbf{F}$	$\mathbf{F} = \dot{\mathbf{p}} = m\mathbf{a}$
kinetic energy	E_{kin}	$E_{kin} = \frac{m}{2}v^2$
angle	$\vec{\phi}$	basic unit
angular velocity	$\vec{\omega}$	$\vec{\omega} = \dot{\mathbf{r}}$
angular acceleration	$\vec{\alpha}$	$\vec{\alpha} = \dot{\vec{\omega}}$
inertial moment (continuous density)	I	$I = \int r_\perp^2 dm = \int_V \rho(\mathbf{r})[\mathbf{r}^2 - (\mathbf{r} \cdot \hat{\mathbf{e}}_\omega)]dV$
inertial moment (discrete density)	I	$I = \sum_i m_i r_i^2$
angular momentum	$\mathbf{L}$	$\mathbf{L} = I\vec{\omega} = \mathbf{r} \times \mathbf{p}$
torque	$\vec{\tau}$	$\vec{\tau} = \dot{\mathbf{L}} = I\vec{\alpha} = \mathbf{r} \times \mathbf{F}$
rotational energy	E_{rot}	$E_{rot} = \frac{m}{2}\omega^2 r^2$
potential energy	E_{pot}	$E_{pot}^{grav} = mgh$, $E_{pot}^{sprng} = \frac{k}{2}x^2$
work	W	$W = \int_{s_1}^{s_2} \mathbf{F} \cdot d\mathbf{s}$
power	P	$P = \dot{W}$

8.2.1 Particular forces

gravitation	$F_{grav} = mg$
Hooke's for elastic spring	$F_{mola} = -k\Delta x$
friction	$F_{at} = -\mu N$
Stokes' friction	$F_{fr} = -\gamma v$
Newton's friction	$F_{fr} = -\gamma v^2$

8.2.2 Inertial momentum

Steiner's theorem	$I_{\omega_2} = I_{\omega_1} + md^2$, where d is the distance between parallel axes
theorem of perpendicular axes	$I_z = I_x + I_y$ para $\rho(\mathbf{r}) = \delta(z)\sigma(x,y)$

8.2.3 Inertial forces due to transitions to translated and rotated systems

transformation to an accelerated frame	$\mathbf{F}_{Gal} = -m\mathbf{a}$
centrifugal force	$\mathbf{F}_{cf} = -m\vec{\omega} \times (\vec{\omega} \times \mathbf{r})$
Coriolis force	$\mathbf{F}_{Cor} = -2m\vec{\omega} \times \mathbf{v}$

8.2.4 Conservation laws

energy conservation	$\sum_k E_{kin}^{(ini)} + \sum_k E_{pot}^{(ini)} = \sum_k E_{kin}^{(fin)} + \sum_k E_{pot}^{(fin)}$
linear momentum conservation	$\sum_k \mathbf{p}_k^{(ini)} = \sum_k \mathbf{p}_k^{(fin)}$
angular momentum conservation	$\sum_k \mathbf{L}_k^{(ini)} = \sum_k \mathbf{L}_k^{(fin)}$
definition of the center-of-mass	$\mathbf{r}_{cm} \equiv \frac{\sum_k m_k \mathbf{r}_k}{\sum_k m_k}$

8.2.5 Rigid bodies, minimum required number of equations of motion

1. estimate number of moving masses	m_1, m_2, ...
2. identify possible movement (degree of freedom) for every mass	$v_{1x}, v_{2x}, ...$ $v_{1y}, v_{2y}, ...$ $v_{1z}, v_{2z}, ...$ $\omega_1, \omega_2, ...$
3. write down for every degree of freedom an equation of motion	$m\dot{v}_{kl} = \sum_j F_j$ $I\dot{\omega}_k = \sum_j \tau_j$

8.2.6 Gravitational laws

Newton's law	$\mathbf{F}(\mathbf{r}) = -\frac{GMm}{\lvert\mathbf{R}-\mathbf{r}\rvert^2}\hat{\mathbf{e}}_{Rr} = -\nabla V(\mathbf{r})$
gravitational potential	$V(\mathbf{r}) = -\int \frac{Gm}{\lvert\mathbf{r}-\mathbf{r}'\rvert^2}\rho(\mathbf{r}')dV'$

8.2.7 Volume elements

cartesian coordinates	$dV = dxdydz$
cylindrical coordinates	$dV = \rho d\rho d\phi dz$
spherical coordinates	$dV = r^2 \sin\theta dr d\theta d\phi$

8.2.8 Oscillations $ma + bv + kx = F_0 \cos\omega t$

dissipative motion	$k = 0,\ F_0 = 0$	$x(t) = Ae^{-\gamma t},\ \gamma = \frac{b}{2m}$
harmonic oscillation	$b = 0,\ F_0 = 0$	$x(t) = A\cos(\omega_0 t + \delta),\ \omega_0 = \sqrt{\frac{k}{m}}$
damped oscillation	$F_0 = 0$	$x(t) = Ae^{-\gamma t}\cos(\omega t + \delta),\ \omega = \sqrt{\omega_0^2 - \gamma^2}$
forced oscillation		$x(t) = A\cos(\omega t + \delta)\ ,\ A = \frac{F_0}{\sqrt{m^2(\omega_0^2-\omega^2)^2+b^2\omega^2}}\ ,$ $\tan\delta = \frac{b\omega}{m(\omega_0^2-\omega^2)}$

8.3 Probability distributions

8.3.1 Binomial distribution

The *binomial distribution* is defined by,

$$B_k^{(n)} = \binom{n}{k} p^k (1-p)^{n-k}\ . \tag{8.1}$$

It normalized,

$$1 = \sum_{k=0}^{n} \binom{n}{k} p^k (1-p)^{n-k}\ , \tag{8.2}$$

and,

$$\begin{aligned}\int_0^1 B_k^{(n)}(p)dp &= \binom{n}{k}\int_0^1 p^k(1-p)^{n-k}dp \\ &= \binom{n}{k+1}\int_0^1 p^{k+1}(1-p)^{n-k-1}dp = \int_0^1 p^n dp = \frac{1}{n+1}\ .\end{aligned} \tag{8.3}$$

8.3.2 Poisson distribution

The *Poisson distribution* is defined by,

$$P_k = \frac{\lambda^k}{k!}e^{-\lambda}\ . \tag{8.4}$$

For large n (typically $n > 100$) and small p (typically $p < 10$), we get $B_k^{(n)} \simeq P_k$ with $\lambda = np$. To see this, we use two approximation formulas. The first formula,

$$\log(1-p) \simeq -p \tag{8.5}$$

immediately follows a Taylor expansion. The second formula,

$$\frac{N!}{(N-n)!} \simeq N^n \tag{8.6}$$

follows from,

$$\frac{N!}{(N-n)!} \equiv \prod_{j=0}^{n-1}(N-j) \overset{n \ll N}{\simeq} \prod_{j=0}^{n-1} N \equiv N^n \ . \tag{8.7}$$

Hence,

$$\begin{aligned}(1-p)^{N-n} &= \exp\left(log(1-p)^{N-n}\right) \\ &= \exp\left(N-n\right)\log\left(1-p\right) \simeq \exp\left(-N\,p\right) = \exp\left(-\alpha\right) \ .\end{aligned} \tag{8.8}$$

Finally,

$$\frac{N!}{(N-n)!}\,p^n \simeq N^n\,p^n = \alpha^n \ . \tag{8.9}$$

8.3.3 Gaussian distribution

The *Gaussian distribution* is defined by,

$$G_k = \frac{1}{2\pi\sigma^2} e^{-(k-\lambda)^2/2\sigma^2} \ . \tag{8.10}$$

For large n, we get $B_k^{(n)} \simeq G_k$ with $\sigma = \sqrt{np(1-p)}$.

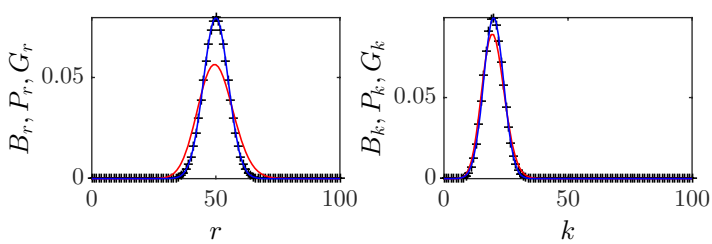

Figure 8.1: (code) (black) Binomial, (red) Poissonian, and (blue) Gaussian probability distribution for $N = 100$ and (left) $Np = 50$ and (right) $Np = 20$.

8.3.4 Some useful formulae

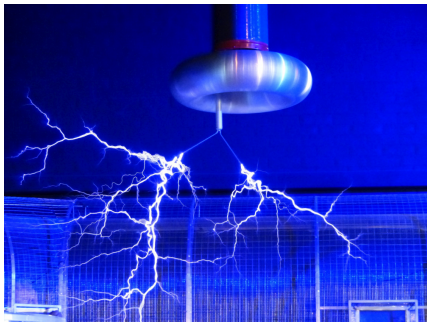
If the limits of two functions tend to 0, $\lim_{t\to t_0} f(t) = 0 = \lim_{t\to t_0} g(t)$ a rule called *l'Hôpital's rule* goes like,

$$\lim_{t\to t_0}\frac{f(t)}{g(t)} = \lim_{t\to t_0}\frac{f'(t)}{g'(t)} \ . \tag{8.11}$$

Part II

Electrodynamics

Preface to the part *Electrodynamics*



Electricity and magnetism were discovered as physical phenomena in the 18-th and 19-th century. Careful and systematic experimentation led to the identification of laws ruling the mechanical effects of electromagnetism, which culminated in a unified theory of mechanics, electricity, and magnetism called electrodynamics.

The course is divided into two parts. The first part represented by chapters 9 to 13 gives an introduction to electromagnetism at the level of an undergraduate course. From electrical and magnetic phenomena observed in experiments we derive the fundamental laws of Coulomb, Gauss, Faraday, Ampère, and Maxwell allowing a complete description of electromagnetism, which culminates in Maxwell's equations. The procedure in the second part represented by Chps. 14 to 17 is inverse. From Maxwell's equations we deduce electromagnetic phenomena, such as the radiation of accelerated charges or the role of electromagnetic forces in atoms. Also, we derive fundamental conservation laws and the relationship of electromagnetism with the theory of special relativity. This part is a postgraduate course in classical electrodynamics.

Chapter 9

Foundations and mathematical formalism

The electrodynamic force is one of the four fundamental forces, together with gravitation, the strong nuclear force, and the weak nuclear force. It is a long-range force ($F \propto r^{-2}$) in the same way as gravitation, but unlike nuclear forces, which are short-ranged. Unlike gravitation, it can be attractive or repulsive. The experimentally

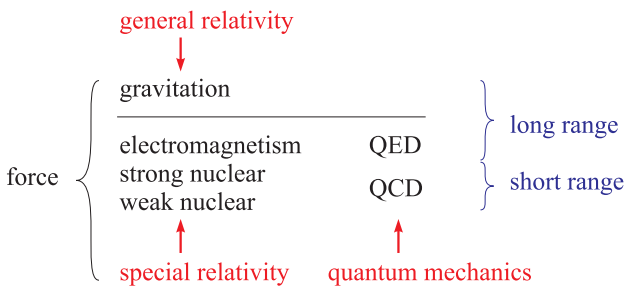


Figure 9.1: The four known fundamental forces.

observed fact, that two spatially separated bodies can exert mutual forces (beyond gravitation), is not explained within classical mechanics. It is necessary to introduce a new degree of freedom called *electric charge* which, to take account of the existence of attractive and repulsive forces, must exist in two different types called positive or negative charges. *Identical charges repel each other, different charges attract each other.* Other observations suggest that the charge is a *conserved and quantized* quantity.

Electrodynamics is an *field theory*, that is, it can describe all electric or magnetic phenomena observed in the following way: Every charge gives rise to a force field, called field electric $\vec{\mathcal{E}}$, which accelerates other charges. But other experimental observations suggest the existence of another force field, called the magnetic field $\vec{\mathcal{B}}$, whose existence is necessary to understand forces only acting on moving charges. That is, the electric and magnetic fields are introduced to explain the forces named after Coulomb and Lorentz,

$$\mathbf{F} = q\vec{\mathcal{E}} + \mathbf{v} \times \vec{\mathcal{B}} \; . \tag{9.1}$$

Thus, fields are quantities distributed in space, which in addition can vary in time,

$$\mathbf{F} = \mathbf{F}(\mathbf{r}, t) \; . \tag{9.2}$$

The concept of a field represents a powerful mathematical tool for describing forces, which are the only observable magnitudes of electromagnetism. That is, we have no sense to *see* the electricity. We can only infer their existence from the observation of forces. On the other hand, the formulation of electrodynamics via vectorial force fields, can be replaced by a description via potentials, which are either scalar or vectorial fields. In many circumstances, potentials facilitate the resolution of electrodynamic problems, but it is important to keep in mind, that potentials are not directly observable.

Maxwell's electrodynamics has a very deep relationship to Einstein's theory of special relativity, such that each theory is conditioned to the validity of the other. The relativistic formulation allows to distill the symmetry inherent to electrodynamics in a highly aesthetic way.

In view of the fundamental role played by scalar and vector fields in electrodynamics, we will start this course the basic mathematical notions of field theory, that is, differential and integral calculus with fields in Cartesian or curvilinear coordinates. We will also have to review basic notions of complex numbers and the Dirac distribution.

9.1 Differential calculus

9.1.1 Scalar and vector fields

The most basic application of vectors is the designation of positions in space, $\mathbf{r} = x\hat{\mathbf{e}}_x + y\hat{\mathbf{e}}_y + z\hat{\mathbf{e}}_z$. But other physical quantities may also depend on the position where they are measured. In case the quantity varying with position is a scalar, $\Phi = \Phi(\mathbf{r})$, we speak of *scalar field*. An example for a scalar field is the temperature distribution across a room. In the case the quantity is a vector, $\mathbf{A} = \mathbf{A}(\mathbf{r})$, we speak of *vector field*. Light propagating through space is an example for a vector field.

A position is generally defined with respect to the center of the coordinate system, called the origin, such that the distance from the center is given by,

$$r \equiv \sqrt{\mathbf{r}\cdot\mathbf{r}} = \sqrt{x^2+y^2+z^2}\ , \tag{9.3}$$

with $\hat{\mathbf{e}}_r$ being a unit vector pointing in the direction of $\mathbf{r}$. In electrodynamics we will often deal with quantities (fields) that depend on the distance between a source located at a position $\mathbf{r}'$ and a detector placed at a position $\mathbf{r}$, such as $\Phi(R) = \Phi(\mathbf{r}-\mathbf{r}')$,

$$\hat{\mathbf{e}}_R = \frac{(x-x')\hat{\mathbf{e}}_x + (y-y')\hat{\mathbf{e}}_y + (z-z')\hat{\mathbf{e}}_z}{\sqrt{(x-x')^2+(y-y')^2+(z-z')^2}}\ . \tag{9.4}$$

9.1.2 The gradient

The derivative of a one-dimensional function $\Phi(x)$ measures, how fast the function changes when we move the position x. That is, when we change x by an amount dx, Φ changes by an amount $d\Phi$ given by,

$$d\Phi = \left(\frac{d\Phi}{dx}\right) dx\ . \tag{9.5}$$

Of course it gets trickier, when Φ is a field depending on three coordinates, because we need to specify in which direction we are changing the position. We have,

$$d\Phi = \left(\frac{\partial \Phi}{\partial x}\right) dx + \left(\frac{\partial \Phi}{\partial y}\right) dy + \left(\frac{\partial \Phi}{\partial z}\right) dz \ . \tag{9.6}$$

This equation resembles the scalar product because,

$$d\Phi = \left(\hat{\mathbf{e}}_x \frac{\partial \Phi}{\partial x} + \hat{\mathbf{e}}_y \frac{\partial \Phi}{\partial y} + \hat{\mathbf{e}}_z \frac{\partial \Phi}{\partial z}\right) \cdot (dx\hat{\mathbf{e}}_x + dy\hat{\mathbf{e}}_y + dz\hat{\mathbf{e}}_z) \equiv \nabla\Phi \cdot d\mathbf{r} \ , \tag{9.7}$$

where we defined a new operator called *nabla*,

$$\nabla \equiv \begin{pmatrix} \partial/\partial x \\ \partial/\partial y \\ \partial/\partial z \end{pmatrix} \ . \tag{9.8}$$

The three-dimensional derivative $\nabla\Phi$ is called the *gradient* of the scalar field Φ,

$$\nabla\Phi(\mathbf{r}) = \hat{\mathbf{e}}_x \frac{\partial \Phi}{\partial x} + \hat{\mathbf{e}}_y \frac{\partial \Phi}{\partial y} + \hat{\mathbf{e}}_z \frac{\partial \Phi}{\partial z} \ , \tag{9.9}$$

and it measures the variation of the value of the field from Φ to $\Phi + d\Phi$, when we move the vector by an infinitesimal amount between two points $\mathbf{r}$ and $\mathbf{r} + d\mathbf{r}$.

We understand the geometric interpretation of the gradient through its formulation as a scalar product:

$$d\Phi = \nabla\Phi \cdot d\mathbf{r} = |\nabla\Phi| \cdot |d\mathbf{r}| \cos\theta \ , \tag{9.10}$$

where θ is the angle between the gradient and the infinitesimal displacement. Now, we fix a *magnitude* of the displacement $|d\mathbf{r}|$ and look for the direction θ in which the variation $d\Phi$ is maximum. Obviously, we find the direction $\theta = 0$, that is, when the gradient points in the same direction as the predefined displacement.

> *The gradient of a scalar field $\Phi(\mathbf{r})$ calculated at a point $\mathbf{r}$ indicates the direction of the greatest field variation from this point, and its absolute value is a measure for the variation.*

The concept of the gradient is easy to understand in a two-dimensional landscape: Imagine being on the slope of a mountain. Depending on the direction in which you are heading and the duration of the journey $d\mathbf{r}$, you will gain or lose a certain amount of potential energy $d\Phi$, which you can calculate by the scalar product $\nabla\Phi \cdot d\mathbf{r}$. If the direction chosen is that indicated by the gradient, you will lose (or gain) a maximum of potential energy. If you choose to go in a direction perpendicular to the gradient, that is, along an equipotential line, the potential energy remains unchanged. This is illustrated in Fig. 9.2.

Let us consider the example of a parabolic field, $\Phi(\mathbf{r}) = -r^2$:

$$\nabla(-r^2) = \begin{pmatrix} -2x \\ -2y \\ -2z \end{pmatrix} = -2\mathbf{r} \ . \tag{9.11}$$

We find that at all points of space the variation is faster in radial direction.

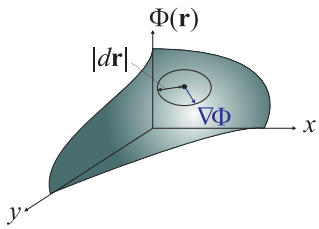

Figure 9.2: The gradient indicates the direction of the largest field variation Φ.

Although the operator ∇ has the shape of a vector, it has no meaning by itself. In fact, it is a *vector operator*, that is, a mathematical *prescription* telling us what to do with the scalar field on which it acts. Nevertheless, it assimilates all the properties of a vector. (We will see in quantum mechanics, that this is more than a coincidence.) Thus, in a way similar as done for the gradient of scalar fields, we can try to apply the ∇ operator on vector fields using the definitions of the scalar and vector products,

$$\text{grad } \Phi(\mathbf{r}) \equiv \nabla\Phi(\mathbf{r}) \qquad \text{and} \qquad \text{div } \mathbf{A}(\mathbf{r}) \equiv \nabla \cdot \mathbf{A}(\mathbf{r}) \qquad \text{and} \qquad \text{rot } \mathbf{A}(\mathbf{r}) \equiv \nabla \times \mathbf{A}(\mathbf{r}) \ . \tag{9.12}$$

We practice the calculation with the ∇ operator in the Excs. 9.1.7.1 to 9.1.7.3.

9.1.3 The divergence

Let us now analyze the possible meaning of the expression $\nabla \cdot \mathbf{A}$ called *divergence*. It is easy to show,

$$\nabla \cdot \mathbf{A}(\mathbf{r}) = \frac{\partial A_x}{\partial x} + \frac{\partial A_y}{\partial y} + \frac{\partial A_z}{\partial z} \ . \tag{9.13}$$

Obviously the divergence is a scalar field calculated from a vector field.

> *The divergence measures how much a vector field $\mathbf{A}(\mathbf{r})$ spreads out starting from a point $\mathbf{r}$. For a given infinitesimal volume it measures the difference between the number of incoming and outgoing field lines.*

Exposed to a field with divergence, an extended distribution of masses will start to concentrate (spread out) in case of a drain (source). The field lines trace the masses trajectories.

> **Example 32 (*Divergence of a radial field*):** We consider the example of the radial field, $\mathbf{A}(\mathbf{r}) = \mathbf{r}$:
>
> $$\nabla \cdot \mathbf{r} = \frac{\partial x}{\partial x} + \frac{\partial y}{\partial y} + \frac{\partial z}{\partial z} = 3 \ . \tag{9.14}$$

9.1.4 The rotation

Let us now examine the possible meaning of the expression $\nabla \times \mathbf{A}$ called *rotation*. It is easy to show,

$$\nabla\times\mathbf{A}(\mathbf{r}) = \begin{vmatrix} \hat{\mathbf{e}}_x & \hat{\mathbf{e}}_y & \hat{\mathbf{e}}_z \\ \partial_x & \partial_y & \partial_z \\ A_x & A_y & A_z \end{vmatrix} = \hat{\mathbf{e}}_x \left(\frac{\partial A_z}{\partial y} - \frac{\partial A_y}{\partial z}\right) + \hat{\mathbf{e}}_y \left(\frac{\partial A_x}{\partial z} - \frac{\partial A_z}{\partial x}\right) + \hat{\mathbf{e}}_z \left(\frac{\partial A_y}{\partial x} - \frac{\partial A_x}{\partial y}\right) . \tag{9.15}$$

Obviously the rotation is a vector field calculated from another vector field.

> *The rotation measures how many of the field lines of a vector field* $\mathbf{A}(\mathbf{r})$ *passing through an infinitesimal volume, return into it.*

Exposed to a field with rotation, an extended distribution of masses will start spinning in closed orbits.

We consider the examples shown in Fig. 9.3. The properties of divergence and rotation are complementary. There are fields exhibiting only one of the properties, or both, or none of them. In cases where there is rotation, it is problematic to specify equipotential lines: Either, the field lines are not orthogonal to the equipotential lines, or they come back.

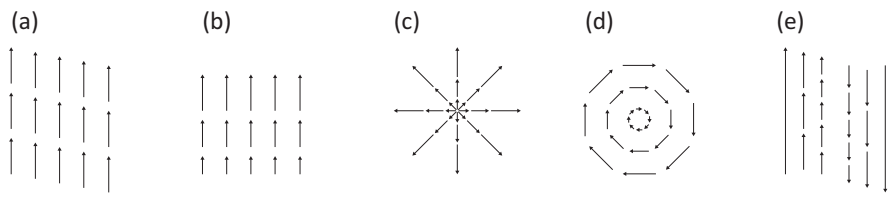

Figure 9.3: (a) Field without divergence, (b) with constant divergence, (c) with radial divergence, (d) with rotation, and (e) with rotation.

Example 33 (*Rotation of a radial field*): We consider the example of a radial field, $\mathbf{A}(\mathbf{r}) = -y\hat{\mathbf{e}}_x + x\hat{\mathbf{e}}_y$:

$$\nabla \times \mathbf{A} = \begin{pmatrix} 0 - \partial_z x \\ \partial_z(-y) - 0 \\ \partial_x x - \partial_y(-y) \end{pmatrix} = 2\hat{\mathbf{e}}_z \ . \tag{9.16}$$

We practice the calculation with divergence and rotation in the Excs. 9.1.7.4 to 9.1.7.7.

9.1.5 Taylor expansion of scalar and vector fields

We know well the Taylor expansion of functions of one variable:

$$\Phi(x+h) = \exp(h\tfrac{d}{dx})\Phi(x) = \sum_{\nu=0}^{\infty} \tfrac{1}{\nu!}(h\tfrac{d}{dx})^\nu \Phi(x) = \Phi(x) + h\Phi'(x) + \tfrac{h}{2}\Phi''(x) + \dots \ . \tag{9.17}$$

The generalization of the expansion to a scalar field, which depends on a vector, is,

$$\begin{aligned}\Phi(\mathbf{r}+\mathbf{h}) &= \exp(\mathbf{h}\cdot\nabla_{\mathbf{r}})\Phi(\mathbf{r}) = \sum_{\nu=0}^{\infty}\frac{1}{\nu!}(\mathbf{h}\cdot\nabla_{\mathbf{r}})^{\nu}\Phi(\mathbf{r}) \\ &= \Phi(\mathbf{r}) + (\mathbf{h}\cdot\nabla_{\mathbf{r}})\Phi(\mathbf{r}) + \tfrac{1}{2}(\mathbf{h}\cdot\nabla_{\mathbf{r}})(\mathbf{h}\cdot\nabla_{\mathbf{r}})\Phi(\mathbf{r}) + \dots\ .\end{aligned} \tag{9.18}$$

We see that the operator $\nabla_{\mathbf{r}}$ generates a translation. We study the Taylor expansion of scalar fields in Exc. 9.1.7.8.

The generalization of the gradient of a vector field is the Jacobian,

$$\mathbf{A} = \begin{pmatrix} A_1 \\ \vdots \\ A_n \end{pmatrix} \qquad \Longrightarrow \qquad J[\mathbf{A}] = \begin{pmatrix} \frac{\partial A_1}{\partial x_1} & \dots & \frac{\partial A_1}{\partial x_n} \\ \vdots & \ddots & \vdots \\ \frac{\partial A_n}{\partial x_1} & \dots & \frac{\partial A_n}{\partial x_n} \end{pmatrix}\ . \tag{9.19}$$

Therefore, the generalization of the expansion to a vector field is,

$$\begin{aligned}\mathbf{A}(\mathbf{r}+\mathbf{h}) &= \exp(\mathbf{h}\cdot\nabla_{\mathbf{r}})\mathbf{A}(\mathbf{r}) = \mathbf{A}(\mathbf{r}) + \begin{pmatrix} (\mathbf{h}\cdot\nabla_{\mathbf{r}})A_1 \\ \vdots \\ (\mathbf{h}\cdot\nabla_{\mathbf{r}})A_n \end{pmatrix} + \dots \\ &= \mathbf{A}(\mathbf{r}) + \begin{pmatrix} h_1\frac{\partial F_1}{\partial x_1} + \dots + h_n\frac{\partial F_1}{\partial x_n} \\ \vdots \\ h_1\frac{\partial F_n}{\partial x_1} + \dots + h_n\frac{\partial F_n}{\partial x_n} \end{pmatrix} + \dots = \mathbf{A}(\mathbf{r}) + J[\mathbf{A}]\mathbf{h} + \dots\ .\end{aligned} \tag{9.20}$$

9.1.6 Rules for calculation with derivatives

In total there are four possible ways of defining products involving scalar and vector fields, $\Phi\Psi$, $\Phi\mathbf{A}$, $\mathbf{A}\cdot\mathbf{B}$, and $\mathbf{A}\times\mathbf{B}$, and six product rules to calculate the following expressions,

$$\nabla(\Phi\Psi) \quad , \quad \nabla(\mathbf{A}\cdot\mathbf{B}) \quad , \quad \nabla\cdot(\Phi\mathbf{A}) \quad , \quad \nabla\cdot(\mathbf{A}\times\mathbf{B}) \quad , \quad \nabla\times(\Phi\mathbf{A}) \quad , \quad \nabla\times(\mathbf{A}\times\mathbf{B})\ . \tag{9.21}$$

Second derivatives can also be defined in six different combinations,

$$\nabla\cdot(\nabla\phi) \quad , \quad \nabla\times(\nabla\phi) \quad , \quad \nabla(\nabla\cdot\mathbf{A}) \quad , \quad \nabla\cdot(\nabla\times\mathbf{A}) \quad , \quad \nabla\times(\nabla\times\mathbf{A})\ . \tag{9.22}$$

As these rules are used frequently, we summarized them in Secs. 18.6.1 and 18.6.2.

The rules can be derived componentwise from scalar product rules. Very useful tools for this are the *Kronecker symbol* and the *Levi-Civita tensor*. Let us consider a Cartesian coordinate system $i = 1, 2, 3$. The coordinates in this system are x_i and the derivatives $\partial_i \equiv \frac{\partial}{\partial x_i}$. The Kronecker symbol is defined by,

$$\delta_{mn} = \begin{cases} 1 & \text{for } m = n \\ 0 & \text{else} \end{cases}\ . \tag{9.23}$$

The Levi-Civita tensor is defined by,

$$\epsilon_{kmn} = \begin{cases} 1 & \text{when } (kmn) \text{ is an even permutation of } (123) \\ -1 & \text{when } (kmn) \text{ is an odd permutation of } (123) \\ 0 & \text{when at least two indices are identical} \end{cases} . \tag{9.24}$$

Adopting Einstein's summing convention, we automatically take the sum of an expression over all indexes appearing twice. For example, the scalar product can be written,

$$\mathbf{A} \cdot \mathbf{B} = \sum_i A_i B_i \equiv A_i B_i \ . \tag{9.25}$$

For the vector product we obtain,

$$(\mathbf{A} \times \mathbf{B})_k \equiv \epsilon_{kmn} A_m B_n \ . \tag{9.26}$$

Other examples will be discussed in the Excs. 9.1.7.9 to 9.1.7.11.

9.1.7 Exercises

9.1.7.1 Ex: Differential operators

Find the gradients of the following scalar fields:
a. $\Phi(\mathbf{r}) = x^2 + y^3 + z^4$,
b. $\Phi(\mathbf{r}) = x^2 y^3 z^4$,
c. $\Phi(\mathbf{r}) = e^x \sin y \ln z$.

9.1.7.2 Ex: 2D landscape

A 2D landscape is parametrized by $h(x, y) = 10(2xy - 3x^2 - 4y^2 - 18x + 28y + 12)$.
a. Where is mountain top?
b. What is its height?

9.1.7.3 Ex: Differential operators

Calculate $\nabla_{\mathbf{r}'} |\mathbf{r} - \mathbf{r}'|^n$.

9.1.7.4 Ex: Differential operators

Calculate the divergence and the rotation of the vector field $\mathbf{A} = e^{-x^2 y} \hat{\mathbf{e}}_x + \frac{z}{1+y^2} \hat{\mathbf{e}}_y + x \hat{\mathbf{e}}_z$ at the position $(0, 1, 1)$.

9.1.7.5 Ex: Sources and vertices

a. Determine the divergence and the rotation of the vector field $\mathbf{A} = A_x \hat{\mathbf{e}}_x + A_y \hat{\mathbf{e}}_y + A_z \hat{\mathbf{e}}_z$.
b. Calculate for the following fields the sources and vortices:

$$\mathbf{A}_1 = -y \hat{\mathbf{e}}_x + x \hat{\mathbf{e}}_y \quad , \quad \mathbf{A}_2 = +y \hat{\mathbf{e}}_x + x \hat{\mathbf{e}}_y \ ,$$
$$\mathbf{A}_3 = +x \hat{\mathbf{e}}_x + y \hat{\mathbf{e}}_y \quad , \quad \mathbf{A}_4 = +x \hat{\mathbf{e}}_x + x \hat{\mathbf{e}}_y \ .$$

c. Make a graphic illustration of the fields and give a geometric interpretation of div and rot.

9.1.7.6 Ex: Sources and vertices

Calculate the divergence $\nabla \cdot \frac{\mathbf{r}}{r^3}$.

9.1.7.7 Ex: Chain rule for functions of vector field

Apply the chain rule to the gradient of a scalar function of a vector field: $\nabla\phi(\mathbf{E}(\mathbf{r}))$. Use the rule to calculate $\nabla\sqrt{a\mathbf{r}^2}$.

9.1.7.8 Ex: Taylor expansion in 3D

Consider the function,

$$f(\mathbf{x}) = \frac{1}{|\mathbf{d} - \mathbf{x}|} \ .$$

Calculate the Taylor expansion in x of this function in Cartesian coordinates at the position $x = 0$ (in all three spatial coordinates) up to second-order.

9.1.7.9 Ex: Levi-Civita tensor

Prove the following relationships for the Kronecker symbol and the Levi-Civita tensor by distinguishing the cases in the indices,
a. $\epsilon_{ijk}\delta_{ij} = 0$,
b. $\epsilon_{ijk}\epsilon_{ijk} = 6$,
d. $\epsilon_{ijk}\epsilon_{imn} = \delta_{jm}\delta_{kn} - \delta_{jn}\delta_{km}$,
c. $\epsilon_{ijk}\epsilon_{ijn} = 2\delta_{kn}$.

9.1.7.10 Ex: Levi-Civita tensor

Let the vectors $\mathbf{A}$, $\mathbf{B}$, $\mathbf{C}$, and $\mathbf{D} \in \mathbb{R}^3$ be given. Using the Kronecker Symbol and the Levi-Civita Tensor
a. show $\{\mathbf{A} \times \mathbf{B}\}_i = \epsilon_{ijk} A_j B_k$;
b. prove the relationship, $(\mathbf{A} \times \mathbf{B}) \cdot \mathbf{C} = (\mathbf{B} \times \mathbf{C}) \cdot \mathbf{A} = (\mathbf{C} \times \mathbf{A}) \cdot \mathbf{B}$; c. Using the formulas of (b) derive the following rules of calculation:

$$\begin{aligned} &\text{i.} \quad (\mathbf{A} \times \mathbf{B})^2 = \mathbf{A}^2\mathbf{B}^2 - (\mathbf{A} \cdot \mathbf{B})^2 \\ &\text{ii.} \quad (\mathbf{A} \times \mathbf{B}) \cdot (\mathbf{C} \times \mathbf{D}) = (\mathbf{A} \cdot \mathbf{C})(\mathbf{B} \cdot \mathbf{D}) - (\mathbf{A} \cdot \mathbf{D})(\mathbf{B} \cdot \mathbf{C}) \ ; \end{aligned}$$

d. prove that:

$$\begin{aligned} &\text{i.} \quad (\mathbf{A} \times \mathbf{B}) \cdot [(\mathbf{B} \times \mathbf{C}) \times (\mathbf{C} \times \mathbf{A})] = [\mathbf{A} \cdot (\mathbf{B} \times \mathbf{C})]^2 \\ &\text{ii.} \quad \mathbf{A} \times (\mathbf{B} \times \mathbf{C}) + \mathbf{B} \times (\mathbf{C} \times \mathbf{A}) + \mathbf{C} \times (\mathbf{A} \times \mathbf{B}) = 0 \ . \end{aligned}$$

9.1.7.11 Ex: Levi-Civita tensor and vector tautologies

Be Ψ and Φ scalar fields and $\mathbf{A}$, $\mathbf{B}$, $\mathbf{C}$, and $\mathbf{D}$ vector fields. Show the following identities with the help of the Kronecker symbol.:
a. $\mathbf{A}\cdot(\mathbf{B}\times\mathbf{C}) = \mathbf{B}\cdot(\mathbf{C}\times\mathbf{A})$,
b. $(\mathbf{A}\times\mathbf{B})\cdot(\mathbf{C}\times\mathbf{D}) = (\mathbf{A}\cdot\mathbf{C})(\mathbf{B}\cdot\mathbf{D}) - (\mathbf{B}\cdot\mathbf{C})(\mathbf{A}\cdot\mathbf{D})$,
c. $(\mathbf{A}\times\mathbf{B})\times(\mathbf{C}\times\mathbf{D}) = ((\mathbf{A}\times\mathbf{B})\cdot\mathbf{D})\mathbf{C} - ((\mathbf{A}\times\mathbf{B})\cdot\mathbf{C})\mathbf{D}$,
d. $\nabla(\Phi\Psi) = \Phi\nabla\Psi + \Psi\nabla\Phi$,
e. $\nabla\times(\Phi\mathbf{A}) = (\nabla\Phi)\times\mathbf{A} + \Phi\nabla\times\mathbf{A}$,
f. $\nabla\times(\mathbf{A}\times\mathbf{B}) = (\mathbf{B}\cdot\nabla)\mathbf{A} - (\mathbf{A}\cdot\nabla)\mathbf{B} + \mathbf{A}(\nabla\cdot\mathbf{B}) - \mathbf{B}(\nabla\cdot\mathbf{A})$,
g. $\nabla(\mathbf{A}\cdot\mathbf{B}) = \mathbf{A}\times(\nabla\times\mathbf{B}) + \mathbf{B}\times(\nabla\times\mathbf{A}) + (\mathbf{A}\cdot\nabla)\mathbf{B} + (\mathbf{B}\cdot\nabla)\mathbf{A}$,
h. $\nabla\cdot(\nabla\Phi) = \Delta\Phi$,
i. $\mathbf{A}\cdot(\nabla\Phi) = (\mathbf{A}\cdot\nabla)\Phi$,
j. $\mathbf{A}\times(\nabla\Phi) = (\mathbf{A}\times\nabla)\Phi$.
k. $\nabla\cdot(\mathbf{A}\times\mathbf{B}) = \mathbf{B}\cdot(\nabla\times\mathbf{A}) - \mathbf{A}\cdot(\nabla\times\mathbf{B})$,
l. $\nabla(\Psi\mathbf{A}) = \mathbf{A}\cdot\nabla\Psi + \Psi\nabla\cdot\mathbf{A}$,
m. $\nabla\cdot(\Psi\nabla\Psi) = \Psi\Delta\Psi + (\nabla\Psi)^2$
n. $\nabla\cdot(\mathbf{A}\times\mathbf{B}) = \mathbf{B}\cdot(\nabla\times\mathbf{A}) - \mathbf{A}\cdot(\nabla\times\mathbf{B})$,
o. $\nabla\cdot(\nabla\times\mathbf{A}) = 0$,
p. $\nabla\times(\nabla\Phi) = 0$,
q. $\nabla\times(\nabla\times\mathbf{A}) = \nabla(\nabla\cdot\mathbf{A}) - \nabla^2\mathbf{A}$.

9.2 Integral calculus

Three types of integrals are often used in electrodynamics, the *path integral*, the *surface integral*, and the *volume integral*.

9.2.1 Path integral

The path integral is defined on a trajectory $\mathcal{C}(\mathbf{a},\mathbf{b})$ through a (scalar or vector) field linking a start point $\mathbf{a}$ to an end point $\mathbf{b}$. While following the path point by point, incrementing the infinitesimal displacement vector $d\mathbf{l}$ (see Fig. 9.4), we evaluate the local value and the direction of the field, multiply it with $d\mathbf{l}$, and sum it up,

$$\int_{\mathcal{C}(\mathbf{a},\mathbf{b})} \Phi d\mathbf{l} \quad , \quad \int_{\mathcal{C}(\mathbf{a},\mathbf{b})} \mathbf{A}\cdot d\mathbf{l} \ . \tag{9.27}$$

Note that in case of a vector field, the integral is taken over the scalar product between the local field vector and the path element. The work exerted by a force field, $W \equiv \int \mathbf{F}\cdot\mathbf{l}$ is an example. For a path through a field crossing all force lines under right angle, the path integral zeroes, meaning that no work is accumulated.

Depending on the properties of the field, the integral may only depend on the points $\mathbf{a}$ and $\mathbf{b}$ and not on the path $\mathcal{C}$ chosen to go from one to the other. In this case, we say that the vector field is *conservative*, but this is not always the case. Choosing $\mathbf{a} = \mathbf{b}$ we get a closed path, which can be thought of as delimiting a surface in 3D space. We use the notation,

$$\oint_{\partial\mathcal{S}} \mathbf{A}\cdot d\mathbf{l} \ , \tag{9.28}$$

where the symbol ∂S suggests, that the path goes along the edge of the surface S.

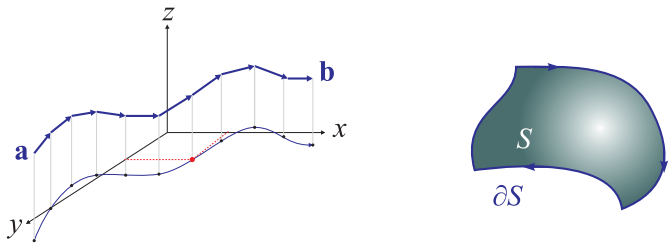

Figure 9.4: Integrating along a path in three-dimensional space.

In practice, it is often useful to find a parametrization $\mathbf{l}(t)$ for the path with a parameter (e.g. time) defined over $t \in [0, 1]$. It allows us to calculate explicitly,

$$\int_{\mathcal{C}(\mathbf{a},\mathbf{b})} \nabla\Phi \cdot d\mathbf{l} = \int_0^1 \nabla\Phi(\mathbf{r}) \cdot \frac{d\mathbf{l}(t)}{dt} dt \ . \tag{9.29}$$

Example 34 (*Path integral*): As an example, we will calculate the integral along the path parametrized by $\mathbf{l}(t) = \hat{\mathbf{e}}_x \cos t + \hat{\mathbf{e}}_y \sin t$, which is a unit circle around the origin, inside the field $\mathbf{A}(\mathbf{r}) = -y\hat{\mathbf{e}}_x + x\hat{\mathbf{e}}_y$:

$$\oint \mathbf{A} \cdot d\mathbf{l} = \int_0^{2\pi} (-y\hat{\mathbf{e}}_x + x\hat{\mathbf{e}}_y) \cdot \frac{dl}{dt} dt \tag{9.30}$$

$$= \int_0^{2\pi} (-\hat{\mathbf{e}}_x \sin t + \hat{\mathbf{e}}_y \cos t) \left(\hat{\mathbf{e}}_x \frac{d\cos t}{dt} + \hat{\mathbf{e}}_y \frac{d\sin t}{dt} \right) dt = \int_0^{2\pi} (\sin^2 t + \cos^2 t) dt = 2\pi \ .$$

We calculate other examples of path integrals in the Excs. 9.2.7.1 to 9.2.7.4.

9.2.2 Surface integral

The surface integral is defined on a surface $\mathcal{S}$, which can be folded in three-dimensional space. The surface is parceled into infinitesimal areas $d\mathbf{S}$, the local value and the direction of the field are evaluated, multiplied with $d\mathbf{S}$, and summed up,

$$\int_{\mathcal{S}} \Phi d\mathbf{S} \quad , \quad \int_{\mathcal{S}} \mathbf{A} \cdot d\mathbf{S} \ . \tag{9.31}$$

The vector of the area $d\mathbf{S}$ is the local normal vector. In case of the vector field, the integral is taken over the scalar product between the field and the local area. The flux, that is the field lines crossing a surface, $\Psi \equiv \int \mathbf{E} \cdot d\mathbf{S}$ it is an example. The normal vector of the surface of a volume is usually taken as pointing *out of the volume*. For example, a surface element of the x-y plane can be written $d\mathbf{S} = \hat{\mathbf{e}}_z dxdy$ in Cartesian coordinates. For curved surfaces or in curvilinear coordinates the expression will be more complicated.

Often we consider closed surfaces, which can be considered as delimiting a volume in 3D space. We use the notation,

$$\oint_{\partial\mathcal{V}} \mathbf{A} \cdot d\mathbf{S} \ , \tag{9.32}$$

where the symbol $\partial\mathcal{V}$ suggests that the surface encloses the volume $\mathcal{V}$.

Example 35 (*Flow of a field*): As an example, we calculate the field flux $\mathbf{A} = -y\hat{\mathbf{e}}_x + x^2 y\hat{\mathbf{e}}_y$ through the unit cube:

$$\begin{aligned}\oint_{cubo} \mathbf{A}\cdot dS &= \int_{-1}^{1}\int_{-1}^{1} \mathbf{A}|_{z=1}\hat{\mathbf{e}}_z dxdy + \int_{-1}^{1}\int_{-1}^{1} \mathbf{A}|_{z=-1}(-\hat{\mathbf{e}}_z)dxdy + \int_{-1}^{1}\int_{-1}^{1} \mathbf{A}|_{x=1}\hat{\mathbf{e}}_x dydz \\ &+ \int_{-1}^{1}\int_{-1}^{1} \mathbf{A}|_{x=-1}dydz + \int_{-1}^{1}\int_{-1}^{1} \mathbf{A}|_{y=1}\hat{\mathbf{e}}_y dzdx + \int_{-1}^{1}\int_{-1}^{1} \mathbf{A}|_{y=-1}(-\hat{\mathbf{e}}_y)dzdx \\ &= 0 + 0 + \int_{-1}^{1}\int_{-1}^{1}(-y)dydz + \int_{-1}^{1}\int_{-1}^{1} ydydz + \int_{-1}^{1}\int_{-1}^{1} x^2 dzdx + \int_{-1}^{1}\int_{-1}^{1} x^2 dzdx \\ &= \frac{8}{3}\ . \end{aligned} \tag{9.33}$$

We calculate other examples of surface integrals in Excs. 9.2.7.5 to 9.2.7.8.

9.2.3 Volume integral

The volume integral defined by,

$$\int_{\mathcal{V}} \Phi dV \quad , \quad \int_{\mathcal{V}} \mathbf{A} dV\ . \tag{9.34}$$

In the case of a vector field, we simply write: $\hat{\mathbf{e}}_x \int A_x dV + \hat{\mathbf{e}}_y \int A_y dV + \hat{\mathbf{e}}_z \int A_z dV$.

Example 36 (*Integral de volume*): As an example, we calculate the mass of a cube with homogeneous density ρ_0:

$$m = \int_{-a/2}^{a/2}\int_{-a/2}^{a/2}\int_{-a/2}^{a/2} \rho_0 dxdydz = a^3\rho_0\ . \tag{9.35}$$

We calculate another example of a volume integral in Exc. 9.2.7.9.

9.2.4 Fundamental theorem for gradients

The fundamental theorem of infinitesimal calculus says,

$$\int_{f_a}^{f_b} df = \int_a^b F(x)dx = f(b) - f(a) \qquad \text{or} \qquad df = F(x)dx\ , \tag{9.36}$$

for $F(x) = \frac{df}{dx}$. That is, derivation and integration are inverse operations.

Now in vector analysis, as explained above, we know three different types of derivatives. For each one we need to formulate the fundamental theorem in a specific way. For gradients,

$$\boxed{\int_{\mathcal{C}(\mathbf{a},\mathbf{b})} \nabla\Phi\cdot d\mathbf{l} = \Phi(\mathbf{b}) - \Phi(\mathbf{a})} \qquad \text{or} \qquad d\Phi = \nabla\Phi\cdot d\mathbf{l}\ . \tag{9.37}$$

Since the right-hand side does not depend on the path $\mathcal{C}$, the integral of the gradient can not either. As a consequence,

$$\boxed{\oint_{\mathcal{C}} \nabla\Phi\cdot d\mathbf{l} = 0}\ . \tag{9.38}$$

The geometric interpretation of the fundamental theorem for gradients is simple: Climbing a mountain following a path step by step and gaining at each step the potential energy $d\Phi = \nabla\Phi dx$, we accumulate between the end and the start point of the path the energy $\Phi(\mathbf{b}) - \Phi(\mathbf{a})$. Path independence is an inherent property of gradients.

Example 37 (*Fundamental theorem for gradients*): Let us consider the following example. To travel inside the potential $\Phi(\mathbf{r}) = xy^2$ between the points $\mathbf{r}_1 = (0,0,0)$ and $\mathbf{r}_2 = (2,1,0)$, we can choose between several paths, f.ex. $\mathbf{l}_1(t) = \hat{\mathbf{e}}_x 2t + \hat{\mathbf{e}}_y t$ or $\mathbf{l}_2(t) = \hat{\mathbf{e}}_x 2t + \hat{\mathbf{e}}_y t^2$ with $t \in [0,1]$. In both cases we gain the same potential energy $\Phi(\mathbf{r}_2) - \Phi(\mathbf{r}_1) = 2$:

$$\int_{\mathcal{C}(\mathbf{r}_1,\mathbf{r}_2)} \nabla\Phi \cdot d\mathbf{l}_1 = \int_0^1 (\hat{\mathbf{e}}_x y^2 + \hat{\mathbf{e}}_y 2xy) \cdot (\hat{\mathbf{e}}_x 2 + \hat{\mathbf{e}}_y)dt = \int_0^1 (2t^2 + 4t^2)dt = 2 \tag{9.39}$$

$$\int_{\mathcal{C}(\mathbf{r}_1,\mathbf{r}_2)} \nabla\Phi \cdot d\mathbf{l}_2 = \int_0^1 (\hat{\mathbf{e}}_x y^2 + \hat{\mathbf{e}}_y 2xy) \cdot (\hat{\mathbf{e}}_x 2 + \hat{\mathbf{e}}_y 2t)dt = \int_0^1 (2t^4 + 8t^4)dt = 2\ .$$

An example for the application of the fundamental theorem for gradients is discussed in Exc. 9.2.7.10.

9.2.5 Stokes' theorem

Stokes' theorem allows us *to convert a surface integral into a path integral* provided the field to be integrated can be expressed as a rotation,

$$\boxed{\int_{\mathcal{S}} (\nabla \times \mathbf{A}) \cdot d\mathbf{S} = \oint_{\partial\mathcal{S}} \mathbf{A} \cdot d\mathbf{l}}\ . \tag{9.40}$$

To find a geometric interpretation we remember that the rotation measures the *twist* of a field $\mathbf{A}$. The integral over the rotation within a given surface (or, more precisely, the flux of the rotation through this surface) measures the total amount of vorticity. A rotating region is like a *kitchen beater* stirring the surface of an incompressible liquid: The more beaters are in the area, the more the liquid will be moved along the edges of the area. Instead of measuring the number of beaters (left-hand side of the theorem (9.40)), we can also walk along the edge of the area and measure the flux along the rim (right-hand side of the theorem (9.40)).

An interesting consequence of Stokes' theorem is that the path integral is independent of the shape of the surface. That is, if the field to be integrated can be expressed bin terms of a rotation, we can deform the surface (without touching the edge) without changing the twist of the field,

$$\boxed{\oint_{\mathcal{S}} (\nabla \times \mathbf{A}) \cdot d\mathbf{S} = 0}\ . \tag{9.41}$$

This is analogous to the corollary obtained for gradients (9.38).

Example 38 (*Teorema de Stokes*): Consider the following example. A field be given by, $\mathbf{A} = -y\hat{\mathbf{e}}_x + x\hat{\mathbf{e}}_y$, such that $\nabla \times \mathbf{A} = 2\hat{\mathbf{e}}_z$. The surface be a disk of

radius R enclosed by a circular path parametrized by, $\mathbf{l} = \begin{pmatrix} R\cos\omega t \\ R\sin\omega t \\ 0 \end{pmatrix}$. Then,

$$\oint_{circle} \mathbf{A}\cdot dl = \int_0^{2\pi} \mathbf{A}\cdot \dot{l}dt = \int_0^{2\pi/\omega} \begin{pmatrix} -y \\ x \\ 0 \end{pmatrix} \cdot \begin{pmatrix} -R\omega\sin\omega t \\ R\omega\cos\omega t \\ 0 \end{pmatrix} dt = 2\pi R^2$$

$$\int_{disk} (\nabla\times\mathbf{A})\cdot dS = \int_{disk} \begin{pmatrix} 0 \\ 0 \\ 2 \end{pmatrix} \hat{\mathbf{e}}_z d\mathbf{A} = 2\int_{disk} dA = 2\pi R^2 \ .$$

In the Excs. 9.2.7.11 and 9.2.7.12 we show applications of Stokes' theorem.

9.2.6 Gauß' theorem

Gauß theorem allows us *to convert a volume integral into a surface integral* provided the field to be integrated can be expressed by a divergence,

$$\boxed{\int_{\mathcal{V}} (\nabla\cdot\mathbf{A})\cdot dV = \oint_{\partial\mathcal{V}} \mathbf{A}\cdot d\mathbf{S}} \ . \tag{9.42}$$

To find a geometric interpretation we remember that the divergence measures the *expansion* force of the field $\mathbf{A}$. The integral over the divergence within a given volume measures the total amount of expansion. A divergent region with is like a tap releasing an incompressible liquid: The more taps are in the volume, the more liquid will be expelled by the edges of the volume. Instead of measuring the number of taps (left-hand side of the theorem (9.42)), we can also bypass the volume by measuring the flux through the surface (right-hand side of the theorem (9.42)).

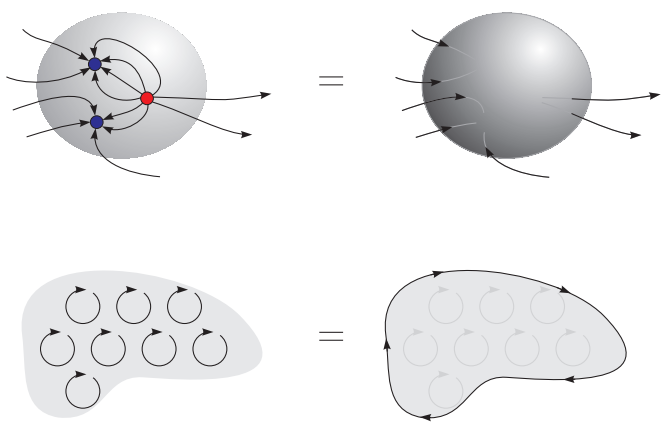

Figure 9.5: Illustration of the theorems of Gauß (above) and Stokes (below).

Example 39 (*Gauß theorem*): Consider the following example. A field be given by, $\mathbf{A} = \mathbf{r}$, such that $\nabla \cdot \mathbf{A} = 3$. The volume be a sphere of radius R enclosed by a surface. So:

$$\oint_{sphericalsurface} \mathbf{A} \cdot d\mathbf{S} = \int_{sphericalsurface} \mathbf{r} \cdot \hat{\mathbf{e}}_r dS = rr^2 \int_0^{2\pi} \int_0^{\pi} \sin\theta d\theta d\phi = 4\pi R^3$$
$$\int_{sphere} (\nabla \cdot A) dV = \int_{sphere} 3dV = 3\frac{4\pi}{3} R^3 = 4\pi R^3 \ .$$

In the Excs. 9.2.7.13 to 9.2.7.16 we show applications of Gauß' theorem.

The theorems of Stokes and Gauß are often used in the context of cylindrical or spherical coordinates. Therefore, we will postpone the presentation of further examples, until we have discussed curvilinear coordinates.

9.2.7 Exercises

9.2.7.1 Ex: Path integral and work

Be the field electric $\mathbf{A}(\mathbf{r}) = \mathcal{E}_0 z \hat{\mathbf{e}}_z$ be given. A charge $+q$ be shifted on a straight line from the point $(0, 0, 0)$ to the point $(1, 1, 1)$.
a. Write down parametrization for the trajectory.
b. Calculate the work spent on this charge explicitly along the path integral $W = q \int \mathbf{E}(\mathbf{r}) \cdot d\mathbf{r}$.
c. Calculate the work via the potential ϕ.

9.2.7.2 Ex: Path integral and work

Consider a field $\vec{\mathcal{E}}$ depending on z in the following way $\vec{\mathcal{E}} = \mathcal{E}_0 z \hat{\mathbf{e}}_z$. A charge q is moved on a spiral-shaped trajectory $\mathbf{r}(t)$ with radius R,

$$\mathbf{r}(t) = \begin{pmatrix} R\cos t \\ R\sin t \\ \frac{h}{6\pi} t \end{pmatrix}$$

between $z = 0$ until $z = h$. Make a scheme of $\mathbf{r}(t)$. Calculate work made on the charge explicitly via a path integral $W = q \int \vec{\mathcal{E}} \cdot d\mathbf{r}$. How can we calculate work more easily?

9.2.7.3 Ex: Path integral and work

Calculate the path integral in the field $\Phi = x^2 \hat{\mathbf{e}}_x + 2yz \hat{\mathbf{e}}_y + y^2 \hat{\mathbf{e}}_z$ from the origin to the point $(1, 1, 1)$ on three different paths:
a. For the path $(0, 0, 0) \longrightarrow (1, 0, 0) \longrightarrow (1, 1, 0) \longrightarrow (1, 1, 1)$;
b. for the path $(0, 0, 0) \longrightarrow (0, 0, 1) \longrightarrow (0, 1, 1) \longrightarrow (1, 1, 1)$;
c. and on a straight line.

9.2.7.4 Ex: Curve parametrization

The movement of a mass point is given in Cartesian coordinates by the vector $\mathbf{r}(t) = (\rho\cos\phi(t), \rho\sin\phi(t), z_0)$ with $\rho = vt$ and $\phi = \omega t + \phi_0$. What is the geometric figure dashed by the movement? Express the speed $\dot{\mathbf{r}}(t)$ and the acceleration $\ddot{\mathbf{r}}(t)$ in Cartesian coordinates. Calculate $|\mathbf{r}(t)|^2$, $|\dot{\mathbf{r}}(t)|^2$,$\mathbf{r}(t)\cdot\ddot{\mathbf{r}}(t)$ and $\mathbf{r}(t)\times\dot{\mathbf{r}}(t)$.

9.2.7.5 Ex: Surface integrals

Given be the vector field $\mathbf{A} = zy\hat{\mathbf{e}}_x + y^3\sin^2 x\hat{\mathbf{e}}_y + xy^2e^z\hat{\mathbf{e}}_z$. Calculate the integrals $\int \mathbf{A}\cdot d\mathbf{F}$ over the triangle $(0,0,0) \to (0,3,0) \to (0,0,3) \to (0,0,0)$, and over the rectangle $(2,2,0) \to (2,4,0) \to (4,4,0) \to (4,2,0) \to (2,2,0)$.

9.2.7.6 Ex: Surface integrals

Calculate the integral over a closed surface
a. of the field $\mathbf{A} = \mathbf{r}$ over the cube $0 \le x \le 1$, $0 \le y \le 1$, $0 \le z \le 1$ e
b. of the field $\mathbf{A} = \rho\vec{\mathcal{E}}_\rho$ over the radial surface of the cylinder $0 \le z \le 1$, $0 \le \rho \le 1$.

9.2.7.7 Ex: Surface integrals

Calculate for the vector field $\mathbf{A}(\mathbf{r}) = c\mathbf{r}$ with $c =$constant the surface integral

$$I = \int_F \mathbf{A}(\mathbf{r}) \times d\mathbf{S}$$

a. over the surface of a sphere (radius R, center in the origin of coordinates)
b. over the surface of a cylinder (radius R, length L).

9.2.7.8 Ex: Surface integrals

Prove the relationship:

$$t_{ij} \equiv \int_{O(a)} d\mathbf{f} x_i x_j = \frac{4\pi}{3} a^4 \delta_{ij} \ ,$$

where $i, j = 1, 2, 3$, $x_1 = x$, $x_2 = y$, $x_3 = z$, and the integral has to be calculated on the surface of a sphere with radius a.

9.2.7.9 Ex: Volume integrals

Calculate the volume integral of the function $\Phi = z^2$ over the tetrahedron with the corners in $(0,0,0)$, $(1,0,0)$, $(0,1,0)$, and $(0,0,1)$.

9.2.7.10 Ex: Fundamental theorem for gradients

What is the energy gain within the potential $\Phi(\mathbf{r}) = \Phi_0 \frac{\sin kr}{kr}$ along a path keeping a constant distance from the origin.

9.2.7.11 Ex: Stokes integral theorem

Calculate for following field,

$$\mathbf{A}(\mathbf{r}) = \begin{pmatrix} yz \\ azx \\ xy \end{pmatrix}$$

using Stokes' law the path integral $\oint \mathbf{A} \cdot \mathbf{r}$ for an integration along a circle with radius R around the z-axis at the position $z = h$.

9.2.7.12 Ex: Stokes integral theorem

Calculate the integral $\oint_{\mathcal{C}} x(\hat{\mathbf{e}}_x + \hat{\mathbf{e}}_y)\, d\mathbf{r}$, where $\mathcal{C}$ be the unit circle in the x-y-plane.

9.2.7.13 Ex: Gauß integral theorem

Calculate the flux of the vector field $\mathbf{A}(\mathbf{r}) = \mathbf{r}$ through a sphere with radius R
a. by the surface integral and
b. with the help of Gauß's theorem for the volume integral over the divergence.

9.2.7.14 Ex: Gauß integral theorem

Let F be the surface of an arbitrary volume V. Determine for $\mathbf{A}(x_1, x_2, x_3) = (ax_1, bx_2, cx_3)$ the validity of the relationship,

$$\oint_F d\mathbf{F} \cdot \mathbf{A} = (a + b + c)V \ .$$

9.2.7.15 Ex: Gauß integral theorem

Be a a scalar field and $\mathbf{B}$ a vector field. Show,

$$\int_V d^3\mathbf{r}\ \mathbf{B} \cdot \nabla a = \int_{O(V)} a\mathbf{B}\ \cdot\ d\mathbf{F} - \int_V d^3\mathbf{r}\ a\nabla \cdot \mathbf{B}\ .$$

9.2.7.16 Ex: Gauß integral theorem

Calculate the integral $\oint_{\mathcal{C}} x(\hat{\mathbf{e}}_x + \hat{\mathbf{e}}_y) \cdot d\mathbf{r}$ about a unitary circular path $\mathcal{C}$ along the equator and the integral $\oint_{\mathcal{F}} x(\hat{\mathbf{e}}_x + \hat{\mathbf{e}}_y) \cdot d\mathbf{F}$, where $\mathcal{F}$ be the surface of a unit sphere.

9.3 Curvilinear coordinates

The most commonly used coordinate systems are Cartesian, cylindrical and spherical. Cylindrical coordinates are expressed in terms of Cartesian coordinates by,

$$\begin{pmatrix} x \\ y \\ z \end{pmatrix} = \begin{pmatrix} \rho\cos\phi \\ \rho\sin\phi \\ z \end{pmatrix} . \tag{9.43}$$

And spherical coordinates are expressed in terms of Cartesian coordinates by,

$$\begin{pmatrix} x \\ y \\ z \end{pmatrix} = \begin{pmatrix} r\sin\theta\cos\phi \\ r\sin\theta\sin\phi \\ r\cos\theta \end{pmatrix} . \tag{9.44}$$

The task now is to express the differential elements (that is, line, surface and volume elements), as well as differential operators (that is, the gradient, divergent and rotation) and the Laplacian in term of curvilinear coordinates.

Let us first consider the general case. The transformation from a Cartesian coordinate system (x, y, z) into a general, curvilinear system (u, v, w) is given by,

$$\mathbf{r} \equiv \begin{pmatrix} x(u,v,w) \\ y(u,v,w) \\ z(u,v,w) \end{pmatrix} . \tag{9.45}$$

The change $d_u\mathbf{r}$ resulting from a small variation du is then $d_u\mathbf{r} = \frac{\partial\mathbf{r}}{\partial u}du$ and occurs in the direction of the new unit vector $\hat{\mathbf{e}}_u$. The unit vectors of the new system, therefore, can be written as,

$$\hat{\mathbf{e}}_u = U(u,v,w)\frac{\partial\mathbf{r}}{\partial u} \quad , \quad \hat{\mathbf{e}}_v = V(u,v,w)\frac{\partial\mathbf{r}}{\partial v} \quad , \quad \hat{\mathbf{e}}_w = W(u,v,w)\frac{\partial\mathbf{r}}{\partial w} , \tag{9.46}$$

where

$$U = \left|\frac{\partial\mathbf{r}}{\partial u}\right|^{-1} \quad , \quad V = \left|\frac{\partial\mathbf{r}}{\partial v}\right|^{-1} \quad , \quad W = \left|\frac{\partial\mathbf{r}}{\partial w}\right|^{-1} . \tag{9.47}$$

In the Excs. 9.3.8.1 we study transformations into cylindrical and spherical coordinates.

9.3.1 Differential elements in curvilinear coordinates

In the following we restrict ourselves to orthogonal coordinates, where the unit vectors are perpendicular. In this case, the total differential $d\mathbf{r}$ has the form,

$$d\mathbf{r} = \frac{\partial\mathbf{r}}{\partial u}du + \frac{\partial\mathbf{r}}{\partial v}dv + \frac{\partial\mathbf{r}}{\partial w}dw = \hat{\mathbf{e}}_u\frac{du}{U} + \hat{\mathbf{e}}_v\frac{dv}{V} + \hat{\mathbf{e}}_w\frac{dw}{W} , \tag{9.48}$$

and has the length,

$$|d\mathbf{r}|^2 = \left(\frac{du}{U}\right)^2 + \left(\frac{dv}{V}\right)^2 + \left(\frac{dw}{W}\right)^2 \ . \tag{9.49}$$

The volume element is,

$$d\tau = ds_u ds_v ds_w \ . \tag{9.50}$$

9.3.2 Gradient in curvilinear coordinates

We can now express the gradient of a scalar field Φ in orthogonal curvilinear coordinates,

$$\text{grad } \Phi = \nabla\Phi = f_u \hat{\mathbf{e}}_u + f_v \hat{\mathbf{e}}_v + f_w \hat{\mathbf{e}}_w \ , \tag{9.51}$$

where the f_i are functions which have yet to be determined. To this end we compare the coefficients of the expressions,

$$d\Phi = \frac{\partial\Phi}{\partial u} du + \frac{\partial\Phi}{\partial v} dv + \frac{\partial\Phi}{\partial w} dw \ , \tag{9.52}$$

and, inserting (9.48) and (9.51),

$$d\Phi = d\mathbf{r} \cdot \nabla\Phi = \frac{f_u}{U} du + \frac{f_v}{V} dv + \frac{f_w}{W} dw \ . \tag{9.53}$$

We obtain,

$$\nabla\Phi = \left(U \frac{\partial\Phi}{\partial u}\right) \hat{\mathbf{e}}_u + \left(V \frac{\partial\Phi}{\partial v}\right) \hat{\mathbf{e}}_v + \left(W \frac{\partial\Phi}{\partial w}\right) \hat{\mathbf{e}}_w \ . \tag{9.54}$$

9.3.3 Divergence in curvilinear coordinates

Now we will show how to express the divergence of a vector field $\mathbf{A}$ in orthogonal curvilinear coordinates,

$$\text{div } \mathbf{A} = \nabla \cdot \mathbf{A} \ . \tag{9.55}$$

The derivation is a bit complicated. We begin by expressing the unit vectors $\hat{\mathbf{e}}_u$, $\hat{\mathbf{e}}_v$, and $\hat{\mathbf{e}}_w$ by the gradients ∇u, ∇v, and ∇w, using the expression for the gradient (9.54),

$$\nabla u = U \hat{\mathbf{e}}_u \quad , \quad \nabla v = V \hat{\mathbf{e}}_v \quad , \quad \nabla w = W \hat{\mathbf{e}}_w \ . \tag{9.56}$$

We now express each unit vector as the vector product of two of these gradients,

$$\begin{aligned} \nabla u \times \nabla v &= UV \ \hat{\mathbf{e}}_u \times \hat{\mathbf{e}}_v = UV \hat{\mathbf{e}}_w \\ \nabla v \times \nabla w &= VW \ \hat{\mathbf{e}}_v \times \hat{\mathbf{e}}_w = VW \hat{\mathbf{e}}_u \\ \nabla w \times \nabla u &= WU \ \hat{\mathbf{e}}_w \times \hat{\mathbf{e}}_u = WU \hat{\mathbf{e}}_v \ . \end{aligned} \tag{9.57}$$

After that we write $\mathbf{A} = a_u\hat{\mathbf{e}}_u + a_v\hat{\mathbf{e}}_v + a_w\hat{\mathbf{e}}_w$ and start considering the first term of the divergence:

$$\begin{aligned}
&\nabla\cdot(a_u\hat{\mathbf{e}}_u) = \nabla\cdot\left(\frac{a_u}{VW}\nabla v\times\nabla w\right) \qquad (9.58)\\
&= (\nabla v\times\nabla w)\cdot\nabla\left(\frac{a_u}{VW}\right) + \frac{a_u}{VW}\nabla\cdot(\nabla v\times\nabla w) \quad \text{using} \quad \nabla\cdot(\alpha\mathbf{A}) = \mathbf{A}\cdot(\nabla\alpha) + \alpha(\nabla\cdot\mathbf{A})\\
&= VW\hat{\mathbf{e}}_u\cdot\left[\hat{\mathbf{e}}_u U\frac{\partial}{\partial u}\left(\frac{a_u}{VW}\right) + \hat{\mathbf{e}}_v V\frac{\partial}{\partial v}\left(\frac{a_v}{VW}\right) + \hat{\mathbf{e}}_w W\frac{\partial}{\partial w}\left(\frac{a_w}{VW}\right)\right]\\
&\quad + \frac{a_u}{VW}\left[\nabla w\cdot(\nabla\times\nabla v) - \nabla v\cdot(\nabla\times\nabla w)\right] \quad \text{using} \quad \nabla\cdot(\mathbf{A}\times\mathbf{B}) = \mathbf{B}\cdot(\nabla\times\mathbf{A}) - \mathbf{A}\cdot(\nabla\times\mathbf{B})\\
&= UVW\frac{\partial}{\partial u}\left(\frac{a_u}{VW}\right) \quad \text{using} \quad \nabla\times(\nabla\alpha) = 0\ .
\end{aligned}$$

Similarly we can show,

$$\nabla\cdot(a_v\hat{\mathbf{e}}_v) = UVW\frac{\partial}{\partial v}\left(\frac{a_v}{UW}\right) \qquad \text{and} \qquad \nabla\cdot(a_w\hat{\mathbf{e}}_w) = UVW\frac{\partial}{\partial w}\left(\frac{a_w}{UV}\right)\ . \qquad (9.59)$$

With this we finally get,

$$\nabla\cdot\mathbf{A} = UVW\left[\frac{\partial}{\partial u}\left(\frac{a_u}{VW}\right) + \frac{\partial}{\partial v}\left(\frac{a_v}{UW}\right) + \frac{\partial}{\partial w}\left(\frac{a_w}{UV}\right)\right]\ . \qquad (9.60)$$

9.3.4 Rotation in curvilinear coordinates

Now we will show how to express the rotation of a vector field $\mathbf{A}$ in orthogonal curvilinear coordinates,

$$\text{rot}\ \mathbf{A} = \nabla\times\mathbf{A}\ . \qquad (9.61)$$

We write again, $\mathbf{A} = a_u\hat{\mathbf{e}}_u + a_v\hat{\mathbf{e}}_v + a_w\hat{\mathbf{e}}_w$ and start considering the first term of the rotation:

$$\begin{aligned}
&\nabla\times(a_u\hat{\mathbf{e}}_u) = \nabla\times\left(\frac{a_u}{U}\nabla u\right) \quad \text{using} \quad (9.56) \qquad (9.62)\\
&= \left(\nabla\frac{a_u}{U}\right)\times\nabla u + \frac{a_u}{U}(\nabla\times\nabla u) \quad \text{using} \quad \nabla\times(\alpha\mathbf{A}) = (\nabla\alpha)\times\mathbf{A} + \alpha(\nabla\times\mathbf{A})\\
&= U\left(\nabla\frac{a_u}{U}\right)\times\hat{\mathbf{e}}_u \quad \text{and} \quad \nabla\times(\nabla\alpha) = 0 \quad \text{using} \quad (9.56)\\
&= U\left[\hat{\mathbf{e}}_u U\frac{\partial}{\partial u}\left(\frac{a_u}{U}\right) + \hat{\mathbf{e}}_v V\frac{\partial}{\partial v}\left(\frac{a_u}{U}\right) + \hat{\mathbf{e}}_w W\frac{\partial}{\partial w}\left(\frac{a_u}{U}\right)\right]\times\hat{\mathbf{e}}_u\\
&= U\left[\hat{\mathbf{e}}_v W\frac{\partial}{\partial w}\left(\frac{a_u}{U}\right) - \hat{\mathbf{e}}_w V\frac{\partial}{\partial v}\left(\frac{a_u}{U}\right)\right]\\
&= UVW\left[\hat{\mathbf{e}}_v\frac{1}{V}\frac{\partial}{\partial w}\left(\frac{a_u}{U}\right) - \hat{\mathbf{e}}_w\frac{1}{W}\frac{\partial}{\partial v}\left(\frac{a_u}{U}\right)\right]\ .
\end{aligned}$$

Similarly we can show,

$$\begin{aligned}
\nabla\times(a_v\hat{\mathbf{e}}_v) &= UVW\left[\hat{\mathbf{e}}_w\frac{1}{W}\frac{\partial}{\partial u}\left(\frac{a_v}{V}\right) - \hat{\mathbf{e}}_u\frac{1}{U}\frac{\partial}{\partial w}\left(\frac{a_v}{V}\right)\right] \qquad (9.63)\\
\nabla\times(a_w\hat{\mathbf{e}}_w) &= UVW\left[\hat{\mathbf{e}}_u\frac{1}{U}\frac{\partial}{\partial v}\left(\frac{a_w}{W}\right) - \hat{\mathbf{e}}_v\frac{1}{V}\frac{\partial}{\partial u}\left(\frac{a_w}{W}\right)\right]\ .
\end{aligned}$$

With this we finally obtain,

$$\nabla \times \mathbf{A} = \hat{\mathbf{e}}_u VW \left[\frac{\partial}{\partial v}\left(\frac{a_w}{W}\right) - \frac{\partial}{\partial w}\left(\frac{a_v}{V}\right)\right] + \hat{\mathbf{e}}_v UW \left[\frac{\partial}{\partial w}\left(\frac{a_u}{U}\right) - \frac{\partial}{\partial u}\left(\frac{a_w}{w}\right)\right] + \hat{\mathbf{e}}_w UV \left[\frac{\partial}{\partial u}\left(\frac{a_v}{V}\right) - \frac{\partial}{\partial v}\left(\frac{a_u}{U}\right)\right] , \tag{9.64}$$

or, written as a determinant,

$$\nabla \times \mathbf{A} = UVW \det \begin{pmatrix} \frac{\hat{\mathbf{e}}_u}{U} & \frac{\hat{\mathbf{e}}_v}{V} & \frac{\hat{\mathbf{e}}_w}{W} \\ \frac{\partial}{\partial u} & \frac{\partial}{\partial v} & \frac{\partial}{\partial w} \\ \frac{a_u}{U} & \frac{a_v}{V} & \frac{a_w}{W} \end{pmatrix} . \tag{9.65}$$

9.3.5 Cylindrical coordinates

Let us now identify the general coordinates u, v, and w with the cylindrical coordinates ρ, θ, and ϕ defined in Eq. (9.43). In Exc. 9.3.8.2 we calculate for the line element,

$$d\mathbf{r} = d\rho \hat{\mathbf{e}}_\rho + \rho d\phi e_\phi + dz \hat{\mathbf{e}}_z , \tag{9.66}$$

the distance element,

$$|d\mathbf{r}|^2 = (d\rho)^2 + (\rho d\phi)^2 + (dz)^2 , \tag{9.67}$$

the surface element given by $z = z(\rho, \phi)$,

$$d\mathbf{s} = \left(-\frac{\partial z}{\partial \rho}\hat{\mathbf{e}}_\rho - \frac{1}{\rho}\frac{\partial z}{\partial \phi}\hat{\mathbf{e}}_\phi + \hat{\mathbf{e}}_z \right) \rho d\rho d\phi , \tag{9.68}$$

and the volume element,

$$d\tau = r dz \phi dr . \tag{9.69}$$

In the Excs. 9.3.8.3 to 9.3.8.5 we calculate, respectively, the gradient,

$$\nabla \Phi = \hat{\mathbf{e}}_\rho \frac{\partial \Phi}{\partial \rho} + \hat{\mathbf{e}}_\phi \frac{1}{\rho}\frac{\partial \Phi}{\partial \phi} + \hat{\mathbf{e}}_z \frac{\partial \Phi}{\partial z} , \tag{9.70}$$

the divergence,

$$\nabla \cdot \mathbf{A} = \frac{1}{\rho}\frac{\partial}{\partial \rho}[\rho\ a_\rho] + \frac{1}{\rho}\frac{\partial}{\partial \phi}[a_\phi] + \frac{\partial}{\partial z}[a_z] , \tag{9.71}$$

the rotation,

$$\nabla \times \mathbf{A} = \hat{\mathbf{e}}_\rho \frac{1}{\rho}\left[\frac{\partial a_z}{\partial \phi} - \rho\frac{\partial a_\phi}{\partial z}\right] + \hat{\mathbf{e}}_\phi \left[\frac{\partial a_\rho}{\partial z} - \frac{\partial a_z}{\partial \rho}\right] + \hat{\mathbf{e}}_z \frac{1}{\rho}\left[\frac{\partial}{\partial \rho}(\rho a_\phi) - \frac{\partial a_\rho}{\partial \phi}\right] \tag{9.72}$$

and the Laplace operator,

$$\Delta \Phi \equiv \nabla \cdot (\nabla \Phi) = \frac{1}{\rho}\frac{\partial}{\partial \rho}\left(\rho \frac{\partial \Phi}{\partial \rho}\right) + \frac{1}{\rho^2}\frac{\partial^2 \Phi}{\partial \phi^2} + \frac{\partial^2 \Phi}{\partial z^2} . \tag{9.73}$$

in cylindrical coordinates.

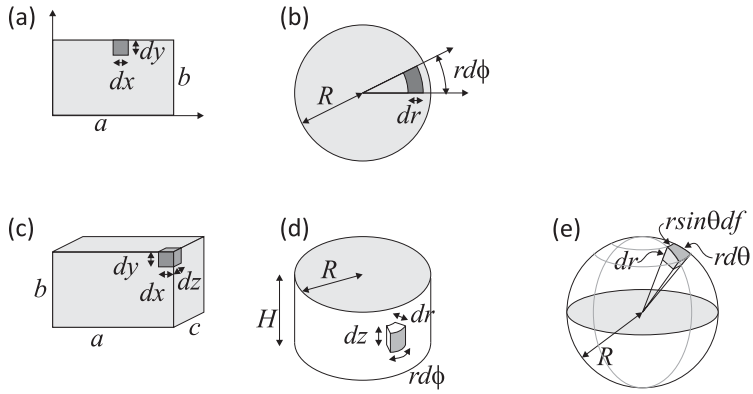

Figure 9.6: Illustration of Cartesian, polar, cylindrical and spherical coordinates.

9.3.6 Spherical coordinates

Let us now identify the general coordinates u, v, and w with the spherical coordinates r, θ, and ϕ defined in Eq. (9.44). In Exc. 9.3.8.2 we calculate for the line element,

$$d\mathbf{r} = dr\hat{\mathbf{e}}_r + rd\theta e_\theta + r\sin\theta d\phi\hat{\mathbf{e}}_\phi \ , \tag{9.74}$$

the distance element,

$$|d\mathbf{r}|^2 = (dr)^2 + (rd\theta)^2 + (r\sin\theta d\phi)^2 \ , \tag{9.75}$$

the surface element given by $r = r(\theta, \phi)$,

$$d\mathbf{s} = \left(\hat{\mathbf{e}}_r - \frac{1}{r}\frac{\partial r}{\partial\theta}\hat{\mathbf{e}}_\theta - \frac{1}{r}\frac{1}{\sin\theta}\frac{\partial r}{\partial\phi}\hat{\mathbf{e}}_\phi\right) r^2\sin\theta d\theta d\phi \ , \tag{9.76}$$

and the volume element,

$$d\tau = ds_u ds_v ds_w = r^2\sin\theta d\theta d\phi dr \ . \tag{9.77}$$

In the Excs. 9.3.8.3 to 9.3.8.5 we calculate, respectively, the gradient,

$$\nabla\Phi = \hat{\mathbf{e}}_r \ \frac{\partial\Phi}{\partial r} + \hat{\mathbf{e}}_\theta \ \frac{1}{r}\ \frac{\partial\Phi}{\partial\theta} + \hat{\mathbf{e}}_\phi \ \frac{1}{r\sin\phi}\ \frac{\partial\Phi}{\partial\phi} \ , \tag{9.78}$$

the divergence,

$$\nabla\cdot\mathbf{A} = \frac{1}{r^2}\frac{\partial}{\partial r}[r^2 a_r] + \frac{1}{r\sin\theta}\frac{\partial}{\partial\theta}[\sin\theta\ a_\theta] + \frac{1}{r\sin\theta}\frac{\partial}{\partial\phi}[a_\phi] \ , \tag{9.79}$$

the rotation,

$$\nabla\times\mathbf{A} = \hat{\mathbf{e}}_r \ \frac{1}{r\sin\theta}\left[\frac{\partial}{\partial\theta}(\sin\theta a_\phi) - \frac{\partial}{\partial\phi}(a_\theta)\right] + \hat{\mathbf{e}}_\theta \ \frac{1}{r\sin\theta}\left[\frac{\partial}{\partial\phi}(a_r) - \sin\theta\frac{\partial}{\partial r}(ra_\phi)\right] + \hat{\mathbf{e}}_\phi \ \frac{1}{r}\left[\frac{\partial}{\partial r}(ra_\theta) - \frac{\partial}{\partial\theta}(a_r)\right] \tag{9.80}$$

and the Laplace operator,

$$\Delta\Phi \equiv \nabla\cdot(\nabla\Phi) = \frac{1}{r^2}\frac{\partial}{\partial r}\left(r^2\frac{\partial\Phi}{\partial r}\right) + \frac{1}{r^2\sin\theta}\frac{\partial}{\partial\theta}\left(\sin\theta\frac{\partial\Phi}{\partial\theta}\right) + \frac{1}{r^2\sin^2\theta}\frac{\partial^2\Phi}{\partial\phi^2} \ , \quad (9.81)$$

in spherical coordinates. We note that the radial part of the Laplace operator can also be written,

$$\frac{1}{r}\frac{\partial^2}{\partial r^2}(r\Phi) \ . \quad (9.82)$$

9.3.7 Differential operators for tensor fields

Until now, we restricted to scalar and vector fields, that is spatially dependent physical quantities such as the temperature or the magnetic field distribution in a room. Some quantities, however, need to be given as matrices or even higher-dimensional objects, for example, gravity gradients or the susceptibility of a crystal. These objects are called tensors. With the definition,

$$\hat{\mathbf{e}}_k \otimes \hat{\mathbf{e}}_l = \hat{\mathbf{e}}_k\hat{\mathbf{e}}_l^\intercal \quad (9.83)$$

we can express a scalar, vector, and second-order tensor as,

$$\Phi \quad , \quad \mathbf{A} = A_k\hat{\mathbf{e}}_k \quad , \quad \mathcal{G} = G_{kl}\hat{\mathbf{e}}_k \otimes \hat{\mathbf{e}}_l \ . \quad (9.84)$$

For instance, in Cartesian coordinates a second-order tensor reads,

$$\mathcal{G} = G_{xx}\hat{\mathbf{e}}_x\hat{\mathbf{e}}_x^\intercal + G_{xy}\hat{\mathbf{e}}_x\hat{\mathbf{e}}_y^\intercal + G_{yx}\hat{\mathbf{e}}_y\hat{\mathbf{e}}_x^\intercal + G_{yy}\hat{\mathbf{e}}_y\hat{\mathbf{e}}_y^\intercal = \begin{pmatrix} G_{xx} & G_{xy} \\ G_{xy} & G_{yy} \end{pmatrix} \ . \quad (9.85)$$

If a tensor $\mathcal{T} = \Phi(\mathbf{r}), \mathbf{A}(\mathbf{r}), \mathcal{G}(\mathbf{r})$ varies in space, we can apply differential operators to it. The gradient $\nabla\mathcal{T}(\mathbf{r})$ of a tensor field in the direction of an arbitrary constant vector $\mathbf{x}$ is defined as,

$$\boxed{\mathbf{x}\cdot\nabla\mathcal{T} = \lim_{\alpha\to 0}\frac{d}{d\alpha}\mathcal{T}(\mathbf{r}+\alpha\mathbf{x})} \ . \quad (9.86)$$

The gradient of a tensor field of order n is a tensor field of order $n+1$. In Cartesian coordinates, $\mathbf{x} = x\hat{\mathbf{e}}_x + y\hat{\mathbf{e}}_y + z\hat{\mathbf{e}}_z$,

$$\nabla\Phi = \hat{\mathbf{e}}_k\frac{\partial}{\partial x_k}\Phi \equiv \Phi_{,k}\hat{\mathbf{e}}_k = \begin{pmatrix} \partial_x\Phi \\ \partial_y\Phi \end{pmatrix} \quad (9.87)$$

$$\nabla\mathbf{A} = \hat{\mathbf{e}}_k\frac{\partial}{\partial x_k}\otimes A_l\hat{\mathbf{e}}_l \equiv A_{,kl}\hat{\mathbf{e}}_k\otimes\hat{\mathbf{e}}_l = \begin{pmatrix} \partial_x A_x & \partial_y A_x \\ \partial_x A_y & \partial_y A_y \end{pmatrix}$$

$$\nabla\mathcal{G} = \hat{\mathbf{e}}_k\frac{\partial}{\partial x_k}\otimes G_{lm}\hat{\mathbf{e}}_l\otimes\hat{\mathbf{e}}_m \equiv G_{,klm}\hat{\mathbf{e}}_k\otimes\hat{\mathbf{e}}_l\otimes\hat{\mathbf{e}}_m = \begin{pmatrix} \partial_x \\ \partial_y \end{pmatrix}\begin{pmatrix} G_{xx} & G_{xy} \\ G_{xy} & G_{yy} \end{pmatrix} \ .$$

The divergence of a tensor field $\mathcal{T}(\mathbf{r})$ is defined using the recursive relation,

$$\begin{aligned}(\nabla\cdot\mathbf{A})\cdot\mathbf{x} &= \mathrm{Tr}\,(\nabla\mathbf{A}) \\ (\nabla\cdot\mathcal{G})\cdot\mathbf{x} &= \nabla\cdot(\mathbf{x}\cdot\mathcal{G}^{\mathsf{T}})\ .\end{aligned} \tag{9.88}$$

In Cartesian coordinates the divergence is,

$$\begin{aligned}\nabla\cdot\mathbf{A} &= \hat{\mathbf{e}}_k\frac{\partial}{\partial x_k}\cdot A_l\hat{\mathbf{e}}_l = \frac{\partial A_k}{\partial x_k} \equiv A_{k,k} \\ \nabla\cdot\mathcal{G} &= \hat{\mathbf{e}}_k\frac{\partial}{\partial x_k}\cdot G_{lm}\hat{\mathbf{e}}_l\otimes\hat{\mathbf{e}}_m = \frac{\partial G_{lk}}{\partial x_k}\otimes\hat{\mathbf{e}}_l \equiv G_{lk,k}\hat{\mathbf{e}}_l\ .\end{aligned} \tag{9.89}$$

The curl of an order $n > 1$ tensor field $\mathcal{T}(\mathbf{r})$ is also defined using the recursive relation,

$$\begin{aligned}(\nabla\times\mathbf{A})\cdot\mathbf{x} &= \nabla\cdot(\mathbf{A}\times\mathbf{c}) \\ (\nabla\times\mathcal{G})\cdot\mathbf{x} &= \nabla\times(\mathbf{x}\cdot\mathcal{G}^{\mathsf{T}})\ ,\end{aligned} \tag{9.90}$$

where c is an arbitrary constant vector. In Cartesian coordinates the divergence the rotation is,

$$\begin{aligned}\nabla\times\mathbf{A} &= \epsilon_{klm}\hat{\mathbf{e}}_k\partial_l A_m \\ \nabla\times\mathcal{G} &= \epsilon_{klm}\hat{\mathbf{e}}_m\otimes\hat{\mathbf{e}}_n\partial_k G_{nl}\ .\end{aligned} \tag{9.91}$$

9.3.8 Exercises

9.3.8.1 Ex: Spherical and cylindrical coordinates

a. Express the cylindrical coordinates ρ, φ, z in terms of the Cartesian ones x, y, z.
b. Express the spherical coordinates r, θ, φ in terms of the Cartesian ones x, y, z.

9.3.8.2 Ex: Differential elements in curvilinear coordinates

We have seen in class that the transformation from a Cartesian coordinate system (x, y, z) to another curvilinear and orthogonal system (u, v, w) is given by $\mathbf{r} \equiv (x(u, v, w), y(u, v, w), z(u, v, w))$. Now consider the spherical polar coordinates $\mathbf{r} \equiv (x(r, \theta, \phi), y(r, \theta, \phi), z(r, \theta, \phi)$ defined in class.
a. Calculate the functions U_r, V_θ, W_ϕ defined by,

$$U_r = \left|\frac{\partial\mathbf{r}}{\partial r}\right|^{-1} \quad , \quad V_\theta = \left|\frac{\partial\mathbf{r}}{\partial\theta}\right|^{-1} \quad , \quad W_\phi = \left|\frac{\partial\mathbf{r}}{\partial\phi}\right|^{-1}\ .$$

b. Determine the Cartesian coordinates of the new unit vectors $\hat{\mathbf{e}}_r$, $\hat{\mathbf{e}}_\theta$, $\hat{\mathbf{e}}_\phi$, draw the position of these vectors at a point $\mathbf{r}_0$, and check the orthogonality of the unit vectors. Express the Cartesian unit vectors by the spherical ones.
c. Determine the total differential $d\mathbf{r}$, the line element $(ds)^2 = |d\mathbf{r}|^2$, and the volume element $d\tau = ds_u ds_v ds_w$ in terms of the new coordinates.
d. Repeat steps (a)-(c) for planar polar coordinates.

9.3.8.3 Ex: Spherical and cylindrical coordinates

Calculate $\nabla\Phi$, $\nabla\cdot\mathbf{A}$, $\nabla\times\mathbf{A}$ and $\Delta\Phi=\nabla\cdot(\nabla\Phi)$
a. in spherical coordinates $(r,\ \theta,\ \phi)$.
b. in cylindrical coordinates $(\rho,\ \phi,\ z)$.

9.3.8.4 Ex: Divergence in curvilinear coordinates

Calculate the divergence of the force field $\mathbf{F}(\mathbf{r})=\begin{pmatrix} x^2y \\ 2yz \\ x+z \end{pmatrix}$ (a) in Cartesian and (b) cylindrical coordinates and compare the results.

9.3.8.5 Ex: Differential operators in curvilinear coordinates

In Cartesian coordinates the differential line element has the form $d\mathbf{r}=\hat{\mathbf{e}}_x dx+\hat{\mathbf{e}}_y dy+\hat{\mathbf{e}}_z dz$ and in arbitrary orthogonal coordinates $d\mathbf{r}=\hat{\mathbf{e}}_1 h_1 dq_1+\hat{\mathbf{e}}_2 h_2 dq_2+\hat{\mathbf{e}}_3 h_3 dq_3$ with $\hat{\mathbf{e}}_i=\frac{\partial\mathbf{r}}{\partial q_i}\cdot\left|\frac{\partial\mathbf{r}}{\partial q_i}\right|^{-1}$ and $h_i=\left|\frac{\partial\mathbf{r}}{\partial q_i}\right|$. For spherical coordinates (r,ϕ,θ) we find $h_r=1, h_\phi=r\sin\theta, h_\theta=r$; for cylindrical coordinates (ρ,ϕ,z) we find $h_\rho=1, h_\phi=\rho, h_z=1$.
a. The gradient has the general form,

$$\nabla_i\Phi(\mathbf{r})=\frac{1}{h_i}\frac{\partial}{\partial q_i}\Phi(\mathbf{r})\ .$$

Determine the gradient in spherical and cylindrical coordinates.
b. The divergence of a vector field $\mathbf{A}$ has the general form,

$$\nabla\cdot\mathbf{A}(\mathbf{r})=\frac{1}{h_1h_2h_3}\left[\frac{\partial}{\partial q_1}(A_1h_2h_3)+\frac{\partial}{\partial q_2}(A_2h_1h_3)+\frac{\partial}{\partial q_3}(A_3h_1h_2)\right]\ .$$

Determine $\nabla\cdot\mathbf{A}$ in spherical and cylindrical coordinates.
c. Use the results of (a) and (b) to determine the Laplace operator

$$\Delta=\nabla\cdot\nabla$$

in spherical coordinates.

9.3.8.6 Ex: Acceleration in spherical coordinates

In spherical coordinates the velocity vector has the following form,

$$\mathbf{v}=\frac{d\mathbf{r}}{dt}=\dot{r}\hat{\mathbf{e}}_r+r\dot{\theta}\hat{\mathbf{e}}_\theta+\dot{\phi}r\sin\theta\hat{\mathbf{e}}_\phi\ .$$

Calculate the acceleration vector in spherical coordinates. Respect the fact that the basis vectors must also be derived by time.

9.3.8.7 Ex: Volume element in curvilinear coordinates

a. Calculate the surface of a rectangle with width a and height b in Cartesian coordinates.
b. Calculate the surface of a disk of radius R in polar coordinates.
c. Calculate the volume of a cuboid with dimensions a, b, c in Cartesian coordinates.
d. Calculate the volume of a cylinder with the radius R and height H in cylindrical coordinates.
e. Calculate the volume a sphere with the radius R in spherical coordinates. See Fig, 9.6.

9.3.8.8 Ex: Spherical volume

The volume of a body is given by the following formula:

$$V = \int_V 1 \, dV \ .$$

a. Calculate the volume of a 3D-sphere in spherical coordinates.
By the Gauß integral law we can establish a relationship between the volume of the sphere and its surface. (**Help:** For which vector field $\mathbf{A}$ holds: $\nabla \cdot \mathbf{A} = 1$?)
b. Now calculate the volume of the sphere in this sense. You may assume that the surface of the sphere is known.
c. Similarly to the above formula, derive a general relationship between the volume of an n-dimensional hypersphere and its $(n-1)$-dimensional hypersurface. **Help:** Gauß's law holds in arbitrary dimensions with the n-dimensional operator nabla-operator defined by, $\nabla = (\partial/\partial x_1, \ldots, \partial/\partial x_n)$.

9.3.8.9 Ex: Spherical volume

The density distribution of a gas be given by $n(\mathbf{r}) = C^2 - \frac{x^2}{r_0^2} - \frac{y^2}{r_0^2} - \frac{z^2}{r_0^2}$. Determine the constant C in such a way that the density $n(\mathbf{r})$ is normalized to the number of atoms in the gas, i.e., $\int_{\mathcal{V}} n(\mathbf{r}) d^3\mathbf{r} = N$, where $\mathcal{V}$ is the volume within which the density is positive, $n(\mathbf{r}) \geq 0$.

9.3.8.10 Ex: Spherical and cylindrical volume

a. Integrate a circular surface with radius R in Cartesian coordinates and then in polar coordinates.
b. The density distribution of a trapped atomic gas is described by $n(\mathbf{r}) = n_0 e^{-r^2/\bar{r}^2}$, where $n_0 = 10^{13}\,\mathrm{cm}^{-1}$ is the maximum density and $\bar{r} = 100\,\mu\mathrm{m}$ a measure for the extent of the distribution. Calculate the number of atoms $N = \int_{\mathbb{R}^3} n(\mathbf{r}) d^3\mathbf{r}$, integrating over Cartesian coordinates and then over polar coordinates.
c. Calculate the density of a homogeneous cylinder of mass 10 kg and length 20 cm by integrating over its volume..
d. The density distribution of a trapped atomic gas is described by
$n(\rho, z) = \max\left\{0, n_0 \cdot \left(1 - \frac{\rho^2}{\rho_m^2} - \frac{z^2}{z_m^2}\right)\right\}$, where $n_0 = 10^{13}\,\mathrm{cm}^{-3}$ is the maximum density and $z_m = 2\rho_m = 100\,\mu\mathrm{m}$ a measure for the extent of the distribution. Calculate the number of atoms by integrating over cylindrical coordinates.

9.3.8.11 Ex: Cylindrical volume

Consider a material (gas or liquid) whose mass density $\rho(\mathbf{r})$ depends on the z-coordinate as follows: $\rho(\mathbf{r}) = \rho_0(1 - \alpha z)$. This material is filled into a cylinder (radius R and height c) until the total mass in the cylinder is M. The cylinder stands in a circular area above the xy in $z = 0$.
a. Calculate the density parameter ρ_0.
b. Calculate vector of center of mass $\mathbf{r}_s$ of the material in the cylinder.
c. Now fill the same material inside a sphere of radius R instead of the cylinder. What are the results in this case if $\alpha = 0.1$ /m, $R = 1$ m, and $M = 10$ kg.
d. A cake of mass M, height h and radius R be cut into fourth equal pieces. Calculate the center of mass of a piece. Calculate the center of mass of the rest of the cake when a piece is taken.

9.3.8.12 Ex: Vector potential in curvilinear coordinates

Be given a constant field $\mathbf{B}$ oriented in z-direction. What is the vector potential $\mathbf{A}$ in (a) spherical coordinates, (b) cylindrical coordinates, and (c) Cartesian coordinates? For case (c) also consider the gauge transformation $\mathbf{A}' = \mathbf{A} + \nabla\lambda$ with $\lambda = \pm Bxy/2$.

9.3.8.13 Ex: Gauß' theorem in curvilinear coordinates

a. Check Gauß' theorem for function $\mathbf{A} = r^2\hat{\mathbf{e}}_r$ using the volume of a sphere of radius R.
b. Do the same for the function $\mathbf{B} = r^{-2}\hat{\mathbf{e}}_r$ and discuss the result.

9.3.8.14 Ex: Gauß' theorem in curvilinear coordinates

Calculate the divergence of the function,

$$\mathbf{A} = r\hat{\mathbf{e}}_r \cos\theta + r\hat{\mathbf{e}}_\theta \sin\theta + r\hat{\mathbf{e}}_\varphi \sin\theta\cos\varphi \ .$$

Verify Gauß's theorem for this function using the volume of an inverted semisphere of radius R lying in the x-y-plane.

9.3.8.15 Ex: Gauß' theorem in curvilinear coordinates

Calculate the gradient and Laplacian of the function $T = r(\cos\theta + \sin\theta\cos\varphi)$. Check the Laplacian by converting T into Cartesian coordinates. Verify Gauß's theorem using the path $l_1(t) = 2\hat{\mathbf{e}}_x \cos\pi t + 2\hat{\mathbf{e}}_y \sin\pi t$ for $t \in [0, 0.5]$ followed by $l_2(t) = 2\hat{\mathbf{e}}_y \sin\pi t - 2\hat{\mathbf{e}}_z \cos\pi t$ para $t \in [0.5, 1]$.

9.3.8.16 Ex: Gauß' theorem in curvilinear coordinates

a. Find the divergence of the function,

$$\mathbf{A} = \rho\hat{\mathbf{e}}_\rho(2 + \sin^2\varphi) + \rho\hat{\mathbf{e}}_\varphi \sin\varphi\cos\varphi + 3z\hat{\mathbf{e}}_z \ .$$

b. Verify Gauß' theorem for this function using a quadrant of cylinder with radius $R = 2$ and height $h = 5$.
c. Find the rotation of $\mathbf{A}$.

9.4 Differential geometry in curved space

In previous sections we mainly concentrated on orthogonal coordinate systems, such as Cartesian, cylindrical, or spherical. In cases one has to use non-orthogonal systems the formalism needs to be generalized. For this purpose it is necessary to introduce some new concepts and notations.

Repeat expressions in index formalism *Einstein's sum rule*, $a^n a_n = \sum_a^n a_n$,

$$\boxed{ds^2 = g_{mn} dx^m dx^n} \ . \tag{9.92}$$

9.4.1 Co- and contravariant tensors

A *contravariant* vector or tangent vector (often abbreviated simply as vector, such as a direction vector or velocity vector) has components that contra-vary with a change of basis to compensate. That is, the matrix that transforms the vector components must be the inverse of the matrix that transforms the basis vectors. Examples of contravariant vectors include the position of an object relative to an observer, or any derivative of position with respect to time, including velocity and acceleration. Contravariant components are denoted with upper indices as in,

$$\mathbf{v} = v^i \mathbf{e}_i \ . \tag{9.93}$$

A *covariant* vector or cotangent vector has components that co-vary with a change of basis. That is, the components must be transformed by the same matrix as the change of basis matrix. Examples of covariant vectors generally appear when taking a gradient of a function. Covariant components are denoted with lower indices as in,

$$\mathbf{w} = w_i \mathbf{e}^i \ . \tag{9.94}$$

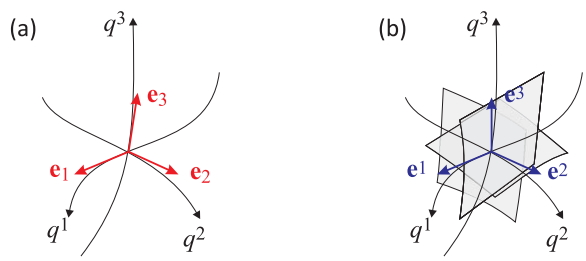

Figure 9.7: (a) Covariant and (b) contravariant basis.

9.4.2 Jacobian for coordinate transformations

The *Jacobian* of a vector field $\mathbf{F}$ is a matrix defined by,

$$\mathbf{J} \equiv \frac{\partial(F_1, .., F_m)}{\partial(x_1, .., x_n)} \equiv \left(\frac{\partial F_m}{\partial x_n} \right) \equiv (J^m_{\ n}) \ . \tag{9.95}$$

We may understand a curvilinear coordinate system $\{x^\mu\}$ as a vector field in Cartesian space $\{x'^\nu\}$,

$$x^\mu = x^\mu(x'^1, .., x'^\nu, .., x'^m) \tag{9.96}$$

for $\mu = 1, .., m$. The Jacobian of this field represents a tool used to transform between the coordinate systems by taking the rate of change of each component of an old basis with respect to each component of a new basis and expressing them as coefficients that make up an old basis. Do the Excs. 9.4.4.2 and 9.4.4.3,

$$\boxed{J^i{}_j \equiv \frac{\partial^i x}{\partial x'^j}} \ . \tag{9.97}$$

Example 40 (*Jacobian for polar coordinates*): For example, the Jacobian matrix that transforms polar coordinates to Cartesian coordinates in 2 dimensions is given by,

$$J^i{}_j = \begin{pmatrix} \partial_r x & \partial_\theta x \\ \partial_r y & \partial_\theta y \end{pmatrix} = \begin{pmatrix} \cos\theta & r\sin\theta \\ \sin\theta & r\cos\theta \end{pmatrix} \ . \tag{9.98}$$

The components of Cartesian basis vectors can now be written as a linear combination of these coefficients and their corresponding polar bases,

$$\begin{aligned} \hat{\mathbf{e}}_x &= \frac{\partial x}{\partial r}\hat{\mathbf{e}}_r + \frac{\partial x}{\partial \theta}\hat{\mathbf{e}}_\theta = \hat{\mathbf{e}}_r\cos\theta - \hat{\mathbf{e}}_\theta r\sin\theta \\ \hat{\mathbf{e}}_y &= \frac{\partial y}{\partial r}\hat{\mathbf{e}}_r + \frac{\partial y}{\partial \theta}\hat{\mathbf{e}}_\theta = \hat{\mathbf{e}}_r\sin\theta + \hat{\mathbf{e}}_\theta r\cos\theta \ . \end{aligned} \tag{9.99}$$

In the case of relating the Jacobian to the *metric* tensor, the Jacobian can be used to transform the components of one metric to another via the following method,

$$g'_{ij} = \frac{\partial}{\partial x'^i}\frac{\partial}{\partial x'^j} = \left(\frac{\partial x^a}{\partial x'^i}\frac{\partial}{\partial x^a}\right)\left(\frac{\partial x^b}{\partial x'^i}\frac{\partial}{\partial x^b}\right) = \frac{\partial x^a}{\partial x'^i}\frac{\partial x^b}{\partial x'^i}\left(\frac{\partial}{\partial x^a}\frac{\partial}{\partial x^b}\right) = J^a{}_i J^b{}_j g_{ab} \ . \tag{9.100}$$

Knowing this, taking the determinant of the metric g_{ij} requires taking the determinant of the Jacobian matrices and g_{ab} as well,

$$\det g'_{ij} = (\det J^a{}_i)(\det J^b{}_j)(\det g_{ab}) \ . \tag{9.101}$$

Since both Jacobian terms are part of the same matrix and are just written using different indices to differentiate between the components of the old basis,

$$(\det J^a{}_i)(\det J^b{}_j) = (\det J)^2 \ . \tag{9.102}$$

In the case of our old basis being written in Cartesian coordinates,

$$\det g_{ab} = \det \mathbb{I} = 1 \ . \tag{9.103}$$

Therefore the equation of our new transformed metric g_{ij}, simplifies to,

$$\det g_{ij} = (\det J)^2 \quad \Longrightarrow \quad \det J = \sqrt{\det g_{ij}} \ . \tag{9.104}$$

It can be shown that,

$$\frac{d}{dt}\frac{\partial(u,v)}{\partial(x,y)} \equiv \frac{\partial(\frac{d}{dt}u, v)}{\partial(x,y)} + \frac{\partial(u, \frac{d}{dt}v)}{\partial(x,y)} \ . \tag{9.105}$$

The *Hessian* is a square matrix of second-order partial derivatives of a scalar field.

9.4.3 Metric and geodesic equation in Euclidean space

For an arbitrary curvilinear coordinate system u^i we define tangent vectors forming a basis,

$$\mathbf{e}_i = \frac{\partial}{\partial u^i} = \partial_i \ , \tag{9.106}$$

the metric tensor is,

$$g_{ij} \equiv \mathbf{e}_i \cdot \mathbf{e}_j \ . \tag{9.107}$$

See also Secs. 6.4 and 17.5.

9.4.3.1 Metric in spherical coordinates

For spherical coordinates,

$$\mathbf{r} = \begin{pmatrix} x \\ y \\ z \end{pmatrix} = \begin{pmatrix} r\sin\theta\cos\phi \\ r\sin\theta\sin\phi \\ r\cos\theta \end{pmatrix} \quad , \quad \begin{pmatrix} r \\ \theta \\ \phi \end{pmatrix} = \begin{pmatrix} \sqrt{x^2+y^2+z^2} \\ \arccos\frac{z}{\sqrt{x^2+y^2+z^2}} \\ \arctan\frac{y}{x} \end{pmatrix} \ , \tag{9.108}$$

the tangent vectors are,

$$\begin{aligned} \mathbf{e}_r &= \frac{\partial \mathbf{r}}{\partial r} = \hat{\mathbf{e}}_x \sin\theta\cos\phi + \hat{\mathbf{e}}_y \sin\theta\sin\phi + \hat{\mathbf{e}}_z \cos\theta = \hat{\mathbf{e}}_r \\ \mathbf{e}_\theta &= \frac{\partial \mathbf{r}}{\partial \theta} = r\hat{\mathbf{e}}_x \cos\theta\cos\phi + r\hat{\mathbf{e}}_y \cos\theta\sin\phi - r\hat{\mathbf{e}}_z \sin\theta = r\hat{\mathbf{e}}_\theta \\ \mathbf{e}_\phi &= \frac{\partial \mathbf{r}}{\partial \phi} = -r\sin\theta\hat{\mathbf{e}}_x \sin\phi + r\sin\theta\hat{\mathbf{e}}_y \cos\phi = r\sin\theta\hat{\mathbf{e}}_\phi \ . \end{aligned} \tag{9.109}$$

Note that, in contrast to the basis vectors $\hat{\mathbf{e}}_i$ the tangent vectors $\mathbf{e}_i$ are not normalized. The spherical metric is,

$$g_{ij} = \frac{\partial x_a}{\partial u^i}\frac{\partial x^a}{\partial u^j} = \begin{pmatrix} \mathbf{e}_r\cdot\mathbf{e}_r & \mathbf{e}_r\cdot\mathbf{e}_\theta & \mathbf{e}_r\cdot\mathbf{e}_\phi \\ \mathbf{e}_\theta\cdot\mathbf{e}_r & \mathbf{e}_\theta\cdot\mathbf{e}_\theta & \mathbf{e}_\theta\cdot\mathbf{e}_\phi \\ \mathbf{e}_\phi\cdot\mathbf{e}_r & \mathbf{e}_\phi\cdot\mathbf{e}_\theta & \mathbf{e}_\phi\cdot\mathbf{e}_\phi \end{pmatrix} = \begin{pmatrix} 1 & 0 & 0 \\ 0 & r^2 & 0 \\ 0 & 0 & r^2\sin^2\theta \end{pmatrix} \ ,$$

with $x_a = x, y, z$, $u^i = r, \theta, \phi$, and the contra-variant spherical metric being,

$$g^{ij} = \frac{\partial u^i}{\partial x_a}\frac{\partial u^j}{\partial x^a} = \begin{pmatrix} 1 & 0 & 0 \\ 0 & r^{-2} & 0 \\ 0 & 0 & r^{-2}\sin^{-2}\theta \end{pmatrix} \ . \tag{9.110}$$

we obtain the contra-variant tangent vectors,

$$\begin{aligned} \mathbf{e}^r &= g^{rr}\mathbf{e}_r = \hat{\mathbf{e}}_x \sin\theta\cos\phi + \hat{\mathbf{e}}_y \sin\theta\sin\phi + \hat{\mathbf{e}}_z \cos\theta = \hat{\mathbf{e}}_r \\ \mathbf{e}^\theta &= g^{\theta\theta}\mathbf{e}_\theta = \frac{1}{r}\hat{\mathbf{e}}_x \cos\theta\cos\phi + \frac{1}{r}\hat{\mathbf{e}}_y \cos\theta\sin\phi - \frac{1}{r}\hat{\mathbf{e}}_z \sin\theta = \frac{1}{r}\hat{\mathbf{e}}_\theta \\ \mathbf{e}^\phi &= g^{\phi\phi}\mathbf{e}_\phi = -\frac{1}{r\sin\theta}\hat{\mathbf{e}}_x \sin\phi + \frac{1}{r\sin\theta}\hat{\mathbf{e}}_y \cos\phi = \frac{1}{r\sin\theta}\hat{\mathbf{e}}_\phi \ . \end{aligned} \tag{9.111}$$

The diagonal shape of the metrics are comes from the fact that spherical coordinates are orthogonal. In the example 41 we discuss the metric of an non-orthogonal coordinate system.

Example 41 (*Metric in elliptical coordinates*): In contrast to polar, cylindrical, or spherical coordinates, elliptical coordinates given by,

$$\mathbf{r} = \begin{pmatrix} x \\ y \end{pmatrix} = \begin{pmatrix} ar\cos\phi \\ br\sin\phi \end{pmatrix} \quad , \quad \begin{pmatrix} r \\ \phi \end{pmatrix} = \begin{pmatrix} \sqrt{(\frac{x}{a})^2 + (\frac{y}{b})^2} \\ \arctan\frac{ay}{bx} \end{pmatrix} , \tag{9.112}$$

are not orthogonal. The tangent vectors are,

$$\begin{aligned} \mathbf{e}_r &= \frac{\partial \mathbf{r}}{\partial r} = \hat{\mathbf{e}}_x a\cos\phi + \hat{\mathbf{e}}_y b\sin\phi \\ \mathbf{e}_\phi &= \frac{\partial \mathbf{r}}{\partial \phi} = -\hat{\mathbf{e}}_x ar\sin\phi + \hat{\mathbf{e}}_y br\cos\phi \ . \end{aligned} \tag{9.113}$$

Note that, in contrast to the basis vectors $\hat{\mathbf{e}}_i$ the tangent vectors $\mathbf{e}_i$ are not normalized. The elliptical metric is,

$$g_{ij} = \frac{\partial x_a}{\partial u^i}\frac{\partial x^a}{\partial u^j} = \begin{pmatrix} \mathbf{e}_r\cdot\mathbf{e}_r & \mathbf{e}_r\cdot\mathbf{e}_\phi \\ \mathbf{e}_\phi\cdot\mathbf{e}_r & \mathbf{e}_\phi\cdot\mathbf{e}_\phi \end{pmatrix} = \begin{pmatrix} a^2\cos^2\phi + b^2\sin^2\phi & (b^2-a^2)r\sin\phi\cos\phi \\ (b^2-a^2)r\sin\phi\cos\phi & (a^2\sin^2\phi + b^2\cos^2\phi)r^2 \end{pmatrix} ,$$

with $x_a = x, y$, $u^i = r, \phi$, and the contra-variant elliptical metric being,

$$g^{ij} = \frac{\partial u^i}{\partial x_a}\frac{\partial u^j}{\partial x^a} = \frac{1}{a^2b^2r^2}\begin{pmatrix} a^2r^2\sin^2\phi + b^2r^2\cos^2\phi & (a^2-b^2)r\sin\phi\cos\phi \\ (a^2-b^2)r\sin\phi\cos\phi & a^2\cos^2\phi + b^2\sin^2\phi) \end{pmatrix} . \tag{9.114}$$

we obtain the cotangent vectors,

$$\begin{aligned} \mathbf{e}^r &= g^{ri}\mathbf{e}_i = g^{rr}\mathbf{e}_r + g^{r\phi}\mathbf{e}_\phi = \hat{\mathbf{e}}_x a^{-1}\cos\phi + \hat{\mathbf{e}}_y b^{-1}\sin\phi \\ \mathbf{e}^\phi &= g^{\phi i}\mathbf{e}_i = g^{\phi r}\mathbf{e}_r + g^{\phi\phi}\mathbf{e}_\phi = -\hat{\mathbf{e}}_x a^{-1}r^{-1}\sin\phi + \hat{\mathbf{e}}_y b^{-1}r^{-1}\cos\phi \ . \end{aligned} \tag{9.115}$$

The fact that the metric is not diagonal is due to the elliptical coordinates not being orthogonal. One verifies,

$$\mathbf{e}^r\cdot\mathbf{e}_\phi = 0 = \mathbf{e}_r\cdot\mathbf{e}^\phi \quad , \quad \mathbf{e}^r\cdot\mathbf{e}_r = 1 = \mathbf{e}_\phi\cdot\mathbf{e}^\phi \ . \tag{9.116}$$

Interestingly, while neither the tangent nor the cotangent vectors are orthogonal, they are mutually orthogonal.

9.4.3.2 Christoffel symbols

The Christoffel symbols are defined by,

$$\Gamma^k{}_{ij} \equiv \frac{\partial \mathbf{e}_i}{\partial x^j}\cdot\mathbf{e}^k \ . \tag{9.117}$$

They yields for spherical coordinates with $j = r, \theta, \phi$,

$$\Gamma^a{}_{ir} = \begin{pmatrix} 0 & 0 & 0 \\ 0 & r^{-1} & 0 \\ 0 & 0 & r^{-1} \end{pmatrix} \quad , \quad \Gamma^a{}_{i\theta} = \begin{pmatrix} 0 & -r & 0 \\ r^{-1} & 0 & 0 \\ 0 & 0 & -\tan\theta \end{pmatrix} \tag{9.118}$$

$$\Gamma^a{}_{i\phi} = \begin{pmatrix} 0 & 0 & -r\cos^2\theta \\ 0 & r^{-1} & \sin\theta\cos\theta \\ r^{-1} & -\tan\theta & 0 \end{pmatrix} .$$

Do the Exc. 9.4.4.4.

9.4.3.3 Geodesic equation

In differential geometry the *geodesic equation* is a curve representing in some sense the shortest path between two points in a surface, or more generally in a Riemannian manifold. It is a generalization of the notion of a 'straight line'. The geodesic line is obtained by solving the differential equation,

$$\frac{d^2x^k}{ds^2} + \Gamma^k{}_{ab}\frac{dx^a}{ds}\frac{dx^b}{ds} = 0 . \tag{9.119}$$

9.4.4 Exercises

9.4.4.1 Ex: Tensors of rank n

Be given $\mathbf{F} = \mathbf{E} + \imath\mathbf{B}$ and $\mathbf{F}^* = \mathbf{E} - \imath\mathbf{B}$. Identify (in this order) the scalar $\mathbf{F}^* \cdot \mathbf{F}/(8\pi)$, teh vector $\mathbf{F}^* \times \mathbf{F}/(8\pi\imath)$, and the dyade (tensor) $(\mathbf{F}^* \cdot \mathbf{F} + \mathbf{F} \cdot \mathbf{F}^*)/(8\pi)$. What happens to these quantities if we exchange $\mathbf{F}$ for $e^{-\imath\phi}\mathbf{F}$, where ϕ is supposed constant?

9.4.4.2 Ex: Jacobian for transformation into curvilinear coordinates

a. Calculate the Jacobian of the transformation from cylindrical coordinates (ρ, z, φ) to Cartesian coordinates (x, y, z).
b. Calculate the Jacobian of the transformation from spherical coordinates (r, θ, φ) to Cartesian coordinates (x, y, z).

9.4.4.3 Ex: Jacobian for Galilei and Lorentz transform

Determine the Jacobean of the Galilei transformation,

$$ct' = ct \quad \text{and} \quad x' = x \quad \text{and} \quad y' = y \quad \text{and} \quad z' = z - \tfrac{u}{c}ct ,$$

and the Lorentz transformation,

$$ct' = \gamma(ct - \tfrac{u}{c}x) \quad \text{and} \quad x' = x \quad \text{and} \quad y' = y \quad \text{and} \quad z' = \gamma(z - \tfrac{u}{c}z) .$$

9.4.4.4 Ex: Christoffel symbols for two-dimensional polar coordinates

Derive the Christoffel symbols for two-dimensional polar coordinates.

9.4.4.5 Ex: Distorted polar coordinates

a. Study the coordinate system,

$$\mathbf{r} = \begin{pmatrix} x \\ y \end{pmatrix} = \begin{pmatrix} f(r)\cos\phi \\ g(r)\sin\phi \end{pmatrix}$$

for arbitrary radial functions $f(r)$ and $g(r)$.
b. Consider the particular cases (i) $f = g$ and (ii) $f = ar$ and $g = br$.

9.4.4.6 Ex: Metric for ellipsoidal coordinates

Generalize the metric for ellipsoidal coordinates.

9.5 Dirac's δ-function

Calculating the divergence of the vector field $\mathbf{A} = \mathbf{r}/r^3$ in spherical coordinates [1],

$$\nabla \cdot \mathbf{A} = \frac{1}{r^2}\frac{\partial}{\partial r}\left(r^2 \frac{1}{r^2}\right) = 0 \ , \tag{9.120}$$

we expect,

$$\int_{\text{sphere}} \nabla \cdot \mathbf{A} dV = 0 \ . \tag{9.121}$$

This is surprising, because intuition tells us to expect a huge divergence near the origin. The problem is that the field $\mathbf{A}$ diverges at the origin, which calls for a modification of the expression for the gradient. Gauß' law gives us an indication since, according to this law, the result (9.121) should be equal to the surface integral,

$$\oint_{\partial \text{ sphere}} \mathbf{A} \cdot d\mathbf{S} = \int_0^{2\pi} \int_0^{\pi} \frac{\hat{\mathbf{e}}_r}{R^2} \cdot (R^2 \sin\theta d\theta d\phi \hat{\mathbf{e}}_r) = 4\pi \ . \tag{9.122}$$

As the integral (9.121) contains a divergence within the volume of integration, we conclude that the integral (9.122), which has no divergence within the integration surface is more reliable. Therefore, we look for a function δ satisfying,

$$\int_{\text{sphere}} \nabla \cdot \mathbf{A}(\mathbf{r}) dV = \int_{\text{sphere}} 4\pi\delta(\mathbf{r}) dV = 4\pi \ , \tag{9.123}$$

that is, a function having the property of killing integrals.

[1] Or in Cartesian coordinates: $\nabla \cdot \mathbf{A} = \frac{\partial}{\partial r^3}\frac{x}{r^3} + \frac{\partial}{\partial r^3}\frac{y}{r^3} + \frac{\partial}{\partial r^3}\frac{z}{r^3} = \frac{3r^3 - 3x^2 r}{r^6} + ... = 0$.

9.5.1 The Dirac function in 1 dimension

In one dimension the *Dirac function* is defined by,

$$\boxed{\delta(x) \equiv \begin{cases} 0 & \text{for} \quad x \neq 0 \\ \infty & \text{for} \quad x = 0 \end{cases}} \ , \tag{9.124}$$

such that,

$$\int_{-\infty}^{\infty} \delta(x) dx = 1 \ . \tag{9.125}$$

The Dirac function can be expressed as the limit of a series of continuous functions,

$$\begin{aligned} \delta(x) &= \lim_{n\to\infty} \frac{n}{\pi} \frac{1}{1+n^2x^2} \qquad (9.126) \\ \delta(x) &= \lim_{n\to\infty} \frac{n}{\pi} \left(\frac{\sin nx}{nx}\right)^2 \\ \delta(x) &= \lim_{n\to\infty} \frac{1}{\pi} \frac{\sin nx}{x} = \lim_{n\to\infty} \frac{1}{2\pi} \int_{-n}^{+n} e^{\imath kx} dk \ . \end{aligned}$$

We also note that the Dirac function is even, $\delta(-x) = \delta(x)$, non-linear, $\delta(ax) = \delta(x)/|a|$, and can be interpreted as the derivative of the *Heavyside function*,

$$\int_{-\infty}^{x} \delta(x') dx' = \Theta(x) \qquad \text{or} \qquad \frac{d\Theta}{dx} = \delta(x) \ . \tag{9.127}$$

We will train the calculus with the Dirac function in Excs. 9.5.4.1 to 9.5.4.3.

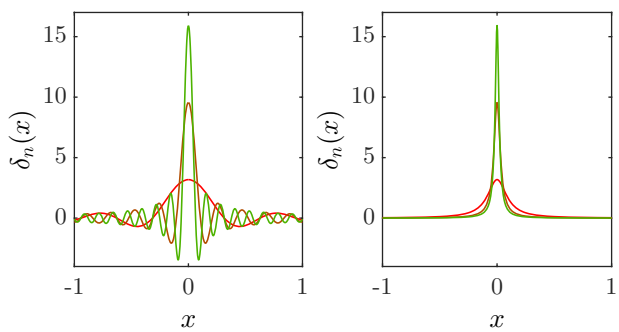

Figure 9.8: (code) Illustration of the function $\frac{1}{\pi}\frac{\sin nx}{x}$ (left) and of the function $\frac{1}{\pi}\frac{n}{1+n^2x^2}$ (right) for various $n \to \infty$.

When the argument of a Dirac function is itself a function $f(x)$, the Dirac is evaluated at each zero-passage of f,

$$\boxed{\int_a^b dx \ g(x)\delta(f(x)) = \int_a^b dx \ g(x) \sum_i \frac{\delta(x-x_i)}{|f'(x_i)|}} \ , \tag{9.128}$$

where $f'(x_i) \neq 0$. We will apply this theorem in Exc. 9.5.4.4.

9.5.2 The Dirac function in 2 and 3 dimensions

In more dimensions the δ-function is often used to parametrize points, paths, or surfaces within a volume. For example, a point charge Q at the position $\mathbf{a}$ can be described by the three-dimensional density distribution,

$$\rho(\mathbf{r}) = Q\delta^3(\mathbf{r}-\mathbf{a}) = Q\delta(x-a_x)\delta(y-a_y)\delta(z-a_z) \ , \tag{9.129}$$

a current I in a circular loop with radius R within the $z=0$ plane generates a current density,

$$\mathbf{j} = I\delta(r-R)\delta(z)\hat{\mathbf{e}}_\phi \ , \tag{9.130}$$

called a *current yarn*. Similarly, a two-dimensional arrangement of charges σ homogeneously distributed over the surface of a sphere with radius R can be described by the three-dimensional density distribution,

$$\rho(\mathbf{r}) = \sigma\delta(r-R) \ . \tag{9.131}$$

Such parametrizations are useful, because they can be applied in fundamental laws of electromagnetism (see Exc. 9.5.4.5).

Example 42 (*Parametrization of a current distribution*): As an example we calculate the current I produced by the distribution (9.130) crossing a rectangular area around the point $\mathbf{r} = R\hat{\mathbf{e}}_x$,

$$\int_{area} \mathbf{j}\cdot d\mathbf{A} = I\int_{R-\Delta x}^{R+\Delta x}\int_{-\Delta z}^{\Delta z}\delta(r-R)\delta(z)\hat{\mathbf{e}}_y d\mathbf{A} = I\int_{r-\Delta x}^{r+\Delta x}\delta(x-R)dx = I \ .$$

Example 43 (*Parametrization of a charge distribution*): In another example we calculate the total charge Q produced by the distribution (9.131),

$$\int_{volume}\rho(\mathbf{r})dV = \sigma\int_0^{2\pi}\int_0^{\pi}\int_0^{\infty}\delta(r-R)r^2\sin\theta d\theta d\phi dr = \sigma 4\pi R^2 = Q \ .$$

Example 44 (*Dirac function in Coulomb's Law*): In a third example we show that the field of a point charge, $\varrho(\mathbf{r}) = Q\delta(x)\delta(y)\delta(z)$, can be obtained from Coulomb's law,

$$\vec{\mathcal{E}} = \int \frac{\varrho(\mathbf{r}')}{4\pi\varepsilon_0}\frac{\mathbf{r}-\mathbf{r}'}{|\mathbf{r}-\mathbf{r}'|^3}dV' = \frac{Q}{4\pi\varepsilon_0}\frac{\mathbf{r}}{r^3} \ .$$

9.5.3 Analytical signals

In signal processing theory, an *analytic signal* is a complex-valued function without negative frequency components. The real and imaginary parts of an analytic signal are mutually related by a *Hilbert transform*. Conversely, the analytic representation of a real-valued function is an analytic signal, which comprises the original function and its Hilbert transform. This representation facilitates many mathematical manipulations. The basic idea is that the negative frequency components of the Fourier transform

(or spectrum) of a real function are superfluous due to the Hermitian symmetry of such a spectrum. These negative-frequency components can be discarded without loss of information, as long as we are willing to deal with a complex function. This makes certain attributes of the function more accessible, particularly for application in radiofrequency manipulation techniques.

While the manipulated function has no negative frequency components (that is, it is still analytic), the inverse conversion from complex to real is just a matter of discarding the imaginary part. The analytical representation is a generalization of the *phasor* concept: while the phasor is restricted to time-invariant amplitudes, phases and frequencies, the analytic signal allows for temporally variable parameters.

9.5.3.1 Transfer function generating an analytical signal

We consider a real function $s(t)$ with its Fourier transform $S(f)$. Then the transformed function exhibits a Hermitian symmetry about the point $f = 0$, since,

$$S(-f) = S(f)^* \ , \tag{9.132}$$

The function,

$$S_{\mathrm{a}}(f) \equiv \begin{cases} 2S(f) & \text{for } f > 0 \\ S(f) & \text{for } f = 0 \\ 0 & \text{for } f < 0 \end{cases} = S(f) + \mathrm{sgn}(f)S(f) \ , \tag{9.133}$$

where $\mathrm{sgn}(f)$ calculates the sign of f, only contains the non-negative components of $S(f)$. This operation is reversible due to the Hermitian symmetry of $S(f)$:

$$S(f) = \begin{cases} \frac{1}{2}S_{\mathrm{a}}(f) & \text{para } f > 0 \\ S_{\mathrm{a}}(f) & \text{para } f = 0 \\ \frac{1}{2}S_{\mathrm{a}}(-f)^* & \text{para } f < 0 \end{cases} = \tfrac{1}{2}[S_{\mathrm{a}}(f) + S_{\mathrm{a}}(-f)^*] \ . \tag{9.134}$$

The analytical signal of $s(t)$ is the inverse Fourier transform of $S_{\mathrm{a}}(f)$,

$$\begin{aligned} s_{\mathrm{a}}(t) &\equiv \mathcal{F}^{-1}[S_{\mathrm{a}}(f)] = \mathcal{F}^{-1}[S(f) + \mathrm{sgn}(f) \cdot S(f)] \\ &= \mathcal{F}^{-1}[S(f)] + \mathcal{F}^{-1}[\mathrm{sgn}(f)] \star \mathcal{F}^{-1}[S(f)] = s(t) + \imath \left[\tfrac{1}{\pi t} \star s(t)\right] = s(t) + \imath \hat{s}(t) \ , \end{aligned} \tag{9.135}$$

where $\star$ denotes the convolution.

$$\boxed{\hat{s}(t) \equiv \mathcal{H}[s(t)] \equiv \tfrac{1}{\pi t} \star s(t) = \tfrac{1}{\pi}\mathcal{P}\int_{-\infty}^{\infty} \frac{s(\tau)}{t-\tau} d\tau} \ , \tag{9.136}$$

with $\mathcal{P}$ denoting Cauchy's principal value, is the definition of the *Hilbert transform* of $s(t)$ [2].

[2] Also holds,

$$\begin{aligned} \hat{s}(t) &= -\tfrac{1}{\pi} \lim_{\epsilon \to 0} \int_{\epsilon}^{\infty} \frac{s(t+\tau) - s(t-\tau)}{\tau} d\tau \\ \mathcal{H}(\mathcal{H}(s))(t) &= -s(t) \ . \end{aligned}$$

Example 45 (*Analytical signal of the cosine function*): We consider the signal $s(t) = \cos\omega t$, where $\omega > 0$. Now

$$\hat{s}(t) = \cos(\omega t - \tfrac{\pi}{2}) = \sin\omega t \ ,$$
$$s_{\rm a}(t) = s(t) + \imath\hat{s}(t) = \cos\omega t + \imath\sin\omega t = e^{\imath\omega t} \ .$$

In general, the analytical representation of a simple sinusoidal function is obtained by expressing it in terms of complex exponentials, discarding the negative frequency components, and doubling the positive frequency components, as in the example $s(t) = \cos(\omega t + \theta) = \frac{1}{2}(e^{\imath(\omega t+\theta)} + e^{-\imath(\omega t+\theta)})$. Here, we get directly from Euler's formula,

$$s_{\rm a}(t) = \begin{cases} e^{\imath(\omega t+\theta)} & = & e^{\imath|\omega|t}e^{\imath\theta} & \text{if } \omega > 0 \\ e^{-\imath(\omega t+\theta)} & = & e^{\imath|\omega|t}e^{-\imath\theta} & \text{if } \omega < 0 \end{cases} \ .$$

The analytical representation of a sum of sinusoidal functions is the sum of the analytical representations of the individual sinuses.

We note that it is not forbidden to compute $s_{\rm a}(t)$ for a complex $s(t)$. But this representation may be irreversible, since the original spectrum is usually not symmetric. Therefore, with the exception of the case $s(t) = e^{-\imath\omega t}$ with $\omega > 0$, where,

$$\hat{s}(t) = \imath e^{-\imath\omega t} \tag{9.137}$$
$$s_{\rm a}(t) = e^{-\imath\omega t} + \imath^2 e^{-\imath\omega t} = e^{-\imath\omega t} - e^{-\imath\omega t} = 0 \ ,$$

we assume real $s(t)$.

We also note that, since $s(t) = \mathfrak{Re}\,[s_{\rm a}(t)]$, we can retrieve the negative-frequency components simply by discarding $\mathfrak{Im}\,[s_{\rm a}(t)]$, which may seem counterintuitive. On the other hand, the conjugate complex part $s_{\rm a}^*(t)$ contains only the negative-frequency components. Therefore, $s(t) = \mathfrak{Re}\,[s_{\rm a}^*(t)]$ retrieves the suppressed positive frequency components. In Exc. 9.5.4.7 we calculate the intensity of an electromagnetic wave.

9.5.3.2 Envelope and instantaneous phase

An analytical signal can also be expressed in polar coordinates,

$$s_{\rm a}(t) = |s_{\rm a}(t)|e^{\imath\phi(t)} \ , \tag{9.138}$$

in terms of an instantaneous amplitude or *envelope* $|s_{\rm a}(t)|$ varying with time and an instantaneous phase angle $\phi(t) \equiv \arg[s_{\rm a}(t)]$. In Fig. 9.9 the blue curve shows $s(t)$ and the red curve shows $|s_{\rm a}(t)|$.

The time derivative of the unwrapped instantaneous phase is the instantaneous angular frequency,

$$\omega(t) \equiv \frac{d\phi(t)}{dt} \ . \tag{9.139}$$

The instantaneous amplitude and the instantaneous phase and frequency are used in some applications to measure and detect local characteristics of the signal or to describe the demodulation of a modulated signal. Polar coordinates conveniently separate amplitude and phase modulation effects.

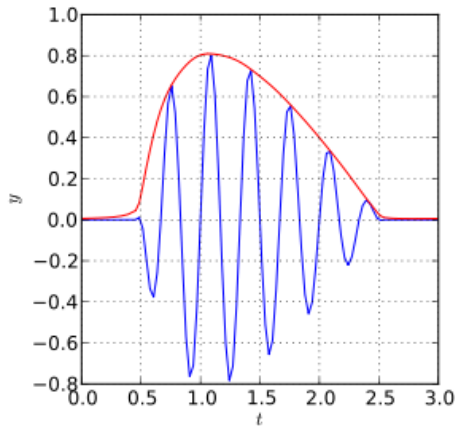

Figure 9.9: Illustration of a function (blue) and the magnitude of its analytical representation (red).

Analytical signals are often frequency-shifted (down-converted) to 0 Hz, which can create negative (non-symmetric) frequency components:

$$s'_{\mathrm{a}}(t) \equiv s_{\mathrm{a}}(t)e^{-\imath\omega_0 t} = s_m(t)e^{\imath(\phi(t)-\omega_0 t)} \ , \tag{9.140}$$

where ω_0 is an arbitrary reference angular frequency. The function $s'_{\mathrm{a}}(t)$ is called *complex envelope* or 'baseband'. The complex envelope is not unique, but determined by the choice of ω_0. This concept is often used to deal with band-pass signals. When $s(t)$ is a modulated signal, ω_0 is conveniently chosen as the carrier frequency.

9.5.4 Exercises

9.5.4.1 Ex: Dirac's δ function

a. Calculate $\int_0^\pi \ d\theta \ \sin^3\theta \ \delta(\cos\theta - \cos\frac{\pi}{3})$.
b. Now, be $\mathbf{r}_0$ a fixed three-dimensional vector with Cartesian coordinates x_0, y_0, and z_0. For the three-dimensional δ-function holds,

$$\int\limits_V f(\mathbf{r})\delta(\mathbf{r}-\mathbf{r}_0)d^3r = \begin{cases} f(\mathbf{r}_0) & \text{if } \mathbf{r}_0 \text{ is within the volume } V \\ 0 & \text{else} \end{cases} .$$

In Cartesian coordinates, $\delta^{(3)}(\mathbf{r}-\mathbf{r}_0) \equiv \delta(x-x_0)\delta(y-y_0)\delta(z-z_0)$. Express $\delta^{(3)}(\mathbf{r}-\mathbf{r}_0)$ in cylindrical coordinates (ρ, φ, z) as a product of three one-dimensional functions δ in $\rho-\rho_0$, $\varphi-\varphi_0$, and $z-z_0$.

9.5.4.2 Ex: Dirac's δ function

Calculate the following expressions:
a. $\int_{-1}^{+1} \delta(x)[f(x)-f(0)] \ dx$,
b. $\int_{-1}^{3} (x^3-x)\sin\left(\frac{\pi}{4}x\right)\delta(x-2) \ dx$,

c. $\int_0^{2\pi} \sin x \; \delta(\cos x) dx$,
d. $\int_{\mathbb{R}^3} \delta(r-R) d^3\mathbf{r}$,
e. $\int_{\mathbb{R}^3} \delta(r-R)\delta(z) d^3\mathbf{r}$,
f. $\int_{-\infty}^{\infty} \left(\frac{d}{dx}\delta(x)\right) f(x) dx$ por integration parcial,
g. $\int_{-\infty}^{\infty} \left(\frac{d^n}{dx^n}\delta(x)\right) f(x) dx$.

9.5.4.3 Ex: Dirac's δ function

Show,

$$\int_{-\infty}^{\infty} 1 \cdot \hat{f}(k) dk = \int_{-\infty}^{\infty} \hat{1}(x) f(x) dx = 2\pi f(0) \ ,$$

where $\hat{f}(k) \equiv \int_{-\infty}^{\infty} e^{-\imath kx} dx$ is the Fourier transform and $f(x) \equiv \int_{-\infty}^{\infty} e^{\imath kx} dk$ the inverse transform. Also show,

$$\hat{1} = 2\pi\delta(x) \ .$$

Help: $1 = e^{\imath k 0}$.

9.5.4.4 Ex: Dirac's δ function

The following properties are, among others, characteristics for Dirac's δ-function,

$$\int_{\mathrm{a}}^{b} f(x)\delta(x-c) \; dx = \begin{cases} f(c) & \text{if } c \in [a,b] \\ 0 & \text{else} \end{cases} \ .$$

Being $g(x)$ a function with simple zero passages x_n, that is, $g(x_n) = 0$ and $g'(x_n) \neq 0$, we have

$$\delta(g(x)) = \sum_n \frac{1}{|g'(x_n)|} \delta(x - x_n) \ .$$

Use these relationships to solve the following integrals,
a. $\int_{-2}^{5} \; dx \; (x^2 - 5x + 6) \; \delta(x-3)$.
b. $\int_{-\infty}^{\infty} \; dx \; x^2 \; \delta(x^2 - 3x + 2)$.

9.5.4.5 Ex: Dirac's δ function

Demonstrate the following property of the δ-function:

$$\delta(\omega_1 - \omega)\delta(\omega_2 - \omega) = \frac{\delta(\omega_1 - \omega) + \delta(\omega_2 - \omega)}{|\omega_1 - \omega_2|} \ .$$

9.5.4.6 Ex: Parametrization of currents

Parametrize the current density $\mathbf{j}(\mathbf{r}')$ of a current loop
a. in Cartesian coordinates and
b. in spherical coordinates.

9.5.4.7 Ex: Intensity of an electromagnetic wave

Calculate the intensity of the electromagnetic wave given by (a) $\vec{\mathcal{E}}(\mathbf{r},t) = \vec{\mathcal{E}}_0 \cos(kz - \omega t)$ and (b) $\vec{\mathcal{E}}(\mathbf{r},t) = \vec{\mathcal{E}}_0 e^{\imath kz - \imath\omega t}$. Discuss!

Chapter 10

Electrostatics

We have already seen that all electromagnetic phenomena are due to charges, that these charges are quantized and conserved, and that the superposition principle holds for electromagnetic forces. In principle, it should be possible to explain all electromagnetic phenomena by calculation the forces exerted by every charge on every other charge for arbitrary charge distributions. In reality however, the situation is much more complex, because the forces not only depend on the position of the charges, but also on their speed and acceleration. In addition, any information on the actual state of a charge is only transmitted at the finite speed of light, which gives rise to retardation effects.

To simplify the problem we will initially only consider immobile charges. The theory dealing with immobile electric charges is named *electrostatics*. Its fundamental task of electrostatics resides in calculating the force exerted by spatial distributions of charges.

10.1 The electric charge and the Coulomb force

10.1.1 Quantization and conservation of the charge

We know that ordinary matter consists of electrically neutral atoms. An atom, consists of a heavy nucleus and a shell of very light-weighted electrons. The nucleus, in turn, is made up of a number of protons and neutrons. Each proton carries a positive elementary charge $Q = +e$, that is, the charge is quantized in units of e. For an atom to be neutral, the number of electrons (with negative charge $-e$) in the shell must be equal to the number of atoms.

Macroscopic bodies are usually neutral, but that does not mean that positive and negative charges are annihilated. What they can do, is to bunch by equal numbers within restricted regions of space. Then, the forces exerted by the positive and negative charges of a specific region on other far-away charges compensate each other. This effect is called shielding.

Nevertheless, it is possible, exerting work, to separate positive and negative charges, to generate polarizations in dielectric materials or currents in conducting metals, and to perform experiments with electrically charged macroscopic objects.

10.1.2 Coulomb's law

To begin with, we consider a single point charge Q at the position $\mathbf{r}'$ exerting a force on another charge located in $\mathbf{r}$. The so-called *Coulomb force* is,

$$\mathbf{F}_{\mathrm{C}} = \frac{Qq}{4\pi\varepsilon_0}\frac{\mathbf{r}-\mathbf{r}'}{|\mathbf{r}-\mathbf{r}'|^3} \ , \tag{10.1}$$

where ε_0 is a constant called the permittivity of free space. The Coulomb force decreases quadratically with the distance and is directed along the straight line connecting the two charges. Note that the force can be attractive (for $Qq < 0$) or repulsive (for $Qq > 0$). See the Excs. 10.1.3.1 to 10.1.3.22.

According to the *superposition principle* the force acting on the charge is not influenced by the possible existence of other forces, for example, exerted by other charges Q_k located in other positions $\mathbf{r}_k$,

$$\mathbf{F} = \mathbf{F}_1 + \mathbf{F}_2 + ... = \sum_k \frac{Q_k q}{4\pi\varepsilon_0}\frac{\mathbf{r}-\mathbf{r}_k}{|\mathbf{r}-\mathbf{r}_k|^3} \ . \tag{10.2}$$

Introducing an abbreviation,

$$\vec{\mathcal{E}} = \sum_k \frac{Q_k}{4\pi\varepsilon_0}\frac{\mathbf{r}-\mathbf{r}_k}{|\mathbf{r}-\mathbf{r}_k|^3} \ , \tag{10.3}$$

called the *electric field*, we can express the Coulomb force as,

$$\boxed{\mathbf{F}_{\mathrm{C}} = q\vec{\mathcal{E}}} \ . \tag{10.4}$$

Using the Dirac function we can parametrize the distribution of charges by,

$$\varrho(\mathbf{r}) = \sum_k Q_k \delta^3(\mathbf{r}-\mathbf{r}_k) \ . \tag{10.5}$$

The charge of a single electron is small, and often many charges are involved in electrical phenomena. Thus, the discrete character of the charge does not appear, and the charge distribution appears as a smooth distribution of *charge density*, such that,

$$\int_{\mathbb{R}} \varrho(\mathbf{r}')dV' = \int_{\mathbb{R}} \sum_k Q_k \delta^3(\mathbf{r}'-\mathbf{r}_k)dV' = \sum_k Q_k \ . \tag{10.6}$$

With this (fluid model) approximation,

$$\sum_k Q_k ... \longrightarrow \int dV' \varrho(\mathbf{r}')... \ , \tag{10.7}$$

the *Coulomb law* can be written,

$$\boxed{\vec{\mathcal{E}} = \int \frac{\varrho(\mathbf{r}')}{4\pi\varepsilon_0}\frac{\mathbf{r}-\mathbf{r}'}{|\mathbf{r}-\mathbf{r}'|^3}dV'} \ , \tag{10.8}$$

since by inserting the discrete distribution (10.5) we recover Coulomb's law (10.3).

It is also possible to define from ϱ a two-dimensional *surface charge density* σ or a one-dimensional *linear charge density* λ using the Dirac function. For example, the surface charge density on a spherical shell,

$$\varrho(\mathbf{r}) = \sigma(\theta, \phi)\delta(r - R) \ , \tag{10.9}$$

or the linear charge density on a ring,

$$\varrho(\mathbf{r}) = \lambda(\phi)\delta(r - R)\delta(z) \ . \tag{10.10}$$

Substituting ϱ of the Coulomb law with these expressions, we reduce the dimensionality of the integral. We will study problems related to charge distributions in the Excs. 10.2.4.1 to 10.2.4.12.

10.1.3 Exercises

The exercises showing a • are taken from Tipler's book [921].

10.1.3.1 Ex: • Coulomb force

A point charge of $-2.0\,\mu\text{C}$ and a point charge of $4.0\,\mu\text{C}$ are separated by a distance L. Where should a third point charge be placed in order for the electrostatic force on this third charge to be zero?

10.1.3.2 Ex: • Coulomb force

A point particle with a charge of $-1.0\,\mu\text{C}$ is located at the origin; a second point particle with a charge of $2.0\,\mu\text{C}$ is located at $x = 0$, $y = 0.1\,\text{m}$; and a third point particle with a charge of $4.0\,\mu\text{C}$ is located at $x = 0.2\,\text{m}$, $y = 0$. Determine the electrostatic force on each of the three particles.

10.1.3.3 Ex: • Coulomb force

A point charge of $-5.0\,\mu\text{C}$ is located at $x = 4.0\,\text{m}$, $y = -2.0\,\text{m}$, and a second point charge of $12.0\,\mu\text{C}$ is located at $x = 1.0\,\text{m}$, $y = 2.0\,\text{m}$.
a. Determine the absolute value, the direction and the orientation of the electric field in $x = -1.0\,\text{m}$, $y = 0$.
b. Calculate the absolute value, the direction and the orientation of the electric force acting on an electron placed in the electric field at $x = -1.0\,\text{m}$, $y = 0$.

10.1.3.4 Ex: Coulomb force

Imagine an electron near the Earth's surface. At what point should we place a second electron in order for the electrostatic force between the electrons to compensate the gravitational force acting on the first electron?

10.1.3.5 Ex: Coulomb force

Three positive point charges Q_1, Q_2, and Q_3 are placed at the corners of an equilateral triangle with the edge length $L = 10\,\text{cm}$. Calculate the value and direction of the force acting on an electron located in the center of the triangle.

10.1.3.6 Ex: Coulomb force

Two particles carrying equal charges q are placed at a mutual distance of $r = 3\,\mathrm{mm}$ and then released. The acceleration of the first particle after having been released is $a_1 = 7\,\mathrm{m/s^2}$, and the acceleration of the second particle is $a_2 = 2\,\mathrm{m/s^2}$. The mass of the first particle is $m_1 = 6 \cdot 10^{-7}\,\mathrm{kg}$.
a. What is the mass of the second particle?
b. What is the charge of the particles?

10.1.3.7 Ex: Coulomb force

A small ball of graphite (mass $m = 1\,\mathrm{kg}$) suspended on a wire is touched by an electrically charged plastic stick and picks up 1% of its charge. The result is that the ball is displaced by an angle of 30°, while the stick is held in place at the former position of the ball. The distance between the center of the ball and the end of the stick is 10 cm.
a. Calculate the force exerted by the wire on the ball?
b. Assume that the charge on the stick is fully concentrated at its end. What are the charges on the ball and on the stick?

10.1.3.8 Ex: • Acceleration of charges

An electron has an initial velocity of $v_0 = 2 \cdot 10^6\,\mathrm{m/s}$ in $+x$-direction. It enters a region of uniform electric field $\vec{\mathcal{E}} = (300\,\mathrm{N/C})\,\hat{\mathbf{e}}_x$.
a. Determine the acceleration of the electron.
b. How long does it take for the electron to travel a distance of $s = 10.0\,\mathrm{cm}$ along the x-axis towards $+x$ in the region that has field.
c. At what angle and in what direction does the motion of the electron deflect as it travels 10.0 cm in x-direction?

10.1.3.9 Ex: • Acceleration of charges

A charged particle of 2.0 g is released from rest in a region that has a uniform electric field, $\vec{\mathcal{E}} = (300\,\mathrm{kN/C})\hat{\mathbf{e}}_x$. After traveling a distance of 0.5 m in this region, the particle has a kinetic energy of 0.12 J. Determine the particle's charge.

10.1.3.10 Ex: Charged copper coins

The positive proton charge and the negative electron charge have the same absolute value. Assume that the absolute values would have a relative difference of only 0.0001%. Consider copper coins with $3 \cdot 10^{22}$ atoms. What would be the repulsive force of two coins 1 m apart?
Help: A neutral copper atom contains 29 protons and the same amount of electrons.

10.1.3.11 Ex: Weight of the electron

A metal sphere is charged with $Q = +1\,\mu\mathrm{C}$. Determine whether the mass of the sphere increases or decreases due to the charging and calculate the value?

10.1.3.12 Ex: The hydrogen atom

In the hydrogen atom the typical distance between the positively charged proton and the negatively charged electron is $d \sim 5 \cdot 10^{-11}$ m.
a. Calculate the Coulomb force.
b. Compare this force with the gravitational force between the two particles.
c. What should be the speed of the electron around the nucleus to compensate for the gravitational attraction by the centrifugal force?

10.1.3.13 Ex: Exercise of understanding

Two metallic spheres are placed at a distance d from each other and respectively charged with $+Q$ and $-2Q$.
a. Do spheres attract or repel each other?
b. What happens if we let the spheres contact each other and then put them at the same distance d. How much does the force change?

10.1.3.14 Ex: Charged sphere on a spring

A ball with the m is suspended on a spring with the spring constant f.
a. What will be the displacement of the ball due to its weight? What will be the frequency of oscillation?
b. Now the ball is loaded with the charge Q and a second ball with the same charge is approached from below the first ball. Derive the relationship between the position of the first ball z_1 and the position of the second z_2. The position $z_1 = 0$ is the resting position of the spring, that is, the position that the spring would have without suspended mass. CAUTION: you'll get a third order equation in z_1, don't try to solve it!
c. For which position z_2 of the second ball does the first ball stay at the resting position of the spring, that is, for which z_2 do we find $z_1 = 0$ to be solution? Are there any other solutions? What are your interpretations?
d. What is the frequency of oscillation under these conditions, when ball 1 is only slightly displaced around $z_1 = 0$? Use the approximation $\frac{1}{(a-x)^2} \approx \frac{1}{a^2} + \frac{2}{a^3}x$, which holds for $x \ll a$.

10.1.3.15 Ex: Stability of a charge distribution

The charge distributions shown in the figure are given. All positive and negative charges have the same absolute value.
a. Determine whether one of these distributions is stable? What happens in different cases?
b. Is it possible to choose the absolute values of the charges in such a way as to make the configurations stable?

10.1.3.16 Ex: Stability of a charge distribution

Three balls with mass m and each charged with the charge Q are placed in a parabolic bowl. This can be described as a surface in space, where the coordinate z of the surface is given by $z = z(x, y) = A(x^2 + y^2)$. Gravitation shows into $-\hat{\mathbf{e}}_z$ direction. What is

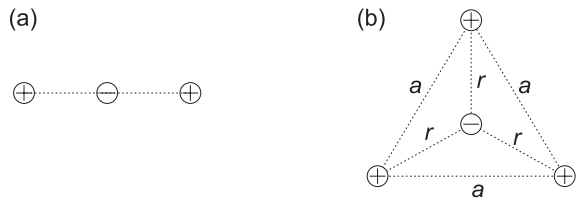

Figure 10.1: Geometry of charge distribution.

the distance the balls adopt, when we set as an additional condition, that all charges are at the same height?

10.1.3.17 Ex: Ions in a harmonic potential

Two ions with the positive charge $+e$ are confined to an isotropic harmonic potential. Each ion has the potential energy $U = \frac{1}{2}m\omega^2 r^2$, where r is the distance from the center of the potential. The ions are at rest, only consider two dimensions.
a. What is the distance of the two ions from the center?
b. Calculate the distance for three identical ions.

10.1.3.18 Ex: Spheres on a wire

Two identical spheres with mass $m = 0.1\,\mathrm{kg}$ are suspended at the same point of a ceiling by a 1 m long wire and have the same charge. What is the value of the charge if the two centers of the spheres are 4 cm apart. Use the approximation $\sin\alpha \approx \tan\alpha \approx \alpha$ for small angles α.

10.1.3.19 Ex: Oscilloscope

We consider a simple model of an oscilloscope. Inside the device is a Braun tube, inside which electrons are accelerated by a voltage U to a speed v. Then, the electrons fly through the plates of a capacitor and are deflected by the electric field E of the capacitor. (In a real oscilloscope there are two capacitors: one for horizontal deviation and one for vertical.) Behind the capacitor, the electrons fly to a screen, where they produce a bright spot.
a. Calculate the electron velocity v for an accelerating voltage of $U = 1\,\mathrm{kV}$. (Do not consider relativistic effects!)
b. The capacitor has a length of $l = 5$ cm and a distance from the plates of $d = 2\,\mathrm{cm}$. What is the maximum allowable voltage $U_{\max}$ at the capacitor to prevent electrons from hitting one of the capacitor plates? (Electrons enter the capacitor in the center between the plates.)
c. What should be the distance between the plates and the screen (which is 10 cm wide), so that with maximum voltage $U_{\max}$ the entire area of the screen is used?
Comment: Disregard capacitor edge effects!

10.1.3.20 Ex: Electron between charged plates

Between two parallel horizontal plates there is a homogeneous electric field $|\vec{\mathcal{E}}| = 2 \cdot 10^3\,\mathrm{N/C}$. The lower plate is charged with a positive charge, the upper plate with a negative, such that the field is oriented upwards. The length of the plates is $L = 10\,\mathrm{cm}$, their distance $d = 2\,\mathrm{cm}$. From the left edge of the bottom plate an electron is shot at an initial velocity $|v_0| = 6 \cdot 10^6\,\mathrm{m/s}$ under an angle $45°$ into the space between the plates.
a. When will the electron hit one of the plates?
b. Which plate is eventually hit and at what horizontal distance from the firing point?

10.1.3.21 Ex: The Coulomb-Kepler problem

We consider two particles charged with charges Q_1 and Q_2 and masses $m = m_1 = m_2$ which, for simplicity, can only move along the $\hat{\mathbf{e}}_z$-axis and are subject to mutual Coulomb forces.
a. Derive the differential equations for the positions z_1 and z_2 of the two particles. Reduce the number of variables of the problem by introducing the difference variable $z = z_2 - z_1$ and establish the differential equation for z.
b. The differential equation obtained has the same shape as that of the Kepler problem in mechanics, which, however, is not defined along an axis but on a plane. What are the solutions to Kepler's problem? What important physical quantity does not appear to constrain the freedom of movement to one axis? What would be the impact of this constraint on the solutions to Kepler's problem? What is the additional degree of freedom in the Coulomb-Kepler problem as compared to the Kepler problem?
c. Kepler's differential equation is not easy to solve. Even so, we can learn something by looking at the phase space diagram. For this, we consider two identical particles $Q = Q_1 = Q_2$ and $m = m_1 = m_2$, placed at a distance z_0. What is going to happen? How will the velocities v_1 and v_2 of the two particles behave with respect to each other? Derive a relationship between the distance z and the velocity v of one of the particles (energy conservation). What is the value of the velocity for $z \to \infty$? Prepare a phase space diagram in (z, v) for three different distances z_0.

10.1.3.22 Ex: • Particle spinning around a charged wire

An infinitely long line uniformly charged with negative charge, has a charge density of λ and is located on the z-axis. A small positively charged particle has mass m and a charge q and is on circular orbit of radius R in the xy-plane centered on the charge line.
a. Deduce an expression for the velocity of the particle.
b. Obtain an expression for the period of the particle's orbit.

10.2 Properties of the electric field

In principle the fundamental problem of electrostatics is solved by Coulomb's law. In practice however, the calculation of the electric field generated by a charge distribution can be complicated. On the other hand, electrostatic problems often exhibit

symmetries, which allow for their resolution by other techniques avoiding the integrals of Coulomb's law.

10.2.1 Field lines and the electric flux

When we calculate the electric vector field for a charge distribution on a matrix of points in space, we get diagrams like the one shown in Fig. 10.2. The arrows represent, through the lengths of the vectors, the value of the field and, through the orientation of the vector, the direction of the force exerted by the field. The diagram suggests to connect the arrows thus forming lines called *field lines*. These lines are nothing more than the trajectories taken by test charges placed inside the field [1]. Field lines can never intersect (otherwise the direction of force acting on a test charge would be ambiguous) and can never begin or end in free space. They always start from a positive charge and end up in a negative charge.

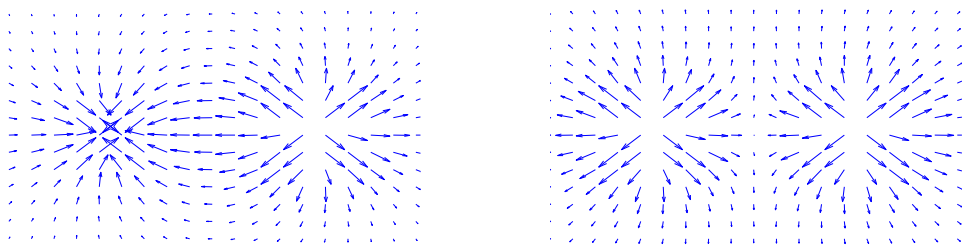

Figure 10.2: Field lines of two equal charges (right) and two opposed charges (left).

The *electric flux* is a measure for the density of field lines crossing a surface. As we have already said, the field line density corresponds to the amplitude of the electric field $\vec{\mathcal{E}}$. The normal vector of the surface $\mathbf{S}$ being locally perpendicular to the plane, we must calculate the flux by taking the integral of the scalar product,

$$\boxed{\Psi_E \equiv \int_{\mathcal{S}} \vec{\mathcal{E}} \cdot d\mathbf{S}} \,. \tag{10.11}$$

Then, instead of illustrating the amplitude of a field through the length of the arrows representing the force exerted on a charge, $\vec{\mathcal{E}} \propto \mathbf{F}$, we can illustrate the amplitude through the local density of lines field, $\vec{\mathcal{E}} \propto \Psi_E$.

The concept of the flux allows us to quantitatively formulate the statement, that field lines can not start or end in free space, but always come out (or penetrate) into charges. For this, we calculate the flux through a sphere around an electric charge q located at the origin using Coulomb's law:

$$\oint_{\text{spherical surface}} \vec{\mathcal{E}} \cdot d\mathbf{S} = \oint_{\text{spherical surface}} \frac{1}{4\pi\varepsilon_0} \frac{q}{|\mathbf{r}|^2} \hat{\mathbf{e}}_{\mathbf{r}} \cdot r^2 \sin\theta d\theta d\phi \hat{\mathbf{e}}_{\mathbf{r}} = \frac{q}{\varepsilon_0} \,. \tag{10.12}$$

[1] Note, that the representation by lines (instead of vectors) misses the information about the local field strength. However, this information is still encoded in the local density of the field lines.

With the superposition principle we can generalize this result to arbitrary distributions of charges Q. The so-called *Gauß' law*, or Maxwell's third equation,

$$\boxed{\oint_{\partial\mathcal{V}} \vec{\mathcal{E}} \cdot d\mathbf{S} = \frac{Q}{\varepsilon_0}} \ , \tag{10.13}$$

states, that the number of field lines entering a charge-free volume $\mathcal{V}$ through a closed surface $\partial\mathcal{V}$ must equal the number of lines leaving it. The law also states that *there exist electric charges* acting as sources or drains of field lines. We will resolve flux problems in the Excs. 10.2.4.13 to 10.2.4.29.

10.2.2 Divergence of the electric field and Gauß' law

Gauß' integral theorem (9.42) allows us to rewrite Gauß' law (10.13). On the one hand, we have,

$$\oint_{\partial\mathcal{V}} \vec{\mathcal{E}} \cdot d\mathbf{S} = \int_{\mathcal{V}} \nabla \cdot \vec{\mathcal{E}} dV \ , \tag{10.14}$$

on the other hand, we can express the total charge inside the volume $\mathcal{V}$ as a sum over the charge distribution,

$$Q = \int_{\mathcal{V}} \varrho(\mathbf{r}) dV \ . \tag{10.15}$$

comparing the integrands, we obtain the differential form of Gauß' law or Maxwell's third equation:

$$\boxed{\nabla \cdot \vec{\mathcal{E}} = \frac{\varrho}{\varepsilon_0}} \ . \tag{10.16}$$

The Gauß law can also be derived directly from the general Coulomb law: We calculate the divergence of the field of formula (10.8),

$$\begin{aligned} \nabla \cdot \vec{\mathcal{E}} &= \nabla_{\mathbf{r}} \cdot \int \frac{\varrho(\mathbf{r}')}{4\pi\varepsilon_0} \frac{\mathbf{r}-\mathbf{r}'}{|\mathbf{r}-\mathbf{r}'|^3} dV' = \frac{1}{4\pi\varepsilon_0} \int \varrho(\mathbf{r}') \nabla_{\mathbf{r}} \cdot \frac{\mathbf{r}-\mathbf{r}'}{|\mathbf{r}-\mathbf{r}'|^3} dV' \\ &= \frac{1}{4\pi\varepsilon_0} \int \varrho(\mathbf{r}') 4\pi\delta^3(\mathbf{r}-\mathbf{r}') dV' = \frac{\varrho(\mathbf{r})}{\varepsilon_0} \ . \end{aligned} \tag{10.17}$$

In the integral form, Gauß' law is very useful for calculating electric fields particularly in situations with a high degree of symmetry. Let us discuss some examples in the following.

Example 46 (*Electric field outside a charged sphere*): We consider a sphere with radius R carrying the total charge Q. Gauß' law says,

$$\oint_{\partial\mathcal{V}} \vec{\mathcal{E}} \cdot d\mathbf{S} = \frac{Q}{\varepsilon_0} \ ,$$

where we choose as volume a sphere with radius $r > R$. At first glance, this does not seem to help much because the field, in which we are interested, is under the integral. But we can explore the symmetry of the system to simplify the integral, since $\vec{\mathcal{E}} = \mathcal{E}\hat{\mathbf{e}}_r$ and $\mathrm{d}\mathbf{S} = dS\hat{\mathbf{e}}_r$, such that we can write the integral,

$$\int_0^{\pi} \int_0^{2\pi} \mathcal{E} r^2 \sin\theta d\theta d\phi = 4\pi r^2 \mathcal{E} = \frac{Q}{\varepsilon_0} \ .$$

Hence,

$$\vec{\mathcal{E}} = \frac{Q}{4\pi\varepsilon_0 r^2}\hat{\mathbf{e}}_r \ .$$

This is precisely Coulomb's law. It is interesting to note that the field does not depend on the distribution ϱ of the charge within the volume. Of course, to take advantage of the symmetry of the system, it is important to choose the adequate volume.

Example 47 (*Box containing an interface*): Let us now give another example of the utility of Gauß' law. We are interested in the electric field generated by an infinitely extended plane carrying a homogeneous surface charge density σ. By symmetry, the $\vec{\mathcal{E}}$-field must cross the plane perpendicularly and have opposite directions above and below the plane. We now imagine a rectangular pill box enclosing a small area of the plane, so that two surfaces of the box (with area S) are parallel to the plane. Inside the box we find the charge,

$$Q = \varepsilon_0 \oint_{\mathcal{S}_{box}} \vec{\mathcal{E}} \cdot d\mathbf{S} = \varepsilon_0 \int_{\mathcal{S}_{upper}} \mathcal{E} dS + \varepsilon_0 \int_{\mathcal{S}_{lower}} \mathcal{E} dS = 2S\mathcal{E} \ .$$

On the other hand, $Q = \int_{\mathcal{V}_{box}} \varrho dV = \sigma S$. Hence,

$$\vec{\mathcal{E}} = \frac{\sigma}{2\varepsilon_0}\hat{\mathbf{n}} \ .$$

It may seem strange that the electric field does not depend on the distance from the plane, but this is due to the fact that the plane is supposed infinite, which is an unrealistic concept. For a limited surface we expect field components not being perpendicular to the interface, which come from the edges of the surface.

10.2.3 Rotation of the electric field and Stokes' law

Stokes' integral theorem (9.40) allows us to rewrite Maxwell's fourth equation(10.23). From

$$\boxed{\oint_{\partial\mathcal{S}} \vec{\mathcal{E}} \cdot d\mathbf{r} = 0} = \int_{\mathcal{S}} (\nabla \times \vec{\mathcal{E}}) \cdot d\mathbf{S} \ , \tag{10.18}$$

we obtain the differential form of Maxwell's second equation:

$$\boxed{\nabla \times \vec{\mathcal{E}} = 0} \ . \tag{10.19}$$

The second Maxwell equation (applied to electrostatics) can also be derived directly from the general Coulomb law: We calculate the rotation of the field of formula (10.3),

$$\nabla \times \vec{\mathcal{E}} = \nabla_{\mathbf{r}} \times \int \frac{\varrho(\mathbf{r}')}{4\pi\varepsilon_0} \frac{\mathbf{r}-\mathbf{r}'}{|\mathbf{r}-\mathbf{r}'|^3} dV' = \frac{1}{4\pi\varepsilon_0} \int \varrho(\mathbf{r}') \nabla_{\mathbf{r}} \times \frac{\mathbf{r}-\mathbf{r}'}{|\mathbf{r}-\mathbf{r}'|^3} dV' = 0 \ . \tag{10.20}$$

The fact that the rotation of any electrostatic field must vanish is a severe constraint. For example, there is no charge distribution leading to a field of the form $\vec{\mathcal{E}} = y\hat{\mathbf{e}}_x$.

A direct consequence of this law is that we can introduce the concept of the potential. This is fundamental, because electrodynamics can be fully formulated in terms of scalar potentials. We will devote the whole next section to electric potentials.

10.2.4 Exercises

10.2.4.1 Ex: Use of Dirac's function in Coulomb's law

Show how the following Coulomb law formulas for one-, two- and three-dimensional density distributions,

$$\vec{\mathcal{E}}(\mathbf{r}) = \frac{1}{4\pi\varepsilon_0}\int_{\mathrm{V}} \frac{\mathbf{r}-\mathbf{r}'}{|\mathbf{r}-\mathbf{r}'|^3}\rho(\mathbf{r}')dV'$$
$$\vec{\mathcal{E}}(\mathbf{r}) = \frac{1}{4\pi\varepsilon_0}\int_{\mathrm{A}} \frac{\mathbf{r}-\mathbf{r}'}{|\mathbf{r}-\mathbf{r}'|^3}\sigma(\mathbf{r}')dA'$$
$$\vec{\mathcal{E}}(\mathbf{r}) = \frac{1}{4\pi\varepsilon_0}\int_{\mathrm{C}} \frac{\mathbf{r}-\mathbf{r}'}{|\mathbf{r}-\mathbf{r}'|^3}\lambda(\mathbf{r}')dC'$$

are linked using Dirac's δ-function, defined by,

$$\delta(x) = \left\{ \begin{array}{ll} \infty & \text{for} \quad x = 0 \\ 0 & \text{for} \quad x \neq 0 \end{array} \right\} \qquad \text{such that} \qquad \int f(x)\delta(x-a)dx = f(a)\infty\frac{1}{\infty} = f(a) \ .$$

Use the examples of a. A linear charge distribution along the x-axis, given by $\rho(\mathbf{r}') = \lambda(x')\delta(y')\delta(z')$, and b. a surface charge distribution in the $z = 0$ plane, given by$\rho(\mathbf{r}') = \sigma(x', y')\delta(z')$.

10.2.4.2 Ex: Electric field generated by a linear charge distribution

Calculate the electric field generated by a linear charge distribution. Analyze the field in a remote region.

10.2.4.3 Ex: Electric field produced by a charged disc

a. Calculate the electric field along the symmetry axis generated by a thin disk of radius R evenly charged with the charge Q.
b. Discuss the limit $R \to \infty$ assuming that the surface charge density is kept constant.

10.2.4.4 Ex: Electric field produced by a spherical layer

A charge q is deposited on a solid conducting sphere of radius R.
a. Parametrize the charge distribution $\rho(\mathbf{r})$.
b. Determine the surface charge density σ on the sphere's surface.
c. Using the Gauß law, $\oint_{\partial V} \vec{\mathcal{E}}(\mathbf{r})\cdot d\mathbf{a} = \frac{Q}{\varepsilon_0}$, calculate the electric field inside and outside the sphere.
d. Using the Coulomb law, $\vec{\mathcal{E}}(\mathbf{r}) = \frac{1}{4\pi\varepsilon_0}\int_A \frac{\mathbf{r}-\mathbf{r}'}{|\mathbf{r}-\mathbf{r}'|^3}\sigma(\mathbf{r}')dA'$ in spherical coordinates,

$$\mathbf{r}' = \begin{pmatrix} R\sin\theta'\cos\phi' \\ R\sin\theta'\sin\phi' \\ R\sin\theta' \end{pmatrix} \qquad \text{and} \qquad dA' = R^2\sin\theta' d\theta d\phi' \ ,$$

calculate the electric field $E_z(z)$ along the z-axis in- and outside the sphere. Help:

$$\int_{-R}^{R} \frac{z-z'}{\sqrt{z^2-2zz'+R^2}^3} dz' = \begin{cases} \frac{-2R}{z^2} & z < -R \\ 0 \quad \text{for} & -R < z < R \\ \frac{2R}{z^2} & R < z \end{cases} .$$

10.2.4.5 Ex: Field of a homogeneously charged sphere

Calculate with the Gauß law the electric field of a homogeneously charged sphere (charge Q, radius R)
a. for $r < R$ and
b. for $r \geq R$.

10.2.4.6 Ex: Field of a charge distribution with spherical symmetry

The electric field generated by a spherically symmetric charge distribution $\rho(r)$ can be given in the form,

$$\vec{\mathcal{E}}(\mathbf{r}) = \frac{\mathbf{r}}{r^3}\, 4\pi \int_0^r dr'\; r'^{\,2}\; \rho(r') \;,$$

where the origin is in the center of the sphere and $r = |\mathbf{r}|$.
a. Show that $\text{div}\vec{\mathcal{E}} = 4\pi\ \rho$ and $\text{rot}\vec{\mathcal{E}} = 0$.
b. Calculate the field for a sphere of radius R, which is homogeneously charged in the entire volume with the total charge Q.
c. Resolve (b) for a homogeneously charged hollow concentric sphere with inner radius R_i, outer radius R_a and full load Q.
d. Resolve (c) for the case, that the center of the hollow spherical part is displaced by a vector $\mathbf{d}$ with respect to the center of the spherical surface.
Help: The electric field is an additive quantity.

10.2.4.7 Ex: Field of a charge distribution with spherical symmetry

A sphere of radius R is in a vacuum. It is made of a material with a constant permittivity ε and carries the charge q in its center.
a. Calculate the field the electrostatic field $\vec{\mathcal{E}}$ inside and outside the sphere.
b. Calculate the electrostatic potential Φ in the entire space.

10.2.4.8 Ex: Charge distribution

We consider the charge density $\rho(\mathbf{r}) = cr \int_0^R dr' \delta(r'-r)$, where $r = |\mathbf{r}|$, $R > 0$ and $c = const$. The total charge be Q.
a. Make a scheme of the function $\rho(\mathbf{r})$. What is the relationship between the constant c and the total charge Q?
b. Start by showing that the electric field created by a spherically symmetric charge distribution ρ can be written as $\vec{\mathcal{E}}(\mathbf{r}) = \frac{\mathbf{r}}{r^3} \int_0^r dr' r'^2 \frac{1}{\varepsilon_0} \rho(r')$. Here, $\mathbf{r}$ is the vector starting from the origin at the center of symmetry and reaching the surface. Determine

the absolute value and direction of the electric field $\vec{\mathcal{E}}(\mathbf{r})$ for $|\mathbf{r}| < R$ and $|\mathbf{r}| > R$ for the given charge distribution. Make a scheme of the profile $|\vec{\mathcal{E}}(\mathbf{r})|$.

10.2.4.9 Ex: • Charge distribution

A thin, square and conductive sheet has $d = 5.0$ m long edges and a charge of $Q = 80\,\mu\text{C}$. Assume that the load is evenly distributed on the faces of the sheet.
a. Determine the charge density on each face of the sheet and the electric field in the vicinity of one face.
b. The sheet is placed to the right of an infinite, non-conductive plane charged with the charge density $\sigma_{inf} = 2.0\ \mu\text{C/m}^2$, with the faces of the sheet parallel to the plane. Determine the electric field on each face of the sheet and determine the charge density on each face.

10.2.4.10 Ex: • Charge distribution

A large, flat, non-conductive and non-uniformly charged surface is placed along the $x = 0$ plane. At the origin, the charge density is $\sigma = 3.1\,\mu\text{C/m}^2$. At a short distance from the surface in the positive direction of the x-axis, the x-component of the electric field is $\mathcal{E}_{dir} = 4.65 \cdot 10^5$ N/C. What is the value of $\mathcal{E}_x$ a short distance from the surface in the negative direction of the axis x.

10.2.4.11 Ex: • Charge distribution

An infinite flat non-conductive blade with surface charge density $\sigma_1 = +3.0\,\mu\text{C/m}^2$ is located in the $y_0 = -0.6$ m plane. A second infinite flat blade with surface charge density of $\sigma_2 = -2.0\,\mu\text{C/m}^2$ is located in the $x_0 = 1.0$ m plane. Finally, a thin non-conductive spherical shell with radius $R = 1.0$ m and its center in the $z_0 = 0$ plane at the intersection of the two charged blades, has a surface charge density of $\sigma_3 = -3.0\,\mu\text{C/m}^2$. Determine the magnitude, direction, and orientation of the electric field along the x-axis and
a. $x_1 = 0.4$ m and
b. $x_2 = 2.5$ m.

10.2.4.12 Ex: • Charged sphere

A solid non-conducting sphere with radius $R = 1.0$ cm carries a uniform volumetric charge density. The magnitude of the electric field at a distance $r = 2.0$ cm from the center of the sphere is $\mathcal{E}_r = 1.88 \cdot 10^3$ N/C.
a. What is the volumetric charge density of the sphere?
b. Determine the magnitude of the electric field at a distance $d = 5.0$ cm from the center of the sphere.

10.2.4.13 Ex: Electrical flow

A point charge Q is placed in the center of a hypothetical ball with radius R, which on one side is cut at a height h. What is the flow of electric field $\vec{\mathcal{E}}$ through the plane of the cut A illustrated in the figure?

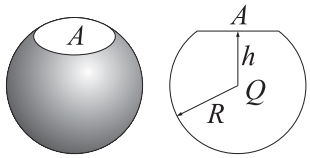

Figure 10.3: Scheme.

10.2.4.14 Ex: Electrical flow

The cube shown in the figure has an edge length of $d = 1.4\,\mathrm{m}$ and is located inside an electric field.
a. Calculate the electrical flux through the right surface of the cube for an electric field given by $\vec{\mathcal{E}} = -3\,\mathrm{V/m}\cdot\hat{\mathbf{e}}_x + 4\,\mathrm{V/m}\cdot\hat{\mathbf{e}}_z$. What is the total flux across the entire surface of the cube?
b. Calculate the total flux across the entire surface of the cube for the electric field $\vec{\mathcal{E}} = -4\,\mathrm{V/m}^2\cdot\hat{\mathbf{e}}_x + (6\,\mathrm{V/m} + 3\,\mathrm{V/m}^2\cdot y)\hat{\mathbf{e}}_y$. What charge is contained in the cube?

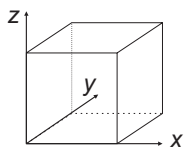

Figure 10.4: Scheme.

10.2.4.15 Ex: Electrical flow

Calculate the electric field flux $\vec{\mathcal{E}}(\mathbf{r}) = \mathcal{E}_0\hat{\mathbf{e}}_z$ through the semi-sphere with radius R shown in the figure.

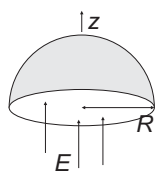

Figure 10.5: Scheme.

10.2.4.16 Ex: Electrical flow

Calculate the flow of the vector field with cylindrical symmetry $\vec{\mathcal{E}}(\mathbf{r}) = \mathcal{E}_0\hat{\mathbf{e}}_\rho$ through the half cylindrical surface shown in the figure with radius R and length L.

10.2.4.17 Ex: Electric field of a charged sheet

An infinitely extended non-conductive sheet carries a charge with a surface density of $0.1\,\mu\mathrm{C/m}^2$ on either side. What is the distance of the equipotential surfaces for a

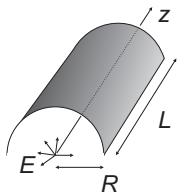

Figure 10.6: Scheme.

potential difference of 50 V?

10.2.4.18 Ex: Electric field between charged planes

Consider two thin, non-conductive planes with infinite length perpendicular to the x-axis and crossing this axis at the positions x_1 and x_2 with $x_1 < x_2$. The planes are uniformly charged with charge densities σ_2. Calculate the electric fields in the three regions $x < x_1$ and $x_1 < x < x_2$ and $x_2 < x$. Discuss the particular cases $\sigma_2 = \sigma_1$ and $\sigma_2 = -\sigma_1$.

10.2.4.19 Ex: Electric field of a photocopier

The electric field just above the surface of the electrically charged drum of a photocopier has the absolute value $2.3 \cdot 10^5$ N/C. The drum has a length of 42 cm and a diameter of 12 cm.
a. What is the charge density on the surface supposed conductive?
b. What is the total charge on the drum?
c. Decreasing the drum to 8 cm in order to build a more compact photocopier, the field on the surface must remain the same. What should the charge be in this case?

10.2.4.20 Ex: Geiger counter

A Geiger-Müller meter consists essentially of a metal tube filled with gas (inner radius r_a) with a thin wire inside (radius r_i). A high voltage is applied between the two. The meter serves, for example, to detect charged particles, which produce pairs of electrons and ions from the gas, which are then extracted by an applied voltage and detected as an electrical signal.
a. Calculate the potential $\phi(r)$, where $\phi(r_a) = 0$ and $\phi(r_i) = U = 1000$ V.
b. Be $r_i = 15\,\mu$m, $r_a = 1$ cm. Calculate the strength of the field at the tube's surface.
c. The average free path in the gas is $L = 3\,\mu$m. At what distance R_I from the wire does an avalanche form, that is, an electron stopped due to a collision is accelerated over a distance L up to the ionization energy $E_I = 5$ eV and, thus, can generate another electron-ion pair in the subsequent collision?

10.2.4.21 Ex: • Electrical flow

A thin, non-conductive uniformly charged spherical shell with radius R, has a total positive charge equal to Q. A small piece is removed from the surface.
a. What are the absolute value, the direction and the orientation of the electric field

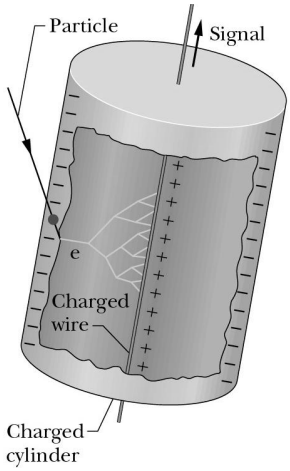

Figure 10.7: Geiger counter.

at the center of the void?
b. The piece is placed back into the void. Determine the electrical force exerted on the piece.
c. Using the strength of the force, calculate the electrostatic pressure that tends to expand the sphere.

10.2.4.22 Ex: • Flow through a cone

An imaginary straight circular cone with base angle θ and base radius R is in a charge-free region exposed to a uniform electric field $\vec{\mathcal{E}}$ (the field lines are vertical to the cone axis). What is the ratio between the number of field lines per unit area entering the base and the number of lines per unit area entering the cone's conical surface. Use Gauß's law in your answer.

10.2.4.23 Ex: Flow of a field

Consider the rectangle with the corners,

$$\begin{pmatrix} x_i \\ y_i \\ z_i \end{pmatrix} = \begin{pmatrix} b \\ \frac{a}{\sqrt{2}} \\ 0 \end{pmatrix}, \begin{pmatrix} 0 \\ \frac{a}{\sqrt{2}} \\ 0 \end{pmatrix}, \begin{pmatrix} 0 \\ 0 \\ \frac{a}{\sqrt{2}} \end{pmatrix}, \begin{pmatrix} b \\ 0 \\ \frac{a}{\sqrt{2}} \end{pmatrix}$$

and calculate the flux integral of the field $\mathbf{A}(\mathbf{r})$ through the area $\mathbf{F}$ of the rectangle,

$$\mathbf{A}(\mathbf{r}) = \begin{pmatrix} y^2 \\ 2xy \\ 3z^2 - x^2 \end{pmatrix}.$$

10.2.4.24 Ex: Flow of a vector field

Calculate the flux of the vector field $\mathbf{A}(\mathbf{r})$ across the surface of a sphere of radius R around the origin of the coordinate system for
a.

$$\mathbf{A}(\mathbf{r}) = 3\frac{\mathbf{r}}{\mathbf{r}^2} \ .$$

b.

$$\mathbf{A}(\mathbf{r}) = \begin{pmatrix} 3z - 2y \\ x + 5z \\ y + x \end{pmatrix} \ .$$

10.2.4.25 Ex: Van de Graaff generator

The spherical shell (radius R) of a Van de Graaf generator must be charged until a potential difference of 10^6 V. What should be the minimum diameter of the sphere to avoid lightning discharge?
Help: The field for disruptive discharge in air is $3 \cdot 10^6$ V/m.

10.2.4.26 Ex: • Van de Graaff accelerator

Protons are released from rest in a Van de Graaff accelerator system. The protons are initially located at a position where the electrical potential has a value of 5.0 MV, and then, they travel through vacuum to a region where the potential is zero.
a. Determine the final velocity of these electrons.
b. Determine the magnitude of the accelerating electric field if the potential changes uniformly over a distance of 2 m.

10.2.4.27 Ex: Faraday cage

Show that in a space confined by a grounded surface the electric field must disappear.

10.2.4.28 Ex: • Waveguide

The figure shows a portion of the cross section of an infinitely long concentric cable. The inner conductor has a linear charge density of 6 nC/m and the outer conductor has no net charge.
a. Determine the electric field for all values of R, where R is the distance perpendicular to the common axis in the cylindrical system.
b. What are the surface charge densities on the surfaces inside and outside the outer conductor?

10.2.4.29 Ex: Fundamental equations of electrostatics

a. Gives the fundamental electrostatic equations in integral and differential form.
b. Gives the fundamental equation in terms of the electrostatic potential.

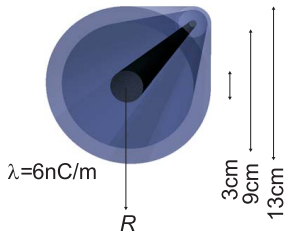

Figure 10.8: Waveguide.

10.3 The scalar electrical potential

We already noted that the electric field generates a force that can accelerate a charge Q along a field line. Therefore, the electric field contains a potential energy which it can convert into kinetic energy by exerting work, $W = \int \mathbf{F} \cdot \mathbf{r} = Q \int \vec{\mathcal{E}} \cdot \mathbf{r}$. The quantity [2],

$$\boxed{\Phi_{\mathbf{a},\mathbf{b}} \equiv \int_{\mathcal{C}_{\mathbf{a},\mathbf{b}}} \vec{\mathcal{E}} \cdot d\mathbf{r}} \tag{10.21}$$

is called the difference of *electric potential* between the points $\mathbf{a}$ and $\mathbf{b}$ connected by a path $\mathcal{C}_{\mathbf{a},\mathbf{b}}$.

Stokes' law (10.18) allows us to state, that the potential difference (10.21) does not depend on the path chosen, because for two different paths $\mathcal{C}$ and $\mathcal{C}'$ between the points $\mathbf{a}$ and $\mathbf{b}$ we have,

$$\int_{\mathcal{C}(\mathbf{a},\mathbf{b})} \vec{\mathcal{E}} \cdot d\mathbf{r} - \int_{\mathcal{C}'(\mathbf{a},\mathbf{b})} \vec{\mathcal{E}} \cdot d\mathbf{r} = 0 \ . \tag{10.22}$$

Consequently, the potential defined between a reference point $\mathcal{O}$ and any observation point $\mathbf{r}$ is unambiguous,

$$\Phi(\mathbf{r}) = -\int_{\mathcal{O}}^{\mathbf{r}} \vec{\mathcal{E}} \cdot d\mathbf{r} \ , \tag{10.23}$$

and the potential difference between two points $\mathbf{a}$ and $\mathbf{b}$ is well defined,

$$\Phi(\mathbf{b}) - \Phi(\mathbf{a}) = -\int_{\mathbf{a}}^{\mathbf{b}} \vec{\mathcal{E}} \cdot d\mathbf{r} \ . \tag{10.24}$$

The fundamental theorem for gradients, on the other hand, says that,

$$\Phi(\mathbf{b}) - \Phi(\mathbf{a}) = \int_{\mathbf{a}}^{\mathbf{b}} (\nabla\Phi) \cdot d\mathbf{r} \ . \tag{10.25}$$

These results being valid for any choice of points $\mathbf{a}$ and $\mathbf{b}$, we conclude by comparing these two equations,

$$\boxed{\vec{\mathcal{E}} = -\nabla\Phi} \ . \tag{10.26}$$

[2] We note that the electric potential is linked to potential energy, but is not the same.

Example 48 (*Potential of a point charge*): For an electric field generated by an electric charge e located at the origin we can easily calculate the integral along a path $\mathcal{C}$ between two points a and b using Coulomb's law:

$$\int_{\mathcal{C}} \vec{\mathcal{E}} \cdot d\mathbf{r} = \int_{\mathbf{a}}^{\mathbf{b}} \frac{1}{4\pi\varepsilon_0} \frac{e}{|\mathbf{r}|^2} \hat{\mathbf{e}}_{\mathbf{r}} \cdot (\hat{\mathbf{e}}_{\mathbf{r}} dr + \hat{\mathbf{e}}_\theta r d\theta + \hat{\mathbf{e}}_\phi r \sin\theta d\phi)$$
$$= \frac{1}{4\pi\varepsilon_0} \int_{\mathbf{a}}^{\mathbf{b}} \frac{e}{r^2} dr = \frac{1}{4\pi\varepsilon_0} \left(\frac{e}{r_a} - \frac{e}{r_b} \right) .$$

With the superposition principle we can generalize this result for distributions of arbitrary charges Q.

Some comments are appropriate at this point:

- The formulation by the potential (a scalar field) instead of the vector electric field is more compact. It summarized the Coulomb (10.8) law along with the constraint (10.19).
- The reference point $\mathcal{O}$ is arbitrary. Exchanging this reference point by another $\mathcal{O}'$ only adds a global constant to the potential,

$$\Phi'(\mathbf{r}) = -\int_{\mathcal{O}'}^{\mathbf{r}} \vec{\mathcal{E}} \cdot d\mathbf{r} = -\int_{\mathcal{O}'}^{\mathcal{O}} \vec{\mathcal{E}} \cdot d\mathbf{r} - \int_{\mathcal{O}}^{\mathbf{r}} \vec{\mathcal{E}} \cdot d\mathbf{r} = K + \Phi(\mathbf{r}) , \tag{10.27}$$

  but does not affect neither the difference of two potentials,

$$\Phi'(\mathbf{b}) - \Phi'(\mathbf{a}) = \Phi(\mathbf{b}) - \Phi(\mathbf{a}) , \tag{10.28}$$

  nor the electric field,

$$\nabla\Phi' = \nabla\Phi . \tag{10.29}$$

  We conclude that the potential is not a real quantity, but a mathematical trick to simplify our life [3]. Generally, the reference point is placed at infinity, $\mathcal{O} = \infty$, fixing the free choice of the global constant by,

$$\Phi(\infty) \equiv 0 . \tag{10.30}$$

- In the same way as the electric field, the electric potential also obeys the superposition principle.

10.3.1 The equations of Laplace and Poisson

We already learned the two equations defining the electrostatic field (10.19) and (10.16), that is, $\nabla \times \vec{\mathcal{E}} = 0$ and $\nabla \cdot \vec{\mathcal{E}} = \varrho/\varepsilon_0$. Let us now rewrite these equations for the electric potential,

$$\nabla \times (\nabla\Phi) = 0 \quad , \quad \nabla \cdot \nabla\Phi = \Delta\Phi = -\varrho/\varepsilon_0 . \tag{10.31}$$

Thus, the formulation by the potential (10.21) automatically satisfies the requirement (10.22), that the rotation must disappear.

On the other side, we have a second-order differential equation called the *Poisson equation*. In regions with no charge, this equation turns into a *Laplace equation*,

$$\Delta\Phi = 0 . \tag{10.32}$$

[3] We shall see later that this conclusion must be reviewed in quantum mechanics in the context of the Aharonov-Bohm effect.

10.3.2 Potential generated by localized charge distributions

The Poisson equation allows us to reconstruct a charge distribution once its potential is known. However, we usually want to do the opposite. Let us start with a point charge, located at the origin, the potential of which is,

$$\Phi(\mathbf{r}) = -\int \vec{\mathcal{E}} \cdot d\mathbf{r}' = \frac{-1}{4\pi\varepsilon_0} \int \frac{Q}{r'^2} dr' = \frac{1}{4\pi\varepsilon_0} \frac{Q}{r'}\bigg|_{\infty}^{\mathbf{r}} = \frac{1}{4\pi\varepsilon_0} \frac{Q}{r} \ . \tag{10.33}$$

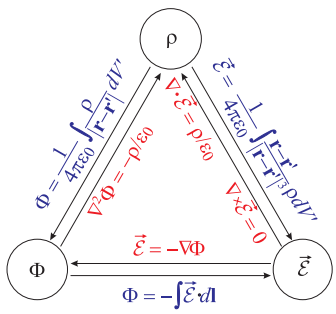

Figure 10.9: The fundamental laws of electrostatics relate the three fundamental quantities, the charge distribution ϱ, the electric field $\vec{\mathcal{E}}$, and the electric potential Φ.

According to the superposition principle, for a discrete distribution of charges Q_k located at the positions $\mathbf{r}_k$,

$$\Phi(\mathbf{r}) = \frac{1}{4\pi\varepsilon_0} \sum_k \frac{Q_k}{|\mathbf{r} - \mathbf{r}_k|} \ . \tag{10.34}$$

Finally, for a continuous distribution $\varrho(\mathbf{r}')$, we obtain the fundamental solution of the electrostatic problem,

$$\boxed{\Phi(\mathbf{r}) = \frac{1}{4\pi\varepsilon_0} \int \frac{dQ'}{|\mathbf{r} - \mathbf{r}'|} = \frac{1}{4\pi\varepsilon_0} \int \frac{\varrho(\mathbf{r}')}{|\mathbf{r} - \mathbf{r}'|} d^3r'} \ . \tag{10.35}$$

From this equation we can derive the Coulomb law (10.8).

Low-dimensional distributions can be treated by suitable parametrization, as in the examples (10.9) and (10.10).

10.3.3 Electrostatic boundary conditions

We have already noticed that the electric field always suffers a discontinuity when passing through a surface charge distribution. To study this, we consider a charged interface traversed by an external electric field $\vec{\mathcal{E}}_{\text{ext}}$. Now, we make two thought experiments: (1) We envision a rectangular pill box enclosing a small part of the interface, as shown in Fig. 10.10. The height ϵ of the box is so small that the flux through the sides of the box can be neglected. With this,

$$\oint \vec{\mathcal{E}} \cdot d\mathbf{S} = \tfrac{1}{\varepsilon_0} Q = \tfrac{1}{\varepsilon_0} \sigma S \ , \tag{10.36}$$

where $\vec{\mathcal{E}}$ is the total electric field (that is, the sum of the field generated by the surface charge and field $\vec{\mathcal{E}}_{\text{ext}}$). A is the surface of the box. This gives,

$$\mathcal{E}^{\perp}_{\text{top}} - \mathcal{E}^{\perp}_{\text{bottom}} = \tfrac{1}{\varepsilon_0}\sigma \ . \tag{10.37}$$

(2) We imagine a rectangular surface perpendicular to the interface and cutting through the interface. As shown in Fig. 10.10, the height ϵ of the surface is so small that the potential difference along the vertical branches can be neglected. With this,

$$\oint \vec{\mathcal{E}} \cdot d\mathbf{l} = \int \vec{\mathcal{E}}_{\text{top}} \cdot d\mathbf{l} + \int \vec{\mathcal{E}}_{\text{bottom}} \cdot d\mathbf{l} = (\vec{\mathcal{E}}_{\text{top}} - \vec{\mathcal{E}}_{\text{bottom}}) \cdot \mathbf{l} = 0 \ , \tag{10.38}$$

where l is the length of the surface. This gives,

$$\vec{\mathcal{E}}^{\parallel}_{\text{top}} = \vec{\mathcal{E}}^{\parallel}_{\text{bottom}} \ . \tag{10.39}$$

That is, when traversing a charged interface, only the part of the electric field which is perpendicular to the interface suffers a discontinuity. This simply reflects the fact that the charge generates its own electric field, which is perpendicular to the interface and superposes to the external field.

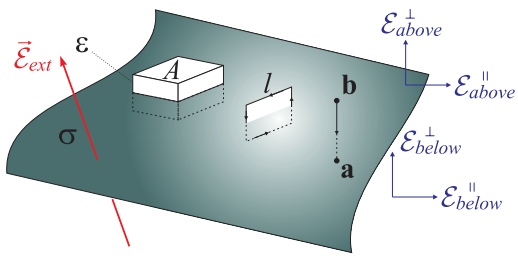

Figure 10.10: Surface S around a box-shaped volume enclosing a small part of the interface, path l around a small area cutting through the interface, and potential difference between two points **a** and **b**.

The potential, on the other hand, is continuous, since the integral between a point **a** above the interface and a point **b** below is,

$$\int_{\mathbf{b}}^{\mathbf{a}} \vec{\mathcal{E}} \cdot d\mathbf{l} = \Phi(\mathbf{b}) - \Phi(\mathbf{a}) \xrightarrow{\mathbf{a}\to\mathbf{b}} 0 \ . \tag{10.40}$$

We study the electrostatic boundary conditions in Exc. 10.3.4.18.

10.3.4 Exercises

10.3.4.1 Ex: Earnshaw theorem

Show that the electrostatic potential in free space does not exhibit a maximum. **Comment:** This is why it is not possible to confine charged particles in electrostatic fields.

10.3.4.2 Ex: • Electrical potential between point charges

A point particle with a charge equal to $+2\,\mu\text{C}$ is fixed at the origin.
a. hat is the electrical potential V at a point $4\,\text{m}$ from the origin, considering that $V = 0$ at infinity?
b. How much work must be done to bring a second point charge with a charge of $+3\,\mu\text{C}$ from infinity to a distance of $4.0\,\text{m}$ from the first charge?

10.3.4.3 Ex: • Electrical potential between point charges

Three identical point particles with charge q are located at the corners of an equilateral triangle that is circumscribed in a circle of radius a contained in the plane $z = 0$ and centered at the origin. The values of q and a are $+3.0\,\mu\text{C}$ and $60\,\text{cm}$, respectively. (Consider that, far from all charges, the potential is zero.)
a. What is the electrical potential at the origin?
b. What is the electrical potential at the point of the z-axis being at $z = a$?
c. How would your responses to the parts (a) and (b) change if the charges q were larger? Explain your answer.

10.3.4.4 Ex: • Electrical potential between point charges

Two identical positively charged point particles are fixed to the x-axis at $x = +a$ and $x = -a$.
a. Write down an expression for the electrical potential $V(x)$ as a function of x for all points on the x-axis.
b. Draw $V(x)$ versus x for all points on the x-axis.

10.3.4.5 Ex: • Electrical potential between point charges

The electric field on the x-axis due to a fixed point charge at the origin is given by $\vec{\mathcal{E}} = (b/x^2)\hat{\mathbf{e}}_x$, where $b = 6.0\,\text{kV}\cdot\text{m}$ and $x \neq 0$.
a. Determine the amplitude and sign of the point charge.
b. Determine the potential difference between the points on the x-axis at $x = 1\,\text{m}$ and $x = 2\,\text{m}$. Which of these points is at a higher potential?

10.3.4.6 Ex: • Dielectric disruption of air

Determine the maximum surface charge density σ_{max} that can exist on the surface of any conductor before dielectric discharge in the air occurs.

10.3.4.7 Ex: • Potential energy of a charged sphere

a. How much charge is on the surface of an isolated spherical conductor that has a radius of $R = 10.0\,\text{cm}$ and is charged with $2.0\,\text{kV}$?
b. What is the electrostatic potential energy of this conductor? (Consider that the potential is zero far from the sphere.)

10.3.4.8 Ex: • Energy of a particle in a potential

Four point charges are attached to the vertices of a square centered on the origin. The length of each side of the square is $2a$. The charges are located as follows: $+q$ is in $(-a, +a)$, $+2q$ is in $(+a, +a)$, $-3q$ is in $(+a, -a)$, and $+6q$ is in $(-a, -a)$. A fifth particle with mass m and charge $+q$ is placed at the origin and released from rest. Determine its velocity when it is far from the origin.

10.3.4.9 Ex: • Energy of a particle in a potential

Two metallic spheres have radii of 10 cm each. The centers of the two spheres are separated by 50 cm. The spheres are initially neutral, but a charge Q is transferred from one sphere to another, creating a potential difference between them of 100 V. A proton is released from rest at the surface of the positively charged sphere and travels to the negatively charged sphere.
a. What is the kinetic energy once it reaches the negatively charged sphere?
b. At what velocity does it collide with the sphere?

10.3.4.10 Ex: • Potential of connected spheres

A spherical conductor of radius R_1 is charged with $V_i = 20\,\text{kV}$. When it is connected through a very thin and long conductive wire to a second very distant spherical conductor, its potential drops to $V_f = 12\,\text{kV}$. What is the radius of the second sphere?

10.3.4.11 Ex: • Potential of a charged disk

Along the central axis of a uniformly loaded disc, at a point 0.6 m away from the center of the disc, the potential is 80 V and the field intensity is 80 V/m. At a distance of 1.5 m, the potential is 40 V and the electric field strength is 23.5 V/m. (Consider that the potential is very far from the disk). Determine the total charge of the disk.

10.3.4.12 Ex: • Potential of spherical shells

Two conductive concentric spherical shells have equal charges with opposite signs. The inner shell has an external radius a and the charge $+q$; the outer shell has an internal radius b and the charge $-q$. Determine the potential difference $V_a - V_b$ between the shells.

10.3.4.13 Ex: • Electrical potential of a disk

A disk of radius R has a surface charge distribution given by $\sigma = \sigma_0 r^2/R^2$, where σ_0 is a constant and R is the distance from the center of the disk.
a. Determine the total charge on the disk.
b. Find the expression for the electrical potential at a distance z from the center of the disk along the axis that passes through the center of the disk and is perpendicular to its plane.

10.3.4.14 Ex: • Electrical potential of a rod

A stick of length L has a total charge Q evenly distributed along its length. The stick is placed along the x-axis with its center at the origin.
a. What is the electrical potential as a function of the position along the x-axis for $x > L/2$?
b. Show that for $x \gg L/2$, your result reduces to that due to a point charge Q.

10.3.4.15 Ex: Potential of a thin disk

Calculate the electrical potential of a thin disc homogeneously charged with the charge Q along the symmetry axis.

10.3.4.16 Ex: Electrical potential of four wires

Consider four wires oriented parallel to the z-direction, as shown in the figure. The wires are charged with the charge per unit length q/L.
a. Calculate the electrical potential as a function of x and y.
b. Expand the potential around $x = 0$ and $y = 0$ ($|x|, |y| \ll a$) up to second order. What is the shape of the potential at this point?

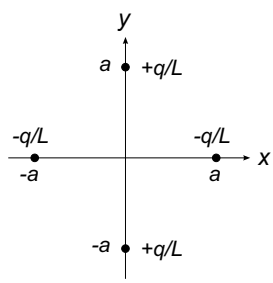

Figure 10.11: Four wires.

10.3.4.17 Ex: Stokes law

Consider a thin straight wire of infinite length uniformly charged with linear charge density λ.
a. Parametrize the linear load density using the δ-function.
b. Using Gauss' law, calculate the electric field.
c. Calculate the path integral $\int \vec{\mathcal{E}} \cdot d\mathbf{s}$ for the path parametrized by $\mathbf{s}(t) = \rho(\hat{\mathbf{e}}_x \cos t + \hat{\mathbf{e}}_y \sin t)$ with $t \in [0, 2\pi]$.
d. From the electric field obtained in (b) calculate $\nabla \times \vec{\mathcal{E}}$ in Cartesian or cylindrical coordinates.
Help: $\nabla \times \mathbf{S} = \hat{\mathbf{e}}_\rho \, \frac{1}{\rho} \left[\frac{\partial S_z}{\partial \phi} - \rho \frac{\partial S_\phi}{\partial z} \right] + \hat{\mathbf{e}}_\phi \, \left[\frac{\partial S_\rho}{\partial z} - \frac{\partial S_z}{\partial \rho} \right] + \hat{\mathbf{e}}_z \, \frac{1}{\rho} \left[\frac{\partial}{\partial \rho}(\rho S_\phi) - \frac{\partial S_\rho}{\partial \phi} \right]$.

10.3.4.18 Ex: Surface of a conductor

Consider an arbitrary macroscopic conductor whose surface is closed and smooth. Starting from Gauss's law and the electrostatic rotation of the electric field:
a. calculate the electric field inside the conductor;
b. obtain the normal component of the electric field on the outer surface of the conductor in terms of the surface charge density;
c. obtain the tangential component of the electric field on the outer surface of the conductor.

10.4 Electrostatic energy

We calculate the work required to move a test charge q between two points $\mathbf{a}$ and $\mathbf{b}$ within the potential created by a charge distribution,

$$W = -\int_{\mathbf{a}}^{\mathbf{b}} \mathbf{F} \cdot d\mathbf{r} = -q \int_{\mathbf{a}}^{\mathbf{b}} \vec{\mathcal{E}} \cdot d\mathbf{r} = q[\Phi(\mathbf{b}) - \Phi(\mathbf{a})] \ . \tag{10.41}$$

Since the work does not depend on the path, we call the potential *conservative*. Taking the test charge from the reference point to infinity,

$$W = q[\Phi(\mathbf{b}) - \Phi(\infty)] = q\Phi(\mathbf{b}) \ . \tag{10.42}$$

In this sense, the potential is nothing more than the energy per unit of charge q required to take a particle from infinity to a point $\mathbf{r}$.

10.4.1 Energy of a charge distribution

The next question is, what energy is needed to put together a distribution of charges taking them one by one from infinity to predefined points. Every charge Q_k uses an amount of work W_k, only the first charge does not, $W_1 = 0$. Using the abbreviation,

$$W_{k,m} \equiv \frac{1}{4\pi\varepsilon_0} \frac{Q_k Q_m}{|\mathbf{r}_k - \mathbf{r}_m|} \ , \tag{10.43}$$

the work is easily calculated for the second charge, $W_2 = W_{1,2}$. For the third and fourth charge we need *additionally* the amounts of work,

$$W_3 = W_{1,3} + W_{2,3} \qquad \text{and} \qquad W_4 = W_{1,4} + W_{2,4} + W_{3,4} \ . \tag{10.44}$$

The general rule is obvious: For N charges we need in *total* to provide the work,

$$W = \sum_{k=1}^{N} W_k = \sum_{k=1}^{N} \sum_{\substack{m=1 \\ m<k}}^{N} W_{k,m} = \frac{1}{2} \sum_{k=1}^{N} \sum_{\substack{m=1 \\ m\neq k}}^{N} W_{k,m} \ . \tag{10.45}$$

Explicitly, calling Φ the potential created by all charges minus the charge Q_k,

$$\Phi(\mathbf{r}_k) \equiv \sum_{\substack{m=1 \\ m\neq k}}^{N} \frac{1}{4\pi\varepsilon_0} \frac{Q_m}{|\mathbf{r}_k - \mathbf{r}_m|} \ , \tag{10.46}$$

we can write the energy as,

$$W = \tfrac{1}{2}\sum_k Q_k \Phi(\mathbf{r}_k) \ . \tag{10.47}$$

For continuous distributions, this equation turns into,

$$W = \tfrac{1}{2}\int \Phi dQ = \tfrac{1}{2}\int \varrho \Phi dV \ . \tag{10.48}$$

10.4.2 Energy density of an electrostatic field

The energy of a continuous charge distribution can be rewritten using Gauß' law,

$$W = \tfrac{\varepsilon_0}{2}\int (\nabla\cdot\vec{\mathcal{E}})\Phi dV \ . \tag{10.49}$$

Integration by parts allows transferring the derivative of $\vec{\mathcal{E}}$ to Φ,

$$W = \tfrac{\varepsilon_0}{2}\left[\oint_{\partial\mathcal{V}} \Phi\vec{\mathcal{E}}\cdot d\mathbf{S} - \int_{\mathcal{V}} \vec{\mathcal{E}}\cdot(\nabla\Phi)dV\right] \ . \tag{10.50}$$

The surface integral can be neglected, because we can choose the integration volume arbitrarily large $\mathcal{V}$. Expressing the gradient by the field,

$$W = \tfrac{\varepsilon_0}{2}\int_{\mathcal{V}} \vec{\mathcal{E}}^2 dV = \tfrac{\varepsilon_0}{2}\int_{\mathcal{V}} u dV \ , \tag{10.51}$$

introducing the *energy density*,

$$\boxed{u \equiv \tfrac{\varepsilon_0}{2}\vec{\mathcal{E}}^2} \ . \tag{10.52}$$

Example 49 (*Electrostatic energy of a charged spherical layer*): As an example we calculate the electrostatic energy of a spherical shell of radius R uniformly charged with the total charge Q. Using the formula (10.48) we obtain,

$$W = \frac{1}{2}\int \varrho\Phi dV = \frac{1}{2}\int \frac{Q}{4\pi R^2}\delta(r-R)\Phi R^2 \sin\theta d\theta d\phi dr = \frac{Q}{2}\Phi(R) = \frac{Q}{2}\frac{1}{4\pi\varepsilon_0}\frac{Q}{R} = \frac{Q^2}{8\pi\varepsilon_0}\frac{1}{R} \ .$$

Alternatively, we calculate by the formula (10.51),

$$W = \frac{\varepsilon_0}{2}\int_{\mathbb{R}^3} \vec{\mathcal{E}}^2 dV = \frac{\varepsilon_0}{2}\int_{r\geq R}\left(\frac{1}{4\pi\varepsilon_0}\frac{Q}{R^2}\right)^2 R^2\sin\theta d\theta d\phi dr = \frac{Q^2}{8\pi\varepsilon_0}\int_R^\infty \frac{1}{R^2}dr = \frac{Q^2}{8\pi\varepsilon_0}\frac{1}{R} \ .$$

1. Comparing the expressions for the electrostatic energy (10.47) and (10.51) [4] we perceive an inconsistency, since the second only allows positive energies, while the former allows positive and negative energies, for example, in the case of two charges with opposed signs aiming to attract each other.

   In fact, both equations are correct, but they describe slightly different situations. Equation (10.47) does not take into account of the work necessary to create these

[4] Or equivalently (10.48), which also can not be negative.

elementary point charges in the first place. In fact, equation (10.51) indicates that the energy of a point charge diverges,

$$W = \frac{\varepsilon_0}{2}\frac{1}{(4\pi\varepsilon_0)^2}\int_{\mathbb{R}^3}\left(\frac{e}{r^2}\right)^2 r^2 \sin\theta dr d\theta d\phi = \frac{e^2}{8\pi\varepsilon_0}\int_0^\infty \frac{1}{r^2} r^2 \sin\theta dr d\theta d\phi \to \infty \ .$$

The equation (10.51) is more complete in the sense that it gives the total energy stored in the charge configuration, but the (10.47) is more appropriate when working with point charges, because we then prefer to ignore the part needed for the construction of the electrons. Anyway, we do not know how to create or dismount electrons.

The inconsistency enters the derivation, when we make the transition between the Eqs. (10.47) and (10.48). In the first equation, $\Phi(\mathbf{r}_i)$ represents the potential due to all the other charges except q_i, while in the second $\Phi(\mathbf{r})$ is the total potential. For continuous distributions there is no difference, since the amount of charge at any mathematical point $\mathbf{r}$ is negligible, and its contribution to the potential is zero.

In practice, the divergence does not appear because, when we use Eq. (10.51), generally we consider smooth distributions of charges and not point-like charges.

2. The energy is stored in the entire electrostatic field, that is, we need to integrate over the entire space $\mathbb{R}^3$.

3. The superposition principle is not valid for electrostatic energy, since it is quadratic in the fields, $\int(\vec{\mathcal{E}}_1 + \vec{\mathcal{E}}_2)^2 dV \neq \int(\vec{\mathcal{E}}_1^2 + \vec{\mathcal{E}}_2^2)dV$.

10.4.3 Dielectrics and conductors

In an *insulating* material, such as rubber or glass, all electrons are attached to individual atoms. They can be displaced inside the atom by an external electric field, which creates a polarization of the atom. But they do not move away from the atom. In contrast, in a *conducting* material, such that a metal, one or more electrons per atom can move freely.

What are the characteristics of an ideal conductor?

1. $\vec{\mathcal{E}} = 0$ **inside a conductor.** The electric field inside a conductor must vanish, otherwise there would be forces on the charges working to rearrange them until the forces (and the motion of charges) compensate. In the presence of an external electric field, the charges arrange themselves in such a way as to generate their own field designed to compensate the external field.

2. $\varrho = 0$ **inside a conductor.** Since there is no electric field, Gauß' law prevents residual charges in the interior, since $\varrho = \nabla \cdot \vec{\mathcal{E}}/\varepsilon_0$.

3. **All residual charge is on the surface,** simply because it can not be inside.

4. **Conductor as an equipotential.** As there is no electric field, Stokes' law prevents different potentials because $\Phi(\mathbf{b}) - \Phi(\mathbf{a}) = -\int_{\mathbf{a}}^{\mathbf{b}} \vec{\mathcal{E}} \cdot d\mathbf{r} = 0$.

5. $\vec{\mathcal{E}}$ **is perpendicular to the surface near the surface.** Otherwise, the electric field components parallel to the surface would create forces to rearrange the residual charges until the parallel components disappear. Consequently, electric field lines always meet a conductor orthogonally to the surface $\vec{\mathcal{E}} \perp \partial V$.

10.4.4 Induction of charges (influence)

When we place a charge in front of a neutral conductor we measure an attraction force. The reason is that free charges of the conductor with opposite sign are attracted, while charges with the same sign are repelled [5]. Now, since the charges with opposite sign are closer to the charge in front than those with the same sign, the attractive force will dominate the repulsive force (see Fig. 10.12 left).

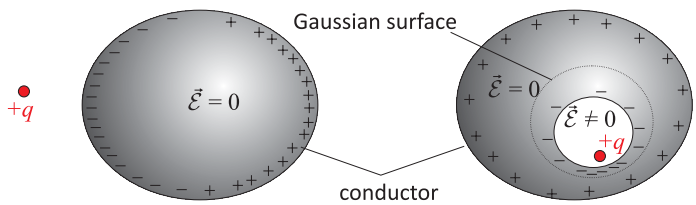

Figure 10.12: Electrostatic induction.

The electric field inside a conductor must vanish, but this only holds for the conductor's bulk material and not necessarily for dielectric impurities or cavities enclosed by the conductor. For example, in the case where there is a charge $+q$ inside a enclosed cavity [see Fig. 10.12(right)], the electric field inside the cavity is clearly nonzero. However, since it must vanish within the conductor, Gauß' law requires that within a volume enclosed by a Gaussian surface, the total charge must be zero. Choosing this Gaussian surface very close to the cavity, we find that a surface charge must have formed at the edges of the cavity, compensating for the charge $+q$ inside the cavity. This charge can only come from the outer surface, which is now charged with the opposite charge, as well. In this way *the charge $+q$ becomes visible from the outside of the conductor.*

The electric field inside a cavity without charges enclosed by a conductor must be zero, because without charges, the field lines could only traverse the cavity. However, the entrance and exit points between the cavity and the conductor are on the same potential, and have no surface charge. This is the principle of *Faraday's cage*, where people inside a conductive cage are shielded and thus protected from electrical phenomena like lightning discharges.

The migration of free excess charges in conductors to the surface is also called *skin effect*: The potential inside the metal the same everywhere, and the electric field disappears $\vec{\mathcal{E}} = 0$.

Example 50 (*Conductors with enclosed cavities*): Two cavities with radii a and b are excavated from a neutral conducting sphere of radius R. In the center of each cavity there be charges, q_a and q_b, respectively.

[5] That is, the charges in the conductor rearrange to compensate for the electric field created by the charge in front until the total field inside the conductor has vanished.

- The charges on the surfaces of the cavities σ_a and σ_b must be organized such as to shield the charges $q_{a,b}$ in order to prevent the formation of an electric field inside the conductor. If the charges are at the centers of the spheres we simply obtain, $\sigma_a = \frac{q_a}{4\pi a^2}$ and $\sigma_b = \frac{q_b}{4\pi b^2}$. The charges used for shielding are missing from the conductor and must be compensated for by charges of opposite sign. The only place where these opposite charges can accumulate is the outer surface of the conductor. Thus, we have the surface charge $\sigma_R = \frac{-q_a - q_b}{4\pi R^2}$.
- The field outside the driver is consequently, $\vec{\mathcal{E}} = \frac{q_a+q_b}{4\pi\varepsilon_0}\frac{\mathbf{r}}{r^3}$, where $\mathbf{r}$ is the point of observation with respect to the center of the conductor.
- Inside each cavity the electric field is determined by Gauß' law, $\vec{\mathcal{E}} = \frac{q_{a,b}}{4\pi\varepsilon_0}\frac{r}{r^3}$, where $\mathbf{r}$ is the observation point respect to the center of the cavity. Note that the surface charge $\sigma_{a,b}$ does not influence the field.
- Since the charges $q_{a,b}$ do not feel external fields, they are not subject to forces.
- Putting a third charge q_c near the conductor, the charge distribution σ_R would change in order to compensate the field within the conductor. Thus, the other quantities determined in (a)-(d) would not change. *The conductor effectively decouples all processes occurring on disconnected surfaces.*

10.4.5 Electrostatic pressure

What is the force exerted by an applied electric field $\vec{\mathcal{E}}_{\text{ext}}$ on a charged conductive surface? We know that the surface charge causes a discontinuity of the electric field, so that we need to calculate the force on a surface element dS as the average of the forces acting from above and from below,

$$d\mathbf{F} = dS\frac{\sigma}{2}(\vec{\mathcal{E}}_{\text{top}} + \vec{\mathcal{E}}_{\text{bottom}}) = \vec{\mathcal{P}}dS \ , \tag{10.53}$$

where $\vec{\mathcal{P}}$ is the *electrostatic pressure* (see Fig. 10.13).

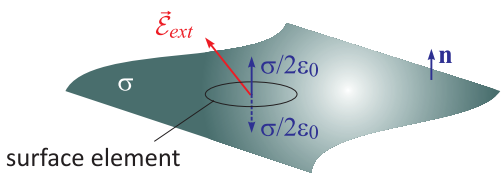

Figure 10.13: Electrostatic pressure exerted by a field $\vec{\mathcal{E}}_{\text{ext}}$ on a charged surface element.

In the case of a thin surface, we have,

$$\vec{\mathcal{E}}_{\text{top}} = \vec{\mathcal{E}}_{\text{ext}} + \frac{\sigma}{2\varepsilon_0}\hat{\mathbf{n}} \quad , \quad \vec{\mathcal{E}}_{\text{bottom}} = \vec{\mathcal{E}}_{\text{ext}} - \frac{\sigma}{2\varepsilon_0}\hat{\mathbf{n}} \ , \tag{10.54}$$

such that the pressure is,

$$\vec{\mathcal{P}} = \sigma\vec{\mathcal{E}}_{\text{ext}} \ . \tag{10.55}$$

In the case of a charged surface of a massive conductor without external field,

$$\vec{\mathcal{E}}_{\text{outside}} = \frac{\sigma}{\varepsilon_0}\hat{\mathbf{n}} \quad , \quad \vec{\mathcal{E}}_{\text{inside}} = 0 \ , \tag{10.56}$$

such that the pressure is,

$$\vec{\mathcal{P}} = \frac{\sigma}{2}\frac{\sigma}{2\varepsilon_0}\hat{\mathbf{n}} = \frac{\varepsilon_0}{2}\mathcal{E}^2_{\text{outside}}\hat{\mathbf{n}} \ . \tag{10.57}$$

That is, even without external field a charged conductor suffers a force trying to push it into the field created by itself, regardless of the sign of the charge. It is interesting to note that this force goes with the square of σ and of $\vec{\mathcal{E}}_{\text{outside}}$.

10.4.6 Exercises

10.4.6.1 Ex: Motion of two charges

Two particles with masses m_1 and m_2 and charges $Q_1 > 0$ and $Q_2 > 0$ are placed at a mutual distance d_0 and can move freely in space.
a. What will happen to the particles qualitatively? Which relation holds at all times for the velocities v_1 and v_2 of the two particles?
b. Calculate the velocities of the two particles as a function of their distance and plot the functions $v_1(d)$, respectively $v_2(d)$ (phase space diagrams). What are the velocities reached in the limit $d \to \infty$?

10.4.6.2 Ex: Paul trap

We consider four parallel wires oriented along the z-direction and forming a quadrupolar configuration in the xy-plane, as shown in the figure. The wires are charged with $\pm q$ per unit of length l. Calculate the electrical potential as a function of x and y in the center between the wires and expand around $x = 0$ and $y = 0$ ($|x|, |y| \ll a$) up to second order. What is the shape of the potential at this position? Do you think it is possible to trap a charged particle in this potential?

10.4.6.3 Ex: Energy of the electron

Supposing that the charge is homogeneously distributed over a sphere, calculate the *classical electron radius*.

10.4.6.4 Ex: Radius of the electron

a. Try to calculate the electrostatic energy of the field of an electron via,

$$E_F = \int_{\mathbb{R}^3} \frac{\varepsilon_0}{2}\vec{\mathcal{E}}^2(\mathbf{r})\ d^3r$$

What problem appears in the calculation of the radial part of the integral $\int dr$, if the lower limit of integration goes to $r_0 \to 0$?
b. This problem is known as *self-energy divergence*. It is possible to work around this problem, leaving the limits out and choosing the classic electron radius r_0 as the integration limit. The energy E_F of the electric field is then identified with half the energy $E = \frac{1}{2}m_e c^2$ of the electron rest mass m_e. Calculate the classic electron radius!

10.4.6.5 Ex: Electrostatic energy

a. Write the potential energy of a charge q in an external field $\vec{\mathcal{E}} = -\vec{\nabla}\Phi$?
b. What is the value of the electrostatic energy of N point charges?
c. What is the value of the energy of a charge distribution in the electric field $\vec{\mathcal{E}}(\mathbf{r})$?
d. What are the boundary conditions for the $\vec{\mathcal{E}}$-field on a conductor's surface?
e. Draw the electric field of a point charge q located in front of a metallic plane. What is the induced charge? What is the value of the force on the charge q?

10.4.6.6 Ex: Electrostatic energy

What is the electrostatic energy of
a. four equal charges Q located at the corners of a tetrahedron with the edge length d?
b. a dielectric sphere with radius R homogeneously charged with the charge Q? To do this, calculate the electric field inside and outside the sphere using Gauß' law.

10.4.6.7 Ex: Electrostatic energy

a. Eight point charges q are placed in the corners of a cube with the edge length l. Calculate the electrostatic energy of this configuration.
b. A balloon with radius R is charged homogeneously with the charge Q. What is the value of electrostatic energy? What is the force required to inflate the balloon even more, neglecting the elastic force of the balloon?

10.4.6.8 Ex: Charge separation

Two conducting neutral spheres are in contact and attached to insulating rods on a large wooden table. A positively charged stick is brought close to the surface of one of the spheres on the side opposite the point of contact with the other sphere.
a. Describe the charges induced in the two conductive spheres and discuss the charge distribution in both.
b. The two spheres are separated and then the charged stick is taken away. Then, the spheres are separated by a great distance. Discuss the charge distributions on the spheres after they are separated.

10.5 Treatment of boundary conditions and the uniqueness theorem

In practice, the solution of an electrostatic problem, that is, the resolution of the Poisson equation, can be hampered by boundary conditions. For example, charges in front of conducting surfaces induce a redistribution of charges in the conductor which modifies the electric field. The field is unequivocally determined by the charge and the boundary conditions. In this section we will discuss the method of image charges, which is a heuristic model, and the mathematical treatment of boundary conditions.

10.5.1 The method of images charges

One way to simulate boundary conditions is to 'invent' imaginary charges and distribute them in a way that the total field automatically satisfies these boundary conditions. This is usually only helpful when the boundary conditions exhibit a high degree of symmetry. This is the method of the so-called *image charge*s.

The simplest case is that of the point charge Q at a distance d in front of a conductive and grounded plane. By induction the charge will cause a redistribution of charges on the surface of the conductor in such a way, that the field lines cross the surface of the conductor at right angles. But the same boundary conditions can be satisfied by replacing the conductive plane with a second imaginary charge with opposite sign at the position of the image of the first charge regarding the plane as a mirror. From the point of view of the electric field the two configurations are equivalent, but the field is much easier to calculate for a charge and its image using Coulomb's law. See Excs. 10.5.6.1, 10.5.6.2, 10.5.6.3, 10.5.6.4, and 10.5.6.5.

Example 51 (*Induced surface charge*): In the case of the point charge in front of a conducting plane, which is the simplest case imaginable, the boundary conditions are,

$$\Phi(x,y,0) = 0 \quad , \quad \Phi(|\mathbf{r}| \gg d) = 0 \ ,$$

the potential is,

$$\Phi(\mathbf{r}) = \frac{1}{4\pi\varepsilon_0}\left(\frac{Q}{\sqrt{x^2+y^2+(z-d)^2}} + \frac{-Q}{\sqrt{x^2+y^2+(z+d)^2}}\right) \ ,$$

and the field is,

$$\vec{\mathcal{E}} = -\nabla\Phi = \frac{-Q}{4\pi\varepsilon_0}\left(\frac{-1}{\sqrt{x^2+y^2+(z-d)^2}^3}(\hat{\mathbf{e}}_z - \mathbf{r}) + \frac{1}{\sqrt{x^2+y^2+(z+d)^2}^3}(\hat{\mathbf{e}}_z + \mathbf{r})\right) \ .$$

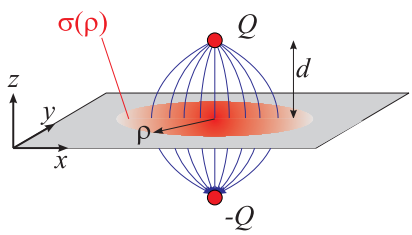

Figure 10.14: Point charge in front of a conductive plane.

We can now calculate the charge distribution on the surface. Gauß' law says,

$$\int_{box} \vec{\mathcal{E}} \cdot d\mathbf{S} = \frac{Q}{\varepsilon_0} = \frac{1}{\varepsilon_0}\int \varrho(\mathbf{r})dV = \frac{1}{\varepsilon_0}\int \sigma(x,y)\delta(z)dV = \frac{1}{\varepsilon_0}\int \sigma(x,y)dA \ .$$

Therefore, on the surface,

$$\hat{\mathbf{e}}_z \cdot \vec{\mathcal{E}}(x,y,z=0) = \frac{\sigma(x,y)}{\varepsilon_0} \ .$$

Resolving by the charge density,

$$\sigma(x,y) = \varepsilon_0 \hat{\mathbf{e}}_z \cdot \vec{\mathcal{E}}(x,y,z=0) = \frac{-Q}{4\pi} \frac{2}{\sqrt{x^2+y^2+d^2}^3} \ .$$

Also, we can verify that the total surface charge is, $Q_s = -Q$.

10.5.2 Formal solution of the electrostatic problem

The solution of the Laplace equation will, in general, depend on boundary conditions imposed by the geometry of the system. For example, a charge in free space will generate another field than a charge above a conductive surface. The two most common boundary conditions are named after *Dirichlet* and *von Neumann*. The Dirichlet condition fixes the value of the potential on a geometry of surfaces enclosing a volume, $\Phi|_{\partial\mathcal{V}} = \Phi_0$, while the von Neumann condition fixes the value of the potential gradient, $\nabla\Phi|_{\partial\mathcal{V}} = \vec{\mathcal{E}}_0$. Let us discuss these conditions in the following.

Using the following four relationships,

$$\begin{aligned}
&\text{(i)} \quad \nabla^2 \tfrac{1}{4\pi|\mathbf{r}-\mathbf{r}'|} = -\delta(\mathbf{r}-\mathbf{r}') \\
&\text{(ii)} \quad \nabla\cdot(\phi\mathbf{F}) = \phi(\nabla\cdot\mathbf{F}) + (\nabla\phi)\cdot\mathbf{F} \\
&\text{(iii)} \quad \int_{\mathcal{V}} \nabla\cdot\mathbf{F} dV' = \int_{\partial V} \mathbf{F}\cdot d\mathbf{S}' \\
&\text{(iv)} \quad \nabla^2\Phi = -\tfrac{\varrho}{\varepsilon_0} \ ,
\end{aligned} \tag{10.58}$$

we now solve the Poisson equation,

$$\begin{aligned}
\Phi(\mathbf{r}) &= \int_{\mathcal{V}} \Phi(\mathbf{r}')\delta(\mathbf{r}-\mathbf{r}')dV' = \tfrac{-1}{4\pi}\int_{\mathcal{V}} \underbrace{\Phi(\mathbf{r}')}_{\phi}\nabla\cdot\underbrace{\left(\nabla\tfrac{1}{|\mathbf{r}-\mathbf{r}'|}\right)}_{\mathbf{F}} dV' \qquad \text{with (i)} \\
&= \tfrac{1}{4\pi}\int_{\mathcal{V}} \underbrace{\nabla\Phi(\mathbf{r}')}_{\mathbf{F}}\cdot\nabla\underbrace{\tfrac{1}{|\mathbf{r}-\mathbf{r}'|}}_{\phi} dV' - \tfrac{1}{4\pi}\int_{\mathcal{V}} \nabla\cdot\left(\Phi(\mathbf{r}')\nabla\tfrac{1}{|\mathbf{r}-\mathbf{r}'|}\right) dV' \qquad \text{with (ii)} \\
&= -\tfrac{1}{4\pi}\int_{\mathcal{V}} \tfrac{1}{|\mathbf{r}-\mathbf{r}'|}\nabla\cdot\nabla\Phi(\mathbf{r}')dV' + \tfrac{1}{4\pi}\int_{\mathcal{V}} \nabla\cdot\left(\tfrac{1}{|\mathbf{r}-\mathbf{r}'|}\nabla\Phi(\mathbf{r}')\right) dV' - \tfrac{1}{4\pi}\int_{\mathcal{V}} \nabla\cdot\left(\Phi(\mathbf{r}')\nabla\tfrac{1}{|\mathbf{r}-\mathbf{r}'|}\right) dV' \ .
\end{aligned} \tag{10.59}$$

Finally, using relations (iii and iv), we obtain the final result,

$$\boxed{\Phi(\mathbf{r}) = \tfrac{1}{4\pi\varepsilon_0}\int_{\mathcal{V}} \tfrac{\varrho(\mathbf{r}')}{|\mathbf{r}-\mathbf{r}'|}dV' + \tfrac{1}{4\pi}\oint_{\partial\mathcal{V}} \left(\Phi(\mathbf{r}')\nabla'\tfrac{1}{|\mathbf{r}-\mathbf{r}'|} - \tfrac{1}{|\mathbf{r}-\mathbf{r}'|}\nabla'\Phi(\mathbf{r}')\right)\cdot d\mathbf{S}'} \ , \tag{10.60}$$

which is an integral version of the Poisson equation. For volumes going to infinity, where the potential disappears, the surface integrals can be neglected, and we get the familiar form of Coulomb's law. For finite volumes, boundary conditions on surfaces can dramatically influence the potential.

Example 52 (*Consistency of Green's relationship*): Obviously, by imposing boundary conditions that coincide with equipotential surfaces of the field created by the charge distribution, the surface terms vanish. Choosing as an

example a point charge placed at the origin, $\varrho(\mathbf{r}') = Q\delta^3(\mathbf{r}')$, and inserting its potential,

$$\Phi(\mathbf{r} = R\hat{\mathbf{e}}_r) = \frac{Q}{4\pi\varepsilon_0}\frac{1}{R} = \frac{Q}{4\pi\varepsilon_0}\left.\frac{1}{|\mathbf{r}-\mathbf{r}'|}\right|_{\mathbf{r}\in\partial\mathcal{V}} . \tag{10.61}$$

in the relationship (10.60), we find that the surface integrals cancel out.

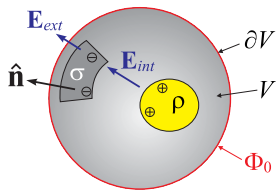

Figure 10.15: Illustration of boundary conditions.

The surface term can be interpreted in terms of a surface charge density, because we know that the normal electric field is discontinuous when crossing a charged surface [6]:

$$\tfrac{\sigma(\mathbf{r}')}{\varepsilon_0} = -\nabla'\Phi(\mathbf{r}')\cdot\hat{\mathbf{n}} . \tag{10.62}$$

We consider the example of a charge distribution, $\varrho(\mathbf{r}')$, surrounded by a surface on which the potential is zero, $\Phi(\mathbf{r}')|_{\partial\mathcal{V}'} = 0$, such that the first surface term of the relation (10.60) fades away. Inserting the expression (10.62) in the second surface term, the relation becomes,

$$\Phi(\mathbf{r}) = \frac{1}{4\pi\varepsilon_0}\int_{\mathcal{V}}\frac{\varrho(\mathbf{r}')}{|\mathbf{r}-\mathbf{a}|} + \frac{1}{4\pi\varepsilon_0}\oint_{\partial\mathcal{V}}\frac{\sigma(\mathbf{r}')}{|\mathbf{r}-\mathbf{r}'|}dS' . \tag{10.63}$$

The interpretation of this modified Coulomb law is, that the charge induces a density distribution of surface charges σ within the conducting plane which modifies the electric potential, such that the boundary condition is satisfied.

10.5.3 Green's Function

The function $\frac{1}{4\pi|\mathbf{r}-\mathbf{r}'|}$ not the only one to satisfy the condition (10.58)(i). In fact, there is an entire class of functions called Green functions defined by,

$$\nabla^2 G(\mathbf{r},\mathbf{r}') \equiv -\delta(\mathbf{r}-\mathbf{r}') . \tag{10.64}$$

[6] We can derive this considering a thin disk located within the x-y plane and homogeneously charged with the charge density σ_0,

$$\Phi(z\hat{\mathbf{e}}_z) = \frac{1}{4\pi\varepsilon_0}\int_{\text{disco}}\frac{\sigma(\mathbf{r}')}{|z\hat{\mathbf{e}}_z-\mathbf{r}'|}dA' = \frac{\sigma_0}{2\varepsilon_0}\int_0^R\frac{1}{\sqrt{r'^2+z^2}}r'dr' = \frac{\sigma_0}{2\varepsilon_0}[\sqrt{R^2+z^2}-z] ,$$

and therefore,

$$E_z = -\frac{d\Phi(z\hat{\mathbf{e}}_z)}{dz} = -\frac{\sigma_0}{2\varepsilon_0}\left(\frac{z}{\sqrt{R^2+z^2}}-1\right) \overset{z\ll R}{\longrightarrow} \frac{\sigma_0}{2\varepsilon_0} .$$

Obviously, for these functions the formula derived in (10.59) will be generalized,

$$\boxed{\Phi(\mathbf{r}) = \frac{1}{\varepsilon_0}\int_{\mathcal{V}} \varrho(\mathbf{r}')G(\mathbf{r},\mathbf{r}')dV' + \oint_{\partial\mathcal{V}} \left(\Phi(\mathbf{r}')\nabla G(\mathbf{r},\mathbf{r}') - G(\mathbf{r},\mathbf{r}')\nabla\Phi(\mathbf{r}')\right)\cdot d\mathbf{S}'} \ . \tag{10.65}$$

The advantage of the Green function is, that we have the freedom to add any function F,

$$G(\mathbf{r},\mathbf{r}') = \frac{1}{4\pi|\mathbf{r}-\mathbf{r}'|} + F(\mathbf{r},\mathbf{r}') \tag{10.66}$$

satisfying the Laplace equation,

$$\nabla^2 F(\mathbf{r},\mathbf{r}') = 0 \ , \tag{10.67}$$

and the Green function (10.66) will still satisfy the definition (10.64). In particular, we can choose the function F in a way to eliminate one of the two surface integrals in Eq. (10.65) and to obtain an expression only involving Dirichlet's or von Neumann's boundary conditions.

10.5.4 Poisson equation with Dirichlet's boundary conditions

The first *uniqueness theorem* proclaims,

> *The solution of the Poisson (or Laplace) equation in a volume $\mathcal{V}$ is uniquely determined, if Φ is specified on the surface of the volume $\partial\mathcal{V}$.*

To prove this theorem, let us specify that the potential adopts the (not necessarily constant) value Φ_0 on the surface and consider two possible solutions of the Laplace equation, Φ_1 and Φ_2. The difference $\Phi_3 \equiv \Phi_1 - \Phi_2$ disappears on the surface, $\Phi_3|_{\partial\mathcal{V}} = 0$, and must also satisfy the Laplace equation: $\nabla^2\Phi_3 = 0$. Now, since the Laplace equation does not allow local maxima or minima [7], Φ_3 must be zero throughout space (see Fig. 10.16 left).

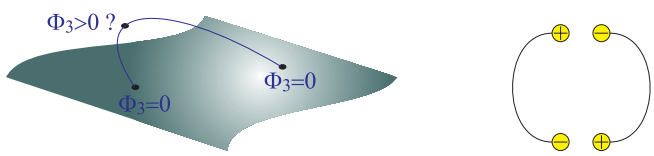

Figure 10.16: Illustration of the uniqueness theorems.

We consider as an example a finite volume V without charges, $\varrho = 0$, surrounded by a conducting border ∂V maintained at a fixed potential, $\Phi(\mathbf{r} \in \partial\mathcal{V}) = \Phi_0 = const.$ This is a typical situation realized, for example, in conductive materials such as metals. Therefore, $\Delta\Phi = 0$ within the volume. A possible trivial solution of the Laplace equation is, $\Phi(\mathbf{r}) = \Phi_0$. The uniqueness theorem now tells us that this is the *unique* solution.

To implement this theorem we choose the following boundary conditions,

$$G_{\mathrm{D}}(\mathbf{r},\mathbf{r}'_{\in\partial\mathcal{V}}) = 0 \ , \tag{10.68}$$

[7] For in a hypothetical maximum (minimum) we would have $\nabla^2\Phi_3 < 0$ (> 0).

such that the relationship (10.64) becomes,

$$\boxed{\Phi(\mathbf{r}) = \frac{1}{\varepsilon_0}\int_{\mathcal{V}} \varrho(\mathbf{r}')G_{\mathrm{D}}(\mathbf{r},\mathbf{r}')dV' + \oint_{\partial\mathcal{V}} \Phi(\mathbf{r}')\nabla' G_{\mathrm{D}}(\mathbf{r},\mathbf{r}')\cdot d\mathbf{S}'} \ . \tag{10.69}$$

Do the Excs. 10.5.6.7, 10.5.6.8, 10.5.6.9, and 10.5.6.10.

10.5.5 Poisson equation with von Neumann's boundary conditions

The second uniqueness theorem proclaims,

> *In a volume $\mathcal{V}$ surrounded by conductors and containing a specified charge density ϱ, the electric field is uniquely determined by the total charge of each conductor.*

To prove this theorem, we will consider a sample of conductors i each one carrying the charge Q_i. Assuming that there are two solutions for the electric field between the conductors, $\vec{\mathcal{E}}_1$ and $\vec{\mathcal{E}}_2$, each of these fields must satisfy, $\nabla\cdot\vec{\mathcal{E}}_1 = \nabla\cdot\vec{\mathcal{E}}_2 = Q_i$. The difference $\vec{\mathcal{E}}_3 \equiv \vec{\mathcal{E}}_1 - \vec{\mathcal{E}}_2$ must also satisfy Gauss' law $\nabla\cdot\vec{\mathcal{E}}_3 = 0$. Hence, $\vec{\mathcal{E}}_3$ must be vanish throughout the space (see Fig. 10.16 right) [8].

In the case of von Neumann boundary conditions we choose,

$$\nabla' G_{\mathrm{N}}(\mathbf{r},\mathbf{r}'_{\in\partial\mathcal{V}}) = -\frac{\hat{\mathbf{n}}}{S} \ , \tag{10.70}$$

because we must satisfy the definition (10.60),

$$-1 = \int_{\mathcal{V}} \nabla'^2 G_{\mathrm{N}}(\mathbf{r},\mathbf{r}')dV' = \oint_{\partial\mathcal{V}} \nabla' G_{\mathrm{N}}(\mathbf{r},\mathbf{r}')\cdot d\mathbf{S} = \oint_{\partial\mathcal{V}} \frac{-\hat{\mathbf{n}}}{S}\cdot d\mathbf{S} \tag{10.71}$$

such that,

$$\boxed{\Phi(\mathbf{r}) = \frac{1}{\varepsilon_0}\int_{\mathcal{V}} \varrho(\mathbf{r}')G_{\mathrm{N}}(\mathbf{r},\mathbf{r}')dV' - \frac{1}{A}\oint_{\partial\mathcal{V}} \Phi(\mathbf{r}')dA' - \oint_{\partial\mathcal{V}} G_{\mathrm{N}}(\mathbf{r},\mathbf{r}')\nabla'\Phi(\mathbf{r}')\cdot d\mathbf{S}'} \ . \tag{10.72}$$

The first surface term is simply the average of the potential over the area of the surface.

10.5.6 Exercises

10.5.6.1 Ex: Mirror charge

A long, thin wire is suspended along the y-direction at a distance $z = d$ parallel to a grounded metal plate located in the $z = 0$-plane. The surface of the wire carries the charge Q/l per unit length.
a. Draw a scheme of the electric field in the semi-space $z > 0$. **Help:** Use the principle of image charges!
b. Calculate the profile of the electric field near the surface of the plate.

[8] We present here a slightly simplified argumentation. See [386] for a more complete proof.

c. What is the surface density $\sigma(x, y)$ of charges on the plate surface.
d. What is the charge induced in the plate per unit length in y-direction?
Comment: A similar problem occurs for conductors on printed circuits. The metal plate corresponds to the copper coating on the backside of the circuit board.

10.5.6.2 Ex: Mirror charge

Consider the scheme, illustrated in the figure, of a point charge $+q$ in front of a corner of a grounded wall.
a. Determine the positions and values of the image charges.
b. Calculate the electrostatic potential $\Phi(\mathbf{r})$ in the upper right quadrant.

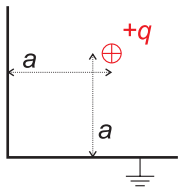

Figure 10.17: Mirror charge.

10.5.6.3 Ex: Mirror charge

Inside a grounded hollow metallic sphere with the inner radius a be a charge $+Q$ at the position $\mathbf{r}_1 = (0, 0, z_1)$. Determine the charge Q' and the position $\mathbf{r}_2$ of an image charge with which it is possible to describe the potential $\Phi(\mathbf{r})$ of the original charge distribution using only the system consisting of the charge and the image charge. Determine $\Phi(\mathbf{r})$.
Help: The position $\mathbf{r}_2$ and the charge Q' are not unambiguously determined. Choose $\mathbf{r}_1 = (0, 0, z_1)$ and $z_2/a = a/z_1$.

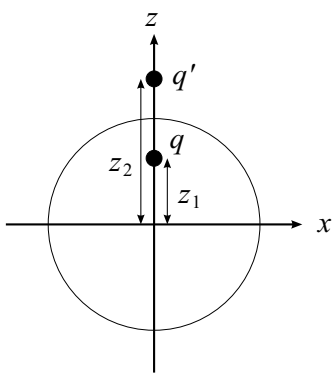

Figure 10.18: Mirror charge.

10.5.6.4 Ex: Mirror charge

A conductive surface in the (x, y)-plane has a protrusion in the form of a semi-sphere with radius R. The center of the sphere is in the plane and at the origin of the coordinates. On the symmetry axis $\hat{\mathbf{e}}_z$ at a distance $d > R$ from the plane there is a point charge Q. Determine with the image charge method the potential $\Phi(\mathbf{r})$ and the force $\mathbf{F}$ on the charge Q.
a. To make the surface of the semisphere an equipotential surface ($\Phi \equiv 0$) we need a mirror charge Q_1 on the z-axis at a distance z_1 from the origin. Determine Q_1 and z_1.
b. For the (x, y)-plane to become an equipotential surface as well, we need two more image charges Q_2 and Q_3. Determine the value and position of these charges.
c. With the values and positions of the charges determine: The electrostatic potential $\Phi(\mathbf{r})$ at an arbitrary point $\mathbf{r}$ above the conductive surface, the force $\mathbf{F}$ on the charge Q and its direction (repulsive or attractive).

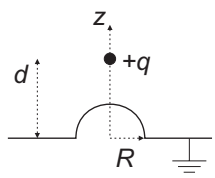

Figure 10.19: Mirror charge.

10.5.6.5 Ex: Mirror charge

Consider a hollow conducting sphere with radius R whose center is at the origin. At the position with the vector $\mathbf{a}$ ($|\mathbf{a}| > R$) be a point charge q.
a. The sphere is grounded (that is, $\Phi = 0$ at the edge of the hollow sphere). Calculate the potential outside the sphere using the image charge method.
b. Calculate the charge induced on the surface of the sphere.
c. What changes when the sphere is not grounded, but neutral?

10.5.6.6 Ex: Point charges in front of a conductor

Consider a point charge Q located at a distance d in front of an infinitely extended conductive plane.
a. Find the parametrization $\varrho(\mathbf{r})$ of the volume charge distribution for the charge and its image.
b. Calculate the potential from the distribution $\varrho(\mathbf{r})$.
c. Calculate the electric field from the distribution $\varrho(\mathbf{r})$.
d. Calculate the surface charge distribution $\sigma(\rho)$ induced in the conductor using Gauss' law.
e. Calculate the potential $\Phi(z)$ along the z-axis from Coulomb's law using the surface charge distribution $\sigma(\rho)$.
f. Compare the result obtained in (e) with the potential produced by the image charge

calculated in (b).
Help:: $\int \frac{1}{\sqrt{u^2+a^2}^3} \frac{1}{\sqrt{u^2+b^2}} u du = \frac{1}{a^2-b^2} \sqrt{\frac{u^2+b^2}{u^2+a^2}}$

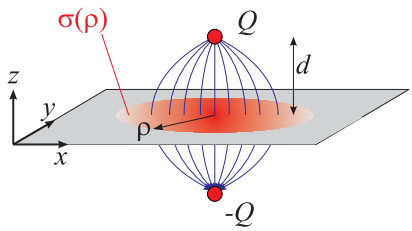

Figure 10.20: Mirror charge.

10.5.6.7 Ex: Dirichlet boundary conditions by the Green method

Here we want to analyze the problem of a potential in the semi-space defined by $z \geq 0$ with Dirichlet boundary conditions in the $z = 0$-plane and at infinity.
a. Determine the corresponding Greens function.
b. The potential has in the $z = 0$-plane within a circle of radius a the fixed value Φ_0. Outside this circle and on the same plane the potential is $\Phi = 0$. Derive the integral expression for the potential at a point in the upper semi-space with the cylindrical coordinates (ρ, ϕ, z).
c. Now show that the potential along an axis perpendicularly traversing the center of the circle is given by $\Phi(z) = \Phi_0(1 - z/\sqrt{a^2 + z^2})$.

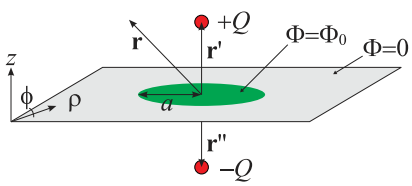

Figure 10.21: Green's function.

10.5.6.8 Ex: Conductor plates with mirror charges by the Green method

We consider two flat conductive plates (infinitely extended) with the mutual distance L. Exactly in the middle between the plates there is a point charge $+q$. Use the method of an infinite series of mirror images to calculate the potential between the plates and the force on a plate.

10.5.6.9 Ex: Hollow sphere by the Green method

We consider an infinitely thin conductive hollow sphere with radius a. In spherical coordinates, the potential on the surface of the sphere is given by $\Phi(a, \theta, \phi) = \Phi_0 \cos\theta$.
a. Calculate, using the Green function for the sphere, the potential and the field inside

the sphere on the z-axis.
b. Show that $\Phi(r,\theta,\phi) = \Phi_0(r/a)\cos\theta$ is the solution for the interior of the sphere and that $\vec{\mathcal{E}}(\mathbf{r}) = -(\Phi_0/a)\hat{\mathbf{e}}_z$.

10.5.6.10 Ex: Unambiguity of the solution of the contour problem

Show that with the Dirichlet boundary condition $\Phi(\mathbf{r}) = \Phi_0(\mathbf{r})|_{\in\partial V}$ or the von Neumann boundary condition $\frac{\partial\Phi}{\partial n}\big|_{\partial V} = -\frac{\sigma}{\varepsilon_0}$ within the region of the volume V the potential Φ is unambiguously determined by the Poisson equation $\Delta\Phi = -\frac{1}{\varepsilon_0}\rho(\mathbf{r})$and a constant.

10.6 Solution of the Laplace equation in situations of high symmetry

The Poisson (or Laplace) equation is a second order partial differential equation, which depends on three spatial coordinates. Many situations are characterized by symmetries, which allow us to disregard some spatial dimensions and dramatically simplify the mathematical problem. In the following, we will discuss situations of Cartesian, cylindrical and spherical symmetry.

10.6.1 Variable separation in Cartesian coordinates

In situations where the symmetry of the problem suggests a separation of the Cartesian variables, we can make the ansatz,

$$\Phi(\mathbf{r}) = X(x)Y(y)Z(z) \ . \tag{10.73}$$

In Cartesian coordinates the Laplace equation is written,

$$\left[\frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} + \frac{\partial^2}{\partial z^2}\right]\Phi = 0 \ . \tag{10.74}$$

Inserting the ansatz into the Laplace equation and dividing by Φ,

$$\frac{1}{X}\frac{\partial^2 X}{\partial x^2} + \frac{1}{Y}\frac{\partial^2 Y}{\partial y^2} + \frac{1}{Z}\frac{\partial^2 Z}{\partial z^2} = 0 \ . \tag{10.75}$$

The three terms are functions of different variables and must therefore be constant independently and separately,

$$\frac{1}{X}\frac{\partial^2 X}{\partial x^2} = C_1 \quad , \quad \frac{1}{Y}\frac{\partial^2 Y}{\partial y^2} = C_2 \quad , \quad \frac{1}{Z}\frac{\partial^2 Z}{\partial z^2} = C_3 = -C_1 - C_2 \ . \tag{10.76}$$

The advantage of this procedure is that, the differential equations for the three spatial coordinates being decoupled, we can be solve them separately. In the best case, the field is homogeneous in one of the coordinates, which reduces the dimensionality of the problem.

Example 53 (*Field of a grounded board*): For example, to calculate the field of a plate held at a fixed potential Φ_0 and being infinitely extended in the x-y-plane, we can let $X'(x) = Y'(y) = 0$ and solve the equation,

$$\frac{\partial^2 Z}{\partial z^2} = 0 \ , \tag{10.77}$$

which gives, $\Phi(\mathbf{r}) = Z(z) = Cz + \Phi_0$ and $\vec{\mathcal{E}} = C\hat{\mathbf{e}}_z$. The constants C and Φ_0 must be specified by additional boundary conditions. See Exc. 10.6.4.1.

10.6.2 Variable separation in cylindrical coordinates

In situations where the symmetry of the problem suggests a possible separation of cylindrical variables, we can try the ansatz,

$$\Phi(\mathbf{r}) = R(r)F(\phi)Z(z) \ . \tag{10.78}$$

In cylindrical coordinates the Laplace equation is written,

$$\left[\frac{1}{\rho}\frac{\partial}{\partial\rho}\left(\rho\frac{\partial}{\partial\rho}\right) + \frac{1}{\rho^2}\frac{\partial^2}{\partial\phi^2} + \frac{\partial^2}{\partial z^2}\right]\Phi = 0 \ . \tag{10.79}$$

Inserting the ansatz into the Laplace equation and dividing by Φ,

$$\frac{1}{R\rho}\frac{\partial}{\partial\rho}\left(\rho\frac{\partial R}{\partial\rho}\right) + \frac{1}{F}\frac{\partial^2 F}{\partial\phi^2} + \frac{1}{Z}\frac{\partial^2 Z}{\partial z^2} = 0 \ . \tag{10.80}$$

The three terms are functions of different variables and must therefore be constant separately,

$$\frac{1}{R\rho}\frac{\partial}{\partial\rho}\left(\rho\frac{\partial R}{\partial\rho}\right) = C_1 \quad , \quad \frac{1}{F}\frac{\partial^2 F}{\partial\phi^2} = C_2 \quad , \quad \frac{1}{Z}\frac{\partial^2 Z}{\partial z^2} = C_3 = -C_1 - C_2 \ . \tag{10.81}$$

Example 54 (*Field of a straight wire*): Many geometries have cylindrical symmetry, such that the equations in θ and z become trivial. For example, to calculate the field of a straight and infinite wire maintained at a fixed potential, it is enough to solve a radial differential equation,

$$\frac{\partial}{\partial\rho}\left(\rho\frac{\partial R}{\partial\rho}\right) = 0 \ ,$$

which gives, $\Phi(\mathbf{r}) = R(\rho) = C\ln\rho + \Phi_0$ and $\vec{\mathcal{E}} = C\hat{\mathbf{e}}_\rho/\rho$. The constants C and Φ_0 must be specified by additional boundary conditions.

10.6.3 Variable separation in spherical coordinates

In situations where the symmetry of the problem suggests a possible separation of the spherical variables, we can try the make ansatz,

$$\Phi(\mathbf{r}) = R(r)T(\theta)F(\phi) \ . \tag{10.82}$$

In spherical coordinates the Laplace equation is written,

$$\left[\frac{1}{r^2}\frac{\partial}{\partial r}\left(r^2\frac{\partial}{\partial r}\right)+\frac{1}{r^2\sin\theta}\frac{\partial}{\partial\theta}\left(\sin\theta\frac{\partial}{\partial\theta}\right)+\frac{1}{r^2\sin^2\theta}\frac{\partial^2}{\partial\phi^2}\right]\Phi=0\ . \tag{10.83}$$

Inserting the ansatz into the Laplace equation and dividing by Φ,

$$\frac{1}{R}\frac{\partial}{\partial r}\left(r^2\frac{\partial R}{\partial r}\right)+\frac{1}{T\sin\theta}\frac{\partial}{\partial\theta}\left(\sin\theta\frac{\partial T}{\partial\theta}\right)+\frac{1}{Fr^2\sin^2\theta}\frac{\partial^2 F}{\partial\phi^2}=0\ . \tag{10.84}$$

The three terms are functions of different variables and must therefore be constant separately,

$$\frac{1}{R}\frac{\partial}{\partial r}\left(r^2\frac{\partial R}{\partial r}\right)=C_1 \quad , \quad \frac{1}{T\sin\theta}\frac{\partial}{\partial\theta}\left(\sin\theta\frac{\partial T}{\partial\theta}\right)=\ell(\ell+1) \tag{10.85}$$
$$\frac{1}{Fr^2\sin^2\theta}\frac{\partial^2 F}{\partial\phi^2}=m=-C_1-\ell(\ell+1)\ .$$

Example 55 (*Sphere with fixed potential*): Many geometries have spherical symmetry, such that the equations in θ and ϕ become trivial. For example, to calculate the field of a sphere held at a fixed potential, we only have to solve a radial differential equation,

$$\frac{1}{R}\frac{\partial}{\partial r}\left(r^2\frac{\partial R}{\partial r}\right)=0\ ,$$

which gives, $\Phi(\mathbf{r})=R(r)=-C/r+\Phi_0$ and $\vec{\mathcal{E}}=C\hat{\mathbf{e}}_r/r^2$. The constants C and Φ_0 must be specified by additional boundary conditions.

In case of *only azimuthal* symmetry, we have $m=0$ and $C_1=-\ell(\ell+1)$. The solutions of the radial equation are simple,

$$R(r)=A_\ell r^\ell+\frac{B_\ell}{r^{\ell+1}}\ . \tag{10.86}$$

The solutions of the angular equation are called *Legendre polynomials*,

$$T(\theta)=P_\ell(\cos\theta)\ . \tag{10.87}$$

They can be derived from the *Rodrigues formula*,

$$P_\ell(z)=\frac{1}{2^\ell\ell!}\left(\frac{d}{dz}\right)^\ell(z^2-1)^\ell\ . \tag{10.88}$$

The first polynomials are,

$$P_0(z)=1 \quad , \quad P_1(z)=z \quad , \quad P_2(z)=\tfrac{1}{2}(3z^2-1) \quad , \quad P_3(z)=\tfrac{1}{2}(5z^3-3z)\ . \tag{10.89}$$

All in all we get,

$$\boxed{\Phi(\mathbf{r})=\sum_{\ell=0}^{\infty}\left(A_\ell r^\ell+\frac{B_\ell}{r^{\ell+1}}\right)P_\ell(\cos\theta)}\ . \tag{10.90}$$

Example 56 (*Charged spherical layer*): In this example we consider a spherical shell carrying a surface charge described by $\sigma(\theta)$. The regions $r \leq R$ and $r \geq R$ are treated separately. The ansatz (10.90) can not diverge, neither within the sphere where we must let $B_\ell = 0$, nor outside the sphere where we have to let $A_\ell = 0$. On the surface even the potential has to be continuous, such that

$$0 = [\Phi_\geq - \Phi_\leq]_{r=R} = \sum_{\ell=0}^{\infty} \frac{B_l}{R^{\ell+1}} P_\ell(\cos\theta) - \sum_{\ell=0}^{\infty} A_\ell R^\ell P_\ell(\cos\theta) \ ,$$

resulting in $B_\ell = A_\ell R^{2\ell+1}$. On the other hand, the electric field is discontinuous,

$$-\frac{\sigma(\theta)}{\varepsilon_0} = \left[\frac{\partial \Phi_\geq}{\partial r} - \frac{\partial \Phi_\leq}{\partial r}\right]_{r=R} = \sum_{\ell=0}^{\infty} (2\ell+1) A_\ell R^{\ell-1} P_\ell(\cos\theta) \ .$$

The coefficients are,

$$A_\ell = \frac{1}{2\varepsilon_0 R^{\ell-1}} \int_0^\pi \sigma(\theta) P_\ell(\cos\theta) \sin\theta d\theta \ ,$$

which can be verified from the orthogonality relation,

$$\int_{-1}^{1} P_\ell(z) P_{\ell'}(z) dz = \frac{2\delta_{\ell,\ell'}}{2\ell+1} \ .$$

Particularly for the case $\sigma(\theta) = \sigma_0 \cos\theta = \sigma_0 P_1(\cos\theta)$ we obtain,

$$A_\ell = \frac{\sigma_0}{2\varepsilon_0 R^{\ell-1}} \int_0^\pi P_1(z) P_l(z) dz = \frac{\sigma_0}{2\varepsilon_0 R^{\ell-1}} \frac{2}{2\ell+1} \delta_{\ell,1} = \frac{\sigma_0}{3\varepsilon_0} \delta_{\ell,1} \ .$$

Finally,

$$\Phi(\mathbf{r}) = \begin{cases} \frac{\sigma_0}{3\varepsilon_0} r\cos\theta = \frac{\sigma_0}{3\varepsilon_0} \mathbf{r}\cdot\hat{\mathbf{e}}_z & \text{for} \quad r \leq R \\ \frac{\sigma_0 R^3}{3\varepsilon_0} \frac{1}{r^2} \cos\theta = \frac{\sigma_0 R^3}{3\varepsilon_0} \frac{\mathbf{r}\cdot\hat{\mathbf{e}}_z}{r^3} & \text{for} \quad r \geq R \end{cases} \ .$$

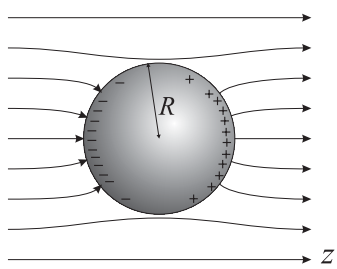

Figure 10.22: Distortion of a homogeneous field by a metallic sphere.

10.6.4 Exercises

10.6.4.1 Ex: Variable separation

Calculate the potential within an infinite rectangular waveguide in the z-direction by solving the Laplace equation using the variable separation method.

10.6.4.2 Ex: Field of a sphere with a hole

On the surface of a hollow sphere of radius R, from which a cap defined by the opening angle $\theta = \alpha$ was cut out at the north pole, there is a homogeneously distributed surface charge density $Q/4\pi R^2$.
a. Show that the potential within the volume of the sphere can be written in the form,

$$\Phi(r,\theta,\phi) = \frac{Q}{2}\sum_{\ell=0}^{\infty}\frac{1}{2\ell+1}\left[P_{\ell+1}(\cos\alpha) - P_{\ell-1}(\cos\alpha)\right]\ \frac{r^\ell}{R^{\ell+1}}\ P_\ell(\cos\theta)$$

where for $\ell = 0$ we have to let $P_{\ell-1}(\cos\alpha) = -1$. What is the shape of the potential outside the hollow sphere?
b. Determine the absolute value and the direction of the electric field at the origin.
c. What potential do we get for $\alpha \to 0$?
Help: Use the following relation for the surface charge density:

$$-\frac{\sigma}{\varepsilon_0} = \left[\frac{\partial\Phi_>}{\partial r} - \frac{\partial\Phi_<}{\partial r}\right]_{r=R} ,$$

where the indices $<$ resp. $>$ hold for regions inside resp. outside the sphere. For the integration, the following recursion relation is useful,

$$P_l(x) = \frac{1}{2\ell+1}\left(\frac{dP_{\ell+1}(x)}{dx} - \frac{dP_{\ell-1}(x)}{dx}\right)$$

that holds for $\ell > 0$.

10.7 Multipolar expansion

The basic idea of *multipolar expansion* is the approximate description of the potential generated by an arbitrary distribution of charges localized within a volume $\mathcal{V}$. The larger the distance between the observation point and the charge distribution in comparison to the extent of the volume $\mathcal{V}$, the more the potential looks like that of a point charge. The smaller the distance, the more terms (multipole moments) must be taken into account, $\Phi(\mathbf{r}) = \sum_k \Phi_k(\mathbf{r})$. High multipolar orders decay faster (like r^{-k}) with the distance between the observation point and the volume where the charge is concentrated.

We have already seen how to do the Taylor expansion of scalar fields in the formula (9.17) [9]. Here, we want to expand in terms of r^{-1}. We start by expanding the function,

$$\frac{1}{|\mathbf{r}-\mathbf{r}'|} = \frac{1}{r}\sum_{\ell=0}^{\infty}\left(\frac{r'}{r}\right)^\ell P_\ell(\cos\theta') , \tag{10.91}$$

[9] Using the following property of the Legendre polynomials,

$$\frac{1}{\sqrt{1+\eta(\eta-2z)}} = \sum_\ell \eta^\ell P_\ell(z) ,$$

where the left side is called the generating function of the polynomials.

where θ' is the angle between $\mathbf{r}$ and $\mathbf{r}'$. Inserting the expansion into Coulomb's law (10.35),

$$\Phi(\mathbf{r}) = \frac{1}{4\pi\varepsilon_0}\int \frac{\varrho(\mathbf{r}')}{|\mathbf{r}-\mathbf{r}'|}d^3r' = \frac{1}{4\pi\varepsilon_0}\sum_{\ell=0}^{\infty}\frac{1}{r^{\ell+1}}\int \varrho(\mathbf{r}')r'^{\ell}P_\ell(\cos\theta')d^3r' \ . \tag{10.92}$$

Example 57 (*Multipolar expansion by Legendre polynomials*): To discuss the multipolar expansion of the function $\frac{1}{|\mathbf{r}-\mathbf{r}'|}$ we chose the axis $\hat{\mathbf{r}}$ as the symmetry axis, as shown in Fig. 10.23, because in this coordinate system the function has azimuthal symmetry in the variable $\mathbf{r}'$. Therefore, we can apply the solution of the Laplace equation in spherical coordinates derived above,

$$\Phi(\mathbf{r}') = \sum_{\ell=0}^{\infty}\left(A_\ell r'^{\ell} + \frac{B_\ell}{r'^{\ell+1}}\right)P_\ell(\cos\theta') \ .$$

We consider two cases: In a first case in which $r' < r$, for the solution $\Phi(\mathbf{r}')$ to converge, we need to guarantee $B_\ell = 0$ such that,

$$\frac{1}{|\mathbf{r}-\mathbf{r}'|} = \sum_{\ell=0}^{\infty} A_\ell(r)r'^{\ell}P_\ell(\cos\theta') \ .$$

In the second case in which case $r' > r$, we need to ensure $A_\ell = 0$, such that,

$$\frac{1}{|\mathbf{r}-\mathbf{r}'|} = \sum_{\ell=0}^{\infty}\frac{B_\ell(r)}{r'^{\ell+1}}P_\ell(\cos\theta') \ ,$$

The coefficients $A_\ell(\mathbf{r})$ and $B_\ell(\mathbf{r})$ can not depend on $\mathbf{r}'$. Let us now have a closer look at this second case and rename the variables $\mathbf{r} \leftrightarrow \mathbf{r}'$:

$$\frac{1}{|\mathbf{r}'-\mathbf{r}|} = \sum_{\ell=0}^{\infty}\frac{B_\ell(r')}{r^{\ell+1}}P_\ell(\cos\theta) \ .$$

Comparing this to the first case and using $\theta = -\theta'$ we find,

$$A_\ell(r)r^{\ell+1} = \frac{B_\ell(r')}{r'^{\ell}} = const = C \ .$$

Hence,

$$\frac{1}{|\mathbf{r}-\mathbf{r}'|} = \sum_{\ell=0}^{\infty} C\frac{r'^{\ell}}{r^{\ell+1}}P_\ell(\cos\theta') \ .$$

The constant C can be calibrated considering a particular case, for example $\mathbf{r} \parallel \mathbf{r}'$ and $r \gg r'$. In this case, since $P_\ell(1) = 1$, the multipolar expansion,

$$\frac{1}{|\mathbf{r}-\mathbf{r}'|} = \frac{1}{|r-r'|} = \sum_{\ell=0}^{\infty} C\frac{r'^{\ell}}{r^{\ell+1}} \ ,$$

is nothing more than a Taylor expansion around the point $r - r' \simeq r$.

10.7.1 The monopole

For $n = 0$ the contribution of the *monopole moment* Q to the potential is,

$$\boxed{\Phi_0(\mathbf{r}) = \frac{Q}{4\pi\varepsilon_0}\frac{1}{r}} \quad \text{where} \quad \boxed{Q = \int_{\mathcal{V}} d^3r' \ \varrho(\mathbf{r}')} \tag{10.93}$$

is just the electric charge.

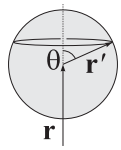

Figure 10.23: In the coordinate system $\hat{\mathbf{r}} = \hat{\mathbf{e}}_z$ the function $|\mathbf{r}-\mathbf{r}'|^{-1}$ has azimuthal symmetry.

10.7.2 The dipole

For $n = 1$ the contribution of the *electric dipole moment* $\mathbf{d}$ to the potential follows immediately from formula (10.91),

$$\begin{aligned}\Phi_1(r) &= \tfrac{1}{4\pi\varepsilon_0}\tfrac{1}{r^2}\int \varrho(\mathbf{r}')r'P_1(\cos\theta')d^3r' \\ &= \tfrac{1}{4\pi\varepsilon_0}\tfrac{1}{r^3}\int \varrho(\mathbf{r}')rr'\cos\theta' d^3r' = \tfrac{1}{4\pi\varepsilon_0}\tfrac{\mathbf{r}}{r^3}\cdot\int \varrho(\mathbf{r}')\mathbf{r}'d^3r' \ .\end{aligned}$$

We obtain,

$$\boxed{\Phi_1(\mathbf{r}) = \frac{1}{4\pi\varepsilon_0}\sum_k d_k\frac{x_k}{r^3}} \quad \text{where} \quad \boxed{\mathbf{d} = \int_{\mathcal{V}} d^3r' \ \mathbf{r}'\varrho(\mathbf{r}')} \ . \tag{10.94}$$

10.7.3 The quadrupole

For $n = 2$ the contribution of the *electric quadrupole moment* $q_{i,j}$ to the potential follows immediately from the formula(10.91),

$$\begin{aligned}\Phi_2(r) &= \tfrac{1}{4\pi\varepsilon_0}\tfrac{1}{r^3}\int \varrho(\mathbf{r}')r'^2P_2(\cos\theta')d^3r' = \tfrac{1}{4\pi\varepsilon_0}\tfrac{1}{r^3}\int \varrho(\mathbf{r}')r'^2\tfrac{3\cos^2\theta'-1}{2}d^3r' \\ &= \tfrac{1}{4\pi\varepsilon_0}\tfrac{1}{2r^5}\int \varrho(\mathbf{r}')(3(\mathbf{r}\cdot\mathbf{r}')^2 - r^2r'^2)d^3r' \\ &= \tfrac{1}{4\pi\varepsilon_0}\tfrac{1}{2r^5}\sum_{k,m}\int \varrho(\mathbf{r}')(3x_kx'_kx_mx'_m - x_kx_mr'^2\delta_{k,m})d^3r' \ .\end{aligned}$$

We obtain,

$$\boxed{\Phi_2(\mathbf{r}) = \frac{1}{4\pi\varepsilon_0}\frac{1}{2}\sum_{k,m} q_{k,m}\frac{x_kx_m}{r^5}} \quad \text{where} \quad \boxed{q_{k,m} = \int_{\mathcal{V}} d^3r' \ (3x'_kx'_m - r'^2\delta_{k,m})\varrho(\mathbf{r}')} \ . \tag{10.95}$$

Example 58 (*Multipole moments of a dipole*): As an example, we consider the simplest dipole, which consists of two charges e and $-e$ separated by a fixed distance a, which we choose parallel to the z-axis. The monopolar moment is,

$$Q = \int d^3r' \ [e\delta(\tfrac{a}{2}\hat{\mathbf{e}}_z - \mathbf{r}') - e\delta(\tfrac{a}{2}\hat{\mathbf{e}}_z + \mathbf{r}')] = 0 \ ,$$

as expected. The dipole moment is,

$$\mathbf{d} = \int d^3r' \; \mathbf{r}'[e\delta(\tfrac{a}{2}\hat{\mathbf{e}}_z - \mathbf{r}') - e\delta(\tfrac{a}{2}\hat{\mathbf{e}}_z + \mathbf{r}')] = ea \begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix} ,$$

and the quadrupolar moment is,

$$\begin{aligned} q_{k,m} &= \int d^3r' \; (3x'_k x'_m - r'^2\delta_{km})[e\delta(\tfrac{a}{2}\hat{\mathbf{e}}_z - \mathbf{r}') - e\delta(\tfrac{a}{2}\hat{\mathbf{e}}_z + \mathbf{r}')] \\ &= \frac{ea^2}{4}\begin{pmatrix} -1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & 2 \end{pmatrix} - \frac{ea^2}{4}\begin{pmatrix} -1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & 2 \end{pmatrix} = 0 \; . \end{aligned}$$

See the Excs. 10.7.5.1 to 10.7.5.10.

Example 59 (*The electric dipole*): The gradient of the potential of a dipole is,

$$\begin{aligned} \vec{\mathcal{E}}_1 &= -\nabla \frac{\mathbf{r}\cdot\mathbf{d}}{4\pi\varepsilon_0 r^3} = \frac{-1}{4\pi\varepsilon_0}\hat{\mathbf{e}}_x \frac{\partial}{\partial x}\frac{xd_x + yd_y + zd_z}{(x^2+y^2+z^2)^{3/2}} + ... \\ &= \frac{-1}{4\pi\varepsilon_0}\hat{\mathbf{e}}_x \frac{d_x(x^2+y^2+z^2)^{3/2} - (xd_x + yd_y + zd_z)3x(x^2+y^2+z^2)^{1/2}}{(x^2+y^2+z^2)^3} + ... \\ &= \frac{-1}{4\pi\varepsilon_0}\hat{\mathbf{e}}_x \frac{d_x r^2 - \mathbf{r}\cdot\mathbf{d}3x}{r^5} + ... = \frac{1}{4\pi\varepsilon_0}\frac{3(\hat{\mathbf{e}}_r\cdot\mathbf{d})\hat{\mathbf{e}}_r - \mathbf{d}}{r^3} \; . \end{aligned}$$

10.7.4 Expansion into Cartesian coordinates

The multipolar expansion can also be done in Cartesian coordinates by a Taylor series of the Green function [10]. To take this into account, we evaluate the function $G(\mathbf{r},\mathbf{r}') = G(\mathbf{r}-\mathbf{r}')$ around the distance $\mathbf{r}-\mathbf{r}' \simeq \mathbf{r}$,

$$G(\mathbf{r}-\mathbf{r}') = \sum_k \frac{1}{k!}(\mathbf{r}'\cdot\nabla)^k G(\mathbf{r}) = G(\mathbf{r}) + \sum_{k=1} x'_k \frac{\partial}{\partial x_k}G(\mathbf{r}) + \frac{1}{2!}\left(\sum_{k=1}^{3} x'_k \frac{\partial}{\partial x_k}\right)^2 G(\mathbf{r}) + ... \tag{10.96}$$

$$\begin{aligned} &= G(\mathbf{r}) + \sum_{k=1} x'_k \frac{\partial}{\partial x_k}G(\mathbf{r}) + \frac{1}{2!}\sum_{k,m=1}^{3} x'_k x'_m \frac{\partial^2}{\partial x_k \partial x_m}G(\mathbf{r}) + ... \\ &= G(\mathbf{r}) + \sum_{k=1} x'_k \frac{\partial}{\partial x_k}G(\mathbf{r}) + \frac{1}{6}\sum_{k,m=1}^{3}(3x'_k x'_m - r'^2\delta_{k,m})\frac{\partial^2}{\partial x_k \partial x_m}G(\mathbf{r}) + ... \end{aligned}$$

The last transformation is valid if the function G satisfies the Laplace equation, $\nabla^2 G = 0$.

[10] We can imagine the Green function as the potential created by a point-charge distribution, $\varrho(\mathbf{r}') = Q\delta(\mathbf{r}-\mathbf{a})$, since $\Phi(\mathbf{r}) = \int G(\mathbf{r}-\mathbf{r}')\varrho(\mathbf{r}')dV' = QG(\mathbf{r}'-\mathbf{a})$. That is, the multipolar terms come into play due to a small stretching of the charge distribution around the point $\mathbf{r}' = \mathbf{a}$

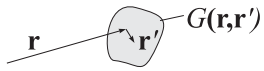

Figure 10.24: Taylor expansion of the Green function around the point $\mathbf{r}-\mathbf{r}' \simeq \mathbf{r}$.

Example 60 (*Cartesian multipolar expansion*): As an example, we expand the Coulomb potential, $G(\mathbf{r}-\mathbf{r}') = \frac{1}{|\mathbf{r}-\mathbf{r}'|}$. The first derivatives,

$$\frac{\partial}{\partial x_k}\frac{1}{|\mathbf{r}-\mathbf{r}'|} = \frac{x_k - x_k'}{|\mathbf{r}-\mathbf{r}'|^3} \ ,$$

and the second derivatives,

$$\frac{\partial^2}{\partial x_k \partial x_m}\frac{1}{|\mathbf{r}-\mathbf{r}'|} = \frac{3(x_k - x_k')^2 - (\mathbf{r}-\mathbf{r}')^2\delta_{k,m}}{|\mathbf{r}-\mathbf{r}'|^5} \ ,$$

allow us to calculate,

$$\frac{1}{|\mathbf{r}-\mathbf{r}'|} = \frac{1}{r} + \frac{\mathbf{r}\cdot\mathbf{r}'}{r^3} + \frac{1}{6}\sum_{k,m=1}^{3}\frac{3x_k x_m - r^2\delta_{k,m}}{r^5}(3x_k' x_m' - r'^2\delta_{k,m}) \ .$$

The octupolar term of the multipole expansion of the Coulomb potential is,

$$\frac{1}{3!}(\mathbf{r}'\cdot\nabla)^3\frac{1}{r'} = \frac{1}{6}\sum_{k,m,n=1}^{3} x_k' x_m' x_n' \frac{-15x_k x_m x_n + 3r''(x_k\delta_{mn} + x_m\delta_{kn} + x_n\delta_{mk})}{r^7} \ .$$

Inserting this into Coulomb's Law,

$$\Phi(\mathbf{r}) = \frac{1}{4\pi\varepsilon_0}\int\frac{\varrho(\mathbf{r}')}{|\mathbf{r}-\mathbf{r}'|}dV' = \frac{1}{4\pi\varepsilon_0}\left(\frac{1}{r}Q + \frac{\mathbf{r}}{r^3}\cdot\mathbf{d} + \frac{1}{6}\sum_{k,m=1}^{3}\frac{3x_k x_m - r^2\delta_{k,m}}{r^5}q_{k,m} + \ldots\right) \ ,$$

with the definitions of the multipole moments.

10.7.5 Exercises

10.7.5.1 Ex: Multipoles

A point charge $+2Q$ is at the position $(0,0,a)$ and another charge $+1Q$ at the position $(0,0,-a)$. Calculate a. The monopolar, b. the dipolar, and c. the quadrupolar contribution of the multipolar expansion.

10.7.5.2 Ex: Di- and quadrupolar momenta of spherical charge distributions

Do spherically symmetrical load distributions have dipole or quadrupolar moments? Justify!

10.7.5.3 Ex: Electric dipole

An electrical dipole consists of two charges of the value $q = 1.5\,\mathrm{nC}$ distant by $a = 6\,\mu\mathrm{m}$.
a. What is the dipole moment?
b. Calculate the dipole potential along the $\hat{\mathbf{e}}_z$ axis of symmetry and in the xy-plane.
c. The dipole is in an $1100\,\mathrm{N/C}$ electric field. What is the difference in potential energies comparing parallel and antiparallel orientations of the dipole.

10.7.5.4 Ex: Electric dipole

An electric dipole with the moment $\mathbf{d}$ is at the position $\mathbf{r}$. At the origin of the coordinate system there is a point charge e.
a. Calculate the potential energy of the dipole.
b. Calculate the force acting on the dipole.
c. Calculate the force acting on the charge. Is Newton's axiom of mechanics valid: 'actio = reactio'?

10.7.5.5 Ex: Electric dipole in a field

What is the force acting on an electric dipole $\mathbf{d} = ea \cdot \hat{\mathbf{e}}_r$ at a point $\mathbf{r}$ being aligned along the field lines of an external field produced by a sphere with radius R homogeneously charged with a charge Q?

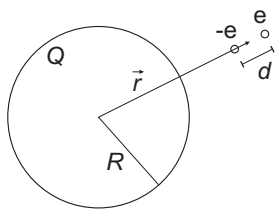

Figure 10.25: Electric dipole in a field.

10.7.5.6 Ex: Electric dipole in a field

Consider a molecule that consists of two rigidly bound masses $m_1 = m_2 = 10^{-25}\,\mathrm{kg}$ at a distance of $a = 10^{-12}\,\mathrm{m}$ and with charges $+e$ resp. $-e$.
a. Calculate the electric dipole moment $\mathbf{d} = d \cdot \hat{\mathbf{e}}_x$ of this charge distribution.
b. Now the molecule is put into rotation by a homogeneous electric field $\vec{\mathcal{E}} = \hat{\mathbf{e}}_z \cdot 100\,\mathrm{V/m}$. Calculate the rotation speed of the molecule as a function of the angle between the dipole moment and the electric field.
Help: The sum of the kinetic and electrostatic energies is conserved during the rotation.

10.7.5.7 Ex: Dipolar field in two dimensions

Consider two infinitely long parallel conductors with distance d carrying the linear charge density $+\lambda$ resp. $-\lambda$ (charge $\pm Q$ per length l of the conductor). Using the Gauß theorem, first calculate the electric field and the electric potential of one conductor. Then calculate the potential of both conductors by overlapping the individual potentials as a function of the distance r and the angle α (see Fig. 10.26). **Note:** Choose as integration volume a cylinder with length l and radius r along the symmetry axis around the wire. Determine the asymptotic behavior for $r \gg d/2$ and for $r \ll d/2$. To do this, do a Taylor expansion of the expression using: $\ln \frac{1+\epsilon}{1-\epsilon} \approx -2\epsilon + O(\epsilon^3)$. Write the result as a function of the dipole moment $\mathbf{p}$, where $p = |\mathbf{p}| = \lambda d$ is positive and indicates the direction of the dipole moment vector showing from the positive conductor to the negative.

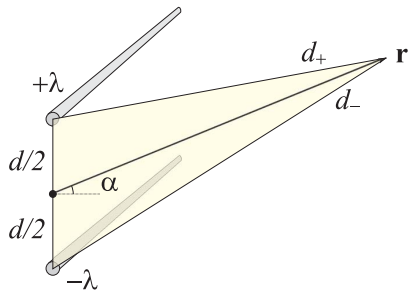

Figure 10.26: Dipolar field.

10.7.5.8 Ex: Dipolar and quadrupolar fields

Let us consider a system of three point charges aligned to the z-axis. At the positions $z = \pm a$ we have charges $+Q$, at the position $z = 0$ the charge $-2Q$.
a. Determine the charge distribution in terms of the δ-function in Cartesian coordinates.
b. Calculate the electrostatic potential $\Phi(\mathbf{r})$ of this charge distribution and approximate for long distances $|\mathbf{r}| \gg a$. (**Help:** Write the denominators that appear as $\frac{1}{|\mathbf{r}\pm\mathbf{a}|} = \frac{1}{r}\frac{1}{\sqrt{1+x}}$ with $x \equiv \frac{a^2 \pm 2\mathbf{a}\cdot\mathbf{r}}{r^2}$ and expand up to second order in a.)
c. Calculate the monopolar moment and the Cartesian components of the dipolar moment and the quadrupolar tensor.
d. Calculate the monopolar, dipolar, and quadrupolar potentials and show that the results coincides with the expansion (b).
e. Now rotate the coordinate system around the x-axis by an angle of 45°. What are the new values for multipolar moments? (**Help:** The quadrupolar tensor is transformed with the rotation matrix λ as $q'_{il} = \lambda_{il} q_{lm} \lambda^{\dagger}_{mj}$).

10.7.5.9 Ex: Multipoles

The two charge distributions shown in the graph are given.
a. Calculate for both cases first the electrical potential Φ for the distances $r = 2a$, $r = 10a$, and $r = 100a$ for the angles $\alpha = 0°$, $\alpha = 45°$, and $\alpha = 90°$, respectively.
b. The results must now be compared with those of the quadrupolar expansion. What are the monopolar, dipolar and quadrupolar moments for these two geometries? Calculate the monopolar, dipolar and quadrupolar contributions of the electrical potential for the same positions as above. Compare these values with those calculated exactly and identify the dominant contributions.

10.7.5.10 Ex: Multipoles

Four point charges $+e$ and $-e$ are located at the Cartesian coordinates $(x, y, z) = (0, d, 0)$, $(0, -d, 0)$, $(0, 0, d)$, $(0, 0, -d)$ and four other charges $-e$ at the points $(-d, 0, 0)$, $(-\frac{d}{2}, 0, 0)$, and $(d, 0, 0)$. Calculate the monopolar moment and the Cartesian components of the dipolar and quadrupolar moment of this charge distribution.

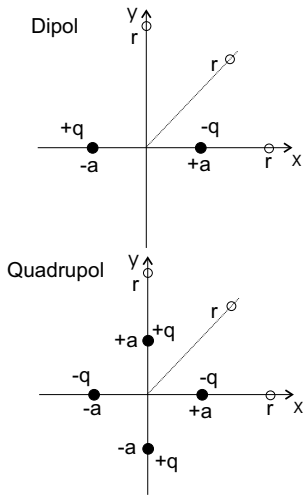

Figure 10.27: Multipoles.

10.7.5.11 Ex: Multipolar moments of a charge distribution

An ideal hollow sphere with radius R_0 has the surface charge density $\sigma(r,\theta,\phi) = \sigma_0 \cos\theta$ with σ_0 =const. Calculate:
a. The multipolar moments of this charge distribution.
b. The electrostatic potential outside the sphere.

10.7.5.12 Ex: Multipolar moment of an atomic nucleus

A simple model of a deformed atomic nucleus is a body homogeneously charged with the full charge Ze and being delimited by the quadrupolar surface $R(\theta) = R_0(a(\beta) + \beta Y_{20}(\theta))$. We now assume that the absolute value of the deformation parameter β is very small with respect to 1. For the average radius it is $R_0 = 1.2\ A^{1/3}$ [fm], where A is the number of nucleons present.
a. Visualize the shape of the nucleus.
b. Determine $a(\beta)$ up to second order in β from the request, that the core volume is always $V = 4\pi R_0^3/3$.
c. Calculate the multipolar moments Q_{lm} up to the octupolar term and up to the linear terms in β. Are there any multipolar moments that zero exactly?
d. Calculate also the electrostatic potential also up to linear terms in β.

10.7.5.13 Ex: Dipole-dipole interaction

a. Consider an electric dipole with dipole moment $\mathbf{d}$. Show that the electric field of the dipole is given by:

$$\vec{\mathcal{E}}(\mathbf{r} = r\hat{\mathbf{e}}_r) = -\frac{1}{4\pi\varepsilon_0}\frac{\mathbf{d} - 3\hat{\mathbf{e}}_r(\hat{\mathbf{e}}_r \cdot \mathbf{d})}{r^3} \ .$$

You may use the expression for a dipole potential.
b. Use this result to calculate the interaction energy U_{12} of two equal dipoles located

at a distance d from one another for the dipole configurations shown in the scheme.

Help: To calculate the interaction energy $U_{12}(\mathbf{a})$ between the two dipoles we con-

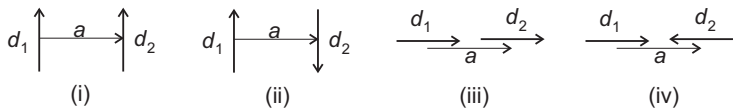

Figure 10.28: Dipole-dipole interaction.

sider the energy of dipole 1 in the electric field of dipole 2. So, $U_{12}(\mathbf{a}) = -\mathbf{d}_1\vec{\mathcal{E}}_2$. In which configurations do the dipoles attract, in which do they repel each other?

c. A current research area deals with cold dipolar molecules, for example, RbLi molecules having a permanent dipole electrical moment of $d_{RbLi} = 4.3$ Debye. What should be the atomic density n, where $n = a^{-3}$, in order to obtain a dipolar interaction U_0 at least as large as the thermal energy of the molecules? Ultra-cold molecular gases typically have a temperature around 10^{-6} K.

10.7.5.14 Ex: • Photoelectric effect

During the process described by the photoelectric effect, ultraviolet light can be used to electrically charge a piece of metal.

a. If this light strikes a bar of conductive material electrons, and are ejected with sufficient energy to escape from the surface of the metal, after how much time will the metal have accumulated a charge of $+1.5\,\mathrm{nC}$ if $1.0 \cdot 10^6$ electrons are ejected per second?

b. If 1.3 eV is required to eject an electron from the surface, what is the power of the light beam? (Consider the process to be 100% efficient.)

10.7.5.15 Ex: Polonium and the use of the Green function

The radioactive metal Polonium (Po), discovered by Marie and Pierre Curie in 1898, crystallizes in a simple cubic lattice (each atom has six neighbors on a regular grid). The nucleus contains 84 protons and the diameter of the atom is approximately $3 \cdot 10^{-8}$ cm. Calculate the distribution of the potential within a primitive cell of a Po crystal traversed by a constant current. Suppose the following model for the crystal: Atomic nuclei (radius $\sim 9 \cdot 10^{-13}$ cm) are at positions $\mathbf{x}'_{\lambda\mu\nu} = (\lambda a + a/2, \mu a + a/2, \nu a + a/2)$ for $\lambda, \mu\nu = 0, \pm 1, \pm 2, ...$, and will be treated as point charges. The electronic shell of a Po atom is represented by charges induced in a grounded conducting cube of size a, in the middle of which is located the positively charged nucleus inducing these charges. Proceed as follows:

a. Start showing that,

$$G(\mathbf{r}, \mathbf{r}') = \frac{32}{\pi a} \sum_{l,m,n=1}^{\infty} \frac{1}{l^2+m^2+n^2} \sin\frac{l\pi x}{a} \sin\frac{l\pi x'}{a} \sin\frac{m\pi y}{a} \sin\frac{m\pi y'}{a} \sin\frac{n\pi z}{a} \sin\frac{n\pi z'}{a} \ ,$$

is the Green function for the Dirichlet contour problem of a cube with edge length a.

b. Calculate the potential in the atom at the position $(a/2, a/2, a/2)$, where we assume

for the interior of the cube a charge $\rho(x', y', z') = q\delta(x' - a/2)\delta(y' - a/2)\delta(z' - a/2)$ and that the potential on the six surfaces of the cube adopts the following values: $\Phi(\mathbf{r}') = 0$ on the surface $x' = 0$, $\Phi(\mathbf{r}') = V_0$ on the surface $x' = a$, and $\Phi(\mathbf{r}') = V_0 x'/a$ on the other 4 surfaces $y' = 0,\ y' = a,\ z' = 0,\ z' = a$.
c. Reformulate the term describing the contribution of the surface to the potential using that for $0 < x < \pi$ holds: $1 = (4/\pi)(\sin x + (1/3)\sin 3x + (1/5)\sin 5x + ...)$ and $x = 2(\sin x - (1/2)\sin 2x + (1/3)\sin 3x - (1/4)\sin 4x + ...)$.

10.7.5.16 Ex: Electrostatic potential of a hollow sphere via Green function

On the surface of a hollow sphere with radius b without charge there be a certain potential $V(\theta, \phi) = V_0[P_2(\cos\theta) + \alpha P_3(\cos\theta)]$. Calculate the electrostatic potential $\Phi(\mathbf{r})$ inside the sphere.
Help: Green's function for the interior space between two concentric spheres with radii a and b ($a < b$) is,

$$G(\mathbf{r}, \mathbf{r}') = \sum_{l=0}^{\infty} \frac{4\pi}{2l+1}\left[1 - \left(\frac{a}{b}\right)^{2l+1}\right]\left[r_<^l - \frac{a^{2l+1}}{r_<^{l+1}}\right]\left[\frac{1}{r_>^{l+1}} - \frac{r_>^l}{b^{2l+1}}\right]\sum_{m=-l}^{+l} Y_{lm}(\Omega)Y_{lm}^*(\Omega')\,.$$

where $r_< \equiv \min(|\mathbf{r}|, |\mathbf{r}'|)$ and $r_> \equiv \max(|\mathbf{r}|, |\mathbf{r}'|)$. We also know, $Y_{l0}(\theta, \phi) = \sqrt{(2l+1)/4\pi}P_l(\cos\theta)$.

Chapter 11

Electrical properties of matter

There are many types of materials, such as solids, liquids, gases, metals, wood or glass, all of which respond differently to applied electric fields. However, most materials can at least roughly be classified into two categories: In materials called *dielectrics* (or insulators) the electrons are strongly bound to the atoms, while in *metals* there are free electrons. Some materials, such as semiconductors, have particular properties, which do not fit into these categories.

Under the influence of electric (or magnetic) forces the electrons can be displaced within a macroscopic body, thus producing a polarization, when the electrons are bound, or a current, when the electrons are free.

11.1 Polarization of dielectrics

Let us first discuss dielectrics. The elementary blocks (molecules) of dielectric materials can react in various ways to applied electric fields, For example, they can be insensitive to electric fields or behave like *permanent dipoles*. Permanent dipoles exist independently of the application of an external field, but generally (without external field) they have random and disorderly orientations. Under the influence of an external field the dipoles will try to reorient themselves, which is called *orientation polarization*.

It is also possible that a material does not have intrinsic dipole moments, but *develops* dipole moments under the action of an external field. In this case we speak of *induced dipoles*. Induced dipoles are formed in the presence of a field displacing bound positive and negative charges in molecules against each other, thus producing a *translation polarization*.

11.1.1 Energy of permanent dipoles

Polar molecules exhibit permanent electric moments. Water is an example or salt Na^+Cl^-. The reason is that halogens, which have a much higher electro-affinity than alkalines, and try to steal electrons from their partner and monopolize the electronic cloud.

The potential energy of a dipole depends on its orientation with respect to the electric field. Using the parametrization $\varrho(\mathbf{r}') = Q[\delta^3(\mathbf{r}' - \frac{\mathbf{a}}{2}) - \delta^3(\mathbf{r}' + \frac{\mathbf{a}}{2})]$, we find

for the interaction energy with a homogeneous field given by $\Phi(\mathbf{r}') = -\mathcal{E}_0 z'$,

$$H_{\text{int}} = \int \varrho(\mathbf{r}')\Phi(\mathbf{r}')dV = -Q\mathcal{E}_0 a_z = -\mathbf{d}\cdot\vec{\mathcal{E}}\,. \tag{11.1}$$

Hence [1],

$$\boxed{H_{\text{int}} = -\mathbf{d}\cdot\vec{\mathcal{E}}}\,. \tag{11.2}$$

The energy is minimal when $\mathbf{d} \parallel \vec{\mathcal{E}}$.

To calculate the interaction energy between two dipoles $\mathbf{d}_1$ and $\mathbf{d}_2$ we calculate the energy of $\mathbf{d}_1$ within the field created by $\mathbf{d}_2$ (which has been derived in the example 58),

$$H_{\text{int}} = -\mathbf{d}_1\cdot\vec{\mathcal{E}}_2 = -\mathbf{d}_1\cdot\frac{1}{4\pi\varepsilon_0}\frac{3(\hat{\mathbf{e}}_r\cdot\mathbf{d}_2)\hat{\mathbf{e}}_r - \mathbf{d}_2}{r^3} = \frac{1}{4\pi\varepsilon_0}\frac{\mathbf{d}_1\cdot\mathbf{d}_2 - 3(\mathbf{d}_1\cdot\hat{\mathbf{e}}_r)(\mathbf{d}_2\cdot\hat{\mathbf{e}}_r)}{r^3}\,. \tag{11.3}$$

11.1.1.1 Alignment of permanent dipoles

In a homogeneous field the force on an (neutral) electric dipole $\mathbf{d} = Q\mathbf{a}$ vanishes, since $\mathbf{F} = Q\vec{\mathcal{E}} + (-Q)\vec{\mathcal{E}} = 0$. However, there will be a torque because,

$$\vec{\tau} = \frac{\mathbf{a}}{2}\times Q\vec{\mathcal{E}} + \frac{-\mathbf{a}}{2}\times(-Q)\vec{\mathcal{E}} = \mathbf{d}\times\vec{\mathcal{E}}\,. \tag{11.4}$$

This means that a freely moving molecule will rotate about its mass center, as illustrated in Fig. 11.1, until (in the presence of dissipation) it finds the orientation with the lowest energy. In this orientation the molecule is aligned to the applied field. See Exc. 11.1.7.1.

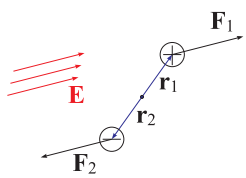

Figure 11.1: Torque on a dipole exerted by an electric field.

In a *non-homogeneous* field, the forces on the charges $\pm Q$ do not compensate [2], $\mathbf{F} = Q\vec{\mathcal{E}}_+ - Q\vec{\mathcal{E}}_- = Q(\mathbf{a}\cdot\nabla)\vec{\mathcal{E}}$. Hence,

$$\boxed{\mathbf{F} = (\mathbf{d}\cdot\nabla)\vec{\mathcal{E}}}\,. \tag{11.5}$$

Placed in front of a conductive surface a dipole feels the forces exerted by the charge of its own image. In Exc. 11.1.7.2 we calculate the torque exerted by a conducting surface on a dipole.

[1] We can also calculate the energy of a dipole in an electric field by the work required to rotate it away from its rest position, $H_{\text{int}} = \int\vec{\tau}\cdot d\theta = \int \mathbf{d}\times\vec{\mathcal{E}}d\theta = \int_0^\theta dE\sin\theta d\theta = -dE\cos\theta$.

[2] We note that the force that a field exerts on a dipole can be calculated as a gradient of the interaction energy: $\mathbf{F} = -\nabla H_{\text{int}} = \nabla(\mathbf{d}\cdot\vec{\mathcal{E}}) = (\mathbf{d}\cdot\nabla)\vec{\mathcal{E}} + (\vec{\mathcal{E}}\cdot\nabla)\mathbf{d} + (\mathbf{d}\times\nabla)\times\vec{\mathcal{E}} + (\vec{\mathcal{E}}\times\nabla)\times\mathbf{d} = (\mathbf{d}\cdot\nabla)\vec{\mathcal{E}}$.

11.1.2 Induction of dipoles in dielectrics

A priori, neutral non-polar atoms and molecules should not react to applied electric fields. However, the fact that atoms are composed of positive charge distributions (concentrated in a heavy nucleus) and negative ones (concentrated in a light-weighed electron shell), permits a more or less important displacement of these charge distributions with respect to the center-of-mass. Consequently, an electric field *polarizes the atom* and induces an electric dipole moment whose magnitude is approximately proportional to the field,

$$\boxed{\mathbf{d} = \alpha_{\rm pol}\vec{\mathcal{E}}} \ , \tag{11.6}$$

where the constant $\alpha_{\rm pol}$ is called *polarizability*.

Example 61 (*Polarizability of a primitive atom*): In a primitive model we envision an atom as a point-like nucleus carrying the charge $+Q$ surrounded by a uniformly charged electron sphere with radius a carrying the inverse charge $-Q$. In the presence of an external field $\vec{\mathcal{E}}$ the nucleus will be slightly shifted by a distance $\epsilon/2$ to one side and the electron sphere by a distance $-\epsilon/2$ to the opposite side. The polarized atom is in equilibrium, when the field created by the induced dipole $\mathcal{E}_{\rm dp}$ (calculated in Exc. 10.2.4.5) equalizes the external field, i.e.,

$$\mathcal{E}_{\rm dp} = \frac{1}{4\pi\varepsilon_0}\frac{Q\epsilon}{a^3} = \mathcal{E} \ .$$

Hence,

$$\frac{\alpha_{\rm pol}}{4\pi\varepsilon_0} = \frac{d}{4\pi\varepsilon_0\mathcal{E}} = a^3 \approx 0.15\cdot 10^{-30}\,{\rm m}^3 \ ,$$

using for $a = a_B$ the Bohr radius. Despite the simplicity of the model, this results represents a good approximation. A slightly better model is discussed in Exc. 11.1.7.3.

The values for the atomic polarizability range from $\alpha_{\rm pol}/4\pi\varepsilon_0 = 0.205\cdot 10^{-30}\,{\rm m}^3$ for helium to $59.6\cdot 10^{-30}\,{\rm m}^3$ for cesium. This shows that it is far more difficult to polarize atoms with closed electron shells (like noble gases) than atoms with isolated valence electron (such as alkaline atoms). Molecules may react in a more complicated way to the applied fields necessitating an interpretation of the polarizability $\alpha_{\rm pol}$ in terms of a tensor represented by a matrix.

11.1.2.1 Energy of induced dipoles

We now calculate the energy of a polarizable molecule inside an external electric field. We expect two contributions: The first one is the energy $W_{\rm ind}$ stored in the field created by the separation of charges under the action of the external field. The second contribution is the energy $H_{\rm int}$ due to the interaction of the induced dipole with the external field.

$W_{\rm ind}$ is calculated by the work spent on separating the charges. Let e be the valence charge bound to the molecule. The force between this charge and the molecule is described, in first approximation, by a harmonic oscillator with the spring constant k. Inside the electric field, the charge feels the force $e\vec{\mathcal{E}}$, but at the same time the force of the 'molecular spring' goes in the opposite direction. In equilibrium,

$$-k\mathbf{a} + e\vec{\mathcal{E}} = 0 \ . \tag{11.7}$$

To induce this dipole, the electric field must do the work,

$$W_{\text{ind}} = \tfrac{1}{2}ka^2 = \tfrac{1}{2}e\mathcal{E}a \ . \tag{11.8}$$

Defining the induced dipole as $\mathbf{d}_{\text{ind}} \equiv Ze\mathbf{d}$, we obtain:

$$W_{\text{ind}} = \tfrac{1}{2}\mathbf{d}_i \cdot \vec{\mathcal{E}} \ . \tag{11.9}$$

Since the energy of a dipole in an external electric field is, $H_{\text{int}} = -\mathbf{d}_i \cdot \vec{\mathcal{E}}$, for the induced dipole we obtain the total energy,

$$H_{\text{tot}} = H_{\text{int}} + W_{\text{ind}} = -\tfrac{1}{2}\mathbf{d}_i \cdot \vec{\mathcal{E}} \ . \tag{11.10}$$

The energy value is less than in the case of a permanent dipole (11.5), since part of the energy had to be spent on creating the dipole in the first place. Expressing the dipole moment by the polarizability (11.6),

$$\boxed{H_{\text{tot}} = -\frac{\alpha_{\text{pol}}}{2}\vec{\mathcal{E}}^2} \ . \tag{11.11}$$

11.1.3 Macroscopic polarization

With these results we can now describe, what happens to a dielectric material placed in an electric field: If the substance consists of neutral atoms (or non-polar molecules), the field will induce in each particle a small dipole moment pointing in the direction of the field. If the substance consists of polar molecules, each permanent dipole will try to orientate itself along the field [3].

Note that both mechanisms produce the same result: a multitude of small dipoles aligned along the applied field. The sum of the microscopic moments gives rise to a macroscopic *polarization* defined by the sum over all dipole moments,

$$\vec{\mathcal{P}} = \frac{N\mathbf{d}}{V} \ . \tag{11.12}$$

In reality, the two types of polarization are not always well separated, and there are cases where both contribute. Nevertheless, it is usually much easier to rotate a molecule (rotational energy) than to stretch it (vibrational energy). In some (ferroelectric) materials it is possible to freeze the polarization.

11.1.4 Electrostatic field on a polarized or dielectric medium

In this section we will describe the electric field inside a polarized medium forgetting the physical cause of the polarization $\vec{\mathcal{P}}$. The field produced by the polarization (not the external field) can be calculated by the sum of the fields produced by the individual dipoles,

$$\Phi(\mathbf{r}) = \frac{1}{4\pi\varepsilon_0}\sum_k \frac{\mathbf{d}_k \cdot (\mathbf{r}-\mathbf{r}_k)}{|\mathbf{r}-\mathbf{r}_k|^3} \longrightarrow \frac{1}{4\pi\varepsilon_0}\int_{\mathcal{V}} dV' \frac{\vec{\mathcal{P}}(\mathbf{r}') \cdot (\mathbf{r}-\mathbf{r}')}{|\mathbf{r}-\mathbf{r}'|^3} \ , \tag{11.13}$$

[3] Note that thermal motion, particularly at high temperatures, competes with this process, such that the alignment will never be perfect.

introducing the dipole moment distribution $\vec{\mathcal{P}}(\mathbf{r}')$ by $\mathbf{d}_k \to \vec{\mathcal{P}} dV'$. We can rewrite the integral in the form,

$$\Phi(\mathbf{r}) = \frac{1}{4\pi\varepsilon_0}\int_{\mathcal{V}} \vec{\mathcal{P}}(\mathbf{r}')\cdot\nabla'\frac{1}{|\mathbf{r}-\mathbf{r}'|}dV' = \frac{1}{4\pi\varepsilon_0}\left[\int_{\mathcal{V}}\nabla'\cdot\frac{\vec{\mathcal{P}}(\mathbf{r}')}{|\mathbf{r}-\mathbf{r}'|}dV' - \int_{\mathcal{V}}\frac{1}{|\mathbf{r}-\mathbf{r}'|}\nabla'\vec{\mathcal{P}}(\mathbf{r}')dV'\right]$$
$$= \frac{1}{4\pi\varepsilon_0}\oint_{\partial\mathcal{V}}\frac{\vec{\mathcal{P}}(\mathbf{r}')}{|\mathbf{r}-\mathbf{r}'|}dS' - \frac{1}{4\pi\varepsilon_0}\int_{\mathcal{V}}\frac{1}{|\mathbf{r}-\mathbf{r}'|}\nabla'\cdot\vec{\mathcal{P}}(\mathbf{r}')dV' \ . \tag{11.14}$$

Defining,

$$\boxed{\sigma_{\mathrm{b}} \equiv \vec{\mathcal{P}}\cdot\mathbf{n}_S} \quad \text{and} \quad \boxed{\varrho_{\mathrm{b}} \equiv -\nabla\cdot\vec{\mathcal{P}}}\ , \tag{11.15}$$

we obtain

$$\Phi(\mathbf{r}) = \frac{1}{4\pi\varepsilon_0}\oint_{\partial\mathcal{V}}\frac{\sigma_{\mathrm{b}}}{|\mathbf{r}-\mathbf{r}'|}dS' - \frac{1}{4\pi\varepsilon_0}\int_{\mathcal{V}}\frac{\varrho_{\mathrm{b}}}{|\mathbf{r}-\mathbf{r}'|}dV' \ . \tag{11.16}$$

The meaning of this result is that the potential (and therefore the field) of a polarized object is the same as the one produced by a volume distribution ϱ_{b} plus a surface charge distribution σ_{b}. The index b indicates the fact that we consider here 'bound charges' (i.e. localized charges). Instead of integrating the field contributions of all individual infinitesimal dipoles, as in Eq. (11.13), we can try to find these bound charges, and then calculate the fields they produce, as we already did in the previous chapter.

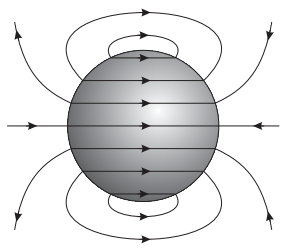

Figure 11.2: Distortion of polarization.

Example 62 (*Microscopic theory of induced dipoles*): As an example we calculate the electric field produced by a homogeneous polarization within a sphere. While the volume charge is zero (otherwise $\vec{\mathcal{P}}$ could not be uniform), the surface charge is $\sigma_{\mathrm{b}} = \vec{\mathcal{P}}\cdot\mathbf{n}_S = \mathcal{P}\cos\theta$. This charge distribution generates a potential which, applying the result derived in example 56, we can write,

$$\Phi(r,\theta) = \begin{cases} \frac{\mathcal{P}}{3\varepsilon_0} r\cos\theta = \frac{1}{4\pi\varepsilon_0}\frac{\mathbf{d}\cdot\mathbf{r}}{R^3} & \text{for} \quad r \le R \\ \frac{\mathcal{P}}{3\varepsilon_0}\frac{R^3}{r^2}\cos\theta = \frac{1}{4\pi\varepsilon_0}\frac{\mathbf{d}\cdot\mathbf{r}}{r^3} & \text{for} \quad r \ge R \end{cases},$$

with $\mathbf{d} = \frac{4\pi}{3}R^3\vec{\mathcal{P}}$. The potential produces a field, which is uniform within the sphere,

$$\vec{\mathcal{E}} = -\nabla\Phi = \begin{cases} -\frac{\mathcal{P}}{3\varepsilon_0}\hat{\mathbf{e}}_z\frac{\partial\Phi}{\partial z} = -\frac{\vec{\mathcal{P}}}{3\varepsilon_0} & \text{for} \quad r \le R \\ \frac{\mathcal{P}}{3\varepsilon_0}\frac{R^3}{r^2}\cos\theta = \frac{1}{4\pi\varepsilon_0}\frac{3(\hat{\mathbf{e}}_r\cdot\mathbf{d})\hat{\mathbf{e}}_r - \mathbf{d}}{r^3} & \text{for} \quad r \ge R \end{cases}.$$

The physical interpretation of the surface charge produced by a uniform polarization is simply a displacement of all the electrons of the body with respect to the positively charged nuclei. Since the electrons remain attached to the nuclei, the volume charge inside the sphere remains neutral. However, the edges of the body accumulate negative charge on one side and positive charge on the other.

11.1.5 Electric displacement

In the previous section we found that the phenomenon of polarization can be understood as being due to a volume charge $\varrho_\mathrm{b} = -\nabla \cdot \vec{\mathcal{P}}$ inside the dielectric and a surface charge on the surface of the body $\sigma_\mathrm{b} = \vec{\mathcal{P}} \cdot \mathbf{n}_S$. However, many materials have dielectric characteristics and at the same time conductive characteristics, which do not result from a polarization and which we take into account via a distribution of free charges, ϱ_f, the index f indicating 'free charges'.

11.1.5.1 Gauß' Law in dielectric media

Gauß's law can now be generalized for arbitrary media,

$$\varepsilon_0 \nabla \cdot \vec{\mathcal{E}} = \varrho = \varrho_\mathrm{b} + \varrho_\mathrm{f} = -\nabla \cdot \vec{\mathcal{P}} + \varrho_\mathrm{f} \ , \tag{11.17}$$

where $\vec{\mathcal{E}}$ is the total electric field. Defining a new field called the *electric displacement*,

$$\boxed{\vec{\mathcal{D}} \equiv \varepsilon_0 \vec{\mathcal{E}} + \vec{\mathcal{P}}} \ , \tag{11.18}$$

we can now write,

$$\nabla \cdot \vec{\mathcal{D}} = \varrho_\mathrm{f} \ . \tag{11.19}$$

The electric displacement is that part of the electric field, which comes only from free charges (which is the part useful for generating currents). We can also define the *electric susceptibility* χ_ε via,

$$\vec{\mathcal{P}} = \varepsilon_0 \chi_\varepsilon \vec{\mathcal{E}} \ , \tag{11.20}$$

or the *permittivity* ε via,

$$\vec{\mathcal{D}} = \varepsilon \vec{\mathcal{E}} = \varepsilon_0 (1 + \chi_\varepsilon) \vec{\mathcal{E}} \ . \tag{11.21}$$

Note that the rotation of the polarization *does not necessarily vanish*, since the susceptibility may depend on position, $\chi_\varepsilon = \chi_\varepsilon(\mathbf{r})$,

$$\nabla \times \vec{\mathcal{D}} = \varepsilon_0 (\nabla \times \vec{\mathcal{E}}) + \nabla \times \vec{\mathcal{P}} = \nabla \times (\varepsilon_0 \chi_\varepsilon \vec{\mathcal{E}}) \neq 0 \ . \tag{11.22}$$

Therefore, $\vec{\mathcal{D}}$ generally can not be derived from a potential, and Coulomb's law is not valid for $\vec{\mathcal{D}}$.

11.1.5.2 Boundary conditions involving dielectrics

The integral version of Gauß's law, $\oint \vec{\mathcal{D}} \cdot d\mathbf{S} = Q_\mathrm{f}$, allows us to determine the behavior of the electric displacement near interfaces,

$$\mathcal{D}^\perp_\mathrm{top} - \mathcal{D}^\perp_\mathrm{bottom} = \sigma_\mathrm{f} \ . \tag{11.23}$$

On the other hand, Stokes' law $\nabla \times \vec{\mathcal{D}} = \varepsilon_0 \nabla \times \vec{\mathcal{E}} + \nabla \times \vec{\mathcal{P}} = \nabla \times \vec{\mathcal{P}}$ yields,

$$\vec{\mathcal{D}}^{\parallel}_{\text{top}} - \vec{\mathcal{D}}^{\parallel}_{\text{bottom}} = \vec{\mathcal{P}}^{\parallel}_{\text{top}} - \vec{\mathcal{P}}^{\parallel}_{\text{bottom}} \ . \tag{11.24}$$

This is in contrast to the behavior of the electric $\vec{\mathcal{E}}$ field at interfaces described by Eqs. (10.37) and (10.39).

11.1.6 Electrical susceptibility and permittivity

11.1.6.1 Linear dielectrics

In many materials, as long as the applied electric field is not too strong, the polarization is proportional to the field, $\vec{\mathcal{P}} \propto \vec{\mathcal{E}}$, that is, the electric susceptibility depends on the material's microscopic properties and external factors such as temperature, but not on the applied field, $\chi_\varepsilon \neq \chi_\varepsilon(\vec{\mathcal{E}})$. Hence, linear media can be characterized by a constant,

$$\varepsilon_r \equiv \frac{\varepsilon}{\varepsilon_0} \ , \tag{11.25}$$

called *relative permittivity*.

In *non-linear* media, in contrast, the susceptibility $\chi_\varepsilon(\vec{\mathcal{E}})$ depend on the strength of the electric field. Often the polarization can be expanded in orders of the electric field,

$$\vec{\mathcal{P}}(\vec{\mathcal{E}}) = \varepsilon^{(1)}\vec{\mathcal{E}} + \varepsilon^{(2)}\vec{\mathcal{E}}^2 + \varepsilon^{(3)}\vec{\mathcal{E}}^3 + \dots \ . \tag{11.26}$$

In *anisotropic* materials the situation gets more complicated, because the susceptibility and the permittivity must be understood as tensors,

$$\mathcal{P}_k(\vec{\mathcal{E}}) = \sum_m \varepsilon^{(1)}_{km}\mathcal{E}_m + \sum_{ml} \varepsilon^{(2)}_{kml}\mathcal{E}_m\mathcal{E}_l + \sum_{mlj} \varepsilon^{(3)}_{kmlj}\mathcal{E}_m\mathcal{E}_l\mathcal{E}_j + \dots \ . \tag{11.27}$$

Example 63 (*Microscopic theory of induced dipoles*): We know that an *external electric field* $\vec{\mathcal{E}}_{\text{ext}}$ applied to a linear purely dielectric medium generates a *macroscopic polarization* proportional to the field,

$$\vec{\mathcal{P}} = \chi_\varepsilon \varepsilon_0 \vec{\mathcal{E}}_{\text{ext}} \ .$$

On the other hand, if the material consists of atoms (or non-polar molecules), the *microscopic dipole moment* induced in each atom is proportional to the *local field*,

$$\mathbf{d}_{\text{ind}} = \alpha_{\text{pol}} \vec{\mathcal{E}}_{\text{loc}} \ .$$

Here, $\vec{\mathcal{E}}_{\text{loc}}$ is the *total field* due to the applied field $\vec{\mathcal{E}}_{\text{ext}}$ plus the field $\vec{\mathcal{E}}_{self}$ generated by the polarization of the other atoms which are around. The question now is, what is the relationship between the atomic polarizability α_{pol} (characterizing the sample from a microscopic point of view) and the susceptibility χ_e (characterizing the sample from a macroscopic point of view)?

To begin with we consider low densities, in which case it is a good approximation to suppose that the atom does not feel the polarization of its neighbors, that is $\vec{\mathcal{E}}_{\text{loc}} \simeq \vec{\mathcal{E}}_{\text{ext}}$. We already noticed in Eq. (11.12) that the polarization is nothing more than the sum over all the dipole moments induced by the local

electric field, such that, comparing the last two relations, a first trial would be to affirm,

$$\chi_\varepsilon = \frac{N}{V}\frac{\alpha_{\rm pol}}{\varepsilon_0} \ .$$

But for dense gases, there will be a correction, and the local field will be a superposition of the external field and the field generated by the surrounding dipoles, $\vec{\mathcal{E}}_{\rm loc} = \vec{\mathcal{E}}_{\rm ext} + \vec{\mathcal{E}}_{\rm self}$. To estimate this field, we imagine a single dipole located inside a sphere. The polarization of the surrounding medium is modeled by a surface charge density with the value $\sigma_{\rm b} \equiv -\mathcal{P}\cos\theta$. The electric field produced by this charge distribution was calculated in example 62: $\vec{\mathcal{E}}_{self} = \vec{\mathcal{P}}/3\varepsilon_0$. With this we calculate,

$$\chi_\varepsilon = \frac{\mathcal{P}}{\varepsilon_0\mathcal{E}_{\rm ext}} = \frac{\mathcal{P}}{\varepsilon_0(\mathcal{E}_{\rm loc}-\mathcal{E}_{\rm self})} = \frac{\mathcal{P}}{\varepsilon_0(\frac{p_{\rm ind}}{\alpha_{\rm pol}}-\frac{\mathcal{P}}{3\varepsilon_0})} = \frac{N\alpha_{\rm pol}/\varepsilon_0 V}{1-N\alpha_{\rm pol}/3\varepsilon_0 V} \ . \quad (11.28)$$

This equation is known as *Clausius-Mossotti formula*. The difference between the denominator and 1, called *Lorentz-Lorenz shift*, comes from the energy displacements of the atoms due to the dipole-dipole interactions. At low densities we recover the linear relation. In terms of the relative permittivity we can also write,

$$\frac{\alpha_{\rm pol}}{\varepsilon_0} = \frac{3V}{N}\frac{\varepsilon_r-1}{\varepsilon_r+2} \ .$$

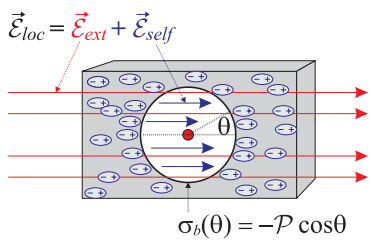

Figure 11.3: The local field $\vec{\mathcal{E}}_{\rm loc}$ is the sum of the external field $\vec{\mathcal{E}}_{\rm ext}$ and the field generated by the polarization $\vec{\mathcal{E}}_{\rm self}$.

11.1.7 Exercises

11.1.7.1 Ex: Torque on dipoles

Calculate the torque on a dipole in front of a conducting surface.

11.1.7.2 Ex: Torque on dipoles

Consider the configuration of two dipoles shown in the figure and calculate the reciprocal torques.

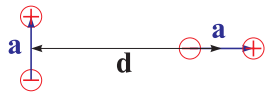

Figure 11.4: Dipoles.

11.1.7.3 Ex: Polarizability of hydrogen

In quantum mechanics we find for the electronic charge distribution in a hydrogen atom,

$$\varrho(r) = \frac{Q}{\pi a_B^3} e^{-2r/a_B} \ .$$

Calculate the polarizability.

11.1.7.4 Ex: Susceptibility

One liter of water is evaporated in $10\,\mathrm{m}^3$ of dry air at room temperature $T = 300\,\mathrm{K}$.
a. Calculate the dipolar density n of the air. Assume that only the dipolar moments of the evaporated molecules contribute.
b. Determine the susceptibility χ_ε of the air. Use the relation $\mathcal{P} = \varepsilon_0 \chi_\varepsilon \mathcal{E}$, as well as Curie's law for the polarization $\mathcal{P}$.

11.2 Influence of charges and capacitance

We now assume that we have two separate conductors, one carrying the charge $+Q$ and the other $-Q$. Since the potential of each conductor is the same at each point of its body, we can specify a potential difference, called *voltage*, between them,

$$U \equiv \Phi_+ - \Phi_- = -\int_{(-)}^{(+)} \vec{\mathcal{E}} \cdot d\mathbf{l} \ , \tag{11.29}$$

which does not depend on the distribution of the charges throughout the conductors. However, we know from Coulomb's law that the electric field is proportional to the charge Q and from the above equation, also the voltage. The proportionality factor is called *capacitance*,

$$C \equiv \frac{Q}{U} \ . \tag{11.30}$$

11.2.1 Capacitors and storage of electric energy

A device capable of storing charges is called *capacitor*.

Example 64 (*Plate capacitor*): The simplest geometry for a capacitor are two parallel conducting plates (area S) maintained at a distance d. The surface charge distribution $\sigma = Q/S$ produces a field $\mathcal{E} = \sigma/\varepsilon_0$ and a potential difference $U = \mathcal{E}d$, such that,

$$C = \varepsilon_0 \frac{S}{d} \ . \tag{11.31}$$

To charge a capacitor we must bring electrons from the positive side to the negative side of the capacitor. For a single electron, this requires the work

$$\Delta W_e = \int_0^d \mathbf{F} \cdot d\mathbf{r} = ed|\vec{\mathcal{E}}| = eU \ .$$

For a small amount of charge dq,

$$\Delta W_e = \int U \ dQ = \int_0^Q \frac{Q}{C} dQ = \frac{Q^2}{2C} = \frac{1}{2} C U^2 \ .$$

Resolve the Excs. 11.2.2.1 to 11.2.2.10.

11.2.1.1 Capacitors with dielectrics

In the presence of a dielectric the capacitance increases, $C = \varepsilon_r C_{vac}$. Thus, the field energy also increases by a factor of ε_r.

We consider a capacitor filled with a linear dielectric and charged with the free charge ϱ_f, which generates a voltage U between the electrodes. We want to know the work needed to add a little bit more charge $\delta\varrho_\mathrm{f}$ to the volume element dV,

$$\delta W = \int U \ \delta\varrho_\mathrm{f} dV \ . \tag{11.32}$$

Now, with Eq. (11.19) we write $\varrho_\mathrm{f} = \nabla \cdot \vec{\mathcal{D}}$ and $\delta\varrho_\mathrm{f} = \nabla \cdot \delta\vec{\mathcal{D}}$, such that,

$$\delta W = \int_\mathcal{V} U \nabla \cdot \delta\vec{\mathcal{D}} dV = \int_{\partial\mathcal{V}} U \ \delta\vec{\mathcal{D}} \cdot d\mathbf{S} - \int_\mathcal{V} \delta\vec{\mathcal{D}} \cdot \nabla U dV = \int_\mathcal{V} \delta\vec{\mathcal{D}} \cdot \vec{\mathcal{E}} dV \ . \tag{11.33}$$

For a linear dielectric, $\vec{\mathcal{D}} = \varepsilon\vec{\mathcal{E}}$, such that, $\vec{\mathcal{E}} \cdot \delta\vec{\mathcal{D}} = \vec{\mathcal{E}}\varepsilon \cdot \delta\vec{\mathcal{E}} = \frac{1}{2}\delta(\varepsilon E^2) = \frac{1}{2}\delta(\vec{\mathcal{D}} \cdot \vec{\mathcal{E}})$, giving,

$$\delta W = \tfrac{1}{2} \int \delta(\vec{\mathcal{D}} \cdot \vec{\mathcal{E}}) dV \ . \tag{11.34}$$

Finally, to charge the capacitor completely,

$$W = \int \delta W = \tfrac{1}{2} \int \vec{\mathcal{D}} \cdot \vec{\mathcal{E}} = \int u dV \ , \tag{11.35}$$

with the energy density,

$$\boxed{u = \frac{1}{2} \vec{\mathcal{E}} \cdot \vec{\mathcal{D}}} \ . \tag{11.36}$$

Do the Excs. 11.2.2.11 to 11.2.2.18.

Example 65 (*Forces on dielectrics*): Dielectrics in electric fields are subjected to forces due to the polarization induced in the medium. Let us consider the example of a plate capacitor inside which we insert a dielectric. In the scheme shown in Fig. 11.5 the electric field homogeneously traverses the capacitor and also the dielectric body, such that the forces should disappear. On the other hand, on its edges the dielectric distorts the field, such that forces become possible.

The easiest way to calculate these forces is via the potential energy gradient, $\mathbf{F} = -\nabla W$. If the dielectric body is free to move in x-direction, we have,

$$\mathbf{F} = -\frac{dW}{dx} = -\frac{d}{dx}\frac{Q^2}{2C} = -\frac{d}{dx}\frac{CU^2}{2} \ .$$

We use the first expression, in case the charge on the capacitor is kept constant, and the second, when the voltage on the capacitor is kept constant. Gradually inserting the dielectric, a part of the volume of the capacitor will be empty and another part will be filled with the dielectric medium:

$$C = C_{vac}\frac{x}{a} + C_{vac}\varepsilon_r\frac{a-x}{a} \ .$$

Keeping the charge constant, we get,

$$\mathbf{F} = \frac{Q^2}{2C^2}\frac{dC}{dx} = -\frac{d}{dx}\frac{Q^2}{2(C_{vac}\frac{x}{a} + C_{vac}\varepsilon_r\frac{a-x}{a})} = \frac{Q^2}{2C_{vac}}\frac{-a\chi_\varepsilon}{(a-x\chi_\varepsilon)^2} \ .$$

Since the force is negative, the dielectric is drawn into the capacitor.
The situation is different when we keep the voltage constant, for example, by connecting the capacitor to a battery. In this case we need to use the second expression. However, we must take into account the work UdQ that the battery must do to increase the charge on the capacitor in order to maintain the voltage constant while we increase the capacity via $C_{vac} \to C$,

$$dW = -Fdx + UdQ \ .$$

Hence,

$$F = -\frac{dW}{dx} + U\frac{dQ}{dx} = -\frac{U^2}{2}\frac{dC}{dx} + U^2\frac{dC}{dx} = \frac{Q^2}{2C^2}\frac{dC}{dx} \ ,$$

and we get the same result as in the case where we kept the charge constant.

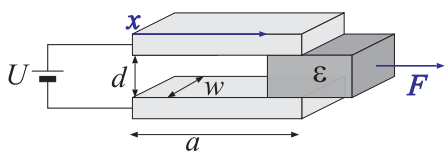

Figure 11.5: Force on the dielectric between the plates of a capacitor.

11.2.1.2 Capacitor circuits

For parallel circuits $C_{\text{tot}} = C_1 + C_2$, for circuits in series $C_{\text{tot}}^{-1} = C_1^{-1} + C_2^{-1}$. Do the Excs. 11.2.2.19 to 11.2.2.27.

11.2.2 Exercises

11.2.2.1 Ex: Capacitors

Be given two isolated conductors carrying equal charges but with opposite signs $\pm Q$. The capacity of this configuration is the ratio between the absolute value of the charge of one conductor and the absolute value of the potential difference between the two

conductors. Using Gauß' law calculate the capacity of
a. 2 large parallel plates with area A being at a short distance d;
b. 2 concentric cylindrical conductors (without surfaces at the ends of the cylinders) with radii ρ_1 and ρ_2.
c. 2 concentric spherical surfaces with radii r_1 and r_2.
Help: Choose integration volumes that fits the symmetry of your system.

11.2.2.2 Ex: Capacitance of a mercury drop

The capacity of a spherical drop of mercury with radius R is given by $C = 4\pi\varepsilon_0$. Now, two of these drops merge. What is the capacity of this larger drop?

11.2.2.3 Ex: Charged plates

Consider a thin, very extended metal plate, $d^2 \ll A$, with area A and thickness d carrying the charge Q. Calculate the charge distribution (surface charge density) and the electric field on both sides of the plate neglecting edge effects. How do the charge distribution and the electric field change, when we have two plates instead of one with thickness d at a distance l, one being charged with the charge Q and the other with $-Q$.

11.2.2.4 Ex: Plate capacitor

A capacitor is made of two flat metal plates with the surfaces $1\,\mathrm{m}^2$. What should be the distance of the plates to give the capacitor a capacity of $1\,\mathrm{F}$? Is it possible to build such a capacitor?

11.2.2.5 Ex: Cylindrical capacitor

A cylindrical capacitor is made of two infinitesimally thin coaxial cylindrical surfaces with radii R_1 and R_2. For simplicity, assume that the cylinders are infinitely extended in z-direction. The charge per unit length on the inner cylinder is $+Q/l$, on the outer cylinder $-Q/l$. Calculate the electric field $\vec{\mathcal{E}}(r)$ as a function of the distance r from the symmetry axis for $r \leq R_1$, $R_1 < r < R_2$, and $r \geq R_2$.
Help: Use the symmetry of the problem and Gauß' law.

11.2.2.6 Ex: Cylindrical capacitor

Two concentric infinitely thin hollow conductive cylinders with radii a and b ($a < b$) and length l are charged with charges $+q$ resp. $-Q$. l is much larger than b, such that border effects are negligible. For symmetry reasons, the electric field can only have one radial component.
a. Write down the charge distribution $\varrho(\mathbf{r})$ in cylindrical coordinates (r, ϕ, z) with the help of the δ-function.
b. Calculate the electric field $\vec{\mathcal{E}}(r, \phi, z)$ in the whole space ($r < a,\ a < r < b,\ b < r$). Use for this the fundamental equations of electrostatics and $\nabla \cdot \vec{\mathcal{E}} = \frac{1}{r}\frac{d}{dr}(eE_r)$. Alternatively, this part can be resolved using Gauß' law.
c. Calculate the potential difference $|\Phi(r = b) - \Phi(r = a)|$ between the two surface of

the cylinders. To do this, calculate the line integral $\int \vec{\mathcal{E}} \cdot d\mathbf{r}$ along a suitable path.
d. The capacity C of the device is defined by the absolute value of the ratio between the charge on one cylinder and the potential difference between the cylinders. Calculate the capacity of this 'cylindrical capacitor'.

11.2.2.7 Ex: Spherical capacitor

Consider a homogeneously charged ball with radius R_1 and an infinitely thin spherical homogeneously charged shell with radius R_2. The ball has the full charge $+Q$, the shell $-Q$. Calculate the electric field $\vec{\mathcal{E}}(r)$ for $r \leq R_1$, $R_1 < r < R_2$ and $r \geq R_2$.
Help: Use the fact that $\vec{\mathcal{E}}$ must be, for symmetry reasons, radially symmetrical, and depends on the charge density via $\nabla \cdot \vec{\mathcal{E}}(r) = \varrho(r)/\varepsilon_0$. Also use Gauß' law.

11.2.2.8 Ex: Thunderstorm

The cloud of a thunderstorm with $17\,\mathrm{km}^2$ of total area floats at a height of $900\,\mathrm{m}$ above the Earth's surface and forms with it a plate capacitor.
a. Calculate the capacity of this plate capacitor (the area to be considered on Earth is equal to that of the cloud).
b. What is the maximum charge of the thundercloud before the capacitor discharges? (The discharge electric field in air is $10^4\,\mathrm{V/cm}$).
c. The capacitor is totally discharged by a lightning, once the critical field strength is reached. What is the current flowing to Earth if the lightning's duration is $1\,\mathrm{ms}$?
d. What power does this correspond to? For how long a power station with a power of $2000\,\mathrm{MW}$ needs to work to produce the energy released by lightning?

11.2.2.9 Ex: Spherical capacitor

A spherical capacitor consists of two concentric conducting spheres of radii R_1 and R_2, with $R_1 < R_2$. The inner sphere has a charge $+Q$ and the outer sphere has a charge $-Q$.
a. Calculate the absolute value of the electric field and the energy density as a function of r, where r is the radial distance from the center of the spheres for any r.
b. Determine the capacitance C of the capacitor.
c. Calculate the energy associated with the electric field integrated over a spherical shell of radius r, thickness dr, and volume $4\pi r^2 dr$ located between the conductors. Integrate the obtained expression to find the total energy between the conductors. Give your answer in terms of the charge Q and the capacitance C.

11.2.2.10 Ex: Lightning rod

The absorption of lightning by a lightning rod can be described by the following model (outlined in the figure): The (x, y) plane of a Cartesian coordinate system divides a half space with the conductivity κ (the soil of the Earth, $z < 0$) from a space with conductivity 0 (air, $z > 0$). In the center of the coordinates is an extremely conductive semispherical electrode connected with the lightning rod of diameter d. Current I can cross the semisphere and enter the conducting half space. For symmetry reasons, the current density may only depend on the distance r from the origin of the coordinates

and must be oriented radially: $\mathbf{j} = j_r(r)\hat{\mathbf{e}}_r$. All of the following questions refer to points in the conductive semi-space outside the electrode.
a. Calculate the current density $\mathbf{j}$ as a function of the current amplitude I and the distance r from the source. **Help:** The current flowing from the electrode to the conducting half space must also exit the semisphere K.
b. Determine the electric field $\vec{\mathcal{E}}(\mathbf{r})$.
c. Determine the electrical voltage $U(x, s)$ between two points on the positive x-axis, having the coordinates x and $x + s$, respectively.
d. Determine the voltage U_{tot} for $x = d/2$ and $s \to \infty$. What ohmic resistance can be attributed to the conducting half space?

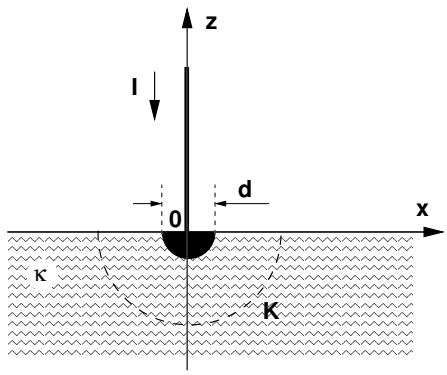

Figure 11.6:

11.2.2.11 Ex: Plate capacitor

An ideal plate capacitor consists of two parallel plates at a distance d. One of the plates, defined by the corners $(0, 0, 0)$, $(a, 0, 0)$, $(a, b, 0)$, and $(0, b, 0)$), be charged with the charge $-Q$, the other plate, defined by the corners $(0, 0, d)$, $(a, 0, d)$, (a, b, d) and $(0, b, d)$, has the charge $+Q$. A part of the intermediate space (up to the surface between the points $(x, 0, 0)$, $(x, b, 0)$, (x, b, d), and $(x, 0, d)$) be filled with a homogeneous dielectric with the dielectric constant ε; the rest of the space between the plates is empty. We assume that a and b are very large, such that border effects can be neglected.
a. Calculate the electric field $\vec{\mathcal{E}}$ and the dielectric displacement $\vec{\mathcal{D}}$ between the plates. **Help:** Use $\nabla \times \vec{\mathcal{E}} = 0$ and $\nabla \cdot \vec{\mathcal{D}} = \varrho$. Use surface charge densities.
b. Calculate the energy of the electrostatic field W of this device.
c. What force $F = -dW/dx$ acts on the dielectric for an infinitesimal displacement dx?

11.2.2.12 Ex: Spherical capacitor with dielectric

Two concentric conducting spheres with radii a and b ($a < b$) carry the charges $\pm Q$. Half of the space between the spheres is filled by a dielectric $\varepsilon = const$.
a. Determine the electric field at all points between the spheres.

b. Calculate the surface charge distribution on the inner sphere.
c. Calculate the polarization charge density induced on the surface of the dielectric at $r = a$.

11.2.2.13 Ex: Potential of a charged sphere

A sphere of radius R be in the vacuum. It consists of a material with the dielectricity constant $\varepsilon = const$ and carries in its center the charge q. Calculate the potential in full space.

11.2.2.14 Ex: Plate capacitor with dielectric

We consider two parallel electrodes with area A and distance d (see figure). Calculate the force on the upper electrode in the x-direction, once for constant voltage V_0 and once for constant charge Q for the following two cases:
a. The electrodes are inside a dielectric liquid with permittivity ε;
b. a fixed dielectric with permittivity ε is introduced between capacitor plates. In the residual gap there is no dielectric medium.

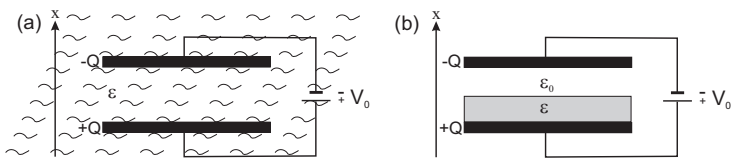

Figure 11.7: Plate capacitor.

11.2.2.15 Ex: Plate capacitor with dielectric

The plate capacitor shown in the figure has a plate surface of $A = 115\,\text{cm}^2$ and a plate distance of $d = 1.24\,\text{cm}$. Between the plates we have the potential difference $U_0 = 85.5\,\text{V}$ produced by a battery. Now, the battery is removed and a dielectric $b = 0.78\,\text{cm}$ thick plate with dielectric constant $\varepsilon = 2.61$ is inserted, as shown in the figure. First calculate
a. capacitance without dielectric and
b. the free charge on the capacitor plates.
c. Now, the dielectric is inserted. Calculate the electric field in the voids and within the dielectric, as well as
d. the potential difference between the plates.
e. What is the capacitance with dielectric?
f. Now assume that the battery remains connected to the capacitor while the dielectric is inserted into the space between the plates. Calculate now the capacitance,
g. the charge on the capacitor plates, and
h. the electric field in the void and inside the dielectric.

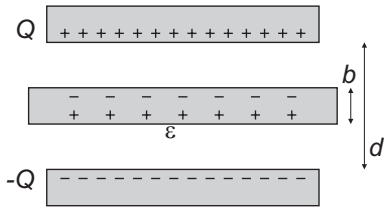

Figure 11.8: Plate capacitor.

11.2.2.16 Ex: Plate capacitor with dielectric

Consider a quadratic plate capacitor with edge length l and plate distance d.
a. What is the capacity of the empty capacitor? What is the electrostatic energy when the plates are charged with the charges kept fixed $+Q$ and $-Q$?
b. A dielectric with thickness d, width $L > l$, and dielectric constant ε is now inserted from the side. What is the electrostatic energy as a function of penetration depth x for $0 < x < l$?
c. What is the force acting on the dielectric with function of x for $0 < x < l$?

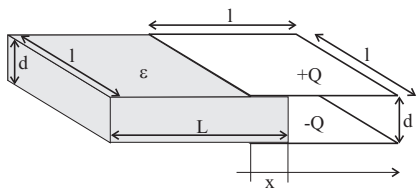

Figure 11.9: Plate capacitor.

11.2.2.17 Ex: Plate capacitor with dielectric

At a plate capacitor consisting of two parallel metal plates of area $0.5\,\mathrm{m}^2$ and distant by $d = 10\,\mathrm{cm}$, there be a voltage of $U_0 = 1000\,\mathrm{V}$.
a. What are the values for the capacitance of the capacity C, the electrical field E between plates, and the charge surface density σ on the plates?
b. A quarter of the capacitor volume is now filled with a dielectric ($\varepsilon = 5$), as shown in the diagram. What is now the capacitance C_g?
Help: We may construct an equivalent circuit diagram by inserting imaginary capacitor plates along equipotential surfaces.

11.2.2.18 Ex: Water capacitor

Consider a plate capacitor (plate distance $d = 20\,\mathrm{cm}$, plate surface area $A = 400\,\mathrm{cm}^2$), which can be half filled with water (dielectric constant $\varepsilon_w = 80.3$). We apply a voltage of $U = 240\,\mathrm{V}$.
a. Calculate the capacitance of the capacitor for the following cases:
i. No water.
ii. The water is perpendicular to the plates..

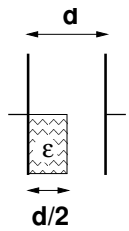

Figure 11.10: Plate capacitor.

iii. The water is parallel to the plates.
b. Calculate the charges on the plates for these three cases.
c. Compare the electric field energy of the cases (i) and (iii). From what source does the energy difference come from when the capacitor is filled with water?

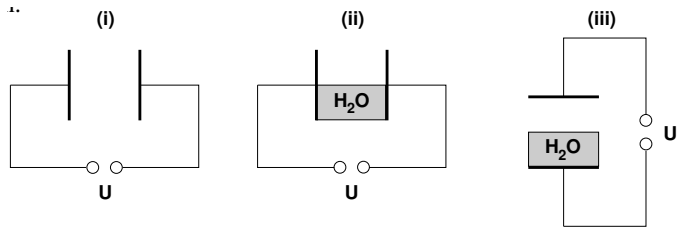

Figure 11.11: Capacitor.

11.2.2.19 Ex: Capacitor circuit

The capacitance of the capacitors in the schematic circuit are $C_1 = 10\,\mu\text{F}$, $C_2 = 5\,\mu\text{F}$ and $C_3 = 4\,\mu\text{F}$. The voltage is $U = 100\,\text{V}$.
a. Calculate the total capacitance.
b. Determine for each capacitor the value of the charge, voltage, and stored energy.

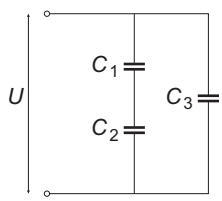

Figure 11.12: Capacitor.

11.2.2.20 Ex: Capacitor circuit

Calculate the total capacitance of the circuits shown in the figure.
a. between the points P1 and P3,
b. between the points P1 and P2.

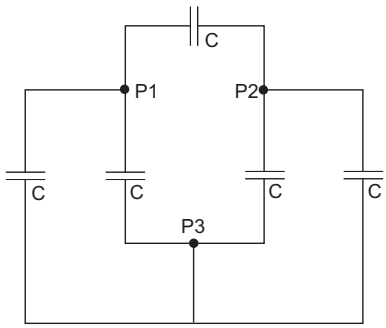

Figure 11.13: Capacitor circuit.

11.2.2.21 Ex: Capacitor circuit

Calculate the total capacitance of the circuits shown in the figure.

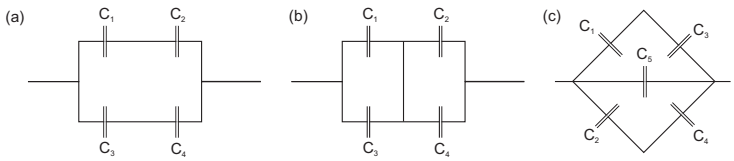

Figure 11.14: Capacitor circuit.

11.2.2.22 Ex: • Energy in combinations of capacitors

a. Two identical capacitors are connected in parallel. This combination is then connected to the terminals of a battery. How does the total energy stored in the parallel combination of these two capacitors compare to the total energy stored if only one of the capacitors were connected to the terminals of the same battery?
b. Two identical discharged capacitors are connected in series. This combination is then connected to the terminals of a battery. How does the total energy stored in the in-series combination of these two capacitors compare to the total energy stored if only one of the capacitors were connected to the terminals of the same battery?

11.2.2.23 Ex: • Plate capacitor

An air-filled plate capacitor consists of plates of $2.0\,\mathrm{m}^2$ area separated by $1\,\mathrm{mm}$ and is charged with $100\,\mathrm{V}$.
a. What is the electric field between the plates?
b. What is the electrical energy density between the plates?
c. Determine the total energy by multiplying the response to part (b) with the volume between the plates.
d. Determine the capacitance of this arrangement.
e. Calculate the total energy using $U = \frac{1}{2}CV^2$ and compare your answer with the result of part (c).

11.2.2.24 Ex: • Combination of capacitors

A 10.0 μF capacitor and a 20.0 μF capacitor are connected in parallel to the terminals of a 6.0 V battery.
a. What is the equivalent capacitance of this combination?
b. What is the potential difference in each capacitor?
c. Determine the charge on each capacitor.
d. Determine the energy stored in each capacitor.

11.2.2.25 Ex: • Infinite series of capacitors

What is the equivalent capacitance (in terms of C, which is the capacitance of one of the capacitors) of the infinite chain shown in the figure.

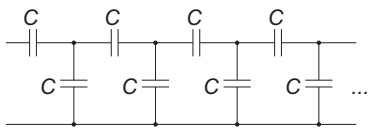

Figure 11.15: Capacitor circuit.

11.2.2.26 Ex: • Reconnecting capacitors

A 100 pF capacitor and a 400 pF capacitor are both charged at 2.0 kV. They are then disconnected from the voltage source and connected together, positive plate to positive plate and negative plate to negative plate.
a. Determine the resulting potential difference at each capacitor.
b. Determine the dissipated energy when the connection is made.

11.2.2.27 Ex: • Reconnecting capacitors

A 1.2 μF capacitor is charged at 30 V. After charging the capacitor is disconnected from the voltage source and is connected to the terminals of a second capacitor that had previously been discharged. The final voltage on the 1.2 μF capacitor is 10 V.
a. What is the capacitance of the second capacitor?
b. How much energy was dissipated when the connection was made?

11.3 Conduction of current and resistance

To charge a capacitor we need to carry charges to its electrodes. By permitting a displacement of charges we escape, in this section, for the first time from the premises of electrostatics and introduce the concept of a *current* as being due to a movement of charges within a conductor. For now, let us not raise the question, how this current will act on other charges or currents, this subject being discussed in the next chapter.

11.3.1 Motion of charges in dielectrics and conductors

In electrostatics the *electromotive force* accelerating a charge Q is the Coulomb force, $\mathbf{F} = Q\vec{\mathcal{E}}$. Interpreting the current as the sum of the motions v_k of all charges $\sum_k \frac{N_k}{V} Q_k$ within a volume V, we introduce the *current density* in a way analogous to the charge density,

$$\mathbf{j}(\mathbf{r}) = \sum_k \tfrac{N_k Q_k}{V} \mathbf{v}_k \longrightarrow \varrho(\mathbf{r}) \mathbf{v}_{\text{med}}(\mathbf{r}) \ , \tag{11.37}$$

where the average is calculated over a small volume. The flow of charges in and out of the volume satisfies the *continuity equation*,

$$\boxed{\nabla \cdot \mathbf{j} + \partial_t \varrho = 0} \ . \tag{11.38}$$

To interpret this equation we consider a volume $\mathcal{V}$ and calculate the flow of charges through the surface of the volume,

$$I \equiv \oint_{\partial \mathcal{V}} \mathbf{j} d\mathbf{S} = \int_{\mathcal{V}} \nabla \cdot \mathbf{j} dV = \int_{\mathcal{V}} \dot{\varrho} dV = \dot{Q} \ . \tag{11.39}$$

That is, the charges passing through the surface must accumulate within the volume. The charge flow I is called *current*.

11.3.2 Ohm's law, stationary currents in continuous media

In the case of free charges inside a conductor, we empirically observe that the electromotive force leads to a stationary current. Obviously, this current depends on the electric field,

$$\mathbf{j} = \mathbf{j}(\vec{\mathcal{E}}) \ , \tag{11.40}$$

despising the magnetic force, which is usually weak. Moreover, we find empirically that the current is often proportional to the field,

$$\boxed{\mathbf{j} = \varsigma \vec{\mathcal{E}}} \ . \tag{11.41}$$

with the *conductivity* ς. This observation is called *Ohm's law*.

We said earlier that $\vec{\mathcal{E}} = 0$ inside a conductor for electrostatic situations, $\mathbf{j} = 0$. This remains valid for perfect conductors, $\vec{\mathcal{E}} = \mathbf{j}/\varsigma = 0$, even when current is flowing.

11.3.2.1 Microscopic view of conduction

Ohm's law may seem surprising, since the current arising from charges accelerated by a potential difference, we would expect that the flow of charges (i.e. the current) should grow in time as the velocity of the charges increases. But in fact, the accelerated electrons often collide with the atoms of the conducting material and are decelerated by the electromotive force $F = m_e a$ or redirected. Moreover, at finite temperature, the thermal velocity of the electrons is very high,

$$v_{\text{therm}} = \sqrt{\frac{2k_B T}{3m_e}} \approx 6700\,\text{m/s} \ , \tag{11.42}$$

so that the average velocity is constant. The time between two collisions of an electron can be related to its mean free path λ by,

$$t = \frac{\lambda}{v_{\text{therm}}} \ . \tag{11.43}$$

Now, the average velocity is,

$$v_{\text{med}} = \frac{1}{t}\int_0^t v(t')dt' = \frac{at}{2} \ . \tag{11.44}$$

Finally, with n_a molecules per unit volume, each one providing N free electrons, the current density is,

$$\mathbf{j} = n_a N Q \mathbf{v}_{\text{med}} = n_a N q \frac{t}{2m_e}\mathbf{F} = n_a N Q \frac{\lambda}{2m_e v_{\text{therm}}}\mathbf{F} = \frac{n_a N Q^2 \lambda}{2m_e v_{\text{therm}}}\vec{\mathcal{E}} \ . \tag{11.45}$$

That is, the conductivity can be estimated as,

$$\varsigma = \frac{n_a N Q^2 \lambda}{2m_e v_{\text{therm}}} \ . \tag{11.46}$$

The *resistivity* is

$$\rho \equiv \frac{1}{\varsigma} \ . \tag{11.47}$$

We note that the resistivity depends on the temperature, $\rho \propto T^{1/2}$.

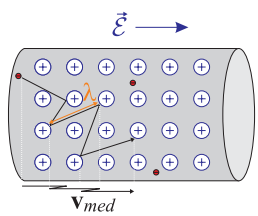

Figure 11.16: Microscopic view of the current.

Example 66 (*Estimation of the average velocity of electrons in a conductor*): Based on Eq. (11.37) we now want to estimate the average propagation velocity of electrons in a copper wire (radius $R = 1\,\text{mm}$) carrying a current of $I = 1\,\text{A}$. With the density of copper of $\rho_m = 8920\,\text{kg/m}^3$, its atomic mass $m_a = 63.5u$ and $N = 1$ valence electron per atom we estimate,

$$v_{\text{med}} = \frac{I}{n_a N e \pi R^2} = \frac{Iu}{m_a e \pi R^2} \simeq 8.5\,\text{cm/h} \ .$$

11.3.2.2 Resistors and energy consumption

Let us consider the conductor with the most common geometry: a metallic wire with the shape of a cylinder with cross section S and length L. Applying an electric field, we get,

$$I = \mathbf{j} \cdot \mathbf{S} = \varsigma \vec{\mathcal{E}} \cdot \mathbf{S} = \frac{\varsigma S}{L} U \ , \tag{11.48}$$

where $R = l/\varsigma A$ is called *resistance*. In this form the Ohm's law adopts the following form,

$$\boxed{U = RI} \ . \tag{11.49}$$

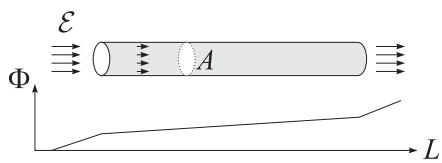

Figure 11.17: Concept of resistance.

A consequence of the frequent collisions of the electrons with the atoms is, that the conductor heats up. The power wasted on a resistance R is,

$$P = VI = RI^2 \ . \tag{11.50}$$

11.3.2.3 Resistor circuits

For parallel circuits $R_{\text{tot}}^{-1} = R_1^{-1} + R_2^{-1}$, for circuits in series $R_{\text{tot}} = R_1 + R_2$.

11.3.3 Exercises

11.3.3.1 Ex: The α-particle

A beam of α-particles ($q = +2e$), which move with constant kinetic energy $E = 20\,\text{MeV}$, corresponds to a current of $I = 0.25\,\mu\text{A}$. The beam is directed perpendicular to a flat surface.
a. How many α-particles hit the surface in $t = 3\,\text{s}$?
b. How many α-particles are at each instant of time within a $s = 20\,\text{cm}$ long beam segment?
c. What potential difference does an α-particle have to travel to be accelerated from rest to an energy of $20\,\text{MeV}$?

11.3.3.2 Ex: Electric power

A potential difference of $120\,\text{V}$ powers a heater whose resistance is $1\,\Omega$ when it is hot.
a. At what rate does this device transform electricity into heat?
b. What is the electricity consumption bill for $t = 5\,\text{h}$ of operation with a price for electricity of $S = 5\,\text{ct/kWh}$?

11.3.3.3 Ex: Ohm's Law and electric Power

By how many degrees does a copper conductor of 100 m in length and 1.2 mm^2 in diameter heat up, when it is traversed for 1 hour by a current of 6 A? Assume the heat is not dissipated and use the following data: specific resistivity: $\rho = 0.02\,\Omega\text{mm}^2/\text{m}$; density: $\rho_{\text{Cu}} = 8.93\,\text{kg/dm}^3$; specific heat capacity: $c_{\text{Cu}} = 389.4\,\text{J/kg K}$.

11.3.3.4 Ex: Continuity equation and conserved quantities

The continuity equation,

$$\dot{\rho} + \nabla \cdot (\vec{v}\rho) = 0 \ ,$$

appears in various areas of physics and describes, for example, the conservation of matter, charge or probability.
a. Explain, based on Gauß' law, the relationship between the continuity equation and charge conservation.
b. Consider a simple mechanical example: A 10 l gas bottle is opened letting gas escape. Determine with the help of the continuity equation after how many minutes half of the gas is gone, if the gas exits at a constant velocity of $v = 1\,\text{m/s}$ and the outlet valve has a cross-sectional area of $A = 10\,\text{mm}^2$?

11.3.3.5 Ex: • Drift of electrons in a conducting wire

A gold wire has a circular cross section of 0.1 mm diameter. The ends of this wire are connected to the terminals of a 1.5 V battery. If the wire length is 7.5 cm, how long does it take on average for two electrons leaving the negative terminal of the battery to reach the positive terminal? Consider a resistivity of gold of $2.44 \cdot 10^{-8}\,\Omega\text{m}$.

11.4 The electric circuit

Within a (ideal) conductor potential differences vanish everywhere $\Delta\Phi = 0$, regardless of the conductor's length or shape. In a stationary situations, that is, in the presence of static electric fields, the free electrons of the conductor self-organize their spatial distribution (if necessary by creating local charge imbalances) in order to satisfy this condition. As soon as the condition is satisfied, the movement of charges, necessary for their spatial reorganization, comes to an end.

To sustain a stationary current we need to recycle the electrons, that is, waste the electrons accumulated on the side, where the conductor is connected to the positive potential and provide new electrons on the side, where the conductor is connected to the negative potential. In other words, we need to *close* the circuit by an source-drain device for electrons, called *voltage source* or *current source* depending on the properties of the device.

In addition to the source, there is a wide variety of electronic components capable of manipulating the potential or the current in different ways, such as resistors, capacitors, inductors or transistors. In a circuit, these components are interconnected by conductive wires assumed to be ideal in the sense that they a potential without losses from one component to another.

11.4.1 Kirchhoff's rules

Electrical circuits can be more complicated and consist of several branches. The *mesh rule*,

$$\sum_k U_k = 0 \tag{11.51}$$

and the *node rule*,

$$\sum_k I_k = 0 \ , \tag{11.52}$$

govern the behavior of the potentials and currents in any circuit and serve to analyze its properties.

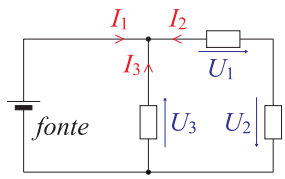

Figure 11.18: Illustration of Kirchhoff mesh and node rules.

Example 67 (*R-C circuit in series*): In addition to the voltage source we got to know two types of elements which can locally influence the voltage or the current: the capacitor and the resistor. The simplest imaginable electrical circuit containing these two components is the *R-C* circuit shown in Fig. 11.19. This circuit can be treated by Kirchhoff's laws,

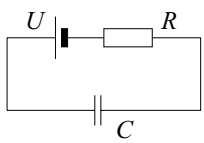

Figure 11.19: Illustration of a *R-C*-circuit.

$$0 = U_F + U_C + U_R \qquad \text{and} \qquad I_F = I_C = I_R \ . \tag{11.53}$$

Since the current is the same at each point of the circuit, we get the differential equation,

$$0 = U_F + \frac{Q}{C} + RI = U_F + \tfrac{1}{C}\int_0^t I dt' + RI \ , \tag{11.54}$$

which can quickly be solved by imposing the condition that the charge of the capacitor is initially zero,

$$I(t) = I_0(1 - e^{-t/RC}) \ . \tag{11.55}$$

11.4.2 Measuring instruments

Instruments for voltage and current measurement are discussed in the applied undergraduates courses, and we will not repeat this here.

11.4.3 Exercises

11.4.3.1 Ex: Motor starter issues

The starter of a car runs too slow. The mechanic has to decide which part is defective: the motor, the power cord, or the battery. According to the manufacturer's technical instructions, the internal resistance of the $U_0 = 12\,\mathrm{V}$ battery should not exceed $R_{\mathrm{bat}} < 0.02\,\Omega$, resistance of the motor must not exceed $R_{\mathrm{mot}} < 0.2\,\Omega$, and the resistance of the power cord must not exceed $R_{\mathrm{cab}} < 0.04\,\Omega$. Examining the starter motor the mechanic finds a potential difference of 11.4 V at the battery, 3 V in the cable, and a current of 50 A in the starter circuit. Which element of the starter is defective?

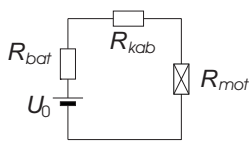

Figure 11.20: Motor starter circuit.

11.4.3.2 Ex: Solar cell

A solar cell generates a voltage of 0.1 V at a resistive load of $500\,\Omega$, but only a voltage of 0.15 V at a resistive load of $1000\,\Omega$. Consider the cell as a *real* voltage source with an internal resistance.
a. What are the internal resistance and unloaded voltage of the cell?
b. Calculate the efficiencies obtained with the two mentioned loads.

11.4.3.3 Ex: Current and voltage measurement

Circuit (a) shows an arrangement with an amperemeter with internal resistance R_A and a voltmeter with internal resistance R_U to measure resistance R. The value of the resistance follows from $R = U_V/I_R$, where U_V is the value indicated by the voltmeter and I_R the current through the resistance. A part of the current I_A measured by the amperemeter, however, flows through the voltmeter, such that the ratio U_V/I_A of the measured values only indicates an apparent resistance, which we will call R'.
a. How are the true resistance R and the apparent resistance R' interconnected through the internal resistance R_V voltmeter? How should the internal resistance of the voltmeter be chosen to guarantee that $R' \to R$?
b. With the circuit (b) it is also possible to measure a resistance with an amperemeter and a voltmeter, and also in this case the ratio between the measured values gives only an apparent resistance. How can we determine the true resistance R in this circuit, and how should the internal resistance R_A of the amperemeter be chosen?

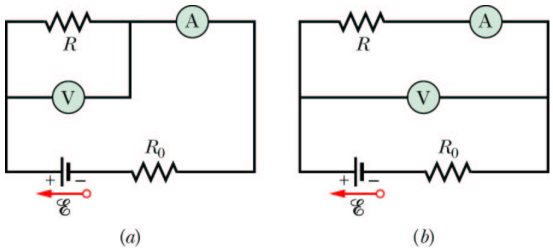

Figure 11.21: Current and voltage measurement.

11.4.3.4 Ex: Real current source

a. How should the internal resistance of a current source R_i be specified in order to obtain a current as independent as possible from the consuming load?
b. You want to run 40 A through an electric coil. The coil has the ohmic resistance of $R = 1\,\Omega$. What should be the internal resistance of the current source in order for a 10% increase in resistance not to change the current by more than 0.1%?

11.4.3.5 Ex: Real voltage source

A battery can be understood as a real voltage source, consisting of an ideal voltage source U_0 and an internal resistance R_i. The voltage supplied by the battery depends on the consuming load. Which current flows through the resistor R and which voltage U_{out} does the battery supply? How must the resistive load be chosen to maximize the power spent at the ohmic resistor?

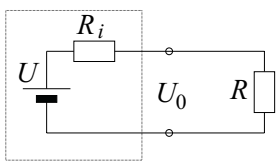

Figure 11.22: Battery.

11.4.3.6 Ex: Battery circuit

Two batteries 1 and 2 (voltages $U_1 = 2\,\mathrm{V}$ and $U_2 = 0.5\,\mathrm{V}$) and three resistors $R_1 = R_2 = R_3 = 1\,\Omega$ are connected as shown in the figure.
a. What currents flow through the resistors R_1, R_2, and R_3?
b. What is the voltage drop between points A and B?

11.4.3.7 Ex: Circuit with battery

Three batteries ($U_1 = 20\,\mathrm{V}$, $U_2 = 5\,\mathrm{V}$, $U_3 = 20\,\mathrm{V}$) each with a finite internal resistance of $0.1\,\Omega$ are connected in parallel. In series with this circuit two resistors are connected ($R_1 = 100\,\Omega$, $R_2 = 200\,\Omega$) (see scheme). What is the electrical voltage at R_1 and R_2?

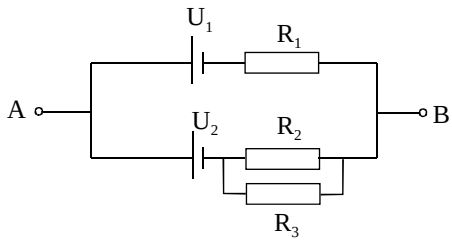

Figure 11.23: Battery circuit.

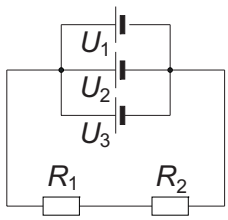

Figure 11.24: Battery circuit.

11.4.3.8 Ex: Kirchhoff's rules

The current circuit shown in the figure consists of voltage sources, $U_1 = 20\,\mathrm{V}$ and $U_2 = 10\,\mathrm{V}$ and resistors, $R_1 = 150\,\Omega$, $R_2 = R_3 = R_5 = 100\,\Omega$, and $R_4 = 50\,\Omega$. What is the current measured by the Ampèremeter A?

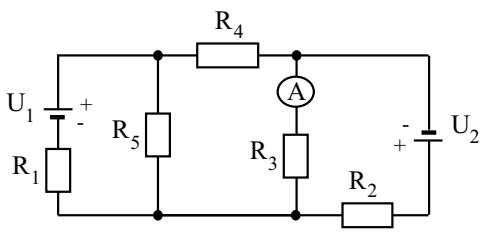

Figure 11.25: Circuits.

11.4.3.9 Ex: Kirchhoff's rules

Be given $R_1 = 1\,\Omega$, $R_2 = 2\,\Omega$, as well as $\varepsilon_1 = 2\,\mathrm{V}$ and $\varepsilon_2 = \varepsilon_3 = 4\,\mathrm{V}$.
a. Show that Kirchhoff's node rule for steady currents is a consequence of the continuity equation $\oint \vec{j} d\vec{A} = \frac{dq}{dt}$.
b. Calculate the currents across the three ideal batteries in the circuit shown in figure.
c. Calculate the potential difference between points a and b.

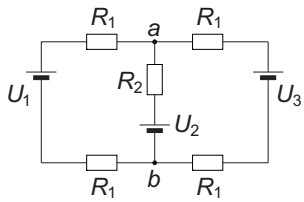

Figure 11.26: Circuits.

11.4.3.10 Ex: Kirchhoff's rules

Consider the following circuit fed by a battery of voltage V. Using Kirchhoff's laws calculate the voltages and currents at the points $P1$ and $P2$. What is the total resistance of this circuit?

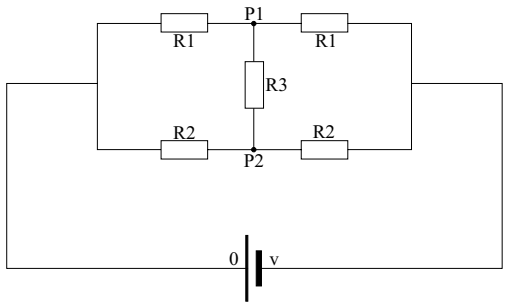

Figure 11.27: Circuits.

11.4.3.11 Ex: Combination of resistors

You have a maximum of 5 resistors of $100\,\Omega$ each. With these try to build circuits having the total resistance of a. $R = 25\,\Omega$, b. $R = 66.\bar{6}\,\Omega$, c. $R = 120\,\Omega$.

11.4.3.12 Ex: Circuit with capacitors and resistors

In the circuit shown in the figure be $R_1 = 600\,\Omega$, $R_2 = 200\,\Omega$, $R_3 = 300\,\Omega$, $C = 20\,\mu\text{F}$, and $U = 12\,\text{V}$.
a. Calculate the voltages measured at the individual resistors and the capacitor as well as the total current I_{ges} when the capacitor is fully charged (stationary case).
b. At time $t = 0$ the switch S is opened. After which time the capacitor voltage drops to $10\,\text{mV}$?

11.4.3.13 Ex: Circuits with resistors and capacitors

Consider the circuit shown in the figure with the following values, $R_1 = R_3 = 100\,\Omega$, $R_2 = R_4 = 200\,\Omega$, $C_1 = C_2 = 10\,\mu\text{F}$, and $U_0 = 20\,\text{V}$.
a. Calculate equivalent resistance and the equivalent capacity of the circuit.
b. At time $t = 0$ the switch S is closed. Find the differential equation for the voltage

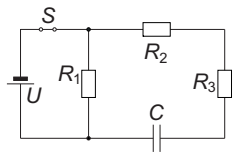

Figure 11.28: Circuits.

$U(t)$ at the capacitor C_1 and solve it. When does the voltage drop to $1/e$ of its maximum value?
c. Determine the evolution of the amplitude of the resistor current R_3.

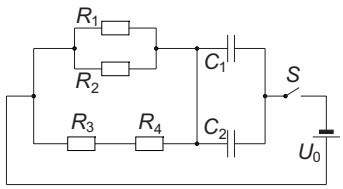

Figure 11.29: Circuits.

11.4.3.20 Ex: • Real voltmeter

The voltmeter shown in the figure can be modeled as an *ideal* voltmeter (a voltmeter that has an infinite internal resistance) in parallel with a 10 MΩ resistor. Calculate the voltmeter reading when
a. $R = 1.0\,\mathrm{k\Omega}$,
b. $R = 10.0\,\mathrm{k\Omega}$,
c. $R = 1.0\,\mathrm{M\Omega}$,
d. $R = 10.0\,\mathrm{M\Omega}$,
e. $R = 100.0\,\mathrm{M\Omega}$.
f. What is the largest possible value of R if the measured voltage should be within 10% of the *true* voltage (i.e. the voltage drop at R without placing the voltmeter)?

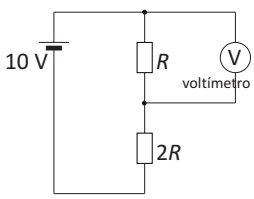

Figure 11.34: Voltmeter.

11.4.3.21 Ex: • Circuit with battery and capacitor

The switch shown in the figure is closed after having been open for a long time.
a. What is the initial value of battery current right after the switch S has been closed?
b. What is the battery current a long time after the key has been closed?
c. What are the charges on the capacitor plates a long time after the switch has been closed?

d. Now, the switch S is opened again. What are the charges on the capacitor plates a long time after the switch has been reopened?

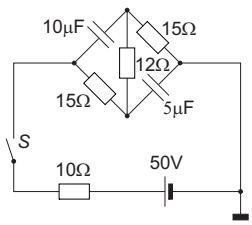

Figure 11.35: Circuits.

11.4.3.22 Ex: • Circuit with battery and capacitor

In the circuit shown in the figure, the capacitor has a capacitance of 2.5 μF and the resistor has a resistance of 0.5 MΩ. Before the switch is closed, the potential drop in capacitor is 12 V, as shown in the figure. The switch S is closed at $t = 0$.
a. What is the current immediately after the switch has been closed?
b. At what instant of time t is the voltage on the capacitor 24 V?

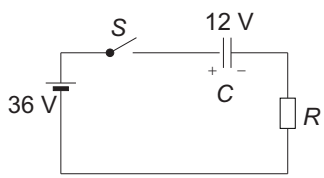

Figure 11.36: Circuits.

11.4.3.23 Ex: Three-phase current

Three-phase current is generated by three potential differences with respect to ground described by,

$$U_n(t) = U_0 \sin(\omega t + n\tfrac{2\pi}{3}) \ ,$$

where $n = 1, 2, 3$ labels the three phases. Assuming $U_0 = 127$ V.
a. What is the period-averaged voltage of each phase with respect to ground?
b. What is the period-averaged voltage difference between two phases?
c. What is the amplitude of the voltage difference between two phases?
d. Derive the time-dependent expressions for all currents labeled in Fig. 11.37(a).

Chapter 12

Magnetostatics

Magnetostatics is the theory dealing with stationary currents, the fundamental problem being the calculation of the force exerted by spatial current distributions. Since a current is always due to displacement of charges, it is obviously not stationary in the strict sense. On the other hand, if the charge is transported in such a way that every charge leaving a volume element is immediately replaced by another equivalent charge, the integral over the volume element yields a stationary charge distribution.

12.1 Electric current and the Lorentz force

In the previous chapter we have shown that charges can travel through electric conductors, thus producing currents. We observe experimentally that electrically neutral conductors can exert reciprocal forces. For example, passing currents through two parallel, almost infinitely long thin wires, we find that they attract (repel) each other when their directions are (anti-)parallel. We also observe that a compass needle is deflected near a current-carrying conductor in directions describing concentric circles around the conductor. If the compass needle traces the field lines of a yet unknown field, the force attracting (or repelling) two currents DOES NOT point in the direction of the field lines. These observations show the presence of another phenomenon and another force not explained by Coulomb's law (see Fig. 12.1).

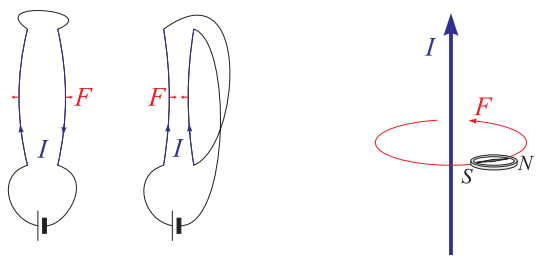

Figure 12.1: Mutual force between two conductors carrying antiparallel and parallel currents. Torque exerted by a current on a compass.

Apparently, the new force is not oriented in the direction of the current I, nor in the direction of the lines described by the compass needle, but perpendicular to the two. To describe this fact, we postulate the existence of a field $\vec{\mathcal{B}}$ called *magnetic*

field, such that the force is described by the vector product,

$$\mathbf{F}_{\mathrm{L}} = I\mathbf{l} \times \vec{\mathcal{B}} \ , \tag{12.1}$$

where $\mathbf{l}$ is an element of the current path. This force is called *Lorentz force*. Note, that this force behaves like a pseudo-vector(see Exc. 1.5.4.16).

In order to analyze this phenomenon from the microscopic point of view, we put forward the hypothesis that the observed force has to do with the *motion* of the charges constituting the current within the postulated magnetic field. We have already introduced in the previous chapter the notion of the *current*, and we connected the current density with the propagation velocity of charges in the Eqs. (11.37) and (11.45),

$$\mathbf{j}(\mathbf{r}') = \varrho(\mathbf{r}')\mathbf{v}' \ . \tag{12.2}$$

With this we get,

$$\begin{aligned} \mathbf{F}_{\mathrm{L}} &= I \int_{\mathcal{C}} d\mathbf{l}' \times \vec{\mathcal{B}} = I \int_{\mathcal{C}} \hat{\mathbf{e}}'_j \times \vec{\mathcal{B}} dl' \\ &= \int_{\mathcal{V}} I\delta^2(\mathbf{r}'_\perp - \mathbf{l}_\perp)\hat{\mathbf{e}}'_j \times \vec{\mathcal{B}} dV' = \int_{\mathcal{V}} \mathbf{j}(\mathbf{r}') \times \vec{\mathcal{B}} dV' = \int_{\mathcal{V}} \varrho(\mathbf{r}')\mathbf{v}' \times \vec{\mathcal{B}}(\mathbf{r}') dV' \ , \end{aligned} \tag{12.3}$$

where we simplified the notation $\mathbf{j}(\mathbf{r}') = I\delta^2(\mathbf{r}'_\perp - \mathbf{l}_\perp)\hat{\mathbf{e}}'_j = I\delta(\hat{\mathbf{e}}_1 \cdot \mathbf{r}' - \hat{\mathbf{e}}_1 \cdot \mathbf{l})\delta(\hat{\mathbf{e}}_2 \cdot \mathbf{r}' - \hat{\mathbf{e}}_2 \cdot \mathbf{l})\hat{\mathbf{e}}'_j$, where $\hat{\mathbf{e}}_{1,2}$ and $\hat{\mathbf{e}}'_j$ are all mutually orthogonal. We conclude,

$$\boxed{\mathbf{F}_{\mathrm{L}} = Q\mathbf{v} \times \vec{\mathcal{B}}} \ . \tag{12.4}$$

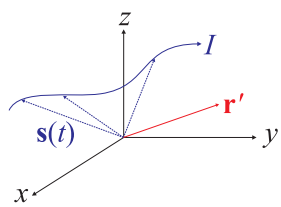

Figure 12.2: Parametrization of a yarn of current using the following recipe: For each point in space $\mathbf{r}' \in \mathbb{R}$ check that this point is also in $\mathbf{r}' \in \mathcal{C}$, that is, whether there exists a t such that $\mathbf{r}' = \mathbf{l}(t)$. At this point determine the direction of the path, $\hat{\mathbf{e}}'_j = d\mathbf{l}/|d\mathbf{l}|$, find two orthogonal unit vectors $\hat{\mathbf{e}}_{1,2}$ and apply the Dirac distribution to these dimensions.

Example 68 (*Cyclotron and synchrotron motion*): A consequence of the fact that, according to (12.4), the force on moving charges is always perpendicular to their velocity is, that their trajectory in a homogeneous magnetic field are *circular*. The centrifugal force compensates for the Lorentz force when,

$$F_{\mathrm{L}} = Qv\mathcal{B} = m\frac{v^2}{R} = F_{cf} \ ,$$

which allows to determine the radius R of the circle [1].

This fact is used in particle accelerators called *cyclotrons*, where beams of

[1] This behavior can be observed by injecting a charged particles into a homogeneous magnetic field. Collimated electron beams can be created by an electrode device called the *Wehnelt's cylinder* used in cathode ray tubes called *Braun's tube*.

charged particles are accelerated in by electric fields and deflected by homogeneous magnetic fields located between the regions of acceleration.

An important consequence of the particular form of the Lorentz force is the fact that *magnetic forces do not work*,

$$W_{\mathrm{mg}} = \int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{l} = 0 \ .$$

The direction of motion of a charge can be changed by magnetic fields, but not the absolute value of its velocity. This may seem surprising, as we know that magnets can exert forces of iron bodies.

Example 69 (*Work exerted by magnetic fields*): We consider a conductive wire loop carrying current and being partially immersed in a homogeneous magnetic field, as shown in Fig. 12.3. The device is in equilibrium, when,

$$F = Ia\mathcal{B} = mg \ .$$

When the current exceeds the value $mg/a\mathcal{B}$, a vertical force lifting the device is observed, such that the device gains potential energy,

$$W = Fh \ ,$$

where h is the acquired height. However, the vertical motion corresponds to a current $I\hat{\mathbf{e}}_z$, which creates a force contrary to the current I, such that the battery feeding the wire loop needs to work to maintain the current. The magnetic field only reorients the force into a direction having a parallel component to the horizontal part of the wire loop, thus allowing the battery to work against this force. We shall discuss this from another point of view in context of the Lenz-Faraday law.

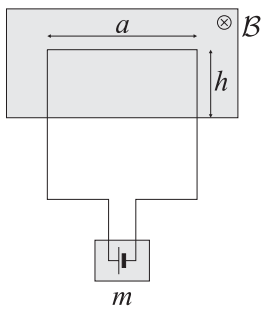

Figure 12.3: Hypothetical device to make the magnetic field work.

12.1.1 The Hall effect

As an example we consider the *Hall effect*: As shown in Fig. 12.4, a current flows to the right through a rectangular rod made of conductive material in the presence of a perpendicular uniform magnetic field $\vec{\mathcal{B}}$. If the mobile charges are positive, they will

be deflected by the magnetic field in downward direction. This deflection results in an accumulation of charges on the upper and lower boundaries of the rod which, in turn, generates an electric Coulomb force counteracting the magnetic force. A balance is reached when the two forces compensate:

$$F_{\mathrm{C}} = Q\mathcal{E} = Q\frac{U_{\mathrm{H}}}{w} = Qv_{med}\mathcal{B} = F_{\mathrm{L}} \ . \tag{12.5}$$

The difference of the electric potentials on the upper and lower boundaries is called *Hall voltage*. The average velocity of the charges can be estimated from Eq. (11.45),

$$v_{med} = \frac{j}{n_a NQ} \ , \tag{12.6}$$

where n_a is the volumetric density of molecules of the rod material, each molecule providing N free electrons. Now, using the dimensions of the rod outlined in Fig. 12.4, we calculate the Hall voltage,

$$U_{\mathrm{H}} = v_{med}\mathcal{B}w = \frac{j}{n_a NQ}\mathcal{B}w = \frac{I\mathcal{B}}{d\ n_a NQ} = A_{\mathrm{H}}\frac{I\mathcal{B}}{d} \ , \tag{12.7}$$

where $A_{\mathrm{H}} = 1/n_a NQ$ is a constant which depends on the rod material.

If the mobile charges were negative, the Hall voltage would change its sign. This fact can be used to identify the sign of free charges in unknown current conductors. Resolve the Excs. 12.1.3.1-12.1.3.13.

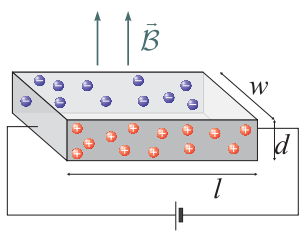

Figure 12.4: Illustration of the Hall Effect.

12.1.2 Biot-Savart's law

In the same way as we parametrize charge distributions (linear, superficial and volumetric) in electrostatics,

$$\sum_k (..)Q_k \longrightarrow \int_{\mathcal{C}} (..)\lambda dl \sim \int_{\mathcal{S}} (..)\sigma dS \sim \int_{\mathcal{V}} (..)\varrho dV \ , \tag{12.8}$$

we can parametrize current distributions (linear, superficial and volumetric) in magnetostatics,

$$\sum_k (..)Q_k\mathbf{v}_k \longrightarrow \int_{\mathcal{C}} (..)\mathbf{I}dl \sim \int_{\mathcal{S}} (..)\vec{\kappa}dS \sim \int_{\mathcal{V}} (..)\mathbf{j}dV \ . \tag{12.9}$$

In electrostatics we had the condition $\dot{\varrho} = 0$, which implies, via the continuity equation (11.38),

$$\nabla \cdot \mathbf{j} = 0 \ . \tag{12.10}$$

In magnetostatics we furthermore demand that $\dot{\mathbf{j}} = 0$.

The equivalent of Coulomb's law in magnetostatics is the Biot-Savart law,

$$\boxed{\vec{\mathcal{B}}(\mathbf{r}) = \frac{\mu_0}{4\pi}\int_{\mathcal{C}} \frac{\mathbf{I}(\mathbf{r}') \times (\mathbf{r}-\mathbf{r}')}{|\mathbf{r}-\mathbf{r}'|^3} dl' = \frac{\mu_0 I}{4\pi}\int_{\mathcal{C}} \frac{d\mathbf{l}' \times (\mathbf{r}-\mathbf{r}')}{|\mathbf{r}-\mathbf{r}'|^3} = \frac{\mu_0}{4\pi}\int_{\mathcal{V}} \mathbf{j}(\mathbf{r}') \times \frac{\mathbf{r}-\mathbf{r}'}{|\mathbf{r}-\mathbf{r}'|^3} dV'} \ . \tag{12.11}$$

Analogously to the way in which we apply Coulomb's law to electrostatics to calculate the electric field produced by charge distributions, we can apply the Biot-Savart's law in magnetostatics to calculate the magnetic field produced by currents.

Example 70 (*Magnetic field of a straight current wire*): We consider an infinitely long and thin wire oriented along the z-axis carrying a current I parametrized by $\mathbf{j}(\mathbf{r}') = \hat{\mathbf{e}}_z I\delta(x')\delta(y')$. Using $\mathbf{r} = \rho\hat{\mathbf{e}}_\rho + z\hat{\mathbf{e}}_z$ and $\mathbf{r}' = z'\hat{\mathbf{e}}_z$ we calculate,

$$\begin{aligned}\vec{\mathcal{B}}(\mathbf{r}) &= \frac{\mu_0 I}{4\pi}\int_{-\infty}^{\infty} dz' \frac{\hat{\mathbf{e}}_z \times (\mathbf{r}-\mathbf{r}')}{|\mathbf{r}-\mathbf{r}'|^3} = \frac{\mu_0 I}{4\pi}\hat{\mathbf{e}}_z \times \rho\hat{\mathbf{e}}_\rho \int_{-\infty}^{\infty} \frac{dz'}{\sqrt{\rho^2 + (z-z')^2}^3} \\ &= \frac{\mu_0 I}{4\pi}\hat{\mathbf{e}}_z \times \rho\hat{\mathbf{e}}_\rho \left[\frac{z'}{\rho^2}(\rho^2 + z'^2)^{-\frac{1}{2}}\right]_{-\infty}^{\infty} = \frac{\mu_0 I}{4\pi}\hat{\mathbf{e}}_z \times \rho\hat{\mathbf{e}}_\rho \frac{2}{\rho^2} = \frac{\mu_0 I}{2\pi\rho}\hat{\mathbf{e}}_\phi \ .\end{aligned}$$

With this we can now calculate the force exerted by this current on another current I_2 flowing in parallel direction but at a distance ρ:

$$\mathbf{F} = I_2 l\hat{\mathbf{e}}_z \times \vec{\mathcal{B}} = \frac{\mu_0 I I_2 l}{2\pi\rho}(-\hat{\mathbf{e}}_\rho) \ .$$

So the force is attractive.

Example 71 (*Magnetic field of a loop of circular current*): We consider a circular current parametrized by $\mathbf{j}(\mathbf{r}') = \hat{\mathbf{e}}_\phi I\delta(z)\delta(\rho - R)$. Following the Biot-Savart law the generated magnetic field is,

$$\vec{\mathcal{B}}(\mathbf{r}) = \frac{\mu_0}{4\pi}\int_{\mathcal{V}} \frac{\mathbf{j}(\mathbf{r}') \times (\mathbf{r}-\mathbf{r}')}{|\mathbf{r}-\mathbf{r}'|^3} dV' = \frac{\mu_0 I}{4\pi}\oint_{\mathcal{C}} \frac{\hat{\mathbf{e}}_{\phi'} \times (\mathbf{r} - R\hat{\mathbf{e}}_{r'})}{|\mathbf{r} - R\hat{\mathbf{e}}_{r'}|^3} R d\phi' \ .$$

On the symmetry axis $\mathbf{r} = z\hat{\mathbf{e}}_z$ we get,

$$\begin{aligned}\vec{\mathcal{B}}(z\hat{\mathbf{e}}_z) &= \frac{\mu_0 I R}{4\pi}\oint_{\mathcal{C}} \frac{\hat{\mathbf{e}}_{\phi'} \times (z\hat{\mathbf{e}}_z - R\hat{\mathbf{e}}_{r'})}{\sqrt{R^2\cos^2\phi' + R^2\sin^2\phi' + z^2}^3} d\phi' \\ &= \frac{\mu_0 I R}{4\pi}\oint_{\mathcal{C}} \frac{z\hat{\mathbf{e}}_r + R\hat{\mathbf{e}}_z}{\sqrt{R^2 + z^2}^3} d\phi' = \frac{\mu_0 I R^2}{2\sqrt{R^2 + z^2}^3}\hat{\mathbf{e}}_z \ ,\end{aligned}$$

where the integral containing the term $z\hat{\mathbf{e}}_r$ vanishes by symmetry.

Resolve the Excs. 12.1.3.14 to 12.1.3.15.

12.1.3 Exercises

12.1.3.1 Ex: Force on a current conductor

A piece wire having the shape of a semicircle (radius R) congruent to the xy-plane at $z = 0$ is immersed in a homogeneous magnetic $\vec{\mathcal{B}}$-field oriented along $\hat{\mathbf{e}}_z$, as shown in the scheme. Through the wire runs a current I. Calculate the force on the loop and compare it to the force on a piece of straight wire oriented along the y-axis with length $2R$. The current in this wire runs along $\hat{\mathbf{e}}_y$.

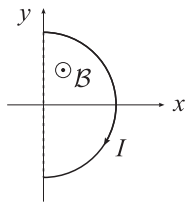

Figure 12.5: Wires.

12.1.3.2 Ex: Lorentz force

In a wooden cylinder of mass $m = 0.25\,\mathrm{kg}$ and length $L = 10\,\mathrm{cm}$ is wound a 10 turns coil of conducting wire such that the axis of the cylinder is within the plane of the coil. The cylinder is (not slipping) on an plane inclined by $\alpha = 30°$ with respect to the horizontal, so that the plane of the coil is parallel to the inclined plane. The whole setup is subject to a homogeneous vertical magnetic field with the absolute value $\mathcal{B} = 0.5\,\mathrm{T}$. What should be the minimum current through the coil to prevent the coil from rotating around its center of mass?

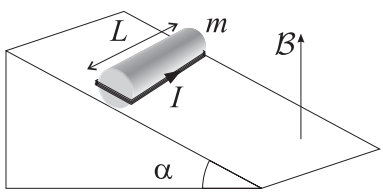

Figure 12.6: Lorentz force.

12.1.3.3 Ex: Magnetic field mass spectrometer

A spectrometer is used to separate doubly ionized uranium ions of mass 3.92×10^{-25} kg from other similar isotopes. The ions are first accelerated by a potential difference of 100 kV and then enter a homogeneous magnetic field, where they are deviated into a circular orbit of radius 1 m. After having covered an angle of 180°, they enter through a 1 mm wide and 1 cm high slit and are accumulated in a collector.
a. Determine the magnetic field of the mass spectrometer from the energy balance of

the (individual) ions.
b. The device should be able to separate 100 mg of the desired ions per hour. What should be the intensity of the ionic flux in the beam?
c. What heat is produced in the collector in one hour?

12.1.3.4 Ex: • Mass spectrometer

In a mass spectrometer, a $^{24}Mg^+$ ion has a mass of $3.983 \cdot 10^{-26}$ kg and is accelerated by a potential difference of 2.5 kV. It then enters a region, where it is deflected by a magnetic field of 557 G.
Determine the radius of curvature of the orbits of the ion.
b. What is the difference between the radii of the orbits of the ions $^{26}Mg^+$ and $^{24}Mg^+$? Consider a ratio between the masses of 26 : 24.

12.1.3.5 Ex: Magnetron

A magnetron consists of a diode tube, an anode shaped like a circular cylinder with radius R_A = cm in the center of which the cathode filament is coaxially located. On the glass tube of this diode is a wound cylindrical coil whose axis coincides with the anode. The coil is long enough that the magnetic field along the cathode can be considered homogeneous. The electrons emitted from the cathode wire simultaneously are subject to the electric field between cathode and anode, $U = 1000$ V and the magnetic field $\mathcal{B} = 0.533 \cdot 10^{-2}$ T. The latter has been adjusted so that the electrons barely do not reach the anode. The whole apparatus is basically a velocity filter for electrons and thus a compact version of J.J. Thomson's e/m experiment (1987). From the equation of motion of an electron in the tube, determine the ratio e/m.

12.1.3.6 Ex: Conductive copper strips

A copper strip of length $l = 2$ cm, width $b = 1$ cm, and thickness $d = 150$ µm lies within a homogeneous magnetic field $\vec{\mathcal{B}}$ of value 0.65 T, oriented perpendicular to the flat side of the strip. The concentration of free charges in copper is 8.47×10^{28} electrons/m^3. What is the potential difference V across the width of the tape, if it is traversed by a current of $I = 23$ A?

12.1.3.7 Ex: • Lorentz force

A firm, horizontal, 25 cm long linear wire has a mass of 5 g and is connected to an emf-source via light and flexible wires. A magnetic field of 1.33 T is horizontal and perpendicular to the wire. Determine the current needed for the wire to float, that is, when the wire is released from rest, it remains at rest.

12.1.3.8 Ex: • Lorentz force

A current carrying wire is bent in a closed semicircle of radius R in the xy-plane. The wire is inside a uniform magnetic field oriented in $+z$-direction, as shown in the figure. Verify that the force exerted on the ring is zero.

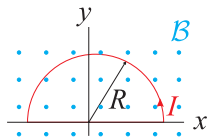

Figure 12.7: Lorentz force.

12.1.3.9 Ex: • Coulomb and Lorentz force

Two equal point charges are, at some instant of time, located at $(0, 0, 0)$ and $(0, b, 0)$. Both are moving with velocity v in $+x$-direction (consider $v \ll c$). Determine the ratio between the magnitude of the magnetic force and the magnitude of the electric force at each charge.

12.1.3.10 Ex: Penning trap

In Penning traps, charged particles move under the influence of a homogeneous magnetic field $\vec{\mathcal{B}} = \mathcal{B}_h \hat{\mathbf{e}}_z$ and a quadrupolar electric field $\vec{\mathcal{E}} = \mathcal{E}_q(\rho\hat{\mathbf{e}}_\rho - 2z\hat{\mathbf{e}}_z)$. On which orbits do the particle move?
Help: Consider the axial and radial movements separately. For the radial motion consider two cases:
1. The influence of the electric field is negligible,
2. centripetal force is negligible.

12.1.3.11 Ex: Magnetic trap near a current wire

An infinitely long conducting wire (radius R, axis in z-direction at position $x = y = 0$) carries the current I.
a. Calculate the magnetic field inside and outside the wire.
b. Now a homogeneous magnetic field is added, $\vec{\mathcal{B}}_{apl} = \mathcal{B}_0\hat{\mathbf{e}}_x$. Calculate the absolute value of the total magnetic field $|\vec{\mathcal{B}}_{\text{tot}}|$ inside and outside of wire.
c. Where inside and outside the wire do appear points where $|\vec{\mathcal{B}}_{\text{tot}}|$ vanishes? What conditions for the parameters I, R, and $\mathcal{B}_0$ must be met for such points to exist?

12.1.3.12 Ex: Charge in homogeneous fields

A charge e moves in vacuum under the influence of homogeneous fields $\vec{\mathcal{E}}$ and $\vec{\mathcal{B}}$. Suppose that $\vec{\mathcal{E}} \cdot \vec{\mathcal{B}} = 0$ and $\mathbf{v} \cdot \vec{\mathcal{B}} = 0$. At what speed does the charge move without acceleration? What is the absolute value of its speed if $|\vec{\mathcal{E}}| = |\vec{\mathcal{B}}|$?

12.1.3.13 Ex: Rain accelerated by the Earth's magnetic field

Analyze the following train propulsion concept. The train shall be propelled by the magnetic force of the vertical component of the Earth's magnetic field acting on the current-carrying axes of the train. The value of the vertical component of the Earth's magnetic field is 10 μT, the axes have a length of 3 m. The current is fed by the rails and flows from one rail through the conducting wheels and axles to the other rail.
a. What must be the amplitude of the current to generate the modest force of 10 kN

on an axis?
b. What is the rate of electric energy loss due to heat production?

12.1.3.14 Ex: Biot-Savart law

We consider an infinitely long and thin wire oriented along the z-axis and concentrically embraced by a hollow conductor with radius R and negligible wall thickness. Through the conductor flows the current I_0 and through the wire the current I_1.
a. Calculate based on the Biot-Savart law the magnetic field produced by the inner wire at a distance d from the z-axis.
b. Calculate the force exerted by the magnetic field of the inner wire on a surface element of the current conductor.
c. What is the resulting pressure with $I_1 = -I_0 = 10$ A, $R = 1$ mm?
Help:

$$\int_a^b (c^2 + x^2)^{-\frac{3}{2}} dx = \left[\frac{x}{c^2}(c^2 + x^2)^{-\frac{1}{2}}\right]_a^b$$

12.1.3.15 Ex: Biot-Savart law

We consider an infinitely long hollow conductor running along the z-axis with finite wall thickness with inner radius $R - \epsilon$ and outer radius $R + \epsilon$. The current density j_0 within the hollow conductor is constant and the total current is I_0.
a. Calculate j_0 from I_0, ϵ, and R.
b. Calculate, based on Ampere's law, the magnetic field produced by the hollow conductor at a distance ρ from the z-axis for $R - \epsilon < \rho < R + \epsilon$.
c. Calculate the resulting force on a volume element of the current-carrying conductor.
d. Integrate the radial force and calculate the limit $\epsilon \to 0$.
e. What is the resulting pressure in $I_0 = 10$ A, $R = 1$ mm? Does the force act inward or outward?

12.1.3.16 Ex: • Magnetic field of the Earth

The Earth's magnetic field is approximately 0.6 G at the magnetic poles and points vertically downwards at the magnetic pole of the northern hemisphere. If the magnetic field were due to an electric current circulating on a ring with a radius equal to Earth's inner iron core (approximately 1300 km),
a. what would be the required amplitude of the current?
b. What orientation would the current need to have, the same as Earth's rotational motion or the opposite? Justify.

12.1.3.17 Ex: Biot-Savart law

Consider the following device: A current I runs through two identical infinitely thin rings with radius R. The common center of the two rings is at the origin of the coordinates. One ring lies in the xy-plane and the other on the xz-plane.
a. Parametrize the current density $\mathbf{j}$ in spherical coordinates.

b. Show that the $\vec{\mathcal{B}}$ field resulting from this device at source is given by:

$$\vec{\mathcal{B}}(\mathbf{0}) = -\frac{\mu_0 I}{2}\frac{1}{R}\hat{\mathbf{e}}_z - \frac{\mu_0 I}{2}\frac{1}{R}\hat{\mathbf{e}}_y \ .$$

Help: A δ-function in spherical coordinates for the r variable must be multiplied by $\frac{1}{r}$; a δ-function in spherical coordinates for the ϕ variable must be multiplied by $\frac{\pi}{2}$.

12.2 Properties of the magnetic field

12.2.1 Field lines and magnetic flux

The *magnetic flux* is introduced in the same way as the electric flux,

$$\boxed{\Psi_M \equiv \int_{\mathcal{S}} \vec{\mathcal{B}} \cdot d\mathbf{S}} \ . \tag{12.12}$$

Resolve the Exc. 12.2.4.1.

12.2.2 Divergence of the magnetic field and Gauß's law

Let us compute the divergence of a magnetic field given by Biot-Savart's law [2],

$$\nabla_r \cdot \vec{\mathcal{B}} = \frac{\mu_0}{4\pi}\int_{\mathcal{V}} [\nabla_r \times \mathbf{j}(\mathbf{r}')] \cdot \frac{\mathbf{r}-\mathbf{r}'}{|\mathbf{r}-\mathbf{r}'|^3} dV' - \frac{\mu_0}{4\pi}\int_{\mathcal{V}} \mathbf{j}(\mathbf{r}') \cdot \left[\nabla_r \times \frac{\mathbf{r}-\mathbf{r}'}{|\mathbf{r}-\mathbf{r}'|^3}\right] dV' = 0 \ , \tag{12.13}$$

since, as we have already shown, the rotation of a Coulombian field is zero. Therefore,

$$\boxed{\nabla \cdot \vec{\mathcal{B}} = 0} \ . \tag{12.14}$$

With Gauß' law we can derive the integral version of this statement,

$$\boxed{\oint_{\partial\mathcal{V}} \vec{\mathcal{B}} \cdot d\mathbf{S} = 0} \ . \tag{12.15}$$

Comparing this equation with the corresponding electrostatic equation (10.13), we deduce the following interpretation: The total magnetic flux Ψ_M across a closed surface must vanish and can not be changed by *hypothetical magnetic charges*, i.e. *magnetic charges do not exist*!

A direct consequence of this law is that we can introduce the concept of the vector potential, which is fundamental in the sense that it allows us to formulate electrodynamics completely in terms of potentials. We will dedicate the whole next section to magnetic potentials.

[2] Using the rule $\nabla \cdot (\vec{\mathcal{E}} \times \vec{\mathcal{B}}) = (\nabla \times \vec{\mathcal{E}}) \cdot \vec{\mathcal{B}} - \vec{\mathcal{E}} \cdot (\nabla \times \vec{\mathcal{B}})$.

12.2.3 Rotation of the magnetic field and Ampère's law

Let us now calculate the rotation of the magnetic field given by Biot-Savart's law [3],

$$\nabla_r \times \vec{\mathcal{B}} = \frac{\mu_0}{4\pi}\int_{\mathcal{V}} -[\mathbf{j}(\mathbf{r}')\cdot\nabla_r]\frac{\mathbf{r}-\mathbf{r}'}{|\mathbf{r}-\mathbf{r}'|^3}dV' + \frac{\mu_0}{4\pi}\int_{\mathcal{V}}\mathbf{j}(\mathbf{r}')\left(\nabla_r\cdot\frac{\mathbf{r}-\mathbf{r}'}{|\mathbf{r}-\mathbf{r}'|^3}\right)dV' \tag{12.16}$$

$$= \frac{\mu_0}{4\pi}\int_{\mathcal{V}}[\mathbf{j}(\mathbf{r}')\cdot\nabla_{r'}]\frac{\mathbf{r}-\mathbf{r}'}{|\mathbf{r}-\mathbf{r}'|^3}dV' + \frac{\mu_0}{4\pi}\int_{\mathcal{V}}\mathbf{j}(\mathbf{r}')4\pi\delta(\mathbf{r}-\mathbf{r}')dV'$$

$$= \frac{\mu_0}{4\pi}\int_{\mathcal{V}}[\mathbf{j}(\mathbf{r}')\cdot\nabla_{r'}]\frac{\mathbf{r}-\mathbf{r}'}{|\mathbf{r}-\mathbf{r}'|^3}dV' + \mu_0\mathbf{j}(\mathbf{r})\ . \tag{12.17}$$

Considering the x-component,

$$(\nabla_r \times \vec{\mathcal{B}})_x = \frac{\mu_0}{4\pi}\int_{\mathcal{V}}\mathbf{j}(\mathbf{r}')\cdot\nabla_{r'}\frac{x-x'}{|\mathbf{r}-\mathbf{r}'|^3} + \mu_0 j_x(\mathbf{r})$$

$$= -\frac{\mu_0}{4\pi}\oint_{\partial\mathcal{V}}\mathbf{j}(\mathbf{r}')\frac{x-x'}{|\mathbf{r}-\mathbf{r}'|^3}d\mathbf{S}' + \frac{\mu_0}{4\pi}\int_{\mathcal{V}}\frac{x-x'}{|\mathbf{r}-\mathbf{r}'|^3}\nabla_{r'}\cdot\mathbf{j}(\mathbf{r}')dV' + \mu_0 j_x(\mathbf{r})\ .$$

The surface integral vanishes when the volume goes to infinity. On the other hand, $\nabla\cdot\mathbf{j} = -\dot{\varrho} = 0$. With this, we obtain,

$$\boxed{\nabla\times\vec{\mathcal{B}} = \mu_0\mathbf{j}}\ . \tag{12.18}$$

The results (12.14) and (12.18) represent parts of Maxwell's first and fourth equations. The equation (12.18) is also called *Ampère's law*. The integral version can be obtained from Stokes' law,

$$\boxed{\oint_{\mathcal{C}}\vec{\mathcal{B}}\cdot d\mathbf{l} = \mu_0 I}\ . \tag{12.19}$$

The interpretation of Ampere's law is, that *every current produces a rotational magnetic field*, that is, a field with closed field lines. Measuring the magnetic field along an closed path we can evaluate the current passing through the surface delimited by the path.

Ampère's law has many applications. Let's discuss some in the next.

Example 72 (*Magnetic field of a straight current-carrying wire*): Let us re-evaluate the example 70 using Ampere's law,

$$\oint\vec{\mathcal{B}}\cdot d\mathbf{l} = B\int_0^{2\pi}\rho d\phi = \mathcal{B}2\pi\rho = \mu_0 I\ .$$

Hence,

$$\mathcal{B} = \frac{\mu_0 I}{2\pi\rho}\ .$$

[3] Using the rule $\nabla\times(\vec{\mathcal{E}}\times\vec{\mathcal{B}}) = (\vec{\mathcal{B}}\cdot\nabla)\vec{\mathcal{E}} - (\vec{\mathcal{E}}\cdot\nabla)\vec{\mathcal{B}} + \vec{\mathcal{E}}(\nabla\cdot\vec{\mathcal{B}}) - \vec{\mathcal{B}}(\nabla\cdot\vec{\mathcal{E}})$.

Example 73 (*Ampère's law*): We can use Ampère's law to show that a locally uniform magnetic field, such as the one shown in Fig. 12.8, is impossible. Let us have a look at the rectangular curve shown by the dashed lines. With the chosen geometry, the curve does not include current,

$$\mu_0 I = 0 \ .$$

On the other hand, the magnetic field accumulated along the curve is,

$$\oint_{\mathrm{C}} \vec{\mathcal{B}} \cdot d\mathbf{l} \neq 0 \ .$$

This is a contradiction. Thus, this example shows that, in the absence of cur-

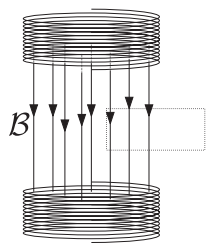

Figure 12.8: Impossibility of a localized homogeneous magnetic field.

rents, any magnetic field is conservative. We could then define a scalar potential whose gradient would be the magnetic field, but this potential must be *simply connected*, i.e. not be traversed by currents, which limits the practical use of such a potential.

Example 74 (*Field of a solenoid*): A solenoid is a very long coil (the distance between two consecutive turns is much smaller than the radius and the total length l of the coil) carrying a current I (see diagram in Fig. 12.9). Ampère's law can be used to easily calculate the magnetic field inside a solenoid composed of N turns,

$$\mathcal{B}\, dl = \oint_{\mathcal{C}} \vec{\mathcal{B}} \cdot d\mathbf{r} = \mu_0 I \, dN \ .$$

Hence,

$$\mathcal{B} = \mu_0 I \frac{dN}{dl} \ .$$

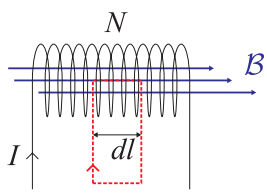

Figure 12.9: Scheme of a solenoid with loop density dN/dl.

Resolve the Excs. 12.2.4.2 to 12.2.4.9. In the Excs. 12.2.4.10 to 12.2.4.12 we apply the Biot-Savart law to *Helmholtz coils* and *anti- Helmholtz coils*.

12.2.4 Exercises

12.2.4.1 Ex: • Magnetic flux

A long solenoid has n turns per unit length, radius R_1, and carries a current I. A circular coil with radius R_2 and N turns is coaxial to the solenoid and is equidistant from its ends.
a. Determine the magnetic flux through the coil if $R_2 < R_1$.
b. Determine the magnetic flux through the coil if $R_2 > R_1$.

12.2.4.2 Ex: Magnetic field of a conducting ring and Ampère's law

A ring-shaped conducting loop lies in the yz-plane; the loop's symmetry axis is the x-axis. It is traversed by a current I generating on the axis the field $\mathcal{B}_x = \frac{1}{2}\mu_0 I R^2 (x^2 + R^2)^{-3/2}$.
a. Calculate the line integral $\int \vec{\mathcal{B}} \cdot d\mathbf{s}$ along the x-axis between $x = -L$ and $x = +L$.
b. Show that for $L \to \infty$ the line integral converges to $\mu_0 I$.
Help: This result can also be obtained with Ampère's law, when we close the integration path through a semicircle with radius L, for which holds $\mathcal{B} \simeq 0$, when L is very large.

12.2.4.3 Ex: Biot-Savart's and Ampère's laws

a. Calculate the magnetic field generated by a constant current I on a straight conductor piece of length L.
b. Show that for an infinitely long conductor the Biot-Savart law becomes Ampere's law.

12.2.4.4 Ex: Solenoid

a. To determine the number of turns of a solenoid with diameter $D = 4\,\text{cm}$ and length $L = 10\,\text{cm}$, an experimenter passes a current $I = 1\,\text{A}$ through the coil. He measures the magnetic field $\mathcal{B} = 10\,\text{mT}$. How many windings are there?
b. To confirm it measures the diameter of the copper wire ($d = 1\,\text{mm}$) and ohmic resistance finding $R = 2\,\Omega$. On the internet he finds the resistivity of copper $\rho = 1.7 \cdot 10^{-8}\,\Omega\text{m}$.

12.2.4.5 Ex: Toroidal coil

A coil with N turns is arranged in a toroidal form with rotational symmetry around z-axis and has its center at the origin of the coordinates. The coil is densely wound and traversed by a current I (see scheme).
a. Calculate the $\hat{\mathbf{e}}_\phi$-component of the $\vec{\mathcal{B}}$-field for $z = 0$ (xy-plane) as a function of distance ρ from the origin.
b. Determine the $\hat{\mathbf{e}}_\phi$-component of the $\vec{\mathcal{B}}$-field in the entire *inner* space outside the toroid. Draw the $\hat{\mathbf{e}}_\phi$ component as a function of ρ.
c. What should be the value of b, so that $\mathcal{B}_\phi$ is constant within the toroid with an accuracy of $\alpha = 1\%$, when $a = 1\,\text{cm}$? [That is: $\mathcal{B}_\phi(b-a) - \mathcal{B}_\phi(b+a) < \alpha \cdot \mathcal{B}_\phi(b)$]

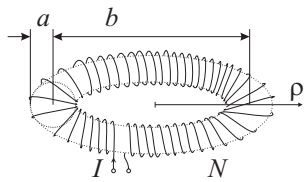

Figure 12.10: Toroidal coil.

12.2.4.6 Ex: • Toroidal coil

A toroidal coil tightly wound with 1000 turns has an inner radius of 1.0 cm, an outer radius of 2.0 cm, carries a current of 1.5 A. The torus is centered at the origin with the centers of the individual turns in the $z = 0$ plane. What is the intensity of the magnetic field in the $z = 0$ plane a distance of (a) 1.1 cm and (b) 1.5 cm away from the origin?

12.2.4.7 Ex: Inhomogeneous current density

The current density on a straight wire of infinite length with the radius R grows linearly from the center outward, $\mathbf{j}(r) = j_0 r \hat{\mathbf{e}}_z$, where $\hat{\mathbf{e}}_z$ shows in the direction of the wire and the total current going through the wire is I.
a. Calculate j_0 as a function of I.
b. Calculate, using Ampere's law, the magnetic field inside and outside the wire.
c. Make a graph of the normalized magnetic field, $\mathcal{B}(r)/\mathcal{B}_R$, versus r/R, where $\mathcal{B}_R \equiv \mu_0 I/2\pi R$.

12.2.4.8 Ex: Magnetic field in a coaxial cable

A coaxial cable consists of an inner conductor with radius R_1 and a cylindrical outer conductor with inner radius R_2 and outer radius R_3. In both conductors flows the same current I in opposite directions. The current densities in each conductor are homogeneous.
a. Calculate the current densities in each conductor.
b. Calculate the magnetic field $\mathcal{B}(r)$ for $r \leq R_1$,
c. for $R_1 \leq r \leq R_2$,
d. for $R_2 \leq r \leq R_3$,
e. for $R_3 \leq r$.

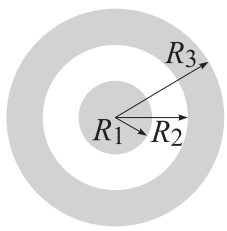

Figure 12.11: Magnetic field in a coaxial cable.

12.2.4.9 Ex: Magnetic field of a current conductor

In a straight, infinitely long conductor with circular cross-sectional area with radius R runs a current I with a uniform current density distribution. How are the magnetic induction field lines $\vec{\mathcal{B}}$?
a. Calculate $\vec{\mathcal{B}}$ inside and outside the conductor.
b. Prepare a scheme of the profile $\mathcal{B}(r) \equiv |\vec{\mathcal{B}}(r)|$, where r be the distance from the symmetry axis of the conductor in a direction perpendicular to it.

12.2.4.10 Ex: Helmholtz and anti-Helmholtz coils

a. Show that the magnetic field of a round current loop conductor with radius R on the symmetry axis is given by,

$$\vec{\mathcal{B}}(z) = -\frac{\mu_0 I}{2} \frac{R^2}{\sqrt{R^2 + z^2}^3} \hat{\mathbf{e}}_z \ .$$

b. Now consider two identical parallel loops placed on the symmetry axis with distance $d = R$. The loops are traversed by currents of equal amplitude. What is the behavior of the magnetic field on the symmetry axis for (i) equal directions of currents (ii) opposite directions? Choosing as the origin the center between the two coils, expands the magnetic field to second order in a Taylor series around the origin.

12.2.4.11 Ex: Helmholtz coils

Two identical circular coils of radius R and negligible thickness are mounted with their axes coinciding with the z-axis, as shown in the figure below. Their centers are separated by a distance d, with the midpoint P coinciding with the origin of the z-axis. The coils carry electric currents of the same intensity I, and both counterclockwise.
a. Use the Biot-Savart law to show that the magnetic field $\mathcal{B}(z)$ along the z-axis is,

$$\vec{\mathcal{B}}_{t+}(z) = -\frac{\mu_0 I}{2} \hat{\mathbf{e}}_z \left(\frac{R^2}{\sqrt{R^2 + (z - R/2)^2}^3} \pm \frac{R^2}{\sqrt{R^2 + (z + R/2)^2}^3} \right) \ .$$

b. Assuming that the spacing d is equal to the radius R of the coils, show that at point P the following equalities are valid: $d\mathcal{B}/dz = 0$ and $d^2\mathcal{B}/dz^2 = 0$.
c. Looking at the graphs below, which curve describes the magnetic field along the z-axis in the configuration of item (b)? Justify!
d. Assuming that the current in the upper coil is reversed, calculate the new value of the magnetic field at point P.

12.2.4.12 Ex: • Helmholtz coils

A pair of identical coils, each with a radius of 30 cm, is separated by a distance equal to their radii. Called Helmholtz coils, they are coaxial and carry equal currents oriented such that their axial fields point into the same z-direction. A feature of Helmholtz coils is, that the resulting magnetic field in the region between the coils is quite uniform. Assume that the current in each one is 15 A and that there are 250 turns for each coil. Using a spreadsheet, calculate and plot the magnetic field

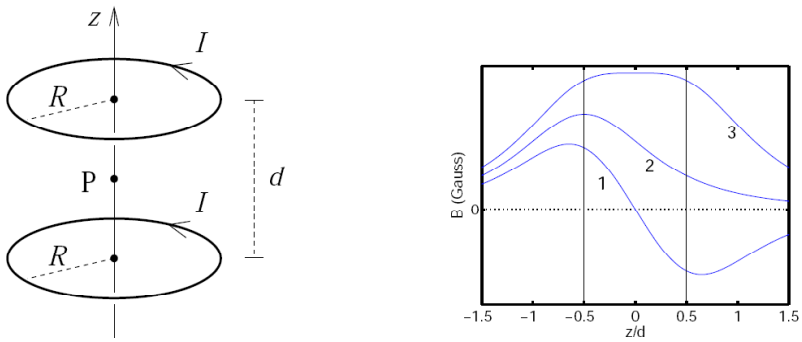

Figure 12.12: (code) Geometry and magnetic field amplitude of a pair of Helmholtz coils.

along the z-axis for $-30\,\text{cm} < z < +30\,\text{cm}$. Within which z-range does the field vary by less than 20%?

12.3 The magnetic vector potential

The fact that the divergence of the magnetic field vanishes, $\nabla \cdot \vec{\mathcal{B}} = 0$, allows us to introduce a vector field $\mathbf{A}$ called *vector potential* of which the magnetic field is the rotation,

$$\boxed{\vec{\mathcal{B}} = \nabla \times \mathbf{A}} \; . \tag{12.20}$$

12.3.1 The Laplace and Poisson equations

Ampère's law says,

$$\mu_0 \mathbf{j} = \nabla \times \vec{\mathcal{B}} = \nabla \times (\nabla \times \mathbf{A}) = \nabla(\nabla \cdot \mathbf{A}) - \nabla^2 \mathbf{A} \; . \tag{12.21}$$

Note that, just as we can add a constant to the electrostatic potential without changing the electric field, we have the freedom to add to the vector potential the *gradient of a scalar field*,

$$\nabla \times \mathbf{A} = \nabla \times (\mathbf{A} + \nabla\chi) \; , \tag{12.22}$$

since the rotation of a gradient always vanishes. This freedom allows us to impose other conditions on this scalar field $\chi(\mathbf{r})$. One of them is called the *Coulomb gauge*,

$$\boxed{\nabla \cdot \mathbf{A} \equiv 0} \; . \tag{12.23}$$

To show that it is always possible to choose a function χ such, that the potential vector $\mathbf{A} + \nabla\chi$ satisfies the condition (12.23) and at the same time produces the same magnetic field (12.22), we just insert this potential into Eq. (12.23) and find a formal solution of the following Poisson equation,

$$\nabla^2 \chi = -\nabla \cdot \mathbf{A} \; . \tag{12.24}$$

is simply the Coulomb potential [see (10.33)],

$$\chi(\mathbf{r}) = \frac{1}{4\pi}\int_{\mathcal{V}} \frac{\nabla_{r'}\cdot\mathbf{A}(\mathbf{r}')}{|\mathbf{r}-\mathbf{r}'|}dV' \ , \tag{12.25}$$

supposing that $\nabla\cdot\mathbf{A} \overset{r\to\infty}{\longrightarrow} 0$.

Within the Coulomb gauge the Eq. (12.21) also adopts the simple form of a Poisson equation,

$$\boxed{\nabla^2\mathbf{A} = -\mu_0\mathbf{j}} \ , \tag{12.26}$$

which we can solve,

$$\boxed{\mathbf{A}(\mathbf{r}) = \frac{\mu_0}{4\pi}\int \frac{\mathbf{j}(\mathbf{r}')}{|\mathbf{r}-\mathbf{r}'|}d^3\mathbf{r}'} \ . \tag{12.27}$$

This relationship is the equivalent of the electrostatic potential (10.35). We verify that we recover Biot-Savart's law (12.8) via,

$$\nabla_r\times\mathbf{A}(\mathbf{r}) = \frac{\mu_0}{4\pi}\int_{\mathcal{V}}\mathbf{j}(\mathbf{r}')\times\frac{|\mathbf{r}-\mathbf{r}'|}{|\mathbf{r}-\mathbf{r}'|^3}dV' \ . \tag{12.28}$$

Example 75 (*Vector potential of a one-dimensional current*): As an example we consider a one-dimensional current, $\mathbf{j}(\mathbf{r}') = I\delta^2(\mathbf{r}'-\mathbf{s}_\perp)\hat{\mathbf{e}}'_j$,

$$\mathbf{A}(\mathbf{r}) = \frac{\mu_0 I}{4\pi}\int_{\mathcal{C}}\frac{d\mathbf{s}'}{|\mathbf{r}-\mathbf{r}'|} \qquad \text{and} \qquad \vec{\mathcal{B}}(\mathbf{r}) = \frac{\mu_0 I}{4\pi}\int_{\mathcal{C}}\frac{d\mathbf{s}'\times|\mathbf{r}-\mathbf{r}'|}{|\mathbf{r}-\mathbf{r}'|^3} \ .$$

For a current element oriented along the z-axis,

$$\mathbf{A}(\mathbf{r}) = \frac{\mu_0 I}{4\pi}\int_0^a \frac{\hat{\mathbf{e}}_z dz'}{\sqrt{\rho^2+(z-z')^2}} = \frac{\mu_0 I}{4\pi}\hat{\mathbf{e}}_z \ln\frac{-(z-a)+\sqrt{r^2+(z-a)^2}}{-z+\sqrt{r^2+z^2}} \ .$$

The scheme 12.13 summarizes the fundamental laws of magnetostatics.

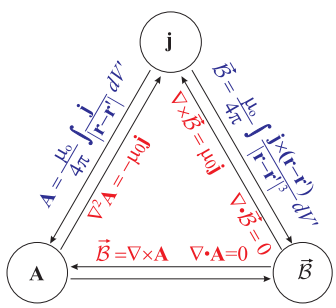

Figure 12.13: Organization chart for the fundamental laws of magnetostatics. Note, that there is no simple expression to calculate $\mathbf{A}$ from $\vec{\mathcal{B}}$.

12.3.2 Magnetostatic boundary conditions

In order to find the magnetostatic boundary conditions imposed by current-carrying interfaces, we proceed in the same way as in the electrostatic case. First, we consider a 'pill box', as schematized in Fig. 12.14. From

$$\oint \vec{\mathcal{B}} \cdot d\mathbf{S} = 0 \ , \tag{12.29}$$

we find for the component of the magnetic field perpendicular to the interface,

$$\mathcal{B}^{\perp}_{\text{top}} = \mathcal{B}^{\perp}_{down} \ . \tag{12.30}$$

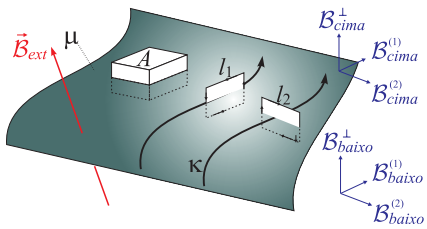

Figure 12.14: Illustration of the pillbox-shaped volume delimited by the surface A cutting through a small part of the interface. Also shown are paths on the interface being perpendicular (l_1) or parallel (l_2) to the surface current κ.

We now consider a closed loop in the plane defined by the magnetic field and perpendicular to the current. From

$$\oint \vec{\mathcal{B}} \cdot d\mathbf{l}_2 = (\mathcal{B}^{(2)}_{\text{top}} - \mathcal{B}^{(2)}_{\text{bottom}}) l_2 = \mu_0 I = \mu_0 \kappa l_2 \ , \tag{12.31}$$

where we defined $\kappa \equiv I/l_2$ as the surface current density, that is, the current dI flowing through a ribbon of width dl_2 sticking to the interface. We find,

$$\mathcal{B}^{(2)}_{\text{top}} - \mathcal{B}^{(2)}_{\text{bottom}} = \mu_0 \kappa \ . \tag{12.32}$$

Thus, the component of $\vec{\mathcal{B}}$ parallel to the surface but perpendicular to the current is discontinuous by a value $\mu_0 \kappa$.

Similarly, a closed loop in the direction parallel to the current shows that the parallel component of $\vec{\mathcal{B}}$ is continuous,

$$\oint \vec{\mathcal{B}} \cdot d\mathbf{l}_1 = (\mathcal{B}^{(1)}_{\text{top}} - \mathcal{B}^{(1)}_{\text{bottom}}) l_1 = 0 \ . \tag{12.33}$$

In summary,

$$\vec{\mathcal{B}}_{\text{top}} - \vec{\mathcal{B}}_{\text{bottom}} = \vec{\mathcal{B}}^{\parallel}_{\text{top}} - \vec{\mathcal{B}}^{\parallel}_{\text{bottom}} = \mu_0 \vec{\kappa} \times \hat{\mathbf{n}} \ . \tag{12.34}$$

In the same way as the scalar potential in electrostatics, the potential vector remains continuous through the interface,

$$\mathbf{A}_{\text{top}} = \mathbf{A}_{\text{bottom}} \ , \tag{12.35}$$

because $\nabla \cdot \mathbf{A} = 0$ ensures that the normal component is continuous and,

$$\oint \mathbf{A} \cdot d\mathbf{l} = \int \nabla \times \mathbf{A} \cdot d\mathbf{S} = \int \vec{\mathcal{B}} \cdot d\mathbf{S} = \Psi_M \ , \tag{12.36}$$

means that the tangential components are continuous (the flux through an Amperian loop of negligible thickness vanishes). On the other hand, the derivative of $\mathbf{A}$ inherits the discontinuity of $\vec{\mathcal{B}}$:

$$\frac{\partial \mathbf{A}_{\text{top}}}{\partial n} - \frac{\partial \mathbf{A}_{\text{bottom}}}{\partial n} = -\mu_0 \vec{\kappa} \ , \tag{12.37}$$

where n is the coordinate perpendicular to the surface.

Example 76 (*Proof of the discontinuity of the derivative of the vector potential*): To prove the statement (12.37) we consider a surface current in the direction $\vec{\kappa} = \kappa \hat{\mathbf{e}}_x$ within an interface located in the x-y-plane. So,

$$\vec{\mathcal{B}}_{\text{top}} - \vec{\mathcal{B}}_{\text{bottom}} = \begin{pmatrix} 0 \\ \mu_0 \kappa \\ 0 \end{pmatrix} = \begin{pmatrix} \partial_y A^{(z)}_{\text{top}} - \partial_z A^{(y)}_{\text{top}} \\ \partial_z A^{(x)}_{\text{top}} - \partial_x A^{(z)}_{\text{top}} \\ \partial_x A^{(y)}_{\text{top}} - \partial_y A^{(x)}_{\text{top}} \end{pmatrix} - \begin{pmatrix} \partial_y A^{(z)}_{\text{bottom}} - \partial_z A^{(y)}_{\text{bottom}} \\ \partial_z A^{(x)}_{\text{bottom}} - \partial_x A^{(z)}_{\text{bottom}} \\ \partial_x A^{(y)}_{\text{bottom}} - \partial_y A^{(x)}_{\text{bottom}} \end{pmatrix} .$$

Now,

$$0 = \partial_y A^{(z)}_{\text{top}} - \partial_y A^{(z)}_{\text{bottom}} = \partial_z A^{(y)}_{\text{top}} - \partial_z A^{(y)}_{\text{bottom}} = \partial_x A^{(y)}_{\text{top}} - \partial_x A^{(y)}_{\text{bottom}} = \partial_y A^{(x)}_{\text{top}} - \partial_y A^{(x)}_{\text{bottom}}$$
$$\mu_0 \kappa_x = \partial_z A^{(x)}_{\text{top}} - \partial_z A^{(x)}_{\text{bottom}} - \partial_x A^{(z)}_{\text{top}} + \partial_x A^{(z)}_{\text{bottom}} \ .$$

Assuming a uniform field, only the derivative in z can contribute, such that,

$$\mu_0 \kappa_x = \partial_z A^{(x)}_{\text{top}} - \partial_z A^{(x)}_{\text{bottom}} \ .$$

12.3.3 Exercises

12.3.3.1 Ex: Vector potential and electric field of a rotating charged sphere

On the surface of a hollow sphere with radius R be evenly distributed the charge Q. The sphere rotates at constant angular velocity $\vec{\omega}$ around one of its diameters.
a. Determine the current density generated by the motion $\mathbf{j}(\mathbf{r})$.
b. Derive the components of the potential vector $\mathbf{A}(\mathbf{r})$ and the magnetic field $\vec{\mathcal{B}}(\mathbf{r})$.

12.3.3.2 Ex: Magnetic field of a rotating spherical layer with spherical harmonics

Calculate the vector potential, magnetic field and magnetization of a charged rotating spherical layer using spherical harmonics.

12.3.3.3 Ex: Conducting thin loops

Consider a circular conducting loop with radius R. The wire of the loop is infinitely thin (δ-function). Through the loop flows a continuous current I.
a. What is the expression for current density $\mathbf{j}(\mathbf{r})$? Express the result in spherical coordinates considering that the integral of the current over a surface perpendicular to the wire must give I.
b. Calculate the magnetic dipolar moment of this current loop,

$$\mathbf{m} = \frac{1}{2}\int [\mathbf{r} \times \mathbf{j}(\mathbf{r})] d^3r \ .$$

c. For large distances from a localized current distribution, the potential vector $\mathbf{A}$ is dominated by the dipolar contribution,

$$\mathbf{A}(\mathbf{r}) = \frac{\mathbf{m} \times \mathbf{r}}{r^3} \ .$$

What are, in this approximation, the values of the potential vector $\mathbf{A}$ and the magnetic field $\vec{\mathcal{B}}$ for the conducting loop?

12.3.3.4 Ex: Conducting thin loops

Consider a system of N different conducting loops (use δ-functions) through which runs a current I_j ($j = 1, \ldots, N$). The magnetic flux through the j-th loop is then given by,

$$\Phi_j = \sum_{m=1}^{N} \int_{F_j} \vec{\mathcal{B}}_m \cdot d\mathbf{S} \ ,$$

where the integral must be taken over the area enclosed by the current loops j and $\vec{\mathcal{B}}_m$ is the part of the magnetic field due to the j-th loop.
a. Show,

$$\Phi_j = c \sum_{m=1}^{N} L_{jm} I_m$$

with the induction coefficient,

$$\frac{L_{jm} = \frac{1}{c^2}\int_j \int_m d\mathbf{r}_j \cdot d\mathbf{r}_m}{|\mathbf{r}_j - \mathbf{r}_m| \ ,}$$

where the integrals are taken over the loops j and m.
b. Also show that the magnetic field energy of the loop system is given by,

$$W = \frac{1}{2}\sum_{j,m} L_{jm} I_j I_m \ .$$

12.3.3.5 Ex: Conducting thin loops

A conducting loop made of two semicircles (see diagram) with radii $r_i = 0.3\,\mathrm{m}$ and $r_a = 0.5\,\mathrm{m}$ carries a current $I = 1.5\,\mathrm{A}$.
a. Calculate the magnetic moment $\vec{\mu}$ of the conducting loop.
b. The conducting loop is now traversed by a $\mathcal{B}$-field of amplitude $\mathcal{B} = 0.3\,\mathrm{T}$. Calculate the resulting torque $\mathbf{m}$ on the loop, when the $\mathcal{B}$-field is directed (i) toward z, (ii) toward x, and (iii) orthogonal to the plane of the scheme.

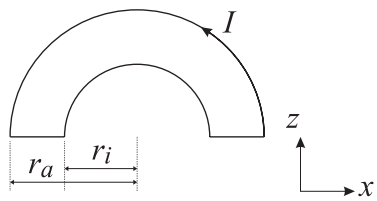

Figure 12.15: Loop.

12.3.3.6 Ex: Gauge transformation

Be given the potential vector,

$$\mathbf{A}(\mathbf{r}) = \frac{1}{y^2 + z^2 + a^2} \begin{pmatrix} 0 \\ z \\ -y \end{pmatrix} .$$

Discusses the corresponding magnetic field $\vec{\mathcal{B}} = \nabla \times \mathbf{A}$.
a. Show that the potential

$$\mathbf{A}'(\mathbf{r}) = \frac{1}{y^2 + z^2 + a^2} \begin{pmatrix} 0 \\ y + z \\ z - y \end{pmatrix}$$

gives the same magnetic field as the potential $\mathbf{A}(\mathbf{x})$.
b. Show:

$$\mathbf{A}'(\mathbf{r}) = \mathbf{A}(\mathbf{r}) - \nabla\alpha(\mathbf{r})$$

and determine $\alpha(\mathbf{r})$.

12.3.3.7 Ex: Coulomb gauge

Be given the vector potential,

$$\mathbf{A}(x, y, z) = \frac{(x + y)\hat{\mathbf{e}}_x + (-x + y)\hat{\mathbf{e}}_y}{\sqrt{x^2 + y^2}} .$$

Find a gauge transformation $\alpha(x, y, z)$, where $\mathbf{A} \to \mathbf{A}' = \mathbf{A} - \nabla\alpha$, such that transformed vector potential satisfies the Coulomb gauge.
Help: The Laplace operator in cylindrical coordinates has the form,

$$\Delta = \frac{1}{\rho}\frac{\partial}{\partial\rho}\left(\rho\frac{\partial}{\partial\rho}\right) + \frac{\partial^2}{\partial z^2} + \frac{1}{\rho^2}\frac{\partial^2}{\partial\phi^2} \ .$$

where $\rho^2 = x^2 + y^2$.

12.3.3.8 Ex: Vector potential of a homogeneous field

We consider a homogeneous magnetic field in z-direction,

$$\vec{\mathcal{B}} = \mathcal{B}\hat{\mathbf{e}}_z \ .$$

Invent a potential vector $\mathbf{A}$, such that $\vec{\mathcal{B}} = \text{rot } \mathbf{A}$. How does the potential vector look like in the Coulomb gauge (that is, under the condition: div $\mathbf{A} = 0$).

12.4 Multipolar expansion

Using the expansion (10.91) we can expand the vector potential in the same way as we did with the electrostatic potential in formula (10.92),

$$\mathbf{A}(\mathbf{r}) = \frac{\mu_0 I}{4\pi}\oint \frac{1}{|\mathbf{r}-\mathbf{r}'|}d\mathbf{l}' = \frac{\mu_0 I}{4\pi}\sum_{\ell=0}^{\infty}\frac{1}{r^{\ell+1}}\oint r'^{\ell}P_\ell(\cos\theta')d\mathbf{l}' \ . \tag{12.38}$$

Explicitly,

$$\mathbf{A}(\mathbf{r}) = \frac{\mu_0 I}{4\pi}\left[\frac{1}{r}\oint d\mathbf{l}' + \frac{1}{r^2}\oint r'\cos\theta' d\mathbf{l}' + \frac{1}{r^3}\oint r'^2(\tfrac{3}{2}\cos^2\theta' - \tfrac{1}{2})d\mathbf{l}' + ...\right] \ . \tag{12.39}$$

12.4.1 Multipolar magnetic moments

Since there are no magnetic monopoles, the first term of the multipolar expansion will be $\oint d\mathbf{l}' = 0$. The next term is the dipole term,

$$\mathbf{A}_{\text{dip}} = \frac{\mu_0 I}{4\pi r^2}\oint \hat{\mathbf{r}}\cdot\mathbf{r}' d\mathbf{l}' \ . \tag{12.40}$$

Doing the calculation,

$$\begin{aligned}\mathbf{c}\cdot\oint\hat{\mathbf{r}}\cdot\mathbf{r}'d\mathbf{l}' &= \oint \mathbf{c}(\hat{\mathbf{r}}\cdot\mathbf{r}')\cdot d\mathbf{l}' = \int \nabla_{r'}\times[\mathbf{c}(\hat{\mathbf{r}}\cdot\mathbf{r}')]\cdot d\mathbf{S}' \qquad (12.41)\\ &= -\int[\mathbf{c}\times\nabla_{r'}(\hat{\mathbf{r}}\cdot\mathbf{r}')]\cdot d\mathbf{S}' = -(\mathbf{c}\times\hat{\mathbf{r}})\cdot\int d\mathbf{S}' = -\mathbf{c}\cdot\left(\hat{\mathbf{r}}\times\int d\mathbf{S}'\right) \ ,\end{aligned}$$

for arbitrary constants $\mathbf{c}$, we find,

$$\boxed{\mathbf{A}_{\text{dip}} = -\frac{\mu_0 I}{4\pi r^2}\hat{\mathbf{r}}\times\int d\mathbf{S}' = \frac{\mu_0}{4\pi}\frac{\mathbf{m}\times\hat{\mathbf{r}}}{r^2}} \quad \text{where} \quad \boxed{\mathbf{m} \equiv I\int d\mathbf{S}} \tag{12.42}$$

is the *magnetic dipole moment*.

Example 77 (*Magnetic moment of a current loop*): The magnetic moment of a conductive coil of radius R lying in the x-y-plane and traversed by a current is calculated by,

$$\mathbf{m} = I \int d\mathbf{S} = I\pi R^2 \hat{\mathbf{e}}_z \ .$$

We will show in Exc. 12.4.2.1 how the magnetic dipole moment of a current loop can also be calculated from a suitable parametrization via the definition,

$$\boxed{\mathbf{m} = \tfrac{1}{2} \int \mathbf{r}' \times \mathbf{j}(\mathbf{r}', t) d^3 r'} \ . \tag{12.43}$$

12.4.2 Exercises

12.4.2.1 Ex: Magnetic moment

Calculate the torque on a rectangular coil with N loops placed in a homogeneous magnetic field, as shown in the figure.

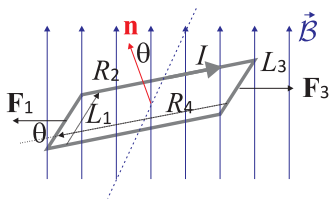

Figure 12.16: Magnetic moment.

12.4.2.2 Ex: Magnetic moment

a. Determine the magnetic moment of a circular conducting loop with radius R carrying a current I_1. The loop is in the xy-plane.
b. Now two outer segments of the circle are deformed at a distance a at right angles to the direction $-\hat{\mathbf{e}}_z$. What is the magnetic moment of the new configuration.
c. Now consider an infinitely long current line I_2 at a distance d from the origin and oriented in z-direction. What is the torque acting on the configurations in (a) and (b).

12.4.2.3 Ex: Magnetic moment of a cube

A conductor carries the current $I = 6\,\mathrm{A}$ along the path shown in the figure, which runs through 8 of the 12 corners of the cube whose length is $L = 10\,\mathrm{cm}$.
a. Calculate dipole magnetic moment along the way.
b. Calculate the magnetic induction $\vec{\mathcal{B}}$ at the points $(x, y, z) = (0, 5\,\mathrm{m}, 0)$ and $(x, y, z) = (5\,\mathrm{m}, 0, 0)$.

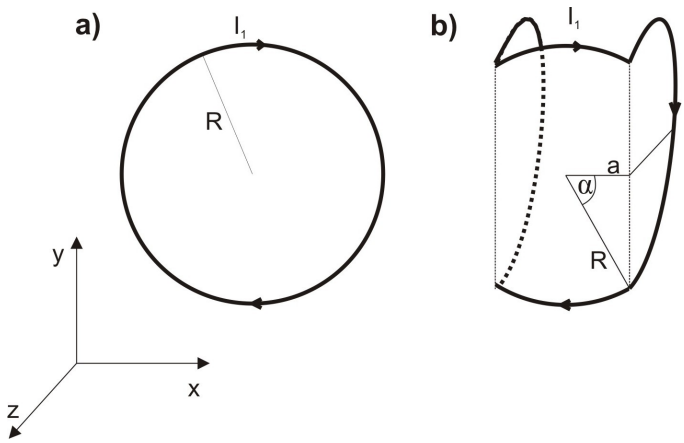

Figure 12.17: Magnetic moment.

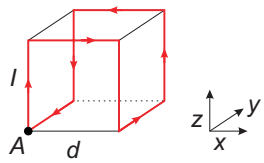

Figure 12.18: Magnetic moment.

12.4.2.4 Ex: Magnetic moment of thin circular disk

Consider a very thin disk with radius R, homogeneously charged with the charge Q, and spinning around the z-axis with angular velocity ω.
a. Parametrize the charge and current distributions.
b. Calculate the magnetic moment.

12.4.2.5 Ex: Magnetic compass

A topographer uses a magnetic compass while standing 6.1 m under a high voltage line on which flows a current of 100 A. The horizontal component of the Earth's magnetic field at this place is 20 µT. How large is the magnetic field due to the current at the position of the compass? Will the magnetic field disturb the compass noticeably?

12.4.2.6 Ex: Torque of a magnetic needle

A magnetic needle has a dipolar magnetic moment $\mu = 10^{-2}\,\mathrm{Am}^2$. Calculate the torque on the needle due to the horizontal component of the Earth's magnetic field at the equator ($\mathcal{B}_\mathrm{H} = 4 \cdot 10^{-5}\,\mathrm{T}$), if the magnetic north pole of the needle points in northeastern direction.

12.4.2.7 Ex: Curved conductive circuit

A rectangular conducting loop is deformed in the middle of the edges (length a) to form a right angle. The conducting loop is traversed by a current I. Calculate the dipolar magnetic moment $\mathbf{m}$ of this configuration. Give the absolute value and orientation of $\mathbf{m}$.
Help: Use the overlapping principle and replace the above geometry with an overlap of two conductive loops.

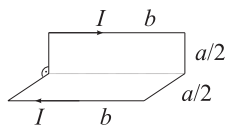

Figure 12.19: Curved conductive circuit.

12.4.2.8 Ex: Magnetic dipole

A magnetic dipole $\vec{\mu} = \mu\hat{\mathbf{e}}_z$ is at origin of the coordinate system and has the value $\mu = 1\,\text{esu}\cdot\text{cm}$. This dipole generates a magnetic field of the form,

$$\vec{\mathcal{B}}(\mathbf{r}) = \frac{3\mathbf{r}(\vec{\mu}\cdot\mathbf{r}) - r^2\vec{\mu}}{r^5} \ .$$

a. At what distance from the origin does the absolute value of $\vec{\mathcal{B}}$ take the value $1\,\text{esu/cm}^2$ going (i) in z-direction, (ii) in x-direction, and (iii) in a diagonal direction with in the xz-plane?
b. Which direction does $\vec{\mathcal{B}}$ point in these three cases?

12.4.2.9 Ex: Fields of electric and magnetic point dipoles

a. Calculate the field of an electric dipole taking care to remove the divergence in the center of origin by calculating the field averaged over a sphere and comparing it with known results.
b. Repeat the procedure of (b) for a magnetic dipole.

12.4.2.10 Ex: Magnetic dipole moment of a rectangular conducting loop

A (ideal) rectangular conducting loop with edge lengths a and b carries a current I.
a. Give the current density distribution $\mathbf{j}$.
b. Calculate the corresponding dipolar magnetic moment $\vec{\mathcal{M}}$.

12.4.2.11 Ex: Dipolar magnetic moment of a rectangular loop

The rectangular conducting loop of Exc. 12.4.2.10 is deformed in the middle of the edges (length a) to form a right angle (see figure). It is traversed by a current I. Calculate the dipolar magnetic moment of this geometry.

12.4.2.12 Ex: Force on the walls of a hollow cylinder

Consider an infinitely long cylindrical shell of radius a in which flows a current. The magnetic force on this hollow cylinder is such that it tries to compress the cylinder. To counteract this force, we can fill the inside of the cylinder with a gas of pressure P. What is the pressure required to balance the magnetic force?

12.4.2.13 Ex: Infinitely dense coil

A coil with N 'infinitely dense' windings carries a current I. It forms with respect to the z-axis a torus with rotational symmetry with an inner radius $b - a$ and an outer radius $b + a$. The figure shows the cross-sectional area of a cut in the plane perpendicular to the xy-plane.
a. Calculate by exploiting the symmetric geometry of this device in cylindrical coordinates (ρ, ϕ, z) a ϕ-component of the magnetic $\vec{\mathcal{B}}$-field in the xy-plane (that is, for $z = 0$) as a function of the distance ρ from the origin of the coordinate system. **Help:** Use Stokes' law.
b. What is the value of the ϕ-component of $\vec{\mathcal{B}}$ in the entire space *outside* of the torus (that is, also for $z \neq 0$).
c. Draw the profile of $\mathcal{B}_\phi(\rho)$ in the $z = 0$ plane as a function of ρ.
d. Let $a = 1$ cm. What should be the value of b in first approximation, so that $\mathcal{B}_\phi$ in the torus is constant within 1%? **Help:** $(1 \pm \epsilon)^{-1} \approx 1 \mp \epsilon$.

12.4.2.14 Ex: Magnetic field in a cylindrical hollow space

Parallel to the axis of an infinitely long massive conducting cylinder of radius a at a distance d from it, there is a hollow cylindrical space of radius b $(d + b < a)$. The current density within this perforated metal cylinder is homogeneous and oriented parallel to the symmetry axis. Using Ampère's law and the linear superposition principle, determine the absolute value and orientation of the magnetic field inside the hollow space.

12.4.2.15 Ex: Torque of a conducting cylinder

Determine the torque (per unit length) felt by a massive conducting cylinder of radius R that slowly rotates with constant angular velocity ω inside a homogeneous $\vec{\mathcal{B}}$-field around its symmetry axis. $\vec{\mathcal{B}}$ be oriented orthogonal to the axis of the cylinder.

12.4.2.16 Ex: Rotating rings

Consider two 'infinitely thin' concentric rings with radii a and b $(a < b)$. The rings are in the xy-plane and their common center is at the origin. On the inner ring there is a homogeneously distributed charge $+q$ (that is, the linear charge density is constant), and the outer ring carries the homogeneously distributed charge $-q$.
a. Write down the charge density $\rho(\mathbf{r}) = \rho(r, \phi, z)$ in cylindrical coordinates.
b. Now the entire device rotates with constant angular velocity ω around the symmetry axis z. Determine the resulting current density $\mathbf{j}(\mathbf{r}) = \mathbf{j}(r, \phi, z)$ in cylindrical coordinates, as well.

c. What are the Cartesian components of current density $\mathbf{j}$?
d. Calculate the magnetic dipole moment $\mathbf{m}$ of the rotating device.

12.4.2.17 Ex: Magnetic field inside a current tube

A thin hollow conducting tube is traversed by a current along its symmetry axis. The current is homogeneously distributed. Calculate the magnetic field inside and outside
a. from Ampère's law,
b. from the Biot-Savart law.

12.4.2.18 Ex: Magnetic induction in a hollow conductor

A conductor (ideal and infinitely thin) be on the z-axis and carries a current I flowing in $+z$-direction. This conductor is enclosed by a conductive hollow cylinder with radius R, within which a homogeneously distributed total current I runs in the opposite direction $-z$ (coaxial cable). Calculate the magnetic induction inside and outside this device.

12.4.2.19 Ex: Current ring

A (ideal) current ring in the xy-plane with radius a and centered at the origin is traversed by a current I. In spherical coordinates the current density is given by,

$$\mathbf{j}(\mathbf{r}) = \mathbf{j}(r,\theta,\phi) = \frac{I}{a}\delta(\cos\theta)\delta(r-a)\hat{\mathbf{e}}_\phi \ .$$

For $|\mathbf{r}| \gg a$ the corresponding potential then has the form,

$$\mathbf{A}(\mathbf{r}) = \mathbf{A}(r,\theta,\phi) = \frac{I\pi a^2}{cr^2}\sin\theta\hat{\mathbf{e}}_\phi \ .$$

and for magnetic field holds,

$$\vec{\mathcal{B}}(\mathbf{r}) = \vec{\mathcal{B}}(r,\theta,\phi) = \frac{I\pi a^2}{cr^3}\left(2\cos\theta\hat{\mathbf{e}}_r + \sin\theta\hat{\mathbf{e}}_\theta\right) \ .$$

where $\hat{\mathbf{e}}_r$, $\hat{\mathbf{e}}_\theta$, and $\hat{\mathbf{e}}_\phi$ are the unit vectors in r, θ, and ϕ-direction.
a. Calculate the Cartesian components of $\mathbf{j}(\mathbf{r})$.
b. Calculate the Cartesian components of the dipolar magnetic moment $\vec{\mathcal{M}}$ using the formula,

$$\vec{\mathcal{M}} = \frac{1}{2c}\int d^3r'(\mathbf{r}'\times\mathbf{j}(\mathbf{r}')) \ .$$

c. What are the components of $\vec{\mathcal{M}}$ in r, θ, and ϕ-direction.
d. Show with the help of (c) that the magnetic field at a point $\mathbf{r}$ of the arbitrary surface can be written,

$$\vec{\mathcal{B}}(\mathbf{r}) = \frac{3\hat{\mathbf{e}}_r(\vec{\mathcal{M}}\cdot\hat{\mathbf{e}}_r) - \vec{\mathcal{M}}}{r^3} \ .$$

e. Calculate the Cartesian components of magnetic field and check, with the help of (b), that also in Cartesian coordinates holds,

$$\vec{\mathcal{B}}(\mathbf{r}) = \frac{3\mathbf{r}(\vec{\mathcal{M}}\cdot\mathbf{r}) - r^2\vec{\mathcal{M}}}{r^5} \ .$$

12.4.2.20 Ex: Magnetic field of a long coil

Determine the magnetic $\vec{\mathcal{H}}$-field inside a very long current-carrying coil. The number of turns is n, the length of the coil l, its radius a, and the amplitude of the current I. How does the magnetic field change, if the coil has an iron core with the permeability μ?

12.4.2.21 Ex: Shielded dipolar field

The magnetic field of a dipole is shielded by a hollow sphere (inner radius a, outer radius b) made of a material with permeability μ. The dipole $\vec{\mathcal{P}}_M$ is in the center of the sphere and points towards z.
a. Show that the magnetic field $\vec{\mathcal{H}}$ in the entire space can be written as the negative gradient of a potential $\Phi_M(\mathbf{r})$.
b. Show that this magnetic potential satisfies the Laplace equation in whole space, $\triangle\Phi_M(\mathbf{r}) = 0$.
c. To solve this Laplace equation, do the following ansatz of variable separation,

$$\Phi_M^{(i)}(r,\theta\phi) = \sum_{l=0}^{\infty}\sum_{m=-l}^{+l}\frac{4\pi}{2l+1}\left[\beta_{lm}^{(i)}r^l + \gamma_{lm}^{(i)}\frac{1}{r^{l+1}}\right]Y_{lm}(\theta,\phi)\ .$$

where the $\beta_{lm}^{(i)}$ and $\gamma_{lm}^{(i)}$ be constant and $i = I, II, II$ denote the different regions ($I : 0 \leq r < a\ , II : a \leq r \leq b\ , III : b < r$). What are the consequences for $\beta_{lm}^{(i)}$ and $\gamma_{lm}^{(i)}$ due to the fact that Φ_M
i. is, in the origin, the potential of a pure dipolar field $\vec{\mathcal{P}}_M$?
ii. is cylindrically symmetrical about the z-axis?
iii. disappears at infinity?
d. At the interfaces between the different regions the normal component of the magnetic $\vec{\mathcal{B}}$-field and the tangential component of the $\vec{\mathcal{H}}$-field are discontinuous. Use these conditions to establish a system of equations for the coefficients $\beta_{lm}^{(i)}$ and $\gamma_{lm}^{(i)}$, using $\text{grad}_r\Phi_M = \frac{\partial\Phi_M}{\partial r}$, $\text{grad}_\theta\Phi_M = \frac{1}{r}\frac{\partial\Phi_M}{\partial\theta}$, $\frac{\partial Y_{10}}{\partial\theta} = \sqrt{\frac{2l+1}{4\pi}}P_l^1(\cos\theta)$, as well as the orthogonality relations $\int d\Omega Y_{l0}^*(\Omega)Y_{l'0}(\Omega) = \delta_{ll'}$ and $\int_{-1}^{+1}dxP_l^1(x)P_{l'}^1(x) = \delta_{ll'}\frac{2}{2l+1}\frac{(l+1)!}{(l-1)!}$.
e. Solve the equation system first for the case $l \neq 1$.
f. Solve the system of equations for $l = 1$.
g. What does the magnetic field look like outside the sphere for $\mu \gg 1$?

Chapter 13

Magnetic properties of matter

The most common manifestations of magnetism are certainly magnets, compass needles, and the Earth's magnetic field, and it is not obvious how they are related to the magnetic fields produced by currents, discussed in the previous chapter. Nevertheless, all magnetic phenomena are ultimately due to currents, even if they are microscopic, for example, electrons orbiting atomic nuclei or spinning around their own axis. From the macroscopic point of view we can treat these circular currents as magnetic dipoles. Generally, the dipoles of a medium have random orientations, such that the generated magnetic fields cancel out. However, when we apply a *external* magnetic field, the dipoles can realign and *magnetize* the medium.

13.1 Magnetization

There are several macroscopic manifestations of microscopic dipole moments known as para-, dia-, and ferromagnetism. We will discuss these in the following sections.

13.1.1 Energy of permanent dipoles and paramagnetism

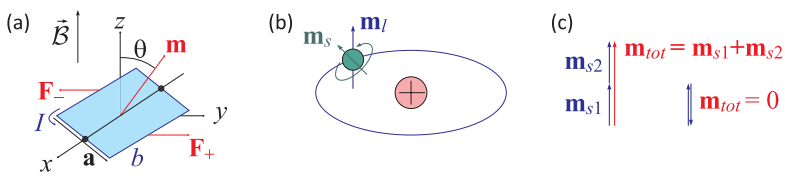

Figure 13.1: (a) Illustration of the torque exerted by a magnetic field on a magnetic dipole. (b) An electron spinning around a nucleus may have orbital and intrinsic angular momentum. (c) Dipole moments are added as vectors.

We consider current loops of rectangular shape [1]. In the case of the geometry shown in Fig. 13.1(a) the Lorentz forces acting on the wire sections a being parallel to the z-y-plane compensate each other, because the forces and the points on which they act are all on a straight line. On the other side, the forces acting on the wire sections b,

$$\mathbf{F}_{\pm} = \pm I\mathbf{b} \times \vec{\mathcal{B}} = \pm Ib\mathcal{B}\hat{\mathbf{e}}_y \ , \tag{13.1}$$

[1] Arbitrary shapes can be constructed by two-dimensional arrays of rectangular loops.

both contribute to create a torque,

$$\vec{\tau} = \tfrac{\mathbf{a}}{2} \times \mathbf{F}_+ + \tfrac{-\mathbf{a}}{2} - \times \mathbf{F}_- = I\mathcal{B}b\mathbf{a} \times \hat{\mathbf{e}}_y = Iab\mathcal{B}\hat{\mathbf{e}}_x \sin\theta \ , \tag{13.2}$$

With the definition of the magnetic moment (12.42) we find,

$$\boxed{\vec{\tau} = \mathbf{m} \times \vec{\mathcal{B}}} \ . \tag{13.3}$$

We can also calculate the energy of a dipole in a magnetic field by the work required to rotate it out of its equilibrium position,

$$H_{\text{int}} = \int_0^\theta \vec{\tau} \cdot d\theta = \int_0^\theta \mathbf{m} \times \vec{\mathcal{B}} d\theta = \int_0^\theta m\mathcal{B} \sin\theta d\theta = -m\mathcal{B}\cos\theta \ , \tag{13.4}$$

such that,

$$\boxed{H_{\text{int}} = -\mathbf{m} \cdot \vec{\mathcal{B}}} \ . \tag{13.5}$$

The formula (13.3) holds for homogeneous magnetic fields or, alternatively, for almost point-like dipoles in inhomogeneous fields. It represents the magnetic equivalent of the torque on electric dipoles (11.4). The torque is oriented so as to align the dipole moment to the direction of the magnetic field. This mechanism is used to explain the phenomenon of paramagnetism [see Fig. 13.3(a)].

In atomic physics we learn that electrons bound to atoms may have, besides an orbital angular momentum due to the planetary motion around the atomic nucleus, an *intrinsic angular momentum* called *spin* as if the electron were a small electrically charged sphere rotating about its own axis [see illustration of Fig. 13.1(b)]. The spins of the various electrons in the electron layer of an atom generally couple to form a total dipole moment, which then interacts with external magnetic fields. This is called *Zeeman effect*. The spins may pair and add up or compensate pairwise such as to zero the magnetic dipole moment of the atom [see illustration of Fig. 13.1(c)]. Note that a strong external magnetic field can break the angular momentum coupling and interact with the electron spins separately. This is called *Paschen-Back effect*.

The phenomenon of *paramagnetism* is observed in materials whose molecules have permanent magnetic dipole moments, that is, in chemical elements with unpaired valence electrons. It is not observed in noble gases, covalent crystals, etc..

Unlike the torque, the *force exerted by a homogeneous field* on a dipole vanishes,

$$\mathbf{F} = I \oint d\mathbf{l} \times \vec{\mathcal{B}} = I \left(\oint d\mathbf{l} \right) \times \vec{\mathcal{B}} = 0 \ . \tag{13.6}$$

For inhomogeneous fields we need to calculate the force from the energy gradient as,

$$\mathbf{F} = -\nabla H_{\text{int}} = \nabla(\mathbf{m} \cdot \vec{\mathcal{B}}) = \mathbf{m} \times (\nabla \times \vec{\mathcal{B}}) + (\mathbf{m} \cdot \nabla)\vec{\mathcal{B}} = (\mathbf{m} \cdot \nabla)\vec{\mathcal{B}} \ . \tag{13.7}$$

This formula can be obtained by Taylor expansion of the magnetic field (see Exc. 13.1.7.1).

13.1.2 Impact of magnetic fields on electronic orbits and diamagnetism

A magnetic field can have another effect on the motion of electrons. Let us consider an electron rotating on a circular orbit of radius R. If the motion of the electron is

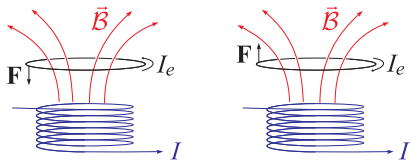

Figure 13.2: Illustration of the force exerted by an inhomogeneous magnetic field on a magnetic dipole: A dipole oriented in the same direction as the magnetic field will be drawn to the field maximum, if it is oriented anti-parallel, it is repelled from the field maximum.

fast, it will generate a current,

$$I = \frac{-e}{T} = \frac{-ev}{2\pi R} \ , \tag{13.8}$$

creating a dipole moment,

$$\mathbf{m} = I\mathbf{A} = \frac{-e}{T}\pi R^2 \hat{\mathbf{e}}_z = \frac{-e}{2} v R \hat{\mathbf{e}}_z \ . \tag{13.9}$$

Now, the orbit of the electron can be, for example, an atomic orbital or a trajectory of a free electron in a conductor. The magnetism of a free electron gas in a metal is treated by the theory of *Landau diamagnetism*. This theory considers the trajectories of electrons as being curved by the Lorentz force which, because of the rule of Lenz, generates a field contrary to the applied magnetic field. That is, the magnetic flux is expelled from the material. Hence, in inhomogeneous magnetic fields, diamagnetic materials are repelled from high field regions [2].

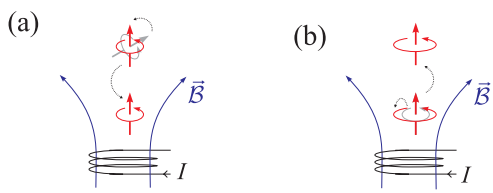

Figure 13.3: Classical interpretation of paramagnetism (a) and diamagnetism (b): In paramagnetic materials the permanent dipoles reorient in the direction of the external field. Exposed to inhomogeneous fields, the dipoles are thus attracted to field maxima. In diamagnetism, currents are forced into circular orbits, and the so-formed dipoles are oriented in a direction opposite the external external. Exposed to inhomogeneous fields, the dipoles are thus repelled from the field maxima.

The case of electronic orbitals in atoms is treated by the theory of *Langevin diamagnetism*. In this theory we consider Bohr orbitals of electrons bound to a nucleus by the Coulomb force. In the presence of an external magnetic field the dipole feels a torque, but in addition, the field has the effect of accelerating or decelerating the electron depending on its orientation. To estimate this effect we consider the equilibrium condition for an electronic orbit,

$$\mathbf{F}_{\mathrm{C}} = \frac{1}{4\pi\varepsilon_0}\frac{e^2}{R^2} = m_e \frac{v^2}{R} = \mathbf{F}_{centrifugal} \ . \tag{13.10}$$

[2] Note that some metals may be weakly paramagnetic due to an effect called *Pauli paramagnetism*.

Adding a magnetic field oriented along the rotation axis [3],

$$\mathbf{F}_{\mathrm{C}} + \mathbf{F}_{\mathrm{L}} = \frac{1}{4\pi\varepsilon_0}\frac{e^2}{R^2} + ev'\Delta\mathcal{B} = m_e\frac{v'^2}{R} = \mathbf{F}_{centrifugal} \ . \tag{13.11}$$

Subtracting these equations,

$$ev'\Delta\mathcal{B} = \frac{m_e}{R}(v'^2 - v^2) = \frac{m_e}{R}(v' - v)(v' + v) \simeq \frac{2m_e}{R}v'\Delta v \ , \tag{13.12}$$

such that,

$$\Delta v = \frac{eR\Delta\mathcal{B}}{2m_e} \ . \tag{13.13}$$

The acceleration of the electron, when we switch on the magnetic field, increases the value of the dipole moment because, with the formula (13.9),

$$\Delta\mathbf{m} = \frac{-e}{2}\Delta v R\hat{\mathbf{e}}_z = -\frac{e^2R^2}{4m_e}\Delta\vec{\mathcal{B}} \ . \tag{13.14}$$

But the ***variation*** is *always contrary to the direction of the magnetic field*, even if the dipole moment was initially aligned to the field [see Fig. 13.3(b)] [4]. Therefore, the dipole is repelled by an inhomogeneous magnetic field. Note that changing the sign of the charge does not affect $\Delta\mathbf{m}$.

Diamagnetism is a property of all materials, but is often hidden by the presence of permanent magnetic moments. Therefore, to observe diamagnetism, one must choose materials with no permanent magnetic moment, such as atoms with completely filled electron shells. Many amorphous materials (such as wood, glass, rubber, etc.) and many metals as diamagnets.

It is worth mentioning that the magnetic behavior of a macroscopic body is not necessarily the same as the one of its elementary components. For example, metallic sodium is diamagnetic, while gaseous sodium is paramagnetic.

paramagnetism	diamagnetism
atoms with unpaired e^-	atoms with paired e^-
$\mathbf{m}$ robust and independent of $\vec{\mathcal{B}}$	$\mathbf{m}$ weak and $\mathbf{m} \propto \vec{\mathcal{B}}$
$\vec{\mathcal{M}} \parallel \vec{\mathcal{B}} \curvearrowright$ attractive force	$\vec{\mathcal{M}} \parallel -\vec{\mathcal{B}} \curvearrowright$ repulsive force
$\mu > 1 \curvearrowright \chi > 0$	$\mu < 1 \curvearrowright \chi < 0$

It is also important to note that essential aspects of *para- and atomic diamagnetism are quantum*. That is, quantitative theories must be formulated within quantum mechanics. A classical theory can only give an qualitative picture of the effect.

[3] In Exc. 13.1.7.2 we have shown, that the radius of the electronic orbit does not change under the influence of an external magnetic field.

[4] If the charge distribution is spherically symmetric, we can assume $\langle x^2\rangle = \langle y^2\rangle = \langle z^2\rangle = \frac{1}{3}\langle r^2\rangle$, where $\langle r^2\rangle$ is the average distance between the electron and the nucleus. Therefore, $\langle R^2\rangle = \langle x^2\rangle + \langle y^2\rangle = \frac{2}{3}\langle r^2\rangle$. If N is the number of atoms per unit volume, we have $\chi = \frac{\mu_0 Nm}{\mathcal{B}} = -\frac{\mu_0 NZe^2}{6m}\langle r^2\rangle$.

13.1.3 Macroscopic magnetization

In the presence of a magnetic field, matter becomes magnetized, that is, the atomic or molecular dipoles align in a particular direction. We have already discussed two possible mechanisms causing this reorientation, the para- and the diamagnetism. Regardless of the mechanism we measure the degree of alignment by the vector quantity,

$$\vec{\mathcal{M}} = \frac{N\mathbf{m}}{V} \tag{13.15}$$

called *magnetization*. It plays the same role as the polarization in electrostatics. In the following section we will calculate for a given magnetization $\vec{\mathcal{M}}$ the field that it produces.

In most materials diamagnetism and paramagnetism are very weak effects and can only be detected by sensitive measurements and strong magnetic fields. In *non-ferromagnetic* materials, the weakness of the magnetization allows us to neglect the magnetic field produced by magnetization. In contrast, in iron, nickel or cobalt the forces are between 10^4 and 10^5 greater.

13.1.4 Magnetostatic field of a magnetized material

We consider a sample of magnetic dipoles. According to the formula (12.42), the vector potential is given by,

$$\mathbf{A}(\mathbf{r}) = \frac{\mu_0}{4\pi}\sum_k \frac{\mathbf{m}\times(\mathbf{r}-\mathbf{r}')}{|\mathbf{r}-\mathbf{r}'|^3} \longrightarrow \frac{\mu_0}{4\pi}\int_{\mathcal{V}} dV' \frac{\vec{\mathcal{M}}\times(\mathbf{r}-\mathbf{r}')}{|\mathbf{r}-\mathbf{r}'|^3} \ , \tag{13.16}$$

where we introduced the dipole moment distribution $\vec{\mathcal{M}}(\mathbf{r}')$ via $\mathbf{m}_k \to \vec{\mathcal{M}}dV'$. As in the electrostatic case, we can rewrite the integral in the form,

$$\begin{aligned}
\mathbf{A}(\mathbf{r}) &= \frac{\mu_0}{4\pi}\int_{\mathcal{V}} \vec{\mathcal{M}}(\mathbf{r}')\times\nabla'\frac{1}{|\mathbf{r}-\mathbf{r}'|}dV' \\
&= \frac{\mu_0}{4\pi}\left[-\int_{\mathcal{V}}\nabla'\times\frac{\vec{\mathcal{M}}(\mathbf{r}')}{|\mathbf{r}-\mathbf{r}'|}dV' + \int_{\mathcal{V}}\frac{1}{|\mathbf{r}-\mathbf{r}'|}\nabla'\times\vec{\mathcal{M}}(\mathbf{r}')dV'\right] \\
&= \frac{\mu_0}{4\pi}\oint_{\partial\mathcal{V}}\frac{\vec{\mathcal{M}}(\mathbf{r}')\times d\mathbf{S}'}{|\mathbf{r}-\mathbf{r}'|} + \frac{\mu_0}{4\pi}\int_{\mathcal{V}}\frac{1}{|\mathbf{r}-\mathbf{r}'|}\nabla'\times\vec{\mathcal{M}}(\mathbf{r}')dV' \ .
\end{aligned} \tag{13.17}$$

Comparing these terms with the formula (12.27), we find that the first term looks like the potential of a surface current, while the second term looks like the potential of a volume current. Defining,

$$\boxed{\vec{\kappa}_b \equiv \vec{\mathcal{M}}\times\mathbf{n}_S} \quad \text{and} \quad \boxed{\mathbf{j}_b \equiv \nabla\times\vec{\mathcal{M}}} \ , \tag{13.18}$$

we obtain,

$$\mathbf{A}(\mathbf{r}) = \frac{\mu_0}{4\pi}\oint_{\partial\mathcal{V}}\frac{\vec{\kappa}_b}{|\mathbf{r}-\mathbf{r}'|}dS' + \frac{\mu_0}{4\pi}\int_{\mathcal{V}}\frac{\mathbf{j}_b}{|\mathbf{r}-\mathbf{r}'|}dV' \ . \tag{13.19}$$

The meaning of this result is that the potential (and therefore the field) of a magnetized object is the same as the one produced by a volume current distribution

$\mathbf{j}_b$ plus a surface current distribution $\vec{\kappa}_b$. Instead of integrating the contributions of all individual infinitesimal dipoles, as in Eq. (13.17), we can try to find these bound currents, and then calculate the fields they produce, as we did in the previous chapter.

13.1.5 The H-field

In the previous section we found that the phenomenon of magnetization of a body can be understood as being due to *localized currents* inside the material, $\mathbf{j}_b = \nabla \times \vec{\mathcal{M}}$, and on the surface of the body, $\vec{\kappa}_b = \vec{\mathcal{M}} \times \hat{n}_S$. The magnetization field is the magnetic field produced by these currents. In addition, there are obviously *free currents*, such as those generated by the motion of free electrons in a metal.

13.1.5.1 Ampère's law in magnetized materials

Ampère's law can now be generalized for arbitrary media,

$$\tfrac{1}{\mu_0}\nabla \times \vec{\mathcal{B}} = \mathbf{j} = \mathbf{j}_b + \mathbf{j}_f = \nabla \times \vec{\mathcal{M}} + \mathbf{j}_f \ , \tag{13.20}$$

where $\vec{\mathcal{B}}$ is the total magnetic field. Defining a new field $\vec{\mathcal{H}}$, sometimes called *magnetic excitation*,

$$\boxed{\vec{\mathcal{H}} \equiv \mu_0^{-1}\vec{\mathcal{B}} - \vec{\mathcal{M}}} \ , \tag{13.21}$$

we can now write,

$$\nabla \times \vec{\mathcal{H}} = \mathbf{j}_f \ . \tag{13.22}$$

The field $\vec{\mathcal{H}}$ is that part of the magnetic field, which comes only from free currents. We can also define the *magnetic susceptibility* χ_μ via [5],

$$\vec{\mathcal{M}} = \chi_\mu \vec{\mathcal{H}} \ , \tag{13.23}$$

or the *permeability* μ via,

$$\vec{\mathcal{B}} = \mu\vec{\mathcal{H}} = \mu_0(1+\chi_\mu)\vec{\mathcal{H}} \ . \tag{13.24}$$

Note, that the divergence of the *magnetization does not necessarily vanish*, since the susceptibility may depend on position, $\chi_\mu = \chi_\mu(\mathbf{r})$,

$$\nabla \cdot \vec{\mathcal{H}} = \mu_0^{-1}\nabla \cdot \vec{\mathcal{B}} - \nabla \cdot \vec{\mathcal{M}} = -\nabla \cdot (\chi_\mu \vec{\mathcal{H}}) \neq 0 \ . \tag{13.25}$$

Hence, $\vec{\mathcal{H}}$ generally can not be derived from a vector potential, and Biot-Savart's law is not valid for $\vec{\mathcal{H}}$. In anisotropic materials the susceptibility and the permeability must be understood as tensors.

[5] Note, that this definition is not symmetric with that of the electric susceptibility (11.20).

13.1.5.2 Boundary conditions involving magnetic materials

The integral version of Eq. (13.25), $\oint \vec{\mathcal{H}} \cdot d\mathbf{S} = -\oint \vec{\mathcal{M}} \cdot d\mathbf{S}$, allows us to determine the behavior of the magnetic excitation near interfaces,

$$H^{\perp}_{\text{top}} - H^{\perp}_{\text{bottom}} = -M^{\perp}_{\text{top}} + M^{\perp}_{\text{bottom}} \ . \tag{13.26}$$

On the other hand Ampère's law, $\nabla \times \vec{\mathcal{H}} = \mathbf{j}_f$, yields,

$$\vec{\mathcal{H}}^{\parallel}_{\text{top}} - \vec{\mathcal{H}}^{\parallel}_{\text{bottom}} = \vec{\kappa}_f \times \hat{\mathbf{n}} \ . \tag{13.27}$$

This is in contrast to the behavior of the magnetic $\vec{\mathcal{B}}$ field at interfaces described by Eqs. (12.30), (12.32), and (12.34). Do the Excs. 13.1.7.7 to 13.1.7.9.

13.1.6 Magnetic susceptibility and permeability

Materials respond to applied magnetic fields $\vec{\mathcal{H}}$ generating a magnetization $\vec{\mathcal{M}}$, such that the total magnetic field is $\vec{\mathcal{B}} = \mu_0 \vec{\mathcal{H}} + \mu_0 \vec{\mathcal{M}}$. The behavior of a material depends on the value of its susceptibility. In vacuum $\chi_\mu = 0$, for typical diamagnets $\chi_\mu \lesssim 0$, for superconductors $\chi_\mu = -1$, for paramagnets $\chi_\mu \gtrsim 0$, and for ferromagnets $\chi_\mu \gg 1$.

Typical values are listed in the following table:

material	$\chi_\mu[10^{-5}]$	type of magnetism
superconductor	-10^5	dia-
carbon	-2.1	Langevin dia-
copper	-1	Landau dia-
water	-0.9	Langevin dia-
hydrogen	-0.00022	Langevin dia-
oxygen (gas)	0.2	para-
sodium (metal)	0.7	Pauli para-
magnesium	1.2	Pauli para-
lithium	1.4	Pauli para-
cesium	5.1	Pauli para-
platinum	28	
oxygen(liquid)	390	
gadolinium	48000	ferro-
iron		ferro-

13.1.6.1 Linear media

In many materials, as long as the applied magnetic field is not too strong, the magnetization is proportional to the field, $\vec{\mathcal{M}} \propto \vec{\mathcal{B}}$, i.e. the magnetic susceptibility depends

on the material's microscopic properties and external factors, such as temperature, but not on the applied field, $\chi_\mu \neq \chi_\mu(\vec{\mathcal{B}})$. Hence, linear media can be characterized by a constant,

$$\mu_r \equiv \frac{\mu}{\mu_0} \ , \tag{13.28}$$

called *relative permeability*.

13.1.6.2 The role of temperature in paramagnetism

Experiments show, that in inhomogeneous magnetic fields, paramagnetic materials are attracted toward high field regions, but with a force that decreases with temperature. This is understood by the Zeeman effect: The dipole moment can only adopt a few possible (quantized) values corresponding to levels of well-defined positive or negative energy (called Zeeman sub-levels). At high temperature all Zeeman sub-levels are equally populated, such that the total force cancels. At low temperature the populations are distributed according to Boltzmann's law, $n_k/n_l = e^{-(E_k-E_l)/k_\mathrm{B}T}$, that is, the lower levels (which are precisely the *high-field seekers*) dominate.

Example 78 (*Paramagnetism of hot samples*): As an example, we consider atoms with two possible orientations for the permanent magnetic moment, $\mathbf{m}\cdot\vec{\mathcal{B}} = \pm m\mathcal{B}$. The magnetization produced by $n = n_+ + n_-$ atoms is then $\vec{\mathcal{M}} = n_+\mathbf{m}_+ + n_-\mathbf{m}_-$. The two orientations are populated according to Boltzmann's law $n_+/n_- = e^{-2m\mathcal{B}/k_\mathrm{B}T}$, such that,

$$\frac{\vec{\mathcal{M}}}{n} = \frac{e^{m\mathcal{B}/k_\mathrm{B}T} - e^{-m\mathcal{B}/k_\mathrm{B}T}}{e^{m\mathcal{B}/k_\mathrm{B}T} + e^{-m\mathcal{B}/k_\mathrm{B}T}}\mathbf{m} \simeq \frac{m\mathcal{B}}{k_\mathrm{B}T}\mathbf{m} \ .$$

For weak fields, we obtain the *Curie law*,

$$\chi_\mu = \frac{M}{H} \simeq \frac{nm^2\mathcal{B}}{k_\mathrm{B}TH} \simeq \frac{\mu_0 n m^2}{k_\mathrm{B}T} \sim T^{-1} \ .$$

For strong fields, the magnetization saturates. Assuming $m \simeq \mu_\mathrm{B}$ (see Exc. 13.1.7.4), we estimate for a metal with $n \approx 10^{22}\,\mathrm{cm}^{-3}$ at room temperature, $\chi_\mu \approx 2.6 \times 10^{-4}$ [6].

13.1.6.3 Ferromagnetism

In a linear medium the alignment of the magnetic dipoles is maintained by the application of an external field. There are, however, magnetic materials that do not depend on applied fields. This phenomenon of 'frozen' magnetization is called *ferromagnetism*. As in the case of paramagnetism, ferromagnets develop dipoles associated with the spins of unpaired electrons, but in addition, the dipoles strongly interact with

[6] In metals free electrons contribute to paramagnetism. In metals the Curie law does not apply, but χ is found to be almost constant. The reason is, that the Boltzmann distribution is inappropriate for electrons, so we need to use the Fermi-Dirac distribution. The energy distribution $\rho(\epsilon)n_{FD}(\epsilon)$ of the electrons depends on the orientation of their spin with respect to the applied magnetic field: electrons with (anti-)parallel spin see their energy increased (reduced). To maintain a uniform E_F, electrons with parallel spin will flip it to antiparallel spin, such that the entire system is slightly *high-field seeking*. This is called *Pauli paramagnetism*. This effect always competes with diamagnetism, which involves all electrons and has opposite sign.

each other and, for reasons that can only be understood within a quantum theory, like to orient themselves in parallel [7].

The correlation is so strong that within regions called *Weiss domains* almost 100% of the dipoles are aligned. On the other hand, a block of ferromagnetic material consists of many spatially separated domains, each domain having a magnetization pointing in a random direction, such that the block as a whole does not exhibit macroscopic magnetization. Inside a Weiss domain the magnetization is so strong that even a strong external magnetic field can not influence the alignment. On the other hand, at the boundaries between Weiss domains the alignment is not well defined, such that the external field can exert a torque $\tau = \mathbf{m} \times \vec{\mathcal{B}}$ shifting the boundaries in a way to favor those domains, which are already aligned. For a sufficiently strong field one domain will prevail and the ferromagnetic material saturate.

Experiments show that the alignment is not fully reversible, that is, not all Weiss domains return to their initial orientation (before the external magnetic field was applied). Consequently, the material remains permanently magnetized. This effect is called *remanescence*.

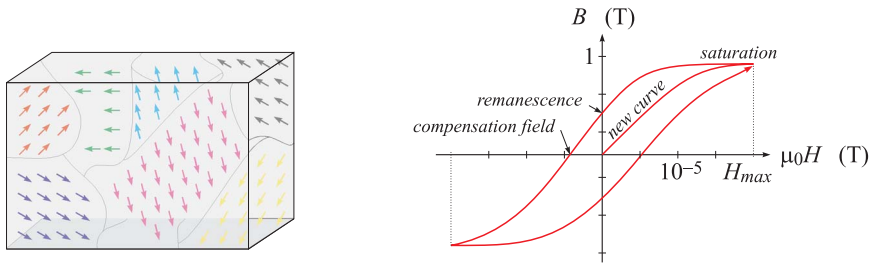

Figure 13.4: Hysteresis curve of magnetization. To allow for a comparison of the scales we plot in real units (Tesla) the applied field ($\vec{\mathcal{H}} \propto I$ in the case of a solenoid) versus the obtained field ($\vec{\mathcal{B}} \simeq \vec{\mathcal{M}}$).

To compensate for remanescence, it is necessary to apply a *compensation field* oriented in the opposite direction (see Fig. 13.4) [8] Beyond the compensation field we observe saturation in the opposite direction. Finally, returning to the initial situation, we draw a curve called *hysteresis curve*, which indicates that magnetization does not only depend on the applied magnetic field, but also on the 'history' of applied fields. Fig. 13.4 shows how an applied field can be dramatically amplified by ferromagnetism.

As already discussed, temperature tends to randomize the alignment of atomic dipoles. At low temperature the heat will not be sufficient to misalign the dipoles within the Weiss domains. But interestingly, beyond a well-defined temperature (the *Curie temperature* of iron is 770 C), the iron undergoes an abrupt phase transition to a paramagnetic state.

[7] The survival of domains in thermal reservoirs can not be understood by classical interactions between dipoles, but we need to contemplate band structure models. In particular, the $3d$ orbital bands provide electrons to the ferromagnetic elements Fe, Co, Ni. These bands are so close that the exchange interaction influences the orientation of spins in neighboring bands, which induces correlations between the spins of neighboring atoms.

[8] In practice, to demagnetize an iron block, we apply an alternating voltage gradually reducing its amplitude.

Note, that there are also antiferromagnetic materials (MnO_2), where neighboring atoms have antiparallel spins.

Example 79 (*Microscopic theory of induced dipoles*): The permittivity and relative permeability of a dense gas can be connected to the microscopic quantities through the *Clausius-Mossotti formula*,

$$\varepsilon_r = \frac{1+\frac{2}{3}\frac{N}{V}\alpha_{\mathrm{pol},e}}{1-\frac{1}{3}\frac{N}{V}\alpha_{\mathrm{pol},e}} \quad , \quad \mu_r = \frac{1+\frac{2}{3}\frac{N}{V}\alpha_{\mathrm{pol},m}}{1-\frac{1}{3}\frac{N}{V}\alpha_{\mathrm{pol},m}} \ , \tag{13.29}$$

that is, to the susceptibilities,

$$\chi_\varepsilon = \varepsilon_r - 1 = \frac{\frac{N}{V}\alpha_{\mathrm{pol},e}}{1-\frac{1}{3}\frac{N}{V}\alpha_{\mathrm{pol},e}} \quad , \quad \chi_\mu = \mu_r - 1 = \frac{\frac{N}{V}\alpha_{\mathrm{pol},m}}{1-\frac{1}{3}\frac{N}{V}\alpha_{\mathrm{pol},m}} \ , \tag{13.30}$$

where the induced electric and magnetic polarizabilities are,

$$\alpha_{\mathrm{pol},e} = \frac{2d_{fi}}{|\vec{\mathcal{E}}_p|}\rho_{if} \quad , \quad \alpha_{\mathrm{pol},m} = \frac{2m_{fi}}{|\vec{\mathcal{B}}_p|}\rho_{if} \ . \tag{13.31}$$

d_{fi} and m_{fi} are the dipole moments for electric and magnetic transitions and ρ_{if} the coherences excited in these transitions, which can be calculated from the Bloch equations. The relative strength between magnetic and electrical transitions is,

$$\frac{2\mu_{\mathrm{B}}}{cea_{\mathrm{B}}} = \alpha \ . \tag{13.32}$$

13.1.7 Exercises

13.1.7.1 Ex: Dipole in an inhomogeneous field

Derive the formula for the force on a dipole in an inhomogeneous field.

13.1.7.2 Ex: Langevin diamagnetism

An electron circulates around its atomic nucleus on an orbit of radius R.
a. Calculate the magnetic dipole moment generated by this movement as a function of velocity.
b. Now a weak magnetic field $\vec{\mathcal{B}}$ is slowly turned on perpendicular to the orbital plane. Calculate the increase of the electron's velocity due to the electric field induced by turning on the magnetic field using Faraday's law.
c. Show that the increase in kinetic energy, ΔE_{kin}, corresponds to the interaction energy between the electronic dipole moment and the magnetic field.
d. Does the turning on of the magnetic field change the radius of the electronic orbit? Justify your answer!

13.1.7.3 Ex: Magnetic susceptibility

By molecular magnetism it is possible to lift any objects in a sufficiently strong magnetic field. Estimate the magnetic field $|\vec{\mathcal{B}}|$ and the field gradient $\nabla|\vec{\mathcal{B}}|^2$ (one may estimate $\nabla|\vec{\mathcal{B}}|^2 = 2|\vec{\mathcal{B}}|\nabla|\vec{\mathcal{B}}| \simeq |\vec{\mathcal{B}}|^2/l$ with $l \simeq 10\,\mathrm{cm}$ as the typical length for such strong magnetic fields), needed to lift a frog. Water is predominantly diamagnetic with $\chi_\mu \simeq -0.9 \cdot 10^{-5}$ is the magnetic susceptibility of water.

Figure 13.5: Magnetic susceptibility.

13.1.7.4 Ex: Larmor precession of a Bohr atom in a magnetic field

As a model of the Larmor precession, consider the Bohr's atom model: An electron flying on circular orbits around a proton. Only certain discrete orbits with the radii $r_n = n^2 a_{\mathrm{B}}$, where $a_{\mathrm{B}} = 4\pi\varepsilon_0 \frac{\hbar^2}{m_e e^2}$, are allowed. The movement of the electron on these orbits is not accompanied by radiative emission.
a. Calculate the velocity of the electron in its ground state $n = 1$ and compare the result with the speed of light in vacuum c.
b. What is the orbital momentum $\mathbf{L}$ of the electron in a hydrogen atom in this state?
c. Relate the magnetic moment $\mathbf{m}_{\mathrm{L}}$ due to the circular current generated by the electron to the orbital momentum $\mathbf{L}$.
d. Placed in a magnetic field of $\mathcal{B} = 1\,\mathrm{T}$ the atom suffers a torque, which creates a precession of the angular momentum vector $\mathbf{L}$ around the direction of the $\vec{\mathcal{B}}$-field. Determine the frequency of this Larmor precession from $\omega_{\mathrm{L}} = \dot{L}/(L\sin\theta)$, where θ is the angle between $\mathbf{m}_{\mathrm{L}}$ and $\vec{\mathcal{B}}$. ($\hbar = 1.034 \cdot 10^{-34}\,\mathrm{Js}$, $e = 1.602 \cdot 10^{-19}\,\mathrm{C}$, $\varepsilon_0 = 8.854 \cdot 10^{-8}\,\mathrm{As/Vm}$.

13.1.7.5 Ex: $\mathcal{H}$-field of a cylindrical current wire

A cylindrical wire with radius a and permeability μ is traversed by a constant current density $\mathbf{j}$.
a. Calculate the absolute values and the directions of the $\vec{\mathcal{H}}$ and $\vec{\mathcal{B}}$-fields in- and outside the wire using Stokes law.
b. The electric field $\vec{\mathcal{E}}$ within the wire and the current $\mathbf{j}$ are connected by Ohm's law $\mathbf{j} = \sigma\vec{\mathcal{E}}$, where σ is the electrical conductivity. What is the value and direction of the Poynting vector $\mathbf{s}$ on the wire surface?
c. Calculate the total energy flow across the surface of a piece of wire of length L. Show that the energy flow corresponds exactly to the power converted, in this piece of wire, to ohmic heat.
Help: The energy conservation law of electrodynamics is given by: $-\frac{\partial u}{\partial t} = \nabla\cdot\mathbf{s} + \mathbf{j}\cdot\vec{\mathcal{E}}$, where $u = \frac{1}{2}(\vec{\mathcal{E}}\cdot\vec{\mathcal{D}} + \vec{\mathcal{B}}\cdot\vec{\mathcal{H}})$ is the total energy density, $\mathbf{s} = \vec{\mathcal{E}}\times\vec{\mathcal{H}}$ the flow of energy, and $\mathbf{j}\cdot\vec{\mathcal{E}}$ the work done by the field on the electric current density.

13.1.7.6 Ex: Ferromagnetism

a. Make a scheme of the dependence of the magnetization $\mathcal{M}$ of a ferromagnetic material on the magnetic 'excitation' $\mathcal{H}$ with the initial condition $\mathcal{M} = \mathcal{H} = 0$ and

letting $\mathcal{H}(t)$ cycle through $0 \to \mathcal{H}_{\max} \to -\mathcal{H}_{\max} \to \mathcal{H}_{\max}$. Indicate the remaining magnetization in the scheme.
b. How does the magnetization of a ferromagnet change when we heat it up above the Curie temperature T_C? How does the magnetic susceptibility behave in this case χ_m?
c. It explains the order of the atomic magnetic moments in ferro-, antiferro- and ferrimagnets and its influence on their magnetization.

13.1.7.7 Ex: Rectangular toroidal coil

A circular coil is made of a core with rectangular cross-sectional area, $A = h(r_2 - r_1)$, on which two coils are densely wound on top of each other, one with the number of turns N_1 and the other with N_2. Establishes a relationship for the mutual inductance L of the two coils.
Help: To calculate the mutual inductance, invoke the flux equation for the case that the coil N_1 is traversed by the current I_1, that is, $\oint \mathcal{H} \cdot d\mathbf{s} = N_1 I_1$ and calculate the induced flux Φ.

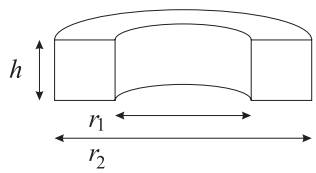

Figure 13.6: Rectangular toroidal coil.

13.1.7.8 Ex: Toroidal coil

Consider a toroidal coil with the average radius R, which consists of N turns carrying the current I. The coil is filled with an iron core of permeability μ.
a. Calculate the amplitude of the fields $\mathcal{H}$ and $\mathcal{B}$ inside the coil.
b. Now consider a core with an air gap d with $d \ll R$ interrupting the torus. Calculate once again the fields $\mathcal{H}$ and $\mathcal{B}$ within the slot.

13.1.7.9 Ex: Toroidal coil

A slotted steel ring has the dimensions: $b = 20\,\text{mm}$, $r = 80\,\text{mm}$, $a = 15\,\text{mm}$, and $d = 1\,\text{mm}$ (see the figure).
a. Calculate, first without air gap, for a magnetic flux density $\mathcal{B}$ the total magnetic flux Ψ_M and the corresponding $\mathcal{H}$ field. What is the amount of current I required generate this flux in a coil of N turns?
b. How must $\mathcal{H}$ and I be modified, if the ring is interrupted by a 1 mm wide air gap, to reach the same flux? Use $\mathcal{B} = 1.2\,\text{T}$, $N = 300$, $\mu_r = 650$.

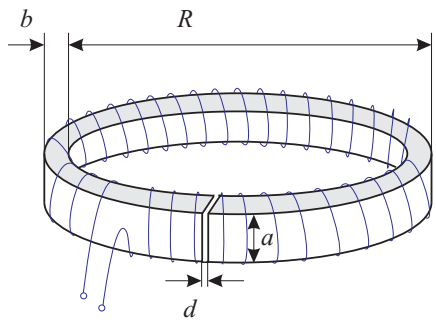

Figure 13.7: Toroidal coil.

13.2 Induction of currents and inductance

We have already seen that the fundamental cause of current $\mathbf{j}$ is a motion of charges Q [see Eq. (11.37)]. To incite charges to move we need a force,

$$\boxed{\mathbf{j} = \varsigma \frac{\mathbf{F}}{Q}} \,, \tag{13.33}$$

where ς is a proportionality factor called *conductivity* and $\mathbf{F}$ is the Coulomb-Lorentz force, such that,

$$\boxed{\mathbf{j} = \varsigma(\vec{\mathcal{E}} + \mathbf{v} \times \vec{\mathcal{B}})} \,. \tag{13.34}$$

The first part, $\mathbf{j} = \varsigma\vec{\mathcal{E}}$, is Ohm's law already discussed in Sec. 11.3. Now, in addition to taking into account the Coulomb force acting on electrons traveling in conductors, let us also consider the Lorentz force.

13.2.1 The electromotive force

When we consider a closed electric circuit with a current source and a consumer, knowing the slow average velocity of the electrons carrying the current (see Exc. 11.3.3.5), it is not immediately obvious why the current starts to flow simultaneously in all parts of the circuit. The explanation is that if this were not the case, charges would accumulate in parts of the circuit creating local imbalances. The consequence of this would be the creation of electric fields working to eliminate the imbalances. These fields $\vec{\mathcal{E}}$ are superposed to the electromotive force $\mathbf{f}_0$ exerted by the current source. If the source has an internal resistance, as schematized in Fig. 13.8(a), part of the electromotive force $\mathbf{f}_i$ is spent on it,

$$\mathbf{f}_i = \mathbf{f}_0 + \vec{\mathcal{E}} \,. \tag{13.35}$$

In the case of an ideal source, $\mathbf{f}_i = 0$, the path integral along the circuit,

$$\mathcal{E} \equiv \int_+^- \mathbf{f}_0 \cdot d\mathbf{l} = -\int_+^- \vec{\mathcal{E}} \cdot d\mathbf{l} = U \,, \tag{13.36}$$

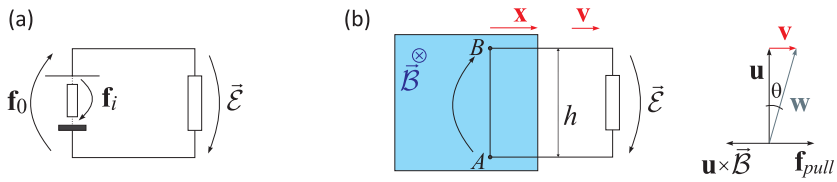

Figure 13.8: (a) Illustration of the electromotive force $\mathbf{f}_0$ exerted by an arbitrary voltage source, the force $\mathbf{f}_i$ spent on the internal resistance of the source, and the electrostatic force $\vec{\mathcal{E}}$ on the circuit. (b) Electromotive force $\mathbf{f}_0$ generated by the motion of a part of the circuit inside a magnetic field.

yields exactly the voltage.

The electromotive force can be caused by batteries, photocells, generators, etc. In the case of a generator, the electromotive force is the Lorentz force acting on the free charges of a conductor moved within an applied magnetic field. Let us consider the setup schematized in Fig. 13.8(b). When the part of the conductor between the points A and B (length h) is moved to the right with velocity $\mathbf{v}$ within the magnetic field $\vec{\mathcal{B}}$, positive charges are accelerated upwards, as in the case of the Hall effect. We obtain an electromotive force,

$$\mathcal{E} \equiv \oint \mathbf{f}_{\mathrm{L}} \cdot d\mathbf{l} = hv\mathcal{B} \ , \tag{13.37}$$

which acts as a source of voltage. Of course, it is not the magnetic field which does the work through the Lorentz force, but the person pushing the conductor: Calling u the velocity along the conductor acquired by the accelerated charges, this velocity creates inside the magnetic field an electromotive force $\mathbf{u} \times \vec{\mathcal{B}}$ against the motion of the conductor exerting per unit of charge the work,

$$\begin{aligned} \int \mathbf{f}_{pull} \cdot d\mathbf{l}_w = -\int (\mathbf{u} \times \vec{\mathcal{B}}) \cdot d\mathbf{l}_w &= \int u\mathcal{B}\hat{\mathbf{e}}_x \cdot d\mathbf{l}_w \\ &= \int_0^h \frac{v}{\tan\theta}\mathcal{B}\cos(90^\circ - \theta)\frac{dh}{\cos\theta} = hv\mathcal{B} = \mathcal{E} \ . \end{aligned} \tag{13.38}$$

We find that the work exerted per unit of charge exactly compensates the electromotive force.

Applying the definition of the magnetic flux (12.12), to the situation illustrated in Fig. 13.8(b),

$$\Psi_M = \int \vec{\mathcal{B}} \cdot d\mathbf{S} = \mathcal{B}hx \ , \tag{13.39}$$

we can reshape the Eq. (13.37),

$$h\mathcal{B}v = -h\mathcal{B}\dot{x} = \boxed{-\frac{d\Psi_M}{dt} = \mathcal{E}} \ . \tag{13.40}$$

Hence, the temporal variation of the magnetic flux induces a *counteracting* electromotive force. This is known as *Lenz's rule*.

13.2.2 The Faraday-Lenz law

In a series of experiments *Michael Faraday* demonstrated that the relationship (13.40) can be generalized to any geometry of the circuit immersed in a magnetic field, to any velocity of the motion, and even to time-varying geometries. The applications of this effect are innumerable, see Exc. 13.2.3.1 to 13.2.3.23. Relating the electromotive force on one side to the generation of a voltage (13.36), $\mathcal{E} = \oint \vec{\mathcal{E}} \cdot d\mathbf{l}$, and on the other side to the variation of the flux (13.40), $\mathcal{E} = -\frac{d\Psi_M}{dt}$, we can write,

$$\boxed{\oint \vec{\mathcal{E}} \cdot d\mathbf{l} = -\frac{\partial}{\partial t} \int \vec{\mathcal{B}} \cdot d\mathbf{S}} \ . \tag{13.41}$$

In the differential version we get,

$$\boxed{\nabla \times \vec{\mathcal{E}} = -\frac{\partial \vec{\mathcal{B}}}{\partial t}} \ . \tag{13.42}$$

Note that, without temporal variations of the magnetic field, we recover electrostatics, $\nabla \times \vec{\mathcal{E}} = 0$.

13.2.2.1 Mutual inductance

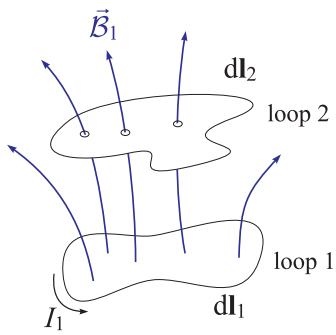

Figure 13.9: Indução.

Here, we consider two loops of arbitrary shapes. The first loop carries the current I_1 and produces a magnetic field, which we can calculate, for example, by Biot-Savart's law,

$$\vec{\mathcal{B}}_1 = \frac{\mu_0 I_1}{4\pi} \oint \frac{d\mathbf{l}_1 \times (\mathbf{r} - \mathbf{r}')}{|\mathbf{r} - \mathbf{r}'|^3} \ . \tag{13.43}$$

The part of the magnetic flux passing through the second loop is,

$$\Psi_{M2} = \int \vec{\mathcal{B}}_1 \cdot d\mathbf{S}_2 \equiv M_{21} I_1 \ , \tag{13.44}$$

where M_{21} is a constant that depends only on the geometry of the two loops. It is

called *mutual inductance* and can be expressed as,

$$M_{21} = \frac{1}{I_1}\int \nabla \times \mathbf{A}_1 \cdot d\mathbf{S}_2 = \frac{1}{I_1}\oint \mathbf{A}_1 \cdot d\mathbf{l}_2 \tag{13.45}$$
$$= \frac{1}{I_1}\oint \left(\frac{\mu_0 I_1}{4\pi}\oint \frac{d\mathbf{l}_1}{|\mathbf{r}-\mathbf{r}'|}\right)\cdot d\mathbf{l}_2 = \frac{\mu_0}{4\pi}\oint\oint \frac{d\mathbf{l}_1 \cdot d\mathbf{l}_2}{|\mathbf{r}-\mathbf{r}'|} \ .$$

The symmetry of this formula suggests,

$$M_{21} = M_{12} = M \ . \tag{13.46}$$

We can drop the indices and call both constants M. The conclusion of this is that, regardless of the shapes and positions of the loops, the flux through loop 2 when we throw a current I into the loop 1 is identical to the flux through 1 when we throw the same current I into 2,

$$I_1 = I_2 = I \Longrightarrow \int \vec{\mathcal{B}}_1 \cdot d\mathbf{S}_2 = \int \vec{\mathcal{B}}_2 \cdot d\mathbf{S}_1 \ . \tag{13.47}$$

Example 80 (*Dynamo*): We consider a rotating coil set in motion by a crank inside a magnetic field, as shown in the figure. The voltage wasted by the resistor is,

$$U = \oint \vec{\mathcal{E}} \cdot d\mathbf{l} = -\frac{d}{dt}\Psi_M = -\frac{d}{dt}\int \vec{\mathcal{B}} \cdot d\mathbf{A} = -\frac{d}{dt}\mathcal{B}A\cos\omega t = \omega\mathcal{B}A\sin\omega t \ .$$

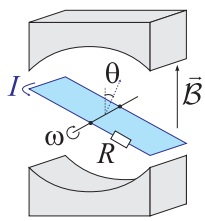

Figure 13.10: Schematic of a generator of alternating voltage (or dynamo).

13.2.2.2 Self-inductance

The magnetic flux produced by the current in loop 1 not only traverses the second loop, but also the first loop itself. Therefore, any variation of the flux will also induce an electromotive force in this loop 1,

$$\Psi_{M1} = M_{11}I_1 \equiv LI_1 \ , \tag{13.48}$$

where the constant L is called *self-inductance*. With the law of Lenz-Faraday,

$$\mathcal{E} = -\frac{d\Psi_M}{dt} = -L\dot{I} \ . \tag{13.49}$$

Example 81 (*Self-inductance of a solenoid*): Consider the solenoid shown in Fig. 13.11. With the formula of the example 80 we calculate the magnetic flux,

$$\Psi_M = \int \vec{\mathcal{B}} \cdot d\mathbf{A} = \mu I \frac{N}{l} \; N\pi R^2 \; .$$

Comparing with the formula (13.48), we find self-inductance,

$$L = \mu \frac{N^2}{l} \; \pi R^2$$

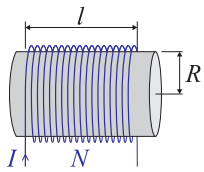

Figure 13.11: Scheme of a solenoid characterized by a self-inductance L.

13.2.3 Exercises

13.2.3.1 Ex: Application of the Faraday-Lenz law

The current in a coil characterized by the inductance $L = 1\,\text{mH}$ is linearly reduced in one second from 1 A to 0. Calculate the induced voltage.

13.2.3.2 Ex: Breathing charge distribution

A radially symmetric charge distribution varies over time as $\lambda(t)$ in a 'breathing oscillation',

$$\varrho(\mathbf{r}, t) = \varrho_0 \lambda(t) \frac{1}{r^2} e^{-a\lambda(t) r} \; ,$$

where $\varrho_0 = const.$ and $a = const.$
a. What is the value of the total charge?
b. Calculate the current density $\mathbf{j}(\mathbf{r}, t)$, which corresponds to $\varrho(\mathbf{r}, t)$ from the continuity equation.
c. Determine $\vec{\mathcal{E}}(\mathbf{r}, t)$ from the ansatz $\vec{\mathcal{E}}(\mathbf{r}, t) = \mathcal{E}(r, t)\frac{\mathbf{r}}{r}$ (radial symmetry).
d. Calculate the corresponding magnetic field $\vec{\mathcal{B}}$.
e. Show that the solutions for $\vec{\mathcal{E}}$ and $\vec{\mathcal{B}}$ satisfy Maxwell's equations.

13.2.3.3 Ex: Law of induction

a. Explain the concept of magnetic flux across an area F. How does magnetic flux depend on the choice of surface?
b. What is the form of Faraday's induction law? What are the experimental observations underlying this law?
c. What is the physical content of Lenz's law?

d. What is Maxwell's displacement current? Give a physical justification for this current.
e. Write down Maxwell's equations.
f. What is the motivation for introducing the electromagnetic potentials Φ and $\mathbf{A}$?
g. What is the allowed gauge transformation for electromagnetic potentials?
h. What is the meaning of the Lorentz gauge? What advantages does it offer?
i. Formulate the energy conservation law of electrodynamics.
j. What is the physical meaning of the Poynting vector?

13.2.3.4 Ex: Induction and Lorentz force

Two parallel metal rods are tilted by an angle φ with respect to the ground (see diagram). Between the rods a third movable rod of mass m and length L placed at right angles glides without friction. A homogeneous magnetic field $\vec{\mathcal{B}}$ crosses perpendicularly the plane defined by the three rods. The parallel rods are connected at the top end by a capacitor C, such that a closed current circuit is formed together with the transverse rod.
a. Set up the equation of motion for the transverse rod.
b. Determine the solution $x(t)$ of the equation of motion for the initial condition $x(0) = v(0) = 0$.

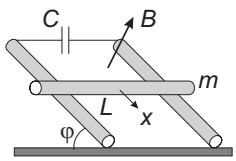

Figure 13.12: Induction.

13.2.3.5 Ex: Magnetic flux and induction

Consider the conductive ring of radius l and negligible electrical resistance shown in the figure. Perpendicular to the plane of the ring there is a homogeneous magnetic field $\vec{\mathcal{B}}$. A rod 2 rotates with angular frequency ω. Calculate the current I across the resistance R of another resting rod 1.

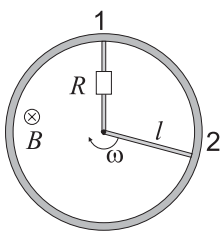

Figure 13.13: Induction.

13.2.3.6 Ex: Induction

Consider the conductive loop at right angle shown in the figure. There is a homogeneous magnetic field given by,

$$\vec{\mathcal{B}}(\mathbf{r}) = \mathcal{B}_0 \hat{e}_y \ .$$

The conductive loop rotates around the bending axis (z-axis) with constant angular frequency.ω.
a. What is the voltage induced in the loop as a function of time?
b. Calculate the time average of the induced voltage.

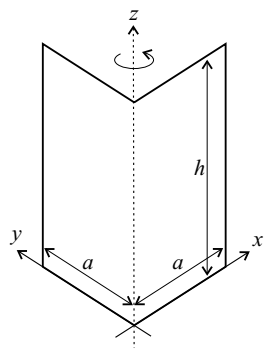

Figure 13.14: Induction.

13.2.3.7 Ex: Induction

A circular ring with radius R rotates with constant angular velocity ω around a diameter. Perpendicular to the rotation axis there is a magnetic field $\vec{\mathcal{B}}$.
a. Calculate the voltage induced in the ring as a function of time.
b. The ring consists of a metallic wire with conductivity σ. What current $I(t)$ flows through the ring, assuming the current is evenly distributed across the cross section of the wire?

13.2.3.8 Ex: Induction

An equidistant triangle-shaped conductive loop (edge length S) in the xy-plane is 'immersed' with constant velocity $\mathbf{v} = v\hat{\mathbf{e}}_x$ starting at the tip into a homogeneous magnetic field $\vec{\mathcal{B}} = \mathcal{B}\hat{\mathbf{e}}_z$ ($\mathcal{B}$ is constant) (see diagram) until being completely inside the magnetic field.
a. Calculate the maximum voltage induced in the loop.
b. Make a scheme of the time evolution of the induced voltage.

13.2.3.9 Ex: Induction

A rectangular conducting loop with height $2a$ and width $2b$ rotates with angular velocity ω around the z-axis. At time $t = 0$ the conducting loop is in the xz-plane. In addition, the loop is exposed to the inhomogeneous time-varying magnetic field $\vec{\mathcal{B}}(\mathbf{r}, t) = \mathcal{B}_0 t z^2 \hat{\mathbf{e}}_x$.

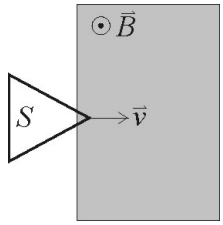

Figure 13.15: Induction.

a. Show, $\nabla \cdot \vec{\mathcal{B}}(\mathbf{r}, t) = 0$.
b. Calculate the magnetic flux $\Psi(\mathbf{r}, t) = \int \vec{\mathcal{B}} \cdot d\mathbf{F}$ through the rotating loop as a function of time.
c. What is the value of the voltage $U_{ind}(t)$ induced in the loop as a function of time?

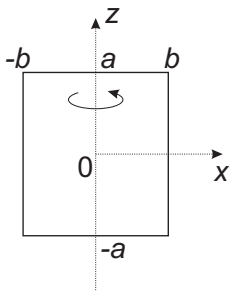

Figure 13.16: Induction.

13.2.3.10 Ex: Induction in a coil

Calculate the magnetic $\mathcal{B}$-field in the middle and at the end of a coil of length $L = 1\,\mathrm{m}$. The number of turns is $N = 2000$, the radius $r = 2\,\mathrm{cm}$, and the current through the coil $I = 5\,\mathrm{A}$. To do this first calculate, using the Biot-Savart law, the magnetic field $\mathcal{B}_1(0, 0, z)$ of a single circular conductor with radius r located at a point z_1 of the coil's symmetry axis. Use the formula obtained for $\mathcal{B}_1$ to describe the magnetic field generated by a coil element dz.

13.2.3.11 Ex: Induction in a rectangular mesh

A rectangular conducting loop has the length a and the width b. In the same plane defined by the loop, parallel to a distance d is a straight conductor traversed by a current I, as shown in the figure.
a. Calculate the magnetic field produced by the current.
b. Calculate the flux through the loop.
c. Calculate the self-inductance imposed on the current circuit by the existence of the

loop.
d. Linearize the expression of self-inductance for $b/d \ll 1$.

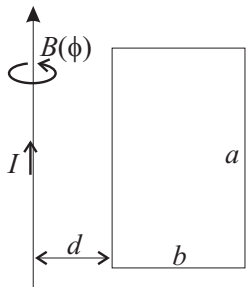

Figure 13.17: Induction.

13.2.3.12 Ex: Falling rod

A metal rod of $L = 1\,\mathrm{m}$ length falls in the gravitational field of the Earth. At time $t = 0$ the initial velocity is 0. The rod is oriented parallel to the ground. Perpendicular to the rod and parallel to the ground there is a magnetic field $\vec{\mathcal{B}}$ with the absolute value $2 \cdot 10^{-5}\,\mathrm{T}$.
a. What voltage is induced between the ends of the rod as a function of the distance traveled h?
b. What value is obtained for the voltage after a fall of $5\,\mathrm{m}$?

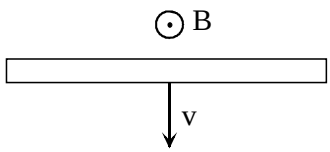

Figure 13.18: Induction.

13.2.3.13 Ex: Sliding rod

We consider two parallel metal rails (distance $d = 10\,\mathrm{cm}$) inclined by an angle ϕ with respect to the ground. Between the rails slides a frictionless rod (mass $M = 100$ g). At a right angle to the plane defined by the rails there is a homogeneous magnetic field $\mathcal{B}$ (amplitude: $0.1\,\mathrm{T}$). We sent a current of $I = 9.8\,\mathrm{A}$ through the rails and through the rod. What is the maximum allowable value of ϕ necessary to let the rod move upward along the rails?

13.2.3.14 Ex: Conductive ring in oscillating magnetic field

A circular conductive loop (inductance L, resistance R) is traversed by an oscillating magnetic flux, $\Psi = \Psi_0 e^{\imath\omega t}$.

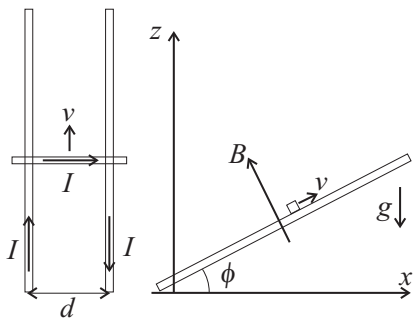

Figure 13.19: Sliding rod.

a. Calculate the amplitude of the current in the conductor as well as its phase relative to Ψ.
b. What is the average power dissipated in the conductor? Also discuss the limiting cases $\omega \to 0$ and $\omega \to \infty$.
Help: Start setting up an equivalent circuit incorporating a voltage source, a resistance, and an inductance.

13.2.3.15 Ex: Self-inductance of a current loop

Calculate the self-inductance of a current loop.

13.2.3.16 Ex: Potentials

Be given are scalar potential and vector potential:

$$\Phi(\mathbf{r},t) = b\frac{\mathbf{r}\hat{\mathbf{e}}_z}{r^3}e^{\imath\omega t} \qquad \text{and} \qquad A(\mathbf{r},t) = \imath kb\frac{e^{\imath kr}}{r^3}e^{\imath\omega t}\hat{\mathbf{e}}_z \ ,$$

where $\omega = ck$ and $r = |\mathbf{r}|$. Calculate the corresponding electric field $\vec{\mathcal{E}}(\mathbf{r},t)$ and the magnetic field $\vec{\mathcal{B}}(\mathbf{r},t)$.

13.2.3.17 Ex: • Motion-induced electromotive force

In the figure a conductive rod of mass m and negligible resistance is free to slide without friction along two parallel rails that have negligible resistances, are separated by a distance ℓ, and connected by a resistance R. The rails are attached to a long plane inclined by an angle θ from the horizontal. There is a magnetic field pointing upwards as shown.
a. Show that there is a retarding force directed upward on the inclined plane given by $F = (\mathcal{B}^2\ell^2 v\cos^2\theta)/R$.
b. Show that the terminal velocity of the stick is $v_t = mgR\sin\theta/(\mathcal{B}^2\ell^2\cos^2\theta)$.

13.2.3.18 Ex: • Induction

An insulated wire with resistance of $18.0\,\Omega/\mathrm{m}$ and length of $9.0\,\mathrm{m}$ will be used to build a resistor. First the wire is bent in half and doubled, and then the double wire

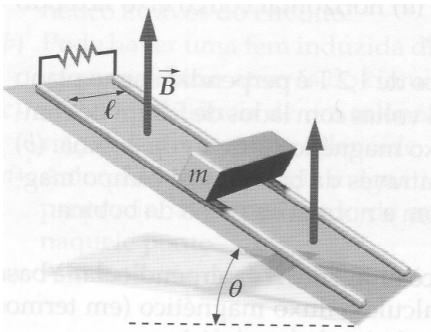

Figure 13.20: Motion-induced electromotive force.

is wound into a cylindrical shape (see figure) to create a 25 cm long, 2.0 cm diameter helix. Determine the resistance and inductance of this twisted wire resistor.

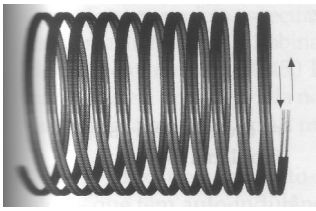

Figure 13.21: Induction.

13.2.3.19 Ex: • R-L-circuit

In the circuit shown in the figure the inductor has negligible internal resistance, and the switch S has been left open for a long time. Now, the switch is closed.
a. Determine the current in the battery, the current in the 100 Ω resistor, and the current in the inductance immediately after the switch has been closed.
b. Determine the current in the battery, the current in the 100 Ω resistor, and the current in the inductance a long time after the switch has been closed.
c. After being closed for a long time, the key is now opened again. Determine the current in the battery, the current in the 100 Ω resistor, and the current in the inductance immediately after the switch has been opened.
d. Determine the current in the battery, the current in the 100 Ω resistor, and the current in the inductance a long time after the key has been reopened.

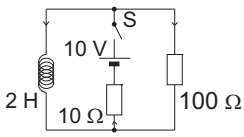

Figure 13.22: Circuit.

13.2.3.20 Ex: • Low pass filter

The circuit shown in the figure is an example of a *low-pass filter*. (Consider that the output is connected to a load that conducts negligible current.)
a. If the input voltage is given by $V_{\text{in}} = V_{in,pico} \cos \omega t$, shows that the output voltage is $V_{\text{out}} = V_{\text{L}} \cos(\omega t - \phi)$, where $V_{\text{L}} = V_{in,pico}/\sqrt{1 + (\omega RC)^{-2}}$.
b. Discuss the trend in the limiting cases $\omega \to 0$ and $\omega \to \infty$.

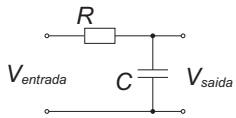

Figure 13.23: Low pass filter.

13.2.3.21 Ex: • Notch filter

The circuit shown in the figure is a *cutoff filter*. (Consider that the output is connected to a load carrying a negligible current.)
a. Show that the cutoff filter rejects signals in a frequency band centered in $\omega = 1/\sqrt{LC}$.
How does the width of the rejected frequency band depend on R?

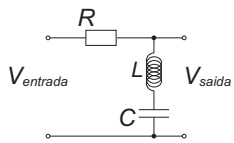

Figure 13.24: Notch filter.

13.2.3.22 Ex: Effective power

Show that the expression $P_{\text{med}} = R\mathcal{E}_{\text{rms}}^2/Z^2$ provides the correct result for a circuit containing only one ideal *ac*-generator and
a. one resistor R,
b. one capacitor C and
c. one inductance L. In the given expression, P_{med} is the average power supplied by the generator, $\mathcal{E}_{\text{rms}}$ is the average quadratic value of the emf-generator.

13.2.3.23 Ex: • R-L-C-circuit

In the circuit shown in the figure the ideal generator produces a voltage of 115 V when operated at 60 Hz. What is the *rms*-voltage between the points
a. A and B, b. B and C, c. C and D, d. A and C, and e. B and D?

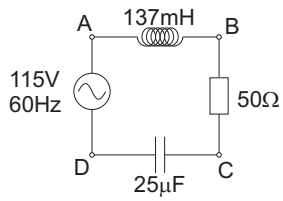

Figure 13.25: Circuit.

13.3 Magnetostatic energy

To calculate the magnetostatic energy stored in a magnetic field we will proceed as follows: We will look for a general expression guessed by analogy with the electrostatic energy, $W = \frac{1}{2}\int \varrho\Phi dV$, and show that, applied to a current-carrying loop, this expression gives the correct result. The analogous formula is,

$$W = \tfrac{1}{2}\int \mathbf{j}\cdot\mathbf{A}dV \ . \tag{13.50}$$

13.3.1 Energy density of a magnetostatic field

The energy of a current distribution can be rewritten using Ampere's law,

$$W = \tfrac{1}{2\mu_0}\int (\nabla\times\vec{\mathcal{B}})\cdot\mathbf{A}dV \ . \tag{13.51}$$

Integration by parts allows transferring the derivative from $\vec{\mathcal{B}}$ to $\mathbf{A}$,

$$W = \tfrac{1}{2\mu_0}\left[-\oint(\mathbf{A}\times\vec{\mathcal{B}})\cdot d\mathbf{S} + \int \vec{\mathcal{B}}\cdot(\nabla\times\mathbf{A})dV\right] \ . \tag{13.52}$$

The surface integral can be neglected because we can choose the integration volume $\mathcal{V}$ to be arbitrarily large. Expressing the rotation by the field,

$$W = \tfrac{1}{2\mu_0}\int \vec{\mathcal{B}}^2 dV = \tfrac{1}{2\mu_0}\int u dV \ , \tag{13.53}$$

and introducing the *energy density*,

$$\boxed{u \equiv \tfrac{1}{2\mu_0}\vec{\mathcal{B}}^2} \ . \tag{13.54}$$

It may seem strange, that we need energy to build up a magnetic field which in turn can not exert work. On the other hand, to create this magnetic field, we have to ramp it up from zero which, according to Faraday's law induces an electric field. This field, in turn, can work. Initially there is no $\vec{\mathcal{E}}$ and at the end of the process there is no $\vec{\mathcal{E}}$ neither; but in between, while $\vec{\mathcal{B}}$ is being constructed, there is. The work has to be exerted against the $\vec{\mathcal{E}}$-field.

13.3.2 Inductors and storage of magnetostatic energy

Using the magnetostatic energy formula,

$$W = \frac{1}{2}\int \mathbf{j}\cdot\mathbf{A}dV = \frac{1}{2}\oint \mathbf{I}\cdot\mathbf{A}dl = \frac{I}{2}\oint \mathbf{A}\cdot d\mathbf{l} = \frac{I}{2}\int (\nabla\times\mathbf{A})\cdot d\mathbf{S} = \frac{I}{2}\int \vec{\mathcal{B}}\cdot d\mathbf{S} = \frac{I}{2}\Psi_M \ . \tag{13.55}$$

Finally, considering a coil and using the formula (13.48),

$$\boxed{W = \frac{1}{2}LI^2} \ , \tag{13.56}$$

which corresponds to the power,

$$\frac{dW}{dt} = -\mathcal{E}I = LI\frac{dI}{dt} \ . \tag{13.57}$$

13.3.3 Exercises

13.3.3.1 Ex: Switching processes

Consider the RL-circuit show in the figure, where the ohmic resistor $R = R(t)$ varies over time. Let τ be the length of the switching-on process starting at time $t = 0$. The resistance be,

$$R(t) = \begin{cases} \infty & \text{for } t < 0 \\ R_0\tau/t & \text{for } 0 \le t \le \tau \\ R_0 \text{for } \tau \le t & \end{cases} \ .$$

a. Set up for the time intervals $t \in [0, \tau]$ and $t \in [\tau, \infty]$ separate differential equations for the current $I(t)$.
b. Solve the differential equations (using a simple ansatz or a method of variable separation) and connect the solutions continuously at $t = \tau$. What is the condition for fast or slow switching?

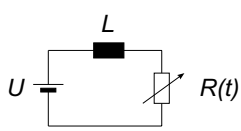

Figure 13.26: Circuit.

13.3.3.2 Ex: Current density of a rotating charge

The surface of a hollow sphere with radius R carries a uniformly distributed charge Q. The sphere rotates with the constant angular velocity ω around one of its diameters.
a. Determine the current density $\mathbf{j}(\mathbf{r})$ generated by this movement.
b. Calculate the magnetic moment produced by $\mathbf{j}$.
c. Derive the components of the potential vector $\mathbf{A}(\mathbf{r})$ and the magnetic field $\vec{\mathcal{B}}(\mathbf{r})$.

13.3.3.3 Ex: Train track

The two iron rails of a toy train have a thickness of $d = 5\,\mathrm{mm}$ and a reciprocal distance of $a = 50\,\mathrm{mm}$ They are connected by a metal rod of mass $m = 0.5\,\mathrm{g}$, which is movable without friction in a direction perpendicular to the rails. A current applied to the rails, which also runs through the metal rod, causes the rod to accelerate along the rails.
a. Calculate the magnetic field between the two rails, if through them runs the same current I but in inverse directions. Neglect inhomogeneities at the ends of the rails and the magnetic field generated by the current passing through the rod.
b. How strong is the force accelerating the rod along the rails?
c. What current would be needed to accelerate the rod over a distance of $l = 5\,\mathrm{m}$, up to a speed of $10\,\mathrm{m/s}$? Ignore all friction effects.

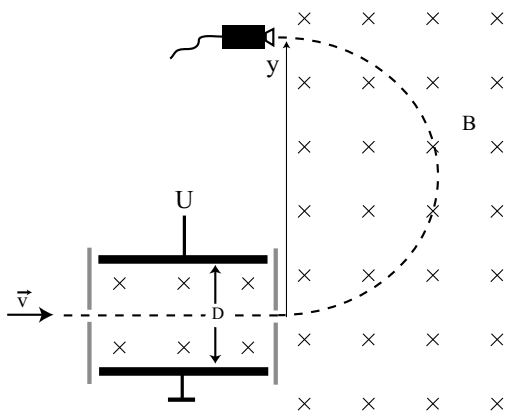

Figure 13.27: Circuit.

13.3.3.4 Ex: Mass spectrometer

A mass spectrometer consists, as shown in the figure, of a plate capacitor with $D = 5\,\mathrm{mm}$ distance between the electrodes, placed within a magnetic field $\mathcal{B} = 0.4\,\mathrm{T}$ with homogeneous amplitude. A mixture of isotopes of carbon ion $^{12}\mathrm{C}^+$ and $^{14}\mathrm{C}^+$ penetrates the capacitor through a circular slot. After transit through the capacitor the ions move in the magnetic field on a semicircular path and are counted by a detector, whose distance y from the slot can be varied.
a. What voltage should be applied to the plates of the capacitor to ensure that only ions with the velocity $v = 10^5\,\mathrm{m/s}$ can exit the capacitor through the second slot?
b. At what distances y can the two isotopes be detected respectively?

13.3.3.5 Ex: Transformer

Consider two similar coils with number of turns N_1 and N_2 connected by an iron yoke. In the first coil we apply a time-varying voltage U_1. Therefore, in this coil (called primary) runs a current I_1, producing a magnetic flux Ψ, which is transmitted entirely

through the iron yoke to the second (second) coil. Here, a voltage U_2 is induced.
a. Calculate the ratio U_2/U_1 as a function of the number of turns. What is the behavior of the phase between U_1 and U_2.
b. What are the phases of the currents I_1 and I_2 running through the coils with respect to phases of the voltages? What is the consequence for the average power in the coils?

13.3.3.6 Ex: Resonant L-R-C-circuit

Consider an excited LRC serial circuit. The components of the oscillating circuit have the values $R = 5\,\Omega$, $C = 10\,\mu\text{F}$, $L = 1\,\text{H}$, and $U = 30\,\text{V}$.
a. At what excitation frequency ω_a does the amplitude of the current have its maximum value? Give the value of the current?
b. At what angular frequencies ω_{a1} and ω_{a2} does the amplitude of the current have exactly half the maximum value? What is therefore the FWHM width of the resonance curve for this oscillating circuit? Show that the width of the resonance curve is given by,

$$\frac{\omega_{a1} - \omega_{a2}}{\omega_a} = R\sqrt{\frac{3C}{L}}\ .$$

c. Make a scheme of some resonance curves for various values of R.

13.3.3.7 Ex: Inductive circuit

Consider the circuit shown in the figure, which consists of a coil L, a voltage source U, and an ohmic resistor $R = 100\,\Omega$. The coil is a long solenoid with 50 turns per cm and an inductance of 200 mH. For times $t < 0$ there is no current flow through the solenoid. At time $t = 0$, the voltage is suddenly increased from 0 to 10 V. How long does it take the magnetic field in the solenoid to reach the value $\pi \cdot 10^{-4}$ T?

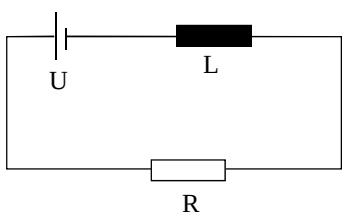

Figure 13.28: Circuit.

13.3.3.8 Ex: Inductive circuit

Consider the circuit shown in the figure, which consists of a coil L, a voltage source $U_0 = 10\,\text{V}$, and three ohmic resistors $R = 100\,\Omega$. The coil is a long solenoid with 50 turns per cm and an inductance of 200 mH. Initially, the switch is open for a long time. Then at time $t = 0$, it is closed.
a. What is the initial value of the magnetic field in the solenoid while the switch is still open?

b. Using Kirchhoff's laws, derive the formula describing the temporal evolution of the field after the switch has been closed.
c. Determine the field for long times after the switch has been closed.

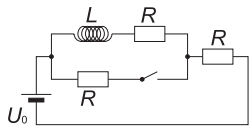

Figure 13.29: Circuit.

13.3.3.9 Ex: Conductive circular rings

Consider two infinitely thin conducting rings. They are concentric with radii a and b ($a < b$) and arranged in the xy-plane with a common center at the coordinate origin. The inner ring carries a homogeneously distributed charge $+q$ (that is, with linear constant charge density), the outer ring carries the homogeneously distributed charge $-q$.
a. First, write the charge density $\rho(\mathbf{r}) = \rho(r, \phi, z)$ in cylindrical coordinates. Now, let the inner ring rotate with the constant angular velocity ω about the symmetry axis (that is, the z-axis). Write the resulting current density also in cylindrical coordinates. **Help:** $\mathbf{j}(\mathbf{r}) = \rho(\mathbf{r}) \cdot \mathbf{v}(\mathbf{r})$ where $\mathbf{v}(\mathbf{r})$ is the velocity at the position $\mathbf{r}$. b. Determine by an explicit calculation the dipolar magnetic moment $\mathbf{m} = \frac{1}{2} \int d^3r \; \mathbf{r} \times \mathbf{j}(\mathbf{r})$ of the rotating ring.

13.4 Alternating current

13.4.1 Electromagnetic oscillations

We have already met the plate capacitor as the most basic device for storing electrostatic energy in an (homogeneous) electric field. Similarly, the solenoid is the most basic device for storing magnetostatic energy in a (homogeneous) magnetic field. Placing a solenoid with inductance L and a capacitor with capacitance C in an electric circuit we find that electric energy can be converted into magnetic energy (and vice versa) in an analogous way as potential energy can be converted into kinetic energy (and vice versa) in a mass-spring system. This can generate (electromagnetic) oscillations.

Example 82 (*Oscillating circuits*): Let us first consider a circuit with a coil and a capacitor connected in series. Kirchhoff's law of meshes requires, $U_{ind} = U_C$, which gives,

$$-L\frac{dI}{dt} = \frac{Q}{C}$$

or

$$L\ddot{I} + C^{-1}I = 0 \; .$$

We now consider a circuit with a battery, a switch, a coil, and a resistor in series.

Kirchhoff's law of meshes requires, $U_0 = -U_{ind} + U_R = L\dot{I} + RI$, which gives,

$$\frac{dI}{I - U_0/R} = -\frac{R}{L}dt$$

with the solution

$$I(t) = \frac{U_0}{R} + \left(I_0 - \frac{U_0}{R}\right) e^{-Rt/L} \ ,$$

where we choose the initial current $I_0 = 0$.

13.4.2 Alternating current circuits

To discuss alternating voltages, we consider the circuit shown in Fig. 13.30 fed by a voltage source, $U(t) = U_0 e^{\imath\omega t}$. To simplify the mathematical expressions we adopt a complex notation. The objective is to calculate the current for the various types of consumers Z that we already got to know. In the case of an ohmic resistance we have,

$$I = \frac{U_0}{R} e^{\imath\omega t} = \frac{U}{R} \ . \tag{13.58}$$

Hence,

$$Z = \frac{U}{I} = R \ . \tag{13.59}$$

In the case of a capacitance we have,

$$I = \dot{Q} = CU_0 \frac{d}{dt} e^{\imath\omega t} = \imath\omega CU \ . \tag{13.60}$$

Hence,

$$Z = \frac{U}{I} = \frac{1}{\imath\omega C} \ . \tag{13.61}$$

In the case of an inductance we have,

$$I = \int_0^t LU_0 e^{\imath\omega t} dt = \frac{U}{\imath\omega L} \ . \tag{13.62}$$

Hence,

$$Z = \frac{U}{I} = \imath\omega L \ . \tag{13.63}$$

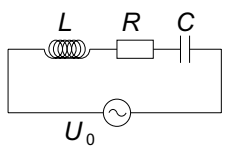

Figure 13.30: L-R-C circuit powered by an alternating voltage.

These results can be interpreted graphically (plotting Im U versus Re U) or analytically substituting $\imath = e^{\imath\pi/2}$. For the above three cases we obtain,

$$R = \frac{U_0 e^{\imath\omega t}}{I_0 e^{\imath\omega t + \pi/2}} \quad , \quad L\omega = \frac{U_0 e^{\imath\omega t}}{I_0 e^{\imath\omega t + \imath\pi/2}} \quad , \quad \frac{1}{C\omega} = \frac{U_0 e^{\imath\omega t}}{I_0 e^{\imath\omega t - \imath\pi/2}} \ . \tag{13.64}$$

This means that in the case of an inductance or capacitance, the voltage is not in phase with the current but has, respectively, an advance or a delay of 90°.

In cases of combinations of resistors and reactants the expression to calculate this phase shift becomes more complicated and may vary with the frequency imposed by the alternating source. Let us see how to calculate it at the example of the *L-R-C* circuit in series, writing in the same way as before,

$$Z = \frac{U}{I} = \imath L\omega + R + \frac{1}{\imath C\omega} = |Z|e^{\imath\phi} \ . \tag{13.65}$$

Hence,

$$|Z| = ZZ^* = \sqrt{R^2 + \left(L\omega - \frac{1}{\imath C\omega}\right)^2} \qquad \text{and} \qquad \tan\phi = \frac{\sin\phi}{\cos\phi} = \frac{L\omega - \frac{1}{C\omega}}{R} \ . \tag{13.66}$$

A resonance is met when $\omega = 1/\sqrt{LC}$. Other combinations of components are treated in the same way.

13.4.3 Exercises

13.4.3.1 Ex: High-pass filter

The circuits shown in the figure are called (a) first-order and (b) second-order high-pass filter. Calculate for both cases the ratio of output voltage U_a and input voltage U_e. Suppose that $U_e(t) = U_e \cos\omega t$ and $U_a(t) = U_a \cos(\omega t + \phi)$. Plot the result as a function of frequency on a logarithmic graph with the y-axis $\log(U_a/U_e)$ and the x-axis $\log\omega$. (This graph is called 'Bode diagram'.) What is the phase shift ϕ as a function of frequency?

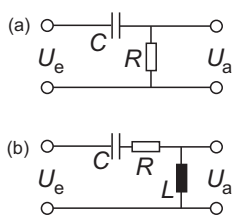

Figure 13.31: High pass.

13.4.3.2 Ex: Band and notch filter

The circuits shown in the figure are called (a) bandpass and (b) notch filter. Calculate for both cases the output voltage $U_a(t)$ under the condition that the input voltage is a sinusoidal oscillation, $U_e(t) = U_0 \cos\omega t$. Draw the amplitude of the output voltages as a function of frequency.

a. How do the amplitudes behave in the resonant case?

b. Discuss the limiting cases (i) $L \to 0$ resp., (ii) $C \to \infty$ based on transfer functions.

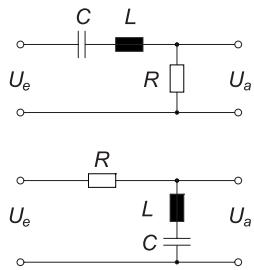

Figure 13.32: Filter.

13.4.3.3 Ex: Coaxial cable

A coaxial cable consists of a cylindrical conductor of radius a and a thin cylindrical waveguide of radius $b > a$. Between the conductors there is a voltage difference of U, and inside them flow currents in opposite directions I. Calculate the Poynting vector in the empty space and the power carried through the cable.
Help: Calculate the electric field between the conductors using Gauß' law and the magnetic field between the conductors using Ampere law.

13.4.3.4 Ex: *ac*-resistance

Calculate the work performed by an alternating current $I = I_0 \sin \omega t$ on a conductor with ohmic resistance R over a time period T. Make a scheme of the evolution in a diagram power versus time.

13.4.3.5 Ex: *ac*-motor

An alternating voltage motor provides with an alternating voltage of $U = 220\,\mathrm{V}$ at $f = 50\,\mathrm{Hz}$ with the power $P = UI\cos\phi = 2.2\,\mathrm{kW}$. The power factor of the engine is $\cos\phi = 0.6$ and the efficiency $\eta = P_{\mathrm{out}}/P_{\mathrm{in}} = 0.89$.
a. What current does the motor receive?
b. Which capacitor must be connected in parallel to the terminals of the motor in order to increase the power factor to a value of $\cos\phi = 0.9$? Sketch the current pointer in the U-I-plane.

13.4.3.6 Ex: Displacement current

a. Explain the significance of the continuity equation,

$$\oint \mathbf{j} \cdot d\mathbf{S} + \frac{d}{dt} \int \rho dV = 0 \ .$$

b. Consider an enclosed area $S_1 + S_2$, because here the continuity equation has the form,

$$\oint \mathbf{j} \cdot d\mathbf{S} - \frac{d}{dt} \int \vec{\mathcal{D}} \cdot d\vec{\mathcal{D}} V = 0 \ .$$

Show that holds,

$$\oint_{\mathrm{C}} \vec{\mathcal{H}} \cdot d\mathbf{l} = \int_{S_2} \frac{d}{dt} \int \vec{\mathcal{D}} \cdot d\mathbf{S} \ .$$

Help: No field lines penetrate through the area S_1, and no current flows through the area S_2.

13.4.3.7 Ex: Resonant LC-circuit

The capacitor of an undamped oscillating electromagnetic circuit has the capacity $C = 22$ nF. The eigenfrequency of the circuit is $f_0 = 5735\,\mathrm{Hz}$. At time $t = 0$ the capacitor has its maximum charge: $Q_0 = 0.33\,\mu\mathrm{C}$.
a. Derive for the undamped oscillating circuit the differential equation for $Q(t)$ from the energy conservation law and determine the solution. Write down the equation for eigenfrequency f.
b. Calculate inductance of the coil.
c. Set up equations for the energy content of the coil and and the capacitor as a function of time t.
d. Calculate the instant of time t_2, at which the energy content of the coil is, for the second time, half the energy content of the capacitor.

13.4.3.8 Ex: Resonant LRC-circuit

The oscillating LRC-circuit shown in 13.30 is excited by the alternating voltage source $U(t) = U_0 \cos \omega t$.
a. Calculate the total impedance Z as a function of ω and prepare graphs of the amplitude response $|Z(\omega)|$ and the phase response $\phi(\omega) = \arctan \frac{\mathfrak{Im}\, Z(\omega)}{\mathfrak{Re}\, Z(\omega)}$.
b. Establish the differential equation for the current. Start by solving the homogeneous differential equation and then the inhomogeneous one.

13.4.3.9 Ex: Resonant LRC-circuit

The components of an RLC-circuit (see 13.30) have the values $R = 5\ \Omega$, $C = 10\,\mu\mathrm{F}$, $L = 1\,\mathrm{H}$, and $U = 30\,\mathrm{V}$.
a. At what angular frequency ω_a does the current amplitude have its maximum value? What is the corresponding current?
b. At what angular frequencies ω_{a1} and ω_{a2} does the amplitude of the current have half the maximum value? What is the relative half-width of the resonance curve for this resonant circuit?
c. Show with the help of the formulas of (b) that the relative half-width of each resonance curve is given by,

$$\frac{\Delta_a}{\omega} = R\sqrt{\frac{3C}{L}} \ ,$$

where Δ_a is the width of the resonance profile at half the maximum amplitude.
d. Prepare schemes of the resonance profile for various values of R. When is the current circuit predominantly capacitive and when inductive?
e. Show that the damping term $e^{-Rt/2L}$ (containing L but not C!) can be written in

a more symmetrical form in L and C as follows,

$$e^{-\pi R \frac{t}{T} \sqrt{\frac{C}{L}}} \ .$$

Here, T is the period of oscillation when we neglect resistance. What is the SI-unit of the term $\sqrt{C/L}$?
f. Show, based on the result (e), that the condition for a smaller relative energy loss per oscillation cycle is: $R \ll \sqrt{L/C}$.

13.4.3.10 Ex: Resonant LRC-circuit

Consider a dampened oscillating RLC-circuit. The charge $\bar{q}$ on the capacitor is described by the differential equation,

$$L\frac{d^2\bar{q}}{dt^2} + R\frac{d\bar{q}}{dt} + \frac{1}{C}\bar{q} = 0 \ .$$

a. Use the ansatz $\bar{q} = q_0 e^{\imath\omega t}$ and show that,

$$\omega_{1,2} = \imath\frac{R}{2L} \pm \omega' \qquad \text{where} \qquad \omega' = \omega_0\sqrt{1 - \frac{R^2 C}{4L}}$$

with $\omega_0 = 1/\sqrt{LC}$ solves the differential equation.
b. Since this is a second order differential equation, we need two boundary conditions to determine the general solution of the form,

$$\bar{q}(t) = a\bar{q}_1(t) + b\bar{q}(t) \qquad \text{with} \qquad \bar{q}_{1,2} = \bar{q}_0 e^{-\frac{R}{2L}t} e^{\pm\imath\omega' t} \ .$$

Use the conditions $\bar{q}(0) = 0$ and $\dot{\bar{q}}(0) = I_0$ and determine the coefficients a and b. What is the solution for the charge $\bar{q}(t)$ in this case, and for the current $I(t) = \dot{\bar{q}}(t)$?
c. Sketch the evolution of the charge and the current on the capacitor for the following set of parameters and interpret the curves. What is the respective duration T of an oscillation period? Give for each of the following parameter sets the respective general solution before entering the values:
i. $I_0 = 1\,\text{mA}$, $R = 10\,\Omega$, $L = 1\,\text{mH}$, $C = 0.1\,\mu\text{F}$
ii. $I_0 = 1\,\text{mA}$, $R = 200\,\Omega$, $L = 1\,\text{mH}$, $C = 0.1\,\mu\text{F}$
iii. $I_0 = 1\,\text{mA}$, $R = 500\,\Omega$, $L = 1\,\text{mH}$, $C = 0.1\,\mu\text{F}$

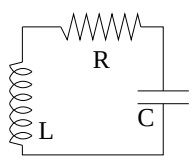

Figure 13.33: Resonant LRC-circuit.

13.4.3.11 Ex: Magnetized sphere

We consider a sphere with radius R magnetized such that, inside the sphere, the magnetic field density is given by $\vec{\mathcal{B}} = \mathcal{B}_0 \hat{\mathbf{e}}_z$. The outer space is empty, that is, there are no currents, such that rot $\vec{\mathcal{B}} = 0$ and div $\vec{\mathcal{B}} = 0$. Therefore, we can let for the outer space,

$$\vec{\mathcal{B}} = -\text{grad}\Psi \quad \text{and} \quad \Psi(r, \vartheta, \varphi) = \sum_{l=0}^{\infty} \alpha_l \frac{P_l(\cos\vartheta)}{r^{l+1}} \ ,$$

with P_l the Legendre polynomials and r, ϑ and φ the usual spherical coordinates. Consider the boundary conditions for $\mathcal{B}_r$, $\mathcal{B}_\theta$ as well as for $\mathcal{H}_r$ and $\mathcal{H}_\theta$ at the transition between the inner and outer space of the sphere. Determine from this the expansion coefficients α_l as well as the magnetization $\vec{\mathcal{M}}$ inside the sphere. With this we finally get the magnetic field density $\vec{\mathcal{B}}$ magnetic $\vec{\mathcal{H}}$-field in the inner and outer space.

13.4.3.12 Ex: Magnetic dipole moving through a conductive loop

What is the current signal produced by a ^{87}Rb Bose-Einstein condensate with its spin being polarized in the state $|F, m_F\rangle = |2, 2\rangle$ when it falls through a SQUID? Assume that the SQUID has the diameter $2a = 3\,\text{cm}$, the condensate consists of $N = 100000$ atoms and has a constant velocity of $v_z = 10\,\text{cm/s}$.

13.4.3.13 Ex: Electric current and magnetism

a. How are current and current density defined? What is a 'current line'?
b. What conditions should charge and current densities meet in magnetostatics?
c. How is the magnetic field $\vec{\mathcal{B}}$ defined empirically?
d. Writes the general form of Ampère's law. How is Ampère's law expressed in the case of two parallel conductors carrying currents I_1 and I_2?
e. What does the Ampère's law say?
f. What is the magnetic moment of an arbitrary, flat, closed current circuit?
g. What are the force and thye torque on a magnetic dipole in an external field $\vec{\mathcal{B}}(\mathbf{r})$.
h. Explain the term 'magnetization current density'.
i. What are the macroscopic equations of the magnetostatic field?
j. What is diamagnetism and paramagnetism? What differentiates these two phenomena? What is ferromagnetism?

13.4.3.14 Ex: Electro-motor

Consider the electromotor of the scheme. Two pairs of Helmholtz coils aligned along the x- and y-axes are powered by alternating currents, $I_x(t) = I_0 \cos\omega t$ and $I_y(t) = I_0 \sin\omega t$, respectively. In the field there is a rotating rectangular coil traversed by a constant current I. The inertial moment of the coil is $\mathcal{I}$.
a. Show that the field in the center is given by $\mathcal{B}_x(0) = \frac{-8}{5\sqrt{5}} \frac{\mu_0 I_x \hat{\mathbf{e}}_x}{R}$.
b. Describes the temporal behavior of the magnetic field.
c. Relate the torque with the angular acceleration of the coil.
d. Calculate the instantaneous torque acting on the coil.
e. Suppose that the coil initially rotates with an angular velocity Ω such that, $\theta(t) = \theta_0 + \Omega t$. How you should choose Ω and the initial angle θ_0 to ensure an always positive

torque? **Help:** $\sin\alpha\cos\beta + \cos\alpha\sin\beta = \sin(\alpha+\beta)$
f. Calculate the voltage induced in the coil. **Help:** $\sin\alpha\sin\beta + \cos\alpha\cos\beta = \cos(\alpha-\beta)$
g. Suppose the coil has an ohmic resistance ...

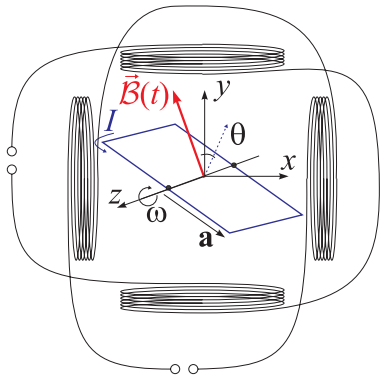

Figure 13.34: Electro-motor.

13.4.3.15 Ex: Magnetism

A given magnetic material is composed of N non-interacting atoms, whose magnetic moments μ can point in three possible directions, as shown in the figure, μx, μy, and $-\mu x$. The system is in thermal equilibrium at temperature T and subject to a uniform magnetic field oriented along the y-direction, $\vec{\mathcal{H}} = \mathcal{H}\hat{\mathbf{e}}_y$, so the energy levels corresponding to a single atom are $\varepsilon_0 = -\mu\mathcal{H}$, $\varepsilon_1 = 0$, and $\varepsilon_2 = 0$.
a. Get the canonical partition function z for one atom, the canonical partition function Z of the system, and the Helmholtz free energy f per atom.
b. Determine the mean energy $u \equiv \langle\varepsilon_n\rangle$ and the entropy s/k_{B} per atom.
c. Get magnetization per atom $\mathbf{m} \equiv \langle\vec{\mu}_n\rangle = m_x\hat{x} + m_y\hat{y}$.
d. Verify that the isothermal susceptibility $\chi_T \equiv (\partial m_y/\partial\mathcal{H})_T \propto 1/T$ at zero field obeys Curie's law of paramagnetism, $\chi_T(\mathcal{H}\to 0) \propto 1/T$.

Chapter 14

Maxwell's equations

In the first part of the course, we derived the laws of electromagnetism from experimental observations related to the Coulomb force on electric charges and the Lorentz force on electric currents. We have found that these forces can be understood by introducing electric fields $\vec{\mathcal{E}}$ and magnetic fields $\vec{\mathcal{B}}$, to which the laws of electromagnetism apply. These laws were all known before Maxwell. These are,

$$\begin{aligned}
\nabla \times \vec{\mathcal{B}} &= \mu_0 \mathbf{j} && \textit{Ampère's law} \text{ leading to } \textit{Biot-Savart's law} \\
\nabla \times \vec{\mathcal{E}} &= -\partial_t \vec{\mathcal{B}} && \textit{Faraday's law} \\
\nabla \cdot \vec{\mathcal{E}} &= \varepsilon_0^{-1} \varrho && \textit{Gauß' law} \text{ leading to } \textit{Poisson's lawPoisson} \text{ and } \textit{Coulomb's law} \\
\nabla \cdot \vec{\mathcal{B}} &= 0 && \text{absence of magnetic monopoles}
\end{aligned} \tag{14.1}$$

As we will show shortly, well-behaved vector fields are entirely defined by their divergences and rotations, so that we can expect that the set of laws (14.1) be complete, that is, it should be able to describe all electromagnetic phenomena.

However, by comparing the laws of Faraday and Ampère, we perceive an inconsistency: taking the divergences of the rotations, we expect them to zero:

$$\begin{aligned}
0 &= \nabla \cdot (\nabla \times \vec{\mathcal{E}}) = \nabla \cdot \left(-\frac{\partial \vec{\mathcal{B}}}{\partial t} \right) = -\frac{\partial}{\partial t} (\nabla \cdot \vec{\mathcal{B}}) \\
0 &= \nabla \cdot (\nabla \times \vec{\mathcal{B}}) = \mu_0 (\nabla \cdot \mathbf{j}) = -\mu_0 \frac{\partial \varrho}{\partial t} \neq 0 \ ,
\end{aligned} \tag{14.2}$$

where the last step makes use of the continuity equation (11.38). For temporal variations of the charge distribution the second equation can not be correct.

Maxwell's idea for solving the problem was to simply subtract from Ampère's law the term that prevents the second equation (14.2) from zeroing. With

$$\boxed{\nabla \times \vec{\mathcal{B}} = \mu_0 \mathbf{j} + \varepsilon_0 \mu_0 \frac{\partial \vec{\mathcal{E}}}{\partial t}} \ , \tag{14.3}$$

we verify,

$$\nabla \cdot (\nabla \times \vec{\mathcal{B}}) = \mu_0 \nabla \cdot \mathbf{j} + \varepsilon_0 \mu_0 \frac{\partial \nabla \cdot \vec{\mathcal{E}}}{\partial t} = \mu_0 \left(\nabla \cdot \mathbf{j} + \frac{\partial \varrho}{\partial t} \right) = 0 \ , \tag{14.4}$$

where, once more, we used the continuity equation. The Eq. (14.3) could be called *Maxwell's law* and the surface integral of the additional term,

$$\varepsilon_0 \frac{\partial}{\partial t} \oint_{\mathcal{S}} \vec{\mathcal{E}} \cdot d\mathbf{S} \equiv \oint_{\mathcal{S}} \mathbf{j}_d \cdot d\mathbf{S} = I_d \ . \tag{14.5}$$

is named *displacement current*. We will study consequences of this law in the Excs. 14.1.5.1 and 14.1.5.2.

Example 83 (*Necessity of a displacement current*): We consider the circuit shown in Fig. 14.1. On the one hand, the current passing through the Ampèrian loop must be independent of the shape of the enclosed area,

$$I = \int_{\mathcal{S}} \mathbf{j} \cdot d\mathbf{S} = \tfrac{1}{\mu_0} \oint_{\partial \mathcal{S}} \vec{\mathcal{B}} \cdot d\mathbf{l} \ .$$

On the other hand, we know that the current can not cross the capacitor and must accumulate on one of the electrodes.
The problem is solved by identifying the electric field, which is developing due to the accumulated charge,

$$\frac{\partial Q}{\partial t} = \varepsilon_0 \frac{\partial}{\partial t} \int_{\mathcal{V}} \nabla \cdot \vec{\mathcal{E}} dV = \varepsilon_0 \frac{\partial}{\partial t} \int_{\partial \mathcal{V}} \vec{\mathcal{E}} \cdot d\mathbf{S} \equiv I_d \ ,$$

with a *displacement current* I_d.

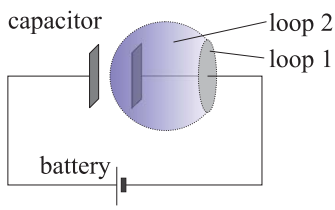

Figure 14.1: Necessity for a displacement current: The magnetic field at the edge of the loops 1 and 2 can not depend on the shape of the chosen surface.

14.1 The fundamental laws of electrodynamics

With these results we can finally summarize the *Maxwell equations* as,

$$\boxed{\begin{array}{lrcl} \text{(i)} & \nabla \times \vec{\mathcal{B}} - \varepsilon_0 \mu_0 \partial_t \vec{\mathcal{E}} & = & \mu_0 \mathbf{j} \\ \text{(ii)} & \nabla \times \vec{\mathcal{E}} + \partial_t \vec{\mathcal{B}} & = & 0 \\ \text{(iii)} & \nabla \cdot \vec{\mathcal{E}} & = & \varepsilon_0^{-1} \varrho \\ \text{(iv)} & \nabla \cdot \vec{\mathcal{B}} & = & 0 \end{array}} \ . \tag{14.6}$$

These equations form the complete basis of the electrodynamical theory initially motivated by the empirical observation of forces acting on features of matter identified

as *charges* and *currents*, that is, the electric (Coulomb) force and magnetic (Lorentz) force,

$$\mathbf{F}_{\text{Lor}} = Q(\vec{\mathcal{E}} + \mathbf{v} \times \vec{\mathcal{B}}) \ , \tag{14.7}$$

where $\vec{\mathcal{E}}$ is a *polar vector* ($\vec{\mathcal{E}} = -\vec{\mathcal{E}}_{\text{mirrored}}$) [1] and $\vec{\mathcal{B}}$ is an *axial vector* ($\vec{\mathcal{B}} = \vec{\mathcal{B}}_{\text{mirrored}}$). The electric field $\vec{\mathcal{E}}$ and the magnetic field $\vec{\mathcal{B}}$ and their field equations were 'invented' to explain the Coulomb-Lorentz force. They are only observable through their action on charged particles. According to the *Helmholtz theorem* discussed in the next section, arbitrary (but well-behaved) field vectors are fully defined by their divergence and rotation properties. That is exactly what Maxwell's equations do with the electric and magnetic fields.

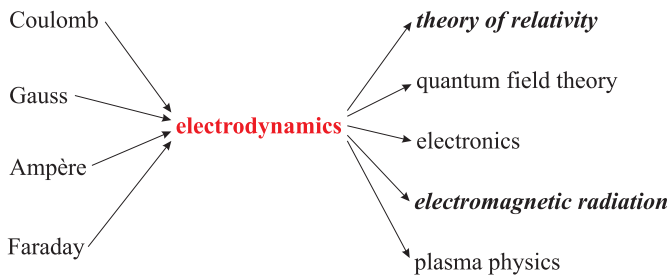

Figure 14.2: Construction and application of the theory of electrodynamics.

Once we know the fundamental laws of electromagnetism [2], we can reverse the reasoning by placing them as postulates and deriving the observable phenomena from them. This will be the procedure of this second part of the course of electromagnetism.

Example 84 (*Derivation of electro- and magnetostatics from Maxwell's equations*): For static systems we can let $\dot{\mathbf{E}} = \dot{\mathbf{B}} = 0$. In particular for the electrostatic case, we ignore currents, $\mathbf{j} = 0$, and for the magnetostatic case we ignore charges, $\varrho = 0$. Maxwell's equations then simplify considerably and can often be replaced by the Poisson equations,

$$-\nabla \cdot \vec{\mathcal{E}} = \nabla \cdot (\nabla \Phi) = \nabla^2 \Phi = -\varepsilon_0^{-1} \varrho$$
$$-\nabla \times \vec{\mathcal{B}} = -\nabla \times (\nabla \times \mathbf{A}) = \nabla^2 \mathbf{A} - \nabla(\cancelto{0}{\nabla \cdot \mathbf{A}}) = -\mathbf{j} \ ,$$

where the divergence of $\mathbf{A}$ is set to zero in the Coulomb gauge.

We will apply Maxwell's equations to solve the Excs. 14.1.5.3 to Excs. 14.1.5.5. In the Excs. 14.1.5.6, 14.1.5.7, and 14.1.5.8 we study implications of a supposed existence of *magnetic charges* or *magnetic monopoles*.

[1] Mirroring means inversion of the dynamic quantities $\mathbf{v} \to -\mathbf{v}$, $\mathbf{F}_{\text{Lor}} \to -\mathbf{F}_{\text{Lor}}$. Examples for polar vectors are $\mathbf{r}$, $\mathbf{p}$, $\vec{\mathcal{E}}$. Examples for axial vectors are $\mathbf{L}$, ω, $\vec{\mathcal{B}}$. We have for axial vectors $\mathbf{a}_i$ and polar vectors $\mathbf{p}_i$, the following relations,

$$\mathbf{a}_1 \times \mathbf{a}_2 = \mathbf{a}_3 \quad , \quad \mathbf{p}_1 \times \mathbf{p}_2 = \mathbf{a}_3 \quad , \quad \mathbf{p}_1 \times \mathbf{a}_2 = \mathbf{p}_3 \ .$$

[2] We note, that Maxwell's laws can be deduced from more fundamental principles, including the conservation laws for energy, momentum, angular momentum, and charge and the relativistic Lorentz transform.

14.1.1 Helmholtz's theorem

The *Helmholtz theorem* says that, knowing the divergence and the rotation of an unknown vector field $\mathbf{F}$, we can reconstruct this field under the condition that the divergence and the rotation disappear sufficiently fast in the infinity [3] and that $|\mathbf{F}|$ disappears at least as fast as $1/r^2$. That is, knowing the scalar field,

$$D(\mathbf{r}) \equiv \nabla \cdot \mathbf{F}(\mathbf{r}) \tag{14.8}$$

and the vectorial field,

$$\mathbf{C}(\mathbf{r}) \equiv \nabla \times \mathbf{F}(\mathbf{r}) \ , \tag{14.9}$$

the field $\mathbf{F}$ is completely defined. Note that obviously, $\nabla \cdot \mathbf{C} = 0$.

To prove this, we show that,

$$\mathbf{F} = -\nabla\Phi + \nabla \times \mathbf{A} \ , \tag{14.10}$$

where

$$\Phi(\mathbf{r}) \equiv \frac{1}{4\pi}\int_{\mathbb{R}^3} \frac{D(\mathbf{r}')}{|\mathbf{r}-\mathbf{r}'|}dV' \qquad \text{and} \qquad \mathbf{A}(\mathbf{r}) \equiv \frac{1}{4\pi}\int_{\mathbb{R}^3} \frac{\mathbf{C}(\mathbf{r}')}{|\mathbf{r}-\mathbf{r}'|}dV' \ , \tag{14.11}$$

meets the requirements (14.8) and (14.9). The divergence is,

$$\begin{aligned}\nabla_{\mathbf{r}} \cdot \mathbf{F} &= -\nabla^2_{\mathbf{r}}\Phi + \cancelto{0}{\nabla_{\mathbf{r}} \cdot \nabla_{\mathbf{r}} \times \mathbf{A}} \\ &= -\frac{1}{4\pi}\int D(\mathbf{r}')\nabla^2_{\mathbf{r}}\left(\frac{1}{|\mathbf{r}-\mathbf{r}'|}\right)dV' = \int D(\mathbf{r}')\delta^3(\mathbf{r}-\mathbf{r}')dV' = D(\mathbf{r}) \ .\end{aligned} \tag{14.12}$$

We verify,

$$\begin{aligned}4\pi\nabla_{\mathbf{r}} \cdot \mathbf{A} &= \int \mathbf{C}(\mathbf{r}') \cdot \nabla_{\mathbf{r}} \frac{1}{|\mathbf{r}-\mathbf{r}'|}dV' = -\int \mathbf{C}(\mathbf{r}') \cdot \nabla_{\mathbf{r}'} \frac{1}{|\mathbf{r}-\mathbf{r}'|}dV' \\ &= -\int \frac{1}{|\mathbf{r}-\mathbf{r}'|}\cancelto{\nabla \cdot \nabla \times \mathbf{F} = 0}{\nabla_{\mathbf{r}'} \cdot \mathbf{C}(\mathbf{r}')}dV' - \oint \frac{1}{|\mathbf{r}-\mathbf{r}'|}\mathbf{C}(\mathbf{r}') \cdot d\mathbf{S}' \longrightarrow 0 \ ,\end{aligned} \tag{14.13}$$

because the surface integral can be arbitrarily reduced by choosing very distant surfaces $\mathbf{r}' \to \infty$. Finally, the rotation is,

$$\begin{aligned}\nabla_{\mathbf{r}} \times \mathbf{F} &= \cancelto{0}{-\nabla_{\mathbf{r}} \times \nabla_{\mathbf{r}}\Phi} + \nabla_{\mathbf{r}} \times \nabla_{\mathbf{r}} \times \mathbf{A} = -\nabla^2_{\mathbf{r}}\mathbf{A} + \nabla_{\mathbf{r}}(\cancelto{0}{\nabla_{\mathbf{r}} \cdot \mathbf{A}}) \\ &= -\frac{1}{4\pi}\int \mathbf{C}(\mathbf{r}')\nabla^2_{\mathbf{r}}\left(\frac{1}{|\mathbf{r}-\mathbf{r}'|}\right)dV' = \int \mathbf{C}(\mathbf{r}')\delta^3(\mathbf{r}-\mathbf{r}')dV' = \mathbf{C}(\mathbf{r}) \ ,\end{aligned} \tag{14.14}$$

using rules of vector analysis summarized in (18.89).

14.1.2 Potentials in electrodynamics

In electrodynamics, two fields are required to describe the Coulomb and Lorentz forces, the electric and the magnetic field. With Helmholtz's theorem we can now

[3] Faster than $1/r$ in order to guarantee that the integrals (14.8) and (14.9) converge.

declare that four equations are necessary and sufficient to completely characterize these fields through the following rotations and divergences,

$$\text{rot}\,\vec{\mathcal{B}} = \ldots \quad , \quad \text{rot}\,\vec{\mathcal{E}} = \ldots \quad , \quad \text{div}\,\vec{\mathcal{E}} = \ldots \quad , \quad \text{div}\,\vec{\mathcal{B}} = \ldots \,. \tag{14.15}$$

These equations are precisely those of Maxwell. In addition, the derivation of the preceding section showed that

> *each vector field which disappears fast enough at long distances can be expressed as the sum of the gradient of a scalar function and rotation of a vector function,*

since,

$$\mathbf{F} = -\nabla\Phi + \nabla\times\mathbf{A} = -\nabla\frac{1}{4\pi}\int_{\mathbb{R}^3}\frac{D(\mathbf{r}')}{|\mathbf{r}-\mathbf{r}'|}dV' + \nabla\times\frac{1}{4\pi}\int_{\mathbb{R}^3}\frac{\mathbf{C}(\mathbf{r}')}{|\mathbf{r}-\mathbf{r}'|}dV' \,. \tag{14.16}$$

The functions Φ and $\mathbf{A}$ are called *scalar potential* and *vector potential*, respectively.

Irrotational fields, that is, fields without vortices are conservative and can be expressed by the gradient of a scalar field,

$$\nabla\times\mathbf{F} = 0 \quad\Longleftrightarrow\quad \mathbf{A} = 0 \quad\Longleftrightarrow\quad \mathbf{F} = -\nabla\Phi \quad\Longleftrightarrow\quad \oint \mathbf{F}\cdot d\mathbf{l} = 0 \,. \tag{14.17}$$

> **Example 85 (*Potentials in electrostatics*):** Electrostatics is an example for an irrotational field, since Maxwell's electrostatic equations are precisely, $\nabla\times\vec{\mathcal{E}} = 0$ and $\nabla\cdot\vec{\mathcal{E}} = D = \varrho/\varepsilon_0$. Therefore, there is an electric potential Φ, such that $-\nabla\Phi = \vec{\mathcal{E}}$.

Fields without divergences, that is, without sources or sinks, can be expressed by the rotation of a vector field,

$$\nabla\cdot\mathbf{F} = 0 \quad\Longleftrightarrow\quad \Phi = 0 \quad\Longleftrightarrow\quad \mathbf{F} = \nabla\times\mathbf{A} \quad\Longleftrightarrow\quad \oint \mathbf{F}\cdot d\mathbf{S} = 0 \,. \tag{14.18}$$

> **Example 86 (*Potentials in magnetostatics*):** Magnetostatics is an example for a field without divergences, since Maxwell's magnetostatic equations are precisely, $\nabla\times\vec{\mathcal{B}} = \mathbf{C} = \mu_0\mathbf{j}$ and $\nabla\cdot\vec{\mathcal{B}} = 0$. Therefore, there is a vector potential $\mathbf{A}$, such that $\nabla\times\mathbf{A} = \vec{\mathcal{B}}$.

We will train the calculation with potentials in Excs. 14.1.5.9 and 14.1.5.10.

14.1.3 The macroscopic Maxwell equations

Electric and magnetic fields and electromagnetic waves survive in vacuum. Maxwell's equations (14.6) are formulated for this environment. On the other hand, we saw in the first part of the course, that charges (11.17) and currents (13.20) that are free or localized in a medium generate a polarization and a magnetization of the medium which can influence the fields.

In this section, we will repeat the derivation of the equations (11.18), respectively, (13.21) in a more stringent way from a microscopic model of matter. We suppose

matter to be made of molecules, each one being constructed from atoms composed of positively charged nuclei orbited by negatively charged electrons. On each of these elementary particles considered as point-like, the electromagnetic field diverges. But doing this statement, we are talking about microscopic electromagnetic fields, which can not be measured by macroscopic probes which, are composed of atoms themselves. We can not directly measure microscopic quantities with a macroscopic apparatus.

According to the model of matter already formulated by Democritus 300 years before Christ, we suppose the space between the elementary particles to be empty, such that we can assume the validity of Maxwell's equations for vacuum in a *microscopic environment*, that is, we believe in the equations (14.6) for the fields $\vec{\mathcal{E}}_{\rm mic}$ and $\vec{\mathcal{B}}_{\rm mic}$, where the subscript *mic* indicates the presence of localized or moving point-like charges. A macroscopic measurement apparatus will always deliver an effective mean value, averaged in space and time, of electromagnetic quantities. We will show in the following [473] how, via spatial averaging of Maxwell's microscopic equations, it is possible to deduce Maxwell's macroscopic equations taking account of polarization and magnetization (11.18), respectively, (13.21).

We obtain the spatial average by smearing out the microscopic quantities within a characteristic volume defined by a spherically symmetric function $f(r)$, chosen to cancel out exponentially at sufficiently large distances [4]. The reach of this function must be adapted to the resolution of the macroscopic device. For example, the resolution limit for devices based on optics will limit the reach of the function $f(r)$ to some 100 nm [5]. The spatial average of the electromagnetic quantities $\vec{\mathcal{E}}_{\rm mic}(\mathbf{r},t)$, $\vec{\mathcal{B}}_{\rm mic}(\mathbf{r},t)$, $\varrho_{\rm mic}(\mathbf{r},t)$, and $\mathbf{j}_{\rm mic}(\mathbf{r},t)$ is then,

$$\langle X_{\rm mic}(\mathbf{r},t)\rangle \equiv \int_{\mathbb{R}^3} d^3\mathbf{r}' f(\mathbf{r}') X_{\rm mic}(\mathbf{r}-\mathbf{r}',t) \ . \tag{14.19}$$

The macroscopic fields are defined as the averages of the respective microscopic fields:

$$\vec{\mathcal{E}}(\mathbf{r},t) \equiv \langle \vec{\mathcal{E}}_{\rm mic}(\mathbf{r},t)\rangle \qquad \text{and} \qquad \vec{\mathcal{B}}(\mathbf{r},t) \equiv \langle \vec{\mathcal{B}}_{\rm mic}(\mathbf{r},t)\rangle \ , \tag{14.20}$$

where macroscopic quantities do not have the subscript *mic*.

Now, taking the averages of the microscopic Maxwell equations, we obtain,

$$\begin{array}{lrcl} \text{(i)} & \langle \nabla\times\vec{\mathcal{B}}_{\rm mic}(\mathbf{r},t)\rangle - \varepsilon_0\mu_0 \left\langle \frac{\partial \vec{\mathcal{E}}_{\rm mic}(\mathbf{r},t)}{\partial t}\right\rangle & = & \mu_0 \langle \mathbf{j}_{\rm mic}(\mathbf{r},t)\rangle \\ \text{(ii)} & \langle \nabla\times\vec{\mathcal{E}}_{\rm mic}(\mathbf{r},t)\rangle + \left\langle \frac{\partial \vec{\mathcal{B}}_{\rm mic}(\mathbf{r},t)}{\partial t}\right\rangle & = & 0 \\ \text{(iii)} & \langle \nabla\cdot\vec{\mathcal{E}}_{\rm mic}(\mathbf{r},t)\rangle & = & \frac{1}{\varepsilon_0}\langle \varrho_{\rm mic}(\mathbf{r},t)\rangle \\ \text{(iv)} & \langle \nabla\cdot\vec{\mathcal{B}}_{\rm mic}(\mathbf{r},t)\rangle & = & 0 \end{array} \ . \tag{14.21}$$

However,

$$\begin{aligned} \langle \nabla\cdot\vec{\mathcal{E}}_{\rm mic}(\mathbf{r},t)\rangle &= \nabla\cdot\langle \vec{\mathcal{E}}_{\rm mic}(\mathbf{r},t)\rangle = \nabla\cdot\vec{\mathcal{E}}(\mathbf{r},t) \\ \langle \nabla\times\vec{\mathcal{E}}_{\rm mic}(\mathbf{r},t)\rangle &= \nabla\times\langle \vec{\mathcal{E}}_{\rm mic}(\mathbf{r},t)\rangle = \nabla\times\vec{\mathcal{E}}(\mathbf{r},t) \ , \end{aligned} \tag{14.22}$$

[4] An example for a normalized smoothing function is $f(\mathbf{r}') \equiv (a/\pi)^{3/2} e^{-ar'^2}$, as it satisfies $\int_{\mathbb{R}^3} f(\mathbf{r}') d^3r' = 1$.

[5] In contrast, X-rays with a resolution of about 10 nm allow for an analysis of the microscopic structure of matter.

and analogously for $\vec{\mathcal{B}}_{\rm mic}$, since ∇ acts only on $\mathbf{r}$ and not on the integration variable $\mathbf{r}'$. On the other hand, the partial time-derivative also does not act on $\mathbf{r}$ nor on $\mathbf{r}'$,

$$\left\langle \frac{\partial \vec{\mathcal{E}}_{\rm mic}(\mathbf{r},t)}{\partial t} \right\rangle = \frac{\partial}{\partial t}\langle \vec{\mathcal{E}}_{\rm mic}(\mathbf{r},t)\rangle = \frac{\partial \vec{\mathcal{E}}(\mathbf{r},t)}{\partial t} \ , \tag{14.23}$$

and analogously for $\vec{\mathcal{B}}_{\rm mic}$. Thus, we already deduced the two homogeneous macroscopic Maxwell equations (ii) and (iv), and the set of equations (14.21) simplifies to:

$$\begin{array}{lrcl} \text{(i)} & \nabla\times\vec{\mathcal{B}}(\mathbf{r},t) - \varepsilon_0\mu_0\partial_t\vec{\mathcal{E}}(\mathbf{r},t) & = & \mu\langle \mathbf{j}_{\rm mic}(\mathbf{r},t)\rangle \\ \text{(ii)} & \nabla\times\vec{\mathcal{E}}(\mathbf{r},t) + \partial_t\vec{\mathcal{B}}(\mathbf{r},t) & = & 0 \\ \text{(iii)} & \nabla\cdot\vec{\mathcal{E}}(\mathbf{r},t) & = & \frac{1}{\varepsilon_0}\langle \varrho_{\rm mic}(\mathbf{r},t)\rangle \\ \text{(iv)} & \nabla\cdot\vec{\mathcal{B}}(\mathbf{r},t) & = & 0 \end{array} \ , \tag{14.24}$$

but we still need to calculate $\langle \varrho_{\rm mic}(\mathbf{r},t)\rangle$ and $\langle \mathbf{j}_{\rm mic}(\mathbf{r},t)\rangle$.

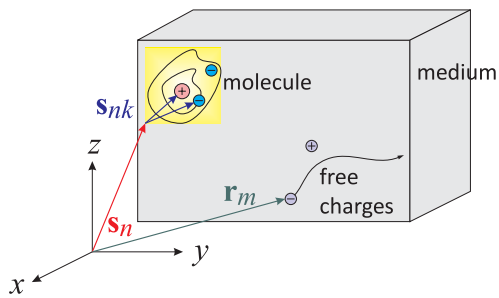

Figure 14.3: Charges localized in molecules and free charges.

To do so we imagine that, as illustrated in Fig. 14.3, there are N charges in each molecule of the material and, for simplicity, we also assume the material to be a pure substance, that is to say, composed of identical molecules. Be $\vec{\mathcal{S}}_n$ the position of the n-th molecule, measured from an arbitrary origin of the coordinate system. Thus, the k-th charge q_{kn} of the n-th molecule is at the point $\vec{\mathcal{S}}_{kn}$, with respect to the position vector of the molecule $\vec{\mathcal{S}}_n$. This means that, with respect to the origin of the coordinate system, the position of the charge q_{kn} is given by $\vec{\mathcal{S}}_{kn} + \vec{\mathcal{S}}_n$. We will also allow for free charges, q_m, at positions $\mathbf{r}_m$. As all the charges can move, all their positions $\mathbf{r}_m(t)$, $\vec{\mathcal{S}}_n(t)$, and $\vec{\mathcal{S}}_{kn}(t)$ must be considered as functions of time.

First, we will calculate the charge density,

$$\varrho_{\rm mic}(\mathbf{r},t) = \sum_m q_m\delta^{(3)}(\mathbf{r}-\mathbf{r}_m) + \sum_{n,k} q_{kn}\delta^{(3)}(\mathbf{r}-\vec{\mathcal{S}}_{kn}-\vec{\mathcal{S}}_n) \ , \tag{14.25}$$

and using the definition of the spatial average (14.19),

$$\langle \varrho_{\rm mic}(\mathbf{r},t)\rangle = \cancelto{\varrho(\mathbf{r},t)}{\sum_m q_m f(\mathbf{r}-\mathbf{r}_m)} + \sum_{n,k} q_{kn} f(\mathbf{r}-\vec{\mathcal{S}}_{kn}-\vec{\mathcal{S}}_n) \ , \tag{14.26}$$

where we recall, that the first term represents the macroscopic density of free charges $\varrho(\mathbf{r},t)$. Typically, $|\vec{\mathcal{S}}_{kn}|$ is on the order of some Angströms only, and therefore the 'smoothing' function $f(\mathbf{r}-\vec{\mathcal{S}}_{kn}-\vec{\mathcal{S}}_n)$ does not appreciably differ from $f(\mathbf{r}-\vec{\mathcal{S}}_n)$, such that we can approximate:

$$f(\mathbf{r}-\vec{\mathcal{S}}_{kn}-\vec{\mathcal{S}}_n) \simeq f(\mathbf{r}-\vec{\mathcal{S}}_n) - \vec{\mathcal{S}}_{kn}\cdot\nabla f(\mathbf{r}-\vec{\mathcal{S}}_n) + \tfrac{1}{2}(\vec{\mathcal{S}}_{kn}\cdot\nabla)^2 f(\mathbf{r}-\vec{\mathcal{S}}_n) \ , \tag{14.27}$$

and, with this approximation, obtain,

$$\begin{aligned}
\langle\varrho_{\rm mic}(\mathbf{r},t)\rangle &\simeq \varrho(\mathbf{r},t) + \sum_{n,k} q_{kn} f(\mathbf{r}-\vec{\mathcal{S}}_n) - \sum_{n,k} q_{kn}\vec{\mathcal{S}}_{kn}\cdot\nabla f(\mathbf{r}-\vec{\mathcal{S}}_n) \\
&\quad + \sum_{n,k} q_{kn}\tfrac{1}{2}(\vec{\mathcal{S}}_{kn}\cdot\nabla)^2 f(\mathbf{r}-\vec{\mathcal{S}}_n) \\
&= \varrho(\mathbf{r},t) + \cancelto{0}{\sum_{n,k} q_{kn}} f(\mathbf{r}-\vec{\mathcal{S}}_n) - \nabla\cdot\sum_n\left(\sum_k q_{kn}\vec{\mathcal{S}}_{kn}\right) f(\mathbf{r}-\vec{\mathcal{S}}_n) \\
&\quad + \tfrac{1}{6}\sum_n \nabla\cdot\left[\cancelto{0}{\left(3\sum_k q_{kn}\vec{\mathcal{S}}_{kn}\vec{\mathcal{S}}_{kn}\right)}\cdot\nabla f(\mathbf{r}-\vec{\mathcal{S}}_n)\right] \\
&= \varrho(\mathbf{r},t) - \nabla\cdot\sum_n \mathbf{d}_n f(\mathbf{r}-\vec{\mathcal{S}}_n) \ .
\end{aligned} \tag{14.28}$$

In the last line we assumed that each molecule is neutral,

$$\sum_k q_{kn} = 0 \ , \tag{14.29}$$

we use the definition of the electric dipole moment of the n-th molecule,

$$\mathbf{d}_n = \sum_k q_{kn}\vec{\mathcal{S}}_{kn} \ , \tag{14.30}$$

and we suppose, to simplify our calculations below, that the electric quadrupole momentum of the n-th molecule,

$$\overleftrightarrow{Q}_n \equiv 3\sum_k q_{kn}\vec{\mathcal{S}}_{kn}\vec{\mathcal{S}}_{kn} \stackrel{!}{=} \overleftrightarrow{0} \ , \tag{14.31}$$

is zero, that is, that the molecules of the material have zero electric quadrupolar momentum. As shown in the discussion of the relationship (11.12), the polarization of a medium is the sum of the individual instantaneous dipole moments of each molecule,

$$\vec{\mathcal{P}}_{\rm mic}(\mathbf{r},t) = \sum_n \mathbf{d}_n\delta^{(3)}(\mathbf{r}-\vec{\mathcal{S}}_n) \ , \tag{14.32}$$

With these observations, we conclude that,

$$\langle\vec{\mathcal{P}}_{\rm mic}(\mathbf{r},t)\rangle = \sum_n \mathbf{d}_n f(\mathbf{r}-\vec{\mathcal{S}}_n) \ , \tag{14.33}$$

and, identifying this quantity in the expression (14.28), we get,

$$\langle \varrho_{\rm mic}(\mathbf{r},t)\rangle \simeq \varrho(\mathbf{r},t) - \nabla\cdot\vec{\mathcal{P}}(\mathbf{r},t)\ , \tag{14.34}$$

where we introduced the abbreviation, $\vec{\mathcal{P}}(\mathbf{r},t) \equiv \langle \vec{\mathcal{P}}_{\rm mic}(\mathbf{r},t)\rangle$, analogously to the electrostatic case. The macroscopic Gauß law (14.21)(iii) becomes then,

$$\nabla\cdot\vec{\mathcal{E}}(\mathbf{r},t) = \tfrac{1}{\varepsilon_0}[\varrho(\mathbf{r},t) - \nabla\cdot\vec{\mathcal{P}}(\mathbf{r},t)]\ , \tag{14.35}$$

that is,

$$\nabla\cdot\vec{\mathcal{D}}(\mathbf{r},t) = \varrho(\mathbf{r},t)\ , \tag{14.36}$$

where we defined the field of *electric displacement* as,

$$\boxed{\vec{\mathcal{D}}(\mathbf{r},t) \equiv \varepsilon_0\vec{\mathcal{E}}(\mathbf{r},t) + \vec{\mathcal{P}}(\mathbf{r},t)}\ . \tag{14.37}$$

Let us now calculate, $\langle \mathbf{j}_{\rm mic}(\mathbf{r},t)\rangle$. From the very definition of the microscopic current we have,

$$\mathbf{j}_{\rm mic}(\mathbf{r},t) \equiv \varrho_{\rm mic}(\mathbf{r},t)\mathbf{v}_{\rm mic}(\mathbf{r},t)\ , \tag{14.38}$$

where $\mathbf{v}_{\rm mic}(\mathbf{r},t)$ is the velocity field of the charges of the material medium. By inserting the expression (14.25) for the charge density,

$$\begin{aligned}\mathbf{j}_{\rm mic}(\mathbf{r},t) &= \sum_m q_m\delta^{(3)}(\mathbf{r}-\mathbf{r}_m)\mathbf{v}_{\rm mic}(\mathbf{r},t) + \sum_{n,k} q_{kn}\delta^{(3)}(\mathbf{r}-\vec{\mathcal{S}}_{kn}-\vec{\mathcal{S}}_n)\mathbf{v}_{\rm mic}(\mathbf{r},t) \\ &= \sum_m q_m\dot{\mathbf{r}}_m\delta^{(3)}(\mathbf{r}-\mathbf{r}_m) + \sum_{n,k} q_{kn}(\dot{\mathbf{s}}_{kn}+\dot{\mathbf{s}}_n)\delta^{(3)}(\mathbf{r}-\vec{\mathcal{S}}_{kn}-\vec{\mathcal{S}}_n)\ ,\end{aligned} \tag{14.39}$$

where the field of charge velocities calculated exactly at the location of the m-th charge gives the value of its velocity,

$$\delta^{(3)}(\mathbf{r}-\mathbf{x})\mathbf{v}_{\rm mic}(\mathbf{r},t) = \delta^{(3)}(\mathbf{r}-\mathbf{x})\dot{\mathbf{x}}\ .$$

We can now evaluate the average (14.19),

$$\langle \mathbf{j}_{\rm mic}(\mathbf{r},t)\rangle = \underbrace{\sum_m q_m\dot{\mathbf{r}}_m f(\mathbf{r}-\mathbf{r}_m)}_{\mathbf{j}(\mathbf{r},t)} + \sum_{n,k} q_{kn}(\dot{\mathbf{s}}_{kn}+\dot{\mathbf{s}}_n)f(\mathbf{r}-\vec{\mathcal{S}}_{kn}-\vec{\mathcal{S}}_n)\ , \tag{14.40}$$

where we recall, that the first term represents the macroscopic density of free current $\mathbf{j}(\mathbf{r},t)$. Approximating again,

$$f(\mathbf{r}-\vec{\mathcal{S}}_{kn}-\vec{\mathcal{S}}_n) \simeq f(\mathbf{r}-\vec{\mathcal{S}}_n) - \vec{\mathcal{S}}_{kn}\cdot\nabla f(\mathbf{r}-\vec{\mathcal{S}}_n)\ , \tag{14.41}$$

and, with this approximation, we obtain,

$$\langle \mathbf{j}_{\rm mic}(\mathbf{r},t)\rangle \simeq \mathbf{j}(\mathbf{r},t) + \sum_{n,k} q_{kn}(\dot{\mathbf{s}}_{kn}+\dot{\mathbf{s}}_n)f(\mathbf{r}-\vec{\mathcal{S}}_n) - \sum_{k,n} q_{kn}(\dot{\mathbf{s}}_{kn}+\dot{\mathbf{s}}_n)\vec{\mathcal{S}}_{kn}\cdot\nabla f(\mathbf{r}-\vec{\mathcal{S}}_n)\ . \tag{14.42}$$

As we are now working to obtain the macroscopic Ampère-Maxwell equation, we need to let appear in the above results the rotation of the magnetization, in addition to the time derivative of the polarization. Recalling that the magnetic dipole moment of the n-th molecule $\vec{\mu}_n$ is defined by equation (12.43) as,

$$\vec{\mu}_n \equiv \tfrac{1}{2}\sum_k q_{kn}\vec{\mathcal{S}}_{kn} \times \dot{\mathbf{s}}_{kn} \ , \tag{14.43}$$

based on the relationship (13.15), we can write magnetization as the sum of the instantaneous magnetic dipole moments of every molecule,

$$\vec{\mathcal{M}}_{\text{mic}}(\mathbf{r},t) = \sum_n \vec{\mu}_n \delta^{(3)}(\mathbf{r}-\vec{\mathcal{S}}_n) \ , \tag{14.44}$$

Thus, we want to identify, in the expression for $\langle \mathbf{j}_{\text{mic}}(\mathbf{r},t)\rangle$, the rotation of $\langle \vec{\mathcal{M}}_{\text{mic}}(\mathbf{r},t)\rangle$:

$$\begin{aligned}\nabla \times \langle \vec{\mathcal{M}}_{\text{mic}}(\mathbf{r},t)\rangle &= \nabla \times \sum_n \vec{\mu}_n f(\mathbf{r}-\vec{\mathcal{S}}_n) = -\sum_n \vec{\mu}_n \times \nabla f(\mathbf{r}-\vec{\mathcal{S}}_n) \\ &= -\tfrac{1}{2}\sum_{n,k} q_{kn}(\vec{\mathcal{S}}_{kn}\times\dot{\mathbf{s}}_{kn})\times\nabla f(\mathbf{r}-\vec{\mathcal{S}}_n) \\ &= -\tfrac{1}{2}\sum_{n,k} q_{kn}\dot{\mathbf{s}}_{kn}[\vec{\mathcal{S}}_{kn}\cdot\nabla f(\mathbf{r}-\vec{\mathcal{S}}_n)] + \tfrac{1}{2}\sum_{n,k} q_{kn}\vec{\mathcal{S}}_{kn}[\dot{\mathbf{s}}_{kn}\cdot\nabla f(\mathbf{r}-\vec{\mathcal{S}}_n)] \ ,\end{aligned} \tag{14.45}$$

using the BAC-CAB rule (18.88)(v), and continuing,

$$\begin{aligned}\nabla \times \langle \vec{\mathcal{M}}_{\text{mic}}(\mathbf{r},t)\rangle &= -\sum_{n,k} q_{kn}\dot{\mathbf{s}}_{kn}\vec{\mathcal{S}}_{kn}\cdot\nabla f(\mathbf{r}-\vec{\mathcal{S}}_n) + \tfrac{1}{2}\sum_n\left[\sum_k q_{kn}\frac{d}{dt}(\vec{\mathcal{S}}_{kn}\vec{\mathcal{S}}_{kn})\right]\cdot\nabla f(\mathbf{r}-\vec{\mathcal{S}}_n) \\ &= -\sum_{n,k} q_{kn}\dot{\mathbf{s}}_{kn}\vec{\mathcal{S}}_{kn}\cdot\nabla f(\mathbf{r}-\vec{\mathcal{S}}_n) + \tfrac{1}{6}\sum_n\left[\frac{d}{dt}\left(\cancelto{0}{3\sum_k q_{kn}\vec{\mathcal{S}}_{kn}\vec{\mathcal{S}}_{kn}}\right)\right]\cdot\nabla f(\mathbf{r}-\vec{\mathcal{S}}_n) \ .\end{aligned} \tag{14.46}$$

The second term is zero again because, as in (14.31), we are assuming that $\overset{\leftrightarrow}{Q}_n \overset{!}{=} \overset{\leftrightarrow}{0}$. Continuing the calculation (14.42),

$$\begin{aligned}\langle \mathbf{j}_{\text{mic}}(\mathbf{r},t)\rangle &= \mathbf{j}(\mathbf{r},t) + \sum_{n,k} q_{kn}\dot{\mathbf{s}}_{kn} f(\mathbf{r}-\vec{\mathcal{S}}_n) + \cancelto{0}{\sum_{n,k} q_{kn}}\,\dot{\mathbf{s}}_n f(\mathbf{r}-\vec{\mathcal{S}}_n) \\ &\quad + \nabla\times\langle \vec{\mathcal{M}}_{\text{mic}}(\mathbf{r},t)\rangle - \sum_{n,k} q_{kn}\dot{\mathbf{s}}_n\vec{\mathcal{S}}_{kn}\cdot\nabla f(\mathbf{r}-\vec{\mathcal{S}}_n) \ .\end{aligned} \tag{14.47}$$

The third term disappears, because again we are assuming that the total charge of every molecule is zero, $\sum_k q_{kn} = 0$. The partial temporal derivative of the polarization is given by the expression (14.33),

$$\begin{aligned}\frac{\partial\vec{\mathcal{P}}(\mathbf{r},t)}{\partial t} &= \frac{\partial}{\partial t}\sum_{n,k} q_{kn}\vec{\mathcal{S}}_{kn} f(\mathbf{r}-\vec{\mathcal{S}}_n) = \sum_{n,k} q_{kn}\frac{\partial\vec{\mathcal{S}}_{kn}}{\partial t} f(\mathbf{r}-\vec{\mathcal{S}}_n) + \sum_{n,k} q_{kn}\vec{\mathcal{S}}_{kn}\frac{\partial}{\partial t} f(\mathbf{r}-\vec{\mathcal{S}}_n) \\ &= \sum_{n,k} q_{kn}\dot{\mathbf{s}}_{kn} f(\mathbf{r}-\vec{\mathcal{S}}_n) - \sum_{n,k} q_{kn}\vec{\mathcal{S}}_{kn}\dot{\mathbf{s}}_n\cdot\nabla f(\mathbf{r}-\vec{\mathcal{S}}_n) \ .\end{aligned} \tag{14.48}$$

We can use this result to replace the second term in equation (14.47),

$$\langle \mathbf{j}_{\rm mic}(\mathbf{r},t)\rangle \simeq \mathbf{j}(\mathbf{r},t) + \nabla\times\langle\vec{\mathcal{M}}_{\rm mic}(\mathbf{r},t)\rangle + \frac{\partial\vec{\mathcal{P}}(\mathbf{r},t)}{\partial t} + \sum_{n,k} q_{kn}[\vec{\mathcal{S}}_{kn}\dot{\mathbf{s}}_n\cdot\nabla f(\mathbf{r}-\vec{\mathcal{S}}_n) - \dot{\mathbf{s}}_n\vec{\mathcal{S}}_{kn}\cdot\nabla f(\mathbf{r}-\vec{\mathcal{S}}_n)] \ . \tag{14.49}$$

Note, that the last term of this expression is identical to (14.45) with the difference, that the electronic velocities $\dot{\mathbf{s}}_{kn}$ of that expression or now replaced by the molecular velocities $\dot{\mathbf{s}}_n$.

Now let us suppose that the material itself is not in motion, so that the (averaged absolute) velocities of the molecules, $\dot{\mathbf{s}}_n$, are much smaller than the (averaged absolute) velocities of the charges in every molecule, $\dot{\mathbf{s}}_{kn}$. With this, we can neglect the last term of the above equation in comparison to the first,

$$\mu_0\langle \mathbf{j}_{\rm mic}(\mathbf{r},t)\rangle \simeq \mu_0\mathbf{j}(\mathbf{r},t) + \mu_0\frac{\partial\vec{\mathcal{P}}(\mathbf{r},t)}{\partial t} + \mu_0\nabla\times\langle\vec{\mathcal{M}}_{\rm mic}(\mathbf{r},t)\rangle \ . \tag{14.50}$$

The Ampère-Maxwell equation, then reads in its spatial average (14.21)(i),

$$\begin{aligned}\nabla\times\vec{\mathcal{B}}(\mathbf{r},t) &= \mu_0\langle\mathbf{j}_{\rm mic}(\mathbf{r},t)\rangle + \varepsilon_0\mu_0\left\langle\frac{\partial\vec{\mathcal{E}}_{\rm mic}(\mathbf{r},t)}{\partial t}\right\rangle \\ &= \mu_0\mathbf{j}(\mathbf{r},t) + \mu_0\frac{\partial\vec{\mathcal{P}}(\mathbf{r},t)}{\partial t} + \mu_0\nabla\times\langle\vec{\mathcal{M}}_{\rm mic}(\mathbf{r},t)\rangle + \varepsilon_0\mu_0\frac{\partial\vec{\mathcal{E}}(\mathbf{r},t)}{\partial t} \ ,\end{aligned} \tag{14.51}$$

or,

$$\nabla\times[\vec{\mathcal{B}}(\mathbf{r},t) - \mu_0\nabla\times\langle\vec{\mathcal{M}}_{\rm mic}(\mathbf{r},t)\rangle] = \mu_0\mathbf{j}(\mathbf{r},t) + \mu_0\frac{\partial}{\partial t}[\varepsilon\vec{\mathcal{E}}(\mathbf{r},t) + \vec{\mathcal{P}}(\mathbf{r},t)] \ , \tag{14.52}$$

Introducing the abbreviation,

$$\vec{\mathcal{M}}(\mathbf{r},t) \equiv \langle\vec{\mathcal{M}}_{\rm mic}(\mathbf{r},t)\rangle \ , \tag{14.53}$$

defining *magnetic excitation* field,

$$\boxed{\vec{\mathcal{H}}(\mathbf{r},t) \equiv \tfrac{1}{\mu_0}\vec{\mathcal{B}}(\mathbf{r},t) - \vec{\mathcal{M}}(\mathbf{r},t)} \ , \tag{14.54}$$

and recognizing the electric displacement field, $\vec{\mathcal{D}}(\mathbf{r},t) = \varepsilon_0\vec{\mathcal{E}}(\mathbf{r},t) + \vec{\mathcal{P}}(\mathbf{r},t)$, we obtain,

$$\nabla\times\vec{\mathcal{H}}(\mathbf{r},t) = \frac{\partial\vec{\mathcal{D}}(\mathbf{r},t)}{\partial t} + \mathbf{j}(\mathbf{r},t) \ , \tag{14.55}$$

which is the macroscopic Ampère-Maxwell equation.

The above derivations show that $\vec{\mathcal{P}}$ and $\vec{\mathcal{M}}$ do not exist as exact physical quantities in the microscopic sense. They are artifacts of a process of smearing out the microscopic charges and currents over smooth macroscopic distributions, with the aim of facilitating the calculation with macroscopic quantities.

14.1.4 The fundamental laws in polarizable and magnetizable materials

The derivations made in the previous chapter led to Maxwell's macroscopic equations, which correspond to the Maxwell equations for vacuum complemented by material equations characterizing the medium. In short,

$$\boxed{\begin{array}{llcl} \text{(i)} & \nabla \times \vec{\mathcal{H}} & = & \partial_t \vec{\mathcal{D}} + \mathbf{j} \\ \text{(ii)} & \nabla \times \vec{\mathcal{E}} & = & -\partial_t \vec{\mathcal{B}} \\ \text{(iii)} & \nabla \cdot \vec{\mathcal{D}} & = & \varrho \\ \text{(iv)} & \nabla \cdot \vec{\mathcal{B}} & = & 0 \end{array}} \; . \tag{14.56}$$

The fields are related by the macroscopic *polarization* and *magnetization*,

$$\vec{\mathcal{P}} = \vec{\mathcal{D}} - \varepsilon_0 \vec{\mathcal{E}} \qquad \text{and} \qquad \vec{\mathcal{M}} = \mu_0^{-1} \vec{\mathcal{B}} - \vec{\mathcal{H}} \; . \tag{14.57}$$

For a given free charge density distribution $\varrho(\mathbf{r}, t)$ and a free current density distribution $\mathbf{j}(\mathbf{r}, t)$, the above six equations (14.56) and (14.57) define the six components of the fields unambiguously. In vacuum $\varepsilon_0 \vec{\mathcal{E}} = \vec{\mathcal{D}}$ and $\mu_0^{-1} \vec{\mathcal{B}} = \vec{\mathcal{H}}$ Maxwell's equations simplify. In material media, however, the secondary quantities $\vec{\mathcal{D}}$ and $\vec{\mathcal{H}}$ are not equal to the fields.

Depending on its structure, a medium may have (or not) bound or free charges and currents, responding in a specific way to applied electric and magnetic fields and giving rise to a wide variety of features. For example, a medium is *non-conductive* when, even in the presence of electric fields applied to the medium, there is no flux of current. A medium is *linear* when the polarization and the magnetization depend linearly on the electric and magnetic fields, respectively. A medium is *homogeneous* when the susceptibilities do not vary across the medium. When the directions of induced polarization and magnetization are parallel, respectively, to the electric and magnetic fields, the medium is said to be *isotropic*, otherwise it is said to be *anisotropic*.

Depending on the type of material and its properties the equations do sometimes simplify. For example, we have for a

medium	condition
dielectric	$\vec{\mathcal{D}} = \varepsilon \vec{\mathcal{E}}$, $\vec{\mathcal{P}} = \chi_\varepsilon \varepsilon_0 \vec{\mathcal{E}}$, $\varepsilon = 1 + \chi_\varepsilon$
non-linear dielectric	$\vec{\mathcal{D}} = \vec{\mathcal{D}}(\vec{\mathcal{E}}) \nsim \vec{\mathcal{E}}$
dia- and paramagnetic	$\vec{\mathcal{B}} = \mu \vec{\mathcal{H}}$, $\vec{\mathcal{M}} = \chi_\mu \vec{\mathcal{H}}$, $\mu = 1 + \chi_\mu$
non-linear magnetic	$\vec{\mathcal{B}} = \vec{\mathcal{B}}(\vec{\mathcal{H}}) \nsim \vec{\mathcal{B}}$
neutral	$\rho = 0$
isolating	$\mathbf{j} = 0$
ohmic	$\mathbf{j} = \sigma \vec{\mathcal{E}}$
non ohmic	$\mathbf{j} = \mathbf{j}(\vec{\mathcal{E}}) \nsim \vec{\mathcal{E}}$

The material equations define the material constants, that is, the *permittivity* ε, the *permeability* μ, and the *conductivity* σ. These quantities are scalar for isotropic media and tensors for anisotropic media. Resolve the Exc. 14.1.5.11.

14.1.5 Exercises

14.1.5.1 Ex: Displacement current

Consider a straight big conducting wire of radius a with a small transverse gap of width $w \ll a$ carrying a constant current I. Find the magnetic field in the gap for distances of the symmetry axis $r < a$ as a function of the current.

14.1.5.2 Ex: Plate capacitor

A disk-shaped plate capacitor with radius R, distance d, and $\varepsilon = 1$ is charged by a constant current I.
a. Calculate from the continuity equation, neglecting edge effects, the temporal variation of the charges on the plates $q(t)$, respectively, $-q(t)$.
b. Calculate the temporal variation of the electric field between the plates and Maxwell's displacement current density.
c. Calculate the magnetic field $\vec{\mathcal{B}}$ between the plates along a circular path Γ inside ($\rho < R$) and outside ($\rho > R$) the capacitor.
d. Show that the $\vec{\mathcal{B}}$-field between the plates is, for $\rho > R$, equal to the $\vec{\mathcal{B}}$-field produced by the charging current I around the conductors feeding the capacitor.

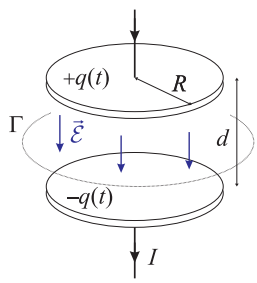

Figure 14.4: Plate capacitor.

14.1.5.3 Ex: Maxwell's equations for a particular charge and current density distribution

Determine the charge and current density distributions producing the fields,

$$\vec{\mathcal{E}}(\mathbf{r},t) = -\frac{1}{4\pi\varepsilon_0}\frac{q}{r^2}\Theta(vt-r)\hat{\mathbf{e}}_r \qquad \text{and} \qquad \vec{\mathcal{B}}(\mathbf{r},t) = 0 \ ,$$

where Θ is the Heavyside function and v is a constant. Show that the fields satisfy all Maxwell equations. Describe the physical situation producing these fields.

14.1.5.4 Ex: Atomic diamagnetism

An electron (charge q) orbits a nucleus (charge Q) at a distance r, the centripetal acceleration being provided by the Coulomb attraction. Now, a small magnetic field $d\mathcal{B}$ is slowly ramped up, perpendicular to the plane of the orbit. Show that the increase of the kinetic energy, dT, transferred to the electron via the induced electric field, is exactly the one necessary to keep the circular motion on the original radius r. (This allows us, in the discussion of *diamagnetism*, to assume a fixed electron radius.)

14.1.5.5 Ex: Variable charge with constant current

Suppose that $\mathbf{j}(\mathbf{r})$ is constant over time, but not $\varrho(\mathbf{r}, t)$. Such conditions can prevail, for example, during the charging process of a capacitor.
a. Show that the charge density at any point is a linear function of time: $\varrho(\mathbf{r}, t) = \varrho(\mathbf{r}, 0) + \dot{\varrho}(\mathbf{r}, 0)t$.
b. Despite the fact that this configuration is not electrostatic or magnetostatic, both the Coulomb law and the Biot-Savart law remain valid, since they satisfy Maxwell's equations. Show in particular that,

$$\vec{\mathcal{B}}(\mathbf{r}) = \frac{\mu_0}{4\pi} \int \frac{\mathbf{j}(\mathbf{r}') \times \hat{\mathbf{e}}_R}{R^2} d^3r'$$

with $R \equiv |\mathbf{r} - \mathbf{r}'|$ obeys Ampère's law including Maxwell's displacement term.

14.1.5.6 Ex: Force on magnetic monopoles

In free space Maxwell's equations are perfectly symmetric under the operation $\vec{\mathcal{E}} \to \vec{\mathcal{B}} \to -\varepsilon_0\mu_0\vec{\mathcal{E}}$. But the existence of charges and electric currents breaks this symmetry. The introduction of 'magnetic charges' and 'magnetic currents' would restore the symmetry, but they were never observed [6]. In this exercise we assume the existence of a 'Coulomb law' for 'magnetic charges' q_m,

$$\mathbf{F} = \frac{\mu_0}{4\pi} \frac{q_{m_1} q_{m_2}}{|\mathbf{r} - \mathbf{r}'|^3} (\mathbf{r} - \mathbf{r}') \ .$$

a. Find the force law for a magnetic charge moving with velocity $\mathbf{v}$ through electric and magnetic fields $\vec{\mathcal{E}}$ and $\vec{\mathcal{B}}$ [777].
b. One of the methods used to search for magnetic monopoles in laboratory [150] consists of passing them through a wire loop with the self-inductance L. What current would be induced in the circuit by the passage of a magnetic monopole?

[6] Dirac showed that the existence of magnetic charges would explain the quantization of charge.

14.1.5.7 Ex: Duality transform

a. In the case of existing magnetic charges and currents, Maxwell's equations would take the form,

$$\begin{aligned}
&\text{(i)} && \nabla \times \vec{\mathcal{B}} - \varepsilon_0 \mu_0 \partial_t \vec{\mathcal{E}} = \mu_0 \mathbf{j}_e \\
&\text{(ii)} && \nabla \times \vec{\mathcal{E}} + \partial_t \vec{\mathcal{B}} = -\mu_0 \mathbf{j}_m \\
&\text{(iii)} && \nabla \cdot \vec{\mathcal{E}} = \varepsilon_0^{-1} \varrho_e \\
&\text{(iv)} && \nabla \cdot \vec{\mathcal{B}} = \mu_0 \varrho_m \ .
\end{aligned}$$

Show that these equations are invariant under the *duality transform* given by,

$$\begin{pmatrix} \vec{\mathcal{E}}' \\ c\vec{\mathcal{B}}' \end{pmatrix} = \begin{pmatrix} \cos\alpha & \sin\alpha \\ -\sin\alpha & \cos\alpha \end{pmatrix} \begin{pmatrix} \vec{\mathcal{E}} \\ c\vec{\mathcal{B}} \end{pmatrix} \quad , \quad \begin{pmatrix} cq_e' \\ q_m' \end{pmatrix} = \begin{pmatrix} \cos\alpha & \sin\alpha \\ -\sin\alpha & \cos\alpha \end{pmatrix} \begin{pmatrix} cq_e \\ q_m \end{pmatrix} \ ,$$

where α is an arbitrary rotation angle in the $\mathcal{E}$-$\mathcal{B}$ space. Densities of charges and currents transform in the same way as q_e and q_m. This means, in particular, that if you would know the fields produced by an electric charge configuration, you could immediately (using $\alpha = 90°$) deduce the fields produced by a corresponding arrangement of the magnetic charge.
b. Show that the force law derived in Exc. 14.1.5.6,

$$\mathbf{F} = q_e(\vec{\mathcal{E}} + \mathbf{v} \times \vec{\mathcal{B}}) + q_m(\vec{\mathcal{B}} - \tfrac{1}{c^2}\mathbf{v} \times \vec{\mathcal{E}})$$

is also invariant under duality transformation.

14.1.5.8 Ex: Quantization of magnetic monopoles

a. Show that the vector potential,

$$\mathbf{A} = \frac{g(1-\cos\theta)}{r\sin\theta}\hat{\mathbf{e}}_\phi$$

produces a Coulomb-type magnetic field [749].
b. Calculate the magnetic flux across the solid angle delimited by the polar angle θ.
c. Calculate the vector potential $\mathbf{A}'$ obtained by a gauge transformation with the gauge field $\chi = 2g\phi$.
d. Now consider the vector potential defined by $\mathbf{A}'' \equiv \mathbf{A}$ for $\theta \leq \frac{\pi}{2}$ and $\mathbf{A}'' \equiv \mathbf{A}'$ for $\theta \geq \frac{\pi}{2}$. This potential has no more singularity. Derive, from the condition that the transformation $U_{cl} = e^{-\imath e\chi/\hbar}$ be unique, the value of the magnetic charge.

14.1.5.9 Ex: Green's identities

Be ϕ and ψ two continuously differentiable functions and V a volume with the border ∂V. Show with the help of Gauß' theorem,
a.

$$\int_{\mathcal{V}} \left[\phi\nabla^2\psi + (\nabla\phi)\cdot(\nabla\psi)\right] \, dV = \int_{\partial\mathcal{V}} \phi(\nabla\psi) \, d\mathbf{S} \ ,$$

b.

$$\int_{\mathcal{V}} \left[\phi\nabla^2\psi - \psi\nabla^2\phi\right] \, dV = \int_{\partial\mathcal{V}} \left[\phi\nabla\psi - \psi\nabla\phi\right] \, d\mathbf{S} \; .$$

14.1.5.10 Ex: Decomposition of vector fields

Be $\mathbf{F}(\mathbf{r},t)$ an arbitrary vector field defined on $\mathbb{R}$, which tends (along with its derivatives) to zero in sufficiently high order, when $|\mathbf{r}| \to \infty$. This field can be decomposed into a sum of a longitudinal and a transverse component, $\mathbf{F} = \mathbf{F}_l + \mathbf{F}_t$ with $\nabla \times \mathbf{F}_l = 0$ and $\nabla \cdot \mathbf{F}_t = 0$.
a. Prove,

$$\mathbf{F}_l(\mathbf{r},t) = -\frac{1}{4\pi}\nabla \int \frac{\nabla' \cdot \mathbf{F}(\mathbf{r}',t)}{|\mathbf{r}-\mathbf{r}'|} d^3r' \quad \text{and} \quad \mathbf{F}_t(\mathbf{r},t) = +\frac{1}{4\pi}\nabla \times \nabla \times \int \frac{\mathbf{F}(\mathbf{r}',t)}{|\mathbf{r}-\mathbf{r}'|} d^3r' \; .$$

Help: Begin showing that,

$$\mathbf{F}(\mathbf{r},t) = -\frac{1}{4\pi}\triangle \int \frac{\mathbf{F}(\mathbf{r}',t)}{|\mathbf{r}-\mathbf{r}'|} d^3r'$$

and use the vector identity,

$$\nabla \times \nabla \times \mathbf{A} = \nabla(\nabla \cdot \mathbf{A}) - \triangle\mathbf{A} \; .$$

b. Show that the vector field $\mathbf{F}(\mathbf{r})$ is unequivocally given by its sources, $\nabla \cdot \mathbf{F}(\mathbf{r})$, and vertices, $\nabla \times \mathbf{F}(\mathbf{r})$.

14.1.5.11 Ex: Conductivity of seawater

Sea water has at the frequency $v = 4 \cdot 10^8\,\mathrm{Hz}$ the permittivity $\varepsilon = 81\varepsilon_0$, the permeability $\mu = \mu_0$, and the resistivity $\rho = 0.23\,\Omega\mathrm{m}$. What is the ratio between the conduction current and the displacement current? **Help:** Consider a parallel-plate capacitor immersed in seawater and driven by a voltage $V_0 \cos(2\pi\nu t)$.

14.2 Conservation laws in electromagnetism

The importance of *conservation laws* and *symmetries* lies in their universal validity and their independence of a particular theory (mechanics, electrodynamics, ..). They often allow the derivation of laws, which are specific for a theory and of equations of motion for particular systems. For example, in classical mechanics, we can derive Newtonian axioms from the conservation of linear momentum, and in electrodynamics, as we shall see later, we can derive Maxwell's equations from the principles of Lorentz invariance, gauge invariance, and electric charge conservation, as expressed by the continuity equation. The question which we will elucidate in the following sections will be that of the validity of other mechanical conservation laws in electrodynamics, that is, the laws of energy, linear momentum, and angular momentum conservation.

In the context of preparing the deductions, let us defined some important quantities [7],

$$
\begin{array}{llll}
\text{(i)} & u = \frac{1}{2}(\vec{\mathcal{E}}\cdot\vec{\mathcal{D}} + \vec{\mathcal{B}}\cdot\vec{\mathcal{H}}) & \textit{energy density} & (14.58) \\
\text{(ii)} & \vec{\mathcal{S}} = \vec{\mathcal{E}}\times\vec{\mathcal{H}} & \textit{energy flux} \text{ or } \textit{Poynting vector} & \\
\text{(iii)} & \mathbf{f} = \varrho\vec{\mathcal{E}} + \mathbf{j}\times\vec{\mathcal{B}} & \textit{Lorentz force density} & \\
\text{(iv)} & \vec{\wp}^A = \varepsilon_0\mu_0\vec{\mathcal{S}} = \frac{1}{c^2}\vec{\mathcal{E}}\times\vec{\mathcal{H}} & \textit{Abraham momentum density} & \\
\text{(iv)} & \vec{\wp}^M = \vec{\mathcal{D}}\times\vec{\mathcal{B}} & \textit{Minkowski momentum density} & \\
\text{(v)} & \vec{\ell} = \mathbf{r}\times\vec{\wp} & \textit{angular momentum density} & \\
\text{(vi)} & \overleftrightarrow{\mathbf{T}} = \vec{\mathcal{D}}\otimes\vec{\mathcal{E}} + \vec{\mathcal{H}}\otimes\vec{\mathcal{B}} - \frac{1}{2}u\mathbb{I} & \textit{Maxwell stress tensor}\,. &
\end{array}
$$

All fields are time-dependent. From Maxwell's equations we derive the *electrodynamical continuity equation*, the *Poynting theorem*, and the conservation of linear and angular momentum. Resolve the Exc. 14.2.5.1.

14.2.1 Charge conservation and continuity equation

Calculating the divergence of Maxwell's first equation and using the third,

$$\nabla\cdot(\nabla\times\vec{\mathcal{H}}) = \partial_t\nabla\cdot\vec{\mathcal{D}} + \nabla\cdot\mathbf{j} = \boxed{\partial_t\varrho + \nabla\cdot\mathbf{j} = 0}\,. \tag{14.59}$$

This law describes *charge conservation* in electrodynamics.

14.2.2 Energy conservation and Poynting's theorem

The time derivative of the energy density (14.58)(i) is,

$$\partial_t u = \frac{1}{2}(\vec{\mathcal{E}}\cdot\partial_t\vec{\mathcal{D}} + \vec{\mathcal{D}}\cdot\partial_t\vec{\mathcal{E}} + \vec{\mathcal{B}}\cdot\partial_t\vec{\mathcal{H}} + \vec{\mathcal{H}}\cdot\partial_t\vec{\mathcal{B}}) = \vec{\mathcal{E}}\cdot\partial_t\vec{\mathcal{D}} + \vec{\mathcal{H}}\cdot\partial_t\vec{\mathcal{B}}\,, \tag{14.60}$$

supposing $\vec{\mathcal{D}} = \varepsilon\vec{\mathcal{E}}$ and $\vec{\mathcal{H}} = \vec{\mathcal{B}}/\mu$ with time- and space-independent $\varepsilon, \mu = const$. The divergence of the Poynting vector is,

$$\nabla\cdot\vec{\mathcal{S}} = \nabla\cdot(\vec{\mathcal{E}}\times\vec{\mathcal{H}}) = \vec{\mathcal{H}}\cdot(\nabla\times\vec{\mathcal{E}}) - \vec{\mathcal{E}}\cdot(\nabla\times\vec{\mathcal{H}}) = -\vec{\mathcal{H}}\cdot\partial_t\vec{\mathcal{B}} - \vec{\mathcal{E}}\cdot(\partial_t\vec{\mathcal{D}} + \mathbf{j})\,. \tag{14.61}$$

With this we immediately see,

$$\boxed{\partial_t u + \nabla\cdot\vec{\mathcal{S}} = -\mathbf{j}\cdot\vec{\mathcal{E}}}\,. \tag{14.62}$$

To better understand this theorem, we calculate the work exerted by the Coulomb-Lorentz force per unit time on a test charge q,

$$\frac{dW}{dt} = \frac{d}{dt}\int_{\mathcal{C}}\mathbf{F}\cdot d\mathbf{l} = \frac{d}{dt}\int q(\vec{\mathcal{E}} + \cancel{\mathbf{v}\times\vec{\mathcal{B}}}^{\,0})\cdot\mathbf{v}dt = q\mathbf{v}\cdot\vec{\mathcal{E}}\,. \tag{14.63}$$

[7] The question of the correct expression for the momentum density is difficult and will be dealt with later.

The current generated by the charge can be derived from the parametrization $\mathbf{j}(\mathbf{r}) = q\mathbf{v}\delta^3(\mathbf{r}-\mathbf{r}')$. Thus, we derive the *Poynting theorem*,

$$\frac{dW}{dt} = \int_{\mathcal{V}} \vec{\mathcal{E}} \cdot \mathbf{j} dV = -\frac{d}{dt}\int_{\mathcal{V}} u dV - \int_{\mathcal{V}} \nabla \cdot \vec{\mathcal{S}} dV = -\frac{dU_{\text{erg}}}{dt} - \oint_{\partial\mathcal{V}} \vec{\mathcal{S}} \cdot d\mathbf{S} \ . \tag{14.64}$$

This theorem postulates *energy conservation*. That is, the electromagnetic energy U_{erg} within a volume $\mathcal{V}$ can only change (1) by diffusion out of the volume via a flux $\int \vec{\mathcal{S}} \cdot d\mathbf{S}$ of the Poynting vector, or (2) when mechanical work W is done on the volume or when the electromagnetic energy in the volume is dissipated into other forms of energy, for example heat. We apply the Poynting theorem to a current-carrying wire in Exc. 14.2.5.2.

Example 87 (*Derivation of Ohm's law by the Poynting vector*): The current flux through a wire exerts *work*, because the wire heats up. We calculate the energy transferred to the wire per unit time via the Poynting vector. The electric field (assumed to be uniform) along the wire (length L and radius a) is,

$$\mathcal{E} = \frac{U}{L} \ ,$$

where U is the voltage between the ends of the wire. The magnetic field at the surface of the wire is,

$$\mathcal{B} = \frac{\mu_0 I}{2\pi a} \ .$$

Therefore, the absolute value of the Poynting vector is,

$$s = \frac{1}{\mu_0}\mathcal{E}\mathcal{B} = \frac{UI}{2\pi a L} \ .$$

pointing into the wire, $\vec{\mathcal{S}} \propto -\hat{\mathbf{e}}_r$. The energy per unit of time passing through the surface of the wire is therefore,

$$\int \vec{\mathcal{S}} \cdot d\mathbf{S} = s(2\pi a L) = UI \ ,$$

confirming previously obtained results. As the fields are stationary, the electromagnetic energy does not vary with time, neither, $\partial_t U_{\text{erg}} = 0$.

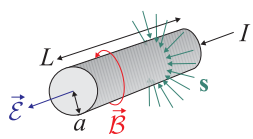

Figure 14.5: Energy flux into the wire causes heating.

14.2.3 Conservation of linear momentum and Maxwell's stress tensor

The interaction between two charges is described by the Coulomb-Lorentz force. However, when these charges accelerate each other mutually, they generate non-stationary

fields, so that the force laws of Coulomb and Biot-Savart do not apply. We will see later, how to generalize these laws.

Nevertheless, at first glance, the Coulomb force seems compatible with the third Newton law: *actio* = *reactio*, but not with the Lorentz force.

Example 88 (*Linear momentum of the electromagnetic field*): To see this, we consider two charged particles with trajectories,

$$\mathbf{l}_1(t) = vt\hat{\mathbf{e}}_y \quad , \quad \mathbf{l}_2(t) = vt\hat{\mathbf{e}}_x \ .$$

Charge 1 produces a field $\vec{\mathcal{B}}_1$ at the position of charge 2 and vice versa. At time $t = 0$, when they collide, the forces become orthogonal:

$$\mathbf{F}_{12} = q\mathbf{v}_2 \times \vec{\mathcal{B}}_1 \perp q\mathbf{v}_1 \times \vec{\mathcal{B}}_2 = \mathbf{F}_{21} \ .$$

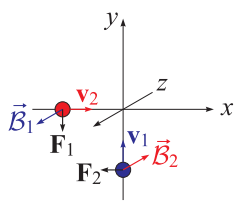

Figure 14.6: The Lorentz forces exerted by approaching charges are mutually orthogonal.

Obviously, in electrodynamics, the Lorentz force flagrantly violates Newton's third law in way to raise questions about the validity of momentum conservation. The solution is that in electrodynamics, *the electromagnetic field itself may lose or gain momentum* and should be included in the formulation of a law of momentum conservation. Moreover, the field does not move instantaneously, but propagates at the speed of light and is subject to retardation effects. The law *actio* = *reactio* postulates the existence of forces acting at a distance that, as we nowadays know, do not exist [8]. We shall return to this problem in the discussion of the relativistic Lorentz transformation.

14.2.3.1 Maxwell's tress tensor

We now consider the Lorentz force density, which we will try to express totally in terms of fields, eliminating the charge and current densities [651],

$$\mathbf{f} = \varrho\vec{\mathcal{E}} + \mathbf{j} \times \vec{\mathcal{B}} = \vec{\mathcal{E}}(\nabla \cdot \vec{\mathcal{D}}) + \left(\nabla \times \vec{\mathcal{H}} - \frac{\partial \vec{\mathcal{D}}}{\partial t}\right) \times \vec{\mathcal{B}} \ . \tag{14.65}$$

We reformulate the last term,

$$-\frac{\partial \vec{\mathcal{D}}}{\partial t} \times \vec{\mathcal{B}} = \vec{\mathcal{D}} \times \frac{\partial \vec{\mathcal{B}}}{\partial t} - \frac{\partial}{\partial t}(\vec{\mathcal{D}} \times \vec{\mathcal{B}}) = -\vec{\mathcal{D}} \times (\nabla \times \vec{\mathcal{E}}) - \frac{\partial}{\partial t}(\vec{\mathcal{D}} \times \vec{\mathcal{B}}) \ . \tag{14.66}$$

[8] One of the important changes of paradigm in the history of physics is from interaction at a distance to local interaction. Newton was a supporter of non-local interaction for gravity. Ironically he argued against waves in favor of particles for light. Today the opinion thinks the other way round: Particles are mediators of local interactions, while only waves can mediate non-local features.

Knowing $\vec{\mathcal{H}}(\nabla\cdot\vec{\mathcal{B}})=0$, we can add this term to the force without cost,

$$\mathbf{f}=\vec{\mathcal{E}}(\nabla\cdot\vec{\mathcal{D}})-\vec{\mathcal{D}}\times(\nabla\times\vec{\mathcal{E}})+\vec{\mathcal{H}}(\nabla\cdot\vec{\mathcal{B}})-\vec{\mathcal{B}}\times(\nabla\times\vec{\mathcal{H}})-\frac{\partial}{\partial t}(\vec{\mathcal{D}}\times\vec{\mathcal{B}})\ . \tag{14.67}$$

We use the rule from vector analysis,

$$\begin{aligned}\nabla(\vec{\mathcal{E}}\cdot\vec{\mathcal{D}})&=\vec{\mathcal{E}}\times(\nabla\times\vec{\mathcal{D}})+\vec{\mathcal{D}}\times(\nabla\times\vec{\mathcal{E}})+(\vec{\mathcal{E}}\cdot\nabla)\vec{\mathcal{D}}+(\vec{\mathcal{D}}\cdot\nabla)\vec{\mathcal{E}}\\&=2\vec{\mathcal{D}}\times(\nabla\times\vec{\mathcal{E}})+2(\vec{\mathcal{E}}\cdot\nabla)\vec{\mathcal{D}}\ ,\end{aligned} \tag{14.68}$$

and analogously for $\vec{\mathcal{B}}\cdot\vec{\mathcal{H}}$. The second equation holds, because for $\vec{\mathcal{D}}=\varepsilon\vec{\mathcal{E}}$ with $\varepsilon=const$, we can arbitrarily exchange the order of products between $\vec{\mathcal{D}}$ and $\vec{\mathcal{E}}$. We also assume $\mu=const$, which allows us to exchange the order of products between $\vec{\mathcal{H}}$ and $\vec{\mathcal{B}}$. We use the rule (14.68) to replace the terms with vector products in equation (14.67),

$$\begin{aligned}\mathbf{f}&=\vec{\mathcal{E}}(\nabla\cdot\vec{\mathcal{D}})-\tfrac{1}{2}\nabla(\vec{\mathcal{E}}\cdot\vec{\mathcal{D}})+(\vec{\mathcal{E}}\cdot\nabla)\vec{\mathcal{D}}\\&+\vec{\mathcal{H}}(\nabla\cdot\vec{\mathcal{B}})-\tfrac{1}{2}\nabla(\vec{\mathcal{H}}\cdot\vec{\mathcal{B}})+(\vec{\mathcal{H}}\cdot\nabla)\vec{\mathcal{B}}-\partial_t\vec{\mathcal{D}}\times\vec{\mathcal{B}}\ .\end{aligned} \tag{14.69}$$

The last term is nothing more than the time derivative of the *Minkowski momentum density* of the electromagnetic field defined in (14.58), $\vec{\wp}^M\equiv\vec{\mathcal{D}}\times\vec{\mathcal{B}}$, which still awaits interpretation.

Now we introduce the *Maxwell stress tensor* (in Minkowski's form) by [9],

$$\boxed{T^M_{ij}\equiv\mathcal{D}_i\mathcal{E}_j+\mathcal{H}_i\mathcal{B}_j-\tfrac{\delta_{ij}}{2}(\vec{\mathcal{E}}\cdot\vec{\mathcal{D}}+\vec{\mathcal{H}}\cdot\vec{\mathcal{B}})}\ . \tag{14.70}$$

Defining the divergent of a matrix, we obtain using Einstein's sum convention,

$$\begin{aligned}(\nabla\cdot\overleftrightarrow{\mathbf{T}})_j\equiv(\partial_iT_{ij})_j&=\Big(\partial_i(\mathcal{D}_i\mathcal{E}_j)+\partial_i(\mathcal{H}_i\mathcal{B}_j)-\partial_i\tfrac{\delta_{ij}}{2}(\vec{\mathcal{E}}\cdot\vec{\mathcal{D}}+\vec{\mathcal{H}}\cdot\vec{\mathcal{B}})\Big)_j\\&=\Big(\mathcal{E}_j\nabla\cdot\vec{\mathcal{D}}+\vec{\mathcal{D}}\cdot\nabla\mathcal{E}_j+\mathcal{B}_j\nabla\cdot\vec{\mathcal{H}}+\vec{\mathcal{H}}\cdot\nabla\mathcal{B}_j-\tfrac{1}{2}\partial_j(\vec{\mathcal{E}}\cdot\vec{\mathcal{D}}+\vec{\mathcal{H}}\cdot\vec{\mathcal{B}})\Big)_j\ .\end{aligned} \tag{14.71}$$

These terms coincide with those of the equation (14.69) except for the last one. Now, we can reshape the Lorentz force,

$$\boxed{-\partial_t\vec{\wp}^M+\nabla\cdot\overleftrightarrow{\mathbf{T}}=\mathbf{f}}\ . \tag{14.72}$$

The mechanical force acting on a volume $\mathcal{V}$,

$$\mathbf{F}=\oint_{\partial\mathcal{V}}\overleftrightarrow{\mathbf{T}}\cdot d\mathbf{S}-\frac{d}{dt}\int_{\mathcal{V}}\vec{\wp}^M dV\ , \tag{14.73}$$

can be expressed by a momentum flux escaping the volume plus a 'stress' acting on its surface in every direction. The diagonal components T_{ii} represent 'pressures' and the non-diagonal 'shear stresses'. In static situations only the stress results in forces.

[9] In matrix notation,

$$\nabla\cdot\overleftrightarrow{T}=\begin{pmatrix}\frac{d}{dx} & \frac{d}{dy} & \frac{d}{dz}\end{pmatrix}\begin{pmatrix}T_{xx} & T_{xy} & T_{xz}\\T_{yx} & T_{yy} & T_{xz}\\T_{zx} & T_{zy} & T_{zz}\end{pmatrix}\ .$$

Example 89 (*Force on a charged body*): As an example of application of the stress tensor we calculate the force exerted by a solid uniformly charged (charge Q) sphere of radius R on its own upper part. The volume of the upper hemisphere is enclosed by two surfaces: one hemispheric surface and a flat one. In Cartesian coordinates,

$$\hat{\mathbf{e}}_r = \hat{\mathbf{e}}_x \sin\theta\cos\phi + \hat{\mathbf{e}}_y \sin\theta\sin\phi + \hat{\mathbf{e}}_z \cos\theta \ ,$$

for the hemispherical surface, we write the electric field and the surface element as,

$$\vec{\mathcal{E}} = \frac{1}{4\pi\varepsilon_0}\frac{Q}{R^2}\hat{\mathbf{e}}_r \qquad \text{and} \qquad d\mathbf{a} = \hat{\mathbf{e}}_r R^2 \sin\theta d\theta d\phi \ .$$

We calculate the stress tensor,

$$\overleftrightarrow{\mathbf{T}} = \varepsilon_0 \begin{pmatrix} \mathcal{E}_x^2 - \frac{1}{2}\mathcal{E}^2 & \mathcal{E}_x\mathcal{E}_y & \mathcal{E}_x\mathcal{E}_z \\ \mathcal{E}_x\mathcal{E}_y & \mathcal{E}_y^2 - \frac{1}{2}\mathcal{E}^2 & \mathcal{E}_y\mathcal{E}_z \\ \mathcal{E}_x\mathcal{E}_z & \mathcal{E}_y\mathcal{E}_z & \mathcal{E}_z^2 - \frac{1}{2}\mathcal{E}^2 \end{pmatrix}$$

$$= \varepsilon_0 \left(\frac{1}{4\pi\varepsilon_0}\frac{Q}{R^2}\right)^2 \begin{pmatrix} \sin^2\theta\cos^2\phi - \frac{1}{2} & \sin^2\theta\cos\phi\sin\phi & \cos\theta\sin\theta\cos\phi \\ \sin^2\theta\cos\phi\sin\phi & \sin^2\theta\sin^2\phi - \frac{1}{2} & \cos\theta\sin\theta\sin\phi \\ \cos\theta\sin\theta\cos\phi & \cos\theta\sin\theta\sin\phi & \cos^2\theta - \frac{1}{2} \end{pmatrix} \ .$$

The integral of the tensor over the surface can be evaluated by Maple,

$$\int \overleftrightarrow{\mathbf{T}} d\mathbf{a} = \int_0^{2\pi}\int_0^{\pi/2} \overleftrightarrow{\mathbf{T}}\hat{\mathbf{e}}_r R^2 \sin\theta d\theta d\phi = \frac{Q^2}{32\pi\varepsilon_0 R^2}\hat{\mathbf{e}}_z \ .$$

For the flat surface we write,

$$\vec{\mathcal{E}} = \frac{1}{4\pi\varepsilon_0}\frac{Q}{R^3} r\hat{\mathbf{e}}_r \qquad \text{and} \qquad d\mathbf{a} = -\hat{\mathbf{e}}_z r dr d\phi \ .$$

Now we calculate with $\theta = \pi/2$,

$$\overleftrightarrow{\mathbf{T}} = \varepsilon_0 \frac{1}{(4\pi\varepsilon_0)^2}\frac{Q^2}{R^6} \begin{pmatrix} r^2\cos^2\phi - \frac{1}{2} & r^2\cos\phi\sin\phi & 0 \\ r^2\cos\phi\sin\phi & r^2\sin^2\phi - \frac{1}{2} & 0 \\ 0 & 0 & -\frac{1}{2}r^2 \end{pmatrix} \ .$$

The integral over the surface gives,

$$\int \overleftrightarrow{\mathbf{T}} d\mathbf{a} = -\int_0^{2\pi}\int_0^{R} \overleftrightarrow{\mathbf{T}}\hat{\mathbf{e}}_z r dr d\phi = \frac{Q^2}{64\pi\varepsilon_0 R^2}\hat{\mathbf{e}}_z \ .$$

Combining the results we obtain the force by the equation (14.73),

$$\mathbf{F} = \oint_{\text{hemisphere}} \overleftrightarrow{\mathbf{T}} d\mathbf{a} = \frac{3Q^2}{64\pi\varepsilon_0 R^2}\hat{\mathbf{e}}_z \ .$$

The result of this example demonstrates, how we can reduce the calculation of a force acting on a volume to an integral over the surface enclosing the volume. We will calculate other examples in Excs. 14.2.5.3 to 14.2.5.6.

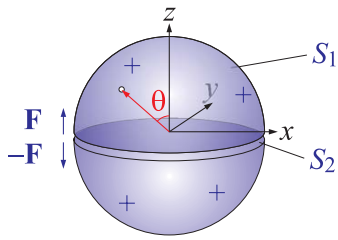

Figure 14.7: Electrostatic forces inside a charged sphere.

14.2.3.2 Conservation of linear momentum

According to Newton's second law, $\mathbf{F} = \partial_t \mathbf{p}_{mec}$ or $\mathbf{f} = \partial_t \vec{\wp}_{mec}$, the Lorentz force produces a variation of the *mechanical momentum*. In addition, there is a momentum $\mathbf{p}^M = \int_{\mathcal{V}} \vec{\wp}^M dV$, which must be attributed to the *electromagnetic field*, since it only exists in the presence of both electric and magnetic fields. $\mathbf{p}_{mec}$ and $\mathbf{p}^M$ can be interconverted, as in the example of the photonic recoil received by an atom upon an absorption process. But the sum of the mechanical momentum and the momentum of the field can only change through the term $\nabla \cdot \overleftrightarrow{\mathbf{T}}$. This is the law of *linear momentum conservation*. Evidently, $-\overleftrightarrow{\mathbf{T}}$ is the momentum flux density, playing a role similar to the one of the current density $\mathbf{j}$ in the continuity equation or of the energy flux density $\vec{\mathcal{S}}$ in Poynting's theorem. $-T_{ij}$ is the momentum per unit area and time in the direction i passing a surface oriented in j-direction.

We note two very different roles of the Poynting vector: In the energy conservation equation $\vec{\mathcal{S}}$ is the energy per unit area and time carried by electromagnetic fields, while in the momentum conservation equation, $\vec{\wp}^M = \varepsilon_0 \mu_0 \vec{\mathcal{S}}$ is the momentum per unit volume stored in these fields. Similarly, $\overleftrightarrow{\mathbf{T}}$ plays two roles: $\overleftrightarrow{\mathbf{T}}$ is the electromagnetic stress (i.e. a force per unit area or pressure) acting on a surface, while $-\overleftrightarrow{\mathbf{T}}$ describes the momentum flux (momentum current density) carried by these fields.

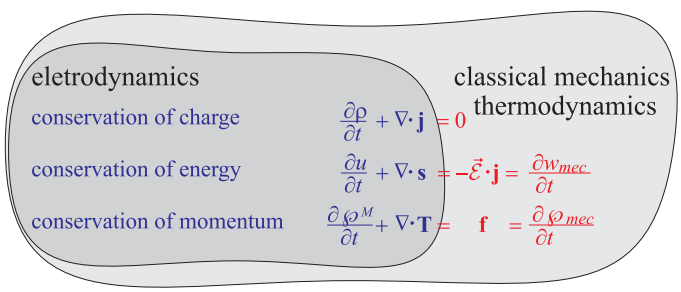

Figure 14.8: The laws of energy and momentum conservation connect the theories of electrodynamics with classical mechanics and thermodynamics.

Forces exerted by (non-radiating) fields on particles can be interpreted as being due to a scattering of 'virtual particles'. For example, the electrostatic force between charged particles and the magnetostatic force between magnetic dipoles are caused

by an exchange of virtual photons. These photons carry momentum that is transferred via recoil in a scattering event. Since the photon has no mass, the electric (respectively, magnetic) potential has infinite range.

The photonic concept can be extended to electromagnetic fields, as demonstrated by *Max Planck* in his discussion of the blackbody radiation. The spontaneous emission of a photon during the decay of an excited atom, postulated by *Albert Einstein*, is forbidden in 'classical' quantum mechanics, and requires quantization of the electromagnetic field for its explanation. The quantized energy packets, called photons, also carry momentum, which can be transferred to bodies absorbing the radiation. The fact that light beams can exert forces is nowadays commonly exploited in techniques for cooling atomic gases. This process is called *radiation pressure* and will be discussed elsewhere.

Example 90 (*The Abraham-Minkowski dilemma*): The expression $\vec{\wp}^A = \frac{1}{c^2}\vec{\mathcal{E}} \times \vec{\mathcal{H}}$ for the momentum flux in dielectric media was proposed by Abraham in 1909, but it is not obvious that this expression is correct. In fact, in the same year 1909 Minkowski proposed the expression $\vec{\wp}^M = \vec{\mathcal{D}} \times \vec{\mathcal{B}}$, and until today this *Abraham-Minkowski dilemma* is not satisfactorily solved [64, 956]. See also (watch talk).

In an (over-)simplified way, we may illustrate the dilemma by the fact that even the correct expression for the photonic momentum within a dielectric is unknown. For, knowing that the phase velocity is reduced in a dielectric medium, $c \to c/n$, we could derive from the kinetic momentum in vacuum, $p = m\frac{c}{n}$, where the mass follows from Einstein's formula, $m = \frac{\hbar\omega}{c^2}$. That is, the photonic momentum within a dielectric medium should be,

$$p = \frac{\hbar\omega}{nc} \ .$$

This is Abraham's conclusion, which emphasizes the corpuscular aspect of the photon. On the other side, starting with de Broglie's expression, $p = \frac{h}{\lambda}$, using the dispersion relation, $\lambda = \frac{c}{n\nu}$, we would conclude that the photonic momentum within a dielectric medium must be,

$$p = \frac{n\hbar\omega}{c} \ ,$$

which is Minkowski's result emphasizing the undulating features of the photon. In fact, the dilemma arises because, a priori, it is not clear whether the correct expression for the momentum carried by an electromagnetic wave is,

$$\vec{\wp}^A = \tfrac{1}{c^2}\mathbf{S} = \tfrac{1}{c^2}\vec{\mathcal{E}} \times \vec{\mathcal{H}} \qquad \text{or} \qquad \vec{\wp}^M = \vec{\mathcal{D}} \times \vec{\mathcal{B}} \ .$$

In vacuum there is no difference, but in the case of a plane wave inside a dielectric medium, $\vec{\mathcal{E}}(\mathbf{r},t) = \mathcal{E}_0\hat{\mathbf{e}}_x \cos\omega(t - \frac{n}{c}z)$ and $\vec{\mathcal{B}}(\mathbf{r},t) = \frac{n}{c}\hat{\mathbf{e}}_z \times \vec{\mathcal{E}}(\mathbf{r},t)$, we calculate,

$$\begin{aligned}
\wp^A &\equiv \tfrac{1}{c^2}\overline{\vec{\mathcal{E}} \times \vec{\mathcal{H}}} = \tfrac{1}{\mu_0 c^2}\overline{\vec{\mathcal{E}} \times \vec{\mathcal{B}}} = \tfrac{1}{\mu_0 c^2}\mathcal{E}_0^2\hat{\mathbf{e}}_z\tfrac{n}{c}\overline{\cos^2\omega(t - \tfrac{n}{c}z)} \\
&= \tfrac{1}{\mu_0 c^2}\mathcal{E}_0^2\hat{\mathbf{e}}_z\tfrac{n}{c}\tfrac{1}{2} = \tfrac{1}{\varepsilon_0\mu_0 c^2} - \hat{\mathbf{e}}_z\tfrac{u}{nc} = \hat{\mathbf{e}}_z\tfrac{u}{nc} \\
\wp^M &\equiv \overline{\vec{\mathcal{D}} \times \vec{\mathcal{B}}} = \varepsilon_0\overline{\vec{\mathcal{E}} \times \vec{\mathcal{B}}} = \varepsilon_0\mu_0 c^2\vec{\wp}^A = n^2\vec{\wp}^A \ .
\end{aligned}$$

14.2.4 Conservation of angular momentum of the electromagnetic field

The *angular momentum conservation* (14.58) is also ruled by Maxwell's equations. But its derivation is complicated [386, 473] and will not be reproduced here. In Exc. 14.2.5.7 we calculate the angular momentum stored in a static combination of electric and magnetic fields. In Exc. 14.2.5.8 we calculate the torque acting on charges due to a temporal variation of electromagnetic fields. Finally, in Exc. 14.2.5.9 we try classical discussion of the intrinsic angular momentum (spin) of the electron.

Example 91 (*Angular momentum of electromagnetic fields*): Imagine a very long solenoid with radius R, n windings per unit length, and carrying the current I. Coaxially to the solenoid there are two long cylindrical layers of length d. The first one, of radius a, lies inside the solenoid and carries a charge $+Q$ evenly distributed over the surface; the other one, of radius b, is outside the solenoid and carries the charge $-Q$, as shown in Fig. 14.9. We suppose $d \gg b$. When the current in the solenoid is gradually reduced, the cylinders begin to rotate. The question is, where does the angular momentum come from?

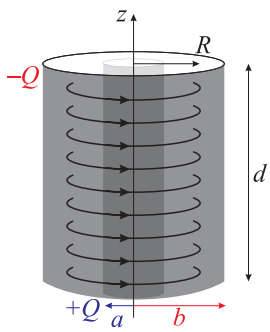

Figure 14.9: Device with a solenoid and charged cylinders illustrating the conservation of angular momentum.

Let us first calculate the angular momentum stored in the electric and magnetic field before we started to reduce the current. In the region between the cylinders, $a < \rho < b$, we had the electric field $\vec{\mathcal{E}} = \frac{Q}{2\pi\varepsilon_0 d}\frac{\hat{\mathbf{e}}_\rho}{\rho}$, and in the inner region of the solenoid, $\rho < R$, the magnetic field, $\vec{\mathcal{B}} = \mu_0 nI\hat{\mathbf{e}}_z$. Therefore, in the region $a < \rho < R$, the momentum density (14.58) was,

$$\vec{\wp} = \varepsilon_0 \vec{\mathcal{E}} \times \vec{\mathcal{B}} = -\frac{\mu_0 QnI}{2\pi\rho d}\hat{\mathbf{e}}_\phi$$

The angular momentum density,

$$\vec{\ell} = \mathbf{r} \times \vec{\wp} = -\frac{\mu_0 nIQ}{2\pi d}\hat{\mathbf{e}}_z \ ,$$

was constant, which facilitates the calculation of the total orbital angular momentum,

$$\mathbf{L} = \int \vec{\ell} dV = \vec{\ell}\pi(R^2 - a^2)d = -\tfrac{1}{2}\mu_0 nIQ(R^2 - a^2)\hat{\mathbf{e}}_z \ .$$

Apparently, the existence of an orbital angular momentum is conditioned to the presence of both, a charge and a current.
Now, when the current is turned off, the variation of the magnetic field induces a circumferential electric field, given by Faraday's law:

$$\vec{\mathcal{E}} = -\tfrac{1}{2}\mu_0 n \frac{dI}{dt}\hat{\mathbf{e}}_\phi \begin{cases} \rho & \text{for} \quad \rho < R \\ \frac{R^2}{\rho} & \text{for} \quad \rho > R \end{cases} .$$

The Coulomb force exerted by the electric field on the charged outer cylinder produces a torque on the cylinder,

$$\mathbf{N}_b = \mathbf{r} \times (-Q\vec{\mathcal{E}}) = \tfrac{1}{2}\mu_0 n Q R^2 \frac{dI}{dt}\hat{\mathbf{e}}_z \ ,$$

so that it receives the angular momentum,

$$\mathbf{L}_b = \int_0^\infty \mathbf{N}_b dt = \tfrac{1}{2}\mu_0 n Q R^2 \hat{\mathbf{e}}_z \int_I^0 \frac{dI}{dt} dt = -\tfrac{1}{2}\mu_0 n I Q R^2 \hat{\mathbf{e}}_z \ .$$

In the same way, we obtain for the inner cylinder,

$$\mathbf{N}_a = -\tfrac{1}{2}\mu_0 n Q a^2 \frac{dI}{dt}\hat{\mathbf{e}}_z \quad , \quad \mathbf{L}_a = \tfrac{1}{2}\mu_0 n I Q a^2 \hat{\mathbf{e}}_z \ .$$

Hence, we verify that $\mathbf{L} = \mathbf{L}_a + \mathbf{L}_b$. The angular momentum lost by the fields is precisely equal to the angular momentum acquired by the cylinders, that is, the total angular momentum is conserved.

14.2.5 Exercises

14.2.5.1 Ex: Poynting vector for free charges and currents

Write down the Poynting vector and the momentum density for the case, that there are only free *charges and currents*.

14.2.5.2 Ex: Energy flux in a current-carrying wire

A cylindrical wire with radius a and permeability μ is traversed by a constant current density $\mathbf{j}$. The electric field $\vec{\mathcal{E}}$ inside the wire and the current density $\mathbf{j}$ are connected by Ohm's law $\mathbf{j} = \varsigma\vec{\mathcal{E}}$, where ς is the electrical conductivity.
a. What absolute value and which direction does the Poynting vector $\vec{\mathcal{S}}$ have in the wire and on the wire surface?
b. Calculate the total energy flux running through the surface of a piece of wire of length l. Show that this flux of energy is precisely the power dissipated within this piece for the production of ohmic heat.
Help: The law of energy conservation in electrodynamics is given by $-\frac{du}{dt} = \nabla\vec{\mathcal{S}} + \mathbf{j}\cdot\vec{\mathcal{E}}$, where $u = \frac{1}{2}(\vec{\mathcal{E}}\cdot\vec{\mathcal{D}} + \vec{\mathcal{B}}\cdot\vec{\mathcal{H}})$ is the total energy density, $\vec{\mathcal{S}} = \vec{\mathcal{E}} \times \vec{\mathcal{H}}$ the energy flux and $\mathbf{j}\cdot\vec{\mathcal{E}}$ the work exerted on the electric current density.

14.2.5.3 Ex: Intrinsic force in a rotating charged shell via Maxwell's tensor

Calculate the attractive magnetic force between the north and south hemispheres of a uniformly charged spherical shell (radius R and surface charge density Q) rotating with the angular velocity ω. Use the result of Exc. 12.3.3.1 (clicking on the title).

14.2.5.4 Ex: Coulomb force via Maxwell's tensor

Consider two equal (or opposite) point charges q, separated by distance $2a$. Construct the plane which is equidistant from the two charges. Determine the mutual force between the charges.

14.2.5.5 Ex: Force on a current distribution in a magnetic field

The force felt by a current distribution $\mathbf{j}(\mathbf{r})$ in an external magnetic field is,

$$\mathbf{F} = \int_{\mathcal{V}} d^3r' \mathbf{j}(\mathbf{r}') \times \vec{\mathcal{B}}(\mathbf{r}') \ .$$

Show that this force can also be written as an integral over the surface $\mathcal{S} \equiv \partial\mathcal{V}$ enclosing the volume $\mathcal{V}$:

$$F_j = \oint_{\mathcal{S}} \sum_{i=1}^{3} dS_i \ T_{ij} \qquad \text{with} \qquad T_{ij} = \tfrac{1}{\mu_0} \left(\mathcal{B}_i \mathcal{B}_j - \tfrac{1}{2} \mathcal{B}^2 \delta_{ij} \right) \ .$$

14.2.5.6 Ex: Force on the plates of a capacitor

Consider an infinite parallel-plate capacitor, with the lower plate (at $z = -d/2$) carrying the charge density $-\sigma$ and the upper plate (at $z = +d/2$) carrying the charge density σ. Determine the stress tensor in the region between the plates.

14.2.5.7 Ex: Angular momentum of an electromagnetic field

Assuming the existence of an electric charge q_e and a magnetic monopole q_m, calculate the total angular momentum stored in the fields,

$$\vec{\mathcal{E}} = \frac{q_e}{4\pi\varepsilon_0} \frac{\hat{\mathbf{e}}_r}{R^2} \qquad \text{and} \qquad \vec{\mathcal{B}} = \frac{\mu_0 q_m}{4\pi} \frac{\hat{\mathbf{e}}_r}{R^2} \ ,$$

when the two charges are separated by a distance d.

14.2.5.8 Ex: Torque on a demagnetized or discharged iron sphere

We imagine an iron sphere of radius R carrying a charge Q and a uniform magnetization $\vec{\mathcal{M}} = \mathcal{M}\hat{\mathbf{e}}_z$. The sphere is initially at rest.
a. Calculate the angular momentum stored in the electromagnetic fields.
b. Suppose the sphere is gradually (and uniformly) demagnetized (perhaps by heating it beyond the Curie point). Use Faraday's law to determine the induced electric field and find the torque that this field exerts on the sphere. Calculate the total angular momentum transferred to the sphere during demagnetization.
c. Suppose that, instead of demagnetizing the sphere, we discharge it by connecting the north pole of the sphere via a wire to Earth. Suppose that the current flows on the surface in such a way, that the charge density remains uniform. Use the Lorentz force law to determine the torque on the sphere and calculate the total angular momentum given to the sphere during the discharge. (The magnetic field is discontinuous on the surface ... does this matter?)

14.2.5.9 Ex: Magnetic moment of the electron

In relativistic quantum mechanics the magnetic moment of the electron has the value,

$$\mu = g\mu_B \frac{1}{2} = \frac{e\hbar}{2mc} = 9.28 \cdot 10^{-25}\ \mathrm{T\ m}^3 \ .$$

This exercise aims to show that the classical interpretation of this magnetic moment, as being due to a rotating charge distribution, leads to intrinsic contradictions. Let us regard the electron as a sphere of mass m_e with radius r_e carrying the charge e homogeneously distributed over its surface. It rotates around its z-axis with the angular velocity ω. Classically, the movement of the surface charge causes a magnetic moment.
a. Calculate the total energy contained in the electromagnetic fields.
b. Calculate the total angular momentum contained in the fields.
c. According to Einstein's formula, $W_{ED} = m_e c^2$, the energy in the fields must contribute to the mass of the electron. Lorentz and other scientists have speculated that the entire mass of the electron could be understood in this way. Suppose, furthermore, that the rotational angular momentum (spin) of the electron is entirely attributable to the electromagnetic fields: $L_{ED} = \hbar/2$. From these two premisses, determine the radius and the angular velocity of the electron, as well as the product ωr_e. Does this classical model make sense?
d. Determine the magnetic moment of the rotating electron.

14.3 Potential formulation of electrodynamics

14.3.1 The vector and the scalar potential

All quantities involved in Maxwell's equations for vacuum, the fields $\vec{\mathcal{E}}(\mathbf{r},t)$ and $\vec{\mathcal{B}}(\mathbf{r},t)$ as well as charge ($\rho(\mathbf{r},t)$) and current ($\mathbf{j}(\mathbf{r},t)$) distributions they depend on space and time. Knowing that the divergence of a field is zero everywhere, $\nabla\cdot\vec{\mathcal{B}} = 0$, we conclude that this field must be the rotation of another field. That is, there is a vector field $\mathbf{A}(\mathbf{r},t)$, such that,

$$\vec{\mathcal{B}}(\mathbf{r},t) = \nabla \times \mathbf{A}(\mathbf{r},t) \ . \tag{14.74}$$

Substituting the so-called *vector potential* $\mathbf{A}(\mathbf{r},t)$ in Faraday's law, $\nabla \times \vec{\mathcal{E}} = -\frac{\partial \vec{\mathcal{B}}}{\partial t}$, we obtain,

$$\nabla \times \vec{\mathcal{E}} = -\frac{\partial}{\partial t}(\nabla \times \mathbf{A}) = -\nabla \times \frac{\partial \mathbf{A}}{\partial t} \ . \tag{14.75}$$

Hence,

$$\nabla \times \left(\vec{\mathcal{E}} + \frac{\partial \mathbf{A}}{\partial t}\right) = 0 \ . \tag{14.76}$$

Now, since the rotational field within the parentheses is null everywhere, it follows that there exists a scalar field $\Phi(\mathbf{r},t)$, called *scalar potential*, such that,

$$\vec{\mathcal{E}} + \frac{\partial \mathbf{A}}{\partial t} = -\nabla\Phi \ . \tag{14.77}$$

The minus sign in front of the gradient of $\Phi(\mathbf{r},t)$, is introduced to recover the electrostatic case when $\mathbf{A}(\mathbf{r},t)$ does not depend on time. In summary, if we know the vector and scalar potentials, we can calculate the fields $\vec{\mathcal{E}}(\mathbf{r},t)$ and $\vec{\mathcal{B}}(\mathbf{r},t)$ following the prescription expressed by the equations:

$$\boxed{\vec{\mathcal{E}}(\mathbf{r},t) = -\nabla\Phi(\mathbf{r},t) - \frac{\partial \mathbf{A}(\mathbf{r},t)}{\partial t} \qquad \text{and} \qquad \vec{\mathcal{B}}(\mathbf{r},t) = \nabla\times\mathbf{A}(\mathbf{r},t)} \,. \tag{14.78}$$

14.3.2 Gauge transformation

Substituting the expression for the electric field by the vector and scalar potentials in Gauß' law, $\nabla\cdot\vec{\mathcal{E}} = \frac{\varrho}{\varepsilon_0}$,

$$\frac{\varrho}{\varepsilon_0} = \nabla\cdot\left(-\nabla\Phi - \frac{\partial\mathbf{A}}{\partial t}\right) = -\nabla^2\Phi - \frac{\partial\nabla\cdot\mathbf{A}}{\partial t} \,. \tag{14.79}$$

Replacing the fields $\vec{\mathcal{E}}(\mathbf{r},t)$ and $\vec{\mathcal{B}}(\mathbf{r},t)$ by the potentials defined in (14.78), within the law of Ampère-Maxwell, $\nabla\times\vec{\mathcal{B}} = \mu_0\mathbf{j} + \varepsilon_0\mu_0\frac{\partial\vec{\mathcal{E}}}{\partial t}$, we obtain,

$$\nabla\times(\nabla\times\mathbf{A}) = \nabla(\nabla\cdot\mathbf{A}) - \nabla^2\mathbf{A} = \mu_0\mathbf{j} - \frac{1}{c^2}\frac{\partial}{\partial t}\left(-\nabla\Phi - \frac{\partial\mathbf{A}}{\partial t}\right) \,. \tag{14.80}$$

that is,

$$\nabla^2\mathbf{A} - \frac{1}{c^2}\frac{\partial\mathbf{A}^2}{\partial t^2} - \nabla\left(\nabla\cdot\mathbf{A} + \frac{1}{c^2}\frac{\partial\Phi}{\partial t}\right) = -\mu_0\mathbf{j} \,. \tag{14.81}$$

The coupled differential equations (14.79) and (14.81) allow us, in principle, to derive a set of potentials Φ and $\mathbf{A}$, generated by a charge and current distribution ϱ and $\mathbf{j}$, from which the fields $\vec{\mathcal{E}}$ and $\vec{\mathcal{B}}$ can be calculated. However, these *potentials are not unique*. To see this, let us suppose new potentials,

$$\Phi_1 \equiv \Phi - \frac{\partial\chi}{\partial t} \qquad \text{and} \qquad \mathbf{A}_1 \equiv \mathbf{A} + \nabla\chi \,. \tag{14.82}$$

Obviously, these potentials produce the same fields, since,

$$\vec{\mathcal{B}}_1 = \nabla\times(\mathbf{A} + \nabla\chi) = \vec{\mathcal{B}} \,, \tag{14.83}$$

using the expressions (14.78) and,

$$\vec{\mathcal{E}}_1 = -\nabla\left(\Phi - \frac{\partial\chi}{\partial t}\right) - \frac{\partial}{\partial t}(\mathbf{A} + \nabla\chi) = -\nabla\Phi - \frac{\partial}{\partial t}\mathbf{A} = \vec{\mathcal{E}} \,. \tag{14.84}$$

Thus, it is clear that the fields are the same for an infinite number of different potentials, provided they follow from each other by a so-called *gauge transform*,

$$\boxed{\mathbf{A} \longrightarrow \mathbf{A} + \nabla\chi \qquad \text{and} \qquad \Phi \longrightarrow \Phi - \partial_t\chi} \,. \tag{14.85}$$

This *gauge invariance* leaves the observable fields $\vec{\mathcal{E}}$ and $\vec{\mathcal{B}}$ invariant.

The freedom of choosing an appropriate gauge field can be employed to simplify the set of equations (14.79) and (14.81) for particular problems, as we will discuss in the following sections.

14.3.2.1 Lorentz gauge

We note that if the expression within the brackets of Eq. (14.81) were zero,

$$\boxed{\nabla \cdot \mathbf{A} + \frac{1}{c^2}\frac{\partial \Phi}{\partial t} \stackrel{!}{=} 0} \tag{14.86}$$

we would have from the equations (14.79) and (14.81) 'wave' type equations for the potentials,

$$\nabla^2 \Phi - \frac{1}{c^2}\frac{\partial^2 \Phi}{\partial t^2} = -\frac{\varrho}{\varepsilon_0} \qquad \text{and} \qquad \nabla^2 \mathbf{A} - \frac{1}{c^2}\frac{\partial^2 \mathbf{A}}{\partial t^2} = -\mu_0 \mathbf{j} \ . \tag{14.87}$$

To analyze the viability of the expression (14.86), we apply a gauge transformation,

$$\nabla \cdot (\mathbf{A} + \nabla \chi) + \frac{1}{c^2}\frac{\partial(\Phi - \partial_t \chi)}{\partial t} = \nabla^2 \chi - \frac{1}{c^2}\frac{\partial^2 \chi}{\partial t^2} = 0 \ . \tag{14.88}$$

Hence, imposing the additional condition (14.86) is legal, because it can always be satisfied by a simple gauge transformation with a field χ satisfying the wave equation (14.88).

The equation (14.86) is known as the *Lorentz gauge*. We emphasize that *it is not necessary to postulate the equation*, but it is always possible to find a scalar function χ, which allows the use of new potentials, giving the same $\vec{\mathcal{E}}$ and $\vec{\mathcal{B}}$ fields and satisfying this equation [10].

Introducing the notation of the *d'Alembert operator*,

$$\Box \equiv \nabla^2 - \varepsilon_0 \mu_0 \frac{\partial^2}{\partial t^2} \ , \tag{14.89}$$

the wave equations (14.87) become,

$$\Box \Phi = -\varepsilon_0^{-1} \varrho \qquad \text{and} \qquad \Box \mathbf{A} = -\mu_0 \mathbf{j} \ . \tag{14.90}$$

They generalize the electro- and magnetostatic equations (14.6) to include temporal variations simply by replacing the Laplacian with a d'Alembertian. The democratic treatment of Φ and $\mathbf{A}$ by a Poisson-like equation in four space-time dimensions is particularly interesting in the context of special relativity. We study examples of the Lorentz gauge in Excs. 12.3.3.6 to 12.3.3.8 and 14.3.8.1 to 14.3.8.7.

14.3.2.2 Coulomb gauge, transverse and longitudinal currents

Another condition that can be applied to the potentials in order to simplify the differential equations (14.86) and (14.88) consists in setting,

$$\boxed{\nabla \cdot \mathbf{A} \stackrel{!}{=} 0} \ . \tag{14.91}$$

[10] E.g. choosing χ such that $\nabla \chi = -\mathbf{A}$ and $c^{-1}\partial_t \chi = \phi$.

This is called the *Coulomb gauge*. With this condition we obtain from (14.79) the *Poisson equation* as well as an equation for the vector potential,

$$-\nabla^2\Phi = \frac{\varrho}{\varepsilon_0} \tag{14.92}$$

$$-\nabla^2\mathbf{A} + \frac{1}{c^2}\left(\frac{\partial^2\mathbf{A}}{\partial t^2} + \frac{\partial}{\partial t}\nabla\Phi\right) = \mu_0\mathbf{j} \ .$$

These two equations determine the vector and scalar potentials if the current and charge density distributions are specified [11]. The first Eq. (14.92) is solved by *Coulomb's law*, letting $\Phi(\infty) = 0$,

$$\Phi(\mathbf{r}, t) = \frac{1}{4\pi\varepsilon_0}\int \frac{\varrho(\mathbf{r}', t)}{|\mathbf{r} - \mathbf{r}'|} d^3r' \ . \tag{14.93}$$

It is important to be aware that, unlike in electrostatics, we need to know also $\mathbf{A}(\mathbf{r}, t)$ to be able to calculate the field $\vec{\mathcal{E}}(\mathbf{r}, t)$ through the formula (14.78).

It may seem strange that the scalar potential in Coulomb's gauge is determined by the instantaneous charge distribution: Moving an electron at a point $\mathbf{r}'$, the potential at a distant point, $\Phi(\mathbf{r})$, immediately captures this change, not being limited by the speed limit for the transmission of information postulated by special relativity. The explanation is, that Φ is not an observable physical quantity. To infer a change of ϱ, we must measure $\vec{\mathcal{E}}$, which depends on $\mathbf{A}$ as well. Somehow it is encoded into the Coulomb gauge that, while $\Phi(\mathbf{r})$ instantly reflects all variations of $\varrho(\mathbf{r}')$, the vector potential depends in a much more complicated way on these variations, such that the combination $-\nabla\Phi - \partial\mathbf{A}/\partial t$ only responds to the variations after a long enough time for information to arrive.

The advantage of the Coulomb gauge is that the scalar potential is simple to calculate. The disadvantage is that, in addition to the non-causal appearance of Φ, it is particularly difficult to calculate $\mathbf{A}$: The differential equation for $\mathbf{A}$ in the Coulomb gauge is (14.81).

In order to obtain an equation involving only the vector field and the current density, we use Helmholtz's theorem to write the current density as the sum of *transverse* and *longitudinal* components,

$$\mathbf{j} = \mathbf{j}_T + \mathbf{j}_L \ , \tag{14.94}$$

where the terms 'transverse' and 'longitudinal' are defined by the following two conditions,

$$\boxed{\nabla\cdot\mathbf{j}_T = 0 \qquad \text{and} \qquad \nabla\times\mathbf{j}_L = 0} \ . \tag{14.95}$$

Calculating the rotation of the second equation (14.92) we see that the term containing the gradient of the scalar potential vanishes. Hence,

$$-\nabla^2\mathbf{A} + \frac{1}{c^2}\frac{\partial^2\mathbf{A}}{\partial t^2} = \mu_0\mathbf{j}_T \ , \tag{14.96}$$

which shows that the transverse component of $\mathbf{j}$ is fully associated only with the vector potential. Now, substituting this result into the second equation (14.92) we are left with,

$$\varepsilon_0\frac{\partial}{\partial t}\nabla\Phi = \mathbf{j}_L \ . \tag{14.97}$$

[11] The determination still leaves the freedom to add fields satisfying $\nabla^2\Theta = 0$.

That is, the longitudinal component of $\mathbf{j}$ is fully associated to the scalar potential. The solution of Eq. (14.96) requires some preparation and will be given in the following sections.

14.3.3 Green's function

A useful tool for solving Laplace equations, such as derived in Eq. (14.87) or (14.96), is the *Green's function*. The dynamics of physical systems are often described by differential equations of the type,

$$\mathcal{L}u(\mathbf{r}) = \varrho(\mathbf{r}) \ , \tag{14.98}$$

where $\mathcal{L} = \mathcal{L}(\mathbf{r})$ is a linear *differential operator*. While this operator has a very generic form, the behavior of a particular system depends on the choice of the function ϱ. The Laplace equation, where $\mathcal{L}(\mathbf{r}) \equiv \nabla^2$ and ϱ is a particular charge distribution is an example.

One method of solving this differential equation is to first solve the following equation,

$$\mathcal{L}\mathcal{G}(\mathbf{r}, \mathbf{x}) = \delta^3(\mathbf{r} - \mathbf{x}) \ , \tag{14.99}$$

where $\mathcal{G}(\mathbf{r}, \mathbf{x})$ is called the Green function of the operator. In general, the Green function is not unique. However, in practice, some combination of symmetry, boundary conditions and/or other externally imposed criteria can make the Green function unique.

Green functions are useful tools for solving wave and diffusion equations. In quantum mechanics, the Green function of the Hamiltonian is intrinsically connected to the concept of density of states. If the operator is invariant under translations, that is, if $\mathcal{L}$ has constant coefficients with respect to $\mathbf{r}$, then the Green function can be taken as the convolution [12],

$$\mathcal{G}(\mathbf{r}, \mathbf{x}) = \mathcal{G}(\mathbf{r} - \mathbf{x}) \ . \tag{14.100}$$

If such a function $\mathcal{G}$ can be found for the operator $\mathcal{L}$, then multiplying Eq. (14.99) for the Green function by $\varrho(\mathbf{x})$, and then integrating by the variable $\mathbf{x}$, we obtain:

$$\int \mathcal{L}\mathcal{G}(\mathbf{r}, \mathbf{x})\varrho(\mathbf{x})d^3x = \int \delta^3(\mathbf{r} - \mathbf{x})\varrho(\mathbf{x})d^3x = \varrho(\mathbf{r}) = \mathcal{L}u(\mathbf{r}) \ , \tag{14.101}$$

comparing the result with the Eq. (14.98). As we assume, that the operator $\mathcal{L} = \mathcal{L}(\mathbf{r})$ is linear and acts only on the variable $\mathbf{r}$ (and not on the integration variable $\mathbf{x}$), we can put $\mathcal{L}$ out of the integral on the right side. We conclude,

$$u(\mathbf{r}) = \int \mathcal{G}(\mathbf{r}, \mathbf{x})\varrho(\mathbf{x})d^3x \ . \tag{14.102}$$

Hence, we can obtain the function $u(\mathbf{r})$ from the Green function $\mathcal{G}(\mathbf{r}, \mathbf{x})$, determined by Eq. (14.99), and the source term $\varrho(\mathbf{x})$.

[12] In this case, the Green function is the same as the *pulse response* in the theory of time-independent linear systems.

The Green function, also called the fundamental solution associated with the operator $\mathcal{L}$, can be considered as the inversion of $\mathcal{L} \equiv \mathcal{G}^{-1}$. Not every operator $\mathcal{L}$ admits a Green function. In practice, not only calculating the Green function can be difficult for a particular operator, but also evaluating the integral in Eq. (14.102). In Exc. 14.3.8.8 we will get to know a Green function of the wave equation.

Example 92 (*Solving the Laplace equation by Green's method*): The Laplace equation is,

$$\nabla^2\Phi(\mathbf{r}) = -\varepsilon_0^{-1}\varrho(\mathbf{r}) \ .$$

The Green function,

$$\mathcal{G}(\mathbf{r},\mathbf{r}') = \mathcal{G}(\mathbf{r}-\mathbf{r}') = -\frac{1}{4\pi|\mathbf{r}-\mathbf{r}'|} \ ,$$

resolves the Poisson equation,

$$\nabla^2\mathcal{G}(\mathbf{r}-\mathbf{r}') = \delta^3(\mathbf{r}-\mathbf{r}') \ .$$

Therefore, the solution of the Laplace equation is,

$$\Phi(\mathbf{r}) = \frac{1}{4\pi\varepsilon_0}\int\frac{\varrho(\mathbf{r}')d^3r'}{|\mathbf{r}-\mathbf{r}'|} \ .$$

To solve the wave equations (14.90), we need to find the Green function for a spatio-temporal differential operator $\mathcal{L}(\mathbf{r},t) = \Box$. We will do this in the example 93, but for now, in the following section, we will adopt more empirical arguments.

14.3.4 Retarded potentials of continuous charge distributions

In the Lorentz gauge Φ and $\mathbf{A}$ satisfy the inhomogeneous wave equations (14.90) incorporating a 'source' term. We will use in the following exclusively the Lorentz gauge within which the entire electrodynamics comes down to solving (14.90).

But before that, let us take a look at the static situation, where the equations (14.90) reduce to Poisson equations,

$$\nabla^2\Phi = -\varepsilon_0^{-1}\varrho \qquad \text{and} \qquad \nabla^2\mathbf{A} = -\mu_0\mathbf{j} \ , \tag{14.103}$$

with the known solutions,

$$\Phi(\mathbf{r}) = \frac{1}{4\pi\varepsilon_0}\int\frac{\varrho(\mathbf{r}')}{|\mathbf{r}-\mathbf{r}'|}d^3r' \qquad \text{and} \qquad \mathbf{A}(\mathbf{r}) = \frac{\mu_0}{4\pi}\int\frac{\mathbf{j}(\mathbf{r}')}{|\mathbf{r}-\mathbf{r}'|}d^3r' \ . \tag{14.104}$$

In the dynamic case, the charge confined in the volume dV' (see Fig. 14.10) can move, but for the information on this movement to reach the point of observation $\mathbf{r}$ it takes a time determined by the propagation velocity of the light: $|\mathbf{r}-\mathbf{r}'|/c$. Introducing the distance R between the position of the charge and the observation point and the time retardation t_r by,

$$\mathbf{R} \equiv \mathbf{r}-\mathbf{r}' \qquad \text{and} \qquad t_r \equiv t - \tfrac{R}{c} \ , \tag{14.105}$$

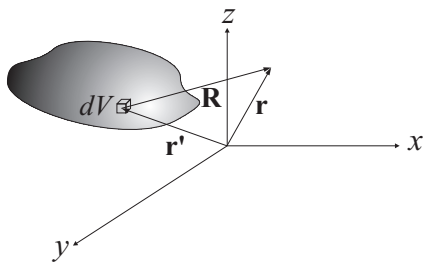

Figure 14.10: Geometry of source and the observation point.

we expect the following generalization of the equation (14.104),

$$\boxed{\Phi(\mathbf{r},t) = \frac{1}{4\pi\varepsilon_0}\int \frac{\varrho(\mathbf{r}',t_r)}{R}d^3r' \qquad \text{and} \qquad \mathbf{A}(\mathbf{r}) = \frac{\mu_0}{4\pi}\int \frac{\mathbf{j}(\mathbf{r}',t_r)}{R}d^3r'}\,, \tag{14.106}$$

called *retarded potential*.

The argument given above seems reasonable, but does not represent a stringent derivation, which will be given in the following. In fact, the same argument applied to the fields $\vec{\mathcal{E}}$ and $\vec{\mathcal{B}}$ would give false results, as we shall see later.

To verify the correctness of the assertion (14.106) we can simply show that it satisfies the wave equation (14.90) and the Lorentz gauge (14.89). However, this is not trivial, since the integral expressions depend on $\mathbf{r}$ explicitly (via the distance R in the denominator) and implicitly (via the retarded time t_d). Here, we present the calculation for the scalar potential,

$$\begin{aligned}\nabla_r\Phi(\mathbf{r}) &= \frac{1}{4\pi\varepsilon_0}\int \nabla_r \frac{\varrho(\mathbf{r}',t-\frac{|\mathbf{r}-\mathbf{r}'|}{c})}{|\mathbf{r}-\mathbf{r}'|}d^3r' \\ &= \frac{1}{4\pi\varepsilon_0}\int\left[\frac{1}{R}\nabla_r\varrho + \varrho\nabla_r\frac{1}{R}\right]d^3r' = \frac{1}{4\pi\varepsilon_0}\int\left[\frac{1}{R}\frac{-\dot{\varrho}}{c}\frac{\mathbf{R}}{R} + \varrho\frac{-\mathbf{R}}{R^3}\right]d^3r'\,.\end{aligned} \tag{14.107}$$

The divergence of the gradient,

$$\begin{aligned}\nabla_r^2\Phi(\mathbf{r}) &= \frac{1}{4\pi\varepsilon_0}\int\left[\frac{-\dot{\varrho}}{c}\left(\nabla_r\cdot\frac{\mathbf{R}}{R^2}\right) - \frac{\mathbf{R}}{R^2}\cdot\left(\frac{\nabla_r\dot{\varrho}}{c}\right) - (\nabla_r\varrho)\cdot\frac{\mathbf{R}}{R^3} - \varrho\left(\nabla_r\cdot\frac{\mathbf{R}}{R^3}\right)\right]d^3r' \\ &= \frac{1}{4\pi\varepsilon_0}\int\left[\cancel{\frac{-\dot{\varrho}}{c}\frac{1}{R^2}} - \frac{\mathbf{R}}{R^2}\cdot\left(\frac{-\ddot{\varrho}\mathbf{R}}{c^2R}\right) - \cancel{\left(-\frac{\dot{\varrho}\mathbf{R}}{cR}\right)\cdot\frac{\mathbf{R}}{R^3}} - \varrho 4\pi\delta^3(\mathbf{R})\right]d^3r' \\ &= \frac{1}{4\pi\varepsilon_0}\int\left[\frac{\ddot{\varrho}}{c^2R} - 4\pi\varrho\delta^3(\mathbf{R})\right]d^3r' = \frac{1}{c^2}\frac{\partial^2\Phi}{\partial t^2} - \frac{\varrho(\mathbf{r},t)}{\varepsilon_0}\,,\end{aligned} \tag{14.108}$$

where we replaced in the last line the integral of $\ddot{\varrho}/c^2R$ by the expression (14.106), reproduces the wave equation. In Exc. 14.3.8.9 we verify that the retarded potentials (14.106) satisfy the Lorentz gauge.

It is interesting to note that the same calculation can be made for advanced times, where the potential would be affected by a *future* movement of the charge, $t_a = t + \frac{R}{c}$. But this would violate causality.

Example 93 (*Resolution of the wave equation by the Greens function*): We showed in the previous section that in the Lorentz gauge, given the sources ϱ and $\mathbf{j}$, all we have to do to find the scalar and vector potentials is to solve wave type differential equations (14.87),

$$\nabla^2\psi(\mathbf{r},t) - \frac{1}{c^2}\frac{\partial^2\psi(\mathbf{r},t)}{\partial t^2} = f(\mathbf{r},t) \ ,$$

where ψ is a variable to denote the fields Φ or $\mathbf{A}$ and f to denote the sources ϱ or $\mathbf{j}$. First, we want to find a particular solution of this equation. To this end, we use the Green function $\mathcal{G}(\mathbf{r},t,\mathbf{r}',t')$, which by definition satisfies,

$$\boxed{\nabla^2\mathcal{G}(\mathbf{r},t,\mathbf{r}',t') - \frac{1}{c^2}\frac{\partial^2}{\partial t^2}\mathcal{G}(\mathbf{r},t,\mathbf{r}',t') = \delta^{(3)}(\mathbf{r}-\mathbf{r}')\delta(t-t')} \ .$$

We can perform the Fourier transform with respect to the variable t and obtain,

$$\nabla^2 g(\mathbf{r},\omega,\mathbf{r}',t') + \frac{\omega^2}{c^2}g(\mathbf{r},\omega,\mathbf{r}',t') = \delta^{(3)}(\mathbf{r}-\mathbf{r}')\frac{e^{\imath\omega t'}}{2\pi} \ ,$$

where we used the integral representation of the Dirac delta function, i.e.,

$$\delta(t-t') = \frac{1}{2\pi}\int_{-\infty}^{\infty} e^{-\imath\omega(t-t')}d\omega$$

and we defined,

$$\mathcal{G}(\mathbf{r},t,\mathbf{r}',t') \equiv \int_{-\infty}^{\infty} e^{-\imath\omega t} g(\mathbf{r},\omega,\mathbf{r}',t')d\omega \ .$$

As we will explain later, instead of solving the above differential equation, we will modify it:

$$\nabla^2 g_\eta(\mathbf{r},\omega,\mathbf{r}',t') + (k_0+\imath\eta)^2 g_\eta(\mathbf{r},\omega,\mathbf{r}',t') = \delta^{(3)}(\mathbf{r}-\mathbf{r}')\frac{e^{\imath\omega t'}}{2\pi} \ ,$$

with $k_0 \equiv \omega/c$ assuming positive and negative values for ω: We can now take the Fourier transform with respect to the variable $\mathbf{r}$ and obtain,

$$-k^2\bar{g}_\eta(\mathbf{k},\omega,\mathbf{r}',t') + (k_0+\imath\eta)^2\bar{g}_\eta(\mathbf{k},\omega,\mathbf{r}',t') = \frac{e^{-\imath\mathbf{k}\cdot\mathbf{r}'+\imath\omega t'}}{(2\pi)^4} \ ,$$

where we used,

$$\delta^{(3)}(\mathbf{r}-\mathbf{r}') = \frac{1}{(2\pi)^3}\int_{\mathbb{R}^3} e^{\imath\mathbf{k}\cdot(\mathbf{r}-\mathbf{r}')}d^3k \ ,$$

and defined,

$$g_\eta(\mathbf{r},\omega,\mathbf{r}',t') \equiv \int e^{\imath\mathbf{k}\cdot\mathbf{r}}\bar{g}_\eta(\mathbf{k},\omega,\mathbf{r}',t')d^3k \ .$$

Hence,

$$\bar{g}_\eta(\mathbf{k},\omega,\mathbf{r}',t') = \frac{e^{-\imath\mathbf{k}\cdot\mathbf{r}'+\imath\omega t'}}{(2\pi)^4[-k^2+(k_0+\imath\eta)^2]} \ ,$$

and therefore,

$$g_\eta(\mathbf{r},\omega,\mathbf{r}',t') = \int \frac{e^{-\imath\mathbf{k}\cdot(\mathbf{r}-\mathbf{r}')+\imath\omega t'}}{(2\pi)^4[-k^2+(k_0+\imath\eta)^2]}d^3k \ .$$

Note that, if we had not modified the original equation (i.e. set $\eta = 0$), the integral above would not converge, and we could not find a Green function by the present method. Now, however, the Green function is,

$$\mathcal{G}_\eta(\mathbf{r}-\mathbf{r}', t-t') = \int_{-\infty}^{\infty} e^{-\imath\omega t} g_\eta(\mathbf{r}, \omega, \mathbf{r}', t') d\omega = \int d^3k \int_{-\infty}^{\infty} d\omega \frac{e^{\imath\mathbf{k}\cdot(\mathbf{r}-\mathbf{r}')-\imath\omega(t-t')}}{(2\pi)^4[-k^2 + (k_0 + \imath\eta)^2]} ,$$

or yet,

$$\mathcal{G}_\eta(\mathbf{r}, t) = \int d^3k \int_{-\infty}^{\infty} \frac{d\omega\ e^{\imath\mathbf{k}\cdot\mathbf{r}-\imath\omega t}}{(2\pi)^4[-k^2 + (k_0 + \imath\eta)^2]} = \frac{1}{(2\pi)^4} \int_{-\infty}^{\infty} d\omega e^{-\imath\omega t} \int \frac{d^3k\ e^{\imath\mathbf{k}\cdot\mathbf{r}}}{[k^2 - (k_0 + \imath\eta)^2]} .$$

In polar coordinates, choosing the orientation of the $\mathbf{k}$-vector space such that k_z is parallel to the vector $\mathbf{r}$,

$$\begin{aligned}
\int d^3k \frac{e^{\imath\mathbf{k}\cdot\mathbf{r}}}{[k^2 - (k_0 + \imath\eta)^2]} &= \int_0^\infty k^2 dk \frac{1}{[k^2 - (k_0 + \imath\eta)^2]} \int_0^{2\pi} d\phi_k \int_0^\pi d\theta_k \sin\theta_k e^{\imath\mathbf{k}\cdot\mathbf{r}} \\
&= \int_0^\infty dk \frac{k^2}{[k^2 - (k_0 + \imath\eta)^2]} \int_0^{2\pi} d\phi_k \int_0^\pi d\theta_k \sin\theta_k e^{\imath kr\cos\theta_k} \\
&= \int_0^\infty dk \frac{2\pi k^2}{[k^2 - (k_0 + \imath\eta)^2]} \int_{-1}^{1} du e^{\imath kru} \\
&= \frac{2\pi}{\imath r} \int_0^\infty dk \frac{k}{[k^2 - (k_0 + \imath\eta)^2]} (e^{\imath kr} - e^{-\imath kr}) ,
\end{aligned}$$

where we used the substitution $u \equiv \cos\theta_k$. Since,

$$\int_0^\infty dk \frac{ke^{-\imath kr}}{[k^2 - (k_0 + \imath\eta)^2]} = -\int_{-\infty}^0 dk \frac{ke^{\imath kr}}{[k^2 - (k_0 + \imath\eta)^2]} ,$$

we can write,

$$\int d^3k \frac{e^{\imath\mathbf{k}\cdot\mathbf{r}}}{[k^2 - (k_0 + \imath\eta)^2]} = \frac{2\pi}{\imath r} \int_{-\infty}^\infty dk \frac{ke^{\imath kr}}{[k^2 - (k_0 + \imath\eta)^2]} .$$

The poles of this integral are given by,

$$Z_\pm = \pm(k_0 + \imath\eta) .$$

We consider the integral in the complex plane:

$$\oint_{\mathcal{C}} \frac{Ze^{\imath rZ}}{(Z - Z_+)(Z - Z_-)} dZ ,$$

where the contour is closed over the upper complex half-plane. When $\eta \to 0^+$ [see Fig. 14.11(a)], we get,

$$\oint_{\mathcal{C}} \frac{Ze^{\imath rZ}}{(Z - Z_+)(Z - Z_-)} dZ = 2\pi\imath \frac{Z_+ e^{\imath rZ_+}}{Z - Z_+} = \imath\pi e^{\imath k_0 r} .$$

When $\eta \to 0^-$ [see Fig. 14.11(b)], we get,

$$\oint_{\mathcal{C}} \frac{Ze^{\imath rZ}}{(Z - Z_+)(Z - Z_-)} dZ = \imath\pi e^{-\imath k_0 r} .$$

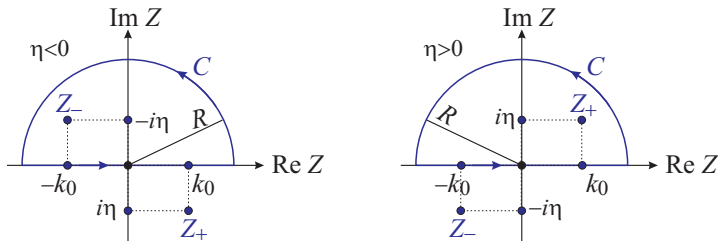

Figure 14.11: Illustration of the integration path.

But, with the closed contour over the upper complex half-plane,

$$\int_{-\infty}^{\infty} dk \frac{ke^{\imath kr}}{[k^2-(k_0+\imath\eta)^2]} = \oint_{\mathcal{C}} \frac{Ze^{\imath rZ}}{(Z-Z_+)(Z-Z_-)} dZ = \imath\pi e^{\pm\imath k_0 r} \ .$$

With these results, we can conclude that,

$$\int d^3k \frac{e^{\imath\mathbf{k}\cdot\mathbf{r}}}{[k^2-(k_0+\imath\eta)^2]} = \frac{2\pi^2}{r} e^{\pm\imath k_0 r} \ ,$$

and hence,

$$\mathcal{G}_\pm(\mathbf{r},t) = -\frac{1}{(2\pi)^4}\int_{-\infty}^{\infty} d\omega e^{-\imath\omega t}\frac{2\pi^2}{r}e^{\pm\imath k_0 r} = -\frac{1}{8\pi^2 r}\int_{-\infty}^{\infty} d\omega e^{-\imath\omega(t\mp\frac{r}{c})} = -\frac{1}{4\pi r}\delta(t\mp\tfrac{r}{c}) \ .$$

Thus, we also have,

$$\mathcal{G}_\pm(\mathbf{r}-\mathbf{r}',t-t') = -\frac{1}{4\pi}\frac{1}{|\mathbf{r}-\mathbf{r}'|}\delta(t-t'\mp\tfrac{|\mathbf{r}-\mathbf{r}'|}{c}) \ .$$

There are, therefore, two possible solutions to the problem:

$$\begin{aligned}\psi(\mathbf{r},t) &= \int d^3r' \int_{-\infty}^{\infty} dt' \mathcal{G}_\pm(\mathbf{r}-\mathbf{r}',t-t') f(\mathbf{r}',t') \\ &= -\frac{1}{4\pi}\int \frac{d^3r'}{|\mathbf{r}-\mathbf{r}'|}\int_{-\infty}^{\infty} dt'\delta(t'-t\pm\tfrac{|\mathbf{r}-\mathbf{r}'|}{c}) f(\mathbf{r}',t') = -\frac{1}{4\pi}\int d^3r' \frac{f(\mathbf{r}',t\mp\frac{|\mathbf{r}-\mathbf{r}'|}{c})}{|\mathbf{r}-\mathbf{r}'|} \ .\end{aligned}$$

In this case, we will use retarded rather than advanced solutions, i.e.,

$$\Phi(\mathbf{r},t) = \frac{1}{4\pi\varepsilon_0}\int \frac{\varrho(\mathbf{r}',t-\frac{|\mathbf{r}-\mathbf{r}'|}{c})}{|\mathbf{r}-\mathbf{r}'|} d^3\mathbf{r}' \quad \text{and} \quad \mathbf{A}(\mathbf{r},t) = \frac{\mu_0}{4\pi}\int \frac{\mathbf{j}(\mathbf{r}',t-\frac{|\mathbf{r}-\mathbf{r}'|}{c})}{|\mathbf{r}-\mathbf{r}'|} d^3\mathbf{r}' \ .$$

14.3.5 Retarded fields in electrodynamics and Jefimenko's equations

From the retarded potentials (14.106) we can determine the fields through equations (14.78),

$$\vec{\mathcal{E}}(\mathbf{r},t) = -\nabla_r\Phi - \frac{\partial\mathbf{A}}{\partial t} = -\frac{1}{4\pi\varepsilon_0}\int\left[\frac{1}{R}\frac{-\dot{\varrho}}{c}\frac{\mathbf{R}}{R} + \varrho\frac{-\mathbf{R}}{R^3}\right] d^3r' - \frac{\mu_0}{4\pi}\int \frac{\dot{\mathbf{j}}(\mathbf{r}',t_r)}{R} d^3r' \ ,$$

using the result (14.107). With $c^2 = 1/\varepsilon_0\mu_0$ we obtain the time-dependent generalization of Coulomb's law,

$$\boxed{\vec{\mathcal{E}}(\mathbf{r},t) = \frac{1}{4\pi\varepsilon_0}\int\left[\frac{\varrho(\mathbf{r}',t_r)}{R^2}\hat{\mathbf{e}}_R + \frac{\dot{\varrho}(\mathbf{r}',t_r)}{cR}\hat{\mathbf{e}}_R - \frac{\dot{\mathbf{j}}(\mathbf{r}',t_r)}{c^2R}\right]d^3r'} \ . \tag{14.109}$$

In static situations the second and third term cancel, $\varrho(\mathbf{r}',t') = \varrho(\mathbf{r}')$ becomes independent of time, and we recover the electrostatic Coulomb law.

We now calculate the magnetic field via the rotation,

$$\vec{\mathcal{B}}(\mathbf{r},t) = \nabla_r \times \mathbf{A} = \frac{\mu_0}{4\pi}\int\left[\frac{1}{R}(\nabla_r \times \mathbf{j}) - \mathbf{j}\times\nabla_r\left(\frac{1}{R}\right)\right]d^3r' \ . \tag{14.110}$$

With,

$$\begin{aligned}[\nabla_r \times \mathbf{j}(\mathbf{r}',t-\tfrac{R}{c})]_x &= \frac{\partial j_z}{\partial y} - \frac{\partial j_y}{\partial z} = \dot{j}_z\frac{\partial t_r}{\partial y} - \dot{j}_y\frac{\partial t_r}{\partial z} \\ &= -\frac{1}{c}\left(\dot{j}_z\frac{\partial R}{\partial y} - \dot{j}_y\frac{\partial R}{\partial z}\right) = \left[\frac{1}{c}\dot{\mathbf{j}}\times\nabla_r R\right]_x = \left[\frac{1}{c}\dot{\mathbf{j}}\times\frac{\mathbf{R}}{R}\right]_x \ .\end{aligned} \tag{14.111}$$

Thus, the time-dependent generalization of the Biot-Savart law is,

$$\boxed{\vec{\mathcal{B}}(\mathbf{r},t) = \frac{\mu_0}{4\pi}\int\left[\frac{\mathbf{j}(\mathbf{r}',t_r)}{R^2} + \frac{\dot{\mathbf{j}}(\mathbf{r}',t_r)}{cR}\right]\times\frac{\mathbf{R}}{R}d^3r'} \ . \tag{14.112}$$

The equations (14.109) and (14.112) are the (causal) solutions of Maxwell's equations published by *Jefimenko* in 1966. In practice, these equations are of limited utility, since it is usually easier to calculate the retarded potentials, instead of going directly to the fields. However, they provide the satisfying sensation of a closed theory. We note that the simple replacement of the times t by t_r made for the potentials in (14.106) does not apply to the fields, as it would only produce the first terms of Jefimenko's expressions.

In the Excs. 14.3.8.10 and 14.3.8.11 we evaluate the fields for slow current variations.

14.3.6 The Liénard-Wiechert potentials

The goal now is to calculate the retarded electromagnetic potentials produced by a moving point charge q along a predefined path $\mathbf{w}(t)$. The presence of the charge at a time t_r at a point $\mathbf{w}(t_r)$, called the *retarded position* of this trajectory, has an impact on an arbitrary point of space $\mathbf{r}$ at a time t given by,

$$t = t_r + \tfrac{|\mathbf{r}-\mathbf{w}(t_r)|}{c} \ . \tag{14.113}$$

At a given instant of time t, the potentials $\Phi(\mathbf{r},t)$ and $\mathbf{A}(\mathbf{r},t)$ evaluated at the point $\mathbf{r}$ *depend only on a single point* of the trajectory $\mathbf{w}(t_r)$ occupied by the charge in the

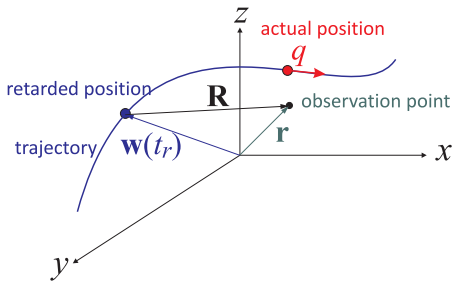

Figure 14.12: Retardation of potentials.

past. The equation (14.106) now allows you to calculate the potentials. For a given trajectory $\mathbf{w}(t')$ the charge and current densities are parametrized by,

$$\boxed{\varrho(\mathbf{r}',t') = q\delta^3(\mathbf{r}'-\mathbf{w}(t')) \qquad \text{and} \qquad \mathbf{j}(\mathbf{r}',t') = \mathbf{v}\varrho(\mathbf{r}',t')} \ . \tag{14.114}$$

However, we need the density at the retarded time t_r [13],

$$\varrho(\mathbf{r}',t_r) = q\int \delta^3(\mathbf{r}'-\mathbf{w}(t'))\delta(t'-t_r)dt' \ . \tag{14.115}$$

We obtain,

$$\begin{aligned}\Phi(\mathbf{r},t) = \frac{q}{4\pi\varepsilon_0}\int \frac{\varrho(\mathbf{r}',t_r)}{|\mathbf{r}-\mathbf{r}'|}d^3r' &= \frac{q}{4\pi\varepsilon_0}\int\int \frac{\delta^3(\mathbf{r}'-\mathbf{w}(t'))}{|\mathbf{r}-\mathbf{r}'|}\delta(t'-t_r)d^3r'dt' \\ &= \frac{q}{4\pi\varepsilon_0}\int \frac{1}{|\mathbf{r}-\mathbf{w}(t')|}\delta(t'-(t-\tfrac{|\mathbf{r}-\mathbf{w}(t')|}{c}))dt' \ ,\end{aligned} \tag{14.116}$$

where spatial integration replaced $\mathbf{r}' = \mathbf{w}(t')$.

To evaluate a function $\delta(g(x))$ which depends on another function $g(x)$, we make the substitution,

$$u \equiv g(x) \qquad \text{with} \qquad du = \tfrac{dg}{dx}dx \ , \tag{14.117}$$

such that,

$$\int \delta(g(x))dx = \int \frac{\delta(u)}{|dg/dx|}du = \frac{1}{\left|\frac{dg(x_0)}{dx}\right|} \ , \tag{14.118}$$

where x_0 is defined by $u = g(x_0) = 0$. Applied to our problem, we identify,

$$u = g(t') = t' - \left(t - \tfrac{|\mathbf{r}-\mathbf{w}(t')|}{c}\right) = t' - t_r \ . \tag{14.119}$$

That is, the time when $u = g(t') = 0$ is simply $t' = t_r$. Now, the time derivative is,

$$\frac{dg}{dt'} = 1 + \frac{1}{c}\frac{d}{dt'}|\mathbf{r}-\mathbf{w}(t')| = 1 - \frac{\mathbf{v}(t')}{c}\cdot\frac{\mathbf{r}-\mathbf{w}(t')}{|\mathbf{r}-\mathbf{w}(t')|} \ , \tag{14.120}$$

[13] Can not simply replace $t' \to t_r$ in the argument of $\mathbf{w}(t')$, because t_r implicitly depends on $\mathbf{w}(t')$ via the expression (14.113).

with $\mathbf{v} \equiv \dot{\mathbf{w}}$. With this, the expression (14.116) becomes,

$$\Phi = \frac{q}{4\pi\varepsilon_0} \int \frac{1}{|\mathbf{r} - \mathbf{w}(t')|} \frac{\delta(u)}{\left|\frac{dg}{dt'}\right|} du = \frac{q}{4\pi\varepsilon_0} \frac{1}{|\mathbf{r} - \mathbf{w}(t_r)|} \frac{1}{|1 - \frac{\mathbf{v}(t_r)}{c} \cdot \frac{\mathbf{r}-\mathbf{w}(t_r)}{|\mathbf{r}-\mathbf{w}(t_r)|}|} \ , \tag{14.121}$$

where the application of the $\delta(u)$ function comes down to replacing t' by t_r. Finally, recalling the abbreviation $\mathbf{R} \equiv \mathbf{r} - \mathbf{w}(t_r)$,

$$\boxed{\Phi(\mathbf{r}, t) = \frac{1}{4\pi\varepsilon_0} \frac{qc}{Rc - \mathbf{R} \cdot \mathbf{v}}} \quad \text{and} \quad \boxed{\mathbf{A}(\mathbf{r}, t) = \frac{\mu_0}{4\pi} \frac{qc\mathbf{v}}{Rc - \mathbf{R} \cdot \mathbf{v}} = \frac{\mathbf{v}}{c^2} \Phi(\mathbf{r}, t)} \ , \tag{14.122}$$

where the vector potential is obtained in an analogous way. These are the so-called *Liénard-Wiechert potentials* [14]. In Exc. 14.3.8.12 we calculate the potentials of a point charge in uniform motion.

14.3.7 The fields of a moving point charge

Fields produced by a moving point charge are calculated from the potentials (14.122) using (14.78). The calculation is complicated, because we must evaluate both, distance and speed,

$$\mathbf{R} = \mathbf{r} - \mathbf{w}(t_r) \qquad \text{and} \qquad \mathbf{v} = \dot{\mathbf{w}}(t_r) \tag{14.123}$$

at the retarded time, which is implicitly defined by the equation,

$$R = |\mathbf{r} - \mathbf{w}(t_r)| = c(t - t_r) \ . \tag{14.124}$$

We start with the gradient of the scalar potential (14.122),

$$\nabla\Phi = \frac{qc}{4\pi\varepsilon_0} \frac{-1}{(Rc - \mathbf{R} \cdot \mathbf{v})^2} \nabla(Rc - \mathbf{R} \cdot \mathbf{v}) \ , \tag{14.125}$$

and evaluate both terms separately. Using (14.124) we find,

$$\nabla(Rc) = -c^2 \nabla t_r \ , \tag{14.126}$$

where we leave the calculation of the gradient of retarded time for later. Also, using the rule (18.89)(ix), we find,

$$\nabla(\mathbf{R} \cdot \mathbf{v}) = (\mathbf{R} \cdot \nabla)\mathbf{v} + (\mathbf{v} \cdot \nabla)\mathbf{R} + \mathbf{R} \times (\nabla \times \mathbf{v}) + \mathbf{v} \times (\nabla \times \mathbf{R}) \ . \tag{14.127}$$

The first term of this expression gives,

$$(\mathbf{R} \cdot \nabla)\mathbf{v}(t_r) = R_x \frac{\partial t_r}{\partial x} \frac{d\mathbf{v}}{dt_r} + R_y \frac{\partial t_r}{\partial y} \frac{d\mathbf{v}}{dt_r} + R_z \frac{\partial t_r}{\partial z} \frac{d\mathbf{v}}{dt_r} = \mathbf{a}(\mathbf{R} \cdot \nabla t_r) \ , \tag{14.128}$$

where $\mathbf{a} \equiv \dot{\mathbf{v}}$ is the acceleration at the retarded time. The second term is,

$$(\mathbf{v} \cdot \nabla)\mathbf{R} = (\mathbf{v} \cdot \nabla)\mathbf{r} - (\mathbf{v} \cdot \nabla)\mathbf{w} = \mathbf{v} - \mathbf{v}(\mathbf{v} \cdot \nabla t_r) \ . \tag{14.129}$$

[14] We get the same result from the argument, that light needs a finite time to cross the volume of the charge distribution $d^3r' = dV'$, such that the volume appears stretched at the time instant t_r, $dV' \longrightarrow \frac{dV'}{1-\hat{\mathbf{e}}_r \cdot \mathbf{v}/c}$.

Now, using,

$$\nabla \times \mathbf{v} = \left(\frac{\partial t_r}{\partial y} \frac{dv_z}{dt_r} - \frac{\partial t_r}{\partial z} \frac{dv_y}{dt_r} \right) \hat{\mathbf{e}}_x + ... = -\mathbf{a} \times \nabla t_r \ , \tag{14.130}$$

the third term becomes,

$$\mathbf{R} \times (\nabla \times \mathbf{v}) = -\mathbf{R} \times (\mathbf{a} \times \nabla t_r) \ . \tag{14.131}$$

Finally, using,

$$\nabla \times \mathbf{R} = \cancelto{0}{\nabla \times \mathbf{r}} - \nabla \times \mathbf{w} = \mathbf{v} \times \nabla t_r \ , \tag{14.132}$$

the fourth term is,

$$\mathbf{v} \times (\nabla \times \mathbf{R}) = \mathbf{v} \times (\mathbf{v} \times \nabla t_r) \ . \tag{14.133}$$

With these results the expression (14.127) becomes,

$$\begin{aligned} \nabla(\mathbf{R} \cdot \mathbf{v}) &= \mathbf{a}(\mathbf{R} \cdot \nabla t_r) + \mathbf{v} - \mathbf{v}(\mathbf{v} \cdot \nabla t_r) - \mathbf{R} \times (\mathbf{a} \times \nabla t_r) + \mathbf{v} \times (\mathbf{v} \times \nabla t_r) \\ &= \mathbf{v} + (\mathbf{R} \cdot \mathbf{a} - v^2) \nabla t_r \ , \end{aligned} \tag{14.134}$$

using in the last step the rule $\mathbf{A} \times (\mathbf{B} \times \mathbf{C}) = \mathbf{B}(\mathbf{A} \cdot \mathbf{C}) - \mathbf{C}(\mathbf{A} \cdot \mathbf{B})$. Now, we calculate ∇t_r,

$$\begin{aligned} \nabla t_r &= -\tfrac{1}{c} \nabla R = -\tfrac{1}{c} \nabla \sqrt{\mathbf{R} \cdot \mathbf{R}} = -\frac{1}{2c\sqrt{\mathbf{R} \cdot \mathbf{R}}} \nabla(\mathbf{R} \cdot \mathbf{R}) \\ &= -\frac{1}{cR} [(\mathbf{R} \cdot \nabla)\mathbf{R} \ + \ \mathbf{R} \times (\nabla \times \mathbf{R})] \\ &= -\frac{1}{cR} [(\mathbf{R} \cdot \nabla)\mathbf{r} - (\mathbf{R} \cdot \nabla)\mathbf{w} \ + \ \mathbf{R} \times (\nabla \times \mathbf{R})] \\ &= -\frac{1}{cR} [\mathbf{R} - \mathbf{v}(\mathbf{R} \cdot \nabla t_r) \ + \ \mathbf{R} \times (\mathbf{v} \times \nabla t_r)] = -\frac{1}{cR} [\mathbf{R} - (\mathbf{R} \cdot \mathbf{v}) \nabla t_r)] \ . \end{aligned} \tag{14.135}$$

To get $(\mathbf{R} \cdot \nabla)\mathbf{w}$ we did a calculation similar to (14.128) and $\nabla \times \mathbf{R}$ was already calculated in (14.132). Solving the result (14.135) by ∇t_r,

$$\nabla t_r = -\frac{\mathbf{R}}{cR - \mathbf{R} \cdot \mathbf{v}} \ . \tag{14.136}$$

Finally, the gradient of the scalar potential (14.125) is,

$$\nabla \Phi = \frac{1}{4\pi\varepsilon_0} \frac{qc}{(cR - \mathbf{R} \cdot \mathbf{v})^3} \left[(cR - \mathbf{R} \cdot \mathbf{v})\mathbf{v} - (c^2 - v^2 + \mathbf{R} \cdot \mathbf{a})\mathbf{R} \right] \ . \tag{14.137}$$

A similar calculation for the temporal derivative of the vector potential gives the result,

$$\frac{\partial \mathbf{A}}{\partial t} = \frac{1}{4\pi\varepsilon_0} \frac{qc}{(cR - \mathbf{R} \cdot \mathbf{v})^3} \left[(cR - \mathbf{R} \cdot \mathbf{v})(-\mathbf{v} + \frac{R}{c}\mathbf{a}) + \frac{R}{c}(c^2 - v^2 + \mathbf{R} \cdot \mathbf{a})\mathbf{v} \right] \ . \tag{14.138}$$

The rotation of the vector potential yields,

$$\begin{aligned}\nabla\times\mathbf{A} &= \frac{1}{c^2}\nabla\times(\Phi\mathbf{v}) = \frac{1}{c^2}[\Phi(\nabla\times\mathbf{v})-\mathbf{v}(\nabla\Phi)] \\ &= -\frac{1}{c}\frac{q}{4\pi\varepsilon_0}\frac{1}{(\mathbf{R}\cdot\mathbf{u})^3}\mathbf{R}\times[(c^2-v^2)\mathbf{v}+(\mathbf{R}\cdot\mathbf{a})\mathbf{v}+(\mathbf{R}\cdot\mathbf{u})\mathbf{a}]\ ,\end{aligned} \tag{14.139}$$

using the expressions (14.130) and (14.137) and introducing the abbreviation $\mathbf{u}\equiv c\hat{\mathbf{e}}_R-\mathbf{v}$.

Combining these results with equations (14.78), we find the fields,

$$\boxed{\vec{\mathcal{E}}(\mathbf{r},t)=\frac{q}{4\pi\varepsilon_0}\frac{R}{(\mathbf{R}\cdot\mathbf{u})^3}[(c^2-v^2)\mathbf{u}+\mathbf{R}\times(\mathbf{u}\times\mathbf{a})]}\ , \tag{14.140}$$

and,

$$\boxed{\vec{\mathcal{B}}(\mathbf{r},t)=\tfrac{1}{c}\hat{\mathbf{e}}_R\times\vec{\mathcal{E}}(\mathbf{r},t)}\ . \tag{14.141}$$

Obviously, the magnetic field of a point charge is always perpendicular to the electric field and to the vector of the retarded point. The first term in $\vec{\mathcal{E}}$ (involving $(c^2-v^2)\cdot\mathbf{u}$) falls off like $1/R^2$. If the velocity $\mathbf{v}$ and the acceleration $\mathbf{a}$ were zero, this term survives and reduces to the old electrostatic result (10.3). For this reason, this term is called the generalized Coulomb field. The second term (involving $\mathbf{R}\times(\mathbf{u}\times\mathbf{a})$) falls off like $1/R$ and thus becomes dominant at large distances. As we will see in Sec. 16.4, this is the term responsible for electromagnetic radiation.

Knowing the fields generated by the moving charge q we can, by the laws of the *Coulomb force* and the *Lorentz force*, determine the force acting on a test particle Q located at $\mathbf{r}$ and moving with velocity $\mathbf{V}$,

$$\begin{aligned}\mathbf{F}(\mathbf{r},t) = \frac{qQ}{4\pi\varepsilon_0}\frac{R}{(\mathbf{R}\cdot\mathbf{u})^3}\Big\{&[(c^2-v^2)\mathbf{u}+\mathbf{R}\times(\mathbf{u}\times\mathbf{a})] \\ &+\frac{\mathbf{V}}{c}\times\big[\hat{\mathbf{e}}_R\times[(c^2-v^2)\mathbf{u}+\mathbf{R}\times(\mathbf{u}\times\mathbf{a})]\big]\Big\}\ ,\end{aligned} \tag{14.142}$$

where $\mathbf{r}$, $\mathbf{u}$, $\mathbf{v}$, and $\mathbf{a}$ are all evaluated at the retarded time. The entire classical electrodynamics is contained in this equation because, since the charge is quantized, we can apply the superposition principle and calculate the impact of any charge distribution on a test particle Q. However, in view of the complexity of (14.142), the necessary effort seems huge. The scheme 14.13 summarizes the fundamental laws of electrodynamics.

Resolve the Excs. 14.3.8.13 to 14.3.8.16.

Example 94 (*Electric and magnetic fields generated by a uniformly moving charge*): Letting $\mathbf{a}=0$ in (14.140),

$$\vec{\mathcal{E}}(\mathbf{r},t)=\frac{q}{4\pi\varepsilon_0}\frac{R}{(\mathbf{R}\cdot\mathbf{u})^3}(c^2-v^2)\mathbf{u}\ ,$$

we can express the position of the charge at the retarded time by its constant velocity, $\dot{\mathbf{w}}=\mathbf{v}$. We calculate using the definition of $\mathbf{u}$,

$$R\mathbf{u}=c\mathbf{R}-R\mathbf{v}=c\mathbf{R}-R\dot{\mathbf{w}}=c(\mathbf{r}-\mathbf{v}t_r)-c(t-t_r)\mathbf{v}=c(\mathbf{r}-\mathbf{v}t)\ .$$

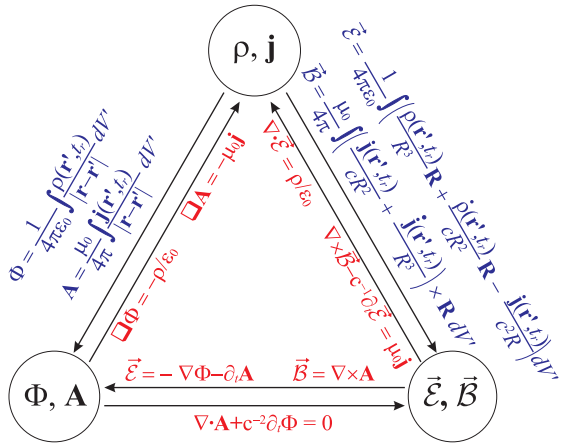

Figure 14.13: Organization chart of the fundamental laws of electrodynamics. Compare with the corresponding charts in electrostatics Fig. 10.9 and magnetostatics Fig. 12.13.

The square of the relationship $|\mathbf{r} - \mathbf{v}t_r| = c(t - t_r)$ resolved by t_r gives,

$$t_r = \frac{(c^2 t - \mathbf{r}\cdot\mathbf{v}) \pm \sqrt{(c^2 t - \mathbf{r}\cdot\mathbf{v})^2 + (c^2 - v^2)(r^2 - c^2 t^2)}}{c^2 - v^2} \ ,$$

where we only consider the sign $-$. With this we calculate,

$$\begin{aligned}
\mathbf{R}\cdot\mathbf{u} &= Rc - \mathbf{R}\cdot\mathbf{v} = c^2(t - t_r) - (\mathbf{r} - \mathbf{v}t_r)\cdot\mathbf{v} = c^2 t - \mathbf{r}\cdot\mathbf{v} - (c^2 - v^2)t_r \\
&= \sqrt{(c^2 t - \mathbf{r}\cdot\mathbf{v})^2 + (c^2 - v^2)(r^2 - c^2 t^2)} \\
&= \sqrt{(c^2 - v^2)(\mathbf{r} - \mathbf{v}t)^2 + [(\mathbf{r} - \mathbf{v}t)\cdot\mathbf{v}]^2} \\
&= \sqrt{(c^2 - v^2)d^2 + (\mathbf{d}\cdot\mathbf{v})^2} = d\sqrt{c^2 - v^2 + v^2\cos^2\theta} = dc\sqrt{1 - \tfrac{v^2}{c^2}\sin^2\theta} \ ,
\end{aligned}$$

where the abbreviation $\mathbf{d} \equiv \mathbf{r} - \mathbf{v}t$ is the vector between $\mathbf{r}$ and the *actual position* of the particle and θ is the angle between $\mathbf{d}$ and $\mathbf{v}$. Then,

$$\vec{\mathcal{E}}(\mathbf{r}, t) = \frac{q}{4\pi\varepsilon_0}\frac{1 - v^2/c^2}{(1 - \frac{v^2}{c^2}\sin^2\theta)^{3/2}}\frac{\hat{\mathbf{e}}_d}{d^2} \ .$$

Note that $\vec{\mathcal{E}}$ points along the distance $\mathbf{d}$. This is an extraordinary coincidence; after all, the 'message' came from the retarded position. Because of the $\sin^2\theta$ in the denominator, the field of a charge moving fast is flattened like a pancake in the direction perpendicular to the motion (see Fig. 14.14). In the forward and backward directions $\vec{\mathcal{E}}$ is reduced by a factor $(1 - v^2/c^2)$ with respect to the field of a charge at rest; in the perpendicular direction is amplified by a factor $1/\sqrt{1 - v^2/c^2}$.
To get $\vec{\mathcal{B}}$ we calculate,

$$\hat{\mathbf{e}}_R = \frac{\mathbf{r} - \mathbf{v}t_r}{R} = \frac{(\mathbf{r} - \mathbf{v}t) + (t - t_r)\mathbf{v}}{R} = \frac{\mathbf{d}}{R} + \frac{\mathbf{v}}{c} \ ,$$

and hence,

$$\vec{\mathcal{B}} = \tfrac{1}{c}(\hat{\mathbf{e}}_R \times \vec{\mathcal{E}}) = \tfrac{1}{c^2}(\mathbf{v} \times \vec{\mathcal{E}}) \ .$$

The $\vec{\mathcal{B}}$-field lines form circles around the charge, as shown in Fig. 14.14. At low velocities, $v \ll c$,

$$\vec{\mathcal{E}}(\mathbf{r},t) = \frac{q}{4\pi\varepsilon_0}\frac{\mathbf{d}}{d^2} \quad , \quad \vec{\mathcal{B}} = \frac{\mu_0 q}{4\pi}\frac{\mathbf{v}\times\hat{\mathbf{e}}_d}{d^2} \ .$$

we recover the laws of Coulomb and Biot-Savart for point charges.

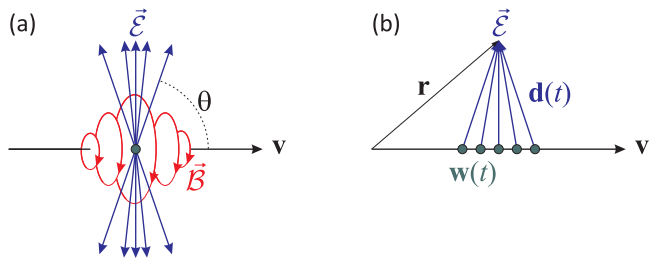

Figure 14.14: (a) Electric and magnetic field generated by of a point charge in uniform motion. (b) Electric field seen from an observation point $\mathbf{r}$ fixed in space.

14.3.8 Exercises

14.3.8.1 Ex: Potentials, fields and the Lorentz gauge

Consider a scalar field and a vector field of the form,

$$\Phi(\mathbf{r},t) = cd\frac{\mathbf{r}\cdot\hat{\mathbf{e}}_z}{r^3}e^{\imath\omega t} \qquad \text{and} \qquad \mathbf{A}(\mathbf{r},t) = \imath kd\frac{e^{\imath kr}}{r}e^{\imath\omega t}\ \hat{\mathbf{e}}_z \ .$$

where $k = \omega/c$.
a. Calculate the corresponding fields $\vec{\mathcal{B}}$ and $\vec{\mathcal{E}}$.
b. Show that for small r the given potentials satisfy the Lorentz gauge.

14.3.8.2 Ex: Fields, potentials, and the gauge transformation

Find the charge and current distributions producing the following potential,

$$\Phi(\mathbf{r},t) = 0 \qquad \text{and} \qquad \mathbf{A}(\mathbf{r},t) = \frac{\mu_0 k}{4c}(ct-|x|)^2\hat{\mathbf{e}}_z\ \Theta(|x|-ct) \ ,$$

where $k = const$.

14.3.8.3 Ex: Fields derived from potentials

Show that the differential equations for Φ and $\mathbf{A}$ can be written in a more symmetric form as,

$$\Box\Phi + \frac{\partial L}{\partial t} = -\frac{\varrho}{\varepsilon_0} \qquad \text{and} \qquad \Box\mathbf{A} - \nabla L = -\mu_0\mathbf{j} \ ,$$

where $L \equiv \nabla\cdot\mathbf{A} + \varepsilon_0\mu_0\frac{\partial\Phi}{\partial t}$.

14.3.8.4 Ex: Fields derived from potentials

a. Find the fields and the charge and current distributions corresponding to,

$$\Phi(\mathbf{r},t) = 0 \qquad \text{and} \qquad \mathbf{A}(\mathbf{r},t) = -\frac{1}{4\pi\varepsilon_0}\frac{qt}{r^2}\hat{\mathbf{e}}_r \ .$$

b. Use the gauge function $\chi = -\frac{1}{4\pi\varepsilon_0}\frac{qt}{r}$ to transform the potentials in (a), and comment the result.
c. Check whether the potentials are in the Lorentz or in the Coulomb gauge.

14.3.8.5 Ex: Fields derived from potentials

a. Suppose $\Phi = 0$ and $\mathbf{A} = A_0 \sin(kx - \omega t)\hat{\mathbf{e}}_y$, where A_0, ω, and k are constants. Find $\vec{\mathcal{E}}$ and $\vec{\mathcal{B}}$, and verify, that they satisfy Maxwell's equations in vacuum. What conditions should be imposed to ω and k?
b. Check whether the potentials are in the Lorentz or in the Coulomb gauge.

14.3.8.6 Ex: Other gauges

Check the viability of a gauge defined by $\Phi \equiv 0$ and a gauge defined by $\mathbf{A} \equiv 0$.

14.3.8.7 Ex: Coulomb gauge

a. Show that the vector potential can be expressed by the magnetic field as,

$$\mathbf{A}(\mathbf{r},t) = \nabla \times \int \frac{\vec{\mathcal{B}}(\mathbf{r}',t)}{4\pi|\mathbf{r}-\mathbf{r}'|} d^3r' \ .$$

Show that, given by this expression, the potential vector satisfies the Coulomb gauge.
b. Show that for uniform and constant magnetic fields,

$$\mathbf{A}(\mathbf{r},t) = -\tfrac{1}{2}\mathbf{r} \times \vec{\mathcal{B}} \ .$$

Why can't you use the formula in (a) to solve the problem?

14.3.8.8 Ex: Green function

Show that $G(\mathbf{r},\mathbf{r}') = \frac{e^{ik|\mathbf{r}-\mathbf{r}'|}}{4\pi|\mathbf{r}-\mathbf{r}'|}$ is the Green function of the operator $\mathcal{L} = \nabla^2 + k^2$.

14.3.8.9 Ex: Gauge of retarded potentials

Confirm, that retarded potentials (14.106) are in the Lorentz gauge.

14.3.8.10 Ex: Jefimenko with constant current

Suppose that $\mathbf{j}(\mathbf{r})$ is constant in time, such that $\varrho(\mathbf{r},t) = \varrho(\mathbf{r},0) + \dot{\varrho}(\mathbf{r},0)t$. Demonstrate the validity of Coulomb's law with the charge density evaluated at the *non-retarded* time.

14.3.8.11 Ex: Jefimenko with slowly varying current

Suppose a current density varying sufficiently slowly so that we can ignore all higher derivatives of the Taylor expansion $\mathbf{j}(\mathbf{r}, t_r) = \mathbf{j}(\mathbf{r}, t) + (t_r - t)\dot{\mathbf{j}}(\mathbf{r}, t_r) + \ldots$. Demonstrate the validity of the Biot-Savart law with the charge density evaluated at the *non-retarded* time. This means that the quasi-static approximation is much better than could have expected.

14.3.8.12 Ex: Potentials of a point charge in uniform motion

a. Calculate the potentials (14.122) produced by the uniform motion, $w(t) = \mathbf{v}t$, of a charge q.
b. Verify that these potentials satisfy the Lorentz gauge.

14.3.8.13 Ex: Liénard-Wiechert potentials for a rotating charge

A particle of charge q moves circularly with constant angular velocity ω in the center of the x-y-plane. At time $t = 0$ the charge is at the position $(a, 0)$. Find the Liénard-Wiechert potentials for the points of the z-axis.

14.3.8.14 Ex: Point charge moving on a straight line

Assume that a point charge q is constrained to move along the x-axis. Calculate the fields at points on the axis in front of and behind the charge.

14.3.8.15 Ex: Charge on a hyperbolic motion

Determine the Liénard-Wiechert potentials for a charge on a hyperbolic motion, i.e. $\mathbf{w}(t) = \hat{\mathbf{e}}_x\sqrt{b^2 + c^2t^2}$.

14.3.8.16 Ex: Actio=reactio with the Lorentz force

Suppose that two charges in uniform motion, the first one along the x-axis and the second along the y-axis, are at the origin at time $t = 0$. Calculate the reciprocal Coulomb-Lorentz forces.

Chapter 15

Electromagnetic waves

The phenomenon of waves is usually introduced in undergraduate Physics courses. We already discussed that, unlike classical longitudinal or transverse waves, *electromagnetic waves* do not require a propagation medium, but move through the vacuum with the speed of light. And we showed that the wave equation is form-invariant to the Lorentz, but not to the Galilei transform [1].

The electromagnetic waves are generated when charges change their positions. Therefore, the theory of electromagnetic waves is also a consequence of electrodynamic theory, which is summarized in the *Maxwell equations*. In this chapter we will consider these equations as given and deduce from them the properties of electromagnetic waves.

15.1 Wave propagation

By *wave* we mean the propagation of a perturbation $f(\mathbf{r}, t)$, which can be a scalar or vector quantity. When it propagates in one dimension, the wave is described by the *wave equation*,

$$\frac{\partial^2 f}{\partial z^2} = \frac{1}{v^2}\frac{\partial^2 f}{\partial t^2} \ , \tag{15.1}$$

where v is the propagation velocity of the wave. The most common waveform is the sine wave,

$$f(z,t) = A\cos(kz - \omega t + \delta) = \mathfrak{Re}\,[\tilde{A}e^{\imath(kz-\omega t)}] = \mathfrak{Re}\,\tilde{f}(z,t) \ , \tag{15.2}$$

in complex notation (often ornamented by a tilde) introducing the complex amplitude $\tilde{A} \equiv Ae^{\imath\delta}$. The wave equation satisfies the superposition principle allowing for the expansion of any wave type according to,

$$\tilde{f}(z,t) = \int_{-\infty}^{\infty} \tilde{A}(k)e^{\imath(kz-\omega t)}dk \ . \tag{15.3}$$

We will show in Exc. 15.1.8.1, that all functions satisfying $f(z,t) = g(z \pm vt)$ automatically obey the wave equation. The most general solution of the wave equation is given by,

$$f(z,t) = g_1(z - vt) + g_2(z + vt) \ . \tag{15.4}$$

We show this in the following example directly generalizing to three dimensions.

[1] See script on *Vibrations and waves* (2020), Sec. 2.2.3.

Example 95 (*General solution of the wave equation*): The three-dimensional wave equation is,

$$\frac{1}{c^2}\frac{\partial^2 f}{\partial t^2} - \nabla^2 f = 0 \ .$$

Using for the Dirac function the representation, $\delta^{(3)}(\mathbf{r}-\mathbf{r}') = \frac{1}{(2\pi)^3}\int d^3k e^{\imath\mathbf{k}\cdot(\mathbf{r}-\mathbf{r}')}$, we can write,

$$\begin{aligned} f(\mathbf{r},t) &= \int_{V_\infty} d^3r'\delta^{(3)}(\mathbf{r}-\mathbf{r}')f(\mathbf{r}',t) \\ &= \int d^3k e^{\imath\mathbf{k}\cdot\mathbf{r}} \int_{V_\infty} d^3r' \frac{e^{-\imath\mathbf{k}\cdot\mathbf{r}'}}{(2\pi)^3} f(\mathbf{r}',t) = \int d^3k e^{\imath\mathbf{k}\cdot\mathbf{r}} A(\mathbf{k},t) \ , \end{aligned}$$

where $A(\mathbf{k},t) \equiv \int_{V_\infty} d^3r' \frac{1}{(2\pi)^3} e^{-\imath\mathbf{k}\cdot\mathbf{r}'} f(\mathbf{r}',t)$ is the Fourier transform of f. Applying the operator $\nabla^2 - \frac{1}{c^2}\frac{\partial^2}{\partial t^2}$ to the expression for f gives,

$$\begin{aligned} 0 = \frac{1}{c^2}\frac{\partial^2 f}{\partial t^2} - \nabla^2 f &= \frac{1}{c^2}\int d^3k e^{\imath\mathbf{k}\cdot\mathbf{r}} \frac{\partial^2 A(\mathbf{k},t)}{\partial t^2} - \int d^3k A(\mathbf{k},t)\nabla^2 e^{\imath\mathbf{k}\cdot\mathbf{r}} \\ &= \int d^3k e^{\imath\mathbf{k}\cdot\mathbf{r}} \left[\frac{1}{c^2}\frac{\partial^2 A(\mathbf{k},t)}{\partial t^2} + k^2 A(\mathbf{k},t)\right] \ . \end{aligned}$$

Hence,

$$\frac{1}{c^2}\frac{\partial^2 A(\mathbf{k},t)}{\partial t^2} + k^2 A(\mathbf{k},t) = 0 \ .$$

The general solution of this equation can be written as,

$$A(\mathbf{k},t) = a(\mathbf{k})e^{\imath kct} + b(\mathbf{k})e^{-\imath kct} \ ,$$

where $a(\mathbf{k})$ and $b(\mathbf{k})$ are arbitrary functions of $\mathbf{k}$. Thus, the general solution for f is given by,

$$f(\mathbf{r},t) = \int a(\mathbf{k})e^{\imath\mathbf{k}\cdot\mathbf{r}+\imath kct}d^3k + \int b(\mathbf{k})e^{\imath\mathbf{k}\cdot\mathbf{r}-\imath kct}d^3k \ .$$

Since f is a real quantity, $f(\mathbf{r},t)^* = f(\mathbf{r},t)$, we must have,

$$a(-\mathbf{k})^* = b(\mathbf{k}) \ ,$$

and,

$$f(\mathbf{r},t) = \mathfrak{Re}\left[\int 2b(\mathbf{k})e^{\imath\mathbf{k}\cdot\mathbf{r}-\imath kct}d^3k\right] \ .$$

The scalar functions $e^{\imath\mathbf{k}\cdot\mathbf{r}-\imath kct}$ satisfy the wave equation for all $\mathbf{k}$.

Waves of vector quantities must be characterized by a *polarization vector* $\hat{\epsilon} \equiv \mathbf{b}/b$. Therefore, we define,

$$\vec{\mathcal{E}} = \mathfrak{Re}\,\vec{\tilde{\mathcal{E}}} \qquad \text{with} \qquad \vec{\tilde{\mathcal{E}}}(\mathbf{r},t) = \hat{\epsilon}\mathcal{E}_0 e^{\imath\mathbf{k}\cdot\mathbf{r}-\imath kct} \ , \tag{15.5}$$

where $\mathcal{E}_0$ is real and $\omega \equiv kc$, as the vector functions forming the functional basis for the fields. These functions represent plane waves, because on a wavefront, the value of $\vec{\tilde{\mathcal{E}}}(\mathbf{r},t)$ is fixed, and this occurs only when $e^{\imath\mathbf{k}\cdot\mathbf{r}-\imath kct}$ is constant [2].

[2] We shall see later that, when a wave passes through zones with different propagation velocities v, the amplitude $\mathbf{A}$ and the polarization $\hat{\epsilon}$ may change. However, any change must be such that $\tilde{\mathbf{F}}(z_0,t)$ and the derivative $\tilde{\mathbf{F}}'(z_0,t)$ are continuous at the transition point z_0.

To calculate the magnetic field from the complex representation of the electric field, we write first,

$$\vec{\mathcal{B}} = \mathfrak{Re}\,\vec{\tilde{\mathcal{B}}} \qquad \text{with} \qquad \vec{\tilde{\mathcal{B}}}(\mathbf{r},t) = \hat{\epsilon}'\mathcal{B}_0 e^{\imath\mathbf{k}'\cdot\mathbf{r}-\imath k'ct} \ , \tag{15.6}$$

where $\vec{\tilde{\mathcal{B}}}$ is the magnetic plane wave, since both $\vec{\tilde{\mathcal{E}}}$ as well as $\vec{\tilde{\mathcal{B}}}$ satisfy the same wave equation. With Maxwell's equations in the absence of sources, it is obvious that,

$$\mathbf{k} = \mathbf{k}' \ , \tag{15.7}$$

because the equations that couple $\vec{\tilde{\mathcal{E}}}$ and $\vec{\tilde{\mathcal{B}}}$ must be satisfied at every point of space and at every instant of time.

15.1.1 Helmholtz's equation

Electromagnetic waves differ from classical longitudinal or transverse waves in several aspects. For example, they do not require a propagation medium, but move through the vacuum at extremely high speed. Being exactly $c = 299792458$ m/s the speed of light is so high, that the laws of classical mechanics are no longer valid. And because there is no propagation medium, in vacuum all inertial systems are equivalent, and this will have important consequences for the Doppler effect. We will show that the electromagnetic wave equation almost comes out as a corollary of the theory of special relativity.

We have shown in Sec. 5.1 how the periodic conversion between kinetic and potential energy in a pendulum can propagate in space, when the pendulum is coupled to other pendulums hung in an array, and that this model explains the propagation of a pulse along a string. We also discussed, how electric and magnetic energy can be interconverted in an electronic L-C circuit constiting of a capacitor (storing electrical energy) and an inductance (a coil storing magnetic energy). The law of electrodynamics describing the transformation of electric field variations into magnetic energy is *Ampère's law*, and the law describing the transformation of magnetic field variations into electric energy is *Faraday's law*,

$$\frac{\partial\vec{\mathcal{E}}}{\partial t} \curvearrowright \vec{\mathcal{B}}(t) \qquad , \qquad \frac{\partial\vec{\mathcal{B}}}{\partial t} \curvearrowright -\vec{\mathcal{E}}(t) \ . \tag{15.8}$$

Extending the L-C circuit to an array, it is possible to show that the electromagnetic oscillation propagates along the array. This model describes well the propagation of electromagnetic energy along a coaxial cable or the propagation of light in free space.

The *electrical energy* stored in the capacitor and the *magnetic energy* stored in the coil are given by,

$$E_{\text{ele}} = \tfrac{\varepsilon_0}{2}|\vec{\mathcal{E}}|^2 \qquad , \qquad E_{\text{mag}} = \tfrac{1}{2\mu_0}|\vec{\mathcal{B}}|^2 \ , \tag{15.9}$$

where the constants $\varepsilon_0 = 8.854 \cdot 10^{-12}$ As/Vm and $\mu_0 = 4\pi \cdot 10^{-7}$ Vs/Am are called *vacuum permittivity* and *vacuum permeability*. The constant $Z_0 \equiv \sqrt{\mu_0/\varepsilon_0}$ is called *vacuum impedance*.

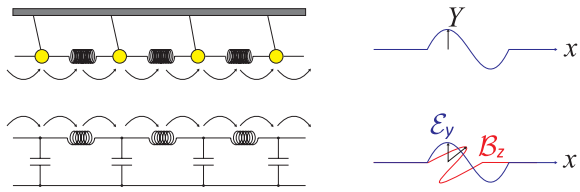

Figure 15.1: Analogy between propagation of mechanical waves (above) and electromagnetic waves (below).

From Maxwell's equations in free space,

$$\nabla \times \vec{\mathcal{B}} - \varepsilon_0 \mu_0 \partial_t \vec{\mathcal{E}} = 0 \qquad \text{and} \qquad \nabla \times \vec{\mathcal{E}} + \partial_t \vec{\mathcal{B}} = 0 \ , \tag{15.10}$$

deriving the first and inserting this into the second, and using the fact that the divergences vanish,

$$\begin{aligned} \frac{1}{c^2}\frac{\partial^2 \vec{\mathcal{E}}}{\partial t^2} &= \frac{1}{\varepsilon_0 \mu_0 c^2}\frac{\partial}{\partial t}\nabla \times \vec{\mathcal{B}} = -\nabla \times (\nabla \times \vec{\mathcal{E}}) = -\nabla(\nabla \cdot \vec{\mathcal{E}}) + \nabla^2 \vec{\mathcal{E}} = \nabla^2 \vec{\mathcal{E}} \\ \frac{1}{c^2}\frac{\partial^2 \vec{\mathcal{B}}}{\partial t^2} &= -\frac{1}{c^2}\frac{\partial}{\partial t}\nabla \times \vec{\mathcal{E}} = -\frac{1}{\varepsilon_0 \mu_0 c^2}\nabla \times (\nabla \times \vec{\mathcal{B}}) = -\nabla(\nabla \cdot \vec{\mathcal{B}}) + \nabla^2 \vec{\mathcal{B}} = \nabla^2 \vec{\mathcal{B}} \ . \end{aligned} \tag{15.11}$$

These are the homogeneous *Helmholtz equations*. We will check in Exc. 15.1.8.2, that

- electromagnetic waves (in free space) are transverse;
- the amplitude of the electric field, the magnetic field, and the direction of propagation are orthogonal;
- the propagation velocity is the speed of light, because $c^2 = 1/\varepsilon_0 \mu_0$.

15.1.2 The polarization of light

A consequence of the requirement, $\nabla \cdot \vec{\mathcal{E}} = 0 = \nabla \cdot \vec{\mathcal{B}}$, following from Maxwell's equations in vacuum is, that the electromagnetic waves are transverse with orthogonal electric and magnetic fields. This is easy to see in the case of plane wave:

$$0 = \nabla \cdot \vec{\mathcal{E}} = \vec{\mathcal{E}}_0 \cdot \nabla e^{\imath(\mathbf{k}\cdot\mathbf{r}-\omega t)} = \imath \vec{\mathcal{E}}_0 \cdot \mathbf{k} e^{\imath(\mathbf{k}\cdot\mathbf{r}-\omega t)} \ , \tag{15.12}$$

and analogously for $\vec{\mathcal{B}}$. We conclude,

$$\boxed{\mathbf{k} \cdot \vec{\mathcal{E}} = 0 = \mathbf{k} \cdot \vec{\mathcal{B}}} \ . \tag{15.13}$$

In addition, from Faraday's law,

$$\vec{\mathcal{B}}_0 \ \imath\omega e^{\imath(\mathbf{k}\cdot\mathbf{r}-\omega t)} = -\frac{\partial \vec{\mathcal{B}}}{\partial t} = \nabla \times \vec{\mathcal{E}} = -\vec{\mathcal{E}}_0 \times \nabla e^{\imath(\mathbf{k}\cdot\mathbf{r}-\omega t)} = -\vec{\mathcal{E}}_0 \times \imath \mathbf{k} e^{\imath(\mathbf{k}\cdot\mathbf{r}-\omega t)} \ . \tag{15.14}$$

together with an analogous result obtained from Ampère-Maxwell's law, we can summarize,

$$\boxed{\vec{\mathcal{B}} = \tfrac{\mathbf{k}}{\omega} \times \vec{\mathcal{E}} \qquad \text{and} \qquad \vec{\mathcal{E}} = -\tfrac{c^2 \mathbf{k}}{\omega} \times \vec{\mathcal{B}}} \ . \tag{15.15}$$

We conclude that the fields $\vec{\mathcal{E}}$ and $\vec{\mathcal{B}}$ and the propagation wavevector are all mutually orthogonal for waves in free space. In the Excs. 15.1.8.3 and 15.1.8.4 we study the polarization of light.

Example 96 (*Circular polarization*): Let us study the example of polarized light,

$$\vec{\tilde{\mathcal{E}}} = (\mathcal{E}_x \hat{\mathbf{e}}_x + \imath \mathcal{E}_y \hat{\mathbf{e}}_y) e^{\imath k_z z - \imath \omega t} \ .$$

If $\mathcal{E}_x = \mathcal{E}_y$, we have circular polarization. If $\mathcal{E}_x \neq \mathcal{E}_y$, the polarization is said to be elliptical. The reason is easily seen by taking the real part of the plane wave:

$$\vec{\mathcal{E}} = \mathfrak{Re}\, \vec{\tilde{\mathcal{E}}} = \mathcal{E}_x \hat{\mathbf{e}}_x \cos(k_z z - \omega t) - \mathcal{E}_y \hat{\mathbf{e}}_y \sin(k_z z - \omega t) \ .$$

In the plane defined by $z = z_0$, with z_0 constant, the electric field vector describes an ellipse as time passes; the ellipse is a circle if $\mathcal{E}_x = \mathcal{E}_y$.
Other polarizations are possible in free space although sometimes a bit more difficult to realize in practice, for example, radial polarization,

$$\vec{\tilde{\mathcal{E}}} = \mathcal{E}_0 \hat{\mathbf{e}}_r e^{\imath k_z z - \imath \omega t} \qquad \text{and} \qquad \vec{\tilde{\mathcal{B}}} = \mathcal{B}_0 \hat{\mathbf{e}}_\theta e^{\imath k_z z - \imath \omega t} \ .$$

15.1.2.1 Polarization optics

A laser generally has a well-defined polarization, for example, linear or circular. The polarizations can be transformed into each other through *birefringent optical elements*, such as birefringent waveplates, Fresnel rhombs, or electro-optical modulators. Superpositions of different polarizations can be separated with polarizing *beam splitters*.

It is important to distinguish between the *polarization*, which is always specified in relation to a fixed coordinate system, and *helicity*, i.e. the rotation direction of the polarization vector with respect to the propagation direction of the light beam. The polarization of a beam propagating in z-direction can easily be expressed by a vector of complex amplitude,

$$\vec{\mathcal{E}}(\mathbf{r}, t) = \begin{pmatrix} a \\ b \\ 0 \end{pmatrix} e^{\imath \mathbf{k}\cdot\mathbf{r} - \imath\omega t} = \begin{pmatrix} 1 \\ e^{-\imath\phi}|b|/|a| \\ 0 \end{pmatrix} |a| e^{\imath \mathbf{k}\cdot\mathbf{r} - \imath\omega t} \ . \tag{15.16}$$

The angle $\phi = \arctan \frac{\mathfrak{Im}\, ab^*}{\mathfrak{Re}\, ab^*}$ determines the polarization of the light beam. The polarization is linear for $\phi = 0$ and circular for $\phi = \pi/2$. $|b|/|a|$ then gives the degree of ellipticity. A device rotating the (linear) polarization of a light beam (e.g. a sugar solution) is described by the so-called *Jones matrix* (we restrict ourselves to the xy-plane orthogonal to the propagation direction),

$$M_{\text{rotator}}(\phi) = \begin{pmatrix} \cos\phi & \sin\phi \\ -\sin\phi & \cos\phi \end{pmatrix} \ , \tag{15.17}$$

where ϕ is the angle of rotation. For birefringent half-waveplates the rotation angle is independent on the propagation direction. In devices called *Faraday rotators*, in

contrast, the sign of the rotation angle depends on the propagation direction of the laser beam,

$$M_{\text{Faraday}}(\phi) = \begin{pmatrix} \cos\phi & \mathbf{k}\cdot\hat{\mathbf{e}}_z \sin\phi \\ -\mathbf{k}\cdot\hat{\mathbf{e}}_z \sin\phi & \cos\phi \end{pmatrix} , \tag{15.18}$$

A *polarizer* projects the polarization to a specific axis. In case of a polarizer aligned to the x-axis the Jones matrix is,

$$M_{\text{polarizer}} = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix} , \tag{15.19}$$

while for an arbitrary axis given by the angle ϕ, it is,

$$M_{\text{polarizer}}(\phi) = \begin{pmatrix} \cos\phi & \sin\phi \\ -\sin\phi & \cos\phi \end{pmatrix} \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix} \begin{pmatrix} \cos\phi & \sin\phi \\ -\sin\phi & \cos\phi \end{pmatrix}^{-1} . \tag{15.20}$$

A birefringent crystal acts only on one of the two optical axes. Assuming that only the y-axis is optically active, its Jones's matrix is,

$$M_{\theta\text{-waveplate}} = \begin{pmatrix} 1 & 0 \\ 0 & e^{\imath\theta} \end{pmatrix} . \tag{15.21}$$

For $\theta = 2\pi/n$ we obtain a so-called λ/n-*waveplate*. When we rotate the waveplate (and therefore the optically active about the inactive axis) by an angle ϕ, the Jones matrix becomes [3],

$$\begin{aligned} M_{\theta\text{-waveplate}}(\phi) &= \begin{pmatrix} \cos\phi & \sin\phi \\ -\sin\phi & \cos\phi \end{pmatrix} \begin{pmatrix} 1 & 0 \\ 0 & e^{\imath\theta} \end{pmatrix} \begin{pmatrix} \cos\phi & \sin\phi \\ -\sin\phi & \cos\phi \end{pmatrix}^{-1} \\ &= \begin{pmatrix} \cos^2\phi + e^{\imath\theta}\sin^2\phi & -\sin\phi\cos\phi + e^{\imath\theta}\sin\phi\cos\phi \\ -\sin\phi\cos\phi + e^{\imath\theta}\sin\phi\cos\phi & \sin^2\phi + e^{\imath\theta}\cos^2\phi \end{pmatrix} . \end{aligned} \tag{15.22}$$

We use in most cases $\lambda/4$-waveplates,

$$M_{\lambda/4}(\phi) = \begin{pmatrix} \cos^2\phi + \imath\sin^2\phi & (-1+\imath)\sin\phi\cos\phi \\ (-1+\imath)\sin\phi\cos\phi & \sin^2\phi + \imath\cos^2\phi \end{pmatrix} \tag{15.23}$$

or $\lambda/2$-waveplates,

$$M_{\lambda/2}(\phi) = \begin{pmatrix} \cos 2\phi & -\sin 2\phi \\ -\sin 2\phi & -\cos 2\phi \end{pmatrix} . \tag{15.24}$$

Note that interestingly $M_{\lambda/2}(\phi)^2 = \mathbb{I}$.

[3] See script on *Optical spectroscopy* (2020), Sec. 2.3.1.

Example 97 (*Generating circular polarization*): We can use $\lambda/4$-waveplates to create, from linearly polarized light, circularly polarized light. Choosing an angle $\theta = 45°$ we get from (15.23),

$$M_{\lambda/4}(\pm\pi/4)\begin{pmatrix}1\\0\end{pmatrix} = \begin{pmatrix}\frac{1}{2}+\frac{1}{2}\imath & \mp\frac{1}{2}\pm\frac{1}{2}\imath\\ \mp\frac{1}{2}\pm\frac{1}{2}\imath & \frac{1}{2}+\frac{1}{2}\imath\end{pmatrix}\begin{pmatrix}1\\0\end{pmatrix} = \frac{e^{\imath\pi/4}}{\sqrt{2}}\begin{pmatrix}1\\ \pm\imath\end{pmatrix} .$$

Example 98 (*Polarization behavior of upon reflection from a mirror*): A light beam reflected from a mirror under normal incidence does not changes its polarization vector, but only its wavevector. This can be interpreted as conservation of the angular momentum of light upon reflection. One consequence of this is, that $\sigma^{\pm}$ light turns into $\sigma^{\pm}$ light upon reflection.

Example 99 (*Action of birefringent waveplates as a function of propagation direction*): The Jones matrices for λ/n-waveplates *do not depend* on the propagation direction, simply because the wavevector does not appear in the expressions. That is, the polarization $\hat{\epsilon} = \hat{\mathbf{e}}_x$ of a beam propagating towards $\pm k\hat{\mathbf{e}}_z$ is transformed by a $M_{\lambda/4}(\pi/4)$ waveplate into σ^+-polarized light regardless of the propagation direction. A consequence of this is that a beam traversing the waveplate $M_{\lambda/4}(\pi/4)$ twice in the round-trip (e.g. being reflected by a mirror) will undergo a rotation of amplitude by 90°,

$$M_{\lambda/4}(\tfrac{\pi}{2})\begin{pmatrix}1\\0\end{pmatrix} = \begin{pmatrix}\imath\\0\end{pmatrix}$$
$$M_{\lambda/4}(\tfrac{\pi}{4})M_{\lambda/4}(\tfrac{\pi}{4}) = \begin{pmatrix}0 & -1\\ -1 & 0\end{pmatrix} .$$

This feature is often used to separate counterpropagating light fields via a polarizing beamsplitter.
On the other hand, for $\lambda/2$-waveplates, it is easy to check the following results,

$$M_{\lambda/2}(\tfrac{\pi}{4})\begin{pmatrix}1\\0\end{pmatrix} = \begin{pmatrix}0\\-1\end{pmatrix}$$
$$M_{\lambda/2}(\tfrac{\pi}{8})\begin{pmatrix}1\\0\end{pmatrix} = \tfrac{1}{\sqrt{2}}\begin{pmatrix}1\\-1\end{pmatrix} .$$

In addition, for any ϕ,

$$M_{\lambda/2}(\phi)M_{\lambda/2}(\phi) = \begin{pmatrix}1 & 0\\ 0 & 1\end{pmatrix} .$$

Thus, the double passage through a $\lambda/2$-waveplate cancels its effect.

15.1.3 The energy density and flow in plane waves

The energy densities stored in the electric field and the magnetic field are given by,

$$u_{\text{ele}} = \tfrac{\varepsilon_0}{2}|\vec{\mathcal{E}}|^2 \quad , \quad u_{\text{mag}} = \tfrac{1}{2\mu_0}|\vec{\mathcal{B}}|^2 \ . \tag{15.25}$$

In the case of a monochromatic wave parametrized by $\vec{\mathcal{E}}(\mathbf{r},t) = \vec{\mathcal{E}}_0\cos(\mathbf{k}\cdot\mathbf{r}-\omega t)$ the calculus (15.15) shows that $|\vec{\mathcal{B}}| = \frac{k}{\omega}|\vec{\mathcal{E}}| = \frac{1}{c}|\vec{\mathcal{E}}|$, such that the average energy density is,

$$\langle u(\mathbf{r})\rangle = \left\langle |\varepsilon_0\vec{\mathcal{E}}_0\cos(\mathbf{k}\cdot\mathbf{r}-\omega t)|^2\right\rangle = \tfrac{1}{2}\varepsilon_0|\vec{\mathcal{E}}_0|^2 = \tfrac{1}{2\mu_0}|\vec{\mathcal{B}}_0|^2 \ , \tag{15.26}$$

consistent with the expressions (14.58). When the wave propagates, it carries with it this amount of energy. The energy flux density is calculated by the *Poynting vector*,

$$\langle\vec{\mathcal{S}}(\mathbf{r})\rangle = \tfrac{1}{\mu_0}\left\langle\vec{\mathcal{E}}(\mathbf{r},t)\times\vec{\mathcal{B}}(\mathbf{r},t)\right\rangle = \tfrac{1}{2}c\varepsilon_0|\vec{\mathcal{E}}_0|^2\hat{\mathbf{e}}_k \ . \tag{15.27}$$

The absolute value is the *intensity* of the light field,

$$\langle I(\mathbf{r},t)\rangle = \langle|\vec{\mathcal{S}}(\mathbf{r},t)|\rangle \ . \tag{15.28}$$

In addition, a radiation field can have linear momentum. In vacuum, the momentum is connected to the Poynting vector,

$$\langle\wp\rangle = \left\langle c\varepsilon_0|\vec{\mathcal{E}}(\mathbf{r},t)|^2\hat{\mathbf{e}}_k\right\rangle = c\varepsilon_0|\vec{\mathcal{E}}_0|^2\hat{\mathbf{e}}_k \ . \tag{15.29}$$

but in dielectric media things are different, as we will see later. The *momentum density* is responsible for the *radiation pressure*. When light hits the surface A of a perfect absorber, it transfers, during the time interval Δt, the momentum $\Delta\mathbf{p} = \langle\wp\rangle Ac\Delta t$ to the body. Thus, the pressure is,

$$P = \frac{1}{A}\frac{\Delta p}{\Delta t} = \frac{\varepsilon_0\mathcal{E}_0^2}{2} = \frac{I}{c} \ . \tag{15.30}$$

Note that for a perfect reflector the pressure is doubled.

In Exc. 15.1.8.5 we show a trick how to quickly calculate the temporal average of expressions containing products of oscillating field. We solve problems about the radiative pressure in Excs. 15.1.8.6 to 15.1.8.8. In the Excs. 15.1.8.10 to 15.1.8.12 we calculate u and $\vec{\mathcal{S}}$ for various types of waves.

15.1.3.1 Spherical waves

Other wave geometries are possible (see Exc. 15.1.8.13). For example, it is easy to show that spherical scalar fields of the type $\Phi(\mathbf{r},t) = \Phi_0\frac{e^{\imath(kr-\omega t)}}{r}$ and spherical vector fields of the type $\mathbf{A}(\mathbf{r},t) = \mathbf{A}_0\frac{e^{\imath(kr-\omega t)}}{r}$ satisfy the wave equation,

$$\begin{aligned} 0 &= \nabla^2\Phi - \frac{1}{c^2}\frac{\partial^2\Phi}{\partial t^2} \\ &= \frac{1}{r^2}\frac{\partial}{\partial r}\left(r^2\frac{\partial\Phi}{\partial r}\right) + \cancelto{0}{\frac{1}{r^2\sin\theta}\frac{\partial}{\partial\theta}\left(\sin\theta\frac{\partial\Phi}{\partial\theta}\right)} + \cancelto{0}{\frac{1}{r^2\sin^2\theta}\frac{\partial^2\Phi}{\partial\phi^2}} - \frac{1}{c^2}\frac{\partial^2\Phi}{\partial t^2} \\ &= -k^2\Phi + \frac{\omega^2}{c^2}\Phi \ . \end{aligned} \tag{15.31}$$

This also applies to electric and magnetic fields,

$$\vec{\mathcal{E}}(\mathbf{r},t) \stackrel{?}{=} \vec{\mathcal{E}}_0 \frac{e^{\imath(kr-\omega t)}}{r} \qquad \text{and} \qquad \vec{\mathcal{B}}(\mathbf{r},t) \stackrel{?}{=} \vec{\mathcal{B}}_0 \frac{e^{\imath(kr-\omega t)}}{r} \ . \tag{15.32}$$

But it does not mean that these fields obey Maxwell's equations. In fact, the simplest possible spherical wave corresponds a the dipole radiation, which will be discussed in the next chapter. We will find in Exc. 16.1.6.3 that the expressions for electric dipole radiation satisfy Maxwell's equations and in Exc. 15.1.8.14, that the expressions (15.32) do not satisfy them. In Excs. 15.1.8.15 and 15.1.8.16 we will deepen this discussion.

15.1.4 Slowly varying envelope approximation

The slowly varying envelope approximation [29] (SVEA) is the assumption that the envelope of a forward-traveling wave pulse varies slowly in time and space compared to a period or wavelength. This requires the spectrum of the signal to be narrow-banded. The SVEA is often used because the resulting equations are in many cases easier to solve than the original equations, reducing the order of all (or some) of the highest-order partial derivatives. But the validity of the assumptions which are made need to be justified.

For example, consider the electromagnetic wave equation:

$$\nabla^2 \mathcal{E} - \mu_0 \varepsilon_0 \frac{\partial^2 \mathcal{E}}{\partial t^2} = 0 \ . \tag{15.33}$$

If k_0 and ω_0 are the wave number and angular frequency of the (characteristic) carrier wave for the signal $\mathcal{E}(\mathbf{r},t)$, the following representation is useful:

$$\mathcal{E}(\mathbf{r},t) = \mathfrak{Re}\left[\mathcal{E}_0(\mathbf{r},t) e^{\imath(\mathbf{k}_0\cdot\mathbf{r}-\omega_0 t)}\right] \ . \tag{15.34}$$

In the SVEA it is assumed that the complex amplitude $\mathcal{E}_0(\mathbf{r},t)$ only varies slowly with $\mathbf{r}$ and t. This inherently implies that $\mathcal{E}_0(\mathbf{r},t)$ represents waves propagating forward, predominantly in the $\mathbf{k}_0$ direction. As a result of the slow variation of $\mathcal{E}_0(\mathbf{r},t)$, when taking derivatives, the highest-order derivatives may be neglected [143]:

$$|\nabla^2 \mathcal{E}_0| \ll |\mathbf{k}_0 \cdot \nabla \mathcal{E}_0| \qquad \text{and} \qquad \left|\frac{\partial^2 \mathcal{E}_0}{\partial t^2}\right| \ll \left|\omega_0 \frac{\partial \mathcal{E}_0}{\partial t}\right| \ . \tag{15.35}$$

Consequently, the wave equation is approximated in the SVEA as,

$$2\imath \mathbf{k}_0 \cdot \nabla \mathcal{E}_0 + 2\imath \omega_0 \mu_0 \varepsilon_0 \frac{\partial \mathcal{E}_0}{\partial t} - (k_0^2 - \omega_0^2 \mu_0 \varepsilon_0)\mathcal{E}_0 = 0 \ . \tag{15.36}$$

It is convenient to choose k_0 and ω_0 such that they satisfy the dispersion relation, $k_0^2 - \omega_0^2 \mu_0 \varepsilon_0 = 0$. This gives the following approximation to the wave equation,

$$\mathbf{k}_0 \cdot \nabla \mathcal{E}_0 + \omega_0 \mu_0 \varepsilon_0 \frac{\partial \mathcal{E}_0}{\partial t} = 0 \ . \tag{15.37}$$

This is a hyperbolic partial differential equation, like the original wave equation, but now of first-order instead of second-order. It is valid for coherent forward-propagating

waves in directions near the k_0-direction. The space and time scales over which $\mathcal{E}_0$ varies are generally much longer than the spatial wavelength and temporal period of the carrier wave. A numerical solution of the envelope equation thus can use much larger space and time steps, resulting in significantly less computational effort.

Example 100 (*Parabolic SVEA approximation*): Assuming that the wave propagation is dominantly in z-direction, and k_0 is taken in this direction. The SVEA is only applied to the second-order spatial derivatives in the z-direction and time. If $\nabla_\perp = \hat{\mathbf{e}}_x \partial/\partial x + \hat{\mathbf{e}}_y \partial/\partial y$ is the gradient in the x-y plane, the result is [898],

$$k_0 \frac{\partial \mathcal{E}_0}{\partial z} + \omega_0 \mu_0 \varepsilon_0 \frac{\partial \mathcal{E}_0}{\partial t} - \tfrac{1}{2} \imath \nabla_\perp^2 \mathcal{E}_0 = 0 \ .$$

This is a parabolic partial differential equation. This equation has enhanced validity as compared to the full SVEA: it represents waves propagating in directions significantly different from the z-direction. It is the starting point of the theory of Gaussian beams, which will be studied in Sec. 15.4.1.

15.1.5 Plane waves in linear dielectrics and the refractive index

In dielectric (non-conducting) media we have $\varrho = 0$ and $\mathbf{j} = 0$ but $\dot{\vec{\mathcal{E}}}, \dot{\vec{\mathcal{B}}} \neq 0$. If the medium is linear and homogeneous, the permittivity ε and the permeability μ are constant, and we can substitute $\vec{\mathcal{D}} = \varepsilon \vec{\mathcal{E}}$ and $\vec{\mathcal{H}} = \mu^{-1} \vec{\mathcal{B}}$. Thus, Maxwell's equations (14.56) become equal to those holding for vacuum (14.6) but with the generalizations $\varepsilon_0 \to \varepsilon$ and $\mu_0 \to \mu$. Therefore, the wave equations remain valid,

$$\left(\frac{1}{c_n^2} \frac{\partial^2}{\partial t^2} - \nabla^2 \right) \vec{\mathcal{E}} = 0 = \left(\frac{1}{c_n^2} \frac{\partial^2}{\partial t^2} - \nabla^2 \right) \vec{\mathcal{B}} \ , \tag{15.38}$$

with the propagation velocity now reading,

$$c_n = \frac{1}{\sqrt{\varepsilon \mu}} = \frac{c}{n} \ , \tag{15.39}$$

where we defined the index of refraction,

$$n \equiv \sqrt{\frac{\varepsilon \mu}{\varepsilon_0 \mu_0}} \ . \tag{15.40}$$

In dielectric media, we must use the original definitions for the energy and momentum densities and flows (14.58). The polarization and magnetization of the medium may cause new phenomena. For example, in anisotropic optical media the Poynting vector is not necessarily parallel to the wave vector. Resolve the Excs. 15.1.8.17 to 15.1.8.22.

15.1.6 Reflection and transmission by interfaces and Fresnel's formulas

So far we have considered homogenous media. An interesting question is, what happens when a field traverses regions characterized by different ε and μ. The boundary

conditions can be discussed from the integral form of the Maxwell equations, which follow immediately from the differential form via the theorems of Gauss and Stokes:

$$\begin{array}{lrcl} \text{(i)} & \oint_{\partial\mathcal{S}} \vec{\mathcal{H}} \cdot d\mathbf{l} & = & \frac{d}{dt}\int_{\mathcal{S}} \vec{\mathcal{D}} \cdot d\mathbf{S} + I_{\text{enc}} \\ \text{(ii)} & \oint_{\partial\mathcal{S}} \vec{\mathcal{E}} \cdot d\mathbf{l} & = & -\frac{d}{dt}\int_{\mathcal{S}} \vec{\mathcal{B}} \cdot d\mathbf{S} \\ \text{(iii)} & \oint_{\partial\mathcal{V}} \vec{\mathcal{D}} \cdot d\mathbf{S} & = & Q_{\text{enc}} \\ \text{(iv)} & \oint_{\partial\mathcal{V}} \vec{\mathcal{B}} \cdot d\mathbf{S} & = & 0 \end{array} \quad . \tag{15.41}$$

Let us consider two media with different permittivities $\varepsilon_{1,2}$ and permeabilities $\mu_{1,2}$ joined together at an interface. The closed path $\partial\mathcal{S}$ around a surface $\mathcal{S}$ and the closed surface $\partial\mathcal{V}$ around a volume $\mathcal{V}$ are chosen such as to cross the interface, as illustrated in Figs. 10.10 and 12.14. The surface integrals in equations (i) and (ii) vanish in the limit, where we choose the path $\partial\mathcal{S}$ very close to the interface.

From these equations, and as already shown in the derivations of the static equations (10.37), (10.39), (12.30), and (12.32), we have for linear media and in the absence of free surface charges σ_{f} and free surface currents $\mathbf{k}_{\text{f}}$,

$$\begin{array}{lrcl} \text{(i)} & \frac{1}{\mu_1}\vec{\mathcal{B}}_1^{\parallel} - \frac{1}{\mu_2}\vec{\mathcal{B}}_2^{\parallel} & = & |\mathbf{k}_{\text{f}} \times \hat{\mathbf{e}}_n| \longrightarrow 0 \\ \text{(ii)} & \vec{\mathcal{E}}_1^{\parallel} - \vec{\mathcal{E}}_2^{\parallel} & = & 0 \\ \text{(iii)} & \varepsilon_1\vec{\mathcal{E}}_1^{\perp} - \varepsilon_2\vec{\mathcal{E}}_2^{\perp} & = & \sigma_{\text{f}} \longrightarrow 0 \\ \text{(iv)} & \vec{\mathcal{B}}_1^{\perp} - \vec{\mathcal{B}}_2^{\perp} & = & 0 \end{array} \quad . \tag{15.42}$$

We will use these equations to establish the theory of reflection and refraction.

15.1.6.1 Normal incidence

Electromagnetic waves can be guided by interfaces (waveguides). From Maxwell's equations we can deduce useful rules for the behavior of waves near interfaces. First, we consider a plane wave propagating in the direction z within a dielectric medium characterized by the refraction index n_1,

$$\vec{\mathcal{E}}_{\text{i}}(z,t) = \hat{\mathbf{e}}_x \mathcal{E}_{\text{i}} e^{\imath(k_{z1}z-\omega t)} \quad , \quad \vec{\mathcal{B}}_{\text{i}}(z,t) = \hat{\mathbf{e}}_y \frac{n_1\mathcal{E}_{\text{i}}}{c} e^{\imath(k_{z1}z-\omega t)} \ . \tag{15.43}$$

At position $z = 0$ there be a partially reflecting interface, as shown in Fig. 15.2(a). The reflected part is,

$$\vec{\mathcal{E}}_{\text{r}}(z,t) = \hat{\mathbf{e}}_x \mathcal{E}_{\text{r}} e^{\imath(-k_{z1}z-\omega t)} \quad , \quad \vec{\mathcal{B}}_{\text{r}}(z,t) = -\hat{\mathbf{e}}_y \frac{n_1\mathcal{E}_{\text{r}}}{c} e^{\imath(-k_{z1}z-\omega t)} \ . \tag{15.44}$$

The negative sign comes from the relation $\vec{\mathcal{B}}(\mathbf{r},t) = \frac{1}{c}\mathbf{k} \times \vec{\mathcal{E}}(\mathbf{r},t)$. The transmitted part is,

$$\vec{\mathcal{E}}_{\text{t}}(z,t) = \hat{\mathbf{e}}_x \mathcal{E}_{\text{t}} e^{\imath(k_{z2}z-\omega t)} \quad , \quad \vec{\mathcal{B}}_{\text{r}}(z,t) = \hat{\mathbf{e}}_y \frac{n_2\mathcal{E}_{\text{t}}}{c} e^{\imath(k_{z2}z-\omega t)} \ . \tag{15.45}$$

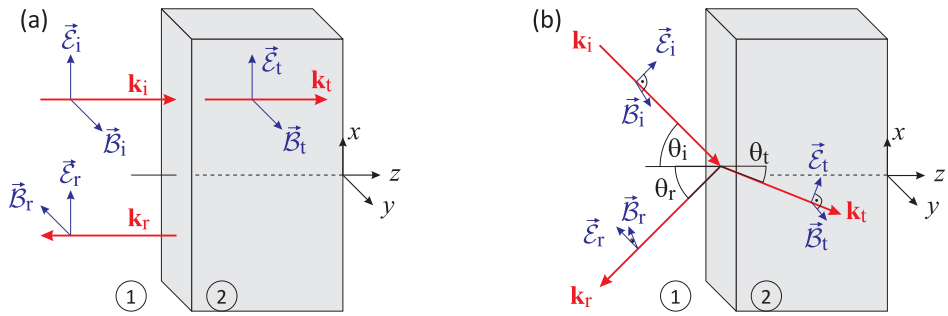

Figure 15.2: Electric and magnetic fields reflected and transmitted at an interface under (a) normal and (b) inclined incidence.

At the position $z = 0$ the total radiation must satisfy the boundary conditions. Since under normal incidence, there are only parallel components,

$$\vec{\mathcal{E}}_i(0,t) + \vec{\mathcal{E}}_r(0,t) = \vec{\mathcal{E}}_t(0,t) \quad , \quad \tfrac{1}{\mu_1}[\vec{\mathcal{B}}_i(0,t) + \vec{\mathcal{B}}_r(0,t)] = \tfrac{1}{\mu_2}\vec{\mathcal{B}}_t(0,t) \ . \tag{15.46}$$

Dividing all terms by $e^{-\imath\omega t}$,

$$\mathcal{E}_i + \mathcal{E}_r = \mathcal{E}_t \quad , \quad \tfrac{n_1}{\mu_1 c}[\mathcal{E}_i - \mathcal{E}_r] = \tfrac{n_2}{\mu_2 c}\mathcal{E}_t \ . \tag{15.47}$$

Solving the system of equations,

$$\boxed{\frac{\mathcal{E}_r}{\mathcal{E}_i} = \frac{1-\beta}{1+\beta} \quad , \quad \frac{\mathcal{E}_t}{\mathcal{E}_i} = \frac{2}{1+\beta}} \ , \tag{15.48}$$

defining

$$\beta \equiv \frac{\mu_1 n_2}{\mu_2 n_1} \ . \tag{15.49}$$

Example 101 (*Reflection on an air-glass interface*): We consider an air-glass interface, $n_1 = 1$ and $n_2 = 1.5$. Taking $\mu_1 = \mu_2 = \mu_0$ we have $\beta = 1.5$, and we calculate that the interface reflects the energy,

$$R \equiv \frac{I_r}{I_i} = \frac{\varepsilon_1 c_1 |\vec{\mathcal{E}}_r|^2}{\varepsilon_1 c_1 |\vec{\mathcal{E}}_i|^2} = \left(\frac{1-\beta}{1+\beta}\right)^2 = 0.04 \ ,$$

and transmits the energy,

$$T \equiv \frac{I_t}{I_i} = \frac{\varepsilon_2 c_2 |\vec{\mathcal{E}}_t|^2}{\varepsilon_1 c_1 |\vec{\mathcal{E}}_i|^2} = \frac{\varepsilon_2 c_2}{\varepsilon_1 c_1}\left(\frac{2}{1+\beta}\right)^2 = 0.96 \ .$$

We check $R + T = 1$.

15.1.6.2 Inclined incidence and geometric optics

When the wave strikes perpendicular to the interface, the polarization of the light is irrelevant. This is no longer true for inclined incidence, as shown in Fig. 15.2(b). In this case the Eqs. (15.43)-(15.45) must be generalized,

$$\vec{\mathcal{E}}_m(\mathbf{r},t) = \vec{\mathcal{E}}_{0m} e^{\imath(\mathbf{k}_m\cdot\mathbf{r}-\omega t)} \quad , \quad \vec{\mathcal{B}}_m(\mathbf{r},t) = \frac{n_m}{c}\hat{\mathbf{k}}_m \times \vec{\mathcal{E}}_m(\mathbf{r},t) \ , \tag{15.50}$$

for $m = \text{i,r,t}$. Obviously the frequency is the same for all waves, such that by inserting each wave into the wave equation we find,

$$k_{\rm i} c_{\rm i} = k_{\rm r} c_{\rm r} = k_{\rm t} c_{\rm t} = \omega \ , \tag{15.51}$$

with $c_m \equiv c/n_m$ and $c_{\rm i} = c_r \equiv c_1$ and $c_{\rm t} \equiv c_2$. We now need to join the fields $\vec{\mathcal{E}}_{\rm i} + \vec{\mathcal{E}}_{\rm r}$ and $\vec{\mathcal{B}}_{\rm i} + \vec{\mathcal{B}}_{\rm r}$ of one side of the interface with the fields $\vec{\mathcal{E}}_{\rm t}$ and $\vec{\mathcal{B}}_{\rm t}$ of the other side at the plane $z = 0$, respecting the boundary conditions (15.42). We get generic expressions,

$$(\cdot) e^{\imath(\mathbf{k}_{\rm i}\cdot\mathbf{r}-\omega t)} + (\cdot) e^{\imath(\mathbf{k}_{\rm r}\cdot\mathbf{r}-\omega t)} = (\cdot) e^{\imath(\mathbf{k}_{\rm t}\cdot\mathbf{r}-\omega t)} \qquad \text{at} \qquad z = 0 \tag{15.52}$$

at all times t, where $(\cdot) \equiv \varepsilon_m \vec{\mathcal{E}}_m^{\perp}, \vec{\mathcal{E}}_m^{\parallel}, \vec{\mathcal{B}}_m^{\perp}, \frac{1}{\mu_m}\vec{\mathcal{B}}_m^{\parallel}$. Since the equation (15.52) must be valid at any point (x, y) of the plane $z = 0$, the exponential factors must be equal,

$$e^{\imath\mathbf{k}_{\rm i}\cdot\mathbf{r}} = e^{\imath\mathbf{k}_{\rm r}\cdot\mathbf{r}} = e^{\imath\mathbf{k}_{\rm t}\cdot\mathbf{r}} \ , \tag{15.53}$$

that is,

$$\boxed{\mathbf{k}_{\rm i}\cdot\hat{\mathbf{e}}_x = \mathbf{k}_{\rm r}\cdot\hat{\mathbf{e}}_x = \mathbf{k}_{\rm t}\cdot\hat{\mathbf{e}}_x \qquad \text{and} \qquad \mathbf{k}_{\rm i}\cdot\hat{\mathbf{e}}_y = \mathbf{k}_{\rm r}\cdot\hat{\mathbf{e}}_y = \mathbf{k}_{\rm t}\cdot\hat{\mathbf{e}}_y} \ , \tag{15.54}$$

that is, the wavevectors $\mathbf{k}_{\rm i}$, $\mathbf{k}_{\rm r}$, $\mathbf{k}_{\rm t}$ and the normal vector $\hat{\mathbf{e}}_z$ of the interface are in the same plane. We can orient the coordinate system such that $\mathbf{k}_{\rm i}\cdot\hat{\mathbf{e}}_y \equiv 0$ (see Fig. 15.2). Defining the angles of incidence, reflection and refraction, we find,

$$\mathbf{k}_m\cdot\hat{\mathbf{e}}_x = k_{\rm i}\sin\theta_{\rm i} = k_{\rm r}\sin\theta_{\rm r} = k_{\rm t}\sin\theta_{\rm t} \ . \tag{15.55}$$

With (15.51) we deduce the *law of reflection*:

$$\boxed{\theta_{\rm i} = \theta_{\rm r}} \ , \tag{15.56}$$

and the *law of refraction* or *Snell's law*:

$$\boxed{\frac{\sin\theta_{\rm t}}{\sin\theta_{\rm i}} = \frac{n_1}{n_2}} \ . \tag{15.57}$$

The equations (15.54), (15.56), and (15.57) form the basis of geometric optics.

15.1.6.3 Polarization behavior and Fresnel's formulas

Going back to the condition (15.52) and eliminating the exponentials, we get,

$$\begin{aligned}
\text{for } \vec{\mathcal{B}}_m^{\parallel} \ : \quad \tfrac{1}{\mu_1}\vec{\mathcal{B}}_{\rm i}\cdot\hat{\mathbf{e}}_{x,y} + \tfrac{1}{\mu_1}\vec{\mathcal{B}}_{\rm r}\cdot\hat{\mathbf{e}}_{x,y} &= \tfrac{1}{\mu_2}\vec{\mathcal{B}}_{\rm t}\cdot\hat{\mathbf{e}}_{x,y} \\
\text{for } \vec{\mathcal{E}}_m^{\parallel} \ : \quad \vec{\mathcal{E}}_{\rm i}\cdot\hat{\mathbf{e}}_{x,y} + \vec{\mathcal{E}}_{\rm r}\cdot\hat{\mathbf{e}}_{x,y} &= \vec{\mathcal{E}}_{\rm t}\cdot\hat{\mathbf{e}}_{x,y} \\
\text{for } \vec{\mathcal{E}}_m^{\perp} \ : \quad \varepsilon_1\vec{\mathcal{E}}_{\rm i}\cdot\hat{\mathbf{e}}_z + \varepsilon_1\vec{\mathcal{E}}_{\rm r}\cdot\hat{\mathbf{e}}_z &= \varepsilon_2\vec{\mathcal{E}}_{\rm t}\cdot\hat{\mathbf{e}}_z \\
\text{for } \vec{\mathcal{B}}_m^{\perp} \ : \quad \vec{\mathcal{B}}_{\rm i}\cdot\hat{\mathbf{e}}_z + \vec{\mathcal{B}}_{\rm r}\cdot\hat{\mathbf{e}}_z &= \vec{\mathcal{B}}_{\rm t}\cdot\hat{\mathbf{e}}_z \ .
\end{aligned} \tag{15.58}$$

We again orient the coordinate system such that $\mathbf{k}_{\rm i}\cdot\hat{\mathbf{e}}_y \equiv 0$. We first assume, that the polarization of the incident field is within the plane of incidence (that is, the

plane spanned by the vectors $\mathbf{k}_\mathrm{i}$ and $\mathbf{k}_\mathrm{r}$), that is, $\vec{\mathcal{E}}_\mathrm{i}\cdot\hat{\mathbf{e}}_y = 0 = \vec{\mathcal{B}}_\mathrm{i}\cdot\hat{\mathbf{e}}_x$. This is called *p-polarization*. In this case, the conditions (15.58) become,

$$\begin{aligned}
\tfrac{1}{\mu_1}\vec{\mathcal{B}}_\mathrm{i}\cdot\hat{\mathbf{e}}_y + \tfrac{1}{\mu_1}\vec{\mathcal{B}}_\mathrm{r}\cdot\hat{\mathbf{e}}_y = \tfrac{1}{\mu_1}\mathcal{B}_\mathrm{i} + \tfrac{1}{\mu_1}\mathcal{B}_\mathrm{r} = \tfrac{1}{\mu_1 c_1}(\mathcal{E}_\mathrm{i}-\mathcal{E}_\mathrm{r}) &\stackrel{!}{=} \tfrac{1}{\mu_2 c_2}\mathcal{E}_\mathrm{t} = \tfrac{1}{\mu_2}\mathcal{B}_\mathrm{t} = \tfrac{1}{\mu_2}\vec{\mathcal{B}}_\mathrm{t}\cdot\hat{\mathbf{e}}_y \\
\vec{\mathcal{E}}_\mathrm{i}\cdot\hat{\mathbf{e}}_x + \vec{\mathcal{E}}_\mathrm{r}\cdot\hat{\mathbf{e}}_x = \mathcal{E}_\mathrm{i}\cos\theta_i + \mathcal{E}_\mathrm{r}\cos\theta_r = (\mathcal{E}_\mathrm{i}+\mathcal{E}_\mathrm{r})\cos\theta_r &\stackrel{!}{=} \mathcal{E}_\mathrm{t}\cos\theta_t = \vec{\mathcal{E}}_\mathrm{t}\cdot\hat{\mathbf{e}}_x \\
\varepsilon_1\mathcal{E}_\mathrm{i}\sin\theta_\mathrm{i} + \varepsilon_1\mathcal{E}_\mathrm{r}\sin\theta_r = \varepsilon_1(\mathcal{E}_\mathrm{i}-\mathcal{E}_\mathrm{r})\sin\theta_\mathrm{i} &\stackrel{!}{=} \varepsilon_2\mathcal{E}_\mathrm{t}\sin\theta_t \\
0 &\stackrel{!}{=} 0\ .
\end{aligned} \tag{15.59}$$

Using the abbreviation (15.49) and introducing another abbreviation,

$$\alpha \equiv \frac{\cos\theta_\mathrm{t}}{\cos\theta_\mathrm{i}} = \frac{\sqrt{1-(n_1/n_2)^2\sin^2\theta_\mathrm{i}}}{\cos\theta_\mathrm{i}}\ , \tag{15.60}$$

and solving the system of equations (15.59), we find *Fresnel's formula* for p-polarization [4],

$$\boxed{r_p \equiv \left.\frac{\mathcal{E}_\mathrm{r}}{\mathcal{E}_\mathrm{i}}\right|_p = \frac{\alpha-\beta}{\alpha+\beta} = \frac{n_1\cos\theta_\mathrm{t} - n_2\cos\theta_\mathrm{i}}{n_1\cos\theta_\mathrm{t} + n_2\cos\theta_\mathrm{i}} \quad \text{and} \quad t_p \equiv \left.\frac{\mathcal{E}_\mathrm{t}}{\mathcal{E}_\mathrm{i}}\right|_p = \frac{2}{\alpha+\beta}}\ . \tag{15.61}$$

We now assume that the polarization of the incident field is perpendicular to the plane of incidence, $\vec{\mathcal{E}}_\mathrm{i}\cdot\hat{\mathbf{e}}_x = 0 = \vec{\mathcal{B}}_\mathrm{i}\cdot\hat{\mathbf{e}}_y$. This is called *s-polarization*. In this case the equations (15.58) yield,

$$\begin{aligned}
\tfrac{1}{\mu_1}\vec{\mathcal{B}}_\mathrm{i}\cdot\hat{\mathbf{e}}_x + \tfrac{1}{\mu_1}\vec{\mathcal{B}}_\mathrm{r}\cdot\hat{\mathbf{e}}_x = \tfrac{1}{\mu_1 c_1}(\mathcal{E}_\mathrm{i}\cos\theta_i - \mathcal{E}_\mathrm{r}\cos\theta_r) &\stackrel{!}{=} \tfrac{1}{\mu_2 c_2}\mathcal{E}_\mathrm{t}\cos\theta_\mathrm{t} = \tfrac{1}{\mu_2}\vec{\mathcal{B}}_\mathrm{t}\cdot\hat{\mathbf{e}}_x \\
\vec{\mathcal{E}}_\mathrm{i}\cdot\hat{\mathbf{e}}_y + \vec{\mathcal{E}}_\mathrm{r}\cdot\hat{\mathbf{e}}_y = \mathcal{E}_\mathrm{i} + \mathcal{E}_\mathrm{r} &\stackrel{!}{=} \mathcal{E}_\mathrm{t} = \vec{\mathcal{E}}_\mathrm{t}\cdot\hat{\mathbf{e}}_y \\
0 &\stackrel{!}{=} 0 \\
\mathcal{B}_\mathrm{i}\sin\theta_\mathrm{i} + \mathcal{B}_\mathrm{r}\sin\theta_\mathrm{r} = \tfrac{1}{c_1}(\mathcal{E}_\mathrm{i}-\mathcal{E}_\mathrm{r})\sin\theta_i &\stackrel{!}{=} \tfrac{1}{c_2}\mathcal{E}_\mathrm{t}\sin\theta_\mathrm{t} = \mathcal{B}_\mathrm{t}\sin\theta_t\ .
\end{aligned} \tag{15.62}$$

Similar to the case of p-polarization we obtain the Fresnel formulas for s-polarization,

$$\boxed{r_s \equiv \left.\frac{\mathcal{E}_\mathrm{r}}{\mathcal{E}_\mathrm{i}}\right|_s = -\frac{1-\alpha\beta}{1+\alpha\beta} = -\frac{n_1\cos\theta_\mathrm{i} - n_2\cos\theta_\mathrm{t}}{n_1\cos\theta_\mathrm{i} + n_2\cos\theta_\mathrm{t}} \quad \text{and} \quad t_s \equiv \left.\frac{\mathcal{E}_\mathrm{t}}{\mathcal{E}_\mathrm{i}}\right|_s = \frac{\sqrt{\alpha\beta}}{1+\alpha\beta}}\ . \tag{15.63}$$

See also Exc. 15.1.8.23.

The power flux density incident on the interface is the projection of the intensity, $\vec{\mathcal{S}}\cdot\hat{\mathbf{e}}_z$. Therefore the intensities are,

$$I_m = \tfrac{1}{2}\varepsilon_1 c_m \mathcal{E}_m^2\cos\theta_m\ , \tag{15.64}$$

[4] Using Snell's law (15.57) the Fresnel formulas can also be written as,

$$\begin{aligned}
r_p^2 &= \frac{\tan^2(\theta_\mathrm{i}-\theta_\mathrm{t})}{\tan^2(\theta_\mathrm{i}\theta_\mathrm{t})} \quad \text{and} \quad r_s^2 = \frac{\sin^2(\theta_\mathrm{i}-\theta_\mathrm{t})}{\sin^2(\theta_\mathrm{i}+\theta_\mathrm{t})} \\
t_p^2 &= \frac{\sin 2\theta_\mathrm{i}\sin 2\theta_\mathrm{t}}{\sin^2(\theta_\mathrm{i}+\theta_\mathrm{t})\cos^2(\theta_\mathrm{i}-\theta_\mathrm{t})} \quad \text{and} \quad t_s^2 = \frac{\sin 2\theta_\mathrm{i}\sin 2\theta_\mathrm{t}}{\sin^2(\theta_\mathrm{i}+\theta_\mathrm{t})}\ .
\end{aligned}$$

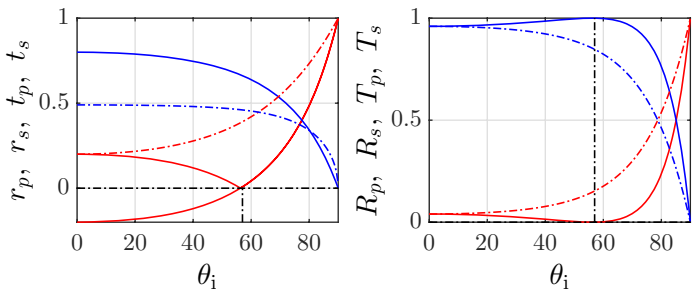

Figure 15.3: (code) Fresnel formulas for the transmitted (blue) and reflected (red) amplitude (left) and intensity (right). The dotted curve holds for s-polarization and the solid curve for p-polarization.

with $m = i, r, t$. Thus the reflection and the transmission are for p-polarization,

$$R_p = \left(\frac{\mathcal{E}_\mathrm{r}}{\mathcal{E}_\mathrm{i}}\right)_p^2 = \left(\frac{\alpha-\beta}{\alpha+\beta}\right)^2 \quad \text{and} \quad T_p = \frac{\varepsilon_2 c_2}{\varepsilon_1 c_1}\frac{\cos\theta_\mathrm{t}}{\cos\theta_\mathrm{i}}\left(\frac{\mathcal{E}_\mathrm{t}}{\mathcal{E}_\mathrm{i}}\right)_p^2 = \alpha\beta\left(\frac{2}{\alpha+\beta}\right)^2 = 1 - R_p\ . \tag{15.65}$$

For s-polarization we have,

$$R_s = \left(\frac{\mathcal{E}_\mathrm{r}}{\mathcal{E}_\mathrm{i}}\right)_s^2 = \left(\frac{1-\alpha\beta}{1+\alpha\beta}\right)^2 \quad \text{and} \quad T_s = \frac{\varepsilon_2 c_2}{\varepsilon_1 c_1}\frac{\cos\theta_\mathrm{t}}{\cos\theta_\mathrm{i}}\left(\frac{\mathcal{E}_\mathrm{t}}{\mathcal{E}_\mathrm{i}}\right)_s^2 = \alpha\beta\left(\frac{2}{1+\alpha\beta}\right)^2 = 1 - R_s\ . \tag{15.66}$$

15.1.6.4 The Brewster angle

For an angle of incidence of $\theta_\mathrm{i} = 0°$ ($\alpha = 1$) we recover the expressions (15.48). For $\theta_\mathrm{i} = 90°$ ($\alpha \to \infty$), all light is reflected. Looking at the formula (15.61) it is interesting to note the existence of an angle, where the reflection vanishes for the case of the s-polarization. It is given by $\alpha = \beta$, that is,

$$\sin^2\theta_\mathrm{i,B} \equiv \sin^2\theta_\mathrm{i} = \frac{1-\beta^2}{(n_1/n_2)^2 - \beta^2}\ . \tag{15.67}$$

θ_B is the *Brewster angle*. When $\mu_1 \simeq \mu_2$ we can simplify to,

$$\boxed{\theta_\mathrm{i,B} = \arcsin\frac{1-\beta^2}{(n_1/n_2)^2-\beta^2} \simeq \arctan\frac{n_2}{n_1}}\ . \tag{15.68}$$

That is, a p-polarized beam of light traveling in a vacuum and encountering a dielectric with refractive index $n_2 = 1.5$ under the angle of $\theta_\mathrm{i,B} \approx 56.3°$ is fully transmitted. This is seen in Fig. 15.3(right), where the reflected intensity I_r/I_0 of p-polarized light vanishes at a specific angle, and illustrated in Fig. 15.4(a).

15.1.6.5 Internal total reflection and the Goos-Hänchen shift

We now consider a light beam traveling in a dielectric with refractive index n_1 and encountering an interface to an optically less dense medium, $n_2 < n_1$, as illustrated

in Fig. 15.4(b). Increasing the angle of incidence θ_i, according to Snell's law (15.57) we will come to a point, where the outgoing angle reaches $\theta_t = 90°$. Snell's law gives the critical angle for this to happen,

$$\boxed{\theta_{\mathrm{i,tot}} = \arcsin \frac{n_2}{n_1}} \ . \tag{15.69}$$

For an index of refraction $n_1 = 1.5$ this angle is $\theta_{\mathrm{i,tot}} \approx 41.8°$. Above this angle, $\theta_\mathrm{i} > \theta_{\mathrm{i,tot}}$, all energy is reflected by the optically denser medium. This phenomenon of *total internal reflection* is used e.g. to guide light in optical fibers. Nevertheless, the fields do not completely disappear in the medium 2 but form, a so-called *evanescent wave*, which is exponentially attenuated and does not carry energy into the medium 2. A quick way to construct the evanescent wave consists in simply extending to the complex domain the formulas obtained for inclined incidence of light on interfaces. For $\theta_i > \theta_{\mathrm{i,tot}}$,

$$\sin\theta_\mathrm{t} = \frac{n_1}{n_2}\sin\theta_\mathrm{i} > \frac{n_1}{n_2}\sin\theta_{\mathrm{i,tot}} = \sin\theta_{\mathrm{t,tot}} = 1 \ , \tag{15.70}$$

Obviously θ_t can no longer be interpreted as an angle! We will show in Exc. 15.1.8.24 that, for the geometry illustrated in Fig. 15.4(b), the electric field generated in region 2 is given by,

$$\vec{\mathcal{E}}_\mathrm{t}(\mathbf{r},t) = \vec{\mathcal{E}}_0 e^{-\kappa z} e^{\imath(kx-\omega t)} \ , \tag{15.71}$$

where

$$\kappa \equiv \tfrac{\omega}{c}\sqrt{(n_1\sin\theta_\mathrm{i})^2 - n_2^2} \qquad \text{and} \qquad k \equiv \tfrac{\omega n_1}{c}\sin\theta_\mathrm{i} \ . \tag{15.72}$$

(15.71) is a wave propagating in x-direction, parallel to the interface, and being

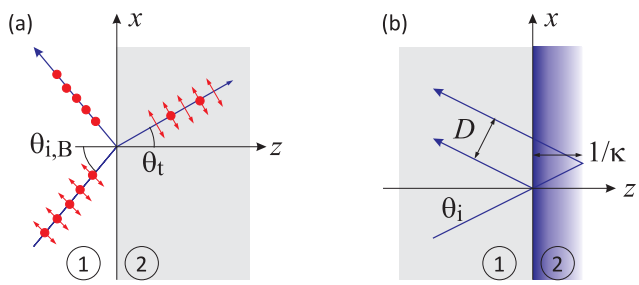

Figure 15.4: (a) Illustration of the effect of the Brewster angle on the polarization of light. (b) Illustration of the Goos-Hänchen shift.

attenuated in z-direction. The penetration depth of is κ^{-1}. Also in Exc. 15.1.8.24 we will show that for both polarizations p and s the reflection coefficient is 1, which confirms that there is no energy transported into the medium 2.

Example 102 (*The Goos-Hänchen shift*): The fact that the light wave penetrates region 2 up to a depth of κ^{-1} causes a transverse displacement of the wave known as *Goos-Hänchen shift* named after *Gustav Goos* and *Hilda Hänchen*. From Fig. 15.4 it is easy to verify that this displacement is of the order of magnitude $D \simeq \frac{2}{\kappa}\sin\theta_i$. It can be measured taking a beam of light with finite radial extent.

15.1.7 Transfer matrix formalism

For a propagating wave the amplitude of the field at a point $z = 0$ can be related to another point z via $\vec{\mathcal{E}}_z = M\vec{\mathcal{E}}_0$, where M is a phase factor of the type $e^{\imath kz}$. A counter-propagating wave (e.g. generated by partial reflection at an interface) suffers, over the same distance, a phase shift of $e^{-\imath kz}$. Since both waves interfere, it is useful to set up a model describing in a compact manner the amplitude and phase variations of the two counterpropagating waves along the optical axis. The *transfer matrix formalism* represents such a model.

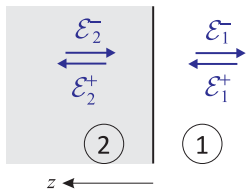

Figure 15.5: Illustration of the transfer matrix formalism.

15.1.7.1 The $\mathcal{T}$-matrix

Let us consider a beam of light propagating along the z-axis toward $+\infty$ through an inhomogeneous dielectric medium described by the refractive index $n(z)$. Each interface where the refractive index varies causes a partial reflection of the beam into the opposite direction. The fields reflected at different positions z interfere constructively or destructively depending on the accumulated phase. To address the problem mathematically, we divide the medium into layers treated as homogeneous and delimited by interfaces located at positions z, as shown in Fig. 15.5. We define the complex *transfer matrix* or $\mathcal{T}$-matrix describing the transition between from medium (1) to medium (2) by,

$$\boxed{\begin{pmatrix} \mathcal{E}_2^+ \\ \mathcal{E}_2^- \end{pmatrix} = \mathcal{T}_{12} \begin{pmatrix} \mathcal{E}_1^+ \\ \mathcal{E}_1^- \end{pmatrix}} \,. \tag{15.73}$$

Here, the fields $\mathcal{E}^\pm$ propagate toward $\pm\infty$. That is, the fields $\mathcal{E}_1^+$ and $\mathcal{E}_2^-$ move toward the interface and the fields $\mathcal{E}_1^-$ and $\mathcal{E}_2^+$ move away from the interface. In (15.48) we showed that the reflectivity and the transmissivity of the interface for a transition from region (1) to region (2) are given by,

$$r_{12} = \frac{n_1 - n_2}{n_1 + n_2} \qquad \text{and} \qquad t_{12} = \frac{2n_1}{n_1 + n_2} \,. \tag{15.74}$$

Obviously, we have $r_{21} = -r_{12}$ and $t_{21} = \frac{n_2}{n_1} t_{12}$. Therefore,

$$\mathcal{E}_2^+ = t_{12}\mathcal{E}_1^+ + r_{21}\mathcal{E}_2^- \qquad \text{and} \qquad \mathcal{E}_1^- = t_{21}\mathcal{E}_2^- + r_{12}\mathcal{E}_1^+ \,, \tag{15.75}$$

or introducing the *scattering matrix* or $\mathcal{S}$-matrix,

$$\boxed{\begin{pmatrix}\mathcal{E}_2^+\\ \mathcal{E}_1^-\end{pmatrix} = \mathcal{S}_{12}\begin{pmatrix}\mathcal{E}_1^+\\ \mathcal{E}_2^-\end{pmatrix} \qquad \text{with} \qquad \mathcal{S}_{12} = \begin{pmatrix} r_{12} & r_{12}\\ r_{12} & r_{12}\end{pmatrix}} \,. \tag{15.76}$$

Resolving (15.75) by the fields in medium (2),

$$\mathcal{E}_2^+ = \left(t_{12} - \tfrac{r_{12}r_{21}}{t_{21}}\right)\mathcal{E}_1^+ + \tfrac{r_{21}}{t_{21}}\mathcal{E}_1^- \qquad \text{and} \qquad \mathcal{E}_2^- = -\tfrac{r_{12}}{t_{21}}\mathcal{E}_1^+ + \tfrac{1}{t_{21}}\mathcal{E}_1^- \,. \tag{15.77}$$

The matrix, therefore, is,

$$\boxed{\mathcal{T}_{12} = \begin{pmatrix} t_{12} - \frac{r_{12}r_{21}}{t_{21}} & \frac{r_{21}}{t_{21}}\\ -\frac{r_{12}}{t_{21}} & \frac{1}{t_{21}}\end{pmatrix} = \frac{1}{2n_2}\begin{pmatrix} n_2+n_1 & n_2-n_1\\ n_2-n_1 & n_2+n_1\end{pmatrix}} \,. \tag{15.78}$$

The determinant is $\det\mathcal{T} = \frac{t_{12}}{t_{21}} = \frac{n_1}{n_2}$.

The simple propagation over a distance Δz through a homogeneous medium simply causes a phase shift, since $\mathcal{E}_z^+ = e^{\imath kz}\mathcal{E}_0^+$ and $\mathcal{E}_0^- = e^{\imath kz}\mathcal{E}_z^-$. The corresponding transfer matrix is,

$$\boxed{\mathcal{T}_{\Delta z} = \begin{pmatrix} e^{\imath k\Delta z} & 0\\ 0 & e^{-\imath k\Delta z}\end{pmatrix}} \,. \tag{15.79}$$

Absorption losses can attenuate the beam. This can be taken into account via an absorption coefficient α in the matrix,

$$\boxed{\mathcal{T}_{\text{abs}} = \begin{pmatrix} e^{-\alpha} & 0\\ 0 & e^{\alpha}\end{pmatrix}} \,. \tag{15.80}$$

satisfying $\det\mathcal{T} = 1$.

15.1.7.2 AR and HR coating

Concatenating the matrices (15.78) and (15.79), $\mathcal{M} = \mathcal{T}_{\Delta z}\mathcal{T}_{12}\mathcal{T}_{\text{abs}}$, we can now describe the transmission of a light beam through a dielectric layer with refractive index n_2 and thickness Δz [576, 577].

Example 103 (*Anti-reflection coating*): Here we consider the transition between a medium n_0 through a thin layer n_1 of thickness $\lambda/4$ to a medium n_2. The transition is described by the concatenation of three matrices,

$$\begin{pmatrix}\mathcal{E}_2^+\\ 0\end{pmatrix} = \mathcal{T}_{12}\mathcal{T}_{\lambda/4}\mathcal{T}_{01}\begin{pmatrix}\mathcal{E}_0^+\\ \mathcal{E}_0^-\end{pmatrix} = \begin{pmatrix} M_{11} & M_{12}\\ M_{21} & M_{22}\end{pmatrix}\begin{pmatrix}\mathcal{E}_0^+\\ \mathcal{E}_0^-\end{pmatrix} = \begin{pmatrix} M_{11} - \frac{M_{12}M_{21}}{M_{22}}\\ 0\end{pmatrix}\mathcal{E}_0^+ \,.$$

The total matrix is,

$$\mathcal{M} = \frac{1}{2n_2}\begin{pmatrix} n_2+n_1 & n_2-n_1 \\ n_2-n_1 & n_2+n_1 \end{pmatrix}\begin{pmatrix} e^{\imath\pi/2} & 0 \\ 0 & e^{-\imath\pi/2} \end{pmatrix}\frac{1}{2n_1}\begin{pmatrix} n_1+n_0 & n_1-n_0 \\ n_1-n_0 & n_1+n_0 \end{pmatrix}$$
$$= \frac{\imath}{2n_1n_2}\begin{pmatrix} n_1^2+n_0n_2 & n_1^2-n_0n_2 \\ -n_1^2+n_0n_2 & -n_1^2-n_0n_2 \end{pmatrix} .$$

Finally, we obtain the fields,

$$\mathcal{E}_2^+ = \left(M_{11} - \frac{M_{12}M_{21}}{M_{22}}\right)\mathcal{E}_0^+ = \frac{2\imath n_0 n_1}{n_1^2+n_0n_2}\mathcal{E}_0^+ \overset{n_1^2\equiv n_0n_2}{\longrightarrow} \frac{\imath n_0}{n_1}\mathcal{E}_0^+$$
$$\mathcal{E}_0^- = -\frac{M_{21}}{M_{22}}\mathcal{E}_0^+ = \frac{n_1^2-n_0n_2}{n_1^2+n_0n_2}\mathcal{E}_0^+ \overset{n_1^2\equiv n_0n_2}{\longrightarrow} 0 .$$

Choosing $n_1^2 \equiv n_0n_2$ we can cancel out the reflection and maximize the transmission. We check,

$$T = \frac{I_t}{I_i} = \frac{\varepsilon_2 c_2|\mathcal{E}_2^+|^2}{\varepsilon_0 c_0|\mathcal{E}_0^+|^2} = \frac{\frac{n_2^2}{c^2}\frac{c}{n_2}\left|\frac{2\imath n_0n_1}{n_1^2+n_0n_2}\right|^2}{\frac{n_0^2}{c^2}\frac{c}{n_0}} = \frac{4n_0n_1^2n_2}{(n_1^2+n_0n_2)^2}$$
$$R = \frac{I_r}{I_i} = \frac{\varepsilon_0 c_0|\mathcal{E}_0^-|^2}{\varepsilon_0 c_0|\mathcal{E}_0^+|^2} = \left|\frac{n_1^2-n_0n_2}{n_1^2+n_0n_2}\right|^2 = 1-T .$$

Fig. 15.6 shows the transmission through a stack of dielectric layers. The transfer matrix is,

$$\mathcal{M} = (\mathcal{T}_{21}\mathcal{T}_{\Delta z_2}\mathcal{T}_{\text{abs}}\mathcal{T}_{12}\mathcal{T}_{\Delta z_1}\mathcal{T}_{\text{abs}})^N\mathcal{T}_{01} . \tag{15.81}$$

We observe a large reflection band (600..660 nm) called one-dimensional *photonic band gap*. Dielectric mirrors can, nowadays, achieve reflections up to $R = 99.9995\%$, while the reflectivity of metal mirrors is always limited by losses. Exc. 15.1.8.25 can be solved using transfer matrices.

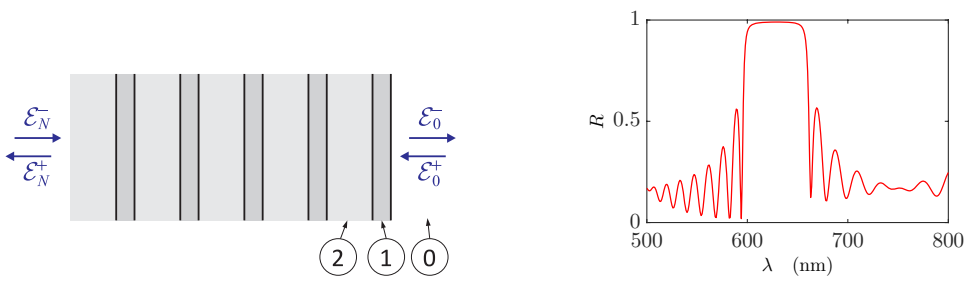

Figure 15.6: (code) Reflection by a high reflecting mirror made of 10 layers with $n_1 = 2.4$ and $\Delta z_1 = 80$ nm alternating with 10 layers with $n_2 = 1.5$ and $\Delta z_2 = 500$ nm. The absorption coefficient for each layer is supposed to be $\alpha = 0.2\%$. The beam impinges from vacuum, $n_0 = 1$.

The transfer matrix formalism can also be applied to modeling the passage of a laser beam through a gas of two levels atoms periodically organized in one dimension

like a stack of pancakes [859, 821]. One only has to consider that the variation of the density of the gas along the optical axis generates a spatial modulation of the refractive index [5].

Furthermore, we will show in Sec. 15.3.6 how to use the transfer matrix formalism for impedance matching of optical cavities.

15.1.8 Exercises

15.1.8.1 Ex: Wave equation and Galilei transform

Show that any function of the form $y(x,t) = f(x - vt)$ or $y(x,t) = g(x + vt)$ satisfies the wave equation.

15.1.8.2 Ex: Plane waves

Consider a set of solutions for plane electromagnetic waves in vacuum, whose fields (electric or magnetic) are described by the real part of the functions $\mathbf{u}(\mathbf{r},t) = \mathbf{A}e^{\imath(\mathbf{k}\cdot\mathbf{r}-\omega t)}$, with constant phase $(\mathbf{k}\cdot\mathbf{r}-\omega t)$. In these expressions, $\mathbf{k}$ is the wavevector (determining the propagation direction of the wave) and $\omega = vk$ is the angular frequency, where $v = 1/\sqrt{\varepsilon\mu}$ is the propagation velocity of the waves.
a. Show that the divergent $\mathbf{u}(x,t)$ satisfies: $\nabla \cdot \mathbf{u} = \imath\mathbf{k} \cdot \mathbf{u}$;
b. Show that the rotation $\mathbf{u}(x,t)$ satisfies: $\nabla \times \mathbf{u} = \imath\mathbf{k} \times \mathbf{u}$;
c. Show that the waves are transverse and that the vectors $\vec{\mathcal{E}}$, $\vec{\mathcal{B}}$, and $\mathbf{k}$ are mutually perpendicular.

15.1.8.3 Ex: Polarization of a wave in vacuum

A transverse electromagnetic wave propagates through an isotropic, non-conducting medium without charges (vacuum) in positive z-direction. The projection of the vector of the electric field on the plane x-y has the form,

$$\vec{\mathcal{E}} = \vec{\mathcal{E}}_0 \sin(kz - \omega t) = (\mathcal{E}_{0x}, \mathcal{E}_{0y}, 0) \sin(kz - \omega t) \ .$$

a. Illustrate the motion of the electric field vector by a scheme. How is the wave polarized?
b. Show from Maxwell's equations, that the magnetic field vector can be written as,

$$\vec{\mathcal{B}}(\mathbf{r},t) = \frac{1}{\omega}(\mathbf{k} \times \vec{\mathcal{E}})$$

with the wavevector $\mathbf{k} = k\hat{\mathbf{e}}_z$.
c. Calculate the energy flux of the wave (Poynting vector) $\vec{\mathcal{S}}(\mathbf{r},t)$ as a function of the (phase) velocity of the wave c_0. How does the phase change in other media ($\mu \neq \mu_0$ and $\varepsilon \neq \varepsilon_0$)? What does this mean for $\vec{\mathcal{S}}(\mathbf{r},t)$.

[5] We will discuss this system in Sec. 44.5.2 .

15.1.8.4 Ex: Jones matrices for a three-beam MOT

A three-beam magneto-optical trap (MOT) is characterized by the fact that each of three linearly polarized laser beams passes through a $\lambda/4$-waveplate rotated in a way to leave them circularly polarized. Then the beam traverses the MOT a first time, behind the MOT it passes through a second waveplate, and being finally reflected by a mirror, it makes all the way back, as shown in the figure. Show that the polarization of the laser beam at the position of the mirror is always *linear* independently of the rotation angle of the second waveplate.

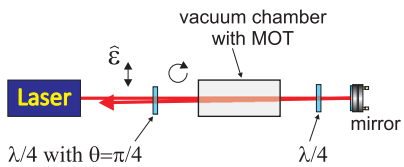

Figure 15.7: One of three retroreflected beams of a MOT.

15.1.8.5 Ex: Temporal average of waves in complex notation

In complex notation there is a practical recipe for finding the temporal average of a product of waves. Consider $f(\mathbf{r},t) = \cos(\mathbf{k}\cdot\mathbf{r}-\omega t+\delta_a)$ and $g(\mathbf{r},t) = \cos(\mathbf{k}\cdot\mathbf{r}-\omega t+\delta_\mathrm{b})$. Show $\overline{fg} = \frac{1}{2}\mathfrak{Re}\,(\tilde{f}\tilde{g}^*)$. Note, that this only works, when the two waves have the same wavevector $\mathbf{k}$ and the same frequency ω, but they may have arbitrary amplitudes and phases. For example,

$$\langle u\rangle = \tfrac{1}{4}\mathfrak{Re}\,(\varepsilon_0\tilde{\vec{\mathcal{E}}}\cdot\tilde{\vec{\mathcal{E}}}^* + \tfrac{1}{\mu_0}\tilde{\vec{\mathcal{B}}}\cdot\tilde{\vec{\mathcal{B}}}^*) \qquad \text{and} \qquad \langle\vec{\mathcal{S}}\rangle = \tfrac{1}{2\mu_0}\mathfrak{Re}\,(\tilde{\vec{\mathcal{E}}}\times\tilde{\vec{\mathcal{B}}}^*)\ .$$

15.1.8.6 Ex: Radiation pressure of a plane wave

A plane electromagnetic wave impinges vertically on a plane.
a. Show that the radiation pressure exerted on a surface is equal to the energy density in the incident beam. Does this ratio depend on the reflected part of the radiation?
b. Now consider a beam of small massive balls of mass m incident on a plane. What is the relationship between the mean pressure on the surface and the kinetic energy in this case?

15.1.8.7 Ex: Radiation pressure of solar light

Estimate the radiation pressure force exerted by the Sun on the Earth, and compare this force to the gravitational force on Earth and at the atmospheric pressure. (The intensity of sunlight at the Earth's orbit is $I = 1.37\,\mathrm{kW/m^2}$).
b. Repeat part (a) for Mars, which has an average distance of $2.28\cdot 10^8$ km from the Sun and has a radius of 3400 km.
c. What is the exerted radiation pressure when light strikes a perfect absorber (reflector)?

15.1.8.8 Ex: Radiation pressure of a point-like emitter onto a plane

A punctual and intense source of light isotropically radiates 1.0 MW. The source is located 1.0 m above an infinite and perfectly reflecting plane. Determine the force that the radiation pressure exerts on the plane.

15.1.8.9 Ex: Maxwell's tensor for a plane wave

Find all the elements of Maxwell's stress tensor for a monochromatic plane wave traveling in z-direction and being linearly polarized in y-direction. Interpret the result remembering that $\overleftrightarrow{T}$ represents a momentum flux density. How is $\overleftrightarrow{T}$ related to the energy density in this case?

15.1.8.10 Ex: Superposition of waves

Suppose $Ae^{\imath ax} + Be^{\imath bx} = Ce^{\imath cx}$ $\forall x$. Prove that $a = b = c$ and $A + B = C$.

15.1.8.11 Ex: Poynting vector of a superposition of two waves

The electric fields of two harmonic electromagnetic waves of angular frequencies ω_1 and ω_2 are given by $\vec{\mathcal{E}}_1 = \mathcal{E}_{10}\cos(k_1x - \omega_1 t)\hat{\mathbf{e}}_y$ and by $\vec{\mathcal{E}}_2 = \mathcal{E}_{20}\cos(k_2x - \omega_2 t + \delta)\hat{\mathbf{e}}_y$. For the superposition of these two waves, determine
a. the instantaneous Poynting vector and
b. the temporal average of the Poynting vector.
c. Repeat parts (a) and (b) for an inverted propagation direction of the second wave, i.e. $\vec{\mathcal{E}}_2 = \mathcal{E}_{20}\cos(k_2x + \omega_2 t + \delta)\hat{\mathbf{e}}_y$.

15.1.8.12 Ex: Poynting vector of a standing wave

The electric field $\vec{\mathcal{E}}(\mathbf{r}, t)$ of a standing electromagnetic wave in vacuum be given by,

$$\vec{\mathcal{E}}(\mathbf{r}, t) = \mathfrak{Re}\left(\mathcal{E}_0\hat{\mathbf{e}}_x e^{\imath(kz-\omega t)} - \mathcal{E}_0\hat{\mathbf{e}}_x e^{\imath(-kz-\omega t)}\right) = 2\mathcal{E}_0 \sin kz \sin \omega t \hat{\mathbf{e}}_x$$

with $\mathcal{E}_0 \in \mathbb{R}$.
a. Determine the corresponding magnetic field $\vec{\mathcal{B}}(\mathbf{r}, t)$.
b. Calculate the Poynting vector $\vec{\mathcal{S}}(\mathbf{r}, t)$. What follows for the energy flow $\bar{s}$ of the standing electromagnetic wave in the temporal average, that is, calculate

$$\bar{s} = \frac{\int dt\ s}{\int dt}\ ,$$

where both integrals should be evaluated between $t = 0$ and $t = 2\pi/\omega$.

15.1.8.13 Ex: Phase fronts of planar and spherical waves

Describes the phase front for (a) a plane wave and (b) a spherical wave.

15.1.8.14 Ex: Fake spherical wave

We verified in class, that spherical waves of the form

$$\vec{\mathcal{E}}_{\pm}(\mathbf{r},t) = \vec{\mathcal{E}}_0 \frac{1}{r} e^{\imath(kr \pm \omega t)} \qquad \text{and} \qquad \vec{\mathcal{B}}_{\pm}(\mathbf{r},t) = \vec{\mathcal{B}}_0 \frac{1}{r} e^{\imath(kr \pm \omega t)}$$

with $\omega = ck$, $c^2 = 1/(\varepsilon_0 \mu_0)$ satisfy the Helmholtz equation. Argue, why nevertheless, they can not be electromagnetic waves. Check whether such waves satisfy the homogeneous Maxwell equations.

15.1.8.15 Ex: Spherical wave

Consider a spherical electromagnetic wave,

$$\vec{\mathcal{E}}(\mathbf{r},t) = \vec{\mathcal{E}}_0(r,\theta) e^{\imath(kr-\omega t)} \qquad \text{and} \qquad \vec{\mathcal{B}}(\mathbf{r},t) = \vec{\mathcal{B}}_0(r,\theta) e^{\imath(kr-\omega t)} \ .$$

Show that the validity of Maxwell's equations for $\nabla \cdot \vec{\mathcal{E}} = 0 = \nabla \cdot \vec{\mathcal{B}}$ for the case of vanishing charge and current densities implies that $\vec{\mathcal{E}}$, $\vec{\mathcal{B}}$, and $\hat{\mathbf{e}}_r$ are mutually orthogonal (transversality).

15.1.8.16 Ex: Spherical wave in a neutral dielectric medium

a. Show that spherical waves $\vec{\mathcal{E}}(\mathbf{r},t) = \frac{\vec{\mathcal{E}}_0}{r} e^{\imath(kr-\omega t)}$ solve the wave equation in a vacuum, when $\omega = ck$. The Laplace operator in spherical coordinates is,

$$\nabla^2 = \frac{1}{r^2} \frac{\partial}{\partial r} \left(r^2 \frac{\partial}{\partial r} \right) + \frac{1}{r^2} \Delta_{\theta,\phi} \ .$$

The second term only acts on the parts that depend on the angles. Verify that $\Delta_{\theta,\phi} \vec{\mathcal{E}} \equiv 0$.
b. Show that the wave equations have the form,

$$\nabla^2 \vec{\mathcal{E}} - \frac{1}{c^2} \frac{\partial^2 \vec{\mathcal{E}}}{\partial t^2} = \frac{1}{\varepsilon_0 c^2} \frac{\partial^2 \vec{\mathcal{P}}}{\partial t^2} \ ,$$

when the wave does not propagate in a vacuum, but in a neutral dielectric medium (i.e. without free charges). Assume the simple case that the dielectric displacement $\vec{\mathcal{D}} = \varepsilon_0 \vec{\mathcal{E}} + \vec{\mathcal{P}}$ has the form,

$$\vec{\mathcal{P}} = \varepsilon_0 \chi \vec{\mathcal{E}} \ .$$

What is the form of the wave equations in this case? How do you change the phase velocity c of the wave? You can identify the meaning of the quantity $n \equiv \sqrt{1+\chi}$?

15.1.8.17 Ex: Refraction in a bath of water

An observer stands at the edge of a basin filled with water down to a depth of $h = 2.81$ m. He looks at an object lying on the bottom. At what depth h' appears the image of the object, if the direction of observation in which the observer perceives the image forms with the normal direction to the water surface an angle of $\alpha = 60°$? Prepare a scheme.

15.1.8.18 Ex: Poynting vector of a partially reflected wave

A plane wave $\vec{\mathcal{E}}_{\text{in}}(z,t)$ which is linearly polarized in x-direction runs along the z-axis from $-\infty$ towards an interface ($z = 0$-plane). At the interface, a part r of the wave is reflected without phase shift.
a. Give the amplitudes of the electric and the magnetic field in the half-space $z < 0$ in real numbers.
b. Give the Poynting vector $\vec{\mathcal{S}}(z,t)$ and its time average.

15.1.8.19 Ex: Energy flow upon refraction

Two infinitely extended media with relative dielectric constants ϵ_1 and ϵ_2 and permeabilities $\mu_1 = \mu_2 = \mu_0$, that is, with refraction indices $n_1 = \sqrt{\epsilon_1}$ and $n_2 = \sqrt{\epsilon_2}$, be separated by the $z = 0$-plane. Coming from the medium n_1 traveling in x-direction a linearly polarized plane wave with frequency ω and wavenumber k_1 hits the interface perpendicularly. The amplitude is $\mathcal{E}_0$.
a. Use the continuity of the normal components of $\vec{\mathcal{D}}$ and $\vec{\mathcal{B}}$, as well as of the tangential components of $\vec{\mathcal{E}}$ and $\vec{\mathcal{H}}$, at the interface to calculate the amplitudes of refracted part and the reflected part of the incident wave.
b. The energy flux is defined by the temporal average of the real part of the Poynting vector $\vec{\mathcal{S}}$: $\vec{\varphi} \equiv \mathfrak{Re}\,[\vec{\mathcal{E}} \times \vec{\mathcal{H}}^*]$. Calculate the incident, reflected, and refracted energy fluxes. What is the total flux in front and behind of the interface?
c. Determine the reflection coefficient r (the ratio between the absolute values of the reflected and incident fluxes) and the transmission coefficient t (the ratio between the absolute values of the transmitted and incident fluxes).

15.1.8.20 Ex: Birefringent crystal

An optically anisotropic crystal has in the x-direction the dielectric constant ε_1 (that is, the refractive index $n_1 = c\sqrt{\varepsilon_1\mu_1}$) and in the y-direction ε_2, respectively, n_2. A linearly polarized plane wave with frequency ω propagating in z-direction impinges, coming from the vacuum, at normal incidence on a disc of thickness d of this material in such a way, that the plane of the polarization forms with the x and y-axes an angle of 45°. What is the polarization of the plane wave after the transition through the disk? How should we choose d, so that the wave is circularly polarized? Express this thickness in terms of the vacuum wavelength.

15.1.8.21 Ex: Glass cube

At the center of a glass cube of length $d = 10\,\text{mm}$ with the refractive index $n = 1.5$ there is a small spot. Which parts should the surfaces be covered so that the spot is invisible from outside the cube regardless of the direction of vision? Neglect the light refracted out of the cube after a first reflection inside the cube.

15.1.8.22 Ex: Total internal reflection

a. We consider the transition of a beam of light from an optically dense medium (1) to a more dilute medium (2). Extending the theory of light refraction at interfaces beyond the angle of total internal reflection (15.70), derive the expression for the

electric field in the medium (2).
b. Noting that α [from Eq. (15.60)] is now imaginary, use the equation (15.61) to calculate the reflection coefficient for the polarization parallel to the plane of incidence [6].
c. Do the same for polarization that is perpendicular to the plane of incidence.
d. In case of perpendicular polarization, show that the (real) evanescent fields are,

$$\vec{\mathcal{E}}(\mathbf{r},t) = \mathcal{E}_0 e^{-\kappa z}\cos(kx-\omega t)\hat{\mathbf{e}}_y \quad , \quad \vec{\mathcal{B}}(\mathbf{r},t) = \mathcal{E}_0 e^{-\kappa z}[\kappa\sin(kx-\omega t)\hat{\mathbf{e}}_x + k\cos(kx-\omega t)\hat{\mathbf{e}}_z] \ .$$

e. Verify that the fields in (d) satisfy all Maxwell equations without sources.
f. For the fields in (d), construct the Poynting vector and show that, on average, no energy is transmitted in z-direction.

15.1.8.23 Ex: Fresnel formulae

Rewrite the Fresnel formulae (15.61) and (15.63) in terms of the wavevectors of the incident, reflected and transmitted waves.

15.1.8.24 Ex: The Goos-Hänchen effect

The Goos-Hänchen shift is an optical phenomenon in which a linearly polarized light beam with finite transverse extension suffers, under total internal reflection from a plane interface, a small lateral displacement within the plane of incidence. The effect is due to an interference of the partial waves composing the finite-sized beam, hitting the interface under different angles and thus undergoing different phase shifts upon reflection. The sum of the reflected waves with different phase shifts form an interference pattern transverse to the mean propagation direction leading to a lateral displacement of the beam. Thus, the Goos-Hänchen effect is a coherence phenomenon [367, 368, 473].
To describe this phenomenon quantitatively, we consider a linearly polarized light beam of wavelength λ, with finite transverse size. This beam is fully internally reflected at the interface between two non-permeable media with refractive indices n_1 and $n_2 < n_1$. The relationship between the reflected and incident amplitudes is a complex number, which can be expressed by $\mathcal{E}_0''/\mathcal{E}_0 = e^{\imath\phi(\theta_\mathrm{i},\theta_\mathrm{i,total})}$ for the angle of incidence $\theta_\mathrm{i} > \theta_\mathrm{i,total}$, where $\sin\theta_\mathrm{i,total} = \frac{n_2}{n_1}$.
a. Show that for a beam of 'monochromatic' radiation in z-direction with an electric field amplitude of $\mathcal{E}(x)e^{\imath kz-\imath\omega t}$, where $\mathcal{E}(x)$ is smooth and finite in transverse direction (albeit extending over many wavelengths), the first approximation in terms of plane waves is,

$$\vec{\mathcal{E}}(x,z,t) = \hat{\epsilon}\int A(\kappa)e^{\imath\kappa x+\imath kz-\imath\omega t}d\kappa \ ,$$

where $\hat{\epsilon}$ is a polarization vector and $A(\kappa)$ is the Fourier transform of $\mathcal{E}(x)$ with respect to κ around $\kappa = 0$ small compared to k. The finite-sized beam consists of plane waves with a small range of angles of incidence centered around the valor predicted by geometric optics.
b. Consider the reflected beam and show that for $\theta_\mathrm{i} > \theta_\mathrm{i,total}$ the electric field can be expressed approximately as,

$$\vec{\mathcal{E}}_\mathrm{r}(x,z,t) = \hat{\epsilon}_\mathrm{r}\mathcal{E}(\xi-\delta\xi)e^{\imath\mathbf{k}_\mathrm{r}\cdot\mathbf{r}-\imath\omega t+\imath\phi(\theta_\mathrm{i})} \ ,$$

[6] We observe 100% reflection, which is better than on a conductive surface.

where $\hat{\epsilon}_{\rm r}$ is a polarization vector, ξ is the coordinate perpendicular to $\mathbf{k}_{\rm r}$, which is the reflected wavevector and $\delta\xi = -\frac{1}{k}\frac{d\phi(\theta_{\rm i})}{d\theta_{\rm i}}$.
c. With the Fresnel expressions for the phases $\phi(\theta_{\rm i})$ and for the two polarization states of the plane, show that the lateral displacements of the beams with respect to the position predicted by geometric optics are,

$$\mathcal{D}_s = \frac{\lambda}{\pi}\frac{\sin\theta_{\rm i}}{\sqrt{\sin^2\theta_{\rm i} - \sin^2\theta_{\rm i,total}}} \qquad \text{and} \qquad \mathcal{D}_p = \mathcal{D}_s\frac{\sin^2\theta_{\rm i,total}}{\sin^2\theta_{\rm i} - \cos^2\theta_{\rm i}\sin^2\theta_{\rm i,total}} \ .$$

15.1.8.25 Ex: Interfaces

A light field of angular frequency ω passes from a medium (1), through a slab of thickness d representing a medium (2), to a medium (3). All three media are linear and homogeneous. Calculate the transmission coefficient between the media 1 and 3 for normal incidence.

15.2 Optical dispersion in material media

15.2.1 Plane waves in conductive media

When there are free charges in the propagation medium, we can not neglect neither $\varrho_{\rm f}$ nor $\mathbf{j}_{\rm f}$ in the Maxwell equations used to describe the wave propagation, because the electric field of the wave will itself generate a current $\mathbf{j}_{\rm f} = \varsigma\vec{\mathcal{E}}$, where ς is the conductivity introduced in Eq. (11.41). Thus, for linear media we must use the complete equations (14.6).

For a homogeneous and linear medium, the continuity equation gives,

$$\frac{\partial\varrho_{\rm f}}{\partial t} = -\nabla\cdot\mathbf{j}_{\rm f} = -\varsigma\nabla\cdot\vec{\mathcal{E}} = -\frac{\varsigma}{\varepsilon}\varrho_{\rm f} \ , \tag{15.82}$$

with the solution

$$\varrho_{\rm f}(t) = e^{-(\varsigma/\varepsilon)t}\varrho_{\rm f}(0) \ . \tag{15.83}$$

Therefore, every initial free charge density $\varrho_{\rm f}(0)$ diffuses within a characteristic time $\tau = \varepsilon/\varsigma$. This reflects the familiar fact that free charges in a conductor migrate to its edges with a speed that depends on the conductivity ς. For a good conductor, the relaxation time is much shorter than other characteristic times of the system, e.g. for oscillatory systems $\tau \ll \omega^{-1}$. In stationary situations we can assume, $\varrho = 0$, such that the relevant Maxwell equations,

$$\begin{array}{lrcl} \text{(i)} & \nabla\times\vec{\mathcal{B}} - \varepsilon\mu\partial_t\vec{\mathcal{E}} & = & \mu\varsigma\vec{\mathcal{E}} \\ \text{(ii)} & \nabla\times\vec{\mathcal{E}} + \partial_t\vec{\mathcal{B}} & = & 0 \\ \text{(iii)} & \nabla\cdot\vec{\mathcal{E}} & = & 0 \\ \text{(iv)} & \nabla\cdot\vec{\mathcal{B}} & = & 0 \end{array} \ , \tag{15.84}$$

only differ from the Maxwell equations for dielectric media by the existence of the term $\mu\varsigma\vec{\mathcal{E}}$.

Letting the rotation operator act on equations (i) and (ii) and exploiting the disappearance of the field divergences we obtain generalized wave equations,

$$\nabla^2\vec{\mathcal{E}} = \varepsilon\mu\frac{\partial^2\vec{\mathcal{E}}}{\partial t^2} + \varsigma\mu\frac{\partial\vec{\mathcal{E}}}{\partial t} \quad \text{and} \quad \nabla^2\vec{\mathcal{B}} = \varepsilon\mu\frac{\partial^2\vec{\mathcal{B}}}{\partial t^2} + \varsigma\mu\frac{\partial\vec{\mathcal{B}}}{\partial t} \ . \tag{15.85}$$

These equations still accept plane wave solutions,

$$\vec{\mathcal{E}}(z,t) = \vec{\mathcal{E}}_0 e^{\imath(\tilde{k}z-\omega t)} \quad \text{and} \quad \vec{\mathcal{B}}(z,t) = \vec{\mathcal{B}}_0 e^{\imath(\tilde{k}z-\omega t)} \ , \tag{15.86}$$

but this time the wavevector is complex,

$$\tilde{k}^2 = \varepsilon\mu\omega^2 + \imath\varsigma\mu\omega \ , \tag{15.87}$$

which can easily be verified by inserting a plane wave into the wave equations (15.85). The root of this expression gives,

$$\boxed{\begin{aligned} \tilde{k} = k + \imath\kappa \quad \text{with} \quad k &\equiv \omega\sqrt{\frac{\varepsilon\mu}{2}}\left(\sqrt{1+\left(\frac{\varsigma}{\varepsilon\omega}\right)^2}+1\right)^{1/2} \\ \text{and} \quad \kappa &\equiv \omega\sqrt{\frac{\varepsilon\mu}{2}}\left(\sqrt{1+\left(\frac{\varsigma}{\varepsilon\omega}\right)^2}-1\right)^{1/2} \end{aligned}} \ . \tag{15.88}$$

The imaginary part results in an attenuation of the wave in z-direction:

$$\vec{\tilde{\mathcal{E}}}(z,t) = \vec{\tilde{\mathcal{E}}}_0 e^{-\kappa z} e^{\imath(kz-\omega t)} \quad \text{and} \quad \vec{\tilde{\mathcal{B}}}(z,t) = \vec{\tilde{\mathcal{B}}}_0 e^{-\kappa z} e^{\imath(kz-\omega t)} \ . \tag{15.89}$$

The typical attenuation distance, κ^{-1}, called *skin depth*, measures the penetration depth of the wave in a conductor, while the real part k determines the propagation of the wave. As before, the equations (15.84)(iii) and (iv) exclude components perpendicular to the interface. The wave only has transverse components, that is, parallel to the interface, so that we can let the electric field be along $\hat{\mathbf{e}}_x$,

$$\vec{\tilde{\mathcal{E}}}(z,t) = \tilde{\mathcal{E}}_0\hat{\mathbf{e}}_x e^{-\kappa z} e^{\imath(kz-\omega t)} \quad \text{and} \quad \vec{\tilde{\mathcal{B}}}(z,t) = \tilde{\mathcal{B}}_0\hat{\mathbf{e}}_y e^{-\kappa z} e^{\imath(kz-\omega t)} \ . \tag{15.90}$$

By the equation (15.84)(ii) we verify,

$$\tilde{\mathcal{B}}_0 = \frac{\tilde{k}}{\omega}\tilde{\mathcal{E}}_0 \ . \tag{15.91}$$

Expressing the wavevector and the complex amplitudes by phase factors,

$$\tilde{k} = Ke^{\imath\phi} \quad , \quad \tilde{\mathcal{E}}_0 = \mathcal{E}_0 e^{\imath\delta_E} \quad , \quad \tilde{\mathcal{B}}_0 = \mathcal{B}_0 e^{\imath\delta_B} \ , \tag{15.92}$$

with $K, \mathcal{E}_0, \mathcal{B}_0 \in \mathbb{R}$, we finally find,

$$\mathcal{B}_0 e^{\imath\delta_B} = \frac{Ke^{\imath\phi}}{\omega}\mathcal{E}_0 e^{\imath\delta_E} \ , \tag{15.93}$$

that is,

$$\frac{\mathcal{B}_0}{\mathcal{E}_0} = \frac{K}{\omega} = \frac{\sqrt{k^2+\kappa^2}}{\omega} = \sqrt{\varepsilon\mu\sqrt{1+\left(\frac{\varsigma}{\varepsilon\omega}\right)^2}} \tag{15.94}$$

and

$$\begin{aligned}\vec{\mathcal{E}}(z,t) &= \mathcal{E}_0\hat{\mathbf{e}}_x e^{-\kappa z}\cos(kz-\omega t+\delta_E) \\ \vec{\mathcal{B}}(z,t) &= \mathcal{B}_0\hat{\mathbf{e}}_y e^{-\kappa z}\cos(kz-\omega t+\delta_E+\phi)\ ,\end{aligned} \tag{15.95}$$

as illustrated in Fig. 15.8. Such a wave is called *evanescent wave*. From Eqs. (15.94) and (15.88) we immediately deduce,

$$\begin{aligned} K &\overset{\varsigma\to 0}{\longrightarrow} \frac{\omega}{c_n} \quad \text{and} \quad \phi = \arctan\frac{\kappa}{k} \overset{\varsigma\to 0}{\longrightarrow} 0 \\ K &\overset{\varsigma\to\infty}{\longrightarrow} \infty \quad \text{and} \quad \phi \overset{\varsigma\to\infty}{\longrightarrow} \tfrac{\pi}{4}\ . \end{aligned} \tag{15.96}$$

Do the Exc. 15.2.7.1 and 15.2.7.2.

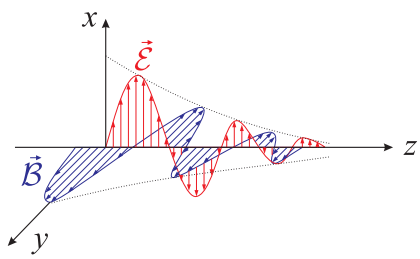

Figure 15.8: Attenuation of a wave by a conducting medium.

15.2.1.1 Reflection by a conductive surface

In the presence of free charges and currents the boundary conditions derived in (15.42) must be generalized,

$$\begin{array}{lrcl} \text{(i)} & \frac{1}{\mu_1}\vec{\mathcal{B}}_1^{\parallel} - \frac{1}{\mu_2}\vec{\mathcal{B}}_2^{\parallel} & = & \mathbf{k}_\mathrm{f}\times\hat{\mathbf{e}}_n \\ \text{(ii)} & \vec{\mathcal{E}}_1^{\parallel} - \vec{\mathcal{E}}_2^{\parallel} & = & 0 \\ \text{(iii)} & \varepsilon_1\vec{\mathcal{E}}_1^{\perp} - \varepsilon_2\vec{\mathcal{E}}_2^{\perp} & = & \sigma_\mathrm{f} \\ \text{(iv)} & \vec{\mathcal{B}}_1^{\perp} - \vec{\mathcal{B}}_1^{\perp} & = & 0 \end{array}\ , \tag{15.97}$$

where σ_f is the density of free surface charges, $\mathbf{k}_\mathrm{f}$ is the density of free surface currents, and $\hat{\mathbf{e}}_n$ the normal vector of the surface pointing into the direction of medium 1 (compare with Fig. 12.14).

We now assume that the interface at $z=0$ separates the dielectric medium 1 from the conductive medium 2. A monochromatic plane wave is partially reflected and

transmitted, as discussed above,

$$\begin{aligned}
\vec{\tilde{\mathcal{E}}}_{\rm i}(z,t) &= \tilde{\mathcal{E}}_{0\rm i}\hat{\mathbf{e}}_x e^{\imath(k_1 z-\omega t)} &,\quad \vec{\tilde{\mathcal{B}}}_{\rm i}(z,t) &= -\tfrac{1}{c_1}\tilde{\mathcal{E}}_{0\rm i}\hat{\mathbf{e}}_y e^{\imath(k_1 z-\omega t)} \\
\vec{\tilde{\mathcal{E}}}_{\rm r}(z,t) &= \tilde{\mathcal{E}}_{0\rm r}\hat{\mathbf{e}}_x e^{\imath(-k_1 z-\omega t)} &,\quad \vec{\tilde{\mathcal{B}}}_{\rm r}(z,t) &= \tfrac{1}{c_1}\tilde{\mathcal{E}}_{0\rm r}\hat{\mathbf{e}}_y e^{\imath(k_1 z-\omega t)} \quad , \\
\vec{\tilde{\mathcal{E}}}_{\rm t}(z,t) &= \tilde{\mathcal{E}}_{0\rm t}\hat{\mathbf{e}}_x e^{\imath(\tilde{k}_2 z-\omega t)} &,\quad \vec{\tilde{\mathcal{B}}}_{\rm t}(z,t) &= \tfrac{\tilde{k}_2}{\omega}\tilde{\mathcal{E}}_{0\rm t}\hat{\mathbf{e}}_y e^{\imath(\tilde{k}_2 z-\omega t)}
\end{aligned} \tag{15.98}$$

Obviously, the transmitted wave penetrating the conductive medium is attenuated.

The boundary conditions at $z=0$ become, for the considered case ($\vec{\mathcal{E}}^{\perp}=0=\vec{\mathcal{B}}^{\perp}$) and with $\mathbf{k}_{\rm f}=0$,

$$\begin{aligned}
&\text{(i)} & \tfrac{1}{\mu_1 c_1}(\mathcal{E}_{0\rm i}-\mathcal{E}_{0\rm r}) &= \tfrac{\tilde{k}_2}{\mu_2\omega}\mathcal{E}_{0\rm t} \\
&\text{(ii)} & \tilde{\mathcal{E}}_{0\rm i}+\tilde{\mathcal{E}}_{0\rm r} &= \tilde{\mathcal{E}}_{0\rm t} \\
&\text{(iii)} & 0 &= \sigma_{\rm f} \\
&\text{(iv)} & 0 &= 0\ .
\end{aligned} \quad , \tag{15.99}$$

Defining,

$$\tilde{\beta} \equiv \frac{\mu_1\tilde{k}_2}{\mu_2 k_1}\ , \tag{15.100}$$

we derive,

$$\frac{\tilde{\mathcal{E}}_{0\rm r}}{\tilde{\mathcal{E}}_{0\rm i}} = \frac{1-\tilde{\beta}}{1+\tilde{\beta}} \quad \text{and} \quad \frac{\tilde{\mathcal{E}}_{0\rm t}}{\tilde{\mathcal{E}}_{0\rm i}} = \frac{2}{1+\tilde{\beta}}\ . \tag{15.101}$$

The formulas are formally similar to (15.48), but they are complex. For a bad conductor ($\varsigma=0 \quad\rightarrow\quad \kappa=0$) we recover the equation (15.48). For a perfect conductor ($\varsigma=\infty \quad\rightarrow\quad \kappa=\infty \quad\rightarrow\quad \tilde{\beta}=\imath\infty$) we find $\tilde{\mathcal{E}}_{0\rm r}=-\tilde{\mathcal{E}}_{0\rm i}$ and $\tilde{\mathcal{E}}_{0\rm t}=0$. That is, the wave is fully reflected with a phase change of 180° [7].

15.2.2 Linear and quadratic dispersion

The refractive index may depend on the wavelength. Even the *refractive index of air* exhibits dispersion, as shown in Fig. 15.9 [8].

We consider a superposition of two waves,

$$\begin{aligned}
Y_1(x,t)+Y_2(x,t) &= a\cos(k_1x-\omega_1 t)+a\cos(k_2x-\omega_2 t) \\
&= 2a\cos\left[\tfrac{(k_1-k_2)x}{2}-\tfrac{(\omega_1-\omega_2)t}{2}\right]\cos\left[\tfrac{(k_1+k_2)x}{2}-\tfrac{(\omega_1+\omega_2)t}{2}\right]\ .
\end{aligned} \tag{15.102}$$

The resulting wave can be seen as a wave of frequency $\frac{1}{2}(\omega_1+\omega_2)t$ and wavelength $\frac{1}{2}(k_1+k_2)$ whose amplitude is modulated by an envelope of frequency $\frac{1}{2}(\omega_1-\omega_2)t$ and wavelength $\frac{1}{2}(k_1-k_2)x$.

[7] The 'skin depth' in silver (for optical frequencies) is in the order of 10 nm. For this reason, thin layers of good conductors already represent good mirrors.

[8] The refractive index of air can be calculated by the formula $n=1+(n_s-1)\frac{0.00185097\ P}{1+0.003661\ T}$ with $n_s=\sqrt{1+\frac{4.334446\cdot 10^{-4}\lambda^2}{\lambda^2-3.470339\cdot 10^{-3}}+\frac{1.118728\cdot 10^{-4}\lambda^2}{\lambda^2-1.394001\cdot 10^{-2}}}$, where T is the temperature in Celsius and P the atmospheric pressure in mbar.

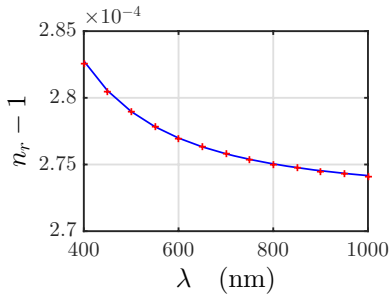

Figure 15.9: (code) Refractive index of air. The crosses were calculated by the *Cauchy* formula (15.147), with $A = 0.0002725$ and $B = 0.0059$.

In the absence of dispersion the *phase velocities* of the two waves and the propagation velocity of the envelope, called *group velocity*, are equal,

$$c = \frac{\omega_1}{k_1} = \frac{\omega_2}{k_2} = \frac{\omega_1 - \omega_2}{k_1 - k_2} = \frac{\Delta\omega}{\Delta k} = v_g \ . \tag{15.103}$$

But the phase velocities of the two harmonic waves may be different, $c = c(k)$, such that the frequency depends on the wavelength, $\omega = \omega(k)$. In this case, the group velocity also varies with the wavelength,

$$v_g = \frac{d\omega}{dk} = \frac{d}{dk}(kc) = c + k\frac{dc}{dk} \ . \tag{15.104}$$

Often, this variation is not very strong, such that it is possible to expand around an average value ω_0 of the spectral region of interest,

$$\boxed{\begin{aligned} \omega(k) &= \omega_0 + \left.\frac{d\omega}{dk}\right|_{k_0} \cdot (k - k_0) + \frac{1}{2}\left.\frac{d^2\omega}{dk^2}\right|_{k_0} \cdot (k - k_0)^2 \\ &\equiv \omega_0 + v_g(k - k_0) + \beta(k - k_0)^2 \end{aligned}} \ . \tag{15.105}$$

Generally, $v_g < c$, in which situation we speak of *normal dispersion*. But there are situations of *anomalous dispersion*, where $v_g > c$, e.g. close to resonances or when the wave under study is a *matter wave* characterized by quadratic dispersion [9], $\hbar\omega = (\hbar k)^2/2m$.

Example 104 (*Rectangular wave packet with linear dispersion*): As an example we determine the shape of the wavepacket for a rectangular amplitude distribution, $A(k) = A_0\chi_{[k_0-\Delta k/2, k_0+\Delta k/2]}$, subject to linear dispersion (expan-

[9] Since $c = \frac{\omega}{c} = \frac{\hbar k}{2m} < \frac{\hbar k}{m} = v_g$.

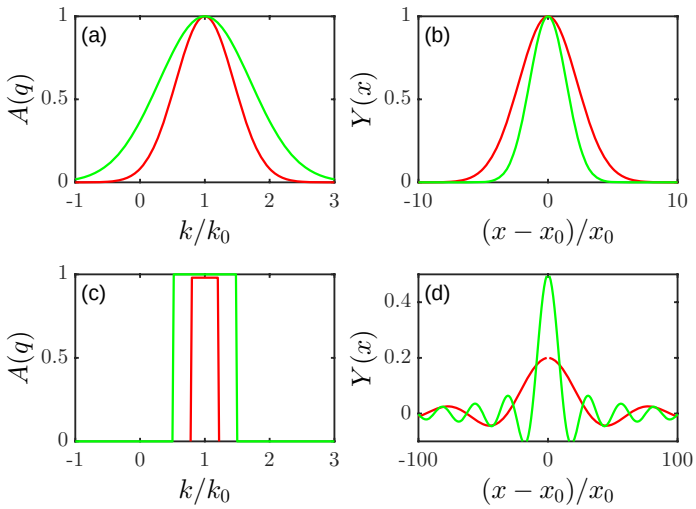

Figure 15.10: (code) Gaussian amplitude distribution (a,b) and rectangular distribution (c,d) in momentum space (a,c) and in position space (b,d).

sion up to the linear term in Eq. (15.105)). Via the Fourier theorem,

$$\begin{aligned}
Y(x,t) &= \int_{-\infty}^{\infty} A(k) e^{\imath(kx-\omega t)} dk = A_0 \int_{k_0-\Delta k/2}^{k_0+\Delta k/2} e^{\imath(kx-\omega_0 t + v_g(k-k_0)t)} dk \\
&= A_0 e^{\imath(k_0 x - \omega_0 t)} \int_{k_0-\Delta k/2}^{k_0+\Delta k/2} e^{\imath(k-k_0)(x-v_g t)} dk \\
&= A_0 e^{\imath(k_0 x - \omega_0 t)} \int_{-\Delta k/2}^{\Delta k/2} e^{\imath k(\cancelto{u}{x - v_g t})} dk \\
&= A_0 \frac{e^{\imath u \Delta k/2} - e^{-\imath u \Delta k/2}}{\imath u} e^{\imath(k_0 x - \omega_0 t)} = 2A_0 \frac{\sin \frac{u\Delta k}{2}}{u} e^{\imath(k_0 x - \omega_0 t)} \equiv A(x,t) e^{\imath(k_0 x - \omega_0 t)} \ .
\end{aligned}$$

The envelope $A(x,t)$ has the shape of a 'sinc' function, such that the wave intensity is,

$$|Y(x,t)|^2 = A_0^2 \Delta k^2 \ \mathrm{sinc}^2 \left[\tfrac{\Delta k}{2}(x - v_g t) \right] \ .$$

Obviously, the *wave packet* is at any time t localized in space, as illustrated by the lower graphs of Figs. 15.10. It *moves with group velocity*, v_g, but it does not spread.

The last example showed, that linear dispersion does not lead to spreading (or diffusion) of a wavepacket, as opposed to quadratic dispersion, which we will show in the following example.

Example 105 (*Dispersion of a Gaussian wavepacket subject to quadratic dispersion*): Quadratic dispersion causes spreading of wavepackets. We show this at the example of the Gaussian wavepacket, $A(k) = A_0 e^{-\alpha(k-k_0)^2}$, expanding the dispersion relation (15.105) up to the quadratic term. Via the Fourier

theorem,

$$
\begin{aligned}
Y(x,t) &= \int_{-\infty}^{\infty} A(k) e^{\imath(kx-\omega t)} dk = A_0 e^{\imath(k_0 x-\omega_0 t)} \int_{-\infty}^{\infty} e^{\imath(k-k_0)(x-v_g t)-(\alpha+\imath\beta t)(k-k_0)^2} dk \\
&= A_0 e^{\imath(k_0 x-\omega_0 t)} \int_{-\infty}^{\infty} e^{\imath k(\cancelto{u}{x-v_g t})-(\cancelto{v}{\alpha+\imath\beta t})k^2} dk \\
&\equiv A_0 e^{\imath(k_0 x-\omega_0 t)} \int_{-\infty}^{\infty} e^{\imath ku-vk^2} dk = A_0 \sqrt{\tfrac{\pi}{v}} e^{\imath(k_0 x-\omega_0 t)} e^{-u^2/4v} \ .
\end{aligned}
$$

The absolute square of the solution describes the spatial energy distribution of the packet,

$$
|Y(x,t)|^2 = A_0^2 \frac{\pi}{\sqrt{vv^*}} e^{-u^2/4v-u^2/4v^*} = A_0^2 \frac{\pi}{x_0\sqrt{\alpha/2}} e^{-(x-v_g t)^2/x_0^2} \ ,
$$

with $x_0 \equiv \sqrt{2\alpha}\sqrt{1+\frac{\beta^2}{\alpha^2}t^2}$. Obviously, for long times the pulse spreads with constant velocity. Since the constant α gives the initial width of the pulse, we realize that an initially compressed pulse spreads faster. Therefore, the angular coefficient of the dispersion relation determines the group velocity, while the curvature determines the spreading velocity. See upper graphs of Figs. 15.10.

Resolve the Excs. 15.2.7.3 to 15.2.7.5.

15.2.3 Microscopic dispersion and the Lorentz model

Obviously, the structure that we assume for the matter also influences its reaction to electromagnetic waves, which interact differently with the charged components of the matter. The planetary model proposed by *E. Rutherford* considers matter to be made of atoms, which in turn are composed of *bound electrons* orbiting small positively charged nuclei. On the other side, metals have free electrons. The inertia of the charged particles (free or bound electrons, ions) being accelerated by incident electromagnetic waves is the reason for the dispersion phenomena that we will treat in the following sections.

Thomson scattering is the elastic scattering of light (photons) by free or quasi-free electrically charged particles (that is, weakly bound as compared to photon energies). A charged particle is prompted by the field of an electromagnetic wave to perform harmonic oscillations within the plane spanned by the electric and the magnetic field vectors. As the oscillation is an accelerated motion, the particle simultaneously re-emits energy in the form of an electromagnetic wave with the same frequency (dipole radiation). Thomson scattering does not consider photonic recoil, that is, there is no transfer of momentum from the photon to the electron, which is only a good assumption when the energy of the incident photons is small enough, that is, $\hbar\omega \ll m_e c^2$, so that the wavelength of the electromagnetic radiation is much longer than the Compton wavelength $\lambda \gg \lambda_{\mathrm{C}} = h/mc \simeq 2.4\,\mathrm{pm}$ of the electron (which is the case for optical wavelengths). For higher energies, it is necessary to take the recoil of the electron into consideration (as done in the case of Compton scattering) [10].

[10] Thomson scattering can be considered the limiting case of *Compton scattering* for small photon energies. The Thomson model holds for free electrons in a metal, whose resonant frequency tends, due to the absence of restoring forces, to zero. Scattering by bound electrons is called *Rayleigh*

15.2.3.1 Lorentz model

In classical physics the scattering of light by charges is described by the *Lorentz model* [388]. Assuming a harmonic electric field, $\vec{\mathcal{E}}(t) = \vec{\mathcal{E}}_0 e^{-\imath\omega t}$, we derive a force acting on an electron harmonically bound to a potential [11],

$$\mathbf{F} = -e\vec{\mathcal{E}}(t) \tag{15.106}$$

with e the elementary charge. The equation of motion is that of a damped harmonic oscillator:

$$m_e\ddot{\mathbf{r}} + m_e\gamma_\omega\dot{\mathbf{r}} + m_e\omega_0^2\mathbf{r} = -e\vec{\mathcal{E}}(t) \tag{15.107}$$

with the mass m_e of the electron, the damping γ_ω (by collisions, radiative losses, etc.), and a resonance frequency ω_0. We note, that the damping may depend on the excitation frequency.

After some time, when the transient processes are damped out, the electrons oscillate with the angular frequency ω of the external field. For this inhomogeneous solution we make the ansatz:

$$\mathbf{r}(t) = \mathbf{r}_e e^{-\imath\omega t} \tag{15.108}$$

with the constant complex amplitude $\mathbf{r}_e$. Inserting this into the equation of motion, we obtain for the atomic dipole moment induced by the electromagnetic field [12]:

$$\boxed{\mathbf{d}(t) \equiv -e\mathbf{r}(t) = \frac{e^2/m_e}{\omega_0^2 - \omega^2 - \imath\gamma_\omega\omega}\vec{\mathcal{E}}(t) \equiv \alpha_{\text{pol}}(\omega)\vec{\mathcal{E}}(t)} \ , \tag{15.109}$$

where we used the *electric polarizability* α_{pol} introduced in (11.6) and relating the amplitudes of the field and the dipole moment. The imaginary term in the denominator means that the oscillation of $\mathbf{d}$ is out of phase with $\vec{\mathcal{E}}$ being delayed by an angle

$$\varphi = \arctan\frac{\gamma_\omega\omega}{\omega_0^2 - \omega^2} \ , \tag{15.110}$$

which is very small when $\omega \ll \omega_0$ and approaches π when $\omega \gg \omega_0$ [858]. This is illustrated in Fig. 15.13(left).

The temporal average of the dipole moment is,

$$\sqrt{\overline{d^2}} = \alpha_{\text{pol}}\mathcal{E}_0\sqrt{\tfrac{1}{T}\int_0^T \cos^2\omega t dt} = \alpha_{\text{pol}}\mathcal{E}_0\sqrt{\tfrac{1}{2}} \equiv d_0\sqrt{\tfrac{1}{2}} \ . \tag{15.111}$$

To calculate the emitted radiation we must borrow a result from future lessons: From the electromagnetic fields (16.40) of an oscillating dipole we will derive the expression for the Poynting vector (16.44),

$$\langle\vec{\mathcal{S}}\rangle = \tfrac{1}{\mu_0}\langle\vec{\mathcal{E}}\times\vec{\mathcal{B}}\rangle = \frac{\mu_0 d_0^2\omega^4}{16\pi^2 c}\frac{\sin^2\theta}{r^2}\hat{\mathbf{e}}_r = \frac{d_0^2\omega^4}{32\pi^2\varepsilon_0 c^3}\frac{\sin^2\theta}{r^2}\hat{\mathbf{e}}_r \ . \tag{15.112}$$

scattering.

In practice, Thomson scattering is used to determine the electron density through the intensity and temperature of the spectral distribution of scattered radiation assuming a Maxwell distribution for the electron velocities.

[11] Let us imagine for the sake of illustration that the displacement of the electron from its equilibrium position generates (to first order) an elastic restoring force with resonances at certain frequencies.

[12] See Sec. 4.3.

Obviously, the radiation is not isotropic, but concentrated in directions perpendicular to the dipole moment. In fact, the spherical harmonic function ($\sin\theta$), responsible for this toroidal angular distribution, is precisely the p-wave [13]. The total power radiated by the dipole can be derived from the Poynting vector,

$$\boxed{P = \int_0^{2\pi}\int_0^{\pi} \langle\vec{\mathcal{S}}\rangle\cdot\hat{\mathbf{e}}_r r^2 \sin\theta d\theta d\phi = \frac{\mu_0 d_0^2\omega^4}{32\pi^2 c}\, 2\pi \int_0^{\pi} \sin^3\theta d\theta = \frac{\mu_0\omega^4 d_0^2}{12\pi c}} \ , \tag{15.113}$$

knowing $\int_0^{\pi}\sin^3 x dx = \frac{4}{3}$. This result is known as the *Larmor formula*.

15.2.3.2 Thompson and Rayleigh scattering

We now imagine that the dipole is excited by an incident wave of intensity,

$$I = \tfrac{1}{2}\varepsilon_0 c\vec{\mathcal{E}}_0^2 \ , \tag{15.114}$$

and scatters the radiation to a solid angle $d\Omega$, such that the angular distribution of scattered power is,

$$\frac{dP}{d\Omega} = |\langle\vec{\mathcal{S}}\rangle| r^2 \ . \tag{15.115}$$

We can now calculate the differential *scattering cross section* inserting the polarizability (15.109),

$$\begin{aligned}\frac{d\sigma}{d\Omega} &= \frac{dP/d\Omega}{I} = \frac{d_0^2\omega^4\sin^2\theta}{32\pi^2\varepsilon_0 c^3 r^2} r^2 \frac{1}{\frac{1}{2}\varepsilon_0 c\mathcal{E}_0^2} = \frac{|\alpha_{\rm pol}|^2\mathcal{E}_0^2\omega^4\sin^2\theta}{16\pi^2\varepsilon_0^2 c^4\mathcal{E}_0^2} \\ &= \left|\frac{e^2/m_e}{\omega_0^2-\omega^2-\imath\gamma_\omega\omega}\right|^2 \frac{\omega^4\sin^2\theta}{16\pi^2\varepsilon_0^2 c^4} = \frac{r_e^2\omega^4\sin^2\theta}{(\omega_0^2-\omega^2)^2+\gamma_\omega^2\omega^2} \ ,\end{aligned} \tag{15.116}$$

where we defined the abbreviation,

$$r_e \equiv \frac{1}{4\pi\varepsilon_0}\frac{e^2}{m_e c^2} \approx 2.8\cdot 10^{-15}\,\mathrm{m} \tag{15.117}$$

being the *classical electron radius*. The total cross section,

$$\boxed{\sigma(\omega) = \int_{\mathbb{R}^2}\frac{d\sigma}{d\Omega}d\Omega = \frac{8\pi}{3}r_e^2\frac{\omega^4}{(\omega_0^2-\omega^2)^2+\gamma_\omega^2\omega^2}} \ , \tag{15.118}$$

describes a resonance of Lorentzian profile.

We have the following limiting cases:

- $\omega \gg \omega_0$ Thomson scattering ,
- $\omega = \omega_0$ resonance fluorescence ,
- $\omega \ll \omega_0$ Rayleigh scattering .

[13] $Y_1^{\pm 1}(\theta,\phi) = \mp\frac{1}{2}\sqrt{\frac{3}{2\pi}}e^{\pm\imath\phi}\sin\theta$.

A *Thomson cross section* follows in the limit of high energies in comparison with the eigenfrequency, $\omega \gg \omega_0 \gg \gamma_\omega$ from the Lorentz model [14],

$$\sigma_{\text{Thom}} = \frac{8\pi}{3} r_e^2 \approx 6.65 \cdot 10^{-29}\,\text{m}^2 \quad . \tag{15.119}$$

Example 106 (*Rayleigh scattering and the blue sky*): We consider the scattering cross section (15.118). For $\omega \to \omega_0$ we obtain a resonant amplification of the cross session of ω^2/γ_ω^2. The resonances of the particles in the atmosphere are in the blue region of the electromagnetic spectrum. Therefore, the visible frequencies are $\omega \ll \omega_0$, and the cross session is $\propto \omega^4$. For this reason, the blue region dominates. The sky just does not look violet, because the eyes are not sensitive for these colors.
The dependence on the observation angle $\propto \sin^2\theta$, where $\theta = \angle(\hat{\epsilon}, \mathbf{k}_s)$ is only valid for polarized light. For non-polarized light, which can be understood as a superposition of two waves with orthogonal polarization, the dependence is $\propto 1 + \cos^2\vartheta$, where $\vartheta = \angle(\mathbf{k}, \mathbf{k}_s)$.

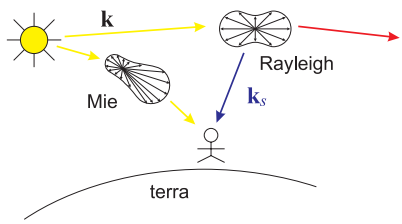

Figure 15.11: Dependence of the Rayleigh and Mie scattering on the observation angle.

Rayleigh scattering dominates for molecules and small scattering objects, $< \lambda/10$. *Mie scattering* is more important for $> \lambda/10$, e.g. water drops. This type of scattering is governed by boundary conditions defined by the surfaces of objects. The angular distributions are strongly oriented in forward direction, particularly when the objects are large. Therefore, this type of scattering only dominates at small angles with respect to the sun, where we observe a bleaching of the blue color of the sky).

15.2.3.3 Atomic polarizability

In atoms, the damping rate γ_ω is due to the radiative energy loss (given by Larmor's formula). It is calculated as the ratio between the classically radiated power and the kinetic energy of the electron orbiting the nucleus,

$$\gamma_\omega = \frac{P}{E_{\text{kin}}} = \frac{\mu_0 e^2 a^2/12\pi c}{m_e \omega^2 r^2/2} \quad , \tag{15.120}$$

[14] A better approximation for small energies is obtained by expansion of the Klein-Nishina formula,

$$\sigma(\nu) = \sigma_{\text{Thom}} \left(1 - 2\alpha + \tfrac{56}{5}\alpha^2 + \dots\right)$$

with the factor $\alpha = \frac{h\nu}{m_e c^2}$.

where $a = \omega^2 r$ is the acceleration of the electron. We get [388] [15],

$$\boxed{\gamma_\omega = \frac{e^2\omega^2}{6\pi\varepsilon_0 m_e c^3}} \,. \tag{15.121}$$

Defining $\Gamma \equiv \gamma_{\omega_0}$ and inserting into equation (15.109), we can calculate the polarizability within the Lorentz model,

$$\alpha_{\text{pol}} = 6\pi\varepsilon_0 c^3 \frac{\Gamma/\omega_0^2}{\omega_0^2 - \omega^2 - \imath(\omega^3/\omega_0^2)\Gamma} \,. \tag{15.122}$$

Close to narrow resonances we can approximate $(\omega_0 + \omega) \to 2\omega_0$ and $(\omega^3/\omega_0^2)\Gamma \to \omega_0\Gamma$ in the denominator of the formula (15.122). Hence, the *polarizability* simplifies to,

$$\boxed{\frac{\alpha_{\text{pol}}}{\varepsilon_0} \simeq \frac{6\pi}{k_0^3}\frac{-1}{\imath + 2\Delta/\Gamma}} \,, \tag{15.123}$$

defining the detuning $\Delta \equiv \omega - \omega_0$. Resolve the Excs. 15.2.7.6 to 15.2.7.9.

15.2.4 Classical theory of radiative forces

The Lorentz model permits a classical calculation of the forces exerted by a radiation wave on an electric dipole moment oscillating with the excitation frequency ω [473, 388] [16]. With the dipole moment given by equation (15.109) and the polarizability given by equation (15.122) we can write the dipolar interaction potential as the time-average,

$$\boxed{U_{\text{dip}}(\mathbf{r}) = -\frac{1}{2}\overline{\mathbf{d}\cdot\vec{\mathcal{E}}} = -\frac{1}{2\varepsilon_0 c} I(\mathbf{r})\mathfrak{Re}\,\alpha_{\text{pol}}} \,, \tag{15.124}$$

with the field intensity $I = 2\varepsilon_0 c|\vec{\mathcal{E}}|^2$. The factor $\frac{1}{2}$ takes into account the fact, that the dipole moment is induced rather than permanent, as shown in equation (11.10).

Therefore, the potential energy of the atom in the field is proportional to the intensity $I(\mathbf{r})$ and the real part of the polarizability, which describes the *in-phase* component of the dipolar oscillation, being responsible for the dispersive properties of the interaction. The dipole force comes from the gradient of the interaction potential,

$$\mathbf{F}_{\text{dip}}(\mathbf{r}) = -\nabla U_{\text{dip}}(\mathbf{r}) = \frac{1}{\varepsilon_0 c}\nabla I(\mathbf{r})\mathfrak{Re}\,\alpha_{\text{pol}} \,. \tag{15.125}$$

It is a conservative force proportional to the intensity gradient of the light field. As illustrated in Fig. 15.12, below resonance ($\omega < \omega_0$) the induced electric dipole will be

[15] In quantum mechanics we learn, that the rate for spontaneous emission is, $\Gamma = d^2k^3/3\pi\varepsilon_0\hbar$. This rate coincides with Eq. (15.121) when we assume an amplitude for the electron's oscillation equal to the size of the ground state of a harmonic oscillator,

$$d_0 = er = e\sqrt{\frac{\hbar}{m_e\omega}} = \overline{d^2}\sqrt{2} \,.$$

[16] In principle, we could also use Maxwell's stress tensor.

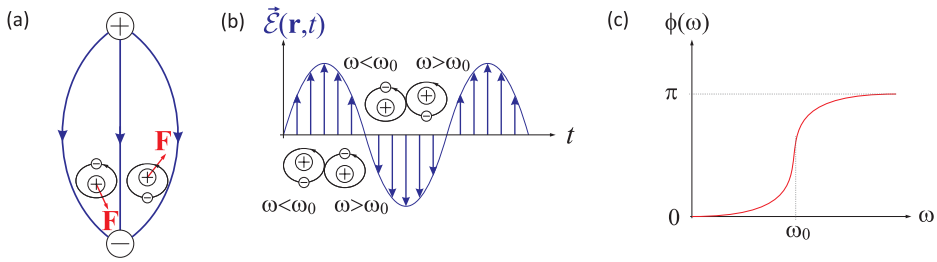

Figure 15.12: (a) Lorentz force on electric dipoles in an electrostatic field gradient. (b) Orientation of induced dipoles in an electromagnetic field. (c) Phase-shift of a harmonic oscillator with a resonance frequency at ω_0 driven at frequency ω.

oriented parallel to the electric field such as to minimize its energy by seeking strong field regions. Above resonance ($\omega > \omega_0$) the orientation is reversed so that the dipole can minimize its energy by seeking low field regions.

The power of the field absorbed by the dipolar oscillator (and reemitted as dipolar radiation) is given by,

$$P_{\rm abs} = \overline{\dot{\mathbf{d}} \cdot \vec{\mathcal{E}}} = 2\omega \mathfrak{Im}\, \tilde{\mathbf{d}} \cdot \vec{\mathcal{E}} = -\frac{\omega}{\varepsilon_0 c} I(\mathbf{r}) \mathfrak{Im}\, \alpha_{\rm pol} \ . \tag{15.126}$$

The absorption results from the imaginary part of the polarizability, which describes the *out of phase* component of the dipolar oscillation. Considering the light as a stream of photons with energy $\hbar\omega$, the absorptive part can be interpreted in terms of photon absorption processes followed by spontaneous reemission. The corresponding scattering rate is,

$$\boxed{\Gamma_{\rm sct}(\mathbf{r}) = \frac{P_{\rm abs}}{\hbar\omega} = \frac{1}{\hbar\varepsilon_0 c} I(\mathbf{r}) \mathfrak{Im}\, \alpha_{\rm pol}} \ . \tag{15.127}$$

We emphasize that these expressions are valid for any polarizable neutral particle exposed to an oscillating electric field, provided that saturation effects can be neglected. That it, the expressions hold for atoms and molecules excited near or far from resonances, as well as for a classical antenna [17].

Inserting the polarizability (15.122) in the expressions (15.124) for the dipolar potential and (15.127) for the (Rayleigh) scattering rate we obtain, for the case of large detunings in comparison to the transition linewidth, $\Delta \gg \Gamma$, and negligible saturation,

$$\begin{aligned} U_{\rm dip}(\mathbf{r}) &= -\frac{1}{2\varepsilon_0 c} I(r) \mathfrak{Re}\, \frac{6\pi\varepsilon_0 c^3 \Gamma/\omega_0^2}{\omega_0^2 - \omega^2 - \imath(\omega^3/\omega_0^2)\Gamma} \\ &\simeq -\frac{3\pi c^2}{\omega_0^2} I(\mathbf{r}) \frac{\Gamma}{\omega_0^2 - \omega^2} = -\frac{3\pi c^2}{2\omega_0^3} I(\mathbf{r}) \left(\frac{\Gamma}{\omega_0 - \omega} + \frac{\Gamma}{\omega_0 + \omega} \right) \ , \end{aligned} \tag{15.128}$$

[17] An important difference between quantum and classical oscillators is the possible occurrence of saturation. When the intensity of the driving field is too high, the excited state becomes strongly populated and the derived results are no longer valid. However, for large detunings we are far below the saturation, such that the expressions can be used even for quantum oscillators.

and

$$\hbar\Gamma_{\rm sct}(\mathbf{r}) = \frac{1}{\varepsilon_0 c} I(\mathbf{r}) \mathfrak{Im} \frac{6\pi\varepsilon_0 c^3 \Gamma/\omega_0^2}{\omega_0^2 - \omega^2 - \imath(\omega^3/\omega_0^2)\Gamma} \tag{15.129}$$
$$\simeq \frac{-6\pi c^2 \Gamma^2 \omega^3}{\omega_0^4} I(\mathbf{r}) \frac{1}{(\omega_0^2 - \omega^2)^2} = \frac{-3\pi c^2}{2\omega_0^3} \left(\frac{\omega}{\omega_0}\right)^3 I(\mathbf{r}) \left(\frac{\Gamma}{\omega_0 - \omega} + \frac{\Gamma}{\omega_0 + \omega}\right)^2 .$$

These expressions exhibit two resonant contributions: In addition to the usual resonance at $\omega = \omega_0$, there is a so-called *counter-rotating* term resonant at $\omega = -\omega_0$. In most applications the radiation source is tuned relatively close to the resonance at ω_0, such that the counter-rotating term can be neglected, which simplifies the expressions to,

$$\boxed{U_{\rm dip}(\mathbf{r}) = \frac{3\pi c^2}{2\omega_0^3} \frac{\Gamma}{\Delta} I(\mathbf{r}) \qquad \text{and} \qquad \hbar\Gamma_{\rm sct}(\mathbf{r}) = \frac{3\pi c^2}{2\omega_0^3} \frac{\Gamma^2}{\Delta^2} I(\mathbf{r})} . \tag{15.130}$$

The obvious relationship between the scattering rate and the dipolar potential,

$$\hbar\Gamma_{\rm sct} = \frac{\Gamma}{\Delta} U_{\rm dip} , \tag{15.131}$$

is a direct consequence of the profound relationship between the absorptive and dispersive responses of the oscillator. We furthermore emphasize the following relevant points:

- The sign of the detuning: Below an atomic resonance ('red detuning', $\Delta < 0$) the dipolar potential is negative and the interaction attracts the atom to regions of high intensity, e.g. toward the optical axis of a Gaussian light beam or towards the anti-nodes of a standing light wave. Above the atomic resonance ('blue detuning', $\Delta > 0$) is the opposite; the atom is repelled out of high-intensity regions.

- Intensity and detuning-dependence: The dipolar potential is $\propto I/\Delta$, while the scattering rate is $\propto I/\Delta^2$. Therefore, dipolar optical traps are generally realized at large detunings and high intensities in order to reduce the scattering rate while maintaining the potential depth.

15.2.4.1 Microscopic model of the susceptibility, anomalous dispersion

Until now we considered a single valence electron bound to a nucleus. If there are several electrons, the relationship (15.109) must be generalized. Electrons located at different orbitals of a molecule feel different spring constants f_j, natural frequencies ω_j, and damping coefficients γ_j. In the presence of several electrons per molecule and N molecules per volume unit, the polarization $\vec{\mathcal{P}}$ is given by the real part of (11.12),

$$\vec{\tilde{\mathcal{P}}} = \frac{Nq^2}{m} \left(\sum_j \frac{f_j}{\omega_j^2 - \omega^2 - \imath\gamma_j\omega} \right) \vec{\tilde{\mathcal{E}}} . \tag{15.132}$$

In equation (11.20) we defined the electric susceptibility χ_ε as proportionality constant between the electric field and the polarization. In the case considered here, $\vec{\mathcal{P}}$ *is not*

proportional to $\vec{\mathcal{E}}$ (strictly speaking, it is not a linear medium), because there is a phase shift between $\vec{\mathcal{P}}$ and $\vec{\mathcal{E}}$. But at least the *complex* polarization $\tilde{\vec{\mathcal{P}}}$ *is proportional to the complex field* $\tilde{\vec{\mathcal{E}}}$, which suggests the introduction of a *complex susceptibility* $\tilde{\chi}_\varepsilon$,

$$\tilde{\vec{\mathcal{P}}} = \varepsilon_0 \tilde{\chi}_\varepsilon \tilde{\vec{\mathcal{E}}} \ . \tag{15.133}$$

All manipulations made so far remain valid, if we assume that the physical polarization is the real part of $\tilde{\vec{\mathcal{P}}}$, in the same way as the physical field is the real part of $\tilde{\vec{\mathcal{E}}}$. In particular, the proportionality between $\tilde{\vec{\mathcal{D}}}$ and $\tilde{\vec{\mathcal{E}}}$ is the complex permittivity $\tilde{\varepsilon} = \varepsilon_0(1+\tilde{\chi}_\varepsilon)$, and the complex dielectric constant (in this model) is,

$$\tilde{\epsilon} \equiv \frac{\tilde{\varepsilon}}{\varepsilon_0} = 1 + \frac{Nq^2}{m\varepsilon_0} \sum_j \frac{f_j}{\omega_j^2 - \omega^2 - \imath\gamma_j\omega} \ . \tag{15.134}$$

Generally, the imaginary part is despicable; however, when ω is very close to one of the resonant frequencies ω_j, it will play a crucial role, as we shall see later.

In a dispersive medium the wave equation for a given frequency is,

$$\nabla^2 \tilde{\vec{\mathcal{E}}} = \tilde{\varepsilon}\mu_0 \frac{\partial^2 \tilde{\vec{\mathcal{E}}}}{\partial t^2} \ . \tag{15.135}$$

It admits plane wave solutions as before,

$$\tilde{\vec{\mathcal{E}}}(z,t) = \tilde{\vec{\mathcal{E}}}_0 e^{\imath(\tilde{k}z - \omega t)} \ , \tag{15.136}$$

with the complex wavenumber,

$$\tilde{k} = \omega\sqrt{\tilde{\varepsilon}\mu_0} = \tfrac{\omega}{c}\sqrt{\tilde{\epsilon}} \ . \tag{15.137}$$

Writing $\tilde{k}$ in terms of its real and imaginary parts, $\tilde{k} = k + \imath\kappa$, the plane wave becomes,

$$\tilde{\vec{\mathcal{E}}}(z,t) = \tilde{\vec{\mathcal{E}}}_0 e^{-\kappa z} e^{\imath(kz - \omega t)} \ . \tag{15.138}$$

Obviously, the wave is attenuated (this is not surprising, since the damping absorbs energy). Since the intensity is proportional to $\vec{\mathcal{E}}^2$ (and consequently to $e^{-2\kappa z}$), the quantity,

$$\alpha \equiv 2\kappa \tag{15.139}$$

is called *absorption coefficient*. The relationship,

$$I \propto e^{-\alpha z} \tag{15.140}$$

is called the *Lambert-Beer law*. However, the velocity of the wave is ω/k, and the *refraction index* is,

$$n = \frac{ck}{\omega} \ . \tag{15.141}$$

In the present case k and κ have nothing to do with conductivity, as in the case of Eq. (15.88); but they are determined by the parameters of our damped harmonic

oscillator. For gases, the second term in (15.134) is small, and we can approximate the square root (15.137) by the first term of the binomial expansion $\sqrt{1+\tilde{\chi}_\varepsilon} \simeq 1 + \frac{1}{2}\tilde{\chi}_\varepsilon$. Hence,

$$\tilde{k} = \frac{\omega}{c}\sqrt{\tilde{\epsilon}} \simeq \frac{\omega}{c}\left(1 + \frac{\tilde{\chi}_\varepsilon}{2}\right) = \frac{\omega}{c}\left(1 + \frac{Nq^2}{2m\varepsilon_0}\sum_j \frac{f_j}{\omega_j^2 - \omega^2 - \imath\gamma_j\omega}\right) . \tag{15.142}$$

therefore,

$$\boxed{\begin{aligned} n &= \mathfrak{Re}\sqrt{\epsilon} &\simeq\ & 1 + \frac{Nq^2}{2m\varepsilon_0}\sum_j \frac{f_j(\omega_j^2 - \omega^2)}{(\omega_j^2 - \omega^2)^2 + \gamma_j^2\omega^2} \\ \alpha &= \frac{2\omega}{c}\mathfrak{Im}\sqrt{\epsilon} &\simeq\ & \frac{Nq^2\omega^2}{m\varepsilon_0 c}\sum_j \frac{f_j\gamma_j}{(\omega_j^2 - \omega^2)^2 + \gamma_j^2\omega^2} \end{aligned}} . \tag{15.143}$$

In Fig. 15.13 we plot the refractive index and the absorption coefficient in the neighborhood of one of the resonances $\omega_0 = \omega_j$. In most cases the refractive index gradually increases with frequency, which is consistent with our experience in optics (Fig. 15.9). However, near a resonance the refraction index drops abruptly. Being atypical, this behavior is called *anomalous dispersion*. We observe that the region of anomalous dispersion ($\omega_1 < \omega < \omega_2$ in the figure) coincides with the region of maximum absorption. In fact, the material can be almost opaque in this spectral region. The reason is, we now excite the electrons on their 'preferred' frequency; the amplitude of their oscillation is relatively large, and therefore much energy is dissipated by the damping mechanism.

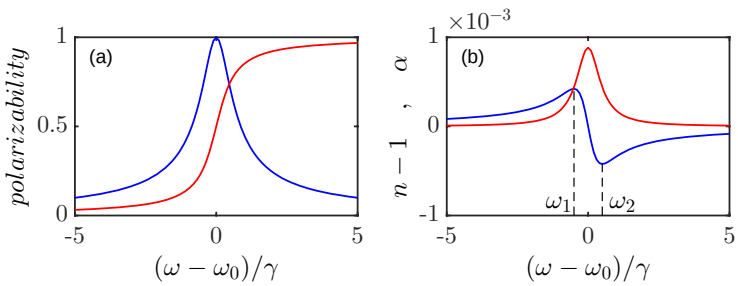

Figure 15.13: (code) (a) Profile of the polarizability $|\alpha_{\rm pol}|$ (blue curve) and of the phase shift $\arctan\frac{\mathfrak{Im}\,\alpha_{\rm pol}}{\pi\mathfrak{Re}\,\alpha_{\rm pol}}$ (red curve). (b) Refractive index (blue curve) and the absorption (red curve). In the spectral region between ω_1 and ω_2 we have anomalous dispersion.

The refractive index n plotted in Fig. 15.13 may be below 1 above the resonance, suggesting that the *velocity of the wave exceeds c*. But we must remember that energy propagates at the group velocity, which is always below c. The graph does not include the contributions of other terms in the sum, because they are negligible when the resonances are narrow or distant from each other. Out of the resonances, the damping can be ignored, and the formula for the refractive index simplifies:

$$n = 1 + \frac{Nq^2}{2m\varepsilon_0}\sum_j \frac{f_j}{\omega_j^2 - \omega^2} . \tag{15.144}$$

For most substances the natural frequencies ω_j are distributed across the spectrum in a chaotic way. In transparent materials, the resonances are in the ultraviolet regime, such that the visible frequencies ω are far below the resonances, $\omega \ll \omega_j$. In this case,

$$\frac{1}{\omega_j^2 - \omega^2} \simeq \frac{1}{\omega_j^2}\left(1 + \frac{\omega^2}{\omega_j^2}\right) . \tag{15.145}$$

and (15.144) adopts the form,

$$n = 1 + \frac{Nq^2}{2m\varepsilon_0}\sum_j \frac{f_j}{\omega_j^2} + \omega^2 \frac{Nq^2}{2m\varepsilon_0}\sum_j \frac{f_j}{\omega_j^4} . \tag{15.146}$$

Or, in terms of vacuum wavelengths ($\lambda = 2\pi c/\omega$):

$$\boxed{n = 1 + A\left(1 + \frac{B}{\lambda^2}\right)} . \tag{15.147}$$

This is the *Cauchy formula*; the constant A is called the *refraction coefficient* and B is called *dispersion coefficient*. The Cauchy equation applies reasonably well to most gases in the optical regime. Fig. 15.9 shows the example of the refractive index of air.

The Lorentz model certainly does not account for all dispersion phenomena in non-conductive media. But at least, it indicates how the damped harmonic motion of electrons can generate a dispersive refractive index, and it also explains why n is usually a slowly increasing function of ω with occasional 'anomalous' regions.

Example 107 (*Energy density and Poynting vector in a dielectric medium*): The energy density in vacuum, $\bar{u} = \frac{\varepsilon_0}{4}|\vec{\mathcal{E}}|^2 + \frac{1}{4\mu_0}|\vec{\mathcal{B}}|^2$, becomes in a dielectric medium,

$$\begin{aligned}\bar{u}^{(\chi)} &= \frac{1}{4}\mathfrak{Re}\left(\varepsilon\vec{\mathcal{E}}\cdot\vec{\mathcal{E}}^* + \frac{1}{\mu_0}\vec{\mathcal{B}}\cdot\vec{\mathcal{B}}^*\right) = \frac{\mathfrak{Re}\,\varepsilon}{4}|\vec{\mathcal{E}}|^2 + \frac{1}{4\mu_0}\left|\frac{k+\imath\kappa}{\omega}\vec{\mathcal{E}}\right|^2 \\ &= \frac{\varepsilon_0}{4}(1+\chi_e')\mathcal{E}_0^2 + \frac{\varepsilon_0}{4\omega^2}|k+\imath\kappa|^2\mathcal{E}_0^2 = (k^2-\kappa^2+k^2+\kappa^2)\frac{\varepsilon_0}{4}\mathcal{E}_0^2 = \frac{\varepsilon_0}{2}\frac{k^2}{\omega^2}\mathcal{E}_0^2 ,\end{aligned}$$

where we only consider the real part of the susceptibility χ_ε. On the other hand, the Poynting vector is,

$$\bar{I} = \frac{1}{2\mu_0}\mathfrak{Re}\left[\vec{\mathcal{E}}\times\vec{\mathcal{B}}^*\right] = \frac{\varepsilon_0 c^2}{2}\mathcal{E}_0^2\left[e^{-2\omega\kappa z/c}\mathfrak{Re}\,\frac{k+\imath\kappa}{\omega}\right] = \frac{\varepsilon_0 c^2}{2}\frac{k}{\omega}\mathcal{E}_0^2 e^{-2\omega\kappa z/c} .$$

15.2.4.2 The Fresnel-Fizeau effect

Naively, the index of refraction is due to a finite time lag between photon absorption and emission. The time spend in an excited state slows down the light propagation velocity. If during this time the atom travels, the atomic velocity adds to (or reduces) the light propagation velocity. This effect which is known as *Fresnel-Fizeau effect* is an internal degrees of freedom effect. Consider a medium with the index of refraction n

(measured in the moving frame) which is moving with velocity v. The copropagation velocity of light is for $v \ll c$,

$$c_v = \frac{c}{n_{\rm rf}} \frac{c + n_{\rm rf} v}{c + v/n_{\rm rf}} \approx \frac{c}{n_{\rm rf}} + v \left(1 - \frac{1}{n_{\rm rf}^2}\right) . \tag{15.148}$$

This is the Fresnel 'drag' coefficient. In particular, it is easy to show that,

$$c_{-v} < c/n_{\rm rf} < c_v < c . \tag{15.149}$$

Expressing the refraction index by the susceptibility, $n_{\rm rf} = \sqrt{1+\chi_\varepsilon} \approx 1 + \frac{1}{2}\chi_\varepsilon$, we get,

$$\frac{c_v - c_{-v}}{2v} = 1 - \frac{1}{n_{\rm rf}^2} = \frac{\chi_\varepsilon}{1+\chi_\varepsilon} . \tag{15.150}$$

Knowing that,

$$\chi_\varepsilon = \frac{2nd^2}{3\varepsilon_0\hbar} \frac{\Delta + \imath\Gamma}{4\Delta^2 + 2\Omega^2 + \Gamma^2} \qquad \text{and} \qquad d = \sqrt{\frac{3\pi\varepsilon_0\hbar\Gamma}{k^3}} \tag{15.151}$$
$$\mathfrak{Re}\,\chi_\varepsilon = \frac{2\pi\Gamma n}{k^3} \frac{\Delta}{4\Delta^2 + 2\Omega^2 + \Gamma^2}$$

it follows,

$$\frac{c_v - c_{-v}}{2v} = \frac{1}{1 + \left(\frac{2\pi\Gamma n}{k^3} \frac{\Delta}{4\Delta^2+2\Omega^2+\Gamma^2}\right)^{-1}} . \tag{15.152}$$

For small detunings within the natural linewidth,

$$\frac{c_v - c_{-v}}{2v} \approx \frac{1}{1 + \frac{k^3}{2\pi n}\frac{\Gamma}{\Delta}} , \tag{15.153}$$

a long excited state lifetime is advantageous. For very large detunings and $\Omega \to 0$,

$$\frac{c_v - c_{-v}}{2v} \approx \frac{1}{1 + \frac{2k^3}{\pi n}\frac{\Delta}{\Gamma}} . \tag{15.154}$$

This shows that (far from resonance) the effect increases for large densities, broad linewidths and smaller detunings. For example, the *Rb* D_1 line for typical conditions the coefficient is $\frac{2k^3}{\pi n} \approx 1000$ [18].

15.2.5 Light interaction with metals and the Drude model

The *Drude model* is based on a classical kinetic theory of non-interacting electrons in a metal. Since the conduction electrons are considered to be free, the Drude oscillator is an extension of the Lorentz model of a single oscillator to the case, when the restoring

[18] For the high-finesse ring-cavity CARL experiment this means that the Fresnel-Fizeau effect is negligible. Far from resonance the atoms do not spend time in the excited state. The adiabatic elimination of the internal degrees of freedom removes the effect from the theoretical model. It also means that the counter-propagating modes of the ring-cavity do not split because of the atomic velocity, $n_{rf+} = n_{rf-}$. The calculation shows that the back-scattered light is not perfectly resonant, but that this shift is negligibly small.

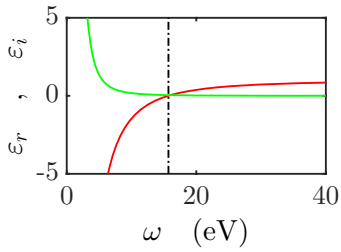

Figure 15.14: (code) Real (red) and imaginary (green) parts of the dielectric function as a function of the excitation frequency.

force and the atomic resonance frequency are zero, $\Gamma_0 = \omega_0 = 0$. The equation of motion is,

$$m\frac{d\mathbf{v}}{dt} + m\Gamma_d\mathbf{v} = -e\vec{\mathcal{E}}\ , \tag{15.155}$$

where $m\frac{d\mathbf{v}}{dt}$ is the force accelerating the electron, $m\Gamma_d\mathbf{v}$ is the friction due to collisions with ions of the crystalline lattice and $-e\vec{\mathcal{E}} = -e\vec{\mathcal{E}}_0 e^{\imath\omega t}$ is the Coulomb force exerted by the oscillating field. We find,

$$\mathbf{v} = \mathbf{v}_0 e^{\imath\omega t} = -\frac{e}{m}\frac{\vec{\mathcal{E}}_0}{\imath\omega + \Gamma_d}e^{\imath\omega t}\ . \tag{15.156}$$

The current density corresponding to the motion of n electrons per unit volume is,

$$\mathbf{j}_c(\omega) = -ne\mathbf{v} = \frac{ne^2}{m(\Gamma_d + \imath\omega)}\vec{\mathcal{E}}\ . \tag{15.157}$$

In addition we have the current that corresponds to the electric displacement in vacuum,

$$\mathbf{j}_d(\omega) = \frac{\partial\vec{\mathcal{D}}}{\partial t} = \imath\omega\varepsilon_0\vec{\mathcal{E}}\ , \tag{15.158}$$

where $\vec{\mathcal{D}} = \varepsilon_0\vec{\mathcal{E}}$. The total current density is given by,

$$\mathbf{j}(\omega) = \mathbf{j}_c(\omega) + \mathbf{j}_d(\omega) = \left[\frac{ne^2}{m(\Gamma_d + \imath\omega)} + \imath\omega\varepsilon_0\right]\vec{\mathcal{E}}\ . \tag{15.159}$$

Assuming the total current as being created by a total electric displacement, $\vec{\mathcal{D}}_{\text{tot}} = \tilde{\varepsilon}\vec{\mathcal{E}}$, where again the electric field and the displacement are related by a complex permittivity, we find,

$$\mathbf{j}(\omega) = \frac{\partial\vec{\mathcal{D}}_{\text{tot}}}{\partial t} = \imath\omega\tilde{\varepsilon}\vec{\mathcal{E}}\ , \tag{15.160}$$

and comparing the last two expressions,

$$\left[\frac{ne^2}{m(\Gamma_d + \imath\omega)} + \imath\omega\varepsilon_0\right]\vec{\mathcal{E}} = \imath\omega\tilde{\varepsilon}(\omega)\vec{\mathcal{E}}\ . \tag{15.161}$$

Resolving by $\tilde{\varepsilon}$,

$$\boxed{\tilde{\epsilon}(\omega) = 1 - \frac{\omega_p^2}{\imath\omega\Gamma_d - \omega^2}} \ , \tag{15.162}$$

where

$$\omega_p \equiv \sqrt{\frac{ne^2}{m\varepsilon_0}} \tag{15.163}$$

is called the *plasma frequency*, which corresponds to the energy, where $\epsilon(\omega_p) \simeq 0$. Separated into real and imaginary parts,

$$\epsilon'(\omega) = 1 - \frac{\omega_p^2}{\Gamma_d^2 + \omega^2} \quad , \quad \epsilon''(\omega) = \frac{\omega_p^2 \Gamma_d}{\omega(\Gamma_d^2 + \omega^2)} \tag{15.164}$$

For $\omega < \omega_p$ and small Γ_d, the real part ϵ' is negative. No electric field can penetrate the metal, which therefore becomes fully reflecting.
For $\omega = \omega_p$, the real part ϵ' is zero. That is, the electrons oscillate in phase with the field along the propagation distance in the metal.
For $\omega \gg \omega_p$, the imaginary (absorptive) part ε'' disappears at high frequencies. For metals, usually we have $\omega_p = (2\pi)\ 1000...4000\,\mathrm{THz}$ and $\Gamma_d \approx 100\,\mathrm{s}^{-1}$.

Note that the Drude model has its limitations. It provides simple pictures for electric conduction in metals and related phenomena, such as the Hall effect. On the other hand, it fails when the electronic wave nature or the energetic band structure of the material, e.g. in semiconductors come into play.

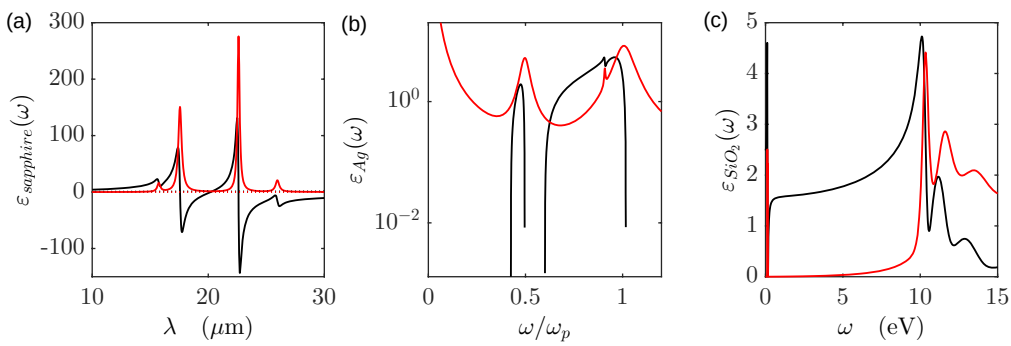

Figure 15.15: (code) Examples of frequency-dependent permittivities for (a) sapphire [312, **?**], (b) silver [762], and (c) amorphous glas [263].

15.2.6 Causality connecting $\vec{\mathcal{D}}$ with $\vec{\mathcal{E}}$ and the Kramers-Kronig relations

A consequence of the dispersion of $\varepsilon(\omega)$ is the temporarily nonlocal connection between the displacement $\vec{\mathcal{D}}$ and the electric field $\vec{\mathcal{E}}$. Calculating the Fourier transform of,

$$\vec{\mathcal{D}}(\mathbf{r}, \omega) = \varepsilon(\omega)\vec{\mathcal{E}}(\mathbf{r}, \omega) = \varepsilon_0[1 + \chi_\varepsilon(\omega)]\vec{\mathcal{E}}(\mathbf{r}, \omega) \ , \tag{15.165}$$

we obtain, using the convolution theorem,

$$\begin{aligned}\vec{\mathcal{D}}(\mathbf{r},t) &= \frac{1}{\sqrt{2\pi}}\int_{-\infty}^{\infty}\varepsilon(\omega)\vec{\mathcal{E}}(\mathbf{r},\omega)e^{-\imath\omega t}d\omega \\ &= \varepsilon_0\vec{\mathcal{E}}(\mathbf{r},t) + \frac{\varepsilon_0}{\sqrt{2\pi}}\int_{-\infty}^{\infty}\chi_\varepsilon(\omega)\vec{\mathcal{E}}(\mathbf{r},\omega)e^{-\imath\omega t}d\omega \\ &= \varepsilon_0\vec{\mathcal{E}}(\mathbf{r},t) + \frac{\varepsilon_0}{\sqrt{2\pi}}\int_{-\infty}^{\infty}\chi_\varepsilon(\tau)\vec{\mathcal{E}}(\mathbf{r},t-\tau)d\tau\ ,\end{aligned} \tag{15.166}$$

where $\chi_\varepsilon(\tau)$ is the Fourier transform of the electric susceptibility. This results shows that the displacement field $\vec{\mathcal{D}}$ depends on all values the incident electric field $\vec{\mathcal{E}}$ had at all times. Only if $\chi_\varepsilon(\omega)$ were independent of ω would we have $\chi_\varepsilon(\tau)\propto\delta(\tau)$.

Example 108 (*Simple model of the susceptibility*): To illustrate the implications of equation (15.166) we consider a permittivity of the following form,

$$\frac{\varepsilon(\omega)}{\varepsilon_0} = \frac{\omega_p}{\omega_0^2-\omega^2-\imath\gamma\omega}\ . \tag{15.167}$$

The kernel related to the susceptibility,

$$\chi_\varepsilon(\tau) = \frac{\omega_p^2}{2\pi}\int_{-\infty}^{\infty}\frac{e^{-\imath\omega\tau}d\tau}{\omega_0^2-\omega^2-\imath\gamma\omega}\ , \tag{15.168}$$

can be evaluated by contour integration, the result being,

$$\chi_\varepsilon(\tau) = \omega_p^2 e^{-\gamma\tau/2}\frac{\sin\tau\sqrt{\omega_0^2-(\gamma/2)^2}}{\sqrt{\omega_0^2-(\gamma/2)^2}}\Theta(\tau)\ , \tag{15.169}$$

where $\Theta(\tau)$ is the Heaviside function.

This example shows that the displacement field $\vec{\mathcal{D}}$ only depends on the electric field at *past times*, which is fortunate as it allows causality to be respected.

15.2.6.1 The Kramers-Kronig relations

The *Kramers-Kronig relations* are bidirectional mathematical relations, connecting the real and imaginary parts of any complex function that is an *analytic function* on the upper half-plane [19]. These relationships are often used to calculate the real part of response functions in physical systems from the imaginary part (or vice versa). This works because, in stable physical systems, *causality and analyticity* are equivalent conditions. Be $\chi(\omega)$ a complex function of the complex variable ω. We assume this function to be analytic in the upper closed half-plane of ω and to disappear as $1/|\omega|$ or faster for $|\omega|\to\infty$. The Kramers-Kronig relations are given by,

$$\boxed{\mathfrak{Re}\,\chi(\omega) = \frac{1}{\pi}\mathcal{P}\int_{-\infty}^{\infty}\frac{\mathfrak{Im}\,\chi(\omega')}{\omega'-\omega}d\omega' \quad\text{and}\quad \mathfrak{Im}\,\chi(\omega) = -\frac{1}{\pi}\mathcal{P}\int_{-\infty}^{\infty}\frac{\mathfrak{Re}\,\chi(\omega')}{\omega'-\omega}d\omega'}\ , \tag{15.170}$$

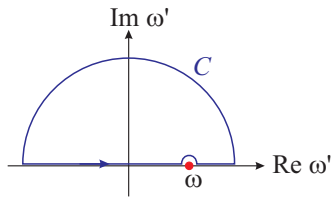

Figure 15.16: Path of the contour integral illustrating Cauchy's theorem.

where $\mathcal{P}$ denotes the *Cauchy principal value*. Thus, the real and imaginary parts of such a function are not independent, and the complete function can be reconstructed from only one of its parts.

For any analytic function χ defined on the upper closed half-plane, the function $\omega' \to \chi(\omega')/(\omega' - \omega)$ where $\omega \in \mathbb{R}$, will also be analytic in the upper half-plane. The *Cauchy's residue theorem* for integration consequently says, that

$$\oint \frac{\chi(\omega')}{\omega' - \omega} d\omega' = 0 \ . \tag{15.171}$$

We chose the contour to follow the real axis, making a loop around the pole at $\omega' = \omega$, and a large semicircle in the upper half-plane, as shown in Fig. 15.16. We now decompose the integral into its contributions along each one of these three paths and then evaluate the limits. The length of the semicircular path increases proportionally to $|\omega'|$, but the integral along it disappears in this limit, since $\chi(\omega')$ disappears at least as fast as $1/|\omega'|$. Letting the size of the semicircle go to zero we get,

$$0 = \oint \frac{\chi(\omega')}{\omega' - \omega} d\omega' = \mathcal{P} \int_{-\infty}^{\infty} \frac{\chi(\omega')}{\omega' - \omega} d\omega' - \imath\pi\chi(\omega) \ . \tag{15.172}$$

The second term in the last expression is obtained using the Sokhotski-Plemelj theorem of residues. After rearrangement we arrive at the compact form of the Kramers-Kronig relations,

$$\chi(\omega) = \frac{1}{\imath\pi} \mathcal{P} \int_{-\infty}^{\infty} \frac{\chi(\omega')}{\omega' - \omega} d\omega' \ . \tag{15.173}$$

The imaginary unit in the denominator makes the connection between the real and the imaginary components. Finally, we separate $\chi(\omega)$ and the equation (15.173) into their real and imaginary parts, and we get the expressions from above (15.170).

15.2.6.2 Physical interpretation in terms of causality

We can apply the Kramers-Kronig formalism to response functions. In certain linear and time-invariant physical systems or signal processing applications, the response function $h(t)$ describes, how some time-dependent property of the system, responds to a force $F(t')$ pulsed during a time t'. For example, the property of the system can be the angle of a pendulum and the force applied by a motor kicking the pendulum.

[19] A function is analytic if and only if its Taylor series about a point $\mathbf{r}_0$ converges to the function in some neighborhood for every $\mathbf{r}_0$ in its domain. Hence, analytic functions must be infinitely differentiable.

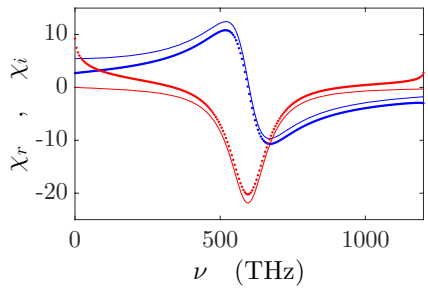

Figure 15.17: (code) Real (blue) and imaginary (red) parts of the susceptibility. The dashed curves are calculated by the Kramers-Kronig formulas.

The response function must be zero for $t < 0$, since the system can not respond to the force before it has been applied. It can be shown that this request for causality *in time domain* implies *in frequency domain*, that the Fourier transform $\chi(\omega)$ of $h(t)$ is analytical inside the upper half-plane. Furthermore, if we subject the system to an oscillating force with a frequency much higher than its highest resonance frequency, there will be almost no time for the system to respond before the forcing has alternated the direction, and hence the frequency response $\chi(\omega)$ converges to zero, when ω becomes very large. From these physical considerations, we see that $\chi(\omega)$ will normally satisfy the conditions necessary for the Kramers-Kronig relations to apply.

The frequency response of a system forced to generate an impulse response $h(t)$ is given by the Fourier-transform,

$$\chi(\omega) = \tfrac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} h(t) e^{-\imath\omega t} dt = \mathcal{F}[h(t)] \ , \tag{15.174}$$

which for an electrical system corresponds to its impedance. Now, the boundary condition of causality can be implemented with the use of the Heaviside step function $\Theta(t)$,

$$\chi(\omega) = \tfrac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} h(t)\Theta(t) e^{-\imath\omega t} dt = \mathcal{F}[h(t)\Theta(t)] = \mathcal{F}[h(t)\Theta(t)\Theta(t)] \ . \tag{15.175}$$

Note that the implementation of causality via the Heaviside step function is directly implemented when replacing the Fourier transform by the *Laplace transform*. Applying the convolution theorem to the Fourier transform and using the Fourier transform of the Heaviside function we get [20],

$$\boxed{\chi(\omega) = \mathcal{F}[h(t)\Theta(t)] \star \mathcal{F}[\Theta(t)] = \chi(\omega) \star (\mathcal{F}\Theta)(\omega) = \chi(\omega) \star \left(\tfrac{1}{2\pi\imath\omega} + \tfrac{1}{2}\delta(\omega)\right)} \ . \tag{15.176}$$

This equality can be considered an early or raw form of the Kramers-Kronig relations and will turn out to be equivalent to them. To see this, we carry out the convolution explicitly,

$$\chi(\omega) = \frac{1}{2\pi} \int_{-\infty}^{\infty} \frac{\chi(\omega')d\omega'}{\imath(\omega - \omega')} + \frac{1}{2}\chi(\omega) \ , \tag{15.177}$$

[20] $\mathcal{F}[\Theta(t)] = \frac{1}{\imath\sqrt{2\pi}\omega} + \sqrt{\frac{\pi}{2}}\delta(\omega)$

or isolating $\chi(\omega)$,

$$\chi(\omega) = \frac{1}{\pi}\int_{-\infty}^{\infty} \frac{\chi(\omega')d\omega'}{\imath(\omega-\omega')} \ . \tag{15.178}$$

This is the frequency response of causal systems being invariant under a Hilbert-transform. It is equivalent to the Kramers-Kronig relations (15.170). Rewriting it for only positive integration limits, the integral splits up like,

$$\chi(\omega) = \frac{1}{\pi}\int_{0}^{\infty} \frac{\chi(\omega')d\omega'}{\imath(\omega-\omega')} + \frac{1}{\pi}\int_{0}^{\infty} \frac{\chi(-\omega')d\omega'}{\imath(\omega+\omega')} \ . \tag{15.179}$$

From the definition of the Fourier integral of the real quantity $h(t)$ follows directly $\chi(-\omega) = \chi^*(\omega)$, that is, the positive frequency response determines the negative frequency response. Therefore,

$$\begin{aligned}\chi(\omega) &= \frac{1}{\pi}\int_{0}^{\infty} \frac{\chi(\omega')(\omega+\omega') + \chi^*(\omega')(\omega-\omega')}{\imath(\omega^2-\omega'^2)}d\omega' \\ &= \frac{1}{\pi}\int_{0}^{\infty} \frac{\omega'\mathfrak{Im}\,\chi(\omega') - \imath\omega\mathfrak{Re}\,\chi^*(\omega')}{\omega^2-\omega'^2}d\omega' \ .\end{aligned} \tag{15.180}$$

from which we obtain the Kramers-Kronig relations for the real and imaginary parts in a format, where they are useful for physically realistic response functions,

$$\boxed{\mathfrak{Re}\,\chi(\omega) = \frac{2}{\pi}\int_{0}^{\infty} \frac{\omega'\mathfrak{Im}\,\chi(\omega')}{\omega^2-\omega'^2}d\omega' \quad \text{and} \quad \mathfrak{Im}\,\chi(\omega) = \frac{-2}{\pi}\int_{0}^{\infty} \frac{\omega\mathfrak{Re}\,\chi(\omega')}{\omega^2-\omega'^2}d\omega'} \ . \tag{15.181}$$

The imaginary part of a response function describes, being *out of phase* with the driving force, how a system dissipates energy. The Kramers-Kronig relations imply that observing the *dissipative* response of a system is sufficient to determine its (reactive) *in-phase* response, and vice versa.

15.2.7 Exercises

15.2.7.1 Ex: Skin depth

a. Consider a piece of glass containing some free charges. How long does it take for the charges to migrate to the surface?
b. Suppose you were designing a microwave experiment at a frequency of 10^{10} Hz. How thick would you make a silver coating?
c. Find the wavelength and propagation velocity in copper for radio waves at 1 MHz. Compare with the corresponding values in air (or vacuum).

15.2.7.2 Ex: Complex refractive index

A light wave described by the electric field $\mathcal{E}_{\rm i} = \mathcal{E}_0 e^{\imath k_0 z}$ comes from the vacuum and impinges on a metal surface characterized by the complex refractive index $n = n' + \imath n''$. Determine from the relation $n = \sqrt{\epsilon}$ the relative dielectric constant ϵ.
a. At what depth the field falls to e^{-1}, if $\mathcal{E}_{met} \simeq 0.05\mathcal{E}_0$ and $k_{met} = nk_0$.
b. Now despise the penetrating field, $|\mathcal{E}_{met}| \simeq 0$, and consider the reflected field $\mathcal{E}_{\rm r} = \mathcal{E}_0 e^{-\imath kx + \imath\Delta\phi}$. Calculate the intensity resulting from the superposition of $\mathcal{E}_{\rm i}$ and $\mathcal{E}_{\rm r}$.

15.2.7.3 Ex: Fourier expansion

The Fourier inversion theorem says that,

$$f(z) = \int_{-\infty}^{\infty} A(k) e^{\imath kz} dk \qquad \Longleftrightarrow \qquad A(k) = \tfrac{1}{2\pi} \int_{-\infty}^{\infty} f(z) e^{-\imath kz} dz \ .$$

Use the theorem to determine $A(k)$ for the wavepacket given by $f(z,t) = \int_{-\infty}^{\infty} A(k) e^{\imath[kz - \omega(k)t]} dk$ as a function of the real parts $\mathfrak{Re}\, f(z,0)$ and $\mathfrak{Re}\, \dot{f}(z,0)$.

15.2.7.4 Ex: Electromagnetic wave

In a dispersionless medium ($\varepsilon = \varepsilon_0$ and $\mu = \mu_0$) we have for a component $u(x,t)$ of an electromagnetic wave (here without dimension),

$$u(x,t) = \frac{1}{\sqrt{2\pi}} \int\limits_{-\infty}^{\infty} dk A(k) e^{\imath kx - \imath\omega(k)t} \qquad \text{with} \qquad \omega(k) = ck \ ,$$

and

$$A(k) = \frac{1}{\sqrt{2\pi}} \int\limits_{-\infty}^{\infty} dx u(x,0) e^{-\imath kx} \ .$$

a. Show that $u(x,t)$ satisfies the one-dimensional wave equation for vacuum.
b. Calculate the spectral distribution $A(k)$ for $u(x,t) = e^{\imath k_0 x - \imath\omega_0 t}$.
c. Calculate the spectral distribution $A(k)$ for $\{u(x,t) = e^{\imath k_0 x - \imath\omega_0 t}$ for $-L < x - (\omega_0/k_0)t < L$ and 0 else$\}$.
d. Calculate $u(x,t)$, when $u(x,0) = \int_{-a}^{+a} \delta(x-a) da$.
e. Try to understand in an elementary way the relation of part (c) between the bandwidth and the length of the wavepacket. Perform the transition to the limit $L \to \infty$ explicitly. For the case (d) discuss the propagation of the wavepacket in space.
Formulas:

$$\delta(k_0 - k) = \frac{1}{2\pi} \int\limits_{-\infty}^{\infty} dx e^{\imath(k_0 - k)x} = \frac{1}{\pi} \lim_{L\to\infty} \frac{\sin(k_0 - k)}{k_0 - k}$$

$$\Theta(a) = \frac{1}{2\pi\imath} \int\limits_{-\infty}^{\infty} dk \frac{e^{\imath ka}}{k} = \begin{cases} 1 & \text{for } a > 0 \\ 0 & \text{else} \end{cases} \ .$$

15.2.7.5 Ex: Phase and group velocity

Let us study the one-dimensional motion of a wavepacket in x-direction, which spreads in infinite space. The law of dispersion is given by $\omega = \omega(k)$. The motion of a wavepacket is then described by,

$$u(x,t) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} dk A(k) e^{\imath kx - \imath\omega(k)t} \ ,$$

where the spectral distribution $A(k)$ is given by shape of the wavepacket at time $t = 0$:

$$A(k) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} dx u(x,0) e^{-\imath kx} \ .$$

The maximum of $A(k)$ be at $k = k_0$. We call $v_{ph} = \omega(k)/k$ the *phase velocity* and $v_{gr} = [d\omega(k)/dk]_{k_0}$ the *group velocity*, because in specific idealized situations a wavepacket propagates precisely at this speed. In the following we consider a propagation of the wavepacket given by,

$$u(x,0) = c \exp\left\{-\frac{x^2}{2a^2} + \imath k_0 x\right\}$$

for a medium characterized by the dispersion relation $\omega(k) = b^2 k^2$ (for a de Broglie matter wave).
a. Plot the shape of the wavepacket at time $t = 0$ via the intensity distribution $|u(x,0)|^2$. The 'width' of a Gaussian profile is given by the points, where the profile fell to $(1/e)$ of the maximum value. Calculate the width $\triangle x(t = 0)$ of the intensity distribution.
b. Calculate the spectral distribution $A(k)$ and the width $\triangle k$ of the corresponding intensity distribution $|A(k)|^2$.
c. Now calculate $u(x,t)$ at a later time t. Express $u(x,t)$ in the form
$u(x,t) = \alpha e^{-(x-\beta t)^2/\gamma} e^{\imath(k_0 x - \omega(k_0)t)} e^{\imath\phi}$, where α, β, γ, and ϕ are real quantities which, nevertheless, may depend on t and x.
d. Calculate the intensity distribution $|u(x,t)|^2$ at time t. At what speed does the maximum move? Calculate the width $\triangle x(t)$ of the intensity distribution. What is the temporal evolution of $\triangle x(t) \triangle k$?
e. Compare $|u(x,t)|^2$ width $|u(x,0)|^2$.
Help:

$$\int_{-\infty}^{+\infty} dx \ e^{-ax^2+bx+c} = \sqrt{\tfrac{\pi}{a}} \exp\left[\tfrac{b^2+4ac}{4a}\right] \ .$$

15.2.7.6 Ex: Radiation force acting on a small dielectric particle

The polarizability of a small ($a \ll \lambda$) dielectric particle with complex refraction index $n_p = \mathfrak{Re}\, n_p - \imath \frac{\alpha\lambda}{4\pi}$ immersed in a medium of refraction index n_m is given by,

$$\alpha_{rad} = \frac{4\pi a^3 \frac{n_p^2 - n_m^2}{n_p^2 + 2n_m^2} n_m^2 \varepsilon_0}{1 - \frac{n_p^2 - n_m^2}{n_p^2 + 2n_m^2}\left[\left(\frac{n_m \omega_0}{c} a\right)^2 - \frac{2}{3}\imath \left(\frac{n_m \omega_0}{c} a\right)^3\right]} \ .$$

Calculate the total force acting on it when subject to an electromagnetic field.

15.2.7.7 Ex: Lorentz model

Based on the Lorentz model, derive the differential equation for the oscillation amplitude of the electrons and calculate the response of the matter reacting via a polarization $P = Nex$, where N is the number of electrons and x their oscillation amplitude.

Calculate the absorptive part $\mathfrak{Im}\,\chi$ and the dispersive part $\mathfrak{Re}\,\chi$ of the susceptibility $\chi \equiv P/\varepsilon_0\mathcal{E}$.
With this calculate the index of refraction n and the coefficient of absorption α in the Lorentz model.

15.2.7.8 Ex: Lorentz force on a single atomic dipole

Calculate the Lorentz force on a single atom within the dipole approximation from the expression [443],

$$\mathbf{F} = \int d^3r[\varrho(\mathbf{r})\vec{\mathcal{E}}(\mathbf{r}) + \mathbf{j}(\mathbf{r}) \times \vec{\mathcal{B}}(\mathbf{r})] \ .$$

15.2.7.9 Ex: The Faraday effect

Derive the *Faraday effect* from the Lorentz model using the following procedure:
a. Formulate the equation of motion for the position $\mathbf{s}$ of a bound electron according to (15.107) in the presence of a homogeneous magnetic field $\vec{\mathcal{B}} = \mathcal{B}\hat{\mathbf{e}}_z$ and an electromagnetic wave characterized by $\vec{\mathcal{E}}(z,t) = \mathcal{E}(z)\hat{\epsilon}e^{-\imath\omega t}$ and assumed to be initially linearly polarized in x-direction.
b. Express the motion of the electron in the xy-plane in a new basis given by $\hat{\mathbf{e}}_\pm = \frac{1}{\sqrt{2}}(\hat{\mathbf{e}}_x \pm \imath\hat{\mathbf{e}}_y)$.
c. Solve the equations of motion for the decoupled components $s_\pm(z,t) \equiv s_x \mp \imath s_y$ and determine the susceptibility.
d. Calculate the electric field and the angle by which the linear polarization vector is rotated as a function of z.

15.2.7.10 Ex: Complex refraction index and extinction coefficient

a. Derive the relations $n'^2 - n''^2 = 1 + \chi'_\varepsilon$ and $2n'n'' = \chi_\varepsilon$. **Note:** In a transparent dielectric medium there is no absorption, such that, $n'^2 = 1 + \chi'_\varepsilon = \frac{\varepsilon}{\varepsilon_0}$.
b. Calculate the *absorption coefficient* for a light field traversing a dielectric medium.

15.3 Plasmons, waveguides and resonant cavities

15.3.1 Green's tensor for wave propagation in dielectric media

The electromagnetic field in the presence of macroscopic dielectrics is governed by an inhomogeneous vector Helmholtz equation. Defining the permittivity and the permeability as tensor fields $\vec{\mathcal{D}}(\mathbf{r},\omega) = \epsilon(\mathbf{r},\omega)\varepsilon_0\vec{\mathcal{E}}(\mathbf{r},\omega)$ and $\vec{\mathcal{B}}(\mathbf{r},\omega) = \mu(\mathbf{r},\omega)\mu_0\vec{\mathcal{H}}(\mathbf{r},\omega)$

the Maxwell equations (14.6), become after a temporal Fourier transform,

$$\begin{aligned} \nabla \times \vec{\mathcal{H}} &= -\imath\omega\epsilon\varepsilon_0\vec{\mathcal{E}} + \mathbf{j} \\ \nabla \times \vec{\mathcal{E}} &= \imath\omega\mu\mu_0\vec{\mathcal{H}} \\ \nabla \cdot \epsilon\varepsilon_0\vec{\mathcal{E}} &= \varrho \\ \nabla \cdot \mu\mu_0\vec{\mathcal{H}} &= 0 \ . \end{aligned} \tag{15.182}$$

It is easy to see, that the *inhomogeneous Helmholtz equation* [564, 686, 135],

$$\boxed{\left[\nabla \times \frac{1}{\mu(\mathbf{r},\omega)}\nabla \times -\frac{\omega^2}{c^2}\epsilon(\mathbf{r},\omega)\right]\vec{\mathcal{E}}(\mathbf{r},\omega) = \imath\omega\mu_0\mathbf{j}(\mathbf{r},\omega)} \tag{15.183}$$

satisfies the above Maxwell equations with $\vec{\mathcal{E}}(\mathbf{r},\omega) \to 0$ for $r \to \infty$. Using the Green's function formalism, the solution to the Helmholtz equation can be given by,

$$\vec{\mathcal{E}}(\mathbf{r},\omega) = \imath\omega\mu_0 \int_V d^3r' \mathcal{G}(\mathbf{r},\mathbf{r}',\omega)\cdot\mathbf{j}(\mathbf{r}',\omega) \ , \tag{15.184}$$

where the *Green's tensor* is the solution to

$$\boxed{\left[\nabla_{\mathbf{r}} \times \frac{1}{\mu(\mathbf{r},\omega)}\nabla_{\mathbf{r}} \times -\frac{\omega^2}{c^2}\epsilon(\mathbf{r},\omega)\right]\mathcal{G}(\mathbf{r},\mathbf{r}',\omega) = \delta^{(3)}(\mathbf{r}-\mathbf{r}')\mathbb{I}} \tag{15.185}$$

together with the boundary condition $\mathcal{G}(\mathbf{r},\mathbf{r}',\omega) \to 0$ for $|\mathbf{r}-\mathbf{r}'| \to \infty$. The volume of integration V is a small volume surrounding the point $\mathbf{r} = \mathbf{r}'$ in order to avoid the singularity.

The Green's tensor represents the electric field radiated at position $\mathbf{r}$ by three orthogonal dipoles located at $\mathbf{r}'$.

15.3.1.1 Bulk medium

Let us now consider the simplest case of a bulk medium, i.e. an infinitely extended, homogeneous dielectric independent of $\mathbf{r}$, that is, $\epsilon(\mathbf{r},\omega) = \epsilon(\omega)$ and $\mu(\mathbf{r},\omega) = \mu(\omega)$. In this case, the Helmholtz equation further simplifies to,

$$[\nabla_{\mathbf{r}} \times \nabla_{\mathbf{r}} \times -k(\omega)^2]\vec{\mathcal{E}}_{\mathrm{b}}(\mathbf{r},\omega) = \imath\omega\mu_0\mathbf{j}(\mathbf{r},\omega) \tag{15.186}$$

with $k(\omega)^2 = \frac{\omega^2}{c^2}\mu(\omega)\epsilon(\omega)$ defined at $\mathbf{r}$. The Green tensor is then the solution to,

$$\nabla_{\mathbf{r}} \times \nabla_{\mathbf{r}} \times \mathcal{G}_{\mathrm{b}}(\mathbf{r},\mathbf{r}',\omega) - k^2\mathcal{G}_{\mathrm{b}}(\mathbf{r},\mathbf{r}',\omega) = \delta^{(3)}(\mathbf{r}-\mathbf{r}')\mathbb{I} \ . \tag{15.187}$$

15.3.1.2 The scalar Helmholtz equation

The bulk medium vector Helmholtz equation (15.187) can be reduced to a scalar Helmholtz equation. To that end, we take its divergence and find,

$$\nabla \cdot \mathcal{G}_{\mathrm{b}}(\mathbf{r},\mathbf{r}',\omega) = -\tfrac{1}{k^2}\nabla\delta^{(3)}(\mathbf{r}-\mathbf{r}') \ . \tag{15.188}$$

Using this identity and expanding,

$$\nabla_{\mathbf{r}}\times\nabla_{\mathbf{r}}\times\mathcal{G}_{\rm b} = \begin{pmatrix} \partial_x^2-\triangle & \partial_x\partial_y & \partial_x\partial_z \\ \partial_x\partial_y & \partial_y^2-\triangle & \partial_y\partial_z \\ \partial_x\partial_z & \partial_y\partial_z & \partial_z^2-\triangle \end{pmatrix} \begin{pmatrix} G_{xx} & G_{xy} & G_{xz} \\ G_{yx} & G_{yy} & G_{yz} \\ G_{zx} & G_{zy} & G_{zz} \end{pmatrix} = (\nabla\otimes\nabla - \mathbb{I}\triangle)\,\mathcal{G}_{\rm b}\ , \tag{15.189}$$

we may write,

$$\begin{aligned} [\Delta+k^2]\mathcal{G}_{\rm b}(\mathbf{r},\mathbf{r}',\omega) &= \nabla\nabla\cdot\mathcal{G}_{\rm b}(\mathbf{r},\mathbf{r}',\omega) - \nabla\times\nabla\times\mathcal{G}_{\rm b}(\mathbf{r},\mathbf{r}',\omega) + k^2\mathcal{G}_{\rm b}(\mathbf{r},\mathbf{r}',\omega) \\ &= \nabla\nabla\cdot\mathcal{G}_{\rm b}(\mathbf{r},\mathbf{r}',\omega) - \delta^{(3)}(\mathbf{r}-\mathbf{r}')\mathbb{I} \\ &= -\tfrac{1}{k^2}\nabla\nabla\delta^{(3)}(\mathbf{r}-\mathbf{r}') - \delta^{(3)}(\mathbf{r}-\mathbf{r}')\mathbb{I} = -\left[\mathbb{I}+\tfrac{1}{k^2}\nabla\nabla\right]\delta^{(3)}(\mathbf{r}-\mathbf{r}')\ . \end{aligned} \tag{15.190}$$

The vector Helmholtz equation can hence be solved by writing,

$$\mathcal{G}_{\rm b}(\mathbf{r},\mathbf{r}',\omega) = \left[\mathbb{I}+\tfrac{1}{k^2}\nabla\nabla\right] g(\mathbf{r},\mathbf{r}',\omega)\ , \tag{15.191}$$

where the scalar Green function g obeys the scalar Helmholtz equation,

$$\boxed{[\triangle+k^2]g(\mathbf{r},\mathbf{r}',\omega) = -\delta^{(3)}(\mathbf{r}-\mathbf{r}')}\ , \tag{15.192}$$

the solution of which is simply,

$$g(\mathbf{r},\mathbf{r}',\omega) = \frac{e^{\imath k|\mathbf{r}-\mathbf{r}'|}}{4\pi|\mathbf{r}-\mathbf{r}'|}\ , \tag{15.193}$$

where the boundary condition at infinity implies that k must have a positive imaginary part, $k=\sqrt{\varepsilon(\omega)}\frac{\omega}{c}$ with $\mathfrak{Im}\,k>0$. Combining these results, we obtain the Green tensor of a bulk medium [715, 135],

$$\begin{aligned} \mathcal{G}_{\rm b}(\mathbf{r},\mathbf{r}',\omega) &= \left[\mathbb{I}+\tfrac{1}{k^2}\nabla\nabla\right]\frac{e^{\imath k|\mathbf{r}-\mathbf{r}'|}}{4\pi|\mathbf{r}-\mathbf{r}'|} \\ &= \frac{\delta^{(3)}(\mathbf{R})\mathbb{I}}{3k^2} - \frac{e^{\imath kR}}{4\pi k^2R^3}\left\{[1-\imath kR-(kR)^2]\mathbb{I} - [3-3\imath kR-(kR)^2]\hat{\mathbf{e}}_R\otimes\hat{\mathbf{e}}_R\right\}\ , \end{aligned} \tag{15.194}$$

with $\mathbf{R}\equiv\mathbf{r}-\mathbf{r}'$, as will be shown in Exc. 15.3.7.1. The real and imaginary part are (for $\mathbf{R}\neq 0$),

$$\begin{aligned} \tfrac{4\pi}{k}\mathfrak{Re}\,\mathcal{G}_{\rm b}(\mathbf{r},\mathbf{r}',\omega_0) &= (\mathbb{I}-\hat{\mathbf{e}}_R\otimes\hat{\mathbf{e}}_R)\frac{\cos kR}{kR} - (\mathbb{I}-3\hat{\mathbf{e}}_R\otimes\hat{\mathbf{e}}_R)\left(\frac{\sin kR}{k^2R^2}-\frac{\cos kR}{k^3R^3}\right) \\ \tfrac{4\pi}{k}\mathfrak{Im}\,\mathcal{G}_{\rm b}(\mathbf{r},\mathbf{r}',\omega_0) &= (\mathbb{I}-\hat{\mathbf{e}}_R\otimes\hat{\mathbf{e}}_R)\frac{\sin kR}{kR} + (\mathbb{I}-3\hat{\mathbf{e}}_R\otimes\hat{\mathbf{e}}_R)\left(\frac{\cos kR}{k^2R^2}-\frac{\sin kR}{k^3R^3}\right)\ . \end{aligned} \tag{15.195}$$

Furthermore is is possible to show [135],

$$\mathfrak{Re}\,\mathcal{G}_{\rm b}(\mathbf{r},\mathbf{r},\omega) = 0 \qquad \text{and} \qquad \mathfrak{Im}\,\mathcal{G}_{\rm b}(\mathbf{r},\mathbf{r},\omega) = \frac{k}{6\pi}\mathbb{I}\ . \tag{15.196}$$

Example 109 (*Electric field of a point dipole in an inhomogeneous dielectric*): Parametrizing the current generated by a point dipole located at $\mathbf{r} = \mathbf{r}_s$ by

$$\mathbf{j}(\mathbf{r}, \omega) = -\imath\omega \mathbf{d}_s \delta^{(3)}(\mathbf{r} - \mathbf{r}_s) \ , \tag{15.197}$$

the generated electric field in an environment characterized by the Green function $\mathcal{G}(\mathbf{r}, \mathbf{r}_s, \omega)$ can be evaluated from Eq. (15.184),

$$\vec{\mathcal{E}}(\mathbf{r}, \mathbf{r}_s, \omega) = \omega^2 \mu_0 \mathcal{G}(\mathbf{r}, \mathbf{r}_s) \cdot \mathbf{d}_s \ . \tag{15.198}$$

Using the solution (15.194) for bulk media we find,

$$\vec{\mathcal{E}}_{\mathrm{b}}(\mathbf{r}, \mathbf{r}_s, \omega) = \omega^2 \mu_0 \left[-\frac{e^{\imath kR}}{4\pi k^2 R^3} \left\{ [1 - \imath kR - (kR)^2]\mathbb{I} - [3 - 3\imath kR - (kR)^2] \hat{\mathbf{e}}_R \otimes \hat{\mathbf{e}}_R \right\} \right] \cdot \mathbf{d}_s \ . \tag{15.199}$$

with $k = k(\omega)$.

15.3.1.3 Bulk medium Green tensor projected on particular orientations

The Green tensor can be used to relate two dipoles $\hat{\mathbf{e}}_d$ and $\hat{\mathbf{e}}'_d$ respectively located at $\mathbf{r}$ and $\mathbf{r}'$. Using the identity,

$$R^2 \hat{\mathbf{e}}'^*_d (\hat{\mathbf{e}}_R \otimes \hat{\mathbf{e}}_R) \hat{\mathbf{e}}_d = \begin{pmatrix} d'_x & d'_y & d'_z \end{pmatrix} \begin{pmatrix} x^2 & xy & xz \\ xy & y^2 & yz \\ xz & yz & z^2 \end{pmatrix} \begin{pmatrix} d_x \\ d_y \\ d_z \end{pmatrix} = R^2 (\hat{\mathbf{e}}'_d \cdot \hat{\mathbf{e}}_R)(\hat{\mathbf{e}}_d \cdot \hat{\mathbf{e}}_R) \ , \tag{15.200}$$

we calculate from (15.195),

$$\begin{aligned} &\tfrac{4\pi}{k} \hat{\mathbf{e}}'^*_d \ \mathfrak{Re}\, \mathcal{G}_{\mathrm{b}}(\mathbf{r}, \mathbf{r}', \omega) \ \hat{\mathbf{e}}_d \\ &= [\hat{\mathbf{e}}'_d \cdot \hat{\mathbf{e}}_d - (\hat{\mathbf{e}}'_d \cdot \hat{\mathbf{e}}_R)(\hat{\mathbf{e}}_R \cdot \hat{\mathbf{e}}_d)] \frac{\cos kR}{kR} - [\hat{\mathbf{e}}'_d \cdot \hat{\mathbf{e}}_d - 3(\hat{\mathbf{e}}'_d \cdot \hat{\mathbf{e}}_R)(\hat{\mathbf{e}}_R \cdot \hat{\mathbf{e}}_d)] \left(\frac{\sin kR}{k^2 R^2} - \frac{\cos kR}{k^3 R^3} \right) \\ &\tfrac{4\pi}{k} \hat{\mathbf{e}}'^*_d \ \mathfrak{Im}\, \mathcal{G}_{\mathrm{b}}(\mathbf{r}, \mathbf{r}', \omega) \ \hat{\mathbf{e}}_d \\ &= [\hat{\mathbf{e}}'_d \cdot \hat{\mathbf{e}}_d - (\hat{\mathbf{e}}'_d \cdot \hat{\mathbf{e}}_R)(\hat{\mathbf{e}}_R \cdot \hat{\mathbf{e}}_d)] \frac{\sin kR}{kR} + [\hat{\mathbf{e}}'_d \cdot \hat{\mathbf{e}}_d - 3(\hat{\mathbf{e}}'_d \cdot \hat{\mathbf{e}}_R)(\hat{\mathbf{e}}_R \cdot \hat{\mathbf{e}}_d)] \left(\frac{\cos kR}{k^2 R^2} - \frac{\sin kR}{k^3 R^3} \right) \ . \end{aligned} \tag{15.201}$$

Note that dipole moment is complex in the case of circular polarization. The formula (15.201) simplifies when the dipoles are parallel,

$$\begin{aligned} \tfrac{4\pi}{k} \hat{\mathbf{e}}^*_d \ \mathfrak{Re}\, \mathcal{G}_{\mathrm{b}}(\mathbf{r}, \mathbf{r}', \omega) \ \hat{\mathbf{e}}_d &= [1 - (\hat{\mathbf{e}}_d \cdot \hat{\mathbf{e}}_R)^2] \frac{\cos kR}{kR} - [1 - 3(\hat{\mathbf{e}}_d \cdot \hat{\mathbf{e}}_R)^2] \left(\frac{\sin kR}{k^2 R^2} + \frac{\cos kR}{k^3 R^3} \right) \\ \tfrac{4\pi}{k} \hat{\mathbf{e}}^*_d \ \mathfrak{Im}\, \mathcal{G}_{\mathrm{b}}(\mathbf{r}, \mathbf{r}', \omega) \ \hat{\mathbf{e}}_d &= [1 - (\hat{\mathbf{e}}_d \cdot \hat{\mathbf{e}}_R)^2] \frac{\sin kR}{kR} + [1 - 3(\hat{\mathbf{e}}_d \cdot \hat{\mathbf{e}}_R)^2] \left(\frac{\cos kR}{k^2 R^2} - \frac{\sin kR}{k^3 R^3} \right) \ . \end{aligned} \tag{15.202}$$

Example 110 (*Interaction between induced dipoles at small distances*): At small distances, $kR \ll 1$, so that $\sin kR \simeq kR$ and $\cos kR \simeq 1$, and the expressions (15.202) simplify to,

$$\begin{aligned} \lim_{kR \to 0} \frac{4\pi}{k} \hat{\mathbf{e}}^*_d \mathfrak{Re}\, \mathcal{G}_{\mathrm{b}}(\mathbf{r}, \mathbf{r}', \omega) \hat{\mathbf{e}}_d &\simeq \frac{-1 + 3(\hat{\mathbf{e}}_d \cdot \hat{\mathbf{e}}_R)^2}{k^3 R^3} \\ \lim_{kR \to 0} \frac{4\pi}{k} \hat{\mathbf{e}}^*_d \mathfrak{Im}\, \mathcal{G}_{\mathrm{b}}(\mathbf{r}, \mathbf{r}', \omega) \hat{\mathbf{e}}_d &\simeq 1 - (\hat{\mathbf{e}}_d \cdot \hat{\mathbf{e}}_R)^2 \ . \end{aligned} \tag{15.203}$$

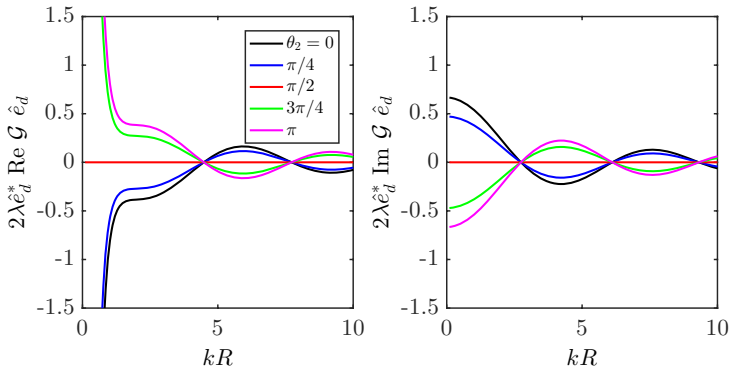

Figure 15.18: (code) Real and imaginary part of the bulk Green tensor for various orientations of the dipoles: $\hat{\mathbf{e}}_d'^* = \hat{\mathbf{e}}_x$ and $\hat{\mathbf{e}}_d$ as indicated in the legend.

This result plays a role in the context of collisions between ground and excited atoms, which can be treated as interactions between induced dipoles,

$$\lim_{kR\to 0} \hat{\mathbf{e}}_d^* \mathfrak{Re}\, \mathcal{G}_\mathrm{b}(\mathbf{r},\mathbf{r}',\omega)\hat{\mathbf{e}}_d \to \frac{1}{4\pi k^2 R^3} \begin{cases} -1 & \text{for} \quad \hat{\mathbf{e}}_d \cdot \hat{\mathbf{e}}_R = 0 \\ 2 & \text{for} \quad \hat{\mathbf{e}}_d = \hat{\mathbf{e}}_R \end{cases} \tag{15.204}$$

$$\lim_{kR\to 0} \hat{\mathbf{e}}_d^* \mathfrak{Im}\, \mathcal{G}_\mathrm{b}(\mathbf{r},\mathbf{r}',\omega)\hat{\mathbf{e}}_d \to \begin{cases} 1 & \text{for} \quad \hat{\mathbf{e}}_d \cdot \hat{\mathbf{e}}_R = 0 \\ 0 & \text{for} \quad \hat{\mathbf{e}}_d = \hat{\mathbf{e}}_R \end{cases} .$$

15.3.1.4 Dispersion relation in anisotropic media

A homogeneous medium can still be anisotropic if,

$$\epsilon(\mathbf{r},\omega) = \epsilon(\omega) \qquad \text{although} \qquad \epsilon(\omega)\cdot\hat{\mathbf{e}}_r \neq const\ . \tag{15.205}$$

Then, $\epsilon(\omega)$ and $\mu(\omega)$ still need to be represented by tensors, which however do not depend on coordinates. The Helmholtz equation then simplifies to,

$$\left[\nabla_\mathbf{r} \times \nabla_\mathbf{r} \times - \frac{\omega^2}{c^2}\mu(\omega)\epsilon(\omega)\right] \vec{\mathcal{E}}_\mathrm{b}(\mathbf{r},\omega) = \imath\omega\mu_0 \mathbf{j}(\mathbf{r},\omega)\ , \tag{15.206}$$

in analogy to (15.186). Assuming no currents, $\mathbf{j}(\mathbf{r},\omega) = 0$, and plane electromagnetic waves, $\vec{\mathcal{E}}_\mathrm{b}(\mathbf{r},\omega) = \vec{\mathcal{E}}_0(\omega)e^{\imath\mathbf{k}\cdot(\mathbf{r}-\mathbf{r}')}$, we obtain with the identity (15.189),

$$\begin{aligned} 0 &= \left[\nabla_\mathbf{r} \otimes \nabla_\mathbf{r} - \mathbb{I}\triangle - \frac{\omega^2}{c^2}\mu\epsilon\right] \vec{\mathcal{E}}_0 e^{\imath\mathbf{k}\cdot(\mathbf{r}-\mathbf{r}')} \\ &= \left[-\mathbf{k}\otimes\mathbf{k} + k^2 - \frac{\omega^2}{c^2}\mu\epsilon\right] \vec{\mathcal{E}}_0 e^{\imath\mathbf{k}\cdot(\mathbf{r}-\mathbf{r}')}\ , \end{aligned} \tag{15.207}$$

where $\mu\epsilon$ is to be understood as a product between two matrices. From this we derive the dispersion relation,

$$0 = \left| -k_i k_j + k^2\delta_{ij} - \frac{\omega^2}{c^2}(\mu)_{il}(\epsilon)_{lj} \right|\ , \tag{15.208}$$

for $i, j = x, y, z$.

We will discuss anisotropic homogeneous media in the context of hyperbolic metamaterials in Sec. 15.3.3.

15.3.1.5 Interaction between dipoles near dielectric media

The vector Green tensor describes the interaction between two points in space via an electromagnetic field. It can be used to solve a variety of problems, for example,

- the interaction between dipoles in free space;
- the modification of a dipole due to the presence of a dielectric boundary (Purcell effect);
- the modification of the interaction between dipoles due to the presence of a dielectric boundary.

The linearity of Maxwell's equations allows us to exploit the superposition principle applying it to the Green tensor. For example, we can express the interaction between two point dipoles $\mathbf{r}_1$ and $\mathbf{r}_2$ near a dielectric boundary by simply adding to the bulk tensor for their interaction in free space $\mathcal{G}_\mathrm{b}(\mathbf{r}_1, \mathbf{r}_2, \omega)$ a tensor $\mathcal{G}_\mathrm{d}(\mathbf{r}_1, \mathbf{r}_2, \omega)$ accounting for the presence of the dielectric,

$$\boxed{\mathcal{G} = \mathcal{G}_\mathrm{b} + \mathcal{G}_\mathrm{d}} \,. \tag{15.209}$$

See also Secs. 45.2.2 and 46.3.3 and Excs. 45.2.3.1 and 45.2.3.2.

15.3.2 Plasmons at metal-dielectric interfaces

A *surface plasmon polariton* (SPP) or simply *plasmon* is an electromagnetic wave in the infrared or visible spectral regime, which propagates along a metal-dielectric or metal-air interface. The term SPP explains that the wave involves both, the motion of charges in the metal and electromagnetic waves in the air or the dielectric.

SPPs are a type surface waves, guided along the interface in a similar way as light can be guided by an optical fiber. The wavelengths of SPPs are shorter than that of the incident light, which created them. Thus, they can be more localized and more intense. Perpendicularly to the interface, they are confined to the scale of a wavelength. The propagation of SPPs along the interface is limited by absorption losses in the metal or by photon scattering into other directions, e.g. into free space.

SPPs can be excited by electronic or photonic bombardment. For a photon to excite an SPP, both must have the same frequency and the same momentum. However, at a given frequency, a free space photon has less momentum than an SPP because the two have different dispersion relations (see below). Therefore, a photon coming from free space can not directly couple to an SPP. For the same reason, an SPP (on a perfectly smooth metal surface) can not emit photons into free space (assumed uniform). This incompatibility is analogous to the absence of transmission at total internal reflection.

However, the coupling of photons to SPPs can be achieved using a coupling medium, such as a dielectric or a grating, designed to match the wavevectors of photons and SPPs, until their momenta coincide. For example, a glass prism may

be positioned against a thin metal film in Kretschmann configuration, as shown in Fig. 15.19(a). Single insulated surface defects, such as isolated or periodic grooves, slits or elevations, provide a mechanism coupling free space radiation and SPPs, which then can exchange energy.

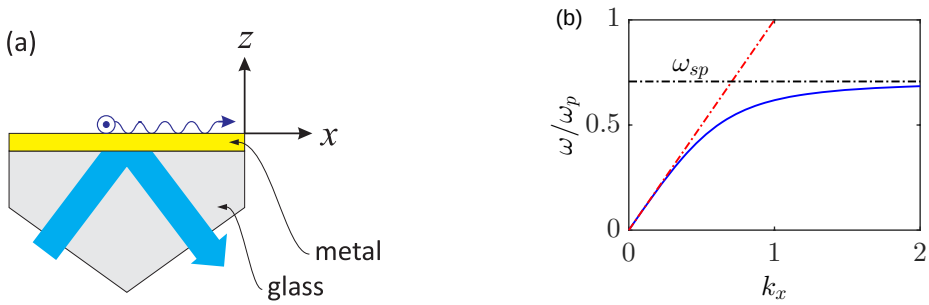

Figure 15.19: (code) (a) Kretschmann configuration of attenuated total reflection for the coupling of surface plasmons. The component of the scattered wavevector parallel to the surface forms SPPs, which then propagate along the metal-dielectric interface. (b) Dispersion curve for a SPP (blue). At low k_x it approaches the photonic dispersion curve (red).

15.3.2.1 Fields and plasmonic dispersion relation

The properties of a SPP can be derived from Maxwell's equations. Let $z > 0$ be the space occupied by the dielectric and $z < 0$ the space occupied by the metal. The electric and magnetic fields must obey Maxwell's equations and, in particular, the boundary conditions (15.42)(i-iv) at the interface. We will show in Exc. 15.3.7.2, that the fields must have the following form:

$$\boxed{\vec{\mathcal{H}}_n(\mathbf{r},t) = \begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix} \mathcal{H}_0 e^{\imath k_x x + \imath k_{z,n}|z| - \imath\omega t} \quad , \quad \vec{\mathcal{E}}_n(\mathbf{r},t) = \begin{pmatrix} \pm k_{z,n} \\ 0 \\ -k_x \end{pmatrix} \frac{\mathcal{H}_0}{\omega\varepsilon_n} e^{\imath k_x x + \imath k_{z,n}|z| - \imath\omega t}} \ , \tag{15.210}$$

under the condition that,

$$\frac{k_{z,\mathrm{m}}}{\varepsilon_\mathrm{m}} = -\frac{k_{z,\mathrm{d}}}{\varepsilon_\mathrm{d}} \ , \tag{15.211}$$

where n indicates the material ($n = \mathrm{m}$ for the metal and $n = \mathrm{d}$ for the dielectric). This condition guarantees the continuity of the electric field parallel to the boundary. Upper signs apply to the dielectric region ($z > 0$) and lower signs to the metallic region ($z < 0$). That is, SPPs are always transverse magnetic waves (TM). The wavevector $\mathbf{k}$ is complex. In case of a lossless SPP, the k_x component is real and the k_z component imaginary,

$$k_{z,m} = \imath\kappa_{z,\mathrm{m}} \ , \tag{15.212}$$

such that the wave propagates along the x-direction and decays exponentially toward $\pm z$. While k_x is always the same in both materials, $k_{z,\mathrm{m}}$ is generally different from

$k_{z,\mathrm{d}}$. Entering the fields (15.210) in the wave equation,

$$\nabla^2 \vec{\mathcal{H}}_n = \varepsilon_n \mu_n \frac{\partial^2 \vec{\mathcal{H}}_n}{\partial t^2} \ , \tag{15.213}$$

we easily verify that,

$$k_x^2 + k_{z,n}^2 = \omega^2 \varepsilon_n \mu_n = \epsilon_n \left(\frac{\omega}{c}\right)^2 \ , \tag{15.214}$$

where we assume $\mu_n = \mu_0$ and $\varepsilon_n = \varepsilon_0 \epsilon_n$, where the 'breve' denotes relative permittivities. Solving the two equations (15.214) for $n = \mathrm{m}, \mathrm{d}$ together with the relationship (15.211), we obtain the dispersion relation for a plasmon wave propagating on the surface,

$$\boxed{k_x = \frac{\omega}{c}\sqrt{\frac{\epsilon_\mathrm{d}\epsilon_\mathrm{m}}{\epsilon_\mathrm{d} + \epsilon_\mathrm{m}}}} \ . \tag{15.215}$$

To apply this relation in practice, we must specify the two permittivities ϵ_n. For simplicity, we assume $\epsilon_\mathrm{d} = 1$, and for ϵ_m we resort to the *Drude model* using (15.162), where for now we despise the attenuation $\Gamma_d = 0$,

$$\epsilon_m(\omega) = 1 - \frac{\omega_p^2}{\omega^2} \ , \tag{15.216}$$

where ω_p is the plasma frequency (15.163). Joining the expressions (15.215) and (15.216) we obtain,

$$ck_x = \sqrt{\frac{\omega^2 - \omega_p^2}{2\omega^2 - \omega_p^2}} \ . \tag{15.217}$$

This relationship is plotted in Fig. 15.19(b).

At low k_x, the SPP behaves like a photon, but as k_x increases, the dispersion relation becomes flatter and reaches an asymptotic limit ω_sp called 'surface plasma frequency'. If $\omega < \omega_\mathrm{sp}$, the SPP has a shorter wavelength than the radiation in the free space, such that the components $k_{z,\mathrm{m}}$ are purely imaginary and exhibit evanescent decay. The plasma frequency at the surface ($\epsilon_\mathrm{d} = 1$) is,

$$\omega_\mathrm{sp} = \lim_{k_x \to \infty} \omega = \frac{\omega_p}{\sqrt{2}} \ . \tag{15.218}$$

15.3.2.2 Absorption of plasmons

The formula (15.216) predicts $\varepsilon_\mathrm{m} < 0$ below the plasmon frequency. Electromagnetic waves propagating in metals suffer damping due to ohmic losses and interactions between the electrons and the atoms of the metallic lattice. These effects appear as an imaginary component of the dielectric function. To take this into account, we express the dielectric function of a metal in the complex plane,

$$\epsilon_\mathrm{m} = \epsilon'_\mathrm{m} + \imath \epsilon''_\mathrm{m} \ . \tag{15.219}$$

Generally, we have, $|\epsilon'_\mathrm{m}| \gg \epsilon''_\mathrm{m}$, such that the wavevector can be expressed in terms of its real and imaginary components as (see Exc. 15.3.7.3),

$$k_x = k'_x + \imath k''_x = \frac{\omega}{c}\sqrt{\frac{\epsilon_d \epsilon'_\mathrm{m}}{\epsilon_\mathrm{d} + \epsilon'_\mathrm{m}}} + \imath \frac{\omega}{c}\sqrt{\frac{\epsilon_d \epsilon'_\mathrm{m}}{\epsilon_\mathrm{d} + \epsilon'_\mathrm{m}}}^3 \frac{\epsilon''_\mathrm{m}}{2(\epsilon'_\mathrm{m})^2} \ . \tag{15.220}$$

The wavevector gives us insight into the physically significant properties of the electromagnetic wave, such as its spatial extent and mode matching conditions.

15.3.2.3 Distance of propagation and depth of penetration

As an SPP propagates along the surface, it loses energy to the metal due to absorption. The intensity of the surface plasmon decays with the square of the electric field, therefore, over a distance x, the intensity decreases by a factor of $e^{-2k_x x}$. The propagation length is defined as the distance, where the SPP intensity has decreased by a factor of $1/e$. This condition is satisfied at a length $L = \frac{1}{2k_x''}$.

Likewise, the electric field decays perpendicular to the surface of the metal. At low frequencies, the penetration depth of the SPP into the metal is commonly approximated using the skin depth formula. In a dielectric, the field will decay much more slowly. The decay depth in the metal and the dielectric medium can be expressed as

$$z_n = \frac{\lambda}{2\pi}\left(\frac{|\epsilon_{\mathrm{m}}'| + \epsilon_{\mathrm{d}}}{\epsilon_n^2}\right)^{1/2} , \tag{15.221}$$

where n indicates the propagation medium. SPPs are very sensitive to small perturbations within the skin depth and, therefore, are often used to probe surface inhomogeneities. Resolve the Exc. 15.3.7.4.

15.3.3 Negative refraction and metamaterials

The general dispersion relation for anisotropic media has been derived in (15.203),

$$\boxed{\left|\frac{\omega^2}{c^2}\epsilon_{il}\mu_{lj} - k^2\delta_{ij} + k_i k_j\right| = 0} , \tag{15.222}$$

which, for isotropic media simplifies to $\frac{\omega^2}{c^2}n^2 = k^2$, where $n^2 = \epsilon\mu$. Apparently, inverting the signs of both, the permittivity and the permeability, $\varepsilon, \mu < 0$ has no effect on the equations. However, one can show [937], that inserting into the first and second Maxwell equations,

$$\begin{aligned} \nabla \times \vec{\mathcal{H}} = \partial_t \vec{\mathcal{D}} \quad &, \quad \nabla \times \vec{\mathcal{E}} = -\partial_t \vec{\mathcal{B}} \\ \text{with} \quad \vec{\mathcal{D}} = \varepsilon \vec{\mathcal{E}} \quad &, \quad \vec{\mathcal{B}} = \mu \vec{\mathcal{H}} \end{aligned} \tag{15.223}$$

a plane wave, $\vec{\mathcal{E}}, \vec{\mathcal{D}}, \vec{\mathcal{B}}, \vec{\mathcal{H}} \propto e^{\imath(\mathbf{k}\cdot\mathbf{r} - \omega t)}$,

$$\mathbf{k} \times \vec{\mathcal{H}}_0 = -\omega\varepsilon\vec{\mathcal{E}}_0 \quad , \quad \mathbf{k} \times \vec{\mathcal{E}}_0 = \omega\mu\vec{\mathcal{H}}_0 , \tag{15.224}$$

one obtains for $\varepsilon, \mu > 0$, a right-handed triplet of vectors $\mathbf{k}$, $\vec{\mathcal{E}}$, $\vec{\mathcal{H}}$, whereas for $\varepsilon, \mu < 0$ one obtains a left-handed triplet. Defining the handedness via,

$$p \equiv \frac{(\mathbf{k} \times \vec{\mathcal{E}}) \cdot \vec{\mathcal{H}}}{|(\mathbf{k} \times \vec{\mathcal{E}}) \cdot \vec{\mathcal{H}}|} , \tag{15.225}$$

if $p = \pm 1$, we call the material is right(left)-handed. The energy flux,

$$\vec{\mathcal{S}} = \vec{\mathcal{E}} \times \vec{\mathcal{H}} \tag{15.226}$$

is parallel to $\mathbf{k}$ for right-handed materials and anti-parallel for left-handed, which means that phase and group velocities are reversed. Also, in left-handed materials we expect a reversed Doppler effect.

At the interface between two materials with different handednesses, $\varepsilon_1, \mu_1 > 0$ and $\varepsilon_2, \mu_2 < 0$, the equations (15.42) must still hold,

$$\begin{array}{ll} \text{(i)} & \vec{\mathcal{H}}_1^{\parallel} = \vec{\mathcal{H}}_2^{\parallel} \\ \text{(ii)} & \vec{\mathcal{E}}_1^{\parallel} = \vec{\mathcal{E}}_2^{\parallel} \\ \text{(iii)} & \varepsilon_1 \vec{\mathcal{E}}_1^{\perp} = \varepsilon_2 \vec{\mathcal{E}}_2^{\perp} \\ \text{(iv)} & \mu_1 \vec{\mathcal{H}}_1^{\perp} = \mu_2 \vec{\mathcal{H}}_2^{\perp} \end{array} . \tag{15.227}$$

but now, the signs of $\mathcal{E}_2^{\perp}$ and $\mathcal{H}_2^{\perp}$ are inverted. We calculate,

$$\vec{\mathcal{E}}_0 \times \vec{\mathcal{H}}_0 = \frac{1}{\omega\mu} \vec{\mathcal{E}}_0 \times (\mathbf{k} \times \vec{\mathcal{E}}_0) = \frac{1}{\omega\mu} [\mathbf{k}(\vec{\mathcal{E}}_0 \cdot \vec{\mathcal{E}}_0) - \vec{\mathcal{E}}_0(\mathbf{k} \cdot \vec{\mathcal{E}}_0)] = \frac{\mathcal{E}_0^2}{\omega\mu} \mathbf{k} \upuparrows -\vec{\mathcal{S}} . \tag{15.228}$$

As a consequence Snell's law (15.57) must be corrected,

$$\frac{\sin\theta_{\mathrm{t}}}{\sin\theta_{\mathrm{i}}} = \frac{n_1}{n_2} = \frac{p_2}{p_1} \left| \sqrt{\frac{\varepsilon_2 \mu_2}{\varepsilon_1 \mu_1}} \right| . \tag{15.229}$$

The *complex refractive index*,

$$n = n' + \imath n'' = c\sqrt{\varepsilon\mu} = c\sqrt{(\varepsilon' + \imath\varepsilon'')(\mu' + \imath\mu'')} = c\sqrt{|\varepsilon\mu|} e^{\imath\phi/2} \tag{15.230}$$

can have negative real part, $\mathfrak{Re}\, n < 0$, if the angle is $\phi > \pi$, that is, if,

$$\sin\phi = \frac{\mathfrak{Im}\, \varepsilon\mu}{|\varepsilon\mu|} = \frac{\varepsilon''\mu' + \varepsilon'\mu''}{|\varepsilon\mu|} < 0 . \tag{15.231}$$

Since the absorption is necessarily $\varepsilon'', \mu'' > 0$, the condition (15.231) is satisfied if $\varepsilon', \mu' < 0$. More generally, a sufficient but not necessary condition for *negative refraction* is,

$$\varepsilon'|\mu' + \imath\mu''| + \mu'|\varepsilon' + \imath\varepsilon''| < 0 . \tag{15.232}$$

The direction of the phase velocity is $\mathbf{k}$, while the energy flows along $\vec{\mathcal{S}} = \vec{\mathcal{E}} \times \vec{\mathcal{H}}$. For $n' > 0$ the dispersive medium is called *right-handed*, because $\mathbf{k}$, $\vec{\mathcal{E}}$ and $\vec{\mathcal{H}}$ form a tripod. For $n' < 0$ the medium is called *left-handed*, because $-\mathbf{k}$, $\vec{\mathcal{E}}$ and $\vec{\mathcal{H}}$ form a tripod, that is, $\mathbf{k}$ and $\vec{\mathcal{S}}$ are contrary. We will check this in Exc. 15.3.7.5. Such media are always very dispersive.

Left-handed media have attracted much attention, because of the theoretical possibility of performing *perfect lenses* with a focusing power not being limited by diffraction. Left-handed media are studied in non-homogeneous and non-isotropic *metamaterials* [21], but there are also ideas on how to design them in homogeneous and isotropic atomic gases [22]

[21] See [722, 723, 838, 600, 601, 603, 602, 724, 41, 906, 167, 136, 594, 837, 566].
[22] See Sec. 39.6 and Excs. 39.7.3.11 and 39.7.3.12 .

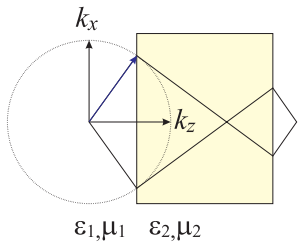

Figure 15.20: Refraction at the interface between 'right-handed' and 'left-handed' media.

15.3.3.1 Hyperbolic metamaterials

Hyperbolic metamaterials (HMM) are artificial media with sub-optical-wavelength nano-structuring, which exhibit unusual optical properties. In particular, they are characterized by extreme anisotropy, behaving like dielectrics when illuminated from one side and like metals when illuminated from another. As already mentioned in Sec. 15.3.1, in a hyperbolic metamaterial the dispersion relation is anisotropic, corresponding to permittivity and permeability tensors of the form,

$$\varepsilon = \begin{pmatrix} \varepsilon_\perp & & \\ & \varepsilon_\perp & \\ & & \varepsilon_{\shortparallel} \end{pmatrix} \quad \text{and} \quad \mu = \begin{pmatrix} \mu_\perp & & \\ & \mu_\perp & \\ & & \mu_{\shortparallel} \end{pmatrix} . \tag{15.233}$$

In the case $\varepsilon_\perp \varepsilon_{\shortparallel} < 0$ or $\mu_\perp \mu_{\shortparallel} < 0$ the dispersion relation,

$$\frac{k_x^2 + k_y^2}{\varepsilon_{\shortparallel}} + \frac{k_z^2}{\varepsilon_\perp} = \frac{(\omega/c)^2}{\varepsilon_0} , \tag{15.234}$$

becomes hyperbolic [23]. In Exc. 15.3.7.7 we derive from the Maxwell equations, allowing for an anisotropic (but homogeneous) permittivity tensor, the hyperbolic dispersion relation.

Example 111 (*Interest of hyperbolic metamaterials*): Hyperbolic metamaterials are investigated for their potential interest in engineering the decay routes of quantum emitters by manipulating the local density-of-states. The reason is, that HMMs allow for the propagation of modes with wavevectors (known as high-k modes) much higher than the free-space wavevector. Thus, the evanescent waves (also with high-k) of an emitter couple more easily to a sufficiently close HMM, and thus emitting their photons faster.
The elementary cells of a metamaterial are often complicated, and a *stratification* is helpful to describe its response to incident light. For example, many features of an HMM can be grasped by frequency-dependent effective permittivity and permeability tensors.

[23] Note that a more correct treatment would need to account for the polarizations of the electric and magnetic fields. We leave this to an upcoming version of the script.

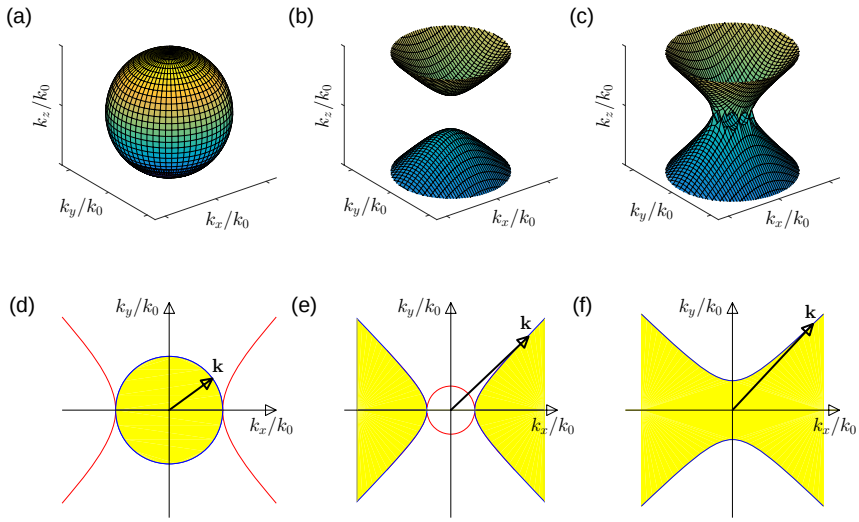

Figure 15.21: Isofrequency surfaces of hyperbolic dispersion relations. (a) Isotropic dielectric ($\varepsilon_\perp = \varepsilon_{\shortparallel}$); (b) two-sheeted hyperboloid ($\varepsilon_\perp < 0$ and $\varepsilon_{\shortparallel} > 0$); (c) one-sheeted hyperboloid ($\varepsilon_\perp > 0$ and $\varepsilon_{\shortparallel} < 0$). (d-f) Projection of the two-dimensional isofrequency surfaces shown in (a-c) on the $k_y = 0$ plane. The yellow-shaded areas correspond to lossy regions (real parts).

In Exc. 15.3.7.8 we show, that the effective permittivity of a nanostructure having the shape of a stack of alternating intrinsically homogeneous layers with permittivities ε_d and ε_m and thicknesses $d_\mathrm{d}, d_\mathrm{m} \ll \lambda$ [see Fig. 15.22(b)] is given by [796],

$$\varepsilon_{\shortparallel} = \frac{\varepsilon_\mathrm{d} d_\mathrm{d} + \varepsilon_\mathrm{m} d_\mathrm{m}}{d_\mathrm{d} + d_\mathrm{m}} \qquad \text{and} \qquad \frac{1}{\varepsilon_\perp} = \frac{d_\mathrm{d}/\varepsilon_\mathrm{d} + d_\mathrm{m}/\varepsilon_\mathrm{m}}{d_\mathrm{d} + d_\mathrm{m}} \ . \tag{15.235}$$

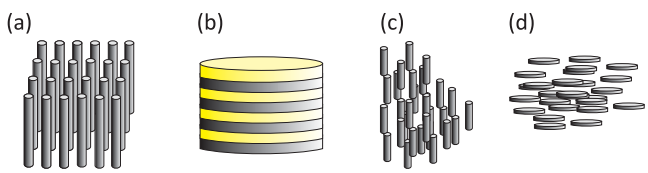

Figure 15.22: Hyperbolic dispersion materials. In order to achieve a negative permittivity in a given direction, the electrons must move freely along it, like in a metal.

Example 112 (*Anisotropy of a metamaterial*): For example, choosing $d_\mathrm{m} = d_\mathrm{d}$, $\varepsilon_\mathrm{d} = 1$ and $\varepsilon_\mathrm{m} = -2$, we obtain $\varepsilon_{\shortparallel} = \frac{1}{4}$ and $\varepsilon_\perp = -\frac{1}{2}$.

In Exc. 15.3.7.9 we discuss, whether it is possible to realize a hyperbolic dispersion relation in an atomic gas.

15.3.4 Wave guides

The presence of conductive interfaces influences the propagation of electromagnetic waves. Interfaces, which influence the propagation direction of electromagnetic waves are called *waveguides*. Let us consider a waveguide such as the one illustrated in Figs. 15.23. In the volume enclosed by the waveguide, supposedly perfectly conductive ($\vec{\mathcal{E}} = 0 = \vec{\mathcal{B}}$ inside the wave guide material), every electromagnetic field must satisfy the boundary conditions (15.42), that is, we have,

$$\boxed{\vec{\mathcal{E}}^{\parallel} = 0 \qquad \text{and} \qquad \vec{\mathcal{B}}^{\perp} = 0} \tag{15.236}$$

on all interior surfaces of the waveguide. Free surface charges and currents will automatically be generated in such a way as to endorse these conditions, and all conclusions derived in the following sections are basically corollaries of these boundary conditions.

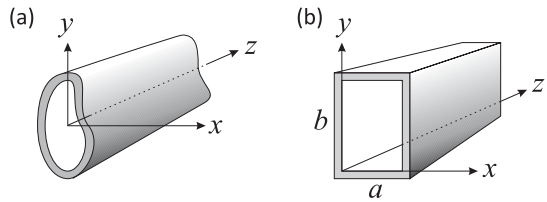

Figure 15.23: Waveguides of arbitrarily (i) and rectangular (ii) shape.

Let us now consider monochromatic waves propagating along a tube oriented in z-direction,

$$\vec{\mathcal{E}}(x,y,z,t) = \vec{\mathcal{E}}(x,y)e^{\imath(k_z z-\omega t)} \qquad \text{and} \qquad \vec{\mathcal{B}}(x,y,z,t) = \vec{\mathcal{B}}(x,y)e^{\imath(k_z z-\omega t)} \ . \tag{15.237}$$

Obviously, the $\vec{\mathcal{E}}$ and $\vec{\mathcal{B}}$ fields must simultaneously satisfy the vacuum Maxwell equations (14.6) inside the guide and the boundary conditions (15.236). To implement these conditions, we reformulate Maxwell's equations. We insert (15.237) and the expansions $\vec{\mathcal{E}}(x,y) = \sum_{k=x,y,z} \mathcal{E}_k(x,y)\hat{\mathbf{e}}_k$ and $\vec{\mathcal{B}}(x,y) = \sum_{k=x,y,z} \mathcal{B}_k(x,y)\hat{\mathbf{e}}_k$ in the Maxwell equations (14.6)(i) and (ii) and obtain,

$$\begin{array}{llllllll}
\text{(i)} & \partial_y\mathcal{E}_z - \imath k_z\mathcal{E}_y & = & \imath\omega\mathcal{B}_x & \text{(ii)} & \partial_y\mathcal{B}_z - \imath k_z\mathcal{B}_y & = & -\imath\frac{\omega}{c^2}\mathcal{E}_x \\
\text{(iii)} & \imath k_z\mathcal{E}_x - \partial_x\mathcal{E}_z & = & \imath\omega\mathcal{B}_y & \text{(iv)} & \imath k_z\mathcal{B}_x - \partial_x\mathcal{B}_z & = & -\imath\frac{\omega}{c^2}\mathcal{E}_y \\
\text{(v)} & \partial_x\mathcal{E}_y - \partial_y\mathcal{E}_x & = & \imath\omega\mathcal{B}_z & \text{(vi)} & \partial_x\mathcal{B}_y - \partial_y\mathcal{B}_x & = & -\imath\frac{\omega}{c^2}\mathcal{E}_z \ .
\end{array} \tag{15.238}$$

Inserting the component $\mathcal{B}_y$ of the third into the second equation, the $\mathcal{B}_x$ of the first into the fourth equation, the $\mathcal{E}_y$ of the fourth into the first equation, and the $\mathcal{E}_x$ of the second in the third equation, we arrive at,

$$\begin{array}{ll}
\text{(i)} & \mathcal{E}_x = \frac{\imath}{(\omega/c)^2-k_z^2}(k_z\partial_x\mathcal{E}_z + \omega\partial_y\mathcal{B}_z) \\
\text{(ii)} & \mathcal{E}_y = \frac{\imath}{(\omega/c)^2-k_z^2}(k_z\partial_y\mathcal{E}_z - \omega\partial_x\mathcal{B}_z) \\
\text{(iii)} & \mathcal{B}_x = \frac{\imath}{(\omega/c)^2-k_z^2}(k_z\partial_x\mathcal{B}_z - \frac{\omega}{c^2}\partial_y\mathcal{E}_z) \\
\text{(iv)} & \mathcal{B}_y = \frac{\imath}{(\omega/c)^2-k_z^2}(k_z\partial_y\mathcal{B}_z + \frac{\omega}{c^2}\partial_x\mathcal{E}_z) \ .
\end{array} \tag{15.239}$$

And inserting these equations into Maxwell's equations (iii) and (iv), we arrive at,

$$\left[\frac{\partial^2}{\partial x^2}+\frac{\partial^2}{\partial y^2}+(\omega/c)^2-k_z^2\right]\mathcal{E}_z=0=\left[\frac{\partial^2}{\partial x^2}+\frac{\partial^2}{\partial y^2}+(\omega/c)^2-k_z^2\right]\mathcal{B}_z\ . \tag{15.240}$$

Hence, we can solve the waveguide problem by first solving the wave equations for the components $\mathcal{E}_z$ and $\mathcal{B}_z$ and then inserting the solutions into Eqs. (15.239) in order to obtain the other field components.

When $\mathcal{E}_z = 0$ we call these waves *transverse electric waves* (TE), when $\mathcal{B}_z = 0$ we call them *transverse magnetic waves* (TM), and when $\mathcal{E}_z = 0 = \mathcal{B}_z$ we call them *transverse electro-magnetic waves* (TEM). TEM waves can not exist in a hollow waveguide, as we will show in Exc. 15.3.7.10.

15.3.4.1 Waveguide with constant rectangular cross section

Here, we consider the transmission of TE waves through a waveguide of constant rectangular cross-section, as shown in Fig. 15.23(ii). Similarly to the procedure for solving the Laplace equation in electrostatics, we make a separation ansatz for the variables in a way suggested by the symmetry of the problem, that is, we assume the existence of two functions X and Y, such that inserting the ansatz

$$\mathcal{E}_z=0 \qquad \text{and} \qquad \mathcal{B}_z=X(x)Y(y)\ , \tag{15.241}$$

in the wave equation,

$$Y\frac{d^2X}{dx^2}+X\frac{d^2Y}{dy^2}+[(\omega/c)^2-k_z^2]=0\ , \tag{15.242}$$

leaves us with,

$$\frac{1}{X}\frac{d^2X}{dx^2}=-k_x^2 \quad \text{and} \quad \frac{1}{Y}\frac{d^2Y}{dy^2}=-k_y^2 \quad \text{with} \quad -k_x^2-k_y^2+(\omega/c)^2-k_z^2=0\ . \tag{15.243}$$

$\mathcal{B}_x$ must vanish on the surfaces at $x = 0, a$ and, because of (15.239)(iii) $\partial_x\mathcal{B}_z$ as well, such that $dX/dx = 0$, that is, X is a cosine. In the same way, $\mathcal{B}_y$ must vanish on the surfaces at $y = 0, b$, such that Y is a cosine. Therefore, the solution is,

$$\mathcal{B}_z=\mathcal{B}_0\cos k_x x\cos k_y y \qquad \text{with} \qquad k_x=\tfrac{m\pi}{a} \qquad \text{and} \qquad k_y=\tfrac{n\pi}{b}\ . \tag{15.244}$$

With this, the wavevector becomes,

$$k_z=\sqrt{(\omega/c)^2-\pi^2[(m/a)^2+(n/b)^2]}\ . \tag{15.245}$$

Consequently, the frequency must be higher than,

$$\omega>c\pi\sqrt{(m/a)^2+(n/b)^2}\equiv\omega_{mn}\ , \tag{15.246}$$

to avoid exponentially attenuated fields. The frequency ω_{mn} is called *cut-off frequency*. The components $\mathcal{B}_x$ and $\mathcal{B}_y$ can be determined from (15.239)(iii) and (iv),

$$\boxed{\begin{aligned} \vec{\mathcal{E}} &= \mathcal{E}_0 \begin{pmatrix} \frac{\imath\omega k_y}{k_x^2+k_y^2}\cos k_x x \sin k_y y \\ \frac{-\imath\omega k_x}{k_x^2+k_y^2}\sin k_x x \cos k_y y \\ 0 \end{pmatrix} e^{\imath(k_z z-\omega t)} \\ \vec{\mathcal{B}} &= \mathcal{B}_0 \begin{pmatrix} \frac{\imath k_z k_x}{k_x^2+k_y^2}\sin k_x x \cos k_y y \\ \frac{\imath k_z k_y}{k_x^2+k_y^2}\cos k_x x \sin k_y y \\ \cos k_x x \cos k_y y \end{pmatrix} e^{\imath(k_z z-\omega t)} \end{aligned}} \quad . \tag{15.247}$$

Inserting ω_{mn} in the dispersion relation (15.245), we notice that the formula for the phase propagation velocity,

$$c = \frac{\omega}{k_z} = \frac{c}{\sqrt{1-(\omega_{mn}/\omega)^2}} > c \ , \tag{15.248}$$

predicts a velocity above the speed of light. However, the group velocity,

$$v_g = \frac{1}{dk_z/d\omega} = c\sqrt{1-(\omega_{mn}/\omega)^2} < c \ , \tag{15.249}$$

is slower. Resolve Exc. 15.3.7.11 and 15.3.7.12 [24].

15.3.5 The coaxial line

We have already mentioned the possibility of TEM waves in a *coaxial waveguide*, as shown in Fig. 15.24. Inserting $\mathcal{E}_z = 0 = \mathcal{B}_z$ in the equations (15.238) we obtain,

$$\begin{aligned} c\mathcal{B}_y = \mathcal{E}_x \qquad & \text{and} \qquad c\mathcal{B}_x = -\mathcal{E}_y \\ \partial_x\mathcal{E}_y - \partial_y\mathcal{E}_x = \quad 0 \quad & = \partial_x\mathcal{B}_y - \partial_y\mathcal{B}_x \quad , \\ \partial_x\mathcal{E}_x + \partial_y\mathcal{E}_y = \quad 0 \quad & = \partial_x\mathcal{B}_x + \partial_y\mathcal{B}_y \end{aligned} \tag{15.250}$$

where we join the Maxwell equations (iii) and (iv) in the last line. In Exc. 15.3.7.13 we will show that,

$$\vec{\mathcal{E}}(\rho,\phi,z,t) = \frac{A\cos(k_z z-\omega t)}{\rho}\hat{\mathbf{e}}_\rho \qquad \text{and} \qquad \vec{\mathcal{B}}(\rho,\phi,z,t) = \frac{A\cos(k_z z-\omega t)}{c\rho}\hat{\mathbf{e}}_\phi \ , \tag{15.251}$$

satisfies Maxwell's equations. Solve Exc. 15.3.7.14.

[24] Rectangular waveguides are used, for example, in radio detection and ranging (RADAR) systems to guide microwave signals from a synthesizer to an antenna.

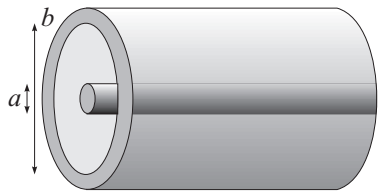

Figure 15.24: Guia de onda coaxial.

15.3.6 Cavities

An *optical resonator* consists of an arrangement of mirrors reflecting light beams in such a way as to form a closed path. Light which entered the cavity carries out many round-trips before it is transmitted again through a (partially reflecting) mirror, scattered out of the cavity mode or absorbed by impurities in the mirrors. Thus, the light power is considerably increased. That is, cavities can store light. Do Exc. 15.3.7.15 to 15.3.7.17.

In order to resonate in a cavity, a light beam must satisfy the boundary condition, that the mirror surfaces coincide with nodes of the standing light wave formed by the beam and its reflections at the mirrors. Therefore, in a cavity of length L, only a discrete spectrum of wavelengths $N\lambda/2 = L$ can be resonantly amplified, where N is a natural number. Because of this property, cavities are often used as frequency filters or optical spectrum analyzers: Only frequencies close to $\nu = N\delta_{\text{fsr}}$ are transmitted, where $\delta_{\text{fsr}} = c/2L$ is the called the *free spectral range* of the cavity.

A cavity is characterized on one hand by its geometry, that is, the curvature and the distance of its mirrors, and on the other hand by its finesse, which is given by the reflectivity of its mirrors. Let us first study the finesse and postpone the discussion of its geometry to Sec. 15.4.1. Treating the cavity as a multiple path interferometer (or *Fabry-Perot cavity*), we can derive an expression for the reflected and transmitted intensity as a function of frequency,

$$(k + \Delta k)L = \frac{(\omega_c + \Delta)L}{c} = \frac{\omega_c + \Delta}{2\delta_{\text{fsr}}} = \pi N + \frac{\Delta}{2\delta_{\text{fsr}}} \,. \tag{15.252}$$

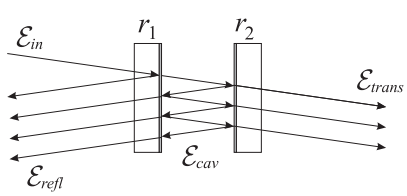

Figure 15.25: Multiple interference in an optical cavity of two mirrors characterized by reflectivities $r_{1,2}$.

The so-called *Airy formulas* for reflection and transmission are,

$$\boxed{\begin{aligned} I_{\text{refl}} &= I_{\text{in}} \frac{(2F/\pi)^2 \sin^2(\Delta/2\delta_{\text{fsr}})}{1+(2F/\pi)^2 \sin^2(\Delta/2\delta_{\text{fsr}})} \\ I_{\text{trns}} &= I_{\text{in}} \frac{1}{1+(2F/\pi)^2 \sin^2(\Delta/2\delta_{\text{fsr}})} \end{aligned}} \,, \tag{15.253}$$

where $R = |r|^2$ is the reflectivity of a mirror and Δ the detuning between the laser and the cavity (in radians/s). We will derive the formulas in Exc. 15.3.7.18 and 15.3.7.19. The transmission curve of the cavity has a finite bandwidth κ_{int}, which depends on the reflectivity of the mirrors. The *finesse* of the cavity is defined by,

$$F \equiv \frac{2\pi\delta_{\text{fsr}}}{\kappa_{\text{int}}} = \frac{\pi\sqrt{R}}{1-R} \,. \tag{15.254}$$

Note that δ_{fsr} is given in terms of a real frequency, while κ_{int} is a radiant [25].

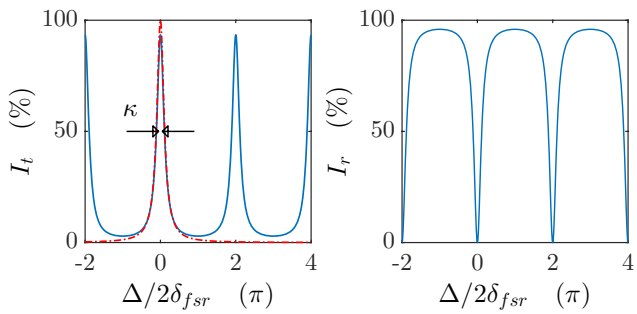

Figure 15.26: (code) Transmission and reflection of a resonator. The chosen mirror reflectivities are $R = 70\%$, the absorption losses $S = 1\%$. The red dash-dotted line is the Lorentzian approximation. Apparently, it fails off resonance.

The Airy formula was derived under the assumption of plane waves, but this assumption is not always realistic. Indeed, as we will show in Sec. 15.4.1, light propagates in transversely delimited modes and is subject to diffraction. We will see, that the resonance of a cavity not only depends on the order number N of the *longitudinal mode*, but also on the order of the *transverse mode*. The free space modes are TEM-modes.

15.3.6.1 Damping of the cavity

The decay time τ of the cavity is defined by the number of 'round-trips' with reflections at both mirrors R_1 and R_2, that a light beam can do before its intensity falls to e^{-1} of its original value [997](p.148):

$$I(\tau) = I_0 \sqrt{R_1 R_2}^{\,c\tau/2L} \stackrel{!}{=} e^{-1} I_0 \,. \tag{15.255}$$

[25] Note, that κ_{int} is defined as the FWHM of the intensity transmission curve.

Letting $R_1 = R_2 = 1 - T$, this yields,

$$\tau = \frac{2L}{c}\frac{\ln e^{-1}}{\ln R_1 R_2} = \frac{1}{\delta_{\rm fsr}}\frac{-1}{\ln(1-T)^2} \simeq \frac{1}{\delta_{\rm fsr}}\frac{1}{2T} \tag{15.256}$$
$$= \frac{1}{2\delta_{\rm fsr}}\frac{1}{1-\sqrt{R_1 R_2}} \simeq \frac{F}{2\pi\delta_{\rm fsr}} = \frac{1}{\kappa_{\rm int}} \ ,$$

approximating $\sqrt{R} \simeq 1$. Hence, $\kappa_{\rm int}$ has also the meaning of a intensity decay constant [26].

Example 113 (*Use of transfer matrices in cavities*): The transfer matrix formalism can be used for *impedance matching* the reflection of optical cavities [27]. In order to deserve the label *mode*, a geometric configuration of a cavity must be self-consistent, that is, any field $\mathcal{E}^{\pm}(z)$ wanting to fill the mode must be the same after a round-trip around the cavity.
We proceed to calculating the real and imaginary parts of the transfer matrices,

$$\begin{pmatrix} \mathcal{E}_z^+ + \mathcal{E}_z^- \\ \mathcal{E}_z^+ - \mathcal{E}_z^- \end{pmatrix} = \mathcal{M} \begin{pmatrix} \mathcal{E}_0^+ + \mathcal{E}_0^- \\ \mathcal{E}_0^+ - \mathcal{E}_0^- \end{pmatrix} \ .$$

For example, the phase shift due to free space propagation is described by the matrix,

$$\mathcal{M}_{\rm phase} = \begin{pmatrix} \cos kz & \imath \sin kz \\ \imath \sin kz & \cos kz \end{pmatrix} \ .$$

Reflection and transmission from a classical object with can be written as, $\vec{\mathcal{E}}_z^+ = t_a \mathcal{E}_0^+ + r_a \vec{\mathcal{E}}_z^-$ and $\mathcal{E}_0^- = t_a \vec{\mathcal{E}}_z^- - r_a \mathcal{E}_0^+$, where $r_a^2 + t_a^2 = 1$. Transforming to the basis $\mathcal{E}_j^+ \pm \mathcal{E}_j^-$, we obtain,

$$\mathcal{M}_{\rm pump} = \begin{pmatrix} \frac{1+r_a}{t_a} & 0 \\ 0 & \frac{1-r_a}{t_a} \end{pmatrix} \ .$$

Let us assume that the cavity is pumped from one side by the field $\mathcal{E}_{\rm in}$. We get after a round-trip,

$$\begin{pmatrix} \mathcal{E}^+ + \mathcal{E}^- \\ \mathcal{E}^+ - \mathcal{E}^- \end{pmatrix} = \mathcal{M} \begin{pmatrix} \mathcal{E}^+ + \mathcal{E}^- \\ \mathcal{E}^+ - \mathcal{E}^- \end{pmatrix} + t_{\rm in} \begin{pmatrix} \mathcal{E}_{\rm in}^+ + \mathcal{E}_{\rm in}^- \\ \mathcal{E}_{\rm in}^+ - \mathcal{E}_{\rm in}^- \end{pmatrix} = t_{\rm in}(1-\mathcal{M})^{-1} \begin{pmatrix} \mathcal{E}_{\rm in}^+ + \mathcal{E}_{\rm in}^- \\ \mathcal{E}_{\rm in}^+ - \mathcal{E}_{\rm in}^- \end{pmatrix} \ .$$

The phase minimum of the determinant $\det(1-\mathcal{M})$ determines the eigenvalues of the cavity. For a round-trip with losses in the mirrors the determinant is $\det(1 - \mathcal{M}_{\rm phase}\mathcal{M}_{loss}) = 2 - (t_c + t_c^{-1})\cos\phi$, where t_c is the total transmission coefficient of the cavity. Phase minima always occur when $\phi = 2\pi n$. The amplification of the intensity at theses phases is given by,

$$\frac{I_{\rm cav}}{I_{\rm in}} = \frac{|\mathcal{E}^+ + \mathcal{E}^-|^2}{|\mathcal{E}_{\rm in}^+ + \mathcal{E}_{\rm in}^-|^2} = \frac{t_{\rm in}^2}{(1-t_c)^2} \ .$$

Do the Exc. 15.3.7.20.

[26] It should not be confused with the electric field *amplitude* decay rate defined as $\kappa = \kappa_{\rm int}/2$.

[27] Not to be confused with *phase matching* of optical cavities, which is an important requirement for coupling light efficiently into a cavity, but must be treated within the theory of Gaussian optics.

15.3.7 Exercises

15.3.7.1 Ex: Green function for vector Helmholtz equation

Derive the expression (15.194) in Cartesian coordinates.

15.3.7.2 Ex: The fields of a plasmon

From the ansatz,

$$\vec{\mathcal{H}}_n(\mathbf{r},t) = \begin{pmatrix} 0 \\ \mathcal{H}_{y,n} \\ 0 \end{pmatrix} e^{\imath k_x x + \imath k_{z,n}|z| - \imath\omega t}$$

for a plasmonic wave, with $n = \mathrm{m}$ in the metallic region ($z < 0$) and $n = \mathrm{d}$ in the dielectric region ($z > 0$), construct the electric and magnetic fields on both sides of a metal-dielectric interface.

15.3.7.3 Ex: Absorption of plasmons

Derive the expression (15.220).

15.3.7.4 Ex: Poynting vector of plasmons

At the interface between the vacuum and a metal surface there live solutions of the Maxwell equations, which decay exponentially in z-direction. We consider in this exercise only those parts of the waves, which live on the vacuum side $z > 0$, as illustrated in Fig. 15.19(a). The magnetic field, in this scheme, takes the following form:

$$\vec{\mathcal{H}}(\mathbf{r},t) = \begin{pmatrix} 0 \\ \mathcal{H}_0 \\ 0 \end{pmatrix} \cos(kx - \omega t) e^{-\kappa z} \ (z > 0) \ .$$

a. Derive with the help of Maxwell's equation $\nabla \times \vec{\mathcal{H}} - \frac{\partial \vec{\mathcal{D}}}{\partial t} = \mathbf{j}$ the corresponding electric field $\vec{\mathcal{E}}(\mathbf{r},t)$ in the half-space $z > 0$.
b. Calculate the Poynting vector $\vec{\mathcal{S}}(\mathbf{r},t)$ in the half-space $z > 0$.
c. Calculate the total energy flow in x-direction. To do this, calculate the average over an oscillation period and integrate over the half-space $z > 0$.

15.3.7.5 Ex: Negative refraction

Show that a medium with negative refractive index is left-handed and allows for perfect focusing.

15.3.7.6 Ex: Negative refraction in chiral media

In a *chiral medium* the electric polarization $\vec{\mathcal{P}}$ couples to the magnetic field $\vec{\mathcal{H}}$ of an electromagnetic wave and the magnetization $\vec{\mathcal{M}}$ couples to the electric field $\vec{\mathcal{E}}$ like,

$$\vec{\mathcal{P}} = \varepsilon_0 \chi_\varepsilon \vec{\mathcal{E}} + \tfrac{1}{c}\xi_{EH}\vec{\mathcal{H}} \qquad \text{and} \qquad \vec{\mathcal{M}} = \tfrac{1}{c}\xi_{HE}\vec{\mathcal{E}} + \chi_m \vec{\mathcal{H}} \ ,$$

where ξ_{EH} and ξ_{HE} are the complex chirality coefficients. Show that a chiral medium allows for a negative refraction coefficient.

15.3.7.7 Ex: Hyperbolic metamaterials

Hyperbolic metamaterials are artificial media with sub-wavelength nanostructuring below exhibiting uncommon optical properties, such as an extreme anisotropy giving rise to permittivity and permeability tensors of the form,

$$\epsilon = \begin{pmatrix} \varepsilon_\perp & & \\ & \varepsilon_\perp & \\ & & \varepsilon_{\shortparallel} \end{pmatrix} \qquad \text{and} \qquad \mu = \begin{pmatrix} \mu_\perp & & \\ & \mu_\perp & \\ & & \mu_{\shortparallel} \end{pmatrix} \ .$$

In the case $\varepsilon_\perp \varepsilon_{\shortparallel} < 0$ or $\mu_\perp \mu_{\shortparallel} < 0$ the dispersion relation,

$$\frac{k_x^2 + k_y^2}{\varepsilon_{\shortparallel}} + \frac{k_z^2}{\varepsilon_\perp} = \frac{(\omega/c)^2}{\varepsilon_0} \ ,$$

becomes hyperbolic.
Derive from the Maxwell equations, allowing for an anisotropic (but homogeneous) permittivity tensor, the hyperbolic dispersion relation.

15.3.7.8 Ex: Stacked layer metamaterial

Show that the effective permittivity of a nanostructure having the shape of an alternating stack of two different but intrinsically homogenous layers with the permittivity ε_d and ε_m and thicknesses $d_d, d_m \ll \lambda$ is given by,

$$\varepsilon_\perp = \frac{\varepsilon_d d_d + \varepsilon_m d_m}{d_d + d_m} \qquad \text{and} \qquad \varepsilon_{\shortparallel} = \frac{d_d/\varepsilon_d + d_m/\varepsilon_m}{d_d + d_m} \ .$$

15.3.7.9 Ex: Hyperbolic dispersion relation in gases

Discuss, whether it is possible to realize a hyperbolic dispersion relation in an atomic gas.

15.3.7.10 Ex: TEM waves in a hollow wave guide

Verify that TEM waves can not occur in hollow waveguides. Do not use the already derived results (15.239).

15.3.7.11 Ex: The TE_{00} mode in the rectangular waveguide

Show that the TE_{00} mode can not occur in a rectangular waveguide.

15.3.7.12 Ex: Cut-off frequency

Calculate the radial size of a hollow rectangular wave guide capable of guiding a (i) 60 Hz signal, (ii) a 10 MHz signal, and (iii) a 9.1 GHz signal.

15.3.7.13 Ex: Cylindrical waveguide

Show that the fields (15.251) satisfy the Maxwell equations with the boundary conditions (15.236) [386](p.411).

15.3.7.14 Ex: Propagation of a TEM mode along a coaxial cable

A transmission line made of two concentric circular metallic cylinders with conductivity ρ and skin depth δ is filled with a lossless uniform dielectric (ε, μ). A TEM mode propagates along this line.
a. Show that the time averaged energy flux along the line is,

$$P = \sqrt{\frac{\mu}{\varepsilon}} \pi a^2 |\mathcal{H}_0|^2 \ln \frac{b}{a} \ ,$$

where H_0 is the maximum value of the azimuthal magnetic field on the surface of the inner conductor.
b. Show that the transmitted power is attenuated along the line like,

$$P(z) = P_0 e^{-2\gamma z} \ ,$$

where,

$$\gamma = \frac{1}{2\sigma\delta} \sqrt{\frac{\varepsilon}{\mu}} \frac{a^{-1} + b^{-1}}{ln(b/a)} \ .$$

c. The characteristic impedance Z_0 of the line is defined as the ratio between the voltage between the cylinders and the current flowing in axial direction inside one of the cylinders at any position z. Show that for this line,

$$Z_0 = \frac{1}{2\pi} \sqrt{\frac{\mu}{\varepsilon}} \ln \frac{b}{a} \ .$$

d. Show that the resistance and the serial inductance per unit length of the line are,

$$R = \frac{1}{2\pi\sigma\delta} \left(\frac{1}{a} + \frac{1}{b} \right) \quad , \quad L = \frac{\mu}{2\pi} \ln \frac{b}{a} + \frac{\mu_c \delta}{4\pi} \left(\frac{1}{a} + \frac{1}{b} \right) \ ,$$

where μ_c is the permeability of the conductor. The correction for the inductance comes from the penetration of the flux into the conductors by the distance of the order δ.

15.3.7.15 Ex: Resonant cavity

Consider a perfectly conducting resonant cavity having the shape of a 3D rectangular box with the volume defined by $x \in [0, L_x]$, $y \in [0, L_y]$, and $z \in [0, L_z]$. Show that the resonant frequencies for both the TE and TM modes are given by $\omega_{n_x,n_y,n_z} = c\pi\sqrt{(n_x/L_x)^2 + (n_y/L_y)^2 + (n_z/L_z)^2}$ for integers n_i. Find the associated electric and magnetic fields.

15.3.7.16 Ex: Spherical holes in conductors such as cavities

A spherical hole of radius a in a conductive medium may serve as an electromagnetic resonant cavity.
a. Assuming infinite conductivity, determine the transcendental equations for the characteristic frequencies $\omega_{\ell m}$ of the cavity for TE and TM modes.
b. Calculate numerical values for the wavelength $\lambda_{\ell m}$ in units of the radius a for the four lowest modes for TE and TM waves.
c. Explicitly calculate the electric and magnetic fields inside the cavity for the lowest TE mode and the lowest TM mode.

15.3.7.17 Ex: Schumann resonances

A resonant cavity consists of the void space between two perfectly conducting and concentric spherical layers. The smaller one has the external radius a, the larger one the internal radius b. The azimuthal magnetic field has a radial dependence given by spherical Bessel functions, $j_\ell(kr)$ and $n_\ell(kr)$, where $k = \omega/c$.
a. Write the transcendental equation for the characteristic frequencies of the cavity for arbitrary ℓ.
b. For $\ell = 1$ use the explicit forms of the spherical Bessel functions to show that the characteristic frequencies are given by,

$$\frac{\tan kh}{kh} = \frac{k^2 + (ab)^{-1}}{k^2 + ab(k^2 - a^{-2})(k^2 - b^{-2})} \ ,$$

where $h = b - a$.
c. For $h/a \ll 1$, verify that the result of part (b) reproduces the frequency found in [473], Sec. 8.9, and determine the first-order corrections in h/a.
Now, we apply this cavity as a model for the atmosphere enclosed by the Earth's surface and its ionosphere.
d. For the Schumann resonances of Sec. 8.9 calculate the values Q under the assumption that the Earth has the conductivity σ_e and the ionosphere the conductivity σ_i with corresponding skin depths δ_e and δ_i. Show that in the lowest order in h/a the value Q is given by $Q = Nh/(\delta_e + \delta_i)$ and determine the numerical factor N for all ℓ.
e. For the lowest Schumann resonance evaluate the value Q assuming $\sigma_e = 0.1\ (\Omega m)^{-1}$, $\sigma_e = 10^{-5}\ (\Omega m)^{-1}$, $h = 100$ km.
f. Discuss the validity of the approximations used in part (a) for the parameter regime used in part (b).

15.3.7.18 Ex: Airy formula

To derive the *Airy formulas*, consider a light field described by $\mathcal{E}_{\text{in}}$ incident on a Fabry-Pérot cavity of length L. The cavity mirrors are glass substrates having a surface with dielectric coating. The surfaces of the two mirrors are characterized by the transmission rates t_1, t_2 and reflection rates r_1, r_2. Note, that the reflected wave suffers a phase shift of π, when the reflection occurs at a denser medium $n > 1$. Disregard energy losses by absorption.

15.3.7.19 Ex: Airy formula for ring cavities

Derive the Airy formula for a ring cavity with one input coupler of reflectivity r and N high reflecting mirrors of reflectivity 1. Calculate the resonant enhancement factor.

15.3.7.20 Ex: Linear cavity via transfer matrices

Derive the Airy formula using the *transfer matrix formalism* introduced in Sec. 15.1.7.

15.4 Beam and wave optics

While the propagation of high wavelength radiation is dominated by diffraction effects, we observe that visible light tends to form bundles that apparently propagate (in homogeneous media) in a straight line. With the invention of the laser, the optical regime has become the preferred spectral regime for many spectroscopic applications. Therefore, we will dedicate the following section to the propagation of laser beams, which is understood within the theory of Gaussian optics.

15.4.1 Gaussian optics

At first glance, one might think that the propagation of laser light is well described by the laws of geometrical optics. Closer inspection, however, shows that a laser beam in many ways behaves more like a wave, although its energy is concentrated near an optical axis. The fields satisfy the wave equation. By inserting the propagating wave $u = \psi_z(x, y)e^{\imath(kz-\omega t)}$, we obtain an equation similar to the Schrödinger equation [526],

$$0 = \left[\frac{1}{c^2}\frac{\partial^2}{\partial t^2} - \nabla^2\right]\psi e^{\imath(kz-\omega t)} = e^{\imath(kz-\omega t)}\left(2\imath k\frac{\partial\psi}{\partial z} - \nabla^2\psi\right) . \tag{15.257}$$

In the so-called *paraxial approximation*, we neglect the second derivative for z, we obtain,

$$\left[2\imath k\frac{\partial}{\partial z} - \left(\frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2}\right)\right]\psi = 0 . \tag{15.258}$$

To describe a Gaussian beam, we choose an exponential ansatz and introduce two parameters that may vary along the propagation axis z: $\varphi(z)$ is a complex phase shift

and $q(z)$ a complex parameter, whose imaginary part describes the diameter of the beam. Inserting the ansatz

$$\psi = e^{-\imath\left[\varphi(z)+k(x^2+y^2)/2q(z)\right]} \tag{15.259}$$

into the Schrödinger equation, we obtain,

$$\begin{aligned} 0 = 2\imath k e^{-\imath[\varphi+k(x^2+y^2)/2q]}\left(-\imath\frac{\partial\varphi}{\partial z}+\frac{\imath k(x^2+y^2)}{2q^2}\frac{\partial q}{\partial z}\right) - 2e^{-\imath[\varphi+k(x^2+y^2)/2q]}\frac{-\imath k}{q} \\ - e^{-\imath[\varphi+k(x^2+y^2)/2q]}\left(\frac{-\imath kx}{q}\right)^2 - e^{-\imath[\varphi+k(x^2+y^2)/2q]}\left(\frac{-\imath ky}{q}\right)^2 . \end{aligned} \tag{15.260}$$

This leads directly to the equation,

$$0 = (q'-1)\frac{\imath k(x^2+y^2)}{q^2} - 2\imath\varphi' + \frac{2}{q} . \tag{15.261}$$

For Eq. (15.261) to be valid at all x and y, we need $q' = 1$ and $\varphi' = \frac{-\imath}{q}$. Integrating q', we find,

$$q(z) = q_0 + z . \tag{15.262}$$

It is practical to introduce real beam parameters

$$\boxed{\frac{1}{q} \equiv \frac{1}{R} - \imath\frac{\lambda}{\pi w^2}} . \tag{15.263}$$

Inserting this into the ansatz (15.259),

$$\psi = e^{-\imath\varphi - \imath\frac{k(x^2+y^2)}{2R^2} - \frac{(x^2+y^2)}{w^2}} , \tag{15.264}$$

it becomes clear that $R(z)$ is the radius of curvature and $w(z)$ is the diameter of the beam. Evaluating q_0 at the position of the focus (beam waist), where $R = \infty$, we get from (15.262) along with the definition (15.263),

$$\frac{1}{\frac{1}{R_z} - \imath\frac{\lambda}{\pi w_z^2}} = q(z) = q_0 + z = \frac{1}{\frac{1}{\infty} - \imath\frac{\lambda}{\pi w_0^2}} + z = \imath\frac{\pi w_0^2}{\lambda} + z , \tag{15.265}$$

The separation of this result into a real part and an imaginary part gives,

$$\frac{z}{R} + \frac{w_0^2}{w^2} = 1 \qquad \text{and} \qquad \frac{\pi w^2}{\lambda R} = \frac{\lambda z}{\pi w_0^2} . \tag{15.266}$$

Solving the second equation for $1/R$ and replacing this in the first equation gives an equation for w,

$$\boxed{w^2 = w_0^2\left[1 + \left(\frac{\lambda z}{\pi w_0^2}\right)^2\right]} . \tag{15.267}$$

This expression can now be replaced in the second equation,

$$\boxed{R = z\left[1 + \left(\frac{\pi w_0^2}{\lambda z}\right)^2\right]} . \tag{15.268}$$

We call $z_R \equiv q_0$ the *Rayleigh length*. Now we integrate φ',

$$\varphi = \int_0^z \frac{-\imath}{q} dz = \int_0^z \frac{-\imath dz}{\imath z_R + z} = -\imath \int_0^z \frac{z dz}{z_R^2 + z^2} - \int_0^z \frac{z_R dz}{z_R^2 + z^2} \tag{15.269}$$
$$= -\frac{\imath}{2} \ln \frac{z_R^2 + z^2}{z_R^2} - \arctan \frac{z}{z_R} = -\imath \ln \frac{w}{w_0} - \arctan \frac{\lambda z}{\pi w_0^2} \ .$$

Hence,

$$\boxed{\psi(\mathbf{r}) = \frac{w_0}{w} e^{\imath \arctan(-z/q_0) - \imath k(x^2+y^2)/2q}} \ . \tag{15.270}$$

We note that the function $|\psi|^2$ is normalized by the radial integral,

$$\int |\psi|^2 dxdy = \frac{w_0^2}{w^2} \int |e^{-k(x^2+y^2)/2q(z)}|^2 dxdy \tag{15.271}$$
$$= \frac{w^2}{w_0^2} \left(\int_{-\infty}^{\infty} e^{-2x^2/w^2} dx \right)^2 = \frac{\pi w_0^2}{2} \ ,$$

which is independent of z and thus ensures conservation of energy along the beam. The intensity profile of a Gaussian beam is proportional to $|\psi|^2$ and normalized to the total power P, that is,

$$\boxed{I(\mathbf{r}) = \frac{2P}{\pi w_0^2} |\psi(\mathbf{r})|^2 = \frac{2P}{\pi w(z)^2} e^{-2(x^2+y^2)/w(z)^2}} \ . \tag{15.272}$$

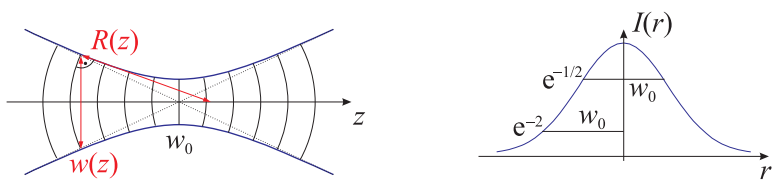

Figure 15.27: (Left) Propagation of the beam along the optical axis. (Right) Cross section of the Gaussian beam.

The above treatment shows that modes do not only exist in cavities but also in free space. In Excs. 15.4.4.1 and 15.4.4.2 we are dealing with modes of Gaussian light beams that are often used in laser beam optics.

Example 114 (*Gaussian optics*): The expansion of the Gaussian beam $\mathcal{E}(\mathbf{r}) = \mathcal{E}_0 e^{-(x^2+y^2)/w(z)^2 - z^2/z_R^2}$ into plane waves simply is,

$$\mathcal{E}(\mathbf{k}) = \int \mathcal{E}(\mathbf{r}) e^{\imath \mathbf{k}\cdot\mathbf{r}} d^3r = \mathcal{E}_0 e^{-(k_x^2+k_y^2)w(z)^2 - k_z^2 z_R^2} \ .$$

15.4.1.1 Optical components

In *geometrical optics* (or ray optics) we work a lot with *transfer matrices* $\mathcal{M}$ defined by their feature of transforming the two-component vector, which consists of the distance of a ray from the optical axis $y(z)$ and its divergence $y'(z)$ [28]:

$$\begin{pmatrix} y(z) \\ y'(z) \end{pmatrix} = \mathcal{M} \begin{pmatrix} y(0) \\ y'(0) \end{pmatrix} . \tag{15.273}$$

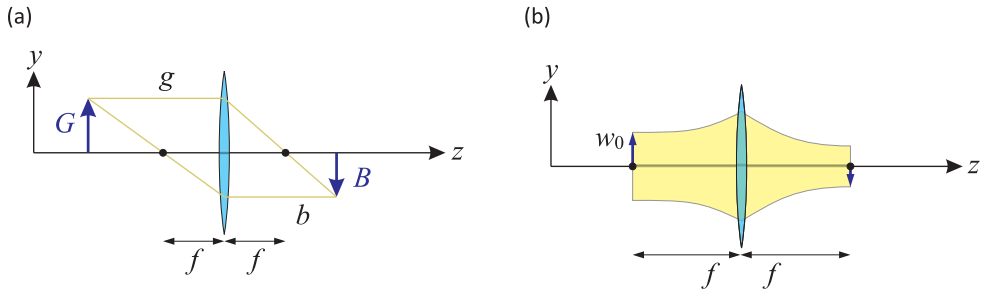

Figure 15.28: (a) Image formation through a lens with ray optics. (b) Focusing a laser beam with Gaussian optics.

Now, it is possible to show that the same matrix $\mathcal{M}$ can describe the transformation of a Gaussian beam through optical components along the optical axis, provided that we apply the transformation to the beam parameter q in the following way:

$$\boxed{q(z) = \frac{M_{11}q(0) + M_{12}}{M_{21}q(0) + M_{22}}} . \tag{15.274}$$

Hence, the transfer matrices allow us to calculate, how the parameters R and w transform along the optical axis through optical elements or in free propagation. The most common optical elements are lenses, crystals, prisms, mirrors, and cavities. For example, the matrix for free propagation of a beam over a distance d is,

$$\mathcal{M}_{dist} = \begin{pmatrix} 1 & d \\ 0 & 1 \end{pmatrix} , \tag{15.275}$$

and the matrix describing the passage through a thin lens with focal length f,

$$\mathcal{M}_{\text{lens}} = \begin{pmatrix} 1 & 0 \\ -1/f & 1 \end{pmatrix} . \tag{15.276}$$

In Exc. 15.4.4.3 we use these matrices to derive the lens equations in ray optics and Gaussian optics.

[28] Note that these matrices have nothing to do with the matrices describing the transmission and reflection of electric and magnetic fields by interfaces.

15.4.1.2 Modes of a linear cavity

We will now apply the formalism of the transfer matrices to calculate the modal structure of a linear cavity. Let $\mathcal{M}$ be the matrix describing the round-trip of a beam of light in the cavity. For the cavity to be stable, the fields must be stationary. This is only possible if the mode geometry is self-consistent. That is, at any position z, the beam parameter $q(z) = q_z$ must satisfy [526],

$$q_z = \frac{M_{11}q_z + M_{12}}{M_{21}q_z + M_{22}} \ . \tag{15.277}$$

Using, $M_{11}M_{22} - M_{12}M_{21} = 1$, the condition (15.277) can be solved by,

$$\frac{1}{q_z} = \frac{M_{22} - M_{11}}{2M_{12}} \pm \frac{\imath}{2M_{12}}\sqrt{4 - (M_{11} + M_{22})^2} \ , \tag{15.278}$$

or separating the real part from the imaginary part according to the definition (15.263) of the beam parameter,

$$w_z^2 = \frac{2\lambda M_{12}}{\pi\sqrt{4 - (M_{11} + M_{22})^2}} \qquad \text{and} \qquad R_z = \frac{2M_{12}}{M_{22} - M_{11}} \ . \tag{15.279}$$

Figure 15.29: (code) (Left) Scheme of a linear cavity. (Right) Radial profiles of the lowest order transverse Hermite-Gaussian modes TEM_{mn} of a linear cavity.

We now consider the cavity of length L schematized in Fig. 15.29. It consists of two mirrors with radii of curvature ρ_a and ρ_b. The transfer matrix for a round-trip beginning and ending at the position of mirror 'a' is,

$$\begin{aligned}\mathcal{M} &= \begin{pmatrix} 1 & 0 \\ -1/f_a & 1 \end{pmatrix}\begin{pmatrix} 1 & L \\ 0 & 1 \end{pmatrix}\begin{pmatrix} 1 & 0 \\ -1/f_\mathrm{b} & 1 \end{pmatrix}\begin{pmatrix} 1 & L \\ 0 & 1 \end{pmatrix} \\ &= \frac{1}{f_a f_\mathrm{b}}\begin{pmatrix} f_a(f_\mathrm{b} - L) & f_a L(2f_\mathrm{b} - L) \\ L - f_\mathrm{b} - f_a & L(L - 2f_\mathrm{b}) + f_a(f_\mathrm{b} - L) \end{pmatrix} \ ,\end{aligned} \tag{15.280}$$

where $f_k = -\rho_k/2$ are the focal lengths of the mirrors. With (15.279) we obtain the diameter w_a and the radius of curvature R_a of the beam at the position of the mirror 'a',

$$w_a^2 = \frac{2\lambda f_a L(2f_\mathrm{b} - L)}{\pi\sqrt{4f_a^2 f_\mathrm{b}^2 - (L^2 - 2f_a L - 2f_\mathrm{b} L + 2f_a f_\mathrm{b})^2}} \qquad \text{and} \qquad R_a = -2f_a \ . \tag{15.281}$$

Applying the second equation (15.266), we find,

$$\frac{\lambda a}{\pi w_0^2} = \frac{\pi w_a^2}{\lambda R_a} = \frac{L(2f_\mathrm{b} - L)}{\sqrt{4f_a^2 f_\mathrm{b}^2 - (L^2 - 2f_a L - 2f_\mathrm{b} L + 2f_a f_\mathrm{b})^2}} \ , \tag{15.282}$$

and analogously for $\lambda b/\pi w_0^2$. We replace $f_k = \rho_k/2$ and introduce the abbreviation,

$$x_a \equiv \frac{\pi w_a^2}{\lambda R_a} = \frac{\frac{2L}{\rho_a}\left(1 - \frac{L}{\rho_\mathrm{b}}\right)}{\sqrt{1 - \left(1 - \frac{2L}{\rho_a} - \frac{2L}{\rho_\mathrm{b}} + \frac{2L^2}{\rho_a \rho_\mathrm{b}}\right)^2}} \ , \tag{15.283}$$

and analogously for x_b. With the help of MAPLE we calculate,

$$\frac{x_a x_\mathrm{b} - 1}{\sqrt{(1 + x_a^2)(1 + x_\mathrm{b}^2)}} = \sqrt{1 - \frac{L}{\rho_a}}\sqrt{1 - \frac{L}{\rho_\mathrm{b}}} \ . \tag{15.284}$$

The phase shift between the waist of the beam and mirror 'a' is given by the real part of the formula (15.269). The phase shift accumulated between the mirrors 'a' and 'b' is,

$$\begin{aligned} \varphi = \varphi_a + \varphi_\mathrm{b} &= \arctan x_a + \arctan x_\mathrm{b} \\ &= \pi - \arccos \frac{x_a x_\mathrm{b} - 1}{\sqrt{1 + x_a^2}\sqrt{1 + x_\mathrm{b}^2}} = \pi - \arccos \sqrt{1 - \frac{L}{\rho_a}}\sqrt{1 - \frac{L}{\rho_\mathrm{b}}} \ , \end{aligned} \tag{15.285}$$

where we used tabulated trigonometric relationships to convert the arctan into a arccos.

The spectrum of transverse modes follows from the condition, that the total phase is a multiple of π, i.e.,

$$N = \frac{kL + \varphi}{\pi} = \frac{2L\nu}{c} + \frac{\varphi}{\pi} \ , \tag{15.286}$$

that is,

$$\boxed{\frac{\nu}{\delta_\mathrm{fsr}} = N - 1 + \frac{1}{\pi} \arccos \sqrt{\left(1 - \frac{L}{\rho_a}\right)\left(1 - \frac{L}{\rho_\mathrm{b}}\right)}} \ , \tag{15.287}$$

where we used the *free spectral range* $\delta_\mathrm{fsr} \equiv c/2L$. This formula represents a generalization of the previously derived formula (15.252), which only holds in the limit of plane waves, $\rho_k \to \infty$.

The diameter of the beam waist in the cavity is,

$$w_0 = \sqrt[4]{\left(\frac{\lambda}{\pi}\right)^2 \frac{L(\rho_a - L)(\rho_\mathrm{b} - L)(\rho_a + \rho_\mathrm{b} - L)}{(\rho_a + \rho_\mathrm{b} - 2L)^2}} \ . \tag{15.288}$$

For optimum coupling, the geometries of the Gaussian light beam and of the cavity must be matched, i.e. the diameter and divergence of the laser beam must be adjusted to the cavity mode, e.g. using a suitable arrangement of lenses. In Exc. 15.4.4.4, we will extend the calculation to ring cavities.

15.4.1.3 Hermite-Gaussian transverse modes

We can generalize the ansatz (15.259) to allow for more complicated radial intensity distributions described by the functions g and h,

$$\psi = g\left(\frac{x}{w}\right) h\left(\frac{y}{w}\right) e^{-\imath\left[\varphi(z)+k(x^2+y^2)/2q(z)\right]} \ . \tag{15.289}$$

Inserting the ansatz into the equation (15.258), we will show in Exc. 15.4.4.5, that the solution is given by,

$$\psi(x,y,z) = \frac{w_0}{w} H_m\left(\frac{\sqrt{2}x}{w}\right) H_n\left(\frac{\sqrt{2}y}{w}\right) e^{\imath(m+n+1)\arctan\frac{2z}{kw_0^2} - r^2\left(\frac{1}{w^2}+\frac{\imath k}{2R}\right)} \ . \tag{15.290}$$

Fig. 15.29(right) shows radial profiles of the lowest order transverse Hermite-Gaussian modes TEM_{mn} of a linear cavity.

In the presence of higher-order transverse modes TEM_{mn} the cavity spectrum becomes,

$$\boxed{\frac{\nu}{\delta_{\mathrm{fsr}}} = N - 1 + \frac{m+n+1}{\pi} \arccos\sqrt{\left(1-\frac{L}{\rho_a}\right)\left(1-\frac{L}{\rho_{\mathrm{b}}}\right)}} \ . \tag{15.291}$$

This formula can be derived using the self-consistency requirement for the light beam circulating inside the cavity. It represents yet another generalization of the formula (15.252) and lifts the degeneracy of the longitudinal modes described by the Airy formula and exhibited in Fig. 15.26. On the other hand, a *confocal cavity* with degenerate transverse modes, $\rho_a = \rho_{\mathrm{b}} = L$, is particularly suited to work as a spectrum analyzer, as we will show in Exc. 55.1.10.8.

15.4.1.4 Splitting of TEM_{mn} modes having the same $m+n$

In a cylindrically symmetric mode, all modes TEM_{mn} with the same $m+n$ are degenerate. If however cylindrical symmetry is broken, e.g. due to alignment imperfection or in the case of a ring cavity, the degeneracy is lifted [847]. If the problem of tilted incidence of the beams onto a mirror surface can be boiled down to assuming elliptically shaped mirrors, i.e. mirrors having different radii of curvatures in two orthogonal axis, the different phase shifts for the two axis can be calculated, as discussed in Exc. 15.4.4.4 and in Ref. [304]:

$$\nu/\delta_{\mathrm{fsr}} = (q+1) + 2\frac{2m+1}{2\pi}\phi_h + 2\frac{2n+1}{2\pi}\phi_v \ . \tag{15.292}$$

where $\phi_k = \arccos\sqrt{\left(1-\frac{2a}{\rho_k}\right)\left(1-\frac{b}{\rho_k}\right)}$ for $k = h, v$. The splitting between the TEM_{01} and TEM_{10} modes is,

$$\tfrac{2}{\pi}\arccos\sqrt{\left(1-\tfrac{2a}{\rho_h}\right)\left(1-\tfrac{b}{\rho_h}\right)} - \tfrac{2}{\pi}\arccos\sqrt{\left(1-\tfrac{2a}{\rho_v}\right)\left(1-\tfrac{b}{\rho_v}\right)} \ . \tag{15.293}$$

The splitting observed for ring cavities is on the same order as the free spectra range.

Furthermore, different phase shifts in the dielectric surfaces lead to different resonance conditions [576]. Since, according to Fresnel's formulas, s and p-polarized light fields have different reflectivities under inclined incidence on mirrors, they also suffer different phase shifts and, hence, exhibit different eigenfrequencies of the cavity. In high-finesse ring cavities this leads to a dramatic splitting of s and p-polarized modes, which can be on the order of the free spectral range itself.

15.4.2 Non-Gaussian beams

The Hermite-Gaussian ansatz (15.289) to solve the wave equation represents only one possibility. But we nowadays know a large variety of beams with different transverse distributions of intensity, polarization and angular momentum. Examples are transverse Gaussian modes with Cartesian or circular symmetry, Bessel modes, Laguerre-Gaussian modes with angular momentum, and modes with radial or azimuthal polarization.

15.4.2.1 Bessel beams

Ideally, a *Bessel beam* (BB) is a non-diffracting monochromatic solution to the scalar wave equation in cylindrical coordinates carrying an infinite amount of energy [283, 628]. Inserting into the wave equation,

$$\left(\frac{1}{c^2}\frac{\partial^2}{\partial t^2} - \nabla^2\right)\psi(\mathbf{r},t) = 0 \tag{15.294}$$

the ansatz,

$$\psi(\mathbf{r},t) = e^{\imath(\beta z-\omega t)}\int_0^{2\pi} A(\phi)e^{\imath\alpha(x\cos\phi+y\sin\phi)}d\phi \ , \tag{15.295}$$

we get the dispersion relation,

$$\alpha^2+\beta^2 = \frac{\omega^2}{c^2} \ . \tag{15.296}$$

For β real the intensity profile does not vary along the z-axis,

$$|\psi(\mathbf{r},t)|^2 = \left|\int_0^{2\pi} A(\phi)e^{\imath\alpha(x\cos\phi+y\sin\phi)}d\phi\right|^2 = |\psi(x,y,z=0,t)|^2 \ . \tag{15.297}$$

For axial symmetry $A(\phi)=A$, we get what is called the 2st type 0-order Bessel beam,

$$\psi(\mathbf{r},t) = Ae^{\imath(\beta z-\omega t)}\int_0^{2\pi} e^{\imath\alpha(x\cos\phi+y\sin\phi)}d\phi = Ae^{\imath(\beta z-\omega t)}J_0(\alpha\rho) \ . \tag{15.298}$$

For $0<\alpha\leq\omega/c$ we get a non-trivial solution decaying like $(\alpha\rho)^{-1}$.

In its simplest form, the electric field of an arbitrary ν-th order BB with wavelength λ can be written as,

$$\mathcal{E}(\rho,\phi,z) = A_0\exp(\imath k_z z)J_\nu(k_\rho\rho)\exp(\imath\nu\phi) \ , \tag{15.299}$$

where A_0 is the electric field strength and J_ν is the ν-th order Bessel function of the first kind. In Eq. (15.299), k_z and k_ρ are the longitudinal and transverse wave numbers satisfying the dispersion relation $k^2 = k_z^2 + k_\rho^2 = (2\pi/\lambda)^2$, such that $k_z = k\cos\theta$ and $k_\rho = k\sin\theta$, being θ the axicon angle associated to the tilted plane of waves propagating along the surface of a cone of half-angle θ in the angular spectrum decomposition. Cylindrical coordinates (ρ, ϕ, z) have been adopted, and a time harmonic factor $e^{\imath\omega t}$ has been omitted for brevity. For our purposes, the Rayleigh range is an essential parameter to be considered since the non-diffracting beam must propagate through a 20 cm long differential vacuum tube to minimize losses of atoms during their guidance to the science chamber. The maximum propagation distance up to which a BB can overcome diffraction is given by $Z_{max} = 2\pi R\bar{r}/\lambda$, where R is the aperture radius and $\bar{r}$ is the beam radius [283]. It should be noticed that, in general, Z_{max} is much greater than the Rayleigh range of a Gaussian beam with an equivalent beam waist radius $w_g = \bar{r}$.

Example 115 (*Frozen Bessel beams*): Certain superposition of these non-diffracting Bessel beams have interesting properties,

$$\psi(\mathbf{r}, t) = e^{-\imath\omega t} \sum_{n=-N}^{N} A_n J_0(k_{\rho n}\rho) e^{\imath\beta_n z} \ . \tag{15.300}$$

A *frozen Bessel beam* can be constructed by a continuous superposition of 0th-order scalar BBs over the longitudinal wavenumber k_z, as given by the following integral solution of the scalar Helmholtz equation with azimuthal symmetry,

$$\Psi_0(\rho, z, t) = e^{-\imath\omega t} \int_{-k}^{k} S(k_z) J_0(\rho\sqrt{k^2 - k_z^2}) e^{-\imath k_z z} dk_z \ , \tag{15.301}$$

where $k \equiv \omega/c$ and $k_\rho^2 \equiv \omega^2/c^2 - k_z$ is the transverse wave number. The quantity k_ρ^2 must be positive since evanescent waves do come into play.
Higher-order Bessel beams can be constructed via [1009, 1008],

$$\Psi_1(\rho, \phi, z) = \mathcal{U}\Psi_0(\rho, z) \qquad \text{with} \qquad \mathcal{U} \equiv e^{\imath\phi}\left(\frac{\partial}{\partial\rho} + \frac{\imath}{\rho}\frac{\partial}{\partial\phi}\right) \ , \tag{15.302}$$

Apparently, they can carry angular orbital momentum.

15.4.3 Fourier optics

We have derived in Sec. 5.3.5 the Fresnel integral for the description of the propagation of phase fronts. In the following sections we will show that the expression can also be derived from the more general Huygens principle, and how they can be used for numerical calculations of phase front propagation. We will also show how it can be used for numerical calculations of phase front propagation.

15.4.3.1 Rayleigh-Sommerfeld solution

We consider the propagation of monochromatic light from a 2D planar source of area Σ indicated by the coordinates ξ and η, as illustrated in Fig. 15.30. The field distribution in the source plane is given by $\psi_0(\xi, \eta)$, and the field $\psi_z(x, y)$ in a distant

observation plane can be predicted using the first Rayleigh-Sommerfeld diffraction solution [366, 939],

$$\boxed{\psi_z(x,y) = \frac{1}{\imath\lambda}\iint\limits_{\Sigma} \frac{z}{r_{12}}\frac{e^{\imath k r_{12}}}{r_{12}}\psi_0(\xi,\eta)d\xi d\eta} \ . \tag{15.303}$$

The formula will be derived from the wave equation in Exc. 15.4.4.6. Here, z is the distance between the centers of the source and observation coordinate systems and

$$r_{12} = \sqrt{z^2 + (x-\xi)^2 + (y-\eta)^2} \tag{15.304}$$

is the distance between a position on the source plane and a position in the observation plane, with the planes assumed to be parallel.

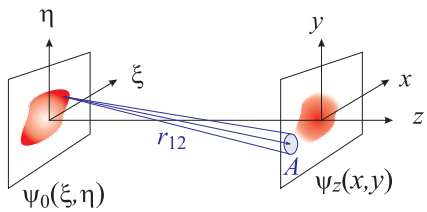

Figure 15.30: Propagation geometry for parallel source and observation planes. Every point of the source plane generates a spherical wave $\propto e^{\imath k r_{12}}/r_{12}$. The projection of the field within a solid angle element onto the xy-plane, which is proportional to z/r_{12} generates a new spherical wave propagating further along the z optical axis.

Expression (15.303) is a statement of the *Huygens-Fresnel principle*, which supposes that the source acts as an infinite collection of fictitious point sources located at (ξ,η), each one producing a spherical wave. The interference of the spherical waves at any observation position (x,y), expressed by the projection onto the propagation axis z in (15.303), can be written as a two-dimensional convolution integral,

$$\psi_z(x,y) = \iint\limits_{\Sigma} h_z(x-\xi, y-\eta)\psi_0(\xi,\eta)d\xi d\eta = (h_z * \psi_0)(x,y) \ , \tag{15.305}$$

where the general form of the *Rayleigh-Sommerfeld impulse response*,

$$h_z(x,y) = \frac{z}{\imath\lambda}\frac{e^{\imath k r}}{r^2} \ , \tag{15.306}$$

where $r = \sqrt{z^2 + x^2 + y^2}$ is simply the field distribution $\psi_z(x,y)$ observed in case of a point-like source $\psi_0(\xi,\eta) = \delta(\xi)\delta(\eta)$.

The Fourier convolution theorem allows to write Eq. (15.305) as,

$$\psi_z(x,y) = \mathcal{F}^{-1}\{\mathcal{F}[h_z * \psi_0](x,y)\} = \mathcal{F}^{-1}\{\mathcal{F}[h_z(x,y)]\mathcal{F}[\psi_0(x,y)]\} \ , \tag{15.307}$$

where $\mathcal{F}$ denotes the two-dimensional Fourier transform. Introducing the *Rayleigh-Sommerfeld transfer function* H_z, we may also write,

$$\boxed{\begin{array}{rrcl} & \psi_z(x,y) & = & \mathcal{F}^{-1}\{H_z(f_x,f_y)\cdot\mathcal{F}[\psi_0(x,y)]\} \\ \text{where} & H_z(f_x,f_y) & = & e^{\imath k z\sqrt{1-(\lambda f_x)^2-(\lambda f_y)^2}} \end{array}} \ . \tag{15.308}$$

Strictly speaking, $\sqrt{f_x^2 + f_y^2} < \lambda^{-1}$ must be satisfied for propagating field components. The Rayleigh-Sommerfeld expression is the most accurate diffraction solution as, other than the assumption of scalar diffraction, this solution only requires that $r \gg \lambda$, the distance between the source and the observation position, be much greater than a wavelength.

15.4.3.2 Fresnel approximation

Let us simplify the transfer function by expanding the distance (15.304),

$$r_{12} \simeq z + \tfrac{1}{2}\tfrac{(x-\xi)^2}{z} + \tfrac{1}{2}\tfrac{(y-\eta)^2}{z} \ , \tag{15.309}$$

which amounts to assuming a parabolic radiation wave rather than a spherical wave for the fictitious point sources. Furthermore, we use the approximation $r_{12} \simeq z$ in the denominator of Eq. (15.303) to arrive at the Fresnel diffraction expression:

$$\boxed{\psi_z(x,y) = \frac{e^{\imath kz}}{\imath\lambda z} \iint_\Sigma e^{\imath k[(x-\xi)^2+(y-\eta)^2]/2z} \psi_0(\xi,\eta) d\xi d\eta} \ . \tag{15.310}$$

This expression is also a convolution of the form in Eq. (15.305), where the impulse response is,

$$h_z(x,y) = \frac{e^{\imath kz}}{\imath\lambda z} e^{\imath k\rho^2/2z} \ , \tag{15.311}$$

and the transfer function is,

$$H_z(f_x, f_y) = e^{\imath kz} e^{-\imath\pi z\lambda(f_x^2+f_y^2)} \ . \tag{15.312}$$

The expressions in Eqs. (15.308) are again applicable in this case for computing diffraction results.

Another useful form of the Fresnel diffraction expression is obtained by moving the quadratic phase term in x and y outside the integrals:

$$\psi_z(x,y) = \frac{e^{\imath kz}}{\imath\lambda z} e^{\imath k(x^2+y^2)/2z} \iint_\Sigma e^{\imath k(\xi^2+\eta^2)/2z} e^{-\imath k(x\xi+y\eta)/z} \psi_0(\xi,\eta) d\xi d\eta \ . \tag{15.313}$$

15.4.3.3 Fraunhofer approximation

Fraunhofer diffraction, which refers to diffraction patterns in a regime that is commonly known as the 'far field', is arrived at by approximating the chirp term multiplying the initial field within the integrals of Eq. (15.313) as unity. The assumption involved is,

$$z \gg \max[\tfrac{k}{2}(\xi^2+\eta^2)] \tag{15.314}$$

and results in the Fraunhofer diffraction expression:

$$\boxed{\begin{aligned} \psi_z(x,y) &= \frac{e^{\imath kz}}{\imath\lambda z} e^{\imath k\rho^2/2z} \iint_\Sigma e^{-\imath k(x\xi+y\eta)/z} \psi_0(\xi,\eta) d\xi d\eta \\ &= \frac{e^{\imath kz}}{\imath\lambda z} e^{\imath\frac{k}{2z}\rho^2} (\mathcal{F}\psi_0)(\tfrac{kx}{z}, \tfrac{ky}{z}) \end{aligned}} \ . \tag{15.315}$$

Along with multiplicative factors out front, the Fraunhofer expression can be recognized simply as a Fourier transform of the source field. The condition of Eq. (15.314), typically, requires very long propagation distances relative to the source support size. However, a form of the Fraunhofer pattern also appears in the propagation analysis involving lenses. The Fraunhofer diffraction expression is a powerful tool and finds use in many applications such as laser beam propagation, image analysis, and spectroscopy.

The Fraunhofer expression cannot be written as a convolution integral, so there is no impulse response or transfer function. But, since it is a scaled version of the Fourier transform of the initial field, it can be relatively easy to calculate, and as with the Fresnel expression, the Fraunhofer approximation is often used with success in situations where Eq. (15.314) is not satisfied. For simple source structures such as a plane-wave illuminated aperture, the Fraunhofer result can be useful even when Eq. (15.314) is violated by more than a factor of 10, particularly if the main quantity of interest is the irradiance pattern at the receiving plane. Using the *Fresnel number* defined as,

$$N_{\mathrm{F}} = \frac{\max(\xi^2 + \eta^2)}{z\lambda} \ , \tag{15.316}$$

the commonly accepted requirement for the Fraunhofer region is $N_{\mathrm{F}} \ll 1$.

15.4.3.4 Diffraction limit and Rayleigh criterion

In Exc. 15.4.4.8 we calculate the angle at which light diffracted by a circular pinhole of diameter $2a$ has its first destructive interference fringe,

$$\theta_0 \simeq \sin\theta_0 = 1.22\frac{\lambda}{2a} \ . \tag{15.317}$$

Thus, a second pinhole displaced from the first one by a distance $d > 2a$ can be resolved. This is called the *Rayleigh criterion* for resolving two incoherent point sources. Smaller distances cannot be resolved, as they are below the so-called *diffraction limit*.

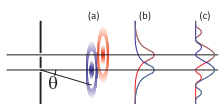

Figure 15.31: Illustration of the Rayleigh criterion.

15.4.3.5 Propagation of phase fronts across optical elements

To propagate an optical phase front located at z_0, we conveniently start from a Gaussian laser beam,

$$\psi_{\mathrm{Gauss}}(\rho) = e^{-\rho^2/w_0^2} \ . \tag{15.318}$$

with $\rho = \sqrt{x^2 + y^2}$ the distance from the optical axis. For a given total power the electric field is obtained via normalization,

$$\mathcal{E}_0 = \sqrt{\frac{P}{\frac{1}{2}\varepsilon_0 c \int |u|^2 d^2\rho}} \ , \tag{15.319}$$

where $\eta \equiv \sqrt{\mu_0/\varepsilon_0} = 1/(\varepsilon_0 c)$ is the vacuum impedance.

Optical elements can shape the phase front of a light beam by phase shift or absorption. If the element can be assumed to be thin we may neglect the axial displacement, $\Delta z \simeq 0$, and simply multiply the phase front with an xy-matrix,

$$\boxed{\psi_z'(x,y) = e^{-\alpha_{\text{component}}(x,y)}\psi_z(x,y)} \ , \tag{15.320}$$

where $\alpha(x,y) = \sigma(x,y) + \imath\delta(x,y)$. For instance, a *pinhole* with radius R will transform a phase front like,

$$\alpha_{\text{pinhole}}(\rho) = \infty\Theta(\rho - R) \ , \tag{15.321}$$

where Θ is the Heavyside function. A *thin lens* with focal distance f will transform a phase front like,

$$\alpha_{\text{lens}}(\rho) = \imath\tfrac{k}{R}\rho^2 = \imath\tfrac{k}{2f}\rho^2 \ , \tag{15.322}$$

where R is the radius of the spherical lens. For an *axicon* of base angle α made of material with refractive index n_{rfr},

$$\alpha_{\text{axicon}}(\rho) = \imath k(n_{\text{rfr}} - 1)\rho\tan\alpha \ . \tag{15.323}$$

In Excs. 15.4.4.7 to 15.4.4.9 we will derive the phase front transformation matrices for other interesting optical components. We will do a numerical simulation in 15.4.4.10.

15.4.4 Exercises

15.4.4.1 Ex: Gaussian light mode

The light of a laser propagates in light modes called Gaussian. A beam propagating along $\hat{\mathbf{e}}_z$ and linearly polarized along $\hat{\mathbf{e}}_x$ is described by the potential vector, $\mathbf{A}(\mathbf{r},t) = \hat{\mathbf{e}}_x u(\mathbf{r})e^{\imath(\omega t - kz)}$, where $u(\mathbf{r}) = \frac{u_0}{w(z)}e^{-(x^2+y^2)/w(z)^2}$ is the energy density and $w(z) = w_0\sqrt{1 + (\lambda z/\pi w_0^2)^2}$ the diameter of the beam at the position z. Calculate the Poynting vector in the Lorentz gauge, $\Phi = -\frac{c^2}{\imath\omega}\nabla\cdot\mathbf{A}$.

15.4.4.2 Ex: Volume and power of a Gaussian beam mode

a. Derive the expression for the mode volume V_m of a Gaussian beam of length L from the definition $I(0)V_m = \int I(\mathbf{r})dV$.
b. In quantum mechanics we learn, that the zero point energy of the harmonic oscillator is $\hbar\omega/2$. Use this notion to calculate the maximum electric field amplitude $\mathcal{E}_1(0)$ created by a single photon in terms of the mode volume.
c. A linear cavity of length L has the free spectral range $\delta_{\text{fsr}} = c/2L$. Express the power of the beam in terms of the number of photons contained in the cavity.

15.4.4.3 Ex: The lens in ray and wave optics

a. Use the transfer matrices (15.275) and (15.276) to derive the lens equations of geometric optics from the relation (15.273).
b. Now, use the transfer matrices (15.275) and (15.276) to derive, from the relation (15.273), the transformation of a Gaussian beam. How do the waists behave upon

transformation?
c. You have a laser of $\lambda = 632\,\text{nm}$ wavelength producing a Gaussian beam of diameter $w_1 = 1\,\text{mm}$ in its waist. Now, you want to match the beam into a cavity, whose mode (defined by the radii of curvature of the mirrors) has a waist of diameter $w_2 = 100\,\mu\text{m}$. To do this, you have at your disposal a lens of $f = 500\,\text{mm}$ focal distance. Using the formulas derived in (b), determine, how the distances d_1 (between the location of the waist of the laser beam and the lens) and d_2 (between the lens and the location of the waist of the cavity) must be chosen.

15.4.4.4 Ex: Transverse modes of a ring cavity

In this exercise we consider a ring cavity made of a plane input coupler and two identical curved high-reflectors (radius of curvature $\rho = 2f$) forming an isosceles triangle. Let $a = L/(2+\sqrt{2})$ be the two short distances and $b = L/(1+\sqrt{2})$ the long one, so that $L = 2a + b$.
a. How many waists does the cavity modes have, and where are they located?
b. Derive the round-trip matrix starting from the location of any one of the waists.
c. Calculate the waists.
d. Calculate the transverse mode spectrum, and prepare a plot for $\rho = 30\,\text{cm}$ and $L = 8.7\,\text{cm}$.
e. The above results presume cylindrical symmetry. However, incidence on curved mirrors under a tilted angle θ produces astigmatism. This can be accounted for by assuming different radii of curvature for the horizontal and vertical axis:

$$R_\text{h} = R\cos\theta \qquad \text{and} \qquad R_\text{v} = R/\cos\theta\ . \tag{15.324}$$

Calculate the impact waist sizes in the horizontal and vertical axis.

15.4.4.5 Ex: Transverse Hermite-Gauss modes

Derive the spectrum of Hermite-Gauss transverse modes.

15.4.4.6 Ex: Derivation of the Rayleigh-Sommerfeld formula

Derive the Rayleigh-Sommerfeld formula (15.303).

15.4.4.7 Ex: Phasefront distorsion by an axicon and a thin lens

Calculate the phasefront distorsion suffered by a plane wave upon traversing (a) an axicon with base angle α and (b) a thin lens with focal length f.

15.4.4.8 Ex: Transmission through a pinhole

Calculate the light field distribution after a circular pinhole of radius a.

15.4.4.9 Ex: Transmission through a various optical components

Calculate the phase front transformation matrix
a. for a Fresnel zone plate
b. for a Laguerre-Gauss zone plate.

15.4.4.10 Ex: Numerical phasefront propagation

Numerical phasefront propagation through a thin lens.

Chapter 16

Radiation

In the previous sections we discussed the propagation of electromagnetic waves, but we do not say how these waves were produced in the first place. For now, we only know, that it need's accelerated charges or varying currents. Now, we will show how such 'sources' can emit energy by 'radiating' electromagnetic waves.

To begin with, let us consider sources located near the origin and confined within a sphere of radius r. The total power crossing the sphere's surface is the integral of the Poynting vector,

$$P(r) = \oint \vec{\mathcal{S}} \cdot d\mathbf{a} = \tfrac{1}{\mu_0} \oint (\vec{\mathcal{E}} \times \vec{\mathcal{B}}) \cdot d\mathbf{a} \ . \tag{16.1}$$

The radiated power is then the energy per unit area transported to infinity without ever returning,

$$P_{\text{rad}} = \lim_{r \to \infty} P(r) \ . \tag{16.2}$$

Now, the area of the sphere's surface is $4\pi r^2$ such that, in order to have non-vanishing radiation, the Poynting vector must decrease (for large r) no faster than as $1/r^2$. Following the Coulomb law, electrostatic fields decrease like $1/r^2$ or faster, when the total enclosed charge is zero. And Biot-Savart's law states that magnetostatic fields decrease at least as fast as $1/r^2$, such that $|\vec{\mathcal{S}}| \propto 1/r^4$, for static configurations. Hence, static sources do not radiate. On the other hand, Jefimenko's equations (14.109) and (14.112) indicate the existence of time-dependent terms (involving $\dot{\varrho}$ and $\dot{\mathbf{j}}$), which are proportional to $1/r$. These are the terms responsible for electromagnetic radiation. To study the radiation we choose the parts of $\vec{\mathcal{E}}$ and $\vec{\mathcal{B}}$ going as $1/r$ at large distances from the source, combine them to terms going as $1/r^2$ in the Poynting vector $\vec{\mathcal{S}}$, and integrate $\vec{\mathcal{S}}$ on a large spherical surface taking the limit $r \to \infty$.

16.1 Multipolar expansion of the radiation

16.1.1 The radiation of an arbitrary charge distribution

In this section we will calculate the radiation emitted by arbitrary time-dependent variations of charge and current distributions, but which are confined within a small volume near the origin. The retarded scalar potential is according to (14.106),

$$\Phi(\mathbf{r}, t) = \frac{1}{4\pi\varepsilon_0} \int \frac{\varrho(\mathbf{r}', t - R/c)}{R} d^3r' \ , \tag{16.3}$$

where $R = \sqrt{r^2 + r'^2 - 2\mathbf{r}\cdot\mathbf{r}'}$, as illustrated in Fig. 14.10. Within the small source approximation, $r' \ll r$, we have,

$$R \simeq r\left(1 - \frac{\mathbf{r}\cdot\mathbf{r}'}{r^2}\right) \qquad \text{and} \qquad \frac{1}{R} \simeq \frac{1}{r}\left(1 + \frac{\mathbf{r}\cdot\mathbf{r}'}{r^2}\right) , \tag{16.4}$$

such that, defining,

$$t_0 \equiv t - \tfrac{r}{c} , \tag{16.5}$$

we obtain,

$$\varrho(\mathbf{r}', t - R/c) \simeq \varrho(\mathbf{r}', t - \tfrac{r}{c} + \tfrac{\hat{\mathbf{e}}_r\cdot\mathbf{r}'}{c}) \equiv \varrho(\mathbf{r}', t_0 + \tfrac{\hat{\mathbf{e}}_r\cdot\mathbf{r}'}{c}) . \tag{16.6}$$

Expanding ϱ in a Taylor series around the retarded time at the origin t_0, we get,

$$\varrho(\mathbf{r}', t - R/c) \simeq \varrho(\mathbf{r}', t_0) + \dot{\varrho}(\mathbf{r}', t_0)\tfrac{\hat{\mathbf{e}}_r\cdot\mathbf{r}'}{c} + \dots . \tag{16.7}$$

Substituting the numerator and denominator in the formula (16.3) by the expansions (16.4) and (16.7) we get up to the first order,

$$\Phi(\mathbf{r}, t) = \frac{1}{4\pi\varepsilon_0 r}\left[\int \varrho(\mathbf{r}', t_0)d^3r' + \frac{\hat{\mathbf{e}}_r}{r}\cdot\int \mathbf{r}'\varrho(\mathbf{r}', t_0)d^3r' + \frac{\hat{\mathbf{e}}_r}{c}\cdot\frac{d}{dt}\int \mathbf{r}'\varrho(\mathbf{r}', t_0)d^3r'\right] . \tag{16.8}$$

The first integral is simply the charge [1], the other two represent the electric dipole at time t_0,

$$\Phi(\mathbf{r}, t) = \frac{1}{4\pi\varepsilon_0}\left[\frac{Q}{r} + \frac{\hat{\mathbf{e}}_r\cdot\mathbf{d}(t_0)}{r^2} + \frac{\hat{\mathbf{e}}_r\cdot\dot{\mathbf{d}}(t_0)}{cr}\right] . \tag{16.9}$$

In the static case, the first two terms are the contributions of the monopole and dipole to the multipolar expansion of Φ, the third term would not be present.

The vector potential,

$$\mathbf{A}(\mathbf{r}, t) = \frac{\mu_0}{4\pi}\int \frac{\mathbf{j}(\mathbf{r}', t - R/c)}{R}d^3r' , \tag{16.10}$$

is easily expanded up to first order by,

$$\mathbf{A}(\mathbf{r}, t) \simeq \frac{\mu_0}{4\pi r}\int \mathbf{j}(\mathbf{r}', t_0)d^3r' , \tag{16.11}$$

since, as we will show in Exc. 16.1.6.1,

$$\boxed{\mathbf{A}(\mathbf{r}, t) \simeq \frac{\mu_0}{4\pi}\frac{\dot{\mathbf{d}}(t_0)}{r}} , \tag{16.12}$$

that is, $\mathbf{d} \sim \mathbf{r}'$ is already of first order in $\mathbf{r}'$.

Now we must calculate the fields. Again, we are interested in the radiation zone (that is, in fields surviving great distances from the source), discarding all terms in $\vec{\mathcal{E}}$ and $\vec{\mathcal{B}}$ which decrease like $1/r^2$ or faster, which will not be the case for the first term

[1] The charge is evaluated at time t_0, but since it is conserved, it stays the same at all times.

(Coulomb) and the second term in (16.9). Therefore, considering the abbreviation (16.5), we obtain,

$$\nabla\Phi \simeq \frac{1}{4\pi\varepsilon_0}\nabla\frac{\hat{\mathbf{e}}_r\cdot\dot{\mathbf{d}}(t_0)}{rc} = \frac{1}{4\pi\varepsilon_0}\left[\cancelto{0}{\frac{\dot{\mathbf{d}}(t_0)}{cr^2}} + \frac{\hat{\mathbf{e}}_r\cdot\ddot{\mathbf{d}}(t_0)}{cr}\nabla t_0 - \cancelto{0}{\frac{2\hat{\mathbf{e}}_r\cdot\dot{\mathbf{d}}(t_0)}{cr^2}}\hat{\mathbf{e}}_r\right]$$
$$\simeq \frac{1}{4\pi\varepsilon_0}\frac{\hat{\mathbf{e}}_r\cdot\ddot{\mathbf{d}}(t_0)}{cr}\left(-\frac{\hat{\mathbf{e}}_r}{c}\right) . \tag{16.13}$$

Similarly,

$$\nabla\times\mathbf{A} = \nabla\times\frac{\mu_0}{4\pi}\frac{\dot{\mathbf{d}}(t_0)}{r} = \frac{\mu_0}{4\pi}\left[\frac{1}{r}\nabla\times\dot{\mathbf{d}}(t_0) + \left(\nabla\frac{1}{r}\right)\times\dot{\mathbf{d}}(t_0)\right] \tag{16.14}$$
$$= \frac{\mu_0}{4\pi}\left[-\frac{\ddot{\mathbf{d}}(t_0)}{r}\times\nabla t_0 - \cancelto{0}{\frac{\hat{\mathbf{e}}_r\times\dot{\mathbf{d}}(t_0)}{r^2}}\right] = -\frac{\mu_0}{4\pi}\frac{\ddot{\mathbf{d}}(t_0)}{r}\times\left(\frac{-\hat{\mathbf{e}}_r}{c}\right) = -\frac{\mu_0}{4\pi}\frac{\hat{\mathbf{e}}_r\times\ddot{\mathbf{d}}(t_0)}{cr} .$$

and,

$$\frac{\partial\mathbf{A}}{\partial t} \simeq \frac{\mu_0}{4\pi}\frac{\ddot{\mathbf{d}}(t_0)}{r} . \tag{16.15}$$

Hence, the Eqs. (14.78) tell us,

$$\vec{\mathcal{E}}(\mathbf{r},t) \simeq \frac{\mu_0}{4\pi r}[(\hat{\mathbf{e}}_r\cdot\ddot{\mathbf{d}}(t_0))\hat{\mathbf{e}}_r - \ddot{\mathbf{d}}(t_0)] = \frac{\mu_0}{4\pi r}[\hat{\mathbf{e}}_r\times(\hat{\mathbf{e}}_r\times\ddot{\mathbf{d}}(t_0)] \tag{16.16}$$
$$\vec{\mathcal{B}}(\mathbf{r},t) \simeq -\frac{\mu_0}{4\pi cr}[\hat{\mathbf{e}}_r\times\ddot{\mathbf{d}}(t_0)] .$$

In spherical coordinates,

$$\vec{\mathcal{E}}(r,\theta,\phi,t) \simeq \frac{\mu_0\ddot{d}(t_0)}{4\pi}\frac{\sin\theta}{r}\hat{\mathbf{e}}_\theta \quad \text{and} \quad \vec{\mathcal{B}}(r,\theta,\phi,t) \simeq \frac{\mu_0\ddot{d}(t_0)}{4\pi c}\frac{\sin\theta}{r}\hat{\mathbf{e}}_\phi . \tag{16.17}$$

The Poynting vector is,

$$\boxed{\vec{\mathcal{S}} \simeq \tfrac{1}{\mu_0}\vec{\mathcal{E}}\times\vec{\mathcal{B}} = \frac{\mu_0\ddot{d}(t_0)^2}{16\pi^2 c}\frac{\sin^2\theta}{r^2}\hat{\mathbf{e}}_r} , \tag{16.18}$$

which is a result that we already used in (15.112). And for total radiated power we get the *Larmor formula*,

$$P \simeq \oint \vec{\mathcal{S}}\cdot d\mathbf{a} = \frac{\mu_0\ddot{d}(t_0)}{6\pi c} . \tag{16.19}$$

The calculation is equivalent to a multipolar expansion of the retarded potentials up to the lowest order in r' which can still radiate, and which turns out to be an electric dipole radiation. Multipolar orders of radiation usually only come into play, when for some reason (e.g. a selection rule) the electric dipole radiation cancels. The next multipolar order will be, as we will soon see, a combination of magnetic dipole and quadrupolar electric radiation.

16.1.2 Multipolar expansion of retarded potentials

In order to simplify the multipolar treatment, we use the superposition principle, allowing us to decompose any temporal oscillation of a charge distribution into harmonic oscillations,

$$\varrho(\mathbf{r}, t_r) = \varrho(\mathbf{r})e^{-\imath\omega t_r} \quad \text{and} \quad \mathbf{j}(\mathbf{r}, t_r) = \mathbf{j}(\mathbf{r})e^{-\imath\omega t_r} \ . \tag{16.20}$$

By inserting these dependencies into the *retarded potentials* (14.106), we obtain with $t_r = t - |\mathbf{r} - \mathbf{r}'|/c$,

$$\Phi(\mathbf{r}) = \frac{1}{4\pi\varepsilon_0}\int \varrho(\mathbf{r}_r)\frac{e^{\imath k|\mathbf{r}-\mathbf{r}'|}}{|\mathbf{r}-\mathbf{r}'|}d^3r' \quad \text{and} \quad \mathbf{A}(\mathbf{r}) = \frac{\mu_0}{4\pi}\int \mathbf{j}(\mathbf{r}')\frac{e^{\imath k|\mathbf{r}-\mathbf{r}'|}}{|\mathbf{r}-\mathbf{r}'|}d^3r' \ , \tag{16.21}$$

with $k = \omega/c$ and implying $\Phi(\mathbf{r}, t) = \Phi(\mathbf{r})e^{-\imath\omega t}$ and $\mathbf{A}(\mathbf{r}, t) = \mathbf{A}(\mathbf{r})e^{-\imath\omega t}$.

From these expressions we can, knowing the sources (16.20), calculate the fields via the expressions (14.78) or alternatively (based only on the vector potential) via,

$$\vec{\mathcal{B}} = \nabla \times \mathbf{A} \quad \text{and} \quad \vec{\mathcal{E}} = \tfrac{\imath c^2}{\omega}\nabla \times \vec{\mathcal{B}} \quad \text{and} \quad \vec{\mathcal{B}} = \tfrac{-\imath}{\omega}\nabla \times \vec{\mathcal{E}} \ , \tag{16.22}$$

where $\vec{\mathcal{E}}$ is evaluated outside the source. We will consider sources which are small (size d) compared to the wavelength λ and distinguish three regions characterized by fields with very different properties:

- near-field (or static) zone $\quad r' < d \ll r \ll \lambda$
- intermediate (or inductive) zone $\quad r' < d \ll r \sim \lambda$
- far-field (or radiative) zone $\quad r' < d \ll \lambda \ll r$

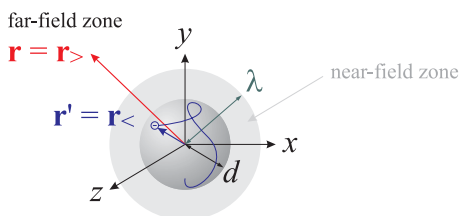

Figure 16.1: Geometry of source ($r' < d$) and observer ($r > d$) coordinates.

To handle the expression (16.21) we expand the Green function into spherical harmonics,

$$\frac{e^{\imath k|\mathbf{r}-\mathbf{r}'|}}{4\pi|\mathbf{r}-\mathbf{r}'|} = \imath k\sum_{\ell=0}^{\infty} h_\ell^{(1)}(kr_>)j_\ell(kr_<)\sum_{m=-\ell}^{\ell} Y_{\ell m}^*(\theta', \phi')Y_{\ell m}(\theta, \phi) \ , \tag{16.23}$$

where (placing the observer out of the source region) $r_< \equiv \min(r, r') = r'$ and $r_> \equiv \max(r, r') = r$. j_ℓ and $h_\ell^{(1)}$ are the *Bessel functions* and *Hankel functions* of the first type. This formula can be simplified by the sum rule,

$$\sum_{m=-\ell}^{\ell} Y_{\ell m}^*(\hat{\mathbf{e}}_{r'})Y_{\ell m}(\hat{\mathbf{e}}_r) = \frac{2\ell+1}{4\pi}P_\ell(\hat{\mathbf{e}}_{r'} \cdot \hat{\mathbf{e}}_r) \ , \tag{16.24}$$

where P_ℓ are *Legendre polynomials*. We write,

$$\frac{e^{\imath k|\mathbf{r}-\mathbf{r}'|}}{|\mathbf{r}-\mathbf{r}'|} = \imath k \sum_{\ell=0}^{\infty}(2\ell+1)h_\ell^{(1)}(kr)j_\ell(kr')P_\ell(\hat{\mathbf{e}}_{r'}\cdot\hat{\mathbf{e}}_r) \ . \tag{16.25}$$

For observation points $\mathbf{r}$ out of the source (which is certainly satisfied in the limit $r' \ll r$) the Eq. (16.21) becomes,

$$\mathbf{A}(\mathbf{r}) = \frac{\mu_0}{4\pi}(2\ell+1)\imath k \sum_{\ell=0}^{\infty} h_\ell^{(1)}(kr)\int \mathbf{j}(\mathbf{r}')j_\ell(kr')P_\ell(\hat{\mathbf{e}}_{r'}\cdot\hat{\mathbf{e}}_r)d^3r' \ . \tag{16.26}$$

Since we will always be considering the limit $kr' \ll 1$, we can expand the Bessel function for small arguments,

$$j_\ell(x) \overset{x\to 0}{\longrightarrow} \frac{x^\ell}{(2\ell+1)!!}\left(1-\frac{x^2}{2(2\ell+3)}+...\right) \ . \tag{16.27}$$

We obtain for the vector potential,

$$\boxed{\mathbf{A}(\mathbf{r}) \simeq \frac{\mu_0}{4\pi}\imath k \sum_{\ell=0}^{\infty}\frac{1}{(2\ell-1)!!}h_\ell^{(1)}(kr)\int \mathbf{j}(\mathbf{r}')(kr')^\ell P_\ell(\hat{\mathbf{e}}_{r'}\cdot\hat{\mathbf{e}}_r)d^3r'} \ . \tag{16.28}$$

Now, let us discuss the limiting cases by comparing the observation distance r with the wavelength. In the *near-field zone*, where $kr \ll 1$, we can also expand the Bessel function for small arguments,

$$n_\ell(x) \overset{x\to 0}{\longrightarrow} -\frac{(2\ell-1)!!}{x^{\ell+1}}\left(1-\frac{x^2}{2(1-2\ell)}+...\right) \tag{16.29}$$

$$\text{and} \qquad h_\ell^{(1)}(x) = j_\ell(x) + \imath n_\ell(x) \overset{x\to 0}{\longrightarrow} \imath n_\ell(x) \ ,$$

resulting in the vector potential,

$$\boxed{\mathbf{A}(\mathbf{r}) \overset{kr\to 0}{\longrightarrow} \frac{\mu_0}{4\pi}k \sum_{\ell=0}^{\infty}\frac{1}{(kr)^{\ell+1}}\int \mathbf{j}(\mathbf{r}')(kr')^\ell P_\ell(\hat{\mathbf{e}}_{r'}\cdot\hat{\mathbf{e}}_r)d^3r'} \ . \tag{16.30}$$

This formula could already have been derived by approximating the exponential of the formula (16.21) by $e^{\imath k|\mathbf{r}-\mathbf{r}'|} \simeq 1$ and expanding the following Green function into spherical harmonics [2],

$$\frac{1}{4\pi|\mathbf{r}-\mathbf{r}'|} = \sum_{\ell=0}^{\infty}\sum_{m=-\ell}^{\ell}\frac{1}{2\ell+1}\frac{r_<^\ell}{r_>^{\ell+1}}Y_{\ell m}^*(\theta',\phi')Y_{\ell m}(\theta,\phi) \ . \tag{16.31}$$

[2] This expansion is obtained by expanding the Legendre polynomials in the expansion (10.91),

$$\frac{1}{|\mathbf{r}-\mathbf{r}'|} = \frac{1}{r}\sum_{\ell=0}^{\infty}\frac{r_<^\ell}{r_>^{\ell+1}}P_\ell(\cos\theta') \qquad \text{with} \qquad P_\ell(\cos\theta') = \frac{4\pi}{2\ell+1}\sum_{m=\ell}^{\ell}Y_{\ell m}^*(\theta',\phi')Y_{\ell m}(\theta,\phi) \ ,$$

.

The absence of propagating terms in the expression (16.30) (the wave vector k can be eliminated from the expression (16.30)) demonstrates the *quasi-static* character of the fields within the near zone, that is, apart from a uniform and harmonic oscillation described by $e^{-\imath\omega t}$. The radial components depend on the details of the source's geometry. The scalar and vector potentials are of the form already derived in electrostatics (10.92) and magnetostatics (12.39).

On the other hand, in *far-field zone*, where $kr \gg 1$, the exponential in (16.21) oscillates rapidly and determines the behavior of vector potential. Here, we must resort to the complete expression (16.28), but we can expand the Hankel functions like,

$$h_\ell^{(1)}(x) = (-\imath)^{\ell+1}\frac{e^{\imath x}}{x}\sum_{m=0}^{\ell}\frac{\imath^m}{m!(2x)^m}\frac{(\ell+m)!}{(\ell-m)!} \ . \tag{16.32}$$

Knowing,

$$\begin{aligned} h_0^{(1)}(x) &= -\imath\tfrac{e^{\imath x}}{x} &&, \quad P_0(x) = 1 \\ h_1^{(1)}(x) &= -\tfrac{e^{\imath x}}{x}\left(1-\tfrac{1}{\imath x}\right) &&, \quad P_1(x) = x \ . \end{aligned} \tag{16.33}$$

we calculate the potentials,

$$\begin{aligned} \mathbf{A}_{\ell=0}(\mathbf{r}) &\simeq \frac{\mu_0}{4\pi}\frac{e^{\imath kr}}{r}\int \mathbf{j}(\mathbf{r}')d^3r' \\ \mathbf{A}_{\ell=1}(\mathbf{r}) &\simeq -\frac{\mu_0}{4\pi}\imath k\frac{e^{\imath kr}}{r}\left(1-\frac{1}{\imath kr}\right)\int \mathbf{j}(\mathbf{r}')\mathbf{r}'\cdot\hat{\mathbf{e}}_r d^3r' \ , \end{aligned} \tag{16.34}$$

We will see in the following sections that $\mathbf{A}_{\ell=0}$ is the potential for electric dipole radiation and $\mathbf{A}_{\ell=1}$ the potential for magnetic dipole radiation and electric quadrupolar radiation.

Example 116 (*The far-field limit*): Assuming that the spatial extent of the radiation source is small, $r' \lesssim d \ll r$, it is sufficient to approximate directly in the expression (16.21),

$$|\mathbf{r}-\mathbf{r}'| \simeq r - \hat{\mathbf{e}}_r\cdot\mathbf{r}' \ .$$

Moreover, if only the principal term in kr is desired [3], the inverse distance in (16.21) can be replaced by r. Then, the vector potential is,

$$\lim_{kr\to\infty}\mathbf{A}(\mathbf{r}) = \frac{\mu_0}{4\pi}\frac{e^{\imath kr}}{r}\int \mathbf{j}(\mathbf{r}')e^{-\imath k\hat{\mathbf{e}}_r\cdot\mathbf{r}'}d^3r' \ .$$

This shows that, in the far-field zone, the vector potential behaves like a spherically expanding wave modulated by an angular coefficient. It is easy to show, that the fields calculated from (16.22) are transverse to the radius vector and fall off as $1/r$. They correspond thus to the radiation fields. If the size of the source

[3] The expansion by $\frac{1}{kr}$ gives,

$$\frac{e^{-\imath k\hat{\mathbf{e}}_r\cdot r'}}{kr-k\hat{\mathbf{e}}_r\cdot r'} = \frac{e^{-\imath k\hat{\mathbf{e}}_r\cdot r'}}{kr}\left[\frac{\hat{\mathbf{e}}_r\cdot r'}{r}+\left(\frac{\hat{\mathbf{e}}_r\cdot r'}{r}\right)^2+...\right] \simeq \frac{e^{-\imath k\hat{\mathbf{e}}_r\cdot r'}}{kr} \ .$$

is small compared to a wavelength, it is appropriate to expand the exponential in the integral in (16.25) in powers of k,

$$\lim_{kr\to\infty} \mathbf{A}(\mathbf{r}) = \frac{\mu_0 k}{4\pi} \sum_n \frac{(-\imath)^n}{n!} \frac{e^{\imath kr}}{kr} \int \mathbf{j}(\mathbf{r}')(\hat{\mathbf{e}}_r \cdot k\mathbf{r}')^n d^3r' \ .$$

The magnitude of the n-th term is given by $\frac{1}{n!}\int \mathbf{j}(\mathbf{r}')(\hat{\mathbf{e}}_r \cdot k\mathbf{r}')^n d^3r'$. Since the order of magnitude of $\mathbf{r}'$ is d, and since we assumed $kr' \ll 1$, consecutive terms decrease rapidly with n. Consequently, the radiation emitted from the source comes mainly from the first terms of the expansion (16.26).

16.1.2.1 The electric monopole

We notice that the lowest order radiation found in the expansion of $\mathbf{A}$ is dipolar. How about monopolar fields? Let us examine the issue of electric monopole fields, when the sources vary in time. The contribution of the electric monopole is obtained by substituting $|\mathbf{r}-\mathbf{r}'| \to |\mathbf{r}| = r$ in the integral (16.21) for the potential Φ. The result is,

$$\Phi_{\text{monopole}}(\mathbf{r},t) = \frac{1}{4\pi\varepsilon_0}\frac{e^{\imath kr}}{r}\int \rho(\mathbf{r}')d^3r' = \frac{Q}{4\pi\varepsilon_0}\frac{e^{\imath kr}}{r} \ . \tag{16.35}$$

where $q(t)$ is the total charge of the source. Since the charge is localized in the source (and therefore conserved), the total charge q is independent of time. Thus, the electrical monopole part of the potential of a localized source is necessarily static. Radiation with harmonic temporal dependence, $e^{-\imath\omega t}$, does not have monopolar terms in the fields.

Now let us go back to multipolar fields. Since these fields can be calculated from the vector potential via (16.23), we omit explicit references to the scalar potential in the following.

16.1.3 Radiation of an oscillating electric dipole

Keeping only the first term in (16.30) we get the potential vector (16.33),

$$\mathbf{A}(\mathbf{r}) = \frac{\mu_0}{4\pi}\frac{e^{\imath kr}}{r}\int \mathbf{j}(\mathbf{r}')d^3r' \ . \tag{16.36}$$

which is valid everywhere outside the source. Using the continuity equation we can rewrite it, using a result from Exc. 16.1.6.1,

$$\mathbf{A}(\mathbf{r}) = -\frac{\mu_0}{4\pi}\frac{e^{\imath kr}}{r}\int \mathbf{r}'(\nabla'\cdot\mathbf{j})d^3r' = -\frac{\mu_0}{4\pi}\frac{e^{\imath kr}}{r}\imath\omega\int \mathbf{r}'\varrho(\mathbf{r}')d^3r' \ . \tag{16.37}$$

With the *electric dipole moment*,

$$\mathbf{d} \equiv \int \mathbf{r}'\varrho(\mathbf{r}')d^3r' \ , \tag{16.38}$$

defined in electrostatics we write,

$$\boxed{\mathbf{A}(\mathbf{r}) = -\frac{\mu_0}{4\pi}\frac{e^{\imath kr}}{r}\imath\omega\mathbf{d}} \ . \tag{16.39}$$

We obtain the fields via the equations (16.22),

$$\boxed{\begin{aligned}\vec{\mathcal{B}} &= -\frac{ck^3\mu_0}{4\pi}(\hat{\mathbf{e}}_r\times\mathbf{d})\frac{e^{\imath kr}}{kr}\left(1-\frac{1}{\imath kr}\right)\\ \vec{\mathcal{E}} &= \frac{k^3}{4\pi\varepsilon_0}\left\{(\hat{\mathbf{e}}_r\times\mathbf{d})\times\hat{\mathbf{e}}_r\frac{e^{\imath kr}}{kr}+[3\hat{\mathbf{e}}_r(\hat{\mathbf{e}}_r\cdot\mathbf{d})-\mathbf{d}]\left(\frac{1}{(kr)^3}-\frac{\imath}{(kr)^2}\right)e^{\imath kr}\right\}\end{aligned}} \ . \tag{16.40}$$

We observe that the magnetic field is transverse to the radius vector $\hat{\mathbf{e}}_r$ at all distances, but that the electric field has components parallel and perpendicular to $\hat{\mathbf{e}}_r$. In Exc. 16.1.6.2 we will derive the fields (16.40) directly from the potentials.

In the radiation zone $kr \gg 1$ the fields adopt the typical behavior,

$$\vec{\mathcal{B}} = -\frac{ck^3\mu_0}{4\pi}(\hat{\mathbf{e}}_r\times\mathbf{d})\frac{e^{\imath kr}}{kr} \quad \text{and} \quad \vec{\mathcal{E}} = \frac{k^3}{4\pi\varepsilon_0}(\hat{\mathbf{e}}_r\times\mathbf{d})\times\hat{\mathbf{e}}_r\frac{e^{\imath kr}}{kr} \ . \tag{16.41}$$

In the near-field zone $kr \ll 1$,

$$\vec{\mathcal{B}} = \frac{\imath\omega\mu_0}{4\pi}(\hat{\mathbf{e}}_r\times\mathbf{d})\frac{1}{r^2} \quad \text{and} \quad \vec{\mathcal{E}} = \frac{1}{4\pi\varepsilon_0}[3\hat{\mathbf{e}}_r(\hat{\mathbf{e}}_r\cdot\mathbf{d})-\mathbf{d}]\frac{1}{r^3} \ , \tag{16.42}$$

does not have the propagation term $e^{\imath kr}$. The electric field, apart from its temporal oscillations, is just a static electric dipole. The magnetic field is, apart from a constant $Z_0 \equiv \sqrt{\mu_0/\varepsilon_0}$ called *vacuum impedance*, smaller by a factor kr than the electric field in the region where $kr \ll 1$. Thus, the fields in the near-field zone are of predominantly electrical nature. The magnetic field disappears, obviously, in the static limit $k \to 0$. In this case, the near-field zone extends to infinity.

The Poynting vector in the far-field due to the oscillation of the dipole moment $\mathbf{d}$ is, inserting (16.41),

$$\begin{aligned}\vec{\mathcal{S}} &= \frac{1}{2\mu_0}\vec{\mathcal{E}}\times\vec{\mathcal{B}}^* = -\frac{ck^4}{32\pi^2\varepsilon_0 r^2}\{[\hat{\mathbf{e}}_r\times\mathbf{d})\times\hat{\mathbf{e}}_r]\times(\hat{\mathbf{e}}_r\times\mathbf{d})\} \\ &= -\frac{ck^4}{32\pi^2\varepsilon_0 r^2}(d^2-d_r^2)\hat{\mathbf{e}}_r = -\frac{ck^4}{32\pi^2\varepsilon_0 r^2}\hat{\mathbf{e}}_r d^2\sin^2\theta \ .\end{aligned} \tag{16.43}$$

The radiated power is given by the absolute value of (16.43) per solid angle element [4]. If the components of $\mathbf{d}$ all have the same phase, the angular distribution is a typical dipole pattern,

$$\frac{dP}{d\Omega} = \frac{c}{32\pi^2\varepsilon_0}k^4|\mathbf{d}|^2\sin^2\theta \ . \tag{16.44}$$

where the angle θ is measured from the direction of $\mathbf{d}$. The total radiated power, regardless of the relative phases of the components of $\mathbf{d}$, is,

$$P = \frac{cZ_0}{12\pi\varepsilon_0}|\mathbf{d}|^2 = \frac{\mu_0}{12\pi c}|\mathbf{d}|^2 \ , \tag{16.45}$$

[4] When writing angular distributions of radiation, we will always exhibit the polarization explicitly by writing the absolute square of a vector that is proportional to the electric field. If the angular distribution of a particular polarization is desired, it can then be obtained by taking the scalar product of the vector with the appropriate polarization vector before the square.

which is half of the value calculated in the derivation of the Larmor formula (16.19), because in (16.43) we choose to calculate directly the temporal average of the Poynting vector.

Resolve the 16.1.6.3. In Exc. 16.1.6.4 we will verify the gauge of the dipolar potential and in Exc. 16.1.6.5 we calculate the fields of a linear antenna.

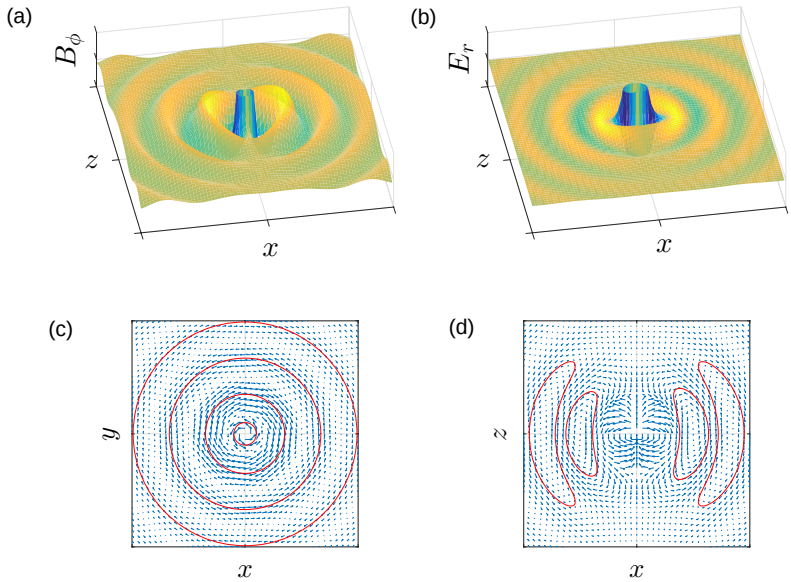

Figure 16.2: (code) Electric dipole radiation patterns. (a) Cut through $\vec{\mathcal{B}}_\phi$, (b) cut through $\vec{\mathcal{E}}_r$, (c) field lines of $\vec{\mathcal{B}}$ in the xy-plane, and (d) field lines of $\vec{\mathcal{E}}$ in the xz-plane. A movie can be seen at (watch movie).

Example 117 (*Linear antenna*): As an example, we calculate the power radiated by an oscillating charge $\varrho(\mathbf{r},t) = Q\delta(x)\delta(y)\delta(z - z_0 e^{-\imath\omega t})$. The dipole moment is,

$$\mathbf{d} = \int \mathbf{r}'\varrho(\mathbf{r}',t)dV' = Q\hat{\mathbf{e}}_z z_0 e^{-\imath\omega t} \ .$$

Inserted into the formula (16.45),

$$P = \frac{cZ_0 Q^2 z_0^2}{12\pi\varepsilon_0} \ .$$

Example 118 (*Linear antenna*): As another example we calculate the power radiated by a simple linear antenna, characterized by a current distribution $\mathbf{j}(\mathbf{r},t) = I_0\hat{\mathbf{e}}_z\delta(x)\delta(y)(1 - 2|z|/a)e^{-\imath\omega t}$. The dipole moment is,

$$\mathbf{d} = \frac{\imath}{\omega}\int \mathbf{j}dV' = \frac{\imath}{\omega}I_0\hat{\mathbf{e}}_z e^{-\imath\omega t}\int_{-a/2}^{a/2}\mathbf{j}dV'\left(1 - \frac{2|z'|}{a}\right)dz' = \frac{\imath I_0 a}{2\omega}\hat{\mathbf{e}}_z e^{-\imath\omega t} \ .$$

Inserted into the formula (16.45),

$$P = \frac{Z_0 I_0^2 (ka)^2}{48\pi} \ .$$

16.1.4 Magnetic dipole and electric quadrupole radiation

The term $\ell = 1$ in the expansion (16.28) leads to the second vector potential (16.34),

$$\mathbf{A}(\mathbf{r}) = -\imath\frac{\mu_0}{4\pi}\imath k h_1^{(1)} \int \mathbf{j}(\mathbf{r}')(\hat{\mathbf{e}}_r \cdot \mathbf{r}')d^3r' = \frac{\mu_0}{4\pi}\frac{e^{\imath kr}}{r}\left(\frac{1}{r} - \imath k\right)\int \mathbf{j}(\mathbf{r}')(\hat{\mathbf{e}}_r \cdot \mathbf{r}')d^3r' \ . \tag{16.46}$$

This vector potential can be written as the sum of two terms: one gives a transverse magnetic field and the other gives a transverse electric field. These physically distinct contributions can be separated by rewriting the integrand in (16.46) as the sum of a part, which is symmetric about an exchange of $\mathbf{j}$ and $\mathbf{r}'$, and an antisymmetric part. Therefore,

$$(\hat{\mathbf{e}}_r \cdot \mathbf{r}')\mathbf{j} = \tfrac{1}{2}[(\hat{\mathbf{e}}_r \cdot \mathbf{r}')\mathbf{j} + (\hat{\mathbf{e}}_r \cdot \mathbf{j})\mathbf{r}'] - \hat{\mathbf{e}}_r \times \tfrac{1}{2}(\mathbf{r}' \times \mathbf{j}) \ , \tag{16.47}$$

using the rule $B(AC) - C(AB)$. The second (antisymmetric) part is recognizable as the magnetization due to the current $\mathbf{j}$:

$$\vec{\mathcal{M}} = \tfrac{1}{2}(\mathbf{r}' \times \mathbf{j}) \ . \tag{16.48}$$

We will see, that the first (symmetric) term is related to the electric quadrupole moment density.

16.1.4.1 Magnetic dipole radiation

Considering, for the moment, only the magnetization term, we get the vector potential,

$$\boxed{\mathbf{A}(\mathbf{r}) = \frac{\imath k\mu_0}{4\pi}(\hat{\mathbf{e}}_r \times \mathbf{m})\frac{e^{\imath kr}}{r}\left(1 - \frac{1}{\imath kr}\right)} \ , \tag{16.49}$$

where $\mathbf{m}$ is the *magnetic dipole moment*,

$$\mathbf{m} = \int \vec{\mathcal{M}} d^3r = \tfrac{1}{2}\int (\mathbf{r} \times \mathbf{j})d^3r \ . \tag{16.50}$$

The fields can be determined by observing that the vector potential (16.49) is proportional to the magnetic field (16.40) of an electric dipole (except that we have to exchange the electric by the magnetic dipole moment). Thus, we can use the calculations we already made and transfer the results to the fields of a magnetic dipole via Eqs. (16.22):

$$\boxed{\begin{aligned} \vec{\mathcal{B}} &= \frac{k^3\mu_0}{4\pi}\left\{(\hat{\mathbf{e}}_r \times \mathbf{m}) \times \hat{\mathbf{e}}_r \frac{e^{\imath kr}}{kr} + [3\hat{\mathbf{e}}_r(\hat{\mathbf{e}}_r \cdot \mathbf{m}) - \mathbf{m}]\left(\frac{1}{(kr)^3} - \frac{\imath}{(kr)^2}\right)e^{\imath kr}\right\} \\ \vec{\mathcal{E}} &= -\frac{ck^3\mu_0}{4\pi}(\hat{\mathbf{e}}_r \times \mathbf{m})\frac{e^{\imath kr}}{kr}\left(1 - \frac{1}{\imath kr}\right) \end{aligned}} \ . \tag{16.51}$$

In Exc. 16.1.6.6 we will derive the fields (16.51) directly from the potentials.

All arguments concerning the behavior of the fields in the near-field and far-field regions are the same as those proposed for the electric dipole radiation with the modifications,

$$\begin{aligned} \vec{\mathcal{E}}^{(M1)} &\overset{\mathbf{m}\leftrightarrow c\mathbf{d}}{\longleftrightarrow} c\vec{\mathcal{B}}^{(E1)} \\ c\vec{\mathcal{B}}^{(M1)} &\overset{\mathbf{m}\leftrightarrow c\mathbf{d}}{\longleftrightarrow} \vec{\mathcal{E}}^{(E1)} \ . \end{aligned} \tag{16.52}$$

Likewise, the radiation pattern and the total radiated power are the same for the two types of dipole. The only difference in the radiation fields are their polarizations. For an electric dipole, the electric field vector lies in the plane defined by $\hat{\mathbf{e}}_r$ and $\mathbf{d}$, whereas for a magnetic dipole, it is perpendicular to the plane defined by $\hat{\mathbf{e}}_r$ and $\mathbf{m}$.

16.1.4.2 Electric quadrupole radiation

The integral of the symmetric term in (16.47) can be transformed using the continuity equation and integrating by parts:

$$\tfrac{1}{2}\int[(\hat{\mathbf{e}}_r\cdot\mathbf{r}')\mathbf{j}+(\hat{\mathbf{e}}_r\cdot\mathbf{j})\mathbf{r}']d^3r' = -\tfrac{\imath\omega}{2}\int\mathbf{r}'(\hat{\mathbf{e}}_r\cdot\mathbf{r}')\varrho(\mathbf{r}')d^3r' \ . \tag{16.53}$$

This will be demonstrated in Exc. 16.1.6.1. Since this integral involves the second moments of charge density, it corresponds to a quadrupolar electric radiation source. The potential vector is,

$$\boxed{\mathbf{A}(\mathbf{r}) = -\frac{\mu_0 ck^2}{8\pi}\frac{e^{\imath kr}}{r}\left(1-\frac{1}{\imath kr}\right)\int\mathbf{r}'(\hat{\mathbf{e}}_r\cdot\mathbf{r}')\varrho(\mathbf{r}')d^3r'} \ . \tag{16.54}$$

The expressions for the fields are a bit complicated, such that we focus on the radiation zone, where it is easy to verify that,

$$\vec{\mathcal{B}} = \nabla\times\mathbf{A} = \imath k\hat{\mathbf{e}}_r\times\mathbf{A} \quad , \quad \vec{\mathcal{E}} = \imath ck(\hat{\mathbf{e}}_r\times\mathbf{A})\times\hat{\mathbf{e}}_r \ . \tag{16.55}$$

Consequently, the magnetic field is,

$$\vec{\mathcal{B}} = -\frac{\imath ck^3\mu_0}{8\pi}\frac{e^{\imath kr}}{r}\int(\hat{\mathbf{e}}_r\times\mathbf{r}')(\hat{\mathbf{e}}_r\cdot\mathbf{r}')\varrho(\mathbf{r}')d^3re' \ . \tag{16.56}$$

With the definition of the tensor of the quadrupolar moment,

$$Q_{\alpha\beta} \equiv \int(3x_\alpha x_\beta - r^2\delta_{\alpha\beta})\varrho(\mathbf{r}')d^3r' \ , \tag{16.57}$$

the integral (16.56) can be written as,

$$\hat{\mathbf{e}}_r\times\int\mathbf{r}'(\hat{\mathbf{e}}_r\cdot\mathbf{r}')\varrho(\mathbf{r}')d^3\mathbf{r}' = \tfrac{1}{3}\hat{\mathbf{e}}_r\times\mathbf{Q}(\hat{\mathbf{e}}_r) \ , \tag{16.58}$$

where the vector $\mathbf{Q}(\hat{\mathbf{e}}_r)$ is defined via its components,

$$Q_\alpha = \sum_{\alpha\beta} Q_{\alpha\beta}\hat{\mathbf{e}}_\beta \ . \tag{16.59}$$

We note that its magnitude and direction depend on the direction of observation as well as on the properties of the source. With these definitions, we get the magnetic field,

$$\vec{\mathcal{B}} = -\frac{\imath c k^3 \mu_0}{24\pi} \frac{e^{\imath k r}}{r} \hat{\mathbf{e}}_r \times \mathbf{Q}(\hat{\mathbf{e}}_r) \ , \tag{16.60}$$

and the time-averaged power radiated into a solid angle,

$$\frac{dP}{d\Omega} = \frac{c^2 Z_0}{1152\pi^2} k^6 |[\hat{\mathbf{e}}_r \times \mathbf{Q}(\hat{\mathbf{e}}_r)] \times \hat{\mathbf{e}}_r|^2 \ . \tag{16.61}$$

The final expressions are complicated [473], but for the example of a ellipsoidal charge distribution periodically changing its 'aspect ratio', it is possible to show that the angular distribution of the radiation pattern exhibits four lobes,

$$\frac{dP}{d\Omega} = \frac{c^2 Z_0 k^6}{512\pi^2} Q_0^2 \sin^2\theta \cos^2\theta \ , \tag{16.62}$$

and the total radiated power is,

$$P = \frac{c^2 Z_0 k^6}{960\pi} Q_0^2 \ . \tag{16.63}$$

For multipoles of higher order the formulas become more and more complicated. Other techniques based on the multipolar expansion of the wave equation, rather than deriving the radiation patterns directly from the retarded potentials, are more suitable. Resolve the Exc. 16.1.6.7.

16.1.5 Multipolar expansion of the wave equation

The radiation from sources which are small in comparison with the observation distance exhibits a symmetry suggesting a reformulation of the wave equation in spherical coordinates, as we have already done in Sec. 10.6.3. In short, we consider a scalar field $\psi(\mathbf{r}, t)$ satisfying the wave equation,

$$\nabla^2 \psi - \frac{1}{c^2} \frac{\partial^2 \psi}{\partial t^2} = 0 \ . \tag{16.64}$$

The temporal dependency is separated by a Fourier transform,

$$\psi(\mathbf{r}, t) = \int_{-\infty}^{\infty} \phi(\mathbf{r}, \omega) e^{-\imath\omega t} d\omega \ , \tag{16.65}$$

yielding a distribution of the amplitudes which satisfying the Poisson equation,

$$(\nabla^2 + k^2)\phi(\mathbf{r}, \omega) = 0 \ , \tag{16.66}$$

with $\omega^2 = c^2 k^2$. Expanding into spherical harmonics by the ansatz,

$$\phi(\mathbf{r}, \omega) = \sum_{\ell, m} f_\ell(r) Y_{\ell,m}(\theta, \phi) \ , \tag{16.67}$$

we transform (16.66), where the Laplacian is expressed in spherical coordinates, into a differential equation which is independent of m,

$$\left[\frac{d^2}{dr^2}+\frac{2}{r}\frac{d}{dr}+k^2-\frac{\ell(\ell+1)}{r^2}\right]f_\ell(r)=0\ . \tag{16.68}$$

This equation is precisely the spherical Bessel equation, whose solutions are linear combinations of spherical Bessel and von Neumann functions,

$$A_\ell j_\ell(kr)+B_\ell n_\ell(kr)\ . \tag{16.69}$$

With respect to the spherical part, we note that the spherical harmonics are the eigenfunctions of the square of an angular momentum operator $\hat{\mathbf{L}}$, which can be identified with the angular part of the Laplacian in spherical coordinates,

$$\hat{\mathbf{L}}^2=-\left[\frac{1}{\sin\theta}\frac{\partial}{\partial\sin\theta}\left(\sin\theta\frac{\partial}{\partial\sin\theta}\right)+\frac{1}{\sin^2\theta}\frac{\partial}{\partial\phi}\right]\ , \tag{16.70}$$

and has as eigenvalues the integer numbers $\ell(\ell+1)$,

$$\hat{\mathbf{L}}^2Y_{\ell m}=\ell(\ell+1)Y_{\ell m}\ . \tag{16.71}$$

The Lie algebra ruling the calculation with angular momentum operators will not be reproduced here [5].

Clearly, the simplicity of the multipolar expansion of the wave equation (16.64) into spherical coordinates is due to its scalar nature, and a similar procedure is used to solve the scalar Schrödinger equation for the hydrogen atom. Electromagnetic fields, however, are vectorial which complicates the calculus, as we will see in the following.

16.1.5.1 Multipolar expansion of the fields

Assuming a time dependence as $e^{-\imath\omega t}$ and combining the Maxwell equations for the field rotations to derive the Helmholtz equation, we obtain a set of equations, which is equivalent to the Maxwell equations,

$$(\nabla^2+k^2)\vec{\mathcal{B}}=0 \qquad \text{and} \qquad \nabla\cdot\vec{\mathcal{B}}=0 \qquad \text{with} \qquad \vec{\mathcal{E}}=\imath\frac{c}{k}\nabla\times\vec{\mathcal{B}}\ , \tag{16.72}$$

or alternatively,

$$(\nabla^2+k^2)\vec{\mathcal{E}}=0 \qquad \text{and} \qquad \nabla\cdot\vec{\mathcal{E}}=0 \qquad \text{with} \qquad \vec{\mathcal{B}}=\imath\frac{1}{ck}\nabla\times\vec{\mathcal{E}}\ . \tag{16.73}$$

Now, we have for any well-behaved vector field $\mathbf{X}$,

$$\nabla^2(\mathbf{r}\cdot\mathbf{X})=\mathbf{r}\cdot(\nabla^2\mathbf{X})+2\nabla\cdot\mathbf{X}\ . \tag{16.74}$$

Applying this relation to the electromagnetic fields, we find,

$$\boxed{(\nabla^2+k^2)(\mathbf{r}\cdot\vec{\mathcal{B}})=0 \qquad \text{and} \qquad (\nabla^2+k^2)(\mathbf{r}\cdot\vec{\mathcal{E}})=0}\ . \tag{16.75}$$

[5] See the treatment of spherical potentials in Sec. 23.5.1 .

The *transverse magnetic field* and the *transverse electric field* can be rewritten by the rotation of the equations (16.72) respectively (16.73),

$$\begin{aligned} \mathbf{r}\cdot\vec{\mathcal{B}} &= \tfrac{\imath}{ck}\mathbf{r}\cdot(\nabla\times\vec{\mathcal{E}}) = \tfrac{\imath}{ck}(\mathbf{r}\times\nabla)\cdot\vec{\mathcal{E}} \equiv \tfrac{1}{ck}\mathbf{L}\cdot\vec{\mathcal{E}} \\ \mathbf{r}\cdot\vec{\mathcal{E}} &= \tfrac{\imath c}{k}\mathbf{r}\cdot(\nabla\times\vec{\mathcal{B}}) = \tfrac{\imath c}{k}(\mathbf{r}\times\nabla)\cdot\vec{\mathcal{B}} \equiv \tfrac{c}{k}\mathbf{L}\cdot\vec{\mathcal{B}} \end{aligned} , \tag{16.76}$$

defining in this way the operator for the orbital angular momentum $\mathbf{L}$.

These scalar fields can now be expanded as demonstrated in (16.67) and (16.69). That is, we can expand the transverse parts of electric and magnetic fields into magnetic (electric) multipoles as,

$$\begin{aligned} \mathbf{r}\cdot\vec{\mathcal{B}}^{(M)}_{\ell m} &= \tfrac{\ell(\ell+1)}{k}g_\ell(kr)Y_{\ell m}(\theta,\phi) = \tfrac{1}{ck}\mathbf{L}\cdot\vec{\mathcal{E}}^{(M)}_{\ell m} \quad \text{and} \quad \mathbf{r}\cdot\vec{\mathcal{E}}^{(M)}_{\ell m} = 0 \\ \mathbf{r}\cdot\vec{\mathcal{E}}^{(E)}_{\ell m} &= -Z_0\tfrac{\ell(\ell+1)}{k}f_\ell(kr)Y_{\ell m}(\theta,\phi) = \tfrac{c}{k}\mathbf{L}\cdot\vec{\mathcal{B}}^{(E)}_{\ell m} \quad \text{and} \quad \mathbf{r}\cdot\vec{\mathcal{B}}^{(E)}_{\ell m} = 0 \end{aligned} . \tag{16.77}$$

where g_ℓ is a linear combination of Bessel and Hankel functions and $\ell(\ell+1)/k$ a convenient normalization factor.

We can see (by simplifying the argument a bit) that, by comparing (16.77) with the equation (16.71) the field $\vec{\mathcal{E}}^{(M)}$ must contain the operator $\mathbf{L}$,

$$\boxed{\begin{aligned} \vec{\mathcal{E}}^{(M)} &= cg_\ell(kr)\mathbf{L}Y_{\ell m}(\theta,\phi) \quad \text{with} \quad \vec{\mathcal{B}}^{(M)} = -\tfrac{\imath}{ck}\nabla\times\vec{\mathcal{E}}^{(M)}_{\ell m} \\ \vec{\mathcal{B}}^{(E)} &= \mu_0 g_\ell(kr)\mathbf{L}Y_{\ell m}(\theta,\phi) \quad \text{with} \quad \vec{\mathcal{E}}^{(E)} = -\tfrac{\imath c}{k}\nabla\times\vec{\mathcal{B}}^{(E)}_{\ell m} \end{aligned}} . \tag{16.78}$$

The functions,

$$\mathbf{X}_{\ell m}(\theta,\phi) = \frac{1}{\sqrt{\ell(\ell+1)}}\mathbf{L}Y_{\ell m}(\theta,\phi) , \tag{16.79}$$

are known as *vector spherical harmonics*. Combining the expansions into electric and magnetic multipoles we obtain,

$$\begin{aligned} \vec{\mathcal{B}} &= \sum_{\ell m}\left[a^{(E)}_{\ell,m}f_\ell(kr)\mathbf{X}_{\ell,m} - \tfrac{\imath}{k}a^{(M)}_{\ell,m}\nabla\times g_\ell(kr)\mathbf{X}_{\ell m}\right] \\ \vec{\mathcal{E}} &= \sum_{\ell m}\left[\tfrac{\imath}{k}a^{(E)}_{\ell,m}\nabla\times f_\ell(kr)\mathbf{X}_{\ell,m} - a^{(M)}_{\ell,m}g_\ell(kr)\mathbf{X}_{\ell m}\right] . \end{aligned} \tag{16.80}$$

The coefficients can be determined from the radial projections of the fields.

16.1.5.2 Vector spherical harmonics

The *vector spherical harmonics* defined above are a particular case of those defined for the coupling of two spins $\mathbf{L}$ and $\mathbf{S}$ with $S=1$ in the following sense,

$$\boxed{\mathbf{Y}_{j\ell m} = \sum_q \begin{pmatrix} J & 1 & L \\ -m & q & m-q \end{pmatrix} Y^{(\ell)}_{m-q}\hat{\mathbf{e}}_q} , \tag{16.81}$$

where the basis is in Cartesian coordinates,

$$\hat{\mathbf{e}}_0 = \hat{\mathbf{e}}_z \qquad \text{and} \qquad \hat{\mathbf{e}}_\pm = -\tfrac{1}{\sqrt{2}}(\hat{\mathbf{e}}_x \pm \imath \hat{\mathbf{e}}_y) \ . \tag{16.82}$$

These functions are tensor operators of rank $(1,\ell)$, since $\mathbf{Y}_{j\ell m} = (Y^{(\ell)} \otimes \hat{\mathbf{e}}^{(1)})^{(j)}_m$. This means they have vectorial properties via $\hat{\mathbf{e}}^{(1)}_q$ and, at the same time, are tensor operators just like the spherical harmonics $Y^{(\ell)}_m$. It is possible to check the following expressions,

$$\begin{aligned} \mathbf{J}^2\mathbf{Y}_{j\ell m} &= j(j+1)\mathbf{Y}_{j\ell m} \\ \mathbf{L}^2\mathbf{Y}_{j\ell m} &= \ell(\ell+1)\mathbf{Y}_{j\ell m} \\ \mathbf{S}^2\mathbf{Y}_{j\ell m} &= 2\mathbf{Y}_{j\ell m} \\ \mathbf{J}_z\mathbf{Y}_{j\ell m} &= m\mathbf{Y}_{j\ell m} \ . \end{aligned} \tag{16.83}$$

Furthermore, comparing (16.83) and (16.79),

$$\begin{aligned} \frac{\mathbf{L}}{\sqrt{\ell(\ell+1)}} Y^{(\ell)}_m &= -\imath \mathbf{Y}_{\ell\ell m} = \mathbf{X}_{\ell m} \\ \frac{\mathbf{r}}{r} Y^{(\ell)}_m &= \imath\sqrt{\frac{\ell+1}{2\ell+1}}\mathbf{Y}_{\ell\ \ell+1\ m} - \imath\sqrt{\frac{l}{2\ell+1}}\mathbf{Y}_{\ell\ \ell-1\ m} \\ 0 &= \mathbf{r}\cdot\mathbf{Y}_{\ell\ell m} = \mathbf{p}\cdot\mathbf{Y}_{\ell\ell m} \ . \end{aligned} \tag{16.84}$$

In 16.1.6.8 we calculate the following examples, $\mathbf{Y}_{000} = 0$ and,

$$r\mathbf{Y}_{110} = \sqrt{\tfrac{3}{16\pi}}\begin{pmatrix} -\imath y \\ \imath x \\ 0 \end{pmatrix} \quad , \quad r\mathbf{Y}_{11\pm1} = \sqrt{\tfrac{3}{16\pi}}\begin{pmatrix} z \\ \pm\imath \\ -(x\pm\imath y) \end{pmatrix} \quad , \quad r\mathbf{Y}_{10\pm1} = -\sqrt{\tfrac{1}{24\pi}}\begin{pmatrix} x \\ \pm\imath y \\ 0 \end{pmatrix} \ . \tag{16.85}$$

Also,

$$\mathbf{Y}^2_{\kappa\kappa m} = [\kappa(\kappa+1)-m(m+1)]|Y_{\kappa\ m+1}|^2 + 2m^2|Y_{\kappa\ m}|^2 + [\kappa(\kappa+1)-m(m-1)]|Y_{\kappa\ m-1}|^2 \ . \tag{16.86}$$

Applying the formulas [966](Chp. 10.1) to scalar and vector products of vector spherical harmonics, it is possible to derive the energy density $\frac{\varepsilon_0}{2}\vec{\mathcal{E}}^2_{jm\tau} + \frac{1}{2\mu_0}\vec{\mathcal{B}}^2_{jm\tau}$ and the Poynting vector $\varepsilon_0|\vec{\mathcal{E}}_{jm\tau}\times\vec{\mathcal{B}}_{jm\tau}|$. The calculation is complicated, because we must calculate $(3j)$, $\{6j\}$, and $\{9j\}$ coefficients. Considering that the angular distribution is the same for electric and magnetic multipolar radiation, we obtain,

$$u_{jm\tau}(\mathbf{r}) = \frac{1}{2\mu_0}\vec{\mathcal{B}}^2_{jm\tau}(\mathbf{r}) = -\frac{\hbar\omega}{4V}\left(\frac{j+1}{2j+1}\right)^2 \frac{(kr)^{2j}}{(2j+1)!!^2}\mathbf{Y}^2_{jjm} \ , \tag{16.87}$$

The question now is, with what polarization ε and under what angle of incidence $\mathbf{k}$ can we excite a particular multipolar transition. The transition can only be excited by a mode, to which it couples and, therefore, into which it can radiate light. Therefore, it is sufficient to analyze the angular distribution and the polarization of spontaneously

emitted radiation. In the far-field of a point source the electric and magnetic fields satisfy the Helmholtz equation [966],

$$(\triangle + \mathbf{k}^2)\vec{\mathcal{E}}(\mathbf{r},t) = 0 \ , \tag{16.88}$$

and similarly for the magnetic field $\vec{\mathcal{B}}(\mathbf{r},t)$. An atomic transition $|J,m_J\rangle \leftrightarrow |J+\kappa, m_J+m\rangle$ interacts with the electric or magnetic multipolar part κ of the radiation field. The general solution of the Helmholtz equation, therefore, is expanded into spherical harmonics $Y_{\kappa m}(\theta,\phi)$:

$$\vec{\mathcal{E}} = \sum_{\kappa=0}^{\infty}\sum_{m=-\kappa}^{\kappa}\left(\vec{\mathcal{E}}_m^{(E\kappa)} + \vec{\mathcal{E}}_m^{(M\kappa)}\right) \tag{16.89}$$

and similarly for the magnetic field. The angular distributions of the multipolar electric field components are calculated by,

$$\vec{\mathcal{E}}_m^{(E\kappa)} = -\imath k^{-1}\nabla\times\vec{\mathcal{B}}_m^{(E\kappa)} \tag{16.90}$$

$$\vec{\mathcal{B}}_m^{(E\kappa)} = -\imath\,(\mathbf{k}\times\nabla)\,Y_{\kappa m}(\theta,\phi) \equiv \sqrt{\kappa(\kappa+1)}\mathbf{Y}_{\kappa\kappa m}(\theta,\phi) \ , \tag{16.91}$$

and similarly for the magnetic field. The field components can be expressed by the vector spherical harmonics $\mathbf{Y}_{\kappa\kappa m}$. The angular distribution of the radiated intensity follows from the absolute value of the Poynting vector,

$$I_m^{(E\kappa)}(\mathbf{r}) = \mu_0^{-1}\left|\vec{\mathcal{E}}_m^{(E\kappa)}(\mathbf{r})\times\vec{\mathcal{B}}_m^{(E\kappa)}(\mathbf{r})\right| = \mu_0^{-1}\left|\vec{\mathcal{B}}_m^{(E\kappa)}(\mathbf{r})\right|^2 \propto \mathbf{Y}_{\kappa\kappa m}(\theta,\phi)^2 \ . \tag{16.92}$$

The multipolar order of a radiation can, in principle, be determined by measuring its angular distribution. The above distribution integrate over all possible polarizations. If polarized light is used, in order to excite transitions between selected Zeeman levels, the angular intensity distribution of *polarized radiation* must be calculated. The transition rate between two levels $|a\rangle$ and $|b\rangle$ for light incident from a given direction $\mathbf{r}$ with a given polarization $\hat{\varepsilon}$ is, $|\langle b|\hat{\varepsilon}\vec{\mathcal{E}}_m^{(E\kappa)}(\mathbf{r})|a\rangle|^2$, where $\vec{\mathcal{E}}_m^{(E\kappa)}(\mathbf{r}) = -\imath k^{-1}\nabla\times\vec{\mathcal{B}}_m^{(E\kappa)}(\mathbf{r})$. The cases of linear polar polarization (respectively axial) of the light field in relation to the quantization axis are expressed by the fractions $\hat{\varepsilon}_{polar}\cdot\mathbf{Y}_{\kappa\kappa m}$, respectively, $\hat{\varepsilon}_{axial}\cdot\mathbf{Y}_{\kappa\kappa m}$, the absolute square values of which add up to the angular intensity distribution,

$$\begin{aligned}
u_{10} &\sim 4|Y_1^{(1)}|^2 &&= \tfrac{3}{4\pi}2\sin^2\theta\\
u_{1\pm1} &\sim 2|Y_1^{(1)}|^2 + 2|Y_0^{(1)}|^2 &&= \tfrac{3}{4\pi}(1+\cos^2)\\
u_{20} &\sim 12|Y_1^{(2)}|^2 &&= \tfrac{5}{4\pi}18\sin^2\cos^2\\
u_{2\pm1} &\sim 4|Y_2^{(2)}|^2 + 2|Y_1^{(2)}|^2 + 6|Y_0^{(2)}|^2 &&= \tfrac{5}{4\pi}3(4\cos^2 - 3\cos^2 + 1)\\
u_{2\pm2} &\sim 8|Y_2^{(2)}|^2 + 4|Y_1^{(2)}|^2 &&= \tfrac{5}{4\pi}3\sin^2(1+\cos^2)\\
u_{30} &\sim 24|Y_1^{(3)}|^2 &&= \tfrac{7}{4\pi}\tfrac{9}{2}\sin^2(5\cos^2 - 1)^2\\
u_{3\pm1} &\sim 10|Y_2^{(3)}|^2 + 2|Y_1^{(3)}|^2 + 12|Y_0^{(3)}|^2 &&= \tfrac{7}{4\pi}\tfrac{3}{8}(225\cos^6 - 305\cos^4 + 111\cos^2 + 1)\\
u_{3\pm2} &\sim 6|Y_3^{(3)}|^2 + 8|Y_2^{(3)}|^2 + 10|Y_1^{(3)}|^2 &&= \tfrac{7}{4\pi}\tfrac{15}{4}\sin^2(9\cos^4 - 2\cos^2 + 1)\\
u_{3\pm3} &\sim 18|Y_3^{(3)}|^2 + 6|Y_2^{(3)}|^2 &&= \tfrac{7}{4\pi}\tfrac{45}{8}\sin^4(1+\cos^2) \ .
\end{aligned} \tag{16.93}$$

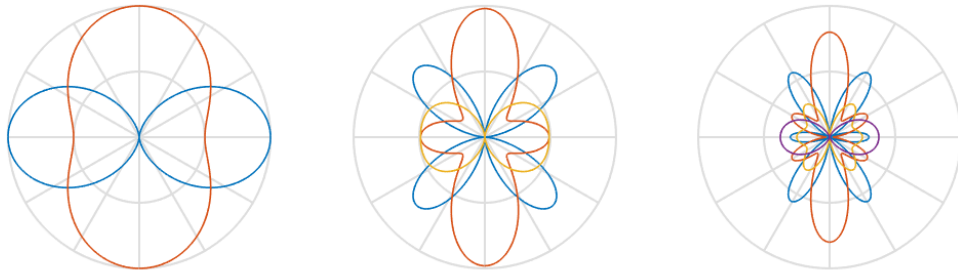

Figure 16.3: (code) Angular dependence of dipolar radiation u_{1m} (left), quadrupolar u_{2m} (center) and u_{3m} octupolar (right) with their respective contributions $m = 0$ (blue), $m = \pm 1$ (red), $m = \pm 2$ (yellow) and $m = \pm 3$ (magenta).

In the equatorial plane, only the parts $u_{j\pm 1}$ contribute; but these disappear in polar direction. All other components lie in the equatorial plane. For non-polarized radiation the angular distribution is uniform,

$$\sum_{m=-j}^{j} u_{jm} \sim \tfrac{2j+1}{4\pi} 2(j+1)! \ . \tag{16.94}$$

16.1.6 Exercises

16.1.6.1 Ex: Relationship between current density and electric dipole moment

a. For a charge and current configuration contained in a volume $\mathcal{V}$ show that, $\int_{\mathcal{V}} \mathbf{j} dV = \frac{d\mathbf{d}}{dt}$, where $\mathbf{d}$ is the total dipolar moment.
b. Demonstrate the relationship, $\int \mathbf{r}'(\hat{\mathbf{e}}_r \cdot \mathbf{r}')\dot{\varrho}(\mathbf{r}')d^3r' = \int \{\mathbf{j}(\mathbf{r}')(\hat{\mathbf{e}}_r \cdot \mathbf{r}') + \mathbf{r}'[\hat{\mathbf{e}}_r \cdot \mathbf{j}(\mathbf{r}')]\} \, d^3r'$.

16.1.6.2 Ex: Hertz dipole

A Hertz dipole with vertical orientation is in the focus of a parabolic antenna PA1 and emits electromagnetic radiation with a frequency of 3 GHz. The shape of the antenna is such that the electromagnetic radiation is reflected forming a 'parallel' beam with diameter $d = 3\,\mathrm{m}$. The electric field within the beam can be roughly described by the following formula:

$$\vec{\mathcal{E}}_1(\mathbf{r}, t) = \vec{\mathcal{E}}_0 \cos(\mathbf{k}_1 \cdot \mathbf{r} - \omega t) \ \hat{\mathbf{e}}_z \qquad \text{where} \qquad \mathbf{k}_1 = -k\hat{\mathbf{e}}_x \sin\alpha + k\hat{\mathbf{e}}_y \cos\alpha \ .$$

a. Determine the parameter k using the wave equation.
b. What is the amplitude $\vec{\mathcal{E}}_0$ of the electric field assuming that the parabolic antenna emits a power of 5 W?
c. There is a second Hertz dipole, acting as a detector, oriented orthogonal to $\mathbf{k}_1$. The maximum amplitude of the electric field detected by D2 is around 0.1 V/m. Estimate the angle of the orientation of the dipole with respect to the vertical axis (without calculation, but with a short justification).

d. Now, the emitter dipole D1 is also rotated in such a way that, regardless of the orientation of the dipole D2, it does not receive signals. What is the orientation of the dipole emitter? Give a short justification.
e. The dipole emitter is again oriented vertically. Another parabolic antenna PA2, identical to PA1, is now integrated into the experiment, as shown in the figure. Calculate the power density S on the axis x in the time average. ($\alpha = 5°$)
Help: Addition theorems:

$$\cos(\alpha \pm \beta) = \cos\alpha\cos\beta \mp \sin\alpha\sin\beta \qquad \text{and} \qquad \cos 2\alpha = \cos^2\alpha - \sin^2\alpha$$

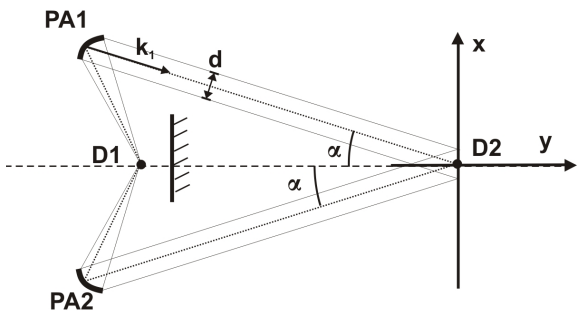

Figure 16.4: Hertz dipole.

16.1.6.3 Ex: Dipolar spherical waves

We derived in class, starting from the relations $\vec{\mathcal{B}} = \nabla \times \mathbf{A}$ and $\vec{\mathcal{E}} = \frac{\imath c}{k}\nabla \times \vec{\mathcal{B}}$, the expressions (16.40) for the magnetic and electric fields of a electric dipole radiation produced by the dipole moment $\mathbf{d} = d\hat{\mathbf{e}}_z$.
a. Show that the magnetic field can be expressed in the form $\vec{\mathcal{B}} = \vec{\mathcal{B}}_\phi(r,\theta)\hat{\mathbf{e}}_\phi$.
b. Show that the electric field can be expressed in the form $\vec{\mathcal{E}} = \vec{\mathcal{E}}_r(r,\theta)\hat{\mathbf{e}}_r + \vec{\mathcal{E}}_\theta(r,\theta)\hat{\mathbf{e}}_\theta$.
c. The purpose of this exercise is to check in spherical coordinates, where the divergence and rotation are given by (9.79) and (9.80), that these fields satisfy Maxwell's equations.

16.1.6.4 Ex: Gauges of dipolar potentials

Verify that the retarded potentials of an oscillating dipole,

$$\Phi(r,\theta,t) = \frac{p_0\cos\theta}{4\pi\varepsilon_0 r}\left\{-\frac{\omega}{c}\sin[\omega(t-r/c)] + \frac{1}{r}\cos[\omega(t-r/c)]\right\}$$
$$\mathbf{A}(r,\theta,t) = -\frac{\mu_0 p_0\omega}{4\pi r}\sin[\omega(t-r/c)]\hat{\mathbf{e}}_z \ ,$$

satisfy the Lorentz gauge.

16.1.6.5 Ex: Electric and magnetic fields of an oscillating electric dipole

Calculate the electric and magnetic fields of an oscillating electric dipole in the dipolar approximation ($kr' \ll 1$) but for arbitrary distances ($kr \lesseqgtr 1$) directly from the retarded potentials in spherical coordinates. Find the Poynting vector and show that the radiation intensity is exactly the same, as the one derived within the far-field approximation ($kr \gg 1$).

16.1.6.6 Ex: Electric and magnetic fields of an oscillating magnetic dipole

Calculate the electric and magnetic fields of an oscillating magnetic dipole in the dipolar approximation ($kr' \ll 1$), but for arbitrary distances ($kr \lesseqgtr 1$) directly from the retarded potentials in spherical coordinates. Compare with the fields of an oscillating electric dipole. Find the Poynting vector and show that the intensity of the radiation is exactly the same, as the one derived within the far-field approximation ($kr \gg 1$).

16.1.6.7 Ex: Spherical harmonics

The spherical harmonic function for $\ell = 2$ and $m = 1$ has the form,

$$Y_{21}(\vartheta, \varphi) = \sqrt{\tfrac{15}{8\pi}} \sin\vartheta \cos\vartheta (\cos\varphi + \imath \sin\varphi) \ .$$

Express the quadrupolar momentum q_{21} as a linear combination in Cartesian coordinates,

$$Q_{ij} = \int \rho(\mathbf{r})(3x_i x_j - \delta_{ij} r^2) \ dr^3 \ .$$

16.1.6.8 Ex: Vector spherical harmonics

Calculate the angular distribution of $E1$ and $M1$ radiation.Derive Eq. (16.85).

16.2 Radiation of point charges

The fundamental structure of matter is based on electromagnetic forces: Electrons are bound to nuclei by the Coulomb-Lorentz force, the orbital motion of the electrons produces magnetic fields, which can interact with the intrinsic spins of electrons and nuclei, external electromagnetic fields can influence the motion of electrons. Therefore, it is of primary interest to understand the radiation emitted by accelerated point-like electric charges.

16.2.1 Power radiated by an accelerated point charge

We derived in an earlier chapter the fields (14.140) and (14.141) produced by an arbitrary moving charge,

$$\begin{aligned}\vec{\mathcal{E}}(\mathbf{r},t) &= \frac{q}{4\pi\varepsilon_0}\frac{R}{(\mathbf{R}\cdot\mathbf{u})^3}[(c^2-v^2)\mathbf{u}+\mathbf{R}\times(\mathbf{u}\times\mathbf{a})] \\ \vec{\mathcal{B}}(\mathbf{r},t) &= \tfrac{1}{c}\mathbf{R}\times\vec{\mathcal{E}}(\mathbf{r},t)\ ,\end{aligned} \tag{16.95}$$

with $\mathbf{u} = c\hat{\mathbf{e}}_r - \mathbf{v}$. We call the first term in (16.95) *velocity field* and the second *acceleration field*. The Poynting vector is,

$$\vec{\mathcal{S}} = \tfrac{1}{\mu_0}(\vec{\mathcal{E}}\times\vec{\mathcal{B}}) = \tfrac{1}{\mu_0 c}[\vec{\mathcal{E}}\times(\mathbf{R}\times\vec{\mathcal{E}})] = \tfrac{1}{\mu_0 c}[\mathcal{E}^2\hat{\mathbf{e}}_r - (\hat{\mathbf{e}}_r\cdot\vec{\mathcal{E}})\vec{\mathcal{E}}]\ . \tag{16.96}$$

However, not all of this energy flow constitutes radiation; part of it is field energy *transported* by the particle as it moves. The *radiated* energy is the part that separates from the charge and propagates to infinity. To calculate the total power radiated by the particle at time t_r we draw a large sphere of radius R, centered on the position of the particle at time t_r, we wait for the appropriate interval,

$$t - t_r \equiv \frac{R}{c}\ , \tag{16.97}$$

for the radiation to reach the sphere and, at that moment, we integrate the Poynting vector on the surface. The notation t_r points to the fact, that this is the retarded time for all points on the sphere at time t. Now, the area of the sphere is proportional to R^2, hence any term in $\vec{\mathcal{S}}$ that goes like $1/R^2$ will produce a finite response, but terms like $1/R^3$ or $1/R^4$ will not contribute in the limit $R\to\infty$. For this reason, only the acceleration field truly radiates:

$$\vec{\mathcal{E}}_{\rm rad} = \frac{q}{4\pi\varepsilon_0}\frac{R}{(\mathbf{R}\cdot\mathbf{u})^3}[\mathbf{R}\times(\mathbf{u}\times\mathbf{a})]\ . \tag{16.98}$$

Since $\vec{\mathcal{E}}_{\rm rad}\perp\mathbf{R}$, the second term in Eq. (16.96) disappears:

$$\vec{\mathcal{S}}_{\rm rad} = \frac{1}{\mu_0 c}\vec{\mathcal{E}}^2_{\rm rad}\hat{\mathbf{e}}_r\ . \tag{16.99}$$

Example 119 (*Radiation at the turning point*): If at time t_r the charge is instantaneously at rest, $\mathbf{v}(t_r) = 0$, for example at the turning points of a harmonic oscillation, then $\mathbf{u} = c\hat{\mathbf{e}}_r$, and,

$$\vec{\mathcal{E}}_{\rm rad} = \frac{q}{4\pi\varepsilon_0 c^2 R}[\hat{\mathbf{e}}_r\times(\hat{\mathbf{e}}_r\times\mathbf{a})] = \frac{\mu_0 q}{4\pi R}[(\hat{\mathbf{e}}_r\cdot\mathbf{a})\hat{\mathbf{e}}_r - \mathbf{a}]\ . \tag{16.100}$$

In this case,

$$\vec{\mathcal{S}}_{\rm rad} = \frac{1}{\mu_0 c}\left(\frac{\mu_0 q}{4\pi R}\right)^2[a^2-(\hat{\mathbf{e}}_r\cdot\mathbf{a})^2]\hat{\mathbf{e}}_r = \frac{\mu_0 q^2 a^2}{16\pi^2 c}\frac{\sin^2\theta}{R^2}\ , \tag{16.101}$$

where θ is the angle between $\hat{\mathbf{e}}_r$ and $\mathbf{a}$. No power is radiated in forward or backward directions. Instead, it is emitted in a torus around the instantaneous

acceleration, as shown in Fig. 16.5(a).
The total radiated power is evidently,

$$P = \oint \vec{\mathcal{S}}_{\rm rad} \cdot d\mathbf{S} = \frac{\mu_0 q^2 a^2}{16\pi^2 c} \int \frac{\sin^2\theta}{R^2} R^2 \sin\theta d\theta d\phi = \frac{\mu_0 q^2 a^2}{6\pi c} \ . \tag{16.102}$$

This, again, is the *Larmor formula*, which we previously obtained via another route (16.19). Although derived under the assumption that $v = 0$, the equations (16.101) and (16.102) represent a good approximation, since $v \ll c$.

An exact treatment of the case $v \neq 0$ is more difficult for two reasons. The first obvious reason is, that $\vec{\mathcal{E}}_{\rm rad}$ is more complicated, and the second more subtle reason is that $\vec{\mathcal{S}}_{\rm rad}$, which is the rate at which energy passes through the sphere, is not equal to the rate at which the energy separated from the particle. Suppose someone is throwing a stream of bullets through the window of a moving car. The rate N_t at which the bullets hit a stationary target is not the same as the rate N_g at which they left the weapon, because of the movement of the car. In fact, we can easily verify that $N_g = (1 - v/c)N_t$, if the car is moving toward the target, and,

$$N_g = \left(1 - \tfrac{\hat{\mathbf{e}}_r \cdot \mathbf{v}}{c}\right) N_t \tag{16.103}$$

for arbitrary directions (here v is the speed of the car, c is the velocity of the bullets, and $\mathbf{R}$ is a unit vector pointing from the car towards the target). In our case, if dW/dt is the rate at which energy passes through the sphere of radius R, then the rate at which the energy separated from the charge was,

$$\frac{dW}{dt_r} = \frac{dW/dt}{\partial t_r/\partial t} \ . \tag{16.104}$$

We calculate the denominator from the relation (16.97),

$$\begin{aligned} \frac{\partial t_r}{\partial t} &= 1 - \frac{\partial\sqrt{[\mathbf{r} - \mathbf{w}(t_r)]^2}}{c\partial t} = 1 - \frac{-2[\mathbf{r} - \mathbf{w}(t_r)]}{2c\sqrt{[\mathbf{r} - \mathbf{w}(t_r)]^2}} \cdot \frac{\partial \mathbf{w}(t_r)}{\partial t_r}\frac{\partial t_r}{\partial t} \\ &= 1 + \frac{\mathbf{R}}{cR} \cdot \mathbf{v}\frac{\partial t_r}{\partial t} = \frac{1}{1 - \hat{\mathbf{e}}_R \cdot \mathbf{v}/c} = \frac{cR}{\mathbf{R} \cdot \mathbf{u}} \ . \end{aligned} \tag{16.105}$$

This factor is precisely that of the relation (16.103) between N_g and N_t; is a purely geometric factor (the same as in the Doppler effect).

Therefore, the power radiated by the particle into an area element, $R^2 \sin\theta d\theta d\phi = R^2 d\Omega$ of the sphere is, using the Poynting vector (16.99) and the radiated field (16.98), given by,

$$\frac{dP}{d\Omega} = \frac{\vec{\mathcal{S}}_{\rm rad}}{\partial t_r/\partial t} = \frac{\mathbf{R} \cdot \mathbf{u}}{Rc}\frac{1}{\mu_0 c}\vec{\mathcal{E}}^2_{\rm rad} R^2 = \frac{q^2}{16\pi^2\varepsilon_0}\frac{|\hat{\mathbf{e}}_r \times (\mathbf{u} \times \mathbf{a})|^2}{(\hat{\mathbf{e}}_r \cdot \mathbf{u})^5} \ , \tag{16.106}$$

where $d\Omega = \sin\theta d\theta d\phi$ is the solid angle at which this energy is radiated. Integrating over θ and ϕ to obtain the total radiated power is not easy, such that we simply quote the answer:

$$\boxed{P = \frac{\mu_0 q^2 \gamma^6}{6\pi c}\left(a^2 - \left|\frac{\mathbf{v} \times \mathbf{a}}{c}\right|^2\right)} \ , \tag{16.107}$$

where $\gamma \equiv 1/\sqrt{1-v^2/c^2}$. This is *Liénard's generalization* of Larmor's formula, to which it reduces when $v \ll c$. The factor γ^6 means that the radiated power increases enormously as the velocity of the particle approaches the speed of light.

Resolve the Excs. 16.2.3.1 to 16.2.3.5.

16.2.1.1 Bremsstrahlung

Suppose that $\mathbf{v}$ and $\mathbf{a}$ be instantaneously collinear (at time t_r), such as for a motion on a straight line. In this case $\mathbf{u} \times \mathbf{a} = (c\hat{\mathbf{e}}_r - \cancel{\mathbf{v}}^{\,0}) \times \mathbf{a}$, then the angular distribution of radiation (16.106) gives,

$$\frac{dP}{d\Omega} = \frac{q^2c^2}{16\pi^2\varepsilon_0}\frac{|\hat{\mathbf{e}}_r \times (\hat{\mathbf{e}}_r \times \mathbf{a})|^2}{(c - \hat{\mathbf{e}}_r \cdot \mathbf{v})^5} \ . \tag{16.108}$$

Now with $|\hat{\mathbf{e}}_r \times (\hat{\mathbf{e}}_r \times \mathbf{a})| = a \sin\theta$ and letting $\mathbf{v} \equiv v\hat{\mathbf{e}}_z$,

$$\frac{dP}{d\Omega} = \frac{\mu_0 q^2 a^2}{16\pi^2 c}\frac{\sin^2\theta}{(1-\beta\cos\theta)^5} \ , \tag{16.109}$$

where $\beta \equiv v/c$. This is consistent with the result (16.101), in the case $v = 0$. However, for very large v ($\beta \approx 1$), the torus of the radiation illustrated in Fig. 16.5(a) is stretched and pushed forward by a factor $(1-\beta\cos\theta)^{-5}$, as indicated in Fig. 16.5(b). Although there is still no radiation in the exact forward direction, most of the radiation is concentrated in an increasingly narrow cone around the forward direction.

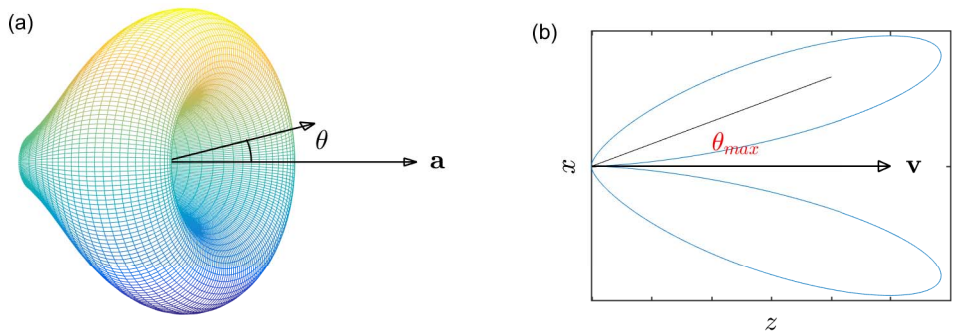

Figure 16.5: (code) (a) Radiation pattern of an accelerated charge. (b) Angular distribution of the bremsstrahlung.

The total emitted power is found by integrating equation (16.110) over all angles:

$$\begin{aligned} P &= \int \frac{dP}{d\Omega}d\Omega = \frac{\mu_0 q^2 a^2}{16\pi^2 c}\int \frac{\sin^2\theta}{(1-\beta\cos\theta)^5}\sin\theta d\theta d\phi \\ &= \frac{\mu_0 q^2 a^2}{8\pi c}\int_{-1}^{+1}\frac{1-x^2}{(1-\beta x)^5}dx = \frac{\mu_0 q^2 a^2}{8\pi c}\tfrac{4}{3}(1-\beta^2)^{-3} = \frac{\mu_0 q^2 a^2 \gamma^6}{6\pi c} \ . \end{aligned} \tag{16.110}$$

This result is consistent with the Liénard's formula (16.107), for the case when $\mathbf{v}$ and $\mathbf{a}$ are collinear. Note that the angular distribution of radiation is the same,

whether the particle is accelerating or decelerating; it does not depend on $\mathbf{a}$, but only on velocity being concentrated in forward direction (with respect to the velocity) in both cases. When a high-speed electron hits a metal target, it decelerates rapidly, releasing what is called bremsstrahlung. This example is essentially the classical theory of *bremsstrahlung*.

We will calculate the *synchrotron radiation* in Exc. 16.2.3.6 and the *Cherenkov radiation* in Exc. 16.2.3.7. A movie illustrating the Cherenkov radiation emission can be viewed at (watch movie).

Example 120 (*Bremsstrahlung of thermal electrons*): The power lost by bremsstrahlung for not extremely relativistic velocities is,

$$P = \frac{\mu_0 q^2 a^2 \gamma^2}{6\pi c} \simeq \frac{\mu_0 q^2 a^2}{6\pi c} \ ,$$

such that,

$$\vec{\mathcal{E}}_{\text{rad}} = \int_0^t P dt = \frac{\mu_0 q^2 a^2}{6\pi c} \int_{v_0}^0 \frac{dv}{\dot{v}} = \frac{\mu_0 q^2 a}{6\pi c} \int_{v_0}^0 dv = \frac{\mu_0 q^2 a}{6\pi c} v_0 \ .$$

For an electron in a metal with a free path of $d \approx 3$ nm and a thermal velocity $v_0 = 100000$ m/s the deceleration $a = \frac{v_0^2}{2d}$ leads to a negligible radiated fraction,

$$\frac{\vec{\mathcal{E}}_{\text{rad}}}{E_{kin}} = \frac{\frac{\mu_0 q^2 a}{6\pi c} v_0}{\frac{m}{2} v_0^2} = \frac{\mu_0 q^2 a}{3\pi c m v_0} = \frac{\mu_0 q^2}{3\pi c m} \frac{v_0}{2d} \approx 2 \cdot 10^{-10} \ .$$

16.2.2 Radiation reaction

According to the laws of classical electrodynamics, an accelerated charge radiates. This radiation takes energy, which must come at the expense of the particle's kinetic energy. Under the influence of a given force, therefore, a charged particle accelerates less than a neutral particle of the same mass. The radiation evidently exerts a reactive force $\mathbf{F}_{\text{rad}}$ corresponding to a recoil. We will now derive the *radiation reaction* force from energy conservation.

For a non-relativistic particle ($v \ll c$), the total radiated power P is given by the *Larmor formula* (16.102). The conservation of energy suggests that this is also the rate at which the particle loses energy, under the influence of the radiative reaction force $\mathbf{F}_{\text{rad}}$:

$$\mathbf{F}_{\text{rad}} \cdot \mathbf{v} \stackrel{?}{=} -\frac{\mu_0 q^2 a^2}{6\pi c} = -P \ . \tag{16.111}$$

However, this equation is really wrong. For, to derive Larmor's formula, we calculated the radiated power by integrating the Poynting vector on a sphere of 'infinite' radius; in this calculation the velocity fields *did not contribute*, since they fall off very rapidly as a function of R. However, the velocity fields *carry* energy; they simply do not carry it to infinity. As the particle accelerates and decelerates, it exchanges energy with the velocity fields, while another part of the energy is irremediably radiated away by the acceleration fields. The equation (16.111) only takes into account this lost energy, but if we want to know the recoil force exerted by the fields on the charge, we must consider the power lost at each instant of time, not only the radiatively

escaping power. (In this sense the term 'radiation reaction' is misleading and should be replaced by 'field reaction'.) In fact, we shall see shortly that $F_{\rm rad}$ is determined by the time derivative of the acceleration and can be nonzero, even if the acceleration is instantaneously zero, such that the particle does not radiate.

The energy lost by the particle during a given time interval, therefore, must equal the energy carried away by radiation plus the extra energy that has been pumped into the velocity fields. However, if we agree to consider only time intervals $[t_1, t_2]$ over which the *system returns to its initial state*, then the energy in the velocity fields is the same at both times, and the only loss is through radiation. Thus, equation (16.111), while instantly incorrect, is valid on average:

$$\int_{t_1}^{t_2} \mathbf{F}_{\rm rad} \cdot \mathbf{v} dt = -\frac{\mu_0 q^2}{6\pi c} \int_{t_1}^{t_2} a^2 dt \ , \tag{16.112}$$

with the stipulation that the state of the system is identical at times t_1 and t_2. In the case of periodic movements, for example, we must integrate over a total number of complete cycles. Now, the right-hand side of the equation (16.112) can be integrated by parts:

$$\int_{t_1}^{t_2} \mathbf{a}^2 dt = \mathbf{v} \cdot \frac{d\mathbf{v}}{dt}\bigg|_{t_1}^{t_2} - \int_{t_1}^{t_2} \frac{d^2\mathbf{v}}{dt^2} \cdot \mathbf{v} dt \ . \tag{16.113}$$

The boundary term cancels, since the velocities and accelerations are identical at t_1 and t_2, then the equation (16.112) can be written in an equivalent way as,

$$\int_{t_1}^{t_2} \left(\mathbf{F}_{\rm rad} - \frac{\mu_0 q^2}{6\pi c} \dot{\mathbf{a}} \right) \cdot \mathbf{v} dt = 0 \ . \tag{16.114}$$

This equation will certainly be satisfied if,

$$\boxed{\mathbf{F}_{\rm rad} = \frac{\mu_0 q^2}{6\pi c} \dot{\mathbf{a}}} \ . \tag{16.115}$$

This is the *Abraham-Lorentz formula* for the radiation reaction force. Obviously, the equation (16.114) does not prove (16.115), because it does not say anything about the component of $\mathbf{F}_{\rm rad}$ perpendicular to $\mathbf{v}$; and only informs us on the time-average of the parallel component for, moreover, very special time intervals.

The Abraham-Lorentz formula has disturbing implications, which are not fully understood nearly a century after the law was first proposed. Let us assume that a particle is not subject to external forces; then Newton's second law tells us,

$$F_{\rm rad} = \frac{\mu_0 q^2}{6\pi c} \dot{a} = ma \ , \tag{16.116}$$

yielding,

$$a(t) = a_0 e^{t/\tau} \qquad \text{with} \qquad \tau = \frac{\mu_0 q^2}{6\pi m c} \ . \tag{16.117}$$

In the case of an electron, $\tau = 6 \cdot 10^{-24}$ s. The acceleration increases spontaneously exponentially with time! This absurd conclusion can be avoided, if we insist that $a_0 = 0$. But it turns out, that the systematic exclusion of such catastrophic solutions

has an even more unpleasant consequence: if we now *switch on* an external force, the particle begins to respond to it *before it actually has been switch on* (see Exc. 16.2.3.8 and 16.2.3.9).

Example 121 (*Radiative damping*): Here, we calculate the radiative damping rate τ of a charged particle fixed to a spring by solving the equation of motion,

$$m\ddot{x} = F_{sprng} + F_{\rm rad} + F_{excit} = -m\omega_0^2 x + m\tau\,\dddot{x} + F_{excit}\ .$$

With the oscillating system, $x(t) = x_0\cos(\omega t + \delta)$, we have,

$$\dddot{x} = -\omega^2\dot{x}\ .$$

Therefore,

$$m\ddot{x} + m\omega^2\tau\dot{x} + m\omega_0^2 x = F_{excit}\ ,$$

and the damping factor is given by $\omega^2\tau$.

Example 122 (*Radiation reaction*): In previous chapters, the problems of electrodynamics were divided into two classes: one class in which the charge and current sources are specified and the resulting electromagnetic fields are calculated, and the other class in which external electromagnetic fields are specified and the motion of charged particles of currents are calculated. Occasionally, as in the discussion of the bremsstrahlung, the two problems are combined. But the treatment is recursive: first, the motion of a charged particle in an external field is determined neglecting the radiation it emits; then the radiation of the particle is calculated from its (accelerated) trajectory treating the particle as a source of charge and current.
Obviously, this way of dealing with electrodynamical problems can only be approximate. The (accelerated) motion of charged particles within force fields necessarily involves the emission of radiation, removing energy, angular momentum, and momentum from the particles and thus influencing their subsequent motion. Consequently, the motion of radiation sources is (partially) determined by the emission of radiation, and a correct treatment must take account of the reaction of the radiation onto the motion of the sources. Fortunately, for many problems of electrodynamics the radiative reaction is negligibly small. On the other hand, there exists no completely satisfactory classical treatment. The difficulties presented by this problem touch upon fundamental aspects of physics, such as the nature of elementary particles. Nevertheless, there are viable partial solutions with limited regimes of validity. In quantum mechanics, the introduction of renormalization techniques was able to solve the divergences within the theory of *quantum electrodynamics* (QED).
In order to give a gross idea of 'radiative reaction', let us consider a charge q of a point particle distributed in space. For simplicity we choose 'sub-charges' $\frac{q}{2}$ located at two positions $\mathbf{d}_{1,2} = \pm\frac{d}{2}\hat{\mathbf{e}}_y$ and moving in an accelerated way in x-direction, that is, $\mathbf{a} = a\hat{\mathbf{e}}_x$. Only after the calculations will we go to the limit $d \to 0$. So with (14.140) we obtain for the electric field generated by the charge 2 at the place of the charge 1,

$$\begin{aligned}\vec{\mathcal{E}}_1(\mathbf{r},t) &= \frac{q/2}{4\pi\varepsilon_0}\frac{R}{(\mathbf{R}\cdot\mathbf{u})^3}[(c^2 - v^2)\mathbf{u} + \mathbf{R}\times(\mathbf{u}\times\mathbf{a})] \\ &= \frac{q/2}{4\pi\varepsilon_0}\frac{R}{(\mathbf{R}\cdot\mathbf{u})^3}[(c^2 - v^2 + \mathbf{R}\cdot\mathbf{a})\mathbf{u} - \mathbf{a}(\mathbf{R}\cdot\mathbf{u})]\ .\end{aligned}$$

Now, we assume that the charge be instantly at rest, $\mathbf{v} = 0$, that is, $\mathbf{u} \equiv c\hat{\mathbf{e}}_r - \mathbf{v} = c\hat{\mathbf{e}}_r$. In Cartesian coordinates, $\mathbf{R} \equiv l\hat{\mathbf{e}}_x + d\hat{\mathbf{e}}_y$, where $l \equiv x(t) - x(t_r)$ is the distance between the actual position and the retarded position, we can write the x-component of the electric field as,

$$\vec{\mathcal{E}}_{x,1} = \frac{q/2}{4\pi\varepsilon_0}\frac{R}{c^3R^3}[(c^2 + \mathbf{R}\cdot\mathbf{a})u_x - (\mathbf{R}\cdot\mathbf{u})a_x] = \frac{q}{8\pi\varepsilon_0 c^2}\frac{c^2 l - d^2 a}{\sqrt{l^2+d^2}^3} \ .$$

By symmetry, $\vec{\mathcal{E}}_{x,1} = \vec{\mathcal{E}}_{x,2}$, such that the force on the dumbbell is,

$$\mathbf{F}_{\text{self}} = \frac{q}{2}(\vec{\mathcal{E}}_1 + \vec{\mathcal{E}}_2) = \frac{q}{8\pi\varepsilon_0 c^2}\frac{c^2 l - d^2 a}{\sqrt{l^2+d^2}^3}\hat{\mathbf{e}}_x \ .$$

Now, we expand l in terms of the retarded time,

$$l = x(t_r + T) - x(t_r) = \cancel{vT}^{\,0} + \tfrac{1}{2}aT^2 + \tfrac{1}{6}\dot{a}T^3 + \dots \ ,$$

such that,

$$d = \sqrt{(cT)^2 - l^2} = cT\sqrt{1 - \left(\tfrac{aT}{2c} + \tfrac{\dot{a}T^2}{6c} + \dots\right)^2} = cT - \frac{a^2}{8c}T^3 + \dots \simeq cT - \frac{a^2}{8c}\left(\frac{d}{c}\right)^3 + \dots \ ,$$

where we replaced, in the last step, the first order solution in the expansion, $T \simeq d/c$, for the third order. Resolving by T,

$$T \simeq \frac{d}{c} + \frac{a^2 d^3}{8c^5} \ .$$

and inserting into the expansion of l,

$$l \simeq \frac{1}{2}a\left(\frac{d}{c} + \frac{a^2d^3}{8c^5}\right)^2 + \frac{1}{6}\dot{a}\left(\frac{d}{c} + \frac{a^2d^3}{8c^5}\right)^3 + \dots \simeq \frac{1}{2}a\left(\frac{d}{c}\right)^2 + \frac{1}{6}\dot{a}\left(\frac{d}{c}\right)^3 \ .$$

With this we obtain for reaction force,

$$\begin{aligned}\mathbf{F}_{\text{self}} \simeq \frac{q}{8\pi\varepsilon_0 c^2}\frac{c^2 l - d^2 a}{\sqrt{l^2+d^2}^3}\hat{\mathbf{e}}_x &\simeq \frac{q}{8\pi\varepsilon_0 c^2}\frac{c^2\left(\frac{1}{2}a\left(\frac{d}{c}\right)^2 + \frac{1}{6}\dot{a}\left(\frac{d}{c}\right)^3\right) - d^2 a}{\sqrt{(..)d^4 + d^2}^3}\hat{\mathbf{e}}_x \\ &\simeq \frac{q}{4\pi\varepsilon_0 c^2}\left(-\frac{a}{4d} + \frac{\dot{a}}{12c}\right)\hat{\mathbf{e}}_x \ ,\end{aligned}$$

considering that d is small. The acceleration is still expressed in terms of the retarded time, but this is easily remedied by,

$$a(t_r) = a(t) + \dot{a}(t)(t - t_r) = a(t) - \dot{a}(t)\frac{d}{c} \ .$$

Inserting into the force,

$$\begin{aligned}\mathbf{F}_{\text{self}} \simeq \frac{q}{4\pi\varepsilon_0 c^2}\left(-\frac{a}{4d} + \frac{\dot{a}}{12c}\right)\hat{\mathbf{e}}_x &= \frac{q}{4\pi\varepsilon_0}\left(-\frac{a(t)}{4c^2 d} - \frac{-\dot{a}(t)}{4c^3} + \frac{\dot{a}(t)}{12c^3}\right)\hat{\mathbf{e}}_x \\ &= \frac{q}{4\pi\varepsilon_0}\left(\frac{a(t)}{4c^2 d} + \frac{\dot{a}(t)}{3c^3}\right)\hat{\mathbf{e}}_x \ .\end{aligned}$$

Finally,

$$\mathbf{F} = m_{\text{tot}}a + \mathbf{F}_{\text{rad}} = \left(m_0 + \frac{1}{4\pi\varepsilon_0}\frac{q^2}{4dc^2}\right)\mathbf{a} + \frac{\mu_0 q^2 \dot{\mathbf{a}}}{12\pi c} \ ,$$

where m_0 is the sum of the two partial masses. We retrieve the Abraham-Lorentz formula by the second term. The missing factor of 2, when compared to (16.116), comes from the fact that we only consider the mutual reactions of partial charges. The expression in the parentheses corresponds to a correction of the inertial mass of the particle due to the Coulombian repulsion between the charges.

16.2.3 Exercises

16.2.3.1 Ex: Radiation emitted by a rotating electron

A particle with charge q moves with constant angular velocity ω in a circular orbit with radius R around the origin in the plane x-y. Its trajectory therefore is,

$$\mathbf{R}'(t) = R(\hat{\mathbf{e}}'_x \cos\omega t + \hat{\mathbf{e}}'_y \sin\omega t) \ .$$

a. Calculate the associated (temporary) charge density $\varrho(\mathbf{r}', t)$ and the dipole moment using the general rule,

$$\mathbf{d}(t) = \int \mathbf{r}' \varrho(\mathbf{r}', t) d^3\mathbf{r}' \ .$$

b. The rotating particle can be seen as a source of radiation. At a point $\mathbf{r}$ far from this source, in the dipole approximation, the associated electromagnetic fields are given by,

$$\vec{\mathcal{B}} = \tfrac{\mu_0}{4\pi c r} \hat{\mathbf{e}}_r \times \ddot{\mathbf{d}} \qquad \text{respectively} \qquad \vec{\mathcal{E}} = c\vec{\mathcal{B}} \times \hat{\mathbf{e}}_r \ .$$

Calculate the Poynting vector,

$$\vec{\mathcal{S}} = \tfrac{1}{\mu_0} \vec{\mathcal{E}} \times \vec{\mathcal{B}}$$

as well as its component $\mathcal{S}_n \equiv \hat{\mathbf{e}}_r \cdot \vec{\mathcal{S}}$ in the direction of the point $\mathbf{r}$. **Help:** Use the formula $\mathbf{a} \times \mathbf{b} \times \mathbf{c} = \mathbf{b}(\mathbf{a} \cdot \mathbf{c}) - \mathbf{c}(\mathbf{a} \cdot \mathbf{b})$.
c. Now calculate the time average of $\mathcal{S}_n$ over an orbit of the particle, that is, calculate $\bar{\mathcal{S}}_n = \int dt \mathcal{S}_n \ / \ \int dt$ with the two integrals taken between $t = 0$ and $t = 2\pi/\omega$. Express the result in spherical coordinates, so that $r^2 \bar{S}_n$ is precisely the average power radiated to the solid angle element $d\Omega$ in the direction $\mathbf{r}$. Now integrate over the entire solid angle and evaluate the total emitted power P.

16.2.3.2 Ex: Rutherford's atom model

In Rutherford's 'classical' atom model a hydrogen atom is described by an electron (charge $-e$) orbiting a nucleus (charge $+e$) in a circular trajectory with constant angular velocity ω. The equilibrium condition is chosen so that the Coulomb force and the centrifugal force compensate each other. However, according to the Exc. 16.2.3.1, such an electron represents a source of radiation. The radiated power decreased the energy of the electron [$dE/dt = -P$ with P taken from Exc. 16.2.3.1(c)]. Derive a differential equation for the temporal variation of the radius $R(t)$ of the electronic orbit, and integrate it with the boundary conditions $t_0 = 0$ and $R(t_0) = a_B$, where $a_B = 0.53 \times 10^{-8}$ cm is the Bohr radius. After what time T do we get $R(T) = 0$?

16.2.3.3 Ex: Dynamics of charged point particles

Consider a point particle with charge q and mass m and general electromagnetic fields in vacuum, $\vec{\mathcal{E}}(\mathbf{r},t)$ and $\vec{\mathcal{B}}(\mathbf{r},t)$, which are not perturbed neither by the charge nor the current resulting from the particle's motion. On the particle acts the Coulomb-Lorentz force.
a. What are the equations of motion for the particle? What is the temporal variation of its total kinetic energy? What condition must be satisfied to ensure that the kinetic energy of the particle is temporally constant?
b. We now consider homogeneous fields $\vec{\mathcal{E}}(\mathbf{r},t) = \mathcal{E}_0\hat{\mathbf{e}}_z$ and $\vec{\mathcal{B}}(\mathbf{r},t) = \mathcal{B}_0\hat{\mathbf{e}}_z$. What are the equations of motion now?
c. The particle is at time $t = 0$ at the origin of the coordinate system and has the velocity $\mathbf{v}_0$. Solve the equations of motion. **Help:** Use the complex variable $\eta = x+\imath y$ and add the equations of motion to obtain a complex equation motion for η of the type $\ddot{\eta} = -\imath\omega\dot{\eta}$ with $\omega = q\vec{\mathcal{B}}_0/(mc)$.
d. How does the kinetic energy of the particle vary over time?

16.2.3.4 Ex: Excitation of an electron by circularly polarized light

Derive the expression for the dipole radiation from the Maxwell equations proceeding in the following way:
a. Derive the equation of motion of a point particle of charge q and mass m in an electromagnetic field ($\vec{\mathcal{E}}$, $\vec{\mathcal{B}}$) neglecting the emission of radiation by the moving charge. Determine the temporal variation of the particle's energy W inside the external field.
b. A circularly polarized monochromatic wave in vacuum is described by the electric field, $\vec{\mathcal{E}}(\mathbf{r},t) = \mathcal{E}[\cos(kz-\omega t)\hat{\mathbf{e}}_x + \sin(kz-\omega t)\hat{\mathbf{e}}_y]$. Calculate the corresponding magnetic field $\vec{\mathcal{B}}(\mathbf{r},t)$.
c. Calculate the Poynting vector $\vec{\mathcal{S}}(\mathbf{r},t)$.
d. For an energy flux of the electromagnetic wave of $10\,\mathrm{W/m^2}$ calculate the amplitudes of the electric and the magnetic field.
e. For the particle of part (a) moving in the fields of part (b) establish the equation of motion.
f. Initially ($t = 0$) the particle is at the origin of the coordinate system. How should the initial condition for the velocity be chosen in order to obtain a constant energy for the particle?
g. Determine the momentum $\mathbf{p}$ of the particle and verify that $\mathbf{p}_\perp = p_x\hat{\mathbf{e}}_x + p_y\hat{\mathbf{e}}_y$ coincides at every instant of time with the direction of $\vec{\mathcal{B}}$.
h. Solve the equation of motion with the initial conditions of part (d).
i. What is the form of the particle's trajectory in the x-y plane?

16.2.3.5 Ex: Charge and current densities for radiative atomic transitions

The charge and current densities for radiative atomic transitions from the state $m = 0$, $2p$ of hydrogen to the ground state $1s$, are (neglecting the spin),

$$\varrho(r,\theta,\phi,t) = \frac{2e}{\sqrt{6}a_B^4} r e^{-3r/2a_B} Y_{00} Y_{10} e^{-\imath\omega_0 t} \quad , \quad \mathbf{j}(r,\theta,\phi,t) = -\imath v_0 \left(\frac{\hat{\mathbf{e}}_r}{2} + \frac{a_B}{z}\hat{\mathbf{e}}_z\right) \varrho(r,\theta,\phi,t) \ ,$$

where $v_0 = \alpha c$ is the orbital velocity of the electron, a_B the Bohr radius, and α the Sommerfeld constant.
a. Show that the effective transitional orbital 'magnetization' is,

$$\vec{\mathcal{M}}_{ef}(r,\theta,\phi,t) = -\imath\frac{\alpha c a_B}{2}\tan\theta(\hat{\mathbf{e}}_x\sin\phi - \hat{\mathbf{e}}_y\cos\phi)\varrho(r,\theta,\phi,t)\ .$$

Calculate $\nabla\cdot\vec{\mathcal{M}}_{ef}$ and evaluate the electric and magnetic dipole moments.
b. In the electric dipole approximation, calculate the temporal average of the total radiated power. Express your response in units of $(\hbar\omega_0)(\alpha^4 c/a_B)$.
c. Interpreting the classically calculated power as the energy of a photon $(\hbar\omega_0)$ times the transition probability, numerically evaluate the transition probability in units of reciprocal seconds.
d. If, instead of the semiclassic charge density used above, the electron in the $2p$ state is described by a circular Bohr orbit of radius $2a_B$, rotating with the transition frequency ω_0, what would be the radiated power? Express your answer in the same units as in part (b), and evaluate the ratio of the two powers numerically.

16.2.3.6 Ex: Synchrotron radiation

In the discussion of the Bremsstrahlung in class we assumed that the velocity and the acceleration were (at least instantaneously) *collinear*. Do the same analysis for the case, that they are *perpendicular*. Choose your axes so that v is along the z-axis and a along the x-axis (see Fig. 16.5), such that $\mathbf{v} = v\hat{\mathbf{e}}_z$, $\mathbf{a} = \hat{\mathbf{e}}_x$ and $\mathbf{R} = \sin\theta\cos\phi\hat{\mathbf{e}}_x + \sin\theta\sin\phi\hat{\mathbf{e}}_y + \cos\theta\hat{\mathbf{e}}_z$. Verify whether P is consistent with the Liénard formula.

16.2.3.7 Ex: Cherenkov radiation

Cherenkov radiation is observed, when a charge moves with relativistic velocity within a dielectric medium, which reduces the speed of light below the velocity of the particle. A blue superluminal shock wave is then formed.
a. Calculate the angle θ_c between the propagation direction of the charge and the propagation direction of the shock wavefront.
b. We now imagine the deceleration process of the charge inside the dielectric as being due to a collision with a heavy molecule of the dielectric material. The collision creates a photon emitted under the angle θ_c and the momentum of charge is deflected. We despise the recoil of the molecule. Based on relativistic energy and momentum conservation, calculate the angle θ_c in terms of the momenta of charge before and after the collision and of the radiated frequency.
c. Comparing the results obtained in (a) and (b), calculate the rest mass of the charge.
d. Calculate the retarded Liénard-Wiechert potentials inside and outside of the cone.

16.2.3.8 Ex: Electron subject to gravity

An electron is released from rest and falls under the influence of gravity. Within the first centimeter, what fraction of the lost potential energy is radiated?

16.2.3.9 Ex: Radiation reaction

Including the radiative reaction force (16.115), Newton's second law for a charged particle becomes,

$$a = \tau \dot{a} + \frac{F}{m} \ ,$$

where F is an external force acting on the particle.
a. In contrast to the case of an uncharged particle ($a = F/m$), the acceleration (in the same way as position and velocity) must be a continuous function of time, even when the force changes abruptly. (Physically, the radiative reaction dampens out any rapid variation in a.) Show that a is continuous at any time t by integrating the given equation of motion between $(t - \epsilon)$ and $(t + \epsilon)$ and evaluating the limit $\epsilon \to 0$.
b. A particle be subjected to a constant force F, beginning at time $t = 0$ and remaining until the time T. Find the most general solution $a(t)$ of the equation of motion in each of the three stages: (i) $t < 0$; (ii) $0 < t < T$; and (iii) $t > T$.
c. Impose the continuity condition (a) at times $t = 0$ and $t = T$. Show, that it is possible to *either* eliminate 'runaway-acceleration' in region (iii) *or* avoid 'pre-acceleration' in region (i), but not both.
d. Choosing to eliminate the runaway-acceleration, what will be the acceleration, as a function of time, in each stage (i-iii)? How will the velocity behave, which obviously must be continuous at $t = 0$ and $t = T$. Assume, that the particle was initially at rest: $v(-\infty) = 0$. Prepare schemes of $a(t)$ and $v(t)$ and compare with the behavior of a neutral particle.
e. Repeat (d) choosing the option to eliminate pre-acceleration.

16.2.3.10 Ex: Charges accelerated by gravity

Compare the emission of radiation of a electron resting in the lab frame with the one of a free falling electron in its inertial frame [391].

16.3 Diffraction and scattering

Radiation (let us call it 'light' for simplicity) incident on a target (e.g. a charge and current distribution, a dielectric body, an atomic cloud, or anything else) will be absorbed, diffracted or scattered. In the absence of absorption, the entire incident energy must be re-emitted. Whether the re-emission process is best described by *diffraction* or *scattering* models depends on the wavelength λ of light in relation to the size of the target and its structure. When the target is small, we can treat the problem in the lowest (usually dipolar) multipolar order; for a target of comparable size with λ, a complete multipolar treatment is required, and in the limit of a large target, we can resort to semi-geometrical methods to explain deviations from geometric optics caused by diffraction.

The topic of diffraction and scattering is well covered in the literature [473]. Rather than reproducing these theories here, we will give in this course a brief introduction to the *coupled-dipoles model*. This model, which has received much attention in recent years, has proven capable, albeit renouncing of notions such as the refraction index, to give a microscopic view of many macroscopic scattering and diffraction phenomena.

16.3.1 Coupled dipoles model

The electrodynamics contained in Maxwell's macroscopic equations describes the interaction of light with matter characterized by a refractive index $n(\mathbf{r})$. The refractive index is understood as a continuous field, which fully describes the reaction of the target to incident light. On the other hand, we know how the microscopic constituents, that is, the atoms and molecules of the target material, react individually to incident light. In the simplest case, a two-level atom will absorb a photon carrying an electron to a higher orbit, and when the electron returns to the original state, it will emit a photon into an arbitrary direction, that is, isotropically in the time average.

The difficulty now resides in the linking of the macro- and microscopic images, illustrated in Fig. 16.6, to a complete theory. Indeed, all atoms or molecules in the crystal must *cooperate* in some way to generate a refractive index and macroscopic scattering phenomena described by the laws of Snellius, Lambert-Beer, or Ewald-Oseen [116]. The details of how this cooperation works are being studied in several laboratories around the world [832, 834, 198].

Figure 16.6: (Left) Macroscopic refraction and (right) microscopic scattering. See also (watch talk).

From a microscopic point of view, the refractive index is an artifact; it does not exist like an atom exists! Since Democritus' reflections on the nature of matter 350 years before Christ, we know that what does exist are 'atoms and empty space, the remainder is mere opinion'. The index of refraction can help us to simplify the description of how light interacts with macroscopic objects. But this does not always work, and in some circumstances even leads to paradoxical results, that are difficult to resolve within Maxwell's theory of electromagnetism. This is, for example, the case of the famous Abraham and Minkowski dilemma, which since 1909, when these two physicists proposed different calculations for the photonic momentum inside a dielectric medium leading to different results, still gives rise to debates. But there are also other situations, where microscopic theory is able to describe phenomena beyond the macroscopic approximation of continuous media. These are phenomena due to disorder, such as Anderson's localization of light or the spontaneous synchronization of atomic dipoles in superradiance.

In the simplest version of the coupled-dipoles model we imagine the target as a (more or less dense) sample of point-like two-level atoms, so that the radiation of the atoms can be described in the dipolar limit, $a_B \ll \lambda$, where the Bohr radius gives a typical scale for the extension of the radiation source. We will not reproduce integrally the derivation of the coupled-dipoles model here, which borrows from the theory of quantum mechanics. Instead, we will superficially trace the line of argumentation and justify the results by showing that, in the limit of a smooth distribution of the atomic scatterers, we recover the classical laws of Maxwell's theory.

16.3.1.1 Rayleigh scattering

To describe the Rayleigh scattering from an atom, we need to understand the phenomenon of spontaneous emission. This is usually achieved by the *Weisskopf-Wigner theory* starting from the Hamiltonian describing the interaction of a single two-level atom of the sample (labeled j) interacting with an incident laser,

$$\begin{aligned}\hat{H}_j &= \hbar g_{\mathbf{k}_0}\left(\hat{\sigma}_j e^{-\imath\omega_a t} + \hat{\sigma}_j^\dagger e^{\imath\omega_a t}\right)\left(\hat{a}_{\mathbf{k}_0}^\dagger e^{\imath\omega_0 t - \imath\mathbf{k}_0\cdot\mathbf{r}_j} + \hat{a}_{\mathbf{k}_0} e^{-\imath\omega_0 t + \imath\mathbf{k}_0\cdot\mathbf{r}_j}\right) \\ &+ \sum_{\mathbf{k}} \hbar g_{\mathbf{k}}\left(\hat{\sigma}_j e^{-\imath\omega_a t} + \hat{\sigma}_j^\dagger e^{\imath\omega_a t}\right)\left(\hat{a}_{\mathbf{k}}^\dagger e^{\imath\omega_k t - \imath\mathbf{k}\cdot\mathbf{r}_j} + \hat{a}_{\mathbf{k}} e^{-\imath\omega_k t + \imath\mathbf{k}\cdot\mathbf{r}_j}\right) \ .\end{aligned} \tag{16.118}$$

Here, ω_0, ω_a, and ω_k are, respectively, the frequencies of the incident laser, the atomic resonance and the scattered light [6]. $g_{\mathbf{k}_0}$ is the coupling strength between the atom and the incident light mode and $g_k = d\sqrt{\omega/(\hbar\varepsilon_0 V)}$ describes the coupling between the atom and a vacuum mode with the volume V. $\hat{\sigma}_j = |g\rangle\langle e|$ is the lowering operator of the atomic excitation, that is, it describes the transition of the jth atom from the excited state $|e\rangle$ to the ground state $|g\rangle$. $\hat{a}_{\mathbf{k}}$ is the annihilation operator of a photon in the mode $\mathbf{k}$.

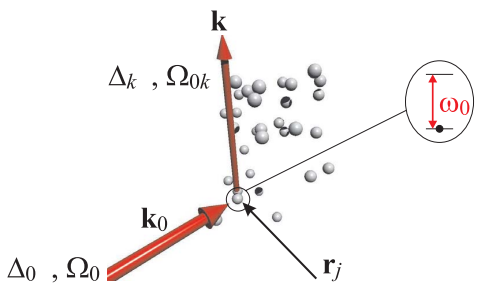

Figure 16.7: Scheme of the interaction of a light beam with a sample of atoms.

Now, considering an incident light mode (e.g. a laser beam) with high power,

$$\hat{a}_{\mathbf{k}_0}|n_0\rangle_{\mathbf{k}_0} = \sqrt{n_0}|n_0 - 1\rangle_{\mathbf{k}_0} \simeq \alpha_0|n_0\rangle_{\mathbf{k}_0} \ , \tag{16.119}$$

$\hat{a}_{\mathbf{k}_0}$ is approximately an observable, whose amplitude is proportional to the root of the intensity. As $[\hat{a}_{\mathbf{k}_0}, \hat{a}_{\mathbf{k}_0}^\dagger] \simeq 0$, we can disregard the quantum nature and treat the incident light as a classical field by replacing $\Omega_0 \equiv 2\alpha_0 g_{k_0}$, where Ω_0 is the Rabi frequency. The *rotating wave approximation* (RWA) allows us to neglect those terms of the Hamiltonian, which (in the first perturbative order) do not conserve energy, that is, terms proportional to $\hat{\sigma}_j^- \hat{a}$ and $\hat{\sigma}_j^+ \hat{a}^\dagger$. Introducing the abbreviations,

$$\Delta_0 \equiv \omega_0 - \omega_a \qquad \text{and} \qquad \Delta_k \equiv \omega_k - \omega_a \ . \tag{16.120}$$

the Hamiltonian becomes,

$$\hat{H} = \tfrac{\hbar}{2}\Omega_0\left(\hat{\sigma}\hat{a}_{\mathbf{k}_0}^\dagger e^{\imath\Delta_0 t} + h.c.\right) + \hbar\sum_{\mathbf{k}}\left(g_k\hat{\sigma}\hat{a}_{\mathbf{k}}^\dagger e^{\imath\Delta_k t} + h.c.\right) \ . \tag{16.121}$$

[6] We are only considering fixed atoms in space, that is, we do not allow acceleration by photonic recoil.

The system can be found in three states,

$$|\Psi(t)\rangle = \alpha(t)|0\rangle_a|0\rangle_{\mathbf{k}} + \beta(t)|1\rangle_a|0\rangle_{\mathbf{k}} + \sum_{\mathbf{k}} \gamma_{\mathbf{k}}(t)|0\rangle_a|1\rangle_{\mathbf{k}} \ . \tag{16.122}$$

Before the scattering the system is, with the probability amplitude α, in the state $|0\rangle_a|0\rangle_{\mathbf{k}}$. After the absorption of a photon, with the probability amplitude β, the atom is excited $|1\rangle_a|0\rangle_{\mathbf{k}}$. Finally, after the reemission of the photon to a mode $\mathbf{k}$, with the probability amplitude $\gamma_{\mathbf{k}}$, the state of the system is $|0\rangle_a|1\rangle_{\mathbf{k}}$. The temporal evolution of the probability amplitudes is obtained by inserting the Hamiltonian (16.121) and the ansatz (16.122) into the Schrödinger equation,

$$\frac{d}{dt}|\Psi(t)\rangle = -\frac{\imath}{\hbar}\hat{H}|\Psi(t)\rangle \ . \tag{16.123}$$

We get, after a calculation which is not reproduced here [7] and which makes use of the so-called *Markov approximation* postulating that the variation of the amplitudes $\beta_j(t)$ is slower than the evolution of the system given by $e^{\imath(\omega_k-\omega_0)t}$, the following equation of motion for the amplitudes β_j,

$$\boxed{\dot{\beta}_j = \left(\imath\Delta_0 - \frac{\Gamma}{2}\right)\beta_j - \frac{\imath\Omega_0}{2}e^{\imath\mathbf{k}_0\cdot\mathbf{r}_j}} \ . \tag{16.124}$$

This equation correctly describes the dynamics of the probability amplitude of finding an atom exposed to a laser beam and subject to spontaneous emission of its excited state.

16.3.1.2 Collective scattering

In the presence of several atoms, the full Hamiltonian for the atomic cloud is simply obtained by summing over the N atoms [8],

$$\hat{H} = \sum_{j=1}^{N} \hat{H}_j \ . \tag{16.125}$$

Following the same scheme as in the last section, the Schrödinger equation with the Hamiltonian (16.125) where (16.118) can be resolved to the limit of weak excitation: Let us restrict to the situation in which at most a single photon or a single atomic excitation can be in the system. This assumption is realistic, when the time for reemitting a photon is short. The state created by the passage of a single photon is a collective state, because the atomic sample can either be entirely in the ground state before a scattering event, $|g_1,..,g_N\rangle|0\rangle_{\mathbf{k}}$, or after a scattering event, $|g_1,..,g_N\rangle|1\rangle_{\mathbf{k}}$, or else any one of the atoms j can be excited, $|g_1,..,e_j,..,g_N\rangle|0\rangle_{\mathbf{k}}$, during the scattering event. All information on the system is coded in the temporal dependencies of the

[7] See Sec. 44.1.2 .

[8] We do not consider in this Hamiltonian collisional interactions between the atoms, for example, of the van der Waals type, which can have a great impact at high densities $n \gg \lambda^{-3}$.

probability amplitudes for these states, which we obtain through the insertion of the wavefunction [9],

$$|\Psi\rangle = \alpha(t)|g_1 \dots g_N\rangle|0\rangle_{\mathbf{k}} + e^{-\imath\Delta_0 t}\sum_{j=1}^{N}\beta_j(t)|g_1 \dots e_j \dots g_N\rangle|0\rangle_{\mathbf{k}} \tag{16.126}$$
$$+\sum_{\mathbf{k}}\gamma_{\mathbf{k}}(t)|g_1 \dots g_N\rangle|1\rangle_{\mathbf{k}} + \sum_{m,n=1}^{N}\epsilon_{m<n,\mathbf{k}}(t)|g_1 \dots e_m \dots e_n \dots g_N\rangle|1\rangle_{\mathbf{k}} \,.$$

within the Schrödinger equation. What we get is a set of integro-differential equations for the amplitudes α, β, and $\gamma_{\mathbf{k}}$, which can be solved within the Markov approximation,

$$\boxed{\dot{\beta}_j = \left(\imath\Delta_0 - \frac{\Gamma}{2}\right)\beta_j - \frac{\imath\Omega_0}{2}e^{\imath\mathbf{k}_0\cdot\mathbf{r}_j} - \frac{\Gamma}{2}\sum_{m\neq j}\frac{e^{\imath k_0|\mathbf{r}_j-\mathbf{r}_m|}}{\imath k_0|\mathbf{r}_j-\mathbf{r}_m|}\beta_m} \,. \tag{16.127}$$

We note, that the first two terms of this equation correspond to the equation describing the dynamics of a single atom (16.124). The third term corresponds to processes, where photons scattered at an atom are reabsorbed by another atom.

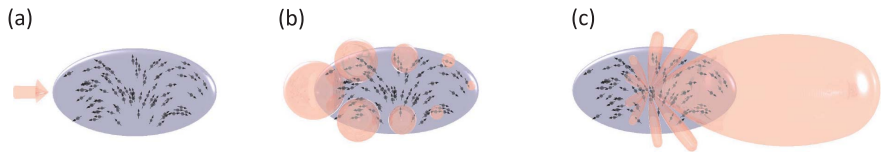

Figure 16.8: Illustration of cooperative scattering: From (a) to (c) a photon traversing an atomic cloud first excites the upstream dipoles, which immediately begin to radiate. The downstream dipoles are excited later on. The phase lag of the reemission processes leads to a radiative emission pattern being strongly peaked into forward direction.

The claim is now that equation (16.127) (or at least its generalization to level systems allowing to take account of the vectorial nature of light) is capable of reproducing all phenomena of macroscopic scattering, usually described by Maxwell's theory, for example, refraction, diffraction, Mie and Bragg scattering, etc. In addition, it correctly describes microscopic scattering phenomena, such as cooperative Rayleigh scattering, Anderson location, photonic band gaps, etc.

16.3.2 The limit of the Mie scattering and the role of the refractive index

In practice, the exploitation of the N coupled equations (16.127) (one for each atom), which needs to be done numerically, is limited by computer capacity to some 100 000

[9] The fourth term corresponds to the presence of two simultaneously excited atoms plus a (virtual) photon with 'negative' energy. These states need to be taken into account, if we do not want to make use ofthe RWA approximation.

atoms. On the other hand, at least, in the limit of high densities, we may hope, that the atomic cloud be well described by a continuous density distribution,

$$\sum_j \beta_j \to \int \beta(\mathbf{r}')\rho(\mathbf{r}')dV' \ . \tag{16.128}$$

Considering the stationary case, $\dot{\beta}_j = 0$, we arrive at,

$$\frac{\Omega_0}{2} e^{\imath \mathbf{k}_0 \cdot \mathbf{r}} = (\Delta_0 + \imath\Gamma)\beta(\mathbf{r}) + \frac{\Gamma}{2} \int \frac{e^{\imath k_0 |\mathbf{r}-\mathbf{r}'|}}{k_0|\mathbf{r}-\mathbf{r}'|} \beta(\mathbf{r}')\rho(\mathbf{r}')dV' \ . \tag{16.129}$$

We note that the kernel of the above equation is the Green function of the Helmholtz equation, since,

$$[\nabla^2 + k_0^2] \frac{e^{\imath k_0 |\mathbf{r}-\mathbf{r}'|}}{4\pi|\mathbf{r}-\mathbf{r}'|} = -\delta^{(3)}(\mathbf{r}-\mathbf{r}') \ . \tag{16.130}$$

Now, by applying the operator $[\nabla^2 + k_0^2]$ to both sides of equation (16.129), we arrive at,

$$0 = (\Delta_0 + \imath\Gamma)[\nabla^2 + k_0^2]\beta(\mathbf{r}) - 2\pi\Gamma \frac{\beta(\mathbf{r})\rho(\mathbf{r})}{k_0} \ , \tag{16.131}$$

that is [320, 45, 46],

$$\boxed{[\nabla^2 + k_0^2 n(\mathbf{r})^2]\beta(\mathbf{r}) = 0 \qquad \text{defining} \qquad n^2(\mathbf{r}) \equiv 1 - \frac{4\pi\rho(\mathbf{r})}{k_0^3(2\Delta_0/\Gamma + \imath)}} \ . \tag{16.132}$$

This is the *Helmholtz equation* of Maxwell's theory. The reappearance of the refractive index $n(\mathbf{r})$ is the price to pay for smoothing the density distribution, and with it we lose all effects related to discretization and cloud disorder. In Exc. 16.3.3.1 we compare the result of the smoothed coupled-dipole model (16.132) to the macroscopic susceptibility derived from the Lorentz model (15.143), and to the Clausius-Mossotti formula (11.28).

Example 123 (*Bragg scattering by partially disordered clouds*): Fig. 16.9 shows the example of Bragg scattering by an atomic cloud. Without disorder we would expect an incident laser beam to be partially reflected and partially transmitted. The simulation of the stationary version of equation (16.127) for the scattering of the cloud illustrated in (a) shows, in addition to transmission and reflection, a random pattern of specular scattering in all directions, which can be attributed to disorder.

Example 124 (*Collective radiative pressure*): The internal and the global structure of an atomic cloud both dramatically influence the radiative pressure force exerted on its center of mass. We compare two limiting cases [198]: (a) For large dilute clouds, scattering by intrinsic disorder prevails. The more atoms are in the cloud, the more pronounced is the forward scattering of the light. Therefore, the radiative pressure force *per atom* exerted by the incident light decreases with N. (b) For small dense clouds, the scattering is rather governed by the global inhomogeneous shape of the cloud. The more atoms are in the cloud,

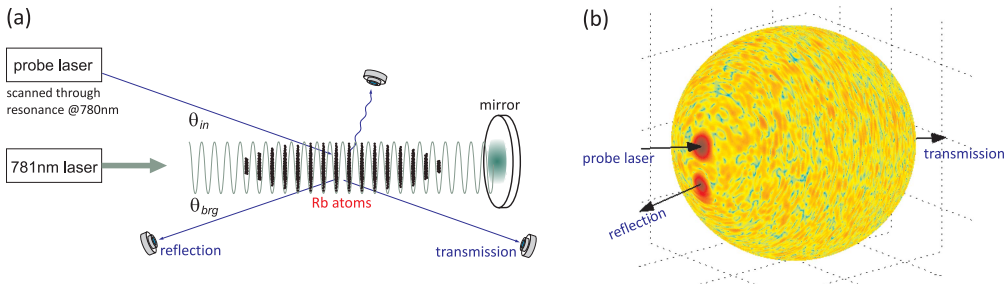

Figure 16.9: (a) Experimental scheme for Bragg reflection by an ordered atomic cloud in a periodic pile of pancakes. (b) Simulation of the stationary cloud scattering equation schematized in (a).

the greater the variation of the refractive index and the greater the refractive deflection of photons off the optical axis [77]. Therefore, the radiation pressure force per atom exerted by the incident light increases with N, as shown in Fig. 16.10(c).

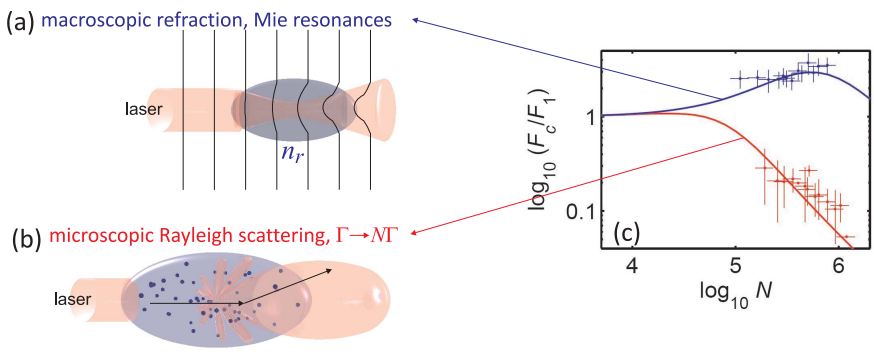

Figure 16.10: (a) Rayleigh scattering by a disordered cloud. (b) Mie scattering via wavefront deformation by the refractive index of an optically dense cloud. (c) Dependence of the radiation pressure force on the number of atoms for the two cases (a) and (b).

Microscopic collective scattering depends on one hand on the internal spatial distribution of the scatterers, that is, the intrinsic disorder, and on the other hand on the global distribution, i.e. the shape and the size of the cloud and its density distribution near the edges, which may be smooth or abrupt. In the limit of despicable disorder, we have seen that the theory of collective scattering is equivalent to Maxwell's macroscopic theory. In this limit, we can describe the cloud of scatterers as a (locally) homogeneous sphere characterized by a refractive index $n(\mathbf{r})$, which varies spatially with the density of the scatterers. Let us assume, for simplicity, a spherical cloud with a homogeneous refraction index $n(\mathbf{r}) = n_0$ inside the cloud and $n(\mathbf{r}) = 1$ outside. The scattering of a plane wave of radiation by a dielectric sphere is known

as *Mie scattering* . In Mie's theory we expand the incident plane wave into partial spherical waves,

$$e^{\imath \mathbf{k}\cdot\mathbf{r}} = \sqrt{4\pi}\sum_{\ell=0}^{\infty}\sqrt{2\ell+1}\,\imath^{\ell} j_{\ell}(kr) Y_{\ell 0}(\hat{\mathbf{e}}_r) \ , \tag{16.133}$$

which must satisfy the boundary condition for electromagnetic waves at the outer edge of the sphere. This is illustrated in Fig. 16.11. Theoretically it should be possible to observe Mie resonances with atomic clouds, albeit strictly speaking, they do not have a surface which could act like an abrupt boundary condition.

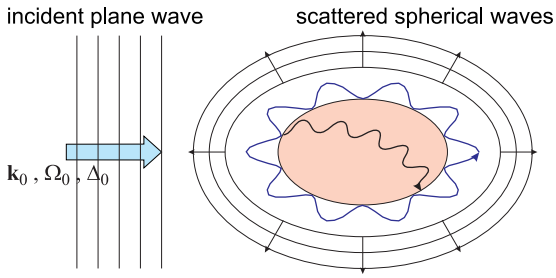

Figure 16.11: Two types of Mie resonances are possible: (i) Waves propagating in the interior of the body and form a stationary wave bounded by the surface and (ii) evanescent waves that propagate on the surface of the body (whispering gallery modes). The resonances of type (ii) require abrupt boundary conditions.

16.3.3 Exercises

16.3.3.1 Ex: Coupled dipoles versus Clausius-Mossotti

Compare the result of the smoothed coupled-dipole model (16.132) to the macroscopic susceptibility derived from the Lorentz model (15.143), and to the Clausius-Mossotti formula (11.28).

Chapter 17

Theory of special relativity

Until the end of the nineteenth century people believed in the existence of an 'ether', that is, a medium capable of carrying oscillations of the electromagnetic field in a similar way as water transports surface waves or the air propagates the sound. The propagation velocity of the light must then have a certain value c in this ether. But when measured in another inertial system, according to the Galilei transformation, propagation velocity should be the sum of c and the velocity v of the inertial system through the ether. This ether would be fixed to the universe, and the earth would have a velocity v with respect to this ether.

With the objective of measuring the relative velocity between a fixed laboratory and the ether, *Michelson* and *Morley* did an experiment known as *Michelson-Morley experiment*, and which now represents one of the foundations of the theory of special relativity. It consists of a *Michelson interferometer*, which can be rotated in space. If an 'ether' existed, which is not fixed to the Earth, the speed of light must be anisotropic and the interference fringes observed in the interferometer must move when the interferometer is rotated. This was not observed.

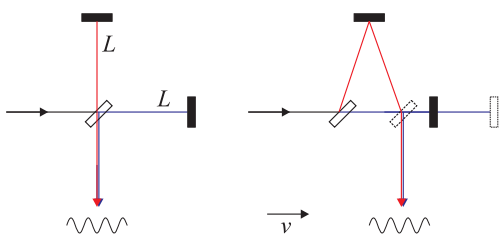

Figure 17.1: Scheme of the Michelson-Morley experiment.

Within the resting system (the ether) the times required for light to travel through each of the interferometer arms are,

$$t_{1,2} = \frac{2L}{c} \ . \tag{17.1}$$

In a frame moving in the direction of one of the arms these times would be,

$$t_1 = \frac{2L}{c}\frac{1}{\sqrt{1-\beta^2}} \qquad \text{and} \qquad t_2 = \frac{L}{c+v} + \frac{L}{c-v} = \frac{2L}{c}\frac{1}{1-\beta^2} \ . \tag{17.2}$$

The experiment confirms the result (17.1) *regardless of the rotation of the interferometer.*

Guided by Michelson's observation it was *Poincaré*, who first proposed the absence of an ether, which motivated *Einstein* to formulate the following postulates:

Law A: *The laws of physics do not depend on a translatory motion of the system as a whole. There is no particular system, in which the 'ether' would be at rest.*

Law B: *The speed of light is constant in all inertial systems and regardless of the speed of the emitting source.*

These postulates revolutionized classical mechanics. The new theory, called the theory of *special relativity*, still contains classical mechanics in the limit of slow velocities, but extends its validity to the limit of velocities approaching the speed of light. Moreover, special relativity reconciles mechanics with electrodynamics in a natural way, as we will show in the following sections.

17.1 Relativistic metric and Lorentz transform

In the theory of relativity, the space represented by the vector $\mathbf{r}$ and the time represented by the scalar ct (where we multiply the universal speed of light for dimensionality reasons) are treated on equal footing. There are other combinations of scalar and vectorial physical quantities such as energy E/c and linear momentum $\mathbf{p}$ which, when combined to a four-dimensional entity, allow for a more symmetrical representation of the fundamental laws of physics. Let us, in the following, set the foundations of this new formalism developed by Poincaré, Lorentz, Einstein, and Minkowski.

17.1.1 Ricci's calculus, Minkowski's metric, and space-time tensors

In the notation of 4-dimensional space-time vectors the physical quantities are described (or combined) by tensors of rank k, e.g. scalars A, vectors A^μ, matrices $A^{\mu\nu}$, and tensors of higher ranks $A^{\mu\nu\lambda\cdots}$. Tensors can be *contravariant*, A^μ, or *covariant*, A_μ, with respect to an index, depending on their behavior regarding the Lorentz transform (as we shall see shortly). Co- (or contra-) variant scalars are independent of the inertial system and, therefore, called *Lorentz invariants*. The contra- and covariant tensors are related by the *Minkowski metric* defined by (see also Sec. 9.4),

$$\boxed{(g^{\mu\nu}) \equiv \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \\ 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & -1 \end{pmatrix}} \,, \tag{17.3}$$

using the *sum rule of Einstein*, which consists in summing over all pairs of co- and contravariant indices,

$$a^\mu a_\mu \equiv \sum\nolimits_\mu a^\mu a_\mu \ , \tag{17.4}$$

via

$$a^\mu = g^{\mu\nu} a_\nu \ . \tag{17.5}$$

We note that the first index in a matrix counts the columns and the second index the rows. For flat space-time (that is, without curvature),

$$g_\mu{}^\nu = g_{\mu\alpha} g^{\alpha\nu} = \delta_\mu^\nu \quad , \quad g_{\mu\nu} = g^{\mu\nu} \quad \text{that is} \quad \check{g}^{-1} = \check{g} = \check{g}^\intercal \ , \tag{17.6}$$

where δ_μ^ν is the *Kronecker symbol* and the decoration '$\vee$' denotes a matrix, $\check{a} \equiv (a_{\mu\nu})$. Thus, the identity and the metric are the two faces of the same tensor, $\check{\delta} = \check{g}$. The norm is defined by,

$$\|(a^\mu)\| \equiv \sqrt{a_\mu a^\mu} = \sqrt{a^\mu g_{\mu\nu} a^\nu} \ . \tag{17.7}$$

The product between two contravariant vectors is given by,

$$a^\mu b^\mu \equiv a^\mu g_{\mu\nu} b^\nu \ . \tag{17.8}$$

The tensors are represented by scalars, vectors and matrices. The vector symbol is used for the contravariant column vector,

$$\vec{a} \equiv (a^\mu) = \begin{pmatrix} a^0 \\ \mathbf{a} \end{pmatrix} \quad , \quad \check{a} \equiv (a^{\mu\nu}) = \begin{pmatrix} a^0 & (a^{m0}) \\ (a^{0n}) & (a^{mn}) \end{pmatrix} \ . \tag{17.9}$$

The covariant vector is also represented by a column,

$$\check{g}\vec{a} = (a_\mu) = (g_{\mu\nu} a^\nu) = \begin{pmatrix} a^0 \\ -\mathbf{a} \end{pmatrix} \ . \tag{17.10}$$

Often, Greek letters are used as indices for space-time tensors, while Roman letters are used as indices for spatial components. In order to work with vectors within Minkowski's formalism, we must interpret them as two-dimensional 1×4 matrices,

$$\vec{a} \equiv (a^{\mu 1}) \ , \tag{17.11}$$

where the '1' indicates the number of columns of the matrix. Introducing the *transposition*, denoted by the symbol '$\intercal$', as an exchange of the indices labeling rows and columns,

$$F_{\mu\nu} = (F^\intercal)_{\nu\mu} \ , \tag{17.12}$$

we can represent the transposition of a vector by a 4×1 matrix,

$$\vec{a}^\intercal = (a^{\mu 1})^\intercal = (a^{1\mu}) = \begin{pmatrix} a^0 & \mathbf{a} \end{pmatrix} \ , \tag{17.13}$$

and define the scalar product between vectors in terms of the product between matrices as,

$$\begin{aligned} \vec{a} \cdot \vec{b} \equiv (a^{\mu 1} b_{\mu 1}) = (a^\intercal)^{1\mu} (b_{\mu 1}) = (a^\intercal)^{1\mu} g_{\mu\nu} (b^{\nu 1}) = \check{a}^\intercal \check{g} \check{b} \\ = \begin{pmatrix} a^0 & (a^m) \end{pmatrix} \begin{pmatrix} 1 & 0 \\ 0 & (-\delta^{mn}) \end{pmatrix} \begin{pmatrix} a^0 \\ (a^n) \end{pmatrix} \ . \end{aligned} \tag{17.14}$$

We conclude emphasizing that, to be able to multiply tensores as matrices, the indices to be contracted must be adjacent. If necessary, the tensors must be transposed,

$$A^{\mu\alpha} B^\nu{}_\alpha = A^{\mu\alpha} (B^\intercal)_\alpha{}^\nu \ . \tag{17.15}$$

One has to be very careful, because in general $A^{\mu\alpha} \neq A^{\alpha\mu} \neq A_{\alpha\mu} \neq A_{\mu\alpha} \neq A_\alpha{}^\mu \neq A_\mu{}^\alpha \neq A^\mu{}_\alpha \neq A^\alpha{}_\mu$.

17.1.2 Lorentz transform

We are now in the shape to officially introduce our first explicit space-time vector by combining the physical quantities time and position,

$$\boxed{(r^\mu) \equiv \begin{pmatrix} ct \\ \mathbf{r} \end{pmatrix}} \,. \tag{17.16}$$

In classical mechanics the transformation to a system moving at velocity $\beta = v/c$ is described by the *Galilei transform* given by,

$$(G^\mu{}_\nu) \equiv \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ -\beta & 0 & 0 & 1 \end{pmatrix} \quad , \quad (G^\mu{}_\nu)^{-1} = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ \beta & 0 & 0 & 1 \end{pmatrix} \,. \tag{17.17}$$

Example 125 (*Galilei transform*): Let us try out the Galilei transform on the space-time vector (17.16):

$$\begin{pmatrix} ct' \\ x' \\ y' \\ z' \end{pmatrix} = (r'^\mu) = (G^\mu{}_\nu)(r_\nu) = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ -\beta & 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} ct \\ x \\ y \\ z \end{pmatrix} = \begin{pmatrix} ct \\ x \\ y \\ z - vt \end{pmatrix} \,.$$

In classical mechanics wave propagation is conditioned to the existence of a medium. Consequently, different inertial systems are not equivalent and, as will be shown in a later section, the wave equation *is not invariant* to the Galilei transform. Let us therefore look for another transformation, which preserves the shape of the wave equation. We may, for example, request the transformation to ensure that the propagation of the phase fronts of a spherical wave is independent of the inertial system: $c^2t'^2 - \mathbf{r}'^2 = c^2t^2 - \mathbf{r}^2$.

The story of the *Lorentz transform* begins with Poincaré, who introduced the idea of local time: According to him, simultaneity depends on the reference system. Voigt attempted in 1897 for the first time to find a transformation that would conserve the value of c, but it was Lorentz who found a transformation leaving Maxwell's equations invariant and, consequently, Helmholtz's wave equation as well. The Lorentz transform is linear with respect to the preservation of space-time intervals in Minkowski space and, as we will see shortly, it removes the contradictions between classical mechanics and electrodynamics.

Consider a system S' moving through our lab S at a velocity $\mathbf{v} = v\hat{\mathbf{e}}_z$. We define,

$$\beta = \frac{v}{c} \qquad \text{and} \qquad \gamma = \frac{1}{\sqrt{1-\beta^2}} \,. \tag{17.18}$$

The matrix describing the Lorentz transform from system S to system S' is,

$$\boxed{\check{\Lambda} = (\Lambda^{\mu}{}_{\nu}) \equiv \begin{pmatrix} \gamma & 0 & 0 & -\gamma\beta \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ -\gamma\beta & 0 & 0 & \gamma \end{pmatrix}} \quad , \quad \check{\Lambda}^{-1} = (\Lambda^{\mu}{}_{\nu})^{-1} = \begin{pmatrix} \gamma & 0 & 0 & \gamma\beta \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ \gamma\beta & 0 & 0 & \gamma \end{pmatrix} \tag{17.19}$$

that is, the inverse of the transformation matrix is obtained by changing the sign of the velocity, $v \to -v$. For the Lorentz transform tensor we can show,

$$\begin{aligned} (\Lambda^{\mu}{}_{\nu})^{-1} = g_{\mu\omega}\Lambda^{\omega}{}_{\kappa}g^{\kappa\nu} = \Lambda_{\mu}{}^{\nu} \qquad &\text{that is} \qquad \check{\Lambda}^{-1} = \check{g}\check{\Lambda}\check{g} \\ \text{and} \qquad \Lambda^{\omega}{}_{\mu}g_{\omega\kappa}\Lambda^{\kappa}{}_{\nu} = g_{\mu\nu} \qquad &\text{that is} \qquad \check{\Lambda}^{\intercal}\check{g}\check{\Lambda} = \check{g} \ . \end{aligned} \tag{17.20}$$

The transformation from a laboratory reference frame S into a rest frame S' is done by,

$$A'^{\mu} = \Lambda^{\mu}{}_{\nu}A^{\nu} \ . \tag{17.21}$$

Time-space scalars are always Lorentz invariant. We consider, for example,

$$x'_{\mu}x'^{\mu} = \Lambda_{\mu}{}^{\nu}x_{\nu}\Lambda^{\mu}{}_{\omega}x^{\omega} = (\check{\Lambda}^{-1}\check{\Lambda})^{\nu}{}_{\omega}x_{\nu}x^{\omega} = \mathbb{I}\ x^{\omega}x_{\omega} \ . \tag{17.22}$$

For space-time differentials, since,

$$dx'^{\mu} = \frac{\partial x'^{\mu}}{\partial x^{\nu}}dx^{\nu} \ , \tag{17.23}$$

comparing with the relationship (17.21), we can identify,

$$\Lambda^{\mu}{}_{\nu} = \frac{\partial x'^{\mu}}{\partial x^{\nu}} \ . \tag{17.24}$$

Contra- and covariant tensors are defined by their different behavior under arbitrary coordinate transformation. For example, in the case of Lorentz transforms,

$$A'_{\mu} = \frac{\partial x^{\nu}}{\partial x'^{\mu}}A_{\nu} \qquad , \qquad A'^{\mu} = \frac{\partial x'^{\mu}}{\partial x^{\nu}}A^{\nu} \ . \tag{17.25}$$

Similarly, tensors or higher rank satisfy,

$$A'_{\mu\nu} = \frac{\partial x^{\mu}}{\partial x'^{\nu}}\frac{\partial x^{\nu}}{\partial x'^{\beta}}A_{\nu\beta} \qquad , \qquad A'^{\mu\nu} = \frac{\partial x'^{\mu}}{\partial x^{\nu}}\frac{\partial x'^{\nu}}{\partial x^{\beta}}A^{\nu\beta} \ , \tag{17.26}$$

and also,

$$A'^{\mu_1..\mu_n}{}_{\nu_1..\nu_m} = \Lambda^{\mu_1}{}_{\omega_1}..\Lambda^{\mu_n}{}_{\omega_n}\Lambda_{\nu_1}{}^{\kappa_1}..\Lambda_{\nu_n}{}^{\kappa_n}A^{\omega_1..\omega_n}{}_{\kappa_1..\kappa_m} \ . \tag{17.27}$$

In Exc. 17.1.7.1 we show that the derivative by a covariant coordinate is contravariant.

Example 126 (*Lorentz transform*): In the limit of slow velocities, $v \ll c$, the Lorentz transform converges to the Galilei transform. This can be seen rewriting the Lorentz transform as,

$$\begin{pmatrix} t' \\ z' \end{pmatrix} = \begin{pmatrix} \gamma & -\frac{\gamma\beta}{c} \\ -\gamma\beta & \gamma \end{pmatrix}\begin{pmatrix} t \\ z \end{pmatrix} \simeq \begin{pmatrix} 1 & 0 \\ -\beta & 1 \end{pmatrix}\begin{pmatrix} t \\ z \end{pmatrix} \ .$$

Example 127 (*Lorentz transform*): We have,

$$\Lambda^{\mu}{}_{\nu} = \frac{\partial x'^{\mu}}{\partial x^{\nu}} = \left(\frac{\partial x'_{\mu}}{\partial x_{\nu}}\right)^{-1} = \left(\frac{\partial x^{\nu}}{\partial x'^{\mu}}\right)^{-1} = (\Lambda_{\mu}{}^{\nu})^{-1} \ .$$

17.1.3 Contraction of space

Einstein's theory has important consequences, such as the *contraction of space* and the *dilatation of time*. Let us consider a rod moving through the lab S with velocity v. The rod delimits two points $j = 1, 2$ in space-time for which we measure in the lab (at time $t = t_1 = t_2$) the distance $z_2 - z_1$. The spatio-temporal points are Lorentz-transformed to the system S', in which the rod is at rest (neglecting transverse spatial dimensions), by,

$$\begin{pmatrix} ct'_j \\ z'_j \end{pmatrix} = (\Lambda^{\mu}{}_{\nu}) \begin{pmatrix} ct \\ z_j \end{pmatrix} = \begin{pmatrix} \gamma ct - \gamma\beta z_j \\ -\gamma\beta ct + \gamma z_j \end{pmatrix} \ . \tag{17.28}$$

Hence,

$$z'_2 - z'_1 = -\gamma\beta ct + \gamma z_2 + \gamma\beta ct - \gamma z_1 = \gamma(z_2 - z_1) \ . \tag{17.29}$$

Consequently, in the lab the distance seems smaller than in the rest frame [1].

17.1.4 Dilatation of time

We consider a clock flying through the lab S at a velocity v. The clock produces regular time intervals, for which we measure in the lab the duration $t_2 - t_1$. The spatio-temporal points are Lorentz-transformed to the system S' in which the clock is at rest ($z' = z'_1 = z'_2$) via,

$$\begin{pmatrix} ct'_j \\ z' \end{pmatrix} = (\Lambda^{\mu}{}_{\nu}) \begin{pmatrix} ct_j \\ z_j \end{pmatrix} = \begin{pmatrix} \gamma ct_j - \gamma\beta z_j \\ -\gamma\beta ct_j + \gamma z_j \end{pmatrix} \ . \tag{17.30}$$

Hence,

$$\begin{aligned} t'_2 - t'_1 &= \gamma t_2 - \gamma\beta\frac{z_2}{c} - \gamma t_1 + \gamma\beta\frac{z_1}{c} \\ &= \gamma t_2 - \beta\left(\frac{z'}{c} + \gamma\beta t_2\right) - \gamma t_1 + \beta\left(\frac{z'}{c} + \gamma\beta t_1\right) = \gamma^{-1}(t_2 - t_1) \ . \end{aligned} \tag{17.31}$$

Consequently, in the lab the time interval seems longer than in the rest frame.

A good illustration of the effect of time dilatation is the *twin paradox*. A twin begins an interstellar voyage aboard a space ship traveling at a constant velocity. Twin B, who remained on Earth calculates, that the time elapsed for his twin A is smaller than his own time. Twin B calculates that the elapsed time for his twin A is shorter. Who's right? Twin A is wrong, because his system must be accelerated when taking off from Earth. Note that only special relativity is required to understand

[1] Alternatively, we can measure the instants of time t_j when the ends of the rod pass by a certain point z of the lab, such that $l = v(t_2 - t_1)$.

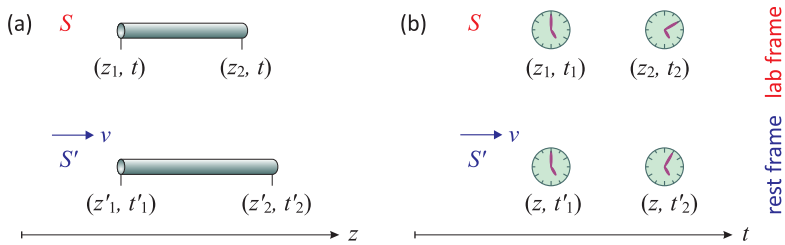

Figure 17.2: Illustration of (a) contraction of space and (b) dilatation of time.

the effect [2]: Take for example, a third person traveling back to Earth after having synchronized its clock with twin A. We calculate in Excs. 17.1.7.2 to 17.1.7.5 examples of temporal dilatation.

17.1.5 Transformational behavior of the wave equation

In the previous section we have seen that the relativistic metric is based on the covariant formulation of mechanics with the definition of relativistic space-time vectors. We introduced the *quadri-vectors* of the displacement Δr^μ, of the position (r^μ), and of the gradient (∂^μ),

$$\boxed{(\Delta r^\mu) \equiv \begin{pmatrix} c\Delta t \\ \Delta \mathbf{r} \end{pmatrix} \quad , \quad (r^\mu) \equiv \begin{pmatrix} ct \\ \mathbf{r} \end{pmatrix} \quad , \quad (\partial^\mu) \equiv \begin{pmatrix} \frac{1}{c}\frac{\partial}{\partial t} \\ -\nabla \end{pmatrix}} \; . \tag{17.32}$$

The contraction of quadri-vectors produces Lorentz invariants, such as the *quadri-scalars* of space-time intervals Δs^2, of proper time $\Delta\tau$, of proper distance $|\Delta\vec{\mathcal{S}}|$, or of the d'Alembertian $\Box$, given by,

$$\begin{aligned} \Delta s^2 &\equiv \Delta r_\mu \Delta r^\mu = c^2 \Delta t^2 - \Delta \mathbf{r}^2 \; , \\ \Delta\tau &\equiv \sqrt{\tfrac{\Delta s^2}{c^2}} \qquad \text{for 'time'-like intervals} \qquad \Delta s^2 > 0 \; , \\ |\Delta \mathbf{s}| &\equiv \sqrt{-\Delta s^2} \qquad \text{for 'space'-like intervals} \qquad \Delta s^2 < 0 \; , \\ \Box &\equiv \partial_\mu \partial^\mu = \tfrac{1}{c^2}\tfrac{\partial^2}{\partial t^2} - \nabla^2 \; . \end{aligned} \tag{17.33}$$

With these definitions we can write the wave equation in the absence of sources,

$$\boxed{\Box\psi = \partial^\mu \partial_\mu \psi = 0} \; . \tag{17.34}$$

The covariant form of the wave equation already shows its compatibility with the Lorentz transform. Nevertheless, we will discuss the transformation properties in the following. These are fundamental, since the propagation of light, whose invariant velocity triggered the theory of relativity, is an undulatory phenomenon.

[2] [http://de.wikipedia.org/wiki/Zwillingsparadox]

17.1.5.1 Wave equation under Galilei transformation

The Galilei transformation claims that we obtain the coordinates of an object in a system S' simply by substituting $z \to z'$ and $t \to t'$ with [3],

$$\begin{aligned} t' \equiv t \quad &\text{and} \quad z' \equiv z - v_0 t \quad \text{or} \\ t \equiv t' \quad &\text{and} \quad z \equiv z' + v_0 t \ , \end{aligned} \tag{17.35}$$

which implies

$$v' = \frac{\partial z'}{\partial t'} = \frac{\partial z}{\partial t} - v_0 = v - v_0 \ . \tag{17.36}$$

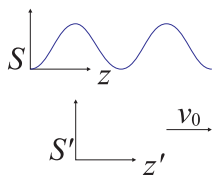

Figure 17.3: Wave in the inertial system S as seen by an observer in the system S' moving at a velocity u.

Newton's classical mechanics is *Galilei invariant*, which means that the fundamental equations of the type,

$$m\dot{v}_i = -\nabla_{x_i} \sum_j V_{ij}(|x_i - x_j|) \ , \tag{17.37}$$

do not change their shape under the *Galilei transform*. In contrast, the wave equation is *not* Galilei invariant. To see this, we consider a wave in the inertial system S, which is resting with respect to the propagation medium, being described by $Y(z,t)$ and satisfying the wave equation,

$$\frac{\partial^2 Y(z,t)}{\partial t^2} = c^2 \frac{\partial^2 Y(z,t)}{\partial z^2} \ . \tag{17.38}$$

An observer sits in the inertial system S' moving with respect to S with the speed v_0, such that $z' = z - v_0 t$. The question now is, what is the equation of motion for this wave described by $Y'(z',t')$, that is, we want to check the validity of

$$\frac{\partial^2 Y'(z',t')}{\partial t'^2} \stackrel{?}{=} c^2 \frac{\partial^2 Y'(z',t')}{\partial z'^2} \ . \tag{17.39}$$

For example, the wave $Y(z,t) = \sin k(z - ct)$ traveling to the right is perceived in the system S', which is also traveling to the right, as $Y'(z',t') = \sin k[z' - (c - v_0)t'] = Y(z,t)$ applying the Galilei transform. Therefore,

$$Y'(z',t') = Y(z,t) \ , \tag{17.40}$$

[3] Note that the Galilei transform (17.17) is unitary because $\det G = 1$.

that is, we expect that the laws valid in S are also valid in S'. We calculate the partial derivatives,

$$\frac{\partial Y'(z',t')}{\partial t'} = \frac{\partial Y(z,t)}{\partial t'} = \frac{\partial t}{\partial t'}\left.\frac{\partial Y(z,t)}{\partial t}\right|_{z=const} + \frac{\partial z}{\partial t'}\left.\frac{\partial Y(z,t)}{\partial z}\right|_{t=const} = \frac{\partial Y(z,t)}{\partial t} + v_0\frac{\partial Y(z,t)}{\partial z}$$
$$\frac{\partial Y'(z',t')}{\partial z'} = \frac{\partial Y(z,t)}{\partial z'} = \frac{\partial t}{\partial z'}\left.\frac{\partial Y(z,t)}{\partial t}\right|_{z=const} + \frac{\partial z}{\partial z'}\left.\frac{\partial Y(z,t)}{\partial z}\right|_{t=const} = \frac{\partial Y(z,t)}{\partial z} \ . \quad (17.41)$$

Therefore, we conclude that the wave equation in the propagating system is modified:

$$\begin{aligned}\frac{\partial^2 Y'(z',t')}{\partial t'^2} &\overset{\rightarrow}{=} \frac{\partial^2 Y(z,t)}{\partial t^2} + v_0^2\frac{\partial^2 Y(z,t)}{\partial z^2} + 2v_0\frac{\partial^2 Y(z,t)}{\partial t\partial z} \\ &\overset{\text{eq.onda}}{=} c^2\frac{\partial^2 Y(z,t)}{\partial z^2} + v_0^2\frac{\partial^2 Y(z,t)}{\partial z^2} + 2v_0\frac{\partial^2 Y(z,t)}{\partial t\partial z} \\ &\overset{\leftarrow}{=} (c^2 - v_0^2)\frac{\partial^2 Y'(z',t')}{\partial z'^2} + 2v_0\frac{\partial^2 Y'(z',t')}{\partial t'\partial z'} \ .\end{aligned} \quad (17.42)$$

Only in cases where the wave function can be written as $Y(z,t) = f(z-ct) = f(z'-(c-v_0)t') = f'(z'-ct') = Y'(z',t')$, will we obtain a similar wave equation to that of the system S, but with a modified propagation velocity. We calculate,

$$\frac{\partial f'(z'-ct')}{\partial t'} = \frac{\partial f(z'-(c-v_0)t')}{\partial t'} = (v_0-c)\frac{\partial f(z'-(c-v_0)t')}{\partial z'} = (v_0-c)\frac{\partial f'(z'-ct')}{\partial z'} \ , \quad (17.43)$$

and the second derivative,

$$\frac{\partial^2 f'(z'-ct')}{\partial t'^2} = (c-v_0)^2\frac{\partial^2 f'(z'-ct')}{\partial z'^2} \ . \quad (17.44)$$

The observation that the wave equation is not Galilei invariant expresses the fact, that there is a preferential system for the wave to propagate, which is simply the system in which the propagation medium is at rest. Only in this inertial system will a spherical wave propagate isotropically.

Example 128 (*Wave equation under Galilei transformation*): Let us now verify the correctness of the wave equation in the propagating system S' using the example of a sine wave,

$$\begin{aligned}&(c^2 - v_0^2)\frac{\partial^2 \sin k[z'-(c-v_0)t']}{\partial z'^2} + 2v_0\frac{\partial^2 \sin k[z'-(c-v_0)t']}{\partial z'\partial t'} \\ &= -k^2(c^2-v_0^2)\sin k[z'-(c-v_0)t'] + 2uk^2(c-v_0)\sin k[z'-(c-v_0)t'] \\ &= -k^2(c-v_0)^2\sin k[z'-(c-v_0)t'] = \frac{\partial^2 \sin k[z'-(c-v_0)t']}{\partial t'^2} \ .\end{aligned}$$

17.1.5.2 Wave equation under Lorentz transformation

The question now is, how to deal with electromagnetic waves which are lacking a propagation medium, as we have already noted and as has been verified by Michelson's famous experiment. If there is no propagation medium, all inertial systems should be equivalent, and the wave equation should be the same in all systems, and so should

be the propagation velocity, i.e. the speed of light. These were the consideration of *Jules Henry Poincaré*. To solve the problem we need another transformation than that of *Galileo Galilei*. It was *Hendrik Antoon Lorentz* who found the solution, but the biggest intellectual challenge was to accept all consequences of this new transformation. *Albert Einstein* accepted the challenge and created a new mechanics, which he called *relativistic mechanics*. The wave equation for electromagnetic waves, called the *Helmholtz equation*, being a direct consequence of Maxwell's theory, it is not surprising that the relativistic theory proved not only compatible with electrodynamic theory, but provides a much deeper understanding of the latter.

We begin with the ansatz of a general transformation connecting temporal and spatial coordinates via four unknown parameters, γ, $\tilde{\gamma}$, β, and $\tilde{\beta}$,

$$ct = \gamma(ct' + \beta z') \qquad \text{and} \qquad z = \tilde{\gamma}(z' + \tilde{\beta} ct') \ . \tag{17.45}$$

A similar calculation as the one made for the Galilei transformation now gives the first derivatives,

$$\frac{\partial Y'(z',t')}{c\partial t'} = \frac{\partial Y(z,t)}{c\partial t'} = \frac{\partial t}{\partial t'}\,\frac{\partial Y(z,t)}{c\partial t}\bigg|_{z=const} + \frac{\partial z}{c\partial t'}\,\frac{\partial Y(z,t)}{\partial z}\bigg|_{t=const} = \gamma\frac{\partial Y(z,t)}{c\partial t} + \tilde{\gamma}\tilde{\beta}\frac{\partial Y(z,t)}{\partial z} \tag{17.46}$$

$$\frac{\partial Y'(z',t')}{\partial z'} = \frac{\partial Y(z,t)}{\partial z'} = \frac{c\partial t}{\partial z'}\,\frac{\partial Y(z,t)}{c\partial t}\bigg|_{z=const} + \frac{\partial z}{\partial z'}\,\frac{\partial Y(z,t)}{\partial z}\bigg|_{t=const} = \gamma\beta\frac{\partial Y(z,t)}{c\partial t} + \tilde{\gamma}\frac{\partial Y(z,t)}{\partial z} \ .$$

The second derivatives and the application of the wave equation in the system S give,

$$\begin{aligned}\frac{\partial^2 Y'(z',t')}{c^2\partial t'^2} &\stackrel{\rightarrow}{=} \gamma^2\frac{\partial^2 Y(z,t)}{c^2\partial t^2} + 2\gamma\tilde{\gamma}\tilde{\beta}\frac{\partial^2 Y(z,t)}{c\partial t\partial z} + (\tilde{\gamma}\tilde{\beta})^2\frac{\partial^2 Y(z,t)}{\partial z^2} \\ &\stackrel{\text{wave eq.}}{=} \gamma^2\frac{\partial^2 Y(z,t)}{\partial z^2} + 2\gamma\tilde{\gamma}\tilde{\beta}\frac{\partial^2 Y(z,t)}{c\partial t\partial z} + (\tilde{\gamma}\tilde{\beta})^2\frac{\partial^2 Y(z,t)}{c^2\partial t^2} \\ &\stackrel{!}{=} (\gamma\beta)^2\frac{\partial^2 Y(z,t)}{c^2\partial t^2} + 2\gamma\tilde{\gamma}\beta\frac{\partial^2 Y(z,t)}{c\partial t\partial z} + \tilde{\gamma}^2\frac{\partial^2 Y(z,t)}{\partial z^2} \stackrel{\leftarrow}{=} \frac{\partial^2 Y'(z',t')}{\partial z'^2} \ .\end{aligned} \tag{17.47}$$

That is, the wave equation in the system S' has the same form [4], under the condition that,

$$\gamma = \tilde{\gamma} \qquad \text{and} \qquad (\gamma\beta)^2 = (\tilde{\gamma}\tilde{\beta})^2 \qquad \text{and} \qquad \beta = \tilde{\beta} \ . \tag{17.48}$$

In addition, the transformation

$$\begin{pmatrix} ct' \\ z' \end{pmatrix} = \Lambda \begin{pmatrix} ct \\ z \end{pmatrix} \qquad \text{with} \qquad \Lambda \equiv \begin{pmatrix} \gamma & \gamma\beta \\ \gamma\beta & \gamma \end{pmatrix} \tag{17.49}$$

has to be unitary, that is,

$$1 = \det\Lambda = \gamma\tilde{\gamma} - \gamma\tilde{\gamma}\beta\tilde{\beta} = \gamma^2(1-\beta^2) \ , \tag{17.50}$$

which allows to relate the parameters γ and β by,

$$\gamma = \frac{1}{\sqrt{1-\beta^2}} \ . \tag{17.51}$$

[4] Note that the computation is dramatically simplified in the covariant formalism of 4-dimensional *space-time vectors* introduced by *Hermann Minkowski* and *Gregory Ricci-Curbastro*.

Finally and obviously, we expect to recover the Galilei transformation at low velocities,

$$ct = \gamma(ct' + \beta z') \to ct' \qquad \text{and} \qquad z = \gamma(z' + \beta ct') \to z' + v_0 t' \ . \tag{17.52}$$

That is, the limit is obtained by $\gamma \to 1$ and $\gamma\beta c \to v_0$, such that,

$$\beta = \frac{v_0}{c} \ . \tag{17.53}$$

The *Lorentz transform* from an inertial system S to another S' is,

$$\begin{aligned} t' &= \gamma\left(t - \tfrac{v_0}{c^2} z\right) \qquad \text{and} \qquad z' = \gamma(z - v_0 t) \qquad \text{or} \\ t &= \gamma\left(t' + \tfrac{v_0}{c^2} z'\right) \qquad \text{and} \qquad z = \gamma(z' + v_0 t') \ . \end{aligned} \tag{17.54}$$

17.1.6 The Lorentz boost

In this section we will construct the Lorentz transform from *infinitesimal generators* [473]. To begin with we introduce 6 fundamental matrices. The matrices,

$$K_k \equiv \begin{pmatrix} 0 & \hat{\mathbf{e}}_k \\ \hat{\mathbf{e}}_k & \mathbf{0}_3 \end{pmatrix} \ , \tag{17.55}$$

with the unit vectors $\hat{\mathbf{e}}_k = \hat{\mathbf{e}}_x, \hat{\mathbf{e}}_y, \hat{\mathbf{e}}_z$ generate linear boosts and the matrices,

$$S_k \equiv \begin{pmatrix} 0 & \mathbf{0} \\ \mathbf{0} & \mathbf{S}_k \end{pmatrix} \quad \text{with} \quad \mathbf{S}_x \equiv \hat{\mathbf{e}}_z\hat{\mathbf{e}}_y^\dagger - \hat{\mathbf{e}}_y\hat{\mathbf{e}}_z^\dagger \ , \ \mathbf{S}_y \equiv \hat{\mathbf{e}}_x\hat{\mathbf{e}}_z^\dagger - \hat{\mathbf{e}}_z\hat{\mathbf{e}}_x^\dagger \ , \ \mathbf{S}_z \equiv \hat{\mathbf{e}}_y\hat{\mathbf{e}}_x^\dagger - \hat{\mathbf{e}}_x\hat{\mathbf{e}}_y^\dagger \ , \tag{17.56}$$

generate spatial rotations around the 3 Cartesian axes. We note that the squares of all matrices S_k and K_k are diagonal and that,

$$[S_i, S_j] = \epsilon_{ijk} S_k \quad , \quad [S_i, K_j] = \epsilon_{ijk} K_k \quad , \quad [K_i, K_j] = -\epsilon_{ijk} S_k \ . \tag{17.57}$$

Example 129 (*Actions of the matrices K_k and S_k*): For example, the operation

$$(x'^\mu) = (\mathbb{I}_4 + K_z)^\mu{}_\nu (x^\nu) = \begin{pmatrix} 1 & \hat{\mathbf{e}}_z \\ \hat{\mathbf{e}}_z & \mathbb{I}_3 \end{pmatrix} \begin{pmatrix} ct \\ \mathbf{r} \end{pmatrix}$$

transports a space-time point $(ct, \mathbf{r})$ with light velocity along the z-axis to another point, $(ct', \mathbf{r}') = (ct + z, \mathbf{r} + ct\hat{\mathbf{e}}_z)$. And the operation

$$(x'^\mu) = (\mathbb{I}_4 + S_z)^\mu{}_\nu (x^\nu) = \begin{pmatrix} 1 & \mathbf{0} \\ \mathbf{0} & \mathbb{I}_3 + S_z \end{pmatrix} \begin{pmatrix} ct \\ \mathbf{r} \end{pmatrix} = \begin{pmatrix} ct \\ \begin{pmatrix} 1 & -1 & 0 \\ 1 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix} \mathbf{r} \end{pmatrix} = \begin{pmatrix} ct \\ x - y \\ y + x \\ z \end{pmatrix}$$

transports a space-time point $(ct, \mathbf{r})$ around the z-axis to another point, $(ct', \mathbf{r}') = (ct, x - y, y + x, z)$.

The *Lorentz boost* can now be written as,

$$\boxed{\begin{aligned} \Lambda = e^L \quad \text{with} \quad L &= -\vec{\omega}\cdot\mathbf{S} - \vec{\zeta}\cdot\mathbf{K} \\ \text{where} \quad \mathbf{S} &\equiv \begin{pmatrix} S_x & S_y & S_z \end{pmatrix} \\ \text{and} \quad \mathbf{K} &\equiv \begin{pmatrix} K_x & K_y & K_z \end{pmatrix} \end{aligned}} \ . \tag{17.58}$$

We verify that,

$$\det\Lambda = \det e^L = e^{\mathrm{Tr}\ L} = \pm 1 \ . \tag{17.59}$$

Example 130 (*Lorentz-boost without rotation*): For a Lorentz-boost without rotation,

$$\Lambda = e^{-\vec{\zeta}\cdot\mathbf{K}} \quad \text{with} \quad \vec{\zeta} = \hat{\mathbf{e}}_\beta \tanh^{-1}\beta \ ,$$

we get,

$$\Lambda = \begin{pmatrix} \gamma & -\gamma\beta_x & -\gamma\beta_y & -\gamma\beta_z \\ -\gamma\beta_x & 1+\frac{(\gamma-1)\beta_x^2}{\beta^2} & \frac{(\gamma-1)\beta_x\beta_y}{\beta^2} & \frac{(\gamma-1)\beta_x\beta_z}{\beta^2} \\ -\gamma\beta_y & \frac{(\gamma-1)\beta_x\beta_y}{\beta^2} & 1+\frac{(\gamma-1)\beta_y^2}{\beta^2} & \frac{(\gamma-1)\beta_y\beta_z}{\beta^2} \\ -\gamma\beta_z & \frac{(\gamma-1)\beta_x\beta_z}{\beta^2} & \frac{(\gamma-1)\beta_y\beta_z}{\beta^2} & 1+\frac{(\gamma-1)\beta_z^2}{\beta^2} \end{pmatrix} = \begin{pmatrix} \gamma & -\gamma\vec{\beta} \\ -\gamma\vec{\beta} & \mathbb{I}_3 + (\gamma-1)\hat{\beta}_i\hat{\beta}_j \end{pmatrix} , \tag{17.60}$$

as will be shown in Exc. 17.1.7.6. The Lorentz transform (17.19) into a system moving along the z-axis follows immediately with $\beta_x = \beta_y = 0$.

17.1.6.1 The Thomas precession

We consider the circular motion of an electron around a nucleus about the z-axis subject to a centripetal (Coulombian) force. The nucleus is fixed in the lab frame S, the electron's rest frame S' moves with respect to the lab frame at the instantaneous velocity $\mathbf{v}(t) = c\vec{\beta}(t)$, as illustrated in Fig. 17.4.

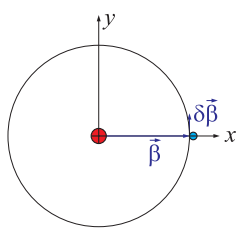

Figure 17.4: Circular motion of an electron around a nucleus.

At time t, when the electron's velocity is $\vec{\beta}(t)$, the Lorentz transform from S to S' is described by [473],

$$x'(t) = \Lambda_{\text{boost}}(\vec{\beta})x \ , \tag{17.61}$$

Note, that the nucleus' position does not change in the frame S, $x(t+\delta t) = x(t) = x$. At a later time $t+\delta t$, when the electron's velocity is $\vec{\beta}(t+\delta t) = \vec{\beta}(t) + \delta\vec{\beta}(t)$, the

Lorentz transform,

$$x'(t+\delta t) = \Lambda_{\rm boost}(\vec{\beta}+\delta\vec{\beta})x = \Lambda_{\rm boost}(\vec{\beta}+\delta\vec{\beta})\Lambda^{-1}_{\rm boost}(\vec{\beta})x'(t) \tag{17.62}$$

can be expressed as a Lorentz transform from the electron's system S' at time t to the same S' at time $t+\delta t$. From the expression (17.60) for a Lorentz-boost without rotation, setting $\beta_z = 0$, we get for Lorentz-boost in the xy-plane,

$$\Lambda^{\pm 1}_{\rm boost}(\beta_x\hat{\mathbf{e}}_x + \beta_y\hat{\mathbf{e}}_y) = \begin{pmatrix} \gamma & \mp\gamma\beta_x & \mp\gamma\beta_y & 0 \\ \mp\gamma\beta_x & 1+\frac{(\gamma-1)\beta_x^2}{\beta^2} & \frac{(\gamma-1)\beta_x\beta_y}{\beta^2} & 0 \\ \mp\gamma\beta_y & \frac{(\gamma-1)\beta_x\beta_y}{\beta^2} & 1+\frac{(\gamma-1)\beta_y^2}{\beta^2} & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix} . \tag{17.63}$$

Now, setting the initial position of the electron along the direction $\vec{\beta}(t) = \beta\hat{\mathbf{e}}_x$, as shown in Fig. 17.4, we get,

$$\Lambda^{-1}_{\rm boost}(\vec{\beta}) = \begin{pmatrix} \gamma & \gamma\beta & 0 & 0 \\ \gamma\beta & \gamma & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix} , \tag{17.64}$$

and, expanding γ for small velocity changes like,

$$\gamma + \delta\gamma = \frac{1}{\sqrt{1-(\beta+\delta\beta)^2}} \simeq \gamma + \gamma^3\beta\delta\beta , \tag{17.65}$$

we find,

$$\begin{aligned} \Lambda_{\rm boost}(\vec{\beta}+\delta\vec{\beta}) &= \begin{pmatrix} \gamma+\delta\gamma & -(\gamma+\delta\gamma)(\beta+\delta\beta_x) & -(\gamma+\delta\gamma)\delta\beta_y & 0 \\ -(\gamma+\delta\gamma)(\beta+\delta\beta_x) & 1+\frac{(\gamma+\delta\gamma-1)(\beta+\delta\beta_x)^2}{(\beta+\delta\beta_x)^2} & \frac{(\gamma+\delta\gamma-1)(\beta+\delta\beta_x)\delta\beta_y}{(\beta+\delta\beta_x)^2} & 0 \\ -(\gamma+\delta\gamma)\delta\beta_y & \frac{(\gamma+\delta\gamma-1)(\beta+\delta\beta_x)\delta\beta_y}{(\beta+\delta\beta_x)^2} & 1+\frac{(\gamma+\delta\gamma-1)(\delta\beta_y)^2}{(\beta+\delta\beta_x)^2} & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix} \\ &\simeq \begin{pmatrix} \gamma+\gamma^3\beta\delta\beta_x & -\gamma\beta-\gamma^3\delta\beta_x & -\gamma\delta\beta_y & 0 \\ -\gamma\beta-\gamma^3\delta\beta_x & \gamma+\gamma^3\beta\delta\beta_x & \frac{\gamma-1}{\beta}\delta\beta_y & 0 \\ -\gamma\delta\beta_y & \frac{\gamma-1}{\beta}\delta\beta_y & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix} . \end{aligned} \tag{17.66}$$

Multiplying the matrices (17.65) and (17.66) we get,

$$\Lambda_{Th}(\vec{\beta}+\delta\vec{\beta}) = \Lambda_{\rm boost}(\vec{\beta}+\delta\vec{\beta})\Lambda^{-1}_{\rm boost}(\vec{\beta}) \simeq \begin{pmatrix} 1 & -\gamma^2\delta\beta_x & -\gamma\delta\beta_y & 0 \\ -\gamma^2\delta\beta_x & 1 & \frac{\gamma-1}{\beta}\delta\beta_y & 0 \\ -\gamma\delta\beta_y & -\frac{\gamma-1}{\beta}\delta\beta_y & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix} . \tag{17.67}$$

This represents an infinitesimal Lorentz transformation that, expressing the components of $\delta\vec{\beta}$ parallel and perpendicular to β by,

$$\delta\vec{\beta}_{\parallel} = \tfrac{\delta\vec{\beta}\cdot\vec{\beta}}{\beta^2}\vec{\beta} \qquad \text{and} \qquad \delta\vec{\beta}_{\perp} = \delta\vec{\beta} - \tfrac{\delta\vec{\beta}\cdot\vec{\beta}}{\beta^2}\vec{\beta} \tag{17.68}$$

can be written in terms of the matrices $\mathbf{S}$ and $\mathbf{K}$ as [5],

$$\boxed{\begin{aligned} \Lambda_{Th}(\vec{\beta}+\delta\vec{\beta}) &= \mathbb{I} - \tfrac{\gamma-1}{\beta^2}(\vec{\beta}\times\delta\vec{\beta})\cdot\mathbf{S} - (\gamma^2\delta\vec{\beta}_{\parallel} + \gamma\delta\vec{\beta}_{\perp})\cdot\mathbf{K} \\ &\simeq R(\Delta\vec{\Omega})\ \Lambda_{\text{boost}}(\Delta\vec{\beta}) \end{aligned}} \ . \tag{17.69}$$

Here, we defined the *commuting* infinitesimal boosts and rotations called *Wigner rotations*,

$$\Lambda_{\text{boost}}(\Delta\vec{\beta}) \equiv \mathbb{I} - \Delta\vec{\beta}\cdot\mathbf{K} \qquad \text{and} \qquad R(\Delta\vec{\Omega}) \equiv \mathbb{I} - \Delta\vec{\Omega}\cdot\mathbf{S} \tag{17.70}$$

in terms of velocity and rotation angle,

$$\Delta\vec{\beta} \equiv \gamma^2\delta\vec{\beta}_{\parallel} + \gamma\delta\vec{\beta}_{\perp} \qquad \text{and} \qquad \Delta\vec{\Omega} \equiv \frac{\gamma-1}{\beta^2}\vec{\beta}\times\delta\vec{\beta}\ . \tag{17.71}$$

Clearly, the second line of (17.69) holds to first order in $\delta\vec{\beta}$. Thus, the pure Lorentz boost (17.62) to the frame with velocity $c(\vec{\beta}+\delta\vec{\beta})$ is equivalent to a boost (17.61) to a frame moving with velocity $c\vec{\beta}$, followed by an infinitesimal Lorentz transformation consisting of a boost with velocity $c\vec{\Delta}\beta$ and a rotation $\Delta\vec{\Omega}$.

In summary, we got,

$$\begin{aligned} x'(t+\delta t) &= \Lambda_{\text{boost}}(\vec{\beta}+\delta\vec{\beta})x = \Lambda_{\text{boost}}(\vec{\beta}+\delta\vec{\beta})\Lambda^{-1}_{\text{boost}}(\vec{\beta})x'(t) \\ &= \Lambda_{Th}(\vec{\beta}+\delta\vec{\beta})x'(t) = R(\Delta\Omega)\Lambda_{\text{boost}}(\Delta\vec{\beta})x'(t)\ . \end{aligned} \tag{17.72}$$

In terms of the interpretation of the moving frames as successive rest frames of the electron we do not want rotations as well as boosts. Non-relativistic equations of motion can be expected to hold provided the evolution of the rest frame is described by infinitesimal boosts without rotations. We are thus led to consider the rest-frame coordinates at time $t+\delta t$ that are given from those at time t by the boost $\Lambda_{\text{boost}}(\Delta\vec{\beta})$ instead of Λ_{Th}. Denoting these coordinates by $\tilde{x}'$ we have,

$$\begin{aligned} \tilde{x}'(t+\delta t) &= \Lambda_{\text{boost}}(\Delta\vec{\beta})x'(t) \\ &= R(-\Delta\vec{\Omega})x'(t+\delta t) = R(-\Delta\vec{\Omega})\Lambda_{\text{boost}}(\vec{\beta}+\delta\vec{\beta})x\ . \end{aligned} \tag{17.73}$$

The rest system of coordinates defined by $\tilde{x}'$ is rotated by $R(-\Delta\vec{\Omega})$ relative to the boosted laboratory axes x'. If a physical vector $\mathbf{G}$ has a (proper) time rate of change

[5] We note that, for the case $\vec{\beta}(t) = \beta\hat{\mathbf{e}}_x$ Eq. (17.69) can be written as,

$$\Lambda_{Th} = \mathbb{I} - \frac{\gamma-1}{\beta}S_z\delta\beta_y - \gamma^2 K_x\delta\beta_x - \gamma K_y\delta\beta_y\ ,$$

which reproduces exactly Eq. (17.67).

$(d\mathbf{G}/d\tau)$ in the rest frame, the precession of the rest-frame axes with respect to the laboratory makes the vector have a total time rate of change with respect to the laboratory axes of,

$$\left(\frac{d\mathbf{G}}{dt}\right)_{non-rot} = \left(\frac{d\mathbf{G}}{dt}\right)_{rest} + \vec{\omega}_{Th} \times \mathbf{G} \ . \tag{17.74}$$

with

$$\vec{\omega}_{Th} = -\lim_{\delta t \to 0} \frac{\Delta\Omega}{\delta t} = \frac{\gamma^2}{\gamma+1} \frac{\mathbf{a} \times \mathbf{v}}{c^2} \ , \tag{17.75}$$

where $\mathbf{a}$ is the acceleration in the laboratory frame and, to be precise,

$$\left(\frac{d\mathbf{G}}{dt}\right)_{rest} = \gamma^{-1} \left(\frac{d\mathbf{G}}{d\tau}\right)_{rest} \ . \tag{17.76}$$

The *Thomas precession* is purely kinematical in origin. If a component of acceleration exists perpendicular to $\mathbf{v}$, for whatever reason, then there is a Thomas precession, independent of other effects such as precession of the magnetic moment in a magnetic field.

Example 131 (*Circular motion*): Assuming a constant circular motion about the z-axis, as parametrized by $\mathbf{v} = r\dot{\theta}\hat{\mathbf{e}}_\theta$ and $\mathbf{a} = -r\dot{\theta}^2\hat{\mathbf{e}}_r = -\dot{\theta}v\hat{\mathbf{e}}_r$ with $\dot{\theta} = const$, we find,

$$\vec{\omega}_{Th} = \frac{\gamma^2}{\gamma+1} \frac{\mathbf{a} \times \mathbf{v}}{c^2} = \frac{\gamma^2}{\gamma+1} \frac{-\dot{\theta}v^2}{c^2} \hat{\mathbf{e}}_z = -\frac{\gamma^2\beta^2}{\gamma+1} \dot{\theta}\hat{\mathbf{e}}_z = -(\gamma-1)\dot{\theta}\hat{\mathbf{e}}_z \ .$$

17.1.6.2 Spin-Orbit coupling

For electrons in atoms the acceleration is caused by the screened Coulomb field. Thus the Thomas angular velocity is,

$$\vec{\omega}_{Th} \simeq -\frac{1}{2c^2} \frac{\mathbf{r} \times \mathbf{v}}{m} \frac{1}{r} \frac{dV}{dr} = -\frac{1}{2m^2c^2} \mathbf{L} \frac{1}{r} \frac{dV}{dr} \ . \tag{17.77}$$

It is evident that the extra contribution to the energy from the Thomas precession reduces the spin-orbit coupling, yielding,

$$U = \frac{-ge}{2mc} \vec{\mathcal{S}} \cdot \vec{\mathcal{B}} + \frac{(g-1)}{2m^2c^2} \vec{\mathcal{S}} \cdot \mathbf{L} \frac{1}{r} \frac{dV}{dr} \ . \tag{17.78}$$

17.1.7 Exercises

17.1.7.1 Ex: Contravariant partial derivation

Show that the partial derivative by the contravariant coordinate x^μ is covariant.

17.1.7.2 Ex: Time dilatation

Proxima Centauri, which is the closest star to our solar system with a distance of 4.22 light-years from Earth, is a so-called Red Dwarf of class M. At its 34th anniversary, Peter embarks on a journey from Earth to this star. His spaceship flies with a speed of 250000 km/s. How old is Peter when he arrives? What is the age of Peter's twin brother, who remained on Earth at this time?

17.1.7.3 Ex: The twin paradox

Explain the twin paradox by applying the Lorentz transform to the twin traveling on a round-trip to α-Centauri assuming a fixed distance between Earth and α-Centauri.

17.1.7.4 Ex: Muons

In the upper layers of the atmosphere (at 20 km altitude) about 250 muons are generated per square meter and second. After that they move with 99.98% of the speed of light towards the surface of the Earth. Muons at rest have a lifetime of 1.52 µs.
a. Assuming that there were no time dilatation, how many muons would arrive per square meter and second at the surface of the Earth?
b. How many muons actually reach the surface of the Earth?

17.1.7.5 Ex: Atomic clocks

In 1971 atomic clocks were taken by a high-speed aircraft to measure time dilatation directly. How long must an aircraft fly at a speed of 3000 km/h, so that the airplane's clock and a clock fixed on Earth show, due to time dilatation, a difference of one second?

17.1.7.6 Ex: Lorentz-boost without rotation

Derive the matrix (17.60) for the Lorentz-boost without rotation to a system moving in arbitrary direction.

17.2 Relativistic mechanics

17.2.1 The inherent time of an inertial system

The key to constructing relativistic theories is to find the quantities behaving well under Lorentz transformations. We have already defined some quantities in (17.32) and (17.33). But we need more to establish a *relativistic mechanics*. In the following sections we will analyze how other kinematic variables (velocity, momentum, and acceleration) fit into four-vectors. Since these variables are defined through time derivatives, an accurate characterization of the notion of *time intervals* is necessary.

We consider an object following a space-time trajectory. As the evaluation of traveled distances and elapsed time intervals depends on the observer's inertial system, there is no universal parametrization. But there is at least one 'natural' parametrization that all observers can agree on, which is the proper time τ, which is the duration of time felt by the object itself. Due to time dilatation, an observer sitting in some inertial system and measuring the motion of the object with the old-fashioned Newtonian tri-velocity $\mathbf{v}(t)$ infers, that the relation between his own time t and the proper time τ of the particle is given by,

$$\boxed{\frac{dt}{d\tau} = \gamma_v \equiv \frac{1}{\sqrt{1 - v^2/c^2}} > 1} \,. \tag{17.79}$$

Example 132 (*Common velocity under Lorentz transformation*): We could define the *common velocity* of a body via the distance $\mathbf{r}$ covered in a time interval t measured in the laboratory system (in relation to which the body travels with this velocity),

$$(v^\mu) \equiv \frac{d(r^\mu)}{dt} = \begin{pmatrix} c \\ \mathbf{v} \end{pmatrix}$$

However, the contraction of this 4-vector is not a Lorentz invariant because,

$$v_\mu v^\mu = c^2 - v^2 \neq c^2 - v'^2 = v'_\mu v'^\mu \ .$$

On the other hand, the notion of *proper time* allows us to define a true quadri-velocity. We assume that in some inertial system, the body follows the trajectory $r^\mu(\tau)$. Then the quantity,

$$\boxed{u^\mu \equiv \gamma_v v^\mu = \gamma_v \frac{dr^\mu}{dt} = \gamma_v \frac{d\tau}{dt}\frac{dr^\mu}{d\tau} = \frac{dr^\mu}{d\tau} \qquad \text{that is} \qquad (u^\mu) = \begin{pmatrix} \gamma_v c \\ \gamma_v \mathbf{v} \end{pmatrix}} \ , \tag{17.80}$$

called *proper velocity* is a Lorentz invariant, since,

$$u_\mu u^\mu = c^2 \ . \tag{17.81}$$

A useful illustration of the relation between space and time, as proposed by Minkowski, is exhibited in Fig. 17.5. The inner region of the cone represents the space-time points in a lab frame that a moving body can reach within a given time interval. The cone's surface are the points that can be reaches traveling at light speed, and the outer region remains inaccessible.

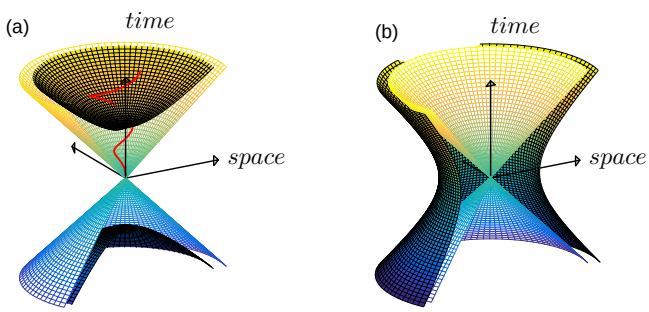

Figure 17.5: Two-dimensional illustration of Minkowski space-time. The cones delimits accessible (inside) from inaccessible (outside) regions. The red curve in (a) represents a possible trajectory for a moving body. The hyperboloid in (a) represents the hyperspace where a system S' with its *proper velocity* v is found after a time τ elapsed in the system S'. The hyperboloid in (b) represents the hyperspace of 'space'-like intervals according to (17.33).

17.2.2 Adding velocities

The Lorentz transformation from system S' moving with respect to another system S with the relative velocity v_0 must be applied to the proper velocity,

$$\begin{pmatrix} \gamma_{v'}c \\ \gamma_{v'}v' \end{pmatrix} = (\Lambda^{\mu}{}_{\nu}) \begin{pmatrix} \gamma_v c \\ \gamma_v v \end{pmatrix} = \begin{pmatrix} \gamma & -\gamma\beta \\ -\gamma\beta & \gamma \end{pmatrix} \begin{pmatrix} \gamma_v c \\ \gamma_v v \end{pmatrix} = \gamma_v\gamma \begin{pmatrix} c - \beta v \\ -\beta c + v \end{pmatrix} , \tag{17.82}$$

where we denote $\gamma \equiv \gamma_{v_0}$. Eliminating $\gamma_{v'}$ and resolving by v' we get,

$$\boxed{v' = \frac{v - v_0}{1 - v_0 v/c^2}} . \tag{17.83}$$

Obviously, the speed of light can not be exceeded. The velocity in the system S' is limited to $-c \leq v' \leq c$, even if $v = c$. Similar calculations can be made for the two transverse directions, and we obtain the general formula reproduced here without proof,

$$\mathbf{v} = \frac{\mathbf{v}' + \mathbf{v}_0 \left[\gamma(1 + \mathbf{v_0} \cdot \mathbf{v}'/v_0^2) - \mathbf{v}_0 \cdot \mathbf{v}'/v_0^2\right]}{\gamma(1 + \mathbf{v}_0 \cdot \mathbf{v}'/c^2)} . \tag{17.84}$$

We calculate in Exc. 17.2.7.1 an example of relativistic addition of velocities.

17.2.3 Relativistic momentum and rest energy

The *relativistic linear momentum* is given by,

$$\boxed{p^\mu \equiv m u^\mu = m\gamma_v v^\mu \qquad \text{or} \qquad (p^\mu) = \begin{pmatrix} E/c \\ \mathbf{p} \end{pmatrix}} . \tag{17.85}$$

We will show in Exc. 17.2.7.2 that an identification of the momentum p^μ with mv^μ would be inconsistent with the principle of momentum conservation and the principle of relativity. For zero velocity of the particle, $\mathbf{v} = 0$, the first line of the expression (17.85) is the famous Einstein equation on the equivalence of mass and energy,

$$E = mc^2 . \tag{17.86}$$

Thus, the mass is nothing more than the energy of the particle in its rest frame.

Transforming into the rest frame, we have:

$$p'_\mu p'^\mu = \left\| \begin{pmatrix} E/c \\ \mathbf{p} \end{pmatrix} \right\|^2 = \left\| \begin{pmatrix} mc \\ \mathbf{0} \end{pmatrix} \right\|^2 = p_\mu p^\mu , \tag{17.87}$$

yielding,

$$E = \sqrt{m^2c^4 + c^2\mathbf{p}^2} = mc^2\sqrt{1 + \gamma_v^2 \frac{\mathbf{v}^2}{c^2}} = \gamma_v mc^2 . \tag{17.88}$$

The kinetic energy in the non-relativistic limit follows from a Taylor expansion of the expression (17.88) for low velocities,

$$E_{kin} \equiv E - mc^2 = mc^2(\gamma_v - 1) \simeq \frac{p^2}{2m} - \frac{p^4}{8m^3c^2} . \tag{17.89}$$

Do the Exc. 17.2.7.3.

Example 133 (*Compton scattering*): Here we consider the interaction of a photon with an electron. The electron has the rest mass m_e. Thus, transforming to the rest frame, we find its energy via, $(p_e)_\mu(p_e)^\mu = E_e^2/c^2 - \mathbf{p}^2 = m_e^2c^4$. The photon has no rest mass. Thus, transforming to the rest frame, we find its energy via, $(p_\gamma)_\mu(p_\gamma)^\mu = (\hbar k)^2 = (\hbar\omega)^2/c^2$.

Now we let the photon with energy $\hbar\omega_i$ bounce off an electron initially at

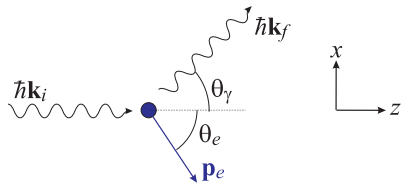

Figure 17.6: Scattering of a photon from an electron.

rest. After the collision the photon and the electron move away under angles of $\sin\theta_\gamma$, respectively, $\sin\theta_e$, with respect to the collision axis. As shown in Fig. 17.6, we can choose the collision axis along the z-axis and within the xy-plane. The photon has changed its energy to $\hbar\omega_f$ and its momentum to $\hbar k_f$, the electron now has the momentum $\mathbf{p}_f$. For an elastic collision, energy and linear momentum conservation request,

$$p_i^\mu \equiv \begin{pmatrix} E_i/c \\ p_i^x \\ p_i^y \\ p_i^z \end{pmatrix} = \begin{pmatrix} \hbar\omega_i/c + m_ec \\ 0 \\ 0 \\ \hbar k_i \end{pmatrix} \stackrel{!}{=} \begin{pmatrix} \hbar\omega_f/c + \sqrt{m_e^2c^2 + p_f^2} \\ -\hbar k_f \sin\theta_\gamma + p_f \sin\theta_e \\ 0 \\ \hbar k_f \cos\theta_\gamma + p_f \cos\theta_e \end{pmatrix} = \begin{pmatrix} E_f/c \\ p_f^x \\ p_f^y \\ p_f^z \end{pmatrix} \equiv p_f^\mu \,.$$

Solving the second line by θ_e and substituting into the fourth,

$$\begin{aligned} \frac{\hbar\omega_i}{c} &= \hbar k_i = p_f \cos\theta_e + \hbar k_f \cos\theta_\gamma = p_f\sqrt{1-\sin^2\theta_e} + \hbar k_f \cos\theta_\gamma \\ &= p_f\sqrt{1-\left(\frac{\hbar k_f}{p_f}\right)^2 \sin^2\theta_\gamma} + \hbar k_f \cos\theta_\gamma \,. \end{aligned}$$

Solving this by p_f,

$$\begin{aligned} c^2p_f^2 &= (\hbar\omega_i - c\hbar k_f\cos\theta_\gamma)^2 - (c\hbar k_f)^2\sin^2\theta_\gamma = (\hbar\omega_i)^2 - 2\hbar\omega_i c\hbar k_f\cos\theta_\gamma + (c\hbar k_f)^2 \\ &= (\hbar\omega_i)^2 - 2\hbar\omega_i\hbar\omega_f\cos\theta_\gamma + (\hbar\omega_f)^2 \,. \end{aligned}$$

Inserting this result into energy conservation,

$$\hbar\omega_i + m_ec^2 = \hbar\omega_f + \sqrt{m_e^2c^4 + c^2p_f^2} = \hbar\omega_f + \sqrt{m_e^2c^4 + (\hbar\omega_i)^2 - 2\hbar\omega_i\hbar\omega_f\cos\theta_\gamma + (\hbar\omega_f)^2} \,.$$

Solving this by ω_f,

$$\frac{hc}{\lambda_f} = \hbar\omega_f = \frac{1}{(1-\cos\theta_\gamma)/m_ec^2 + 1/\hbar\omega_i} \,,$$

or defining the *Compton wavelength* of the electron,

$$\lambda_C \equiv \frac{h}{m_ec}$$

we find for the wavelength of the scattered photon,

$$\lambda_f = \lambda_i + \lambda_C(1 - \cos\theta_\gamma) \ .$$

Other examples of relativistic collisions will be studied in Excs. 17.2.7.4 to 17.2.7.6.

17.2.4 Relativistic Doppler effect

We have seen at the example of sonic waves, that the magnitude of the Doppler effect depends on who moves with respect to the *medium*: the source or the receiver. Electromagnetic waves, however, propagate in empty space, that is, there is no material medium, ether, or wind. According to Einstein's theory of relativity, there is no absolute motion and the propagation velocity of light is the same for all inertial systems. Therefore, the classical theory of the Doppler effect can not apply to electromagnetic waves.

By the fact that the vector k_μ given by,

$$\boxed{k^\mu \equiv \frac{p^\mu}{\hbar} \qquad \text{that is} \qquad (k^\mu) = \begin{pmatrix} \omega/c \\ \mathbf{k} \end{pmatrix}} \tag{17.90}$$

is a space-time vector,

$$k_\mu k^\mu = \omega^2/c^2 - k^2 = 0 \ , \tag{17.91}$$

we know that this vector transforms like,

$$\begin{aligned} \begin{pmatrix} \omega/c \\ k \end{pmatrix} &= (\Lambda_{\mu\nu})^{-1} \begin{pmatrix} \omega'/c \\ k' \end{pmatrix} = \begin{pmatrix} \gamma & \gamma\beta \\ \gamma\beta & \gamma \end{pmatrix} \begin{pmatrix} \omega'/c \\ k' \end{pmatrix} \\ &= \begin{pmatrix} \gamma\frac{\omega'}{c} + \gamma\beta k' \\ \gamma\beta\frac{\omega'}{c} + \gamma k' \end{pmatrix} = \frac{\omega'}{c}\gamma(1+\beta) \begin{pmatrix} 1 \\ 1 \end{pmatrix} \ , \end{aligned} \tag{17.92}$$

such that,

$$\boxed{\omega = ck = \omega'\sqrt{\frac{1+\beta}{1-\beta}} = \gamma\omega'(1+\beta)} \ . \tag{17.93}$$

Including the transverse motion, we obtain

$$\omega = \gamma\omega'\left(1 + \frac{\mathbf{v}_0 \cdot \mathbf{v}}{vc}\right) \ , \tag{17.94}$$

where $\mathbf{v}_0$ is the speed of the source. It is interesting to note that, even in case of a purely transverse motion $\mathbf{v}_0 \cdot \mathbf{v} = 0$, we observe a Doppler shift.

Example 134 (*Doppler effect on a moving laser*): We now consider a light source flying through the lab S, for example, a laser operating at a frequency ω', which is well-defined by an atomic transition of the active medium. A spectrometer installed in the same rest frame S' as the laser will measure just this

frequency. We now ask, what frequency would be measured by a spectrometer installed in the lab frame. The classical response has already been derived for a moving sound source,

$$\omega' = \omega - kv = \omega - \frac{\omega}{c}v = \frac{\omega}{1+\frac{v}{c}} \ ,$$

with $k = \omega/c$. Because of time dilatation, we need to multiply by γ,

$$\omega' = \frac{\gamma^{-1}\omega}{1+\frac{v}{c}} = \omega\sqrt{\frac{1-\beta}{1+\beta}} \simeq \omega\left(1 \pm \frac{v}{c} + \frac{v^2}{2c^2}\right) \ .$$

The above example shows that, for non-relativistic velocities, one can distinguish the *first-order Doppler effect* from the *relativistic Doppler effect* due to time dilatation,

$$\boxed{\omega' \simeq \omega \pm kv + \tfrac{1}{2}\omega\beta^2} \ . \tag{17.95}$$

We will study the Doppler effect for the case of ultracold atoms in Excs. 17.2.7.7 to 17.2.7.9.

17.2.5 Relativistic Newton's law

The relativistic form of *Newton's law*,

$$\mathbf{F} = \frac{d\mathbf{p}}{dt} \ , \tag{17.96}$$

with the momentum given by (17.85) defines the *common* relativistic force. However, because it is derived from the momentum with respect to common time, the common force $\mathbf{F}$ *can not* be extended to a Lorentz invariant of the type F^μ. In contrast, *Minkowski force* defined as,

$$\boxed{K_\mu = \frac{dp_\mu}{d\tau} = \frac{\gamma_v dp_\mu}{dt} \qquad \text{that is} \qquad (K^\mu) = \begin{pmatrix} \gamma_v P/c \\ \gamma_v \mathbf{F} \end{pmatrix}} \ , \tag{17.97}$$

is covariant. Nevertheless, we will often be interested in the common force $\mathbf{F}$ acting on moving bodies as measured in a laboratory frame.

The work exerted on a particle increases its kinetic energy, such that,

$$\begin{aligned} W \equiv \int \mathbf{F}\cdot d\mathbf{l} &= \int \frac{d\mathbf{p}}{dt}\cdot d\mathbf{l} = \int \frac{d\mathbf{p}}{dt}\cdot \mathbf{v}\ dt = \int \frac{d}{dt}(\gamma_v m\mathbf{v})\cdot\mathbf{v}\ dt \\ &= \int (\gamma_v^3 m\dot{\mathbf{v}})\cdot\mathbf{v}\ dt = \int mc^2\frac{d\gamma_v}{dt}dt = \int \frac{dE}{dt}dt = E_{final} - E_{initial} \ . \end{aligned} \tag{17.98}$$

Unlike the first two Newton laws, the third one (actio = reactio) does *not* apply in the relativistic regime. Indeed, the simultaneity of 'actions' and reactions' in the forces that two distant bodies A and B exert on each other depends on the velocity of the observer.

17.2.6 Uniform acceleration

17.2.6.1 Rindler coordinates

In special relativity, a uniformly accelerated particle undergoes a hyperbolic motion in space-time, for which a uniformly accelerated reference frame in which the particle is at rest can be chosen as its proper reference frame. We may for example consider a homogeneous gravitational field. Let us denote the inertial coordinates by (cT, X, Y, Z) and the hyperbolic coordinates by (ct, x, y, z). These hyperbolic coordinates can be separated into two main variants depending on the accelerated observer's position: If the observer is located at time $T = 0$ at position $X = 1/a$ (with a as the constant proper acceleration measured by a comoving accelerometer), then the hyperbolic coordinates are often called *Rindler coordinates* with the corresponding Rindler metric.

The worldline of a body in hyperbolic motion having constant proper acceleration a in the Z-direction as a function of proper time τ an rapidity $a\tau$ can be given by,

$$T = z \sinh \alpha\tau \quad , \quad Z = z \cosh \alpha\tau \ , \tag{17.99}$$

where $z = 1/a$ is constant and $a\tau$ is variable, with the worldline resembling the hyperbola $Z^2 - T^2 = z^2$. Sommerfeld showed that the equations can be reinterpreted by defining z as variable and $a\tau$ as constant, so that it represents the simultaneous 'rest shape' of a body in hyperbolic motion measured by a comoving observer. By using the proper time of the observer as the time of the entire hyperbolically accelerated frame by setting $\tau = t$, the transformation formulas between the inertial coordinates and the hyperbolic coordinates are consequently,

$$T = z \sinh at \quad , \quad X = x \quad , \quad Y = y \quad , \quad Z = z \cosh at \tag{17.100}$$

with the inverse

$$t = \frac{1}{a} ar \tanh \frac{T}{X} \quad , \quad x = X \quad , \quad y = Y \quad , \quad z = \sqrt{Z^2 - T^2} \ . \tag{17.101}$$

Differentiated and inserted into the Minkowski metric $ds^2 = -dT^2 + dX^2 + dY^2 + dZ^2$, the metric in the hyperbolically accelerated frame follows,

$$ds^2 = -(\alpha x)^2 dt^2 + dx^2 + dy^2 + dz^2 \ . \tag{17.102}$$

17.2.7 Exercises

17.2.7.1 Ex: Adding velocities

Imagine an array of flash lamps at rest in the system S. The lamps are aligned at distances of $\Delta s = 10\,\mathrm{m}$ from each other. The array extends over a distance of many light-years. Now, the lamps are flashed successively (from left to right), so that the light seems to move to the right.

a. At what time interval Δt two adjacent lamps need to flash in order to generate an apparent velocity of $v_1 = 1.2c$?

b. An inertial system S' moves relative to S with velocity $v_2 = -0.56c$ in opposite direction to that of the motion of the flashes. At what velocity the flashes seem to be moving in the system S'?

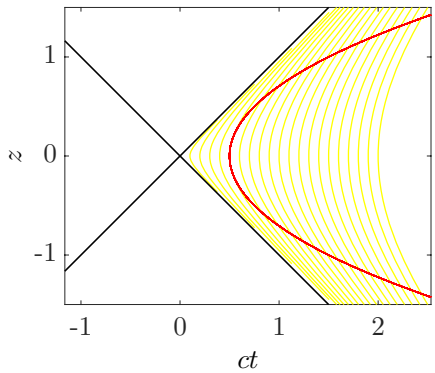

Figure 17.7: (code) Rindler coordinates.

17.2.7.2 Ex: Covariant momentum

Show that an identification of the momentum p^μ with mv^μ would be inconsistent with the principle of momentum conservation and the principle of relativity.

17.2.7.3 Ex: Covariant momentum

Show that an the space-time acceleration is necessarily perpendicular to the space-time velocity.

17.2.7.4 Ex: Inelastic collision

A particle of mass m whose total energy is twice its rest energy collides with an identical particle at rest. If they stick together, what is the mass of the resulting particle compound? What is its velocity?

17.2.7.5 Ex: Relativistic collision

Consider a relativistic completely inelastic frontal collision of two particles moving along the x-axis. Both particles have mass m. Before the collision, an observer A sitting in an inertial frame, notices that the masses move with the same constant velocities but in the opposite direction, that is, the particle 1 moves with velocity v and the particle 2 moves with velocity $-v$. According to another observer B, however, particle 1 is initially at rest.
a. Determine the velocity v'_x of particle 2 measured by observer B before collision.
b. Find the velocities v_A and v'_B of the particle resulting from the collision, measured, respectively, by the observers A and B.
c. Use the relativistic mass-energy conservation and calculate the mass M of the particle resulting from the collision.

17.2.7.6 Ex: γ-rays

γ-rays produced by paired annihilation exhibit considerable Compton scattering. Consider a photon produced with the energy m_0c^2 by the annihilation of an elec-

tron and a positron, where m_0 is the rest mass of the electron. Suppose that this photon be scattered by a free electron and that the scattering angle is θ_γ, as shown in Fig. 17.6.
a. Find the maximum possible kinetic energy for the recoiling electron.
b. If the scattering angle were $\theta_\gamma = 120°$, determine the photon energy and the kinetic energy of the electron after the scattering.
c. If $\theta_\gamma = 120°$, what is the direction of motion of the electron after the scattering with respect to the direction of the incident photon?

17.2.7.7 Ex: Second order Doppler shift

The *second order Doppler shift* comes from the relativistic dilation of time. Periodic events occurring in a moving inertial system appear dilated to an observer in another system. Consider a strontium atom, which has a resonance at the wavelength $\lambda = 461\,\text{nm}$, located inside a resonant laser beam from which it absorbs and reemits photons.
a. Assume the atom initially at rest. What will be it's velocity after having absorbed a single photon?
b. Calculate the first and second order Doppler shift for the remitted photon as a function of the emission direction.

17.2.7.8 Ex: Recoil- and Doppler-shift upon photon absorption

Derive the expressions for the recoil- and Doppler-shift upon the absorption of a photon of frequency ω_i by an atom with the initial velocity $\mathbf{v}_i$ using relativistic mechanics.

17.2.7.9 Ex: Recoil- and Doppler-shift upon photon scattering in relativistic mechanics

Derive the expression for the recoil- and Doppler-shift upon the absorption and reemission of a photon of frequency ω_i by an atom with the initial velocity $\mathbf{v}_i$ using relativistic mechanics. Discuss the particular case, $\mathbf{v}_i = 0$.

17.3 Relativistic electrodynamics

17.3.1 Relativistic current and magnetism

To begin with, we introduce the space-time current density by,

$$\boxed{(j^\mu) \equiv \begin{pmatrix} c\varrho \\ \mathbf{j} \end{pmatrix}} \,. \tag{17.103}$$

This notation allows us to formulate the continuity equation as,

$$\boxed{\partial_\mu j^\mu = 0} \,. \tag{17.104}$$

Example 135 (*Electric charge under Lorentz transformation*): In order to convince ourselves that it makes sense to combine charge density and current as quadri-vectors, we consider a situation in which there are only static charges with density ϱ_0 and has no current: $j_\mu = (c\varrho_0\ \mathbf{0})$. Now, in an inertial system moving at velocity $\mathbf{v}$, the charge density will appear as a current,

$$(j'^\mu) = (\Lambda^\mu{}_\nu j^\nu) = \begin{pmatrix} \gamma c\varrho_0 \\ -c\gamma\beta\varrho_0\hat{\mathbf{e}}_z \end{pmatrix} = \begin{pmatrix} \gamma\varrho \\ -\gamma\varrho\mathbf{v} \end{pmatrix} .$$

That is, different observers observe different charge densities. The current $-\gamma\varrho\mathbf{v}$ appears due to the motion of the charge being contrary to the motion of the observer. Moreover, as the charge density is defined per unit volume and the volume is compressed due to Lorentz contraction, the observed charge density $\gamma\varrho_0$ appears to be increased.

The observation that a moving charge gives rise to a current is not new. But the fact that we can transform charge into current through a Lorentz transform already points to the close connection between the phenomena of electricity and magnetism in the theory of relativity: moving electric fields must generate magnetic fields. We will study the details of how this happens shortly. But first, let us have a look at a simple example, where we re-derive the magnetic force purely from the Coulomb force and a Lorentz contraction.

Example 136 (*Electric current under Lorentz transform*): We consider a sample of positive charges $+q$ moving along a conducting wire with velocity $+v$ and a sample of negative charges $-q$ moving in opposite direction with velocity $-v$, as shown Fig. 17.8. If the densities n of positive and negative charges is equal, the total charge density vanishes, while the currents add up to $I = 2nAqv$, where A is the cross section of the wire. We now consider a test particle, also carrying a charge q, which moves parallel to the wire at some velocity v_0. This charge does not feel any electrical force, because the wire is neutral, but we know that it experiences a magnetic force. We will now show, how to find an expression for this force without ever invoking the phenomenon of magnetism. The trick is to go to the inertial system S' of the test particle, which means that

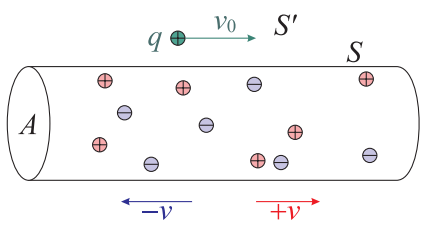

Figure 17.8: Illustration of the relativistic origin of the Lorentz force.

we have to transform to a velocity v_0. The formula for summing relativistic velocities tells us, that the velocities of the positive and negative charges are now different,

$$v_\pm = \frac{v \mp v_0}{1 \mp v_0 v/c^2} .$$

But with this transformation comes a Lorentz contraction modifying the density of the charges. In addition, the different velocities of the positive and negative

charges cause that, seen from the system S' (rest frame of the test particle), the wire is no longer neutral. Let us see how this works: First, we introduce the density of positively (negatively) charged particles n_0 in the system S_+ (S_-) in which they are at rest. With this, the charge densities in the lab system S (rest frame of the wire) are,

$$\varrho_\pm = qn_\pm = \gamma_v qn_0 \ .$$

In the system S, the wire is neutral because the positive and negative charges travel at the same velocity, albeit in opposite directions, $\varrho_+ + \varrho_- = 0$. Now, in the system S', the charge densities are,

$$\begin{aligned}\varrho'_\pm = q\gamma_{v_\pm} n_0 &= \frac{1}{\sqrt{1-\left(\frac{v\mp v_0}{c\mp vv_0/c}\right)^2}} qn_0 \\ &= \frac{-c^2 \pm vv_0}{\sqrt{(c^2-v^2)(c^2-v_0^2)}} qn_0 = \left(1 \mp \frac{v_0 v}{c^2}\right)\gamma_{v_0}\gamma_v qn_0 \ ,\end{aligned}$$

Since $v_- > v_+$, we have $n'_- > n'_+$, and the wire carries negative charge. That is, the total charge density in the new system is,

$$\varrho' = q(n'_+ - n'_-) = -\frac{2v_0 v}{c^2}\gamma_{v_0} qn_\pm \ .$$

But we know that a line of electric charges creates an electric field (using Gauß' law) of,

$$\vec{\mathcal{E}}'(r) = \frac{\varrho' A}{2\pi\varepsilon_0 r}\hat{\mathbf{e}}_r = -\frac{2v_0 v}{c^2}\gamma_{v_0} qn_\pm \frac{A}{2\pi\varepsilon_0 r}\hat{\mathbf{e}}_r \ ,$$

where r is the radial direction perpendicular to the wire. This means that in its rest frame, the particle experiences a force,

$$F' = q\mathcal{E}'(r) = -v_0\gamma_{v_0}\frac{n_\pm A q^2 v}{\pi\varepsilon_0 c^2 r} \ ,$$

where the negative sign tells us, that the force is in radial direction toward the center of the wire for $v_0 > 0$. But if there is a force in one system, there must also be a force in the other one. Transforming back to the lab system S, we conclude that even when the wire is neutral, there will be a force,

$$F = \frac{F'}{\gamma_{v_0}} = -v_0\frac{n_\pm A q^2 v}{\pi\varepsilon_0 c^2 r} = -v_0 q\frac{\mu_0 I}{2\pi r} \ .$$

But this agrees precisely with the Lorentz force attracting or repelling two neutral current-carrying wires.

This analysis provides an explicit demonstration of how an electric force in one reference system is interpreted as a magnetic force in another. Another surprising observation is the following. We are accustomed to think of Lorentz contraction as an exotic result, which is only important, when we approach the speed of light. However, the electrons traveling on a wire are very slow, taking about an hour to travel a meter! Nevertheless, we can easily detect the magnetic force between two wires which, as we have seen above, can be directly attributed to the length contraction of the electronic density [6].

[6] The above discussion needs a small adjustment for real wires. In the rest frame of the wire

17.3.2 Electromagnetic potential and tensor

The shape of the *scalar and vector relativistic potentials* (14.104), as expressed by the laws of Coulomb and Biot-Savart, suggests their combination to a quadri-vector,

$$\boxed{(A^\mu) \equiv \begin{pmatrix} \frac{1}{c}\Phi \\ \mathbf{A} \end{pmatrix}} \,. \tag{17.105}$$

with this the *gauge transform* defined in (14.85) adopts the form,

$$\boxed{A^\mu \to A^\mu - \partial^\mu \chi} \,. \tag{17.106}$$

In particular, the *Lorentz gauge* (14.86) becomes,

$$\boxed{\partial_\mu A^\mu = 0} \,. \tag{17.107}$$

Now, let us have a look at the following antisymmetric construction,

$$\boxed{F^{\mu\nu} \equiv \partial^\mu A^\nu - \partial^\nu A^\mu} \,. \tag{17.108}$$

Obviously, this tensor is invariant under gauge transformation, since,

$$F^{\mu\nu} \to \partial^\mu (A^\nu - \partial^\nu \chi) - \partial^\nu (A^\mu - \partial^\mu \chi) = F^{\mu\nu} - \partial^\mu \partial^\nu \chi + \partial^\nu \partial^\mu \chi \,. \tag{17.109}$$

which already suggests, that the components of $F^{\mu\nu}$ have something to do with electromagnetic fields.

In fact, analyzing each component of (17.108) in the light of the equations (14.78), we find the so-called *electromagnetic field tensor*,

$$\check{F} = (F^{\mu\nu}) = \begin{pmatrix} 0 & -\frac{1}{c}\mathcal{E}_x & -\frac{1}{c}\mathcal{E}_y & -\frac{1}{c}\mathcal{E}_z \\ \frac{1}{c}\mathcal{E}_x & 0 & -\mathcal{B}_z & \mathcal{B}_y \\ \frac{1}{c}\mathcal{E}_y & \mathcal{B}_z & 0 & -\mathcal{B}_x \\ \frac{1}{c}\mathcal{E}_z & -\mathcal{B}_y & \mathcal{B}_x & 0 \end{pmatrix} = \begin{pmatrix} 0 & -\frac{1}{c}\vec{\mathcal{E}} \\ \frac{1}{c}\vec{\mathcal{E}} & (-\epsilon_{mnk}\mathcal{B}_k) \end{pmatrix} \,. \tag{17.110}$$

where ϵ_{mnk} it is the Levi-Civita tensor.

17.3.2.1 Maxwell's equations

The dual tensor is,

$$\check{\mathcal{F}} = (\mathcal{F}^{\mu\nu}) = (\tfrac{1}{2}\epsilon^{\mu\nu\alpha\beta}F_{\alpha\beta}) = \begin{pmatrix} 0 & -\mathcal{B}_x & -\mathcal{B}_y & -\mathcal{B}_z \\ \mathcal{B}_x & 0 & \frac{1}{c}\mathcal{E}_z & -\frac{1}{c}\mathcal{E}_y \\ \mathcal{B}_y & -\frac{1}{c}\mathcal{E}_z & 0 & \frac{1}{c}\mathcal{E}_x \\ \mathcal{B}_z & \frac{1}{c}\mathcal{E}_y & -\frac{1}{c}\mathcal{E}_x & 0 \end{pmatrix} = \begin{pmatrix} 0 & -\vec{\mathcal{B}} \\ \vec{\mathcal{B}} & (\frac{1}{c}\epsilon_{mnk}\mathcal{E}_k) \end{pmatrix} \,. \tag{17.111}$$

the positive charges, which are ions, are fixed while the electrons move. According to the above explanation, we might think that this will lead to an imbalance of the charge densities. But this is not correct. The current is due to electrons injected by the battery into one end of the battery and drained at the other end in such a way, that the wire remains neutral in the rest frame, with the electron density accurately compensating the ionic density. In contrast, if we moved to a system in which ions and electrons had equal and opposite speeds, the wire would appear charged.

The spatio-temporal *Maxwell equations* are written,

$$\boxed{\partial_\mu F^{\mu\nu} = \mu_0 j^\nu \qquad , \qquad \partial_\mu \mathcal{F}^{\mu\nu} = 0} \ . \tag{17.112}$$

The first space-time Maxwell equation incorporates the familiar form of Maxwell's first and third equations,

$$\begin{aligned}(\partial_\mu F^{\mu\nu}) &= \begin{pmatrix} \frac{\partial}{c\partial t} & \nabla \end{pmatrix} \begin{pmatrix} 0 & -\frac{1}{c}\vec{\mathcal{E}} \\ \frac{1}{c}\vec{\mathcal{E}} & (-\epsilon_{mnk}\mathcal{B}_k) \end{pmatrix} = \begin{pmatrix} \frac{1}{c}\nabla\cdot\vec{\mathcal{E}} \\ -\frac{1}{c^2}\frac{\partial}{\partial t}\vec{\mathcal{E}} - \nabla\cdot(\epsilon_{mnk}B_k) \end{pmatrix}^\intercal \\ &= \begin{pmatrix} \frac{1}{c}\nabla\cdot\vec{\mathcal{E}} \\ -\frac{1}{c^2}\frac{\partial}{\partial t}\vec{\mathcal{E}} + \left(\epsilon_{mkn}\frac{\partial}{\partial x^m}\mathcal{B}_k\right) \end{pmatrix}^\intercal = \begin{pmatrix} \frac{1}{c}\nabla\cdot\vec{\mathcal{E}} \\ -\frac{1}{c^2}\frac{\partial}{\partial t}\vec{\mathcal{E}} + \nabla\times\vec{\mathcal{B}} \end{pmatrix}^\intercal = \mu_0 \begin{pmatrix} c\rho \\ \mathbf{j} \end{pmatrix}^\intercal = (\mu_0 j^\nu) \ ,\end{aligned} \tag{17.113}$$

using the definition of the vector product,

$$(\mathbf{a}\times\mathbf{b})_k = \epsilon_{mnk} a_m b_n \ . \tag{17.114}$$

The second space-time Maxwell equation incorporates Maxwell's second and fourth equations. With the definition of the Levi-Civita tensor, we can rewrite the equation as,

$$\epsilon^{\mu\nu\kappa\lambda}\partial_\kappa F_{\mu\nu} = \partial_\kappa F_{\mu\nu} + \partial_\mu F_{\nu\kappa} + \partial_\nu F_{\kappa\mu} = 0 \ . \tag{17.115}$$

This form satisfies the requirement of cyclical permutability and also takes into account the fact, that all indexes must be different. If two indexes are equal, for example, $\mu = \kappa$, we would have $\partial_\kappa F_{\mu\mu} + \partial_\mu F_{\mu\kappa} + \partial_\mu F_{\kappa\mu}$. This expression is certainly zero because the field tensor is antisymmetric, $F^{\mu\nu} = -F^{\nu\mu}$.

17.3.3 Lorentz transformation of electromagnetic fields

The rapid motion of the electron within the electrostatic field $\vec{\mathcal{E}}$ of the nucleus produces, according to the theory of relativity, a magnetic field $\vec{\mathcal{B}}'$ in the reference frame of the electron. In atomic physics [7] we learn that this field can interact with the spin of the electron, thus giving rise to a considerable energy shift called the fine structure of the atomic spectrum. We calculate the interaction energy in the following.

In relativistic mechanics defined by the metric (17.3) and the Lorentz transform (17.19) the Maxwell field tensor is given by (17.110). With this we can calculate the field transformed into an inertial system propagating along the z-axis,

$$F'^{\mu\nu} = \Lambda^\mu{}_\alpha F^{\alpha\beta}\Lambda_\beta{}^\nu = \begin{pmatrix} 0 & -\frac{\gamma}{c}\mathcal{E}_x + \gamma\beta\mathcal{B}_y & -\frac{\gamma}{c}\mathcal{E}_y - \gamma\beta\mathcal{B}_x & -\frac{1}{c}\mathcal{E}_z \\ \frac{\gamma}{c}\mathcal{E}_x - \gamma\beta\mathcal{B}_y & 0 & -\mathcal{B}_z & -\gamma\frac{\beta}{c}\mathcal{E}_x + \gamma\mathcal{B}_y \\ \frac{\gamma}{c}\mathcal{E}_y + \gamma\beta\mathcal{B}_x & \mathcal{B}_z & 0 & -\gamma\frac{\beta}{c}\mathcal{E}_y - \gamma\mathcal{B}_x \\ \frac{1}{c}\mathcal{E}_z & \gamma\frac{\beta}{c}\mathcal{E}_x - \gamma B_y & \gamma\frac{\beta}{c}\mathcal{E}_y + \gamma B_x & 0 \end{pmatrix} \ . \tag{17.116}$$

[7] See script on *Quantum mechanics* (2023).

Using $\mathbf{v} = v_z \hat{\mathbf{e}}_z$, that is $\beta_x = 0 = \beta_y$ and $\beta_z = \beta$, we find,

$$\vec{\mathcal{E}}' = \begin{pmatrix} \mathcal{E}'_x \\ \mathcal{E}'_y \\ \mathcal{E}'_z \end{pmatrix} = \begin{pmatrix} \gamma\mathcal{E}_x - \beta_z c\gamma\mathcal{B}_y \\ \gamma\mathcal{E}_y + \beta_z c\gamma\mathcal{B}_x \\ \mathcal{E}_z \end{pmatrix} = \begin{pmatrix} \gamma\mathcal{E}_x + \gamma c\beta_y\mathcal{B}_z - \gamma c\beta_z\mathcal{B}_y - \frac{\gamma^2}{\gamma+1}\beta_x\vec{\beta}\cdot\mathcal{E} \\ \gamma\mathcal{E}_y + \gamma c\beta_z\mathcal{B}_x - \gamma c\beta_x\mathcal{B}_z - \frac{\gamma^2}{\gamma+1}\beta_y\vec{\beta}\cdot\mathcal{E} \\ \gamma\mathcal{E}_z + \gamma c\beta_x\mathcal{B}_y - \gamma c\beta_y\mathcal{B}_x - \frac{\gamma^2}{\gamma+1}\beta_z\vec{\beta}\cdot\mathcal{E} \end{pmatrix} \tag{17.117}$$

$$\vec{\mathcal{B}}' = \begin{pmatrix} \mathcal{B}'_x \\ \mathcal{B}'_y \\ \mathcal{B}'_z \end{pmatrix} = \begin{pmatrix} \gamma\mathcal{B}_x + \frac{\beta_z}{c}\gamma\mathcal{E}_y \\ \gamma\mathcal{B}_y - \frac{\beta_z}{c}\gamma\mathcal{E}_x \\ \mathcal{B}_z \end{pmatrix} = \begin{pmatrix} \gamma\mathcal{B}_x - \gamma\frac{\beta_y}{c}\mathcal{E}_z + \gamma\frac{\beta_z}{c}\mathcal{E}_y - \frac{\gamma^2}{\gamma+1}\beta_x\vec{\beta}\cdot\mathcal{B} \\ \gamma\mathcal{B}_y - \gamma\frac{\beta_z}{c}\mathcal{E}_x + \gamma\frac{\beta_x}{c}\mathcal{E}_z - \frac{\gamma^2}{\gamma+1}\beta_y\vec{\beta}\cdot\mathcal{B} \\ \gamma\mathcal{B}_z - \gamma\frac{\beta_x}{c}\mathcal{E}_y + \gamma\frac{\beta_y}{c}\mathcal{E}_x - \frac{\gamma^2}{\gamma+1}\beta_z\vec{\beta}\cdot\mathcal{B} \end{pmatrix} .$$

yielding,

$$\boxed{\begin{aligned} \vec{\mathcal{E}}' &= \gamma(\vec{\mathcal{E}} + c\vec{\beta}\times\vec{\mathcal{B}}) - \frac{\gamma^2}{\gamma+1}\vec{\beta}(\vec{\beta}\cdot\vec{\mathcal{E}}) \\ \vec{\mathcal{B}}' &= \gamma(\vec{\mathcal{B}} - \tfrac{1}{c}\vec{\beta}\times\vec{\mathcal{E}}) - \frac{\gamma^2}{\gamma+1}\vec{\beta}(\vec{\beta}\cdot\vec{\mathcal{B}}) \end{aligned}} . \tag{17.118}$$

Although having been derived for the special case $\vec{\beta} = \beta\hat{\mathbf{e}}_z$, this result holds for arbitrary velocities, $\gamma \to 1$, in any direction $\vec{\beta}$. At lower velocities the result simplifies to,

$$\vec{\mathcal{E}}' \simeq \vec{\mathcal{E}} + c\vec{\beta}\times\vec{\mathcal{B}} \qquad \text{and} \qquad \vec{\mathcal{B}}' = \vec{\mathcal{B}} - \tfrac{1}{c}\vec{\beta}\times\vec{\mathcal{E}} . \tag{17.119}$$

The first of these equations is the Coulomb-Lorentz force: In the charge's rest frame the Lorentz part of the force has to disappear. The second equation becomes important only for relativistic velocities. Let us consider, for example, the orbital motion of an electron within the Colombian field generated by a proton. From the point of view of the proton, the motion of the electron corresponds to a circular current producing a magnetic field in the place of the proton, which can be approximated to first order in v/c by [8],

$$\vec{\mathcal{B}}' \simeq -\frac{\mathbf{v}}{c^2}\times\vec{\mathcal{E}} . \tag{17.120}$$

We conclude that magnetism can be seen as a relativistic electrical phenomenon. Do the Exc. 17.3.7.2.

17.3.3.1 Lorentz force

The spatio-temporal *Lorentz force* is,

$$\boxed{K^\mu = \frac{dp^\mu}{d\tau} = qF^{\mu\nu}u_\nu} , \tag{17.121}$$

using the definition of the proper velocity (17.80) and of the proper momentum (17.85). Being covariant it is a Minkowski force of the type (17.97). Extracting

[8] Note, however, that this derivation does not account for the rotation of electrons reference system giving rise to the so-called Thomas precession.

the spatial components,

$$\mathbf{F} = \frac{d\mathbf{p}}{dt} = \frac{d\mathbf{p}}{\gamma d\tau} = q(\vec{\mathcal{E}} + \mathbf{v} \times \vec{\mathcal{B}}) \ , \tag{17.122}$$

Remembering that $\mathbf{p} = m\gamma\mathbf{v}$ is the relativistic momentum.

The temporal component of the Lorentz force,

$$\frac{dE/c}{dt} = \frac{dE/c}{\gamma d\tau} = \frac{q}{c}\vec{\mathcal{E}} \cdot \mathbf{v} \ , \tag{17.123}$$

simply informs us, that the kinetic energy $m\gamma c^2 - mc^2$ increases under the action of work, and the only the electric field works.

The spatio-temporal *Lorentz force density* is,

$$\boxed{f^u = F^{\mu\nu} j_\nu} \ . \tag{17.124}$$

From this we obtain the equations,

$$\begin{aligned} f^u = F^{\mu\nu} j_\nu &= \begin{pmatrix} 0 & -\frac{1}{c}\vec{\mathcal{E}} \\ \frac{1}{c}\vec{\mathcal{E}} & (-\epsilon_{mnk}\mathcal{B}_k) \end{pmatrix} \begin{pmatrix} c\varrho \\ \mathbf{j} \end{pmatrix} = \begin{pmatrix} -\frac{1}{c}\vec{\mathcal{E}} \cdot \mathbf{j} \\ \varrho\vec{\mathcal{E}} - (\epsilon_{mnk} j_m \mathcal{B}_k) \end{pmatrix} \\ &= \begin{pmatrix} -\frac{1}{c}\vec{\mathcal{E}} \cdot \mathbf{j} \\ \varrho\vec{\mathcal{E}} + \mathbf{j} \times \vec{\mathcal{B}} \end{pmatrix} = \begin{pmatrix} \frac{1}{c}P \\ \mathbf{f} \end{pmatrix} \ . \end{aligned} \tag{17.125}$$

17.3.4 Energy and momentum tensor

The meaning of the 4-dimensional energy-momentum tensor is illustrated with the following matrix,

$$T^{\alpha\beta} = \begin{pmatrix} \text{density} & \text{flux} & \text{flux} & \text{flux} \\ \text{flux} & \text{pressure} & \text{shear} & \text{shear} \\ \text{flux} & \text{shear} & \text{pressure} & \text{shear} \\ \text{flux} & \text{shear} & \text{shear} & \text{pressure} \end{pmatrix} \ . \tag{17.126}$$

The *Maxwell stress tensor* for an electromagnetic field in the absence of sources is defined by,

$$T^{\mu\nu} = \frac{1}{\mu_0}\left(F^{\mu}{}_{\alpha} F^{\alpha\nu} + \frac{1}{4} F_{\alpha\beta} F^{\alpha\beta} g^{\mu\nu}\right) \ . \tag{17.127}$$

In matrix notation this gives,

$$
\begin{aligned}
(T^{\mu\nu}) &= \tfrac{1}{\mu_0}\left(F^{\mu\gamma}g_{\gamma\alpha}F^{\alpha\nu} + \tfrac{1}{4}g_{\alpha\gamma}F^{\gamma\delta}g_{\delta\beta}F^{\alpha\beta}g^{\mu\nu}\right) = \tfrac{1}{\mu_0}\check{F}\check{g}\check{F} + \tfrac{1}{4\mu_0}\left\|\check{F}(\check{g}\check{F}\check{g})\right\|\check{g} \qquad (17.128)\\
&= \begin{pmatrix} u & \frac{1}{c}\vec{\mathcal{S}} \\ \frac{1}{c}\vec{\mathcal{S}} & -(T_{mn}) \end{pmatrix}\\
&= \begin{pmatrix} u & \frac{1}{c}\mathcal{S}_x & \frac{1}{c}\mathcal{S}_y & \frac{1}{c}\mathcal{S}_z \\ \frac{1}{c}\mathcal{S}_x & -\varepsilon_0\mathcal{E}_x^2 - \frac{1}{\mu_0}\mathcal{B}_x^2 + \frac{1}{\mu_0}\mathcal{B}^2 & -\varepsilon_0\mathcal{E}_x\mathcal{E}_y - \frac{1}{\mu_0}\mathcal{B}_y\mathcal{B}_x & -\varepsilon_0\mathcal{E}_x\mathcal{E}_z - \frac{1}{\mu_0}\mathcal{B}_z\mathcal{B}_x \\ \frac{1}{c}\mathcal{S}_y & -\varepsilon_0\mathcal{E}_x\mathcal{E}_y - \frac{1}{\mu_0}\mathcal{B}_y\mathcal{B}_x & -\varepsilon_0\mathcal{E}_y^2 - \frac{1}{\mu_0}\mathcal{B}_y^2 + \frac{1}{\mu_0}\mathcal{B}^2 & -\varepsilon_0\mathcal{E}_y\mathcal{E}_z - \frac{1}{\mu_0}\mathcal{B}_z\mathcal{B}_y \\ \frac{1}{c}\mathcal{S}_z & -\varepsilon_0\mathcal{E}_x\mathcal{E}_z - \frac{1}{\mu_0}\mathcal{B}_z\mathcal{B}_x & -\varepsilon_0\mathcal{E}_y\mathcal{E}_z - \frac{1}{\mu_0}\mathcal{B}_z\mathcal{B}_y & -\varepsilon_0\mathcal{E}_z^2 - \frac{1}{\mu_0}\mathcal{B}_z^2 + \frac{1}{\mu_0}\mathcal{B}^2 \end{pmatrix}\\
&\quad + \left(\tfrac{\varepsilon_0}{2}\mathcal{E}^2 - \tfrac{1}{2\mu_0}\mathcal{B}^2\right)(g^{\mu\nu}) \ ,
\end{aligned}
$$

with the energy density $u = \frac{\varepsilon_0}{2}\mathcal{E}^2 + \frac{1}{2\mu_0}\mathcal{B}^2$, the Poynting vector $\vec{\mathcal{S}} = \frac{1}{\mu_0}\vec{\mathcal{E}} \times \vec{\mathcal{B}}$, the Maxwell stress tensor $\overleftrightarrow{\mathbf{T}} = \varepsilon_0\mathcal{E}_m\mathcal{E}_n + \frac{1}{\mu_0}\mathcal{B}_m\mathcal{B}_n - u\delta_{mn}$.

17.3.4.1 Energy and momentum conservation

Using the space-time formalism the energy and momentum conservation laws can be summarized by,

$$f^\mu + \partial_\nu T^{\mu\nu} = 0 \qquad \text{and} \qquad T^{\mu\nu} = T^{\nu\mu} \ . \tag{17.129}$$

This can be seen by applying Maxwell's equations,

$$F^{\mu\nu}j_v + \tfrac{1}{\mu_0}\partial_\nu\left(F^\mu{}_\alpha F^{\alpha\nu} + \tfrac{1}{4}F_{\alpha\beta}F^{\alpha\beta}g^{\mu\nu}\right) = 0 \ . \tag{17.130}$$

In matrix notation we obtain,

$$\begin{pmatrix} 0 & -\frac{1}{c}\vec{\mathcal{E}} \\ \frac{1}{c}\vec{\mathcal{E}} & -(\epsilon_{mnk}\mathcal{B}_k) \end{pmatrix} + \begin{pmatrix} \frac{\partial}{c\partial t}u + \frac{1}{c}\nabla\cdot\vec{\mathcal{S}} \\ \varepsilon_0\mu_0\frac{\partial}{\partial t}\vec{\mathcal{S}} - \nabla(T_{mn}) \end{pmatrix} = 0 \ , \tag{17.131}$$

and therefore,

$$
\begin{aligned}
\begin{pmatrix} P/c & \mathbf{f} \end{pmatrix} + \begin{pmatrix} \frac{\partial}{c\partial t} & \nabla \end{pmatrix}\begin{pmatrix} u & \frac{1}{c}\vec{\mathcal{S}} \\ \frac{1}{c}\vec{\mathcal{S}} & -(T_{mn}) \end{pmatrix} &= \begin{pmatrix} \frac{P}{c} + \frac{\partial}{c\partial t}u + \frac{1}{c}\nabla\cdot\vec{\mathcal{S}} \\ \mathbf{f} + \frac{1}{c}\frac{\partial}{c\partial t}\vec{\mathcal{S}} - \nabla(T_{mn}) \end{pmatrix}^{\mathsf{T}} \qquad (17.132)\\
&= \begin{pmatrix} -\frac{1}{c}\mathbf{j}\cdot\vec{\mathcal{E}} + \frac{\partial}{c\partial t}u + \frac{1}{c}\nabla\cdot\vec{\mathcal{S}} \\ \rho\vec{\mathcal{E}} + \mathbf{j}\times\vec{\mathcal{B}} + \varepsilon_0\mu_0\frac{\partial}{\partial t}\vec{\mathcal{S}} - \nabla(T_{mn}) \end{pmatrix}^{\mathsf{T}} = 0 \ .
\end{aligned}
$$

17.3.4.2 Properties of the energy and momentum tensor

Note however, that in a dielectric medium, the matrix elements can be decomposed into separate contributions of the radiation field and the medium. Taken by parts the contributions do not necessarily satisfy the symmetry requirements [9].

[9] See the Abraham-Minkowski controversy.

Defining the angular momentum density of the shear via,

$$M^{\mu\nu g} = T^{\mu\nu} x^g - T^{\mu g} x^\nu \ . \tag{17.133}$$

Conservation of angular momentum means,

$$\partial_\mu M^{\mu\nu g} = 0 \ . \tag{17.134}$$

17.3.5 Solution of the covariant wave equation

Inserting into Maxwell's equations (17.112) the representation of the fields in terms of potentials (17.108), we calculate,

$$\mu_0 j^\mu = \partial_\mu F^{\mu\nu} = \partial_\mu(\partial^\mu A^\nu - \partial^\nu A^\mu) = \Box A^\nu + \partial^\nu \cancelto{0}{(\partial_\mu A^\mu)} \ . \tag{17.135}$$

The second term disappears in the Lorentz gauge (17.107). Then, the inhomogeneous wave equation is,

$$\boxed{\Box A^\mu = \mu_0 j^\mu} \ . \tag{17.136}$$

Analogously to the three-dimensional Green function (14.99) we can define a four-dimensional one,

$$\Box D(x) \equiv \delta^{(4)}(x) \tag{17.137}$$

with $x = r - r'$. With the representation of the Dirac function,

$$\delta^{(4)}(x) = \tfrac{1}{(2\pi)^4} \int d^4k e^{-\imath k\cdot x} \ , \tag{17.138}$$

where $k \cdot x = k^\mu x_\mu = \omega t - \mathbf{k}\cdot\mathbf{r}$, and the Fourier transform of the Green function,

$$D(x) = \tfrac{1}{(2\pi)^4} \int d^4k \tilde{D}(k) e^{-\imath k\cdot x} \ , \tag{17.139}$$

the equation (17.136) becomes,

$$\begin{aligned}\left[\frac{1}{c^2}\frac{\partial^2}{\partial t^2} - \nabla^2\right] \frac{1}{(2\pi)^4} \int d^4k \tilde{D}(k) e^{-\imath k\cdot x} &= \frac{1}{(2\pi)^4} \int d^4k \tilde{D}(k) \left(-\frac{\omega^2}{c^2} + \mathbf{k}^2\right) e^{-\imath k\cdot x} \\ &= \frac{1}{(2\pi)^4} \int d^4k e^{-\imath k\cdot x} = \delta^{(4)}(x) \ , \end{aligned} \tag{17.140}$$

that is,

$$\tilde{D}(k) = -\frac{1}{k\cdot k} \ . \tag{17.141}$$

With this, the Green function becomes,

$$D(x) = \tfrac{-1}{(2\pi)^4} \int d^4k \frac{e^{-\imath k\cdot x}}{k\cdot k} \ . \tag{17.142}$$

The integral can be solved by contour integration [473], yielding,

$$D_{r,a}(r - r') = \tfrac{1}{2\pi}\theta(\pm ct \mp ct')\delta[(r - r')^2] \ , \tag{17.143}$$

where the index 'r' refers to *retarded* and 'a' to *advanced*. Finally the solution of inhomogeneous wave equation is,

$$\boxed{A^\mu(r) = A^\mu_{r,a}(r) + \mu_0 \int d^4r' D_{r,a}(r-r') j^\mu(r')} \ , \tag{17.144}$$

where $A^\mu_{r,a}(r)$ are the solutions of the homogeneous wave equation for an incoming, respectively, outgoing wave.

The radiation fields are defined by the difference of the incident and outgoing fields. Thus, the vector potential of the radiation is,

$$A^\mu_{rad}(r) = A^\mu_{out}(r) - A^\mu_{in}(r) = \mu_0 \int d^4r' D(r-r') j^\mu(r') \ , \tag{17.145}$$

with $D(x) \equiv D_r(x) - D_a(x)$.

We can generalize the parametrization of 4-current by,

$$j^\mu(r) = ec \int d\tau u^\mu(\tau) \delta^{(4)}[r - r'(\tau)] \ . \tag{17.146}$$

By inserting this current into (17.144) we obtain the Liénard-Wiechert potentials.

17.3.6 Emission of radiation by a charged particle in gravity

Heavy mass = inert mass. Albert Einstein extended this principle, formulating Einstein's so called *strong equivalence principle* representing a cornerstone of general relativity theory: *The outcome of any local experiment in a freely falling laboratory is independent of the velocity of the laboratory and its location in space-time. This means not only that locally, the effects of gravity are indistinguishable from the effects of acceleration, but also that every law of nature is the same for free falling particles, i.e. in homogeneous gravitational fields. This includes the laws of electromagnetism.*

In Sec. 17.2.6 we derived the trajectory of a uniformly accelerated particle in space-time. An interesting question now concerns the emission of radiation in case the particle is charged. Indeed, according to Einstein's equivalence principle, seen from its rest frame the charge should not radiated, while seen from an accelerated observer, it should.

The apparent paradox can be solved within the framework of special relativity.

17.3.7 Exercises

17.3.7.1 Ex: Motion in constant fields

In the Newtonian world, electric fields accelerate particles on straight lines and magnetic fields make the particles move in circles. Here, we will re-analyze the Coulomb-Lorentz force in the relativistic framework. The force remains the same, but the momentum is now $\mathbf{p} = m\gamma\mathbf{u}$.

a. Consider a constant electric field $\vec{\mathcal{E}} = \mathcal{E}\hat{\mathbf{e}}_x$ without magnetic field.

b. Consider a constant magnetic field $\vec{\mathcal{B}} = \mathcal{B}\hat{\mathbf{e}}_z$ without electric field.

17.3.7.2 Ex: Electric and magnetic dipole moment of moving dipoles

The electric dipole moment $\mathbf{d}$ and the magnetic dipole moment $\vec{\mu}$ of a particle in its rest frame will appear in a lab frame through which the particle is moving with velocity $\mathbf{v}$ as,

$$\boxed{\mathbf{d}' = \mathbf{d} + \tfrac{1}{c^2}\mathbf{v} \times \vec{\mu} \qquad \text{and} \qquad \vec{\mu}' = \vec{\mu} - \tfrac{1}{2}\mathbf{v} \times \mathbf{d}} \,.$$

Verify this for a particle with a purely magnetic dipole moment via a Lorentz transform using by the following procedure:
a. Derive the Lorentz transform from a rest frame S, flying through the lab frame S' into arbitrary direction $\vec{\beta}$, back into the lab frame for (i) the charge-current density quadrivector, (ii) the time-position quadrivector, and (iii) a volume element using the generalized Lorentz boost (17.60).
b. Parametrize the electric and magnetic dipole moment by appropriate charge and current densities, e.g. assuming two equal charges dislocated in opposite directions of the z-axis, respectively, a circular current in the xy-plane.
c. Apply the Lorentz transform to the electric dipole moment by transforming all quantities of the defining formula. (It is convenient to choose $\beta_y = 0$.)

17.4 Lagrangian formulation of electrodynamics

17.4.1 Relation with quantum mechanics

In classical and relativistic mechanics we learn to deal with *masses* and in electrodynamics with *charges* and with fields and electromagnetic waves. We will show in Sec. 17.4.2.1 how electrodynamics can be integrated into the classical and relativistic mechanics by the prescription of *minimal coupling*,

$$\boxed{p^\mu \to p^\mu - qA^\mu} \,. \tag{17.147}$$

Revolutionary discoveries in the early twentieth century culminated in the development of quantum mechanics, where we learned to accept that the microscopic world works differently. On one hand, massive particles have undulating properties; they can diffract and interfere. On the other side, light has corpuscular properties; it consists of indivisible energy packets called *photons*. Fortunately, classical theories can be incorporated into quantum mechanics by canonical procedures called first and second quantization.

17.4.1.1 Treatment of massive particles in quantum mechanics

In quantum mechanics we learn [10] that matter propagates like a scalar wave (in contrast to electromagnetic waves, which are vectorial). Consequently, in quantum mechanics, massive particles are described by wavefunctions obeying wave equations. Slow particles obey the Schrödinger equation, whereas bosonic relativistic particles obey a wave equation called *Klein-Gordon equation* and fermions obey the *Dirac*

[10] See script on *Quantum mechanics* (2023).

equation. The Schrödinger and Klein-Gordon equations are obtained from a simple prescription for canonical quantization:

$$\boxed{p^\mu \to \imath\hbar\partial^\mu} \ . \tag{17.148}$$

Obtaining the Dirac equation is a bit more involved.

17.4.1.2 Quantization of the electromagnetic field

We also learn in quantum mechanics [11] that light consists of indivisible energy packets. This fact is taken into account, by dividing space into modes that can be filled with discrete numbers of photons. Each mode is treated as a harmonic oscillator. Quantum field theories explain, how we must quantize non-radiative electric and magnetic fields.

These topics will not be covered in this course.

17.4.2 Classical mechanics of a point particle in a field

For a system with m degrees of freedom specified by generalized coordinates $q_1, .., q_m$ and the generalized velocities $\dot{q}_1, .., \dot{q}_m$ the classical action is determined by the *Lagrangian* $\mathcal{L}(q_i, \dot{q}_i)$ via,

$$\mathcal{S}[q_i, \dot{q}_i] = \int dt \mathcal{L}(q_i, \dot{q}_i, t) \ . \tag{17.149}$$

Thus, the action is a functional of the generalized coordinates. According to Hamilton's *least action principle*, the dynamics of a classical system is described by equations that minimize the action, $\delta\mathcal{S} = 0$. These equations of motion can be expressed by the Lagrangian in the form of *Euler-Lagrange equations*,

$$\frac{d}{dt}\frac{\partial\mathcal{L}}{\partial\dot{q}_i} - \frac{\partial\mathcal{L}}{\partial q_i} = 0 \ . \tag{17.150}$$

The *canonical momentum* is given by equation,

$$p_i(q_i, \dot{q}_i, t) = \frac{\partial\mathcal{L}}{\partial\dot{q}_i} \ , \tag{17.151}$$

and the Hamiltonian is defined by the *Legendre transform*,

$$\mathcal{H}(q_i, p_i) = \dot{q}_i\frac{\partial\mathcal{L}}{\partial\dot{q}_i} - \mathcal{L} = p_i\dot{q}_i - \mathcal{L}(q_i, \dot{q}_i) \ . \tag{17.152}$$

using Einstein's summing convention. Comparing the differentials of the left with the one of the right-hand side of this equation,

$$\begin{aligned}\frac{\partial\mathcal{H}}{\partial q_i}dq_i + \frac{\partial\mathcal{H}}{\partial p_i}dp_i + \frac{\partial\mathcal{H}}{\partial t}dt &= d\mathcal{H} \\ &= \dot{q}_i dp_i + p_i d\dot{q}_i - \frac{\partial\mathcal{L}}{\partial q_i}dq_i - \frac{\partial\mathcal{L}}{\partial\dot{q}_i}d\dot{q}_i - \frac{\partial\mathcal{L}}{\partial t}dt \ ,\end{aligned} \tag{17.153}$$

[11] See script on *Quantum mechanics* (2023).

we obtain Hamilton's equations of motion,

$$\boxed{\dot{q}_i = \frac{\partial \mathcal{H}}{\partial p_i} \quad , \quad \dot{p}_i = -\frac{\partial \mathcal{H}}{\partial q_i} \quad , \quad \frac{\partial \mathcal{H}}{\partial t} = -\frac{\partial \mathcal{L}}{\partial t}} \ . \tag{17.154}$$

From these equations it follows, that if the Hamiltonian is independent of a particular coordinate q_i, the corresponding moment p_i is constant. For conservative forces, the Lagrangian and the Hamiltonian can be written as $\mathcal{L} = T - V$ and $\mathcal{H} = T + V$, with T the kinetic energy and V the potential energy [12].

17.4.2.1 Electrodynamic Lagrangian

So far we have focused on free particles or particles confined by scalar potentials. In what follows, we will address the influence of a magnetic field on a charged particle. Classically, the force on a charged particle in electric and magnetic fields is given by the Lorentz force law and the exerted work by Ohm's law:

$$\frac{dW}{dt} = e\mathbf{v} \times \vec{\mathcal{E}} \qquad \text{and} \qquad \mathbf{F} = q(\vec{\mathcal{E}} + \mathbf{v} \times \vec{\mathcal{B}}) \ , \tag{17.155}$$

where q denotes the charge and $\mathbf{v}$ the velocity. In this case, the generalized coordinates $q_i \equiv r_i \equiv (r_1, r_2, r_3)$ are precisely the Cartesian coordinates specifying the position, and $\dot{q}_i = \dot{r}_i = (\dot{r}_1, \dot{r}_2, \dot{r}_3)$ the velocity of the particles. These equations of motion are sufficient to describe the dynamics of a system. The force which depends on the velocity and is associated with the magnetic field is quite different from the conservative forces associated with scalar potentials. Let us now study, how the Lorentz force appears in the Lagrange formulation of classical mechanics.

With revised these foundations, we will return to the problem of the influence of an electromagnetic field on the dynamics of a charged particle. Since the Lorentz force depends on velocity, it can not simply be expressed as a gradient of some potential. However, the classical trajectory of the particle is still specific to the least action principle.

The electric and magnetic fields can be expressed in terms of a scalar and a vector potential as,

$$\vec{\mathcal{E}} = -\nabla\Phi - \partial_t \mathbf{A} \qquad \text{and} \qquad \vec{\mathcal{B}} = \nabla \times \mathbf{A} \ . \tag{17.156}$$

The Lorentz force is,

$$\mathbf{F} = q\left[-\nabla\Phi - \frac{\partial \mathbf{A}}{\partial t} + \mathbf{v} \times (\nabla \times \mathbf{A})\right] \ . \tag{17.157}$$

We now analyze the x-component,

$$\begin{aligned} F_x &= q\left[-\frac{\partial\Phi}{\partial x} - \frac{\partial A_x}{\partial t} + v_y\left(\frac{\partial A_y}{\partial x} - \frac{\partial A_x}{\partial y}\right) - v_z\left(\frac{\partial A_x}{\partial z} - \frac{\partial A_z}{\partial x}\right) + v_x\frac{\partial A_x}{\partial x} - v_x\frac{\partial A_x}{\partial x}\right] \\ &= q\left[-\frac{\partial\Phi}{\partial x} + \mathbf{v}\cdot\frac{\partial \mathbf{A}}{\partial x} - \frac{dA_x}{dt}\right] \ , \end{aligned} \tag{17.158}$$

[12] Thus, a particle chooses its trajectory in a way to minimize the conversion between kinetic and potential energy.

where we used,

$$\frac{d}{dt} = \frac{\partial}{\partial t} + v_i \frac{\partial}{\partial x_i} \ . \tag{17.159}$$

Since the potentials do not depend on the velocity, we can also write,

$$F_x = q\left[-\frac{\partial \Phi}{\partial x} + \frac{\partial \mathbf{v}\cdot\mathbf{A}}{\partial x} - \frac{d}{dt}\frac{\partial \mathbf{v}\cdot\mathbf{A}}{\partial v_x}\right] = -\frac{\partial U}{\partial x} + \frac{d}{dt}\frac{\partial U}{\partial v_x} \ , \tag{17.160}$$

introducing the generalized potential,

$$U \equiv q\Phi - q\mathbf{A}\cdot\mathbf{v} \ . \tag{17.161}$$

The corresponding Lagrangian takes the form:

$$\boxed{\mathcal{L}(r_i, \dot{r}_i) = \tfrac{m}{2}\dot{\mathbf{r}}^2 - q\Phi + q\dot{\mathbf{r}}\cdot\mathbf{A} = \tfrac{m}{2}\dot{r}_i\dot{r}_i - q\Phi + q\dot{r}_i A_i} \ . \tag{17.162}$$

The important point is that the *canonical momentum*

$$\boxed{p_i = \frac{\partial \mathcal{L}}{\partial \dot{r}_i} = m\dot{r}_i + qA_i} \tag{17.163}$$

is no longer equal to velocity times the mass, $mv_i \neq p_i$, because there is an extra term!

Using the definition of the corresponding Hamiltonian,

$$\begin{aligned}\mathcal{H}(r_i, p_i) &= (m\dot{r}_i + qA_i)\dot{r}_i - \tfrac{m}{2}\dot{r}_i\dot{r}_i + q\Phi - q\sum_i \dot{r}_i A_i \\ &= \left(\tfrac{m}{2}\dot{r}_i + qA_i\right)\dot{r}_i + q\Phi = \tfrac{m}{2}\mathbf{v}^2 + q\Phi \ .\end{aligned} \tag{17.164}$$

Obviously, the Hamiltonian has just the familiar form of the sum of kinetic and potential energies. However, to obtain Hamilton's equations of motion, the Hamiltonian must be expressed only in terms of the coordinates and the canonical momenta, that is,

$$\boxed{\mathcal{H}(r_i, p_i) = \frac{1}{2m}(\mathbf{p} - q\mathbf{A})^2 + q\Phi = qv_j\frac{\partial A_j}{\partial r_i} + q\Phi} \ . \tag{17.165}$$

Let us now consider Hamilton's equations of motion,

$$\begin{aligned}\dot{r}_i &= \frac{\partial \mathcal{H}}{\partial p_i} = \frac{1}{m}(p_i - qA_i) \\ \dot{p}_i &= -\frac{\partial \mathcal{H}}{\partial r_i} = -\frac{1}{2m}\frac{\partial}{\partial r_i}(p_j - qA_j)^2 - q\frac{\partial \Phi}{\partial r_i} \ .\end{aligned} \tag{17.166}$$

The first equation reproduces the canonical momentum (17.162), while the second gives the Lorentz force. To understand how, we need to remember that dp/dt *is not the acceleration*: The term dependent on $\mathbf{A}$ also varies over time in a rather complicated way, since it is the field seen by the moving particle.

Example 137 (*Lorentz force from the Lagrangian*): Obviously, we can recover the Lorentz force from the Hamiltonian: Differentiating the canonical momentum (17.162),

$$\begin{aligned} m\ddot{r}_i &= -q\dot{A}_i + \dot{p}_i = -q\dot{A}_i - \frac{\partial \mathcal{H}}{\partial r_i} \\ &= -q\dot{A}_i - \frac{\partial}{\partial r_i} q \left(\sum_j v_j \frac{\partial A_j}{\partial r_i} - \frac{\partial \Phi}{\partial r_i} \right) = -q\dot{A}_i + q\nabla_i(\mathbf{A}\cdot\mathbf{v}) - q\nabla_i\Phi \ . \end{aligned}$$

that is,

$$\begin{aligned} m\ddot{\mathbf{r}} &= -q\nabla\Phi + q\mathbf{v}\times(\nabla\times\mathbf{A}) + q(\mathbf{v}\cdot\nabla)\mathbf{A} - q\frac{d\mathbf{A}}{dt} \\ &= -q\nabla\Phi + q\mathbf{v}\times(\nabla\times\mathbf{A}) - q\frac{\partial\mathbf{A}}{\partial t} = q\vec{\mathcal{E}} + q\mathbf{v}\times\vec{\mathcal{B}} \end{aligned}$$

using the rules (17.159) and $\mathbf{v}\times(\nabla\times\mathbf{A}) = \nabla(\mathbf{A}\cdot\mathbf{v}) - (\nabla\cdot\mathbf{v})\mathbf{A}$.

Using the Coulomb gauge $\nabla\cdot\mathbf{A} = 0$ the Coulomb-Lorentz force can be derived from the Lagrangian via the equation (17.162) or from the Hamiltonian via the second equation (17.166).

17.4.3 Generalization to relativistic mechanics

We now want to generalize the Lagrangian treatment of a particle to relativistic mechanics. Not all forces known in classical mechanics can be put into a covariant form. One example is the Newtonian gravitational force, understood as a force acting at a distance, which is incompatible with the theory of relativity. On the other side, electrodynamics is automatically Lorentz-invariant. Therefore, let us discuss the Lagrangian only for two examples: 1. a totally free particle and 2. a particle under the influence of electromagnetic forces.

Analogously to the classical case, we want to derive, from the principle of minimum action (17.149) Euler-Lagrange type equations (17.150). To put the action into a Lorentz-invariant form, we go to the particle's rest frame via $t = \gamma\tau$,

$$\mathcal{S}[r^\mu, u^\mu] = \int \gamma\mathcal{L}(q^\mu, u^\mu, \tau)d\tau \ . \tag{17.167}$$

We note, however, that we must now distinguish co- and contravariant indices to take account of non-Euclidean metrics. Since $\mathcal{S}$ is an invariant scalar, $\gamma\mathcal{L}$ must be an invariant scalar as well. The Euler-Lagrange equations are now,

$$\frac{d}{d\tau}\frac{\partial\mathcal{L}}{\partial u_\mu} - \frac{\partial\mathcal{L}}{\partial x_\mu} = 0 \ . \tag{17.168}$$

The ansatz for the Lagrangian,

$$\mathcal{L} \equiv \tfrac{m}{2} u_\mu u^\mu \tag{17.169}$$

inserted into the Euler-Lagrange equation gives,

$$\frac{d}{d\tau} m u^\mu - 0 = \frac{d}{d\tau} p^\mu = 0 \ , \tag{17.170}$$

which makes sense in the absence of external forces [13].

[13] We note, that any ansatz $\mathcal{L}(z) \equiv \mathcal{L}(u_\mu u^\mu)$ satisfying $\partial_z\mathcal{L} = \frac{m}{2}$ is possible. We will show this in Exc. 33.1.3.2.

17.4.3.1 Lagrangian relativistic electrodynamics

We now consider a charged particle interacting with an external electromagnetic field [473]. In relativistic notation the Lorentz force and the Ohm's law (17.149) become [compare (17.121)],

$$\frac{mdu^\mu}{d\tau} = qF^{\mu\nu}u_\nu \ , \tag{17.171}$$

where m is the resting mass, τ the proper time in the particle's system, and $(u^\mu) = (\gamma c, \gamma \mathbf{u}) = (p^\mu/m)$ its 4-velocity. Following the classical model (17.161) we can make for the Lagrangian the covariant ansatz [364],

$$\boxed{\mathcal{L} = \mathcal{L}_{\text{free}} + \mathcal{L}_{\text{int}} = \tfrac{m}{2}u_\mu u^\mu + qu_\mu A^\mu} \ . \tag{17.172}$$

The canonical momenta are,

$$p_\mu = \frac{\partial \mathcal{L}}{\partial u^\mu} = mu_\mu + qA_\mu \ , \tag{17.173}$$

such that the Euler-Lagrange equations (17.168) result in,

$$\frac{d}{d\tau}(mu_\mu + qA_\mu) - \frac{\partial}{\partial x_\mu}(qu_\nu A^\nu) = 0 \ . \tag{17.174}$$

That is,

$$K_\mu = \frac{d}{d\tau}mu_\mu = \frac{\partial}{\partial x_\mu}(qu_\nu A^\nu) - \frac{d}{d\tau}(qA_\mu) \ , \tag{17.175}$$

which is precisely the Minkowski type Lorentz force.

The total energy is,

$$E_{\text{tot}} = cp^0 = c(E + q\Phi) \ , \tag{17.176}$$

where E is the kinetic energy including the rest mass (17.88). We calculate,

$$m^2 u_\mu u^\mu = m^2c^2 = (p_\mu - qA_\mu)(p^\mu - qA^\mu) = m^2 u_0 u^0 - (\mathbf{p} - q\mathbf{A})^2 = E^2/c^2 - (\mathbf{p} - q\mathbf{A})^2 \ . \tag{17.177}$$

That is,

$$E^2 = (\mathbf{p} - q\mathbf{A})^2 - m^2c^2 \ . \tag{17.178}$$

In Exc. 17.4.5.3 we show an example for the application of the relativistic electrodynamic Lagrangian.

17.4.3.2 Charges and currents interacting with an electromagnetic field

In the case of continuous variables we use Lagrangian densities,

$$\mathcal{L} = \sum_i \mathcal{L}_i(q_i, \dot{q}_i) \longrightarrow \int \mathcal{L}(\phi_k, \partial^\alpha \phi_k) d^3x \ . \tag{17.179}$$

For example, the Lagrangian of the electromagnetic field is [365],

$$\mathcal{L} = T - V = \mathcal{L}_{field} + \mathcal{L}_{\text{int}} = -\tfrac{1}{4\mu_0}F^{\mu\nu}F_{\mu\nu} - A_\mu j^\mu \ , \tag{17.180}$$

but we will not deepen this here.

17.4.4 Symmetries and conservation laws

Symmetry is a feature of a system conserving specific properties under some transformation.

For example, the geometry of a system does not change, when we apply a reflection and the interaction energy between two charges does not change when we switch their coordinates.

In the Lagrangian formalism we call a quantity (or generalized momentum) *conserved*, when the Lagrangian does not depend on the associated coordinate,

$$\mathcal{L} \neq \mathcal{L}(q_k) \qquad \Longrightarrow \qquad p_k \ \text{ is conserved} \ . \tag{17.181}$$

We can see this by the Euler-Lagrange equation,

$$\frac{dp_k}{dt} = \frac{d}{dt}\frac{\partial \mathcal{L}}{\partial \dot{q}_k} = \frac{\partial \mathcal{L}}{\partial q_k} = 0 \ . \tag{17.182}$$

Emmy Noether formulated the theorem, that a *symmetry transformation*, that is, a transformation that does not change the action,

$$t \to t + \delta t \qquad \text{and} \qquad \mathbf{q} \to \mathbf{q} + \delta \mathbf{q} \ , \tag{17.183}$$

conserves the following quantities:

$$\boxed{\left(\dot{\mathbf{q}} \cdot \frac{\partial \mathcal{L}}{\partial \dot{\mathbf{q}}} - \mathcal{L}\right)\delta t - \frac{\partial \mathcal{L}}{\partial \dot{\mathbf{q}}} \cdot \delta \mathbf{q}} \ . \tag{17.184}$$

For example, a *temporal translation*, $\delta t \neq 0$ without another transformed coordinate $\delta q_\alpha = 0$, $\forall \alpha$, leaves the *total energy*,

$$\dot{\mathbf{q}} \cdot \frac{\partial \mathcal{L}}{\partial \dot{\mathbf{q}}} - \mathcal{L} = \mathcal{H} \ , \tag{17.185}$$

(known by the Legendre transform) unchanged. The *spatial translation*, $\delta q_\alpha \neq 0$ but $\delta t = 0$, leave the *linear momentum*,

$$\frac{\partial \mathcal{L}}{\partial \dot{q}_\alpha} = p_\alpha \ , \tag{17.186}$$

unchanged. We note that in relativistic theory, these two conservation laws are related. *Spatial rotation* around an axis $\hat{\mathbf{e}}_n$, defined in Cartesian coordinates by,

$$\mathbf{r} \to \mathbf{r} + \delta\vec{\theta} = \mathbf{r} + \delta(\hat{\mathbf{e}}_n \times \mathbf{r}) \ , \tag{17.187}$$

with $\delta t \neq 0$, leaves the angular momentum,

$$\frac{\partial \mathcal{L}}{\partial \dot{\mathbf{q}}} \cdot \delta(\hat{\mathbf{e}}_n \times \mathbf{r}) = \mathbf{p} \cdot (\hat{\mathbf{e}}_n \times \mathbf{r}) = \hat{\mathbf{e}}_n \cdot (\mathbf{r} \times \mathbf{p}) = \hat{\mathbf{e}}_n \cdot \mathbf{L} = 0 \ , \tag{17.188}$$

unchanged.

symmetry class	symmetry	invariance	conserved quantity

17.4.5 Exercises

17.4.5.1 Ex: Lagrangian relativistic of a free particle

Show that the Lagrangian $\mathcal{L}(z) = \mathcal{L}(u_\mu u^\mu)$ with $\mathcal{L}' = \frac{m}{2}$ satisfies the Euler-Lagrange equation.

17.4.5.2 Ex: Motion of charged particles in a magnetic field

A non-relativistic particle with mass m and charge q be in a static magnetic field,

$$\vec{\mathcal{B}}(\mathbf{r}) = \mathcal{B}_x(x,y,z)\hat{\mathbf{e}}_x + \mathcal{B}_y(x,y,z)\hat{\mathbf{e}}_y + \mathcal{B}_z(x,y,z)\hat{\mathbf{e}}_z \ .$$

Its Lagrange function is then,

$$\mathcal{L} = \frac{1}{2}m\mathbf{v}^2 + \frac{q}{c}\mathbf{v}\cdot\mathbf{A} \ ,$$

where $\mathbf{v}$ is the velocity of the particle and $\mathbf{A}$ the vector potential corresponding to the magnetic field $\vec{\mathcal{B}}$.
a. If $\mathbf{A} = A_x(x,y,z)\hat{\mathbf{e}}_x + A_y(x,y,z)\hat{\mathbf{e}}_y + A_z(x,y,z)\hat{\mathbf{e}}_z$ is given, what are the Cartesian components of $\vec{\mathcal{B}}$?
b. Using the formula $\frac{d}{dt}\frac{\partial L}{\partial \dot{q}} = \frac{\partial L}{\partial q}$ derive the equations of motion for the Cartesian components of $\mathbf{v}$.
c. What is the condition for $\mathcal{B}_x = \mathcal{B}_y = 0$ and $\mathcal{B}_z = \mathcal{B}_0$ to be constant?
d. Now, consider $A_x = A_y = 0$ and $A_y = \mathcal{B}_0 x$. What equations of motion for v_x, v_y, and v_z follow from this?
e. Calculate $v_x(t)$, $v_y(t)$, and $v_z(t)$. Contour conditions be given by $v_z(t=0) = v_0^{(\|)}$, $v_y(t=0) = 0$ and $v_x(t=0) = v_0^{(\perp)}$. Use the abbreviation $\omega_0 = \frac{q\mathcal{B}_0}{mc}$.
f. Calculate $x(t)$, $y(t)$, and $z(t)$ choosing $x(t=0) = y(t=0) = z(t=0) = 0$. What is the form of the trajectory that corresponds to this motion?
g. Suppose now that $A_x = A_y = 0$ and $A_y = \mathcal{B}(z)x$. What is the consequence of this for $\mathcal{B}_x$, $\mathcal{B}_y$, and $\mathcal{B}_z$? What are the corresponding equations of motion for v_x, v_y, and v_z ?
h. Now, let $\frac{\partial \mathcal{B}(z)}{\partial z} = \mathcal{B}'$ =constant. Discuss the motion equation for v_z, inserting as

an approximation for $v_y(t)$ and $x(t)$ the solutions of parts (e) and (f). What, under this circumstance, is the consequence for $v_z(t)$?

17.4.5.3 Ex: Connection between kinetic and canonical momentum and the Abraham-Minkowski debate

The nonrelativistic Lagrangian that governs the interaction of a particle with electric and magnetic dipole moment with external electromagnetic fields can be written,

$$\mathcal{L} = \tfrac{m}{2}v^2 + \vec{\mathcal{E}} \cdot \mathbf{d} + \vec{\mathcal{B}} \cdot \vec{\mu} \ .$$

a. Based on the results of Exc. 17.3.7.2 calculate the kinetic and canonical momenta of a particle with flying at velocity $\mathbf{v}$ through a lab.
b. Now, average over a macroscopic number of particles introducing the polarization $\vec{\mathcal{P}} = \langle \sum_n \mathbf{d}_n \delta^3(\mathbf{r} - \vec{\mathcal{S}}_n) \rangle$ and the magnetization $\vec{\mathcal{M}} = \frac{1}{2}\langle \sum_n \vec{\mu}_n \delta^3(\mathbf{r} - \vec{\mathcal{S}}_n) \rangle$, and compare the kinetic and canonical momenta with the Abraham and Minkowski expressions for the linear momentum density.

17.5 Relativistic gravity

The starting point of Einstein's theory on *general relativity* is the famous *equivalence principle* stating that there is no difference in heavy mass and inert mass, that is, gravity and acceleration are fundamentally the same. Taking this axiom seriously, we must accept a series of astonishing corollaries, such as the fact that space-time is neither Euclidian, nor Minkowskian, but distorted by the presence of mass. Time and space coordinates are intertwined (see also Secs. 6.4 and 47.4.1).

In the following, we briefly recapitulate Minkowskian metrics in Cartesian and spherical coordinates before introducing Schwarzschild metrics as a special case.

17.5.1 Metric and geodesic equation in curved space-time

Minkowskian metrics in Cartesian coordinates has been introduced in Sec. 17.1.1. In the following sections, we will briefly recapitulate it and extend it to spherical coordinates before generalizing the metrics to curved space-time.

17.5.1.1 Minkowski metrics

In Cartesian coordinates the line element and tetrad are given by,

$$\begin{aligned} ds^2 &= c^2t^2 - dx^2 - dy^2 - dz^2 \\ \mathbf{e}_t &= \frac{1}{c}\partial_t \quad , \quad \mathbf{e}_x = \partial_x \quad , \quad \mathbf{e}_y = \partial_y \quad , \quad \mathbf{e}_z = \partial_z \\ \mathbf{e}^t &= cdt \quad , \quad \mathbf{e}^x = dx \quad , \quad \mathbf{e}^y = dy \quad , \quad \mathbf{e}^z = dz \ , \end{aligned} \tag{17.189}$$

and the metric tensor by,

$$g_{\mu\nu} = \frac{\partial x_\alpha}{\partial \xi^\mu}\frac{\partial x^\alpha}{\partial \xi^\nu} = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \\ 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & -1 \end{pmatrix} . \tag{17.190}$$

Note that the matrix representation of the metric is defined via,

$$\boxed{ds^2 = g^{\mu\nu} dx_\mu dx_\nu} . \tag{17.191}$$

In spherical coordinates,

$$\begin{pmatrix} t \\ x \\ y \\ z \end{pmatrix} = \begin{pmatrix} t \\ r\sin\theta\cos\phi \\ r\sin\theta\sin\phi \\ r\cos\theta \end{pmatrix} , \tag{17.192}$$

the line element and tetrad are given by,

$$ds^2 = c^2t^2 - dr^2 - r^2 d\theta^2 - r^2\sin^2\theta d\phi^2 \tag{17.193}$$

$$\mathbf{e}_t = \frac{1}{c}\partial_t \quad , \quad \mathbf{e}_r = \partial_r \quad , \quad \mathbf{e}_\theta = \frac{1}{r}\partial_\theta \quad , \quad \mathbf{e}_\phi = \frac{1}{r\sin\theta}\partial_\phi ,$$

and the metric tensor,

$$g_{\mu\nu} = \frac{\partial x_\alpha}{\partial \xi^\mu}\frac{\partial x^\alpha}{\partial \xi^\nu} = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \\ 0 & 0 & -r^2 & 0 \\ 0 & 0 & 0 & -r^2\sin^2\theta \end{pmatrix} , \tag{17.194}$$

with $\xi^\mu, \xi^\nu = t, r, \theta, \phi$ and $x_\alpha = t, x, y, z$. The Minkowski metrics is a generalization of Euclidian metric to four-dimensional space-time.

17.5.2 Schwarzschild metric

General relativity breaks with the concept of Euclidian space allowing for space-time to be distorted. The simplest example is the *Schwarzschild metric* which assumes a distortion of time and space as a function of the distance from a heavy mass. Schwarzschild's solution was the first exact solution of Einstein's field equations. It holds on the outside of non-charged non-rotating masses.

Metric and tetrad of Schwarzschild coordinates (t, r, θ, ϕ) are given by,

$$c^2 d\tau^2 = \left(1 - \tfrac{r_s}{r}\right) c^2 dt^2 - \left(1 - \tfrac{r_s}{r}\right)^{-1} dr^2 - r^2 d\theta^2 - r^2\sin^2\theta d\phi^2 \tag{17.195}$$

$$\mathbf{e}_t = \frac{1}{c\sqrt{1 - r_s/r}}\partial_t \quad , \quad \mathbf{r} = \sqrt{1 - \frac{r_s}{r}}\partial_r \quad , \quad \mathbf{e}_\theta = \frac{1}{r}\partial_\theta \quad , \quad \mathbf{e}_r = \frac{1}{r\sin\theta}\partial_\phi ,$$

where,

$$r_s \equiv \frac{2\gamma_N M}{c^2} \ , \tag{17.196}$$

is called the *Schwarzschild radius*. The metric tensor in free (massless) space is,

$$g_{\mu\nu} = \frac{\partial x_\alpha}{\partial \xi^\mu}\frac{\partial x^\alpha}{\partial \xi^\nu} = \begin{pmatrix} 1-\frac{r_s}{r} & 0 & 0 & 0 \\ 0 & -(1-\frac{r_s}{r})^{-1} & 0 & 0 \\ 0 & 0 & -r^2 & 0 \\ 0 & 0 & 0 & -r^2\sin^2\theta \end{pmatrix} \ . \tag{17.197}$$

For $r \gg r_s$ this reduces to the Minkowski metric.

17.5.3 Christoffel symbols for relativistic space-time, geodesic equation

The Christoffel symbols are defined by,

$$\Gamma^\mu{}_{\alpha\beta} \equiv \frac{\partial \mathbf{e}_\alpha}{\partial x^\beta}\cdot \mathbf{e}^\mu = \frac{\partial^2 \xi^\gamma}{\partial x^\alpha \partial x^\beta}\frac{\partial x^\mu}{\partial \xi^\gamma} \ . \tag{17.198}$$

They yields for spherical coordinates,

$$\Gamma^a{}_{it} = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix} \quad , \quad \Gamma^a{}_{ir} = \begin{pmatrix} 0 & 0 & -r & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix} \tag{17.199}$$

$$\Gamma^a{}_{i\theta} = \begin{pmatrix} 0 & 0 & -r & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix} \quad , \quad \Gamma^a{}_{i\phi} = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix} \ .$$

In relativistic space-time the *geodesic equation* is a curve representing in some sense the shortest path between two points in a surface. The geodesic line is obtained by solving the differential equation,

$$\boxed{\frac{d^2x^\mu}{d\tau^2} + \Gamma^\mu{}_{\alpha\beta}\frac{dx^\alpha}{d\tau}\frac{dx^\beta}{d\tau} = 0} \ . \tag{17.200}$$

Define *Einstein tensor*, *Ricci tensor* (see 9.4.3).

Chapter 18

Appendices to 'Electrodynamics'

18.1 Special topic: Goos-Hänchen shift with light and matter waves

Newton's corpuscular light model predicts a lateral shift of a light beam when totally reflected from an interface to an optically thin medium. Photons leaving the optically dense medium are reattracted to it by gravitation. The lateral distance covered during their ballistic flight corresponds to the shift, called *Goos-Hänchen shift* (GHS). It seems as if the light beam was reflected at a plane lying behind the boundary within the region of the evanescent wave (EW). Although the underlying model is incorrect (although De Broglie himself conjectured that the effect could point towards a finite photon mass), newer model based on the Maxwell theory also predict an energy flux within the EW forming within the thin medium. Many unsuccessful attempts have been undertaken to observe this flux, and it has still not been directly observed nowadays. The problem is that any probe brought into the EW undermines it and vanishes the GHS. Goos and Hänchen circumvented the problem by measuring only the lateral shift in the optically dense medium [367, 368, 129]. The agreement of their observations with Maxwell theory gives confidence in the existence of the flux.

18.1.1 Evanescent wave potentials

A light field reflected at an angle θ ($= 52°$ for Landragin's dielectric prism) on a boundary to an optically thin medium is described by

$$\mathcal{E}(\mathbf{r}) = \mathcal{E}_0 e^{\imath q x - \kappa z} \ , \tag{18.1}$$

where $q = kn\sin\theta$ and $\kappa = k\sqrt{n^2\sin^2\theta - 1}$. Introducing the Rabi frequency

$$\Omega(\mathbf{r}) = \sqrt{\frac{\sigma_0\Gamma}{\hbar\omega} I(\mathbf{r})} = \sqrt{\frac{\epsilon_0 c^2 \sigma_0 \Gamma}{\hbar\omega}} \mathcal{E}_0 e^{-\kappa z} \ , \tag{18.2}$$

the interaction energy reads $\mathbf{d}\cdot\vec{\mathcal{E}} = \Omega(\mathbf{r})e^{\imath q x}$. The force $\mathbf{F} = -\nabla\mathbf{d}\cdot\vec{\mathcal{E}}$ is made of two contributions. Using the optical Bloch equations, we find the stationary solutions for

the dipole and the dissipative forces [14]

$$\mathbf{F}_{\rm dip} = -\frac{\hbar\Delta\Omega}{4\Delta^2 + 2\Omega(\mathbf{r})^2 + \Gamma^2}\nabla\Omega(\mathbf{r}) \ , \tag{18.3}$$

$$\mathbf{F}_{\rm diss} = \frac{\hbar\Gamma\Omega^2}{4\Delta^2 + 2\Omega(\mathbf{r})^2 + \Gamma^2}\nabla\theta(\mathbf{r}) \ .$$

Treating the mechanical effects of light analogously to the Laguerre-Gaussian modes. For LGM the phase gradient is almost parallel with the Poynting vector except for higher order corrections for the axial component.

The dipole force can be derived from a conservative evanescent potential

$$V(z) = \frac{\Omega^2}{\Delta}e^{-2\kappa z} = \frac{\pi c^2\Gamma}{2\omega^3}\ I\ \left(\frac{1}{\Delta_{D1}} + \frac{2}{\Delta_{D2}}\right)e^{-2\kappa z} \ .$$

Apparently, radiation pressure accelerates the atoms not in the direction of the wavevector, but of the phase gradient [16]. Is this the same as the Poynting vector? This may lead to observable effects in evanescent waves. Hence, the observation of a transverse radiation pressure would already prove a Goos-Hänchen shift.

18.1.2 Energy flux in the evanescent wave

An incoming laser beam be expanded after phases

$$\mathcal{E}_i(x) = \mathcal{E}_{ip}\int f(\theta)e^{-\imath x k_{ix_0}\theta}d\theta \ . \tag{18.4}$$

The reflected beam then reads

$$\mathcal{E}_r(x) = \mathcal{E}_{ip}\int r(\theta)f(\theta)e^{-\imath x k_{ix_0}\theta}d\theta \ , \tag{18.5}$$

where $r(\theta) = \frac{a-\imath b}{a+\imath b}$ according to the Fresnel equations or $r = e^{i\varphi}$. We assume that we can linearize the phase $\varphi(\theta) = \varphi(\theta_0) + (\theta-\theta_0)\partial_\theta\varphi(\theta_0) \equiv \chi + \theta\partial_\theta\varphi(\theta_0)$. Then equation (18.5) can be written

$$\mathcal{E}_r(x) = \mathcal{E}_{ip}e^{-\imath\chi}\int f(\theta)e^{-\imath(x-\Delta x_{\rm GH})k_{ix_0}\theta}d\theta = \mathcal{E}_i(x-\Delta x_{\rm GH})e^{-\imath\chi} \ , \tag{18.6}$$

where $\Delta x_{\rm GH} = \frac{2\cos\theta_0}{k_{ix_0}}\partial_\theta\varphi(\theta_0) = \frac{2}{k_i}\partial_\theta\varphi(\theta_0)$. The reflected laser beam is parallel shifted.

Calculations show [775, 589] that the energy flux penetrates the thin medium only where the transverse profile of the beam shows a gradient. In the regions of constant intensity the flux is inside the plane of incidence and parallel to the surface. Hence, the Goos-Hänchen shift is only observable with spatially inhomogeneous beams.

18.1.2.1 Expression for the shift

Let us now estimate the GHS for a prism $n_1 = 1.5$, the Rb D_2-line for which $\lambda = 2\pi/k = 780$ nm. The EW penetration depth ζ is given by $k\zeta = \sqrt{n_1^2\sin^2\theta - n_2^2}^{-1}$

$$\frac{\Delta_{\rm GH}}{2\zeta} = \frac{n_1^2 n_2^2\sin\theta\cos^2\theta}{n_1^4\sin^2\theta + n_2^4\cos^2\theta - n_1^2 n_2^2} \ . \tag{18.7}$$

We assume that the angle of incidence is close to the critical angle $\theta = \theta_c + \xi = \arcsin n_1^{-1} + \xi$. Near the critical angle the GHS diverges as does the penetration depth. Hence, the GHS should be measured very close to the critical angle. The expansion in ξ yields

$$\frac{\Delta_{\rm GH}}{2\zeta} = \frac{n_1}{n_2}\left(1 + \xi\frac{n_2^2 n_1^2 - n_2^4 - 2n_1^4}{n_2^3\sqrt{n_1^2 - n_2^2}}\right) . \tag{18.8}$$

The Goos-Hänchen shift is proportional to the penetration depth of the evanescent wave. It has been measured by [129].

18.1.2.2 Goos-Hänchen shift with resonant absorbers

Resonant absorbers have an impact on the evanescent wave and hence on the Goos-Hänchen shift as has been measured by [732]. Hence, we now consider the presence of an resonant gas with a small index of refraction, $n_2 = 1 + \bar{n}$, so that

$$\frac{k\Delta_{\rm GH}}{2} = \frac{1}{\sqrt{n_1^2\sin^2\theta - (1+\bar{n})^2}}\frac{n_1^2(1+\bar{n})^2\sin\theta\cos^2\theta}{n_1^4\sin^2\theta + (1+\bar{n})^4\cos^2\theta - n_1^2(1+\bar{n})^2} . \tag{18.9}$$

To first order in $\bar{n}$ and ξ

$$\Delta_{\rm GH}(\bar{n},\xi) \approx \frac{A\bar{n}}{\sqrt{\xi}\,(B\xi - \bar{n})} + \Delta_{\rm GH}(\bar{n}=0,\xi) . \tag{18.10}$$

According to [691] (Eq. 4.6),

$$\begin{aligned} T &= -\frac{N|d\epsilon_1|^2}{\eta\varepsilon_0\hbar|\epsilon_1|^2}\int d\mathbf{v}W(\mathbf{v})\theta(v_z)\frac{1}{\Gamma + \eta k v_z - \imath\,(\Delta - \alpha k v_x)} \qquad (18.11)\\ &= -\frac{N|d|^2}{\eta\varepsilon_0\hbar}\left(\frac{3}{2\pi v_0^2}\right)^{3/2}\int_0^\infty dv_z e^{-3v_z^2/2v_0^2}\int_{-\infty}^\infty dv_y e^{-3v_y^2/2v_0^2}\int_{-\infty}^\infty dv_x e^{-3v_x^2/2v_0^2}\frac{1}{\Gamma - \imath\Delta}\\ &= -\frac{N|d|^2}{\eta\varepsilon_0\hbar}\frac{1}{\sqrt{2}}\frac{1}{\Gamma - \imath\Delta} . \end{aligned}$$

An effective refractive index variation may be define [691] (Eq. 3.16) with $\beta = i\eta$,

$$\delta n = -\beta T = \beta\frac{N|d|^2}{\sqrt{2}\eta\varepsilon_0\hbar}\frac{1}{\Gamma - \imath\Delta} = \imath\frac{N|d|^2}{\sqrt{2}\varepsilon_0\hbar}\frac{\Gamma + \imath\Delta}{\Gamma^2 + \Delta^2} . \tag{18.12}$$

The interesting question is, whether the energy flux in the evanescent wave is directly observable. The existence of an EW is not questionable. On the contrary it has become an important in quantum optics, where near-resonant EWs are used for *selective reflection spectroscopy*. In cold atom optics, far-off resonant EWs are used to repel ultracold atoms from surfaces. Does the energy flux related to the GHS leave any footprints in the atomic cloud (possibly a BEC)? Certainly, one has to stay at a detuning, where the flux in the evanescent wave satisfies $\mathfrak{Im}\,\mathbf{k} \perp \mathfrak{Re}\,\mathbf{k}$, so that there is no energy transfer. Think about phase shift of the de Broglie wave underneath a fixed envelope, analogy to geometric phases or the Aharonov-Bohm effect.

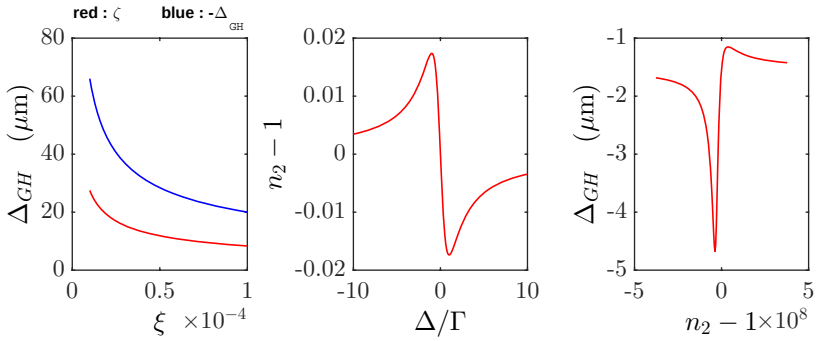

Figure 18.1: (code) Selective reflection Goos.

18.1.3 Imbert-Fedorov shift

A transverse shift should be expected for circularly polarized light or Laguerre-Gaussian modes. This shift called Imbert-Fedorov shift can be described with the flux method. The effect should be small, $\Delta x_{\rm IF} \approx 0.1\ \Delta x_{\rm GH}$. It has been observed with microwaves [205] and light [736].

For this case it is interesting that the wavevector $\mathbf{k}$ and the flux $\mathbf{S}$ are both parallel to the surface, but orthogonal on each other. The flux is perpendicular to the plane of incidence.

The symmetry breaking (upward or downward flux) is inherent in the circularly polarized laser beam [17, 333, 705]. Here the Poynting vector describes a helix about the optical axis.

For matter waves the index of refraction can be tuned via the particle energy, which is not possible with light. E.g. if $E = V_2 > V_1$, the critical angle for total reflection is $\alpha = 0$. Do we expect a Imbert-Fedorov shift for spinor condensates? Is the plane wave approximation good or should be use real BEC wavefronts?

The total reflection of Laguerre-Gaussian beams has also been studied [702].

18.1.4 Matter wave Goos-Hänchen shift at a potential step

The phase of a BEC could be a sensitive probe for the Goos-Hänchen shift. Here, it is important that the de Broglie wavelength be longer than the edge of the potential. Otherwise, the effect is trivial even in the classical particle picture.

Matter waves behave analogously to optical waves, except that the Schrödinger equation must be used. Consider the situation of a particle moving towards a potential step at an angle α as shown in Fig. 18.2. The energy of the particle is $E > V_2 > V_1$. The incidence region V_1 corresponds to the atom optically thick medium (the de Broglie wavelength is shorter, the propagation velocity fast, $\hbar k_1 = \sqrt{2m(E - V_1)}$. V_2 is the atom optically thin medium.

Consequently we expect a critical angle α_c beyond which the matter wave is totally reflected,

$$\sin \alpha_c = \sqrt{\frac{E - V_2}{E - V_1}}\ . \tag{18.13}$$

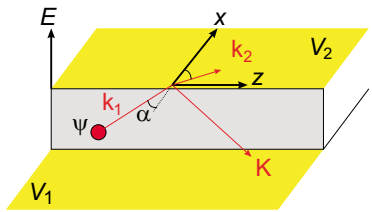

Figure 18.2: Matter wave refraction at a potential step.

For partial reflection, if the incident wave is described by [775] $\psi_0 = e^{\imath x k_{x1} + \imath y k_{y1}}$, the reflected and refracted wave are

$$\psi_1 = \frac{\cos\alpha - \sqrt{\sin^2\alpha_c - \sin^2\alpha}}{\cos\alpha + \sqrt{\sin^2\alpha_c - \sin^2\alpha}} e^{-\imath x k_{x1} + \imath y k_{y1}} \tag{18.14}$$
$$\psi_2 = \frac{2\cos\alpha}{\cos\alpha + \sqrt{\sin^2\alpha_c - \sin^2\alpha}} e^{-\imath x \sqrt{k_2^2 - k_{y1}^2} + \imath y k_{y1}} \ .$$

For total reflection,

$$\psi_1 = \exp\left(-\imath 2 \arctan\sqrt{\frac{\sin^2\alpha - \sin^2\alpha_c}{1 - \sin^2\alpha}}\right) e^{-\imath x k_{x1} + \imath y k_{y1}} \tag{18.15}$$
$$\psi_2 = \frac{2\cos\alpha}{\cos\alpha + \imath\sqrt{\sin^2\alpha - \sin^2\alpha_c}} e^{-x\sqrt{k_{1y}^2 - k_2^2} + \imath y k_{y1}} \ .$$

The matter wave Goos-Hänchen shift Δ_{GH} can be estimated by comparing the matter wave flux $\mathbf{J} = -i\frac{\hbar}{2m}\left(\psi^*\nabla\psi - \psi\nabla\psi^*\right)$ in the evanescent wave with the flux in a Δ_{GH} wide strip of the reflected beam. The result [775] is

$$\frac{\Delta_{\mathrm{GH}}}{2} = \frac{\sin\alpha\cos^2\alpha}{k\cos^2\alpha_c\sqrt{\sin^2\alpha - \sin^2\alpha_c}} \ . \tag{18.16}$$

See [775, 434].

The difficult question is now what the matter wave analogue of the Imbert-Fedorov shift would be. It is known for relativistic electrons that momentum and velocity must not necessarily be collinear [229]. How about particles with a real angular orbital momentum, e.g. the reflection of vortices?

18.2 Special topic: The dilemma of Abraham and Minkowski

If Minkowski is correct, then as a photon enters an atomic cloud with $n > 1$, then the cloud receives a collective momentum in the direction opposite to the photon propagation [153]. 'Momentum conservation requires then that the medium also has a mechanical momentum. When a pulse of light enters the medium, the particles in

the medium are accelerated by the leading edge of the pulse and decelerated by the trailing edge.' However, near resonance the refraction index is dispersive. I.e. for blue-detuning we should expect $n < 1$ and hence a collective momentum in the direction of photon propagation.

A picturesque interpretation would be, that the acceleration of the atoms by the leading or trailing edge of the light pulse is due to the dipole force (real part of susceptibility). For red (blue) detuning, the atoms are accelerated backwards (forwards) by the leading edge of the pulse and forwards (backwards) by the trailing edge. In case, that the cloud absorbs or diffracts photons, a net momentum should remain in the cloud: [591] "The propagation of an optical pulse through a transparent dielectric causes no transfer of momentum to the material, as a positive Lorentz force in the leading part of the pulse is exactly balanced by a negative Lorentz force in its trailing part. However, this balance is removed in the present problem because of the attenuation of the light by its interaction with the charge carriers. This causes the leading part of the pulse at a given time to be weaker than the trailing part and produces a net negative transfer of momentum to the bulk semiconductor."

Out side the medium, we know that the photon momentum is,

$$p_{\text{out}} = mc \ , \tag{18.17}$$

with $m = \hbar\omega/c^2$. Inside the medium, it is

$$p_{\text{in}} = m\frac{c}{\eta} = \frac{\hbar\omega}{\eta c} \ . \tag{18.18}$$

According to Minkowski, we must use $m = \hbar\omega/(c/\eta)^2$.

18.2.1 Calculation of the momentum of light in a dielectric medium

Let us consider [651] a plane light wave within a dielectric medium given by $\varepsilon = \eta^2\varepsilon_0$ and $\mu = \mu_0$,

$$\vec{\mathcal{E}}(\mathbf{r},t) = \hat{\mathbf{e}}_x\mathcal{E}_0\cos\omega\,(t - z/c) \qquad \text{and} \qquad \vec{\mathcal{H}}(\mathbf{r},t) = \hat{\mathbf{e}}_y\sqrt{\frac{\varepsilon}{\mu_0}}\mathcal{E}_0\cos\omega(t - z/c) \ , \tag{18.19}$$

The energy densities and the energy flows, called 'Poynting vector', are (taking the temporal average),

$$u = \frac{1}{2}(\vec{\mathcal{E}}\cdot\vec{\mathcal{D}} + \vec{\mathcal{B}}\cdot\vec{\mathcal{H}}) = \tfrac{1}{2}\varepsilon\mathcal{E}_0^2 \qquad \text{and} \qquad \mathbf{S} = \vec{\mathcal{E}}\times\vec{\mathcal{H}} = \tfrac{1}{2}\sqrt{\frac{\varepsilon}{\mu_0}}\mathcal{E}_0^2\hat{\mathbf{e}}_z = \frac{c}{\eta}u\hat{\mathbf{e}}_z \ . \tag{18.20}$$

Therefore, the intensity of a light field, $I = |\mathbf{S}|$, is increased by the dielectric. Rewriting this in terms of the average number of photons q in a volume V, we obtain for the energy,

$$\int u d^3r = \tfrac{1}{2}\varepsilon\mathcal{E}_0^2 V = N\hbar\omega \ . \tag{18.21}$$

The energy flow of a field of light is equal to the momentum carried by the photons. For a single photon, we have,

$$\mathbf{p}_{\text{Abr}} \equiv \frac{1}{N}\frac{1}{c^2}\int \mathbf{S}d^3r = \frac{\hbar\mathbf{k}_0}{\eta} \ . \tag{18.22}$$

However, Minkowski's point of view was,

$$\mathbf{p}_{\text{Min}} = \frac{1}{N}\int dV \vec{\mathcal{D}} \times \vec{\mathcal{B}} = \eta\hbar\mathbf{k}_0 \ . \tag{18.23}$$

The recoil frequency is modified from $\hbar\omega_{rec} = \frac{\hbar^2 k^2}{2m}$ to $\hbar\omega_{rec}^{\eta} = \eta^2\omega_{rec}$ [153].

18.2.2 Exercises

18.2.2.1 Ex: Einstein box Gedankenexperiment with a BEC

Estimate whether the Einstein box experiment is feasible with a BEC using EIT to cancel absorption?

18.3 Special topic: Advanced Gaussian optics

The most common mode is a Gaussian laser beam, which is the lowest order Hermite-Gaussian mode. But other modes are possible.

18.3.1 Laguerre-Gaussian beams

Since several years, attention has been drawn on an unusual feature of light: The fact that it carries angular momentum when it is in special modes called a *Laguerre-Gaussian mode* [850]. Furthermore, while it is well-known that the light polarization couples to the internal degrees of freedom of atoms, the light angular momentum has been predicted to couple to external degrees of freedom, i.e. light should be able to exert a torque to the atomic motion [15, 44, 16, 14, 17, 704]. The torque has been observed on macroscopic particles [850]. For a hot atomic gas, the Doppler-effect precludes the direct observation of torsional effect. Recently, phase-conjugation by Non-Degenerate Four-Wave Mixing (ND4WM) in a Magneto-Optical Trap (MOT) has been used to indirectly proof that the atoms acquired angular momentum from light [904]. Also, magneto-optical trap have been constructed based on laser beams [544, 862]. Those experiments exploited the doonat-shaped intensity distribution of the LG modes, but did not demonstrate the effect of the torque. And frequency shift [203]. Most traps for neutral atoms are based on light forces, for example the MOT works with radiation pressure. Deliberate misalignement of the optical beams within a plane can give rise to vortex forces and set up a racetrack for the atoms [949, 50].

Laguerre-Gaussian modes can be generated using a *Fresnel zone plate*.

18.3.1.1 Energy density in Laguerre-Gaussian modes

Besides plane and spherical waves, Gaussian beams and many other functions, the Laguerre-Gaussian modes (LGM) are a solution of Maxwell's equations, i.e. they satisfy $\nabla^2 u + k^2 u = 0$, where u is the scalar mode function of the beam [526]. The vector potential in the Lorentz gauge, $\Phi = -\frac{1}{\imath k}\nabla\cdot\mathbf{A}$, of those modes in the paraxial

approximation [559] is given by [15],

$$\boxed{\begin{aligned} \mathbf{A}_{nm}(\mathbf{r}) &= \hat{\mathbf{e}}_x u_{nm}(\mathbf{r}) e^{-\imath kz} \\ u_{nm}(\mathbf{r}) &= u_{00}(\mathbf{r}) \left(\frac{r\sqrt{2}}{w(z)}\right)^{|l|} L_p^{|l|}\left(\frac{2r^2}{w(z)^2}\right) e^{-\imath l\phi} e^{\imath(2p+|l|)\arctan\frac{z}{z_R}} \\ u_{00}(\mathbf{r}) &= \frac{u_0}{\sqrt{z^2+z_R^2}} e^{-\frac{r^2}{w(z)^2}} e^{-\frac{\imath kr^2 z}{2(z^2+z_R^2)}} e^{\imath\arctan\frac{z}{z_R}} \end{aligned}} \quad , \tag{18.24}$$

where $l = n - m$ and $p = \min(n, m)$. In the following we will use the convenient cylindrical coordinate system defined in (9.43). Note that, for $l = p = 0$ we recover a Gaussian beam, as will be shown in Exc. 18.3.2.3.

18.3.1.2 Poynting vector in Laguerre-Gaussian modes

The energy flux is given by the Poynting vector $\vec{\mathcal{S}} = \mu_0^{-1}\vec{\mathcal{E}} \times \vec{\mathcal{B}} = c^2\mathbf{p}$. $|\vec{\mathcal{S}}|$ is the beam intensity. The energy density is $u = \frac{1}{2}(\varepsilon_0|\vec{\mathcal{E}}|^2 + \mu_0^{-1}|\vec{\mathcal{B}}|^2)$. The linear momentum and angular momentum densities and total momenta are defined as,

$$\begin{aligned} \mathbf{p} &= \int \vec{\wp} d^3r \qquad \text{with} \quad \vec{\wp} = \varepsilon_0 \vec{\mathcal{E}} \times \vec{\mathcal{B}} \\ \mathbf{L} &= \int \vec{\ell} d^3r \qquad \text{with} \quad \vec{\ell} = \mathbf{r} \times \vec{\wp} \end{aligned} \quad . \tag{18.25}$$

The cycle-average of the real part of the linear momentum density can in the paraxial approximation be traced back to the mode function u, respectively, the scalar potential Φ and the vector potential $\mathbf{A}$ using (14.78),

$$\begin{aligned} \langle\vec{\wp}\rangle &= \frac{\varepsilon_0}{2}(\vec{\mathcal{E}}^* \times \vec{\mathcal{B}} + \vec{\mathcal{E}} \times \vec{\mathcal{B}}^*) \\ &= \imath\omega\frac{\varepsilon_0}{2}(u^*\nabla u - u\nabla u^*) + \omega k\varepsilon_0|u|^2\hat{\mathbf{e}}_z + \omega\sigma\frac{\varepsilon_0}{2}\frac{\partial|u|^2}{\partial r}\hat{\mathbf{e}}_\phi \ . \end{aligned} \tag{18.26}$$

The components of the linear momentum density are [17],

$$\vec{\wp} = \varepsilon_0\omega k|u|^2\left[\hat{\mathbf{e}}_z + \frac{rz}{z^2+z_r^2}\hat{\mathbf{e}}_r + \left(\frac{l}{kr} - \frac{\sigma}{2|u|^2}\frac{\partial|u|^2}{k\partial r}\right)\hat{\mathbf{e}}_\phi\right] \ . \tag{18.27}$$

The Poynting vector is in general not parallel to the wavevector $\mathbf{k}$, but spirals about the optical axis.

18.3.1.3 Poynting vector in Hermite-Gaussian modes

This holds even for Hermite-Gaussian beams, as we will show in the following. We start from the energy density of a LGM in Eq. (18.24). For a Gaussian mode $l = p = 0$,

$$|u_{00}(\mathbf{r})| = \frac{u_0 e^{-r^2/w(z)^2}}{w(z)} \ . \tag{18.28}$$

we find, as will be shown in Exc. 18.3.2.3,

$$\vec{\wp} = \varepsilon_0 \omega k |u|^2 \left[\hat{\mathbf{e}}_z + \frac{rz}{z^2 + z_r^2} \hat{\mathbf{e}}_r + \sigma \frac{r z_R}{z^2 + z_R^2} \hat{\mathbf{e}}_\phi \right] . \tag{18.29}$$

i.e. the radial component vanishes for small beam divergence, the azimuthal component is on the order $w_0/z_R \approx 500$ times smaller.

Inserting the full expression of the energy density of a LGM, one finds one term containing σ and hence predicting spin-orbit coupling. It can be shown that it results in a dissipative force proportional to $l\sigma$ [14].

18.3.1.4 Mechanical forces exerted by Laguerre-Gaussian modes

The Laguerre-Gaussian modes are labeled by n and m, where $l = n - m$ and $p = \min(n, m)$, such that $2p + |l| = m + n$. We should recover the Gaussian field for $l = 0$. The electric field $\mathcal{E}_{lp}(\mathbf{r}) = \varepsilon_{lp}(\mathbf{r}) e^{i\theta_{lp}(\mathbf{r})}$ is,

$$\begin{aligned} \varepsilon_{lp}(\mathbf{r}) &= \varepsilon_{00} \sqrt{\frac{p!}{(|l|+p)!}} \, \frac{e^{-r^2/w(z)^2}}{\sqrt{1 + z^2/z_R^2}} \left(\frac{r\sqrt{2}}{w(z)} \right)^{|l|} L_p^{|l|} \left(\tfrac{2r^2}{w(z)^2} \right) , \\ \theta_{lp}(\mathbf{r}) &= \frac{kr^2 z}{2\,(z^2 + z_R^2)} + l\phi + (2p + l + 1) \arctan \frac{z}{z_R} + kz . \end{aligned} \tag{18.30}$$

With the Rabi frequency defined through,

$$\Omega_{lp}(\mathbf{r}) = \Omega_0 \frac{w_0}{w(z)} \, e^{-r^2/w(z)^2} \left(\frac{r\sqrt{2}}{w(z)} \right)^{|n-m|} L_{\min(n,m)}^{|n-m|} \left(\tfrac{2r^2}{w(z)^2} \right) , \tag{18.31}$$

Using the optical Bloch equations, we find the stationary solutions for the dipole and the dissipative forces [14],

$$\begin{aligned} \mathbf{F}_{\text{dip}} &= -2\hbar \Omega_{lp}(\mathbf{r}) \, \frac{\Delta}{4\Delta^2 + 2\Omega_{lp}(\mathbf{r})^2 + \Gamma^2} \nabla \Omega_{lp}(\mathbf{r}) , \\ \mathbf{F}_{\text{diss}} &= 2\hbar \Omega_{lp}^2(\mathbf{r}) \, \frac{\Gamma}{4\Delta^2 + 2\Omega_{lp}(\mathbf{r})^2 + \Gamma^2} \nabla \theta_{lp}(\mathbf{r}) . \end{aligned} \tag{18.32}$$

where the gradients are,

$$\nabla \Omega_{lp}(\mathbf{r}) = ... \tag{18.33}$$

and,

$$\begin{aligned} \nabla \theta_{lp}(\mathbf{r}) &= -\nabla \left[-kz - l\phi - \frac{kr^2 z}{2(z^2 + z_R^2)} - (n + m + 1) \tan^{-1} \frac{z}{z_R} \right] \\ &= \left(k + \frac{kr^2}{2(z^2 + z_R^2)} \left(1 - \frac{2z^2}{z^2 + z_R^2} \right) + \frac{(n + m + 1) z_R}{z^2 + z_R^2} \right) \hat{\mathbf{e}}_z + \frac{krz}{z^2 + z_R^2} \hat{\mathbf{e}}_r + \frac{l}{r} \hat{\mathbf{e}}_\phi . \end{aligned} \tag{18.34}$$

Here we assume the velocity cold enough not to influence the detuning. Otherwise, we must substitute $\Delta \to \Delta - \mathbf{v} \nabla \theta$. At the waist $z = 0$ and for typical experimental conditions $r, k^{-1} \ll z_R$,

$$\nabla \theta_{lp}(\mathbf{r}) \approx k \hat{\mathbf{e}}_z + \frac{l}{r} \hat{\mathbf{e}}_\phi . \tag{18.35}$$

We can now write the azimuthal force and the torque in analogy to the radiation pressure,

$$\mathbf{F}_{az} = \hbar \frac{\mathbf{l}}{r} \frac{I}{\hbar\omega} \sigma(\Delta) \tag{18.36}$$

and,

$$\mathbf{T} = \hbar \frac{\mathbf{r} \times \mathbf{l}}{r} \frac{I}{\hbar\omega} \sigma(\Delta) \ . \tag{18.37}$$

If we further concentrate on the first Laguerre-Gaussian mode given by $l = 1$ and $p = 0$ or $n = 1$ and $m = 0$, and assume low saturation $\Omega \ll \Gamma$, we find the force,

$$\mathbf{F}_{\text{diss}} = -\hbar\Gamma \left[k\hat{\mathbf{e}}_z + \frac{\hat{\mathbf{e}}_\phi}{r} \right] e^{-2r^2/w_0^2} \frac{2r^2}{w_0^2} \frac{\Omega_0^2}{4\Delta^2 + \Gamma^2} \ . \tag{18.38}$$

It consists of a rotational torque and a component in $\mathbf{k}$ direction. For a normal Gaussian field, $l = 0$. The LG modes have a ring-shaped intensity distribution $I^{(Lag)}(x, y)$. Therefore, the rotational force depends on the distance from the axis and has a maximum at the radius $r = w_0/2$. The dipole force contribution may be neglected close to resonance, and higher-order contributions from the LG mode as well.

18.3.1.5 Laguerre-Gaussian standing wave

Many experiments are performed within the Rayleigh range, $z \ll z_R$, where,

$$\mathcal{E}_{pl}(r, \phi) = \mathcal{E}_0 f_{pl}(r) \ e^{-il\phi} e^{\imath(\omega t - kz)} \ , \tag{18.39}$$

$$f_{pl}(r) = \frac{\Omega_{pl}(r)}{\Omega_0} = \frac{e^{-r_w^2/2}}{z_R} \ r_w^{|l|} \ L_p^{|l|}(r_w^2) \ .$$

where we introduced the normalized paraxial distance $r_w \equiv r\sqrt{2}/w_0$. When such a Laguerre-Gaussian beam is reflected form a mirror reflected from a mirror it changes the signs of $k \longrightarrow -k$ but not $l \to l$. We obtain a standing wave, made of ring-shaped potentials,

$$\left| f_{pl}(r) \ e^{-\imath l\phi} e^{\imath(\omega t - kz)} + f_{pl}(r) \ e^{-\imath l\phi} e^{\imath(\omega t + kz)} \right|^2 = 4 f_{pl}^2(r) \cos^2 kz \ . \tag{18.40}$$

At $z = 0$ the potential reads

$$U_{pl} = \frac{\Omega^2}{4\Delta} = \frac{\sigma_0 \Gamma I(x, y)}{\hbar\omega 4\Delta} = \frac{\Omega_0^2}{4\Delta} 4 f_{pl}^2(r) \ , \tag{18.41}$$

If in contrast the counterpropagating beam has an inverse angular momentum,

$$\left| f_{pl}(r) \ e^{-\imath l\phi} e^{i(\omega t - kz)} + f_{pl}(r) \ e^{\imath l\phi} e^{\imath(\omega t + kz)} \right|^2 = 4 f_{pl}^2(r) \cos^2(kz - l\phi) \ , \tag{18.42}$$

the superposition of a Laguerre-Gaussian beam with a reflected beam gives an azimuthally periodic modulation like a circular $1D$ lattice, which is twisted along the $\hat{z}$-axis. However there is no axial confinement. The intensity resembles a knot of l worms winding about the $\hat{z}$-axis at constant distance like helices. Axial modulation has to be obtained by an additional plane wave [19].

Let us calculate the dipole force via $\mathbf{F} = -\nabla U$,

$$\begin{aligned}\frac{\partial f_{pl}^2(r)}{\partial x} &= 2 f_{pl}(r) \frac{\partial r}{\partial x} \frac{\partial}{\partial r} \frac{e^{-r_w^2/2}}{z_R}\, r_w^{|l|}\, L_p^{|l|}(r_w^2) \\ &= f_{pl}(r)^2 \frac{8x}{w_0^2} \left[\frac{|l|}{2r_w^2} - \frac{1}{2} - \frac{L_{p-1}^{|l|+1}(r_w^2)}{L_p^{|l|}(r_w^2)} \right]\end{aligned} \tag{18.43}$$

using $\frac{d}{dx} L_n^{(m)}(x) = -L_{n-1}^{(m+1)}(x)$.

18.3.1.6 Creation of Laguerre-Gaussian modes

The polarization of light couples to the internal degrees of freedom of the atoms. But special light modes, i.e. the higher-order Laguerre-Gaussian (LG) modes, may carry orbital angular momentum. This angular momentum couples to the external degrees of freedom of the atoms [15, 44, 16, 14], i.e. the light exerts a torque onto the atoms. This light force is, however, very weak and in a gas cell with hot atoms, the Doppler-effect smears out the motional effect. Nevertheless, the torque has been observed with macroscopic particles [850]. And in a Magneto-Optical Trap (MOT), phase-conjugation by nondegenerate four-wave mixing has been used to indirectly prove the transfer of angular momentum to the atoms [904]. Finally, MOTs using Laguerre-Gaussian laser beams been constructed, however without demonstrating the effect of the torque [544, 862].

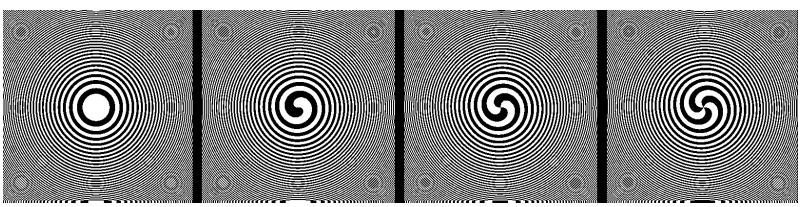

Figure 18.3: Masks for generating Laguerre-Gaussian beams.

The interference of such a mode with a plane wave v yields interference patterns proportional to,

$$u_{nm}(\mathbf{r})e^{-ikz} + v_{nm}(\mathbf{r})e^{-ikz} \propto \cos\left(-l\phi - \frac{kr^2 z}{2z_R^2} - (m+n+1)\arctan\frac{z}{z_R}\right) . \tag{18.44}$$

At some distance $z \neq 0$ and for $l \neq 0$ the patterns have Yin-Yang spiral shape. Inversely, like in holography, plane waves are *diffracted* at the spiral patterns in such a way that they generated a Laguerre-Gaussian mode. This is not an image. Images are also formed with undiffracted parts of the plane wave. The patterns form a fundamental focus at a distance f and subfoci at distances $f/2$, $f/3$, ... The fundamental beam is separated from the undiffracted and higher-order Fresnel modes by a short focal length lens placed in the fundamental focus. A spiral mask can be generated by setting $z = z_R$ in Eq. (18.44) and filling black the region where r and ϕ satisfy [421],

$$\cos\left(-l\phi - \frac{kr^2}{2z_R} - \pi(n+1/2)\right) > 0 . \tag{18.45}$$

A special case is defined by $l = 0$ which reproduces the *Fresnel zone plate*. The orbital momentum may be transferred to the atomic motion. Perhaps this also has an effect on the internal degrees of freedom: The higher-order orbital angular momentum may couple to higher multipole moments. At reflection on a mirror, the symmetry of the LG mode is inverted. Therefore, we can build a standing wave LG beam with no axial force (if the intensities are balanced and the waists matched) and twice the torque. LG modes can also be created from normal Gaussian modes with an arrangement of cylindrical lenses.

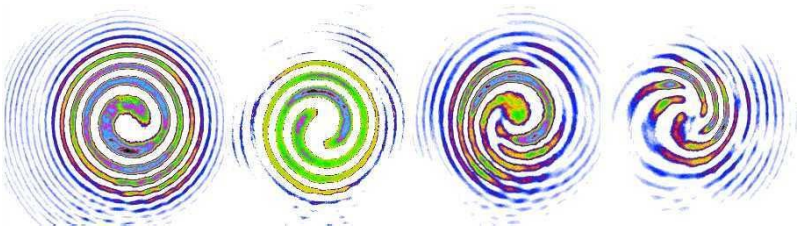

Figure 18.4: Laguerre-Gaussian beams with various charges.

18.3.1.7 Optical signatures

The interference of a Laguerre-Gaussian mode (LGM) with a phase-matched plane wave Gaussian beam yields interference patterns shown in the above figure. In the far-field, the laser beam forms a ring-shaped LGM. Higher-order topological charges are easily detected in the interference patterns through the occurrence of bifurcations or by the number of arms spiraling into the center.

18.4 Special topic: Superconductivity

At low temperatures some metals completely give up electric resistance. This effect found by Kammerlingh-Onnes is called *superconductivity* and has been explained through Bose-Einstein condensation of electron pairs [193]. But before we outline this theory let us try a classical approach based on electrodynamics as proposed by Fritz and Heinz London.

18.4.1 London model of superconductivity and the Meissner effect

We learned in Sec. 11.3.2 that *Ohm's law* is explained within the Drude model by the fact that the acceleration of electrons in a conductor of conductivity ς by the Coulomb force of an electric field, $m\dot{\mathbf{v}} = -e\vec{\mathcal{E}}$, is spoiled by collisions,

$$\mathbf{j} = \varsigma\vec{\mathcal{E}} \,. \tag{18.46}$$

Let us now suppose a perfect conductor, where collisions are absent. Then, if we want the current density $\mathbf{j} = \varrho\mathbf{v}$ to be constant,

$$0 = \dot{\mathbf{j}} = \varrho\dot{\mathbf{v}} = \frac{e^2 n_e}{m}\vec{\mathcal{E}} \,, \tag{18.47}$$

where $\varrho = -en_e$ is the free electron charge density.

Let us now study the behavior of the magnetic field in a conductor. Maxwell's equations require,

$$\nabla \times \vec{\mathcal{E}} = -\dot{\vec{\mathcal{B}}} \qquad \text{and} \qquad \nabla \times \vec{\mathcal{B}} = \mu_0\mathbf{j} + \dot{\vec{\mathcal{D}}} \,. \tag{18.48}$$

Assuming $\dot{\vec{\mathcal{D}}} = 0$ the above equations can easily be solved, yielding,

$$\boxed{\nabla^2\dot{\vec{\mathcal{B}}} = -\frac{\mu_0 n_e e^2}{m}\dot{\vec{\mathcal{B}}}} \,. \tag{18.49}$$

This equation describes the behavior of a magnetic field in and around a perfect conductor.

As we will see in Exc. 18.4.5.1, the solution of Eq. (18.49) predicts an expulsion of the magnetic field out of the conductor, as illustrated in Fig. 18.6. This effect is termed the *Meissner-Ochsenfeld effect*. That is, in the absence of resistivity, a conductor acts like a perfect diamagnetic (magnetic susceptibility $\chi_m = 1$). According to the Lenz

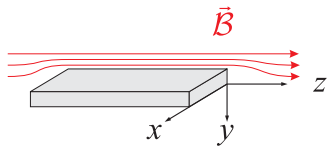

Figure 18.6: Scheme of the Meissner effect. An applied magnetic field is expelled from the superconductor.

rule, the electrons try to compensate any $\mathcal{B}$-field change by collectively rotating such as to counteract the change. The electrons rotate in such a way that the $\mathcal{B}$-field disappears inside the conductor, which leads to an amplification of the field near the surfaces. As a consequence, permanent magnets are repelled from superconducting surfaces.

The problem is that the discontinuity of the magnetic field at the periphery of the superconductor should violate the continuity equation. And in fact, it is experimentally observed, that the magnetic field is not completely expelled from thin superconducting films, because the magnetic field penetrates somewhat into the superconductor with the penetration depth λ_{L}. In order to understand this, it is necessary to replace the classical *Ohm's law* for the current density $\mathbf{j}$ and the electric field $\vec{\mathcal{E}}$, $\mathbf{j} = \varsigma\vec{\mathcal{E}}$, by the *London equation*.

The London brothers postulates that the magnetic field inside a superconductor would not only be constant, as predicted by Eq. (18.49) by vanish altogether,

$$\boxed{\nabla^2\vec{\mathcal{B}} = \frac{\mu_0 n_e e^2}{m}\vec{\mathcal{B}} = \frac{1}{\lambda_{\mathrm{L}}}\vec{\mathcal{B}}} \ , \tag{18.50}$$

where we defined the London penetration depth,

$$\lambda_{\mathrm{L}} \equiv \sqrt{\frac{m}{\mu_0 e^2 n_e}} \ . \tag{18.51}$$

We will study consequences of this equation in Exc. 18.4.5.2.

18.4.1.1 Derivation of the London equation

The London equation can be derived in the framework of quantum mechanics, considering the superconducting state as a macroscopically extended quantum state described by the following wavefunction,

$$\psi(\mathbf{r}) = \psi_0 e^{\imath S(\mathbf{r})} \ , \tag{18.52}$$

where $S = S(\mathbf{r})$ is the phase of the macroscopic wavefunction. $\psi_0^2 = n_e$ corresponds to the density of the number of Cooper pairs in the superconductor. The implicit assumption of a homogeneous density of the Cooper pairs is reasonable, since the pairs are negatively charged and repel each other. Any imbalance of the density of pairs would therefore generate an electric field, which would be compensated immediately. The kinetic momentum operator in the presence of a magnetic field, $\mathbf{p} = -\imath\hbar\nabla -$

$q\mathbf{A}$, where $\mathbf{A} = \mathbf{A}(\mathbf{r}, t)$ is the vector potential of the magnetic field, applied to the wavefunction ψ gives,

$$m\mathbf{v}\psi = \mathbf{p}\psi = (\hbar\nabla S - q\mathbf{A})\psi \ . \tag{18.53}$$

That is,

$$\mathbf{v} = \frac{\hbar}{m}\nabla S - \frac{q}{m}\mathbf{A} \ . \tag{18.54}$$

With $\mathbf{j} = qn_e\mathbf{v}$ follows immediately,

$$\boxed{\mathbf{j} = \frac{n_e q\hbar}{m}\nabla S - \frac{n_e q^2}{m}\mathbf{A}} \ . \tag{18.55}$$

This is the London equation.

There are two useful forms of this equation, sometimes referred to as the 1st and the 2nd London equation,

$$\partial_t \mathbf{j} = \frac{n_e q^2}{m}\vec{\mathcal{E}} \ , \tag{18.56}$$

and

$$\nabla \times \mathbf{j} = \frac{n_e q^2}{m}\vec{\mathcal{B}} \ . \tag{18.57}$$

The phase S does not contribute to these two equations. It does not contribute to the first equation, because the phase is only dependent on the position and therefore constant in time, and it does not contribute to the second equation, because $\nabla \times \nabla S = 0$ [1].

18.4.2 BCS theory

Many-body effects like superconductivity are not explained by the free electron or the Bloch model. Superconductivity is characterized by two main features: The disappearance of electrical resistance in some metals at temperatures below roughly $T \simeq 10\,\mathrm{K}$, and the expulsion of magnetic flux lines out of the metals, known as Meissner-Ochsenfeld effect.

According to Bardeen-Cooper-Schrieffer near the edge of the Fermi surface induced by weak attractive interactions strong correlations in momentum space may build up. Such interations can be mediated by local polarization traces, i.e. deformations of the lattice or phonons, imprinted by a moving electron into the metallic lattice and sensed by a second electron following at a reasonable distance [133, 162]. Thus Fermi gases are unstable with respect to formation of bound fermion pairs. However, fermion pairs are not bound in the ordinary sense, and the presence of a filled Fermi sea is essential. Rather, we have a many-body state. Hence, the interpretation as a Bose-condensate of Cooper pairs explains some characteristics like the existence of a delocalized macroscopic wavefunction and the superfluid-like behavior suppressing

[1] Note that, although the phase does not contribute to the last two formulas, it should not be neglected! If the phase component were not included, it would mean that the current density without magnetic field would have to be zero. In reality, however, the phase gradient can also contribute to the current density, which therefore need not necessarily be zero, i.e. the current density is not zero, although no magnetic field is applied.

the electrical resistance. But it oversimplifies and does not account for the important role of fermionic statistics in the many-body state.

The requirements for Cooper pairing are 1. low temperature to rule out thermal phonons, 2. strong electron-lattice interaction, 3. many electrons just below $E_{\rm F}$, 4. anti-parallel spins, and 5. antiparallel momentum of the electrons.

Below T_c the motions of the electrons and the ions in the lattice are highly correlated. Cooper pairs are weakly bound, in thermal equilibrium with unpaired electrons, and have a vanishing total momentum. The typical distance of the electrons in a pair is roughly 100 nm. Although the fraction of paired electrons is only 10^{-4}, their number within the volume occupied by a single pair is 10^6.

Cooper-pairs form through scattering processes. Since all states below the Fermi surface are occupied, the final momenta must be above k_F. In other words, the two electrons are excited from slightly below $E = E_{\rm F}$ to slightly above $E + E_g/2 = E_{\rm F}$, where they profit from the large amount of available empty states allowing for their high mobility and letting them transit into the strongly correlated pairing state. The pairs then have the binding energy E_g, because the increase in kinetic energy must be overcompensated by the potential energy. Such processes smooth out the Fermi edge even at $T = 0$, as if the temperature really were at $T \simeq T_c$.

An energy gap forms which has just the width E_g. Its origin is understood as follows: If an electron could slightly change its energy, the pair correlation would immediately break up and the binding energy E_g liberated. But this energy cannot be dissipated. Since the binding energy for Cooper pairs is roughly $E_g \simeq 3k_BT_c$, a thermal noise source must at least provide the energy $3k_BT_c$, which is not possible if $T < T_c$. At higher temperatures, the pairing gap narrows and vanishes at $T = T_c$. The gap can be spectroscopically probed with IR radiation.

Higher $\mathcal{B}$ fields require lower critical temperatures. The critical temperature drops with rising mass of the ions, $T_c m^{1/2} = const$. This indicates that the vibration of the lattice ions is crucial for superconductivity.

Magnetic fields trying to penetrate superconducting wires perturb the superconductivity. This problem can be reduced in type II superconductors, where the size of the Cooper pairs are reduced and employing superconducting wires containing normal conducting channels.

The quantitative treatment starts with the two-body Schrödinger equation,

$$\left[-\frac{\hbar^2}{2m}(\nabla_1^2 + \nabla_2^2) + V(r_1 - r_2)\right]\Psi(r_1, r_2) = (E + 2E_{\rm F})\Psi(r_1, r_2)\ . \tag{18.58}$$

Here we assume singlet pairing s-wave collisions. Center-of-mass and relative coordinates are now separated, giving,

$$\left[-2\frac{\hbar^2}{2m}\nabla_r^2 + V(r)\right]\psi(r) = \left(E + 2E_{\rm F} - \frac{\hbar^2 K^2}{4m}\right)\Psi(r)\ . \tag{18.59}$$

Transforming into momentum space, assuming that the Fourier transform $V(p, p') = V^{-1}\int e^{-\imath(p-p')r}V(r)d^3r$ is only nonzero, $= V_0$, inside an energy interval smaller than

the Debye frequency $\hbar\omega_D$ close to the Fermi surface, we finally arrive at the binding energy of the Cooper-pair,

$$E = -\frac{2\hbar\omega_D}{e^{2/V_o D(E_\mathrm{F})} - 1} \ , \tag{18.60}$$

where $D(E_\mathrm{F}) \propto k_F$ is the density of states at the Fermi surface. Estimating $V(r) \approx \hbar^2/ma^2$ the Fourier transform goes like $V_0 \propto a$, so that $k_B T_{BCS} \propto -e^{-\pi/2k_F|a_s|}$.

A full quantum treatment reveals the presence of a gap. This gap can also be understood in the following way. In the normal state the energy spectrum is twofold degenerate. A state with a hole in the Fermi surface has the same energy as a state with an electron above the Fermi surface. Cooper-pairing couples those states, which leads to energy splitting and introduces a *pairing gap*,

$$\begin{aligned} |u_k|^2 &= \frac{1}{2}\left[1 + \frac{\epsilon_k - E_\mathrm{F}}{\sqrt{\Delta_0^2 + (\epsilon_k - E_\mathrm{F})^2}}\right] = 1 - |v_k|^2 \\ \Delta &= -\sum_k u_k v_k \ . \end{aligned} \tag{18.61}$$

The product $u_k v_k$ only contributes near the Fermi surface. We get a density of states,

$$D_s(E) = D_n \frac{|E - E_\mathrm{F}|}{\sqrt{-\Delta_0^2 + (\epsilon_k - E_\mathrm{F})^2}} \ , \tag{18.62}$$

which has a gap. The states are redistributed toward the edges of the gap.

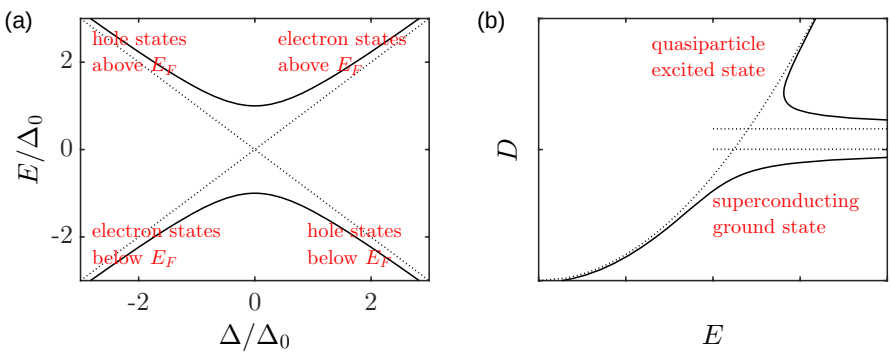

Figure 18.7: Pairing gap in the energy spectrum and the density of states.

18.4.3 Josephson junctions

Two superconductors that are joined by a nm thin isolating oxide layer build a *Josephson junction* (JJ) [493]. Cooper pairs may tunnel through the junction producing a current flow i_J. The basic JJ is described by,

$$i_\mathrm{J} = I_c \sin\varphi \qquad \text{and} \qquad v = \frac{\Phi_0}{2\pi}\frac{d\varphi}{dt} \ , \tag{18.63}$$

where

$$\Phi_0 = \frac{h}{2e} \ . \tag{18.64}$$

I_c is the critical supercurrent of the junction, and v is the voltage at the JJ. φ is a dynamical variable describing the phase difference between the macroscopic wave functions on both sides of the junction. Note that for small φ we have $u \propto i$ similar to the situation in a magnetic coil. The *ac*-Josephson effect consists in applying a constant voltage. Then φ increases linearly in time and the Josephson-current oscillates at a given (microwave) frequency [353],

$$f_{\rm J} = \frac{v}{\Phi_0} \ . \tag{18.65}$$

This allows a very precise measurement of h/e.

18.4.4 Synchronization of coupled Josephson junctions

The superconducting flux is quantized. A *superconducting quantum interference device* consist of two JJs connected in parallel. In that way the *supercurrent* is split and recombined.

18.4.4.1 Resistively shunted junctions

In a widely accepted model of nonideal *resistively shunted junctions* (RSJ) [734] the junction current consists of three components: A superconducting current $i_{\rm J} = I_c \sin\varphi$, a resistive current $i_R = v/R$, and a capacitance current $\dot{v}C$ (see Fig. 18.8). From Kirchhoff's laws using (18.63),

$$C\frac{\Phi_0}{2\pi}\frac{d^2\varphi}{dt^2} + \frac{1}{R}\frac{\Phi_0}{2\pi}\frac{d\varphi}{dt} + I_c \sin\varphi = i \ , \tag{18.66}$$

if the resistance is assumed independent of the applied voltage. Located in front of the term $\dot{\varphi}$ the resistivity is inversely proportional to the dissipation. The reason for this is that dissipation occurs via *single-particle tunneling*. Note that the equation is identical to that of an overdamped rotator or of a phase-locked loop.

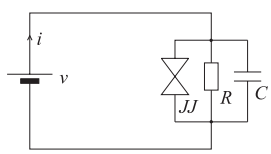

Figure 18.8: Resistively shunted Josephson junction.

Neglecting the resistance, the equation of motion can be derived from the Hamiltonian,

$$\hat{H} = \frac{p_\varphi^2}{2C\Phi_0/2\pi} - i\varphi - I_c \cos\varphi \ , \tag{18.67}$$

via $\dot{\varphi} = \frac{\partial H}{\partial p_\varphi}$ and $\dot{p}_\varphi = -\frac{\partial H}{\partial \varphi}$. The φ and p_φ are conjugate variables,

$$[\varphi, p_\varphi] = \imath \ . \tag{18.68}$$

Let us go to scaled variables via $\tilde{H} \equiv H/(C\Phi_0/2\pi)$, $\tilde{p_\varphi} \equiv p_\varphi/(C\Phi_0/2\pi)$, $K \equiv I_c/(C\Phi_0/2\pi)$, and $\lambda \equiv i/(C\Phi_0/2\pi)$,

$$\tilde{H} = \frac{\tilde{p}_\varphi^2}{2} - \lambda\varphi - K\cos\varphi \ , \tag{18.69}$$

In these units,

$$[\varphi, \tilde{p}_\varphi] = \imath\frac{e}{\hbar C} \ . \tag{18.70}$$

18.4.4.2 Response to *ac* driving sources

Let the applied voltage be $v(t) = V_0 + V_s\cos\omega_s t$. We may substitute the voltage in (18.63) and integrate,

$$\varphi = \varphi(0) + \frac{2\pi}{\Phi_0}V_0 t + \frac{2\pi}{\Phi_0}\frac{V_s}{\omega_s}\sin\omega_s t \ . \tag{18.71}$$

The resistive current is then,

$$i_R = \frac{V_0}{R} + \frac{V_s}{R}\cos\omega_s t \ , \tag{18.72}$$

and plugging (18.71) this into the Josephson current (18.63),

$$\begin{aligned} i_{\rm J} &= I_c\sin\left(\varphi(0) + \frac{2\pi}{\Phi_0}V_0 t + \frac{2\pi V_s}{\Phi_0\omega_s}\sin\omega_s t\right) \\ &= I_c\sum_n (-1)^n J_n\left(\frac{2\pi V_s}{\Phi_0\omega_s}\right)\sin\left[(f_{\rm J} - n\omega_s)t + \varphi(0)\right] \ , \end{aligned} \tag{18.73}$$

where we expanded the double sine into Bessel-functions. The time-averaged Josephson current disappears unless $f_{\rm J} = n\omega_s$,

$$\bar{i}_{\rm J} = I_c\sum_n (-1)^n J_n\left(\frac{2\pi V_s}{\Phi_0\omega_s}\right)\sin\left[\varphi(0)\right]\ \delta(f_{\rm J} - n\omega_s) \ . \tag{18.74}$$

The averaged total current $\bar{i} = \bar{i}_R + \bar{i}_{\rm J}$ as a function of the applied voltage v thus obtains a washboard-type characteristics,

$$\bar{i} = \frac{V_0}{R} + I_c\sum_n (-1)^n J_n\left(\frac{2\pi V_s}{\Phi_0\omega_s}\right)\sin\left[\varphi(0)\right]\ \delta(v - n\omega_s\Phi_0) \ . \tag{18.75}$$

The plateaus in the i-v characteristics are called *Shapiro steps*. They appear at voltages $n\hbar\omega_s/4\pi e$. In the case of arrays of m JJs, steps are also observed at voltages corresponding to rational fractions of frequencies $m\omega_j = n\omega_s$, provided the JJs are locked [165].

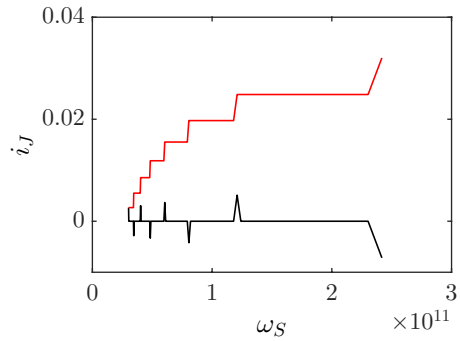

Figure 18.9: (code) Shapiro steps and their derivative.

18.4.4.3 Locking

To study the locking phenomenon we simplify the JJ equation by neglecting dissipation, $C = 0$,

$$\frac{\Phi_0}{2\pi}\frac{d\varphi}{dt} = Ri + RI_c \sin\varphi \ . \tag{18.76}$$

This is the so-called *Adler equation*,

$$\frac{d\psi}{dt} = -\nu + \varepsilon \sin\psi \ , \tag{18.77}$$

whose formal solution is [734],

$$t = \int \frac{d\psi}{\varepsilon \sin\psi - \nu} \ . \tag{18.78}$$

The beat frequency is,

$$\Omega_\psi = 2\pi \left| \int \frac{d\psi}{\varepsilon\left(1 - \frac{\psi^2}{2}\right) - \nu} \right|^{-1} \ , \tag{18.79}$$

expanding around the maximum at $\psi = \pi/2$,

$$\Omega_\psi \simeq \pi\varepsilon \left| \int \frac{d\psi}{-\psi^2 - 2\frac{\nu}{\varepsilon} + 2} \right|^{-1} = \pi\sqrt{2\varepsilon}\sqrt{\varepsilon - \nu} \left| \int \frac{d\tilde{\psi}}{1 - \tilde{\psi}^2} \right|^{-1} \simeq \pi\sqrt{2\varepsilon}\sqrt{\nu - \varepsilon} \ . \tag{18.80}$$

This is due to a locking of the drive frequency and the frequency of the oscillators.

18.4.4.4 Devil's staircase

Locking can also happen between higher harmonics. To see this we chose an alternative treatment goes as follows. The equation of motion with a pure ac driving voltage without resistance is,

$$C\frac{\Phi_0}{2\pi}\frac{d^2\varphi}{dt^2} + I_c \sin\left(\varphi(0) + \frac{2\pi V_0}{\Phi_0}t + \frac{2\pi V_s}{\Phi_0\omega_s}\sin\omega_s t\right) = 0 \ . \tag{18.81}$$

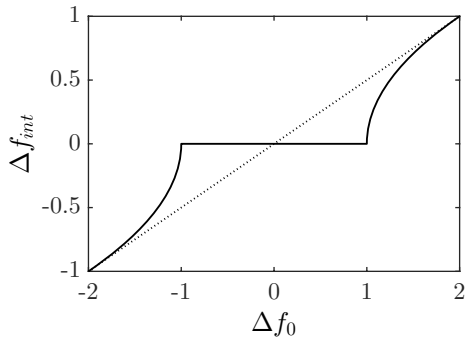

Figure 18.10: (code) Arnold tongue.

It can be derived from the Hamiltonian,

$$\hat{H} = \frac{p_\varphi^2}{2C\Phi_0/2\pi} - I_c \cos\left(\varphi(0) + \frac{2\pi V_0}{\Phi_0}t + \frac{2\pi V_s}{\Phi_0\omega_s}\sin\omega_s t\right) \ . \tag{18.82}$$

Substituting $\tilde{H} \equiv H/(C\Phi_0/2\pi)$, $\tilde{p_\varphi} \equiv p_\varphi/(C\Phi_0/2\pi)$, $K \equiv I_c/(\omega_s C\Phi_0/2\pi)$, and $\lambda \equiv \imath/(\omega_s C\Phi_0/2\pi)$, ...

We now go to the annulus map describing the Josephson junction. The JJ map can be interpreted as a δ-kicked rotor. The dissipative map [1012] predicts the occurrences of locking regions, known as Shapiro steps observed at all simple rational numbers m/n. They are equivalent to those of a *devil's staircase*.

18.4.4.5 Quantized JJ

The quantized energy levels of the JJ $\cos\psi$ potential result in a phase quantization. As a consequence, the energy exchange between an oscillating driving pump, ω_s, and the JJ, only occurs in multiples of $\omega_{\rm J}$.

To visualize quantum effects, one has to go to the quantum map $|\psi_{n+1}\rangle = \hat{U}\psi_n$.

18.4.5 Exercises

18.4.5.1 Ex: Perfect conductor

Calculate the magnetic field near a perfect conductor by solving equation (18.49).

18.4.5.2 Ex: Perfect conductor

Quantify the Meissner effect for a thin layer by solving equation (18.50).

18.4.5.3 Ex: Meissner-Ochsenfeld effect

Calculate the magnetic field inside a thin superconducting layer as a function of layer thickness and temperature.

18.5 Quantities and formulas in electromagnetism

18.5.1 Electromagnetic quantities

charge	Q	basic SI unit [C]
electric field (Coulomb law)	$\vec{\mathcal{E}}$	$d\vec{\mathcal{E}}(\mathbf{r}) = \frac{1}{4\pi\epsilon_0}\frac{dQ(\mathbf{r}-\mathbf{r}')}{\lvert\mathbf{r}-\mathbf{r}'\rvert^3}$
Coulomb law		$\vec{\mathcal{E}}(\mathbf{r}) = \frac{1}{4\pi\epsilon_0}\int_{\mathcal{V}}\frac{\rho(\mathbf{r}')(\mathbf{r}-\mathbf{r}')}{\lvert\mathbf{r}-\mathbf{r}'\rvert^3}d^3r'$

18.5.3 CGS units

Often used in electrodynamics are *CGS units*, also called *Gaussian units*. In this script we will use exclusively *SI units* of the *Système International d'Unités*. To do

the conversion between the unit systems, it is enough let,

$$\begin{aligned} e \to e_{CGS}\sqrt{4\pi\varepsilon_0} \quad &, \quad \mathbf{j} \to \mathbf{j}_{CGS}\sqrt{4\pi\varepsilon_0} \\ \vec{\mathcal{E}} \to \vec{\mathcal{E}}_{CGS}\sqrt{\tfrac{1}{4\pi\varepsilon_0}} \quad &, \quad \vec{\mathcal{B}} \to \vec{\mathcal{B}}_{CGS}\sqrt{\tfrac{\mu_0}{4\pi}} \\ \vec{\mathcal{D}} \to \vec{\mathcal{D}}_{CGS}\sqrt{\tfrac{\varepsilon_0}{4\pi}} \quad &, \quad \vec{\mathcal{H}} \to \vec{\mathcal{H}}_{CGS}\sqrt{\tfrac{1}{4\pi\mu_0}} \\ \vec{\mathcal{P}} \to \vec{\mathcal{P}}_{CGS}\sqrt{4\pi\varepsilon_0} \quad &, \quad \vec{\mathcal{M}} \to \vec{\mathcal{M}}_{CGS}\sqrt{\tfrac{4\pi}{\mu_0}} \ . \end{aligned} \tag{18.83}$$

Maxwell's equations in the irrational Gaussian system are,

$$\text{rot}\ \vec{\mathcal{H}} = \tfrac{1}{c}\partial_t\vec{\mathcal{D}} + \tfrac{4\pi}{c}\mathbf{j} \quad , \quad \text{div}\ \vec{\mathcal{D}} = 4\pi\varrho \ . \tag{18.84}$$

Moreover,

$$u = \tfrac{1}{8\pi}(\vec{\mathcal{E}}^2 + \vec{\mathcal{B}}^2) \quad , \quad \mathbf{S} = \tfrac{c}{4\pi}(\vec{\mathcal{E}} \times \vec{\mathcal{B}}) \ . \tag{18.85}$$

The material equations for dielectric media are,

$$\vec{\mathcal{D}} = \varepsilon\vec{\mathcal{E}} \quad , \quad \vec{\mathcal{P}} = \chi_\varepsilon\vec{\mathcal{E}} \quad , \quad \varepsilon = 1 + 4\pi\chi_\varepsilon \ , \tag{18.86}$$

and for dia- and paramagnetic media,

$$\vec{\mathcal{B}} = \mu\vec{\mathcal{H}} \quad , \quad \vec{\mathcal{M}} = \chi_\mu\vec{\mathcal{H}} \quad , \quad \mu = 1 + 4\pi\chi_\mu \ . \tag{18.87}$$

18.6 Rules of vector analysis

18.6.1 Basic rules

(i) $$\mathbf{A}\cdot\mathbf{B} = \mathbf{B}\cdot\mathbf{A} \quad \text{but} \quad \mathbf{A}\cdot\nabla \neq \nabla\cdot\mathbf{A} \ , \tag{18.88}$$

(ii) $$\phi\mathbf{B} = \mathbf{B}\phi \quad \text{but} \quad \phi\nabla \neq \nabla\phi \ ,$$

(iii) $$\mathbf{A}\times\mathbf{B} = -\mathbf{B}\times\mathbf{A} \quad \text{but} \quad \mathbf{A}\times\nabla \neq -\nabla\times\mathbf{A} \ ,$$

(iv) $$\mathbf{A}\cdot(\mathbf{B}\times\mathbf{C}) = \mathbf{B}\cdot(\mathbf{C}\times\mathbf{A}) \ ,$$

(v) $$\mathbf{A}\times(\mathbf{B}\times\mathbf{C}) = \mathbf{B}(\mathbf{A}\cdot\mathbf{C}) - \mathbf{C}(\mathbf{A}\cdot\mathbf{B}) \ ,$$

(vi) $$\nabla f(\phi(\mathbf{r})) = \frac{\partial f}{\partial\phi}\nabla\phi(\mathbf{r}) \quad \text{chain rule} \ ,$$

(vii) $$\nabla(\mathbf{A}\cdot\mathbf{B}) = \nabla(A\mathbf{B}) + \nabla(\mathbf{A}B) \quad \text{product rule for scalars and vectors} \ .$$

18.6.2 Deduced rules

$$
\begin{aligned}
&\text{(i)} && \nabla(\phi+\psi) = \nabla\phi + \nabla\psi \ , && (18.89)\\
&\text{(ii)} && \nabla(\phi\psi) = \phi\nabla\psi + \psi\nabla\phi \ , \\
&\text{(iii)} && \nabla\cdot(\mathbf{A}+\mathbf{B}) = \nabla\cdot\mathbf{A} + \nabla\cdot\mathbf{B} \ , \\
&\text{(iv)} && \nabla\times(\mathbf{A}+\mathbf{B}) = \nabla\times\mathbf{A} + \nabla\times\mathbf{B} \ , \\
&\text{(v)} && \nabla\cdot(\phi\mathbf{A}) = \phi(\nabla\cdot\mathbf{A}) + (\nabla\phi)\cdot\mathbf{A} \ , \\

(vi) $$\int_{\mathcal{V}} \phi(\triangle\psi) dV = \int_{\mathcal{V}} (\triangle\phi)\psi dV \tag{18.91}$$

where $\triangle$ is hermitian, when $\lim_{r\to\infty} r\phi(r) = 0 = \lim_{r\to\infty} r\psi(r)$,

(vii) $$\frac{d}{dt}\int_{a(t)}^{b(t)} f(x,t)dx = \int_{a(t)}^{b(t)} \frac{\partial f}{\partial\tau}(x,t)dx + \frac{db(t)}{dt} f(b,t)dx - \frac{da(t)}{dt} f(a,t)dx \ .$$

Notation,

$$\nabla\phi\cdot d\mathbf{S} = \nabla\phi\cdot\mathbf{n}\ dS = \frac{\partial\phi}{\partial\mathbf{n}}\ dS \ . \tag{18.92}$$

18.7 Rules for Laplace and Fourier transforms

18.7.1 Laplace transform

Formulas for the *Laplace transform*:

(definition) $$(\mathcal{L}f)(p) = \int_0^\infty f(t)e^{-pt}dt \tag{18.93}$$

(inversion) $$\mathcal{L}^{-1}\mathcal{L}f = f \quad \text{where} \quad (\mathcal{L}^{-1}\mathcal{L}f)(t) = \int_{\varepsilon-\imath\omega}^{\varepsilon+\imath\omega} \mathcal{L}f(p)e^{pt}\frac{dp}{2\pi\imath}$$

(linearity) $$\mathcal{L}(af+bg) = a\mathcal{L}(f) + b\mathcal{L}(g)$$

(similarity) $$\mathcal{L}[f(at)] = a^{-1}\mathcal{L}f(a^{-1}p)$$

(translation) $$\mathcal{L}\mathcal{T}f = \mathcal{L}f \cdot e^{-pT} \quad \text{where} \quad \mathcal{T}f(t) = f(t-T)$$

$$\mathcal{L}\left(fe^{qt}\right) = \mathcal{T}\mathcal{L}f$$

(differentiation) $$\mathcal{L}\partial_t f = p\mathcal{L}f - f(0)$$

$$\mathcal{L}(-tf) = \partial_p\mathcal{L}f$$

(pulse response) $$\mathcal{L}\delta = 1 \quad \text{where} \quad \delta(t) = \mathcal{L}^{-1}1$$

(step response) $$\mathcal{L}\delta' = p^{-1}$$

(integration) $$\mathcal{L}\int_0^t dt\ f = p^{-1}\mathcal{L}f$$

$$\mathcal{L}(t^{-1}f) = \int_p^\infty dp\ \mathcal{L}f$$

(convolution) $$\mathcal{L}(f\star g) = \mathcal{L}f\cdot\mathcal{L}g$$

(periodic functions) $$\mathcal{L}(f=\mathcal{T}f) = \int_0^{-T} dt\ \frac{e^{-pt}f(t)}{1-e^{pT}}$$

(eigenfunctions) $$f\star e^{pt} = \mathcal{L}f\cdot e^{pt}\ .$$

18.7.2 Correlation

Formulas for the *correlation*:

(definition) $$(f\diamond g)(t) = \int_{-\infty}^\infty f(\tau)g(t+\tau)d\tau \tag{18.94}$$

(non-commutativity) $$(f\diamond g)(t) = (g\diamond f)^s$$

(complex autocorrelation) $$|f\diamond g^*| \le f\diamond g^*(0)\ .$$

18.7.3 Fourier transform

Formulas for the *Fourier transform*:

(definition) $$(\mathcal{F}f)(\omega) = \int_{-\infty}^{\infty} f(t)e^{-\imath\omega t}dt \tag{18.95}$$

(inversion) $$\mathcal{F}^{-1}\mathcal{F}f = f \quad \text{where} \quad (\mathcal{F}^{-1}\mathcal{F}f)(t) = \int_{-\infty}^{\infty} \mathcal{F}f(\omega)e^{\imath\omega t}d\omega$$

(linearity) $$\mathcal{F}(af + bg) = a\mathcal{F}(f) + b\mathcal{F}(g)$$

(similarity) $$?$$

(translation) $$\mathcal{F}\mathcal{T}f = \mathcal{F}f \cdot e^{-\imath\omega T} \quad \text{where} \quad \mathcal{T}f(t) = f(t-T)$$
$$\mathcal{F}\left(fe^{\imath\omega t}\right) = \mathcal{T}\mathcal{F}f$$

(differentiation) $$\mathcal{F}[tf(t)] = \imath\partial_\omega(Ff)(\omega)$$
$$\mathcal{F}[f'(t)] = \imath\omega(Ff)(\omega)$$

(pulse response) $$\mathcal{F}\delta = 1 \quad \text{where} \quad \delta(t) = \mathcal{F}^{-1}1$$

(step response) $$\mathcal{F}\delta' = ?$$

(duality) $$\mathcal{F}\mathcal{F}\ f = f^s \quad \text{where} \quad f^s(t) = f(-t)$$
$$\mathcal{F}\ f^* = (\mathcal{F}\ f)^{*s} \quad \text{where} \quad f^s(t) = f(-t)$$

(symmetry) $$f = f^s = f^* \quad \Leftrightarrow \quad \mathcal{F}\ f = (\mathcal{F}\ f)^s$$
$$f = -f^s = f^* \quad \Leftrightarrow \quad \mathcal{F}\ f = -(\mathcal{F}\ f)^*$$
$$f = f^* \quad \Leftrightarrow \quad \mathcal{F}\ f = (\mathcal{F}\ f)^{*s}$$

(convolution) $$\mathcal{F}(f \star g) = \mathcal{F}f \cdot \mathcal{F}g$$
$$\mathcal{F}(f \cdot g) = \mathcal{F}f \star \mathcal{F}g$$

(eigenfunctions) $$f \star e^{\imath\omega t} = \mathcal{F}f \cdot e^{\imath\omega t}\ .$$

18.7.3.1 Fast Fourier transform

The *discrete Fourier transform* is defined by,

$$\begin{aligned} H_n &= \sum_{k=0}^{N-1} e^{-2\pi\imath nk/N} h_k \\ &= \sum_{k=0}^{N-1} e^{-2\pi\imath nk/(N/2)} h_{2k} + e^{-2\pi\imath k/N} \sum_{k=0}^{N/2-1} e^{-2\pi\imath nk/(N/2)} h_{2k+1} \\ &= even + odd\ . \end{aligned} \tag{18.96}$$

The inverse transform is,

$$h_k = \frac{1}{N}\sum_{k=0}^{N-1} e^{2\pi\imath nk/N} H_n\ . \tag{18.97}$$

The sine transform of a real vector s_k is,

$$S_n = \frac{2}{N}\sum_{k=1}^{N-1} s_k \sin \pi nk/N\ . \tag{18.98}$$

In MATLAB the fast Fourier transform is defined by:

$$F(k+1) = \sum_{n=0}^{N-1} f(n+1)e^{-2\pi\imath/N\cdot kn} \ . \tag{18.99}$$

inversion:

$$f(n+1) = \frac{1}{N}\sum_{k=0}^{N-1} F(k+1)e^{2\pi\imath/N\cdot kn} \ . \tag{18.100}$$

symmetry,

$$\begin{aligned} f(n+1) &= f^*(n+1) \qquad (18.101)\\ \Longrightarrow K(k+1) &= \sum_{n=0}^{N-1} f^*(n+1)e^{-2\pi\imath/N\cdot kn}e^{-2\pi\imath/N\cdot Nn} = F^*(N-k+1) \ . \end{aligned}$$

and,

$$\begin{aligned} f(N-n) &= f(n+1) = f^*(n+1) \qquad (18.102)\\ \Longrightarrow F(k+1) &= \sum_{n=0}^{N-1} f^*(N-n)e^{-2\pi\imath/N\cdot kn}\\ &= \sum_{n=0}^{N-1} f^*(n'+1)e^{2\pi\imath/N\cdot kn'}e^{-2\pi\imath/N\cdot(N-1)} = F^*(k+1)e^{2\pi\imath/N} \ . \end{aligned}$$

and,

$$\begin{aligned} -f(N-n) &= f(n+1) = f^*(n+1) \qquad (18.103)\\ \Longrightarrow F(k+1) &= \sum_{n=0}^{N-1} -f^*(N-n)e^{-2\pi\imath/N\cdot kn}\\ &= \sum_{n=0}^{N-1} -f^*(n'+1)e^{2\pi\imath/N\cdot kn'}e^{-2\pi\imath/N\cdot(N-1)} = -F^*(k+1)e^{2\pi\imath/N} \ . \end{aligned}$$

Hence, we choose, $\mathcal{F}f(n+1) = F(k+1)e^{-\pi\imath/N}$.

18.7.3.2 Fourier expansion

The complex *Fourier expansion* is defined by,

$$\boxed{f_N(x) = \sum_{n=-N}^{N} c_n e^{\imath nx} \qquad \text{where} \qquad c_n \equiv \frac{1}{2\pi}\int_{2\pi} f(x)e^{-\imath nx}dx} \ . \tag{18.104}$$

It can be verified easily that $\lim_{N\to\infty} f_N(x) = f(x)$ using,

$$\int_{2\pi} e^{\imath(n'-n)x}dx = 2\pi\delta_{nn'} \qquad \text{or} \qquad \sum_{n=-\infty}^{\infty} e^{\imath n(x-x')} = 2\pi\delta(x-x') \ . \tag{18.105}$$

18.7.4 Convolution

Formulas for the *convolution*:

$$
\begin{aligned}
&\text{(definition)} && (f\star g)(t) = \int_{-\infty}^{\infty} f(\tau)g(t-\tau)d\tau && (18.106)\\
&\text{(neutral element)} && f\star\delta^{(n)} = f^{(n)} \\
&\text{(distributivity)} && (f+g)\star h = f\star h + g\star h \\
& && af\star g = f\star ag \\
&\text{(commutativity)} && f\star g = g\star f \\
&\text{(associativity)} && (f\star g)\star h = f\star(g\star h) \\
&\text{(translational invariance)} && \mathcal{T}(f\star g) = \mathcal{T}f\star g = f\star\mathcal{T} \\
&\text{(differentiation)} && \partial_x(f\star g) = \partial_x f\star g = f\star\partial_x g \\
&\text{(integration)} && \int_x (f\star g) = \int_x f\int_x g \\
&\text{(complexity)} && f = f_r + \imath f_i \\
&\text{(Dirac function)} && \mathcal{T}f = f\star\mathcal{T}\delta \\
& && f(T) = f\cdot\mathcal{T}\delta\ .
\end{aligned}
$$

Example 138 (*Convolution of two Lorentzians*): The convolution of two *Lorentzians*,

$$\mathcal{L}_a(x) \equiv \frac{a}{\pi}\frac{1}{x^2+a^2} \qquad \text{with} \qquad \int_{-\infty}^{\infty}\mathcal{L}_a(x)dx = 1\ ,$$

is simply another Lorentzian with the linewidth $a+b$,

$$\boxed{(\mathcal{L}_a\star\mathcal{L}_b)(x) = \mathcal{L}_{a+b}(x)}\ .$$

In order to demonstrate this, we first we apply the method of partial fractions to the expression,

$$\frac{1}{y^2+a^2}\frac{1}{(x-y)^2+b^2} = \frac{A}{y^2+a^2} + \frac{B}{(x-y)^2+b^2}$$
$$\text{with}\quad A = \frac{2xy+(x^2-a^2+b^2)}{(x^2+a^2+b^2)^2-4a^2b^2}\quad,\quad B = \frac{-2x(y-x)+(x^2+a^2-b^2)}{(x^2+a^2+b^2)^2-4a^2b^2}\ .$$

Now, we calculate the convolution,

$$
\begin{aligned}
(\mathcal{L}_a\star\mathcal{L}_b)(x) &= \frac{ab}{\pi^2}\int_{-\infty}^{\infty}\frac{1}{y^2+a^2}\frac{1}{(x-y)^2+b^2}dy \\
&= \frac{ab}{\pi^2}\frac{1}{(x^2+a^2+b^2)^2-4a^2b^2}\left(\int_{-\infty}^{\infty}\frac{2xy+(x^2-a^2+b^2)}{y^2+a^2}dy + \int_{-\infty}^{\infty}\frac{-2x(y-x)+(x^2+a^2-b^2)}{(x-y)^2+b^2}dy\right) \\
&= \frac{ab}{\pi^2}\frac{1}{(x^2+a^2+b^2)^2-4a^2b^2}\left((x^2-a^2+b^2)\int_{-\infty}^{\infty}\frac{1}{y^2+a^2}dy + (x^2+a^2-b^2)\int_{-\infty}^{\infty}\frac{1}{(x-y)^2+b^2}dy\right) \\
&= \frac{ab}{\pi^2}\frac{(x^2-a^2+b^2)\frac{\pi}{a}+(x^2+a^2-b^2)\frac{\pi}{b}}{(x^2+a^2+b^2)^2-4a^2b^2} = \frac{a+b}{\pi}\frac{1}{x^2+(a+b)^2} = \mathcal{L}_{a+b}(x)\ .
\end{aligned}
$$

Example 139 (*Convolution of two Gaussians*): The convolution of two *Gaussians*,

$$\mathcal{G}_a(x) \equiv \sqrt{\frac{1}{\pi}}\frac{1}{a}e^{-x^2/a^2} \qquad \text{with} \qquad \int_{-\infty}^{\infty}\mathcal{G}_a(x)dx = 1 \ ,$$

is simply another Gaussian with the linewidth $\sqrt{a^2+b^2}$,

$$\boxed{(\mathcal{G}_a \star \mathcal{G}_b)(x) = \mathcal{G}_{\sqrt{a^2+b^2}}(x)} \ .$$

We demonstrate this by calculating,

$$\begin{aligned}
(\mathcal{G}_a \star \mathcal{G}_b)(x) &= \frac{1}{\pi ab}\int_{-\infty}^{\infty} e^{-y^2/a^2}e^{-(x-y)^2/b^2}dy = \frac{\sqrt{ab}}{\pi}\int_{-\infty}^{\infty} e^{-(a^{-2}+b^{-2})y^2+2b^{-2}xy-b^{-2}x^2}dy \\
&= \frac{1}{\pi ab\sqrt{(a^{-2}+b^{-2})}}\int_{-\infty}^{\infty} e^{-\tilde{y}^2+\frac{2x}{b^2\sqrt{a^{-2}+b^{-2}}}\tilde{y}-b^{-2}x^2}d\tilde{y} \\
&= \frac{1}{\pi\sqrt{a^2+b^2}}\int_{-\infty}^{\infty} e^{-\left(\tilde{y}-\frac{x}{\sqrt{b^4/a^2+b^2}}\right)^2-\frac{x^2}{a^2+b^2}}d\tilde{y} \\
&= \frac{1}{\pi\sqrt{a^2+b^2}}e^{-\frac{x^2}{a^2+b^2}}\int_{-\infty}^{\infty} e^{-\tilde{y}^2}d\tilde{y} = \frac{1}{\sqrt{\pi}\sqrt{a^2+b^2}}e^{-\frac{x^2}{a^2+b^2}} = \mathcal{G}_{\sqrt{a^2+b^2}}(x) \ .
\end{aligned}$$

18.7.5 Green's functions

If a differential operator $\mathcal{L}_x$ acting on a variable x admits a *Green's function* $\mathcal{G}$ such that,

$$\boxed{\mathcal{L}_x\mathcal{G}(x,x') = \delta(x-x')} \ , \tag{18.107}$$

The Green function can be used to solve any equation,

$$\mathcal{L}_x f(x) = \varrho(x) \tag{18.108}$$

by calculating,

$$f(x) = \int \mathcal{G}(x,x')\varrho)(x)dx \ . \tag{18.109}$$

18.7.5.1 List of Green functions

The following table provides a list of useful Green functions.

differential operator $\mathcal{L}$	Green function $\mathcal{G}$
∂_t^n	$\frac{t^{n-1}}{(n-1)!}\Theta(t)$
$\partial_t + \gamma$	$\Theta(t)e^{-\gamma t}$
$\triangle$	$-\frac{1}{4\pi r}$
$\nabla\cdot$	$-\frac{\mathbf{r}-\mathbf{r}'}{4\pi R^3}$
$\nabla\times$	$-\frac{(\mathbf{r}-\mathbf{r}')\times(\mathbf{r}-\mathbf{r}')}{4\pi R^3}$
$\Box$	$-\frac{1}{4\pi r}\delta(t \mp \frac{1}{c}r)$
$\triangle + k^2$	$-\frac{e^{ikr}}{4\pi r}$
$-\nabla\times\nabla\times + k^2$	see Sec. 15.3.1

Example 140 (*Green function for time derivation*): To solve the differential equation,

$$(\partial_t + \gamma)f(t) = c \ ,$$

we search the Green function for the equation,

$$(\partial_t + \gamma)\mathcal{G}(t,t') = \delta(t-t') \ .$$

From the above table, we get,

$$f(t) = \int_{-\infty}^{\infty} \mathcal{G}(t,t') \ c \ dt' = c\int_{-\infty}^{\infty} \Theta(t-t')e^{-\gamma(t-t')}dt' = \frac{c}{\gamma}e^{-\gamma t} \ .$$

Part III

Thermodynamics

Preface to the part *Thermodynamics*

Thermodynamics is the physical theory originally developed to describe the connection between temperature, energy, and heat. Nowadays, it is however better defined by the efforts to identify features in the behavior of large systems, i.e. systems composed of a large number of particles, that can be formulated as rules and laws. The emergence of such rules in completely disordered systems can often be astonishing, and will only be put on firm grounds by the theory of statistical physics presented in part V of the script.

In chapter 19 we set the basis for a phenomenological approach to thermodynamics, emphasizing the central role of the concept of equilibrium. In Chp. 20 we apply these notions to physical, albeit often idealized, fluid and solid systems.

Chapter 19

Foundations and mathematical formalism

Thermodynamics is a central branch of modern science, and its general laws govern the physical and chemical processes which occur in our world. An important early application of thermodynamics dealt with steam engines, in which heat is converted to mechanical energy. Phenomenological thermodynamics was developed in the nineteenth and in the beginning of the twentieth century by Watt, Carnot, Clausius, Joule, von Helmholtz, Lord Kelvin, Nernst, Boltzmann, and Gibbs, culminating in the discovery of the Laws of Thermodynamics. These laws set general limits for the conversion of one form of energy, for example heat or chemical energy, to another one, for example mechanical work.

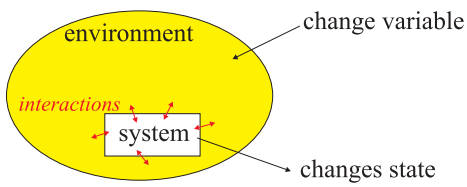

Figure 19.1: Reaction of a system to a sudden change in its environment.

The generic question addressed by thermodynamics is, how a given system responds to environmental changes. Indeed, the sudden modification of an environment will force the system to seek a new state of equilibrium, as illustrated in Fig. 19.1. On the other hand, thermodynamics is limited to describing equilibrium. It does not tell us step by step, *how* the new equilibrium is reached, only *what* the final state will be. Nevertheless, this is sufficient to establish complete *phase diagrams*, which are maps of equilibrium states. Fig. 19.2 shows as an example the phase diagram of water.

19.1 Phenomenological thermodynamics at equilibrium

To begin with, we consider each system as a structureless glop endowed with properties to be identified and defined, such as temperature, pressure, composition, heat capacity, expansion coefficient, compressibility, entropy, and various measures of the

system's energy. The minimum set of properties on which information is necessary to compute the state of the system depends on its complexity. For example, a unary system, i.e. an ensemble of identical particles belonging to the same species, is completely characterized by its heat capacity, expansion coefficient, and compressibility, while additional information is required for systems exhibiting several phases or made up of several chemical components, or even subject to chemical reactions [239].

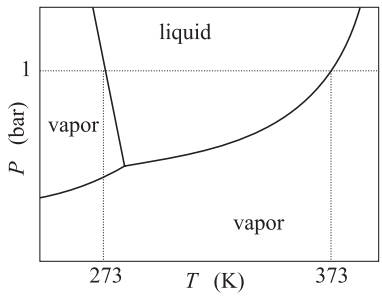

Figure 19.2: Phase diagram of water.

Fundamental concepts of thermodynamics, such as temperature, pressure, or heat have been unraveled before the discovery, that any type of matter consist of smallest components, atoms and molecules. The fact that heat flows from hot to cold bodies brought into contact is an everyday experience. *Joseph Michel and Jacques Etienne Montgolfier* demonstrated that hot air is lighter than cold air. And *James Watt* invented the steam engine before *Amedeo Avogadro* and *John Dalton* reintroduced the notion of the atom, which had initially been postulated by Democritus 500 A.C.. With the knowledge of the composition of any matter we could in principle give up the phenomenologically derived laws that represent the framework of thermodynamics. To characterize a system with N particles, we just need to specify the position and velocity of each particle as well as the forces acting between them or exerted by external fields. However, in the case of a macroscopic system, the number of particles is extremely large and this task becomes very difficult.

An alternative approach to the problem is to work with averaged values, which represent the behavior of a system as a whole. Let's embark on this approach by defining some macroscopic quantities that determine the state of the system. Let us consider a gas made up of N molecules in a container of volume V. Microscopically, the movement of each particle is rectilinear and uniform, until it collides with another molecule or with the walls of the container. This type of movement is called *Brownian motion*. The average distance that the particle travels between two successive collisions is called the *mean free path*.

The collisions of the particles with the walls of the container result in momentum transfers and, consequently, in an average force exerted onto the walls. Integrated over a surface, this force generates a pressure that the gas exerts on the walls, and despite its microscopic origin, the pressure represents a macroscopic quantity that describes an average property of the global system. Apart from pressure, other macroscopic quantities that are important for the description of a system are its volume, internal energy and temperature, the two latter ones being associated with the translational, vibrational and rotational movement of the particles. All these macroscopic quantities

can be measured experimentally, and the objective of thermodynamics is to establish relationships between them, in order to predict the behavior of some quantities when other quantities are changed.

When the macroscopic properties of a system do not change over time, we call it in *thermodynamic equilibrium*. In this case, the system of interest must be kept in contact with a second system, called a *reservoir* or *heat bath*, which determines the parameters of the equilibrium. The set of macroscopic quantities associated with a system in equilibrium is called a *macroscopic state*. It should be noted that the *microscopic state* of the system determines the macroscopic state, but the inverse does not hold, because from average values it is impossible to find $\mathbf{r}$ and $\mathbf{p}$ for all particles in the system.

Macroscopic quantities are somehow interconnected. To see this, we may consider a piston containing a gas, as schematized in Fig. 19.3(a), and heat it. As a consequence, the system temperature will increase. If we keep the position of the piston fixed, the pressure will increase, as well. If, on the other hand, we leave the piston moveable with friction, the volume will increase. Thus, both the increase in pressure and volume are consequences of an increasing temperature, from which we conclude that these quantities are, in some way, related.

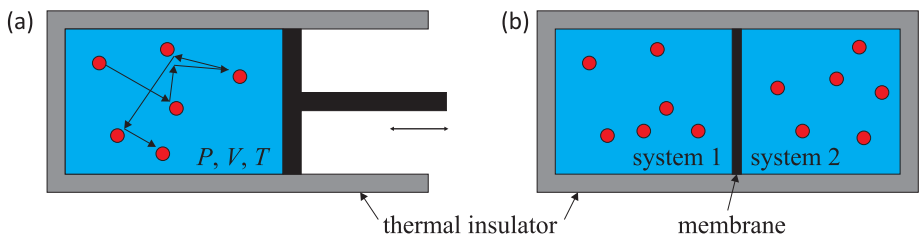

Figure 19.3: (a) Cylinder with a piston containing a gas. (b) Interaction between two systems through a wall.

If we have two systems in thermal contact, it is important to know in which way they interact. An interaction is often made through walls, as shown in Fig. 19.3(b). If the wall is at a fixed position and the temperature of one of the systems is varied, either (i) the temperature of the other system does not change, which is the case of a perfectly *insulating wall* (also called adiabatic wall) or (ii) the temperature of the other system follows the changes of the first and, which is the case of a *diathermal wall*. In case (ii), the temperatures of the two systems evolve, until they reach a common value. When the temperatures of the two systems are equal, the systems are considered to be at thermal equilibrium.

19.1.1 Temperature

Temperature is, in general, measured by observing some quantity which is sensitive to its variation. Defining a temperature scale on this quantity in a particular system, we construct a *thermometer*. An example is the *mercury thermometer*, where a certain volume of liquid mercury is placed in a capillary glass tube and the thermal expansion of mercury is observed as a function of temperature. The length L of the mercury column (usually calibrated in degrees Celsius) varies approximately linearly

with temperature T, that is, $T = aL + b$, where a and b are two constants that depend on chosen reference temperatures. Conventionally, the melting temperatures of ice (triple point) at $0\,^\circ\mathrm{C}$ and the boiling temperature of water at $100\,^\circ\mathrm{C}$ are used, so that,

$$a = \frac{100}{L_\mathrm{v} - L_\mathrm{g}} \qquad \text{and} \qquad b = -\frac{100 L_\mathrm{g}}{L_\mathrm{v} - L_\mathrm{g}} \ . \tag{19.1}$$

The *gas thermometer* illustrated in Fig. 19.4 is another possible realization, in which the volume of a gas is used as thermometric quantity.

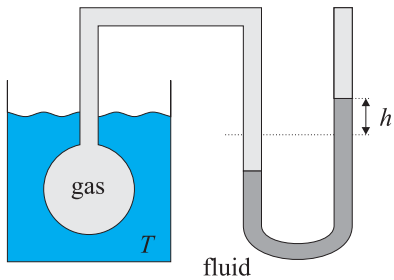

Figure 19.4: (a) Gas thermometer.

The aforementioned *Celsius* temperature scale is widely used in everyday life. In scientific applications, the *Kelvin* (or absolute) scale is mostly employed. We will see later, that it is based on microscopic properties of matter. The zero on this scale corresponds to the temperature at which all energy (except zero point fluctuations) is removed from the system. The scale is related to the Celsius scale through the expression: $T_\mathrm{K} = \frac{1\,\mathrm{K}}{1\,^\circ\mathrm{C}} T_\mathrm{C} + 273.15\,\mathrm{K}$. Another scale only used the USA is the *Fahrenheit* scale, which is related to the Celsius scale through the expression: $T_\mathrm{F} = \frac{9\,^\circ\mathrm{F}}{5\,^\circ\mathrm{C}} T_\mathrm{C} + 32\,^\circ\mathrm{F}$.

19.1.1.1 Ideal and real gases

The *equation of state* of a system is a mathematical relationship between the various macroscopic quantities that define the state of the system. In general, knowing the state equation allows to compute all thermodynamic properties of the system.

For gases with very low pressures, interactions between molecules in the system can be neglected. In this case, the gas is called *ideal* and the relationship between the macroscopic quantities that define its thermodynamic state is given by,

$$\boxed{PV = N k_\mathrm{B} T} \ . \tag{19.2}$$

where T is the absolute temperature (in K), N is the number of molecules contained in the volume V, and k_B is the Boltzmann constant. This is the most famous equation of state, and it is based on experimental observations of *Boyle*, *Mariotte*, and *Gay-Lussac*. Eq. (19.3) can also be written in terms of the number of moles, which is a quantity defined by $n = N/N_\mathrm{A}$, where N_A is Avogadro's number. In this case,

$$PV = n R_\mathrm{g} T \ , \tag{19.3}$$

where $R_g = N_A k_B = 8.314\,\mathrm{J/mol\,K} = 0.082\,\mathrm{atm\,l/mol\,K}$ is called *universal gas constant*.

The gas thermometer and the barometric formula are examples of the numerous applications of the ideal gas law. In Excs. 19.1.4.1 and 19.1.4.2 we will study gas thermometers and in Excs. 19.1.4.3 to 19.1.4.6 applications of the barometric formula. Real gas models will be studied in Sec. 19.2.7.

19.1.2 Kinetic theory and microscopic interpretation of temperature

We will now develop a microscopic theory of temperature following a line of thought proposed by Maxwell. Let us consider a cubic box with volume V and surface A, and let us suppose that

(i) the gas is made up of a large number N of particles that collide elastically with each other and with the walls of the container;

(ii) there are no attractive forces between the particles (ideal gas approximation);

(iii) the movement is completely random, with no direction or position privileged.

We also disregard external forces. Since the movement is completely random, the average velocities are the same in the x, y, and z directions, $\bar{v}_x = \bar{v}_y = \bar{v}_z$, so that we may restrict our considerations to the x-direction.

Looking at a small portion of the gas in the vicinity of the wall (see Fig. 19.5), we can imagine that a large number of particles will collide with this wall. We divide the particles into i classes of velocities v_{xi}, each one filled with N_i particles. Because collisions with the wall are elastic, the momentum transferred when a single particle encounters the wall of the box is,

$$\Delta p_{xi} = 2mv_{xi} \ . \tag{19.4}$$

Since half of the particles move to the left, the number of collisions in the time interval Δt is given by,

$$\# = \frac{1}{2}\frac{N_i}{V}\ Av_{xi}\Delta t \ . \tag{19.5}$$

The total change of momentum is,

$$\Delta I = \Delta p_{xi}\# = \frac{N_i m v_{xi}^2 A\Delta t}{V} \ , \tag{19.6}$$

and the pressure is,

$$P_i = \frac{\Delta I}{A\Delta t} = \frac{N_i m v_{xi}^2}{V} \ . \tag{19.7}$$

Hence, as the movement is isotropic,

$$P = \sum_i P_i = \frac{m}{V}\sum_i N_i v_{xi}^2 \equiv \frac{m}{V}\overline{v_x^2} = \frac{N}{3V}m\overline{v^2} = \frac{2}{3}N\bar{E}_{kin} \ . \tag{19.8}$$

See Excs. 19.1.4.7 to 19.1.4.8.

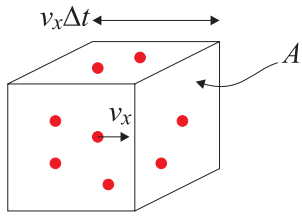

Figure 19.5: Box with N molecules colliding with the wall of a container.

Using the ideal gas state equation (19.3), Eq. (19.8) yields,

$$\boxed{\frac{3}{2}k_{\mathrm{B}}T = \frac{mv^2}{2}} \ , \tag{19.9}$$

from which we conclude that temperature is associated with translational energy of ideal gas molecules. This expression is also known as the theorem of energy *equipartition*. Generally speaking, we assign to each degree of freedom of a system the term $\frac{1}{2}k_{\mathrm{B}}T$. In the example above, we have 3 degrees of freedom, which correspond to translations in the x, y and z directions. If energy can be stored in vibrations or rotations of a molecule, we also have to assign a term $\frac{1}{2}k_{\mathrm{B}}T$ to each of these degrees of freedom.

Example 141 (*Johnson noise*): As an example demonstrating the usefulness of the energy equipartition theorem, let us consider a resistor R subject to a certain temperature T. If we associate $\frac{1}{2}k_{\mathrm{B}}T$ with the average power $\bar{P}_{\mathrm{J}}$ dissipated by the resistor within a time Δt we have,

$$\bar{P}_{\mathrm{J}}\Delta t = \frac{\bar{U}_{\mathrm{J}}^2}{R}\Delta t = \frac{1}{2}k_{\mathrm{B}}T \Longrightarrow \bar{U}_{\mathrm{J}} = \sqrt{\frac{k_{\mathrm{B}}TR}{2\Delta t}} \ , \tag{19.10}$$

that is, a small voltage $\bar{U}_{\mathrm{J}}$ appears at the resistor terminals, which is known as *Johnson noise*. For a $1\,\Omega$ resistor at ambient temperature we find $\bar{U}_{\mathrm{J}} \approx 4.0\,\mathrm{nV}$ averaged over 1 second. This voltage is small, but must be taken into account in high precision measurements.

19.1.2.1 Thermal expansion

When we heat a solid, it generally changes size. This is due to the fact that the potential energy between its constituents, atoms or molecules idealized as being connected by springs, has non-harmonic terms, as shown in Fig. 19.6(a). As we increase temperature, we give more energy to the system and the atoms of the solid vibrate with great amplitude, producing on average a greater separation between the constituents of the system.

The variation in the length of a solid along a direction $i = x, y, z$ follows the law,

$$\Delta L_i = \alpha L_i \Delta T \ , \tag{19.11}$$

where α is called the linear expansion coefficient and characteristic for each material, as shown in Tab. 19.1, although it generally also depends on temperature. Consequently,

$$L_i = L_{i0}(1 + \alpha\Delta T) \ . \tag{19.12}$$

The surface expansion of a body is then, with $A = L_1 L_2 = L_{10} L_{20} + 2\alpha L_{10} L_{20} \Delta T + L_{10} L_{20} \alpha^2 \Delta T^2$ and assuming α to be very small,

$$\Delta A \simeq A_0 2\alpha \Delta T \ . \tag{19.13}$$

Similarly, volumetric expansion is described by,

$$\Delta V \simeq V_0 3\alpha \Delta T \ . \tag{19.14}$$

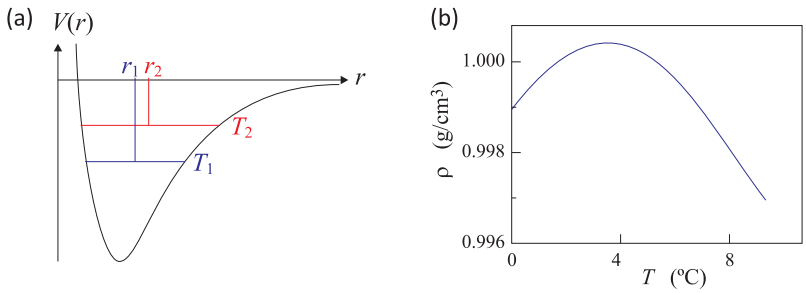

Figure 19.6: (a) Interaction energy between two atoms. (b) temperature-dependence of the density of water.

Table 19.1: Expansion coefficient, compressibility, and heat capacity coefficients ($C_P(T) = a + bT + c/T^2$) for selected materials at 298 K.

material	$\alpha \times 10^6$	$\kappa \times 10^7$	a	$b \times 10^3$	$c \times 10^{-5}$
	(K^{-1})	(bar^{-1})	(J/K)	(J/K^2)	(J K)
aluminum	23.5	12	20.7	12.3	-
silver	-	-	21.3	8.5	1.5
graphite	-	340	-	-	-
diamond	-	-	9.12	13.2	-

invar	0.7	-	-	-	-
silica glas	22.2	42	15.6	11.4	-
tungsten	-	2.9	24.0	3.2	-
pyrex	32	-	-	-	-

Liquids and gases also undergo volume variations with temperature. In this case, it is quite common to work with the fluid density instead of volume:

$$\rho = \frac{m}{V} \quad \Longrightarrow \quad \Delta\rho = -\frac{m}{V^2}\Delta V = -\frac{m}{V^2}\gamma V \Delta T \ , \tag{19.15}$$

where γ is the volumetric expansion coefficient. Therefore, $\Delta\rho = -\gamma\rho_0\Delta T$. In general, γ is positive, and the density of the fluid decreases with temperature. An exception to this rule is the case of water, as shown in Fig. 19.6(b), which below 4 °C it has $\gamma < 0$ and thus, between 4 °C and 0 °C the density increases with the temperature. This explains why during winter lakes freeze starting from the surface. Do the Excs. 19.1.4.9 to 19.1.4.12.

19.1.3 Heat and work

When we place two bodies with different temperatures in thermal contact, there is a transfer of energy from one body to the other so that the two temperatures evolve towards a common value. The energy transferred is called *heat*. We cannot say that a body at a given temperature contains a certain amount of heat. Heat is the *change in energy* between one state and another. In this sense, heat is very similar to mechanical work, and we will denote this fact by assigning to both the symbol δ, that is δQ for heat changes and δW for work executed.

Analogously to mechanical inertia, a body has a certain heat inertia called *heat capacity*, which is the capacity of a body to retain thermal energy. The formal definition of heat capacity is,

$$\boxed{C \equiv \frac{\delta Q}{dT}} \ . \tag{19.16}$$

The unit of heat is the Joule J, but it is also very common to use the calorie, which is the amount of heat required to raise the temperature of 1 g of water from 14.5 °C to 15.5 °C. The mechanical equivalent of a calorie is 1 cal = 4.184 J. The unit of heat capacity is therefore J/°C. Do the Excs. 19.1.4.13 to 19.1.4.14.

Instead of heat capacity, it is common to use the *specific heat* defined as,

$$c \equiv \frac{C}{m} \ , \tag{19.17}$$

where m is the mass of the system. Hence,

$$\delta Q = mc\ dT \ , \tag{19.18}$$

meaning that when a certain amount of heat is given to the system, this one increases its temperature. This expression, however, is not always valid. For example, upon phase transitions from solid to liquid or from liquid to gas, the temperature does not change when heat is supplied to the system. For a certain mass m of material, the heat supplied for the phase transition to occur is,

$$\delta Q = mL \ , \tag{19.19}$$

where L is called the *latent heat* of fusion or evaporation.

When several bodies are placed in thermal contact, heat flows between them in such a way that,

$$\sum_{i=1}^{N} \delta Q_i = 0 \ . \tag{19.20}$$

This is due to energy conservation, and this property is important for the determination of the specific heat of any of the bodies. When heat stops flowing, the bodies are all in thermal equilibrium and, in this case, the 0th law of thermodynamics applies: *If a body A is in thermal equilibrium simultaneously with bodies B and C, then B is in equilibrium with C.*

19.1.3.1 Heat transport

Heat can be transported in three different ways: through conduction, radiation or convection. In the case of *conduction*, although a material medium conducting the heat is needed, no mass is transported. In a solid, molecules in the hot part of the solid vibrate with large amplitudes and transmit this vibration via collision to neighboring molecules. In metals, conduction electrons also participate in the heat transport mechanism.

In the case of *convection*, heat is transported via displacement of masses. When part of a fluid is heated, density and/or pressure variations cause matter to move and carry heat from one volume to another. One already mentioned example is a freezing lake, where cold and therefore less dense water moves to the surface. When the fluid is forced to move due to the action of some external agent, for example a fan, we speak of forced convection.

The third way of transporting heat is through *radiation*. In this case, the presence of a material medium is not required to transmit energy. This transport is caused by (mostly infrared) electromagnetic radiation, which is emitted from any hot body.

In the following we will concentrate on heat transport through conduction. Let us consider a bar of cross section A and length L, whose ends are in thermal contact with two bodies maintained at constant temperatures T_1 and $T_2 < T_1$, as shown in Fig. 19.7. For given position x along the bar, the amount of heat per unit of time (thermal current) crossing the surface A at that position depends on the following factors:

(i) Type of bar material. – There are materials that conduct heat better than others, e.g. copper conducts heat better than steel. A measure is provided by the thermal conductivity K.

(ii) The cross section A. – The larger it is, the greater the thermal current, as more atoms are participating in the conduction process.

(iii) The temperature gradient. – The thermal current depends on the difference in temperature between adjacent layers of atoms (left and right of the plane at position x).

Based on the above considerations, we can write the following expression for the thermal current H:

$$H = \frac{\delta Q}{dt} = -KA\frac{dT}{dx} \ . \tag{19.21}$$

If the bar is thermally insulated, as is the case in Fig. 19.7, the current is conserved, that is, all the heat entering one end of the bar will come out at the other, as there are no losses. In this situation, H is independent of x and, consequently, $\frac{dT}{dx}$ is constant.

Hence,

$$\frac{dT}{dx} = \frac{T_2 - T_1}{L} \ , \tag{19.22}$$

and consequently,

$$H = KA\frac{T_2 - T_1}{L} \ . \tag{19.23}$$

In this case, the temperature distribution is a straight line, as shown in Fig. 19.7(b). On the other hand, if the lateral surface of the bar is not insulated, there will be heat losses by convection and the thermal current decreases as x increases. In this case, $\frac{dT}{dx}$ also decreases and, as a consequence, we have a temperature distribution like the one illustrated by the dotted line in Fig. 19.7(b).

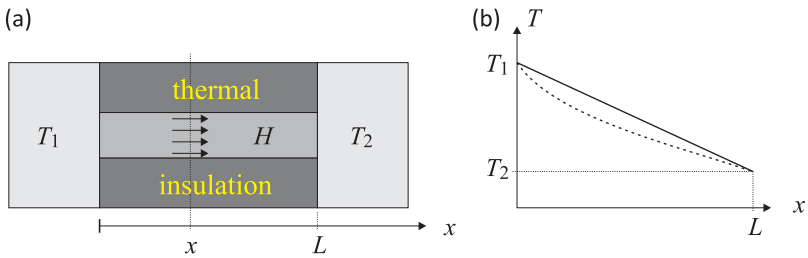

Figure 19.7: (a) Heat conduction through a laterally insulated bar. (b) Temperature distribution along an insulated bar (a) and not isolated (b) laterally.

We will now analyze two examples where the equation of conductivity (19.23) applies.

Example 142 (*Thermal conduction along rods*): In the first example, we will consider two bars having the same cross-section, but made of different materials and thus having different conductivities, as shown in Fig. 19.8(a). The bars are thermally insulated on their (upper and lower) sides. We want to determine the temperature at the junction between the two bars. As the bars are insulated, the thermal current is constant and, therefore:

$$H = K_1 A\frac{T_1 - T}{L_1} = K_2 A\frac{T - T_2}{L_2} \ , \tag{19.24}$$

yielding,

$$T = \frac{K_2 L_1 T_2 + K_1 L_2 T_1}{K_2 L_1 + K_1 L_2} \ . \tag{19.25}$$

Substituting this in the expression for H we get,

$$H = \frac{K_1 K_2 A}{K_2 L_1 + K_1 L_2}(T_1 - T_2) \ . \tag{19.26}$$

In the particular case in which $K_1 = K_2$ we recover the result (19.23) derived for a single isolated bar. The temperature distribution along the bars depends on the ratio between K_1 and K_2. If $K_1 > K_2$, we have the temperature distribution shown in Fig. 19.8(b).

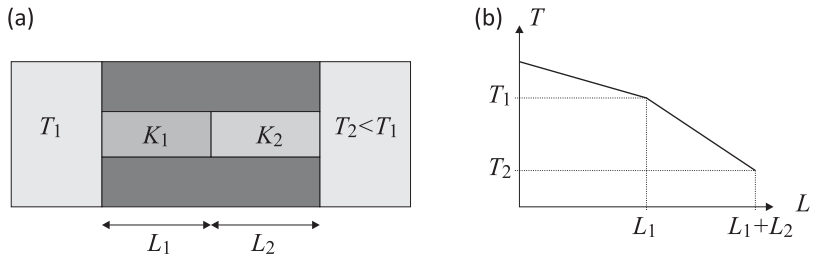

Figure 19.8: (a) Bars of different materials placed in series. (b) Temperature distribution along two bars of different materials placed in series.

Example 143 (*Thermal conduction in a hollow cylinder*): As a second example, let us consider a hollow cylinder with outer radius b and inner radius a. The inner part of the cylinder is kept at a temperature T_1, while the external temperature is maintained at T_2 ($T_2 < T_1$). The length of the cylinder is L and the conductivity is K. The orientation of the thermal current is obviously radial. The area is given by $A = 2\pi r L$ and, therefore:

$$H = -KA\frac{dT}{dr} = -K2\pi r L\frac{dT}{dr} \ . \tag{19.27}$$

As H is constant, since there are no losses, we can integrate this equality between $a \leq r \leq b$ assuming $T_1 \geq T \geq T_2$. We find the result,

$$H = \frac{2\pi LK}{\ln(b/a)}(T_1 - T_2) \ . \tag{19.28}$$

Let us now briefly cover the other two types of heat transmission mentioned in the beginning. In the case of convection, we are typically interested in the following type of problem: given a body at a temperature T surrounded by atmospheric air colder by an amount ΔT, how much heat does it lose per unit of time? The thermal current from the body to the air is described by a similar formula as thermal conduction,

$$H = hA\Delta T \ , \tag{19.29}$$

where A is the area through which heat is being lost and h is a number that depends on ΔT (in general $h \propto \Delta T^{1/4}$), the geometry of the body and its orientation in space (since convection is due to the fact that hot air rises). Therefore, a lying plate has a different h as compared to a standing plate.

Heat transport by radiation is proportional to T^4, where T is the absolute temperature (in Kelvin):

$$R = e\sigma T^4 \ . \tag{19.30}$$

Here, R is the thermal current emitted per unit area, e is the emissivity of the body ($0 \leq e \leq 1$), and σ is the Stefan-Boltzmann constant. Do the Exc. 19.1.4.15 to 19.1.4.18.

19.1.3.2 Work

Heat can be injected into a system in various ways, e.g. via thermal contact with a reservoir, via electrical dissipation or discharge, or by carrying out mechanical work. The amount of energy (translational, rotational and vibrational) contained in a system is called *internal energy*. The law of energy conservation demands that the heat δQ supplied to a system is used to change its internal energy E and/or to perform mechanical work δW. This principle is known as the 1st law of thermodynamics and can be expressed mathematically as:

$$\boxed{dE = \delta Q + \delta W} \ . \tag{19.31}$$

Let us consider an ideal gas contained in a cylinder with a piston, as shown in Fig. 19.3(a). By moving the piston, it is possible to compress or expand the gas, and in this process there will be pressure and/or temperature variation, since these variables are linked by the ideal gas equation (19.3).

Now, we imagine that the pressure P of the gas is greater than the atmospheric pressure. In this situation, the gas will try to push the piston out of the cylinder. If the piston slowly moves by a distance dx, the work done by the gas will be,

$$\delta W = F dx = P A dx = P dV \ , \tag{19.32}$$

where A is the cross area of the piston and $dV = A dx$ is the variation of volume during expansion. Thus, if the gas expands from a volume V_1 to a volume V_2, the total work done is,

$$W = \int_{V_1}^{V_2} P dV \ . \tag{19.33}$$

If we follow the evolution of pressure with volume on a PV diagram, as in Fig. 19.9(a), the work done by the gas will be the area under the curve. This area obviously depends on how the gas is taken from point 1 to point 2: the area under the path (i) is different from that under the path (ii). This means that work can be done along a closed path, as shown in Fig. 19.9(b): The system initially undergoes an isochoric transformation (constant volume), followed by a isobaric one (constant pressure), then again an isochoric, and finally an isobaric transformation. The area under the curve (i) corresponds to the work $P_1(V_2 - V_1)$, and the area under the curve (ii) to the work $P_2(V_1 - V_2)$. Although the processes are different, they produce the same variation in the internal energy of the gas $\Delta E = E_2 - E_1$, as this only depends on the initial and final states of the system. For a closed loop the total change in internal energy is zero, $\Delta E = 0$, and therefore, by the 1st law of thermodynamics, the transferred heat must compensate the executed work,

$$\delta W = -\delta Q \ . \tag{19.34}$$

The internal energy of an ideal gas, as we discussed previously, essentially comes from the kinetic energy of its constituents,

$$\boxed{E = \tfrac{3}{2} N k_{\text{B}} T} \ , \tag{19.35}$$

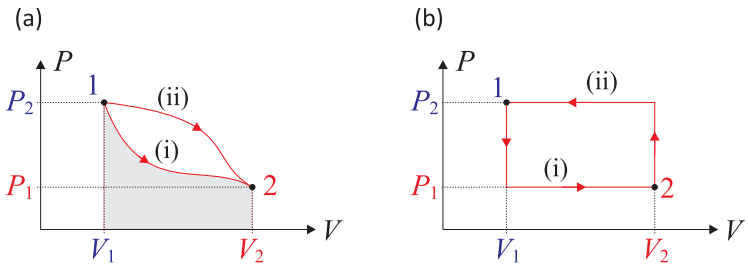

Figure 19.9: (a) PV diagram of a gas showing work carried out in two different processes leading from an initial state (1) to a final state (2). (b) Work performed in a complete gas cycle.

that is, for processes maintaining the temperature constant, $\Delta E = 0$. This relationship was experimentally verified by *Joule*, who found that when a gas adiabatically expands (without heat exchange nor work executed) its temperature stays constant.

After the warm-up provided by the previous sections, let us now start setting up the framework of phenomenological thermodynamics in the following sections.

19.1.4 Exercises

19.1.4.1 Ex: Gas thermometer

A gas thermometer filled with an ideal gas and working at a constant volume is calibrated on the one hand in dry ice (carbon dioxide in its solid state at a temperature of $-80.0\,°\mathrm{C}$) and on the other hand in boiling alcohol ($78.0\,°\mathrm{C}$). At these respective temperatures, the pressure in the gas thermometer is $0.900\,\mathrm{bar}$ or $1.635\,\mathrm{bar}$. At absolute zero, the gas in the thermometer is still gaseous, but the pressure has dropped to $0.000\,\mathrm{bar}$.
a. At what °C is the absolute zero?
b. What is the pressure at the freezing point of water and what is it at the boiling point?

19.1.4.2 Ex: Gas thermometer

A gas thermometer 'a is connected to a second gas thermometer 'b, which is kept in a water bath at a constant temperature. The connecting capillary has a cross-sectional area A and is filled with mercury ($\rho = 13.5\,\mathrm{g/cm^3}$). At the same temperature T_0 in the two thermometers, the mercury level in both capillaries is the same. Now the gas in thermometer 'a' is heated by ΔT. This increases the pressure P_a and thus the volume $V_a \to V_a + \Delta V$. The mercury column is displaced accordingly.
a. What is the relationship between the volume increase ΔV and the temperature increase ΔT in this setup?
b. To simplify, assume that the volumes $V_a = V_b = V_0$ and thus the particle numbers $N_a = N_b = N_0$ are the same. How much has the temperature of the gas in thermometer 'a' increased if the following conditions exist in the coupled thermometer: $N_0 = 10^{22}$, $h = 5\,\mathrm{mm}$, $T_0 = 300\,\mathrm{K}$, $V_0 = 1000\,\mathrm{cm^3}$, $A = 1\,\mathrm{cm^2}$?

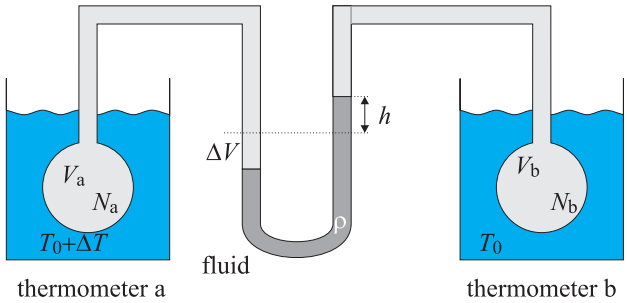

Figure 19.10: Gas thermometer.

19.1.4.3 Ex: Barometric formula

The air pressure P at a height h is equal to the weight mg of the air column, which at this height rests on an (imaginary) horizontal base divided by the base area A of the column [$m = m(h)$: mass of the air column, neglect the curvature of the Earth and the height dependence of the temperature]. Therefore, we have for the change dP of the pressure upon a small change of height dh, with the local density $\rho = \rho(h)$:

$$dP = \frac{g\,dm}{A} = \frac{g\rho\,dV}{A} = -g\rho\,dh\ . \tag{19.36}$$

Here $dV = -A\,dh$ is the change in volume of the air column (located above the base). The air should be treated approximately as a substance with a uniform molar mass $\tilde{M}$.
a. Show with the help of the ideal gas equation that Eq. (19.36) can be cast into the form $dP = -kP\,dh$ under the given conditions with the constant k. Which is the expression for k?
b. What is the integral relationship $P = P(h)$? At what height h is the air pressure at $T = 273\,\mathrm{K}$ and $\tilde{M} = 29\,\mathrm{g/mol}$ only half the size of $P(0)$?
c. What is the air pressure on the Mont Blanc (4794 m) and the Mount Everest (8848 m) at $T = 273\,\mathrm{K}$ as compared to $P(0)$ at sea level? How big is the pressure difference ΔP compared to normal zero on the Tübingen market place ($h = 341\,\mathrm{m}$)?

19.1.4.4 Ex: Barometric formula

The barometric height formula is usually derived assuming constant temperature. Now suppose that the temperature depends on the height h above the surface of the Earth according to the relationship $T = T_0/(1 + \alpha h)$.
a. Show that the pressure p then must satisfy the following differential equation,

$$\frac{dP}{dh} = -\frac{mg}{k_\mathrm{B}T_0}(1 + \alpha h)P\ .$$

b. Find the solution to this differential equation. What is the sign of the constant α? Is the pressure at a fixed height larger or smaller than the value resulting from the height formula at a fixed temperature?

19.1.4.5 Ex: Depth gauge

You want to build a depth gauge for diving operations and take advantage of the compressibility of air. To do this, you take a glass cylinder with a movable flask (volume $V = Ax$, footprint A) and a millimeter scale located in the flask. To what water depth h can the device deliver the targeted measuring accuracy of $\pm 1\,\mathrm{m}$, if the piston position x can be read with an accuracy of $\pm 1\,\mathrm{mm}$ and $x(P_0) = 0.2\,\mathrm{m}$ at the water surface?

19.1.4.6 Ex: Scuba diving

A diver is at a water depth of h_0 and breathes air from a compressed air bottle. When exhaling, he creates (spherical) air bubbles with the volume V_0. Assume that the surface water temperature is T_1 and decreases evenly to a depth of h_0 by an amount of temperature α per meter.
a. Assume a constant water density ρ and calculate the pressure P depending on the water depth at an atmospheric pressure P_1.

Figure 19.11: Jacques Mayol

b. Calculate the volume of the bubbles as a function of water depth. How big is the volume just below the water surface? Why is it important for the diver to exhale continuously as he ascends?
Numerical values: Water depth $h_0 = 40\,\mathrm{m}$, $V_0 = 1\,\mathrm{cm}^3$, $T_1 = 20\,°\mathrm{C}$, $\alpha = 0.2\,°\mathrm{C/m}$, $\rho = 1\,\mathrm{kg/L}$, and $P_1 = 1013\,\mathrm{hPa}$.

19.1.4.7 Ex: Particle collisions with a container

How many particle collisions Z does a wall surface $A = 1\,\mathrm{dm}^2$ experience in $\Delta t = 1\,\mathrm{s}$ at $T = 298\,\mathrm{K}$ and $P = 1\,\mathrm{bar}$ through the particles of an ideal gas, if $\langle |v_x| \rangle$, the mean value of the particle velocity in the x direction, has the value $330\,\mathrm{m/s}$?
Hint: Imagine a cuboid box in an xyz coordinate system and assume the wall surface of interest as one of the cuboid surfaces perpendicular to the x-axis. The width of the box is Δx, so its volume is $V = A \cdot \Delta x$. There is a simple relationship for the mean number $\langle \nu_x \rangle$ of impacts that a single particle does exert on the wall within a time Δt depending on Δx, Δt and $\langle |v_x| \rangle$. To get Z you have to consider that the gas contains N particles.

19.1.4.8 Ex: Kinetic pressure

A closed box with end face A and side length L is divided into two equal halves by a movable plate (see figure). Both halves contain one mole of helium under a pressure of P_0. The movable plate is now shifted to the right by the distance x. The shift takes place at constant temperature $T = 20\,°\mathrm{C}$.
a. Give the volume of the right or left sub-box as a function of x. Give the pressure in the right or left sub-box as a function of x.
b. Calculate the work W that needs to be done to move the plate from $x = 0$ to $x = L/4$. Specify W in Joules.

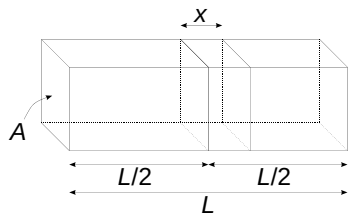

Figure 19.12: Ideal gas in a box.

19.1.4.9 Ex: Bi-metal

Two bars of different materials, with lengths, Young's modules and thermal expansion coefficients given respectively by L_1, L_2, Y_1, Y_2, α_1, and α_2, are pinched between two walls, as shown in Fig. 19.13. Calculate the distance traveled by the junction point of the bars when the system is heated by an amount ΔT. What is the tension on the bars?

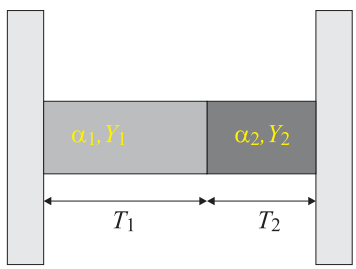

Figure 19.13:

19.1.4.10 Ex: Bi-metal

In the sketched construction two thin metal strips with different linear expansion coefficients (aluminum and copper) $\alpha_{\mathrm{Al}} = 24 \cdot 10^{-6}\,\mathrm{K}^{-1}$ and $\alpha_{\mathrm{Cu}} = 17 \cdot 10^{-6}\,\mathrm{K}^{-1}$ are connected to each other by $L = 10\,\mathrm{cm}$ bars so that they have a fixed distance $d = 1\,\mathrm{mm}$. When the temperature increases, the two strips expand so that they form circular segments with different radii, as shown in the figure. An angle of the circle segment of $\phi = 1°$ is measured. How big is the temperature increase?

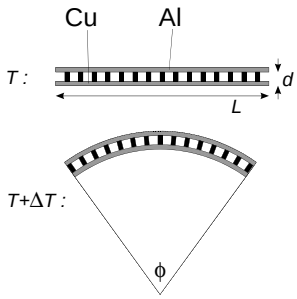

Figure 19.14: Bimetal.

19.1.4.11 Ex: Linear expansion

The length of a 10 cm long spacer made of quartz glass with linear expansion coefficient $\alpha_1 = -1\,\mathrm{cm/m/°C}$ is to be kept constant by using a spacer made of Invar steel with a linear expansion coefficient $\alpha_1 = 10\,\mathrm{cm/m/°C}$. How long must the spacer be?

19.1.4.12 Ex: Thermal expansion

Consider a solid body with momentum of inertia I. Show that due to a small temperature variation ΔT, this momentum varies by $\Delta I = 2\alpha\Delta T$, where α is the linear expansion coefficient. With this result, calculate how much the period of a physical pendulum varies when subject to a temperature variation ΔT.

19.1.4.13 Ex: Heat capacity and energy of air

a. How many air molecules are in one kilogram of air, knowing that air has the relative molecular mass $m_{\mathrm{air}} \approx 29u$.
b. Supposing air is essential composed of oxygen and nitrogen, what is are the relative abundances of both elements.
c. Estimate the molar and specific heat capacities of air.
d. Calculate the kinetic energy as well as the average molecular velocity in 1 kg of air at $T = 300\,\mathrm{K}$.

19.1.4.14 Ex: Calorimetry

a. A calorimeter initially contains a volume of $V_1 = 100\,\mathrm{mL}$ of water in thermal equilibrium with the calorimeter at temperature $T_1 = 15\,°\mathrm{C}$. Now we add a volume $V_2 = 100\,\mathrm{mL}$ of water at temperature $T_2 = 40\,°\mathrm{C}$. After reaching thermal equilibrium again, the temperature becomes $T_{\mathrm{f}} = 25\,°\mathrm{C}$. What is the heat capacity of the calorimeter?
b. Starting from the final condition of the previous item, we add to the calorimeter a metallic body with mass $m_3 = 80\,\mathrm{g}$ and temperature $T_3 = 90\,°\mathrm{C}$. After reaching thermal equilibrium again, the temperature becomes $T_{\mathrm{ff}} = 35\,°\mathrm{C}$. What is the specific heat of the body?

19.1.4.15 Ex: Thermal conduction

Show that the thermal current in a substance of conductivity K located between the surfaces of two concentric spheres is given by:

$$\frac{dQ}{dt} = H = (T_1 - T_2)\frac{4\pi k r_1 r_2}{r_2 - r_1} \ ,$$

where r_1 and r_2 are respectively the radii of the inner and outer surfaces and $T_1 > T_2$.

19.1.4.16 Ex: Thermal conduction

A bar with thermal expansion coefficient α and Young's modulus Y $\left(\frac{F}{A} = Y\frac{\Delta L}{L}\right)$ is stuck between two walls, as shown in Fig. 19.15. Calculate the stress in the bar when the temperature is increased by ΔT.

Figure 19.15:

19.1.4.17 Ex: Thermal conduction

Find the temperature gradient and thermal current in a bar of conductivity K, length L and irregular cross section, as shown in Fig. 19.16.

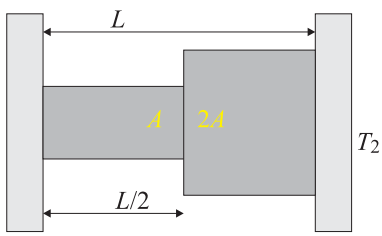

Figure 19.16:

19.1.4.18 Ex: Tramway

A tram with mass $m_{\mathrm{B}} = 12500\,\mathrm{kg}$ brakes from a speed $v = 57.6\,\mathrm{km/h}$ to standstill. What is the temperature of the eight cast iron brake blocks when the mass of each block is $9.0\,\mathrm{kg}$ and 60% of the kinetic energy flows into the heating of the blocks?

19.2 Canonical formulation of thermodynamics

Thermodynamics is different from other physical theories, such as classical mechanics, electrodynamics or quantum mechanics, in the sense that it describes phenomena emerging from the presence of large numbers of identical (microscopic) subsystems, which are absent in the individual subsystems, in particular the tendency of large (macroscopic) systems to evolve towards certain equilibrium states. This claim makes thermodynamics pervasive and applicable to all kind of systems that can appear to be completely different. Its task is to provide a way of organizing information on the behavior of systems, generating phase diagrams and data bases on their physical and chemical properties.

Following textbook didactics we approach the area of thermodynamics in two main steps. The first step, outlined in the present chapter 19, is known as *phenomenological thermodynamics*. It ignores the microscopic composition as far as possible. We will, however, see that certain features of the microscopic subsystems can have crucial impact on the macroscopic behavior. This step attempts to structure the macroscopic observations by identifying characteristic physical quantities and formulating laws governing their dynamics.

In the second step, exposed in the subsequent chapter 29, is called *statistical thermodynamics*. It aims at explaining the laws found in phenomenological thermodynamics by deriving them from features of the microscopic subsystems. In particular, some subsystems are small (or cold) enough to behave according to the rules of quantum mechanics, and this can have an important impact on the macroscopic behavior. This is studied in the field of quantum statistics exposed in Sec. 29.2.

The methods introduced in the first two chapters will be illustrated with simple examples (mainly ideal gases and solids). In Chp. 20 we apply them to complex real systems, e.g. multi-component, heterogeneous, or chemically interacting systems.

19.2.1 Tackling thermodynamic systems

The subject of thermodynamics are many-body *systems* the properties of which are characterized by physical quantities, called *thermodynamic variables*, and their *relationships*. We will now attempt to structure the fundamental concepts of the field following the textbook of DeHoff [239].

19.2.1.1 Classification of thermodynamic systems

Before starting to tackle a new unknown system, trying to characterize all of its properties, it is always a good idea to classify them in order to identify those properties which are essential for the information we want to extract from the system. This prevents a waste of efforts into gathering irrelevant data and provides a guideline for the system's characterization. In general a system can be

1. *unary* or *multicomponent* (e.g. a gas of pure argon or atmospheric air),

2. *homogeneous* or *heterogeneous* (e.g. a single phase or two coexisting phases like water and vapor),

3. *closed* or *open* (e.g. isolated from environment or exchanging energy or particles),
4. *non-reacting* or *reacting* (e.g. the molecules of a two-component system may react to form a third component),
5. otherwise *simple* or *complex*.

At first we will exemplify the introduced concepts mostly restricting to unary, homogeneous, closed, non-reacting, otherwise simple systems. In later sections, we will turn our attention to complex systems.

19.2.1.2 State functions and process variables

Thermodynamic variables fall into two distinct classes, *process variables* and *state functions*.

The state of stationary thermodynamic systems may be expressed by *state functions* (or state variables), whose values only depend upon the current state of the system. The most common ones are temperature, pressure, entropy, volume, particle number, chemical potential, and internal energy,

$$T, S, P, V, N, \mu \ . \tag{19.37}$$

The pressure and volume may be replaced by other mechanical variables. Their equilibrium dynamics is confined to trajectories obeying so-called *state equations*, that is, functional relationships such as,

$$f(T, S, P, ...) = 0 \ , \tag{19.38}$$

or their illustration in phase diagrams, such as the one shown in Fig. 19.2. Such state equations are obviously extremely useful, as they allow to abstract from the physical process which led to a particular state of a system, and which might be very complicated. In fact, their discovery represents one of the major achievements of thermodynamics.

In contrast to state functions, the values of *process variables* depend upon the path followed by the process. Consequently, they only have a meaning for changing systems, i.e. for systems traversing a sequence of different states. The process variables fall into two categories, *mechanical work* and *exchanged heat*,

$$\delta Q, \delta W \ . \tag{19.39}$$

The concept of *work* is developed in classical mechanics as the path integral over a force acting on a body along a given path, $W = \int_S \mathbf{F}(\mathbf{s}) \cdot d\mathbf{s}$, and it can be brought into the context of thermodynamics considering, e.g. a piston working against the pressure of a confined gas, as illustrated in Fig. 19.3. Work depends on changes $d\mathbf{s}$ and thus cannot be associated with stationary systems. Any of the forces known in physics, inertial forces in accelerated or rotating systems, electromagnetic forces, or molecular forces, can work.

Work is associated with a displacement of macroscopic matter, e.g. the movement of a piston. Systems may, however, *exchange energy without net displacement of masses via the exchange of heat*. By itself the notion of a 'quantity of heat' in a system is meaningless. Only the amount of heat exchanged with another system in a given process can be quantified.

19.2.1.3 Extensive and intensive properties

State functions can further be classified into extensive and intensive variables of the system. To understand the difference, we imagine the system under consideration subdivided into smaller, identical and not interconnected subsystems. Now, an *intensive variable* describes a *global property*, i.e. a property that does not depend on the system size or the amount of material in the system, for example, temperature or the hardness of an object. No matter how small a diamond is cut, it maintains its intrinsic hardness. Intensive variables are those which can be represented as a *field*, such as the local temperature variation $T(\mathbf{r})$ across the system or the pressure variation in the barometric formula. Nevertheless, intensive properties can also be derived from extensive ones via the concept of *densities*, e.g. the local particle density $n(\mathbf{r}) \equiv dN/dV$. In general, the ratio of two extensive properties is scale-invariant and hence an intensive property.

Examples of intensive parameters are: the chemical potential, concentration, density (or specific gravity), ductility, elasticity, electrical resistivity, hardness, magnetic field, magnetization, malleability, melting point and boiling point, molar absorptivity, pressure, specific energy.

By contrast, an *extensive variable* adds up when independent, non-interacting subsystems are combined. The property is proportional to the amount of material in the system. For example, both the mass and the volume of a diamond are directly proportional to the amount that is left after cutting it from the raw mineral. Mass and volume are extensive properties. An extensive variable characterizes the system as a whole, e.g. the volume of a recipient, the number of enclosed particles, the internal energy or the entropy.

In uniform systems the value of intensive variables does not change, so that the system is characterized by a unique value. This is useful for the description of systems in equilibrium. However, it does not mean that intensive quantities turn into extensive ones. Intensive properties cannot exclusively depend on extensive ones. For example, in the ideal gas equation extensive and intensive quantities are interrelated in such a way that the two intensive quantities $P = P(\mathbf{r})$ and $T = T(\mathbf{r})$ are proportional to each other. Extensive properties can be expressed as integrals of intensive ones over the extend of the system, e.g. $N = \int_V n(\mathbf{r}) d^3r$.

Examples of extensive parameters are: energy, entropy, Gibbs energy, length, mass, particle number, momentum, number of moles, volume, magnetic moment, electrical charge, weight.

19.2.1.4 Classification of thermodynamic relationships

The thermodynamic variables characterizing a system, the state function as well as the process variables, are interrelated by mathematical expressions, and the apparatus of thermodynamics allows to generate connections between new sets of variables, thus leading to an unmanageable number of expressions. It is thus helpful to introduce a classification of thermodynamic relationships into

1. *thermodynamic laws* forming the physical basis for all other relations;

2. *definitions* of new quantities expressed in terms of previously formulated variables with the motivation of simplifying the description of specific classes of

systems;

3. *coefficient relations* between differential forms emerging from the description of changes in state function;

4. *Maxwell relations* relating second derivatives to one another and reflecting the fact that the order of differential operators can be switched; and finally

5. *equilibrium conditions*, which are sets of equations describing the relationships between state functions to be satisfied in a system at equilibrium and used for establishing maps and phase diagrams.

The concept of equilibrium is central to thermodynamics. It describes a situation in which a system coupled to an environment *does not change its state autonomously.* The situation is expressed by a set of equations called equilibrium conditions, relating internal properties of the system.

Example 144 (*Thermodynamic relationships*): Examples for definitions are,

$$H \equiv E + PV \qquad \text{or} \qquad C_P \equiv \left(\frac{\partial E}{\partial T}\right)_{N,P} .$$

An example for a coefficient relation emanating from the real gas equation $T = T(P,V) = \frac{1}{Nk_\mathrm{B}}(P+P^*)(V-V^*)$ is,

$$dT = AdP + BdV = \left(\frac{\partial T}{\partial P}\right)_V dP + \left(\frac{\partial T}{\partial V}\right)_P dV = \frac{V-V^*}{Nk_\mathrm{B}}dP + \frac{P+P^*}{Nk_\mathrm{B}}dV .$$

An example for a Maxwell relation using the above example is,

$$\left(\frac{\partial A}{\partial V}\right)_P = \left(\frac{\partial}{\partial V}\left(\frac{\partial T}{\partial P}\right)_V\right)_P = \left(\frac{\partial}{\partial P}\left(\frac{\partial T}{\partial V}\right)_P\right)_V = \left(\frac{\partial B}{\partial P}\right)_V .$$

Finally, an example for an equilibrium condition considering a mixture of two gases 1 and 2, is the request that their temperatures be equal, $T_1 = T_2$.

19.2.2 The laws of thermodynamics

The laws of thermodynamics are highly condensed expressions forming the basis of empirical thermodynamics. Although not deduced from fundamental principles, they are universal, general, and pervasive. Before discussing them in detail, let us enunciate them altogether:

0. The zeroth law affirms that two systems each one in thermal equilibrium with a third are in equilibrium themselves,

$$T_1 = T_2 \ \wedge \ T_2 = T_3 \quad \Longrightarrow \quad T_1 = T_3 . \tag{19.40}$$

1. The first law states that the total energy is always conserved,

$$dE = \delta Q + \delta W . \tag{19.41}$$

2. The second law states that the entropy of any closed system goes always increasing,

$$dS \geq 0 \ . \tag{19.42}$$

3. The third law states that for $T \to 0$, the entropy difference between systems connected by a reversible process vanishes,

$$\lim_{T \to 0} S = 0 \ . \tag{19.43}$$

This last law has its origins in quantum mechanics.

19.2.2.1 The 0th law of thermodynamics

The zeroth law is a necessary assumption for the existence of a temperature scale for all substances in nature and provides an absolute measure of their tendencies to exchange heat, as already discussed in Sec. 19.1.3.

19.2.2.2 The 1st law of thermodynamics

According to the first law of thermodynamics, there is a property of the universe, called energy, which cannot change no matter what process occurs. The energy can, however, change its appearance (e.g. between kinetic, potential of internal energy), or be exchanged between subsystems or between a system and its environment across the system's boundaries. Hence, defining a thermodynamic state function called *internal energy* E of the system, the first laws states that this quantity can only increase by working on the system or by transferring heat to it. Put in this way, the statement also fixed the sign convention, see Fig. 19.17.

It its mathematical formulation the differential d represents a change in a state function, while the prefix δ just denotes an infinitesimal quantity of work or heat, but cannot be considered a differential: There is no mathematical state function W or Q of which dW or dQ could be a differential.

Despite its fundamental importance, in its form (19.41) the first law is not ready for use in practical applications, because it does not tell us how to evaluate δW or δQ.

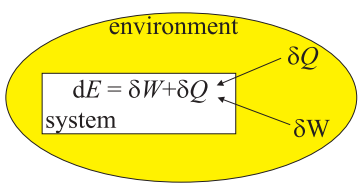

Figure 19.17: Any change of a system's internal energy is due to either work done on it or heat transferred through its borders.

19.2.2.3 The 2nd law of thermodynamics

Many processes in nature are irreversible. Although no fundamental law of physics prevents heat to flow from cold to hot places or mixed gases to spontaneously separate into the components, this is never observed. Time seems to flow in one direction. The second law of thermodynamics distills this aspect of experience and states it succinctly and quantitatively, albeit abstractly, introducing a state function called *entropy*. When summed up for a system and its surroundings, the entropy always increases [1].

While the second law postulates that any closed system always produces (or maintains) entropy ΔS_{prod}, this does not preclude entropy reduction for this system, provided the entropy can be removed from the system via transfer ΔS_{trans} through its boundaries faster than being produced. The net entropy balance of the system is then,

$$\Delta S_{\text{syst}} = \Delta S_{\text{prod}} + \Delta S_{\text{trans}} \leq 0 \ . \tag{19.44}$$

Indeed, many practical applications are based on entropy reduction in subsystems, e.g. lasers. Since entropy transfer between a system and its environment does not change the overall entropy balance, the total entropy production of the universe, consisting of the system plus its environment, must remain positive [2].

The concept of irreversibility is intrinsically connected to the notion of spontaneous breaking of time reversal symmetry, which plays a fundamental role e.g. in quantum optics of open systems. Let us consider an atomic two-level system interacting with a light mode. While coherent processes, such as absorption and stimulated emission of a photon, maintain irreversibility, spontaneous emission into the reservoir of electromagnetic vacuum modes cannot be undone. The size of the phase space potentially occupied by the spontaneously emitted photon is simply too large to yield any reasonable probability for spontaneous reabsorption.

Processes linking systems with a relatively small number of degrees of freedom to much larger systems are called *dissipative*, and the rate of entropy production is a quantitative measure for this dissipation. It not only depends on the strength of the dissipation, but also on how far away the system is from equilibrium: the closer to equilibrium, the smaller dissipation. A quantitative treatment of the correlation between dissipation and distance from equilibrium is, however, very complicated.

For processes sufficiently slow never to move away very far from equilibrium the entropy production is correspondingly small. It completely vanishes, when the system is infinitesimally close to equilibrium, for example, exerting work in incremental steps or adding heat in incremental portions always allowing the system to equilibrate before applying the next change. Systems undergoing such processes can change their entropy only via exchange with other systems, and as no entropy is produced they are reversible. Obviously, the concept of reversibility represents an idealization, since any real process is afflicted with dissipation.

In contrast, systems undergoing quick drastic changes instantaneously deviate from equilibrium and transiently occupy states, in which entropy is produced, before they return to equilibrium. Such processes are irreversible.

[1] Note that the sign of entropy increase is fixed by convention.

[2] We may formulate a continuity-type equation for entropy density and entropy flow.

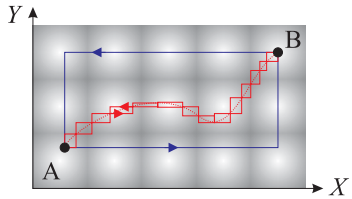

Figure 19.18: Illustration of (blue) an irreversible process forced through an inhomogeneous parameter landscape and (red) a reversible sequence of infinitesimal irreversible processes following a given path. As long as the infinitesimal processes do not recede much from equilibrium (dashed red line), entropy production can be neglected.

For reversible processes the *process variables* are readily calculated, since each intermediate state (red dashed line in Fig. 19.18) is described by just a few state functions, e.g. temperature or pressure. In contrast, this is very complicated for irreversible processes carrying the system to a state whose state functions depend on the trajectory on which the state was reached.

On the other hand, *changes of state functions* are easy to calculate also for irreversible processes, since these only depend on the initial and final states. Thus, changes in state functions for a given complex irreversible process may be calculated by substituting the process by a reversible one. E.g. in Fig. 19.18 instead of following solid red lines, we substitute them by dashed red lines connecting the same initial and final states. This procedure illustrates the fundamental role of state functions and reversible processes in thermodynamics.

Let us now analyze entropy transfer for reversible processes. Let δQ_{rev} be the heat absorbed in an infinitesimal step and T the temperature of the system. Now, although δQ_{rev} is a process variable, $\delta Q_{\text{rev}}/T$ is the differential of a state function, that is, the state function for an infinitesimal process. To prove this, it is sufficient to show that for a general cyclic process, such as the Carnot cycle, the path integral

$$\oint \frac{\delta Q_{\text{rev}}}{T} = 0 \tag{19.45}$$

vanishes. The state function $\delta Q_{\text{rev}}/T$ is defined to be the *entropy*,

$$\boxed{\delta Q_{\text{rev}} = T dS} \; . \tag{19.46}$$

The expression allows us to evaluate the heat absorbed during a reversible process by integrating a combination of two state functions, $Q_{\text{rev}} = \oint T dS$. Note, that Q_{rev} still depends on the path and thus remains a process variable.

Since entropy is a state function, the entropy change for a process can not depend on whether the process is reversible or not. That is,

$$\Delta S_{\text{rev}} = \oint \frac{\delta Q_{\text{rev}}}{T} = \Delta S_{\text{irr}} \; . \tag{19.47}$$

However, an irreversible process will also *produce* entropy,

$$\Delta S_{\text{rev}} = \Delta S_{\text{irr,trans}} + \Delta S_{\text{irr,prod}} \; , \tag{19.48}$$

with $\Delta S_{\text{irr,prod}} > 0$. Associating the irreversible entropy change not due to entropy production with irreversible heat transfer, we find,

$$\Delta S_{\text{irr,trans}} = \oint \frac{\delta Q_{\text{irr}}}{T} < \oint \frac{\delta Q_{\text{rev}}}{T} = \Delta S_{\text{rev}} \ , \tag{19.49}$$

which means that the maximum heat transport is observed for reversible processes. Or in other words, heat transfer becomes irreversible in the presence of losses causing entropy production.

An analogous treatment can also be done for work. We express reversible work by a combination of state functions,

$$\boxed{\delta W_{\text{rev}} = -PdV} \ . \tag{19.50}$$

Combining the first and second law of thermodynamics Eqs. (19.41), (19.46), and (19.50), we find for reversible processes,

$$\boxed{dE = TdS - PdV} \ . \tag{19.51}$$

19.2.2.4 The 3rd law of thermodynamics

Experiments have shown that temperature, as defined in Sec. 19.1.1, does not go below a certain value, consequently identified as *absolute zero temperature*. Experiments have also shown that all substances in any thermodynamic state have the same entropy at $T = 0$. This finding motivates the choice of setting the entropy at absolute zero temperature to zero,

$$\boxed{S(T \to 0) \to 0} \ . \tag{19.52}$$

Example 145 (*Entropy change in chemical reactions*): Experimentally, the process of heating from $T = 0$ a mixture of two atomic species to a temperature where they react to form molecules and then cooling the molecules down back to $T = 0$ is found not to produce entropy, although the initial substances are different from the final ones. This fact can be exploited for the determination of the entropy balance in chemical reactions. For example, given that the absolute entropy at 298 K for the substances Al, O_2, and Al_2O_3 are, respectively,

$$S_{\text{Al}} = 28.3\,\text{J/mol K} \quad , \quad S_{\text{O}_2} = 205.03\,\text{J/mol K} \quad , \quad S_{\text{Al}_2\text{O}_3} = 51.1\,\text{J/mol K} \ ,$$

together with the stoichiometrically balanced reaction, $2\text{Al} + \frac{3}{2}\text{O}_2 = \text{Al}_2\text{O}_3$, yields the entropy change,

$$\Delta S = S_{\text{Al}_2\text{O}_3} - (2S_{\text{Al}} + \tfrac{3}{2}S_{\text{O}_2}) = -313.19\,\text{J/mol K} \ .$$

19.2.3 Thermodynamic potentials

With the statements outlined in Secs. 19.2.1 and 19.2.2 we have laid the foundations of a conceptual world of thermodynamics. Now, we need to show how to use it in practice.

So far we defined the *process variables*

$$Q, W \tag{19.53}$$

and the *state functions*

$$P, V, T, S, E \tag{19.54}$$

appearing in the laws of thermodynamics. In very simple systems, being in equilibrium with themselves and with the environment, the state is completely fixed by *two* state variables. This means that, if two of the five enumerated state functions are known, all others can be expresses as their functions, for example, $V = V(T, P)$ or $E = E(S, V)$ for an ideal gas consisting of exactly N particles.

Furthermore, we already got in contact with *material variables*, such as thermal expansion, compressibility, heat capacity at constant pressure or at constant volume,

$$\alpha, \kappa, C_P, C_V \ . \tag{19.55}$$

These material properties may also depend on temperature or pressure. For a given substance the state equations can be computed from those properties.

The general procedure to tackle a problem is the following:

1. Identify the properties of the system about which information is available. These are the independent variables, for example, T and P.

2. Identify the properties of the system about which information is requested. This property is a dependent variable, which means that it is a function of the independent variables, for example, $V = V(T, P)$.

3. Such functions will necessarily contain material properties, which will have to be looked up from data bases.

The crucial step in this procedure is evidently the second one, which consists in finding the appropriate state function.

Another class of thermodynamic relationships, falling under the category of definitions, is the introduction of state functions with the dimension of energy known as *thermodynamic potentials*. Apart from internal energy, the potentials used in canonical ensembles are the enthalpy, the Helmholtz free energy, and the Gibbs free energy,

$$E, H, F, G \ . \tag{19.56}$$

Which one of the defined potentials is used as a state function in a particular problem is, in principle, arbitrary. However, some processes are easier to describe in terms of particular potentials. Before we define them below, let us present a useful mathematical framework facilitating the conversion between state functions called *Legendre transform*and which has already been introduced in Sec. ??.

19.2.3.1 Legendre transform in thermodynamics

Assume that for a system characterized by three state variables (X, Y, Z) we know the state function $W = W(X, Y, Z)$, so that for given system parameters (A, B, C), we know how the system will evolve upon a set of variations (dX, dY, dZ),

$$\boxed{\begin{aligned} dW &= \left(\frac{\partial W}{\partial X}\right)_{Y,Z} dX + \left(\frac{\partial W}{\partial Y}\right)_{X,Z} dY + \left(\frac{\partial W}{\partial Z}\right)_{X,Y} dZ \\ &\equiv AdX + BdY + CdZ \end{aligned}} \quad . \tag{19.57}$$

The partial derivatives A, B, C are evaluated assuming that the derived quantities do not depend on other variables. Since the order of the derivatives can be inverted, we know,

$$\begin{aligned} \left(\frac{\partial A}{\partial Y}\right)_{X,Z} &= \left(\frac{\partial}{\partial Y}\left(\frac{\partial W}{\partial X}\right)_{Y,Z}\right)_{X,Z} = \left(\frac{\partial}{\partial X}\left(\frac{\partial W}{\partial Y}\right)_{X,Z}\right)_{Y,Z} = \left(\frac{\partial B}{\partial X}\right)_{Y,Z} \\ \left(\frac{\partial A}{\partial Z}\right)_{X,Y} &= \left(\frac{\partial}{\partial Z}\left(\frac{\partial W}{\partial X}\right)_{Y,Z}\right)_{X,Y} = \left(\frac{\partial}{\partial X}\left(\frac{\partial W}{\partial Z}\right)_{X,Y}\right)_{Y,Z} = \left(\frac{\partial C}{\partial X}\right)_{Y,Z} \quad , \end{aligned} \tag{19.58}$$

and analogously for all other second derivatives. Applied to thermodynamic systems these expression are called *Maxwell relations*.

Now, we want to predict how the system will evolve when a different set of variations is applied, for instance (dA, dY, dZ). To solve the problem we first define a new state function $V = V(A, Y, Z)$ via,

$$\boxed{V \equiv W - AX} \quad . \tag{19.59}$$

This substitution is called *Legendre transform*. The new differential is,

$$\begin{aligned} dV &= dW - AdX - XdA = -XdA + BdY + CdZ \\ &= \left(\frac{\partial V}{\partial A}\right)_{Y,Z} dA + \left(\frac{\partial V}{\partial Y}\right)_{A,Z} dY + \left(\frac{\partial V}{\partial Z}\right)_{A,Y} dZ \quad , \end{aligned} \tag{19.60}$$

and each of these three partial derivatives has a physical meaning. The thermodynamic potentials introduced in the next section will exemplify the procedure. Do the Exc. 19.2.8.1.

Useful mathematical identities when working with partial derivatives are,

$$\left(\frac{\partial X}{\partial Z}\right)_Y \left(\frac{\partial Z}{\partial X}\right)_Y = 1 \quad , \quad \left(\frac{\partial Z}{\partial X}\right)_Y \left(\frac{\partial X}{\partial Y}\right)_Z \left(\frac{\partial Y}{\partial Z}\right)_X = -1 \quad . \tag{19.61}$$

19.2.3.2 Internal energy

Let us return to simple systems described by only two independent state variables, for example, a unary gas with a fixed amount of atoms.

The first thermodynamic potential is the *internal energy*,

$$\boxed{E}\ , \tag{19.62}$$

for which we already formulated the combined first and second law of thermodynamics (19.51),

$$dE = TdS - PdV\ . \tag{19.63}$$

Without heat production, $dS = 0$, and work done, $dV = 0$, the internal energy of a systems remains unchanged, $dE = 0$.

19.2.3.3 Enthalpy

The energy function called *enthalpy* is defined as,

$$\boxed{H \equiv E + PV}\ . \tag{19.64}$$

With the expression (19.63) the differential enthalpy becomes,

$$dH = dE + PdV + VdP = TdS + VdP\ . \tag{19.65}$$

It has the same level of generality as the combined first and second laws.

Historically, the enthalpy was introduced to simplify the description of heat engines taken through cycles at atmospheric pressure, $dP = 0$. For isobaric processes in simple systems, $dH_P = TdS_P = \delta Q_{\mathrm{rev},P}$, the enthalpy provides a direct measure of the reversible heat exchange of the engine with the environment.

19.2.3.4 Helmholtz free energy

The energy function called *Helmholtz free energy* is defined as,

$$\boxed{F \equiv E - TS}\ . \tag{19.66}$$

With the expression (19.63) the differential enthalpy becomes,

$$dF = dE - TdS - SdT = -SdT - PdV\ . \tag{19.67}$$

It has the same level of generality as the combined first and second laws.

This function was devised to simplify the description of processes occurring at a fixed (if necessary stabilized) temperature, $dT = 0$. For isothermal processes in simple systems, $dF_T = -PdV_T = \delta W_{rev,T}$, the Helmholtz free energy reports the total reversible work done on the system.

19.2.3.5 Gibbs free energy

The energy function called *Gibbs free energy* is defined as,

$$\boxed{G \equiv E + PV - TS}\ . \tag{19.68}$$

With the expression (19.63) the differential enthalpy becomes,

$$dG = dE + PdV + VdP - TdS - SdT = -SdT + VdP\ . \tag{19.69}$$

It has the same level of generality as the combined first and second laws.

This function was introduced to simplify the description of processes occurring at both temperature, $dT = 0$, and constant pressure, $dP = 0$. For isobaric and isothermal processes in simple systems, $dG_{T,P} = 0$. But in systems undergoing phase transformations or chemical reactions, the Gibbs free energy yields the total work *other than mechanical work*, $dG_{T,P} = \delta W_{T,P}^{\text{non-mech.}}$.

19.2.3.6 Summary of thermodynamic potentials for canonical ensembles

The following list summarizes the *thermodynamic potentials* for *canonical ensembles*, which are the total energy E, the free enthalpy H, the Helmholtz free energy F, and the Gibbs free energy G,

$$\begin{aligned}
& & \delta Q_{\text{rev}} &= TdS \\
& & \delta W_{\text{rev}} &= -PdV \\
E &= Q_{\text{rev}} + W_{\text{rev}} & \Longrightarrow \quad dE &= TdS - PdV \\
H &= E + PV & \Longrightarrow \quad dH &= TdS + VdP \\
F &= E - TS & \Longrightarrow \quad dF &= -SdT - PdV \\
G &= E + PV - TS & \Longrightarrow \quad dG &= -SdT + VdP
\end{aligned} \tag{19.70}$$

19.2.3.7 Material properties

Database variables are defined as conditional derivatives of the state functions or thermodynamic potentials. Mechanical properties such as the *compressibility* κ, the *thermal expansion coefficient* α, and the *stress coefficient* β are prominent examples. In the case of a single substance system, they are defined by,

$$\boxed{\kappa = -\frac{1}{V}\left(\frac{\partial V}{\partial P}\right)_T \quad , \quad \alpha = \frac{1}{V}\left(\frac{\partial V}{\partial T}\right)_P \quad , \quad \beta = \frac{1}{P}\left(\frac{\partial P}{\partial T}\right)_V} \, . \tag{19.71}$$

Table 19.1 lists the coefficient for several materials.

Example 146 (*Links between material properties*): Maxwell's relations applied to the thermal expansion coefficient and the compressibility defined in (19.71) immediately tell us,

$$\left(\frac{\partial \alpha}{\partial P}\right)_T = \left(\frac{\partial \kappa}{\partial T}\right)_P \, , \tag{19.72}$$

for any system.
Furthermore, using the rules (19.61) we calculate,

$$1 = -\left(\frac{\partial V}{\partial P}\right)_T \left(\frac{\partial P}{\partial T}\right)_V \left(\frac{\partial T}{\partial V}\right)_P = -\frac{\left(\frac{\partial V}{\partial P}\right)_T \left(\frac{\partial P}{\partial T}\right)_V}{\left(\frac{\partial V}{\partial T}\right)_P} = \frac{\kappa V \ \beta P}{\alpha V} \, .$$

Hence,

$$\alpha = \kappa\beta P \ . \tag{19.73}$$

That is, the stress coefficient is not an independent quantity, but depends on thermal expansion coefficient and the compressibility.

Thermal properties are grasped by the concept of *heat capacity*. This quantity is measured via the temperature rise of a substance due to reversible absorption of a defined quantity of heat. Since heat is a process variable, the heat capacity measurement will depend on the circumstances, i.e. whether the pressure is kept constant during the measurement or the volume. The heat capacity will be for the respective cases,

$$\boxed{C_P \equiv \left(\frac{\delta Q_{\text{rev}}}{dT}\right)_P \qquad \text{or} \qquad C_V \equiv \left(\frac{\delta Q_{\text{rev}}}{dT}\right)_V} \ . \tag{19.74}$$

Using the relationships listed in (19.70), we find immediately,

$$C_P = T\left(\frac{\partial S}{\partial T}\right)_P = \left(\frac{\partial H}{\partial T}\right)_P \qquad \text{or} \qquad C_V = T\left(\frac{\partial S}{\partial T}\right)_V = \left(\frac{\partial E}{\partial T}\right)_V \ . \tag{19.75}$$

For a system held at constant pressure, absorption of heat will lead to both, an increase in temperature but also an expansion of volume, which corresponds to work. For a system held at constant volume, absorption of heat will only increase temperature, hence, $C_P > C_V$.

Empirically, the heat capacities are found to depend on temperature. A frequently used interpolation expression giving good results at temperatures above room temperature is,

$$C_P(T) = a + b\,T + c/T^2 + d\,T^2 \ , \tag{19.76}$$

where the coefficients are listed in Tab. 19.1 for several materials.

19.2.3.8 Coefficient and Maxwell relations

The differential forms listed in (19.70) immediately allow to express state functions via partial derivatives of thermodynamic potentials in the following coefficient relations,

$$\begin{aligned} T &= \left(\frac{\partial E}{\partial S}\right)_V = \left(\frac{\partial H}{\partial S}\right)_P \quad , \quad -S = \left(\frac{\partial F}{\partial T}\right)_V = \left(\frac{\partial G}{\partial T}\right)_P \\ -P &= \left(\frac{\partial E}{\partial V}\right)_S = \left(\frac{\partial F}{\partial V}\right)_T \quad , \quad V = \left(\frac{\partial H}{\partial P}\right)_S = \left(\frac{\partial G}{\partial P}\right)_T \ . \end{aligned} \tag{19.77}$$

Furthermore, taking the second derivatives of the expressions for the temperature and the pressure, we find,

$$-\left(\frac{\partial P}{\partial S}\right)_V = \left(\frac{\partial T}{\partial V}\right)_S \ , \tag{19.78}$$

and similarly for the other potentials.

19.2.4 Strategy for deriving thermodynamic relations

The conceptual framework of terms and definitions erected in the previous sections allows us to derive general equations expressing any state variable as a function of two (for simple systems) other state variables. For complex systems, more free state variables may be necessary. Below we will provide a recipe for a rigorous general procedure.

As a preparation for the employment of the procedure we will express all state variables as functions of temperature T and pressure P, which are the most commonly used free variables. Once equations for volume $V = V(T, P)$ and entropy $S = S(T, P)$ are found, expressions for the four energy variables as functions of (T, P) readily follow. At the end, we will show how to convert functions of (T, P) into functions of any other pair of variables.

19.2.4.1 State variables as functions of T and P

The differential form of the function $V = V(T, P)$ is,

$$dV = AdT + BdP = \left(\frac{\partial V}{\partial T}\right)_P dT + \left(\frac{\partial V}{\partial P}\right)_T dP = \alpha V dT - \kappa V dP \ , \tag{19.79}$$

where we used the definitions of the material coefficients (19.71). Analogously, the differential form of the function $S = S(T, P)$ is,

$$dS = A'dT + B'dP = \left(\frac{\partial S}{\partial T}\right)_P dT + \left(\frac{\partial S}{\partial P}\right)_T dP = \frac{C_P}{T} dT - \alpha V dP \ . \tag{19.80}$$

For the first coefficient we used the definitions of the heat capacities (19.75). The second coefficient follows from the Maxwell relation applied to the Gibbs free energy differential, $dG = -SdT + VdP$, yielding,

$$-\left(\frac{\partial S}{\partial P}\right)_T = \left(\frac{\partial V}{\partial T}\right)_P \ . \tag{19.81}$$

Inserting the expressions (19.79) and (19.80) into the differential forms (19.70) and separating the coefficients of the differential dT ad dP, we immediately get,

$$\boxed{\begin{aligned}
V = V(T,P) \quad &\Longrightarrow \quad dV = \alpha V dT - \kappa V dP \\
S = S(T,P) \quad &\Longrightarrow \quad dS = \tfrac{C_P}{T} dT - \alpha V dP \\
E = E(T,P) \quad &\Longrightarrow \quad dE = (C_P - \alpha P V) dT + (\kappa P - \alpha T) V dP \\
H = H(T,P) \quad &\Longrightarrow \quad dH = C_P dT + (1 - \alpha T) V dP \\
F = F(T,P) \quad &\Longrightarrow \quad dF = -(S + \alpha P V) dT + \kappa P V dP \\
G = G(T,P) \quad &\Longrightarrow \quad dG = -S dT + V dP
\end{aligned}} \tag{19.82}$$

19.2.4.2 Recipe for change of variables

With the results (19.82) we may now devise the following recipe for changing the independent variables,

1. Identify the new free and dependent state variables: $W = W(X, Y)$.
2. Write the differential form: $dW = AdX + BdY$.
3. Use the Eqs. (19.82) to express dX and dY in terms of the variables dT and dP:
$$dX = \left(\frac{\partial X}{\partial T}\right)_P dT + \left(\frac{\partial X}{\partial P}\right)_T dP \quad , \quad dY = \left(\frac{\partial Y}{\partial T}\right)_P dT + \left(\frac{\partial Y}{\partial P}\right)_T dP \, , \tag{19.83}$$
where the derivatives are the coefficients of dT and dP in the expressions for dX and dY in (19.82).
4. Insert the expressions for dX and dY into the differential form dW and collect terms:
$$dW = \left[A\left(\frac{\partial X}{\partial T}\right)_P + B\left(\frac{\partial Y}{\partial T}\right)_P\right] dT + \left[A\left(\frac{\partial X}{\partial P}\right)_T + B\left(\frac{\partial Y}{\partial P}\right)_T\right] dP \, . \tag{19.84}$$
5. Obtain $W = W(T, P)$ from (19.82),
$$dW = \left(\frac{\partial W}{\partial T}\right)_P dT + \left(\frac{\partial W}{\partial P}\right)_T dP \, . \tag{19.85}$$
6. By comparison of the coefficients of the equations (19.84) and (19.85),
$$\left(\frac{\partial W}{\partial T}\right)_P = A\left(\frac{\partial X}{\partial T}\right)_P + B\left(\frac{\partial Y}{\partial T}\right)_P \quad , \quad \left(\frac{\partial W}{\partial P}\right)_T = A\left(\frac{\partial X}{\partial P}\right)_T + B\left(\frac{\partial Y}{\partial P}\right)_T \, . \tag{19.86}$$
7. Solve the set of equations (19.86) by A and B,
$$A = \frac{\left(\frac{\partial W}{\partial P}\right)_T \left(\frac{\partial Y}{\partial T}\right)_P - \left(\frac{\partial W}{\partial T}\right)_P \left(\frac{\partial Y}{\partial P}\right)_T}{\left(\frac{\partial X}{\partial P}\right)_T \left(\frac{\partial Y}{\partial T}\right)_P - \left(\frac{\partial X}{\partial T}\right)_P \left(\frac{\partial Y}{\partial P}\right)_T} \quad , \quad B = \frac{\left(\frac{\partial W}{\partial T}\right)_P \left(\frac{\partial X}{\partial P}\right)_T - \left(\frac{\partial W}{\partial P}\right)_T \left(\frac{\partial X}{\partial T}\right)_P}{\left(\frac{\partial X}{\partial P}\right)_T \left(\frac{\partial Y}{\partial T}\right)_P - \left(\frac{\partial X}{\partial T}\right)_P \left(\frac{\partial Y}{\partial P}\right)_T} \, . \tag{19.87}$$

Example 147 (*Relating entropy to temperature and volume*): As an example of the procedure developed in the previous sections, we will now express entropy as a function of temperature and volume.

1. The wanted expression is: $S = S(T, V)$.
2. Its differential form is: $dS = AdT + BdV$.
3. Substituting dV from (19.82)(i): $dS = AdT + B(\alpha V dT - \kappa V dP)$.
4. Collecting terms: $dS = (A + B\alpha V)dT - B\kappa V dP$.
5. Obtain $S = S(T, P)$ from (19.82)(ii): $dS = (C_P/T)dT - \alpha V dP$.
6. Compare coefficients: $A + B\alpha V = C_P/T$ and $-B\kappa V = -\alpha V$.

7. Solve by A and B: $A = (C_P/T) - (\alpha^2 V/\kappa)$ and $B = \frac{\alpha}{\kappa}$.

The expression is thus,

$$dS = \left(\frac{C_P}{T} - \frac{\alpha^2 V}{\kappa}\right) dT + \frac{\alpha}{\kappa} dV \ . \tag{19.88}$$

Example 148 (*Relating entropy to pressure and volume*): As second example of the procedure developed in the previous sections, we will now express entropy as a function of pressure and volume.

1. The wanted expression is: $S = S(P, V)$.
2. Its differential form is: $dS = AdP + BdV$.
3. Substituting dV from (19.82)(i): $dS = AdP + B(\alpha V dT - \kappa V dP)$.
4. Collecting terms: $dS = B\alpha V dT + (A - B\kappa V)dP$.
5. Obtain $S = S(T, P)$ from (19.82)(ii): $dS = (C_P/T)dT - \alpha V dP$.
6. Compare coefficients: $B\alpha V = C_P/T$ and $A - B\kappa V = -\alpha V$.
7. Solve by A and B: $A = \frac{\kappa C_P}{\alpha T} - \alpha V$ and $B = \frac{C_P}{\alpha V T}$.

The expression is thus,

$$dS = \left(\frac{\kappa C_P}{\alpha T} - \alpha V\right) dP + \frac{C_P}{\alpha T V} dV \ . \tag{19.89}$$

19.2.5 Ideal gases

One of the most common systems to apply thermodynamic concepts are ideal gases, for which we know that they obey the state equation,

$$\boxed{PV = Nk_{\mathrm{B}}T} \ , \tag{19.90}$$

where we consider for now a fixed number of particles $N = const$. The thermal expansion coefficient and the compressibility are readily calculated from their definitions (19.71),

$$\begin{aligned}
\alpha_{\mathrm{id}} &= \frac{1}{V}\left(\frac{\partial V}{\partial T}\right)_P = \frac{1}{V}\left(\frac{\partial Nk_{\mathrm{B}}T/P}{\partial T}\right)_P = \frac{1}{T} \\
\kappa_{\mathrm{id}} &= -\frac{1}{V}\left(\frac{\partial V}{\partial P}\right)_T = -\frac{1}{V}\left(\frac{\partial Nk_{\mathrm{B}}T/P}{\partial P}\right)_T = \frac{1}{P} \\
\beta_{\mathrm{id}} &= \frac{1}{P}\left(\frac{\partial P}{\partial T}\right)_V = \frac{1}{P}\left(\frac{\partial Nk_{\mathrm{B}}T/V}{\partial T}\right)_V = \frac{1}{T} \ .
\end{aligned} \tag{19.91}$$

The relationship between the heat capacities at constant volume and pressure (19.74) is directly obtained from (19.88),

$$C_V = T\left(\frac{\partial S}{\partial T}\right)_V = C_P - \frac{\alpha_{\mathrm{id}}^2 TV}{\kappa_{\mathrm{id}}} = C_P - Nk_{\mathrm{B}} \ . \tag{19.92}$$

Hence, for an ideal gas, the heat capacities do not depend on T not P, but only on the number of atoms N and their configuration in each gas molecule. With Eq. (19.35),

$$\boxed{C_V = \tfrac{3}{2} N k_{\rm B}} \ . \tag{19.93}$$

We will see later, that for a molecular gas with f degrees of freedom (accessible at the ambient temperature), the results must be generalized to,

$$C_V = \tfrac{f}{2} N k_{\rm B} \ . \tag{19.94}$$

The differential form for the internal energy $E = E(T, P)$ is according to Eq.,(19.82)(iii),

$$dE = (C_P - \alpha_{\rm id} PV) dT + (\kappa_{\rm id} P - \alpha_{\rm id} T) V dP = (C_P - N k_{\rm B}) dT = C_V dT \ . \tag{19.95}$$

Thus, E only depends on T, and since E is a state function, this holds for any process, whether reversible or irreversible. For the other thermodynamic potentials we get, exploiting the relationships (19.70),

$$\boxed{\begin{array}{rclcrcl} E & = & C_V T & , & F & = & (C_V - S) T \\ H & = & C_P T & , & G & = & (C_P - S) T \end{array}} \tag{19.96}$$

Do the Excs. 19.2.8.2 to 19.2.8.12.

19.2.5.1 Adiabatic reversible processes

In thermodynamics *adiabatic processes* are called those in which no heat is exchanged between the system and its environment,

$$\delta Q_{\rm adiab} = 0 \ . \tag{19.97}$$

If additionally a process is reversible,

$$\delta Q_{\rm adiab,rev} = T dS = 0 \ , \tag{19.98}$$

it is *isentropic process*, that is, entropy is neither produced nor transferred.

Let us compute the change in temperature of a reversibly and adiabatically compressed ideal gas. As usual, we start identifying the relevant state variables, $T = T(S, V)$. From (19.70)(iii), using the definition of the heat cavity at constant volume C_V, we find,

$$dT = \frac{T dS - P dV}{C_V} \ , \tag{19.99}$$

and since $dS = 0$,

$$dT_S = -\frac{P}{C_V} dV_S = -\frac{N k_{\rm B} T}{C_V V} dV_S \ . \tag{19.100}$$

Integrating this equation,

$$\int_{T_1}^{T_2} \frac{dT}{T} = \ln \frac{T_2}{T_1} = -\frac{N k_{\rm B}}{C_V} \ln \frac{V_2}{V_1} = -\frac{N k_{\rm B}}{C_V} \int_{V_1}^{V_2} \frac{dV}{V} \ , \tag{19.101}$$

we finally find,

$$\frac{T_2}{T_1} = \left(\frac{V_1}{V_2}\right)^{Nk_\mathrm{B}/C_V} = \left(\frac{P_2}{P_1}\right)^{Nk_\mathrm{B}/C_P} \qquad \text{or} \qquad \frac{P_2}{P_1} = \left(\frac{V_1}{V_2}\right)^{C_P/C_V} . \tag{19.102}$$

The ratio

$$\gamma \equiv \frac{C_P}{C_V} , \tag{19.103}$$

is called the *adiabaticity coefficient*. For the ideal gas studied in the previous section we have, $\gamma = \frac{5}{3}$, and for a molecular gas with f degrees of freedom $\gamma = 1 + \frac{2}{f}$.

With the adiabaticity coefficient the state functions for adiabatic reversible processes can be written,

$$\boxed{PV^\gamma = const \qquad \text{and} \qquad TV^{\gamma-1} = const} , \tag{19.104}$$

where the second relation follows from the ideal gas equations (19.90). Such a process is shown in the PV-diagram of Fig. 19.21.

Since the specific heat can be obtained from the heat capacity simply by dividing by the mass, $c \equiv C/m$, the ratio of the specific heat at constant pressure and to the specific heat at constant volume is also equal to the constant γ, that is, $\gamma = c_P/c_V$. Do the Excs. 19.2.8.13 to 19.2.8.22.

19.2.5.2 Isothermal, isobaric, and isochoric processes

We consider an ideal gas confined in a rigid, thermally insulated box, so that all processes occurring with the box are adiabatic, since no heat is exchanged with the surroundings, $\delta Q_\mathrm{ext} = 0$. Now, we divide the box into two volumes separated by a rigid wall but connected by a valve, which may be opened or closed, as shown in Fig. 19.19. Initially, the entire gas is in volume V_1, and when the valve is opened it expands into the volume V_2. Since, the walls of the box do not move, no work is done on the surroundings, $\delta W_\mathrm{ext} = 0$.

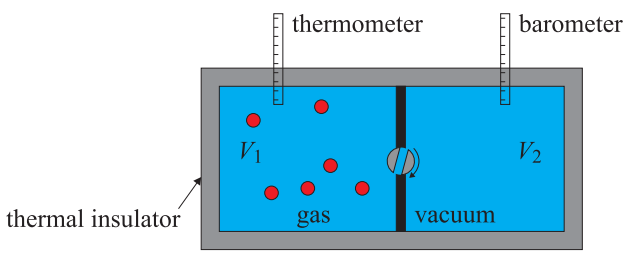

Figure 19.19: Free expansion of a gas.

Since no entropy can flow out of the system, any change in entropy must come from local production arising from irreversible processes. The expansion of the gas is a complicated process occurring far from equilibrium. Nevertheless, since entropy is a state function, the gain in entropy is same as for a fictive reversible process leading to the same final state. Since the initial state of the gas is known (V_1, T_i) as well as the final volume, $V_\mathrm{f} = V_1 + V_2$, the final temperature T_f is determined. Now, since

the internal energy does not change during expansion, $dE = \delta Q + \delta W = 0$, and since for an ideal gas the internal energy is proportional to temperature, the temperature doesn't change,

$$\boxed{PV = Nk_{\mathrm{B}}T = const} \ . \tag{19.105}$$

Such a process is called *isothermal* and is shown in the PV-diagram of Fig. 19.21.

On an isotherm of an ideal gas, we have $PdV + VdP = Nk_{\mathrm{B}}T = 0$ and therefore $\delta W = -PdV = VdP$. Nonetheless,

$$P = \frac{Nk_{\mathrm{B}}T}{V} \quad \Rightarrow \quad dP = -\frac{Nk_{\mathrm{B}}T}{V^2}dV \quad \Rightarrow \quad \delta W = Nk_{\mathrm{B}}T\frac{dV}{V} \ , \tag{19.106}$$

and so, the work done when the gas goes from V_1 to V_2 is,

$$\Delta W_{1-2} = \int_{V_1}^{V_2} Nk_{\mathrm{B}}T\frac{dV}{V} = Nk_{\mathrm{B}}T\ln\frac{V_2}{V_1} \ . \tag{19.107}$$

Similar considerations can be made for *isobaric* and *isochoric processes*. The results are summarized in Tab. 19.2.

19.2.5.3 Entropy of ideal gases

As an example, let us consider entropy changes in PV space. Via Legendre transform we derive from the relationships (19.82) obtained for $S = S(T, P)$,

$$\begin{aligned} S = S(P,V) \qquad \text{with} \qquad dS &= \left(\frac{\kappa C_P}{\alpha T} - \alpha V\right)dP + \frac{C_P}{\alpha TV}dV \\ &\xrightarrow{\text{ideal}} C_V\frac{dP}{P} + C_P\frac{dV}{V} \ , \end{aligned} \tag{19.108}$$

where the last step holds for ideal gases. We can integrate this expression either holding pressure or volume constant,

$$\Delta S_P = \int_{V_{\mathrm{i}}}^{V_{\mathrm{f}}} C_P\frac{dV}{V} = C_P\ln\frac{V_{\mathrm{f}}}{V_{\mathrm{i}}} \qquad \text{or} \qquad \Delta S_V = \int_{P_{\mathrm{i}}}^{P_{\mathrm{f}}} C_V\frac{dP}{P} = C_V\ln\frac{P_{\mathrm{f}}}{P_{\mathrm{i}}} \ . \tag{19.109}$$

Since, entropy is a state function, it is possible to calculate the entropy at any point $S_2 = S(P_2, V_2)$ from the entropy change along an arbitrary path starting from any other point $S_1 = S(P_1, V_1)$, e.g.,

$$\begin{aligned} S(P_2,V_2) &= S(P_2,V_1) + C_P\ln\frac{V_2}{V_1} \\ &= S(P_1,V_1) + C_P\ln\frac{V_2}{V_1} + C_V\ln\frac{P_2}{P_1} = S(P_1,V_2) + C_V\ln\frac{P_2}{P_1} \ . \end{aligned} \tag{19.110}$$

We conclude,

$$\boxed{\Delta S_{1\to 2} = C_P\ln\frac{V_2}{V_1} + C_V\ln\frac{P_2}{P_1} = C_V\ln\frac{P_2V_2^{\gamma}}{P_1V_1^{\gamma}} = C_V\ln\frac{T_2V_2^{\gamma-1}}{T_1V_1^{\gamma-1}}} \ , \tag{19.111}$$

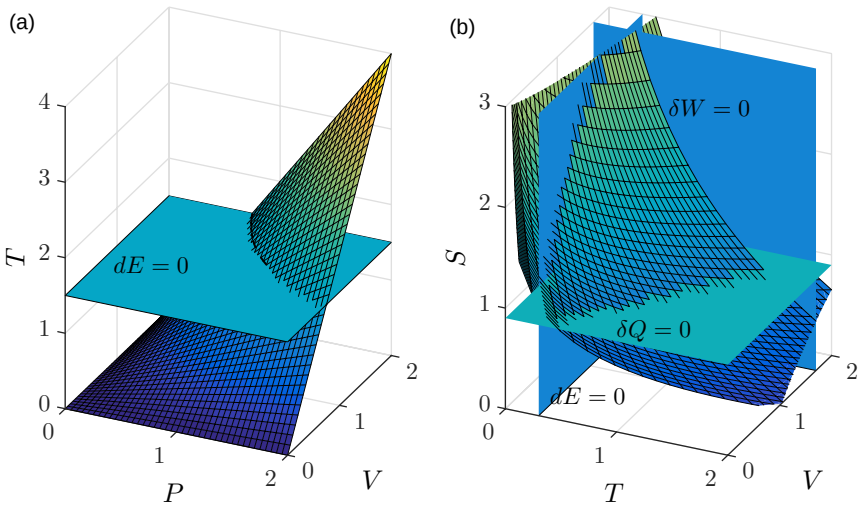

Figure 19.20: (code) (a) Qualitative behavior of the ideal gas law in TPV space. (b) The meshed surface shows the qualitative behavior of the Sackur-Tetrode formula in TSV space with planes corresponding to $\delta Q = 0$, $\delta W = 0$, and $\delta Q + \delta W = 0$.

using the definition (19.103) of the adiabaticity coefficient. Assuming a mono-atomic gas, for which $\gamma = \frac{5}{3}$, we obtain,

$$\Delta S_{1\to 2} = N k_{\mathrm{B}} \ln \frac{V_2 T_2^{3/2}}{V_1 T_1^{3/2}} \ , \tag{19.112}$$

which is known as the *Sackur-Tetrode formula* plotted in Fig. 19.20(b).

19.2.5.4 Entropy, heat and work balance during reversible processes

The heat absorbed and work done during reversible processes can be computed via integration of TdS or $-PdV$ along the path of the process. The integration is simplified if one of the state functions is kept constant during the process. We will now study particularly simple cases, where one of the three variables T, S, P, V is held constant. 12 combinations are possible: (i) isothermal process entropy change, (ii) isothermal pressure change, (iii) isothermal volume change, (iv) isentropic process temperature change, (v) isentropic pressure change, (vi) isentropic volume change, (vii) isobaric process temperature change, (viii) isobaric entropy change, (ix) isobaric volume change, (x) isochoric process temperature change, (xi) isochoric entropy change, and (xii) isochoric pressure change. If one of the six variables $T, S, P, V\mu, N$ is held constant, there are 30 possible combinations.

Table 19.2 summarize the entropy, heat, and work balances for all 12 processes, which will be derived in Exc. 19.2.8.23. Marked in red are those processes not requiring Legendre transforms for calculating entropy, heat, and work changes. The arrows indicate results obtained for ideal gases.

Table 19.2: Summary of entropy, heat, and work balances upon various state changes.

process	$\Delta S_{1\to 2} = \int_{S_1}^{S_2} dS =$	$\Delta Q_{1\to 2} = \int_{S_1}^{S_2} TdS =$	$\Delta W_{1\to 2} = -\int_{V_1}^{V_2} PdV =$

19.2.6 Cyclic processes

Thermal machines are based on cyclic processes. Examples are the Clément-Desormes cycle studied in the next section, the Carnot cycle in Exc. 19.2.8.24, the *Otto cycle* studied in Exc. 19.2.8.25, or the *Diesel cycle* studied in Exc. 19.2.8.26, and others studied in Excs. 19.2.8.27 to 19.2.8.33.

From the first law of thermodynamics $dE = \delta Q + \delta W$ we expect that for cyclic processes going through a sequences of processes j the heat and work balances are compensated, because E as a state variable may not change after an arbitrary excursion through parameter space,

$$0 = \oint TdS - \oint PdV = \sum_j \Delta Q^{>0}_{j\to j+1} + \sum_j \Delta W_{j\to j+1} \ . \tag{19.113}$$

We define the efficiency of a cyclic process as the ratio between net work performed and heat absorbed (not delivered),

$$\boxed{\eta \equiv \frac{-\sum_j \Delta W_{j\to j+1}}{\sum_j \Delta Q^{>0}_{j\to j+1}}} \ . \tag{19.114}$$

19.2.6.1 The Cléments-Desormes method for determining γ

The specific heat of solids and liquids is usually measured with samples under atmospheric conditions and without control of the volume of the material, i.e. we generally measure c_P. In contrast, gases are easier to study when they are contained in a rigid recipient, such as a glass bulb with little thermal expansion within the temperature range of the experiment. Then, the specific heat is measured at constant volume c_V. The value c_P of a gas is larger than c_V because in the experiment, at constant pressure, the heat delivered to the gas also causes its expansion, which means that part of that energy is been converted into work and not into an increase the thermal energy of the gas molecules. The ratio between the specific heats at constant pressure and volume, $\gamma = c_P/c_V$, is a value that often appears in the description of thermodynamic processes in gases. This ratio can be measured by isobaric and isochoric processes, respectively measuring c_P and c_V. The first experiment to measure the factor γ in gases was performed in 1819 by *Desormes* and *Clément*. The method consists in applying to a gas (assume to be ideal), a sequence of three processes illustrated in Fig. 19.21: an isothermal expansion from state (1) to (2), followed by an isochoric cooling from (2) to (3), and finally an adiabatic compression from (3) back to (1). During the adiabatic process from (3) to (1) the relation between pressure and volume is described by $PV^\gamma = const$. Monitoring both during the process thus allows us to measure the adiabaticity coefficient γ.

The heat and work balance of the Clément-Desormes cycle is summarized in the following table. The heats and works exchanged with the reservoir can be looked up in Tab. 19.2,

process		$\Delta Q_{j\to j+1} =$	$\Delta W_{j\to j+1} =$
$1 \to 2$	isotherm	$T_1(S_2 - S_1) = Nk_\mathrm{B}T_1 \ln \frac{V_2}{V_1} > 0$	$-\Delta Q_{1\to 2}$
$2 \to 3$	isochor	$C_V(T_3 - T_2) < 0$	0
$3 \to 1$	isentropic	0	$C_V(T_1 - T_3)$

(19.115)

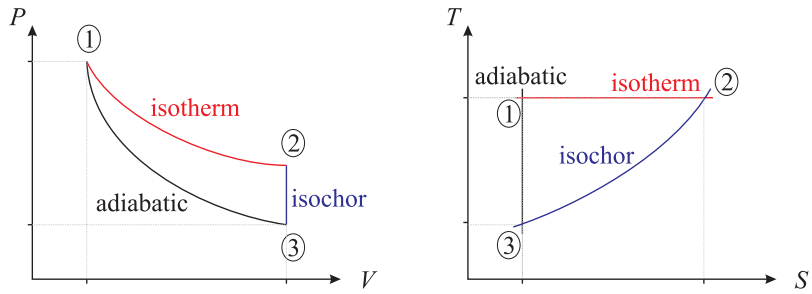

Figure 19.21: PV-diagram (left) and TS-diagram (right) for the Clément-Desormes cyclic process.

with $T_1 = T_2 > T_3$. The efficiency is defined as,

$$\eta = \frac{-\sum \Delta W_{j\to j+1}}{\sum \Delta Q^{>0}_{i\to j}} = \frac{T_1(S_2 - S_1) - C_V(T_1 - T_3) + 0}{T_1(S_2 - S_1)} \tag{19.116}$$
$$= 1 - \frac{C_V(T_1 - T_3)}{Nk_{\rm B}T_1 \ln \frac{V_2}{V_1}} \ .$$

Example 149 (*Rüchardt's method for determining* γ): *Rüchardt's method* shown in Fig. 19.22 allows the measurement of ratio $\gamma = C_P/C_V$ of a gas. Let us consider a gas confined in a large container with volume V. Connected to this container is a tube with cross section A, inside which a metal ball of mass m (which fits perfectly in the tube) can slide up and down thus acting like a piston. Due to the compression and decompression of the gas, this mass oscillates in around its equilibrium position ($y = 0$). The presence of the metallic sphere increases the internal pressure to $P = P_a + mg/A$ in equilibrium position, where P_a is the external (atmospheric) pressure. We will call τ the period of oscillation. See also Exc. 19.2.8.13. Given a displacement y on the sphere,

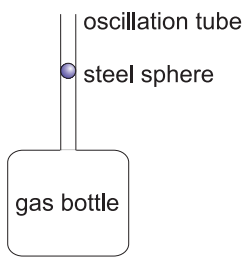

Figure 19.22: Rüchardt's method for determining γ.

the change in the volume of the gas is $\Delta V = yA$, so that there is a pressure variation ΔP accompanying ΔV. This increase in pressure produces a restoring force $F = \Delta PA$. Assuming that the process is nearly static and adiabatic, we have,

$$PV^\gamma = const \quad \Rightarrow \quad \gamma PV^{\gamma-1}\Delta V + V^\gamma \Delta P = 0 \ . \tag{19.117}$$

Using $\Delta P = F/A$ and $\Delta V = yA$, we obtain,

$$\gamma P V^{\gamma-1} yA + V^{\gamma} F/A = 0 \quad \Rightarrow \quad F = -\frac{\gamma P A^2}{V} y \ , \tag{19.118}$$

which leads us to the following equation of motion for the sphere,

$$m\frac{d^2y}{dt^2} + \frac{\gamma P A^2}{V} y = 0 \ , \tag{19.119}$$

which is the differential equation of a simple harmonic motion of frequency:

$$\omega_0^2 = \frac{\gamma P A^2}{mV} \ . \tag{19.120}$$

In this way, knowing P, V, m and A, we can measure τ and obtain γ as,

$$\tau = 2\pi\sqrt{\frac{mV}{\gamma P A^2}} \ . \tag{19.121}$$

19.2.6.2 Carnot cycle

A *Carnot cycle* is an ideal thermodynamic cycle providing, by Carnot's theorem, an upper limit on the efficiency of any classical thermodynamic engine during the conversion of heat into work, or conversely, the efficiency of a refrigeration system in creating a temperature difference through the application of work to the system.

In a Carnot cycle, an engine transfers energy in the form of heat between two thermal reservoirs at temperatures T_{hot} and T_{cold}, and a part of this transferred energy is converted to the work done by the system. The cycle is reversible and hence isentropic. In other words, entropy is conserved; it is only transferred between the thermal reservoirs. When work is applied to the system, heat moves from the cold to hot reservoir, which is exploited in *heat pumps* and *refrigerators*, depending on whether the heat increase of the hot reservoir is exploited or the heat decrease of the cold reservoir. When heat moves from the hot to the cold reservoir, the system applies work to the environment, which can be exploited in *heat engines*.

The work W done by the system or engine to the environment per Carnot cycle depends on the temperatures of the thermal reservoirs and the entropy transferred from the hot reservoir to the system ΔS per cycle such as,

$$\Delta W = (T_{\text{hot}} - T_{\text{cold}})\Delta S = (T_{\text{hot}} - T_{\text{cold}})\frac{\Delta Q_{\text{hot}}}{T_{\text{hot}}} \ , \tag{19.122}$$

where Q_{hot} is heat transferred from the hot reservoir to the system per cycle.

The heat and work balance of the Carnot cycle is summarized in the following table (see Fig. 19.23):

process		$\Delta Q_{j\to j+1} =$	$\Delta W_{j\to j+1} =$
$1 \to 2$	isotherm	$T_1(S_2 - S_1) = Nk_{\text{B}}T_1 \ln\frac{V_2}{V_1} < 0$	$-\Delta Q_{1\to 2} > 0$
$2 \to 3$	isentropic	0	$C_V(T_3 - T_2) > 0$
$3 \to 4$	isotherm	$T_3(S_4 - S_3) = Nk_{\text{B}}T_3 \ln\frac{V_4}{V_3} > 0$	$-\Delta Q_{3\to 4} < 0$
$4 \to 1$	isentropic	0	$C_V(T_1 - T_4) < 0$

(19.123)

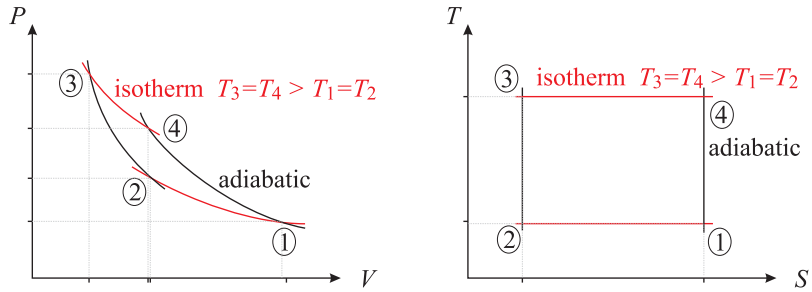

Figure 19.23: PV-diagram (left) and TS-diagram (right) for the Carnot cycle.

with $T_3 = T_4 > T_1 = T_2$ and $S_2 = S_3 > S_1 = S_4$. Because E is a state function a cyclic process must necessarily satisfy, $\Delta E = \sum \Delta W_{j\to j+1} + \sum \Delta Q_{j\to j+1} = 0$. The efficiency is defined as,

$$\begin{aligned}\eta &\equiv \frac{-\sum \Delta W_{j\to j+1}}{\sum \Delta Q^{>0}_{j\to j+1}} \\ &= -\frac{-T_1(S_2-S_1)+C_V(T_3-T_2)-T_3(S_4-S_3)+C_V(T_1-T_4)}{T_3(S_4-S_3)} = 1-\frac{T_1}{T_3}\ .\end{aligned} \tag{19.124}$$

Example 150 (*Efficiency of the Carnot cycle*): According to Eq. (19.113) the total work and heat balances of a cyclic process correspond to the enclosed areas in the PV, respectively, TS-diagrams, and both areas are equal. As illustrated in Fig. 19.24, for given temperatures of the hot and cold reservoir, the largest area $\Delta W = \Delta Q = \oint T dS$ is occupied by a rectangle corresponding to the Carnot cycle. From Fig. 19.24 we see that the efficiency can be optimized by maximizing the red area and minimizing the blue area,

$$\eta = \frac{T_{\rm hot}\Delta S - T_{\rm cold}\Delta S}{T_{\rm hot}\Delta S} = \frac{1}{1+\frac{\Delta Q_{\rm cold}}{\Delta Q_{\rm hot}-\Delta Q_{\rm cold}}}\ . \tag{19.125}$$

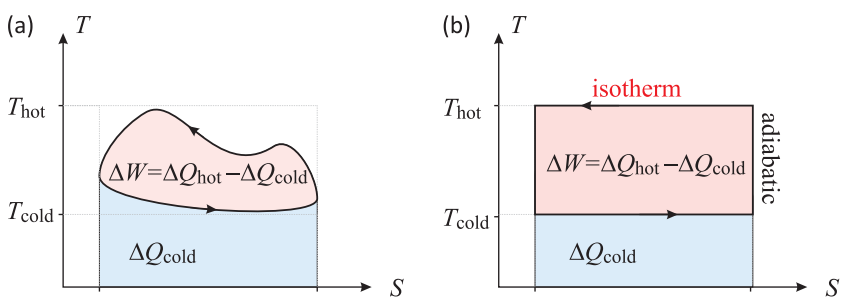

Figure 19.24: TS-diagram for an arbitrary cyclic process (left) and for the Carnot cycle (right).

19.2.7 Real gases, liquids and solids

As long as real gases, liquids, and solids qualify as unary, homogeneous, closed, non-reacting, and otherwise simple systems, the laws and procedures outlined in Secs. 19.2.1 to Sec. 19.2.3 apply to them in the same way as for ideal gases. Additionally, in solids and liquids the material constants α, κ, C_P are generally to a good approximation constant.

The ideal gas law (19.3) is only valid for non-interacting particles. In reality, inter-particle interactions increase the effective pressure and the finite size of the molecules reduces the effective volume. Indeed, even at $T = 0$ the volume V of a real gas cannot be zero, because the molecules have their own volume V^*. And as molecules interact attract each other, the pressure is zero even before $T = 0$. In the van der Waals model the ideal gas equation is generalized to,

$$(P+P^*)(V-V^*) = Nk_\mathrm{B}T \quad \text{with} \quad P^* = \frac{a}{V^2}\left(\frac{N}{N_\mathrm{A}}\right)^2 \quad \text{and} \quad V^* = b\left(\frac{N}{N_\mathrm{A}}\right) \tag{19.126}$$

where a and b are empirical constants specifically depending on the gas. Using molar functions denoted by a tilde ($\tilde{\cdot}$), $N \to N_\mathrm{A}$, $N_\mathrm{A}k_\mathrm{B} \to R_\mathrm{g}$, $V\frac{N}{N_\mathrm{A}} \to \tilde{V}$, etc.,

$$\boxed{\left(P + \frac{a}{\tilde{V}^2}\right)(\tilde{V} - b) = R_\mathrm{g}T} \ . \tag{19.127}$$

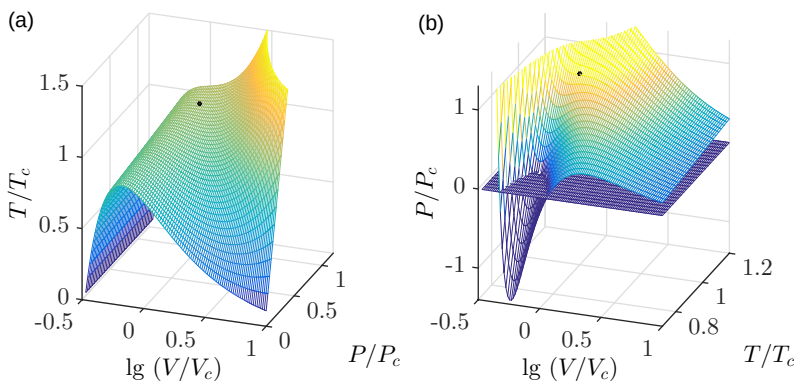

Figure 19.25: (code) Phase diagrams of a real gas obtained from Eq. (19.133) for the parameters $a = 0.36$ and $b = 4.3 \cdot 10^{-5}$. Panel (a) plots $T_\mathrm{r}(P_\mathrm{r}, V_\mathrm{r})$ and panel (b) $P_\mathrm{r}(T_\mathrm{r}, V_\mathrm{r})$.

19.2.7.1 State equation of a real gas

Van der Waals' relationship (19.127) for a *real gas* is characterized by the existence of a unique saddle point called the 'critical point'. It is defined by the conditions,

$$\frac{dP}{d\tilde{V}} = \frac{d^2P}{d\tilde{V}^2} = 0 \ . \tag{19.128}$$

Resolving the real gas equation by the pressure,

$$P(\tilde{V}) = \frac{R_g T}{\tilde{V} - b} - \frac{a}{\tilde{V}^2} \ , \tag{19.129}$$

we obtain the derivatives,

$$\frac{dP}{d\tilde{V}} = -\frac{R_g T}{(\tilde{V} - b)^2} + \frac{2a}{\tilde{V}^3} \qquad \text{and} \qquad \frac{d^2 P}{d\tilde{V}^2} = \frac{2R_g T}{(\tilde{V} - b)^3} - \frac{6a}{\tilde{V}^4} \ . \tag{19.130}$$

At the critical point, when Eqs. (19.134) are fulfilled, we find T_c and $\tilde{V}_c$ as a function of the material constants a and b,

$$T_c = \frac{8a}{27 R_g b} \qquad \text{and} \qquad \tilde{V}_c = 3b \ . \tag{19.131}$$

The pressure at the critical point P_c as a function of a and b is,

$$P_c = \frac{R_g 8a}{27 R_g b 2b} - \frac{a}{9b^2} = \frac{a}{27b^2} \ . \tag{19.132}$$

The van der Waals formula in terms of rescaled parameters, $\tilde{V}_r \equiv \tilde{V}/\tilde{V}_c$, $T_r \equiv T/T_c$, $P_r \equiv P/P_c$, reads,

$$P_r = \frac{8}{3} \frac{T_r}{\tilde{V}_r - 1/3} - \frac{3}{\tilde{V}_r^2} \ , \tag{19.133}$$

and is plotted in Fig. 19.25. In Exc. 19.2.8.34 we study another model for real gases, and in Exc. 19.2.8.35 the van der Waals model is used to calculate isothermal expansion of a real gas.

Example 151 (*Critical point for CO_2*): For CO_2 the values $a = 3.6 \cdot 10^{-6}\,\text{bar m}^6\,\text{mol}^{-2}$ and $b = 4.3 \cdot 10^{-5}\,\text{m}^3\,\text{mol}^{-1}$ are suitable parameters of the van der Waals equation. For one mole of CO_2 the values for the critical point $\tilde{V}_c$, T_c and P_c are,

$$\tilde{V}_c = 12.9 \cdot 10^{-5}\,\text{m}^3/\text{mol} \quad , \quad T_c = 298.35\,\text{K} \quad , \quad P_c = 72.1\,\text{bar} \ .$$

19.2.7.2 Joule-Thomson effect

The *Joule-Thomson effect* describes the temperature change of a real gas or liquid (as differentiated from an ideal gas), when it is forced through a valve or porous plug while keeping it insulated so that no heat is exchanged with the environment (see Exc. 19.2.8.36).

The relationships (19.82)(ii) and (iii) express energy and entropy as a function of temperature and pressure, $\tilde{E} = \tilde{E}(T, P)$ and $\tilde{S} = \tilde{S}(T, P)$. Using the procedure outlined in Sec. 19.2.4 to express energy and entropy as a function of temperature and volume, $\tilde{E} = \tilde{E}(T, \tilde{V})$ and $\tilde{S} = \tilde{S}(T, \tilde{V})$, we find,

$$d\tilde{E} = \left(\tilde{C}_P + P - \alpha P \tilde{V} - \frac{\alpha^2 T \tilde{V}}{\kappa} \right) dT + \left(\frac{\alpha T}{\kappa} - P \right) d\tilde{V} \tag{19.134}$$

$$d\tilde{S} = \left(\frac{\tilde{C}_P}{T} - \frac{\alpha^2 \tilde{V}}{\kappa} \right) dT + \frac{\alpha}{\kappa} d\tilde{V} \ .$$

Hence,

$$\left(\frac{\partial \tilde{E}}{\partial \tilde{V}}\right)_T = T\left(\frac{\partial \tilde{S}}{\partial \tilde{V}}\right)_T - P \ . \tag{19.135}$$

From the Maxwell relation derived from, $d\tilde{F} = -\tilde{S}dT - Pd\tilde{V}$, we find,

$$\left(\frac{\partial P}{\partial T}\right)_V = -\left(\frac{\partial}{\partial T}\left(\frac{\partial \tilde{F}}{\partial \tilde{V}}\right)_T\right)_V = -\left(\frac{\partial}{\partial \tilde{V}}\left(\frac{\partial \tilde{F}}{\partial T}\right)_V\right)_T = \left(\frac{\partial \tilde{S}}{\partial \tilde{V}}\right)_T \ . \tag{19.136}$$

Hence,

$$\left(\frac{\partial \tilde{E}}{\partial \tilde{V}}\right)_T = T\left(\frac{\partial P}{\partial T}\right)_V - P \ . \tag{19.137}$$

Now, we consider a dense real van der Waals gas according to Eq. (19.127) but neglecting the volume parameter, $b = 0$. The pressure P then behaves as a function of temperature T and molar volume $\tilde{V}$ according to the following state equation,

$$P = \frac{R_{\mathrm{g}}T}{\tilde{V}} - \frac{a}{\tilde{V}^2} \ , \tag{19.138}$$

where a is a positive constant and R_{g} is the universal gas constant. From the equation of state we obtain,

$$\left(\frac{\partial P}{\partial T}\right)_V = \frac{R_{\mathrm{g}}}{\tilde{V}} \ , \tag{19.139}$$

which, replaced in the expression (19.137), gives,

$$\left(\frac{\partial \tilde{E}}{\partial \tilde{V}}\right)_T = T\frac{R_{\mathrm{g}}}{\tilde{V}} - P = \frac{a}{\tilde{V}^2} \ . \tag{19.140}$$

Integrating this equation yields,

$$\tilde{E} = -\frac{a}{\tilde{V}} + K(T) \tag{19.141}$$

where $K(T)$ depends only on T. We now have the molar energy $\tilde{E}$ expressed as a function of molar volume $\tilde{V}$.

We now assume that the heat capacity $\tilde{C}_V$ be constant. Differentiating the expression (19.141) by temperature gives,

$$\tilde{C}_V = \left(\frac{\partial \tilde{E}}{\partial T}\right)_V = K'(T) \ . \tag{19.142}$$

Inserting the integral of (19.142), $K(T) = \tilde{C}_V T + K_0$, into (19.141), we end up with,

$$\boxed{\tilde{E} = -\frac{a}{\tilde{V}} + \tilde{C}_V T + K_0} \ . \tag{19.143}$$

In a process of free expansion, $\tilde{E}$ remains invariant and $\tilde{V}$ grows. Thus, resolving (19.143) by temperature and deriving by volume,

$$\left(\frac{\partial T}{\partial \tilde{V}}\right)_E = \left(\frac{\partial}{\partial V}\frac{\tilde{E} + a/\tilde{V} - K_0}{C_V}\right)_E = \frac{-a}{C_V \tilde{V}^2} \ . \tag{19.144}$$

For an ideal gas, $a = 0$, we expect no temperature change. For a gas with positive (negative) a the variation (19.144) will be negative (positive).

Example 152 (*Microscopic interpretation of Joule-Thomson cooling*): In the discussion of the the process illustrated in Fig. 19.19 we stated that an ideal gas does not changes its temperature when it expands flowing through a nozzle from one volume into another. This is in contrast to the behavior of a real gas. Indeed, in a compressed gas the molecules are closer to each other and thus feel attractive (or repulsive) van der Waals forces. When the gas expands, the molecules must overcome these forces at the cost (gain) of kinetic energy.

19.2.8 Exercises

19.2.8.1 Ex: Material parameters

The compressibility κ, the thermal expansion coefficient α, and the stress coefficient β are important material parameters. In the case of a unary system (single substance), they are defined by,

$$\kappa = -\frac{1}{V}\left(\frac{\partial V}{\partial P}\right)_{\nu,T} \quad , \quad \alpha = \frac{1}{V}\left(\frac{\partial V}{\partial T}\right)_{\nu,P} \quad , \quad \beta = \frac{1}{P}\left(\frac{\partial P}{\partial T}\right)_{\nu,V} \ .$$

Here ν is the number of moles.
a. Show that these relationships can be rewritten, using the molar volume $\tilde{V}$, to,

$$\kappa = -\frac{1}{\tilde{V}}\left(\frac{\partial \tilde{V}}{\partial P}\right)_{T} \quad , \quad \alpha = \frac{1}{\tilde{V}}\left(\frac{\partial \tilde{V}}{\partial T}\right)_{P} \quad , \quad \beta = \frac{1}{P}\left(\frac{\partial P}{\partial T}\right)_{\tilde{V}} \ .$$

b. Use the total differential of $V = V(T, P, \nu)$ to show that, in general,

$$\beta = \frac{\alpha}{\kappa P} \ .$$

c. Calculate κ, α and β for an ideal gas as functions of P and T. Show that the relationship from (b) is also fulfilled.

19.2.8.2 Ex: 1. law of thermodynamics

In a thermally insulated container there is one mole of air at the temperature $T_\mathrm{i} = 400\,\mathrm{K}$. Now, it is reversibly compressed, doing the work $W = 100\,\mathrm{cal}$. Calculate the ratio $V_\mathrm{f}/V_\mathrm{i}$ between the final and initial volume. Assume that the air behaves like an ideal gas and that the container itself does not absorb heat from the air.

19.2.8.3 Ex: Specific heat

The specific heat for an isobaric transformation is defined as $C_P = R_\mathrm{g} + C_V$. A mass of $m_{\mathrm{N}_2} = 10\,\mathrm{g}$ of nitrogen is heated at constant pressure $P = 2\,\mathrm{atm}$ and an initial temperature of $T_\mathrm{i} = 20\,^\circ\mathrm{C}$ until its volume increases by 20%. Calculate the initial volume V_i, the final temperature T_f, and the heat supplied Q.

19.2.8.4 Ex: Volumetric thermal expansion of an ideal gas

a. Calculate the volumetric thermal expansion coefficient of an ideal gas at constant pressure.
b. Calculate the volumetric thermal expansion coefficient of an ideal gas during an adiabatic expansion.

19.2.8.5 Ex: Specific heat at constant volume/pressure

a. Explain why the specific heat at constant volume is less than the specific heat at constant pressure.
b. Show that for a diatomic gas $\gamma = \frac{C_P}{C_V} = \frac{7}{5}$.

19.2.8.6 Ex: Heat capacities

a. Two gas containers are brought into thermal contact. They contain gases with the temperatures T_1 and T_2, as well as the heat capacities C_1 and C_2. The thermal capacity of the containers is negligible. What is the temperature of the gases after an equilibrium has been reached?
b. Now consider the temperature equilibrium of three containers, each with 100 g of the gas H_2 at the temperature $T_{H_2} = 10\,^\circ\mathrm{C}$, 50 g of the gas He at the temperature $T_\mathrm{He} = 15\,^\circ\mathrm{C}$, and 200 g of the gas N_2 at temperature $T_{\mathrm{N}_2} = 20\,^\circ\mathrm{C}$. What is the final temperature?

19.2.8.7 Ex: Gas compression

Calculate the temperature change resulting from *adiabatic* compression of an ideal gas of volume $V(T_1)$ to $V(T_2) = V(T_1)/10$.
Compare this with the temperature change through an analog *isobaric* compression of an equally ideal gas. **Note:** $\gamma = c_P/c_V = 1.4$ (for air), $T_1 = 293\,\mathrm{K}$.

19.2.8.8 Ex: Gas compression

An oxygen bottle with the volume $V_2 = 40\,\mathrm{L}$ contains a filling ex works that would have the volume $V_1 = 6\,\mathrm{m}^3$ at atmospheric pressure $P_1 = 101\,\mathrm{kPa}$. The bottle, which has been emptied to atmospheric pressure, is refilled at a constant temperature of $T_1 = 18\,^\circ\mathrm{C}$. What mechanical work W must be added to the gas to compress it isothermally from P_1 to the filling pressure?

19.2.8.9 Ex: Gas expansion

1 kmol of nitrogen under normal conditions ($P_0 = 1.01 \times 10^5$ Pa, $T = 0\,°\mathrm{C}$) adiabatically expands from V_1 to $V_2 = 5V_1$. Calculate the change in the internal energy of the gas and the amount of work the gas does as it expands.

19.2.8.10 Ex: Adiabatic expansion

a. During the adiabatic expansion of a gas the pressure P and the volume V of the gas satisfy the relationship $PV^\gamma = \alpha$, where α is a constant, and γ is the factor of the gas that gives the ratio between the specific heats at constant pressure and volume, i.e. $\gamma = c_P/c_V$. A gas was placed in a cylinder with a movable (frictionless) plunger completely insulated from the external environment. The assembly makes it possible to measure the volume and pressure of the gas during its expansion and the experimental values obtained are given in the table below.
a. From the values in the table below, and using the least squares method, determine the gas factor and the constant α. (**Hint:** To obtain a linear relationship, take $x = \lg V$ and $y = \lg P$.).
b. Determine, through the method of least squares, the uncertainties in the values obtained for γ and α.
c. Using a log×log paper, prepare a graph $P \times V$ and determine the values of γ and α. Compare with the results obtained by the least squares method.
Notes: When displaying the values of γ and α, be sure to indicate the units in which they are expressed.
Display the values of S_x, S_y, S_{x2} and S_{xy} used in the least squares method calculations.

V (L)	P (atm)
40	1.20
41	1.16
43	1.10
44	1.05

19.2.8.11 Ex: 1. law of thermodynamics

In a thermally insulated container B there are n mol of an ideal gas and a body K with the heat capacity C. Specify the relationship between pressure P and volume V, whereby the change in V is carried out so slowly that the following always applies to body and gas: $T_\mathrm{K} = T_\mathrm{G}$.
Note: Body and gas exchange heat. Assume that the container itself does not take heat from the gas or the body.

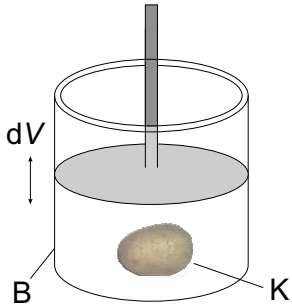

Figure 19.26: Potato.

19.2.8.12 Ex: 1. law of thermodynamics

A container with 1 mol helium and a container of the same size with 1 mol nitrogen are both heated with the same heating power $P_Q = 10\,\mathrm{W}$.
a. Calculate how long it takes to warm up the containers from $T_1 = 20\,°\mathrm{C}$ to $T_2 = 100\,°\mathrm{C}$, if the thermal capacity of the container is $C_{rec} = 10\,\mathrm{J/K}$.
b. How long does it take to warm up to $1000\,°\mathrm{C}$ assuming that the vibrational degrees freedom of N_2 molecules can be excited above $500\,°\mathrm{C}$? Neglect heat loss.

19.2.8.13 Ex: Rüchardt's calorimetric method

A mono-atomic ideal gas with the adiabatic coefficient $\gamma = 1.4$ is in a thermally insulated bottle with a long neck. The total volume of the bottle and the neck is $V_0 = 10\,\mathrm{L}$. At the beginning there is atmospheric pressure. A thermally insulating ball with mass $m = 20\,\mathrm{g}$ is now inserted into the neck (precision tube with a diameter of $d = 16\,\mathrm{mm}$), which hermetically seals the bottle to the outside. The ball can move smoothly.
a. Determine the equilibrium position of the ball. What is the pressure and volume in the part of the bottle sealed by the ball?
b. The ball is now pushed down slightly from the equilibrium position and then released. With what period τ does the ball vibrate.
Help: Relate the instantaneous pressure p in the bottle to small volume changes ΔV and linearize the expression using a Taylor expansion.

19.2.8.14 Ex: Calorimeter for mixtures

The specific heat capacity of platinum c_{Pt} is to be measured with a mixing calorimeter. For this purpose, a platinum body is heated to $100\,°\mathrm{C}$ and then thrown into water of $20\,°\mathrm{C}$. To simplify the evaluation, the mass of the water is chosen to be that of the platinum body. The heat absorption of the calorimeter body should be neglected. The specific heat capacity of water is $c_{\mathrm{H_2O}} = 4.19\,\mathrm{J/(g\,K)}$, the relative atomic mass of platinum is $m_{\mathrm{Pt}} = 195\,\mathrm{u}$, the linear expansion coefficient $\alpha = 9.0 \cdot 10^{-6}\,\mathrm{K^{-1}}$.
a. The mixing temperature is $22.41\,°\mathrm{C}$. What value follows for c_{Pt}?
b. What is the value for c_{Pt} when applying the Dulong-Petit rule?
c. The platinum body and the water have the same mass. What is the ratio of the

number of platinum atoms to the number of water molecules?
d. How many degrees does the platinum body have to be heated to increase its volume by 1 %?

19.2.8.15 Ex: Calorimeter for mixtures

Consider a system for which the equation of state of an ideal gas $PV = Nk_\mathrm{B}T$ applies and the energy is given as $E = C_V T$.
a. Show that for the entropy change of an ideal gas from state A with temperature T_A and volume V_A to state B with temperature T_B and volume V_B holds: $\Delta S = C_V \ln(T_\mathrm{B}/T_\mathrm{A}) + Nk_\mathrm{B} \ln(V_\mathrm{B}/V_\mathrm{A})$.
b. Two insulated containers with the same volume $V = 10\,\mathrm{cm}^3$, the same pressure $P = 1\,\mathrm{bar}$ and the same temperature $T = 100\,^\circ\mathrm{C}$ are filled with nitrogen and oxygen, respectively. Determine the change in entropy when connecting the containers so that the gases can mix.

19.2.8.16 Ex: 2. law of thermodynamics

A thermally insulated container with a total volume of $V = 10\,\mathrm{L}$ is separated into two equal parts by a plate. In each part there are 10 mol of the same ideal atomic gas. In one part the gas has the temperature $T_1 = 300\,\mathrm{K}$, in the other the temperature $T_2 = 400\,\mathrm{K}$. Calculate the change in the total entropy ΔS of the system in the event that:
a. the plate does not insulate heat;
b. a small hole opens in the disc through which the gases can mix slowly and which at the end closes again;
c. the plate is suddenly removed and then put back in after some time without any work being done.
In all three cases we wait for equilibrium to establish.
d. What changes in case the gases in both parts are different?

19.2.8.17 Ex: 2. law of thermodynamics

A heat engine works between two heat sources with temperatures $T_2 > T_1$. If we take away the heat δQ from the second heat source, what is the maximum and minimum work δW_max and δW_min that the heating machine can do? What could the corresponding processes look like?

19.2.8.18 Ex: Specific heat

Calculate the specific heat per mol of an ideal gas for a reversible process according to the law $PV^\gamma = const$ with $\gamma \in \mathbb{R}$. Can such specific heat be negative? Justify the result.

19.2.8.19 Ex: Expansion of a gas

One mole of a simple ideal gas, defined by $E = cR_\mathrm{g}T$, $PV = R_\mathrm{g}T$, is contained in a container of initial volume V_i and pressure P_i. The gas expands from that initial state to the state corresponding to a final volume $V_\mathrm{f} = 2V_\mathrm{i}$, through several different

processes. Determine the work δW done by the gas and the heat δQ received by the gas for each of these processes. Final answers should be given only in terms of $(V_\mathrm{i}, P_\mathrm{i})$ and the constant c.
a. Free expansion: also determine the temperature variation ΔT.
b. Isentropic expansion: also obtain the final pressure P_f, using the fact that in this process for an ideal gas $PV^\gamma = constant$, where $\gamma = (c+1)/c$.
c. Isobaric quasi-static expansion.
d. Isothermal quasi-static expansion.

19.2.8.20 Ex: Adiabatic expansion

A diatomic gas is initially maintained at a pressure of $P_\mathrm{i} = 4000\,\mathrm{hPa}$ in a piston of volume $V_\mathrm{i} = 1\,\mathrm{L}$ at temperature $T_\mathrm{i} = 100\,^\circ\mathrm{C}$. Now the gas pressure forces the piston to move until it reaches half the pressure. Considering the expansion as an adiabatic process,
a. calculate the number of moles η inside the piston;
b. calculate the thermal capacities at constant volume C_V of the gas, as well as at constant pressure C_P, and determine the adiabatic coefficient γ;
c. calculate the final volume of the piston;
d. calculate the final temperature of the gas;
e. calculate the work done by the gas on the piston.
f. Now, the gas cools down gradually while the piston is held fix. Calculate the pressure P_r when the temperature reached $T_r = 20\,^\circ\mathrm{C}$.

19.2.8.21 Ex: Entropy changes

a. What entropy increase results when 200 g of (liquid) water at $0\,^\circ\mathrm{C}$ and 200 g water at $90\,^\circ\mathrm{C}$ are mixed at constant pressure in a heat-insulated recipient? The molar heat c_p of the water should be $75.5\,\mathrm{J/(mol\ K)}$ regardless of the temperature.
b. $1\,\mathrm{dm}^3$ helium at $P_0 = 1\,\mathrm{bar}$ and $T_0 = 0\,^\circ\mathrm{C}$ are heated to the temperature $T = 500\,\mathrm{K}$. How big is the change in entropy upon isochoric and isobaric heating?

19.2.8.22 Ex: Heat capacity

When drilling a brass block of mass $m = 500\,\mathrm{g}$ ($c = 0.1\,\mathrm{cal/(g\ K)}$), a power of 300 W is provided for 2 minutes. What is the temperature rise of the block, if 75% of the heat generated warms it up? What happens to the remaining 25%?

19.2.8.23 Ex: Heat and work upon thermodynamic processes

Calculate the heat generated and the work executed for at least two (non-trivial) equilibrium thermodynamic processes involving the active change of one of the state variables T, S, P, V, while maintaining one other variable fixed. Consider the ideal gas case as a limit of the general formulas. Check with the expressions listed in Tab. 19.2.

19.2.8.24 Ex: Heat power engine and heat pump based on Carnot cycle

Consider a heat power engine and a heat pump based on the Carnot cycle. Calculate the efficiency and the generated, respectively, consumed power as a function of the temperature difference between the hot and the cold bath.

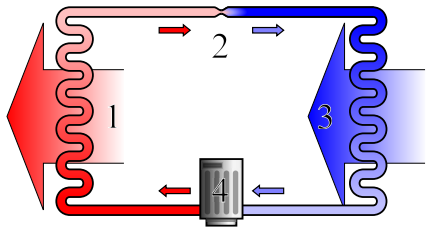

Figure 19.27: Principle of a heat pump.

19.2.8.25 Ex: The Otto cycle

Calculate the yield $\eta = \Delta W/\Delta Q$ of the *Otto cycle*, where ΔQ is the heat received by the system and ΔW the work executed, (see Fig. 19.28). Express the result as a function of the compression $k = V_1/V_2$.

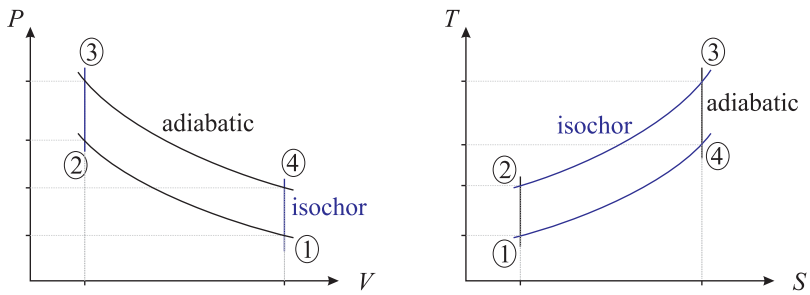

Figure 19.28: Otto cyclic process. The black branches are adiabatic processes.

19.2.8.26 Ex: The Diesel cycle

Calculate the yield $\eta = \Delta W/\Delta Q$ of the *Diesel cycle*, where ΔQ is the heat received by the system and ΔW the work executed, (see Fig. 19.29).

19.2.8.27 Ex: Brayton cycle modeling a gas turbine

Calculate the efficiency of the Brayton cycle modeling a gas turbine, as shown in Fig. 19.30.

19.2.8.28 Ex: Cyclic process

An ideal gas with N atoms and the heat capacities $C_V = \frac{3}{2}Nk_\mathrm{B}$ and $C_P = \frac{5}{2}Nk_\mathrm{B}$ goes through the cycle shown in Fig. 19.31. For the starting point (1) its pressure P_1,

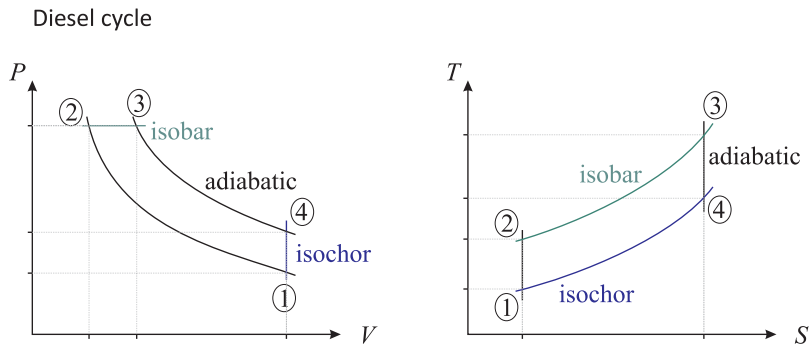

Figure 19.29: PV-diagram (left) and TS-diagram (right) for the Diesel cycle. The black branches are adiabatic processes.

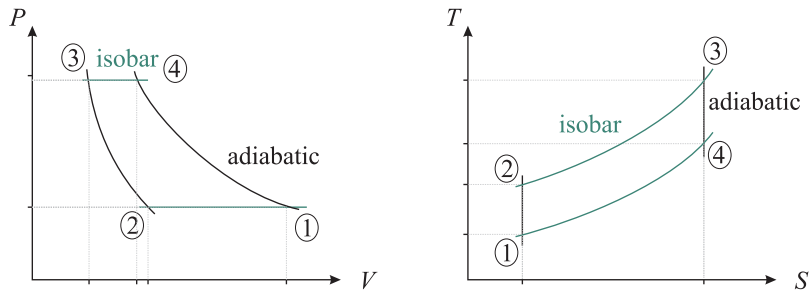

Figure 19.30: PV-diagram (left) and TS-diagram (right) for the Brayton cycle.

volume V_1, and thus also the temperature T_1 are known.
a. Calculate P_2, T_2, P_3 and T_3, if $V_2 = V_3 = 3V_1$.
b. Calculate the work done and the heat input for all three steps of the cyclic process, as well as the efficiency.

19.2.8.29 Ex: Heat engine cycle with two isochoric phases

In a heat power machine (illustrated in Fig. 19.32), the working gas (helium) is sealed off in a cylinder by a movable piston. The gas is alternately heated and cooled from the outside. The piston moves back and forth periodically and drives a shaft. The initial state is: $P = 0.2 \cdot 10^6\,\mathrm{Pa}$, $V = 150\,\mathrm{cm}^3$, $T = 300\,\mathrm{K}$.
a. Calculate the mass of the enclosed helium and the adiabaticity coefficient.
b. During a complete work cycle, the gas undergoes the following changes in its state:
$1 \to 2$ isochoric heating to twice the temperature,
$2 \to 3$ isothermal expansion to twice the volume,
$3 \to 4$ isochoric cooling to the initial temperature,
$4 \to 1$ isothermal compression to initial volume.
Calculate the work done and the heat input for all three steps of the cyclic process.

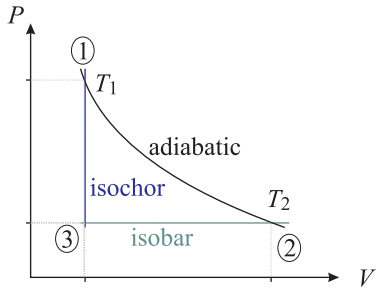

Figure 19.31: Cyclic process.

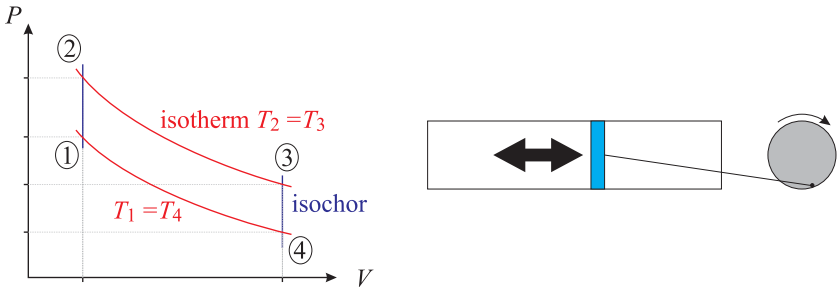

Figure 19.32: Cyclic process and scheme of a heat power engine

19.2.8.30 Ex: Heat engine cycle with two isochoric phases

An engine, whose four work steps consist of two isothermal and two isochoric processes, runs at a speed of $N = 500\,\text{min}^{-1}$. There is $\nu = 0.5\,\text{mol}$ of an ideal, monoatomic gas in the volume of the engine. The parameters for the individually labeled working steps are $T_1 = 50\,°\text{C}$, $P_1 = 2\,\text{bar}$, and $P_2 = 5\,\text{bar}$.
a. Determine the volumes $V_1 = V_2$ and $V_3 = V_4$, the pressure P_4, and the temperature T_2.
b. What efficiency η does the cycle have?
c. How high is the net power P of the engine?

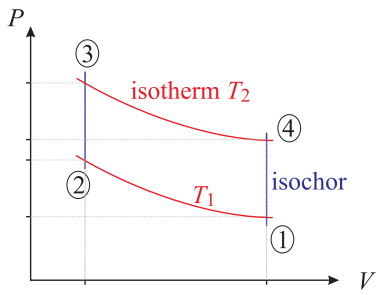

Figure 19.33: Cyclic process.

19.2.8.31 Ex: Cyclic process

A thermodynamic system is brought from an initial state (1) to another state (2), then to (3), and finally back to (1), as illustrated in the diagram in Fig. 19.34. Calculate the work and heat balance for the entire cycle.

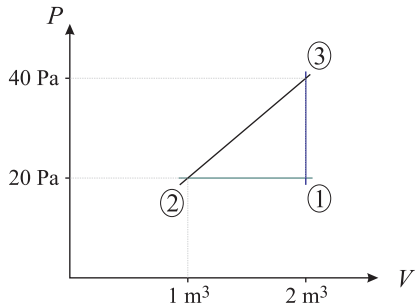

Figure 19.34: Cyclic process

19.2.8.32 Ex: Cyclic process

An ideal gas with N atoms and the heat capacities $C_V = \frac{3}{2}Nk_\mathrm{B}$ and $C_P = \frac{5}{2}Nk_\mathrm{B}$ goes through the cycle shown in Fig. 19.35: First an isotherm from (1) to (2), then an isobar from (2) to (3) and finally an isochor from (3) to (1). For the starting point (1), the temperature T_1 and the volume V_1 are known, for (2) V_2 is given.
a. Calculate the work done and the heat input for all three steps of the cyclic process, as well as the efficiency as a function of V_1 and V_2 and alternatively of T_1 and T_3.
b. Calculate the total changes of internal energy and entropy. Show explicitly that $\Delta Q/T$ remains the same, regardless of whether we go from (1) to (2) via a reversible isothermal process or first with a reversible isobaric process and then with a reversible isochoric process.

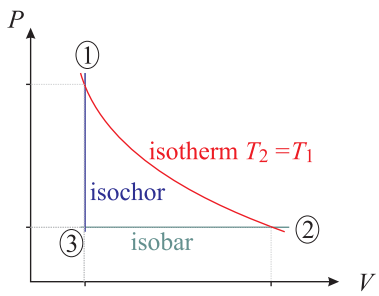

Figure 19.35: Cyclic process.

19.2.8.33 Ex: Cyclic process

Calculate the yield $\eta = \Delta W/\Delta Q$ of the process depicted in Fig. 19.36).

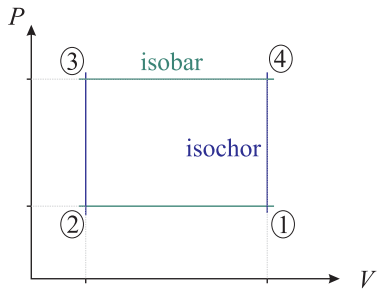

Figure 19.36: Cyclic process.

19.2.8.34 Ex: Dieterici model for a real gas

Assume that one mole of a real gas satisfies the *Dieterici* equation of state (an alternative to the van der Waals equation),

$$Pe^{\alpha/(R_{\mathrm{g}}T\tilde{V})}(\tilde{V}-\beta)=R_{\mathrm{g}}T\ ,$$

where α and β are parameters.
a. In what units α and β have to be specified? What sign do you expect for each parameter?
b. Express the parameters of the critical point T_{c} and V_{c} by α and β.

19.2.8.35 Ex: Isothermal expansion

Calculate the work done during isothermal expansion from V_1 to V_2 of a real gas.

19.2.8.36 Ex: Joule-Thomson process

Here we study the *Joule-Thomson effect*. A gas is forced under constant pressure P_1 from a container B1 through a porous partition into a container B2 with constant pressure $P_2 < P_1$. The constancy of the pressures in the containers is ensured by increasing or decreasing their volumes. Finally, it is assumed that the gas is adiabatically isolated from the environment and therefore only exchanges with it energy in the form of work.
a. Show that the enthalpy H remains constant in both recipients during this process.
b. Show that,

$$\left(\frac{\partial T}{\partial P}\right)_H=\frac{1}{C_P}\left[T\left(\frac{\partial V}{\partial T}\right)_P-V\right]\ ,$$

and calculate $(\partial T/\partial P)_H$ explicitly for an ideal gas.
c. For a real gas, the so-called inversion curve $P(T)$ defined by $(\partial T/\partial P)_H$ is obtained in the PT-plane. Physically interpret the areas above and below this curve. Calculate the inversion curve for the van der Waals gas using the thermal equation of state for real gases.
d. Discuss the behavior of entropy in this process.

19.3 Thermodynamic equilibrium

Until now, we always assumed a system to be in thermal equilibrium, but we did not say how to determine what this state is. In the following, we will lay out general criteria for equilibrium and devise strategies for the calculation of equilibrium maps and phase diagrams.

Upfront let as note that *in an isolated system, the entropy is maximum at equilibrium.* We will translate this principle into a mathematical language consisting in a set of equations, called equilibrium conditions, which determine the relationships that the internal properties of the system must satisfy to find itself in equilibrium.

To discuss equilibrium conditions for a system, we need to allow it to be out of equilibrium. This obviously is not possible with the simple systems studied so far. The mere fact that they can be fully described by a single state function is due to the assumption that they are in equilibrium already, e.g. with the environment. We will thus illustrate the equilibrium conditions at a unary, two-phase system.

The notion of equilibrium is introduced in classical mechanics as a balance of forces(see Sec. 2.4.1). In thermodynamics the factors that influence the evolution of a systems are more general: whatever is doing work, transferring heat, or providing matter can drive a system out of equilibrium. To be at equilibrium a system must (i) be at rest and (ii) be balanced. The first condition means that, if not perturbed by external factors, the system does not change its state during time. The second condition means, that after a transient perturbation driving the system out of equilibrium the system finds back to its original state. The illustration in Fig. 19.37(a) shows on the left a situation satisfying both conditions (i) and (ii) and on the right a situation only satisfying condition (i).

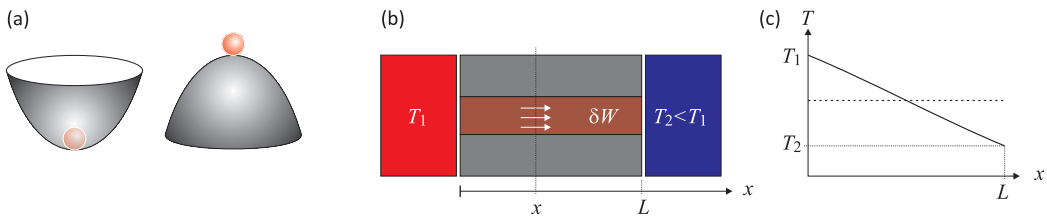

Figure 19.37: (a) Stable and unstable equilibrium positions in a mechanical system. (b) A thermally insulated copper rod conducting heat from a hot source to a cold sink develops a stationary temperature profile across its length (solid line in c). However, when disconnected from its surroundings (source and sink) it changes a temperature profile (dashed line in c).

A system can be at steady-state while being driven by external influences, as illustrated in Fig. 19.37(b). We will, however, consider a system to be at equilibrium only, when it is stationary while being isolated from the environment. In that case, no entropy is exchanged with the environment, $dS_{\text{trans}} = 0$, so that all changes in entropy must result from internal production, $dS_{\text{prod}} > 0$. And since in equilibrium the entropy production comes to a halt, the *state of equilibrium is necessarily the one with the highest entropy.* This principle will be used as a criterion to help us in the quest for the equilibrium state of an isolated system [3].

[3] Note that it doesn't matter how the equilibrium state was reached, e.g. whether it had interacted

19.3.1 Conditions for equilibrium

Mathematically, the first condition for equilibrium is spelled out by requesting the state to sit at an extremum of the state function. For instance, the state function $W = W(X, Y)$, whose differential is,

$$dW = \left(\frac{\partial W}{\partial X}\right)_Y dX + \left(\frac{\partial W}{\partial Y}\right)_X dY \ , \tag{19.145}$$

will have minima at those points (X_0, Y_0) satisfying the conditions,

$$\left(\frac{\partial W}{\partial X}\right)_{Y=Y_0} = 0 = \left(\frac{\partial W}{\partial Y}\right)_{X=X_0} \ . \tag{19.146}$$

The nature of the extrema, whether maximum, minimum, or saddle point, depends on the second derivatives of W at those points. The procedure can easily be extended to state functions of more variables. This procedure holds for independent variables, which generally is not the case. For instance, if the variables depend on each other, $Y = Y(X)$, we got a constraint.

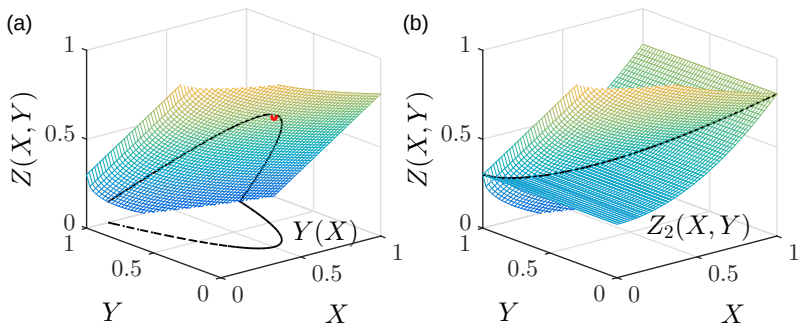

Figure 19.38: (code) Illustration of state function and constraints. The surface in (a) visualizes a state function depending on two variables; the black curve illustrates a possible constraint $Y = Y(x)$ between the variables. Fig. (b) shows the same surface as in (a), now constrained by and additional surface $Z_2 = Z_2(X, Y)$.

A general procedure to handle this is the following:

1. Consider the state function, $W = W(X_1, X_2, ...)$, with the constraints $X_k = X_k(X_1, X_2, ...)$.

2. Write the differential forms for all equations, for the state equation:

$$dW = A_1 dX_1 + A_2 dX_2 + ... \qquad \text{with} \qquad A_j \equiv \left(\frac{\partial W}{\partial X_j}\right)_{\{X_{i|i\neq j}\}} \ , \tag{19.147}$$

and for the constraints:

$$dX_k = B_{1k} dX_1 + B_{2k} dX_2 + ... \qquad \text{with} \qquad B_{1k} \equiv \left(\frac{\partial X_k}{\partial X_j}\right)_{\{X_{i|i\neq j}\}} \ . \tag{19.148}$$

transiently with some pump or sink. If it stays stationary once the pump or sink is removed, it should be considered at equilibrium.

3. Substitute dX_k in Eq. (19.147) and collect the coefficients C_l of the remaining terms $dX_{l|l\neq k}$,
$$dW = C_1 dX_{l_1} + C_2 dX_{l_2} + \dots \ . \tag{19.149}$$

4. Set the coefficients to zero, $C_l = 0$. The solution of the system of equations yields the extremum under the constraint.

Example 153 (*Equilibrium condition with four variables*): To illustrate the procedure, let us consider the state function $W = W(U, V, X, Y)$ with two constraints, $U = U(X, Y)$ and $V = V(X, Y)$. The differential form are,

$$dW = AdU + BdV + CdX + DdY \quad , \quad dU = EdX + FdY \quad , \quad dV = GdX + HdY \ , \tag{19.150}$$

where the coefficients A to H are the partial derivatives taken with all other variables being constant. Substituting dU and dV and collecting terms, we get,

$$\begin{aligned} dW &= A(EdX + FdY) + B(GdX + HdY) + CdX + DdY \\ &= (AE + BG + C)dX + (AF + BH + D)dY \ . \end{aligned} \tag{19.151}$$

Now, setting terms in the brackets to zero,

$$AE + BG + C = 0 = AF + BH + D \ , \tag{19.152}$$

we obtain the desired conditions for the extremum.

19.3.2 Entropy maximization in two-phase systems, chemical potential

Let us consider a unary, two-phase, non-reacting, and otherwise simple system. Both phases are characterized by their own set of extensive and intensive parameters. Now, the values of the extensive properties of both systems sum up,

$$S_1 + S_2 = S_{\text{tot}} \ , \tag{19.153}$$

and analogously for the other state functions V_j, E_j, H_j, F_j, G_j with $j = 1, 2$, but also for the number of particles N_j in each phase. If we now allow particles to move between the phases, as the state functions depend on the particle number, we need to consider this dependency,

$$E_j = E_j(S_j, V_j, N_j) \ , \tag{19.154}$$

and so on for the other state functions. This leads to a generalization of the differential form (19.70),

$$dE_j = T_j dS_j - P_j dV_j + \mu_j dN_j \ , \tag{19.155}$$

where we introduced the coefficient,

$$\boxed{\mu_j \equiv \left(\frac{\partial E_j}{\partial N_j}\right)_{S_j, V_j}} \ , \tag{19.156}$$

called *chemical potential* of the component j.

Resolving Eq. (19.155) by dS_j, we may now calculate the total entropy change,

$$dS_{\text{tot}} = dS_1 + dS_2 = \frac{1}{T_1}dE_1 + \frac{1}{T_2}dE_2 + \frac{P_1}{T_1}dV_1 + \frac{P_2}{T_2}dV_2 - \frac{\mu_1}{T_1}dN_1 - \frac{\mu_2}{T_2}dN_2 \ . \quad (19.157)$$

The fact that the system is closed implies, $dE_1 + dE_2 = 0$, $dV_1 + dV_2 = 0$, and $dN_1 + dN_2 = 0$. Using these constraints in (19.157) we get,

$$dS_{\text{tot}} = \left(\frac{1}{T_1} - \frac{1}{T_2}\right) dE_1 + \left(\frac{P_1}{T_1} - \frac{P_2}{T_2}\right) dV_1 - \left(\frac{\mu_1}{T_1} - \frac{\mu_2}{T_2}\right) dN_1 \ . \quad (19.158)$$

Hence, the systems comes to equilibrium once the following conditions are fulfilled,

$$\boxed{\begin{array}{lcll} T_1 & = & T_2 & \text{thermal equilibrium} \\ P_1 & = & P_2 & \text{mechanical equilibrium} \\ \mu_1 & = & \mu_2 & \text{chemical equilibrium} \end{array}} \ . \quad (19.159)$$

Alternative formulations of the equilibrium criteria may be derived in terms of other thermodynamic state functions. A quick look at the expressions (19.70) informs us, that for systems constraint to

- $S = const$ and $V = const$, E is minimum at equilibrium;
- $S = const$ and $P = const$, H is minimum at equilibrium;
- $T = const$ and $V = const$, F is minimum at equilibrium;
- $T = const$ and $P = const$, G is minimum at equilibrium.

Application of any of these criteria leads to the same set of conditions for equilibrium.

19.3.3 Exercises

19.3.3.1 Ex: Gibbs free energy

Prove the relationship [4],

$$\left(\frac{\partial G}{\partial T}\right)_V = \left(\frac{\partial G}{\partial T}\right)_P + \left(\frac{\partial G}{\partial P}\right)_T \left(\frac{\partial P}{\partial T}\right)_V \ .$$

19.4 Thermodynamic ensembles

When we introduced the main thermodynamic potentials for canonical ensembles (19.70) we implicitly supposed that the particle number N is fixed. If we want to consider N as an equilibrium parameter, it must be treated as an independent state

[4] Note that [239] claims on page 65 that this relationship holds for the enthalpy H, which is wrong.

variable, as shown in Sec. 19.3.2, and consequently the thermodynamic potentials must be generalized.

The following Eqs. (19.161) introduce several new energy state variables. The defined potential $\Omega(T, V, \mu)$ is the called the *Landau grand canonical potential*. The potentials $\Psi(S, V, \mu)$ and $\Phi(S, P, \mu)$ are not used in practice. The potential $O(T, P, \mu)$ only depends on intensive variables and therefore cannot be a state energy, i.e. it must be zero, $O = 0$. This is known as the *Gibbs-Duhem equation*, which will be treated in Sec. 20.2. The potentials will be discussed briefly in Sec. 19.4.1 and in detail in Part 29.

$$
\begin{aligned}
& & \delta Q_{\text{rev}} &= TdS \\
& & \delta W_{\text{rev}} &= -PdV \\
E = \int(TdS - PdV + \mu dN) & \implies & dE &= TdS - PdV + \mu dN \\
\Psi = E - \mu N & \implies & d\Psi &= TdS - PdV - Nd\mu \\
H = E + PV & \implies & dH &= TdS + VdP + \mu dN \\
\Phi = H - \mu N & \implies & d\Phi &= TdS + VdP - Nd\mu \\
F = E - TS & \implies & dF &= -SdT - PdV + \mu dN \\
\Omega = F - \mu N & \implies & d\Omega &= -SdT - PdV - Nd\mu \\
G = H - TS & \implies & dG &= -SdT + VdP + \mu dN \\
O = G - \mu N = 0 & \implies & dO &= -SdT + VdP - Nd\mu
\end{aligned}
\tag{19.160}
$$

Example 154 (*Thermodynamics of grand canonical ensembles*): The goal is here to represent the differentials of the extensive variables as functions of the intensive variables,

$$
S = S(T, P, \mu) \quad , \quad V = V(T, P, \mu) \quad , \quad N = N(T, P, \mu) \; . \tag{19.161}
$$

For grand canonical ensembles we need to define additional material constants,

$$
\begin{array}{c|c|c}
C_P \equiv T\left(\frac{\partial S}{\partial T}\right)_{P,\mu} & -\alpha = \frac{1}{V}\left(\frac{\partial S}{\partial P}\right)_{T,\mu} & \sigma \equiv \mu\left(\frac{\partial S}{\partial \mu}\right)_{T,P} \\
\hline
\alpha \equiv \frac{1}{V}\left(\frac{\partial V}{\partial T}\right)_{P,\mu} & \kappa \equiv -\frac{1}{V}\left(\frac{\partial V}{\partial P}\right)_{T,\mu} & \eta \equiv \frac{1}{V}\left(\frac{\partial V}{\partial \mu}\right)_{T,P} \\
\hline
\sigma = \mu\left(\frac{\partial N}{\partial T}\right)_{P,\mu} & -\eta = \frac{1}{V}\left(\frac{\partial N}{\partial P}\right)_{T,\mu} & \varkappa \equiv \frac{1}{N}\left(\frac{\partial N}{\partial \mu}\right)_{T,P}
\end{array}
\tag{19.162}
$$

where the relationships between corresponding off-diagonal elements are easily derived as Maxwell equations via the second derivative of the thermodynamic potential $O = G - \mu N$. Rearranging the matrix, we finally obtain,

$$
\boxed{
\begin{array}{llll}
dS = & \frac{C_P}{T}dT - & \alpha V dP + & \frac{\sigma}{\mu}d\mu \\
dV = & \alpha V dT - & \kappa V dP + & \eta V d\mu \\
dN = & \frac{\sigma}{\mu}dT - & \eta V dP + & \varkappa N d\mu
\end{array}
}
\; . \tag{19.163}
$$

The question is now, what are the additional material constants γ, $\varkappa$, and η? Do the Exc. 19.4.3.2.

19.4.1 Coupling of thermodynamic ensembles to reservoirs

Application of the thermodynamic apparatus on physical systems requests certain idealizations. In the preceding sections, for instance, we studied the case of systems in equilibrium with themselves, but insulated from the environment. Often, we also tacitly assumed that the number of particles be fixed and termed this condition as *canonical ensemble*. There are, however, numerous real world situations deviating from the above conditions, for example, when a system is held at a given temperature via thermal contact with a 'reservoir', or when chemical equilibrium is maintained via particle exchange with a 'reservoir'.

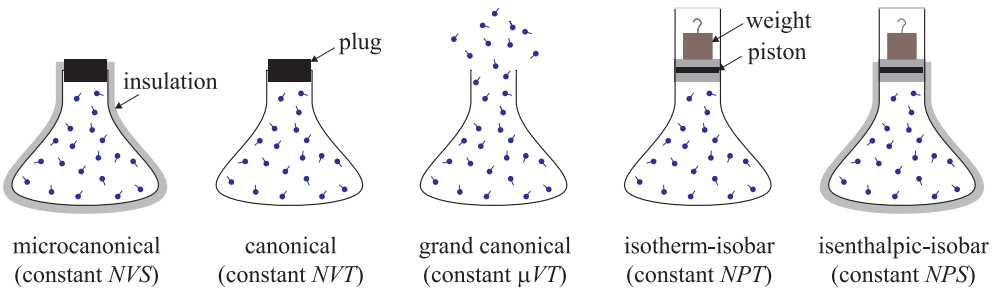

Figure 19.39: Insulated or heat conducting, closed or open, rigid or working systems.

A *reservoir* is here regarded as a system with infinite resources of heat, work, and particles. Thermal, mechanical, or chemical contact with a reservoir will thus force any finite system to equilibrate to the conditions imposed by the reservoir. In practice, the details of the coupling between system and reservoir may however vary, as illustrated in Fig. 19.39. With respect to coupling to a reservoir a system may be insulated ($dS = 0$) or heat conducting ($T \to T_{\rm eq}$), rigid ($dV = 0$) or compressible ($P \to P_{\rm eq}$), closed ($dN = 0$) or open to particle exchange ($\mu \to \mu_{\rm eq}$). From the intensive parameters (T, P, μ) only those parameters whose extensive counterpart are NOT held constant may act as equilibrium parameters. For example, holding S fixed the variable T cannot be an equilibrium parameter, and the system will be unable to exchange heat with the reservoir; holding V fixed the variable P cannot be an equilibrium parameter, and the system will be unable to work; holding N fixed the variable μ cannot be an equilibrium parameter, and the system will be unable to assimilate particles. This is summarized in Tab. 19.3.

19.4.2 Thermodynamic potentials associated to specific ensembles

The choice of which parameters are held fixed and which are treated as equilibrium parameters depends on the properties of the system under consideration. Idealized theoretical models have been developed in the past by Helmholtz, Gibbs, and Landau, among others, for several paradigmatic physical situations. These models are called *thermodynamic ensembles*. They are named after the variables considered as invariant within this model. For example, assuming that holding the entropy, the volume, and

Table 19.3: Various types of couplings to a reservoir.

type of coupling		equilibrium parameter
insulated	$dS = 0$	-
heat conducting	$dS \neq 0$	T
rigid	$dV = 0$	-
compressible	$dV \neq 0$	P
closed	$dN = 0$	-
open	$dN \neq 0$	μ

the particle number constant is a good description of a particular physical system, we will model it by a NVS-ensemble. This frequently used model is also called *microcanonical ensemble*. From Eqs. (19.161) we see that if $dS = dV = dN = 0$, then the internal energy as well cannot change, $dE = 0$. That is, E is the characteristic energy associated to the microcanonical ensemble [5]. Do the Exc. 19.4.3.1.

Analogous statements hold for other ensembles, as summarized in Tab. 19.4. The most common ones are the microcanonical, the canonical, and the grand (or macro-) canonical ensembles. We will briefly introduce them in the following and postpone an in-depth discussion to Chp. 29. It is important, however, to keep in mind that all those ensembles only are approximative models for particular physical situations. The predictions obtained from these ensembles will only be as good as the assumptions they are based on represent a realistic image of the physical reality.

Table 19.4: Various thermodynamic ensembles.

ensemble name	const.param.	extensive parameter	assoc.pot.	equil.param.
microcanonical	NVS	$dS = dV = dN = 0$	$dE = 0$	-
	μVS	$dS = dV = 0$	$d\Psi = 0$	μ
isenthalpic-isobar	NPS	$dS = dN = 0$	$dH = 0$	P
	μPS	$dS = 0$	$d\Phi = 0$	P, μ
canonical	NVT	$dV = dN = 0$	$dF = 0$	T
grand canonical	μVT	$dV = 0$	$d\Omega = 0$	T, μ
isotherm-isobar	NPT	$dN = 0$	$dG = 0$	T, P
	μPT		$dO = 0$	T, P, μ

The various canonical ensembles are important for being starting points for statistical approaches, which will be developed in Part 29.

[5] For this reason, the microcanonical ensemble is also called NVE-ensemble.

19.4.3 Exercises

19.4.3.1 Ex: Thermodynamic potential

What is the most suitable thermodynamic potential to describe a compressible system (compressible in the sense that the systems always adjusts its pressure to that of a large environment) with fixed particle number held at constant temperature via thermal contact with a large reservoir. How is the corresponding ensemble called?

19.4.3.2 Ex: Thermodynamic potential

a. Derive the differential forms for the relationships $S = S(T, V, \mu)$, $P = P(T, V, \mu)$, and $N = N(T, V, \mu)$ from (19.163) via Legendre transform.
b. Derive the differential forms for the relationships $S = S(T, P, N)$, $V = V(T, P, N)$, and $\mu = \mu(T, P, N)$.
c. For $V = V(T, P, N)$ calculate dV for the case of an ideal gas. Determine the material constants σ, η, and $\varkappa$ by comparison with (b).

Chapter 20

Thermodynamics applied to fluids and solids

In the present chapter we will apply the notions in thermodynamics acquired in Chp. 19 to various physical systems including multi-component, heterogeneous, chemically reacting gases and solids.

20.1 Unary heterogeneous systems

Let us first focus on unary systems, i.e. samples composed by a single species of molecules, e.g. H_2O, which nevertheless may be encountered in different states of aggregation: solid, liquid, gaseous, also called *phases*. We call *homogeneous* a system consisting of a single such phase and *heterogeneous*, when two or three phases coexist. Note that the list of phases is not exhaustive, as solids can exist in various allotropic phases depending on how the atoms arrange into a crystalline structure. For example, solid carbon may be exist as graphite or diamond.

20.1.1 Unary phase diagrams in PT-space

Allotropic phases are typically represented in phase diagrams, such as the one shown in Fig. 19.2. They are characterized by lines dividing PT-space into domains:

- Every area corresponds to a *stability domain of each single phase*.
- Every line corresponds to a *stability domain for two phases coexisting in equilibrium*.
- Every point corresponds to a *stability domain for three phases coexisting in equilibrium*.
- There are no regions where more than three phases coexist at equilibrium.

Heterogeneous systems may evolve between different phases when thermodynamic variables are changed in a process called *phase transition*. If such a system is taken through a reversible process represented by a path in the PT-diagram, when that path intersects a phase boundary, the change on pressure and temperature will be arrested while the phase transformation occurs. When the allotropic change is complete, the path may resume.

20.1.1.1 Molar quantities

Let us define intensive variables as extensive ones per particle (or per mole) [1],

$$\tilde{X} \equiv \left(\frac{\partial X}{\partial N}\right)_{T,P} , \tag{20.1}$$

from now on we designate intensive properties which have been converted from extensive ones by a tilde ($\tilde{}$). With the Gibbs free energy $G = E + PV - TS$ defined in (19.68) we find the differential form (19.161),

$$dG = -SdT + VdP + \mu dN , \tag{20.2}$$

from which we get the Gibbs free energy *per particles*,

$$\mu = \left(\frac{\partial G}{\partial N}\right)_{T,P} = \tilde{G} , \tag{20.3}$$

with its differential form,

$$\begin{aligned} d\tilde{G} &= \left(\frac{\partial \tilde{G}}{\partial G}\right)_{T,P} dG + \left(\frac{\partial \tilde{G}}{\partial N}\right)_{T,P} dN = \frac{1}{N}dG - \frac{G}{N^2}dN \\ &= -\frac{S}{N}dT + \frac{V}{N}dP + \mu\frac{1}{N}dN - \frac{\tilde{G}}{N}dN = -\tilde{S}dT + \tilde{V}dP , \end{aligned} \tag{20.4}$$

or

$$\boxed{d\mu = -\tilde{S}dT + \tilde{V}dP} . \tag{20.5}$$

This result only contains intensive quantities. Comparing it with Eq. (20.2) we note that we got rid of the differential dN, which is nice as long as we are not interested in particle number fluctuations.

For heterogeneous systems, the relations

$$\mu^\alpha = \mu^\alpha(T^\alpha, P^\alpha) \qquad \text{and} \qquad \mu^\beta = \mu^\beta(T^\beta, P^\beta) . \tag{20.6}$$

describe surfaces in $TP\mu$-space. Where those surfaces intersect, as illustrated in Fig. 19.38, the phases can coexist. That is, if,

$$\boxed{T^\alpha = T^\beta \quad \wedge \quad P^\alpha = P^\beta \qquad \Longrightarrow \qquad \mu^\alpha(T^\alpha, P^\alpha) = \mu^\beta(T^\beta, P^\beta)} , \tag{20.7}$$

or simply $\mu^\alpha(T, P) = \mu^\beta(T, P)$, then the two phases α and β coexist.

Analogously, the coexistence of three phases, α, β, γ, is described by the intersection of three surfaces in $PT\mu$-space.

[1] The definition per particle is more intuitive when discussing the connection to statistical physics. We then interpret N as particle numbers. The definition per mole is more interesting in the context of solutions and chemical reactions. We then interpret N as number of moles. Both definitions are related by,

$$N_{\text{molar}} = N_{\text{particle}}/N_{\text{A}} \qquad \text{and} \qquad \tilde{X}_{\text{molar}} = \tilde{X}_{\text{particle}} N_{\text{A}} .$$

We will, however, drop the distinction molar/particle when it is clear from the context.

20.1.1.2 Calculation of the chemical potential surface for a single phase

Because the chemical potential is a state function, if it is known at a reference point $\mu(T_0, P_0)$, its value at any other point $\mu(T, P)$ is determined, and we may parametrize an arbitrary path to go from one point to the other. For example, we may first hold T constant and integrate $d\mu$ given by Eq. (20.5) until reaching an intermediate point $\mu(T_0, P)$. In a second step, we hold P constant and continue integrating $d\mu$ until teaching the end point $\mu(T, P)$. Repeating this procedure for all T and P, we generate a chemical potential surface.

For a particular phase γ, we first need to derive the functional dependency of the entropy on T, which can be integrated from Eq. (19.75)(i),

$$\tilde{S}^\gamma(T) = \tilde{S}^\gamma(T_0) + \int_{\tilde{S}^\gamma(T_0)}^{\tilde{S}^\gamma(T)} d\tilde{S}^\gamma = \tilde{S}^\gamma(T_0) + \int_{T_0}^{T} \frac{C_P^\gamma(T')}{T'} dT' \ . \tag{20.8}$$

Then, holding the pressure fixed, $dP = 0$, and exploiting Eq. (20.5), we integrate the chemical potential over temperature,

$$\begin{aligned} \mu^\gamma(T) &= \mu^\gamma(T_0) + \int_{\mu^\gamma(T_0)}^{\mu^\gamma(T)} d\mu^\gamma \\ &= \mu^\gamma(T_0) - \int_{T_0}^{T} \left(\tilde{S}^\gamma(T_0) + \int_{T_0}^{T''} \frac{C_P^\gamma(T')}{T'} dT' \right) dT'' \ . \end{aligned} \tag{20.9}$$

Similarly, we derive the functional dependency of the volume on P, which can be integrated from Eq. (19.71)(i),

$$\ln \tilde{V}^\gamma(P) = \ln \tilde{V}^\gamma(P_0) + \int_{\tilde{V}_0^\gamma}^{\tilde{V}^\gamma} d \ln \tilde{V}^\gamma = \ln \tilde{V}^\gamma(P_0) - \int_{P_0}^{P} \kappa^\gamma(P') dP' \ . \tag{20.10}$$

Then, holding the temperature fixed, $dT = 0$, and exploiting Eq. (20.5), we integrate the chemical potential over pressure,

$$\begin{aligned} \mu^\gamma(P) &= \mu^\gamma(P_0) + \int_{P_0}^{P} \tilde{V}^\gamma(P') dP' \\ &= \mu^\gamma(P_0) + \int_{P_0}^{P} \tilde{V}^\gamma(P_0) e^{-\int_{P_0}^{P''} \kappa^\gamma(P') dP'} dP'' \ . \end{aligned} \tag{20.11}$$

All we need to do, is choose a reference temperature T_0 and pressure P_0, where we can look up in data bases the molar entropy $\tilde{S}^\gamma(T_0)$, the heat capacity C_P^γ, and the compressibility κ^γ. Note, that in general the heat capacity may be temperature-dependent. See Excs. 20.1.4.1 to 20.1.4.2.

Example 155 (*Chemical potential surface for constant heat capacity*): For example, let us consider an ideal gas in a single phase γ, whose heat capacity does not depend on T nor P. Then, the two-step path integral can be solved analytically. The functional dependence of the volume on (T, P) is given by the ideal gas equation,

$$\tilde{V}^\gamma(T, P) = \frac{R_g T}{P} \ . \tag{20.12}$$

The functional dependence of the entropy on T can be integrated from Eq. (19.75)(i),

$$\tilde{S}^\gamma(T) = \tilde{S}^\gamma(T_0) + \int_{T_0}^{T} \frac{C_P^\gamma}{T} dT = \tilde{S}^\gamma(T_0) + C_P^\gamma \ln \frac{T}{T_0} \ . \tag{20.13}$$

Now, we first hold the temperature fixed, $dT = 0$, and exploiting Eq. (20.5) integrate the chemical potential over pressure,

$$\mu^\gamma(T_0, P) = \mu^\gamma(T_0, P_0) + \int_{P_0}^{P} \tilde{V}^\gamma(T_0, P')dP' = \mu^\gamma(T_0, P_0) + R_g T_0 \ln \frac{P}{P_0} \ . \tag{20.14}$$

Then we hold the pressure fixed, $dP = 0$, and exploiting the same Eq. (20.5) integrate the chemical potential over temperature,

$$\begin{aligned} \mu^\gamma(T, P) &= \mu^\gamma(T_0, P) - \int_{T_0}^{T} \tilde{S}^\gamma(T')dT' \qquad (20.15) \\ &= \mu^\gamma(T_0, P) - \tilde{S}^\gamma(T_0)(T - T_0) + C_P^\gamma(T \ln \tfrac{T}{T_0} - T + T_0) \ , \end{aligned}$$

inserting the expression (20.13) for the entropy.

20.1.1.3 Chemical potential change upon crossing a phase transition

The integration demonstrated in the example 155 may be repeated for different phases. However, in order to refer a chemical potential in an arbitrary phase to a single specified set of reference temperature and pressure (T_0, P_0), we may have to cross intersections of surfaces. That is, we must know how to handle the behavior of the chemical potential upon phase transitions.

If the temperature-dependent heat capacities of two phases $\gamma = \alpha, \beta$, that is C_P^α and C_P^β, are known, as well as the entropy change,

$$\Delta S^{\alpha\to\beta}(T_m) \equiv S^\beta(T_m) - S^\alpha(T_m) \tag{20.16}$$

upon a phase transition at a specific temperature T_m, then the entropy difference between two states in different phases and at different temperatures is simply,

$$\tilde{S}^\beta(T) = \tilde{S}^\alpha(T_0) + \int_{T_0}^{T_m} \frac{C_P^\alpha(T')}{T'} dT' + \Delta\tilde{S}^{\alpha\to\beta}(T_m) + \int_{T_m}^{T} \frac{C_P^\beta(T')}{T'} dT' \ , \tag{20.17}$$

now allowing for temperature-dependent heat capacity. Such a path is illustrated in Fig. 20.1.

In order to determine the change in chemical potentials between states localized at different phases and at different temperatures T_0 and T, we need to integrate $\mu^\alpha(T, P_0)$ from T_0 to the phase boundary at T_m and continue integrating $\mu^\beta(T, P_0)$ from T_m to the end point T_m. We calculate,

$$\begin{aligned} \mu^\beta(T) &= \mu^\alpha(T_0) + \int_{\mu^\alpha(T_0)}^{\mu^\alpha(T_m)} d\mu^\alpha + \int_{\mu^\beta(T_m)}^{\mu^\beta(T)} d\mu^\beta \\ &= \mu^\alpha(T_0) - \int_{T_0}^{T_m} \left(\tilde{S}^\alpha(T_0) + \int_{T_0}^{T''} \frac{C_P^\alpha(T')}{T'} dT' \right) dT'' - \int_{T_m}^{T} \left(\tilde{S}^\beta(T_m) + \int_{T_m}^{T''} \frac{C_P^\beta(T')}{T'} dT' \right) dT'' \ , \end{aligned}$$

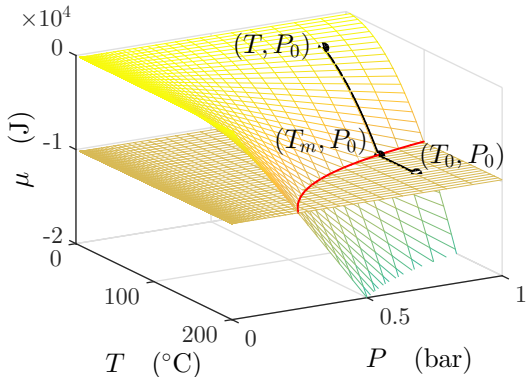

Figure 20.1: (code) Intersecting chemical potential surfaces. The points (T_j, P_0) can be related to each other (see text).

where we used the result (20.9) for both phases. Now, substituting the entropy in phase β at the temperature T_m by the the entropy in phase α using the formula (20.16), we continue,

$$\begin{aligned}
\mu^\beta(T) &= \mu^\alpha(T_0) - \tilde{S}^\alpha(T_0)(T_m - T_0) - \tilde{S}^\alpha(T_m)(T - T_m) - \Delta\tilde{S}^{\alpha\to\beta}(T_m)(T - T_m) \\
&\quad - \int_{T_0}^{T_m}\int_{T_0}^{T''} \frac{C_P^\alpha(T')}{T'} dT' dT'' - \int_{T_m}^{T}\int_{T_m}^{T''} \frac{C_P^\beta(T')}{T'} dT' dT'' \\
&= \mu^\alpha(T_0) - \tilde{S}^\alpha(T_0)(T - T_0) - \left(\Delta\tilde{S}^{\alpha\to\beta}(T_m) + \int_{T_0}^{T_m} \frac{C_P^\alpha(T'')}{T''} dT''\right)(T - T_m) \\
&\quad - \int_{T_0}^{T_m}\int_{T_0}^{T''} \frac{C_P^\alpha(T')}{T'} dT' dT'' - \int_{T_m}^{T}\int_{T_m}^{T''} \frac{C_P^\beta(T')}{T'} dT' dT'' \ . \qquad (20.18)
\end{aligned}$$

Hence, knowing entropy $\tilde{S}^\alpha(T_0)$ at a specific temperature in one of the phases, the entropy change between the phases at a specific temperature, $\Delta\tilde{S}^{\alpha\to\beta}(T_m)$, and the temperature-dependent heat capacities on both phases, $C_P^\alpha(T)$ and $C_P^\beta(T)$, we can relate the chemical potentials at any temperature of both phases.

20.1.2 The Clausius-Clapeyron equation, latent heat

Let us have another look at the three equations (20.7) ruling two-phase coexistence,

$$\begin{aligned}
T^\alpha = T^\beta \quad &\Longrightarrow \quad dT^\alpha = dT^\beta \equiv dT \qquad (20.19) \\
P^\alpha = P^\beta \quad &\Longrightarrow \quad dP^\alpha = dP^\beta \equiv dP \\
\mu^\alpha = \mu^\beta \quad &\Longrightarrow \quad d\mu^\alpha = d\mu^\beta \equiv d\mu \ .
\end{aligned}$$

From (20.5) we conclude,

$$-\tilde{S}^\alpha dT + \tilde{V}^\alpha dP = d\mu = -\tilde{S}^\beta dT + \tilde{V}^\beta dP \ , \qquad (20.20)$$

This expression can be rewritten as,

$$\boxed{\frac{dP}{dT} = \frac{\Delta\tilde{S}^{\alpha\to\beta}}{\Delta\tilde{V}^{\alpha\to\beta}}} \ , \tag{20.21}$$

which is one form of the *Clausius-Clapeyron equation*. It states that state changes along a phase coexistence curve (red line in Fig. 20.1) are ruled by the ratio between the molar entropy change and the molar volume change. Knowing this ratio, we can integrate the $P(T)$ dependence.

In practice, $\Delta\tilde{S}^{\alpha\to\beta}$ is not measured in experiments, but rather the heat produced or absorbed under the transformation (e.g. condensation or evaporation). Since, transformation occurs isobarically under reversible conditions, consulting (19.70) we find,

$$\delta Q^{\alpha\to\beta} = \Delta H^{\alpha\to\beta} \ . \tag{20.22}$$

The molar enthalpy change $\Delta\tilde{H}^{\alpha\to\beta}$ is also called *latent heat*. Sometimes, however, the term latent heat is used for the enthalpy change per mass unit, $L \equiv \Delta H^{\alpha\to\beta}/m$.

Recalling that $G = H - TS$ and $G^\alpha = G^\beta$, we have,

$$\Delta\tilde{H}^{\alpha\to\beta} = T\Delta\tilde{S}^{\alpha\to\beta} \ , \tag{20.23}$$

so that

$$\boxed{\frac{dP}{dT} = \frac{\Delta\tilde{H}^{\alpha\to\beta}}{T\Delta\tilde{V}^{\alpha\to\beta}} \ ,} \tag{20.24}$$

which is the most frequently used form of the Clausius-Clapeyron equation.

20.1.2.1 Integration of the Clausius-Clapeyron equation

Integrating Eq. (20.24) requires knowledge of,

$$\Delta H^{\alpha\to\beta} = \Delta H^{\alpha\to\beta}(T,P) \ . \tag{20.25}$$

From (19.82) we know,

$$d\tilde{H} = C_P dT + (1-\alpha_{\rm th}T)\tilde{V}dP \ . \tag{20.26}$$

Hence,

$$\begin{aligned} d\Delta\tilde{H}^{\alpha\to\beta} &= d\tilde{H}^\beta - d\tilde{H}^\alpha \\ &= C_P^\beta dT - C_P^\alpha dT + (1-\alpha_{\rm th}^\beta T)V^\beta dP - (1-\alpha_{\rm th}^\alpha T)\tilde{V}^\alpha dP \\ &= \Delta C_P^{\alpha\to\beta} dT + [(1-\alpha_{\rm th}^\beta T)\tilde{V}^\beta - (1-\alpha_{\rm th}^\alpha T)\tilde{V}^\alpha]dP \ . \end{aligned} \tag{20.27}$$

In practice, it turns out that the prefactor of the pressure differential is zero for pressure changes below 100000 bar, so that the enthalpy becomes almost pressure-independent and the enthalpy change is very well approximated by,

$$d\Delta\tilde{H}^{\alpha\to\beta}(T,P) = \Delta C_P^{\alpha\to\beta}\ dT \ . \tag{20.28}$$

Often the enthalpy change can be considered as almost temperature-independent, $\Delta\tilde{H}^{\alpha\to\beta} = \Delta\tilde{H}^{(0)}$. Then, the Clausius-Clapeyron equation (20.24) can be rewritten as,

$$\frac{dP}{P} = \frac{\Delta\tilde{H}^{\alpha\to\beta}}{\Delta\tilde{V}^{\alpha\to\beta}}\frac{dT}{PT} = \frac{\Delta\tilde{H}^{\alpha\to\beta}}{R_g}\frac{dT}{T^2} \ , \tag{20.29}$$

using the approximation (20.34). The solution is,

$$\boxed{\ln\frac{P}{P_0} = -\frac{\Delta\tilde{H}^{\alpha\to\beta}}{R_g}\left(\frac{1}{T}-\frac{1}{T_0}\right)} \ . \tag{20.30}$$

and represents a good estimation for phase transitions between gases and fluids or solids.

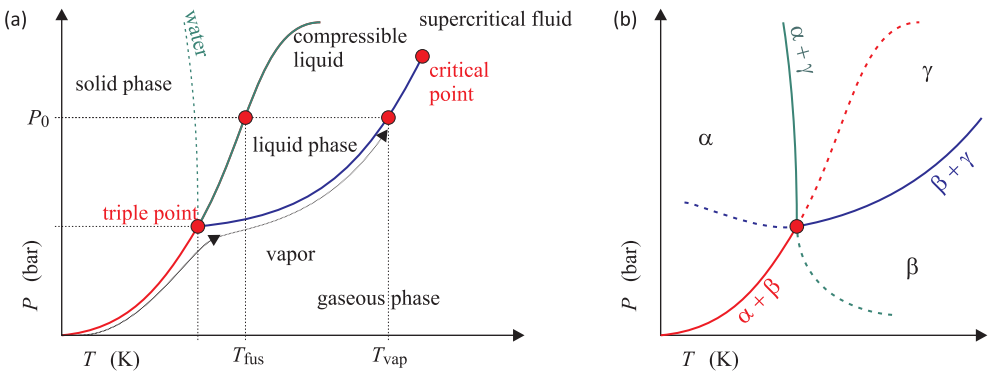

Figure 20.2: (a) PT-phase diagram. (b) Stable and metastable equilibrium lines near a triple point.

Example 156 (*Empirical model for heat capacities*): Using an empirical fit equation to describe the heat capacities in both phases $\gamma = \alpha, \beta$,

$$C_P^\gamma = a^\gamma + b^\gamma\, T + c^\gamma\, T^{-2} + d^\gamma\, T^2 \ , \tag{20.31}$$

we find,

$$\begin{aligned}\Delta\tilde{H}^{\alpha\to\beta}(T,P) &= \int_{T_0}^{T}(\Delta a + \Delta b\, T + \Delta c\, T^{-2} + \Delta d\, T^2)dT \\ &= \Delta a\, T + \tfrac{1}{2}\Delta b\, T^2 - \Delta c\, T^{-1} + \tfrac{1}{3}\Delta d\, T^3 + \Delta\tilde{H}^{(0)} \ .\end{aligned} \tag{20.32}$$

To evaluate the volume change,

$$\Delta\tilde{V}^{\alpha\to\beta} = \Delta\tilde{V}^{\alpha\to\beta}(T,P) \ , \tag{20.33}$$

let us consider a fluid-gas phase transition. Then, to a good approximation, we may neglect the volume change of the fluid phase, $\tilde{V}^\beta \gg \tilde{V}^\alpha$,

$$\Delta\tilde{V}^{\alpha\to\beta} = \tilde{V}^\beta = \frac{R_g T}{P} \ . \tag{20.34}$$

In this case,

$$\frac{dP}{P} = \frac{\Delta\tilde{H}^{\alpha\to\beta}}{\Delta\tilde{V}^{\alpha\to\beta}}\frac{dT}{PT} = \frac{1}{R_\mathrm{g}}\left[\frac{\Delta a}{T} + \frac{\Delta b}{2} - \frac{\Delta c}{T^3} + \frac{\Delta d}{3}T + \frac{\Delta H^{(0)}}{T^2}\right]dT \tag{20.35}$$

with the solution,

$$\begin{aligned}&\ln\frac{P}{P_0} \\ &= \frac{1}{R_\mathrm{g}}\left[\Delta a\ln\frac{T}{T_0} + \frac{\Delta b}{2}(T-T_0) + \frac{\Delta c}{2}\left(\frac{1}{T^2}-\frac{1}{T_0^2}\right) + \frac{\Delta d}{6}(T^2-T_0^2) - \Delta H^{(0)}\left(\frac{1}{T}-\frac{1}{T_0}\right)\right] .\end{aligned} \tag{20.36}$$

Good as long the empirical approximation formula (20.31) holds and gas remains ideal, this formula describes well gas-fluid coexistence curves.

20.1.2.2 Triple points

Three chemical potential surfaces intersect in a point called *triple point*. The point $(P_\mathrm{t}, T_\mathrm{t})$ is also the intersection of three equilibrium lines, as illustrated in Fig. 20.2(b), and thus simultaneously satisfies three Clausius-Clapeyron equations.

It is an important characteristic of a triple point, that property changes across phase boundaries sum up, when several boundaries are crossed. It is ultimately a corollary of the fact that properties are state functions. For example,

$$\Delta\tilde{V}^{\alpha\to\gamma} = \tilde{V}^\gamma - \tilde{V}^\alpha = \tilde{V}^\beta - \tilde{V}^\alpha + \tilde{V}^\gamma - \tilde{V}^\beta = \Delta\tilde{V}^{\alpha\to\beta} + \Delta\tilde{V}^{\beta\to\gamma} , \tag{20.37}$$

and the same holds for $\tilde{S}$ and $\tilde{H}$. E.g. the enthalpy change upon fusion and vaporization sum up to the enthalpy change upon sublimation,

$$\Delta\tilde{H}^\mathrm{sub} = \Delta\tilde{H}^\mathrm{fus} + \Delta\tilde{H}^\mathrm{vap} . \tag{20.38}$$

The sublimation curve [red line in Fig. 20.2(a)] and the vaporization curve [blue line in Fig. 20.2(b)] both share a boundary to the gaseous phase, to that we may use the solution (20.30) of the Clausius-Clapeyron relation for both,

$$\begin{aligned}P_\mathrm{vap}(T) &= P_0 e^{(\Delta\tilde{H}^\mathrm{vap}/R_\mathrm{g})(1/T_\mathrm{vap}-1/T)} \\ P_\mathrm{sub}(T) &= P_\mathrm{t} e^{(\Delta\tilde{H}^\mathrm{sub}/R_\mathrm{g})(1/T_\mathrm{t}-1/T)} .\end{aligned} \tag{20.39}$$

If the boiling temperature T_vap is known, setting $P_0 = 1$ bar obviously fully determines the vapor curve $P_\mathrm{vap} = P_\mathrm{vap}(T)$. In contrast, the sublimation curve $P_\mathrm{sub} = P_\mathrm{sub}(T)$ is not fully determined as long as the triple point is unknown. However, approximating,

$$T_\mathrm{t} = T_\mathrm{fus} \tag{20.40}$$

and relating the enthalpy change via (20.38), we are a good step further. We just need to find the triple pressure P_t using the information, that both curves share the triple point,

$$P_\mathrm{vap}(T_\mathrm{t}) = P_\mathrm{t} = P_\mathrm{sub}(T_\mathrm{t}) = P_\mathrm{sub}(T_\mathrm{fus}) . \tag{20.41}$$

With this we find,

$$P_\mathrm{t} = P_0 e^{(\Delta\tilde{H}^\mathrm{vap}/R_\mathrm{g})(1/T_\mathrm{vap}-1/T_\mathrm{t})} , \tag{20.42}$$

and finally,

$$\boxed{\begin{aligned} P_{\rm sub}(T) &= P_{\rm t} e^{(\Delta\tilde{H}^{\rm sub}/R_{\rm g})(1/T_{\rm t}-1/T)} \\ &= P_0 e^{(\Delta\tilde{H}^{\rm vap}/R_{\rm g})(1/T_{\rm vap}-1/T)+(\Delta\tilde{H}^{\rm fus}/R_{\rm g})(1/T_{\rm fus}-1/T)} \end{aligned}} \quad . \tag{20.43}$$

See Excs. 20.1.4.3 to 20.1.4.9.

Example 157 (*Vapor pressure of strontium*): Eq. (20.43) can be used to obtain the vapor pressure of substances, for example, the partial pressure of metals contained in a cell under vacuum at a fixed volume. All one need to know is the set of data $\Delta\tilde{H}^{\rm fus}$, $\Delta\tilde{H}^{\rm vap}$, $T_{\rm fus}$, and $T_{\rm vap}$, which is specific for the metal. As an example, the curve in Fig. 20.3(a) shows the vapor pressure of strontium as a function of temperature. The triple point and the vaporization point are marked with green circles in Fig. 20.3. See also Sec. 22.1.1.

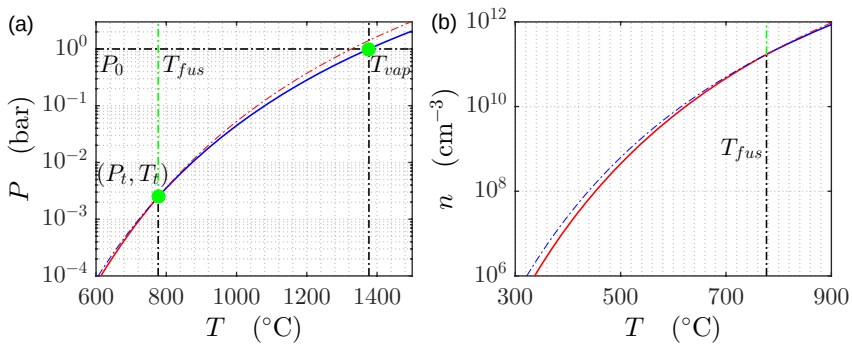

Figure 20.3: (code) (a) Vapor pressure of strontium obtained with $\Delta\tilde{H}^{\rm fus} = 144\,{\rm kJ/mol}$, $\Delta\tilde{H}^{\rm vap} = 8.3\,{\rm kJ/mol}$, $T_{\rm fus} = 1050\,{\rm K}$, and $T_{\rm vap} = 1650\,{\rm K}$. The solid lines corresponds to a path along the phase transition [(see arrow in Fig. 20.2(a)]. The sublimation curve (marked in red) and the vaporization curve (blue) correspond to those emphasized in Fig. 20.2(a) by the same colors. The dash-dotted lines show extensions of the phase boundaries beyond the sublimation curve, respectively, vaporization curve helping to visually emphasize the discontinuity at the triple point. (b) Density of the strontium vapor corresponding to the partial pressure according to the ideal gas law: $n = P/k_{\rm B}T$.

20.1.3 Vacuum technology

Many experiments can only be performed under vacuum, because air molecules could interact with the material under study (pure gases, clean surfaces, etc.) or limit the free path for cold atoms, electron beams in vacuum tubes, epitaxial beams, etc.. In view of the importance of vacuum technology for modern laboratories ranging from material science to quantum optics, we include here a short section summarizing basic notions.

We define here vacuum as a *space in which the pressure is below surrounding atmospheric pressure*. The origins of vacuum science go back to Aristotle, who stated

the 4-th century that 'nature abhors vacuum', meaning that pressure voids are unnatural. This belief was shaken in the 17th century when *Gasparo Berti* created the first verifiable vacuum. The scientific and technological use of vacuum science only began in the 20th century driven by the advent of vacuum tubes used in radio and television. Since then, the applications of vacuum science and technology have grown almost exponentially. Nowadays, vacuum technology is used in a wide range of industrial processes including semiconductors, packaging, drying, degassing, distillation, coating, evacuation, or insulation, etc.. Scientific applications range from analytical and medical instrumentation to the use of vacuum in particle physics, space research, nuclear fusion, material sciences, biology and chemistry. A large panoply of vacuum pumps and pressure sensors are nowadays available for a multitude of applications.

We will restrict to ideal gas mixtures with given partial pressures. In the following, we will only introduce some additional practical concept which are often required in the lab equipped with vacuum systems.

20.1.3.1 Flow and loading rates through apertures and pipes

Vacuum pumps are characterized by their pumping speeds specified in units of L/s. For example, a small ion getter pump may have a pumping speed of $S_{\rm pmp} = 2\,{\rm L/s}$. The pumping speed is defined as the volume of gas passing the cross section of the pump's inlet port per unit time. Of course, the gas removal rate also depends on the pressure $P_{\rm chm}$ in the vacuum chamber,

$$Q_{\rm pmp} = P_{\rm chm} S_{\rm pmp} \ . \tag{20.44}$$

The efficient pump rate, however, also depends on the design of the vacuum system. For example, pumping a vacuum chamber through a small aperture will be less efficient. The flow rate through a circular aperture of diameter $D_{\rm app}$ is,

$$S_{\rm app} = \bar{v}\pi \frac{D_{\rm app}^2}{4} \ , \tag{20.45}$$

where $\bar{v}$ is the mean velocity of gas at room temperature $\bar{v} = \sqrt{k_{\rm B}T/2m} \simeq 120\,{\rm m/s}$. The flow rate through a tube of length $L_{\rm tub}$ with diameter $D_{\rm tub}$ is,

$$S_{\rm tub} = \bar{v}\pi \frac{D_{\rm tub}^3}{L_{\rm tub}} \ . \tag{20.46}$$

The calculation of the flow rate through subsequent apertures/tubes is obtained by concatenation,

$$S_{\rm net} = \left(S_{\rm app}^{-1} + S_{\rm tub}^{-1}\right)^{-1} \ . \tag{20.47}$$

Example 158 (*Inefficient pumping*): Let us, as an example, check whether the pumping speed of a $S_{\rm pmp} = 2\,{\rm L/s}$ ion pump connected to a vacuum chamber is reduced when the pumping is done through a flexible bellow of $L_{\rm tub} = 1\,{\rm m}$ length and $D_{\rm tub} = D_{\rm app} = 16\,{\rm mm}$ diameter (norm CF16). The impedance of the tube is,

$$S_{\rm net} = \left(\frac{4}{\bar{v}\pi D_{\rm app}^2} + \frac{L_{\rm tub}}{\bar{v}\pi D_{\rm tub}^3}\right)^{-1} \simeq \frac{\bar{v}\pi D_{\rm tub}^3}{L_{\rm tub}} \approx 0.65\,{\rm L/s} \ .$$

Hence, the pumping speed of the ion pump is reduced below its capacity by the long and thin bellow.

The gas loading rate of a vacuum chamber through a tube (or a leak) is given by the pressure $P_{\rm res}$ in the reservoir behind the tube and the net flow rate $S_{\rm net}$ across the tube,

$$Q_{\rm tub} = P_{\rm res} S_{\rm net} \ . \tag{20.48}$$

Other processes may contribute to loading gas into the chamber. For instance, objects placed into the vacuum chamber may outgas at a certain rate. Even the chamber material itself can outgas. The gas loading rate due to outgassing depends on the material's characteristic outgassing rate $R_{\rm out}$ and on its surface $A_{\rm srf}$, e.g. the inner surface of the vacuum chamber,

$$Q_{\rm out} = R_{\rm out} A_{\rm srf} \ . \tag{20.49}$$

Obviously the gas loading rate due to possible leaks $Q_{\rm lea}$ and due to outgassing add up to a total feeding rate,

$$Q_{\rm fed} = Q_{\rm lea} + Q_{\rm out} \ . \tag{20.50}$$

Do the Excs. 20.1.4.10 to 20.1.4.11.

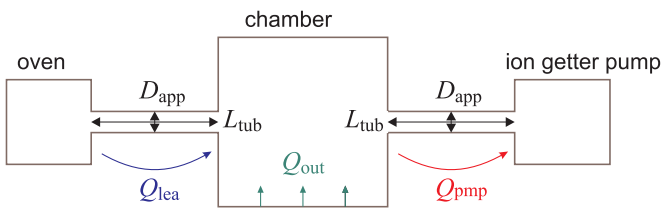

Figure 20.4: Typical scheme for a vacuum system with preparation chamber (or oven), science chamber, and pump.

Example 159 (*Outgassing of steel*): According to [1000], typical outgassing rates of electro-polished steel are $R_{\rm out} = 5 \times 10^{-12}\,{\rm mbar\,L/(s\,cm^2)}$. For 316 steel after 20 h baking at a temperature of 250 °C the outgassing rate drops to $R_{\rm out} = 1.2 \times 10^{-12}\,{\rm mbar\,L/(s\,cm^2)}$, and baking for 2 weeks at 250 °C will decrease the rate even more to $R_{\rm out} = 3 \times 10^{-13}\,{\rm mbar\,L/(s\,cm^2)}$. For this last situation a typical chamber with surface $A_{\rm srf} = 600\,{\rm cm^2}$ will outgas at a rate,

$$Q_{\rm out} = R_{\rm out} A_{\rm srf} \approx 1.8 \times 10^{-10}\,{\rm mbar\,L/s} \ .$$

The pressure change caused by feeding or pumping is simply,

$$\boxed{\dot{P}_{\rm chm} = \frac{Q_{\rm fed} - Q_{\rm pmp}}{V}} \ . \tag{20.51}$$

Hence, the pumping comes to a halt when the feeding speed (20.50) and the pumping speed $Q_{\rm pmp}$ equilibrate, $Q_{\rm fed} = Q_{\rm pmp}$, from which we can estimate the final pressure in the vacuum chamber,

$$P_{\rm chm} = \frac{Q_{\rm fed}}{S_{\rm pmp}} \ . \tag{20.52}$$

Note that the feeding rate can be measured by turning off the pump while recording the pressure increase.

20.1.3.2 Vacuum pumps and pressure measurement

Various types of pumps are commonly used in quantum optics laboratories (see Tab. 20.1 and Fig. 22.2). Every pump is not only characterized by its pumping speed, but also by the pressure range where it is operational. The pumping speed indeed depends on the pressure. It can also depend on the type of gas, for instance, noble gases are harder to remove with ion pumps [574].

Table 20.1: Types of vacuum pumps, their typical pumping speed and operational pressure range.

type	pumping speed	pressure range
rotary pumps	$10^3..10^6$ L/s	$10^3..10^{-3}$ mbar
oil diffusion pumps	$10^2..10^4$ L/s	$10^{-3}..10^{-8}$ mbar
turbo pumps	50..3000 L/s	$10^{-1}..10^{-9}$ mbar
ion getter pumps	0.2..500 L/s	$10^{-5}..10^{-10}$ mbar
titanium sublimation pumps	400..3000 L/s	$10^{-2}..10^{-12}$ mbar

The same holds for vacuum gauges, which exist in a large variety of technologies (see Tab. 20.2 and Fig. 22.3).

Table 20.2: Types of vacuum gauges and their operational pressure range.

type	pressure range
Pirani	$10^{-4}..10^3$ mbar
Bayerd-Alpert	$10^{-9}..10^{-3}$ mbar
cold cathode	$10^{-10}..10^2$ mbar
hot cathode	$10^{-10}..10^2$ mbar

20.1.4 Exercises

20.1.4.1 Ex: Chemical potential surface

Compute and plot the chemical potential surface: (T, P) for a monatomic ideal gas in the range $5\,\mathrm{K} < T < 1000\,\mathrm{K}$ and $10^{-5}\,\mathrm{bar} < P < 10\,\mathrm{bar}$. Suppose the gas is helium with the entropy $S_{298} = 126.04\,\mathrm{J/(mol\ K)}$ at room temperature and $C_P = 5193.2\,\mathrm{J/(kg\ K)}$.

20.1.4.2 Ex: Clausius-Clapeyron relationship

Show that the *Clausius-Clapeyron equation*,

$$\frac{dP}{dT} = \frac{mL}{T(V_{\mathrm{gas}} - V_{\mathrm{fl}})} \ ,$$

where L is the latent heat and m the mass of the component undergoing a phase transition from fluid to gas, can also be derived via a cycle analogous to Carnot's cycle. The working fluid is an evaporating liquid, and the efficiency of this fictitious machine is dT/T, because the temperature difference between the two isotherms is dT. From the heat Q used upon evaporation and the work done $\oint PdV$, which are related on one hand to the latent heat L and on the other to the volume difference of V_{fl} and V_{gas}, results a rise in vapor pressure dP/dT [see Eq. (19.122)].

20.1.4.3 Ex: Measurement of latent heat upon water condensation

A calorimeter with thermal capacity $C = 209\,\text{J/K}$ initially contains $m_1 = 250\,\text{g}$ of water in thermal equilibrium at a temperature of $T_1 = 20\,°\text{C}$. Now, an amount of $m_2 = 40\,\text{g}$ of water vapor is added. After reaching thermal equilibrium again, the temperature is $T_{\text{f}} = 92\,°\text{C}$. Calculate the latent heat of water condensation.

20.1.4.4 Ex: Latent heat in a sauna

A Finnish sauna of $10\,\text{m}^3$ volume is heated to $95\,°\text{C}$. To increase the thermal conductivity of the air, 100 ml of water at a temperature of $20\,°\text{C}$ is added to the oven container, where the water is evaporated. How does the temperature of the sauna evolve if, for simplicity, the impact of the oven on the temperature is disregarded.

20.1.4.5 Ex: Latent heat

How much heat is needed to transform 1 g of ice at $-10\,°\text{C}$ ($c_{\text{ice}} = 0.55\,\text{cal/g/K}$, $L_{\text{fus}} = 80\,\text{cal/g}$) in a vapor at $100\,°\text{C}$ ($c_{\text{aq}} = 1\,\text{cal/g/K}$, $L_{\text{vap}} = 540\,\text{cal/g}$)?

20.1.4.6 Ex: Latent heat

A metal bar with specific heat capacity $c_{\text{mt}} = 0.2\,\text{cal/g/K}$ at $100\,°\text{C}$ is placed on a large block of ice at $0\,°\text{C}$. What is the mass of the bar if, when the system reaches thermal equilibrium, $m_{\text{aq}} = 500\,\text{g}$ of ice have melted?

20.1.4.7 Ex: Latent heat

An ice block with the mass $m_{\text{ice}} = 500\,\text{g}$ and the temperature $-20\,°\text{C}$ is put in an airtight container together with $m_{\text{vap}} = 200\,\text{g}$ of water vapor at $100\,°\text{C}$. What will be the final temperature of the system?

20.1.4.8 Ex: A lake in winter

How long does it take at an air temperature of $-6\,°\text{C}$ to form a $d = 4\,\text{cm}$ thick layer of ice on the surface of a lake (thermal conductivity of ice: $\kappa = 1.7 \times 10^{-2}\,\text{J}/(\text{s cm K})$; density of ice: $\rho = 0.92\,\text{g/cm}^3$; amount of heat that must be dissipated to form 1 g of ice: 335 J)
Note: First consider a layer of ice of thickness z, and then think about how much heat has to be dissipated from the lake in order to to form additional layer of thickness dz.

20.1.4.9 Ex: Equations of state for fluids

a. Find in literature a representation of the PVT-diagram for water or carbon dioxide and discuss it.
b. Find in literature a parametrization of the equation of state for fluid water or carbon dioxide.

20.1.4.10 Ex: Vacuum chambers

a. Estimate the vacuum pressure in a cubic 1 L science chamber made of baked steel and pumped by a 8 L/s vacuum pump.
b. The science chamber is linked to a preparation chamber maintained at $P_{\text{pre}} = 10^{-7}$ mbar via a differential vacuum tube with 2 cm length and 2 mm diameter. Re-estimate the vacuum in the science chamber.

20.1.4.11 Ex: Pumping speed in vacuum chambers

Solve the differential equation (20.51) and plot the time evolution of the pressure in a 10 L vacuum chamber pumped by a 1 L/s and a 2 L/s ion pump assuming feeding rates of $2 \cdot 10^{-10}$ mbar L/s and $4 \cdot 10^{-10}$ mbar L/s.

20.2 Multi-component, homogeneous, non-reacting systems

In this section we will analyze systems made of more than one independent chemical component, in particular, mixtures or solutions. The chemical content of such a system is described by specifying the number of particles N_j (or moles n_j) of each component j, which is an extensive property. In order to handle the multi-component system, we introduce independent chemical potentials μ_j for every component, which are intensive variables.

The composition of a system N_j can vary due (i) to exchange with reservoir or (ii) to conversion via chemical reactions. In this section concentrate on case (i).

20.2.1 The Gibbs-Duhem equation

In Sec. 19.4 we already argued that the energy defined as,

$$O = G - \sum_j \mu_j N_j \quad \Longrightarrow \quad dO = -SdT + VdP - \sum_j N_j d\mu_j \tag{20.53}$$

being by definition an extensive variable, cannot be a state potential because it would only depend on intensive variables. Hence, $O = 0 = dO$, or,

$$\boxed{G = \sum_j \mu_j N_j \quad \Longrightarrow \quad -SdT + VdP = \sum_j N_j d\mu_j \ . \qquad (20.54)}$$

This important result is termed the *Gibbs-Duhem equation*. This equation shows that intensive properties are not independent but related. When pressure and temperature

are variable, for a system with J components only $J-1$ components have independent values of chemical potential [2].

Example 160 (*Derivation of the Gibbs-Duhem equation*): Another way to derive the Gibbs-Duhem equation is by noticing that, as an extensive state function, the Gibbs potential should satisfy $\lambda G(X) = G(\lambda X)$ for any extensive variable λ. In particular, it should be linear in the particle numbers, so that,

$$G = \sum_j N_j \frac{\partial G}{\partial N_j} = \sum_j \mu_j N_j \qquad \text{or} \qquad dG = \sum_j \mu_j dN_j + \sum_j N_j d\mu_j \ .$$

Comparing this to the definition of the Gibbs potential (19.160)(ix),

$$dG = -SdT + VdP + \sum_j \mu_j dN_j$$

we must conclude,

$$-SdT + VdP = \sum_j N_j d\mu_j \ .$$

20.2.2 Partial molal properties

We already mentioned that the number of particles N_j (or moles n_j) of each component j are extensive properties. Corresponding intensive properties that can be defined are the *fractions of particles* N_j/N_{tot} with $N_{\text{tot}} = \sum_j N_j$ (or the molar fractions n_j/n_{tot}). Now, for any arbitrary extensive property $X = X(T, P, N_1, N_2, ...)$ of the system, which can be any of the state functions $X = E, S, V, H, F, G$, we may define a corresponding *partial molal property* of only the component j,

$$\bar{X}_j \equiv \left(\frac{\partial X}{\partial N_j}\right)_{P,T,N_{k\neq j}} \ , \tag{20.55}$$

by holding pressure, temperature, and the number of moles of all other components fixed. Note that, in contrast to the previous decoration $(\tilde{\cdot})$, which referred to molar quantities per *total number of particles*, the new decoration $(\bar{\cdot})$ refers to molal quantities per *number of particles of that species*. Then, the total differential form is,

$$dX = \left(\frac{\partial X}{\partial T}\right)_{P,\{N_j\}} dT + \left(\frac{\partial X}{\partial P}\right)_{T,\{N_j\}} dP + \sum_j \bar{X}_j dN_j \ . \tag{20.56}$$

Example 161 (*Partial molal volume*): Considering, for example, volume $V = V(T, P, N_1, N_2, ...)$. Then,

$$\begin{aligned} dV &= \left(\frac{\partial V}{\partial T}\right)_{P,\{N_j\}} dT + \left(\frac{\partial V}{\partial P}\right)_{T,\{N_j\}} dP + \sum_j \left(\frac{\partial V}{\partial N_j}\right)_{P,T,N_{k\neq j}} dN_j \quad (20.57) \\ &= \alpha V \ dT - V\kappa \ dP + \sum_j \bar{V}_j \ dN_j \ . \end{aligned}$$

[2] The Gibbs-Duhem equation cannot be used for small thermodynamic systems due to the influence of surface effects and other microscopic phenomena.

with the definitions (19.71) of the thermal expansion coefficient and the compressibility,

$$\alpha \equiv \frac{1}{V}\left(\frac{\partial V}{\partial T}\right)_{P,\{N_j\}} \quad , \quad \kappa \equiv -\frac{1}{V}\left(\frac{\partial V}{\partial P}\right)_{T,\{N_j\}} \quad . \tag{20.58}$$

The quantity $\bar{V}_j$ is called *partial molal volume*, and analogous procedures can be followed for $\bar{E}_j, \bar{S}_j, \bar{V}_j, \bar{H}_j, \bar{F}_j, \bar{G}_j$.

For the particular extensive property $X \to G$ and $\bar{X}_j \to \mu_j$ we derived the Gibbs-Duhem equation (20.54), but the result holds for any extensive property satisfying (20.55). E.g. holding temperature and pressure constant, (20.56) becomes,

$$dX_{T,P} = \sum_j \bar{X}_j dN_j \ . \tag{20.59}$$

That is, changes of the partial molal properties of the components *add up* to a total change of the system. The value of the extensive state function $X_{T,P}$ is obtained by integrating (20.59). Fortunately, as an intensive property, $\bar{X}_j$ can only depend on other intensive properties, that is, it cannot depend on N_j. Furthermore, changes of state functions are path-independent. Hence, the total state $X_{T,P}$ reached by adding all the components is,

$$X_{T,P} = \sum_j \int_0^{N_j} \bar{X}_j dN_j = \sum_j \bar{X}_j \int_0^{N_j} dN_j = \sum_j \bar{X}_j N_j \ . \tag{20.60}$$

When we differentiate (20.60),

$$dX_{T,P} = \sum_j \bar{X}_j dN_j + \sum_j N_j d\bar{X}_j \ , \tag{20.61}$$

which only coincides with Eq. (20.59), if the second term vanishes. Hence,

$$\boxed{\sum_j N_j d\bar{X}_j = 0} \ . \tag{20.62}$$

Substituting $\bar{X}_j \to \mu_j$, we recover the Gibbs-Duhem equation (20.54) for the case $T, P = cnst$.

The important message of the Gibbs-Duhem equation is, that the partial molal properties are not all independent. Its integration provides a recipe, how to calculate values of partial molal properties of one component from those of the other components, as we will see later.

20.2.2.1 The mixing process

Temperature, pressure, volume and, according to the third law of thermodynamics, entropy, all have absolute non-zero values. In contrast, the energy functions E, H, F, G are only defined *with respect to some reference state*, i.e. only their *changes* are really of interest.

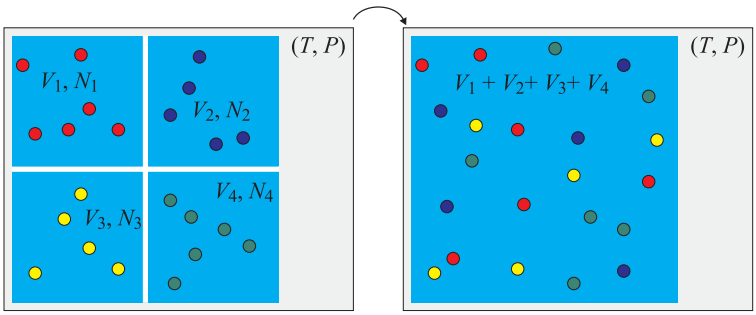

Figure 20.5: Initial 'reference state' and final mixture.

We will now study the mixing process resulting from putting together several components at constant pressure and temperature and waiting for them to form a homogeneous *solution*. In order to guarantee that only the mixing process by itself is studied, we start from a 'reference state' in which all components are spatially separated and held at the same temperature and pressure, as illustrated in Fig. 20.5,

$$X^0 = \sum_j \bar{X}_j^0 N_j \ . \tag{20.63}$$

Mixing changes the value of state functions,

$$X^0 \curvearrowright X^{\text{sol}} = X^0 + \Delta X^{\text{mix}} \ . \tag{20.64}$$

Now,

$$\Delta X^{\text{mix}} = \sum_j \left(\bar{X}_j^{\text{sol}} - \bar{X}_j^0\right) N_j = \sum_j \Delta \bar{X}_j^{\text{mix}} N_j \ . \tag{20.65}$$

$\Delta \bar{X}_j^{\text{mix}}$ measures the change per particle of type j that the state function suffers from being put into the surrounding composed by all other particle types, and ΔX^{mix} is the weighted sum of all these changes. Differentiating Eq. (20.65),

$$d\Delta X^{\text{mix}} = \sum_j \Delta \bar{X}_j^{\text{mix}} \, dN_j + \sum_j N_j \, d\Delta \bar{X}_j^{\text{mix}} \ . \tag{20.66}$$

For the second term of the right hand side we find,

$$\sum_j N_j \, d\Delta \bar{X}_j^{\text{mix}} = \sum_j N_j \, d\bar{X}_j^{\text{sol}} - \sum_j N_j \, d\bar{X}_j^0 \ , \tag{20.67}$$

Here, the second term of the right hand side is zero because $\bar{X}_j^0$ are properties of the reference state, which is fixed by definition. The summation over the first term of the right hand side is zero by the Gibbs-Duhem equation (20.62). Hence,

$$\sum_j N_j d\Delta \bar{X}_j^{\text{mix}} = 0 \ , \tag{20.68}$$

which is the Gibbs-Duhem equation applied to the mixing process. With this we deduce from (20.66),

$$\boxed{d\Delta X^{\text{mix}} = \sum_j \Delta \bar{X}_j^{\text{mix}} \, dN_j} \ . \tag{20.69}$$

20.2.2.2 Partial molal properties from total properties

Obviously, all relationships derived in the previous section can be normalized to the total number of particles (or moles) N_{tot}. We just need to replace all extensive state functions E, S, V, H, F, G by molar quantities, $X \to \tilde{X}$, and particle numbers (or partial moles) by fractions $N_j \to \eta_j \equiv N_j/N_{\text{tot}}$, with $\sum_j \eta_j = 1$.

Let us consider a binary system and rewrite Eq. (20.65) for normalized quantities,

$$\Delta\tilde{X}^{\text{mix}} = \eta_1 \Delta\bar{X}_1^{\text{mix}} + \eta_2 \Delta\bar{X}_2^{\text{mix}} \ . \tag{20.70}$$

Also from (20.69),

$$d\Delta\tilde{X}^{\text{mix}} = \Delta\bar{X}_1^{\text{mix}} d\eta_1 + \Delta\bar{X}_2^{\text{mix}} d\eta_2 \qquad \text{with} \qquad d\eta_1 = -d\eta_2 \ , \tag{20.71}$$

which gives,

$$\frac{d\Delta\tilde{X}^{\text{mix}}}{d\eta_2} = \Delta\bar{X}_1^{\text{mix}} - \Delta\bar{X}_2^{\text{mix}} \ . \tag{20.72}$$

Isolating the terms $\bar{X}_1^{\text{mix}}$ and $\bar{X}_2^{\text{mix}}$ from the system of equations (20.70) and (20.72),

$$\boxed{\Delta\bar{X}_j^{\text{mix}} = \Delta\tilde{X}^{\text{mix}} + (1-\eta_j)\frac{d\Delta\tilde{X}^{\text{mix}}}{d\eta_j}} \qquad \text{with} \qquad j = 1, 2 \ . \tag{20.73}$$

Thus, knowing the the total change of the molal quantity $\Delta\tilde{X}^{\text{mix}}$ and molar fractions η_j of the components, we can compute the partial changes $\Delta\tilde{X}_j^{\text{mix}}$ for all components.

Example 162 (*Partial molal enthalpies upon mixing a binary solution*): In this example we calculate the partial molal enthalpies upon mixing a binary solution for a model enthalpy given by $\Delta H^{\text{mix}} = a\eta_1\eta_2$ and satisfying $\lim_{\eta_1\to 0} \Delta H^{\text{mix}} = 0$. Using $\eta_1 + \eta_2 = 1$ the enthalpy can be rewritten,

$$\Delta H^{\text{mix}} = a(\eta_1 - \eta_1^2) = a(\eta_2 - \eta_2^2) \ .$$

Evaluating,

$$\frac{d\Delta\bar{H}^{\text{mix}}}{d\eta_j} = a(1 - 2\eta_j) \ ,$$

we get,

$$\Delta\bar{H}_1^{\text{mix}} = \Delta H^{\text{mix}} + (1-\eta_1)\frac{d\Delta\bar{H}^{\text{mix}}}{d\eta_1} = a\eta_2^2 \ ,$$

and finally,

$$\Delta\bar{H}_j^{\text{mix}} = a\eta_{i\neq j}^2 \ .$$

A consistency check yields,

$$\Delta H^{\text{mix}} = \Delta\bar{H}_1^{\text{mix}}\eta_1 + \Delta\bar{H}_2^{\text{mix}}\eta_2 \ .$$

20.2.2.3 Partial molal properties of one component from those of others

The partial molal version of the Gibbs-Duhem relation for the mixing process (20.68) is,

$$\sum_j \eta_j d\Delta\bar{X}_j^{\text{mix}} = 0 \ , \tag{20.74}$$

or restricting to two species,

$$d\Delta\bar{X}_1^{\text{mix}} = -\frac{\eta_2}{\eta_1} d\Delta\bar{X}_2^{\text{mix}} \ . \tag{20.75}$$

Now, $\lim_{\eta_2\to 0} \bar{X}_2^{\text{sol}} = \bar{X}_2^0$, since there is nothing to mix. Hence, $\lim_{\eta_2\to 0} \Delta\bar{X}_2^{\text{mix}} = 0$. This condition provides a starting point when integrating the last expression,

$$\Delta\bar{X}_1^{\text{mix}} = -\int_0^{\Delta\bar{X}_2^{\text{mix}}} \frac{\eta_2}{\eta_1} d\Delta\bar{X}_2^{\text{mix}} = -\int_0^{\eta_2} \frac{\eta_2}{\eta_1} \frac{d\Delta\bar{X}_2^{\text{mix}}}{d\eta_2} d\eta_2 \ . \tag{20.76}$$

Example 163 (*Partial molal enthalpies upon mixing a binary solution*): Assume that we have a partial molal enthalpy of component 2 depending on the square of the abundance of the other component 1,

$$\Delta H_2^{\text{mix}} = a\eta_1^2 \ .$$

Then, the above recipe yields,

$$\Delta\bar{H}_1^{\text{mix}} = -\int_0^{\eta_2} \frac{\eta_2}{\eta_1} \frac{d\Delta\bar{H}_2^{\text{mix}}}{d\eta_2} d\eta_2 = -\int_0^{\eta_2} \frac{\eta_2}{\eta_1} \frac{da(1-\eta_2)^2}{d\eta_2} d\eta_2 = a\eta_2^2 \ .$$

20.2.2.4 Relationships among partial molal properties

As seen in Sec. 20.2.2, application of the operator,

$$\boxed{\left(\frac{\partial}{\partial N_j}\right)_{T,P,N_{k\neq j}}} \tag{20.77}$$

to any total property X yields the corresponding molal property. Applying this operator to the definitions, laws, coefficient relations, and Maxwell equations, we obtain the corresponding molal expressions. For example, the counterpart of the relation $H = E + PV$ is,

$$\bar{H}_j \equiv \left(\frac{\partial H}{\partial N_j}\right)_{T,P,N_{k\neq j}} = \left(\frac{\partial E}{\partial N_j}\right)_{T,P,N_{k\neq j}} + P\left(\frac{\partial V}{\partial N_j}\right)_{T,P,N_{k\neq j}} \equiv \bar{E}_j + P\bar{V}_j \ , \tag{20.78}$$

and analogously for all other equations. For a solution with various components, we can simply substitute any extensive variable X for each component j,

$$X \longrightarrow \bar{X}_j \ . \tag{20.79}$$

20.2.3 Chemical potential in solutions

We have seen above that, initially introduced for unary systems in Sec. 19.3.2, the concept of chemical potential can be extended to multicomponent systems. We will show below that, if the chemical potential is known as a function of temperature, pressure and composition, then *all of the partial molal properties of the system may be computed*. The thermodynamic state of a system with J components depends on $J+2$ variables,

$$E = E(T, P, N_1, ..., N_J) \quad \Longrightarrow \quad dE = TdS - PdV + \sum_{j=1}^{J} \mu_j dN_j \tag{20.80}$$

with

$$\mu_j \equiv \left(\frac{\partial E}{\partial N_j}\right)_{S,V,N_{k\neq j}} . \tag{20.81}$$

Comparing the expression (20.80) with the first law, we identify,

$$\boxed{\delta A_{rev} = \sum_{j=1}^{J} \mu_j dN_j} \tag{20.82}$$

as an additional non-mechanical work. We simply need to substitute,

$$\mu dN \longrightarrow \sum_{j=1}^{J} \mu_j dN_j \tag{20.83}$$

in (19.161) to obtain the corresponding expression for multicomponent systems.

Although the chemical potential can be expressed as partial derivatives of various state energies,

$$\mu_j = \left(\frac{\partial E}{\partial N_j}\right)_{S,V,N_{k\neq j}} = \left(\frac{\partial H}{\partial N_j}\right)_{S,P,N_{k\neq j}} = \left(\frac{\partial F}{\partial N_j}\right)_{T,V,N_{k\neq j}} = \left(\frac{\partial G}{\partial N_j}\right)_{T,P,N_{k\neq j}} = \bar{G}_j \ , \tag{20.84}$$

only the last one is a partial molal property, distinguished by the fact that the intensive properties temperature and pressure are held constant, e.g. $\mu_j \neq \bar{E}_j$. If energies other than the Gibbs free energy are to be expressed as partial molal properties, they need to be related to the Gibbs energy using the expressions (19.160),

$$\begin{aligned}
\bar{G}_j &= \mu_j \\
\bar{S}_j &= -\left(\frac{\partial \bar{G}_j}{\partial T}\right)_{P,N_k} &&= -\left(\frac{\partial \mu_j}{\partial T}\right)_{P,N_k} \\
\bar{V}_j &= \left(\frac{\partial \bar{G}_j}{\partial P}\right)_{T,N_k} &&= \left(\frac{\partial \mu_j}{\partial P}\right)_{T,N_k} \\
\bar{H}_j &= \bar{G}_j + T\bar{S}_j &&= \mu_j - T\left(\frac{\partial \mu_j}{\partial T}\right)_{P,N_k} \\
\bar{F}_j &= \bar{G}_j - P\bar{V}_j &&= \mu_j - P\left(\frac{\partial \mu_j}{\partial T}\right)_{T,N_k} \\
\bar{E}_j &= \bar{G}_j + T\bar{S}_j - P\bar{V}_j &&= \mu_j - T\left(\frac{\partial \mu_j}{\partial T}\right)_{P,N_k} - P\left(\frac{\partial \mu_j}{\partial T}\right)_{T,N_k}
\end{aligned} \tag{20.85}$$

The linearity of the expressions allows us to extend them to changes of states, $\Delta\mu_j = \mu_j - \mu_j^0$. For example, for a binary system, the Gibbs-Duhem formula (20.74) applied to Gibbs free energy, $X \longrightarrow G$, reads,

$$\eta_1 d\Delta\bar{G}_1 + \eta_2 d\Delta\bar{G}_2 = \eta_1 d\Delta\mu_1 + \eta_2 d\Delta\mu_2 = 0 \ , \tag{20.86}$$

and the integrated version,

$$\Delta\mu_1 = -\int_0^{\eta_2} \frac{\eta_2}{\eta_1}\frac{d\Delta\mu_2}{d\eta_2} d\eta_2 \ . \tag{20.87}$$

Thus, if $\Delta\mu_2$ is known as a function of composition at any temperature and pressure, we can also calculate $\Delta\mu_1$ and all other partial molar state functions according to (20.85), as well as the total properties according to (20.70).

20.2.3.1 Activity in ideal gas solutions

In experiments, instead of the chemical potential, the *activity of a component* a_j or the *activity coefficient* γ_j are frequently measured,

$$a_j \equiv e^{\Delta\mu_j/k_\mathrm{B}T} \equiv \eta_j\gamma_j \ . \tag{20.88}$$

When a mixture is produced by combining ideal gases initially stored in different volumes at the same temperature and pressure, as illustrated in Fig. 20.5, every species by itself generates a smaller *partial pressure* in the total volume, corresponding to its abundance. Summed up, however, they reproduce the initial pressure. This is called *Dalton's law*,

$$\boxed{P_j \equiv \eta_j P \qquad \text{such that} \qquad P = \sum_j P_j} \ . \tag{20.89}$$

Now, we focus on the change experienced by an individual component j during the mixing process, which corresponds to an isothermal expansion of the component, $(T_0, P_0) \longrightarrow (T_0, P_j = \eta_j P_0)$. The corresponding change in chemical potential is,

$$d\mu_j = d\bar{G}_j = -\bar{S}_j dT + \bar{V}_j dP \quad \overset{dT=0}{\longrightarrow} \quad \bar{V}_j dP \ , \tag{20.90}$$

since temperature does not change. The partial molal volume can be evaluated from,

$$\bar{V}_j = \left(\frac{\partial V}{\partial N_j}\right)_{T,P,N_{k\neq j}} \tag{20.91}$$
$$\overset{\text{ideal}}{\longrightarrow} \quad \left(\frac{\partial \frac{Nk_\mathrm{B}T}{P}}{\partial N_j}\right)_{T,P,N_{k\neq j}} = \left(\frac{\partial \sum_k \frac{N_k k_\mathrm{B}T}{P}}{\partial N_j}\right)_{T,P,N_{k\neq j}} = \frac{k_\mathrm{B}T}{P} \ ,$$

assuming ideal gases. With this we can now proceed to integrate the chemical potential change (20.90),

$$\Delta\bar{G}_j = \Delta\mu_j = \mu_j - \mu_j^0 = \int_{P_0}^{P_j} \bar{V}_j dP_T = k_\mathrm{B}T \ln\frac{P_j}{P_0} = k_\mathrm{B}T\ln\eta_j \ . \tag{20.92}$$

Comparing with the chemical potential obtained from the definition (20.88),

$$\Delta\mu_j = k_\mathrm{B}T \ln a_j \ , \tag{20.93}$$

we see that, for ideal gas solutions the abundance and the activity are identical, which is to say the activity coefficient is $\gamma_j = 1$. Based on the expressions (20.85), we can also calculate the dependence of other partial molal properties on the abundances,

partial molal property			total property	
$\Delta\bar{G}_j$		$= k_\mathrm{B}T \ln \eta_j$	$\Delta\tilde{G}^\mathrm{mix}$	$= k_\mathrm{B}T \sum \eta_j \ln \eta_j$
$\Delta\bar{S}_j$	$= -\left(\frac{\partial \Delta\bar{G}_j}{\partial T}\right)_{P,N_k}$	$= -k_\mathrm{B} \ln \eta_j$	$\Delta\tilde{S}^\mathrm{mix}$	$= -k_\mathrm{B} \sum \eta_j \ln \eta_j$
$\Delta\bar{V}_j$	$= \left(\frac{\partial \Delta\bar{G}_j}{\partial P}\right)_{T,N_k}$	$= 0$	$\Delta\tilde{V}^\mathrm{mix}$	$= 0$
$\Delta\bar{H}_j$	$= \Delta\bar{G}_j + T\Delta\bar{S}_j$	$= 0$	$\Delta\tilde{H}^\mathrm{mix}$	$= 0$
$\Delta\bar{F}_j$	$= \Delta\bar{G}_j - P\Delta\bar{V}_j$	$= k_\mathrm{B}T \ln \eta_j$	$\Delta\tilde{F}^\mathrm{mix}$	$= k_\mathrm{B}T \sum \eta_j \ln \eta_j$
$\Delta\bar{E}_j$	$= \Delta\bar{G}_j + T\Delta\bar{S}_j - P\Delta\bar{V}_j$	$= 0$	$\Delta\tilde{E}^\mathrm{mix}$	$= 0$

(20.94)

The dependencies are plotted in Fig. 20.6(a,b) for a two-component system. We notice that (i) the curves are symmetric with respect to $\eta_j \leftrightarrow 1 - \eta_j$; (ii) their slopes are vertical for $\eta_j \longrightarrow 0, 1$; (iii) ΔS_j^mix is temperature-independent.

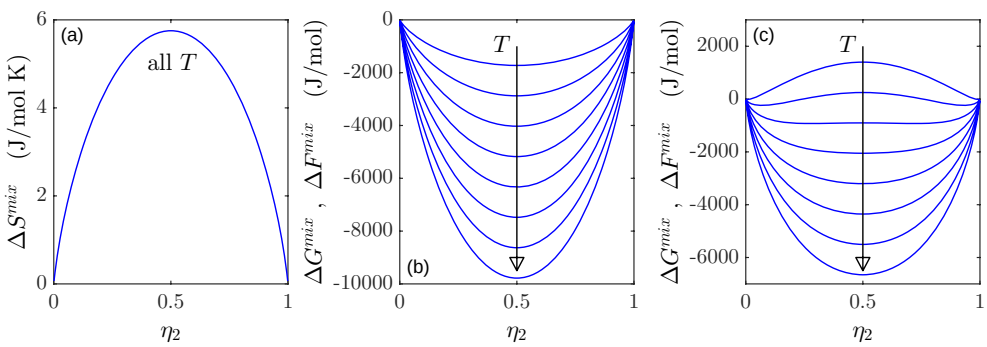

Figure 20.6: (code) Dependence of state functions on composition and temperature in the range between 300 K and 1700 K. (a) The entropy for an ideal gas and a regular solution are identical. (b) Gibbs free and Helmholtz free energy for an ideal gas solution and (c) for a regular solution.

The results (20.94) obtained for an *ideal solution* are extremely useful to benchmark deviations observed in real solutions.

20.2.3.2 Fugacity in real solutions

For *real solutions* for which the ideal gas equation does not hold, the partial molal volume cannot be determined from Eq. (20.91), but must be experimentally determined.

It is often interesting to define a 'deviation volume',

$$\mathfrak{V}_j \equiv \bar{V}_j - \frac{k_\mathrm{B}T}{P} \ . \tag{20.95}$$

In analogy to (20.92), the chemical potential change can then be written,

$$\begin{aligned}\Delta\mu_j &= \int_{P_0}^{P_j} \bar{V}_j dP = \int_{P_0}^{P_j} \left(\frac{k_\mathrm{B}T}{P} + \mathfrak{V}_j\right) dP \\ &= k_\mathrm{B}T \ln\frac{P_j}{P_0} + \int_{P_0}^{P_j} \mathfrak{V}_j dP \equiv k_\mathrm{B}T \ln\frac{f_j}{P_0} \ .\end{aligned} \tag{20.96}$$

The last equality of (20.96) defines the *fugacity* of a component of a mixture,

$$f_j = P_j \exp\left(\frac{1}{k_\mathrm{B}T}\int_{P_0}^{P_j} \mathfrak{V}_j dP\right) \ . \tag{20.97}$$

As the deviation from ideal gas behavior, measured by $\mathfrak{V}_j$ diminishes, the fugacity of component j approaches its partial pressure. Measurement of the fugacity of one component over a range of temperature, pressure, and composition is sufficient to describe the behavior of real gas mixtures completely in that range.

20.2.3.3 Activity in real solutions

Remembering that the chemical potential can also be expressed in terms of activity via Eq. (20.92), we see that activity and fugacity are intrinsically related,

$$f_j = P_0 a_j \ . \tag{20.98}$$

From (20.92),

$$\begin{aligned}&\Delta\bar{G}_j = k_\mathrm{B}T \ln a_j = k_\mathrm{B}T \ln \eta_j\gamma_j = \Delta\bar{G}^\mathrm{id} + \Delta\bar{G}^\mathrm{xs} \\ &\text{with} \qquad \Delta\bar{G}^\mathrm{id} \equiv k_\mathrm{B}T \ln \eta_j \qquad \text{and} \qquad \Delta\bar{G}^\mathrm{xs} \equiv k_\mathrm{B}T \ln \gamma_j \ .\end{aligned} \tag{20.99}$$

The activity coefficient $\gamma_j = \gamma_j(T, P, \eta_j)$ quantifies the deviation from ideal solution behavior; if $\gamma_j > 1$ then the component j 'acts' as if its abundance were more than expected from a supposed ideal gas behavior.

Using the expressions for the thermodynamic potentials of the first column of Tab. (20.93), we can also express the other partial molal properties (PMP) in terms of activity or activity coefficient,

PMP	as a function of activity	activity coefficient
$\Delta\bar{G}_j/k_\mathrm{B}T$	$= \ln a_j$	$= \ln(\gamma_j\eta_j)$
$\Delta\bar{S}_j/k_\mathrm{B}$	$= -\ln a_j - T\left(\frac{\partial \ln a_j}{\partial T}\right)_{P,N_k}$	$= -\ln(\gamma_j\eta_j) - T\left(\frac{\partial \ln \gamma_j}{\partial T}\right)_{P,N_k}$
$\Delta\bar{V}_j/k_\mathrm{B}T$	$= \left(\frac{\partial \ln a_j}{\partial P}\right)_{T,N_k}$	$= \left(\frac{\partial \ln \gamma_j}{\partial P}\right)_{T,N_k}$
$\Delta\bar{H}_j/k_\mathrm{B}T$	$= -T\left(\frac{\partial \ln a_j}{\partial T}\right)_{P,N_k}$	$= -T\left(\frac{\partial \ln \gamma_j}{\partial T}\right)_{P,N_k}$
$\Delta\bar{F}_j/k_\mathrm{B}T$	$= \ln a_j - P\left(\frac{\partial \ln a_j}{\partial P}\right)_{T,N_k}$	$= \ln(\gamma_j\eta_j) - P\left(\frac{\partial \ln \gamma_j}{\partial P}\right)_{T,N_k}$
$\Delta\bar{E}_j/k_\mathrm{B}T$	$= -T\left(\frac{\partial \ln a_j}{\partial T}\right)_{P,N_k} - P\left(\frac{\partial \ln a_j}{\partial P}\right)_{T,N_k}$	$= -T\left(\frac{\partial \ln \gamma_j}{\partial T}\right)_{P,N_k} - P\left(\frac{\partial \ln \gamma_j}{\partial P}\right)_{T,N_k}$

(20.100)

20.2.4 Models of real solutions

The ideal solution assumption disregards any features emanating from properties of the microscopic constituents. Hence, at same temperature and composition all ideal solutions are equal. More sophisticated models are required to remove this degeneracy.

20.2.4.1 Regular and non-regular solutions

One real solution model is the *regular solutions* model. It is based on two assumptions:

1. The mixing entropy is that of an ideal solution:
$$\Delta\tilde{S}^{\mathrm{mix,rl}} = \Delta\tilde{S}^{\mathrm{mix,id}} = -R_{\mathrm{g}}\sum_j \eta_j \ln\eta_j \ . \tag{20.101}$$

2. The solution enthalpy is a function of composition, and not zero as in ideal solutions,
$$\Delta\tilde{H}^{\mathrm{mix,rl}} = \Delta\tilde{H}^{\mathrm{mix,xs}}(\eta_j) \ . \tag{20.102}$$

Because, the excess mixing entropy vanishes $\Delta\tilde{S}^{\mathrm{mix,xs}} \equiv \Delta\tilde{S}^{\mathrm{mix,rl}} - \Delta\tilde{S}^{\mathrm{mix,id}} = 0$, the excess Gibbs free energy $\tilde{G} = \tilde{H} - T\tilde{S}$ becomes equal to the excess mixing enthalpy,
$$\begin{aligned}\Delta\tilde{G}^{\mathrm{mix,xs}} &= (\Delta\tilde{H}^{\mathrm{mix,rl}} - T\Delta\tilde{S}^{\mathrm{mix,rl}}) - (\Delta\tilde{H}^{\mathrm{mix,id}} - T\Delta\tilde{S}^{\mathrm{mix,id}}) \\ &= \Delta\tilde{H}^{\mathrm{mix,xs}} \ .\end{aligned} \tag{20.103}$$

Thus, in regular solutions, because the entropy of mixing is defined to be zero, the excess Gibbs energy is equal to the enthalpy of mixing, which is a function of composition, but not temperature. Since the temperature derivative of the excess Gibbs energy is equal to minus the excess entropy of mixing, $S_j = (\partial G_j/\partial P)_{T,N_j}$, the temperature derivative of $\Delta\bar{G}^{\mathrm{mix,xs}}$ and hence $\Delta\bar{H}^{\mathrm{mix}}$ must be zero.

For the components j, we have from Eq. (20.99),
$$\Delta\bar{G}^{\mathrm{mix,xs}} = k_{\mathrm{B}}T\ln\gamma_j \qquad \Longrightarrow \qquad \gamma_j = e^{\Delta\bar{H}_j^{\mathrm{mix,xs}}/k_{\mathrm{B}}T} \ . \tag{20.104}$$
Since, all properties of a solution can be calculated from a known activity coefficient γ_j, the regular solution model focuses upon the heat of mixing as a function of composition.

Example 164 (*Real solution model with a single adjustable parameter*): Let us suppose the heat of mixing for a binary solution can be described by the simple formula,
$$\Delta\bar{H}_j^{\mathrm{mix}} = \Delta\bar{G}_j^{\mathrm{mix,xs}} = a_0\eta_1\eta_2 \ .$$
Then,
$$\begin{aligned}\Delta\bar{G}^{\mathrm{mix}} &= \sum_j \eta_j(\Delta\bar{G}^{\mathrm{mix,id}} + \Delta\bar{G}^{\mathrm{mix,xs}}) \\ &= k_{\mathrm{B}}T(\eta_1\ln\eta_1 + \eta_2\ln\eta_2) + a_0\eta_1\eta_2 \ .\end{aligned}$$
The behavior is shown in Fig. 20.6(c).

A solution is called 'non-regular' when the coefficients of the solution model additionally depend on temperature, for example,
$$\Delta\bar{H}_j^{\mathrm{mix}} = [a_1(T)\eta_1 + a_2(T)\eta_2]^2 \ . \tag{20.105}$$

20.2.4.2 Atomistic model for real solutions

In Sec. 19.2.7 we have seen, that the behavior of real gases can be somewhat different from that of an ideal gas and how to incorporate this in a heuristic model. The justification of the van der Waals equation (19.127) was the existence of interparticle forces capable of storing energy depending on the mean interparticle distance [see Fig. 19.6(a)].

The interparticle forces obviously depend on the colliding partners, the interaction energy V_{11} ruling a collision between two particles of type $j = 1$ will be different from V_{22} and V_{12}. Hence, in multi-component systems the corrections to the real solution model must depend on the fractions η_1 and η_2.

In a random mixture, the probability for collisions between identical and between different particles scales as,

$$p_{jj} = \eta_j^2 \qquad \text{and} \qquad p_{12} = 2\eta_1\eta_2 \ . \tag{20.106}$$

The presence of collisions different particles motivates the ansatz for the mixing entropy made in example 160,

$$\Delta H^{\text{mix}} = a\eta_1\eta_2 \ . \tag{20.107}$$

Do the Excs. 20.2.6.1 to 20.2.6.4.

20.2.5 Osmotic pressure

Osmosis is a physical process in which any solvent moves across a selectively semi-permeable membrane (permeable to the solvent, but not the solute) separating two solutions of different concentrations, as depicted in Fig. 20.7. Osmosis can be made to do exert work.

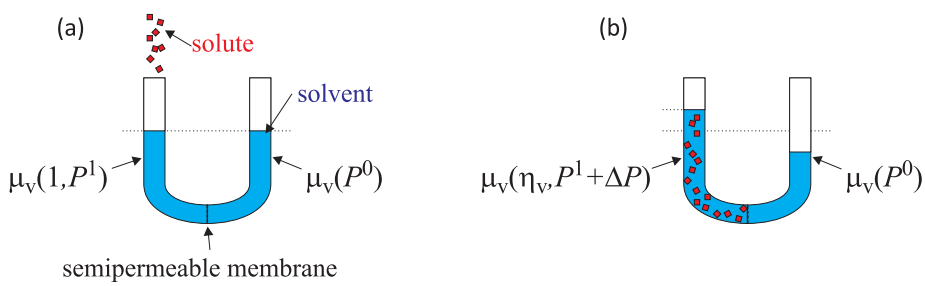

Figure 20.7: Osmosis occurs when two solutions containing different concentrations of solute are separated by a selectively permeable membrane. Solvent molecules pass preferentially through the membrane from the low-concentration solution to the solution with higher solute concentration. The transfer of solvent molecules will continue until osmotic equilibrium is attained. (a) Pressure balance without solute and (b) with solute.

Without solute [situation shown in Fig. 20.7(a)] the chemical potential of the solvent (index 'v') in the compartment left to the membrane (subscript '1') and on the right (subscript '0') are equal,

$$\mu_{\text{v}}^1(P^1) = \mu_{\text{v}}^0(P^0) \qquad \text{where} \qquad P^1 = P^0 \tag{20.108}$$

are the pressures in both compartment.

Having introduced a solute (index 's') into the left compartment [situation shown in Fig. 20.7(b)], the chemical potential in the left compartment must still be the same, as it is forced to equilibrate with the one in the right compartment which remains unchanged [3]. However, the introduction of the solute reduces the molar fraction of the solvent from $\eta_\mathrm{v} = 1$ to a value $\eta_\mathrm{v} \in [0, 1]$. This also reduces the chemical potential which, according to Eq. (20.88) or Fig. 20.6(b) now also depends on η_v. In order to maintain the chemical potential balanced, the system reacts by increasing the pressure $P^{(1)}$ in the left compartment. We can therefore write the chemical potential of the solvent in equilibrium on both sides of the membrane,

$$\mu_\mathrm{v}^1(\eta_\mathrm{v}, P^0 + \Delta P) = \mu_\mathrm{v}^1(1, P^0) = \mu_\mathrm{v}^0(P^0) \ . \tag{20.109}$$

The difference in pressure ΔP of the two compartments is the *osmotic pressure* exerted by the solute.

In order to find the osmotic pressure, we consider equilibrium between a solution containing solute and pure solvent, as described by Eq. (20.109). Exploiting the definition (20.88) of the *activity coefficient* γ_v, we can write the left hand side as,

$$\mu_\mathrm{v}^1(\eta_\mathrm{v}, P^0 + \Delta P) = \mu_\mathrm{v}^1(1, P^0 + \Delta P) + k_\mathrm{B}T \ln(\gamma_\mathrm{v}\eta_\mathrm{v}) \ . \tag{20.110}$$

The product $\gamma_\mathrm{v}\eta_\mathrm{v}$ is also known as the activity of the solvent, which for water is the water activity $a_\mathrm{aq} = \gamma_\mathrm{aq}\eta_\mathrm{aq} = 1$. The pressure change is given by,

$$\mu_\mathrm{v}^1(1, P + \Delta P) = \mu_\mathrm{v}^0(1, P^0) + \int_P^{P+\Delta P} \tilde{V}(P')dP' \ , \tag{20.111}$$

in analogy to (20.96). In order to fulfill the equilibrium condition (20.109), the chemical potential change (20.111) induced by reduction of the molar fraction γ_v must compensate the chemical potential change (20.112) induced by osmotic pressure,

$$\int_P^{P+\Delta P} \tilde{V}(P')dP' \overset{\text{equil.}}{=} -k_\mathrm{B}T \ln(\gamma_\mathrm{v}\eta_\mathrm{v}) \ . \tag{20.112}$$

If the liquid is incompressible, the molar volume is constant, $\tilde{V}(P') \equiv \tilde{V}$, and the integral becomes $\tilde{V}\Delta P$. Thus, we get,

$$\Delta P = -\frac{k_\mathrm{B}T}{\tilde{V}} \ln(\gamma_\mathrm{v}\eta_\mathrm{v}) \ . \tag{20.113}$$

Generally, the activity coefficient is a function of concentration and temperature. However, dilute mixtures (characterized by $\eta_\mathrm{s} \ll 1$ and $N_\mathrm{s} \ll N_\mathrm{v}$) are often well described as ideal solutions, for which $\gamma_\mathrm{v} \simeq 1$,

$$\begin{aligned} \Delta P = -\frac{k_\mathrm{B}T}{\tilde{V}} \ln \gamma_\mathrm{v}\eta_\mathrm{v} &\overset{\gamma_\mathrm{v}\simeq 1}{\simeq} -\frac{k_\mathrm{B}T}{\tilde{V}} \ln \eta_\mathrm{v} = -\frac{k_\mathrm{B}T}{\tilde{V}} \ln(1-\eta_\mathrm{s}) \\ &\overset{\eta_\mathrm{s}\ll 1}{\simeq} \frac{k_\mathrm{B}T}{\tilde{V}}\eta_\mathrm{s} = \frac{k_\mathrm{B}T}{\tilde{V}} \frac{N_\mathrm{s}}{N_\mathrm{s}+N_\mathrm{v}} \\ &\overset{N_\mathrm{s}\ll N_\mathrm{s}}{\simeq} \frac{k_\mathrm{B}T}{\tilde{V}} \frac{N_\mathrm{s}}{N_\mathrm{v}} = \frac{k_\mathrm{B}T}{V} N_\mathrm{s} = k_\mathrm{B}T n_\mathrm{s} \ . \end{aligned} \tag{20.114}$$

[3] Note that the solvent is the only component free to flow toward equilibrium.

In the third line, we defined the density $n_\mathrm{s} \equiv N_\mathrm{s}/V$.

For aqueous solutions of salts, ionization must be taken into account. In such cases, the osmotic pressure can be generalized to the *van't Hoff* law,

$$\boxed{\Delta P = i_\mathrm{vH} R_\mathrm{g} T\, c}\ , \tag{20.115}$$

i_vH van't Hoff factor (the number of particles the solute dissociates into; for example, $i_\mathrm{vH} = 2$ for NaCl, since it dissociates into Na^+ and Cl^-. c is the molarity of the solute (in mol/L). Do the Exc. 20.2.6.5.

20.2.6 Exercises

20.2.6.1 Ex: Partial pressures

A closed cylindrical reservoir with the base area $S = 10\,\mathrm{cm}^2$ is kept at a constant temperature $T = 27\,^\circ\mathrm{C}$. It is divided in two volumes by an airtight mobile disk with the mass $m = 10\,\mathrm{kg}$. The upper volume V_{O_2} contains $\eta_{\mathrm{O}_2} = 1\,\mathrm{mol}$ of oxygen, the lower volume V_{N_2} contains the same amount of nitrogen. Due to its weight the disc finds an equilibrium position when the lower volume is $V_{\mathrm{N}_2} = 10\,\mathrm{L}$.
a. What are the masses m_{O_2} and m_{N_2} of the gases?
b. What are the pressures P_{O_2} and P_{N_2}?
c. What is the upper volume V_{O_2}?
d. What are the densities n_{O_2} and n_{N_2}?
e. Now the disc has a hole, so that the gases can mix and the disc falls to the bottom of the reservoir. What is the final pressure of the mixture?

20.2.6.2 Ex: Gibbs-Duhem integration

For an ideal solution, it is known that for component 2,

$$\Delta \bar{G}_2 = R_\mathrm{g} T \ln \eta_2\ .$$

Use the Gibbs-Duhem integration (20.76) to derive the corresponding relation for component 1.

20.2.6.3 Ex: Oxygen concentration in a metal

Titanium metal is capable of dissolving up to 30 atomic percent oxygen, a feature that is interesting for the realization of ultra high vacuum *sublimation pumps*. Consider a solid solution in the system Ti−O containing an atom fraction, $\eta_\mathrm{O} = 0.12$. The molar volume of this alloy is $\tilde{V}_{\mathrm{Ti+O}} = 10.68\,\mathrm{cm}^3/\mathrm{mol}$. Calculate:
a. The weight percent of O in the solution.
b. The molar concentration ($\mathrm{mol/cm}^3$) of O in the solution.
c. The mass concentration ($\mathrm{g/cm}^3$) of O in the solution.
d. Use these calculations to deduce general expressions for weight percent, molar and mass concentrations of a component in a binary solution in terms of the atom fraction, η_2, the molar volume $\tilde{V}_{1+2}$, and the molecular weights of the elements involved.

20.2.6.4 Ex: Gibbs-Duhem rule

Given that the volume change upon mixing of a solution obeys the relation $\tilde{V}^{\text{mix}} = a\eta_1\eta_2^2$,
a. Derive expressions for the partial molal volumes of each of the components as functions of composition.
b. Demonstrate that your result is correct by using it to compute $\tilde{V}^{\text{mix}}$, demonstrating that the equation above is recovered.

20.2.6.5 Ex: Osmotic pressure of a NaCl solution

Calculate the osmotic pressure in a 1 mol/L solution of NaCl at 25 °.

20.3 Multi-component, heterogeneous, non-reacting systems

20.3.1 Equilibrium conditions

Expressions for multi-component systems require addition of terms describing particle exchange, $\sum_j \mu_j dN_j$. For example, the combined first and second law for homogeneous multi-component reads,

$$dE = TdS - PdV + \sum_{j=1}^{J} \mu_j dN_j \ . \tag{20.116}$$

Now, we assume that each component exists in Γ different phases. Each phase viewed as a system exchanges heat, work, and matter with the other phases and with the reservoir,

$$dE^\gamma = T^\gamma dS^\gamma - P^\gamma dV^\gamma + \sum_{j=1}^{J} \mu_j^\gamma dN_j^\gamma \ , \tag{20.117}$$

for all phases $\gamma = \alpha, \beta, ...$ For the extensive properties V, S, E, H, F, G the value for the property of the system is the sum of the parts,

$$X^{\text{syst}} = \sum_{\gamma=1}^{\Gamma} X^\gamma \ . \tag{20.118}$$

When the system is taken through an arbitrary change of state, then the change of X^{syst} is simply the sum of the changes that each phase experiences,

$$dX^{\text{syst}} = d\left(\sum_{\gamma=1}^{\Gamma} X^\gamma\right) = \sum_{\gamma=1}^{\Gamma} dX^\gamma \ . \tag{20.119}$$

As an example, let us regard a change in internal energy,

$$dE^{\text{syst}} = \sum_{\gamma=1}^{\Gamma} \left(T^\gamma dS^\gamma - P^\gamma dV^\gamma + \sum_{j=1}^{J} \mu_j^\gamma dN_j^\gamma \right) \ . \tag{20.120}$$

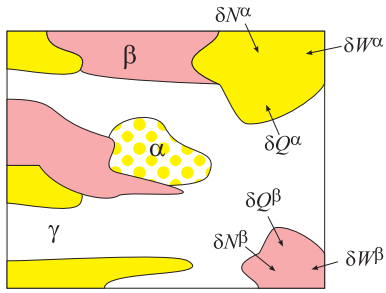

Figure 20.8: Heat work, and particle exchange in a micro structure with 3 components and two phases.

To find the equilibrium conditions, we need to express the entropy. We solve the Eq. (20.117) for dS^γ and sum up the entropies for all phases,

$$dS^{\text{syst}} = \sum_{\gamma=1}^{\Gamma} dS^\gamma = \sum_{\gamma=1}^{\Gamma} \left(\frac{1}{T^\gamma} dE^\gamma + \frac{P^\gamma}{T^\gamma} dV^\gamma - \frac{1}{T^\gamma} \sum_{j=1}^{J} \mu_j^\gamma dN_j^\gamma \right) . \tag{20.121}$$

The condition for equilibrium is $S^{\text{syst}} =$ maximal. Eq. (20.121) contains $\Gamma \times (2+J)$ variables, but their number is reduced if the system is isolated from the reservoir, $dE^{\text{syst}} = dV^{\text{syst}} = dN^{\text{syst}} = 0$. Let us suppose there are only two phases $\gamma = \alpha, \beta$. Then the isolation assumption reads,

$$dE^\alpha = -dE^\beta \quad , \quad dV^\alpha = -dV^\beta \quad , \quad dN^\alpha = -dN^\beta \ , \tag{20.122}$$

and the expression (20.121) becomes,

$$\begin{aligned} dS^{\text{syst,iso}} &= \left(\frac{1}{T^\alpha} - \frac{1}{T^\beta} \right) dE^\alpha + \left(\frac{P^\alpha}{T^\alpha} - \frac{P^\beta}{T^\beta} \right) dV^\alpha - \sum_{j=1}^{J} \left(\frac{\mu_j^\alpha}{T^\alpha} - \frac{\mu_j^\beta}{T^\beta} \right) dN_j^\alpha \\ &\stackrel{!}{=} 0 \ . \end{aligned} \tag{20.123}$$

From this follows,

$$\begin{aligned} T^\alpha &= T^\beta && \text{thermal equilibrium} \\ P^\alpha &= P^\beta && \text{mechanical equilibrium} \\ \mu_j^\alpha &= \mu_j^\beta \quad , \quad \forall j \leq J && \text{chemical equilibrium} \end{aligned} \tag{20.124}$$

This rule can be easily generalized to more than two phases by pairwise comparison of the phases. We immediately see that,

$$\boxed{\begin{aligned} T^\alpha &= T^\beta = \ldots = T^\Gamma && \text{thermal equilibrium} \\ P^\alpha &= P^\beta = \ldots = P^\Gamma && \text{mechanical equilibrium} \\ \mu_j^\alpha &= \mu_j^\beta = \ldots = \mu_j^\Gamma \quad , \quad \forall j \leq J && \text{chemical equilibrium} \end{aligned}} \tag{20.125}$$

These equations form the basis for the construction and calculation of multi-component multi-phase phase diagrams.

20.3.1.1 The Gibbs phase rule

An interesting question is, how many independent variables are needed to completely describe a composite system. This number $\mathfrak{f}$ is called the number of macroscopic thermodynamic degrees of freedom.

The system (20.125) consists of $(\Gamma-1)\times(2+J)$ equations and contains $\Gamma\times(2+J)$ variables. However, the Gibbs-Duhem equation (20.54) imposes additional constraints relating the chemical potentials between the components for all Γ allotropic phases [4]. Hence,

$$\mathfrak{f} = \Gamma \times (2+J) \quad - \quad (\Gamma-1)\times(2+J) \quad - \quad \Gamma \ , \tag{20.126}$$

that is,

$$\boxed{\mathfrak{f} = J + 2 - \Gamma} \ . \tag{20.127}$$

The rule assumes the components do not react with each other. The number of degrees of freedom is the number of independent intensive variables, i.e. the largest number of thermodynamic parameters such as temperature or pressure that can be varied simultaneously and arbitrarily without determining one another.

20.3.2 Structure of phase diagrams

Phase diagrams are graphical representations of the domains of stability of the various classes of structures (one, two, or more phases) that a system may have mostly in (T, P, η_j)-space. A unary system $(J = 1)$ with Γ coexisting phases has, according to the Gibbs phase rule, $\mathfrak{f} = 3 - \Gamma$ degrees of freedom. From the fact that $\mathfrak{f}$ decreases with the number of phases we deduce, that single-phase regions require the largest amount of variables for their specification. Consequently, the graphical space in which the phase diagram is constructed must have $J+1$ independent coordinates to allow for a representation of the full range of behavior of the single-phase regions. A unary system thus can be plotted in a (P, T)-diagram, while a binary system already requires a three-dimensional space, e.g. (T, P, η_2). As printed pages only have two dimensions, one has to resort to sections across multi-phase diagrams or to projections. Sections provide quantitative information, while projections illustrate better general relationships. Do the Exc. 20.3.3.1 and 20.3.3.2.

> **Example 165 (*Phase diagrams*):** According to the Gibbs phase rule, a unary homogeneous system has $\mathfrak{f} = 2$ degrees of freedom. A unary heterogeneous system with two (or more) phases ($\mathfrak{f} \leq 2$) is characterized by phase boundaries (or triple points), which can be conveniently represented in a plane PT-diagram.

20.3.3 Exercises

20.3.3.1 Ex: Volume change in a multi-phase multi-component system

Use Eq. (20.119) to write out a general expression for the change of volume of a three-phase two-component system including all 12 terms.

[4] This comes down to removing particle number N_j as an independent variable.

20.3.3.2 Ex: Phase diagram of water

Sketch the phase diagram for pure water in (P, V) space. Be careful to incorporate the observation that solid water shrinks upon conversion to the liquid state. Discuss complications in the structure of the diagram that derive from this fact.

20.4 Continuous, non-uniform systems exposed to external forces

When we discussed thermodynamic equilibrium in Secs. 19.3 and 20.1, we tacitly assumed that the intensive properties within a phase are uniform, i.e. a single temperature, pressure, or composition can be assigned to a particular phase α, and the same holds for the chemical potential and all partial molal properties. On the other hand, those properties can vary from phase to phase.

In the presence of external force fields the situation is different. Equilibrated systems may then exhibit temperature, pressure, or composition profiles. One example is the atmosphere on Earth, whose vertical temperature and pressure profile is described by the barometric formula studied in Excs. 19.1.4.3 and 19.1.4.3; an atomic gas confined in a harmonic trapping potential develops a radial density profile studied in Excs. 29.1.7.14 to 29.1.7.16; mixtures submitted to centrifuges may experience a separation of their components; and an electrostatic field will separate components with different charges.

To handle thermodynamic properties in such locally homogeneous but globally non-uniform systems, we need to introduce the concept of *densities* of extensive thermodynamic quantities, e.g. the energy density, which are scalar fields, i.e. local intensive properties associated with each point of the system in space.

20.4.1 Thermodynamic densities

For each extensive property of a system, $X \in \{S, V, E, F, H, G, N_j\}$, we may define a corresponding local density,

$$\boxed{x(\mathbf{r}) \equiv \frac{\delta X}{\delta V}} \ , \tag{20.128}$$

where the V is a volume element near the point located at the coordinates $\mathbf{r}$. Here, we use the symbol δ for spatial differentials to distinguish them from thermodynamic state changes denoted by the symbol d. Then, $x(\mathbf{r})\delta V$ is the total value of the extensive property X in the volume element and,

$$X = \int_V x(\mathbf{r})\delta V \tag{20.129}$$

in the whole system. Changes of this property along a thermodynamic process are expressed as usual,

$$dX_V = \int_V dx(\mathbf{r})\delta V \ , \tag{20.130}$$

where we assume that these changes do not modify the volume.

Let us now calculate the differential of the energy density using the prescription (20.128) for a thermodynamic process. Since the process does not change the volume element, we can write,

$$de(\mathbf{r}) = \frac{\delta dE_V}{\delta V} = \frac{\delta}{\delta V}\left(TdS_V - PdV_V + \sum_j \mu_j dN_{jV}\right) \tag{20.131}$$
$$= T\frac{d\delta S_V}{\delta V} + \sum_j \mu_j \frac{d\delta N_{jV}}{\delta V} = Tds(\mathbf{r}) + \sum_j \mu_j dn_j(\mathbf{r}) \ ,$$

where s is the entropy density and n_j the molar density of the component j. That is, we can derive local versions for all thermodynamic relationships.

20.4.2 Equilibrium conditions

20.4.2.1 Without external force field

Integrating Eq. (20.131) we get, resolved by entropy

$$dS = \int_V \left(\frac{1}{T}de - \frac{1}{T}\sum_j \mu_j dn_j\right)\delta V \ . \tag{20.132}$$

If during the thermodynamic process the system is isolated against energy and particle exchange,

$$0 = dE = \int_V de(\mathbf{r})\delta V \qquad \text{and} \qquad 0 = dN_j = \int_V dn_j(\mathbf{r})\delta V \ . \tag{20.133}$$

Equilibrium is reached when the entropy is maximum, and a necessary condition for that is,

$$dS - \sum_j k_\mathrm{B}\alpha_j dN_j - k_\mathrm{B}\beta dE = 0 \tag{20.134}$$

for any value of the Lagrange multipliers α_j and β. Substituting (20.132) and (20.133),

$$0 = \int_V \left(\frac{1}{T}de(\mathbf{r}) - \frac{1}{T}\sum_j \mu_j dn_j(\mathbf{r})\right)\delta V - k_\mathrm{B}\beta\int_V de(\mathbf{r})\delta V - \sum_j k_\mathrm{B}\alpha_j \int_V dn_j(\mathbf{r})\delta V \ , \tag{20.135}$$

which implies,

$$0 = \left(\frac{1}{T} - k_\mathrm{B}\beta\right)de(\mathbf{r}) - \sum_j \left(\frac{\mu_j}{T} + k_\mathrm{B}\alpha_j\right)dn_j(\mathbf{r}) \ . \tag{20.136}$$

We conclude,

$$\beta = \frac{1}{k_\mathrm{B}T} \qquad , \qquad \alpha_j = -\frac{\mu_j}{k_\mathrm{B}T} \ . \tag{20.137}$$

Since α_j and β are constants, this means that temperature and chemical potential cannot depend on position,

$$\boxed{\nabla T = 0 = \nabla\mu_j} \ . \tag{20.138}$$

To derive the condition for mechanical equilibrium, we apply the operator (20.55) on the Gibbs-Duhem relation (20.54) resolved by one of the species j, that is,

$$\left(\frac{\partial}{\partial N_j}\right)_{P,T,N_{k\neq j}} \qquad \text{applied to} \qquad N_j d\mu_j = -SdT + VdP - \sum_{k\neq j} N_k d\mu_k \ , \tag{20.139}$$

and obtain the partial molal equation,

$$d\mu_j = -\bar{S}_j dT + \bar{V}_j dP - \sum_{k\neq j} N_k \left(\frac{\partial d\mu_k}{\partial N_j}\right)_{P,T,N_{k\neq j}} \ . \tag{20.140}$$

We now interpret the differential forms as gradients, $d \to d_{\mathbf{r}} \to \nabla$,

$$\nabla\mu_j = -\bar{S}_j \nabla T + \bar{V}_j \nabla P - \sum_{k\neq j} N_k \left(\frac{\partial \nabla\mu_k}{\partial N_j}\right)_{P,T,N_{k\neq j}} \ . \tag{20.141}$$

As we already found the equilibrium conditions $\nabla T = 0 = \nabla\mu_j$, we get,

$$\bar{V}_j \nabla P = \sum_{k\neq j} N_k \left(\frac{\partial \nabla\mu_k}{\partial N_j}\right)_{P,T,N_{k\neq j}} \ . \tag{20.142}$$

Multiplying both sides with η_j and summing over all components, and exploiting the fact that summation over all partial molal volumes produces the total molar volume, $\sum_j \eta_j \bar{V}_j = \tilde{V}$,

$$\tilde{V}\nabla P = \sum_j \eta_j \sum_{k\neq j} N_k \left(\frac{\partial \nabla\mu_k}{\partial N_j}\right)_{P,T,N_{k\neq j}} \ . \tag{20.143}$$

The right-hand side can be shown to vanish using the Gibbs-Duhem equation (20.62). Hence,

$$\boxed{\nabla P = 0 \ .} \tag{20.144}$$

The results (20.138) and (20.144) were expected and only tell us that there is nothing wrong with the density formalism.

20.4.2.2 With external force field

Let us now study the impact of time invariant external forces. The time invariance is obviously necessary to allow the system to reach a steady state. If the force is conservative, it can be derived from a potential,

$$\mathbf{F}(\mathbf{r}) = -\nabla\Phi(\mathbf{r}) \ . \tag{20.145}$$

The work executed by this force, $\delta W_{\text{ext}} = dW_{\text{ext}} = \mathbf{F}\cdot d\mathbf{r}$, then does not depend on the path taken between start and end point,

$$W_{\text{ext}} = \int_{\mathbf{r}_1}^{\mathbf{r}_2} \mathbf{F}\cdot d\mathbf{r} = -\int_{\mathbf{r}_1}^{\mathbf{r}_2} \nabla\Phi(\mathbf{r})\cdot d\mathbf{r} = -\int_{\Phi(\mathbf{r}_1)}^{\Phi(\mathbf{r}_2)} \delta\Phi(\mathbf{r}) = \Phi(\mathbf{r}_1) - \Phi(\mathbf{r}_2) \ . \tag{20.146}$$

Forces act on masses M_j, or charges Q_j carried by particles. The mass contained in a volume element δV is,

$$\delta m = \sum_j M_j n_j \delta V \ . \tag{20.147}$$

The total potential energy is the sum of the potential energies to which the mass elements δm are subject,

$$E_{\rm pot} = \int_V \frac{\delta\Phi(\mathbf{r})}{\delta V}\delta V = \int_V \frac{\delta\Phi(\mathbf{r})}{\delta m}\delta m(\mathbf{r}) = \int_V \frac{\delta\Phi(\mathbf{r})}{\delta m}\sum_j M_j n_j \delta V \ . \tag{20.148}$$

Including the internal energy the total energy differential is then,

$$dE_{\rm tot} = dE + dE_{\rm pot} = \int_V de(\mathbf{r})\delta V + \int_V \frac{\delta\Phi(\mathbf{r})}{\delta m}\sum_j M_j dn_j \delta V \ . \tag{20.149}$$

Repeating the entropy maximization procedure (20.135), we now get,

$$\begin{aligned} 0 &= dS - k_{\rm B}\beta dE_{\rm tot} - \sum_j k_{\rm B}\alpha_j dN_j \qquad (20.150)\\ &= \int_V \left(\frac{1}{T}de(\mathbf{r}) - \frac{1}{T}\sum_j \mu_j dn_j(\mathbf{r})\right)\delta V \\ &\quad - k_{\rm B}\beta\left(\int_V de(\mathbf{r}) + \int_V \frac{\delta\Phi(\mathbf{r})}{\delta m}\sum_j M_j dn_j(\mathbf{r})\right)\delta V - \sum_j k_{\rm B}\alpha_j \int_V dn_j(\mathbf{r})\delta V \ , \end{aligned}$$

which implies,

$$0 = \left(\frac{1}{T} - k_{\rm B}\beta\right) de(\mathbf{r}) - \sum_j \left(\frac{\mu_j}{T} + k_{\rm B}\beta\frac{\delta\Phi(\mathbf{r})}{\delta m}M_j + k_{\rm B}\alpha_j\right) dn_j(\mathbf{r}) \ . \tag{20.151}$$

We conclude,

$$T = \frac{1}{k_{\rm B}\beta} \quad , \quad \frac{\mu_j}{T} + k_{\rm B}\beta\frac{\delta\Phi(\mathbf{r})}{\delta m}M_j + k_{\rm B}\alpha_j = 0 \ . \tag{20.152}$$

Since α_j and β are constants,

$$\boxed{\nabla T = 0 = \nabla\left(\mu_j + M_j\frac{\delta\Phi(\mathbf{r})}{\delta m}\right)} \ . \tag{20.153}$$

To derive the condition for mechanical equilibrium, we use again the expression (20.141), but now inserting the equilibrium conditions (20.153), we obtain an equation generalizing (20.142),

$$\bar{V}_j \nabla P = -\nabla\left(M_j\frac{\delta\Phi(\mathbf{r})}{\delta m}\right) + \sum_{k\neq j} N_k \left(\frac{\partial\nabla\mu_k}{\partial N_j}\right)_{P,T,N_{k\neq j}} \ . \tag{20.154}$$

Again, multiplying both sides with η_j, summing over all components, and exploiting the Gibbs-Duhem equation (20.62),

$$\tilde{V}\nabla P = -\nabla\left(\sum_j \eta_j M_j \frac{\delta\Phi(\mathbf{r})}{\delta m}\right) , \tag{20.155}$$

or,

$$\boxed{\nabla P = -\frac{M}{\tilde{V}}\frac{\delta\nabla\Phi(\mathbf{r})}{\delta m}} . \tag{20.156}$$

In particular, for an ideal gas,

$$\nabla P \overset{\text{ideal}}{\longrightarrow} -\frac{MP}{k_{\mathrm{B}}T}\frac{\delta\nabla\Phi(r)}{\delta m} = -\frac{\tilde{M}P}{R_{\mathrm{g}}T}\frac{\delta\nabla\Phi(\mathbf{r})}{\delta m} , \tag{20.157}$$

with the solution,

$$P = P_0 \exp\left(-\frac{\tilde{M}}{R_{\mathrm{g}}T}\frac{\delta\Phi(\mathbf{r})}{\delta m}\right) , \tag{20.158}$$

which can easily be verified by inserting (20.158) in (20.157).

Because external force fields primarily affect the mechanical degrees of freedom of a system, the pressure develops a gradient, while the temperature (which is the thermal degree of freedom) remains unchanged. The chemical degrees of freedom (i.e. the chemical potentials of each species) only vary, because the different masses (or charges) of the constituents respond differently to external forces [5]. Solve the Excs. 20.4.3.1 to 20.4.3.3.

Example 166 (*Earth gravitation*): Here, we consider a system in the Earth's gravitational field, whose force is described by,

$$\mathbf{F}(\mathbf{r}) = -\nabla(mgz) = -mg\hat{\mathbf{e}}_z . \tag{20.159}$$

The force can be derived from a potential,

$$\Phi(\mathbf{r}) = mgz \qquad \text{or} \qquad \frac{\delta\Phi(\mathbf{r})}{\delta m} = gz . \tag{20.160}$$

The conditions for equilibrium are,

$$\nabla T = 0 \qquad \text{and} \qquad \nabla\mu_j = -\nabla\left(M_j\frac{\delta\Phi(\mathbf{r})}{\delta m}\right) = -M_j g\hat{\mathbf{e}}_z , \tag{20.161}$$

and,

$$\nabla P = -\frac{M}{\tilde{V}}\frac{\delta\nabla\Phi(\mathbf{r})}{\delta m} = -\frac{M}{\tilde{V}}g\hat{\mathbf{e}}_z . \tag{20.162}$$

Hence, for an ideal gas,

$$dP = -\frac{M}{\tilde{V}}gdz \overset{\text{ideal}}{\longrightarrow} -\frac{\tilde{M}g}{R_{\mathrm{g}}T}Pdz . \tag{20.163}$$

[5] Note that the atmosphere on Earth exhibits a vertical gradient, but this is because the atmosphere, heated on one side by the Earth and cooled on the other by the universe, cannot be considered a closed system.

This is a first-order differential equation in P with the solution,

$$P = P_0 e^{-\tilde{M}gz/R_g T} \ , \tag{20.164}$$

where $\tilde{M}$ is the molar mass.

Example 167 (*Centrifugal field*): Here, we consider system rotating at constant angular velocity ω about the z-axis and thus subject to radial acceleration,

$$\mathbf{a} = \omega^2 \rho \ . \tag{20.165}$$

The centrifugal force can be derived from a potential,

$$\Phi(\mathbf{r}) = -\frac{m}{2}\omega^2(x^2 + y^2) \ . \tag{20.166}$$

The conditions for equilibrium are $\nabla T = 0$ and,

$$\nabla \mu_j = -\nabla \left(M_j \frac{\delta \Phi(\mathbf{r})}{\delta m} \right) = M_j \omega^2 \rho \hat{\mathbf{e}}_\rho \ , \tag{20.167}$$

and,

$$\nabla P = -\frac{M}{\tilde{V}} \frac{\delta \nabla \Phi(\mathbf{r})}{\delta m} = \frac{M}{\tilde{V}} \omega^2 \rho \hat{\mathbf{e}}_\rho \ . \tag{20.168}$$

Hence, for an ideal gas,

$$dP = \frac{M}{\tilde{V}} \omega^2 \rho \, d\rho \xrightarrow{\text{ideal}} \frac{\tilde{M} P}{R_g T} \omega^2 \rho \, dz \ , \tag{20.169}$$

or

$$\frac{dP}{P} = \frac{\tilde{M}\omega^2}{R_g T} \rho \, d\rho \ , \tag{20.170}$$

with the solution,

$$P = P_0 e^{\tilde{M}\omega^2 \rho^2 / 2 R_g T} \ . \tag{20.171}$$

20.4.2.3 With electrostatic field

In electrostatics the Lorentz force is,

$$\mathbf{F}(\mathbf{r}) = q\vec{\mathcal{E}}(\mathbf{r}) \qquad \text{with} \qquad \vec{\mathcal{E}}(\mathbf{r}) = -\nabla \Phi_{\text{el}}(\mathbf{r}) \ , \tag{20.172}$$

where Φ_{el} is the electrostatic potential. In thermodynamics,

$$\mathbf{F}(\mathbf{r}) = -\nabla \Phi(\mathbf{r}) = -q \nabla \Phi_{\text{el}}(\mathbf{r}) \quad \Longrightarrow \quad \Phi_{\text{el}}(\mathbf{r}) = \frac{\delta \Phi(\mathbf{r})}{\delta q} \ . \tag{20.173}$$

The mass and the charge elements are, respectively,

$$\delta m_j = M_j n_j \delta V \qquad \text{and} \qquad \delta Q_j = e n_j \delta V \ . \tag{20.174}$$

Conditions for equilibrium are,

$$\nabla T = 0 \qquad \text{and} \qquad \nabla \mu_j = -\nabla \left(\frac{M_j}{\tilde{V}} \frac{\delta \Phi(\mathbf{r})}{\delta m} \right) = -\frac{M_j}{V} \nabla \frac{\delta}{\delta m} \int \Phi_{\text{el}}(\mathbf{r}) \delta q \ . \tag{20.175}$$

The quantity

$$\mu_j + \frac{M_j}{\tilde{V}} \frac{\delta}{\delta m} \int \Phi_{\rm el}(\mathbf{r}) \delta q \tag{20.176}$$

is also called electrochemical potential, and in thermodynamic equilibrium it should be homogeneous, i.e. its gradient should vanish. For mechanical equilibrium we request,

$$\nabla P = -\frac{M}{\tilde{V}} \frac{\delta \nabla \Phi(\mathbf{r})}{\delta m} = -\frac{M}{\tilde{V}} \nabla \frac{\delta}{\delta m} \int \Phi_{\rm el}(\mathbf{r}) \delta q \ . \tag{20.177}$$

Example 168 (*Electrostatic field*): Given an electrostatic field that decays exponentially with the distance from a surface toward its interior, we want to describe the variation of composition of the components with position when it comes to equilibrium. Let $\eta_j(\infty)$ be the composition well away from the surface corresponding to the chemical potential $\mu_j(\infty)$. Since at equilibrium the electrochemical potential (20.176) is constant,

$$\mu_j + \frac{M_j}{\tilde{V}} \frac{\delta}{\delta m} \int \Phi_{\rm el}(\mathbf{r}) \delta q = \text{const} = \mu_j(\infty) \ . \tag{20.178}$$

Negatively charged components exhibit a chemical potential distribution that mimics the electric field function with μ_j and η_j high near the surface and decaying down to $\eta_j(\infty)$. The distribution for positively charged components is opposite.

20.4.3 Exercises

20.4.3.1 Ex: Pressure in a harmonically trapped ideal gas

Calculate the local pressure in a harmonically trapped ideal gas in thermodynamic equilibrium.

20.4.3.2 Ex: Atmosphere of a planet

Assume the atmosphere of planet X to be composed of a binary mixture of hydrogen and nitrogen. Derive an expression for the variation of composition with altitude treating the elements as ideal gases. Assuming that the planet has a gravitational acceleration of $g = 10\,\mathrm{m/s^2}$, a temperature of $T = 800\,\mathrm{K}$, and a H_2 abundance on the planetary surface of $\eta_{H_2} = 0.35$, calculate the atmosphere composition at 100 km above the surface.

20.4.3.3 Ex: Centrifuges

Consider a dilute solution of ^{85}Rb and ^{87}Rb whose natural abundances are 72.17 : 27.83. Placed in a centrifuge, how fast should it rotate in order to reach ratio of 10 : 90 near the outside radius $\rho = 1\,\mathrm{m}$.

20.5 Reacting systems

Matter consists of molecules and molecules are composed of atoms chosen out of a small number of species. Being the elementary building blocks, the atoms cannot mutate into atoms of another species. However, they may associate to a large variety of

molecules in a multitude of geometric and energetic configurations in a process called *chemical reaction*. The molecules are represented by chemical formulas describing succinctly the numbers of atoms, e.g. CO_2 for carbon dioxide, and a chemical reaction is represented by an equation comparing the number of atoms before and after an association or dissociation, e.g.,

$$2\,H_2 + O_2 \longrightarrow 2\,H_2O\ . \tag{20.179}$$

As already formulated by *Lavoisier*, the number of atoms in a closed system is always conserved.

A system that consists of K elements and J chemical components, some of which are molecules, has

$$R = J - K \tag{20.180}$$

independent reactions. For example, for a system containing H_2, O_2, and H_2O we have $J = 3$ and $K = 2$, so that $R = 1$. Such systems are called *univariant reacting systems*. Now assume that we have also H_2O_2 in the system. Then, we expect two independent chemical reactions,

$$\begin{aligned} 2\,H_2 + O_2 &\longrightarrow 2\,H_2O \\ H_2 + O_2 &\longrightarrow H_2O_2\ . \end{aligned} \tag{20.181}$$

Other reactions that may be formulated, e.g.,

$$2\,H_2O + O_2 \longrightarrow 2\,H_2O_2 \tag{20.182}$$

are linear combinations of (20.181). Systems with $R > 1$ are called bivariant, respectively, multivariant.

In the next section we will first focus on the gas phase, where the components unambiguously exist as molecules. In solids, which are characterized by the existence of multiple bonds between molecules, this is more complicated. Also, we will first treat univariant systems before progressively generalizing to multivariant systems.

20.5.1 Univariant chemical reactions in the gas phase

Let us study again the univariant system composed of H_2, O_2, and H_2O. The objective is to derive conditions for thermodynamic equilibrium. From the combined first and second law of thermodynamics we derive the entropy for the multi-component system,

$$\begin{aligned} dS &= \frac{1}{T}dE + \frac{P}{T}dV - \frac{1}{T}\sum_j \mu_j dN_j \\ &= \frac{1}{T}dE + \frac{P}{T}dV - \frac{1}{T}\left[\mu_{H_2}dN_{H_2} + \mu_{O_2}dN_{O_2} + \mu_{H_2O}dN_{H_2O}\right]\ . \end{aligned} \tag{20.183}$$

As usual, for a closed isolated system, we ask for the entropy to be at maximum, under the constraint that the internal energy and the volume cannot change, $dE = 0 = dV$. On the other hand, the third isolation constraint $dN_j = 0$ does not hold any more, since the components may transform into one another. The total number of atoms of

one species, however, does not change. Hence, from the chemical reaction (20.179), we obtain the constraint,

$$2dN_{\mathrm{H_2}} = dN_{\mathrm{O_2}} = -2dN_{\mathrm{H_2O}} \ . \tag{20.184}$$

Inserting all the constraints into Eq. (20.183) we get,

$$dS^{\mathrm{iso}} = -\frac{1}{T}\left[-\mu_{\mathrm{H_2}} - \tfrac{1}{2}\mu_{\mathrm{O_2}} + \mu_{\mathrm{H_2O}}\right] dN_{\mathrm{H_2O}} \equiv -\frac{A}{T} dN_{\mathrm{H_2O}} \ . \tag{20.185}$$

The linear combination of chemical potentials in brackets is called *affinity* for the reaction (20.179). If temperature, pressure, and composition of the gas mixture are known, then the chemical potential of the components and hence the affinity can be computed.

The affinity can be positive or negative, depending on the chemical potentials of the reactants and products. The third law of thermodynamics, however, requests that for any process $dS^{\mathrm{iso}} > 0$, so that in Eq. (20.185) the affinity and $dN_{\mathrm{H_2O}}$ must have opposite signs. In other words, the affinity decides in which direction a chemical reaction will take place. A state of equilibrium is reached, when $dS^{\mathrm{iso}} = 0$, which implies $A = 0$. The chemical reaction comes to a halt, when the sum of the chemical potentials of the reactants and products are equal, and this condition may require an excess of reactants or products, as illustrated in Fig. 20.9.

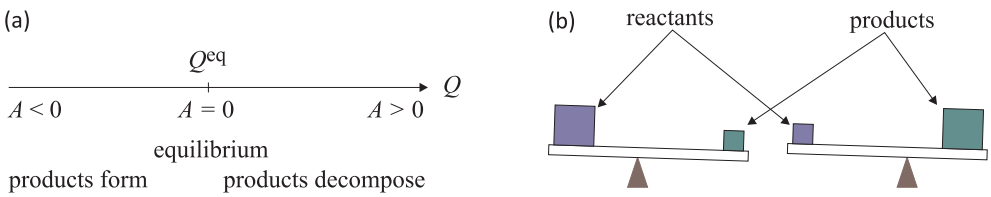

Figure 20.9: (a) Direction of a chemical reaction as a function of affinity. (b) The equilibrium of a chemical reaction may be on the left or right side.

In order to induce chemical reactions, the first thing to do is to mix the components, i.e. make a solution. As stated earlier, what is usually reported in experimental studies of solutions are the activities of the components. In order to express the affinity in terms of activities of the components, we stress Eq. (20.92) saying,

$$\mu_j = \mu_j^0 + R_{\mathrm{g}} T \ln a_j = \tilde{G}_j^0 + R_{\mathrm{g}} T \ln a_j \ , \tag{20.186}$$

where $\tilde{G}_j^0$ is the molar Gibbs free energy of component j, when it is in its reference state. Let us now consider an arbitrary chemical reaction,

$$p\,\mathrm{P} + q\,\mathrm{Q} \longrightarrow x\,\mathrm{X} + y\,\mathrm{Y} \ , \tag{20.187}$$

for which,

$$\begin{aligned} A &= \mu_{\mathrm{product}} - \mu_{\mathrm{reactants}} = x\mu_{\mathrm{X}} + y\mu_{\mathrm{Y}} - p\mu_{\mathrm{P}} - q\mu_{\mathrm{Q}} \\ &= x\tilde{G}_{\mathrm{X}}^0 + y\tilde{G}_{\mathrm{Y}}^0 + p\tilde{G}_{\mathrm{P}}^0 + q\tilde{G}_{\mathrm{Q}}^0 + R_{\mathrm{g}} T \left[x \ln a_{\mathrm{X}} + y \ln a_{\mathrm{Y}} - p \ln a_{\mathrm{P}} - q \ln a_{\mathrm{Q}}\right] \\ &\equiv \Delta G^0 + R_{\mathrm{g}} T \ln \frac{a_{\mathrm{X}} a_{\mathrm{Y}}}{a_{\mathrm{P}} a_{\mathrm{Q}}} \ , \end{aligned} \tag{20.188}$$

where the abbreviation ΔG^0 comprises the four Gibbs free energy terms and describes the change in Gibbs free energy upon complete conversion of p moles of P and q moles of Q in their standard states into x moles of X and y moles of Y in their standard states. The quotient in the logarithm is called the ratio of activities for the reaction,

$$Q \equiv \frac{a_{\mathrm{X}} a_{\mathrm{Y}}}{a_{\mathrm{P}} a_{\mathrm{Q}}} \ . \tag{20.189}$$

As already mentioned, a reaction will go on until the system reaches equilibrium,

$$A = 0 = \Delta G^0 + R_{\mathrm{g}} T \ln Q^{\mathrm{eq}} \ . \tag{20.190}$$

Example 169 (*Synthesis of water*): Let us consider a gas mixture composed of $\eta_{\mathrm{H_2}} = 0.01\,\mathrm{mol}$, $\eta_{\mathrm{O_2}} = 0.03\,\mathrm{mol}$, and $\eta_{\mathrm{H_2O}} = 0.96\,\mathrm{mol}$ at atmospheric pressure. At $700\,^\circ\mathrm{C}$ the reaction (20.179) liberates the Gibbs free energy $\Delta G^0 = -440\,\mathrm{kJ}$. The equilibrium constant can be calculated from (20.190),

$$Q^{\mathrm{eq}} = e^{-\Delta G^0/R_{\mathrm{g}}T} \approx 4.2 \times 10^{23} \ .$$

The large value of Q^{eq} means that the equilibrium is far on the side of the products, in this case $\mathrm{H_2O}$.
A gas mixture may be considered an ideal solution, so that the activities of their components are given by their molar fractions,

$$Q = \frac{a^2_{\mathrm{H_2O}}}{a^2_{2\mathrm{H_2}} a_{\mathrm{O_2}}} = \frac{\eta^2_{\mathrm{H_2O}}}{\eta^2_{2\mathrm{H_2}} \eta_{\mathrm{O_2}}} \approx 3.1 \times 10^5 \ .$$

Although this value is also very large, it is still much smaller than in equilibrium, $Q/Q_{\mathrm{eq}} \approx 7.2 \times 10^{-19}$. Hence, in the reaction process, the 0.01 mol of hydrogen will be completely used up. However, there is an excess of oxygen in the system, as only 0.005 mol are used. Hence, the final composition will be $\eta_{\mathrm{H_2}} \approx 0$, $\eta_{\mathrm{O_2}} = 0.025\,\mathrm{mol}$, and $\eta_{\mathrm{H_2O}} = 0.97\,\mathrm{mol}$. Note also that the total number of moles is reduced to $\eta_{\mathrm{H_2}} + \eta_{\mathrm{O_2}} + \eta_{\mathrm{H_2O}} = 0.995\,\mathrm{mol}$.

20.5.2 Multi-variant chemical reactions in the gas phase

The general strategy for determining the equilibrium composition in a multi-variant reacting system makes use of the independent conditions for chemical equilibrium and conservation laws for the number of atoms of every involved element. For a single-phase system with J components and K different atomic elements, $\mathfrak{A}_{kj}$ denotes the number of atoms of a given species k bound in a molecule representing the j-th component of the mixture. For example, if $k = \mathrm{H}$ and $j = \mathrm{H_2O}$ then $\mathfrak{A}_{kj} = 2$.

The strategy can be summarized in the following sequence of calculations:

1. Identify the types j of molecules involved and their numbers N_j^{in} (or moles or molar fractions) before a chemical reaction is initiated.

2. Determine the chemical structure of each type of molecules j in terms of numbers of atoms $\mathfrak{A}_{kj}$ of each element k.

3. Calculate the total number of atoms of each atomic element in the system from,

$$\mathcal{A}_k = \sum_{j=1}^{J} \mathfrak{A}_{kj} N_j^{\mathrm{in}} \qquad \forall\, k = 1, ..., K \ . \tag{20.191}$$

4. The numbers of atoms per species $\mathfrak{A}_{kj}$ and the chemical composition of the mixture N_j change when the atoms reorganize into different molecules through chemical reactions (labeled $r = 1, ..., R$). Thus, in parallel, we need to identify all R possible chemical reactions transforming a group of molecules $\{j_r\}$ into a group $\{j'_r\}$, and vice versa, with $j_r, j'_r = 1, ..., J$ labeling the types of molecules.

5. The numbers of molecules are controlled by equilibrium conditions associated to every possible chemical reaction. As stated in Eq. (20.180), there are $R = J - K$ independent reactions in this system, and each reaction has its equilibrium condition,

$$\Delta G^0_r = -R_\mathrm{g} T \ln Q^\mathrm{eq}_r = -N_\mathrm{A} k_\mathrm{B} T \ln \frac{\prod_{j'_r} a^\mathrm{eq}_{j'_r}}{\prod_{j_r} a^\mathrm{eq}_{j_r}} \tag{20.192}$$
$$\xrightarrow{\text{ideal}} -N_\mathrm{A} k_\mathrm{B} T \ln \frac{\prod_{j'_r} \eta^\mathrm{eq}_{j'_r}}{\prod_{j_r} \eta^\mathrm{eq}_{j_r}} = -N_\mathrm{A} k_\mathrm{B} T \ln \frac{\prod_{j'_r} N^\mathrm{eq}_{j'_r}}{\prod_{j_r} N^\mathrm{eq}_{j_r}} \qquad \forall\, r = 1, ..., R\ ,$$

for an ideal solution. Thus, each of the equilibrium constants Q^eq_r ruling a chemical reaction r is related to the composition of the system through a non-linear equation.

6. The number of atoms $\mathcal{A}_k$ of a given atomic element is conserved and does not change with time during the reaction process. Hence, the K equations (20.191) also hold after chemical equilibrium is reached. Together with R equations (20.192) we obtain a sufficient set of $K + R = J$ equations,

$$\boxed{\begin{aligned} \textstyle\sum_{j=1}^J \mathfrak{A}_{kj} N^\mathrm{eq}_j &= \mathcal{A}_k & \forall\, k = 1, ..., K \\ \textstyle\sum_{j'_r} \ln N^\mathrm{eq}_{j'_r} - \sum_{j_r} \ln N^\mathrm{eq}_{j_r} &= -\tfrac{\Delta G^0_r}{R_\mathrm{g} T} & \forall\, r = 1, ..., R \end{aligned}} \tag{20.193}$$

for the J unknown values N^eq_j. Note that, while the first equations are linear in the values N^eq_j, the second equations are non-linear.

Note, that the equilibrium composition of the mixture depends on the initial composition that the system had while it was still isolated, but only via the *numbers of atoms of all involved atomic elements*, no matter how these were distributed among the molecular components before these were mixed. The task is to express the final composition N^eq_j as a function of the $\mathcal{A}_k$ and the Q^eq_r. Do the Exc. 20.5.3.1 and 20.5.3.2.

Example 170 (*Chemical equilibrium of a gas mixture*): A gas mixture has the following initial composition,

molecular component	H_2	O_2	H_2O	CO	CO_2	CH_4
initial molar fraction η^in_j	0.05	0.05	0.15	0.25	0.40	0.10

(20.194)

and the goal is to find the equilibrium composition at 600 °C.

We start setting up the equations (20.191),

$$\begin{pmatrix} \mathcal{A}_{\mathrm{C}} \\ \mathcal{A}_{\mathrm{O}} \\ \mathcal{A}_{\mathrm{H}} \end{pmatrix} = \begin{pmatrix} 0 & 0 & 0 & 1 & 1 & 1 \\ 0 & 2 & 1 & 1 & 2 & 0 \\ 2 & 0 & 2 & 0 & 0 & 4 \end{pmatrix} \begin{pmatrix} N_{\mathrm{H_2}} \\ N_{\mathrm{O_2}} \\ N_{\mathrm{H_2O}} \\ N_{\mathrm{CO}} \\ N_{\mathrm{CO_2}} \\ N_{\mathrm{CH_4}} \end{pmatrix} , \tag{20.195}$$

which hold at any time before and after the reactions. Therefore, before the reaction, we have,

$$\begin{aligned} \mathcal{A}_{\mathrm{C}} &= (1\eta^{\mathrm{in}}_{\mathrm{CO}} + 1\eta^{\mathrm{in}}_{\mathrm{CO_2}} + 1\eta^{\mathrm{in}}_{\mathrm{CH_4}})N^{\mathrm{in}}_{\mathrm{tot}} &&= 0.75N^{\mathrm{in}}_{\mathrm{tot}} \\ \mathcal{A}_{\mathrm{O}} &= (2\eta^{\mathrm{in}}_{\mathrm{O_2}} + 1\eta^{\mathrm{in}}_{\mathrm{H_2O}} + 1\eta^{\mathrm{in}}_{\mathrm{CO}} + 2\eta^{\mathrm{in}}_{\mathrm{CO_2}})N^{\mathrm{in}}_{\mathrm{tot}} &&= 1.30N^{\mathrm{in}}_{\mathrm{tot}} \\ \mathcal{A}_{\mathrm{H}} &= (2\eta^{\mathrm{in}}_{\mathrm{H_2}} + 2\eta^{\mathrm{in}}_{\mathrm{H_2O}} + 4\eta^{\mathrm{in}}_{\mathrm{CH_4}})N^{\mathrm{in}}_{\mathrm{tot}} &&= 0.80N^{\mathrm{in}}_{\mathrm{tot}} \end{aligned} \tag{20.196}$$

with $N^{\mathrm{in}}_j = \eta^{\mathrm{in}}_j N^{\mathrm{in}}_{\mathrm{tot}}$ and the total number of molecules,

$$N^{\mathrm{in}}_{\mathrm{tot}} = N^{\mathrm{in}}_{\mathrm{H_2}} + N^{\mathrm{in}}_{\mathrm{O_2}} + N^{\mathrm{in}}_{\mathrm{H_2O}} + N^{\mathrm{in}}_{\mathrm{CO}} + N^{\mathrm{in}}_{\mathrm{CO_2}} + N^{\mathrm{in}}_{\mathrm{CH_4}} . \tag{20.197}$$

After the reaction, we have,

$$\begin{aligned} \mathcal{A}_{\mathrm{C}} &= (1\eta^{\mathrm{eq}}_{\mathrm{CO}} + 1\eta^{\mathrm{eq}}_{\mathrm{CO_2}} + 1\eta^{\mathrm{eq}}_{\mathrm{CH_4}})N^{\mathrm{eq}}_{\mathrm{tot}} &&= 0.75N^{\mathrm{in}}_{\mathrm{tot}} \\ \mathcal{A}_{\mathrm{O}} &= (2\eta^{\mathrm{eq}}_{\mathrm{O_2}} + 1\eta^{\mathrm{eq}}_{\mathrm{H_2O}} + 1\eta^{\mathrm{eq}}_{\mathrm{CO}} + 2\eta^{\mathrm{eq}}_{\mathrm{CO_2}})N^{\mathrm{eq}}_{\mathrm{tot}} &&= 1.30N^{\mathrm{in}}_{\mathrm{tot}} \\ \mathcal{A}_{\mathrm{H}} &= (2\eta^{\mathrm{eq}}_{\mathrm{H_2}} + 2\eta^{\mathrm{eq}}_{\mathrm{H_2O}} + 4\eta^{\mathrm{eq}}_{\mathrm{CH_4}})N^{\mathrm{eq}}_{\mathrm{tot}} &&= 0.80N^{\mathrm{in}}_{\mathrm{tot}} \end{aligned} \tag{20.198}$$

with $N^{\mathrm{eq}}_j = \eta^{\mathrm{eq}}_j N^{\mathrm{eq}}_{\mathrm{tot}}$ and a different total number of molecules,

$$N^{\mathrm{eq}}_{\mathrm{tot}} = N^{\mathrm{eq}}_{\mathrm{H_2}} + N^{\mathrm{eq}}_{\mathrm{O_2}} + N^{\mathrm{eq}}_{\mathrm{H_2O}} + N^{\mathrm{eq}}_{\mathrm{CO}} + N^{\mathrm{eq}}_{\mathrm{CO_2}} + N^{\mathrm{eq}}_{\mathrm{CH_4}} . \tag{20.199}$$

The equations now read,

$$\begin{aligned} \eta^{\mathrm{eq}}_{\mathrm{H_2}} + \eta^{\mathrm{eq}}_{\mathrm{O_2}} + \eta^{\mathrm{eq}}_{\mathrm{H_2O}} + \eta^{\mathrm{eq}}_{\mathrm{CO}} + \eta^{\mathrm{eq}}_{\mathrm{CO_2}} + \eta^{\mathrm{eq}}_{\mathrm{CH_4}} &= 1 \\ \eta^{\mathrm{eq}}_{\mathrm{CO}} + \eta^{\mathrm{eq}}_{\mathrm{CO_2}} + \eta^{\mathrm{eq}}_{\mathrm{CH_4}} &= 0.75\frac{N^{\mathrm{in}}_{\mathrm{tot}}}{N^{\mathrm{eq}}_{\mathrm{tot}}} \\ 2\eta^{\mathrm{eq}}_{\mathrm{O_2}} + \eta^{\mathrm{eq}}_{\mathrm{H_2O}} + \eta^{\mathrm{eq}}_{\mathrm{CO}} + 2\eta^{\mathrm{eq}}_{\mathrm{CO_2}} &= 1.30\frac{N^{\mathrm{in}}_{\mathrm{tot}}}{N^{\mathrm{eq}}_{\mathrm{tot}}} \\ 2\eta^{\mathrm{eq}}_{\mathrm{H_2}} + 2\eta^{\mathrm{eq}}_{\mathrm{H_2O}} + 4\eta^{\mathrm{eq}}_{\mathrm{CH_4}} &= 0.80\frac{N^{\mathrm{in}}_{\mathrm{tot}}}{N^{\mathrm{eq}}_{\mathrm{tot}}} . \end{aligned} \tag{20.200}$$

Now, with $J = 6$ and $K = 3$ we have $R = 3$ independent reactions,

$$\begin{aligned} 2\,\mathrm{H_2} + \mathrm{O_2} &\longleftrightarrow 2\,\mathrm{H_2O} && \text{(i)} \\ 2\,\mathrm{CO} + \mathrm{O_2} &\longleftrightarrow 2\,\mathrm{CO_2} && \text{(ii)} \\ \mathrm{CH_4} + 2\,\mathrm{O_2} &\longleftrightarrow 2\,\mathrm{H_2O} + \mathrm{CO_2} && \text{(iii)} \end{aligned} . \tag{20.201}$$

The standard free energy for these reactions at the specified temperature are,

$$\Delta G^0_{\mathrm{i}} = -404.2\,\mathrm{kJ} \quad , \quad \Delta G^0_{\mathrm{ii}} = -414.5\,\mathrm{kJ} \quad , \quad \Delta G^0_{\mathrm{iii}} = -797.9\,\mathrm{kJ} . \tag{20.202}$$

The corresponding equilibrium constants, assuming an ideal gas mixture so that the activities are equal to the molar fractions, are,

$$\frac{(\eta^{\rm eq}_{\rm H_2O})^2}{(\eta^{\rm eq}_{\rm H_2})^2\eta^{\rm eq}_{\rm O_2}} = Q^{\rm eq}_{\rm i} \quad , \quad \frac{(\eta^{\rm eq}_{\rm CO_2})^2}{(\eta^{\rm eq}_{\rm CO})^2\eta^{\rm eq}_{\rm O_2}} = Q^{\rm eq}_{\rm ii} \quad , \quad \frac{(\eta^{\rm eq}_{\rm H_2O})^2\eta^{\rm eq}_{\rm CO_2}}{\eta^{\rm eq}_{\rm CH_4}(\eta^{\rm eq}_{\rm O_2})^2} = Q^{\rm eq}_{\rm iii} \; . \tag{20.203}$$

With (20.200) and (20.203) there are thus seven equations for the six unknown equilibrium molar fractions and the ratio of total numbers of molecules before and after the reactions $N^{\rm in}_{\rm tot}/N^{\rm eq}_{\rm tot}$, that can be solved numerically. A MATLAB code which is available here, yields,

molecular component	H_2	O_2	H_2O	CO	CO_2	CH_4
final molar fraction $\eta^{\rm eq}_j$	0.136	1.6×10^{-24}	0.144	0.231	0.445	0.052

(20.204)

20.5.3 Exercises

20.5.3.1 Ex: Final composition of an ideal gas mixture

An ideal gas at 1000 K has the following composition,

molecular component	CO	CO_2	O_2
initial molar fraction $\eta^{\rm in}_j$	0.50	0.38	0.12

a. Compute the affinity for the reaction,

$$\mathrm{CO} + \tfrac{1}{2}\,\mathrm{O_2} \longleftrightarrow \mathrm{CO_2} \; .$$

b. Calculate the molecular composition after the reaction.

20.5.3.2 Ex: Hydrogen concentration in a metal

The concentration of hydrogen $c_{\rm H}$, which is dissolved in a metal in the form of H atoms, depends on the pressure P of the H_2 gas around the metal.
a. How are the chemical potentials $\mu_{\rm H}$ and $\mu_{\rm H_2}$ related?
b. Express the chemical potential in terms of its partial pressure in the gas phase.
c. Describing the hydrogen dissolved in the metal as an ideal solution, express the chemical potential in terms of its concentration.
d. Finally, determine the relationship between concentration and pressure.

20.6 Classification of thermodynamic phase transitions

The old *Ehrenfest classification* [458] calls a phase transition of nth order if the derivative $\partial^n\mu/\partial T^n$ is discontinuous. Thus BEC of a trapped ideal gas is a first-order phase transition, because the chemical potential suddenly changes its slope at $T_{\rm c}$.

The modern *Landau classification* distinguishes two types of phase transitions in homogeneous systems: First-order phase transitions exhibit a discontinuity in the

order parameter, while for continuous phase transitions the order parameter does not make jumps.

First order phase transitions are characterized by 1. equilibrium between phases (liquid-gas, liquid-solid), 2. discontinuous entropy, therefore latent heat, 3. at least one derivative of a thermodynamic potential is discontinuous. **The two phases coexist at the transition point.** E.g. at $T = 0\,°\mathrm{C}$ in a closed system water and ice coexist.

Continuous phase transitions are characterized by 1. no equilibrium, 2. no latent heat, but often discontinuous heat capacity, 3. first order derivatives are all continuous, but second order is discontinuous. **There is no phase coexistence at the critical point**. E.g. at $T = T_\mathrm{c}$ there no condensate; only below T_c.

20.6.1 Solid-liquid-vapor

In the case of the *liquid-vapor transition* the two phases are only quantitatively distinct, but have the same symmetry. Therefore, a discontinuity of the thermodynamic potentials is required to reveal the phase transition.

In the case of the *solid-liquid transition* the two phases are qualitatively distinct due to different symmetries. We do not need a discontinuity to distinguish the phases. Landau's theory holds for this class of transitions. It establishes a relationship between symmetry considerations and physical characteristics by introducing the notion of the *order parameter* and *free energy*.

20.6.2 Bose-Einstein condensation

Is the observed Bose-Einstein condensation in trapped gases really a phase transition? A homogeneous gas has strong fluctuations near T_c that can heavily be influenced by interactions, which could result in phase domains. In contrast, a trapped gas is quite robust near T_c due to the modification of the density of states for small energies by the trapping potential, which make the interaction less important (see stabilization of attractive gases). However, T_c is not precisely defined and far from T_c interactions become very important (Thomas-Fermi limit).

The dynamics of phase transition is rules by a competition between internal energy which tries to minimize itself and entropy which tries to maximize itself.

20.7 Materials

20.7.1 Electrons in solids

20.7.1.1 Types of solids

In contrast to a gas, which in most cases consists of isolated particles, the interparticle interaction plays a dominant role in crystals. Solids, or more specifically crystals, are classified according to the predominant type of binding. 1. Molecular binding is responsible for the solidification of binary gases like O_2. Here, fluctuating dipole moments inducing dipole moments in neighboring molecules lead to van der Waals attractive forces on the order of $E_\mathrm{bind} \simeq 10^{-2}\,\mathrm{eV}$ going like r^{-7}. 2. Ionic binding gives rise to periodic structures alternating positive and negative charges, as in NaCl.

3. Covalent binding is directional. This directionality determines the crystalline structure, such as in graphite and diamonds. In those three binding types there are no free electrons and hence no conductance. However, covalently bound crystals can sometimes be semiconductors or transparent. 4. Metallic binding is a limit of covalent binding, in which the valence electrons, which shared by all atoms, overrule the repulsion between the ions. The ionic lattice is immersed in a gas of free electrons. The ions have filled shells and are spherically symmetric. The electrons can easily absorb light, which makes the crystal opaque. The type of binding is studied via X-ray diffraction, via the dielectric properties, etc..

20.7.1.2 Band model

The number of orbitals in the isolated atoms forming the crystal gives the number of states available to the free electron gas. The exchange interaction of the fermionic electrons lifts the degenerescence (generalization of the H_2 molecule) and gives rise to a band structure. The electronic localization determines the width of the band: very delocalized electrons move in large bands. The interatomic distance also influences the band width. The closer the atoms the stronger the interaction, the larger the bands.

Bands connecting to different orbital may finally overlap. Note that the m_l degeneracy is lifted because spherical symmetry is broken by the crystal $[E(3s) \neq E(3p)]$.

20.7.1.3 Electrical conductance

Electrons can only move in presence of a sufficient number of unpopulated states, even under the influence of an external force. If no states are available the crystals becomes isolating. Overlapping filled and empty bands reserve many states and allow for good conductance.

If the Fermi energy E_{F} lies between a completely filled conducting band and an empty valence band. The crystal is isolating. However, at $T > 0$, if the forbidden band is narrow as in the case of semiconductors (for Si $\Delta E \simeq 1\,\mathrm{eV}$), the gap may be bridged by thermal excitations.

The electrons collide with crystal impurities, defects and phonons. While the velocity of the electrons is about $\bar{v} \simeq 10^7\,\mathrm{cm/s}$, the short mean free path λ limits the drift velocity to $v_{\mathrm{d}} \simeq 10^{-2}\,\mathrm{cm/s}$. The Lorentz force eE/m accelerates the electrons between successive collisions occurring at a rate $\bar{v}/\lambda$, such that

$$\frac{j}{ne} = v_{\mathrm{d}} = \frac{eE}{m} \times \frac{\lambda}{\bar{v}} \ , \tag{20.205}$$

where j is the current density and ne the charge density. The fact that $\bar{v}$ and λ do not depends on the electric field is known as Ohm's law. The mobility $\mu \equiv v_d/E$ allows to write the electrical conductance as

$$\rho^{-1} = n_- e_- \mu_- + n_+ e_+ \mu_+ \ . \tag{20.206}$$

The value and sign of the Hall coefficient $1/ne$ can be measured by the Hall effect. It is positive if the conductance occurs primarily through holes and negative if it occurs through electrons.

20.7.1.4 Semiconductors

There is an intrinsic temperature-dependent conductivity (for Si $\rho(600\,\mathrm{K})/\rho(300\,\mathrm{K}) \approx 10^9$). Extrinsic conductivity can be induced by photoexcitation or doping. E.g. Ar/Ga in a Ge crystal has one weakly bound electron more/less than required to fit into the lattice. This generates discrete energy levels slightly below the conducting/above the valence band, $\min(E_\mathrm{c}) - E_\mathrm{n}, E_\mathrm{p} - \max(E_\mathrm{v}) \simeq 0.01\,\mathrm{eV}$.

The Fermi energy E_F is the energy, where half of the electrons are below that. In an isolator is between $\max(E_\mathrm{v})$ and $\min(E_\mathrm{c})$. In the presence of doping E_F is shifted by the additional amount of electrons/holes toward $E_\mathrm{n}, E_\mathrm{p}$. If n and p-doped materials are combined, electrons drift from the n to the p region, such as to minimize energy and obtain a uniform E_F across the hole crystal.

Thermally excited electrons may drift and recombine with holes. The junction is maintained by a steady flux in a dynamic equilibrium. An external voltage can higher/lower the barrier, because the potential drops mostly near the junction, where the resistance is highest. In this case the thermal current is not equilibrated, the diode either blocks or opens. The electrons move to try to rectify E_F.

A transistor is a series of junctions in *npn* of *pnp* configuration. The base-emitter current can be used to switch a collector-emitter current by injecting electrons. A tunnel diode acts like a normal diode except that when the bands come closer together within the junction (at low voltages in conduction polarization), electrons may pass by tunneling from the conducting into the valence band. This flow gradually stops when E_F is leveled (for zero voltage). Tunneling currents react much faster than thermal drift currents.

20.7.2 Plasmas

20.7.2.1 Debye length

Consider a mixture of charges $+$ and $-$, that is, a *plasma*. Energy seeks to be minimized by local compensation of charge imbalance. However, thermal motion spoils perfect homogeneity. That is, if on the one hand, looking at large scales, the environment seems neutral and homogeneous, at small scales there may be charge imbalances producing potential sites with exponentially decreasing ranges,

$$\frac{1}{\lambda_D} = \frac{1}{\lambda_{D-}} + \frac{1}{\lambda_{D+}} = \frac{ne^2}{\varepsilon_0}\left(\frac{1}{k_\mathrm{B}T_+} + \frac{1}{k_\mathrm{B}T_-}\right) . \tag{20.207}$$

The *Debye length* naturally enters the thermodynamic description of large systems of mobile charges. We consider a system of 2 different species of charges $q_\pm$ and $n_\pm(\mathbf{r})$ at locations $\mathbf{r}$. According to the so-called *primitive model*, these charges are distributed in a continuous medium characterized only by its relative static permittivity, ε_r. This distribution of charges through the medium generates an electric potential $\Phi(\mathbf{r})$ that satisfies the *Poisson equation*:

$$\varepsilon\nabla^2\Phi(\mathbf{r}) = -q_+n_+(\mathbf{r}) - q_-n_-(\mathbf{r}) - \rho_E(\mathbf{r}) , \tag{20.208}$$

where $\varepsilon \equiv \varepsilon_r\varepsilon_0$, ε_0 is the dielectric constant, and ρ_E is the charge density outside the medium (logically, not spatially).

The mobile charges do not only generate $\Phi(\mathbf{r})$, but also are moved according to the associated Coulomb force, $-q_\pm \nabla\Phi(\mathbf{r})$. Assuming the system to be in thermodynamic equilibrium with a heat reservoir at an absolute temperature T, the concentrations of discrete charges, $n_\pm(\mathbf{r})$, can be considered as thermodynamic averages (ensemble average) and the associated electrical potential as a thermodynamic mean field. With these assumptions, the concentration of species j is described by the Boltzmann distribution,

$$n_\pm(\mathbf{r}) = n_\pm^0 e^{-q_\pm \Phi(\mathbf{r})/k_\mathrm{B}T} \ , \tag{20.209}$$

where n_j^0 is the mean field concentration of the charge species j.

Identifying the instantaneous concentrations and the potentials in the Poisson equation with their mean-field counterparts in the Boltzmann distribution, we obtain the Poisson-Boltzmann equation:

$$\varepsilon\nabla^2\Phi(\mathbf{r}) = -q_+ n_+^0 e^{-q_+\Phi(\mathbf{r})/k_\mathrm{B}T} - q_- n_-^0 e^{-q_-\Phi(\mathbf{r})/k_\mathrm{B}T} - \rho_E(\mathbf{r}) \ . \tag{20.210}$$

Solutions of this nonlinear equation are known for simple systems. Solutions for more general systems can be obtained in the high-temperature (or low-coupling) limit, $q_j\Phi(\mathbf{r}) \ll k_\mathrm{B}T$, by Taylor expansion of the exponential,

$$e^{-q_\pm\Phi(\mathbf{r})/k_\mathrm{B}T} \approx 1 - \frac{q_\pm\Phi(\mathbf{r})}{k_\mathrm{B}T} \ . \tag{20.211}$$

This approximation gives the linearized Poisson-Boltzmann equation,

$$\varepsilon\nabla^2\Phi(\mathbf{r}) = \left(\frac{n_+^0 q_+^2}{k_\mathrm{B}T} + \frac{n_-^0 q_-^2}{k_\mathrm{B}T}\right)\Phi(\mathbf{r}) - n_+^0 q_+ - n_-^0 q_- - \rho_e(\mathbf{r}) \tag{20.212}$$

also known as *Debye-Hückel equation*. The second term on the right side disappears for electrically neutral systems. The term in parentheses divided by ε, has the unit $1/\mathrm{m}^2$. By a dimensional analysis, it leads to a definition of a characteristic length scale,

$$\lambda_D = \left(\frac{\varepsilon k_\mathrm{B}T}{n_+^0 q_+^2 + n_-^0 q_-^2}\right)^{1/2} \tag{20.213}$$

usually called *Debye-Hückel length*. Being the only characteristic length scale of the Debye-Hückel equation, λ_D defines the scale of variations in the potential and the concentrations of the charged species. All charged species contribute to the Debye-Hückel length in the same manner regardless of the charge signal. For an electrically neutral system, the Poisson equation is,

$$\nabla^2\Phi(\mathbf{r}) = \lambda_D^{-2}\Phi(\mathbf{r}) - \frac{\rho_e(\mathbf{r})}{\varepsilon} \ . \tag{20.214}$$

To illustrate the Debye shielding, the potential produced by an external point-like charge $\rho_e = Q\delta(\mathbf{r})$ is,

$$\Phi(\mathbf{r}) = \frac{Q}{4\pi\varepsilon r} e^{-r/\lambda_D} \ . \tag{20.215}$$

The bare Coulomb potential is exponentially shielded by the medium over a distance corresponding to the Debye length.

The length of Debye-Hückel can be expressed in terms of the length of Bjerrum λ_B as,

$$\lambda_D = \left(4\pi\lambda_B \sum_{j=1}^{N} n_j^0 z_j^2\right)^{-1/2} , \tag{20.216}$$

where $z_j = q_j/e$.

20.7.2.2 Typical values

In plasmas in space, where the electron density is small, the Debye's length can reach macroscopic values.

system	density n_e (m^{-3})	electronic temp. T(K)	magn.field B(T)	Debye length λ_D(m)
solar core	10^{32}	10^7	-	10^{-11}
Tokamak	10^{20}	10^8	10	10^{-4}
gas discharge	10^{16}	10^4	-	10^{-4}
ionosphere	10^{12}	10^3	10^{-5}	10^{-3}
magnetosphere	10^7	10^7	10^{-8}	10^2
solar wind	10^6	10^5	10^{-9}	10
interstellar medium	10^5	10^4	10^{-10}	10
intergalactic medium	1	10^6	-	10^5

20.7.2.3 Length of Debye in a plasma

In a plasma, the background medium may be treated as the vacuum ($\varepsilon_r = 1$), and the length of Debye is,

$$\lambda_D = \sqrt{\frac{\varepsilon_0 k_\mathrm{B}/q_e^2}{n_e/T_e + \sum_j z_j^2 n_j/T_j}} , \tag{20.217}$$

where $T_\pm$ are the temperatures of the electrons and ions, n_- is the density of the electrons and n_+ that of the atomic species j, with positive ionic charge $z_+ q_e$. The ion term is often neglected, giving,

$$\lambda_D = \sqrt{\frac{\varepsilon_0 k_\mathrm{B} T_e}{n_e q_e^2}} , \tag{20.218}$$

although this is valid only, when the mobility of ions is negligible on the time scale of the process.

Chapter 21

Out-of-equilibrium thermodynamics

21.1 Out-of-equilibrium statistics

Classical thermodynamics has played a dominant role in the development of modern science and technology. In suffers, however, from certain limitations, as it cannot be used for the study of irreversible processes but only for reversible processes and transitions between different states of equilibrium. Many of the most important and interesting processes in nature are irreversible. A good example is provided by living organisms which consume chemical energy in the form of nutrients, perform work and excrete waste as well as give off heat to the surroundings without themselves undergoing changes; they represent what is called a stationary or steady state. The boiling of an egg provides another example, and still another one is, a thermocouple with a cold and a hot junction connected to an electrical measuring instrument.

The first investigator who developed a method for the exact treatment of out-of-equilibrium problems, for example of the thermocouple, was Onsager. His approach was, however based on assumptions which in principle make it applicable only to systems close to equilibrium. The contribution of Prigogine to thermodynamic theory is his successful extension of it to systems which are far from thermodynamic equilibrium. This is extremely interesting as large differences compared to conditions close to equilibrium had to be expected. Prigogine has demonstrated that a new form of ordered structures can exist under such conditions, and he has given them the name dissipative structures to stress that they only exist in conjunction with their environment.

21.1.1 Boltzmann's transport equation

Until now we have only treated systems in thermal equilibrium. However many systems are not stable, they drift or oscillate. Even if they are stable, this stability is sometimes only ensured by a continuous feeding with external energy or entropy, which is balanced by some dissipation mechanism. Non-equilibrium systems are difficult to treat.

21.1.1.1 H-theorem

Boltzmann's *H-theorem* is concerned with the tendency of non-equilibrium systems to return to equilibrium. The basic idea is that the fundamental process in gases are collisions. They introduce randomness into the evolution, which breaks the time-reversal symmetry. Other processes may have similar effects. The main point is that a very precisely defined input channel couples to a continuum of output channels, so that the equilibrium lies on the side of the larger mode volume (see Fig. 20.9).

21.1.2 Stoßzahlansatz

Consider a gas with velocity distribution f. The *Boltzmann Stoßzahlansatz* reads,

$$\frac{\partial f}{\partial t} = \mathbf{v}\frac{\partial f}{\partial \mathbf{x}} + \left(\frac{\partial f}{\partial t}\right)_{\text{coll}} . \tag{21.1}$$

A general rate equation for may write,

$$\frac{d\varrho}{dt} = \frac{\partial \varrho}{\partial t} + \mathbf{v}\nabla_r + \mathbf{a}\nabla_v = R^+ - R^- . \tag{21.2}$$

For constant entropy increase $dS/dt \geq 0$, we get,

$$\frac{d\varrho}{dt} = \sum_{z'} \left(W_{zz'}\varrho_{z'} - W_{z'z}\varrho_z\right) . \tag{21.3}$$

And finally follows the *Boltzmann transport equation*,

$$\frac{d\varrho}{dt} = \int |\mathbf{v}-\mathbf{v}'|\sigma(\mathbf{v},\mathbf{v}' \to \mathbf{u},\mathbf{u}')\left[\varrho(t,\mathbf{r},\mathbf{u})\varrho(t,\mathbf{r},\mathbf{u}') - \varrho(t,\mathbf{r},\mathbf{v})\varrho(t,\mathbf{r},\mathbf{v}')\right] d^3\mathbf{v}' d^3\mathbf{u} d^3\mathbf{u}' , \tag{21.4}$$

which holds for binary collisions disregarding inner degrees of freedom, container walls, molecular chaos, and so on. For a free gas consisting of a single particle species, $dS/dt = 0$, the Liouville equation holds,

$$\frac{d\varrho}{dt} = 0 , \tag{21.5}$$

which yields,

$$\varrho(t,\mathbf{r},\mathbf{u}) = C(t,\mathbf{r}) \exp \frac{\left[\mathbf{v} - \mathbf{v}_0(t,\mathbf{r})\right]^2}{-A(t,\mathbf{r})} , \tag{21.6}$$

and from which follows the *Maxwell-Boltzmann distribution*,

$$\varrho(\mathbf{v}) = \left(\frac{3}{2\pi\Delta v^2}\right)^{3/2} \exp - \frac{3[\mathbf{v} - \langle \mathbf{v}\rangle]^2}{2\Delta v^2} . \tag{21.7}$$

21.1.2.1 H quantity and entropy

From the Boltzmann Stoßzahlansatz is it possible to find for the quantity,

$$H \equiv \int f \ \ln f \ d^3\mathbf{p} , \tag{21.8}$$

the inequality,

$$\frac{dH}{dt} \leq 0 \ . \tag{21.9}$$

The equality holds for equilibrium.

It can be shown,

$$S = -k_B H \ . \tag{21.10}$$

Therefore the H quantity is nothing else than the entropy. Due to the derivation from the Stoßzahlansatz, this equation gives a definition of entropy for non-equilibrium systems.

21.1.2.2 Entropy problem

The H theorem is not generally true as is clear from *Loschmidt's reversibility paradox*. This illustrates a certain contradiction between classical mechanics and thermodynamics. Consider the diffusion of a drop of ink in a glass of water. From the point of view of mechanics the process is deterministic, thus our knowledge of the state of the system stays constant, (information) entropy must be constant as well, which is contradicted by thermodynamics.

The solution lies in the unprecisely known initial conditions, in particular in quantum systems due to the Heisenberg uncertainty. The H theorem only makes sense if it is understood in terms of its statistical nature: For equilibrium systems the most probable state is the one with maximum entropy. For non-equilibrium systems we have an overwhelming probability for an increasing entropy, but a decrease is not excluded.

21.1.3 H theorem and Fokker-Planck equation

An H theorem can be derived from *Fokker-Planck equations* [844]. The H quantity is then the non-equilibrium analog to the Helmholtz free energy,

$$\begin{aligned} F &= E - TS \\ H &= E/D - S \ . \end{aligned} \tag{21.11}$$

21.2 Thermodynamic approaches to out-of-equilibrium systems

21.2.1 Irreversibility

Thermodynamics separates into two regimes: Of a *reversible process* and an *irreversible process*. Reversible processes are those, whose trajectories in parameter space can be reverse by inverting the signs of heat exchange Q, mass exchange m and work W. For systems in equilibrium, phase transitions are in general reversible by appropriately tuning some control parameter. For systems far from equilibrium, irreversible *temporal phase transition* may occur. However this classification is phenomenological and insufficient to make the connection to mechanics, in contrast to equilibrium thermodynamics which has been traced back to statistical physics.

For equilibrium statistical mechanics it is the interaction among the degrees of freedom which permits to approach equilibrium. This view coincides with modern views of the role of decoherence. The final (steady) state exhibits no macroscopic dynamics and is in a situation called *detailed balance*. In contrast a flux of energy or matter may result in the emergence of *spatial patterns* or *rhythmic phenomena*. The transition to ordered structures requires a instabilities, i.e. a critical distance from equilibrium and nonlinear kinetics.

For any change of the state of a system the entropy behaves like,

$$dS = d_e S + d_i S \ , \tag{21.12}$$

where $d_e S$ is the entropy exchange with the external world and $d_i S \geq 0$ the internal *entropy production*. This shows that the entropy of a system can be lowered if $d_e S < 0$. The thermodynamics of irreversible processes exhibits linear and nonlinear phenomena. For small (linear) deviations from equilibrium the steady state of a system is characterized by a *minimum entropy production*. This is however *not* generally the case far from equilibrium. This rule is analogous to the change of internal energy,

$$dE = \delta Q + \delta W \ , \tag{21.13}$$

where δQ denotes the heat exchanged with the external world and δW the reversible work applied to the system.

21.2.1.1 Application to the Kuramoto model

According to Prigogine the transition to a dissipative structure is governed by a thermodynamic stability criterion involving excess entropy production. The excess entropy is the amount of dissipation introduced by the disturbance causing the instability. From the above it becomes clear how it is possible that CARL creates order, i.e. lowers entropy: the dissipative force constitutes a large entropy reservoir to which the system may deliver excess entropy.

For Bénard structures and surface waves there is no intrinsic length scale on which the order is expected. In contrast CARL bunching occurs on the order of an optical wavelength. The microsystems are the atoms, the macrosystem is the light.

At first glance the *Kuramoto model* produces order without apparent dissipative force: Universally coupled pendulum exhibit synchronization, i.e., the entropy of the system is reduced. Since the dynamics is deterministic and thus reversible, one would expect no entropy production or reduction. This is however incorrect, the Kuramoto model inherently contains assumptions, which are equivalent to dissipation. This is seen from the derivation of the equations governing weakly coupled pendulum. In fact the Kuramoto does not describe coupled *pendulum* but *pendulum clocks*, i.e. limit cycle oscillations sustained by an external force.

A thermodynamic treatment of the Kuramoto model establishing a link between the Prigogine and Haken point of view is given by Shiino [844]. The non-equilibrium phase transition can also be of first-order [523].

21.2.2 Dissipative structures and synergetics

21.2.2.1 Prigogine's approach

Consider a system that exits far from thermodynamic equilibrium (see thermodynamics), hence efficiently dissipates the heat generated to sustain it, and has the capacity of changing to higher levels of orderliness (see self-organization). According to Prigogine, systems contain subsystems that continuously fluctuate. At times a single fluctuation or a combination of them may become so magnified by possible feedback, that it shatters the preexisting organization. At such revolutionary moments or 'bifurcation points', it is impossible to determine in advance whether the system will disintegrate into 'chaos' or leap to a new, more differentiated, higher level of 'order'. The latter case defines the *dissipative structure* so termed because they need more energy to sustain them than the simpler structures they replace and are limited in growth by the amount of heat they are able to disperse [753].

Quite generally it is possible in principle to distinguish between two types of structures: equilibrium structures, which can exist as isolated systems (for example crystals), and dissipative structures, which can only exist in symbiosis with their surroundings. Dissipative structures display two types of behaviour: close to equilibrium their order tends to be destroyed but far from equilibrium order can be maintained and new structures be formed.

The probability for order to arise from disorder is infinitesimal according to the laws of chance. The formation of ordered, dissipative systems demonstrates, however, that it is possible to create order from disorder. The description of these structures have led to many fundamental discoveries and applications in diverse fields of human endeavor, not only in chemistry. In the last few years applications in biology have been dominating but the theory of dissipative structures has also been used to describe phenomena in social systems [882, 690].

21.2.2.2 Minimum entropy production

Far from equilibrium nonlinear effects in the rate equations get important. This implies the possibility of multiple solutions, each one with different regions of stability. Transitions from one solution to another occur as phase transitions. In the linear regime with one thermodynamic force held fixed (e.g. temperature gradients) the stable state is a steady-state with *minimum entropy production* and it is *unique*. We say the state lies on the thermodynamic branch. Moving away from the linear regime the thermodynamic branch gets unstable. A *linear stability analysis* can tell when the system gets unstable, but it cannot predict where the system is going to go. At some point a non-equilibrium phase transition occurs often accompanied by dramatic macroscopic changes. The new state is characterized by an order parameter. Even if the boundary condition is held fixed and the steady state in the linear regime is homogeneous, the new state can exhibit oscillations in space and time. The symmetry is broken. The new state has more structure (less symmetry). This requires a steady flow of matter or energy, i.e. entropy production to maintain it.

In my words, Prigogine has in mind that a pumped system develops internal invisible coherence. At some point it has to release it (what entropy/coherence) in a kind of temporal phase transition, where the system has two choices: either turn

into chaos or develop a higher order. The state of higher order (or lower symmetry) is called dissipative structure.

21.2.2.3 Criticism

Ilya Prigogine coined the phrase *dissipative structures* as a name for the patterns which self-organize in far-from-equilibrium dissipative systems. Dissipation inspires the wrath of the moralist and the envy of most others; for the physicist, however, it is merely faintly depressing. We call something dissipative if it looses energy to waste-heat. (Technically: if volume in the phase space is not conserved.) The famous Second Law of Thermodynamics amounts to saying that, if something is isolated from the rest of the world, it will dissipate all the free energy it has. Equivalently, it maximizes its entropy. Thermal equilibrium is the state of maximum entropy.

If something is (in a well-defined sense) near thermal equilibrium, one can show that its behavior is governed by linear differential equations (hence the name 'linear thermodynamics' for the appropriate body of theory), and that left to itself it will approach equilibrium exponentially (hence the somewhat more common name 'irreversible thermodynamics'). Here we are guided, not by the entropy, but by 'entropy production', the rate of increase in entropy. Since, once we reach equilibrium, the entropy cannot increase (by definition), the entropy production at equilibrium is zero, and the entropy production is always decreasing (the 'principle of minimum entropy production').

In general, however, things are not well-isolated from the rest of the world. If energy arrives from the outside as quickly as it is dissipated, even bodies in the linear regime can be kept away from equilibrium. (Hence various creationist arguments about the Second Law are worthless: neither living things nor the Earth are well-isolated from the rest of the universe, as may be observed every day at sunrise.) Thus dissipation, and why dissipative systems are not necessarily dull as dish-water. So you can have structures in dissipative systems, and there's no reason not to call them 'dissipative structures', though it's not obvious that there are many interesting generalizations about them.

'Far-from-equilibrium' means that your system is so far from its thermal equilibrium that the linear laws I mentioned a moment ago no longer apply; non-linear terms become important. The only general rule about the solution to non-linear differential equations is that there are no general rules; hence the interest in the subject. (Cf. Chaos and non-linear dynamics.) This is not good news, of course, if what you want to do is extend thermodynamics to the far-from-equilibrium case. But, one might suppose, matters are not totally hopeless; we aren't talking about just any arbitrary system of equations, but the particular ones important in thermodynamics; perhaps there is some general principle (like those of maximum entropy, or minimum entropy production) which can guide us to solutions. What Prigogine claims to have done is to have found, if not another extremum principle, then at least an inequality (a 'universal evolution criterion'), and to have used it to work out the theory of dissipative structures, according to which patterns are supposed to form when the uniform, uninteresting 'thermodynamic branch' of the system becomes unstable. The math for all this is analogous to that of equilibrium phase transitions with 'broken symmetry', where, again, a uniform state becomes unstable, forcing the system into a patterned,

coherent one to minimize free energy. Even without Prigogine's claims that this theory is Very Significant to biology and social science, even without the philosophical and cultural importance he claims for it, this would be very interesting, and the big question is whether he's right, i.e. whether and to what the theory applies.

The authors compare symmetry-breaking in thermodynamic equilibrium systems (leading to phase change) and in systems far from equilibrium (leading to dissipative structures). They conclude that the only similarity between the two is their ability to lead to the emergent property of spatial variation from a homogeneous background. There is a well-developed theory for the equilibrium case involving the order parameter concept, which leads to a strong correlation of the order parameter over macroscopic distances in the broken symmetry phase (as exists, for example, in a ferromagnetic domain). This correlation endows the structure with a self-scaled stability, rigidity, autonomy or permanence. In contrast, the authors assert that there is no developed theory of dissipative structures (despite claims to the contrary) and that perhaps there are no stable dissipative structures at all! Symmetry-breaking effects such as vortices and convection cells in fluids – effects that result from dynamic instability bifurcations – are considered to be unstable and transitory, rather than stable dissipative structures. Thus, the authors do not believe that speculation about dissipative structures and their broken symmetries can, at present, be relevant to questions of the origin and persistence of life.

Prigogine and his school have made a series of attempts to build an analogy between these dissipative far-from-equilibrium systems which form patterns and the Landau free energy and its dependence on the order parameter, which leads to the important properties of equilibrium broken symmetry systems. The attempt is to generalize the principle of maximum entropy production, which holds near equilibrium in steady-state dissipative systems, and to find some kind of dissipation function whose extremum determines the state. As far as we can see, in the few cases in which this idea can be given concrete meaning, it is simply incorrect [554]. In any case, it is clearly out of context in relation to the observed chaotic behavior of real dissipative systems.

21.2.2.4 Haken's approach

The *synergetics* is the theory of cooperation, i.e. the theory of the behavior of coupled systems and in particular of *self-organization* [405].

Equilibrium phase transitions (liquid-solid, ferromagnetic, BEC,...) occur by temperature reduction. The less symmetric (or broken) phase, i.e. the phase with more structure is at lower temperature. This is not generally the case, e.g. living systems tend to die at low temperatures. (The universe will die the 'Kältetod' [Boltzmann, Helmholtz, Clausius]. Did the big bang really have lower entropy, than the today's universe?) Such systems are characterised by a steady flow of energy or matter.

The dynamic systems exhibit transition from disorder to order *analogous* to phase transitions. Those temporal transitions can be understood in the following way. Any system has fluctuations. By continuously emitting small subsystems (fluctuations) out of its equilibrium, the system probes the range of possible motional states it can possibly adopt. If the current state of the system is not stable, a fluctuation may trigger a collective instability. More and more subsystems are slaved into the

collective motion. If several instabilities occur simultaneously, often only the fittest survives. This is called *mode competition* (see superradiance) and often leads to *symmetry breaking*. A mode is called *order parameter* if it slaves subsystems.

Eventually the driven system may find to a dynamically stable state (see Paul-traps). Too strong thermodynamic forcing may lead to *turbulence* or *deterministic chaos*.

Note that one may influence which modes survives by external forces. Furthermore, one may speed up the instability by the application of noise (see *stochastic resonance*).

21.2.2.5 Feedback principle

According to Dawson [228] the state of macroscopic systems made of coupled microscopic subsystems subjected to noise not only is the statistical manifestation of the interacting subsystems as suggested by Boltzmann, but also prescribes the environment felt by the subsystem. This provides a positive feedback: Random perturbation of the microsystems are compensated for and the macrosystem exhibits a coherent self-regulated behavior. However in special circumstances microscopic fluctuations can become amplified by collective action and become important on a macroscopic scale, then termed *critical phenomena*. The distinction between macro- and microsystems breaks down, if the macrosystem gets intrinsically stochastic itself. The role of critical phenomena is ideally studied with bistable systems. It is reminiscent to *stochastic resonance*s.

Feedback is an essential ingredient. It leads to a cyclic causality. Examples are the problem of the hen and the egg, and the self-generated CARL wave. It is very similar to *Darwinism*, the cyclic recurrence of randomness and necessity, of fluctuation and competition, of mutation and selection.

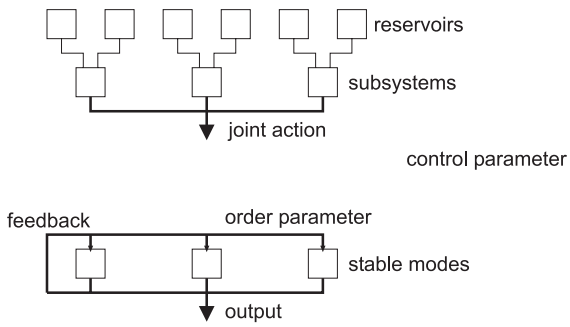

Figure 21.1: Principle of synergetics.

21.2.2.6 Comparison to Prigogine

Prigogine correctly identifies the role of fluctuations.

However he does not rely on feedback. He rather tries to find universal rules based on entropy, i.e. the principle of minimum excess entropy production. Synergetics goes beyond dissipative structures.

Example 171 (*Bénard instability*): Examples range from physical instabilities, autocatalytic chemical reactions to biological, evolutionary, social and economic systems.
The most well-known dissipative structure is perhaps the so-called *Bénard instability*. This is formed when a layer of liquid is heated from below. At a given temperature heat conduction starts to occur predominantly through convection, and it can be observed that regularly spaced, *convection* cells are formed in the layer of liquid. This structure is wholly dependent on the supply of heat and disappears when this ceases. The form of the structures may vary from vertical rolls (distorted to hexagons due to surface tension in the liquid) to concentric rings or spirals. This depends on the exact form of the thermodynamic force, i.e. of the heat gradients.

Example 172 (*Surface waves*): Waves are typically associated with perturbations that propagate in a system and transfer the energy of the system. Wave dynamics is possible both in conservative and dissipative (active) systems. Physical models of nonlinear waves are derived to simplify a complicated system of primary equations in a number of approximations. The same equations at the leading order describe main effects such as non-linearity, dispersion, diffraction, diffusion, damping and driven forces, and resonances that determine wave propagation.
Oceanic waves generated by wind can reach anomalous high amplitudes in 10-20 meters. Such a giant *surface wave* are called a *freak wave* or *rogue wave*. They are formed as a result of a nonlinear interaction of multiple spectral components of the wave perturbations that propagate with different group velocities. The physical model for freak waves is based in the weak amplitude approximation on the *nonlinear Schrödinger equation* (NLS) [1].

Example 173 (*Faraday crispations in fluids*): The undulation of the free surface of a viscous fluid in container under vertical vibration is known as *Faraday crispation*. The forced surface waves, which form many interesting *spatio-temporal dissipative structures*, oscillate at a frequency half the forcing frequency. In presence of large dissipation in a thin layer of viscous fluid, the surface crispation may be synchronous with forcing [305, 78, 306, 546, 679, 161].

Example 174 (*Predator-prey model*): The Lotka-Volterra or *predator-prey model* is an example for a temporal oscillation. The populations of predators and prey interdepend via

$$\begin{aligned} \dot{N}_{\rm py} &= \varepsilon_{\rm py} N_{\rm py} - \gamma_{\rm pr} N_{\rm pd} N_{\rm py} \\ \dot{N}_{\rm pd} &= -\varepsilon_{\rm pd} N_{\rm pd} + \gamma_{\rm pd} N_{\rm py} N_{\rm pd} \ . \end{aligned} \tag{21.14}$$

Example 175 (*Physiology*): Kelso's experiment of finger waved in parallel driven by a metronom. Passed a certain critical frequency the fingers are waves in the antiparallel mode. The transition is a phase transition. Amputierte

[1] http://dmpeli.math.mcmaster.ca/ResearchProjects/ResearchPage4.html

Tausendfüssler spontaneously change their motion pattern: to insect-like for 6 legs left, dog-like for 4 legs left. The movement is not controlled/programmed by brain, but self-organised via backbone.
The brain exhibits self-organization on many different levels. Firing neurons synchronize, synapses tentatively establish new connections which are only confirmed and reinforced if frequently used. The brain thus resembles much more a dynamically moving system than a computer. Cognition and understanding seems to work like self-organization. Perception is an external control parameter which is only received and processed if it fits into an existing frame. If it doesn't it may still trigger a new idea, a though fluctuation, which can change the state of mind to a new one, if the new state appears to be more consistent or satisfying. The idea takes on the role as order parameter, the brain cell is slaved.

Example 176 (*Social systems*): Static systems are often more unstable than dynamic systems if subject to external forcing. E.g. democracies which are based on an institutionalized permanent revolution can be more robust than dictatorships.

Example 177 (*Laser*): The laser is an open system far from equilibrium, because it is coupled to systems with different temperatures. The inversion corresponds to $T < 0$. On the other hand the the emitted photons coupled to ambient atoms at temperatures $T \ll \hbar\omega/k_B$, i.e. $T \approx 0$. Nevertheless, Haken has shown that the laser exhibits all features of a standard equilibrium phase transition.
In particular the equations describing a homogeneously broadened, unidirectional, single mode ring laser are mathematically equivalent to those describing the Bénard instability.
The conversion from a low quality microscopic form of energy (heat, chemical affinity) to a high quality macroscopic form (electricity, work) requires energy itself.

Example 178 (*CARL*): Is a self-organizing system by feedback. As compared to biological systems or even Bénard instabilities, CARL is **very simple**. CARL is **of course** nonlinear: every degrees of freedom is a nonlinear function of the others.

Example 179 (*Vortex patterns*): However there is another example for phase transitions in BECs: The transition from one vortex pattern to another has been classified as a first-order phase transition. But it seems to me that this is rather a non-equilibrium phase transition. I think, *vortex pattern* are *dissipative structures*. They decay by losing the vortices one by one due to relaxation into thermal excitations. On the other hand, vortex pattern are formed by a dissipative force: stirring up a condensate. In fact, an irreversible process is necessary to form a vortex: The BEC is excited by stirring (Dalibard's method) and *decays* into the vortex state. The is perhaps not true even for Cornells method, where the vortex is formed by engineering of the BEC phase.
Vortex pattern are unstable, they have a limited lifetime. It might however

be possible to stabilize them have a continuous stirring. This would be a true dissipative structure: A stirring force relying on friction on one hand, diffusion by thermal decay on the other.

21.2.3 Friction and diffusion

Friction and diffusion arise from coupling to a reservoir. Friction comes from coupling to a 0-temperature reservoir, diffusion to a reservoir at finite temperature. For example the decay of a cavity (friction) can be described by coupling to the external vacuum. However if the vacuum contains blackbody radiation, $T > 0$, photons may be coupled in which leads to diffusion.

21.2.4 Non-equilibrium quantum phase transitions

It might be interesting to look out for nonequilibrium quantum phase transitions. However, those are difficult to imagine. Mott-transitions are clearly in some kind of equilibrium (not really a thermal one). They are reversible via a control parameter. They do not require the feeding with energy or entropy, i.e. heating. Clearly, entropy is and must remain zero at $T = 0$.

21.2.5 Fluctuation-dissipation theorem

In statistical physics, the *fluctuation-dissipation theorem* is derived from the assumption that the response of a system in thermodynamic equilibrium to a small external perturbation is the same as its response to a spontaneous fluctuation. There is therefore a direct relation between the fluctuation properties of the thermodynamic system and its linear response properties.

For example, Einstein in his 1905 paper on Brownian motion noted that the same random forces which cause the erratic motion of a particle in Brownian motion would also cause drag if the particle were pulled through the fluid. In other words, the fluctuation of the particle at rest has the same origin as the dissipative frictional force one must do work against, if one tries to perturb the system in a particular direction. From this observation he was able to use statistical mechanics to derive a previously unexpected connection, the Einstein-Smoluchowski relation: $D = \mu k_B T$, linking the diffusion constant D and the mobility of the particles μ (i.e. the ratio of the particle's terminal drift velocity to an applied force, $\mu = vd/F$).

The fluctuation-dissipation theorem can be used to give an explicit relationship between molecular dynamics at thermal equilibrium, and the macroscopic response that is observed in a dynamic measurement. It thus allows molecular scale models (microscopic models) to be used quantitatively to predict material properties in the context of linear response theory.

The essence of fluctuation-dissipation theorem is that it relates equilibrium fluctuations to out-of-equilibrium quantities, like noise power is related to resistance. The theorem is based on fields that are weak relative to the potential of molecular interaction so that rates of relaxation are not affected by the applied field. 'Out-of-equilibrium' in the above sentence should be understood as close to equilibrium or stationary states.

21.2.6 Long-range interactions

Having been pioneered in astrophysics (e.g. in the formation of coherent structures like galaxies and stars), long-range interactions also play a role in plasma physics, hydrodynamics (e.g. jets, vortices like the gulf stream or the Jupiter vortex), systems with dipolar interactions, cold and ultracold gases, clusters and even in some nuclear systems. Today the most promising systems to experimentally study long-range interactions are atomic gases with electromagnetic interactions. However, those are mostly quantum systems. And one is still far from discerning which properties are genuinely ascribable to long-range interactions (whether fundamental or effective).

Systems with *long-range interaction* can behave very differently from systems with *short-range interaction*. The most prominent features are ensemble inequivalence and negative specific heat.[2] The dynamical aspects of the approach of long-range interacting systems to equilibrium is not yet well understood. The statistical physics has to learn in this domain. In particular, if the interacting particles are microscopic objects with quantized degrees of freedom or quantum statistical constraints.

A short-range interacting system is always [152]

- additive, i.e. the total energy of two parts of a system is $E_1 + E_2$, because the interaction energy between the parts E_{12} is negligibly small (is decreases like the surface-to-volume ratio like $N^{2-\alpha/3}$ for an interaction potential $V(R) \propto R^{-\alpha}$);
- having *extensive thermodynamical potentials* (e.g. energy, free energy, entropy, Gibbs free energy,...), i.e. for given values of the *intensive thermodynamical parameters* (e.g. n, T, p,...) they are proportional to N;
- rapid to find to equilibrium (non-equilibrium states are unstable);
- homogeneous at equilibrium (in the absence of external fields).
- having equivalent micro- and macrocanonical ensembles (i.e. the same values for the thermodynamic potentials are calculated for both situations).

In contrast a long-range interacting system

- is not additive;
- has extensive thermodynamical potentials;
- has non-equilibrium situations lasting for macroscopic times (the metastable states represent local extrema of thermodynamic potentials, the evolution towards other non-equilibrium states is driven by mean-field fluctuations);
- is inhomogeneous at all scales;
- exhibits strange concepts like negative specific heat $C = (\partial E/\partial T) < 0$;
- has non-equivalent micro- and macrocanonical ensembles (probably, one has to pick the appropriate ensemble depending on the experimental condition, i.e. isolated system or system held at a fixed temperature);

[2] A specific statistical ensemble is obtained by keeping two out of four (for a 1 component gas) thermodynamic parameters fixed (p, V, T, N).

- exhibits ergodicity breaking;
- shows non-equilibrium phase transitions.

Interaction potentials are short-range if $\int_{R_0}^{\infty} V(\vec{R}) d^3\vec{R} < \infty$. Alternatively, interaction potentials are short-range if there exist constants $C > 0$ and $R_0 > 0$ for which, $|V(\mathbf{r})| = C/|\mathbf{r}|^\alpha$ for all $|\mathbf{r}| > R_0$, where $\alpha > 3d$ and d is the dimensionality of the system. The main long-range forces of interest are gravitation and electro-magnetic forces, e.g. Coulomb repulsion and radiation pressure.

$\alpha < 3$	$E_{12} \propto N^{2-\alpha/3}$
$\alpha = 3$	$E_{12} \propto N \ln N$
$3 < \alpha < 4$	$E_{12} \propto N^{2-\alpha/3}$
$\alpha = 4$	$E_{12} \propto N^{2/3} \ln N$
$4 < \alpha$	$E_{12} \propto N^{2/3}$

One distinguishes between continuous and lattice systems.

Long-range interaction is a prerequisite of CARL and self-organization.

21.2.6.1 Negative specific heat

In macrocanonical ensembles the specific heat does not get negative, only in microcanonical ensembles, i.e. in systems isolated from heat baths.

Self-gravitating systems can have *negative specific heat*. According to the virial theorem the energy of such a system is $0 > E = E_{\text{kin}} + E_{\text{pot}} = -E_{\text{kin}} = \frac{m}{2}\langle v^2 \rangle = \frac{3}{2} k_B T$. For a gravitationally bound two-body system this is easy to see [3]. Hence, increasing T reduces E. Negative specific heat is usually connected to astrophysical long-range interactions, like self-gravitating clouds, and applies more to equilibrium situations. There is probably no chance of seeing it with CARL. The molasses CARL is best described by a macrocanonical ensemble, since the atoms are not isolated, but connected to a heat bath. The system is completely described by a set of Langevin equations [854].

21.2.6.2 Small systems

A short-range interacting *small system* can exhibit similar features as long-range interaction systems, in particular *non-additivity*. A small system is defined by the fact, that the range of its interaction is similar to the system's size. As an example one may consider an ultracold atomic gas near a Feshbach resonance. The power law of the interaction potential does not change, but the scattering length can be as large as the atomic cloud.

Appendices to 'Thermodynamics'

22.1 Data tables

22.1.1 Material data

The following table shows the specific latent heats (SLH) and change of phase temperatures (at standard pressure) of some common fluids and gases:

Substance	SLH of fusion (kJ/kg)	melting point (°C)	SLH of vaporization (kJ/kg)	boiling point (°C)
ethyl alcohol	108	−114	855	78.3
ammonia	332.17	−77.74	1369	−33.34
carbon dioxide	184	−78	574	−78.46
helium			21	−268.93
hydrogen	58	−259	455	−253
lead	23.0	327.5	871	1750
strontium	0.72	777	12.6	1377
methane	59	−182.6	511	−161.6
oxygen	13.9	−219	213	−183
silicon	1790	1414	12800	3265
water	334	0	2264.705	100

The specific latent heat of condensation of water in the temperature range from $-25\,^\circ\mathrm{C}$ to $40\,^\circ\mathrm{C}$ is approximated by the following empirical cubic function. For sublimation and deposition from and into ice, the specific latent heat is almost constant in the temperature range from $-40\,^\circ\mathrm{C}$ to $0\,^\circ\mathrm{C}$ and can be approximated by the following empirical quadratic function:

$$L_{\mathrm{water}}(T) \simeq \left[2500.8 - 2.36\tfrac{T}{^\circ\mathrm{C}} + 0.0016\left(\tfrac{T}{^\circ\mathrm{C}}\right)^2 - 0.00006\left(\tfrac{T}{^\circ\mathrm{C}}\right)^3\right]\mathrm{J/g} \tag{22.1}$$

$$L_{\mathrm{ice}}(T) \simeq \left[2834.1 - 0.29\tfrac{T}{^\circ\mathrm{C}} - 0.004\left(\tfrac{T}{^\circ\mathrm{C}}\right)^2\right]\mathrm{J/g}\ .$$

Part IV

Quantum Mechanics

Preface to the part *Quantum Mechanics*

Developed at the beginning of the 20th century, quantum mechanics is today the most fundamental and far-reaching theory in physics. It shaped our World more than any other science, as technologies based on quantum mechanical effects are the key to an industry representing today one third of the World's global domestic product. Boosted by the invention of the transistor and the laser, the industry today branches out in many areas including energy generation, electronics, optics, and photonics. Nevertheless and despite its long history and its incomparable success, quantum mechanics is far from being exhausted. The invention of novel techniques for quantum state manipulation and entanglement generation, awarded with various Nobel prizes in the past, and advances in information science during the past 25 years prepared the ground for a second wave of quantum-based technologies called Quantum Revolution 2.0. In terms of economic, military, and social advantages the stakes of this revolution are so important that they triggered a fierce international race for technological domination.

The course starts in chapter 23 with a thorough introduction into the conceptual and mathematical foundations of quantum mechanics, which are disruptive with classical mechanics and electrodynamics. The following Chps. 24 to 26 are organized according to the symmetries (separable in Cartesian space, isotropic, or periodic) underlying the studied systems.

Chapter 23

Foundations and mathematical formalism

This chapter traces briefly the historical conditions and the discoveries that led to the invention of quantum mechanics. The fundamental idea of quantum mechanics is the assumption that there are entities which can not be subdivided beyond a certain limit. Examples are the mass of a body, the speed of an electron orbiting an atom, or the intensity of a beam of light. This idea was first uttered by *Leucippus* 500 years a.c. and his student *Democritus*, who imagined matter being made of smallest particles which they called *atoms*. These atoms move freely, collide, combine, and separate: 'There is nothing else than atoms and free space' they claimed. The microscopic atoms would have the same characteristics as the macroscopic objects they form when they combine, for example, color and shape. The idea of the atom resurfaced and was refined in the course of the 18th century (see Tab. 23.1 below). Today, we know that the basic idea was good, but reality is a little more complicated.

Table 23.1: *Historical time line of the quantization of matter.*

500 a.c.	Democritus	invention of the atom
1800	Avogadro, Dalton	reinvention of the atom
1897	Thomson	charge transport, raisin-in-a-cake model
1909	Rutherford, Geiger, Marsden	α-scattering, charge localized in nuclei
1911	Rutherford	planetary model
1913	Bohr	quantized orbitals
1923	de Broglie	matter has characteristics of waves
1927	Davisson, Germer, Stern	electron and atoms diffraction

Still, at the end of the 19th century, the physical world seemed rather simple: matter and light was all that existed. Matter was made up of atoms and light was a wave. Therefore, to describe a real system, it was enough to calculate the trajectories of its elementary particles and the propagation of light between them. The way that light interacts with polarizable and magnetizable matter via electric and magnetic fields had been perfectly explained by laws discovered by Coulomb, Ampère, Faraday, and Maxwell.

However, new experimental observations, such as the ultraviolet divergence of

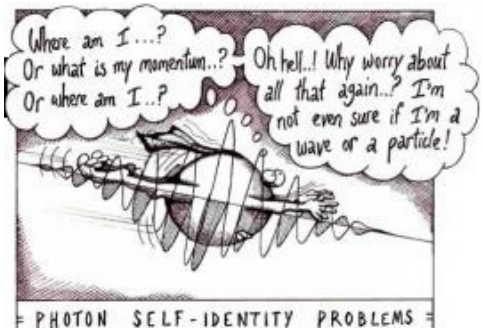

Figure 23.1: Particle-wave duality.

black-body radiation, that appeared in the late 19th century, were incompatible with these traditional concepts. New ideas were pioneered by *Max Planck* who, in 1905, with a little help from Einstein quantized the electromagnetic field, and therefore the light, into small harmonic oscillators. This was the starting point for the development of a new theory called 'quantum mechanics'. Soon, this theory was applied to explain the photoelectric effect. The second important step was initialized by *Niels Bohr*, who quantized the hydrogen atom in 1913 into discrete excitation levels.

Table 23.2: *Historical time line of the quantization of light.*

1801	Young	light is diffracted like a wave
1860	Maxwell	unified theory of electrodynamics including light
1888	Hertz	detection of radio waves
$\sim$ 1890		accurate measurements of black-body radiation spectra
1900	Planck	quantum hypothesis: $E = h\nu$
1905	Einstein	photoelectric effect, light behaves like a particle

Nowadays we know that our universe is not as simple as classical mechanics suggested, and that atoms are also waves and light also behaves like particles. This *duality principle* is one of the fundamental ideas of quantum mechanics. The appearance of an object as a wave or as a particle depends on the situation in which it is observed. While the wave nature of light was well established in classical physics since a long time, Louis de Broglie was the first in 1924 to apply the duality principle also to massive particles and to predict that particles, under certain conditions, behave like waves the wavelengths of which increase as their velocity decreases. Each particle (or body) is delocalized along a distance corresponding to this 'de Broglie wavelength'. This feature of matter was soon discovered experimentally in electron beams and is still used today in commercial devices, for example in electron microscopes.

23.1 The discovery of the atom

23.1.1 Democrit's model

'The principles of reality are atoms and emptiness while other things are mere opinions.' This is a quotation from the Greek philosopher *Democritus* 400 years before Christ and before Socrates. Together with his teacher Leucippus, he formed the first idea of indivisible particles: atoms.

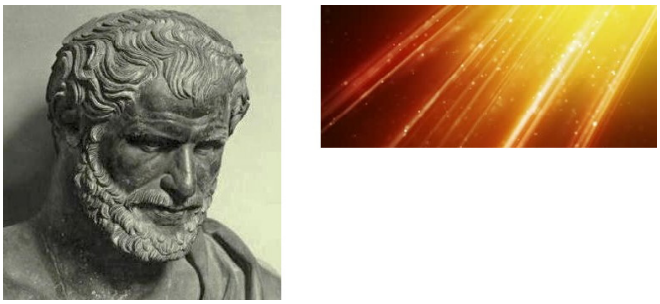

Figure 23.2: Democritus and dust in a sun ray.

Democritus' work only survived as second-hand accounts, the major part of it having been written down by *Aristotle*, who also, defending the idea of the continuum, was the greatest critic of Democritus' theory. Aristotle said that the reasoning that guided Democritus to affirm the existence of atoms was as follows. For a body to change its shape, it is necessary that its parts can move. This presupposes an emptiness (or vacuum) in which the matter moves. But if matter were divided infinitely into ever smaller parts, it would loose its consistency. Nothing could be formed because nothing could arise from the ever more infinitely deep dilution of matter into emptiness. Hence, he concluded that the division of matter can not be infinite, that is, there is an indivisible limit: the atom. 'There is only atoms and emptiness', he said.

Observing dust particles in a whirling motion within a ray of sunlight, Democritus was led to the idea that atoms would behave in the same way, randomly colliding, some crowding, others dispersing, others never yet joining with another atom.

The consistency of clusters of atoms, which makes something look solid, liquid, gaseous, or animated (which is the state of the soul) would then be determined by the shape of the atoms involved and their spatial arrangement. In this sense, water atoms are smooth and slippery; the atoms of steel have shapes with sharp edges that hold them solidly together; the atoms of salt, as their taste shows, are harsh and pointed; the atoms of air are small and little connected, penetrating all other materials; and the atoms of soul and fire are spherical and very delicate.

We know nowadays that Democritus' first theory of the structure of matter was very close to the truth: There really are indivisible particles called atoms composed of a nucleus and an electronic shell, and the space between the atomic nuclei is, in fact, quite empty.

The atomic hypothesis came to be reborn in the modern age with the scientists

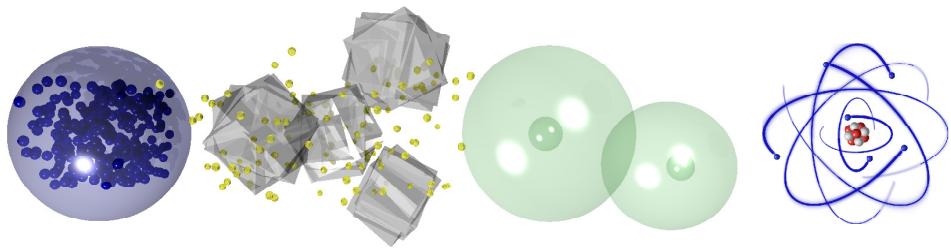

Figure 23.3: Atoms of steel and air, atoms of the soul, and Bohr's atom model.

Boyle, Clausius, Maxwell, and Boltzmann due to their successful explanations of the properties of gases based on the so-called kinetic theory, where they assumed a gas being constituted of identical molecules that collided elastically with each other and with the walls of the recipient containing them. The discovery of the atom through the *laws of proportions* in chemistry and the establishment of Avogadro's number considerably strengthened the atomic hypothesis. The hypothesis was definitely consecrated with the various experiments that established the charge of the electron and the mass ratio between electrons and protons.

By the beginning of the 19th century the atomic nature of matter had definitely been established, and the basic composition of the atoms was already relatively well known. It was known, through experiments, that electrons could be removed from neutral atoms thus creating positively charged ions and that only a certain number of electrons could be removed from each atom. This number proved to be dependent on the atomic species and was called the atomic number Z. This information was fundamental for establishing the basic composition of atoms. The question that arose at this point concerned the dimensions and configurations of the atomic system. How would loads and masses be distributed in this entity?

23.1.2 Thomson's model and Rutherford's experiment

The internal structure of a body can be studied by throwing beams of small particles against it. The detection of the angular distribution of the scattered particles gives access to the structure factor of the body. In crystallography we throw X-rays into super-complicated molecules to learn the architecture e.g. of proteins. And in medicine, X-rays reveal the internal structure of the human body. Obviously, the scattering technique is an extremely powerful tool, used in many areas of modern physics.

In a series of experiments done before 1911, *Ernest Rutherford* analyzed the internal structure of gold atoms using α-particles, i.e., He^{2+} atoms. The experiments carried out by Geiger, Marsden, and Rutherford consisted of observing the deflection of particles from a collimated beam when scattered by a thin metallic sheet (gold of thickness $\sim 1\,\mu\text{m}$) carefully obtained by electroplating [see Fig. 23.4(cd)].

The atomic model proposed by *Joseph John Thomson* suggests a structure resembling a *pudding with raisins*: the electrons would be homogeneously distributed within an extended nucleus (size 0.1 nm) of positive charge thus compensating for the negative charge of the electrons. The α-particles would penetrate the gold nucleus,

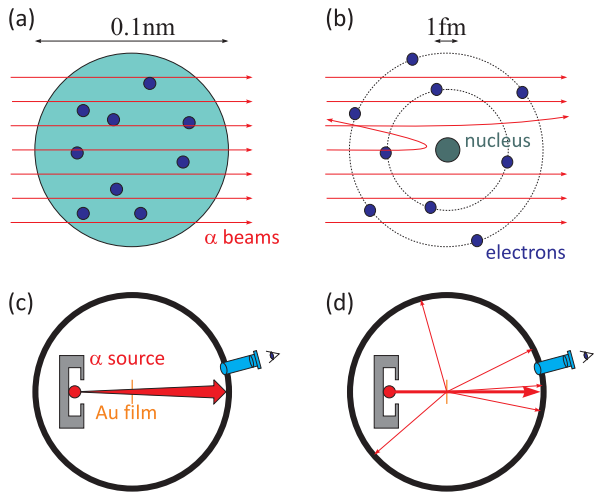

Figure 23.4: Comparison of Rutherford scattering by free electrons and electrons strongly bound to small nuclei. (a) Thomson's 'raisin-in-a-pudding' type atom; (b) Rutherford's 'planetary' atom. (c) Rutherford scattering by a raisin pudding atom and (d) by a planetary atom.

perceived as almost homogeneous, but would suffer multiple deflections due to collisions with the disordered electrons within the nucleus. Since electrons are very light, the angle of deflection θ would be small, even after many collisions. For this model we expect a Gaussian dependence of the particles' deflection angle given by the *scattering cross section* [see Fig. 23.4(a-b)],

$$\frac{d\sigma}{d\Omega} \propto e^{-\theta^2/\theta_0^2} \ , \tag{23.1}$$

where θ_0 is a small angle.

However, the measurements performed on this *Rutherford scattering* showed different results:

- For a fixed scattering angle, the amount of particles scattered into a solid angle element $d\Omega$ is proportional to the thickness of the metal foil.
- For a given fixed angle and a given metal sheet the amount of scattered particles in $d\Omega$ varies inversely with $E_{\rm kin}^2$, where $E_{\rm kin}$ is the kinetic energy of the α-particles.
- For a given energy and a given metal sheet, the number of particles scattered into $d\Omega$ is proportional to $(\sin\frac{\theta}{2})^{-4}$.
- For a given energy and sheet thickness, the number of particles scattered into $d\Omega$ in a given direction is proportional to $Z_{\rm tg}^2$, where $Z_{\rm tg}$ is the atomic number of the element that constitutes the sheet.

The extremely rare deflection of α-particles and their angular distribution can be understood by the assumption that the positive charge is concentrated in a very small

volume (~ 1 fm, that is 10000 times less than the size of the atom itself). This volume is called the atomic nucleus, hence the denomination of *nuclear model*. Since most of the particles pass through the gold sheet without hindrance, there must be a large gap between the nuclei. The electrons, which move within a large (in comparison with the diameter of the nucleus) empty space (the vacuum) around the nucleus, shield the positive nuclear charge, so that the atom appears outwardly neutral.

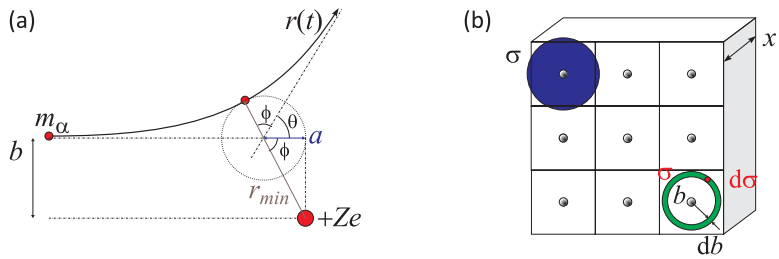

Figure 23.5: (a) Trajectory of an α-particle. (b) Illustration of the scattering cross section.

We now derive Rutherford's scattering formula from the hypothesis of a point-like nucleus. Due to the repulsive action of the Coulomb force,

$$F = \frac{Z_\alpha Z_{\rm tg} e^2}{4\pi\varepsilon_0 r^2} \ , \tag{23.2}$$

we have for the trajectory of the α-particle ($Z_\alpha = 2$) a hyperbola [see Fig. 23.5(a)]. The large half-axis of the hyperbola can be determined from the following ansatz,

$$E_{\rm kin} = \frac{Z_\alpha Z_{\rm tg} e^2}{4\pi\varepsilon_0} \frac{1}{2a} \ , \tag{23.3}$$

where $2a$ is the minimum distance of the particle α, when it collides with the nucleus in a central collision [1]. The distance a depends on the kinetic energy and can also be used for non-central collisions. The collision parameter b is the minimum distance of the α-particle to the nucleus, if it continued to fly in a straight line. In fact the α-particle will be deflected by an angle θ. From the geometry of the hyperbola, as $2\phi + \theta = 180°$, we obtain the following equation:

$$\tan\phi = \tfrac{b}{a} = \tan\left(90° - \tfrac{\theta}{2}\right) = \cot\tfrac{\theta}{2} \ , \tag{23.4}$$

and therefore

$$\cot\tfrac{\theta}{2} = \frac{b}{a} = \frac{8\pi\varepsilon_0 E_{\rm kin}}{Z_\alpha Z_{\rm tg} e^2} b \ , \tag{23.5}$$

replacing a with the formula (23.3). Taking the derivative of this latter formula, we obtain a relation between the width db of the hollow cone and the pertinent width $d\theta$ of the deflection angle θ,

$$-\frac{1}{2\sin^2\frac{\theta}{2}} d\theta = \frac{8\pi\varepsilon_0 E_{\rm kin}}{Z_\alpha Z_{\rm tg} e^2} db \ . \tag{23.6}$$

[1] In a central collision, when the α-particle reaches the minimum distance $2a$, its initial kinetic energy, $E_{\rm kin}$ is fully converted into potential energy.

Let $n_{\rm tg} = \frac{N_{\rm tg}}{V}$ be the density of the particles in the target ($N_{\rm tg}$ atoms per volume V) and x the film thickness. Then $\sigma = \frac{A}{N_{\rm tg}} = \frac{V/x}{N_{\rm tg}} = \frac{1}{n_{\rm tg}x}$ is the average cross-section per atom sensed by the α-particle on its way through the film. The probability $P(\theta)d\theta$ for the α-particle of being within a ring at distance b from the nucleus (whose area is $2\pi bdb$) and being scattered into the angle θ is then given by,

$$P(\theta)d\theta = \frac{2\pi bdb}{\sigma} = n_{\rm tg}x2\pi bdb \ . \tag{23.7}$$

These particles, i.e., dN of the N particles, are deflected into the hollow cone with the probability,

$$\begin{aligned}\frac{dN}{N} = P(\theta)d\theta &= n_{\rm tg}x2\pi\frac{Z_\alpha Z_{\rm tg}e^2}{8\pi\varepsilon_0 E_{\rm kin}}\cot\frac{\theta}{2}\cdot\frac{Z_\alpha Z_{\rm tg}e^2}{8\pi\varepsilon_0 E_{\rm kin}}\cdot\frac{1}{2\sin^2\frac{\theta}{2}}d\theta \\ &= n_{\rm tg}x\frac{Z_\alpha^2 Z_{\rm tg}^2 e^4}{64\pi\varepsilon_0^2 E_{\rm kin}^2}\cdot\frac{\cos\frac{\theta}{2}}{\sin^3\frac{\theta}{2}}d\theta \ ,\end{aligned} \tag{23.8}$$

where we replaced the parameters b and db with the expressions (23.5) and (23.6). The solid angle of the cone can be expressed by,

$$d\Omega = 2\pi\sin\theta d\theta = 4\pi\sin\tfrac{\theta}{2}\cos\tfrac{\theta}{2}d\theta \ . \tag{23.9}$$

Thus, the number dN of particles scattered to the solid angle $d\Omega$ remains,

$$\boxed{\frac{dN}{N} = n_{\rm tg}x\frac{Z_\alpha^2 Z_{\rm tg}^2 e^4}{256\pi^2\varepsilon_0^2 E_{\rm kin}^2}\cdot\frac{1}{\sin^4\frac{\theta}{2}}d\Omega} \ . \tag{23.10}$$

That is Rutherford's scattering formula. Often, the formula is expressed with the *differential* cross section $\frac{d\sigma}{d\Omega}$. We get,

$$\frac{dN}{N} = \frac{d\sigma}{\sigma} = n_{\rm tg}xd\sigma \ , \tag{23.11}$$

and therefore

$$\frac{d\sigma}{d\Omega} = \frac{dN}{Nn_{\rm tg}xd\Omega} = \left(\frac{Z_\alpha Z_{\rm tg}e^2}{4\pi\varepsilon_0\cdot 4E_{\rm kin}}\right)^2\frac{1}{\sin^4\frac{\theta}{2}} \ . \tag{23.12}$$

Here, we have to make some comments:

- The angle $\theta = 0$ is not defined, since there exists a minimum deflection angle $\theta_{\rm min}$. This angle is reached, when the α-particle moves at the distance $b = b_{\rm max}$ from the atom, that is, at the edge of the circular area of the cross section. For a greater collision parameter b, the α-particle traverses the field of the next neighboring atom, and the deflection angle increases again. We have:

$$\sigma = \frac{A}{N_{\rm tg}} = \pi b_{\rm max}^2 \qquad \text{and} \qquad \tfrac{\theta_{\rm min}}{2} \simeq \tan\tfrac{\theta_{\rm min}}{2} = \frac{Z_\alpha Z_{\rm tg}e^2}{8\pi\varepsilon_0 E_{\rm kin}\cdot b_{\rm max}} \ , \tag{23.13}$$

  simply by inverting the formula (23.5). For very large impact parameters, that is, when the α-particle passes the atom outside its electronic layer, the electrons of the atom shield the charge of the nucleus, an effect called *screening*.

- For very high energies, the distribution of the nuclear charge over a finite volume influences the scattering, calling for corrections in the Rutherford formula. Moreover, at short internuclear distances, nuclear forces appear additionally to the electromagnetic interaction.

- The integral over the probability distribution $P(\theta)d\theta$ is normalized,

$$\int_{\theta_{\min}}^{\pi} P(\theta)d\theta = 1 \ . \tag{23.14}$$

Similarly, we have for the surface integrals,

$$\int_{\theta \geqslant \theta_{\min}} \frac{d\sigma}{d\Omega} d\Omega = \sigma \ . \tag{23.15}$$

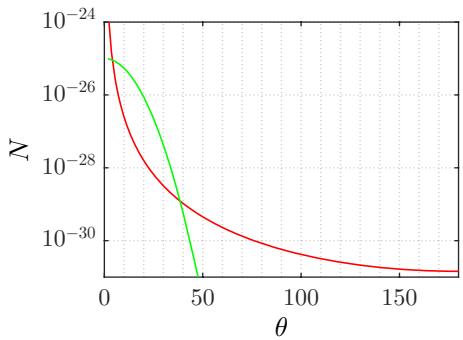

Figure 23.6: (code) Angular dependence of the cross-section corresponding to Thomson's (green) and Rutherford's (red) models.

Rutherford derived the formula (23.12) describing the scattering of α-particles within classical physics. A derivation from the laws governing quantum mechanics using the *Born approximation* shows that Rutherford's formula describes scattering correctly in first order, and that purely quantum effects present only minor corrections. We will review the Rutherford scattering in Excs. 23.1.6.1 and 23.1.6.2 and discuss the screening effect in Exc. 23.1.6.3.

23.1.3 Emission of radiation in the planetary model

The *planetary model* proposed by Rutherford suggests electrons spinning around a positively charged nucleus in circular orbits [2]. This motion of electrons should obey the laws of Maxwell's electrodynamic theory. Let us now calculate some consequences of this picture.

[2] This type of model had already been proposed by Jean Perrin in 1901 and by Hantaro Nagaoka in 1903, around the same time when Thompson developed his model. The planetary model was later on rescued by John William Nicholson in 1911.

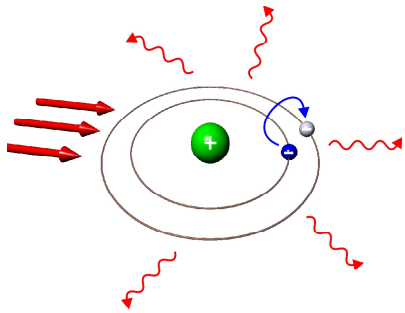

Figure 23.7: Light-induced transitions between orbits in the planetary model.

We now treat the atom as a rotor where the negative particle, the electron, orbits the positive particle. The dipole moment is,

$$p_0 = -er \ . \tag{23.16}$$

We calculate in the Exc. 23.1.6.4 the power emitted by the acceleration $a = \omega^2 r$ of the electron on its circular trajectory,

$$P = \frac{\mu_0 \omega^4 p_0^2}{12\pi c} \ . \tag{23.17}$$

The initial energy of the electron spinning around the nucleus (for a hydrogen atom $Z = 1$),

$$E = \frac{p^2}{2m_e} - \frac{e^2}{4\pi\varepsilon_0 r} = \frac{m_e \omega^2 r^2}{2} - \frac{e^2}{4\pi\varepsilon_0 r} \ , \tag{23.18}$$

is dissipated by radiation of the power (23.17), i.e.,

$$-P = \frac{dE}{dt} = m_e \omega^2 r \frac{dr}{dt} + \frac{e^2}{4\pi\varepsilon_0 r^2}\frac{dr}{dt} = 2m_e \omega^2 r \frac{dr}{dt} \ . \tag{23.19}$$

The latter equation supposes an equilibrium between the centrifugal force and the Coulomb force,

$$m_e \omega^2 r = \frac{e^2}{4\pi\varepsilon_0 r^2} \ , \tag{23.20}$$

allowing to link the revolution frequency ω to the instantaneous radius of the orbit $r(t)$. Resolving the Eq. (23.19) by $\dot{r}$ and replacing the power by the relation (23.17) and the frequency ω by the relation (23.20), we obtain,

$$\frac{dr}{dt} = -\frac{P}{2m_e \omega^2 r} = -\frac{\mu_0 \omega^2 e^2}{24\pi m_e c} r = -\frac{e^4}{96\pi^2 \varepsilon_0^2 m_e^2 c^3}\frac{1}{r^2} \ . \tag{23.21}$$

Integration of this equation gives,

$$t - t_0 = -\frac{32\pi^2 \varepsilon_0^2 m_e^2 c^3}{e^4}[r^3 - r^3(t_0)] \ . \tag{23.22}$$

Now inserting $t_0 = 0$ and assuming $r(t_0) = a_{\rm B}$, the time τ within which the loss of energy due to radiation emission decreases the radius of the electronic orbit to $r = 0$, is,

$$t = \tau = \frac{32\pi^2\varepsilon_0^2 m_e^2 c^3 a_{\rm B}^3}{e^4} \ . \tag{23.23}$$

Insertion of the numerical values gives the decay time $\tau \sim 10^{-10}$ s. This is the effect called *radiation collapse* of the classical atomic model.

23.1.4 Zeeman effect in the planetary model

The orbital motion of the electron generates a ring current $I = e/T = e\omega/2\pi$, which produces an *orbital magnetic moment* which, as shown in Exc. 23.1.6.5, can be calculated following the laws of electromagnetism,

$$\vec{\mu}_\ell = IA\hat{\mathbf{n}} = \frac{e\omega}{2\pi}\pi r^2\hat{\mathbf{n}} \ , \tag{23.24}$$

where $A = \pi r^2$ is the area of the trajectory. Introducing the angular momentum $\mathbf{L} = m_e\omega r^2\hat{\mathbf{n}}$ we get in vector notation,

$$\vec{\mu}_\ell = \frac{e}{2m_e}\mathbf{L} \ . \tag{23.25}$$

We now imagine this atom in the presence of a magnetic field $\vec{\mathcal{B}}$ oriented in the direction that we will call z. This results in a precession of the magnetic moment around the field (similar to the precession of a spinning top in the presence of a gravitational field) governed by the equation,

$$\frac{d\mathbf{L}}{dt} = \vec{\mu}_\ell \times \vec{\mathcal{B}} = \frac{e}{2m_e}\mathbf{L} \times \vec{\mathcal{B}} = -\mathbf{\Omega}_{\rm L} \times \mathbf{L} \ ,$$

with $\mathbf{\Omega}_{\rm L} = \frac{e}{2m_e}\vec{\mathcal{B}}$ representing the precession frequency and being called *Larmor frequency*. It is evident that the presence of the magnetic field considerably alters the state of the atom, even producing profound modifications in the frequency of the orbit of the electron ω_0 and therefore in the energetic state of the atom. This change is called *Zeeman effect*.

The Zeeman effect can be calculated by imagining that the field has an arbitrary direction with respect to $\mathbf{L}$. In this case, the equation describing the electronic motion as resulting from an equilibrium between the centrifugal force and the Coulomb force needs to be complemented by a Lorentz force,

$$m_e\ddot{\mathbf{r}} + m_e\omega_0^2\mathbf{r} = \mathbf{F}_{\rm L} = -e\mathbf{v} \times \vec{\mathcal{B}} \ . \tag{23.26}$$

where $m\ddot{\mathbf{r}}$ is the centrifugal force due to the circular motion of the electron and $m_e\omega_0^2\mathbf{r}$ the centripetal force due to the Coulomb attraction exerted by the nucleus. Assuming the direction of the magnetic field given by $\vec{\mathcal{B}} = \mathcal{B}\hat{\mathbf{e}}_z$ with $\mathcal{B} = 2m_e\Omega_{\rm L}/e$, the equations of motion can be decomposed into,

$$\begin{aligned} \ddot{x} + \omega_0^2 x + 2\Omega_{\rm L}\dot{y} &= 0 \\ \ddot{y} + \omega_0^2 y - 2\Omega_{\rm L}\dot{x} &= 0 \\ \ddot{z} + \omega_0^2 z &= 0 \ . \end{aligned} \tag{23.27}$$

The z-direction is not influenced. With the ansatz $x = ae^{\imath\omega t}$ and $y = be^{\imath\omega t}$ we obtain the system of equations,

$$\begin{aligned} a(\omega_0^2 - \omega^2) + 2\imath\Omega_{\mathrm{L}}\omega b = 0 \\ b(\omega_0^2 - \omega^2) - 2\imath\Omega_{\mathrm{L}}\omega a = 0 \ , \end{aligned} \tag{23.28}$$

which has a non-trivial solution for a and b only when the determinant of the coefficients of a and b vanishes:

$$0 = \begin{vmatrix} \omega_0^2 - \omega^2 & 2\imath\Omega_{\mathrm{L}}\omega \\ -2\imath\Omega_{\mathrm{L}}\omega & \omega_0^2 - \omega^2 \end{vmatrix} = \omega^4 - (2\omega_0^2 + 4\Omega_{\mathrm{L}}^2)\omega^2 + \omega_0^4 \ . \tag{23.29}$$

We get,

$$\omega = \omega_{1,2} = \sqrt{\omega_0^2 + 2\Omega_{\mathrm{L}}^2 \pm 2\Omega_{\mathrm{L}}\sqrt{\omega_0^2 + \Omega_{\mathrm{L}}^2}} = \omega_0 \pm \Omega_{\mathrm{L}} + \frac{1}{2}\frac{\Omega_{\mathrm{L}}^2}{\omega_0} + \dots \ , \tag{23.30}$$

or, as $\Omega_{\mathrm{L}} \ll \omega$, we get $\omega_{1,2} = \omega_0 \mp \Omega_{\mathrm{L}}$. The result is a splitting of the energy levels proportional to the magnetic field,

$$\Delta E = 2\hbar\Omega_{\mathrm{L}} = \frac{\hbar e}{m_e}\mathcal{B} = 2\mu_{\mathrm{B}}\mathcal{B} \ , \tag{23.31}$$

where the abbreviation $\mu_{\mathrm{B}} = e\hbar/2m_e \simeq 9.27 \cdot 10^{-24}\,\mathrm{JT}^{-1}$ is called the *magneton Bohr*.

Although the classical derivation shows quantitative deviations from experimental observations, it is quite interesting, as it illustrates several aspects which have a quantum mechanical equivalence.

Example 180 (*Stern-Gerlach experiment*): Among several historical experiments carried out to unravel the atomic structure, one of the most important is the experiment carried out by *Otto Stern* and *Walther Gerlach* in 1922 to measure the magnetic moment of atoms. The results of this experiment once again demonstrated the need for new concepts to explain the observations.
Using Bohr's quantization rule, $L = n\hbar$, within the formula (23.25) we get,

$$\vec{\mu} = -\mu_{\mathrm{B}}\frac{\mathbf{L}}{\hbar} \ .$$

In the presence of a magnetic field the dipole undergoes an interaction $W = -\vec{\mu}\cdot\vec{\mathcal{B}}$, and therefore a feels a force,

$$\mathbf{F} = -\vec{\mu}\cdot\nabla\vec{\mathcal{B}} \ .$$

By subjecting beams of atoms to the gradient of a magnetic field and detecting this force, Stern and Gerlach were able to measure the magnetic moment produced by the rotation of the electrons around the atomic nuclei.

23.1.5 Bohr's theory and its limitations

The classical model of the planetary atom provides a mechanical illustration of the microscopic world but fails to quantitatively explain experimental observations such as the discrete nature of atomic spectra.

The radiation emitted by hydrogen atoms is characterized by discrete, spectrally very thin lines. The observed lines are grouped in series named after Lyman, Ballmer and others,

$$\frac{1}{\lambda} = R_{\mathrm{H}} \frac{\mu}{m_e} \left(\frac{1}{m^2} - \frac{1}{n^2} \right) , \tag{23.32}$$

where m and n are integers. $R_{\mathrm{H}} = (1/4\pi\epsilon)^2 (m_e e^4/4\pi\hbar^3 c)$ is the Rydberg constant and $\mu = m_e m_{\mathrm{at}}/(m_e + m_{\mathrm{at}})$ the reduced mass.

The discrete nature of spectral lines and the problem of the radiation collapse led *Niels Bohr* to formulate the following *postulates*:

1. There are specific stationary orbits, where electrons do not emit energy.

2. Each emission or absorption of radiation energy by electrons comes with a transition between stationary orbits. The radiation emitted during this transition is homogeneous.

3. The laws of mechanics can describe the dynamic equilibrium of electrons in stationary states, but fails to describe the transition of electrons *between* stationary orbits.

Thus, Bohr's model predicts the quantization of energy levels, known as *first quantization* of quantum mechanics. The radii of the possible orbits can be calculated from the postulate that the orbital angular momentum be quantized in units of $\hbar$, that is, the electrons form stationary de Broglie waves along the orbits [3]. We discuss Bohr's model in Excs. 23.1.6.6 and 23.1.6.7.

In the picture proposed by Bohr, the radiative decay happens as an abrupt transition of an electron between an outer (more energetic) orbit and an inner (less energetic) orbit. Since the energies of stationary orbits are very well defined, the emitted radiation is mono-energetic, i.e., the spectrum consists of discrete characteristic lines.

We note here that the picture of an abrupt transition of electrons between discrete states, called the *quantum jump*, did not receive Schrödinger's blessing. He rather imagined for electrons, within his theory of quantum wave mechanics, wave-shaped orbitals instead of planetary trajectories, thus avoiding the problem of radiation due to charge deceleration and the quantum jump concept. According to him, during a transition between electronic orbits, the energy is transformed into radiation *gradually* [4].

23.1.6 Exercises

23.1.6.1 Ex: Analysis of Rutherford scattering

a. What conclusions can be drawn from the observation that Rutherford's formula describes well the scattering of charged particles traveling through matter over a wide

[3] A generalization of Bohr's theory was provided by *Arnold Johannes Wilhelm Sommerfeld*. Assuming elliptical orbits for the electrons he managed to explain some features of the fine structure, provided the motion of the electron was treated relativistically. The basic premises were 1. stable orbits when the Coulomb attraction is balanced by the centrifugal force, 2. quantization of phase space $\int r_q dq = n_q \hbar$, and 3. quantization of angular momentum $\int L d\theta = n_\theta \hbar$.

[4] We note here, that quantum jumps were observed much later!

range of parameters?
b. Why do we see a deviation from Rutherford's formula for large energies?
c. The scattering of protons with energy E crossing a thin film of thorium is well described up to energies of $E = 4.3\,\mathrm{MeV}$ by Rutherford's formula. Estimate for this case the range of nuclear forces.
d. For small scattering angles θ we observe large deviations from Rutherford's formula. Explain why?
e. Assume the thorium atoms of item (c) to form a periodic crystal with the lattice constant $d = 10a_{\mathrm{B}}$. At which minimum angle θ Rutherford's formula loses its validity.

23.1.6.2 Ex: Rutherford scattering

a. A beam of α-particles with energy $E_{\mathrm{kin}} = 3\,\mathrm{MeV}$ and flux $I = 5\cdot 10^3\,\mathrm{s}^{-1}$ impinges on a thick gold film $x = 1\,\mu\mathrm{m}$. Using Rutherford's formula, calculate how many particles are scattered in $\Delta t = 10$ minutes in the range of angles $10° \leq \theta \leq 30°$.
b. Now, the gold film is replaced with an aluminum film of the same thickness. How many α-particles are scattered under equal circumstances?

23.1.6.3 Ex: Screening of electrons

Consider thin layer of charge $-Z_{\mathrm{tg}}e$ with radius R. This screening causes a scattering angle,

$$\tan\tfrac{\theta}{2} = \frac{D}{2b}\frac{\sqrt{1-(b/R)^2}}{1+D/2R}\ ,$$

with $D \equiv \frac{3Ze^2}{m_2 v^2/2}$ for $b < R$. Verify how the screening changes the differential cross section $\frac{d\sigma}{d\Omega}$.

23.1.6.4 Ex: Radiation of an oscillating dipole

Calculate the angular distribution of the power radiated by an oscillating electric or magnetic dipole from expressions for the emitted electric and magnetic fields found in literature.

23.1.6.5 Ex: Magnetic moments

a. Derive from the expression $\vec{\mu}_L = \frac{1}{2}\int_{\mathbb{R}^3} \mathbf{r}\times\mathbf{j}(\mathbf{r}')d^3r'$ of classical electrodynamics and an appropriate parametrization of the current density $\mathbf{j}$ the relation between the magnetic dipole moment $\vec{\mu}$ due to the orbiting electron and the angular momentum $\mathbf{L}$.
b. The length of the angular momentum vector being given by $|\mathbf{L}| = \hbar$, calculate the magnetic moment for an electron and for a proton.

23.1.6.6 Ex: Bohr's atom

In 1913, Niels Bohr presented his atomic model adapting Rutherford's model to the quantization ideas proposed by Max Planck.
a. Impose the quantization rule for the angular momentum ($L = n\hbar$) of an electron

orbiting an atom of atomic number Z to find an expression for the radii of the allowed orbits.
b. According to Bohr's model, the transition between different orbits is accompanied by the emission (or absorption) of a photon. Determine the energy of a photon emitted during a transition between the first excited state and the ground state of a hydrogen atom.
c. Consider an electron trapped in an infinite one-dimensional box potential of width a. Determine an expression for the electronic energy levels.
d. What should be the width a of this potential, in terms of the Bohr radius, so to ensure that a photon emitted during a transition between the first excited state and the ground state equals that obtained in item (b)?

23.1.6.7 Ex: The hydrogen atom

The hydrogen atom can be seen as a point-like proton and an electron distributed over space with charge density $\rho = Ae^{-2r/a_{\mathrm{B}}}$ around the proton that is in the center. Here, A is a constant and r is the distance from the center.
a. Calculate A considering the fact that the atom is electrically neutral.
b. Calculate the amplitude of the electric field at a radius $r = a_{\mathrm{B}}$.

23.2 The discovery of the photon

The concept of the nature of light has a variable history. Newton proposed around ~ 1650 a corpuscular model to explain Snellius' law on the refraction of a light beam penetrating a crystal. Around the same time Huygens found a wave-based interpretation. The two models predicted different speeds of light within the dense medium. Newton found, that the speed of light is greater in the medium than outside, while Huygens found the opposite [5]. In the late 1800's the wave nature of light was established through observations of interference effects confirming Huygens' hypothesis. However, some observations made were incompatible with this simplistic ideas, for example, the spectrum of blackbody radiation, the Compton effect, the specific heat of the solid, the radiation pressure, and the photoelectric effect. All these observations are readily understood by assuming a corpuscular nature of the light [6].

Nowadays, knowing the theory of quantum mechanics, we are aware that both ideas have their range of validity and that the electromagnetic radiation is dual: In general, propagation and interference effects are best described by waves. However, when interacting with matter, light tends to localize into small energy packets that we call *photons*.

23.2.1 Radiation in a conductive cavity

In the age of lasers a classical treatment of the emission and absorption of light may seem an atavism. However, even with coherent and monochromatic radiation

[5] Note that until today there remain doubts about the correct value of the momentum of light in dielectric media [651].

[6] The corpuscular hypothesis is now called the second quantization of quantum theory or quantization of the electromagnetic field.

sources, the most commonly used physical picture is that of a classical optical field interacting with an atom or a molecule whose energetic structure is treated quantum mechanically. And even the atomic or molecular dipole is often treated like a classical oscillator. The exposition of such a dipole to simple boundary conditions prepares the analogous development of a quantum oscillator and provides a direct path to quantization of the radiation field.

Even if we rarely do experiments by throwing light into a small hole in a metallic box, the electromagnetic fields obtained by solving Maxwell's equation are particularly simple for boundary conditions, where the fields disappear on the inner surfaces of the box. Before discussing the physics of radiation in a perfectly conducting cavity, we have to introduce some basic relations between electromagnetic amplitudes, stored energy, and intensity.

The electric field of a plane wave oscillating with frequency ω and propagating through vacuum in the direction of propagation defined by the *wave vector*,

$$\mathbf{k} = \frac{2\pi}{\lambda}\hat{\mathbf{k}} \ , \tag{23.33}$$

can be written,

$$\vec{\mathcal{E}} = \vec{\mathcal{E}}_0 e^{\imath(\mathbf{k}\cdot\mathbf{r}-\omega t)} \ , \tag{23.34}$$

where $\vec{\mathcal{E}}_0 = \mathcal{E}_0\hat{\mathbf{e}}$ consists of an amplitude $\mathcal{E}_0$ and a polarization $\hat{\mathbf{e}}$. Since the field $\vec{\mathcal{E}}_0$ is transverse to the direction of propagation, the polarization has two components perpendicular to $\mathbf{k}$. The magnetic induction field associated with the wave is,

$$\mathcal{B}_0 = \tfrac{1}{c}\mathcal{E}_0 \ . \tag{23.35}$$

For a propagating wave $\vec{\mathcal{E}}$ and $\vec{\mathcal{B}}$ are in phase, while for a standing wave they are out of phase.

For a given cavity mode we can express the standing wave in this mode as,

$$\vec{\mathcal{E}} = \vec{\mathcal{E}}_0(\mathbf{r})e^{-\imath\omega t} \ . \tag{23.36}$$

The energy of the electromagnetic field of a standing wave, averaged over one oscillation of the frequency ω is,

$$\bar{U} = \frac{1}{2}\int\left(\frac{\varepsilon_0}{2}|\vec{\mathcal{E}}|^2 + \frac{1}{2\mu_0}|\vec{\mathcal{B}}|^2\right)dV \ . \tag{23.37}$$

Now, the *energy density* of the oscillating electromagnetic field is given by,

$$\boxed{\bar{u} = \frac{d\bar{U}}{dV} = \frac{1}{4}\left(\varepsilon_0|\vec{\mathcal{E}}|^2 + \frac{1}{\mu_0}|\vec{\mathcal{B}}|^2\right)} \ . \tag{23.38}$$

From the equation (23.35) we can see that the contributions of the electric and magnetic fields are equal. Therefore,

$$\bar{U} = \tfrac{1}{2}\int \varepsilon_0|\vec{\mathcal{E}}|^2 dV \qquad \text{and} \qquad \bar{u} = \tfrac{1}{2}\varepsilon_0|\vec{\mathcal{E}}|^2 \ . \tag{23.39}$$

Another important quantity is the *flux of electromagnetic energy* through a surface. The *Poynting vector* describing this flux is defined by,

$$\mathbf{I} = \tfrac{1}{\mu_0}\vec{\mathcal{E}} \times \vec{\mathcal{B}} \ . \tag{23.40}$$

Again using the equation (23.35), we find the value averaged over a time period,

$$\boxed{\bar{I} = \tfrac{1}{2}\varepsilon_0 c|\vec{\mathcal{E}}|^2} \ . \tag{23.41}$$

This quantity, called *intensity*, describes the fact that the flux is a density of energy multiplied with the velocity of propagation in vacuum,

$$\bar{u}c = \tfrac{1}{2}\varepsilon_0 c|\vec{\mathcal{E}}|^2 = \bar{I} \ . \tag{23.42}$$

The intensity can also be written,

$$\bar{I} = \frac{1}{2}\sqrt{\frac{\varepsilon_0}{\mu_0}}|\vec{\mathcal{E}}|^2 \ . \tag{23.43}$$

where the factor $\sqrt{\mu_0/\varepsilon_0}$ is called *impedance of free space*, because it has the unit of a resistance and the last equation has the same form as the power dissipated in a resistor,

$$W = \frac{1}{2}\frac{V^2}{R} \ . \tag{23.44}$$

23.2.2 Black body radiation

We now want to calculate the energy density inside the cavity before using the result to describe the interaction between light and a sample of two-level atoms located inside the cavity. The basic idea is to say that the electrons inside the conducting surface of the cavity oscillate because of thermal motion. The oscillation generates a dipolar radiation leading to stationary waves developing within the cavity. As the walls of the cavity are conducting, the electric field $\vec{\mathcal{E}}$ must disappear inside the wall and on its surfaces. The task is now twofold: first count the number of possible standing waves, which satisfy the boundary conditions as a function of frequency; second, determine the energy for each wave and then calculate the spectral distribution of the energy within the cavity.

The equations describing the radiated energy in free space are,

$$\nabla^2\vec{\mathcal{E}} = \frac{1}{c^2}\frac{\partial^2\vec{\mathcal{E}}}{\partial t^2} \qquad \text{and} \qquad \nabla\cdot\vec{\mathcal{E}} = 0 \ . \tag{23.45}$$

The stationary waves solutions separate into terms oscillating in time and in space. Now, respecting the boundary conditions for a three-dimensional box of length L, we have for the components of $\vec{\mathcal{E}}$ [7],

$$\begin{aligned}\vec{\mathcal{E}}(\mathbf{r},t) = e^{-\imath\omega t}[&\hat{\mathbf{e}}_x\cos(k_x x)\sin(k_y y)\sin(k_z z)\\ &+\hat{\mathbf{e}}_y\sin(k_x x)\cos(k_y y)\sin(k_z z)\\ &+\hat{\mathbf{e}}_z\sin(k_x x)\sin(k_y y)\cos(k_z z)] \ ,\end{aligned} \tag{23.46}$$

[7] See script on *Electrodynamics* (2023).

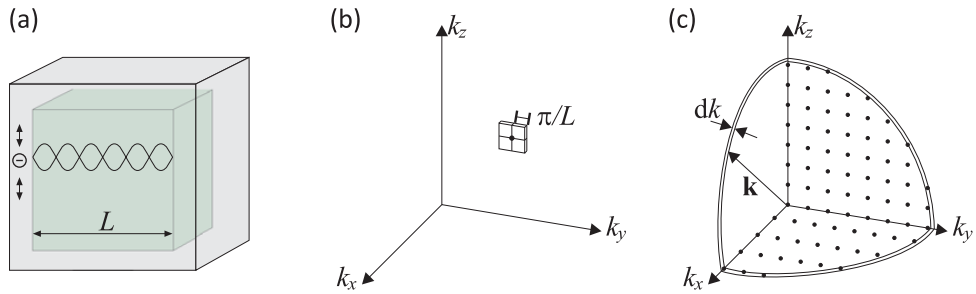

Figure 23.8: (a) Cavity in position space showing the thermal motion of the electrons inside the walls. (b and c) Density-of-states in a cavity in momentum space.

with the components,

$$k_x = \frac{\pi n_x}{L} \qquad \text{for} \qquad n_x = 0, 1, 2, ... \tag{23.47}$$

and similar for k_y and k_z. Note, that for each component $\mathcal{E}_{x,y,z}$ the transverse amplitudes disappear in 0 and L. By inserting this solution into Helmholtz's equation (23.45), we obtain,

$$k_x^2 + k_y^2 + k_z^2 = \frac{\omega^2}{c^2} \ . \tag{23.48}$$

The states $k_{x,y,z}$ (enumerated by integer numbers $n_{x,y,z}$) form a three-dimensional orthogonal lattice of points in space $\mathbf{k}$ separated by a distance along the axes k_x, k_y, k_z of $\frac{\pi}{L}$, as shown in Fig. 23.8. In principle, the number of states that can be placed within a sphere of radius k in the momentum space is,

$$N = \int_{\text{sphere}} dn_x dn_y dn_z \ . \tag{23.49}$$

However, the periodic boundary conditions for $|\mathbf{k}|$ limit the components k_x, k_y, k_z to positive values ($n \geq 0$), that is, the volume under consideration is limited to an octant. On the other hand, we must multiply the number of states by two because of the degeneracy of polarizations. Hence,

$$4N = \int_0^n 4\pi n^2 dn = \left(\frac{L}{\pi}\right)^3 \int_0^k 4\pi k^2 dk = \frac{4L^3}{\pi^2}\frac{k^3}{3} = \frac{4L^3\omega^3}{3\pi^2 c^3} \ . \tag{23.50}$$

With this, we obtain the *mode density*,

$$\frac{N}{L^3} = \frac{\omega^3}{3\pi^2 c^3} \ . \tag{23.51}$$

The *spectral density of modes* ϱ can be given in several units,

$$\int \varrho(n) dn = \int \varrho(k) dk = \int \varrho(\omega) d\omega = \frac{N}{L^3} \ , \tag{23.52}$$

such that,

$$\boxed{\varrho(n) = \frac{\pi n^2}{L^3} \qquad \text{or} \qquad \varrho(k) = \frac{k^2}{\pi^2} \qquad \text{or} \qquad \varrho(\omega) = \frac{\omega^2}{\pi^2 c^3}} \ . \tag{23.53}$$

The density of oscillating modes within the cavity grows like the square of the frequency. Now, the mean energy per mode in a sample of oscillators in thermal equilibrium is, following the equipartition law, equal to,

$$\bar{E} = k_{\mathrm{B}} T \ , \tag{23.54}$$

where k_{B} is the Boltzmann constant. We conclude that the *spectral energy density* $u_{\mathrm{RJ}}(\omega)$ in the cavity is,

$$\boxed{u_{\mathrm{RJ}}(\omega) d\omega = k_{\mathrm{B}} T \varrho(\omega) d\omega = k_{\mathrm{B}} T \frac{\omega^2}{\pi^2 c^3} d\omega} \ . \tag{23.55}$$

This law is known as the *Rayleigh-Jeans law* of *black-body radiation*. As seen in Fig. 23.9, this law suggests the physically impossible fact, called *ultraviolet catastrophe*, that the energy storage in the cavity grows without limits like the square of frequency.

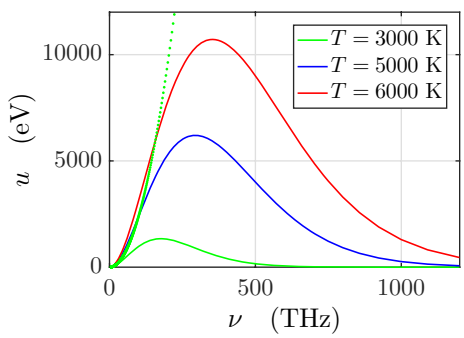

Figure 23.9: (code) Spectral energy density following Rayleigh-Jeans' and Planck's laws.

23.2.3 Planck's distribution of modes

We obtained the result (23.54) by multiplying the number of modes with the mean energy per mode. As there is no doubt about our method of counting the modes, the problem with the ultraviolet catastrophe can only root in the use of the equipartition principle for assigning energy to the oscillators.

Planck's idea to solve this problem was to first consider the probability distribution for exciting the modes (thermal states) for a sample of oscillators in thermal equilibrium at temperature T. This probability distribution p comes from mechanical statistics and can be written in terms of the *Boltzmann factor*, $e^{-E_n/k_{\mathrm{B}}T}$, and the partition function $q = \sum_{n=0}^{\infty} e^{-E_n/k_{\mathrm{B}}T}$ as,

$$p_n = \frac{e^{-E_n/k_{\mathrm{B}}T}}{q} \ . \tag{23.56}$$

Now Planck hypothesized that the energy be quantized, that is, it must be assigned in discrete portions, proportional to the frequency, such that,

$$\boxed{E_n = n\hbar\omega} \ , \tag{23.57}$$

where $n = 0, 1, 2, ..$ and the proportionality constant $\hbar$ is called *Planck's constant*. With the abbreviation $Z \equiv e^{-\hbar\omega/k_\mathrm{B}T}$ and using the rule $\sum_{n=0}^{\infty} Z^n = (1-Z)^{-1}$, we find the average number,

$$\bar{n} = \sum_n n p_n = (1-Z)\sum_n n Z^n = (1-Z)Z\frac{\partial}{\partial Z}\sum_n Z^n = \frac{Z}{1-Z} = \frac{1}{e^{\hbar\omega/k_\mathrm{B}T}-1} \ . \tag{23.58}$$

The probability of occupancy of state n is,

$$p_n = (1-Z)Z^n = \frac{\bar{n}^n}{(1+\bar{n})^{1+n}} \ , \tag{23.59}$$

and the average energy is,

$$\bar{E} = \sum_n E_n p_n = \sum_n n\hbar\omega e^{-n\hbar\omega/k_\mathrm{B}T} = \frac{\hbar\omega}{e^{\hbar\omega/k_\mathrm{B}T}-1} \ , \tag{23.60}$$

in contrast to the initial assumption (23.55).

Finally, we obtain Planck's expression for the energy density inside the cavity by replacing the energy (23.60) for the factor $k_\mathrm{B}T$ in Rayleigh-Jeans' law (23.55),

$$\boxed{u_P(\omega)d\omega = \bar{E}\varrho(\omega)d\omega = \frac{\omega^2}{\pi^2 c^3}\frac{\hbar\omega}{e^{\hbar\omega/k_\mathrm{B}T}-1}d\omega} \ . \tag{23.61}$$

This result, drawn in Fig. 23.9, is much more satisfactory, because now the energy density has an upper bound, and it coincides with the results of experiments. For high temperatures or low excitation energies, $\hbar\omega \ll k_\mathrm{B}T$, Planck's distribution converges to that of Rayleigh-Jeans', $u_P(\omega) \to u_\mathrm{RJ}(\omega)$.

Note, that the form of the expression for the energy depends on the parametrization and must be derived respecting $u(\omega)d\omega = u(\lambda)d\lambda$, etc.. Often the blackbody radiation is expressed in terms of the *spectral radiance*,

$$L(\omega) \equiv \frac{c}{4\pi}u(\omega) \ , \tag{23.62}$$

which can be understood as the (isotropic) energy flux into all directions of space. Solve the Excs. 23.2.9.1 to 23.2.9.7.

23.2.4 The corpuscular nature of the photon

23.2.4.1 The photoelectric effect

Light incident on a metallic surface can expel electrons. For this to occur, the light must have a *minimum frequency*. If the frequency is below this value, there is no point in increasing the light intensity: the electrons won't be expelled. The main experimental observations are: 1. Electrons are ejected without apparent delay, i.e. it is not necessary (and it doesn't help) to accumulate a certain amount of energy. 2. Higher light intensities increase the number of electrons, but not their kinetic energy after expulsion. 3. Red light does not eject electrons, even at high intensities. 4. Weak ultraviolet light only ejects few electrons, but with high kinetic energy.

These observations challenge the classical electromagnetic model according to which the Lorentz acceleration of the electrons should be proportional to the field *amplitude*. The observations were explained by Einstein's theory of the *photoelectric effect*, which assumes the light to be quantized (unlike Planck, who preferred to quantize the process of light absorption),

$$E = h\nu \ . \tag{23.63}$$

Assuming a fixed exit work A for the extraction of an electron, we can measure the constant $\hbar$:

$$h\nu = A + \tfrac{mv^2}{2} = A + eV \qquad \rightarrow \qquad h = \frac{eV}{\nu - \nu_{\mathrm{g}}} \ . \tag{23.64}$$

The energy of the fastest electrons is measured through the decelerating voltage by varying ν and I. We will discuss the photoelectric effect quantitatively later in the Exc. 27.4.5.7.

23.2.4.2 Bremsstrahlung and the Franck-Hertz experiment

Bremsstrahlung is, in a way, the inverse process of the photoelectric effect. Here, electrons are accelerated toward a cathode. Finding a target they are rapidly decelerated, a process in which they emit a continuous spectrum of X-rays (in addition to characteristic lines attributed to electronic transitions in the target atoms). For any given kinetic energy the spectra have a red threshold corresponding to photons that receive the entire energy of the electron.

In the *Franck-Hertz experiment* free electrons produced in a plasma are accelerated by a strong electric field. Having traveled a sufficiently long distance they have acquired enough kinetic energy to excite electronic transitions in the atoms of the plasma. When an excitation occurs, the electron suddenly loses all its energy and must be accelerated again, starting from rest, before it can excite another atom.

23.2.4.3 Radiative pressure and Compton scattering

When light is scattered from a particle, it transfers momentum to it called *photonic recoil*. This effect, known as *radiation pressure*, occurs for example in *Compton scattering*.

X-rays scattered by the electrons of a carbon target are red-shifted by an amount, which increases with the scattering angle. This is the *Compton effect*. The data are understood assuming a corpuscular nature of light and applying the laws of conservation of energy and momentum to the collision processes between photons and electrons. The scattered photon sees its energy reduced and therefore its wavelength increased, as we have already seen in Sec. 17.2.3.

In a material where there are free electrons, this effect will occur at all photon energies. In other materials, it is only observed with high energy photons. For high energy photons, exceeding the atomic binding energy, the electrons can be considered free such that, in the scattering process, the photon is able to eject the electron from its atom. The photon receives the remaining energy and is deviated, such that the overall momentum of the system is conserved. The loss of energy for the photon results in a spectral shift to the red during its passage through the material.

Photons of visible light, on the other hand, do not have enough energy to eject bound electrons. In this case, the mass in the Compton formula must be replaced by the atomic mass, such that the spectral displacement becomes much smaller. This limit, which involves bound electrons, is that of Thomson and Rayleigh scattering.

The relevance of this effect lies in the fact that it shows that light exhibits properties commonly attributed to corpuscles, since Thomson's scattering model, based on the classical theory of charged particles accelerated by electromagnetic fields, can not explain any spectral shift. Compton scattering is discussed quantitatively in Exc. 17.2.7.6.

23.2.5 Einstein's transitions rates

Bohr's atom model explained for the first, time how light interacts with matter: Atoms have discrete excitation levels, and they absorb and emit discrete energy packets $\hbar\omega$. Unfortunately, Bohr's model can not predict transition rates. Here, Einstein helped out by developing a useful theory (see Fig. 23.10).

Figure 23.10: Bohr model and Einstein rate diagram.

We consider a two-level atom or a sample of atoms within a conducting cavity. We have N_1 atoms in the lower energy state E_1 and N_2 in the upper state E_2. Light interacts with these atoms through stimulated resonant absorption and emission. The rates, $B_{12}u(\omega)$ and $B_{21}u(\omega)$ are proportional to the energy spectral density $u(\omega)$ of the cavity modes. The central idea of Einstein is to postulate that atoms in the higher state can emit light spontaneously at a rate A_{21}, which depends only on the density of modes of the cavity, i.e. the volume of the cavity, but not the energy of the field of radiation. With the Einstein coefficients we can formulate valid rate equations in situations, where the spectral distribution of the radiation is wider than the spectral width of the atomic transition and where the spectral distribution of the light flux from the source, $\bar{I}(\omega)$, is weak compared to the saturation intensity of the atomic transition. Even if modern light sources generally have very narrow and intense spectral emission bands, Einstein's coefficients are often used in the spectroscopic literature to characterize the light-matter interaction with atoms and molecules.

The Einstein rate equations describe the energy flux between atoms and the optical modes of the cavity,

$$\begin{aligned}\frac{dN_1}{dt} = -\frac{dN_2}{dt} &= -R_{1\to 2} + R_{2\to 1} + \mathcal{S}_{2\to 1} \\ &= -N_1 B_{12} u(\omega) + N_2 B_{21} u(\omega) + N_2 A_{21}\ .\end{aligned} \tag{23.65}$$

$R_{1\to 2}$ is the *absorption rate*, $R_{2\to 1}$ the *stimulated emission rate* and $\mathcal{S}_{2\to 1}$ the *spontaneous emission rate*. The assumption of a third type of transition, called spontaneous

emission, is necessary, if $B_{12} = B_{21}$ but $N_1 > N_2$ in thermal equilibrium. In thermal equilibrium we have the condition of stationarity, $\frac{dN_1}{dt} = -\frac{dN_2}{dt} = 0$ for a given energy density value $u(\omega) = u_{th}(\omega)$, such that,

$$u_{th}(\omega) = \frac{A_{21}}{\left(\frac{N_1}{N_2}\right) B_{12} - B_{21}} \ . \tag{23.66}$$

The *Boltzmann distribution law* controlling the distribution of the number of atoms in the lower and upper states is given by,

$$\frac{N_1}{N_2} = \frac{g_1}{g_2} e^{-(E_1 - E_2)/k_{\rm B}T} \ , \tag{23.67}$$

where $g_{1,2}$ are the degeneracies of the lower and upper states and $E_2 - E_1 = \hbar\omega_0$. We find,

$$u_{th}(\omega) = \frac{A_{21}}{\frac{g_1}{g_2} e^{\hbar\omega_0/k_{\rm B}T} B_{12} - B_{21}} \ . \tag{23.68}$$

But this result must be consistent with Planck's distribution (23.61). Therefore, by comparing this equation with the equation (23.68), it must be that,

$$\frac{g_1}{g_2} \frac{B_{12}}{B_{21}} = 1 \ . \tag{23.69}$$

and also,

$$\frac{A_{21}}{B_{21}} = \frac{\hbar\omega_0^3}{\pi^2 c^3} \ . \tag{23.70}$$

This equation shows that, once we know one of the three transition rates, we can always calculate the others.

It is useful to compare the rate A_{21} with B_{21} from the equation (23.68) inserting the equation (23.69),

$$\frac{A_{21}}{B_{21} u_{th}(\omega)} = e^{\hbar\omega_0/k_{\rm B}T} - 1 \ . \tag{23.71}$$
