Figure 33.21: (a) Bound state for $\ell = 0$. (b) Bound state for $\ell > 0$ in a potential including the centrifugal barrier $\hbar^2\ell(\ell+1)/2mr^2$. (c) Resonances for $\ell = 0$ are broad and possibly not defined with $\Gamma_r > E_r$. A defined resonance with $\Gamma_r < E_r$ requires that $|\partial_E \alpha_0|$ be large. (d) For $\ell > 0$ we obtain narrow resonances called *shape resonance*s, because the decay of the state is suppressed by the centrifugal barrier.

which gives rise to an attractive and a repulsive potential. The R^{-3} dependence of the resonant dipole interaction means that the associated potentials greatly modify the asymptotic level even at internuclear distances where the ground state van der Waals potential is still relatively shallow. The photoassociation process involves a slow approach of two identical ground state atoms. A mono-modal optical field, tuned to the red of the atomic resonance, is applied. When the two atoms reach an internuclear distance R_C such that the energy of the applied field $\hbar\omega_C$ exactly coincides with the potential difference $V_2(R_c) - V_1(R_c)$, the probability of transferring population from the fundamental molecular state to the excited molecular state is maximal. This molecular resonance is sometimes called *Condon point*. The conventional way of calculating this probability follows the procedure elaborated in Sec. ?? for a two-level atom. First, we would solve the time-independent molecular Schrödinger equation to obtain the molecular wavefunctions. Then, write down the coupled differential equations by describing the time dependence of the expansion coefficients of the relevant molecular wavefunctions, solve for the coefficients and calculate the square of their absolute values. Finally, we would need to integrate the transition probability inside a region ΔR around the Condon point, where the transition probability is not be negligible. The dressed states picture allows to reduce this rather laborious program, essentially, to a problem of a curve crossing of two levels. The bottom panel of Fig. 33.22 illustrates the photoassociation in the dressed states picture. The basis states are now product states made up of the field and the molecular levels. Furthermore, we approximate the molecular states themselves as products of atomic states. This approximation is justified by the long range, weakly perturbative influence of the van der Waals and resonant dipoles interactions. Calling the ground and excited states $|1\rangle$ and $|2\rangle$, respectively, we have

$$|1, n\rangle = |1\|1\rangle|n\rangle \ , \tag{33.192}$$

and for the field-molecule excited state

$$|2, n-1\rangle = |2\|1\rangle|n-1\rangle \ . \tag{33.193}$$

The two molecular curves intersect at the Condon point and optically couple to the applied field. This optical coupling produces an *avoided crossing* near R_C and mixes the states of the molecule-field basis. The well-known *Landau-Zener* formula (LZ) expresses the probability of traversing from one adiabatic molecular state to another as a function of the interaction strength, the relative velocity of the collision partners, and the relative slopes of the two curves. The probability of LZ is given by,

$$\exp \frac{2\pi \langle 1, n|\frac{\Omega}{2}|2, n-1\rangle}{v\left|\frac{d}{dR}\Delta V_{12}(R_C)\right|} \ , \tag{33.194}$$

where v is the relative radial velocity of the approaching particles and $\frac{d}{dR}\Delta V_{12}(R_C)$ is the difference of slopes of the two non-interacting potentials at the Condon point. The dipole-field interaction operator Ω must be taken with the dipole of the molecular transition. A reasonable approximation is to take the moment of molecular transition as twice the atomic moment and average over the whole space. The result is,

$$\exp \frac{\frac{2\pi}{\sqrt{3}} \langle 1, n|\Omega_{at}|2, n-1\rangle}{v\left|\frac{d}{dR}\Delta V_{12}(R_C)\right|} \ , \tag{33.195}$$

where Ω_{at} denotes the atomic operator of the dipole-field interaction. In the case of a crossing of an essentially flat potential V_1 and $V_2(R) = -\frac{C_3}{R}^3$, the absolute value of the derivative of the slope difference is,

$$\left|\frac{d}{dR}\Delta V_{12}(R_C)\right| = \frac{3C_3}{R_C^3} \ . \tag{33.196}$$

Resolve Exc. 33.3.13.1.

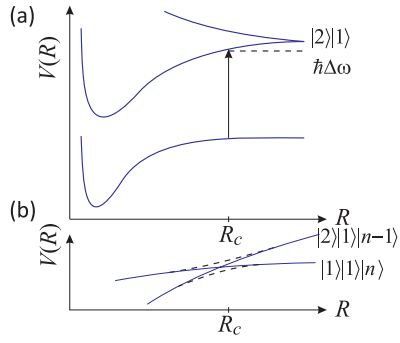

Figure 33.22: (Above) Molecular states resonantly coupled by a light field at the Condon point. (Below) Same coupling of the molecular states represented by an avoided intersection in the dressed states basis.

33.3.5 Ground state collisions

33.3.6 Hyperfine structure

We consider the scheme (32.90), we set $\mathbf{l}_j = 0$, and concentrate on s-waves, $\ell = 0$,

$$\begin{array}{ccccccc} \mathbf{s}_1 & + & \mathbf{s}_2 & = & \mathbf{S} & \xrightarrow{\hat{z}} & \mathbf{\Omega} \\ + & & + & & + & & \\ \mathbf{i}_1 & + & \mathbf{i}_2 & = & \mathbf{I} & & \\ = & & = & & = & & \\ \mathbf{f}_1 & + & \mathbf{f}_2 & = & \mathbf{f} & & \end{array} \tag{33.197}$$

At short distances the coupling $((S,I)f_1,f_2)f$ breaks up and a $((s_1,s_2)S,I)f$ coupling emerges. This does not hold for fully stretched spin states $f_1 + f_2 = f$, because f is a good quantum number at all distances (and small enough magnetic fields). In contrast m_f is a good quantum number at all distances and at all fields.

In order to obtain the potentials coupled by hyperfine interaction, we first calculate for a *single vibrational level* the relative wavefunctions $|\psi_{(f_1,f_2)f}(R)\rangle$ from the known perturbed but uncoupled potentials $V(R) + V_{hf}$, where,

$$V_{hf} = ha_{hf,1}\mathbf{s}_1\cdot\mathbf{i}_1 + ha_{hf,2}\mathbf{s}_2\cdot\mathbf{i}_2 \ . \tag{33.198}$$

The antisymmetric part is negligible [1339], so that $V_{hf} \simeq \frac{1}{2}ha_{hf,1}\mathbf{S}\cdot\mathbf{i}_1 + \frac{1}{2}ha_{hf,2}\mathbf{S}\cdot\mathbf{i}_2$. Then couple the channels via,

$$|\psi_{(S,I)f}(R)\rangle = A\sum_{f_1,f_2}\sqrt{\hat{S}\hat{I}\hat{f}_1\hat{f}_2}\begin{Bmatrix} s_1 & s_2 & S \\ i_1 & i_2 & I \\ f_1 & f_2 & f \end{Bmatrix}|\psi_{(f_1,f_2)f}(R)\rangle \tag{33.199}$$

$$|\psi_{(f_1,f_2)f}(R)\rangle = A^{-1}\sum_{S,I}\sqrt{\hat{S}\hat{I}\hat{f}_1\hat{f}_2}\begin{Bmatrix} s_1 & s_2 & S \\ i_1 & i_2 & I \\ f_1 & f_2 & f \end{Bmatrix}|\psi_{(S,I)f}(R)\rangle \ .$$

which satisfies the orthogonality relation (see Tables in 28.2).

33.3.7 Scattering length in specific channels

The scattering length in specific channels can be expressed via singlet and triplet scattering length,

$$a_{|f_1,m_{f1}\rangle+|f_2,m_{f2}\rangle} = P_{S=0}a_s + P_{S=1}a_t \ . \tag{33.200}$$

The projectors are $P_S = |\langle S|(f_1f_2)f\rangle|$. According to [213] or [889] the recoupling from the uncoupled hyperfine representation into the short range representation is

given by,

$$\langle Sm_S\ Im_I\ \ell' m_{\ell'}|f_1 m_{f1}\ f_2 m_{f2}\ \ell m_\ell\rangle = \delta_{\ell\ell'}\delta_{m_\ell m'_\ell}\sum_{f,m_f}\langle Sm_S\ Im_I|fm_f\rangle\langle f_1 m_{f1}\ f_2 m_{f2}|fm_f\rangle\times \tag{33.201}$$

$$\times\begin{Bmatrix} s_1 & s_2 & S \\ i_1 & i_2 & I \\ f_1 & f_2 & f \end{Bmatrix}\sqrt{\hat{S}\hat{I}\hat{f}_1\hat{f}_2}\left(\frac{1-(1-\delta_{f_1 f_2})(-1)^{S+I+\ell}}{\sqrt{2-\delta_{f_1 f_2}}}\right)\ .$$

The last bracket is dropped for unsymmetrized recoupling. Calculations have been done for ^{87}Rb collisions and for ^{6}Li^{87}Rb collisions. It turns out that the fully stretched states have pure triplet character.

Note that in strong magnetic fields the coupling $(i_1, i_2)I$ easily breaks up, and the recoupling to be considered is rather $\langle Sm_S\ m_{i1}\ m_{i2}\ \ell' m_{\ell'}|f_1 m_{f1}\ f_2 m_{f2}\ \ell m_\ell\rangle$.

33.3.8 Hyperfine coupling in magnetic fields

33.3.8.1 Zeeman splitting of bound states

The splitting of the bound state is described by [1339],

$$\begin{aligned} H^+_{int} &= V^+_{hf} + V_{Zeeman} \\ &= E_B + \frac{1}{2}ha_{hf,1}\mathbf{S}\cdot\mathbf{i}_1 + \frac{1}{2}ha_{hf,2}\mathbf{S}\cdot\mathbf{i}_2 + \mu_B\mathbf{B}(g_S\mathbf{S} + g_1\mathbf{i}_1 + g_2\mathbf{i}_2)\ , \end{aligned} \tag{33.202}$$

such that,

$$\begin{aligned} &\langle m'_{i1}m'_{i2}m'_S|H_{hfs}+H_B|m_S m_{i2}m_{i1}\rangle \\ &= E_B + (g_S m_S + g_{i1}m_{i1} + g_{i2}m_{i2})\mu_B B\delta_{m'_{i1}\ m_{i1}}\delta_{m'_{i2}\ m_{i2}}\delta_{m'_S\ m_S} \\ &+ \tfrac{1}{2}h(a_{hf,1}m_{i1}m_S + a_{hf,2}m_{i2}m_S)\delta_{m'_{i1}\ m_{i1}}\delta_{m'_{i2}\ m_{i2}}\delta_{m'_S\ m_S} \\ &+ \tfrac{1}{4}ha_{hf,1}(i_{1,+}S_-\delta_{m'_S\ m_S+1}\delta_{m'_{i1}\ m_{i1}-1} + i_{1,-}S_+\delta_{m'_{i1}\ m_{i1}-1}\delta_{m'_S\ m_S+1})\delta_{m'_{i2}\ m_{i2}} \\ &+ \tfrac{1}{4}ha_{hf,2}(i_{2,+}S_-\delta_{m'_S\ m_S+1}\delta_{m2\ m_{i2}-1} + i_{2,-}S_+\delta_{m'_{i2}\ m_{i2}-1}\delta_{m'_S\ m_S+1})\delta_{m'_{i1}\ m_{i1}}\ . \end{aligned} \tag{33.203}$$

For an example on how to evaluate the matrix at various magnetic fields and obtain the hyperfine structure of a bound state in the Zeeman and the Paschen-Back regime, we propose the systems ^{6}Li^{23}Na and ^{6}Li^{87}Rb.

33.3.8.2 Magnetic dipole interaction

Reads,

$$V_{dd} = \frac{\mu_0}{4\pi R^3}\left[\mu_1\cdot\mu_1 - 3(\mu_2\cdot\mathbf{R})(\mu_2\cdot\mathbf{R})\right] \tag{33.204}$$

neglecting nuclear spin.

33.3.8.3 Second-order spin-orbit interaction

First-order spin-orbit interaction disappears for ground state collisions. But second-order spin-orbit interaction may occur. These lead to inelastic losses (see next section).

33.3.8.4 Selection rules

The selection rules for bosonic homonuclear collisions are,

$$\begin{aligned} S &= 0, .., s_1 + s_2 \\ I &= 0, .., i_1 + i_2 \\ f_j &= |i_j - s_j|, .., i_j + s_j \\ |I - S| \leq F &\leq I + S \\ |f_1 - f_2| \leq F &\leq f_1 + f_2 \\ (-1)^I &= (-1)^S \quad \text{for all } F \\ (-1)^{f_1} &= -(-1)^{f_2} \quad \text{for all odd } F \ . \end{aligned} \tag{33.205}$$

What does they look like for fermions? What does they look like for heteronuclear collisions?

33.3.9 Inelastic collisions

33.3.9.1 Spin changing collisions

These have their origin in *spin exchange* and spin dipole-dipole processes. Spin exchange occurs when the colliding electronic clouds overlap. At short distances the $((S, I)f_1, f_2)f$ breaks up and a $((s_1, s_2)S, I)f$ coupling remixes, as shown in Exc. 32.3.5.1. Hence, collisions between atoms $|f_1, m_{f1}\rangle|f_2, m_{f2}\rangle$ are subject to spin exchange induced by coupling of the spin states via the exchange interaction, e.g. $|2, 1\rangle|2, 1\rangle \to |2, 2\rangle|2, 0\rangle$. Typical exchange rates are on the order of $10^{-10}\,\mathrm{cm}^3/\mathrm{s}$.

Since f is a good quantum number at all distances (for $B = 0$), spin exchange processes conserve ℓ and f. Hence, the fully stretched spin states $f_1 + f_2 = f$ cannot decay into other states, except by higher-order processes, such as dipolar relaxation. Consequently, the relaxation rates for $|2, 2\rangle + |2, 2\rangle$ or $|1, -1\rangle + |1, -1\rangle$ states are only on the order of $10^{-15}\,\mathrm{cm}^3/\mathrm{s}$.

The cross section for inelastic spin exchange collisions is [1367, 296],

$$\sigma = M_{if}\pi(a_t - a_s)^2 \ , \tag{33.206}$$

where,

$$\begin{aligned} M_{if} &= \left[\sum_{m_S, I, m_I} (C_{S=0} C'_{S=0} - C_{S=1} C'_{S=1}) \right]^2 \\ C &= \langle S, m_S; I, m_I | F_1 m_1; F_2 m_2 \rangle \ . \end{aligned} \tag{33.207}$$

See also [1207]. The reason for the above dependence can be understood as follows. a_s and a_t determine the energy of the last bounds states of the singlet and triplet potentials. The more those energies are different, the stronger the coupling $\propto |E_t - E_s|^{-1}$. An alternative, physical picture is given in [215].

33.3.9.2 Dipolar relaxation

The fully stretched spin states, such as ^{87}Rb $|f = 2, m_f = 2\rangle$ are expected to be quite stable. However, relativistic effects (retardation?) (and 2^{nd} order spin-orbit coupling) break the degeneracy of the molecule-fixed projection $|\Omega| = 0, 1$ of the $^3\Sigma$ potential [889]. When the atoms approach their spins recouple, i.e. from $[(s_1, i_1)f_1\ ,\ (s_2, i_2)f_2]f$ towards $[(s_1, s_2)s\ ,\ (i_1, i_2)i]f$ as described by the $9j$ coefficients Eq. (33.197). Due to the symmetry of the problem, f and its projection m_f are good quantum numbers at all distances. However, if there is a higher-order admixture of the orbit l_j, the symmetry is broken, and the quantum number depends on the coupling schemes. Consequently, transitions between different m_f become possible, i.e. dipolar relaxation may change f, m_f or $\ell = 0$, e.g. a collision can be s-wave in the entrance and d-wave in the exit channel.

33.3.9.3 Three-body collisions

The trapped low-field seeking alkali gases are metastable versus 3-body recombination. 3-body recombination is the combination of two colliding atoms to a dimer in presence of a third atom receiving the excess energy as kinetic energy and results in trap loss of the molecule and of the atom. They are suppressed as the gas gets more and more dilute since the rate goes like n^3. There might be interesting 3-body resonance phenomena like the *Efimov state* predicted for Helium droplets [407], [801] and recently seen in experiment [750, 1267, 186, 828].

3-body recombination is in contrast to the more controlled way of creating molecules via photoassociation or coherent free-bound coupling.

Ultracold collisions are crucial for BEC. They provide the thermalizing elastic collisions necessary for evaporative cooling, they are the cause for the condensate self-energy and give rise to nonlinearities in the condensate dynamics. But they are also interesting by themselves. The spectrum of two-body collisions exhibits interesting features like shape- and Feshbach resonances [300, 648]. Their analysis facilitates detailed conclusions on the nature of the interaction potentials. Three body collisions are important to investigate, because they constitute a decay mechanism of the intrinsically metastable system that represents a trapped Bose-gas.

Three body collisions are not a quantum statistical effect and don't require the presence of a BEC, but they occur only at very high densities comparable to those necessary for BEC. It should be possible to detect them in *photoassociation* (PA) spectra. Photoassociation provides a tool to explore the level structure of excited states by shining in a laser with frequency ν tuned between the colliding channel and a vibrational bound level of the excited state potential. Since the excited state preferentially decays into the continuum, where the atoms have high kinetic energy, the transition rate may be monitored via trap losses. Or we can shine in an additional laser that further excites the excited atoms into the ionized continuum where they can be registered by an ion detector.

Three-body photoassociation processes should reveal themselves by additional lines in the two-body photoassociation spectra. Those lines should only appear at very high densities and their strength should scale as the density cubed,

$$Rb + Rb + Rb + h\nu \rightarrow Rb_3^* \ . \tag{33.208}$$

33.3.9.4 Other processes

Majorana spin flips and collisions involving higher partial waves ℓ can eventually lead to spin relaxation. In Eq. (32.90) we see that f is not necessarily a good quantum number in contrast to F, $|2,2\rangle|2,2\rangle \to |2,1\rangle|2,0\rangle + E_{rot}$. However, the particles must tunnel across the centrifugal barrier, which sets temperature constraints.

33.3.9.5 Collisions between fermions

Very cold three-body collisions are suppressed for fermions, because two of them necessarily must have the same quantum state, which violates the Pauli exclusion principle. This is useful for employing Feshbach resonances to form molecular BECs made of fermions.

33.3.10 Excited states collisions

33.3.10.1 Adiabatic potentials

We consider the scheme (32.90), we set $\mathbf{I} = 0$, and we concentrate on s-waves, $\ell = 0$,

$$\begin{array}{ccccccc} \mathbf{l}_1 & + & \mathbf{l}_2 & = & \mathbf{L} & \xrightarrow{\hat{z}} & \mathbf{\Lambda} \\ + & & + & & + & & + \\ \mathbf{s}_1 & + & \mathbf{s}_2 & = & \mathbf{S} & \xrightarrow{\hat{z}} & \mathbf{\Sigma} \\ = & & = & & = & & = \\ \mathbf{j}_1 & + & \mathbf{j}_2 & = & \mathbf{j} & \xrightarrow{\hat{z}} & \mathbf{\Omega} \end{array} \tag{33.209}$$

The *spin-orbit interaction* splits the potential curves. The recoupling is described by,

$$|\psi_{(L,S)j}(R)\rangle \sim \sum_{j_1,j_2} \sqrt{\hat{L}\hat{S}j_1j_2} \begin{Bmatrix} l_1 & l_2 & L \\ s_1 & s_2 & S \\ j_1 & j_2 & j \end{Bmatrix} |\psi_{(j_1,j_2)j}(R)\rangle \ . \tag{33.210}$$

33.3.10.2 Homonuclear collisions

Let us consider the example of the fine structure in homonuclear ^{87}Rb collisions. Without hyperfine, rotational and Zeeman splitting the recoupling goes like illustrated in Fig. 33.23.

From Fig. 33.23 we see that the molecular states are remixed at long range: Every state $0_g^-, 0_u^-, 0_g^+, 0_u^+, 1_g, 1_u, 2_g, 2_u$ has several molecular states to which it connects, e.g. 0_g^- connects within the fine structure to $(2)^3\Sigma_g^+$ and $(2)^3\Pi_g$. Those multiplets form a closed interacting subspace. According to Movre and Pichler [930, 1305] we

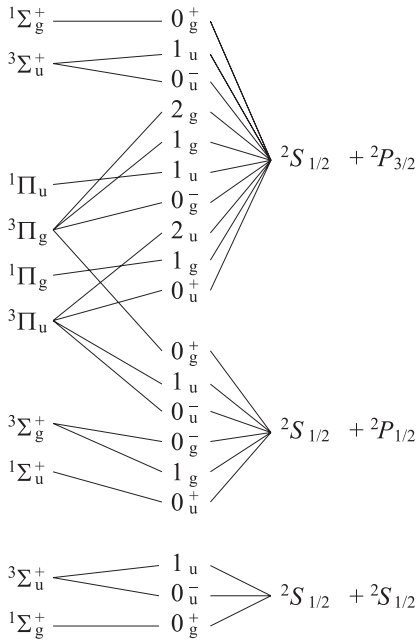

Figure 33.23: Movre coupling scheme.

get with $\Delta = E(^2P_{3/2}) - E(^2P_{1/2}) = \frac{3}{2}A_{so}$,

$$0_\sigma^- = \begin{pmatrix} E(^3\Pi_\sigma) - \frac{1}{3}\Delta & \frac{\sqrt{2}}{3}\Delta \\ -\frac{\sqrt{2}}{3}\Delta & E(^3\Sigma_\sigma^+) \end{pmatrix} \quad , \quad 0_\sigma^+ = \begin{pmatrix} E(^3\Pi_\sigma) - \frac{1}{3}\Delta & -\frac{\sqrt{2}}{3}\Delta \\ -\frac{\sqrt{2}}{3}\Delta & E(^1\Sigma_\sigma^+) \end{pmatrix} \tag{33.211}$$

$$1_\sigma = \begin{pmatrix} E(^3\Pi_\sigma) & \frac{1}{3}\Delta & -\frac{1}{3}\Delta \\ \frac{1}{3}\Delta & E(^1\Pi_\sigma) & -\frac{1}{3}\Delta \\ -\frac{1}{3}\Delta & -\frac{1}{3}\Delta & E(^3\Sigma_\sigma^+) \end{pmatrix} \quad , \quad 2_\sigma = \left(^3\Pi_\sigma\right) \ .$$

At short range the potentials approximately go like,

$$\begin{aligned} E(^1\Sigma_g^+), E(^3\Sigma_u^+) &\propto 2C_3/R^3 \\ E(^1\Pi_u), E(^3\Pi_g) &\propto C_3/R^3 \\ E(^1\Pi_g), E(^3\Pi_u) &\propto -C_3/R^3 \\ E(^1\Sigma_u^+), E(^3\Sigma_g^+) &\propto -2C_3/R^3 \ . \end{aligned} \tag{33.212}$$

Inserting the short range potentials and defining $X = \sigma C_3/3\Delta R^3$, $Y = E/\Delta$ and

$\sigma = +$ for g and $-$ for u,

$$0^-_\sigma = \begin{pmatrix} 3X+\frac{1}{3} & \frac{\sqrt{2}}{3} \\ \frac{\sqrt{2}}{3} & -6X+\frac{2}{3} \end{pmatrix} \quad , \quad 0^+_\sigma = \begin{pmatrix} 3X+\frac{1}{3} & \frac{\sqrt{2}}{3} \\ \frac{\sqrt{2}}{3} & 6X+\frac{2}{3} \end{pmatrix} \tag{33.213}$$
$$1_\sigma = \begin{pmatrix} 3X+\frac{1}{3} & \frac{1}{3} & -\frac{1}{3} \\ \frac{1}{3} & -3X+\frac{1}{3} & -\frac{1}{3} \\ -\frac{1}{3} & -\frac{1}{3} & -6X+\frac{2}{3} \end{pmatrix} \quad , \quad 2_\sigma = (3X+1) \; .$$

Note that the structure looks very much like the transition from the Zeeman to the Paschen-Back regime, where X plays the role of the magnetic field and Y the level shift. The characteristic equations are,

$$\begin{aligned} Y^2 - (1-3X)Y - 18X^2 &= 0 \quad \text{for} \quad 0^-_\sigma \\ Y^2 - (1+9X)Y + (4X+18X^2) &= 0 \quad \text{for} \quad 0^+_\sigma \\ Y^3 + (-2+6X)Y^2 + (1-8X-9X^2)Y + (2X+6X^2-54X^3) &= 0 \quad \text{for} \quad 1_\sigma \\ Y - (1+3X) &= 0 \quad \text{for} \quad 2_\sigma \end{aligned} \tag{33.214}$$

33.3.11 Heteronuclear collisions

For a collision in the channel ^{6}Li P ^{87}Rb S we get the $\{9j\}$-symbol,

$$\begin{Bmatrix} l_6 & l_{87} & L \\ s_6 & s_{87} & S \\ j_6 & j_{87} & j \end{Bmatrix} = \begin{Bmatrix} 0 & 1 & 1 \\ \frac{1}{2} & \frac{1}{2} & S \\ \frac{1}{2} & j_{87} & j \to \Omega \end{Bmatrix} \; . \tag{33.215}$$

We thus expect a fine structure $j_{87} = \frac{1}{2}, \frac{3}{2}$ at long range and exchange interactions $S = 0, 1$ at short range. For the projection onto the internuclear axis $|L-S| \leq \Omega \leq L+S$.

Let $V_k(R)$ be the uncoupled potentials and,

$$\Delta_{kl}(R) = D_{kl} + A_{kl}\left([1 - e^{-B_{kl}(R-R_{kl})}]^2 - 1\right) \tag{33.216}$$

the spin-orbit functions modeled as Morse potentials, where D_{kl} is related to the fine-structure splitting, $D_{kl} = \frac{1}{3}(E_k - E_l)$, for diagonal and, $D_{kl} = \frac{\sqrt{2}}{3}(E_k - E_l)$, for off-diagonal elements. For heteronuclear molecules like ^{6}Li^{87}Rb we have matrices like [129, 128],

H	$\vert^3\Sigma^+\rangle$	$\vert^3\Pi\rangle$	$\vert^1\Sigma^+\rangle$	$\vert^3\Pi\rangle$	$\vert^3\Sigma^+\rangle$	$\vert^1\Pi\rangle$	$\vert^3\Pi\rangle$	$\vert^3\Pi\rangle$
$\langle^3\Sigma^+_{\Omega=0^-}\vert$	$V(^3\Sigma)$	$\Delta_{cb}\sqrt{2}$						
$\langle^3\Pi_{\Omega=0^-}\vert$	$\Delta_{cb}\sqrt{2}$	$V(^3\Pi) - \Delta_{bb}$						
$\langle^1\Sigma^+_{\Omega=0^+}\vert$			$V(^1\Sigma)(-2\Delta_{bb})$	$-\Delta_{bb}$				
$\langle^3\Pi_{\Omega=0^+}\vert$			$-\Delta_{bb}$	$V(^3\Pi)\,(+\Delta_{bb})$				
$\langle^3\Sigma^+_{\Omega=1}\vert$					$V(^3\Sigma)$	Δ_{cB}	Δ_{cb}	
$\langle^1\Pi_{\Omega=1}\vert$					Δ_{cB}	$V(^1\Pi)$	$-\Delta_{bB}$	
$\langle^3\Pi_{\Omega=1}\vert$					Δ_{cb}	$-\Delta_{bB}$	$V(^3\Pi)$	
$\langle^3\Pi_{\Omega=2}\vert$								$V(^3\Pi) + \Delta_{bb}$

(33.217)

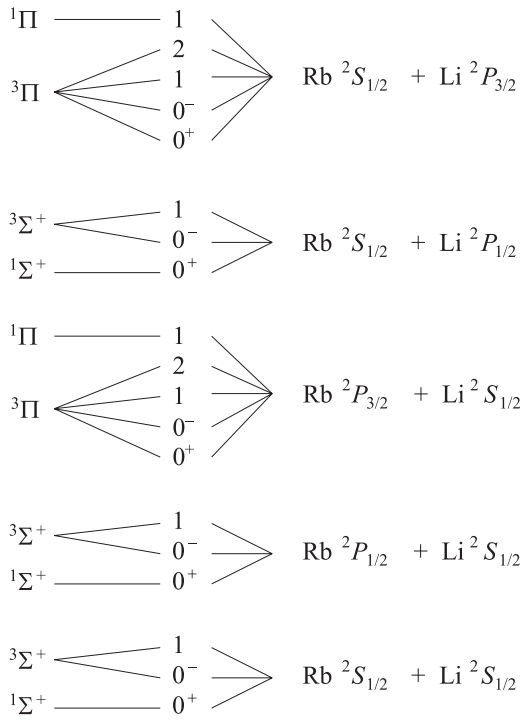

Figure 33.24: Movre type spin-orbit recoupling scheme for heteronuclear molecules.

for every fine structure. For example, there is a matrix for the two ^{6}Li $S_{1/2}$ ^{87}Rb$P_{1,3/2}$ asymptotes and another one for the ^{6}Li $P_{1/2,3/2}$ ^{87}Rb S_1 asymptotes. Additional terms enter via rotational effects [129].

Concretely,

$$\begin{aligned}
\Delta_{bb}(R\to\infty) &= \frac{1}{3}(E_{3/2}-E_{1/2}) \\
\Delta_{cB}(R\to\infty) &= \frac{1}{3}(E_{3/2}-E_{1/2}) \\
\Delta_{bB}(R\to\infty) &= \frac{1}{3}(E_{3/2}-E_{1/2}) \\
\Delta_{cb}(R\to\infty) &= \frac{1}{3}(E_{3/2}-E_{1/2})\ .
\end{aligned} \tag{33.218}$$

33.3.11.1 Inelastic trap losses

Between ground and excited states *fine changing collision*s and *radiative escape* are possible. Between two ground states only *hyperfine changing collision*s may occur.

The nature of the collision process, whether it is a one- [14], two-, or three-body collision, reveals itself via the temporal behavior of trap losses. Using the abbrevia-

[14] By one-body collision we mean collisions with atoms of the background gas.

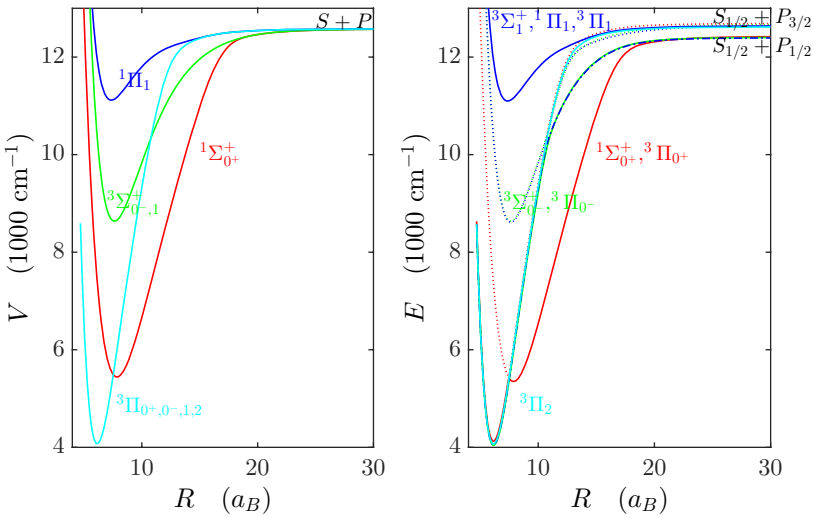

Figure 33.25: (code) Adiabatic potentials.

tion,

$$\langle \eta \rangle \equiv \frac{1}{N} \int \eta(\mathbf{r}) n(\mathbf{r}) d^3 r \ , \tag{33.219}$$

we can write the loss rates due to inelastic one-, two-, and three-body collisions,

$$B\langle 1 \rangle N \quad , \quad K\langle n \rangle N \quad , \quad L\langle n^2 \rangle N \ . \tag{33.220}$$

the prefactors depend on the collision velocity (that is, the temperature of the sample) and atomic parameters (for example, the collision cross section for two-body collisions, which may itself depend on temperature). Hence, the total number of trapped atoms evolves according to,

$$\boxed{\dot{N} = -B\langle 1 \rangle N - K\langle n \rangle N - L\langle n^2 \rangle N} \ . \tag{33.221}$$

Assuming a gaussian density distribution,

$$n(\mathbf{r}) = \frac{N}{(2\pi)^{3/2}\bar{r}^3} e^{-r^2/2\bar{r}^2} \ , \tag{33.222}$$

we calculate,

$$\dot{N} = -BN - \frac{K}{(4\pi)^{3/2}\bar{r}^3} N^2 - \frac{L}{3^{3/2}(2\pi)^3\bar{r}^6} N^3 \ . \tag{33.223}$$

Fig. 33.26 shows a simulation of Eq. (33.223).

For condensates in the Thomas-Fermi limit [1227] found the following differential equations for two- and three-body collisions,

$$\frac{\dot{N}}{N} = -Gc_2 N^{2/5} - \frac{1}{\tau} \quad \text{and} \quad \frac{\dot{N}}{N} = -Lc_3 N^{4/5} - \frac{1}{\tau} \ . \tag{33.224}$$

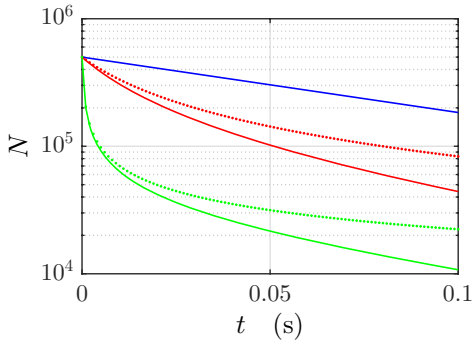

Figure 33.26: (code) One-, two-, and three-body losses.

33.3.12 Heteronuclear electric dipole moment

The *electric dipole moment* of a dimer is highest for big mass difference, as in the case of LiRb and for low vibrational quantum number [744, 63]. The electric dipole moment determines the rate for spontaneous and *black-body radiation*, $\bar{n} = (e^{-\beta\hbar\omega} - 1)^{-1}$, induced transitions between rovibrational states [745], $\Gamma^{tot}_{vlm} = \Gamma^{spnt}_{vlm} + \Gamma^{bb}_{vlm}$. With the transition rate between individual levels,

$$\Gamma^{\alpha}_{vlm\to v'l'm'} = \frac{8\pi}{3}\frac{\omega^3}{hc^3}|\langle|d|\rangle|^2 \ , \tag{33.225}$$

we can estimate the rates for spontaneous emission,

$$\Gamma^{spnt}_{vlm} = \sum\nolimits_{v'l'm'} \Gamma^{em}_{vlm\to v'l'm'} \ , \tag{33.226}$$

and for black-body radiation,

$$\Gamma^{bb}_{vlm} = \sum_{v'l'm'} \bar{n}\Gamma^{em}_{vlm\to v'l'm'} + \sum_{v''l''m''} \bar{n}\Gamma^{abs}_{vlm\to v''l''m''} \ . \tag{33.227}$$

Note that selection rules require $|l - l'| \leq 1$ and $|m - m'| \leq 1$, rotational transitions are inhibited by small ω^3, spontaneous emission is high for intermediate levels for which on one hand ω^3 is large enough and enough final states are available.

From calculations of the R-dependence of the electric dipole moments [63] the dipole moment of a specific vibrational state is easily estimated from,

$$d = \frac{\int \psi(R) R \psi(R) dR}{\int \psi(R)\psi(R) dR} \ . \tag{33.228}$$

In electric fields the dipole moments will lead to Stark shifts. For $|d| = 1$ Debye in a field of 1 V/m we expect a Stark shift of $H_{Stark} \approx 500$ kHz. It may be possible to measure this by photoassociation spectroscopy. Note also that since homonuclear dimers do not have a permanent electric dipole moment, transitions between vibrational ground states are forbidden.

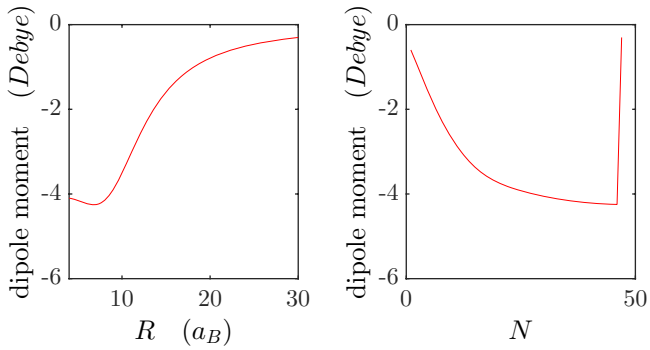

Figure 33.27: (code) (a) Dipole moment at the example of LiRb as a function of interatomic distance. (b) Dipole moment at the example of LiRb as a function of vibrational quantum number.

33.3.13 Exercises

33.3.13.1 Ex: Photoassociation

Consider a laser focused into a cold, confined cloud of Na atoms at a temperature of 450 μK. For a detuning of 600 MHz, calculate the laser intensity (in W/cm^2) required to produce a 25% probability of photoassociation. The transition moment (a.u.) of Na is 2.55.

Solution:

33.3.13.2 Ex: Vibrational structure of LiRb

Calculations of the vibrational structures of several ground states of the heteronuclear molecule LiRb.

Solution: *LiRbPotential_1Sigma:*
LiRbPotential_3Sigma:
LiRbPotential_1Pi:
LiRbPotential_3Pi:
LiRbPotential_13Delta:
LiRbStatesAdiabatic: Long-range interaction of Li with Rb, splitting at collision, Hunds Fall (c) via [Movre77].
LiRbStatesCompare: Compares ab-initio and fitted potentials.
LiRbStatesCoupledChannels: Fourier grid for solving a LiRb potential and mean distance.
LiRbStatesDipolemoment: R-dependent dipolemoment approximated from [Aymar05].
LiRbStatesFit: Fits adapted curve to ab-initio potential.
LiRbStatesFourierGrid: Fourier grid method for a specified LiRb potential.
LiRbStatesFranckCondon: Franck-Condon overlap for a specified LiRb potentials.
LiRbStatesOpenChannel: Finds wavefunction of open channel.

LiRbStatesPlot: Plots heteronuclear potentials [Korek00].
LiRbStatesRecouplingHfs: Recoupling due to hyperfine coupling by recoupling wavefunctions using 9j-coefficients.
LiRbStatesRecouplingHfs2,3: Recoupling due to hyperfine coupling by recoupling potentials using 9j-coefficients.
LiRbStatesRecouplingSo: Recoupling due to spin-orbit coupling using 9j-coefficients.
LiRbStatesSolve: Single eigenvalue and eigenstates in a given intervall.
LiRbStatesSpectrum: Complete eigenspectrum.
LiRbStatesSymb9jTest: Tests correctness of 9j-routine (not ready).
LiRbStates_9j: Subroutine returns 9j-coefficients.
LiRbStates_9jHfs: Subroutine returns 9j-coefficients put together as a matrix.
LiRbStates_Dipole: Subroutine loads R-dependence of dipole moment.
LiRbStates_DGl: Subroutine calculates wavefunction.
LiRbStates_Fit: Subroutine fits adapted curve to ab-initio potential.
LiRbStates_Grid: Subroutine returns wavefunction matrix using Fourier grid method for a specified LiRb potential.
LiRbStates_GridV: Subroutine like LiRbStates_Grid but the potential is provided by the main program.
LiRbStates_Lbl: Subroutine returns nomenclature of a potential.
LiRbStates_Par: Subroutine gets parameter of specified LiRb potential.
LiRbStates_Pot: Subroutine gets specified LiRb potential.
LiRbStates_Rot: Subroutine finds rotational constant, simple.
LiRbStates_RotW: Subroutine finds rotational constant, correct.
LiRbStates_Trn: Subroutine finds turning point.
LiRbStates_Vib: Subroutine counts vibrational quantum number and determines scattering length.
LiRbStates_Zeeman: Subroutine generates matrix for hyperfine splitting of LiRb ground state potentials.
LiRbStates_Zeeman2: Subroutine generates matrix for hyperfine splitting of LiRb ground state potentials.
LiRbScatteringLength: Finds scattering length for a given potential [Weiss00].
LiRbScatteringLength_DGl: Subroutine for Runge-Kutta integration.
LiRbScatteringLength2: Finds scattering length for a given potential [Marinescu99].
LiRbScatteringLength2_DGl: Subroutine for Runge-Kutta integration.
LiRbScatteringLength2_Cs: Subroutine for Cs reference potential.
LiRbScatteringVolume: Finds scattering length for a given potential [Ouerdane04].
LiRbScatteringVolume_DGl: Subroutine for Runge-Kutta integration.
LiRbMappedGrid: Mapped Fourier grid procedure.
LiRbMappedGrid2,3: Mapped Fourier grid procedure for coupled channels.
LiRbMapped_Couple: Subroutine for mapped Fourier grid for coupled channels with settable coupling.
LiRbWavefunctionWKB: Radial wavefunction at all interatomic distances for the groundstate potential.
RbPotentialAdiabatic: Long-range interaction of two 87Rb atoms, splitting at collision, Hunds Fall (c) via [930].
RbPotentialAdiabatic2: Long-range interaction of two 87Rb atoms, splitting at collision, Hunds Fall (c) via [930].

33.4 Resonances in cold collisions

33.4.1 Shape resonances

The 'centrifugal' term can give rise to repulsive walls for attractive potentials. Behind these walls, quasi-bound states can develop and give rise to collision resonances. That is, resonances emerge in the collision cross section as a function of the collision temperature called *shape resonance*s.

33.4.2 Feshbach resonances

The so-called *Feshbach resonance* is due to an energetic match between a collision channel and a bound molecular state [441, 1301, 1302, 906, 435, 907, 1340]. They allow to vary the scattering length a_s almost arbitrarily from zero, where the atomic cloud turns into an ideal gas, up to values exceeding the total size of the cloud.

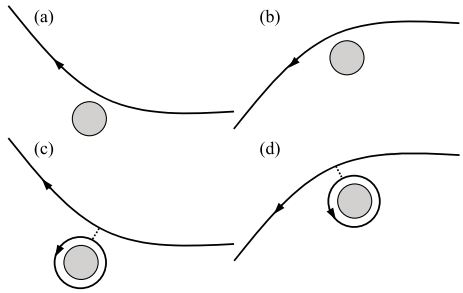

Figure 33.28: Classical illustration of a scattering resonance.

The impact of a Feshbach resonance can be understood as a perturbation of the collisional channel leading to a modification of the depth of the scattering potential. When this leads to the promotion of one more vibrational state into (or from) the continuum, this obviously leads to a dramatic modification of the scattering length a_s [15]

Let us consider two very cold atoms colliding on an attractive interatomic potential $V(R)$ (see Fig. 33.29,right). At long distances the relative wavefunction is a sine characterized by the Broglie wave vector k_{dB}. As the atoms approach each other, they mutually accelerate, and the Broglie wave performs some small and rapid oscillations within the potential. The number of nodes of the wavefunction within the potential corresponds to the number of bound vibrational levels that the potential with a given depth can support. The scattering length a_s is defined as the phase slip, which the Broglie wave would acquire during the collision at the boundary $k_{dB} \to \infty$.

With the possibility of gradually decreasing the depth of the molecular potential, at some point the last state below the ionization threshold goes to the continuum of

[15] Note that the divergence of the scattering length is an artifact of the hard core approximation, that is, the regularization of the interaction potential, since the matrix $\mathcal{T}$ by itself does not diverge.

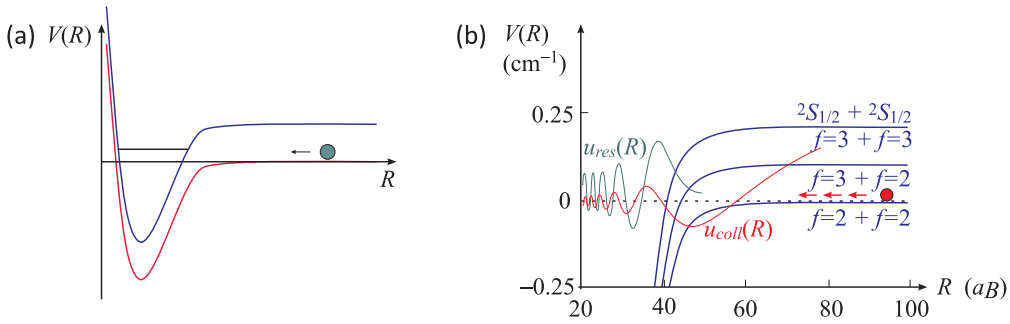

Figure 33.29: (a) The Feshbach resonance is due to a coincidence of collisional and bound channels. (b) Feshbach resonance in ^{85}Rb. The atoms collide in the hyperfine state $F = 2$, and the resonant bound state is in the $F = 3$ multiplet (courtesy [300]).

unbound states, the wavefunction decreases the number of nodes by one unit, while the scattering cross section crosses a singularity. In fact, the potential $V(R)$ *can be manipulated* with the help of radiation fields [435, 161, 907] or, near a collisional *Feshbach resonance*, by magnetic fields [1302, 1303]. Feshbach resonances were predicted in nuclear systems [441]. Its recent revival in the context of cold atomic collisions is due to the prospect of its use for manipulating the scattering length and thus controlling the mean-field energy of a Bose-Einstein condensate [16]

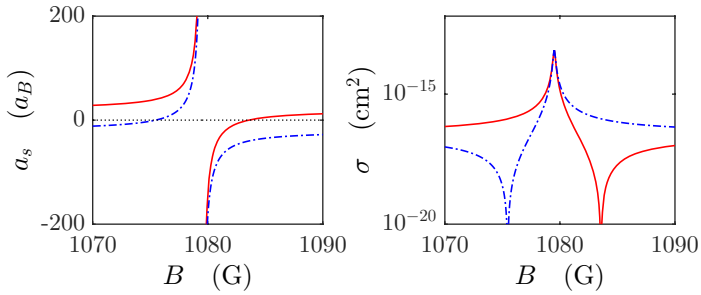

Figure 33.30: (code) (a) Scattering length and (b) collision cross section upon crossing a Feshbach resonance. The scattering length can be positive (solid red line) or negative (dashed blue line). A movie on a simulation of a Feshbach resonance can be watched here (watch movie).

The collisional *Feshbach resonance* arises when the energy of the state of two colliding atoms coincides with the energy of a vibrational molecular level belonging to a higher energy asymptote (see Fig. 33.29,right). This coincidence can strongly perturb the collisional channel, because the resonance shifts the phase of the relative de Broglie wavefunction and allows the atoms to tunnel into the molecular state

[16] It is even possible to invert the sign of the scattering length. This was a prerequisite for condensation of the atomic species of ^{85}Rb [1109]. In addition, Feshbach resonances are interesting because they can install a coherent free-bound coupling between an *open-channel* of colliding atoms and a bound molecular state of the same atoms, as shown in Fig. 33.29. This coupling can lead to the creation of molecular condensates.

for a short period of time, the duration of which is determined by the Heisenberg uncertainty relation. If the sum of the magnetic dipole moments of the atoms is different from the dipole moment of the molecule, the resonance can be tuned via external magnetic fields exploring the Zeeman effect. When a Feshbach resonance is crossed, the scattering length crosses a singularity, as shown in Fig. 33.30(left) [17].

33.4.2.1 Theory of Feshbach resonances

Feshbach resonances [441, 1301, 1302, 906, 435, 907, 1340] result from a coherent coupling between a collisional channel of free atoms and a quasi-bound molecular state. To describe this phenomenon, we first consider a global state consisting of two states located in the subspace of the open channel P and the closed channel Q,

$$|\Psi\rangle = |\Psi_P\rangle + |\Psi_Q\rangle \ , \tag{33.229}$$

with $|\Psi_P\rangle = \hat{P}|\Psi\rangle$ and $|\Psi_Q\rangle = \hat{Q}|\Psi\rangle$. The projection operators $\hat{P}$ and $\hat{Q}$ satisfy the conditions,

$$\hat{P} + \hat{Q} = 1 \qquad \text{and} \qquad \hat{P}\hat{Q} = 0 \ . \tag{33.230}$$

Hence, $\hat{P}^2 = \hat{P}$ and $\hat{Q}^2 = \hat{Q}$. Applying $\hat{P}$ to the Schrödinger equation

$$\hat{H}|\Psi\rangle = E|\Psi\rangle \tag{33.231}$$

and using the above equations, we get,

$$(E - \hat{H}_{PP})|\Psi_P\rangle = \hat{H}_{PQ}|\Psi_Q\rangle \qquad \text{and} \qquad (E - \hat{H}_{QQ})|\Psi_Q\rangle = \hat{H}_{QP}|\Psi_P\rangle \ , \tag{33.232}$$

where we defined $\hat{H}_{AB} \equiv \hat{A}\hat{H}\hat{B}$. This equation can be rewritten,

$$|\Psi_Q\rangle = (E - \hat{H}_{QQ})^{-1}\hat{H}_{QP}|\Psi_P\rangle \ . \tag{33.233}$$

Replacing this within the first Eq. (33.229),

$$(E - \hat{H}_{PP} - \hat{H}'_{PP})|\Psi_P\rangle = 0 \qquad \text{with} \qquad \hat{H}'_{PP} = \hat{H}_{PQ}(E - \hat{H}_{QQ})^{-1}\hat{H}_{QP} \ . \tag{33.234}$$

The term $\hat{H}'_{PP}$ can be interpreted as an effective interaction mediated by a transition from space P to Q and back to P.

The Hamiltonian of the open channel consists of a part $\hat{H}_0$ describing the two individual atoms including their Zeeman interactions with a magnetic field, and another part for the interaction between the two atoms $\hat{V}_1$. With the effective interaction potential through the bound channel $\hat{V}_2 \equiv \hat{H}'_{PP}$, we have,

$$(E - \hat{H}_0 - \hat{V}_1 - \hat{V}_2)|\Psi_P\rangle = 0 \ . \tag{33.235}$$

Now ...

Doing a little bit of algebra we find for the scattering length the following expression:

$$a = a_0 + \frac{\imath}{2k} \ln \frac{E - E_m - \frac{\imath}{2}\Gamma_m}{E - E_m + \frac{\imath}{2}\Gamma_m} = a_0 + \frac{1}{2k} \tan^{-1} \frac{\Gamma_m (E - E_m)}{(E - E_m)^2 + \frac{1}{4}\Gamma_m^2} \ . \tag{33.236}$$

[17] Explain better: The additional vibrational state distorting the collisional wavefunction during the singularity is entering the free-bound coupled-channel potential.

In reality, the channels are distinct due to their different hyperfine spin coupling. In general, the combination of the atoms generates a magnetic moment which is different from that of the molecule, $\mu_a \neq \mu_m$. This allows the resonance condition to be magnetically tuned,

$$a_{eff} = a_0 \left(1 - \frac{\Delta B}{B - B_{FB}}\right) . \tag{33.237}$$

The background scattering length $a_0 \equiv (B = 0)$ determines, on which side of the singularity the collision cross section $\sigma = 8\pi a_s^2$ goes through zero. The dependence of a_s on the magnetic field is monotonically increasing (decreasing), when $a_0 \Delta B > 0$ ($a_0 \Delta B < 0$). Note that ΔB is the distance between the singularity and the field where the scattering length crosses zero [1108]. Physically, a positive (negative) slope of the Feshbach resonance means that the energy of the bound state increases more (less) rapidly with the increase of the magnetic field, than the energy of the open channel, that is, $\mu_m < \sum \mu_a$ ($\mu_m > \sum \mu_a$) [906]. Note also that the divergence of the scattering length is an artifact of the hard-core approximation for the interaction potential, since the $\mathcal{T}$-matrix does not diverge.

33.4.2.2 Magnetic tuning of open and closed channels

The calculation of the Zeeman shift of bound states is relatively simple for a single channel, but this is an approximation. The Zeeman splitting of the open channel is simply the sum of the Zeeman structure of the collision partners. Therefore, it can be treated as shown in Sec. 30.2.4. It is sufficient to calculate the sum of the shifts for all pairs of individual atoms, $\nu_{Zeeman}^{m_F}(B) + \nu_{Zeeman}^{m'_F}(B) - \nu_{Zeeman}(0)$. For example, for $F = 2$ we have $m_F, m'_F = -2, ..., 2$, that is, we expect nine magnetic sublevels [18].

The Zeeman splitting of bound states has been demonstrated in Sec. 33.3.8. These calculations are however single-channel calculations and thus approximations.

The selection rule for coupling an open channel with total magnetic quantum number M_F and a bound channel M'_F is $M_F = M'_F \pm \ell$. I.e. s-wave collisions preserve the magnetic quantum number.

33.4.2.3 Photoassociative signature of Feshbach resonances

Near a Feshbach resonance the amplitude of the wavefunction is resonantly amplified, therefore we expect a larger Franck-Condon overlap, a larger transition rate, and a larger trap loss rate. The PA resonance enhancement has been calculated by [1323]:

$$\begin{aligned} K_{PA}(T, \Delta, B) &= \langle \nu \sigma_{PA}(E, \Delta, B) \rangle_T \\ &= \lambda_{therm}^3 \sum_{\ell=0}^{\infty} (2\ell + 1) \int_0^{\infty} |S_{PA}(E, \ell, \Delta, B)|^2 \exp(-E/k_B T) d(-E/2\pi\hbar) \\ &\xrightarrow{\ell=0} \lambda_{therm}^3 \int_0^{\infty} \frac{\frac{1}{4}\gamma_0 \gamma_L^{res}}{(\Delta + E)^2 + \frac{1}{4}\gamma_0^2} \frac{\sqrt{E/E_{res}}\Gamma^2}{(E - E_{res})^2 + \frac{1}{4}\Gamma^2} \exp(-E/k_B T) d(-E/2\pi\hbar) . \end{aligned} \tag{33.238}$$

[18] We may use this formula to fit the observed Zeeman splitting in the PA line, and calibrate our magnetic field. The excited 0_g^- has no hyperfine structure and does not exhibit Zeeman splitting. The precision of this method of calibration is limited due to line pulling effects induced by overlapping of rotational states.

The expression may be understood as a convolution of a Lorentzian term coming from the PA excitation, a Breit-Wigner resonance term resulting from the Feshbach enhancement, and a thermal Boltzmann velocity distribution. Experimental data are only available for the strong ^{85}Rb Feshbach resonance around 160 G [300]. In this experiment, ...

$$E_{res} = (2\mu_{atom} - \mu_{molecule})(B - B_0) \approx 2.45(B - B_0) \ , \tag{33.239}$$

where $\Gamma \approx 2.45\Delta B$, $T = 100$ μK, $\gamma_0/2\pi = 6$ MHz, $B_0 = 164$ G, $\Delta B = 5.9$ G. In this experiment, the excited state potential has been chosen to be a 0_g^- state, because of the absence of a hyperfine structure and therefore HF mixing. The rotational progression of vibrational states of this potential therefore looks simple and unperturbed. Figure xy shows the rotational spectrum of .... Higher partial waves contributions are small due to the low temperature of the atomic cloud.

33.4.2.4 Particular Feshbach resonances

A *p-wave Feshbach resonance* has been observed (see also Sec. 49.4) in channels of ^{6}Li [1426, **?**] and ^{40}K [1084] collisions. In homonuclear collisions, p-wave resonances occur in channels $|m_f, m_f'\rangle$, which are different form the channels for s-wave collisions. p-wave resonances are identified via inelastic collisions, since elastic collisions are frozen out. In heteronuclear collisions both types should be possible in all channels, only at different B-field values.

Heteronuclear Feshbach resonances have been found (see also Sec. **??**).

33.4.3 Efimov states and the exchange interaction

We assert that Efimov states in heteronuclear mixtures with large mass ratios are atom optical model systems for the very nature of chemical binding, the mechanism that ties atoms together to molecules. The type of chemical binding depends on whether the electrons are shared (covalent binding) or not (ionic binding). In the simplest imaginable molecule, H_2^+, two hydrogen atoms are bound by the exchange of an electron. In this case, the quantum statistical nature of H does not play a role, because the direct H-H interaction is dominated by Coulomb repulsion. The repulsion is overcome by the binding electron orbital, whose quantum nature does not play a role either, because there is only one electron. The same is true for Rb-Li-Rb with the difference that the atoms to not react via Coulomb but via short range van der Waals interactions. Hence, the Rb-Rb interaction is negligible at the long ranges, and the resonantly enhanced Li-Rb interaction is an exchange interaction.

Efimov states in optical lattices have been discussed [1267, 828].

33.4.3.1 Metals

Is exchange interaction by quasi-free electrons at the base of metallic binding? There may exist Bose-metals! How to calculate the lattice constant of a metal using the the Born-Oppenheimer approximation? Metallic binding is the exclusive mechanism for alkalis. $E_b \approx 1$ eV. For transition metals there is additional covalent binding due to exchange interaction $E_b \approx 9$ eV.

How about hydrogen bridge binding?

Table 33.2: List of famous Feshbach resonances. According to equation $a_s = a_{bg}\left(1 - \frac{\Delta B}{B-B_0}\right)$, the slope of a_s is rising with the increase of B, if a_{gb} and ΔB have the same signal. Otherwise it is decreasing. The resonances marked by p are p-wave resonances $|S, m_S, I, m_I\rangle$.

33.4.3.2 Efimov states

The universal limit is reached, when the van der Waals length $\ell \equiv \left(mC_6/\hbar^2\right)^{1/4}$ is largely exceeded by the scattering length $a \gg \ell > 0$. This happens in case of Feshbach resonant enhancement, $a = a(B)$.

For $a > 0$ a shallow two-body bound state forms, whose energy for large a is given by $E_2 = -\frac{\hbar^2}{ma^2}$. Hence, in the universal limit the dimer binding energy is independent of the interaction potential. In a Feshbach resonance this universal bound state can tunnel into a real "chemical" bound state forming a molecule. For $a < 0$ there is no shallow dimer. In this regime three-body losses are only possible via the formation of deeply bound molecules.

There exist an infinite number of Efimov states with identical dependence on a. They accumulate at $a \to \pm\infty$. For a given a however the number of Efimov states is limited. In the diagram 33.31 an Efimov resonance occurs every time a solid line crosses the boundary to continuum (shaded line), $a_* = a(|E_2| = |E_3|)$. Tuning can be done via modifying a via a magnetic field near a Feshbach resonance. For $a < 0$ there are no bound dimers, the Efimov resonance is due to trimers. For $a > 0$ there are bound dimers, the Efimov resonance is due to atom-dimer resonances. There is a lowest Efimov state, which extends into non-universal regions. For this reason the energy offset of the Efimov series depends on the atomic potentials.

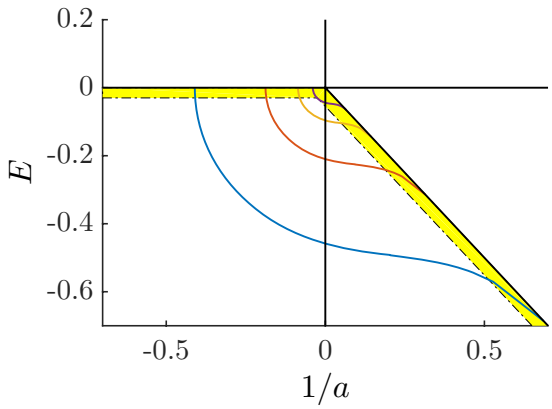

Figure 33.31: Spectrum of Efimov states as a function of $1/a$.

The energies of the Efimov states are given by the roots of,

$$\sin\left(\frac{s_0}{2}\ln(mE_3/\hbar^2\kappa_s^2)\right) \ . \tag{33.240}$$

Hence, the scaling factor for the distance between Efimov states is $e^{\pi/s_0} \simeq 22.7$, where $s_0 \approx 1.00624$ is the root of

$$s_0 \cosh\frac{\pi s_0}{2} - \frac{8}{\sqrt{3}}\sinh\frac{\pi s_0}{6} = 0 \ . \tag{33.241}$$

If one Efimov state is located near a_* then the others are located near $a_* e^{n\pi/s_0}$. I.e. $C(a_*) = C(a_* e^{\pi/s_0})$.

For binary heteronuclear mixtures the scaling factor for Efimov states can be very different. In this case it not only depends on the quantum statistical character of the two atoms (bosons, fermions, or distinguishable atoms), but on the mass ratio of the mixture and on the size of the various scattering lengths. In general, either the intraspecies scattering length between the two identical atoms is Feshbach resonantly enhanced or the interspecies scattering length, but not both simultaneously.

Let us define $\tan\gamma_{12} = \sqrt{(m_1+m_2+m_3)m_3/m_1m_1}$. For $R = 0$ and replacing $\lambda^{1/2} = -s_0$, the Eq. (389) of Ref. [186] can be written

$$\det\begin{pmatrix} \cosh(s_0\frac{\pi}{2}) & -2\frac{\sinh[s_0(\pi/2-\gamma_{12})]}{s_0\sin(2\gamma_{12})} & -2\frac{\sinh[s_0(\pi/2-\gamma_{13})]}{s_0\sin(2\gamma_{13})} \\ -2\frac{\sinh[\lambda^{1/2}(\pi/2-\gamma_{21})]}{s_0\sin(2\gamma_{21})} & \cosh\left(s_0\frac{\pi}{2}\right) & -2\frac{\sinh[s_0(\pi/2-\gamma_{23})]}{s_0\sin(2\gamma_{23})} \\ -2\frac{\sinh[s_0(\pi/2-\gamma_{31})]}{s_0\sin(2\gamma_{31})} & -2\frac{\sinh[s_0(\pi/2-\gamma_{32})]}{s_0\sin(2\gamma_{32})} & \cosh\left(s_0\frac{\pi}{2}\right) \end{pmatrix} = 0\ . \quad (33.242)$$

This holds when all scattering lengths are strong.

Figure 33.32: Various possibilities for Efimov states in binary mixtures of quantum gases.

On the other hand, for the case $m_1 = m_2 \neq m_3$ and $a_{13} = a_{23} \gg a_{12}$, the scaling factor is given by the root of

$$s_0\cosh\frac{\pi s_0}{2} \mp \frac{2\sinh(s_0(\frac{\pi}{2}-\gamma_{12})}{\sin 2\gamma_{12}} = 0\ . \quad (33.243)$$

The upper sign holds if $m_{1,2}$ are bosons, the lower sign for fermions, and a product of both terms if the atoms are distinguishable.

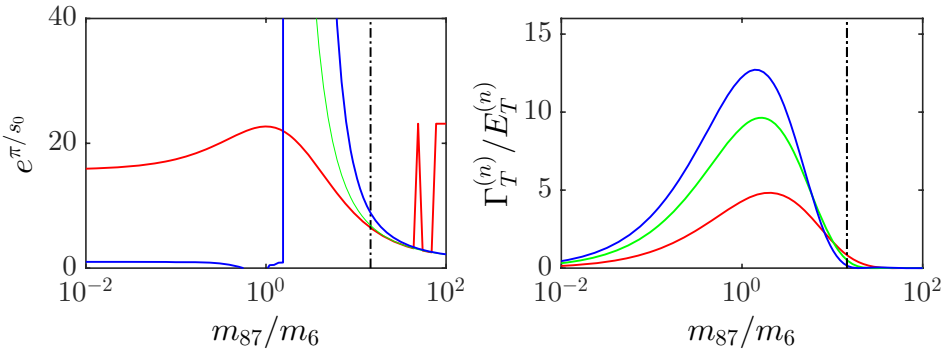

Figure 33.33: Scaling factor as a function of the mass ratio.

The three-body collision rate in the unitarity limit,

$$L_3 = \frac{3C(a)\hbar a^4}{m}\ , \quad (33.244)$$

can be expressed via the recombination length

$$\rho_3 \equiv \left(\frac{2mL_3}{\sqrt{3}\hbar}\right)^{1/4} . \tag{33.245}$$

Efimov states can be observed via L_3 or evtl. Bragg scattering?
According to [750],

$$C(a_{<0}) = \frac{4590 \sinh 2\eta_-}{\sin^2\left(s_0 \ln \frac{|a|}{a_-}\right) + \sinh^2 \eta_-} , \tag{33.246}$$
$$C(a_{>0}) = 67.1 e^{-2\eta_+}\left[\cos^2\left(s_0 \ln \frac{|a|}{a_+}\right) + \sinh^2 \eta_+\right] + 16.8(1 - e^{-4\eta_+}) .$$

$a_\pm$ describes the non-universal short-range potential, $\eta_\pm$ the three-body decay rate.

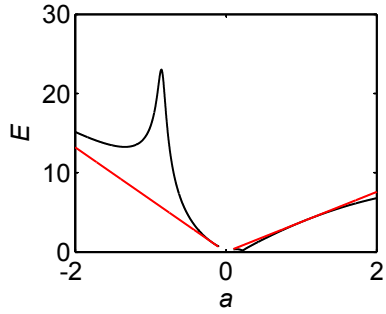

Figure 33.34: Calculated loss spectra for Cs Efimov trimers.

In the absence of Efimov states, we set $a = a_- e^{\pi/2s_0}$ and $a = a_+$, respectively and obtain,

$$C(a_{<0}) = 4590 \times 2 \tanh \eta_- , \tag{33.247}$$
$$C(a_{>0}) = 67.1 e^{-2\eta_+} \cosh^2 \eta_+ + 16.8(1 - e^{-4\eta_+}) .$$

Hence, three-body losses are scaling with a^4 without additional resonances. The decay via into deep bound states is summarized by the constants $\eta_\pm$. Interpolation formula of Shlyapnikov for two heavy bosons/fermions and a light atom. The interspecies scattering length is strong,

$$s_0 = \sqrt{.16M/m - 1/4} \quad \text{for bosons and} \quad s_0 = \sqrt{.16M/m - 9/4} \quad \text{for fermions} . \tag{33.248}$$

33.5 Light-assisted collisions

33.5.1 Photoassociation

Photoassociation is based on binary collisions. Transitions to excited states are followed by spontaneous decay and can be monitored in trap loss experiments. An

alternative way, which suits especially well for sodium is photoassociative ionization. The trap loss rate can be expressed as,

$$\dot{n} = -2K_{PA}n^2 \ . \tag{33.249}$$

The event rate for photoassociation in a thermal cloud with Boltzmann velocity distribution is:

$$\begin{aligned} K_{PA}(T,\Delta_1,I_1) &= \left\langle \frac{\pi v}{k^2}\sum_l (2l+1)|S(E,l,\Delta_1,I_1)|^2 \right\rangle \ , \\ &= \frac{2\pi\hbar}{\mu k}\sum_l (2l+1)\int_0^\infty |S(E,l,\Delta_1,I_1)|^2 e^{-\beta E}d(\beta E) \ , \end{aligned} \tag{33.250}$$

where the *S-matrix* is,

$$|S|^2 = \frac{\gamma_1\gamma_s}{(E-\Delta_1)^2 + \frac{1}{4}(\gamma_1+\gamma_s)^2} \ , \tag{33.251}$$

and γ_1 is the spontaneous linewidth and $\gamma_s(E,l,I_1)/2\pi \approx \Omega_1^2\,|\langle b_1|E,l\rangle|^2$ is the Franck-Condon overlap between the colliding channel and the excited state bound level. For cold ultra-cold collisions, we may only consider s-wave collisions, $l=0$. In the regime of Bose-Einstein condensation $T \lesssim 1$ μK and $n \gtrsim 10^{14}$ cm^{-3}, we can replace $e^{-\beta E} \to \delta(E)$ and $E \to 0$. The photoassociation rate then simplifies to [216],

$$K_{PA}(\Delta_1,I_1) \approx \frac{2\pi\hbar}{\mu k}\frac{\gamma_1\gamma_s}{\Delta^2 + \frac{1}{4}(\gamma_1+\gamma_s)^2} \ . \tag{33.252}$$

Thus the S-matrix is maximized in resonance and saturation, i.e. $\Delta_1 = E$ and $\gamma_s = \gamma_1$ so that $|S|^2 = 1$, which case is called the *unitarity limit*. Note that increasing the laser power beyond saturation, $\gamma_s > \gamma_1$, decreases the photoassociation efficiency again because of *Autler-Townes splitting* [**?**].

33.5.2 Two-color photoassociation

We can also shine in a second laser frequency tuned between the excited potential bound state and a ground potential bound state. This second laser power broadens the resonance and spoils the transition rate for the first laser. Following [161]:

$$K_{PA}(T,\Delta_1,\Delta_2,I_1,I_2) = \left\langle \frac{\pi v}{k^2}\sum_l (2l+1)|S(E,l,\Delta_1,\Delta_2,I_1,I_2)|^2 \right\rangle \ , \tag{33.253}$$

where,

$$|S|^2 = \frac{(E-\Delta_2)^2\gamma_1\gamma_s}{(E-\Delta_+)^2(E-\Delta_-)^2 + \frac{1}{4}(\gamma_1+\gamma_s)^2(E-\Delta_2)^2} \ , \tag{33.254}$$

where,

$$\Delta_\pm = \tfrac{1}{2}(\Delta_1+\Delta_2) \pm \tfrac{1}{2}\sqrt{(\Delta_1-\Delta_2)^2 + 4\Omega_{12}^2} \ . \tag{33.255}$$

Note that $\gamma_s(E,l,I_1)/2\pi \approx \Omega_1^2 \left|\langle b_1|E,l\rangle\right|^2$ and $\Omega_{12} = \Omega_2\langle b_1|b_2\rangle$. The one-color signal follows with $\Omega_{12} \to 0$. Assuming the unitarity limit for the free-bound transition, $\Delta_1 = E$ and $\gamma_s = \gamma_1$ the two-color signal reads:

$$|S|^2 = \frac{1}{1+\Omega_{12}^4/(\Delta_1-\Delta_2)^2\gamma_1^2} \ . \tag{33.256}$$

The width of the two-color spectral lines is mainly limited by the Boltzmann distribution of kinetic energies in the atomic cloud. At very low temperatures, we may .... and the two-color resonance dip may be interpreted as a true dark resonance.

Two-color PA lines have been observed for ^{85}Rb in a FORT [491]. In order to measure this for very low temperatures and even for condensates, one has to switch to ^{87}Rb in a dark MOT. A technical requirement is, of course, that the two lasers involved in the Raman process be very stable, at least with respect to each other. This is easiest achieved by using AOMs, which limits the range of levels to be studied to a few GHz binding energy.

Another important aspect is the requirement of a reasonable Raman transition probability, i.e. large Franck-Condon overlap between the collisional and the bound excited state and between the two bound states. Note also that selection rules hold.

33.5.3 Optical shielding

The adiabatic potential for ground state collisions can be manipulated using light to admix an another potential. The laser light can either be blue-detuned to the continuum of states of a repulsive excited state potential or red-detuned to vibrational resonances of an attractive excited state potential [435, 1349, 1363]. We can also admix another ground state potential with two-photon Raman transitions.

At cold collisions, the atom undergoes *Landau-Zehner transitions* between the mixed states with the probability $P_{LZ} = 1-\exp(-2\pi\hbar\Omega^2/\alpha v)$, where $\alpha = |d\Delta/dR|_{R_C} = |d(U_e(R) - U_g(R))/dR|_{R_C}$ is the slope of the difference potential evaluated at the Condon point. In the dressed states picture the dressed potentials display an avoided crossing. This modification of the collisional potential modifies the dynamics of the collision and the scattering length.

An example is the phenomenon of *optical suppression* or *shielding*. Here, two colliding atoms are inhibited to approach farther than a certain distance defined by the resonance condition set by a laser which is blue-detuned to a repulsive excited potential. The inhibition is probed by a photoassociation laser tuned to a resonance condition at smaller interatomic distances. The optical shielding scheme can be extended in the following way. Two lasers, one tuned to a repulsive another to an attractive excited state potential resonant at different interatomic distances.

33.5.4 Optical Feshbach resonances

We can view the modification of the colliding channel as a changed scattering length. Or do we introduce a temperature dependence $a(T)$? Anyway, if the goal is only to alter the a, we want to avoid spontaneous scattering, i.e. $(\Omega/\Delta)^2$ need to be small. Unfortunately, the effect of the light on the scattering length also scales with $(\Omega/\Delta)^2$. So that blue- or red-detuning optical shielding has small impact. An alternative is

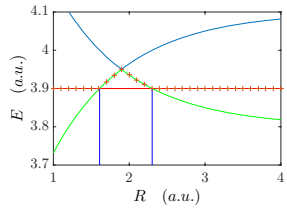

Figure 33.35: Optical shielding and anti-shielding.

resonant enhancement by a bound state for red-detuned shielding. For blue detuning and large Δ, shielding only works at short range R. This is called an *optical Feshbach resonance* [435, 161, 1297]. It can also occur in the microwave regime [907].

We can set up the following non-Hermitian Hamiltonian:

$$\begin{pmatrix} -\hbar^2/m \cdot \Delta_R + U(R) & \Omega\xi(R) \\ \Omega\xi(R) & -\hbar^2/m \cdot \Delta_R + U(R) - \imath R - \delta \end{pmatrix} \begin{pmatrix} \phi(R) \\ \psi(R) \end{pmatrix} = 0 \qquad (33.257)$$

results in a resonance described by the complex scattering length $a = a' - \imath a''$, where the real part governs the self energy and the imaginary part the spontaneous losses.

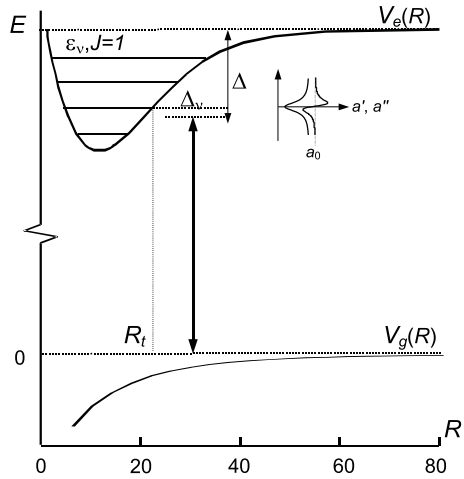

Figure 33.36: Optically induced Feshbach resonances.

33.5.5 Induced dipolar long-range forces

33.5.5.1 Electrostriction

The phenomenon of *electrostriction* is caused by static polarizability: Dipoles in an electric field gradient align themselves to the local field and the field gradient causes forces towards the field minimum. However forces may not only occur between dipoles

and inhomogeneous external fields, but also between pairs of dipoles. And this holds even if the dipole are induced by homogeneous fields. In this picture, *retardation* can induce electrostrictive long-range forces [**?**]. To see the effect, Rayleigh or Bragg scattering or superradiance have to be avoided, e.g. by minimizing the overlap between the dipole radiation pattern and the atomic cloud.

33.5.5.2 Effects due to dipole-dipole interaction

We assume isotropic real dispersion $\alpha_{pol} = \alpha_{pol}(k)$. The *Lippmann-Schwinger equation* is an integral equation describing the modification of the local electric field due to self-interaction including spatial retardation effects,

$$\mathbf{E}_{loc}(\mathbf{r},t) = \mathbf{E}_{ext}(\mathbf{r},t) + \frac{\alpha_{pol}(k)}{\varepsilon_0}\int d^3r' \mathbf{G}^0(\mathbf{r}-\mathbf{r}')n(\mathbf{r}')\mathbf{E}_{loc}(\mathbf{r}',t) \ , \tag{33.258}$$

where $\mathbf{G}^0(\mathbf{r})$ is the propagation tensor,

$$1\mathbf{G}^0(\mathbf{r}) = \frac{e^{\imath kr}}{4\pi r^3}\left[(\delta_{ij}-3\hat{\mathbf{r}}_i\hat{\mathbf{r}}_j)(1-\imath kr) - (\delta_{ij}-\hat{\mathbf{r}}_i\hat{\mathbf{r}}_j)(kr)^2\right] \ . \tag{33.259}$$

In the first Born approximation $\mathbf{E}_{loc}$ under the integral in Eq. (33.258) is replaced $\mathbf{E}_{ext}$. The expression is then used to calculate the polarization, which in term is used to calculate the interaction energy $H_{ind} = -\frac{1}{2}\int d^3\mathbf{r}\mathfrak{Re}\ \mathbf{P}\mathfrak{Re}\ \mathbf{E}_{ext}$. One obtains,

$$\hat{H}_{ind} = -\frac{\alpha_{pol}}{4}\mathbf{E}^2_{ext}\int d^3\mathbf{r} n(\mathbf{r}) + \frac{1}{2}\int d^3\mathbf{r}\int d^3\mathbf{r}' n(\mathbf{r})U(\mathbf{r}-\mathbf{r}')n(\mathbf{r}') \ , \tag{33.260}$$

where,

$$U(\mathbf{r}) = \frac{I\alpha_{pol}(k)^2}{4\pi c\varepsilon_0^2}\hat{\mathbf{E}}^*_i\hat{\mathbf{E}}_j V_{ij}(k,\mathbf{r})\cos\mathbf{kr} \ , \tag{33.261}$$

with $V_{ij}(k,\mathbf{r}) = -4\pi\mathfrak{Re}\ \mathbf{G}^0(\mathbf{r})$.

For $\mathbf{G}^0(\mathbf{r}) = \frac{1}{3}\delta(\mathbf{r})\mathbf{1}_3$,

$$\mathbf{E}_{loc}(\mathbf{r},t) = \mathbf{E}_{ext}(\mathbf{r},t) + \frac{\alpha_{pol}(k)}{3\varepsilon_0}n(\mathbf{r})\mathbf{E}_{loc}(\mathbf{r},t) \ , \tag{33.262}$$

we recover the Clausius-Mossotti formula. For dilute gases $n\alpha_{pol}/3\varepsilon_0 \ll 1$ and may be neglected. In [1118] it is shown that the Lorentz-Lorenz shift is the same for a BEC and therefore the quantum degeneracy does not modify the formula.

33.5.5.3 Rotons

The *Bijl-Feynman formula* links the dispersion relation to the static structure factor,

$$E(k) \le \frac{\hbar^2k^2}{2mS(k)} \ . \tag{33.263}$$

The equality holds for dilute gases. In generalization to thermal gases the structure factor is the Fourier transform of pair correlation functions. In the mean-field theory pair correlations are neglected. However, in the presence of dipole-dipole interactions this is not the case. Pair correlations lead to a maximum in the structure factor at quasi-momenta corresponding to the mean interparticle distance. Consequently there is a minimum in the Bogolubov dispersion relation $E(k)$, called *roton*.

Part V

Quantum Optics

Chapter 34

Semiclassical theory of light-atom interaction

In Part IV of this script we solved the problem of a *stationary* atom using the formalism of quantum mechanics developed in Part III. We now come back to Bohr's original idea that *transitions* between atomic states be induced by absorption and emission of electromagnetic radiation and develop a semi-classical theory of light-atom interaction. That is, the atom will be treated as a quantum object, while the radiation is assumed to obey the rules of classical electrodynamics. The main objective of this chapter will be to derive an equation describing the temporal evolution of atoms interacting with a radiation field.

We begin with a perturbative approach to the excitation of atomic transitions in Sec. 34.1. In quantum mechanics we learned (see in Sec. 27.4) how time-dependent perturbations, such as suddenly applied force fields or periodic oscillations, can induce transitions between eigenstates. We will not repeat the concepts here. Rather we will focus on the calculation of transitions rates employing Fermi's Golden rule derived in Eq. (27.111). In Secs. 22.2 we introduced the Einstein coefficients A and B, which we associated with Planck's spectral distribution of black-body radiation. This procedure allowed us to connect the coefficients for spontaneous and stimulated transitions, but did not provide any method to calculate them from the intrinsic properties of the atoms. The purpose of Sec. 34.2 is to find expressions for the matrix elements coupling different atomic states using quantum mechanics and relate them to the Einstein coefficients in order to calculate the rates of absorption and emission of atomic radiation. In particular, we will dedicate some space to the dipolar approximation and to the derivation of selection rules allowing to quantify transition probabilities as a function of the quantum numbers characterizing the atomic states coupled by radiation.

Perturbation theory can describe the light-atom dynamics only at interaction times short enough, that the initially occupied atomic states is not noticeably depleted. An exception is the two-level atom, for which perturbation theory reproduces the exact results obtained by solving the time-dependent Schrödinger equation. This, however, only holds as long as spontaneous processes can be neglected. To portray systems that contain excitation and relaxation processes occurring simultaneously, a theory based on Schrödinger's equation is no longer sufficient, because it is only capable of explaining stimulated processes, such as the absorption of a monochromatic wave. Dissipative processes, such as spontaneous emission, require a more general approach

to describe the evolution of a system. A single wavefunction is, in general, not enough to represent such a system nor to quantify the probabilities associated with each of its states, but we rather need an ensemble of wavefunctions, which requires the description of the atom in terms of a density operator. This will be done in Sec. 34.3.

The equations of motion ruling the time evolution of the density operator are the so-called Bloch equations. They will be derived and studied in Sec. 34.4, and in Sec. 34.5 we will phenomenologically include spontaneous emission. In Sec. 34.6 we will discuss line broadening mechanisms and in Sec. 34.7 generalize the Bloch equation formalism to multilevel systems.

34.1 Perturbative approach to atomic excitation

In a model of an isolated atom, the atomic energy levels are eigenstates of the Hamiltonian and describe the system completely, i.e. they do not undergo any evolution. Transitions between atomic energy levels may, however, be induced by oscillatory perturbations, such as electromagnetic radiation accelerating bound electrons.

34.1.1 Time-dependent perturbation by a plane wave

Looking at the Hamiltonian (30.11) describing the interaction of a charged particle with an electromagnetic field, we find that the term $\mathbf{A}\cdot\nabla \propto e^{\imath\omega t}$ oscillates with frequency ω, while the term $\mathbf{A}^2 \propto e^{2\imath\omega t}$ oscillates with twice that frequency. We will only consider the interaction term (30.12), which is linear in $\mathbf{A}$, and we will treat this term as first-order perturbation by *time-dependent perturbation theory* (TPDT).

With this scope we separate the Hamiltonian in a stationary part and a time-dependent part [1],

$$\hat{H}(t) = \hat{H}^{(0)} + \hat{H}_{int}(t) \qquad \text{with} \qquad \hat{H}_{int} = \tfrac{e}{m}\mathbf{A}(\mathbf{r},t)\cdot\hat{\mathbf{p}}\ , \tag{34.1}$$

where $\hat{H}^{(0)}$ contains the kinetic energy and the Colombian potential of Eq. (30.11). In Sec. 27.4.4, inserting the expansion,

$$|\psi\rangle = \sum_k a_k(t)|k\rangle e^{-\imath E_k t/\hbar}\ , \tag{34.2}$$

along with the Hamiltonian (34.1) in the Schrödinger equation, we obtained the first order perturbative approximation (27.72). Setting the initial condition to $c_k(t\le 0) = \delta_{ki}$ and supposing that the probability of finding the atom initially in the ground state $|i\rangle$ for short times is 1, we got,

$$\boxed{a_f^{(1)}(t) \simeq \frac{1}{\imath\hbar}\int_0^t \langle f|\hat{H}_{int}|i\rangle e^{\imath\omega_{fi}t'}dt'}\ . \tag{34.3}$$

We now consider a perturbation by an electromagnetic plane wave within the Coulomb gauge,

$$\Phi = 0 \qquad \text{and} \qquad \nabla\cdot\mathbf{A} = 0\ . \tag{34.4}$$

[1] The energy of the light field is not considered in the Hamiltonian, because it is treated as classical, that is, its energy commutes with the other observables of the system.

The solution of the wave equation can be written,

$$\mathbf{A}(\mathbf{r},t) = \mathbf{A}_0^*(\mathbf{r})e^{\imath\omega t} + \mathbf{A}_0(\mathbf{r})e^{-\imath\omega t} \ . \tag{34.5}$$

For plane waves,

$$\mathbf{A}_0(\mathbf{r}) = \mathbf{A}_0 e^{\imath\mathbf{k}\cdot\mathbf{r}} \tag{34.6}$$

and $k = \omega/c$ and $\mathbf{k}\cdot\mathbf{A}_0 = 0$. With this, it is possible to show (see Exc. 34.1.4.1), that the energy density is,

$$u(\omega) = \tfrac{\varepsilon_0}{2}\vec{\mathcal{E}}^2 + \tfrac{1}{2\mu_0}\vec{\mathcal{B}}^2 = 2\varepsilon_0\omega^2 A_0^2 \ . \tag{34.7}$$

On the other hand, the energy density is proportional to the number of photons $N(\omega)$ inside the volume V,

$$u(\omega) = \frac{N(\omega)\hbar\omega}{V} \ . \tag{34.8}$$

The intensity corresponds to a flow of energy,

$$I(\omega) = u(\omega)c \ . \tag{34.9}$$

Separating the polarization $\hat{\epsilon}$ from the amplitude A_0,

$$\mathbf{A} = \hat{\epsilon}A_0 e^{\imath\mathbf{k}\cdot\mathbf{r}}e^{-\imath\omega t} + c.c. \ , \tag{34.10}$$

and inserting the perturbation (34.1) into the approximation (34.3),

$$\begin{aligned} a_f^{(1)}(t) &= -\tfrac{e}{m}\int_0^t dt'\langle f|\mathbf{A}\cdot\nabla|i\rangle e^{\imath\omega_{fi}t'}dt' \qquad (34.11)\\ &= -\tfrac{eA_0}{m}\langle f|e^{\imath\mathbf{k}\cdot\mathbf{r}}\hat{\epsilon}\cdot\nabla|i\rangle\int_0^t dt' e^{\imath(\omega_{fi}-\omega)t'}dt' - \tfrac{eA_0}{m}\langle f|e^{-\imath\mathbf{k}\cdot\mathbf{r}}\hat{\epsilon}\cdot\nabla|i\rangle\int_0^t dt' e^{\imath(\omega_{fi}+\omega)t'}dt' \ . \end{aligned}$$

Which one of the two processes described by Eq. (34.11) takes place, depends on the initial and final energies. For $E_f = E_i + \hbar\omega$ the first term describing the process of *absorption* will dominate, for $E_f = E_i - \hbar\omega$ the second term describing *emission* prevails.

34.1.2 Absorption and stimulated emission

34.1.2.1 Absorption

We define the *matrix element*,

$$M_{fi} \equiv \langle f|e^{\imath\mathbf{k}\cdot\mathbf{r}}\hat{\epsilon}\cdot\nabla|i\rangle \ , \tag{34.12}$$

and concentrate on the absorption process. Defining the detuning by $\Delta \equiv \omega - \omega_{fi}$ and evaluating the integral,

$$\left|\int_0^t e^{-\imath\Delta t'}dt'\right|^2 = \left|\frac{e^{-\imath\Delta t}-1}{-\imath\Delta}\right|^2 = 4\frac{\sin^2\frac{\Delta t}{2}}{\Delta^2} \simeq 2\pi t\delta(\Delta) \ , \tag{34.13}$$

at short times (see the formula (27.76)), the absorption probability becomes,

$$|a_f^{(1)}(t)|^2 = \frac{e^2}{m^2} A_0(\omega)^2 |M_{fi}|^2 \left| \int_0^t dt' e^{\imath(\omega_{fi}-\omega)t'} dt' \right|^2 = \frac{e^2}{m^2} A_0(\omega)^2 |M_{fi}|^2 2\pi t \delta(\Delta) \ . \tag{34.14}$$

The $\delta(\Delta = 0)$ function simply represents conservation of energy. Of course this is only an approximation not taking into account the finite width of the transition line.

Expressing the field by the intensity (34.10), we obtain the transition rate for absorption,

$$\boxed{W_{fi}^{(ab)} = \frac{d}{dt}|a_f^{(1)}(t)|^2 = 2\pi \left(\frac{eA_0}{m}\right)^2 |M_{fi}|^2 \delta(\omega - \omega_{fi}) = \frac{\pi e^2}{\varepsilon_0 m^2 c} \frac{I(\omega)}{\omega^2} |M_{fi}|^2 \delta(\omega - \omega_{fi})} \ . \tag{34.15}$$

We note that the absorption rate is proportional to the intensity of the radiation, which characterizes a typically linear effect.

If we want to express the rate of absorption by atoms in terms of energy, we simply multiply W_{fi} by $\hbar\omega$ and, hence, we can define the cross section for the absorption of radiative energy as,

$$\sigma_{i\to f} \equiv \frac{\text{absorption rate}}{\text{incident intensity}} = \frac{\hbar\omega W_{fi}}{I(\omega)} = \frac{\pi e^2}{\varepsilon_0 m^2 c} \frac{\hbar}{\omega} |M_{fi}(\omega_{fi})|^2 \delta(\omega - \omega_{fi}) \ . \tag{34.16}$$

34.1.2.2 Stimulated emission

For $E_f = E_i - \hbar\omega$ the equation describes the process of *stimulated emission*. Analogously to the calculation of the absorption, we obtain,

$$\boxed{W_{if}^{(st)} = \frac{\pi e^2}{\varepsilon_0 m^2 c} \frac{I(\omega)}{\omega^2} |M_{if}^*|^2 \delta(\omega + \omega_{fi})} \ , \tag{34.17}$$

with $M_{fi}^* = \langle f | e^{-\imath \mathbf{k}\cdot\mathbf{r}} \hat{\epsilon} \cdot \nabla | i \rangle$. Of course,

$$W_{if}^{(st)} = W_{fi}^{(ab)} \ . \tag{34.18}$$

The fact that, in a coupled atom-radiation system in equilibrium, the radiation field excites the same number of transitions in absorption $i \to f$ as in stimulated emission $f \to i$ is called the principle of *detailed balance*.

Obviously, the situation is different, if instead of two states we have several states that can be excited by radiation or decay.

34.1.3 Spontaneous emission

Absorption and stimulated emission are due to the interaction of an atom with a radiation field. However, even in the absence of radiation the atom couples to the field of the electromagnetic vacuum, and an accurate description of the atom must account for this fact. The total system has different eigenstates and their projection on the unperturbed eigenstates changes over time, as any excited atomic state has a constant probability, depending on the coupling to the electromagnetic field, to decay

to another state. The probability of measuring a specific lifetime thus follows a Poisson distribution. The decay process caused by atomic interaction with fluctuations of the electromagnetic vacuum is called *spontaneous emission*. It is understood in the framework of *quantum electrodynamics*, and a thorough discussion is postponed to Sec. 35.6. Here, we will adopt a preliminary heuristic treatment.

Replacing in Eq. (34.17) the intensity by the number of photons (34.8), we obtain,

$$W_{if}^{(st)} = \frac{\pi\hbar e^2 N(\omega)}{\varepsilon_0 m^2 \omega V} |M_{fi}|^2 \delta(\omega - \omega_{fi}) \ . \tag{34.19}$$

In fact, the introduction of the concept of photons already implies the quantization of the electromagnetic field. Adding to the number of photons a photon representing the vacuum fluctuations, $N(\omega) \longrightarrow N(\omega) + 1$, we are able to include spontaneous emission,

$$\boxed{W_{if}^{(st)} + W_{if}^{(sp)} = \frac{\pi\hbar e^2 [N(\omega) + 1]}{\varepsilon_0 m^2 \omega V} |M_{fi}|^2 \delta(\omega + \omega_{fi})} \ . \tag{34.20}$$

This means that even in the absence of a classical radiation field, $N(\omega) = 0$, there is an emission probability. We note that $W_{if}^{(sp)}$ depends on the volume confining the atom, that is, the cavity, since it describes the transfer of energy to this volume. Here, it is clear that an argument is still missing, because the transfer rate must depend in some way on the number of states available to accommodate the emitted photon, that is, on the *density of states* within the cavity. The calculation of this density of states should allow us to evaluate the quantization volume V.

34.1.3.1 Density of states

In Sec. 22.2.2 we calculated the isotropic spectral *density of modes* per volume (22.53),

$$\varrho(\omega) = \frac{\omega^2}{\pi^2 c^3} \ . \tag{34.21}$$

The density of modes in a specific direction of free space (i.e. no boundary conditions imposed e.g. by dielectric surfaces) regardless of the mode volume is then given by [2],

$$\int_{4\pi} \rho_{free}(\omega) d\Omega = V \varrho(\omega) \ , \tag{34.22}$$

that is,

$$\rho_{free}(\omega) = \frac{V}{(2\pi)^3} \frac{\omega^2}{c^3} \ . \tag{34.23}$$

Thus, the spontaneous emission rate of photons into the solid angle $d\Omega$ is,

$$\begin{aligned} \mathcal{W}_{if}^{(sp)} \ d\Omega &= \left(\int_\omega W_{if}^{(sp)} \rho_{free}(\omega) d\omega \right) \ d\Omega \\ &= \int_\omega \frac{\pi\hbar e^2}{\varepsilon_0 m^2 \omega V} |M_{fi}|^2 \delta(\omega + \omega_{fi}) \frac{V}{(2\pi)^3} \frac{\omega^2}{c^3} d\omega \ d\Omega = \frac{\hbar e^2}{8\pi^2 \varepsilon_0 m^2 c^3} |M_{fi}|^2 \omega_{fi} \ d\Omega \ , \end{aligned} \tag{34.24}$$

[2] See also (40.40) and (40.88) in Sec. 40.2.1.

This simplified treatment with only two atomic states considers light as a scalar field. In fact, light is a vector field and can have two independent orthogonal polarizations. The transition matrix may depend on polarization, such that,

$$\mathcal{W}_{if}^{(sp)} = \frac{\hbar e^2}{8\pi^2 \varepsilon_0 m^2 c^3} \int \sum_{\lambda=1,2} |M_{fi}^{\lambda}|^2 \omega_{fi} \, d\Omega \ . \tag{34.25}$$

Example 192 (*Natural linewidth of a transition*): Be $\Gamma \equiv \sum_f W_{if}^{(sp)}$ the spontaneous decay rate of a state $|i\rangle$. This means that its population is decreasing,

$$\dot{N}_i = -\Gamma N_i \ . \tag{34.26}$$

Since $N_i = \langle \psi_i | \psi_i \rangle$, we have $|\psi_i(t)\rangle = |\psi_i(0)\rangle e^{\imath \omega_{if} t - \Gamma t/2}$. The Fourier transform is,

$$\begin{aligned} |\xi(\omega)\rangle &= \frac{1}{\sqrt{2\pi}} \int_0^\infty |\psi_i(t)\rangle e^{-\imath\omega t} dt = \frac{1}{\sqrt{2\pi}} \int_0^\infty e^{\imath\omega_{if} t - \imath\omega t - \Gamma t/2} dt |\psi_i(0)\rangle \quad (34.27) \\ &= \frac{1}{\sqrt{2\pi}} \lim_{t\to\infty} \frac{e^{\imath(\omega_{if}-\omega)t - \Gamma t/2} - 1}{\imath(\omega_{if} - \omega) - \Gamma/2} |\psi_i(0)\rangle = \frac{1}{\sqrt{2\pi}} \frac{1}{\imath(\omega - \omega_{if}) + \Gamma/2} |\psi_i(0)\rangle \ . \end{aligned}$$

The spectrum,

$$|\xi(\omega)|^2 = \frac{1}{2\pi} \frac{1}{(\omega - \omega_{if})^2 + \Gamma^2/4} \ , \tag{34.28}$$

is a *Lorentz distribution*. Note, that the natural linewidth can be blurred by line broadening effects, such as the Doppler broadening or collisions between atoms. These effects will be discussed in the Sec. 34.6.

Excited states can sometimes decay into various states of lower energy. In this case the linewidth is simply given by the sum of the partial decay rates, since the convolution of Lorentz distributions $\mathcal{L}_{\Gamma_k}$ with widths Γ_k is again a Lorentzian with the total width $\Gamma = \sum_k \Gamma_k$.

34.1.4 Exercises

34.1.4.1 Ex: Energy density of plane waves

Derive the result (34.7) for the temporal averages of the squares of the fields $\overline{\vec{\mathcal{E}}(\mathbf{r},t)^2} = \overline{[-\partial_t \mathbf{A}(\mathbf{r},t)]^2}$ and $\overline{\vec{\mathcal{B}}(\mathbf{r},t)^2} = \overline{[\nabla \times \mathbf{A}(\mathbf{r},t)]^2}$.

Solution: *For the plane wave defined by (34.5) and (34.6) we have,*

$$\begin{aligned} \nabla \cdot \mathbf{A}(\mathbf{r},t) &= e^{\imath\omega t} \nabla \cdot \mathbf{A}_0 e^{-\imath \mathbf{k}\cdot\mathbf{r}} + e^{-\imath\omega t} \nabla \cdot \mathbf{A}_0 e^{\imath \mathbf{k}\cdot\mathbf{r}} = -\imath \mathbf{k} \cdot \mathbf{A}_0 (e^{\imath\omega t - \imath \mathbf{k}\cdot\mathbf{r}} - e^{-\imath\omega t + \imath \mathbf{k}\cdot\mathbf{r}}) \\ \frac{\partial \mathbf{A}(\mathbf{r},t)}{\partial t} &= \imath\omega \mathbf{A}_0 (e^{\imath\omega t - \imath \mathbf{k}\cdot\mathbf{r}} - e^{-\imath\omega t + \imath \mathbf{k}\cdot\mathbf{r}}) \\ \nabla \times \mathbf{A}(\mathbf{r},t) &= e^{\imath\omega t} \nabla \times \mathbf{A}_0 e^{-\imath \mathbf{k}\cdot\mathbf{r}} + e^{-\imath\omega t} \nabla \times \mathbf{A}_0 e^{\imath \mathbf{k}\cdot\mathbf{r}} = -\imath \mathbf{k} \times \mathbf{A}_0 (e^{\imath\omega t - \imath \mathbf{k}\cdot\mathbf{r}} - e^{-\imath\omega t + \imath \mathbf{k}\cdot\mathbf{r}}) \end{aligned}$$

and

$$\begin{aligned} \overline{\mathbf{A}(\mathbf{r},t)^2} &= \mathbf{A}_0^2 (2 + \overline{e^{2\imath\omega t - 2\imath \mathbf{k}\cdot\mathbf{r}}} + \overline{e^{-2\imath\omega t + 2\imath \mathbf{k}\cdot\mathbf{r}}}) = 2A_0^2 \\ \overline{[\partial_t \mathbf{A}(\mathbf{r},t)]^2} &= -\omega^2 \mathbf{A}_0^2 (-2 + \overline{e^{2\imath\omega t - 2\imath \mathbf{k}\cdot\mathbf{r}}} + \overline{e^{-2\imath\omega t + 2\imath \mathbf{k}\cdot\mathbf{r}}}) = 2\omega^2 A_0^2 \\ \overline{[\nabla \times \mathbf{A}(\mathbf{r},t)]^2} &= -(\mathbf{k} \times \mathbf{A}_0)^2 (-2 + \overline{e^{2\imath\omega t - 2\imath \mathbf{k}\cdot\mathbf{r}}} + \overline{e^{-2\imath\omega t + 2\imath \mathbf{k}\cdot\mathbf{r}}}) = 2(\mathbf{k} \times \mathbf{A}_0)^2 = 2k^2 A_0^2 \ , \end{aligned}$$

hence for $\mathbf{k}\cdot\mathbf{A}_0 = 0$ *we have* $(\mathbf{k}\times\mathbf{A}_0)^2 = k^2A_0^2$. *Therefore, using the relations (30.2) for electric and magnetic fields,*

$$u(\omega) = \frac{\varepsilon_0}{2}\mathcal{E}^2 + \frac{1}{2\mu_0}\mathcal{B}^2 = \frac{\varepsilon_0}{2}\overline{\partial_t \mathbf{A}(\mathbf{r},t)}^2 + \frac{1}{2\mu_0}\overline{\nabla\times\mathbf{A}(\mathbf{r},t)}^2 = \varepsilon_0\omega^2A_0^2 + \frac{1}{\mu_0}\frac{\omega^2}{c^2}A_0^2 = 2\varepsilon_0\omega^2A_0^2 \ .$$

34.2 The dipolar approximation and beyond

34.2.1 Dipolar transitions

So far, we have used the matrix element $M^\lambda_{fi}(\omega_{fi})$ without saying how it can be calculated, nor when it is significant. In many cases of interest the calculation of this matrix element is considerably simplified by an expansion of the term $e^{-\imath\mathbf{k}\cdot\mathbf{r}}$, which is part of the matrix element (34.12) [3],

$$e^{-\imath\mathbf{k}\cdot\mathbf{r}} = 1 - \imath\mathbf{k}\cdot\mathbf{r} - \tfrac{1}{2!}(\mathbf{k}\cdot\mathbf{r})^2 + \dots \ . \tag{34.29}$$

This expansion is justified by the fact that the wavelength ($\sim 600\,\text{nm}$ in the visible spectrum) is much larger than the size of the scattering atom, $ka_B \ll 1$. The *dipolar approximation* supposes,

$$e^{-\imath\mathbf{k}\cdot\mathbf{r}} \simeq 1 \ , \tag{34.30}$$

such that we can remove the spatial dependence. In this approximation there is only an interaction of the *electric field* of the radiation with the atom via an electric dipole term $\mathbf{d}\cdot\vec{\mathcal{E}}$. Thus,

$$M^\lambda_{fi}(\omega_{fi}) = \langle f|e^{-\imath\mathbf{k}\cdot\mathbf{r}}\hat\epsilon\cdot\nabla|i\rangle \simeq \hat\epsilon\tfrac{\imath}{\hbar}\langle f|\hat{\mathbf{p}}|i\rangle = \hat\epsilon\tfrac{\imath m}{\hbar}\langle f|\dot{\hat{\mathbf{r}}}|i\rangle \ . \tag{34.31}$$

We can calculate the expectation value of the velocity of the moving charge by the Heisenberg equation using the unperturbed Hamiltonian,

$$M^\lambda_{fi}(\omega_{fi}) \simeq \hat\epsilon\tfrac{\imath m}{\hbar}\langle f|\tfrac{1}{\imath\hbar}[\hat{\mathbf{r}},\hat H_0]|i\rangle = \hat\epsilon\tfrac{m}{\hbar^2}\langle f|\hat{\mathbf{r}}\hat H_0 - \hat H_0\hat{\mathbf{r}}|i\rangle = \hat\epsilon\tfrac{m}{\hbar^2}(E_i - E_f)\langle f|\hat{\mathbf{r}}|i\rangle \ . \tag{34.32}$$

The interpretation of the last equation is, that the states $|i\rangle$ and $|f\rangle$ are connected through a displacement of the electronic cloud which, therefore, represents the induction of an electric dipole during the electronic transition. It is convenient to introduce the *electric dipole moment* [4].

$$\mathbf{d}_{fi} \equiv -e\langle f|\hat{\mathbf{r}}|i\rangle \ . \tag{34.33}$$

As a result, the matrix element becomes,

$$\boxed{M^\lambda_{fi}(\omega_{fi}) \simeq \tfrac{m\omega_{fi}}{e\hbar}\hat\epsilon\cdot\mathbf{d}_{fi}} \tag{34.34}$$

[3] Note however, that doing the dipole approximation via $e^{\imath\mathbf{k}\cdot\hat{\mathbf{r}}} \simeq 1$ also deactivates the operator function of the recoil operator dipole, $e^{\imath\mathbf{k}\cdot\hat{\mathbf{r}}} = |\mathbf{p}+\hbar\mathbf{k}\rangle\langle\mathbf{k}|$. For discussions of photonic recoil the operator character must be maintained even in the dipole approximation, which can be done by reinserting the recoil operator in the Hamiltonian after the dipole approximation has been applied.

[4] In the presence of several atoms $\mathbf{d} = -e\sum_j \mathbf{r}_j$, where the $\mathbf{r}_j$ are the radii of the orbits of the various electrons of the atom.

and the absorption rate (34.15) is then, in the dipolar approximation,

$$W_{fi}^{(dp)} = \frac{\pi e^2}{\varepsilon_0 m^2 c}\frac{I(\omega_{fi})}{\omega_{fi}^2}|M_{fi}|^2\delta(\omega-\omega_{fi}) \tag{34.35}$$
$$= \frac{\pi}{\varepsilon_0\hbar^2 c}I(\omega_{fi})|\hat{\epsilon}\cdot\mathbf{d}_{fi}|^2\delta(\omega-\omega_{fi}) = \frac{4\pi^2\alpha}{\hbar}I(\omega_{fi})|\hat{\epsilon}\cdot\mathbf{r}_{fi}|^2\delta(\omega-\omega_{fi})\ .$$

using the definition of the fine structure constant $\alpha = e^2/4\pi\varepsilon_0\hbar c$.

34.2.1.1 Polarization dependence

Following Eq. (34.34) the absorption rate depends on the orientation of the dipole moment with respect to the polarization of light, which therefore plays an important role in this transition. When $\mathbf{d}_{fi}$ between two states is zero, the transition via electric dipole radiation is prohibited. This is not to say that there is no transition, since other terms of the expansion (34.29) are not necessarily zero, and there may be transitions of higher multipolar orders. Even the matrix element $M_{fi}^{\lambda}(\omega_{fi})$ being zero for transitions involving one photon, there is still the possibility of two-photon transitions.

Setting θ as the angle between $\hat{\epsilon}$ and $\mathbf{d}_{fi}$ we obtain,

$$W_{fi}^{(dp)} = \frac{\pi}{\varepsilon_0\hbar^2 c}I(\omega_{fi})|\mathbf{d}_{fi}|^2\cos^2\theta\ \delta(\omega-\omega_{fi})\ . \tag{34.36}$$

In case of unpolarized (or randomly polarized) radiation we can replace the angular distribution $\cos^2\theta$ by its average value,

$$\overline{\cos^2\theta} = \frac{1}{4\pi}\int_0^{2\pi}\int_0^{\pi}\cos^2\theta\sin\theta d\theta d\phi = \tfrac{1}{3}\ , \tag{34.37}$$

such that,

$$\boxed{W_{fi}^{(dp,no-pol)} = \frac{\pi}{3\varepsilon_0\hbar^2 c}I(\omega_{fi})|\mathbf{d}_{fi}|^2\delta(\omega-\omega_{fi})}\ . \tag{34.38}$$

This expression also represents the stimulated emission rate in the electric dipole approximation.

The total spontaneous emission rate can be obtained from Eq. (34.25) integrating over all possible orientations,

$$\mathcal{W}_{fi}^{(sp)} = \frac{\hbar e^2}{8\pi^2\varepsilon_0 m^2 c^3}\int\sum_{\lambda=1,2}|M_{fi}^{\lambda}|^2\omega_{fi}d\Omega \tag{34.39}$$
$$= 2\frac{\hbar e^2}{8\pi^2\varepsilon_0 m^2 c^3}\int_0^{2\pi}\int_0^{\pi}\left|\frac{m\omega_{fi}}{e\hbar}\hat{\epsilon}\cdot\mathbf{d}_{fi}\right|^2\omega_{fi}\sin\theta d\theta d\phi$$
$$= \frac{e^2}{4\pi^2\varepsilon_0\hbar c^3}\omega_{fi}^3|\mathbf{r}_{fi}|^2\int_0^{2\pi}\int_0^{\pi}\cos^2\theta\sin\theta d\theta d\phi = \frac{e^2}{3\pi\varepsilon_0\hbar c^3}\omega_{fi}^3|\mathbf{r}_{fi}|^2\ ,$$

such that, for non-polarized light,

$$\boxed{\mathcal{W}_{fi}^{(sp)} = \frac{4\alpha}{3c^2}\omega_{fi}^3|\mathbf{r}_{fi}|^2 = \frac{4\alpha}{3c^2}\omega_{fi}^3|\mathbf{r}_{fi}|^2 = \Gamma}\ . \tag{34.40}$$

This is the rate of spontaneous decay of an excited atomic state. It can be measured experimentally which, in turn, allows the calculation of the *induced dipole moment*,

$$d_{fi} = \sqrt{\frac{3\pi\varepsilon_0\hbar\Gamma}{k^3}} \ . \tag{34.41}$$

In Exc. 34.2.6.1 we calculate the Rabi frequency from the dipole moment of an atomic transition and the electric field of a radiation field.

34.2.2 Einstein transition rates

Considering the problem of the transfer of energy between the electromagnetic field and a sample of atoms in thermal equilibrium, Einstein realized that the processes of absorption and stimulated emission are not sufficient to understand the radiative coupling between two energy levels, that is, the coupling is not correctly described by Fermi's Golden rule, and we need to introduce the notion of spontaneous emission. Differently from the derivation of the preceding section, Einstein considered atoms whose populations of energy states are in thermal equilibrium with the electromagnetic field of a *black-body*. With this picture he came to the same result for the spontaneous emission rate (34.38), as we will show in the following.

The famous *Einstein coefficients* A_{fi} and B_{fi} are given by (22.70),

$$A_{fi}N_f = W_{fi}^{(sp)} \qquad \text{and} \qquad \frac{A_{fi}}{B_{fi}} = \frac{\hbar\omega_{fi}^3}{\pi^2 c^3} \ , \tag{34.42}$$

where N_f is the population of the excited state. This shows that, in fact, spontaneous emission is a necessary consequence of the interaction of an atom with a *thermal bath* (also called *reservoir*).

We now consider the problem of energy transfer between an electromagnetic field and a sample of atoms. The rate of *absorption* of a light field is,

$$R_{i\to f} \equiv \tfrac{1}{3}\dot{P}_{i\to f} = \frac{\pi}{6\hbar^2}\mathcal{E}_0^2|d_{fi}|^2\varrho(\omega_{fi}) \ , \tag{34.43}$$

with $W_0 = \mathcal{E}_0 d_{fi}$ and d_{fi} being the transition matrix element between atomic states. The factor $\frac{1}{3}$ comes from the fact that the vector $\vec{\mathcal{E}}$ of the electric field can have any polarization, but only polarizations along the direction of the oscillation of the dipole moment contribute.

For a single atom, the result (34.43) is symmetric with respect to an exchange of the initial and final states, that is, the rates for absorption and *induced emission* of light are the same. For a sample of atoms being in *thermal equilibrium*, the populations N_i of the ground state and N_f of the excited state are unequal according to Boltzmann's law. Therefore, as we have shown in Sec. 22.2.5,

$$N_f R_{f\to i} \neq N_i R_{i\to f} \ . \tag{34.44}$$

Thus, Einstein came to the conclusion that Fermi's golden rule correctly describes absorption, but does not contain all contributions of emission. The rates being related to the Einstein coefficients by the equation (22.65), we find,

$$R_{f\to i} = B_{fi}N_f u(\omega_{fi}) \tag{34.45}$$

and

$$\mathcal{S}_{f\to i} = A_{fi}N_f = \frac{\hbar\omega_{fi}^3}{\pi^2c^3}B_{if}N_f = \frac{\hbar\omega_{fi}^3}{\pi^2c^3}\frac{R_{i\to f}}{u(\omega_{fi})} = \frac{\omega_{fi}^3}{3\pi\epsilon_0\hbar c^3}|d_{fi}|^2 \ , \tag{34.46}$$

exploiting the relation (22.70).

Example 193 (*Line and oscillator strength*): Several disciplines such as spectrometry, spectroscopy and astrophysics have developed their own terminologies to describe absorption and emission of light by matter. We will explain how the most frequently used parameters are interrelated by placing particular emphasis on the simplest system, which is the two-level atom with no degeneracy and no spin.
In addition to the Einstein coefficients A_{21}, B_{21}, and B_{12}, the amplitude of the transition dipole moments d_{12} and the absorption cross-section $\sigma_{0a}(\omega)$, three other quantities are sometimes used to characterize atomic transitions: the oscillator strength f, the line strength S, and the spectral absorption cross section σ_ω. In the following sections, we will connect these different concepts.
The line strength S is defined as the square of the transition dipole moment summed over all degeneracies of the ground and excited states,

$$S_{12} = S_{21} = \sum_{m_1,m_2} |\langle\psi_{1,m_1}|d|\psi_{2,m_2}\rangle|^2 \ . \tag{34.47}$$

The notion of the line strength becomes significant when working with real atoms characterized by degenerate ground and excited states. In such cases we need to extend the meaning of d_{12} and consider transitions between each of the degenerate sublevels. For a non-degenerate two-level atom, the quantities d_{12} and A_{21} are simply related by,

$$A_{21} = \frac{\omega_0^3}{3\pi\epsilon_0\hbar c^3}d_{12}^2 \ . \tag{34.48}$$

If the lower level would be degenerate, the spontaneous emission rate coefficient would be given by the sum of all possible deexcitation rates. In this case, d_{12}^2 is defined as the sum of the elements of the transition matrix coupling the excited and the lower states,

$$d_{12}^2 = \sum_{m_1} |\langle\psi_{1,m_1}|d|\psi_2\rangle|^2 \ . \tag{34.49}$$

Now, it can be shown that the spontaneous emission rate from any sublevel of a degenerate excited state toward a lower level (that is, the sum over all lower sublevels) is the same for all excited sublevels [5] This statement reflects the intuitively plausible idea that spontaneous emission must be isotropic and unpolarized, if the sublevels of an excited state are uniformly populated. Therefore, the insertion of Eq. (34.49) into (34.48) should produce correct results, even when the excited state is degenerate. Comparing the sum over all upper and lower degeneracies with the line strength S,

$$S_{12} = \sum_{m_1,m_2} |\langle\psi_{1,m_1}|d|\psi_{2,m_2}\rangle|^2 = g_2d_{12}^2 \ . \tag{34.50}$$

[5] This applies to Zeeman sublevels (summing up $(3j)$-coefficients). Check for other degeneracy (also summing up $\{6j\}$-coefficients)!

Therefore, the insertion of Eq. (34.50) into (34.48) must be accompanied by a factor of $1/g_2$ to correct for the fact that all excited sub-levels radiate at the same rate. Therefore, using the S_{12} of Eq. (34.50) the correct expression relating the transition dipole between degenerate levels to the spontaneous emission rate is,

$$S_{12} = g_2 \frac{3\pi\epsilon_0 \hbar c^3}{\omega_0^3} A_{21} \ , \tag{34.51}$$

meaning that the line strength is proportional to the sum of the spontaneous emission rates A_{21} from each one of the g_2 excited levels toward all fundamental levels.

For an atom with two levels separated by an energy $\hbar\omega_0$ the *oscillator strength for emission* is defined as a measure for the radiative decay rate A_{21} as compared to the radiative decay rate γ_e of a classical electronic oscillator with frequency ω_0:

$$f_{21} = -\frac{1}{3}\frac{A_{21}}{\gamma_e} \ . \tag{34.52}$$

In case of degeneracy the *oscillator strength for absorption* is consequently defined by,

$$f_{12} = -\frac{g_2}{g_1} f_{21} = \frac{g_2}{3g_1}\frac{A_{21}}{\gamma_e} \ . \tag{34.53}$$

The transitions $S \leftrightarrow P$ in real atoms behave roughly as classical oscillators, that is, $A_{21} \simeq \gamma_e$. The factor $\frac{1}{3}$ in the definition compensates for the triple degeneracy of the P levels. So, a transition $S \leftrightarrow P$ which behaves exactly as a classical oscillator would be characterized by an oscillator strength for emission of $f_{21} = -\frac{1}{3}$ and an oscillator strength for absorption of $f_{12} = 1$. The classical expression for γ_e derived from the *Lorentz model* is [547],

$$\gamma_e = \frac{e^2\omega_0^2}{6\pi\epsilon_0 m_e c^3} \ . \tag{34.54}$$

Therefore, in terms of the A_{21} coefficient and of fundamental constants, the oscillator strength for absorption is given by,

$$f_{12} = A_{21}\frac{2\pi\epsilon_0 m_e c^3}{e^2\omega_0^2} \ . \tag{34.55}$$

Oscillator strengths obey certain sum rules that are useful for analyzing the relative intensities of atomic spectral lines. For example, atoms with single valence electrons (which are closer to the classical situation) obey the following sum rule,

$$\sum_k f_{ik} = 1 \ , \tag{34.56}$$

where the sum goes over all the excited states reached from the ground state. Alkaline atoms are approximately one-electron systems, and the oscillator strength of the first transition $S \longrightarrow P$ is typically of the order of $f_{12} = 0.7 - 0.95$. The sum rule tells us that most of the total transition probability for the excitation of the valence electron is concentrated in the first transition $S \to P$, and that transitions to higher states will be comparatively weaker. Another sum rule exists for the excitation and spontaneous emission from excited intermediate states j:

$$\sum_{i<j} f_{ji} + \sum_{k>j} f_{jk} = Z \ , \tag{34.57}$$

which is called the *Thomas-Reiche-Kuhn sum rule*. In the form of many electrons [Eq. (34.57)] this rule is very useful, when Z is the number of equivalent electrons, that is, electrons with the same quantum numbers n, l. Note also, that the numbers are intrinsically negative. Oscillator strengths are often used in astrophysics and plasma spectroscopy [6]. They are sometimes tabulated as $\log gf$, where,

$$g_1 f_{12} = -g_2 f_{21} \equiv gf \ . \tag{34.58}$$

34.2.3 Selection rules and electronic transitions

The selection rules that determine which transitions between two sets of quantum numbers $i \to f$ are allowed, reflect the symmetry properties of the system, e.g. the conservation of angular momentum (including the spin of the photon) or the change of parity, which can be understood by the fact that the emission of a photon in a particular direction must in some way alter the spatial isotropy of the atom. Note that radially symmetric oscillations of the shape of the charge distribution *do not radiate*.

Since the electronic transitions via electric dipole radiation are described by $|\hat{\epsilon} \cdot \mathbf{r}_{fi}|$, we expect a strong dependence of the transition rate on the orientation of the polarization state of the light with respect to the electronic displacement $\mathbf{r}_{fi}$. Let us express $\hat{\epsilon}$ and $\mathbf{r}_{fi}$ in spherical coordinates, which are more adapted to the problem [7]. For an arbitrary vector $\mathbf{r}$ we have,

$$x = \mathbf{r}\cdot\hat{\mathbf{e}}_x = r\sin\vartheta\cos\varphi \quad , \quad y = \mathbf{r}\cdot\hat{\mathbf{e}}_y = r\sin\vartheta\sin\varphi \quad , \quad z = \mathbf{r}\cdot\hat{\mathbf{e}}_z = r\cos\vartheta \ . \tag{34.59}$$

Defining,

$$\hat{\mathbf{e}}_{\pm1} \equiv \tfrac{1}{\sqrt{2}}(\mp\hat{\mathbf{e}}_x - \imath\hat{\mathbf{e}}_y) \qquad , \qquad \hat{\mathbf{e}}_0 \equiv \hat{\mathbf{e}}_z \ . \tag{34.60}$$

we obtain

$$r_{\pm1} \equiv \mathbf{r}\cdot\hat{\mathbf{e}}_\pm = \mathbf{r}\cdot\tfrac{1}{\sqrt{2}}(\mp\hat{\mathbf{e}}_x - \imath\hat{\mathbf{e}}_y) = \tfrac{1}{\sqrt{2}}(\mp x - \imath y) = \mp\tfrac{1}{\sqrt{2}} r\sin\vartheta e^{\pm\imath\varphi} = r\sqrt{\tfrac{4\pi}{3}}Y_{1,\pm1}(\vartheta,\varphi)$$
$$r_0 \equiv \mathbf{r}\cdot\hat{\mathbf{e}}_0 = \mathbf{r}\cdot\hat{\mathbf{e}}_z = z = r\cos\vartheta = r\sqrt{\tfrac{4\pi}{3}}Y_{1,0}(\vartheta,\varphi) \ . \tag{34.61}$$

Now, applying the expansion into spherical coordinates to the polarization, we get,

$$\epsilon_{\pm1} \equiv \hat{\epsilon}\cdot\hat{\mathbf{e}}_\pm \qquad , \qquad \epsilon_0 \equiv \hat{\epsilon}\cdot\hat{\mathbf{e}}_0 \ . \tag{34.62}$$

and applying the expansion to the matrix element $\mathbf{r}_{fi} = \langle f|\mathbf{r}|i\rangle$ with $\hat{\mathbf{e}}_q \cdot \hat{\mathbf{e}}_{q'} = \delta_{qq'}$, it is easy to check,

$$\hat{\epsilon}\cdot\mathbf{r}_{fi} = \sum_{q=0,\pm1}(\hat{\epsilon}\cdot\hat{\mathbf{e}}_q)\hat{\mathbf{e}}_q \cdot \sum_{q=0,\pm1}(\mathbf{r}_{fi}\cdot\hat{\mathbf{e}}_q)\hat{\mathbf{e}}_q = \sum_{q=0,\pm1}\epsilon_q\langle f|r_q|i\rangle = \sqrt{\tfrac{4\pi}{3}}\sum_{q=0,\pm1}\epsilon_q\langle f|rY_{1,q}|i\rangle \ . \tag{34.63}$$

[6] To find information about the atomic transition lines see 'http://www.nist.gov/pml/data/asd.cfm'.

[7] In the presence of a magnetic field it is often useful to choose the quantization axis along the field direction, because this simplifies the interpretation of π and $\sigma_\pm$ transitions in terms of light polarizations (see also Secs. 34.7.4 and 34.8.3).

The matrix elements are evaluated inserting the ansatz (25.18) separating the radial from the angular part of the wavefunction, where the angular part is solved by (25.32),

$$\begin{aligned}\langle f|r_q|i\rangle &= \sqrt{\tfrac{4\pi}{3}}\langle n_f\ell_f m_f|rY_{1,q}|n_i\ell_i m_i\rangle \\ &= \int_0^\infty r^3 R_{n_f,\ell_f}R_{n_i,\ell_i}dr\ \sqrt{\tfrac{4\pi}{3}}\int Y^*_{\ell_f,m_f}Y_{1,q}Y_{\ell_i,m_i}d\Omega\ .\end{aligned} \tag{34.64}$$

The angular integral,

$$\int Y^*_{\ell_f,m_f}Y_{\kappa,q}Y_{\ell_i,m_i}d\Omega = \sqrt{\tfrac{(2\ell_i+1)(2\ell_f+1)}{4\pi(2\kappa+1)}}\left(\begin{array}{cc|c}\ell_i & \kappa & \ell_f\\ 0 & 0 & 0\end{array}\right)\left(\begin{array}{cc|c}\ell_i & \kappa & \ell_f\\ m_i & q & m_f\end{array}\right)\ , \tag{34.65}$$

here with $\kappa = 1$, is only non-zero, if the values of ℓ_i, m_i, ℓ_f, m_f and q satisfy certain conditions called *selection rules* [8].

The radial integral, together with the coefficients of (34.65) which do not depend on the magnetic quantum numbers, is called *reduced matrix element* or *irreducible matrix element* with the notation,

$$\langle n_f\ell_f||r||n_i\ell_i\rangle \equiv \int_0^\infty r^3 R_{n_f,\ell_f}R_{n_i,\ell_i}dr\ \sqrt{\tfrac{(2\ell_i+1)(2\ell_f+1)}{3(2\kappa+1)}}\left(\begin{array}{cc|c}\ell_i & \kappa & \ell_f\\ 0 & 0 & 0\end{array}\right)\ . \tag{34.66}$$

Defining the electric dipole tensor operator,

$$Q^q_1(\mathbf{r}) = er_q(\mathbf{r}) = \sqrt{\tfrac{4\pi}{3}}Y_{1,q}(\vartheta,\varphi)er\ , \tag{34.67}$$

we can finally write,

$$\boxed{\langle n_f\ell_f m_f|Q^q_1(\mathbf{r})|n_i\ell_i m_i\rangle = \langle n_f\ell_f||er||n_i\ell_i\rangle\left(\begin{array}{cc|c}\ell_i & 1 & \ell_f\\ m_i & q & m_f\end{array}\right)}\ . \tag{34.68}$$

This is the *Wigner-Eckart theorem*. The electric dipole operator is a simpler example of a tensor operator $Q^q_\kappa(\mathbf{r})$ characterizing the transition between atomic states. In Excs. 34.2.6.2 and 34.2.6.3 we explicitly calculate, for a hydrogen atom subjected to a magnetic field, components of the electric dipole operator. Resolve Exc. 34.2.6.4.

Selection rules may be violated in higher orders, e.g. by multipolar radiation, as in the cases of *magnetic dipole transitions* or *electric quadrupole transitions*. This also is the case of the phenomenon of *phosphorescence*, which is a type of fluorescence emitted by metastable states.

34.2.3.1 Parity

The *parity* of a state has been defined as,

$$\mathcal{P}\psi_{n\ell m}(\mathbf{r}) = \psi_{n\ell m}(-\mathbf{r}) = (-1)^\ell\psi_{n\ell m}(\mathbf{r})\ , \tag{34.69}$$

[8] Frequently used are the $(3j)$-symbols connected to the Clebsch-Gordan coefficients by,

$$\langle j_i m_i, j_f m_f|J,M\rangle = (-1)^{j_i-j_f+M}\sqrt{2J+1}\left(\begin{array}{ccc}j_i & j_f & J\\ m_i & m_f & -M\end{array}\right)\ .$$

as shown above. That is, states with ℓ pair (impair) have even (odd) parity. Now the integral (34.67) only does not vanish, when $\ell_i + \ell_f + 1 = even$. Therefore, *dipole transitions must change the parity of the states.* F.ex. transitions $S \to P$ would be possible, while $S \to S$ would be prohibited.

34.2.3.2 Angular momentum

The irreducible matrix element (34.66) with $\kappa = 1$ is only non-zero, when $|\ell_f - \ell_i| \leq 1 \leq \ell_f + \ell_i$. That is, *dipole transitions can not change the angular momentum by more than one unit.*

34.2.3.3 Magnetic quantum number

In the decomposition (34.68) the Clebsch-Gordan coefficient is only non-zero, when $|q| \leq 1$. That is, *dipole transitions can not change the magnetic quantum number by more than one unit.* This can also be seen from,

$$\int Y^*_{\ell_f,m_f} Y_{\kappa,q} Y_{\ell_i,m_i} d\Omega \propto \int e^{\imath(m_i+q-m_f)} d\Omega \propto \delta_{m_i+q,m_f} \ . \tag{34.70}$$

34.2.3.4 Selection rules for emission in certain directions

As shown in Eq. (34.63), the excitation rate induced by a light field depends on the relative orientation of the laser polarization $\hat{\epsilon}$ and the atomic quantization axis (which may be set by the orientation of an applied magnetic field $\vec{\mathcal{B}}$). To take this dependence into account, we decompose the polarization vector (which can be linear or elliptical) on a coordinate basis, as shown in Eq. (34.62). Thus, the relative amplitude of the transitions $\Delta m_J = 0$ is proportional to the projection of the polarization vector onto the quantization axis, $\epsilon_0 \equiv \hat{\epsilon} \cdot \hat{\mathbf{e}}_0$. To estimate the amplitude of the transitions $\Delta m_J = \pm 1$, we must project onto the coordinates $\epsilon_{\pm 1} \equiv \hat{\epsilon} \cdot \hat{\mathbf{e}}_\pm$. Note that the direction of incidence of the beam, given by the wavevector $\mathbf{k}$, does not influence the transition probability directly (after all, the spatial dependence $e^{\imath \mathbf{k}\cdot\mathbf{r}}$ was removed by the dipolar approximation (34.29)); only through the fact, that the polarization is perpendicular to the propagation vector, $\hat{\epsilon} \perp \mathbf{k}$.

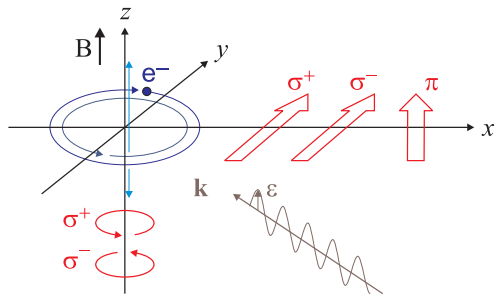

Figure 34.1: Selection rules due to polarization $\hat{\epsilon}$ of the incident light. The projection of this vector onto the axes $\pi = \hat{\epsilon} \cdot \hat{\mathbf{e}}_0$ and $\sigma_\pm = \hat{\epsilon} \cdot \hat{\mathbf{e}}_\pm$ is proportional to the excitation probability (and, obviously, also to the emission probability).

34.2.4 Reduction of the fine and hyperfine structure

In Sec. 34.2.3 we developed the Wigner-Eckart theorem for arbitrary angular momenta ℓ_i and ℓ_f. We will now be more specific identifying them with orbital angular momenta, $(\ell_i, \ell_f) = (\mathbf{L}, \mathbf{L}')$, total angular momenta of the electron shell, $(\ell_i, \ell_f) = (\mathbf{J}, \mathbf{J}')$, or total angular momenta including hyperfine structure, $(\ell_i, \ell_f) = (\mathbf{F}, \mathbf{F}')$.

34.2.4.1 Summary of selection rules including fine structure

The fine structure is due to a coupling of the type $\mathbf{L} + \mathbf{S} = \mathbf{J}$. The reduced matrix element (34.66) can then be recoupled as follows,

$$\boxed{\begin{aligned} \langle J', m'_J|\hat{\mathbf{d}}|J, m_J\rangle &= \langle J'||\hat{\mathbf{d}}||J\rangle \begin{pmatrix} J & \kappa & J' \\ m_J & q & m'_J \end{pmatrix} \quad \text{with} \\ \langle (L', S')J'||\hat{\mathbf{d}}||(L, S)J\rangle &= (-1)^{J+L'+1+S}\sqrt{(2J+1)(2L'+1)} \begin{Bmatrix} L' & L & 1 \\ J & J' & S \end{Bmatrix} \langle L'||\hat{\mathbf{d}}||L\rangle \end{aligned}} \,, \tag{34.71}$$

where the matrix in the second line represents a so-called *{6j}-symbol*, and the first line rewrites the Wigner-Eckart theorem (34.68) for total angular momenta. In this case,

$$\begin{aligned} \langle (L, S)Jm_J|er|(L', S')J'm'_J\rangle &= (-1)^{J+L'+1+S}\sqrt{2J+1}\sqrt{2L'+1} \times \\ &\times \delta_{S'S} \begin{Bmatrix} L & L' & 1 \\ J' & J & S \end{Bmatrix} \begin{pmatrix} J' & 1 & J \\ m'_J & q & -m_J \end{pmatrix} \langle n'L'||er||nL\rangle \\ &\propto \delta_{S'S} \begin{Bmatrix} L & L' & 1 \\ J' & J & S \end{Bmatrix} \begin{pmatrix} J' & 1 & J \\ m'_J & q & -m_J \end{pmatrix} \begin{pmatrix} L' & 1 & L \\ 0 & 0 & 0 \end{pmatrix} , \end{aligned} \tag{34.72}$$

Electric dipolar transitions are excited by Stark-like perturbations,

$$\hat{V}_{stark} = -e\mathbf{d} \cdot \mathcal{E} \,, \tag{34.73}$$

where $\mathcal{E} = \mathcal{E}_0 \cos(\mathbf{k} \cdot \mathbf{r} - \omega t)$ is the electric field of an electromagnetic oscillating wave with polarization $\mathcal{E}_0$. With $\mathbf{d} = ez\hat{\mathbf{e}}_z$, in order to determine which dipole transitions are possible, we must look at the matrix $\langle J'm'_J|\hat{z}|Jm_J\rangle$. Applying the Wigner-Eckart theorem (30.71), it is already possible to determine, between which magnetic quantum numbers m_J and m'_J transitions may occur.

We can compare the amplitudes of the various transitions between states $|m_J\rangle$ and $|m'_J\rangle$ via the Clebsch-Gordan coefficients (see Exc. 30.3.2.1). Again, transitions are only possible between states for which the corresponding Clebsch-Gordan coefficient does not zero. Looking at the equations (30.73), we find for dipolar transitions the following selection rules,

$$\begin{aligned} &\Delta J = 0, \pm 1 \quad \text{but} \quad (J = 0) \to (J' = 0) \quad \text{is prohibited} \\ &\Delta m_J = 0, \pm 1 \quad \text{but} \quad (m_J = 0) \to (m'_J = 0) \quad \text{is prohibited when} \quad \Delta J = 0 \,. \end{aligned} \tag{34.74}$$

In addition, we have for the $\mathbf{L} \cdot \mathbf{S}$ coupling,

$$\Delta S = 0, \Delta L = \pm 1 \quad \text{and for the electron undergoing the transition} \quad \Delta\ell = \pm 1 \,. \tag{34.75}$$

Table 34.1: Allowed transitions: (1-3) rigorous rules, (4-5) LS-coupling, and (6) intermediate coupling (https://en.wikipedia.org/wiki/Selection_rule).

	(E1)	(M1)	(E2)	(M2)	(E3)	(M3)
(1)	$\Delta J = 0, \pm 1$ ($\Delta J = 0 \nleftrightarrow 0$)		$\Delta J = 0, \pm 1, \pm 2$ ($\Delta J = 0 \nleftrightarrow 0, 1; \frac{1}{2} \nleftrightarrow \frac{1}{2}$)		$\Delta J = 0, \pm 1, \pm 2, \pm 3$ ($0 \nleftrightarrow 0, 1, 2; \frac{1}{2} \nleftrightarrow \frac{1}{2}, \frac{3}{2}; 1 \nleftrightarrow 1$)	
(2)	$\Delta M_J = 0, \pm 1$		$\Delta M_J = 0, \pm 1, \pm 2$		$\Delta M_J = 0, \pm 1, \pm 2, \pm 3$	
(3)	$\mathcal{P}_f = -\mathcal{P}_i$	$\mathcal{P}_f = \mathcal{P}_i$		$\mathcal{P}_f = -\mathcal{P}_i$		$\mathcal{P}_f = \mathcal{P}_i$
(4)	one e^- jump $\Delta L = \pm 1$	no e^- jump $\Delta L = 0; \Delta n \neq 0$	none or one e^- jump $\Delta L = 0, \pm 2$	one e^- jump $\Delta L = \pm 1$	one e^- jump $\Delta L = \pm 1, \pm 3$	one e^- jump $\Delta L = 0, \pm 2$
(5)	if $\Delta S = 0$ $\Delta L = 0, \pm 1$ ($L = 0 \nleftrightarrow 0$)	if $\Delta S = 0$ $\Delta L = 0$	if $\Delta S = 0$ $\Delta L = 0, \pm 1, \pm 2$ ($L = 0 \nleftrightarrow 0, 1$)		if $\Delta S = 0$ $\Delta L = 0, \pm 1, \pm 2, \pm 3$ ($L = 0 \nleftrightarrow 0, 1, 2; 1 \nleftrightarrow 1$)	
(6)	if $\Delta S = \pm 1$ $\Delta L = 0, \pm 1, \pm 2$		if $\Delta S = \pm 1$ $\Delta L = 0, \pm 1, \pm 2, \pm 3$ ($L = 0 \nleftrightarrow 0$)	if $\Delta S = \pm 1$ $\Delta L = 0, \pm 1$ ($L = 0 \nleftrightarrow 0$)	if $\Delta S = \pm 1$ $\Delta L = 0, \pm 1, \pm 2, \pm 3, \pm 4$ ($L = 0 \nleftrightarrow 0, 1$)	if $\Delta S = \pm 1$ $\Delta L = 0, \pm 1, \pm 2$ ($L = 0 \nleftrightarrow 0$)

In the presence of a strong magnetic field (Paschen-Back regime) breaking up the $\mathbf{L} \cdot \mathbf{S}$-coupling the selection rules are,

$$\Delta m_S = 0, \Delta m_L = 0, \pm 1 \ . \tag{34.76}$$

For $\mathbf{j} \cdot \mathbf{j}$-coupling,

$$\Delta j = 0, \pm 1 \ \text{ for one electron and } \ \Delta j = 0 \ \text{ for all others} \ . \tag{34.77}$$

For all dipole transitions the parity must change between even and odd.

Example 194 (*Transitions allowed and prohibited in the dipolar approximation*): Examples of allowed transitions are ${}^2S_{1/2} \leftrightarrow {}^2P_{1/2}$, ${}^1S_0 \leftrightarrow {}^1P_0$. Prohibited transitions are ${}^1S_0 \nleftrightarrow {}^3P_1$, ${}^2S_{1/2} \nleftrightarrow {}^2D_{3/2}$, $(5s)^2\ {}^3P_0 \nleftrightarrow (5s6s)\ {}^3P_0$.

34.2.4.2 Summary of selection rules including hyperfine structure

The fine structure is due to a coupling of the type $\mathbf{J} + \mathbf{I} = \mathbf{F}$. The reduced matrix element (34.66) can then be recoupled in a similar way as for the fine structure. Applying the Wigner-Eckart theorem (25.107) to the *hyperfine structure* [1368],

$$\begin{aligned}
\langle F', m'_F | \hat{\mathbf{d}} | F, m_F \rangle &= \langle F' || \hat{\mathbf{d}} || F \rangle \begin{pmatrix} F & \kappa & F' \\ m_F & q & m'_F \end{pmatrix} \quad \text{with} \\
\langle (J', I') F' || \hat{\mathbf{d}} || (J, I) F \rangle &= (-1)^{F+J'+1+I} \sqrt{(2F+1)(2J'+1)} \begin{Bmatrix} J' & J & 1 \\ F & F' & I \end{Bmatrix} \langle J' || \hat{\mathbf{d}} || J \rangle \\
\langle (L', S') J' || \hat{\mathbf{d}} || (L, S) J \rangle &= (-1)^{J+L'+1+S} \sqrt{(2J+1)(2L'+1)} \begin{Bmatrix} L' & L & 1 \\ J & J' & S \end{Bmatrix} \langle L' || \hat{\mathbf{d}} || L \rangle
\end{aligned} \ . \tag{34.78}$$

34.2.5 Irreducible tensor operators

Irreducible tensor operators are defined by their commutation relation with the angular momentum $\mathbf{J}$,

$$[\mathbf{J}, \mathbb{T}^{(k)}_q] = \sum_{q'} \langle kq | \mathbf{J} | kq' \rangle T^{(k)}_{q'} \ . \tag{34.79}$$

Using the spherical unit vectors $\hat{\mathbf{e}}_{\pm 1} = \frac{1}{\sqrt{2}}(\mp\hat{\mathbf{e}}_x - \imath\hat{\mathbf{e}}_y)$ and $\hat{\mathbf{e}}_0 = \hat{\mathbf{e}}_z$, we can reduce Cartesian vector operators to first-order tensor operators:

$$\vec{T} = \sum_q T_q^{(1)}\hat{\mathbf{e}}_q \qquad \text{resp.} \qquad T_q^{(1)} = \vec{T}\cdot\hat{\mathbf{e}}_q \ . \tag{34.80}$$

Examples for tensor operators are $\mathbb{I}_0^{(0)}$, $\hat{\mathbf{e}}_q^{(1)}$, $\mathbf{J}_q^{(1)}$, and $Y_q^{(k)}$. The most general tensor product is defined by:

$$(\mathbb{T}^{(k)} \times \mathbb{U}^{(k')})_m^{(j)} \equiv \sum_{q,q'} \begin{pmatrix} k & k' & j \\ q & q' & -m \end{pmatrix} \mathbb{T}_q^{(k)}\mathbb{U}_{q'}^{(k')} \ . \tag{34.81}$$

With this product it is possible to represent scalar, vector or tensor products of higher ranks,

$$\begin{aligned}
(\mathbb{T}^{(1)} \times \mathbb{U}^{(1)})_0^{(0)} &= \tfrac{1}{\sqrt{3}}\vec{\mathbb{T}}\cdot\vec{\mathbb{U}} \\
(\mathbb{T}^{(1)} \times \mathbb{U}^{(1)})_m^{(1)} &= \tfrac{1}{\sqrt{2}}(\vec{\mathbb{T}}\times\vec{\mathbb{U}})\cdot\hat{\mathbf{e}}_m \\
(\mathbb{T}^{(1)} \times \mathbb{U}^{(1)})_0^{(2)} &= -\tfrac{1}{\sqrt{6}}(3\mathbb{T}_z\mathbb{U}_z - \vec{\mathbb{T}}\cdot\vec{\mathbb{U}}) \\
(\mathbb{T}^{(1)} \times \mathbb{U}^{(1)})_{\pm 1}^{(2)} &= \pm\tfrac{1}{2}[(\mathbb{T}_x\mathbb{U}_z + \mathbb{T}_z\mathbb{U}_x) \pm \imath(\mathbb{T}_y\mathbb{U}_z + \mathbb{T}_z\mathbb{U}_y)] \\
(\mathbb{T}^{(1)} \times \mathbb{U}^{(1)})_{\pm 2}^{(2)} &= -\tfrac{1}{2}[(\mathbb{T}_x\mathbb{U}_x - \mathbb{T}_y\mathbb{U}_y) \pm \imath(\mathbb{T}_x\mathbb{U}_y + \mathbb{T}_y\mathbb{U}_x)] \ .
\end{aligned} \tag{34.82}$$

34.2.5.1 The Wigner-Eckart theorem

Be $\mathbb{T}_q^{(k)}$ an irreducible tensor of rank k. Then, there exists then an irreducible matrix element $\langle j||\mathbb{T}^{(k)}||j'\rangle$, which does not depend on the Zeeman sublevels:

$$\langle jm|\mathbb{T}_q^{(k)}|j'm'\rangle = \begin{pmatrix} j' & k & j \\ m' & q & -m \end{pmatrix} \frac{1}{\sqrt{2j+1}}\langle j||\mathbb{T}^{(k)}||j'\rangle \ . \tag{34.83}$$

From the possible values for the Clebsch-Gordan coefficients follow directly the selection rules for multipolar radiation:

$$\begin{aligned}
\langle jm|\mathbb{T}_q^{(k)}|j'm'\rangle = 0 \qquad \text{else} \qquad & E' - E = \hbar\omega \\
& |j'-j| \le k \le j'+j \\
& m' - m = q \\
& \tau'\tau = T \ .
\end{aligned} \tag{34.84}$$

For tensor products the reduced matrix element can be reduced:

$$\langle j||(\mathbb{T}^{(k)} \times \mathbb{U}^{(k')})^{(l)}||j'\rangle = (-)^{j+\ell+j'}\sqrt{2\ell+1}\sum_q \begin{Bmatrix} k & k' & \ell \\ j' & j & q \end{Bmatrix} \langle j||\mathbb{T}^{(k)}||q\rangle\langle q||\mathbb{U}^{(k')}||\mathbb{j}'\rangle \ . \tag{34.85}$$

In particular, it is possible to show,

$$\begin{aligned}\langle j||\mathbb{I}^{(0)}||j'\rangle &= \sqrt{2j+1}\delta_{jj'} \\ \langle j||\mathbb{J}^{(1)}||j'\rangle &= \sqrt{2j+1}\sqrt{j(j+1)}\delta_{jj'} \\ \langle j||\mathbb{Y}^{(k)}||j'\rangle &= \imath^{j+k+j'}\frac{\sqrt{2j+1}\sqrt{2k+1}\sqrt{2j'+1}}{4\pi}\begin{pmatrix} j & k & j' \\ 0 & 0 & 0\end{pmatrix} .\end{aligned} \tag{34.86}$$

34.2.5.2 Matrix element for angular momentum coupling

We consider states $|(l,s)j\rangle$. If the factors $\mathbb{T}$ and $\mathbb{U}$ of the tensor product act on different angular momenta, it can be reduced as follows:

$$\langle (l,s)j||(\mathbb{T}^{(k)}\times\mathbb{U}^{(k')})^{(l)}||(l',s')j'\rangle = \sqrt{2l+1}\sqrt{2j+1}\sqrt{2j'+1}\begin{Bmatrix} l' & s' & j' \\ k & k' & l \\ l & s & j\end{Bmatrix}\langle l||\mathbb{T}^{(k)}||l'\rangle\langle s||\mathbb{U}^{(k')}||s'\rangle . \tag{34.87}$$

Assuming, in particular, $\mathbb{U}^{(k')} \equiv \mathbb{I}^{(0)}$, we get, with $\mathbb{T}^{(k)} = \left(\mathbb{T}^{(k)}\times\mathbb{I}^{(0)}\right)^{(k)}$,

$$\langle (l,s)j||\mathbb{T}^{(k)}||(l',s')j'\rangle = (-)^{l+s+j'+k}\delta_{ss'}\sqrt{2j+1}\sqrt{2j'+1}\begin{Bmatrix} l & l' & k \\ j' & j & s\end{Bmatrix}\langle l||\mathbb{T}^{(k)}||l'\rangle . \tag{34.88}$$

The last equation therefore applies when $\mathbb{T}^{(k)}$ only acts on the angular momentum component ℓ. If on the other hand, $\mathbb{T}^{(k)}$ only acts on j, then we obviously have,

$$\langle (l,s)j||\mathbb{T}^{(k)}||(l',s')j'\rangle = \langle j||\mathbb{T}^{(k)}||j'\rangle . \tag{34.89}$$

34.2.6 Exercises

34.2.6.1 Ex: Rabi frequency

From the expression for the dipole moment d and the relationship between the intensity I and the electric field derive the Rabi frequency Ω produced by a laser beam of intensity I by exciting an atomic dipole transition with the wavelength λ and decay width Γ.

Solution: *The intensity is related to the electric field by,*

$$I = n\varepsilon_0 c\vec{\mathcal{E}}_1^2 .$$

Using the expression for the dipole moment,

$$d = \sqrt{\frac{3\pi\varepsilon_0\hbar\Gamma}{k^3}} ,$$

we find the Rabi frequency,

$$\Omega_n = \frac{d\mathcal{E}_1\sqrt{n}}{\hbar} = \frac{1}{\hbar}\sqrt{\frac{3\pi\varepsilon_0\hbar\Gamma}{k^3}}\sqrt{\frac{I}{n\varepsilon_0 c}}\sqrt{n} = \sqrt{\frac{3\lambda^2\Gamma I}{\hbar\omega 4\pi^2}} = \sqrt{\frac{\sigma_0\Gamma I}{2\hbar\omega}} ,$$

with the optical cross section $\sigma_0 = \frac{3\lambda^2}{2\pi}$.

34.2.6.2 Ex: Non-stationary state

Construct a non-stationary hydrogen wavefunction with equal contributions of $(n = 1, \ell = 0, m = 0)$ and $(n = 2, \ell = 1, m = 1)$. Calculate the expectation values $\langle|\mathbf{r}|\rangle$ and $\langle\mathbf{r}\rangle$ as a function of time.

Solution: *The wavefunction is,*

$$|\psi\rangle = \tfrac{1}{\sqrt{2}}|\psi_{100}\rangle + \tfrac{e^{-\imath\omega_{21}t}}{\sqrt{2}}|\psi_{211}\rangle = \tfrac{1}{\sqrt{2}}\tfrac{1}{\sqrt{\pi}}\left(\tfrac{Z}{a_B}\right)^{3/2} e^{-Zr/a_B} + \tfrac{e^{-\imath\omega_{21}t}}{\sqrt{2}}\tfrac{1}{8\sqrt{2\pi}}\left(\tfrac{Z}{a_B}\right)^{3/2}\tfrac{Zr}{a_B}e^{-Zr/2a_B}\sin\theta e^{\imath\phi} \ .$$

With this and using the result $\langle\tilde{r}\rangle = \tfrac{n^2 a_B}{Z}\left[1 + \tfrac{1}{2}\left(1 - \tfrac{\ell(\ell+1)}{n^2}\right)\right]$ *we calculate the integral,*

$$\begin{aligned}
\langle\psi|r|\psi\rangle &= \tfrac{1}{2}\langle\psi_{100}|r|\psi_{100}\rangle + \tfrac{1}{2}\langle\psi_{211}|r|\psi_{211}\rangle + \tfrac{e^{-\imath\omega_{21}t}}{2}\int \psi_{100} r \psi_{211} d^3r + c.c. \\
&= \tfrac{1}{2}\tfrac{1^2 a_B}{Z}\left[1 + \tfrac{1}{2}\left(1 - \tfrac{0(0+1)}{1^2}\right)\right] + \tfrac{1}{2}\tfrac{2^2 a_B}{Z}\left[1 + \tfrac{1}{2}\left(1 - \tfrac{1(1+1)}{2^2}\right)\right] \\
&+ \tfrac{e^{-\imath\omega_{21}t}}{2}\tfrac{1}{16\pi}\left(\tfrac{Z}{a_B}\right)^3 \int e^{-Zr/a_B}\tfrac{Zr}{a_B}e^{-Zr/2a_B}\sin\theta e^{\imath\phi} d^3r + c.c. \\
&= \tfrac{3a_B}{4Z} + \tfrac{5a_B}{2Z} + 0 = \tfrac{13a_B}{4Z} + 0 \ .
\end{aligned}$$

We also calculate the integral,

$$\langle\psi|\mathbf{r}|\psi\rangle = \tfrac{1}{2}\int |\psi_{100}|^2 \mathbf{r} d^3r + \tfrac{1}{2}\int |\psi_{211}|^2 \mathbf{r} d^3r + \tfrac{e^{-\imath\omega_{21}t}}{2}\int \psi_{100}\psi_{211}\mathbf{r} d^3r + c.c. \ .$$

The first term gives,

$$\tfrac{1}{2}\int_0^\infty \int_0^\pi \int_0^{2\pi} \tfrac{1}{2\pi}\left(\tfrac{Z}{a_B}\right)^3 e^{-2Zr/a_B}\begin{pmatrix} r\sin\theta\cos\phi \\ r\sin\theta\sin\phi \\ r\cos\theta \end{pmatrix} r^2\sin\theta d\theta d\phi dr = 0 \ ,$$

And the second,

$$\tfrac{1}{2}\int_0^\infty \int_0^\pi \int_0^{2\pi} \tfrac{1}{128\pi}\left(\tfrac{Z}{a_B}\right)^3\left(\tfrac{Zr}{a_B}\right)^2 e^{-Zr/a_B}\sin\theta^2\begin{pmatrix} r\sin\theta\cos\phi \\ r\sin\theta\sin\phi \\ r\cos\theta \end{pmatrix} r^2\sin\theta d\theta d\phi dr = 0 \ ,$$

such that we are left alone with the third,

$$\langle\psi|\mathbf{r}|\psi\rangle = \tfrac{e^{-\imath\omega_{21}t}}{2}\int_0^\infty\int_0^\pi\int_0^{2\pi}\tfrac{1}{16\pi\sqrt{2}}\left(\tfrac{Z}{a_B}\right)^3\tfrac{Zr}{a_B}e^{-3Zr/2a_B}\sin\theta e^{\imath\phi}\begin{pmatrix}r\sin\theta\cos\phi\\ r\sin\theta\sin\phi\\ r\cos\theta\end{pmatrix}r^2\sin\theta d\theta d\phi dr + c.c.$$

$$= \tfrac{\cos\omega_{12}t}{32\pi\sqrt{2}}\tfrac{a_B}{Z}\int_0^\infty\tilde{r}^4e^{-3\tilde{r}/2}dr\begin{pmatrix}\int_0^\pi\sin^3\theta d\theta\int_0^{2\pi}\cos^2\phi d\phi\\ \int_0^\pi\sin^3\theta d\theta\int_0^{2\pi}\sin\phi\cos\phi d\phi\\ 0\end{pmatrix}$$

$$- \tfrac{\sin\omega_{12}t}{32\pi}\tfrac{1}{\sqrt{2}}\tfrac{a_B}{Z}\int_0^\infty\tilde{r}^4e^{-3\tilde{r}/2}dr\begin{pmatrix}\int_0^\pi\sin^3\theta d\theta\int_0^{2\pi}\cos\phi\sin\phi d\phi\\ \int_0^\pi\sin^3\theta d\theta\int_0^{2\pi}\sin^2\phi d\phi\\ 0\end{pmatrix}$$

$$= \tfrac{\cos\omega_{12}t}{8\pi}\tfrac{1}{\sqrt{2}}\tfrac{a_B}{Z}\int_0^\infty\tilde{r}^4e^{-3\tilde{r}/2}dr\begin{pmatrix}\frac{4}{3}\int_0^{2\pi}\cos^2\phi d\phi\\ \frac{4}{3}\int_0^{2\pi}\sin\phi\cos\phi d\phi\\ 0\end{pmatrix}$$

$$+ \tfrac{\sin\omega_{12}t}{8\pi}\tfrac{1}{\sqrt{2}}\tfrac{a_B}{Z}\int_0^\infty\tilde{r}^4e^{-3\tilde{r}/2}dr\begin{pmatrix}\frac{4}{3}\int_0^{2\pi}\cos\phi\sin\phi d\phi\\ \frac{4}{3}\int_0^{2\pi}\sin^2\phi d\phi\\ 0\end{pmatrix}$$

$$= \frac{2^7}{3^3\sqrt{2}}[\hat{\mathbf{e}}_x\cos\omega_{12}t - \hat{\mathbf{e}}_y\sin\omega_{12}t]\ .$$

34.2.6.3 Ex: Transitions between Zeeman substates

Consider a hydrogen atom immersed in a uniform magnetic field, described by the Hamiltonian $\hat{H} = \hat{H}^{(0)} + \hat{H}^{(1)}$, being $\hat{H}^{(0)} = \hat{\mathbf{p}}^2/2m + V(r)$ and $H^{(1)} = -(\mu_B/\hbar)\hat{\mathbf{L}}\cdot\vec{\mathcal{B}}$ despising the spin [9].
a. Given the initial function, $|\psi_m(0)\rangle = \cos\alpha|\phi_{000}\rangle + \sin\alpha|\phi_{21m}\rangle$, determine its shape at time t.
b. Calculate the mean value $\langle\mathbf{d}\rangle_m(t) = \langle\psi_m(t)|\mathbf{d}|\psi_m(t)\rangle$ of the electric dipole operator of the atom $\mathbf{d} = q\mathbf{R}$.
c. Analyze the frequencies and polarizations of the emitted radiation by the transition of the excited states $|\phi_{21m}\rangle$ to the ground state.

Solution: *a. We derive the eigenenergies of the unperturbed Hamiltonian,*

$$E_n = -\tfrac{E_B}{n^2} \qquad with \qquad E_B = -\tfrac{m_e c^2}{2}\alpha^2\ .$$

and eigenfunctions $|\phi_{n\ell m}\rangle$ by Bohr's model. The perturbation causes normal Zeeman type energy shifts, which we calculate in first order TIPT,

$$\Delta E = \langle\phi_{n\ell m}|H^{(1)}|\phi_{n\ell m}\rangle = -\mu_B m\mathcal{B}\ .$$

[9] See Cohen-Tannoudji, Complemento D_VII

Thus, we have with the stationary perturbation,

$$|\psi_m(t)\rangle = e^{-iE_{100}t/\hbar}\cos\alpha|\phi_{100}\rangle + e^{-iE_{21m}t/\hbar}\sin\alpha|\phi_{21m}\rangle$$
$$\text{where} \qquad E_{100} = E_B \qquad \text{and} \qquad E_{21m} = \tfrac{E_B}{4} - \mu_B m\mathcal{B}\ .$$

Introducing the Larmor frequency $\omega_L \equiv \frac{\mu_B\mathcal{B}}{\hbar}$ *and the energy spacing* $\Delta \equiv E_{210} - E_{100}$, *we can write,*

$$|\psi_m(t)\rangle = \cos\alpha|\phi_{100}\rangle + e^{i(\Delta+m\omega_L)t}\sin\alpha|\phi_{21m}\rangle\ .$$

b. For the dipole moment we now expect,

$$\begin{aligned}\langle\psi_m(t)|\mathbf{d}|\psi_m(t)\rangle &= \cos^2\alpha\langle\phi_{100}|q\mathbf{R}|\phi_{100}\rangle + \sin^2\alpha\langle\phi_{21m}|q\mathbf{R}|\phi_{21m}\rangle\\ &+ \sin\alpha\cos\alpha e^{i(\Delta+m\omega_L)t}\langle\phi_{100}|q\mathbf{R}|\phi_{21m}\rangle + \sin\alpha\cos\alpha e^{-i(\Delta+m\omega_L)t}\langle|\phi_{21m}|q\mathbf{R}|\phi_{100}\rangle\\ &= q\cos^2\alpha\langle\phi_{100}|\mathbf{R}|\phi_{100}\rangle + q\sin^2\alpha\langle\phi_{21m}|\mathbf{R}|\phi_{21m}\rangle + q\sin 2\alpha\cos[(\Delta+m\omega_L)t]\langle\phi_{100}|\mathbf{R}|\phi_{21m}\rangle\ .\end{aligned}$$

Now, we need to calculate all elements of the matrix by choosing the quantization axis $\hat{\mathbf{e}}_z$. *Obviously,*

$$\langle\phi_{100}|\mathbf{R}|\phi_{100}\rangle = 0 \qquad \text{and} \qquad \langle\phi_{21m}|\mathbf{R}|\phi_{21m}\rangle = 0\ .$$

Besides that,

$$\begin{aligned}\langle\phi_{210}|\mathbf{R}|\phi_{100}\rangle &= \frac{a_B}{4\pi\sqrt{2}}\int_0^\infty\int_0^\pi\int_0^{2\pi}\tilde{r}e^{-\tilde{r}/2}\cos\theta\begin{pmatrix}\tilde{r}\sin\theta\cos\phi\\ \tilde{r}\sin\theta\sin\phi\\ \tilde{r}\cos\theta\end{pmatrix}e^{-\tilde{r}}\tilde{r}^2\sin\theta d\theta d\phi d\tilde{r}\\ &= \hat{\mathbf{e}}_z\frac{a_B}{2\sqrt{2}}\int_{-1}^1\cos^2\theta d(\cos\theta)\int_0^\infty\tilde{r}^4e^{-3\tilde{r}/2}d\tilde{r} = \hat{\mathbf{e}}_z\frac{a_B}{2\sqrt{2}}\frac{2}{3}\frac{2^8}{3^4} = \hat{\mathbf{e}}_z\frac{2^8a_B}{3^5\sqrt{2}}\ .\end{aligned}$$

and

$$\begin{aligned}\langle\phi_{21\pm1}|\mathbf{R}|\phi_{100}\rangle &= \frac{a_B}{8\pi\sqrt{2}}\int_0^\infty\int_0^\pi\int_0^{2\pi}\tilde{r}e^{-\tilde{r}/2}\sin\theta e^{\pm\imath\phi}\begin{pmatrix}\tilde{r}\sin\theta\cos\phi\\ \tilde{r}\sin\theta\sin\phi\\ \tilde{r}\cos\theta\end{pmatrix}e^{-\tilde{r}}\tilde{r}^2\sin\theta d\theta d\phi d\tilde{r}\\ &= \frac{a_B}{8\pi\sqrt{2}}\begin{pmatrix}\int_0^\pi\sin^3\theta d\theta(\int_0^{2\pi}\cos^2\phi d\phi \pm \imath\int_0^{2\pi}\cos\phi\sin\phi d\phi)\\ \int_0^\pi\sin^3\theta d\theta(\int_0^{2\pi}\cos\phi\sin\phi d\phi \pm i\int_0^{2\pi}\sin^2\phi d\phi)\\ \int_0^\pi\sin^2\theta\cos\theta d\theta\int_0^{2\pi}e^{\pm i\phi}d\phi\end{pmatrix}\int_0^\infty\tilde{r}^4e^{-3\tilde{r}/2}d\tilde{r}\\ &= \frac{a_B}{8\pi\sqrt{2}}\begin{pmatrix}\frac{4}{3}(\pi\pm 0\imath)\\ \frac{4}{3}(0\pm\imath\pi)\\ 0\end{pmatrix}\frac{2^8}{3^4} = \hat{\mathbf{e}}_\pm\frac{2^7a_B}{3^5\sqrt{2}}\ .\end{aligned}$$

c. Choosing $\alpha \equiv \pi/4$ *we get the final result,*

$$\langle\mathbf{d}\rangle_m(t) = \frac{2^7qa_B}{3^5\sqrt{2}}\cos[(\Delta+m\omega_L)t](\delta_{m,\pm1}\hat{\mathbf{e}}_\pm + 2\delta_{m,0}\hat{\mathbf{e}}_z)\ .$$

For $m = \pm1$ *the dipole moment is circular and* $\Delta = \mp m\omega_L$. *For* $m = 0$ *the dipole moment is linear and* $\Delta = 0$.

d. Assuming that the perturbation is suddenly switched on at time $t = 0$, we calculate the transition rates $\langle\phi_{100}|\psi_m(t)\rangle$,

$$\begin{aligned}
a_{i\to f}(t) &= \frac{1}{\imath\hbar}\int_0^t \langle\phi_{100}|W|\phi_{210}\rangle e^{\imath\omega_{if}\tau}d\tau \\
&= \langle\ell,m|\frac{1}{i\hbar}\int_0^t\int \frac{1}{4\pi\sqrt{2}}e^{-\tilde{r}}\frac{\mu_B}{\hbar}\mathbf{L}\cdot\vec{\mathcal{B}}\tilde{r}e^{-\tilde{r}/2}\cos\theta d^3\tilde{r}e^{\imath\omega_{if}\tau}d\tau|\ell,m\rangle \\
&= \frac{\mu_B}{\imath\hbar^2}\frac{1}{4\pi\sqrt{2}}\int_0^t\int e^{-\tilde{r}}\left(\langle 0,0|L_x|1,0\rangle\mathcal{B}\sin\theta\cos\phi + \langle 0,0|L_y|1,0\rangle\mathcal{B}\sin\theta\sin\phi\right. \\
&\quad \left.+\langle 0,0|L_z|1,0\rangle\mathcal{B}\cos\theta\right)\tilde{r}e^{-\tilde{r}/2}\cos\theta d^3\tilde{r}e^{\imath\omega_{if}\tau}d\tau = 0\ .
\end{aligned}$$

The same way,

$$\begin{aligned}
a_{i\to f}(t) &= \frac{1}{\imath\hbar}\int_0^t \langle\phi_{100}|W|\phi_{21\pm1}\rangle e^{\imath\omega_{if}\tau}d\tau \\
&= \langle\ell,m|\frac{1}{\imath\hbar}\int_0^t\int \frac{1}{4\pi\sqrt{2}}e^{-\tilde{r}}\frac{\mu_B}{\hbar}\mathbf{L}\cdot\vec{\mathcal{B}}\tilde{r}e^{-\tilde{r}/2}\sin\theta e^{\pm\imath\phi}d^3\tilde{r}e^{\imath\omega_{if}\tau}d\tau|\ell,m\rangle \\
&= \frac{\mu_B}{\imath\hbar^2}\frac{1}{4\pi\sqrt{2}}\int_0^t\int e^{-\tilde{r}}\left(\langle 0,0|L_x|1,\pm1\rangle\mathcal{B}\sin\theta\cos\phi + \langle 0,0|L_y|1,\pm1\rangle\mathcal{B}\sin\theta\sin\phi\right. \\
&\quad \left.+\langle 0,0|L_z|1,\pm1\rangle\mathcal{B}\sin\theta e^{\pm\imath\phi}\right)\tilde{r}e^{-\tilde{r}/2}\cos\theta d^3\tilde{r}e^{\imath\omega_{if}\tau}d\tau \\
&= \frac{\mu_B\mathcal{B}}{\imath\hbar}\frac{1}{4\pi\sqrt{2}}\int_0^t\int_0^{2\pi}\int_0^{\pi}\left(\frac{1}{\sqrt{2}}\sin\theta\cos\phi \mp \frac{\imath}{\sqrt{2}}\sin\theta\sin\phi + 0\right)\sin\theta e^{\pm\imath\phi}\sin\theta d\theta d\phi \\
&\quad \times\int_0^{\infty} e^{-3\tilde{r}/2}\tilde{r}^3 d\tilde{r}e^{\imath\omega_{if}\tau}d\tau = 0\ .
\end{aligned}$$

34.2.6.4 Ex: Derivation of selection rules

a. Prove $[L_k, r_m] = \imath\hbar r_n\epsilon_{kmn}$ for an *orbital angular momentum.*
b. Using the commutator derived in (a) derive the selection rules for transitions $\langle\alpha' L'm'|\vec{\varepsilon}\cdot\hat{\mathbf{r}}|\alpha Lm\rangle$, where $\vec{\varepsilon}$ is the polarization vector of the radiation field chosen to be $\hat{\mathbf{e}}_0$ or $\hat{\mathbf{e}}_\pm$.
c. Prove $[\hat{L}^2,[\hat{L}^2,\hat{\mathbf{r}}]] = 2\hbar^2(\hat{\mathbf{r}}\hat{L}^2 + \hat{L}^2\hat{\mathbf{r}})$ for an orbital angular momentum $\hat{\mathbf{L}}$.
d. Using the commutator derived in (b) derive the selection rule for $\hat{L}^2$.

Solution: *a. We calculate*

$$\begin{aligned}
[\hat{L}_x,\hat{x}] &= [\hat{\mathbf{r}}\times\hat{\mathbf{p}}_x,\hat{x}] = [\hat{y}\hat{p}_z,\hat{x}] - [z\hat{p}_y,\hat{x}] = 0 \\
[\hat{L}_y,\hat{x}] &= [\hat{\mathbf{r}}\times\hat{\mathbf{p}}_y,\hat{x}] = [\hat{z}\hat{p}_x,\hat{x}] - [x\hat{p}_z,\hat{x}] = \hat{z}[\hat{p}_x,\hat{x}] = -\imath\hbar\hat{z} \\
[\hat{L}_z,\hat{x}] &= [\hat{\mathbf{r}}\times\hat{\mathbf{p}}_z,\hat{x}] = [\hat{x}\hat{p}_y,\hat{x}] - [\hat{y}\hat{p}_x,\hat{x}] = -\hat{y}[\hat{p}_x,\hat{x}] = \imath\hbar\hat{y}\ ,
\end{aligned}$$

resulting in the specified formula.
b. From [880],

$$\begin{aligned}
0 &= \langle\alpha' L'm'|[\hat{L}_z,\hat{z}]|\alpha Lm\rangle = (m'-m)\langle\alpha' L'm'|\hat{z}|\alpha Lm\rangle \\
&= (m'-m)\langle\alpha' L'm'|-\hat{\mathbf{e}}_0\cdot\mathbf{r}|\alpha Lm\rangle\ ,
\end{aligned}$$

we conclude that the operator $-\hat{\mathbf{e}}_0 \cdot \mathbf{r}$ only drives transitions between corresponding Zeeman states: $m' = m$. From,

$$\begin{aligned}\hbar\langle\alpha' L' m'|\imath\hat{y} + \hat{x}|\alpha L m\rangle &= \langle\alpha' L' m'|[\hat{L}_z, \hat{x} + \imath\hat{y}]|\alpha L m\rangle(m' - m)\langle\alpha' L' m'|\hat{x} + \imath\hat{y}|\alpha L m\rangle \\ &= (m' - m)\langle\alpha' L' m'| - \hat{\mathbf{e}}_{-1} \cdot \mathbf{r}|\alpha L m\rangle \ ,\end{aligned}$$

we conclude that the operator $-\hat{\mathbf{e}}_\pm \cdot \mathbf{r}$ only drives transitions between adjacent Zeeman states: $m' = m \pm 1$.
c. We restrict without loss of generality to the x-dimension trying to show $[\hat{L}^2, [\hat{L}^2, \hat{x}]] = 2\hbar^2(\hat{x}\hat{L}^2 + \hat{L}^2\hat{x})$. Now,

$$[\hat{L}^2, [\hat{L}^2, \hat{x}]] = \ldots \ .$$

d. We have on one hand,

$$\begin{aligned}\langle L' m'|[L^2, [L^2, \hat{\mathbf{r}}]]|L, m\rangle &= \langle L' m'|[L^4\hat{\mathbf{r}} - 2L^2\hat{\mathbf{r}}L^2 + \hat{\mathbf{r}}L^4]|L, m\rangle \\ &= \langle L' m'|[\hbar^4 L'^2(L' + 1)^2\hat{\mathbf{r}} - 2\hbar^4 L'(L' + 1)\hat{\mathbf{r}}\hbar^4 L(L + 1) + \hat{\mathbf{r}}\hbar^4 L^2(L + 1)^2]|L, m\rangle \\ &= \hbar^4[L'(L' + 1) - L(L + 1)]^2\langle L' m'|\hat{\mathbf{r}}|L, m\rangle \ .\end{aligned}$$

On the other hand,

$$\langle L' m'|2\hbar^2(\hat{\mathbf{r}}L^2 + L^2\hat{\mathbf{r}})|L, m\rangle = 2\hbar^4[L(L + 1) + L'(L' + 1)]\langle L' m'|\hat{\mathbf{r}}|L, m\rangle \ .$$

By comparison,

$$\begin{aligned}0 &= [L'(L' + 1) - L(L + 1)]^2 - 2[L(L + 1) + L'(L' + 1)] \\ &= (L' + L + 1)^2(L' - L)^2 - 2L(L + 1) - 2L'(L' + 1) \\ &= (L' + L + 1)^2(L' - L)^2 - (L' + L + 1)^2 - (L' - L)^2 + 1 \\ &= [(L' + L + 1)^2 - 1][(L' - L)^2 - 1] \ .\end{aligned}$$

The first term can only be zero if $L = L' = 0$, but this is prohibited since L' is the vector sum of L and $\kappa = 1$ for the photon, and thus cannot be zero. The second term is zero only if $L = 1$. Hence, $\Delta L = 0, \pm 1$ is the selection rule.

34.3 Density matrix

As long as we are only interested in stimulated processes, such as the absorption of a monochromatic wave, the Schrödinger equation suffices to describe the light-atom interaction. A problem arises when we want to describe relaxation processes at the same time as excitation processes. Spontaneous emission (and any other dissipative process) must therefore be included in the physical description of the temporal evolution of our light-atom system. In this case, however, our system is no longer restricted to a single mode of the light field and the two atomic states of excitation. Spontaneous emission populates a statistical distribution of states of the light field and leaves the atom in a superposition of many momentum states. This situation can not be described by a single wavefunction, but only by a distribution of wavefunctions, and we can only expect to calculate the probability of finding the system

within this distribution. The Schrödinger equation, therefore, no longer applies, and we need to trace the time evolution of a system characterized by a density operator describing a statistical mixture of quantum states. The equations which describe the time evolution of the matrix elements of this density operator are the optical Bloch equations, and we must use them instead of the Schrödinger equation. In order to appreciate the origin and the physical content of the optical Bloch equations we begin by reviewing the rudiments of the density matrix theory.

34.3.1 The density operator

We define the *statistical operator* or *density operator* [10],

$$\boxed{\hat{\rho} \equiv \sum_k p_k \hat{P}_k \qquad \text{where} \qquad \hat{P}_k \equiv |\psi_k\rangle\langle\psi_k|} \ , \tag{34.90}$$

where $\{|\psi_k\rangle\}$ is a complete set of orthonormal states of the system under study. We consider a statistical distribution of these states with p_j being the probability of finding $|\psi_j\rangle$ in the set. Obviously, $\sum_k p_k = 1$. That is, the density operator acts on a member of the set $\{|\psi_k\rangle\}$ in a way to extract the probability of finding the system in $|\psi_j\rangle$,

$$\hat{\rho}|\psi_j\rangle = \sum_k p_k |\psi_k\rangle\langle\psi_k|\psi_j\rangle = p_j|\psi_j\rangle \ . \tag{34.91}$$

If all members of the set are in the same state, for example $|\psi_k\rangle$, the density operator reduces to,

$$\hat{\rho} = |\psi_k\rangle\langle\psi_k| \ , \tag{34.92}$$

and the system is in a *pure state* with $p_k = \delta_{1k}$. Each time a quantum state can be expressed by a single wave function, it is a pure state, but it does not have to be an eigenstate. Starting from the equation (34.91) we find,

$$\langle\psi_k|\hat{\rho}|\psi_j\rangle = p_j\delta_{kj} \ . \tag{34.93}$$

The diagonal elements of the density matrix are the probabilities of finding the system in $|\psi_j\rangle$, and assuming that all $|\psi_k\rangle$ are orthonormal, the non-diagonal elements of the incoherent sum (34.90) are necessarily zero [11], Besides that,

$$\sum_k \langle\psi_k|\hat{\rho}|\psi_k\rangle = 1 \ , \tag{34.94}$$

[10] In the presence of degeneracy or a continuous spectrum we can generalize the definition:

$$\hat{\rho} \equiv \sum_k p_k \hat{P}_k + \int p_\lambda \hat{P}_\lambda d\lambda \quad \text{where} \quad \hat{P}_k \equiv \sum_m |km\rangle\langle km| \quad \text{and} \quad \hat{P}_\lambda \equiv \int |\lambda\mu\rangle\langle\lambda\mu| d\mu \ .$$

Here, m and μ are degenerate quantum numbers, m, n are discrete, and λ, μ are continuous quantum numbers. The set of quantum numbers is complete, when

$$\sum\nolimits_{k,m} |km\rangle\langle km| = \hat{1} = \int |\lambda\mu\rangle\langle\lambda\mu| d\lambda d\mu \ .$$

The degree of degeneracy of a state $|k\rangle$ is $\mathrm{Tr}\ \hat{P}_k = \sum_m 1$. The probability of finding the system in the state $|k\rangle$ is $\langle\hat{P}_k\rangle = p_n \sum_m 1$.

[11] This is simply because we constructed the density operator to be diagonal in the basis $\{|\psi_k\rangle\}$. It does not mean, that the density operator cannot have non-diagonal elements in another basis.

so that $\hat{\rho}$ contains all *available* information about the system, that is, our *knowledge* about its state. When the state of the system is unknown, $\hat{\rho}$ describes the probability of finding the system in each state. When the state is fully known, $\hat{\rho}$ describes a pure state, that is, a vector in the Hilbert space, which is unequivocally determined by a complete set of observables with their respective quantum numbers.

The properties of the density operator are,

$$\boxed{\begin{array}{rcll} \hat{\rho} & = & \hat{\rho}^\dagger & \\ \langle\hat{\rho}\rangle & \geq & 0 & \\ \mathrm{Tr}\ \hat{\rho} & = & 1 & \\ \mathrm{Tr}\ \hat{\rho}^2 & \leq & 1 & \\ \det\hat{\rho} & = & 0 & \\ \hat{\rho} & = & \hat{\rho}^2 & \text{for a pure state} \end{array}} \ . \tag{34.95}$$

Example 195 (*Inhomogeneous atomic clouds*): For example, a thermal atomic cloud of N two-level atoms needs in general to be described by a density operator, because the state of every atom is independent of the state of the other atoms. If we knew that all atoms behave in the same way, for instance, when exposed to a radiation field, we could restrict to calculating the evolution of a single atom and extrapolate to N atoms. However, atomic motion and interatomic interactions often influence the dynamics.

34.3.1.1 Entropy

In a very general sense, the *entropy* determines in what direction a reversible process will take place. It is related to the size of the available phase space on both sides of the reaction. For example, the coupling of discrete and continuous modes is governed by entropy considerations.

Entropy measures of the lack of information about a system from which we only know $\langle\hat{H}\rangle$,

$$S \equiv -k_B\langle\ln\hat{\rho}\rangle = -k_B\ \mathrm{Tr}\ (\hat{\rho}\ln\hat{\rho})\ . \tag{34.96}$$

The *information entropy* (or *von Neumann entropy*) of statistically independent systems $\hat{\rho}\equiv\hat{\rho}_1\otimes\hat{\rho}_2$ is additive $S = S_1 + S_2$. We can also define absolute temperatures by $T^{-1}\equiv\partial S/\partial\langle\hat{H}\rangle$. The entropy of a pure state is 0. Hamiltonian processes conserve entropy, for they correspond to non-dissipative unitary transformations. On the other side, relaxation increases the entropy and the phase space volume. Another common definition is the so-called *purity* or *Renyi entropy*,

$$S_R \equiv \langle 1-\hat{\rho}\rangle = 1 - \mathrm{Tr}\ (\hat{\rho}^2)\ . \tag{34.97}$$

Quantum states can exhibit coherences. For example, if we express a state $|\psi\rangle$ on a basis of eigenstates $|1\rangle$ and $|2\rangle$:

$$\hat{\rho} = |\psi\rangle\langle\psi| = \begin{pmatrix} |\langle\psi|1\rangle|^2 & \langle 1|\psi\rangle\langle\psi|2\rangle \\ \langle 2|\psi\rangle\langle\psi|1\rangle & |\langle\psi|2\rangle|^2 \end{pmatrix}\ . \tag{34.98}$$

The evolution of such a state is described by the von Neumann equation,

$$i\hbar\partial_t\hat{\rho}(t) = [\hat{H}, \hat{\rho}(t)] \ . \tag{34.99}$$

The measurement process is not described by this equation. A pure state will always remain pure. If the eigenstates do not interact, the density operator will remain diagonal. The von Neumann equation conserves the properties of hermiticity, $\hat{\rho} = \hat{\rho}^\dagger$, completeness, Tr $\hat{\rho} = 1$, and purity $\det \hat{\rho} = 0$.

The density operator for a *statistical mixture* in a canonical ensemble (where S is maximum, U is variable, and N is fixed) follows from a variational problem with the Lagrange parameters $\delta(S - k_B\alpha\langle\hat{1}\rangle - k_B\beta\langle\hat{H}\rangle) = 0$, since Tr $\hat{\rho}$ and $\langle\hat{H}\rangle$ are fixed by boundary conditions. We find,

$$\boxed{\hat{\rho} = \frac{1}{Z}e^{-\hat{H}/k_BT} \qquad \text{with} \qquad Z \equiv \text{Tr } e^{-\hat{H}/k_BT}} \ . \tag{34.100}$$

We also have the expectation values, $\langle H\rangle = -\partial \ln Z/\partial\beta$ and $(\Delta H)^2 = -\partial\langle\hat{H}\rangle/\partial\beta$ with the abbreviation $\beta \equiv (k_BT)^{-1}$. All quantities are fixed, except the kinetic energy, which balances the interaction with a heat bath. T is the only equilibrium parameter. The density operator satisfies a Boltzmann distribution [12],

$$U = \langle\hat{H}\rangle = \frac{p^2}{2m} = -\frac{\partial}{\partial(1/k_BT)} \ln \int e^{-p^2/2mk_BT} dp = \frac{k_B}{2}T \ . \tag{34.101}$$

34.3.2 Matrix formalism

The next step is to develop matrix representations of the density operator by expanding the state vectors $|\psi_k\rangle$ in a complete orthonormal basis,

$$|\psi_k\rangle = \sum_n c_{nk}|n\rangle = \sum_n |n\rangle\langle n|\psi_k\rangle \ , \tag{34.102}$$

using the *completeness relation* (23.74), that is, $\sum_n |n\rangle\langle n| = \mathbb{I}$, and defining,

$$c_{nk} \equiv \langle n|\psi_k\rangle \tag{34.103}$$

as the projection of the state vector $|\psi_k\rangle$ on the basis vector $|n\rangle$. Now, we can write the density operator matrix representation within the basis $\{|n\rangle\}$ using the definition of $\hat{\rho}$ in Eq. (34.90) and replacing the expansions of $|\psi_k\rangle$ and $\langle\psi_k|$ of Eq. (34.102):

$$\hat{\rho} = \sum_k p_k|\psi_k\rangle\langle\psi_k| = \sum_k p_k \sum_{m,n} |n\rangle\langle n|\psi_k\rangle\langle\psi_k|m\rangle\langle m| = \sum_k p_k \sum_{m,n} c_{nk}c^*_{mk}|n\rangle\langle m| \ . \tag{34.104}$$

The matrix elements of $\hat{\rho}$ in this representation are

$$\rho_{nm} \equiv \langle n|\hat{\rho}|m\rangle = \sum_k p_k c_{nk}c^*_{mk} \tag{34.105}$$

[12] The von Neumann entropy S of a mixture can be expressed in terms of the eigenvalues or in terms of the trace and the logarithm of the density operator $\hat{\rho}$. Since $\hat{\rho}$ is a semi-definite positive operator, its spectrum λ_i, given by $\rho = \sum_i \lambda_i|\varphi_i\rangle\langle\varphi_i|$ where $\{|\varphi_i\rangle\}$ is an orthonormal basis, satisfies $\lambda_i > 0$ and $\sum\lambda_i = 1$. Then the entropy becomes $S = -\sum_i \lambda_i \ln\lambda_i = -\text{Tr } (\rho \ln\rho)$.

with the diagonal elements $\langle n|\hat{\rho}|n\rangle = \sum_k p_k |c_{nk}|^2$ and,

$$\rho^*_{nm} = \langle n|\hat{\rho}|m\rangle^* = \sum_k p_k c^*_{nk} c_{mk} = \sum_k p_k \langle m|\psi_k\rangle\langle\psi_k|n\rangle = \langle m|\rho|n\rangle = \rho_{mn} \ , \quad (34.106)$$

which means that the operator $\hat{\rho}$ is Hermitian.

Example 196 (*Density operator for a single atom*): For a very simple system such as a single atom with several levels, that without spontaneous emission can be described by a single wavefunction $|\psi_1\rangle$, we can let $p_k = \delta_{1k}$. That is, the equations (34.104) and (34.106) reduce to,

$$\hat{\rho} = \sum_{m,n} c_{n1} c^*_{m1} |n\rangle\langle m| \qquad \text{and} \qquad \langle n|\rho|m\rangle = c_{n1} c^*_{m1} \ . \quad (34.107)$$

34.3.3 Measurement and trace

The sum of the diagonal elements of a matrix representing an operator is called the *trace*. This quantity represents a fundamental property of the density operator, since it is invariant with respect to any unitary transformation:

$$\text{Tr } \hat{\rho} \equiv \sum_n \langle n|\hat{\rho}|n\rangle \ . \quad (34.108)$$

With the definition of the density operator (34.90) we can write the Eq. (34.108) as,

$$\text{Tr } \hat{\rho} \equiv \sum_{n,k} p_k \langle n|\psi_k\rangle\langle\psi_k|n\rangle \ . \quad (34.109)$$

Now, using the completeness relation,

$$\text{Tr } \hat{\rho} \equiv \sum_{n,k} p_k \langle\psi_k|n\rangle\langle n|\psi_k\rangle = \sum_k p_k \langle\psi_k|\psi_k\rangle = 1 \ , \quad (34.110)$$

which shows that the trace of the density operator representation is always 1 regardless of the basis of the matrix representation.

Example 197 (*Density operator for a statistical mixture*): Let us imagine an experiment with a single three-level atom coupling a state $|1\rangle$ to two other possible states $|2\rangle$ and $|3\rangle$ via a $\frac{\pi}{2}$-pulse, such that one of the two states,

$$|\psi_1\rangle = \tfrac{1}{\sqrt{2}}(|1\rangle + |2\rangle) \qquad \text{or} \qquad |\psi_2\rangle = \tfrac{1}{\sqrt{2}}(|1\rangle + |3\rangle)$$

be generated with equal probability. We also suppose that the performed experiment doesn't tell us which one of the two states was generated, so that we have to describe the system by a density operator,

$$\hat{\rho} = \sum_{k=1,2} \tfrac{1}{2} |\psi_k\rangle\langle\psi_k| = \tfrac{1}{2}\left[\frac{|1\rangle + |2\rangle}{\sqrt{2}} \frac{\langle 1| + \langle 2|}{\sqrt{2}}\right] + \tfrac{1}{2}\left[\frac{|1\rangle + |3\rangle}{\sqrt{2}} \frac{\langle 1| + \langle 3|}{\sqrt{2}}\right] \ .$$

Choosing an obvious basis, we can represent the density operator by a matrix,

$$\hat{\rho} = \begin{pmatrix} \frac{1}{2} & \frac{1}{4} & \frac{1}{4} \\ \frac{1}{4} & \frac{1}{4} & 0 \\ \frac{1}{4} & 0 & \frac{1}{4} \end{pmatrix} ,$$

for which we verify,

$$\hat{\rho} = \hat{\rho}^\dagger \quad \text{and} \quad \text{Tr } \hat{\rho} = 1 ,$$

but,

$$\hat{\rho}^2 \neq \hat{\rho} \quad \text{and} \quad \text{Tr } \hat{\rho}^2 = \tfrac{5}{8} \leq 1 .$$

Hence the state is not pure.

Expectation values of observables are expressed by,

$$\langle \hat{A} \rangle = \sum_k p_k \langle \psi_k | \hat{A} | \psi_k \rangle . \tag{34.111}$$

On the other side,

$$\hat{\rho}\hat{A} = \sum_k p_k |\psi_k\rangle\langle\psi_k|\hat{A} , \tag{34.112}$$

and in the basis $\{|n\rangle\}$,

$$\langle n|\hat{\rho}\hat{A}|m\rangle = \langle n| \sum_k p_k |\psi_k\rangle\langle\psi_k|\hat{A}|m\rangle = \sum_k p_k \langle n|\psi_k\rangle\langle\psi_k|\hat{A}|m\rangle = \sum_k p_k \langle\psi_k|\hat{A}|m\rangle\langle n|\psi_k\rangle . \tag{34.113}$$

Now, along the diagonal, we have,

$$\langle n|\hat{\rho}\hat{A}|n\rangle = \sum_k p_k \langle\psi_k|n\rangle\langle n|\hat{A}|\psi_k\rangle . \tag{34.114}$$

With the closure relation in the basis $\{|n\rangle\}$, we now have [13],

$$\boxed{\text{Tr } \hat{\rho}\hat{A} = \sum_k p_k \langle\psi_k|\hat{A}|\psi_k\rangle = \langle\hat{A}\rangle} . \tag{34.115}$$

The Eq. (34.115) says that the ensemble average of any dynamic observable $\hat{A}$ can be calculated from the diagonal elements of the operator matrix $\hat{\rho}\hat{A}$: Since the trace is independent of the basis (this will be shown in Exc. 34.3.5.1), each unitary transformation taking the matrix representation from a basis $\{|n\rangle\}$ to another one $\{|t\rangle\}$ leaves the trace invariant. Using the definition of a unitary transformation we can easily show that the trace of a cyclic permutation of a product is invariant. For example,

$$\text{Tr } [\hat{A}\hat{B}\hat{C}] = \text{Tr } [\hat{C}\hat{A}\hat{B}] = \text{Tr } [\hat{B}\hat{A}\hat{C}] , \tag{34.116}$$

and in particular

$$\text{Tr } [\hat{\rho}\hat{A}] = \text{Tr } [\hat{A}\hat{\rho}] = \langle\hat{A}\rangle . \tag{34.117}$$

In the Excs. 34.3.5.2 and 34.3.5.3 we apply the density operator to pure and mixed states of a two-level system. In Excs. 34.3.5.4 and 34.3.5.5 we study thermal mixtures and Exc. 34.3.5.6 Glauber states.

[13] In the presence of degeneracy or a continuous part of the spectrum we can generalize the definition of the expectation,

$$\langle\hat{X}\rangle \equiv \text{Tr } \hat{\rho}\hat{X} = \sum_{k,m} \langle km|\hat{\rho}\hat{X}|km\rangle .$$

34.3.3.1 Measurement process

If an observable $\hat{A}$ has a spectral representation $\hat{A} = \sum_n a_n |a_n\rangle\langle a_n| = \sum_n a_n \hat{P}_n$, with $\hat{P}_n = |a_n\rangle\langle a_n|$, the measurement process will transform the density operator to,

$$\hat{\rho}' = \sum_n \hat{P}_n \hat{\rho} \hat{P}_n \ . \tag{34.118}$$

That is, after the *measurement*, the density operator becomes diagonal on the basis of the eigenvalues of $\hat{A}$ [14], as explained in Sec. 23.2.7. The expression can be thought of as the mathematical formulation of von Neumann's state reduction postulate.

We note that the density operator (34.118) describes the whole ensemble after the measurement. The sub-ensemble corresponding to a particular result a_n of the measurement is described by a different density operator,

$$\hat{\rho}'_n = \frac{\hat{P}_n \hat{\rho} \hat{P}_n}{\text{Tr}\ [\hat{\rho}\hat{P}_n]} \ . \tag{34.119}$$

This is true, when $|a_n\rangle$ is the only eigenvector with the eigenvalue a_n. If not, $\hat{P}_n$ in the expression (34.119) should be replaced by the projection operator onto the sub-space of a_n [15]. In Exc. 34.3.5.7 we study the projection of Glauber states and in Exc. 34.3.5.8 of entangled states.

34.3.3.2 Systems and subsystems

Density operators are very useful for playing with systems and subsystems. Let us, for instance, assume that we have two quantum systems defined on the Hilbert spaces $\mathcal{H}_1$ and $\mathcal{H}_2$. The composite system is then the tensor product $\mathcal{H}_1 \otimes \mathcal{H}_2$. We now suppose that the compound system is in a pure state, $|\psi\rangle \in \mathcal{H}_1 \otimes \mathcal{H}_2$. If the state can be written in the form $|\psi\rangle = |\psi_1\rangle \otimes |\psi_2\rangle$, this means that the state of the first subsystem is $|\psi_1\rangle$. However, in general, $|\psi\rangle$ does not decompose like this. Of course, every vector in $\mathcal{H}_1 \otimes \mathcal{H}_2$ is a linear combination of tensorial products of $\mathcal{H}_1$ and $\mathcal{H}_2$. If $|\psi\rangle$ can not be decomposed as a tensor product, we say that the two systems are *entangled*. In this case, there is no reasonable way of associating a pure state $|\psi_1\rangle \in \mathcal{H}_1$ to the state $\psi \in \mathcal{H}_1 \otimes \mathcal{H}_2$. If, for example, in the case of a two particle wavefunction $\Psi(x_1, x_2)$ there is no way to construct a wavefunction (i.e. a pure state) $\psi_1(x_1)$ describing the state of the first particle, then $\Psi(x_1, x_2) \neq \psi_1(x_1)\psi_2(x_2)$.

[14] A projective measure always increases entropy. The entropy of a pure state is zero, while that of a mixture is always greater than zero. Therefore, a pure state can be converted into a mixture by a measurement, but the reverse can not happen. Thus, the action of measuring induces an irreversible change in the density matrix reminiscent of the collapse of the wavefunction. Strangely, the measurement *reduces* the amount of information by quenching the quantum interference of the compound system in a process called quantum decoherence. A subsystem can be taken from a mixed state to a pure state only at the price of increasing the von Neumann entropy elsewhere in the global system.

[15] In general, assuming that f is a function associating each observable $\hat{A}$ with a number $f(\hat{A})$ (which we may imagine as the expectation value), we can state the following: If f satisfies some natural properties (such as the one to produce positive values for positive operators), then there exists a unique density matrix $\hat{\rho}$, such that $f(\hat{A}) = \text{Tr}\ (\hat{\rho}\hat{A})$ for all $\hat{A}$. That is, every reasonable 'family' of expectation values' can be represented by a density matrix, which suggests that the density matrix provides the most general description of a quantum state.

The point of the discussion is that, even if the total system is in a pure state, the various subsystems that compose it will normally be in mixed states. On the other hand, regardless of whether the composite system is in a pure or mixed state, we can perfectly construct a density matrix that describes the state. Therefore, the use of density matrices is inevitable. Let $\hat{\rho}$ be the density matrix of the system composed of two subsystems. Then the state in $\mathcal{H}_2$ is described by a reduced density operator given by the partial trace of $\hat{\rho}$ over $\mathcal{H}_2$. In the particular case, where the state the density matrix has the form $\hat{\rho} = \hat{\rho}_1 \otimes \hat{\rho}_2$, where $\hat{\rho}_1$ and $\hat{\rho}_2$ are the density matrices in $\mathcal{H}_1$ and $\mathcal{H}_2$, then the partial trace is simply, $\text{Tr}_{\mathcal{H}_2} \hat{\rho}\hat{\rho}_1$.

34.3.4 Temporal evolution of the density operator

As shown in Secs. 23.4.2 to 23.4.4, the equations governing the temporal evolution of a quantum system depend on the choice of the picture, i.e. Schrödinger's (23.142), Heisenberg's (23.148), or the interaction picture (23.155). This, of course, also applies to a system represented by a density matrix.

Returning to the density operator definition (34.90), we can express its temporal dependence in terms of time-dependent quantum states and of the time evolution operator (23.145),

$$\hat{\rho}(t) = \sum_k p_k |\psi_k(t)\rangle\langle\psi_k(t)| = \sum_k p_k U(t,t_0)|\psi_k(t_0)\rangle\langle\psi_k(t_0)|U^\dagger(t,t_0) \ . \tag{34.120}$$

Writing,

$$\hat{\rho}(t_0) = \sum_k p_k |\psi_k(t_0)\rangle\langle\psi_k(t_0)| \ , \tag{34.121}$$

we see immediately,

$$\hat{\rho}(t) = U(t,t_0)\hat{\rho}(t_0)U^\dagger(t,t_0) \ , \tag{34.122}$$

where, for the common case of a time-independent Hamiltonian,

$$U(t,t_0) = e^{-\imath\hat{H}(t-t_0)/\hbar} \ . \tag{34.123}$$

Now we find the time derivative of the density operator differentiating the two sides of (34.122) and substituting the Eqs.

$$\frac{dU}{dt} = \frac{1}{\imath\hbar}\hat{H}U \qquad \text{and} \qquad \frac{dU^\dagger}{dt} = -\frac{1}{\imath\hbar}U^\dagger\hat{H} \tag{34.124}$$

for the time derivatives U and $U^\dagger$. The result is

$$\boxed{\frac{d\hat{\rho}(t)}{dt} = \frac{\imath}{\hbar}[\hat{\rho}(t),\hat{H}]} \ . \tag{34.125}$$

The commutator itself can be considered as a *superoperator* acting, not any more on states but on operators, that is, we can write,

$$\mathcal{L}\hat{\rho}(t) \equiv \frac{\imath}{\hbar}[\hat{\rho}(t),\hat{H}] \ , \tag{34.126}$$

where $\mathcal{L}$ is called *Liouville operator*. The equation (34.125) is called *Liouville equation* or *von Neumann equation*. The Liouville equation describes the *time evolution of the density operator* which, in turn, describes the distribution of an ensemble of quantum states. Even though the form of the Liouville equation resembles the Heisenberg equation, Eq. (34.120) shows that $\hat{\rho}(t)$ is in the *Schrödinger picture* [16].

34.3.4.1 Transformation to the interaction picture

For a two-level system perturbatively interacting with a light field, the Hamiltonian can be decomposed as in (23.152) into a stationary part and a time-dependent part,

$$\hat{H} = \hat{H}_{atom} + \hat{H}_{atom:field}(t) \ , \tag{34.127}$$

where $\hat{H}_{atom}$ is the part of the Hamiltonian describing the atomic structure and $\hat{H}_{atom:field}(t)$ the interaction of the dipole transition with the classical oscillating electric field. The interaction picture is the natural choice for this type of problem. In this case, we can transform the density operator into the interaction picture defined by (23.153),

$$\tilde{\rho}(t) = e^{\imath \hat{H}_{atom}(t-t_0)/\hbar} \hat{\rho}(t_0) e^{-\imath \hat{H}_{atom}(t-t_0)/\hbar} \ , \tag{34.128}$$

where the 'tilde' decoration (replacing the 'hat') emphasizes, that we are now in the *interaction picture*. We look for the time evolution rate of $\tilde{\rho}(t)$ analogously to the Liouville equation. Calculating the time derivatives on both sides of (34.128) and substituting Eq. (34.125) for $\frac{d\hat{\rho}}{dt}$ results in,

$$\boxed{\frac{d\tilde{\rho}(t)}{dt} = \frac{\imath}{\hbar}[\tilde{\rho}(t), \hat{H}_{atom:field}(t)]} \ . \tag{34.129}$$

This equation shows that the time evolution of the density operator in the interaction picture depends only on the time-dependent part of the total Hamiltonian.

In the following we will derive a ready-to-use form of the Hamiltonian governing the interaction of a weak single-mode light field with a two-level atom in the dipolar approximation.

34.3.4.2 Semi-classical two-level atom in the dipolar approximation

According to (34.127) the semi-classical light-atom interaction Hamiltonian comprises two terms which, in the dipolar approximation, can be written,

$$\hat{H} = \begin{pmatrix} 0 & 0 \\ 0 & \hbar\omega_0 \end{pmatrix} - \hat{\mathbf{d}} \cdot \vec{\mathcal{E}}(\mathbf{r}, t) \quad \text{where} \quad \hat{\mathbf{d}} = -e\hat{\mathbf{r}} = \begin{pmatrix} 0 & \langle 1|\mathbf{d}|2\rangle \\ \langle 2|\mathbf{d}|1\rangle & 0 \end{pmatrix} \tag{34.130}$$

is the dipole operator and

$$\vec{\mathcal{E}}(\mathbf{r}, t) = \frac{\vec{\epsilon}}{2}\left[\mathcal{E}_0(\mathbf{r}) e^{\imath(\mathbf{k}\cdot\mathbf{r}-\omega t)} + \mathcal{E}_0^*(\mathbf{r}) e^{-\imath(\mathbf{k}\cdot\mathbf{r}-\omega t)}\right] \tag{34.131}$$

[16] The Heisenberg equation for the density operator in the Schrödinger picture or the master equation in the Heisenberg picture are $d\hat{\rho}_H/dt = 0$.

the electric field. Note that via $\mathcal{E}_0(\mathbf{r}) \to \imath\sqrt{\frac{\hbar\omega}{2\varepsilon_0 V}}\hat{a}$, we can quantize the radiation mode, as will be shown in Sec. 35.1.2. Introducing the Rabi frequencies

$$\hbar\Omega(\mathbf{r}) \equiv -\mathcal{E}_0(\mathbf{r})\vec{\epsilon}\cdot\langle 2|\mathbf{d}|1\rangle \qquad \text{and} \qquad \hbar\Theta(\mathbf{r}) \equiv -\mathcal{E}_0(\mathbf{r})\vec{\epsilon}\cdot\langle 1|\mathbf{d}|2\rangle \tag{34.132}$$

as an abbreviation, we can write the Hamiltonian,

$$\hat{H} = \hbar\begin{pmatrix} 0 & \frac{\Theta(\mathbf{r})}{2}e^{\imath(\mathbf{k}\cdot\mathbf{r}-\omega t)} + \frac{\Omega^*(\mathbf{r})}{2}e^{-\imath(\mathbf{k}\cdot\mathbf{r}-\omega t)} \\ \frac{\Omega(\mathbf{r})}{2}e^{\imath(\mathbf{k}\cdot\mathbf{r}-\omega t)} + \frac{\Theta^*(\mathbf{r})}{2}e^{-\imath(\mathbf{k}\cdot\mathbf{r}-\omega t)} & \hbar\omega_0 \end{pmatrix} . \tag{34.133}$$

As shown in Sec. 23.4.5 the transformation from the Schrödinger to Dirac's interaction picture, is done via,

$$\hat{H}_{atom:field} \equiv U^\dagger \hat{H} U + \hbar\dot{U}^\dagger U \qquad \text{with} \qquad U = e^{-\imath\hat{H}_{atom}t/\hbar} . \tag{34.134}$$

Introducing the abbreviation $\Delta = \omega - \omega_0$ we obtain,

$$\begin{aligned}\hat{H}_{atom:field} = &\begin{pmatrix} 0 & \frac{\hbar}{2}\Omega^*(\mathbf{r})e^{-\imath(\mathbf{k}\cdot\mathbf{r}-\Delta t)} \\ \frac{\hbar}{2}\Omega(\mathbf{r})e^{\imath(\mathbf{k}\cdot\mathbf{r}-\Delta t)} & 0 \end{pmatrix} \\ &+ \begin{pmatrix} 0 & \frac{\hbar}{2}\Theta(\mathbf{r})e^{\imath(\mathbf{k}\cdot\mathbf{r}-\omega t-\omega_0 t)} \\ \frac{\hbar}{2}\Theta^*(\mathbf{r})e^{-\imath(\mathbf{k}\cdot\mathbf{r}-\omega t-\omega_0 t)} & 0 \end{pmatrix} \equiv \hat{H}^{(slow)}_{atom:field} + \hat{H}^{(fast)}_{atom:field} .\end{aligned} \tag{34.135}$$

34.3.4.3 The rotating wave approximation

The transition amplitude in first-order time-dependent perturbation theory is according to (27.71),

$$\begin{aligned} a_{i\to f}(t) &= \frac{1}{\imath\hbar}\int_0^t \langle 2|\hat{H}_{atom:field}(\tau)|1\rangle d\tau = \frac{\hbar}{2}\frac{1}{\imath\hbar}\int_0^t \left[\Omega(\mathbf{r})e^{\imath(\mathbf{k}\cdot\mathbf{r}-\Delta t)} + \Theta^*(\mathbf{r})e^{-\imath(\mathbf{k}\cdot\mathbf{r}-\omega t-\omega_0 t)}\right] d\tau \\ &= \frac{\Omega(\mathbf{r})e^{\imath\mathbf{k}\cdot\mathbf{r}}}{2\Delta}(e^{-\imath\Delta t}-1) + \frac{\Theta^*(\mathbf{r})e^{-\imath\mathbf{k}\cdot\mathbf{r}}}{2(\omega+\omega_0)}\left(e^{-\imath(\omega+\omega_0)\Delta t}-1\right) \\ &\simeq \frac{\Omega(\mathbf{r})e^{\imath\mathbf{k}\cdot\mathbf{r}}}{2\Delta}(e^{-\imath\Delta t}-1) , \end{aligned} \tag{34.136}$$

where the last step corresponds to the *rotating wave approximation*. This allows us to neglect $\hat{H}^{(fast)}_{atom:field}$.

34.3.4.4 Transformation into the rotating frame

Now, we further transform into rotating frame using,

$$\tilde{H}_{atom:field} = U^\dagger \hat{H}_{atom:field} U + \imath\hbar\dot{U}^\dagger U \qquad \text{with} \qquad U = \begin{pmatrix} 1 & 0 \\ 0 & e^{-\imath\Delta t} \end{pmatrix} . \tag{34.137}$$

This yields,

$$\tilde{H}_{atom:field} = \begin{pmatrix} 0 & \frac{\hbar}{2}\Omega^*(\mathbf{r})e^{-\imath\mathbf{k}\cdot\mathbf{r}} \\ \frac{\hbar}{2}\Omega(\mathbf{r})e^{\imath\mathbf{k}\cdot\mathbf{r}} & -\hbar\Delta \end{pmatrix} . \tag{34.138}$$

We always can write the Rabi frequency as $\Omega = |\Omega|e^{\imath\phi}$ and attribute the phase to the atomic position if necessary. Locating the atom in the center of the coordinate system, we finally get,

$$\tilde{H}_{atom:field} = \begin{pmatrix} 0 & \frac{\hbar}{2}\Omega \\ \frac{\hbar}{2}\Omega & -\hbar\Delta \end{pmatrix} , \tag{34.139}$$

yielding the new Liouville equation,

$$\boxed{\frac{d\rho(t)}{dt} = \frac{\imath}{\hbar}[\rho(t), \tilde{H}_{atom:field}]} . \tag{34.140}$$

The matrix representation of the Hamiltonian given in this section are given in the basis of the unperturbed states, but we still need to derive the matrix form of the Liouville equations (34.125), (34.129), and (34.129) in the various pictures. This will be the topic of the next section.

34.3.5 Exercises

34.3.5.1 Ex: Trace of an operator

The trace of an operator $\hat{A}$ is defined by Tr $\hat{A} = \sum_n \langle n|\hat{A}|n\rangle$.
a. Show that the trace is independent of the chosen basis!
b. Show that Tr $\hat{A}\hat{B}$ = Tr $\hat{B}\hat{A}$!

Solution: *a. The basis transformation* $|n\rangle = \sum_m |m\rangle\langle m|n\rangle$ *applied to the trace gives,*

$$Tr\ \hat{A} = \sum_n \langle n|\hat{A}|n\rangle = \sum_{n,m,m'} \langle n|m\rangle\langle m|\hat{A}|m'\rangle\langle m'|n\rangle = \sum_{m,m'} \langle m'|m\rangle\langle m|A|m'\rangle = \sum_m \langle m|\hat{A}|m\rangle .$$

b. Holds $Tr\ \hat{A}\hat{B} = \sum_n \langle n|\hat{A}\hat{B}|n\rangle = \sum_{n,m} \langle n|\hat{A}|m\rangle\langle m|\hat{B}|n\rangle = Tr\ \hat{B}\hat{A}$.

34.3.5.2 Ex: Pure states and mixtures

Consider a system of two levels coupled by a light mode. The Hamiltonian can be written ($\hbar \equiv 1$),

$$\hat{H} = \begin{pmatrix} 0 & \frac{1}{2}\Omega \\ \frac{1}{2}\Omega & \omega_0 \end{pmatrix} .$$

Calculate $\hat{\rho}$, $\hat{\rho}^2$ and $\langle\hat{H}\rangle$ for the following two cases:
a. The atom is in a superposition state, $|\psi\rangle = \alpha|1\rangle + \beta|2\rangle$ and
b. the atom is a statistical mixture of eigenstates, $\hat{\rho} = \mu|1\rangle\langle 1| + \nu|2\rangle\langle 2|$.

Solution: *a. In this case, the system is in a pure state. Therefore, the density*

operator is,

$$\rho = |\psi\rangle\langle\psi| = \alpha|1\rangle\langle 1| + \beta|2\rangle\langle 2| + \alpha\beta^*|1\rangle\langle 2| + \alpha^*\beta|2\rangle\langle 1| = \begin{pmatrix} |\alpha|^2 & \alpha^*\beta \\ \alpha\beta^* & |\beta|^2 \end{pmatrix}$$
$$= \begin{pmatrix} \langle 1|\rho|1\rangle & \langle 1|\rho|2\rangle \\ \langle 2|\rho|1\rangle & \langle 2|\rho|2\rangle \end{pmatrix} = \begin{pmatrix} \langle 1|\psi\rangle\langle\psi|1\rangle & \langle 1|\psi\rangle\langle\psi|2\rangle \\ \langle 2|\psi\rangle\langle\psi|1\rangle & \langle 2|\psi\rangle\langle\psi|2\rangle \end{pmatrix} .$$

Now the trace, which is the sum of the diagonal elements, must be normalized,

$$Tr\ \hat{\rho} = |\alpha|^2 + |\beta|^2 = 1 .$$

The square is,

$$\hat{\rho}^2 = \begin{pmatrix} |\alpha|^4 + \alpha^*\beta\alpha\beta^* & |\alpha|^2\alpha^*\beta + \alpha^*\beta|\beta|^2 \\ |\alpha|^2\alpha\beta^* + \alpha\beta^*|\beta|^2 & \alpha^*\beta\alpha\beta^* + |\beta|^4 \end{pmatrix} = \begin{pmatrix} |\alpha|^2 & \alpha^*\beta \\ \alpha\beta^* & |\beta|^2 \end{pmatrix} = \hat{\rho} .$$

The expectation value of the Hamiltonian is,

$$\langle\hat{H}\rangle = Tr\ \hat{\rho}\hat{H} = Tr \begin{pmatrix} |\alpha|^2 & \alpha^*\beta \\ \alpha\beta^* & |\beta|^2 \end{pmatrix} \begin{pmatrix} 0 & \Omega \\ \Omega & \omega_0 \end{pmatrix} = \alpha^*\beta\Omega + \alpha\beta^*\Omega + |\beta|^2\omega_0$$
$$= \langle\psi|\hat{H}|\psi\rangle = (\alpha^*\langle 1| + \beta^*\langle 2|)\,\hat{H}\,(\alpha|1\rangle + \beta|2\rangle)$$
$$= |\alpha|^2\langle 1|\hat{H}|1\rangle + |\beta|^2\langle 2|\hat{H}|2\rangle + \alpha^*\beta\langle 1|\hat{H}|2\rangle + \alpha\beta^*\langle 2|\hat{H}|1\rangle = |\beta|^2\omega_0 + \alpha^*\beta\Omega + \alpha\beta^*\Omega .$$

b. In the case of a mixture of eigenstates, the density operator is,

$$\hat{\rho} = \mu|1\rangle\langle 1| + \nu|2\rangle\langle 2| = \begin{pmatrix} \mu & 0 \\ 0 & \nu \end{pmatrix} .$$

The trace is always normalized,

$$Tr\ \hat{\rho} = Tr \begin{pmatrix} \mu & 0 \\ 0 & \nu \end{pmatrix} = \mu + \nu = 1 .$$

but the state is not pure, since,

$$\hat{\rho}^2 = \begin{pmatrix} \mu^2 & 0 \\ 0 & \nu^2 \end{pmatrix} \neq \hat{\rho} .$$

The average value of the Hamiltonian is now,

$$\langle\hat{H}\rangle = Tr\ \hat{\rho}\hat{H} = Tr \begin{pmatrix} \mu & 0 \\ 0 & \nu \end{pmatrix} \begin{pmatrix} 0 & \Omega \\ \Omega & \omega_0 \end{pmatrix} = Tr \begin{pmatrix} 0 & \mu\Omega \\ \nu\Omega & \nu\omega_0 \end{pmatrix} = \nu\omega_0 .$$

34.3.5.3 Ex: Mixture of states

A two-level atom is initially in a superposition of two states $|\psi\rangle = \frac{1}{\sqrt{2}}|1\rangle + \frac{1}{\sqrt{2}}|2\rangle$. An apparatus measures the populations of the states, but the experimenter forgot to read the indicated result.
a. Describe the state the atom by the density operator.
b. Now the experimenter returns to the device. Calculate with which probability he reads the state $|1\rangle$.

Solution: *a. The state is,*

$$\hat{\rho} = \tfrac{1}{2}|1\rangle\langle 1| + \tfrac{1}{2}|2\rangle\langle 2| \ .$$

Obviously, $\hat{\rho}^2 \neq \hat{\rho}$*, but* $Tr\ \hat{\rho} = 1$.
b. The probability is,

$$\langle \hat{P}_1 \rangle = Tr\ \hat{\rho}\hat{P}_1 = \sum_k \langle k|\hat{\rho}\hat{P}_1|k\rangle = \sum_k \langle k| \left(\tfrac{1}{2}|1\rangle\langle 1| + \tfrac{1}{2}|2\rangle\langle 2|\right)|1\rangle\langle 1|k\rangle = \tfrac{1}{2} \ .$$

34.3.5.4 Ex: Thermal mixture

We consider a thermal non-interacting atomic gas in one dimension. Instead of describing the state of the atomic ensemble, we can consider a single atom with a distributed probability of having a given velocity v. The density operator of the continuous degree of freedom can be written,

$$\hat{\rho} = \int dv \sqrt{\frac{m}{2\pi k_B T}} e^{-mv^2/2k_B T} |v\rangle\langle v| \ ,$$

and the trace of an arbitrary observable $\hat{A}$,

$$\langle \hat{A} \rangle = \mathrm{Tr}\ \hat{\rho}A = \int du \langle u|\hat{\rho}\hat{A}|u\rangle \ .$$

Now imagine a device capable of measuring the speed of a single atom randomly chosen within the cloud.
a. Express the probability of measuring a specific velocity v' for this atom using the density operator.
b. Express the expectation value of the average velocity by the density operator.

Solution: *a. The probability of measuring exactly the velocity* v' *for an atom is,*

$$\begin{aligned}\langle v'|\hat{\rho}|v'\rangle &= \langle v'| \int dv \sqrt{\frac{m}{2\pi k_B T}} e^{-mv^2/2k_B T} |v\rangle\langle v|v'\rangle \\ &= \int dv \sqrt{\frac{m}{2\pi k_B T}} e^{-mv^2/2k_B T} \delta(v - v') = \sqrt{\frac{m}{2\pi k_B T}} e^{-mv'^2/2k_B T} \ .\end{aligned}$$

b. The expectation value is,

$$\begin{aligned}\langle\hat{v}^2\rangle &= Tr\ \rho v^2 = \int du\langle u|\hat{\rho}\hat{v}^2|u\rangle = \int duu^2\langle u|\hat{\rho}|u\rangle \\ &= \sqrt{\frac{m}{2\pi k_BT}}\int duu^2\langle u|\int dve^{-mv^2/2k_BT}|v\rangle\langle v|u\rangle \\ &= \sqrt{\frac{m}{2\pi k_BT}}\int duu^2\langle u|e^{-mu^2/2k_BT}|u\rangle = \sqrt{\frac{m}{2\pi k_BT}}\int u^2e^{-mu^2/2k_BT}du \\ &= \sqrt{\frac{m}{2\pi k_BT}}\left(\frac{2k_BT}{m}\right)^{3/2}\int_{-\infty}^{\infty}z^2e^{-z^2}dz = \sqrt{\frac{1}{\pi}}\frac{2k_BT}{m}\frac{\sqrt{\pi}}{2} = \frac{k_BT}{m}\ .\end{aligned}$$

34.3.5.5 Ex: Thermal population of a harmonic oscillator

In thermal equilibrium the energy states of a system are populated following Boltzmann's law,

$$P_n = \frac{e^{-n\beta\hbar\omega}}{\sum_m e^{-m\beta\hbar\omega}} \qquad \text{with} \qquad \beta \equiv \frac{1}{k_BT}\ .$$

a. Consider a one-dimensional harmonic oscillator characterized by the secular frequency ω and, using the density operator, calculate the mean quantum number of the population and the mean energy.
b. For an energy spacing of $\omega/2\pi = 10\,\text{MHz}$, how many levels of the harmonic oscillator are necessary at room temperature to accumulate a population of at least 50%. How many for an energy spacing of $\omega/2\pi = 10\,\text{GHz}$. Repeat the calculation for a $1\,\mu\text{K}$ cold atomic cloud.

Solution: *a. The density operator,*

$$\hat{\rho} = \sum_n P_n|n\rangle\langle n|\ ,$$

satisfies $\hat{\rho}^2 \neq \hat{\rho}$ *and* $Tr\ \hat{\rho} = 1$. *It allows to calculate the most likely value for the population and is obtained using the rule* $\sum_{n=0}^{\infty}U^n = (1-U)^{-1}$ *with the abbreviation* $U \equiv e^{-\hbar\omega/k_BT}$,

$$\begin{aligned}\langle\hat{n}\rangle &= Tr\ \hat{\rho}\hat{n} = \sum_m\langle m|\hat{\rho}\hat{n}|m\rangle = \sum_m\langle m|\sum_n P_n|n\rangle\langle n|\hat{n}|m\rangle = \sum_m mP_m\langle m|m\rangle \\ &= \sum_m\frac{me^{-m\beta\hbar\omega}}{\sum_n e^{-n\beta\hbar\omega}} = (1-e^{-\beta\hbar\omega})\sum_m me^{-m\beta\hbar\omega} = (1-e^{-\beta\hbar\omega})\frac{-1}{\hbar\omega}\frac{\partial}{\partial\beta}\sum_m e^{-m\beta\hbar\omega} \\ &= (1-e^{-\beta\hbar\omega})\frac{-1}{\hbar\omega}\frac{\partial}{\partial\beta}\frac{1}{1-e^{-\beta\hbar\omega}} = \frac{e^{-\beta\hbar\omega}}{1-e^{-\beta\hbar\omega}} = \frac{1}{e^{\beta\hbar\omega}-1}\ .\end{aligned}$$

For the average energy, with $E_n = n\hbar\omega$,

$$\langle\hat{E}\rangle = \sum_n E_np_n = \frac{\hbar\omega}{e^{\beta\hbar\omega}-1}\ .$$

This is precisely the distribution proposed by Planck for the light modes in the black-body radiator. We can now express the occupation probability of state n as,

$$P_n = \frac{e^{-n\beta\hbar\omega}}{\sum_m e^{-m\beta\hbar\omega}} = (1 - e^{-\beta\hbar\omega})e^{-n\beta\hbar\omega} = \frac{\langle\hat{n}\rangle^n}{(1 + \langle\hat{n}\rangle)^{n+1}} \ .$$

b. Using the formulas,

$$\sum_{n=1}^{\infty} U^n = \frac{-1}{U-1} \qquad \textit{and} \qquad \sum_{n=1}^{N} U^n = \frac{U^{N+1} - 1}{U-1}$$

we find,

$$50\% = \sum_{n=0}^{N} \frac{e^{-n\beta\hbar\omega}}{\sum_m e^{-m\beta\hbar\omega}} = 1 - e^{-N\beta\hbar\omega} \ ,$$

that is,

$$N = -\frac{\ln 0.5}{\beta\hbar\omega} \ .$$

For the different situations we find,

T	$\omega/2\pi$	N
300 K	10 MHz	$4.3 \cdot 10^6$
300 K	10 GHz	4300
1 µK	10 MHz	0.014
1 µK	10 GHz	$1.4 \cdot 10^{-5}$

34.3.5.6 Ex: Density operator of a Glauber state

a. Write down the density operator of a Glauber state and calculate its purity.
b. How does the density operator look after a measurement of its vibrational level before acknowledging the result? Is it pure?
c. How does it look having acknowledged the result? Is it pure?

Solution: *The density operator is,*

$$\hat{\rho} = \sum_{m,n} \frac{\beta^{*m}\beta^n e^{-|\beta|^2}}{\sqrt{m!n!}} |n\rangle\langle m| \ ,$$

and its square,

$$\hat{\rho}^2 = e^{-2|\beta|^2} \sum_{n,n'} \frac{\beta^{*n'}\beta^n}{\sqrt{n!n'!}} |n\rangle\langle n'| \sum_{m,m'} \frac{\beta^{*m}\beta^{m'}}{\sqrt{m!m'!}} |m'\rangle\langle m|$$

$$= e^{-|\beta|^2} \sum_{m,n,n'} \frac{\beta^n\beta^{*m}}{\sqrt{n!m!}} |n\rangle\langle m| \sum_{n'} \frac{|\beta|^{2n'} e^{-|\beta|^2}}{n'!} = e^{-|\beta|^2} \sum_{m,n,n'} \frac{\beta^n\beta^{*m}}{\sqrt{n!m!}} |n\rangle\langle m|\langle\beta|\beta\rangle = \hat{\rho} \ .$$

b. After the measurement, the density operator reads,

$$\hat{\rho}' = \sum_k \hat{P}_k\hat{\rho}\hat{P}_k = \sum_k |k\rangle\langle k| e^{-|\alpha|^2} \sum_{m,n} \frac{\alpha^{*m}\alpha^n}{\sqrt{m!}\sqrt{n!}} |n\rangle\langle m|k\rangle\langle k| = \sum_k e^{-|\alpha|^2} \frac{|\alpha|^{2k}}{k!} |k\rangle\langle k| \ .$$

This the density operator is not pure, since,

$$\hat{\rho}'^2 = \sum_k \frac{|\alpha|^{2k} e^{-|\alpha|^2}}{k!} |k\rangle\langle k| \sum_n \frac{|\alpha|^{2n} e^{-|\alpha|^2}}{n!} |n\rangle\langle n| = \sum_n \frac{|\alpha|^{4n} e^{-2|\alpha|^2}}{n!^2} |n\rangle\langle n| \neq \hat{\rho} \ .$$

c. Having acknowledged the result, we get the Poisson distribution,

$$\hat{\rho}'' = e^{-|\alpha|^2} \frac{|\alpha|^{2k}}{k!} |k\rangle\langle k| \ ,$$

which obviously is a pure state.

34.3.5.7 Ex: Reduced density operator of a Glauber state

Project the density operator of a Glauber state onto its two lowest Fock states using the formula (34.119). Show that the resulting density operator is pure.

Solution: *With the density operator,*

$$\hat{\rho} = \sum_{m,n} \frac{\beta^{*m} \beta^n e^{-|\beta|^2}}{\sqrt{m!n!}} |n\rangle\langle m|$$

and the projector,

$$P_{1,2} = |0\rangle\langle 0| + |1\rangle\langle 1|$$

we find,

$$\begin{aligned} P_{1,2}\hat{\rho}P_{1,2} &= |0\rangle\langle 0|\hat{\rho}|0\rangle\langle 0| + |1\rangle\langle 1|\hat{\rho}|0\rangle\langle 0| + |0\rangle\langle 0|\hat{\rho}|1\rangle\langle 1| + |1\rangle\langle 1|\hat{\rho}|1\rangle\langle 1| \\ &= e^{-|\beta|^2} \left(|0\rangle\langle 0| + \beta|1\rangle\langle 0| + \beta^*|0\rangle\langle 1| + \beta\beta^*|1\rangle\langle 1|\right) \end{aligned}$$

and

$$Tr\ \hat{\rho}P_{1,2} = \sum_k \langle k|\hat{\rho}P_{1,2}|k\rangle = \sum_{k,m} \frac{\beta^{*m}\beta^k e^{-|\beta|^2}}{\sqrt{m!k!}} \langle m|(|0\rangle\langle 0| + |1\rangle\langle 1|)|k\rangle = e^{-|\beta|^2}(1+\beta^*\beta) \ .$$

Hence,

$$\hat{\rho}_{red} = \frac{P_{1,2}\hat{\rho}P_{1,2}}{Tr\ \hat{\rho}P_{1,2}} = \frac{|0\rangle\langle 0| + \beta|1\rangle\langle 0| + \beta^*|0\rangle\langle 1| + |\beta|^2|1\rangle\langle 1|}{1+|\beta|^2} \ .$$

The purity is given because of,

$$\begin{aligned} \hat{\rho}_{red}^2 &= \frac{|0\rangle\langle 0| + \beta|1\rangle\langle 0| + |\beta|^2|0\rangle\langle 0| + \beta|\beta|^2|1\rangle\langle 0| + \beta^*|0\rangle\langle 1| + |\beta|^2|1\rangle\langle 1| + \beta^*|\beta|^2|0\rangle\langle 1| + |\beta|^4|1\rangle\langle 1|}{(1+|\beta|^2)^2} \\ &= \hat{\rho}_{red} \ . \end{aligned}$$

34.3.5.8 Ex: Partial measurements

Consider the density operator describing the quantum state of two spins, $|\Psi\rangle = |\psi_a\rangle \otimes |\psi_b\rangle$, with $|\psi_a\rangle = a_1|\uparrow\rangle + a_2|\downarrow\rangle$ and $|\psi_b\rangle = b_1|\rightarrow\rangle + b_2|\leftarrow\rangle$.
a. Write down the density operator for the complete system in terms of the expansion coefficients $c_{ij} = a_i b_j$.
b. Assume that the spin $|\psi_b\rangle$ is measured and verify whether the new density operator describing our knowledge of the system is pure.
c. Now consider the entangled state $|\Psi_e\rangle = c_{11}|\uparrow\rangle|\rightarrow\rangle + c_{22}|\downarrow\rangle|\leftarrow\rangle$. Write down again the density operator for the complete system, measure the spin $|\psi_b\rangle$, and verify whether the new density operator describing our knowledge of the system is pure.

Solution: *a. The individual spin states are normalized,*

$$|a_1|^2 + |a_2|^2 = \langle\psi_a|\psi_a\rangle = 1 = \langle\psi_b|\psi_b\rangle = |b_1|^2 + |b_2|^2 \ .$$

The tensorial product is,

$$\begin{aligned}|\Psi\rangle &= a_1 b_1|\uparrow\rangle|\rightarrow\rangle + a_1 b_2|\uparrow\rangle|\leftarrow\rangle + a_2 b_1|\downarrow\rangle|\rightarrow\rangle + a_2 b_2|\downarrow\rangle|\leftarrow\rangle \\ &= c_{11}|\uparrow\rangle|\rightarrow\rangle + c_{12}|\uparrow\rangle|\leftarrow\rangle + c_{21}|\downarrow\rangle|\rightarrow\rangle + c_{22}|\downarrow\rangle|\leftarrow\rangle \ ,\end{aligned}$$

with the normalization,

$$1 = \langle\Psi|\Psi\rangle = |c_{11}|^2 + |c_{12}|^2 + |c_{21}|^2 + |c_{22}|^2 \ ,$$

and

$$|a_1|^2 = |c_{11}|^2 + |c_{12}|^2 \qquad \textit{and} \qquad |a_2|^2 = |c_{21}|^2 + |c_{22}|^2 \ .$$

The complete density operator now reads,

$$\hat{\rho} = \begin{pmatrix} |c_{11}|^2 & c_{11}c_{12}^* & c_{11}c_{21}^* & c_{11}c_{22}^* \\ c_{12}c_{11}^* & |c_{12}|^2 & c_{12}c_{21}^* & c_{12}c_{22}^* \\ c_{21}c_{11}^* & c_{21}c_{12}^* & |c_{21}|^2 & c_{21}c_{22}^* \\ c_{22}c_{11}^* & c_{22}c_{12}^* & c_{22}c_{21}^* & |c_{22}|^2 \end{pmatrix} \ .$$

b. The measurement corresponds to tracing over the measured spin yielding the new density operator,

$$\begin{aligned} Tr_b\ \hat{\rho} &= \sum_{j=\rightarrow,\leftarrow} \langle j|\Psi\rangle\langle\Psi|j\rangle = \langle\rightarrow|\Psi\rangle\langle\Psi|\rightarrow\rangle + \langle\leftarrow|\Psi\rangle\langle\Psi|\leftarrow\rangle \\ &= (c_{11}|\uparrow\rangle + c_{21}|\downarrow\rangle)(\langle\uparrow|c_{11}^* + \langle\downarrow|c_{21}^*) + (c_{12}|\uparrow\rangle + c_{22}|\downarrow\rangle)(\langle\uparrow|c_{12}^* + \langle\downarrow|c_{22}^*) \\ &= \begin{pmatrix} |c_{11}|^2 + |c_{12}|^2 & c_{11}c_{21}^* + c_{12}c_{22}^* \\ c_{11}^*c_{21} + c_{12}^*c_{22} & |c_{21}|^2 + |c_{22}|^2 \end{pmatrix} = \begin{pmatrix} |a_1|^2 & a_1 a_2^* \\ a_1^* a_2 & |a_2|^2 \end{pmatrix} = \hat{\rho}_a \ . \end{aligned}$$

Obviously,

$$Tr_a\ \hat{\rho}_a = 1 \qquad \textit{and} \qquad \hat{\rho}_a = \hat{\rho}_a^\dagger \qquad \textit{and} \qquad \hat{\rho}_a^2 = \hat{\rho}_a \ .$$

c. Normalization requests,

$$\langle\Psi_e|\Psi_e\rangle = |c_{11}|^2 + |c_{22}|^2 = 1 \ .$$

The complete density operator now reads,

$$\hat{\rho}_e = \begin{pmatrix} |c_{11}|^2 & 0 & 0 & c_{11}c_{22}^* \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ c_{11}^* c_{22} & 0 & 0 & |c_{22}|^2 \end{pmatrix}^2 = \hat{\rho}_e^2 \ ,$$

and satisfies,

$$\det \hat{\rho}_e = 0 \qquad \textit{and} \qquad Tr_{a,b}\ \hat{\rho}_e = 1 \ .$$

On the other hand,

$$Tr_b\ \hat{\rho}_e = \begin{pmatrix} |c_{11}|^2 & 0 \\ 0 & |c_{22}|^2 \end{pmatrix} \equiv \hat{\rho}_{e,a} \neq \hat{\rho}_{e,a}^2 \qquad \textit{and} \qquad \det \hat{\rho}_{e,a} \neq 0 \ .$$

Hence, in the entangled case, the traced density operator is not pure.

34.4 Bloch equations for two-level atoms

In this section we will begin to apply the ideas and tools developed in the previous sections. Let us first make use of the density matrix to describe a two-level atom coupled to a single-mode light field without spontaneous emission. We will then introduce the atomic Bloch vector as a convenient and suggestive method to describe the time evolution of a coupled two-level atom.

The internal structure of atoms is analyzed in atomic physics, where we find that the energy levels are discrete (Bohr's axiom). The center of mass motion of the atoms and collisions with other atoms are ignored, and concerning the interaction of the atoms with light, we are only interested in the aspect, that the interaction can induce transitions between internal states via absorption or emission of photons. It is the duty of atomic physics to calculate the frequencies and strengths of transitions (by Hartree-Fock or similar methods), as well as their behavior in external electric and magnetic fields. The results of these calculations are visualized in energy level schemes called *Grotrian diagrams*. In quantum optics we do not care, how the energies of the levels were calculated, but accept them as given. That is, we assume the Hamiltonian of the unperturbed atom to be diagonalized, so that its internal structure can be written as,

$$\hat{H}_{atom} = \sum_j \hbar\omega_j |j\rangle\langle j| \ . \tag{34.141}$$

34.4.1 The matrix elements of the density operator

Since the optical Bloch equations are coupled differential equations relating the elements of the density operator matrix, we must examine the temporal dependence of these matrix elements, based on our knowledge of the operator's properties. This can be done in the Schrödinger picture using Eq. (34.125), in the interaction picture

using Eq. (34.129), or directly in the co-rotating frame using Eq. (34.138). For didactic reason we will begin with the Schrödinger picture and then derive the interaction picture once again.

So, let us begin with the Liouville equation (34.125) and evaluate the elements of the matrix,

$$\begin{aligned}\langle m|\frac{d\hat{\rho}(t)}{dt}|n\rangle &= \tfrac{\imath}{\hbar}\langle m|[\hat{\rho}(t),\hat{H}]|n\rangle = \tfrac{\imath}{\hbar}\langle m|[\hat{\rho}(t),\hat{H}_{atom}+\hat{H}_{atom:field}(t)]|n\rangle \\ &= \tfrac{\imath}{\hbar}(E_n-E_m)\langle m|\hat{\rho}(t)|n\rangle + \tfrac{\imath}{\hbar}\langle m|[\hat{\rho}(t),\hat{H}_{atom:field}(t)]|n\rangle \ ,\end{aligned} \tag{34.142}$$

where $|m\rangle$ and $|n\rangle$ are members of a complete set of vectors of a basis $\{|k\rangle\}$ which are also eigen-kets of $\hat{H}_{atom}$ and span the space of $\hat{H}$. Now, we insert the closing expression $\sum_k |k\rangle\langle k| = \mathbb{I}$ in the commutator on the right-hand side of Eq. (34.142):

$$\begin{aligned}&\langle m|[\hat{\rho}(t),\hat{H}_{atom:field}(t)]|n\rangle \\ &= \sum_k [\langle m|\hat{\rho}(t)|k\rangle\langle k|\hat{H}_{atom:field}|n\rangle - \langle m|\hat{H}_{atom:field}|k\rangle\langle k|\hat{\rho}(t)|n\rangle] \ .\end{aligned} \tag{34.143}$$

For our two-level atom the complete set only includes two states: $|1(t)\rangle = |1\rangle$ and $|2(t)\rangle = e^{-\imath\omega_0 t}|2\rangle$. In addition, the matrix elements of the dipole coupling operator $\hat{H}_{atom:field}$ are only non-diagonal,

$$V \equiv \langle 1|\hat{H}_{atom:field}|2\rangle = \overline{\langle 2|\hat{H}_{atom:field}|1\rangle} = V^* \ . \tag{34.144}$$

Hence, Eq. (34.142) adopts the form,

$$\boxed{\begin{aligned}\frac{d\hat{\rho}_{11}}{dt} &= \tfrac{\imath}{\hbar}[\hat{\rho}_{12}V^* - \hat{\rho}_{21}V] \\ \frac{d\hat{\rho}_{22}}{dt} &= \tfrac{\imath}{\hbar}[\hat{\rho}_{21}V - \hat{\rho}_{12}V^*] = -\frac{d\hat{\rho}_{11}}{dt} \\ \frac{d\hat{\rho}_{12}}{dt} &= \imath\omega_0\hat{\rho}_{12} + \tfrac{\imath}{\hbar}[V(\hat{\rho}_{11}-\hat{\rho}_{22})] \\ \frac{d\hat{\rho}_{21}}{dt} &= -\imath\omega_0\hat{\rho}_{21} + \tfrac{\imath}{\hbar}[V^*(\hat{\rho}_{22}-\hat{\rho}_{11})] = \frac{d\hat{\rho}^*_{12}}{dt}\end{aligned}} \ , \tag{34.145}$$

remembering that the dash of the diagonal terms, called *populations*, must be unitary, and that the non-diagonal terms, called *coherences*, must be complex,

$$\hat{\rho}_{11} + \hat{\rho}_{22} = 1 \quad , \quad \hat{\rho}_{21} = \hat{\rho}^*_{12} \ . \tag{34.146}$$

The above set of equations constitutes the *optical Bloch equations* in the *Schrödinger picture*. It does not include loss terms due to spontaneous emission. We transform the Bloch equations to the *interaction picture* by replacing the Liouville equation (34.125) by (34.129), and calculating the matrix elements. We obtain,

$$\frac{d\tilde{\rho}_{22}}{dt} = \frac{\imath}{\hbar}(V\tilde{\rho}_{21} - V^*\tilde{\rho}_{12}) \quad \text{and} \quad \frac{d\tilde{\rho}_{12}}{dt} = \frac{\imath}{\hbar}V(\tilde{\rho}_{11}-\tilde{\rho}_{22}) \ . \tag{34.147}$$

We would also have obtained this expression via the substitution, $\hat{\rho}_{12} = \tilde{\rho}_{12}e^{\imath\omega_0 t}$. The interaction picture simplifies the expressions for the temporal dependence of the coherences by eliminating the first term on the right-hand side. Transforming to the interaction picture removes the temporal dependence of the basis vectors spanning the Hilbert space of the two-level atom.

We have derived the optical Bloch equations from the Liouville equation, which is the fundamental equation of motion of the density operator, and we have seen how a unitary transformation can be used to *represent* these equations in the Schrödinger, Heisenberg or interaction picture. So far, the Bloch equations do not include the possibility of spontaneous emission. We will learn later, how to include this phenomenon.

34.4.2 Rotating wave approximation

In the following, we will only consider exponentials rotating with the frequency $\Delta \equiv \omega - \omega_0$, and we will neglect terms rotating like $\Delta \equiv \omega + \omega_0$ in the time dependence of the coupling operator,

$$V(t) = \hbar\Omega \cos\omega t \to \tfrac{\hbar}{2}\Omega e^{-\imath\omega t} \ , \tag{34.148}$$

neglecting the part $\frac{1}{2}\hbar\Omega e^{\imath\omega t}$. The amplitude Ω is called *Rabi frequency*. This approximation, called *rotating wave approximation* (RWA) is good, when the is sufficiently small, $\Omega \ll \omega$. Otherwise, we observe an energy correction of the levels called *Bloch-Siegert shift*.

Once the RWA made, we can transform to the rotating system by the prescription,

$$\boxed{\rho_{12} \equiv \hat{\rho}_{12}e^{-\imath\omega t} \quad , \quad \rho_{22} \equiv \hat{\rho}_{22}} \ , \tag{34.149}$$

which, applied to the Bloch equations in the *Schrödinger picture* Eq. (34.145), yields,

$$\frac{d\rho_{22}}{dt} = \frac{\imath\Omega}{2}\rho_{21} - \frac{\imath\Omega^*}{2}\rho_{12} \quad , \quad \frac{d\rho_{12}}{dt} = -\imath\Delta\rho_{12} + \frac{\imath\Omega}{2}(\rho_{11} - \rho_{22}) \ . \tag{34.150}$$

In Exc. 34.4.6.1 we derive the Bloch equations from the equations of motion for the population amplitudes a_1 and a_2.

For arbitrary starting conditions, the solution of these equations is not simple. To solve the problem we write the equations in a matrix form,

$$\boxed{\vec{\rho} \equiv \begin{pmatrix} \rho_{11} \\ \rho_{22} \\ \rho_{12} \\ \rho_{21} \end{pmatrix} \quad , \quad \mathcal{M} \equiv \begin{pmatrix} 0 & 0 & \frac{\imath}{2}\Omega^* & -\frac{\imath}{2}\Omega \\ 0 & 0 & -\frac{\imath}{2}\Omega^* & \frac{\imath}{2}\Omega \\ \frac{\imath}{2}\Omega & -\frac{\imath}{2}\Omega & -\imath\Delta & 0 \\ -\frac{\imath}{2}\Omega^* & \frac{\imath}{2}\Omega^* & 0 & \imath\Delta \end{pmatrix} \quad , \quad \dot{\vec{\rho}} = \mathcal{M}\vec{\rho}} \ . \tag{34.151}$$

To solve this system of differential equations, we calculate the eigenvalues of the matrix,

$$\begin{aligned} \det(\mathcal{M} - \lambda\mathbb{I}_4) = \lambda^2(\Delta^2 + |\Omega|^2) + \lambda^4 = 0 \\ \lambda = 0, \pm\imath G \ , \end{aligned} \tag{34.152}$$

with the *generalized Rabi frequency* $G \equiv \sqrt{\Delta^2 + |\Omega|^2}$. Therefore, the general solution is,

$$\begin{aligned} \rho_{22}(t) &= \rho_{22}^{(1)} + \rho_{22}^{(2)} e^{\imath G t} + \rho_{22}^{(3)} e^{-\imath G t} \\ \rho_{12}(t) &= \rho_{12}^{(1)} + \rho_{12}^{(2)} e^{\imath G t} + \rho_{12}^{(3)} e^{-\imath G t} \ . \end{aligned} \tag{34.153}$$

The coefficients follow from the Bloch equations with particular starting conditions. With a little algebra we get

$$\begin{aligned} \rho_{22}^{(1)} &= \rho_{22}(0) + \tfrac{1}{2G^2}\left[|\Omega|^2\,(1-2\rho_{22}(0)) - \Delta\,(\Omega\rho_{12}^*(0) + \Omega^*\rho_{12}(0))\right] \\ \rho_{22}^{(2)} &= \tfrac{1}{4G^2}\left[-|\Omega|^2(1-2\rho_{22}(0)) + (\Delta+G)\Omega\rho_{12}^*(0) + (\Delta-G)\Omega^*\rho_{12}(0)\right] \\ \rho_{22}^{(3)} &= \tfrac{1}{4G^2}\left[-|\Omega|^2(1-2\rho_{22}(0)) + (\Delta-G)\Omega\rho_{12}^*(0) + (\Delta+G)\Omega^*\rho_{12}(0)\right] \\ \rho_{12}^{(1)} &= \tfrac{1}{2G^2}\left[\Delta\Omega(1-2\rho_{22}(0)) + \Omega\,(\Omega\rho_{12}^*(0) + \Omega^*\rho_{12}(0))\right] \\ \rho_{12}^{(2)} &= \tfrac{\Delta-G}{4G^2}\left[-\Omega(1-2\rho_{22}(0)) + (\Delta+G)\tfrac{\Omega}{\Omega^*}\rho_{12}^*(0) + (\Delta-G)\rho_{12}(0)\right] \\ \rho_{12}^{(3)} &= \tfrac{\Delta+G}{4G^2}\left[-\Omega(1-2\rho_{22}(0)) + (\Delta-G)\tfrac{\Omega}{\Omega^*}\rho_{12}^*(0) + (\Delta+G)\rho_{12}(0)\right] \ . \end{aligned} \tag{34.154}$$

We derive this solution in Exc. 34.4.6.2.

To begin the discussion of this solution, let us consider a sample of atoms initially in the ground state when the light field is switched on at time $t = 0$,

$$\rho_{11}(0) = 1 = 1 - \rho_{22}(0) \quad , \quad \rho_{12}(0) = 0 = \rho_{21}(0) \ . \tag{34.155}$$

In this case, the conditions (34.154) simplify to,

$$\begin{aligned} \rho_{22}^{(1)} &= \tfrac{|\Omega|^2}{2G^2} \quad , \quad \rho_{12}^{(1)} = \tfrac{1}{2G^2}\Delta\Omega \\ \rho_{22}^{(2)} &= \tfrac{-|\Omega|^2}{4G^2} \quad , \quad \rho_{12}^{(2)} = \tfrac{G-\Delta}{4G^2}\Omega \\ \rho_{22}^{(3)} &= \tfrac{-|\Omega|^2}{4G^2} \quad , \quad \rho_{12}^{(3)} = \tfrac{-G-\Delta}{4G^2}\Omega \ , \end{aligned} \tag{34.156}$$

such that,

$$\begin{aligned} \rho_{22} &= \rho_{22}^{(1)} + \rho_{22}^{(2)} e^{\imath G t} + \rho_{22}^{(3)} e^{-\imath G t} = \frac{|\Omega|^2}{4G^2}(2 - e^{\imath G t} - e^{-\imath G t}) \\ \rho_{12} &= \rho_{12}^{(1)} + \rho_{12}^{(2)} e^{\imath G t} + \rho_{12}^{(3)} e^{-\imath G t} = \frac{\Delta\Omega}{2G^2} - \frac{\Delta - G}{4G^2}\Omega e^{\imath G t} - \frac{\Delta + G}{4G^2}\Omega e^{-\imath G t} \\ &= \frac{2\Omega}{4G^2}(\Delta - \Delta\cos Gt + \imath G \sin Gt) \ . \end{aligned} \tag{34.157}$$

Using $\cos x = 1 - 2\sin^2\frac{x}{2}$ and $\sin x = 2\sin\frac{x}{2}\cos\frac{x}{2}$, we finally obtain,

$$\boxed{\rho_{22} = \frac{|\Omega|^2}{G^2}\sin^2\frac{Gt}{2} \quad , \quad \rho_{12} = \frac{\Omega}{G^2}\sin\frac{Gt}{2}\left(\Delta\sin\frac{Gt}{2} + \imath G\cos\frac{Gt}{2}\right)} \ . \tag{34.158}$$

And comparing with the solutions of the Schrödinger equation for a coupled two-level atom obtained in Exc. 23.4.7.1 and (27.93), we verify,

$$\begin{aligned} \rho_{22} &= \left|\tfrac{\imath\Omega}{G}e^{-\imath t\Delta/2}\sin\tfrac{Gt}{2}\right|^2 = |a_2|^2 \\ \rho_{12} &= -e^{-\imath t\Delta/2}\left[\cos\tfrac{Gt}{2} - \imath\tfrac{\Delta}{G}\sin\tfrac{Gt}{2}\right] \ \tfrac{-\imath\Omega}{G}e^{\imath t\Delta/2}\sin\tfrac{Gt}{2} = a_1^* a_2 \ . \end{aligned} \tag{34.159}$$

34.4.3 Pauli matrices and the atomic Bloch vector

Let us come back to the unperturbed atomic Hamiltonian (34.141). The electronic states are orthonormal $\langle i|j\rangle = \delta_{ij}$, and we define the transition operators by

$$\hat{\sigma}_{ij}|k\rangle = \delta_{jk}|i\rangle \ , \tag{34.160}$$

and $\hat{\sigma}_{ij}^{+} = \hat{\sigma}_{ji}$ satisfying the commutation relation,

$$[\hat{\sigma}_{ij}, \hat{\sigma}_{lk}] = \delta_{jl}\hat{\sigma}_{ik} - \delta_{ik}\hat{\sigma}_{lj} \ . \tag{34.161}$$

Many times we will restrict ourselves to atoms of two or three levels. For a two-level system we obtain the *Pauli spin matrix* defined in (23.45). Every 2×2 matrix can be expanded on a Pauli matrix basis (see Exc. 34.4.6.3),

$$\begin{aligned}\begin{pmatrix} \rho_{11} & \rho_{12} \\ \rho_{21} & \rho_{22} \end{pmatrix} &= |1\rangle\rho_{11}\langle 1| + |1\rangle\rho_{12}\langle 2| + |2\rangle\rho_{21}\langle 1| + |2\rangle\rho_{22}\langle 2| \\ &= \rho_{11}(\tfrac{1}{2} + \tfrac{1}{2}\hat{\sigma}_z) + \rho_{12}\hat{\sigma}^{-} + \rho_{21}\hat{\sigma}^{+} + \rho_{22}(\tfrac{1}{2} - \tfrac{1}{2}\hat{\sigma}_z) \\ &= \rho_{11}\hat{\sigma}^{-}\hat{\sigma}^{+} + \rho_{12}\hat{\sigma}^{-} + \rho_{21}\hat{\sigma}^{+} + \rho_{22}\hat{\sigma}^{+}\hat{\sigma}^{-} = \begin{pmatrix} \langle\hat{\sigma}^{-}\hat{\sigma}^{+}\rangle & \langle\hat{\sigma}^{-}\rangle \\ \langle\hat{\sigma}^{+}\rangle & \langle\hat{\sigma}^{+}\hat{\sigma}^{-}\rangle \end{pmatrix} \ .\end{aligned} \tag{34.162}$$

For the two-level case it is useful to introduce an alternative notation based on the *Bloch vector* defined in (23.46),

$$\langle\hat{\vec{\sigma}}\rangle \equiv \begin{pmatrix} 2\ \mathfrak{Re}\ \rho_{12} \\ 2\ \mathfrak{Im}\ \rho_{12} \\ \rho_{22} - \rho_{11} \end{pmatrix} = \begin{pmatrix} \langle\hat{\sigma}^{+}\rangle + \langle\hat{\sigma}^{-}\rangle \\ \imath(\langle\hat{\sigma}^{+}\rangle - \langle\hat{\sigma}^{-}\rangle) \\ \langle\hat{\sigma}^{+}\hat{\sigma}^{-}\rangle - \langle\hat{\sigma}^{-}\hat{\sigma}^{+}\rangle \end{pmatrix} = \begin{pmatrix} \langle\hat{\sigma}_x\rangle \\ \langle\hat{\sigma}_y\rangle \\ \langle\hat{\sigma}_z\rangle \end{pmatrix} \ . \tag{34.163}$$

We also define the torque vector,

$$\boxed{\mathbf{G} \equiv \begin{pmatrix} \mathfrak{Re}\ \Omega \\ \mathfrak{Im}\ \Omega \\ -\Delta \end{pmatrix} \qquad \text{with} \qquad \|G\| = G = \sqrt{|\Omega|^2 + \Delta^2}} \ , \tag{34.164}$$

the length of which is simply the generalized Rabi frequency. Note that here we allow for the possibility of complex Rabi frequency.

Now, using $\hat{\sigma}_z = [\hat{\sigma}^{+}, \hat{\sigma}^{-}]$, we may write the Hamiltonian of an unperturbed two-level system,

$$\hat{H}_0 = -\hbar\Delta\hat{\sigma}^{+}\hat{\sigma}^{-} = -\tfrac{\hbar}{2}\Delta(\hat{\sigma}_z + \mathbb{I}_2) = -\tfrac{\hbar}{2}\Delta\hat{\sigma}_z + \text{offset} \ . \tag{34.165}$$

For the perturbed system,

$$\hat{H} = \hat{\mathbf{s}} \cdot \mathbf{G} = \tfrac{\hbar}{2}\mathbf{G} \cdot \hat{\vec{\sigma}} = -\tfrac{\hbar}{2}\hat{\sigma}_z\Delta + \tfrac{\hbar}{2}\hat{\sigma}_x\mathfrak{Re}\ \Omega + \tfrac{\hbar}{2}\hat{\sigma}_y\mathfrak{Im}\ \Omega = \begin{pmatrix} \frac{\hbar}{2}\Delta & \frac{\hbar}{2}\Omega^{*} \\ \frac{\hbar}{2}\Omega & -\frac{\hbar}{2}\Delta \end{pmatrix} \ . \tag{34.166}$$

The Bloch equations (34.165) then follow as the Heisenberg equation with the Hamiltonian (34.167) using $[\hat{\sigma}_k, \hat{\sigma}_m] = 2\imath\epsilon_{klm}\hat{\sigma}_m$,

$$\frac{d\hat{\vec{\sigma}}}{dt} = \tfrac{\imath}{\hbar}[\hat{H}, \hat{\vec{\sigma}}] = \tfrac{\imath}{2}[\mathbf{G}\cdot\hat{\vec{\sigma}}, \hat{\vec{\sigma}}] \tag{34.167}$$

$$= \tfrac{\imath G_x}{2}[\hat{\sigma}_x, \hat{\vec{\sigma}}] + \tfrac{\imath G_y}{2}[\hat{\sigma}_y, \hat{\vec{\sigma}}] + \tfrac{\imath G_z}{2}[\hat{\sigma}_z, \hat{\vec{\sigma}}] = \begin{pmatrix} G_y\hat{\sigma}_z - G_z\hat{\sigma}_y \\ G_z\hat{\sigma}_x - G_x\hat{\sigma}_z \\ G_x\hat{\sigma}_y - G_y\hat{\sigma}_x \end{pmatrix} = \mathbf{G}\times\hat{\vec{\sigma}}\ .$$

The expectation values yield,

$$\boxed{\frac{d\vec{\varrho}}{dt} = \mathbf{G}\times\vec{\varrho}}\ . \tag{34.168}$$

As will be shown in Exc. 34.4.6.4, these equations are identical to the Liouville equations (34.151). ρ_{12} describes the polarization and $\rho_{22} - \rho_{11}$ the *population inversion* of the atom. The equation is analogous to the equation of motion for a *rigid rotor* or *spinning top* (for example, a dipole in a homogeneous field). It displays phenomena such as *precession* and *nutation*. The physical content and usefulness of the Bloch vector will become clearer when we use the formalism to analyze electric and magnetic couplings. In Exc. 34.4.6.5 we verify that the Bloch vector is normalized (as long as spontaneous emission is not considered).

34.4.4 State manipulations by sequences of radiation pulses

The temporal dependence of the three components of the atomic Bloch vector provides a useful illustration of the atom-field interaction. Resonant coupling, $\Delta = 0$ and $G = \Omega$, puts the solutions (34.158) into the form,

$$\rho_{22}(t) = \tfrac{1}{2}(1 - \cos\Omega t) \quad , \quad \rho_{12}(t) = \tfrac{\imath}{2}\sin\Omega t\ , \tag{34.169}$$

that is,

$$\vec{\varrho}(t) = \begin{pmatrix} 0 \\ \sin\Omega t \\ -\cos\Omega t \end{pmatrix}\ . \tag{34.170}$$

That is, a resonant pulse rotates a Bloch vector initially pointing in the direction $-z$ within the plane z-y, until it arrives, at time $t = \frac{\pi}{2\Omega}$, at the $+y$ direction and at time $t = \frac{\pi}{\Omega}$ at the $+z$ direction. This means that the entire population has been transferred to the excited state. The Bloch vector continues to rotate (the movement is called *nutation*) around the torque vector $\mathbf{G}$ which, as can be seen from Eq. (34.165), points at the $+x$ direction when $\Delta = 0$. The nutation frequency is proportional to the force Ω of the atom-field interaction. With the Eq. (34.158) we see that the population oscillates between the ground and excited state with the frequency Ω. This means that the energy $\hbar\omega$ is periodically exchanged between the atom and the field. A pulse of resonant light of duration such that $\tau = \pi/2\Omega$ is called a $\pi/2$-pulse. The nutation is illustrated in Fig. 34.2(a).

Once the coherence has been excited by a detuned radiation, $\Delta \neq 0$, the Bloch vector does not stand still, even after the radiation has been switched off. To see

this, we consider again the general solution (34.154) now entering $\Omega = 0$. If the Bloch vector is initially at a point in the unitary circle of the plane z-y, it will rotate according to the formula,

$$\rho_{22}(t) = \rho_{22}(0) \quad , \quad \rho_{12}(t) = \rho_{12}(0)e^{-\imath\Delta t} \, , \tag{34.171}$$

that is,

$$\vec{\varrho}(t) = \begin{pmatrix} \rho_{12}(0)\sin\Delta t \\ \rho_{12}(0)\cos\Delta t \\ 2\rho_{22}(0) - 1 \end{pmatrix} \, . \tag{34.172}$$

That is, the Bloch vector performs a motion of *precession* around the symmetry axis. The precession is illustrated in Fig. 34.2(b).

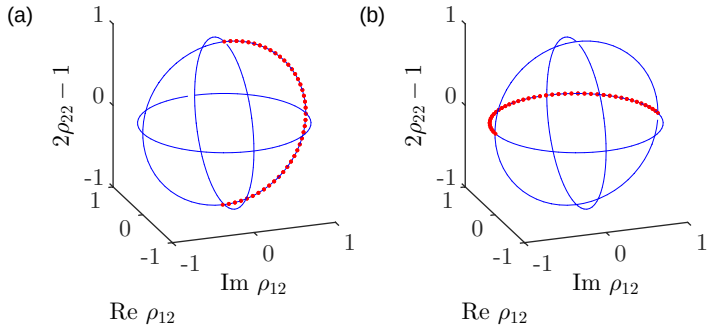

Figure 34.2: (code) (a) Nutation of the Bloch vector. The red circles show the evolution of the Bloch vector on the Bloch sphere for a resonant π-pulse. (b) Precession of the Bloch vector.

The evolution of the Bloch vector on the surface of the Bloch sphere under the influence of radiation fields can be considered a coherent trajectory of the wavefunction of the atomic state, which is therefore subject to interference phenomena [642]. Interferometers can be realized by sequences of consecutive pulses splitting populations, exciting coherences, and remixing populations.

Sensors based on interferometry of atomic excitation are nowadays among the most accurate and most sensitive. We will discuss the method of radiation pulse sequences in several exercises: In the Excs. 34.4.6.6, 34.4.6.7, and 34.4.6.8 the *Ramsey method*.

34.4.4.1 Atomic ensembles

While it is technically challenging to observe the dynamics of single atoms, it is relatively easy monitor the dynamics of ensembles of atoms, provided that they react synchronously to incident radiation. The concentration of a sufficient number of atoms in a small volume can, however, introduce additional (desirable or undesirable) effects. Collisions, for instance, induce (irreversible) decoherence. On the other hand, if the ensemble is sufficiently dense that the mean distance between atoms is less than a resonant wavelength, then the transition dipoles of the individual atoms will couple to produce a collective dipole moment and generate effects known as superradiance.

Thermal motion of the atoms is another undesired effect, because every atom will interact with the radiation on a different Doppler-shifted frequency. This leads to diffusion of the individual atomic Bloch vectors in the x-y-plane, which in turn limits the resolution of interferometric applications. We will discuss in Exc. 34.4.6.9 the *photon echo method*, which allows to circumvent this problem.

34.4.5 Nuclear magnetic resonance

Nuclear magnetic resonance (NMR) is a physical phenomenon in which nuclei in a strong constant magnetic field (up to 20 T) are perturbed by a weak oscillating magnetic field (in the near field) and respond by producing an electromagnetic signal with a frequency characteristic of the magnetic field at the nucleus. This process occurs near resonance, when the oscillation frequency (typically 60..1000 MHz) matches the intrinsic frequency of the nuclei, which depends on the strength of the static magnetic field, the chemical environment, and the magnetic properties of the isotope involved. NMR spectroscopy is widely used to determine the structure of organic molecules in solution and in advanced medical imaging techniques, such as in magnetic resonance imaging (MRI). The most commonly used nuclei are ^{1}H and ^{13}C.

NMR transitions can be excited, when the electron spins do not participate in the interaction, e.g. because they are paired (see Eq. (30.41)), and when the nucleus has an intrinsic nuclear magnetic moment $\hat{\vec{\mu}}_I$ and hence an angular momentum $\hat{\mathbf{I}}$. This is the case for an odd number of protons and/or neutrons. Nuclides with even numbers of both have a total spin of zero and are therefore NMR-inactive.

The principle of NMR usually involves three sequential steps: (i) The alignment of the magnetic nuclear spins in an applied, constant magnetic field $\vec{\mathcal{B}}_0$. (ii) The perturbation of this alignment of the nuclear spins by a weak oscillating magnetic field $\vec{\mathcal{B}}_1(t)$ called rf-pulse. (iii) The detection of the NMR signal during or after the rf-pulse via the voltage induced in a detection coil due to the precession of the nuclear spins around $\vec{\mathcal{B}}_0$. After an rf-pulse, the nuclear dipole moment precesses at the nuclei's intrinsic Larmor frequency without involving transitions between spin states. Choosing the two magnetic fields perpendicular to each other, one maximizes the NMR signal strength,

$$\vec{\mathcal{B}}(t) = \mathcal{B}_{rf}(t)\hat{\mathbf{e}}_x + \mathcal{B}_0\hat{\mathbf{e}}_z \ , \tag{34.173}$$

where, because of $|\mathcal{B}_{rf}(t)| \ll \mathcal{B}_0$, we choose the z-axis as the quantization axis and the rf-field as a perturbation along the x-axis.

The energy of a nuclear magnetic dipole moment placed in a magnetic field is [368],

$$\boxed{\hat{H} = -\hat{\vec{\mu}} \cdot \vec{\mathcal{B}} = -\gamma_I \hat{\mathbf{I}} \cdot \vec{\mathcal{B}}} \ , \tag{34.174}$$

where γ_I is the *gyromagnetic ratio* of the specific nucleus and $\hat{\mathbf{I}}$ the nuclear spin satisfying the usual commutation relation $[\hat{I}_m, \hat{I}_n] = \imath\hbar\epsilon_{kmn}\hat{I}_k$. Hence, as shown in Exc. 34.4.6.10, we can derive from the Heisenberg equation,

$$\imath\hbar\frac{d\hat{\vec{\mu}}}{dt} = [\hat{\vec{\mu}}, \hat{H}] \ , \tag{34.175}$$

the Bloch equations,

$$\boxed{\frac{d\hat{\vec{\mu}}}{dt} = \gamma_I \hat{\vec{\mu}} \times \vec{\mathcal{B}}} \ . \tag{34.176}$$

Now, let us restrict to a two-level system, $I = \frac{1}{2}$ such that $\hat{I}_z = \frac{\hbar}{2}\hat{\sigma}_z$. In thermal equilibrium, without time-dependent perturbation,

$$\hat{H}_0 = -\hat{\vec{\mu}} \cdot \vec{\mathcal{B}}_0 = -\hat{\mu}_z \mathcal{B}_0 = -\gamma_I \hat{I}_z \mathcal{B}_0 \equiv -\omega_L \hat{I}_z \ . \tag{34.177}$$

where we introduced the *Larmor frequency* ω_L. We expect energy levels,

$$E = -\hbar \gamma_I m \mathcal{B}_0 \ , \tag{34.178}$$

with $m = \pm\frac{1}{2}$. The energy difference between the two states, $\Delta E = \gamma_I \hbar \mathcal{B}_0$, results in a small population bias favoring the lower energy state in thermal equilibrium and, hence, in a net spin magnetization $\vec{\mathcal{M}} = \frac{1}{V}\sum_i \langle \vec{\mu}_i \rangle$ along the magnetic field $\vec{\mathcal{B}}_0$. For a thermal statistical mixture, as shown in (34.100), we write the density operator [17],

$$\boxed{\hat{\rho} = \frac{e^{-\hat{H}_0/k_B T}}{Z} = \frac{e^{-\frac{1}{2}\beta\hbar\omega_L \hat{\sigma}_z}}{Z} = \sum_{m=\pm 1/2} |I,m\rangle \frac{e^{-\beta\hbar\omega_L m}}{Z} \langle I,m|} \ , \tag{34.179}$$

with the partition function,

$$Z \equiv \mathrm{Tr}\ e^{-\hat{H}_0/k_B T} = \sum_{m=\pm 1/2} e^{-\beta\hbar\omega_L m} \ . \tag{34.180}$$

Now, as shown in (34.128), we can express the time-evolution of the density operator as,

$$\hat{\rho}(t) = e^{-\imath \hat{H}_0 t} \hat{\rho}(0) e^{\imath \hat{H}_0 t} = e^{-\imath\beta\hbar\omega_L \hat{I}_z t} \hat{\rho}(0) e^{\imath\beta\hbar\omega_L \hat{I}_z t} \ . \tag{34.181}$$

Then, as shown in Exc. 34.4.6.11,

$$\langle \hat{\mathbf{I}}(t) \rangle = \begin{pmatrix} \cos\omega_L t & -\sin\omega_L t & 0 \\ \sin\omega_L t & \cos\omega_L t & 0 \\ 0 & 0 & 1 \end{pmatrix} \langle \hat{\mathbf{I}}(0) \rangle \ , \tag{34.182}$$

which corroborates the result (34.176). Apparently, the nuclear magnetic dipole moment (and hence the spin magnetization) precesses around the magnetic field with the Larmor frequency leaving the populations of the energy levels unaffected.

A perturbation of nuclear spin orientations from equilibrium will occur when an oscillating magnetic field is applied whose frequency ω_{rf} sufficiently closely matches the Larmor precession frequency ω_L. The populations of the spin-up and -down energy levels then undergo Rabi oscillations. The stronger the oscillating field, the faster the Rabi oscillations or the precession around the effective field in the rotating

[17] Note that at high temperatures we get, $Z \simeq 1$ and may approximate,

$$\hat{\rho} - 1 \simeq \beta\hbar\omega_L \hat{I}_z \ .$$

frame. After a certain time (typically on the order of 2..1000 μs), a resonant rf-$\pi/2$-pulse flips the spin magnetization to the transverse plane, while after a twice longer time, the initial magnetization is inverted (π-pulse). It is the transverse magnetization generated by a resonant oscillating field which is usually detected in NMR.

The most important perturbation of the NMR frequency for applications of NMR is the 'shielding' effect of the surrounding shells of electrons. Electrons, similar to the nucleus, are also charged and rotate with a spin to produce a magnetic field opposite to the applied magnetic field. In general, this electronic shielding reduces the magnetic field at the nucleus. The corresponding shift in the NMR frequency due to the electronic molecular orbital coupling to the external magnetic field is called chemical shift, and it explains why NMR is able to probe the chemical structure of molecules, which depends on the electron density distribution in the corresponding molecular orbitals.

After perturbation the nuclear spins return to thermodynamic equilibrium due to relaxation processes. These are phenomenological included in the Bloch equations via decay time constants T_i,

$$\frac{d\hat{\vec{\mu}}}{dt} = \gamma_I \hat{\vec{\mu}} \times \vec{\mathcal{B}} - \frac{\hat{\mu}_z}{T_1}\hat{\mathbf{e}}_z - \frac{\hat{\mu}_x}{T_2}\hat{\mathbf{e}}_x \ . \tag{34.183}$$

$T_1 = \Gamma^{-1}$ is the time constant for 'longitudinal magnetic' relaxation and refers to the mean time for an individual nucleus to return to its thermal equilibrium state of the spins. The precessing nuclei can also fall out of alignment with each other and gradually stop producing a signal. This is called T_2 or transverse relaxation, where $T_2 = 2\gamma^{-1}$. Because of the difference in the actual relaxation mechanisms involved (for example, intermolecular versus intramolecular magnetic dipole-dipole interactions), T_1 is usually longer than T_2, which, in practice, also depends on significant static magnetic field inhomogeneities.

34.4.6 Exercises

34.4.6.1 Ex: Derivation of Bloch equations

Derive the Bloch equations explicitly based on the temporal evolutions of the coefficients $a_{1,2}$ (27.63) knowing that $\rho_{ij} = a_i^* a_j$.

Solution: *We differentiate the density operator,*

$$\frac{d\rho_{mn}}{dt} = a_m \frac{da_n^*}{dt} + \frac{da_m}{dt} a_n^* \ .$$

Substituting the derivatives of the population amplitudes by (27.63) and the transition elements by (27.77),

$$\frac{da_1}{dt} = -\imath\Omega \cos\omega t e^{-\imath\omega_0 t} a_2 \qquad \textit{and} \qquad \frac{da_2}{dt} = -\imath\Omega^* \cos\omega t e^{\imath\omega_0 t} a_1$$

for the time derivatives of (34.150) and letting $\Omega = \Omega^*$,

$$\begin{aligned}\frac{d\rho_{22}}{dt} &= \imath\Omega \cos\omega t e^{-\imath\omega_0 t} a_2 a_1^* - \imath\Omega^* \cos\omega t e^{\imath\omega_0 t} a_1 a_2^* = \imath\Omega_0 \frac{e^{\imath\omega t} + e^{-\imath\omega t}}{2} \left(a_2 a_1^* e^{-\imath\omega_0 t} - a_1 a_2^* e^{\imath\omega_0 t}\right) \\ &\simeq \frac{\imath\Omega}{2}\left(a_2 a_1^* e^{\imath\Delta t} - a_1 a_2^* e^{-\imath\Delta t}\right) = \frac{\imath\Omega}{2}\left(\rho_{21} e^{\imath\Delta t} - \rho_{12} e^{-\imath\Delta t}\right) = -\frac{d\rho_{11}}{dt} \ .\end{aligned}$$

and

$$\frac{d\rho_{12}}{dt} = \imath\Omega\cos\omega t e^{-\imath\omega_0 t}a_1 a_1^* - \imath\Omega\cos\omega t e^{-\imath\omega_0 t}a_2 a_2^* = \imath\Omega\frac{e^{\imath\omega t}+e^{-i\omega t}}{2}e^{-\imath\omega_0 t}(|a_1|^2-|a_2|^2)$$
$$\simeq \frac{\imath\Omega}{2}|a_1|^2 e^{\imath\Delta t} = \frac{\imath\Omega}{2}(\rho_{11}-\rho_{22})e^{\imath\Delta t} = \frac{d\rho_{21}^*}{dt}\ .$$

In this form the Bloch equations are in the interaction representation.

34.4.6.2 Ex: General solution of Bloch equations

Derive the solution (34.154) of the Bloch equations (34.151).

Solution: *We consider the ansatz,*

$$\rho_{22}(0) = \rho_{22}^{(1)} + \rho_{22}^{(2)}e^{\imath Gt} + \rho_{22}^{(3)}e^{-\imath Gt}$$
$$\rho_{12}(0) = \rho_{12}^{(1)} + \rho_{12}^{(2)}e^{\imath Gt} + \rho_{12}^{(3)}e^{-\imath Gt}$$
$$\rho_{21}(0) = \rho_{21}^{(1)} + \rho_{21}^{(2)}e^{\imath Gt} + \rho_{21}^{(3)}e^{-\imath Gt}\ .$$

Normalization and hermiticity require,

$$\rho_{11}^{(1)} + \rho_{11}^{(2)}e^{\imath Gt} + \rho_{11}^{(3)}e^{-\imath Gt} + \rho_{22}^{(1)} + \rho_{22}^{(2)}e^{\imath Gt} + \rho_{22}^{(3)}e^{-\imath Gt} = 1$$
$$\text{and} \qquad \rho_{21}^{(1)*} + \rho_{21}^{(2)*}e^{-\imath Gt} + \rho_{21}^{(3)*}e^{\imath Gt} = \rho_{12}^{(1)} + \rho_{12}^{(2)}e^{\imath Gt} + \rho_{12}^{(3)}e^{-\imath Gt}\ ,$$

such that,

$$\rho_{11}^{(1)} + \rho_{22}^{(1)} = 1 \quad , \quad \rho_{11}^{(2)} = -\rho_{22}^{(2)} \quad , \quad \rho_{11}^{(3)} = -\rho_{22}^{(3)}$$
$$\rho_{21}^{(1)*} = \rho_{12}^{(1)} \quad , \quad \rho_{21}^{(3)*} = \rho_{12}^{(2)} \quad , \quad \rho_{21}^{(2)*} = \rho_{12}^{(3)}\ .$$

Inserting the ansatz into the Bloch equations, we obtain

$$\begin{pmatrix} G\rho_{11}^{(2)}e^{\imath Gt} - G\rho_{11}^{(3)}e^{-\imath Gt} \\ G\rho_{22}^{(2)}e^{\imath Gt} - G\rho_{22}^{(3)}e^{-\imath Gt} \\ G\rho_{12}^{(2)}e^{\imath Gt} - G\rho_{12}^{(3)}e^{-\imath Gt} \\ G\rho_{21}^{(2)}e^{\imath Gt} - G\rho_{21}^{(3)}e^{-\imath Gt} \end{pmatrix}$$
$$= \begin{pmatrix} \frac{\Omega}{2}\left(\rho_{12}^{(1)} + \rho_{12}^{(2)}e^{\imath Gt} + \rho_{12}^{(3)}e^{-\imath Gt}\right) - \frac{\Omega}{2}\left(\rho_{21}^{(1)} + \rho_{21}^{(2)}e^{\imath Gt} + \rho_{21}^{(3)}e^{-\imath Gt}\right) \\ -\frac{\Omega}{2}\left(\rho_{12}^{(1)} + \rho_{12}^{(2)}e^{\imath Gt} + \rho_{12}^{(3)}e^{-\imath Gt}\right) + \frac{\Omega}{2}\left(\rho_{21}^{(1)} + \rho_{21}^{(2)}e^{\imath Gt} + \rho_{21}^{(3)}e^{-\imath Gt}\right) \\ \frac{\Omega}{2}\left(\rho_{11}^{(1)} + \rho_{11}^{(2)}e^{\imath Gt} + \rho_{11}^{(3)}e^{-\imath Gt}\right) - \frac{\Omega}{2}\left(\rho_{22}^{(1)} + \rho_{22}^{(2)}e^{\imath Gt} + \rho_{22}^{(3)}e^{-\imath Gt}\right) - \Delta\left(\rho_{12}' + \rho_{12}^{(2)}e^{\imath Gt} + \rho_{12}^{(3)}e^{-\imath Gt}\right) \\ -\frac{\Omega}{2}\left(\rho_{11}^{(1)} + \rho_{11}^{(2)}e^{\imath Gt} + \rho_{11}^{(3)}e^{-\imath Gt}\right) + \frac{\Omega}{2}\left(\rho_{22}^{(1)} + \rho_{22}^{(2)}e^{\imath Gt} + \rho_{22}^{(3)}e^{-\imath Gt}\right) + \Delta\left(\rho_{21}' + \rho_{21}^{(2)}e^{\imath Gt} + \rho_{21}^{(3)}e^{-\imath Gt}\right) \end{pmatrix}.$$

Since these equations must be valid for all times, we can separate the exponential functions,

	~ 1	$\sim e^{\imath Gt}$	$\sim e^{-\imath Gt}$
$\sim \rho_{11}$	$0 = \frac{\Omega}{2}\rho_{12}^{(1)} - \frac{\Omega}{2}\rho_{21}^{(1)}$	$G\rho_{11}^{(2)} = \frac{\Omega}{2}\rho_{12}^{(2)} - \frac{\Omega}{2}\rho_{21}^{(2)}$	$-\rho_{11}^{(3)}G = \frac{\Omega}{2}\rho_{12}^{(3)} - \frac{\Omega}{2}\rho_{21}^{(3)}$
$\sim \rho_{22}$	$0 = -\frac{\Omega}{2}\rho_{12}^{(1)} + \frac{\Omega}{2}\rho_{21}^{(1)}$	$G\rho_{22}^{(2)} = -\frac{\Omega}{2}\rho_{12}^{(2)} + \frac{\Omega}{2}\rho_{21}^{(2)}$	$-\rho_{22}^{(3)}G = -\frac{\Omega}{2}\rho_{12}^{(3)} + \frac{\Omega}{2}\rho_{21}^{(3)}$
$\sim \rho_{12}$	$0 = \frac{\Omega}{2}\rho_{11}^{(1)} - \frac{\Omega}{2}\rho_{22}^{(1)} - \Delta\rho_{12}^{(1)}$	$G\rho_{12}^{(2)} = \frac{\Omega}{2}\rho_{11}^{(2)} - \frac{\Omega}{2}\rho_{22}^{(2)} - \Delta\rho_{12}^{(2)}$	$-\rho_{12}^{(3)}G = \frac{\Omega}{2}\rho_{11}^{(3)} - \frac{\Omega}{2}\rho_{22}^{(3)} - \Delta\rho_{12}^{(3)}$
$\sim \rho_{21}$	$0 = -\frac{\Omega}{2}\rho_{11}^{(1)} + \frac{\Omega}{2}\rho_{22}^{(1)} + \Delta\rho_{21}^{(1)}$	$G\rho_{21}^{(2)} = -\frac{\Omega}{2}\rho_{11}^{(2)} + \frac{\Omega}{2}\rho_{22}^{(2)} + \Delta\rho_{21}^{(2)}$	$-\rho_{21}^{(3)}G = -\frac{\Omega}{2}\rho_{11}^{(3)} + \frac{\Omega}{2}\rho_{22}^{(3)} + \Delta\rho_{21}^{(3)}$

Consequently

$$\rho_{21}^{(1)} = \rho_{12}^{(1)} \quad , \quad \rho_{21}^{(2)} = \frac{-\Omega}{2(G-\Delta)}(1-2\rho_{22}^{(2)}) \quad , \quad \rho_{21}^{(3)} = \frac{\Omega}{2(G+\Delta)}(1-2\rho_{22}^{(3)})$$
$$\rho_{12}^{(1)} = \frac{\Omega}{2\Delta}(1-2\rho_{22}^{(1)}) \quad , \quad \rho_{12}^{(2)} = \frac{\Omega}{2(G+\Delta)}\left(1-2\rho_{22}^{(2)}\right) \quad , \quad \rho_{12}^{(3)} = \frac{-\Omega}{2(G-\Delta)}(1-2\rho_{22}^{(3)})\ .$$

With this, the starting conditions can be written,

$$\begin{pmatrix}\rho_{22}(0)\\ \rho_{12}(0)\\ \rho_{12}^*(0)\end{pmatrix} = \begin{pmatrix}\rho_{22}^{(1)}+\rho_{22}^{(2)}+\rho_{22}^{(3)}\\ \rho_{12}^{(1)}+\rho_{12}^{(2)}+\rho_{12}^{(3)}\\ \rho_{21}^{(1)}+\rho_{21}^{(2)}+\rho_{21}^{(3)}\end{pmatrix} = \begin{pmatrix}\rho_{22}^{(1)}+\rho_{22}^{(2)}+\rho_{22}^{(3)}\\ \frac{\Omega^2-2\Delta^2}{2\Delta\Omega}-\frac{\Omega}{\Delta}\rho_{22}^{(1)}-\frac{\Omega}{G+\Delta}\rho_{22}^{(2)}+\frac{\Omega}{G-\Delta}\rho_{22}^{(3)}\\ \frac{\Omega^2-2\Delta^2}{2\Delta\Omega}-\frac{\Omega}{\Delta}\rho_{22}^{(1)}+\frac{\Omega}{G-\Delta}\rho_{22}^{(2)}-\frac{\Omega}{G+\Delta}\rho_{22}^{(3)}\end{pmatrix} .$$

Now, all we have to do is to solve this system of equations to find the coefficients $\rho_{22}^{(1)}$, $\rho_{22}^{(2)}$, and $\rho_{22}^{(3)}$ in terms of the initial conditions. We calculate,

$$\begin{pmatrix}1-2\rho_{22}(0)\\ \rho_{12}(0)+\rho_{12}^*(0)\end{pmatrix} = \begin{pmatrix}1-2\left(\rho_{22}^{(1)}+\rho_{22}^{(2)}+\rho_{22}^{(3)}\right)\\ \frac{\Omega^2-2\Delta^2}{\Delta\Omega}-\frac{2\Omega}{\Delta}\rho_{22}^{(1)}+\frac{2\Delta}{\Omega}\rho_{22}^{(2)}+\frac{2\Delta}{\Omega}\rho_{22}^{(3)}\end{pmatrix} .$$

and then,

$$\rho_{22}(0)+\frac{1}{2G^2}\left[\Omega^2(1-2\rho_{22}(0))-\Delta\Omega\left(\rho_{12}(0)+\rho_{12}^*(0)\right)\right] = \frac{\Delta^2}{G^2}+\rho_{22}^{(1)} .$$

This confirms the first equation (34.154) [18]*. In the same way we can check $\rho_{22}^{(2)}$ and $\rho_{22}^{(3)}$ and then $\rho_{12}^{(1)}$, $\rho_{12}^{(2)}$, and $\rho_{12}^{(3)}$.*

34.4.6.3 Ex: Expansion in Pauli matrices

Show explicitly Tr $\hat{\rho}\hat{\sigma}^-\hat{\sigma}^+ = \rho_{11}$.

Solution: *We have,*

$$\begin{aligned}\langle\hat{\sigma}^-\hat{\sigma}^+\rangle = Tr\ \hat{\rho}\hat{\sigma}^-\hat{\sigma}^+ &= \sum_k\langle k|\begin{pmatrix}\rho_{11}&\rho_{12}\\ \rho_{11}&\rho_{12}\end{pmatrix}\begin{pmatrix}1&0\\0&0\end{pmatrix}|k\rangle\\ &= \sum_k\langle k|\left(\rho_{11}|1\rangle\langle 1|+\rho_{12}|1\rangle\langle 2|\right)|k\rangle = \rho_{11} .\end{aligned}$$

34.4.6.4 Ex: Bloch vector and Bloch equations

Show that Eq. (34.168) is equivalent to the Bloch equations (34.151).

Solution: *The explicit equations of motion for the components of the Bloch vector are,*

$$\begin{aligned}\frac{d}{dt}\langle\hat{\vec{\sigma}}\rangle = \vec{G}\times\langle\hat{\vec{\sigma}}\rangle &= \begin{pmatrix}\mathfrak{Re}\ \Omega\\ \mathfrak{Im}\ \Omega\\ \Delta\end{pmatrix}\times\begin{pmatrix}2\mathfrak{Re}\ \rho_{12}\\ 2\mathfrak{Im}\ \rho_{12}\\ \rho_{11}-\rho_{22}\end{pmatrix} = \begin{pmatrix}\frac{1}{2}(\Omega+\Omega^*)\\ \frac{1}{2\imath}(\Omega-\Omega^*)\\ \Delta\end{pmatrix}\times\begin{pmatrix}\rho_{12}+\rho_{21}\\ -\imath(\rho_{12}-\rho_{21})\\ \rho_{11}-\rho_{22}\end{pmatrix}\\ &= \begin{pmatrix}-\frac{\imath}{2}(\Omega-\Omega^*)(\rho_{11}-\rho_{22})+\imath\Delta(\rho_{12}-\rho_{21})\\ -\frac{1}{2}(\Omega+\Omega^*)(\rho_{11}-\rho_{22})+\Delta(\rho_{12}+\rho_{21})\\ -\frac{\imath}{2}\Omega^*\rho_{12}+\frac{\imath}{2}\Omega\rho_{21}\end{pmatrix} .\end{aligned}$$

[18] exception for a constant $\frac{\Delta^2}{G^2}$, I don't know where it comes from!

Hence,

$$\frac{d}{dt}\begin{pmatrix}\rho_{12}+\rho_{21}\\ \rho_{12}-\rho_{21}\\ \rho_{11}-\rho_{22}\end{pmatrix}=\begin{pmatrix}-\frac{\imath}{2}(\Omega-\Omega^*)(\rho_{11}-\rho_{22})+\imath\Delta(\rho_{12}-\rho_{21})\\ -\frac{\imath}{2}(\Omega+\Omega^*)(\rho_{11}-\rho_{22})+\imath\Delta(\rho_{12}+\rho_{21})\\ -\imath\Omega^*\rho_{12}+\imath\Omega\rho_{21}\end{pmatrix}\ ,$$

or,

$$\frac{d}{dt}\begin{pmatrix}\rho_{11}\\ \rho_{22}\\ \rho_{12}\\ \rho_{21}\end{pmatrix}=\begin{pmatrix}0 & 0 & -\frac{\imath}{2}\Omega^* & \frac{\imath}{2}\Omega\\ 0 & 0 & \frac{\imath}{2}\Omega^* & -\frac{\imath}{2}\Omega\\ -\frac{\imath}{2}\Omega & \frac{\imath}{2}\Omega & \imath\Delta & 0\\ \frac{\imath}{2}\Omega^* & -\frac{\imath}{2}\Omega^* & 0 & -\imath\Delta\end{pmatrix}\begin{pmatrix}\rho_{11}\\ \rho_{22}\\ \rho_{12}\\ \rho_{21}\end{pmatrix}\ .$$

34.4.6.5 Ex: Normalization of the Bloch vector

Verify $\|\vec{\rho}\|=1$.

Solution: *The Bloch vector is,*

$$\vec{\beta}=\begin{pmatrix}2\mathfrak{Re}\ \rho_{12} & 2\mathfrak{Im}\ \rho_{12} & \rho_{22}-\rho_{11}\end{pmatrix}=\begin{pmatrix}\rho_{12}+\rho_{21} & -\imath(\rho_{12}-\rho_{21}) & \rho_{22}-\rho_{11}\end{pmatrix}\ .$$

The length of the vector is,

$$\sqrt{\vec{\beta}^t\vec{\beta}}=\sqrt{4\rho_{12}\rho_{21}+\rho_{22}^2-2\rho_{22}\rho_{11}+\rho_{11}^2}=\sqrt{\rho_{22}^2+2\rho_{22}\rho_{11}+\rho_{11}^2}=1\ ,$$

using $\det\rho=\rho_{22}\rho_{11}-\rho_{12}\rho_{21}=0$ *and Tr* $\rho=\rho_{11}+\rho_{22}=1$.

34.4.6.6 Ex: Sequence of Ramsey pulses

Many atomic clocks work according to the Ramsey spectroscopy method: The two-level atom is resonantly excited by a microwave $\pi/2$-pulse. Then, the phase of atomic coherence precesses freely over a period of time T accumulating an angle ϕ. Finally, a second $\pi/2$-pulse is applied and the population of the upper-level is measured. Calculate this population as a function of the angle ϕ. Neglect spontaneous emission.

Solution: *To describe the dynamics of a two-level atom during a Ramsey cycle let us consider the general solutions (34.154) for two specific cases. For* $\Omega=0$, *we get*

$$\rho_{22}^{(1)}=\rho_{22}(0)\qquad\text{and}\qquad\rho_{12}^{(3)}=\rho_{12}(0)\qquad\text{and}\qquad\rho_{22}^{(2)}=0=\rho_{22}^{(3)}=\rho_{12}^{(1)}=\rho_{12}^{(2)}\ .$$

Hence,

$$\begin{aligned}\rho_{22}(t)&=\rho_{22}^{(1)}+\rho_{22}^{(2)}e^{\imath Gt}+\rho_{22}^{(3)}e^{-\imath Gt}=\rho_{22}(0)\\ \rho_{12}(t)&=\rho_{12}^{(1)}+\rho_{12}^{(2)}e^{\imath Gt}+\rho_{12}^{(3)}e^{-\imath Gt}=\rho_{12}(0)e^{-\imath\Delta t}\ .\end{aligned}$$

For $\Delta = 0$, we get

$$\begin{aligned}
\rho_{22}^{(1)} &= \tfrac{1}{2} \\
\rho_{22}^{(2)} &= \tfrac{1}{4}\left[-(1-2\rho_{22}(0)) + \rho_{12}^{*}(0) - \rho_{12}(0)\right] \\
\rho_{22}^{(3)} &= \tfrac{1}{4}\left[-(1-2\rho_{22}(0)) - \rho_{12}^{*}(0) + \rho_{12}(0)\right] \\
\rho_{12}^{(1)} &= \tfrac{1}{2}\left[\rho_{12}^{*}(0) + \rho_{12}(0)\right] \\
\rho_{12}^{(2)} &= \tfrac{1}{4}\left[(1-2\rho_{22}(0)) - \rho_{12}^{*}(0) + \rho_{12}(0)\right] \\
\rho_{12}^{(3)} &= \tfrac{1}{4}\left[-(1-2\rho_{22}(0)) - \rho_{12}^{*}(0) + \rho_{12}(0)\right] \ .
\end{aligned}$$

Hence,

$$\begin{aligned}
\rho_{22}(t) &= \rho_{22}^{(1)} + \rho_{22}^{(2)} e^{\imath\Omega t} + \rho_{22}^{(3)} e^{-\imath\Omega t} = \tfrac{1}{2} - \tfrac{1}{2}\left[1-2\rho_{22}(0)\right]\cos\Omega t + \mathfrak{Im}\ \rho_{12}(0)\sin\Omega t \\
\rho_{12}(t) &= \rho_{12}^{(1)} + \rho_{12}^{(2)} e^{\imath\Omega t} + \rho_{12}^{(3)} e^{-\imath\Omega t} = \mathfrak{Re}\ \rho_{12}(0) + \tfrac{\imath}{2}\left[1-2\rho_{22}(0)\right]\sin\Omega t + \imath\mathfrak{Im}\ \rho_{12}(0)\cos\Omega t \ .
\end{aligned}$$

At the beginning the atom is in $\rho_{22}(0) = 0 = \rho_{12}(0)$. For this case, the equations simplify to,

$$\rho_{22}(t) = \tfrac{1}{2} - \tfrac{1}{2}\cos\Omega t \qquad \textit{and} \qquad \rho_{12}(t) = \tfrac{\imath}{2}\sin\Omega t \ .$$

The application of the first $\pi/2$-pulse raises the population of the state to $\rho_{11}(0) = \rho_{22}(0) = \frac{1}{2}$ and the coherence is $\rho_{12}(0) = \frac{\imath}{2}$. We now imagine that the laser source is a little detuned, so little that the population of the coupled state is not affected. But if $\Delta \neq 0$, looking at solutions for $\Omega = 0$, we find that the Bloch vector begins to precess. After a time T, it rotated by a certain angle $\phi \equiv T\Delta$. After this time, we turn on the laser a second time and apply a second $\pi/2$-pulse. We look now at the solutions for $\Delta = 0$, using the new starting conditions, $\rho_{22}(0) = \frac{1}{2}$ and $\rho_{12}(0) = \frac{\imath}{2}e^{-\imath\phi}$,

$$\begin{aligned}
\rho_{22}(t) &= \tfrac{1}{2} + \mathfrak{Im}\ \tfrac{\imath e^{-\imath\phi}}{2}\sin\Omega t = \tfrac{1}{2} + \tfrac{1}{2}\cos\phi \\
\rho_{12}(t) &= \mathfrak{Re}\ \tfrac{\imath e^{-\imath\phi}}{2} + \imath\mathfrak{Im}\ \tfrac{\imath e^{-\imath\phi}}{2}\cos\Omega t = \tfrac{1}{2}\sin\phi \ .
\end{aligned}$$

That is, we find a phase-dependent oscillation of the excited state population between 0 and 1. Thus, this population, which can be measured experimentally, provides information about the laser detuning.

34.4.6.7 Ex: Analytical treatment of the Ramsey experiment

Derive the analytic formula for the final population ρ_{22} for the Rabi and Ramsey experiments. Derive and compare the line widths of the 'interference fringes' in these two experiments.

Solution: *We consider a two-level system without decay. Its optical Bloch equations are,*

$$\dot{\rho}_{22} = -\dot{\rho}_{11} = \imath\tfrac{\Omega}{2}e^{\imath\Delta t}\rho_{21} + c.c. \qquad , \qquad \dot{\rho}_{12} = -\dot{\rho}_{21}^{*} = \imath\tfrac{\Omega}{2}e^{\imath\Delta t}(\rho_{11} - \rho_{22}) \ ,$$

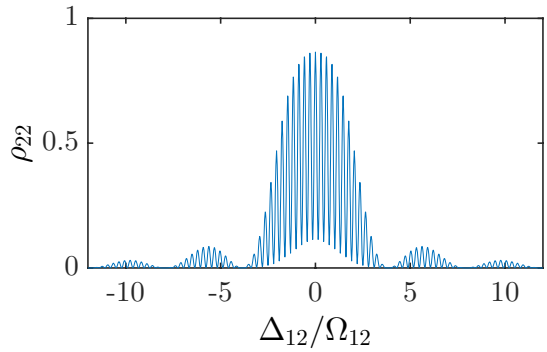

Figure 34.3: (code) Ramsey fringes.

and have the solution, when $\rho_{22}(0) = 0 = \rho_{12}(0)$,

$$\rho_{22} = \frac{|\Omega|^2}{G^2} \sin^2 \frac{Gt}{2} \quad , \quad \rho_{12} = \frac{\Omega}{G^2} \sin \frac{Gt}{2} \left(\Delta \sin \frac{Gt}{2} + \imath G \cos \frac{Gt}{2} \right) .$$

The population therefore oscillates with the generalized Rabi frequency, while the coherence precess with the detuning Δ. *The coherence determines the phase between the atomic dipole and the electromagnetic field. The vector* $(\rho_{12}, \rho_{21}, \rho_{22} - \rho_{11})$ *moves on a Bloch sphere with the radius 1.*
Shutting off the electromagnetic field suddenly at time $t = T$, *the solution of the Bloch equation for* $\Omega = 0$ *must be connected continuously:*

$$\dot{\rho}_{22} = 0 \quad \textit{and} \quad \dot{\rho}_{12} = -\imath \Delta \rho_{12} .$$

This means that the Bloch vector begins to precess without perturbation:

$$\rho_{22} = \frac{|\Omega|^2}{G^2} \sin^2 \frac{GT}{2} \quad , \quad \rho_{12} = \frac{\Omega}{G^2} \sin \frac{GT}{2} \left(\Delta \sin \frac{GT}{2} + \imath G \cos \frac{GT}{2} \right) e^{-\imath \Delta \tau} .$$

After a time τ, *when the phase accumulated an advancement by a factor of* $e^{-\imath \Delta \tau}$ *about the atomic dipole moment, we switch on the electromagnetic field again. Hence, we must solve the Bloch equation with the new boundary condition:*

$$\begin{aligned} \rho_{22} = \frac{\Omega^2}{2G^4} \{ & \left[\Delta^2 (1 - \cos GT)(1 - \cos \Delta\tau) + G^2 - \Delta G \sin GT \sin \Delta\tau \right] \\ & + \frac{e^{\pm \imath G t}}{2} \left[-\Delta^2 (1 - \cos GT) + \cos \Delta\tau \left\{ \Delta^2 (1 - \cos GT) \mp \imath G^2 \sin GT \right\} \right. \\ & \left. + \sin \Delta\tau \left\{ \Delta G \sin GT \pm \imath G \Delta (1 - \cos GT) \right\} \right] \} . \end{aligned}$$

If the second pulse also has the duration T, *the final excited state population is,*

$$\begin{aligned} \rho_{22} = \frac{\Omega^2}{2G^4} \{ & (G^2 + \Delta^2)(1 - \cos GT) + \cos \Delta\tau \left[G^2 \sin^2 GT - \Delta^2 (1 - \cos GT)^2 \right] \\ & + \sin \Delta\tau \left[-2\Delta G \sin GT (1 - \cos GT) \right] \} . \end{aligned}$$

The period of the Ramsey oscillations depends on the detuning Δ, the Rabi frequency Ω, the duration of the interaction T, and the time τ between the interaction periods. The following particular cases are interesting. For $\Omega \ll \Delta$:

$$\rho_{22} = \frac{4\Omega^2}{\Delta^2} \cos\frac{\Delta(\tau+T)}{2} \sin^2\frac{\Delta T}{2} \ .$$

For $\Omega \ll \Delta$:

$$\rho_{22} = \sin^2\frac{\Omega T}{2} + \cos\Delta\tau \sin^2\Omega T \ .$$

The approximation $\Omega \ll \Delta$ is analogous to a temporal double-slit experiment. The interference patterns are described by the approximate population ρ_{22}. This approximation corresponds to a perturbative derivation of the Born approximation.
To estimate the linewidth of the Rabi fringes, we choose the microwave pulses being π-pulses, that is, $\Omega T = \pi$. Then,

$$\rho_{22} = \frac{1}{1+\Delta^2/\Omega^2} \sin^2\frac{\pi}{2}\sqrt{1+\Delta^2/\Omega^2} \ .$$

The linewidth is dominated by Fourier broadening, respectively, power broadening:

$$\sqrt{2}\sin(\pi/2)x_h = x_h \qquad with \qquad x_h = \sqrt{1+\Delta_h^2/\Omega^2} \ .$$

Hence, $x_h = 1.28$, that is, $\Delta_h = 0.8\Omega = 2.5/T$.
To estimate the linewidth of the Ramsey patterns, we choose the microwave pulses to be $\pi/2$-pulses, that is, $\Omega T = \pi/2$. Then, in the approximation $\Omega \gg \Delta$,

$$\rho_{22} = \frac{1}{2} + \cos\Delta\tau \ .$$

The linewidth is neither broadened by the Fourier effect nor by power broadening:

$$\Delta_h = \frac{1}{\tau}\arccos\frac{1}{4} \ .$$

Numerical calculations show that natural decay limits the linewidth and decreases the contrast. A complete analysis (without decay) shows that the width is given by,

$$\Delta_h = \frac{1}{2\tau + 8T/\pi} \ .$$

That is, the width is dominated by the longest of the two times, τ and T.

34.4.6.8 Ex: Atomic clocks by the Ramsey method with spontaneous emission

In this exercise we study the Ramsey method used in atomic clocks. For this, we will consider a two-level system $|1\rangle$ and $|2\rangle$ excited by a microwave radiation field characterized by the Rabi frequency Ω_{12}, and we will compare two cases: without and with spontaneous emission:

a. Write down the Hamiltonian of the system, propose a sequence of pulses allowing the observation of the Ramsey fringes, do a numerical simulation of the Schrödinger equation (based on the prescription (34.287)), and prepare a graph of the type Fig. 34.2 illustrating the temporal evolution of the Bloch vector during the sequence.
b. Calculate numerically from the Schrödinger equation the population ρ_{22} immediately after the pulse sequence as a function of the detuning Δ_{12} of the radiation field, and prepare a graph of the spectrum. Also, assuming a decay rate of $\Gamma_{12} = 0.1\Omega_{12}$, calculate the population ρ_{22} as a function of detuning Δ_{12} from the Bloch equations (making sequences of type (34.287)), prepare a new graph, and compare it with the previous graph obtained by the Schrödinger equation.
c. What happens to the width of the fringes, when the free precession time τ between the Ramsey pulses is increased? Prepare a graph of the inversion $2\rho_{22} - 1$ as a function of Δ_{12} and τ and interprete the results.

Solution: *a. Choosing $\Omega_{12} = 1$ the duration of the $\pi/2$-pulse must be $T = \pi/2\Omega_{12}$. The Hamiltonian and the solution of the Schrödinger equation can be found in the numerical MATLAB code given in the file 'LM_Bloch_RamseySpontaneous.m'. Fig. 34.4(a) shows, that the final inversion $2\rho_{22}(2T + \tau) - 1$ depends on the detuning Δ_{12} and the free precession time τ between the pulses.*
b. The spectrum $\rho_{22,\infty}(\Delta_{12})$ can be obtained by simulation of the Schrödinger equation, but the inclusion of dissipation effects requires the use of Bloch equations. The code 'LM_Bloch_RamseySpontaneous.m' shows the simulations. We notice in Fig. 34.4(b), that the spontaneous emission reduces the contrast of the fringes.
c. A Fig. 34.4(c) shows the results of the simulations. We find that the width of the fringes decreases considerably, when we increase the time of free precession.

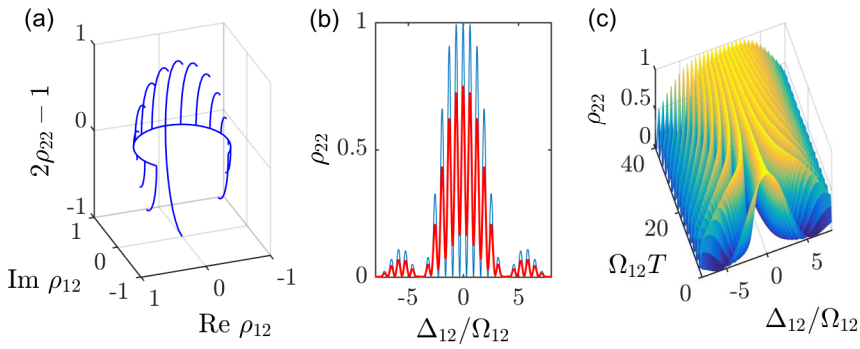

Figure 34.4: (code) (a) Time evolution of the Bloch vector for different detunings. (b) Spectra of the population ρ_{22} calculated by the Schrödinger (blue) and by the Bloch equations (red). (c) Ramsey fringes in the population ρ_{22} varying the time interval between the Ramsey pulses.

34.4.6.9 Ex: Photon echo

'Photon echo' is a powerful spectroscopic technique that allows circumvention of certain dephasing processes, for example, the Doppler shift due to the atomic motion in a thermal sample of atoms. The technique resembles the Ramsey method with the difference, that between the two Ramsey $\pi/2$-pulses, that is, during the free precession time, we apply an additional π-pulse, which inverts the imaginary part of the coherence. We will study this method by numerical simulation of the Schrödinger equation and the Bloch equations for a two-level system with and without spontaneous emission:
a. Write down the Hamiltonian of the system and do a numerical simulation of the Schrödinger equation (concatenating the pulses as explained in Eq. (34.287)) for the following temporal pulse sequence:
(i) resonant $\pi/2$-pulse ($\Delta_{12} = 0$) choosing $\Omega_{12} = 2$,
(ii) evolution for a time T without radiation ($\Omega_{12} = 0$),
(ii) resonant π-pulse using the same parameters as in (i),
(iv) evolution for a time T without radiation, and
(v) resonant $\pi/2$-pulse identical to the first pulse.
Prepare a graph of type Fig. 34.2 illustrating the temporal evolution of the Bloch vector during the sequence. Now, repeat the sequence taking into account a possible Doppler shift leading to $\Delta_{12} \neq 0$.
b. Repeat the calculation of (a), now numerically solving the Bloch equations, which allow the occurrence of spontaneous emission ($\Gamma_{12} = 0.03\Omega_{12}$). Interpret the results.

Solution: *a. Choosing $\Omega_{12} = 1$ the duration of the $\pi/2$-pulse must be $T = \pi/2\Omega_{12}$. The Hamiltonian and the solution of the Schrödinger equation can be found in the numerical MATLAB code given in the file 'LM_Bloch_PhotonEcho.m'. Fig. 34.5(a) shows, that the final inversion $2\rho_{22}(2T+\tau)-1$ depends on the detuning Δ_{12}, and the free precession time τ between the pulses*
b. The code 'LM_Bloch_PhotonEcho.m' shows the simulations.

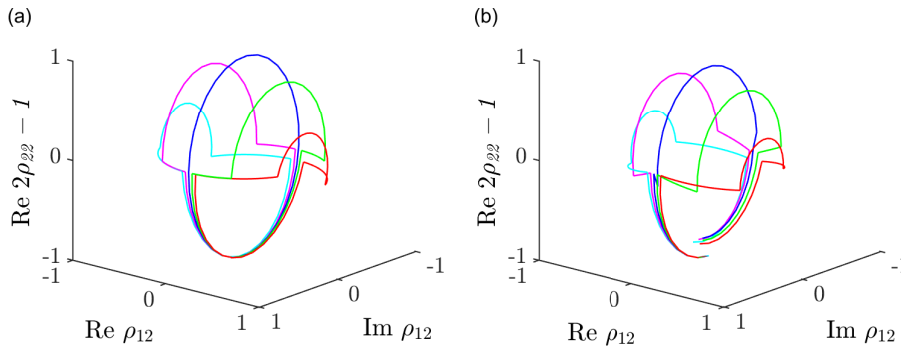

Figure 34.5: (code) (a) Time evolution of the Bloch vector for different detunings Δ_{12} calculated from the Schrödinger equation. (b) Same evolution now calculated from the Bloch equations with $\Gamma_{12} = 0.1\Omega_{12}$ the spontaneous emission rate.

Alternatively we can try an analytical approach: *We use the general solutions*

of the Bloch equations:

$$\begin{aligned}
\rho_{22}^{(1)} &= \rho_{22}(0) + \tfrac{1}{2G^2}\left[|\Omega|^2\left(1-2\rho_{22}(0)\right) - \Delta\left(\Omega\rho_{12}^*(0) + \Omega^*\rho_{12}(0)\right)\right] \\
\rho_{22}^{(2)} &= \tfrac{1}{4G^2}\left[-|\Omega|^2(1-2\rho_{22}(0)) + (\Delta+G)\Omega\rho_{12}^*(0) + (\Delta-G)\Omega^*\rho_{12}(0)\right] \\
\rho_{22}^{(3)} &= \tfrac{1}{4G^2}\left[-|\Omega|^2(1-2\rho_{22}(0)) + (\Delta-G)\Omega\rho_{12}^*(0) + (\Delta+G)\Omega^*\rho_{12}(0)\right] \\
\rho_{12}^{(1)} &= \tfrac{1}{2G^2}\left[\Delta\Omega(1-2\rho_{22}(0)) + \Omega\left(\Omega\rho_{12}^*(0) + \Omega^*\rho_{12}(0)\right)\right] \\
\rho_{12}^{(2)} &= \tfrac{\Delta-G}{4G^2}\left[-\Omega(1-2\rho_{22}(0)) + (\Delta+G)\frac{\Omega}{\Omega^*}\rho_{12}^*(0) + (\Delta-G)\rho_{12}(0)\right] \\
\rho_{12}^{(3)} &= \tfrac{\Delta+G}{4G^2}\left[-\Omega(1-2\rho_{22}(0)) + (\Delta-G)\frac{\Omega}{\Omega^*}\rho_{12}^*(0) + (\Delta+G)\rho_{12}(0)\right] \ ,
\end{aligned}$$

and consider the special cases $\Delta = 0$,

$$\begin{array}{lll}
\rho_{22}^{(1)} = \frac{1}{2} & \rho_{22}^{(2)} = -\frac{1}{4} + \frac{1}{2}\rho_{22}(0) + \frac{\imath}{2}\mathfrak{Im}\ \rho_{12}(0) & \rho_{22}^{(3)} = -\frac{1}{4} + \frac{1}{2}\rho_{22}(0) - \frac{\imath}{2}\mathfrak{Im}\ \rho_{12}(0) \\
\rho_{12}^{(1)} = \mathfrak{Re}\ \rho_{12}(0) & \rho_{12}^{(2)} = \frac{1}{4} - \frac{1}{2}\rho_{22}(0) + \frac{\imath}{2}\mathfrak{Im}\ \rho_{12}(0) & \rho_{12}^{(3)} = -\frac{1}{4} + \frac{1}{2}\rho_{22}(0) - \frac{\imath}{2}\mathfrak{Im}\ \rho_{12}(0)
\end{array}$$

with the solution

$$\begin{aligned}
\rho_{22}(t) &= \rho_{22}^{(1)} + \rho_{22}^{(2)}e^{\imath\Omega t} + \rho_{22}^{(3)}e^{-\imath\Omega t} \\
&= \tfrac{1}{2} + \left[-\tfrac{1}{4} + \tfrac{1}{2}\rho_{22}(0) - \tfrac{\imath}{2}\mathfrak{Im}\ \rho_{12}(0)\right]e^{\imath\Omega t} + \left[-\tfrac{1}{4} + \tfrac{1}{2}\rho_{22}(0) + \tfrac{\imath}{2}\mathfrak{Im}\ \rho_{12}(0)\right]e^{-\imath\Omega t} \\
\rho_{12}(t) &= \rho_{12}^{(1)} + \rho_{12}^{(2)}e^{\imath\Omega t} + \rho_{12}^{(3)}e^{-\imath\Omega t} \\
&= \mathfrak{Re}\ \rho_{12}(0) + \left[\tfrac{1}{4} - \tfrac{1}{2}\rho_{22}(0) + \tfrac{\imath}{2}\mathfrak{Im}\ \rho_{12}(0)\right]e^{\imath\Omega t} + \left[-\tfrac{1}{4} + \tfrac{1}{2}\rho_{22}(0) + \tfrac{\imath}{2}\mathfrak{Im}\ \rho_{12}(0)\right]e^{-\imath\Omega t}
\end{aligned}$$

and the case $\Omega = 0$

$$\begin{array}{lll}
\rho_{22}^{(1)} = \rho_{22}(0) & \rho_{22}^{(2)} = 0 & \rho_{22}^{(3)} = 0 \\
\rho_{12}^{(1)} = 0 & \rho_{12}^{(2)} = 0 & \rho_{12}^{(3)} = \rho_{12}(0)
\end{array}$$

with the solution

$$\begin{aligned}
\rho_{22}(t) &= \rho_{22}^{(1)} + \rho_{22}^{(1)}e^{\imath\Delta t} + \rho_{22}^{(1)}e^{-\imath\Delta t} = \rho_{22}(0) \\
\rho_{12}(t) &= \rho_{12}^{(1)} + \rho_{12}^{(1)}e^{\imath\Delta t} + \rho_{12}^{(1)}e^{-\imath\Delta t} = \rho_{12}(0)e^{-\imath\Delta t} \ .
\end{aligned}$$

We begin with the initial conditions

$$\begin{aligned}
\rho_{22}(0) &= 0 \\
\rho_{12}(0) &= 0 \ .
\end{aligned}$$

We apply a first resonant $\pi/2$*-pulse* ($\Omega t = \pi/2, \Delta = 0$),

$$\begin{aligned}
\rho_{22}(\tfrac{\pi}{2\Omega}) &= \tfrac{1}{2} - \tfrac{1}{2}\cos\Omega t = \tfrac{1}{2} \\
\rho_{12}(\tfrac{\pi}{2\Omega}) &= \tfrac{\imath}{2}\sin\Omega t = \tfrac{\imath}{2} \ .
\end{aligned}$$

Now, we turn off the laser and detune the transition ($\Omega = 0, \Delta_T$)*. After an arbitrary time* T *the state becomes,*

$$\begin{aligned}
\rho_{22}(\tfrac{\pi}{2\Omega} + T) &= \frac{1}{2} \\
\rho_{12}(\tfrac{\pi}{2\Omega} + T) &= \frac{\imath}{2}e^{-\imath\Delta_T T} = \tfrac{1}{2}\sin\Delta_T T + \tfrac{\imath}{2}\cos\Delta_T T \ .
\end{aligned}$$

Now we apply a resonant π-pulse ($\Omega t = \pi, \Delta = 0$),

$$\rho_{22}(\tfrac{\pi}{2\Omega} + T + \pi) = \tfrac{1}{2} - \tfrac{1}{2}\cos\Delta_T T \sin\Omega t = \tfrac{1}{2}$$
$$\rho_{12}(\tfrac{\pi}{2\Omega} + T + \pi) = \tfrac{1}{2}\sin\Delta_T T + \tfrac{\imath}{2}\cos\Delta_T T\cos\Omega t = \tfrac{1}{2}\sin\Delta_T T - \tfrac{\imath}{2}\cos\Delta_T T = -\frac{\imath}{2}e^{\imath\Delta_T T} \ .$$

We let the system evolve once more for a while T without laser ($\Omega = 0, \Delta_T$),

$$\rho_{22}(\tfrac{\pi}{2\Omega} + T + \pi + T) = \frac{1}{2}$$
$$\rho_{12}(\tfrac{\pi}{2\Omega} + T + \pi + T) = -\frac{\imath}{2}e^{\imath\Delta_T T}e^{-\imath\Delta_T t} = -\frac{\imath}{2} \ .$$

Finally, we apply the second $\pi/2$-pulse ($\Omega t = \pi/2, \Delta = 0$)

$$\rho_{22}(\tfrac{\pi}{2\Omega} + T + \tfrac{\pi}{\Omega} + T + \tfrac{\pi}{2\Omega}) = \tfrac{1}{2} + \tfrac{1}{2}\sin\Omega t = 1$$
$$\rho_{12}(\tfrac{\pi}{2\Omega} + T + \tfrac{\pi}{\Omega} + T + \tfrac{\pi}{2\Omega}) = \dots \ .$$

Therefore, for each value of them detuning Δ_T, which may in fact be different for each member of an atomic sample, the final value of the population of the excited state is always 1.
Photon echo is an interference effect in the radiation emitted by many atoms. We assume that many two-level atoms interact with the same radiation mode. To observe photon echoes, we apply a first $\pi/2$-pulse which brings every atom into a coherent superposition of the two energy states. However, because of the Doppler shift, the excitation of the individual atoms may be different, so that the individual Bloch vectors begin to precess at different paces. If after a certain time a π-pulse is applied, the state populations, and therefore the direction of the precession are reversed, so that after a certain time, the Bloch vectors are refocused.
The synchronization of the phases of the individual dipoles generates a cooperative spontaneous emission of the ensemble called photon echo. The signature of a photon echo is twofold: First, the appearance of a fluorescence pulse a delay of τ after the end of the applied π-pulse, and second, a fluorescence rate depending on the square of the excited state population. This unusual behavior emerges from a mutual coupling of the individual dipoles and results in a rapid depopulation of the excited state with a much shorter fluorescent lifetime than for individual atoms. This synchronization of the phases of the individual dipoles is called superradiance. It is important to keep in mind, that the photon echo does not allow to recover the coherence of an irreversible process. It only works for inhomogeneous broadening due to a well-defined distribution of the kinetic energy among the atoms, provided that the temporal evolutions of the individual atoms have not undergone random phase interruptions.

34.4.6.10 Ex: Time-evolution of NMR spin components

Derive the coherent part of the Bloch equations (34.175) from the Heisenberg equation (34.174).

Solution: *The nuclear spins satisfies the usual commutation relation $[\hat{I}_m, \hat{I}_n] =$*

$\imath\hbar\epsilon_{kmn}\hat{I}_k$. With this we obtain from the Heisenberg equation,

$$\imath\hbar\frac{d\hat{\vec{\mu}}}{dt} = [\hat{\vec{\mu}}, \hat{H}] = \hat{\vec{\mu}}(-\hat{\vec{\mu}}\cdot\vec{\mathcal{B}}) - (-\vec{\mu}\cdot\vec{\mathcal{B}})\hat{\vec{\mu}} = \gamma_I^2(\hat{\mathbf{I}}\cdot\vec{\mathcal{B}})\hat{\mathbf{I}} - \gamma_I^2\hat{\mathbf{I}}(\hat{\mathbf{I}}\cdot\vec{\mathcal{B}})$$
$$= \gamma_I^2([\hat{I}_x,\hat{\mathbf{I}}]\mathcal{B}_x + [\hat{I}_y,\hat{\mathbf{I}}]\mathcal{B}_y + [\hat{I}_z,\hat{\mathbf{I}}]\mathcal{B}_z) = \gamma_I^2\imath\hbar\begin{pmatrix}\hat{I}_y\mathcal{B}_z - \hat{I}_z\mathcal{B}_y\\ \hat{I}_z\mathcal{B}_x - \hat{I}_x\mathcal{B}_z\\ \hat{I}_x\mathcal{B}_y - \hat{I}_y\mathcal{B}_x\end{pmatrix} = \imath\hbar\gamma_I\hat{\vec{\mu}}\times\vec{\mathcal{B}}\ .$$

34.4.6.11 Ex: Precession of the nuclear spin in a magnetic field

Show for $\hat{H}_0 = -\frac{\hbar\omega_L}{2}\hat{\sigma}_z$ that,

$$\langle\hat{\vec{\sigma}}(t)\rangle = \begin{pmatrix}\cos\omega_L t & -\sin\omega_L t & 0\\ \sin\omega_L t & \cos\omega_L t & 0\\ 0 & 0 & 1\end{pmatrix}\langle\hat{\vec{\sigma}}(0)\rangle\ .$$

Solution: *For the x-component we calculate,*

$$\langle\hat{\sigma}_x(t)\rangle = Tr\ \hat{\rho}(t)\hat{\sigma}_x = Tr\ e^{-\frac{\imath}{2}\hbar\omega_L t\hat{\sigma}_z}\hat{\rho}(0)e^{\frac{\imath}{2}\hbar\omega_L t\hat{\sigma}_z}\hat{\sigma}_x$$
$$= Tr\begin{pmatrix}e^{-\imath\hbar\omega_L t/2} & 0\\ 0 & e^{\imath\hbar\omega_L t/2}\end{pmatrix}\begin{pmatrix}\rho_{11} & \rho_{12}\\ \rho_{21} & \rho_{22}\end{pmatrix}\begin{pmatrix}e^{\imath\hbar\omega_L t/2} & 0\\ 0 & e^{-\imath\hbar\omega_L t/2}\end{pmatrix}\begin{pmatrix}0 & 1\\ 1 & 0\end{pmatrix}$$
$$= Tr\begin{pmatrix}e^{-\imath\hbar\omega_L t}\rho_{12} & \rho_{11}\\ \rho_{22} & e^{\imath\hbar\omega_L t}\rho_{21}\end{pmatrix} = e^{-\imath\hbar\omega_L t}\rho_{12} + e^{\imath\hbar\omega_L t}\rho_{21}\ .$$

Similarly, we get for the y- and z-components,

$$\langle\hat{\sigma}_y(t)\rangle = \imath e^{-\imath\hbar\omega_L t}\rho_{12} - \imath e^{\imath\hbar\omega_L t}\rho_{21}$$
$$\langle\hat{\sigma}_z(t)\rangle = \rho_{11} - \rho_{22}\ .$$

These equations satisfy the initial conditions,

$$2\rho_{12} = \langle\hat{\sigma}_x(0)\rangle - \imath\langle\hat{\sigma}_y(0)\rangle$$
$$\rho_{11} - \rho_{22} = \langle\hat{\sigma}_z(0)\rangle\ ,$$

from which we immediately derive the result.

34.5 Bloch equations with spontaneous emission

In this section we will introduce spontaneous emission and the important concepts of polarization and susceptibility emanating from an excited sample of oscillating dipoles. Optical Bloch equations including spontaneous emission will be given and their stationary solutions will be discussed. Dissipative processes always broaden transition lines, and thus we will discuss various broadening mechanisms.

34.5.1 Phenomenological inclusion of spontaneous emission

To find the Bloch equations including spontaneous emission, we proceed similarly for Eq. (34.26) and insert the phenomenological decay term $-\imath\gamma a_2$ into the Eqs. (27.63),

$$\Omega^* \cos\omega t e^{\imath\omega_0 t} a_1 - \imath\gamma a_2 = \imath \frac{da_2}{dt} \ , \tag{34.184}$$

that is, the equations of motion can be corrected by simply replacing,

$$\frac{da_2}{dt} \curvearrowright \left(\frac{d}{dt} + \gamma\right) a_2 \ . \tag{34.185}$$

Knowing $\rho_{mn} = a_m^* a_n$, it is easy to check,

$$\frac{d\rho_{22}}{dt} \curvearrowright \left(\frac{d}{dt} + \Gamma\right) \rho_{22} \qquad \text{and} \qquad \frac{d\rho_{12}}{dt} \curvearrowright \left(\frac{d}{dt} + \gamma\right) \rho_{12} \ , \tag{34.186}$$

with $\gamma = \Gamma/2$, such that the Bloch equations become,

$$\boxed{\frac{d}{dt}\begin{pmatrix}\rho_{11}\\ \rho_{22}\\ \rho_{12}\\ \rho_{21}\end{pmatrix} = \begin{pmatrix} 0 & \Gamma & \frac{\imath}{2}\Omega & -\frac{\imath}{2}\Omega \\ 0 & -\Gamma & -\frac{\imath}{2}\Omega & \frac{\imath}{2}\Omega \\ \frac{\imath}{2}\Omega & -\frac{\imath}{2}\Omega & -\imath\Delta - \gamma & 0 \\ -\frac{\imath}{2}\Omega & \frac{\imath}{2}\Omega & 0 & \imath\Delta - \gamma \end{pmatrix}\begin{pmatrix}\rho_{11}\\ \rho_{22}\\ \rho_{12}\\ \rho_{21}\end{pmatrix}} \ . \tag{34.187}$$

Example 198 (*Langevin equation*): The *Heisenberg equation* for the evolution of the internal degrees of freedom, including the phenomenologically introduced decay, is also called *Langevin equation*. It can be written as,

$$\imath \frac{d\hat{\sigma}^-}{dt} = \tfrac{1}{\hbar}[\hat{\sigma}^-, \hat{H}] - \tfrac{\imath}{2}\Gamma\hat{\sigma}^- \ ,$$

and analogously for $\hat{\sigma}_z$. With the Hamiltonian $\hat{H} = \hbar\Delta\hat{\sigma}^+\hat{\sigma}^- + \frac{1}{2}\hbar\Omega(e^{\imath\omega t}\hat{\sigma}^- + h.c.)$ we obtain, using the Pauli spin matrices, exactly the Bloch equations,

$$\begin{aligned}
\imath\dot{\hat{\sigma}}^- &= \Delta[\hat{\sigma}^-, \hat{\sigma}^+\hat{\sigma}^-] + \tfrac{1}{2}\Omega e^{-\imath\omega t}[\hat{\sigma}^-, \hat{\sigma}^+] - \tfrac{\imath}{2}\Gamma\hat{\sigma}^- = \Delta\hat{\sigma}^- - \tfrac{1}{2}\Omega e^{-\imath\omega t}\hat{\sigma}_z - \tfrac{\imath}{2}\Gamma\hat{\sigma}^- \\
\imath\dot{\hat{\sigma}}_z &= \Delta[\hat{\sigma}_z, \hat{\sigma}^+\hat{\sigma}^-] + \tfrac{1}{2}\Omega e^{-\imath\omega t}[\hat{\sigma}_z, \hat{\sigma}^+] + \tfrac{1}{2}\Omega e^{\imath\omega t}[\hat{\sigma}_z, \hat{\sigma}^-] - \tfrac{\imath}{2}\Gamma\hat{\sigma}_z = \Omega(\hat{\sigma}^- - \hat{\sigma}^+) - \tfrac{\imath}{2}\Gamma\hat{\sigma}_z \ .
\end{aligned}$$

34.5.1.1 Stationary solution of the Bloch equations

The dissipation introduced by the spontaneous emission allows the system to reach a steady state. Letting the time derivatives be 0, we obtain the stationary solutions,

$$\boxed{\rho_{22}(\infty) = \frac{\frac{1}{4}|\Omega|^2}{\Delta^2 + \frac{1}{2}|\Omega|^2 + \frac{1}{4}\Gamma^2} \qquad \text{and} \qquad \rho_{12}(\infty) = e^{\imath\Delta t}\frac{\frac{1}{2}\Omega(\Delta - \frac{\imath}{2}\Gamma)}{\Delta^2 + \frac{1}{2}|\Omega|^2 + \frac{1}{4}\Gamma^2}} \ . \tag{34.188}$$

This will be shown in Exc. 34.5.4.1. We see that the populations and coherences both have a Lorentzian frequency dependence, which is similar to the one of the absorption

cross section σ derived in (22.72). However, the denominators have an extra term $\frac{1}{2}\Omega^2$ contributing to an *effective* widths of ρ_{22} and ρ_{12},

$$\Gamma_{\text{eff}} = \sqrt{2|\Omega|^2 + \Gamma^2} \ . \tag{34.189}$$

This effect, called *power broadening* or *saturation broadening*, has already been discussed in (22.102). The phase factor $e^{\imath\Delta t}$ describes the optical precession of the Bloch vector.

By introducing the *saturation parameter*,

$$s \equiv \frac{2|\Omega|^2}{4\Delta^2 + \Gamma^2} \ , \tag{34.190}$$

we can rewrite the stationary dipole moment and the excited state population (34.188) as,

$$\boxed{\rho_{22}(\infty) = \frac{s/2}{1+s} \quad , \quad \rho_{12}(\infty) = e^{\imath\Delta t}\frac{\Delta - \imath\Gamma/2}{\Omega}\frac{s}{1+s} \ .} \tag{34.191}$$

and

$$|\rho_{12}(\infty)|^2 = \frac{s/2}{(1+s)^2} \ . \tag{34.192}$$

Fig. 34.6(a) shows the Rabi oscillations damped by spontaneous emission. For long times the population of the excited state ρ_{22} converges to the asymptote (34.191). Fig. 34.6(b) shows the temporal evolution of the Bloch vector subject to spontaneous emission. In Exc. 34.5.4.2 we the behavior of the phase of the dipole moment ρ_{12} with respect to the driving field. In Exc. 34.5.4.3 and 34.5.4.4 we calculate the impact of

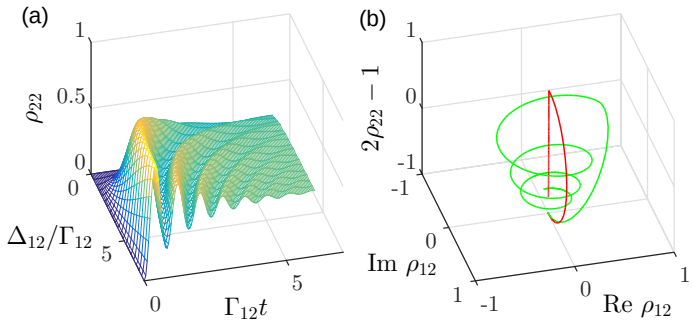

Figure 34.6: (code) (a) Rabi oscillations damped by spontaneous emission for Rabi frequencies between $\Omega/\Gamma = 0.2, .., 5$. (b) Evolution of the Bloch vector subject to spontaneous emission ($\Gamma_{12} = 0.05\Omega_{12}$) after application of a resonant π-pulse (red) and after a π-pulse with detuning $\Delta_{12} = \Omega_{12}/2$ (green).

the spontaneous emission on the determinant of the density operator. Solve the Excs. 34.5.4.5, 34.5.4.6, 34.5.4.7, and 34.5.4.8.

Example 199 (*Resonant excitation and weak excitation*): A case where the Bloch equations can be analytically treated is under resonant excitation,

$\Delta = 0$. In this case, for the initial conditions, $\rho_{12}(0) = \rho_{22}(0) = 0$, the solution including decay is,

$$\rho_{22}(t) = \frac{\Omega^2}{2|\Omega|^2 + \Gamma^2}\left[1 - e^{-3\Gamma t/4}\left(\cos\lambda t + \frac{3\Gamma}{4\lambda}\sin\lambda t\right)\right] \quad \text{and} \quad \rho_{12}(t) = 0 \ , \tag{34.193}$$

where $\lambda \equiv \sqrt{\Omega^2 - \Gamma^2}$. This solution (which will be derived in Exc. 34.5.4.9), describes the optical nutation of the Bloch vector along the ρ_z axis. We note here that, due to spontaneous emission, the norm of the Bloch vector is NOT conserved, i.e. the Bloch vector evolves to the interior of the Bloch sphere.
Another case that can be solved analytically is the weakly excited atom, $|\Omega| \ll \Gamma$,

$$\rho_{22} \simeq \frac{\Omega^2}{4G^2}\left(1 + e^{-2\Gamma t} - 2\cos\Delta t\right) \tag{34.194}$$

$$\text{and} \quad \rho_{12}(t) \simeq \frac{-\imath\Omega}{2\imath\Delta + 2\Gamma}\left(e^{-(\imath\Delta+\Gamma)t} - 1\right) + \rho_{12}(0)e^{-(\imath\Delta+\Gamma)t} \ .$$

34.5.1.2 Nonlinearity of the Bloch equations

Because the Bloch equation go beyond perturbation theory they contain nonlinear optics. We can see this by the simple fact that strong radiation field can saturate atomic transitions. For example, expanding the population and coherence (34.188) by the incident electric field amplitude $\mathcal{E} \propto \Omega$,

$$\rho_{22}(\infty) \simeq \frac{1}{4\Delta^2 + \Gamma^2}\Omega^2 - \frac{2}{(4\Delta^2 + \Gamma^2)^2}\Omega^4 + ... \tag{34.195}$$

$$\rho_{12}(\infty) \simeq e^{\imath\Delta t}\frac{2\Delta - \imath\Gamma}{4\Delta^2 + \Gamma^2}\Omega - 2e^{\imath\Delta t}\frac{2\Delta - \imath\Gamma}{(4\Delta^2 + \Gamma^2)^2}\Omega^3 + ... \ .$$

The theory of nonlinear optics will be developed in Sec. 35.7.2 and Chp. 37.

Example 200 (*Complex susceptibility and absorption coefficient*): The objective of this section is to obtain an expression for the susceptibility in the presence of spontaneous emission. For the present discussion we are only concerned with the temporal dependence of the actual light wave, which we write as,

$$\vec{\mathcal{E}}(t) = \vec{\mathcal{E}}_0 \cos\omega t = \tfrac{1}{2}[e^{\imath\omega t} + e^{-\imath\omega t}] \ . \tag{34.196}$$

Then we consider how to write the polarization in terms of a susceptibility when the field contains two conjugate frequencies, $\pm\omega$. Substituting into the polarization Eq. (14.20), we get,

$$\vec{\mathcal{P}}(t) = \varepsilon_0\chi_e\vec{\mathcal{E}} = \tfrac{1}{2}\varepsilon_0\vec{\mathcal{E}}_0[\chi_e(\omega)e^{\imath\omega t} + \chi_e(-\omega)e^{-\imath\omega t}] \ . \tag{34.197}$$

The polarization can also be expressed in terms of the density of the transition dipoles in a gas of two-level atoms,

$$\vec{\mathcal{P}}(t) = \frac{N}{V}\mathbf{d}_{12}(t) \longrightarrow \frac{N}{V}\langle\mathbf{d}_{12}(t)\rangle \ . \tag{34.198}$$

where $\mathbf{d}$ is the transition dipole of only one atom, N/V is the atomic density, and the quantum expectation value for the transition dipole moment is,

$$\langle\mathbf{d}_{12}\rangle = -e\int \Psi\sum_j \mathbf{r}_j\Psi d^3r \ . \tag{34.199}$$

Now, from Eq. (27.58),

$$\langle \mathbf{d}_{12} \rangle = -e \left[a_1^* a_2 \langle \psi_1 | \sum_j \mathbf{r}_j | \psi_2 \rangle e^{-\imath\omega_0 t} + a_1 a_2^* \langle \psi_2 | \sum_j \mathbf{r}_j | \psi_1 \rangle e^{\imath\omega_0 t} \right] . \quad (34.200)$$

To simplify the notation we define $\langle \mathbf{r}_{mn} \rangle \equiv \langle \psi_m | \sum_j \mathbf{r}_j | \psi_n \rangle$ and obtain,

$$\langle \mathbf{d}_{12} \rangle = -e[a_1^* a_2 \langle \mathbf{r}_{12} \rangle e^{-\imath\omega_0 t} + a_1 a_2^* \langle \mathbf{r}_{21} \rangle e^{\imath\omega_0 t}] . \quad (34.201)$$

Now, we only need to replace the solutions of the coupled equations by relating a_1 and a_2 of the Eqs. (27.63) in (34.201) which, in turn, can be inserted into the equation (34.197). Thus we obtain an expression for the polarization in terms of properties of the atoms and the incident field.
The crucial point now is, that the solution for a_2, Eq. (27.79), does not consider spontaneous emission. Therefore, as already done in Sec. 34.5.1, we will introduce an ad hoc modification of Eq. (27.63) by including a radiative loss constant γ,

$$\Omega^* \cos\omega t e^{\imath\omega_0 t} a_1 - \imath\gamma a_2 = \imath \frac{da_2}{dt} . \quad (34.202)$$

This term does NOT EXPLAIN spontaneous emission. It simply takes into account the existence of the effect and characterizes its amplitude through γ: If the incident field is turned off ($\Omega^* = 0$)

$$-\imath\gamma a_2 = \imath \frac{da_2}{dt} \quad (34.203)$$

and

$$a_2(t) = a_2(0) e^{-\gamma t} . \quad (34.204)$$

Then, the probability of finding an atom in the excited state (or the fraction of excited atoms in an ensemble) is,

$$N_2/N = |a_2(t)|^2 = |a_2(0)|^2 e^{-2\gamma t} . \quad (34.205)$$

Comparing this behavior with the result obtained from the Einstein rate equation, we see immediately,

$$A_{21} = 2\gamma \equiv \Gamma . \quad (34.206)$$

Now, the solution for our improved $a_2(t)$ coefficient is,

$$a_2(t) = -\tfrac{1}{2}\Omega^* \left[\frac{e^{\imath(\omega_0+\omega)t}}{\omega_0 + \omega - \imath\gamma} + \frac{e^{\imath(\omega_0-\omega)t}}{\omega_0 - \omega - \imath\gamma} \right] , \quad (34.207)$$

which solves the differential equation (34.202) in the weak field limit, $a_1(t) \simeq 1$, as will be verified in Exc. 34.5.4.10.
Making the weak field approach, replacing the values obtained for $a_{1,2}$ in the transition dipole (34.201) and replacing the average of the orientations, $|\langle r_{12} \rangle|^2 \longrightarrow \frac{1}{3}|\langle r_{12} \rangle|^2$, in the polarization (34.198), we obtain,

$$\vec{\tilde{\mathcal{P}}}(t) = \varepsilon_0 \tilde{\chi}_e \vec{\mathcal{E}} \quad (34.208)$$
$$= \frac{N}{V} \frac{e^2 |\langle r_{12} \rangle^2 \vec{\mathcal{E}}_0}{6\hbar} \left[\frac{e^{\imath\omega t}}{\omega_0 + \omega - \imath\gamma} + \frac{e^{\imath\omega t}}{\omega_0 - \omega + \imath\gamma} + \frac{e^{-\imath\omega t}}{\omega_0 - \omega - \imath\gamma} + \frac{e^{-\imath\omega t}}{\omega_0 + \omega + \imath\gamma} \right] .$$

Apparently, the presence of spontaneous emission turns the susceptibility into a complex number [see Eq. (18.132)].

Comparing this result with Eq. (34.197) and identifying the susceptibility $\tilde{\chi}_e(\omega)$ in terms of the atomic properties and the frequency of the incident field, we find,

$$\begin{aligned}\tilde{\chi}_e(\omega) &= \frac{Ne^2|\langle r_{12}\rangle|^2}{3\epsilon_0\hbar V}\left[\frac{1}{\omega_0-\omega-\imath\gamma}+\frac{1}{\omega_0+\omega-\imath\gamma}\right] \\ &= \frac{Ne^2|\langle r_{12}\rangle^2}{3\epsilon_0\hbar V}\left[\frac{\omega_0-\omega}{(\omega_0-\omega)^2+\gamma^2}+\frac{\omega_0+\omega}{(\omega_0+\omega)^2+\gamma^2}\right. \\ &\quad \left.+\imath\gamma\left(\frac{1}{(\omega_0-\omega)^2+\gamma^2}+\frac{1}{(\omega_0+\omega)^2+\gamma^2}\right)\right] .\end{aligned} \tag{34.209}$$

In most practical situations in the laboratory ω will not be tuned more than some 100 GHz away from ω_0, hence $|\omega_0-\omega| \lesssim 10^{11}$ Hz. With optical frequencies $\omega \simeq 10^{15}$ Hz, it is clear that the second term on the right hand side of Eq. (34.209) will be negligible compared to the first one. Therefore, we can discard the second term and write the susceptibility as,

$$\begin{aligned}\chi_e(\omega) &\simeq \frac{Ne^2|\langle r_{12}\rangle|^2}{3\epsilon_0\hbar V}\frac{1}{\omega_0-\omega-\imath\gamma} \\ &= \frac{Nd_{12}^2}{3\epsilon_0\hbar V}\frac{-\Delta+\imath\Gamma/2}{\Delta^2+(\Gamma/2)^2} = \frac{n\hbar\Omega^2}{3\epsilon_0 E_0^2}\frac{-\Delta+\imath\Gamma/2}{\Delta^2+(\Gamma/2)^2} .\end{aligned} \tag{34.210}$$

We identify the real and imaginary parts, $\tilde{\chi}_e = \chi_e' + \imath\chi_e''$, and express the absorption coefficient as (see (18.138)),

$$K = \frac{\omega}{c\eta}\chi_e''(\omega) = \frac{\pi N d_{12}^2\omega_0}{3\epsilon_0\hbar c V}\frac{\Gamma/2\pi}{\Delta^2+(\Gamma/2)^2} = \frac{\pi N d_{12}^2\omega_0}{3\epsilon_0\hbar c V}\mathcal{L}(\omega-\omega_0) . \tag{34.211}$$

The Lorentzian profile term governs the frequency dependence of the absorption coefficient. We see that K exhibits a peak at the resonance frequency ω_0 and a width of Γ. The factor of π inserted in the numerator and denominator of the right term of Eq. (34.211) allows to normalize the profile. We have also assumed in Eq. (34.211) that the gas is sufficiently dilute for $n \simeq 1$ to hold, and that the line is sufficiently narrow to be able to replace ω with ω_0, such that,

$$\frac{\omega}{c\eta} \longrightarrow \frac{\omega_0}{c} . \tag{34.212}$$

The absorption cross section has the same lineshape, since from Eqs. (22.72) and (34.211) we have,

$$\sigma_{0a} = \frac{\pi d_{12}^2\omega_0}{3\epsilon_0\hbar c V}\mathcal{L}(\omega-\omega_0) , \tag{34.213}$$

consistent with our previous expression for the frequency dependence of the absorption cross-section. We can also write the imaginary component of the susceptibility in terms of the cross section using the Eqs. (22.72) and (34.211)

$$\chi_e'' = \frac{cN}{\omega_0 V}\sigma_{0a} . \tag{34.214}$$

The frequency-dependent linear *susceptibility* completely describes the linear propagation of an electromagnetic wave within a medium. It is related to the index of refraction and the absorption coefficient. Nonlinear processes should be described by higher order susceptibilities. Electric fields $\vec{\mathcal{E}} = \vec{\mathcal{E}}_0 e^{\imath\omega t} + c.c.$ induce in media characterized by a given susceptibility $\tilde{\chi}_e$ the polarization $\vec{\mathcal{P}} = \varepsilon_0\tilde{\chi}_e\vec{\mathcal{E}}$.

The polarization is the sum of the dipole moments of the individual atoms, $\vec{\mathcal{P}} = n\langle \mathbf{d} \rangle$, where $n = N/V$ is the atomic density. The susceptibility can therefore be expressed by the Hamiltonian interaction $\hat{H} = -\mathbf{d} \cdot \vec{\mathcal{E}}$,

$$\chi_e = -\frac{n}{|\vec{\mathcal{E}}|^2} \langle \hat{H} \rangle \ . \tag{34.215}$$

Using the two-level Hamiltonian (34.209) we obtain,

$$\chi_e = -n \ \frac{\hbar\Omega}{2|\vec{\mathcal{E}}|^2} \ \rho_{12} e^{\imath\Delta t} + c.c. \tag{34.216}$$

for the polarization,

$$\vec{\mathcal{P}} = n \ \mathbf{d}\rho_{12} + c.c. \tag{34.217}$$

and for the susceptibility,

$$\chi_e(\omega) = \frac{2nd^2}{3\varepsilon_0\hbar} \frac{\Delta + \imath\Gamma}{4\Delta^2 + 2|\Omega|^2 + \Gamma^2} \qquad \text{with} \qquad d = \sqrt{\frac{3\pi\varepsilon_0\hbar\Gamma}{k^3}} \ . \tag{34.218}$$

We can insert the new expression (34.188) for ρ_{12} into our previous expression for $\langle d_{12} \rangle$ (34.201) and get new expressions for the polarization $\vec{\mathcal{P}}(t)$, (34.198) and (34.208), and the susceptibility χ (34.210). The modified expression for the susceptibility is,

$$\chi_e = \frac{Nd_{12}^2}{3\epsilon_0\hbar V} \frac{-\Delta + \frac{1}{2}\Gamma}{\Delta^2 + \frac{1}{2}|\Omega|^2 + \frac{1}{4}\Gamma^2} \ . \tag{34.219}$$

In the imaginary component we obtain the new absorption coefficient,

$$K = \frac{\omega}{cn}\chi_e''(\omega) = \frac{\pi N e^2 |\langle \mathbf{r}_{12} \rangle|^2 \omega_0}{3\epsilon_0\hbar c V} \frac{\Gamma/2\pi}{\Delta^2 + \frac{1}{2}\Omega^2 + \frac{1}{4}\Gamma^2} \ , \tag{34.220}$$

and the *optical cross-section* for absorption,

$$\sigma_{0a} = \frac{\pi e^2 |\langle \mathbf{r}_{12} \rangle|^2 \omega_0}{3\epsilon_0\hbar c} \frac{\Gamma/2\pi}{\Delta^2 + \frac{1}{2}\Omega^2 + \frac{1}{4}\Gamma^2} \ . \tag{34.221}$$

The important new property is the effective width $\Gamma_{\rm eff}$, which appears in χ_e, K, and σ_{0a}.

34.5.2 Liouville equation for two levels

In the previous section we chose to include spontaneous emission in the Bloch equations by phenomenological arguments. However, as we will show more ahead, dissipation can be treated from general principles. This treatment, named after *Weisskopf-Wigner*, derives from a Liouville type equation (34.125), but which holds for a total density operator $\rho_{atom\&field}$ describing the atom and the electromagnetic modes, an equation for the density operator of only the atom. The price to pay for this simplification is an additional term appearing in the equation now called *master equation*,

$$\boxed{\begin{array}{rcl} \dot{\hat{\rho}}(t) & = & (\mathcal{L}_0 + \mathcal{L}_{sp})\hat{\rho}(t) \qquad \text{with} \\ \mathcal{L}_0\hat{\rho}(t) & \equiv & \frac{\imath}{\hbar}[\hat{\rho}(t), \hat{H}] \qquad \text{and} \qquad \mathcal{L}_{sp} = \frac{\Gamma}{2}(2\hat{\sigma}\hat{\rho}^-\hat{\sigma}^+ - \hat{\sigma}^+\hat{\sigma}^-\hat{\rho} - \hat{\rho}\hat{\sigma}^+\hat{\sigma}^-) \end{array}} \ , \tag{34.222}$$

where $\hat{\sigma}^\pm$ are the Pauli matrices. We show in Exc. 34.5.4.11, that the known Bloch equations can be derived from the master equation.

34.5.3 The effective Hamiltonian approach

In Sec. 34.5.1 we have shown that spontaneous emission can be phenomenologically be included by substituting $\frac{d}{dt} \curvearrowright \frac{d}{dt} + \frac{\Gamma}{2}$ in the Schrödinger equation,

$$\imath \left(\tfrac{d}{dt} + \tfrac{\Gamma}{2} |2\rangle\langle 2| \right) |\psi\rangle = \hat{H}|\psi\rangle \ . \tag{34.223}$$

Rewriting the Schrödinger equation as,

$$\imath \tfrac{d}{dt}|\psi\rangle = (\hat{H} - \imath \tfrac{\Gamma}{2}|2\rangle\langle 2|)|\psi\rangle \equiv \hat{H}_{eff}|\psi\rangle \ , \tag{34.224}$$

it is tempting to study how far we can go [117, 118] with the emulation of dissipative processes by the Schrödinger equation using a non-Hermitian *effective Hamiltonian*.

More generally let us define,

$$\hat{H}_{eff} \equiv \hat{H} - \imath \hat{D} \ . \tag{34.225}$$

Rederiving the master equation from Schrödinger equation with this Hamiltonian, we get,

$$\begin{aligned} \dot{\hat{\rho}} &= |\psi\rangle \frac{d\langle\psi|}{dt} + \frac{d|\psi\rangle}{dt}\langle\psi| = \imath\hat{\rho}\hat{H}^*_{eff} - \imath\hat{H}_{eff}\hat{\rho} \\ &= \imath[\hat{\rho}, \hat{H}] - \{\hat{\rho}, \hat{D}\} \ . \end{aligned} \tag{34.226}$$

And for the Heisenberg equation,

$$\begin{aligned} \tfrac{d}{dt}\langle\hat{A}\rangle &= \langle\dot{\psi}|\hat{A}|\psi\rangle + \langle\psi|\hat{A}|\dot{\psi}\rangle = \imath\langle\psi|\hat{H}^*_{eff}\hat{A}|\psi\rangle - \imath\langle\psi|\hat{A}\hat{H}_{eff}|\psi\rangle \\ &= \imath\langle\psi|[\hat{H}, \hat{A}]|\psi\rangle - \langle\psi|\{\hat{D}, \hat{A}\}|\psi\rangle \ . \end{aligned} \tag{34.227}$$

Apparently, the dissipation term adds an anti-commutator to the evolution equations. It is now interesting to compare the dissipative terms of the expressions (34.222) and (34.226).

34.5.3.1 Saturation effects by the effective Hamiltonian

The eigenvalues of the *effective Hamiltonian* of a two-level system excited by radiation,

$$\hat{H}_{eff} = \begin{pmatrix} 0 & \frac{1}{2}\Omega \\ \frac{1}{2}\Omega & \Delta - \frac{\imath}{2}\Gamma \end{pmatrix} \ , \tag{34.228}$$

describe possible effects of line broadening and/or displacement due to coupling,

$$\boxed{E_\pm = \tfrac{1}{2}\left(\Delta - \tfrac{\imath}{2}\Gamma\right) \pm \tfrac{1}{2}\sqrt{\left(\Delta - \tfrac{\imath}{2}\Gamma\right)^2 + \Omega^2}} \ . \tag{34.229}$$

The real parts of the eigenvalues $\mathfrak{Re}\ E$ describe shifts and/or splittings of the transition line. The imaginary parts $\mathfrak{Im}\ E$ describe broadening effects of the lines.

In the simplest case, $\Delta = 0$ and $\Gamma > 4\Omega$, we find the *saturation broadening* already discussed in (34.189), and we will deepen it in Exc. 34.8.4.2. For the case $\Gamma < 4\Omega$, we observe a splitting of the line called *Autler-Townes splitting*, which will be studied

in Exc. 34.8.4.1. If $\Omega \neq 0$, the spectrum becomes asymmetrical. In the case of weak excitation, $\Gamma \gg 4\Omega$, we observe a shift of the transition line with dispersive dependence (near the resonance) on the frequency of the incident radiation. This is the *dynamic Stark shift* (or *light shift*). In the case of strong excitation, $\Gamma \ll 4\Omega$, we observe again at the split spectrum, but now the two lines exhibit an *avoided crossing*-type dependence on the radiation frequency. We study these effects in Excs. 34.5.4.12 and Exc. 34.5.4.13.

Obviously, these effects can be studied by the Bloch equation formalism containing the terms of spontaneous relaxation.

34.5.4 Exercises

34.5.4.1 Ex: Stationary solution of the Bloch equations

Derive the stationary solution of the Bloch equations including spontaneous emission. How does the spectrum $\rho_{22}(\Delta)$ change in the presence of phase noise, $\gamma = \frac{\Gamma}{2} + \beta$, in particular if $\beta \gg \frac{\Gamma}{2}$?

Solution: *Starting from the Bloch equations,*

$$0 = \frac{d}{dt}\begin{pmatrix}\rho_{11}\\ \rho_{22}\\ \tilde\rho_{12}\\ \tilde\rho_{21}\end{pmatrix} = \begin{pmatrix} 0 & \Gamma & \frac{\imath}{2}\Omega & -\frac{\imath}{2}\Omega \\ 0 & -\Gamma & -\frac{\imath}{2}\Omega & \frac{\imath}{2}\Omega \\ \frac{\imath}{2}\Omega & -\frac{\imath}{2}\Omega & \imath\Delta-\gamma & 0 \\ -\frac{\imath}{2}\Omega & \frac{\imath}{2}\Omega & 0 & -\imath\Delta-\gamma \end{pmatrix}\begin{pmatrix}\rho_{11}\\ \rho_{22}\\ \tilde\rho_{12}\\ \tilde\rho_{21}\end{pmatrix} ,$$

we find from the first and third line using the normalization condition,

$$0 = \Gamma\rho_{22} + \tfrac{\imath}{2}\Omega\tilde\rho_{12} - \tfrac{\imath}{2}\Omega\tilde\rho_{21} \qquad \textit{and} \qquad 0 = \tfrac{\imath}{2}\Omega - \imath\Omega\rho_{22} + (\imath\Delta-\gamma)\tilde\rho_{12} \ .$$

Solving,

$$\rho_{22} = \frac{\imath\Omega}{2\Gamma}(\tilde\rho_{21} - \tilde\rho_{12}) \qquad \textit{and} \qquad \tilde\rho_{12} = \frac{\imath\Omega}{2(\imath\Delta-\gamma)}(2\rho_{22}-1) \ .$$

Hence,

$$\rho_{22} = \frac{\Omega^2}{4\Gamma}\left(\frac{1}{\imath\Delta+\gamma} + \frac{1}{-\imath\Delta+\gamma}\right)(1-2\rho_{22}) = \frac{\frac{\gamma}{2\Gamma}\Omega^2}{\Delta^2 + \frac{\gamma}{\Gamma}\Omega^2 + \gamma^2}$$

$$\tilde\rho_{12} = \frac{\imath\Omega}{2(\imath\Delta-\gamma)}\left(\frac{\frac{\gamma}{\Gamma}\Omega^2}{\Delta^2 + \frac{\gamma}{\Gamma}\Omega^2 + \gamma^2} - 1\right) = \frac{\frac{\Omega}{2}(-\Delta+\imath\gamma)}{\Delta^2 + \frac{\gamma}{\Gamma}\Omega^2 + \gamma^2} \ .$$

For $\gamma = \frac{\Gamma}{2}$ *we get,*

$$\rho_{22} = \frac{\frac{1}{4}\Omega^2}{\Delta^2 + \frac{1}{2}\Omega^2 + \frac{1}{4}\Gamma^2} \qquad \textit{and} \qquad \tilde\rho_{12} = \frac{\frac{\Omega}{2}(-\Delta + \frac{\imath}{2}\Gamma)}{\Delta^2 + \frac{1}{2}\Omega^2 + \frac{1}{4}\Gamma^2} \ .$$

For $\gamma = \frac{\Gamma}{2} + \beta \gg \frac{\Gamma}{2}$ *we get,*

$$\rho_{22} \simeq \frac{\frac{\beta}{2\Gamma}\Omega^2}{\Delta^2+\beta^2} \overset{\Delta\to 0}{\longrightarrow} \frac{\Omega^2}{2\Gamma\beta} \qquad \textit{and} \qquad \tilde\rho_{12} \simeq \frac{\frac{\Omega}{2}(-\Delta+\imath\beta)}{\Delta^2+\beta^2} \overset{\Delta\to 0}{\longrightarrow} \frac{\imath\Omega}{2\beta} \ .$$

34.5.4.2 Ex: Detuning-dependent phase-shift of the dipole moment

Calculate the phase-shift of the dipole moment with respect to the driving field across resonance.

Solution: *The dipole moment in the interaction picture being given by (34.188),*

$$\rho_{12}(\infty) = e^{\imath\Delta t}\frac{\frac{1}{2}\Omega(\Delta - \frac{\imath}{2}\Gamma)}{\Delta^2 + \frac{1}{2}\Omega^2 + \frac{1}{4}\Gamma^2} \ ,$$

the phase-shift is,

$$\varphi = \arctan\frac{\mathfrak{Im}\ \rho_{12}e^{-\imath\Delta t}}{\mathfrak{Re}\ \rho_{12}e^{-\imath\Delta t}} = \arctan\frac{-\Gamma}{2\Delta} \overset{\Delta\to\pm\infty}{\longrightarrow} \pm\frac{\pi}{2} \ .$$

Note that the total phase-shift of π when sweeping across a resonance is consistent with the Lorentz model treating the oscillation of a bound electron like a harmonic oscillator. Apparently, this feature does not depend on saturation. Experimentally, the phase-shift may we extracted by a homodyne experiment [1219] as one of the quadratures. The other quadrature yields the amplitude,

$$|\hat{\rho}_{12}e^{-\imath\Delta t}| = \frac{\frac{1}{2}\Omega\sqrt{\Delta^2 + \frac{1}{4}\Gamma^2}}{\Delta^2 + \frac{1}{2}\Omega^2 + \frac{1}{4}\Gamma^2} \overset{\Delta\to\pm\infty}{\longrightarrow} \frac{\Omega}{2|\Delta|} \ .$$

34.5.4.3 Ex: Determinant of the Bloch matrix

In Sec. 34.3.1 we already saw that $\det\hat{\rho} = 0$ for conservative systems. Now, show explicitly for the Bloch matrix of a two-level system, that $\det\hat{\rho} = 0$ only holds in the absence of spontaneous emission.

Solution: *The system be initially in the ground state. So, the coherences are null and the determinant must disappear. But the Bloch equations contain the determinant, since,*

$$\begin{aligned}
\frac{d}{dt}\det\begin{pmatrix}\rho_{11} & \rho_{12}\\ \rho_{21} & \rho_{22}\end{pmatrix} &= \dot{\rho}_{gg}\rho_{22} + \rho_{11}\dot{\rho}_{22} - \dot{\rho}_{12}\rho_{21} - \rho_{12}\dot{\rho}_{21}\\
&= \Gamma_{\parallel}\rho_{22}^2 + \tfrac{1}{\imath\hbar}(V_{12}\rho_{21} - \rho_{12}V_{21})\rho_{22}\\
&= -\Gamma_{\parallel}\rho_{22}\rho_{11} + \tfrac{1}{\imath\hbar}(V_{21}\rho_{12} - \rho_{21}V_{12})\rho_{11}\\
&\quad + (-\imath\omega_0 + \Gamma_{\perp})\rho_{12}\rho_{21} + \tfrac{1}{\imath\hbar}V_{12}(\rho_{11} - \rho_{22})\rho_{21}\\
&\quad + (\imath\omega_0 + \Gamma_{\perp})\rho_{21}\rho_{12} - \tfrac{1}{\imath\hbar}V_{21}(\rho_{11} - \rho_{22})\rho_{12}\\
&= \Gamma_{\parallel}\rho_{22}(\rho_{22} - \rho_{11}) + 2\Gamma_{\perp}\rho_{12}\rho_{21} \ .
\end{aligned}$$

34.5.4.4 Ex: Density operator with dissipation

Discuss the phenomenon of dissipation at the example of
a. a thermal sample of two-level systems $|i\rangle = |1\rangle, |2\rangle$ characterized by the density operator $\hat{\rho} = |i\rangle\langle i| \otimes |v\rangle\langle v|$, where $|v\rangle$ is the velocity state of the atom and
b. a two-level atom coupled to a radiation field, $\hat{\rho} = |i\rangle\langle i| \otimes |n\rangle\langle n|$, where $|n\rangle$ is the number of photons inside the mode.

Solution: *We need to show that,*

$$Tr_{reserv}\rho_{atom} \to 0 \qquad while \qquad Tr_{reserv}\begin{pmatrix} \rho_{atom} & 0 \\ 0 & \rho_{reserv} \end{pmatrix} = 1 \ .$$

34.5.4.5 Ex: Bloch vector

A two-level atom with decay rate $\Gamma = 2\pi \times 6\,\mathrm{MHz}$ be excited by a light field detuned by $\Delta = 2\Gamma$ and whose intensity is a quarter of the saturation intensity. Write down the Bloch vector for $t \to \infty$.

Solution: *The Rabi frequency is* $\Omega = \sqrt{\Gamma^2/2 \times I/I_s}$ *and the detuning* $\Delta = 2\Gamma$. *The stationary solution of the Bloch equations are,*

$$\rho_{22} = \frac{\Omega^2}{4\Delta^2 + 2\Omega^2 + \Gamma^2} \qquad and \qquad \rho_{12} = \Omega\frac{2\Delta + \imath\Gamma}{4\Delta^2 + \Gamma^2}(\rho_{22} - \rho_{11}) \ .$$

Hence,

$$\vec{\rho} = \begin{pmatrix} \rho_{12} + \rho_{21} \\ \imath(\rho_{12} - \rho_{21}) \\ \rho_{22} - \rho_{11} \end{pmatrix} = (2\rho_{22} - 1)\begin{pmatrix} \Omega\frac{4\Delta}{4\Delta^2+\Gamma^2} \\ \Omega\frac{2\Gamma}{4\Delta^2+\Gamma^2} \\ 1 \end{pmatrix}$$
$$= \frac{-1}{4\Delta^2 + 2\Omega^2 + \Gamma^2}\begin{pmatrix} 4\Delta\Omega \\ 2\Gamma\Omega \\ 4\Delta^2 + \Gamma^2 \end{pmatrix} = \frac{-1}{17.25}\begin{pmatrix} \sqrt{8} \\ \sqrt{2}^{-1} \\ 17 \end{pmatrix} \ .$$

34.5.4.6 Ex: Purity of two-level atoms with spontaneous emission

Calculate for a driven two-level atom in the stationary limit Tr $\hat{\rho}$ and Tr $\hat{\rho}^2$.

Solution: *From* $1 = \rho_{11}(0) + \rho_{22}(0)$ *follows that Tr* $\rho = 1$ *always. With*

$$\hat{\rho}^2 = \begin{pmatrix} \rho_{11}^2 + \rho_{12}\rho_{21} & \rho_{11}\rho_{12} + \rho_{12}\rho_{22} \\ \rho_{11}\rho_{21} + \rho_{21}\rho_{22} & \rho_{12}\rho_{21} + \rho_{22}^2 \end{pmatrix}$$

follows

$$Tr\ \rho^2 = Tr\ \rho - 2\det\rho = 1 - 2\rho_{22} + 2\rho_{22}^2 + 2\rho_{12}\rho_{21}\ .$$

Inserting the stationary solution (34.188) of the Bloch equations,

$$\rho_{22} = \frac{\Omega^2}{4\Delta^2 + 2\Omega^2 + \Gamma^2} \qquad and \qquad \rho_{12} = e^{\imath\Delta t}\frac{\Omega(2\Delta + \imath\Gamma)}{4\Delta^2 + 2\Omega^2 + \Gamma^2}$$

we calculate,

$$\begin{aligned} Tr\ \rho^2 &= 1 - \frac{2\Omega^2(4\Delta^2 + 2\Omega^2 + \Gamma^2)}{(4\Delta^2 + 2\Omega^2 + \Gamma^2)^2} + \frac{2\Omega^4}{(4\Delta^2 + 2\Omega^2 + \Gamma^2)^2} + \frac{2\Omega^2(4\Delta^2 + \Gamma^2)}{(4\Delta^2 + 2\Omega^2 + \Gamma^2)^2} \\ &= 1 - 2\left(\frac{\Omega^2}{4\Delta^2 + 2\Omega^2 + \Gamma^2}\right)^2 = 1 - 2\rho_{22}^2 < 1\ . \end{aligned}$$

These quantities measure the purity of the state.

34.5.4.7 Ex: Bloch sphere

Check the temporal evolution of the norm of the Bloch vector defined by $\vec{\rho} \equiv (2\ \mathfrak{Re}\ \sigma_+\ ,\ 2\ \mathfrak{Im}\ \sigma_-\ ,\ \sigma_z)$, where the σ_k are the Pauli matrices, for a resonantly excited two-level system with and without spontaneous emission.

Solution:

34.5.4.8 Ex: Atomic beam

An atomic beam is illuminated perpendicular to its propagation direction by (quasi-)monochromatic, collimated laser pulses having the intensity $I = 1\,\mathrm{W/cm^2}$, the wavelength $\lambda = 780\,\mathrm{nm}$, and the duration 200 ns. The laser is tuned to the center of an atomic resonance line ($\Gamma/2\pi = 6\,\mathrm{MHz}$).
a. How does the population of the upper atomic state develop?
b. How does the dynamics change, when the light is detuned by 100 MHz?

Solution: *a. The Rabi frequency follows from,*

$$\Omega = \sqrt{\frac{\sigma_0 \Gamma I}{\hbar\omega}}\ .$$

With $\sigma_0 = 3\frac{\lambda^2}{2\pi}$ we obtain $\Omega/2\pi = 104\,\mathrm{MHz}$. The Rabi frequency is therefore much larger than the decay rate, such that the decay can be neglected at initial times. The solution of the Bloch equations is, therefore,

$$\rho_{22} = \frac{\Omega^2}{\Delta^2 + \Omega^2}\sin^2\frac{\sqrt{\Delta^2 + \Omega^2}}{2}t\ ,$$

that is, at the beginning, the atom is in the ground state, then the population inversion makes some rapid oscillations with maximum amplitude, which relax after a while.

The stationary population finally stabilizes to,

$$\rho_{22}(\infty) = \frac{\Omega^2}{4\Delta^2 + 2\Omega^2 + \Gamma^2} \to \frac{1}{2} \ .$$

When the pulse ends after 200 ns*, the population relaxes exponentially.*
b. When the light frequency is detuned, the generalized Rabi frequency drops to $G = \sqrt{\Delta^2 + \Omega^2} = 2\pi \times 144\,\text{MHz}$*, the amplitude of the Rabi oscillations decreases by half and the average stationary population drops to* $\rho_{22}(\infty) = 0.17$*.*

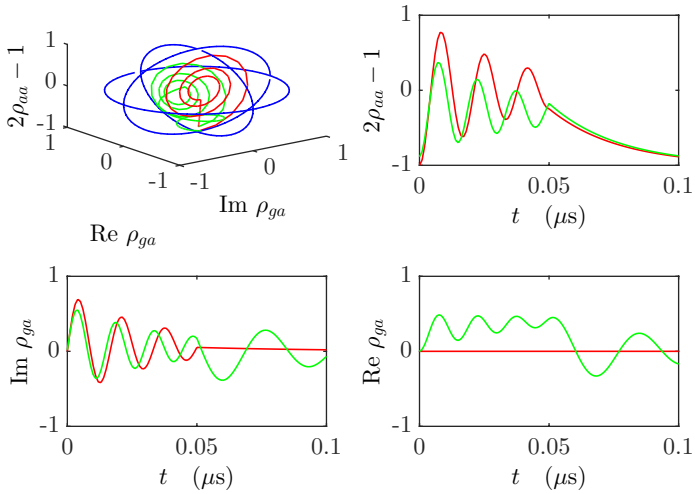

Figure 34.7: (code) Evolution on the sphere of Bloch.

34.5.4.9 Ex: Solution of the Bloch equations for resonant excitation

Derive the solution (34.193) of the Bloch equations with spontaneous emission for resonant excitation.

Solution: *See Exc. 35.6.4.4.*

34.5.4.10 Ex: Solution for the susceptibility

Show that the solution of Eq. (34.202) is given by the result (34.207).

Solution: *We assume weak excitation* $a_1 = 1$*,*

$$\frac{da_2}{dt} = -\imath\Omega^* \cos\omega t e^{\imath\omega_0 t} a_1 - \gamma a_2 \simeq -\imath\Omega^* \cos\omega t e^{\imath\omega_0 t} - \gamma a_2 \ ,$$

and we replace $a_2 \equiv \tilde{a}_2 e^{-\gamma t}$*. Thus the equation (34.202) becomes,*

$$\frac{d\tilde{a}_2}{dt} \simeq -\imath\Omega^* e^{\imath\omega_0 t + \gamma t} \cos\omega t \ .$$

Integrating this equation,

$$\tilde{a}_2 = -\imath\Omega^* \int e^{\imath\omega_0 t+\gamma t}\cos\omega t dt = -\frac{\Omega^*}{2}\left[\frac{e^{\imath(\omega_0+\omega)t+\gamma t}}{\omega_0+\omega+\imath\gamma}+\frac{e^{\imath(\omega_0-\omega)t+\gamma t}}{\omega_0-\omega+\imath\gamma}\right] ,$$

or

$$a_2 = -\frac{\Omega^*}{2}\left[\frac{e^{\imath(\omega_0+\omega)t}}{\omega_0+\omega-\imath\gamma}+\frac{e^{\imath(\omega_0-\omega)t}}{\omega_0-\omega-\imath\gamma}\right] .$$

34.5.4.11 Ex: General form of the master equation

Show that the general form of the master equation: $\dot{\hat{\rho}} = -\frac{\imath}{\hbar}[\hat{H},\hat{\rho}] - \frac{\Gamma}{2}(2\hat{\sigma}\hat{\rho}\hat{\sigma}^+ - \hat{\sigma}^+\hat{\sigma}\hat{\rho} - \hat{\rho}\hat{\sigma}^+\hat{\sigma})$, reproduces the Bloch equations including spontaneous emission.

Solution: *Inserting the Hamiltonian*

$$\hat{H} = \begin{pmatrix} 0 & \frac{1}{2}\hbar\Omega \\ \frac{1}{2}\hbar\Omega & \hbar\Delta \end{pmatrix}$$

into the master equation, we obtain,

$$-\frac{\imath}{\hbar}[\hat{H},\rho] = -\imath\begin{pmatrix} \frac{1}{2}\Omega\rho_{21} - \frac{1}{2}\Omega\rho_{12} & \frac{1}{2}\Omega\rho_{22} - \frac{1}{2}\Omega\rho_{11} - \rho_{12}\Delta \\ \frac{1}{2}\Omega\rho_{11} + \Delta\rho_{21} - \frac{1}{2}\Omega\rho_{22} & \frac{1}{2}\Omega\rho_{12} - \frac{1}{2}\Omega\rho_{21} \end{pmatrix}$$

and

$$\frac{\Gamma}{2}\left(2\sigma\rho\sigma^+ - \sigma^+\sigma\rho - \rho\sigma^+\sigma\right) = \frac{1}{2}\Gamma\begin{pmatrix} 2\rho_{22} & -\rho_{12} \\ -\rho_{21} & -2\rho_{22} \end{pmatrix} .$$

Thereby,

$$\frac{d\rho}{dt} = \begin{pmatrix} -\frac{\imath}{2}\Omega(\rho_{21}-\rho_{12}) + \Gamma\rho_{22} & -\imath\left(\frac{1}{2}\Omega\rho_{22} - \frac{1}{2}\Omega\rho_{11} - \rho_{12}\Delta\right) - \frac{1}{2}\Gamma\rho_{12} \\ -\imath\left(\frac{1}{2}\Omega\rho_{11} + \Delta\rho_{21} - \frac{1}{2}\Omega\rho_{22}\right) - \frac{1}{2}\Gamma\rho_{21} & -\frac{\imath}{2}\Omega(\rho_{12}-\rho_{21}) - \Gamma\rho_{22} \end{pmatrix} ,$$

or,

$$\frac{d}{dt}\begin{pmatrix}\rho_{11}\\ \rho_{22}\\ \rho_{12}\\ \rho_{21}\end{pmatrix} = \begin{pmatrix} 0 & \Gamma & \frac{\imath}{2}\Omega & -\frac{\imath}{2}\Omega \\ 0 & -\Gamma & -\frac{\imath}{2}\Omega & \frac{\imath}{2}\Omega \\ \frac{\imath}{2}\Omega & -\frac{\imath}{2}\Omega & -\frac{1}{2}\Gamma + \imath\Delta & 0 \\ -\frac{\imath}{2}\Omega & \frac{\imath}{2}\Omega & 0 & -\frac{1}{2}\Gamma - \imath\Delta \end{pmatrix}\begin{pmatrix}\rho_{11}\\ \rho_{22}\\ \rho_{12}\\ \rho_{21}\end{pmatrix} .$$

34.5.4.12 Ex: Light-shift

Calculate the light-shift in a driven two-level system from the *effective Hamiltonian*,

$$\hat{H}_{eff} = \begin{pmatrix} 0 & \frac{1}{2}\Omega \\ \frac{1}{2}\Omega & \Delta - \frac{\imath}{2}\Gamma \end{pmatrix} .$$

Prepare spectra of the eigenvalues for $\Gamma/\Omega = 0$, 0.5, and 2.

Solution: *It is easy to show,*

$$\Delta E = \tfrac{1}{2}\left(\Delta - \tfrac{\imath\Gamma}{2}\right) \pm \tfrac{1}{2}\sqrt{\left(\Delta - \tfrac{\imath\Gamma}{2}\right)^2 + \Omega^2}\ .$$

The asymptotes for $|\Delta| \gg \Gamma, \Omega$, *are found to be,*

$$\Delta E \simeq 0, \pm\Delta\ .$$

For $\Gamma \ll \Omega$ *we obtain avoided crossing,*

$$\Delta E \simeq \tfrac{1}{2}\Delta \pm \tfrac{1}{2}\sqrt{\Delta^2 + \Omega^2}\ .$$

And for $\Omega \ll \Gamma$ *we observe dispersive behavior,*

$$\Delta E \simeq \Delta - \tfrac{\imath\Gamma}{2}, \frac{\mp\Omega^2}{4\left(\Delta - \frac{\imath\Gamma}{2}\right)}\ .$$

The figure shows plots of the real and imaginary parts of ΔE.

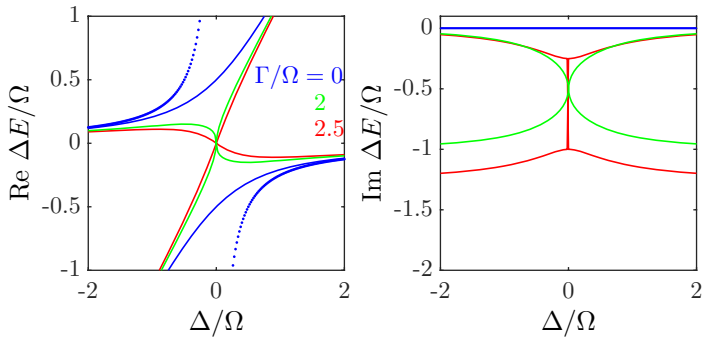

Figure 34.8: (code) Light shifts (dotted) approximated for $\Omega, \Gamma \ll |\Delta|$ and (solid) exact eigenvalues.

34.5.4.13 Ex: Light-shift

In this exercise we study the effect of the dynamic Stark shift (or light shift) of the energy levels of a two-level system $|1\rangle$ and $|2\rangle$ excited by a laser with the Rabi frequency Ω_{12} and the detuning Δ_{12}:
a. From the eigenvalues $E_{1,2}$ of the effective Hamiltonian (34.228) system, find approximations for weak coupling ($\Omega_{12} \ll \Gamma_{12}$) and strong coupling ($\Omega_{12} \gg \Gamma_{12}$). Prepare a graph showing the eigenvalue spectrum (separating the parts $\mathfrak{Re}\ E_{1,2}$ and $\mathfrak{Im}\ E_{1,2}$) as a function of detuning Δ_{12} for various values of Ω_{12}. Also search for approximations valid for large detunings $\Delta_{12} \gg \Gamma_{12}, \Omega_{12}$ and add them to the graph.
The light shift can be experimentally measured in a three-level system in Λ-configuration,

as illustrated in Fig. 34.17(a). To reproduce the experiment by numerical simulations of the Bloch equations (34.279),
b. write the Liouville matrix $\mathcal{M}_{red}$ reduced by the condition to the trace (34.284) and calculate the stationary Bloch vector from equation (34.286) varying the detunings of the two lasers Δ_{12} and Δ_{23}. Choosing the parameters $\Gamma_{23} = \Gamma_{12}$, $\Gamma_{13} = 0.01\Gamma_{12}$, $\Omega_{12} = 2\Gamma_{12}$, and $\Omega_{23} = 0.2\Gamma_{12}$, prepare a 3D curve [similar to Fig. 34.6(a)] of the stationary population $\rho_{22}(\infty)$. Interpret the results.

Solution: *a. The eigenvalues of the effective Hamiltonian (34.228),*

$$E = \tfrac{1}{2}\Lambda \pm \tfrac{1}{2}G_\Gamma \qquad with \qquad \Lambda \equiv \Delta - \tfrac{\imath}{2}\Gamma \qquad and \qquad G_\Gamma \equiv \sqrt{\Omega^2 + \Lambda^2}$$

describe the dynamic Stark shift. Expanding for weak coupling, $\Gamma \gg \Omega$,

$$E = \tfrac{\Lambda}{2} \pm \tfrac{1}{2}\sqrt{\Lambda^2 + \Omega^2} \quad \overset{\Omega \ll \Gamma}{\longrightarrow} \quad \tfrac{\Lambda}{2} \pm \tfrac{\Lambda}{2}\left(1 + \tfrac{\Omega^2}{2\Lambda^2}\right) = \tfrac{\Lambda}{2} \pm \tfrac{\Lambda}{2}(1+s) \ ,$$

with the definition (34.190) of the saturation parameter. Expanding for strong coupling, $\Gamma \ll \Omega$,

$$E = \mathfrak{Re}\ \left(\tfrac{1}{2}\Lambda \pm \tfrac{1}{2}G_\Gamma\right) = \tfrac{1}{2}\Delta \pm \tfrac{1}{2}\sqrt{\sqrt{\tfrac{1}{4}G^4 + \tfrac{1}{8}\Gamma^2\left(G^2 - 2\Omega^2 + \tfrac{1}{8}\Gamma^2\right)} + \tfrac{1}{2}G^2 - \tfrac{1}{8}\Gamma^2}$$
$$\overset{\Omega \gg \Gamma}{\longrightarrow} \quad \tfrac{1}{2}\Delta \pm \tfrac{1}{2}G \mp \tfrac{\Gamma^2\Omega^2}{16G^3} \ ,$$

where G is the common generalized Rabi frequency. For big detunings we can approximate,

$$E \overset{\Gamma \to 0}{\simeq} \tfrac{1}{2}\Delta \pm \tfrac{1}{2}G = \tfrac{1}{2}\Delta \pm \tfrac{\Delta}{2} \mp \tfrac{\Omega^2}{4\Delta} + \dots \ .$$

b. The Liouville matrix can be found in the numerical MATLAB code given in the file 'LM_Bloch_LightShift.m'. Fig. 34.9 shows the results of the simulations. The dynamic Stark splitting $E_1 - E_2$ is a consequence of the breaking of the degeneracy of the states dressed $|1, N\rangle$ and $|2, N-1\rangle$ for strong fields $\Gamma \ll \Omega$. The light shift is the expectation value of the perturbation of the atom by the light field. While the positions of the resonances follow from $\mathfrak{Re}\ (E)$, the linewidth follows from $\mathfrak{Im}\ (E)$. In the weak coupling regime, we observe a dispersive dependence of the energy shift. In the strong coupling regime we observe an avoided crossing.

34.5.4.14 Ex: Line broadening by optical repumping

Check for a two-level system that incoherent optical pumping from the ground into the excited state introduces a transverse decay rate R leading to line broadening.

Solution: *The Liouvillean reads,*

$$\mathcal{M} = \begin{pmatrix} -R & \Gamma & \frac{\imath}{2}\Omega & -\frac{\imath}{2}\Omega \\ R & -\Gamma & -\frac{\imath}{2}\Omega & \frac{\imath}{2}\Omega \\ \frac{\imath}{2}\Omega & -\frac{\imath}{2}\Omega & \imath\Delta - \frac{\Gamma}{2} - \frac{R}{2} & 0 \\ -\frac{\imath}{2}\Omega & \frac{\imath}{2}\Omega & 0 & -\imath\Delta - \frac{\Gamma}{2} - \frac{R}{2} \end{pmatrix} .$$

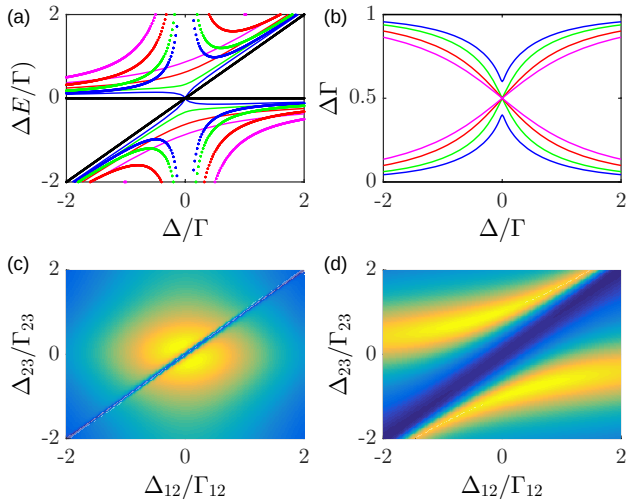

Figure 34.9: (code) (a) Light shift in a two level system varying Ω_{12} between $0.5\Gamma_{12}$ (internal blue curve) and $1\Gamma_{12}$ (external magenta curve). (b) Linewidth for the same parameters as in (a). (c,d) Population of the excited state in a three-level system in Λ-configuration, as shown in Fig. 34.17(a) sweeping the lasers. These figures are discussed later. For (c) $\Omega_{12}/\Gamma_{12} = 0.2$ and for (d) $\Omega_{12}/\Gamma_{12} = 2$.

In steady state,

$$\begin{aligned} 0 &= -R(1-\rho_{22}) + \Gamma\rho_{22} + \tfrac{\imath}{2}\Omega\rho_{12} - \tfrac{\imath}{2}\Omega\rho_{21} \\ 0 &= \tfrac{\imath}{2}\Omega(1-\rho_{22}) - \tfrac{\imath}{2}\Omega\rho_{22} + \left(\imath\Delta - \tfrac{\Gamma}{2} - \tfrac{R}{2}\right)\rho_{12} \ , \end{aligned}$$

so that,

$$\rho_{22} = \frac{\imath\Omega}{2(R+\Gamma)}(\rho_{21}-\rho_{12}) + \frac{R}{R+\Gamma} \qquad \textit{and} \qquad \rho_{12} = \frac{\imath\Omega}{2\imath\Delta - \Gamma - R}(2\rho_{22}-1) \ ,$$

yielding,

$$\rho_{22} = \frac{\frac{1}{4}\Omega^2 + \frac{1}{1+\Gamma/R}\left[\Delta^2 + \frac{1}{4}(\Gamma+R)^2\right]}{\Delta^2 + \frac{1}{2}\Omega^2 + \frac{1}{4}(\Gamma+R)^2} \ .$$

Some limits,

$$\begin{aligned} \rho_{22} &\xrightarrow{R=0} \frac{\frac{1}{4}\Omega^2}{\Delta^2 + \frac{1}{2}\Omega^2 + \frac{1}{4}\Gamma^2} \\ &\xrightarrow{\Gamma=0} 1 - \frac{\frac{1}{4}\Omega^2}{\Delta^2 + \frac{1}{2}\Omega^2 + \frac{1}{4}R^2} \\ &\xrightarrow{\Gamma=R} \frac{1}{2} \ . \end{aligned}$$

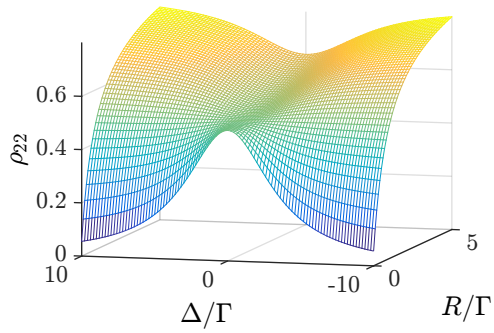

Figure 34.10: (code) Upper state population spectra for varied repumping rates.

34.6 Line broadening mechanisms

The resolution of atomic spectroscopy is generally limited by several perturbative effects, many of them originating in the atomic motion. They manifest themselves as broadening and/or shifts of atomic resonances. Free atoms, as well as atoms confined in potentials, have kinetic energy and evolve on extended phase space trajectories. If the spatial localization is less than the effective cross section of the exciting laser beam, then the interaction time is limited and the resonance lines are broadened by the Fourier effect in a process called *transit time broadening*, and the efficiency of fluorescence collection is reduced. The same happens with the *Doppler effect*: Only those atoms that have a specific velocity along the optical axis defined by the laser beam can interact. Free as well as confined atoms can only scatter when they are in specific cells of the phase space.

There are two different fundamental types of broadening. The so-called *homogeneous broadening* affects all atoms in the same way regardless of their positions or velocities. It usually gives rise to Lorentzian line profiles and can be included in the Bloch equations. It correspond to an acceleration of the relaxation. Examples are the natural linewidth, saturation broadening, and collision broadening.

The so-called *inhomogeneous broadening* is due to a displacement of atomic levels, which may be different for each atom. Averaging over a large sample of atoms, the displacements generate an *effective* broadening usually with a Gaussian line profile. It *can not* be included in the single-atom Bloch equations, but only as an average over all trajectories of all atoms. It does not correspond to an accelerated relaxation. Inhomogeneous broadening is often due to external perturbations, e.g., Doppler broadening and broadening due to temporal fluctuations or spatial inhomogeneities of external electric or magnetic fields. In Exc. 34.6.7.1 we calculate the optical density of atomic clouds. In Exc. 34.6.7.2 we present a spectroscopic technique bypassing the Doppler broadening called *Doppler-free spectroscopy* and calculate the *Lamb-dip* profile. Finally, in Exc. 34.6.7.3, we discuss a cooling technique allowing for the reduction of Doppler broadening, called *Zeeman slower*.

34.6.1 Saturation broadening

Eq. (34.189) shows that when the power of the incident light increases, the population of the excited state saturates at a limit value of $\rho_{22} = \frac{1}{2}$. The *saturation parameter* defined in (34.190) measures the degree of saturation. When the narrowband light source is tuned to resonance, the saturation parameter is basically a measure for the ratio between the stimulated population transfer rate Ω and the spontaneous decay rate A_{21}. We can rewrite the stationary population of the excited level as in (34.191). In resonance and with the saturation parameter $s = 1$, we obtain

$$\Omega = \tfrac{1}{\sqrt{2}}\Gamma \ . \tag{34.230}$$

We can use equation (34.230) to define the *saturation intensity* I_{sat} for an atom with the transition dipole d_{12}. From Eq. (22.41) we have,

$$\mathcal{E}_0 = \sqrt{\frac{2\bar{I}}{\varepsilon_0 c}} \ . \tag{34.231}$$

Therefore, using the definition of the Rabi frequency, $\hbar\Omega = d_{12}\mathcal{E}_0$, and the relationship between d_{12} and Γ given by Eq. (34.41), we have [19],

$$\boxed{I_{sat} = \frac{g_1}{g_2}\frac{2\pi^2 c\hbar}{3\lambda_0^3}\Gamma} \ , \tag{34.232}$$

taking into account the degeneracies g_j of the levels. In Excs. 34.6.7.4 and 34.6.7.5 we calculate the *saturation intensity* of popular atomic transitions.

34.6.2 Collision broadening

The theory of atomic collisions covers a large area of research, including elastic and inelastic, reactive and ionizing processes. In low-pressure gases at room temperature or hotter we need only consider the simpler processes: long-range van der Waals interactions that result in *elastic collisions*. The 'low pressure' criterion requires that the average free path between collisions be greater than any linear dimension of the gas volume. Under these conditions, collisions can be modeled with straight trajectories, along which the interaction time is short and the time between collisions is long in comparison with the radiative lifetime of the excited atomic state. Then, the impact of a collision on the emission of a radiating atom causes a loss of coherence due to a phase interruption of the excited state atomic wavefunction. The term 'elastic' means that the collision does not disturb the populations of the internal states, so we only need to consider the off-diagonal elements of the density matrix,

$$\frac{d\rho_{12}}{dt} = \imath\frac{\Omega_0}{2}e^{\imath(\omega-\omega_0)t}(\rho_{11} - \rho_{22}) - \gamma'\rho_{12} \ , \tag{34.233}$$

where γ' is the sum of the spontaneous emission γ and the collision rate γ_{col},

$$\boxed{\gamma' = \gamma + \gamma_{col}} \ . \tag{34.234}$$

[19] Some authors define the saturation for $s = 2$, as happens when $\Omega = \Gamma$.

The inverse of the collision rate is simply the time between phase interruptions or the time between collisions. Now, for collisions between hard cores of atoms of mass m (with reduced mass $m_{red} = m/2$) and with radius ρ in a gas with density n consisting of a single species, a standard analysis based on the kinetic theory of dilute gases shows that the time between collisions is given by the *collision rate*,

$$\gamma_{col} = \tau_{col}^{-1} = \sigma n \bar{v} \ , \tag{34.235}$$

where $\bar{v} = \sqrt{\frac{8k_BT}{\pi m_{red}}}$ is the average collision velocity in a homogeneous gas at the temperature T and $\sigma = \sqrt{8}\pi\rho^2$ the collision cross section. Thereby,

$$\boxed{\gamma_{col} = \frac{8\rho^2 n}{\sqrt{m_{red}/\pi k_B T}}} \ . \tag{34.236}$$

We can now relate this simple result of gas kinetics to the phase interruption rate by reinterpreting the meaning of the *collision radius*. When an excited atom propagating through space suffers a collision, the long-range interaction will produce a time-dependent perturbation of the energy levels of the radiating atom and a phase shift in the radiation,

$$\eta = \int_{-\infty}^{\infty} [\omega(t) - \omega_0] dt = \int_{-\infty}^{\infty} \Delta\omega(t) dt \ . \tag{34.237}$$

The long-range van der Waals interaction is expressed by,

$$\Delta E = \hbar\omega = \frac{C_n}{[b^2 + (vt)^2]^{n/2}} \ , \tag{34.238}$$

where b is the impact parameter of the collision trajectory and v the collision velocity. The phase shift is then

$$\eta = \frac{1}{\hbar} \int_{-\infty}^{\infty} \frac{C_n}{[b^2 + (vt)^2]^{n/2}} dt \ . \tag{34.239}$$

The integral is easily assessed for the two most frequent cases: non-resonant van der Waals interactions $n = 6$ and resonant van der Waals interactions $n = 3$. The phase shifts are,

$$\eta_6(b) = \frac{2\pi}{3\hbar} \frac{C_6}{b_6^5 v} \qquad \text{and} \qquad \eta_3(b) = \frac{4\pi}{3\sqrt{3}\hbar} \frac{C_3}{b_3^2 v} \ . \tag{34.240}$$

Now, if instead of using the *hard core approximation*, we define a collision as an encounter causing a phase shift of at least 1 radians, we have a new condition for the collision radius,

$$b_6 = \left(\frac{2\pi}{3\hbar} \frac{C_6}{v} \right)^{1/5} \qquad \text{and} \qquad b_3 = \left(\frac{4\pi}{3\sqrt{3}\hbar} \frac{C_3}{v} \right)^{1/2} \ . \tag{34.241}$$

Replacing these collision radiuses for the radius ρ in Eq. (34.236) and inserting the average collision velocity, we find the collision rate,

$$\gamma_{c6} = 4n \left(\frac{\sqrt{2}\pi^2 C_6}{3\hbar} \right)^{2/5} \left(\frac{4\pi k_B T}{\mu} \right) \qquad \text{and} \qquad \gamma_{c3} = 4n \left(\frac{2}{3} \right)^{3/2} \left(\frac{\pi^2 C_3}{\hbar} \right)^{3/10} \ . \tag{34.242}$$

Substituting the generalized γ' of (34.234) for γ in the Bloch equations (34.188), we find the stationary solutions,

$$\rho_{22} = \frac{\frac{1}{4}\frac{\gamma'}{\gamma}|\Omega|^2}{\Delta^2 + \frac{1}{2}\frac{\gamma'}{\gamma}|\Omega|^2 + \gamma'^2} \qquad \text{and} \qquad \rho_{12} = e^{\imath(\omega-\omega_0)t}\frac{\frac{1}{2}\Omega(\Delta - \imath\gamma')}{\Delta^2 + \frac{1}{2}\frac{\gamma'}{\gamma}|\Omega|^2 + \gamma'^2} \ . \quad (34.243)$$

The effective linewidth (radiative and collisions) is,

$$\Gamma'_{\text{eff}} = 2\sqrt{\gamma'^2 + \tfrac{1}{2}\tfrac{\gamma'}{\gamma}|\Omega|^2} \ . \quad (34.244)$$

When the excitation is sufficiently weak, so that power broadening can be neglected in comparison to collision broadening, the second term can be discarded,

$$\Gamma'_{\text{eff}} = 2(\gamma + \gamma_{col}) \ . \quad (34.245)$$

The equations (34.189) and (34.245) express the linewidths in the limits of dominating power and collision broadening, respectively. Note that the susceptibility, absorption coefficient, and absorption cross-section retain their Lorentzian profile, but with a larger width due to collisions. Since each atom is subject to the same broadening mechanism, the broadening is homogeneous. Solve Excs. 34.6.7.6.

34.6.3 Doppler broadening

The *Doppler broadening* is simply the apparent frequency distribution of a sample of radiating atoms at temperature T. The contribution of each atom to the radiation appears detuned by the *Doppler shift* because of its velocity. The frequency shift for a non-relativistically moving particle is $\omega = \omega_0/(1 - \frac{v}{c})$, such that,

$$\Delta \equiv \omega - \omega_0 \simeq \omega_0 \frac{v}{c} = \mathbf{k}\cdot\mathbf{v} = kv_z \ , \quad (34.246)$$

where $\mathbf{k}$ is the wavevector of the light and $\mathbf{v}$ is the velocity of the atom. This distribution of Doppler shifts of a gaseous sample in thermal equilibrium follows the probability distribution of velocities,

$$P(v_z)dv_z \propto e^{-mv_z^2/2k_BT}dv_z = e^{-mc^2\Delta^2/2\omega_0^2 k_BT}\frac{c}{\omega_0}d\omega \ . \quad (34.247)$$

This frequency distribution is a Gaussian centered at $\omega = \omega_0$ and with the width,

$$\text{FWHM} = 2\omega_0\left(\frac{2k_BT\ln 2}{mc^2}\right)^2 \ . \quad (34.248)$$

A measure of the width is also the *standard deviation*,

$$2\sigma = \frac{2\omega_0}{c}\sqrt{\frac{k_BT}{m}} = \frac{\text{FWHM}}{1.177} \ . \quad (34.249)$$

From Eq. (34.247) we can see that the line profile is,

$$\mathcal{D}(\omega - \omega_0) \equiv \frac{1}{\sqrt{2\pi}}\frac{m}{k_BT}e^{-(\omega-\omega_0)^2/2\sigma^2}d\omega \ . \quad (34.250)$$

The profile compares with the Lorentzian profile Eq. (22.73) associated with natural, power, or collision broadening. Doppler broadening is a property of the atomic ensemble, each atom suffering a unique but different displacement than the other atoms. Hence, it is called *inhomogeneous broadening*.

The Liouville equation (34.140) used to derive the Bloch equations assumes immobile atoms. However, we can easily apply the Galilei transformation to a system, where the atoms move with the given velocity $\mathbf{v}$,

$$(\partial_t + \mathbf{v}\cdot\nabla)\hat{\rho}(\mathbf{r},t) = -\tfrac{\imath}{\hbar}[\hat{H},\hat{\rho}(\mathbf{r},t)] \ . \tag{34.251}$$

Since the light fields propagate as $e^{\imath(\omega t - \mathbf{k}\cdot\mathbf{r})}$, the solution of the above equation simply follows from the immobile solution with the substitution $\Delta \to \Delta - \mathbf{k}\cdot\mathbf{v}$. For a cloud obeying Maxwell's velocity distribution, $P(v) \sim e^{-mv^2 k_B T}$,

$$\bar{\rho}(\Delta) = \frac{1}{\sqrt{2\pi}\delta}\int_{\mathbb{R}} e^{-(\mathbf{k}\cdot\mathbf{v})^2/2\delta^2}\hat{\rho}(\Delta - \mathbf{k}\cdot\mathbf{v})d(\mathbf{k}\cdot\mathbf{v}) \ . \tag{34.252}$$

The average of the density operator over all velocities, $\bar{\rho}$, therefore follows as the convolution of the density operator ρ (obtained as the solution of the Bloch equation) and the Gaussian function $G(\Delta) = (2\pi\delta^2)^{-1/2}e^{-\Delta^2/2\delta^2}$,

$$\boxed{\bar{\rho}(\Delta) = (G \star \hat{\rho})(\Delta)} \ . \tag{34.253}$$

34.6.4 Voigt profile

It is clear that in many practical circumstances homogeneous and inhomogeneous processes simultaneously contribute to the broadening of lines. In these cases, we can consider that the radiation of each atom, homogeneously broadened by phase-interruption processes (such as spontaneous emission or collisions), is displaced by the Doppler effect within the Maxwell-Boltzmann distribution corresponding to the temperature T. The profile of the gaseous sample, therefore, is a convolution of homogeneous and inhomogeneous profiles. The resulting profile is called *Voigt profile*:

$$\begin{aligned} V(\omega-\omega_0) &= \int_{-\infty}^{\infty}\mathcal{L}(\omega-\omega_0-\omega')\mathcal{D}(\omega-\omega_0)d\omega' \\ &= \frac{\gamma}{2\sigma\sqrt{2\pi}}\int_{-\infty}^{\infty}\frac{e^{-(\omega-\omega_0)^2/2\sigma^2}}{(\omega-\omega_0-\omega')^2+(\gamma/2)^2}d\omega' \ . \end{aligned} \tag{34.254}$$

This integral has no analytical solution, but it is easy to solve numerically. Resolve Excs. 34.6.7.7, 34.6.7.8, and 34.6.7.9.

34.6.5 Bloch equations with phase modulation

In some situations, the atom vibrates thus producing an oscillating Doppler shift. Also, external magnetic fields or oscillating laser frequencies can produce this effect. We incorporate this temporal modulation (frequency Ω_a) of the light frequency shifts,

induced by the Doppler effect, into the optical Bloch equations via the substitution [1170],

$$\Delta_{ij} \to \Delta_{ij} + \mathbf{k}_{ij} \cdot \mathbf{v} \ \cos \Omega_a t \ . \tag{34.255}$$

The Bloch equations can then be brought into the form,

$$\dot{\hat{\rho}} = (\mathbf{L} + 2\mathbf{X} \ \cos \Omega_a t)\hat{\rho} + \mathbf{b} \ , \tag{34.256}$$

where the matrix $\mathbf{X}$ contains the modulation index of the atomic motion $\mathbf{k}_{ij}\mathbf{v}$. The stationary solution of the differential equation, averaged over the time of an oscillation period, can be expressed as an infinite continuous fraction:

$$\hat{\rho}(\infty) = -(\mathbf{L} + \mathbf{S}^+ + \mathbf{S}^-)^{-1}\mathbf{b} \tag{34.257}$$
$$\text{where} \quad \mathbf{S}^{\pm} = -\mathbf{X}\frac{1}{\mathbf{L} \pm \imath\Omega_a \mathbf{1} - \mathbf{X}\frac{1}{\mathbf{L}\pm\imath\Omega_a\mathbf{1}-\mathbf{X}\frac{1}{\cdots}\mathbf{X}}\mathbf{X}} \ .$$

This solution replicates the correct excitation spectra even for a multilevel system.

Let us be more specific for a two-level system. In this case the Hamiltonian is given by $\hat{H}_{int} = \frac{1}{2}\hbar\Omega e^{-\imath[\omega t - \mathbf{k}\cdot\mathbf{v}/\Omega_a \ \sin \Omega_a t]}$, such that the Bloch equation is,

$$\begin{pmatrix} \dot{\rho}_{22} \\ \dot{\rho}_{12} \\ \dot{\rho}_{21} \end{pmatrix} = \left[\begin{pmatrix} -\Gamma & -\frac{\imath}{2}\Omega & \frac{\imath}{2}\Omega \\ -\frac{\imath}{2}\Omega & -\Lambda & 0 \\ \frac{\imath}{2}\Omega & 0 & -\Lambda^* \end{pmatrix} + 2\cos\Omega_a t \begin{pmatrix} 0 & 0 & 0 \\ 0 & -\frac{\imath}{2}kv & 0 \\ 0 & 0 & \frac{\imath}{2}kv \end{pmatrix} \right] \begin{pmatrix} \rho_{22} \\ \rho_{12} \\ \rho_{21} \end{pmatrix} + \begin{pmatrix} 0 \\ \frac{\imath}{2}\Omega \\ -\frac{\imath}{2}\Omega \end{pmatrix} \ . \tag{34.258}$$

We look for the stationary solution by expanding $\hat{\rho} = \sum_{n=-\infty}^{\infty} \hat{\rho}_n e^{-\imath n\Omega_a t}$, letting $\dot{\hat{\rho}}_n = 0$, and projecting on $e^{-\imath n\Omega_a t}$ via,

$$(\mathbf{L} + \imath n\Omega_a \mathbf{1})\hat{\rho}_n + \mathbf{X}(\hat{\rho}_{n+1} + \hat{\rho}_{n-1}) + \mathbf{b}\delta_{n0} = 0 \ . \tag{34.259}$$

Now we define $\hat{\rho}_{n\pm1} = \mathbf{S}^{\pm}\hat{\rho}_n$ for $n \gtrless 0$. Then, equation (34.259) becomes,

$$\hat{\rho}_0 = -[\mathbf{L} + \mathbf{X}(\mathbf{S}_0^+ + \mathbf{S}_0^-)]^{-1}\mathbf{b} \qquad \text{for} \qquad n = 0, \tag{34.260}$$
$$\mathbf{S}^{\pm}_{n\mp1} = -[\mathbf{L} + \imath n\Omega_a \mathbf{1} + \mathbf{X}\mathbf{S}^{\pm}_n]^{-1}\mathbf{b} \qquad \text{for} \qquad n \gtrless 0 \ .$$

Substituting the equation below into the equation above,

$$\hat{\rho}_0 = -\left[\mathbf{L} + \left(\frac{-\mathbf{X}|}{|\mathbf{L} + \imath\Omega_a} + \frac{-\mathbf{X}|}{|\mathbf{L} + 2\imath\Omega_a} + \dots\right) + \left(\frac{-\mathbf{X}|}{|\mathbf{L} + \imath\Omega_a} + \frac{-\mathbf{X}|}{|\mathbf{L} + 2\imath\Omega_a} + \dots\right)\right]^{-1}\mathbf{b} \ . \tag{34.261}$$

34.6.6 Two-level system interacting with several light fields

When several light fields excite a two-level atom,

$$\hat{H}_{int} = \frac{\hbar\Omega_a}{2}e^{-\imath\omega_a t} + \frac{\hbar\Omega_b}{2}e^{-\imath\omega_b t} \ , \tag{34.262}$$

the transformation into a co-rotating frame is impossible. The density operator must then be expanded into a Taylor series in the field amplitudes and a Fourier series in

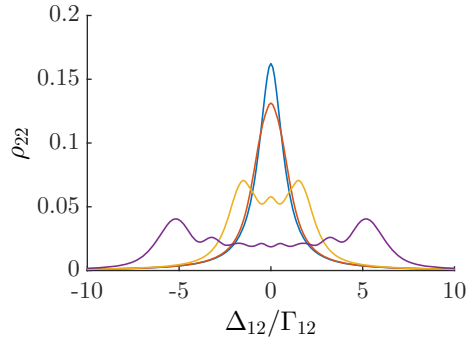

Figure 34.11: (code) Spectral broadening due to the periodic movement of the atom.

the laser frequencies, as well as the sum and difference frequencies:

$$\begin{aligned}\rho_{12}(t) = &[\rho_{12}^{(1)}(\omega_a) + \rho_{12}^{(3)}(\omega_a) + ...]e^{-\imath\omega_a t} \\ &+ [\rho_{12}^{(1)}(\omega_b) + \rho_{12}^{(3)}(\omega_b) + ...]e^{-\imath\omega_b t} \\ &+ [\rho_{12}^{(3)}(2\omega_a - \omega_b) + ...]e^{-\imath(2\omega_a-\omega_b)t} + ...\end{aligned} \tag{34.263}$$

and

$$\begin{aligned}\rho_{22}(t) - \rho_{11}(t) \equiv w_{12}(t) = &[-1 + w_{12}^{(2)}(0)] \\ &+ [w_{12}^{(2)}(\omega_a - \omega_b) + ...]e^{-\imath(\omega_a-\omega_b)t} \\ &+ [w_{12}^{(2)}(\omega_b - \omega_a) + ...]e^{-\imath(\omega_b-\omega_a)t} + ... \ .\end{aligned} \tag{34.264}$$

The solution of the Bloch equations is obtained in successive perturbation steps. The zero order in (34.264) is inserted into the Bloch equation,

$$\dot{\hat{\rho}} = -\frac{\imath}{\hbar}[\hat{H}_{int}, \hat{\rho}] \ , \tag{34.265}$$

and form this the first order in (34.263) is obtained. This in turn is inserted again into the Bloch equation, and so on. In this way the components $\rho_{12}^{(m)}(\omega_x)$ and $w_{12}^{(m)}(\omega_x)$ are calculated and from this the density operator $\hat{\rho}(t)$.

34.6.7 Exercises

34.6.7.1 Ex: Optical density of a cold cloud

The cross section of an atom with the resonant frequency ω_0 moving with velocity v and irradiated by a laser beam of frequency ω is,

$$\sigma(v) = \frac{6\pi}{k^2}\frac{\Gamma^2}{4(\omega - \omega_0 - kv)^2 + \Gamma^2} \ .$$

The normalized one-dimensional Maxwell distribution,

$$\rho(v)dv = \sqrt{\frac{m}{2\pi k_B T}}e^{-mv^2/2k_B T}dv \ .$$

a. Calculate the absorption profile of the resonance line at 461 nm ($\Gamma_{461} = (2\pi)\ 30.5$ MHz) of a strontium gas cooled to the Doppler limit ($k_B T_D = \hbar\Gamma$) of this transition.
b. Calculate the absorption profile of the resonance line at 689 nm ($\Gamma_{689} = (2\pi)\ 7.6$ kHz) of a strontium gas cooled to the Doppler limit of the transition at 461 nm.
c. Compare the optical densities in case of resonance.
Help: To evaluate the convolution integral approximate the narrower distribution by a δ-function maintaining the integral over the distribution normalized.

Solution: *The optical density with Doppler broadening is,*

$$\begin{aligned} OD(T,\omega) &= Ln(T)(\sigma \star \rho)(\omega) = Ln(T)\int_{-\infty}^{\infty}\sigma(v)\rho(v)dv \\ &= L\frac{P}{k_B T}\sqrt{\frac{m}{2\pi k_B T}}\frac{6\pi}{k^2}\int_{-\infty}^{\infty} e^{-mv^2/2k_B T}\frac{\Gamma^2}{4(\omega-\omega_0-kv)^2+\Gamma^2}dv\ . \end{aligned}$$

The Doppler limit yields,

$$k\bar{v} = k\sqrt{\frac{k_B T_D}{m}} = k\sqrt{\frac{\hbar\Gamma}{m}}\ ,$$

where $\bar{v} = \sqrt{k_B T/m}$ is the mean atomic velocity (or the rms*-width) of the Maxwell distribution.*
a. For the transition at 461 nm we get $k\bar{v} = 5.2$ MHz, which is much narrower than the natural linewidth. Therefore, we can approximate the Gaussian by the δ-distribution:

$$\int_{-\infty}^{\infty} e^{-mv^2/2k_B T}dv = \sqrt{\frac{2k_B T}{m}}\int_{-\infty}^{\infty} e^{-x^2}dx = \sqrt{\frac{2\pi k_B T}{m}} = \int_{-\infty}^{\infty}\sqrt{\frac{2\pi k_B T}{m}}\delta(kv)d(kv)\ .$$

Hence,

$$\begin{aligned} OD_{461}(T_D,\omega) &= Ln(T_D)\sqrt{\frac{m}{2\pi k_B T_D}}\frac{6\pi}{k^2}\int_{-\infty}^{\infty}\frac{\Gamma_{461}^2}{4(\omega-\omega_0-kv)^2+\Gamma_{461}^2}\sqrt{\frac{2\pi k_B T_D}{m}}\delta(kv)d(kv) \\ &= Ln(T_D)\frac{6\pi}{k^2}\frac{\Gamma_{461}^2}{4(\omega-\omega_0)^2+\Gamma_{461}^2}\ , \end{aligned}$$

which means that we retrieve the default expression for optical density,

$$OD_{461}(0,\omega) = Ln(T_D)\sigma(T_D)\ .$$

b. The natural width of the transition at 689 nm is much narrower than the Doppler width. Therefore, we can approximate the Lorentzian by the δ-distribution:

$$\int_{-\infty}^{\infty}\frac{\Gamma_{689}^2}{4(\omega-\omega_0-kv)^2+\Gamma_{689}^2}dv = \frac{\Gamma_{689}}{k}\int_{-\infty}^{\infty}\frac{dx}{1+4x^2} = \frac{\pi\Gamma_{689}}{2k} = \int_{-\infty}^{\infty}\frac{\pi\Gamma_{689}}{2k}\delta(\omega-\omega_0-kv)d(kv)\ .$$

Hence,

$$\begin{aligned} OD_{689}(T_D,\omega) &= Ln(T_D)\sqrt{\frac{m}{2\pi k_B T_D}}\frac{6\pi}{k^2}\int_{-\infty}^{\infty} e^{-mv^2/2k_B T_D}\frac{\pi\Gamma_{689}}{2k}\delta(\omega-\omega_0-kv)d(kv) \\ &= Ln(T_D)\sqrt{\frac{m}{2\pi k_B T_D}}\frac{6\pi}{k^2}\frac{\pi\Gamma_{689}}{2k}e^{-m(\omega-\omega_0)^2/2k_B T_D k^2}\ . \end{aligned}$$

In resonance,

$$OD_{689}(T_D, \omega_0) = Ln(T_D)\sqrt{\frac{\pi}{2}}\frac{\sigma_0 \Gamma_{689}}{2k\bar{v}_D} \ ,$$

The fraction $\Gamma_{689}/2k\bar{v}_D$ *can be interpreted as the spectral overlap between the Lorentzian-shaped absorption profile and the Maxwell distribution.*
c. The ratio is,

$$\frac{OD_{689}(T_D, \omega_0)}{OD_{461}(T_D, \omega_0)} = \sqrt{\frac{\pi}{8}}\frac{\Gamma_{689}}{k\bar{v}_D} \ .$$

34.6.7.2 Ex: Saturated absorption spectroscopy

Saturated absorption spectroscopy is a technique to avoid Doppler broadening. The setup, shown in Fig. 34.12, consists of a cell filled with a rubidium gas (resonance frequency $\omega_0 = ck = 2\pi c/780\,\text{nm}$, decay rate $\Gamma = (2\pi)\ 6\,\text{MHz}$) and two laser beams with the same frequency ω but counterpropagating, one called saturation and another called probe. The one-dimensional and normalized Maxwell velocity distribution is,

$$\rho(v)dv = \sqrt{\frac{m}{2\pi k_B T}} e^{-mv^2/2k_B T} dv \ .$$

The gas is at $T = 300\,\text{K}$, where the partial pressure of rubidium is around $P = 10^{-1}\,\text{mbar}$. The length of the cell is $L = 10\,\text{cm}$. The probe laser has an intensity below the saturation limit, such that the cross section of an atom moving at velocity v is,

$$\sigma(v) = \frac{6\pi}{k^2}\frac{\Gamma^2}{4(\omega - \omega_0 - kv)^2 + \Gamma^2} \ .$$

The saturation laser has high intensity. We suppose here, $\Omega \equiv 10\Gamma$, where Ω is the frequency of Rabi caused by the saturation beam. In this way it creates a population N_e of atoms in the excited state. As this population lacks in the ground state, $N_g = N - N_e$, the absorption of the probe beam is decreased by the factor,

$$\frac{N_e}{N} = \frac{\Omega^2}{4(\omega - \omega_0 + kv)^2 + 2\Omega^2 + \Gamma^2} \ .$$

To obtain the laser probe transmission spectrum, first calculate the optical density, $OD(\omega) = Ln\int_{-\infty}^{\infty}\frac{N_g - N_e}{N}\sigma(v)\rho(v)dv$ where n is the gas density, and then the intensity of light transmitted through the cell using the Lambert-Beer law $\frac{I}{I_0} = e^{-OD}$.

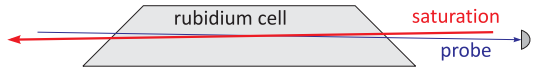

Figure 34.12: Scheme of saturation spectroscopy.

Solution: *The optical density with Doppler broadening is,*

$$\begin{aligned} OD(T,\omega) &= Ln(T)\int_{-\infty}^{\infty}\tfrac{N-2N_e}{N}\sigma(v)\rho(v)dv \\ &= L\frac{P}{k_BT}\sqrt{\frac{m}{2\pi k_BT}}\frac{6\pi}{k^2}\int_{-\infty}^{\infty}\left(1-\frac{2\Omega^2}{4(\Delta+kv)^2+2\Omega^2+\Gamma^2}\right)\times \\ &\qquad\times\frac{\Gamma^2}{4(\Delta-kv)^2+\Gamma^2}e^{-mv^2/2k_BT}dv\ , \end{aligned}$$

with $\Delta\equiv\omega-\omega_0$. The widths of the three velocity distributions are, respectively,

$$\begin{aligned} k\Delta v &= \sqrt{\tfrac{1}{2}\Omega^2+\tfrac{1}{4}\Gamma^2}\approx(2\pi)\ 68\,\text{MHz} \qquad \textit{for the saturation beam} \\ k\bar{v} &= k\sqrt{\tfrac{k_BT}{m}}\approx(2\pi)\ 217\,\text{MHz} \qquad \textit{for Doppler broadening} \\ k\Delta v &= \tfrac{1}{2}\Gamma\approx(2\pi)\ 3\,\text{MHz} \qquad \textit{for the probe beam} \end{aligned}$$

where $\bar{v}=\sqrt{k_BT/m}$ is the mean atomic velocity (or the rms width) of the Maxwell distribution. Since the probe beam spectral width is much smaller, we can substitute

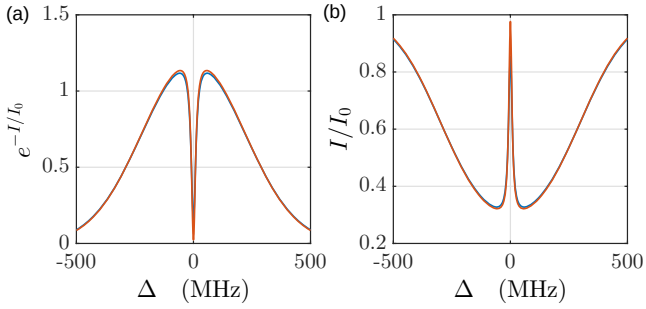

Figure 34.13: (code) (a) Optical density and (b) absorption. (Blue) Integral formula and (green) high temperature approach and high saturation.

a δ-function,

$$\frac{\Gamma^2}{4(\Delta-kv)^2+\Gamma^2}\longrightarrow\frac{\pi\Gamma}{2}\delta(\Delta-kv)\ ,$$

giving,

$$\begin{aligned} OD(T,\omega) &\simeq L\frac{P}{k_BT}\sqrt{\frac{m}{2\pi k_BT}}\frac{6\pi}{k^3}\int_{-\infty}^{\infty}\left(1-2\frac{2\Omega^2}{4(\Delta+kv)^2+2\Omega^2+\Gamma^2}\right)\times \\ &\qquad\times\frac{\pi\Gamma}{2}\delta(\Delta-kv)e^{-mv^2/2k_BT}dkv \\ &= L\frac{P}{k_BT}\sqrt{\frac{m}{2\pi k_BT}}\frac{6\pi}{k^3}\frac{\pi\Gamma}{2}\left(1-\frac{4\Omega^2}{8\Delta^2+2\Omega^2+\Gamma^2}\right)e^{-m(\Delta/k)^2/2k_BT}\ . \end{aligned}$$

34.6.7.3 Ex: The Zeeman slower

Consider a tube through which passes a collimated beam of atoms, all having the same initial velocity $v = v_0$. In the opposite direction to the atomic motion travels a collimated and monochromatic light beam with frequency $\omega = kc$. The absorption rate for photons by an atom has a Lorentzian profile, which can be written as:

$$W(v) = \frac{W_0}{2\pi} \frac{\Gamma^2}{(\omega - \omega_0 + kv)^2 + (\Gamma/2)^2} \ ,$$

where Γ is the natural width of the spectral line at ω_0, and W_0 is a constant. The frequency of the light is tuned in order to compensate for the Doppler effect at the beginning of the tube, $\delta = \omega - \omega_0 = -kv_0$ (the light is tuned to the red of the resonance). As the atoms are decelerated, they cease to be resonant with the light beam and fail to absorb photons. This can be avoided by employing the so-called Zeeman-slowing technique, which compensates for the effect using the Zeeman-shift induced by magnetic fields. In this exercise, we will study what happens if this technique is not used.

a. For an atom with velocity v, write an expression for the mean travel distance

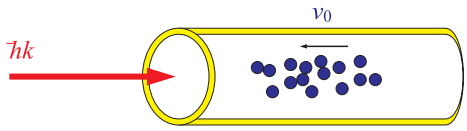

Figure 34.14: Zeeman slower scheme.

$\Delta s(v)$ before it absorbs a photon as a function of the parameters Γ, v_0, k, and W_0. (The mean time it takes to absorb a photon is $W(v)^{-1}$).

b. The velocity of the atom as a function of the number of absorbed photons is $v_n = v_0 - n\frac{\hbar k}{m}$, the second term being the recoil due to the absorption of a single photon. The average total distance traveled by an atom after absorbing N photons is estimated by:

$$S = \sum_{n=0}^{N} \Delta s(v_n) \simeq \int_0^N \Delta s(v_n) dn \ .$$

Calculate the average distance required for the atoms to be slowed down to $v = 0$ (ignoring the Doppler limit). Write the expression as a function of Γ, v_0, k, and W_0.
Help: Do the following change of variables to simplify the evaluation of the integral: $n \to v$.

c. Typically, the detuning of the light, $|\delta| = kv_0$, is much larger than the natural width Γ of the transition. What happens to S in the limit when $kv_0 \gg \Gamma$? Interpret this result, justifying the need for the Zeeman-slowing technique.

Solution: *a. Between two consecutive photon absorptions, the velocity of the atoms is constant. Therefore, the average distance traveled is simply the velocity times the average time:*

$$\Delta s(v) = v \frac{1}{W(v)} = \frac{2\pi v}{W_0 \Gamma^2} [(\omega - \omega_0 + kv)^2 + (\Gamma/2)^2] \ .$$

Using that $\omega - \omega_0 = -kv_0$*:*

$$\Delta s(v) = \frac{2\pi v}{W_0\Gamma^2}[k^2(v-v_0)^2 + (\Gamma/2)^2] \ .$$

b. We must calculate the shown integral for a number of photons N *such that the final velocity is zero. For this, we make the suggested variable change:*

$$v = v_0 - n\frac{\hbar k}{m}$$
$$dv = -\frac{\hbar k}{m}dn \ ,$$

such that $v(n=0) = v_0$ *and* $v(n=N) = 0$*. The integral is then:*

$$S = \int_0^N \Delta s(v_n)dn = \int_{v_0}^0 \Delta s(v)\left(-\frac{dv}{\hbar k/m}\right) = \int_0^{v_0} \frac{2\pi}{W_0\Gamma^2\hbar k/m}[k^2(v-v_0)^2 + (\Gamma/2)^2]dv$$
$$= \frac{2\pi}{W_0\Gamma^2\hbar k/m}\int_0^{v_0} v[k^2v^2 - 2k^2vv_0 + k^2v_0^2 + (\Gamma/2)^2]dv$$
$$= \frac{2\pi}{W_0\Gamma^2\hbar k/m}\left[\frac{k^2v_0^4}{4} - \frac{2k^2v_0v_0^3}{3} + \frac{k^2v_0^2v_0^2}{2} + \left(\frac{\Gamma}{2}\right)^2\frac{v_0^2}{2}\right] = \frac{2\pi v_0^2}{W_0\hbar k/m}\left[\left(\frac{kv_0}{\Gamma}\right)^2\frac{1}{12} + \frac{1}{8}\right] \ .$$

c. If $\Gamma \ll kv_0$*, the numerical factor in the above equation becomes very large, so that the distance required for a complete deceleration of the atoms is very large (Note: an underestimation of the dimensional factor* $v_0^2/(W_0\hbar k/m)$ *gives distances of at least a meter, so that this simplified model predicts that a tube of many meters would be needed to slow down the atoms in this scheme). The interpretation is that if the spectral line is sufficiently narrow, the atoms leave the resonance condition with the light beam in a short time, practically not absorbing photons any more. This justifies the need for a correction (for example) of the spectral line via the Zeeman effect, with fields that vary in space, so as to keep the atoms always in resonance with the light beam.*

34.6.7.4 Ex: Saturation intensity

Calculate the saturation intensity for the sodium transition $3s\ ^2S_{1/2}, F = 2 \longleftrightarrow 3p\ ^2P_{3/2}, F' = 3$. The natural width of the transition is $\Gamma/2\pi = 9.89\,\mathrm{MHz}$ and the wavelength $\lambda = 590\,\mathrm{nm}$.

Solution: *The degeneracies of the levels are* $g_1 = 5$ *and* $g_2 = 7$*. Hence, we get* $I_{sat} = 4.3\,\mathrm{mW/cm^2}$*.*

34.6.7.5 Ex: Saturation intensity of an octupole transition

Calculate the saturation intensity for the $^2S_{1/2}$-$^2F_{7/2}$ transition in Yb^+-ions (neglecting the Zeeman substructure) at $\lambda = 467\,\mathrm{nm}$ (decay time $\tau = 8\,\mathrm{a}$) and the Rabi frequency, when the transition is resonantly driven by a laser beam of $P = 10\,\mathrm{mW}$ power focused into a $w_0 = 20\,\mu\mathrm{m}$ waist.

Solution: *The saturation intensity is,*

$$I_{sat} = \frac{2\pi^2 c\hbar}{3\lambda^3}\Gamma \approx 48\,\mathrm{fW} \ ,$$

and the power broadening,

$$\Omega = \Gamma\sqrt{\frac{I}{2I_{sat}}} = \Gamma\sqrt{\frac{P}{\pi w_0^2 I_{sat}}} \approx 32\,\mathrm{kHz} \ .$$

Hence, it sounds feasible to drive the transition, provided the laser emission bandwidth is narrow than 32 kHz.

34.6.7.6 Ex: Pressure broadening

At what pressure the collision broadening [given by the expression (34.236)] between sodium atoms in the ground state dominates the width of the D2-transition at ambient temperature. The natural width of the D2-line is $\Gamma/2\pi = 6\,\mathrm{MHz}$.

Solution: *The mass of the sodium is* $m = 23u$. *We approximate the radius with* $\rho \simeq a_B$. *Then, with* $pV = Nk_BT$,

$$\tau_{col} = \frac{1}{8\rho^2 n}\sqrt{\frac{m}{2\pi k_B T}} = \frac{1}{8a_B^2 p}\sqrt{\frac{mk_BT}{2\pi}} \ .$$

Hence,

$$p = \frac{\gamma_{col}}{8a_B^2}\sqrt{\frac{mk_BT}{2\pi}} > \frac{\Gamma/2}{8a_B^2}\sqrt{\frac{mk_BT}{2\pi}} \equiv p_{crit} \ ,$$

which gives $p_{crit} = 4200\,\mathrm{Pa} = 42\,\mathrm{mbar}$.

34.6.7.7 Ex: Optical density of a hot cloud

Calculate and draw the effective Lorentz profile, Gauss profile and Voigt profile for the resonance line at 461 nm ($\Gamma = (2\pi)\ 32\,\mathrm{MHz}$) of a strontium gas heated to the temperature 400 C and the pressure $P = 10^{-4}$ mbar inside a 15 cm long cell.

Solution: *The cross-section of an atom with the resonance frequency* ω_0 *moving with velocity* v *and irradiated by a laser beam of frequency* ω *is,*

$$\sigma(v) = \frac{6\pi}{k^2}\frac{\Gamma^2}{4(\omega - \omega_0 - kv)^2 + \Gamma^2} \ .$$

The one-dimensional Maxwell distribution,

$$\rho(v)dv = \sqrt{\frac{m}{2\pi k_B T}}e^{-mv^2/2k_BT}dv \ ,$$

is normalized. The density of the atoms is,

$$n(T) = \frac{P}{k_B T} \approx 10^{18}\,\mathrm{m}^{-3} \ .$$

The optical density is,

$$\begin{aligned} OD(T,\omega) &= Ln(T)(\sigma \star \rho)(\delta) = Ln(T)\int_{-\infty}^{\infty}\sigma(v)\rho(v)dv \\ &= L\frac{P}{k_B T}\sqrt{\frac{m}{2\pi k_B T}}\frac{6\pi}{k^2}\int_{-\infty}^{\infty} e^{-mv^2/2k_B T}\frac{\Gamma^2}{4(\omega-\omega_0-kv)^2+\Gamma^2}dv \ . \end{aligned}$$

At zero temperature, we can approximate the Gaussian by the δ-distribution:

$$\int_{-\infty}^{\infty} e^{-mv^2/2k_B T}dv = \sqrt{\frac{2k_B T}{m}}\int_{-\infty}^{\infty} e^{-x^2}dx = \sqrt{\frac{2\pi k_B T}{m}} = \int_{-\infty}^{\infty}\sqrt{\frac{2\pi k_B T}{m}}\delta(kv)d(kv) \ .$$

Hence,

$$\begin{aligned} OD(0,\omega) &= Ln(T)\sqrt{\frac{m}{2\pi k_B T}}\frac{6\pi}{k^2}\int_{-\infty}^{\infty}\frac{\Gamma^2}{4(\omega-\omega_0-kv)^2+\Gamma^2}\sqrt{\frac{2\pi k_B T}{m}}\delta(kv)d(kv) \\ &= Ln(T)\frac{6\pi}{k^2}\frac{\Gamma^2}{4(\omega-\omega_0)^2+\Gamma^2} \ , \end{aligned}$$

which means that we retrieve the default expression for the optical density,

$$OD(0,\omega) = Ln(T)\sigma(T) \ .$$

When the natural width is very narrow, we can approximate the Lorentzian by the δ-distribution:

$$\int_{-\infty}^{\infty}\frac{\Gamma^2}{4(\omega-\omega_0-kv)^2+\Gamma^2}dv = \frac{\Gamma}{k}\int_{-\infty}^{\infty}\frac{dx}{1+4x^2} = \frac{\pi\Gamma}{2k} = \int_{-\infty}^{\infty}\frac{\pi\Gamma}{2k}\delta(\omega-\omega_0-kv)d(kv) \ .$$

Hence,

$$\begin{aligned} OD(T,\omega) &= Ln(T)\sqrt{\frac{m}{2\pi k_B T}}\frac{6\pi}{k^2}\int_{-\infty}^{\infty} e^{-mv^2/2k_B T}\frac{\pi\Gamma}{2k}\delta(\omega-\omega_0-kv)d(kv) \\ &= Ln(T)\sqrt{\frac{m}{2\pi k_B T}}\frac{6\pi}{k^2}\frac{\pi\Gamma}{2k}e^{-m(\omega-\omega_0)^2/2k_B T k^2} \ . \end{aligned}$$

In resonance,

$$OD(T,\omega_0) = Ln(T)\sqrt{\frac{\pi}{2}}\frac{\sigma_0\Gamma}{2k\bar{v}} \ ,$$

where $\bar{v} = \sqrt{k_B T/m}$ is the average atomic velocity (or the rms*-width of the Maxwell distribution. The fraction $\Gamma/2k\bar{v}$ can be interpreted as the spectral overlap between the Lorentzian absorption profile and the Maxwell distribution.*

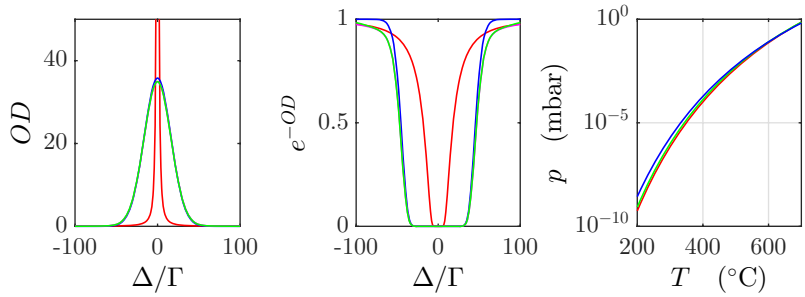

Figure 34.15: (code) (a) Optical density profiles, (red) exact, (green) in the limit $\Gamma = 0$, and (blue) in the limit $T = 0$. (b) Same as (a) but exponential.

34.6.7.8 Ex: Rate equations as a limiting case of Bloch equations

We show in this exercise that, in the limit $\Gamma \gg \Omega$, we can derive, from the Bloch equations, the Einstein rate equations. Proceed as follows:
a. Apply the condition $\dot{\rho}_{12} = 0$ to the Bloch equations for a two-level system (34.188), determine $\rho_{12}(\infty)$, and replace this stationary value in the equations for the populations $\rho_{kk}(t)$ using, as an abbreviation, the transition rate $R \equiv \gamma s$, where s is the saturation parameter (34.190).
b. Integrate the rate equations over the entire spectrum, i.e. $\Delta \in [-\infty, \infty]$, and derive Einstein's equations using the relations (34.7), (34.41), and (34.42).

Solution: *a. The Einstein rate equations can be derived from the Bloch equations following the Wilcox-Lamb procedure [1375, 4]. This consists in applying the condition $\dot{\rho}_{12} = 0$ to the Bloch equation,*

$$\frac{d}{dt}\begin{pmatrix}\rho_{11}\\ \rho_{22}\\ \rho_{12}\\ \rho_{21}\end{pmatrix} = \begin{pmatrix} 0 & \Gamma & \frac{\imath}{2}\Omega & -\frac{\imath}{2}\Omega \\ 0 & -\Gamma & -\frac{\imath}{2}\Omega & \frac{\imath}{2}\Omega \\ \frac{\imath}{2}\Omega & -\frac{\imath}{2}\Omega & \imath\Delta - \gamma & 0 \\ -\frac{\imath}{2}\Omega & \frac{\imath}{2}\Omega & 0 & -\imath\Delta - \gamma \end{pmatrix}\begin{pmatrix}\rho_{11}\\ \rho_{22}\\ \rho_{12}\\ \rho_{21}\end{pmatrix} ,$$

giving,

$$\rho_{12}(\infty) = \frac{-\Omega/2}{\imath\gamma + \Delta}(\rho_{11} - \rho_{22}) .$$

Substituting the coherences in the equations for the populations yields,

$$\frac{d}{dt}\rho_{11} = -\frac{\gamma\Omega^2/2}{\Delta^2 + \gamma^2}\rho_{11} + \Gamma\rho_{22} + \frac{\gamma\Omega^2/2}{\Delta^2 + \gamma^2}\rho_{22}$$

with the abbreviation,

$$R \equiv \frac{\gamma\Omega^2/2}{\Delta^2 + \gamma^2} = \gamma s ,$$

where s is the saturation parameter. We obtain the rate equations,

$$\frac{d}{dt}\begin{pmatrix}\rho_{11}\\ \rho_{22}\end{pmatrix} = \begin{pmatrix} -R & \Gamma + R \\ R & -\Gamma - R \end{pmatrix}\begin{pmatrix}\rho_{11}\\ \rho_{22}\end{pmatrix} .$$

b. Finally, integrating over the entire spectrum,

$$\int_{-\infty}^{\infty} R d\Delta \equiv \int_{-\infty}^{\infty} \frac{\gamma\Omega^2/2}{\Delta^2+\gamma^2} d\Delta = \tfrac{\pi}{2}\Omega^2 \ .$$

Using relationships $\bar{u} = \frac{1}{2}\varepsilon_0 E^2$, $\hbar\Omega = dE$, *and* $B_{12} = \frac{\pi d^2}{3\varepsilon_0\hbar^2}$ *we see,*

$$\tfrac{\pi}{2}\Omega^2 = 3B_{12}\bar{u} \ .$$

Hence, with $N_k/N = \rho_{kk}$,

$$\frac{d}{dt}\begin{pmatrix} N_1 \\ N_2 \end{pmatrix} = \begin{pmatrix} -B_{12}\bar{u} & A_{21} + B_{21}\bar{u} \\ B_{12}\bar{u} & -A_{21} - B_{21}\bar{u} \end{pmatrix}\begin{pmatrix} N_1 \\ N_2 \end{pmatrix} \ .$$

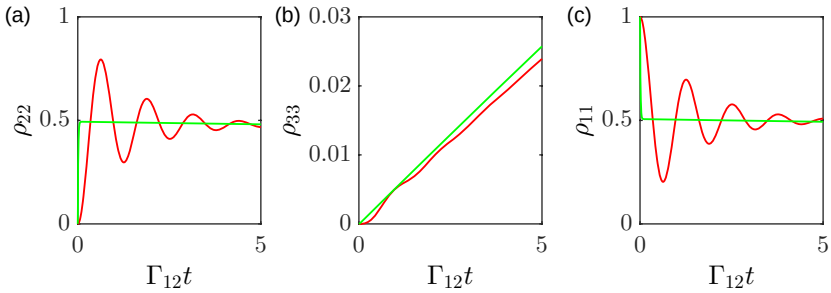

Figure 34.16: (code) Example for temporal evolution of the populations calculated from Bloch and from rate equations.

34.6.7.9 Ex: Blackbody radiation-induced transitions

Blackbody radiation induces incoherent transitions (see Exc. 34.6.7.8). Show that the Lindbladian of the master equation,

$$\dot{\hat{\rho}} = \mathcal{L}_{bb}\hat{\rho} = -\tfrac{R}{2}\left([\hat{\rho}\hat{\sigma}, \hat{\sigma}^\dagger] + [\hat{\sigma}, \hat{\sigma}^\dagger\hat{\rho}]\right) - \tfrac{R+\Gamma}{2}\left([\hat{\rho}\hat{\sigma}^\dagger, \hat{\sigma}] + [\hat{\sigma}^\dagger, \hat{\sigma}\hat{\rho}]\right)$$

reproduces the Einstein rate equation for $\Gamma = 2A_{12}$ and $R = B_{12}u(\omega)$.

Solution: *We calculate from the given expression,*

$$\begin{aligned}\dot{\hat{\rho}} &= -\tfrac{\Gamma}{2}\left(\hat{\rho}\hat{\sigma}^\dagger\hat{\sigma} + \hat{\sigma}^\dagger\hat{\sigma}\hat{\rho} - 2\hat{\sigma}\hat{\rho}\hat{\sigma}^\dagger\right) - \tfrac{R}{2}\left(\hat{\rho}\hat{\sigma}\hat{\sigma}^\dagger + \hat{\rho}\hat{\sigma}^\dagger\hat{\sigma} + \hat{\sigma}\hat{\sigma}^\dagger\hat{\rho} + \hat{\sigma}^\dagger\hat{\sigma}\hat{\rho} - 2\hat{\sigma}^\dagger\hat{\rho}\hat{\sigma} - 2\hat{\sigma}\hat{\rho}\hat{\sigma}^\dagger\right) \\ &= \Gamma\left(|1\rangle\rho_{22}\langle 1| - \tfrac{1}{2}\hat{\rho}|2\rangle\langle 2| - \tfrac{1}{2}|2\rangle\langle 2|\hat{\rho}\right) - R\left(|2\rangle\langle 1|\hat{\rho}|1\rangle\langle 2| + |1\rangle\langle 2|\hat{\rho}|2\rangle\langle 1| - \hat{\rho}\right) \ ,\end{aligned}$$

yielding,

$$\begin{aligned}\dot{\rho}_{22} &= -\dot{\rho}_{11} = -\Gamma\rho_{22} - R(\rho_{11} - \rho_{22}) \\ \dot{\rho}_{12} &= \dot{\rho}_{21}^* = \left(-\tfrac{\Gamma}{2} + R\right)\rho_{12} \ .\end{aligned}$$

The first equation is just the Einstein rate equation. The second equation is decoupled from the first one.

34.6.7.10 Ex: Lorentzian versus Gaussian line profile

Beyond what detuning is a Doppler-broadened transition dominated by the Lorentzian profile of the transition?

Solution: *We consider a cell of length L at temperature T. With the optical cross section,*

$$\sigma = \frac{6\pi}{k^2} \frac{\Gamma^2}{4(\omega - \omega_0 - kv)^2 + 2\Omega^2 + \Gamma^2}$$

and the Maxwell-Boltzmann distribution,

$$\rho dv = \sqrt{\frac{m}{2\pi k_B T}} e^{-mv^2/2k_B T} dv$$

the optical density is,

$$OD(T, \omega) = L \frac{P}{k_B T} \sqrt{\frac{m}{2\pi k_B T}} \frac{6\pi}{k^2} \int_{-\infty}^{\infty} e^{-mv^2/2k_B T} \frac{\Gamma^2}{4(\omega - \omega_0 - kv)^2 + 2\Omega^2 + \Gamma^2} dv \ .$$

Considering normalized profiles,

$$\sigma = \frac{a/\pi}{x^2 + a^2} \qquad \textit{respectively} \qquad \rho = \frac{1}{b\sqrt{\pi}} e^{-x^2/b^2} \ .$$

Expanding by $1/x$?

34.7 Bloch equations for multi-level systems

The two-level system represents an idealization of the real atom, since at least one of the levels is usually degenerate. Many important phenomena in quantum optics are not found in this system, but conditioned to the existence of a third level. Examples are optical pumping (essential for laser operation), quantum jumps or dark resonances [which are at the basis of the phenomenon of electromagnetically induced transparency (EIT)].

To derive the Bloch equations for atoms with several levels excited by several lasers and coupled to free space (i.e. without external cavity), we can use the same master equation (34.222), but with a generalized Hamiltonian in the semiclassical

approximation [20] and a Lindblad operator,

$$\boxed{\begin{aligned}
\hat{H}_{atom} &= \textstyle\sum_i \hbar\omega_i \hat{\sigma}_{ji}\hat{\sigma}_{ij} = \sum_i |i\rangle\hbar\omega_i\langle i| \\
\hat{H}_{atom:field} &= \tfrac{\hbar}{2}\Omega_{ij}\,(e^{-\imath\omega_{ij}t}\hat{\sigma}_{ij} + e^{\imath\omega_{ij}t}\hat{\sigma}_{ji}) = \textstyle\sum_{i<j} |i\rangle \tfrac{\hbar}{2}\Omega_{ij}\langle j|e^{\imath\omega_{ij}t} + c.c. \\
\mathcal{L}_{decay}\hat{\rho} &= \mathcal{L}_\gamma + \mathcal{L}_R + \mathcal{L}_\beta \\
\mathcal{L}_\gamma &= \textstyle\sum_{i,j} \gamma_{ij}\left([\hat{\sigma}_{ij}, \hat{\rho}\hat{\sigma}^\dagger_{ij}] + [\hat{\sigma}_{ij}\hat{\rho}, \hat{\sigma}^\dagger_{ij}]\right) \\
\mathcal{L}_R &= \textstyle\sum_{i,j} R_{ij}\left([\hat{\sigma}^\dagger_{ij}, \hat{\rho}\hat{\sigma}_{ij}] + [\hat{\sigma}^\dagger_{ij}\hat{\rho}, \hat{\sigma}_{ij}]\right) \\
\mathcal{L}_\beta &= \textstyle\sum_{i,j} 2\beta_{ij}\left([\hat{\sigma}_{ij}\hat{\sigma}^\dagger_{ij}, \hat{\rho}\hat{\sigma}_{ij}\hat{\sigma}^\dagger_{ij}] + [\hat{\sigma}_{ij}\hat{\sigma}^\dagger_{ij}\hat{\rho}, \hat{\sigma}_{ij}\hat{\sigma}^\dagger_{ij}]\right)
\end{aligned}} \quad . \tag{34.266}$$

Here, $\hat{\sigma}_{ij} \equiv |i\rangle\langle j| = \hat{\sigma}^\dagger_{ji}$. The constants R_{ij} are eventual incoherent pump rates due to optical pumping, β_{ij} take account of homogeneous broadening, e.g. due to finite laser linewidths. The levels have the energy $\hbar\omega_i$ above the ground level. The Rabi frequency Ω_{ij} is a measure for the force at which the levels $|i\rangle$ and $|j\rangle$ are coupled by the resonantly irradiated light field. The master equation can be simplified by applying the rotating wave approximation and transforming to the coordinate system which rotates with the light frequencies ω_{ij}:

$$\rho_{ij} \to \hat{\rho}_{ij}e^{\imath\omega_{ij}t} \quad , \quad \hat{H}_{atom:field} \to e^{-\imath\hat{H}t/\hbar}\hat{H}_{atom:field}e^{\imath\hat{H}t/\hbar} \; . \tag{34.267}$$

34.7.1 Liouville equation for many levels

The indices for the atomic levels are joined to a single index, such that the master equation takes a simpler form after having introduced a *Liouville operator*:

$$\begin{aligned}
\hat{\rho} &= (...\rho_k...) \equiv \sum\nolimits_{i,j} |i\rangle\rho_{ij}\langle j| \; , \\
\dot{\hat{\rho}} &= \mathcal{L}\hat{\rho}, \\
\hat{\rho} &= e^{\mathcal{L}_{atom}t}\hat{\rho}_0 \; .
\end{aligned} \tag{34.268}$$

The relation with the *von Neumann equation* with $\hat{H} = \sum_{i,j} |i\rangle H_{ij}\langle j|$ and $\hat{\rho} = \sum_{k,l} |k\rangle\rho_{kl}\langle l|$ and $\hat{\sigma}_{ij} = |i\rangle\langle j|$ is:

$$\mathcal{L}_{atom}\hat{\rho} = -\tfrac{\imath}{\hbar}[\hat{H}, \hat{\rho}] = -\imath\sum\nolimits_{k,l,j} H_{kl}\rho_{lj}|k\rangle\langle j| + \imath\sum\nolimits_{k,l,j} H_{lj}\rho_{kl}|k\rangle\langle j| \; . \tag{34.269}$$

For example, for the two-level system with the definition of the external product (23.127):

$$\mathcal{L}_{atom}\hat{\rho} = -\imath\hat{H}\otimes\mathbb{I}\hat{\rho} + \imath\mathbb{I}\otimes\hat{H}\hat{\rho} \; . \tag{34.270}$$

The relaxation terms for spontaneous decay obtained from (34.266) are,

$$\mathcal{L}_{decay}\hat{\rho} = \sum\nolimits_{i,j,k} \left(2\gamma_{ji}\delta_{kj}\rho_{ii} - \gamma_{ij}\rho_{kj} - \gamma_{ik}\rho_{kj}\right)|k\rangle\langle j| \; . \tag{34.271}$$

[20] That is, the atom is quantized and consists of several levels $|i\rangle$ with energies $\hbar\omega_i$, while the light fields are described by factors $e^{\imath\omega_{ij}t}$, with frequencies ω_{ij} tuned near the transitions $|i\rangle - |j\rangle$.

Example 201 (*Liouville equation for two levels*): For example, for the two-level system,

$$\mathcal{L}_{atom} = \begin{pmatrix} 2\gamma_{11} & 0 & 0 & 2\gamma_{21} \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 2\gamma_{12} & 0 & 0 & 2\gamma_{22} \end{pmatrix} - \begin{pmatrix} 2(\gamma_{11}+\gamma_{12}) & 0 & 0 & 0 \\ 0 & \sum_{(kj)}\gamma_{(kj)} & 0 & 0 \\ 0 & 0 & \sum_{(kj)}\gamma_{(kj)} & 0 \\ 0 & 0 & 0 & 2(\gamma_{22}+\gamma_{21}) \end{pmatrix} .$$

Here, we consider $(kj) = (11\ 12\ 21\ 22)$ as a single index.

34.7.1.1 Derivation of the multilevel Bloch equation

Now, inserting the Hamiltonian in the RWA,

$$\hat{H} = \hat{H}_{atom} + \hat{H}_{atom:field} = \sum_i \hbar\omega_i |i\rangle\langle i| + \tfrac{\hbar}{2}\sum_{i<j} \Omega_{ij}\hat{\sigma}_{ij} + h.c. \ , \tag{34.272}$$

into the von Neumann equation together with the dissipative Lindbladian (34.271) and $\rho_{jk} \equiv \langle j|\hat{\rho}|k\rangle$, we derive the multilevel master equation,

$$\dot{\rho}_{jk} = \frac{\imath}{\hbar}\langle j|[\hat{\rho}, \hat{H}]|k\rangle + \langle j|\mathcal{L}_{decay}\hat{\rho}|k\rangle \ . \tag{34.273}$$

First we calculate the unperturbed Hamiltonian part,

$$\begin{aligned} \langle k|[\hat{\rho}, \hat{H}_{atom}]|m\rangle &= \hbar\langle k|\hat{\rho}\sum_a |a\rangle\langle a|\sum_i \omega_i|i\rangle\langle i|m\rangle - \hbar\langle k|\sum_i \omega_i|i\rangle\langle i|\sum_a |a\rangle\langle a|\hat{\rho}|m\rangle \\ &= \hbar(\omega_m - \omega_k)\rho_{km} \ . \end{aligned} \tag{34.274}$$

For the interaction part we get,

$$\begin{aligned} &\langle k|[\hat{\rho}, \hat{H}_{atom-field}]|m\rangle \\ &= \tfrac{\hbar}{2}\sum_a\sum_{i<j}\left[\langle k|\hat{\rho}|a\rangle\langle a|\left(\Omega_{ij}|i\rangle\langle j| + \Omega^*_{ij}|j\rangle\langle i|\right)|m\rangle - \langle k|\left(\Omega_{ij}|i\rangle\langle j| + \Omega^*_{ij}|j\rangle\langle i|\right)|a\rangle\langle a|\hat{\rho}|m\rangle\right] \\ &= \tfrac{\hbar}{2}\sum_{i<j}\left(\Omega_{ij}\rho_{ki}\delta_{jm} + \Omega^*_{ij}\rho_{kj}\delta_{im} - \Omega_{ij}\rho_{jm}\delta_{ki} - \Omega^*_{ij}\rho_{im}\delta_{kj}\right) \ , \end{aligned} \tag{34.275}$$

and for the dissipative part,

$$\begin{aligned} \langle k|\mathcal{L}_{decay}\hat{\rho}|m\rangle &= \langle k|\sum_{i,j}\gamma_{ij}(2|i\rangle\langle j|\hat{\rho}|j\rangle\langle i| - |j\rangle\langle i|i\rangle\langle j|\hat{\rho} - \hat{\rho}|j\rangle\langle i|i\rangle\langle j|)|m\rangle \\ &= \sum_j 2\gamma_{mj}\delta_{km}\rho_{jj} - \sum_i(\gamma_{ik}+\gamma_{im})\rho_{km} \ . \end{aligned} \tag{34.276}$$

So all in all,

$$\boxed{\begin{aligned} \dot{\rho}_{km} &= 2\sum_j \gamma_{mj}\rho_{jj}\delta_{km} - \left[\sum_i(\gamma_{ik}+\gamma_{im}) + \imath(\omega_k - \omega_m)\right]\rho_{km} \\ &+ \tfrac{\imath}{2}\sum_{i<j}\left(\Omega_{ij}\rho_{ki}\delta_{jm} + \Omega^*_{ij}\rho_{kj}\delta_{im} - \Omega_{ij}\rho_{jm}\delta_{ki} - \Omega^*_{ij}\rho_{im}\delta_{kj}\right) \end{aligned}} \ , \tag{34.277}$$

where the index j runs over all levels $|j\rangle$ into which a population ρ_{kk} can decay and the index i runs over all levels $|i\rangle$ into which the levels $|k\rangle$ and $|m\rangle$ of a dipole moment ρ_{km} can decay. In Exc. 34.7.5.1 we will apply this formula to three-level systems.

Finally, the master equation can be reformulated by introducing a *generalized Bloch vector* $\vec{\rho}$, and the matrix representation of the Liouville superoperator $\mathcal{L}$ as a linear system of n^2 coupled differential equations,

$$\frac{d}{dt}\vec{\rho} = \mathcal{M}\vec{\rho} \quad , \quad \vec{\rho} = (\rho_{11} \;\; .. \;\; \rho_{nn} \; \rho_{12} \; \rho_{21} \;\; .. \;\; \rho_{n-1\;\;n} \;\; \rho_{n\;\;n-1}) \; , \tag{34.278}$$

where the Bloch matrix $\mathcal{M}$ is obtained from the Liouvillean $\mathcal{L}$ simply by rearranging the matrix elements.

Alternatively to the complex formulation, the differential equations can be written for the real and imaginary part of the Bloch vector. The components ρ_{ii} correspond to the population probabilities of the levels $|i\rangle$, the non-diagonal elements ρ_{ij} describe the coherences between $|i\rangle$ and $|j\rangle$. Now, we must insert the Hamiltonian (34.266) and the density operator ρ_{ij} into the Liouville equation (34.125) in order to derive the generalized Bloch equations. In practice, these calculations are simple but heavy. Therefore, we describe in Sec. 34.7.4 a simplified recipe for compiling Bloch equations for arbitrary level systems for real atoms.

34.7.2 Bloch equations for three levels

In principle, three-level system can exist in there possible configurations, shown in Fig. 34.17. Note that it is not possible to describe a three-level system with all levels pairwise coupled by three lasers within the formalism of Bloch's equations [21].

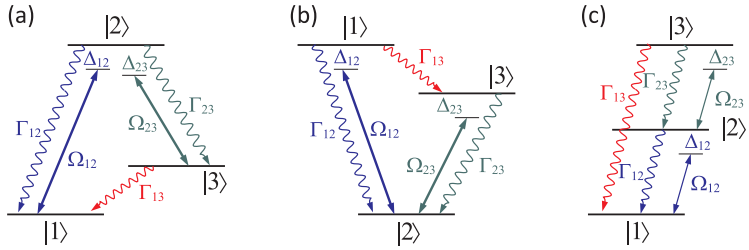

Figure 34.17: Three level system (a) in Λ-configuration, (b) in V-configuration, and (c) in cascade configuration.

Defining the Bloch vector by $\vec{\rho}$, the Bloch equation matrix for three levels in Raman

[21] For the same reason that the three-body problem has no general analytic solution.

configuration (that is, in Λ-configuration) using the labeling of Fig. 34.17(a), is,

$$\dot{\vec{\rho}} = \mathcal{M}\vec{\rho} = \tag{34.279}$$

$$\left(\begin{array}{ccc|ccccccc}
0 & \Gamma_{12} & \Gamma_{13} & \frac{\imath}{2}\Omega_{12} & -\frac{\imath}{2}\Omega_{12} & 0 & 0 & 0 & 0 \\
0 & -\Gamma_{12}-\Gamma_{23} & 0 & -\frac{\imath}{2}\Omega_{12} & \frac{\imath}{2}\Omega_{12} & 0 & 0 & \frac{\imath}{2}\Omega_{23} & -\frac{\imath}{2}\Omega_{23} \\
0 & \Gamma_{23} & -\Gamma_{13} & 0 & 0 & 0 & 0 & -\frac{\imath}{2}\Omega_{23} & \frac{\imath}{2}\Omega_{23} \\
\hline
\frac{\imath}{2}\Omega_{12} & -\frac{\imath}{2}\Omega_{12} & 0 & -\Lambda_{12} & 0 & \frac{\imath}{2}\Omega_{23} & 0 & 0 & 0 \\
-\frac{\imath}{2}\Omega_{12} & \frac{\imath}{2}\Omega_{12} & 0 & 0 & -\Lambda_{12}^* & 0 & -\frac{\imath}{2}\Omega_{23} & 0 & 0 \\
0 & 0 & 0 & \frac{\imath}{2}\Omega_{23} & 0 & -\Lambda_{13} & 0 & -\frac{\imath}{2}\Omega_{12} & 0 \\
0 & 0 & 0 & 0 & -\frac{\imath}{2}\Omega_{23} & 0 & -\Lambda_{13}^* & 0 & \frac{\imath}{2}\Omega_{12} \\
0 & \frac{\imath}{2}\Omega_{23} & -\frac{\imath}{2}\Omega_{23} & 0 & 0 & -\frac{\imath}{2}\Omega_{12} & 0 & -\Lambda_{23} & 0 \\
0 & -\frac{\imath}{2}\Omega_{23} & \frac{\imath}{2}\Omega_{23} & 0 & 0 & 0 & \frac{\imath}{2}\Omega_{12} & 0 & -\Lambda_{23}^*
\end{array}\right)
\left(\begin{array}{c}
\rho_{11} \\ \rho_{22} \\ \rho_{33} \\ \rho_{12} \\ \rho_{21} \\ \rho_{13} \\ \rho_{31} \\ \rho_{23} \\ \rho_{32}
\end{array}\right)$$

with $\Lambda_{mn} = \imath\Delta_{mn} + \gamma_{mn}$ and,

$$\begin{aligned}
&\Delta_{13} = \Delta_{12} - \Delta_{23} \qquad\qquad (34.280)\\
&\gamma_{12} = \tfrac{1}{2}(\Gamma_{12}+\Gamma_{23}) \quad , \quad \gamma_{23} = \tfrac{1}{2}(\Gamma_{12}+\Gamma_{23}+\Gamma_{13}) \quad , \quad \gamma_{13} = \tfrac{1}{2}\Gamma_{13}\ .
\end{aligned}$$

In Exc. 34.7.5.2 we will derive the matrix (34.279).

The coherent terms of the same matrix can be used for the V- and the cascade configurations shown in Figs. 34.17(b,c). Obviously, the incoherent terms, that is, the submatrix 3×3 separated in the matrix (34.279) containing the population decay rates must be adjusted, as well as the decay rates of the coherences on the diagonal. Finally, the definition of the Raman detuning Δ_{13} must be adjusted. For the system in V-configuration we have,

$$\begin{aligned}
&\mathcal{M}_{incoh} = \begin{pmatrix} -\Gamma_{12}-\Gamma_{13} & 0 & 0 \\ \Gamma_{12} & 0 & \Gamma_{23} \\ \Gamma_{13} & 0 & -\Gamma_{23} \end{pmatrix} \quad , \quad \Delta_{13} = \Delta_{12} - \Delta_{23} \qquad (34.281)\\
&\gamma_{12} = \tfrac{1}{2}(\Gamma_{12}+\Gamma_{13}) \quad , \quad \gamma_{23} = \tfrac{1}{2}\Gamma_{23} \quad , \quad \gamma_{13} = \tfrac{1}{2}(\Gamma_{12}+\Gamma_{13}+\Gamma_{23})\ .
\end{aligned}$$

For the cascade system we have,

$$\begin{aligned}
&\mathcal{M}_{incoh} = \begin{pmatrix} 0 & \Gamma_{12} & \Gamma_{13} \\ 0 & -\Gamma_{12} & \Gamma_{23} \\ 0 & 0 & -\Gamma_{13}-\Gamma_{23} \end{pmatrix} \quad , \quad \Delta_{13} = \Delta_{12} - \Delta_{23} \qquad (34.282)\\
&\gamma_{12} = \tfrac{1}{2}\Gamma_{12} \quad , \quad \gamma_{23} = \tfrac{1}{2}(\Gamma_{12}+\Gamma_{23}+\Gamma_{13}) \quad , \quad \gamma_{13} = \tfrac{1}{2}(\Gamma_{13}+\Gamma_{23})\ .
\end{aligned}$$

These matrices serve to describe quantitatively a wealth of phenomena, some of them to be discussed in Sec. 34.8.

34.7.3 Numerical treatment of Bloch equations

Since the differential Bloch equations are linear, they can be easily solved. For example, the prescription

$$\boxed{\vec{\rho}(t) = e^{\mathcal{M}t}\vec{\rho}(0)} \tag{34.283}$$

propagates the Bloch vector to later times.

The matrix $\mathcal{M}$ is not invertible, but by applying the condition Tr $\rho = 1$, a component of the density matrix can be eliminated, for example by letting,

$$\rho_{11} = 1 - \sum_k \rho_{kk} \ . \tag{34.284}$$

The resulting state vector, $\vec{\rho}_{red}$, has the length $n^2 - 1$, and from $\mathcal{M}$ we obtain the (trace-)reduced, now invertible matrix $\mathcal{M}_{red}$ and the inhomogeneity vector $\mathbf{b}$. The differential equation is now,

$$\frac{d}{dt}\vec{\rho}_{red} = \mathcal{M}_{red}\vec{\rho}_{red} + \mathbf{b} \ , \tag{34.285}$$

with the stationary and time-dependent solutions,

$$\boxed{\vec{\rho}_{red}(\infty) = -\mathcal{M}_{red}^{-1}\mathbf{b} \quad , \quad \vec{\rho}_{red}(t) = e^{\mathcal{M}_{red}t}\vec{\rho}_{red}(0) + (1 - e^{\mathcal{M}_{red}t})\vec{\rho}_{red}(\infty)} \ . \tag{34.286}$$

Once the matrix $\mathcal{M}$ or the matrix $\mathcal{M}_{red}$ and the inhomogeneity vector $\mathbf{b}$ are determined for a system, the state of the atom can be calculated at any time, as well as the populations and coherences. The system's free parameters are the natural transition linewidths and the detunings, as well as the intensities and emission bandwidths of the incident light fields.

34.7.3.1 Simulation of the Schrödinger and Bloch equation

Once we have written the solution of the Schrödinger equation in the form (23.144) with a time-independent Hamiltonian $\hat{H}$, or of the Bloch equations in the form (34.283) or (34.286) with a time-independent Liouvillian $\mathcal{M}$, we can easily simulate temporal evolutions of quantum systems. If the Hamiltonian or Liouvillian depend on time, for example, when the Rabi frequencies are pulsed or the detunings are ramped, we must solve the equations iteratively. That is, we chose time intervals Δt sufficiently short, so that the Hamiltonian (or the Liouvillian) can be considered constant during this interval, and we propagate the wavefunction (or the Bloch vector) to later times via:

$$|\psi(t + \Delta t)\rangle = e^{\imath\hat{H}(t)\Delta t}|\psi(t)\rangle \qquad \text{or} \qquad \vec{\rho}(t + \Delta t) = e^{\mathcal{M}(t)\Delta t}\vec{\rho}(t) \ , \tag{34.287}$$

and insert the solution obtained again into equations (34.287) with the Hamiltonian $\hat{H}(t + \Delta t)$ (or the Liouvillian $\mathcal{M}(t + \Delta t)$) adjusted to the new time.

34.7.4 General rules for setting up multilevel Bloch equations

The canonical way of deriving multi-level Bloch equations starts from a von Neumann equation for the total density operator for the atom embedded in the electromagnetic mode structure of the environment including incident laser beams. After tracing over the degrees of freedom of the electromagnetic vacuum and using the Markov and the Born approximations [487], one arrives at a master equation of the form (34.266). Simple but tedious algebraic transformations of the master equation lead,

in the rotating wave approximation, to a set of linear first-order differential equations in the populations of the atomic excitation levels and the coherences between them. The equations are called the optical Bloch equations.

Alternatively, the Bloch equations may be found by breaking down the multi-level scheme into a set of three-level systems. Respecting a few symmetry considerations, the multi-level Bloch equations can then be reassembled from the three-level Bloch equations corresponding to every possible combination of three levels. Based on such considerations, we provide in the following a simple recipe for setting up Bloch matrices for arbitrary level schemes. A movie showing a simulation of multi-level Bloch equations for Li atoms can be watched under the following link: (watch movie).

Let us regard a n-level atom. Its internal state is fully described by the populations ρ_{kk} and the (complex) coherences ρ_{kl}, with $k, l = 1, .., n$. In this work we describe the coherences by their real and imaginary parts. The labeling is such that the levels are sorted according to their excitation energy, $E_k < E_l$ for $k < l$. We define the Bloch vector,

$$\begin{aligned}\vec{\rho} \equiv (&\rho_{11}...\rho_{nn}\mathfrak{Im}\ \rho_{12}\mathfrak{Re}\ \rho_{12}\mathfrak{Im}\ \rho_{13}\ \mathfrak{Re}\ \rho_{13}... \\ &...\mathfrak{Im}\ \rho_{1n}\mathfrak{Re}\ \rho_{1n}\mathfrak{Im}\ \rho_{23}\mathfrak{Re}\ \rho_{23}... \\ &...\mathfrak{Im}\ \rho_{n-1,n}\mathfrak{Re}\ \rho_{n-1,n})\ .\end{aligned} \tag{34.288}$$

The Bloch equations then formally read,

$$\dot{\vec{\rho}} = \mathcal{M}\vec{\rho}\ , \tag{34.289}$$

where in the given Bloch vector basis the matrix $\mathcal{M}$ has the following structure,

$$\mathcal{M} = \begin{pmatrix} (A) & (B_1) \\ (B_2) & \begin{pmatrix} (C) & (D) \\ (D) & (C) \end{pmatrix} \end{pmatrix}\ . \tag{34.290}$$

The different blocks of the matrix have the following significations. Block A handles the transfer of populations by spontaneous decay. Its rank corresponds to the number of levels n. The diagonal elements of this block are the decay rates Γ of the excited states. The off-diagonal elements Γ_{kl} denote the gain of level k from a decaying level l. Conservation of energy thus requires that the sum of the transition rates cancels for every column of matrix A, $\Gamma = \sum_k \Gamma_{kl}$, as it is the case for the two-level Bloch matrix. If the levels are sublevels of a Zeeman and/or hyperfine split multiplet, the rates have to be weighted with Wigner's $(3j)$ and $\{6j\}$ symbols, $\Gamma_{kl} = \Gamma S_{kl}$. The relative oscillator strengths S_{kl} are given in Sec. 34.7.4.2.

The blocks B_k treat the interdependence of the populations and the coherences. B_1 describes how the coherence between any pair of states driven by a light field generating a Rabi frequency Ω_{kl} influences the populations. The block consists of convoluted 2×2 matrices of the form,

$$\begin{pmatrix} \dot{\rho}_{kk} \\ \dot{\rho}_{ll} \end{pmatrix} \sim \begin{pmatrix} -\Omega_{kl} & 0 \\ \Omega_{kl} & 0 \end{pmatrix} \begin{pmatrix} \mathfrak{Im}\ \rho_{kl} \\ \mathfrak{Re}\ \rho_{kl} \end{pmatrix}\ . \tag{34.291}$$

B_2 describes how the populations in turn influence the coherences,

$$\begin{pmatrix} \mathfrak{Im}\ \dot{\rho}_{kl} \\ \mathfrak{Re}\ \dot{\rho}_{kl} \end{pmatrix} \sim \begin{pmatrix} \frac{1}{2}\Omega_{kl} & -\frac{1}{2}\Omega_{kl} \\ 0 & 0 \end{pmatrix} \begin{pmatrix} \rho_{kk} \\ \rho_{ll} \end{pmatrix} \ . \tag{34.292}$$

The Rabi frequencies have to be weighted not only with the relative oscillator strength S_{kl}, but also with the projection H_{kl} of the laser polarization onto the orientation of the magnetic field and the laser polarization, $\Omega_{kl} = \Omega_x S_{kl} H_{kl}$. Here Ω_x is the Rabi frequency generated by a laser on a transition, whose oscillator strength is 1. The projection is calculated in Sec. 34.7.4.3 for the three possible laser polarizations, i.e. for $\sigma^{\pm}$ and for π light.

The matrix C rules the influence of the decays of the coherences, of the detunings $\Delta_{kl} = \omega_x - \omega_{atom}$, and the laser linewidths β_{kl}. Note that the detuning of the laser frequency ω_x is negative for red-detuned light. In the chosen basis it breaks down into an array 2×2 matrices aligned along the diagonal of $\mathcal{M}$. Their shape is,

$$\begin{pmatrix} \mathfrak{Im}\ \dot{\rho}_{kl} \\ \mathfrak{Re}\ \rho_{kl} \end{pmatrix} \sim \begin{pmatrix} -\frac{\gamma_{kl}}{2} & -\Delta_{kl} \\ \Delta_{kl} & -\frac{\gamma_{kl}}{2} \end{pmatrix} \begin{pmatrix} \mathfrak{Im}\ \dot{\rho}_{kl} \\ \mathfrak{Re}\ \rho_{kl} \end{pmatrix} \ . \tag{34.293}$$

where $\gamma_{kl} = \sum_{m,E_m<E_k,E_l} (\Gamma_{km} + \Gamma_{lm}) + 2\beta_{kl}$. Often the levels are sublevels of a Zeeman and/or hyperfine split multiplets. In this case the frequency shift Z_{kl} of the level is added to the detuning Δ_{kl}. The shift is calculated in Sec. 34.7.4.4 for the example of the ^{6}Li D_2 line.

The block D governs the interdependences of all laser-driven coherences of the atom. The block contains 2×2 submatrices at any place of the matrix $\mathcal{M}$, where the row index pair (mn) and the column index pair (kl) have one index in common provided the two different indices correspond to the Rabi frequency of an incident laser:,

$$\begin{pmatrix} \mathfrak{Im}\ \dot{\rho}_{mn} \\ \mathfrak{Re}\ \dot{\rho}_{mn} \end{pmatrix} \sim \begin{pmatrix} 0 & \pm\frac{1}{2}\Omega_{kl} \\ \pm\frac{1}{2}\Omega_{kl} & 0 \end{pmatrix} \begin{pmatrix} \mathfrak{Im}\ \rho_{pq} \\ \mathfrak{Re}\ \rho_{pq} \end{pmatrix} \ . \tag{34.294}$$

The submatrix elements indexed by column (pq) and row (mn) are non-zero if one of the indices p or q is equal to one of the indices m or n and the unequal indices correspond to a laser-driven transition. In order to find the correct signs of the submatrix elements, we distinguish four cases: 1. For $m = p$, $n = k$, and $q = l$ the signs are: $(_-\ ^+)$; 2. for $n = q$, $m = k$, and $p = l$ the signs are: $(_+\ ^-)$; 3. for $m = q$, $n = k$, and $p = l$ the signs are: $(_+\ ^+)$; and 4. for $n = p$, $m = k$, and $q = l$ the signs are: $(_-\ ^-)$. A proper parametrization is proposed in the next section.

34.7.4.1 Recipe for D transitions in alkalines

In order to give a simple algorithm we parametrize the particular choice of sorting the components of the vector, we define a new index μ running from 1 to n^2 by setting $(\varrho_\mu) \equiv (\rho_{kl})$, where,

$$\begin{aligned} \mu(k,k) &= k \\ \mu(k,l) &= 2nk - n - k^2 - k + 2l - 1 \ , \end{aligned} \tag{34.295}$$

so that,

$$\begin{aligned} \varrho_{\mu(k,k)} &= \rho_{kk} \\ \varrho_{\mu(k,l)} &= \mathfrak{Im}\ \rho_{kl} \\ \varrho_{\mu(k,l)+1} &= \mathfrak{Re}\ \rho_{kl}\ . \end{aligned} \tag{34.296}$$

The Bloch equations then formally read,

$$\dot{\varrho}_\mu = \mathcal{M}_{\mu\nu}\varrho_\nu\ . \tag{34.297}$$

We illustrate the procedure by considering the case of the ^{6}Li D_2 line with 6 ground states $k \in G \equiv \{1, ..., 6\}$ belonging to the $^2S_{1/2}$ hyperfine levels $F = \frac{1}{2}, \frac{3}{2}$ and 12 excited states $k \in E \equiv \{7, ..., 18\}$ belonging to the $^2P_{3/2}$ hyperfine levels $F = \frac{1}{2}, \frac{3}{2}, \frac{5}{2}$.

According to the parametrization (34.289) the block A of the matrix $\mathcal{M}$ is filled with the following components,

$$\begin{aligned} \mathcal{M}_{\mu(kk),\mu(kk)} &= -\Gamma \quad \text{for} \quad k \in E \\ \mathcal{M}_{\mu(kk),\nu(ll)} &= \Gamma S_{kl} \quad \text{for} \quad k \in G \quad \text{and} \quad l \in E\ , \end{aligned} \tag{34.298}$$

where the relative oscillator strength S_{kl} is given by Eq. (34.305).

The blocks B_k of the matrix $\mathcal{M}$ are filled with the components,

$$\begin{aligned} &\mathcal{M}_{\mu(k,k),\nu(k,l)} = -\mathcal{M}_{\mu(l,l),\nu(k,l)} \\ &= -2\mathcal{M}_{\mu(k,l),\nu(k,k)} = 2\mathcal{M}_{\mu(k,l),\nu(l,l)} \\ &= -\Omega_{kl}S_{kl}H_{kl}\ , \end{aligned} \tag{34.299}$$

for $k \in G$ and $l \in E$. The projection onto the quantization axis $H_{kl} = H_{kl}\left(\frac{\hat{\epsilon}_{kl}}{|\hat{\epsilon}_{kl}|}, \vec{\mathcal{B}}, m_l - m_k\right)$ is given by Eq. (34.308).

The block C contains the components,

$$\begin{aligned} &\mathcal{M}_{\mu(k,l)\mu(k,l)} = \mathcal{M}_{\mu(k,l)+1\mu(k,l)+1} \\ &= -\tfrac{\Gamma}{2} - \tfrac{\Gamma}{2}\delta_{k\geq 7} - \beta_{pb}\delta_{2<k<7} - \beta_{rp}\delta_{k\leq 2} \end{aligned} \tag{34.300}$$

for $k \in G \cup E$ and $l \in E$ and ,

$$\begin{aligned} &\mathcal{M}_{\mu(k,l),\mu(k,l)+1)} = -\mathcal{M}_{\mu(k,l)+1,\mu(k,l))} \\ &= -\Delta_{pb}\delta_{k>2} - \Delta_{rp}\delta_{k<3} + Z_{kl}(B) \end{aligned} \tag{34.301}$$

for $k \in G$ and $l \in E$,

$$\begin{aligned} &\mathcal{M}_{\mu(k,f),\mu(k,f)+1)} = -\mathcal{M}_{\mu(k,f)+1,\mu(k,f))} \\ &= -\Delta_{pb} + \Delta_{rp} + Z_{k,10}(B) - Z_{f,10}(B) \end{aligned} \tag{34.302}$$

for $k \in \{1, 2\}$ and $f \in \{3, .., 6\}$. The Zeeman shift Z_{kl} is given by Eq. (34.309).

Finally, the block D is filled with the components,

$$\begin{aligned} \mathcal{M}_{\mu(k,f),\mu(f,l)+1} &= (\delta_{f<k} - \tfrac{1}{2})\Omega_{kl}S_{kl}H_{kl} \\ \mathcal{M}_{\mu(k,f)+1,\mu(f,l)} &= (\delta_{l<f} - \tfrac{1}{2})\Omega_{kl}S_{kl}H_{kl} \\ \mathcal{M}_{\mu(l,f),\mu(f,k)+1} &= (\delta_{l<f} - \tfrac{1}{2})\Omega_{kl}S_{kl}H_{kl} \\ \mathcal{M}_{\mu(l,f)+1,\mu(f,k)} &= (\delta_{f<k} - \tfrac{1}{2})\Omega_{kl}S_{kl}H_{kl}\ , \end{aligned} \tag{34.303}$$

where,

$$\begin{aligned}\Omega_{kl} &\equiv (\Omega_{rp}\delta_{k\leq 2} + \Omega_{pb}\delta_{k\geq 3})\delta_{l\geq 7} \\ \hat{\epsilon}_{kl} &\equiv (\hat{\epsilon}_{rp}\delta_{k\leq 2} + \hat{\epsilon}_{pb}\delta_{k\geq 3})\delta_{l\geq 7}\ .\end{aligned} \tag{34.304}$$

for $k \in G \cup E$ and $l \in E$ and $f \in G \cup E$ but $f \neq k, l$. The projection onto the quantization axis $H_{kl} = H_{kl}\left(\frac{\hat{\epsilon}_{kl}}{|\hat{\epsilon}_{kl}|}, \vec{\mathcal{B}}, m_l - m_k\right)$ is given by Eq. (34.308).

The Eqs. (34.298)-(34.303) form together an algorithm to generate the matrix allowing one to numerically solve the Bloch equations (34.297), as has been done in the main text.

34.7.4.2 Relative forces of oscillators

Spontaneous transitions between hyperfine- and Zeeman split levels have to be weighted according to the Wigner-Eckardt theorem using Clebsch-Gordan $(3j)$ and Wigner $\{6j\}$ symbols. Consider the transition $|(J_k, I)F_k, m_k\rangle \leftrightarrow |(J_l, I)F_l, m_l\rangle$. The relative oscillator strength is,

$$\begin{aligned}S_{kl} = &\begin{pmatrix} F_k & \kappa & F_l \\ m_k & \text{sign}\ (m_l - m_k) & -m_l \end{pmatrix}^2 \\ &\begin{Bmatrix} J_l & J_k & \kappa \\ F_k & F_l & I \end{Bmatrix}^2 \frac{(2F_k+1)(2J_l+1)(2\kappa+1)}{2I+1}\ .\end{aligned} \tag{34.305}$$

34.7.4.3 Elliptical laser polarization

The transition rates additionally depend on the relative orientation of the laser polarizations and the magnetic field direction. This dependence is accounted for by decomposing the polarization vector into the,

$$\hat{\mathbf{e}}_3 = \frac{\vec{\mathcal{B}}}{B} \quad , \quad \hat{\mathbf{e}}_2 = \frac{\hat{\mathbf{e}}_3 \times \hat{\mathbf{g}}}{|\hat{\mathbf{e}}_3 \times \hat{\mathbf{g}}|} \quad , \quad \hat{\mathbf{e}}_1 = \frac{\hat{\mathbf{e}}_2 \times \hat{\mathbf{e}}_3}{|\hat{\mathbf{e}}_2 \times \hat{\mathbf{e}}_3|}\ , \tag{34.306}$$

where $\hat{\mathbf{g}}$ is an arbitrarily chosen direction, e.g. gravity. The relative amplitude of the transitions $\Delta m_J = 0$ is proportional to the projection of the polarization vector on the magnetic field axis $\zeta_0 = (\hat{\varepsilon} \cdot \hat{\mathbf{e}}_3)^2$ for π-polarized light. To estimate the amplitude of the transitions $\Delta m_J = \pm 1$, we must project onto the coordinates,

$$\hat{\mathbf{e}}_\pm = \tfrac{1}{\sqrt{2}}(\mp\hat{\mathbf{e}}_1 - \imath\hat{\mathbf{e}}_2)\ , \tag{34.307}$$

and we obtain $\zeta_{\pm 1} = (\hat{\varepsilon} \cdot \hat{\mathbf{e}}_\pm)^2$ for $\sigma^\pm$-polarized light. Hence,

$$H_{kl} = \zeta_{\Delta m_J} = \zeta_{m_l - m_k}\ . \tag{34.308}$$

With this generalization the Bloch equations can e.g. be employed to calculate Hanle resonances quantum mechanically. The Hanle effect occurs when a magnetic and an optical field compete for the quantization axis.

34.7.4.4 Hyperfine and Zeeman splitting

The nuclear spin of the ^{6}Li atom is $I = 1$, its electron spin is $S = \frac{1}{2}$. The excitation states are characterized by quantum numbers J_k, F_k, m_k. The electron angular orbital momentum is $L_k = \delta_{k\geq 7}$, and the electron angular orbital momentum is $J_k = \frac{1}{2}\delta_{k\leq 6} + \frac{3}{2}\delta_{k\geq 7}$. The hyperfine structure of the excited state $^2P_{3/2}$ can be written as $\nu_{hf1} = -2.8$ MHz, $\nu_{hf2} = 0$ MHz, and $\nu_{hf3} = 1.7$ MHz. Hence, the hyperfine splitting is inferior to the natural decay rate $\Gamma = (2\pi)\ 6$ MHz,

$$\begin{aligned} Z_{kl} &= \tfrac{\mu_B|\vec{\mathcal{B}}|}{2\pi\hbar}(g_{F_k}m_k - g_{F_l}m_l) \\ &+ \nu_{hf1}\delta_{7\leq l\leq 8} + \nu_{hf2}\delta_{8\leq l\leq 13} + \nu_{hf3}\delta_{13\leq l\leq 16}\ , \end{aligned} \tag{34.309}$$

where g_{F_k} is the Landé factor of hyperfine level F_k.

34.7.5 Exercises

34.7.5.1 Ex: Derivation of three-level Bloch equations

Derive from the general formula (34.277) the three-level Bloch equations for the system $|1\rangle \overset{\Omega_{12}}{\longleftrightarrow} |2\rangle \overset{\Omega_{23}}{\longleftrightarrow} |3\rangle$.

Solution: *In the case of three-level systems the sum in (34.277) runs over* $(ij) = (12), (13), (23)$*, so that we get,*

$$\begin{aligned} \dot\rho_{km} &= 2\sum_j \gamma_{mj}\rho_{jj}\delta_{km} - [\sum_i(\gamma_{ik}+\gamma_{im}) + \imath(\omega_k - \omega_m)]\rho_{km} \\ &+ \tfrac{\imath}{2}\left(\Omega_{12}\rho_{k1}\delta_{2m} + \Omega_{12}^*\rho_{k2}\delta_{1m} - \Omega_{12}\rho_{2m}\delta_{k1} - \Omega_{12}^*\rho_{1m}\delta_{k2}\right) \\ &+ \tfrac{\imath}{2}\left(\Omega_{13}\rho_{k1}\delta_{2m} + \Omega_{13}^*\rho_{k2}\delta_{1m} - \Omega_{13}\rho_{2m}\delta_{k1} - \Omega_{13}^*\rho_{1m}\delta_{k2}\right) \\ &+ \tfrac{\imath}{2}\left(\Omega_{23}\rho_{k2}\delta_{3m} + \Omega_{23}^*\rho_{k3}\delta_{2m} - \Omega_{23}\rho_{3m}\delta_{k2} - \Omega_{23}^*\rho_{2m}\delta_{k3}\right)\ . \end{aligned}$$

For example, for the components ρ_{11} *and* ρ_{12}*, assuming* $\Omega_{jm}^* = \Omega_{mj} = \Omega_{jm}$*, and* $\Omega_{13} = 0$*,*

$$\begin{aligned} \dot\rho_{11} &= 2\sum_j \gamma_{1j}\rho_{jj} - 2\sum_i(\gamma_{i1}+\gamma_{i1})\rho_{km} + \tfrac{\imath\Omega_{12}}{2}(\rho_{12}-\rho_{21}) \\ \dot\rho_{12} &= -[\sum_i(\gamma_{i1}+\gamma_{i2}) + \imath(\omega_1-\omega_2)]\rho_{12} + \tfrac{\imath\Omega_{12}}{2}(\rho_{11}-\rho_{22}) + \tfrac{\imath\Omega_{23}}{2}\rho_{13}\ . \end{aligned}$$

in agreement with (34.279). The decay terms actually depend on the level configuration. For a λ*-system we have* $E_1, E_2 < E_3$*, for a* V*-system we have* $E_1, E_2 > E_3$*, and for a cascade system* $E_1 < E_2 < E_3$*.*

34.7.5.2 Ex: Bloch equations for three levels

An excited Λ-shaped atom consists of two ground states $|1\rangle$ and $|3\rangle$, which are coupled by two lasers with Rabi frequencies and detunings Ω_{12} and Δ_{12} respectively Ω_{23} and Δ_{23} through an excited level $|2\rangle$. Derive the Bloch equations from this system from the general master equation.

Solution: *Let us first verify that the Bloch equations for two levels follow the formula (34.222). The Hamiltonian is* $\hat{H} = \hbar\omega_0|2\rangle\langle 2| + \frac{\hbar}{2}\Omega e^{-\imath\omega t}|1\rangle\langle 2| + \frac{\hbar}{2}\Omega e^{\imath\omega t}|2\rangle\langle 1|$ *the operator of Liouville is*

$$\begin{aligned}
\mathcal{L}\rho &= \sum\nolimits_{i,j}\gamma_{ij}\Big(|j\rangle\langle i|\sum\nolimits_{m,n}|m\rangle\rho_{mn}\langle n|i\rangle\langle j| - \sum\nolimits_{m,n}|m\rangle\rho_{mn}\langle n|i\rangle\langle j|j\rangle\langle i| \\
&+ |j\rangle\langle i|\sum\nolimits_{m,n}|m\rangle\rho_{mn}\langle n|i\rangle\langle j| - |i\rangle\langle j|j\rangle\langle i|\sum\nolimits_{m,n}|m\rangle\rho_{mn}\langle n|\Big) \\
&= \gamma\Big(|2\rangle\langle 1|\sum\nolimits_{m,n}|m\rangle\rho_{mn}\langle n|1\rangle\langle 2| - \sum\nolimits_{m,n}|n\rangle\rho_{nm}\langle m|1\rangle\langle 2|2\rangle\langle 1| \\
&+ |2\rangle\langle 1|\sum\nolimits_{m,n}|m\rangle\rho_{mn}\langle n|1\rangle\langle 2| - |1\rangle\langle 2|2\rangle\langle 1|\sum\nolimits_{m,n}|n\rangle\rho_{nm}\langle m|\Big) \\
&= \gamma\Big(2|2\rangle\rho_{11}\langle 2| - \sum\nolimits_{n}|n\rangle\rho_{n1}\langle 1| - \sum\nolimits_{m}|1\rangle\rho_{m1}\langle m|\Big)\ .
\end{aligned}$$

Follows the master equation,

$$\begin{aligned}
&\frac{d}{dt}\rho = -\frac{\imath}{\hbar}[H,\rho] + \mathcal{L}\rho \\
&= -\imath\begin{pmatrix} \frac{1}{2}\Omega e^{-\imath\omega t}\rho_{21} - \frac{1}{2}\Omega e^{\imath\omega t}\rho_{12} & \frac{1}{2}\Omega e^{-\imath\omega t}\rho_{22} - \frac{1}{2}\Omega e^{-\imath\omega t}\rho_{11} - \omega_0\rho_{12} \\ \frac{1}{2}\Omega e^{\imath\omega t}\rho_{11} - \frac{1}{2}\Omega e^{\imath\omega t}\rho_{22} + \omega_0\rho_{21} & \frac{1}{2}\Omega e^{\imath\omega t}\rho_{12} - \frac{1}{2}\Omega e^{-\imath\omega t}\rho_{21} \end{pmatrix} + \gamma\begin{pmatrix} 2\rho_{22} & -\rho_{12} \\ -\rho_{21} & -2\rho_{22} \end{pmatrix} \\
&= -\imath\begin{pmatrix} \frac{\Omega}{2}\tilde{\rho}_{21} - \frac{\Omega}{2}\tilde{\rho}_{12} & \frac{\Omega}{2}e^{-\imath\omega t}\rho_{22} - \frac{\Omega}{2}\rho_{11}e^{-\imath\omega t} - \omega_0\tilde{\rho}_{12}e^{-\imath\omega t} \\ \frac{\Omega}{2}e^{\imath\omega t}\rho_{11} - \frac{\Omega}{2}e^{\imath\omega t}\rho_{22} + \omega_0\tilde{\rho}_{21}e^{\imath\omega t} & \frac{\Omega}{2}\tilde{\rho}_{12} - \frac{1}{2}\Omega\tilde{\rho}_{21} \end{pmatrix} + \gamma\begin{pmatrix} 2\rho_{22} & -\rho_{12} \\ -\rho_{21} & -2\rho_{22} \end{pmatrix}
\end{aligned}$$

transforming to the rotating frame, $\tilde{\rho}_{12}e^{-\imath\omega t} = \rho_{12}$,

$$\frac{d}{dt}\tilde{\rho} = \begin{pmatrix} -\frac{\imath}{2}\Omega\tilde{\rho}_{21} + \frac{\imath}{2}\Omega\tilde{\rho}_{12} & -\frac{\imath}{2}\Omega\rho_{22} + \frac{\imath}{2}\Omega\rho_{11} - \imath\Delta\tilde{\rho}_{12} \\ -\frac{\imath}{2}\Omega\rho_{11} + \frac{\imath}{2}\Omega\rho_{22} + \imath\Delta\tilde{\rho}_{21} & -\frac{\imath}{2}\Omega\tilde{\rho}_{12} + \frac{\imath}{2}\Omega\tilde{\rho}_{21} \end{pmatrix} + \gamma\begin{pmatrix} 2\rho_{22} & -\rho_{12} \\ -\rho_{21} & -2\rho_{22} \end{pmatrix}\ .$$

Moving to the Bloch vector notation we find the well-known expression (34.188).
We now generalize to three levels using the equations (34.266). For three levels the Hamiltonian is,

$$\hat{H} = \hbar\omega_2|2\rangle\langle 2| + \hbar\omega_3|3\rangle\langle 3| + \frac{\hbar}{2}\Omega_{12}e^{-\imath\omega_a t}|1\rangle\langle 2| + \frac{\hbar}{2}\Omega_{12}e^{\imath\omega_a t}|2\rangle\langle 1| + \frac{\hbar}{2}\Omega_{23}e^{\imath\omega_b t}|2\rangle\langle 3| + \frac{\hbar}{2}\Omega_{23}e^{-\imath\omega_b t}|3\rangle\langle 2|\ ,$$

and the Liouville operator is,

$$\begin{aligned}
\mathcal{L}\rho = &\gamma_{12}\left(2|1\rangle\rho_{22}\langle 1| - 2|2\rangle\rho_{22}\langle 2| - |1\rangle\rho_{12}\langle 2| - |2\rangle\rho_{21}\langle 1|\right) \\
&+ \gamma_{23}\left(2|3\rangle\rho_{22}\langle 3| - 2|2\rangle\rho_{22}\langle 2| - |2\rangle\rho_{23}\langle 3| - |3\rangle\rho_{32}\langle 2|\right) \\
&+ \gamma_{13}\left(2|1\rangle\rho_{33}\langle 1| - 2|3\rangle\rho_{33}\langle 3| - |1\rangle\rho_{13}\langle 3| - |3\rangle\rho_{31}\langle 1|\right)\ .
\end{aligned}$$

Follows the master equation,

$$\begin{aligned}
&\frac{d}{dt}\rho = -\frac{\imath}{\hbar}[H,\rho] + \mathcal{L}\rho \\
&= -\imath\left[\begin{pmatrix} 0 & \frac{\Omega_{12}}{2}e^{-\imath\omega_a t} & 0 \\ \frac{\Omega_{12}}{2}e^{\imath\omega_a t} & -\imath\omega_2 & -\frac{\imath\Omega_{23}}{2}e^{\imath\omega_b t} \\ 0 & \frac{\Omega_{23}}{2}e^{-\imath\omega_b t} & -\imath\omega_3 \end{pmatrix}, \begin{pmatrix} \rho_{11} & \rho_{12} & \rho_{13} \\ \rho_{21} & \rho_{22} & \rho_{23} \\ \rho_{31} & \rho_{32} & \rho_{33} \end{pmatrix}\right] \\
&+ \begin{pmatrix} 2\gamma_{12}\rho_{22} + 2\gamma_{13}\rho_{33} & -\gamma_{12}\rho_{12} & -\gamma_{13}\rho_{13} \\ -\gamma_{12}\rho_{21} & -2(\gamma_{12}+\gamma_{23})\rho_{22} & -\gamma_{23}\rho_{23} \\ -\gamma_{13}\rho_{31} & -\gamma_{23}\rho_{32} & 2\gamma_{23}\rho_{22} - 2\gamma_{13}\rho_{33} \end{pmatrix}
\end{aligned}$$

Using MAPLE we derive the Bloch equations,

$$\dot\rho_{11} = \tfrac{\imath}{2}\Omega_{12}\left(e^{\imath\omega_a t}\rho_{12} - e^{-\imath\omega_a t}\rho_{21}\right) + 2\gamma_{12}\rho_{22} + 2\gamma_{13}\rho_{33} = 1 - \rho_{22} - \rho_{33}$$
$$\dot\rho_{22} = -\tfrac{\imath}{2}\Omega_{12}\left(e^{\imath\omega_a t}\rho_{12} - e^{-\imath\omega_a t}\rho_{21}\right) + \tfrac{\imath}{2}\Omega_{23}\left(e^{-\imath\omega_b t}\rho_{23} - e^{\imath\omega_b t}\rho_{32}\right) - 2\gamma_{12}\rho_{22} - 2\gamma_{23}\rho_{22}$$
$$\dot\rho_{12} = \tfrac{\imath}{2}\Omega_{12}e^{-\imath\omega_a t}(\rho_{11} - \rho_{22}) + \tfrac{\imath}{2}\Omega_{23}e^{-\imath\omega_b t}\rho_{13} + (\imath\omega_2 - \gamma_{12})\rho_{12} = \dot\rho_{21}^*$$
$$\dot\rho_{13} = \tfrac{\imath}{2}\Omega_{23}e^{-\imath\omega_b t}\rho_{12} - \tfrac{\imath}{2}\Omega_{12}e^{-\imath\omega_a t}\rho_{23} + (\imath\omega_3 - \gamma_{13})\rho_{13} = \dot\rho_{31}^*$$
$$\dot\rho_{23} = -\tfrac{\imath}{2}\Omega_{12}e^{\imath\omega_a t}\rho_{13} + \tfrac{\imath}{2}\Omega_{23}e^{\imath\omega_b t}(\rho_{22} - \rho_{33}) + (\imath\omega_3 - \imath\omega_2 - \gamma_{23})\rho_{23} = \dot\rho_{32}^* \ .$$

This result can be cast into a matrix form.

34.7.5.3 Ex: Adiabatic elimination

Derive the effective two-level Bloch equations for a Λ-type three-level system adiabatically eliminating the excited state under the Raman condition. **Help**: Start from the Liouvillean (34.279), set $\rho_{22} = 0$, assume $\Gamma_{13} \ll \Gamma_{12}, \Gamma_{23} \ll |\Delta_{12}|, |\Delta_{23}|$, and $\Delta_{12} = -\Delta_{23}$.

Solution: *To study adiabatic elimination we start from the Liouvillean (34.279) for a Λ-system and set $\rho_{22} = 0$, which is justified for large detunings, $|\Delta_{12}|$, $|\Delta_{23}| \gg \Gamma_{12}$, Γ_{23} . We also assume $\Gamma_{13} \ll \Gamma_{12}, \Gamma_{23}$,*

$$\dot{\tilde\rho} = \begin{pmatrix}
0 & \Gamma_{13} & \frac{\imath}{2}\Omega_{12} & -\frac{\imath}{2}\Omega_{12} & 0 & 0 & 0 & 0 \\
0 & -\Gamma_{13} & 0 & 0 & 0 & 0 & -\frac{\imath}{2}\Omega_{23} & \frac{\imath}{2}\Omega_{23} \\
\frac{\imath}{2}\Omega_{12} & 0 & -\imath\Delta_{12} - \frac{1}{2}\Gamma & 0 & \frac{\imath}{2}\Omega_{23} & 0 & 0 & 0 \\
-\frac{\imath}{2}\Omega_{12} & 0 & 0 & \imath\Delta_{12} - \frac{1}{2}\Gamma & 0 & -\frac{\imath}{2}\Omega_{23} & 0 & 0 \\
0 & 0 & \frac{\imath}{2}\Omega_{23} & 0 & -\imath\Delta_{13} - \frac{1}{2}\Gamma_{13} & 0 & -\frac{\imath}{2}\Omega_{12} & 0 \\
0 & 0 & 0 & -\frac{\imath}{2}\Omega_{23} & 0 & \imath\Delta_{13} - \frac{1}{2}\Gamma_{13} & 0 & \frac{\imath}{2}\Omega_{12} \\
0 & -\frac{\imath}{2}\Omega_{23} & 0 & 0 & -\frac{\imath}{2}\Omega_{12} & 0 & -\imath\Delta_{23} - \frac{1}{2}\Gamma & 0 \\
0 & \frac{\imath}{2}\Omega_{23} & 0 & 0 & 0 & \frac{\imath}{2}\Omega_{12} & 0 & \imath\Delta_{23} - \frac{1}{2}\Gamma
\end{pmatrix}
\begin{pmatrix} \rho_{11} \\ \rho_{33} \\ \rho_{12} \\ \rho_{21} \\ \rho_{13} \\ \rho_{31} \\ \rho_{23} \\ \rho_{32} \end{pmatrix},$$

with $\Delta_{13} = \Delta_{12} + \Delta_{23}$ and defining $\Gamma \equiv \Gamma_{12} + \Gamma_{23}$. We set the Raman condition $\Delta \equiv \Delta_{12} = -\Delta_{23}$, such that $\Delta_{13} = 0$, and assume the coherences to the excited state to be stationary,

$$\dot\rho_{12} = 0 = \tfrac{\imath}{2}\Omega_{12}\rho_{11} - \left(\imath\Delta + \tfrac{1}{2}\Gamma\right)\rho_{12} + \tfrac{\imath}{2}\Omega_{23}\rho_{13}$$
$$\dot\rho_{23} = 0 = -\tfrac{\imath}{2}\Omega_{23}\rho_{33} - \left(-\imath\Delta + \tfrac{1}{2}\Gamma\right)\rho_{23} - \tfrac{\imath}{2}\Omega_{12}\rho_{13}$$

such that

$$\rho_{12} = \frac{\imath\Omega_{12}\rho_{11} + \imath\Omega_{23}\rho_{13}}{2\imath\Delta + \Gamma} \quad , \quad \rho_{23} = \frac{-\imath\Omega_{23}\rho_{33} - \imath\Omega_{12}\rho_{13}}{-2\imath\Delta + \Gamma} \ .$$

Now substituting this into the remaining Bloch equations,

$$\begin{aligned}
\dot\rho_{11} &= \Gamma_{13}\rho_{33} + \tfrac{\imath}{2}\Omega_{12}\rho_{12} - \tfrac{\imath}{2}\Omega_{12}\rho_{21} \\
&= -\frac{\Omega_{12}^2\Gamma}{4\Delta^2 + \Gamma^2}\rho_{11} + \Gamma_{13}\rho_{33} - \frac{\Omega_{12}\Omega_{23}}{4\imath\Delta + 2\Gamma}\rho_{13} - \frac{\Omega_{12}\Omega_{23}}{-4\imath\Delta + 2\Gamma}\rho_{31} \\
\dot\rho_{33} &= -\Gamma_{13}\rho_{33} - \tfrac{\imath}{2}\Omega_{23}\rho_{23} + \tfrac{\imath}{2}\Omega_{23}\rho_{32} \\
&= -\Gamma_{13}\rho_{33} - \frac{\Omega_{23}^2\Gamma}{4\Delta^2 + \Gamma^2}\rho_{33} - \frac{\Omega_{12}\Omega_{23}}{-4\imath\Delta + 2\Gamma}\rho_{13} - \frac{\Omega_{12}\Omega_{23}}{4\imath\Delta + 2\Gamma}\rho_{31} \\
\dot\rho_{13} &= -\tfrac{1}{2}\Gamma_{13}\rho_{13} + \tfrac{\imath}{2}\Omega_{23}\rho_{12} - \tfrac{\imath}{2}\Omega_{12}\rho_{23} \\
&= \left(-\tfrac{1}{2}\Gamma_{13} - \frac{\Omega_{23}^2}{4\imath\Delta + 2\Gamma} - \frac{\Omega_{12}^2}{-4\imath\Delta + 2\Gamma}\right)\rho_{13} - \frac{\Omega_{12}\Omega_{23}}{4\imath\Delta + 2\Gamma}\rho_{11} - \frac{\Omega_{12}\Omega_{23}}{-4\imath\Delta + 2\Gamma}\rho_{33} \ .
\end{aligned}$$

Neglecting the terms 2Γ *in all denominators and defining* $\Omega \equiv \frac{\Omega_{12}\Omega_{23}}{2\Delta}$,

$$\mathcal{L} \simeq \begin{pmatrix} -\frac{\Omega_{12}^2\Gamma}{4\Delta^2} & \Gamma_{13} & \frac{\imath}{2}\Omega & -\frac{\imath}{2}\Omega \\ 0 & -\Gamma_{13} - \frac{\Omega_{23}^2\Gamma}{4\Delta^2} & -\frac{\imath}{2}\Omega & \frac{\imath}{2}\Omega \\ \frac{\imath}{2}\Omega & -\frac{\imath}{2}\Omega & -\frac{1}{2}\Gamma_{13} + \imath\frac{\Omega_{12}^2-\Omega_{23}^2}{4\Delta} & 0 \\ -\frac{\imath}{2}\Omega & \frac{\imath}{2}\Omega & 0 & -\frac{1}{2}\Gamma_{13} - \imath\frac{\Omega_{12}^2-\Omega_{23}^2}{4\Delta} \end{pmatrix} .$$

34.8 Multi-level phenomena

The multi-level Bloch equations, and in particular the three-level Bloch equations (34.279), allow for the theoretical description of many phenomena beyond the two-level approximation. Among them are the phenomena of *light shift* treated in Excs. 34.5.4.12 and 34.5.4.13, the *Autler-Townes splitting* treated in Exc. 34.8.4.1, the *dark resonances* treated in Excs. 34.8.4.3 to 34.8.4.6, the *STIRAP* method treated in Exc. 34.8.4.7, *adiabatic sweeps* treated in Exc. 34.8.4.8, the dispersive interaction between atoms and light treated in Exc. 34.8.4.9, *Fano resonance*-type line profiles of dark resonances treated in Exc. 34.8.4.10, and the *quantum jumps*, which will be studied in later chapters. In Excs. 34.8.4.11 and 34.8.4.12 we will show, that an atomic gas may have *negative permittivity* and *negative permeability* and, consequently, properties usually only found in artificial metamaterials, as for example, a *negative refractive index*.

34.8.1 Electromagnetically induced transparency

In some special cases, the three-level Bloch equations can be solved analytically. The system in Λ-configuration schematized in Fig. 34.17(a), where the two lasers satisfy the condition $\Delta_{12} = \Delta_{23}$ can exhibit a *dark resonance* leading to the phenomena of *electromagnetically induced transparency* (*EIT*) and *electromagnetically induced absorption*. In these resonances a dramatic change of the refractive index is observed despite the fact that the atom becomes transparent, $\mathfrak{Re}\ \chi \gg 0$ and $|\mathfrak{Im}\ \chi| \ll \mathfrak{Re}\ \chi$:

$$\mathfrak{Re}\ n = \sqrt{1 + \mathfrak{Re}\ \chi} \gg 1 \ , \tag{34.310}$$

resulting in a high group velocity,

$$v_g = \frac{c}{n + \omega\frac{dn}{d\omega}} \ . \tag{34.311}$$

EIT is usually studied in Λ-type systems, but similar phenomena can be found in cascade-type systems [1414, 1395], which will be studied here. Disregarding the decay rate Γ_{13}, the Bloch equations (34.279) and (34.282) give the coherences,

$$\begin{aligned} \dot\rho_{12} &= -\Lambda_{12}\rho_{12} + \tfrac{\imath\Omega_{12}}{2}(\rho_{11} - \rho_{22}) - \tfrac{\imath\Omega_{23}}{2}\rho_{13} \\ \dot\rho_{13} &= -\Lambda_{13}^*\rho_{13} - \tfrac{\imath\Omega_{12}}{2}\rho_{23} - \tfrac{\imath\Omega_{23}}{2}\rho_{12} \\ \dot\rho_{23} &= -\Lambda_{23}\rho_{23} + \tfrac{\imath\Omega_{23}}{2}(\rho_{22} - \rho_{33}) - \tfrac{\imath\Omega_{12}}{2}\rho_{13} \ . \end{aligned} \tag{34.312}$$

Assuming stationarity and negligible depletion of the ground state, $\rho_{11} = 1$,

$$\begin{aligned} 0 &= -\Lambda_{12}\rho_{12} + \tfrac{\imath\Omega_{12}}{2} - \tfrac{\imath\Omega_{23}}{2}\rho_{13} \\ 0 &= -\Lambda_{13}^{*}\rho_{13} - \tfrac{\imath\Omega_{12}}{2}\rho_{23} - \tfrac{\imath\Omega_{23}}{2}\rho_{12} \\ 0 &= -\Lambda_{23}\rho_{23} - \tfrac{\imath\Omega_{12}}{2}\rho_{13} \ . \end{aligned} \tag{34.313}$$

Substituting the third into the first equation,

$$\begin{aligned} 0 &= -\Lambda_{12}\rho_{12} + \tfrac{\imath\Omega_{12}}{2} - \tfrac{\imath\Omega_{23}}{2}\rho_{13} \\ 0 &= -\Lambda_{13}^{*}\rho_{13} - \tfrac{\Omega_{12}^{2}}{4\Lambda_{23}}\rho_{13} - \tfrac{\imath\Omega_{23}}{2}\rho_{12} \ . \end{aligned} \tag{34.314}$$

and finally,

$$\boxed{\rho_{12} = \frac{\imath\Omega_{12}}{2}\frac{4\Lambda_{13}^{*}\Lambda_{23} + \Omega_{12}^{2}}{\Lambda_{12}\left(4\Lambda_{13}^{*}\Lambda_{23} + \Omega_{12}^{2}\right) + \Omega_{23}^{2}\Lambda_{23}}} \ . \tag{34.315}$$

The macroscopic polarization is now $\mathcal{P} = \frac{N}{V} d_{12}\rho_{21}$, with the number of atoms N. In the limit of weak probes, the *dressed* susceptibility follows from $\mathcal{P} = \varepsilon_0\chi\mathcal{E}_{12} = \frac{N}{V} d_{12}\rho_{21}$,

$$\chi = \frac{N d_{12}}{V\varepsilon_0\mathcal{E}_{12}}\rho_{21} = \frac{N|d_{12}|^2}{V\varepsilon_0\hbar\Omega_{12}}\rho_{21} \ . \tag{34.316}$$

For a resonant probe laser, $\Delta_{23} = 0$ and with $\Gamma_{13} \simeq 0$, we have $\Lambda_{13} = \frac{1}{2}\Gamma_{23} + \imath\Delta_{12}$ and $\Lambda_{23} = \frac{1}{2}(\Gamma_{23} + \Gamma_{12})$. The susceptibility in the probe transition is now, using $\Theta \equiv \Gamma_{23} + \frac{\Omega_{12}^{2}}{2\Lambda_{23}}$,

$$\begin{aligned} \chi &= \frac{N|d_{12}|^2}{V\varepsilon_0\hbar\Omega_{12}}\imath\Omega_{12}\frac{\Gamma_{23} + \frac{\Omega_{12}^{2}}{2\Lambda_{23}} - 2\imath\Delta_{12}}{\left(\Gamma_{23} + \frac{\Omega_{12}^{2}}{2\Lambda_{23}} - 2\imath\Delta_{12}\right)(\Gamma_{12} + 2\imath\Delta_{12}) + \Omega_{23}^{2}} \\ &= \frac{N|d_{12}|^2}{V\varepsilon_0\hbar\Omega_{12}}\imath\Omega_{12}\frac{\Theta - 2\imath\Delta_{12}}{(\Theta - 2\imath\Delta_{12})(\Gamma_{12} + 2\imath\Delta_{12}) + \Omega_{23}^{2}} = \chi' + \imath\chi'' \ . \end{aligned} \tag{34.317}$$

Example 202 (*EIT in a cascade system*): We consider, for example, the intercombination line of atomic strontium ${}^{1}S_0$-${}^{3}P_1$ ($\lambda_{12} = 689\,\text{nm}$ and $\Gamma_{12} = (2\pi)\ 7.6\,\text{kHz}$) be the 'dressing' transition ${}^{3}P_1$-(5s4d)${}^{3}D_1$ ($\lambda_{23} = 2700\,\text{nm}$ and $\Gamma_{23} = (2\pi)\ 90.3\,\text{kHz}$), be the 'dressing' transition ${}^{3}P_1$-(5s5d)${}^{3}D_1$ ($\lambda_{23} = 497\,\text{nm}$ and $\Gamma_{23} = (2\pi)\ 2.3\,\text{MHz}$), both characterized by $\Gamma_{23} \gg \Omega_{12}, \Gamma_{12}, |\Delta_{12}|$, such that $\Theta \simeq \Gamma_{23}$. Hence,

$$\chi' + \imath\chi'' = \frac{N|d_{12}|^2}{V\varepsilon_0\hbar}\frac{2\Delta_{12} + \imath\Gamma_{23}}{\Omega_{23}} \ .$$

The refraction index follows with,

$$n = \sqrt{1+\chi} \simeq 1 + \tfrac{1}{2}\chi \ .$$

Its imaginary part originates from the decay term of the atom: it is here responsible for the absorbing nature of the cloud. EIT is characterized by a pronounced dispersion and a small concomitant absorption.

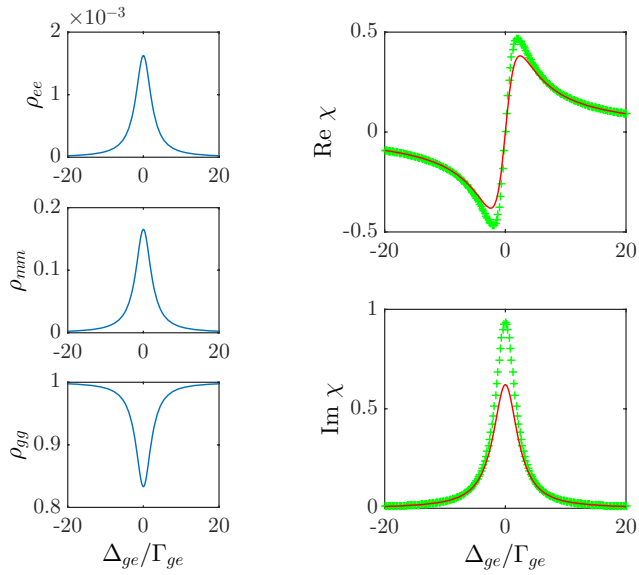

Figure 34.18: (code) EIT signal for the cascade system of strontium with the transitions at 689 nm and 497 nm with $\Omega_{12} = \Gamma_{12}$, $\Omega_{23} = \Gamma_{23}$ and $\Delta_{23} = 0$. The red lines are calculated by numerical integration of the Bloch equations. The dotted lines are obtained from analytical formulas based on the assumptions of weak ground state depletion (which is not really correct in the chosen parameter regime.

34.8.2 Polarization, alignment, and orientation

34.8.2.1 Polarization and helicity

Photons may have the angular momenta $\hat{\mathbf{L}}$, $\hat{\mathbf{S}}$, and $\hat{\mathbf{J}}$, but due to the fact that photons have zero mass, only $\hat{\mathbf{J}}$ is of importance. The *helicity* is defined as,

$$\hat{\mathbf{J}} \cdot \mathbf{k} = (\hat{\mathbf{L}} + \hat{\mathbf{S}}) \cdot \mathbf{k} = \hat{\mathbf{S}} \cdot \mathbf{k} = m_s = \pm 1 \ , \tag{34.318}$$

in beam direction and the *polarization* is,

$$\hat{\mathbf{J}} \cdot \hat{\mathbf{e}}_z = m_j = -j, ...j \ . \tag{34.319}$$

Polarizers prepare the photon in its eigenstate. The angular momentum with respect to $\hat{\mathbf{J}}$ in a basis $\hat{\mathbf{e}}_z$ orthogonal to $\mathbf{k}$ is,

$$\hat{\mathbf{J}} \cdot \mathbf{k}|m\rangle_y = a_m|1\rangle_z + b_m|-1\rangle_z \ . \tag{34.320}$$

The state $|0\rangle_z$ does not exist. For example,

$$\hat{\mathbf{J}} \cdot \mathbf{k}|1\rangle_y = \hat{J}_z \left(\tfrac{1}{2}|1\rangle_z + \imath|0\rangle_z - \tfrac{1}{2}|-1\rangle_z\right) = \tfrac{1}{2}(|1\rangle_z + |-1\rangle_z) \ . \tag{34.321}$$

34.8.2.2 Orientation and alignment

A level $|j\rangle$ with Zeeman degeneracy $|jm\rangle$ can be irreducibly described by Cartesian polarization tensors. Those are the *orientation* and the *alignment* [716, 1292],

$$\boxed{\begin{array}{rcl} O_i & \equiv & \langle \hat{J}_i \rangle \\ A_{ij} & \equiv & \frac{3}{2}\langle [\hat{J}_i, \hat{J}_j]_+ \rangle - \langle \hat{\mathbf{J}}^2 \rangle \delta_{ij} \end{array}} \ , \tag{34.322}$$

with $i, j = x, y, z$. The expectation value is calculated as usual, $\langle ... \rangle = \text{Tr}\ \hat{\rho} ... = \sum_m \langle jm|\hat{\rho}...|jm\rangle$. If $O_i \neq 0$ then the system is said *oriented*, if $A_{ij} \neq 0$ the system is said *aligned* and if either $O_i \neq 0$ or $A_{ij} \neq 0$ then the system is said *polarized*.

The orientation and the alignment depend on the choice of the quantization axis and on the Zeeman splitting of level $|j\rangle$. Choosing z as quantization axis and disregarding Zeeman coherences $\langle m|\hat{\rho}|m'\rangle \sim \delta_{mm'}$, we get the orientation,

$$\mathbf{O} = \hbar \hat{\mathbf{e}}_z \sum_m m \rho_{mm} \tag{34.323}$$

and the alignment,

$$(A_{ij}) = -\hbar^2 j(j+1) - \begin{pmatrix} -\frac{3}{2} & 0 & 0 \\ 0 & -\frac{3}{2} & 0 \\ 0 & 0 & 3 \end{pmatrix} \sum_m \hbar^2 m^2 \rho_{mm} \ , \tag{34.324}$$

if the atom is with certainty in level $|j\rangle$ so that $\text{Tr}\ \hat{\rho} = 1$. These results will be derived in Exc. 34.8.4.14.

34.8.3 Hanle effect

The *Hanle effect* occurs when a magnetic and an optical field compete for the quantization axis. Imagine an atom irradiated by a laser from direction $\mathbf{k} = k\hat{\mathbf{e}}_x$, linearly polarized $\varepsilon = \hat{\mathbf{e}}_y$ and subject to a magnetic field $\vec{\mathcal{B}} = \mathcal{B}\hat{\mathbf{e}}_z$. The fluorescence is detected in direction $\hat{\mathbf{e}}_y$ through a linear polarizer [351]. If $\mathcal{B} = 0$, no light is emitted into the detector since the dipole radiation pattern is a torus with symmetry axis $\hat{\mathbf{e}}_y$. If $\mathcal{B}$ is now increased, the quantization axis is tilted and the torus slowly precesses about the $\hat{\mathbf{e}}_x$ axis. Plotting the time-averaged fluorescence as a function of the magnetic field $\mathcal{B}$, we observe a *dark resonance*. These arguments are rather classical.

Quantum mechanically, Hanle resonances are easily calculated. The transition rates additionally depend on the relative orientation of the laser polarization and the magnetic field direction. This dependence is accounted for by decomposing the polarization vector into the coordinates defined by,

$$\hat{\mathbf{e}}_3 = \frac{\vec{\mathcal{B}}}{\mathcal{B}} \quad , \quad \hat{\mathbf{e}}_2 = \frac{\hat{\mathbf{e}}_3 \times \hat{\mathbf{g}}}{|\hat{\mathbf{e}}_3 \times \hat{\mathbf{g}}|} \quad , \quad \hat{\mathbf{e}}_1 = \frac{\hat{\mathbf{e}}_2 \times \hat{\mathbf{e}}_3}{|\hat{\mathbf{e}}_2 \times \hat{\mathbf{e}}_3|} \ , \tag{34.325}$$

where $\hat{\mathbf{g}}$ is an arbitrarily chosen direction, e.g. gravity. The relative amplitude of the transitions $\Delta m_J = 0$ is proportional to the projection of the polarization vector on

the magnetic field axis $\zeta_\pi = (\hat{\varepsilon} \cdot \hat{\mathbf{e}}_3)^2$. To estimate the amplitude of the transitions $\Delta m = \pm 1$, we must project onto the coordinates,

$$\hat{\mathbf{e}}_\pm = \tfrac{1}{\sqrt{2}}(\mp\hat{\mathbf{e}}_1 - \imath\hat{\mathbf{e}}_2) \ , \tag{34.326}$$

and we obtain $\zeta_{\sigma^\pm} = (\hat{\varepsilon} \cdot \hat{\mathbf{e}}_\pm)^2$.

Example 203 (*Hanle effect with rate equations*): The Hanle effect can be described without coherences, i.e. using only rate equations. Fig. 34.19 shows such a simulation for the case of three ground Zeeman states $|1\rangle = |g, m = +1\rangle$, $|2\rangle = |g, m = 0\rangle$, and $|3\rangle = |g, m = -1\rangle$, and one excited state $|4\rangle = |e, m = 0\rangle$. The rate equations are,

$$\dot{\rho}_{kk} = \mathcal{M}\rho_{kk} \tag{34.327}$$

$$\text{with} \quad \mathcal{M} = \begin{pmatrix} -\Omega_{14} & 0 & 0 & \Omega_{14} + \frac{1}{3}\Gamma \\ 0 & -\Omega_{24} & 0 & \Omega_{24} + \frac{1}{3}\Gamma \\ 0 & 0 & -\Omega_{34} & \Omega_{34} + \frac{1}{3}\Gamma \\ \Omega_{14} & \Omega_{24} & \Omega_{34} & -\Omega_{14} - \Omega_{24} - \Omega_{34} - \Gamma \end{pmatrix}$$

$$\text{and} \quad \Omega_{14} = \Omega_{34} = \zeta_{\sigma^\pm}\Omega \quad \text{and} \quad \Omega_{24} = \zeta_\pi \Omega \ .$$

In Exc. 34.8.4.15 we study the Hanle effect at the Ca^+ Zeeman degenerate level system.

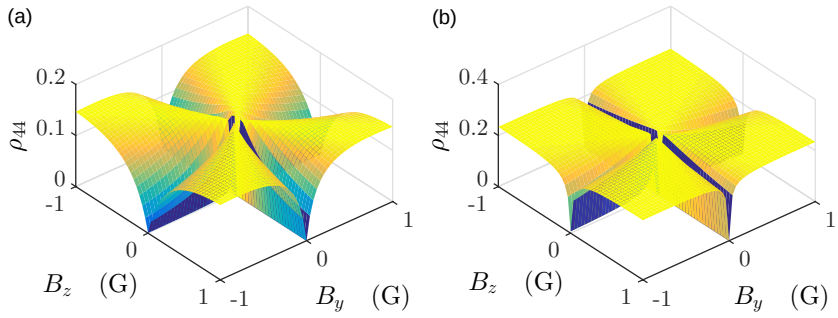

Figure 34.19: (code) Hanle effect in a four-level system with three ground and one excited state with $\hat{\varepsilon} = \hat{\mathbf{e}}_y$ and (a) $\Omega = 0.5\Gamma$ and (b) $\Omega = 5\Gamma$.

34.8.4 Exercises

34.8.4.1 Ex: Autler-Townes splitting

In this exercise we study the Autler-Townes effect in a two-level system $|1\rangle$ and $|2\rangle$ resonantly excited ($\Delta_{12} = 0$) by a laser with the Rabi frequency Ω_{12}:
a. From the eigenvalues $E_{1,2}$ of the effective Hamiltonian (34.228) of the system, describe the behavior of the real part (energy shift) and the imaginary part (linewidth) as a function of the Rabi frequency. Prepare diagrams Ω_{12} versus $\mathfrak{Re}\ E_{1,2}$ and versus $\mathfrak{Im}\ E_{1,2}$ and discuss the limits $\Omega_{12} > \frac{1}{2}\Gamma_{12}$ and $\Omega_{12} < \frac{1}{2}\Gamma_{12}$.
The Autler-Townes effect can be measured experimentally by probing the population

of level $|2\rangle$ via excitation of a third (higher) level by a second laser with the Rabi frequency Ω_{23}. Thus, we obtain a three-level system in cascade configuration, as shown in Fig. 34.17(c). In order to reproduce the experiment by numerical simulations of the Bloch equations (34.279),
b. write down the Liouville matrix $\mathcal{M}_{red}$ reduced by the trace condition (34.284) and c. compute the stationary Bloch vector from equation (34.286) varying the detuning of the probe laser Δ_{23} and the Rabi frequency Ω_{12} of the system under study ($|1\rangle$ and $|2\rangle$). Choosing the parameters $\Gamma_{23} = 0.5\Gamma_{12}$, $\Gamma_{13} = 0.01\Gamma_{12}$, $\Omega_{23} = 0.1\Gamma_{12}$, prepare a 3D curve [similar to Fig. 34.6(a)] of the stationary population $\rho_{22}(\infty)$. Interpret the results.

Solution: *a. The eigenvalues of the effective Hamiltonian (34.228) excited in resonance,*

$$E = -\tfrac{\imath}{4}\Gamma \pm \tfrac{\imath}{4}\sqrt{\Gamma^2 - 4\Omega^2} \ ,$$

describe possible effects of line broadening and/or shift due to the coupling. Two cases are interesting: In the case $\Gamma > 2\Omega$ *we get,*

$$E = \mathfrak{Re}\ E = 0 \qquad , \qquad \Gamma_{eff} = -2\mathfrak{Im}\ E = \tfrac{1}{2}\Gamma \mp \tfrac{1}{2}\sqrt{\Gamma^2 - 4\Omega^2} \to \Gamma \ .$$

That is, the resonance is not shifted or split, but undergoes a line broadening, as already shown in (34.189).
In the case $\Gamma < 2\Omega$*,*

$$E = \mathfrak{Re}\ E = \pm\tfrac{1}{2}\sqrt{\Omega^2 - \tfrac{1}{4}\Gamma^2} \to \pm\Omega \qquad , \qquad \Gamma_{eff} = -2\mathfrak{Im}\ E = \tfrac{1}{2}\Gamma \ .$$

we observe an splitting of the line called Autler-Townes splitting. When saturation is strong, the two new lines are separated by Ω*, each having the natural width* Γ*. Figs. 34.20(a,b) show the bifurcation of the spectrum at the point* $\Omega_{12} = \frac{1}{2}\Gamma$*.*
b. The Liouville matrix can be found in the numerical MATLAB code in given in the file 'LM_Bloch_AutlerTownes.m'.
c. Fig. 34.20(c) shows the results of the simulations. The laser Ω_{23} *probes the population* ρ_{22} *by excitation to a higher level, that is, the fluorescence emitted by the population* ρ_{33} *is representative for the population* ρ_{22}*.*

34.8.4.2 Ex: Quantum Zeno effect and saturation broadening

In this exercise we study saturation broadening effect in a three-level system $|1\rangle$, $|2\rangle$, and $|3\rangle$ in V-configuration, as shown in Fig. 34.17(b), excited by two resonant lasers with the Rabi frequencies Ω_{12} and Ω_{23}.
a. From the eigenvalues $E_{1,2}$ of the effective Hamiltonian (34.228) of the system, describe the behavior of the real part (energy shift) and the imaginary part (linewidth) as a function of the Rabi frequency. Prepare diagrams Ω_{12} versus $\mathfrak{Re}\ E_{1,2}$ and versus $\mathfrak{Im}\ E_{1,2}$ and discuss the limits $\Omega_{12} > \frac{1}{2}\Gamma_{12}$ and $\Omega_{12} < \frac{1}{2}\Gamma_{12}$.
Saturation broadening can be measured experimentally in a three-level system in V-configuration. To reproduce the experiment by numerical simulations of the Bloch equations (34.279),

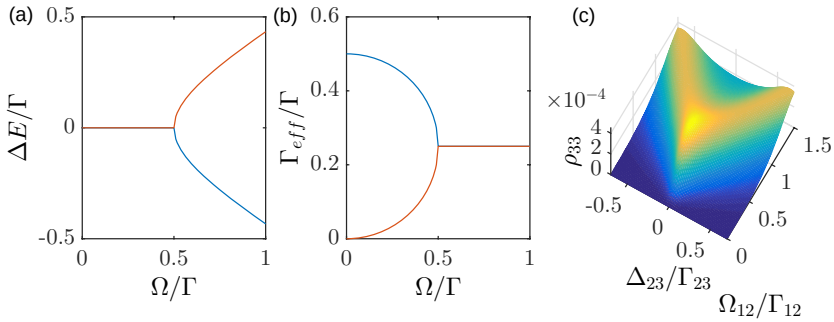

Figure 34.20: (code) (a) Autler-Townes splitting and (b) linewidths as a function of the Rabi frequency. (c) Population of the excited state in a three-level system in cascade configuration, as shown in Fig. 34.17(c) in a function of the Rabi frequencies Ω_{23} and Ω_{12}. The parameters are, $\Gamma_{23} = 0.5\Gamma_{12}$, $\Gamma_{13} = 0.01\Gamma_{12}$, $\Omega_{23} = 0.1\Gamma_{12}$.

b. write down the Liouville matrix $\mathcal{L}$ of the system and calculate the time evolution of the Bloch vector via equation (34.283) varying the Rabi frequency Ω_{12}. Choosing the parameters $\Gamma_{23} = 0.01\Gamma_{12}$, $\Gamma_{13} = 0.0001\Gamma_{12}$, $\Omega_{23} = 400\Gamma_{23}$, and $\Delta_{12} = 0 = \Delta_{23}$, prepare a 3D curve [similar to Fig. 34.6(a)] of the population $\rho_{33}(t)$ as a function of time and the Rabi frequency Ω_{12}.
c. Interpret the results in terms of broadening by saturation. The broadening can also be understood in terms of the quantum Zeno effect, where the transition $|1\rangle$-$|2\rangle$ plays the role of the 'observed system' and the transition $|2\rangle$-$|3\rangle$ the role of the measuring device or 'meter' (for example, we can observe the light scattered on the 'meter transition' to infer the evolution of the 'system transition').

Solution: *a. See the solution of Exc. 34.8.4.1(a).*
b. The Liouville matrix and the results of the simulations can be found in the numerical MATLAB code in given in the file 'LM_Bloch_ZenoEffect.m'.
c. When the 'meter transition' $|1\rangle$-$|2\rangle$ is weakly excited, $\Omega_{12} \ll \Gamma_{12}$, the 'system transition' $|2\rangle$-$|3\rangle$ evolves normally, as expected for an isolated two-level system. As we increase Ω_{12} to be able to observe the light scattered on the 'meter transition' more easily and extract information on the state of the system more quickly, we perturb the evolution of the system and prevent it from evolving: The population ρ_{33} is getting weaker.

34.8.4.3 Ex: EIT and dark resonances

In this exercise we study so-called *dark resonances*, which are responsible for the phenomenon of *electromagnetically induced transparency* (EIT). Such resonances are observed in three-level systems $|1\rangle$-$|2\rangle$-$|3\rangle$ in Λ-configuration, as shown in Fig. 34.17(a), when the laser detunings are chosen so as to satisfy $\Delta_{12} = \Delta_{23}$.
a. From the Bloch equations (34.279) show analytically that, in a stationary situation, the population of the excited state is $\rho_{22}(\infty) = 0$ in the center of the dark resonance. Dark resonances can be observed experimentally. To reproduce the experiment by

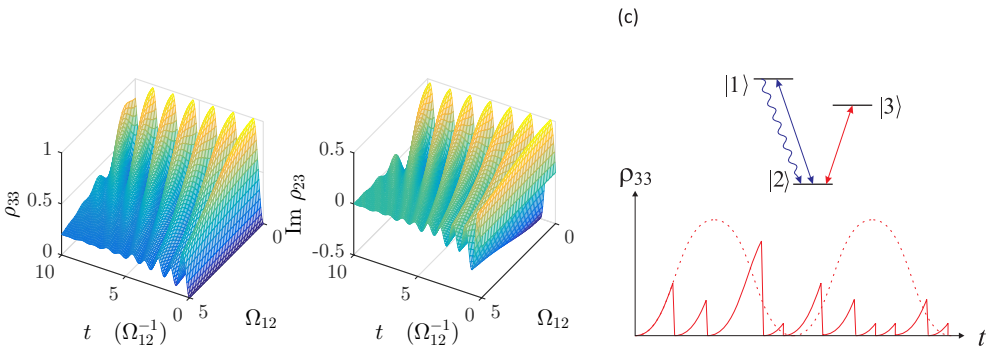

Figure 34.21: (code) (a) Temporal evolution of the excited state population ρ_{33} in a three-level system in V-configuration, as shown in Fig. 34.17(b), as a function of the Rabi frequency Ω_{12} of the 'meter' laser. (b) Temporal evolution of the coherence ρ_{23}. (c) Illustration of the interrupted evolution of the coherence.

numerical simulations of the Bloch equations (34.279), write down the Liouville matrix $\mathcal{M}_{red}$ reduced by the trace condition (34.283) and calculate the stationary Bloch vector from equation (34.284) varying the detunings of the two lasers Δ_{12} and Δ_{23}. Choosing the parameters such that $\Gamma_{23} = \Gamma_{12}$, $\Gamma_{13} = 0.01\Gamma_{12}$, $\Omega_{12} = 2\Gamma_{12}$, and $\Omega_{23} = 0.2\Gamma_{12}$, prepare a 3D curve [similar to Fig. 34.6(a)] of the population $\rho_{22}(\infty)$. Interpret the results.

Solution: *a. We put $\Delta_{12} = \Delta_{23}$ and we consider the stationary solution $\dot{\rho} = 0$. The Bloch equations are,*

$$
\begin{aligned}
0 &= \Gamma_{12}\rho_{22} + \tfrac{\imath}{2}\Omega_{12}(\rho_{12} - \rho_{21}) \\
0 &= \Gamma_{23}\rho_{22} - \tfrac{\imath}{2}\Omega_{23}(\rho_{23} - \rho_{32}) \\
0 &= \left(-\tfrac{1}{2}\Gamma_{12} - \tfrac{1}{2}\Gamma_{13} + \imath\Delta_{12}\right)\rho_{12} + \tfrac{\imath}{2}\Omega_{12}(\rho_{11} - \rho_{22}) + \tfrac{\imath}{2}\Omega_{23}\rho_{13} \\
0 &= \left(-\tfrac{1}{2}\Gamma_{12} - \tfrac{1}{2}\Gamma_{23} + \imath\Delta_{12}\right)\rho_{23} + \tfrac{\imath}{2}\Omega_{23}(\rho_{22} - \rho_{33}) - \tfrac{\imath}{2}\Omega_{12}\rho_{13} \\
0 &= \tfrac{\imath}{2}\Omega_{23}\rho_{12} - \tfrac{\imath}{2}\hbar\Omega_{12}\rho_{23} \ ,
\end{aligned}
$$

Eliminating ρ_{22} in equations I and II gives,

$$
\frac{\Omega_{12}}{\Gamma_{12}}\rho_{12} - \frac{\Omega_{12}}{\Gamma_{12}}\rho_{21} = \frac{\Omega_{23}}{\Gamma_{23}}\rho_{23} - \frac{\Omega_{23}}{\Gamma_{23}}\rho_{32} \ .
$$

Insertion of equation V into this equation gives,

$$
\frac{\Omega_{12}}{\Gamma_{12}}(\rho_{12} - \rho_{21}) = \frac{\Omega_{23}}{\Gamma_{23}}\left(\frac{\Omega_{23}}{\Omega_{12}}\rho_{21} - \frac{\Omega_{23}}{\Omega_{12}}\rho_{12}\right) \ .
$$

Since $\rho_{12} = \rho_{21} = \rho_{12}^*$, the last expression can only be true for arbitrary Rabi frequencies and decay rates if $\mathfrak{Im}\ \rho_{12} = 0$ and, hence, $\rho_{22} = 0$.
b. The Liouville matrix can be found in the numerical MATLAB code given in the file 'LM_Bloch_DarkResonance.m'. Fig. 34.22 shows the results of the simulations. The curves in Fig. 34.22(a) show that the contrast of the dark resonance decreases as the decay rate of coherence increases.

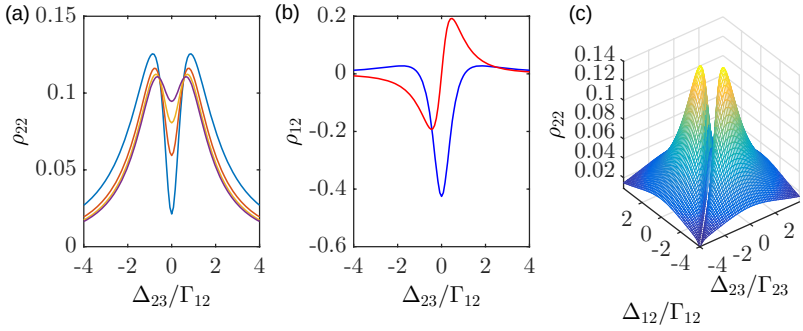

Figure 34.22: (code) (a) Population of the state excited as a function of the detuning Δ_{23} for several decay rates γ_{13} of the coherence. (b) Real and imaginary part of the susceptibility. (c) Population of the excited state as a function of the detunings Δ_{12} and Δ_{23}.

34.8.4.4 Ex: Coherent trapping and dark states

Consider a three-level system $|1\rangle$, $|2\rangle$, and $|3\rangle$ in Λ-configuration interacting with two electromagnetic fields with frequencies ω_a and ω_b. The two states $|1\rangle$ and $|3\rangle$ of lower energies $\hbar\omega_1$ and $\hbar\omega_3$ are coupled to a state $|2\rangle$ of higher energy $\hbar\omega_2$, as illustrated in Fig. 34.17(a). Assume that the transition $|1\rangle \leftrightarrow |3\rangle$ is forbidden and that the Hamiltonian of the system has the form $\hat{H} = \hat{H}_0 + \hat{H}_{int}$ where,

$$\hat{H}_0 = E_1|1\rangle\langle 1| + E_2|2\rangle\langle 2| + E_3|3\rangle\langle 3|$$
$$\hat{H}_{int} = -\tfrac{\hbar}{2}(\Omega_{12}e^{-\imath\omega_a t}|2\rangle\langle 1| + \Omega_{12}^* e^{\imath\omega_a t}|1\rangle\langle 2|) - \tfrac{\hbar}{2}(\Omega_{23}e^{-\imath\omega_b t}|2\rangle\langle 3| + \Omega_{23}^* e^{\imath\omega_b t}|3\rangle\langle 2|)\ .$$

a. Assuming that the system's state is described by $|\psi\rangle = c_1|1\rangle + c_2|2\rangle + c_3|3\rangle$ find the system of equations that describe the dynamics of probability amplitudes c_i with $(i = 1, 2, 3)$.
b. Rewrite the equations for the case where the frequencies of the applied fields are resonant (that is, $\omega_a = \omega_2 - \omega_1$ and $\omega_b = \omega_2 - \omega_3$). Simplify the system by writing in terms of the variables $u_i = c_i e^{\imath\omega_i t}$.
c. Assuming the initial condition $|\psi(0)\rangle = (|1\rangle + |3\rangle)/\sqrt{2}$, solve the system of equations for the resonant case and interpret the result.

Solution: *a. From the Schrödinger equation*

$$\imath\hbar\frac{d|\psi\rangle}{dt} = (\hat{H}_0 + \hat{H}_{int})|\psi\rangle$$

where $|\psi\rangle$ is the state given by the problem, we find the following system of equations,

$$\frac{dc_1}{dt} = -\imath\omega_1 c_1 + \tfrac{\imath\Omega_{12}^*}{2}e^{\imath\omega_a t}c_2$$
$$\frac{dc_2}{dt} = -\imath\omega_2 c_2 + \tfrac{\imath\Omega_{12}}{2}e^{-\imath\omega_a t}c_1 + \tfrac{\imath\Omega_{23}}{2}e^{-\imath\omega_b t}c_3$$
$$\frac{dc_3}{dt} = -\imath\omega_3 c_3 + \tfrac{\imath\Omega_{23}^*}{2}e^{\imath\omega_b t}c_2$$

b. By making the suggested substitutions, the system can be written as,

$$\begin{aligned}\frac{du_1}{dt} &= \frac{\imath\Omega_{12}^*}{2}u_2\\ \frac{du_2}{dt} &= \frac{\imath\Omega_{12}}{2}u_1 + \frac{\imath\Omega_{23}}{2}u_3\\ \frac{du_3}{dt} &= \frac{\imath\Omega_{23}^*}{2}u_2\end{aligned}$$

c. The initial conditions are as $u_2(0) = 0$ *and* $u_1(0) = u_3(0) = 1/\sqrt{2}$*, which will give us solutions of the type,*

$$\begin{aligned}u_1(t) &\simeq \frac{\Omega_{23}}{\sqrt{|\Omega_{12}|^2 + |\Omega_{23}|^2}}\cos\frac{\sqrt{(|\Omega_{12}|^2+|\Omega_{23}|^2)}t}{2}\\ u_2(t) &\simeq 0\\ u_3(t) &\simeq -\frac{\Omega_{12}}{\sqrt{|\Omega_{12}|^2 + |\Omega_{23}|^2}}\cos\frac{\sqrt{(|\Omega_{12}|^2+|\Omega_{23}|^2)}t}{2}\ .\end{aligned}$$

Hence, the final state can be written as $|\psi(t)\rangle = u_1(t)|1\rangle + u_3(t)|3\rangle$*. It is called a dark state, because it is independent of the excited state. This result implies that the population is trapped in the states with lower energy and the phenomenon of absorption will not occur even in the presence of external fields. The coherent trapping occurs due to the destructive quantum interference of the two transitions.*

34.8.4.5 Ex: Cascade EIT scheme in strontium

Consider the Bloch equations for the ^{88}Sr 7-level system consisting of the following levels: $|1\rangle \equiv (5s^2)\ ^1S_0$, $|2-4\rangle \equiv (5s5p)\ ^3P_1$, and $|5-7\rangle \equiv (5s5d)\ ^3D_1$, and check under which circumstances it is possible to observed dark resonances. The Sr level scheme can be consulted under (Sr level scheme). The Liouvillean can be consulted at (Sr Liouvillean).

Solution: *The results are shown in Fig. 34.23.*

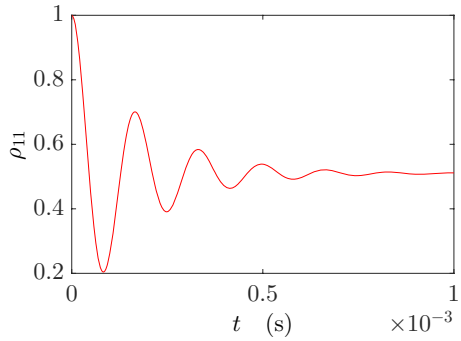

Figure 34.23: (code) Time evolution of the Sr system.

34.8.4.6 Ex: Dark resonances with Zeeman splitting

Calculate the dark resonance spectrum for the Ca^+ three-level system with Zeeman sub-structure consisting of the levels $|1\rangle \equiv {}^2S_{1/2}$, $|2\rangle \equiv {}^2P_{1/2}$, and $|3\rangle \equiv {}^2D_{3/2}$ using optical Bloch equations. **Help:** The decay rates are $\Gamma_{12}/2\pi = 23\,\text{MHz}$, $\Gamma_{23}/2\pi = 1.6\,\text{MHz}$, and $\Gamma_{13}/2\pi = 1\,\text{Hz}$. Assume that both incident lasers saturate the transitions, $\Omega_{12} = \Gamma_{12}$ and $\Omega_{23} = \Gamma_{23}$.

Solution: *The results are shown in Fig. 34.24.*

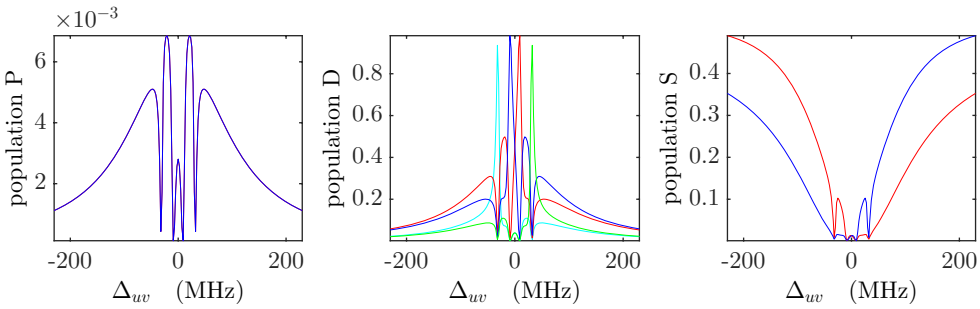

Figure 34.24: (code) Dark resonances in the Ca 3-level system. (red) $m = +1/2$, (blue) $m = -1/2$, (cyan) $m = +3/2$, and (green) $m = -3/2$.

34.8.4.7 Ex: STIRAP

In experiments with cold atoms it is often necessary to transfer populations between ground states, for example, between specific levels of a hyperfine structure. One possible procedure is the method of optical pumping, from the initial ground state to an excited state, which subsequently decays to the final state by spontaneous emission. The problem with this incoherent procedure is, that one can control into which ground state level the atom will decay, and that it heats atoms due to the photonic recoil associated with the scattering of light. In this exercise we studied an alternative method, called *Stimulated Raman Adiabatic Passage* (STIRAP), which allows the coherent transfer of population between two states by counter-intuitive pulse sequences:
a. Consider a three-level system in Λ-configuration, as shown in Fig. 34.17(a), initially being in the state $|1\rangle$. Write the system's Hamiltonian in the interaction picture. Now, choose $\Delta_{12} = 0 = \Delta_{23}$, and a temporal variation of the Rabi frequencies described by $\Omega_{12}(t) = \Gamma_{12}(\frac{1}{2} + \frac{1}{\pi}\arctan\Gamma_{12}t)$ and $\Omega_{23}(t) = \Gamma_{12}(\frac{1}{2} - \frac{1}{\pi}\arctan\Gamma_{12}t)$. With this, solve the Schrödinger equation (34.287) iteratively within the time interval $t \in [-40/\Gamma_{12}, 40/\Gamma_{12}]$, while continuously adjusting the Rabi frequencies.
b. The dynamics can also be calculated via a numerical simulations of the Bloch equations (34.279). Write down the Liouville matrix and prepare a simulation using the same parameters as in (b) and additionally $\Gamma_{23} = \Gamma_{12}/2$, $\Gamma_{13} = \Gamma_{12}/500$.
c. Interpret the results.

Solution: *a. The Hamiltonian is,*

$$\hat{H} = \hbar \begin{pmatrix} 0 & \frac{1}{2}\Omega_{12} & 0 \\ \frac{1}{2}\Omega_{12} & 0 & \frac{1}{2}\Omega_{23} \\ 0 & \frac{1}{2}\Omega_{23} & 0 \end{pmatrix} .$$

It is implemented in the numerical MATLAB code given in the file 'LM_Bloch_Stirap.m'. Fig. 34.25(a) shows the temporal variation of the Rabi frequencies. The result of the simulations is shown in Fig. 34.25(b).
b. The Liouville matrix can be found in the MATLAB numerical code given in the file 'LM_Bloch_Stirap.m'.
c. Fig. 34.25(c) shows the results of the simulations.

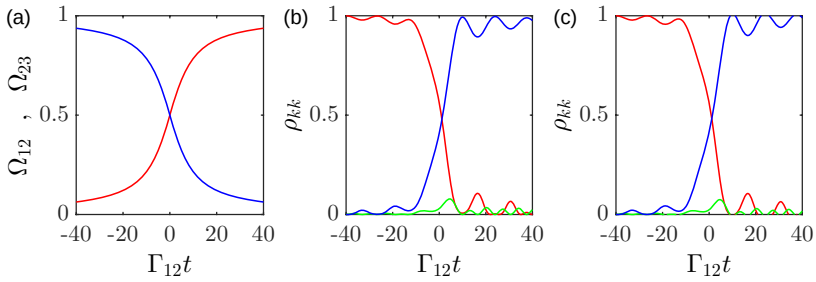

Figure 34.25: (code) (a) Temporal variation of laser intensities. (b) Variation of the populations obtained by simulation of the Schrödinger equation, and (c) of the Bloch equations: ρ_{11} in red, ρ_{22} in green, and ρ_{33} in blue. (Note that the solutions tend to diverge when the time steps are not significantly shorter than all characteristic time scales of the system, e.g. the decay rates $1/\Gamma_{12}$.)

34.8.4.8 Ex: Adiabatic sweeps

In experiments with cold atoms it is often necessary to transfer populations between ground states, for example, between specific levels of a Zeeman structure. One possible procedure is the method of optical pumping, from the initial ground state to an excited state, which subsequently decays to the final state by spontaneous emission. The problem with this incoherent procedure is, that one can control into which ground state level the atom will decay, and that it heats atoms due to the photonic recoil associated with the scattering of light. In this exercise we study an alternative method, called *adiabatic sweep*, which allows the coherent transfer of population between the two outer states of a degenerate multiplet, as shown in Fig. 34.26, via an adiabatic ramp of the frequency of the incident radiation:
a. Write down the Hamiltonian of the system in the interaction picture. Now, choose $\Omega/2\pi = 8\,\text{kHz}$ and apply a linear ramp of the radiation detuning between $-50\,\text{kHz} < \Delta(t)/2\pi < 50\,\text{kHz}$ during a time interval of 2 ms. With this, solve the Schrödinger equation (34.279) iteratively varying the detuning.
b. Write down the Liouville matrix of the system and do a numerical simulation of

the Bloch equations (34.279) using the same parameters as in (a). Interpret the results. What you observe when you introduce a decay rate between adjacent levels of $\Gamma/2\pi = 200\,\mathrm{Hz}$?

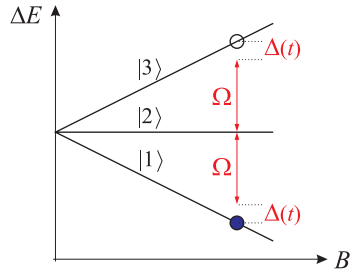

Figure 34.26: Energy levels of an atom in the ground state with Zeeman structure (for example, $|J = 1, m_J = -1, 0, +1\rangle$) as a function of the applied magnetic field.

Solution: *a. The Hamiltonian is,*

$$\hat{H} = \begin{pmatrix} 0 & \frac{1}{2}\Omega & 0 \\ \frac{1}{2}\Omega & \Delta & \frac{1}{2}\Omega \\ 0 & \frac{1}{2}\Omega & 2\Delta \end{pmatrix} .$$

The numerical MATLAB code in is given in the file 'LM_Bloch_AdiaSweep.m'. A Fig. 34.27(a) shows the result of the simulations.
b. The numerical MATLAB code in is given in the file 'LM_Bloch_AdiaSweep.m'. A Fig. 34.27(b) shows the result of the simulations.

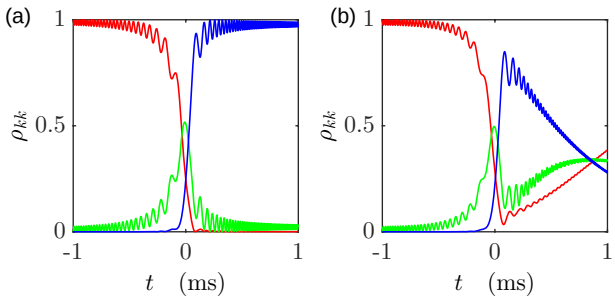

Figure 34.27: (code) Adiabatic sweep of the detuning of the radiation through resonance. The curves show the populations of the states $|1\rangle$ (red), $|2\rangle$ (green), and $|3\rangle$ (blue). (a) Schrödinger equation approach and (b) Bloch equation approach.

34.8.4.9 Ex: Dispersive interaction between an atom and light

Radiation which is tuned far from a resonance can change the phase of an atomic dipole moment without changing the populations [22]. We study this effect in a three-level system in cascade configuration excited by two radiation fields, as illustrated in Fig. 34.17(c), simulating the Schrödinger equation and the Bloch equations.
a. Write down the Hamiltonian $\hat{H}$ for this system letting $\Delta_{12} = 0$.
b. Now, consider the subsystem $|2\rangle$-$|3\rangle$, write down its Hamiltonian $\hat{H}_{23}$, determine the eigenvalues, and assume that this transition be excited very far-off resonance. That is, for $\Delta_{23} \gg \Omega_{23}, \Gamma_{23}$ expand the eigenvalues of $\hat{H}_{23}$ up to second order in Ω_{23}. Finally, replace the submatrix $\hat{H}_{23}$ in the complete Hamiltonian $\hat{H}$ by the matrix of the expanded eigenvalues. This procedure corresponds to treating the transition $|2\rangle$-$|3\rangle$ as a perturbation of the transition $|1\rangle$-$|2\rangle$ until second order.
c. Assume that the atom is initially in the ground state and compute the time evolution of the state via the Schrödinger equation (34.287) using (a) the perturbed Hamiltonian and (b) the exact Hamiltonian for the following *sequence of pulses*:
(i) a $\pi/2$-pulse on the transition $|1\rangle$-$|2\rangle$,
(ii) a pulse with a variable duration between 0 and $\Delta t = \Omega_{23}^2/4\pi\Delta_{23}$ applied to the transition $|2\rangle$-$|3\rangle$,
(iii) a $\pi/2$-pulse on the transition $|1\rangle$-$|2\rangle$. What you observe?
d. Establish the Liouville matrix $\mathcal{L}$ for the same system and calculate the time evolution of the Bloch vector during the sequence by the Bloch equations (34.287) choosing the same parameters as in (c) and additionally $\Gamma_{23} = 1$, $\Gamma_{13} = \Gamma_{23}$, $\Gamma_{12} = 0.01\Gamma_{23}$, and $\Omega_{12} \lll \Delta_{23}, \Gamma_{23}$. Prepare a 3D curve [similar to Fig. 34.6(b)] of the population $\rho_{22}(t)$. Interpret the results.

Solution: *a. The Hamiltonian for the system is,*

$$\hat{H}_{12} = \begin{pmatrix} 0 & \frac{1}{2}\Omega_{12} & 0 \\ \frac{1}{2}\Omega_{12} & 0 & \frac{1}{2}\Omega_{23} \\ 0 & \frac{1}{2}\Omega_{23} & \Delta_{23} \end{pmatrix} .$$

b. The Hamiltonian of the subsystem of the two upper levels is,

$$\hat{H}_{23} = \begin{pmatrix} 0 & \frac{1}{2}\Omega_{23} \\ \frac{1}{2}\Omega_{23} & \Delta_{23} \end{pmatrix} .$$

When excited very far-off resonance, we can expand its eigenvalues for small Ω_{23},

$$E_{1,2} = \tfrac{1}{2}(\Delta_{23} \pm G_{23}) = \frac{1}{2}\Delta_{23} \pm \frac{1}{2}\Delta_{23}\left(1 + \frac{\Omega_{23}^2}{2\Delta_{23}}\right) .$$

By substituting the matrix of corrected eigenvalues in the complete Hamiltonian, we obtain,

$$\hat{H} \simeq \begin{pmatrix} 0 & \frac{1}{2}\Omega_{12} & 0 \\ \frac{1}{2}\Omega_{12} & -\frac{\Omega_{23}^2}{4\Delta_{23}} & 0 \\ 0 & 0 & \Delta_{23} + \frac{\Omega_{23}^2}{4\Delta_{23}} \end{pmatrix} .$$

[22] This type of interaction is used in the implementation of quantum gates in quantum computing.

c. We simulate the evolution of the state to be,

$$|\psi(t)\rangle = e^{\imath\hat{H}^{(3)}\Delta t_3/\hbar}e^{\imath\hat{H}^{(2)}\Delta t_2/\hbar}e^{\imath\hat{H}^{(1)}\Delta t_1/\hbar}|\psi_(0)\rangle \ .$$

The numerical MATLAB code is given in the file 'LM_Bloch_Dispersive'.
d. We simulate the evolution of the Bloch vector to be,

$$\vec{\rho}(t) = e^{\mathcal{L}_3\Delta t_3}e^{\mathcal{L}_2\Delta t_2}e^{\mathcal{L}_1\Delta t_1}\vec{\rho}(0) \ .$$

The numerical MATLAB code is given in the file 'LM_Bloch_Dispersive'. Fig. 34.28 shows the result of the simulations. We find that Δ_{23} must be chosen very large (> 300) to obtain a really dispersive dynamics.

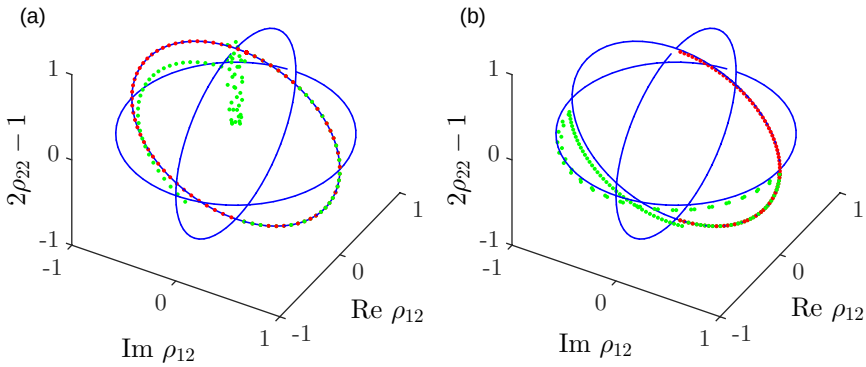

Figure 34.28: (code) (red) Evolution of Bloch vector for a sequence of resonant Ramsey pulses. (blue) Evolution for the occurrence of a dispersive pulse on a transition coupling an upper level.

34.8.4.10 Ex: Fano profile of a dark resonance

The dark resonance studied in Exc. 34.8.4.3 may in some circumstances adopt an asymmetric profile. Calculate, for a three-level system in Λ-configuration, as shown in Fig. 34.17(a), starting from the Bloch equations (34.279) with the Liouville matrix $\mathcal{M}_{red}$ reduced by the trace condition (34.283), the spectrum $\rho_{22}(\Delta_{23})$ for the following set of parameters: $\Gamma_{12} = 2$, $\Gamma_{23} = \Gamma_{12}/2$, $\Gamma_{23} = 0.1\Gamma_{12}$, $\Omega_{12} = 10\Gamma_{12}$, $\Omega_{23} = 5\Gamma_{23}$, $\Delta_{12} = -5\Gamma_{12}$ and $\Delta_{23} = [-1 : .01 : 1]\Gamma_{23}$. Interpret the spectrum in terms of a Fano resonance.

Solution: *a. The numerical MATLAB code is given in the file 'LM_Bloch_FanoResonance'. Fig. 34.29 shows the result of the simulations. For strong Rabi frequencies, the position of the dark resonance is shifted by the light-shift induced in the two transitions by a value of $\delta = \Delta_{12} - \Delta_{23}$. This value corresponds to a two-photon light-shift. The dark resonance is due to the destructive interference between two* one-photon *scattering processes: $|3\rangle \longrightarrow |i\rangle \xrightarrow{spnt} |1\rangle$ and $|1\rangle \longrightarrow |i\rangle \xrightarrow{spnt} |3\rangle$, where $|i\rangle$ is the virtual*

intermediate level. For large detunings, $\Delta_{12} \gg \Gamma_{12}, \Omega_{12}$, a small peak appears next to the dark resonance, which can be interpreted as a Fano resonance. It is due to the constructive interference between a one-photon *scattering process, $|3\rangle \to |i\rangle \xrightarrow{spnt} |1\rangle$, and a* three-photons *scattering process, $|3\rangle \to |i\rangle \to |1\rangle \to |i\rangle \xrightarrow{spnt} |1\rangle$.*

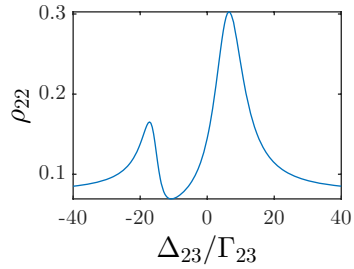

Figure 34.29: (code) Fano resonance.

34.8.4.11 Ex: Gas with negative permittivity

Study EIT on the strontium cascade system consisting of the transitions 689 nm and 497 nm and draw a spectrum of the permittivity. Compare with the permittivity of the 689 nm two-level system. What densities are necessary to get a negative permittivity?

Solution: *The curves are shown in Fig. 34.30.*

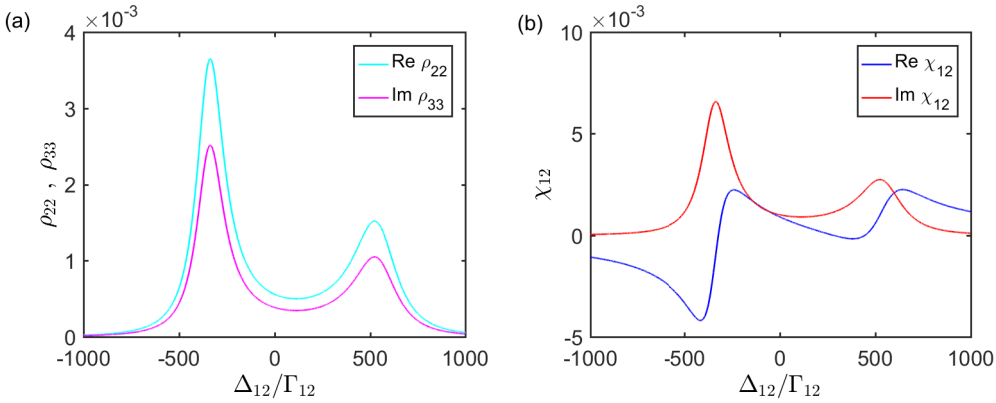

Figure 34.30: (code) Negative permittivity.

34.8.4.12 Ex: Gas with negative permeability

Theoretically, under certain conditions, gases may exhibit *negative* permittivity and permeability, and therefore refraction [1196, 1194, 1195, 968, 769]. To study this phenomenon we consider a three-level system in Λ-configuration with an electric dipole transition and another magnetic dipole transition. The objective is to balance the electrical dipole moment excited by a probe laser and the magnetic dipole moment excited via a Raman transition by both, the probe laser and a control laser. The Raman transition simulates an effective magnetic field. Since the magnetic moment is smaller by a factor of α^2, the electric moment must be reduced by detuning the probe laser, as shown in Fig. 34.31.

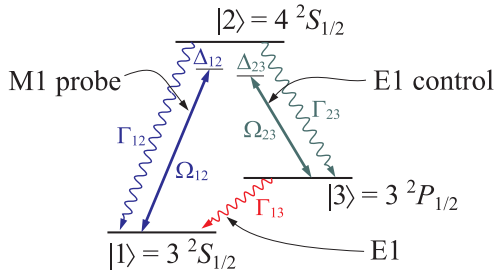

Figure 34.31:

a. Consider a three-level system in Λ-configuration. The transitions $|1\rangle$-$|2\rangle$ and $|2\rangle$-$|3\rangle$ are assumed to be electric dipoles and $|1\rangle$-$|3\rangle$ a magnetic dipole, such that, $\Gamma_{12}, \Gamma_{23} \gg \Gamma_{13}$. Extract from the Bloch equation (34.279) the equations for the coherences ρ_{12}, ρ_{13}, and ρ_{23}.
b. Suppose, that the excitation on the probe transition be so weak, $\Omega_{12} \ll \Gamma_{12}$, that it does not succeed to empty the ground state. In this approximation eliminate the dynamics of ρ_{23} and deduce the stationary solution for ρ_{12} and ρ_{13}.
c. Calculate the magnetic susceptibility χ_m [1195] with the following parameters $\Gamma_{12} = 7 \cdot 10^7\,\mathrm{s}^{-1}$, $\Gamma_{23} = 3 \cdot 10^7\,\mathrm{s}^{-1}$, $\Gamma_{13} = 2 \cdot 10^7\,\mathrm{s}^{-1}$, $\Omega_{12} = 0.1\Gamma_{12}$, $\Omega_{23} = 2 \cdot 10^8\,\mathrm{s}^{-1}$, $\Delta_{23} = 0$ in the regime $\Delta_{12} = [-15\Gamma_{23}, 15\Gamma_{23}]$.
d. Simulate the Bloch equations (34.279) and compare with the numerical solution.

Solution: *a. Assuming stationary populations, we begin by extracting from the equations (34.279) the equations for coherences,*

$$\begin{pmatrix}\dot\rho_{12}\\ \dot\rho_{13}\\ \dot\rho_{23}\end{pmatrix} = \begin{pmatrix}-\Lambda_{12} & \frac{\imath}{2}\Omega_{23} & 0\\ \frac{\imath}{2}\Omega_{23} & -\Lambda_{13} & -\frac{\imath}{2}\Omega_{12}\\ 0 & -\frac{\imath}{2}\Omega_{12} & -\Lambda_{23}\end{pmatrix}\begin{pmatrix}\rho_{12}\\ \rho_{13}\\ \rho_{23}\end{pmatrix} + \begin{pmatrix}\frac{\imath}{2}\Omega_{12}(\rho_{11}-\rho_{22})\\ 0\\ \frac{\imath}{2}\Omega_{23}(\rho_{22}-\rho_{33})\end{pmatrix},$$

where $\Lambda_{12} \equiv \imath\Delta_{12} + \frac{1}{2}(\Gamma_{12}+\Gamma_{23})$, $\Lambda_{23} \equiv \imath\Delta_{23} + \frac{1}{2}(\Gamma_{12}+\Gamma_{23}+\Gamma_{13})$ *and* $\Lambda_{13} \equiv i(\Delta_{12}-\Delta_{23}) + \frac{1}{2}\Gamma_{13}$.
b. Now we let $\Omega_{12} \ll \Gamma_{12}$, *such that* $\rho_{11} \simeq 1$ *the system of equations reduces to,*

$$\begin{pmatrix}\dot\rho_{12}\\ \dot\rho_{13}\end{pmatrix} = \begin{pmatrix}-\Lambda_{12} & \frac{\imath}{2}\Omega_{23}\\ \frac{\imath}{2}\Omega_{23} & -\Lambda_{13}\end{pmatrix}\begin{pmatrix}\frac{\imath}{2}\Omega_{12}\\ 0\end{pmatrix}.$$

The steady state is,

$$\rho_{12} = \frac{\frac{i}{2}\Lambda_{13}\Omega_{12}}{\frac{1}{2}\Omega_{23}^2 + \Lambda_{12}\Lambda_{13}} \quad , \quad \rho_{13} = \frac{-\frac{1}{4}\Omega_{12}\Omega_{23}}{\frac{1}{2}\Omega_{23}^2 + \Lambda_{12}\Lambda_{13}} \ .$$

c. The electrical and magnetic susceptibilities [1196] of the atom are observed in the probe transition,

$$\chi_e = \frac{2Nd_{23}^*\rho_{23}}{\varepsilon_0\mathcal{E}_{23}} = \varepsilon_r - 1$$
$$\chi_m = \frac{2N\mu_{13}^*\rho_{13}}{\mathcal{H}} = \mu_r - 1 \ .$$

The Rabi frequencies are $\hbar\Omega_{12}$ and,

$$\mathcal{H} = \mathcal{E}\sqrt{\varepsilon_0\varepsilon_r/\mu_0\mu_r}$$

d. Simulations of the complete Bloch equations give the results shown in Fig. 34.32. [1196]10.1631/jzus.2004.1322 believes that in practice very high densities of the order

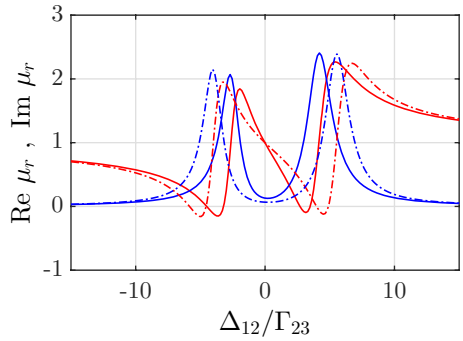

Figure 34.32:

of $10^{18}\,\mathrm{cm}^{-3}$ *are required.*

34.8.4.13 Ex: Magnetic dipole transitions in strontium

Magnetic dipole transitions are characterized by the selection rules $\Delta J = 0, \pm 1$, $\Delta S = 0$, $\Delta L = 0$, and $\Delta n = 0$. There are several transitions starting from the $5s5p\ ^3P_J$ metastable states going to the $5p^2\ 3P_J$ states with strong linewidths:

- $5s5p\ ^3P_1^o \leftrightarrow 5p^2\ ^3P_2$ at 472.2278 nm with $\Gamma = (2\pi)\ 5.7\,\mathrm{MHz}$
- $5s5p\ ^3P_1^o \leftrightarrow 5p^2\ ^3P_1$ at 478.4320 nm with $\Gamma = (2\pi)\ 4.8\,\mathrm{MHz}$

Check whether it is possible to reach negative permeability in a cold strontium gas.

Solution: *The strontium level scheme can be consulted in ⊙. The strontium levels are listed in ⊙.*

34.8.4.14 Ex: Orientation and alignment

Derive the formulas (34.323) and (34.324).

Solution: *We calculate orientation,*

$$\mathbf{O} = \langle \hat{\mathbf{J}} \rangle = Tr\ \hat{\rho}\hat{\mathbf{J}} = \sum_m \langle jm|\hat{\rho}\hat{\mathbf{J}}|jm\rangle = \sum_{m,m'} \langle jm|\hat{\rho}|jm'\rangle\langle jm'|\hat{\mathbf{J}}|jm\rangle \ .$$

If the atom is in a superposition of eigenstates ($\langle jm|\hat{\rho}|jm'\rangle = \rho_{mm}\delta_{m,m'}$), we get,

$$\mathbf{O} = \begin{pmatrix} 0 \\ 0 \\ \langle \hat{J}_z \rangle \end{pmatrix} = \sum_m \hbar m\ {}_z\langle m|\hat{\rho}|m\rangle_z \begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix} \ .$$

Using the rules of the SU(2) algebra for angular momenta Sec. 25.3.2 we find for the alignment,

$$\begin{aligned}(A_{ij}) &= \begin{pmatrix} \langle 3\hat{J}_x^2 - \mathbf{J}^2 \rangle & \langle [\hat{J}_x, \hat{J}_y]_+ \rangle & \langle [\hat{J}_x, \hat{J}_z]_+ \rangle \\ \langle [\hat{J}_x, \hat{J}_y]_+ \rangle & \langle 3\hat{J}_y^2 - \hat{\mathbf{J}}^2 \rangle & \langle [\hat{J}_y, \hat{J}_z]_+ \rangle \\ \langle [\hat{J}_x, \hat{J}_z]_+ \rangle & \langle [\hat{J}_y, \hat{J}_z]_+ \rangle & \langle 3\hat{J}_z^2 - \hat{\mathbf{J}}^2 \rangle \end{pmatrix} \\ &= \begin{pmatrix} -\frac{1}{2}\langle 3\hat{J}_z^2 - \hat{\mathbf{J}}^2 \rangle & 0 & 0 \\ 0 & -\frac{1}{2}\langle 3\hat{J}_z^2 - \hat{\mathbf{J}}^2 \rangle & 0 \\ 0 & 0 & \langle 3\hat{J}_z^2 - \hat{\mathbf{J}}^2 \rangle \end{pmatrix} \ ,\end{aligned}$$

if the atom is in a superposition of eigenstates ($\langle jm|\hat{\rho}|jm'\rangle = \rho_{mm}\delta_{m,m'}$). We finally get,

$$(A_{ij}) = \sum_m \hbar^2[3m^2 - j(j+1)]\ {}_z\langle m|\hat{\rho}|m\rangle_z \begin{pmatrix} -1/2 & 0 & 0 \\ 0 & -1/2 & 0 \\ 0 & 0 & 1 \end{pmatrix} \ .$$

Chapter 35

Atoms in quantized radiation fields

So far we have treated the optical field only as a stationary or propagating classical wave, while our two-level atom has been regarded as an entity obedient to the laws of quantum mechanics and subject to an induced perturbation by an oscillatory electromagnetic field. This procedure naturally leads to oscillations of the atomic states' populations and the coherences between them. However, in strong fields, when atomic energy spectrum is significantly modified, a non-perturbative, time-independent approach can be fruitful. Time-independent solutions for the Schrödinger equation for atoms coupled to fields is called *dressed states*. They were used for the first time to interpret the *splitting* of rotational molecular spectra in the presence of intense classical radiofrequency fields. While the semiclassical treatment is suitable for a wide variety of phenomena and has the virtue of mathematical simplicity and familiarity, it is sometimes worth considering the field as a quantum entity as well. In the dressed states picture, the atom-field interaction corresponds to an exchange of energy quanta between the field (photons) and the atom. This approach allows us to express photonic *number states*, also called *Fock states*, on equal footings with the discrete states of atom excitation and to write the state functions of the coupled atom-field system in a basis of photonic and atomic product states. Diagonalization of the dipole coupling terms in the system's Hamiltonian generates time-independent solutions of dressed states in a completely quantum Schrödinger equation.

We begin this chapter with the quantization of the light field and then express the atom-field interaction in a fully quantized form. We will examine some examples illustrating how the dressed states picture can provide useful information on the light-matter interactions.

35.1 Quantization of the electromagnetic field

We have already seen that the energy of a monochromatic light field with frequency ω is quantized in small equal portions, such that the total energy is $N\hbar\omega$, where N is an integer number. The energy spectrum is the same as the one of the harmonic oscillator. Therefore, we can identify a light mode with an oscillator and adopt the entire formalism developed for the harmonic oscillator. The formalism will be assumed as known in the following. We will, for simplicity use the term *photon* (respectively *phonon*) for excitations of a harmonic oscillator mode. It is however important to be

aware that a photon is not a particle, as it simply *disappears when performing the transition from quantum to classical mechanics* [770].

35.1.1 Field operators

The basic idea behind field quantization is the replacement of the classical harmonic oscillators discussed in Sec. 24.5 by quantum oscillators. The simplest approach to perform this quantization is to introduce the scalar potential Φ and the potential vector $\mathbf{A}$ as done in electrodynamic theory [1]. In free space, without charges nor currents, and within the *Coulomb gauge* we have the solution of the wave equation (34.5) generalized to a distribution of wavevectors $\mathbf{k}$ [2],

$$\mathbf{A}(\mathbf{r},t) = \sum_{\mathbf{k}} \vec{\epsilon}_{\mathbf{k}} [A^{+}_{0\mathbf{k}} e^{-\imath(\mathbf{k}\cdot\mathbf{r}-\omega_{\mathbf{k}}t)} + A^{-}_{0\mathbf{k}} e^{\imath(\mathbf{k}\cdot\mathbf{r}-\omega_{\mathbf{k}}t)}] \; , \tag{35.1}$$

where we already isolated the vectorial character due to the polarization $\vec{\epsilon}_{\mathbf{k}}$ of the light mode $\mathbf{k}$. Obviously, $A^{-}_{0\mathbf{k}} = (A^{+}_{0\mathbf{k}})^{*}$. As each amplitude and polarization of the wave given by the vector potential $\mathbf{A}_{\mathbf{k}}$ and $\mathbf{A}^{*}_{\mathbf{k}}$ must satisfy the wave equation separately, we arrive at the dispersion relation,

$$\omega_{\mathbf{k}} = ck \; . \tag{35.2}$$

With the results (34.7) and (34.8) we know that the energy in each radiative mode containing $n_{\mathbf{k}}$ photons is,

$$E_{\mathbf{k}} = \hbar\omega_{\mathbf{k}} N_{\mathbf{k}} = u_{\mathbf{k}} V = 2\varepsilon_0 V \omega^2_{\mathbf{k}} \overline{\mathbf{A}^2_{0\mathbf{k}}} = 2\varepsilon_0 V \omega^2_{\mathbf{k}} (A^{-}_{0\mathbf{k}} A^{+}_{0\mathbf{k}} + A^{+}_{0\mathbf{k}} A^{-}_{0\mathbf{k}}) \; , \tag{35.3}$$

where the bar denotes cycle-averaging. The second quantization now consists in interpreting the mode as a *quantum harmonic oscillator*, that is, we understand the observables as *operators* satisfying commutation rules, such as $[\hat{A}^{-}_{0\mathbf{k}}, \hat{A}^{+}_{0\mathbf{k}'}] \propto \delta_{\mathbf{k},\mathbf{k}'}$, and hence being affected by quantum fluctuations:

$$\hat{H}_{\mathbf{k}} = \hbar\omega_{\mathbf{k}} (\hat{n}_{\mathbf{k}} + \tfrac{1}{2}) = 2\varepsilon_0 V \omega^2_{\mathbf{k}} (\hat{A}^{-}_{0\mathbf{k}} \hat{A}^{+}_{0\mathbf{k}} + \hat{A}^{+}_{0\mathbf{k}} \hat{A}^{-}_{0\mathbf{k}}) \; . \tag{35.4}$$

We introduce normalized field operators following the commutation rule (24.76) via,

$$\hat{a}_{\mathbf{k}} \sqrt{\tfrac{\hbar}{4\varepsilon_0 V \omega_{\mathbf{k}}}} \equiv \hat{A}^{+}_{0\mathbf{k}} \qquad \text{and} \qquad \hat{a}^{\dagger}_{\mathbf{k}} \sqrt{\tfrac{\hbar}{4\varepsilon_0 V \omega_{\mathbf{k}}}} \equiv \hat{A}^{-}_{0\mathbf{k}} \; , \tag{35.5}$$

such that,

$$\hat{H}_{\mathbf{k}} = \hbar\omega_{\mathbf{k}} (\hat{a}^{\dagger}_{\mathbf{k}} \hat{a}_{\mathbf{k}} + \tfrac{1}{2}) \; . \tag{35.6}$$

The analogy allows us to interpret them as *creation operator* and *annihilation operator* of photons. Finally, we can rewrite (35.1) as,

$$\boxed{\hat{\mathbf{A}}_{\mathbf{k}}(\mathbf{r},t) = \sqrt{\tfrac{\hbar}{4\varepsilon_0 V \omega_{\mathbf{k}}}} \vec{\epsilon}_{\mathbf{k}} \left[\hat{a}_{\mathbf{k}} e^{-\imath(\mathbf{k}\cdot\mathbf{r}-\omega_{\mathbf{k}}t)} + \hat{a}^{\dagger}_{\mathbf{k}} e^{\imath(\mathbf{k}\cdot\mathbf{r}-\omega_{\mathbf{k}}t)} \right]} \; . \tag{35.7}$$

[1] See Sec. 17.3

[2] The atom-light interaction may depend on the polarization of the light with respect to the quantization axis of the atom, as defined e.g. by a magnetic field. In these cases we need to extend the index $\mathbf{k}$ to include the polarization state $(\mathbf{k}, \lambda)$.

We already know such combinations of operators and their complex conjugates from the quantum harmonic oscillator (24.86).

In the Coulomb gauge, the electric and magnetic field operators for the cavity modes can be constructed from,

$$\boxed{\begin{aligned}\hat{\vec{\mathcal{E}}}_{\mathbf{k}} &= -\frac{\partial \hat{\mathbf{A}}_{\mathbf{k}}}{\partial t} = \imath\sqrt{\tfrac{\hbar\omega_{\mathbf{k}}}{2\varepsilon_0 V}}\left(\hat{a}_{\mathbf{k}} e^{-\imath(\mathbf{k}\cdot\mathbf{r}-\omega_{\mathbf{k}}t)} - \hat{a}^{\dagger}_{\mathbf{k}} e^{\imath(\mathbf{k}\cdot\mathbf{r}-\omega_{\mathbf{k}}t)}\right)\vec{\epsilon}_k \\ \hat{\vec{\mathcal{B}}}_{\mathbf{k}} &= \nabla\times\mathbf{A}_{\mathbf{k}} = \imath\sqrt{\tfrac{\hbar\omega_{\mathbf{k}}}{2\varepsilon_0 V}}\left(\hat{a}_{\mathbf{k}} e^{-\imath(\mathbf{k}\cdot\mathbf{r}-\omega_{\mathbf{k}}t)} - \hat{a}^{\dagger}_{\mathbf{k}} e^{\imath(\mathbf{k}\cdot\mathbf{r}-\omega_{\mathbf{k}}t)}\right)\mathbf{k}\times\vec{\epsilon}_k\end{aligned}} \quad . \tag{35.8}$$

We can calculate the cycle-averaged energy of the $\mathbf{k}$-th cavity mode from a quantum version of Eq. (35.3),

$$\bar{E}_{\mathbf{k}} = \tfrac{\varepsilon_0}{2}\int \langle n_{\mathbf{k}}|\hat{\vec{\mathcal{E}}}_{\mathbf{k}}\cdot\hat{\vec{\mathcal{E}}}_{\mathbf{k}}|n_{\mathbf{k}}\rangle dV \ . \tag{35.9}$$

The result (35.6) is exactly Planck's quantum hypothesis (although strictly speaking, he rather suggested a quantization of oscillators in the conducting walls of the cavity, not of the field) on the distribution of the spectral intensity radiated by a black body. We now can see that it follows naturally from the quantization of the cavity field modes. Solve Excs. 35.1.5.1 and 35.1.5.2.

35.1.2 Interaction of quantized fields with atoms

With the results of the previous section the complete field Hamiltonian reads,

$$\hat{H}_{field} = \sum_{\mathbf{k}} \hbar\omega_{\mathbf{k}}(\hat{a}^{\dagger}_{\mathbf{k}}\hat{a}_{\mathbf{k}} + \tfrac{1}{2}) \ . \tag{35.10}$$

Now, that we have a clear picture of the quantized field with the energies in the modes given by Eq. (35.9) and the photon number states given by the eigenstates $|n\rangle$ of the quantized harmonic oscillator, we are in a position to consider our two-level atom interacting with this quantized radiation field. If for the moment, we exclude spontaneous emission and stimulated processes, the Hamiltonian of the combined atom-field system is,

$$\hat{H} = \hat{H}_{atom} + \hat{H}_{field} + \hat{H}_{atom:field} \ . \tag{35.11}$$

We describe the atom by a two-level system,

$$\hat{H}_{atom} = \hbar\omega_g|g\rangle\langle g| + \hbar\omega_e|e\rangle\langle e| = \hbar\omega_g|g\rangle\langle g| + \hbar(\omega_g+\omega_0)|e\rangle\langle e| \ , \tag{35.12}$$

where $\hat{H}_{field}$ is the Hamiltonian of the quantized field, expressed by Eq. (35.6), and $\hat{H}_{atom:field}$ the atom-field interaction. For the Hamiltonian without interaction, $\hat{H} = \hat{H}_{atom} + \hat{H}_{field}$, the eigenstates are simply product states of the atomic states and the photon number states,

$$|g,n\rangle = |g\rangle|n\rangle \qquad \text{and} \qquad |e,n\rangle = |e\rangle|n\rangle \ . \tag{35.13}$$

The left side of Fig. 35.1 shows, how the eigenenergies of the product states consist of two ladders, being displaced by the energy difference $\hbar\Delta$, which corresponds to the

detuning. We write the Hamiltonian of the atom Eq. (35.12) as the sum of projectors on unperturbed eigenstates using the completeness relation and the orthogonality of eigenstates. With the same idea we can rewrite the dipole operator defined in Eq. (34.33),

$$\hat{\mathbf{d}} = \sum_i |\psi_i\rangle\langle\psi_i|\hat{\mathbf{d}}| \sum_j |\psi_j\rangle\langle\psi_j| = \sum_{i,j} |i\rangle\langle i|e^{\imath(\omega_i-\omega_j)t}\hat{\mathbf{d}}|j\rangle\langle j| \tag{35.14}$$
$$= \sum_{i,j} e^{\imath(\omega_i-\omega_j)t}\mathbf{d}_{ij}|i\rangle\langle j| = \sum_{i<j} e^{\imath(\omega_i-\omega_j)t}\mathbf{d}_{ij}|i\rangle\langle j| + e^{-\imath(\omega_i-\omega_j)t}\mathbf{d}_{ij}|j\rangle\langle i| \equiv \hat{\mathbf{d}}^{(+)} + \hat{\mathbf{d}}^{(-)} \ .$$

using $|\psi_n(t)\rangle = e^{-\imath\omega_n t}|n\rangle$. Note that $\hat{\mathbf{d}}$ only has non-diagonal elements.

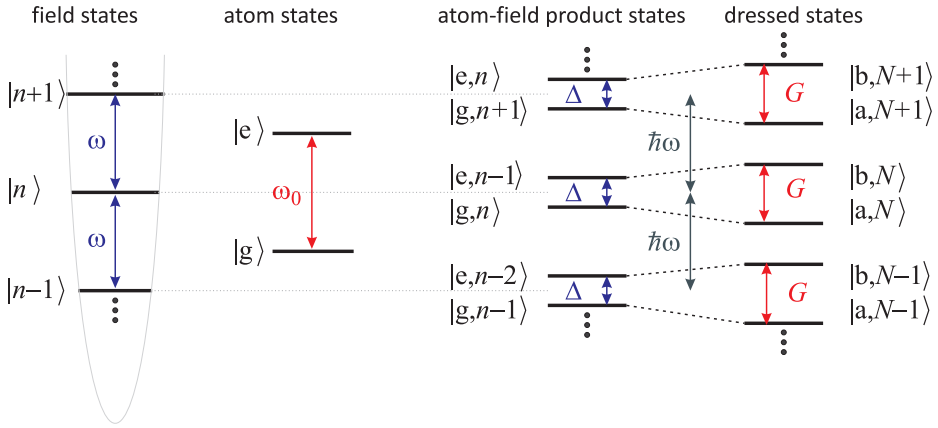

Figure 35.1: (Left) Photons number states and the two stationary states of the two-levels atom. (Center) Double ladder showing the basis of products states of photon number and atomic states. (Right) Dressed states constructed by diagonalization of the full Hamiltonian in the basis of the product states.

Now, let us use the electric field of Eqs. (35.8) to describe the atom-field interaction through the Hamiltonian $\hat{H}_{atom:field} = -\hat{\mathbf{d}} \cdot \hat{\vec{\mathcal{E}}}$,

$$\hat{H}_{atom:field} = \imath \sum_{\mathbf{k}} \sum_{i,j} \sqrt{\frac{\hbar\omega_{\mathbf{k}}}{2\varepsilon_0 V}} \mathbf{d}_{ij} e^{\imath(\omega_j-\omega_i)t}|i\rangle\langle j| \cdot \vec{\epsilon}_{\mathbf{k}} \left[\hat{a}_{\mathbf{k}} e^{-\imath(\mathbf{k}\cdot\mathbf{r}-\omega_{\mathbf{k}}t)} - \hat{a}^\dagger_{\mathbf{k}} e^{\imath(\mathbf{k}\cdot\mathbf{r}-\omega_{\mathbf{k}}t)}\right] \ . \tag{35.15}$$

For our two-level atom interacting with a single mode radiation field, we only have,

$$\hat{H}_{atom:field} = \imath\sqrt{\frac{\hbar\omega_{\mathbf{k}}}{2\varepsilon_0 V}} \mathbf{d}_{ge} \left[e^{\imath(\omega_e-\omega_g)t}|g\rangle\langle e| + e^{\imath(\omega_g-\omega_e)t}|e\rangle\langle g|\right] \cdot \tag{35.16}$$
$$\cdot \vec{\epsilon}_{\mathbf{k}} \left[\hat{a}_{\mathbf{k}} e^{-\imath(\mathbf{k}\cdot\mathbf{r}-\omega_{\mathbf{k}}t)} - \hat{a}^\dagger_{\mathbf{k}} e^{\imath(\mathbf{k}\cdot\mathbf{r}-\omega_{\mathbf{k}}t)}\right] \ .$$

35.1.2.1 Rotating wave approximation for dressed states

We can simplify the notation by identifying $\hat{\sigma}^+ = |e\rangle\langle g|$ and $\hat{\sigma}^- = |g\rangle\langle e|$ of the Eqs. (34.161) and introducing as an abbreviation the *Rabi frequency*,

$$\tfrac{1}{2}\hbar\Omega_1(\mathbf{r}) \equiv \sqrt{\frac{\hbar\omega_{\mathbf{k}}}{2\varepsilon_0 V}} \mathbf{d}_{ge} \cdot \vec{\epsilon}_{\mathbf{k}} e^{\imath\mathbf{k}\cdot\mathbf{r}} \ . \tag{35.17}$$

The interaction Hamiltonian then becomes,

$$\hat{H}_{atom:field} = \tfrac{\imath}{2}\hbar\Omega_1(\mathbf{r})e^{\imath(\omega_{\mathbf{k}}-\omega_0)t}\hat{\sigma}^+\hat{a}_{\mathbf{k}} + \tfrac{\imath}{2}\hbar\Omega_1(\mathbf{r})e^{\imath(\omega_{\mathbf{k}}+\omega_0)t}\hat{\sigma}^-\hat{a}_{\mathbf{k}} - \tfrac{\imath}{2}\hbar\Omega_1^*(\mathbf{r})e^{-\imath(\omega_{\mathbf{k}}+\omega_0)t}\hat{\sigma}^+\hat{a}_{\mathbf{k}}^\dagger - \tfrac{\imath}{2}\hbar\Omega_1^*(\mathbf{r})e^{-\imath(\omega_{\mathbf{k}}-\omega_0)t}\hat{\sigma}^-\hat{a}_{\mathbf{k}}^\dagger \,. \tag{35.18}$$

This Hamiltonian contains four terms describing the following processes [3],

$|g,n\rangle \longrightarrow |e,n-1\rangle$ the atom is excited by the absorption of a photon;

$|e,n\rangle \longrightarrow |g,n-1\rangle$ the atom is deexcited by the absorption of a photon;

$|g,n\rangle \longrightarrow |e,n+1\rangle$ the atom is excited by the emission of a photon;

$|e,n\rangle \longrightarrow |g,n+1\rangle$ the atom is deexcited by the emission of a photon.

Obviously, only the first and forth terms respect energy conservation (in first-order processes) and can serve as initial and final states in real physical processes. Fig. 35.3 shows schemes of these four terms. We see, that neglecting the second and third process (i.e., terms $\propto \hat{\sigma}^\pm\hat{a}^\pm$ of the Hamiltonian) is equivalent to making the rotating wave approximation (RWA), where we despise the terms rotating with the frequency $\pm(\omega_{\mathbf{k}}+\omega_0)$, and that we really only need to consider the coupling between the two dressed states $|g,n\rangle$ and $|e,n-1\rangle$.

Finally, within the RWA the Hamiltonian reads,

$$\boxed{\hat{H}_{atom:field} = \tfrac{\imath}{2}\hbar\Omega_1(\mathbf{r})e^{-\imath\Delta_{\mathbf{k}}t}\hat{\sigma}^+\hat{a}_k - \tfrac{\imath}{2}\hbar\Omega_1^*(\mathbf{r})e^{\imath\Delta_{\mathbf{k}}t}\hat{\sigma}^-\hat{a}_k^\dagger} \,, \tag{35.19}$$

where we introduced the detuning $\Delta_{\mathbf{k}} \equiv \omega_{\mathbf{k}} - \omega_0$ as short hand notation.

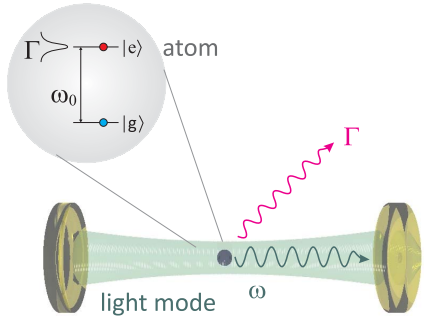

Figure 35.2: Two-level atom interacting with a cavity mode.

It is important to note that the first and fourth term can be important in higher order processes, such as multiphotonic absorption or Raman scattering processes, where the excited state would be a virtual level. In fact, when the Rabi frequency is very large, $\Omega_1 \simeq \omega$, the excitation and deexcitation processes follow each other so rapidly, that energy conservation can be violated for short times. The energy shift caused by terms neglected in the RWA are called *Bloch-Siegert shift* [4].

[3] Remember that the four processes contained in the Hamiltonian are all coherent (absorption and stimulated emission), and that spontaneous emission must be treated separately see next Sec. 35.6.

[4] The shift is not observed, when the non-rotating terms $\sigma^\pm a^\pm$ are forbidden by other conservation or selection rules. For example, when a resonance is excited by $\sigma^\pm$ light, the RWA is accurate.

35.1.3 Dressed states

Within the new dressed states basis, the atom-light coupling problem is reduced to diagonalizing the Hamiltonian of a quasi-degenerate two-level atom ($|\Delta| \ll \omega_0$), in which the non-diagonal elements are given by $\frac{1}{2}\hbar\Omega_1$. The eigenenergies of the complete Hamiltonian $\hat{H}$ are,

$$E_\pm = \tfrac{\hbar}{2}(\omega_{g,n} + \omega_{e,n-1}) \pm \tfrac{\hbar}{2} G_n \ . \tag{35.20}$$

where $\hbar\omega_{g,n}$ and $\hbar\omega_{e,n-1}$ are the energies of the product states $\hbar\omega_g + n\hbar\omega_{\mathbf{k}}$ and $\hbar\omega_e + (n-1)\hbar\omega_{\mathbf{k}}$. The separation between constituents of the same dressed state is $G_n = \sqrt{n\Omega_1^2 + \Delta^2}$. Fig. 35.4 illustrates how the coupling between a field mode and a two-level atom leads to an avoided crossing.

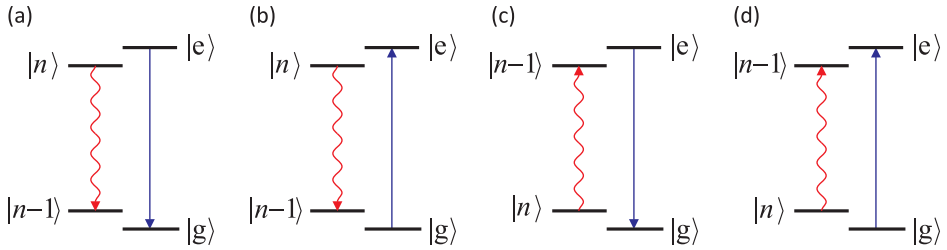

Figure 35.3: Illustration of the four processes in the atom-field interaction. Terms (b) and (c) conserve energy in first-order processes, while (a) and (d) do not conserve.

The atom-field product states offer a natural basis for the Hamiltonian of Eq. (35.11). The states resulting from the diagonalization of the Hamiltonian on this basis are called *dressed states*. As indicated in Fig. 35.1, the neighboring doublets the double ladder 'repel' each other under the influence of the interaction $\hat{H}_{atom:field}$ in Eq. (35.11). The mixed coefficients form the familiar problem of two levels, now called $|a\rangle$ and $|b\rangle$. Note that the semiclassical product state picture and the dressed states picture follow from each other via unitary transformation,

$$\boxed{\begin{pmatrix} |a,N\rangle \\ |b,N\rangle \end{pmatrix} = U \begin{pmatrix} |g,n\rangle \\ |e,n-1\rangle \end{pmatrix}} \ , \tag{35.21}$$

and, hence, are equivalent descriptions of the same reality. But while in the product state picture the system Hamiltonian is diagonal in the *absence* of atom-light interaction, in the dressed states picture the Hamiltonian is diagonal in the *presence* of interaction. The numbers n denote the amount of photons in the laser beam, the numbers N denote the amount of energy packets within the system, that is, the photons *plus* the possible excitation of the atom. The expression of the unitary transformation matrix will be derived in Sec. 35.4.1.

35.1.4 Dipole moments for vector transitions

Until now, we restricted to transitions between two levels without accounting for their possible substructure, which interacts with the vectorial nature of the driving

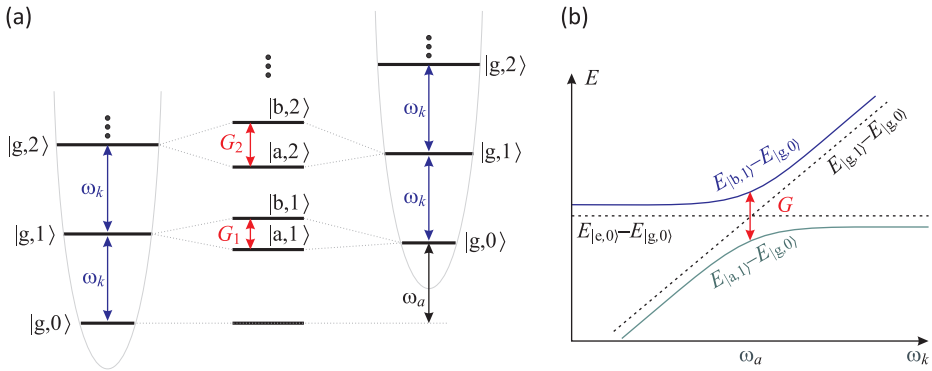

Figure 35.4: (a) Rabi splitting of the lowest dressed states. (b) Avoided crossing of dressed states.

light fields. Resuming the discussion of Sec. 34.2.3, we generalize the treatment of the preceding section considering a two-level atom with an arbitrary hyperfine level substructure $|g,(I,J)F,m\rangle \leftrightarrow |e,(I,J')F',m'\rangle$. The Hamiltonian is,

$$\hat{H} = \sum_{\alpha,\beta} \hbar\omega_{g\alpha}|g_\alpha\rangle\langle g_\alpha| + \hbar\omega_{e\beta}|g_\beta\rangle\langle g_\beta| \ . \tag{35.22}$$

Generalizing the expression (35.14) to vectorial transitions, the electric dipole operator reads,

$$\begin{aligned}\hat{\mathbf{d}} &= \sum_{i,j} |i\rangle\langle i|e^{\imath(\omega_i-\omega_j)t}\hat{\mathbf{d}}|j\rangle\langle j| \qquad (35.23)\\ &= \sum_{\alpha,\beta} |g_\alpha\rangle\langle g_\alpha|e^{\imath(\omega_{g\alpha}-\omega_{e\beta})t}\hat{\mathbf{d}}|e_\beta\rangle\langle e_\beta| + |e_\beta\rangle\langle e_\beta|e^{-\imath(\omega_{g\alpha}-\omega_{e_\beta})t}\hat{\mathbf{d}}|g_\alpha\rangle\langle g_\alpha| \ .\end{aligned}$$

Example 204 (*Vector transition in strontium*): The simplest possible vectorial level scheme consists of one ground and three excited Zeeman states, such as realized, for instance, in the strontium $^1S_0$-$^1P_1$ transition,

$$\hat{H}_{strontium} = \sum_{\beta} \hbar\omega_{e\beta}|g_\beta\rangle\langle g_\beta| \ , \tag{35.24}$$

setting $\omega_{ga} \equiv 0$. For strontium, we may introduce the vectorial lowering operator [365],

$$\hat{\vec{\sigma}} = \hat{\sigma}_x\hat{\mathbf{e}}_x + \hat{\sigma}_y\hat{\mathbf{e}}_y + \hat{\sigma}_z\hat{\mathbf{e}}_z \quad \text{with} \quad \hat{\sigma}_\beta = |g\rangle\langle e_\beta| \quad \text{with} \quad \beta = x,y,z \ . \tag{35.25}$$

In this case, the electric dipole operator reads,

$$\begin{aligned}\hat{\mathbf{d}}_{strontium} &= \sum_{\beta} |g\rangle\langle g|e^{-\imath\omega_{e\beta}t}\hat{\mathbf{d}}|e_\beta\rangle\langle e_\beta| + |e_\beta\rangle\langle e_\beta|e^{\imath\omega_{e\beta}t}\hat{\mathbf{d}}|g\rangle\langle g| \qquad (35.26)\\ &= d\sum_{\beta} e^{-\imath\omega_{e\beta}t}|g\rangle\langle e_\beta|\hat{\mathbf{e}}_\beta + c.c. = de^{-\imath\omega_e t}\hat{\vec{\sigma}} + c.c. \ ,\end{aligned}$$

with $\langle g|\hat{\mathbf{d}}|e_\beta\rangle = d\hat{\mathbf{e}}_\beta$ and $\omega_{e\beta} = \omega_e$.

35.1.5 Exercises

35.1.5.1 Ex: Photon statistics

An optical resonator contains on average 10 photons in the mode TEM_{00q}. What is the probability of finding, at any time, 1 photon resp. 10 photons, when the light is (a) thermal, (b) coherent? For case (a), what is the temperature of the light for $\lambda = 633\,\mathrm{nm}$?

Solution: *a. For thermal light,*

$$P_n = \frac{\bar{n}^n}{(1+\bar{n})^{n+1}} \ ,$$

such that $P_1 = 0.083$ *and* $P_{10} = 0.035$. *The temperature of the light can be evaluated from,*

$$\bar{n} = \frac{1}{e^{\hbar\omega/k_B T} - 1} \ ,$$

yielding $T_1 = 32800\,\mathrm{K}$, *respectively,* $T_{10} = 238000\,\mathrm{K}$.
b. For coherent light,

$$P_n = e^{\bar{n}} \frac{\bar{n}^n}{n!} \ ,$$

such that $P_1 = 4.5 \times 10^{-4}$ *and* $P_{10} = 0.13$.

35.1.5.2 Ex: Converting a pure state into a mixture by incomplete measurement

Consider a dressed two-level atom with the atomic states $|1\rangle$ and $|2\rangle$ and the photon number state $|n\rangle$.
a. Write down the general normalized dressed state and the density operator.
b. Now, perform a measurement of the atomic state tracing over the atomic degree of freedom and verify whether the resulting density operator represents a pure state.
c. Now, perform a measurement of the photon number and verify whether the resulting density operator represents a pure state.

Solution: *a. The state reads* $|\psi\rangle = \frac{1}{\sqrt{2}}|1,n\rangle + \frac{1}{\sqrt{2}}|2,n-1\rangle$. *The density operator*

$$\hat{\rho}_{AB} = |\psi\rangle\langle\psi| = \tfrac{1}{2}|1,n\rangle\langle 1,n| + \tfrac{1}{2}|2,n-1\rangle\langle 1,n| + \tfrac{1}{2}|1,n\rangle\langle 2,n-1| + \tfrac{1}{2}|2,n-1\rangle\langle 2,n-1|$$

obviously represents a pure state, $\hat{\rho}_{AB}^2 = \hat{\rho}_{AB}$.
b. Tracing over the atomic states,

$$\hat{\rho}_B \equiv Tr_A\ \hat{\rho}_{AB} = \sum_{i=1,2} \langle i|\hat{\rho}_{AB}|i\rangle = \tfrac{1}{2}|n\rangle\langle n| + \tfrac{1}{2}|n-1\rangle\langle n-1| \ ,$$

which is not a pure state,

$$\hat{\rho}_B^2 = \tfrac{1}{4}|n\rangle\langle n| + \tfrac{1}{4}|n-1\rangle\langle n-1| \neq \hat{\rho}_B \ .$$

c. Tracing over the photon numbers,

$$\hat{\rho}_A \equiv Tr_B\ \hat{\rho}_{AB} = \sum_m \langle m|\hat{\rho}_{AB}|m\rangle = \tfrac{1}{2}|1\rangle\langle 1| + \tfrac{1}{2}|2\rangle\langle 2|$$

with

$$\hat{\rho}_A^2 = \tfrac{1}{4}|1\rangle\langle 1| + \tfrac{1}{4}|2\rangle\langle 2| \neq \hat{\rho}_A\ .$$

35.1.5.3 Ex: Photon wavefunction

a. Show that for the *photonic wavefunction* $\mathbf{\Psi}$ and the current density $\mathbf{J}$ [1134],

$$\mathbf{\Psi} = \mathbf{\Psi}^+ + \mathbf{\Psi}^- \qquad \text{with} \qquad \mathbf{\Psi}^\pm = \sqrt{\tfrac{\varepsilon_0}{2}}\vec{\mathcal{E}}_\pm \pm \imath\sqrt{\tfrac{1}{2\mu_0}}\vec{\mathcal{B}}_\pm \qquad \text{and} \qquad \hat{\sigma}\mathbf{\Psi}^\pm = \pm\mathbf{\Psi}^\pm$$

$$\mathbf{J} = \mathbf{J}_f + \nabla\times\mathbf{M} + \frac{\partial\mathbf{P}}{\partial t}\ ,$$

where $\vec{\mathcal{E}} \equiv \vec{\mathcal{E}}_+ + \vec{\mathcal{E}}_-$ and $\vec{\mathcal{B}} \equiv \vec{\mathcal{B}}_+ + \vec{\mathcal{B}}_-$ are the real electric and magnetic fields of the photon and $\hat{\sigma}$ is the helicity, the Bialynicki-Birula-Sipe wave equation

$$\boxed{\imath\hbar\frac{\partial\mathbf{\Psi}}{\partial t} = \hbar c\hat{\sigma}\nabla\times\mathbf{\Psi} - \tfrac{\imath\hbar}{\sqrt{2\varepsilon_0}}\mathbf{J} \qquad \text{and} \qquad \nabla\cdot\mathbf{\Psi} = 0}$$

is equivalent to the Maxwell equations.
b. Use the plane wavefunction

$$\mathbf{\Psi} \equiv \sum_s \int d^3k \sqrt{\tfrac{\hbar\omega}{(2\pi)^3}} e^{\imath(\mathbf{k}\cdot\mathbf{r}-\omega t)}\hat{a}_{\mathbf{k}s}\hat{\mathbf{e}}_{\mathbf{k}s}$$

to calculate the total energy $\hat{H} = \frac{1}{2}\int d^3r[\mathbf{\Psi}^\dagger(\mathbf{r},t), \mathbf{\Psi}(\mathbf{r},t)]_+$.

Solution: *a. In vacuum, separating the Eq. by real and imaginary parts, we immediately verify,*

$$\imath\hbar\frac{\partial(\mathbf{\Psi}^+ + \mathbf{\Psi}^-)}{\partial t} = \hbar c\nabla\times(\mathbf{\Psi}^+ - \mathbf{\Psi}^-) \qquad \textit{and} \qquad \nabla\cdot\mathbf{\Psi}^\pm = 0$$

and substituting,

$$\tfrac{1}{\mu_0}\nabla\times\mathbf{B} = \varepsilon_0\frac{\partial\mathbf{E}}{\partial t} + \mathbf{J} \qquad \textit{and} \qquad \nabla\times\mathbf{E} = -\frac{\partial\mathbf{B}}{\partial t} \qquad \textit{and} \qquad \nabla\cdot\mathbf{E} = 0 = \nabla\cdot\mathbf{B}\ .$$

b. Inserting the plane wave we calculate,

$$\begin{aligned}
&\int d^3r\mathbf{\Psi}^\dagger(\mathbf{r},t)\mathbf{\Psi}(\mathbf{r},t)\\
&= \tfrac{1}{(2\pi)^3}\sum_{s,s'}\int d^3k\int d^3k'\left(\hbar\sqrt{\omega\omega'}\hat{a}^\dagger_{\mathbf{k}s}\hat{a}_{\mathbf{k}'s'}\epsilon_{\mathbf{k}s}\epsilon_{\mathbf{k}'s'}\int d^3r e^{-\imath[(\mathbf{k}-\mathbf{k}')\cdot\mathbf{r}-(\omega-\omega')t]}\right)\\
&= \sum_{s,s'}\int d^3k\int d^3k'\left(\hbar\sqrt{\omega\omega'}\hat{a}^\dagger_{\mathbf{k}s}\hat{a}_{\mathbf{k}'s'}\delta_{s,s'}\delta^3(\mathbf{k}-\mathbf{k}')\right) = \sum_s\int d^3k\ \hbar\omega|\hat{a}_{\mathbf{k}s}|^2\ ,
\end{aligned}$$

and consequently,

$$\hat{H} = \tfrac{1}{2}\int d^3r[\mathbf{\Psi}^\dagger(\mathbf{r},t),\mathbf{\Psi}(\mathbf{r},t)]_+ = \sum_s \int d^3k\ \hbar\omega(\hat{a}^\dagger_{\mathbf{k}s}\hat{a}_{\mathbf{k}s} + \tfrac{1}{2})\ .$$

35.2 (Quasi-)probability distribution functions of the coherent state basis

In the previous section we have seen that a light mode can be identified with a harmonic oscillator, which enabled us to harness the whole powerful formalism developed in Secs. 24.5 and 24.6 for the characterization of the quantum states of light. As we have seen in those sections, quantum observables are intrinsically affected by quantum noise, which leads to a spreading of their representation in phase space. For the case of Glauber states of a harmonic oscillator we illustrated in Fig. 24.19 the uncertainty of conjugate variables by circles around their expectation values whose areas are determined by the Heisenberg uncertainty relation. These circular areas represent phase space probability distribution functions. These are distribution functions measuring the probability to encounter the observables at specific points in phase space.

States other than Glauber states are possible, for instance Fock or cat states. Some of these states may exhibit quantum correlations, which we would like to identify in probability distributions. Quantum correlations in systems with small Hilbert spaces, such as the two-level atom, are conveniently represented by a density operator or by the Bloch vector introduced in Eq. (23.47). Large or infinite Hilbert spaces require different approaches. We have seen in Sec. 24.6.1 how to expand the state of a harmonic oscillator on a Fock state basis. On the other hand, we have seen that Glauber states are more 'natural' states for a harmonic oscillator, so that we would like to visualize expansions of arbitrary states into a coherent state basis.

The following sections are devoted to introducing various such distribution functions [1184, 1160] and to calculating them for a selection of particular states, such as the Fock and the Glauber state, the thermal state, and the Schrödinger cat state. We will mostly restrict the discussion to pure states, postponing a discussion of the representation of statistical mixtures to Sec. 35.4, where we will also extend the discussion to quantum correlations in light fields resulting from a Jaynes-Cummings type interaction of an atom with a light mode.

35.2.1 The density operator and distribution functions

35.2.1.1 The density operator

We define the *density operator* for a pure state as,

$$\hat{\rho} \equiv |\psi\rangle\langle\psi|\ . \tag{35.27}$$

A detailed discussion of the density operator for non pure states, that is, statistical mixtures has been given in Sec. 34.3. The definition (35.27) is independent from

a chosen basis, but a proper representation can be found by simply expanding the state $|\psi\rangle$ on a proper basis. The expansion we had in mind in Sec. 34.3.2 was on eigenstates of atomic excitations, which are typically discrete and limited in number. The expansion of the density operator in the infinite but discrete spectrum of Fock states is essentially the same as for atomic excitations and thus straightforward,

$$\begin{aligned} \hat{\rho} &= \sum_n |n\rangle\hat{\rho}\langle n| \equiv \sum_n p_n |n\rangle\langle n| \qquad (35.28)\\ \Longrightarrow p_m = \langle m|\hat{\rho}|m\rangle &= \sum_n p_n |\langle m|n\rangle|^2 \\ &= \sum_n p_n \delta_{mn} = p_m \ , \end{aligned}$$

where the first line can be read as a definition of the photon number distribution function p_n. An analogous expansion in the continuous Glauber basis is, however, more complicated, because the coherent states are not orthogonal,

$$\begin{aligned} \hat{\rho} &= \tfrac{1}{\pi}\int \hat{\rho}|\alpha\rangle\langle\alpha| d^2\alpha \equiv \int P(\alpha,\alpha^*)|\alpha\rangle\langle\alpha| d^2\alpha \qquad (35.29)\\ \Longrightarrow \pi Q(\beta,\beta^*) \equiv \langle\beta|\hat{\rho}|\beta\rangle &= \int P(\alpha,\alpha^*)|\langle\beta|\alpha\rangle|^2 d^2\alpha \\ &= \int P(\alpha,\alpha^*) e^{-|\alpha-\beta|^2} d^2\alpha \neq P(\beta,\beta^*) \ . \end{aligned}$$

That is, we end up with two distribution functions, the so-called *P-function* $P(\alpha,\alpha^*)$ (or *Glauber-Sudarshan representation*) and the *Q-function* $Q(\alpha,\alpha^*)$ (or *Husimi representation*) which, according to (35.29) they are not equal. Before we deepen the discussion in the upcoming sections let us already state here, that the reason for the complication is rooted in the non-commutativity of the field operators $[\hat{a},\hat{a}^\dagger] = 1$. Indeed, expressing the density operator of a system as a function of field operators we have (at least) two choices called the *normal-ordered* arrangement (label N) and the *antinormal-ordered* arrangement (label A),

$$\hat{\rho}_N(\hat{a},\hat{a}^\dagger) = \sum_{m,n} c_{m,n}\hat{a}^{\dagger m}\hat{a}^n \qquad \text{and} \qquad \hat{\rho}_A(\hat{a},\hat{a}^\dagger) = \sum_{m,n} c_{m,n}\hat{a}^m\hat{a}^{\dagger n} \ . \qquad (35.30)$$

Although both expressions can be converted into each other, the functional form of the density operator depends on the arrangement. We will show in Exc. 35.2.5.1 that the $P(\alpha,\alpha^*)$-function defined by the first line of (35.29) is more natural for the antinormal-ordered density operator $\hat{\rho}_A$, while the $Q(\alpha,\alpha^*)$-function defined by the second line of (35.29) is more natural for the normal-ordered density operator $\hat{\rho}_N$:

$$\rho_N(\alpha,\alpha^*) = \tfrac{1}{\pi}Q(\alpha,\alpha^*) \qquad \text{and} \qquad \rho_A(\alpha,\alpha^*) = \pi P(\alpha,\alpha^*) \ . \qquad (35.31)$$

We will discuss the distribution functions more deeply in the upcoming sections.

To prepare the subsequent derivations, let us define the two-dimensional complex Fourier transform by,

$$(\mathcal{F}\chi)(\beta,\beta^*) = \tfrac{1}{\pi}\int \chi(\alpha,\alpha^*) e^{\beta\alpha^* - \beta^*\alpha} d^2\alpha \ , \qquad (35.32)$$

with $d^2\lambda = d\mathfrak{Re}\ \lambda\ d\mathfrak{Im}\ \lambda = dr_\lambda dp_\lambda$. Twofold application of the Fourier transform reproduces the original function,

$$\begin{aligned}(\mathcal{F}\mathcal{F}\chi)(\gamma,\gamma^*) &= \tfrac{1}{\pi}\int(\mathcal{F}\chi)(\beta,\beta^*)e^{\gamma\beta^*-\gamma^*\beta}d^2\beta \\ &= \tfrac{1}{\pi^2}\int\chi(\alpha,\alpha^*)\int e^{\beta^*(\gamma-\alpha)-\beta(\gamma^*-\alpha^*)}d^2\beta d^2\alpha \\ &= \tfrac{1}{\pi^2}\int\chi(\alpha,\alpha^*)\pi^2\delta^{(2)}(\gamma-\alpha)d^2\alpha = \chi(\gamma,\gamma^*)\ ,\end{aligned} \tag{35.33}$$

where we used,

$$\delta^{(2)}(\alpha) = \tfrac{1}{\pi^2}\int e^{\lambda^*\alpha-\lambda\alpha^*}d^2\lambda\ . \tag{35.34}$$

The formula (35.34) can be extended to include field operators [1184],

$$\begin{aligned}\delta(\alpha^*-\hat{a}^\dagger)\delta(\alpha-\hat{a}) &= \tfrac{1}{\pi^2}\int e^{-\lambda(\alpha^*-\hat{a}^\dagger)}e^{\lambda^*(\alpha-\hat{a})}d^2\lambda \\ \delta(\alpha-\hat{a})\delta(\alpha^*-\hat{a}^\dagger) &= \tfrac{1}{\pi^2}\int e^{\lambda^*(\alpha-\hat{a})}e^{-\lambda(\alpha^*-\hat{a}^\dagger)}d^2\lambda\ ,\end{aligned} \tag{35.35}$$

which will be useful in the following.

35.2.1.2 The Glauber-Sudarshan P-distribution

The Glauber-Sudarshan P-function can be formally defined by [1184],

$$\boxed{P(\alpha,\alpha^*) \equiv \mathrm{Tr}\ \hat{\rho}\delta(\alpha^*-\hat{a}^\dagger)\delta(\alpha-\hat{a})}\ . \tag{35.36}$$

The definition (35.29) of the P-function, that is,

$$\boxed{\hat{\rho} \equiv \int P(\alpha,\alpha^*)|\alpha\rangle\langle\alpha|d^2\alpha}\ , \tag{35.37}$$

is equivalent to the definition (35.36), as will be verified in Exc. 35.2.5.2. From (35.37) we see, that the Glauber-Sudarshan P-function is just the distribution that leaves the density matrix diagonal in the coherent state basis. Since $\hat{\rho}$ is Hermitian, $P(\alpha,\alpha^*)$ is real, and since $\mathrm{Tr}\ \hat{\rho} = 1$, it is normalized, $\int P(\alpha,\alpha^*)d^2\alpha = 1$. Hence, the P-distribution functions can be interpreted as the probability of finding the coherent state $|\alpha\rangle$ within the statistical mixture given by (35.37).

In order to unravel its properties let us consider an arbitrary operator $\hat{O}$ being a function of the field operators $\hat{a}$ and $\hat{a}^\dagger$. Using the commutation rule $[\hat{a},\hat{a}^\dagger] = 1$ the operator can always be brought in normal-ordered form,

$$\hat{O}_N(\hat{a},\hat{a}^\dagger) = \sum_{m,n} o_{m,n}\hat{a}^{\dagger m}\hat{a}^n\ . \tag{35.38}$$

The expectation value of this operator is,

$$\langle\hat{O}_N(\hat{a},\hat{a}^\dagger)\rangle = \mathrm{Tr}\ \hat{\rho}\hat{O}_N(\hat{a},\hat{a}^\dagger) = \int P(\alpha,\alpha^*)O_N(\alpha,\alpha^*)d^2\alpha\ , \tag{35.39}$$

as we will show in Exc. 35.2.5.3.

35.2.1.3 The Husimi Q-distribution

The Husimi Q-function is formally defined by [1184],

$$\boxed{Q(\alpha,\alpha^*) \equiv \text{Tr } \hat{\rho}\delta(\alpha-\hat{a})\delta(\alpha^*-\hat{a}^\dagger)} \ . \tag{35.40}$$

The definition (35.29) of the Q-function, that is,

$$\boxed{\langle\alpha|\hat{\rho}|\alpha\rangle = \pi Q(\alpha,\alpha^*)} \ , \tag{35.41}$$

is equivalent to the definition (35.36), as will be verified in Exc. 35.2.5.2. From (35.41) we see, that the Q-distribution function can be interpreted as the expectation value of the density operator (35.27).

The expression resembles Eq. (35.36) except for the order of the δ-functions. We now consider the same arbitrary operator $\hat{O}$ as in (35.38), but now expressed in antinormal ordered form of the field operators $\hat{a}$ and $\hat{a}^\dagger$,

$$\hat{O}_A(\hat{a},\hat{a}^\dagger) = \sum_{m,n} o_{m,n}\hat{a}^m\hat{a}^{\dagger n} \ . \tag{35.42}$$

As we will show in Exc. 35.2.5.3, the expectation value of this operator is,

$$\langle\hat{O}_A(\hat{a},\hat{a}^\dagger)\rangle = \text{Tr } \hat{\rho}\hat{O}_A(\hat{a},\hat{a}^\dagger) = \int Q(\alpha,\alpha^*)O_A(\alpha,\alpha^*)d^2\alpha \ . \tag{35.43}$$

35.2.1.4 The Wigner-Weyl distribution

The *Wigner function* represents something like the spectrum of two-dimensional phase-space correlation function. For a pure state and a one-dimensional system it is defined by,

$$W(x,p) \equiv \tfrac{1}{\pi}\int_{-\infty}^{\infty}\langle\psi|x+y\rangle\langle x-y|\psi\rangle e^{2\imath py/\hbar}dy \ . \tag{35.44}$$

Example 205 (*Wigner function of a free particle in 3D*): For example, for a free particle described by the wavefunction in three-dimensional space,

$$\langle\mathbf{r}|\psi\rangle = \tfrac{1}{\sqrt{V}}e^{\imath\mathbf{k}\cdot\mathbf{r}} \ ,$$

the Wigner function is,

$$\begin{aligned} W(\mathbf{r},\mathbf{p}) &= \frac{1}{\pi^3}\int_{-\infty}^{\infty}\tfrac{1}{\sqrt{V}}e^{-\imath\mathbf{k}\cdot(\mathbf{r}+\mathbf{x})}\tfrac{1}{\sqrt{V}}e^{\imath\mathbf{k}\cdot(\mathbf{r}-\mathbf{x})}e^{(2\imath/\hbar)\mathbf{p}\cdot\mathbf{x}}d^3x \\ &= \frac{1}{\pi^3 V}\int_{-\infty}^{\infty}e^{-2\imath(\mathbf{k}-\mathbf{p}/\hbar)\cdot\mathbf{x}}d^3x = \tfrac{1}{V}\delta^3(\mathbf{p}-\hbar\mathbf{k}) \ . \end{aligned}$$

For a harmonic oscillator, we would like to embed the Wigner function into the formalism of the coherent states distribution functions, such that it can be used to evaluate expectation values,

$$\langle\hat{O}_S(\hat{a},\hat{a}^\dagger)\rangle = \text{Tr } \hat{\rho}\hat{O}_S(\hat{a},\hat{a}^\dagger) = \int W(\alpha,\alpha^*)O_S(\alpha,\alpha^*)d^2\alpha \ , \tag{35.45}$$

where the index S denotes *symmetric order*. How this can be done will be detailed in the next section and in Exc. 35.2.5.3.

Example 206 (*Symmetric order*): Simple examples for Wigner-Weyl ordering are,

$$\begin{aligned}
\hat{a}\hat{a}^\dagger &= \tfrac{1}{2}(\hat{a}\hat{a}^\dagger + \hat{a}^\dagger\hat{a}) - \tfrac{1}{2} \\
\hat{a}^\dagger\hat{a} &= \tfrac{1}{2}(\hat{a}\hat{a}^\dagger + \hat{a}^\dagger\hat{a}) + \tfrac{1}{2} \\
\hat{a}^2\hat{a}^\dagger &= \tfrac{1}{2}(\hat{a}^2\hat{a}^\dagger + \hat{a}^\dagger\hat{a}^2) + \hat{a} \\
\hat{a}\hat{a}^\dagger\hat{a} &= \tfrac{1}{2}(\hat{a}^2\hat{a}^\dagger + \hat{a}^\dagger\hat{a}^2) \\
\hat{a}^\dagger\hat{a}^2 &= \tfrac{1}{2}(\hat{a}^2\hat{a}^\dagger + \hat{a}^\dagger\hat{a}^2) - \hat{a}\ .
\end{aligned}$$

35.2.2 Relation between the P, Q, and Wigner distributions

All three distribution function studied here, the P, the Q, and the Wigner distributions can be brought into a common generic shape writing the density operator as [1184],

$$\boxed{\begin{aligned}
\hat{\rho} \;&=\; \pi \int F_X(\alpha,\alpha^*)\Delta_X(\alpha-\hat{a},\alpha^*-\hat{a}^\dagger)d^2\alpha \\
\text{with}\qquad &\Delta_N(\alpha-\hat{a},\alpha^*-\hat{a}^\dagger) = \tfrac{1}{\pi^2}\int e^{-\lambda(\alpha^*-\hat{a}^\dagger)+\lambda^*(\alpha-\hat{a})}e^{-|\lambda|^2/2}d^2\lambda \\
&\Delta_S(\alpha-\hat{a},\alpha^*-\hat{a}^\dagger) = \tfrac{1}{\pi^2}\int e^{-\lambda(\alpha^*-\hat{a}^\dagger)+\lambda^*(\alpha-\hat{a})}d^2\lambda \\
&\Delta_A(\alpha-\hat{a},\alpha^*-\hat{a}^\dagger) = \tfrac{1}{\pi^2}\int e^{-\lambda(\alpha^*-\hat{a}^\dagger)+\lambda^*(\alpha-\hat{a})}e^{|\lambda|^2/2}d^2\lambda
\end{aligned}}\ , \tag{35.46}$$

with the indices $X = N, S, A$ and the respective distribution functions $F_N = P$, $F_S = W$, and $F_A = Q$. A useful formula helping us to break down the exponential functions is obtained from Glauber's formula (23.210) applied to the displacement operator $D(\alpha) = e^{\lambda\hat{a}^\dagger - \lambda^*\hat{a}}$ defined in (24.111),

$$e^{\lambda\hat{a}^\dagger-\lambda^*\hat{a}} = e^{-\lambda^*\hat{a}}e^{\lambda\hat{a}^\dagger}e^{|\lambda|^2/2} = e^{\lambda\hat{a}^\dagger}e^{-\lambda^*\hat{a}}e^{-|\lambda|^2/2}\ . \tag{35.47}$$

as it allows us to rewrite the formulas (35.46) as,

$$\begin{aligned}
\Delta_N(\alpha-\hat{a},\alpha^*-\hat{a}^\dagger) &= \mathcal{F}[e^{-\lambda^*\hat{a}}e^{\lambda\hat{a}^\dagger}] \\
\Delta_S(\alpha-\hat{a},\alpha^*-\hat{a}^\dagger) &= \mathcal{F}[e^{\lambda\hat{a}^\dagger-\lambda^*\hat{a}}] \\
\Delta_A(\alpha-\hat{a},\alpha^*-\hat{a}^\dagger) &= \mathcal{F}[e^{\lambda\hat{a}^\dagger}e^{-\lambda^*\hat{a}}]\ .
\end{aligned} \tag{35.48}$$

Inserting the density operator (35.46) into definition (35.36) of the Glauber-Sudarshan P-function we calculate,

$$\begin{aligned}
P(\alpha,\alpha^*) &= \mathrm{Tr}\ \hat{\rho}\delta(\alpha^*-\hat{a}^\dagger)(\alpha-\hat{a}) \\
&= \tfrac{1}{\pi^2}\int e^{\lambda^*\alpha-\lambda\alpha^*}\,\mathrm{Tr}\ \hat{\rho}e^{\lambda\hat{a}^\dagger}e^{-\lambda^*\hat{a}}d^2\lambda = \mathcal{F}[\chi_N(\lambda,\lambda^*)]\ ,
\end{aligned} \tag{35.49}$$

where we defined the so-called normal-ordered *characteristic function* $\chi_N \equiv \mathrm{Tr}\ \hat{\rho} e^{\lambda \hat{a}^\dagger} e^{-\lambda^* \hat{a}}$. Similarly, inserting the density operator (35.46) into definition (35.40) of the Husimi Q-function we calculate,

$$\begin{aligned} Q(\alpha, \alpha^*) &= \mathrm{Tr}\ \hat{\rho} \delta(\alpha - \hat{a})(\alpha^* - \hat{a}^\dagger) \\ &= \tfrac{1}{\pi^2} \int e^{\lambda^* \alpha - \lambda \alpha^*} \mathrm{Tr}\ \hat{\rho} e^{-\lambda^* \hat{a}} e^{\lambda \hat{a}^\dagger} d^2\lambda = \mathcal{F}[\chi_A(\lambda, \lambda^*)] \ , \end{aligned} \tag{35.50}$$

where we defined the antinormal-ordered characteristic function $\chi_A \equiv \mathrm{Tr}\ \hat{\rho} e^{-\lambda^* \hat{a}} e^{\lambda \hat{a}^\dagger}$. By analogy we find for the Wigner distribution,

$$W(\alpha, \alpha^*) = \mathcal{F}[\chi_A(\lambda, \lambda^*)] = \tfrac{1}{\pi^2} \int e^{\lambda^* \alpha - \lambda \alpha^*} \mathrm{Tr}\ \hat{\rho} e^{\lambda \hat{a}^\dagger - \lambda^* \hat{a}} d^2\lambda \ . \tag{35.51}$$

In summary, the three coherent distribution functions are expressed by inverse Fourier transforms of the following characteristic functions [5],

$$\boxed{\begin{array}{rclcrcl} \chi_N(\lambda, \lambda^*) & = & \mathrm{Tr}\ \hat{\rho} e^{\lambda \hat{a}^\dagger} e^{-\lambda^* \hat{a}} & , & P & = & \mathcal{F}\chi_N \\ \chi_S(\lambda, \lambda^*) & = & \mathrm{Tr}\ \hat{\rho} e^{\lambda \hat{a}^\dagger - \lambda^* \hat{a}} & , & W & = & \mathcal{F}\chi_S \\ \chi_A(\lambda, \lambda^*) & = & \mathrm{Tr}\ \hat{\rho} e^{-\lambda^* \hat{a}} e^{\lambda \hat{a}^\dagger} & , & Q & = & \mathcal{F}\chi_A \end{array}} \ . \tag{35.52}$$

We see that the distribution functions $\chi_{N,S,A}$ are related to each other via (35.47). We derive in Exc. 35.2.5.4 the so-called disentangling theorem [504],

$$e^{-|\lambda|^2/2} \chi_N(\lambda) = \chi_S(\lambda) = e^{|\lambda|^2/2} \chi_A(\lambda) \ . \tag{35.53}$$

Thus, Q-function corresponds to a smoothed Wigner function, which in turn corresponds to a smoothed P-function. The inverse complex Fourier transformation converts the products in (35.53) into convolutions. Exploiting the useful integral formula,

$$\tfrac{1}{\pi} \int e^{-a|\lambda|^2 + b\lambda + c\lambda^*} d^2\lambda = \tfrac{1}{a} e^{bc/a} \ , \tag{35.54}$$

we find,

$$W = P \star \frac{2}{\pi} e^{-2|\lambda|^2} \qquad \text{and} \qquad Q = W \star \frac{2}{\pi} e^{-2|\lambda|^2} = P \star \frac{1}{\pi} e^{-|\lambda|^2} \ . \tag{35.55}$$

What still needs to be proven is, that the generic definition of the distribution function (35.49), (35.50), and (35.51) coincides with the earlier definitions (35.36), (35.40), and (35.44). This will be done in Exc. 35.2.5.5. Also solve the Excs. 35.2.5.6 to 35.2.5.7.

Example 207 (*Generalized phase space representations*): The fact that the probability distributions Q, W, and P are intrinsically connected suggests setting up a generalized formalism based on the displacement operator

[5] For pure states, the definition of the characteristic functions is simplified to,

$$\chi_X(\lambda, \lambda^*) = \langle \psi | ... | \psi \rangle \ .$$

$D(\alpha)|0\rangle = e^{\lambda\hat{a}^\dagger - \lambda^*\hat{a}}|0\rangle = |\alpha\rangle$ introduced in (24.111) and the parity operator Π_s [732]. Defining the s-parametrized probability distribution,

$$X_\rho(\alpha, s) = \text{Tr}\ \hat{\rho}D(\alpha)\Pi_s D^\dagger(\alpha) \longrightarrow \langle\psi|D(\alpha)\Pi_s D^\dagger(\alpha)|\psi\rangle\ , \tag{35.56}$$

where the second expression holds for pure states, we recover the probability distributions Q, W, and P from,

$$Q_\rho(\alpha) \equiv X_\rho(\alpha, -1) \qquad \text{with} \qquad \Pi_{-1} = \sum_{m,n} \delta_{n0}\delta_{mn}|m\rangle\langle n| \tag{35.57}$$

$$W_\rho(\alpha) \equiv X_\rho(\alpha, 0) \qquad \text{with} \qquad \Pi_0 = \sum_{m,n} 2e^{\imath\pi n}\delta_{mn}|m\rangle\langle n|$$

$$\text{so that} \qquad \Pi_0|\alpha\rangle = \sum_n 2e^{\imath\pi n}|n\rangle\langle n|\alpha\rangle = \sum_n 2e^{-|\alpha|^2/2}\frac{(-\alpha)^n}{\sqrt{n!}}|n\rangle = 2|-\alpha\rangle$$

$$P_\rho(\alpha) \equiv X_\rho(\alpha, 1) \qquad \text{with} \qquad \Pi_1 = \sum_{m,n} \infty\delta_{mn}|m\rangle\langle n|\ .$$

In particular, for the vacuum state we calculate,

$$Q_{|0\rangle}(\alpha) = \sum_n \langle 0|D(\alpha)\delta_{n0}|n\rangle\langle n|D^\dagger(\alpha)|0\rangle = |\langle 0|-\alpha\rangle|^2 = e^{-|\alpha|^2} \tag{35.58}$$

$$W_{|0\rangle}(\alpha) = \sum_n \langle 0|D(\alpha)2e^{\imath\pi n}|n\rangle\langle n|D^\dagger(\alpha)|0\rangle = 2\sum_n e^{\imath\pi n}|\langle n|-\alpha\rangle|^2 = 2e^{-2|\alpha|^2}$$

$$P_{|0\rangle}(\alpha) = ... = \delta^{(2)}(\alpha)\ .$$

The convolution of distribution functions yields,

$$[Y \star X](\alpha) = \int [D^{-1}(\alpha)Y(\alpha')]X(\alpha')d\alpha' = \int Y(\alpha' - \alpha)X(\alpha')d\alpha'$$

$$X_{|0\rangle}(\alpha, s') \star X_\rho(\alpha, s) = X_\rho(\alpha, s + s' - 1)\ . \tag{35.59}$$

For example,

$$P_{|0\rangle}(\alpha) \star X_\rho(\alpha, s) = X_{|0\rangle}(\alpha, 1) \star X_\rho(\alpha, s) = X_\rho(\alpha, s)\ . \tag{35.60}$$

identifying the Glauber-Sudarshan distribution as the identity operator, and

$$W_{|0\rangle}(\alpha) \star W_\rho(\alpha) = X_{|0\rangle}(\alpha, 0) \star X_\rho(\alpha, 0) = X_\rho(\alpha, -1) = Q_\rho(\alpha)\ . \tag{35.61}$$

35.2.3 Characteristic functions for arbitrary HO states in the Fock basis

The various states that a light field can adopt can now be expressed either by photon number distribution in a Fock state basis, or by two-dimensional weighting functions P, Q, W in a coherent state basis. Here, are some examples for these representations.

If a state of a harmonic oscillator can be expanded into Fock states,

$$|\psi\rangle = \sum_n c_n|n\rangle\ , \tag{35.62}$$

the normal-ordered characteristic function (35.52) will be composed of terms like $\langle m|e^{\lambda\hat{a}^\dagger}e^{-\lambda^*\hat{a}}|n\rangle$. To evaluate these terms, we begin calculating [6],

$$\hat{a}^k|n\rangle = \sqrt{\frac{n!}{(n-k)!}}|n-k\rangle \quad \text{for} \quad k \leq n \qquad \text{and} \qquad \hat{a}^k|n\rangle = 0 \quad \text{for} \quad k \geq n \ , \tag{35.63}$$

and,

$$e^{-\lambda^*\hat{a}}|n\rangle = \sum_{k=0}^{\infty}\frac{(-\lambda^*\hat{a})^k}{k!}|n\rangle = \sum_{k=0}^{n}\frac{(-\lambda^*)^k}{\sqrt{k!}}\sqrt{\binom{n}{k}}|n-k\rangle \ . \tag{35.64}$$

Hence, assuming $m \geq n$,

$$\begin{aligned}\langle m|e^{\lambda\hat{a}^\dagger}e^{-\lambda^*\hat{a}}|n\rangle &= \sum_{k=0}^{n}\frac{(-\lambda^*)^k\lambda^{m-n+k}}{\sqrt{k!(m-n+k)!}}\sqrt{\binom{n}{k}\binom{m}{m-n+k}} \\ &= \sqrt{\frac{n!}{m!}}\lambda^{m-n}\sum_{k=0}^{n}\binom{m}{k+m-n}\frac{(-|\lambda|^2)^k}{k!} = \sqrt{\frac{n!}{m!}}\lambda^{m-n}L_n^{m-n}(|\lambda|^2) \ ,\end{aligned} \tag{35.65}$$

where L_n^{m-n} are Laguerre polynomials. Now, exploiting the fact that

$$\begin{aligned}\langle m|e^{\lambda\hat{a}^\dagger}e^{-\lambda^*\hat{a}}|n\rangle &= (\langle n|e^{-\lambda\hat{a}^\dagger}e^{\lambda^*\hat{a}}|m\rangle)^\dagger = \overline{\langle n|e^{-\lambda\hat{a}^\dagger}e^{\lambda^*\hat{a}}|m\rangle} \\ &= \sqrt{\frac{m!}{n!}}(-\lambda^*)^{n-m}L_n^{n-m}(|\lambda|^2) \ ,\end{aligned} \tag{35.66}$$

and with the expansion (35.62) we obtain for the normally-ordered characteristic function,

$$\begin{aligned}\chi_N(\lambda) &= \sum_{m,n}c_m^*c_n\langle m|e^{\lambda\hat{a}^\dagger}e^{-\lambda^*\hat{a}}|n\rangle \\ &= \sum_{m\geq n}(1-\tfrac{1}{2}\delta_{m,n})\left(c_m^*c_n\langle m|e^{\lambda\hat{a}^\dagger}e^{-\lambda^*\hat{a}}|n\rangle + \overline{c_m^*c_n\langle m|e^{-\lambda\hat{a}^\dagger}e^{\lambda^*\hat{a}}|n\rangle}\right) \ .\end{aligned} \tag{35.67}$$

finally yielding,

$$\boxed{\chi_N(\lambda) = \sum_{m\geq n}(1-\tfrac{1}{2}\delta_{m,n})\left[c_m^*c_n\lambda^{m-n} + c_mc_n^*(-\lambda^*)^{m-n}\right]\sqrt{\tfrac{n!}{m!}}L_n^{m-n}(|\lambda|^2)} \ . \tag{35.68}$$

Remembering that the symmetrically ordered function is given by $\chi_S(\lambda) = e^{-|\lambda|^2}\chi_N(\lambda)$ we may obtain the Wigner function by a numerical two-dimensional FFT,

$$W(\alpha) = \tfrac{1}{\pi^2}\int e^{-|\lambda|^2}\chi_N(\lambda)e^{\lambda^*\alpha-\lambda\alpha^*}d^2\lambda \ . \tag{35.69}$$

We will use this result in Sec. 35.4.3 to characterize correlations in an optical mode emanating from a Jaynes-Cummings type coupling to an atom. In Exc. 35.2.5.8 we will try to find an analytic solution for this integral.

[6] See also 24.6.6.6.

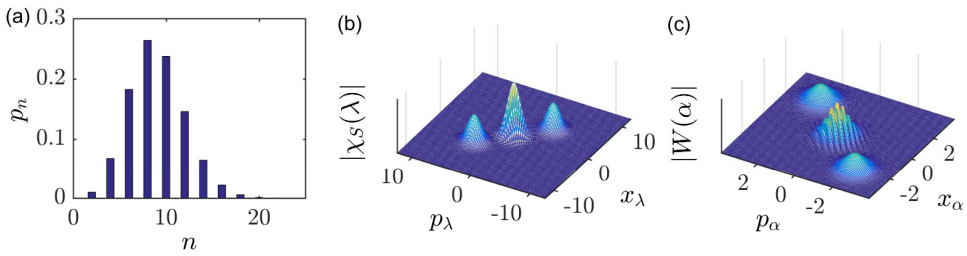

Figure 35.5: (code) Starting from a cat-state photon distribution, as shown in (a), we calculate the symmetrically ordered characteristic function (b) from the expression (35.67), and the Wigner function (c) by an FFT.

35.2.4 Representation of particular states in the Fock and Glauber basis

35.2.4.1 Representations of Glauber states

We have seen earlier that coherent states $|\beta\rangle$ can be expanded on a Fock state basis $|n\rangle$. For the state function, the density operator, and the photon number distribution we have,

$$\boxed{\begin{aligned} |\beta\rangle &= e^{-|\beta|/2}\sum_n \frac{\beta^n}{\sqrt{n!}}|n\rangle \\ \hat{\rho} &= e^{-|\beta|^2}\sum_{m,n}\frac{\beta^n\beta^{*m}}{\sqrt{m!n!}}|n\rangle\langle m| \\ P_n &= |\langle n|\beta\rangle|^2 = e^{-|\beta|^2}\frac{|\beta|^{2n}}{n!} \end{aligned}} \quad . \tag{35.70}$$

Expanding a coherent state on a basis of Glauber states, we will derive in Exc. 35.2.5.9 the P-function, the density matrix, the Q-function, and the Wigner function,

$$\boxed{\begin{aligned} |\psi\rangle &= |\beta\rangle \\ P_{|\beta\rangle}(\alpha) &= \delta^{(2)}(\alpha-\beta) \\ \hat{\rho} &= \int \delta^{(2)}(\alpha-\beta)|\alpha\rangle\langle\alpha|d^2\alpha = |\beta\rangle\langle\beta| \\ Q_{|\beta\rangle}(\alpha) &= \tfrac{1}{\pi}e^{-|\alpha-\beta|^2} \\ W_{|\beta\rangle}(\alpha) &= \tfrac{2}{\pi}e^{-2|\alpha-\beta|^2} \end{aligned}} \quad . \tag{35.71}$$

Example 208 (*State of a laser*): Following [1385, 1131], the correct *state of a laser* beam is not simply a coherent state, but rather,

$$\hat{\rho} = \int |\alpha e^{\imath\varphi}\rangle\langle\alpha e^{\imath\varphi}|\frac{d\varphi}{2\pi} \; . \tag{35.72}$$

After averaging, this state can be written as a superposition of Fock states [313],

$$\hat{\rho} = \sum_n P_n |n\rangle\langle n| \qquad \text{with} \qquad P_n = \frac{e^{-|\alpha|^2}|\alpha|^2 n}{n!} \ , \tag{35.73}$$

but without a specific phase,

$$\hat{\rho} \neq \sum_{m,n} c_m^* c_n |m\rangle\langle n| \ . \tag{35.74}$$

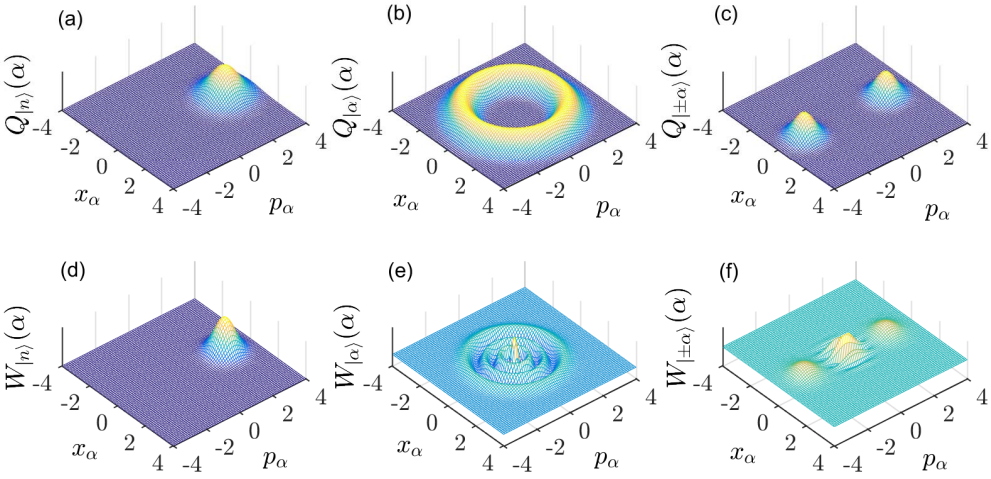

Figure 35.6: (code) (a-c) Q functions and (d-f) Wigner functions of a Glauber state (a,d), a Fock state (b,e), and a Schrödinger cat state (c,f).

35.2.4.2 Representations of Schrödinger cat states

Schrödinger cat states are correlated states of many particles (or quasi-particles). The expansion of the *Schrödinger cat state* $|\beta_0\rangle \pm |\beta_1\rangle$ on a Fock state basis yields, as we have seen in Exc. 24.6.6.5,

$$\boxed{\begin{aligned} |\psi_\pm\rangle &= \sum_n \frac{e^{-|\beta_0|^2/2}\beta_0^n \pm e^{-|\beta_1|^2/2}\beta_1^n}{\sqrt{2n!}}|n\rangle \\ P_n &= |\langle n|\psi_\pm\rangle|^2 \longrightarrow e^{-|\beta_0|^2}\frac{|\beta_0|^{2n}}{n!}\frac{|1\pm(-1)^n|^2}{2} \qquad \text{for} \quad \beta_0 = -\beta_1 \end{aligned}} \ . \tag{35.75}$$

Expanding a Schrödinger cat state on a basis of Glauber states, we will derive in Exc. 35.2.5.10 the P-function, the density matrix, the Q-function, and the Wigner

function,

$$\boxed{\begin{aligned} |\psi_\pm\rangle &= \tfrac{1}{C}(|\beta_0\rangle \pm |\beta_1\rangle) \qquad \text{with} \qquad C = \sqrt{2 \pm 2e^{-|\beta_0-\beta_1|^2}} \\ P_{|\beta_0\rangle|\beta_1\rangle}(\alpha) &= \delta^{(2)}(\alpha-\beta_0) + \delta^{(2)}(\alpha-\beta_1) \\ \hat{\rho} &= |\psi_\pm\rangle\langle\psi_\pm| \\ Q_{|\beta_0\rangle|\beta_1\rangle}(\alpha) &= \tfrac{1}{\pi}e^{-|\alpha-\beta_0|^2} + \tfrac{1}{\pi}e^{-|\alpha-\beta_1|^2} \\ W_{|\beta_0\rangle|\beta_1\rangle}(\alpha) &= \tfrac{2}{C^2\pi}\Big(e^{-2|\alpha-\beta_0|^2} + e^{-2|\alpha-\beta_1|^2} \\ &\pm 2e^{-|\beta_0|^2/2-|\beta_1|^2/2}\mathfrak{Re}\; e^{-2(\beta_1-\alpha)(\beta_0^*-\alpha^*)+\beta_0^*\beta_1}\Big) \end{aligned}} \quad . \tag{35.76}$$

We know from microscopic systems, for instance a two-level atom, that they can live in superposition states $|1\rangle + |2\rangle$. In contrast, the Schrödinger cat states discussed above occur in continuous Schrödinger fields involving many particles. Macroscopic quantum interferences (i.e. interferences that are detectable with macroscopic apparatuses, for example in heterodyne schemes) are named *fuzzy Schrödinger cats*, if the interfering states are conspicuously separated in phase space.

At this point, we have to emphasize the fundamental difference between Schrödinger cats and superpositions of modes,

$$\begin{aligned} |\psi\rangle &= |\alpha\rangle + |\beta\rangle && \neq |\alpha\rangle|\beta\rangle \\ \hat{\rho} &= |\alpha\rangle\langle\alpha| + |\beta\rangle\langle\beta| + |\alpha\rangle\langle\beta| + |\beta\rangle\langle\alpha| && \neq |\alpha\beta\rangle\langle\alpha\beta| \end{aligned} \quad . \tag{35.77}$$

Schrödinger cats exhibit interferences in phase space, whereas for mode superpositions, interferences only appear when a parameter is varied (e.g., the length of an interferometer arm).

Schrödinger cat states are very sensitive to dissipation and easily converted into statistical mixtures. For example, $|\alpha\rangle \pm |-\alpha\rangle$ contains only odd (even) photon numbers in the distribution function P_n. After some time $\sim \tau_{cav}/N$, the distribution is converted into a Poisson distribution. The higher the particle number N, the faster the decoherence will be. Consequently, *truely macroscopic* cat states have never been observed.

35.2.4.3 Representations of Fock states

On the Fock state basis $|n\rangle$, a number state is characterized by,

$$\boxed{\begin{aligned} |n\rangle &= (\hat{a}^\dagger)^n|0\rangle \\ \hat{\rho} &= |n\rangle\langle n| \\ P_k &= \delta_{nk} \end{aligned}} \quad . \tag{35.78}$$

This state can be expanded into Glauber states $|\alpha\rangle$ by following procedure. For large n we first calculate the P-distribution function,

$$P_{|n\rangle}(\alpha) = \delta^{(1)}(|\alpha| - \sqrt{n}) \;, \tag{35.79}$$

because it allows us to derive the density matrix via the formula (35.37),

$$\begin{aligned}\hat{\rho}_{|n\rangle} &= \int \delta^{(1)}(|\alpha| - \sqrt{n})|\alpha\rangle\langle\alpha| d^2\alpha \\ &= \int_0^\infty \int_0^{2\pi} \delta^{(1)}(|\alpha| - \sqrt{n})|\alpha\rangle\langle\alpha| \ |\alpha| d|\alpha| d\varphi_\alpha = \sqrt{n}\int_0^{2\pi} |\alpha\rangle\langle\alpha| d\varphi_\alpha \ .\end{aligned} \tag{35.80}$$

The Q-distribution function becomes, inserting the density operator obtained in (35.80),

$$\begin{aligned}Q_{|n\rangle}(\alpha) &= \tfrac{1}{\pi}\langle\alpha|\hat{\rho}_{|n\rangle}|\alpha\rangle \\ &= \tfrac{1}{\pi} n \int_0^{2\pi} |\langle\alpha|\beta\rangle|^2 d\varphi_\beta = \frac{1}{\pi} n \int_0^{2\pi} e^{-|\alpha - |\beta| e^{\imath\varphi_\beta}|^2} d\varphi_\beta \triangleq \frac{|\alpha|^{2n}}{\pi n!} e^{-|\alpha|^2} \ ,\end{aligned} \tag{35.81}$$

and finally the Wigner function is,

$$W_{|n\rangle}(\alpha) = \frac{2}{\pi} e^{-2|\alpha|^2} (-1)^n \sum_{m=0}^{n} \binom{n}{m} \frac{(-4|\alpha|^2)^m}{m!} = \frac{2}{\pi} e^{-2|\alpha|^2} (-1)^n L_n(4|\alpha|^2) \ , \tag{35.82}$$

where $L_m(4|\alpha|^2)$ are Laguerre polynomials. In Exc. 35.2.5.11 we will learn how to derive the above distribution functions directly from the characteristic functions. In summary, we have,

$$\boxed{\begin{aligned} |\psi\rangle &= |n\rangle \\ P_{|n\rangle}(\alpha) &= \delta^{(1)}(|\alpha| - \sqrt{n}) \\ \hat{\rho} &= \sqrt{n}\int_0^{2\pi} |\alpha\rangle\langle\alpha| d\varphi_\alpha \\ Q_{|n\rangle}(\alpha) &= \frac{|\alpha|^{2n}}{\pi n!} e^{-|\alpha|^2} \\ W_{|n\rangle}(\alpha) &= \frac{2}{\pi} e^{-2|\alpha|^2} (-1)^n L_n(4|\alpha|^2) \end{aligned}} \ . \tag{35.83}$$

35.2.4.4 Representations of thermal states

A light mode in a thermal mixture can not be represented by a pure state, but requires a density matrix description beyond (35.27). The concept of statistical mixtures has been introduced in Sec. 34.3. The following formulas will be derived in Exc. 35.2.5.12 [1184],

$$\boxed{\begin{aligned} \hat{\rho} &= \textstyle\sum_n \frac{\bar{n}^n}{(1+\bar{n})^{1+n}} |n\rangle\langle n| \\ P_n &= \frac{\bar{n}^n}{(1+\bar{n})^{1+n}} \end{aligned}} \ . \tag{35.84}$$

The coherent distribution P-function is,

$$\boxed{\begin{aligned} P_{therm}(\alpha) &= \tfrac{1}{\pi\bar{n}} e^{-|\alpha|^2/\bar{n}} \\ \hat{\rho} &= \tfrac{1}{\pi\bar{n}} \int e^{-|\alpha|^2/\bar{n}} |\alpha\rangle\langle\alpha| d^2\alpha \\ Q_{therm}(\alpha) &= \tfrac{1}{\pi(\bar{n}+1)} e^{-|\alpha|^2/(\bar{n}+1)} \\ W_{therm}(\alpha) &= \tfrac{1}{\pi(\bar{n}+1/2)} e^{-|\alpha|^2/(\bar{n}+1/2)} \end{aligned}} \quad . \tag{35.85}$$

35.2.5 Exercises

35.2.5.1 Ex: Glauber-Sudarshan and Husimi distribution

a. Show that $\rho_A(\alpha,\alpha^*) = \pi P(\alpha,\alpha^*)$ for an anti-normally ordered density operator $\hat{\rho}_A(\hat{a},\hat{a}^\dagger)$.
b. Show that $\rho_N(\alpha,\alpha^*) = \frac{1}{\pi} Q(\alpha,\alpha^*)$ for a normally ordered density operator $\hat{\rho}_N(\hat{a},\hat{a}^\dagger)$.

Solution: *a. For the anti-normal ordered density operator we calculate,*

$$\begin{aligned} \hat{\rho}_A(\hat{a},\hat{a}^\dagger) = \sum_{m,n} c_{m,n} \hat{a}^m \hat{a}^{\dagger n} &= \sum_{m,n} c_{m,n} \hat{a}^m \ \tfrac{1}{\pi} \int |\alpha\rangle\langle\alpha| d^2\alpha \ \hat{a}^{\dagger n} \\ &= \tfrac{1}{\pi} \int \sum_{m,n} c_{m,n} \alpha^j \alpha^{*k} |\alpha\rangle\langle\alpha| d^2\alpha \\ &= \tfrac{1}{\pi} \int \rho_A(\alpha,\alpha^*) |\alpha\rangle\langle\alpha| d^2\alpha = \int P(\alpha,\alpha^*) |\alpha\rangle\langle\alpha| d^2\alpha \ . \end{aligned}$$

b. For the normal ordered density operator we calculate,

$$\begin{aligned} \langle\alpha|\hat{\rho}_N(\hat{a},\hat{a}^\dagger)|\alpha\rangle = \langle\alpha| \sum_{m,n} c_{m,n} \hat{a}^{\dagger m} \hat{a}^n |\alpha\rangle &= \sum_{m,n} c_{m,n} \alpha^{*m} \alpha^n \\ = \rho_N(\alpha,\alpha^*) = \tfrac{1}{\pi} Q(\alpha,\alpha^*) \ . \end{aligned}$$

35.2.5.2 Ex: Glauber-Sudarshan and Husimi distribution

a. Show that the definitions of the Glauber-Sudarshan distribution given by (35.46) and (35.37) are equivalent.
b. Show that the definitions of the Husimi distribution given by (35.46) and (35.41) are equivalent.

Solution: *a. We get,*

$$\begin{aligned} \int P(\alpha,\alpha^*) |\alpha\rangle\langle\alpha| d^2\alpha = \int Tr\ \hat{\rho} \delta(\alpha^* - \hat{a}^\dagger) \delta(\alpha - \hat{a}) |\alpha\rangle\langle\alpha| d^2\alpha \\ = ... = \hat{\rho} \ . \end{aligned}$$

b. Using the completeness of the coherent state basis (24.126) we get,

$$\begin{aligned} Q(\alpha,\alpha^*) &= Tr\ \hat{\rho}\delta(\alpha-\hat{a})\ \tfrac{1}{\pi}\int |\beta\rangle\langle\beta| d^2\beta\ \delta(\alpha^*-\hat{a}^\dagger) \\ &= \tfrac{1}{\pi} Tr\ \int \hat{\rho}\delta(\alpha-\hat{a})|\beta\rangle\langle\beta|\delta(\alpha^*-\hat{a}^\dagger)d^2\beta \\ &= \tfrac{1}{\pi} Tr\ \int \hat{\rho}\delta(\alpha-\beta)|\beta\rangle\langle\beta|\delta(\alpha^*-\beta^*)d^2\beta = \tfrac{1}{\pi} Tr\ \hat{\rho}|\alpha\rangle\langle\alpha| = \tfrac{1}{\pi}\langle\alpha|\hat{\rho}|\alpha\rangle\ . \end{aligned}$$

35.2.5.3 Ex: Moments of Glauber states

a. Prove Eq. (35.39).
b. Prove Eq. (35.43).
c. Prove $\frac{1}{2}\langle\hat{a}\hat{a}^\dagger+\hat{a}^\dagger\hat{a}\rangle = \int W(\alpha,\alpha^*)\alpha\alpha^* d^2\alpha$.
d. Prove $\langle\{\hat{a}_j^{\dagger m}\hat{a}_k^n\}_S\rangle = \int W(\alpha)\alpha_j^m\alpha_k^{*n}\ d\alpha$, where the index S denotes *symmetric ordering*. Symmetric or *Weyl ordering* means that all products $\hat{r}\hat{p}$ must be replaced by the symmetric expressions, such as $(\hat{r}\hat{p}+\hat{p}\hat{r})/2$.
e. Then prove Eq. (35.45).

Solution: *a. The expectation value is,*

$$\begin{aligned} \langle\hat{O}_N(\hat{a},\hat{a}^\dagger)\rangle &= Tr\ \hat{\rho}\hat{O}_N(\hat{a},\hat{a}^\dagger) = \sum_{m,n} o_{m,n}\, Tr\ \hat{\rho}\hat{a}^{\dagger m}\hat{a}^n \\ &= ... = \sum_{m,n} c_{m,n}\, Tr\ \hat{\rho}\ \int \delta(\alpha^*-\hat{a}^\dagger)\delta(\alpha-\hat{a})\alpha^{*m}\alpha^n d^2\alpha \\ &= \int Tr\ \hat{\rho}\delta(\alpha^*\hat{a}^\dagger)\delta(\alpha-\hat{a})O_N(\alpha,\alpha^*)d^2\alpha \\ &= \int P(\alpha,\alpha^*)O_N(\alpha,\alpha^*)d^2\alpha\ . \end{aligned}$$

b. The expectation value is,

$$\begin{aligned} \langle\hat{O}_A(\hat{a},\hat{a}^\dagger)\rangle &= Tr\ \hat{\rho}\hat{O}_A(\hat{a},\hat{a}^\dagger) = \sum_{m,n} o_{m,n}\, Tr\ \hat{\rho}\hat{a}^m\hat{a}^{\dagger n} \\ &= \sum_{m,n} c_{m,n}\, Tr\ \hat{\rho}\hat{a}^m\ \tfrac{1}{\pi}\int |\alpha\rangle\langle\alpha| d^2\alpha\ \hat{a}^{\dagger n} = \tfrac{1}{\pi}\sum_{m,n} c_{m,n}\, Tr\ \int \hat{\rho}\alpha^m\alpha^{*n}|\alpha\rangle\langle\alpha| d^2\alpha \\ &= \tfrac{1}{\pi}\int O_A(\alpha,\alpha^*)\, Tr\ \hat{\rho}|\alpha\rangle\langle\alpha| d^2\alpha = \int Q(\alpha,\alpha^*)O_A(\alpha,\alpha^*)d^2\alpha\ . \end{aligned}$$

c.

35.2.5.4 Ex: Relationship between the characteristic functions

Derive the disentangling theorem (35.53) between the characteristic functions of the Glauber state basis.

Solution: *Using (24.113) we find,*

$$\begin{aligned} D(\lambda) &= e^{\lambda\hat{a}^\dagger - \lambda^*\hat{a}} = e^{-\lambda^*\hat{a}+\lambda\hat{a}^\dagger+[-\lambda^*\hat{a},\lambda\hat{a}^\dagger]/2}e^{|\lambda|^2/2} \\ &= e^{-\lambda^*\hat{a}+\lambda\hat{a}^\dagger-|\lambda|^2/2}e^{|\lambda|^2/2} = e^{-\lambda^*\hat{a}}e^{+\lambda\hat{a}^\dagger}e^{|\lambda|^2/2} \ , \end{aligned}$$

and,

$$\begin{aligned} D(\lambda) &= e^{\lambda\hat{a}^\dagger - \lambda^*\hat{a}} = e^{\lambda\hat{a}^\dagger-\lambda^*\hat{a}-[\lambda\hat{a}^\dagger,-\lambda^*\hat{a}]/2}e^{-|\lambda|^2/2} \\ &= e^{\lambda\hat{a}^\dagger-\lambda^*\hat{a}+|\lambda|^2/2}e^{-|\lambda|^2/2} = e^{\lambda\hat{a}^\dagger}e^{-\lambda^*\hat{a}}e^{-|\lambda|^2/2} \ . \end{aligned}$$

That is,

$$\langle\psi|e^{\lambda\hat{a}^\dagger}e^{-\lambda^*\hat{a}}e^{-|\lambda|^2/2}|\psi\rangle = \langle\psi|e^{\lambda\hat{a}^\dagger-\lambda^*\hat{a}}|\psi\rangle = \langle\psi|e^{-\lambda^*\hat{a}}e^{\lambda\hat{a}^\dagger}e^{|\lambda|^2/2}|\psi\rangle \ ,$$

or, inserting the definitions of the characteristic functions (35.52),

$$\chi_N(\lambda)e^{-|\lambda|^2/2} = \chi_S(\lambda) = \chi_A(\lambda)e^{|\lambda|^2/2} \ .$$

35.2.5.5 Ex: General form of the distribution functions

Show that from the definition (35.46) the common definition of the distribution functions (35.37) and (35.41) are recovered.

Solution: *For the Husimi P-distribution we find,*

$$\begin{aligned} \Delta_N(\alpha-\hat{a},\alpha^*-\hat{a}^\dagger) &= \tfrac{1}{\pi^2}\int e^{\lambda^*(\alpha-\hat{a})}e^{-\lambda(\alpha^*-\hat{a}^\dagger)}d^2\lambda \\ &= \tfrac{1}{\pi^2}\int e^{\lambda^*(\alpha-\hat{a})}\int|\beta\rangle\langle\beta|d^2\beta e^{-\lambda(\alpha^*-\hat{a}^\dagger)}d^2\lambda \\ &= \tfrac{1}{\pi^3}\int\int e^{\lambda^*(\alpha-\beta)}|\beta\rangle\langle\beta|e^{-\lambda(\alpha^*-\beta^*)}d^2\lambda d^2\beta \\ &= \tfrac{1}{\pi}\int\delta^{(2)}(\alpha-\beta)|\beta\rangle\langle\beta|d^2\beta = \tfrac{1}{\pi}|\alpha\rangle\langle\alpha| \ , \end{aligned}$$

and, using the coherent state basis,

$$\langle\beta|\Delta_N(\alpha-\hat{a},\alpha^*-\hat{a}^\dagger)|\beta\rangle = \tfrac{1}{\pi}e^{-|\alpha-\beta|^2} \ ,$$

and hence,

$$\langle\beta|\hat{\rho}|\beta\rangle = \int P(\alpha,\alpha^*)e^{-|\alpha-\beta|^2}d^2\alpha \ .$$

For the Wigner function, we find,

$$\Delta_S(\alpha-\hat{a},\alpha^*-\hat{a}^\dagger) = \tfrac{1}{\pi^2}\int e^{-\lambda(\alpha^*-\hat{a}^\dagger)+\lambda^*(\alpha-\hat{a})}d^2\lambda \ ,$$

and, using the coherent state basis,

$$\langle\beta|\Delta_S(\alpha-\hat{a},\alpha^*-\hat{a}^\dagger)|\beta\rangle = \tfrac{1}{\pi^2}\int\langle\beta|e^{-\lambda(\alpha^*-\hat{a}^\dagger)+\lambda^*(\alpha-\hat{a})}|\beta\rangle d^2\lambda \ ,$$

and hence,

$$\langle\beta|\hat{\rho}|\beta\rangle = \ .$$

For the Glauber-Sudarshan Q-distribution we find,

$$\Delta_A(\alpha-\hat{a},\alpha^*-\hat{a}^\dagger) = \tfrac{1}{\pi^2}\int e^{-\lambda(\alpha^*-\hat{a}^\dagger)}e^{\lambda^*(\alpha-\hat{a})}d^2\lambda \ ,$$

and, using the coherent state basis,

$$\langle\beta|\Delta_A(\alpha-\hat{a},\alpha^*-\hat{a}^\dagger)|\beta\rangle = \tfrac{1}{\pi^2}\int e^{-\lambda(\alpha^*-\beta^*)}e^{\lambda^*(\alpha-\beta)}d^2\lambda \ ,$$

and hence,

$$\begin{aligned}\langle\beta|\hat{\rho}|\beta\rangle &= \tfrac{1}{\pi}\int Q(\alpha,\alpha^*)\int e^{-\lambda(\alpha^*-\beta^*)+\lambda^*(\alpha-\beta)}d^2\lambda d^2\alpha \\ &= \int Q(\alpha,\alpha^*)\pi\delta^{(2)}(\alpha-\beta)d^2\alpha = \pi Q(\beta,\beta^*) \ .\end{aligned}$$

35.2.5.6 Ex: Characteristic functions

a. Evaluate the expression $\left.\frac{\partial^{m+n}\chi_X(\lambda)}{\partial\lambda^{*m}\partial(-\lambda)^n}\right|_{\lambda=0}$ for $X = N, S, A$.
b. Consider the particular case of a coherent state.

Solution: *a. For normal ordering we calculate,*

$$\left.\frac{\partial^{m+n}\chi_N(\lambda)}{\partial\lambda^{*m}\partial(-\lambda)^n}\right|_{\lambda=0} = \left.\langle\psi|\frac{\partial^n e^{-\lambda\hat{a}^\dagger}}{\partial(-\lambda)^n}\frac{\partial^m e^{\lambda^*\hat{a}}}{\partial\lambda^{*m}}|\psi\rangle\right|_{\lambda=0} = \left.\langle\psi|\hat{a}^{\dagger n}e^{-\lambda\hat{a}^\dagger}\hat{a}^m e^{\lambda^*\hat{a}}|\psi\rangle\right|_{\lambda=0} = \langle\hat{a}^{\dagger m}\hat{a}^n\rangle \ .$$

Similarly, we find for symmetric and anti-normal ordering,

$$\left.\frac{\partial^{m+n}\chi_S(\lambda)}{\partial\lambda^{*m}\partial(-\lambda)^n}\right|_{\lambda=0} = \langle\{\hat{a}^{\dagger m}\hat{a}^n\}_S\rangle \qquad \textit{and} \qquad \left.\frac{\partial^{m+n}\chi_A(\lambda)}{\partial\lambda^{*m}\partial(-\lambda)^n}\right|_{\lambda=0} = \langle\hat{a}^m\hat{a}^{\dagger n}\rangle \ ,$$

where the index S denotes symmetric ordering.
b. For a coherent state we find,

$$\langle\alpha|\hat{a}^{\dagger m}\hat{a}^n|\alpha\rangle = \alpha^{*m}\alpha^n \ .$$

35.2.5.7 Ex: Calculating with Wirtinger derivatives

Prove the following identities [504],

$$\hat{a}^\dagger - \alpha^* = \frac{\partial}{\partial \underrightarrow{\alpha}} \quad \text{and} \quad \hat{a}^\dagger - \alpha = \frac{\partial}{\partial \underleftarrow{\alpha}^*} \ .$$

Note, that with the bosonic operators we can construct the observables,

$$\hat{x} + \imath\hat{p} = \sqrt{2}\hat{a} \quad , \quad \partial_x - \imath\partial_p = 2\underrightarrow{\partial_\alpha} \quad , \quad \partial_x + \imath\partial_p = 2\underleftarrow{\partial_{\alpha^*}} \ .$$

In two dimensions [447], $d^2\alpha = d(\mathfrak{Re}\ \alpha)d(\mathfrak{Im}\ \alpha) = dxdp$.

Solution: *This is straightforward using the Fock state expansion. Alternatively, we may start representing,*

$$|\alpha\rangle\langle\alpha| = e^{\alpha\hat{a}^\dagger - \alpha^*\hat{a}}|0\rangle\langle 0|e^{-\alpha\hat{a}^\dagger + \alpha^*\hat{a}} \ .$$

Now,

$$\begin{aligned}\left(\alpha^* + \frac{\partial}{\partial\alpha}\right)|\alpha\rangle\langle\alpha| &= \alpha^*|\alpha\rangle\langle\alpha| + \frac{\partial e^{\alpha\hat{a}^\dagger - \alpha^*\hat{a}}}{\partial\alpha}|0\rangle\langle 0|e^{-\alpha\hat{a}^\dagger + \alpha^*\hat{a}} + e^{\alpha\hat{a}^\dagger - \alpha^*\hat{a}}|0\rangle\langle 0|\frac{\partial e^{-\alpha\hat{a}^\dagger + \alpha^*\hat{a}}}{\partial\alpha} \\ &= \alpha^*|\alpha\rangle\langle\alpha| + \hat{a}^\dagger e^{\alpha\hat{a}^\dagger - \alpha^*\hat{a}}|0\rangle\langle 0|e^{-\alpha\hat{a}^\dagger + \alpha^*\hat{a}} + e^{\alpha\hat{a}^\dagger - \alpha^*\hat{a}}|0\rangle\langle 0|e^{-\alpha\hat{a}^\dagger + \alpha^*\hat{a}}(-\hat{a}^\dagger) \\ &= \alpha^*|\alpha\rangle\langle\alpha| + \hat{a}^\dagger|\alpha\rangle\langle\alpha| + |\alpha\rangle\langle\alpha|(-\hat{a}^\dagger) = \hat{a}^\dagger|\alpha\rangle\langle\alpha| \ .\end{aligned}$$

As a corollary, we get,

$$\left(\alpha + \frac{\partial}{\partial\alpha^*}\right)|\alpha\langle\alpha| = |\alpha\rangle\langle\alpha|\hat{a} = |\alpha\rangle\langle\alpha|\hat{a} \ .$$

35.2.5.8 Ex: Wigner function for arbitrary HO states in the Fock basis

Search an analytic solution for the integral (35.68).

Solution: *The 2D Fourier transform of a radially symmetric function $u(|\lambda|)$ instead of $u_{nm}(\lambda)$ is,*

$$\begin{aligned}\int u(|\lambda|)e^{\alpha\lambda^* - \alpha^*\lambda}d^2\lambda &= \int u(\tfrac{1}{2}|x_\lambda + \imath p_\lambda|)e^{\imath p_\alpha x_\lambda - \imath x_\alpha p_\lambda}dx_\lambda dp_\lambda \\ &= \frac{1}{\imath p_\alpha - x_\alpha}\left[\int e^{+\imath p_\alpha x_\lambda}u(\tfrac{1}{2}x_\lambda)dx_\lambda - \int e^{-\imath x_\alpha p_\lambda}u(\tfrac{1}{2}p_\lambda)dp_\lambda\right] \ .\end{aligned}$$

With this,

$$\begin{aligned}\int e^{+\imath p_\alpha x_\lambda}u_{nm}(\tfrac{x_\lambda}{2})dx_\lambda &= \sqrt{\frac{n!}{m!}}\int e^{-x_\lambda^2/2}x_\lambda^{m-n}L_n^{m-n}(\tfrac{x_\lambda^2}{2})e^{\imath p_\alpha x_\lambda}dx_\lambda \\ &= \sqrt{\frac{n!}{m!}}\sqrt{\frac{\pi}{2}}\frac{1}{n!}(-1)^{int\frac{m-n}{2}}e^{-p_\alpha^2/2}He_n(p_\alpha)He_m(p_\alpha) \ .\end{aligned}$$

The Wigner function is now,

$$W(\alpha) = \sum_{m,n} \frac{1}{\pi^2} c_m^* c_n \frac{-1}{\alpha} \sqrt{\frac{\pi}{2}} \sqrt{\frac{1}{n!m!}} (-1)^{int\frac{m-n}{2}} \left[e^{-p_\alpha^2/2} He_n(p_\alpha) He_m(p_\alpha) + e^{-x_\alpha^2/2} He_n(x_\alpha) He_m(x_\alpha) \right] ,$$

where the He_n are probabilist's Hermite polynomials.

35.2.5.9 Ex: P-, Q-, and Wigner distribution functions for Glauber states

Starting from the characteristic functions $\chi_{A,S,N}(\lambda)$ derive for a coherent state $|\beta\rangle$ (a) the Husimi representation, (b) the Glauber-Sudarshan representation, and (c) the Wigner representation.

Solution: *In the following we will use the definition of the complex Fourier transform (35.46) and of the characteristic functions (35.52).*
a. For the P-representation we calculate,

$$\chi_N(\lambda) = \langle\beta| e^{\lambda \hat{a}^\dagger} e^{-\lambda^* \hat{a}} |\beta\rangle = e^{-\lambda^*\beta + \lambda\beta^*} ,$$

and hence, exploiting the formula (35.54),

$$P_{|\beta\rangle}(\alpha) = \tfrac{1}{\pi^2} \int e^{-\lambda^*(\beta-\alpha)+\lambda(\beta^*-\alpha^*)} d^2\lambda = \tfrac{1}{\pi^2} \int e^{-\lambda^*\eta + \lambda\eta^*} d^2\lambda$$
$$= \tfrac{1}{\pi^2} \int e^{-2\imath r_\lambda p_\eta + 2\imath p_\lambda r_\eta} dr_\lambda dp_\lambda = \delta(p_\eta)\delta(r_\eta) = \delta^{(2)}(\alpha - \beta) .$$

b. For the Q-representation we calculate, $\chi_A(\lambda) = e^{-|\lambda|^2} \chi_N(\lambda)$, and hence,

$$Q_{|\beta\rangle}(\alpha) = \tfrac{1}{\pi^2} \int e^{-\lambda^*(\beta-\alpha)+\lambda(\beta^*-\alpha^*)} e^{-|\lambda|^2} d^2\lambda = \tfrac{1}{\pi} e^{-|\alpha-\beta|^2} .$$

c. For the Wigner representation we calculate, $\chi_S(\lambda) = e^{-|\lambda|^2/2} \chi_N(\lambda)$, and hence,

$$W_{|\beta\rangle}(\alpha) = \tfrac{1}{\pi^2} \int e^{-\lambda^*(\beta-\alpha)+\lambda(\beta^*-\alpha^*)} e^{-|\lambda|^2/2} d^2\lambda = \tfrac{2}{\pi} e^{-2|\alpha-\beta|^2} .$$

35.2.5.10 Ex: P-, Q-, and Wigner distribution functions for cat states

Starting from the characteristic functions $\chi_{A,S,N}(\lambda)$ derive for a normalized cat state $C^{-1}(|\beta_0\rangle + |\beta_1\rangle)$ (a) the Husimi representation, (b) the Glauber-Sudarshan representation, and (c) the Wigner representation.

Solution: *The normalization of the cat state is given by,*

$$C = \sqrt{(\langle\beta_0| \pm \langle\beta_1|)(|\beta_0\rangle \pm |\beta_1\rangle)} = \sqrt{2 \pm 2e^{-|\beta_0-\beta_1|^2}} .$$

a. In Exc. 24.6.6.2 we already derived the expression,

$$\langle\beta_0|\beta_1\rangle = e^{-|\beta_0|^2/2-|\beta_1|^2/2+\beta_0^*\beta_1} \ .$$

With this we obtain,

$$\langle\beta_0|e^{\lambda\hat{a}^\dagger}e^{-\lambda^*\hat{a}}|\beta_1\rangle = e^{\lambda\beta_0^*-\lambda^*\beta_1}\langle\beta_0|\beta_1\rangle = e^{\lambda\beta_0^*-\lambda^*\beta_1-|\beta_0|^2/2-|\beta_1|^2/2+\beta_0^*\beta_1} \ ,$$

and the normally ordered characteristic function,

$$\chi_N(\lambda) = \tfrac{1}{C^2}(\langle\beta_0| \pm \langle\beta_1|)e^{\lambda\hat{a}^\dagger}e^{-\lambda^*\hat{a}}(|\beta_1\rangle \pm |\beta_0\rangle)$$
$$= \tfrac{1}{C^2}\left[e^{\lambda\beta_0^*-\lambda^*\beta_0} + e^{\lambda\beta_1^*-\lambda^*\beta_1} \pm e^{-|\beta_0|^2/2-|\beta_1|^2/2}\left(e^{\lambda\beta_0^*-\lambda^*\beta_1+\beta_0^*\beta_1} + e^{\lambda\beta_1^*-\lambda^*\beta_0+\beta_0\beta_1^*}\right)\right] \ .$$

Hence,

$$P_{|\beta_0\rangle|\beta_1\rangle}(\alpha) =$$

b. The anti-symmetrically ordered characteristic function being $\chi_A(\lambda) = e^{-|\lambda|^2}\chi_N(\lambda)$, we immediately get the Q-function using (35.54),

$$Q_{|\beta_0\rangle|\beta_1\rangle}(\alpha) =$$

c. The symmetrically ordered characteristic function being $\chi_S(\lambda) = e^{-|\lambda|^2/2}\chi_N(\lambda)$, we get the Wigner function using (35.54),

$$W_{|\beta_0\rangle|\beta_1\rangle}(\alpha) = \tfrac{1}{\pi^2}\int \chi_S(\lambda)e^{\lambda^*\alpha-\lambda\alpha^*}d^2\lambda$$
$$= \tfrac{1}{C^2\pi^2}\int\Big[e^{-|\lambda|^2/2-(\alpha^*-\beta_0^*)\lambda+(\alpha-\beta_0)\lambda^*} + e^{-|\lambda|^2/2-(\alpha^*-\beta_1^*)\lambda+(\alpha-\beta_1)\lambda^*}$$
$$\pm e^{-|\beta_0|^2/2-|\beta_1|^2/2}\left(e^{-|\lambda|^2/2-\lambda(\alpha^*-\beta_0^*)+\lambda^*(\alpha-\beta_1)+\beta_0^*\beta_1} + e^{-|\lambda|^2/2+\lambda^*(\alpha-\beta_0)-\lambda(\alpha^*-\beta_1^*)+\beta_0\beta_1^*}\right)\Big]d^2\lambda$$
$$= \tfrac{2}{C^2\pi}\left(e^{-2|\alpha-\beta_0|^2} + e^{-2|\alpha-\beta_1|^2} \pm 2e^{-|\beta_0|^2/2-|\beta_1|^2/2}\mathfrak{Re}\ e^{-2(\beta_1-\alpha)(\beta_0^*-\alpha^*)+\beta_0^*\beta_1}\right) \ .$$

We note that for $|\beta_0\rangle = |\beta_1\rangle$ we recover exactly the Glauber state calculated in Exc. 35.2.5.7(c).

35.2.5.11 Ex: *P*-, *Q*-, and Wigner distribution functions for Fock states

Starting from the characteristic functions $\chi_{A,S,N}(\lambda)$ derive for a number state $|n\rangle$ (a) the Husimi representation, (b) the Glauber-Sudarshan representation, and (c) the Wigner representation.

Solution: *From the expressions following the Fock state expansion (35.62), we derive immediately,*

$$\chi_N(\lambda) = \langle n|e^{\lambda\hat{a}^\dagger}e^{-\lambda^*\hat{a}}|n\rangle = \sum_{q,k=0}^{n}\frac{\lambda^q(-\lambda^*)^k}{\sqrt{q!k!}}\sqrt{\binom{n}{q}\binom{n}{k}}\langle n-q|n-k\rangle$$
$$= \sum_{k=0}^{n}\frac{(-|\lambda|^2)^k}{k!}\binom{n}{k} = L_n^0(|\lambda|^2) \ ,$$

where L_n^0 is a Laguerre polynomial. With this the symmetrically ordered characteristic function becomes,

$$\chi_S(\lambda) = \langle n|e^{\lambda\hat{a}^\dagger - \lambda^*\hat{a}}|n\rangle = e^{-|\lambda|^2/2}\chi_N(\lambda) = e^{-|\lambda|^2/2}L_n^0(|\lambda|^2) \ ,$$

and the anti-symmetrically ordered,

$$\chi_A(\lambda) = \langle n|e^{-\lambda^*\hat{a}}e^{\lambda\hat{a}^\dagger}|n\rangle = e^{-|\lambda|^2}\chi_N(\lambda) = e^{-|\lambda|^2}L_n^0(|\lambda|^2) \ .$$

a. Now, we calculate for the P-representation,

$$P_{|\beta\rangle}(\alpha) =$$

b. For the Q-representation, we get,

$$Q_{|\beta\rangle}(\alpha) =$$

c. Finally, the Wigner function is,

$$\begin{aligned} W_{|n\rangle}(\alpha) &= \tfrac{1}{\pi^2}\int \chi_S(\lambda)e^{-\alpha\lambda^* + \alpha^*\lambda}d^2\lambda = \tfrac{1}{\pi^2}\int e^{-|\lambda|^2/2}L_n^0(|\lambda|^2)e^{-\alpha\lambda^* + \alpha^*\lambda}d^2\lambda \\ &= \tfrac{1}{\pi^2}\int e^{(-\lambda_r^2-\lambda_i^2)/2}L_n^0(\lambda_r^2+\lambda_i^2)e^{2\imath(-\alpha_i\lambda_r + \alpha_r\lambda_i)}d\lambda_r d\lambda_i \ . \end{aligned}$$

35.2.5.12 Ex: Wigner distribution function of a Fock state

Calculate the Wigner function for a harmonic oscillator in a Fock state from its wavefunction $\langle x|n\rangle$.

Solution: *The wavefunction of a Fock state is,*

$$\langle x|n\rangle = \frac{e^{-x^2/2a_{ho}^2}H_n(x/a_{ho})}{\sqrt{a_{ho}\sqrt{\pi}2^n n!}} \ .$$

With this,

$$\begin{aligned} W(x,p) &= \frac{1}{\pi}\int_{-\infty}^{\infty}\langle n|x+y\rangle\langle x-y|n\rangle e^{2\imath py/\hbar}dy \\ &= \frac{1}{\pi a_{ho}\sqrt{\pi}2^n n!}\int_{-\infty}^{\infty}e^{(-x^2-y^2)/a_{ho}^2}H_n(\tfrac{x+y}{a_{ho}})H_n(\tfrac{x-y}{a_{ho}})e^{2\imath py/\hbar}dy \\ &= \frac{1}{\pi\sqrt{\pi}2^n n!}\int_{-\infty}^{\infty}e^{-\tilde{x}^2-\tilde{y}^2}H_n(\tilde{x}+\tilde{y})H_n(\tilde{x}-\tilde{y})e^{2\imath\tilde{p}\tilde{y}}d\tilde{y} \ , \end{aligned}$$

where we introduced $\tilde{x} \equiv x/a_{ho}$ and $\tilde{p} \equiv a_{ho}p/\hbar$. Now, we get from a Taylor expansion the rule,

$$H_n(x+y) = \sum_{k=0}^{n}\binom{n}{k}(2x)^{n-k}H_k(y) \ ,$$

allowing us to rewrite the Wigner function as,

$$W(x,p) = \frac{1}{\pi\sqrt{\pi}2^n n!}\sum_{k,q=0}^{n}\binom{n}{k}\binom{n}{q}(2\tilde{x})^{2n-k-q}e^{-\tilde{x}^2}\int_{-\infty}^{\infty}e^{-\tilde{y}^2}H_k(\tilde{y})H_q(-\tilde{y})e^{2\imath\tilde{p}\tilde{y}}d\tilde{y}\ .$$

This integral can be solved.

35.2.5.13 Ex: Thermal state

a. Show that $\langle-\beta|\hat{\rho}|\beta\rangle e^{|\beta|^2}$ and $P(\alpha,\alpha^*)e^{-|\alpha|^2}$ are related by Fourier transform.
b. Using the relationship of (a), derive the density operator and the distribution function of the Fock and the Glauber basis for a thermal state.

Solution: *a. Let us consider coherent states $|\beta\rangle$ and $|-\beta\rangle$. Then,*

$$\begin{aligned}\langle-\beta|\hat{\rho}|\beta\rangle e^{|\beta|^2} &= e^{|\beta|^2}\int P(\alpha,\alpha^*)\langle-\beta|\alpha\rangle\langle\alpha|\beta\rangle d^2\alpha\\ &= e^{|\beta|^2}\int P(\alpha,\alpha^*)e^{-|\beta|^2/2-|\alpha|^2/2-\beta\alpha^*}e^{-|\alpha|^2/2-|\beta|^2/2+\alpha\beta^*}d^2\alpha\\ &= \int P(\alpha,\alpha^*)e^{-|\alpha|^2}e^{\alpha\beta^*-\alpha^*\beta}d^2\alpha = \mathcal{F}[P(\alpha,\alpha^*)e^{-|\alpha|^2}]\ .\end{aligned}$$

b. With the photon number probability calculated in Eq. (22.59) we have,

$$\hat{\rho} = P_n = \sum_n \frac{\bar{n}^n}{(1+\bar{n})^{1+n}}|n\rangle\langle n|\ .$$

This allows us to calculate,

$$\begin{aligned}\langle-\beta|\hat{\rho}|\beta\rangle &= \sum_n \frac{\bar{n}^n}{(1+\bar{n})^{1+n}}\langle-\beta|n\rangle\langle n|\beta\rangle\\ &= \frac{e^{-|\beta|^2}}{1+\langle n\rangle}\sum_n\frac{(-|\beta|^2)^n}{n!}\left(\frac{\langle n\rangle}{1+\langle n\rangle}\right)^n = \frac{e^{-|\beta|^2}}{1+\langle n\rangle}e^{-|\beta|^2/(1+1/\langle n\rangle)}\ ,\end{aligned}$$

and finally,

$$P(\alpha,\alpha^*) = \tfrac{1}{\pi^2}\mathcal{F}[\langle-\beta|\hat{\rho}|\beta\rangle] = \tfrac{1}{\pi^2}\int\langle-\beta|\hat{\rho}|\beta\rangle e^{-\beta\alpha^*+\beta^*\alpha}d^2\beta = \frac{1}{\pi\langle n\rangle}e^{-|\alpha|^2/\langle n\rangle}\ .$$

35.3 Squeezed states of the harmonic oscillator

35.3.1 The squeezing operator

Let us consider a Hamiltonian of the following form,

$$\boxed{\hat{H}_{sqz} = \hbar\omega\hat{a}^\dagger\hat{a} + \tfrac{\imath}{2}\hbar\xi\hat{a}^{\dagger 2} + \tfrac{\imath}{2}\hbar\xi^*\hat{a}^2}\ . \tag{35.86}$$

leading to the equation of motion,

$$\dot{\hat{a}} = -\imath\omega\hat{a} + 2g\hat{a}^\dagger \ . \tag{35.87}$$

The non-linear, i.e. quadratic, appearance of the field operators suggests that the interaction should include correlated pair production, as is the case for parametric processes or four-wave mixing. We will see later that cavities are good for generating squeezing. However, the unused ports of a cavity let uncorrelated vacuum fluctuations enter, which partially overrule squeezing.

For now, we study, in analogy with the displacement operator (24.111), the propagator $e^{-\imath\hat{H}_{sqz}t/\hbar}$, i.e the operator given by,

$$\boxed{\hat{S}(\xi) \equiv e^{\xi\hat{a}^{\dagger 2}/2 - \xi^*\hat{a}^2/2}} \ , \tag{35.88}$$

which we will call the *squeezing operator* because, applied to the vacuum state, $|\xi\rangle = S(\xi)|0\rangle$, this operator will compress the uncertainty of one quadrature component, as we will see shortly.

In analogy with the calculation (24.112), using the commutation rules, it is possible to verify the unitarity of this operator [818] (see Exc. 35.3.4.1). In particular, using the relationship (??) and the abbreviation $\hat{A} \equiv \frac{\xi}{2}\hat{a}^{\dagger 2} - \frac{\xi^*}{2}\hat{a}^2$, we can show [1265] (see Exc. 35.3.4.2),

$$\begin{aligned}\hat{S}^\dagger(\xi)\hat{a}\hat{S}(\xi) = e^{\hat{A}}\hat{a}e^{-\hat{A}} &= \hat{a} + [\hat{A},\hat{a}] + \tfrac{1}{2!}\Big[\hat{A},[\hat{A},\hat{a}]\Big] + \tfrac{1}{3!}\Big[\hat{A},\Big[\hat{A},[\hat{A},\hat{a}]\Big]\Big] \ldots \\ &= \hat{a} + \xi\hat{a}^\dagger + \tfrac{1}{2!}\xi\xi^*\hat{a} + \tfrac{1}{3!}\xi\xi^*\xi\hat{a}^\dagger + \ldots = \hat{a}\cosh|\xi| + \frac{|\xi|}{\xi^*}\hat{a}^\dagger\sinh|\xi| \ ,\end{aligned} \tag{35.89}$$

and similarly for $\hat{a}^\dagger$, such that with $\xi \equiv re^{\imath\varphi}$,

$$\boxed{\begin{array}{rcl}\hat{S}^\dagger(\xi)\hat{a}\hat{S}(\xi) &=& \hat{a}\cosh r + e^{-\imath\varphi}\hat{a}^\dagger\sinh r \\ \hat{S}^\dagger(\xi)\hat{a}^\dagger\hat{S}(\xi) &=& \hat{a}^\dagger\cosh r + e^{\imath\varphi}\hat{a}\sinh r\end{array}} \ . \tag{35.90}$$

The formulas (35.90) describe a *Bogolubov transform*, as they can be cast into the form,

$$\boxed{\hat{b} \equiv u\hat{a} + v\hat{a}^\dagger \qquad , \qquad \hat{b}^\dagger \equiv u^*\hat{a}^\dagger + v^*\hat{a}} \ , \tag{35.91}$$

for complex numbers u and v. By postulating the same commutation relation for new operators, $[\hat{b},\hat{b}^\dagger] = 1$, we immediately get the condition,

$$|u|^2 - |v|^2 = 1 \ . \tag{35.92}$$

Comparing with the hyperbolic identity $\cosh^2 r - \sinh^2 r = 1$, we can parametrize the constants as,

$$u = \cosh r \qquad \text{and} \qquad v = e^{\imath\varphi}\sinh r \ . \tag{35.93}$$

This is interpreted as a linear simplectic transformation in phase space between pairs of annihilation and creation operators satisfying the same commutation relation $[\hat{a},\hat{a}^\dagger] = 1$.

35.3.1.1 Relation between squeezing and displacement operator

The squeezing operator *does not commute* with the displacement operator. However, from (35.90) we an derive the following simple relation,

$$\hat{S}(\xi)D(\alpha) \neq D(\alpha)\hat{S}(\xi) = \hat{S}(\xi)D(\alpha\cosh r + \alpha^* e^{\imath\theta}\sinh r) \ . \tag{35.94}$$

Solve the Exc. 35.3.4.3.

Squeezed coherent states are generated by coherent displacement of a *squeezed vacuum*,

$$|\alpha,\xi\rangle = \hat{S}(\xi)|0,\xi\rangle = D(\alpha)\hat{S}(\xi)|0\rangle \ . \tag{35.95}$$

On the other hand, from (35.94),

$$\begin{aligned} D(\alpha)\hat{S}(\xi)|0\rangle &= \hat{S}(\xi)D(\alpha\cosh r + \alpha^* e^{\imath\varphi}\sinh r)|0\rangle \\ &= S(\xi)|\alpha\cosh r + \alpha^* e^{\imath\varphi}\sinh r\rangle \ . \end{aligned} \tag{35.96}$$

35.3.1.2 Squeezing of the uncertainty relation

The real and imaginary parts of the transformed operators, defined by $\hat{b} = \hat{x}_b + \imath\hat{y}_b$, are Hermitian and satisfy the Heisenberg uncertainty relation (23.91),

$$[\hat{x}_b,\hat{y}_b] = \tfrac{\imath}{2} \qquad \text{and} \qquad \Delta\hat{x}_b\Delta\hat{y}_b \geq \tfrac{1}{2\imath}\langle[\hat{x}_b,\hat{y}_b]\rangle = \tfrac{1}{4} \ . \tag{35.97}$$

However, let us take a look at the uncertainties separately. They relate to the Glauber mode via,

$$\begin{aligned} \hat{x}_b &= \tfrac{1}{2}(\hat{b}+\hat{b}^\dagger) = \tfrac{1}{2}(\hat{a}\cosh r + \hat{a}^\dagger e^{\imath\varphi}\sinh r) + \tfrac{1}{2}(\hat{a}^\dagger\cosh r + \hat{a}e^{-\imath\varphi}\sinh r) \\ &= \hat{x}_a\cosh r + \tfrac{1}{2}\sinh r(\hat{a}^\dagger e^{\imath\varphi} + \hat{a}e^{-\imath\varphi}) \xrightarrow{\varphi=0} \hat{x}_a e^r \\ \hat{y}_b &= \tfrac{1}{2\imath}(\hat{b}-\hat{b}^\dagger) = \tfrac{1}{2\imath}(\hat{a}\cosh r + \hat{a}^\dagger e^{\imath\varphi}\sinh r) - \tfrac{1}{2\imath}(\hat{a}^\dagger\cosh r + \hat{a}e^{-\imath\varphi}\sinh r) \\ &= \hat{y}_a\cosh r + \tfrac{1}{2\imath}\sinh r(\hat{a}^\dagger e^{\imath\varphi} - \hat{a}e^{-\imath\varphi}) \xrightarrow{\varphi=0} \hat{y}_a e^{-r} \ . \end{aligned} \tag{35.98}$$

The individual fluctuations are (assuming $\varphi = 0$),

$$\begin{aligned} \Delta\hat{x}_b^2 &= \langle\hat{x}_b^2\rangle - \langle\hat{x}_b\rangle^2 = e^{2r}\left(\langle\hat{x}_a^2\rangle - \langle\hat{x}_a\rangle^2\right) \\ &= \tfrac{1}{4}e^{2r}\left(1 + \langle\hat{a}^2\rangle + \langle\hat{a}^\dagger\rangle^2 + 2\langle\hat{a}^\dagger\hat{a}\rangle - \langle\hat{a}\rangle^2 - \langle\hat{a}^\dagger\rangle^2 - 2\langle\hat{a}^\dagger\rangle\langle\hat{a}\rangle\right) \ . \end{aligned} \tag{35.99}$$

With $\langle\hat{a}\rangle = 0$,

$$\begin{aligned} \Delta\hat{x}_b^2 &= e^{2r}\left(\tfrac{1}{2}\mathfrak{Re}\ \langle\hat{a}^2\rangle + \tfrac{1}{4} + \tfrac{1}{2}\langle\hat{a}^\dagger\hat{a}\rangle\right) \\ \Delta\hat{y}_b^2 &= e^{-2r}\left(-\tfrac{1}{2}\mathfrak{Re}\ \langle\hat{a}^2\rangle + \tfrac{1}{4} + \tfrac{1}{2}\langle\hat{a}^\dagger\hat{a}\rangle\right) \ . \end{aligned} \tag{35.100}$$

Looking at the coherent vacuum, $\hat{a}|\alpha\rangle = 0$, hence,

$$\Delta\hat{x}_b = \tfrac{1}{2}e^r \qquad \text{and} \qquad \Delta\hat{y}_b = \tfrac{1}{2}e^{-r} \ , \tag{35.101}$$

and the squeezed state is at the uncertainty minimum.

35.3.2 Squeezed state in the Fock basis

The numbers of photons in the squeezed state is [818],

$$\langle n|\alpha,\xi\rangle = \frac{(\zeta/2)^{n/2}}{\sqrt{n!\cosh r}} e^{-\frac{1}{2}(|\alpha|^2+\alpha^*\zeta)} H_n\left(\frac{\alpha+\alpha^*\zeta}{\sqrt{2\zeta}}\right) , \tag{35.102}$$

with the abbreviation $\zeta \equiv e^{i\theta}\tanh r$. For squeezed vacuum $\alpha = 0$, noting that $H_n(0) = (-2)^{n/2}(n-1)!!$ for even n and $H_n(0) = 0$ for odd n, we find,

$$\langle n|0,\xi\rangle = \frac{(-\zeta)^{n/2}(n-1)!!}{\sqrt{n!\cosh r}} \tag{35.103}$$

for even photon number. Odd photon numbers are excluded. Hence,

$$\boxed{\begin{aligned} |\alpha,\xi\rangle &= \sum_n |n\rangle\langle n|\alpha,\xi\rangle \\ \hat\rho &= |\alpha,\xi\rangle\langle\alpha,\xi| \\ P_n &= |\langle n|\alpha,\xi\rangle|^2 \end{aligned}} . \tag{35.104}$$

In the photon representation we can easily see that the squeezed vacuum is (unlike the coherent and the Fock vacuum) not empty,

$$\begin{aligned} \langle\alpha,\xi|\hat n|\alpha,\xi\rangle &= |\alpha|^2 + \sinh^2|\xi| \overset{\alpha\to 0}{\longrightarrow} \sinh^2|\xi| \\ \Delta_{\alpha,\xi}\hat n &= |\alpha| + 2\cosh^2|\xi|\sinh^2|\xi| \overset{\alpha\to 0}{\longrightarrow} 2\cosh^2|\xi|\sinh^2|\xi| \ . \end{aligned} \tag{35.105}$$

Squeezed vacuum contains contributions from many $|n\rangle$.

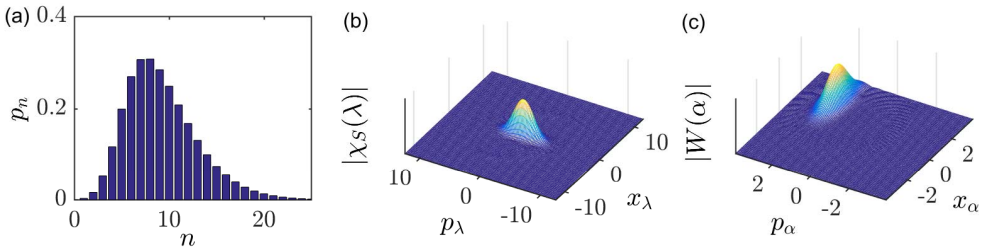

Figure 35.7: (code) Starting from a squeezed state photon distribution with $r = 0.5$, as shown in (a), we calculate the symmetrically ordered characteristic function (b) from the expression (35.68), and the Wigner function (c) by an FFT.

For the squeezed vacuum state the photon number distribution displays odd-even-oscillations. This can be explained by the mathematical form of the squeezing operator, that resembles the operator for two-photon generation and annihilation processes. Photons in a squeezed vacuum state are more likely to appear in pairs.

35.3.3 Squeezed state in the Glauber basis

The *squeezed state* contains non-classical quantum correlations, as we will show by calculating $g^{(1)}$ and $g^{(2)}$ for squeezed states,

$$g^{(2)}(0) = \frac{\langle \hat{b}^\dagger \hat{b} \hat{b}^\dagger \hat{b} \rangle}{\langle \hat{b}^\dagger \rangle^2 \langle \hat{b} \rangle^2} = 1 + \frac{\cosh 2r}{\sinh^2 r} \ . \tag{35.106}$$

The distribution functions in the coherent representation are,

$$\begin{aligned}
|\psi\rangle &= |\beta, \xi\rangle \\
P_{|\beta\rangle}(\alpha) &= \\
\hat{\rho} &= |\beta, \xi\rangle\langle\beta, \xi| \\
Q_{|\beta\rangle}(\alpha) &= \tfrac{\text{sech } r}{\pi} \ e^{-(|\alpha|^2+|\beta|^2)+(\alpha^*\beta+\alpha\beta^*)} \ \text{sech } r - \frac{1}{2}\left[e^{\imath\theta}(\alpha^{*2}-\beta^{*2})+e^{-\imath\theta}(\alpha^2-\beta^2)\right] \ \tanh r \\
W_{|\beta\rangle}(\alpha) &= \tfrac{1}{2\pi} \exp(-\tfrac{(\alpha+\alpha^*)^2}{2e^{-2r}} + \tfrac{(\alpha-\alpha^*)^2}{2e^{2r}})
\end{aligned} \tag{35.107}$$

35.3.4 Exercises

35.3.4.1 Ex: Unitarity of the squeezing operator

Calculate $\langle \hat{E} \rangle$ and $\Delta \hat{E}$.

Solution:

35.3.4.2 Ex: Transformation by the squeezing operator

Demonstrate the relationship (35.89).

Solution: *First we calculate,*

$$\begin{aligned}
[\hat{a}^{\dagger 2}, \hat{a}] &= \hat{a}^\dagger [\hat{a}^\dagger, \hat{a}] + [\hat{a}^\dagger, \hat{a}] \hat{a}^\dagger = -2\hat{a}^\dagger \\
[\hat{a}^2, \hat{a}^\dagger] &= \hat{a}[\hat{a}, \hat{a}^\dagger] + [\hat{a}, \hat{a}^\dagger]\hat{a} = 2\hat{a} \ .
\end{aligned}$$

Now we calculate,

$$\begin{aligned}
& e^{-\xi \hat{a}^{\dagger 2}/2 + \xi^* \hat{a}^2/2} \hat{a} e^{\xi \hat{a}^{\dagger 2}/2 - \xi^* \hat{a}^2/2} \\
&\quad = \hat{a} + \left[-\tfrac{\xi}{2}\hat{a}^{\dagger 2} + \tfrac{\xi^*}{2}\hat{a}^2, \hat{a} \right] + \tfrac{1}{2!}\left[-\tfrac{\xi}{2}\hat{a}^{\dagger 2} + \tfrac{\xi^*}{2}\hat{a}^2, \left[-\tfrac{\xi}{2}\hat{a}^{\dagger 2} + \tfrac{\xi^*}{2}\hat{a}^2, \hat{a} \right] \right] + ... \\
&\quad = \hat{a} + \hat{B}_1 + \hat{B}_2 + \hat{B}_3 ... \ ,
\end{aligned}$$

with $\hat{B}_n = \frac{1}{n}[\hat{a}, \hat{B}_{n-1}]$, *such that,*

$$\begin{aligned}
\hat{B}_1 &= \xi\hat{a}^\dagger \\
\hat{B}_2 &= \tfrac{1}{2}\left[-\tfrac{\xi}{2}\hat{a}^{\dagger 2} + \tfrac{\xi^*}{2}\hat{a}^2, \hat{B}_1\right] = \tfrac{1}{2}\tfrac{|\xi|^2}{2}\left[\hat{a}^2, \hat{a}^\dagger\right] = \tfrac{\xi\xi^*}{2}\hat{a} \\
\hat{B}_3 &= \tfrac{1}{3}\left[-\tfrac{\xi}{2}\hat{a}^{\dagger 2} + \tfrac{\xi^*}{2}\hat{a}^2, \hat{B}_2\right] = \tfrac{1}{3}\tfrac{|\xi|^2}{2}\tfrac{-\xi}{2}\left[\hat{a}^{\dagger 2}, \hat{a}\right] = \tfrac{1}{3}\tfrac{\xi\xi^*\xi}{2}\hat{a}^\dagger \ ,
\end{aligned}$$

confirming the result.

35.3.4.3 Ex: Squeezed states

Squeezed states may be introduced by the application of the operator $S(\xi) \equiv e^{\frac{\xi^*}{2}\hat{a}^2 - \frac{\xi}{2}\hat{a}^{\dagger\ 2}}$ on a Glauber state $|\alpha\rangle$, where ξ is the squeezing parameter.
Calculate $\langle\alpha, \xi|\hat{n}|\alpha, \xi\rangle$ and show with $\alpha \to 0$, that the squeezed vacuum is not empty.

Solution: *With the commutation rules and with* $e^A e^B = e^{A+[A,B]/2+B}$ *it is easy to show the unitarity of the squeezing operator. In particular,*

$$\begin{aligned}
\hat{b} &= S^\dagger(\xi)\hat{a}S(\xi) = e^{\hat{B}}\hat{a}e^{-\hat{B}} \\
&= \hat{a} + \left[\hat{B}, \hat{a}\right] + \tfrac{1}{2!}\left[\hat{B}, [\hat{B}, \hat{a}]\right] + \tfrac{1}{3!}\left[\hat{B}, \left[\hat{B}, [\hat{B}, \hat{a}]\right]\right] ... \\
&= \hat{a} + \xi\hat{a}^\dagger + \tfrac{1}{2!}\xi\xi^*\hat{a} + \tfrac{1}{3!}\xi\xi^*\xi\hat{a}^\dagger + ... = \hat{a}\cosh|\xi| + \frac{|\xi|}{\xi^*}\hat{a}^\dagger \sinh|\xi| \ .
\end{aligned}$$

Hence,

$$\begin{aligned}
\hat{b}^\dagger\hat{b} &= \left(\hat{a}^\dagger\cosh|\xi| + \frac{|\xi|}{\xi}\hat{a}\sinh|\xi|\right)\left(\hat{a}\cosh|\xi| + \frac{|\xi|}{\xi^*}\hat{a}^\dagger\sinh|\xi|\right) \\
&= \hat{a}^\dagger\hat{a}\cosh^2|\xi| + \hat{a}\hat{a}^\dagger\sinh^2|\xi| + \left(\frac{|\xi|}{\xi^*}\hat{a}^\dagger\hat{a}^\dagger + \frac{|\xi|}{\xi}\hat{a}\hat{a}\right)\sinh|\xi|\cosh|\xi| \\
&= \hat{a}^\dagger\hat{a} + \sinh^2|\xi| + \left(\frac{|\xi|}{\xi^*}\hat{a}^\dagger\hat{a}^\dagger + \frac{|\xi|}{\xi}\hat{a}\hat{a}\right)\sinh|\xi|\cosh|\xi| \ .
\end{aligned}$$

Finally,

$$\begin{aligned}
\langle\alpha, \xi|\hat{n}|\alpha, \xi\rangle &= |\alpha|^2 + \sinh^2|\xi| \overset{\alpha\to 0}{\longrightarrow} \sinh^2|\xi| \ , \\
\Delta_{\alpha,\xi}\hat{n} &= |\alpha| + 2\cosh^2|\xi|\sinh^2|\xi| \overset{\alpha\to 0}{\longrightarrow} 2\cosh^2|\xi|\sinh^2|\xi| \ .
\end{aligned}$$

35.3.4.4 Ex: Studying the squeezing operator

Using the Baker-Campbell-Hausdorff braiding identity,

$$e^{\hat{x}}e^{\hat{y}}e^{-\hat{x}} = e^{\hat{y}+[\hat{x},\hat{y}]+\frac{1}{2!}[\hat{x},[\hat{x},\hat{y}]]+...}$$

evaluate the expression $e^{\hat{a}^{\dagger 2}/2}e^{\hat{a}^2/2}e^{-\hat{a}^{\dagger 2}/2}$.

Solution: *We first calculate the commutators,*

$$[\hat{n}, \tfrac{\hat{a}^{\dagger 2}}{2}] = \hat{a}^{\dagger 2} \qquad \textit{and} \qquad [\hat{n}, \tfrac{\hat{a}^2}{2}] = -\hat{a}^2 \qquad \textit{and} \qquad [\tfrac{\hat{a}^2}{2}, \tfrac{\hat{a}^{\dagger 2}}{2}] = \hat{n} + \tfrac{1}{2} \ .$$

Now, identifying $\hat{x} \equiv \frac{\hat{a}^{\dagger 2}}{2}$ *and* $\hat{y} \equiv \frac{\hat{a}^2}{2}$,

$$e^{\hat{a}^{\dagger 2}/2}e^{\hat{a}^2/2}e^{-\hat{a}^{\dagger 2}/2} = e^{\hat{a}^2/2 + \hat{a}^{\dagger 2}/2 - \hat{n}} \ .$$

35.4 The Jaynes-Cummings model

The *Jaynes-Cummings model* describes the dynamics of a single dressed two-level atom in a single monochromatic laser mode in the absence of spontaneous emission processes. The model, illustrated in Fig. 35.2 has become a paradigm of quantum mechanics with applications in quantum information, where it applies to the formulation of entanglement protocols of atomic states and the implementation of quantum gates, which will be discussed in Sec. 41.4. In the following, we will first study the interaction of an atom with an optical mode neglecting dissipation effects and leave the discussion on the impact of dissipation processes to later sections.

The dynamic evolution of pure states is then obtained from the Schrödinger equation. The Hamiltonian of this system is given by (35.19). Letting $\hbar = 1$ and assuming that the atom is located at the origin [such that $\Omega_1(\mathbf{r})e^{\imath \mathbf{k}\cdot\mathbf{r}} = \Omega_1(\mathbf{0})$], we can write the time-dependent Hamiltonian in the *interaction picture* as,

$$\boxed{\begin{aligned} \hat{H}_{atom:field} &= \tfrac{\imath}{2}\Omega_1 e^{-\imath\Delta t}\hat{\sigma}^+\hat{a} - \tfrac{\imath}{2}\Omega_1 e^{\imath\Delta t}\hat{\sigma}^-\hat{a}^\dagger \\ &= \begin{pmatrix} 0 & \frac{\imath}{2}\Omega_1 e^{-\imath\Delta t}\hat{a} \\ -\frac{\imath}{2}\Omega_1 e^{\imath\Delta t}\hat{a}^\dagger & 0 \end{pmatrix} \end{aligned}} \ . \tag{35.108}$$

where ω is the frequency of the radiation, ω_0 the frequency of the atomic transition, $\Delta \equiv \omega - \omega_0$ the detuning, and Ω_1 the Rabi frequency generated by a single photon. The atomic operators $\sigma^\pm$ are related to the *Pauli spin matrices* (23.47), and we use the conventions $\hat{\sigma}^z = [\hat{\sigma}^+, \hat{\sigma}^-] = |2\rangle\langle 2| - |1\rangle\langle 1| = 2\hat{\sigma}^+\hat{\sigma}^- - \mathbb{I}$ and $\omega_0 \equiv \omega_2 - \omega_1 > 0$.

Starting from this Hamiltonian the Jaynes-Cummings model is translated into the *Schrödinger picture* via the unitary transform,

$$U = e^{-\imath(\hat{n}+1/2)\omega t}e^{\imath\hat{\sigma}^z\omega_0 t/2} \ , \tag{35.109}$$

for which we find the relationships,

$$\begin{aligned} -\imath U\dot{U}^\dagger &= \omega(\hat{n} + \tfrac{1}{2}) - \tfrac{1}{2}\omega_0\hat{\sigma}^z \\ U\hat{a}U^\dagger &= \Sigma_{n'}|n'\rangle e^{-\imath n'\omega t}\langle n'|\hat{a}\Sigma_n|n\rangle e^{\imath n\omega t}\langle n| = e^{\imath\omega t}\hat{a} \\ U\hat{\sigma}^- U^\dagger &= e^{\imath\omega_0 t}\hat{\sigma}^- \ . \end{aligned} \tag{35.110}$$

Obviously, the dynamics of the states is now given by $|\psi(t)\rangle = U|\psi_I(t)\rangle$, and the new Hamiltonian in the Schrödinger picture reads,

$$\boxed{\begin{array}{rcl} \tilde{H}_{atom:field} &=& U\hat{H}_{atom:field}U^\dagger - \imath U\dot{U}^\dagger \\ &=& \omega(\hat{n}+\frac{1}{2}) - \frac{1}{2}\omega_0\hat{\sigma}^z + \frac{1}{2}\Omega_1(\hat{a}\hat{\sigma}^+ + \hat{a}^\dagger\hat{\sigma}^-) \\ &=& \begin{pmatrix} (\hat{n}+\frac{1}{2})\omega - \frac{1}{2}\omega_0 & \frac{1}{2}\Omega_1\hat{a}^\dagger \\ \frac{1}{2}\Omega_1\hat{a} & (\hat{n}+\frac{1}{2})\omega + \frac{1}{2}\omega_0 \end{pmatrix} \end{array}} \; . \tag{35.111}$$

We choose the Fock representation (24.81) for the radiation mode, we represent the atomic transitions by the Pauli matrices (23.45), and we span the product space $\hat{\rho}_{field} \otimes \hat{\rho}_{atom}$ generalizing the operators $\hat{a}^\pm \curvearrowright \hat{a}^\pm \otimes \mathbb{I}$ and $\hat{\sigma}^\pm \curvearrowright \mathbb{I} \otimes \hat{\sigma}^\pm$. Explicitly we get,

$$\begin{array}{rclcrcl} \hat{a}^\dagger &=& \sum_n \sqrt{n+1}|n+1\rangle \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \langle n| & \text{and} & \hat{\sigma}^+ &=& \sum_n |n\rangle \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix} \langle n| \\ \hat{a} &=& \sum_n \sqrt{n}|n-1\rangle \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \langle n| & \text{and} & \hat{\sigma}^- &=& \sum_n |n\rangle \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix} \langle n| \; . \end{array} \tag{35.112}$$

35.4.1 Dressed states representation

The basis

$$|1,n\rangle = \begin{pmatrix} 1 \\ 0 \end{pmatrix} |n\rangle \quad , \quad |2,n-1\rangle = \begin{pmatrix} 0 \\ 1 \end{pmatrix} |n-1\rangle \tag{35.113}$$

spans a sub-space of two energetically nearly degenerate states with n photons in the system one out of which can have been absorbed by the atom. The density operator for the subspace is,

$$\hat{\rho}_n = \begin{pmatrix} |n\rangle|1\rangle\langle 1|\langle n| & |n\rangle|1\rangle\langle 2|\langle n-1| \\ |n-1\rangle|2\rangle\langle 1|\langle n| & |n-1\rangle|2\rangle\langle 2|\langle n-1| \end{pmatrix} \; . \tag{35.114}$$

We project the Hamiltonian onto that basis via the projectors $\hat{P} = |1,n\rangle\langle 1,n| + |2,n-1\rangle\langle 2,n-1|$,

$$\boxed{\hat{H}_n = \hat{P}\tilde{H}_{atom:field}\hat{P} = \begin{pmatrix} n\omega + \frac{\Delta}{2} & \frac{1}{2}\Omega_1\sqrt{n} \\ \frac{1}{2}\Omega_1\sqrt{n} & n\omega - \frac{\Delta}{2} \end{pmatrix}} \; . \tag{35.115}$$

That is, the Hamiltonian can be decomposed into sub-hyperspaces which are all orthogonal, because the Hamiltonian $\tilde{H}_{atom:field}$ only contains terms conserving the total number of photons + excitations.

Example 209 (*Orthogonality of submatrices with same numbers of excitations*): This can be seen by expanding the Hamiltonian matrix:

$$\tilde{H}_{atom:field} = \bigoplus_n \hat{H}_n \tag{35.116}$$

$$= \sum_n \left[|n\rangle \begin{pmatrix} n\omega + \frac{\Delta}{2} & 0 \\ 0 & n\omega - \frac{\Delta}{2} \end{pmatrix} + |n-1\rangle \begin{pmatrix} 0 & 0 \\ \frac{\Omega_1}{2}\sqrt{n} & 0 \end{pmatrix} + |n+1\rangle \begin{pmatrix} 0 & \frac{\Omega_1}{2}\sqrt{n+1} \\ 0 & 0 \end{pmatrix} \right] \langle n|$$

$$= \begin{pmatrix} \frac{\Delta}{2} & & & & & & \\ & \omega + \frac{\Delta}{2} & \frac{\Omega_1}{2} & & & & \\ & \frac{\Omega_1}{2} & \omega - \frac{\Delta}{2} & & & & \\ & & & 2\omega + \frac{\Delta}{2} & \frac{\Omega_1}{2}\sqrt{2} & & \\ & & & \frac{\Omega_1}{2}\sqrt{2} & 2\omega - \frac{\Delta}{2} & & \\ & & & & & 3\omega + \frac{\Delta}{2} & \cdots \\ & & & & & \vdots & \ddots \end{pmatrix} .$$

The eigenvalues can be easily calculated by [7],

$$\det \sum_n \hat{H}_n = \sum_n \det \hat{H}_n \ , \tag{35.117}$$

defining the generalized n-photon Rabi frequency, $\varpi_n \equiv \sqrt{\Delta^2 + n\Omega_1^2} = |\varpi_n| e^{\imath \mathbf{k}\cdot\mathbf{R}}$, which contains the spatial mode function of the radiation field. Using the standard procedure outlined in Sec. 23.3.4 we find the diagonal matrix of eigenvalues,

$$\hat{E}_n = \begin{pmatrix} n\omega + \frac{\varpi_n}{2} & 0 \\ 0 & n\omega - \frac{\varpi_n}{2} \end{pmatrix} . \tag{35.118}$$

From the transformation $\hat{H}_n U_n = U_n \hat{E}_n$, under the condition that U_n is unitary and Hermitian, $U_n^\dagger U_n$, and using the abbreviation $\tan 2\phi_n \equiv \sqrt{n}\Omega_1/\Delta$, we obtain:

$$U_n = \begin{pmatrix} \cos\phi_n & \sin\phi_n \\ -\sin\phi_n & \cos\phi_n \end{pmatrix} . \tag{35.119}$$

The unitary matrix U_n describes the transform from the product state basis (35.113) to the dressed state basis (35.21), as illustrated in Fig. 35.4.

The temporal evolution of the Jaynes-Cummings state, $|\psi(t)\rangle = e^{-\imath \tilde{H}_{atom:field} t} |\psi(0)\rangle$, is described by the transformation,

$$\boxed{\begin{aligned} & e^{-\imath \hat{H}_n t} = U_n e^{-\imath \hat{E}_n t} U_n^\dagger = e^{-\imath n\omega t} \times \\ & \times \begin{pmatrix} \cos^2\phi_n e^{-\imath\varpi_n t/2} + \sin^2\phi_n e^{\imath\varpi_n t/2} & \cos\phi_n \sin\phi_n (e^{\imath\varpi_n t/2} - e^{-\imath\varpi_n t/2}) \\ \cos\phi_n \sin\phi_n (e^{\imath\varpi_n t/2} - e^{-\imath\varpi_n t/2}) & \sin^2\phi_n e^{-\imath\varpi_n t/2} + \cos^2\phi_n e^{\imath\varpi_n t/2} \end{pmatrix} , \end{aligned}} \tag{35.120}$$

[7] The following rules apply to determinants,

$$\det(AB) = \det A \det B \qquad \text{and} \qquad (\det A)^{-1} = \det A^{-1} \ .$$

which is essentially the same formula as for the time evolution of a two-level atom driven by a classical light field derived in Exc. 23.4.7.1. The transition probability between dressed states is,

$$|\langle 2,n-1|e^{-\imath\hat{H}_n t}|1,n\rangle|^2 = \frac{n\Omega_1^2}{\varpi_n^2}\sin^2\frac{\varpi_n t}{2} \ . \tag{35.121}$$

The temporal evolution follows with [672],

$$\hat{\rho}(t) = e^{-\imath\hat{H}_n t}\hat{\rho}(0)e^{\imath\hat{H}_n t} \equiv \mathcal{L}(t)\hat{\rho}(0) \ . \tag{35.122}$$

Alternatively to the master equation (35.122) we could describe the time evolution of the system by Heisenberg equations, as done in Exc. 35.4.5.1.

35.4.2 Classical and quantum limits

35.4.2.1 The limit of high laser intensities and resonant interaction

The classical limit is recovered for $n \to \infty$, where a single photon makes no difference, that is, we can treat the states $|n\rangle$ and $|n+1\rangle$ as equivalent. Then, we can approximate the Hamiltonian of the system (35.113) by the trace of this same Hamiltonian taken over the number of photons,

$$\hat{H}_{semi} = \lim_{n\to\infty} \mathrm{Tr}_{field}\hat{\rho}\tilde{H}_{atom:field} = \sum_m \langle m|\hat{\rho}\tilde{H}_{atom:field}|m\rangle \ . \tag{35.123}$$

This situation, as illustrated in Fig. 35.8, describes well the state of a laser as a coherent state, $|\alpha\rangle = \sum_n \frac{\alpha^n}{\sqrt{n!}}|n\rangle e^{-|\alpha|^2/2}$. For $n \to \infty$, the uncertainty of the Poisson distribution is small, $\Delta n/\bar{n} = 1/\sqrt{n} \to 0$, such that the light mode is characterized by the average number of photons, and fluctuations are negligible. This allows us to replace the Poisson distribution, $P_n = |\langle n|\alpha\rangle|^2 = \delta_{n\bar{n}}$. The Hamiltonian (35.115) then becomes,

$$\begin{aligned}\hat{H}_{semi} &= \hat{H}_{field} + \hat{H}_{atom} + \hat{H}_{atom:field} = \sum_m \langle m|\alpha\rangle\langle\alpha|\hat{H}|m\rangle = \langle\alpha|\hat{H}|\alpha\rangle \simeq \langle\bar{n}|\hat{H}|\bar{n}\rangle \\ &= \hat{H}_{\bar{n}} = \begin{pmatrix}\bar{n}\omega & 0\\ 0 & (\bar{n}-1)\omega\end{pmatrix} + \begin{pmatrix}-\frac{\omega_0}{2} & 0\\ 0 & \frac{\omega_0}{2}\end{pmatrix} + \begin{pmatrix}0 & \frac{\varpi_{\bar{n}}}{2}\\ \frac{\varpi^*_{\bar{n}}}{2} & 0\end{pmatrix} \ .\end{aligned} \tag{35.124}$$

Now, in the case of a resonant interaction, $\Delta = 0$, the Jaynes-Cummings evolution is,

$$\boxed{e^{-\imath\hat{H}_{\bar{n}}t} = \frac{1}{\sqrt{2}}e^{-\imath(\bar{n}-1/2)\omega t}\begin{pmatrix}\cos\frac{1}{2}\varpi_{\bar{n}}t & \imath\sin\frac{1}{2}\varpi_{\bar{n}}t\\ \imath\sin\frac{1}{2}\varpi_{\bar{n}}t & \cos\frac{1}{2}\varpi_{\bar{n}}t\end{pmatrix}} \ , \tag{35.125}$$

which is a result already obtained in Exc. 23.4.7.1.

Example 210 (*Resonant* $\pi/2$*-pulse*): In this example, we consider resonant $\pi/2$-pulses, that is, $\sqrt{\bar{n}}\Omega_1 t = \frac{1}{2}\pi$. The Jaynes-Cummings evolution now simplifies to,

$$e^{-\imath\hat{H}_{\bar{n}}t} = \frac{1}{2}e^{-\imath(\bar{n}-1/2)\omega t}\begin{pmatrix}1 & \imath\\ \imath & 1\end{pmatrix} \ . \tag{35.126}$$

For large $\bar{n}$, a resonant $\pi/2$-pulse does (ignoring irrelevant dynamical phases),

$$\begin{pmatrix} |1\rangle|\bar{n}\rangle \\ |2\rangle|\bar{n}-1\rangle \end{pmatrix} \overset{\pi/2}{\curvearrowright} \begin{pmatrix} (\imath|2\rangle|\bar{n}-1\rangle + |1\rangle|\bar{n}\rangle) \\ (|2\rangle|\bar{n}-1\rangle + \imath|1\rangle|\bar{n}\rangle) \end{pmatrix} , \tag{35.127}$$

that is, for a coherent field,

$$\begin{pmatrix} |1\rangle|\alpha\rangle \\ |2\rangle|\alpha\rangle \end{pmatrix} \overset{\pi/2}{\curvearrowright} \begin{pmatrix} (\imath|2\rangle + |1\rangle)|\alpha\rangle \\ (|2\rangle + \imath|1\rangle)|\alpha\rangle \end{pmatrix} . \tag{35.128}$$

Obviously, the structure of the field $|\alpha\rangle$ is not affected, and we recover the dynamics of a two-level atom excited by a resonant classical *radiation* as described by the Bloch equations (34.151). In the language of quantum computation the operation (35.126) corresponds to a Hadamard gate.

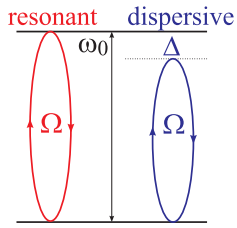

Figure 35.8: Atomic level scheme for the implementation of resonant interactions with classical radiation fields (on the lower transition) and dispersive interactions with quantum fields (on the upper transition).

35.4.2.2 Dispersive interaction, the limit of large detunings

The dispersive Jaynes-Cummings dynamics can be implemented by irradiating a light field, which is sufficiently detuned to avoid Rayleigh scattering processes, as shown in Fig. 35.8. This interaction results in a phase shift of the atomic levels. For $|\Delta| \gg \sqrt{n}\Omega_1$ we consider the radiative coupling as a small perturbation,

$$\hat{H}_n = \hat{H}_n^{(0)} + \hat{H}_n^{(1)} = \begin{pmatrix} n\omega - \frac{\Delta}{2} & 0 \\ 0 & n\omega + \frac{\Delta}{2} \end{pmatrix} + \begin{pmatrix} 0 & \frac{\Omega_1}{2}\sqrt{n} \\ \frac{\Omega_1}{2}\sqrt{n} & 0 \end{pmatrix} . \tag{35.129}$$

In the unperturbed case we have, $\hat{H}_n^{(0)}|\psi_{j,n}\rangle = E_{j,n}|\psi_{j,n}\rangle$, where the n-photon subspace is spanned by the basis $|j\rangle = (1\ 0)$ and $(0\ 1)$. In second perturbation order,

$$\langle\psi_{j,n}|\hat{H}_n^{(1)}|\psi_{j,n}\rangle \simeq \cancelto{0}{\langle j|\hat{H}_n^{(1)} + \hat{H}_n^{(2)}|j\rangle} + \sum_{j\neq i} \frac{\langle j|\hat{H}_n^{(1)}|i\rangle\langle i|\hat{H}_n^{(1)}|j\rangle}{E_{j,n}^{(0)} - E_{i,n}^{(0)}} = \mp\frac{n\Omega_1^2}{4\Delta} , \tag{35.130}$$

where the upper sign holds for $|j\rangle = (1\ 0)$. This result was already obtained in the Excs. 27.1.3.4 and 34.5.4.13. In matrix notation [8],

$$\hat{H}_n^{(1)} \simeq \begin{pmatrix} n\Omega_1^2/4\Delta & 0 \\ 0 & -n\Omega_1^2/4\Delta \end{pmatrix} . \tag{35.131}$$

The temporal propagation operator (35.120) then simplifies to,

$$\boxed{e^{-\imath\hat{H}_n^{(1)}t} = \begin{pmatrix} e^{\imath n\Omega_1^2 t/4\Delta} & 0 \\ 0 & e^{-\imath n\Omega_1^2 t/4\Delta} \end{pmatrix}} . \tag{35.132}$$

The fact that the ground and excited atomic states evolve with different phase factors is important, as we will show in the following example.

Example 211 (*Dispersive π-pulse*): As in the previous case, we consider a two-level atom subject to a coherent field, but now tuned out of resonance. Introducing the abbreviation $\varphi \equiv \Omega_1^2 t/4\Delta$, the Jaynes-Cummings evolution is,

$$e^{-\imath\hat{H}_n^{(1)}t} = \begin{pmatrix} e^{\imath n\varphi} & 0 \\ 0 & e^{-\imath n\varphi} \end{pmatrix} . \tag{35.133}$$

The fact that the phase shift $n\varphi$ depends on the number of photons, and that it goes in opposite directions for the ground and excited states, is crucial. We have already studied in Exc. 34.8.4.9, that the dispersive interaction of the atom with a radiation field can phase-shift the Bloch vector. Now, we observe that in addition, it causes a phase shift of the probability amplitude of having n photons in the radiation field by a value proportional to n, i.e. (ignoring irrelevant dynamical phases),

$$\begin{pmatrix} |1\rangle|n\rangle \\ |2\rangle|n-1\rangle \end{pmatrix} \overset{n\varphi}{\curvearrowright} \begin{pmatrix} e^{-\imath n\varphi}|1\rangle|n\rangle \\ e^{\imath n\varphi}|2\rangle|n-1\rangle \end{pmatrix} . \tag{35.134}$$

Applying this result to Glauber states,

$$\begin{pmatrix} |1\rangle|\alpha\rangle \\ |2\rangle|\alpha\rangle \end{pmatrix} \overset{n\varphi}{\curvearrowright} \begin{pmatrix} |1\rangle \sum_n \frac{\alpha^n}{\sqrt{n!}} e^{-\imath n\varphi}|n\rangle \\ |2\rangle \sum_n \frac{\alpha^n}{\sqrt{n!}} e^{\imath n\varphi}|n\rangle \end{pmatrix} = \begin{pmatrix} |1\rangle|\alpha e^{-\imath\varphi}\rangle \\ |2\rangle|\alpha e^{\imath\varphi}\rangle \end{pmatrix} . \tag{35.135}$$

Apparently, the phase of the radiation field is shifted by a value φ, which depends on the state of the atom.

[8] Note, that the same perturbation expansion applied to the complete Hamiltonian in the interaction picture yields,

$$\tilde{H}_I^{(1)} = \begin{pmatrix} 0 & \frac{1}{2}\Omega_1\hat{a}^\dagger \\ \frac{1}{2}\Omega_1\hat{a} & 0 \end{pmatrix} = \tfrac{1}{2}\Omega_1\hat{a}\hat{\sigma}^+ + \tfrac{1}{2}\Omega_1\hat{a}^\dagger\hat{\sigma}^-$$
$$\simeq \frac{\tilde{H}_I^{(1)}|2\rangle\langle 2|\tilde{H}_I^{(1)}}{\omega_2-\omega_1} + \frac{\tilde{H}_I^{(1)}|1\rangle\langle 1|\tilde{H}_I^{(1)}}{\omega_1-\omega_2} = \frac{\Omega_1^2}{4\Delta}(\hat{\sigma}^-\hat{\sigma}^+\hat{a}^\dagger\hat{a} - \hat{\sigma}^+\hat{\sigma}^-\hat{a}\hat{a}^\dagger) = \frac{\Omega_1^2}{4\Delta}\begin{pmatrix} -\hat{a}^\dagger\hat{a} & 0 \\ 0 & \hat{a}\hat{a}^\dagger \end{pmatrix} .$$

We note here, that the dynamics studied in the last example provides a method of *transferring coherence from an atomic superposition to a quantum correlation of a radiation field*. All we have to do, is to bring the atom into a superposition of states $|1\rangle + |2\rangle$, and the field will automatically evolve toward a Schrödinger cat state $|\alpha e^{\imath\varphi}\rangle + |\alpha e^{-\imath\varphi}\rangle$. The transfer of quantum correlations between coupled degrees of freedom can induce a temporal complete disappearance of any signatures of quantum coherence in the light field. This phenomenon termed *quantum collapse and revival* is genuine of the Jaynes-Cummings model and will be studied in Excs. 35.4.5.2 and 35.4.5.3. Another phenomenon is *vacuum Rabi splitting*, which will be studied in 35.4.5.4.

35.4.3 Observables and correlations of the Jaynes-Cummings dynamics

In the limit of low laser intensities we must consider photonic distributions that are not necessarily coherent. The stationary solution of the Schrödinger equation consists of the dressed states $|1, n\rangle$ and $|2, n-1\rangle$. If we now expand a general Jaynes-Cummings state in amplitudes $c_{jn}(t)$,

$$|\psi\rangle = \sum_n (c_{1,n}|1, n\rangle + c_{2,n-1}|2, n-1\rangle) \ , \tag{35.136}$$

they will follow the Schrödinger equation,

$$\imath\hbar \frac{d}{dt} \begin{pmatrix} c_{1,n} \\ c_{2,n-1} \end{pmatrix} = \hat{H}_n \begin{pmatrix} c_{1,n} \\ c_{2,n-1} \end{pmatrix} \ . \tag{35.137}$$

The evolution of the coefficients c_{jn} completely describes the Jaynes-Cummings dynamics of the system through the formula (35.120). Obviously, the Jaynes-Cummings state is normalized because,

$$\langle\psi|\psi\rangle = \mathrm{Tr}_{field}\ |\psi\rangle\langle\psi| = \sum_{n=0}^{\infty} (|c_{1,n}|^2 + |c_{2,n}|^2) = 1 \ . \tag{35.138}$$

As dissipation processes are neglected, we get a pure state described by,

$$\hat{\rho} = |\psi\rangle\langle\psi| \ . \tag{35.139}$$

The Jaynes-Cummings dynamics involves two coupled degrees of freedom characterized by with their respective observables. If we are interested in them, we can do two things: (a) We ignore the degrees of freedom NOT under study by NOT DOING a measurement of the other degrees. That is, we simply remove the non-interesting degrees of freedom from the state. For example, if our focus is on the optical mode, we ignore the atomic state,

$$|\gamma\rangle \equiv \sum_{j=1,2} \langle j|\psi\rangle = \sum_n c_{1,n}|n\rangle + c_{2,n-1}|n-1\rangle \ . \tag{35.140}$$

Our new density operator remains pure, that is,

$$\hat{\rho}^{(pure)}_{field} = \sum_{i,j=1,2} \langle j|\hat{\rho}|i\rangle = \sum_{i,j=1,2} \langle j|\psi\rangle\langle\psi|i\rangle = |\gamma\rangle\langle\gamma| \ . \tag{35.141}$$

On the other hand, ignoring the optical mode via,

$$|\gamma\rangle \equiv \sum_n \langle n|\psi\rangle = \sum_n c_{1,n}|1\rangle + c_{2,n-1}|2\rangle \ . \tag{35.142}$$

Again, our new density operator remains pure, that is,

$$\hat{\rho}_{atom}^{(pure)} = \sum_{m,n} \langle m|\hat{\rho}|n\rangle = \sum_{m,n} \langle m|\psi\rangle\langle\psi|n\rangle = |\gamma\rangle\langle\gamma| \ . \tag{35.143}$$

(b) We trace over the degrees of freedom NOT under study by DOING a measurement. For example, if again our focus is on the optical mode, we trace over the atomic states,

$$\begin{aligned} \hat{\rho}_{field}^{(mix)} &= \mathrm{Tr}_{atom}\ \hat{\rho} = \sum_{j=1,2} \langle j|\hat{\rho}|j\rangle = \sum_{j=1,2} \langle j|\psi\rangle\langle\psi|j\rangle \\ &= \sum_{n,m} c_{1,m}^* c_{1,n}|n\rangle\langle m| + c_{2,m-1}^* c_{2,n-1}|n-1\rangle\langle m-1| \neq \hat{\rho}_{field}^{(pure)} \ . \end{aligned} \tag{35.144}$$

It is clear, that this incomplete measurement converts the reduced density operator into a statistical mixture, which is free of inneratomic correlations of the type $c_{2,m}^* c_{1,n}$, but this means that we also loose possible field correlations. On the other hand, tracing over the field mode,

$$\begin{aligned} \hat{\rho}_{atom}^{(mix)} &= \mathrm{Tr}_{field}\ \hat{\rho} = \sum_{n=0}^{\infty} \langle n|\hat{\rho}|n\rangle = \sum_{n=0}^{\infty} \langle n|\psi\rangle\langle\psi|n\rangle \\ &= \sum_n \left(c_{1,n}|1\rangle + c_{2,n}|2\rangle\right)\left(c_{1,n}^*\langle 1| + c_{2,n}^*\langle 2|\right) \neq \hat{\rho}_{atom}^{(pure)} \ . \end{aligned} \tag{35.145}$$

After these preliminary remarks let us have a look a some interesting observables.

35.4.3.1 Temporal evolution of the Bloch vector

The expectation value for field observables $\hat{A}|n\rangle = A_n|n\rangle$ is,

$$\langle\psi|\hat{A}|\psi\rangle = \mathrm{Tr}\ \hat{\rho}\hat{A} \sum_{i,n} \langle i|\langle n|\psi\rangle\langle\psi|\hat{A}|n\rangle|i\rangle = \sum_n A_n(|c_{1,n}|^2 + |c_{2,n}|^2) \ . \tag{35.146}$$

An example for a field observable is the photon number operator $\hat{n}$. And for the annihilation operator $\hat{a}|n\rangle = \sqrt{n}|n\rangle$ we have,

$$\langle\psi|\hat{a}|\psi\rangle = \sum_n \sqrt{n}(c_{1,n-1}^* c_{1,n} + c_{2,n-1}^* c_{2,n}) \ . \tag{35.147}$$

To determine the internal state of the atom, we must trace over the light field. The populations and coherences are, therefore,

$$\boxed{\rho_{ij} = \langle i|\mathrm{Tr}_{field}\ \hat{\rho}|j\rangle = \langle i|\sum_n \langle n|\psi\rangle\langle\psi|n\rangle|j\rangle = \sum_n c_{i,n}c_{j,n}^*} \ . \tag{35.148}$$

The projection onto the atomic state is done by,

$$\frac{|j\rangle\langle j|\psi\rangle}{\langle\psi|j\rangle\langle j|\psi\rangle} = \frac{\sum_m c_{j,n}|j,n\rangle}{\sum_m |c_{j,m}|^2} \ . \tag{35.149}$$

With (35.148), we can calculate the atomic Bloch vector (34.163), whose norm is interestingly NOT preserved, since,

$$\begin{aligned} |\vec{\rho}| = \left\| \begin{pmatrix} 2\ \mathfrak{Re}\ \rho_{12} \\ 2\ \mathfrak{Im}\ \rho_{12} \\ \rho_{22}-\rho_{11} \end{pmatrix} \right\| &= 2|\rho_{12}|^2 - 2\rho_{11}\rho_{22} = -2\det\hat{\rho} \\ &= 2\sum_n c_{1,n}c_{2,n}^* \sum_n c_{1,n}^* c_{2,n} - 2\sum_n |c_{2,n}|^2 \sum_n |c_{1,n}|^2 \neq 1 \ . \end{aligned} \tag{35.150}$$

35.4.3.2 The photon number distribution

To determine the state of the light field, we must trace over the atomic state. For example, the probability amplitude of encountering the state $|\psi\rangle$ in $|n\rangle$ is,

$$\langle n|\psi\rangle = c_{1,n}|1\rangle + c_{2,n}|2\rangle \ , \tag{35.151}$$

such that,

$$\boxed{p_n = \langle n|\mathrm{Tr}_{atom}\ \hat{\rho}|n\rangle = \langle n|\sum_{i=1,2}\langle i|\psi\rangle\langle\psi|i\rangle|n\rangle = |\langle n|\psi\rangle|^2 = |c_{1,n}|^2 + |c_{2,n}|^2} \ . \tag{35.152}$$

35.4.3.3 The Glauber-Sudarshan Q-function

To characterize the optical field separately from the atomic state, we can try, by a calculation similar to (35.146), to project the Jaynes-Cummings state onto a basis of coherent states. Thus, the probability amplitude of encountering the state $|\psi\rangle$ in $|\alpha\rangle$ is,

$$\begin{aligned} \langle\alpha|\psi\rangle &= e^{-|\alpha|^2/2}\sum_n \frac{\alpha^{*n}}{\sqrt{n!}}(c_{1,n}|1\rangle + c_{2,n}|2\rangle) \\ |\langle\alpha|\psi\rangle|^2 &= e^{-|\alpha|^2}\sum_n \frac{\alpha^{*n}\alpha^m}{\sqrt{n!}\sqrt{m!}}(c_{1,m}^* c_{1,n} + c_{2,m}^* c_{2,n}) \ , \end{aligned} \tag{35.153}$$

such that,

$$\boxed{\pi Q(\alpha) \equiv \langle\alpha|\mathrm{Tr}_{atom}\ \hat{\rho}|\alpha\rangle = e^{-|\alpha|^2}\left(\left|\sum_n c_{1,n}\frac{\alpha^n}{\sqrt{n!}}\right|^2 + \left|\sum_n c_{2,n}\frac{\alpha^n}{\sqrt{n!}}\right|^2\right)} \ . \tag{35.154}$$

We will derive this result in Exc. 35.4.5.5. This quantity, called *Q-function*, allows the illustration of the state in a coordinate system spanned by $\mathfrak{Re}\ \alpha$ and $\mathfrak{Im}\ \alpha$ [157]. It is generally easy to calculate, but does not exhibit much information, e.g., on

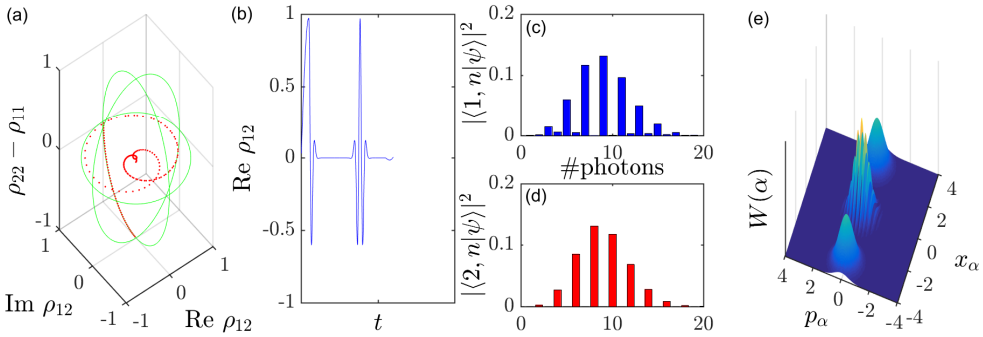

Figure 35.9: (code) Evolution of the state during a Jaynes-Cummings type interaction: (a) Bloch vector, (b,c) photon distribution after projection on the ground and excited atomic state, (d) time evolution of the coherence ρ_{12} showing the phenomenon of collapse and revival, and (e) $W(\alpha)$ function.

interference phenomena caused by quantum correlations. In the following section, we will calculate the Wigner function, which can also be evaluated from the Jaynes-Cummings coefficients [412].

The Jaynes-Cummings dynamics illustrated in Fig. 35.9 demonstrates the transfer of coherence between an atom and a light field. In Exc. 35.4.5.6 we study how to create, via a sequence of Ramsey pulses, a Schrödinger cat state in a light field.

35.4.3.4 The Wigner function in the Glauber picture

We found in (35.132) that a dispersive phase shift of the atomic state $|2\rangle$ leads to a time-dependent phase shift of the Glauber field,

$$|\psi\rangle = \sum_N (c_{1,n}|1,n\rangle + c_{2,n-1}|2,n-1\rangle) = |1,\beta\rangle + e^{\imath\varphi(t)}|2,\beta\rangle \qquad \text{or} \qquad \hat{\rho} = |\psi\rangle\langle\psi| \ , \tag{35.155}$$

with

$$c_{1,n} = e^{-|\beta|^2/2}\frac{\beta^n}{\sqrt{n!}} \qquad \text{and} \qquad c_{2,n} = e^{-|\beta|^2/2}\frac{(e^{\imath\varphi(t)}\beta)^n}{\sqrt{n!}} \ . \tag{35.156}$$

We will now concentrate on the field state by explicitly IGNORING the atomic states $|j\rangle$,

$$|\gamma\rangle = \sum_{j=1,2}\langle j|\psi\rangle = |\beta\rangle + |e^{\imath\varphi}\beta\rangle \qquad \text{or} \qquad \hat{\rho}^{(pure)}_{field} = \sum_{i,j=1,2}\langle j|\psi\rangle\langle\psi|i\rangle = |\gamma\rangle\langle\gamma| \ . \tag{35.157}$$

From the optical cat pure state wavefunction (35.157), we can easily calculate the Wigner function in the Glauber picture, as done in (35.76) and Exc. 35.2.5.10,

$$\boxed{W(\alpha) = \frac{2}{C^2\pi}\left(e^{-2|\alpha-\beta|^2} + e^{-2|\alpha-\beta e^{\imath\varphi}|^2} \pm 2e^{-|\beta|^2}\mathfrak{Re}\ e^{-2(\beta e^{\imath\varphi}-\alpha)(\beta^*-\alpha^*)+|\beta|^2 e^{\imath\varphi}}\right)} \ . \tag{35.158}$$

Now, what happens if we MEASURE the atomic state before we analyze the field state? The incomplete measurement corresponds to tracing over the atomic degrees of

freedom, which transforms our initially pure state (35.155) into a statistical mixture. With $|\psi\rangle$ given by (35.155),

$$\hat{\rho}_{field}^{(mix)} = \mathrm{Tr}_{atom}\hat{\rho} = \sum_{j=1,2}\langle j|\psi\rangle\langle\psi|j\rangle = |\beta\rangle\langle\beta| + |e^{\imath\varphi}\beta\rangle\langle e^{\imath\varphi}\beta| \neq |\gamma\rangle\langle\gamma| \ . \tag{35.159}$$

Calculating the Wigner function from this density operator consequently must yield a different result, because any correlations are lost. A movie of the dynamics can be watched here (watch movie) [228, 340, 16, 1321].

35.4.3.5 The Wigner function in the Fock picture

Let us now calculate the Wigner function in the Fock state picture. This will allow us to consider more general states later on. We start from the expansion,

$$|\psi\rangle = \sum_n c_{1,n}|1,n\rangle + c_{2,n-1}|2,n-1\rangle \ . \tag{35.160}$$

As before, we can now choose to DO or NOT DO a measurement of the atomic state. If we do a measurement tracing over the atomic states, we calculate the normally ordered characteristic function using the density operator (35.144),

$$\begin{aligned}\chi_N(\lambda) &= \mathrm{Tr}\ \hat{\rho}_{field}^{(mix)} e^{\lambda\hat{a}^\dagger} e^{-\lambda^*\hat{a}} = \sum_{n'}\langle n'|\hat{\rho}_{field}^{(mix)} e^{\lambda\hat{a}^\dagger} e^{-\lambda^*\hat{a}}|n'\rangle \\ &= \sum_{n,m} c_{1,m}^* c_{1,n}\langle m|e^{\lambda\hat{a}^\dagger} e^{-\lambda^*\hat{a}}|n\rangle + c_{2,m-1}^* c_{2,n-1}\langle m-1|e^{\lambda\hat{a}^\dagger} e^{-\lambda^*\hat{a}}|n-1\rangle \ .\end{aligned} \tag{35.161}$$

Obviously, this formula does not contain inneratomic correlations and, since non-classical field correlation would be entangled with atomic superposition states, we expect no interesting field correlations, neither.

If on the other hand we decide to ignore the atomic state, we calculate the normally ordered characteristic function using the density operator (35.141),

$$\begin{aligned}\chi_N(\lambda) &= \mathrm{Tr}\ \hat{\rho}_{field}^{(pure)} e^{\lambda\hat{a}^\dagger} e^{-\lambda^*\hat{a}} = \langle\gamma|e^{\lambda\hat{a}^\dagger} e^{-\lambda^*\hat{a}}|\gamma\rangle \\ &= \sum_{n,m}\Big(c_{1,m}^* c_{1,n}\langle m|e^{\lambda\hat{a}^\dagger} e^{-\lambda^*\hat{a}}|n\rangle + c_{2,m-1}^* c_{2,n-1}\langle m-1|e^{\lambda\hat{a}^\dagger} e^{-\lambda^*\hat{a}}|n-1\rangle \\ &\qquad + c_{1,m}^* c_{2,n-1}\langle m|e^{-\lambda\hat{a}^\dagger} e^{\lambda^*\hat{a}}|n-1\rangle + c_{2,m-1}^* c_{1,n}\langle m-1|e^{\lambda\hat{a}^\dagger} e^{-\lambda^*\hat{a}}|n\rangle\Big) \ ,\end{aligned} \tag{35.162}$$

which now contains field correlations. Inserting the results derived in (35.67) we can express the characteristic functions by Laguerre polynomials and obtain the Wigner function as the two-dimensional FFT according to Eq. (35.158). This will be done in Exc. 35.4.5.8.

35.4.4 Jaynes-Cummings model with dissipation

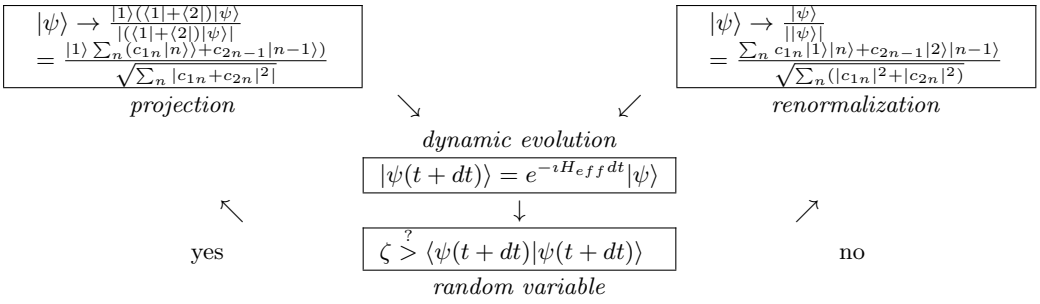
Applying the numerical method of *quantum Monte Carlo wavefunction simulation* to the Jaynes-Cummings model, we write the effective Hamiltonian of the light field as [493],

$$\hat{H}_{eff} = \omega\hat{a}^\dagger\hat{a} + \omega_0\left(\hat{\sigma}^+\hat{\sigma} - \tfrac{1}{2}\right) + \tfrac{\Omega_1}{2}\left(\hat{a}\hat{\sigma}^+ + \hat{a}^\dagger\hat{\sigma}^-\right) + \tfrac{\imath\Gamma}{2}\hat{\sigma}^+\hat{\sigma}^- \ . \tag{35.163}$$

Or in matrix notation,

$$H_{eff} = \begin{pmatrix} -\frac{1}{2}\omega_0 & 0 & & & & & & \\ 0 & \omega - \frac{1}{2}\omega_0 & \frac{1}{2}\Omega_1 & & & & & \\ & \frac{1}{2}\Omega_1 & \frac{1}{2}\omega_0 - \frac{\imath}{2}\Gamma & 0 & & & & \\ & & 0 & 2\omega - \frac{1}{2}\omega_0 & \sqrt{2}\frac{1}{2}\Omega_1 & & & \\ & & & \sqrt{2}\frac{1}{2}\Omega_1 & \omega + \frac{1}{2}\omega_0 - \frac{\imath}{2}\Gamma & 0 & & \\ & & & & 0 & 3\omega - \frac{1}{2}\omega_0 & & \\ & & & & & & \ddots & \end{pmatrix} . \tag{35.164}$$

The simulation flowchart is,



Absorption or scattering of light causes the optical field to decay as $\alpha(t) \propto e^{-\kappa t/2}$. The projection (in component notation) is implemented by,

$$c'_{jn} \equiv \frac{1}{\sqrt{\sum_n (|c_{1n}|^2 + |c_{2n}|^2)}} c_{jn} \ , \tag{35.165}$$

and the dynamical evolution by $c'_{jn} \equiv e^{-\kappa n t/2} c_{jn}$. Note, that the dissipation due to cavity losses can also be taken into account by a *master equation*. Do the Exc. 36.2.6.1.

35.4.4.1 Criticality in the Jaynes-Cummings model

The Jaynes-Cummings Hamiltonian (without counter-rotating terms) is,

$$\hat{H}_{JC} = \hbar\omega_c \hat{a}^\dagger \hat{a} + \hbar\omega_a \frac{\hat{\sigma}_z}{2} + \frac{\hbar\Omega_1}{2}(\hat{a}\hat{\sigma}_+ + \hat{a}^\dagger \hat{\sigma}_-) \ , \tag{35.166}$$

where Ω_1 is the single-photon Rabi frequency. The eigen-energies for the case of zero detuning, $\omega_c = \omega_a$, are

$$E_\pm(n) = \hbar\omega_a(n + \tfrac{1}{2}) \pm \tfrac{1}{2}\hbar\Omega_1\sqrt{n+1} \ . \tag{35.167}$$

One can approximately calculate the canonical partition function,

$$Z = \mathrm{Tr}\ e^{-\imath\beta\hat{H}} = \sum_{\pm,n} e^{-\beta E_\pm(n)} \simeq \int \left(e^{-\beta E_+(n)} + e^{-\beta E_-(n)}\right) dn \equiv \int e^{\Phi(n)} dn \ , \tag{35.168}$$

where the discrete sum was replaced by the integral. We get immediately,

$$\Phi(n) = \ln(e^{-\beta E_+(n)} + e^{-\beta E_-(n)}) = -\beta\hbar\omega_a(n+\tfrac{1}{2}) + \ln\left(2\cosh\tfrac{1}{2}\beta\hbar\Omega_1\sqrt{n+1}\right) \ . \tag{35.169}$$

The normal approach is that the latter integral is calculated by the Gaussian approximation around the maximum of the exponent:

$$0 = \frac{\partial\Phi(n)}{\partial n} = -\beta\hbar\left(\omega_a + \frac{\Omega_1}{4\sqrt{n+1}}\tanh\tfrac{1}{2}\beta\hbar\Omega_1\sqrt{n+1}\right) \ . \tag{35.170}$$

This *criticality* has solutions only if $\Omega > 4\omega_a$, which means that the normal and the superradiant phase, exist only if the field-atom coupling is significantly stronger than the energy difference between the atom levels. When the condition is fulfilled, the equation gives the solution for the order parameter n depending on the inverse of the temperature $1/\beta$, which means non-vanishing ordered field mode.

35.4.5 Exercises

35.4.5.1 Ex: Time-evolution in the Jaynes-Cummings model

Derive the equations of motion for $\hat{\sigma}^-$, $\hat{\sigma}_z$, and $\hat{a}$ in the Jaynes-Cummings model. Show that the number of photons is not a constant of motion, but the total number of excitations.

Solution: *Using the Jaynes-Cummings Hamiltonian,*

$$\hat{H} = \omega\hat{a}^\dagger\hat{a} + \omega_0(\hat{\sigma}^+\hat{\sigma}^- - \tfrac{1}{2}) + \tfrac{1}{2}\Omega_1(\hat{a}\hat{\sigma}^+ + \hat{a}^\dagger\hat{\sigma}^-) \ ,$$

we derive the Heisenberg equations,

$$\begin{aligned}
\dot{\hat{\sigma}}^- &= -\imath[\hat{\sigma}^-, \hat{H}] = -\imath\omega_0\hat{\sigma}_- - \tfrac{\imath}{2}\Omega_1\hat{a}\hat{\sigma}_z \\
\dot{\hat{\sigma}}_z &= -\imath[\hat{\sigma}_z, \hat{H}] = -\tfrac{\imath}{2}\Omega_1(\hat{a}\hat{\sigma}^+ - \hat{a}^\dagger\hat{\sigma}^-) \\
\dot{\hat{a}} &= -\imath[\hat{a}, \hat{H}] = -\imath\omega\hat{a} - \tfrac{\imath}{2}\Omega_1\hat{\sigma}^- \ .
\end{aligned}$$

We also find,

$$[\hat{n}, \hat{H}] = \tfrac{1}{2}\Omega_1[\hat{a}^\dagger\hat{a}, \hat{a}\hat{\sigma}^+ + \hat{a}^\dagger\hat{\sigma}^-] = -[\hat{\sigma}_z, \hat{H}] \ ,$$

which shows that only the total number of excitations $\langle\hat{a}^\dagger\hat{a} + \hat{\sigma}_z\rangle$ is a constant of motion.

35.4.5.2 Ex: The Jaynes-Cummings model

Consider the Jaynes-Cummings Hamiltonian.
a. Determine from the Schrödinger equation the system of differential equations for the temporal evolution of the coefficients $c_{2,n}(t)$ and $c_{1,n+1}(t)$ in the interaction picture within the rotating wave approximation (RWA).
b. Calculate the time evolution for the start condition $c_{2,n}(0) = 1$ and $c_{1,n+1}(0) = 0$ for the particular case $\omega = \omega_0$.

c. Generalize the result of item (a) for a multimode field, for which initially (i) all modes of field $\mathbf{k}$ are empty $|0\rangle$ and (ii) the atom is in the excited state $|a\rangle$. Use the ansatz,

$$|\psi(t)\rangle = c_2(t)e^{-\imath E_2 t/\hbar}|2,0\rangle + \sum_{\mathbf{k}} c_{1,\mathbf{k}}(t)e^{-\imath[E_1/\hbar+\omega_{\mathbf{k}}]t}|1,1_{\mathbf{k}}\rangle \ ,$$

and determine the equations of motion for the amplitudes c_2 and $c_{1,\mathbf{k}}$.

Solution: *a. The Schrödinger equation gives*

$$\begin{aligned}
&\frac{\partial}{\partial t}\left(c_{2,n}e^{-\imath(E_2/\hbar+n\omega)t}\right) = \frac{\partial}{\partial t}\langle 2,n|\psi(t)\rangle = \langle 2,n|\frac{\partial}{\partial t}|\psi\rangle = \tfrac{1}{\imath\hbar}\langle 2,n|\hat{H}|\psi\rangle \\
&= \langle 2,n| - \imath\textstyle\sum_n \frac{\omega_0}{2}c_{2,n}e^{-\imath(E_2/\hbar+n\omega)t}\hat{\sigma}_z|2,n\rangle + \\
&\quad + \langle 2,n| - \imath\textstyle\sum_n \frac{\omega_0}{2}c_{1,n+1}e^{-\imath(E_1/\hbar+(n+1)\omega)t}\hat{\sigma}_z|1,n+1\rangle + \\
&\quad + \langle 2,n| - \imath\textstyle\sum_n \omega c_{2,n}e^{-\imath(E_2/\hbar+n\omega)t}(\hat{a}^\dagger\hat{a}+\tfrac{1}{2})|2,n\rangle + \\
&\quad + \langle 2,n| - \imath\textstyle\sum_n \omega c_{1,n+1}e^{-\imath(E_1/\hbar+(n+1)\omega)t}(\hat{a}^\dagger\hat{a}+\tfrac{1}{2})|1,n+1\rangle + \\
&\quad + \langle 2,n| - \imath\textstyle\sum_n g c_{2,n}e^{-\imath(E_2/\hbar+n\omega)t}(\hat{a}\hat{\sigma}^+ + \hat{a}^\dagger\hat{\sigma}^-)|2,n\rangle + \\
&\quad + \langle 2,n| - \imath\textstyle\sum_n g c_{1,n+1}e^{-\imath(E_1/\hbar+(n+1)\omega)t}(\hat{a}\hat{\sigma}^+ + \hat{a}^\dagger\hat{\sigma}^-)|1,n+1\rangle \\
&= -\tfrac{\imath}{2}\omega_0 c_{2,n}e^{-\imath(E_2/\hbar+n\omega)t} + 0 - \imath(n+\tfrac{1}{2})\omega c_{2,n}e^{-\imath(E_2/\hbar+n\omega)t} + \\
&\quad + 0 - \imath\sqrt{n+1}\,g c_{1,n+1}e^{-\imath(E_1/\hbar+(n+1)\omega)t} \ ,
\end{aligned}$$

where $\hat{\sigma}_z|1\rangle = |1\rangle$ *and* $\hat{\sigma}_z|2\rangle = -|2\rangle$ *and* $\hat{a}|n\rangle = \sqrt{n}|n-1\rangle$ *and* $\hat{a}^\dagger|n\rangle = \sqrt{n+1}|n+1\rangle$. *Furthermore,*

$$\begin{aligned}
\frac{\partial}{\partial t}\left(c_{1,n+1}e^{-\imath(E_1/\hbar+(n+1)\omega)t}\right) &= -\tfrac{\imath}{2}\omega_0 c_{1,n+1}e^{-\imath(E_1/\hbar+(n+1)\omega)t} + 0 - \\
&\quad - \imath(n+\tfrac{1}{2})\omega c_{1,n+1}e^{-\imath(E_1/\hbar+(n+1)\omega)t} + \\
&\quad + 0 - \imath\sqrt{n+1}\,g c_{2,n}e^{-\imath(E_2/\hbar+n\omega)t} \ ,
\end{aligned}$$

also,

$$\begin{aligned}
\dot{c}_{2,n} + (E_2/\hbar + n\omega)c_{2,n} &= \tfrac{1}{2}\omega_0 c_{2,n} + (n+\tfrac{1}{2})\omega c_{2,n} + \sqrt{n+1}\,g c_{1,n+1}e^{\imath(\omega_0-\omega)t} \\
\dot{c}_{1,n+1} + (E_1/\hbar + (n+1)\omega)c_{1,n+1} &= \tfrac{1}{2}\omega_0 c_{1,n+1} + (n+\tfrac{1}{2})\omega c_{1,n+1} + \sqrt{n+1}\,g c_{2,n}e^{\imath(\omega-\omega_0)t} \ .
\end{aligned}$$

b. In short, we can write with $\omega_0 = E_2 - E_1$

$$\frac{\partial}{\partial t}\begin{pmatrix} c_{1,n+1} \\ c_{2,n}\end{pmatrix} = -\imath\begin{pmatrix} \frac{1}{2}\omega_0 - \frac{1}{2}\omega - \frac{1}{\hbar}E_1 & \sqrt{n+1}\,g e^{-\imath(\omega_0-\omega)t} \\ \sqrt{n+1}\,g e^{\imath(\omega_0-\omega)t} & \frac{1}{2}\omega_0 + \frac{1}{2}\omega - \frac{1}{\hbar}E_2\end{pmatrix}\begin{pmatrix} c_{1,n+1} \\ c_{2,n}\end{pmatrix}$$

in resonance we have,

$$\frac{\partial}{\partial t}\begin{pmatrix} c_{1,n+1} \\ c_{2,n}\end{pmatrix} = -\imath\begin{pmatrix} -\frac{1}{\hbar}E_1 & \sqrt{n+1}\,g \\ \sqrt{n+1}\,g & -\frac{1}{\hbar}E_2\end{pmatrix}\begin{pmatrix} c_{1,n+1} \\ c_{2,n}\end{pmatrix}$$

The eigenvalues of the matrix are $E = E_1 \pm g\sqrt{n+1}$. *Placing the ansatz,*

$$\begin{pmatrix} c_{1,n+1}(t) \\ c_{2,n}(t)\end{pmatrix} = \begin{pmatrix} \alpha_g e^{-\imath(-E_1+g\sqrt{n+1})t} + \beta_g e^{-\imath(-E_1-g\sqrt{n+1})t} \\ \alpha_a e^{-\imath(-E_1+g\sqrt{n+1})t} + \beta_a e^{-\imath(-E_1-g\sqrt{n+1})t}\end{pmatrix}$$

gives,

$$
\begin{aligned}
&-\imath(-E_1+g\sqrt{n+1})\alpha_g e^{-\imath gt\sqrt{n+1}}-\imath(-E_1+g\sqrt{n+1})\beta_g e^{\imath gt\sqrt{n+1}}\\
&\quad=\frac{\imath}{\hbar}E_1\alpha_g e^{-\imath gt\sqrt{n+1}}+\frac{\imath}{\hbar}E_1\beta_g e^{\imath gt\sqrt{n+1}}-\imath\sqrt{n+1}g\alpha_a e^{-\imath gt\sqrt{n+1}}-\imath\sqrt{n+1}g\beta_a e^{\imath gt\sqrt{n+1}}\\
&-\imath\left(-E_1+g\sqrt{n+1}\right)\alpha_a e^{-\imath gt\sqrt{n+1}}-\imath\left(-E_1+g\sqrt{n+1}\right)\beta_a e^{\imath gt\sqrt{n+1}}\\
&\quad=\frac{\imath}{\hbar}E_1\alpha_a e^{-\imath gt\sqrt{n+1}}+\frac{\imath}{\hbar}E_1\beta_a e^{\imath gt\sqrt{n+1}}-\imath\sqrt{n+1}g\alpha_g e^{-\imath gt\sqrt{n+1}}-\imath\sqrt{n+1}g\beta_g e^{\imath gt\sqrt{n+1}}
\end{aligned}
$$

and hence $\alpha_a=\alpha_g$ *and* $\beta_g=-\beta_a$. *The initial condition* $c_{2,n}(0)=1$ *and* $c_{1,n+1}(0)=0$ *gives* $\alpha_g+\beta_g=1$ *and* $\alpha_a+\beta_a=0$. *Hence, the solution is,*

$$
\begin{pmatrix}c_{1,n+1}(t)\\ c_{2,n}(t)\end{pmatrix}=e^{\imath E_1 t}\begin{pmatrix}\cos gt\sqrt{n+1}\\ \imath\sin gt\sqrt{n+1}\end{pmatrix}\ .
$$

c. The generalization of the result found in (a) to a multimode field $|\psi(t)\rangle=c_a(t)e^{-\imath E_2 t/\hbar}|a,0\rangle+\sum_{\mathbf{k}}c_{g,\mathbf{k}}(t)e^{-\imath(E_1/\hbar+\omega_{\mathbf{k}})t}|g,1_{\mathbf{k}}\rangle$ *yields,*

$$
\begin{aligned}
\frac{\partial}{\partial t}\left(c_a e^{-E_2 t/\hbar}\right)&=\langle 2,0|-\imath\tfrac{\omega_0}{2}c_a e^{-\imath E_2 t/\hbar}\sigma_z|a,0\rangle+\\
&+\langle 2,0|-\imath\sum_{\mathbf{k}}\tfrac{\omega_0}{2}c_{g,\mathbf{k}}e^{-\imath(E_1/\hbar+\omega_{\mathbf{k}})t}\sigma_z|g,1_{\mathbf{k}}\rangle+\\
&+\langle 2,0|-\imath\omega c_a e^{-\imath E_2 t/\hbar}\left(a^\dagger a+\tfrac{1}{2}\right)|a,0\rangle+\\
&+\langle 2,0|-\imath\sum_{\mathbf{k}}\omega c_{g,\mathbf{k}}e^{-\imath(E_1/\hbar+\omega_{\mathbf{k}})t}(a^\dagger a+\tfrac{1}{2})|g,1_{\mathbf{k}}\rangle+\\
&+\langle 2,0|-\imath g c_a e^{-\imath E_2 t/\hbar}(a\sigma^+ +a^\dagger\sigma^-)|a,0\rangle+\\
&+\langle 2,0|-\imath\sum_{\mathbf{k}}g c_{g,\mathbf{k}}e^{-\imath(E_1/\hbar+\omega_{\mathbf{k}})t}(a\sigma^+ +a^\dagger\sigma^-)|g,1_{\mathbf{k}}\rangle\\
&=-\tfrac{\imath}{2}\omega_0 c_a e^{-\imath E_2 t/\hbar}+0-\imath(0+\tfrac{1}{2})\omega c_a e^{-\imath E_2 t/\hbar}+\\
&+0-\imath g\sum_{\mathbf{k}}c_{g,\mathbf{k}}e^{-\imath(E_1/\hbar+\omega_{\mathbf{k}})t}\ ,
\end{aligned}
$$

and also,

$$\begin{aligned}
\frac{\partial}{\partial t}\left(c_{g,\mathbf{k}}e^{-\imath(E_1/\hbar+\omega_{\mathbf{k}})t}\right) &= \langle g,1_{\mathbf{k}}|-\imath\tfrac{\omega_0}{2}c_a e^{-\imath E_2 t/\hbar}\hat{\sigma}_z|a,0\rangle+\\
&+\langle g,1_{\mathbf{k}}|-\imath\sum_{\mathbf{k}}\tfrac{\omega_0}{2}c_{g,\mathbf{k}}e^{-\imath(E_1/\hbar+\omega_{\mathbf{k}})t}\hat{\sigma}_z|g,1_{\mathbf{k}}\rangle+\\
&+\langle g,1_{\mathbf{k}}|-\imath\omega c_a e^{-\imath E_2 t/\hbar}(a^\dagger a+\tfrac{1}{2})|a,0\rangle+\\
&+\langle g,1_{\mathbf{k}}|-\imath\sum_{\mathbf{k}}\omega c_{g,\mathbf{k}}e^{-\imath(E_1/\hbar+\omega_{\mathbf{k}})t}(\hat{a}^\dagger\hat{a}+\tfrac{1}{2})|g,1_{\mathbf{k}}\rangle+\\
&+\langle g,1_{\mathbf{k}}|-\imath g c_a e^{-\imath E_2 t/\hbar}(a\sigma^+ + a^\dagger\hat{\sigma}^-)|a,0\rangle+\\
&+\langle g,1_{\mathbf{k}}|-\imath\sum_{\mathbf{k}}g c_{g,\mathbf{k}}e^{-\imath(E_1/\hbar+\omega_{\mathbf{k}})t}(\hat{a}\hat{\sigma}^+ + \hat{a}^\dagger\sigma^-)|g,1_{\mathbf{k}}\rangle\\
=0-\imath\sum_{\mathbf{q}}\tfrac{\omega_0}{2}c_{g,\mathbf{q}}e^{-\imath(E_1/\hbar+\omega_{\mathbf{k}})t}\langle 1_{\mathbf{k}}|1_{\mathbf{q}}\rangle+0-&\\
-\imath\sum_{\mathbf{q}}\omega_{\mathbf{q}}c_{g,\mathbf{q}}e^{-\imath(E_1/\hbar+\omega_{\mathbf{k}})t}(1+\tfrac{1}{2})\langle 1_{\mathbf{k}}|1_{\mathbf{q}}\rangle-&\\
-\imath g c_a e^{-\imath E_2 t/\hbar}\langle 1_{\mathbf{k}}|a^\dagger|0\rangle+0\ .&
\end{aligned}$$

From this,

$$\begin{aligned}
\dot{c}_a-\tfrac{\imath}{\hbar}E_2 c_a &= -\tfrac{\imath}{2}(\omega_{\mathbf{k}}+\omega_0)c_a-\imath g\sum_{\mathbf{k}}c_{g,\mathbf{k}}e^{-\imath(-\omega_0+\omega_{\mathbf{k}})t}\\
\dot{c}_{g,\mathbf{k}}-\imath(E_1/\hbar+\omega_{\mathbf{k}})c_{g,\mathbf{k}} &= -\tfrac{\imath}{2}(\omega_0+3\omega_{\mathbf{k}})c_{g,\mathbf{k}}-\imath g c_a e^{-\imath(\omega_0-\omega_{\mathbf{k}})t}\ .
\end{aligned}$$

With a transformation to the interaction picture $\tilde{c}_a = c_a e^{\imath/2(\omega_{\mathbf{k}}-\omega_0)t}$ *and* $\tilde{c}_g = c_g e^{\imath/2(\omega_{\mathbf{k}}+\omega_0)t}$, *where without general restriction* $E_1\equiv 0$,

$$\begin{aligned}
\partial_t\tilde{c}_a &= -\imath g\sum_{\mathbf{k}}\tilde{c}_{g,\mathbf{k}}e^{-\imath(-\omega_0+\omega_{\mathbf{k}})t}\\
\partial_t\tilde{c}_{g,\mathbf{k}} &= -\imath g\tilde{c}_a e^{-\imath(\omega_0-\omega_{\mathbf{k}})t}\ .
\end{aligned}$$

With this we can calculate the spontaneous emission [1184].
d. Background: The formal solution is

$$c_{g,\mathbf{k}}(t) = -g\int_0^t dt'\ e^{\imath(\omega_{\mathbf{k}}-\omega_0)t'}c_a(t')\ .$$

When we introduce the density of the slowly varying states, $\sum_{\mathbf{k}}\to\int_0^\infty d\omega\ \rho(\omega)$, *we get,*

$$\begin{aligned}
\dot{c}_a(t) &= -g^2\sum_{\mathbf{k}}\int_0^t dt'\ e^{\imath(\omega_{\mathbf{k}}-\omega_0)(t-t')}c_a(t')\\
&\approx -g^2\rho(\omega_0)\int_0^t dt'\int_{-\infty}^{\infty}d\omega\ e^{\imath(\omega_{\mathbf{k}}-\omega_0)(t-t')}c_a(t')\\
&= -g^2\rho(\omega_0)\int_0^t dt' 2\pi\delta(t-t')c_a(t') = -\tfrac{\Gamma}{2}c_a(t)\ ,
\end{aligned}$$

with $\Gamma \equiv 4\pi g^2 \rho(\omega_0)$. The presence of many modes blurs the periodicity of the Rabi oscillations, until only remains a purely exponential decay, $|c_a(t)|^2 = e^{-\Gamma t}$, characterizing the spontaneous emission.

35.4.5.3 Ex: Quantum collapse and revival in the Jaynes-Cummings model

Consider the Jaynes-Cummings Hamiltonian and show that the quantum coherence between the two atomic levels can disappear altogether for long periods and reappear later. Explain how this is possible.

Solution: *The figure shows a simulation done in the Julia Language.*

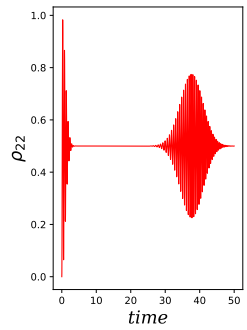


Figure 35.10: (code) Simulation of the time-evolution of the excited state population in the JCM for 200 photons.

35.4.5.4 Ex: Vacuum Rabi splitting

Calculate the Autler-Townes splitting for an excited atom interacting with an empty cavity.

Solution: *Without light in the cavity but with an initially excited atom, the Hamiltonian (35.113) is restricted to,*

$$\hat{H}_n = \begin{pmatrix} \frac{\omega_0}{2} & \frac{\Omega}{2} \\ \frac{\Omega}{2} & \omega - \frac{\omega_0}{2} \end{pmatrix} ,$$

with all the consequences. That is, even without photons in the mode, the atom starts to make a stimulated transition to the ground state. These are the well-known vacuum Rabi oscillations.

35.4.5.5 Ex: The Q-function in a Jaynes-Cummings state

Calculate the Q-function for a Jaynes-Cummings state from its definition (35.154).

Solution: *To begin with, we project the Glauber state onto a Fock state,*

$$\langle n|\alpha\rangle = \langle n|e^{-|\alpha|^2/2}\sum_{m=0}^{\infty}\frac{\alpha^m}{\sqrt{m!}}|m\rangle = e^{-|\alpha|^2/2}\frac{\alpha^n}{\sqrt{n!}}$$

and the Jaynes-Cummings state onto an atomic state,

$$\langle j|\psi\rangle = \langle j|\sum_n (c_{1,n}|1,n\rangle + c_{2,n-1}|2,n-1\rangle) = \sum_n (\delta_{j1}c_{1,n}|n\rangle + \delta_{j2}c_{2,n-1}|n-1\rangle) = \sum_n c_{j,n}|n\rangle \ .$$

With this we calculate the Q-function,

$$\pi Q(\alpha) = \langle\alpha|\, Tr_{atom}\ \hat{\rho}|\alpha\rangle = \langle\alpha|\sum_{j=1,2}\langle j|\psi\rangle\langle\psi|j\rangle|\alpha\rangle = \langle\alpha|\sum_{j=1,2}\sum_n c_{j,n}|n\rangle\sum_m c^*_{j,m}\langle m|\alpha\rangle$$

$$= \sum_{j=1,2}\sum_{n,m} c^*_{j,m}c_{j,n}e^{-|\alpha|^2/2}\frac{\alpha^{*n}}{\sqrt{n!}}\langle n|e^{-|\alpha|^2/2}\frac{\alpha^m}{\sqrt{m!}}|m\rangle = e^{-|\alpha|^2}\sum_{j=1,2}\sum_n |c_{j,n}|^2\frac{|\alpha|^n}{n!} \ .$$

35.4.5.6 Ex: Creation of quantum correlations in an optical mode

a. We will show in this exercise how, via coherent operations in a three-level system, we can create Schrödinger-type quantum-type correlations in an optical mode. In the system shown in Fig. 35.11 we imagine the lower transition excited by $\pi/2$-pulses of a classical resonant microwave radiation (as described by the operation (35.125)). The upper transition is excited by quantum laser pulses tuned very far out of resonance, thus creating a dispersive dynamics (as described by the operation (35.125)). At time $t = 0$ the atom is in state $|1\rangle$. Now, we apply the following pulse sequence: (i) a microwave pulse with $\sqrt{\bar{n}}\Omega_{12}t = \pi/2$, (ii) an optical pulse with $\Omega_{23}^2 t/4\Delta_{23} = \pi$, (iii) another microwave $\pi/2$-pulse, and finally (iv) an optical pulse of light which is resonant with the transition $|2\rangle$-$|3\rangle$ and projects the population of the atom into one of the states of the microwave transition. Describe the evolution of the state of the system during the sequence and determine the final state of the optical mode.
b. Calculate the number of photons for the two cases that, after a measurement, the atom is found in (i) the lower state and (ii) the upper state. Interprete the results.

Solution: *We denote the microwave radiation by $|\mu\rangle$ and the laser light by $|\beta\rangle$. Initially, before the atom interacts with the fields, we have the state,*

$$|\psi(0)\rangle = \begin{pmatrix}1\\0\end{pmatrix}|\mu\rangle|\beta\rangle \ .$$

We now apply a resonant $\pi/2$-pulse to the microwave transition ω_{12}. If the field is coherent, $|\mu|^2 \gg 1$, the atom goes to a superposition of atomic states,

$$|\psi(t)\rangle = \tfrac{1}{\sqrt{2}}\begin{pmatrix}1\\ \imath\end{pmatrix}|\mu e^{-\imath\omega_{12}t}\rangle \ .$$

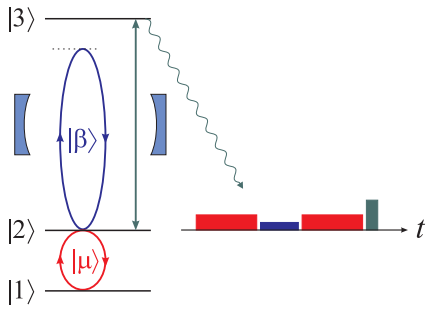

Figure 35.11: (a) Level scheme and (b) pulse sequence.

The microwave field being classical, the atomic state does not get entangled with the field, that is, the microwave field factors out. Now, we apply an optical pulse tuned far away from the resonance $|2\rangle - |3\rangle$*, such that* $|\Delta_{23}| \gg |\beta|^2\Omega_{23}$*. The laser-induced light shift is* $\Omega_{23}^2/4\Delta_{23}$*, such that the atom suffers phase shift of* $\varphi \equiv \Omega_{23}^2 t/4\Delta_{23}$ *provided it is in the state* $|2\rangle$*, but not if it is in the state* $|1\rangle$*. For* $\varphi = \pi$ *we obtain,*

$$|\psi(t+\tau)\rangle = \tfrac{1}{\sqrt{2}}\begin{pmatrix} |\beta'\rangle \\ -\imath|-\beta'\rangle \end{pmatrix} \qquad \textit{with} \qquad \beta' = \beta e^{-\imath\omega_{23}\tau} \ .$$

Therefore, the atomic state is entangled with the coherences of the optical field. Now, a second Ramsey $\pi/2$*-pulse is applied to the microwave transition, such that the correlated state is disentangled:*

$$|\psi(2t+\tau)\rangle = \tfrac{1}{2}\begin{pmatrix} 1 \\ \imath \end{pmatrix}|\beta'\rangle + \tfrac{1}{2}\begin{pmatrix} 1 \\ -\imath \end{pmatrix}|-\beta'\rangle \ .$$

Finally, a resonant optical light pulse measures the population of the state $|2\rangle$*. The measurement reduces the atomic state, and we are left with a pure Schrödinger cat state of the optical field:*

$$|\psi(T)\rangle = \tfrac{\imath}{\sqrt{2}}\begin{pmatrix} 0 \\ \imath \end{pmatrix}(|\beta'\rangle - |\beta'\rangle) \ ,$$

and analogously for the level $|1\rangle$ [9]*.*
b. With,

$$\begin{aligned} |\psi\rangle &= \tfrac{1}{2}\begin{pmatrix} 1 \\ \imath \end{pmatrix}|\beta\rangle + \tfrac{1}{2}\begin{pmatrix} 1 \\ -\imath \end{pmatrix}|-\beta\rangle \\ &= \tfrac{1}{2}|1,\beta\rangle + \tfrac{\imath}{2}|2,\beta\rangle + \tfrac{1}{2}|1,-\beta\rangle - \tfrac{\imath}{2}|2,-\beta\rangle \end{aligned}$$

[9] The detection of quantum correlations is much more complicated than their creation: In principle, it is sufficient to detect the quantum interference fringes appearing in the Wigner distribution via phase-sensitive homodyne detection [1164, 1352]. But in a Schrödinger cat state the number of fringes corresponds to the number of photons in the mode. If the number of photons is too large, the interference fringes are too thin to be resolved. In addition, scattering can wear out the fringes, such that large cats are much more sensitive to dissipation. Since the dissipation corresponds to photon annihilation, the cat is jumping between odd and even cat states.

we get for the photon numbers when the atom is in state $|1\rangle$*,*

$$\begin{aligned}\langle\psi|1\rangle\langle 1|\hat{a}^\dagger\hat{a}|1\rangle\langle 1|\psi\rangle &= \tfrac{1}{4}(\langle\beta| + \langle -\beta|)\hat{a}^\dagger\hat{a}(|\beta\rangle + |-\beta\rangle)\\ &= \tfrac{1}{4}|\beta|^2(\langle\beta| - \langle -\beta|)(\beta\rangle - |-\beta\rangle)\\ &= \tfrac{1}{4}|\beta|^2\left(2 - e^{-|\beta|^2/2-|-\beta|^2/2-\beta^*\beta} - e^{-|-\beta|^2/2-|-\beta|^2/2-\beta^*\beta}\right)\\ &= \tfrac{1}{2}|\beta|^2(1 - e^{-2|\beta|^2}) \simeq \tfrac{1}{2}|\beta|^2\end{aligned}$$

for $|\beta| \gg 1$*, and when the atom is in state* $|2\rangle$*,*

$$\begin{aligned}\langle\psi|2\rangle\langle 2|\hat{a}^\dagger\hat{a}|2\rangle\langle 2|\psi\rangle &= \tfrac{1}{4}(-\langle\beta|\imath + \langle -\beta|\imath)\hat{a}^\dagger\hat{a}(\imath|\beta\rangle - \imath|-\beta\rangle)\\ &= \tfrac{\imath^2}{4}|\beta|^2(-\langle\beta| - \langle -\beta|)(|\beta\rangle + |-\beta\rangle)\\ &= \tfrac{1}{4}|\beta|^2\left(2 + e^{-|\beta|^2/2-|-\beta|^2/2-\beta^*\beta} + e^{-|-\beta|^2/2-|-\beta|^2/2-\beta^*\beta}\right)\\ &= \tfrac{1}{2}|\beta|^2(1 + e^{-2|\beta|^2}) \simeq \tfrac{1}{2}|\beta|^2\ ,\end{aligned}$$

so that the total photon number is,

$$\langle\psi|\hat{a}^\dagger\hat{a}|\psi\rangle = \langle\psi|1\rangle\langle 1|\hat{a}^\dagger\hat{a}|1\rangle\langle 1|\psi\rangle + \langle\psi|2\rangle\langle 2|\hat{a}^\dagger\hat{a}|2\rangle\langle 2|\psi\rangle = |\beta|^2\ .$$

The system realizes a fully quantized model of a beam splitter and a Mach-Zehnder interferometer *with the difference, the two interferometer arms are not spatially separated. The fact that they are entangled is not different from a classical beam spitter (see Sec. 35.8.2). When the dispersive optical pulse realizes a* π *phase shift between the arms, we observe constructive interference in one arm and destructive in the other. In the same time we know that the cat states* $|\psi\rangle \pm |-\psi\rangle$ *are not empty of photons, but have probability distributions of even/odd photon numbers.*

35.4.5.7 Ex: Master equation derived from JC model Hamiltonian for two-level systems

Write down the Liouvillean for a JC system in matrix form for a density operator defined like,

$$\begin{pmatrix}\cdots & \rho_{11}^{n-1} & \rho_{22}^{n} & \rho_{12}^{n} & \rho_{21}^{n} & \rho_{11}^{n} & \rho_{22}^{n+1} & \cdots\end{pmatrix}\ .$$

Solution: *See [1440, 264, 339],*

$$\begin{pmatrix}
\ddots & & & & & & & \\
 & 0 & \Gamma & & & & & \\
 & 0 & -\Gamma & -\frac{\imath}{2}\sqrt{n}\Omega & \frac{\imath}{2}\sqrt{n}\Omega & 0 & & \\
 & & -\frac{\imath}{2}\sqrt{n}\Omega & -\Lambda & 0 & \frac{\imath}{2}\sqrt{n}\Omega & & \\
 & & \frac{\imath}{2}\sqrt{n}\Omega & 0 & -\Lambda^* & -\frac{\imath}{2}\sqrt{n}\Omega & & \\
 & & 0 & \frac{\imath}{2}\sqrt{n}\Omega & -\frac{\imath}{2}\sqrt{n}\Omega & 0 & \Gamma & \\
 & & & & & 0 & -\Gamma & \\
 & & & & & & & \ddots
\end{pmatrix}\ .$$

35.4.5.8 Ex: Laguerre polynomials

Calculate the Wigner function for the field generated by a Jaynes-Cummings dynamics in the photon picture.

Solution: *First we find the series expressions for the Laguerre polynomials* $L_n^{(\alpha)}(x)$ *and* $L_n^{(-\alpha)}(x)$*. According to Wikipedia,*

$$L_n^{(\alpha)}(x) = \sum_{m=0}^{n} \binom{n+\alpha}{n-m} \frac{(-x)^m}{m!} \qquad \text{and} \qquad \frac{(-x)^m}{m!} L_n^{(m-n)}(x) = \frac{(-x)^n}{n!} L_m^{(n-m)}(x) \ .$$

With this,

$$\begin{aligned} L_n^{(-\alpha)}(x) &= \frac{(n-\alpha)!}{n!}(-x)^\alpha L_{n-\alpha}^{(\alpha)}(x) \\ &= \frac{(n-\alpha)!}{n!}(-x)^\alpha \sum_{m=0}^{n-\alpha} \binom{n}{n-\alpha-m} \frac{(-x)^m}{m!} = \sum_{m=0}^{n-\alpha} \binom{n-\alpha}{m} \frac{(-x)^{m+\alpha}}{(m+\alpha)!} \ . \end{aligned}$$

Now, the normally ordered characteristic function is,

$$\begin{aligned} \chi_N(\lambda) = &\sum_{m,n} c_{1,m}^* c_{1,n} \sqrt{\frac{n!}{m!}} \left[\lambda^{m-n}\Theta_{m\geq n} + (-\lambda^*)^{m-n}\Theta_{m<n}\right] L_N^{m-n}(|\lambda|^2) \\ &+ \sum_{m-1,n-1} c_{2,m-1}^* c_{2,n-1} \sqrt{\frac{(n-1)!}{(m-1)!}} \left[\lambda^{m-n}\Theta_{m\geq n} + (-\lambda^*)^{m-n}\Theta_{m<n}\right] L_{n-1}^{m-n}(|\lambda|^2) \\ &+ \sum_{m,n-1} c_{1,m}^* c_{2,n-1} \sqrt{\frac{(n-1)!}{m!}} \left[\lambda^{m-n+1}\Theta_{m\geq n} + (-\lambda^*)^{m-n+1}\Theta_{m<n})\right] L_{n-1}^{m-n+1}(|\lambda|^2) \\ &+ \sum_{m-1,n} c_{2,m-1}^* c_{1,n} \sqrt{\frac{n!}{(m-1)!}} \left[\lambda^{m-1-n}\Theta_{m\geq n} + (-\lambda^*)^{m-1-n}\Theta_{m<n}\right] L_N^{m-1-n}(|\lambda|^2) \ . \end{aligned}$$

This yields after rearrangement,

$$\chi_N(\lambda) = \sum_{m,n} \sqrt{\frac{n!}{m!}} \left[\begin{array}{l} (c_{1,m}^* c_{1,n} + c_{2,m}^* c_{2,n})(\lambda^{m-n}\Theta_{m\geq n} + (-\lambda^*)^{m-n}\Theta_{n<m}) \\ +\lambda^{m-n}\left(c_{1,m}^* c_{2,n}\Theta_{m\geq n+1} + c_{2,m}^* c_{1,n}\Theta_{m\geq n-1}\right) \\ +(-\lambda^*)^{m-n}(c_{1,m}^* c_{2,n}\Theta_{m<n+1} + c_{2,m}^* c_{1,n}\Theta_{m<n-1}) \end{array} \right] L_N^{m-n}(|\lambda|^2) \ .$$

From here we get the Wigner function by numerical FFT according to Eq. (35.158).

35.5 Correlation functions

In the preceding sections and in Sec. 35.2 we have learned, how to characterize quantum fields by (quasi-)probability distribution functions, and how to represent correlations in the Fock or the Glauber basis. But we did not propose experimental schemes

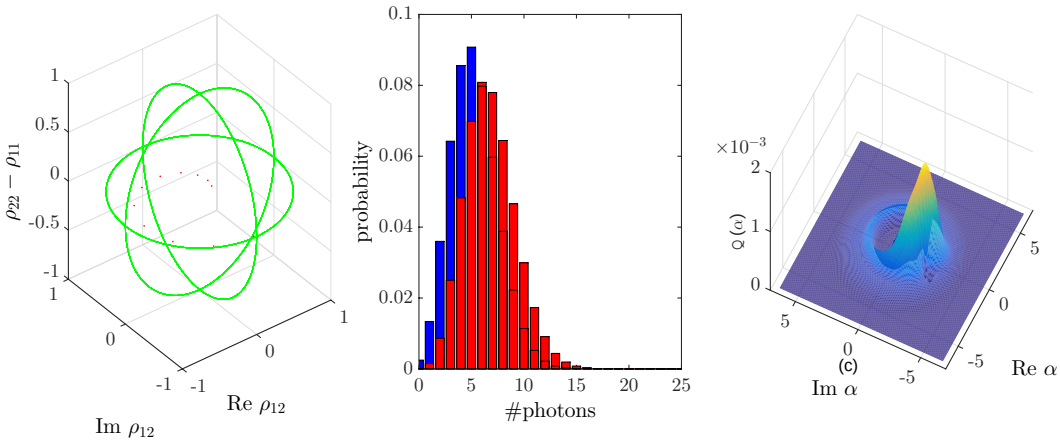

Figure 35.12: (code) Bloch vector, photon number distribution, and Wigner function for JC-coupling in the Fock state representation.

allowing to detect them. Experimental devices, such as interferometers or photon correlators, necessarily involve space or time coordinates. Hence, we need to devise quantities for the characterization of correlations, that are compatible with experimental devices. The *correlation functions* are such quantities, and in the next section we will focus our attention them.

In order to be able to distinguish classical from genuinely quantum correlations, we will first a classical description, before introducing a quantum description of the light field [816].

35.5.1 Classical first and second order coherence

The coherence properties of a light field (or a matter wave) are measured by n^{th} space time order correlation functions. In quantum mechanics, these are defined by,

$$g^{(n)}(\mathbf{r}_1,t_1,..,\mathbf{r}_{2n},t_{2n}) \equiv \frac{\langle \hat{\mathcal{E}}^-(\mathbf{r}_1,t_1)..\hat{\mathcal{E}}^-(\mathbf{r}_n,t_n)\hat{\mathcal{E}}^+(\mathbf{r}_{n+1},t_{n+1})..\hat{\mathcal{E}}^+(\mathbf{r}_{2n},t_{2n})\rangle}{\sqrt{\langle \hat{\mathcal{E}}^-(\mathbf{r}_1,t_1)\hat{\mathcal{E}}^+(\mathbf{r}_1,t_1)\rangle..\langle \hat{\mathcal{E}}^-(\mathbf{r}_{2n},t_{2n})\hat{\mathcal{E}}^+(\mathbf{r}_{2n},t_{2n})\rangle}} \,. \tag{35.171}$$

In the following, we will only consider temporal coherences, e.g. one or more collinear light beams, $\mathbf{k}_m \parallel \mathbf{k}_n$, impinging on a photodetector, $(t_m - \frac{z_m}{c}) - (t_n - \frac{z_n}{c}) = \tau$, since $\hat{\mathcal{E}}(\mathbf{r},t) = \hat{\mathcal{E}}(\omega t - \mathbf{k}\cdot\mathbf{r})$, we can define the the 1^{st} and 2^{nd} order correlation functions $g^{(1)}$ and $g^{(2)}$, which are particularly important,

$$\boxed{g^{(1)}(\tau) \equiv \frac{\langle \hat{\mathcal{E}}^-(t)\hat{\mathcal{E}}^+(t+\tau)\rangle}{\langle \hat{\mathcal{E}}^-(t)\hat{\mathcal{E}}^+(t)\rangle} \quad \text{and} \quad g^{(2)}(\tau) \equiv \frac{\langle \hat{\mathcal{E}}^-(t)\hat{\mathcal{E}}^-(t+\tau)\hat{\mathcal{E}}^+(t+\tau)\hat{\mathcal{E}}^+(t)\rangle}{\langle \hat{\mathcal{E}}^-(t)\hat{\mathcal{E}}^+(t)\rangle^2}} \,. \tag{35.172}$$

Ignoring the quantized nature of light, we may substitute the field operators by complex numbers, $\hat{\mathcal{E}}^+ \to \mathcal{E}$ and $\hat{\mathcal{E}}^- \to \mathcal{E}^*$ and interprete the brackets as pure time

averages,

$$\langle \cdots \rangle_t = \lim_{t\to\infty} \frac{1}{t} \int_0^t \cdots dt' \ . \tag{35.173}$$

Defining the intensity as $I = 2\varepsilon_0 c \mathcal{E}^* \mathcal{E}$, the coherences become,

$$g^{(1)}(\tau) \equiv \tfrac{2\varepsilon_0 c}{I} \langle \mathcal{E}^*(t)\mathcal{E}(t+\tau)\rangle \qquad \text{and} \qquad g^{(2)}(\tau) \equiv \left(\tfrac{2\varepsilon_0 c}{I}\right)^2 \langle I(t)I(t+\tau)\rangle \ . \tag{35.174}$$

The correlation functions must be calculated from the field operators simultaneously respecting *time order* and *normal order*. These functions are useful quantities to describe phenomena such as photon *bunching* or to understand the fluorescence spectra or the scattering of light from correlated atoms. $g^{(1)}$ measures the *coherence* of a light field (how much it resembles a sine wave). $g^{(2)}$ measures, for a given degree of coherence, the deviation of the light field from the quantum state that most closely approximates a classical light (how much it resembles a laser).

The correlation functions $g^{(1)}$ and $g^{(2)}$ are experimentally measured in *Young's experiment* and in the *Hanbury-Brown-Twiss experiment*. The experimental schemes are explained in Figs. 35.13.

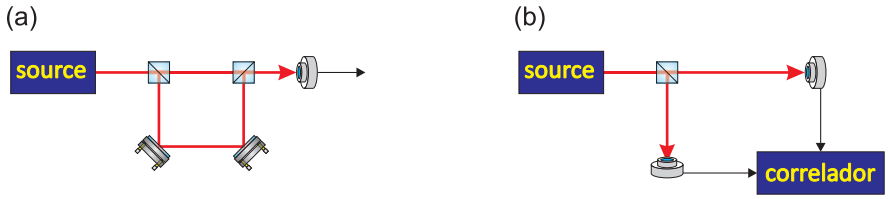

Figure 35.13: (a) Scheme of Young's experiment. (b) Scheme of the experiment of Hanbury, Brown, and Twiss. Young's experiment reveals the coherence of a field, that is, its ability to interfere. In contrast, the Hanbury-Brown-Twist experiment reveals correlations between the (quasi-)particles constituting the field, that is, effects due to quantum statistics or interactions.

Coherence and chaos are contrary properties of light. They leave their imprint in the spectrum of the light or in the autocorrelation functions. The emission spectrum of a light source generally emerges as a combination of various physical effects: The active medium gives rise resonances and broadenings, a resonator containing the active medium imprints a modal structure, and the coupling to a thermal bath gives rise to a thermal distribution of the radiation energy according to $P_n = e^{-\hbar\omega(n+1/2)/k_B T} / \sum_n e^{-\hbar\omega(n+1/2)/k_B T}$.

35.5.2 The Wiener-Khintchine theorem

When the time dependence of a wave is given by $\mathcal{E}(t)$, we call

$$R_{\mathcal{E}}(\tau) = \langle \mathcal{E}^*(t)\mathcal{E}(t+\tau)\rangle_t \tag{35.175}$$

the autocorrelation function and the power density

$$S_{\mathcal{E}}(\omega) = (\mathcal{F}R_{\mathcal{E}})(\omega) = |(\mathcal{F}\mathcal{E})(\omega)|^2 \tag{35.176}$$

the *spectrum*. This relation is called the *Wiener-Khintchine theorem*. We may also consider the normalized quantities, dividing (35.175) and (35.176) by $R_{\mathcal{E}}(0) = \langle \hat{\mathcal{E}}^*(t)\hat{\mathcal{E}}(t)\rangle_t = \int_{-\infty}^{\infty} |(\mathcal{F}\mathcal{E})(\omega)|^2 d\omega = \int_{-\infty}^{\infty} S_{\mathcal{E}}(\omega)d\omega$. We obtain,

$$g^{(1)}(\tau) = \frac{R_{\mathcal{E}}(\tau)}{R_{\mathcal{E}}(0)} \ , \tag{35.177}$$

and,

$$\boxed{F_{\mathcal{E}}(\omega) \equiv (\mathcal{F}g^{(1)})(\omega) = \frac{S_{\mathcal{E}}(\omega)}{R_{\mathcal{E}}(0)} = \frac{1}{2\pi}\int_{-\infty}^{\infty} g^{(1)}(\tau)e^{\imath\omega\tau}d\tau} \ . \tag{35.178}$$

The quantity $F_{\mathcal{E}}(\omega)$ is called line profile or *spectrum*. Note that, since,

$$g^{(1)}(-\tau) = g^{(1)}(\tau)^* \ , \tag{35.179}$$

we may also write,

$$F_{\mathcal{E}}(\omega) = \mathfrak{Re}\ \frac{1}{\pi}\int_0^{\infty} g^{(1)}(\tau)e^{\imath\omega\tau}d\tau \ . \tag{35.180}$$

35.5.3 Coherent and chaotic light

The temporal and spectral properties of a light field are largely determined by the processes leading to its generation in the light source, that is, whether the light is generated by stimulated or spontaneous emission, by a laser or by blackbody radiation, by a single atom or by atomic gases subject to collisional and Doppler-broadening.

35.5.3.1 Correlation functions for laser light

First-order coherent light satisfies $|g^{(1)}(\tau)| = 1$, incoherent light $|g^{(1)}(\tau)| = 0$, and for partially coherent light, we get intermediate values. Second-order coherent light satisfies $g^{(2)}(-\tau) = g^{(2)}(\tau)$ and $1 \leq g^{(2)}(0) \leq \infty$ and $0 \leq g^{(2)}(\tau) \leq \infty$ and $g^{(2)}(0) \geq g^{(2)}(\tau) \overset{\tau \gg \tau_c}{\to} 1$. Let us now look at some specific cases, for which the correlation functions and spectra can be calculated.

With the definitions (35.172) it is easy to calculate the autocorrelation functions and the spectrum of a *laser* light field,

laser

$$\boxed{\begin{aligned} \mathcal{E}(t) &= e^{\imath\omega_0 t} \\ \Longrightarrow \quad g^{(1)}(\tau) &= \frac{t^{-1}\int e^{-\imath\omega_0\tau}dt}{t^{-1}\int dt} = e^{-\imath\omega_0\tau} \\ \Longrightarrow \quad \mathcal{F}\left[g^{(1)}(\tau)\right] &= \frac{1}{2\pi}\int_{-\infty}^{\infty} e^{\imath(\omega-\omega_0)\tau}d\tau = \delta(\Delta) \\ g^{(2)}(\tau) &= 1 \end{aligned}} \ . \tag{35.181}$$

We see that the absolute values of the first and second-order coherences are constant, and that the spectrum is narrow like a δ-function.

35.5.3.2 Correlation functions for laser light subject to white noise

For a laser subject to *white phase noise* (ζ be a normally distributed random number) we have (see also Sec. 56.3.2),

noisy laser

$$\begin{aligned} \mathcal{E}(t) &= e^{\imath[\omega_0 t+\zeta(t)]} \\ \Longrightarrow \quad g^{(1)}(\tau) &= \frac{\int e^{-\imath[\omega_0\tau+\zeta(t+\tau)-\zeta(t)]}dt}{\int dt} = e^{\imath\omega_0\tau-\gamma|\tau|} \\ \Longrightarrow \quad \mathcal{F}[g^{(1)}(\tau)] &= \frac{\gamma/\pi}{\Delta^2+\gamma^2} \\ g^{(2)}(\tau) &= 1 \end{aligned} \quad . \tag{35.182}$$

We see, that the first-order coherence decays exponentially, $|g^{(1)}(\tau)| = e^{-\gamma|\tau|}$ [10], such that the spectrum has a *Lorentzian profile*. This result has already been derived in Eq. (34.28) for the natural linewidth of a transition subject to spontaneous emission. We understand the connection by interpreting spontaneous emission as being induced by *vacuum fluctuations, which do have a white noise spectrum*, indeed.

Example 212 (*Laser broadening due to spontaneous emission*): Laser light is generated by stimulated emission on a transition between two quantized levels. The alternance of absorption and stimulated emission induces coherent Rabi oscillations ensuring the coherence of the emitted light. But we have seen earlier that spontaneous emission leads to randomly occurring interruptions of the coherent Rabi oscillations. The probability of finding a coherent interval decreases exponentially with the evolution time,

$$p(\tau)d\tau = \gamma e^{-\gamma\tau}d\tau \ ,$$

where γ is the spontaneous decay rate of the dipole moment. From $\mathcal{E}(t) = e^{\imath\omega_0 t+\imath\zeta(t)}$ we calculate,

$$\begin{aligned} R_{\mathcal{E}}(\tau) &= \langle e^{\imath\omega_0 t+\imath\zeta(t)}e^{-\imath\omega_0(t+\tau)-\imath\zeta(t+\tau)}\rangle = e^{-\imath\omega_0\tau}\lim_{t\to\infty}\frac{1}{t}\int_0^t e^{\imath[\zeta(t)-\zeta(t+\tau)]}dt \\ &= e^{-\imath\omega_0\tau}\int_\tau^\infty p(\tau')d\tau' = e^{-\imath\omega_0\tau}e^{-\gamma|\tau|} \ , \end{aligned}$$

and,

$$F_{\mathcal{E}}(\omega) = \frac{1}{2\pi}\int_{-\infty}^{\infty}\frac{R_{\mathcal{E}}(\tau)}{R_{\mathcal{E}}(0)}e^{\imath\omega\tau}d\tau = \frac{1}{2\pi}\int_{-\infty}^{\infty}e^{-\imath\omega_0\tau}e^{-\gamma|\tau|}e^{\imath(\omega-\omega_0)\tau}d\tau = \frac{\gamma/\pi}{\Delta^2+\gamma^2} \ .$$

An alternative derivation from Bloch or rate equations is shown in Excs. 35.6.4.3 and 35.6.4.4.

[10] Note that, in order to satisfy (35.179), we must take the absolute value of the delay $|\tau|$.

35.5.3.3 Correlation functions with pressure broadening

In Sec. 34.6.2 we have already seen, that collision or *pressure broadening* can be treated by assuming that the light is emitted as a superposition of coherent waves all having the same frequency, but being randomly interrupted by phase jumps,

$$\mathcal{E}(t) = \sum_n \mathcal{E}_n(t) \qquad \text{with} \qquad \mathcal{E}_n(t) = e^{\imath\omega_0 t + \imath\phi_n(t)} \; . \tag{35.183}$$

The autocorrelation function is then,

$$\begin{aligned} \langle \mathcal{E}^*(t)\mathcal{E}(t+\tau)\rangle &= \frac{1}{t}\int \sum_n e^{-\imath\omega_0 t - \imath\phi_n(t)} \sum_m e^{\imath\omega_0 t + \imath\omega_0\tau + \imath\phi_m(t+\tau)} dt \\ &= e^{\imath\omega_0\tau} \sum_{n,m} \frac{1}{t}\int e^{\imath\phi_m(t+\tau) - \imath\phi_n(t)} dt = N\langle \mathcal{E}_n^*(t)\mathcal{E}_m(t+\tau)\rangle \delta_{nm} \; . \end{aligned} \tag{35.184}$$

The crossed terms $n \neq m$ of this expressions vanish. The pressure broadening is homogeneous, but the fact that the wavepackets are scattered by different atoms results in a modified first-order coherence,

$$\langle \mathcal{E}_n^*(t)\mathcal{E}_n(t+\tau)\rangle = e^{\imath\omega_0\tau} \sum_n \int e^{\imath\phi_n(t+\tau) - \imath\phi_n(t)} dt = e^{\imath\omega_0\tau} \int_\tau^\infty p(\tau) d\tau \; . \tag{35.185}$$

The probability density of finding a coherent interval of duration τ is $p(\tau)d\tau = \gamma_c e^{-\gamma_c\tau} d\tau$, which finally gives,

$$\langle \mathcal{E}^*(t)\mathcal{E}(t+\tau)\rangle = N e^{\imath\omega_0\tau - \gamma_c|\tau|} \; . \tag{35.186}$$

The calculation for the 2^{nd} order correlation function (35.174) is analogous,

$$\begin{aligned} &\langle \mathcal{E}^*(t)\mathcal{E}^*(t+\tau)\mathcal{E}(t+\tau)\mathcal{E}(t)\rangle = \sum_{n,m,n',m'} \langle \mathcal{E}_m^*(t)\mathcal{E}_n(t)\mathcal{E}_{m'}^*(t+\tau)\mathcal{E}_{n'}(t+\tau)\rangle \\ &= \sum_n \langle \mathcal{E}_n^*(t)\mathcal{E}_n(t)\mathcal{E}_n^*(t+\tau)\mathcal{E}_n(t+\tau)\rangle \\ &+ \left(\sum_{n\neq m} \langle \mathcal{E}_n^*(t)\mathcal{E}_n(t)\mathcal{E}_m^*(t+\tau)\mathcal{E}_m(t+\tau)\rangle + \langle \mathcal{E}_m^*(t)\mathcal{E}_n(t)\mathcal{E}_n^*(t+\tau)\mathcal{E}_m(t+\tau)\rangle \right) \; , \end{aligned} \tag{35.187}$$

neglecting all terms which do not satisfy either $\mathcal{E}_n^*(t)\mathcal{E}_n(t)$ or $\mathcal{E}_n^*(t)\mathcal{E}_n(t+\tau)$. Now, assuming a large amount of identical atoms,

$$\begin{aligned} &\langle \mathcal{E}^*(t)\mathcal{E}^*(t+\tau)\mathcal{E}(t+\tau)\mathcal{E}(t)\rangle \\ &= N\langle \mathcal{E}_n^*(t)\mathcal{E}_n(t)\mathcal{E}_n^*(t+\tau)\mathcal{E}_n(t+\tau)\rangle + N(N-1)\left(\langle \mathcal{E}_n^*(t)\mathcal{E}_n(t)\rangle^2 + |\langle \mathcal{E}_n(t)\mathcal{E}_n^*(t+\tau)\rangle|^2\right) \\ &\simeq N^2\left(\langle \mathcal{E}_n^*(t)\mathcal{E}_n(t)\rangle^2 + |\langle \mathcal{E}_n(t)\mathcal{E}_n^*(t+\tau)\rangle|^2\right) \; . \end{aligned} \tag{35.188}$$

Finally, exploiting the result (35.184) and the definitions of the 1^{st} and 2^{nd} order correlations functions,

$$g^{(2)}(\tau) = \frac{\langle \mathcal{E}_n^*(t)\mathcal{E}_n(t)\rangle^2 + |\langle \mathcal{E}_n(t)\mathcal{E}_n^*(t+\tau)\rangle|^2}{\langle \mathcal{E}_n^*(t)\mathcal{E}_n(t)\rangle^2} = 1 + |g^{(1)}(\tau)|^2 \; . \tag{35.189}$$

In summary,

pressure broadening

$$\boxed{\begin{aligned} \mathcal{E}(t) &= \textstyle\sum_n e^{\imath\omega_0 t+\imath\phi_n(t)} \\ \implies g^{(1)}(\tau) &= e^{\imath\omega_0\tau-\gamma_c|\tau|} \\ \implies \mathcal{F}\left[g^{(1)}(\tau)\right] &= \frac{\gamma/\pi}{\Delta^2+\gamma_c^2} \\ g^{(2)}(\tau) &= 1+e^{-\gamma_c|\tau|} \end{aligned}} \quad . \tag{35.190}$$

The spectrum is a Lorentzian with the full linewidth $\gamma' = \gamma + \gamma_c$.

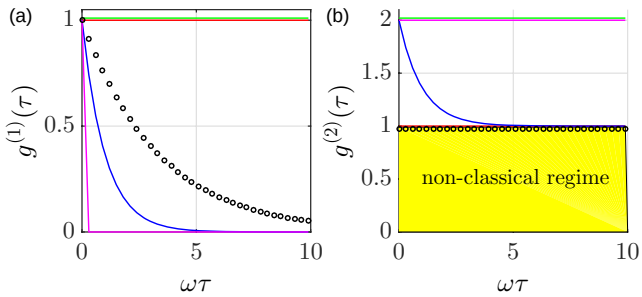

Figure 35.14: (code) First and second-order correlation functions for (red) a laser, (cyan) a laser subject to phase noise, (blue) a laser subject to collision broadening, (magenta) chaotic light, and (green) spectrally filtered thermal light.

35.5.3.4 Correlation functions with thermal broadening

For light emitted by an ensemble of non-colliding atoms in thermal motion, we must allow for different frequencies, $\mathcal{E}_n(t) = e^{\imath\omega_n t+\imath\phi_n}$, but time-independent phases,

$$\begin{aligned} \langle\mathcal{E}^*(t)\mathcal{E}(t+\tau)\rangle &= \int \sum_n e^{-\imath\omega_n t-\imath\phi_n} \sum_m e^{\imath\omega_m t+\imath\omega_m\tau+\imath\phi_m} dt \\ &= \sum_{n,m} \int e^{-\imath\omega_n t-\imath\phi_n+\imath\omega_m t+\imath\omega_m\tau+\imath\phi_m} dt = \sum_n e^{\imath\omega_n\tau} \quad . \end{aligned} \tag{35.191}$$

The crossed terms $n \neq m$ of this expressions vanish. *Doppler broadening* is inhomogeneous. Hence, the probability density for frequencies emitted by thermal atoms is

a Gaussian, $p(\omega)d\omega = (2\pi\delta)^{-1/2}e^{-(\omega_n-\omega_0)^2/2\delta^2}d\omega$, such that,

thermal ensemble

$$\boxed{\begin{aligned} \langle \mathcal{E}^*(t)\mathcal{E}(t+\tau)\rangle &= N(2\pi\delta)^{-1/2}\int e^{\imath\omega_n\tau}e^{-(\omega_n-\omega_0)^2/2\delta^2}d\omega_n \\ \Longrightarrow \quad g^{(1)}(\tau) &= e^{\imath\omega\tau-\delta^2\tau^2/2} \\ \Longrightarrow \quad \mathcal{F}[g^{(1)}(\tau)] &= \sqrt{\frac{\ln 2}{\pi\delta^2}}e^{-\ln 2\cdot\omega^2/\delta^2} \\ g^{(2)}(\tau) &= 1+e^{-\delta^2\tau^2/2} \end{aligned}} \quad . \tag{35.192}$$

For a totally emission *chaotic light*,

chaotic line

$$\boxed{\begin{aligned} g^{(1)}(\tau) &= \delta(0) \\ \mathcal{F}[g^{(1)}(\tau)] &= 1 \\ g^{(2)}(\tau) &= 1+|g^{(1)}(\tau)| \end{aligned}} \quad . \tag{35.193}$$

The last expression is known as *Bloch-Siegert relation*. Mono-mode chaotic light can be seen as incoherent multi-mode light, where all modes except a single mode are filtered by a Fabry-Pérot etalon. This light is characterized by $|g^{(1)}(\tau)| = 1$ and $g^{(2)}(\tau) = 2$, despite the coherence length being $\tau \to \infty$. Do the Excs. 35.5.5.1 to 35.5.5.3.

35.5.4 Photon counting statistics

35.5.4.1 Photon counting with classical fields

There is a nice introduction by [816], p.229. Irradiate a photon counter with efficiency η with a classical light beam of cycle-averaged intensity $I(t)$. The probability density of registering a count is $p(t) = \eta I(t)$. Now consider a time interval $[t, t+T]$. Be $P_m(t,T)$ the probability to encounter m counts. We now separate a time period dt which is too short to yield more than one photon, $[t, t+t'+dt]$. Then the probability of finding m photons in this interval is,

$$P_m(t,t'+dt) = P_m(t,t')[1-p(t)]dt + P_{m-1}(t,t')p(t)dt \ . \tag{35.194}$$

From this one derives a differential equation, whose solution is,

$$P_m(t,T) = \frac{\left(\int_t^{t+T}p(t')dt'\right)^m}{m!}\exp\left(-\int_t^{t+T}p(t')dt'\right) \ . \tag{35.195}$$

Defining $\bar{I}(t,T) \equiv T^{-1}\int_t^{t+T}I(t')dt'$ and averaging over a number of initial start times t,

$$P_m(T) \equiv \langle P_m(t,T)\rangle_t = \left\langle \frac{\left[\eta T\bar{I}(t,T)\right]^m}{m!}\,e^{-\eta T\bar{I}(t,T)}\right\rangle_t \ . \tag{35.196}$$

The probability follows as an approximation to a binomial distribution. One can show that for noise-free light as well as for chaotic light with short coherence length the distribution is Poissonian. For chaotic light with long coherence length it is thermal.

35.5.4.2 Photon counting with quantum fields

Quantum mechanically the probability is obtained by replacing the intensity by an operator and the starting time averaging by a trace over the density operator and the normal-ordered probability P_m [516, 515, 1310, 1154],

$$P_m(T) = \mathrm{Tr}\ \hat{\rho}\mathcal{N}\ \frac{\left[\eta T \hat{I}(T)\right]^m}{m!}\ e^{-\eta T \hat{I}(T)}\ , \tag{35.197}$$

where $\hat{I}(T) \equiv T^{-1}\int_0^T 2\varepsilon_0 c\hat{\mathcal{E}}^-(\mathbf{r},t)\hat{\mathcal{E}}^+(\mathbf{r},t)dt$. The field operators can be expanded, $\hat{\mathcal{E}}^+(\mathbf{r},t) = \imath\hat{\epsilon}\sqrt{\hbar\omega/2\varepsilon_0 V}e^{-\imath\omega t+\imath\mathbf{k}\cdot\mathbf{r}}\hat{b}$, only considering one mode. We obtain,

$$P_m(T) = \mathrm{Tr}\ \hat{\rho}\mathcal{N}\ \frac{(\xi\hat{b}^\dagger\hat{b})^m}{m!}\ e^{-\xi\hat{b}^\dagger\hat{b}}\ . \tag{35.198}$$

where $\xi \equiv \eta c\hbar\omega T/V$ is the quantum efficiency,

$$\begin{aligned} P_m(T) &= \frac{1}{m!}\sum_k \langle k|\,\hat{\rho}\sum_n |n\rangle\langle n|\mathcal{N}\ (\xi\hat{b}^\dagger\hat{b})^m \sum_l \frac{(-\xi\hat{b}^\dagger\hat{b})^l}{l!}|k\rangle \\ &= \sum_{k=m}^{\infty} P_k \sum_{l=0}^{k-m}\frac{\xi^m(-\xi)^l}{m!l!}\langle k|(\hat{b}^\dagger)^{m+l}(\hat{b})^{m+l}\,|k\rangle \\ &= \sum_{k=m}^{\infty} P_k \sum_{l=0}^{k-m}\frac{\xi^m(-\xi)^l}{l!}\frac{k!}{m!(k-m-l)!} \\ &= \sum_{k=m}^{\infty} P_k \binom{k}{m}\xi^m \sum_{l=0}^{k-m}\binom{k-m}{l}(-\xi)^l = \sum_{k=m}^{\infty} P_k\binom{k}{m}\xi^m(1-\xi)^{k-m}\ . \end{aligned} \tag{35.199}$$

Second-order correlation (for a single mode there is no time-dependence),

$$\begin{aligned} \frac{1}{\bar{m}^2}\sum_m m(m-1)P_m(T) &= \frac{1}{(\xi\bar{n})^2}\sum_m m(m-1)\sum_{n=m}^{\infty} P_n\binom{n}{m}\xi^m(1-\xi)^{n-m} \\ &= \frac{1}{\bar{n}^2}\sum_n n(n-1)P_n\sum_{m<n}\binom{n-2}{m-2}\xi^{m-2}(1-\xi)^{n-m} \\ &= \frac{1}{\bar{n}^2}\sum_n n(n-1)P_n = \frac{\langle n(n-1)\rangle}{\langle\bar{n}\rangle^2} \equiv g^{(2)}(\tau)\ . \end{aligned} \tag{35.200}$$

For a photon number state $\rho = |n\rangle\langle n|$ and $P_k = \delta_{nk}$,

$$\begin{aligned} P_m(T) &= \binom{n}{m}\xi^m(1-\xi)^{n-m} \\ g^{(2)}(\tau) &= \frac{1}{\bar{n}^2}\sum_k k(k-1)\delta_{nk} = \frac{1}{n^2}n(n-1) = 1-\frac{1}{n}\ . \end{aligned} \tag{35.201}$$

For a coherent state $\rho = \sum_n \frac{|\alpha|^n e^{-|\alpha|}}{\sqrt{n!}}|n\rangle\langle n|$ and $P_k = \frac{\bar{n}^k}{k!}e^{-\bar{n}}$,

$$P_m(T) = \sum_k \frac{\bar{n}^k}{k!}e^{-\bar{n}}\binom{k}{m}\xi^m(1-\xi)^{k-m} \tag{35.202}$$
$$= \frac{(\xi\bar{n})^m}{m!}e^{-\bar{n}}\sum_{k'=0}^{\infty}\frac{\bar{n}^{k'}(1-\xi)^{k'}}{k'!} = \frac{(\xi\bar{n})^m}{m!}e^{-\xi\bar{n}}$$
$$g^{(2)}(\tau)\frac{1}{\bar{n}^2}\sum_k k(k-1)\frac{\bar{n}^k}{k!}e^{-\bar{n}} = \sum_{k'}\frac{\bar{n}^{k'}}{k'!}e^{-\bar{n}} = 1 \ .$$

Similarly we get for a thermal state,

$$P_m(T) = \frac{(\xi\bar{n})^m}{(1+\xi\bar{n})^{1+m}}g^{(2)}(\tau) = \frac{1}{\bar{n}^2}\sum_k k(k-1)\frac{\bar{n}^k}{(1+\bar{n})^k} \tag{35.203}$$
$$= \frac{1}{(1+\bar{n})^2}\sum_{k'}(k+2)(k+1)\frac{\bar{n}^{k'}}{(1+\bar{n})^{k'}}$$
$$= \frac{1}{(1+\bar{n})^2}\frac{2}{\left[1-\bar{n}/(1+\bar{n})\right]^3} = 2(1+\bar{n}) \ .$$

35.5.4.3 Quantum correlations

Defining the intensity as $\hat{I} = 2\varepsilon_0 c\hat{\mathcal{E}}^+\hat{\mathcal{E}}^-$, the coherences become,

$$g^{(1)}(\tau) \equiv \tfrac{2\varepsilon_0 c}{I}\langle\mathcal{TN}\hat{\mathcal{E}}^-(t)\hat{\mathcal{E}}^+(t+\tau)\rangle \qquad \text{and} \qquad g^{(2)}(\tau) \equiv \left(\tfrac{2\varepsilon_0 c}{I}\right)^2\langle\mathcal{TN}\hat{I}(t)\hat{I}(t+\tau)\rangle \ . \tag{35.204}$$

The correlation functions must be calculated from the field operators simultaneously respecting *time order* and *normal order*.

35.5.4.4 Generalization for time-dependent fields and finite detector bandwidth

The measured count rate is then replaced by,

$$\xi\hat{b}^\dagger\hat{b} \to \int_0^T d\tau\int_0^T d\tau'\xi(\tau-\tau')\hat{b}^\dagger(\tau)\hat{b}(\tau') \tag{35.205}$$

with the spectral sensitivity,

$$\xi(\tau-\tau') \equiv \frac{1}{2\pi}\int_{-\infty}^{\infty}\xi(\omega)e^{-\imath\omega(\tau-\tau')}d\omega \ . \tag{35.206}$$

For large detector bandwidth $\xi(\omega) = \xi$, so that we may set $\xi\hat{b}^\dagger\hat{b} \to \xi\int_0^T d\tau\hat{b}^\dagger(\tau)\hat{b}(\tau)$. For this case the probability becomes,

$$P_m(T) = \mathrm{Tr}\ \hat{\rho}\mathcal{TN}\ \frac{1}{m!}\ \hat{B}(T)^m\ e^{-\hat{B}(T)} \ , \tag{35.207}$$

where $\hat{B}(T) \equiv \xi\int_0^T d\tau\hat{b}^\dagger(\tau)\hat{b}(\tau)$.

Carrying out the ordering we get now,

$$P_k(T) = \left\langle \sum_{l=0}^{\infty} \frac{(-\xi)^{k+l}}{k!l!} \mathcal{TN} \int_0^T d\tau_1 \int_0^T d\tau_2 .. \int_0^T d\tau_{k+l}\ \hat{b}^\dagger(\tau_1)\hat{b}(\tau_1)\hat{b}^\dagger(\tau_2)\hat{b}(\tau_2)..\hat{b}^\dagger(\tau_{k+l})\hat{b}(\tau_{k+l}) \right\rangle \tag{35.208}$$

$$= \left\langle \sum_{l=0}^{\infty} \frac{(-\xi)^{k+l}}{k!l!} \int_0^T d\tau_1 \int_0^{\tau_1} d\tau_2 .. \int_0^{\tau_{k+l-1}} d\tau_{k+l}\ \hat{b}^\dagger(\tau_1)\hat{b}^\dagger(\tau_2)..\hat{b}^\dagger(\tau_{k+l})\hat{b}(\tau_{k+l})..\hat{b}(\tau_2)\hat{b}(\tau_1) \right\rangle ,$$

when we assume $d\tau_1 < d\tau_2 < .. < d\tau_{n+l}$.

The expectation value for registering n counts is,

$$\langle n\rangle(T) = \sum_k k P_k(T) \stackrel{?}{=} \langle \mathcal{TN}\ \hat{B}(T)\rangle \tag{35.209}$$

$$= \sum_k \frac{1}{(k-1)!} \left\langle \mathcal{TN}\ \hat{B}(T)^k\ e^{-\hat{B}(T)} \right\rangle = \xi \int_0^T d\tau \left\langle \hat{b}^\dagger(\tau)\hat{b}(\tau) \right\rangle .$$

The variance is often described by Mandel's Q-function,

$$Q(T) \equiv \frac{\langle \Delta n^2\rangle(T) - \langle n\rangle(T)}{\langle n\rangle(T)} = \frac{\langle n(n-1)\rangle(T) - \langle n\rangle^2(T)}{\langle n\rangle(T)} . \tag{35.210}$$

We have,

$$\langle n(n-1)\rangle(T) = \sum_k k(k-1) P_k(T) \stackrel{?}{=} \langle \mathcal{TN}\ \hat{A}^2(T)\rangle \tag{35.211}$$

$$\stackrel{?}{=} \eta^2 \int_0^T d\tau \int_0^T d\tau' \left\langle \mathcal{TN} \hat{b}^\dagger(\tau)\hat{b}^\dagger(\tau')\hat{b}(\tau')\hat{b}(\tau) \right\rangle . \tag{35.212}$$

The conditional probability to detect a photon at time $t = \tau$ after a successful detection at time $t = 0$ is,

$$g^{(2)}(\tau) \equiv \frac{\left\langle \mathcal{TN} \hat{b}^\dagger(\tau)\hat{b}^\dagger(\tau')\hat{b}(\tau')\hat{b}(\tau) \right\rangle}{\left\langle \hat{b}^\dagger(\tau)\hat{b}(\tau) \right\rangle^2} , \tag{35.213}$$

hence,

$$Q(T) = \langle n\rangle(T) \left(\frac{\int_t^{t+T} d\tau \int_t^{t+T} d\tau' S^2(\tau - \tau')\, \langle \mathcal{TN} \mathcal{E}^-(\tau)\mathcal{E}^-(\tau')\mathcal{E}^+(\tau')\mathcal{E}^+(\tau)\rangle}{\left(S \int_t^{t+T} d\tau \langle \mathcal{E}^-(\tau)\mathcal{E}^+(\tau)\rangle \right)^2} - 1 \right)$$

$$= 2\frac{\langle n\rangle(T)}{T^2} \int_0^T d\tau (T-\tau)[g^{(2)}(\tau) - 1] . \tag{35.214}$$

I.e. we can follow the evolution of the photon number variance as time goes on [1310, 1232, 1266].

35.5.4.5 Waiting time distributions

The conditional probability $\tilde{P}(\tau)$ that after a detection at time 0 any other photon (not necessarily the next one) is detected at time τ is the sum of the probabilities to detect the first, the second, etc. photon,

$$\tilde{P}(\tau) = \sum_k P^{(k)}(\tau) \ . \tag{35.215}$$

Now $P^{(2)}(\tau) = \int_0^\tau P^{(1)}(t)P^{(1)}(\tau - t)dt$, so that

$$g^{(2)}(\tau) \propto \tilde{P}(\tau) \ . \tag{35.216}$$

35.5.5 Exercises

35.5.5.1 Ex: Correlation functions for two light modes

a. Calculate $|g^{(1)}(\tau)|$, $F_{\mathcal{E}}(\omega)$, and $|g^{(2)}(\tau)|$ for two interfering and non-interfering modes neglecting fluctuations.
b. What changes when one mode is broadened by random noise, e.g. induced by spontaneous emission?

Solution: *a. We denote the modes by $\mathcal{E}(t) = e^{\imath\omega_1 t} + e^{\imath\omega_2 t}$, and calculate subsequently the autocorrelation function,*

$$R_{\mathcal{E}}(\tau) = e^{-\imath\omega_1\tau} + e^{-\imath\omega_2\tau} \ ,$$

the $g^{(1)}$-function,

$$g^{(1)}(\tau) = \frac{R_{\mathcal{E}}(\tau)}{R_{\mathcal{E}}(0)} = \frac{e^{-\imath\omega_1\tau} + e^{-\imath\omega_2\tau}}{2}$$

and its absolute value,

$$|g^{(1)}(\tau)| = \sqrt{\tfrac{e^{-\imath\omega_1\tau}+e^{-\imath\omega_2\tau}}{2}\,\tfrac{e^{\imath\omega_1\tau}+e^{\imath\omega_2\tau}}{2}} = \sqrt{\tfrac{1}{2} + \tfrac{1}{2}\cos(\omega_1 - \omega_2)\tau} = \cos\tfrac{(\omega_1-\omega_2)\tau}{2} \ ,$$

and the spectrum,

$$F_{\mathcal{E}}(\omega) = \frac{1}{2\pi}\int_{-\infty}^{\infty} g^{(1)}(\tau)e^{\imath\omega\tau}d\tau = \frac{1}{4\pi}\int_{-\infty}^{\infty}(e^{-\imath\omega_1\tau}+e^{-\imath\omega_2\tau})e^{\imath\omega\tau}d\tau = \tfrac{1}{2}[\delta(\Delta_1)+\delta(\Delta_2)] \ .$$

Hence, while two non-interfering modes without fluctuations satisfy $|g^{(1)}(\tau)| = 1$, two interfering modes without fluctuations satisfy $|g^{(1)}(\tau)| = \cos\frac{1}{2}(\omega_1 - \omega_2)\tau$. The $g^{(2)}$-function is,

$$g^{(2)}(\tau) = \frac{\langle\mathcal{E}^*(t)\mathcal{E}^*(t+\tau)\mathcal{E}(t+\tau)\mathcal{E}(t)\rangle}{\langle\mathcal{E}^*(t)\mathcal{E}(t)\rangle^2} = \frac{\langle\cos^2\frac{(\omega_1-\omega_2)t}{2}\cos^2\frac{(\omega_1-\omega_2)(t+\tau)}{2}\rangle}{\langle\cos^4\frac{(\omega_1-\omega_2)t}{2}\rangle} \ .$$

Using,

$$\lim_{t\to\infty}\tfrac{1}{t}\int_0^t \cos^2 x\cos^2(x+y)dx = \tfrac{1}{4}\cos^2 y + \tfrac{1}{8} \ ,$$

we find,

$$g^{(2)}(\tau) = \tfrac{2}{3} + \tfrac{1}{3}\cos(\omega_1 - \omega_2)\tau \ .$$

b. In analogy to (a) we now consider $\mathcal{E}(t) = e^{\imath\omega_1 t} + e^{\imath\omega_2 t + \zeta(t)}$ *and calculate,*

$$\begin{aligned} R_{\mathcal{E}}(\tau) &= e^{-\imath\omega_1\tau} + e^{-\imath\omega_2\tau}\langle e^{\imath\zeta(t)-\imath\zeta(t+\tau)}\rangle + \cancelto{0}{\langle e^{-\imath\omega_1\tau}e^{\imath(\omega_2-\omega_1)t+\imath\zeta(t)}\rangle} + \cancelto{0}{\langle e^{-\imath\omega_2\tau}e^{\imath(\omega_1-\omega_2)t-\imath\zeta(t+\tau)}\rangle} \\ &= e^{-\imath\omega_1\tau} + e^{-\imath\omega_2\tau}e^{-\gamma\tau} \ , \end{aligned}$$

and

$$g^{(1)}(\tau) = \tfrac{1}{2}e^{-\imath\omega_1\tau} + e^{-\imath\omega_2\tau}e^{-\gamma\tau} \ ,$$

and

$$F_{\mathcal{E}}(\omega) = \delta(\Delta_1) + \frac{\gamma/\pi}{\Delta_2^2 + \gamma^2} \ .$$

35.5.5.2 Ex: Correlation functions and spectra of phase- and amplitude-modulated light

a. Calculate $g^{(1)}(\tau)$, $S_{\mathcal{E}}(\omega)$, and $g^{(2)}(\tau)$ for amplitude-modulated light: $\mathcal{E}_{am}(t) = e^{\imath\omega_0 t}(1 + M\cos\Omega t)$.
b. Calculate $g^{(1)}(\tau)$, $S_{\mathcal{E}}(\omega)$, and $g^{(2)}(\tau)$ for phase-modulated light: $\mathcal{E}_{pm}(t) = e^{\imath\omega_0 t + \imath M\cos\Omega t}$.
c. Repeat the calculation (a) for exponentially decaying amplitude-modulated light: $\mathcal{E}_{dam}(t) = e^{-\gamma t}e^{\imath\omega_0 t}(1 + M\cos\Omega t)$. See also 52.3.3.1.

Solution: *We use the definition of the first-order correlation function,*

$$g^{(1)}(\tau) \equiv \frac{\langle \mathcal{E}^*(t)\mathcal{E}(t+\tau)\rangle}{\langle \mathcal{E}^*(t)\mathcal{E}(t)\rangle} \qquad \textit{where} \qquad \langle ...\rangle \equiv \lim_{t\to\infty}\frac{1}{t}\int_0^t ...dt' \ .$$

a. The electric field of amplitude-modulated light is given by,

$$\mathcal{E}_{am}(t) = e^{\imath\omega_0 t}(1 + M\cos\Omega t) = e^{\imath\omega_0 t}(1 + \tfrac{M}{2}e^{\imath\Omega t} + \tfrac{M}{2}e^{-\imath\Omega t}) \ .$$

From this,

$$\begin{aligned} \langle \mathcal{E}^*_{am}(t)\mathcal{E}_{am}(t+\tau)\rangle &= e^{-\imath\omega_0\tau}\langle [1 + M\cos\Omega t)(1 + M\cos\Omega(t+\tau)]\rangle \\ &= e^{-\imath\omega_0\tau}\langle 1 + M\cos\Omega t + M\cos\Omega(t+\tau) + M^2\cos\Omega\tau\langle\cos^2\Omega t\rangle - M^2\sin\Omega\tau\langle\sin\Omega t\cos\Omega t\rangle \\ &= e^{-\imath\omega_0\tau}\left(1 + \tfrac{1}{2}M^2\cos\Omega\tau\right) \ . \end{aligned}$$

Hence,

$$\boxed{g^{(1)}_{am}(\tau) = e^{-\imath\omega_0\tau}\frac{2 + M^2\cos\Omega\tau}{2 + M^2}} \ . \tag{35.217}$$

The spectrum follows from (35.178),

$$S_{\mathcal{E}}(\omega) = \frac{1}{2\pi}\int_{-\infty}^{\infty} g^{(1)}(\tau)e^{\imath\omega\tau}d\tau \ .$$

Expanding the correlation function (35.217) for amplitude-modulated light in exponentials, using $\int_{-\infty}^{\infty} e^{-\imath\omega\tau}d\tau = \delta(\omega)$*, it is easy to see that,*

$$\boxed{S_{\mathcal{E}}(\omega) = \frac{1}{2\pi}\frac{1}{2+M^2}\left[2\delta(\Delta) + \tfrac{M^2}{2}\delta(\Delta+\Omega) + \tfrac{M^2}{2}\delta(\Delta-\Omega)\right]} \ ,$$

with $\Delta \equiv \omega - \omega_0$*.*
The $g^{(2)}(\tau)$ *function follows easily from its definition,*

$$g^{(2)}(\tau) = \frac{\langle E^*(t)E^*(t+\tau)E(t+\tau)E(t)\rangle}{\langle E^*(t)E(t)\rangle^2} = \frac{\langle (1+M\cos\Omega t)(1+M\cos\Omega(t+\tau))\rangle}{\langle (1+M\cos\Omega t)\rangle^2} \ .$$

Using,

$$\lim_{t\to\infty}\tfrac{1}{t}\int_0^t (1+M\cos x)(1+M\cos(x+y))dx = 1 + \tfrac{M^2}{2}\cos y \ ,$$

we find,

$$g^{(2)}(\tau) = 1 + \tfrac{M^2}{2}\cos\Omega\tau \ .$$

b. The electric field of phase-modulated light is given by,

$$\mathcal{E}_{pm}(t) = e^{\imath\omega t + \imath M\cos\Omega t} = e^{\imath\omega t}\sum_{k=-\infty}^{\infty} J_k(M)e^{\imath k\Omega t} \ .$$

From this,

$$\begin{aligned}\langle \mathcal{E}^-_{pm}(t)\mathcal{E}^+_{pm}(t+\tau)\rangle &= e^{-\imath\omega_0\tau}\langle e^{\imath M\cos\Omega t}e^{-\imath M\cos\Omega(t+\tau)}\rangle \\ &= e^{-\imath\omega_0\tau}\sum_{k,m=-\infty}^{\infty} J_k(M)J_m(-M)e^{\imath m\Omega\tau}\langle e^{\imath(k+m)\Omega t}\rangle = e^{-\imath\omega_0\tau}\sum_{k=-\infty}^{\infty} J_k(M)^2 e^{-\imath k\Omega\tau} \ ,\end{aligned}$$

with $\langle e^{\imath(k+m)\Omega t}\rangle = \delta_{k,-m}$ *and* $J_{-k}(M) = J_k(-M) = (-1)^k J_k(M)$*. Hence, using,*

$$\sum_{k=-\infty}^{\infty} J_k(x) = \sum_{k=-\infty}^{\infty} J_k(x)^2 = 1 \neq \sum_{k=-\infty}^{\infty} |J_k(x)|^2 \ ,$$

we find,

$$\boxed{g^{(1)}_{pm}(\tau) = e^{-\imath\omega_0\tau}\frac{\sum_{k=-\infty}^{\infty} J_k(M)^2 e^{-\imath k\Omega\tau}}{\sum_{k=-\infty}^{\infty} J_k(M)^2}} \ .$$

The spectrum is, in this case,

$$\boxed{S_{\mathcal{E}}(\omega) = \frac{1}{2\pi}\frac{1}{\sum_{k=-\infty}^{\infty} J_k(M)^2}\sum_{k=-\infty}^{\infty} J_k(M)^2\delta(\Delta+k\Omega)} \ .$$

The $g^{(2)}(\tau)$ *function is trivially calculated from its definition,*

$$g^{(2)}(\tau) = \frac{\langle \mathcal{E}^*(t)\mathcal{E}^*(t+\tau)\mathcal{E}(t+\tau)\mathcal{E}(t)\rangle}{\langle \mathcal{E}^*(t)\mathcal{E}(t)\rangle^2} = 1 \ .$$

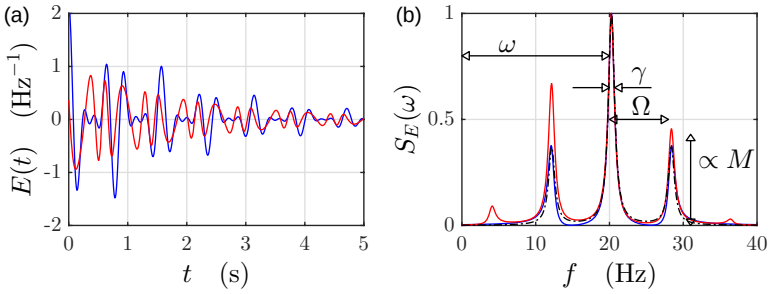

Figure 35.15: (code) (a) AM (blue) and PM-modulated field (red). (b) Numerically calculated pectra for AM (blue) and PM-modulated light (red). Analytically calculated spectrum (black).

c. The electric field of exponentially decaying amplitude-modulated light is given by,

$$\mathcal{E}_{dam}(t) = e^{-\gamma t} e^{\imath\omega_0 t}(1 + M\cos\Omega t) \ .$$

From this,

$$\begin{aligned}
&\langle \mathcal{E}^-_{dam}(t)\mathcal{E}^+_{dam}(t+\tau)\rangle \\
&= e^{-\imath\omega_0\tau-\gamma\tau} \lim_{t\to\infty} \frac{1}{t}\int_0^t e^{-2\gamma t}\left[1 + M\cos\Omega t + M\cos\Omega(t+\tau) + M\cos(\Omega t)M\cos(\Omega(t+\tau))\right] dt \\
&= e^{-\imath\omega_0\tau-\gamma\tau} \lim_{t\to\infty} \frac{1}{t}\int_0^t e^{-2\gamma t} M\cos(\Omega t)M\cos(\Omega(t+\tau))dt \\
&= e^{-\imath\omega_0\tau-\gamma\tau} \lim_{t\to\infty} \left[\begin{array}{l}
\frac{1-e^{-2\gamma t}}{2\gamma t} + \frac{M}{t}\frac{2\gamma - 2\gamma e^{-2\gamma t}\cos\Omega t + \Omega e^{-2\gamma t}\sin\Omega t}{4\gamma^2+\Omega^2} \\
+\frac{M}{t}\frac{2\gamma\cos\Omega\tau - \Omega\sin\Omega\tau - 2\gamma e^{-2\gamma t}\cos\Omega(t+\tau) + \Omega e^{-2\gamma t}\sin\Omega(t+\tau)}{4\gamma^2+\Omega^2} \\
-\frac{M^2}{4\gamma t}\frac{\left(-2\gamma^2-\Omega^2+\gamma^2 e^{-2\gamma t}+\Omega^2 e^{-2\gamma t}\right)\cos\Omega\tau + \gamma\Omega\sin\Omega\tau + e^{-2\gamma t}\gamma^2\cos\Omega(2t+\tau) - e^{-2\gamma t}\gamma\Omega\sin\Omega(2t+\tau)}{\gamma^2+\Omega^2}
\end{array}\right]
\end{aligned}$$

Hence,

$$\begin{aligned}
g^{(1)}_{dam}(\tau) &= e^{-\imath\omega_0\tau-\gamma\tau}\frac{\lim_{t\to\infty}\langle\mathcal{E}^*(t)\mathcal{E}(t+\tau)\rangle}{\lim_{t\to\infty}\langle\mathcal{E}^*(t)\mathcal{E}(t)\rangle} = e^{-\imath\omega_0\tau-\gamma\tau}\frac{\lim_{t\to\infty} t\langle\mathcal{E}^*(t)\mathcal{E}(t+\tau)\rangle}{\lim_{t\to\infty} t\langle\mathcal{E}^*(t)\mathcal{E}(t)\rangle} \\
&= e^{-\imath\omega_0\tau-\gamma\tau}\frac{1 + M\frac{4\gamma^2(1+\cos\Omega\tau) - 2\gamma\Omega\sin\Omega\tau}{4\gamma^2+\Omega^2} + \frac{M^2}{2}\frac{(2\gamma^2+\Omega^2)\cos\Omega\tau + \gamma\Omega\sin\Omega\tau}{\gamma^2+\Omega^2}}{1 + M\frac{8\gamma^2}{4\gamma^2+\Omega^2} + \frac{M^2}{2}\frac{2\gamma^2+\Omega^2}{\gamma^2+\Omega^2}} \ .
\end{aligned}$$

For $\gamma \ll \Omega$ we recover the result (35.217). For $\Omega \ll \gamma$ we get,

$$g^{(1)}_{dam} \overset{\Omega\ll\gamma}{\longrightarrow} e^{-\imath\omega\tau-\gamma\tau}\frac{1 + M + M^2 + M\cos\Omega\tau}{(1+M)^2} \ .$$

The spectrum is, in this case, similar to the amplitude-modulated one, only are the sidebands Lorentz-broadened.

35.5.5.3 Ex: Phase modulation

a. Show that it is not possible to construct a periodic phase modulation function such that the signal has only two sidebands.

b. From $1 = |e^{\imath M \sin \Omega t}|^2$ derive a sum rule for the Bessel functions.
c. Discuss the difference of the spectra $\sum_{k=-\infty}^{\infty} J_k(M) e^{\imath k \Omega t}$ and $\sum_{k=-\infty}^{\infty} |J_k(M)| e^{\imath k \Omega t}$.

Solution: *a. The question is whether there is a periodic function $f(t)$ such that*

$$e^{\imath \omega t + \imath f(t)} = e^{\imath \omega t} + M e^{\imath(\omega+\Omega)t} - M e^{\imath(\omega-\Omega)t}$$

or equivalently $e^{\imath f(t)} = 1 + 2\imath M \sin \Omega t$. Such a function would have to satisfy,

$$1 = |1 + 2\imath M \sin \Omega t|^2 = 1 + 4M^2 \sin^2 \Omega t \ ,$$

which only holds for $M = 0$.
b. In contrast, a sinusoidal phase modulation satisfies,

$$1 = |e^{\imath M \sin \Omega t}|^2 = \left| \sum_{k=-\infty}^{\infty} J_k(M) e^{\imath k \Omega t} \right|^2 = \sum_{k,m=-\infty}^{\infty} J_k(M) J_m(M) e^{\imath(k-m)\Omega t} \ .$$

This can only be true at all times if,

$$1 = \sum_{k=-\infty}^{\infty} J_k(M)^2 \ .$$

c. In Exc. 35.5.5.1(c) we have seen, that the spectrum of phase-modulated light, $\sum_{k=-\infty}^{\infty} J_k(M) e^{\imath k \Omega t}$, is given by,

$$S_{\mathcal{E}}(\omega) = \frac{1}{2\pi} \frac{1}{\sum_{k=-\infty}^{\infty} J_k(M)^2} \sum_{k=-\infty}^{\infty} J_k(M)^2 \delta(\Delta + k\Omega) \ .$$

Similarly, we obtain for $\sum_{k=-\infty}^{\infty} |J_k(M)| e^{\imath k \Omega t}$,

$$S_{\mathcal{E}}(\omega) = \frac{1}{2\pi} \frac{1}{\sum_{k=-\infty}^{\infty} |J_k(M)|^2} \sum_{k=-\infty}^{\infty} J_k(M)^2 \delta(\Delta + k\Omega) \ .$$

Thus, the spectra are indistinguishable, and one must resort to phase-sensitive spectroscopy to distinguish both cases.

35.5.5.4 Ex: Non-classicality of antibunched states

Quantized radiation fields can exhibit the feature of antibunching, which is incompatible with the classical concept of radiation. Show that $g^{(2)}(0) < 1$ entails the possibility of negative values for the Glauber-Sudarshan P-function, that is, $P(\alpha) < 0$ at least for some α.

Solution: *The Glauber-Sudarshan P-function defined via the density operator, $\hat{\rho} = \int P(\alpha) |\alpha\rangle\langle\alpha| d^2\alpha$, allows to express the expectation value as,*

$$\langle \hat{A} \rangle = Tr\ \hat{A}\hat{\rho} = \int P(\alpha) \langle\alpha|\hat{A}|\alpha\rangle d^2\alpha \ .$$

Antibunching, that is $g^{(2)}(0) < 1$, *implies*

$$0 > \langle \hat{a}^\dagger \hat{a}^\dagger \hat{a}\hat{a} \rangle - \langle \hat{a}^\dagger \hat{a} \rangle^2 = \int P(\alpha) |\alpha|^4 d^2\alpha - \left(\int P(\alpha) |\alpha|^2 d^2\alpha \right)^2$$
$$= \int P(\alpha) \left(|\alpha|^2 - \int P(\beta) |\beta|^2 d^2\beta \right)^2 d^2\alpha = \int P(\alpha) \left(|\alpha|^2 \langle \hat{a}^\dagger \hat{a} \rangle \right)^2 d^2\alpha$$

using the normalization condition $\int P(\alpha) d^2\alpha = 1$. *This is only possible to satisfy the quasi-probability distribution is negative at least for some* α.

35.6 Spontaneous emission and light scattering

35.6.1 Interaction of atoms with vacuum modes

The Jaynes-Cummings Hamiltonian (35.11), discussed in Sec. 35.4, describes the purely coherent dynamics of a single immobile two-level atom interacting with a single cavity mode. The model is simple enough to allow for analytical solutions. However, it does not include processes of spontaneous emission, which can be understood as the interaction of the atom with the light modes of the vacuum. That is, we must extend the Hamiltonian,

$$\hat{H} = \hat{H}_{atom} + \hat{H}_{field} + \hat{H}_{atom:field} + \hat{H}_{vacuum} + \hat{H}_{atom:vacuum} \ . \tag{35.218}$$

The evolution of the system represented by the Hamiltonian (35.218) is described by a total density operator, $\hat{\rho}_{total}(t)$, obeying the *von Neumann equation*,

$$\boxed{\frac{d\hat{\rho}_{total}}{dt} = -\frac{\imath}{\hbar}[\hat{H}, \hat{\rho}_{total}]} \ , \tag{35.219}$$

which has the solution,

$$\hat{\rho}_{total}(t) = e^{-\imath \hat{H} t/\hbar} \hat{\rho}_{total}(0) e^{\imath \hat{H} t/\hbar} \equiv e^{-\imath \mathcal{L} t} \hat{\rho}_{total}(0) \ . \tag{35.220}$$

Often, we are only interested in *either* the evolution of the light field, *or* the internal state of the atom. In these cases, we calculate the trace over all those degrees of freedom, which are we are NOT interested in,

$$\hat{\rho}_{atom} = \mathrm{Tr}_{vacuum} \ \hat{\rho}_{total} \ . \tag{35.221}$$

The procedure is the following. We begin choosing the initial state of the electromagnetic vacuum as the photonic vacuum $\hat{\rho}_{vacuum} = |\{0\}\rangle\langle\{0\}|$ and defining a projection operator onto this state, $\hat{P}... \equiv \hat{\rho}_{vacuum}(0)\mathrm{Tr}_{vacuum} ... = \hat{P}^2....$ Then we apply to the von Neumann equation the rotating wave, the Markov and the Born approximations. Finally, tracing over the vacuum field variables, we obtain after some calculations the *Bloch-Lindbladt equation* or *master equation* [1062] for the atom interacting with the driving field. For a discussion of the validity of the Born-Markov approximation [932]. For the relation between the Markov approximation and the Fermi's Golden Rule [17].

We emphasize that the Hamiltonian (35.218) describes the interaction of light with a *single immobile atom* at the most fundamental level. However, it excludes many-body effects introduced by quantum statistics or interatomic interactions (to be discussed in Chp. 45), as well as the center-of-mass motion of the atom and the impact of photonic recoil (to be discussed in Chp. 38).

In the following section we give a simplified derivation concentrating us on the situation of a single motionless atom, excited by a laser and emitting photons into the electromagnetic vacuum.

35.6.1.1 Spontaneous emission

Spontaneous emission can be understood as an energy diffusion process from a system with a restricted number of degrees of freedom into a large thermal bath. For example, although a two-dimensional Hilbert space is sufficient to describe a laser-driven two-level atom, this atom couples to a huge phase-space by spontaneously emitting photons into arbitrary directions. We account for his fact by including in the Hamiltonian not only the interaction of the atom with the incident laser (wavevector $\mathbf{k}_0$, frequency $\omega_{\mathbf{k}_0}$), but also with the modes of the electromagnetic vacuum (wavevector $\mathbf{k}$, frequency $\omega_{\mathbf{k}}$). We will see, that with this Hamiltonian, we can derive, in a calculation is known as *Weisskopf-Wigner theory*, the Schrödinger equation for the amplitudes of the atomic levels (34.184) including spontaneous emission.

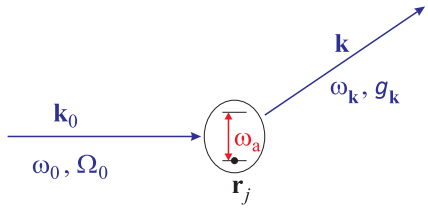

Figure 35.16: Scattering of a laser beam by an atom.

Denoting the frequency of the atomic resonance by ω_a, the interaction part of the Hamiltonian is,

$$\boxed{\begin{aligned}\hat{H} &= \hbar g_{\mathbf{k}_0}\left(\hat{\sigma}^- e^{-\imath\omega_a t}+\hat{\sigma}^+ e^{\imath\omega_a t}\right)\left(\hat{a}^\dagger_{\mathbf{k}_0} e^{\imath\omega_0 t-\imath\mathbf{k}_0\cdot\mathbf{r}}+\hat{a}_{\mathbf{k}_0} e^{-\imath\omega_0 t+\imath\mathbf{k}_0\cdot\mathbf{r}}\right)\\ &+ \sum_{\mathbf{k}}\hbar g_{\mathbf{k}}\left(\hat{\sigma}^- e^{-\imath\omega_a t}+\hat{\sigma}^+ e^{\imath\omega_a t}\right)\left(\hat{a}^\dagger_{\mathbf{k}} e^{\imath\omega_{\mathbf{k}} t-\imath\mathbf{k}\cdot\mathbf{r}}+\hat{a}_{\mathbf{k}} e^{-\imath\omega_{\mathbf{k}} t+\imath\mathbf{k}\cdot\mathbf{r}}\right)\end{aligned}} \quad . \tag{35.222}$$

$g_{\mathbf{k}_0}$ is the coupling strength of the interaction between the atom and the pump mode, $\hat{\sigma}^-$ is the atomic deexcitation operator, $\hat{a}_{\mathbf{k}}$ is the annihilation operator of a photon, and $g_{\mathbf{k}} = d\sqrt{\omega/(\hbar\varepsilon_0 V)}$ describes the coupling between the atom and a vacuum mode whose volume is V. The atom has two states, the ground state $|g\rangle$ and excited state $|e\rangle$. Since we are considering only one atom fixed in space [11], we can as well locate it at the origin $\mathbf{r} = 0$. In addition, considering a high power incident laser,

$$\hat{a}_{\mathbf{k}_0}|n_0\rangle_{\mathbf{k}_0} = \sqrt{n_0}|n_0-1\rangle_{\mathbf{k}_0} \simeq \sqrt{n_0}|n_0\rangle_{\mathbf{k}_0} \ , \tag{35.223}$$

[11] We do not let the atom be accelerated by photonic recoil.

$\hat{a}_{\mathbf{k}_0}$ is approximately an observable proportional to the root of the intensity. As $[\hat{a}_{\mathbf{k}_0}, \hat{a}^\dagger_{\mathbf{k}_0}] \simeq 0$, we can disregard the quantum nature of the incident field and replace, $\Omega_0 \equiv 2\sqrt{n_0} g_{\mathbf{k}_0}$. Within the rotating wave approximation (RWA), the Hamiltonian becomes,

$$\hat{H} = \tfrac{\hbar}{2}\Omega_0 \left[\hat{\sigma}^- e^{\imath\Delta_0 t} + h.c.\right] + \hbar \sum_{\mathbf{k}} \left[g_{\mathbf{k}} \hat{\sigma} \hat{a}^\dagger_{\mathbf{k}} e^{\imath\Delta_{\mathbf{k}} t} + h.c.\right] \ , \tag{35.224}$$

where we introduced the abbreviations,

$$\Delta_0 \equiv \omega_0 - \omega_a \qquad \text{and} \qquad \Delta_{\mathbf{k}} \equiv \omega_{\mathbf{k}} - \omega_a \ . \tag{35.225}$$

The general state of the system is given by,

$$|\Psi(t)\rangle = \alpha(t)|g\rangle_a|0\rangle_{\mathbf{k}} + \beta(t)|e\rangle_a|0\rangle_{\mathbf{k}} + \sum_{\mathbf{k}} \gamma_{\mathbf{k}}(t)|g\rangle_a|1\rangle_{\mathbf{k}} \ , \tag{35.226}$$

where $|j\rangle_a$ denotes the atomic state and $|n\rangle_{\mathbf{k}}$ the number of photons in the scattering mode.

The temporal evolution of the amplitudes is obtained by inserting the Hamiltonian (35.224) and the ansatz (35.226) into the Schrödinger equation,

$$\frac{\partial}{\partial t}|\Psi(t)\rangle = -\frac{\imath}{\hbar}\hat{H}|\Psi(t)\rangle \ . \tag{35.227}$$

As verified in Exc. 35.6.4.1, we obtain,

$$\begin{aligned} \dot{\alpha}(t) &= -\imath\tfrac{\Omega_0}{2} e^{\imath\Delta_0 t}\beta(t) \\ \dot{\beta}(t) &= -\imath\tfrac{\Omega_0}{2}\alpha(t)e^{-\imath\Delta_0 t} - \sum\nolimits_{\mathbf{k}} \imath g_{\mathbf{k}}\gamma_{\mathbf{k}}(t)e^{-\imath\Delta_{\mathbf{k}} t} \\ \dot{\gamma}_{\mathbf{k}}(t) &= -\imath g_{\mathbf{k}} e^{\imath\Delta_{\mathbf{k}} t}\beta(t) \ . \end{aligned} \tag{35.228}$$

Now, we chose the initial conditions,

$$\alpha(0) = 1 \qquad \text{and} \qquad \beta(0) = 0 \qquad \text{and} \qquad \gamma_{\mathbf{k}}(0) = 0 \ , \tag{35.229}$$

we integrate the third equation,

$$\gamma_{\mathbf{k}}(t) = -\imath g_{\mathbf{k}} \int_0^t e^{\imath\Delta_{\mathbf{k}} t'}\beta(t')dt' \ , \tag{35.230}$$

and we substitute it in the second equation,

$$\dot{\beta}(t) = -\imath\tfrac{\Omega_0}{2}\alpha(t)e^{-\imath\Delta_0 t} - \sum_{\mathbf{k}} g^2_{\mathbf{k}} \int_0^t e^{\imath\Delta_{\mathbf{k}}(t'-t)}\beta(t')dt' \ . \tag{35.231}$$

35.6.1.2 The Markov approximation

For small systems (which certainly is the case of a single atom), we can apply the *Markov approximation* [12] claiming that the temporal variation of the amplitudes

[12] The approximation does not necessarily hold for large clouds of atoms.

$\beta(t')$ is slower than the evolution of the system given by $e^{\imath(\omega_{\mathbf{k}}-\omega_a)t}$ in the integro-differential equation, which is equivalent to an arbitrarily high-order equation. Hence, substituting $\beta(t') \to \beta(t)$ into the integro-differential equation, we reduce it to a simple first-order differential equation.

In practice, we redefine the integration variable, $t'' \equiv t - t'$, to obtain,

$$\begin{aligned}\frac{d}{dt}\beta(t) &= -\imath\tfrac{\Omega_0}{2}\alpha(t) - \sum_{\mathbf{k}} g_k^2 \int_0^t e^{\imath(\omega_{\mathbf{k}}-\omega_a)(t'-t)}\beta(t')dt' \\ &= -\imath\tfrac{\Omega_0}{2}\alpha(t) - \sum_{\mathbf{k}} g_k^2 \int_0^t e^{-\imath(\omega_{\mathbf{k}}-\omega_a)t''}\beta(t-t'')dt'' \ ,\end{aligned} \tag{35.232}$$

and implement the Markov approximation by setting $\beta(t-t'') \simeq \beta(t)$, and with $\lim_{t\to\infty}\int_0^t e^{-\imath(\omega_{\mathbf{k}}-\omega_a)t'}dt' = \pi\delta(\omega_{\mathbf{k}}-\omega_a)$, and replacing $\sum_{\mathbf{k}} \longrightarrow \frac{V}{(2\pi)^3}\int d^3\mathbf{k}$, we arrive at,

$$\begin{aligned}\frac{d}{dt}\beta(t) &\simeq -\imath\tfrac{\Omega_0}{2}\alpha(t) - \sum_{\mathbf{k}} g_{\mathbf{k}}^2\beta(t)\pi\delta(\omega_{\mathbf{k}}-\omega_a) \\ &= -\imath\tfrac{\Omega_0}{2}\alpha(t) - \tfrac{V}{(2\pi)^3}\beta(t)\int g_{\mathbf{k}}^2\pi\delta(\omega_{\mathbf{k}}-\omega_a)d^3\mathbf{k} \\ &= -\imath\tfrac{\Omega_0}{2}\alpha(t) - \tfrac{V}{(2\pi)^3}\beta(t)4\pi g_{\mathbf{k}_a}^2\pi k_a^2\tfrac{1}{c} = -\imath\tfrac{\Omega_0}{2}\alpha(t) - \tfrac{\Gamma}{2}\beta(t) \ .\end{aligned} \tag{35.233}$$

In the last step we introduced, as an abbreviation, the spontaneous emission rate,

$$\Gamma \equiv \sum_{\mathbf{k}} 2g_{\mathbf{k}}^2\pi\delta(\omega_{\mathbf{k}}-\omega_a) = \tfrac{V}{\pi c}k_a^2 g_{\mathbf{k}_a}^2 \ , \tag{35.234}$$

Finally,

$$\boxed{\frac{d}{dt}\alpha(t) = -\imath\frac{\Omega_0}{2}\beta(t) \qquad \text{and} \qquad \frac{d}{dt}\beta(t) = -\imath\frac{\Omega_0}{2}\alpha(t) - \frac{\Gamma}{2}\beta(t)} \ . \tag{35.235}$$

These are exactly the equations for the probability amplitudes (34.184) derived from the Schrödinger equation, only that now, the spontaneous emission term has been derived explicitly. Solve the Exc. 35.6.4.2.

Example 213 (*Emission stimulated by vacuum fluctuations*): Spontaneous emission can be regarded as an emission stimulated by vacuum fluctuations. To see this, we write down the resonant optical cross section ($\omega_0 = \omega_a$) of a driven two-level atom without degeneracies, $\sigma_0 = \lambda^2/2\pi$, and the intensity of an incident laser field, $\bar{I} = cN\hbar\omega_0/V$, generating the Rabi frequency (see (22.107)),

$$\Omega_0^2 = \sigma_0\frac{\bar{I}}{\hbar\omega_a}\Gamma = \frac{2\pi c}{k_a^2}\frac{N}{V}\Gamma \ . \tag{35.236}$$

Now, we assume that the field is, in fact, a vacuum mode containing only half a photon, $N = 1/2$, which corresponds to vacuum fluctuations in the mode k_0. Then,

$$\Omega_{1/2}^2 = \frac{\pi c}{k_a^2 V}\Gamma = g^2 \ . \tag{35.237}$$

35.6.2 Resonance fluorescence and (in-)coherent light scattering

The typical situation for a spectroscopy experiment is illustrated in Fig. 35.17: When a beam of light, understood as a plane wave, strikes an atom (or a cloud of many atoms), a part of the light is absorbed and reemitted into a direction indicated by a solid angle $d\Omega$. Light scattering is, of course, a second order process involving two atomic transitions, one absorption and one emission.

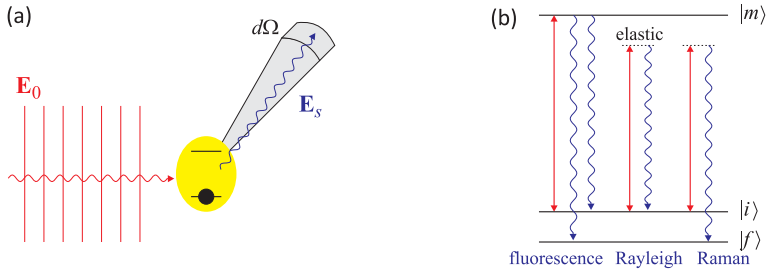

Figure 35.17: (a) Geometry of a scattering experiment. (b) Spectral contributions of light scattered elastically and inelastically by a three-level atom.

Radiation can be absorbed or scattered by an atom in different ways, depending on whether the interaction is an *elastic scattering* or an *inelastic scattering* process, a coherent or incoherent, a spontaneous or (bosonically) stimulated process. These properties characterize many processes, in particular, resonance fluorescence (i.e. absorption and reemission), *Rayleigh scattering*, or *Raman scattering*. In the following, we will clarify this classification.

Every scattering process is either spontaneous or stimulated [13]. Rayleigh scattering is elastic, that is, the kinetic energy of the scattering atom is the same, before and after the scattering process. In contrast, Raman scattering is inelastic. Spontaneous emission is due to the decay of population from an excited state, and spontaneous Rayleigh scattering is due to the decay of an induced dipole moment. Both spontaneous processes can be regarded as being stimulated by vacuum fluctuations.

35.6.2.1 Deriving the source field expression

We will now calculate the electric field due to spontaneous emission by an atom from the interaction Hamiltonian for atom-vacuum coupling (35.222) in the RWA,

$$\hat{H} = \sum_{\mathbf{k}} \hbar g_{\mathbf{k}} \hat{\sigma}^- \hat{a}^\dagger_{\mathbf{k}} e^{\imath\omega_{\mathbf{k}} t - \imath\omega_a t - \imath\mathbf{k}\cdot\mathbf{R}} + h.c. \ . \tag{35.238}$$

Now, we assume isotropic coupling, $g_{\mathbf{k}} = g_k$, and $\omega_{\mathbf{k}} = \omega_k$, and for simplicity we position the atom in the origin, $\mathbf{R} = 0$. We use the Heisenberg equation with the

[13] Classical theories of light scattering through the excitation of an electronic motion based on the models of Lorentz or Drude can be found in Secs. 18.2.3 . Although being classical, these model are useful for a deeper understanding of many aspects of *Compton scattering*, *Thomson scattering*, and *Rayleigh scattering*.

commutation rule $[\hat{a}_{\mathbf{k}}, \hat{a}^{\dagger}_{\mathbf{k}'}] = \delta_{\mathbf{k},\mathbf{k}'}$ to derive the temporal evolution of the field operators,

$$\frac{d\hat{a}_{\mathbf{k}}}{dt} = \tfrac{1}{\imath\hbar}[\hat{a}_{\mathbf{k}}, \hat{H}] = -\imath\hat{\sigma}^{-} g_k e^{\imath(\omega_k - \omega_a)t} \ . \tag{35.239}$$

Neglecting for simplicity polarization, the electric field is given by,

$$\hat{\mathcal{E}}^{+}_{sct}(\mathbf{r}, t) = \sum_{\mathbf{k}} \mathcal{E}_1 \hat{a}_{\mathbf{k}}(t) e^{\imath(\mathbf{k}\cdot\mathbf{r} - \omega_k t)} \ , \tag{35.240}$$

where $\mathbf{r}$ is now the observation point of the electric field. We restrict to the far-field and substitute the annihilation operator with the integral of Eq. (35.239) using the initial condition $\hat{a}_{\mathbf{k}}(0) = 0$,

$$\hat{\mathcal{E}}^{+}_{sct}(\mathbf{r}, t) = \sum_{\mathbf{k}} \mathcal{E}_1 g_k \int_0^t \hat{\sigma}^{-}(t') e^{\imath(\omega_k - \omega_a)t'} dt' e^{\imath(\mathbf{k}\cdot\mathbf{r} - \omega_k t)} \ . \tag{35.241}$$

Now, we substitute the sum over $\mathbf{k}$ by an integral, as done in (35.233),

$$\hat{\mathcal{E}}^{+}_{sct}(\mathbf{r}, t) = -\imath \frac{V}{(2\pi)^3} \int_{\mathbb{R}^3} \mathcal{E}_1 g_k \int_0^t \hat{\sigma}^{-}(t') e^{\imath(\omega_k - \omega_a)t'} dt' e^{\imath(\mathbf{k}\cdot\mathbf{r} - \omega_k t)} d^3k \ . \tag{35.242}$$

Using the relationships,

$$g_k = \frac{d_{12}\mathcal{E}_1}{\hbar} \qquad \text{and} \qquad \mathcal{E}_1 = \sqrt{\frac{\hbar\omega_k}{2\varepsilon_0 V}} \ , \tag{35.243}$$

the final result of the integration yields [816],

$$\hat{\mathcal{E}}^{+}_{sct}(\mathbf{r}, t) \simeq -\imath \frac{d_{12} k_a^2}{4\pi\varepsilon_0 r} \hat{\sigma}^{-}(t - \tfrac{r}{c}) \ . \tag{35.244}$$

35.6.2.2 Resonance fluorescence

When we introduced the second quantization (35.8) we learned that the field of light emitted by a radiator in the radiation zone ($\lambda \ll r$) is, taking into account retardation [14], given by,

$$\langle \hat{\vec{\mathcal{E}}}^{+}_s(\mathbf{r}, t) \rangle \propto \langle \hat{\sigma}^{-} \rangle \propto \tilde{\rho}_{21} \qquad \text{and} \qquad \langle \hat{\vec{\mathcal{E}}}^{-}_s(\mathbf{r}, t) \hat{\vec{\mathcal{E}}}^{+}_s(\mathbf{r}, t) \rangle \propto \langle \hat{\sigma}^{+}\hat{\sigma}^{-} \rangle \propto \rho_{22} \ . \tag{35.245}$$

Therefore, the electric field emitted by an atom and the intensity of scattered light are given by,

$$\boxed{\begin{aligned} \langle \hat{\vec{\mathcal{E}}}^{+}_s(\mathbf{r}, t) \rangle &= -\frac{e\omega_a^2 \hat{\epsilon}\cdot\mathbf{r}_{12}}{4\pi\varepsilon_0 c^2 r} \tilde{\rho}_{21}(t - \tfrac{r}{c}) e^{-\imath\omega(t - r/c)} \\ \bar{I}_s = c\varepsilon_0 \langle \hat{\vec{\mathcal{E}}}^{-}_s(\mathbf{r}, t) \hat{\vec{\mathcal{E}}}^{+}_s(\mathbf{r}, t) \rangle &= \frac{\alpha\hbar\omega_a^4 |\hat{\epsilon}\cdot\mathbf{r}_{12}|^2}{4\pi c^2 r^2} \rho_{22}(t - \tfrac{r}{c}) \end{aligned}} \ , \tag{35.246}$$

[14] The classical version of this formula is (19.41) .

with the definition of the Sommerfeld constant $\alpha = e^2/4\pi\varepsilon_0\hbar c$. We calculate the total flux of emitted photons,

$$W_{fi}^{(sp)} = \int \frac{\bar{I}_s r^2}{\hbar\omega_a} d\Omega = \frac{1}{\hbar\omega_a} \int \frac{\alpha\hbar\omega_a^4 |\mathbf{r}_{12}|^2 \cos^2\theta}{4\pi c^2} \rho_{22}(t - \tfrac{r}{c}) \sin\theta d\theta d\phi \qquad (35.247)$$
$$= \frac{8\pi}{3\hbar\omega_a} \frac{\alpha\hbar\omega_a^4 |\mathbf{r}_{12}|^2}{4\pi c^2} \rho_{22}(t - \tfrac{r}{c}) = \frac{2\alpha}{3c^2} \omega_a^3 |\mathbf{r}_{12}|^2 \rho_{22}(t - \tfrac{r}{c}) \ .$$

The result *coincides with the spontaneous emission rate* Γ calculated in (34.40).

A *differential scattering cross section* can be defined by,

$$\frac{d\sigma}{d\Omega} \equiv \frac{\omega \bar{I}_s r^2}{\omega_s \bar{I}_0} \ . \qquad (35.248)$$

35.6.2.3 Coherently scattered light and saturation

The total intensity of the scattered light being $\bar{I}_s$, the fraction of the coherently scattered light is,

$$\frac{\bar{I}_s^{\rm coh}}{\bar{I}_s} = \frac{\langle \hat{\vec{\mathcal{E}}}_s^-(\mathbf{r},t)\rangle \langle \hat{\vec{\mathcal{E}}}_s^+(\mathbf{r},t)\rangle}{\langle \hat{\vec{\mathcal{E}}}_s^-(\mathbf{r},t) \hat{\vec{\mathcal{E}}}_s^+(\mathbf{r},t)\rangle} \ . \qquad (35.249)$$

Inserting the expressions (35.246) and the stationary solution of the Bloch equations (34.188) with the saturation parameter defined in (34.190),

$$\frac{\bar{I}_s^{\rm coh}}{\bar{I}_s} = \frac{|\tilde{\rho}_{21}(\infty)|^2}{\rho_{22}(\infty)} = \frac{1}{1+s} = 1 - \frac{\bar{I}_s^{\rm incoh}}{\bar{I}_s} \ . \qquad (35.250)$$

That is, since the resonance fluorescence is proportional to the excited state population, we may define a quantity $S_{tot} \equiv \rho_{22}(\infty)$, so that the coherent and incoherent parts of the fluorescence are,

$$\boxed{S_{coh} = |\rho_{21}(\infty)|^2 = \frac{s/2}{(1+s)^2} \quad \text{and} \quad S_{incoh} = \rho_{22}(\infty) - |\rho_{21}(\infty)|^2 = \frac{s^2/2}{(1+s)^2}} \ . \qquad (35.251)$$

Hence, $S_{incoh} = s S_{coh}$.

The result (35.251), illustrated in Fig. 35.18(a), means that *below saturation* scattering is dominated by elastic scattering. Incident light excites the atomic dipole moment ρ_{12}, that is, charge oscillations which, in turn, emit electromagnetic radiation like a classical antenna. *Above saturation* the excited atomic state accumulates an considerable amount of population ρ_{22} giving rise to spontaneous emission, which is interpreted as inelastic scattering. This intrinsically quantum feature is a consequence of the quantized nature of the atomic energy levels and has no classical counterpart. Another interesting feature seen in Fig. 35.18(b) is that, when the incident light is tuned sufficiently far from resonance, elastic scattering will dominate at any saturation parameter.

35.6.3 The spectrum of resonance fluorescence

The *correlation functions* defined in (35.172) represent an interesting concept for describing resonance fluorescence and for phenomena such as *antibunching* observed in resonance fluorescence.

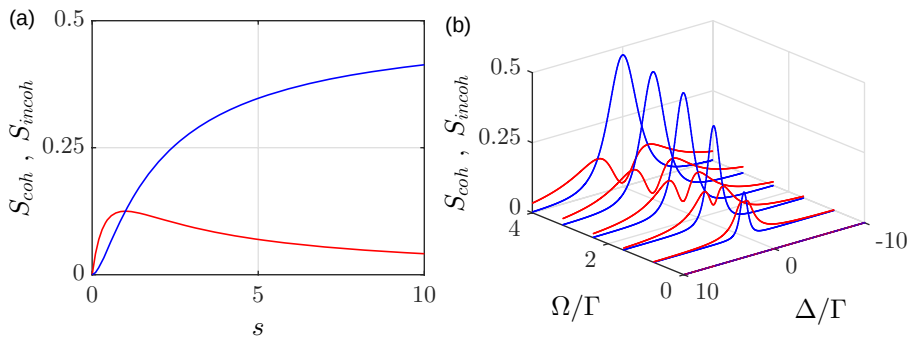

Figure 35.18: (code) Elastic (red) versus inelastic scattering (blue) as a function of the saturation parameter (a) at resonance and (b) for various detunings.

35.6.3.1 The quantum regression theorem

From (35.178) we see that, to compute the spectra of *resonance fluorescence*, we only need to compute the correlation function $g^{(1)}$, i.e. the amplitudes of the field $\hat{\mathcal{E}}(t)$, which in turn are related to the field operators (35.8). The field operators follow the solutions of the Bloch equation, which, being linear, have the following generic form,

$$\rho_{ij}(t+\tau) = \sum_{k,l} \alpha_{ijkl}(\tau)\rho_{ij}(t) + \beta_{ij}(\tau) \ . \tag{35.252}$$

The trace condition is satisfied, when $(i,j),(k,l) \neq (1,1)$.

To be able to explore the above relationship to calculate correlation functions, we have to invoke the so-called *quantum regression theorem*,

$$\boxed{\langle \hat{A}(t+\tau)\rangle = \sum_i \xi_i(\tau)\langle \hat{A}_i(t)\rangle \quad \Longrightarrow \quad \langle \hat{B}(t)\hat{A}(t+\tau)\hat{C}(t)\rangle = \sum_i \xi_i(\tau)\langle \hat{B}(t)\hat{A}_i(t)\hat{C}(t)\rangle} \ . \tag{35.253}$$

Example 214 (*Quantum regression applied to the Langevin equation*): We have,

$$\begin{aligned} \dot{A}_\mu &= D_\mu(t) + F_\mu(t) \\ \langle F_\mu(t)F_\nu(t)\rangle &= 2\langle D_{\mu\nu}\rangle\delta(t-t') \ . \end{aligned} \tag{35.254}$$

We know,

$$\langle A_\mu(t)F_\nu(t)\rangle = \langle D_{\mu\nu}\rangle \quad \text{and} \quad \langle F_\mu(t)A_\nu(t)\rangle = \langle D_{\mu\nu}\rangle \tag{35.255}$$

and the quantum regression theorem gives,

$$\frac{d}{dt}\langle A_\mu(t)A_\nu(t')\rangle = \langle D_\mu(t)A_\nu(t')\rangle \ , \tag{35.256}$$

because if $t' < t$, the term $\langle F_\mu(t)A_\nu(t')\rangle$ vanishes for a *Markovian process*.

35.6.3.2 Bloch equation for a two-level system

The Fourier transform of the first-order coherence, $g^{(1)}(\tau) = e^{-\imath\omega\tau}G(\tau)$, gives,

$$F(\nu) = (\mathcal{F}g^{(1)})(\nu) = \mathcal{F}[e^{-\imath\omega\tau}] \star \mathcal{F}[G(\tau)] = \delta(\nu-\omega) \star \mathcal{F}[G(\tau)] = (\mathcal{F}G)(\nu-\omega) \ . \tag{35.257}$$

Therefore, we can look at the unshifted spectrum, $(\mathcal{F}G)(\nu)$. Since the fluorescence spectrum is determined by the first-order coherence, which depends on the field operators, which in turn depend on the atomic populations and coherences, we have to solve the Bloch equation.

For a two-level atom the Bloch equations, having been reduced by the normalization condition (34.284) are,

$$\dot{\vec{\rho}}_{red} = \mathcal{M}\vec{\rho}_{red} + \mathbf{b} = \begin{pmatrix} -\Gamma & -\frac{\imath}{2}\Omega & \frac{\imath}{2}\Omega \\ -\imath\Omega & -\frac{1}{2}\Gamma - \imath\Delta & 0 \\ \imath\Omega & 0 & -\frac{1}{2}\Gamma + \imath\Delta \end{pmatrix} \begin{pmatrix} \rho_{22} \\ \rho_{12} \\ \rho_{21} \end{pmatrix} + \begin{pmatrix} 0 \\ \frac{\imath}{2}\Omega \\ -\frac{\imath}{2}\Omega \end{pmatrix} \tag{35.258}$$

with the solution (34.286), that is, $\vec{\rho}(t+\tau) = e^{\mathcal{M}\tau}\vec{\rho}(t) + (1-e^{\mathcal{M}\tau})\vec{\rho}(\infty)$ with $\rho(\infty) = -\mathcal{M}^{-1}b$. This solution can be cast in the following form,

$$\rho_{kl}(t+\tau) = \sum_{(mn)} \alpha_{(kl)(mn)}(\tau)\rho_{mn}(t) + \beta_{(kl)}(\tau) \ , \tag{35.259}$$

where $(mn), (kl) = (22), (12), (21)$ identifying,

$$\alpha_{(kl)(mn)}(\tau) = \begin{pmatrix} \alpha_{22,22} & \alpha_{12,22} & \alpha_{21,22} \\ \alpha_{22,12} & \alpha_{12,12} & \alpha_{21,12} \\ \alpha_{22,21} & \alpha_{12,21} & \alpha_{21,21} \end{pmatrix} \equiv \begin{pmatrix} (e^{\mathcal{M}\tau})_{11} & . & . \\ . & . & . \\ . & . & . \end{pmatrix} = e^{\mathcal{M}\tau} \tag{35.260}$$

$$\beta_{(kl)}(\tau) = \begin{pmatrix} \beta_{22} \\ \beta_{12} \\ \beta_{21} \end{pmatrix} \equiv \begin{pmatrix} -[(1-e^{\mathcal{M}\tau})\mathcal{M}^{-1}\mathbf{b}]_1 \\ . \\ . \end{pmatrix} = -(1-e^{\mathcal{M}\tau})\mathcal{M}^{-1}\mathbf{b} \ .$$

Using quantum operators in the interaction image, $|k\rangle\langle l| = \hat{\sigma}_{kl}$, we have,

$$\langle\hat{\sigma}_{12}(t)\rangle = \langle\hat{\sigma}_{21}^{\dagger}(t)\rangle = \rho_{12}(t)e^{\imath\omega_0 t} \qquad \text{and} \qquad \langle\hat{\sigma}_{22}(t)\rangle = \langle\hat{\sigma}_{12}(t)\hat{\sigma}_{21}(t)\rangle = \rho_{22}(t) \ . \tag{35.261}$$

yielding,

$$\langle e^{(k-l)\imath\omega_0(t+\tau)}\hat{\sigma}_{kl}(t+\tau)\rangle = \sum_{(mn)} \alpha_{(kl)(mn)}(\tau)\langle e^{(m-n)\imath\omega_0 t}\hat{\sigma}_{mn}(t)\rangle + \beta_{(mn)}(\tau)\langle 1\rangle \ , \tag{35.262}$$

or,

$$\langle\hat{\sigma}_{kl}(t+\tau)\rangle \tag{35.263}$$
$$= \sum_{(mn)} e^{(l-k)\imath\omega_0\tau}\alpha_{(kl)(mn)}(\tau)\langle e^{(l-k+m-n)\imath\omega_0 t}\hat{\sigma}_{mn}(t)\rangle + e^{(l-k)\imath\omega_0\tau}\beta_{(mn)}(\tau)\langle e^{(l-k)\imath\omega_0 t}\rangle \ .$$

Applying the quantum regression theorem to the Bloch equations, we get for an arbitrary time-dependent operator $\hat{B}(t)$,

$$\boxed{\begin{aligned}\langle \hat{B}(t)\hat{\sigma}_{kl}(t+\tau)\rangle &= \sum_{(mn)} e^{(l-k)\imath\omega_0\tau}\alpha_{(kl)(mn)}(\tau)\langle e^{(l-k+m-n)\imath\omega_0 t}\hat{B}(t)\hat{\sigma}_{mn}(t)\rangle \\ &\qquad + e^{(l-k)\imath\omega_0\tau}\beta_{(mn)}(\tau)\langle e^{(l-k)\imath\omega_0 t}\hat{B}(t)\rangle\end{aligned}} \ . \tag{35.264}$$

35.6.3.3 Correlation functions

We now look at the radiation field, which is related to the dipole moment operator via,

$$\hat{\mathcal{E}}^- = \gamma\hat{\sigma}_{21} \ , \tag{35.265}$$

where γ is simply a constant. Substituting this relation in the correlation functions (35.172) we obtain,

$$\begin{aligned} g^{(1)}(\tau) &= \frac{\langle\hat{\sigma}_{21}(t)\hat{\sigma}_{12}(t+\tau)\rangle}{\langle\hat{\sigma}_{21}(t)\hat{\sigma}_{12}(t)\rangle} = \frac{\langle\hat{\sigma}_{21}(t)\hat{\sigma}_{12}(t+\tau)\rangle}{\langle\hat{\sigma}_{22}(t)\rangle} \\ g^{(2)}(\tau) &= \frac{\langle\hat{\sigma}_{21}(t)\hat{\sigma}_{21}(t+\tau)\hat{\sigma}_{12}(t+\tau)\hat{\sigma}_{12}(t)\rangle}{\langle\hat{\sigma}_{21}(t)\hat{\sigma}_{12}(t)\rangle^2} = \frac{\langle\hat{\sigma}_{22}(t)\hat{\sigma}_{22}(t+\tau)\rangle}{\langle\hat{\sigma}_{22}(t)\rangle^2} \ . \end{aligned} \tag{35.266}$$

Now we can calculate, letting $\xi_i(\tau) \equiv \alpha_{(12)(mn)}$, $\hat{C}(t) \equiv 1$, and $\hat{B}(t) \equiv \hat{\sigma}_{21}(t)$,

$$g^{(1)}(\tau) = \frac{\sum_{(mn)} e^{\imath\omega_0(t+\tau)}e^{(m-n)\imath\omega_0 t}\alpha_{(12)(mn)}(\tau)\langle\hat{\sigma}_{21}(t)\hat{\sigma}_{mn}(t)\rangle + e^{\imath\omega_0(t+\tau)}\beta_{(12)}(\tau)\langle\hat{\sigma}_{21}(t)\rangle}{\langle\hat{\sigma}_{22}(t)\rangle} \tag{35.267}$$

$$g^{(2)}(\tau) = \frac{\sum_{(mn)} e^{(m-n)\imath\omega_0 t}\alpha_{(22)(mn)}(\tau)\langle\hat{\sigma}_{22}(t)\hat{\sigma}_{mn}(t)\rangle + \beta_{(22)}(\tau)\langle\hat{\sigma}_{22}(t)\rangle}{\langle\hat{\sigma}_{22}(t)\rangle^2} \ .$$

Using $\hat{\sigma}_{21}\hat{\sigma}_{mn} = \hat{\sigma}_{2n}\delta_{m1}$,

$$\begin{aligned} g^{(1)}(\tau) &= e^{\imath\omega_0\tau}\frac{\alpha_{(12)(12)}(\tau)\langle\hat{\sigma}_{21}(t)\hat{\sigma}_{12}(t)\rangle + \beta_{(12)}(\tau)\langle e^{\imath\omega_0 t}\hat{\sigma}_{21}(t)\rangle}{\langle\hat{\sigma}_{22}(t)\rangle} \\ g^{(2)}(\tau) &= \frac{\alpha_{(22)(21)}(\tau)\langle e^{\imath\omega_0 t}\hat{\sigma}_{22}(t)\hat{\sigma}_{21}(t)\rangle + \alpha_{(22)(22)}(\tau)\langle\hat{\sigma}_{22}(t)\hat{\sigma}_{22}(t)\rangle + \beta_{(22)}(\tau)\langle\hat{\sigma}_{22}(t)\rangle}{\langle\hat{\sigma}_{22}(t)\rangle^2} \ . \end{aligned} \tag{35.268}$$

Returning to the density operator and letting $t \to \infty$,

$$g^{(1)}(\tau) = e^{\imath\omega_0\tau}\left[\alpha_{(12)(12)}(\tau) + \beta_{(12)}(\tau)\frac{\rho_{21}(\infty)}{\rho_{22}(\infty)}\right] \qquad \text{and} \qquad g^{(2)}(\tau) = e^{\imath\omega_0\tau}\frac{\beta_{(22)}(\tau)}{\rho_{22}(\infty)} \ , \tag{35.269}$$

that is,

$$\boxed{\begin{aligned} g^{(1)}(\tau) &= e^{\imath\omega_0\tau}\left[\left[e^{\mathcal{M}\tau}\right]_{(12)(12)} - \left[(\mathbb{I}-e^{\mathcal{M}\tau})\mathcal{M}^{-1}\mathbf{b}\right]_{(12)}\frac{\left[\mathcal{M}^{-1}\mathbf{b}\right]_{(21)}}{\left[\mathcal{M}^{-1}\mathbf{b}\right]_{(22)}}\right] \\ g^{(2)}(\tau) &= e^{\imath\omega_0\tau}\frac{\left[(\mathbb{I}-e^{\mathcal{M}\tau})\mathcal{M}^{-1}\mathbf{b}\right]_{(22)}}{\left[\mathcal{M}^{-1}\mathbf{b}\right]_{(22)}} \end{aligned}} \ . \tag{35.270}$$

These correlation functions can easily be calculated via a numerical resolution of the Bloch equations (35.258). Fig. 35.19 shows the correlation functions and the fluorescence spectrum derived by Fourier transform of the first-order correlation function (35.177). Assuming resonant excitation, $\Delta = 0$, analytic formulas can be derived, as will be exercised in Excs. 35.6.4.3 and Exc. 35.6.4.4.

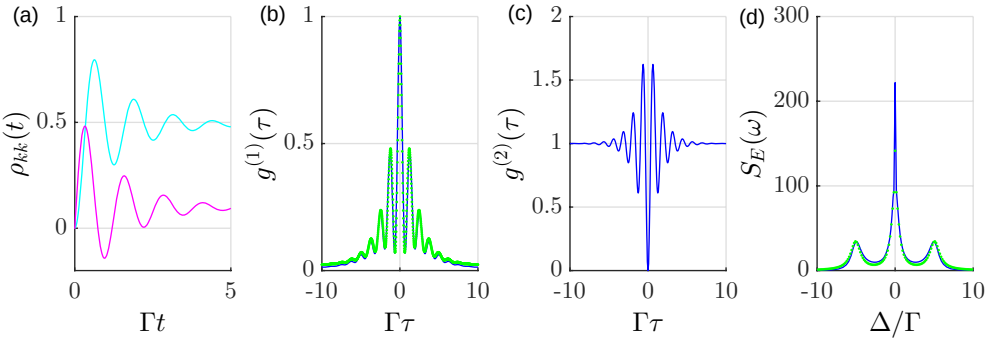

Figure 35.19: (code) (a) Temporal evolution of the excited state population $\rho_{22}(t)$ (cyan) and coherence $\rho_{12}(t)$ (magenta) of a laser-driven two-level atom with $\Omega = 5\Gamma$. (b) Correlation function $g^{(1)}(\tau)$ and (c) $g^{(2)}(\tau)$. The blue curves in (b-c) are obtained by numerical simulations of the Bloch equations and subsequent application of the quantum regression theorem (35.270). The green dots are obtained from an analytic solution derived in Exc. 35.6.4.3. (d) Mollow spectrum obtained by numerical FFT of $g^{(1)}(\tau)$.

The spectrum 35.19(d) exhibits three lines known as the *Mollow triplet*. Note that the spontaneous emission triplet is only observed in the presence of a driving laser, because it is the laser excitation which causes the splitting. Indeed, the splitting and the position of the lines are easily understood in the dressed states picture visualized in Fig. 35.1: The coupling of the two-level atom to a light field splits up the levels $|n\rangle$ and $|n+1\rangle$ by an amount corresponding to the Rabi frequency Ω. Now, the transition from the two excited state $|n+1\rangle$ levels to the ground state $|n\rangle$ levels can occur on three different frequencies. In Exc. 35.6.4.5 we calculate the Mollow spectrum for a transition between one ground and three excited Zeeman states. Fig. 35.20 illustrates the various methods to analyze scattered light, but not all of them yield information on the Mollow triplet.

35.6.3.4 Mollow spectrum from effective Hamiltonian

The Mollow triplet is easily understood in the dressed states picture. On the other hand, we know that (for classical light) the semi-classical picture is totally equivalent (its just a unitary transform of the dressed states picture). Developing a physical picture the Mollow triplet in the semi-classical framework may give us a deeper insight. Generally, the Mollow spectrum is anyhow calculated using the semi-classical Bloch equations, via the correlation function $g^{(1)}(\tau)$ and the Wiener-Khintchine theorem, but the on the way the physical intuition is lost.

For example, looking at the stationary solution of the Bloch equations (34.188), we see that $\vec{\rho}(\infty)$ is time-independent, so that we might be *surprised to see correla-*

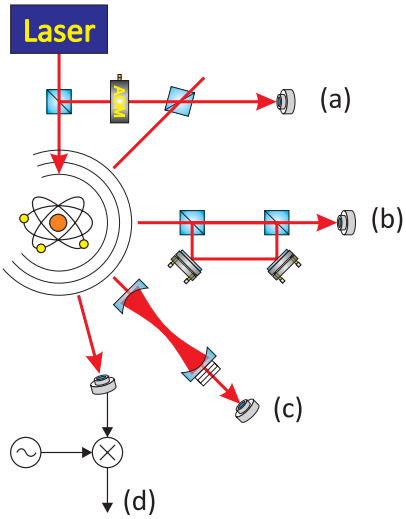

Figure 35.20: Schemes for analyzing resonance fluorescence: (a) Heterodyning [980], (b) temporal correlation, (c) spectrum [1235, 981], (d) demodulation. Only the schemes (b) and (c) yield information on the Mollow triplet.

tions in time domain (and consequently a structured spectrum) at all. This surprise results from a common misconception that may arise considering the damping of $\vec{\rho}(t)$ predicted by the Bloch model, as illustrated e.g. in Fig. 34.6: It seems that the atoms eventually cease oscillating between the ground and excited states. In most experiments, measurement are made on a large number of atoms and indeed the oscillations are damped.

In fact, however, every individual atom undergoes a complicated unpredictable trajectory alternating times of coherent evolution with spontaneous emission events (called quantum jumps). The damped behavior only results as an average over many such quantum trajectories. In this light, the reason for $g^{(1)}$-type correlations is a subtle interplay between coherently and incoherently scattered light: *The spontaneous emission probability is amplitude-modulated with the Rabi frequency.*

An alternative way to calculate the Mollow spectrum consists in solving the Schrödinger equation with the effective Hamiltonian, as done in Exc. 35.6.4.2 and 35.6.4.6. The results are shown in Fig. 35.21. While providing an intuitive picture of the origin of of the Mollow triplet a quantitatively correct treatment requires a Monte-Carlo wavefunction simulation [913] (see Sec. 36.1.2).

35.6.3.5 Weak excitation and the role of collisions

For the case of a weakly excited two-level atom, $|\Omega| \ll \Gamma$, we have analytic solutions (34.194) of the Bloch equation. We can then take the coefficients α_{ijkl} and β_{ij} and

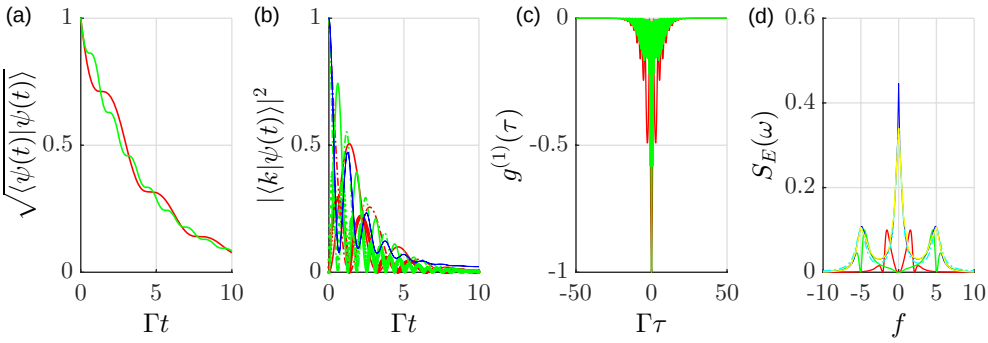

Figure 35.21: (code) (a) Time evolution of the norm of a decaying driven two-level atom. (b) Time evolution of the ground and excited state amplitudes. (c) First-order autocorrelation function, and (d) spectrum.

insert them into the correlation functions,

$$
\begin{aligned}
g^{(1)}(\tau) &= e^{-\imath\omega\tau} \ , \\
g^{(2)}(\tau) &= 1 + e^{-2\gamma\tau} - 2\cos\Delta\tau \ , \\
F(\omega_s) &= (\mathcal{F}g^{(1)})(\omega_s) = \delta(\omega_s - \omega) \ .
\end{aligned}
\tag{35.271}
$$

These functions show that the spectrum is essentially composed of *Rayleigh scattering* at the frequency of the incident light. The δ-shaped fluorescence spectrum shows, that the contribution of elastically scattered light dominates below saturation, which confirms the results (35.251) illustrated in Fig. 35.18. The light is 'antibunched' and, at higher τ exhibits a damped oscillation around the value 1.

If pressure broadening is taken into account, the two-level Bloch equations are given by (34.188), where $\gamma' = \gamma + \gamma_{coll}$ is the width of the collision-broadened line. Within this model and in the limit $\Omega \ll \Gamma$, the resonance fluorescence spectrum is given by [816],

$$
F(\omega_s) = \frac{\gamma' - \Gamma}{\gamma'} \frac{\gamma'/\pi}{(\omega_0 - \omega_s)^2 + \gamma'^2} + \frac{\Gamma}{\gamma'} \delta(\omega_s - \omega) \ . \tag{35.272}
$$

So, we find that, even at low intensities, a continuous spectrum due to *inelastic scattering* appears around the resonance frequency ω_0 additionally to the elastic Rayleigh peak.

35.6.4 Exercises

35.6.4.1 Ex: Derivation of the rate equations for two-level atoms

Inserting the ansatz (35.226) into the Schrödinger equation, derive the equations of motion (35.228) for the wavefunction amplitudes.

Solution: *The Schrödinger equation is,*

$$\begin{aligned}
&\dot\alpha|g\rangle_a|0\rangle_{\mathbf{k}} + \dot\beta|e\rangle_a|0\rangle_{\mathbf{k}} + \sum_{\mathbf{k}} \dot\gamma_{\mathbf{k}}|g\rangle_a|1\rangle_{\mathbf{k}} \\
&= -\frac{\imath}{\hbar}\left(\tfrac{\hbar}{2}\Omega_0|g\rangle_a\langle 1|e^{\imath\Delta_0 t} + \tfrac{\hbar}{2}\Omega_0|e\rangle_a\langle 0|e^{-\imath\Delta_0 t} + \hbar\sum_{\mathbf{k}} g_k|g\rangle_a\langle 1|\hat a^\dagger_{\mathbf{k}}e^{\imath\Delta_{\mathbf{k}}t} + \hbar\sum_{\mathbf{k}} g_k|e\rangle_a\langle 0|\hat a_{\mathbf{k}}e^{-\imath\Delta_k t}\right) \\
&\qquad \left(\alpha|g\rangle_a|0\rangle_{\mathbf{k}} + \beta|e\rangle_a|0\rangle_{\mathbf{k}} + \sum_{\mathbf{k}}\gamma_{\mathbf{k}}|g\rangle_a|1\rangle_{\mathbf{k}}\right) \\
&= -\imath\left(\tfrac{\Omega_0}{2}e^{-\imath\Delta_0 t} + \sum_{\mathbf{k}} g_k\hat a_{\mathbf{k}}e^{-\imath\Delta_k t}\right)\alpha|e\rangle_a|0\rangle_{\mathbf{k}} - \imath\left(\tfrac{\Omega_0}{2}e^{\imath\Delta_0 t} + \sum_{\mathbf{k}} g_k\hat a^\dagger_{\mathbf{k}}e^{\imath\Delta_k t}\right)\beta|g\rangle_a|0\rangle_{\mathbf{k}} \\
&\qquad -\imath\left(\tfrac{\Omega_0}{2}e^{-\imath\Delta_0 t} + \sum_{\mathbf{k}} g_k\hat a_{\mathbf{k}}e^{-\imath\Delta_k t}\right)\sum_{\mathbf{k}'}\gamma_{\mathbf{k}'}|e\rangle_a|1\rangle_{\mathbf{k}'} \\
&= -\imath\tfrac{\Omega_0}{2}e^{-\imath\Delta_0 t}\alpha|e\rangle_a|0\rangle_{\mathbf{k}} - \imath\tfrac{\Omega_0}{2}e^{\imath\Delta_0 t}\beta|g\rangle_a|0\rangle_{\mathbf{k}} - \imath\sum_{\mathbf{k}} g_k e^{\imath\Delta_k t}\beta|g\rangle_a|1\rangle_{\mathbf{k}} \\
&\qquad -\imath\tfrac{\Omega_0}{2}e^{-\imath\Delta_0 t}\sum_{\mathbf{k}}\gamma_{\mathbf{k}}|e\rangle_a|1\rangle_{\mathbf{k}} - \imath\sum_{\mathbf{k}} g_k e^{-\imath\Delta_k t}\gamma_{\mathbf{k}}|e\rangle_a|0\rangle_{\mathbf{k}}\ .
\end{aligned}$$

Note that the term $|e\rangle_a|1\rangle_{\mathbf{k}'}$ should be neglected, as it is not allowed within the RWA. We get,

$$\begin{aligned}
\dot\alpha|g\rangle_a|0\rangle_{\mathbf{k}} &= -\imath\tfrac{\Omega_0}{2}e^{\imath\Delta_0 t}\beta|g\rangle_a|0\rangle_{\mathbf{k}} \\
\dot\beta|e\rangle_a|0\rangle_{\mathbf{k}} &= -\imath\tfrac{\Omega_0}{2}e^{-\imath\Delta_0 t}\alpha|e\rangle_a|0\rangle_{\mathbf{k}} - \imath\sum_{\mathbf{k}} g_k e^{-\imath\Delta_k t}\gamma_{\mathbf{k}}|e\rangle_a|0\rangle_{\mathbf{k}} \\
\sum_{\mathbf{k}}\dot\gamma_{\mathbf{k}}|g\rangle_a|1\rangle_{\mathbf{k}} &= -\imath\sum_{\mathbf{k}} g_k e^{\imath\Delta_k t}\beta|g\rangle_a|1\rangle_{\mathbf{k}}\ .
\end{aligned}$$

The final result follows when we cut the states on both sides of the equation.

35.6.4.2 Ex: Non-Hermitian time evolution

Study the time evolution $|\psi(t)\rangle = e^{-\imath\hat H_{eff}t/\hbar}|\psi(0)\rangle$ with the effective Hamiltonian,

$$\hat H_{eff} = \begin{pmatrix} 0 & \frac{\hbar}{2}\Omega \\ \frac{\hbar}{2}\Omega & -\frac{\imath\hbar}{2}\Gamma \end{pmatrix}$$

starting from the initial condition $\langle 2|\psi(0)\rangle = 1$. Calculate the evolution of $|\psi(t)\rangle$ and the norm $\langle\psi(t)|\psi(t)\rangle$. Plot the time evolution of the norm for various ratios Ω/Γ and interpret the curves.

Solution: *To solve the Schrödinger equation,*

$$\imath\hbar\frac{d}{dt}|\psi\rangle = \hat H_{eff}|\psi\rangle \qquad with \qquad |\psi(t)\rangle = \begin{pmatrix} c_1(t) \\ c_2(t)\end{pmatrix} \qquad and \qquad \hat H_{eff} = \begin{pmatrix} 0 & \frac{\hbar}{2}\Omega \\ \frac{\hbar}{2}\Omega & -\frac{\imath\hbar}{2}\Gamma \end{pmatrix}\ ,$$

we need to solve the set of differential equation,

$$\begin{aligned}
\imath\dot c_1 &= \tfrac{\Omega}{2}c_2 \\
\imath\dot c_2 &= \tfrac{\Omega}{2}c_1 - \tfrac{\imath\Omega}{2}\Gamma c_2\ .
\end{aligned}$$

Differentiating the second equation and substituting the first,

$$\ddot c_2 = -\tfrac{\Gamma}{2}\dot c_2 - \tfrac{\Omega^2}{4}c_2\ .$$

The ansatz $c_2 = ae^{\lambda t}$ leads to the characteristic equation,

$$\lambda^2 + \tfrac{\Gamma}{2}\lambda + \tfrac{\Omega^2}{4} = 0 \qquad \Longrightarrow \qquad \lambda = -\tfrac{\Gamma}{4} \pm \tfrac{1}{4}\sqrt{\Gamma^2 - 4\Omega^2} \equiv -\tfrac{\Gamma}{4} \pm \tfrac{\Lambda}{4}$$

defining the abbreviation,

$$\Lambda \equiv \sqrt{\Gamma^2 - 4\Omega^2} \ .$$

Hence, our solution has the shape $c_2(t) = a_+ e^{\lambda_+ t} + a_- e^{\lambda_- t}$. Now,

$$\begin{aligned} c_2(t) &= e^{-\Gamma t/4}\left(a_+ e^{\Lambda t/4} + a_- e^{-\Lambda t/4}\right) \\ &\xrightarrow{\Omega\to 0} e^{-\Gamma t/2} \\ &\xrightarrow{\Gamma\to 0} a_+ e^{\imath\Omega t/2} + a_- e^{-\imath\Omega t/2} \ . \end{aligned}$$

The ground state amplitude follows by integration,

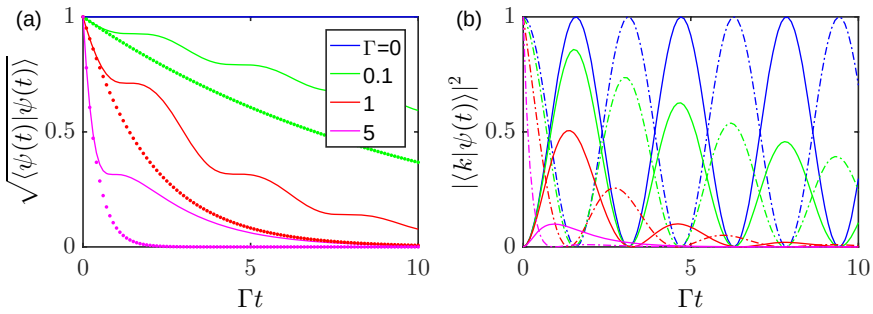

Figure 35.22: (code) (a) Time evolution of the norm of a resonantly driven two-level system with spontaneous emission for $\Omega = 2$ (solid lines) and $\Omega = 0$ (dotted lines). (b) Time evolution of the excited state (dash-dotted lines) and ground state (solid lines) populations.

$$c_1(t) = \tfrac{\Omega}{2\imath}\int_0^t c_2(t')dt' = 2\imath\Omega\left(a_+\frac{e^{-\Gamma t/4+\Lambda t/4}-1}{\Gamma-\Lambda} + a_-\frac{e^{-\Gamma t/4-\Lambda t/4}-1}{\Gamma+\Lambda}\right) \ .$$

Note the normalization condition cannot be used, here, to fix the coefficients. Instead, we use,

$$1 = c_2(0) = a_+ + a_- \qquad \textit{and} \qquad 0 = c_2(\infty) \ ,$$

yielding,

$$1 - a_- = a_+ = -\frac{2\Omega^2/\Lambda}{\Gamma+\Lambda} \ .$$

Finally,

$$\begin{pmatrix} c_1(t) \\ c_2(t) \end{pmatrix} = \begin{pmatrix} \frac{2\imath\Omega}{\Gamma+\Lambda}\left[\frac{2\Omega^2}{\Lambda}\left(\frac{1-e^{-(\Gamma-\Lambda)t/4}}{\Gamma-\Lambda} - \frac{1-e^{-(\Gamma+\Lambda)t/4}}{\Gamma+\Lambda}\right) - 1 + e^{-(\Gamma+\Lambda)t/4}\right] \\ e^{-\Gamma t/4}\left[\frac{2\Omega^2/\Lambda}{\Gamma+\Lambda}\left(e^{-\Lambda t/4} - e^{\Lambda t/4}\right) + e^{-\Lambda t/4}\right] \end{pmatrix} \ .$$

Introducing the new abbreviation $\Lambda = 2\imath\tilde{\Omega}$, we can simplify this expression,

$$\boxed{\begin{pmatrix} c_1(t) \\ c_2(t) \end{pmatrix} = e^{-\Gamma t/4} \begin{pmatrix} -\imath\frac{\Omega}{\tilde{\Omega}} \sin\frac{\tilde{\Omega}t}{2} \\ \cos\frac{\tilde{\Omega}t}{2} - \frac{\Gamma}{2\tilde{\Omega}} \sin\frac{\tilde{\Omega}t}{2} \end{pmatrix}} .$$

We readily find the following limits,

$$\begin{pmatrix} c_1(t) \\ c_2(t) \end{pmatrix} \stackrel{\Gamma\to 0}{\longrightarrow} \begin{pmatrix} -\imath \sin\frac{\Omega t}{2} \\ \cos\frac{\Omega t}{2} \end{pmatrix} \qquad \textit{and} \qquad \stackrel{\Omega\to 0}{\longrightarrow} \begin{pmatrix} 0 \\ e^{-\Gamma t/2} \end{pmatrix} .$$

The norm is,

$$\langle\psi(t)|\psi(t)\rangle = e^{-\Gamma t/2}\left(1 - \frac{\Gamma}{\tilde{\Omega}} \cos\frac{\tilde{\Omega}t}{2} \sin\frac{\tilde{\Omega}t}{2} + \frac{\Gamma^2}{2\tilde{\Omega}^2} \sin^2\frac{\tilde{\Omega}t}{2}\right)$$
$$\stackrel{\Gamma\to 0}{\longrightarrow} 1 \qquad \textit{and} \qquad \stackrel{\Omega\to 0}{\longrightarrow} e^{-\Gamma t} .$$

The decaying normalization and the exponential decay of the excited state population in the case of strong driving, $\Omega > \Gamma$, observed in Fig. 35.22 is, of course, not realistic, and points to the fact that the Schrödinger equation is unable to account for spontaneous emission. It is, however, possible to correct for the decay by continuously renormalization procedures [321].

Alternative solution:

We set $\hbar = 1$ and calculate the eigenvalues $E_\pm$ and the unitary transformation matrix U, where $U\hat{H}_{eff} = \hat{E}U$ and

$$\hat{E} \equiv \begin{pmatrix} E_+ & 0 \\ 0 & E_- \end{pmatrix} .$$

The eigenvalues are,

$$E_\pm = -\tfrac{\imath\Gamma}{4} \pm \tfrac{1}{4}\sqrt{4\Omega^2 - \Gamma^2} \stackrel{\Omega\to 0}{\longrightarrow} 0, -\tfrac{\imath}{2}\Gamma .$$

The unitary transformation matrix is nothing else than the eigenvector matrix,

$$U = \begin{pmatrix} \frac{2E_+ + \imath\Gamma}{\Omega} & \frac{2E_- + \imath\Gamma}{\Omega} \\ 1 & 1 \end{pmatrix} = \begin{pmatrix} \frac{\imath\Gamma}{2\Omega} + \sqrt{1 - \frac{\Gamma^2}{4\Omega^2}} & \frac{\imath\Gamma}{2\Omega} - \sqrt{1 - \frac{\Gamma^2}{4\Omega^2}} \\ 1 & 1 \end{pmatrix} .$$

We get for the evolution,

$$
\begin{aligned}
e^{-\imath\hat{H}_{eff}t}\begin{pmatrix}0\\1\end{pmatrix} &= Ue^{-\imath\hat{E}t}U^{-1}\begin{pmatrix}0\\1\end{pmatrix} \\
&= \begin{pmatrix}\frac{2E_+ +\imath\Gamma}{\Omega} & \frac{2E_- +\imath\Gamma}{\Omega}\\ 1 & 1\end{pmatrix}\begin{pmatrix}e^{-\imath E_+ t} & 0\\ 0 & e^{-\imath E_- t}\end{pmatrix}\begin{pmatrix}\frac{2E_+ +\imath\Gamma}{\Omega} & \frac{2E_- +\imath\Gamma}{\Omega}\\ 1 & 1\end{pmatrix}^{-1}\begin{pmatrix}0\\1\end{pmatrix} \\
&= \begin{pmatrix}-\frac{(2E_+ +\imath\Gamma)(2E_- +\imath\Gamma)}{2\Omega(E_+ -E_-)}(e^{-\imath E_+ t}-e^{-\imath E_- t}) \\ -\frac{(2E_- +\imath\Gamma)}{2(E_+ -E_-)}e^{-\imath E_+ t}+\frac{(2E_+ +\imath\Gamma)}{2(E_+ -E_-)}e^{-\imath E_- t}\end{pmatrix} \\
&= \begin{pmatrix}\frac{\Omega}{\sqrt{4\Omega^2-\Gamma^2}}(e^{-\imath E_+ t}-e^{-\imath E_- t}) \\ \frac{1}{2}\left(1-\frac{\imath\Gamma}{\sqrt{4\Omega^2-\Gamma^2}}\right)e^{-\imath E_+ t}+\frac{1}{2}\left(1+\frac{\imath\Gamma}{\sqrt{4\Omega^2-\Gamma^2}}\right)e^{-\imath E_- t}\end{pmatrix} \\
&= e^{-\Gamma t/4}\begin{pmatrix}\frac{-2\imath\Omega}{\sqrt{4\Omega^2-\Gamma^2}}\sin\frac{t\sqrt{4\Omega^2-\Gamma^2}}{4} \\ \cos\frac{t\sqrt{4\Omega^2-\Gamma^2}}{4}-\frac{\Gamma}{\sqrt{4\Omega^2-\Gamma^2}}\sin\frac{t\sqrt{4\Omega^2-\Gamma^2}}{4}\end{pmatrix}\ .
\end{aligned}
$$

The result is identical to the one previously derived.

35.6.4.3 Ex: Resonance fluorescence and antibunching via Bloch equations

a. Derive the analytic solution of the Bloch equations for a resonantly driven two-level atom.
b. Calculate the 1^{st}-order correlation function $g^{(1)}(\tau)$ from the formula (35.270).
c. Derive the spectrum of resonance fluorescence [912].
d. Derive the 2^{nd}-order correlation function $g^{(2)}(\tau)$ from the formula (35.270).

Solution: *a. The Bloch equations for a single driven two-level atom become, after elimination of the ground state population,*

$$\dot{\vec{\rho}}_{red} = \mathcal{M}\vec{\rho}_{red} + \mathbf{b}\ ,$$

where $\vec{\rho}_{red} = (\rho_{22}\ \rho_{21}\ \rho_{12})^\dagger$ *and*

$$\mathcal{M} = \begin{pmatrix}-\Gamma & -\frac{\imath}{2}\Omega & \frac{\imath}{2}\Omega \\ -\imath\Omega & -\frac{1}{2}\Gamma-\imath\Delta & 0 \\ \imath\Omega & 0 & -\frac{1}{2}\Gamma+\imath\Delta\end{pmatrix} \quad \textit{and} \quad \mathbf{b} = \begin{pmatrix}0\\ \frac{\imath}{2}\Omega \\ -\frac{\imath}{2}\Omega\end{pmatrix}\ .$$

The stationary solution is (using MAPLE) found to be,

$$\vec{\rho}_{red}(\infty) = -\mathcal{M}^{-1}\mathbf{b} = \frac{\imath\Omega}{4\Delta^2+2\Omega^2+\Gamma^2}\begin{pmatrix}-\imath\Omega \\ \Gamma-2\imath\Delta \\ -\Gamma-2\imath\Delta\end{pmatrix}\ .$$

We now simplify the calculation assuming $\Delta = 0$,

$$\mathcal{M} = \begin{pmatrix}-\Gamma & -\frac{\imath}{2}\Omega & \frac{\imath}{2}\Omega \\ -\imath\Omega & -\frac{1}{2}\Gamma & 0 \\ \imath\Omega & 0 & -\frac{1}{2}\Gamma\end{pmatrix} = UEU^{-1}$$

with

$$E=\begin{pmatrix}-\frac{3}{4}\Gamma+\frac{1}{4}\Lambda & 0 & 0\\ 0 & -\frac{3}{4}\Gamma-\frac{1}{4}\Lambda & 0\\ 0 & 0 & -\frac{1}{2}\Gamma\end{pmatrix} \quad \textit{and} \quad U=\begin{pmatrix}-\frac{\imath\Gamma}{4\Omega}+\frac{\imath\Lambda}{4\Omega} & -\frac{\imath\Gamma}{4\Omega}-\frac{\imath\Lambda}{4\Omega} & 0\\ 1 & 1 & 1\\ -1 & -1 & 1\end{pmatrix},$$

where we introduced the abbreviation $\Lambda\equiv\sqrt{\Gamma^2-16\Omega^2}$. *Now,*

$$e^{\mathcal{M}t}=Ue^{Et}U^{-1}=e^{-\gamma t}\times$$
$$\begin{pmatrix}\frac{-\Gamma+\Lambda}{2\Lambda}e^{-\frac{(\Gamma-\Lambda)t}{4}}+\frac{\Gamma+\Lambda}{2\Lambda}e^{-\frac{(\Gamma+\Lambda)t}{4}} & -\frac{\imath\Omega}{\Lambda}\left(e^{-\frac{(\Gamma-\Lambda)t}{4}}-e^{-\frac{(\Gamma+\Lambda)t}{4}}\right) & \frac{\imath\Omega}{\Lambda}\left(e^{-\frac{(\Gamma-\Lambda)t}{4}}-e^{-\frac{(\Gamma+\Lambda)t}{4}}\right)\\ -\frac{2\imath\Omega}{\Lambda}\left(e^{-\frac{(\Gamma-\Lambda)t}{4}}-e^{-\frac{(\Gamma+\Lambda)t}{4}}\right) & \frac{\Gamma+\Lambda}{4\Lambda}e^{-\frac{(\Gamma-\Lambda)t}{4}}+\frac{-\Gamma+\Lambda}{4\Lambda}e^{-\frac{(\Gamma+\Lambda)t}{4}}+\frac{1}{2} & \frac{-\Gamma-\Lambda}{4\Lambda}e^{-\frac{(\Gamma-\Lambda)t}{4}}+\frac{\Gamma-\Lambda}{4\Lambda}e^{-\frac{(\Gamma+\Lambda)t}{4}}+\frac{1}{2}\\ \frac{2\imath\Omega}{\Lambda}\left(e^{-\frac{(\Gamma-\Lambda)t}{4}}-e^{-\frac{t}{2}(\gamma+\lambda)}\right) & \frac{-\Gamma-\Lambda}{4\Lambda}e^{-\frac{(\Gamma-\Lambda)t}{4}}+\frac{\Gamma-\Lambda}{4\Lambda}e^{-\frac{(\Gamma+\Lambda)t}{4}}+\frac{1}{2} & \frac{\Gamma+\Lambda}{4\Lambda}e^{-\frac{(\Gamma-\Lambda)t}{4}}+\frac{-\Gamma+\Lambda}{4\Lambda}e^{-\frac{t(\gamma+\lambda)}{2}}+\frac{1}{2}\end{pmatrix}.$$

Hence,

$$(\mathbb{I}-e^{\mathcal{M}t})\vec{\rho}_{red}(\infty)$$
$$=\frac{\Omega}{2\Lambda(\Gamma^2+2\Omega^2)}\left[\begin{pmatrix}2\Omega\Lambda\\ 2\imath\Gamma\Lambda\\ -2\imath\Gamma\Lambda\end{pmatrix}+e^{-\frac{t}{4}(3\Gamma+\Lambda)}\begin{pmatrix}-(3\Gamma-\Lambda)\Omega\\ -\imath(\Gamma\Lambda-\Gamma^2+4\Omega^2)\\ \imath(\Gamma\Lambda-\Gamma^2+\Omega^2)\end{pmatrix}+e^{-\frac{t}{4}(3\Gamma-\Lambda)}\begin{pmatrix}-(3\Gamma+\Lambda)\Omega\\ -\imath(\Gamma\Lambda+\Gamma^2-4\Omega^2)\\ \imath(\Gamma\Lambda+\Gamma^2-\Omega^2)\end{pmatrix}\right].$$

After sufficiently long times t *the solution found in (34.286) becomes,*

$$\boxed{\vec{\rho}_{red}(t)=e^{\mathcal{M}t}\vec{\rho}_{red}(0)+(\mathbb{I}-e^{\mathcal{M}t})\vec{\rho}_{red}(\infty)\overset{\gamma t,\Omega t\gg 1}{\longrightarrow}(\mathbb{I}-e^{\mathcal{M}t})\vec{\rho}_{red}(\infty)}.$$

The same solution applies for arbitrary times choosing $\rho_{red}(0)=0$ *as the initial condition.*

b. With the expression for the correlation function (35.270),

$$g^{(1)}(\tau)=e^{\imath\omega_0\tau}\left[[e^{\mathcal{M}\tau}]_{(12)(12)}+[(\mathbb{I}-e^{\mathcal{M}\tau})\vec{\rho}_{red}(\infty)]_{(12)}\frac{[\vec{\rho}_{red}(\infty)]_{(21)}}{[\vec{\rho}_{red}(\infty)]_{(22)}}\right]$$

we get from the above solution of the Bloch equations,

$$g^{(1)}(\tau)=e^{\imath\omega_0\tau}\left[\frac{\Gamma^2}{\Gamma^2+2\Omega^2}+\frac{1}{2}e^{-\Gamma\tau/2}+\sum_{\pm}\frac{-\Gamma^2(\Lambda\pm\Gamma)+2\Omega^2(\Lambda\pm 5\Gamma)}{4\Lambda(\Gamma^2+2\Omega^2)}e^{-(3\Gamma\mp\Lambda)\tau/4}\right].$$

For weak driving, $\Omega\ll\Gamma$,

$$g^{(1)}(\tau)\simeq e^{\imath\omega_0\tau}\left(1+\tfrac{\Omega^2}{\Gamma^2}e^{-\Gamma\tau}\right).$$

For strong driving,

$$g^{(1)}(\tau)\simeq e^{\imath\omega_0\tau}\left[\tfrac{\Gamma^2}{2\Omega^2}+\tfrac{1}{2}e^{-\frac{1}{2}\Gamma\tau}+\tfrac{1}{2}e^{-\frac{3}{4}\Gamma\tau}\cos\Omega\tau\right].$$

Let us now rewrite the expression for $g^{(1)}(\tau)$ *introducing the abbreviation* $\tilde{\Omega}\equiv\sqrt{\Omega^2-\Gamma^2/16}=\imath\Lambda/4$. *Then,*

$$\boxed{g^{(1)}(\tau)=e^{\imath\omega_0\tau}\left[\frac{\Gamma^2}{\Gamma^2+2\Omega^2}+\frac{1}{2}e^{-\Gamma\tau/2}+\sum_{\pm}\frac{4\tilde{\Omega}(2\Omega^2-\Gamma^2)\pm\imath\Gamma(10\Omega^2-\Gamma^2)}{16\tilde{\Omega}(\Gamma^2+2\Omega^2)}e^{-3\Gamma\tau/4\mp\imath\tilde{\Omega}\tau}\right]}. \tag{35.273}$$

c. The spectrum is just the Fourier transform, for which the following rules hold,

$$(\mathcal{F})(\omega) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} f(\tau) e^{-\imath\omega\tau} d\tau \quad , \quad (f * g)(\omega) = \int_{-\infty}^{\infty} f(t) g(\tau - t) dt$$

$$\mathcal{F}[1](\omega) = \sqrt{2\pi}\delta(\omega) \quad , \quad \mathcal{F}[\theta(\tau) e^{-a\tau}] = \frac{1}{\sqrt{2\pi}} \frac{1}{\imath\omega + a} \quad \Longrightarrow \quad \mathcal{F}[e^{-a|\tau|}] = \sqrt{\frac{2}{\pi}} \frac{a}{\omega^2 + a^2} \ .$$

Applying them to the above function $g^{(1)}(\tau)$ we get for $\tilde{\Omega} \in R$,

$$S_{\mathcal{E}}(\omega) = \mathcal{F}[g^{(1)}(\tau)] \ .$$

In the case of weak driving, the spectrum is readily obtained,

$$S_{\mathcal{E}}(\omega) = \frac{1}{2\pi} \int_{-\infty}^{\infty} e^{\imath\omega_0\tau} \left(1 + \frac{\Omega^2}{\Gamma^2} e^{-\Gamma\tau}\right) e^{-\imath\omega\tau} d\tau = \delta(\Delta) + \frac{\Omega^2}{\Gamma^2} \frac{\Gamma/\pi}{\Delta^2 + \Gamma^2} \ .$$

In the case of string driving, we must resort to Eq. (35.274). The first term gives,

$$T_1 = \delta(\omega - \omega_0) * \frac{\Gamma^2}{\Gamma^2 + 2\Omega^2} \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} e^{-\imath\omega\tau} d\tau = \frac{\Gamma^2}{\Gamma^2 + 2\Omega^2} \delta(\omega - \omega_0) \ .$$

The second term gives,

$$T_2 = \delta(\omega - \omega_0) * \frac{1}{2} \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} e^{-\imath\omega\tau} e^{-\Gamma\tau/2} d\tau = \frac{1}{2} \frac{1}{\sqrt{2\pi}} \frac{1}{\imath(\omega - \omega_0) + \Gamma/2} \ .$$

Finally, the third term is,

$$\begin{aligned} T_3 &= \delta(\omega - \omega_0 \pm \tilde{\Omega}) * \sum_{\pm} \frac{4\tilde{\Omega}\left(2\Omega^2 - \Gamma^2\right) \pm \imath\Gamma(10\Omega^2 - \Gamma^2)}{16\tilde{\Omega}(\Gamma^2 + 2\Omega^2)} \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} e^{-\imath\omega\tau} e^{-3\Gamma\tau/4} d\tau \\ &= \frac{1}{\sqrt{2\pi}} \sum_{\pm} \frac{4\tilde{\Omega}(2\Omega^2 - \Gamma^2) \pm \imath\Gamma(10\Omega^2 - \Gamma^2)}{16\tilde{\Omega}(\Gamma^2 + 2\Omega^2)} \frac{1}{\imath(\omega - \omega_0 \pm \tilde{\Omega}) + \frac{3}{4}\Gamma} \ . \end{aligned}$$

The spectrum follows as the real part of these four terms,

$$\boxed{\begin{aligned} \mathfrak{Re}\ S_{\mathcal{E}}(\omega) &= \frac{\Gamma^2}{\Gamma^2 + 2\Omega^2} \delta(\omega - \omega_0) + \frac{1}{\sqrt{2\pi}} \frac{\Gamma/4}{(\omega - \omega_0)^2 + (\Gamma/2)^2} \\ &+ \frac{1}{\sqrt{2\pi}} \sum_{\pm} \frac{3\Gamma\tilde{\Omega}(2\Omega^2 - \Gamma^2) \mp (\omega - \omega_0 \pm \tilde{\Omega})\Gamma(10\Omega^2 - \Gamma^2)}{16\tilde{\Omega}(\Gamma^2 + 2\Omega^2)\left[(\omega - \omega_0 \pm \tilde{\Omega})^2 + (\frac{3}{4}\Gamma)^2\right]} \end{aligned}} \ . \tag{35.274}$$

Note that the sidebands are partially correlated (especially for strong driving) and partially anti-correlated [15]*. For strong driving, we get,*

$$\mathfrak{Re}\ S_{\mathcal{E}}(\omega) \simeq \frac{\Gamma}{4\sqrt{2\pi}} \frac{1}{\Delta^2 + (\frac{1}{2}\Gamma)^2} + \frac{3\Gamma}{16\sqrt{2\pi}} \sum_{\pm} \frac{1}{(\Delta \pm \Omega)^2 + (\frac{3}{4}\Gamma)^2} \ . \tag{35.275}$$

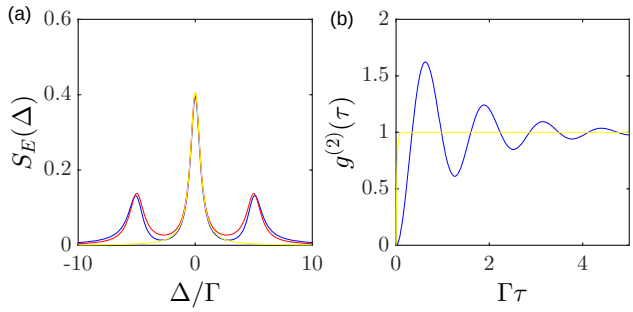

Figure 35.23: (code) (a) Analytical shape of the fluorescence spectrum for $\Omega = 5\Gamma$ calculated from the (blue) full formula (35.274), (red) high power limit (35.275). (b) $g^{(2)}(\tau)$.

The exact spectrum and its strong driving approximation are shown in Fig. 35.23(a).
d. With the expression for the correlation function (35.270),

$$g^{(2)}(\tau) = e^{\imath\omega_0\tau}\frac{[(\mathbb{I} - e^{\mathcal{M}\tau})\mathcal{M}^{-1}\mathbf{b}]_{(22)}}{[\mathcal{M}^{-1}\mathbf{b}]_{(22)}} \ .$$

we get from the above solution of the Bloch equations,

$$\boxed{g^{(2)}(\tau) = -e^{\imath\omega_0\tau}\left[1 + \left(\frac{1}{2} - \frac{3\Gamma}{2\Lambda}\right)e^{-\frac{\tau}{4}(3\Gamma+\Lambda)} - \left(\frac{1}{2} + \frac{3\Gamma}{2\Lambda}\right)e^{-\frac{\tau}{4}(3\Gamma-\Lambda)}\right]} \ .$$

The absolute value of $|g^{(2)}(\tau)|$ is shown in Fig. 35.23(b).

35.6.4.4 Ex: Resonance fluorescence via rate equations

Repeat Exc. 35.6.4.3 neglecting coherences, i.e. replacing the Bloch equations by rate equations,

$$\dot{\vec{\rho}} = \begin{pmatrix} -R & R+\Gamma & 0 & 0 \\ R & -R-\Gamma & 0 & 0 \\ 0 & 0 & -\gamma & 0 \\ 0 & 0 & 0 & -\gamma \end{pmatrix}\vec{\rho} \ ,$$

where $R = \Omega^2/2\gamma$ is the pump rate.

Solution: *a. Eliminating ρ_{11} from the rate equations, we write $\dot{\vec{\rho}}_{red} = \mathcal{M}\vec{\rho}_{red} + \mathbf{b}$, where,*

$$\mathcal{M} = \begin{pmatrix} -2R-\Gamma & 0 & 0 \\ 0 & -\gamma & 0 \\ 0 & 0-\gamma & \end{pmatrix} \qquad \textit{and} \qquad \mathbf{b} = \begin{pmatrix} R \\ 0 \\ 0 \end{pmatrix} \ .$$

[15] This is reminiscent to AM and PM: $|1 + Me^{\imath\Omega t} \pm Me^{-\imath\Omega t}|^2 = 1 + 2(1 \pm 1)M\cos\Omega t + 2M^2(1 \pm \cos 2\Omega t)$.

b. From this we obtain,

$$\vec{\rho}_{red}(\infty) = -\mathcal{M}^{-1}\mathbf{b} = \begin{pmatrix} (2+\frac{\Gamma}{R})^{-1} \\ 0 \\ 0 \end{pmatrix} \quad \textit{and} \quad e^{\mathcal{M}t} = \begin{pmatrix} e^{(-2R-\Gamma)t} & 0 & 0 \\ 0 & e^{-\gamma t} & 0 \\ 0 & 0 & e^{-\gamma t} \end{pmatrix} ,$$

which allows us the calculate, with the expression for the correlation function (35.270),

$$g^{(1)}(\tau) = e^{\imath\omega_0\tau}\left[[e^{\mathcal{M}t}]_{(12)(12)} + [(\mathbb{I}-e^{\mathcal{M}t})\vec{\rho}_{red}(\infty)]_{(12)}\frac{[\vec{\rho}_{red}(\infty)]_{(21)}}{[\vec{\rho}_{red}(\infty)]_{(22)}}\right] = e^{\imath\omega_0\tau-\gamma\tau} .$$

c. The spectrum is,

$$\mathfrak{Re}\ S_{\mathcal{E}}(\omega) = \frac{\gamma/\pi}{\Delta^2 + (\frac{1}{2}\Gamma)^2} .$$

d. With the expression for the correlation function (35.270),

$$g^{(2)}(\tau) = e^{\imath\omega_0\tau}\frac{[(\mathbb{I}-e^{\mathcal{M}\tau})\mathcal{M}^{-1}\mathbf{b}]_{(22)}}{[\mathcal{M}^{-1}\mathbf{b}]_{(22)}} .$$

we get from the above solution of the Bloch equations,

$$g^{(2)}(\tau) = e^{\imath\omega_0\tau}\left[1-e^{(-2R-\Gamma)\tau}\right] .$$

The absolute value of $|g^{(2)}(\tau)|$ is shown in Fig. 35.23(b).

35.6.4.5 Ex: Fluorescence spectrum of a four-level system

A more realistic transition, allowing for a vectorial nature of the radiation field, involves one ground and three excited Zeeman states (e.g. the strontium $^1S_0$-$^1P_1$ transition). In this case, the emitted light is,

$$\hat{\mathcal{E}}^-(t) = \hat{\mathcal{E}}^-_{\sigma^-}(t) + \hat{\mathcal{E}}^-_{\pi}(t) + \hat{\mathcal{E}}^-_{\sigma^+}(t) .$$

Calculate the first-order correlation function and the fluorescence spectrum of this transition.

Solution: *The correlation function is,*

$$\begin{aligned} g^{(1)}(\tau) &\equiv \frac{\langle\hat{\mathcal{E}}^-(t)\hat{\mathcal{E}}^+(t+\tau)\rangle}{\langle\hat{\mathcal{E}}^-(t)\hat{\mathcal{E}}^+(t)\rangle} \\ &= \frac{\langle[\hat{\mathcal{E}}^-_{\sigma^-}(t)+\hat{\mathcal{E}}^-_{\pi}(t)+\hat{\mathcal{E}}^-_{\sigma^+}(t)][\hat{\mathcal{E}}^+_{\sigma^-}(t+\tau)+\hat{\mathcal{E}}^+_{\pi}(t+\tau)+\hat{\mathcal{E}}^+_{\sigma^+}(t+\tau)]\rangle}{\langle[\hat{\mathcal{E}}^-_{\sigma^-}(t)+\hat{\mathcal{E}}^-_{\pi}(t)+\hat{\mathcal{E}}^-_{\sigma^+}(t)][\hat{\mathcal{E}}^+_{\sigma^-}(t)+\hat{\mathcal{E}}^+_{\pi}(t)+\hat{\mathcal{E}}^+_{\sigma^+}(t)]\rangle} . \end{aligned}$$

Labeling the states,

$$\hat{\mathcal{E}}^-_{\sigma^-} = \gamma\hat{\sigma}_{21} \quad , \quad \hat{\mathcal{E}}^-_{\pi} = \gamma\hat{\sigma}_{31} \quad , \quad \hat{\mathcal{E}}^-_{\sigma^+} = \gamma\hat{\sigma}_{41} ,$$

we arrive at,

$$
\begin{aligned}
g^{(1)}(\tau) &= \frac{\langle[\gamma\hat{\sigma}_{21}(t)+\gamma\hat{\sigma}_{31}(t)+\gamma\hat{\sigma}_{41}(t)][\gamma\hat{\sigma}_{12}(t+\tau)+\gamma\hat{\sigma}_{13}(t+\tau)+\gamma\hat{\sigma}_{14}(t+\tau)]\rangle}{\langle[\gamma\hat{\sigma}_{21}(t)+\gamma\hat{\sigma}_{31}(t)+\gamma\hat{\sigma}_{41}(t)][\gamma\hat{\sigma}_{12}(t)+\gamma\hat{\sigma}_{13}(t)+\gamma\hat{\sigma}_{14}(t)]\rangle} \\
&= \frac{\begin{array}{c}\sum_{(mn)}\alpha_{(12)(mn)}(\tau)\langle[\hat{\sigma}_{21}(t)+\hat{\sigma}_{31}(t)+\hat{\sigma}_{41}(t)]\,\hat{\sigma}_{12}(t)\rangle+\beta_{(12)}(\tau)\langle\hat{\sigma}_{21}(t)\rangle \\ +\sum_{(mn)}\alpha_{(13)(mn)}(\tau)\langle[\hat{\sigma}_{21}(t)+\hat{\sigma}_{31}(t)+\hat{\sigma}_{41}(t)]\,\hat{\sigma}_{13}(t)\rangle+\beta_{(13)}(\tau)\langle\hat{\sigma}_{31}(t)\rangle \\ +\sum_{(mn)}\alpha_{(14)(mn)}(\tau)\langle[\hat{\sigma}_{21}(t)+\hat{\sigma}_{31}(t)+\hat{\sigma}_{41}(t)]\,\hat{\sigma}_{14}(t)\rangle+\beta_{(14)}(\tau)\langle\hat{\sigma}_{41}(t)\rangle\end{array}}{\langle[\hat{\sigma}_{21}(t)+\hat{\sigma}_{31}(t)+\hat{\sigma}_{41}(t)]\,[\hat{\sigma}_{12}(t)+\hat{\sigma}_{13}(t)+\hat{\sigma}_{14}(t)]\rangle} \\
&= \frac{\begin{array}{c}\alpha_{(12)(12)}(\tau)\langle\hat{\sigma}_{21}(t)\hat{\sigma}_{12}(t)\rangle+\beta_{(12)}(\tau)\langle\hat{\sigma}_{21}(t)\rangle \\ +\alpha_{(13)(13)}(\tau)\langle\hat{\sigma}_{31}(t)\hat{\sigma}_{13}(t)\rangle+\beta_{(13)}(\tau)\langle\hat{\sigma}_{31}(t)\rangle \\ +\alpha_{(14)(14)}(\tau)\langle\hat{\sigma}_{41}(t)\hat{\sigma}_{14}(t)\rangle+\beta_{(14)}(\tau)\langle\hat{\sigma}_{41}(t)\rangle\end{array}}{\langle[\hat{\sigma}_{21}(t)+\hat{\sigma}_{31}(t)+\hat{\sigma}_{41}(t)][\hat{\sigma}_{12}(t)+\hat{\sigma}_{13}(t)+\hat{\sigma}_{14}(t)]\rangle} \\
&= \frac{\begin{array}{c}\alpha_{(12)(12)}(\tau)\rho_{22}(\infty)\rangle+\beta_{(12)}(\tau)\rho_{21}(\infty)+\alpha_{(13)(13)}(\tau)\rho_{33}(\infty) \\ +\beta_{(13)}(\tau)\rho_{31}(\infty)+\alpha_{(14)(14)}(\tau)\rho_{44}(\infty)+\beta_{(14)}(\tau)\rho_{41}(\infty)\end{array}}{\rho_{22}(\infty)+\rho_{33}(\infty)+\rho_{44}(\infty)+\rho_{23}(\infty)+\rho_{32}(\infty)+\rho_{24}(\infty)+\rho_{42}(\infty)+\rho_{34}(\infty)+\rho_{43}(\infty)} \,.
\end{aligned}
$$

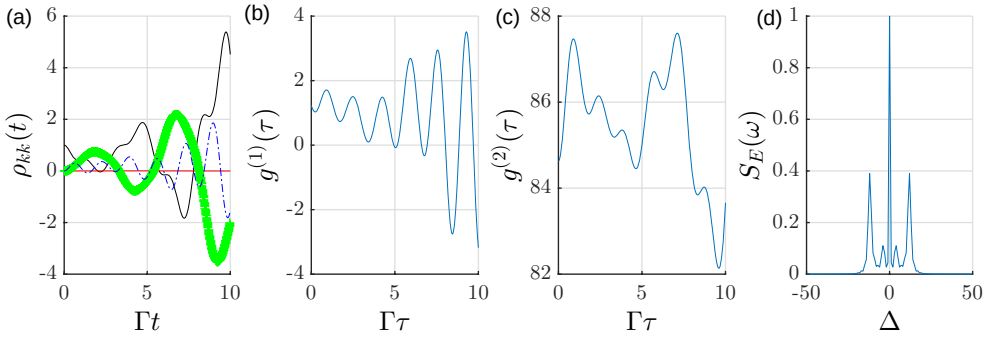

Figure 35.24: Resonance fluorescence spectrum of a degenerate four-level system.

35.6.4.6 Ex: Semi-classical picture of the Mollow triplet

Calculate the first-order correlation function from the solution of the Schrödinger equation with the effective Hamiltonian derived in Exc. 35.6.4.2.

Solution: *Solving the Schrödinger equation with the effective Hamiltonian we derived the following solution in Exc. 35.6.4.2,*

$$
|\psi(t)\rangle = e^{-\Gamma t/4}\begin{pmatrix} \frac{-\imath\Omega}{\tilde{\Omega}}\sin\frac{\tilde{\Omega}t}{2} \\ \cos\frac{\tilde{\Omega}t}{2}-\frac{\Gamma}{2\tilde{\Omega}}\sin\frac{\tilde{\Omega}t}{2}\end{pmatrix} \quad , \quad \tilde{\Omega}\equiv\sqrt{\Omega^2-\tfrac{\Gamma^2}{4}} \,.
$$

The populations and coherences are then,

$$\langle 2|2\rangle = e^{-\Gamma t/2}\left(\frac{\Omega^2}{2\tilde{\Omega}^2} + \frac{2\Omega^2-\Gamma^2}{\tilde{\Omega}^2}\cos\tilde{\Omega}t - \frac{\Gamma}{2\tilde{\Omega}}\sin\tilde{\Omega}t\right)$$
$$\langle 1|1\rangle = e^{-\Gamma t/2}\frac{\Omega^2}{2\tilde{\Omega}^2}(1-\cos\tilde{\Omega}t)$$
$$\langle 2|1\rangle = ie^{-\Gamma t/2}\frac{\Omega}{2\tilde{\Omega}}\left(\frac{\Gamma}{2\tilde{\Omega}} - \frac{\Gamma}{2\tilde{\Omega}}\cos\tilde{\Omega}t - \sin\tilde{\Omega}t\right) .$$

The field radiated by resonance fluorescence is $\mathcal{E} \propto \sigma^- = |1\rangle\langle 2|$. From this we can calculate the correlation,

$$\begin{aligned}&\langle t\mathcal{E}(t)\mathcal{E}^+(t+\tau)\rangle \\ &= e^{-\Gamma\tau/2}\left(\frac{\Omega}{2\tilde{\Omega}}\right)^2 \lim_{t\to\infty}\int_0^t e^{-\Gamma t}\left(\tfrac{\Gamma}{2\tilde{\Omega}} - \tfrac{\Gamma}{2\tilde{\Omega}}\cos\tilde{\Omega}t - \sin\tilde{\Omega}t\right)\left(\tfrac{\Gamma}{2\tilde{\Omega}} - \tfrac{\Gamma}{2\tilde{\Omega}}\cos\tilde{\Omega}(t+\tau) - \sin\tilde{\Omega}(t+\tau)\right)dt \\ &= e^{-\Gamma\tau/2}\frac{-\Omega^2}{2\tilde{\Omega}^2}\frac{\Gamma^2-(\Gamma^2+2\tilde{\Omega}^2)\cos\tilde{\Omega}\tau - \Gamma\tilde{\Omega}\sin\tilde{\Omega}\tau}{8\Gamma(\Gamma^2+\tilde{\Omega}^2)} .\end{aligned}$$

Hence,

$$g^{(1)}(\tau) = \frac{\langle t\mathcal{E}(t)\mathcal{E}^+(t+T)\rangle}{\langle t\mathcal{E}(t)\mathcal{E}^+(t)\rangle} = e^{-\Gamma\tau/2}\frac{-\Gamma^2+(\Gamma^2+2\tilde{\Omega}^2)\cos\tilde{\Omega}\tau + \Gamma\tilde{\Omega}\sin\tilde{\Omega}\tau}{2\tilde{\Omega}^2} .$$

35.6.4.7 Ex: Monte-Carlo simulation of the Mollow triplet

Implement a Monte-Carlo simulation of the Mollow triplet for a driven two-level atom according to [321, 913].

Solution: *We consider a single laser-driven two-level atom,*

$$\hat{H} = \tfrac{\hbar\Omega}{2}(\hat{\sigma}^+ + \hat{\sigma}^-) + (\hbar\omega_0 + \imath\hbar\Gamma)\hat{\sigma}_z = \begin{pmatrix} 0 & \frac{\hbar\Omega}{2} \\ \frac{\hbar\Omega}{2} & \hbar\omega_0 + \imath\frac{\Gamma}{2}\end{pmatrix} ,$$

where $\hat{\sigma}^- = |1\rangle\langle 2|$. We are interested in calculating the first-order correlation function $g^{(1)}(\tau) = \langle\hat{\sigma}^+(t+\tau)\hat{\sigma}^-(t)\rangle$. The MCWF is performed by starting with the atom in the ground state, $|\psi(0)\rangle = |1\rangle$, and applying the procedure,

$$|\psi(t_1)\rangle \to \begin{cases} e^{-\imath\hat{H}t_1/\hbar}|\psi(t_1)\rangle & \text{for} \quad \zeta < \sqrt{\langle\psi|\psi\rangle} \\ |\psi(0)\rangle & \text{for} \quad \zeta > \sqrt{\langle\psi|\psi\rangle}\end{cases}$$

Now, we consider new states,

$$|\chi_\pm(0)\rangle \equiv \tfrac{1}{\sqrt{\mu_\pm}}(1\pm\hat{\sigma}^-)|\psi(t)\rangle \qquad \text{and} \qquad |\chi'_\pm(0)\rangle \equiv \tfrac{1}{\sqrt{\mu'_\pm}}(1\pm\imath\hat{\sigma}^-)|\psi(t)\rangle ,$$

where $\mu_\pm = \langle\psi|(1\pm\hat{\sigma}^+)(1\pm\hat{\sigma}^-)|\psi\rangle$,

$$|\chi_\pm^{(\prime)}(\tau)\rangle \to \begin{cases} e^{-\imath\hat{H}t_1/\hbar}|\chi_\pm^{(\prime)}(t_1)\rangle & \text{for} \quad \zeta < \sqrt{\langle\psi|\psi\rangle} \\ |\chi_\pm^{(\prime)}(0)\rangle & \text{for} \quad \zeta > \sqrt{\langle\psi|\psi\rangle}\end{cases} .$$

The first-order correlation function is obtained from,

$$g^{(1)}(\tau) = \tfrac{1}{4}\left(\mu_+\overline{\langle\chi_+(\tau)|\hat{\sigma}^+|\chi_+(\tau)\rangle} - \mu_-\overline{\langle\chi_-(\tau)|\hat{\sigma}^+|\chi_-(\tau)\rangle} - \imath\mu'_+\overline{\langle\chi'_+(\tau)|\hat{\sigma}^+|\chi'_+(\tau)\rangle} + \imath\mu'_+\overline{\langle\chi'_-(\tau)|\hat{\sigma}^+|\chi'_-(\tau)\rangle}\right) .$$

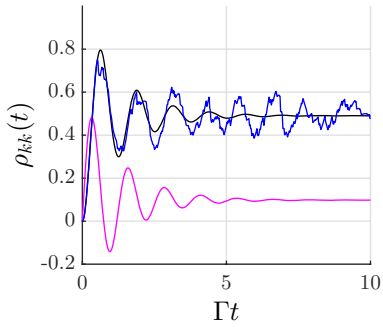

Figure 35.25: (code) Monte-Carlo simulation of the Mollow triplet.

35.7 Light scattering from multi-level atoms

35.7.1 Quantum beats

The phenomenon of *quantum beats* is another simple example of effects beyond semi-classical theory, requiring a full second-quantized calculation. In semi-classical theory (SCT), there is an interference or beat note term for both V-type and Λ-type atoms, while in quantum electrodynamics (QED) only V-type atoms exhibits a beat term.

In the semi-classical picture, the state vector of electrons is [1184],

$$\psi(t)\rangle = c_1 e^{-\imath\omega_1 t}|1\rangle + c_2 e^{-\imath\omega_2 t}|2\rangle + c_3 e^{-\imath\omega_3 t}|3\rangle \ . \tag{35.276}$$

Writing the non-vanishing dipole matrix elements as $d_{12} = e\langle 1|r|2\rangle$, $d_{23} = e\langle 2|r|3\rangle$ a three-level atom has two microscopic oscillating dipoles,

$$\mathcal{P}(t) = d_{12}(c_1^* c_2)e^{\imath\omega_{12}t} + d_{23}(c_2^* c_3)e^{\imath\omega_{23}t} + c.c. \ . \tag{35.277}$$

In the semi-classical picture, the radiated field will be a sum of these two terms,

$$\mathcal{E}^+ = \mathcal{E}_1 e^{-\imath\omega_{12}t} + \mathcal{E}_2 e^{-\imath\omega_{23}t} \ . \tag{35.278}$$

This leads to an interference or beat note term in a square-law detector,

$$|\mathcal{E}^+|^2 = |\mathcal{E}_{12}|^2 + |\mathcal{E}_{23}|^2 + \mathcal{E}_{12}^*\mathcal{E}_{23}e^{[\imath(\omega_{12}-\omega_{23})t]} + c.c. \ , \tag{35.279}$$

regardless of whether state $|2\rangle$ decays simultaneously to $|1\rangle$ and $|3\rangle$ or vice versa.

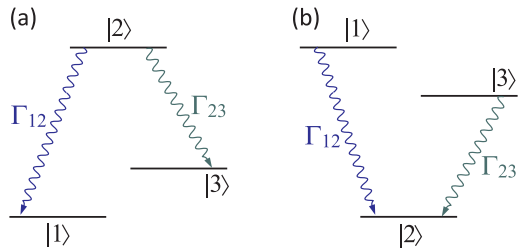

Figure 35.26: Level configuration of a Λ-system (left) and a V-system (right).

35.7.1.1 Quantum electrodynamics calculation

For the quantum electrodynamical calculation, we use the creation and annihilation operators from second quantization of quantum mechanics. Let $\hat{\mathcal{E}}_n^+ = \hat{a}_n e^{-\imath\omega_n t}$ be the annihilation operator and $\hat{\mathcal{E}}_n^- = \hat{a}_n^\dagger e^{\imath\omega_n t}$ be the creation operator with $n = (12)$ or $n = (23)$. Then the beat note becomes,

$$\langle\psi_V(t)|\hat{\mathcal{E}}_{12}^-(t)\hat{\mathcal{E}}_{23}^+(t)|\psi_V(t)\rangle \qquad \text{and} \qquad \langle\psi_\Lambda(t)|\hat{\mathcal{E}}_{12}^-(t)\hat{\mathcal{E}}_{23}^+(t)|\psi_\Lambda(t)\rangle \tag{35.280}$$

for the Λ and the V-system, respectively. The state vector for each type of system is,

$$|\psi_V(t)\rangle = \sum_{i=1,2,3} c_i|i,0\rangle + c_1|c,1_{12}\rangle + c_2|c,1_{23}\rangle \tag{35.281}$$

and,

$$|\psi_\Lambda(t)\rangle = \sum_{i=1,2,3} c_i'|i,0\rangle + c_1'|b,1_{12}\rangle + c_2'|c,1_{23}\rangle \ . \tag{35.282}$$

The beat note term becomes,

$$\begin{aligned}\langle\psi_V(t)|\hat{\mathcal{E}}_1^-(t)\hat{\mathcal{E}}_2^+(t)|\psi_V(t)\rangle &= \kappa\langle 1_{12}0_{23}|a_1^\dagger a_2|0_{12}1_{23}\rangle e^{[\imath(\omega_{12}-\omega_{23})t]}\langle 3|3\rangle \\ &= \kappa e^{[\imath(\omega_{12}-\omega_{23})t]}\langle 3|3\rangle\end{aligned} \tag{35.283}$$

for the V-system and

$$\begin{aligned}\langle\psi_\Lambda(t)|\hat{\mathcal{E}}_1^-(t)\hat{\mathcal{E}}_2^+(t)|\psi_\Lambda(t)\rangle &= \kappa'\langle 1_{12}0_{23}|a_1^\dagger a_2|0_{12}1_{23}\rangle e^{[\imath(\omega_{12}-\omega_{23})t]}\langle 2|3\rangle \\ &= \kappa' e^{[\imath(\omega_{12}-\omega_{23})t]}\langle 2|3\rangle\end{aligned} \tag{35.284}$$

for the Λ-system. However, orthogonality of the eigenstates requires $\langle 3|3\rangle = 1$ and $\langle 2|3\rangle = 0$. Therefore, there is a quantum beat note term for V-type atoms, but not for Λ-type atoms.

This difference originates in quantum mechanical uncertainty. A V-type atom decays to state $|3\rangle$ via the emission with ω_{12} and ω_{23}. Since both transitions decayed to the same state, one cannot determine along which path each decayed, similar to Young's double-slit experiment. However, Λ-type atoms decay to two different states. Therefore, in this case we can identify the path by the end product.

Quantum beat spectroscopy is a technique which allows for Doppler-free resolution provided the separation of the adjacent levels is less than the Doppler width. It consists in generating a coherently distributed population of two upper states, e.g. via a short laser pulse, and detecting the beat frequency.

35.7.2 Two-photon transitions

We will now apply the *Kramers-Heisenberg formula* (27.111) to photon scattering processes $\omega \to \omega_s$. The states are then product states of atomic excitations and photonic modes $|m, n, n_s\rangle$. In particular, the final state must take into account the mode into which light is scattered,

$$\frac{1}{\tau} = \frac{2\pi}{\hbar^2} \sum_f \sum_{\mathbf{k}_s} \Big| \langle f, n-1, 1|\hat{H}^{(2)}|i, n, 0\rangle + \frac{1}{\hbar} \sum_m \frac{\langle f, n-1, 1|\hat{H}^{(1)}|m\rangle\langle m|\hat{H}^{(1)}|i, n, 0\rangle}{\omega_i - \omega_m} \Big|^2 \delta(\omega_f - \omega_i) \; . \tag{35.285}$$

The initial energy is $\omega_i \to n\omega$, the final energy $\omega_f \to (n-1)\omega + \omega_s + \omega_f$, two intermediate states are possible, $|m\rangle \to |m, n-1, 0\rangle$ and $|m\rangle \to |m, n, 1\rangle$ over which we must sum, that is $\omega_m \to \omega_m + (n-1)\omega$ and $\omega_m \to \omega_m + n\omega + \omega_s$. They are illustrated by the Feyman diagrams in Fig. xx. Hence, and neglecting the non-linear contribution $\hat{H}^{(2)}$,

$$\frac{1}{\tau} = \frac{2\pi}{\hbar^3} \sum_f \sum_{\mathbf{k}_s} \Big| \sum_m \frac{\langle f, n-1, 1|\hat{H}^{(1)}|m, n, 0\rangle\langle m, n, 0|\hat{H}^{(1)}|i, n, 0\rangle}{\omega - \omega_m} + \frac{\langle f, n-1, 1|\hat{H}^{(1)}|m, n-1, 1\rangle\langle m, n-1, 1|\hat{H}^{(1)}|i, n, 0\rangle}{-\omega_m - \omega_s} \Big|^2 \delta(\omega_f - \omega + \omega_s) \; . \tag{35.286}$$

Evaluated far from resonance, $\omega \gg \omega_m$, this result leads to Thomson and Compton scattering. Close to resonance the second term of the sum may neglected.

The matrix elements can be evaluated by the electric dipole Hamiltonian in second quantization,

$$\frac{1}{\tau} = \frac{2\pi}{\hbar} \sum_{\mathbf{k}_s} \Big| \sum_m \frac{\Omega_{fm}\Omega_{mi}}{\omega - \omega_m} \Big|^2 \delta(\omega_f - \omega + \omega_s) \; . \tag{35.287}$$

We convert the transition rate into a cross section via,

$$\sum_{\mathbf{k}_s} \to \frac{V}{(2\pi)^3} \int\int k_s^2 dk_s d\Omega = \frac{V}{(2\pi c)^3} \int\int \omega_s^2 d\omega_s d\Omega \; . \tag{35.288}$$

35.7.2.1 Transition rates for n-photon processes

It is adequate to move to a continuum of final states of the field. The sum over the final states includes a sum over the modes $\mathbf{k}$ and the polarizations λ,

$$\sum_f = \sum_{\mathbf{k}} \sum_{\lambda} \longrightarrow \frac{1}{h^3} \int_{\mathbb{R}^6} d^3p d^3r \sum_{\lambda} = \frac{V}{(2\pi c)^3} \int_\Omega d\Omega \; d\omega \; \omega^2 \sum_{\lambda} \; . \tag{35.289}$$

We now insert for the matrix element (first term in ()) the cartesian multipole expansion () and obtain,

$$\frac{1}{\tau} = \frac{2\pi}{\hbar^2}\sum_f \left|\langle f| - \imath e\sqrt{\frac{\hbar\omega}{2\varepsilon_0 V}}[\hat{\varepsilon}\cdot\mathbf{d}_E + ...]|i\rangle\right|^2 \delta(\omega-\omega_f)\sum_\lambda \tag{35.290}$$
$$\longrightarrow \frac{2\pi}{\hbar^2}\frac{V}{(2\pi c)^3}\frac{e^2\hbar\omega}{2\varepsilon_0 V}\omega^2\sum_\lambda\int |\hat{\varepsilon}\cdot\langle g|\mathbf{d}_E|e\rangle + \imath\hat{\varepsilon}\cdot\langle g|\mathbf{q}_E|e\rangle\cdot\mathbf{k}...] - ...|^2\, d\Omega\ .$$

Finally, letting $\sum_\lambda = 2$,

$$\frac{1}{\tau} = \frac{\alpha\omega^3}{\pi c^2}\int |\hat{\varepsilon}\cdot\langle g|\text{multipole-tensor}|e\rangle\text{wavenumber-tensor}|^2\, d\Omega\ . \tag{35.291}$$

For example, for dipole radiation, letting $\hat{\varepsilon} = \hat{\mathbf{e}}_z$,

$$\frac{1}{\tau} = \frac{\alpha\omega^3}{\pi c^2}\int |\hat{\varepsilon}\cdot\langle g|\mathbf{d}_E|e\rangle|^2\, d\cos\theta d\phi \tag{35.292}$$
$$= \frac{\alpha\omega^3}{\pi c^2}|\langle g|\mathbf{d}_E|e\rangle|^2\int |\cos\theta|^2 d\cos\theta d\phi = \frac{4\alpha\omega^3}{3c^2}|\langle g|\mathbf{d}_E|e\rangle|^2\ .$$

35.7.2.2 Absorption

In first order perturbation theory we have Fermi's Golden rule,

$$\frac{1}{\tau} = \frac{2\pi}{\hbar^2}\sum_f |\langle f|\hat{H}_{int}|i\rangle|^2\delta(\omega_f-\omega_i)\ . \tag{35.293}$$

In the dipolar approximation, $\hat{H}_{int} = -\mathbf{d}\cdot\vec{\mathcal{E}}$, and separating the field and atomic degrees of freedom, $|f\rangle = |N_f\rangle|A_f\rangle$, we get for absorption processes,

$$\frac{1}{\tau} = \frac{2\pi e^2}{\hbar^2}\sum_{N_f}\left|\langle N_f|\hat{\mathcal{E}}^-|N_i\rangle\cdot\langle A_f|\hat{\varepsilon}\cdot\hat{\mathbf{d}}|A_i\rangle\right|^2\delta(\omega_f-\omega_i)\ . \tag{35.294}$$

Generalizing to a statistical mixture of Fock states via $\sum_{N_f,N_i}\langle N_i|\hat{E}^+|N_f\rangle p_i\langle N_f|\hat{E}^-|N_i\rangle = \text{Tr}\ (\hat{\rho}\hat{\mathcal{E}}^+\hat{\mathcal{E}}^-)$, we may also write,

$$\frac{1}{\tau} = \frac{2\pi e^2}{\hbar^2}|M_{abs}|^2\delta(\omega_f-\omega_i)\text{Tr}\ (\hat{\rho}\hat{\mathcal{E}}^+\hat{\mathcal{E}}^-)\ , \tag{35.295}$$

where

$$|M_{abs}|^2 \equiv \langle A_f|\hat{\varepsilon}\cdot\hat{\mathbf{d}}|A_i\rangle\ . \tag{35.296}$$

For an incoming photon ω, we get $\omega_f = E_f$ and $\omega_i = E_i + \omega$. See Fig. 35.27(a).

35.7.2.3 Spontaneous and stimulated emission

In complete analogy to the absorption process, but now using the scattered field, $\hat{H}_{int} = -\mathbf{d}\cdot\hat{\vec{\mathcal{E}}}_s$, we get for emission processes,

$$\frac{1}{\tau} = \frac{2\pi e^2}{\hbar^2}|M_{em}|^2\delta(\omega_f-\omega_i)\text{Tr}\ (\hat{\rho}\hat{\mathcal{E}}_s^+\hat{\mathcal{E}}_s^-)\ , \tag{35.297}$$

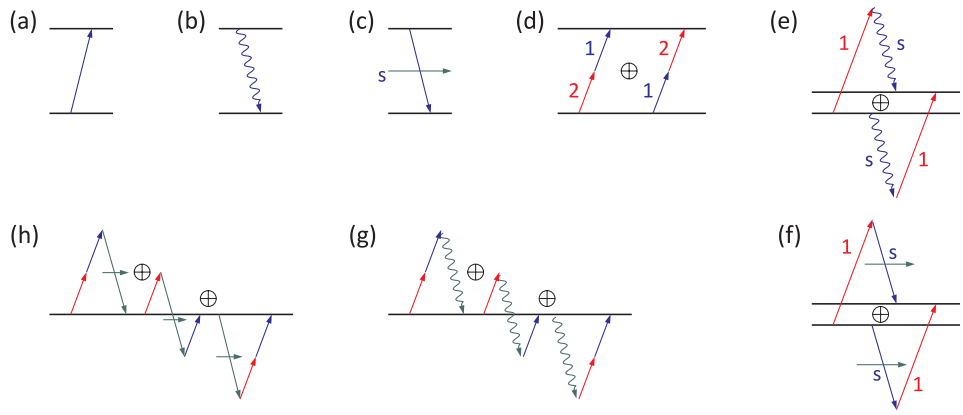

Figure 35.27: Feynman graphs for (a) absorption, (b) spontaneous emission, (c) stimulated emission, (d) two-photon absorption, (e) spontaneous Raman, (f) stimulated Raman, (g) spontaneous second harmonic generation, (h) and stimulated second harmonic generation.

where

$$|M_{em}|^2 \equiv \langle A_f|\hat{\varepsilon}_s \cdot \hat{\mathbf{d}}|A_i\rangle \ . \tag{35.298}$$

For an outgoing photon ω_s, we get $\omega_f = E_f + \omega_s$ and $\omega_i = E_i$.

35.7.2.4 Two-photon absorption

In second order perturbation theory we have the Kramers-Heisenberg rule,

$$\frac{1}{\tau} = \frac{2\pi}{\hbar^2}\sum_f \left|\sum_m \frac{\langle f|\hat{H}_{int}|m\rangle\langle m|\hat{H}_{int}|i\rangle}{\omega - \omega_m}\right|^2 \delta(\omega_f - \omega_i) \ . \tag{35.299}$$

In the dipolar approximation, $\hat{H}_{int} = -\mathbf{d}\cdot\hat{\vec{\mathcal{E}}}_1 - \mathbf{d}\cdot\hat{\vec{\mathcal{E}}}_2$, and separating the field and atomic degrees of freedom, $|f\rangle = |N_f\rangle|A_f\rangle$, we get for two-photon absorption processes,

$$\frac{1}{\tau} = \frac{2\pi e^4}{\hbar^4}\sum_{N_f}\left|\sum_{N_m,A_m}\frac{\langle N_f|\mathcal{E}_2^-|N_m\rangle\langle N_m|\mathcal{E}_1^-|N_i\rangle\langle A_f|\hat{\varepsilon}_2\cdot\hat{\mathbf{d}}|A_m\rangle\langle A_m|\hat{\varepsilon}_1\cdot\hat{\mathbf{d}}|A_i\rangle}{\omega_1 - \omega_m}\right. \tag{35.300}$$

$$\left. + \frac{\langle N_f|\mathcal{E}_1^-|N_m\rangle\langle N_m|\mathcal{E}_2^-|N_i\rangle\langle A_f|\hat{\varepsilon}_1\cdot\hat{\mathbf{d}}|A_m\rangle\langle A_m|\hat{\varepsilon}_2\cdot\hat{\mathbf{d}}|A_i\rangle}{\omega_2 - \omega_m}\right|^2 \delta(\omega_f - \omega_1 - \omega_2) \ .$$

Generalizing to a statistical mixture of Fock states via $\sum_{N_f,N_i} p_i|\langle N_f|\hat{\mathcal{E}}_2^-\hat{\mathcal{E}}_1^-|N_i\rangle = \mathrm{Tr}\ (\hat{\rho}\hat{\mathcal{E}}_1^+\hat{\mathcal{E}}_2^+\hat{\mathcal{E}}_2^-\hat{\mathcal{E}}_1^-)$, we may also write,

$$\frac{1}{\tau} = \frac{2\pi e^4}{\hbar^4}|M_{tpa}|^2\delta(\omega_f - \omega_i)\mathrm{Tr}\ (\hat{\rho}\hat{\mathcal{E}}_1^+\hat{\mathcal{E}}_2^+\hat{\mathcal{E}}_2^-\hat{\mathcal{E}}_1^-) \ , \tag{35.301}$$

where

$$M_{tpa} \equiv \langle A_f|\hat{\varepsilon}_2 \cdot \hat{\mathbf{d}} G(E_i + \omega_1)\hat{\varepsilon}_1 \cdot \hat{\mathbf{d}}|A_i\rangle + \langle A_f|\hat{\varepsilon}_1 \cdot \hat{\mathbf{d}} G(E_i + \omega_2)\hat{\varepsilon}_2 \cdot \hat{\mathbf{d}}|A_i\rangle \ . \quad (35.302)$$

For two incoming photons ω, we get $\omega_f = E_f$ and $\omega_i = E_i + \omega_1 + \omega_2$. Here, G denotes the *photon propagator*,

$$G(\omega) = \sum_m \frac{|A_m\rangle\langle A_m|}{\omega - E_m} \ . \quad (35.303)$$

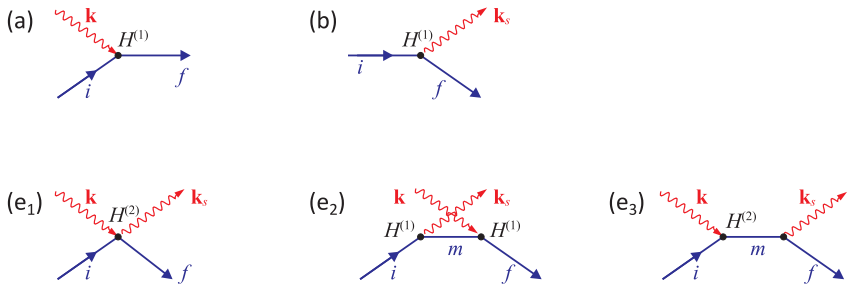

Figure 35.28: Feynman graphs for (a) absorption, (b) spontaneous emission, (c) stimulated emission, (e)(i-iii) spontaneous Raman.

35.7.2.5 Spontaneous and stimulated Raman process

In complete analogy to the two-photon absorption process, but now using the incident and the scattered fields, $\hat{H}_{int} = -\mathbf{d}\cdot\vec{\mathcal{E}}_1 - \mathbf{d}\cdot\vec{\mathcal{E}}_s$, we get for spontaneous and stimulated Raman processes,

$$\frac{1}{\tau} = \frac{2\pi e^4}{\hbar^4}|M_{ram}|^2\delta(\omega_f - \omega_i)\mathrm{Tr}\ (\hat{\rho}\hat{\mathcal{E}}_1^+\hat{\mathcal{E}}_s^-\hat{\mathcal{E}}_s^+\hat{\mathcal{E}}_1^-) \ , \quad (35.304)$$

where

$$M_{ram} \equiv \langle A_f|\hat{\varepsilon}_s \cdot \hat{\mathbf{d}} G(E_i + \omega_1)\hat{\varepsilon}_1 \cdot \hat{\mathbf{d}}|A_i\rangle + \langle A_f|\hat{\varepsilon}_1 \cdot \hat{\mathbf{d}} G(E_i - \omega_s)\hat{\varepsilon}_s \cdot \hat{\mathbf{d}}|A_i\rangle \ . \quad (35.305)$$

For an incoming photon ω_1 and a scattered photon ω_s, we get $\omega_f = E_f + \omega_s$ and $\omega_i = E_i + \omega_1$.

35.7.2.6 General n-photon processes

The transition probability in n-th order perturbation theory can be formulated in a general way as,

$$\frac{1}{\tau} = \frac{2\pi e^2}{\hbar^{2n}}|M_{fi}^{(n)}|^2\delta(\omega_f - \omega_i)\mathrm{Tr}\ (\hat{\rho}\hat{\mathcal{E}}_1^{\pm}\hat{\mathcal{E}}_2^{\pm}...\hat{\mathcal{E}}_2^{\mp}\hat{\mathcal{E}}_1^{\mp}) \ , \quad (35.306)$$

where

$$\begin{aligned} M_{fi}(\omega_n, ..., \omega_1) \equiv \mathcal{S}_p\langle A_f|\hat{\varepsilon}_n\hat{\mathbf{d}}G(E_i \pm \omega_1 \pm ... \pm \omega_{n-2} \pm \omega_{n-1})\ ... \quad (35.307)\\ ...\ \hat{\varepsilon}_{n-1}\hat{\mathbf{d}}G(E_i \pm \omega_1 \pm ... \pm \omega_{n-2})\ ...\\ ...\ \hat{\varepsilon}_1 \cdot \hat{\mathbf{d}}G(E_i \pm \omega_1)|A_i\rangle \ . \end{aligned}$$

The upper signs hold for absorbed photons (up to n), the lower for emitted photons, $\omega_f = E_f + \omega_1 + ... + \omega_n$ and $\omega_i = E_i + \omega_1 + ... + \omega_n$.

For n-photon processes, there are theoretically up to $n + 1$ different types, each one with $n!$ possible temporal sequences, which can be illustrated in Feynman graphs. Additionally, for every emitted photon can be either spontaneous or stimulated. The number of possible time sequences is reduced, if some absorbed or emitted photons have the same frequency by $m!$ (if m is the number og identical photons).

For example there are (3+1) different types of three-photon processes: 3 photons in, 2 photons in 1 out, 1 photon in 2 out, 3 photons out.

For example second harmonic generation: 3! possible time sequences, 2 processes, 2 equivalent photons = $\frac{3!2}{2!}$ possible Feynman graphs.

35.7.3 Exercises

35.7.3.1 Ex: Two-photon transitions in rubidium

Considering the following transitions of rubidium, $5S_{1/2} - 5P_{1/2}$ at 795 nm with $\Gamma_{795} = (2\pi)$ 6 MHz linewidth $5S_{1/2} - 5P_{3/2}$ at 780 nm with $\Gamma_{780} = (2\pi)$ 6MHz, and $5P_{3/2} - 5D_{5/2}$ at 776 nm with $\Gamma_{776} = (2\pi)$ 700 kHz linewidth. Calculate the rate for resonant two-photon transitions from the ground state to the $5D_{5/2}$ level without bothering about hyperfine splitting induced by a laser intensity of $I = 1$ mW/cm^2.

Solution:

35.7.3.2 Ex: Spin relaxation in a dipole trap

Consider a transition in a hypothetical atomic species without nuclear spin between two levels $^2S_{1/2}$ and $^2P_{1/2}$ driven far-off resonance. Calculate the spin relaxation rate as a function of the detuning.

Solution: *Spin relaxation means that atoms polarized in a specific Zeeman state, say $^2S_{1/2}$, $m_J = +\frac{1}{2}$, may transit to the $m_J = -\frac{1}{2}$ state due to spontaneous Raman scattering.*

35.7.3.3 Ex: Rayleigh scattering and spin relaxation

Derive the rates for Rayleigh scattering and spin relaxation for ^{87}Rb driven far-off resonance. **Help**: Determine the hyperfine structure of the D1 and D2 lines and calculate the transition rates between sublevels from the Kramers-Heisenberg formula.

Solution: *The hyperfine structure is [895, 271, 1245].*

35.8 Beam splitting and quantum amplification

The beam splitter is one of the most important devices not only in practical optical setups, but also for its conceptual role in quantum mechanics. It thus deserves a dedicated section.

A classical beam splitter divides a beam of light into two branches, which are distinct by their orientation in space or by other degrees of freedom. On the other hand, a photonic picture obviously requires a quantum description. For one reason, the photon numbers scattered into the two branches are quantum mechanically entangled. Furthermore, the very concept of the beam splitter necessitates a second entrance port which, even if empty, unavoidably introduces quantum noise. Finally, in quantum mechanics, as we already learned for the case of measurement devices, the beam splitting device needs to be included in a full description of the beam splitting dynamics, which has important concequences. In fact, quantum mechanically the beam splitting resembles more a scattering problem, where the light beam represents one entrance and output channel and the physical beam splitter the other one (see Fig. 35.29).

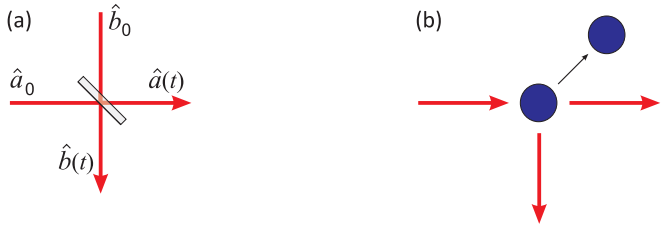

Figure 35.29: (a) Classical beam splitting. (b) Scattering of two modes.

This section is organized as follows. In Secs. 35.8.1 and 35.8.2 we discuss beam splitting at a macroscopic splitting device, i.e. we neglect backaction of the beam splitting event on the splitting device (e.g. recoil or transitions between electronic levels). Backaction on the splitting device is then treated in 35.8.3.

35.8.1 The beam splitter in various representations

We have learned in Sec. 35.4 how a two-level quantum systems couples to a harmonic oscillator via terms in the Hamiltonian containing expressions such as $\hat{\sigma}_+\hat{a}$. We will now see how two quantum harmonic oscillators couple together via terms such as $\hat{a}^\dagger\hat{b}$, where $\hat{a}$ and $\hat{b}$ are the field operators of two oscillator modes. A device providing such a coupling is called *beam splitter*. It *mixes two modes* according to the Hamiltonian,

$$\boxed{\hat{H} = \tfrac{\hbar}{2}\Omega(\hat{a}\hat{b}^\dagger + \hat{a}^\dagger\hat{b})}\,. \tag{35.308}$$

The beam splitter can be described in the Schrödinger or the Heisenberg picture exploiting the formalism introduced in Sec. 24.5.

35.8.1.1 Schrödinger picture

In the Schrödinger picture, if $|\psi_0\rangle = |\alpha_0\rangle|\beta_0\rangle$ is the state of the modes before the beam splitter, the Schrödinger equation, $\imath\hbar\partial_t|\psi(t)\rangle = \hat{H}|\psi(t)\rangle$, gives us the state after the splitter via its solution,

$$\boxed{|\psi(t)\rangle = e^{\imath\Omega t/2(\hat{a}\hat{b}^\dagger + \hat{a}^\dagger\hat{b})}|\psi_0\rangle} \ . \tag{35.309}$$

A 50% beam splitter corresponds to a $\Omega t = \pi/2$ pulse.

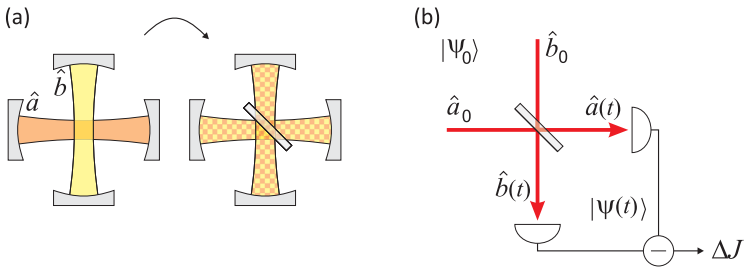

Figure 35.30: (a) Coupling of two cavity modes by insertion of a beam splitter. (b) Beam splitter mixing two propagating modes.

35.8.1.2 Heisenberg picture

We can also describe the beam splitter in the Heisenberg picture. With the commutation rules,

$$[\hat{a}, \hat{a}^\dagger] = 1 = [\hat{b}, \hat{b}^\dagger] \quad , \quad [\hat{a}, \hat{b}] = 0 \ , \tag{35.310}$$

and the Heisenberg equations,

$$\begin{aligned} \dot{\hat{a}} &= \tfrac{\imath}{\hbar}[\hat{H}, \hat{a}] = \tfrac{\imath}{2}\Omega[(\hat{a}\hat{b}^\dagger + \hat{a}^\dagger\hat{b}), \hat{a}] = -\tfrac{\imath}{2}\Omega\hat{b} \\ \dot{\hat{b}} &= \tfrac{\imath}{\hbar}[\hat{H}, \hat{b}] = \tfrac{\imath}{2}\Omega[(\hat{a}\hat{b}^\dagger + \hat{a}^\dagger\hat{b}), \hat{b}] = -\tfrac{\imath}{2}\Omega\hat{a} \ , \end{aligned} \tag{35.311}$$

we calculate,

$$\ddot{\hat{a}} = -\tfrac{1}{4}\Omega^2\hat{a} \quad \text{and} \quad \ddot{\hat{b}} = -\tfrac{1}{4}\Omega^2\hat{b} \ , \tag{35.312}$$

the solution of which is,

$$\begin{pmatrix} \hat{a}(t) \\ \hat{b}(t) \end{pmatrix} = \begin{pmatrix} \cos\frac{1}{2}\Omega t & -\imath\sin\frac{1}{2}\Omega t \\ -\imath\sin\frac{1}{2}\Omega t & \cos\frac{1}{2}\Omega t \end{pmatrix} \begin{pmatrix} \hat{a}_0 \\ \hat{b}_0 \end{pmatrix} \ . \tag{35.313}$$

Introducing the abbreviation $\eta \equiv \cos^2(\Omega t/2)$, we can describe the evolution as,

$$\boxed{\begin{pmatrix} \hat{a}(t) \\ \hat{b}(t) \end{pmatrix} = \begin{pmatrix} \sqrt{\eta} & -\imath\sqrt{1-\eta} \\ -\imath\sqrt{1-\eta} & \sqrt{\eta} \end{pmatrix} \begin{pmatrix} \hat{a}_0 \\ \hat{b}_0 \end{pmatrix}} \ . \tag{35.314}$$

For a $\Omega t = \pi/2$ pulse, we get,

$$\begin{pmatrix} \hat{a}(t) \\ \hat{b}(t) \end{pmatrix} = \sqrt{\tfrac{1}{2}} \begin{pmatrix} 1 & -\imath \\ -\imath & 1 \end{pmatrix} \begin{pmatrix} \hat{a}_0 \\ \hat{b}_0 \end{pmatrix} \ . \tag{35.315}$$

that each the reflected beam suffers a phase shift of $\pi/2$ [16]. Resolve the Excs. 35.8.9.1 to 35.8.9.3.

35.8.1.3 Glauber representation

In the Heisenberg picture, the wavefunctions of the quantum states (and hence the density operator and the Wigner function) remain unchanged during the evolution, i.e.,

$$\begin{aligned} |\psi\rangle \equiv |\alpha\rangle|\beta\rangle = |\alpha_0\rangle|\beta_0\rangle \equiv |\psi_0\rangle \ , \\ \rho_{|\psi\rangle} = \rho_{|\psi_0\rangle} \ , \\ W_{|\psi\rangle}(\gamma) = W_{|\psi_0\rangle}(\gamma) \ , \\ P_{|\psi\rangle}(\gamma) = P_{|\psi_0\rangle}(\gamma) \ , \\ Q_{|\psi\rangle}(\gamma) = Q_{|\psi_0\rangle}(\gamma) \ , \end{aligned} \tag{35.316}$$

where the $|\psi\rangle$ are arbitrary quantum states and the $|\gamma\rangle$ are Glauber's states. This means that two field modes mixed at a beam splitter do not interfere with phase space, i.e. do not develop quantum correlations. Of course, that would be too easy, indeed; we will soon see in Sec. 35.3, that we need to work a little harder to produce quantum correlations.

Setting $\theta \equiv \Omega t/2$ and $\hat{b} \curvearrowright -\imath\hat{b}$ in the propagator of Eq. (35.309), we may define a beam splitting operator in analogy to the displacement operator (24.111),

$$\boxed{\hat{B}(\theta) \equiv e^{\theta(\hat{a}^\dagger \hat{b} - \hat{a}\hat{b}^\dagger)}} \ , \tag{35.317}$$

which is an equivalent beam splitter description. We find,

$$\boxed{\begin{aligned} \hat{B}(\theta)^\dagger \hat{a} \hat{B}(\theta) &= \hat{a}\cos\theta + \hat{b}\sin\theta \\ \hat{B}(\theta)^\dagger \hat{b} \hat{B}(\theta) &= -\hat{a}\sin\theta + \hat{b}\cos\theta \end{aligned}} \ , \tag{35.318}$$

as will be shown in Exc. 35.8.9.4 [17].

35.8.1.4 Fock representation

Alternatively, we can describe the beam splitter in the Fock representation [18]. The Hamiltonian of the beam splitter couples two modes of harmonic oscillators. Expanding on a two-dimensional Fock basis via $|\psi\rangle \equiv (...|0\rangle|n_a\rangle....|n_b\rangle|0\rangle...)$ we can gain more

[16] This fact is a consequence of *time-reversal invariance* at the beam splitter. We will see later that, in fact, only the beam reflected at the surface of an optically denser medium suffers a phase-shift of π, while the beam reflected at an optically thinner medium does not suffer any phase shift.

[17] Compare to the formulas (24.119), (35.90), and (35.361).

[18] A more in-depth discussion is found in Ref. [791].

insight:

$$\begin{aligned}\hat{H} &= \tfrac{\hbar}{2}\Omega(\hat{a}\hat{b}^\dagger + \hat{a}^\dagger\hat{b}) \qquad (35.319)\\ &= \tfrac{\hbar}{2}\Omega\sum_{n_a,n_b}\sqrt{n_a(n_b+1)}|n_a-1,n_b+1\rangle\langle n_a,n_b| + \sqrt{(n_a+1)n_b}|n_a+1,n_b-1\rangle\langle n_a,n_b|\\ &= \sum_{n_a+n_b}\hat{H}_{a+b}\ ,\end{aligned}$$

where,

$$\hat{H}_{a+b} = \tfrac{\hbar}{2}\Omega\begin{pmatrix} 0 & \sqrt{1n_b} & & & & \\ \sqrt{1n_b} & 0 & \sqrt{2(n_b-1)} & & & \\ & \sqrt{2(n_b-1)} & \ddots & & & \\ & & & \ddots & \sqrt{n_a 1} & \\ & & & \sqrt{n_a 1} & 0 & \end{pmatrix}. \qquad (35.320)$$

The sub-spaces with n_a+n_b+1 photons are completely degenerate, since $\det(\lambda\mathbb{I}_{a+b} - \hat{H}_{a+b}) = \lambda^{n_a+n_b+1} = 0$. The degeneracy is removed, when we introduce loss mechanisms into one of the modes. Thus, the Hamiltonian can be understood as a Dicke system with the multiplicity $\frac{1}{2}\widehat{(n_a+n_b)} = n_a+n_b+1$. See also Exc. 35.8.9.2.

Example 215 (*Beam splitter with 0 or 1 photons*): As an example, we consider $n_a, n_b = 0, 1$. Then, in the basis $\begin{pmatrix}|0,0\rangle & |0,1\rangle & |1,0\rangle & |0,2\rangle & |1,1\rangle & |2,0\rangle & \cdots\end{pmatrix}^t$ the matrix of the Hamiltonian becomes,

$$\hat{H} = \tfrac{1}{2}\Omega\begin{pmatrix} 0 & & & & & & \\ & 0 & 1 & & & & \\ & 1 & 0 & & & & \\ & & & 0 & \sqrt{2} & 0 & \\ & & & \sqrt{2} & 0 & \sqrt{2} & \\ & & & 0 & \sqrt{2} & 0 & \end{pmatrix}.$$

It is easily verified that the matrix of eigenvectors and the matrix of eigenvalues,

$$U = \begin{pmatrix} 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & -1 & 1 & 0 & 0 & 0 \\ 0 & 1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & -\frac{1}{2}\sqrt{2} & -1 & \frac{1}{2}\sqrt{2} \\ 0 & 0 & 0 & 1 & 0 & 1 \\ 0 & 0 & 0 & -\frac{1}{2}\sqrt{2} & 1 & \frac{1}{2}\sqrt{2} \end{pmatrix} \quad \text{respectively} \quad E = \tfrac{\hbar}{2}\Omega\begin{pmatrix} 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & -2 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 2 \end{pmatrix}$$

satisfy $U^{-1}HU = E$. Hence,

$$|\psi\rangle = U^{-1}e^{\imath Et}U|\psi_0\rangle\ ,$$

and we find, that the state $|1,1\rangle = \begin{pmatrix}0 & 0 & 0 & 0 & 1 & 0\end{pmatrix}^T$ is transformed into a superposition,

$$\begin{pmatrix}0 & 0 & 0 & \frac{1}{\sqrt{2}}\imath\sin\Omega t & \cos\Omega t & \frac{1}{\sqrt{2}}\imath\sin\Omega t\end{pmatrix}^T \overset{\Omega t=\pi/2}{\longrightarrow} \frac{\imath}{\sqrt{2}}(|0,2\rangle + |2,0\rangle)\ .$$

Similarly, we find that the superposition state $\frac{1}{\sqrt{2}}(|1,0\rangle+|0,1\rangle) = \begin{pmatrix}0 & 1 & -1 & 0 & 0 & 0\end{pmatrix}^T$ is transformed into,

$$e^{-\frac{1}{2}\imath\Omega t}\begin{pmatrix}0 & 1 & -1 & 0 & 0 & 0\end{pmatrix}^T \overset{\Omega t=\pi/2}{\longrightarrow} e^{-\imath\pi/4}\frac{1}{\sqrt{2}}(|1,0\rangle + |0,1\rangle) \ .$$

35.8.2 Fock and Glauber states at a beam splitter

A beam splitter divides a Fock state containing N photons into two Glauber states,

$$\begin{aligned}|\psi\rangle &= \frac{1}{2^{N/2}\sqrt{N!}}(\hat{a}_1^\dagger + \hat{a}_2^\dagger)^N|0,0\rangle = \frac{1}{2^{N/2}\sqrt{N!}}\sum_{n=0}^{N}\binom{N}{n}(\hat{a}_1^\dagger)^n(\hat{a}_2^\dagger)^{N-n}|0,0\rangle \qquad (35.321)\\ &= \frac{1}{2^{N/2}}\sum_{n=0}^{N}\sqrt{\binom{N}{n}}|n,N-n\rangle = \sum_{n=0}^{N}\sqrt{\binom{N}{n}0.5^n 0.5^{N-n}}|n,N-n\rangle\\ &\simeq \sum_{n=0}^{N}\sqrt{\frac{(N/2)^n}{n!}e^{-N/2}}|n,N-n\rangle = e^{-|\alpha|/2}\sum_{n=0}^{N}\frac{\alpha^n}{\sqrt{n!}}|n,N-n\rangle \ ,\end{aligned}$$

approximating the binomial distribution by the Poisson distribution,

$$\binom{N}{n}p^n(1-p)^{N-n} \overset{N\to\infty}{\longrightarrow} \frac{(pN)^n}{n!}e^{-pN} \ . \qquad (35.322)$$

and defining $\alpha \equiv N/2$. The normalization is $\langle\psi|\psi\rangle = 1$. The population in an individual mode is,

$$\begin{aligned}\langle\hat{n}_1\rangle = \langle\psi|\hat{a}_1^\dagger\hat{a}_1|\psi\rangle &= \frac{1}{2^N}\langle m,N-m|\sum_{n,m=0}^{N}\sqrt{\binom{N}{m}}\hat{a}_1^\dagger\hat{a}_1\sqrt{\binom{N}{n}}|n,N-n\rangle \qquad (35.323)\\ &= \frac{1}{2^N}\sum_{n=0}^{N}\binom{N}{n}n = \frac{N}{2} \ .\end{aligned}$$

The result (35.321) shows that, ignoring (tracing over) one of the modes, the other mode automatically becomes a Glauber state [19].

Besides that,

$$\begin{aligned}\langle\hat{n}_1^2\rangle &= \frac{1}{2^n}\sum_{n=0}^{n}\binom{N}{n}n^2 = \frac{N}{2^n}\sum_{n=0}^{N-1}\binom{N}{n}(n+1) = \frac{N(N+1)}{4} \qquad (35.324)\\ \langle\hat{n}_1\hat{n}_2\rangle &= \frac{1}{2^n}\sum_{n=0}^{n}\sqrt{\binom{N}{n}}n(N-n) = N\langle\hat{n}_1\rangle - \langle\hat{n}_1^2\rangle = \frac{N(N-1)}{4}\end{aligned}$$

[19] This does not mean that the output modes are uncorrelated. For instance, if we measure n photons in one mode, we know that the other must contain exactly $N-n$ photons. However, the correlations are so dense in phase space that they are not resolvable or decohere rapidly. In fact, it can be shown that coherent states are the only pure states that produce uncorrelated outputs when mixed by a passive linear-optics device [16, 14].

The squeezing parameter is,

$$\xi_{12} = \frac{\sigma^2(\hat{n}_1 - \hat{n}_2)}{\langle \hat{n}_1 \rangle + \langle \hat{n}_2 \rangle} = \frac{\langle \hat{n}_1^2 - 2\hat{n}_1\hat{n}_2 + \hat{n}_2^2 \rangle}{N} = \frac{2\langle \hat{n}_1^2 \rangle - 2\langle \hat{n}_1\hat{n}_2 \rangle}{N} = 1 \ . \tag{35.325}$$

The correlation functions at equal times are,

$$g_{11} = \frac{\left\langle \hat{a}_1^\dagger \hat{a}_1^\dagger \hat{a}_1 \hat{a}_1 \right\rangle}{\langle \hat{n}_1 \rangle^2} = \frac{1}{\langle \hat{n}_1 \rangle^2} \frac{1}{2^n} \sum_{n=2}^{n} \binom{N}{n} n(n-1) = \frac{\langle \hat{n}_1^2 \rangle - \langle \hat{n}_1 \rangle}{\langle \hat{n}_1 \rangle^2} = 1 \tag{35.326}$$

$$g_{12} = \frac{\left\langle \hat{a}_1^\dagger \hat{a}_2^\dagger \hat{a}_2 \hat{a}_1 \right\rangle}{\langle \hat{n}_1 \rangle \langle \hat{n}_2 \rangle} = \frac{1}{\langle \hat{n}_1 \rangle^2} \frac{1}{2^n} \sum_{n=0}^{N} \binom{N}{n} n(N-n) = \frac{N\langle \hat{n}_1 \rangle - \langle \hat{n}_1^2 \rangle}{\langle \hat{n}_1 \rangle^2} = \frac{N-1}{N}$$

The Cauchy-Schwarz inequality and the quantum inequality are both met,

$$\begin{aligned} g_{12} &\leq \sqrt{g_{11} g_{22}} \\ g_{12} &\leq \sqrt{\left(g_{11} + \frac{1}{\langle \hat{n}_1 \rangle} \right) \left(g_{22} + \frac{1}{\langle \hat{n}_2 \rangle} \right)} \end{aligned} \tag{35.327}$$

In comparison, a Glauber state is normally divided,

$$\begin{aligned} |\psi\rangle = |\alpha_1\rangle|\alpha_2\rangle &= e^{-|\alpha_1|^2/2} \sum_n \frac{\alpha_1^n}{\sqrt{n!}} |n\rangle e^{-|\alpha_2|^2/2} \sum_m \frac{\alpha_2^m}{\sqrt{m!}} |m\rangle \\ &= e^{-|\alpha_1|^2/2 - |\alpha_2|^2/2} \sum_{n,m} \frac{\alpha_1^n \alpha_2^m}{\sqrt{n!}\sqrt{m!}} |n\rangle|m\rangle \ . \end{aligned} \tag{35.328}$$

35.8.2.1 Density matrix representation

The density matrix for a pure state is,

$$\hat{\rho} = |\psi\rangle\langle\psi| = \begin{pmatrix} |\langle\psi|1\rangle|^2 & \langle 1|\psi\rangle\langle\psi|2\rangle \\ \langle 2|\psi\rangle\langle\psi|1\rangle & |\langle\psi|2\rangle|^2 \end{pmatrix} \ . \tag{35.329}$$

The evolution of such a state is described by the von Neumann equation:

$$\imath\hbar\partial_t \hat{\rho}(t) = [\hat{H}, \hat{\rho}(t)] \ . \tag{35.330}$$

For the beam splitter we obtain,

$$\hat{\rho} = |\psi\rangle\langle\psi| = \begin{pmatrix} |\langle\psi|0,0\rangle|^2 & \langle 0,0|\psi\rangle\langle\psi|0,1\rangle & \langle 0,0|\psi\rangle\langle\psi|1,0\rangle & \\ \langle 0,1|\psi\rangle\langle\psi|0,0\rangle & |\langle\psi|0,1\rangle|^2 & \langle 0,1|\psi\rangle\langle\psi|1,0\rangle & \\ \langle 1,0|\psi\rangle\langle\psi|0,0\rangle & \langle 1,0|\psi\rangle\langle\psi|0,1\rangle & |\langle\psi|1,0\rangle|^2 & \\ & & & \ddots \end{pmatrix} \ . \tag{35.331}$$

Example 216 (*Density matrix for the beam splitter with 0 or 1 photons*): For the case of the superposition states, $|\psi\rangle = \frac{1}{\sqrt{2}}(|0,1\rangle \pm |1,0\rangle)$,

$$\hat{\rho} = \begin{pmatrix} 0 & 0 & 0 & \\ 0 & \frac{1}{2} & \pm\frac{1}{2} & \\ 0 & \pm\frac{1}{2} & \frac{1}{2} & \\ & & & \ddots \end{pmatrix} .$$

Obviously, $\hat{\rho} = \hat{\rho}^2$. For the above superposition state, $\partial_t \hat{\rho}(t) = 0$.

35.8.3 Backaction of the splitting device

In quantum mechanics, beam splitting is ALWAYS an interaction between two degrees of freedom, the mode suffering the splitting (which we already treated quantum mechanically in the preceding sections), and the splitting device (which we will treat as an ancilla in the following, similarly as we did for a quantum measurement). In classical beam splitters, the dynamics of the ancilla is neglected, but in quantum beam splitters the ancilla serves as a witness of a splitting event. In practice, it can be a recoiling atom, a phase shift of an internal atomic state, or something else.

We will now develop a generic model allowing us to describe quantum mechanically (i) strong measurement directly on the system or (ii) weak measurements via an ancilla. For simplicity, we will assume the beam splitting device to be a two-level atom including its internal and external degrees of freedom. The light mode may then interact with the atom (or not) and be scattered into different directions of space. In order to emulate a beam splitter we need to ensure the existence of only two scattered exit modes. This can be done by putting the atom in a ring cavity, where the only modes available are the forward and the backward scattered mode. It is fair to say that this model represents the simplest possible beam splitter description including backaction. In the same time, the system exhibits a dynamics known as collective atomic recoil lasing (CARL), which is extensively discussed in Chp. 42.

35.8.4 Shot noise

As any quantized degree of freedom, a light mode is subject to intrinsic quantum noise imposed by the Heisenberg uncertainty relation, as we have seen for the harmonic oscillator (24.124). The Heisenberg limit in the quadrature phases of a light field determines the *shot noise* noise in the intensity of the light beam. To measure this noise, we divide the laser beam by a beam splitter into two beams $\hat{a}$ and $\hat{b}$ and recombine them with a second beam splitter,

$$\hat{c} = \tfrac{1}{\sqrt{2}}(\hat{a} + \hat{b}) \quad , \quad \hat{d} = \tfrac{1}{\sqrt{2}}(\hat{a} - \hat{b}) \; . \tag{35.332}$$

Detected by photodetectors with the gain coefficient g, these two beams produce currents,

$$\hat{I}_c = g\hat{c}^\dagger \hat{c} \quad , \quad \hat{I}_d = g\hat{d}^\dagger \hat{d} \; . \tag{35.333}$$

We add and subtract these currents,

$$\hat{I}_+ \equiv \hat{I}_c + \hat{I}_d = g(\hat{a}^\dagger \hat{a} + \hat{b}^\dagger \hat{b}) \quad , \quad \hat{I}_- \equiv \hat{I}_c - \hat{I}_d = g(\hat{a}^\dagger \hat{b} + \hat{b}^\dagger \hat{a}) \; . \tag{35.334}$$

and,

$$\hat{I}_+^2 = g^2[\hat{n}_a^2+\hat{n}_b^2+2\hat{n}_a\hat{n}_b] \quad , \quad \hat{I}_-^2 = g^2[(\hat{a}^\dagger\hat{b})^2+(\hat{b}^\dagger\hat{a})^2+\hat{a}^\dagger\hat{a}+\hat{b}\hat{b}^\dagger+\hat{a}\hat{a}^\dagger+\hat{b}^\dagger\hat{b}] \ . \quad (35.335)$$

The expectation values are,

$$\begin{aligned} \langle\hat{I}_+\rangle = g\langle\hat{n}_a\rangle_a \quad &, \quad \langle\hat{I}_+\rangle = 0 \\ \langle\hat{I}_+^2\rangle = g\langle(\hat{a}^\dagger\hat{a})^2\rangle_a \quad &, \quad \langle\hat{I}_-^2\rangle = g^2\langle\hat{n}_a\rangle_a \ . \end{aligned} \quad (35.336)$$

Now, with the definition, $\langle(\Delta\hat{I})^2\rangle \equiv \langle\hat{I}^2\rangle - \langle\hat{I}\rangle^2$, we get the intensity noise of the field,

$$\langle\Delta\hat{I}_+^2\rangle = \langle(\Delta\hat{I}_+)^2\rangle = g^2\langle(\Delta\hat{n}_a)^2\rangle \ , \quad (35.337)$$

and the shot noise [20] ,

$$\langle\Delta\hat{I}_-^2\rangle = g^2 I_a \ . \quad (35.338)$$

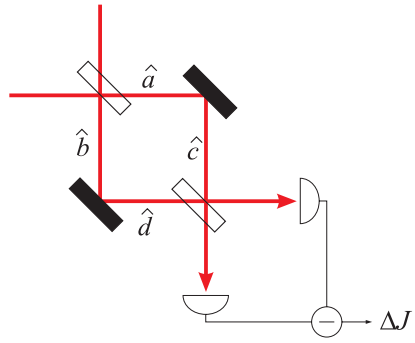

Figure 35.31: Shot noise measurement.

35.8.5 Quantum amplifier

We will call in the following as *quantum signals* degrees of freedom subject to quantum noise. Typically a quantum signal will be a mode of an electric field, represented by an annihilation operator $\hat{a}$. Such a mode can be enhanced by *quantum amplifier*, which is a device amplifying quantum signals according to the rules of quantum mechanics. Examples include the active elements of lasers and optical parametric amplifiers. A quantum amplifier is characterized by its gain and its own intrinsic quantum noise, which are interdependent parameters; the higher the gain, the larger the uncertainty noise. In the case of lasers, the uncertainty corresponds to the amplified spontaneous emission of the active medium.

Quantum amplification is a unitary transformation $\hat{U}$, acting in an initial state $|in\rangle$ and producing (in the Schrödinger figure) the amplified state,

$$|out\rangle = \hat{U}|in\rangle \ . \quad (35.339)$$

[20] Insert citation, f.ex., [Hans Marin Flores, PhD thesis].

The amplification depends on the mean value $\langle\hat{a}\rangle$ of the annihilation operator and its dispersion $\langle\hat{a}^\dagger\hat{a}\rangle - \langle\hat{a}^\dagger\rangle\langle\hat{a}\rangle$. A coherent state is a state with minimal uncertainty; when the state is transformed, the uncertainty may increase. This increase can be interpreted as noise in the amplifier. The gain G can be defined as follows:

$$G = \frac{\langle\hat{a}\rangle_{out}}{\langle\hat{a}\rangle_{in}} \ . \tag{35.340}$$

The quantum amplifier can also be described in the Heisenberg picture; the changes are attributed to the amplification of the field operator. Thus, the evolution of the operator $\hat{a}_{out}$ is given by

$$\hat{a}_{out} = \hat{U}^\dagger\hat{a}\hat{U} \ , \tag{35.341}$$

while the state vector remains unchanged. The gain is then given by,

$$G = \frac{\langle\hat{a}_{out}\rangle_{in}}{\langle\hat{a}\rangle_{in}} \ . \tag{35.342}$$

In general, the gain G may be complex, and it may depend on the initial state. For laser applications, the amplification of coherent states is important. Therefore, it is usually assumed that the initial state is a coherent state characterized by a complex-valued initial parameter α, such that $|in\rangle = |\alpha\rangle$. Even with such a restriction, the gain may depend on the amplitude or phase of the initial field.

In the following, the Heisenberg representation is used; all brackets are assumed to be evaluated with respect to the initial coherent state,

$$\text{noise} = \langle\hat{a}^\dagger_{out}\hat{a}_{out}\rangle - \langle\hat{a}^\dagger_{out}\rangle\langle\hat{a}_{out}\rangle - (\langle\hat{a}^\dagger\hat{a}\rangle - \langle\hat{a}^\dagger\rangle\langle\hat{a}\rangle) \ . \tag{35.343}$$

The expectation values are assumed to be evaluated with respect to the initial coherent state. This quantity characterizes the increase of the uncertainty of the field due to amplification. As the uncertainty of the field operator does not depend on its parameter, the quantity above shows how much output field differs from a coherent state.

35.8.5.1 Linear phase-invariant amplifier

Linear phase-invariant amplifiers may be described as follows. Assume that the unitary operator U amplifies in such a way that the input $\hat{a}$ and the output $\hat{a}_{out} = \hat{U}^\dagger\hat{a}\hat{U}$, are related by a linear equation,

$$\hat{a}_{out} = c\hat{a} + s\hat{b}^\dagger \ , \tag{35.344}$$

where c and s are c-numbers and $\hat{b}^\dagger$ is a creation operator characterizing the amplifier. Without loss of generality, it may be assumed that c and s are real. The commutator of the field operators is invariant under unitary transformation U:

$$[\hat{a}_{out}, \hat{a}^\dagger_{out}] = 1 = [\hat{a}, \hat{a}^\dagger] \quad , \quad [\hat{a}_{in}, \hat{a}^\dagger_{out}] = 0 = [\hat{a}_{out}, \hat{a}^\dagger_{in}] \ . \tag{35.345}$$

From the unitarity of U, it follows that $\hat{b}$ satisfies the same commutation relations. The c-numbers are then $c^2 - s^2 = 1$. Hence, the phase-invariant amplifier acts by

introducing an additional mode to the field, with a large amount of stored energy, behaving as a boson. Calculating the gain and the noise of this amplifier, one finds $G = c$, and

$$\text{noise} = \mathrm{c}^2 - 1 \ . \tag{35.346}$$

The coefficient $g = |G|^2$ is sometimes called the intensity amplification coefficient. The noise of the linear phase-invariant amplifier is given by $g - 1$. The gain can be dropped by splitting the beam; the estimate above gives the minimal possible noise of the linear phase-invariant amplifier. The linear amplifier has an advantage over the multi-mode amplifier: if several modes of a linear amplifier are amplified by the same factor, the noise in each mode is determined independently;that is, modes in a linear quantum amplifier are independent.

To obtain a large amplification coefficient with minimal noise, one may use homodyne detection, constructing a field state with known amplitude and phase, corresponding to the linear phase-invariant amplifier. The uncertainty principle sets the lower bound of quantum noise in an amplifier. In particular, the output of a laser system and the output of an optical generator are not coherent states.

The multiplicative amplifier D also adds additive noise F. We have $DD^\dagger = 1$,

$$\begin{pmatrix} \hat{a}^\dagger_{out} \\ \hat{a}_{out} \end{pmatrix} = D \begin{pmatrix} \hat{a}^\dagger_{in} \\ \hat{a}_{in} \end{pmatrix} + \begin{pmatrix} F_1 \\ F_2 \end{pmatrix} \ . \tag{35.347}$$

35.8.6 Homodyne detection and inverse Radon transform

In the method of *homodyne detection* or *phase-sensitive detection* the signal is obtained by superposing the field mode of interest with a local oscillator with a relative phase θ at a beam splitter and a subtraction of the photo currents in the two ports of the interferometer:

$$\begin{aligned} \Delta\hat{J} &= \hat{a}^\dagger_t \hat{a}_t - \hat{b}^\dagger_t \hat{b}_t \qquad (35.348) \\ &= (2\eta - 1)(\hat{a}^\dagger_0 \hat{a}_0 + \hat{b}^\dagger_0 \hat{b}_0) + 2\sqrt{(1-\eta)\eta}(\hat{a}^\dagger_0 \hat{a}_0 + \hat{b}^\dagger_0 \hat{b}_0) \overset{\eta \to 1/2}{\longrightarrow} \hat{a}^\dagger_0 \hat{a}_0 + \hat{b}^\dagger_0 \hat{b}_0 \ . \end{aligned}$$

If the local oscillator is a classical light field $\hat{b}_0 = \alpha_{LO} e^{-\imath\theta}$,

$$\begin{aligned} \Delta\hat{J} &= |\alpha_{LO}|(\hat{a}_0 e^{-\imath\theta} + \hat{a}^\dagger_0 e^{\imath\theta}) \qquad (35.349) \\ &= \sqrt{2}|\alpha_{LO}|\hat{x}_\theta \ , \end{aligned}$$

where the field mode is expressed by the Hermitian quadrature components $\hat{a}_0 = 2^{-1/2} \cdot (\hat{x}_\theta + \imath\hat{y}_\theta)$. The expectation value of $\Delta\hat{J}$ is afflicted with the Heisenberg uncertainty and can be expressed as the first moment of the Wigner function $W(\alpha)$:

$$\begin{aligned} \langle\psi|\Delta\hat{J}|\psi\rangle &= \int W_{|\psi\rangle}(\alpha)\Delta\hat{J}d^2\alpha \qquad (35.350) \\ &= \sqrt{2}|\alpha_{LO}| \int W_{|\psi\rangle}(x_\theta, p_\theta) x_\theta dx_\theta dp_\theta = \sqrt{2}|\alpha_{LO}| \int_{-\infty}^{\infty} w_\theta(x_\theta) x_\theta dx_\theta \ . \end{aligned}$$

Here, the distribution function integrated over a rotated quadrature component p_θ is given by,

$$w_\theta(x_\theta) \equiv \int_{-\infty}^{\infty} W_\theta(x_\theta, p_\theta) dp_\theta \ . \tag{35.351}$$

This is called the *radon transform*. The distribution function $w_\theta(p_\theta)$ as well as the Wigner function are normalized to 1. Multiple measurements of the expectation value $x_\theta = \langle\psi|\hat{x}_\theta|\psi\rangle$ now yields a histogram $H_{|\psi\rangle}(x_\theta)$ reflecting, if normalized, $w_{|\psi\rangle}(x_\theta) = H_{|\psi\rangle}(x_\theta)/\int H_{|\psi\rangle}(x_\theta)$ exactly the distribution function.

Considering the finite detector efficiency [791] $w_\theta(x_\theta)$ must be generalized to a convolution with an apparatus function $\zeta(x)$:

$$w_\theta^{\rm real}(\sqrt{\eta}x_\theta) = (w_\theta^{ideal} \star \zeta) \qquad \text{where} \qquad \zeta(x) = \frac{1}{\sqrt{\pi(1-\eta)}} e^{-\eta\alpha^2/(1-\eta)} \ . \tag{35.352}$$

A finite detector efficiency degrades the contrast of the quantum interference structures.

With the procedure of optical *homodyne tomography* or *quantum state endoscopy* the Wigner function for e.g. a Schrödinger cat state can be reconstructed from a set of distribution functions $w_\theta(x_\theta) = \int W(\alpha e^{\imath\theta})dp_\theta$ measured for various phases θ [791]. To do this the data set is exposed to an inverse *radon transform*:

$$W(\alpha) = \frac{1}{4\pi^2}\int_{-\infty}^{\infty}\int_0^\pi\int_{-\infty}^{\infty} w_\theta(x_\theta)|\zeta|e^{\imath\zeta\left[\mathfrak{Re}\ (2^{-1/2}\alpha e^{-\imath\theta})-x_\theta\right]}dx d\theta d\zeta \ . \tag{35.353}$$

In contrast to the conventional homodyne detection, where the phase dependency of amplitude noise is recorded, the homodyne tomography allows the complete reconstruction of a quantum state through measurement of the distribution of the amplitude noise power,

$$P_s = \frac{\omega_s}{2\pi}\int_0^{\omega_s/2\pi} dt|\langle I(t)\rangle|^2 \tag{35.354}$$

for various phases.

Alternatively, to the homodyne method, one may reconstruct the photon distribution in field modes from their temporal evolution [1352]. Another method could be to use atoms as sensors for the quantum state of a light field in a Jaynes-Cummings type dynamics.

35.8.6.1 Homodyne signature of squeezed states

Let us mix squeezed light $\hat{b}$ with a local oscillator $\hat{a}$ at a beam splitter,

$$\begin{pmatrix}\hat{x}\\ \hat{y}\end{pmatrix} = \frac{1}{\sqrt{2}}\begin{pmatrix}1 & -\imath\\ -\imath & 1\end{pmatrix}\begin{pmatrix}\hat{b}\\ \hat{a}\end{pmatrix} \ . \tag{35.355}$$

The homodyne signal is,

$$\begin{aligned} P_{hody} &\propto \hat{x}^\dagger\hat{x} - \hat{y}^\dagger\hat{y} \\ &= \imath\hat{a}^\dagger\hat{b} - \imath\hat{a}\hat{b}^\dagger \\ &= \imath(\hat{a}^\dagger - \hat{a})\hat{b}_r - (\hat{a}^\dagger + \hat{a})\hat{b}_p \\ &= 2|\alpha|\left(\hat{b}_r\sin\theta - \hat{b}_p\cos\theta\right) \ , \end{aligned} \tag{35.356}$$

if the local oscillator can be considered as classical, $\alpha = |\alpha|e^{\imath\theta}$. I.e. the phase of the local oscillator permits us to select either one of the quadrature components.

35.8.7 Multimode squeezing

Define,

$$\hat{b} = \mu\hat{a} + \nu\hat{c}^\dagger \ . \tag{35.357}$$

Again using $\mu^2 - \nu^2 = 1$, the standard commutation rules for $\hat{a}$ and $\hat{c}$ give,

$$\begin{aligned} [\hat{b}, \hat{b}^\dagger] &= 1 \\ [\hat{b}_r, \hat{b}_p] &= \tfrac{\imath}{2} \ . \end{aligned} \tag{35.358}$$

The individual variances read,

$$\begin{aligned} \Delta\hat{b}_r^2 &= \langle \hat{b}_r^2 \rangle - \langle \hat{b}_r \rangle^2 \\ &= \tfrac{1}{4}\langle (\hat{b} + \hat{b}^\dagger)^2 \rangle - \tfrac{1}{4}\langle \hat{b} + \hat{b}^\dagger \rangle^2 \\ &= \tfrac{1}{4}\langle (\mu\hat{a} + \mu\hat{a}^\dagger + \nu\hat{c} + \nu\hat{c}^\dagger)^2 \rangle \\ &= \tfrac{1}{4}\mu^2 + \tfrac{1}{4}\nu^2 + \tfrac{1}{2}\mu^2\langle \hat{a}^\dagger\hat{a} \rangle + \tfrac{1}{2}\nu^2\langle \hat{c}^\dagger\hat{c} \rangle + \tfrac{1}{2}\mu\nu \left(\langle \hat{a}\hat{c} \rangle + \langle \hat{a}^\dagger\hat{c}^\dagger \rangle \right) \rangle \ . \end{aligned} \tag{35.359}$$

using $\langle \hat{a} \rangle = \langle \hat{c} \rangle = \langle \hat{a}^\dagger\hat{c} \rangle = 0$.

Two-mode squeezing can exist even if the individual modes are not squeezed,

$$|r, \phi\rangle = \cosh^{-1} r \sum\nolimits_n \tanh^n r e^{\imath n\phi} |r, \phi\rangle_a |r, \phi\rangle_b \ . \tag{35.360}$$

A *two-mode squeezed vacuum state* can be generated by the squeezing operator

$$\boxed{S(\xi) \equiv \exp\left(\tfrac{\xi^*}{2}\hat{a}\hat{b} - \tfrac{\xi}{2}\hat{a}^\dagger b^\dagger \right)} \ . \tag{35.361}$$

Remember that the single-mode squeezing is obtained if $\hat{a} = \hat{b}$. In a number state base

$$|r, \phi\rangle = \frac{1}{\cosh r} \sum\nolimits_n (\tanh r)^n e^{\imath n\phi} |n\rangle_a |n\rangle_b \ . \tag{35.362}$$

Two-mode relative number squeezing parameter

$$\xi_{i,j} = \frac{\sigma^2(n_i - \langle n_j \rangle)}{\langle n_i \rangle + \langle n_j \rangle} \ . \tag{35.363}$$

35.8.8 Coupled quantum oscillators with/out counter-rotating terms

The Hamiltonian of a beam splitter resembles the one of a system of two *coupled oscillators* with identical eigenfrequencies. Here, we are interested in calculating the time evolution of such a system. We rewrite the Hamiltonian in terms of the *normal modes*. We start from the Hamiltonian with counter-rotating terms [426],

$$\boxed{\hat{H} = \hbar\omega(\hat{a}^\dagger\hat{a} + \tfrac{1}{2}) + \hbar\omega(\hat{b}^\dagger\hat{b} + \tfrac{1}{2}) + \tfrac{\hbar\Omega}{2}(\hat{a} + \hat{a}^\dagger)(\hat{b} + \hat{b}^\dagger)} \ , \tag{35.364}$$

which we rewrite in terms of the quadrature components given by,

$$\begin{pmatrix} \hat{x}_a \\ \hat{p}_a \\ \hat{x}_b \\ \hat{p}_b \end{pmatrix} = \mathcal{T}_{ab} \begin{pmatrix} \hat{a} \\ \hat{a}^\dagger \\ \hat{b} \\ \hat{b}^\dagger \end{pmatrix} \qquad \text{with} \qquad \mathcal{T}_{ab} \equiv \sqrt{\frac{\hbar\omega}{2}} \begin{pmatrix} \omega^{-1} & \omega^{-1} & 0 & 0 \\ \imath & -\imath & 0 & 0 \\ 0 & 0 & \omega^{-1} & \omega^{-1} \\ 0 & 0 & \imath & -\imath \end{pmatrix} , \tag{35.365}$$

as

$$\hat{H} = \tfrac{1}{2}(\hat{p}_a^2 + \omega^2 \hat{x}_a^2) + \tfrac{1}{2}(\hat{p}_b^2 + \omega^2 \hat{x}_b^2) + \Omega\omega \hat{x}_a \hat{x}_b \ . \tag{35.366}$$

Setting $\omega_\pm = \sqrt{\omega^2 \pm \Omega\omega}$ allows us to rewrite the Hamiltonian as,

$$\hat{H} = \tfrac{1}{4}(\hat{p}_a + \hat{p}_b)^2 + \tfrac{1}{4}\omega_+^2(\hat{x}_a + \hat{x}_b)^2 + \tfrac{1}{4}(\hat{p}_a - \hat{p}_b)^2 + \tfrac{1}{4}\omega_-^2(\hat{x}_a - \hat{x}_b)^2 \ . \tag{35.367}$$

Now, we apply the transform,

$$\begin{pmatrix} \hat{x}_A \\ \hat{p}_A \\ \hat{x}_B \\ \hat{p}_B \end{pmatrix} = \mathcal{M} \begin{pmatrix} \hat{x}_a \\ \hat{p}_a \\ \hat{x}_b \\ \hat{p}_b \end{pmatrix} \qquad \text{with} \qquad \mathcal{M} \equiv \sqrt{\frac{1}{2}} \begin{pmatrix} 1 & 0 & 1 & 0 \\ 0 & 1 & 0 & 1 \\ 1 & 0 & -1 & 0 \\ 0 & 1 & 0 & -1 \end{pmatrix} = M^{-1} , \tag{35.368}$$

and rewrite the Hamiltonian again as,

$$\hat{H} = \tfrac{1}{2}(\hat{p}_A^2 + \omega_+^2 \hat{x}_A^2) + \tfrac{1}{2}(\hat{p}_B^2 + \omega_-^2 \hat{x}_B^2) \ . \tag{35.369}$$

We go back from the quadrature components to the field mode operators via,

$$\begin{pmatrix} \hat{x}_A \\ \hat{p}_A \\ \hat{x}_B \\ \hat{p}_B \end{pmatrix} = \mathcal{T}_{AB} \begin{pmatrix} \hat{A} \\ \hat{A}^\dagger \\ \hat{B} \\ \hat{B}^\dagger \end{pmatrix} \qquad \text{with} \qquad \mathcal{T}_{AB} \equiv \sqrt{\frac{\hbar}{2}} \begin{pmatrix} 1/\sqrt{\omega_+} & 1/\sqrt{\omega_+} & 0 & 0 \\ \imath\sqrt{\omega_+} & -\imath\sqrt{\omega_+} & 0 & 0 \\ 0 & 0 & 1/\sqrt{\omega_-} & 1/\sqrt{\omega_+} \\ 0 & 0 & \imath\sqrt{\omega_-} & -\imath\sqrt{\omega_+} \end{pmatrix} , \tag{35.370}$$

and finally obtain,

$$\boxed{\hat{H} = \hbar\omega_+(\hat{A}^\dagger \hat{A} + \tfrac{1}{2}) + \hbar\omega_-(\hat{B}^\dagger \hat{B} + \tfrac{1}{2})} \ . \tag{35.371}$$

The Heisenberg equations of motion for the oscillator modes,

$$\frac{d}{dt} \begin{pmatrix} \hat{a} \\ \hat{a}^\dagger \\ \hat{b} \\ \hat{b}^\dagger \end{pmatrix} = -\tfrac{\imath}{\hbar} \left[\begin{pmatrix} \hat{a} \\ \hat{a}^\dagger \\ \hat{b} \\ \hat{b}^\dagger \end{pmatrix} , \hat{H} \right] = \mathcal{X} \begin{pmatrix} \hat{a} \\ \hat{a}^\dagger \\ \hat{b} \\ \hat{b}^\dagger \end{pmatrix} \qquad \text{with} \qquad \mathcal{X} \equiv \begin{pmatrix} -\imath\omega & 0 & -\frac{\imath\Omega}{2} & -\frac{\imath\Omega}{2} \\ 0 & \imath\omega & \frac{\imath\Omega}{2} & \frac{\imath\Omega}{2} \\ -\frac{\imath\Omega}{2} & -\frac{\imath\Omega}{2} & -\imath\omega & 0 \\ \frac{\imath\Omega}{2} & \frac{\imath\Omega}{2} & 0 & \imath\omega \end{pmatrix} , \tag{35.372}$$

are difficult to integrate. In contrast, the Heisenberg equations for the normal modes,

$$\frac{d}{dt}\begin{pmatrix}\hat{A}\\ \hat{A}^\dagger\\ \hat{B}\\ \hat{B}^\dagger\end{pmatrix} = -\tfrac{\imath}{\hbar}\left[\begin{pmatrix}\hat{A}\\ \hat{A}^\dagger\\ \hat{B}\\ \hat{B}^\dagger\end{pmatrix}, \hat{H}\right] = E_{\mathcal{X}}\begin{pmatrix}\hat{A}\\ \hat{A}^\dagger\\ \hat{B}\\ \hat{B}^\dagger\end{pmatrix} \tag{35.373}$$

$$\text{with} \qquad E_{\mathcal{X}} = U_{\mathcal{X}}^{-1}\mathcal{X}U_{\mathcal{X}} = \begin{pmatrix}-\imath\omega_+ & 0 & 0 & 0\\ 0 & \imath\omega_+ & 0 & 0\\ 0 & 0 & -\imath\omega_- & 0\\ 0 & 0 & 0 & \imath\omega_-\end{pmatrix}$$

$$\text{and} \qquad U_{\mathcal{X}} = \begin{pmatrix}-1-\frac{2}{\Omega}(\omega+\omega_+) & -1-\frac{2}{\Omega}(\omega-\omega_+) & 1-\frac{2}{\Omega}(\omega+\omega_-) & 1-\frac{2}{\Omega}(\omega-\omega_-)\\ 1 & 1 & -1 & -1\\ -1-\frac{2}{\Omega}(\omega+\omega_+) & -1-\frac{2}{\Omega}(\omega-\omega_+) & -1+\frac{2}{\Omega}(\omega+\omega_-) & -1+\frac{2}{\Omega}(\omega-\omega_-)\\ 1 & 1 & 1 & 1\end{pmatrix},$$

are easily solved by,

$$\begin{pmatrix}\hat{A}(t)\\ \hat{A}^\dagger(t)\\ \hat{B}(t)\\ \hat{B}^\dagger(t)\end{pmatrix} = e^{E_{\mathcal{X}}t}\begin{pmatrix}\hat{A}(0)\\ \hat{A}^\dagger(0)\\ \hat{B}(0)\\ \hat{B}^\dagger(0)\end{pmatrix} \qquad \text{with} \qquad e^{E_{\mathcal{X}}t} \equiv \begin{pmatrix}e^{-\imath\omega_+ t} & 0 & 0 & 0\\ 0 & e^{\imath\omega_+ t} & 0 & 0\\ 0 & 0 & e^{-\imath\omega_- t} & 0\\ 0 & 0 & 0 & e^{\imath\omega_- t}\end{pmatrix}. \tag{35.374}$$

Hence, the oscillator modes evolve as,

$$\begin{pmatrix}\hat{a}(t)\\ \hat{a}^\dagger(t)\\ \hat{b}(t)\\ \hat{b}^\dagger(t)\end{pmatrix} = e^{\mathcal{X}t}\begin{pmatrix}\hat{a}(0)\\ \hat{a}^\dagger(0)\\ \hat{b}(0)\\ \hat{b}^\dagger(0)\end{pmatrix} \qquad \text{with} \qquad e^{\mathcal{X}t} = \mathcal{T}_{ab}^{-1}\mathcal{M}^{-1}\mathcal{T}_{AB}e^{E_{\mathcal{X}}t}\mathcal{T}_{AB}^{-1}\mathcal{M}\mathcal{T}_{ab} = U_{\mathcal{X}}e^{E_{\mathcal{X}}t}U_{\mathcal{X}}^{-1}. \tag{35.375}$$

35.8.8.1 Rotating-wave approximation

The rotating-wave approximation is performed via $\omega_\pm \simeq \omega \pm \frac{1}{2}\Omega$. It leads to the Hamiltonian,

$$\boxed{\hat{H} = \hbar\omega(\hat{a}^\dagger\hat{a} + \tfrac{1}{2}) + \hbar\omega(\hat{b}^\dagger\hat{b} + \tfrac{1}{2}) + \tfrac{\hbar\Omega}{2}(\hat{a}\hat{b}^\dagger + \hat{a}^\dagger\hat{b})}\,. \tag{35.376}$$

In this approximation, we find $\mathcal{T}_{AB}^{-1}\mathcal{M}\mathcal{T}_{ab} \simeq \mathcal{M}$ and the transformation defined in (35.368),

$$\begin{pmatrix}\hat{A}\\ \hat{A}^\dagger\\ \hat{B}\\ \hat{B}^\dagger\end{pmatrix} = \mathcal{M}\begin{pmatrix}\hat{a}\\ \hat{a}^\dagger\\ \hat{b}\\ \hat{b}^\dagger\end{pmatrix}, \tag{35.377}$$

takes us directly from the Hamiltonian (35.376) to [21],

$$\boxed{\hat{H} = (\hbar\omega + \tfrac{\hbar\Omega}{2})(\hat{A}^\dagger\hat{A} + \tfrac{1}{2}) + (\hbar\omega - \tfrac{\hbar\Omega}{2})(\hat{B}^\dagger\hat{B} + \tfrac{1}{2})} \,. \tag{35.378}$$

Do the Excs. 35.8.9.5 and 35.8.9.6.

Note, that two coupled oscillator model becomes *criticality*, when the atom-field coupling strength exceeds the frequencies of the mode and the atomic two-level system.

35.8.8.2 Interaction-free measurement

Beam splitters and coupled cavities have been proposed for the realization of *interaction-free measurements* 35.8.9.7 and 35.8.9.8 [413, 1322, 764, 742].

35.8.9 Exercises

35.8.9.1 Ex: Conservation law at a beam splitter 1

Show that the beam-split transformation

$$\begin{pmatrix} \hat{c} \\ \hat{d} \end{pmatrix} = \begin{pmatrix} t & -r \\ r & t \end{pmatrix} \begin{pmatrix} \hat{a} \\ \hat{b} \end{pmatrix}$$

preserves the commutations relations and the photon number.

Solution: *From*

$$\hat{c} = t\hat{a} - r\hat{b} \qquad \textit{and} \qquad \hat{d} = r\hat{a} + t\hat{b}$$

follows

$$\begin{aligned} [\hat{c}, \hat{d}] &= [t\hat{a} - r\hat{b}, r\hat{a} + t\hat{b}] = 0 \\ [\hat{c}, \hat{c}^\dagger] &= [t\hat{a} - r\hat{b}, t\hat{a}^\dagger - r\hat{b}^\dagger] = |t|^2 + |r|^2 = 1 \end{aligned}$$

with

$$\det U = |t|^2 + |r|^2 = 1 \ .$$

Furthermore,

$$\begin{aligned} \hat{c}^\dagger\hat{c} + \hat{d}^\dagger\hat{d} &= (t^*\hat{a}^\dagger - r^*\hat{b}^\dagger)(t\hat{a} - r\hat{b}) + (r\hat{a}^\dagger + t\hat{b}^\dagger)(r\hat{a} + t\hat{b}) \\ &= (|t|^2 + |r|^2)(\hat{a}^\dagger\hat{a} + \hat{b}^\dagger\hat{b}) + (rt - rt)\hat{a}\hat{b}^\dagger + (rt - rt)\hat{a}^\dagger\hat{b} = \hat{a}^\dagger\hat{a} + \hat{b}^\dagger\hat{b} \ . \end{aligned}$$

[21] Note the different behavior of a beam splitter under this transformation,

$$\begin{aligned} \hat{H} &= \hbar\omega(\hat{a}^\dagger\hat{a} + \tfrac{1}{2}) + \hbar\omega(\hat{b}^\dagger\hat{b} + \tfrac{1}{2}) + \tfrac{\hbar\Omega}{2}\left(\hat{a}\hat{b}^\dagger - \hat{a}^\dagger\hat{b}\right) \\ &= \hbar\omega(\hat{A}^\dagger\hat{A} + \tfrac{1}{2}) + \hbar\omega(\hat{B}^\dagger\hat{B} + \tfrac{1}{2}) + \tfrac{\hbar\Omega}{2}(-\hat{A}\hat{B}^\dagger + \hat{A}^\dagger\hat{B}) \ . \end{aligned}$$

35.8.9.2 Ex: Conservation law at a beam splitter 2

Derive from the Hamiltonian (35.308) that $\hat{a}^\dagger\hat{a} + \hat{b}^\dagger\hat{b} = const.$

Solution: *With the Hamiltonian (35.308) we have,*

$$\frac{d}{dt}(\hat{a}^\dagger\hat{a}) = \frac{\imath}{\hbar}[\hat{H}, \hat{a}^\dagger\hat{a}] = \frac{\imath}{2}\Omega[\hat{a}\hat{b}^\dagger + \hat{a}^\dagger\hat{b}, \hat{a}^\dagger\hat{a}] = \frac{\imath}{2}\Omega(\hat{a}\hat{b}^\dagger - \hat{a}^\dagger\hat{b})$$
$$\frac{d}{dt}(\hat{b}^\dagger\hat{b}) = \frac{\imath}{\hbar}[\hat{H}, \hat{b}^\dagger\hat{b}] = \frac{\imath}{2}\Omega[\hat{a}\hat{b}^\dagger + \hat{a}^\dagger\hat{b}, \hat{b}^\dagger\hat{b}] = -\frac{\imath}{2}\Omega(\hat{a}\hat{b}^\dagger - \hat{a}^\dagger\hat{b}) \ .$$

Hence,

$$\hat{a}^\dagger\hat{a} + \hat{b}^\dagger\hat{b} = const \ .$$

35.8.9.3 Ex: Beam splitter

Show that $\hat{B}|1,0\rangle = \cos\theta|1,0\rangle - \sin\theta|0,1\rangle$ and $\hat{B}|0,n\rangle = \sum_{k=0}^{\infty}\sqrt{\binom{n}{k}}\cos^k\theta\sin^{n-k}\theta|n-k,k\rangle$.

Solution: *a. From*

$$(\hat{a}\hat{b}^\dagger - \hat{a}^\dagger\hat{b})|1,0\rangle = |0,1\rangle \qquad and \qquad (\hat{a}\hat{b}^\dagger - \hat{a}^\dagger\hat{b})|0,1\rangle = -|1,0\rangle$$

we deduce

$$(\hat{a}\hat{b}^\dagger - \hat{a}^\dagger\hat{b})^{2k}|1,0\rangle = (-1)^k|1,0\rangle \qquad and \qquad (\hat{a}\hat{b}^\dagger - \hat{a}^\dagger\hat{b})^{2k+1}|1,0\rangle = -(-1)^k|0,1\rangle$$

and then

$$\begin{aligned} e^{\theta(\hat{a}\hat{b}^\dagger - \hat{a}^\dagger\hat{b})}|1,0\rangle &= \sum_k \frac{\theta^k}{k!}(\hat{a}\hat{b}^\dagger - \hat{a}^\dagger\hat{b})^k|1,0\rangle \\ &= \sum_k \frac{\theta^{2k}}{(2k)!}(\hat{a}\hat{b}^\dagger - \hat{a}^\dagger\hat{b})^{2k}|1,0\rangle + \sum_k \frac{\theta^{2k+1}}{(2k+1)!}(\hat{a}\hat{b}^\dagger - \hat{a}^\dagger\hat{b})^{2k+1}|1,0\rangle \\ &= \sum_k \frac{\theta^{2k}}{(2k)!}(-1)^k|1,0\rangle - \sum_k \frac{\theta^{2k+1}}{(2k+1)!}(-1)^k|0,1\rangle \\ &= \cos\theta|1,0\rangle - \sin\theta|0,1\rangle \ . \end{aligned}$$

b. We can express the vacuum state via a Fock state by,

$$|n,0\rangle = \frac{\hat{a}^{\dagger n}}{\sqrt{n!}}|0,0\rangle \qquad and \qquad |0,n\rangle = \frac{\hat{b}^{\dagger n}}{\sqrt{n!}}|0,0\rangle \ .$$

Using the results of a. we calculate,

$$\begin{aligned} \hat{B}\hat{a}^{\dagger n}\hat{B}^\dagger &= (\hat{B}\hat{a}^n\hat{B}^\dagger)^\dagger = (\hat{B}\hat{a}\hat{B}^\dagger)^{n\dagger} = (\hat{a}^\dagger\cos\theta + \hat{b}^\dagger\sin\theta)^{n\dagger} \\ &= \sum_k \binom{n}{k}\hat{a}^{k\dagger}\cos^k\theta + (\hat{b}^{n-k})^\dagger\sin^{n-k}\theta \ . \end{aligned}$$

Finally, because of,

$$(\hat{a}\hat{b}^\dagger - \hat{a}^\dagger\hat{b})|0,0\rangle = 0 \qquad \Longrightarrow \qquad \hat{B}|0,0\rangle = e^{\theta(\hat{a}\hat{b}^\dagger - \hat{a}^\dagger\hat{b})}|0,0\rangle = 1$$

we get

$$\begin{aligned}\hat{B}|n,0\rangle = \hat{B}\frac{\hat{a}^{\dagger n}}{\sqrt{n!}}|0,0\rangle &= \frac{1}{\sqrt{n!}}\left(\sum_k \binom{n}{k}\hat{a}^{k\dagger}\cos^k\theta + (\hat{b}^{n-k})^\dagger \sin^{n-k}\theta\right)\hat{B}|0,0\rangle \\ &= \frac{1}{\sqrt{n!}}\sum_k \binom{n}{k}\hat{a}^{k\dagger}\cos^k\theta(\hat{b}^{n-k})^\dagger \sin^{n-k}\theta \ .\end{aligned}$$

35.8.9.4 Ex: Beam splitter

Show that for $\hat{B} \equiv e^{\theta(\hat{a}\hat{b}^\dagger - \hat{a}^\dagger\hat{b})}$ holds,

$$\hat{B}\hat{a}\hat{B}^\dagger = \hat{a}\cos\theta + \hat{b}\sin\theta \qquad \text{and} \qquad \hat{B}\hat{b}\hat{B}^\dagger = -\hat{a}\sin\theta + \hat{b}\cos\theta \ .$$

Solution: *The two expressions can be recombined to,*

$$\hat{B}(\hat{a} \pm \imath\hat{b})\hat{B}^\dagger = (\hat{a} \pm \imath\hat{b})e^{\mp\imath\theta} \ .$$

Now, we define the new quantities,

$$\hat{x} \equiv \hat{a} + \imath\hat{b} \qquad \textit{and} \qquad \hat{A} \equiv \hat{a}\hat{b}^\dagger - \hat{a}^\dagger\hat{b} \ ,$$

for which,

$$[\hat{A}, \hat{x}] = -\imath\hat{x} \ ,$$

and rewrite one of the expressions as,

$$e^{\theta\hat{A}}\hat{x}e^{-\theta\hat{A}} = \hat{x}e^{-\imath\theta} \ .$$

Now, we use (23.179) which has been derived in Exc. 23.5.6.1,

$$e^{\hat{A}}\hat{x}e^{-\hat{A}} = \hat{x} + [\hat{A}, \hat{x}] + \tfrac{1}{2!}[\hat{A}, [\hat{A}, \hat{x}]] + ... \ ,$$

and obtain,

$$\begin{aligned}e^{\hat{A}}\hat{x}e^{-\hat{A}} &= \hat{x} + \theta[\hat{A}, \hat{x}] + \tfrac{\theta^2}{2!}[\hat{A}, [\hat{A}, \hat{x}]] + ... \\ &= \hat{x} - \theta\imath\hat{x} + \tfrac{\imath\theta^2}{2!}\imath\hat{x} + ... = \hat{x}e^{-\imath\theta} \ .\end{aligned}$$

35.8.9.5 Ex: Coupled harmonic oscillators with different eigenfrequencies and damping

Here, we generalize the calculation of Sec. 35.8.8 for coupling of oscillators with different eigenfrequencies.
a. From,

$$\hat{H} = \hbar\omega_a(\hat{a}^\dagger\hat{a} + \tfrac{1}{2}) + \hbar\omega_b(\hat{b}^\dagger\hat{b} + \tfrac{1}{2}) + \tfrac{\hbar\Omega}{2}(\hat{a}\hat{b}^\dagger + \hat{a}^\dagger\hat{b}) + \tfrac{\hbar\Omega'}{2}(\hat{a}\hat{b} + \hat{a}^\dagger\hat{b}^\dagger)$$

derive the Hamiltonian in terms of the quadrature components $\hat{x}_{a,b}$ and $\hat{p}_{a,b}$.
b. Set up the Heisenberg equations for the field operators $\hat{a}$, $\hat{a}^\dagger$, $\hat{b}$, and $\hat{b}^\dagger$ and determine the eigenvalues of the matrix $\mathcal{X}$ defined by,

$$\frac{d}{dt}\begin{pmatrix}\hat{a}\\ \hat{a}^\dagger\\ \hat{b}\\ \hat{b}^\dagger\end{pmatrix} = X\begin{pmatrix}\hat{a}\\ \hat{a}^\dagger\\ \hat{b}\\ \hat{b}^\dagger\end{pmatrix} \ .$$

c. Extend the Heisenberg equations by including loss terms for the cavity modes κ_a and κ_b and determine the corresponding matrix $\mathcal{X}_\kappa$, as well as its eigenvalues for the simplifying case $\Omega' \equiv \Omega$.

Solution: *a. Transforming like,*

$$\begin{pmatrix}\hat{x}_a\\ \hat{p}_a\\ \hat{x}_b\\ \hat{p}_b\end{pmatrix} = \mathcal{T}_{ab}\begin{pmatrix}\hat{a}\\ \hat{a}^\dagger\\ \hat{b}\\ \hat{b}^\dagger\end{pmatrix} \qquad \textit{with} \qquad \mathcal{T}_{ab} \equiv \begin{pmatrix}\sqrt{\frac{\hbar}{2\omega_a}} & \sqrt{\frac{\hbar}{2\omega_a}} & 0 & 0\\ \imath\sqrt{\frac{\hbar\omega_a}{2}} & -\imath\sqrt{\frac{\hbar\omega_a}{2}} & 0 & 0\\ 0 & 0 & \sqrt{\frac{\hbar}{2\omega_b}} & \sqrt{\frac{\hbar}{2\omega_b}}\\ 0 & 0 & \imath\sqrt{\frac{\hbar\omega_b}{2}} & -\imath\sqrt{\frac{\hbar\omega_b}{2}}\end{pmatrix} ,$$

we obtain,

$$\hat{H} = \tfrac{1}{2}(\hat{p}_a^2 + \omega_a^2\hat{x}_a^2) + \tfrac{1}{2}(\hat{p}_b^2 + \omega_b^2\hat{x}_b^2) + \tfrac{(\Omega+\Omega')\sqrt{\omega_a\omega_b}}{2}\hat{x}_a\hat{x}_b + \tfrac{\Omega-\Omega'}{2\sqrt{\omega_a\omega_b}}\hat{p}_a\hat{p}_b \ .$$

b. The Heisenberg equations are,

$$\frac{d}{dt}\begin{pmatrix}\hat{a}\\ \hat{a}^\dagger\\ \hat{b}\\ \hat{b}^\dagger\end{pmatrix} = -\tfrac{\imath}{\hbar}\left[\begin{pmatrix}\hat{a}\\ \hat{a}^\dagger\\ \hat{b}\\ \hat{b}^\dagger\end{pmatrix}, \hat{H}\right] = \mathcal{X}\begin{pmatrix}\hat{a}\\ \hat{a}^\dagger\\ \hat{b}\\ \hat{b}^\dagger\end{pmatrix} \qquad \textit{with} \qquad \mathcal{X} \equiv \begin{pmatrix}-\imath\omega_a & 0 & -\frac{\imath\Omega}{2} & -\frac{\imath\Omega'}{2}\\ 0 & \imath\omega_a & \frac{\imath\Omega'}{2} & \frac{\imath\Omega}{2}\\ -\frac{\imath\Omega}{2} & -\frac{\imath\Omega'}{2} & -\imath\omega_b & 0\\ \frac{\imath\Omega'}{2} & \frac{\imath\Omega}{2} & 0 & \imath\omega_b\end{pmatrix} .$$

The eigenvalues are $\pm\omega_\pm$ with,

$$\omega_\pm \equiv \tfrac{1}{\sqrt{2}}\sqrt{\omega_a^2 + \omega_b^2 + \tfrac{\Omega^2-\Omega'^2}{2} \pm \sqrt{(\omega_a^2-\omega_b^2)^2 + (\omega_a+\omega_b)^2\Omega^2 - (\omega_a-\omega_b)^2\Omega'^2}} \ .$$

For $\Omega = \Omega'$ we recover,

$$\omega_\pm = \tfrac{1}{\sqrt{2}}\sqrt{\omega_a^2 + \omega_b^2 \pm \sqrt{(\omega_a^2-\omega_b^2)^2 + 4\omega_a\omega_b\Omega^2}} \ ,$$

for $\omega_a = \omega_b$ we recover,

$$\omega_\pm = \sqrt{\omega^2 \pm \omega\Omega + \tfrac{\Omega^2 - \Omega'^2}{4}} \ ,$$

and finally for $\Omega = \Omega'$ and $\omega_a = \omega_b$ we recover $\omega_\pm = \sqrt{\omega^2 \pm \omega\Omega}$.
c. The extended Heisenberg-Liouville equations are,

$$\frac{d}{dt}\hat{a} = -\tfrac{\imath}{\hbar}[\hat{a}, \hat{H}] - \kappa_a \hat{a} \qquad with \qquad \frac{d}{dt}\hat{b} = -\tfrac{\imath}{\hbar}[\hat{b}, \hat{H}] - \kappa_b \hat{b} \ ,$$

such that,

$$\mathcal{X}_\kappa = \begin{pmatrix} -\imath\omega_a - \kappa_a & 0 & -\frac{\imath\Omega}{2} & -\frac{\imath\Omega'}{2} \\ 0 & \imath\omega_a - \kappa_a & \frac{\imath\Omega'}{2} & \frac{\imath\Omega}{2} \\ -\frac{\imath\Omega}{2} & -\frac{\imath\Omega'}{2} & -\imath\omega_b - \kappa_b & 0 \\ \frac{\imath\Omega'}{2} & \frac{\imath\Omega}{2} & 0 & \imath\omega_b - \kappa_b \end{pmatrix} \ .$$

The eigenvalues for the case $\Omega' \equiv \Omega$ are,

$$\omega_{1,2,3,4} = -\tfrac{\kappa_a + \kappa_b}{2} \pm \sqrt{(\tfrac{\kappa_a - \kappa_b}{2})^2 - \omega^2 \pm \omega\sqrt{\Omega^2 - (\kappa_a - \kappa_b)^2}} \ .$$

35.8.9.6 Ex: Equivalence of beam splitter and coupled oscillator models

Show that the beam splitter and the coupled oscillators model for degenerate frequencies are equivalent.

Solution: *The prescription $\hat{A} \equiv \hat{a}$ and $\hat{B} = -\imath\hat{b}$ transforms the Hamiltonian between the beam splitter and coupled oscillators model,*

$$\begin{aligned} \hat{H} &= \hbar\omega(\hat{a}^\dagger\hat{a} + \tfrac{1}{2}) + \hbar\omega(\hat{b}^\dagger\hat{b} + \tfrac{1}{2}) + \Omega(\hat{a}\hat{b}^\dagger + \hat{a}^\dagger\hat{b}) \\ &= \hbar\omega(\hat{A}^\dagger\hat{A} + \tfrac{1}{2}) + \hbar\omega(\hat{B}^\dagger\hat{B} + \tfrac{1}{2}) + \imath\Omega(\hat{A}\hat{B}^\dagger - \hat{A}^\dagger\hat{B}) \ . \end{aligned}$$

In matrix notation we may write,

$$\begin{pmatrix} \hat{x}_a \\ \hat{p}_a \\ \hat{x}_b \\ \hat{p}_b \end{pmatrix} = \mathcal{T} \begin{pmatrix} \hat{a} \\ \hat{a}^\dagger \\ \hat{b} \\ \hat{b}^\dagger \end{pmatrix} \qquad with \qquad \mathcal{T} \equiv \begin{pmatrix} 1 & 1 & 0 & 0 \\ \imath & -\imath & 0 & 0 \\ 0 & 0 & 1 & 1 \\ 0 & 0 & \imath & -\imath \end{pmatrix}$$

$$\begin{pmatrix} \hat{A} \\ \hat{A}^\dagger \\ \hat{B} \\ \hat{B}^\dagger \end{pmatrix} = \mathcal{M} \begin{pmatrix} \hat{a} \\ \hat{a}^\dagger \\ b \\ b^\dagger \end{pmatrix} \qquad where \qquad \mathcal{M} \equiv \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & -\imath & 0 \\ 0 & 0 & 0 & \imath \end{pmatrix}$$

$$\begin{pmatrix} \hat{x}_A \\ \hat{p}_A \\ \hat{x}_B \\ \hat{p}_B \end{pmatrix} = \mathcal{T}\mathcal{M}\mathcal{T}^{-1} \begin{pmatrix} \hat{x}_a \\ \hat{p}_a \\ \hat{x}_b \\ \hat{p}_b \end{pmatrix} \qquad with \qquad \mathcal{T}\mathcal{M}\mathcal{T}^{-1} = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & -\imath \\ 0 & 0 & -\imath & 0 \end{pmatrix} \ .$$

We verify the commutation rules,

$$[\hat{A},\hat{A}^\dagger]=[\hat{a},\hat{a}^\dagger]=1 \quad , \quad [\hat{B},\hat{B}^\dagger]=[-\imath\hat{B},\imath\hat{B}^\dagger]=[\hat{b},\hat{b}^\dagger]=1 \ ,$$

and the conservation laws,

$$[\hat{H},\hat{a}^\dagger\hat{a}+\hat{b}^\dagger\hat{b}]=\Omega[\hat{a}b^\dagger+\hat{a}^\dagger b,\hat{a}^\dagger\hat{a}+\hat{b}^\dagger\hat{b}]=0$$
$$[\hat{H},\hat{A}^\dagger\hat{A}+\hat{B}^\dagger\hat{B}]=\Omega[\hat{A}\hat{B}^\dagger-\hat{A}^\dagger\hat{B},\hat{A}^\dagger\hat{A}+\hat{B}^\dagger\hat{B}]=0 \ .$$

35.8.9.7 Ex: Elitzur and Vaidman bomb tester

a. Write down the beam splitter Hamiltonian in the Fock representation for a the case of a single photon, diagonalize it, and determine the propagator $e^{\imath\hat{H}t/\hbar}$ for a 50/50 beam splitter.
b. Based on the propagator derived in (a) draw an analogy between a Mach-Zehnder interferometer and a resonantly driven two-level system. Interpreting the interferometer as a qubit explain the *Elitzur and Vaidman bomb testing problem*. What is the probability?
c. Reformulate the interaction-free bomb tester in a quantum computing language.

Solution: *a. Knowing that there is exactly 1 photon in the interferometer, we may reduce the Hamiltonian (35.320) to,*

$$\hat{H}_{a+b}=\hat{H}_1=\frac{\hbar\Omega}{2}\begin{pmatrix}0&1\\1&0\end{pmatrix}=\hat{U}\begin{pmatrix}-\frac{\hbar}{2}\Omega&0\\0&\frac{\hbar}{2}\Omega\end{pmatrix}\hat{U}^\dagger$$
$$with \qquad \hat{U}=\begin{pmatrix}\cos\frac{\pi}{4}&\sin\frac{\pi}{4}\\-\sin\frac{\pi}{4}&\cos\frac{\pi}{4}\end{pmatrix} \ .$$

Hence, the propagator reads,

$$e^{\imath\hat{H}t/\hbar}=\hat{U}\begin{pmatrix}e^{-\imath\Omega t/2}&0\\0&e^{\imath\Omega t/2}\end{pmatrix}\hat{U}^\dagger \overset{\Omega t=\pi/2}{\longrightarrow} \tfrac{1}{\sqrt{2}}\begin{pmatrix}1&\imath\\\imath&1\end{pmatrix} \ .$$

This propagator also describes nutations in a driven two-level atom.
b. We define the states,

$$|1\rangle\equiv|1,0\rangle=\begin{pmatrix}1\\0\end{pmatrix} \qquad and \qquad |2\rangle\equiv|0,1\rangle=\begin{pmatrix}0\\1\end{pmatrix}$$

as those in which a photon is moving, respectively, horizontally and vertically. Then, we can describe the action of the beam splitter as,

$$|1\rangle \xrightarrow{BS} e^{\imath\hat{H}t/\hbar}|1\rangle=\tfrac{1}{\sqrt{2}}(|1\rangle+\imath|2\rangle)$$
$$|2\rangle \xrightarrow{BS} e^{\imath\hat{H}t/\hbar}|1\rangle=\tfrac{1}{\sqrt{2}}(|2\rangle+\imath|1\rangle) \ .$$

A path difference between the interferometer arms acts like,

$$|1\rangle \xrightarrow{L} |1\rangle \qquad \textit{and} \qquad |2\rangle \xrightarrow{L} e^{\imath k\Delta L}|2\rangle \ .$$

An obstacle in the second interferometer arms acts like,

$$|2\rangle \xrightarrow{O} |0\rangle \ .$$

Hence, without obstacle the interferometer does,

$$\begin{aligned}
|1\rangle &\xrightarrow{BS} \tfrac{1}{\sqrt{2}}(|1\rangle + \imath|2\rangle) \\
&\xrightarrow{L} \tfrac{1}{\sqrt{2}}(|1\rangle + \imath e^{\imath k\Delta L}|2\rangle) \\
&\xrightarrow{BS} \tfrac{1}{\sqrt{2}}\left[\tfrac{1}{\sqrt{2}}(|1\rangle + \imath|2\rangle) + \imath e^{\imath k\Delta L}\tfrac{1}{\sqrt{2}}(|2\rangle + \imath|1\rangle)\right] = \tfrac{1}{2}\left[(1 - e^{\imath k\Delta L})|1\rangle + \imath(1 + e^{\imath k\Delta L})|2\rangle\right] \ .
\end{aligned}$$

We align the interferometer such that $e^{\imath k\Delta L} = -1$. Then,

$$|1\rangle \xrightarrow{BS} \xrightarrow{L} \xrightarrow{BS} |1\rangle \ .$$

This means that the photon only interferes constructively on detector D_{constr}, but destructively on detector D_{destr}.
Now, the presence of an obstacle in the second arm spoils the interference,

$$\begin{aligned}
|1\rangle &\xrightarrow{BS} \tfrac{1}{\sqrt{2}}(|1\rangle + \imath|2\rangle) \\
&\xrightarrow{O} \tfrac{1}{\sqrt{2}}(|1\rangle + |0\rangle) \\
&\xrightarrow{BS} \tfrac{1}{\sqrt{2}}\left[\tfrac{1}{\sqrt{2}}(|1\rangle + \imath|2\rangle) + |0\rangle\right] = \tfrac{1}{2}(|1\rangle + \imath|2\rangle) + \tfrac{1}{\sqrt{2}}|0\rangle) \ .
\end{aligned}$$

That is, the probability for counting a photon on detector D_{destr} is $\frac{1}{4}$. A detection of a photon on detector D_{destr} tells us the presence of an obstacle (bomb) in the second interferometer arm, despite the fact that photon went to the first arm and, hence, didn't hit the bomb.
The probability for counting a photon on detector D_{constr} is $\frac{1}{4}$, but in this case we don't know by which interferometer arm it passed. We have to repeat the test with another photon, which will tell us the presence of a bomb with the accumulated probability $\frac{1}{4}\frac{1}{4}$. For n consecutive photons we calculate the probability for detecting the obstacle without hitting it as (see Thorlabs educational kit),

$$\sum_{k=1}^{n} \tfrac{1}{4^k} \overset{n\to\infty}{\longrightarrow} \tfrac{1}{3} \ .$$

c. Fig. 35.32(c) shows a representation of the bomb tester in the quantum computing language: The qubit q_1 represents the interferometer and the qubit q_0 the bomb. The first Hadamard gate and the subsequent cNOT gate entangle both qubits. The bomb's release mechanism represents a measurement of q_0, which projects it to the ground state, $q_0 \to |0\rangle$. Meanwhile, q_1 is remixed, and the interferometer output ports measured,

$$|\psi_{out}\rangle = (H \otimes \mathbb{I})\overset{c}{X}_{10}(H \otimes \mathbb{I})|0\rangle \ .$$

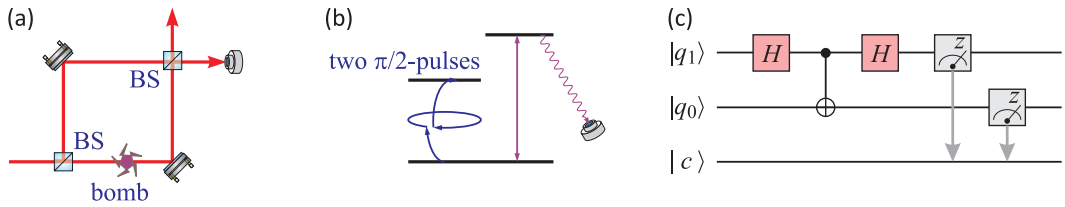

Figure 35.32: The main reason for the analogy between a Mach-Zehnder-Interferometer (a) and a driven two-level atoms (b) is the existence of a coherence between two states residing in the wave nature of light in (a) and of electronic orbitals in (b). (c) Quantum computing language formulation of the bomb tester.

35.8.9.8 Ex: Multiple beam splitters for improved bomb testing

In the original Elitzur and Vaidman bomb tester photons are sent through a single interferometer. Now, let the photons be sent repeatedly through the same beam splitter. Assume the photon wavepacket to be shorter than the length of the interferometer arms so that it *does not interfere with itself*. How many times must the photons be sent to the beam splitter to be totally transferred?

Solution: *We use the transfer matrix model describing the beam splitting by,*

$$\begin{pmatrix} a_n \\ b_n \end{pmatrix} = T \begin{pmatrix} a_{n-1} \\ b_{n-1} \end{pmatrix} = T^n \begin{pmatrix} a_0 \\ b_0 \end{pmatrix} \qquad \text{with} \qquad T = \begin{pmatrix} r & t \\ -t & r \end{pmatrix} .$$

In order to conserve energy, $a_n^2+b_n^2 = a_{n-1}^2+b_{n-1}^2$*, the matrix must satisfy,* $r^2+t^2 = 1$*. We may therefore introduce a new variable* θ *such that* $r = \cos\theta$ *and* $t = \sin\theta$*. The beam splitting matrix can be unitarily transformed into a diagonal matrix via,*

$$T = U \begin{pmatrix} e^{\imath\theta} & 0 \\ 0 & e^{-\imath\theta} \end{pmatrix} U^{-1} \qquad \text{with} \qquad U \equiv \tfrac{1}{\sqrt{2}} \begin{pmatrix} -\imath & \imath \\ 1 & 1 \end{pmatrix} ,$$

satisfying $\det U = 1$*. Hence, the multiple beam splitting is described by,*

$$T^n = U \begin{pmatrix} e^{\imath n\theta} & 0 \\ 0 & e^{-\imath n\theta} \end{pmatrix} U^{-1} = \begin{pmatrix} \cos n\theta & \sin n\theta \\ -\sin n\theta & \cos n\theta \end{pmatrix} .$$

With the initial condition $a_0 = 1$ *and* $b_0 = 0$ *and supposing the reflectivity of the beam splitter to be adjusted such that after* n *round trips,* $a_n = 0$ *and* $b_n = 1$*, we find,*

$$\begin{pmatrix} a_n \\ b_n \end{pmatrix} = \begin{pmatrix} \cos n\theta \\ -\sin n\theta \end{pmatrix} \equiv \begin{pmatrix} 0 \\ 1 \end{pmatrix} .$$

Hence,

$$0 \equiv \cos n\theta \Longrightarrow n = \frac{\pi}{2 \arccos r} .$$

Note, that the transfer matrix model can be extended to account for finite transmissions of the in- and output coupling mirrors,

$$\begin{pmatrix} a_n \\ b_n \end{pmatrix} = R_{in} T \begin{pmatrix} a_{n-1} \\ b_{n-1} \end{pmatrix} + T_{in} \begin{pmatrix} a_{in} \\ b_{in} \end{pmatrix} \qquad \text{with} \qquad R_{in} = \begin{pmatrix} r_a & 0 \\ 0 & r_b \end{pmatrix} \quad , \quad T_{in} = \begin{pmatrix} t_a & 0 \\ 0 & t_b \end{pmatrix} .$$

35.8.9.9 Ex: Hamiltonian approach to coupled cavities for improved bomb testing

a. Consider two identical weakly coupled cavities. Solving the Heisenberg equations with the Hamiltonian for two coupled oscillators calculate how the photon number evolves in each cavity (see Exc. 35.8.9.5). How does the field amplitudes change after one cavity round trip?
b. How does the photon number in cavity 'b' evolve if an absorber is inserted into the cavity 'a' [764]? How does the field amplitudes change in this case after one cavity round trip?
c. Now, we model the absorber by a two-level atom being in resonance with the light field and subject to spontaneous emission. Set up the Hamiltonian, derive the equations of motion, and solve them numerically. Interpret the results.
Comments: The multiple path model leading to the Airy formulas describes a physical process involving beam propagation and reflection and transmission at a real object like an atom or a beam splitter. The complete dynamics is only partially grasped by a Hamiltonian and a master equation treating the cavity as a closed system and being restricted to describing energy fluxes into and out of the system.
One manifestation of it is the necessity of approximating the Airy function close to resonance by a Lorentzian in order to link the cavity transmission to a decay rate.
Another manifestation is the discrepancy in the coupled cavity description via multiple paths and via Hamiltonian for coupled oscillators: The models only coincide of $r = \sqrt{R} \stackrel{!}{=} 1$.

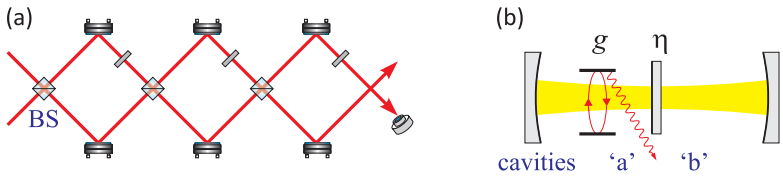

Figure 35.33: (a) Illustration of the multiple paths model and (b) the coupled cavities model for improved bomb testing.

Solution: *a. The Hamiltonian of the coupled system is,*

$$\hat{H} = -\Delta_c \hat{a}^\dagger \hat{a} - \Delta_c \omega \hat{b}^\dagger \hat{b} + \tfrac{\Omega}{2}(\hat{a}\hat{b}^\dagger + \hat{a}^\dagger \hat{b}) \ .$$

The Heisenberg-Liouville equations are,

$$\dot{\hat{a}} = -\imath[\hat{a}, \hat{H}] = \imath\Delta_c \hat{a} - \imath\tfrac{\Omega}{2}\hat{b} - \kappa_a \hat{a}$$
$$\dot{\hat{b}} = -\imath[\hat{b}, \hat{H}] = \imath\Delta_c \hat{b} - \imath\tfrac{\Omega}{2}\hat{a} - \kappa_b \hat{b} \ .$$

On resonance, $\Delta_a = 0$, and without decay, $\kappa_a = 0 = \kappa_b$, they read,

$$\begin{pmatrix} \dot{\hat{a}} \\ \dot{\hat{b}} \end{pmatrix} = -\imath \begin{pmatrix} 0 & \frac{\Omega}{2} \\ \frac{\Omega}{2} & 0 \end{pmatrix} \begin{pmatrix} \hat{a} \\ \hat{b} \end{pmatrix} = -\imath U \hat{E} U^{-1} \begin{pmatrix} \hat{a} \\ \hat{b} \end{pmatrix}$$

$$\text{with} \quad U = \begin{pmatrix} -\frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}} \\ \frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}} \end{pmatrix} \quad \text{and} \quad \hat{E} = \begin{pmatrix} -\frac{\Omega}{2} & 0 \\ 0 & \frac{\Omega}{2} \end{pmatrix} ,$$

and have the solution,

$$\begin{pmatrix} \hat{a}(t) \\ \hat{b}(t) \end{pmatrix} = U e^{-\imath \hat{E} t} U^{-1} = \begin{pmatrix} \cos\frac{\Omega t}{2} & -\imath \sin\frac{\Omega t}{2} \\ -\imath \sin\frac{\Omega t}{2} & \cos\frac{\Omega t}{2} \end{pmatrix} \begin{pmatrix} \hat{a}(0) \\ \hat{b}(0) \end{pmatrix} .$$

The photon numbers are now,

$$\hat{n}_a(t) = \hat{a}^\dagger(t)\hat{a}(t) = \hat{n}_a(0)\cos^2\tfrac{\Omega t}{2} + \hat{n}_b(0)\sin^2\tfrac{\Omega t}{2} + [\hat{b}^\dagger(0)\hat{a}(0) - \hat{a}^\dagger(0)\hat{b}(0)]\imath \sin\tfrac{\Omega t}{2}\cos\tfrac{\Omega t}{2}$$
$$\hat{n}_b(t) = \hat{b}^\dagger(t)\hat{b}(t) = \hat{n}_a(0)\sin^2\tfrac{\Omega t}{2} + \hat{n}_b(0)\cos^2\tfrac{\Omega t}{2} - [\hat{b}^\dagger(0)\hat{a}(0) - \hat{a}^\dagger(0)\hat{b}(0)]\imath \sin\tfrac{\Omega t}{2}\cos\tfrac{\Omega t}{2} .$$

That is, the total photon number is conserved, $\hat{n}_a(t) + \hat{n}_b(t) = \hat{n}_a(0) + \hat{n}_b(0)$. If initially $\hat{n}_b(0) = 0$, we get,

$$\hat{n}_a(t) = \hat{n}_a(0)\cos^2\tfrac{\Omega t}{2} = \hat{n}_a(0) - \hat{n}_b(t) .$$

One cavity round trip lasts δ_{fsr}^{-1}, where δ_{fsr} is the cavities' free spectral range. After one round trip the field amplitudes become,

$$\begin{pmatrix} \hat{a}(t + \delta_{fsr}^{-1}) \\ \hat{b}(t + \delta_{fsr}^{-1}) \end{pmatrix} = \begin{pmatrix} \cos\frac{\Omega}{2\delta_{fsr}} & -\imath \sin\frac{\Omega}{2\delta_{fsr}} \\ -\imath \sin\frac{\Omega t}{2\delta_{fsr}} & \cos\frac{\Omega t}{2\delta_{fsr}} \end{pmatrix} \begin{pmatrix} \hat{a}(t) \\ \hat{b}(t) \end{pmatrix} ,$$

or

$$\begin{pmatrix} \hat{a}_n \\ \hat{b}_n \end{pmatrix} = \begin{pmatrix} r & -\imath t \\ -\imath t & r \end{pmatrix} \begin{pmatrix} a_{n-1} \\ b_{n-1} \end{pmatrix} ,$$

with the identification,

$$t \equiv \sin\tfrac{\Omega}{2\delta_{fsr}} \qquad \text{and} \qquad r \equiv \cos\tfrac{\Omega}{2\delta_{fsr}} = \sqrt{1 - t^2} .$$

See Fig. 35.34.

b. Now, we insert an absorber into the cavity 'b'. This obviously destroys the coherent coupling between both cavities, which means that we are left with cavity 'a' and a loss rate κ_a,

$$\hat{H} = -\Delta_c \hat{a}^\dagger \hat{a} ,$$

described by the Heisenberg-Liouville equation,

$$\dot{\hat{a}} = -\imath[\hat{a}, \hat{H}] = \imath\Delta_c \hat{a} - \kappa_a \hat{a} .$$

On resonance, the solution is an exponential decay of the photon number,

$$\hat{n}_a(t) = \hat{n}_a(0) e^{-2\kappa_a t} .$$

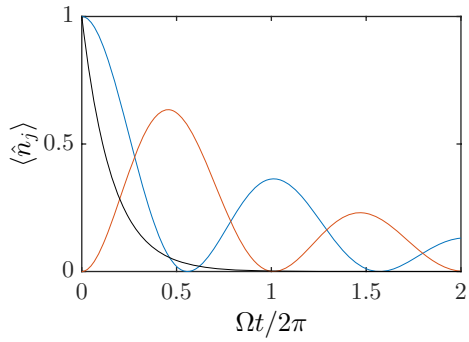

Figure 35.34: (code) (blue) Photon number in a cavity 'a' coupled to a cavity 'b' subject to losses. (red) Photon number in a cavity 'b'. (black) Photon number in a cavity 'a' coupled to an absorber.

After one round trip the field amplitudes become,

$$a(t + \delta_{fsr}^{-1}) = e^{-\kappa_a/\delta_{fsr}} a(t) \ ,$$

or

$$a_{n+1} = e^{-\kappa_a/\delta_{fsr}} a_n = r^2 a_n \ .$$

From this we deduce the identities,

$$r^2 = e^{-\kappa_a/\delta_{fsr}} \simeq 1 - \frac{\kappa_a}{\delta_{fsr}} \ ,$$

that is,

$$T = 1 - R = 1 - r^2 = \frac{\kappa_a}{\delta_{fsr}} = \frac{\pi}{F} \ .$$

However, we constantly evaluate the photo detector signal. As long as no photon is registered, we know that the intracavity photon number did not change.
In the bomb tester language, having let the cavities interact for a time corresponding to $2\pi/\Omega$, there are three possible outcomes: (i) No photon is observed in cavity 'a': This tells us that there is no bomb in cavity 'b'. (ii) A photon is observed in cavity 'a': This tells us that there is a 'bomb' in cavity 'b', although the photon never had a chance to interact with the it. (iii) The bomb explodes.
c. From the Hamiltonian,

$$\hat{H} = -\Delta_c \hat{a}^\dagger \hat{a} - \Delta_a \hat{\sigma}^z + g(\hat{\sigma}^- \hat{a}^\dagger + \hat{\sigma}^+ \hat{a}) - \Delta_c \hat{b}^\dagger \hat{b} + \tfrac{\Omega}{2}(\hat{a}\hat{b}^\dagger + \hat{a}^\dagger \hat{b}) \ ,$$

we derive the equations of motion,

$$\begin{aligned}
\dot{\hat{a}} &= -\imath[\hat{a}, \hat{H}] - \kappa_a \hat{a} = (\imath\Delta_c - \kappa_a)\hat{a} - \imath\tfrac{\Omega}{2}\hat{b} - \imath g\hat{\sigma}^- \\
\dot{\hat{b}} &= -\imath[\hat{b}, \hat{H}] - \kappa_b \hat{b} = (\imath\Delta_c - \kappa_b)\hat{b} - \imath\tfrac{\Omega}{2}\hat{a} \\
\dot{\hat{\sigma}}^- &= -\imath[\hat{\sigma}^-, \hat{H}] - \tfrac{\Gamma}{2}\hat{\sigma}^- = (\imath\Delta_a - \tfrac{\Gamma}{2})\hat{\sigma}^- + \imath g\hat{a}\hat{\sigma}^z \\
\dot{\hat{\sigma}}^z &= -\imath[\hat{\sigma}^z, \hat{H}] - \Gamma\hat{\sigma}^z = -2\imath g\hat{a}\hat{\sigma}^+ + 2\imath g\hat{a}^\dagger\hat{\sigma}^- - \Gamma(\mathbb{I}_2 + \hat{\sigma}^z) \ .
\end{aligned}$$

For simplicity we assume resonant excitation and no cavity decay,

$$\begin{aligned}\dot{\hat{a}} &= -\imath\tfrac{\Omega}{2}\hat{b} - \imath g\hat{\sigma}^- \\ \dot{\hat{b}} &= -\imath\tfrac{\Omega}{2}\hat{a} \\ \dot{\hat{\sigma}}^- &= -\tfrac{\Gamma}{2}\hat{\sigma}^- + \imath g\hat{a}\hat{\sigma}^z \\ \dot{\hat{\sigma}}^z &= -2\imath g\hat{a}\hat{\sigma}^+ + 2\imath g\hat{a}^\dagger\hat{\sigma}^- - \Gamma(\mathbb{I}_2 + \hat{\sigma}^z)\ .\end{aligned}$$

Treating cavity 'a' like a reservoir by setting $\eta \equiv \frac{\Omega}{2\imath}\alpha$ *the Hamiltonian for cavity 'b' becomes,*

$$\hat{H} = -\Delta_c\hat{b}^\dagger\hat{b} + \tfrac{\Omega}{2}(\alpha^*\hat{b} + \alpha\hat{b}^\dagger) = -\Delta_c\hat{b}^\dagger\hat{b} - \imath(\eta^*\hat{b} - \eta\hat{b}^\dagger)\ .$$

Fig. 35.34 shows the time evolution.

35.8.9.10 Ex: Simulation of the quantum Zeno effect with qubit gates

Design a quantum circuit simulating the quantum Zeno effect ruling the bomb tester and its extension to multiple paths.

Solution: *In matricial language the bomb tester reads,*

$$(H\otimes\mathbb{I})\overset{c}{X}_{10}(H\otimes\mathbb{I})|0\rangle\ .$$

The multiple paths extension reads,

$$\left([\mathbb{I}\otimes|0\rangle\langle 0|]\left[R_x(\tfrac{\pi}{n})\otimes\mathbb{I}\right]\overset{c}{X}_{10}\right)^n\left[R_x(\tfrac{\pi}{n})\otimes\mathbb{I}\right]|0\rangle\ .$$

As seen in Fig. 35.35 the detection efficiency increases with n asymptotically approaching 1.
Now [764, 765], instead of Hadamard gates, we consider a small rotation by $\vartheta = \frac{\pi}{2n}$,

$$U_3(\vartheta,0,0) = \begin{pmatrix}\cos\vartheta & -\sin\vartheta\\ \sin\vartheta & \cos\vartheta\end{pmatrix} \quad \textit{so that} \quad U_3(\vartheta,0,0)\otimes\mathbb{I} = \begin{pmatrix}\cos\vartheta & 0 & -\sin\vartheta & 0\\ 0 & \cos\vartheta & 0 & -\sin\vartheta\\ \sin\vartheta & 0 & \cos\vartheta & 0\\ 0 & \sin\vartheta & 0 & \cos\vartheta\end{pmatrix}\ .$$

With,

$$\mathbb{I}\otimes|0\rangle\langle 0| = \begin{pmatrix}1&0&0&0\\0&0&0&0\\0&0&1&0\\0&0&0&0\end{pmatrix} \quad \textit{and} \quad \overset{c}{X}_{10} = \begin{pmatrix}1&0&0&0\\0&1&0&0\\0&0&0&1\\0&0&1&0\end{pmatrix}\ ,$$

we find,

$$T = (\mathbb{I}\otimes|0\rangle\langle 0|)\ \ (U_3(\vartheta,0,0)\otimes\mathbb{I})\ \ \overset{c}{X}_{10} = \begin{pmatrix}\cos\vartheta & 0 & 0 & -\sin\vartheta\\ 0&0&0&0\\ \sin\vartheta&0&0&\cos\vartheta\\ 0&0&0&0\end{pmatrix}\ .$$

Finally,

$$|\psi\rangle = T^n \;\; (U_3(\vartheta,0,0)\otimes\mathbb{I}) \;\; |0\rangle = \cos^n\vartheta \begin{pmatrix} \cos\vartheta \\ 0 \\ \sin\vartheta \\ 0 \end{pmatrix} \;\; ,$$

respectively, $\hat{\rho}_{out} = T\;\hat{\rho}_{in}\;T^\dagger$.

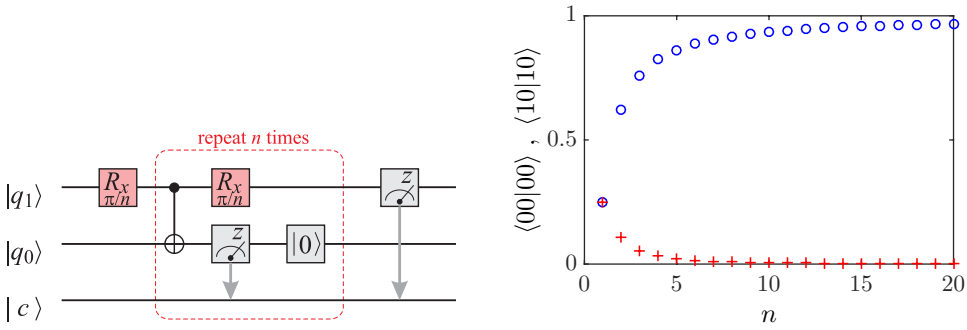

Figure 35.35: (code) Detection efficiency of the multiple path bomb tester as a function of the number of paths n.

35.8.9.11 Ex: Link between entanglement and squeezing

Prove that, if $\hat{a}_1$ and $\hat{a}_2$ are EPR-entangled beams with respect to quadrature components, then beams $\hat{b}_{1,2} = \frac{1}{\sqrt{2}}(\hat{a}_1 \pm \hat{a}_2)$ are squeezed with respect to two orthogonal quadrature components and vice versa [1087, 1088, 822].

Solution: *We consider independent modes characterized by their field operators,*

$$[\hat{a}_m, \hat{a}_n^\dagger] = \delta_{mn} = [\hat{b}_m, \hat{b}_n^\dagger] \qquad but \qquad [\hat{a}_1, \hat{b}_1^\dagger] = \tfrac{1}{\sqrt{2}} \;\; .$$

The Hamiltonian,

$$\hat{H} = \imath\hbar g\alpha(\hat{a}_1^\dagger\hat{a}_2^\dagger - \hat{a}_1\hat{a}_2)$$

describes parametric down-conversion in the non-degenerate configuration and in the approximation of a classical undepleted pump α. As is well known, in the non-degenerate configuration the two beams $\hat{a}_1$ and $\hat{a}_2$ are entangled both with respect to the photon number and with respect to the two quadrature components. The entanglement can be explicitly shown by applying the time evolution operator corresponding to the Hamiltonian to the uncorrelated vacuum state, for an interaction time τ,

$$e^{-\imath/\hbar\hat{H}\tau}|0\rangle_1|0\rangle_2 = \sum_{n=0}^{\infty} \frac{\tanh^n g\tau/\hbar}{\cosh g\tau/\hbar}|n\rangle_1|n\rangle_2 \;\; .$$

On the other hand, the Hamiltonian obtained by the transformation,

$$\hat{a}_{1,2} = \tfrac{1}{\sqrt{2}}(\hat{b}_1 \pm \hat{b}_2)$$

is

$$\hat{H} = \frac{\imath\hbar g\alpha}{2}(\hat{b}_1^{\dagger 2} - \hat{b}_1^2) - \frac{\imath\hbar g\alpha}{2}(\hat{b}_2^{\dagger 2} - \hat{b}_2^2) \ ,$$

which corresponds to the sum of two interaction Hamiltonians for parametric down-conversion in the degenerate configuration. Hence the beams $\hat{b}_1$ and $\hat{b}_2$ are squeezed, and because of the minus sign in front of the second term, the squeezing is in orthogonal quadrature components. For example, when α is real $\hat{b}_1$ is squeezed with respect to the Y quadrature (imaginary part of the annihilation operator) and $\hat{b}_2$ is squeezed with respect to the X quadrature (real part of the annihilation operator).

Chapter 36

Quantum measurement

Since its foundation, the theory of quantum mechanics was driven by the urge to clarify the relationship between the world and what we can learn about it, that is, between reality and the observer. Scientists such as Bohr, Heisenberg, Schrödinger, and Einstein defended controversial positions and struggled for the correct interpretation of quantum mechanics. The *measurement* process is supposed to provide information about the world out there, but it is not clear whether this information can be complete and accurate, or whether there are limitations or hidden variables. Also, it was unclear, to what extend a measurement can be non-invasive or whether it would always perturb the phenomenon under investigation. The most important step in this question was the *Copenhagen interpretation* formulated by Bohr, Heisenberg and Born in 1927 and elaborated later by von Neumann and Dirac. Although contested many times in the past, it's essence still remains valid today.

In this chapter we will study the measurement process from the viewpoint quantum mechanics and discuss some seemingly paradoxical effects, that will allow us to deepen our understanding. Among them are the quantum jump, Schrödinger's cat, the quantum Zeno effect, and the Einstein-Podolski-Rosen paradox.

36.1 The reality and the observer

According to the Copenhagen interpretation, theoretical predictions have a probabilistic character. However, this is not an expression of the imperfection of the theory, but of the intrinsically indeterministic character of quantum processes [1]. Moreover, the Copenhagen interpretation desists to attribute to objects of the quantum formalism, such as wavefunctions and operators, an immediate reality. Instead, the objects of the formalism only represent vehicles for a probabilistic prediction of the results of measurements. These results are *only truly real* elements of quantum theory. It is obvious, that the quantum theory and its interpretations are of fundamental importance to the scientific view of the world and our concept of nature.

36.1.1 Schrödinger's cat

In the microscopic world, the relationship between the sample and the observer is very delicate. And this delicacy is at the origin of quantum effects that seem paradoxical

[1] Note that it is problematic to identify unpredictability and indeterminism. We may be unable to predict specific events, without having to assume that these events occur in a random manner.

through our classical concept of the world. It is, thus, not surprising that one of the most fascinating areas of investigations is the *interface* between the classical and the quantum, the macroscopic and the microscopic worlds. For the pioneers of quantum mechanics the most important questions were of the type: 'How is it possible that a microscopic particle flies simultaneously through two slits?' Nowadays, we are accustomed to such paradoxes, and we simply accept the fact that we have to consider a particle as a wave. Nevertheless, we still do not understand very well, why the classical and the quantum world behave so differently. 'Why does quantum mechanics allow for quantum superpositions states, which are absolutely forbidden in classical physics?', 'Why are the fundamental laws of the quantum world invariant to the arrow of time, while the macroscopic world always evolves from the past to the future?, 'How can it be that quantum mechanics allows for effects having no cause, like spontaneous emission, while the everyday world seems to be deterministic?'

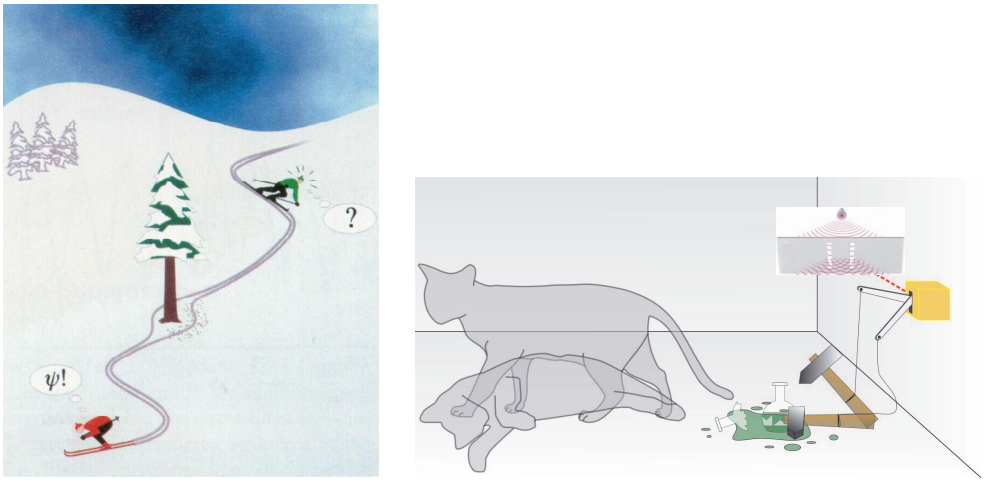

Figure 36.1: Double slit and Schrödinger's cat.

Quantum mechanics must, in some limit, clearly encompass classical physics. But in spite of *Ehrenfest's correspondence principle*, this fact is far from being trivial. Some predictions of classical and quantum physics are fundamentally different and, in some cases, even contradictory. The famous *Schrödinger cat* states are the epitome of this fact: In one version of this paradox, a particle crosses a double slit. Behind one of the slits is a detector which, as soon as it registers a particle, actuates a device killing a cat. We know that in quantum reality the particle crosses both slits in a superposition state, so that the cat should be in a superposition state as well. Hence, quantum cats can be in a superposition of 'dead' and 'alive'.

We believe nowadays that the answers to the above questions are somehow buried in processes that destroy the quantum superposition of Schrödinger cats during the transition from the microscopic to the macroscopic world. However, the details of these quantum coherence destruction processes, called *decoherence*, are very complicated and the subject of serious efforts in contemporary research. It is one of the motivations for trying to create in laboratories the largest possible (quasi-macroscopic) quantum systems, bring them in Schrödinger cat-like superposition states and study

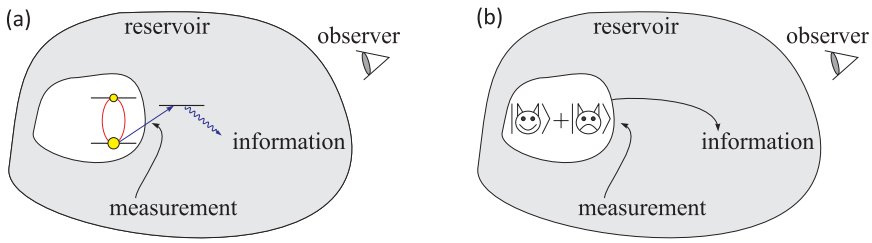

Figure 36.2: The measurement of a quantum system presupposes the interaction of the system with a reservoir, which disturbs its dynamics.

their decoherence [2].

36.1.1.1 Quantum measurement

Every unperturbed system follows the Schrödinger equation. Once its Hamiltonian has been determined, the formal solution,

$$|\psi\rangle = e^{-\imath\hat{H}t/\hbar}|\psi_0\rangle \ , \tag{36.1}$$

allows to calculate the time evolution, that is, the trajectory of the wavefunction. The evolution is *coherent and reversible* in time.

Now, the process of measuring a pure quantum state includes –according the Copenhagen interpretation and as discussed in Sec. 23.2.7– two consecutive steps: In the *first step*, the interaction of the quantum sample with the measuring device (which from now on we will call *meter*) destroys all coherences and projects the pure state into a statistical mixture of eigenstates of the meter. Following von Neumann, the impact of the meter on the quantum system is so strong, that its coherent evolution is interrupted and it is projected onto the degree of freedom that the apparatus wants to measure, e.g. its position or its momentum, but not both in the same time. The projection transforms a pure quantum state $|\psi\rangle$ into a statistical mixture ρ of eigenstates,

$$\hat{\rho}_{sample} = |\psi(t)\rangle\langle\psi(t)| \curvearrowright \hat{\rho}_{proj} = \sum\nolimits_k |\langle\psi|k\rangle|^2 |k\rangle\langle k| \ . \tag{36.2}$$

This process is irreversible, that is, it separates the past from the future. The projection is *not* described by the Schrödinger equation. Instead, the sudden reduction of the state must be postulated, as done by von Neumann's famous axiom.

In a *second step*, the observer looks at the measuring device and confirms one of the possible results. Thus, he transforms the state into a eigenstate of the device [3]:

$$\hat{\rho}_{proj} \curvearrowright \hat{\rho}_{meter} = |k\rangle\langle k| \ . \tag{36.3}$$

From this moment, we can again leave the quantum system alone until the next measure.

[2] There are attempts to introduce the concept of the time arrow also in the microscopic world: 'In an isolated system, spontaneous processes occur in the direction of increasing entropy.' [896, 500].

[3] We note that, only if *all* commuting observables of the system are measured *and* acknowledged, $\hat{\rho}_{meter}$ becomes a pure state. Otherwise ρ_{meter} remains a partial mixture.

From the viewpoint of the quantum system, the evolution of the measurement process appears *discontinuous*, because it destroys all possible coherences between its states. In fact, the problem comes from the non-ideal behavior of the measuring device (symbolized by $|\uparrow\rangle$ before the measurement). An ideal non-invasive measurement [4] would leave the quantum state $|\psi\rangle$ unchanged:

$$|\psi\rangle|\uparrow\rangle \xrightarrow{H} |\psi\rangle|\nearrow\rangle \ , \tag{36.4}$$

while the measuring device changes to a state ($|\nearrow\rangle$ after the measurement) indicating the current state of the system. However, this is normally impossible without previously established correlation between $|\psi\rangle$ and $|\uparrow\rangle$. In a real meter device, the coupling between $|\psi\rangle$ and $|\uparrow\rangle$ requires that the meter and the system to be non-orthogonal.

36.1.1.2 Measurement-induced decoherence

A more modern view of the quantum measurement is the following: When the outer world (called reservoir, observer or meter) *reads* a quantum system, it causes, due to this transfer of information, an irreversible demolition of coherence. Consequently, the density operator condenses to its diagonal. On the other hand, the system as a whole (including the sample and the reservoir) always evolves coherently according to the von Neumann equation with the Hamiltonian of everything $\hat{H}_{all}$:

$$\dot{\hat{\rho}} = \frac{\imath}{\hbar}[\hat{\rho}, \hat{H}_{all}] \ . \tag{36.5}$$

If $\hat{H}_{sample}$ is the small quantum system under investigation, a complete description of the measurement process requires the inclusion of the observer, that is, the total Hamiltonian is,

$$\hat{H} = \hat{H}_{sample} \otimes \hat{H}_{meter} = \begin{pmatrix} \text{sample} & 0 \\ 0 & \text{meter} \end{pmatrix} \ . \tag{36.6}$$

Ideally, the system evolves independently without being disturbed by the meter. Unfortunately, this also means that the meter evolves independently, that is, it is not influenced by the system and thus does not provide information about the system. To allow a transfer of information, we need to couple the respective spaces by an interaction Ω, such that,

$$\hat{H} = \begin{pmatrix} \text{sample} & \Omega \\ \Omega & \text{meter} \end{pmatrix} \ . \tag{36.7}$$

Tracing over all degrees of freedom of the universe *except* those of the quantum system, the von Neumann equation (36.5) turns into a master equation,

$$\dot{\hat{\rho}}_{sample} = \frac{\imath}{\hbar}[\hat{\rho}, \hat{H}_{sample}] + \mathcal{L}_{reserv}\rho \ . \tag{36.8}$$

[4] See the discussion of the *quantum non-demolition measurement*.

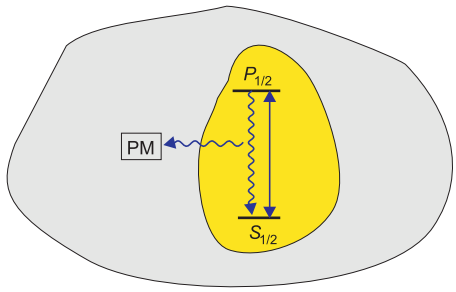

Figure 36.3: Spontaneous emission can be seen as a coupling of the system under investigation to an external meter, because it delivers information to the meter, even if only to tell us: 'The system was in an excited state, but now it's in a ground state.'

Example 217 (*Quantum measurement in a two-qubit system*): To discuss this at an example, we consider the simplest imaginable system: Two two-level atoms, the first one representing the quantum system under investigation and the second the meter. We introduce the following basis:

$$|1\rangle \equiv |\downarrow\rangle|\downarrow\rangle = \begin{pmatrix}1\\0\\0\\0\end{pmatrix} , \; |2\rangle \equiv |\uparrow\rangle|\downarrow\rangle = \begin{pmatrix}0\\1\\0\\0\end{pmatrix} , \; |3\rangle \equiv |\downarrow\rangle|\uparrow\rangle = \begin{pmatrix}0\\0\\1\\0\end{pmatrix} , \; |4\rangle \equiv |\uparrow\rangle|\uparrow\rangle = \begin{pmatrix}0\\0\\0\\1\end{pmatrix} .$$

The Hamiltonian of independent atoms is,

$$\hat{H} = |\downarrow\rangle\langle\downarrow| \otimes |\uparrow\rangle\langle\uparrow| .$$

The discussion about the correct interpretation of the measurement process is still ongoing. Modern theories describe the state reduction in terms of *quantum decoherence* due to interactions of the system with the environment. Other interpretations involve *decoherent histories* or assume *multiple worlds* [1004]. On the practical side, the current interest in quantum decoherence is motivated by the fact that this phenomenon may turn out to be the fundamental factor limiting the useful operation of quantum computers. Another interesting area where quantum mechanics meets classical physics is the phenomenon of quantum chaos.

36.1.2 The quantum jump

Obviously, the whole quantum measurement process, including the discontinuity of the state projection, could be fully understood within a grand model of the complete system, which would include the measuring device. In practice, this is illusory, because of the excessive number of degrees of freedom of the classical measuring device (e.g. a Schrödinger cat).

On the other hand, many characteristics of quantum measurement can be illustrated in a simple *three-level atom* with a weak transition representing the quantum sample and a strong transition representing the meter. The assertion defended in

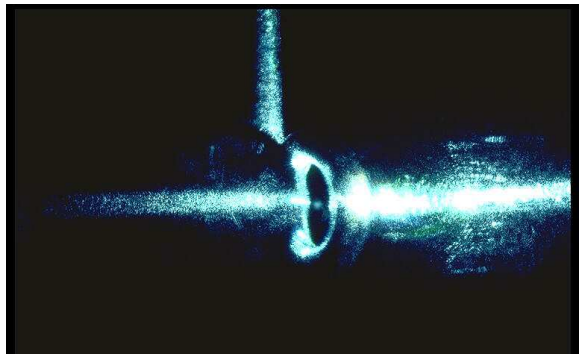

Figure 36.4: One of the first pictures of a single Ba^+ ion.

the following is, that this three-level system, called *quantum amplifier*, gives a deep insight into what happens during the process of state reduction and, therefore, can be considered as paradigmatic for theories on quantum measurement.

To be able to discuss the dynamics of this system on a firmer ground, we will first introduce the quantum Monte Carlo wavefunction simulation method (MCWF).

36.1.2.1 Quantum Monte-Carlo wavefunction simulation of a two-level system

The possible occurrence of spontaneous emission produces a dynamics called *quantum trajectory*, which can be described by a non-hermitian *effective Hamiltonian*,

$$\hat{H}_{eff} = \hbar\Delta\sigma_z + \hbar\Omega\sigma^+ + c.c. - \frac{\imath}{2}\Gamma\sigma_z = \begin{pmatrix} 0 & \Omega \\ \Omega & \Delta - \imath\frac{\Gamma}{2} \end{pmatrix} , \tag{36.9}$$

aiming at including energy dissipation processes. The problem with this Hamiltonian is that, for being non-hermitian, $[\hat{H}_{eff}, \hat{H}^\dagger_{eff}] \neq 0$, it also generates a non-unitary dynamics, $e^{-\imath\hat{H}_{eff}t} \neq e^{\imath\hat{H}^\dagger_{eff}t}$. This means that the mere *possibility* of spontaneous emission prevents the reversibility of the dynamics. We observe a temporal decrease of the norm $\langle\psi(t)|\psi(t)\rangle$ indicating a loss of energy,

$$\langle\psi|\psi\rangle = \langle\psi_0|e^{-\imath\hat{H}_{eff}t}e^{\imath\hat{H}_{eff}t}|\psi_0\rangle \longrightarrow e^{-\Gamma t} . \tag{36.10}$$

The loss of normalization during the evolution, until the next quantum jump occurs, is due to the dissipation of energy toward the reservoir,

$$\text{Tr } \rho_{sample} \to 0 \qquad \text{while} \qquad \text{Tr} \begin{pmatrix} \rho_{sample} & 0 \\ 0 & \rho_{reserv} \end{pmatrix} = 1 , \tag{36.11}$$

and represents a measure of the probability that an irreversible process has occurred during the evolution time.

Dissipative processes can be simulated by playing dices with random numbers ζ. We divide time into small intervals dt and propagate the wavefunction from $\psi(t)$

to $\psi(t+dt)$. After each interval we evaluate the probability $p = 1 - \langle\psi(t)|\psi(t)\rangle$ accumulated during the time period $[0, t+dt]$ that a dissipative process (such as spontaneous emission) has occurred. Now, we generate a random number ζ, uniformly distributed between 0 and 1, which we compare to probability the probability p. In case, $\zeta > 1 - \langle\psi(t)|\psi(t)\rangle$, we conclude that there was no dissipative process, and we let the system proceed in peace, only renormalizing the wavefunction to compensate for the losses [893, 321]. Otherwise, if $\zeta < 1 - \langle\psi(t)|\psi(t)\rangle$, we conclude that there was a dissipative process, and the system is projected into the eigenstate ψ_0. This projection is abrupt and called *quantum jump*. Now, the evolution restarts from zero, ruled by the effective Hamiltonian. The simulation implemented via,

$$|\psi(t)\rangle \curvearrowright |\psi(t+dt)\rangle \equiv \begin{pmatrix} \frac{(1-\imath\hat{H}dt)|\psi(t+dt)\rangle}{\sqrt{\langle\psi(t)|\psi(t)\rangle}} & \text{if} \quad \zeta > 1 - \langle\psi(t)|\psi(t)\rangle \\ |\psi_0\rangle \quad \text{if} \quad \zeta < 1 - \langle\psi(t)|\psi(t)\rangle \end{pmatrix} . \tag{36.12}$$

This is the method called *quantum Monte Carlo wavefunction simulation*.

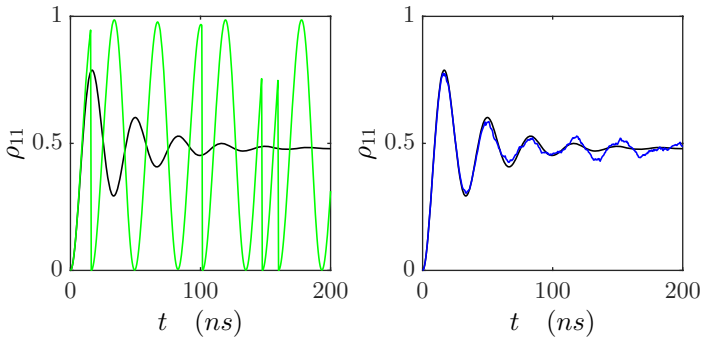

Figure 36.5: (code) a) Quantum Monte Carlo wavefunction simulation. It is important to be aware, that a trajectory generated by a MCWF simulation (36.12) only represents *one* of many possible trajectories of the system. (b) The evolution of the density matrix $\rho(t) = |\psi(t)\rangle\langle\psi(t)|$ (blue curve) is nothing else, than the average (black curve) over all possible MCWF trajectories for the system. A movie of this simulation can be watched here (watch movie).

The effective two-level Hamiltonian (36.9) dissipates via spontaneous emission, which is included in the dynamics through the *possibility* for the system to suffer a *state reduction*. The modification of $|\psi(t)\rangle$ by *non-observation* of spontaneous emission, reduces the population of the state excited by $1 - \frac{1}{2}\Gamma dt$, while the ground state population remains unchanged. Every quantum jump projecting the system into the ground state constitutes a measurement, because it corresponds to a detected fluorescence photon.

36.1.2.2 Three-level systems: The epitome of quantum measurement

Let us now return to the mysterious interaction between the sample and the meter, which we want to unravel by comparing two possible procedures: 1. treating the

sample and the meter separately and explain the extraction of information following the von Neumann postulate; 2. treating the sample and the meter by a global theory.

As said above, the inclusion of the meter in a global theory is, in general, difficult. For this reason, to perform the comparison, we choose the simplest imaginable system: the *three-level system* with two transitions connecting to a common ground state and excited by radiation fields. As shown in Fig. 36.6(a) this three-level system can be an atom with a strong transition and a weak transition, for example, the dipolar transition $S_{1/2} - P_{1/2}$ and the forbidden quadrupolar transition $S_{1/2} - D_{5/2}$ in a single Ba^+ ion. We will now name the 'strong transition' as *meter* and the 'weak transition' as *sample* and show that this system allows to study the von Neumann measurement process including the direct observation of quantum jumps [5]. At the same time, the system is simple enough for a complete theoretical description. In this sense, the three-level system becomes the *epitome of a quantum measurement device.*

We turn our attention to the three-level atom: Obviously, the atom will preferentially scatters photons on its strong dipolar transition. However, at times when the valence electron is 'shelved' in the metastable state excited by the quadrupole transition, no fluorescence can be observed on the strong transition.

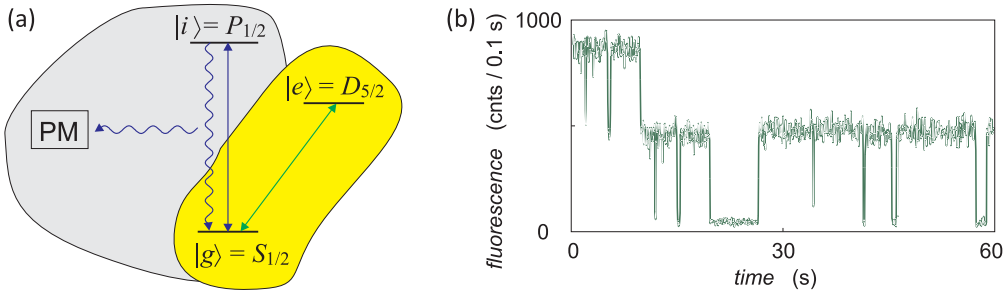

Figure 36.6: (a) Quantum measurement at the example of a three-level atom incorporating a weak (sample) transition and a strong (meter) transition. (b) *Random Telegraph signal* in the resonance fluorescence due to quantum jumps.

Quantum jumps were experimentally observed in single trapped ions, whose lowest energies form a three-level systems [943, 1147, 1148, 130].

36.1.2.3 Quantum Monte-Carlo wavefunction simulation of the quantum amplifier

When both lasers driving the weak and the strong transition are irradiated simultaneously, the coherence on the weak transition is easily perturbed by the dynamics of the strong transition. To resolve this problem *Dehmelt* invented what he called the *quantum amplifier*. The idea consists in alternately irradiating the *sample* laser (at stage $S - D$ in Fig. 36.7) and the *meter* laser (at stage $S - P$ in Fig. 36.7) [6].

[5] The observability of quantum jumps as manifestations of sudden state reductions has been the object of long-standing debates: 'If we have to go on with these damned quantum jumps, then I'm sorry that I ever got involved with quantum mechanics.' [1169].

[6] The absence of the 'meter' laser during the 'sample' stage avoids saturation broadening and light-shifts of the ground state. Since the ground state is shared by both transitions, its broadening

The alternating irradiation of the lasers $S-D$ and $S-P$ can also be treated by the Monte Carlo quantum wavefunction simulation method (36.12) using the effective Hamiltonian,

$$\hat{H}_{eff} = \begin{pmatrix} 0 & \frac{1}{2}\Omega_{sp} & \frac{1}{2}\Omega_{sd} \\ \frac{1}{2}\Omega_{sp} & -\Delta_{sp} - \frac{i}{2}\Gamma_{sp} & 0 \\ \frac{1}{2}\Omega_{sd} & 0 & -\Delta_{sd} \end{pmatrix} , \tag{36.13}$$

where the Rabi frequencies Ω_{sd} and Ω_{sd} are switched on alternately.

In the simulation 36.7 the quantum jumps to the shelved metastable state $D_{5/2}$ appear as long periods without population in the $P_{1/2}$ level (first period $S-P$, where the population of $S_{1/2}$, illustrated by the red curve, gradually tends to 0 for long times). The reduction of the system to the shelved state actually occurs by *non-observation* of fluorescence on the strong transition. The projection needs a finite time, simply because we can not be sure whether the non-observation is actually due to shelving or the incidental absence of scattering events on the $S-P$ transition: After all, it is not predictable, when the next photon will be spontaneously emitted, even though the lifetime of the excited state is short. But for longer observation times it becomes increasingly unlikely that the absence of photons is *not* due to shelving. It is this unlikeliness, which lets the population rapidly converge towards the metastable state. In the second $S-P$ period, Fig. 36.7 shows fast transitions to the $P_{1/2}$ followed by sudden decays to the ground state. These processes correspond to photon absorption and spontaneous reemission by the strong transition. The succession of the photon scattering events is so fast, that the signal recorded by photodetectors appears as a continuous fluorescence. The sudden transitions between bright and dark periods shown in Fig. 36.6(b), which occur totally randomly, are interpreted as quantum jumps.

36.1.2.4 Comparison with Bloch equations and interpretation of quantum jumps

We already mentioned in Fig. 36.5, that a trajectory generated by a MCWF simulation (36.12) represents *one* possible evolution of the system. In Chp. 34 we got to know an alternative way of predicting the evolution of a system, based on density operator obeying a *master equation*, which in the context of atomic excitation levels is called Bloch equation. Comparing MCWF trajectories (red curves in Fig. 36.7) with Bloch vector evolutions (green curves) it becomes apparent, that the Bloch vector evolution does not produce quantum jumps, but is always smooth and continuous.

In most cases, our knowledge about the actual state of an atom comes from the collection of spontaneously emitted photons. The observation of a photon projects the atomic state into the ground state. However, this concept is not included in the Bloch equations, as we just saw in Fig. 36.7. So, as it seems, we have to take back our statement, that the three-level Bloch equation describe the complete system, although they somehow contain spontaneous emission.

---

would reduce the spectral overlap between the 'sample' transition and the driving laser and therefore the probability to excite the metastable level. This inhibition of the coherent dynamic by too strong or too frequent measurements is known as *quantum Zeno effect*: The more an observer tries to extract information from a system, the more he inhibits its evolution. We will discuss this effect in more detail in Sec. 56.3.2.2.

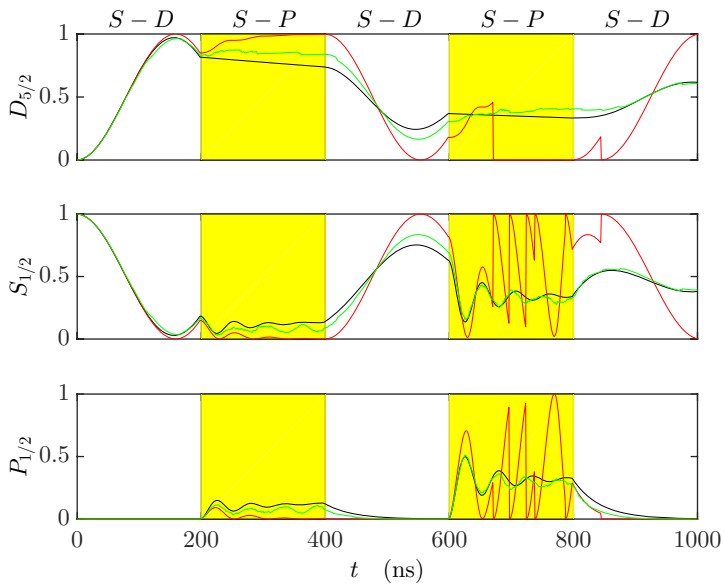

Figure 36.7: (code) Quantum amplifier comparing Monte-Carlo quantum simulations (red lines) and Bloch equations (black lines), which coincide well with the averages over 100 Monte-Carlo trajectories (green lines). The periods $S-D$ (white background) represent the free evolution of the quantum system, the periods $S-P$ (yellow background) represent the measurement periods.

Let us go one step back and ask, where the Bloch equations came from. In fact, as we learned in Sec. 35.6 and will deepen in Sec. 36.2, they are derived from a von Neumann equation for the three-level system *plus* the degrees of freedom of the vacuum modes receiving the spontaneously emitted photons by *tracing over the latter ones*.

We will not be able to handle all degrees of freedom. However, we can generalize the Bloch equations in the following way [912, 1440]. We project the total density operator ρ_{AFR} of the atom plus the driving field plus the reservoir of vacuum modes into the subspace of the atom and the driving field consisting of exactly n photons,

$$\rho^{(n)} = \mathrm{Tr}_R \left(P^{(n)} \rho_{AFR} \right) , \tag{36.14}$$

and derive, from the von Neumann equation, the master equation for the atomic state $\rho^{(n)}$ under the constraint of a fixed number of photons n in the field. The master equation differs only in one term from the usual Bloch equations: The expression $\Gamma_{12}\rho_{22}^{(n)}$, which describes the spontaneous decay of the population of the excited state of the meter transition, is replaced by the expression $\Gamma_{12}\rho_{22}^{(n-1)}$:

$$\frac{d}{dt}\rho^{(n)} = (\mathcal{L}|1\rangle\Gamma_{12}\langle 2|)\rho_{(n)} + |1\rangle\Gamma_{12}\langle 2|\rho^{(n-1)} , \tag{36.15}$$

The substate with of n photons violates the trace condition, $\sum_j \rho_{jj}^{(n)} \neq 1$. The physical explanation for this is the following: While induced emission and absorption

maintain the number of photons in the combined light-atom system (like in the Jaynes-Cummings model), spontaneous emission decreases the number of photons, leading to an irreversible loss of energy. The quantum jump observed in MCWF model corresponds, in the modified equations (36.15), to a collapse of the subspace described by $\rho^{(n)}$ with the time constant Γ_{12} and a birth of another subspace $\rho^{(n-1)}$, whose evolution is guided by another (analogous) Bloch equation, now for $n-1$ photons. Each fluorescence detection at time $t = 0$ determines the initial condition for the future development of the system: $\rho^{(n)}(0) = 0$ and $\rho^{(n-1)}(0) = |1\rangle\langle 1|$. The probability density $c(t)$ for a new observation of spontaneous emission at time t with detection efficiency η, or in other words, the histogram of the durations of dark periods in the fluorescence signal is related to the solution $\rho^{(n)}$ of the homogeneous part of the equation (36.14) via,

$$c(t) = \eta\Gamma_{12}\tilde{\rho}_{22}^{(n)}(t) = \eta\sum_{j=1}^{4}\frac{d}{dt}\tilde{\rho}_{jj}^{(n)}(t)\ , \tag{36.16}$$

The second step immediately follows from the homogeneous part of equation (36.15).

36.1.2.5 Final remarks

The explanations of the last sections show that Bohr's and Schrödinger's views can be reconcealed. They simply depend on whether the measuring transition is excluded or included in the description of the dynamics. *The quantum jump is an* ***artifact*** *arising from the separation of the quantum system under study (object) from the meter (observer) assumed to strongly interact with the system!* In any case (strong or weak interaction), this separation is not compulsory once a more complete model including the meter is at hand. However, as the dynamics of the meter and the object evolve on different time scales, a separation of the dynamics leading to apparently discontinuous trajectories is *only meaningful for strong meter interactions.*

As soon as this has been understood, that is since the 1980-th, the apparent paradox is simply not on the agenda any more. Recent claims of having unraveled the mystery [901] are just not timely and only show that the author did not understand the full meaning of a 'quantum jump' or, at most, did not read the pertinent literature.

36.1.3 Weak measurements

Strong measurements leave the measured quantum system in a eigenstate without uncertainty. But it is possible to imagine a situation, where the measured device does not strongly interact with the quantum system, so that the system is not heavily perturbed. The price to pay will, however, be an uncertain result of the measurement (*no free lunch theorem*).

We consider the use of an ancilla, i.e. an adjunct degree of freedom, for example, a field or a current, to probe a quantum system. The interaction between the system and the probe correlates the two systems.

36.1.3.1 Weak interaction and measurement by coupling to an ancilla

Let us consider a system initially in the quantum state $|\psi\rangle$ and an ancilla initially in the state $|\phi\rangle$, such that the combined state is, $|\Psi\rangle = |\psi\rangle \otimes |\phi\rangle$. The two systems

interact through the Hamiltonian $\hat{H} = \hat{A} \otimes \hat{B}$, which generates the temporal evolution $U(t) = e^{-\imath x t \hat{H}}$ (in units where $\hbar = 1$), where x is the *strength of the interaction* (in angular frequency unit). We assume a fixed interaction time $t = \Delta t$ such that, $\lambda = x\Delta t$ is very small, that is, $\lambda^3 \approx 0$. The expansion of U λ gives,

$$U \approx \mathbb{I} \otimes \mathbb{I} - \imath\lambda\hat{H} - \tfrac{\lambda^2}{2}\hat{H}^2 + O(\lambda^3) = \mathbb{I} \otimes \mathbb{I} - \imath\lambda\hat{A} \otimes \hat{B} - \tfrac{\lambda^2}{2}\hat{A}^2 \otimes \hat{B}^2 \ . \tag{36.17}$$

In cases, where it is sufficient to expand the unitary transformation into low perturbation orders, we speak of *weak interaction*. Since λ and λ^2 are small, the combined state after the interaction will not be very different from the initial state,

$$|\Psi'\rangle = (\mathbb{I} \otimes \mathbb{I} - \imath\lambda\hat{A} \otimes \hat{B} - \tfrac{\lambda^2}{2}\hat{A}^2 \otimes \hat{B}^2)|\Psi\rangle \ . \tag{36.18}$$

Now, we make a measurement on the ancilla to extract information from the system. This is called *ancilla-mediated measurement*. We consider measurements in the basis $|q\rangle$ (of the ancilla system), such that $\sum_q |q\rangle\langle q| = \mathbb{I}$. The action of the measurement on the total system is described by the action of the projector $\Pi_q = \mathbf{1} \otimes |q\rangle\langle q|$ onto $|\Psi'\rangle$. According to the theory of quantum measurement, the conditional state after the measurement is,

$$|\Psi_q\rangle = \frac{\Pi_q|\Psi'\rangle}{\sqrt{\langle\Psi'|\Pi_q|\Psi'\rangle}} = \frac{\mathbf{1} \otimes |q\rangle\langle q| \left(\mathbb{I} \otimes \sum_k |k\rangle\langle k| - \imath\lambda\hat{A} \otimes \hat{B} - \frac{\lambda^2}{2}\hat{A}^2 \otimes \hat{B}^2\right)}{\mathcal{N}}|\psi\rangle \otimes |\phi\rangle \tag{36.19}$$

$$= \frac{\mathbb{I} \otimes \sum_k |q\rangle\langle q|k\rangle\langle k| - \imath\lambda\hat{A} \otimes |q\rangle\langle q|\hat{B} - \frac{\lambda^2}{2}A^2 \otimes |q\rangle\langle q|B^2}{\mathcal{N}}|\psi\rangle \otimes |\phi\rangle$$

$$= \frac{\mathbb{I}\langle q|\phi\rangle - \imath\lambda\hat{A}\langle q|\hat{B}|\phi\rangle - \frac{\lambda^2}{2}\hat{A}^2\langle q|\hat{B}^2|\phi\rangle}{\mathcal{N}}|\psi\rangle \otimes |q\rangle \ ,$$

where $\mathcal{N} = \sqrt{\langle\Psi'|\Pi_q|\Psi'\rangle}$ is the normalization factor for the wavefunction. Note, that the status of the ancilla records the result of the measurement. The object,

$$M_q \equiv \langle q|e^{-\imath\hat{A}\otimes\hat{B}}|\phi\rangle \simeq \mathbb{I}\langle q|\phi\rangle - \imath\lambda\hat{A}\langle q|\hat{B}|\phi\rangle - \tfrac{\lambda^2}{2}\hat{A}^2\langle q|\hat{B}^2|\phi\rangle \tag{36.20}$$

is an operator acting on the total Hilbert space and called the *Kraus operator*. With respect to Kraus operators the state of the combined system after the measurement is,

$$|\Psi_q\rangle = \frac{M_q|\psi\rangle}{\sqrt{\langle\psi|M_q^\dagger M_q|\psi\rangle}} \otimes |q\rangle \ . \tag{36.21}$$

The objects $E_q = M_q^\dagger M_q$ are elements of the so-called *positive operator valued (probability) measurement* (POVM) and must obey $\sum_q E_q = \mathbb{I}$, such that the corresponding probabilities add up to unity: $\sum_q \Pr(q|\psi) = \sum_q \langle\psi|E_q|\psi\rangle = 1$. The ancilla system is no longer correlated with the primary system. It simply records the result of the measurement, such that we can calculate the trace over it. Doing so, we come to the conditional state of the primary system alone,

$$|\psi_q\rangle = \frac{M_q|\psi\rangle}{\sqrt{\langle\psi|M_q^\dagger M_q|\psi\rangle}} \ , \tag{36.22}$$

which we still label with the result q of the measurement. In fact, these considerations allow us to derive a *quantum trajectory*.

36.1.3.2 Kraus operator for position measurement

As a canonical example of a Kraus operator [91, 242] we take $\hat{H} = \hat{x} \otimes \hat{p}$, where the position and the momentum satisfy the commutation relation, $[\hat{x}, \hat{p}] = i$. The initial state of the ancilla be a Gaussian distribution,

$$|\phi\rangle = \frac{1}{(2\pi\sigma^2)^{1/4}} \int dq' e^{-q'^2/4\sigma^2} |q'\rangle \ . \tag{36.23}$$

The position wavefunction of the ancilla is,

$$\phi(q) = \langle q|\phi\rangle = \frac{1}{(2\pi\sigma^2)^{1/4}} e^{-q^2/4\sigma^2} \ . \tag{36.24}$$

The Kraus operators are (compared to the previous discussion, we now let $\lambda = 1$),

$$M(q) = \langle q|e^{-\imath\hat{x}\otimes\hat{p}}|\phi\rangle = \frac{1}{(2\pi\sigma^2)^{1/4}} e^{-(q-x)^2/4\sigma^2} \ , \tag{36.25}$$

since the operator $e^{-\imath\hat{x}\otimes\hat{p}}$ makes a spatial translation when applied to the degree of freedom of the position. The corresponding POVM elements are,

$$E(q) = M_q^\dagger M_q = \frac{1}{\sqrt{2\pi\sigma^2}} e^{-(q-x)^2/2\sigma^2} \ , \tag{36.26}$$

which obey $\int dq E(q) = \mathbb{I}$.

Calculate $\langle\psi_q|\psi_q\rangle = \langle\psi'|M(q)^\dagger M(q)|\psi'\rangle$.

Note that $\lim_{\sigma\to 0} E(q) = |x = q\rangle\langle x = q|$. That is, in a particular limit, these operators converge to a strong measurement of position. For $\sigma \to \infty$, we speak of weak measurement.

Another example would be the three-level atom of Dehmelt's quantum amplifier.

36.1.4 *Welcher Weg* information

36.1.4.1 The Elitzur and Vaidman bomb testing problem

Mixing the concepts of particles and waves we sometimes arrive at seemingly paradoxical conclusions. One example is Elitzur and Vaidman's *bomb testing problem*. They imagined a Mach-Zehnder interferometer with the particularity that the reflecting mirror of one of the arms be connected to a device measuring the photonic recoil. That is, when a photon passes through this arm, the mirror undergoes a small acceleration, which is sufficient to activate an explosive bomb.

Now, we distinguish two cases: 1. The recoil detector *does not work*, i.e. the bomb is not armed. 2. The bomb is *armed*. We now adjust the interferometer in a way to produce destructive interference in one of the two interferometer output ports. If, having sent many photons through the interferometer, we never saw any photons in the 'dark' port, we can be almost sure that the bomb is *not operational*.

In case the bomb is operational, the observation of a photonic recoil destroys the interference pattern at the interferometer outputs. It *has* to do so, because the exploding bomb informs us, in which arm the photon has passed. However, with an operational bomb the interference pattern is *also* destroyed, when the photon passes through the other arm, since the fact that the bomb didn't explode tells us, that the photon went the other way.

The funny conclusion is now, that it may happen, that a photon traverses the interferometer in the arm that does *not* contain the bomb and exits through the 'dark port'. The probability of this happening is only 25%, but nevertheless the observation of a photon in the 'dark port' informs to us that the pump is operative without ever having interacted with it [7].

36.1.5 Exercises

36.1.5.1 Ex: Schwartzeneggers cat

Explain why we will never observe a real cat in a dead-alive superposition.

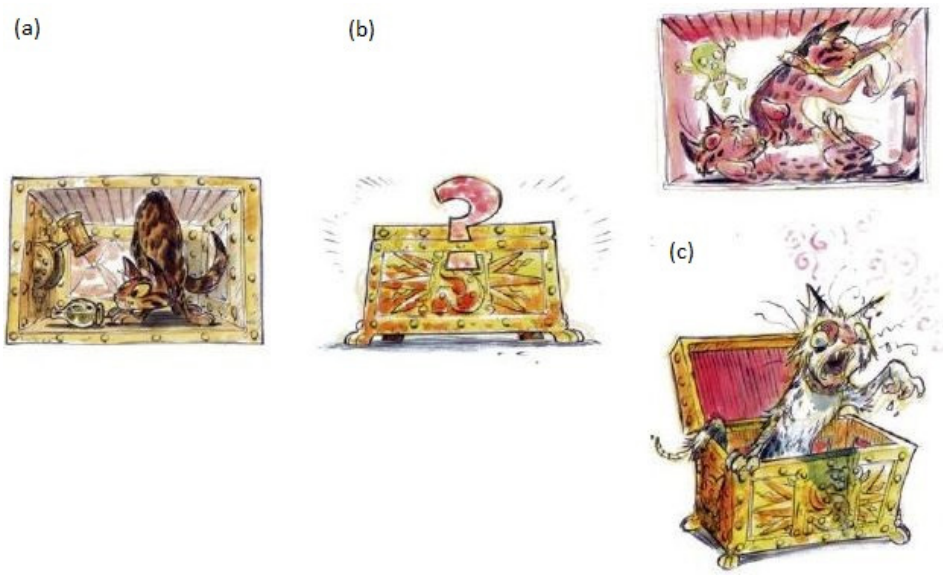

Figure 36.8: Schrödinger's cat according to *Ekhö, Le monde miroir* by Arleston and Barbucco: Quantum superposition or zombie cat?

Solution:

[7] See https://www.thorlabs.com/newgrouppage9.cfm?objectgroup_id=6635

36.1.5.2 Ex: Dispersive quantum jumps

Consider a three-level system in V-configuration, as depicted in Fig. 34.17(b), with an unstable state $|1\rangle$, a ground state $2\rangle$, and a metastable state $|3\rangle$. Discuss whether the atom shelved in state $|3\rangle$ is sensitive to light-shift and power broadened induced by a laser resonant to the $|1\rangle - |2\rangle$ transition. E.g. will power-broadening only effect the transition rate $|1\rangle \longrightarrow |3\rangle$ or also $|3\rangle \longrightarrow |1\rangle$?

Solution: *We assume that both transitions $|1\rangle - |2\rangle$ and $|1\rangle - |3\rangle$ are simultaneously driven. The probability to find the system in the shelved state $|3\rangle$ is then [952],*

$$n_{33}(t) = \frac{R_+}{R_+ + R_-}(1 - e^{-(R_+ + R_-)t}) \ .$$

The rates $R_\pm$ are easily obtained via numerical fit to the solution of the optical Bloch equations.
Then the 'dark' state is not a reached by projection, because it corresponds to a non-observation *of photons. ρ_{33} only increases gradually, ruled by $\hat{H}_{eff}$ and under steady renormalization of the total wavefunction, until a stationary superposition $|1\rangle - |3\rangle$ is reached with a small admixture of $|2\rangle$. This admixture guarantees that R_+ as well as R_- are light-shifted. For the ensemble the Bloch equations must hold. The decay of the 'dark' state is induced by the admixture of ρ_{22}. The light-shift is obtained as an eigenvalue of $\hat{H}_{eff}$ and, hence, is conceptually stationary. That is, it depends on the parameters Ω_{ij}, Δ_{ij}, and Γ_{ij}, which also determine toward which stationary populations and coherences the atom will evolve.*

36.2 Open systems and the master equation

Let us now derive the master equation for an open quantum system. We assume that the environment (also called *bath* or *reservoir*) and the system under consideration are quantum systems in the sense that (1) the relevant degrees of freedom are completely characterized by state vectors (or density matrices), and (2) the temporal evolution of the total system is unitary $U(t) = e^{-\imath \hat{H} t}$. The total Hamiltonian, $\hat{H} = \hat{H}_{sys} + \hat{H}_{res} + V$ is assumed to be independent of time and consists of three parts, namely the Hamiltonian of the system $\hat{H}_{sys}$, the Hamiltonian of the bath $\hat{H}_{res}$, and the interaction V between the system and the bath. The purpose of the master equation is to find the dynamics of the system by tracing over all degrees of freedom of the bath. This is not always possible, and we will assume that the interaction V is sufficiently weak, so that perturbation theory is applicable.

In the interaction representation the evolution of the total density matrix $\hat{\rho}_{tot}$ becomes,

$$\boxed{\imath\hbar \frac{d\tilde{\rho}_{tot}}{dt} = [\tilde{V}(t), \tilde{\rho}_{tot}]} \ . \tag{36.27}$$

where $\tilde{\rho}_{tot}(t) \equiv U_0^\dagger \rho_{tot} U_0$ and $\tilde{V}(t) \equiv U_0^\dagger V U_0$ and $U_0 = e^{-\imath(\hat{H}_{sys} + \hat{H}_{res})t/\hbar}$. This

evolution is, for the time being, very general, and the solution can be formally written,

$$\tilde{\rho}_{tot}(t) = \tilde{\rho}_{tot}(0) + \frac{1}{\imath\hbar}\int_0^t dt_1[\tilde{V}(t_1), \tilde{\rho}_{tot}(t_1)] \ . \tag{36.28}$$

Iterating once again:

$$\tilde{\rho}_{tot}(t) = \tilde{\rho}_{tot}(0)+\frac{1}{\imath\hbar}\int_0^t dt_1[\tilde{V}(t_1), \tilde{\rho}_{tot}(0)]+\frac{1}{(\imath\hbar)^2}\int_0^t dt_1\int_0^{t_1} dt_2\left[\tilde{V}(t_1), [\tilde{V}(t_2), \tilde{\rho}_{tot}(t_2)\right] \ . \tag{36.29}$$

In the following, we will call several approximations to simplify the calculations, in particular, the Born approximation, the assumption that the initial state is a product state and, later-on, the Markov approximation.

36.2.1 Born approximation for weak coupling

We will now assume the interaction $\tilde{V}$ to be weak. We can then expect that, repeating the iterative process, the series will converge and write the general solution as,

$$\tilde{\rho}_{tot}(t) = \tilde{\rho}_{tot}(0) + \sum_{n\geq 1}\frac{1}{(\imath\hbar)^n}\int_0^t dt_1 ... \int_0^{t_{n-1}} dt_n\left[\tilde{V}(t_1), ..., [\tilde{V}(t_n), \tilde{\rho}_{tot}(0)]\right] \ . \tag{36.30}$$

This way of terminating an iterative equation by $\rho_{tot}(0)$ is generally known as the *Born approximation*. Here, we will just go to second order in $\tilde{V}$. Tracing over the bath,

$$\tilde{\rho}_{sys}(t) = \mathrm{Tr}_{res}\ \tilde{\rho}_{tot}(t) \ , \tag{36.31}$$

we extract the density matrix for only the system,

$$\begin{aligned}\tilde{\rho}_{sys}(t) = \tilde{\rho}_{sys}(0) + \frac{1}{\imath\hbar}\int_0^t dt_1 \mathrm{Tr}_{res}[\tilde{V}(t_1), \tilde{\rho}_{tot}(0)] \\ + \frac{1}{(\imath\hbar)^2}\int_0^t dt_1\int_0^{t_1} dt_2 \mathrm{Tr}_{res}\left[\tilde{V}(t_1), [\tilde{V}(t_2), \tilde{\rho}_{tot}(0)]\right] \ .\end{aligned} \tag{36.32}$$

36.2.2 Assumption of an initial product state

Next, we need to make the quite important assumption, that the initial state between the system and the environment are not correlated, or mathematically speaking, they can be written as product states,

$$\tilde{\rho}_{tot}(0) = \tilde{\rho}_{sys}(0) \otimes \rho_{res}(0) \ . \tag{36.33}$$

Another assumption, which is not essential but often valid, is that $\mathrm{Tr}_{res}[\tilde{V}(t_1), \tilde{\rho}_{tot}(0)] = 0$. If this is the case, then the first-order term will vanish. In second order, we can write,

$$\begin{aligned}&\tilde{\rho}_{sys}(t) = e^{\mathcal{M}(t)}\tilde{\rho}_{sys}(0) \\ &\text{where} \quad \mathcal{M}(t)\chi \equiv \frac{1}{(\imath\hbar)^2}\int_0^t dt_1\int_0^{t_1} dt_2 \mathrm{Tr}_{res}\left[\tilde{V}(t_1), [\tilde{V}(t_2), \chi\otimes\rho_{res}]\right] \ ,\end{aligned} \tag{36.34}$$

is a *superoperator* acting on the operator density of the system. Taking the temporal derivative, we have the explicit master equation,

$$\boxed{\begin{array}{rcl}\frac{d\tilde{\rho}_{sys}(t)}{dt} = \mathcal{L}\rho_{sys}(t) &=& \frac{d}{dt}\left(\mathcal{M}(t)\tilde{\rho}_{sys}(t)\right) \\ &=& \frac{1}{(\imath\hbar)^2}\int_0^t d\tau\ \mathrm{Tr}_{res}\left[\tilde{V}(t),[\tilde{V}(\tau),\tilde{\rho}_{sys}(t)\otimes\rho_{res}]\right]\end{array}} \ . \tag{36.35}$$

The superoperator $\mathcal{L}$ is called *Lindblad operator*.

36.2.3 Markov approximation for short memory

Here, we have to evaluate the terms involving the average with respect to the thermal bath, which is assumed to have a short memory, in the sense that the correlation time is very short. Mathematically,

$$\begin{aligned}\int_0^t d\tau\ \mathrm{Tr}_{res}\left(\tilde{V}(t)\tilde{V}(\tau)\rho_{res}\right) &= \int_0^t d\tau\ \mathrm{Tr}_{res}\left(\tilde{V}(t-\tau)\tilde{V}(0)\rho_{res}\right) \\ &\simeq \int_0^\infty d\tau\ \mathrm{Tr}_{res}\left(\tilde{V}(t-\tau)\tilde{V}(0)\rho_{res}\right)\ .\end{aligned} \tag{36.36}$$

In other words, the two-point correlation function is significant only, when $t \simeq \tau$, and it is valid to extend the upper bound to infinity. This is the *Markov approximation*.

36.2.4 Example: Damped harmonic quantum oscillator

As an example, we let us consider the master equation for the *Brownian motion of a quantum harmonic oscillator*. It can be written,

$$\frac{d\tilde{\rho}_{sys}}{dt} = \frac{1}{(\imath\hbar)^2}\int_0^t d\tau\ \mathrm{Tr}_{res}\left\{\begin{array}{c}\tilde{V}(t)\tilde{V}(\tau)\tilde{\rho}(t)\otimes\rho_{res} - \tilde{V}(t)\tilde{\rho}_{sys}(t)\otimes\rho_{res}\tilde{V}(\tau) \\ -\tilde{V}(\tau)\tilde{\rho}_{sys}(t)\otimes\rho_{res}\tilde{V}(t) + \tilde{\rho}_{sys}(t)\otimes\rho_{res}\tilde{V}(\tau)\tilde{V}(t)\end{array}\right\} . \tag{36.37}$$

The coupling of the system to the bath is assumed to be of the form,

$$\tilde{V} = \hbar\left(\hat{a}^\dagger\hat{\Gamma}(t)e^{\imath\Omega t} + \hat{a}\hat{\Gamma}^\dagger(t)e^{-\imath\Omega t}\right)\ , \tag{36.38}$$

where $\hat{\Gamma}(t) = \sum_k g_k\hat{b}_k e^{-\imath\omega_k t}$, the bosonic operators $\hat{a}$ and $\hat{b}_k$ act, respectively, on the system (with the frequency Ω) and the bath (with the frequency ω_k). Here, g_k characterizes the coupling force between the oscillators of the system and the bath. Hence,

$$\frac{d\tilde{\rho}_{sys}}{dt} = -\int_0^t d\tau\ \mathrm{Tr}_{res}\left\{\begin{array}{l}\left(\hat{a}^\dagger\hat{\Gamma}(t)e^{\imath\Omega t} + \hat{a}\hat{\Gamma}^\dagger(t)e^{-\imath\Omega t}\right)\left(\hat{a}^\dagger\hat{\Gamma}(\tau)e^{\imath\Omega\tau} + \hat{a}\hat{\Gamma}^\dagger(\tau)e^{-\imath\Omega\tau}\right)\tilde{\rho}(t)\otimes\rho_{res} \\ -\left(\hat{a}^\dagger\hat{\Gamma}(t)e^{\imath\Omega t} + \hat{a}\hat{\Gamma}^\dagger(t)e^{-\imath\Omega t}\right)\tilde{\rho}(t)\otimes\rho_{res}\left(\hat{a}^\dagger\hat{\Gamma}(\tau)e^{\imath\Omega\tau} + \hat{a}\hat{\Gamma}^\dagger(\tau)e^{-\imath\Omega\tau}\right) \\ -\left(\hat{a}^\dagger\hat{\Gamma}(\tau)e^{\imath\Omega\tau} + a\hat{\Gamma}^\dagger(\tau)e^{-\imath\Omega\tau}\right)\tilde{\rho}(t)\otimes\rho_{res}\left(\hat{a}^\dagger\hat{\Gamma}(t)e^{\imath\Omega t} + a\hat{\Gamma}^\dagger(t)e^{-\imath\Omega t}\right) \\ +\tilde{\rho}(t)\otimes\rho_{res}\left(\hat{a}^\dagger\hat{\Gamma}(\tau)e^{\imath\Omega\tau} + \hat{a}\hat{\Gamma}^\dagger(\tau)e^{-\imath\Omega\tau}\right)\left(\hat{a}^\dagger\hat{\Gamma}(t)e^{\imath\Omega t} + \hat{a}\hat{\Gamma}^\dagger(t)e^{-\imath\Omega t}\right)\end{array}\right\} . \tag{36.39}$$

Let's take a closer look at one of the terms,

$$\hat{T} \equiv -\int_0^t d\tau \mathrm{Tr}_{res}\left\{\hat{a}^\dagger\hat{\Gamma}(t)e^{\imath\Omega t}\hat{a}\hat{\Gamma}^\dagger(\tau)e^{-\imath\Omega\tau}\tilde{\rho}(t)\otimes\rho_{res}\right\} \tag{36.40}$$
$$= -\hat{a}^\dagger\hat{a}\tilde{\rho}(t)\int_0^t d\tau\langle\hat{\Gamma}(t)\hat{\Gamma}^\dagger(\tau)\rangle_{res}e^{\imath\Omega t}e^{-\imath\Omega\tau} \ .$$

We will have to evaluate quantities such as

$$\mathrm{Tr}_{res}\left(V(t)V(s)\rho_{res}\right) = \hbar^2\hat{a}^\dagger\hat{a}\langle\hat{\Gamma}(t)\hat{\Gamma}^\dagger(t)\rangle_{res}e^{\imath\Omega(t-s)} + \hbar^2\hat{a}\hat{a}^\dagger\langle\hat{\Gamma}^\dagger(t)\hat{\Gamma}(t)\rangle_{res}e^{-\imath\Omega(t-s)} \ , \tag{36.41}$$

where $\langle\hat{\Gamma}(t)\hat{\Gamma}^\dagger(t)\rangle_{res} \equiv \mathrm{Tr}_{res}[\hat{\Gamma}(t)\hat{\Gamma}^\dagger(t)\rho_{res}]$, and for the thermal bath, $\langle\hat{b}_j^\dagger\hat{b}_k\rangle = \delta_{jk}n_k$ and $\langle\hat{b}_j\hat{b}_k^\dagger\rangle = \delta_{jk}(1+n_k)$ and $n_k = (e^{\beta\hbar\omega_k}-1)^{-1}$. Hence,

$$\hat{T} = -\hat{a}^\dagger\hat{a}\tilde{\rho}(t)\sum_{j,k}g_jg_k\langle b_jb_k^\dagger\rangle_{res}\int_0^t d\tau e^{\imath(\omega_jt-\omega_k\tau)}e^{\imath\Omega(t-\tau)} \tag{36.42}$$
$$\simeq -\hat{a}^\dagger\hat{a}\tilde{\rho}(t)\sum_k g_k^2n_k\int_0^\infty d\tau e^{\imath(\omega_k-\Omega)(t-\tau)} \ .$$

Then we will have to use the relationship,

$$\int_0^\infty d\tau e^{\pm\imath\varepsilon\tau} = \pi\delta(\varepsilon) \pm \imath PV \ , \tag{36.43}$$

where PV denotes Cauchy part of the principal value. These correspond to a 'Lamb shift' and a 'Stark shift' of the frequency, which are considered to be small in comparison to Ω and should be neglected here,

$$\hat{T} = -\hat{a}^\dagger\hat{a}\tilde{\rho}(t)\sum_k g_k^2\left(e^{\beta\hbar\omega_k}-1\right)^{-1}\int_0^\infty d\tau e^{\imath(\omega_k-\Omega)(t-\tau)} \tag{36.44}$$
$$= -\hat{a}^\dagger\hat{a}\tilde{\rho}(t)\sum_k g_k^2\left(e^{\beta\hbar\omega_k}-1\right)^{-1}\pi\delta(\omega_k-\Omega)$$
$$= -\hat{a}^\dagger\hat{a}\tilde{\rho}(t)\sum_k g_k^2\left(e^{\beta\hbar\Omega}-1\right)^{-1}\pi = -\pi\bar{n}\hat{a}^\dagger\hat{a}\tilde{\rho}(t)\sum_k g_k^2\delta(\omega_k-\Omega) = \bar{n}\hat{a}\hat{a}^\dagger\tilde{\rho}(t)\pi\frac{\gamma}{2} \ .$$

where $\bar{n} \equiv \left(e^{\beta\hbar\Omega}-1\right)^{-1}$. We define $\frac{\gamma}{2} \equiv \sum_k g_k^2\delta(\omega_k-\Omega)$. The procedure can be repeated for all terms in the master equation. We then obtain the master equation for a damped harmonic oscillator,

$$\frac{d\tilde{\rho}}{dt} = \tfrac{\gamma}{2}(\bar{n}+1)\left(2\hat{a}\tilde{\rho}\hat{a}^\dagger - \hat{a}^\dagger\hat{a}\tilde{\rho} - \tilde{\rho}\hat{a}^\dagger\hat{a}\right) - \tfrac{\gamma}{2}\bar{n}\left(2\hat{a}^\dagger\tilde{\rho}\hat{a} - \hat{a}\hat{a}^\dagger\tilde{\rho} - \tilde{\rho}\hat{a}\hat{a}^\dagger\right) \ . \tag{36.45}$$

36.2.4.1 Thermalization

To complete the discussion, let us consider the evolution time of the mean number of photons $\langle\hat{a}^\dagger\hat{a}\rangle$. Note that $\mathrm{Tr}_{res}\hat{a}\hat{a}^\dagger\tilde{\rho} = \mathrm{Tr}_{res}\hat{a}\hat{a}^\dagger\rho$, which can be useful (with $\hat{n} = \hat{a}^\dagger\hat{a}$ and $\hat{n}\hat{a} = \hat{a}\hat{n} - \hat{a}$) for simplifying the right-hand side of the master equation. We get,

$$\frac{d\langle\hat{a}^\dagger\hat{a}\rangle}{dt} = -\gamma\langle\hat{a}^\dagger\hat{a}\rangle + \gamma N \ , \tag{36.46}$$

and the solution of this equation is,

$$\langle \hat{n}(t) \rangle = \langle \hat{n}(0) \rangle e^{-\gamma t} + \bar{n}(1 - e^{-\gamma t}) \ , \tag{36.47}$$

which suggests that $\langle n(t \to \infty) \rangle \to \bar{n} = (e^{\beta\hbar\Omega} - 1)^{-1}$, as expected for the thermalization rate [1062]. For a discussion of the validity of the Born-Markov approximation, see [932]. For the relationship between the Markov approximation and Fermi's Golden Rule, see [17].

36.2.5 Deriving the Heisenberg-Langevin from the master equation

The Heisenberg-Langevin equation for the operators $\hat{A}$ of a system subject to dissipation with rates γ_k via the degrees of freedom $\hat{L}_k$ and the *master equation* for the density operator $\hat{\rho}$ are equivalent descriptions for the time-evolution of a system,

$$\boxed{\begin{array}{rcccl} \frac{d\hat{\rho}}{dt} & = & \mathcal{L}\hat{\rho} & = & -\frac{\imath}{\hbar}[\hat{H}, \hat{\rho}] + \sum_k \gamma_k \left(\hat{L}_k \hat{\rho} \hat{L}_k^\dagger - \frac{1}{2} \hat{L}_k^\dagger \hat{L}_k \hat{\rho} - \frac{1}{2} \hat{\rho} \hat{L}_k^\dagger \hat{L}_k \right) \\ \frac{d\hat{A}}{dt} & = & \mathcal{L}^\dagger \hat{A} & = & \frac{\imath}{\hbar}[\hat{H}, \hat{A}] + \sum_k \gamma_k \left(\hat{L}_k^\dagger \hat{A} \hat{L}_k - \frac{1}{2} \hat{L}_k^\dagger \hat{L}_k \hat{A} - \frac{1}{2} \hat{A} \hat{L}_k^\dagger \hat{L}_k \right) \end{array}} \ , \tag{36.48}$$

as we will show in Exc. 36.2.6.2. The former stresses the Schrödinger picture and the latter the Heisenberg picture. In particular, the dissipative *Lindblad terms* are equivalent. That is, open systems are sufficiently characterized by the system Hamiltonian $\hat{H}$ and a set of the so-called *jump operators* $\hat{L}_k$ with their corresponding rates γ_k.

36.2.6 Exercises

36.2.6.1 Ex: Master equation for cavities

Consider a cavity laser-pumped at a rate η, subject to losses by transmission through the mirrors at a rate κ, and incoherently pumped by thermal photons at a rate $\kappa\bar{n}$, where $\bar{n}$ is the number of thermal photons.
a. Write down the Hamiltonian and the Heisenberg-Liouville equation for an arbitrary operator $\hat{a}$ of the system.
b. Derive the equation of motion for the field annihilation operator $\hat{a}$ and for the photon number operator $\hat{n}$.
c. Solve the equation of motion for the photon number operator for the case of no coherent pumping, $\eta = 0$.
d. Write down the master equation of the system.
e. Derive the equation of motion for the components of the density operator $\rho_{m,n}$.
f. Calculate the phton number evolution from (e).

Solution: *a. The Hamiltonian is,*

$$\hat{H} = -\Delta_c \hat{a}^\dagger \hat{a} - \imath\eta(\hat{a} - \hat{a}^\dagger) \ ,$$

and the Heisenberg-Liouville equation for an arbitrary operator $\hat{A}$ of the system is,

$$\frac{d\hat{A}}{dt} = -\imath[\hat{A}, \hat{H}] + \tfrac{\kappa}{2}(\bar{n} + 1)(\hat{a}^\dagger[\hat{A}, \hat{a}] + [\hat{a}^\dagger, \hat{A}]\hat{a}) + \tfrac{\kappa}{2}\bar{n}(\hat{a}[\hat{A}, \hat{a}^\dagger] + [\hat{a}, \hat{A}]\hat{a}^\dagger) \ .$$

b. Using the standard commutation rules we derive the equation of motion for the field annihilation operator,

$$\begin{aligned}\frac{d\hat{a}}{dt} &= -\imath[\hat{a},\hat{H}] + \tfrac{\kappa}{2}(\bar{n}+1)(\hat{a}^\dagger[\hat{a},\hat{a}] + [\hat{a}^\dagger,\hat{a}]\hat{a}) + \tfrac{\kappa}{2}\bar{n}(\hat{a}[\hat{a},\hat{a}^\dagger] + [\hat{a},\hat{a}]\hat{a}^\dagger) \\ &= (\imath\Delta_c - \tfrac{\kappa}{2})\hat{a} + \eta \ .\end{aligned}$$

The equation of motion for the photon number operator is [8]*,*

$$\begin{aligned}\frac{d\hat{n}}{dt} &= -\imath[\hat{a}^\dagger\hat{a},\hat{H}] + \tfrac{\kappa}{2}(\bar{n}+1)(\hat{a}^\dagger[\hat{a}^\dagger\hat{a},\hat{a}] + [\hat{a}^\dagger,\hat{a}^\dagger\hat{a}]\hat{a}) + \tfrac{\kappa}{2}\bar{n}(\hat{a}[\hat{a}^\dagger\hat{a},\hat{a}^\dagger] + [\hat{a},\hat{a}^\dagger\hat{a}]\hat{a}^\dagger) \\ &= -\eta[\hat{a}^\dagger\hat{a},\hat{a}-\hat{a}^\dagger] - \kappa(\bar{n}+1)\hat{a}^\dagger\hat{a} + \kappa\bar{n}\hat{a}\hat{a}^\dagger = \eta(\hat{a}^\dagger+\hat{a}) - \kappa\hat{n} + \kappa\bar{n} \ .\end{aligned}$$

c. The solution for the case $\eta = 0$ is,

$$\hat{n}(t) = \hat{n}(0)e^{-\kappa t} + \bar{n}(1-e^{-\kappa t}) \ .$$

d. The master equation for the density operator defined by $\hat{\rho} \equiv \sum_{m,n}\rho_{m,n}|m\rangle\langle n|$ is,

$$\frac{d\hat{\rho}}{dt} = \imath[\hat{\rho},\hat{H}] + \kappa_+(2\hat{a}\hat{\rho}\hat{a}^\dagger - \hat{a}^\dagger\hat{a}\hat{\rho} - \hat{\rho}\hat{a}^\dagger\hat{a}) + \kappa_-(2\hat{a}^\dagger\hat{\rho}\hat{a} - \hat{a}\hat{a}^\dagger\hat{\rho} - \hat{\rho}\hat{a}\hat{a}^\dagger) \ .$$

using the abbreviations $\kappa_+ \equiv \frac{\kappa}{2}(\bar{n}+1)$ and $\kappa_- \equiv \frac{\kappa}{2}\bar{n}$.
e. For the components we get,

$$\begin{aligned}\dot{\rho}_{n,m} &= \langle n|\dot{\hat{\rho}}|m\rangle \\ &= \imath\langle n|[\hat{\rho}, -\Delta_c\hat{a}^\dagger\hat{a} - \imath\eta(\hat{a}-\hat{a}^\dagger)]|m\rangle \\ &\quad + \kappa_+[\langle n|2\hat{a}\hat{\rho}\hat{a}^\dagger|m\rangle - \langle n|\hat{a}^\dagger\hat{a}\hat{\rho}|m\rangle - \langle n|\hat{\rho}\hat{a}^\dagger\hat{a}|m\rangle] \\ &\quad + \kappa_-[\langle n|2\hat{a}^\dagger\hat{\rho}\hat{a}|m\rangle - \langle n|\hat{a}\hat{a}^\dagger\hat{\rho}|m\rangle - \langle n|\hat{\rho}\hat{a}\hat{a}^\dagger|m\rangle] \\ &= \imath\Delta_c(n-m)\rho_{n,m} + \eta[\sqrt{m}\rho_{n,m-1} - \sqrt{m+1}\rho_{n,m+1} - \sqrt{n+1}\rho_{n+1,m} + \sqrt{n}\rho_{n-1,m}] \\ &\quad + \kappa_+[2\sqrt{n+1}\sqrt{m+1}\rho_{n+1,m+1} - (n+m)\rho_{n,m}] \\ &\quad + \kappa_-[2\sqrt{nm}\rho_{n-1,m-1} - (n+m)\rho_{n,m} - 2\rho_{n,m}] \ .\end{aligned}$$

In particular, for the diagonal,

$$\begin{aligned}\dot{\rho}_{n,n} = \eta\left(\sqrt{n}(\rho_{n,n-1}+\rho_{n-1,n}) - \sqrt{n+1}(\rho_{n,n+1}+\rho_{n+1,n})\right) \\ + 2\kappa_+\left[(n+1)\rho_{n+1,n+1} - n\rho_{n,n}\right] + 2\kappa_-\left[n\rho_{n-1,n-1} - (n+1)\rho_{n,n}\right] \ .\end{aligned}$$

f. The photon number evolves like,

$$\begin{aligned}\frac{d}{dt}\langle\hat{n}\rangle &= \frac{d}{dt}\,Tr\,\hat{\rho}\hat{n} = \frac{d}{dt}\sum_n\langle n|\hat{\rho}\hat{n}|n\rangle = \sum_n n\dot{\rho}_{n,n} \\ &= \sum\nolimits_n n\eta\left(\sqrt{n}\rho_{n,n-1} - \sqrt{n+1}\rho_{n,n+1} - \sqrt{n+1}\rho_{n+1,n} + \sqrt{n}\rho_{n-1,n}\right) \\ &\quad + 2\kappa_+\left[n(n+1)\rho_{n+1,n+1} - n^2\rho_{n,n}\right] + 2\kappa_-\left[n^2\rho_{n-1,n-1} - n(n+1)\rho_{n,n}\right] \\ &= \sum\nolimits_n \eta\langle n|\hat{a}^\dagger\hat{\rho} + \hat{a}\hat{\rho}|n\rangle - 2\tfrac{\kappa}{2}(\bar{n}+1)n\rho_{n,n} + 2\tfrac{\kappa}{2}\bar{n}(n+1)\rho_{n,n} \\ &= \eta(\langle\hat{a}^\dagger\rangle + \langle\hat{a}\rangle) - \kappa\langle\hat{n}\rangle + \kappa\bar{n} \ ,\end{aligned}$$

[8] Curiously this not equal to,

$$\dot{\hat{a}}^\dagger\hat{a} + \hat{a}^\dagger\dot{\hat{a}} = \hat{a}^\dagger\left[(\imath\Delta_c - \tfrac{\kappa}{2})\hat{a} + \eta\right] + \left[(-\imath\Delta_c - \tfrac{\kappa}{2})\hat{a}^\dagger + \eta\right]\hat{a} = \eta(\hat{a}^\dagger + \hat{a}) - \kappa\hat{n} \ .$$

in accordance with the result of (b).

36.2.6.2 Ex: Deriving the Heisenberg-Langevin from the master equation

Derive the Heisenberg-Langevin from the master equation including the dissipative Lindblad terms.

Solution: *To derive the Heisenberg-Langevin from the master equation we simply demand that the expectation value of an operator $\hat{A}$ is the same in the Schrödinger picture (density matrix evolves) and the Heisenberg picture (operator evolves). That is,*

$$\langle \hat{A} \rangle = Tr\ \hat{A}(0)\hat{\rho}(t) = Tr\ \hat{A}(t)\hat{\rho}(0)\ ,$$

where $\hat{A}(t)\hat{\rho}(0)$ is the operator in the Heisenberg picture, while $\hat{A}(0)\hat{\rho}(t)$ is the operator in the Schrödinger picture. The Lindblad equation can be written in the Schrödinger picture as,

$$\frac{d\hat{\rho}}{dt} = \mathcal{L}\hat{\rho} = -\tfrac{i}{\hbar}[\hat{H},\hat{\rho}] + \sum_k \gamma_k \left(\hat{L}_k \hat{\rho} \hat{L}_k^\dagger - \tfrac{1}{2}\hat{L}_k^\dagger \hat{L}_k \hat{\rho} - \tfrac{1}{2}\hat{\rho}\hat{L}_k^\dagger \hat{L}_k \right)\ .$$

The formal solution of the Lindblad equation can then be written as,

$$\hat{\rho}(t) = e^{\mathcal{L}t}\hat{\rho}(0)\ ,$$

where the exponential of the superoperator $\mathcal{L}$ is defined as usual by its Taylor series expansion. Now, we define the adjoint Liouvillian $\mathcal{L}^\dagger$ by,

$$Tr\ \hat{P}[\mathcal{L}\hat{Q}] = Tr\ [\mathcal{L}^\dagger \hat{P}]\hat{Q}\ ,$$

where $\hat{P}$ and $\hat{Q}$ are arbitrary operators. It follows from the definitions that,

$$Tr\ \hat{A}(0)\hat{\rho}(t) = Tr\ \hat{A}(0)e^{\mathcal{L}t}\hat{\rho}(0) = Tr\ [e^{\mathcal{L}^\dagger t}\hat{A}(0)]\hat{\rho}(0)\ ,$$

from which we identify

$$\hat{A}(t) = e^{\mathcal{L}^\dagger t}\hat{A}(0)$$

as the operator $\hat{A}$ in the Heisenberg picture, which obviously satisfies the differential equation,

$$\frac{d\hat{A}}{dt} = \mathcal{L}^\dagger \hat{A}\ .$$

All that remains is to check that indeed,

$$\mathcal{L}^\dagger \hat{A} = \tfrac{i}{\hbar}[\hat{H},\hat{A}] + \sum_k \gamma_k \left(\hat{L}_k^\dagger \hat{A} \hat{L}_k - \tfrac{1}{2}\hat{L}_k^\dagger \hat{L}_k \hat{A} - \tfrac{1}{2}\hat{A}\hat{L}_k^\dagger \hat{L}_k \right)\ ,$$

which can be shown using the definition of $\mathcal{L}^\dagger$ and the cyclicity of the trace.

36.3 Repeated measurements

36.3.1 The quantum Zeno effect

A famous problem raised by the Greek philosopher (490-430 AC) *Zeno* goes like this: Achilles and a turtle organize a race. The arrogant Achilles leaves a 100-meter lead to the turtle. The race begins. Achilles soon covers the 100 meters, only to find out that meanwhile the turtle has advanced by 10 meters. He continues running to cover the 10 meters, only to find out that meanwhile the turtle has advanced by 1 meter, and so on [9]. A presentation on the subject is available at (watch talk).

Interestingly, Zeno's problem has a counterpart in quantum mechanics. Let us do the following Gedankenexperiment: A laser beam passes through a dense series of n polarizers, each one being rotated by an angle $\frac{\pi}{2n}$ with respect to the preceding one. Each polarizer performs a local measurement of beam polarization. The result of this arrangement is that, in the limit of an infinitely dense series, the continuous measurement of the system completely governs its evolution and rotates the polarization by an angle of $\pi/2$ [10].

In every version of the *Zeno effect*, the system is inhibited from evolving freely, because of too frequent measurements of its current state. Achilles would surely be able to overtake the turtle, if he did not always check on her to assess the remaining distance [654] [11].

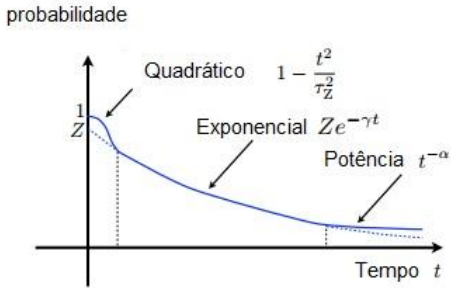

Figure 36.9: Quadratic time dependence of an excited state population.

The temporal evolution of the wavefunction of a system described by the Hamiltonian $\hat{H}$ is $|\psi(t)\rangle = e^{-i\hat{H}t/\hbar}|\psi_0\rangle$. We can then calculate the amplitude and probability

[9] In another version of his paradox, Zeno questions the possibility of motion at the example of a flying arrow: At any instant of time it occupies a space equal to its size. That is, at any particular moment of its flight, it is at rest, in a space that does not move. That is, any kind of motion is impossible. Nowadays, we know that this paradox is false, because time and motion are not discrete. But this can only be understood on the basis of infinitesimal calculus [902].

[10] An analogous experiment can be imagined by a series of Stern-Gerlach measurements of the spin of an atom.

[11] The quantum Zeno effect was often used to justify the physical relevance of the state reduction postulate. It was shown, however, that this postulate is not essential for understanding the quantum Zeno effect [112]. The effect already follows directly from the Schrödinger equation and therefore has a purely dynamical nature. This shows that the projection is a purely mathematical construct without physical reality (see Sec. 36.1.2).

for the system to stay in the initial state,

$$\langle\psi_0|\psi(t)\rangle = \langle\psi_0|e^{-\imath\hat{H}t/\hbar}|\psi_0\rangle \qquad \text{and} \qquad P(t) = |\langle\psi_0|\psi(t)\rangle|^2 \ . \tag{36.49}$$

For short times we can expand,

$$\langle\psi_0|\psi(\delta t)\rangle = |\psi_0\rangle - \frac{\imath}{\hbar}\hat{H}\delta t/\hbar|\psi_0\rangle - \frac{1}{2\hbar^2}\hat{H}^2\delta t^2|\psi_0\rangle + ... = |\psi_0\rangle + |\delta\psi\rangle \ , \tag{36.50}$$

such that,

$$\langle\psi_0|\psi(\delta t)\rangle \simeq 1 - \frac{\imath}{\hbar}\hat{H}\delta t - \frac{1}{2\hbar^2}\hat{H}^2\delta t^2 \quad \text{and} \quad P(\delta t) \simeq 1 - \frac{1}{\hbar^2}(\langle\hat{H}^2\rangle_0 - \langle\hat{H}\rangle_0^2)\delta t^2 \ . \tag{36.51}$$

In this way we can extract the Zeno time from the above equations, $\tau_Z = \hbar^2/\sqrt{\langle\hat{H}^2\rangle_0 - \langle\hat{H}\rangle_0^2}$. We now make N successive von Neumann measurements within a time t, which leads to a measurement frequency of τ^{-1}. The measurements are conceived as to verify, whether the system is still in its initial state, but each measurement projects our system back to its initial state, from where it has to start the transition process from scratch. Under these conditions, the population of the initial state will evolve like,

$$P^{(N)}(\tau) = P^{(N)}(t/N)^N \ . \tag{36.52}$$

Fig. 36.10 shows the evolution for five measurements separated by time intervals τ. In comparison with the evolution, when no measurements are taken (dashed line), the evolution with measurements inhibits the depletion of the initial state. Extrapolating the number of measurements to infinity, the probability (36.52) converges to 1,

$$\left[1 - \left(\frac{t}{N\tau_Z}\right)^2\right]^N \overset{N\ large}{\longrightarrow} e^{-t^2/N\tau_Z^2} \overset{N\to\infty}{\longrightarrow} 1 \ . \tag{36.53}$$

See Excs. 36.3.4.1 and 36.3.4.2.

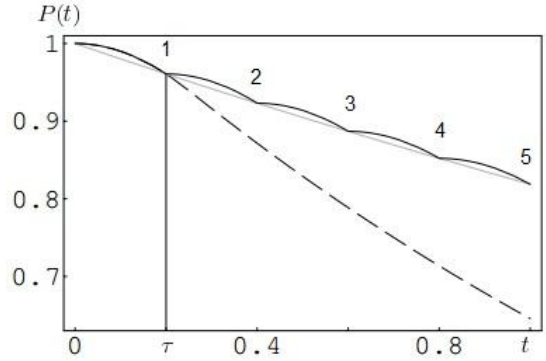

Figure 36.10: Inhibition of the decay of a state by repeated measurements (here $N = 5$). The dashed (solid) line represents the survival probability with (without) measurements. The gray line represents an exponential interpolation function.

Suppression of the evolution of a quantum system due to the quantum Zeno effect was observed experimentally [654] using beryllium ions. Nevertheless, the discussion about the correct interpretation of this effect and its relationship to trivial power broadening is not closed. Some works have even proposed the possibility of an anti-Zeno effect [25, 1344], where observation would accelerate the evolution of the system. Currently the quantum Zeno effect is also studied for possible applications in metrology, computation, and quantum information [717].

When the quantum Zeno effect was proposed for the first time, it was considered a paradox: How could an unstable particle never decay, just by being continually observed? And what would happen to Schrödinger's cat, whose live depends on state of the particle? Could we save it from its cruel fate just by observing it?

Another interesting question concerns the quantum nature of the quantum Zeno effect. Is it really non-classical? On one hand, the quantum Zeno effect supposes the complete reduction of the system to an eigenstate. However, we can imagine classical measurements that also reduce the state (such as the above-mentioned measurement of the polarization of a beam of light).

36.3.2 Quantum projection noise

The intrinsic indeterminism of quantum mechanics has serious consequences for metrology. To show this, we consider the example of a system of two levels $|+\rangle$ and $|-\rangle$. This system can be in a superposition state $|\psi\rangle$. The probability [12] to find the system in one of the two states $|\pm\rangle$ is,

$$p_\pm = \langle \hat{P}_\pm \rangle = |\langle \psi | \pm \rangle|^2 = 1 - p_\mp \ , \tag{36.54}$$

where $\hat{P}_\pm$ is the projection operator. The result of a measurement of the population is afflicted by an inherent uncertainty expressed by the variance,

$$(\Delta p_\pm)^2 = \langle \hat{P}_\pm^2 \rangle - \langle \hat{P}_\pm \rangle^2 = \langle \pm|\psi\rangle\langle\psi|\psi\rangle\langle\psi|\pm\rangle - (\langle \pm|\psi\rangle\langle\psi|\pm\rangle)^2 = p_\pm(1-p_\pm) \ . \tag{36.55}$$

In other words, the random projection of the system on the eigenstate basis induces a noise called *quantum projection noise* [13]. This noise inhibits the determination of the probabilities $p_\pm$ in a single measurement. On the other hand, by measuring populations on a sample of N atoms or by repeating the measurement N times with a single atom under identical conditions, we can reduce the uncertainty. The probability of finding an atom r times in the state $|+\rangle$ is [653],

$$\boxed{P_{N,r,+} = \binom{N}{r} p_+^r (1-p_+)^{N-r}} \ . \tag{36.56}$$

The expectation value and variance of this binomial distribution are [653],

$$\bar{r} = \sum_{r=0}^{N} r P_{N,r,+} = N p_+ \quad , \quad (\Delta r)^2 = \sum_{r=0}^{N} (r - N p_+)^2 P_{N,r,+} = N p_+ (1-p_+) \ . \tag{36.57}$$

[12] We adopt here the viewpoint of the Copenhagen interpretation of the quantum state reduction, but we note that a discussion based on statistical mixtures described by density matrices gives the same results.

[13] Projection noise can be interpreted as *shot noise*. However, the optical shot noise in photodetectors is generated by the repartition of the field energy into discrete photons, the projection noise is the consequence of the discretization of the electronic excitation levels.

Thus, the standard deviation decreases with the number of atoms or measurements,

$$\sigma = \frac{\Delta r}{\bar{r}} \sim \frac{1}{\sqrt{N}} \,. \tag{36.58}$$

The increase of knowledge on the population of a two-level system by repeated measurements can be illustrated by a simple simulation exhibited in Fig. 36.11(a). Experiments are performed by comparing p_2 with a random number η. Two outcomes are possible $r = 0, 1$. The histograms narrow as the number of experiments increases. In practice, a measurement is performed using the quantum amplifier method illus-

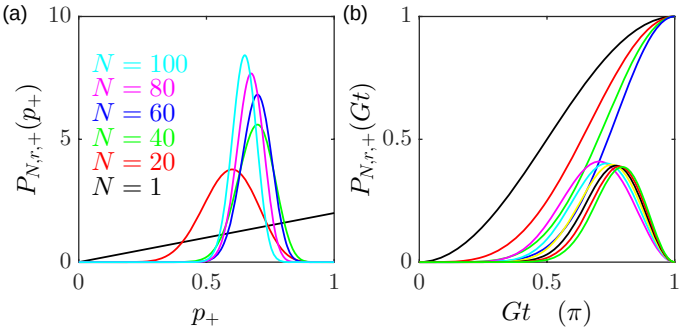

Figure 36.11: (code) (a) Simulation of the increase of knowledge on the population of a two-level system by repeated measurement, $P_{N,r,+}(p_+)/\int_0^1 P_{N,r,+}(p_+)dp_+$. The population of the state $|+\rangle$ was set to $p_+ = 0.2$. (b) Determination of the most likely Rabi pulse length $Gt = 2\arcsin(r/N)^{1/2}$.

trated in Fig. 36.6 [642].

36.3.2.1 Rabi experiments

The method of repeated measurements can be extended to map time-dependent dynamics of the two-level system. Under the influence of a radiation field, the population of the two-level system (which we assume free of spontaneous emission) performs Rabi oscillations, $\rho_{++}(t) = \frac{\Omega^2}{G^2}\sin^2\frac{Gt}{2}$, where $G = \sqrt{\Delta^2 + \Omega^2}$. The probability of finding the system in state $|2\rangle$, therefore, varies in time, $p_+(t) = \rho_{++}(t)$, and the binomial distribution (36.56) becomes,

$$P_{N,r,+}(t) = \binom{N}{r} \left(\tfrac{\Omega}{G}\right)^{2N} \sin^{2r}\tfrac{Gt}{2} \cos^{2N-2r}\tfrac{Gt}{2} \,. \tag{36.59}$$

When we increase the number of measurements, $N \to \infty$, this function condenses around a narrow peak at the position $Gt = 2\arcsin\sqrt{r/N}$. The width of the peak evolves like $2\arccos(2^{-1/2N})$. Fig. 36.11(b) shows a simulation demonstrating how repeated measurements gradually pin down the pulse area Ωt.

In summary, even for perfectly efficient population measurements (e.g. using the microwave-optical double resonance method) it is impossible to measure the probability p_+ with a single atom in a single experiment. As such an observation only

admits two possible results, 'fluorescence observed' or 'fluorescence not observed', i.e. $\rho_{++} = 1$ or $\rho_{++} = 0$, a whole range of possible populations between 0 and 1 is excluded. Therefore, a single observation only provides 'partial' information, which can be gradually improved with each consecutive observation.

A presentation on this topic is available here (watch talk).

36.3.2.2 Ramsey experiments

The Ramsey experiment is basically equivalent to the Rabi experiment described above except for an additional rotation in configuration space allowing for the measurement of the phase precession of the coherence between the Ramsey pulses via population spectroscopy. The Ramsey fringes are approximated by $p_+ = 0.5(1 + \cos[(\omega - \omega_0)T])$. The interesting magnitude is the frequency uncertainty,

$$\frac{\Delta r}{(\partial r/\partial\omega)|_{(\omega-\omega_0)T=\pi/2}} = \frac{\sqrt{Np_+(1-p_+)}}{N(\partial p_+/\partial\omega)} = \frac{1}{T\sqrt{N}} \ . \tag{36.60}$$

36.3.2.3 Spin squeezing and the Heisenberg limit

The above considerations apply to *independent measurements*. When the atoms are maximally correlated they occupy EPR-like states, $|\psi\rangle = p_+|+++..\rangle + p_-|---..\rangle$, such that it is sufficient to measure a single atom to know the state of all others. This means that the ratio $\Delta r/\bar{r}$ is just the one of a single measurement, but the signal strength and hence the signal-to-noise ratio increase by the factor N. Thus the standard deviation scales with $1/N$ rather than with $1/\sqrt{N}$. This is the so-called *Heisenberg limit*. For Ramsey interferometers we get [1380, 166, 184, 885],

$$\frac{\Delta r}{(\partial r/\partial\omega)|_{(\omega-\omega_0)T=\pi/2}} = \frac{1}{TN} \ . \tag{36.61}$$

Example 218 (*Interferometry with condensates*): It is an interesting question, whether condensates can improve metrology and enhance the precision of atomic clocks. The answer is *no*, if we only replace the thermal atomic cloud by a condensate! To see this, we consider an interferometer in configuration space measuring a phase (and therefore a frequency shift) by the method of Ramsey spectroscopy. The states are coupled by a radiation adjusted for $\pi/2$ pulses. The condensate *Fock state* factorizes the Schrödinger equation with the Hamiltonian $\hat{H} = \sum_{i=1}^{N}(H^{(i)} + V_{12}^{(i)})$ into N identical equations for every single atom. The dynamic evolution of this state will be the same as the one for a thermal state. However, this is not true for two Fock state condensates in both entrance channels of the interferometer.

The first radiative beamsplitter divides N_1. This division produces an atom number uncertainty in each state, which come together with a well-defined phase relationship between the two states. By providing at the second port of the interferometer another Fock state N_2, one increases the atom number uncertainty and therefore (because entropy must be conserved in coherent processes) the phase precision. It's a bit like a massive parallel computing for every possible repartition of the populations of both states. Of course the two Fock states cannot be obtained by dividing a single condensate in two in a coherent manner,

except if the repartition is measured afterward.
The Fock state is a maximally *spin-squeezed state* (sub-Poissonian statistics). The beam-splitters (which only perform unitary rotations) create starting from the Fock state a quantum entanglement, which is the deeper reason for the improvement of the resolution of the interferometer up the the Heisenberg limit by reducing the *quantum projection noise* [184].

Quantum correlations and spin-squeezed states are the same phenomena seen in different bases. Often the term of *quantum entanglement* is used in an energy bases, while spin squeezing is described in a Dicke state bases.

We may also consider real space interferometers. This allows us to use for creating the Fock states the recently discovered method of transforming BECs into *Mott insulator* states. Of course it is important to use condensates. First of all, we need Fock states, i.e. states with strong on-site quantum correlations with well-defined phase relations between every pair of atoms from the same site. Furthermore, Mott insulators have thus far only been seen with CBEs. Solve Exc. 36.3.4.4.

36.3.2.4 Noise in light fields

Quantum noise in lasers limit their emission bandwidth to the so-called *Schawlow-Townes limit*, while *shot noise* comes in additionally through the detection process. Let us define the stability by,

$$\boxed{\sigma = \frac{1}{Q}\frac{1}{S/N_{noise}} \qquad \text{with} \qquad Q = \frac{\omega}{\Gamma_{nat}+\Gamma_{pert}}} \ , \tag{36.62}$$

for a laser oscillator optimally stabilized on an atomic resonance with quality factor Q, when we directly detect the fluorescence $S = \Gamma\tau$ (neglecting background). The photon shot noise is then,

$$N_\Gamma = \sqrt{S} = \sqrt{\Gamma\tau} \ . \tag{36.63}$$

Assume now, that we discretize the measurement process, e.g. in order to perform a Ramsey type experiment on a single ion using the *microwave-optical double-resonance* (MODR) detection scheme. The signal is $S = KN$, where K is the number of photons detected on the monitor transition for a single attempt and N is the number of attempts *assumed to be independent*. K and N are both subject to stochastic fluctuations

$$N_{shot} = \sqrt{S} = \sqrt{KN} \qquad , \qquad N_{proj} = K\sqrt{N} \ .$$

We have again the photon shot noise, but we also have *projection noise* [653] due to the random result of the projection of hyperfine resonance coherence. If the MODR detection scheme is cyclic, $K \gg 1$, we may neglect the uncertainty du to photon shot noise. But if not (in the case of $^{171}Yb^+$ a leak in the detection cycle results in $K \lesssim 1$), projection noise will be covered.

Example 219 (*Schawlow-Townes limit*): When a laser is locked to an external cavity, its spectral noise density is,

$$S_r = \frac{\delta\nu^2}{\zeta^2}\frac{4\hbar}{\omega P\eta} \ ,$$

where $\delta\nu/2\pi$ is the cavity linewidth, ζ is a factor accounting for losses in the signal generation, η the quantum efficiency of the detector, and P the light power coupled into the resonator. The corresponding emission bandwidth is,

$$\beta = \frac{\delta\nu^2}{\zeta^2}\frac{\hbar\omega}{P\eta} \ .$$

36.3.3 Quantum non-demolition measurements

36.3.4 Exercises

36.3.4.1 Ex: The quantum Zeno effect

Discuss the quantum Zeno effect at the example of a laser beam passing through a birefringent medium. Compare the situations without polarizers and with an infinite number of vertical polarizers.

Solution: *When we subdivide a rotation into n small rotations by angles of $\pi/2n$, we can calculate, using the Jones matrices, the polarization of the laser beam after its passage through the birefringent medium,*

$$\lim_{n\to\infty}\left[\begin{pmatrix}\cos\frac{\pi}{2n} & -\sin\frac{\pi}{2n}\\ \sin\frac{\pi}{2n} & \cos\frac{\pi}{2n}\end{pmatrix}^n\right]\begin{pmatrix}1\\0\end{pmatrix} = \lim_{n\to\infty}\begin{pmatrix}\cos\frac{\pi}{2} & -\sin\frac{\pi}{2}\\ \sin\frac{\pi}{2} & \cos\frac{\pi}{2}\end{pmatrix}\begin{pmatrix}1\\0\end{pmatrix} = \begin{pmatrix}0\\1\end{pmatrix} \ .$$

Inserting after every tiny rotation a polarizer,

$$\lim_{n\to\infty}\left\{\left[\begin{pmatrix}\cos\frac{\pi}{2n} & -\sin\frac{\pi}{2n}\\ \sin\frac{\pi}{2n} & \cos\frac{\pi}{2n}\end{pmatrix}\begin{pmatrix}1 & 0\\0 & 0\end{pmatrix}\right]^n\right\}\begin{pmatrix}1\\0\end{pmatrix} = \lim_{n\to\infty}\begin{pmatrix}\cos^n\frac{\pi}{2n} & 0\\ \sin\frac{\pi}{2n}\cos^{n-1}\frac{\pi}{2n} & 0\end{pmatrix}\begin{pmatrix}1\\0\end{pmatrix}$$
$$= \lim_{n\to\infty}\begin{pmatrix}1-\frac{n}{2}\left(\frac{\pi}{2n}\right)^2+\ldots\\ \frac{\pi}{2n}-\ldots\end{pmatrix} = \begin{pmatrix}1\\0\end{pmatrix} \ .$$

36.3.4.2 Ex: The quantum Zeno effect

A two-level atom resonantly driven by a laser can be described by the Hamiltonian:

$$H = \begin{pmatrix}0 & \frac{1}{2}\Omega\\ \frac{1}{2}\Omega & 0\end{pmatrix} \ .$$

The solution of the Schrödinger equation gives,

$$|\psi(t)\rangle = e^{-\imath t\hat{H}/\hbar}|\psi_0\rangle = \begin{pmatrix}\cos\frac{1}{2}\Omega t & \imath\sin\frac{1}{2}\Omega t\\ \imath\sin\frac{1}{2}\Omega t & \cos\frac{1}{2}\Omega t\end{pmatrix}\begin{pmatrix}1\\0\end{pmatrix}$$

provided the atom is initially in the ground state $\langle\psi_0| = \begin{pmatrix}1 & 0\end{pmatrix}$. A measurement of the ground state population can only be done by a projection of the wavefunction,

that is, the measurement yields the result $\| |1\rangle\langle 1|\psi(t)\rangle \|^2$. What is the final state of the atom,
a. when the ground state population is measured once after an evolution time of $t = \pi/\Omega$;
b. when the ground state population is measured once after n time intervals $t_n = \pi/n\Omega$;
c. when the ground state population is measured n times after evolution times of $t_n = \pi/n\Omega$;
d. when $n \to \infty$.

Solution: *a. The measurement of the ground state is described by,*

$$|\psi(t)\rangle = |1\rangle\langle 1|e^{-it\hat{H}/\hbar}|\psi_0\rangle = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix} \begin{pmatrix} \cos\frac{1}{2}\Omega t & -\imath \sin\frac{1}{2}\Omega t \\ -\imath\sin\frac{1}{2}\Omega t & \cos\frac{1}{2}\Omega t \end{pmatrix} \begin{pmatrix} 1 \\ 0 \end{pmatrix} = \begin{pmatrix} \cos\frac{1}{2}\Omega t \\ 0 \end{pmatrix}$$

After a time $t = \pi/\Omega$, we obtain $\| |\psi(t)\rangle \|^2 = \cos^2\frac{\pi}{2} = 0$, that is, the atom is inverted.
b. The measurement after n consecutive evolutions during intervals $t_n = \pi/n\Omega$ is,

$$|\psi(t)\rangle = |1\rangle\langle 1| \left(e^{-it_n\hat{H}/\hbar}\right)^n |\psi_0\rangle = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix} \begin{pmatrix} \cos\frac{n}{2}\Omega t & -\imath \sin\frac{n}{2}\Omega t \\ -\imath\sin\frac{n}{2}\Omega t & \cos\frac{n}{2}\Omega t \end{pmatrix} \begin{pmatrix} 1 \\ 0 \end{pmatrix} = \begin{pmatrix} \cos\frac{n}{2}\Omega t \\ 0 \end{pmatrix}$$

After n time periods of $t = \pi/n\Omega$, we have $\| |\psi(t)\rangle \|^2 = \cos^2\frac{\pi}{2} = 0$, which is the same result as above.
c. The repeated measurement of ground state is described by,

$$\begin{aligned} |\psi(t)\rangle &= \left(|1\rangle\langle 1|e^{-\imath t\hat{H}/n\hbar}\right)^n |\psi_0\rangle = \begin{pmatrix} \cos\frac{\pi}{2n} & -\imath\sin\frac{\pi}{2n} \\ 0 & 0 \end{pmatrix}^n \begin{pmatrix} 1 \\ 0 \end{pmatrix} \\ &= \begin{pmatrix} \cos^n\frac{\pi}{2n} & -\imath\sin\frac{\pi}{2n}\cos^{n-1}\frac{\pi}{2n} \\ 0 & 0 \end{pmatrix} \begin{pmatrix} 1 \\ 0 \end{pmatrix} = \begin{pmatrix} \cos^n\frac{\pi}{2n} \\ 0 \end{pmatrix} \end{aligned}$$

Therefore, the probability of finding the atom in the ground state is $\| |\psi(t)\rangle \|^2 = \cos^{2n}\frac{\pi}{2n}$.
d. For an infinite number of measurements,

$$|\psi(t)\rangle = \lim_{n\to\infty} \left(|1\rangle\langle 1|e^{-\imath t\hat{H}/n\hbar}\right)^n |\psi_0\rangle = \lim_{n\to\infty} \begin{pmatrix} \cos^n\frac{\pi}{2n} \\ 0 \end{pmatrix}$$

Therefore, the probability of finding the atom in the ground state is,

$$\| |\psi(t)\rangle \|^2 = \lim_{n\to\infty} \cos^{2n}\frac{\pi}{2n} = \lim_{n\to\infty} \left(1 - \frac{1}{2}\left(\frac{\pi}{2n}\right)^2 + ...\right)^{2n} = \lim_{n\to\infty} \left[1 - \frac{2n}{2}\left(\frac{\pi}{2n}\right)^2 + ...\right] = 1\ .$$

That is, the atom is not excited at all.

36.3.4.3 Ex: The quantum Zeno effect

Consider a system described by a time-independent Hamiltonian $\hat{H}$.
a. Calculate the probability $P(t)$ of the system to remain in its initial state $|\Psi_0\rangle$ in the short time approximation, that is, considering until the second-order expression expansion term for the probability. Use the simplification:

$$\tau_z = \frac{\hbar}{\sqrt{\langle \hat{H}^2 \rangle - \langle \hat{H} \rangle^2}} \ ,$$

where the term τ_z is called the Zeno time.
b. If N measurements are performed during a time t, we have the time interval $T = t/N$ between measurements. When a measurement is performed, the system is projected on the initial state and the temporal evolution must start from zero. Thus, after N measurements, the probability of the system remaining in the initial state is given by $[P(T)]^N$. Show that for an infinite number of measurements, $N \to \infty$, the system remains in the initial state without loss of probability: $[P(T)]^N = 1$. Interpret the result.
c. One of the simplest imaginable systems, a laser-driven two-level system executing Rabi oscillation, is described by the Hamiltonian:

$$\hat{H} = \begin{pmatrix} 0 & \Omega \\ \Omega & 0 \end{pmatrix} \ .$$

Find the expression for τ_z as a function of the Rabi frequency Ω for the initial state $(1 \ \ 0)^\dagger$.
d. Choosing the evolution time $t = 0.01\tau_z \ll \tau_z$ and performing $N = 5$ measurements during this time interval, how likely is the system to remain in the initial state?
e. Let us now include a decay channel for the state $(0 \ \ 1)^\dagger$ with $\Gamma = 4\gamma$, such as to simulate a system with continuous measurement. The system is initially prepared in the state $(1 \ \ 0)^\dagger$. If we now observe emission by decay, it means that the system *left* the initial state. We now have the effective Hamiltonian:

$$\hat{H} = \begin{pmatrix} 0 & \Omega \\ \Omega & -2\imath\gamma \end{pmatrix} \ .$$

For this system, the probability amplitude for the initial state is:

$$\langle \Psi_0 | \Psi(t) \rangle = \frac{1}{2}\left(1 + \frac{\gamma}{\Delta}\right) e^{-(\gamma - \Delta)t/\hbar} + \frac{1}{2}\left(1 - \frac{\gamma}{\Delta}\right) e^{-(\gamma + \Delta)t/\hbar} \ ,$$

with $\Delta = \sqrt{\gamma^2 - \Omega^2}$. For a decay rate $\gamma \ll \Omega$, calculate the probability that the system remains in the initial state. Interpret the result.
Formulas:

$$e^x = 1 + x + \tfrac{x^2}{2} + \mathcal{O}(x^3) \quad , \quad (1-x)^N = 1 - Nx + \mathcal{O}(x^2)$$

$$\cos^2(x) = 1 - x^2 + \mathcal{O}(x^3) \quad , \quad \hat{H} = \begin{pmatrix} 0 & \Omega \\ \Omega & 0 \end{pmatrix} \to e^{-i\hat{H}t/\hbar} = \begin{pmatrix} \cos\frac{\Omega t}{\hbar} & -\imath \sin\frac{\Omega t}{\hbar} \\ -\imath \sin\frac{\Omega t}{\hbar} & \cos\frac{\Omega t}{\hbar} \end{pmatrix} \ .$$

Solution: *a. The initial state is denoted by* $|\Psi_0\rangle$*, the temporal evolution is* $|\Psi(t)\rangle = e^{-\imath\hat{H}t/\hbar}|\Psi_0(t)\rangle$*. The probability amplitude for remaining in the initial state is,*

$$A(t) = \langle\Psi_0|\Psi(t)\rangle = \langle\Psi_0|e^{-\imath\hat{H}t/\hbar}|\Psi_0\rangle$$

Expanding the exponential and considering terms up to second order in t *(see formulas):*

$$A(t) \approx \langle\Psi_0|1 - \frac{i\hat{H}t}{\hbar} - \frac{\hat{H}^2t^2}{2\hbar^2}|\Psi_0\rangle = 1 - \imath\langle\hat{H}\rangle t/\hbar - \langle\hat{H}^2\rangle t^2/2\hbar^2 \ .$$

The probability is:

$$\begin{aligned} P(t) = |A(t)|^2 &= \left(1 - \langle\hat{H}^2\rangle t^2/2\hbar^2 - \imath\langle\hat{H}\rangle t/\hbar\right)\left(1 - \langle\hat{H}^2\rangle t^2/2\hbar^2 + \imath\langle\hat{H}\rangle t/\hbar\right) \\ &= \left(1 - \langle\hat{H}^2\rangle t^2/2\hbar^2\right)^2 + \left(\langle\hat{H}\rangle t/\hbar\right)^2 \ . \end{aligned}$$

Neglecting the term in t^4*:*

$$P(t) = 1 - \langle\hat{H}^2\rangle t^2/\hbar^2 + \langle\hat{H}\rangle^2 t^2/\hbar^2 = 1 - t^2\left(\langle\hat{H}^2\rangle - \langle\hat{H}\rangle^2\right)/\hbar^2 = 1 - t^2/\tau_z^2 \ .$$

b. We have $T = t/N$*, hence,*

$$P(T) = 1 - \frac{t^2}{N^2\tau_z^2} \ ,$$

and,

$$[P(T)]^N = \left(1 - \frac{t^2}{N^2\tau_z^2}\right)^N \simeq 1 - \frac{t^2}{N\tau_z^2} \ ,$$

where we expand the power for large N *and only retain terms of up to first order (see formulas). For* $N \to \infty$*, we have* $[P(T)]^N = 1$*. Thus, if we perform a sufficiently large number of measurements during a time interval* t*, the system stays in the initial state and evolution is inhibited. This is the Zeno Effect.*
c. Building the exponential of the given Hamiltonian (see formulas),

$$e^{-\imath\hat{H}t/\hbar} = \begin{pmatrix} \cos\frac{\Omega t}{\hbar} & -\imath\sin\frac{\Omega t}{\hbar} \\ -\imath\sin\frac{\Omega t}{\hbar} & \cos\frac{\Omega t}{\hbar} \end{pmatrix} \ .$$

The probability amplitude for the state $(1\ ,\ 0)$ *is,*

$$A(t) = \begin{pmatrix} 1 & 0 \end{pmatrix} e^{-\imath\hat{H}t/\hbar}\begin{pmatrix} 1 \\ 0 \end{pmatrix} = \cos\frac{\Omega t}{\hbar} \ .$$

And the probability,

$$P(t) = |A(t)|^2 = \cos^2(\Omega t/\hbar) \simeq 1 - \Omega^2 t^2/\hbar^2 \ ,$$

where we expand the $\cos^2 x$ *for small* t *(see formulas). Comparing with the expression of item (a):*

$$\tau_z = \frac{\hbar}{\Omega}$$

d. With $t \ll \tau_z$*, we expand the power and use the expression already calculated in item (b):*

$$[P(T)]^N = 1 - \frac{t^2}{N\tau_z^2} \ .$$

With $N = 5$ *and* $t = 0.01\tau_z$ *we obtain,*

$$[P(T)]^N = 1 - \frac{0.01^2}{5} = 1 - 2.0 \times 10^{-5} = 0.99998$$

Thus, if we know the Rabi frequency for the driven two-level system, we can choose a sufficiently short time interval and inhibit the evolution of the system.
e. The expression for the probability amplitude has already been given. We have to calculate the probability $P(t) = |A(t)|^2$ *in the limit* $\gamma \gg \Omega$*. Calculating the square of the given expression, we get,*

$$P(t) = \frac{1}{4}\left(1 + \frac{\gamma}{\Delta}\right)^2 e^{-2(\gamma-\Delta)t/\hbar} + \frac{1}{4}\left(1 - \frac{\gamma}{\Delta}\right)^2 e^{-2(\gamma+\Delta)t/\hbar} + \frac{1}{2}\left(1 - \frac{\gamma^2}{\Delta^2}\right) e^{-2\gamma t/\hbar} \ .$$

Looking at the term γ/Δ*, remembering that* $\Delta = \sqrt{\gamma^2 - \Omega^2}$*,*

$$\frac{\gamma}{\Delta} = \frac{1}{\sqrt{1 - \Omega^2/\gamma^2}}$$

As $\gamma \gg \Omega$*, we have* $1 - \Omega^2/\gamma^2 \approx 1$*. Hence,* $\gamma/\Delta \approx 1$*, and we can consider only the first term of the above expression, since:*

$$\left(1 + \frac{\gamma}{\Delta}\right) \gg \left(1 - \frac{\gamma}{\Delta}\right) \quad \textit{and} \quad \left(1 + \frac{\gamma}{\Delta}\right) \gg \left(1 - \frac{\gamma^2}{\Delta^2}\right)$$

Thus, looking at the exponential term:

$$\gamma - \Delta = \gamma(1 - \sqrt{1 - \Omega^2/\gamma^2}) \ ,$$

expanding the root,

$$\gamma - \Delta = \gamma(1 - [1 - \Omega^2/2\gamma^2]) = \Omega^2/2\gamma \ ,$$

we get for the exponential,

$$e^{-2(\gamma-\Delta)t/\hbar} \approx e^{-\Omega^2 t/\gamma\hbar} \ .$$

The multiplicative term is,

$$\frac{1}{4}\left(1 + \frac{\gamma}{\Delta}\right)^2 = \left(\frac{1}{2} + \frac{\gamma}{2\Delta}\right)^2 = \left(\frac{1}{2} + \frac{1}{2\sqrt{1 - \Omega^2/\gamma^2}}\right)^2 = \left(\frac{\sqrt{1 - \Omega^2/\gamma^2} + 1}{2\sqrt{1 - \Omega^2/\gamma^2}}\right)^2 \ .$$

Expanding the root we get,

$$\left(\frac{2-\Omega^2/2\gamma^2}{2(1-\Omega^2/2\gamma^2)}\right)^2 = \left(\frac{2-\Omega^2/2\gamma^2}{2-\Omega^2/\gamma^2)}\right)^2 = \left(1+\frac{\Omega^2/2\gamma^2}{2-\Omega^2/\gamma^2}\right)^2 .$$

Doing $2-\Omega^2/\gamma^2 \approx 2$ *and expanding the power up to first order* ($\Omega/\gamma \ll 1$),

$$\left(1+\frac{\Omega^2/2\gamma^2}{2-\Omega^2/\gamma^2}\right)^2 = \left(1+\frac{\Omega^2}{4\gamma^2}\right)^2 = 1+\frac{\Omega^2}{2\gamma^2} .$$

Finally, the probability is:

$$P(t) = \left(1+\frac{\Omega^2}{2\gamma^2}\right) e^{-\Omega^2 t/\gamma\hbar} .$$

For $t = 0$ *there is a small error in the normalization due to the approximations made. Looking at the exponential term, the probability decay rate is* $t_d = \Omega^2/\gamma\hbar$. *This means that, if we increase* γ, *the probability of the system to leave the initial state decays more slowly.*
Once we prepare the system in the initial state $(1\ ,\ 0)$, *the system starts oscillating between the initial state and the state* $(0\ ,\ 1)$ *with the Rabi frequency* Ω. *In the presence of a decay channel to* $(0\ ,\ 1)$ *with* $\Gamma = 4\gamma$, *intuitively, we expect to observe a faster emission, i.e. the system leaves its initial state sooner when* Γ *is increased. However, due to the quantum Zeno effect, the opposite is true!*

36.3.4.4 Ex: Scaling with the number of measurements

Imagine you have a coin which you suspect to be manipulated so that, when tossed, it doesn't provide a 50% chance to show the face side. Assuming that all flip trials are independent, how many trials are necessary to prove that the probability for "face" is 60%? How many for 51%? What would be necessary to obtain a more favorable scaling with the number of trials?

Solution: *For independent measurements the probability distribution is binomial. In order to detect a deviation of* $\Delta p = 10\%$ *(*1%*) from* $p_+ = \frac{1}{2} = p_-$ *we need to perform enough measurements* N *that*

$$\frac{\Delta r}{r} = \frac{\sqrt{Np_+p_-}}{Np_+} \simeq \tfrac{1}{\sqrt{N}} < \Delta p .$$

That is we need $N = 100$ *(*10000*) measurements. A more favorable scaling necessarily requires some sort of correlation between the trials.*

36.4 Geometric and topological phases

We consider a Hamiltonian $\hat{H}(\mathbf{R}(t))$, which only depends implicitly on time, that is, via some time-dependent parameter $\mathbf{R}(t)$. Then the Hamiltonian evolves by developing a *non-measurable* dynamic phase and additionally accumulates a *geometric phase*

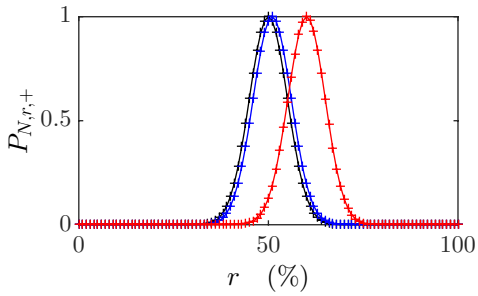

Figure 36.12: (code) Binomial distributions for tossing a coin $N = 100$ times with (black) $p_+ = 0.5$, (blue) $p_+ = 0.6$, and (red) $p_+ = 0.51$.

(also called *topological phase* or *Berry phase*. This geometric phase, which *depends on the trajectory*, is adiabatically followed in parameter space. Let us consider the time-evolution of a state $|\psi(t)\rangle$ [134],

$$\hat{H}|\psi(t)\rangle = \imath\hbar\partial_t|\psi(t)\rangle \ , \tag{36.64}$$

assuming that at any instant of time the system stays in a eigenstate $|n(\mathbf{R})\rangle$,

$$\hat{H}|n(\mathbf{R})\rangle = E_n(\mathbf{R})|n(\mathbf{R})\rangle \ . \tag{36.65}$$

When $\hat{H}$ moves along a trajectory $C : t \to \mathbf{R}(t)$, then we see from,

$$\boxed{|\psi(t)\rangle = \exp\left[-\tfrac{\imath}{\hbar}\int_0^t E_n(\mathbf{R}(t'))dt'\right]\exp(\imath\gamma_n(C))|n(\mathbf{R}(t))\rangle} \ , \tag{36.66}$$

that, while the first exponential describes the standard dynamical phase, the phase $\gamma_n : C \to \gamma_n(C)$ is not integrable, i.e. γ_n cannot be expressed as a function of $\mathbf{R}(t)$ and is not single-valued meaning that from $\mathbf{R}(T) = \mathbf{R}(0)$ we cannot infer $\gamma_n(T) = \gamma_n(0)$. Substituting (36.66) in (36.64), we find,

$$\hat{H}(\mathbf{R}(t))|\psi(t)\rangle = \imath\hbar|\dot{\psi}(t)\rangle = \left(E_n + \imath\hbar\dot{\imath}\dot{\gamma}_n(t) + \imath\hbar\dot{\mathbf{R}}(t)\cdot\nabla_{\mathbf{R}}\right)|\psi(t)\rangle \ . \tag{36.67}$$

Since for a particular eigenstate,

$$\hat{H}(\mathbf{R}(t))|n(\mathbf{R}(t))\rangle = E_n|n(\mathbf{R}(t))\rangle \ , \tag{36.68}$$

we infer,

$$\dot{\gamma}_n(t) = \imath\dot{\mathbf{R}}(t)\cdot\langle n(\mathbf{R}(t))|\nabla_{\mathbf{R}}|n(\mathbf{R}(t))\rangle \ . \tag{36.69}$$

The integrated phase change upon evolution of the state from $|\psi(0)\rangle$ to $|\psi(T)\rangle$ around a closed loop is then,

$$\boxed{\gamma_n(C) = \imath\oint_C \langle n(\mathbf{R})|\nabla_{\mathbf{R}}|n(\mathbf{R})\rangle\cdot d\mathbf{R} \equiv \oint_C \vec{\mathcal{A}}(\mathbf{R})\cdot d\mathbf{R}} \ , \tag{36.70}$$

where $\vec{\mathcal{A}}$ is known as *Berry connection*.

The condition of adiabaticity is essential for emergence of geometric phases. The system always remains in an eigenstate (fixed quantum numbers) when we vary parameters of the environment more slowly than all characteristic constants of the system, even when the Hamiltonian is time-dependent (variable eigenvalues).

36.4.1 Properties of the Berry phase

36.4.1.1 Gauge invariance

We have seen in 23.5.4 that the gauge transformation (??), $U_{cl}(\xi) = e^{-\imath\xi(\mathbf{R})}$, leaves the Schrödinger equation invariant. Applied to an eigenstate,

$$|\tilde{n}(\mathbf{R})\rangle = e^{-\imath\xi(\mathbf{R})}|n(\mathbf{R})\rangle \ , \tag{36.71}$$

the Berry connection becomes,

$$\tilde{\vec{\mathcal{A}}}(\mathbf{R}) = \imath\langle e^{\imath\xi(\mathbf{R})}n(\mathbf{R})|\nabla_{\mathbf{R}}|e^{-\imath\xi(\mathbf{R})}n(\mathbf{R})\rangle = \vec{\mathcal{A}}(\mathbf{R}) + \nabla_{\mathbf{R}}\xi(\mathbf{R}) \ . \tag{36.72}$$

It is apparently gauge-dependent, so that the local Berry connection $\vec{\mathcal{A}}_n(\mathbf{R})$ can never be physically observable. On the other hand, the Berry phase is,

$$\tilde{\gamma}_n(C) = \gamma_n(C) + \int_C \nabla_{\mathbf{R}}\xi \cdot d\mathbf{R} = \gamma_n(C) + \xi(t) - \xi(0) \ . \tag{36.73}$$

For a *closed loop*, continuity of the gauge field requires $\xi(T) - \xi(0) = 2\pi m$. Hence, up to an integer multiple of 2π, *closed loop Berry phases remain gauge-invariant* under arbitrary gauge transformation and may be related to physical observables.

36.4.1.2 Berry curvature

It is often advantageous to convert the path integral (36.70) into a surface integral using Stokes' theorem. Defining the Berry curvature as,

$$\vec{\mathcal{V}}_n(\mathbf{R}) \equiv \nabla_{\mathbf{R}} \times \mathbf{A}_n(\mathbf{R}) \ , \tag{36.74}$$

we obtain,

$$\gamma_n(C) = \iint_S \vec{\mathcal{V}}_n(\mathbf{r}) \cdot d\mathbf{S} \ . \tag{36.75}$$

The Berry curvature can be expressed as [134],

$$\mathbf{V}_n(\mathbf{r}) = \mathrm{Im} \sum_{m\neq n} \frac{\langle n(\mathbf{r})|\nabla_{\mathbf{r}}\hat{H}(\mathbf{r})|m(\mathbf{r})\rangle \cdot \langle m(\mathbf{r})|\nabla_{\mathbf{r}}\hat{H}(\mathbf{r})|n(\mathbf{r})\rangle}{(E_m(\mathbf{r}) - E_n(\mathbf{r}))^2} \ . \tag{36.76}$$

This will be shown in Exc. 36.4.3.1.

Example 220 (*Geometric phase in a two-level system*): We consider the following state [1086],

$$n_\pm(\mathbf{r}) = \cos\theta|g\rangle \pm e^{\pm\imath\phi}\sin\theta|e\rangle \ .$$

Now, we want to calculate the geometric phase,

$$\gamma_\pm = \oint_C \imath\langle n_\pm(\mathbf{r})|\nabla_{\mathbf{r}}|n_\pm(\mathbf{r})\rangle d\mathbf{r} \ .$$

Applying the gradient in spherical coordinates,

$$\nabla_{\mathbf{r}} = \hat{\mathbf{e}}_\theta \frac{1}{r}\frac{\partial}{\partial\theta} + \hat{\mathbf{e}}_\phi \frac{1}{\mathbf{r}\sin\theta}\frac{\partial}{\partial\phi} + \hat{\mathbf{e}}_r \frac{\partial}{\partial r}$$

to the function $|n_+\rangle$, we find,

$$\nabla_{\mathbf{r}}|n_+(\mathbf{r})\rangle = -\hat{\mathbf{e}}_\theta \frac{\sin\theta}{r}|g\rangle + \hat{\mathbf{e}}_\theta \frac{e^{\pm\imath\phi}\cos\theta}{\mathbf{r}}|e\rangle + \hat{\mathbf{e}}_\phi \frac{\imath e^{\imath\phi}}{r}|e\rangle \ ,$$

and,

$$\imath\langle n_\pm(\mathbf{r})|\nabla_{\mathbf{r}}|n_\pm(\mathbf{r})\rangle = \imath\hat{\mathbf{e}}_\phi \frac{\imath\sin\theta}{r} \ .$$

Finally,

$$\gamma_+ = \oint_C \frac{-\sin\theta}{r}\hat{\mathbf{e}}_\phi d\mathbf{R} = \oint_C \frac{-\sin\theta}{r} r\sin\theta d\phi = \oint_C \sin^2\theta\dot{\phi}dt \ .$$

Example 221 (*Berry phase on the Bloch sphere*): We consider the example of a two-level system without decay described by the Bloch vector $\vec{\varrho}$ defined in (34.163) and whose evolution is govern by the Hamiltonian (34.166),

$$\hat{H} = \tfrac{1}{2}\mathbf{G}\cdot\sigma \equiv \begin{pmatrix} \mathfrak{Re}\ \Omega \\ \mathfrak{Im}\ \Omega \\ \Delta/2 \end{pmatrix}\begin{pmatrix} \sigma_x \\ \sigma_y \\ \sigma_z \end{pmatrix} \ .$$

Now, we change the parameters regrouped in $\mathbf{G}$ adiabatically. It is easy to see that,

$$E_\pm = \pm R/2 \qquad \text{and} \qquad \nabla_{\mathbf{G}}\hat{H} = \vec{\sigma}/2 \ ,$$

such that,

$$\mathbf{V}_n(\mathbf{r}) = \mathrm{Im}\frac{\langle n_\pm(\mathbf{G})|\nabla_{\mathbf{G}}\hat{H}(\mathbf{G})|n_\mp(\mathbf{G})\rangle\cdot\langle n_\mp(\mathbf{G})|\nabla_{\mathbf{G}}\hat{H}(\mathbf{G})|n_\pm(\mathbf{G})\rangle}{(E_+(\mathbf{G})-E_-(\mathbf{G})^2} = \pm\frac{\mathbf{G}}{2G^3} \ .$$

The geometric phase accumulated on a closed loop $C = \partial S$ surrounding an area $S = 4\pi\Omega_S$ on the surface of the Bloch sphere is,

$$\gamma_n(C) = \mp\oint_C \frac{dS}{2G^2} = 4\pi \mp \oint_C dR = \mp\frac{\Omega_S(C)}{2}$$

and thus equal to half the enclosed solid angle Ω_S. The Berry phase can be measured in Ramsey experiments, as discussed in Exc. 36.4.3.2.

36.4.1.3 Generalization of the Berry phase according to Aharonov

We will now drop the conditions imposed to the Hamiltonian with regard to its adiabatic behavior and request that the state must be a eigenstate [274]:

$$\hat{H}|\psi(t)\rangle = \imath\hbar|\dot{\psi}(t)\rangle \ . \tag{36.77}$$

A process is cyclic, when there is a τ, such that,

$$|\psi(\tau\rangle = e^{\imath[f(\tau)-f(0)]}|\psi(0)\rangle \ . \tag{36.78}$$

Defining the space of radii by $|\tilde{\psi}(t)\rangle = e^{-\imath f(t)}|\psi(t)\rangle$, we obtain,

$$|\tilde{\psi}(\tau)\rangle = |\tilde{\psi}(0)\rangle \ , \tag{36.79}$$

and from the Schrödinger equation we obtain,

$$f(t) - f(0) = -\tfrac{1}{\hbar}\int_0^t \langle\psi(t)|\hat{H}(t)|\psi(t)\rangle dt + \int_0^t \langle\tilde{\psi}(t)|\imath\tfrac{d}{dt}|\tilde{\psi}(t)\rangle \equiv \delta + \beta \ . \tag{36.80}$$

Therefore, in the space of radii we have a closed curve:

$$\begin{array}{c} C : [0,\tau] \longrightarrow \psi(t) \in \mathcal{H} \\ \downarrow e^{-\imath f(t)} \\ C' : [0,\tau] \longrightarrow \tilde{\psi}(t) \in \mathcal{P} \ . \end{array} \tag{36.81}$$

The dynamic phase δ can be zeroed by an appropriate choice of $\hat{H}(t)$, but not the topological phase β. β does not depend on $\hat{H}(t)$, but is a geometric property of the curve, which projects $\mathcal{H}$ onto $\mathcal{P}$. In contrast to $e^{\imath\beta}$, the phase β is only determined modulo $2\pi n$.

36.4.2 Aharonov-Bohm effect

A particular case for topological phases is the *Aharonov-Bohm effect*, which we will discuss in the following. The only observables of electromagnetism are the forces of Coulomb and Lorentz which, in the theory of electrodynamics, are described by electric and magnetic fields. Electromagnetic potentials can be introduced to simplify calculations, but they are not observables with a physical reality. In contrast, in quantum mechanics, electromagnetic potentials are more fundamental than electromagnetic fields. This is demonstrated by the Aharonov-Bohm effect.

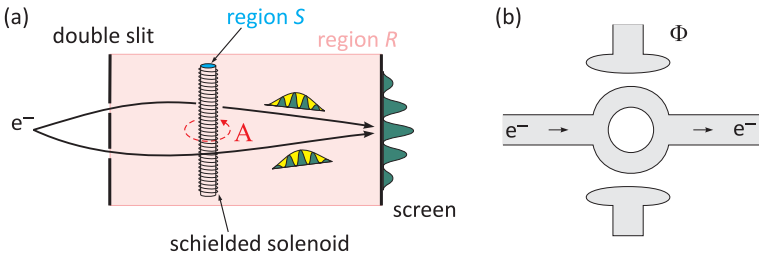

Figure 36.13: (a) Scheme for measuring the Aharonov-Bohm effect. The electrons propagate as wavepackets whose centers-of-mass are not subject to forces, but whose de Broglie waves are phase-shifted by the vector potential. (b) Aharonov-Casher effect: the electrodes Φ do not produce electric fields inside the conductors; even so, one observes constructive or destructive interference at the output of the interferometer, depending on the applied potential.

The idea of this effect is schematized in Fig. 36.13. An electron beam is coherently divided into two arms (e.g. by a double slit) passing both sides of an infinitely extended and perfectly shielded solenoid. In this way the magnetic field $\vec{\mathcal{B}}$ vanishes in the region outside the solenoid, but there must exist nonetheless a potential vector $\mathbf{A}$, because

we observe on the screen an interference pattern of the two arms of the electronic interferometer. When pass a current through the solenoid, we observe a displacement of the interference pattern.

36.4.2.1 Aharonov-Bohm effect and gauge transformation

Let R and S be two disconnected spatial regions. Suppose that the electric and magnetic fields are kept zero in region R. Then, it is *classically impossible* to measure some change in the dynamics of a body confined to the region R resulting from a change of the magnetic field confined to the region S. The Aharonov-Bohm effect shows that the *opposite* is true: Electrons in the magnetic field-free region R do sense magnetic field fluxes in a region S, despite the regions R and S having no intersection!

In the classical theory of electromagnetism, in a region of empty space (except for electric charges and electric currents), the electric $\vec{\mathcal{E}}(\mathbf{r},t)$ and magnetic fields $\vec{\mathcal{B}}(\mathbf{r},t)$ are related to the electric charge $\rho(\mathbf{r},t)$ and current densities $\mathbf{j}(\mathbf{r},t)$ according to the *Maxwell equations*. When we know for a spatial region the sources ρ and $\mathbf{j}$ and the boundary conditions that the fields $\vec{\mathcal{E}}$ and $\vec{\mathcal{B}}$ must fulfill, we can determine the fields as solutions of Maxwell's system of partial differential equations.

In classical electrodynamics, observed from some inertial frame, the electromagnetic force $\mathbf{F}_{em}$ acting on a point-like body with charge q, at position $\mathbf{r}$, and with velocity $\mathbf{v}$, is given by the Lorentz force:

$$\mathbf{F}_{em}(\mathbf{r}(t),t) = q\vec{\mathcal{E}}(\mathbf{r}(t),t) + q\mathbf{v}(t)\times\vec{\mathcal{B}}(\mathbf{r}(t),t)\ . \tag{36.82}$$

Electrodynamic theory affirms the existence of two functions $\Phi(\mathbf{r},t)$ and $\mathbf{A}(\mathbf{r},t)$, such that,

$$\vec{\mathcal{B}}(\mathbf{r},t) = \nabla\times\mathbf{A}(\mathbf{r},t) \qquad \text{and} \qquad \vec{\mathcal{E}}(\mathbf{r},t) = -\nabla\Phi(\mathbf{r},t) - \frac{\partial\mathbf{A}(\mathbf{r},t)}{\partial t}\ . \tag{36.83}$$

Thus, we can use the equations (36.83) to rewrite the Maxwell equations.

The so-defined potentials Φ and $\mathbf{A}$ are not unique, but any Φ and $\mathbf{A}$ leading to the same fields $\vec{\mathcal{E}}$ and $\vec{\mathcal{B}}$, and thus to the same physics, are equivalent. We will, however, fix Φ and $\mathbf{A}$ adopting an additional condition that must be obeyed, i.e. we will adopt a particular gauge. For the discussion of the Aharonov-Bohm effect, we will adopt the *Lorentz gauge* defined by,

$$\nabla\cdot\mathbf{A}(\mathbf{r},t) + \frac{1}{c^2}\frac{\partial\Phi(\mathbf{r},t)}{\partial t} = 0\ , \tag{36.84}$$

where c is the propagation velocity of light in vacuum.

36.4.2.2 Equation for quantum particle exposed to a vector potential A

Assume a particle (without spin) of mass m and charge q, whose wavefunction is confined to a region R (connected by paths). We demand $\Phi = 0$ and $\vec{\mathcal{E}} = 0 = \vec{\mathcal{B}}$, but we let $\mathbf{A}\neq 0$, that is, $\nabla\times\mathbf{A}(\mathbf{r},t) = 0$. Note that along with (36.83) this forces $\mathbf{A}$ to be stationary. According to quantum mechanics the wavefunction Ψ of the particle must obey the following Schrödinger equation:

$$\frac{1}{2m}\left(\frac{\hbar}{\imath}\nabla - q\mathbf{A}(\mathbf{r})\right)^2\Psi(\mathbf{r},t) + V(\mathbf{r})\Psi(\mathbf{r},t) = \imath\hbar\frac{\partial\Psi(\mathbf{r},t)}{\partial t}\ . \tag{36.85}$$

In (36.85) the potential vector $\mathbf{A}$ is present, even if ϕ, $\vec{\mathcal{E}}$, and $\vec{\mathcal{B}}$ are kept zero throughout the region R.

Since the rotation $\mathbf{A}$ vanishes in R, considering that the integral can be calculated for any path contained in R that is deformable to a (arbitrarily chosen) point $O \in R$, we can define the following scalar field:

$$g(\mathbf{r}) \equiv \frac{q}{\hbar} \int_0^{\mathbf{r}} \mathbf{A}(\mathbf{x}) \cdot d\mathbf{x} \ . \tag{36.86}$$

From (36.86) we have:

$$\nabla g(\mathbf{r}) = \frac{q}{\hbar} \mathbf{A}(\mathbf{r}) \ . \tag{36.87}$$

Now, we have already shown in Sec. 23.5.4, that the wavefunction

$$\psi(\mathbf{r}, t) \equiv e^{-\imath g(\mathbf{r})} \Psi(\mathbf{r}, t) \tag{36.88}$$

corresponds to the gauge transform (??) and, given the condition (??), satisfies the same Schrödinger equation as $\Psi(\mathbf{r}, t)$. We showed this explicitly in Exc. 36.4.3.3. Thus, the presence of a potential vector in the region R, even in the absence of fields, causes a phase shift $e^{\imath g(\mathbf{r})}$ of the wavefunction. An interesting issue studied in Exc. 36.4.3.4 is, whether this implies that the freedom of choice of the gauge field is lost.

Example 222 (*Observation of the Aharonov-Bohm effect*): Imagine an electron beam passing through a double-slit, as shown in Fig. 36.13(a). The electronic wavefunction diffracts through both slits, which produces an interference pattern on a subsequent screen. Now, just after the double-slit, in the shade of the region separating the two slits, we place an ideal infinitely long solenoid traversed on its axis by a constant, however, adjustable flux of magnetic field. The magnetic (and also the electric) field of the solenoid is confined to a region S, and the confinement can be guaranteed, e.g. with layers of shielding materials, including superconductors. On the other hand, the wavefunctions of the electrons are manifestly zero in this S region. In the R region, where the electronic wavefunction may be non-zero, the fields are kept zero. R and S have no overlap, both R and S are *separately* connected by paths.
We will show that the flux of the magnetic field in S can be measured through the electronic dynamics in the region R, although the electron is *never* in the region S, but confined to the field-free region R. This is the Aharonov-Bohm (magnetic) effect.
The field $\vec{\mathcal{B}}$ in the inner region of the solenoid is given by (I is the electric current in the wire, N is the density of windings),

$$\vec{\mathcal{B}}(\mathbf{r}, t) = \mu_0 I N \hat{\mathbf{e}}_z \ .$$

Outside the solenoid, that is, for $\rho > a$, we have,

$$\mathbf{A}(\mathbf{r}, t) = \frac{\Phi_B}{2\pi\rho} \hat{\mathbf{e}}_\phi \ ,$$

where $\Phi_B = \pi a^2 B(0, t)$ is the magnetic field flux $\vec{\mathcal{B}}$ through the cross section of the solenoid.
At a point $\mathbf{r}_{sim}$ of the screen, located in the plane of symmetry of the system,

we calculate $g(\mathbf{r}_{sim})$ from Eq. (36.86) for two different paths: both starting at the source and ending at the screen, but one going through the left slit, the other through the right slit:

$$g(\mathbf{r}_{sim}) = \frac{q}{\hbar}\int_0^{\mathbf{r}_{sim}} \mathbf{A}(\mathbf{x})\cdot d\mathbf{x} = \frac{q\Phi_B}{2\pi\hbar}\int\left(\frac{1}{\rho}\hat{\phi}\right)\cdot(\rho\hat{\phi}d\phi) = \pm\frac{q\Phi_B}{2\hbar}\ .$$

The + sign means, that the integration was done in the sense parallel to $\mathbf{A}$, and thus in the sense of I in the solenoid. The sign - holds for the other integration path. The phase difference, at point $\mathbf{r}_{sim}$, between these two paths will be:

$$\delta = \frac{q\Phi_B}{\hbar}\ .$$

That is, the phase difference (experimentally observable via a shift of the interference pattern) is directly proportional to the magnetic field flux $\vec{\mathcal{B}}$, even though the wavefunction is zero in the region S, where the $\vec{\mathcal{B}}$ field is confined. Let us also imagine another situation: Instead of an electron source producing a beam, let us confine an electronic wavefunction on a closed path circling the solenoid at a distance b, but inside the region of R. That is, the electron follows a field line $BA \propto \hat{\mathbf{e}}_\phi$. Then it can be shown, that the flow Φ_B removes the degeneracy of the energy levels of the electron:

$$E_n = \frac{\hbar^2}{2mb}\left(n - \frac{q\Phi_B}{2\pi\hbar}\right)^2\ ,$$

with integer, that is, $n = 0, \pm1, \pm2, ...$ [546].

The *Aharonov-Bohm phase is a (topological) Berry-phase* [134]. This is shown explicitly in Exc. 36.4.3.5.

36.4.2.3 Generalizations of the Aharonov-Bohm effect

The Aharonov-Bohm effect can be generalized to the internal degrees of freedom of a single atom, that is, from real space to configuration space. Let us imagine a Mach-Zehnder interferometer, where one of the arms crosses a constant homogeneous field region. The corresponding Lorentz force $\mathbf{F} = \int d^3r\ \rho(\mathbf{r})\vec{\mathcal{E}}(\mathbf{r}) + \mathbf{j}(\mathbf{r})\times\vec{\mathcal{B}}(\mathbf{r})$ vanishes, but the de Broglie wave undergoes a phase shift $\chi = \int \hat{H}_{int}dt$:

scalar potentials		
$\chi = -\int e\phi dt$	$\nabla\phi = 0$	for e^-
$-\int \mathbf{d}\cdot\vec{\mathcal{E}}dt$	$\nabla\times\vec{\mathcal{E}} = \nabla\cdot\vec{\mathcal{E}} = 0$	Mg, Yb^+
$-\int \vec{\mu}\cdot\vec{\mathcal{B}}dt$	$\nabla\times\vec{\mathcal{B}} = \nabla\cdot\vec{\mathcal{B}} = 0$	n, Yb^+
vector potentials		
$-\oint e\mathbf{A}d\mathbf{r}$	$\nabla\times\mathbf{A} = 0$	e^-, (ABE)
$-\oint d\times\vec{\mathcal{B}}d\mathbf{r}$		?
$-\oint \mu\times\vec{\mathcal{E}}d\mathbf{r}$		n, Ca, (ACE)

Example 223 (*Topological phase in configuration space*): We consider a temporal Ramsey experiment with a single trapped ion by exciting a hyperfine

transition. Between the pulses we apply a magnetic field for a time t. The accumulated phase will be $\phi = (\vec{\mu} \cdot \vec{\mathcal{B}}/\hbar)t$. This phase corresponds to the precession of the dipole moment excited by the first Ramsey pulse. The phase can be interpreted in analogy to Aharonov-Bohm effect, considering that 1. the magnetic field is homogeneous, and 2. despite this fact still acts on the spin, not exerting a force, but causing a phase shift.

36.4.3 Exercises

36.4.3.1 Ex: Derivation of the Berry curvature

Derive the expression (36.76) for the Berry curvature.

Solution: *We rewrite the Berry curvature from its definition (36.74),*

$$\vec{\mathcal{V}}_{n,\mu\nu} = \frac{\partial}{\partial R^\mu}\vec{\mathcal{A}}_{n,\nu} - \frac{\partial}{\partial R^\nu}\vec{\mathcal{A}}_{n,\mu} \ .$$

Using the Stokes theorem and expanding on a basis $\{|m\rangle\}$, we recover the expressions (36.76).

36.4.3.2 Ex: Measurement of the Berry phase in a two-level system

Discuss how the Berry phase in a two-level system can be measured via a Ramsey experiment.

Solution: *Following [12] we consider the Hamiltonian,*

$$\hat{H} = \hbar \begin{pmatrix} \Delta/2 & \Omega \\ \Omega/2 & -\Delta/2 \end{pmatrix} \ .$$

The solution of the Schrödinger equation is $|\psi(t)\rangle e^{-\imath \hat{H} t/\hbar}|\psi(0)\rangle$. The eigenvalue matrix is,

$$\hat{E} = \frac{\hbar}{2} G \hat{\sigma}_z \qquad with \qquad G \equiv \sqrt{\Delta^2 + \Omega^2} \qquad and \qquad \hat{\sigma}_z = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} \ .$$

The total phase shift after a precession cycle is,

$$\phi = \tfrac{\hat{H}}{\hbar} t = \tfrac{1}{2} G t = \pi \ .$$

The dynamic phase is,

$$\delta = \tfrac{1}{\hbar} \int_0^{2\pi/G} \langle \psi(t)|\hat{H}|\psi(t)\rangle dt = \tfrac{1}{\hbar} \int_0^{2\pi/G} \langle e^{\imath G t/2}\psi(0)|\tfrac{\hbar}{2} G|e^{-\imath G t/2}\psi(0)\rangle dt \ .$$

Starting from the initial state $\psi = \begin{pmatrix} \cos\theta \\ \imath \sin\theta \end{pmatrix}$,

$$\delta = \tfrac{1}{\hbar} \frac{\hbar}{2} \int_0^{2\pi/G} (\cos^2\theta - \sin^2\theta) > dt = -\pi \cos\theta \ .$$

The geometric phase corresponds to the enclosed solid angle,

$$\beta = \phi - \delta = \pi(1 - \cos\theta) = \tfrac{1}{2}\Omega(C) \ ,$$

although the atom is not in an eigenstate and has no adiabatic variation of the parameters.
After a first Ramsey pulse we introduce a short perturbation shifting the energies of the two-levels.

36.4.3.3 Ex: The Aharonov-Bohm effect as a gauge transform

Show explicitly that the wavefunction transformed by a gauge transformation (36.88) satisfies the Schrödinger equation.

Solution: *We assume that the wavefunction $\Psi(\mathbf{r})$ satisfies the Schrödinger equation. The objective is to show that $\psi(\mathbf{r},t) \equiv e^{\imath g(\mathbf{r})}\Psi(\mathbf{r},t)$ also satisfies it. In (36.86) we have,*

$$\nabla g(\mathbf{r}) = \frac{q}{\hbar}\mathbf{A}(\mathbf{r}) \ .$$

Hence,

$$\frac{1}{2m}\left(\frac{\hbar}{\imath}\nabla - q\mathbf{A}(\mathbf{r})\right)^2 \Psi(\mathbf{r},t) + V(\mathbf{r})\Psi(\mathbf{r},t) = \imath\hbar\frac{\partial\Psi(\mathbf{r},t)}{\partial t} \ .$$

In (36.85) the vector potential $\mathbf{A}$ is present, even if ϕ, $\vec{\mathcal{E}}$ and $\vec{\mathcal{B}}$ are kept zero throughout the region R.

36.4.3.4 Ex: Aharonov-Bohm effect and gauge transformation

The phase of the interference pattern in the Aharonov-Bohm effect is fixed by the magnetic flux through the solenoid. Does that mean, that we lose the freedom of choosing an arbitrary gauge potential?

Solution: *No! See the discussion of Griffiths,* Quantum Mechanics*, p.390.*

36.4.3.5 Ex: Aharonov-Bohm effect as a geometric phase

Show that the Aharonov-Bohm effect represents a particular case of a geometric phase.

Solution: *The state of a charge q confined to a volume centered around $\mathbf{R}$ in the vicinity of a magnetic flux line is given by the Schrödinger equation (36.85). That is, in the presence of flux, we may write,*

$$\hat{H}(\hat{\mathbf{r}} - \mathbf{R}, \mathbf{p} - q\mathbf{A}(\hat{\mathbf{r}}))|n(\mathbf{R})\rangle = E_n|n(\mathbf{R})\rangle \ ,$$

with eigenenergies independent of $\mathbf{r}$*. The spatial wavefunction of this state is found by adding a Dirac phase factor,*

$$\langle \mathbf{r}|n(\mathbf{R})\rangle = e^{(\imath q/\hbar)\int_R^r \mathbf{A}(\mathbf{r}')\cdot d\mathbf{r}'}\Psi_n(\mathbf{r}-\mathbf{R}) \ .$$

Now, we calculate the gradient,

$$\begin{aligned}\nabla_{\mathbf{R}}\langle \mathbf{r}|n(\mathbf{R})\rangle &= e^{(\imath q/\hbar)\int_{\mathbf{R}}^{\mathbf{r}} \mathbf{A}(\mathbf{r}')\cdot d\mathbf{r}'}\frac{-\imath q}{\hbar}\mathbf{A}(\mathbf{r})\Psi_n(\mathbf{r}-\mathbf{R}) + e^{(\imath q/\hbar)\int_{\mathbf{R}}^{\mathbf{r}} \mathbf{A}(\mathbf{r}')\cdot d\mathbf{r}'}\nabla_{\mathbf{R}}\Psi_n(\mathbf{r}-\mathbf{R}) \\ &= e^{(\imath q/\hbar)\int_{\mathbf{R}}^{\mathbf{r}} \mathbf{A}(\mathbf{r}')\cdot d\mathbf{r}'}\left(\frac{-\imath q}{\hbar}\mathbf{A}(\mathbf{r}') + \nabla_{\mathbf{R}}\right)\Psi_n(\mathbf{r}-\mathbf{R}) \ ,\end{aligned}$$

and the Berry connection,

$$\begin{aligned}\vec{\mathcal{A}}_n(\mathbf{r}) &= \imath\langle n(\mathbf{r})|\nabla_{\mathbf{R}} n(\mathbf{R})\rangle = \imath\langle n(\mathbf{r})|\int_V d^3r|\mathbf{r}\rangle\langle\mathbf{r}|\nabla_{\mathbf{R}} n(\mathbf{r})\rangle \\ &= \imath\int_V d^3r e^{(-\imath q/\hbar)\int_{\mathbf{R}}^{\mathbf{r}} \mathbf{A}(\mathbf{r}')\cdot d\mathbf{r}'}\Psi_n^*(\mathbf{r}-\mathbf{R})e^{(\imath q/\hbar)\int_{\mathbf{R}}^{\mathbf{r}} \mathbf{A}(\mathbf{r}')\cdot d\mathbf{r}'}\times \\ &\quad\times\left[\frac{-\imath q}{\hbar}\mathbf{A}(\hat{\mathbf{r}})\Psi_n(\mathbf{r}-\mathbf{R}) + \nabla_{\mathbf{R}}\Psi_n(\mathbf{r}-\mathbf{R})\right] \\ &= \frac{q}{\hbar}\int_V d^3r'\Psi_n^*(\mathbf{r}-\mathbf{R})\left[\mathbf{A}(\hat{\mathbf{r}})\Psi_n^*(\mathbf{r}-\mathbf{R}) + \nabla_{\mathbf{r}}\Psi_n^*(\mathbf{r}-\mathbf{R})\right] = \frac{q}{\hbar}\mathbf{A}(\hat{\mathbf{r}}) \ .\end{aligned}$$

Hence, $\gamma_n(C) = \frac{q}{\hbar}\int \mathbf{A}(\mathbf{r}')\cdot d\mathbf{r}'$ *is the geometric Aharonov-Bohm phase. Furthermore, for trajectories around a singularity, it is topological.*

36.5 Frequency metrology and sensing in quantum mechanics

Absolute space and time do not exist. According to the restricted and the general theory of relativity they are interconnected by velocity and they depend on the presence of masses exerted gravitational forces. These relationships and the question how quantum mechanics can be harnessed to improve measurements of time and forces, in particular gravity, will be treated in the following sections.

36.5.1 Atomic clocks

Before we start talking about clocks, we should spend a few words on the physical quantity they are supposed to measure: *time*. In the same way as it is meaningless to talk about space with nothing in it, time is only there, because things are happening. Space is the distance between things and time is nothing else than the distance between events.

In our current physical understanding of the universe the most elementary events are collisions between (real or virtual) particles. Obviously, our universe is full of time. In order to bring any succession of such events into a logical and causal order, a reference time line is needed. It allows for historical book keeping of sequences of

Figure 36.14: (left) 'Time persistence' by Salvatore Dali. (center) Recurrent events. (right) Periodic astronomical cycles.

events, that we may call *histories*. And in order to facilitate a comparison between different histories, this reference time line should follow a simple deterministic rule, e.g. be periodic or exponentially decaying. In fact, both types of processes are currently used for time measurements. E.g. exponential processes, such as radioactive decay is commonly used in radioactive dating.

The most common practical approach to the measurement of time, however, is based on the observation of recurrent phenomena that we think of being periodic, such as a day on Earth, the dripping of a water pipe, or the oscillation of a pendulum or of an atomic excitation. Assuming the time intervals separating the recurrent phenomena as being all the same, we build a ruler for time which we call *clock*.

But now comes a tricky question: How do we know whether a clock is really periodic? In fact, we never know for sure whether the time intervals are really all the same. We only know that some clocks deserve a greater degree of confidence based on the fact that *more care has been taken in their design and construction*, or based on the observation that clocks built in a certain manner tend to deviate less from each other than clocks built in a different manner. The other approach would be to compare several totally *independent* clocks and to give preference to those who deviate less from each other.

An important criterion for a useful clock concerns its duty cycle. The shorter the cycling time, the faster we can extract information from the clock, and the higher is the accuracy we can reach in a given integration time. Ancient time standards had been link to the periodic motion of celestial bodies, e.g. the revolution time of the Earth around the sun. Therefore, clocks with smaller duty cycles have been engineered, such as the clepsydra or the hour glass. But their calibration to periodical astronomical cycles remained tedious and slow. Historically, the development of ever precise clocks has been motivated by navigation. Indeed, 1 minute of inaccuracy in the clock generates an uncertainty of 28 km in global positioning. And this motivation still prevails nowadays, although, meanwhile, atomic clocks are reaching uncertainties of below 10^{-18} and extremely short duty cycles on the order of femto-seconds.

The left part of Fig. 36.15 shows the basic idea of any human-made clock, which consists in locking an oscillating mechanism, whose time constant can be manipulated,

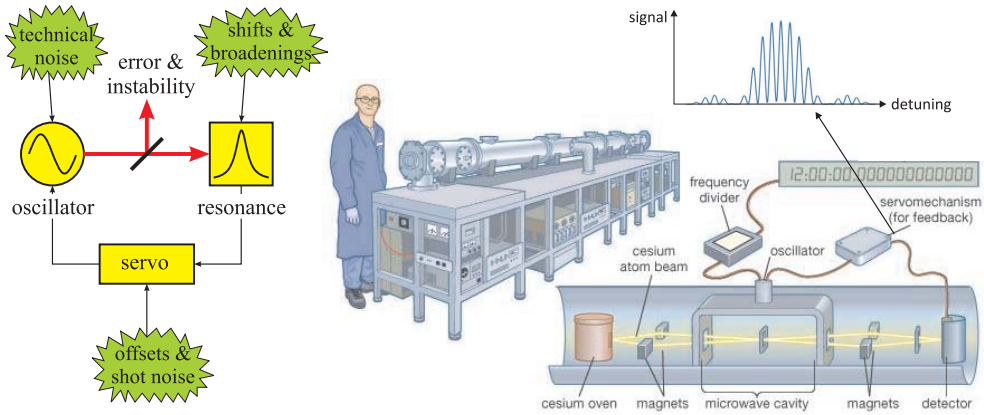

Figure 36.15: (left) Principle of any clock and possible perturbations. (right) Cesium beam atomic clock and Ramsey interference fringes.

for instance a pendulum or a laser, by a very precise periodic process, that we call *resonance*. This resonance can be an astronomic period or the transition of an atomic between two states of excitation. Expressing the stability of a clock that can be obtained in a given integration time as,

$$\sigma = \frac{\Gamma_{nat} + \Gamma_{pert}}{\omega} \frac{1}{S/N_{noise}} \ , \tag{36.89}$$

we see that we better look for oscillators and resonances operating at high frequencies ω, having very narrow widths Γ_{nat}, being subject to very weak perturbations and line broadenings Γ_{pert}, and delivering a good signal-to-noise ratio. The right part of Fig. 36.15 shows the concept of a cesium beam *atomic clock*. A microwave oscillator operating at $\omega/2\pi = 9.1\,\mathrm{GHz}$ excites cesium atoms passing through a microwave cavity thus generating in a detector a frequency-dependent error signal which can be used to correct the oscillator frequency.

36.5.2 Gravitational red-shift

Clocks and gravimeters are intrinsically related the gravitational redshift. The *gravitational red-shift* is that phenomenon in which electromagnetic waves or photons traveling out of a gravitational well (seem to) lose energy. This loss of energy corresponds to a decrease in the wave frequency and increase in the wavelength. Gravitational redshift can be interpreted (i) as a consequence of the *equivalence principle* stating that gravity and acceleration are equivalent and the redshift is caused by the Doppler effect. It can also be understood (ii) as a consequence of the mass-energy equivalence stating that 'falling' photons gain energy (though there are numerous subtleties that complicate a rigorous derivation). Finally, it can be understood (iii) in terms of gravitational time dilation at the source of the radiation: an oscillator (producing electromagnetic radiation) will seem to 'tick' faster when exposed to a stronger gravitational potential.

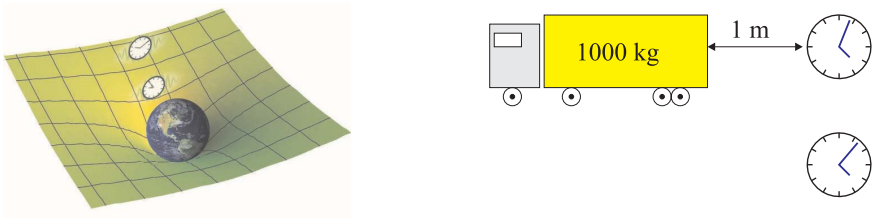

Figure 36.16: Gravitational redshift is due to the dilation of time near heavy masses.

To first approximation, the gravitational redshift is proportional to the difference in gravitational potential. In a homogeneous field(see Sec. ??),

$$\frac{\Delta\nu}{\nu} = \frac{\Delta\lambda}{\lambda} \simeq \frac{g\Delta z}{c^2} \ , \tag{36.90}$$

where Δz is the change in height. Accounting for the accompanying gravitational time dilation affecting the atomic clock in the satellite is crucially important for accurate navigation. For this reason, *metrology* of time and *gravimetry* are closely interrelated. Do the Exc. 36.5.4.1.

Example 224 (*Prediction by the equivalence principle and general relativity for a uniform gravitational field or acceleration*): Einstein's theory of general relativity incorporates the equivalence principle, which can be stated in various different ways. One such statement is that gravitational effects are locally undetectable for a free-falling observer. Therefore, in a laboratory experiment at the surface of the earth, all gravitational effects should be equivalent to the effects that would have been observed if the laboratory had been accelerating through outer space at g. One consequence is a gravitational Doppler effect. If a light pulse is emitted at the floor of the laboratory, then a free-falling observer says that by the time it reaches the ceiling, the ceiling has accelerated away from it, and therefore when observed by a detector fixed to the ceiling, it will be observed to have been Doppler shifted toward the red end of the spectrum. This shift, which the free-falling observer considers to be a kinematic Doppler shift, is thought of by the laboratory observer as a gravitational redshift. Such an effect was verified in the 1959 Pound-Rebka experiment. Since this prediction arises directly from the equivalence principle, it does not require any of the mathematical apparatus of general relativity, and its verification does not specifically support general relativity over any other theory that incorporates the equivalence principle.

36.5.3 Quantum sensing

Let us first define what we mean by a *sensor* in general before discussing what quantum mechanics has to do with it. A *sensor* is a device, module, machine, or subsystem whose purpose is to detect events or changes in its environment and send the information to other electronics, frequently a computer processor. Progress in engineering, science, medicine, and other disciplines is unavoidably conditioned to sensing: What

you cannot measure, you cannot improve! In many areas of applications, however, conventional sensing techniques have met fundamental limitations, and novel disruptive approaches are required in order to reach higher sensitivity and precision.

In many cases, limitations are imposed by the macroscopic, i.e. *classical*, nature of the sensor, and much can be gained by using microscopic sensors. These however, follow different rules of physics given by *quantum mechanics*. Nuclear magnetic resonance spectroscopy (NMR), magnetic resonance imaging, and the development of transistors, LEDs, solar panels, and lasers are examples of technologies developed during the first so-called quantum revolution in the 20th century, which was based on the exploitation of the particle-wave duality. However, the full potential of quantum mechanics goes much further. Today *quantum sensing* is, together with quantum computation and quantum communication (see Sec. 41.6.5), one of the key technologies anticipated to drive the quantum revolution 2.0.

Let us discuss the disruptive role of quantum mechanics at the example of an *atom*, which is a paradigmatic example for a sensor subject to quantum laws. The reasons for this are numerous: (i) Because all atoms of a given species are strictly identical (that is, indistinguishable in the quantum statistical sense) they can be used in different sensing devices, places and countries. We do not need to duplicate reference standards, such as the Original Meter or the Original Kilogram safely kept in Paris. We simply recommend to people wishing to construct their own clock standard to gather cesium atoms (wherever you can find them) and try to excite the 9.1 GHz hyperfine transition (with whatever technique you prefer). In the end, you just need to prove that your clock is sufficiently good. (ii) Some atomic species have ultranarrow transitions outperforming any imaginable artificial device by many orders of magnitude, which makes them ideal candidates for clock resonances. (iii) Atoms can easily be moved in space with extremely high precision, which makes them suitable for matter wave interferometers, which are useful for the measurement of distances and the sensing of forces.

The main reason, however, for the superiority of atoms (and other quantum devices, such as SQUIDs, quantum dots or nitrogen-vacancy (NV) centers in diamond) with respect to classical objects in sensing applications is, that they can exist in superposition states (of their internal excitation or of their center-of-mass motion) whose evolution delicately depends on external parameters, such as forces. We can now define a *quantum sensor* as a measurement device exploiting quantum correlations in order to enhance sensitivity and resolution, f.ex. quantum superpositions or entanglement [343]. Typically its core is a single atomic two-level system (or any other kind of qubit), whose superposition states (i) are sensitive to some environment parameter, (ii) can be manipulated in a controlled way, and (iii) can be read out.

In fact, quantum sensors already exist since the invention of atomic clocks and matter wave interferometers, which build on the control and detection of quantum states in individual qubits, even though in practice, most of these device are operated with large incoherent ensembles of qubits. Even if perturbations related to uncontrolled inter-qubit interactions (collisions, thermal excitations, etc.) can be avoided, the sensitivity that can be reached with such ensembles is bound to the standard quantum limit imposed by quantum projection noise (see Secs. 36.3.2 and 41.1.4). Novel approaches investigate the possibilities of overcoming these limits via the creation of strong interparticle correlations via entanglement, spin-squeezing [1380], or

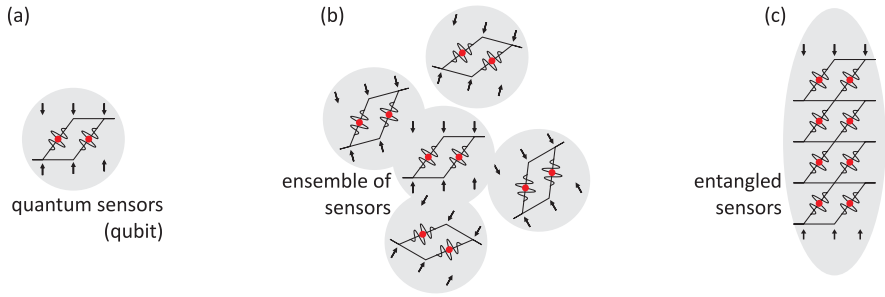

Figure 36.17: (left) Single qu-bit. (center) Larger signals can be observed using ensemble of qu-bits. (right) Collective manipulations on entangled qu-bits allow precisions beyond the standard quantum limit.

superradiant lasing [1005]. Such correlations have been created with atoms, which therefore qualify as building blocks of quantum computers or sensing devices capable of overruling the standard quantum limit.

36.5.3.1 Working principle of a quantum sensor

As mentioned above, in order to measure a weak force it is not sufficient to sense it, one also has to read the result. In the field of atom optics, this can conveniently be done with light fields taking the information from an atom isolated in a vacuum chamber to the macroscopic world. In order not to loose information already at the level of the light-atom interaction, one generally tries to avoid dissipation and keep the interaction coherent [14].

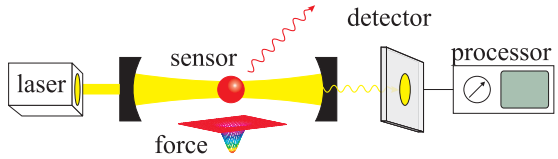

Figure 36.18: Taking information from the sensor to the detector.

A typical quantum sensor can be described by the generic Hamiltonian [343],

$$\hat{H}(t) = \hat{H}_{qbit} + \hat{H}_{cntrl}(t) + \hat{H}_{int}(t) \ , \tag{36.91}$$

composed of a (known) internal Hamiltonian $\hat{H}_{qbit}$, a control Hamiltonian $\hat{H}_{cntrl}$ allowing to manipulate or tune the sensor, and a signal Hamiltonian $\hat{H}_{int}$ allowing to pass information about the state of the system to the outside world.

Typically, the internal Hamiltonian is static and defines the energy eigenstates $|0\rangle$ and $|1\rangle$,

$$\hat{H}_{qbit} = E_0|0\rangle\langle 0| + E_1|1\rangle\langle 1| \ . \tag{36.92}$$

[14] E.g. by using two-level systems not subject to motion, collisions, spontaneous emission, etc.. Sometimes spontaneous emission can be controlled by confining both, the atom and the interrogating light field, in a cavity.

The qubit internal Hamiltonian may contain additional interactions, such as couplings to other qubits or time-dependent stochastic terms due to interactions with an environment.

Many quantum sensing protocols require to manipulate the qubit either before, during, or after the sensing process. This is achieved via a control Hamiltonian, which allows implementing a sequence of appropriate quantum gates, such as the Hadamard gate or Pauli X and Y gates. These gates are nothing else than what, in the language of atom interferometry is known as $\pi/2$ or π-pulses around different axes. Advanced sensing schemes employing more than one sensor qubit may further require conditional gates, especially controlled-NOT gates to generate entanglement, swap gates to exploit memory qubits, and controlled phase shifts in quantum phase estimation (see Sec. 41.6). Finally, the control Hamiltonian can include control fields for systematically tuning the transition frequency $\hbar\omega_0 = E_1 - E_2$.

Finally, the signal Hamiltonian represents the coupling between the sensor qubit and a signal $V(t)$ to be measured. When the signal is weak (which is assumed here) $\hat{H}_{int}$ adds a small perturbation to the internal Hamiltonian. The signal Hamiltonian can then be separated into two qualitatively different contributions,

$$\hat{H}_{int} = \hat{H}_{int,\parallel} + \hat{H}_{int,\perp} \ , \tag{36.93}$$

where $\hat{H}_{int,\parallel}$ is the parallel (commuting) and $\hat{H}_{int,\perp}$ the transverse (non-commuting) components, respectively. The two components can quite generally be captured by,

$$\begin{aligned} \hat{H}_{int,\parallel} &= \tfrac{\gamma}{2} V_\parallel(t)[|1\rangle\langle 1| - |0\rangle\langle 0|] \\ \hat{H}_{int,\perp} &= \tfrac{\gamma}{2}[V_\perp(t)|1\rangle\langle 0| + V_\perp^\dagger(t)|0\rangle\langle 1|] \ , \end{aligned} \tag{36.94}$$

where γ is the coupling or transduction parameter of the qubit to the signal $V(t)$. Examples of coupling parameters include the Zeeman shift parameter or the Stark shift parameter of electric dipoles in an electric field. The parallel and transverse components of a signal have distinctly different effects on the quantum sensor. A commuting perturbation $\hat{H}_{int,\parallel}$ leads to shifts of the energy levels and an associated change of the transition frequency ω_0. A non-commuting perturbation $\hat{H}_{int,\perp}$, by contrast, can induce transitions between levels, manifesting through an increased transition rate. Most often, this requires the signal to be time-dependent (resonant with the transition) in order to have an appreciable effect on the quantum sensor.

An important class of signals are vector signal $\mathbf{V}(t)$, in particular, those provided by electric or magnetic fields. The interaction between a vector signal and a qubit can be described by the signal Hamiltonian,

$$\hat{H}_{int} = \gamma \mathbf{V}(t) \cdot \hat{\vec{\sigma}} \ , \tag{36.95}$$

where $\hat{\vec{\sigma}}$ is the vector of Pauli matrices (23.46). For a vector signal, the two signal functions $V_\parallel(t)$ and $V_\perp(t)$ are,

$$\begin{aligned} V_\parallel(t) &= V_z(t) \\ V_\perp(t) &= V_x(t) + \imath V_y(t) \ , \end{aligned} \tag{36.96}$$

where the z-direction is defined by the qubit's quantization axis. The corresponding signal Hamiltonian,

$$\hat{H}_V(t) = \gamma\hat{\sigma}_x \mathfrak{Re}\ V_\perp(t) + \gamma\hat{\sigma}_y \mathfrak{Im}\ V_\perp(t) + \gamma\hat{\sigma}_z V_\parallel(t) \ , \tag{36.97}$$

is just the one of the Rabi model extensively discussed in Sec. 34.4.

36.5.3.2 Sensing forces by matter wave interferometry

Matter wave interferometry is ideal for sensing weak forces or sensing strong forces with high precision. Many interferometers employ the Ramsey scheme, which consists in sandwiching the sensing Hamiltonian between two $\pi/2$-control Hamiltonian pulses $\hat{H}_{cntrl}$ preparing and reading out the atomic coherence. Between the pulses (or interaction zones), the atomic coherence is influenced by the parallel part of the sensing Hamiltonian $\hat{H}_{int,\parallel}$.

The basic idea is the following: One takes a matter wave and lets it fall in the Earth's gravitational field. But before that, apply a laser pulse separating the matter wave into two parts taking different paths. Thus, the Broglie waves of the two parts will accumulate different phases, which results in an interference pattern when the waves are superimposed again. As illustrated in Fig. 36.19, the matter wave interferometry works similarly to the Ramsey method used in atomic clocks with the difference that in the former the trajectories of the atomic center-of-mass motion must be separated in real space as much as possible (see Sec. 34.4.5 on Ramsey pulses and NMR, Sec. 24.1.3 on gravity with Excs. 23.5.6.2 and 23.5.6.3, Sec. 47.2.2 on Bragg interferometry and photon echos with Excs. 47.2.4.1) [15].

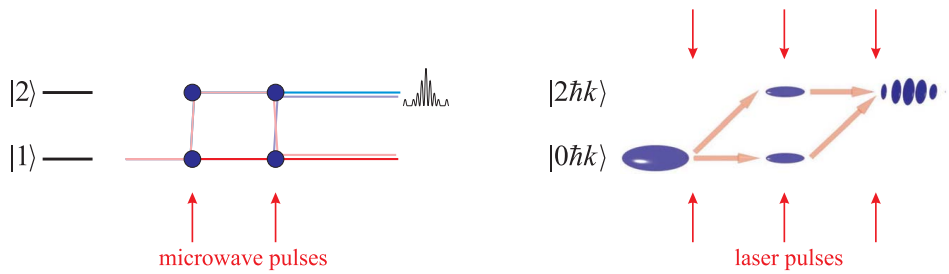

Figure 36.19: Difference between clocks and interferometers. (left) Ramsey-type clock. (right) Ramsey-Bordé interferometer. A movie can be seen at (watch movie).

A particularly smart way to do matter wave interferometry is via the observation of Bloch oscillations of matter waves in a periodic lattice (see Sec. 26.2.2). The Bloch oscillations can be understood in the following picture: A resting atom has infinite de Broglie wavelength. Being constantly accelerated by gravity, the matter wave reduces its de Broglie wavelength from ∞ to a value, where it becomes commensurate with the periodicity of the standing light wave potential. At this moment Bragg scattering comes into play, reflecting the atomic motion back into upward direction, and the process starts over again. The atoms evolve like jumping on a trampoline with a frequency given,

$$\nu_{blo} = \frac{mg}{2\hbar k_{lat}} \ . \tag{36.98}$$

[15] See also Sec. 53.5 and 54.5 on interferometric and spectroscopic techniques.

36.5.4 Exercises

36.5.4.1 Ex: Red-shift of sun light and on Earth

a. Calculate the gravitational redshift of light escaping from the sun.
b. Calculate the blue-shift of navigational signals from GPS satellites orbiting at 20000 km altitude with respect to the surface of Earth. Compare it to the Doppler shift resulting from their orbital velocity.
c. In astronomy, the magnitude of a gravitational redshift is often expressed as the velocity that would create an equivalent shift through the relativistic Doppler effect. Calculate the sunlight redshift and the GPS signal blue-shift in terms of this velocity.

Solution: *a. Light escaping from the surface of the sun was predicted by Einstein in 1911 to be red-shifted by roughly* $2 \cdot 10^{-6}$.
b. The signals emitted from GPS satellites are perceived as blue-shifted by approximately $5 \cdot 10^{-10}$ *corresponding to an increase of less than* 1 Hz *in the frequency of a* 1.5 GHz *signal.*
c. In such units, sunlight redshift corresponds to a 633 m/s *receding velocity, roughly of the same magnitude as convective motions in the sun, thus complicating the measurement. In astronomical objects with strong gravitational fields the redshift can be much greater; for example, light from the surface of a white dwarf is gravitationally red-shifted on average by around* 50 km/s/c.

Chapter 37

Nonlinear optics

The discipline of *nonlinear optics* studies phenomena that occur as a consequence of modifications of the optical properties of materials by the presence of light. Such modifications are appreciable only, when the interacting light is sufficiently intense, i.e. of the order of the interatomic electric field,

$$\mathcal{E}_{at} = \frac{e^2}{4\pi\varepsilon_0 a_B^2} \simeq 5.14 \cdot 10^{11}\,\mathrm{V/m}\ , \tag{37.1}$$

which explains that nonlinear effects could only be studied properly after the advent of the laser.

In general, light-matter interaction is expressed through the relationship between the polarization induced in the medium, $\mathcal{P}(\omega)$, with the optical light field, $\mathcal{E}(\omega)$. In linear optics this relation can be expressed as,

$$\tilde{\mathcal{P}}(\omega) = \varepsilon_0 \chi(\omega)\tilde{\mathcal{E}}(\omega)\ . \tag{37.2}$$

But in the perturbative regime of non-linear optics this expression must be generalized to a series of powers of the electric field,

$$\tilde{\mathcal{P}}(\omega) = \varepsilon_0[\chi^{(1)}(\omega)\tilde{\mathcal{E}}(\omega) + \chi^{(2)}(\omega)\tilde{\mathcal{E}}^2(\omega) + \chi^{(3)}(\omega)\tilde{\mathcal{E}}^3(\omega) + ...]\ , \tag{37.3}$$

so that higher order polarization terms, $\mathcal{P}^{(n)}(\omega) = \varepsilon_0\chi^{(n)}\mathcal{E}^N(\omega)$, are considered. Therefore, the phenomena are non-linear in the sense that they depend non-linearly on the optical field applied to the material. In a more complete treatment, in terms of the optical properties of materials, $\tilde{\mathcal{P}}$ and $\tilde{\mathcal{E}}$ are vector fields and the electric susceptibility is a tensor. However, to simplify the treatment, we consider the fields as scalars and $\chi^{(n)}$ as constants independent of the frequency ω.

Examples of non-linear optical phenomena are: parametric processes of sum and difference frequency generation, as shown in Fig. 37.1, optical parametric oscillation, and the dependence of the refractive index with the optical intensity. Examples of non-parametric processes are: multi-photonic absorption, stimulated Raman scattering, and saturated absorption. In the latter example, the absorption coefficient of the material decreases with increasing light intensity:

$$\alpha = \frac{\alpha_0}{1 + I/I_s}\ . \tag{37.4}$$

Saturated absorption is an example where a perturbative approach is not capable of providing good results, and its most reliable description is given by the approximation of a two-level quantum system.

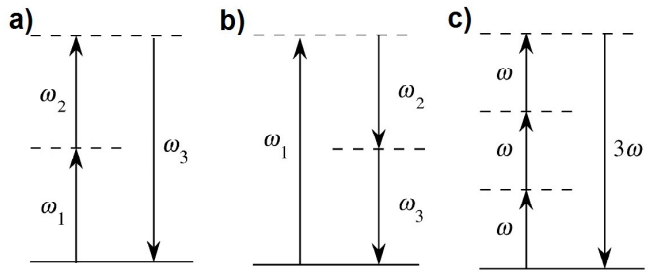

Figure 37.1: Parametric (a) sum and (b) difference frequency generation. (c) Third harmonic generation.

It is also important to emphasize that parametric processes are those, in which the initial and final quantum states of a system are identical. Consequently, the population of an initial state can only be moved to a virtual state, different in energy by ΔE, for a short time lapse limited by Heisenberg's uncertainty principle ($\hbar/\Delta E$). Nonparametric processes are those involving population transfer between real energy levels, eigenstates of the system's Hamiltonian. In terms of the electrical susceptibility of the medium, $\chi^{(n)}$ is a real quantity for parametric and an imaginary one for non-parametric processes.

37.1 The nonlinear optical susceptibility

The description of nonlinear optical phenomena can be approached from a variety of perspectives, most of which are semi-classical in the sense that the matter is treated quantum mechanically, while the electromagnetic radiation is treated classically. One possible description explores the wave nature of the radiation, using Maxwell's equations to describe the generation of new spectral components by the nonlinear terms of the polarization. More generally, this description explains how different frequencies can be coupled through their nonlinear interaction with the material. It can be shown that the electromagnetic wave equation in the nonlinear regime is,

$$\nabla\tilde{\mathcal{E}} - \frac{n^2}{c^2}\frac{\partial^2}{\partial t^2}\tilde{\mathcal{E}} = \frac{1}{\varepsilon_0 c^2}\frac{\partial^2}{\partial t^2}\tilde{\mathcal{P}} \ , \tag{37.5}$$

such that $\tilde{\mathcal{P}} = \tilde{\mathcal{P}}^{(1)} + \tilde{\mathcal{P}}^{nl}$. In this view, $\tilde{\mathcal{P}}^{nl}$ acts as a source of frequencies, several of that are incident.

Although electromagnetic theory is capable of explaining several aspects of nonlinear optics, it is the quantum description that provides explicit expressions for nonlinear optical susceptibility. There are three main motivations for obtaining quantum expressions:

- They reveal a functional form of the nonlinear optical susceptibility and show how they depend on microscopic parameters of the material, such as transition dipole moments and atomic energy levels.
- They exhibit the intrinsic symmetries of nonlinear susceptibility.

- They can be used to calculate numerically the values of nonlinear susceptibilities.

The numerical predictions of quantum theory for nonlinear optical susceptibilities are particularly accurate in the case of atomic vapors, because the atomic parameters of these are known with sufficient precision for the theory to provide reliable results.

Two quantum mechanical formalisms can be used for the calculation of nonlinear optical susceptibilities. Perturbation theory is used to make predictions on non-resonant systems, i.e. situations where the photon energy is much smaller than the energy separation between two eigenstates of the material. On the other hand, when the interactions are close to resonance, such that it becomes necessary to include relaxation processes, the state-density matrix formalism is used. Although this approach is more complex, it provides better results.

37.1.1 Expansion of the nonlinear susceptibility

In non-linear anisotropic media the *susceptibility* $\chi(\vec{\mathcal{E}})$ can depend on the electric field in a complicated manner. Often it is possible to expand it in orders of the field amplitude,

$$\boxed{\begin{array}{rcl} \chi(\vec{\mathcal{E}}) & = & \chi^{(1)}\vec{\mathcal{E}} + \chi^{(2)}\vec{\mathcal{E}} : \vec{\mathcal{E}} + \chi^{(3)}\vec{\mathcal{E}} : \vec{\mathcal{E}} : \vec{\mathcal{E}} + ... \\ \text{with} \quad (\chi^{(n)}\vec{\mathcal{E}}^n)_\mu & = & \sum_{\nu_1,...,\nu_n} \chi^{(n)}_{\mu,\nu_1,...,\nu_n} \vec{\mathcal{E}}_{\nu_1} ... \vec{\mathcal{E}}_{\nu_n} \end{array}} , \tag{37.6}$$

where μ and ν are components of Cartesian coordinates. That is, all the products in the first line of equation (37.6) are, in fact, tensor products. In isotropic media, only the first-order susceptibility contributes. We can Fourier transform in equation (37.2) the polarization $\vec{\mathcal{P}}$ and the field amplitude $\vec{\mathcal{E}}$. Since the susceptibilities $\chi^{(n)}$ are time-dependent, in the frequency domain the product turns into a convolution,

$$\vec{\mathcal{P}}(\mathbf{r}, t) = \int_{-\infty}^{\infty} e^{-\imath\omega t} \vec{\mathcal{P}}(\mathbf{r}, \omega) dt \ , \tag{37.7}$$

where $\vec{\mathcal{P}}^*(\mathbf{r}, \omega) = \vec{\mathcal{P}}(\mathbf{r}, -\omega)$.

Hence,

$$\vec{\mathcal{P}}(\mathbf{r}, \omega) = \sum_{n=1}^{\infty} [\chi^{(n)} * \vec{\mathcal{E}}(\mathbf{r}) * ... * \vec{\mathcal{E}}(\mathbf{r})](\omega) \tag{37.8}$$

$$= \sum_{n=1}^{\infty} \int_{\mathbb{R}^n} \chi^{(n)}(-\omega, \omega_1, ..., \omega_n) * \vec{\mathcal{E}}(\mathbf{r}, \omega_1) * ... * \vec{\mathcal{E}}(\mathbf{r}, \omega_n) \delta(\omega - \omega_1 - ... - \omega_n) d\omega_1 ... d\omega_n \ .$$

The δ-function expressed energy conservation. For the susceptibilities holds,

$$\chi^*(-\omega, \omega_1, ..., \omega_n) = \chi(\omega, -\omega_1, ..., \omega_n) \ . \tag{37.9}$$

There is a $n = 0$ term, which disappears for isotropic media...! Eq. (37.8) only holds in the dipole approximation, since $\mathbf{r}$ is supposed equal on both sides (local response).

Now, we suppose for $\vec{\mathcal{E}}(t) = \frac{1}{2}\sum_{\omega>0}(\vec{\mathcal{E}}_\omega e^{-\imath\omega t} + \vec{\mathcal{E}}_{-\omega} e^{\imath\omega t})$ a sum of monochromatic waves. Then we must substitute in Eq. (37.7) $\vec{\mathcal{E}}(\omega) = \frac{1}{2}\sum_{\mu_i} \vec{\mathcal{E}}_{\mu_i}\delta(\omega - \mu_i)$:

$$\begin{aligned}\vec{\mathcal{P}}(\mathbf{r},\omega) &= \sum_{n=1}^{\infty} \sum_{\mu_1,...,\mu_n} \tfrac{1}{2^n}\chi^{(n)}(-\omega,\mu_1,...,\mu_n)\vec{\mathcal{E}}_{\mu_1}...\vec{\mathcal{E}}_{\mu_n}\delta(\omega-\mu_1-...-\mu_n) \qquad (37.10)\\ &= \sum_{n=1}^{\infty} \sum_{\substack{\omega_1,\,...,\,\omega_n \\ \omega_1+...+\omega_n=\omega}} \tfrac{1}{2^{n-1}}\chi^{(n)}(-\omega,\omega_1,...,\omega_n)\vec{\mathcal{E}}_{\omega_1}...\vec{\mathcal{E}}_{\omega_n}\ .\end{aligned}$$

The frequencies ω_i do not have to be all different, but the modes can also differ by their polarizations. We have,

$$\chi^*(-\omega,\omega_1,\omega_2,...,\omega_n) = \chi(-\omega,\omega_2,\omega_1,...,\omega_n)\ . \qquad (37.11)$$

Therefore we can, using the number of permutations $n!/m_1!m_2!...$, where $m_1, m_2, ...$ are the numbers of equal frequencies $\omega_1, \omega_2, ...$, rewrite the sum in Eq. (37.10),

$$\sum_{\substack{\omega_1,\,...,\,\omega_n \\ \omega_1+...+\omega_n=\omega}} = \sum_{\substack{\omega_1,\,...,\,\omega_n \\ \omega_1+...+\omega_n=\omega \\ \omega_1\le...\le\omega_n}} \frac{n!}{m!}\ . \qquad (37.12)$$

From stationary perturbation theory we can deduce,

$$\chi^{(n)}(-\omega_{n+1},\omega_n,...,\omega_1) = \frac{N}{n!V\varepsilon_0\hbar^n}\sum_i \rho(E_i)\overline{M_{ii}^{(n+1)}}\ , \qquad (37.13)$$

where the transition hyperpolarizability is,

$$\begin{aligned}M_{fi}^{(n+1)} = \mathrm{Tr}\ \langle f|\hat{\epsilon}_{n+1}\cdot\hat{\mathbf{d}}\ G(E_i+\omega_1+...+\omega_{n-1}+\omega_n)\times \qquad (37.14)\\ \times\ \hat{\epsilon}_n\cdot\hat{\mathbf{d}}\ G(E_i+\omega_1+...+\omega_{n-1})\times...\times\hat{\epsilon}_1\cdot\hat{\mathbf{d}}\ G(E_i+\omega_1)|i\rangle\ .\end{aligned}$$

Here $G(\omega) \equiv \sum_i \int \frac{|A_i\rangle\langle A_i|}{\omega - E_\ell}$ is the photon propagator for the intermediate level $|A_\ell\rangle$. γ_{fi} describes thus the temporal succession of the absorption processes of the photons ω_1 to ω_n.

Since after the total process the atoms again needs to be in the initial state $|A_i\rangle$ we have $\omega_{n+1} = \omega_1 + ... + \omega_n$. The permutation operator described in (37.12) guarantees that every permutation of intermediate states appears in the sum. The matrix element $M_{fi}^{(n)}$ also appears in the transition probability $1/\tau$.

Here are a few nonlinear processes and their susceptibilities:

absorption and stimulated emission	$\chi^{(1)}(-\omega;\omega)$
two-photon emission	$\chi^{(1)}(-\omega;\omega)$
spontaneous Rayleigh or Raman scattering	$\chi^{(1)}(-\omega;\omega)$
self focusing and defocusing (nonlinear index of refraction)	$\chi^{(3)}(-\omega;\omega,-\omega,\omega)$
phase conjugation	$\chi^{(3)}(-\omega;\omega,-\omega,\omega)$
stimulated Rayleigh or Raman scattering (CARS)	$\chi^{(3)}(-\omega;\omega_s,-\omega_s,\omega)$
Kerr effect	$\chi^{(3)}(-\omega;\omega_s,-\omega_s,\omega)$
third harmonic generation	$\chi^{(3)}(-3\omega;\omega,\omega,\omega)$
four wave mixing (4WM)	$\chi^{(3)}(-\omega;\omega_1,\omega_2,\omega_3)$
hyper Raman scattering	$\chi^{(3)}$
two-photon absorption	$\chi^{(3)}(-\omega;\omega_s,-\omega_s,\omega)$
enhanced spontaneous emission	

37.1.1.1 Non-linear spectroscopy

Several light field create in an atom a dielectric polarization $\hat{\mathbf{d}}$. The polarization of the medium is calculated via $\vec{\mathcal{P}} = \frac{N}{V}\mathrm{Tr}\,\hat{\rho}\hat{\mathbf{d}}$. Hence, the density operator must be calculated from the non-linear Bloch equations. It can be expanded in perturbation orders of susceptibilities, $\vec{\mathcal{P}} = \sum_n \chi^{(n)}\vec{\mathcal{E}}_1 \cdot ... \cdot \vec{\mathcal{E}}_n$. The polarization radiates a light field according to $\Box\vec{\mathcal{E}}_d = \ddot{\vec{\mathcal{P}}}$.

37.1.2 Four-wave mixing

Assume motionless atoms. In a gas cell, a non-linear polarization develops,

$$\mathcal{P}(\omega) = \chi^{(1)}(\omega)\mathcal{E}_p(\omega) + \chi^{(3)}(\omega)\mathcal{E}_s^*(\omega_s)\mathcal{E}_p(\omega)\mathcal{E}_s(\omega_s)\ . \tag{37.15}$$

The *four-wave mixing* (4WM) procedure by $\chi^{(3)}(\omega)$ can be interpreted as a perturbation series,

$$\rho_{22} \xrightarrow{\mathcal{E}_s} \rho_{21} \xrightarrow{\mathcal{E}_s^*} \rho_{11} \xrightarrow{\mathcal{E}_p} \rho_{02} \xrightarrow{\mathcal{P}} \rho_{00}\ . \tag{37.16}$$

The time-reversed undergoing *phase-conjugation* wave is perfectly anti-collinear and has the same frequency. The phase-matching condition $\mathbf{k}\mathbf{k}_s \to 1$ must only hold for one-photon transitions. For two-photon transition arbitrary $\mathbf{k}\mathbf{k}_s$ are acceptable.

The *coherent anti-Stokes Raman scattering* (CARS) is related to 4WM. Phase-matching is necessary if the atomic states are unchanged by the process.

37.1.3 Optical parametric oscillator

An *optical parametric oscillator* is a device exhibiting a resonance, which driven with a specific phase lag displays amplification. The optical parametric oscillators (OPO) and the *optical parametric amplifier* (OPA) are common devices of nonlinear optics. In quantum language terms like $\hat{a}^\dagger\hat{c}^\dagger$, which describe the creation of entangled pairs of particles are typical for OPAs.

37.1.4 Optical bistability

The phenomenon of *optical bistability* can be observed in lasers and passive cavities [886]. Optical bistability can also be induced by atomic motion [942].

37.1.4.1 Dispersive bistability

Consider a ring cavity with a two-level medium inside resonantly pumped by a laser. The *dispersive optical bistability* is easily explained as the medium under the influence of the pump laser shifting the refractive index and thus the cavity resonance away from the incoupled laser beam, so the pump transmission ceases. Assume the phase shift is $\beta = \beta_0 + \beta_2 I_T$. The transmitted intensity follows an Airy-function, which close to resonance resembles a Lorentzian,

$$\frac{I_T}{I} = \frac{1}{1 + R\beta^2/T^2} \tag{37.17}$$

or,

$$I = I_T \left[1 + (\beta_0 + \beta_2 I_T)^2 \, R/T^2\right] \ . \tag{37.18}$$

This expression gives the typical bistable curve.

37.1.4.2 Absorptive bistability

The *absorptive optical bistability* occurs upon bleaching of the medium. With $\alpha = \alpha_0/(1 + I_T)$,

$$\frac{I_T}{I} = \frac{1}{(1 + \alpha l/T)^2} \tag{37.19}$$

or,

$$I = I_T \left[1 + \frac{\alpha_0 l}{T(1 + I_T)}\right]^2 \ . \tag{37.20}$$

This expression gives the typical bistable curve.

37.1.5 Exercises

37.2 Quantum interference

We have seen earlier that a *dark resonance* in Λ-shaped three-level systems create superposition states between the two stable ground states which allow the adiabatic elimination of the excited state. Dark resonances may be understood as destructively interfering excitation paths at Raman-coherences between inneratomic transitions. Quantum interference is at the origin of various other phenomena which are discussed in the following sections.

37.2.1 Lasing without inversion

The question of the necessity of population inversion to construct a laser has been the subject of debates. Indeed, even an ordinary two-level system may exhibit gain with a small frequency interval [911] known as *Mollow gain*. Lasing without population inversion may also result from a splitting of emission and absorption spectra caused by atomic recoil as in the example of CARL [173].

Various schemes of a *laser without inversion* (LWI) have been proposed. Here is one of them [947]. We will discuss an example in Exc. 37.2.7.1.

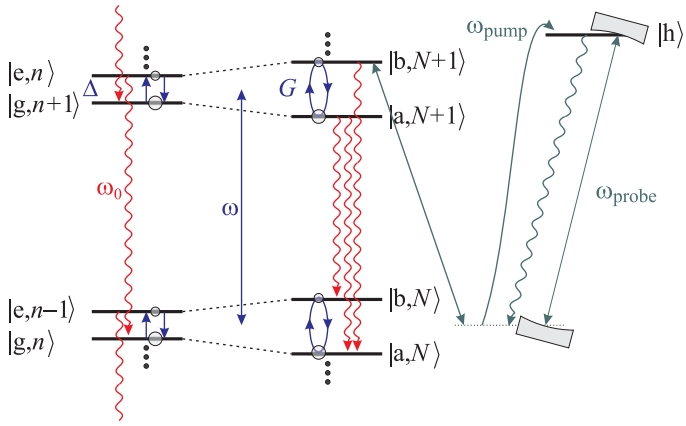

Figure 37.2: Dressed states level scheme for LWI. Quantum interference between two possible Raman transitions (green) leads to a cancellation of the ground state population. When the upper level $|h\rangle$ is incoherently pumped, gain can be reached for a weak probe field. Inserting the atoms in a cavity one can reach lasing [636].

37.2.2 Correlated spontaneous emission lasing

In a V-shaped three-level system in which the excited levels are coherently coupled, the spontaneous emission is correlated under certain circumstances. This feature may be used to suppress the relative noise beneath the shot noise limit and has triggered the idea of *correlated spontaneous emission* (CEL) lasing. The CEL is described by a complicated laser theory. Various simplifications allow to boil it down to an *Adler-Langevin equation* (this is similar to simplifying CARL into Kuramoto), describing the evolution of the phase difference $\theta \equiv \theta_1 - \theta_2$ between the lasers,

$$\frac{d\theta}{dt} = a - b\sin\theta + \xi_1(t) + \xi_2(t) \tag{37.21}$$
$$\langle \xi_k(t) \rangle = 0 \qquad \text{and} \qquad \langle \xi_k^\dagger(t)\xi_l(s) \rangle = 2D_{kl}\delta(t-s) \ ,$$

where a is the frequency difference and b the coupling constant.

For the case of purely additive noise $D_{k\neq l} = 0$ [1161], the equation is identical to the Kuramoto equations for two coupled oscillators, as shown in Sec. 42.6.4. This case which describes the *phase-locked laser* (PLL) is a Kuramoto system. The CEL in

contrast is defined by the fact that the noise is multiplicative (maximum correlation is obtained for $D_{11} + D_{22} = 2\mathfrak{Re}\ D_{12}$).

The fact that the laser coupling reduces the drift of $\theta(t)$ leading to a stationary value $\theta(\infty)$ is not necessarily due to CEL, but already occurs in Kuramoto systems. In fact phase-locking may occur independently from phase noise reduction. For interferometric purposes noise reduction without locking is preferable [1251].

37.2.2.1 Stochastic modulation peak

The random occurence of quantum jumps gives rise to a sharp Lorentzian peak called *stochastic resonance* on top of a fluorescence peak [594].

37.2.3 Superluminal group velocity

The *phase velocity* $v_{ph} = \omega/k$ of Fourier components of a light pulse is certainly not limited to the speed of light. But even the group velocity can, in highly non-dispersive media exceed the speed of light $v_g = d\omega/dk > c$, or even be negative. The *superluminal group velocity* without deformation of the pulse shape has been observed [762] via double-peaked Raman amplification. It has been argued that a properly defined *signal velocity* of signal transfer is limited by increased quantum noise to the subluminal regime, $v_s < c$.

37.2.4 Dark-state polaritons

We consider a gaseous medium made up of λ-shaped three-level system whose one transition is driven by a low-atomnumber photonic quantum field and the other by a classical laser. We define collective slowly-varying atomic operators, setup the Hamiltonian, write down the propagation equation for the optical field Heisenberg operators in the slowly-varying amplitude approximation and the Heisenberg-Langevin equation for the atomic evolution. If we assume very low photonnumbers in the optical quantum mode, and a rather slow variation of the classical mode Rabi frequency (perturbative and adiabatic approximation), we obtain simple equations describing the propagation of the light pulse and the atomic excitation. The canonical transformation to the bosonic quasi-particle quantum field allows the interpretation of the propagating perturbation in terms of the *dark-state polariton* [455]. This type of polaritons can be viewed as mixtures of photonic and Raman-like matter branches.

The propagation velocity depends on the classical control field, which should allow the slowing, stopping and reaccelerating of the light pulse [586, **?**], where we define the propagation velocity as $v_g = (d\mathcal{E}/dt)/(d\mathcal{E}/dz)$. This is achieved by mapping the shape of the light pulse, i.e. the photonic quantum correlations, to collective atomic (internal) (Raman) coherences. This does not require degeneracy of the external atomic states. We have seen the transfer of coherence between different types of degrees of freedoms earlier at the example of quantum collaps and revival in Jaynes-Cummings type couplings.

Unlike solitons polaritons are not shape-dependent. Look up analogy to excitons in solids !

Particularly interesting is the possible use of dark-state polaritons for creating non-classical atomic quantum states, entangling distant atomic samples, studying quan-

tum scattering in systems involving coherent cold collisions and investigating their impact collective excitations of the center-of-mass motion like solitons and vortices.

37.2.5 Brillouin scattering

Stimulated scattering of phonons is called *stimulated Brillouin scattering* (SBS). Like *Raman-scattering* (SRS) Brillouin-scattering is a limiting factor for the transmission efficiency in optical fibers. It is used in acousto-optic modulators (AOM). While SBS is based on the exchange of phonons between atoms bound in crystals, SRS is based on the exchange of phonons between atoms bound in molecules.

Raman-scattering (in a restricted historical sense) is very common technique of molecular spectroscopy. The process is Rayleigh-scattering at an electronic transition, but towards a different vibrational substate. Brillouin-scattering also involves the motional state of the scatterer, but its center-of-mass motion rather than some internal degree of freedom. It is also related to *polariton scattering* in solids, which produces optical phonons, rather than acoustic phonons.

If a strong electromagnetic field (pump laser) is irradiated into a medium (typically a crystal or a fluid) it produces a time-varying *electrostrictive strain*, which can be understood as the reaction force of particles dislocated from their equilibrium position. The strain is quantized into *phonons* and may drive a sound wave. This wave modulates the optical dielectric constant ε and thus create a periodic polarization $\vec{\mathcal{P}}$. This polarization may now interact with the incident electric field (pump laser $\omega_2, \mathbf{k}_2, \vec{\mathcal{E}}_2$). The resulting energy exchange can, under suitable circumstances, lead to simultaneous amplification of a probe wave $(\omega_2, \mathbf{k}_2, \vec{\mathcal{E}}_2)$ and a sound wave $(\omega_s, \mathbf{k}_s, u_s)$.

Let us consider a $1D$ geometry, $\mathbf{k}_j = k_j \hat{\mathbf{e}}_z$ and $\vec{\mathcal{E}}_j = \mathcal{E}_j \hat{\mathbf{e}}_x$. (More general geometries can be considered [1407]). The pump field $\mathcal{E}_2(t,z)$ causes a strain $\partial u_s/\partial z$ via longitudinal displacements $u_s(z,t)$ of test volumes. This strain produces a modulation of ε by $\delta\varepsilon = -\gamma \partial u_s/\partial z$, where γ is the strain coefficient (or coupling strength). The modulation of the dielectric constant $\delta\varepsilon$ now modulates the interaction energy $\delta U = -\frac{1}{2}\delta\varepsilon \mathcal{E}_2$, which exerts work $p\partial u_s/\partial z = \delta U$ against the pressure p. The pressure modulation creates a force $F = -\partial p/\partial z = \frac{1}{2}\gamma \partial \mathcal{E}_2^2/\partial z$. We can now set up a Fokker-Planck type force equation,

$$\rho \frac{\partial^2 u_s}{\partial t^2} = \frac{\gamma}{2}\frac{\partial \mathcal{E}_2^2}{\partial z} - \eta \frac{\partial u_s}{\partial t} + T \frac{\partial^2 u_s}{\partial z^2} \ , \tag{37.22}$$

where ρ is the mass density, T the elastic constant and η acoustic dissipation. $v_s \equiv \omega_s/k_s = \sqrt{T/\rho}$ is the free propagation velocity of sound. Simultaneously we know that the light wave propagates like,

$$\frac{\partial^2 \mathcal{E}_j}{\partial z^2} + \mu\varepsilon \frac{\partial^2 \mathcal{E}_j}{\partial t^2} + \mu \frac{\partial^2 \mathcal{P}_{NL,j}}{\partial t^2} \ . \tag{37.23}$$

We insert the ansatz $\mathcal{E}_j(t,z) = \frac{1}{2}\mathcal{E}_{0j}(z) e^{\imath(\omega_j t - k_j z)} + c.c.$ and $u_s(t,z) = \frac{1}{2} u_{0s}(z) e^{\imath(\omega_s t - k_s z)} + c.c.$ first into the above equations. We use the approximations $k_s^2 u_s \gg d^2 u_s/dz^2 \ll k_s du_s/dz$ and $|\partial(\mathcal{E}_2 \mathcal{E}_1^*)/\partial z| \ll |k_s \mathcal{E}_2 \mathcal{E}_1^*|$ and focus on the real parts. Assuming that the pump field $\mathcal{E}_2$ is undepleted, stimulated Brillouin-scattering is described by the

following set of equations,

$$\frac{d\mathcal{E}_1^*}{dz} = -\frac{\alpha}{2}\mathcal{E}_1^* - \frac{\gamma k_1 k_s}{4\varepsilon_1}\mathcal{E}_2^* u_s \qquad (37.24)$$
$$\frac{du_s}{dz} = -\frac{\eta}{2\rho v_s}u_s - \frac{\gamma}{8\rho v_s^2}\mathcal{E}_2\mathcal{E}_1^* \ .$$

Here ρ is the mass density, optical losses are described by α, and η is the dissipation constant for phonons. $\varepsilon_1 \approx \varepsilon_0$. The scattering satisfies the *Bragg condition* $\mathbf{k}_2 - \mathbf{k}_1 = \mathbf{k}_s$. The above equations describe *exponential gain* and *threshold behavior* for $\mathcal{E}_1$ and u_s. For backscattering $\mathbf{k}_1\mathbf{k}_2 = -k_1 k_2$ the rate of growth for the probe $\mathcal{E}_1$ is influenced by the values of $\mathcal{E}_1$ lying ahead in the direction $\mathbf{k}_1$. This is by virtue of the sound beam propagating in opposite direction to E_1 and provides the positive feedback being at the origin of exponential gain.

The equations are reminiscent to the CARL equations. The difference is the nature of the mediating force field: The CARL force is mediated by photons. The mediation is thus instantaneous. Photons do not require a medium in order to propagate. In contrast, the Brillouin-gain is mediated by phonons. Phonons propagate through a gas by collisions. Sound needs a medium to propagate. In dilute gases where CARL is observed, collisions are totally neglegible. Brillouin-scattering may lead to bunching, which propagates along $\mathbf{k}_s$. But similar to water waves, which do not transport the water molecules, the bunching does not lead to a net transport of atoms.

Just like CARL and the superradiant Rayleigh scattering in BECs SBS can be understood as being mediated by dipole-dipole interactions (i.e. the exchange of real or virtual photons between atoms). In a BECs SBS can be interpreted as phonon-like excitations (smaller momentum transfer) due to dipole-dipole interactions [514], while CARL are particle-like excitations due to dipole-dipole interactions (the nature of scattered particles changes from recoiling atoms to phonons). Note that while ultralow temperatures are necessary, these effects are not base on superfluidity, i.e. binary collisions. Thus the speed of sound is not the Bogolubov sound. The question is whether quantum degeneracy plays a role.

37.2.6 Selective reflection spectroscopy

The considered system is light at the interface of a dielectric and a gas phase. The gas may influence the reflection behavior of the light [165, 1206, 953, 1028], but the light may also influence the atomic excitation and motional state.

The range of interesting questions include: 1. The gas may absorb resonant light from an evanescent wave, it should be possible to image this. 2. Non-resonant light is phase-shifted by the gas and in the same time generates a dipole potential. Is it possible to do phase-contrast imaging. 3. Light force in near-fields: What is the force acting on atoms: $\mathbf{S}$ or $\mathbf{k}$? The response may be tested via the Goos-Hänchen shift.

The propagation direction of the phase fronts of a field $\arctan \frac{\Im\mathfrak{m}\ \mathcal{E}}{\Re\mathfrak{e}\ \mathcal{E}} = kz - \omega t$ may be different from the flux $\mathbf{S} = \vec{\mathcal{E}} \times \vec{\mathcal{B}}$. In the evanescent wave $\mathbf{k}$ is parallel to the surface [1233].

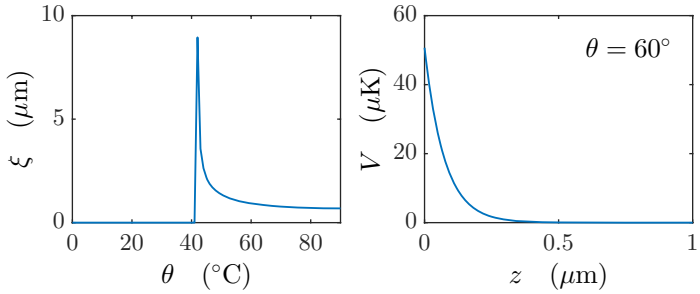

Figure 37.3: (code) Evanescent wave.

37.2.6.1 Fresnel's formulas

The reflected light comes from interference of reflection at the interface and the gas polarization [953]. The reflection at the interface is given by the Fresnel formulae, the response of the gas polarization is labeled S,

$$\vec{\mathcal{E}}_1(\mathbf{r}) = \mathcal{E}_0 \begin{pmatrix} \frac{2nb}{n\beta+b}\sin\phi \\ \frac{2nb}{nb+\beta} \\ -\frac{2nb}{n\beta+b}\cos\phi \end{pmatrix} \quad \text{and} \quad \vec{\mathcal{E}}_2(\mathbf{r}) = \mathcal{E}_0 \begin{pmatrix} \frac{n\beta-b}{n\beta+b}\sin\phi \\ \frac{nb-\beta}{nb+\beta} \\ -\frac{n\beta-b}{n\beta+b}\cos\phi \end{pmatrix} + S \begin{pmatrix} \frac{\beta^2-\alpha^2}{n\beta+b} \\ \frac{1}{nb+\beta} \\ \frac{\beta^2-\alpha^2}{n\beta+b} \end{pmatrix} . \tag{37.25}$$

For small angles of incidence ϕ (partial reflection, no evanescent wave) $\beta = \sqrt{1-n^2\sin^2\phi}$ is real. Then,

$$S = \frac{\imath k}{\epsilon_0}\int_0^\infty dz_0 e^{\imath\beta k z_0}\mathcal{P}_0(z_0) \ , \tag{37.26}$$

is the sum of the contributions of the polarizations at different places shifted by the displacement factor $e^{\imath\beta k z_0}$ away from the surface. In the evanescent case, S is the Laplace transform of the polarization at different phases kz_0 yields the spectrum of the response arising from different penetration depths $\imath\beta$.

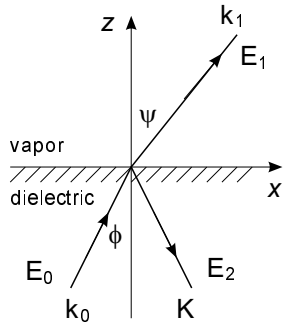

Figure 37.4: Selective reflection.

The polarization at a given location,

$$\frac{1}{\epsilon_0 \mathcal{E}_1}\mathcal{P}_0(z) = \frac{\hbar\Omega N}{I_1}\int d^3\mathbf{v} W(\mathbf{v}) e^{\imath\beta kz}\left[\theta(v_z)\sigma_+(\mathbf{v}, z/v_z) + \theta(-v_z)\bar{\sigma}_+(\mathbf{v})\right] \ . \quad (37.27)$$

The Maxwell-Boltzmann velocity distribution $W(\mathbf{v}) = \left(3/2\pi v_0^2\right)^{3/2} e^{-3\mathbf{v}^2/2v_0^2}$ is normalized, where mean velocity $v_0 = \sqrt{k_B T/m}$. The definition of the Laplace transform is,

$$\hat{\sigma}_+(\mathbf{v}, s) = \int_0^\infty dt e^{-st}\sigma_+(\mathbf{v}, t) \ . \quad (37.28)$$

Solution of two-level Bloch equations,

$$s\hat{\sigma}_+(\mathbf{v}, s) = \frac{\imath\Omega}{2}\frac{\imath\left(\Delta - \mathbf{kv}\right) + \gamma + s}{\left(\Delta - \mathbf{kv}\right)^2 + \frac{\gamma+s}{\Gamma+s}\Omega^2 + \left(\gamma + s\right)^2} \ . \quad (37.29)$$

The steady-state simply follows from $\bar{\sigma}_+(\mathbf{v}) = \lim_{s\to 0} s\hat{\sigma}_+(\mathbf{v}, s)$. We chose $\Gamma = (2\pi)6$ MHz and $\gamma = \frac{\Gamma}{2}$,

$$\frac{S}{\mathcal{E}_1} = -\frac{N\hbar\Omega}{2\beta I_1}\int d^3\mathbf{v} W(\mathbf{v})\left[\theta(v_z)(-2\imath\beta k v_z)\hat{\sigma}_+(\mathbf{v}, -2\imath\beta k v_z) + \theta(-v_z)\bar{\sigma}_+(\mathbf{v})\right] \ . \quad (37.30)$$

37.2.6.2 Gas of two-level atoms

Plugging in the solution of the Bloch equations,

$$\begin{aligned}\mathfrak{Re}\ \frac{S}{\mathcal{E}_1} = -\frac{N\hbar\Omega}{2\beta I_1}\left(\frac{3}{2\pi v_0^2}\right)^{3/2}\mathrm{Re}\int dv_x dv_y dv_z e^{-3v_x^2/2v_0^2} e^{-3v_y^2/2v_0^2} e^{-3v_z^2/2v_0^2}\times \quad (37.31)\\ \times\frac{\imath\Omega}{2}\left[\theta(v_z)\frac{\imath(\Delta - k_x v_x - k_y v_y - k_z v_z) + \gamma - 2\imath\beta k v_z}{(\Delta - k_x v_x - k_y v_y - k_z v_z)^2 + \frac{\gamma - 2\imath\beta k v_z}{\Gamma - 2\imath\beta k v_z}\Omega^2 + (\gamma - 2\imath\beta k v_z)^2}\right.\\ \left. + \theta(-v_z)\frac{\imath(\Delta - k_x v_x - k_y v_y - k_z v_z) + \gamma}{(\Delta - k_x v_x - k_y v_y - k_z v_z)^2 + \frac{\gamma}{\Gamma}\Omega^2 + \gamma^2}\right] \ .\end{aligned}$$

For normal incidence $k_x = k_y = 0$, $k_z = k$, and $\beta = 1$ and neglecting collisions $\gamma = \frac{1}{2}\Gamma$,

$$\begin{aligned}\mathfrak{Re}\ \frac{S}{\mathcal{E}_1} = -\frac{N\hbar\Omega^2}{4I_1}\left(\frac{3}{2\pi v_0^2}\right)^{1/2}\int dv_z e^{-3v_z^2/2v_0^2}\times \quad (37.32)\\ \times\ \mathfrak{Re}\left[\theta(v_z)\frac{-\Delta + 3kv_z + \frac{\imath}{2}\Gamma}{(\Delta - kv_z)^2 + \frac{\frac{1}{2}\Gamma - 2\imath\beta k v_z}{\Gamma - 2\imath\beta k v_z}\Omega^2 + \left(\frac{1}{2}\Gamma - 2\imath k v_z\right)^2}\right.\\ \left. +\theta(-v_z)\frac{-\Delta + kv_z + \frac{\imath}{2}\Gamma}{(\Delta - kv_z)^2 + \frac{1}{2}\Omega^2 + \gamma^2}\right] \ .\end{aligned}$$

Define a normalized function $\Phi = \frac{k^4 v_0}{NA}\mathrm{Re}\frac{S}{\mathcal{E}_1} = \frac{2\pi I_1 k v_0}{N\hbar\Omega^2}\mathrm{Re}\frac{S}{E_1}$,

$$\Phi = -\sqrt{\frac{3\pi}{8}}\int dk v_z e^{-3v_z^2/2v_0^2}\mathrm{Re}\left[\frac{\theta(v_z)\left(-\Delta+3kv_z+\frac{\imath}{2}\Gamma\right)}{(\Delta-kv_z)^2+\frac{\frac{1}{2}\Gamma-2\imath\beta k v_z}{\Gamma-2\imath\beta k v_z}\Omega^2+\left(\frac{1}{2}\Gamma-2\imath k v_z\right)^2}\right.$$
$$\left.+\frac{\theta(-v_z)\left(-\Delta+kv_z+\frac{\imath}{2}\Gamma\right)}{(\Delta-kv_z)^2+\frac{1}{2}\Omega^2+\gamma^2}\right] . \tag{37.33}$$

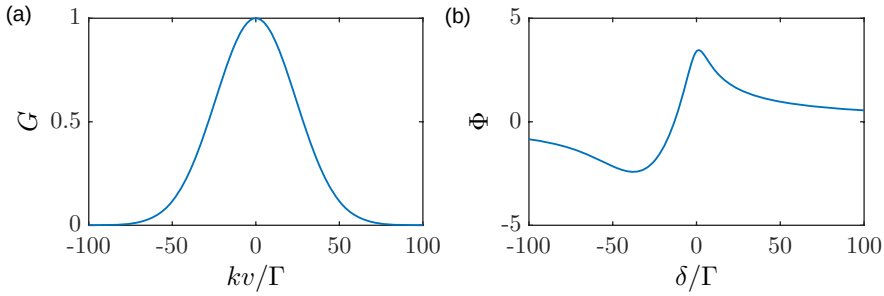

Figure 37.5: (code) Selective reflection profile.

37.2.6.3 Cold atoms

The vapor pressure of Rb at 100 C is $P = 1.5\times10^{-4}$ hPa. The density is then $n = p/k_BT = 3\times10^{18}\,\mathrm{m}^{-3}$. If there is no buffer gas the distance covered between two collisions is $\sqrt{k_BT/m}/\gamma_{coll} = 1/\sigma n = 1$ mm.

The atomic excitation reaches its steady-state value during a time on the order of $1/\Gamma$. In a thermal gas the distance covered by a thermal gas atom during this time is much larger than an optical wavelength, $\sqrt{k_BT/m}/\Gamma \approx 4$ μm. In contrast, if the atoms move less than a wavelength during this time, the Voigt theory of complex refraction index is recovered. In Eq. (37.30) we may set $kv_z = 0$,

$$\frac{S}{\mathcal{E}_1} = -\frac{N\hbar\Omega}{2\beta I_1}\int d^3\mathbf{v} W(\mathbf{v})\bar{\sigma}_+(\mathbf{v}) . \tag{37.34}$$

As long as $k\bar{v} \gg \Gamma$, the Voigt profile is dominated by temperature, the Lorentz profile $\bar{\sigma}_+$ can be approximated by a δ-distribution and the dependence on detuning is averaged out by the integral.

37.2.6.4 Ultracold atoms

At even lower temperatures, $k\bar{v} \ll \Gamma$, the Doppler width is narrower than the natural linewidth. E.g. at 1 μK the atom moves less than 0.3 nm during a radiative lifetime. Let us assume low velocities and far detunings $\Delta \gg \mathbf{kv}$, so that the internal dynamics does not depend much on atomic motion. Eq. (37.27) then reads,

$$\frac{1}{\epsilon_0\mathcal{E}_1}\mathcal{P}_0(z) = \frac{\hbar\Omega N}{I_1}\left(\frac{3}{2\pi v_0^2}\right)^{1/2} e^{\imath\beta kz}\int dv_z e^{-3v_z^2/2v_0^2}\bar{\sigma}_+(\mathbf{0}) . \tag{37.35}$$

If the atoms were immobile, they would all be in steady-state, regardless of their motion. Using,

$$\delta(x-x_0)=\lim_{\varepsilon\to 0}\frac{1}{\sqrt{\pi\varepsilon}}e^{-(x-x_0)^2/\varepsilon}\ , \tag{37.36}$$

Eq. (37.35) can be rewritten,

$$\frac{\mathcal{P}_0(z)}{\epsilon_0\mathcal{E}_1}=\frac{\hbar\Omega N}{I_1}e^{\imath\beta kz}\int dv_z\delta(v_z)\left[\theta(v_z)\sigma_+(\mathbf{0},z/v_z)+\theta(-v_z)\frac{\imath\Omega}{2}\frac{\imath\Delta+\gamma}{\Delta^2+\frac{1}{2}\Omega^2+\frac{1}{4}\Gamma^2}\right]\ . \tag{37.37}$$

Finally,

$$\frac{1}{\epsilon_0\mathcal{E}_1}\mathcal{P}_0(z)=\frac{\hbar\Omega N\bar{\sigma}_+}{I_1}e^{\imath\beta kz}\ . \tag{37.38}$$

Hence, for $z>v_zt_{ss}$ or $v_z<0$ there is no z-dependence. The only case when z dependence can occur is immediately after a collision, i.e. during the time $t_{ss}=2\pi/\sqrt{\Delta^2+\Omega^2}$ it takes to approach steady state. The distance v_0t_{ss} covered during this time is short. *The polarization is homogeneous without atomic motion.*

37.2.6.5 Crossed Kerr effect

The most interesting thing is the fact that matter wave phases are proportional to the light field intensity and the light phases to the matter wave intensity: $\delta\phi_\psi\propto\delta|\mathcal{E}|^2$ and $\delta\phi_\mathcal{E}\propto\delta|\psi|^2$. This leads to quantum nondemolition measurements [1033, 1034, 55, 304].

The question arises, why only a narrow region near the surface contributes to the selective reflection signal, and whether this fact gives rise to a dipole force. Let us first find out the reason for spatially inhomogeneous polarization near the surface.

Spatial dispersion only results from the symmetry-breaking effect of the wall on the atomic motion. Hence, we need to keep the atomic motion in consideration. Anyway, even if there were spatial dispersion leading to inhomogeneous density, is would be washed out by thermal motion quickly.

Looking at the selective reflection signal, the lineshape is approximately the derivative of a Gaussian distorted by an asymmetry, which disappears for lower temperatures. The width is on the order of the Doppler-width kv_0. As the temperature is reduced the lineshape narrows until it has becomes the derivative of a Lorentzian with the natural linewidth Γ, as predicted by formula (37.37).

The knackpoint is now using Eq. (37.26),

$$S=\mathcal{E}_1\frac{\hbar\Omega N}{2I_1}\int_0^\infty d(2\imath kz_0)\bar{\sigma}_+e^{2\imath\beta kz_0}=\mathcal{E}_1\frac{\hbar\Omega N}{2I_1}\bar{\sigma}_+\int_0^\infty dse^{-\beta s}=\mathcal{E}_1\frac{\hbar\Omega N}{2I_1}\bar{\sigma}_+\frac{1}{\beta}\ . \tag{37.39}$$

Substituting $s\equiv-2\imath kz_0$.

The question about the width of the contributing region is probably in the Laplace transform, which is known to exhibit memory-like behavior.

37.2.7 Exercises

37.2.7.1 Ex: Lasing without inversion

Explain the phenomenon of lasing without inversion in the dressed states picture for a V-type three-level system.

Chapter 38

Atomic motion in force fields

So far – and especially in Sec. 24.7.2– we analyzed the motion of quantum particles in potential landscapes without specifying the physical origin of the potentials. We know the *gravitational force*, which can be derived from the Earth's homogeneous attraction,

$$\mathbf{F} = -\nabla V_{grav} = -\nabla(mgz) = -gm\hat{\mathbf{e}}_z \ . \tag{38.1}$$

Another fundamental force comes from electromagnetism. We have already studied – mainly in Sec. 30.4– the reaction of the electronic shell in atoms subjected to applied electromagnetic fields.

In contrast, the present chapter is devoted to the motion of the *atomic center-of-mass* subject to forces resulting from interactions with *electromagnetic fields*. We will begin, in the first section, with electromagnetic forces of the Coulomb-Lorentz type acting on charges (e.g. ions), permanent electric dipoles (e.g. polar molecules), or permanent magnetic dipoles (e.g. paramagnetic atoms). Also, more complex situations will be discussed, such as the scattering of light by confined atoms, atoms interacting with optical cavities, and adiabatic potentials.

The second section will entirely be devoted to the forces exerted by light beams, in particular the *radiation pressure* and the *optical dipole force*, which are nowadays widely used in atomic cooling and trapping experiments. We will leave the issue of the application of these forces to Chp. 43 and concentrate here on the (semiclassical or quantum) derivation and the interpretation of the forces. In fact, to understand optical forces acting on atoms, we need to consider their internal degrees of freedom.

Apart from the degrees of freedom related to their center-of-mass motion (kinetic or potential energy), many quantum objects are endowed with internal degrees of freedom, for example, the motion of electrons inside atoms or molecules. In the simplest case, the Hamiltonian of such a system is composed of an outer part, comprising the kinetic and the potential energy, and an inner part counting for the excitation energy $\hbar\omega_0$ of an internal state $|e\rangle$,

$$\hat{H}_{atom} = \frac{\mathbf{p}^2}{2m} + V(\mathbf{r}) + \hbar\omega_0 |e\rangle\langle e| \ . \tag{38.2}$$

The time scale of the electronic motion is usually very rapid compared to the motion of the nucleus, where (almost) the entire mass of the atom is concentrated. Therefore, the external (nuclear) dynamics decouples from the internal (electronic) one, which allows the separation of the total wavefunction in two parts,

$$|\psi\rangle = |\psi\rangle_{ext}|\psi\rangle_{ele} \ , \tag{38.3}$$

where for a simple two-level atom, $|\psi(t)\rangle_{ele} = c_g(t)|g\rangle + c_e(t)|e\rangle$, with the atomic ground state $|g\rangle$ and the excited state $|e\rangle$. The external states are eigenstates of the momentum in the case of a free particle, $|\psi\rangle_{ext} = |\mathbf{p}\rangle$. For particles confined in a potential the external states are the vibrational eigenstates, $|\psi\rangle_{ext} = |n\rangle$. The temporal evolutions of the internal and external degrees of freedom are governed by independent Schrödinger equations. For cold atomic clouds the kinetic energy is much smaller than the excitation energy, which allows the separation of the energy scales. That is, the internal degrees of freedom are frozen in the ground state. Many phenomena, for example, Bose-Einstein condensation and the dynamics of condensates are described in this regime.

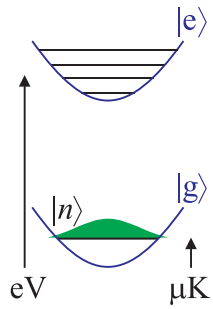

Figure 38.1: The internal degrees of freedom of cold atoms are thermally frozen.

Nevertheless, the fact that it is thermally frozen does not prevent the intentional excitation of the internal degree of freedom by irradiating electromagnetic fields tuned close to resonances and coupling electronic energy levels. In the case of coupling, the external and internal degrees of freedom must both be considered.

38.1 Electromagnetic forces

Obviously, in order to allow for forces acting on the atomic center-of-mass, the atomic Hamiltonian must contain terms depending on the center-of-mass coordinates:

$$\mathbf{F} = -\langle \nabla \hat{H}_{atom:field} \rangle \ . \tag{38.4}$$

We will see shortly that some of the terms may be dissipative, other conservative.

The impact of electromagnetic fields on the internal dynamics of atoms has already been studied in the Chp. 30. Here, we will focus on the force on the center-of-mass exerted by the gradient of *electromagnetic potentials*, where the Hamiltonian in Eq. (38.4) of a charge interacting with electromagnetic fields is obtained in minimum coupling (30.11) by,

$$\boxed{\hat{H}_{atom:field} = \frac{1}{2m}(-\imath\hbar\nabla - q\mathbf{A})^2 + q\Phi \simeq \frac{-\hbar^2}{2m}\nabla^2 + \frac{\imath\hbar q}{m}\mathbf{A}\cdot\nabla + q\Phi} \ . \tag{38.5}$$

From this formula we can, in principle, calculate all electromagnetic forces.

The coupling of external and internal degrees of freedom is mediated by the photonic recoil transferred to the atom during absorption and emission processes. That

is, the feature that the interaction with light simultaneously *excites* the atom and exerts a *force* couples the degrees of freedom. This fact manifests itself in the Hamiltonian of the atom interacting with a light field (35.17) by the appearance of terms joining operators acting on different degrees of freedom,

$$\hat{H} = \hbar\omega\hat{a}^\dagger\hat{a} + \hat{H}_{atom:field} + \hat{H}_{atom} \qquad (38.6)$$
$$\text{where} \qquad \hat{H}_{atom:field} = \hbar g(\hat{\mathbf{r}})e^{\imath\mathbf{k}\cdot\hat{\mathbf{r}}}\hat{a}^\dagger\hat{\sigma} + c.c. \ ,$$

where $\hat{\sigma} \equiv |g\rangle\langle e|$ and $\hat{a} \equiv \sum_n n|n\rangle\langle n+1|$ and $\hbar g(\hat{\mathbf{r}}) \equiv \mathbf{d}_{12}\cdot\vec{\mathcal{E}}_1(\hat{\mathbf{r}})$ is the coupling constant or one-photon *Rabi frequency* derived from (14.10). The Hamiltonian is that of the Jaynes-Cummings model, except that in addition to the field operators $\hat{a}$ and the atom transition operators $\hat{\sigma}$, appears an operator for the position of the atom $\hat{\mathbf{r}}$, whose quantum features we have not taken very seriously so far. It appears in the Rabi frequency and also in the term $e^{\imath\mathbf{k}\cdot\hat{\mathbf{r}}}$. Now, we must remember, that

$$U_{recoil} = e^{-\imath\mathbf{k}\cdot\hat{\mathbf{r}}} = |\mathbf{p}+\hbar\mathbf{k}\rangle\langle\mathbf{p}| \qquad (38.7)$$

is the unitary operator of the photonic recoil in the absorption process introduced in Sec. 23.5.3 and extensively discussed in Sec. 24.6.2. We shall shortly see, that it is precisely this term in the Hamiltonian that gives rise to all phenomena related to light forces on atoms.

The presence of the position operator in the Jaynes-Cummings Hamiltonian introduces a new degree of freedom. With no external potential (that is, the system is invariant to spatial translations), this degree of freedom is simply the atomic center-of-mass momentum, such that the new set of quantum numbers is $|j, n, \mathbf{p}\rangle$. Strictly speaking we have to span the whole Hilbert space by an external product, $\hat{H}_{ele} \otimes \hat{H}_{field} \otimes \hat{H}_{ext}$.

Often a *semi-classical* description treating the light field a classically is sufficient, $\hat{a} \simeq \sqrt{n}$ with n the number of photons. Then the Hamiltonian (38.6) simplifies to,

$$\hat{H}_{atom:field} = \hbar\Omega(\hat{\mathbf{r}})e^{\imath\mathbf{k}\cdot\hat{\mathbf{r}}}\hat{\sigma} + c.c. \ , \qquad (38.8)$$

with the Rabi frequency $\Omega(\mathbf{r}) = \sqrt{n}g(\mathbf{r})$.

38.1.1 Forces on charges and electric dipole moments

As shown in Eq. (30.8), the equations (38.4) and (38.5) (obviously) lead to Coulomb-Lorentz forces on charges and currents.

In atomic optics, the Coulomb-Lorentz force is used, for example, to accelerate or trap ions (see Sec. 43.5) and other electrically charged particles.

Atoms naturally do not exhibit *permanent electric dipole moments*, when they are not subject to external electric fields. In contrast, polar molecules (such as heteronuclear dimers), which have permanent electric dipole moments can have their motion be influenced by inhomogeneous electric fields (see Sec. 43.5.3).

38.1.2 Forces on magnetic dipole moments

Neutral atoms are insensitive to electric fields. But as we have already seen in Chp. 30, the orbital motion of the electrons corresponds to a circular current generating a permanent magnetic dipole moment $\vec{\mu}$, which can interact with external magnetic fields. We have already shown in the calculation (30.15) and (30.19) that the interaction energy (38.5) can be written as,

$$\hat{H}_{magn} = -\vec{\mu}_J \cdot \vec{\mathcal{B}} = -\frac{g_J \mu_B}{\hbar} \mathbf{J} \cdot \vec{\mathcal{B}} \longrightarrow -\frac{g_J \mu_B}{\hbar} |\mathbf{J}| \cdot |\vec{\mathcal{B}}| = -g_J \mu_B m_J \mathcal{B} \ , \tag{38.9}$$

where the *Landé factor* is given by the formula (30.21),

$$g_J = 1 + \frac{J(J+1) + S(S+1) - L(L+1)}{2J(J+1)} \ . \tag{38.10}$$

Here, $\mathbf{J} = \mathbf{L} + \mathbf{S}$ is the total angular momentum resulting from the coupling of the total angular orbital momentum and the total spin of all electrons. If the atom has a nuclear spin I other than zero, then $\mathbf{F} = \mathbf{J} + \mathbf{I}$ replaces $\mathbf{J}$ in Eq. (38.9), and the g-factor generalizes to (30.35) [1],

$$g_F \simeq g_J \frac{F(F+1) + J(J+1) - I(I+1)}{2F(F+1)} \ . \tag{38.11}$$

In Sec. 30.2 we used the formula (38.9) to calculate the Zeeman shift of internal energy levels. But, according to the formula (38.4), the interaction also generates a force acting on the center-of-mass of atom,

$$\boxed{\mathbf{f} = -g_F \mu_B m_F \nabla \mathcal{B}} \ . \tag{38.12}$$

In case of absence of hyperfine structure we simply replace F by J.

Obviously, force is conditioned by the existence of a gradient of the absolute value of the magnetic field. It was first used in the famous *Stern-Gerlach experiment*, which led to the discovery of the electron (see Sec. 25.3.3). In atomic optics (see Sec. 43.4), this force is widely used to create *magnetic traps* for cold atoms. Resolve the Excs. 30.2.8.2, 38.1.4.1, and 38.1.4.2.

38.1.3 Adiabatic potentials

Adiabatic potentials can be used to realize more complicated trapping geometries [299]. To study adiabatic potentials we consider the two-level system $|\frac{1}{2}, \frac{1}{2}\rangle \leftrightarrow |\frac{1}{2}, -\frac{1}{2}\rangle$ coupled by an incident radiation (e.g. a radiofrequency). A generalization to multilevel systems $F > \frac{1}{2}$ is simple. The dressed states Hamiltonian of our two-level system is a 2×2 matrix,

$$\hat{H}_{adiab}(z) = \begin{pmatrix} \frac{1}{2}\mu_B g_F \mathcal{B}(z) - \frac{1}{2}\hbar\omega & \frac{1}{2}\hbar\Omega \\ \frac{1}{2}\hbar\Omega & -\frac{1}{2}\mu_B g_F \mathcal{B}(z) + \frac{1}{2}\hbar\omega \end{pmatrix} \ . \tag{38.13}$$

[1] Note that the formula only applies to weak fields. For strong fields the Zeeman unfolding changes to the Paschen-Back unfolding of the hyperfine structure.

For simplicity, we assume a one-dimensional geometry, $\mathcal{B} = \mathcal{B}(z)$, but we can easily generalize to three dimensions. The eigenvalues of $\hat{H}$ are,

$$E_{\pm}(z) = \pm\tfrac{1}{2}\sqrt{\hbar^2\Omega^2 + \left[\mu_B g_F \mathcal{B}(z) - \hbar\omega\right]^2} \,. \tag{38.14}$$

Sufficiently far from resonance, $\hbar\Omega \ll |\mu_B g_F \mathcal{B}(z) - \hbar\omega|$, we obtain,

$$E_{\pm}(z) \simeq \pm\tfrac{1}{2}[\mu_B g_F \mathcal{B}(z) - \hbar\omega] \pm \frac{\hbar^2\Omega^2}{4[\mu_B g_F \mathcal{B}(z) - \hbar\omega]} \,, \tag{38.15}$$

where the second term can be interpreted as the dynamic Stark shift of the energy levels.

To illustrate the influence of the radiofrequency, we calculate the potential energy and the dressed states assuming a linear $1D$ magnetic field gradient $\mathcal{B}(z) \equiv zb$. Fig. 38.2(a) illustrates the radiofrequency coupling and Fig. 38.2(b) the dressed states for two magnetic substates coupled by a radiofrequency. The minimum emerging in

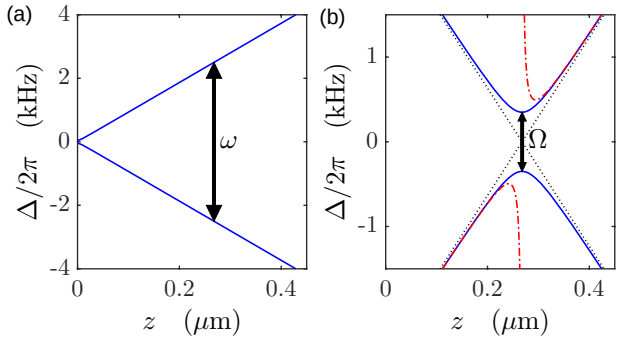

Figure 38.2: (code) (a) Potential energies for a hyperfine structure $F = \frac{1}{2}$ with a g-fator of $g = -\frac{2}{3}$ (as e.g. in the ground state ${}^2S_{1/2}$ of ^{6}Li). A radiofrequency (arrow) couples the substates $m_F = \pm\frac{1}{2}$. Here, $b = 200\,\mathrm{G/cm}$ and $\omega = 2\pi \times 5\,\mathrm{kHz}$. (b) Uncoupled dressed states (dotted line), coupled dressed states (solid line), and dynamic Stark shifts (dash-dotted) approximated far away from resonance. The Rabi frequency is $\Omega = 2\pi \times 700\,\mathrm{Hz}$.

the upper curve of Fig. 38.2(a) may serve as a confinement potential. Using an rf-radiation composed by several frequencies, potential minima can be realized at several distances z. In Exc. 38.1.4.3 we calculate an example.

In the dressed states basis with the Hamiltonian (38.13), the force is calculated from,

$$\mathbf{F}(\mathbf{r}) = \langle\hat{\mathbf{F}}(\mathbf{r})\rangle = -\mathrm{Tr}_{\,atom:laser}\,\hat{\rho}\nabla_{\mathbf{r}}\hat{H}_{adiab} = -\sum_{n,j}\langle n,j|\hat{\rho}\nabla_{\mathbf{r}}\hat{H}_{adiab}|j,n\rangle \,. \tag{38.16}$$

We consider only one dimension and disregard the degrees of freedom of the radiation field,

$$F(z) = -\mathrm{Tr}_{\,atom:laser}\,\hat{\rho}\partial_z\hat{H}_{adiab} \tag{38.17}$$
$$= -\sum_j \langle j|\hat{\rho}\partial_z\left(\tfrac{\mu_B g_F\mathcal{B}}{2}|1\rangle\langle 1| - \tfrac{\hbar\omega}{2}|1\rangle\langle 1| - \tfrac{\mu_B g_F\mathcal{B}}{2}|2\rangle\langle 2| + \tfrac{\hbar\omega}{2}|2\rangle\langle 2| + \tfrac{\hbar\Omega}{2}e^{\imath kz}\hat{\sigma}^+ + c.c.\right)|j\rangle \,.$$

Here we neglect any possible position dependence of Ω,

$$F(z) = -\tfrac{1}{2}\mu_B g_F \partial_z \mathcal{B} \sum_j \langle j|\hat{\rho}(|1\rangle\langle 1| - |2\rangle\langle 2|)|j\rangle = -\tfrac{1}{2}\mu_B g_F \partial_z \mathcal{B}(\rho_{11} - \rho_{22}) \ . \quad (38.18)$$

If the atoms enter the coupling area adiabatically, the populations of the adiabatic potentials will only depend on z. This is analogous to the *adiabatic transfer* via adiabatic sweeps or STIRAP pulse sequences. If the atoms are too fast, the populations also depend on history (i.e. the recent trajectory of the atoms), which can result in Landau-Zener transitions to other (possibly untrapped) states.

38.1.4 Exercises

38.1.4.1 Ex: The Stern-Gerlach effect

Consider initially motionless ^{87}Rb atoms trapped in a superposition of two the trappable Zeeman states $|F, m_F\rangle = |2, +2\rangle$ and $|1, -1\rangle$. Suddenly a magnetic gradient of $\partial_z \mathcal{B} = 100\,\mathrm{G/cm}$ is applied for 2 ms. Calculate the spatial separation of the atoms being in either one of the two states after 10 ms of ballistic expansion.

Solution: *We first need to calculate the Landé-factors for the states using $I = \frac{3}{2}$. From formulae (30.21) and (30.35) we get for the ground state $^2S_{1/2}$,*

$$g_J = 2 \qquad \textit{and} \qquad g_F = \begin{cases} -\frac{1}{2} & \textit{for} \quad F = 1 \\ +\frac{1}{2} & \textit{for} \quad F = 2 \end{cases} .$$

Hence, atoms in the state $|2, +2\rangle$ are accelerated by the force,

$$F = -\partial_z(-\mu_B g_F m_F \mathcal{B}) = \mu_B \partial_z \mathcal{B} \begin{cases} -\frac{1}{2}(-1) & \textit{for} \quad F = 1 \\ +\frac{1}{2}(2) & \textit{for} \quad F = 2 \end{cases} .$$

After $t_{frc} = 2$ ms the force has accelerated the atoms to a final velocity,

$$v = \frac{F}{m} t_{frc} \ ,$$

and after $t_{bll} = 10$ ms ballistic expansion the displacement is,

$$z = \frac{F}{2m} t_{frc} t_{bll} = 1.3\,\mathrm{mm} \begin{cases} \frac{1}{2} & \textit{for} \quad F = 1 \\ 1 & \textit{for} \quad F = 2 \end{cases} .$$

38.1.4.2 Ex: Potential for magnetic trapping

Invent a potential for magnetic confinement.

Solution: *The simplest example is, of course, the quadrupolar potential generated by a magnetic field produced by current-carrying coils in anti-Helmholtz configuration,*

$$\vec{\mathcal{B}} = \begin{pmatrix} x \\ y \\ -2z \end{pmatrix} \partial\mathcal{B} \ ,$$

yielding,

$$\mathcal{B} = \partial\mathcal{B}\sqrt{r^2 + 4z^2} \ .$$

Another example, is the Ioffe-Pritchard trap generated by a magnetic field such as,

$$\vec{\mathcal{B}} = \begin{pmatrix} x\partial\mathcal{B} \\ -y\partial\mathcal{B} \\ \mathcal{B}_0 + \alpha z^2 \end{pmatrix} \ .$$

This corresponds to a linear quadrupole along the z-axis superposed to a magnetic bottle along the same direction and yields,

$$\begin{aligned} |\mathbf{B}| &= \sqrt{x^2\partial\mathcal{B}^2 + y^2\partial\mathcal{B}^2 + (\mathcal{B}_0 + \alpha z^2)^2} \\ &\simeq \sqrt{\mathcal{B}_0^2 + r^2\partial\mathcal{B}^2 + 2\alpha\mathcal{B}_0 z^2} \simeq \mathcal{B}_0 + \frac{\partial B^2}{2B_0^2} r^2 + \frac{\alpha}{B_0} z^2 \ , \end{aligned}$$

for small enough field curvature α close to the center of the potential.

38.1.4.3 Ex: Adiabatic potentials

An *adiabatic potential* can be used to create more complicated trapping potentials [299]. To study these potentials we consider a system of two Zeeman states $m = \frac{1}{2}$ coupled by a radiofrequency radiation $\hbar\omega$. The dressed states Hamiltonian of our two-level system is a 2×2 matrix,

$$\hat{H} = \begin{pmatrix} \frac{1}{2}\mu_B\mathcal{B} - \frac{1}{2}\hbar\omega & \frac{1}{2}\hbar\Omega \\ \frac{1}{2}\hbar\Omega & -\frac{1}{2}\mu_B\mathcal{B} + \frac{1}{2}\hbar\omega \end{pmatrix} \ ,$$

defining the energetic zero in the middle between the states. Now, assume that the magnetic field grows linearly along the axis z, $\mathcal{B}(z) = z\partial_z\mathcal{B}$, where $\partial_z\mathcal{B}$ is the gradient. Also assume that the radiofrequency is tuned in resonance with the difference of the energies of the Zeeman states at some distance z_0 such that, $\hbar\omega = \mu_B z_0 \partial_z\mathcal{B}$.
a. Calculate the eigenenergies of the coupled system as a function of z.
b. Expands eigenenergies around the position z_0.
c. What would be the oscillation frequency of the trapped atoms inside the adiabatic potential?
d. Expands the eigenenergies in $\hbar\Omega$ for locations away from resonance.

Solution: *a. The eigenvalues of H are,*

$$E_{1,2}(z) = \pm\frac{1}{2}\sqrt{(\mu_B z\partial_z\mathcal{B} - \hbar\omega)^2 + \hbar^2\Omega^2} = \pm\frac{1}{2}\sqrt{(\mu_B\partial_z\mathcal{B})^2(z - z_0)^2 + \hbar^2\Omega^2} \ .$$

b. The expansion around z_0 gives,

$$E_{1,2}(z) = \pm\frac{1}{2}\left(\hbar\Omega + \frac{1}{2}\frac{(\mu_B\partial_z\mathcal{B})^2}{\hbar\Omega}(z-z_0)^2 + ...\right) .$$

c. We obtain a harmonic adiabatic potential,

$$E_{1,2}(z) = \frac{1}{2}\frac{(\mu_B\partial_z\mathcal{B})^2}{\hbar\Omega}(z-z_0)^2 = \frac{m}{2}\omega_{ho}^2(z-z_0)^2 ,$$

such that,

$$\omega_{ho} = \frac{\mu_B\partial_z\mathcal{B}}{\sqrt{m\hbar\Omega}}$$

is the oscillation frequency.
d. Sufficiently far away from resonance, $\hbar\Omega \ll |\mu_B\mathcal{B}(z) - \hbar\omega|$, we obtain

$$E_{1,2}(z) \approx \pm\frac{1}{2}\left[\mu_B z\partial_z\mathcal{B} - \hbar\omega\right] \pm \frac{\hbar^2\Omega^2}{4\left[\mu_B z\partial_z\mathcal{B} - \hbar\omega\right]} ,$$

where the second term can be interpreted as the dynamic Stark shift of the energy levels.
To illustrate the impact of the radiofrequency, we calculate the potential energy and the dressed states for ^6Li atoms. For simplicity, we assume a linear $1D$ magnetic field gradient $\mathcal{B}(z) \equiv zb$. Fig. 38.2(a) shows the radiofrequency coupling and Fig. 38.2(b) dressed states for two magnetic substates coupled by a radiofrequency.
Fig. 38.2(a) shows the potential energies for a level scheme $F = \frac{1}{2}$ with a g-factor of $g = -\frac{2}{3}$ (as in the case of the ground state $^2S_{1/2}$ of ^6Li). A radiofrequency (arrow) couples the substates $m_F = \pm\frac{1}{2}$. Here, $b = 200\,\mathrm{G/cm}$ and $\omega = 2\pi\times 5\,\mathrm{kHz}$. Fig. 38.2(b) shows the uncoupled dressed states (dotted line), the dressed states (solid line), and dynamic Stark shifts (dash-dotted) calculated in the approximation for far detuning. The Rabi frequency is $\Omega = 2\pi \times 700$ Hz. The minimum appearing on the upper curve of Fig. 38.2(a) may serve a confinement potentials. Using rf-radiation with several frequency components potential minima can be generated at various distances z.

38.2 Optical forces

Light carries momentum, and the scattering of light by an object produces a force on that object. Although these properties of light are direct consequences of Maxwell's classical theory of electromagnetism, they were only verified in 1933 by *Frisch*, who observed a very small transverse deviation ($3 \cdot 10^{-5}$ rad) of an atomic sodium beam exposed to the light of a lamp. With the invention of the laser, it became easier to observe the light's mechanical effects, because the more intense and highly directional laser light exerts much larger forces. Although these results sparked the interest in using light forces to control the motion of neutral atoms, the fundamental bases for understanding the physics of light forces were not developed before the late 1970s. Unequivocal experimental demonstrations of cooling and trapping of atoms were not performed before the mid-1980s. In this section we will discuss some fundamental

aspects of light forces. Practical schemes used to cool and trap neutral atoms will be presented in Secs. 43.2 and 43.3.

The light force acting on an atom can be of two types: a spontaneous dissipative force and a conservative dipole force. The spontaneous force arises from the recoil experienced by an atom when it absorbs or emits a quantum of light. As we saw in Sec. 22.2.6, when an atom scatters light, the resonant scattering cross section can be written as in Eq. (22.72), $\sigma_{0a} = \frac{g_2}{g_1}\frac{\lambda_0^2}{2\pi}$, where λ_0 is the resonant wavelength. In the optical region of the electromagnetic spectrum the wavelengths of light are of the order of several hundred nanometers, and the resonant cross sections for scattering become very large, ($\sim 10^{-9}\,\mathrm{cm}^2$). Each absorbed photon transfers a quantum of momentum $\hbar k$ to the atom in the direction of propagation. Spontaneous emission following an absorption process occurs in random directions and, hence, averaged over many absorption-emission cycles, it cancels to zero. Consequently, the total spontaneous force acts on the atom in the propagation direction of the light, as shown schematically in the diagram of Fig. 38.3. The saturated photon scattering rate via spontaneous emission (the reciprocal value of the excited state's lifetime) sets the upper limit for the magnitude of the force. This force is called *radiation pressure* force.

The *dipolar gradient force* can be easily understood by considering light as a classical wave. It is simply the time-averaged force resulting from the interaction of the transition dipole –induced by the oscillating electric field of the light– with the gradient of the electric field amplitude. The strength of this gradient can be controlled, e.g. by focusing the light beam. By tuning the optical frequency below or above an atomic transition, we can control the sign of the force acting on the atom: Tuning the light below resonance attracts the atom to the center of the light beam, tuning it above resonance repels it. The dipole force is a stimulated process without energy exchange between the field and the atom. Photons are absorbed in one light mode and reappear by stimulated emission in another one. However, conservation of momentum requires that the change in the propagation direction of the scattered photons from an initial mode to a final mode leaves the atom with a recoil. Contrary to spontaneous force, there is, in principle, no upper limit for the magnitude of the dipole force, since it is a function of the field gradient only and the detuning.

Within the theory of electromagnetism we calculate radiative forces on charges via *Maxwell's stress tensor* [2]. The interaction of radiation with atoms having internal degrees of freedom exhibiting resonances can be treated qualitatively by the *Lorentz model* [3].

In the following, we will show quantitative semi-classical and quantum calculations: The force of a light beam on an atom can be calculated in many different ways, each emphasizing a slightly different aspect: From the classical Lorentz force exerted on an atom by electromagnetic fields we can derive a semi-classical Fokker-Planck equation [1263]. In Sec. 38.2.1 we will derive the two contributions (dipole force and radiative pressure) within a semi-classical theory [526]. Wineland *et al.* [1382] chose as starting point the cross section for an elementary scattering process (Sec. 38.2.3).

[2] See script on *Electrodynamics* (2023), Sec. 6.2.3.
[3] See script on *Electrodynamics* (2023), Sec. 7.2.4.

Dalibard *et al.* [322] developed a quantum theory using the dressed states representation (Sec. 38.2.2). And Cirac *et al.* [265] showed an approach based on the master equation (Sec. 38.2.3).

38.2.1 The dipolar gradient force and the radiation pressure force

To compute the forces of light on an atom, we describe the atom as a two-level system: A fundamental level $|1\rangle$ and an excited level $|2\rangle$ decaying to the fundamental level with the rate Γ. The energy difference between the levels is $\omega_0 \equiv E_2 - E_1$. The light with frequency ω is derived from a laser beam, which can be detuned from the atomic transition, $\Delta \equiv \omega - \omega_0$. To describe the interaction, we consider the part (38.6) of the total Hamiltonian describing the interaction [322]. Using the semi-classical density operator $\hat{\rho}$ [4], we can calculate the force that the light field exerts on the atom,

$$\begin{aligned}\mathbf{F}(\mathbf{r}) = \langle\hat{\mathbf{F}}(\mathbf{r})\rangle &= -\mathrm{Tr}_{at}\ \hat{\rho}\nabla_{\mathbf{r}}\hat{H}_{atom:field} \\ &= -\tfrac{1}{2}\hbar\sum\nolimits_j \langle j|\hat{\rho}|\nabla_{\mathbf{r}}\left(\Omega(\mathbf{r})e^{\imath\mathbf{k}\cdot\mathbf{r}-\imath\Delta t}|2\rangle\langle 1| + \Omega(\mathbf{r})e^{-\imath\mathbf{k}\mathbf{r}+\imath\Delta t}|1\rangle\langle 2|\right)|j\rangle \\ &= -\tfrac{1}{2}\hbar\nabla_{\mathbf{r}}\Omega(\mathbf{r})\left(\langle 1|\hat{\rho}e^{\imath\mathbf{k}\cdot\mathbf{r}-\imath\Delta t}|2\rangle + \langle 2|\hat{\rho}e^{-\imath\mathbf{k}\cdot\mathbf{r}+\imath\Delta t}|1\rangle\right) \\ &\quad - \tfrac{\imath}{2}\hbar\mathbf{k}\Omega(\mathbf{r})\left(\langle 1|\hat{\rho}e^{\imath\mathbf{k}\cdot\mathbf{r}-\imath\Delta t}|2\rangle - \langle 2|\hat{\rho}e^{-\imath\mathbf{k}\cdot\mathbf{r}+\imath\Delta t}|1\rangle\right)\ .\end{aligned} \tag{38.19}$$

Now, we let the atom be at the position $\mathbf{r} = 0$,

$$\mathbf{F}(\mathbf{0}) = -\tfrac{1}{2}\hbar\nabla_{\mathbf{r}}\Omega(\mathbf{0})(\rho_{12}e^{-\imath\Delta t} + \rho_{21}e^{\imath\Delta t}) - \tfrac{\imath}{2}\hbar\mathbf{k}\Omega(\mathbf{0})(\rho_{12}e^{-\imath\Delta t} - \rho_{21}e^{\imath\Delta t})\ . \tag{38.20}$$

The quantities $\rho_{12} \equiv \langle 1|\hat{\rho}|2\rangle = \rho_{21}^*$ are the coherences, which develop in a two-level system excited by a laser beam. Inserting the stationary solutions of the Bloch equations (34.188),

$$\rho_{22} = \frac{\Omega^2}{4\Delta^2 + 2\Omega^2 + \Gamma^2} \qquad \text{and} \qquad \rho_{12} = \frac{(2\Delta - \imath\Gamma)\Omega}{4\Delta^2 + 2\Omega^2 + \Gamma^2}e^{-\imath\Delta t}\ . \tag{38.21}$$

we obtain

$$\mathbf{F}(\mathbf{0}) = -\tfrac{1}{2}\hbar\frac{4\Delta\Omega}{4\Delta^2 + 2\Omega^2 + \Gamma^2}\nabla_{\mathbf{r}}\Omega + \hbar\mathbf{k}\frac{\Gamma\Omega^2}{4\Delta^2 + 2\Omega^2 + \Gamma^2}\ . \tag{38.22}$$

With the definition of the cross section, $\sigma_a(\Delta) = \sigma_{a0}\frac{\Gamma^2}{4\Delta^2+2\Omega^2+\Gamma^2}$,

$$\mathbf{F}(\mathbf{0}) = -\tfrac{1}{2}\hbar\Delta\nabla_{\mathbf{r}}\ln\left(1 + \frac{2\Omega^2}{4\Delta^2 + \Gamma^2}\right) + \hbar\mathbf{k}\frac{\Omega^2}{\Gamma}\frac{\sigma_a(\Delta)}{\sigma_{a0}}\ . \tag{38.23}$$

The resonant cross section for a 'classical' transition is $\sigma_{a0} = 3\lambda^2/2\pi$.

Apparently, the force comprises two contributions. The *dipolar gradient force* can be derived from a potential. It is proportional to the intensity gradient and can

[4] Treating the motional and the optical degrees of freedom as classical the density operator only contains the atomic excitation.

be interpreted as resulting from absorption processes immediately followed by self-stimulated emission. Near resonance it is dispersive. Far from resonance it can be approximated by,

$$\boxed{\mathbf{F}_{dp} = \nabla_{\mathbf{r}} \frac{-\hbar\Delta\Omega^2}{4\Delta^2+\Gamma^2} \overset{|\Delta|\gg\Gamma}{\longrightarrow} -\nabla_{\mathbf{r}} \frac{\hbar\Omega^2}{4\Delta}} \ . \tag{38.24}$$

The *radiation pressure* force is dissipative. Close to resonance it is absorbing. It is proportional to the phase gradient and the only force exerted by plane waves. It can be interpreted as resulting from absorption processes followed by spontaneous emission. With $\Omega^2 = \sigma_{a0}\Gamma I/\hbar\omega$ we get a formula,

$$\boxed{\mathbf{F}_{rp} = \hbar\mathbf{k}\frac{I}{\hbar\omega}\sigma_a(\Delta) = \hbar\mathbf{k}\gamma_{sct}} \ , \tag{38.25}$$

which describes the force as a product of the number of photons in the incident beam, $I/\hbar\omega$, the absorption cross section, $\sigma_a(\Delta)$, and the recoil momentum per photon, $\hbar k$. γ_{sct} is the scattering rate. Fig. 38.3(a) illustrates the radiation pressure force.

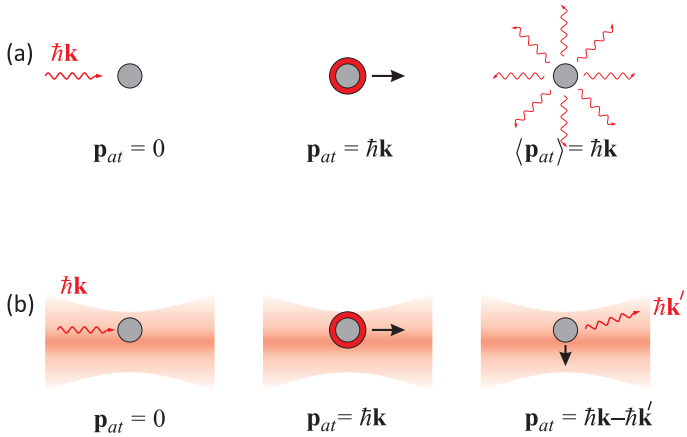

Figure 38.3: (a) Upon absorption of a photon an initially resting atom receives a recoil momentum kick $\hbar k_L$. As the re-emission is isotropic, averaged over many absorption-emission cycles, the net force is only given by the absorption process. (b) The dipole force may be interpreted as a coherent redistribution of photons between spatial modes of a focused light beam.

The dipole gradient force (and the associated potential) is often used to spatially confine atoms, and the radiation pressure force is often used to cool them down. Note that we still need to correct Eqs. (38.24) and (38.25) to take into account the square of the average over the possible spatial orientations of the transition matrix element $d_{12}/3$. As illustrated in Fig. 38.3(b), the dipole force may be interpreted as being due to coherent redistribution of photons between partial spatial modes of a non-uniform (e.g. focused) light beam. The orientation of the force depends on the sign of the detuning and can be understood in terms of the Lorentz model treating the atom as classical radiator (see Sec. 18.2.4).

The saturation parameter,

$$s = \frac{\frac{1}{2}\Omega^2}{\Delta^2 + \frac{1}{4}\Gamma^2} \ , \tag{38.26}$$

allows to write the dipolar gradient force and the radiative pressure force as,

$$\mathbf{F}_{dp} = -\frac{\hbar\Delta}{6}\frac{1}{1+s}\nabla s = \frac{\hbar\Delta}{6}\nabla \ln[1+s] \quad \text{and} \quad \mathbf{F}_{rp} = \frac{\hbar\mathbf{k}\Gamma}{6}\frac{s}{1+s} \ . \tag{38.27}$$

Eq. (38.27) shows that the radiation pressure force 'saturates' as s increases, and is therefore limited by the spontaneous emission rate. The saturation parameter essentially describes the relative importance of terms appearing in the denominator of the line profile function for the light forces. The spontaneous emission rate is an intrinsic property of the atom, proportional to the square of the atomic transition dipole moment, whereas the square of the Rabi frequency is a function of the incident laser intensity. If $s \ll 1$, the spontaneous emission is fast compared to any stimulated process, and the light field is said to be weak. If $s \gg 1$, the Rabi oscillation is fast compared to spontaneous emission and the field is considered as strong. The line profile factor indicates a 'power broadening' by saturation of a factor of $\sqrt{2}$. Note that the dipolar gradient force and potential, Eqs. (38.27), do not saturate when the intensity of the light field is increased. Usually $\mathbf{F}_{dp}$ and U_{dp} are used to manipulate and trap atoms in a laser beam tuned far away from resonance in order to avoid absorption.

Often, the transition moment can be oriented using circularly polarized light. In this case, all previous expressions for $\mathbf{F}_{dp}$, $\mathbf{F}_{rp}$, and U_{dp} should be multiplied by 3. From now on we will abandon the average over the orientations and only use d_{12}^2 for the square of the transition dipole moment. Solve Excs. 38.2.5.1 and 38.2.5.2.

38.2.2 Semiclassical calculation of dipole force and radiative pressure

In quantum mechanics we calculate the force from the Heisenberg equation [526],

$$\hat{\mathbf{F}} = \frac{d}{dt}\hat{\mathbf{p}} = \frac{\imath}{\hbar}[\hat{H}, \hat{\mathbf{p}}] = -\nabla_{\mathbf{r}}\hat{H}_{atom:field} \ . \tag{38.28}$$

Thus, the force is given by the gradient of the interaction energy between the atom and the light field. Within the dipole approximation the interaction energy is given by $\mathbf{d}\cdot\vec{\mathcal{E}}(\mathbf{r})$. The force is now,

$$\begin{aligned}\mathbf{F}(\mathbf{r}) = \langle\hat{\mathbf{F}}(\mathbf{r})\rangle = \langle\nabla_{\mathbf{r}}[\mathbf{d}\cdot\vec{\mathcal{E}}(\mathbf{r})]\rangle = \langle(\mathbf{d}\cdot\nabla_{\mathbf{r}})\vec{\mathcal{E}}(\mathbf{r})\rangle - \langle\mathbf{d}\times(\nabla_{\mathbf{r}}\times\vec{\mathcal{E}}(\mathbf{r}))\rangle \\ \equiv \mathbf{F}_C(\mathbf{r}) + \mathbf{F}_L(\mathbf{r}) \ .\end{aligned} \tag{38.29}$$

The first contribution can be interpreted as the Coulomb force acting on the electron performing rapid oscillations at the position $\mathbf{r}(t) = \mathbf{r}_0 + e^{-1}\vec{\mathcal{P}}(\mathbf{r}_0, t)$. The second term is the time-averaged Lorentz force acting on the oscillating electric dipolar moment [604, 607, 605],

$$\mathbf{F}_C = e\langle\vec{\mathcal{E}}\rangle \quad \text{and} \quad \mathbf{F}_L = -\langle\mathbf{d}\times\partial_t\vec{\mathcal{B}}\rangle = \langle\partial_t\mathbf{d}\times\vec{\mathcal{B}}\rangle \ . \tag{38.30}$$

The relation between the light-induced electric dipole moment and the polarizability, $\mathbf{d} = \alpha(\vec{\mathcal{E}})\vec{\mathcal{E}}$, where $\alpha_{\nu\nu} \equiv \alpha_\nu + \imath\beta_\nu$ and $\mathcal{E}_\nu \equiv \sqrt{I_\nu}e^{\imath\psi_\nu}$, becomes,

$$\mathbf{F} = \sum_{\nu=1}^{3} \alpha_\nu \nabla I_\nu + 2\sum_{\nu=1}^{3} \beta_\nu I_\nu \nabla\psi_\nu \ . \tag{38.31}$$

38.2.3 Force exerted by a quantized radiation field

Photons carry one unit of momentum $\mathbf{p} = \hbar\mathbf{k}$, which they transfer to the atom during an absorption or emission process. That is, the light exerts a recoil on the atoms. Spontaneous emission couples to all radiative modes of the electromagnetic vacuum, $\hat{H}_{cm:vacuum} = \sum_j \hat{H}_{cm:laser}(\mathbf{k}_j)$. We can trace over these variables and only keep those of the atom and the laser. Following Cirac *et al.* [1382, 265], the randomness of the recoil by spontaneous emission is accounted for by,

$$\hat{\rho} \to \int_{4\pi\mathbb{R}^2} S(\mathbf{r}) e^{\imath\mathbf{k}\cdot\mathbf{r}} \hat{\rho} e^{-\imath\mathbf{k}\cdot\mathbf{r}} d\Omega \ , \tag{38.32}$$

such that the *Lindblad operator* becomes,

$$\begin{aligned} \mathcal{L}_{atom}\hat{\rho} &= -\Gamma\{\hat{\sigma}^\dagger\hat{\sigma}\hat{\rho}(t) - \tfrac{3}{4\pi}\int S(\mathbf{r}) e^{\imath\mathbf{k}\cdot\mathbf{r}}\hat{\sigma}\hat{\rho}(t)\hat{\sigma}^\dagger e^{-\imath\mathbf{k}\cdot\mathbf{r}} d\Omega + \hat{\rho}(t)\hat{\sigma}^\dagger\hat{\sigma}\} \\ \mathcal{L}_{cavity}\hat{\rho} &= -\kappa\{\hat{a}^\dagger\hat{a}\hat{\rho}(t) - 2\hat{a}\rho(t)\hat{a}^\dagger + \hat{\rho}(t)\hat{a}^\dagger\hat{a}\} \ , \end{aligned} \tag{38.33}$$

where $e^{\pm\imath\mathbf{k}\cdot\mathbf{r}} = \sum_{\mathbf{p}} |\mathbf{p} \mp \imath\mathbf{k}\cdot\mathbf{r}\rangle\langle\mathbf{p}|$ and $S(\mathbf{r}) = \frac{1}{2}\left(1 + (\frac{\mathbf{k}\cdot\mathbf{r}}{kr})^2\right)$ and $d\Omega = d\varphi d\cos\vartheta$. From this they calculate the force and establish a *Fokker-Planck equation* for the *Wigner function*.

38.2.4 Refraction of atoms by light and of light by atoms

Non-resonant light acts on the external degrees of freedom of atoms by a *phase shift of the Broglie wave*, $\exp\left[\imath\hbar^{-1}\int U(\mathbf{r},t)dt\right]$, and simultaneously on the internal degrees of freedom by a *dynamic Stark shift* or *light shift* of the energy levels by the value of $U(\mathbf{r})$. The Bloch vector defined by,

$$\rho \equiv \begin{pmatrix} \frac{1}{\sqrt{2}} c_g c_e^* \\ \frac{1}{\sqrt{2}} c_g^* c_e \\ |c_e|^2 - |c_g|^2 \end{pmatrix} \tag{38.34}$$

describes, under the influence of the dispersive interaction, a precession around the polar axis. This was discussed in Exc. 34.8.4.9. The Stark shift causes a rotation of $\hbar^{-1}U(\mathbf{r})t$. Simultaneously, the atom is subjected to a force, which corresponds to the gradient of the potential $-\nabla U(\mathbf{r})$, as illustrated in Fig. 38.4(a). We see that the phase shifts of the Broglie wave and the Bloch vector are equal. Finally, the light mode phase is also shifted by the same amount in an effect called *refraction*. That is, the internal, external, and optical degrees of freedom are entangled.

This fact has a practical use in atomic interferometers, because it is often easier to detect an interference of internal excitation states rather than of Broglie waves.

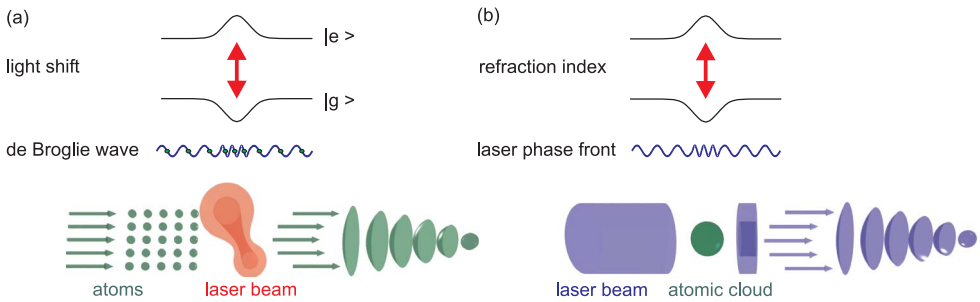

Figure 38.4: Diagram (a) shows product states and dressed states for blue detuning. Note that the population is in the upper level and that the atom is subject to a repulsive weak field seeking force when it enters the laser beam. Diagram (b) is similar, but for red detuning. The population is in the lower level and the atom is subject to an attractive high field seeking force.

Because of the entanglement, it is sufficient to measure *one* interference pattern to know the *other one*.

By local variations of the potential $U(\mathbf{r})$, e.g. induced by a focused laser beam, it is possible to manipulate a Broglie wavefront in the same way that, in classical optics, we manipulate the wavefront of a light beam by lenses or other objects, such as for instance, the refractive index represented by an atomic cloud near resonance, as illustrated in Fig. 38.4(b).

The orientation of the force depends on the light frequency as compared to the resonant frequency. The dipolar force attracts the atom to regions where the light field is strong, when the frequency is tuned below ω_0, and it attracts the atom to regions of weak fields, when tuned above ω_0. Integration over the relevant spatial coordinates results in an effective potential or barrier to the atom. The qualitative behavior of the dipolar potential and its effect on the motion of atoms is easily visualized in the dressed states picture. Fig. 38.5 shows what happens when an atom enters a well defined region of an optical field, for example a focused laser beam.

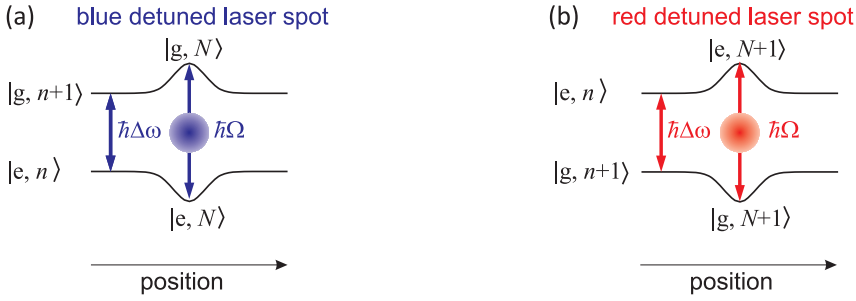

Figure 38.5: Analogy between light optics and atomic optics.

Outside the atom-dipole coupling zone the expression $\hbar\Omega$ is despicable and the 'dressed states' are just the atom-field product states. When the atom enters the

field, this expression becomes nonzero and the atom-field states combine to produce a set of dressed states. The energy levels of the product states 'repel' each other and approach the dressed states levels. Assuming that the laser is sufficiently detuned to maintain the absorption rate negligible, the population remains in the ground state. We see that blue (red) detuning leads to a repulsive (attractive) potential for atoms remaining in the grounded state. In addition, since $\hbar\Omega$ is directly proportional to the root of the laser intensity, an increase in that intensity (optical power per unit area) obviously amplifies the force on the atom ($\mathbf{F} \simeq \nabla_R \Omega$).

38.2.5 Exercises

38.2.5.1 Ex: Dipole force for large detunings

Verify that in the limit of large detunings the dipole potential Eq. (38.23) tends to $\longrightarrow \frac{\Omega^2}{4\Delta}$.

Solution:

38.2.5.2 Ex: Radiation pressure

Calculate the radiation pressure force exerted on a strontium atom by a laser beam in plane wave geometry ($I = 10\,\mathrm{mW/cm^2}$) tuned 50 MHz below the resonance at 461 nm ($\Gamma/2\pi = 30.5\,\mathrm{MHz}$).

Solution: *The force is,*

$$F = \hbar k \frac{\Gamma}{2} \frac{I/I_s}{1 + I/I_s} \simeq \hbar k \frac{\Gamma}{2} \approx 1.3 \cdot 10^{-19}\,\mathrm{N} \ ,$$

because the saturation intensity,

$$I_s = \frac{2\pi^2 c\hbar\Gamma}{3\lambda^3} \approx 38.6\,\mathrm{mW/cm^2} \ ,$$

is much higher than the intensity I of the laser beam. The acceleration becomes $a = F/m \approx 10^5 g$.

38.2.5.3 Ex: lin-lin standing wave

Calculate the electric field of two counter-propagating linearly polarized laser beams of equal intensities,

$$\vec{\mathcal{E}}_{lat}(\mathbf{r}, t) = \tfrac{1}{2} \sum_{\mathbf{k}=\pm k\hat{\mathbf{e}}_z} \mathcal{E}_0 \vec{\varepsilon}_{\mathbf{k}} e^{\imath(\mathbf{k}\cdot\mathbf{r} - \omega_{\mathbf{k}} t + \phi_{\mathbf{k}})} + c.c. \ ,$$

but different polariztions in the spherical basis.

Solution: *The spherical basis is defined by,*

$$\hat{\mathbf{e}}_{\pm 1} = \tfrac{1}{\sqrt{2}}(\mp\hat{\mathbf{e}}_x - \imath\hat{\mathbf{e}}_y) \quad , \quad \hat{\mathbf{e}}_0 = \hat{\mathbf{e}}_z \quad , \quad \hat{\mathbf{e}}_x = \tfrac{1}{\sqrt{2}}(\hat{\mathbf{e}}_{-1} - \hat{\mathbf{e}}_1) \quad , \quad \hat{\mathbf{e}}_y = \tfrac{\imath}{\sqrt{2}}(\hat{\mathbf{e}}_1 + \hat{\mathbf{e}}_{-1}) \ .$$

Hence, we get (focussing only on the $e^{-\imath\omega_{\mathbf{k}}t}$ terms),

$$\begin{aligned}\vec{\mathcal{E}}_{lat}(\mathbf{r}) &= \mathcal{E}_0 \begin{pmatrix}1\\0\\0\end{pmatrix} e^{\imath kz} + \mathcal{E}_0 \begin{pmatrix}\cos\theta\\ \sin\theta\\ 0\end{pmatrix} e^{-\imath kz} \\ &= \mathcal{E}_0 \left(e^{\imath kz} + \tfrac{e^{\imath\theta}+e^{-\imath\theta}}{2} e^{-\imath kz}\right)\hat{\mathbf{e}}_x + \mathcal{E}_0 \tfrac{e^{\imath\theta}-e^{-\imath\theta}}{2\imath} e^{-\imath kz}\hat{\mathbf{e}}_y \\ &= \tfrac{\mathcal{E}_0}{\sqrt{2}}\left[-(e^{\imath kz}+e^{-\imath kz-\imath\theta})\hat{\mathbf{e}}_1 + (e^{\imath kz}+e^{-\imath kz+\imath\theta})\hat{\mathbf{e}}_{-1}\right] \\ &= \sqrt{2}\mathcal{E}_0\left[-e^{-\imath\theta/2}\cos(kz+\tfrac{\theta}{2})\hat{\mathbf{e}}_1 + e^{\imath\theta/2}\cos(kz-\tfrac{\theta}{2})\hat{\mathbf{e}}_{-1}\right] .\end{aligned}$$

38.2.5.4 Ex: Sub-lattices

Consider two laser standing wave laser beams crossing each other under an angle of 90°,

$$\vec{\mathcal{E}}_1 = \vec{\varepsilon}_1 e^{\imath(kx-\omega t)} \qquad \text{and} \qquad \vec{\mathcal{E}}_2 = \vec{\varepsilon}_2 e^{\imath(ky-\omega t)} ,$$

with arbitrary elliptical polarizations $\vec{\varepsilon}_i$ and study the scalar light-shift potential,

$$U_s = -\frac{\alpha_s}{4}|\vec{\mathcal{E}}|^2 ,$$

as well as the vector light-shift potential,

$$U_v = \vec{\mathcal{B}}_{eff}\cdot\mathbf{F} \qquad \text{where} \qquad \vec{\mathcal{B}}_{eff} = \imath\alpha_v\vec{\varepsilon}^{*}\times\vec{\varepsilon}$$

in the xy-plane. α_v is the vector part of the atomic polarizability and $\vec{\mathcal{B}}_{eff}$ an effective magnetic field [362, 783, 28].

Solution: *See the figure 38.6.*

38.3 Photonic recoil on free and confined atoms

A trap confining the atomic motion can dramatically modify the way in which they interact with light [5]. For instance, a trapping potential may alter the scattering rate, the scattering angle, and the transfer of photonic recoil. However, *potentials do not exist* in microscopic reality, not more than friction forces do. What exists, as we learn in electrodynamics, are *electromagnetic fields* exerting Coulomb and Lorentz forces. When we write down the Hamiltonian $\hat{H} = \mathbf{p}^2/2m + V(\mathbf{r})$ in quantum mechanics, we already make an important approximation, because the potential $V(\mathbf{r})$ is an artifact obtained by tracing over all those degrees of freedom, which are necessary to generate a force field that can be approximated by a conservative potential.

[5] The interaction also depends on other parameters, such as the geometry of the confinement potential and on cooperative effects (bosonic stimulation), but this will be discussed later.

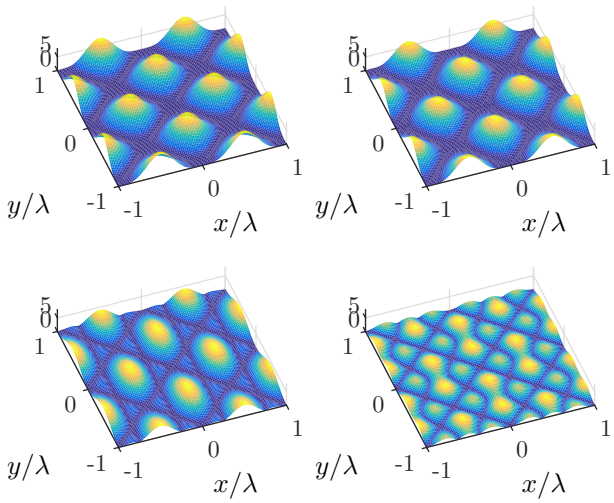

Figure 38.6: (code) Lattice potential for different polarizations.

In the great majority of situations, the approximation is very good. Problems may however arise, when the momentum conservation comes into play, which is the case e.g. of light scattering from ultracold atoms being accelerated by the photonic recoil and shifting the scattered light via the Doppler effect. We then have to address the issue of photonic recoil conserving (or not) the momentum.

Let us begin with a recapitulation of the classical picture of the scattering process applying the rules of energy and momentum conservation to the elastic collision between a free atom and a photon. This process is known as *Compton scattering*.

38.3.1 Recoil- and Doppler-shift in classical mechanics

In classical mechanics we speak of *elastic scattering* when no energy is transferred to internal degrees of freedom of the collision partners, so that *kinetic* energy and momentum stay conserved. This concept can be transferred to quantum particles (e.g. atoms) and photons. In elastic Compton scattering, if the atoms keep their initial internal excitation, the law of momentum conservation requires the transfer of photonic momentum to the scattering atom which, consequently, changes its kinetic energy. To compensate for this kinetic energy change, the frequency of the scattered light must change in order to preserve the total energy, as illustrated in Fig. 38.7(b).

We will calculate in the following the frequency distribution of the light scattered by an atom as a function of its initial velocity $\mathbf{p}_1$, of the frequency ω_1 of the incident light and of the scattering angle, that is, the angle between the modes $\mathbf{k}_1$ and $\mathbf{k}_2$. We begin by writing the laws of conservation of energy and momentum,

$$\begin{aligned} \hbar\mathbf{k}_1 + \mathbf{p}_1 &= \hbar\mathbf{k}_2 + \mathbf{p}_2 \\ \hbar\omega_1 + \frac{p_1^2}{2m} &= \hbar\omega_2 + \frac{p_2^2}{2m} \ . \end{aligned} \tag{38.35}$$

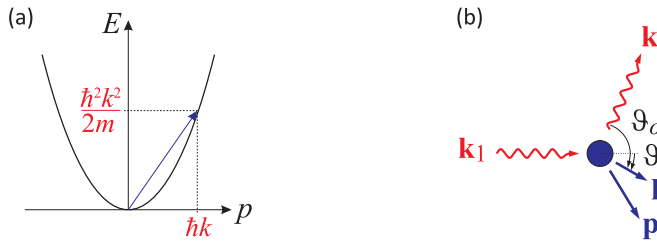

Figure 38.7: (a) Kicking an atom along its dispersion relation. (b) Scheme of the Compton-scattering of light.

Eliminating $\mathbf{p}_2$ from the second equations, we obtain,

$$\hbar\omega_1 - \frac{\hbar^2 k_1^2}{2m} - \frac{\hbar \mathbf{k}_1 \cdot \mathbf{p}_1}{m} = \hbar\omega_2 + \frac{\hbar^2 k_2^2}{2m} - \frac{(\hbar \mathbf{k}_1 + \mathbf{p}_1) \cdot \hbar \mathbf{k}_2}{m} \ . \tag{38.36}$$

The photonic recoils of the incident and of the scattered light are almost equal,

$$\omega_{rec} \equiv \frac{\hbar k_1^2}{2m} \simeq \frac{\hbar k_2^2}{2m} \ , \tag{38.37}$$

such we can approximate,

$$\omega_2 = \omega_1 \frac{1 - \frac{\hbar\omega_1}{mc^2} - \frac{p_1}{mc}\cos\sphericalangle(k_1, p_1)}{1 - \frac{\hbar\omega_1}{mc^2}\cos\sphericalangle(k_1, k_2) - \frac{p_1}{mc}\cos\sphericalangle(p_1, k_2)} \ , \tag{38.38}$$

using $\omega_1 = ck_1$, or also,

$$\omega_2 - \omega_1 = \omega_1 \frac{\frac{\hbar\omega_1}{mc^2}\left[-1 + \cos(\vartheta_{in} - \vartheta_{out})\right] + \frac{p_1}{mc}(\cos\vartheta_{out} + \cos\vartheta_{in})}{1 - \frac{\hbar\omega_1}{mc^2}\cos(\vartheta_{in} - \vartheta_{out}) - \frac{p_1}{mc}\cos\vartheta_{out}} \ , \tag{38.39}$$

where we call the angles $\vartheta_{in} = \sphericalangle(k_1, p_1)$, $\vartheta_{out} = \sphericalangle(k_2, p_1)$, and $\vartheta = \vartheta_{in} - \vartheta_{out} = \sphericalangle(k_1, k_2)$. For non-relativistic velocities, the denominator is approximately 1:

$$\boxed{\omega_2 - \omega_1 = 2\omega_{rec}(-1 + \cos\vartheta) + k_1 v_1(\cos\vartheta_{out} + \cos\vartheta_{in})} \ , \tag{38.40}$$

with $\mathbf{p}_1 = m\mathbf{v}_1$. The first term describes the recoil shift and the second term the Doppler shift.

The second term vanishes for initially at resting atoms, $\mathbf{p}_1 = 0$, and Eq. (38.40) simplifies to,

$$\omega_2 - \omega_1 = 2\omega_{rec}(-1 + \cos\vartheta) \ . \tag{38.41}$$

It also vanishes for atoms which have no velocity component in the scattering plane spanned by the wavevectors $\mathbf{k}_1$ and $\mathbf{k}_2$, that is $\vartheta_{out} = 180° - \vartheta_{in}$ [6], for which case we get the maximum recoil shift,

$$\omega_2 - \omega_1 = -4\omega_{rec} \ . \tag{38.42}$$

[6] This situation is often realized in Bragg scattering from optical lattices [1219, 1221, 1220].

The recoil shift is a consequence of momentum conservation.

The recoil shift is typically on the order of $\omega_2 - \omega_1 \approx (2\pi)\ 10$ kHz, which in many situations is negligible (e.g. when we deal with thermal atomic clouds), such that we can consider the scattering as elastic., i.e. the first term can be disregarded. Considering, for simplicity, only backscattering, $\cos\vartheta_{out} = \cos\vartheta_{in} = 1$, then Eq. (38.40) simplifies to,

$$\omega_2 - \omega_1 = 2k_1 v_1 \ . \tag{38.43}$$

Obviously, the frequency shift depends on the initial velocity through the Doppler shift $k_1 v_1$. In a thermal gas, the velocities are distributed according to the Maxwell-Boltzmann distribution. Therefore, Rayleigh scattering of light off a cloud of free thermal atoms is subject to Doppler broadening [7].

38.3.1.1 Roadmap

For the discussion of optical forces on confined atoms we will consecutively discuss the following questions:

1. Energy and momentum conservation upon scattering of light from a single atom confined in **weak** or **strong** trapping potentials (inhomogeneous systems);

2. scattering from atoms confined in anisotropic traps (strong confinement in one and weak confinement in the other direction);

3. cooperativity (bosonic stimulation) (of the scattered light, not of the atomic momentum) shapes the static structure factor [8];

4. discrete translation invariant (periodic) systems, where quasi-momentum (Bloch bands, lattices);

5. lattices made of laser beams with fixed phase, explicit pots. $V(\mathbf{r}) = \hbar g e^{\imath \mathbf{k}\cdot\mathbf{r}} \hat{b} + c.c.$;

6. lattices made of laser beams with mobile phase.

7. how does the trap modify scattering rates, scattering angles (in particular in case of anisotropic traps), dynamic structure factor?

8. how to calculate a dynamic structure factor?

9. differentiate the term elastic scattering with respect to resonance fluorescence (internal) and recoil (external).

[7] This Doppler broadening is explored e.g. in RIR spectroscopy, where the momentum distribution in p_1 reveals as a frequency distribution $\Delta\omega = \omega_2 - \omega_1$ of Bragg-scattered light, which can be measured by beating with an irradiated idler mode, which can be chosen as being identical to $\mathbf{k}_2$.

[8] In [1219, 1220], we argue that $\mathbf{p}_f = 0$ and that $\hat{\mathbf{e}}_z \cdot \mathbf{k}_i = -\hat{\mathbf{e}}_z \cdot \mathbf{k}_f$, so that we can disregard momentum conservation. The scattering is elastic although (electronically) on resonance, because it is not vibrationally on resonance.

38.3.2 Kicking a free atom

A conceptual difficulty arises from the incompatibility of scattering picture (generally described in homogeneous space with momentum conservation) and the trapping picture (when it is described in inhomogeneous space without momentum conservation). The difficulty can be avoided by separating the processes into a 'kick' followed by a harmonic oscillation, for which we have to calculate the time-dependence of the states and the observables. We will leave the discussion of such a scattering process to 38.3.3 and for the time being just focus on the time evolution of a harmonic oscillator that just received a kick.

By a 'kicking' an atom we denote a change of momentum within an arbitrarily short amount of time. The shorter the kick-time the larger is, according to Heisenberg's uncertainty relation, the spectrum of possible kinetic energies that can be reached by the kick (see Sec. 27.4.3). However, the spectrum is restricted by the free-particle dispersion relation, as illustrated in Fig. 38.7(a).

The kick is not a realistic physical concept, as it corresponds to an infinitely strong and infinitely short force [9]. In a microscopic scattering process it assumes an infinitely heavy collision partner, while we are more interested in photon scattering. Consequently, in this case the spectrum of reachable energies is determined by the frequency of the photon *and* the free-particle dispersion relation. We will now turn our attention to the (Compton-)scattering of light by free atoms.

38.3.3 (In-)elastic light scattering from a single weakly or strongly confined atom

We mentioned in the last subsection that a scattering process is elastic when none of the collision partners changes its internal excitation energy. The situation becomes, however, more complex when one of the collision partners is confined in a potential, as we will show in the following.

38.3.3.1 Cooperativity in light scattering

In light scattering *cooperativity* means *breaking of the isotropic symmetry* for the angular distribution of scattered modes. In this sense, the anisotropic scattering from an atom confined in an anisotropic trap is cooperative. But there are other cooperative scattering effects messing with isotropy and shaping the density-of-states, like the Purcell effect in the presence of an optical cavity or a photonic band gap concentrating optical modes in a specific solid angles [596]. Another cooperative effect, which is observed in the presence of other atoms, has to do with bosonic stimulation by the optical output mode (as in Bragg scattering [1219, 1221, 1220]) or the momentum sidemode (as in stimulated matter wave 4WM). These effects, which all need to be considered in calculations of the static structure factor ruling the scattering of light, are often strong enough to hide the role of an anisotropic trapping potential. In the following subsections we will disregard all these effects and concentrate on a *single trapped atom*.

The simple picture of Compton scattering presented in Sec. 38.3.1 holds for *free atoms*, whose dynamics is totally understood in terms of their internal electronic

[9] which is what allows us to write down a potential

excitation ($\hat{H}_{ele}$), the kinetic energy of their center-of-mass ($\hat{H}_{cm} = \frac{\mathbf{p}^2}{2m}$), the radiation field ($\hat{H}_{rad}$) (which may be treated classically under the circumstances discussed here), and the coupling ($\hat{H}_{int}$) of all three degrees of freedom,

$$\hat{H}_{free} = \hat{H}_{ele} + \hat{H}_{cm} + \hat{H}_{rad} + \hat{H}_{int} \ . \tag{38.44}$$

Transition probabilities are readily calculated using Fermi's Golden rule, because the density-of-states distributions for the final radiation modes receiving the scattered photons (photonic density-of-states) and the recoil modes receiving the scattered atoms (phononic density-of-states) are white, that is, without resonances, and isotropic.

In the presence of an imposed trapping potential, an additional term appears in the Hamiltonian, which has the capacity of dramatically changing the scattering features,

$$\hat{H}_{cm} = \frac{\mathbf{p}^2}{2m} + \hat{V}_{trap}(\mathbf{r}) \ . \tag{38.45}$$

The confining potential may or may not depend on the internal state of the atom. For ions in a Paul trap it does not depend, but for atoms in magnetic traps it usually depends,

$$\begin{aligned} \hat{H}_{atom} &= |g\rangle \hat{H}_{cm,g} \langle g| + |e\rangle (\hat{H}_{cm,e} + \hbar\omega_0) \langle e| \\ \hat{H}_{cm,j} &= \frac{\hat{p}^2}{2m} + V_j(\mathbf{r}) \ , \end{aligned} \tag{38.46}$$

where ω_0 is the frequency of the atomic transition. In the following, however, we will treat potentials that are independent of the internal atomic state.

38.3.3.2 Resolved sideband regime

As discussed in Sec. 34.6.5, incident light is absorbed by an atom harmonically oscillating in a trap with frequency ω_{trp} on a spectrum of discrete sidebands separated by ω_{trp} with amplitudes given by $J_n(kv_0/\omega_{trp})$. The modulation index $kv_0/\omega_{trp} = kx_0 = 2\pi x_0/\lambda$ corresponds to the Lamb-Dicke parameter. When the modulation amplitude is within the so-called *Lamb-Dicke regime*, $kv_0 \ll \omega_{trp}$, the first sidebands become smaller than the carrier, $J_1(kv_0/\omega_{trp}) < J_0(kv_0/\omega_{trp})$ and, therefore, do not contribute to the Doppler width of the frequency distribution. That is, the linear Doppler effect vanishes.

The relative size of the characteristic frequencies ω_{rec}, ω_{trp}, and Γ define characteristic regimes, as illustrated in the table.

confinement		sidebands	
weak	$\eta > 1$	unresolved	$\frac{\omega_{trp}}{\Gamma} < 1$
strong	$\eta < 1$	resolved	$\frac{\omega_{trp}}{\Gamma} > 1$

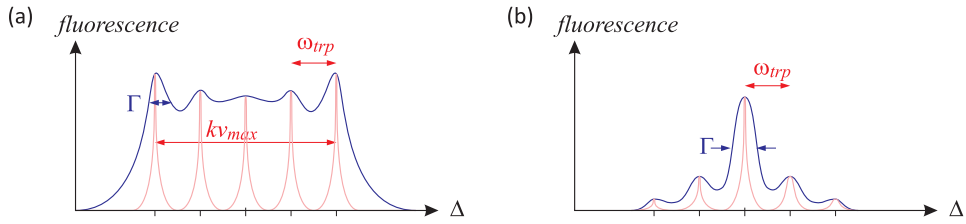

Figure 38.8: Absorption profile in the regimes of (a) weak binding ($\eta > 1$) for the cases of and unresolved sidebands (blue curve) and resolved sidebands (red curve), and (b) strong binding (Lamb-Dicke regime $\eta < 1$) for the same cases as in (a).

38.3.3.3 The Mößbauer effect

The role of photonic recoil in the scattering of light by confined atoms has been unraveled by *Mößbauer*, who performed scattering experiments of γ-photons on a ^{57}Fe crystal on a narrow transition of this isotope at 14 keV (0.086 nm). The linewidth of this transition, $\Gamma \approx (2\pi)\ 1\,\text{MHz}$, is much narrower than the recoil-shift, $\omega_{rec} \approx (2\pi)\ 500\,\text{MHz} \gg \Gamma$, so that we should expect the scattered light to be considerably recoil-shifted and Doppler-broadened. In fact, the recoil-shift should be so large, that scattered photons cannot be reabsorbed by other atoms on this transition being at rest. This is *not* what Mößbauer observed in his experiments. He found that scattered photons can be reused for subsequent scattering, which means that the scattering must be elastic.

The explanation for this unexpected observation is that, if the nucleus is embedded in a crystal, the vibrational frequencies, which are even higher than the photonic recoil frequency, $\omega_{trp} \approx 2\pi \cdot 3\,\text{THz}$, are unreachable. That is to say, we are in the *resolved sidebands Lamb-Dicke regime*, $\omega_{trp} \gg \omega_{rec} \gg \Gamma$. Here, the phonons corresponding to the vibrations cannot be excited, so that the recoil momentum must be absorbed by the whole lattice, whose entire mass is so large, that the photon frequency is not recoil-shifted by the scattering process. Hence, the first-order *Doppler effect* is avoided and the measured width of the transition is just the natural linewidth. Furthermore, the atom remains in the same vibrational state of their localizing potential. This is the *Mößbauer effect*.

	γ for ^{57}Fe	optical for $^{172}Yb^{+}$
photon energy	$\approx 14\,\text{keV} \quad \approx 4 \times 10^{18}\,\text{Hz}$	$\approx 3\,\text{eV} \quad \approx 640\,\text{THz}$
recoil	$\approx 2\,\text{meV} \quad \approx 500\,\text{MHz} \quad \approx 10^{-10}$	$\approx 20\,\text{peV} \quad \approx 5\,\text{kHz} \quad \approx 10^{-11}$
linewidth	$\approx 5\,\text{neV} \quad \approx 1\,\text{MHz} \quad \approx 2 \times 10^{-13}$	$\approx 5\,\text{feV} \quad \approx 1\,\text{Hz} \quad \approx 2 \times 10^{-15}$
lattice vibrations	$\approx 10\,\text{meV} \quad \approx 3\,\text{THz}$	$\approx 3\,\text{neV} \quad \approx 1\,\text{MHz}$

Table 38.1: Comparison of γ-radiation and the optical regime.

A similar effect can be observed with trapped atoms driven on very narrow transitions, as we will discuss in the following.

38.3.3.4 Coupling of internal and external motion by photonic recoil, tracing over the internal excitation

When discussing the transfer of momentum to a harmonic oscillator in 24.6.2, we did not say how the momentum shift could be realized in practice. As we have seen in the example of the Mößbauer effect, a possible way is via the photonic recoil received on a light scattering process. The coupling of the relevant degrees of freedom of the system induced by the absorption of a photon by an atom is accounted for by an additional interaction term $\hat{H}_{int}$ in the Hamiltonian. The relevant degrees of freedom are the electronic orbital $|i\rangle$, the vibrational state $|n\rangle$, and the number of photons $|N\rangle$ in the light mode, assumed to be a plane wave $\vec{\mathcal{E}}(\mathbf{r},t) = E_0\hat{\mathbf{e}}_y e^{\imath k_z z - \imath\omega t}$. Neglecting the quantum nature of the light, we will disregard this degree of freedom in the following. Assuming that the trapping potential is the same for all electronic orbitals, as in (38.46), the total state can be expressed as a product state, $|n,i\rangle \equiv |i\rangle \otimes |n\rangle$. The interaction Hamiltonian,

$$\hat{H}_{int} = \frac{\hbar\Omega}{2}(e^{\imath k\hat{z}}\hat{a}|e\rangle\langle g| + e^{-\imath k\hat{z}}\hat{a}^\dagger|g\rangle\langle e|) - |e\rangle\hbar\omega\langle e| \ , \tag{38.47}$$

couples the dynamics on the internal transition, given by the Rabi frequency $\hbar\Omega \equiv \langle e|d_y|g\rangle\mathcal{E}_0$, with the absorption (or stimulated emission) of a photon $\hat{a}$, and the transfer of a recoil momentum. The last term comes from the transformation into the interaction picture [10]. With this our total Hamiltonian (38.46) becomes,

$$\boxed{\hat{H} = \hbar\omega_{trp}(\hat{b}^\dagger\hat{b} + \tfrac{1}{2}) + |e\rangle\hbar(\omega_0-\omega)\langle e| + \tfrac{\hbar\Omega}{2}(e^{\imath k\hat{z}}|e\rangle\langle g| + e^{-\imath k\hat{z}}|g\rangle\langle e|)} \ . \tag{38.48}$$

So, vibrational states are only coupled via electronic transitions,

$$\langle n,g|\hat{H}_{int}|0,g\rangle = 0 \qquad \text{and} \qquad \langle n,e|\hat{H}_{int}|0,g\rangle = \tfrac{1}{2}\hbar\Omega\langle n,e|e^{\imath k\hat{z}}|0,g\rangle \ . \tag{38.49}$$

Hence, we have to span the complete Hilbert space of all operators like $\hat{\sigma}^\dagger = \sum_n |n\rangle\langle n| \otimes |e\rangle\langle g|$.

We can expand the system's state into,

$$|\psi(t)\rangle = \sum_{n=0}^{\infty}(c_{n,g}|n,g\rangle + c_{n,e}|n,e\rangle \ , \tag{38.50}$$

and insert it together with the Hamiltonian (38.48) into the Schrödinger equation. Projecting onto the states $\langle n,g|$ and $\langle n,e|$, we easily derive the following equations of motion,

$$\boxed{\begin{aligned} \frac{dc_{n,g}}{dt} &= -\imath\omega_{trp}(n+\tfrac{1}{2})c_{n,g} - \frac{\imath\Omega}{2}\sum_{m=0}^{\infty} c_{m,e}\langle n|e^{-\imath k\hat{z}}|m\rangle \\ \frac{dc_{n,e}}{dt} &= -\imath\omega_{trp}(n+\tfrac{1}{2})c_{n,e} - \imath(\omega_0-\omega)c_{n,e} - \frac{\imath\Omega}{2}\sum_{m=0}^{\infty} c_{m,g}\langle n|e^{\imath k\hat{z}}|m\rangle \end{aligned}} \ . \tag{38.51}$$

[10] Note, that this Hamiltonian cannot be used to describe spontaneous emission. To do so, we need to allow for 3D systems and decay modes,

$$\hat{H} = \hbar\omega_{trp}(|\mathbf{n}\rangle\langle\mathbf{n}| + \tfrac{1}{2}) + \hbar(\omega_0-\omega)|e\rangle\langle e| + \tfrac{\hbar\Omega}{2}(e^{-\imath\mathbf{k}_i\cdot\hat{\mathbf{r}}}\hat{\sigma}^\dagger\hat{a}_{\mathbf{k}_i} + c.c.) + \hbar g\sum_{\mathbf{k}_f}(e^{\imath\mathbf{k}_f\cdot\hat{\mathbf{r}}}\hat{\sigma}\hat{a}^\dagger_{\mathbf{k}_f} + c.c.) \ .$$

The fact that only terms proportional to $\langle n|e^{ik\hat{z}}|m\rangle$ contribute can be understood in terms of the *Franck-Condon overlap* between the vibrational states to be coupled. And the fact that the energy of the harmonic oscillator, and thus the effective detuning $\Delta_n \equiv \omega - \omega_0 - \omega_{trp}(n + \frac{1}{2})$, depend on the vibrational state couples the internal and the external dynamics.

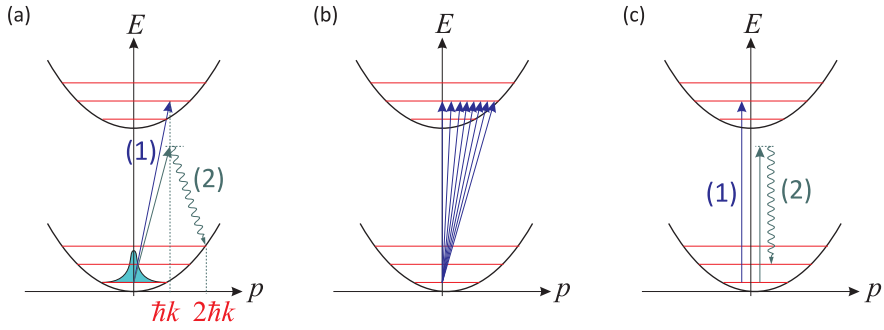

Figure 38.9: (a) Absorption (1) and Rayleigh scattering (2) in a weakly confining trap, where the momentum must stay conserved. (b) Illustration of the regime $\omega_{rec} > \Gamma$, where the atom moves during the absorption process. (c) Absorption and Rayleigh scattering in a strongly confining trap.

Nevertheless, the off-diagonal coupling elements only contain the degrees of freedom of the harmonic oscillator.

38.3.3.5 Momentum kick by photonic recoil

We said earlier that a momentum kick can drive an atom from the vibrational ground state $|0\rangle$ into a coherent superposition of states $|\alpha\rangle$, except when the Lamb-Dicke parameter is very small. When the kick is realized via photonic recoil, e.g. when an electronically excited atom decays to the ground state, the frequency of the emitted photon depends on the final vibrational state of the atom. That is we expect a coherent superposition of light frequencies, which in the limit $\eta > 1$ generates a *Doppler broadening* and in the limit $\eta < 1$ stays unshifted as for *elastic scattering*.

Let us now consider a single confined atom and address the question of the absorption probability. In first-order perturbation, using the Hamiltonian (38.48), the transition rate for absorption of a photon incident in z-direction is given by Fermi's Golden Rule,

$$\begin{aligned}\frac{1}{\tau} &= \frac{d}{dt}|\langle n,e|e^{\imath\hat{H}t/\hbar}|0,g\rangle|^2 \simeq \frac{2\pi}{\hbar^2}|\langle n,e|\hat{H}|0,g\rangle|^2 \\ &= \frac{2\pi}{\hbar^2}|\langle n,e|\tfrac{\hbar\Omega}{2}(e^{\imath k\hat{z}}\hat{\sigma}^\dagger + e^{-\imath k\hat{z}}\hat{\sigma})|0,g\rangle|^2 = \frac{\pi\Omega^2}{2}|\langle n,e|e^{\imath k\hat{z}}|0,e\rangle|^2 \ .\end{aligned} \tag{38.52}$$

Obviously, it is thus sufficient to calculate $\langle n|e^{ik\hat{z}}|0\rangle$, i.e. we can trace over the internal degrees of freedom. Using our previous results (24.136), we find with $\alpha = -ika_{trp}/\sqrt{2}$,

$$\boxed{\frac{1}{\tau} = \frac{\pi\Omega^2}{2}|\langle n|\alpha\rangle|^2 = \frac{\pi\Omega^2}{2}e^{-|\alpha|^2}\frac{|\alpha^n|^2}{n!}} \ . \tag{38.53}$$

The interpretation of this result is that the absorption of a photon by an atom in state $|0,g\rangle$ transfers recoil by *leaving the vibrational state of the atom in a coherent superposition state*. Inversely, for the emission process from state $|0,e\rangle$ within the Lamb-Dicke regime, most of the time we will encounter the emitted photon at the resonance frequency ω_0, and rarely at $\omega_0 - \omega_{trp}$. In any case, energy conservation is satisfied, since,

$$\sum_n n\hbar\omega_{trp}\langle n|\alpha\rangle\langle\alpha|n\rangle = \sum_n n\hbar\omega_{trp}e^{-|\alpha|^2}\frac{|\alpha|^{2n}}{n!} = \hbar\omega_{trp}|\alpha|^2\sum_n ne^{-|\alpha|^2}\frac{|\alpha|^{2n-2}}{(n-1)!}$$
$$= \frac{\hbar^2k^2}{2m}\langle\alpha|\alpha\rangle = \hbar\omega_{rec}\ . \tag{38.54}$$

Thus energy and momentum conservation are automatically satisfied by the way the kick is implemented.

38.3.3.6 A single anisotropically trapped atom in first-order perturbation

Let us now consider a single atom (e.g. a trapped ion) confined in an 3-dimensional anisotropic trap (e.g. strong confinement in one and weak confinement in the other direction) and address the question, whether the scattering will be anisotropic, as well. We generalize the problem to three dimensions by allowing for quantized vibrational states in three dimensions, $\hat\sigma^\dagger = \sum_{\mathbf{n}}|\mathbf{n}\rangle\langle\mathbf{n}|\otimes|e\rangle\langle g|$ with $|\mathbf{n}\rangle = |n_x,n_y,n_z\rangle$.

In first-order perturbation, using the Hamiltonian (38.48), the transition rate for absorption or emission is given by Fermi's Golden Rule,

$$\frac{1}{\tau} = \frac{d}{dt}|\langle\mathbf{n},e|e^{\imath\hat Ht/\hbar}|\mathbf{0},g\rangle|^2 \simeq \frac{2\pi}{\hbar^2}|\langle\mathbf{n},e|\tfrac{\hbar\Omega}{2}(e^{\imath\mathbf{k}\cdot\hat{\mathbf{r}}}\hat\sigma^\dagger + e^{-\imath\mathbf{k}\cdot\hat{\mathbf{r}}}\hat\sigma)|\mathbf{0},g\rangle|^2 \tag{38.55}$$
$$= \frac{\pi\Omega^2}{2}|\langle n_x,e|e^{\imath k\hat x}|0,e\rangle\langle n_y,e|e^{\imath k\hat y}|0,e\rangle\langle n_z,e|e^{\imath k\hat z}|0,e\rangle|^2\ .$$

Obviously, it is thus sufficient to calculate $\langle n_j|e^{\imath k\hat z}|0\rangle$, i.e. we can trace over the internal degrees of freedom. Using our previous results (24.136), we find with $\alpha_j = -\imath k_j a_{trp,j}/\sqrt{2}$,

$$\boxed{\frac{1}{\tau} = \frac{\pi\Omega^2}{2}|\langle n_x|\alpha_x\rangle\langle n_y|\alpha_y\rangle\langle n_z|\alpha_z\rangle|^2 = \frac{\pi\Omega^2}{2}e^{-|\alpha_x|^2-|\alpha_y|^2-|\alpha_z|^2}\frac{|\alpha_x^{n_x}\alpha_y^{n_y}\alpha_z^{n_z}|^2}{n_x!n_y!n_z!}}\ .$$

In Exc. 38.3.5.1 we calculate and illustrate the transition matrix elements $\langle\mathbf{0}|e^{\imath k\hat z}|0\rangle$ and $\langle\mathbf{n}|e^{\imath k\hat z}|0\rangle$.

38.3.3.7 A single anisotropically trapped atom in second-order perturbation

To understand Rayleigh scattering, we need to go to second perturbation order summing over all intermediate vibrational states according to the Kramers-Heisenberg

formula,

$$\begin{aligned}\frac{d\sigma}{d\Omega} &= \frac{d}{dt}|\langle \mathbf{n}, g, \mathbf{k}_f|e^{\imath\hat{H}t/\hbar}|\mathbf{0}, g, \mathbf{k}_i\rangle|^2 \simeq \frac{2\pi}{\hbar^2}|\langle \mathbf{n}, g, \mathbf{k}_f|\sum_{\mathbf{m}}\frac{\hat{H}^{(1)}|\mathbf{m}, e\rangle\langle \mathbf{m}, e|\hat{H}^{(1)}}{\omega_i - \omega_m}|\mathbf{0}, g, \mathbf{k}_i\rangle|^2 \\ &= \frac{\pi\hbar^2\Omega^4}{8}\left|\sum_{\mathbf{m}}\frac{\langle \mathbf{n}, \mathbf{k}_f|e^{-\imath\mathbf{q}\cdot\hat{\mathbf{r}}}|\mathbf{m}\rangle\langle \mathbf{m}|e^{\imath\mathbf{q}\cdot\hat{\mathbf{r}}}|\mathbf{0}, \mathbf{k}_i\rangle}{E_i/\hbar + (0\omega_x + 0\omega_y + 0\omega_z + \frac{3}{2}) - E_m/\hbar - (m_x\omega_x + m_y\omega_y + m_z\omega_z + \frac{3}{2})}\right|^2 \\ &= \frac{\pi\hbar^2\Omega^4}{8}\left|\sum_{m_x,m_y,m_z}\frac{\langle n_x, n_y, n_z|e^{-i\mathbf{k}_f\cdot\hat{\mathbf{r}}}|m_x, m_y, m_z\rangle\langle m_x, m_y, m_z|e^{\imath\mathbf{k}_i\cdot\hat{\mathbf{r}}}|0, 0, 0\rangle}{(E_i - E_m)/\hbar - m_x\omega_x - m_y\omega_y - m_z\omega_z}\right|^2 \\ &= \frac{\pi\hbar^2\Omega^4}{8}\left|\sum_{m_x,m_y,m_z}\prod_{j=x,y,z}\frac{\langle n_j|e^{-ik_{jf}r_j}|m_j\rangle\langle m_j|e^{ik_{ji}\mathbf{r}_j}|0\rangle}{(E_i - E_m)/\hbar - m_x\omega_{mx} - m_y\omega_{my} - m_z\omega_{mz}}\right|^2 .\end{aligned} \tag{38.56}$$

The transition matrix elements can be calculated via (24.141). This expression represents (in the same time) the *dynamic structure factor* of the single trapped atom.

Example 225 (*Axial incidence*): Let us consider the particular case of Rayleigh scattering from the ground state of light incident in the direction $\mathbf{k}_i \equiv k_{iz}\hat{\mathbf{e}}_z$. We can then simplify,

$$\begin{aligned}\frac{d\sigma}{d\Omega} &= \frac{\pi\hbar^2\Omega^4}{8}\left|\sum_{m_z}\frac{\langle 0|e^{-\imath k_{xf}\hat{x}}|0\rangle\langle 0|e^{-\imath k_{yf}\hat{y}}|0\rangle\langle 0|e^{-\imath k_{zf}\hat{z}}|m_z\rangle\langle m_z|e^{\imath k_{zi}\hat{z}}|0\rangle}{-m_z\omega_{trp}}\right|^2 \\ &= \frac{\pi\hbar^2\Omega^4}{8}e^{-|\alpha_{fx}|^2-|\alpha_{fy}|^2-|\alpha_{fz}|^2-|\alpha_{iz}|^2}\left|\sum_{m_z}\frac{1}{(E_m - E_i)/\hbar - m_z\omega_{trp,z}}\frac{\alpha_{fz}^{m_z}\alpha_{iz}^{m_z}}{m_z!}\right|^2 \\ &= \frac{\pi\hbar^2\Omega^4}{8}e^{-(\mathbf{k}_f\cdot\mathbf{a}_{trp})^2/2-(\mathbf{k}_i\cdot\mathbf{a}_{trp})^2/2}\left|\sum_{m_z}\frac{1}{(E_m - E_i)/\hbar - m_z\omega_{trp,z}}\frac{(-\frac{1}{2}k_{fz}k_{iz}a_{trp,z}^2)^{m_z}}{m_z!}\right|^2 ,\end{aligned}$$

where $\mathbf{a}_{trp} \equiv (a_{trp,x}\ a_{trp,y}\ a_{trp,z})$. Looking into scattering into transverse direction, $\mathbf{k}_{f,z} = 0$, we get,

$$\left(\frac{d\sigma}{d\Omega}\right)_{\perp} = \frac{\pi\hbar^4\Omega^4}{8|E_m - E_i|^2}e^{-\mathbf{k}_{fx}^2a_{trp,x}^2/2-\mathbf{k}_{fy}^2a_{trp,y}^2/2-\mathbf{k}_{iz}^2a_{trp,z}^2/2} .$$

Looking into backscattering, $\mathbf{k}_{f,z} = -\mathbf{k}_{i,z}$,

$$\left(\frac{d\sigma}{d\Omega}\right)_{\parallel} = \frac{\pi\hbar^2\Omega^4}{8}e^{-\mathbf{k}_i a_{trp,z})^2}\left|\sum_{m_z}\frac{1}{(E_m - E_i)/\hbar - m_z\omega_{trp,z}}\frac{(-\frac{1}{2}k_{iz}^2a_{trp,z}^2)^{m_z}}{m_z!}\right|^2 .$$

we expect a spectrum with vibrational resonances.

38.3.3.8 Discussion of scattering from a single weakly or strongly confined particle

We assume that the lifetime of an atomic transition is much shorter than an oscillation period (or the Rabi-frequency), $\Gamma, \Omega \gg \omega_{trp}$, the position of the atoms does not change

during a transition process, i.e. we have a *Franck-Condon transition* in position space [853] [11].
For weakly confined particles:

- Energy and momentum conservation holds during absorption or scattering process. Absorption, fluorescence, and Rayleigh scattering are just like for free particles (i.e. inelastic because of photon recoil). Thus, transitions must start and end on the dispersion curve, e.g. for scattering at an initially resting atom,

$$\hbar\omega_i = \hbar\omega_f + \frac{p_f^2}{2m} - \hbar\Delta\omega_{trap} \qquad \text{and} \qquad \mathbf{k}_i = \hbar\mathbf{k}_f + \mathbf{p}_f \ . \tag{38.57}$$

- U-shaped absorption spectrum
- Doppler-cooling picture of shrinking ellipse in phase space [655], but not during the oscillation of the atom in the trap.
- Message: *If your atom is weakly confined, you may not neglect the recoil-shift.*
- The momentum is conserved during the scattering process, provided the process is fast enough, i.e. $\Gamma \gg \omega_{trp}$. What the trap does afterward with the momentum is its own problem [1383], not the one of the light field.

For strongly confined particles:

- Momentum conservation does not hold during the scattering process, it is absorbed by the trap. Light scattering is totally elastic (no recoil shift). Nevertheless, absorption and fluorescence, Rayleigh and Raman scattering must end up on vibrational sidebands.
- motional sideband spectrum
- in the resolved sideband regime, we may achieve sideband cooling [422]
- when the sidebands are not resolved, we still can do stimulated Raman sideband cooling (Bragg spectroscopy)
- Message: *If your atom is strongly confined, you may do Rayleigh or Raman.*

Discuss momentum conservation from (??) comparing $\hbar^2k^2/2m$ and $m\omega_{trp}^2\hat{z}^2/2$.

38.3.3.9 Rigid lattice: single atom in a standing wave cavity mode

Let us restrict to a single dimension and discuss the problem of kicking a single atom confined in a standing plane light wave. We want to describe the physical situation after an attempted kick *including* the optical lattice system and *satisfying all conservation laws*. The problem is that we need to describe the atomic motion quantum-mechanically! [12].

[11] Vertical transitions in the potential curve.
[12] The harmonic oscillator picture cannot we used for shallow potentials supporting only 0 or 1 vibrational states.

The situation in a linear optical cavity is different, because the counterpropagating light modes just form a single one,

$$\hat{a}_- = \hat{a}_+ \ , \tag{38.58}$$

so a photon backscattered between the two modes always ends up in original mode after having been reflected from a cavity mirror. Then, the dipole potential terms simplifies to,

$$2\hbar U_0 |\alpha_+|^2 \sin 2k_{lat}\hat{z} \ . \tag{38.59}$$

Now, the momentum of the cavity light fields is certainly *not conserved*, since the photonic recoil upon reflection of light at a mirror is absorbed by the mirror, which is not included in our model. However, the atom does (probably) not know about the photon's problems: when, accelerated by the dipole force, it redistributes photons between counterpropagating light modes, it wants to see its momentum conserved. But if both light modes are identical, then the momentum transfer can only be in exact units of $2\hbar k_{lat}$, without frequency- or phase-shifts of the light modes possible. Or in other words: Either the momentum kick satisfies $\Delta p = 2\hbar k_{lat}$, or it simply *does not occur*, the atom gets transparent with respect any attempt of motional excitation.

In practice, this means nothing else, than that the process of scattering a photon incident from an arbitrary direction at an optical lattice needs to fulfill the Bragg condition *not only for the optical modes, but also for the recoil modes*, and that the scattering must be elastic, as in the Mößbauer effect.

For the case that the momentum kick is commensurate with twice the photonic recoil of the laser beams,

$$\Delta p = 2\hbar k_{lat} \ , \tag{38.60}$$

we have a simple picture in terms of a coherent redistribution of photons between lattice beams. But what happens, if this is not the case?

In the case of an atom vibrationally embedded in a crystal, the distribution of phononic modes is so dense and broad, that the interesting questions are: 'Where does the momentum go?' and 'How is it distributed over the modes?' In the case of a single atom sitting in a 1D optical lattice, the distribution of phononic modes is sparse and sharp, since it is shaped by the commensurability condition. Here, the interesting questions should be: 'How likely is it, that the atom really responds to my momentum kick attempt?' and 'How does this probability depend on the amplitude Δp of the kick?'

The second term of the Hamiltonian (38.58) is the dipole potential generated by the counterpropagating laser beams. It contains the *phononic* reservoir. Its expression is more complicated than that of a harmonic oscillator, which can easily be quantized in a canonical way. Nevertheless, hence, should be possible to derive from it (i) the vibrational structure of the standing wave potential and (ii) the transition probability between vibrational states, when the atom is kicked.

The scattering of light off a rigid lattice is totally understood in terms of the dynamic structure factor [878]. Indeed, the dynamic structure factor includes all kind of cooperative effects: those due to 'bosonic stimulation', to peculiarities of the spatial distribution, and of the photonic density of states [878]. We want to calculate the scattering rate. For internal energetic excitation we would calculate,

$$\frac{1}{\tau} \propto |\langle f|e^{-i\hat{H}t}|i\rangle|^2 \ . \tag{38.61}$$

In first order, the expansion of the expression yields Fermi's Golden rule (in second order the Kramers-Heisenberg rule). From there we get the photonic density of states ...

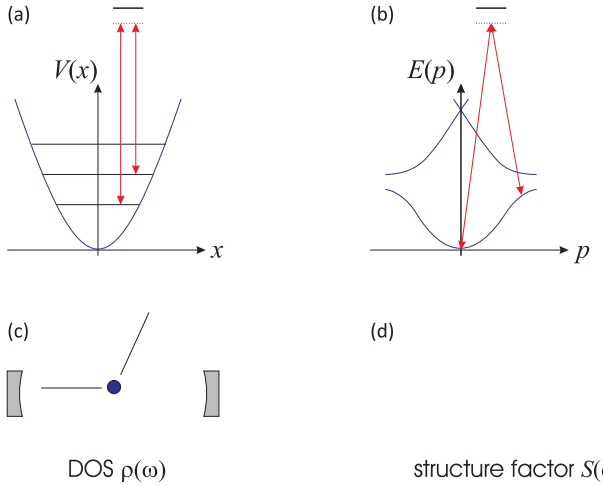

Figure 38.10: (a) Raman anti-Stokes transition on a particle confined in a trapping potential V(z). (b) Raman anti-Stokes transition on a free particle between motional states determined by the dispersion relation $E(p)$.

For momentum kicks it would be,

$$\frac{d\sigma}{d\Omega} \propto |\langle f|e^{-i\mathbf{k}\cdot\hat{\mathbf{r}}}|i\rangle|^2 \ . \tag{38.62}$$

Expanding this do we get in first order the structure factor? And the phononic density of states?

How elastic is the scattering from an atom trapped in the Lamb-Dicke regime in a ring cavity standing wave?

The dynamic structure factor is measured by Bragg spectroscopy. We did NOT Bragg spectroscopy [1219, 1157] and we found elastic scattering (no recoil-shift). How is this possible? Also we measured the static structure factor in [1219]. How about the dynamic?

What are the question we want to respond?

- Bragg spectroscopy from trapped particles avoids to have to treat spontaneous emission!
- Imagine an excited atom in the vibrational ground state of an anisotropic trap. Will it emit preferentially in particular directions? I.e. will light be preferentially scattered within a frozen dimension?
- What is the relationship to Hemmerich's ring cavity quantum computer [606] (see Sec. 42.2.5)?

38.3.4 Optical cooling in of trapped atoms

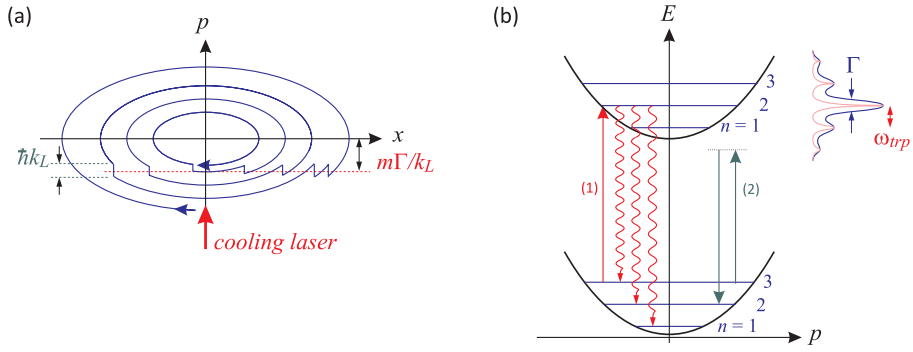

Figure 38.11: (a) Illustration of Doppler cooling of strongly trapped ions via a shrinking of the phase-space ellipse, (b) sideband cooling.

38.3.5 Exercises

38.3.5.1 Ex: Transition elements in anisotropic harmonic traps

a. Calculate and illustrate $\langle \mathbf{0}|e^{-\imath \mathbf{k}\cdot\hat{\mathbf{r}}}|\mathbf{0}\rangle$ for an anisotropic trap with cylindrical symmetry.
b. Calculate $\langle \mathbf{n}|e^{-\imath \mathbf{k}\cdot\hat{\mathbf{r}}}|\mathbf{0}\rangle$ and $\sum_{n_x,n_y,n_z}\langle \mathbf{n}|e^{-\imath \mathbf{k}\cdot\hat{\mathbf{r}}}|\mathbf{0}\rangle$.

Solution: *a. We characterize our trap by* $\mathbf{a}_{trp} = (a_{r,trp}\ a_{r,trp}\ a_{z,trp})$ *and calculate,*

$$\begin{aligned}\langle \mathbf{0}|e^{-\imath \mathbf{k}\cdot\hat{\mathbf{r}}}|\mathbf{0}\rangle &= \langle 0|e^{-\imath k_x\hat{x}}|0\rangle\langle 0|e^{-\imath k_y\hat{y}}|0\rangle\langle 0|e^{-\imath k_z\hat{z}}|0\rangle = \langle 0|\alpha_x\rangle\langle 0|\alpha_y\rangle\langle 0|\alpha_z\rangle \\ &= e^{-|\alpha_x|^2/2}e^{-|\alpha_y|^2/2}e^{-|\alpha_z|^2/2} = e^{-k_r^2a_{trp,r}^2}e^{-k_z^2a_{trp,z}^2/2}\ .\end{aligned}$$

The result exhibited in Fig. 38.12 shows that the transition between vibrational ground states is facilitated in directions, where the Lamb-Dicke parameter is small. This is simply, because for large Lamb-Dicke parameter higher vibrational states may be excited.
b. The results are exhibited in Fig. 38.13.

38.3.5.2 Ex: Periodicity of a lattice

Calculate $e^{\imath a\hat{p}}e^{2\imath k\hat{z}}e^{-\imath a\hat{p}}$.

Solution: *Using the Baker-Hausdorff formula,*

$$\begin{aligned}e^{\imath a\hat{p}/\hbar}e^{2\imath k\hat{z}}e^{-\imath a\hat{p}/\hbar} &= e^{\imath a\hat{p}/\hbar}e^{2\imath k\hat{z}-\imath a\hat{p}+[2\imath k\hat{z},-\imath a\hat{p}/\hbar]/2} \\ &= e^{\imath a\hat{p}/\hbar}e^{-\imath a\hat{p}/\hbar+2\imath k\hat{z}+[-\imath a\hat{p}/\hbar,2\imath k\hat{z}]/2-2ak[\hat{p}/\hbar,\hat{z}]} \\ &= e^{\imath a\hat{p}/\hbar}e^{-\imath a\hat{p}/\hbar}e^{2\imath k\hat{z}}e^{-2\imath ak} = e^{2\imath k(\hat{z}-a)}\ .\end{aligned}$$

(b) Angular distribution of the Lamb-Dicke parameter for $\lambda = 689$ nm, $m = 88u$, $\omega_x = \omega_y = 10^5\,\mathrm{s}^{-1}$, and $\omega_z/\omega_x = 1, 2, 3$ (red,green,blue). (c) Corresponding angular distribution of the transition matrix element.

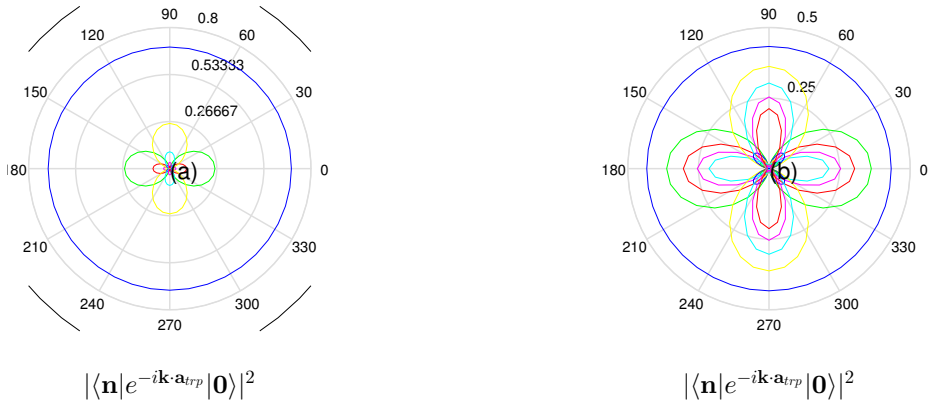

Figure 38.13: (code) (Left) Angular distribution of the transition matrix elements.

38.3.5.3 Ex: Energy commutators

Calculate the commutator between the kinetic and the potential energy for (a) a harmonic oscillator and (b) a standing wave dipolar potential.

Solution: *a. For a harmonic oscillator we have,*

$$\begin{aligned}\hat{H} &= \frac{\hat{p}^2}{2m} + \frac{m}{2}\omega^2\hat{z}^2 \\ \hat{z}(t) &= e^{-\imath\hat{H}t/\hbar}\hat{z}(0)e^{\imath\hat{H}t/\hbar} \\ \hat{p}(t) &= e^{-\imath\hat{H}t/\hbar}\hat{p}(0)e^{\imath\hat{H}t/\hbar}\ .\end{aligned}$$

With this we calculate the commutator between kinetic and potential energy for a harmonic oscillator,

$$[\frac{\hat{p}^2}{2m}, \frac{m}{2}\omega^2\hat{z}^2] = \frac{\omega^2}{4}[\hat{p}^2, \hat{z}^2] = \frac{\omega^2}{4}\left(\hat{p}[\hat{p},\hat{z}]\hat{z} + \hat{p}\hat{z}[\hat{p},\hat{z}] + [\hat{p},\hat{z}]\hat{z}\hat{p} + \hat{z}[\hat{p},\hat{z}]\hat{p}\right) = -\imath\frac{\hbar\omega^2}{2}(\hat{p}\hat{z}+\hat{z}\hat{p}) \ .$$

b. For a standing wave dipolar potential we have,

$$\begin{aligned}
\hat{H} &= \frac{\hat{p}^2}{2m} + U_0 \sin^2 k\hat{z} = \frac{\hat{p}^2}{2m} + U_0\left(k^2\hat{z}^2 - \frac{1}{3}k^4\hat{z}^4 + \frac{2}{45}k^6\hat{z}^6 + ...\right) \\
\hat{z}(t) &= e^{-\imath\hat{H}t/\hbar}\hat{z}(0)e^{\imath\hat{H}t/\hbar} \\
\hat{p}(t) &= e^{-\imath\hat{H}t/\hbar}\hat{p}(0)e^{\imath\hat{H}t/\hbar} \ .
\end{aligned}$$

With Baker-Hausdorff $e^{\hat{A}}e^{\hat{B}} = e^{\hat{A}+\hat{B}+[\hat{A},\hat{B}]/2}$ *we find,*

$$\begin{aligned}
[\hat{A},\hat{B}] = \left[\frac{\hat{p}^2}{2m}, U_0\sin^2 k\hat{z}\right] &= \frac{U_0}{2m}\left[\hat{p}^2, (k\hat{z})^2 - \tfrac{(k\hat{z})^4}{3} + ...\right] \\
&= \frac{k^2U_0}{2m}\left(\hat{p}[\hat{p},\hat{z}]\hat{z} + \hat{p}\hat{z}[\hat{p},\hat{z}] + [\hat{p},\hat{z}]\hat{z}\hat{p} + \hat{z}[\hat{p},\hat{z}]\hat{p}...\right) \\
&= \frac{-\imath\hbar k^2U_0}{m}(2\hat{p}\hat{z} - \imath\hbar...) = ... \\
e^{-\imath\hat{H}t/\hbar} &= e^{-(\imath/\hbar)t\left(\frac{\hat{p}^2}{2m} + U_0\sin^2 k\hat{z}\right)} = ... \ .
\end{aligned}$$

38.4 Driven atomic motion

The degree of freedom of atomic motion can be used for interesting studies of a new kind. For them being a microscopic object we expect the emergence of quantum effects in some circumstances. In free space the spectrum of atomic motion is continuous.

38.4.1 Map representations

38.4.1.1 Poincaré map

Given is the differential equation,

$$\dot{x} = f(x,t) \ , \tag{38.63}$$

with the initial condition $x(\tau) = x_0$ with the solution $x(x_0, t, \tau)$. Be $t = a$ and $t = b$ two fixed points. The *Poincaré map* ϕ relates in initial value a to the value of the solution at point b, i.e. $x_0 \leftarrow \phi x_0 = x(x_0, b, a)$. In other words, if one can find the system function Φ of the time-discrete dynamical system, $\phi_{n+1} = \Phi(\phi_n)$, then P is the Poincaré map.

In dynamical systems, a Poincaré map or Poincaré section, is the intersection of a trajectory which moves periodically (or quasi-periodically, or chaotically), in

a space of at least three dimensions, with a transversal hypersurface of one fewer dimension. More precisely, one considers a trajectory with initial conditions on the hyperplane and observes the point at which this trajectory returns to the hyperplane. Imagine as stroboscopic illumination. The Poincaré section refers to the hyperplane, and the Poincaré map refers to the map of points in the hyperplane induced by the intersections.

It differs from a recurrence plot in that space, not time, determines when to plot a point. For instance, the locus of the moon when the earth is at perihelion is a recurrence plot; the locus of the moon when it passes through the plane perpendicular to the earth's orbit and passing through the sun and the earth at perihelion is a Poincaré map.

38.4.1.2 Circle map and annulus map for periodic forcing

The equation of motion of a periodically forced dynamical system, e.g. a self-sustained oscillator, in the vicinity of a limit cycle can be reduced to [1031],

$$\dot{\phi} = \omega_0 + \epsilon F(\phi, t) \ . \tag{38.64}$$

Note that this equation does not describe a real motion, since there is only one spatial variable. Nevertheless, it is useful whenever inertia can be neglected. The r.h.s. of this equation is a 2π periodic function of phase ϕ and a T periodic function of time t. Thus the phase space of the dynamical system is a two-dimensional torus (see Fig. 38.14).

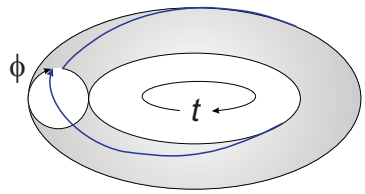

Figure 38.14: Toroidal phase space of the limit-cycle oscillator. Time goes along the ring, phase winds around the cross section.

If $\epsilon \ll 1$, then $\dot{\phi} \approx (\phi(t+T) - \phi(t))/T$, and the phase space can be reduced to a one-dimensional map called *circle map* by stroboscopic mapping with time interval T,

$$\phi(t+T) = \phi(t)+\omega_0 T+\epsilon \int_t^{t+T} F dt = \phi(t)+\omega_0 T+\epsilon[G(t+T)-G(t)] \simeq \phi(t)+\omega_0 T+\epsilon T G(t) \ . \tag{38.65}$$

Defining $\phi_n \equiv \phi(t+nT)$,

$$\phi_{n+1} = \mathrm{mod}_{2\pi} \left[\phi_n + \omega_0 T + \epsilon F(\phi_n)\right] \ . \tag{38.66}$$

If $\epsilon = 0$, we get a circle shift. For rational periods $\omega_0 T = 2\pi p/q$, each point of the circle is periodic with period q. The *rotation number* is,

$$\rho(\phi_0) = \lim_{n\to\infty} \frac{\phi_n - \phi_0}{2\pi n} \ . \tag{38.67}$$

The observed frequency is $\Omega = \rho\omega_0$. Close to rational periods it tends to lock. This is visualized by the *devil's staircase* and the *Arnold tongue*.

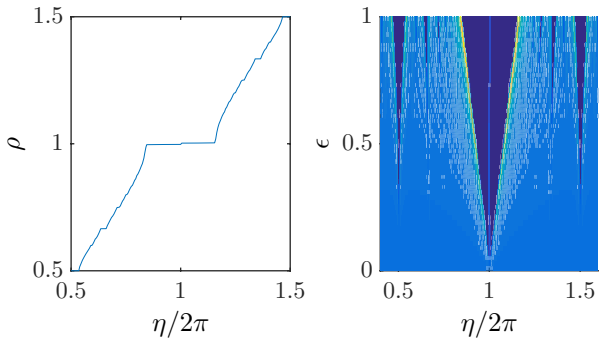

Figure 38.15: (code) (a) Devil's staircase of locking ranges and (b) Arnold tongues in the circle map $\phi_{n+1} = \phi_n + \omega_0 T + \epsilon \sin\phi_n$.

The *annulus map* is used in 2D. As an example, the standard map for the equation $\ddot{\phi} + K\sin\phi = 0$ would be $\phi_{n+1} = \phi_n + P_{n+1}$ and $P_{n+1} = P_n + K\sin\phi_n$.

38.4.2 Driven oscillators

A driven *self-sustained oscillator* or *limit-cycle oscillator* are described by circle maps, as shown above. Their dynamics is described by the so-called *Kuramoto model* explained below. Although forced rotators are not self-sustained, they behave in a similar way, if driven by a constant force. Examples are the δ-kicked rotor and the resistively shunted Josephson junction discussed in Sec. 21.4.4.

38.4.2.1 Self-sustained oscillators and the Kuramoto model

The Kuramoto model is given by the following equation [667] [13],

$$\boxed{\dot{\theta}_n = \frac{K}{N}\sum_m \sin(\theta_n - \theta_m) - \xi_n(t)} \ . \tag{38.68}$$

The Kuramoto model describes, how an ensemble of coupled harmonic oscillators oscillating at different frequencies will synchronize, if their number and their mutual coupling exceeds a critical value. This paradigm is very rich of examples, since it applies as well to physical systems like Huygens' coupled pendulums (illustrated in

[13] For *two coupled limit-cycle oscillators* the Kuramoto equations read,

$$\dot{\theta}_1 = \omega_1 + \tfrac{1}{2}K\sin(\theta_2 - \theta_1) \qquad \text{and} \qquad \dot{\theta}_2 = \omega_2 + \tfrac{1}{2}K\sin(\theta_1 - \theta_2) \ ,$$

such that, defining $\theta \equiv \theta_1 - \theta_2$, we obtain the so-called *Adler equation* (see (21.99) and 37.2.2),

$$\dot{\theta} = \Delta\omega - K\sin\theta \ .$$

.

Fig. 38.16) and arrays of Josephson junctions or lasers, as it describes biological systems like the cardiac pacemakers cells, firing neurons, firefly flashes and cricket concerts [1273]. The variance of the oscillator frequencies introduces a random mixing of the phase space, which may be described by a stochastic Langevin force, which introduces fluctuations in the (otherwise deterministic) center-of-motion. Another prominent system is the collective atomic recoil laser discussed in Sec. 42.2. The Kuramoto model corresponds to a mean-field theory. It has been shown that this leads to a phase transition (in time domain). Cooperative action starts at a threshold value.

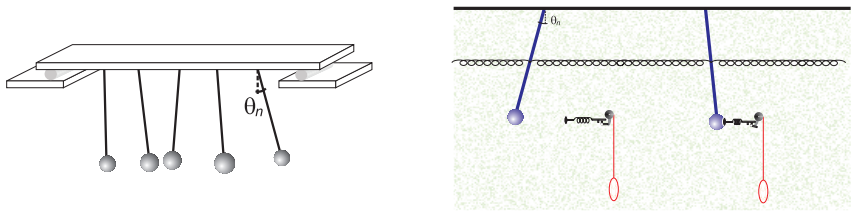

Figure 38.16: Huygen's pendulum.

38.4.2.2 Synchronization of limit-cycle oscillators

It is an interesting question, why the Kuramoto model is able to map physical systems anyway! While it is clear, that it predicts synchronization of the phases θ_n in equation (38.68), its application to coupled pendulums is less obvious. Indeed, we would rather expect coupled pendulums to beat, rather then synchronize their oscillations. Synchronization would lower entropy, which is not possible in closed systems. In fact, Huygens did his observation with *pendulum clocks* rather than physical pendulums, which is totally different, because each clock provides energy and friction in such a way as to maintain the oscillation at a constant amplitude. Hence, the physical system is not closed, as the Kuramoto model suggests.

But even for pendulum clocks synchronization seems to be an artefact of the Kuramoto model, because in order to synchronize two pendulums, one has to speed up the first and slow down the second. If the pendulums have finite mass, this requires inertial terms, which are absent from the Kuramoto model. Hence, the Kuramoto equation does not follow immediately from a mechanical model, but at some limit or approximation.

The Kuramoto model does *not* map exactly a real physical system, but grasps some of their features and exhibits them in an illustrative way. In this sense, its applicability to a vast variety of systems is not surprising.

Even in the case of coupled driven pendulums, a derivation of the Kuramoto equation from first principles is not obvious. One might start from the mechanical eequations of motion,

$$\ddot{x}_n + \beta\dot{x}_n + \omega_n^2 x_n + g\sum_m (x_n - x_m) = F\cos\omega t \ , \tag{38.69}$$

where we let the oscillators have different frequencies ω_n, but they couple with the same strength g to all other oscillators, where $\omega_n^2 \gg g$. As a simplification we only

consider *limit-cycle oscillation* of the individual oscillators. The role of the force is reduced to assuring this boundary condition, so that if we impose solutions like $x_n \equiv e^{\imath\omega t+\imath\theta_n}$ we do not need an explicit force term, $F \equiv 0$,

$$\imath\ddot{\theta}_n e^{\imath\omega t+\imath\theta_n} - (\omega^2 + \dot{\theta}_n^2)e^{\imath\omega t+\imath\theta_n} + \imath\beta\left(\omega + \dot{\theta}_n\right)e^{\imath\omega t+\imath\theta_n} + \omega_n^2 e^{\imath\omega t+\imath\theta_n} + g\sum_m \left(e^{\imath\omega t+\imath\theta_n} - e^{\imath\omega t+\imath\theta_m}\right) = 0 \ . \tag{38.70}$$

The imaginary part is,

$$\ddot{\theta}_n + \beta\dot{\theta}_n + \beta\omega - g\sum_m \sin(\theta_m - \theta_n) = 0 \ . \tag{38.71}$$

Neglect inertia and defining $K \equiv g/\beta$ and $re^{\imath\psi} \equiv N^{-1}\sum_m e^{\imath\theta_m}$,

$$\dot{\theta}_n = \omega + Kr\sin(\psi - \theta_n) \ . \tag{38.72}$$

This shows that dissipation is an essential ingredient for the Kuramoto model. The assumption of a driving and a friction force is necessary to ensure a constant kinetic energy for every oscillator despite the existence of a coupling, i.e. an energy exchange between the oscillators. Every oscillator is coupled to a reservoir, and this coupling provides or receives the excess energy and entropy resulting from the mutual coupling between the oscillators. The model also has been extended to include inertial effect [3],

$$m\ddot{\theta}_n + \dot{\theta}_n = \omega + Kr\sin(\psi - \theta_n) \ . \tag{38.73}$$

The numerical simulation of Eq. (38.68) with *real coupling* does not exhibit synchronization (be careful to avoid numerical errors). This is not astonishing, because it is a *linear closed system not driven by any dissipative force*. Energy is not lost, the evolution is deterministic, thus reversible, thus no entropy is produced or reduced. In contrast synchronization would indicate that entropy has been reduced. Therefore synchronization must have something to do with imaginary coupling...? And nonlinearity in the case of Huygens' pendulum.

38.4.3 Forced rotator

38.4.3.1 Constant forcing

The phase space of a free undamped rotator is shown in Fig. 38.17.

By adding a torque and friction, we obtain the *forced rotator*. Its behavior is similar that of the δ-kicked rotor. The damped rotator equation has many applications in various domains. In the form,

$$\frac{d^2\varphi}{dt^2} + \gamma\frac{d\varphi}{dt} + \frac{g}{l}\sin\varphi = T/I \ , \tag{38.74}$$

it describes a physical pendulum of length l and moment of inertia I, if a friction force and a torque T are applied (see Sec. 4.1.7). In the form,

$$\frac{d^2\varphi}{dt^2} + \frac{1}{\tau}\frac{d\varphi}{dt} + KAB\sin\varphi = -\frac{1}{\tau}(\omega_{lo} - \omega_0) \ , \tag{38.75}$$

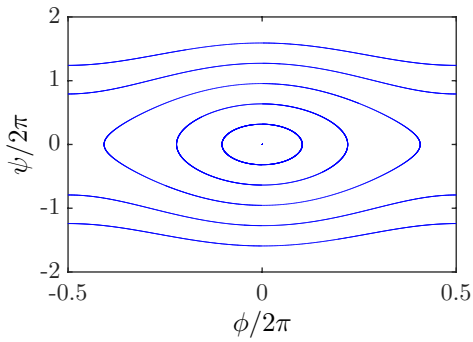

Figure 38.17: (code) Phase space trajectories of undamped pendulum.

it describes a phase-locked loop (PLL) (see Sec. 55.3.5). Here τ is the integration time of the low-pass filter, A and B are the amplitudes of the master and slave lasers, K the amplitude of the local oscillator, ω_{lo} its frequency, and ω the center frequency of the VCO. In the form,

$$C\frac{\Phi_0}{2\pi}\frac{d^2\varphi}{dt^2}+\frac{1}{R}\frac{d\varphi}{dt}+I_c\sin\varphi=i\ , \tag{38.76}$$

it describes resistively shunted Josephson junctions (see Sec. 21.4.4). Here $\Phi_0=h/2e$, C is the capacitance of the junction, R its resistance, and I_c the critical current through the junction. In the form,

$$\frac{1}{2U}\frac{d^2\varphi}{dt^2}+\frac{8\nu g^2N^2\kappa}{\left(\kappa^2+4\nu^2\right)^2}\frac{d\varphi}{dt}+\frac{\Omega_{mw}N}{2}\sin\varphi=\frac{g^2N^2\kappa}{\kappa^2+4\nu^2}\ , \tag{38.77}$$

it describes merging BECs in a ring cavity (see Sec. 47.5.4). The synchronizing degrees of freedom are relative phases of the Broglie waves. Irreversible dissipation is obtained via coupling to an optical cavity followed cavity decay.

Harmonically forced rotators are described by annulus maps. In the presence of dissipation, the rotator can be overdamped, e.g. vanishing capacitance in the JJ. The equation of motion then reduces to that of a self-sustained oscillator described by a circle map. Phase-locking of the dipole moments of the transitions in a V-type three-level system, like for the *Correlated spontaneous Emission Laser* (CEL) is such an example. The Adler equation, which describes the CEL, resembles the equation for a resistively shunted Josephson junction [663] for the approximation $\ddot{\Phi}=0$. For the CEL irreversibility, is achieved via optical pumping followed by spontaneous emission.

In all cases, quantum systems synchronize, provided there is some resistive dissipation (spontaneous emission, cavity friction, ..). I.e. *forcing against friction is a necessary precondition for synchronization.*

38.4.3.2 Periodic forcing

Expect classically chaotic behavior.

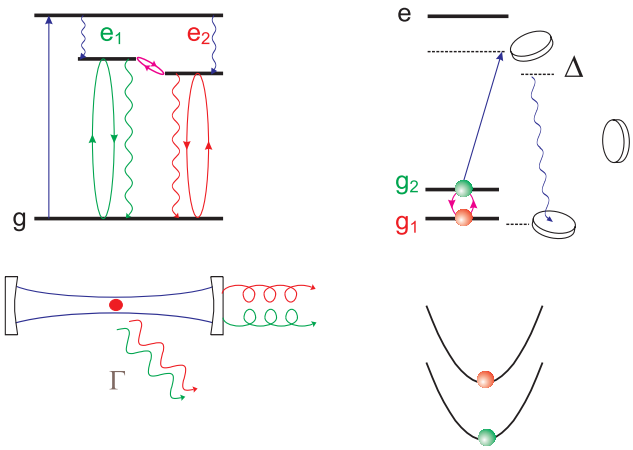

Figure 38.18: (a) Schemes for PLL/CEL and (b) merging BEC (right). PLL corresponds to a locking of the induced dipole moments (green and red elliptic curves). CEL corresponds to a correlation of the spontaneous emission (green and red waves). Noise reduction by synchronization analogous to CEL.

An interesting question is whether the Kuramoto phase transitions considered here are quantum phase transitions, i.e. whether they occur at $T = 0$. For the merging BEC system the temperature resides in thermal excitations. How about the PLL, where *inversion* is a precondition for lasing?

A rich system to study *dynamical localization*, *quantum resonance*, and *quantum synchronization* is the *δ-kicked rotor*.

38.4.4 Periodically kicked quantum rotor

The *δ-kicked rotor* is the paradigm of Hamiltonian chaos. Experimentally, 100 μK cold atoms are released from a MOT, and a fast succession of light pulses is applied. The light is a far-detuned standing wave.

Atom optical systems have a number of advantages: 1. It is relatively simple to generate highly nonlinear potentials, in which the dynamics of trapped particles exhibits classical chaos. 2. The duration of an experiment can easily exceed the quantum break time. 3. The isolation from environment is sufficient to allow for persistent quantum interferences. 4. Negligible dissipation permits quantum effects to get visible.

A presentation on the subject is available here (watch talk).

38.4.4.1 Classical evolution

At short times (shorter than the quantum break time) the δ-kicked rotor behaves classically. I.e. the initial spatial distribution of the MOT diffuses into a Gaussian momentum distribution. The energy growth is diffusive. These are signatures of

chaotic behavior. The Hamiltonian of a δ-kicked rotor is,

$$\hat{H}' = \frac{\hat{p}'^2}{2m} + V_0 \cos 2k_L \hat{x}' \sum_{n=-\infty}^{\infty} \delta(t - nT) \ , \tag{38.78}$$

where T is the time interval between the pulses, t is an integer counting the pulses. The equation of motion follows from $\dot{\hat{x}}' = \partial \hat{H}/\partial \hat{p}'$ and $\dot{\hat{p}}' = -\partial H/\partial \hat{x}'$,

$$m\ddot{\hat{x}}' = 2k_L V_0 \sin 2k_L \hat{x} \sum_{n=-\infty}^{\infty} \delta(t - n) \ . \tag{38.79}$$

With the abbreviations $\omega_r \equiv 2\hbar k_L^2/m$ and $\bar{k} \equiv 2\omega_r T$, we go to dimensionless units via $\hat{H} = \hat{H}'\bar{k}^2/2\hbar\omega_r$, $K = V_0\bar{k}^2/2\hbar\omega_r$, $t = t'/T$, $\hat{x} = 2k_L\hat{x}'$, and $\hat{p} = \hat{p}'\bar{k}/2\hbar k_L$, we get,

$$\hat{H} = \frac{\hat{p}^2}{2} + K \cos \hat{x} \sum_{n=-\infty}^{\infty} \delta(t - n) \ . \tag{38.80}$$

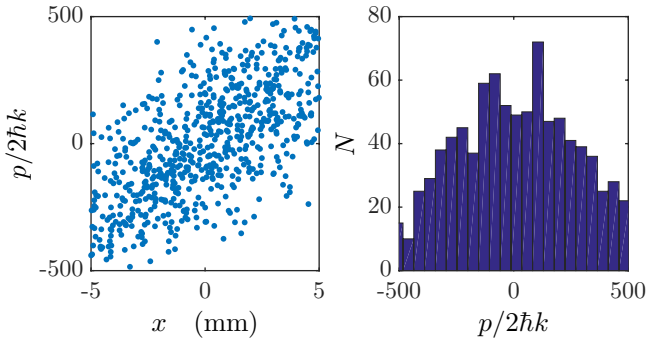

Figure 38.19: (code) (a) Phase diagram and (b) histogram of the classical kicked rotor.

38.4.4.2 Dynamical localization

At longer times the momentum distribution turns exponential, which is a clear indication of dynamical localization. This is quantum suppression of chaotic diffusion, i.e. of stochasticity. This is at first surprising, because all quantum problems have probabilistic, i.e. stochastic interpretations. Apparently, the fact that the density of states in quantum mechanics is discrete, leads to periodic time evolutions. (This is because the Fourier spectrum of a periodic motion is discrete.) This gives rise to periodic orbits in situations, where classical mechanics predicts chaos.

The suppression of energy transport in the rotor can be interpreted as Anderson localization (in angular momentum rather than in space) [450]. The randomness of disordered lattices in the Anderson problem is replaced by pseudo-randomness in the phase of the δ-kicks. Dynamical localization suppressed chaotic diffusion by coherence effects. Typical pulse lengths for δ-kicks are 300 ns. This would work in the ring cavity at low finesse.

The classical dynamics of the δ-kicked rotor is solely determined by the stochasticity parameter K. For $K > 4$ the dynamics is predominantly chaotic. The quantum mechanics are additionally specified by $\bar{k}$. The scaled version of commutation relation, $[\hat{x}', \hat{p}'] = \imath\hbar$, reads,

$$[\hat{x}, \hat{p}] = \imath\bar{k} \ . \tag{38.81}$$

Obviously, k has the meaning of a scaled Planck constant measuring the action scale of our system.

Technical issues are: 1. Finite pulse shapes reduce chaos and hence dynamical localization [728, 729]. 2. Noise and dissipation also lead to delocalization, i.e. the classical limits are recovered, i.e. instead of localization after the quantum break time, momentum continues to diffuse with a coefficient dependent on the amount of noise.

38.4.4.3 Quantum resonance

However, at specific periods between the kicks, i.e. when time interval equals the inverse of the recoil shift, the ballistic expansion is observed, i.e. there is a constant and uniform acceleration force. There is no localization any more, but a quadratic increase of energy. This is due to quantum resonance. Quantum resonances occur when $\bar{k}/2\pi$ is integer or a simple rational number. This can be understood as follows: The kicks occur when $Tv = \lambda/4 \times m/n$, the Bragg condition is fulfilled, i.e. the transitions takes place at the edges of a Brillouin zone. While quasimomentum is always conserved, with every kick the atoms jump into the next higher band increasing their energy by one recoil unit. These are the accelerator modes.

38.4.4.4 δ-kicked rotor in the gravitational field

Gravitation [451, 1163] helps stabilizing quantum resonances.

In the gravitational field, $-mg\hat{x}'$, the equation of motion reads,

$$m\ddot{\hat{x}}' = 2k_L V_0 \sin 2k_L\hat{x} \sum_{n=-\infty}^{\infty} \delta(t-n) + mg \ . \tag{38.82}$$

The scaled Hamiltonian of a δ-kicked rotor is, using $f \equiv mgT/\hbar k_L$,

$$\hat{H} = \frac{\hat{p}^2}{2} - f\hat{x} + K\cos\hat{x} \sum_{n=-\infty}^{\infty} \delta(t-n) \ , \tag{38.83}$$

We transform into the accelerated frame via $\hat{P} = \hat{p} - ft$,

$$\hat{H}_g = e^{\imath f\hat{x}t}\hat{H}e^{-\imath f\hat{x}t} = \frac{1}{2}(\hat{P} + ft)^2 + K\cos\hat{x} \sum_{n=-\infty}^{\infty} \delta(t-n) \ . \tag{38.84}$$

Separate band and quasimomentum via $\hat{P} = N + \beta$, $N = -\imath\frac{\partial}{\partial\theta}$. The evolution over one period is then,

$$e^{-\imath\hat{H}_g t} = e^{-\imath K\cos\hat{x}_{\mathrm{mod}2\pi} - \frac{\imath\tau}{2}(N+\beta+fn+f/2)^2} \ . \tag{38.85}$$

38.4.4.5 Impact of noise and dissipation

The standard map of a δ-kicked rotor is [451, 206]

$$\begin{aligned} J_{n+1} &= J_n - k\sin\theta_{n+1} - \mathrm{sgn}(\epsilon)\tau\eta \\ \theta_{n+1} &= \theta_n \mathrm{sgn}(\epsilon) J_n \mathrm{mod} 2\pi \ . \end{aligned} \tag{38.86}$$

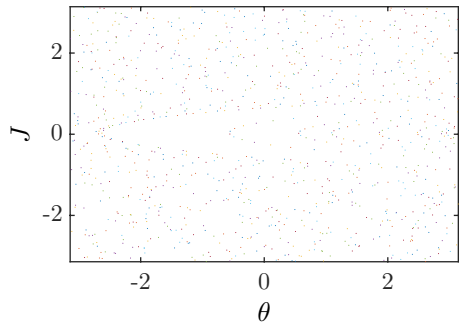

Figure 38.20: (code) Standard map of the gravitationally accelerated δ-kicked rotor. The parameters are $\tau = 6.26$, $k = 1.329$, $\eta = \tau * pi/20$, $\theta_0 = 0.42$, and $J_0 = 0$.

In the presence of dissipation, the *dissipative map* is derived [1431]

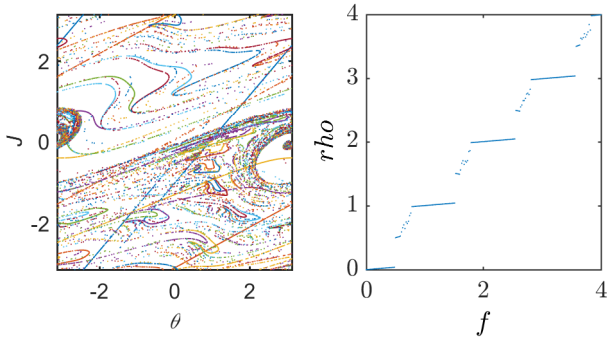

Figure 38.21: (code) Dissipative map of the gravitationally accelerated δ-kicked rotor.

38.4.4.6 Quantum synchronization

Quantum accelerator modes are the non-dissipative counterparts of mode locking: The δ-kicked rotor with gravity leads to the same map as the Josephson junction with dissipation. Hence, the classical mode locking mechanism underlying quantum accelerator modes renders them a robust tool for efficient quantum state control, deep in the quantum realm [206]. Accelerator modes are due to stability islands in pseudo-classical phase space.

All map are necessarily classical constructs. To get quantum maps, a master equation treating dissipation via additional Lindblad terms can be simulated by quantum Monte-Carlo procedures [1431]. As an example, one may consider the formation of Shapiro steps in δ-kicked atomic clouds in the presence of dissipation. For strong dissipation, quantum fluctuations can be suppressed by *quantum synchronization* when the system is close to the classical limit. In the quantum limit, there is a steady phase slip washing out the synchronization plateaus. For weak dissipation in the classical limit, chaotic behavior can lead to multivalued synchronization frequencies (the dissipative map can have different attractors). In the quantum limit, chaos is stabilized.

A dissipative quantum system at zero temperature can only tunnel towards its lowest energy state when a biasing dc-signal is applied. As the bias periodically changes its sign due to the action of a driving field, tunneling makes the particle move periodically towards its corresponding lowest energy state, as long as the driving period is much *longer* than the typical tunneling time. In contrast, a *short* driving periods, finite temperature quantum noise promotes and assists synchronization. This is similar to the stochastic resonance.

One could have the impression that the whole quantum synchronization business is nothing else a reinvention of the CEL [1251].

One of the defining features of quantum mechanics in entanglement, i.e. the impossibility to factorize a system into its constituents. It seems, that in an appropriate classical limit only chaotic systems can preserve a significant amount of entanglement [429]. E.g. as long as two coupled oscillators are classically uncorrelated and behave chaotically, quantum entanglement can exist no matter the value of $\hbar$. As soon as they synchronize, chaos disappears and so does entanglement. In fact chaos disappears mainly in the classical limit, since it does really exist in the quantum limit, where quantum noise is large enough to drive the system away from periodic attractors and swamp the fractal structure found in the chaotic classical attractor.

The quantum correlations do not have classical counterparts yet they persist in the classical limit. Some understanding can be gained if we consider that in order to obtain the classical limit, it is sufficient that the state of the system be localized relative to a large classical action. However, in order to guarantee that the entanglement between the two oscillators can be eliminated from the system, we require that the localization of the wavefunction be of the order of $\hbar$. Hence, satisfying the classical limit does not imply that entanglement will be removed.

38.4.5 Chaos

'Chaos is found in greatest abundance wherever order is being sought. It always defeats order, because it is better organized.' [T. Pratchett, Diskworld novela, 'Interesting times']

38.4.5.1 Classical chaos versus quantum chaos

The *classical chaos* or *deterministic chaos* arises of unprecisely known initial conditions. The signatures of chaos are an exponential sensitivity of the systems' trajectory

to initial conditions and *self-similarity*. The first one is measured by the *Lyapunov exponent*. *Hopf bifurcation*.

While in the classical world chaos is encountered everywhere, in quantum mechanics this is not obvious, because the fundamental equation of motion, the Schrödinger equation, is linear. Counterintuatively, and although quantum mechanics is intrinsically probabilistic, there are systems at the boundary of quantum and classicality where chaos is inhibited and stabilized by quantum mechanics. The *quantum chaos* thus behaves very differently from classical chaos.

38.4.5.2 Quantum synchronization

How to find a system that suits for quantum synchronization? Start checking the following requirements: 1. In the classical limit the system should behave chaotic (this is fulfilled with the CARL). 2. There must be a continuous degree of freedom that can be quantized, e.g. atomic motion, tunneling flux, etc.. 3. Feasibility of weak dissipation. 4. ...

A particularity of atoms interacting with optical ring cavities is that they are literally haunted by synchronization. Examples are: 1. Kuramoto type synchronization of the motion of individual atoms. This effects is known as CARL. 2. Mode locking of the optical fields to resonances of the cavity. This effect is at the origin of laser cooling. 3. Fusion of independent but coupled BECs under the action of an irreversible cycling scheme. This effects is analogous to resistively shunted Josephson junctions. 4. Tunneling between adjacent wells of the standing wave in the cavity, and the interplay of superfluidity and Mott insulation.

Some of the synchronization phenomena are essentially classical. Nevertheless, the protagonists of the system are all quantum objects. For example, 1. the momentum of individual atoms is discretized when $k_B T < \hbar\omega_r$. 2. Quantum statistical effects, quantum correlations and entanglement come into play when $T < T_c$. 3. BECs are zero-temperature objects, and (at optical wavelengths) the universe represents an effective zero-temperature reservoir to which the cavity couples. Hence, it is an obvious question whether and in what sense quantum effects are going to effect the synchronization process itself. It is important to be aware that the fact that the synchronizing modes are quantum objects does not mean that the coupling force exhibits quantum behavior.

To construct an approach to quantum synchronization in the ring cavity system, in the following, we will start recalling another well-studied system, the atom optical δ-kicked rotor. This system bears analogies with an array of coupled Josephson junctions. Both, the coupled JJs and the δ-kicked rotor, have been proposed for studies of quantum synchronization [533]. We will try to find out analogies with ring cavity dynamics, e.g. the JJ like fusion of BECs [663].

The question addressed is that of classical-quantum mechanical correspondence, i.e. what happens if $\hbar \to 0$?

For strong coupling, classical nonlinear synchronization phenomena emerge on microscopic scales. Is mode locking necessarily strictly a (semi-)classical effect? No! An example is the atom optical quantum accelerator, i.e. δ-kicked atoms in the field of gravity. The δ-kicked rotor serves as prototype for classical and quantum chaos. In Sec. 42.8.2 we show how to simulate quantized motion.

Collective Scattering of Light

Chapter 39

Cooperativity in light scattering

In Chp. 34 we discussed the interaction of light with individual atoms. In the practice of spectroscopy, however, we often work with ensembles of scatterers. Depending on their *spatial distribution* (e.g. disordered, quasi-continuous, periodic), their *motion* (hot gas or cold cloud), the possible existence of *correlations* between them, the presence of *boundary conditions* (e.g., free space, cavities, or photon bands), and finally, in case of degenerate quantum gases, of a possible *bosonic stimulation* of the scattering process, we expect new collective effects. In this chapter we will discuss several examples, in particular, localization effects induced by disorder, super- and subradiance, Bragg scattering, and the formation of forbidden photonic bands in periodic lattices. Phenomena leading to self-organization, such as the collective atomic recoil laser, will be discussed in Chp. 42.

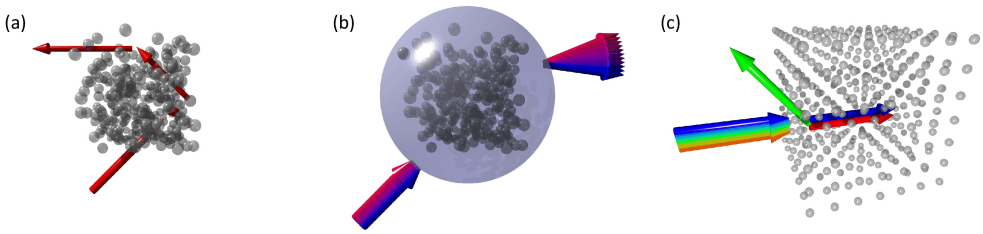

Figure 39.1: (a) Artist's view of multiple scattering of a photon through a dilute cloud. (b) Atomic cloud as a bulk object characterized by a refraction index $n(\mathbf{r})$. (c) Illustration of a photonic band in an optical lattice.

This chapter starts with introducing as the main theoretical tools the *structure factor* and the *coupled dipoles model*. In Sec. 39.1 we will derive the formalism and learn, how to employ it to calculate, e.g. the spatial distribution of light scattered by an atomic cloud and the radiation pressure force on the atoms focusing on situations, where interatomic interactions induced by the incident light can be neglected. In Sec. 39.2 we will, disregarding the atomic's cloud graininess and disorder, introduce the *smooth density approximation* and compare it to macroscopic Mie scattering. In Sec. 39.3 we will focus on cooperative effects inducing collective lineshifts and broadenings, such as the Lorentz-Lorenz and the Lamb shift. We will also discuss disorder-induced localization effects, super- and subradiance. In Sec. 39.2 we investi-

gate Bragg scattering, i.e. scattering from periodically ordered atoms, and finally in Sec. 40.2 we study scattering from correlated atoms.

39.1 Theoretical tools and models

As mentioned above, the process of light scattering by an atomic cloud depends on several factors, many of which can be summarized by a quantity called the *structure factor*. This structure factor, obtained in perturbation theory, describes the probability for the light to be scattered into a particular direction as a function of the properties of the atomic cloud (spatial distribution, motion, etc.). The quantity is well suited for dealing with stationary situations.

On the other hand we have at our disposal a microscopic theory called the *coupled dipole model*. In this model we treat every individual atom as a dipole, which interacts with all other atoms by rescattering the incident light. The resolution of the Schrödinger equation allows, several approximations having been made, to calculate the dynamics of the system.

39.1.1 The structure factor and definition of cooperativity

One way of characterizing the scattering process is by structure factor. The *static structure factor* is the normalized response of a system to a perturbation with the wave vector $\mathbf{q}$. It can be understood as the final density of states for the atom after the scattering process. In contrast, the *dynamic structure factor* also considers the final density of states for the emitted or scattered photon. That is, on one hand, the frequency and momentum of the photon must satisfy the Bragg condition. On the other hand, the density of available states can also be structured, for example, when the scattering process takes place inside a cavity.

In lowest-order perturbation theory (Fermi's Golden Rule) we get the general expressions [713],

$$\boxed{\frac{d\sigma}{d\Omega_s d\omega} = \left(\frac{d\sigma}{d\Omega_s}\right)_1 S(\mathbf{q},\omega)}\,, \tag{39.1}$$

that is, the effective scattering cross section is reduced to the effective Rayleigh scattering cross section by an isolated atom times a geometric term called *dynamic structure factor*,

$$\boxed{S(\mathbf{q},\omega) \equiv \tfrac{1}{2\pi}\int dt e^{\imath\omega t}\langle\hat{\rho}(\mathbf{q},t)\hat{\rho}^\dagger(\mathbf{q},0)\rangle}\,, \tag{39.2}$$

where,

$$\hat{\rho}(\mathbf{q},t) = \int_V \hat{n}(\mathbf{r},t)e^{\imath\mathbf{q}\cdot\mathbf{r}}d^3r \tag{39.3}$$

is Fourier transform of the atomic density. Thus, $S(\mathbf{q},\omega)$ is the Fourier transform of the density-density correlation function. On the other hand, $\int e^{\imath\omega t}d\omega = 2\pi\delta(t)$, and we calculate the *static structure factor*,

$$\boxed{S(\mathbf{q}) \equiv \int S(\mathbf{q},\omega)d\omega = \langle\hat{\rho}(\mathbf{q},0)\hat{\rho}^\dagger(\mathbf{q},0)\rangle}\,. \tag{39.4}$$

In the equations (39.2) and (39.3) we have written the quantities $\hat{\rho}(\mathbf{q},t)$ and $\hat{n}(\mathbf{r},t)$ as operators, in order to allow for the possibility, that the atomic ensemble is a quantum gas, i.e. a Bose-Einstein condensate characterized by a single wavefunction $\hat{\psi}(\mathbf{r},t)$ normalized to the density distribution, $\hat{\rho}(\mathbf{r},t)=\hat{\psi}^\dagger(\mathbf{r},t)\hat{\psi}(\mathbf{r},t)$. We shall return to this subject in Sec. 47.1.1. In the following, we will restrict ourselves to atoms localized in space with well-defined velocities and calculate the structure factor (i) for disordered clouds of atoms excited by the passage of a photon in Sec. 39.1.6 and (ii) for Bragg scattering by optical lattices in Sec. 39.4. In these cases, we find in the literature often another definition of the structure factor as the expectation value of the Fourier transform of the atomic density,

$$\mathcal{S}(\mathbf{q})=\langle\hat{\rho}(\mathbf{q})\rangle\ , \tag{39.5}$$

Thus, it describes the amplitude of the electric field of the scattered radiation. In order to avoid confusion we will call this quantity *structure coefficient* and denote it by a calligraphic $\mathcal{S}$. We study the structure factor for various atomic density distributions in Excs. 39.1.8.1 to 39.1.8.3.

Example 226 (*Structure factor of a discrete cloud*): In case of discrete clouds, $n(\mathbf{r},t)=\sum_j\delta^{(3)}(\mathbf{r}-\mathbf{r}_j)$, we can disregard the quantum nature of the operators. The relationship (39.3) immediately gives,

$$\rho(\mathbf{q},t)=\sum_j e^{\imath\mathbf{q}\cdot\mathbf{r}_j(t)} \tag{39.6}$$

and the relationship (39.2),

$$S(\mathbf{q},\omega)=\tfrac{1}{2\pi}\int dt e^{\imath\omega t}\rho(\mathbf{q},t)\rho^*(\mathbf{q},0)=\tfrac{1}{2\pi}\int dt e^{\imath\omega t}\sum_{j,k}e^{\imath\mathbf{q}\cdot[\mathbf{r}_j(t)-\mathbf{r}_k(0)]}\ . \tag{39.7}$$

Assuming atoms fixed in space, $\mathbf{r}_j(t)=\mathbf{r}_j$,

$$S(\mathbf{q},\omega)=\sum_{j,k}e^{\imath\mathbf{q}\cdot(\mathbf{r}_j-\mathbf{r}_k)}\delta(\omega)\ . \tag{39.8}$$

That is, without recoil the light must be scattered elastically.

The notion of *cooperativity* is fundamental for any problem involving scattering of radiation and, depending on the specific area of physics, is called by many different names, such as Purcell factor, cavity-to-free-space scattering ratio, or phase matching condition. Here, we will regard cooperativity as any ***deviation of the structure factor from isotropy***. For example, Bragg scattering and optical cavities are highly cooperative, because they favor scattering in particular directions [1].

39.1.2 The scalar coupled dipoles model

In the following, we develop the coupled dipoles model, within which we define the structure factor for light scattering by a cloud of scatterers making the following assumptions:

[1] Note that cooperativity does not request the atoms to interact and exists in the single scattering regime. In the multiple scattering regime other forms of collective phenomena, such as collective Lamb shifts emerge, as we will see later on.

- The light is (mostly) treated as a scalar field. That is, we disregard effects due to the polarization of light and assume two-level atoms. Generalizations are shown in Sec. 39.5.4 [1214, 859].
- Atoms are supposed to be fixed in space. That is, we disregard the Doppler shift of moving atoms and the photonic recoil. Therefore, it will suffice to consider the static structure factor.
- Atoms are initially uncorrelated and not degenerate. That means that we neglect effects such as bosonic stimulation or Fermi blocking [2].

Be ω_0 the frequency of the incident light, ω_a the frequency of the atomic resonance, and ω the frequency of the scattered light. The Hamiltonian is nothing more than the generalization of (35.222) to several assumed atoms located at the positions r_j,

$$\boxed{\begin{aligned}\hat{H} &= \sum_{j=1}^{N} \hbar g_{\mathbf{k}_0}(\hat{\sigma}_j e^{-\imath\omega_a t} + \hat{\sigma}_j^\dagger e^{\imath\omega_a t})(\hat{a}_{\mathbf{k}_0}^\dagger e^{\imath\omega_0 t - \imath\mathbf{k}_0\cdot\mathbf{r}_j} + \hat{a}_{\mathbf{k}_0} e^{-\imath\omega_0 t + \imath\mathbf{k}_0\cdot\mathbf{r}_j}) \\ &+ \sum_{\mathbf{k}}\sum_{j=1}^{N} \hbar g_{\mathbf{k}}(\hat{\sigma}_j e^{-\imath\omega_a t} + \hat{\sigma}_j^\dagger e^{\imath\omega_a t})(\hat{a}_{\mathbf{k}}^\dagger e^{\imath\omega_k t - \imath\mathbf{k}\cdot\mathbf{r}_j} + \hat{a}_{\mathbf{k}} e^{-\imath\omega_k t + \imath\mathbf{k}\cdot\mathbf{r}_j})\end{aligned}} \quad . \tag{39.9}$$

Here, $\Omega_0 = 2g_{k_0}\sqrt{n_0}$ is the Rabi frequency of the interaction between an atom and the incident light (which is treated as a classical field with n_0 photons), $\hat{\sigma}_j$ is the deexcitation operator for the j-th atom, $\hat{a}_{\mathbf{k}}$ is the photon annihilation operator, and $g_k = d\sqrt{\omega/(\hbar\epsilon_0 V_{ph})}$ describes the coupling between the atom and the vacuum modes the volume of which is V_{ph}. The j-th atom has its lower and upper states denoted by $|g_j\rangle$ and $|e_j\rangle$, respectively. That is, we treat the atoms as simple two-level systems. We also assume that all atoms are excited by the same unperturbed incident laser beam, thus neglecting their dephasing along the laser path or induced by near-field effects (which could arise for large spatial densities).

Within the *rotating wave approximation* RWA the Hamiltonian simplifies to,

$$\begin{aligned}\hat{H} &= \hbar\sum_{j=1}^{N}[g_{k_0}\hat{\sigma}_j\hat{a}_{\mathbf{k}_0}^\dagger e^{\imath(\omega_0-\omega_a)t - \imath\mathbf{k}_0\cdot\mathbf{r}_j} + h.c.] \\ &+ \hbar\sum_{j=1}^{N}\sum_{\mathbf{k}}[g_k\hat{\sigma}_j\hat{a}_{\mathbf{k}}^\dagger e^{\imath(\omega_k-\omega_a)t - \imath\mathbf{k}\cdot\mathbf{r}_j} + h.c.] \ .\end{aligned} \tag{39.10}$$

The RWA only considers energy-conserving terms in single-photon processes. But this is an artifact from the field quantization. Energy conservation can be warranted by considering multi-photon virtual processes, which as a whole, conserve energy. These terms appear in the full Hamiltonian, but are neglected in the RWA. While the RWA often is a good assumption in single atom quantum optics, this is frequently not the case for collective scattering. Here, we adopt the RWA to a simplify the subsequent solution of the Schrödinger equation, but we will need to generalize the results obtained a posteriori, as shown in the discussion of Sec. 39.1.4.

[2] Spontaneous emission by an atom in a Fermi gas of temperature $T = 0$ can not occur if the photon wave vector is inside the Fermi lake, $q < k_F$.

We call $|0\rangle_a = |g_1,..,g_N\rangle$ the atomic ground state, $|j\rangle_a = |g_1,..,e_j,..,g_N\rangle$ the state where only the atom j is excited, and we assume that the system is in a the superposition of states described by [3],

$$|\Psi(t)\rangle = \alpha(t)|0\rangle_a|n_0\rangle_{\mathbf{k}_0}|0\rangle_{\mathbf{k}} + \sum_{j=1}^{N}\beta_j(t)|j\rangle_a|n_0-1\rangle_{\mathbf{k}_0}|0\rangle_{\mathbf{k}} + \sum_{\mathbf{k}}\gamma_{\mathbf{k}}(t)|0\rangle_a|n_0-1\rangle_{\mathbf{k}_0}|1\rangle_{\mathbf{k}} \ . \tag{39.11}$$

With this ansatz we imply that at every instant of time, there can be at most only one excitation in the atomic cloud. The temporal evolution of the amplitudes is obtained by inserting the Hamiltonian and the ansatz into the Schrödinger equation, $\imath\hbar\partial_t|\Psi(t)\rangle = \hat{H}|\Psi(t)\rangle$. Once the evolution of the amplitudes is calculated, we can determine the observables of the system, such as the radiative pressure force or the amplitudes of the scattered radiation fields or the fields inside the cloud.

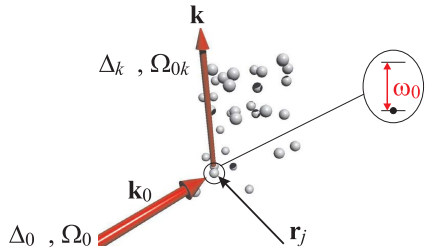

Figure 39.2: Scheme of the interaction of a light beam with a sample of atoms.

Example 227 (*Interaction Hamiltonian in the rotating frame*): The Hamiltonian in the rotating wave approximation is,

$$\hat{H} = \hbar g\left(\hat{\sigma}e^{-\imath\omega_a t} + \hat{\sigma}^\dagger e^{\imath\omega_a t}\right)\left(\hat{a}^\dagger e^{\imath\omega_0 t} + \hat{a}e^{-\imath\omega_0 t}\right) \simeq \hbar g\left(\hat{\sigma}\hat{a}^\dagger e^{\imath\Delta_0 t} + \hat{\sigma}^\dagger\hat{a}e^{-\imath\Delta_0 t}\right) \ .$$

For the Pauli matrices we have the following rules,

$$[\hat{\sigma}_z,\hat{\sigma}] = -\hat{\sigma} \qquad \text{and} \qquad [\hat{\sigma}_z,\hat{\sigma}^\dagger] = \hat{\sigma}^\dagger \ ,$$

such that,

$$\begin{aligned}
[\hat{\sigma}_z,\hat{H}] &= \hbar g\left(-e^{\imath\Delta_0 t}\hat{a}^\dagger\hat{\sigma} + e^{-\imath\Delta_0 t}\hat{a}\hat{\sigma}^\dagger\right)\\
[\hat{\sigma}_z,[\hat{\sigma}_z,\hat{H}]] &= \hbar g\left(e^{\imath\Delta_0 t}\hat{a}^\dagger\hat{\sigma} + e^{-\imath\Delta_0 t}\hat{a}\hat{\sigma}^\dagger\right) = \hat{H}\\
[\hat{\sigma}_z,[...[\hat{\sigma}_z,\hat{H}]]...] &= \hbar g\left[(-1)^n e^{\imath\Delta_0 t}\hat{a}^\dagger\hat{\sigma} + e^{-\imath\Delta_0 t}\hat{a}\hat{\sigma}^\dagger\right] \ .
\end{aligned}$$

[3] This ansatz is well adapted to situations where the RWA holds. Otherwise, additional counter-rotating terms must be included [458].

Using the Baker-Haussdorff formula,

$$\begin{aligned} e^{\imath\omega_0 t\hat{\sigma}_z}\hat{H}e^{-\imath\omega_0 t\hat{\sigma}_z} &= \hat{H} + [\imath\omega_0 t\hat{\sigma}_z, \hat{H}] + \tfrac{1}{2!}[\imath\omega_0 t\hat{\sigma}_z, [\imath\omega_0 t\hat{\sigma}_z, \hat{H}]] + ... \\ &= \hbar g \sum_{n=0}^{\infty} \tfrac{(\imath\omega_0 t)^n}{n!} \left[(-1)^n e^{\imath\Delta_0 t}\hat{a}^\dagger\hat{\sigma} + e^{-\imath\Delta_0 t}\hat{a}\hat{\sigma}^\dagger\right] \\ &= \hbar g e^{\imath\Delta_0 t}\hat{a}^\dagger\hat{\sigma}\sum_{n=0}^{\infty}\tfrac{(-\imath\omega_0 t)^n}{n!} + \hbar g e^{-\imath\Delta_0 t}\hat{a}\hat{\sigma}^\dagger\sum_{n=0}^{\infty}\tfrac{(\imath\omega_0 t)^n}{n!} \\ &= \hbar g\left(e^{-\imath\omega_a t}\hat{a}^\dagger\hat{\sigma} + e^{\imath\omega_a t}\hat{a}\hat{\sigma}^\dagger\right) . \end{aligned}$$

39.1.2.1 Temporal evolution of the amplitudes

The time evolution of the amplitudes is obtained by inserting the Hamiltonian $\hat{H}$ and the ansatz $|\Psi(t)\rangle$ into the Schrödinger equation,

$$\frac{\partial}{\partial t}|\Psi(t)\rangle = -\frac{\imath}{\hbar}\hat{H}|\Psi(t)\rangle \ . \tag{39.12}$$

one obtains with $\Omega_0 = 2g_{k_0}\sqrt{n_0}$,

$$\begin{aligned} \dot{\alpha}(t) &= -\imath\tfrac{\Omega_0}{2}e^{\imath\Delta_0 t}\sum_{j=1}^{N}\beta_j(t)e^{-\imath\mathbf{k}_0\cdot\mathbf{r}_j} \\ \dot{\beta}_j(t) &= -\imath\tfrac{\Omega_0}{2}\alpha(t)e^{-\imath\Delta_0 t+\imath\mathbf{k}_0\cdot\mathbf{r}_j} - \sum_{\mathbf{k}}\imath g_k\gamma_{\mathbf{k}}(t)e^{-\imath\Delta_k t+\imath\mathbf{k}\cdot\mathbf{r}_j} \\ \dot{\gamma}_{\mathbf{k}}(t) &= -\imath g_k e^{\imath\Delta_k t}\sum_{j=1}^{N}\beta_j(t)e^{-\imath\mathbf{k}\cdot\mathbf{r}_j} \ . \end{aligned} \tag{39.13}$$

We set the initial conditions,

$$\alpha(0) = 1 \quad , \quad \beta_j(t) = 0 \quad , \quad \gamma_{\mathbf{k}}(t) = 0 \ . \tag{39.14}$$

For low excitation rate, we can set $\alpha(t) \simeq 1$. Integrating the third equation,

$$\gamma_{\mathbf{k}}(t) = -\imath g_k\sum_{j=1}^{N}e^{-\imath\mathbf{k}\cdot\mathbf{r}_j}\int_0^t e^{\imath\Delta_k t'}\beta_j(t')dt' \ , \tag{39.15}$$

and substituting it into the second equation,

$$\dot{\beta}_j(t) = -\imath\tfrac{\Omega_0}{2}\alpha(t)e^{-\imath\Delta_0 t+\imath\mathbf{k}_0\cdot\mathbf{r}_j} - \sum_{\mathbf{k}}g_k^2\sum_{m=1}^{N}e^{\imath\mathbf{k}\cdot(\mathbf{r}_j-\mathbf{r}_m)}\int_0^t e^{\imath\Delta_k(t'-t)}\beta_m(t')dt' \ . \tag{39.16}$$

39.1.3 The Markov approximation

For small systems, $R < \lambda$, we can make use of the Markov approximation, which holds when the collective decay time $t_{decay} < R/c$. Larger systems persist memory effects, which may lead to (Rabi) *collective Rabi oscillations*. In the Markov approximation given by $\beta_j(t') \simeq \beta_j(t)$ the integro-differential equation (which is equivalent to a differential equation of arbitrarily high order) reduces to a simple first order differential equation. Defining [4],

$$\beta_j \equiv \tilde{\beta}_j e^{-\imath\Delta_0 t + \imath \mathbf{k}_0\cdot\mathbf{r}_j} \ , \tag{39.17}$$

we obtain,

$$\frac{d}{dt}\alpha(t) = -\imath\frac{\Omega_0}{2}\sum_{j=1}^{N}\tilde{\beta}_j(t) \tag{39.18}$$

$$\frac{d}{dt}\tilde{\beta}_j(t) = \imath\Delta_0\tilde{\beta}_j(t) - \frac{\Omega_0^2}{4}\sum_{m=1}^{N}\int_0^t \tilde{\beta}_m(t')dt' - \sum_{\mathbf{k}} g_k^2 \sum_{m=1}^{N} e^{\imath(\mathbf{k}-\mathbf{k}_0)\cdot(\mathbf{r}_j-\mathbf{r}_m)}\int_0^t e^{-\imath(\omega_k-\omega_0)t''}\tilde{\beta}_m(t-t'')dt'' \ ,$$

where we substituted $t'' \equiv t - t'$ in the last integral. Now, using the Markov approximation $\tilde{\beta}_m(t-t'') \simeq \tilde{\beta}_m(t)$, with $\lim_{t\to\infty}\int_0^t e^{-\imath(\omega_k-\omega_0)t'}dt' = \pi\delta(\omega_k-\omega_0)$, and with the rate of spontaneous emission,

$$\boxed{\Gamma \equiv \frac{V_{ph}}{\pi c}k_0^2 g_{k_0}^2} \ , \tag{39.19}$$

the third term becomes for the case $m = j$,

$$\sum_{\mathbf{k}} g_k^2\int_0^t e^{-\imath(\omega_k-\omega_0)t''}\tilde{\beta}_j(t-t'')dt'' \simeq \sum_{\mathbf{k}} g_k^2\tilde{\beta}_j(t)\pi\delta(\omega_k-\omega_0) \tag{39.20}$$

$$= \frac{V_{ph}}{(2\pi)^3}\tilde{\beta}_j(t)\int g_k^2\pi\delta(\omega_k-\omega_0)d^3k = \frac{V_{ph}}{(2\pi)^3}\tilde{\beta}_j(t)4\pi g_{k_0}^2\pi k_0^2\frac{1}{c} = \frac{\Gamma}{2}\tilde{\beta}_j(t) \ .$$

The third term becomes for the case $m \neq j$, evaluating the sum over the wavevectors by $\sum_{\mathbf{k}} \to \frac{V_{ph}}{(2\pi)^3}\int d^3k$,

$$\sum_{\mathbf{k}} g_k^2\sum_{m\neq j}^{N} e^{\imath(\mathbf{k}-\mathbf{k}_0)\cdot(\mathbf{r}_j-\mathbf{r}_m)}\int_0^t e^{-\imath(\omega_k-\omega_0)t''}\tilde{\beta}_m(t-t'')dt'' \tag{39.21}$$

$$\simeq \sum_{\mathbf{k}} g_k^2\sum_{m\neq j}^{N} e^{\imath(\mathbf{k}-\mathbf{k}_0)\cdot(\mathbf{r}_j-\mathbf{r}_m)}\tilde{\beta}_m(t)\pi\delta(\omega_k-\omega_0)$$

$$= \frac{V_{ph}}{(2\pi)^3}\sum_{m\neq j}^{N}\tilde{\beta}_m(t)\int g_k^2 e^{\imath(\mathbf{k}-\mathbf{k}_0)\cdot(\mathbf{r}_j-\mathbf{r}_m)}\pi\delta(\omega_k-\omega_0)d^3k = \frac{\Gamma}{2}\sum_{m\neq j}^{N}\gamma_{jm}\tilde{\beta}_m(t) \ ,$$

[4] Later on we will be particularly interested in so-called *timed Dicke states* characterized by $\tilde{\beta}_j = \tilde{\beta}$ independent on j.

with

$$\gamma_{jm} \equiv \frac{2}{\Gamma}\frac{V_{ph}}{(2\pi)^3}\int_0^\infty\int_0^\pi\int_0^{2\pi} g_k^2 e^{\imath(\mathbf{k}-\mathbf{k}_0)\cdot(\mathbf{r}_j-\mathbf{r}_m)}\frac{\pi}{c}\delta(k-k_0)k^2\sin\theta dk d\theta d\phi \ . \quad (39.22)$$

Finally,

$$\frac{d}{dt}\tilde{\beta}_j(t) = \imath\Delta_0\tilde{\beta}_j(t) - \frac{\Omega_0^2}{4}\sum_{m=1}^N\int_0^t\tilde{\beta}_m(t')dt' - \frac{\Gamma}{2}\sum_{m=1}^N\gamma_{jm}\tilde{\beta}_m(t) \ , \quad (39.23)$$

or

$$\frac{d}{dt}\alpha(t) = -\imath\frac{\Omega_0}{2}\sum_{j=1}^N\tilde{\beta}_j(t) \quad (39.24)$$

$$\frac{d}{dt}\tilde{\beta}_j(t) = \imath\Delta_0\tilde{\beta}_j(t) - \imath\frac{\Omega_0}{2}\alpha(t) - \frac{\Gamma}{2}\sum_{m=1}^N\gamma_{jm}\tilde{\beta}_m(t) \ .$$

This means that the problem is reduced to finding the γ_{jm}. Continuing the evaluation of Eq. (39.22),

$$\begin{aligned}\gamma_{jm} &= \frac{1}{\Gamma}g_k^2\frac{V_{ph}}{4\pi^2 c}e^{-\imath\mathbf{k}_0\cdot(\mathbf{r}_j-\mathbf{r}_m)}\int_0^\infty\int_0^{2\pi}\int_{-1}^1 e^{\imath k|\mathbf{r}_j-\mathbf{r}_m|\cos\theta}d\cos\theta d\phi\delta(k-k_0)k^2dk \\ &= \frac{1}{\Gamma}g_k^2\frac{V_{ph}}{\pi c}e^{-\imath\mathbf{k}_0\cdot(\mathbf{r}_j-\mathbf{r}_m)}\int_0^\infty\frac{\sin k|\mathbf{r}_j-\mathbf{r}_m|}{k|\mathbf{r}_j-\mathbf{r}_m|}\delta(k-k_0)k^2dk \\ &= e^{-\imath\mathbf{k}_0\cdot(\mathbf{r}_j-\mathbf{r}_m)}\frac{\sin k_0|\mathbf{r}_j-\mathbf{r}_m|}{k_0|\mathbf{r}_j-\mathbf{r}_m|} \ . \end{aligned} \quad (39.25)$$

Isolating the self-decaying term and assuming low saturation, $\alpha(t) = 1$, we get,

$$\boxed{\dot{\tilde{\beta}}_j = \left(\imath\Delta_0 - \frac{\Gamma}{2}\right)\tilde{\beta}_j - \frac{\imath\Omega_0}{2} - \frac{\Gamma}{2}\sum_{m\neq j}\gamma_{jm}\tilde{\beta}_m} \ . \quad (39.26)$$

In Exc. 39.1.8.4 we will analyze the validity of the Markov approximation for typical cold atoms experiments.

39.1.4 General solution with exponential kernel, validity of the RWA

The RWA is valid for $\max(\Omega, \Gamma_n) \ll \omega$,

$$\int_0^t dt\cdot e^{-\imath(\omega_k-\omega_0)t} \simeq \mathcal{P}\left(\frac{1}{\omega_k+\omega_0}\right) - \imath\mathcal{P}\left(\frac{1}{\omega_k-\omega_0}\right) + \pi\delta(\omega_k-\omega_0) \ . \quad (39.27)$$

The whole expression leads to the exponential kernel, the first two terms are the cosine part, the third term is the sine part. The rotating wave approximation consists in neglecting the first term, i.e. it only concerns the cosine part of the kernel.

Within the RWA we got [5,6],

$$\gamma_{jm} = e^{-\imath \mathbf{k}_0 \cdot (\mathbf{r}_j - \mathbf{r}_m)} \frac{\imath \sin(k_0 |\mathbf{r}_j - \mathbf{r}_m|)}{\imath k_0 |\mathbf{r}_j - \mathbf{r}_m|} \ . \tag{39.28}$$

Without the RWA we would have found [1186, 1178, 1180, 1283],

$$\gamma_{jm} = e^{-\imath \mathbf{k}_0 \cdot (\mathbf{r}_j - \mathbf{r}_m)} \frac{e^{\imath k_0 |\mathbf{r}_j - \mathbf{r}_m|}}{\imath k_0 |\mathbf{r}_j - \mathbf{r}_m|} \ . \tag{39.29}$$

An alternative derivation from a Green function approach to the master equation is presented in Sec. 41.3.2 (see Eq. (41.94)).

There has been a controversy between Friedberg and Scully about the role of virtual photons (or *collective Lamb-shift*) [468, 1282, 469, 1181]. These terms result from counterrotating terms in the rotating wave approximation. Scully assumes timed Dicke states in *infinitely large* clouds and finds the contributions weak. Friedberg does a mode expansion of the cloud and finds that different modes decay at different velocities. This yields time-dependent radiation patterns, which can be temporarily larger in backward direction.

Normally, the RWA is a good approximation, when $\Omega \ll \omega$. Deviations from this approximations lead e.g. to the Bloch-Siegert shift and important corrections for very far-detuned (quasi-electrostatic) optical trapping. The above requirement is not well satisfied for our experiment, since $\Omega_N = \sqrt{N}\Omega \simeq 1..10$ THz.

Be $|b_1 b_2 ... a_j ... b_N\rangle$ the state with all atoms in the ground state except atom j being in the excited state. Hence, the cloud's state is simply expressed by the wavefunction,

$$\Psi_{atom}(t) = \sum_{j=1}^{N} \beta_j(t) |b_1 b_2 ... a_j ... b_N\rangle \ . \tag{39.30}$$

For large σ the radiation pressure is independent on the choice of the kernel. In fact we may even set the kernel to 0. For small σ there appears a considerable deviation. Interestingly, the imaginary part of the kernel gets important for higher densities, even when the optical density is maintained, e.g. by compressing the cloud in z-direction. This means that the collective Lamb shift becomes more apparent is small compressed clouds. But we postpone a more thorough discussion to Sec. 39.3.

The analytic expansion into eigenmodes assumes the RWA. Hence, the numerics deviate from the analytics for small σ and large N. Is it possible to generalize the expansion to the exponential kernel (see [1283])? The authors also suggest that the scattered radiation be frequency-shifted due to the imaginary part of the kernel. This might be an interesting observable for experiments.

39.1.4.1 Low collective saturation

Note that for low *saturation*, $\alpha(t) = 1$, the first term simply becomes $-\frac{\imath}{2}\Omega_0$. Even though the single atom excitation rate may be small in case of large detuning, the

[5] Note that dipole-dipole interactions are mediated by the exchange of virtual photons. Hence, they are included in the Hamiltonian when the RWA is NOT applied.

[6] Note that Maxwell's equations contain non-RWA terms.

collective Rabi frequency $\sqrt{N}\Omega$ can be large. The presence of many excitations in the cloud means, that higher Dicke states are populated. Then we may expect a complicated many-body dynamics, if decay into other states than the timed Dicke state is possible.

Even though the single atom excitation rate may be small in case of large detuning, the *collective* Rabi frequency $\sqrt{N}\Omega$ can be large. The presence of many excitations in the cloud means, that higher Dicke states are populated. Then we may expect a complicated many-body dynamics, if decay into other states than the timed Dicke state is possible.

The model we use (ground state + first excited state in the times Dicke basis) does not allow more than 1 photon for N atoms. For such a model, neglecting saturation means 'much' less than 1 atom in the excited state, i.e. the probability of having the any atom in the excited state is less than 1. But having N atoms, this means that each atoms should have a excited state population of much less than $1/N$. Including the saturation in the naive way, means that when this term $N\Omega_0^2$ is not negligible, than we will have less atoms in the first excited state of the timed Dicke basis, than if when we would neglect saturation. This is precisely why we call this saturation, we cannot take more atoms away from the ground state, because the system cannot absorb more than one photon. But when this term is not longer negligible, then in a cloud of N atoms, this does not prevent us from taking atoms away from the ground state (we have N atoms which each can take one photon). Either the term is negligible (and we could drop it) or we will try to keep its contribution (even at first order in $N\Omega_0^2$), but then we cannot neglect the possibility of having 2 atoms excited.

39.1.4.2 Steady-state solution

In steady-state the equations of the coupled dipoles model can be solved numerically for an arbitrary (ordered or disordered) cloud of immobile atoms located at positions $\mathbf{r}_j$ illuminated by an electric field.

Assuming scalar light and the validity of the Markov approximation, and furthermore defining $\bar{\beta}_j \equiv \tilde{\beta}_j e^{\imath \mathbf{k}_0 \cdot \mathbf{r}_j}$ and $\bar{\Omega}_0(\mathbf{r}_j) \equiv \Omega_0(\mathbf{r}_j) e^{\imath \mathbf{k}_0 \cdot \mathbf{r}_j}$, and using the exponential kernel,

$$\bar{\gamma}_{jm} = \frac{e^{\imath k_0 |\mathbf{r}_j - \mathbf{r}_m|}}{\imath k_0 |\mathbf{r}_j - \mathbf{r}_m|} \ , \tag{39.31}$$

the Eq. (39.26) for the atomic states reads,

$$\frac{d}{dt}\bar{\beta}_j = \left(\imath\Delta_0 - \frac{\Gamma}{2}\right)\bar{\beta}_j - \frac{\imath\bar{\Omega}_0(\mathbf{r}_j)}{2} - \frac{\Gamma}{2}\sum_{m\neq j}\bar{\gamma}_{jm}\bar{\beta}_m \ . \tag{39.32}$$

Defining the matrix,

$$M_{jm} \equiv (\imath\Delta_0 - \tfrac{\Gamma}{2})\delta_{jm} - \tfrac{\Gamma}{2}(1-\delta_{jm})\bar{\gamma}_{jm} = \begin{pmatrix} \imath\Delta_0 - \frac{\Gamma}{2} & \imath\gamma_{12}\frac{\Gamma}{2} & \cdots \\ \imath\gamma_{21}\frac{\Gamma}{2} & \imath\Delta_0 - \frac{\Gamma}{2} & \\ \vdots & & \ddots \end{pmatrix} \ , \tag{39.33}$$

we can rewrite Eq. (39.34) as,

$$\boxed{\frac{d}{dt}\bar{\beta}_j = \sum_m M_{jm}\bar{\beta}_m - \frac{\imath}{2}\bar{\Omega}_0(\mathbf{r}_j)} \; . \tag{39.34}$$

The steady-state solution of is simply obtained by $\dot{\bar{\beta}}_j = 0$ [298, 225],

$$M_{jm}\bar{\beta}_m(\infty) = \tfrac{\imath}{2}\bar{\Omega}_0(\mathbf{r}_j) \; . \tag{39.35}$$

This equation can now be solved by the dipole moment amplitudes,

$$\boxed{\bar{\beta}_m(\infty) = (M_{jm})^{-1} \; \tfrac{\imath}{2}\bar{\Omega}_0(\mathbf{r}_j)} \; , \tag{39.36}$$

where we use the exponential kernel,

$$\gamma_{jm} = \frac{e^{\imath k_0(|\mathbf{r}_j - \mathbf{r}_m| + \delta_{jm})}}{\imath k_0(|\mathbf{r}_j - \mathbf{r}_m| + \delta_{jm})} \; , \tag{39.37}$$

where the trick with the δ_{jm}-symbol helps to remove divergences for equal atom positions.

In this form the solution is immediately suitable for numerical implementation of the coupled dipoles model, although in practice the number of atoms is limited to $N < 10000$ for ordinary PCs.

39.1.4.3 Limit of dilute clouds

Dilute clouds are characterized by a large interatomic distance $k_0|\mathbf{r}_j - \mathbf{r}_m| \gg 1$. In this case, the non-diagonal elements of the kernel (39.33) quickly vanish, and the equations of motion (39.34) decouple to,

$$\frac{d}{dt}\bar{\beta}_j = \left(\imath\Delta_0 - \frac{\Gamma}{2}\right)\bar{\beta}_j - \frac{\imath}{2}\bar{\Omega}_0(\mathbf{r}_j) \; . \tag{39.38}$$

39.1.4.4 Characterization of the atomic cloud in steady-state

Plot the spacial dependence of the phases of the atomic dipoles, $\phi(\mathbf{r}_j) = \mathfrak{Im}\,(\ln\tilde{\beta}_j)$.

39.1.4.5 Time-dependence

In order to calculate the time-dependence, we reconsider the equation (39.34) for the excitation amplitudes. Its solution is formally given by the sum of the general solution of the homogeneous equation and a particular (e.g. the asymptotic) solution of the inhomogeneous equation,

$$\bar{\beta}_j(t) = e^{M_{jm}t}\bar{\beta}_m(0) + (\mathbb{I} - e^{M_{jm}t})\bar{\beta}_m(\infty) \; . \tag{39.39}$$

Inserting the steady-state solution we finally get,

$$\boxed{\bar{\beta}_j(t) = e^{M_{jm}t}\bar{\beta}_m(0) + (\mathbb{I} - e^{M_{jn}t})M^{-1}_{mn} \; \tfrac{\imath}{2}\bar{\Omega}_0(\mathbf{r}_m)} \; . \tag{39.40}$$

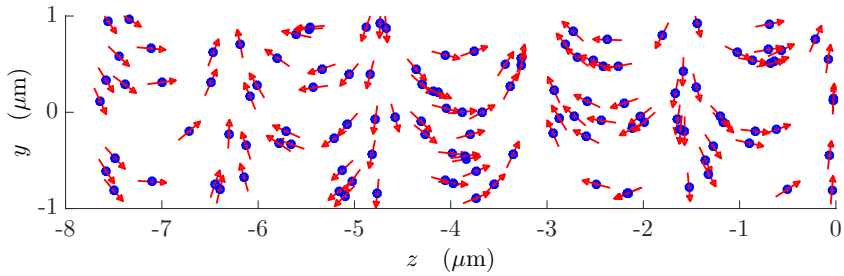

Figure 39.3: Phase delay in the excitation of the atomic dipoles (a) without rescattering ($\gamma_{jm} = 0$) and (b) with rescattering.

39.1.5 Calculation of light scattering in steady-state

To calculate the distribution of scattered light, we start from the Heisenberg equation for the field operator [458],

$$\frac{d\hat{a}_{\mathbf{k}}}{dt} = \frac{1}{\imath\hbar}[\hat{a}_{\mathbf{k}}, \hat{H}] = -\imath g_{\mathbf{k}} e^{\imath(\omega_{\mathbf{k}}-\omega_a)t} \sum_{j=1}^{N} \hat{\sigma}_j e^{-\imath\mathbf{k}\cdot\mathbf{r}_j} \ . \tag{39.41}$$

where the fast oscillating term proportional to $e^{\imath(\omega_{\mathbf{k}}+\omega_a)t}$ has been neglected. Now,

$$\hat{\mathcal{E}}_{sct}(\mathbf{r}, t) = \sum_{\mathbf{k}} \mathcal{E}_k \hat{a}_{\mathbf{k}}(t) e^{\imath(\mathbf{k}\cdot\mathbf{r}-\omega_k t)} \ , \tag{39.42}$$

where $\mathcal{E}_k = \sqrt{\hbar\omega_k/2\varepsilon_0 V_{ph}}$. Integrating Eq. (39.41) with $\hat{a}_{\mathbf{k}}(0) = 0$, inserting it in Eq. (39.42), and approximating the sum over the modes $\mathbf{k}$ by an integral, we obtain,

$$\hat{\mathcal{E}}_{sct}(\mathbf{r}, t) = -\imath \frac{V_{ph}}{8\pi^3} \sum_{j=1}^{N} \int_0^t dt' \hat{\sigma}_j(t-t') e^{\imath\omega_a t} \int d^3k \ \mathcal{E}_k g_k e^{\imath\mathbf{k}\cdot(\mathbf{r}-\mathbf{r}_j)-\imath ckt'} \ . \tag{39.43}$$

Introducing spherical coordinates, $d^3k = dkk^2 d\phi d\theta \sin\theta$, and integrating the angular part Eq. (39.43) becomes,

$$\begin{aligned} \hat{\mathcal{E}}_{sct}(\mathbf{r}, t) = -\imath \frac{V_{ph}}{4\pi^2} \sum_{j=1}^{N} \frac{1}{|\mathbf{r}-\mathbf{r}_j|} \int_0^t dt' \hat{\sigma}_j(t-t') e^{\imath\omega_a t'} \times \\ \times \int dk k \mathcal{E}_k g_k [e^{-\imath ck(t'-|\mathbf{r}'-\mathbf{r}_j|/c)} - e^{-\imath ck(t'+|\mathbf{r}'-\mathbf{r}_j|/c)}] \ . \end{aligned} \tag{39.44}$$

Assuming the radiation spectrum centered around $k \simeq k_0$, we approximate $k\mathcal{E}_k g_k \simeq k_0 \mathcal{E}_{k_0} g_{k_0}$. Then, extending the lower limit of integration of k to $-\infty$, we obtain for $t < |\mathbf{r}-\mathbf{r}_j|/c$ [1049, 816],

$$\hat{\mathcal{E}}_{sct}(\mathbf{r}, t) \simeq -\frac{dk_0^2}{4\pi\varepsilon_0} \sum_{j=1}^{N} \frac{e^{\imath k_0|\mathbf{r}-\mathbf{r}_j|}}{|\mathbf{r}-\mathbf{r}_j|} \hat{\sigma}_j(t-|\mathbf{r}-\mathbf{r}_j|/c) \ . \tag{39.45}$$

where we may neglect the radiation retardation in the limit $t \gg \sigma_R/c$. Using (39.19) and expressing the coupling strength,

$$\hbar g_k = d\mathcal{E}_k \qquad \text{with} \qquad \mathcal{E}_k = \sqrt{\frac{\hbar\omega_k}{2\varepsilon_0 V_{ph}}} \ , \tag{39.46}$$

we get,

$$\hat{\mathcal{E}}_{sct}(\mathbf{r},t) \simeq -\frac{\imath\hbar\Gamma}{2d}\sum_{j=1}^{N}\gamma_{oj}(\mathbf{r})\hat{\sigma}_j(t) \ , \tag{39.47}$$

where we defined the abbreviation,

$$\gamma_{oj}(\mathbf{r}) \equiv \frac{e^{\imath k_0|\mathbf{r}-\mathbf{r}_j|}}{\imath k_0|\mathbf{r}-\mathbf{r}_j|} \ . \tag{39.48}$$

When applied on the state of Eq. (39.11), neglecting virtual transitions, it yields $\hat{\mathcal{E}}_{sct}|\Psi\rangle = \mathcal{E}_{sct}|g_1,...,g_N\rangle$, where $\mathcal{E}_{sct}$ is the electric field radiated by the excited atoms. Once the excitation amplitudes $\beta_j(\infty)$ are known, the scattered light field and the total field can easily be calculated via [1137],

$$\boxed{\mathcal{E}_{sct}(\mathbf{r}) = \langle\hat{\mathcal{E}}_{sct}(\mathbf{r})\rangle = -\frac{\imath\hbar\Gamma}{2d}\sum_{j=1}^{N}\gamma_{oj}(\mathbf{r})\beta_j(\infty) \qquad \text{and} \qquad \mathcal{E}_{tot} = \mathcal{E}_{las} + \mathcal{E}_{sct}} \ , \tag{39.49}$$

Example 228 (*Light scattering from a Gaussian beam*): Fig. 39.4 shows an example of light scattering from an incident light field parametrized as a Gaussian beam, as shown in (18.293),

$$\mathcal{E}_{las}(\mathbf{r}) = \hat{\epsilon}\mathcal{E}_0\frac{w_0}{w(z)}e^{-r^2/w(z)^2+\imath kz+z\imath kr^2/2R(z)-\imath\varphi(z)} = \hat{\epsilon}\frac{\hbar}{|\mathbf{d}|}\Omega_0(\mathbf{r})e^{\imath\mathbf{k}_0\cdot\mathbf{r}} \ . \tag{39.50}$$

Note that, for the chosen parameters, the result does not depend on the interaction terms. I.e. we can as well set the kernel to 0.

Note, that the phase factor $e^{\imath\mathbf{k}_0\cdot\mathbf{r}}$ can either be attributed to the atomic dipole moments or to the field. Here, $N = 125$ atoms are periodically arranged in a three-dimensional cubic lattice.

39.1.6 Calculation of the steady-state radiation pressure force

Let us now calculate the radiative pressure force exerted by an incident beam of light $\mathbf{k}_0$ on an atom j located at position $\mathbf{r}_j$ inside an atomic cloud, as illustrated in Fig. 39.2,

$$\frac{d\hat{\mathbf{p}}_j}{dt} = \hat{\mathbf{F}}_j = -\nabla_{\mathbf{r}_j}\hat{H} \ . \tag{39.51}$$

Inserting the Hamiltonian in the RWA (39.10),

$$\begin{aligned}\hat{\mathbf{F}}_j = {} & \imath\hbar\mathbf{k}_0 g_{k_0}\left[\hat{\sigma}_j\hat{a}^\dagger_{\mathbf{k}_0}e^{\imath(\omega_0-\omega_a)t-\imath\mathbf{k}_0\cdot\mathbf{r}_j} - h.c.\right] \\ & + \sum_{\mathbf{k}}\imath\hbar\mathbf{k}g_k\left[\hat{\sigma}_j\hat{a}^\dagger_{\mathbf{k}}e^{\imath(\omega_k-\omega_a)t-\imath\mathbf{k}\cdot\mathbf{r}_j} - h.c.\right] \ .\end{aligned} \tag{39.52}$$

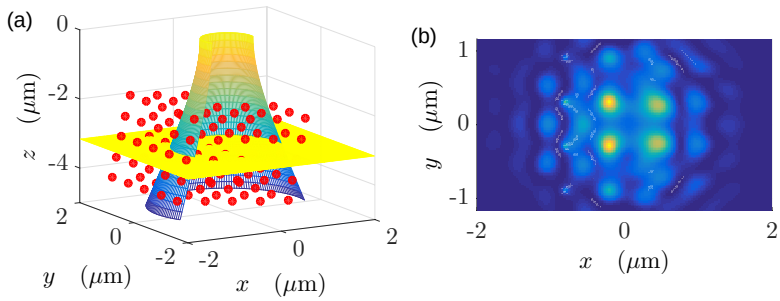

Figure 39.4: (code) (a) Geometry of light scattering from a cubic lattice with lattice constant $d = 100\,\mathrm{nm}$. The light is irradiated from below and is partially reflected. (b) Intensity distribution of scattered light along the yellow plane.

Introducing $\Delta_0 = \omega_0 - \omega_a$, the expectation value of the force separates in two contribution,

$$\begin{aligned}\langle \hat{\mathbf{F}}_j \rangle \equiv \mathbf{F}_{aj} + \mathbf{F}_{ej} &= \imath\hbar\mathbf{k}_0 g_{k_0} \left[\alpha^*(t)\beta_j(t)e^{\imath\Delta_0 t - \imath\mathbf{k}_0\cdot\mathbf{r}_j} - c.c.\right] \\ &\quad + \sum_{\mathbf{k}} \imath\hbar\mathbf{k} g_k \left[\beta_j(t)\gamma^*_{\mathbf{k}}(t)e^{\imath(\omega_k-\omega_a)t - \imath\mathbf{k}\cdot\mathbf{r}_j} - c.c.\right] \\ &= \imath\hbar\mathbf{k}_0 g_{k_0}[\alpha^*(t)\tilde{\beta}_j(t) - c.c.] \\ &\quad + \sum_{\mathbf{k}} \imath\hbar\mathbf{k} g_k \left[\tilde{\beta}_j(t)e^{-\imath(\omega_0-\omega_k)t + \imath(\mathbf{k}_0-\mathbf{k})\cdot\mathbf{r}_j}\gamma^*_{\mathbf{k}}(t) - c.c.\right] ,\end{aligned} \tag{39.53}$$

where we reintroduced the abbreviation (39.17). In particular, the term $m = j$ in the sum of $\mathbf{F}_{ej}$ vanishes since $\sum_{\mathbf{k}} \mathbf{k} = 0$. Substituting $\gamma_{\mathbf{k}}$ with equation (39.16),

$$\begin{aligned}\mathbf{F}_{aj} + \mathbf{F}_{ej} &= \imath\hbar\mathbf{k}_0 g_{k_0}[\alpha^*(t)\tilde{\beta}_j(t) - c.c.] \\ &\quad - \sum_{\mathbf{k}} \hbar\mathbf{k} g_k^2 \left[\tilde{\beta}_j(t)e^{-\imath(\omega_0-\omega_k)t + \imath(\mathbf{k}_0-\mathbf{k})\cdot\mathbf{r}_j} \sum_{m=1}^{N} e^{\imath\mathbf{k}\cdot\mathbf{r}_m} \int_0^t e^{-\imath(\omega_k-\omega_a)t'}\tilde{\beta}^*_m(t')dt' - c.c.\right] \\ &= -2\hbar\mathbf{k}_0 g_{k_0}\mathfrak{Im}\,[\alpha^*(t)\tilde{\beta}_j(t)] \\ &\quad - \sum_{\mathbf{k}} \hbar\mathbf{k} g_k^2 \sum_{m=1}^{N} \left[\tilde{\beta}_j(t)e^{\imath(\mathbf{k}_0-\mathbf{k})\cdot(\mathbf{r}_j-\mathbf{r}_m)} \int_0^t e^{\imath(\omega_0-\omega_k)(t'-t)}\tilde{\beta}^*_m(t')dt' - c.c.\right] ,\end{aligned} \tag{39.54}$$

and applying the Markov approximation (39.20),

$$\begin{aligned}\mathbf{F}_{aj} + \mathbf{F}_{ej} &= -2\hbar\mathbf{k}_0 g_{k_0}\mathfrak{Im}\,[\alpha^*(t)\tilde{\beta}_j(t)] \\ &\quad - \sum_{\mathbf{k}} \hbar\mathbf{k} g_k^2 \sum_{m=1}^{N} [e^{\imath(\mathbf{k}_0-\mathbf{k})\cdot(\mathbf{r}_j-\mathbf{r}_m)}\tfrac{\pi}{c}\delta(k-k_0)\tilde{\beta}_j(t)\tilde{\beta}^*_m(t) - c.c.] .\end{aligned} \tag{39.55}$$

This is the expression for the force acting on an atom at the position $\mathbf{r}_j$. Knowing the stationary excitation amplitudes $\beta_j(\infty)$ and assuming $\alpha(\infty) \simeq 1$, the radiation pressure force can numerically be calculated. Remembering $\Omega_0 = 2g_{k_0}$ we get for the

absorption force acting on atom j,

$$\mathbf{F}_{aj} = -2\hbar\mathbf{k}_0 g_{k_0} \Im\mathfrak{m}\ \tilde{\beta}_j(\infty)\ . \tag{39.56}$$

To evaluate the emission force acting on atom j, for every atom m of the sum, we need to average over all possible scattering angles. To do so, we choose a reference frame in which the z-component of $\mathbf{k}$ is directed along $\hat{\mathbf{r}}_{jm} = \frac{\mathbf{r}_j - \mathbf{r}_m}{|\mathbf{r}_j - \mathbf{r}_m|}$, that is,

$$\mathbf{k} = \hat{\mathbf{e}}_{x,jm} k \sin\theta_{jm}\cos\phi_{jm} + \hat{\mathbf{e}}_{y,jm} k \sin\theta_{jm}\sin\phi_{jm} + \hat{\mathbf{r}}_{jm} k\cos\theta_{jm}\ , \tag{39.57}$$

and evaluate the sum over the wavevectors by $\sum_{\mathbf{k}} \to \frac{V_{ph}}{(2\pi)^3}\int d^3k$,

$$\begin{aligned}
\mathbf{F}_{ej} &= -\sum_{m=1}^{N} \tilde{\beta}_j(\infty)\tilde{\beta}_m^*(\infty)\frac{V_{ph}}{(2\pi)^3}\frac{\pi}{c}\int_{\mathbb{R}^3} d\theta_{jm}d\phi_{jm}dk\ \hbar k \begin{pmatrix}\sin\theta_{jm}\cos\phi_{jm}\\ \sin\theta_{jm}\sin\phi_{jm}\\ \cos\theta_{jm}\end{pmatrix}\times \\
&\times g_k^2[e^{\imath(\mathbf{k}_0-\mathbf{k})\cdot(\mathbf{r}_j-\mathbf{r}_m)}\delta(k-k_0)k^2\sin\theta_{jm} - c.c. \\
&= -\hbar k_0\frac{\Gamma}{8\pi}\sum_{m=1}^{N} e^{\imath\mathbf{k}_0\cdot(\mathbf{r}_j-\mathbf{r}_m)}\tilde{\beta}_j(\infty)\tilde{\beta}_m^*(\infty)\int_0^{\pi}\int_0^{2\pi} d\theta_{jm}d\phi_{jm}\begin{pmatrix}\sin\theta_{jm}\cos\phi_{jm}\\ \sin\theta_{jm}\sin\phi_{jm}\\ \cos\theta_{jm}\end{pmatrix}\times \\
&\times e^{-\imath k\cdot|\mathbf{r}_j-\mathbf{r}_m|\cos\theta_{jm}}\sin\theta_{jm} - c.c.\ .
\end{aligned} \tag{39.58}$$

remembering $\Gamma = \frac{V_{ph}}{\pi c}k_0^2 g_{k_0}^2$ from Eq. (39.19). The integrals over ϕ_{jm} vanishes whereas the integral over θ_{jm} becomes, using,

$$\int_0^{\pi} d\theta \sin\theta\cos\theta e^{-\imath\alpha\cos\theta} = 2\imath\frac{\alpha\cos\alpha - \sin\alpha}{\alpha^2} = -2\imath j_1(\alpha)\ , \tag{39.59}$$

we find,

$$\begin{aligned}
\mathbf{F}_{ej} &= -\hbar k_0\frac{\Gamma}{4}\sum_{m=1}^{N} e^{\imath\mathbf{k}_0\cdot(\mathbf{r}_j-\mathbf{r}_m)}\tilde{\beta}_j(\infty)\tilde{\beta}_m^*(\infty)\hat{\mathbf{r}}_{jm}\times \\
&\times\int_0^{\pi}\cos\theta_{jm}\sin\theta_{jm}e^{-\imath k|\mathbf{r}_j-\mathbf{r}_m|\cos\theta_{jm}}d\theta_{jm} - c.c. \\
&= \imath\hbar k_0\frac{\Gamma}{2}\sum_{m=1}^{N} e^{\imath\mathbf{k}_0\cdot(\mathbf{r}_j-\mathbf{r}_m)}\tilde{\beta}_j(\infty)\tilde{\beta}_m^*(\infty)\hat{\mathbf{r}}_{jm}j_1(k|\mathbf{r}_j-\mathbf{r}_m|) - c.c. \\
&= -\imath\hbar k_0\frac{\Gamma}{2}\sum_{m=1}^{N}\mathbf{f}_{jm}\tilde{\beta}_j(\infty)\tilde{\beta}_m^*(\infty) - c.c.\ ,
\end{aligned} \tag{39.60}$$

where we defined [7],

$$\mathbf{f}_{jm} = -j_1(k|\mathbf{r}_j-\mathbf{r}_m|)e^{\imath\mathbf{k}_0\cdot(\mathbf{r}_j-\mathbf{r}_m)}\hat{\mathbf{r}}_{jm}\ . \tag{39.61}$$

[7] For exploitation in MATLAB we may express the spherical Bessel function by a Bessel function of the first kind: $j_n(x) = \sqrt{\pi/2x}J_{n+1/2}(x)$.

In summary we got,

$$\boxed{\begin{aligned}\mathbf{F}_{aj} &= -\imath\hbar k_0\Omega_0\Im\mathfrak{m}\ \tilde{\beta}_j(\infty)\\ \mathbf{F}_{ej} &= -\imath\hbar k_0\Gamma\sum_{m=1}^{N}\mathbf{f}_{jm}\Im\mathfrak{m}\ [\tilde{\beta}_j(\infty)\tilde{\beta}^*_m(\infty)]\end{aligned}}\ . \tag{39.62}$$

The steady state absorption and the emission part of the radiation pressure force on the *center of mass* of the atomic cloud follow from,

$$\mathbf{F}_a = \frac{1}{N}\sum_j\langle\hat{\mathbf{F}}_{aj}\rangle \qquad \text{and} \qquad \mathbf{F}_e = \frac{1}{N}\sum_j\langle\hat{\mathbf{F}}_{ej}\rangle\ . \tag{39.63}$$

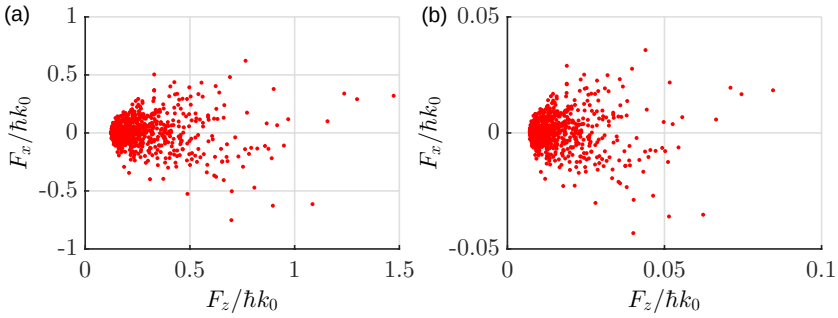

Figure 39.5: (code) Force distribution upon scattering of a photon by an atom of an spherical Gaussian cloud (a) without and (b) with rescattering according to Eqs. (39.63).

As long as the RWA and the Markov approximation are valid and only the lowest Dicke state is considered (no collective saturation), this simulation is supposed to be exact and contains all the physics including, e.g. multiple scattering. Fig. 39.5 shows a comparison of the cases when the off-diagonal components of the kernel (39.37) are present or not. Apparently, the presence of rescattering dramatically spoils the radiation pressure force, a phenomenon that we will extensively study in Secs. 39.1.7 and 39.2 [458, 66, 67, 1035, 139, 68].

39.1.7 The structure coefficient of the 'timed' Dicke state

When a beam of light passes through an atomic cloud, its phase fronts will excite the atomic dipole moments as it traverses the cloud. That is, understanding the beam as a plane wave $e^{\imath(\mathbf{k}_0\cdot\mathbf{r}-\omega t)}$, the dipoles start to oscillate with relative phase delays $e^{\imath\mathbf{k}_0\cdot(\mathbf{r}_j-\mathbf{r}_m)}$ depending on their position along the optical axis $\mathbf{k}_0$. The resulting collective state has been termed *timed Dicke state* [1182]. Assuming that this phase delay is the only parameter distinguishing two atoms, we may write with Eq. (39.17),

$$\tilde{\beta}_j(t) = \beta_j(t)e^{\imath(\Delta_0 t-\mathbf{k}_0\cdot\mathbf{r}_j)} \equiv \frac{1}{\sqrt{N}}\beta(t)\ , \tag{39.64}$$

where β is the macroscopic dipole moment. Note, that the fact that $\beta(t)$ does not depend on the atomic position does not imply a continuous density distribution. The atoms are still sitting at their positions $\mathbf{r}_j$; only are their dipole moments synchronized to the incident light wave.

The assumption of a timed Dicke state for the atomic cloud is, nevertheless, an approximation which is not always good [458]. For example, it neglects dispersive phase shifts of the excitation of the atomic dipole moments by the pump laser beam being delayed on its propagation due to its interaction with the atoms. If such phase shifts (and absorption as well) are radially inhomogeneous, this can lead to deformation of the pump laser beam's phase front and thus to lensing. We will discuss this in Exc. 39.1.8.5 and in Sec. 39.2.

39.1.7.1 Structure coefficient for 'timed' Dicke states

We start again with the Eqs. (39.24) inserting the ansatz of *timed Dicke* states,

$$\begin{aligned}\dot{\beta}(t) &= \frac{1}{N}\sum_{j=1}^{N}\dot{\beta}(t) = \frac{1}{\sqrt{N}}\sum_{j=1}^{N}\frac{d}{dt}\tilde{\beta}_j(t) \\ &= \frac{1}{\sqrt{N}}\sum_{j=1}^{N}\left(\imath\Delta_0\tilde{\beta}_j(t) - \imath\frac{\Omega_0}{2}\alpha(t) - \frac{\Gamma}{2}\sum_{m=1}^{N}\gamma_{jm}\tilde{\beta}_m(t)\right) \\ &= \left(\imath\Delta_0 - \frac{\Gamma}{2}Ns_N\right)\beta(t) - \imath\frac{\sqrt{N}\Omega_0}{2}\alpha(t)\ ,\end{aligned} \tag{39.65}$$

where we introduced the abbreviation,

$$s_N \equiv \frac{1}{N}\frac{1}{N}\sum_{j,m=1}^{N}\gamma_{jm}\ . \tag{39.66}$$

Taking the kernel from (39.25), we get,

$$\begin{aligned}s_N &= \frac{1}{N}\frac{2}{\Gamma}\frac{V_{ph}}{(2\pi)^3}\int_{\mathbb{R}^3} g_k^2\frac{1}{N}\sum_{j,m=1}^{N} e^{\imath(\mathbf{k}-\mathbf{k}_0)\cdot(\mathbf{r}_j-\mathbf{r}_m)}\frac{\pi}{c}\delta(k-k_0)k^2\sin\theta dk d\theta d\phi \\ &= \frac{1}{N}\frac{2}{\Gamma}\frac{V_{ph}}{(2\pi)^3}\int_0^\infty\int_0^\pi\int_0^{2\pi} g_k^2 N|S_N(k,\theta,\phi)|^2\frac{\pi}{c}\delta(k-k_0)k^2\sin\theta dk d\theta d\phi \\ &= \frac{1}{4\pi}\int_0^\pi\int_0^{2\pi}|S_N(k_0,\theta,\phi)|^2\sin\theta d\theta d\phi\ ,\end{aligned} \tag{39.67}$$

introducing the normalized *structure coefficient*,

$$\boxed{\mathcal{S}_N(\mathbf{k}) \equiv \rho(\mathbf{q}) = \frac{1}{N}\sum_{j=1}^{N} e^{\imath(\mathbf{k}-\mathbf{k}_0)\cdot\mathbf{r}_j}}\ , \tag{39.68}$$

where $\mathbf{q} = \mathbf{k} - \mathbf{k}_0$ and $\rho(\mathbf{q})$ is the structure coefficient defined in (39.3).

In steady state, $\dot{\beta}(t) = 0$, and disregarding saturation, $\alpha(t) \simeq 1$, the solution of (39.65) reads,

$$\boxed{\beta(\infty) = \frac{\sqrt{N}\Omega_0}{2\Delta_0 + \imath\Gamma N s_N}}\,, \tag{39.69}$$

such that,

$$\begin{aligned} |\beta(\infty)|^2 &= \frac{N\Omega_0^2}{4\Delta_0^2 + N^2\Gamma^2 s_N^2} \\ \mathfrak{Im}\left[\alpha(\infty)\beta^*(\infty)\right] &= \frac{N^{3/2}\Gamma\Omega_0 s_N}{4\Delta_0^2 + N^2\Gamma^2 s_N^2}\,. \end{aligned} \tag{39.70}$$

The time-dependent solution is easily obtained as,

$$\beta(t) = \beta(0)e^{(\imath\Delta_0 - \Gamma N s_n/2)t} + \beta(\infty)\,. \tag{39.71}$$

The evolution of the cloud very much depends on the initial conditions, e.g. $\beta_j(0) = 1$ for the uniformly excited *symmetric state* $\beta_j(0) = e^{\imath\mathbf{k}_0\cdot\mathbf{r}_j}$ for timed Dicke states.

In cylindrical coordinates the structure coefficient can be written,

$$\mathcal{S}(k,\theta,\phi) = \frac{1}{N}\sum_{j=1}^{N} e^{\imath(kx_j\sin\theta\cos\phi + ky_j\sin\theta\cos\phi + (k\cos\theta - k_0)z_j)}\,. \tag{39.72}$$

It basically tells the angular distribution of the scattered light. Fig. 39.6 shows numerical calculations and analytical approximations of the structure factor for various shapes and sizes of the atomic cloud. Obviously, the radiation pattern very much depends on the size of the spherical cloud. For $R < \lambda$ it is isotropic, for $R > \lambda$ scattering mainly occurs in forward direction. Furthermore, if the cloud is ellipsoidal the radiation pattern is shifted into forward direction.

39.1.7.2 Time evolution of radiation modes

We are interested in the power emitted into the solid angle $\Omega_{\mathbf{k}}$, $P(t) \propto |\gamma_{\mathbf{k}}(t)|^2$. For timed Dicke state (39.64) we get immediately from the equations of motion,

$$\begin{aligned} \dot{\gamma}_{\mathbf{k}}(t) &= -\imath g_k e^{\imath\Delta_k t}\sum_{j=1}^{N}\beta_j(t)e^{-\imath\mathbf{k}\cdot\mathbf{r}_j} \\ &= -\imath g_k e^{\imath(\Delta_k - \Delta_0)t}\frac{1}{\sqrt{N}}\beta(t)\sum_{j=1}^{N} e^{\imath(\mathbf{k}_0 - \mathbf{k})\cdot\mathbf{r}_j} = -\imath g_k e^{\imath(\Delta_k - \Delta_0)t}\sqrt{N}\mathcal{S}_N(\mathbf{k})\,. \end{aligned} \tag{39.73}$$

We see that the time-dependence factorizes from the structure factor, which is the only component containing an angular dependence. The same holds for *symmetric Dicke states* defined by $|\beta_j| = |\beta_m|$.

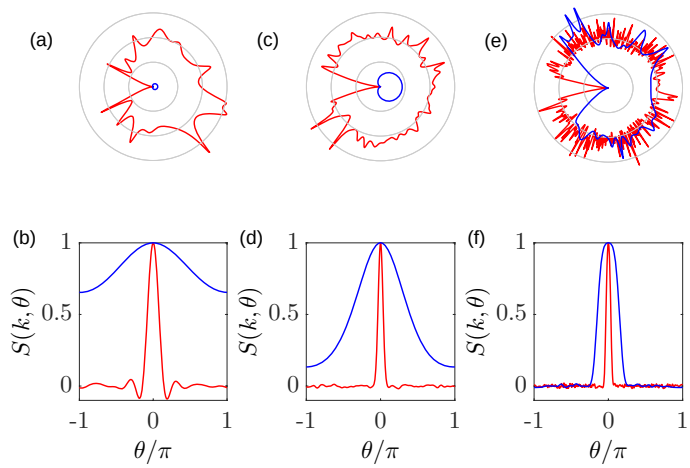

Figure 39.6: (code) Numerical calculation of $\mathcal{S}(k,\theta)$ according to (39.68) for 10^4 atomic positions r_j chosen by a random number generator. For the graphs (a-b) the cloud is *homogeneous and spherical* and has the sizes $R = \lambda$ (red) and $R = 10\lambda$ (blue). For the graphs (c-d) the cloud is *Gaussian and spherical* and has the same sizes as (a-b). For the graphs (d-e) the cloud is *homogeneous and ellipsoidal with aspect ratio* $R_z/R_\rho = 3$ and has the same radial sizes as in (a-b).

39.1.7.3 Light scattering in the 'timed Dicke state'

The scalar electric field scattered by an arbitrary distribution of atoms has been calculated in (39.49). Substituting the stationary timed Dicke state (39.69), we get,

$$\mathcal{E}_{sct}(\mathbf{r}) = -\frac{\imath\hbar\Gamma}{2d}\frac{\sqrt{N}\Omega_0}{2\Delta_0 + \imath\Gamma N s_N}\sum_{j=1}^{N}\frac{e^{\imath k_0|\mathbf{r}-\mathbf{r}_j|}}{\imath k_0|\mathbf{r}-\mathbf{r}_j|} \ . \tag{39.74}$$

Note that the 'timed Dicke' state starts from the assumption of an infinitely extended plane wave incident light field. This excludes situations where the incident beam size is smaller than the cloud's size.

39.1.7.4 Force in the 'timed Dicke state' on a particular atom in a cloud

The time-dependent expressions (39.56) for the forces in the coupled dipoles model can be further evaluated for timed Dicke states (39.64),

$$\begin{aligned}
&\mathbf{F}_{aj} + \mathbf{F}_{ej} \qquad\qquad (39.75)\\
&= -\frac{2\hbar\mathbf{k}_0 g_{k_0}}{\sqrt{N}}\mathfrak{Im}\ \beta(t) - \sum_{\mathbf{k}}\frac{\hbar\mathbf{k}g_k^2}{N}\sum_{m=1}^{N}\left[e^{\imath(\mathbf{k}_0-\mathbf{k})\cdot(\mathbf{r}_j-\mathbf{r}_m)}\frac{\pi}{c}\delta(k-k_0)|\beta(t)|^2 - c.c.\right]\\
&= -\frac{2\hbar\mathbf{k}_0 g_{k_0}}{\sqrt{N}}\mathfrak{Im}\ \beta(t) - \sum_{\mathbf{k}}\hbar\mathbf{k}g_k^2\left[\mathcal{S}_N(\mathbf{k})e^{-\imath(\mathbf{k}-\mathbf{k}_0)\cdot\mathbf{r}_j}\frac{\pi}{c}\delta(k-k_0)|\beta(t)|^2 - c.c.\right] \ .
\end{aligned}$$

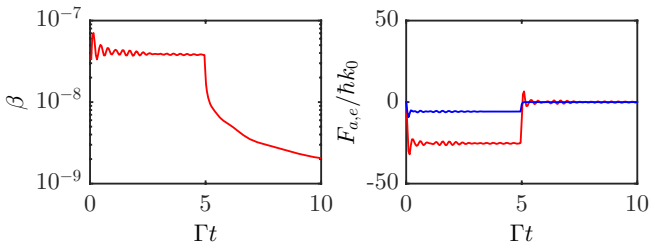

Figure 39.7: (code) Time-dependent of (a) the dipole amplitudes and (b) the forces for $\sigma = 1$, $\Delta_0 = 20\Gamma$, $\Omega_0 = 0.01\Gamma$, and $\eta = 1$.

Evaluating the sum over the wavevectors by $\sum_{\mathbf{k}} \to \frac{V_{ph}}{(2\pi)^3}\int d^3k$,

$$\mathbf{F}_{aj} + \mathbf{F}_{ej} = \frac{-2\hbar\mathbf{k_0} g_{k_0}}{\sqrt{N}} \Im\mathfrak{m}\ \beta(t) \tag{39.76}$$
$$- |\beta(t)|^2 \frac{V_{ph}}{(2\pi)^3}\int_0^\infty \int_0^\pi \int_0^{2\pi} \hbar\mathbf{k} g_k^2 \left[\mathcal{S}_N(k,\theta,\phi) e^{-i(\mathbf{k}-\mathbf{k}_0)\cdot\mathbf{r}_j} \frac{\pi}{c}\delta(k-k_0) - c.c.\right] k^2 \sin\theta d\theta d\phi dk\ .$$

Let us consider an atom sitting on axis, $\mathbf{r}_j = 0$, and use cylindrical coordinates, $\mathbf{k}_0 = k_0\hat{\mathbf{e}}_z$ and $\mathbf{k} = \hat{\mathbf{e}}_x k\sin\theta\cos\phi + \hat{\mathbf{e}}_y k\sin\theta\sin\phi + \hat{\mathbf{e}}_z k\cos\theta$, and using the definition (39.19) of Γ,

$$\mathbf{F}_{aj} + \mathbf{F}_{ej} = \frac{-2\hbar k_0 g_{k_0}}{\sqrt{N}} \hat{\mathbf{e}}_z \Im\mathfrak{m}\ \beta(t) \tag{39.77}$$
$$- |\beta(t)|^2 \frac{\Gamma}{8\pi}\hbar k_0 \int_0^\pi \int_0^{2\pi} (\hat{\mathbf{e}}_x \sin\theta\cos\phi + \hat{\mathbf{e}}_y \sin\theta\sin\phi + \hat{\mathbf{e}}_z\cos\theta)\left[\mathcal{S}_N(k,\theta,\phi) - c.c.\right]\sin\theta d\theta d\phi\ .$$

Using the abbreviation,

$$\tilde{f}_N \equiv \frac{1}{4\pi}\int_0^\pi \int_0^{2\pi} \Re\mathfrak{e}\ \mathcal{S}_N(k_0,\theta,\phi)\sin\theta\cos\theta d\theta d\phi\ , \tag{39.78}$$

the z-component becomes,

$$F_{zaj} + F_{zej} = -\frac{2\hbar k_0 g_{k_0}}{\sqrt{N}} \Im\mathfrak{m}\ \beta(t) - |\beta(t)|^2 \Gamma\hbar k_0 \tilde{f}_N\ . \tag{39.79}$$

In steady state and normalizing to the standard radiation pressure,

$$F_{z1j} = \Gamma\hbar k_0 \frac{\Omega_0^2}{4\Delta_0^2 + \Gamma^2} = \hbar k_0 \sigma(\Delta)\frac{I}{\hbar\omega}\ , \tag{39.80}$$

where $\sigma(\Delta_0)$ is the optical cross section and I the intensity of the incident light, we can write,

$$\frac{F_{zaj} + F_{zej}}{F_{z1j}} = \left(-\frac{2\hbar k_0 g_{k_0}}{\sqrt{N}} \Im\mathfrak{m}\ \beta(\infty) - |\beta(\infty)|^2 \Gamma\hbar k_0 \tilde{f}_N\right)\frac{4\Delta_0^2 + \Gamma^2}{\Gamma\hbar k_0 \Omega_0^2}\ . \tag{39.81}$$

Finally, inserting the the expression (39.69) for the dipole moment, we obtain for the timed Dicke state,

$$\boxed{\frac{F_{zaj} + F_{zej}}{F_{z1j}} = \frac{(2\Delta_0/\Gamma)^2 + 1}{(2\Delta_0/\Gamma)^2 + N^2 s_N^2} N(s_N - \tilde{f}_N)}\ , \tag{39.82}$$

using $\Omega_0 = 2g_{k_0}$.

The factors s_N and f_N can be calculated exactly, as will be done in Exc. 39.1.8.6,

$$s_N = \frac{1}{N^2}\sum_{j,m=1}^{N}\frac{\sin(k_0|\mathbf{r}_j-\mathbf{r}_m|)}{k_0|\mathbf{r}_j-\mathbf{r}_m|}\cos[k_0(z_j-z_m)] \tag{39.83}$$

$$f_N = \sqrt{\frac{\pi}{2}}\frac{1}{N^2}\sum_{j,m=1}^{N}\frac{J_{3/2}(k_0|\mathbf{r}_j-\mathbf{r}_m|)}{(k_0|\mathbf{r}_j-\mathbf{r}_m|)^{3/2}}k_0(z_j-z_m)\sin[k_0(z_j-z_m)]\ .$$

However, this is only practicable for atom numbers small enough for numerical simulations. For larger atom number we may use the analytic expressions including the disorder term [141].

39.1.7.5 Force on the center of mass of the cloud

The force acting on the center of mass of the atomic cloud is given by the average of the forces (39.76) sensed by particular atoms,

$$\begin{aligned}\mathbf{F}_a+\mathbf{F}_e &= \frac{1}{N}\sum_{j=1}^{N}(\mathbf{F}_{aj}+\mathbf{F}_{ej}) \qquad (39.84)\\ &= -\frac{2\hbar\mathbf{k_0}g_{k_0}}{\sqrt{N}}\mathfrak{Im}\ \beta(t)\\ &\quad -|\beta(t)|^2\frac{V_{ph}}{(2\pi)^3}\int_{\mathbb{R}^3}\hbar\mathbf{k}g_k^2\left[\mathcal{S}_N(k,\theta,\phi)\frac{1}{N}\sum_{j=1}^{N}e^{-\imath(\mathbf{k}-\mathbf{k}_0)\cdot\mathbf{r}_j}\frac{\pi}{c}\delta(k-k_0)-c.c.\right]k^2\sin\theta d\theta d\phi dk\\ &= \frac{-2\hbar\mathbf{k_0}}{\sqrt{N}}g_{k_0}\mathfrak{Im}\ \beta(t)-|\beta(t)|^2\frac{V_{ph}}{(2\pi)^3}\int_{\mathbb{R}^3}\hbar\mathbf{k}g_k^2 2|\mathcal{S}_N(k,\theta,\phi)|^2\frac{\pi}{c}\delta(k-k_0)k^2\sin\theta d\theta d\phi dk\ .\end{aligned}$$

Using cylindrical coordinates, $\mathbf{k}_0 = k_0\hat{\mathbf{e}}_z$ and $\mathbf{k} = \hat{\mathbf{e}}_x k\sin\theta\cos\phi + \hat{\mathbf{e}}_y k\sin\theta\sin\phi + \hat{\mathbf{e}}_z k\cos\theta$, and the definition of Γ,

$$\begin{aligned}\mathbf{F}_a+\mathbf{F}_e &= \frac{-2\hbar k_0}{\sqrt{N}}\hat{\mathbf{e}}_z g_{k_0}\mathfrak{Im}\ \beta(t) \qquad (39.85)\\ &\quad -|\beta(t)|^2\frac{\Gamma}{8\pi}\hbar k_0\int_0^{\pi}\int_0^{2\pi}(\hat{\mathbf{e}}_x\sin\theta\cos\phi+\hat{\mathbf{e}}_y\sin\theta\sin\phi+\hat{\mathbf{e}}_z\cos\theta)\,2|\mathcal{S}_N(k,\theta,\phi)|^2\sin\theta d\theta d\phi\ .\end{aligned}$$

Using the abbreviation,

$$f_N \equiv \frac{1}{4\pi}\int_0^{\pi}\int_0^{2\pi}|\mathcal{S}_N(k_0,\theta,\phi)|^2\sin\theta\cos\theta d\theta d\phi\ , \tag{39.86}$$

we get for the z-component an analogous formula to (39.79),

$$\begin{aligned}F_{za}+F_{ze} &= \frac{-2\hbar k_0 g_{k_0}}{\sqrt{N}}\mathfrak{Im}\ \beta(t)-|\beta(t)|^2\frac{\Gamma}{8\pi}\hbar k_0\int_0^{\pi}\int_0^{2\pi}2|\mathcal{S}_N(k,\theta,\phi)|^2\sin\theta\cos\theta d\theta d\phi\\ &= -\frac{2\hbar k_0 g_{k_0}}{\sqrt{N}}\mathfrak{Im}\ \beta(t)-|\beta(t)|^2\Gamma\hbar k_0 f_N\ . \qquad (39.87)\end{aligned}$$

In steady state and normalizing again to the standard radiation pressure (39.80),

$$\frac{F_{za}+F_{ze}}{F_{z1}} = \left(-\frac{2\hbar k_0 g_{k_0}}{\sqrt{N}}\mathfrak{Im}\ \beta(\infty)-|\beta(\infty)|^2\Gamma\hbar k_0 f_N\right)\frac{4\Delta_0^2+\Gamma^2}{\Gamma\hbar k_0\Omega_0^2}\ . \tag{39.88}$$

Finally, inserting the the expression (39.69) for the dipole moment, we obtain for the timed Dicke state,

$$\boxed{\frac{F_{za}+F_{ze}}{F_{z1}} = \frac{(2\Delta_0/\Gamma)^2+1}{(2\Delta_0/\Gamma)^2+N^2 s_N^2} N(s_N - f_N)} \,, \tag{39.89}$$

using $\Omega_0 = 2g_{k_0}$. Inserting the expressions (39.67) for s_N and (39.86) for f_N, we may also write,

$$\frac{F_{0a}+F_{0e}}{F_{z1}} = \frac{(2\Delta_0/\Gamma)^2+1}{(2\Delta_0/\Gamma)^2+N^2 s_N^2} N \frac{1}{4\pi} \int_0^\pi \int_0^{2\pi} |\mathcal{S}_N(k,\theta,\phi)|^2 (1-\cos\theta)\sin\theta d\theta d\phi \,. \tag{39.90}$$

Let us assume in the following that the scattering of every single photon can be treated independently [1180]. In particular, the density distribution may change between two scattering events. The force is something like the first moment of the structure factor. This makes it so adapted to measure fluctuation-induced deviations from the structure coefficient [8].

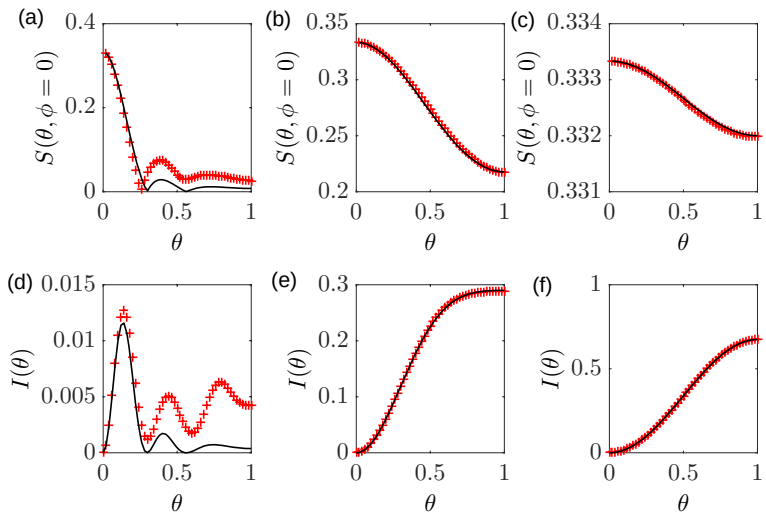

Figure 39.8: (code) (a-c) Calculation of the structure coefficient $|\mathcal{S}(k=k_0,\theta,\phi=0)|^2$ for an isotropic homogeneous density distribution. (d-f) Calculation of the force $I(\theta) = \int_0^{2\pi} |\mathcal{S}(k=k_0,\theta,\phi)|^2(1-\cos\theta)d\phi$. The red curves show numerical calculations based on (39.68), the green curves show analytical calculations according to (39.98). (a,d) $k_0R = 1$ and $N = 100$. (b,e) $k_0R = 5$ and $N = 100$. (c,f) $k_0R = 5$ and $N = 1000$.

We want to compare this force to the force acting on a cloud of N uncorrelated scatterers, i.e. atoms receiving recoil from the pump photons but reemitting isotrop-

[8] Insert a clarifying discussion of what we said in the EPDJ and what we did not: We said there is a collective effect coming from the structure factor of the cloud. We did NOT say that interatomic interactions are essential...!

ically,

$$\langle F_{unc,z}\rangle = \frac{V_{ph}}{(2\pi)^3}\sigma(\Delta)\frac{I}{\hbar\omega}\hbar k_0 \int_0^\infty \int_0^\pi \int_0^{2\pi} |\mathcal{S}_N(k,\theta,\phi)|^2 k^2 \sin\theta d\theta d\phi dk \ . \quad (39.91)$$

For such a cloud the structure coefficient is $\mathcal{S}_N = N^{-1/2}$. Note that this is unlike N atoms in the Dicke limit, where $\mathcal{S}_N = 1$.

A dense homogeneous cloud with $\mathcal{S}_N(\mathbf{k}) \propto \delta^3(\mathbf{k}_0 - \mathbf{k})$ does not scatter light and experiences no force, $\langle F_{hom}\rangle = 0$. This is however not true any more in the limit of small extended clouds, where fluctuations introduce disorder. This can be shown by simulating a random atomic distribution $\mathbf{r}_j$ and integrating the resulting force over all possible $\mathbf{k}$. For simplicity we assume a very sharp momentum distribution, $|\mathbf{k}| = |\mathbf{k}_0|$ or $\frac{V_{ph}}{2\pi^2}\int_0^\infty k^2 dk = 1$,

$$\langle F_z\rangle = \sigma(\Delta)\frac{I}{\hbar\omega}k_0(s_N - f_N) \ . \quad (39.92)$$

Finally to compare with experiment we evaluate the ratio,

$$\frac{\langle F_z\rangle}{\langle F_{unc,z}\rangle} = 1 - \frac{f_N}{s_N} \ . \quad (39.93)$$

We describe the cloud as being made of two fractions: An isotropically scattering fraction of $N_0 = \sqrt{N}$ disordered atoms, whose structure factor is $\mathcal{S}_{iso}(\mathbf{k}) = 1$, and a forward scattering homogeneous cloud with structure factor $\mathcal{S}_{hom}(\mathbf{k}) = \delta_{\mathbf{k}_0,\mathbf{k}}$. The surface integration of the total structure factor,

$$\mathcal{S}_N(\mathbf{k}) = \frac{N_0}{N}\mathcal{S}_{iso}(\mathbf{k}) + \frac{N-N_0}{N}\mathcal{S}_{hom}(\mathbf{k}) = \frac{N_0}{N} + \frac{N-N_0}{N}\delta_{\mathbf{k}_0,\mathbf{k}} \simeq \frac{N_0}{N} \quad (39.94)$$

yields the same N-dependence of the force,

$$\frac{\langle F_z\rangle}{\langle F_{iso,z}\rangle} = \frac{1}{4\pi N^2}\int_0^\pi \int_0^{2\pi} |\sqrt{N}|^2(1-\cos\theta)\sin\theta d\theta d\phi = \frac{1}{N} \ . \quad (39.95)$$

The interpretation is the following. In the experimentally realized situation, we are very far in the large cloud limit completely dominated by forward scattering, which means that *if the cloud were homogeneous no radiation pressure force should be expected* at all. However diffuse scattering from disordered atoms (or fluctuations) disturbs the forward scattering. It is this scattering which gives rise to radiation pressure.

There is an interesting analogy: Diffuse scattering not only inhibits forward scattering in homogeneous clouds, but also coherent backscattering from ordered structures. E.g. in optical lattices [1220] it disturbs the detection of photonic band gaps. In an optical lattice the atoms are in the Dicke limit and do not absorb photonic recoil. Hence, no displacement due to radiation pressure is expected. However, diffuse scattering is observed as absorptive features in the spectra [146, 1220].

The Bragg scattering is expressed by a periodic structure factor. A widely used approach to describe the impact of disordered atoms in lattices is to divide the cloud into a perfectly ordered part with density nf_{DW} and isotropically scattering part with density $n(1-f_{DW})$ [1220]. The factor f_{DW} is known as Debye-Waller factor. In Exc. 39.1.8.7 we try an alternative traetment of radiation pressure based on a Monte-Carlo simulation.

39.1.7.6 Cooperative scattering and single photon superradiance

A non-isotropic structure factor scattering light into a specific direction of space (e.g. the Bragg angle) at a rate scaling like N^α with $\alpha > 1$ needs several 'cooperating' particles. In this sense cooperation only means, that the particles be arranged in space in a particular way, i.e. in a lattice or in a particular bulk shape like a homogeneous sphere or a Gaussian cigar-shaped density distribution. It also immediately becomes clear that disorder ought to play a major role. However, cooperation goes further, since cooperative scattering can be observed in spontaneous emission of an atomic cloud being excited by just a single photon. Single-photon superradiance is the topic of the following sections.

For now let us state that a non-isotropic structure factor results in collective scattering. The density distribution (which is the Fourier transform of the structure factor) can adopt two extremes: A periodic lattice results in backscattering into specific directions, a homogeneous clouds shows nothing but forward scattering. Both situations are never perfectly realized, but are subject to density fluctuations (Debye-Waller factor in a lattice, radiation pressure in a homogeneous cloud).

A single photon on its trip through an atomic cloud successively excites the atomic dipole moment thus establishing a phase relation between potential radiators [404, 1284, 1181, 1286]. One could think that the scattering process localizes atom and photon, i.e. only one atom scatters. However, we don't know which atom scatters, and this introduces a correlation of the dipole moments along the propagation direction of the light beam.

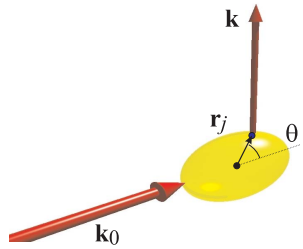

Figure 39.9: Scattering of a photon by an atom of an ellipsoidal cloud.

While normally the radiation rate of a dilute cloud is $\propto N$, in the presence of coherent interactions it scales as $\propto N^2$. Coherent interactions are not conditioned to overlapping space functions of the atoms, i.e. it is not compulsory that the density be $n^{-1/3} > \lambda$. For example, scattering from ordered structures also scales as $\propto N^2$ [691]. However, the scattering will be dramatically different if $n^{-1/3} < \lambda$.

Spontaneous emission radiation pattern from uncorrelated scatterers only depend on the relative orientation of $\hat{\sigma}$ and $\vec{\mathcal{B}}$, but not on the $\mathbf{k}$-vector of the incident light. This also holds for Dicke superradiance in the small cloud limit, but not for large clouds. Here forward scattering dominates.

We have seen in this section that, despite its simplicity, the coupled dipoles model has a large range of applications. It allows for a deeper understanding of known classical phenomena and, as we will study in Excs. 41.2.4.7 to 41.2.4.1 and in forthcoming sections, it allows to unravel new effects.

39.1.8 Exercises

39.1.8.1 Ex: Structure coefficient of a linear array

a. Based on the definition (39.1) compute the structure factor of a linear array of point-like scatterers.
b. Based on the definition (39.2) compute the structure factor of a linear array of 10 Gaussian density distributions.

Solution: *a. See Fig. 39.10. b. See Fig. 39.11.*

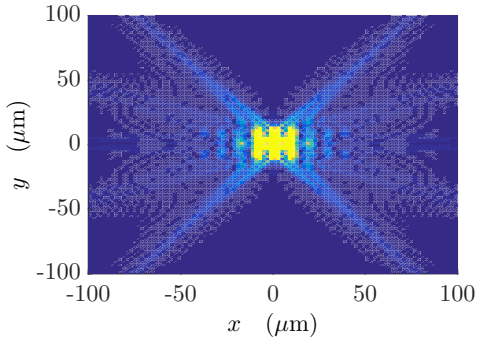

Figure 39.10: (code) Linear array of scatterers separated by 2 nm at $\lambda = 797$ nm.

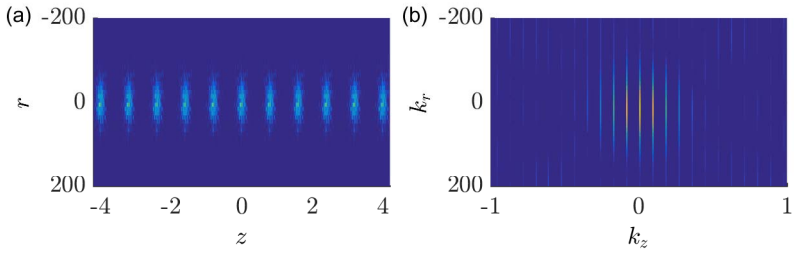

Figure 39.11: (code) Linear array of Gaussian density distributions separated by 2 nm at $\lambda = 797$ nm.

39.1.8.2 Ex: Structure factor of a cloud

a. Based on the definition (39.1) compute the structure coefficient of (i) a slit, (ii) a pinhole, and (iii) a homogeneous spherical cloud.
b. Based on the definition (39.3) compute the structure coefficient of a homogeneous spherical cloud.

Solution: *a. The structure coefficient is the Fourier transform of the density,* $\mathcal{S}(\mathbf{k}) =$

$\int n(\mathbf{r})e^{\imath\mathbf{k}\cdot\mathbf{r}}d^3r$. *In 1D it describes the diffraction through a slit,*

$$\int_{-R}^{R} e^{\imath kr}dr = \frac{2}{k}\sin kR \ .$$

In 2D it describes the diffraction by a pinhole,

$$\int_{disk} e^{\imath\mathbf{k}\cdot\mathbf{r}}d^2\mathbf{r} = \int_0^R\int_0^{2\pi} re^{\imath kr}d\phi dr = \frac{2\pi}{k^2}\left[\cos kR + kR\sin kR - 1 + \imath(\sin kR - kR\cos kR)\right] \ .$$

In 3D the structure factor is,

$$\int_{sphere} e^{\imath\mathbf{k}\cdot\mathbf{r}}d^3r = \int_0^R\int_0^{2\pi}\int_0^{\pi} r^2e^{\imath kr\cos\theta}\sin\theta d\theta d\phi dr = \frac{4\pi}{k^3}(\sin kR - kR\cos kR) \ .$$

b. The structure factor can be evaluated from $S(\mathbf{q}) = \langle\rho(\mathbf{q})\rho^*(\mathbf{q})\rangle$, *where* $\rho(\mathbf{q}) = \int_V n(\mathbf{r})e^{\imath\mathbf{q}\cdot\mathbf{r}}d^3r$ *[1085, 333],*

$$\begin{aligned} S(\mathbf{q}) &= \int d^3r\int d^3r' n(\mathbf{r})n(\mathbf{r}')e^{\imath q\cdot(\mathbf{r}-\mathbf{r}')} = \frac{4\pi}{V}\int_0^R r^2e^{\imath\mathbf{q}\cdot\mathbf{r}}dr\frac{4\pi}{V}\int_0^R r'^2e^{-\imath\mathbf{q}\cdot\mathbf{r}'}dr' \\ &= \left(\frac{4\pi}{q^3V}\right)^2(\sin qR - qR\cos qR)^2 = 9\frac{(\sin qR - qR\cos qR)^2}{(qR)^6} \ , \end{aligned}$$

with $V = \frac{4\pi}{3}R^3$ *and* $n(\mathbf{r}) = \frac{1}{V}$. *In particular we have,*

$$S(\mathbf{q}) \overset{R\ll\lambda}{\longrightarrow} 1 \qquad \textit{and} \qquad S(\mathbf{q}) \overset{R\gg\lambda}{\longrightarrow} 0 \ .$$

The structure factor is then identical to the collective cooperativity $\Upsilon_N = S(\mathbf{q})$.

39.1.8.3 Ex: Structure coefficient and Snell's law

Calculate the structure coefficient for a light beam passing through a plane interface between two dielectrics.

Solution: *We set the interface in the xy-plane and assume that for* $z < 0 >$ *the refraction index in 1, and for* $z > 0$ *it is* n_{rfr}. *The structure coefficient is the Fourier transform of the density. Hence,*

$$\begin{aligned} \mathcal{S}(\mathbf{k}) &= \int[1 + (n_{rfr} - 1)\Theta(z)]e^{\imath\mathbf{k}\cdot\mathbf{r}}d^3r = \delta(\mathbf{k}) + (n_{rfr} - 1)\delta(k_x)\delta(k_y)\int_0^\infty e^{\imath k_z z}dz \\ &= \delta(\mathbf{k}) + (n_{rfr} - 1)\delta(k_x)\delta(k_y)\frac{1}{\imath k_z} = \ldots \ . \end{aligned}$$

39.1.8.4 Ex: Validity of Markov approximation

a. Calculate the single-atom scattering rate for a rubidium cloud of $N = 10^6$ atoms driven with $P = 100\,\mathrm{mW}$ laser power focused into a waist of $w_0 = 100\,\mu\mathrm{m}$ and detuned by $\Delta = (2\pi)\ 100\,\mathrm{GHz}$ from the D_2-line at 780 nm [225].
b. Assume for the cloud a homogeneous spherical density distribution with radius $R = 250/k_0$. Based on Ref. [1284] estimate whether the Markov approximation is valid.

Solution: *a. The single-atom excitation rate is for the specified parameters,*

$$\gamma_{ex} = N\frac{\sigma(\Delta)I}{\hbar\omega} \simeq 6.5\cdot 10^9\ \ \mathrm{s}^{-1}\ .$$

b. The superradiant deexcitation rate is for $k_0R = 250$ assuming a homogeneous spherical cloud [1284],

$$\gamma_{deex} = N\frac{27\Gamma}{8(k_0R)^2} \simeq 2\cdot 10^9\,\mathrm{s}^{-1}\ .$$

Hence the assumption of single-photon Dicke superradiance is questionable. The condition for having less than one photon in the cloud is for smooth clouds $\gamma_{ex} \ll \gamma_{deex}$. This means,

$$\frac{N\Gamma}{(2\sigma)^2} \gg N\sigma_{opt}\frac{I}{\hbar\omega} = N\frac{\Gamma^2}{4\Delta_0^2+2\Omega_0^2+\Gamma^2}\frac{\Omega_0^2}{\Gamma} \ll \frac{N\Gamma}{(2\sigma)^2}$$

using $\Omega_0^2 = \sigma_0\Gamma\frac{I}{\hbar\omega}$. For $\Delta_0 \gg \Gamma, \Omega_0$ we get,

$$\frac{\Omega_0^2}{4\Delta_0^2}(2\sigma)^2 \ll 1\ .$$

For disordered clouds the condition reads

$$\frac{\Omega_0^2}{4\Delta_0^2}N \ll 1\ .$$

39.1.8.5 Ex: Lensing by a dense atomic cloud with the coupled dipoles model

Simulate the pump laser phase shift and lensing by a small dense cloud by the coupled dipoles model for red and blue detuning. Discuss the influence of rescattering by removing artificially the off-diagonal terms from the scattering kernel. Discuss whether lensing is observed within the timed Dicke approximation.

Solution: *The question is, whether the fact that the pump laser is depleted (partially absorbed) and phase-shifted is contained in the CDM, although we assumed in its derivation $\alpha \simeq 1$. As illustrated in Fig. 39.12, red detuning leads to focusing, blue*

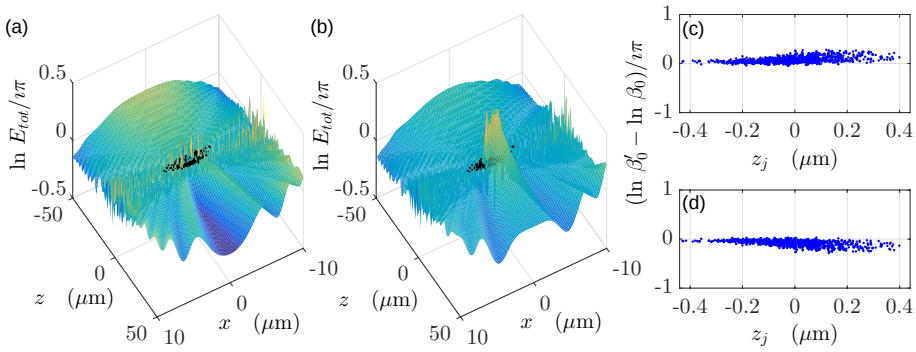

Figure 39.12: (code) Phase profile upon scattering from a (strontium) spherical Gaussian cloud $k_0\sigma_r = 15$ of 1000 atoms for (a) red detuning of $\Delta = -5\Gamma$ and (b) blue detuning $\Delta = 5\Gamma$. (c,d) Difference of the phase shifts of the atomic dipoles located at positions z_j of the optical axis calculated by Eqs. (39.36) and (39.69).

detuning to defocusing. Note, that removing the off-diagonal elements of the kernel does not change the result. Lensing also occurs when calculating the steady-state of the atomic cloud within the timed Dicke approximation. However, the phase shift will be underestimated by an amount depending on the cloud's optical density.

39.1.8.6 Ex: Exact calculation of projected structure coefficients

Calculated the integrals (39.66), (39.78), and (39.86).

Solution: *With the real part of the kernel (39.25), we see immediately,*

$$s_N \equiv \frac{1}{4\pi}\int_0^\pi\int_0^{2\pi} |\mathcal{S}_N(k_0,\theta,\phi)|^2 \sin\theta d\theta d\phi = \frac{1}{N^2}\sum_{j,m=1}^{N} \mathfrak{Re}\ \gamma_{jm}$$

$$= \frac{1}{N^2}\sum_{j,m=1}^{N} \frac{\sin k_0 r_{jm}}{k_0 r_{jm}} \cos k_0 z_{jm}\ .$$

Also,

$$f_N \equiv \frac{1}{4\pi}\int_0^\pi\int_0^{2\pi} |\mathcal{S}_N(k_0,\theta,\phi)|^2 \sin\theta\cos\theta d\theta d\phi = ...$$

$$= \frac{1}{N^2}\sum_{j,m=1}^{N} \frac{j_1(k_0 r_{jm})}{k_0 r_{jm}} k_0 z_{jm} \sin k_0 z_{jm}\ .$$

Finally,

$$\tilde{f}_N \equiv \frac{1}{4\pi}\int_0^\pi\int_0^{2\pi} \mathfrak{Re}\ \mathcal{S}_N(k_0,\theta,\phi) \sin\theta\cos\theta d\theta d\phi = ...$$

39.1.8.7 Ex: Monte-Carlo simulation of cooperative radiation pressure

In a regime of negligible interatomic interaction single photons are scattered by individual atoms, which thereby receive the entire photonic recoil. That is, the acceleration occurs in quantized steps, which can be easily resolved in experiments [649, 1217] with Bose-Einstein condensates. In the absence of collective effects, we generally observe halo-shaped momentum distributions. Because of the recoil received upon absorption, the halos are centered at $\hbar k$, and since the emission is generally isotropic, they have a radius of $\hbar k$. On the other hand, as we have seen earlier, cooperative effects can suppression radiation pressure. In the following we try a different approach based on a Monte-Carlo simulation with a Langevin force.
This approach starts from the idea that it is possible to simulate the radiation pressure without explicit calculation of the force by treating the scattering process as a Langevin force. The simulation describes the scattering of single photons by individual atoms. Cooperativity is included 1. in the scattering rate, which is *influenced by collective effects*, 2. by weighing the probability for the direction (θ, ϕ) into which the photons are scattered with the structure factor. The enhancement of the collective scattering rate corresponds to the rate of absorption part of the radiation pressure, [9,10]

$$\gamma_c = \gamma_R \frac{F_{c,abs}}{F_{1,abs}} = \sigma_{opt}(\Delta_0)\frac{I}{\hbar\omega} \cdot \frac{4\Delta_0^2 + \Gamma^2}{4\Delta_0^2 + N^2\Gamma^2 s_N^2} N \ ,$$

where $s_N = N^{-1} + (2\sigma)^{-2}$. The structure factor is numerically calculated for a randomly distributed cloud.

Solution: *We proceed as follows,*

1. *For a given push laser intensity, detuning and atom number we estimate the total number of scattered photons within a given time interval, $n_{ph} = \gamma_c \Delta t$.*

2. *We generate a random distribution of N atom in position space, $\{\mathbf{r}_j(0) | j \in [1, N]\}$.*

3. *We calculate the structure factor $S(\theta, \phi) = \frac{1}{N}\sum_{j=1}^{N} e^{i(\mathbf{k}_0 - \mathbf{k})\mathbf{r}_j}$.*

4. *We generate a random distribution of N atom in the momentum space $\{\mathbf{p}_j(0)\}$, e.g. for a BEC $\mathbf{p}_j(0) = 0$.*

5. *Now we simulate the scattering of a single photon by picking an atom labeled $\mu = int(N\zeta)$ chosen from a uniformly distributed random number $\zeta \in [0, 1]$.*

6. *Then we pick a randomly chosen direction for the emitted photon by identifying the azimuth $\phi = 2\pi\xi_\phi$ with a uniformly distributed random number $\xi_\phi \in [0, 1]$, and extracting the elevation θ from $2\pi \int_0^\theta |S(\theta, \phi)|^2 \sin\theta' d\theta' = \xi_\theta \in [0, 1]$.*

[9] Note that in reality the scattering of a photon converts the scattering atom into a coherent superposition of directions into which the atom might have scattered. This is of course not described by the simulation.

[10] Although the atomic motion is frozen, it is not correct to say that the external degree of freedom is not involved in the collective dynamics, since the spatial atomic distribution shapes the structure factor.

7. *The momentum of the μ^{th} atom is modified by $\mathbf{p}_\mu(t+dt) = \mathbf{p}_\mu(t) + \hbar\mathbf{k} - \hbar\mathbf{k}_0$, where the recoil is given by $\mathbf{k}-\mathbf{k}_0 = k_0\hat{\mathbf{e}}_x \sin\theta\cos\phi + k_0\hat{\mathbf{e}}_y \sin\theta\sin\phi + k_0\hat{\mathbf{e}}_z(\cos\theta - 1)$.*

8. *We repeat the steps 2 to 6 n_{ph} times.*

The final momentum distribution $\{\mathbf{p}_j(\Delta t)\}$ can now be converted into a density $n(\mathbf{r})$ by discretizing the space. The density is now projected onto a CCD camera by column-integration, $A(x,z) = \sum_y n(\mathbf{r})$. Finally, we calculate from this image the center-of-mass displacement, $\Delta z_{cm} = \sum_{x,z} zA(x,z)$. Note that in this picture we don't

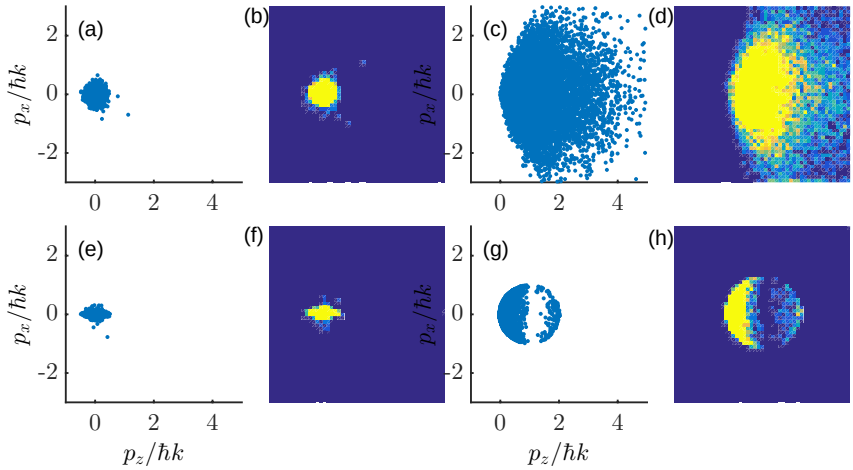

Figure 39.13: (code) Langevin simulation of radiation pressure for $N = 10000$ atoms and 50000 scattered photons with (a,b) $\sigma = 1$ and (b,d) $\sigma = 3$. $\eta = 30$. The figures (b,d) simulate time-of-flight absorption images taken from the momentum distributions (a,c). (d-h) Same as (a-d), but now every atom scatters exactly 1 photon.

need any knowledge about the collective optical cross section to predict the correct momentum pattern after a certain amount of scattering events. However, the rate at which photons are scattered (and hence the time scale to be chosen for the simulation) is subject to collective effects.
However, the Monte-Carlo simulations do not give the same quantitative results as the analytical calculations. Particularly the N-dependence is different. My present guess is that the calculation of the scattering rate and its N-dependence are oversimplified.

39.1.8.8 Ex: Super- and subradiance with two atoms

Super- and subradiance have been observed in two ion crystals [1047, 364]. In this exercise, we study this system in the framework of the coupled dipoles model.
a. Calculate the structure coefficient of this system.
b. Write down the equations of motion (39.26) and solve them in steady-state.

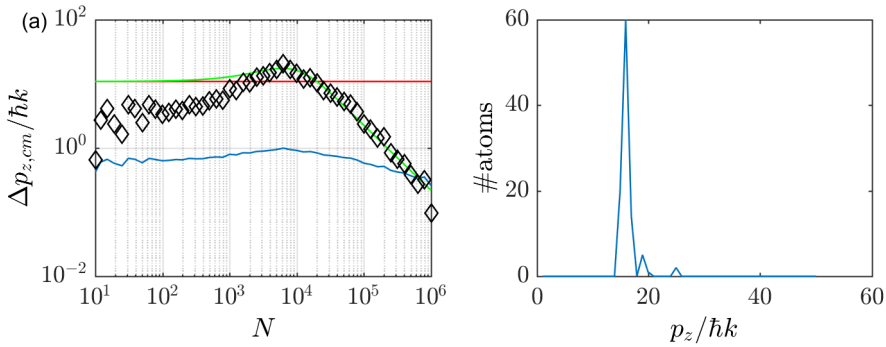

Figure 39.14: (code) (a) Simulated N-dependence of Δz_{cm}. The deviation from the theoretical expectation is quite large. In contrast $21\Delta z_{cm}^4$ (black diamonds) fits much better. Why? (b) Histogram of the axial momentum distribution.

Solution: *a. Two atoms separated by λ do not scatter only into forward and backward direction. Their structure factor is,*

$$\mathcal{S}_2(\mathbf{k}) = \tfrac{1}{2}\left(e^{\imath(\mathbf{k}-\mathbf{k}_0)\mathbf{r}_0} + e^{\imath(\mathbf{k}-\mathbf{k}_0)(\mathbf{r}_0+\lambda\hat{\mathbf{e}}_z)}\right) = \tfrac{1}{2}e^{\imath(\mathbf{k}-\mathbf{k}_0)\mathbf{r}_0}(1-e^{\imath\lambda\hat{\mathbf{e}}_z\mathbf{k}}) = \tfrac{1}{2}(1-e^{2\pi\imath\cos\theta}) \ ,$$

setting $\mathbf{r}_0 = 0$ and $k \simeq k_0$.
b. Let us consider two atoms separated by $d \equiv |\mathbf{r}_1 - \mathbf{r}_2|$. Then the equations of motion read,

$$\begin{aligned}\dot{\beta}_j(t) &= -\Gamma\sum_{m=1}^{N}\left(\frac{\sin k_0|\mathbf{r}_j-\mathbf{r}_m|}{k_0|\mathbf{r}_j-\mathbf{r}_m|} - \imath\frac{\cos k_0|\mathbf{r}_j-\mathbf{r}_m|}{k_0|\mathbf{r}_j-\mathbf{r}_m|}\right)\beta_m(t) \\ &= -\Gamma\beta_j(t) - \Gamma\sum_{m\neq j}^{N}\left(\frac{\sin k_0|\mathbf{r}_j-\mathbf{r}_m|}{k_0|\mathbf{r}_j-\mathbf{r}_m|} - \imath\frac{\cos k_0|\mathbf{r}_j-\mathbf{r}_m|}{k_0|\mathbf{r}_j-\mathbf{r}_m|}\right)\beta_m(t) \ .\end{aligned}$$

We find,

$$\beta_j(t) = e^{-\left(1\pm\frac{\sin k_0 d}{k_0 d}\right)\Gamma t} \ ,$$

in qualitative agreement with [364].

39.1.8.9 Ex: Signatures of subradiance

Super- and subradiance are contained in the coupled dipoles model. Try to identify the presence of subradiant states via a reduced decay rate of $\beta(t)$ starting from the timed Dicke state.

Solution: *Simplifying by $\Delta_0 = \Omega_0 = 0$, we recover from Eq. (39.26)) [1180, 1283, 1286],*

$$\dot{\beta}_j(t) = -\Gamma\beta_j(t) + \imath\Gamma\sum_{j'\neq j}^{N}\frac{e^{\imath k_0|\mathbf{r}_j-\mathbf{r}_m|}}{k_0|\mathbf{r}_j-\mathbf{r}_m|}\beta_m(t) \ .$$

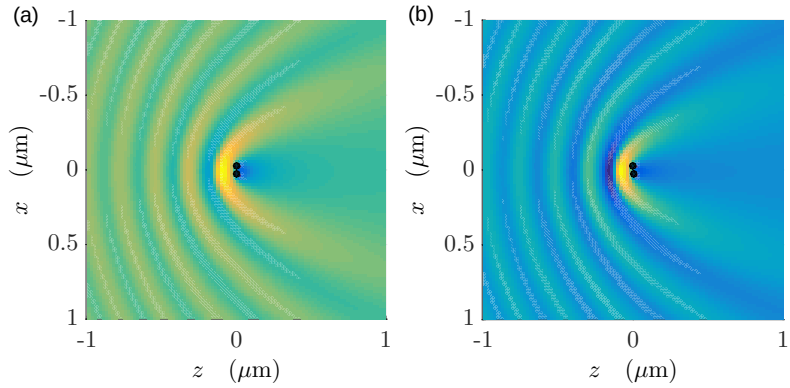

Figure 39.15: (code) Phase profile of the total light in the presence of two atoms illuminated by a Gaussian laser beam (a) without and (b) with off-diagonal elements of the kernel.

We numerically evaluate the equation in the Markov approximation. We find that the offset (see Fig. 39.16).
1. is much larger for homogeneous than for Gaussian distributions;
2. is smaller for large clouds than for small ones;
3. is much larger for large aspect ratios σ.

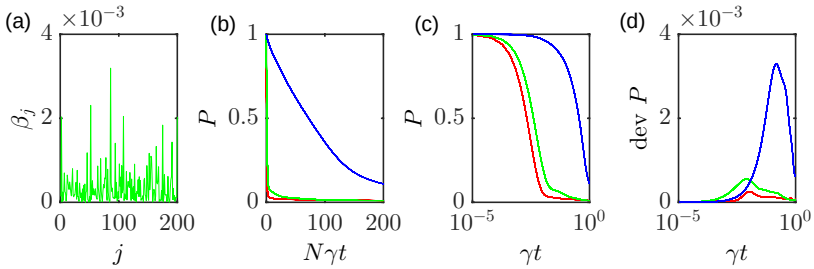

Figure 39.16: (code) Calculation of the time evolution of P within the Markov approximation for $N = 200$ atoms. Red: Gaussian distribution with $\sigma = 1$ and $R = 5/k_0$ starting from a timed Dicke state. Green: uniform distribution with $\sigma = 1$ and $R = 5/k_0$ starting from a timed Dicke state. Blue: uniform distribution with $\sigma = 5$ and $R = 5/k_0$ starting from a timed Dicke state. Yellow: uniform distribution with $\sigma = 1$ and $R = 20/k_0$ starting from a timed Dicke state. Cyan: uniform distribution with $\sigma = 1$ and $R = 20/k_0$ starting from a uniform excitation state.

39.1.8.10 Ex: Other applications of the coupled dipoles model

Discuss whether the coupled dipoles model can be extended to provide a microscopic description of gaseous metamaterials (negative refractive index) and the Goos-Hänchen, Imbert-Fedorov, Spin-Hall, and *Ewald-Oseen effects*, and interference with a LO. Is it possible to check Ewald-Oseen's theorem in media with negative refractive

index?

Solution:

39.2 Continuous density distributions and Mie scattering

In the last sections we developed the coupled dipoles model describing light scattering from ensembles of individual microscopic particles by a set of equations of motion, in the simplest case, one for every atomic dipole. This limits the number of atoms that can be considered in numerical simulations to a few 1000. On the other hand, most cold atom experiments nowadays are performed with 10^5 to 10^9 atoms. The following section are devoted to introducing concepts and approximations allowing us to understand light scattering from large atomic clouds.

The main step will consist in an approximation called smooth or *continuous density approximation*, where the discrete distribution of point-like scatterers is replaced by an inhomogeneous but smooth continuous density distribution characterized by a refraction index field $n_{rfr}(\mathbf{r})$. The interaction of this density distribution with light is then treated in the framework of Maxwell's equations, i.e. inhomogeneities are treated as macroscopic boundary conditions to the electromagnetic fields. In the following we will term this regime as *Mie scattering*.

At first sight Rayleigh scattering from point-like particles and Mie scattering from extended objects are quite different phenomena. Rayleigh scattering exhibits resonances due to the internal structure of the particles, e.g. an atom. Mie scattering shows resonances induced by the boundary conditions the scattering objects impose to the field. On the other hand, from a microscopic viewpoint, any extended object (e.g. a dielectric sphere) is nothing but an assembly of microscopic scattering particles. The question we need to study is then whether a description of the diffraction from this object as the sum of the radiation patterns scattered from the individual constituent particles is correct; or in how far the graininess of the cloud's density distribution and cooperative effects arising from the interaction *between* the individual particles play a role [225].

Interesting phenomena are expected in the transition regime between the limits of a dense bunch of individual scatterers and macroscopic dielectric objects. One of them is a strong modification of the radiation pressure force [298], which can conveniently be studied with atomic ensembles. The reason is that, in the smooth density approximation, the cloud can be understood as a macroscopic object characterized by a refraction index, which can be tuned over huge ranges by changing the cloud's density and volume, or by tuning the frequency of the incident light exploiting the existence of atomic resonances. We will see in the following that it is possible to study radiation pressure with cold atoms in the Rayleigh-Debye-Gans limit of small phase-shifts, as well as in the Mie limit of large phase shifts [66]. Despite the absence of sharp boundaries for the atomic cloud, we predict the occurrence of Mie resonances, which could be detected experimentally [67].

39.2.1 Continuous density approximation

In light scattering experiments, disorder (or granularity) plays a role when the number of atoms projected onto a cross section perpendicular to the incident beam is small enough so that a light mode focused down to the diffraction limit (that is $\sim \lambda^2$) would be able to resolve and count the atoms. In other words, the stochastic fluctuations induced by the random positions of the atoms can be neglected when the total number of atoms N is larger than the number of modes $\sim \sigma^2$ that fit into the cloud's cross section, i.e. when the optical density is $b_0 = 3N/\sigma^2 \gg 1$. Under this hypothesis, the differential equation (39.26) for $\tilde{\beta}_j$ can be simplified by replacing the discrete sum over atom positions by an integral over a density distribution $\rho(\mathbf{r})$,

$$\boxed{\sum_{j=1}^{N} \to \int \rho(\mathbf{r}')d^3r' \qquad \text{and} \qquad \tilde{\beta}_j(t) \to \tilde{\beta}(\mathbf{r}', t)} \,. \tag{39.96}$$

For example, the smoothed structure coefficient reads,

$$\mathcal{S}(\mathbf{k}) = \frac{1}{N}\sum_{j=1}^{N} e^{\imath(\mathbf{k}-\mathbf{k}_0)\mathbf{r}_j} = \frac{1}{N}\int d^3r' \; \rho(\mathbf{r}')e^{\imath(\mathbf{k}-\mathbf{k}_0)\mathbf{r}'} \,. \tag{39.97}$$

In the Exc. 39.2.5.1 we calculate the structure coefficients for a homogeneous spherical cloud of radius R and for a Gaussian ellipsoidal cloud with the *rms*-width $\sigma_{\rho,z}$:

$$\begin{aligned} \mathcal{S}_{\text{homog.sphere}}(\mathbf{k}) &= \tfrac{3}{q^3R^3}(\sin qR - qR\cos qR) \\ \mathcal{S}_{\text{gauss.ellipse}}(\mathbf{k}) &= e^{-\frac{1}{2}k^2\sigma_\rho^2\sin^2\theta - \frac{1}{2}\sigma_z^2(k\cos\theta - k_0)^2} \,. \end{aligned} \tag{39.98}$$

The simulated structure factor (red curve in Figs. 39.17) agrees well with the analytical expression (green curve). Since small clouds have a larger fluctuations, the fact that the total force is a sum of intensities rather than amplitudes leads to a finite value at large scattering angles θ.

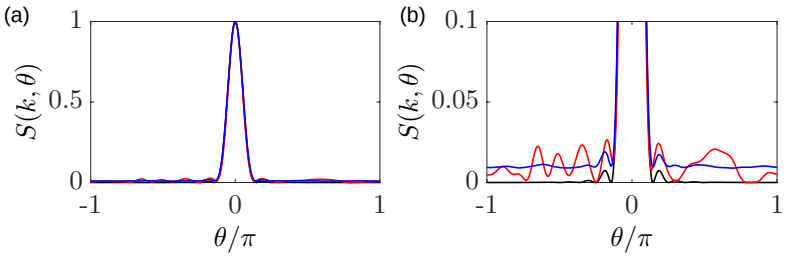

Figure 39.17: (code) (a) The red curve shows a calculation of the structure factor: $|\mathcal{S}(k = k_0, \theta, \phi = 0)|^2$ for 200 atoms randomly distributed in a homogeneous spherical cloud of size $R = 10/k_0$. The blue curve shows an average over 500 realizations of such a cloud according to $\sum_{m=1}^{200} |\mathcal{S}(k, \theta, \phi = 0)|^2$. The black curve is an analytical calculation according to Eq. (39.98) [1284]. (b) Same curves as in (a) but with a stretched y-axis.

In the continuous limit defined by (39.96) for the equations of motion (39.32) [11],

$$\dot{\tilde{\beta}}(\mathbf{r},t) = \imath\left(\Delta_0 + \imath\frac{\Gamma}{2}\right)\tilde{\beta}(\mathbf{r},t) - \frac{\imath}{2}\Omega_0 - \frac{\Gamma}{2}\int d^3r'\rho(\mathbf{r}')\frac{\sin(k_0|\mathbf{r}-\mathbf{r}'|)}{k_0|\mathbf{r}-\mathbf{r}'|}\tilde{\beta}(\mathbf{r}',t)e^{-\imath\mathbf{k}_0\cdot(\mathbf{r}-\mathbf{r}')} \,. \tag{39.99}$$

Transforming back to $\beta_j \equiv \tilde{\beta}e^{\imath\mathbf{k}_0\cdot\mathbf{r}}$, we obtain the fundamental equation for the dipolar excitation field,

$$\boxed{\dot{\beta}(\mathbf{r},t) = \imath\left(\Delta_0 + \imath\frac{\Gamma}{2}\right)\beta(\mathbf{r},t) - \frac{\imath\Omega_0}{2}e^{\imath\mathbf{k}_0\cdot\mathbf{r}} - \frac{\Gamma}{2}\int d^3r'\rho(\mathbf{r}')\frac{\sin(k_0|\mathbf{r}-\mathbf{r}'|)}{k_0|\mathbf{r}-\mathbf{r}'|}\beta(\mathbf{r}',t)} \,. \tag{39.100}$$

Example 229 (*Connection between coupled dipoles model and Helmholtz equation*): The steady-state solution of (39.100) can also be obtained from the *Helmholtz equation* of Maxwell's theory [458, 66, 67], as shown in Sec. 19.3.2,

$$\boxed{[\nabla^2 + k_0^2 n_{rfr}^2(\mathbf{r})]\beta(\mathbf{r}) = 0 \qquad \text{defining} \qquad n_{rfr}^2(\mathbf{r}) \equiv 1 - \frac{4\pi\rho(\mathbf{r})}{k_0^3(2\Delta_0/\Gamma + \imath)}} \,. \tag{39.101}$$

39.2.2 Simulations of the time evolution

We start from the second equation (39.18),

$$\dot{\tilde{\beta}}_j(t) = \imath\Delta_0\tilde{\beta}_j(t) - \frac{\Omega_0^2}{4}\sum_{m=1}^{N}\int_0^t \tilde{\beta}_m(t')dt' \tag{39.102}$$
$$- \sum_{\mathbf{k}} g_k^2 \sum_{m=1}^{N} e^{\imath(\mathbf{k}-\mathbf{k}_0)(\mathbf{r}_j-\mathbf{r}_m)}\int_0^t e^{-\imath(\omega_k-\omega_0)(t-t')}\tilde{\beta}_m(t')dt' \,.$$

Substituting the timed Dicke state (39.64),

$$\dot{\beta}(t) = \frac{1}{N}\sum_{j=1}^{N}\dot{\beta}(t) = \frac{1}{\sqrt{N}}\sum_{j=1}^{N}\dot{\tilde{\beta}}_j(t) \tag{39.103}$$
$$= \imath\Delta_0\beta(t) - \frac{N\Omega_0^2}{4}\int_0^t \beta(t')dt' - \frac{V_{ph}}{(2\pi)^3}\int d^3k\; g_k^2N^2|\mathcal{S}(\mathbf{k})|^2\int_0^t e^{-\imath(\omega_k-\omega_0)(t-t')}\frac{\tilde{\beta}_m(t')}{\sqrt{N}}dt' \,,$$

where we used $\sum_{m=1}^{N} e^{\imath(\mathbf{k}-\mathbf{k}_0)(\mathbf{r}_j-\mathbf{r}_m)} = N^2|\mathcal{S}(\mathbf{k})|^2$ from Eq. (39.67). Finally, at resonance and low saturation we may neglect the first two terms,

$$\dot{\beta}(t) = -N\frac{V_{ph}}{(2\pi)^3}\int_{\mathbb{R}} d^3k\int_0^t dt'\; g_k^2\beta(t')e^{\imath(\nu_k-\omega)(t-t')}|\mathcal{S}(\mathbf{k})|^2 \tag{39.104}$$
$$= -N\frac{V_{ph}}{(2\pi)^3}\int_0^t dt'\;\beta(t')\int_0^\infty\int_0^\pi g_k^2e^{\imath(\nu_k-\omega)(t-t')}|\mathcal{S}(k,\theta)|^2 2\pi k^2\sin\theta d\theta dk$$
$$= -N\frac{V_{ph}}{(2\pi)^3}g_k^2\int_0^t dt'\;\beta(t')\int_0^\infty e^{\imath(\nu_k-\omega)(t-t')}k^2I(k)dk = -\Omega_N^2\int_0^t dt'\;\beta(t')G(t-t') \,,$$

[11] Note that the 'timed Dicke' assumption (39.64) has not been used here.

with the collective Rabi frequency $\Omega_N = \sqrt{N} g_k$ and the surface integrated structure factor,

$$I(k) = \int_0^{2\pi} \int_0^{\pi} |\mathcal{S}(k,\theta,\phi)|^2 \sin\theta d\theta d\phi \ , \tag{39.105}$$

and

$$G(\tau) = \frac{V_{ph}}{(2\pi)^3} e^{-\imath\omega\tau} \int_0^{\infty} e^{\imath ck\tau} k^2 I(k) dk \ , \tag{39.106}$$

with $\omega = ck_0$ and $\nu_k = ck$. The integral $I(k)$ has been solved by Nicola for an ellipsoidal Gaussian density distribution. It is quite close to,

$$I(k) \simeq I(k_0) \simeq \sqrt{\frac{\pi}{2}} \frac{1}{k\sigma_z} e^{F^2/2} [1 - \mathrm{erf}\ (F/\sqrt{2})] \ , \tag{39.107}$$

with the Fresnel number $F = k\sigma_r^2/\sigma_z$.

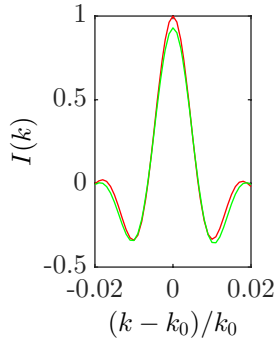

Figure 39.18: (code) Averaging of the structure factor over the whole k-space.

39.2.2.1 Analytical method

To evaluate the above integro-differential equation, we use the rule for differentiating integrals with variable boundaries,

$$\frac{\partial}{\partial t} \int_{\phi(t)}^{\psi(t)} f(x,t) dx = \int_{\phi(t)}^{\psi(t)} \frac{\partial f(x,t)}{\partial t} dx + f(\psi(t),t)\psi'(t) - f(\phi(t),t)\phi'(t) \ , \tag{39.108}$$

it is easy to show,

$$\frac{\partial}{\partial t} \int_0^t f(t')G(t-t')dt' = f(t)G(0) + \int_0^t f(t')\dot{G}(t-t')dt' \tag{39.109}$$

and to thusly evaluate the integral until $\frac{\partial^n}{\partial t^n} G(t-t')$ gets smooth enough to be neglected.

39.2.2.2 Numerical method

We can directly solve the integro-differential equation numerically using,

$$G(\tau) = \left[1 + \frac{3c}{4R}\tau - \frac{c^3}{16R^3}\tau^3\right]\Theta(3R - c\tau) \ , \tag{39.110}$$

for a homogeneous spherical cloud and,

$$G(\tau) = \frac{k\sigma_r^2}{k\sigma_r^2 + ic\tau} e^{-(c\tau/\sigma_z)^2/2} \ , \tag{39.111}$$

for an ellipsoidal Gaussian cloud. The iteration is done via,

$$\beta(t + dt) = \beta(t) - dt\ \Omega_N^2 \int_0^t \beta(t')G(t - t')dt' \ . \tag{39.112}$$

The discretization is done via,

$$\begin{aligned} t_{m+1} &= t_m + dt \\ \beta_{m+1} &= \beta_m - dt\ Ng_k^2 \sum_{m'=1}^{m} \beta_{m'} G(t_m - t_{m'})dt \ . \end{aligned} \tag{39.113}$$

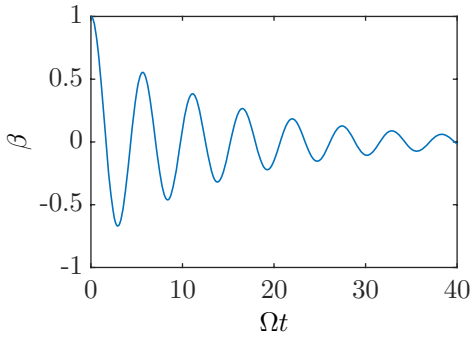

Figure 39.19: (code) Calculation of the time evolution of β for a homogeneous spherical cloud. The parameters are $\lambda \simeq 780\,\text{nm}$ and $c/\Omega \simeq 30\,\text{cm}$ with $\Omega = \sqrt{N}g_k$ for typically $g_k \simeq 1\,\text{MHz}$ and $N \simeq 10^6$.

With the solution of the integro-differential equation $\beta(t)$, we can calculate the probability that atoms are excited [1284] [12],

$$P(t) = |\beta(t)|^2 = \sum_j |\beta_j(t)|^2 = \int d^3r |\beta(t, \mathbf{r})|^2 \ . \tag{39.114}$$

[12]Compare to Jaynes-Cummings model in a CQED environment: A single photon is coherently exchanged between the cavity and the atomic excitation, we get Rabi oscillations. Here, the atomic cloud is the cavity.
We know that the Mollow triplet in the dressed states picture gives rive to an oscillating decay curve resembling that of Fig. 39.19. Does this curve also have an interpretation in terms of collective dressed states?

Example 230 (*Solutions for a homogeneous spherical cloud*): For a homogeneous spherical cloud, we find three regimes characterized by the size of the cloud compared to the two length scales λ and c/Ω:

$$\beta(t) = \beta(0) \begin{cases} e^{-N\Gamma t} & \text{for } R < \lambda \ll c/\Omega \\ e^{-27N\Gamma t/8(k_0 R)^2} & \text{for } \lambda < R \ll c/\Omega \\ \cos\Omega t e^{-3ct/8R} & \text{for } \lambda \ll c/\Omega < R \end{cases} .$$

39.2.2.3 Complete numerical simulation

In order to be independent from initial conditions, we generate a random distribution $\mathbf{r}_{j'}$ and solve the differential equation,

$$\dot{\beta}_j(t) = -Ng_k^2 \int_0^t dt' \, \frac{V_{ph}}{(2\pi)^3} \int d^3k \, \frac{1}{N} \sum_{j'=1}^{N} \beta_{j'}(t') e^{\imath(\nu_k - \omega)(t-t') + \imath \mathbf{k}(\mathbf{r}_j - \mathbf{r}_{j'})} . \quad (39.115)$$

We propagate the amplitudes in time via,

$$\beta_j(t+dt) = \beta_j(t) - dtg_k^2 \frac{V_{ph}}{(2\pi)^3} \int_0^t dt' \, \sum_{j'=1}^{N} \beta_{j'}(t') \int_0^\infty k^2 e^{\imath(ck-\omega)(t-t')} I_{jj'}(k) dk , \quad (39.116)$$

where $I_{jj'}(k) \equiv \int_0^\pi \int_0^{2\pi} e^{\imath k\left[(x_j - x_{j'})\sin\theta\cos\phi + (y_j - y_{j'})\sin\theta\sin\phi + (z_j - z_{j'})\cos\theta\right]} \sin\theta d\theta d\phi$, and discretize via,

$$t_{m+1} = t_m + dt \quad (39.117)$$

$$\beta_j(t_{m+1}) = \beta_j(t_m) - dt^2 g_k^2 \sum_{m'=1}^{m} \sum_{j'=1}^{N} \beta_{j'}(t_{m'}) G_{jj'}(t_m - t_{m'}) ,$$

with $G_{jj'}(t_m - t_{m'}) = \frac{V_{ph}}{(2\pi)^3} \int_0^\infty k^2 e^{\imath(ck-\omega)(t_m - t_{m'})} I_{jj'}(k) dk$.

39.2.3 Radiation pressure force in macro- and microscopic scattering

As mentioned at the beginning of this section, scattering of light by an extended object such as an atomic ensemble or a dielectric sphere is fundamentally different from scattering at a point-like scatterer such as a single atom. On one hand, the finite size of the object leads to Mie scattering. On the other hand, the spatial distribution of the scatterers rules the degree of cooperativity. Homogeneous and periodic distributions tend to scatter cooperatively, whereas disorder suppresses cooperativity. In an atomic cloud, the amount of disorder can be tuned via the optical density seen by the incident light, and its role can be studied via the radiation pressure exerted by the light on the atomic cloud. We present an analytic expression for the radiation pressure valid for any numbers of atoms and arbitrary density distributions, which interpolates between the regimes of dominating disorder and dominating cooperativity. Furthermore, we present first experimental signatures of radiation pressure reduction due to cooperative scattering.

The radiation pressure exerted by a plane wave laser beam with frequency ω_0 and wave vector $\mathbf{k}_0 = k_0\hat{\mathbf{e}}_z$ on a single two-level atom with resonance frequency $\omega_a = \omega_0 - \Delta_0$ is correctly described by the standard formula (39.80). Generalization to scattering by atomic ensembles and extended objects is only possible, if a number of effects is explicitly taken into account. The most important ones are named in the following. a. *Cooperativity* and b. *disorder*: Cooperativity is the tendency of atoms located in the same area of space, forming regular structures or being forced by the mode structure of the environment (e.g. optical cavities) to scatter light synchronously into the same direction, as in the case of Dicke superradiance. While homogeneously or periodically distributed atoms concentrate the scattered light in specific solid angles by forward or Bragg scattering, randomly distributed atoms do not cooperate and scatter light isotropically. In this respect, cooperativity and disorder are antagonists. c. *Mie scattering and refraction*: The finite volume and the shape of the cloud represent an inhomogeneity at which light is scattered in a global way. As long as the optical density is low, the pump mode depletion is mainly due to the fact, that the atomic cloud distorts the phase front of the incident light. For high optical density, scattering is predominantly absorptive. d. *Multiple scattering* and e. *resonance fluorescence*: Near resonance, multiple scattering leads to radiation trapping. Even off-resonance, inelastic scattering pumps resonant photons into the atomic cloud, which have a high probability to be reabsorbed. Taking account of all these effects, the real radiation pressure can differ by orders of magnitude from the naive prediction of the above formula.

For smooth density distributions F_c is only limited by Mie scattering at the inhomogeneity represented by the *finite extend* of the atomic cloud [298]. The radiation pressure depends on the number of atoms N in the volume, and the scaling $F_c(N)$ depends on the pump laser detuning and the radial cross section of the cloud. But small scale inhomogeneity *within the cloud*, i.e. disorder, can play an eminent role for collective scattering. This is the case, when the number of atoms is beyond a critical value, which mainly depends on the volume and shape of the cloud. In the following we will derive an analytic expression for the radiation pressure as a function of atom number, which interpolates between the regimes of dominating disorder (single-atom Rayleigh scattering) and dominating cooperativity (pure Mie scattering).

On the other hand, we point out, that we do not consider multiple scattering in our treatment. This is a good assumption far from resonance, where the scattering is predominantly Rayleigh scattering and inelastic scattering can safely be disregarded. In contrast, our extensions of single to multi-atom scattering are not valid near resonance.

The radiation pressure provides sensitive signatures for the impact of cooperativity and disorder. We describe an experiment measuring the displacement of cold atoms confined in a far-off resonance dipole trap and interpret our observations in terms of collective scattering.

39.2.3.1 Radiation pressure for timed Dicke states

As a first approach we will calculate the radiation pressure for a timed Dicke state from Eq. (39.89) by explicit analytical integration of the surface-integrated structure factors s_∞ and f_∞ in the smooth density limit (39.96) for an ellipsoidal Gaussian

smooth density distribution, as shown in Exc. 39.2.5.2. In the spherical case,

$$\rho(\mathbf{r}) = \rho_0 e^{-r^2/2\bar{r}^2} \qquad \text{with} \qquad \rho_0 = \frac{N}{(2\pi)^{3/2}\bar{r}^3} \ , \tag{39.118}$$

and introducing $\sigma \equiv k\bar{r}$, we get,

$$\begin{aligned} s_\infty &= \frac{1 - e^{-4\sigma^2}}{4\sigma^2} \overset{\sigma\gg1}{\longrightarrow} \frac{1}{4\sigma^2} \\ f_\infty &= \frac{1}{4\sigma^2}\left[1 - \frac{1}{2\sigma^2} + \left(1 + \frac{1}{2\sigma^2}\right) e^{-4\sigma^2}\right] \overset{\sigma\gg1}{\longrightarrow} s_\infty - 2s_\infty^2 \ . \end{aligned} \tag{39.119}$$

Hence,

$$\boxed{\frac{F_{za} + F_{ze}}{F_{z1}} = \frac{(2\Delta_0/\Gamma)^2 + 1}{(2\Delta_0/\Gamma)^2 + N^2 s_\infty^2} N(s_\infty - f_\infty)} \ . \tag{39.120}$$

Note that the radiation pressure calculated from Eq. (39.120) also holds for elongated ellipsoidal Gaussian clouds characterized by an aspect ratio $\eta > 1$, even though the expressions for the surface-integrated structure factors become more complicated.

It is revealing to compare the smooth density expressions (39.120) with numerical simulations based on randomly generated atomic distributions from which the structure factor is directly from the sum (39.68). Interestingly, we find in certain parameter regimes (in particular at low atom numbers) considerable deviations between s_N, f_N and s_∞, f_∞ and consequently between the numerical simulations and the analytic calculations of the radiation pressure. We attribute these deviations to disorder in the atomic cloud, which is not seen in the smooth density limit, but naturally incorporated in the numerical approach.

By comparison to numerical simulations [black solid lines and blue circles in Figs. 39.20(a)] we found that the surface-integrated structure factors in the presence of disorder are well described by [141],

$$s_N = \frac{1}{N} + s_\infty \qquad \text{and} \qquad f_N = f_\infty \ . \tag{39.121}$$

39.2.3.2 Cooperativity versus disorder

We expect disorder to play a dominant role, when the coarse graininess, which is related to the average distance between two atoms, $|\mathbf{r}_i - \mathbf{r}_j|$, can be resolved by the incident light. For the *absorption process*, this means that disorder gets important, when the number of spatial modes supported by the pump laser in a radial cross section of the atomic cloud,

$$N_{ca} = s_\infty^{-1} \simeq 4\sigma^2 \ , \tag{39.122}$$

(for voluminous clouds) surpasses the number of atoms, $N < N_{ca}$. This is just the case, when the mean resonant optical density (for a ray passing through the center of the cloud $x = y = 0$) is larger than 1,

$$b_0 = \int_{-\infty}^{\infty} dz \ \rho(z)\sigma_{opt} = \frac{3N}{\sigma^2} = \frac{12N}{N_{ca}} > 1 \ , \tag{39.123}$$

where $\sigma_{opt} = \frac{3\lambda^2}{2\pi}$ is the resonant optical cross section and $\rho(\mathbf{r})$ the spherical Gaussian density distribution (39.118). For the *scattering process*, the number of modes available for the reemitted light also counts. Hence, the critical number of atoms that can be resolved by light scattering is larger than N_{ca}:

$$N_{ce} = (s_\infty - f_\infty)^{-1} \simeq \tfrac{1}{2}(2\sigma)^4 = \tfrac{1}{2} N_{ca} \cdot \sigma^2 \ . \tag{39.124}$$

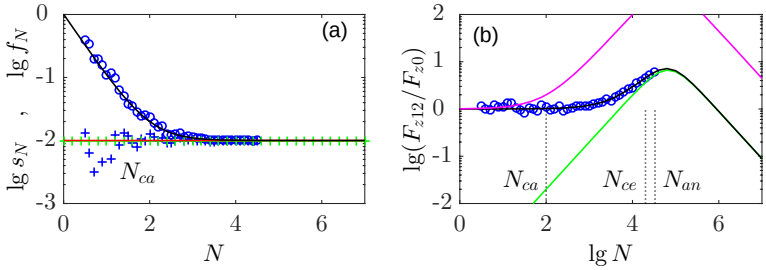

Figure 39.20: (code) (a) Numerical evaluation of s_N (blue circles) and f_N (blue crosses) [225]. Analytical calculation of s_N (black solid line) according to Eq. (39.121). Smooth density limit of s_∞ (red solid line) and f_∞ (green crosses). The cloud is assumed spherical, $\eta = 1$, and Gaussian with size $\sigma = 5$. (b) Numerical evaluation (blue circles) of the corresponding force ratio as a function of atom number N for $\Delta_0 = (2\pi)\ 2\,\mathrm{GHz}$ and small collective saturation, $\sqrt{N}\Omega_0 \ll \Delta_0$. Analytical calculation in the smooth density limit (green solid line) and according to Eq. (39.126) (black solid line). The magenta line traces the radiation pressure force resulting from pump photon absorption only.

In order to simplify the discussion, we neglect saturation, $\Omega_0 \to 0$. Using $\Delta_0 \gg \Gamma$ and defining a third characteristic atom number,

$$N_{cr} = \frac{2\Delta_0}{\Gamma s_\infty} \ , \tag{39.125}$$

Eq. (39.120) can be written,

$$\frac{F_c}{F_1} \simeq \frac{1 + N/N_{ce}}{1 + (N/N_{cr})^2} \ . \tag{39.126}$$

In the limit of very large detunings, $\Delta_0/\Gamma \gg \sigma^2 \gg 1$, the three introduced characteristic atom numbers introduced in Eqs. (39.122), (39.124) and (39.125) satisfy $N_{ca} < N_{ce} < N_{cr}$, and we obtain the N-dependence of the radiation pressure depicted in Fig. 39.20.

In the regime $N < N_{ca}$, radiation pressure is dominated by the absorption process, $s_N \gg f_N$, because the emission is isotropic. The absorption radiation pressure exerted on a hypothetical smooth density distribution occupying the same volume as the atomic cloud [green line in Fig. 39.20] is dramatically reduced with respect to the single-atom radiation pressure (cyan dash-dotted line). However, disorder suppresses cooperativity and increases the radiation pressure up to the single-atom value. The novelty as compared to Ref. [1180] is the fact that cooperativity and disorder not

only influence the collective emission of a photon by an atomic cloud, but also the collective *absorption* of a photon from a pump laser beam.

Neglecting the photon reemission at higher atom numbers would result in an increase of radiation pressure in the regime $N_{ca} < N < N_{ce}$ (magenta line). However, in this regime, the emission process becomes increasingly important, $s_N \simeq f_N$, because the emission changes its radiation pattern from isotropic to forward scattering. Consequently, the radiation pressure is reduced with respect to its purely absorptive component. This regime is still ruled by disorder, so that the critical atom number for the impact of disorder on the absorption process, N_{ca}, has no impact. It does not even show up in the formula (39.126).

In the regime $N_{ce} < N < N_{cr}$, disorder steps back and cooperativity wins, so that the radiation pressure approaches the smooth density limit. Since in this regime, the smooth density radiation pressure depends on atom number like $\propto N$, as already shown in Ref. [298], we observe an increase of the radiation pressure beyond the single-atom value. This is only possible, because the collective enhancement of absorption (magenta line) rises as fast with N, as the collective enhancement of emission.

For even higher atom numbers, $N_{cr} < N$, the radiation pressure dramatically alters its N-dependency from $\propto N$ to $\propto N^{-1}$. This change of behavior is *not* caused by the interplay of cooperativity and disorder, but can be understood within the framework of Mie scattering, as discussed in the next section.

39.2.3.3 Rayleigh-Debye-Gans versus Mie scattering

Radiation pressure is observed in many experiments, as it is the basis for optical cooling techniques (like magneto-optical traps) and limits the efficiency of resonant absorption imaging of cold atoms, because their acceleration leads to considerable Doppler-shifts. However, as stated before, the impact of disorder on radiation pressure can only be seen for large optical densities, $b \gg 1$, which may partially explain, why this effect has not been observed until two experiments explicitly searched for it [141, 119] (see Fig. 39.21).

Depending on the parameter regime chosen, the measurements exhibited in Fig. 39.21 present data for reduced or enhanced radiation pressure for larger N. As explained above, the reduction is understood as microscopic Rayleigh scattering at disordered atoms together with superradiant acceleration of the decay, while the enhancement is observed when the bulk cloud becomes so small and dense that it turns into an inhomogeneous dielectric sphere refracting and lensing incident light by macroscopic Mie scattering.

The question then remains why the radiation pressure, with increasing N, after an initial rise the drops again. To answer this question we must have a look at the phase shift induced in the pumjp light by the cloud's refraction index.. From calculations done in Secs. 18.2.4, 22.2.7 and 43.6.1 we know that (below saturation) the optical density b and the phase shift φ are linked to the refraction index n_{rfr} and the optical

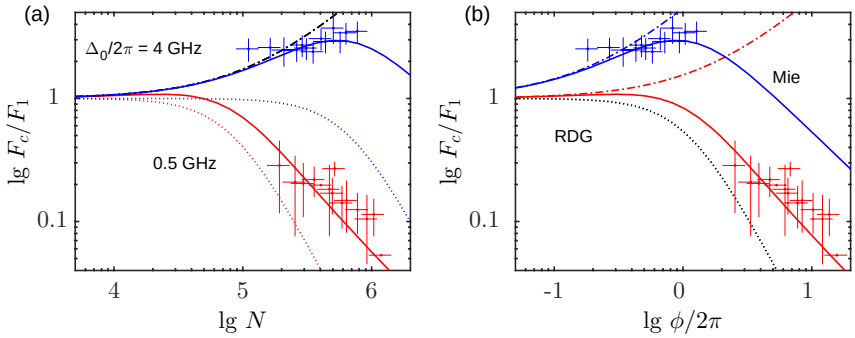

Figure 39.21: (code) (a) Double-logarithmic plot of the measured (symbols) and calculated (lines) N dependence of the radiation pressure force. The red symbols and lines correspond to the detuning $\Delta_0 = (2\pi)\ 0.5\,\mathrm{GHz}$ and the intensity $I_0 = 95\,\mathrm{mW/cm^2}$. For the blue symbols and lines, $\Delta_0 = (2\pi)4\,\mathrm{GHz}$ and $I_0 = 730\,\mathrm{mW/cm^2}$. The red (bottom) and blue (top) solid lines show calculations based on the full expression (39.120) without adjustable parameters. The red (bottom) and blue (top) dotted lines represent just the fraction of expression (39.120). The dash-dotted lines representing just the parentheses coincide for both values of Δ_0. (b) Same data as (a), but plotted as a function of the push beam phase shift φ. In this diagram the dotted lines representing the fraction coincide for both values of Δ_0 [119].

scattering cross section σ_{opt} via,

$$\frac{\imath b}{2} + \varphi = \frac{\omega}{c}\int_{-\infty}^{\infty}[n_{rfr}(\mathbf{r}) - 1]dz = \left(\imath - \frac{2\Delta_0}{\Gamma}\right)\sigma_{opt}(\Delta_0)\int_{-\infty}^{\infty}\rho(\mathbf{r})dz \qquad (39.127)$$

$$\text{where} \quad \sigma_{opt}(\Delta_0) = \frac{2\pi}{k^2}\frac{\Gamma^2}{4\Delta_0^2 + \Gamma^2} \qquad \text{and} \qquad n_{rfr}(\mathbf{r}) - 1 = -\frac{4\pi\rho(\mathbf{r})}{k_0^3(2\Delta_0/\Gamma + \imath)}\ ,$$

such that,

$$\boxed{b = -\sigma_{opt}(\Delta_0)\int_{-\infty}^{\infty}\rho(\mathbf{r})dz = b_0\frac{\Gamma^2}{4\Delta_0^2 + \Gamma^2} \qquad \text{and} \qquad \varphi = \frac{2\Delta_0}{\Gamma}b}\ . \qquad (39.128)$$

Estimating coarsely $k\int_{-\infty}^{\infty}[n_{rfr}(\mathbf{r}) - 1]dz \simeq \sigma[n_{rfr}(\mathbf{r}) - 1]$, where $\sigma \equiv k\bar{r}$, we may simplify,

$$\frac{\imath b}{2} + \varphi = \sigma[n_{rfr}(\mathbf{r}) - 1]\ . \qquad (39.129)$$

At high atom numbers (i.e. in the smooth density limit), the dependency of the radiation pressure on atom number (39.126) exhibits a maximum at N_{cr}. For an atomic cloud with density n and the resonant optical density b_0, the characteristic atom number can be expressed in terms of the phase shift φ experienced by the pump laser beam on its path across the cloud. Absorption losses for the pump beam (e.g. resonance fluorescence, whose differential cross section contributes σ_{opt} to the total scattering cross section [816]) is completely negligible at large detunings. Only elastic Rayleigh scattering occurs, which in the smooth density limit of Mie scattering becomes pure

diffraction (real part of the refraction index). We can than understand the atomic cloud as a non-absorbing dielectric sphere with a Gaussian index of refraction.

Rewriting Eq. (39.126) in terms of the refraction index,

$$\frac{F_c}{F_1} \simeq \frac{N}{1+(2\varphi)^2}\frac{2}{(2\sigma)^4} \ , \tag{39.130}$$

we see that, as long as $\varphi < \frac{1}{2}$, the force increases linearly like $\propto N$. The proportionality comes from the perfect (in the sense of not spoiled by disorder) cooperative enhancement of the scattering rate in the smooth density limit. The enhancement is only limited by the finite size σ of the cloud, which is accounted for in the second fraction. This regime, characterized by [13],

$$\sigma[n_{rfr}(\mathbf{r}) - 1] \ll 1 \tag{39.131}$$

is termed the *Rayleigh-Debye-Gans regime*.

For larger phase shifts, $\varphi > \frac{1}{2}$, refraction more and more distorts the wavefront of the pump beam, which spoils the pump mode depletion and hence reduces radiation pressure. Consequently, the radiation pressure decreases again like N^{-1}. This is the *Mie regime* of scattering. The maximum is thus a pure diffraction effect, a so-called Mie resonance. It corresponds to the n_{rfr}, where the Rayleigh-Debye-Gans scattering approximation looses its validity according to (39.131). In Excs. 39.2.5.3 and 39.2.5.4 we study Mie and Rayleigh-Debye-Gans scattering, and in 39.2.5.5 we discuss the question is whether recoil is imparted to individual atoms or to the center-of-mass of the whole cloud.

In the limit of the approximations made, our formula correctly describes the radiation pressure force on extended objects. These objects can either be ensembles of scatterers like homogeneous, ordered or disordered atomic clouds of arbitrary shapes and volumes, or macroscopic objects like dielectric spheres. The formula thus represents a bridge between microscopic Rayleigh scattering and macroscopic Mie scattering. At very low atom numbers, the atomic cloud basically represents a randomly distributed bunch of scatterers, whose intrinsic disorder spoils cooperativity. The radiation pressure is then well described by the single-atom value. At large atom numbers, the atomic cloud forms a smooth density distribution characterized by an almost perfect a cooperativity, which is only limited by Mie scattering.

39.2.3.4 Light scattering in the continuous density approximation

The scalar electric field scattered by an arbitrary distribution of atoms has been calculated in (39.49). In the continuous density approximation (39.96), we get,

$$\vec{\mathcal{E}}_{sct}(\mathbf{r}) = -\frac{\imath\hbar\Gamma}{2d}\sum_{j=1}^{N}\frac{e^{\imath k_0|\mathbf{r}-\mathbf{r}_j|}}{\imath k_0|\mathbf{r}-\mathbf{r}_j|}\beta_j(\infty) \to -\frac{\imath\hbar\Gamma}{2d}\int d^3r'\rho(\mathbf{r}')\frac{e^{\imath k_0|\mathbf{r}-\mathbf{r}'|}}{\imath k_0|\mathbf{r}-\mathbf{r}'|}\beta(\mathbf{r}',\infty) \ . \tag{39.132}$$

[13] Note the necessity of another condition $[n_{rfr}(\mathbf{r}) - 1] \ll 1$ termed Born approximation, which demands that the incident wave be not appreciably reflected.

In particular, for a timed Dicke state,

$$\vec{\mathcal{E}}_{sct}(\mathbf{r}) = -\frac{\imath\hbar\Gamma}{2d}\frac{\sqrt{N}\Omega_0}{2\Delta_0 + \imath\Gamma N s_N}\sum_{j=1}^{N}\frac{e^{\imath k_0|\mathbf{r}-\mathbf{r}_j|}}{\imath k_0|\mathbf{r}-\mathbf{r}_j|} \tag{39.133}$$
$$\to -\frac{\imath\hbar\Gamma}{2d}\frac{\sqrt{N}\Omega_0}{2\Delta_0 + \imath\Gamma(1+N s_\infty)}\int d^3r'\rho(\mathbf{r}')\frac{e^{\imath k_0|\mathbf{r}-\mathbf{r}'|}}{\imath k_0|\mathbf{r}-\mathbf{r}'|} \ .$$

39.2.4 Spherical harmonics expansion and generalized timed Dicke state

The results derived in (39.120) assumed the cloud to be in a timed Dicke state. As we have seen in Exc. 39.1.8.5, timed Dicke states do not account for pump laser phase shifts induced by the cloud's refraction index. The timed Dicke states might work well for homogeneous cylinders, but not for ellipsoidal clouds, which we assume in our analytical treatments. Therefore, a better approach consists in expanding the cloud into spherical harmonics. Under the assumption that the cloud is radially symmetric, $\rho(\mathbf{r}) = \rho(r)$, we get [458],

$$\beta(r,\theta,t) = \sum_{n=0}^{\infty}\sqrt{\frac{2n+1}{4\pi}}\alpha_n(t)j_n(k_0 r)P_n(\cos\theta)e^{-\imath k_0 r\cos\theta} \ , \tag{39.134}$$

where the coefficients α_n are the solutions of,

$$\dot{\alpha}_n = \left[\imath\Delta_0 - \frac{\Gamma}{2}(1+\lambda_n)\right]\left[\alpha_n - \alpha_n(\infty)\right] \ , \tag{39.135}$$

In steady state,

$$\alpha_n(\infty) = \frac{2\imath^n\sqrt{\pi(2n+1)}\Omega_0}{2\Delta_0 + \imath\Gamma(1+\lambda_n)} \ , \tag{39.136}$$

where,

$$\lambda_n \equiv 4\pi\int_0^\infty dr\rho(r)j_n^2(k_0 r) \tag{39.137}$$

is the decay rate of eigenmode n.

Inserting this into the steady-state solution (39.100) and integrating over the volume,

$$\langle\beta_\infty\rangle \equiv \frac{2\pi}{N}\int_0^{2\pi}d\theta\sin\theta\int_0^\infty dr^2\rho(r)\beta(r,\theta) = \frac{\Omega_0}{N}\sum_{n=0}^{\infty}\frac{(2n+1)\lambda_n}{2\Delta_0 + \imath\Gamma(1+\lambda_n)} \tag{39.138}$$
$$\langle|\beta_\infty|^2\rangle \equiv \frac{2\pi}{N}\int_0^{2\pi}d\theta\sin\theta\int_0^\infty dr^2\rho(r)|\beta(r,\theta)|^2 = \frac{\Omega_0^2}{N}\sum_{n=0}^{\infty}\frac{(2n+1)\lambda_n}{4\Delta_0^2 + \Gamma^2(1+\lambda_n)^2} \ .$$

Example 231 (*Spherical harmonics expansion for a Gaussian density distribution*): The density distribution determines the coefficients λ_n. For a Gaussian distribution $n(r) = N/[(2\pi)^{3/2}\sigma_R^3]e^{-r^2/2\sigma_R^2}$ using the sine kernel,

$$\lambda_n = N\sqrt{\frac{\pi}{2}}\frac{e^{-\sigma^2}}{\sigma}I_{n+1/2}(\sigma^2) \ .$$

For a homogeneous sphere, $n(r) = n_0$, of radius $\sigma = k_0 R$, using the sine kernel [[1283], Eq. (18)],

$$\lambda_n = \frac{3N}{2}[j_n^2(\sigma) - j_{n-1}(\sigma) j_{n+1}(\sigma)] \ .$$

39.2.4.1 Expansion of the radiation pressure forces

This allows us to calculate the forces,

$$F_a = -\hbar k_0 \Omega_0 \Gamma \Im\mathfrak{m} \, \langle \beta_\infty \rangle \tag{39.139}$$

$$F_e = -\hbar k_0 \Omega_0^2 \Gamma \sum_{n=0}^{\infty} \frac{2(n+1)\lambda_n \lambda_{n+1}[4\Delta_0^2 + \Gamma^2(1+\lambda_n)(1+\lambda_{n+1})]}{[4\Delta_0^2 + \Gamma^2(1+\lambda_n)(1+\lambda_{n+1})]^2 + 4\Delta^2\Gamma^2(\lambda_{n+1}-\lambda_n)^2} \ .$$

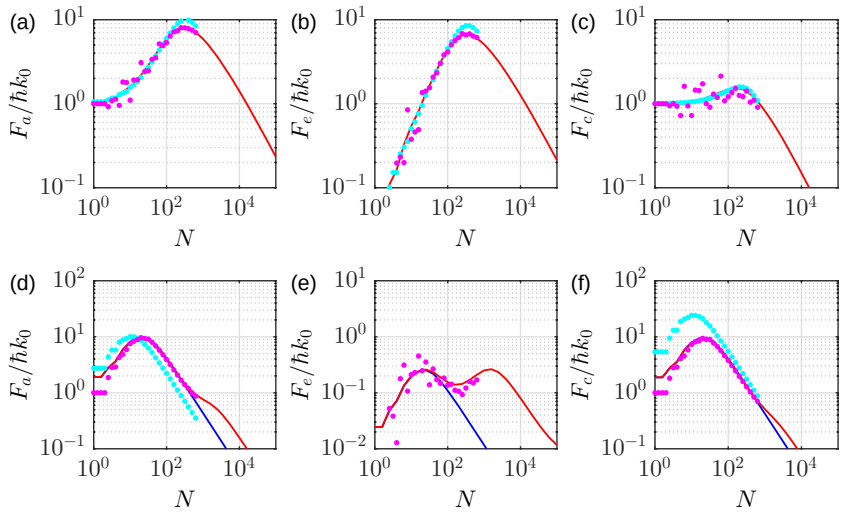

Figure 39.22: (code) (a) Absorption, (b) emission, and (c) total force for a Gaussian cloud with the following parameters: $\sigma = 2$, $\Delta_0 = 10\Gamma$, $\Omega_0 = 0.001\Gamma$, and $\eta = 1$. The magenta dots show a fully numerical calculation for a randomly generated cloud according to formula (39.63). The red lines show a calculation according to the complete formula (39.139). The cyan dots show a calculation assuming timed Dicke states according to (39.82) via numerical calculation of the structure factor according to (39.83) for the same randomly generated cloud as for the full simulation. The blue lines are obtained within the timed Dicke state approximation with structure factors estimated from formula (39.120). (d-f) Same as (a-c) but with $\sigma = 0.2$.

As seen in Fig. 39.22, the results obtained via the complete analytical formula (39.139) coincide with the fully numerical simulations according to formula (39.63). But both disagree with analytical and numerical results obtained within the timed Dicke state approximation.

It is possible to approximate the Bessel function $I_{n+1/2}(\sigma^2)$ and to obtain analytical solutions. The new formula works for $\sigma \gg 1$ and $\eta = 1$ [458],

$$F_a = \frac{\Omega_0^2}{\Gamma}\frac{\sigma^2}{N}\ln\left(1+\frac{N^2\Gamma^2 s_N}{\sigma^2(4\Delta_0^2+\Gamma^2)}\right) = \frac{\Omega_0^2}{4N\Gamma s_\infty}\ln\left(1+\frac{4N^2\Gamma^2 s_\infty s_N}{4\Delta_0^2+\Gamma^2}\right) \tag{39.140}$$

$$F_e = -F_a + \frac{\Omega_0^2}{\Delta_0}\frac{\sigma^2}{N}\arctan\frac{\Delta\Gamma N}{\sigma^2\left(4\Delta_0^2+\Gamma^2+\frac{\Gamma^2 N}{2\sigma^2}\right)} = \frac{\Omega_0^2}{4N\Delta_0 s_\infty}\arctan\frac{4\Delta_0\Gamma N s_\infty}{4\Delta_0^2+\Gamma^2+2\Gamma^2 N s_\infty}$$

$$b_0 = \frac{3N}{\sigma^2}$$

$$s_N = \frac{1}{N} + s_\infty = \frac{1}{N} + \frac{1}{(2\sigma)^2}\ .$$

39.2.4.2 Expansion of the scattered radiation intensity

The incident electric field is ...

The radiated electric field $\hat{\vec{\mathcal{E}}}^{(+)}(\mathbf{r},t)|\psi\rangle$ where $\hat{\vec{\mathcal{E}}}^{(+)}(\mathbf{r},t) = \sum_{\mathbf{k}} \varepsilon_{\mathbf{k}}\hat{a}_{\mathbf{k}}e^{\imath\mathbf{k}\cdot\mathbf{r}-\imath\omega_k t}$,

$$\begin{aligned}\hat{\vec{\mathcal{E}}}^{(+)}(\mathbf{r},t)|\psi\rangle &= \sum_{\mathbf{k}} \varepsilon_{\mathbf{k}}\gamma_{\mathbf{k}}(t)e^{\imath\mathbf{k}\cdot\mathbf{r}-\imath\omega_k t}|0\rangle|1\rangle_{\mathbf{k}} \\ &= -\imath\frac{V_{ph}g_{k_0}\varepsilon_{k_0}k_0}{4\pi c\sqrt{N}}e^{-\imath\omega_0 t}\sum_{j=1}^{N}\beta_j(t)e^{\imath\mathbf{k}_0\cdot\mathbf{r}_j}\frac{e^{\imath k_0|\mathbf{r}-\mathbf{r}_j|}-e^{-\imath k_0|\mathbf{r}-\mathbf{r}_j|}}{|\mathbf{r}-\mathbf{r}_j|}\ .\end{aligned} \tag{39.141}$$

We neglect the second term, which describes an incoming wave and go to smooth densities. We expand into spherical harmonics and obtain,

$$\hat{\vec{\mathcal{E}}}^{(+)}(\mathbf{r},t)|\psi\rangle = e^{-\imath\omega_0 t}\sum_{n=0}^{\infty}\frac{V_{ph}g_{k_0}\varepsilon_{k_0}}{c\sqrt{N}}\frac{\lambda_n}{2\Delta_0+\imath\Gamma(1+\lambda_n)}\Omega_0(2n+1)\imath^n h_n^{(1)}(k_0 r)P_n(\cos\theta)\ . \tag{39.142}$$

39.2.4.3 Mie resonances

It is an interesting question whether the maxima found in the curves of Fig. 39.22 can be associated with Mie resonances [164, 1228, 125]. To show this we need to apply the formalism of Mie scattering to atomic clouds with the smooth density approximation, where it is described by a continuous refraction index, as studied in Ref. [66]. The Mie formalism had been developed for homogeneous spheres, which can be dielectric or absorptive. For more general refractive index distribution the formalism gets quickly cumbersome [14]. Also Mie resonances are generally though of being conditioned to the existence of sharp boundaries.

The results of Ref. [66] surprisingly show that Mie resonances are expected for parabolic distributions of atoms, as is the case for example for Bose-Einstein condensates in the Thomas-Fermi limit. However, the spectra of Mie resonances exhibit much less structure. This is understood by the fact that 'whispering galery' Mie resonances may live on the surface of a sphere whose refraction index drops quadratically to zero, while cavity type Mie resonances may not.

[14] There is a treatment for parabolic radial variations [703].

39.2.5 Exercises

39.2.5.1 Ex: Structure coefficient of a homogeneous spherical and of a Gaussian ellipsoidal cloud

a. Calculate the structure coefficient of a homogeneous spherical cloud of radius R, and discuss the limits $qR < 1$ and $qR < 1$. Plot the structure coefficient as a function of θ for various radii R.
b. Calculate the structure coefficient of an ellipsoidal Gaussian cloud having the *rms*-widths σ_z and σ_r, and discuss the limits $qR < 1$ and $qR < 1$. Plot the structure coefficient as a function of θ for various aspect ratios σ_z/σ_ρ.

Solution: *a. The case of a homogeneous cloud with volume V is recovered by $n(\mathbf{r}) = \frac{N}{V}\chi_{[\mathbf{r}\in V]}$. For a homogeneous spherical cloud [1178] of volume $V = (4\pi/3)R^3$ the structure coefficient becomes with $\mathbf{q} \equiv \mathbf{k} - \mathbf{k}_0$,*

$$\begin{aligned}\mathcal{S}_\infty(\mathbf{k}) &= \frac{1}{V}\int_{sphere} e^{\imath\mathbf{q}\cdot\mathbf{r}} d^3r = \frac{3}{4\pi R^3}\int_0^R\int_0^{2\pi}\int_0^\pi r^2 e^{\imath qr\cos\theta}\sin\theta d\theta d\phi dr \\ &= \frac{3}{2R^3}\int_0^R r^2\int_{-1}^1 e^{\imath qru} du dr = \frac{3}{q^3R^3}(\sin qR - qR\cos qR)\ .\end{aligned}$$

In the small cloud limit, $qR \ll 1$, the density is well described by $n(\mathbf{r}) = N\delta^3(\mathbf{r})$, and the structure factor becomes,

$$\mathcal{S}_\infty(\mathbf{k}) = 1\ .$$

For large homogeneous clouds, $qR > 1$, of limited size V we get,

$$\mathcal{S}_\infty(\mathbf{k}) = \delta_{\mathbf{k},\mathbf{k}_0} = \frac{n_0}{N}\int_V e^{\imath(\mathbf{k}-\mathbf{k}_0)\mathbf{r}} d^3r = \frac{(2\pi)^3}{V}\delta^3(\mathbf{k}-\mathbf{k}_0) = \frac{6\pi^2}{R^3}\delta^3(\mathbf{k}-\mathbf{k}_0)\ .$$

b. The volume of an ellipsoidal Gaussian with the density distribution $n(\mathbf{r}) = n_0 e^{-\rho^2/2\bar\rho^2 - z^2/2\bar z^2}$ is $V = (2\pi)^{3/2}\sigma_\rho^2\sigma_z$. We write the incident wavevector as $\mathbf{k} = k\hat{\mathbf{e}}_z$ and the scattered wavevector as $\mathbf{k} = k\sin\theta(\hat{\mathbf{e}}_x\cos\phi + \hat{\mathbf{e}}_y\sin\phi) + k\hat{\mathbf{e}}_z\cos\theta$. With the Fourier transform $\int e^{-x^2/2\sigma^2} e^{\imath kx} dx = \sqrt{2\pi}\sigma\ e^{-\sigma^2x^2/2}$ the structure coefficient becomes,

$$\begin{aligned}\mathcal{S}_\infty(\mathbf{k}) &= \frac{1}{N}\int_{\mathbb{R}^3} n_0 e^{-\rho^2/2\sigma_\rho^2 - z^2/2\sigma_z^2} e^{\imath\mathbf{q}\cdot\mathbf{r}} d^3r \\ &= \frac{1}{(2\pi)^{3/2}\sigma_\rho^2\sigma_z}\int_{\mathbb{R}^3} e^{-\rho^2/2\sigma_\rho^2 - z^2/2\sigma_z^2} e^{\imath(\mathbf{k}-\mathbf{k}\hat{\mathbf{e}}_z)\cdot\mathbf{r}} d^3r \\ &= \frac{1}{(2\pi)^{3/2}\sigma_\rho^2\sigma_z}\int_{\mathbb{R}^3} e^{-x^2/2\sigma_\rho^2 + \imath kx\sin\theta\cos\phi} e^{-y^2/2\sigma_\rho^2 + \imath ky\sin\theta\sin\phi} e^{-z^2/2\sigma_z^2 + \imath kz(\cos\theta-1)} d^3r \\ &= e^{-\frac{1}{2}\sigma_\rho^2k^2\sin^2\theta\cos^2\phi} e^{-\frac{1}{2}\sigma_\rho^2k^2\sin^2\theta\sin^2\phi} e^{-\frac{1}{2}\sigma_z^2k^2(\cos\theta-1)^2} \\ &= e^{-\frac{1}{2}k^2\sigma_\rho^2\sin^2\theta - \frac{1}{2}k^2\sigma_z^2(\cos\theta-1)^2}\ .\end{aligned}$$

Again in the small cloud limit, $\sigma_\rho, \sigma_z < \lambda$, the structure coefficient becomes

$$\mathcal{S}_\infty(\mathbf{k}) = 1\ .$$

In the large cloud limit, we get,

$$\mathcal{S}_\infty(\mathbf{k}) = \delta_{\mathbf{k},\mathbf{k}_0} = \frac{(2\pi)^{3/2}}{\sigma_\rho^2 \sigma_z}\delta^3(\mathbf{k}-\mathbf{k}_0) \ .$$

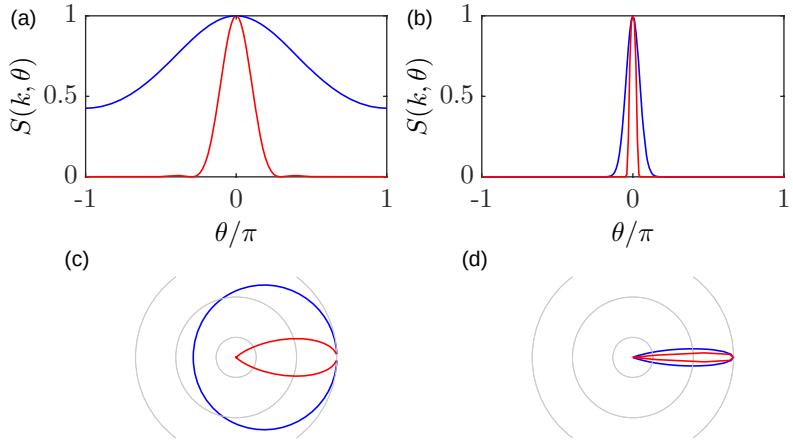

Figure 39.23: θ-dependence of the structure coefficients of (a) a homogeneous sphere for $kR = 1$ (blue) and $kR = 5$ (red) and of an ellipsoidal Gaussian cloud (b) for $\sigma_z/\sigma_\rho = 1$ (blue) and $\sigma_z/\sigma_\rho = 50$ (red). The figures (c) and (d) are polar representations of the curves in (a-b).

39.2.5.2 Ex: Force coefficients of a homogeneous spherical and of a Gaussian ellipsoidal cloud

a. Calculate the force coefficients s_N, $\tilde{f}_N$, and f_N from the Eqs. (39.66), Eqs. (39.78), and Eqs. (39.86), respectively, for a homogeneous spherical cloud of radius R.
b. Repeat the calculation of (a) for an ellipsoidal Gaussian cloud having the *rms*-widths σ_z and σ_r.

Solution: *a.*
b. The force coefficients are, setting $k \simeq k_0$ [298] and $\eta \equiv \sigma_z/\sigma_r$ and using the result from Exc. 39.2.5.1(a),

$$\begin{aligned} s_\infty &= \frac{1}{4\pi}\int_0^\pi \int_0^{2\pi} |\mathcal{S}_\infty(k_0,\theta,\phi)|^2 \sin\theta d\theta d\phi \\ &= \frac{\sqrt{\pi} e^{\sigma^2/(\eta^2-1)}}{4\sigma\sqrt{\eta^2-1}} \left[erf\left(\frac{\sigma(2\eta^2-1)}{\sqrt{\eta^2-1}}\right) - erf\left(\frac{\sigma}{\sqrt{\eta^2-1}}\right)\right] \\ &\xrightarrow{\eta=1} \frac{1-e^{-4\sigma^2}}{4\sigma^2} \xrightarrow{\sigma\gg 1} \frac{1}{4\sigma^2} \ . \end{aligned}$$

Also,

$$\tilde{f}_\infty = \frac{1}{4\pi}\int_0^\pi \int_0^{2\pi} \mathfrak{Re}\ \mathcal{S}_\infty(k_0,\theta,\phi)\sin\theta\cos\theta d\theta d\phi = \dots\ .$$

And,

$$\begin{aligned} f_\infty &= \frac{1}{4\pi}\int_0^\pi \int_0^{2\pi} |\mathcal{S}_\infty(k_0,\theta,\phi)|^2 \sin\theta\cos\theta d\theta d\phi \\ &= \frac{1}{\eta^2-1}\left[\eta^2 s_\infty - \frac{1}{4\sigma^2}(1-e^{-4\eta^2\sigma^2})\right] \\ &\xrightarrow{\eta=1} \frac{1}{4\sigma^2}\left[1-\frac{1}{2\sigma^2}+\left(1+\frac{1}{2\sigma^2}\right)e^{-4\sigma^2}\right] \xrightarrow{\sigma\gg 1} s_\infty - 2s_\infty^2\ . \end{aligned}$$

39.2.5.3 Ex: RDG and Mie

Estimate whether it is possible to distinguish Rayleigh-Debye-Gans scattering from Mie scattering in strontium spectra.

Solution: *We need,*

$$k\bar{v}, \omega_{rec} \ll \Gamma\ .$$

On the blue line,

$$\begin{aligned} k\bar{v} &= k\sqrt{\frac{k_B T}{m}} \simeq k\sqrt{\frac{\hbar\Gamma_{blue}}{2m}} \approx (2\pi)580\,\text{kHz} \\ \omega_{rec} &= \frac{\hbar k^2}{2m} = (2\pi)11\,\text{kHz}\ . \end{aligned}$$

It is easier on the red line

$$\begin{aligned} k\bar{v} &= k\sqrt{\frac{k_B T}{m}} \simeq k\sqrt{\frac{\hbar\Gamma_{red}}{2m}} \approx (2\pi)8.7\,\text{kHz} \\ \omega_{rec} &= \frac{\hbar k^2}{2m} = (2\pi)5\,\text{kHz}\ . \end{aligned}$$

39.2.5.4 Ex: Mie scattering from absorbing spheres

Calculate the force on a homogeneous dielectric sphere as a function of the absorptive and dispersive part of the refraction index [703].

Solution: *The result is shown in Fig. 39.24.*

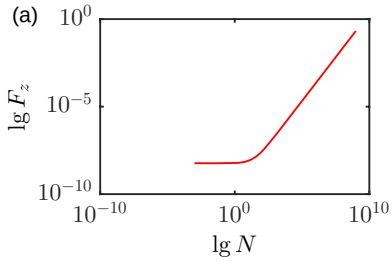

Figure 39.24: (code) Force on a homogeneous dielectric sphere as a function of n_{rfr}.

39.2.5.5 Ex: Momentum halos and heating, is the recoil cooperative?

Discuss the question is whether recoil is imparted to individual atoms or to the center-of-mass of the whole cloud.

Solution: *The individual recoil case corresponds to a product state, the shared recoil case to an entangled sum state. From radiation pressure force measurements it is impossible to distinguish between both, but perhaps analyzing fluctuations versus heating? On the other hand, even if a shared recoil state is generated, it may quickly decohere into individual recoil states.*
It might be necessary to include the external degrees of freedom into the formalism to see which degrees is really affected by cooperativity [15]*. There might be an interesting analogy between the transfer of recoil to individual particles and the photoeffect, where individual electrons are ejected from a solid..*
Let us consider cooperative scattering from two atoms. In the individual recoil case, the momentum halo should be a spherical shell with azimuthal modulation. In the shared recoil case, we expect a momentum blob somewhere inside the sphere. The effect is analogous to the Mössbauer effect, where the interatomic interaction is mediated by the lattice. In our case, it is induced by light (light shift imprinted by the dipole induced in atom j in atom m leads to level splitting gg, $eg + ge$, ee).

39.3 Scattering from disordered and dense clouds

39.3.1 Collective shifts and broadenings, vectorial light

The calculations show that the term identified as being responsible for disordered scattering comes from the self-decaying term (diagonal in the matrix γ_{jm}), i.e. when the excitation amplitude of the j-th atom decays by spontaneous emission. The other process, that the j-th atom decays because of the decay of the m-th atom, is described by the non-diagonal elements.

The classical radiation pressure formula is recovered for $\lambda_n = 0$, which means that the scattering is purely isotropic. The smooth density interpolation formula [298] is recovered when $\lambda_n \ll 1$ is assumed at all N.

[15] Note that the external degree of freedom is already contained in the Hamiltonian via the exponential $e^{\imath k\mathbf{r}}$. The coordinate just has to be interpreted as an operator.

The impact of *multiple scattering* gets important, when the off-resonant optical density exceeds 1, i.e. when,

$$b_0 > \frac{4\Delta_0^2}{\Gamma^2} \ . \tag{39.143}$$

We are interested in the question, whether it is possible to find signatures of collective Lamb shift in experiments with cold atoms. The Lamb shift should appear, e.g. in the spectra of the $\frac{1}{N}\sum_j |\beta_j|^2$ (calculated or simulated using exponential kernels). Indeed the dependence on Δ show asymmetries in certain parameter regimes. One of the features of the spectra is a strong central peak, which can be attributed to multiple scattering.

But what if we were able to inhibit multiple scattering? In the case of the strontium intercombination line, singly scattered photons are frequency-shifted by photonic recoil, such that they cannot be reabsorbed by other atoms. This feature is not contained in the coupled dipoles Hamiltonian, since in this model the external degrees of freedom are frozen. Then, how does the time-evolution have to be modified for Sr? Is it possible to construct the Hamiltonian in such a way that scattering intrinsically occurs only once without having to include external degrees of freedom, photonic recoil and the corresponding Doppler shift?

The eigenstates of the differential equation are found via $\beta_j(t) = \beta_j e^{-\lambda_n t}$, where $\mathfrak{Re}\ \lambda_n$ are the decay rates of the modes n and $\mathfrak{Im}\ \lambda_n$ are the frequency shifts [140].

According to [467] various frequency shifts may occur in ensembles of atoms due to a. collisions (of ground state atoms) and b. radiation-induced interactions (particularly resonant interactions). The shifts can be categorized as follows:
1. Coulomb shift (instantaneous interactions), for E1-radiation the Coulomb shift gives rise to the Lorentz shift for $\sigma \gg 0$, for $\sigma \ll 0$ the Lorentz shift goes to zero;
2. cooperative Lamb shift (exchange of virtual photons), photons are not only emitting and reabsorbing virtual photons, but the photons may be reabsorbed by adjacent atoms;
3. resonant collision shift (temporal correlations of dipole orientations), note that the scattering amplitude is non-linear in the potential;
4. van der Waals shift (due to buffer gas collisions or to non-resonant levels, the latter, however, being small).

39.3.1.1 Real and virtual photons

A virtual particle is a transient quantum fluctuation that exhibits some of the characteristics of an ordinary particle, while having its existence limited by the Heisenberg uncertainty principle. The concept of virtual particles arises in perturbation theory of quantum field theory, where interactions between ordinary particles (e.g. particle scattering or Casimir forces) are described in terms of exchanges of virtual particles with limited lifetime. A process involving virtual particles can be described by a schematic representation known as a *Feynman diagram*, in which virtual particles are represented by internal lines.

A virtual particle does not necessarily carry the same mass as the corresponding real particle, although it always conserves energy and momentum. The closer its characteristics come to those of ordinary particles, the longer its lifetime. Virtual photons

are the exchange particle for the electromagnetic interaction. I.e. electromagnetic repulsion or attraction between two charges can be thought of as due to the exchange of virtual photons between the charges.

As a consequence of quantum mechanical uncertainty, any object or process that exists for a limited time or in a limited volume cannot have a precisely defined energy or momentum. Hence, virtual particles which exist only temporarily do not typically obey the mass-shell relation $m^2c^2 = E^2 - p^2c^2$. The longer the lifetime of a virtual particle, the more the energy and momentum approach the mass-shell relation ruling the behavior of real particles. For instance, electromagnetic radiation consists of real photons which may travel light years between the emitter and absorber, but electrostatic attraction and repulsion is a relatively short-range force that is a consequence of the exchange of virtual photons.

By expressing an interaction in terms of the exchange of a virtual particle with four-momentum q, where q is given by the difference between the four-momenta of the particles entering and leaving the interaction vertex, both momentum and energy are conserved at the interaction vertices of the Feynman diagram. A virtual particle does not precisely obey the energy-momentum (or mass-shell) relation, that is, its kinetic energy may not have the usual relationship to velocity, as it can be negative. This is expressed by the expression *off mass shell*. The probability amplitude for a virtual particle to exist tends to be canceled out by destructive interference over longer distances and times. As a consequence, a real photon is massless and thus has only two polarization states, whereas a virtual one, being effectively massive, has three polarization states. Quantum field theory considers real particles as being *detectable* excitations of underlying quantum fields, while virtual particles appear only as forces, i.e. *non-detectable* excitations. Virtual particles are 'temporary' in the sense that they appear never appear as the observable inputs and outputs of a physical process.

Many observable physical phenomena can be interpreted in terms of virtual particles. For bosonic particles that exhibit rest mass when free and real, virtual interactions are characterized by a relatively short range of the interaction force. Confinement can lead to a short range, too. Examples of such short-range interactions are the strong and weak forces, and their associated field bosons. For the gravitational and electromagnetic forces, the zero rest-mass of the associated bosonic exchange particle allows for long-range forces. However, in the case of photons, power and information transfer by virtual particles is relatively short-ranged (restricted to only a few wavelengths of the field source), as is the case of inductive and capacitive coupling in the near field zone of coils and antennas.

Some field interactions which may be interpreted in terms of virtual particles are:

- The electrostatic Coulomb force between electric charges and the magnetostatic Lorentz force between magnetic dipoles are caused by the exchange of virtual photons. In symmetric 3-dimensional space this exchange results in the inverse square law for the electrostatic force and the inverse cube law for the magnetostatic force. Since the photon has no mass, the electric and magnetic potentials have infinite range.

- Electromagnetic induction transfers energy to and from a magnetic coil via a changing (electro)magnetic field. Much of the so-called near-field of radio

antennas, where the magnetic and electric effects of the changing current in the antenna wire and the charge effects of the wire's capacitive charge may be (and usually are) important contributors to the total EM field close to the source, but both of which effects are dipole effects that decay with increasing distance from the antenna much more quickly than do the influence of 'conventional' electromagnetic waves that are 'far' from the source. These far-field waves, for which $\mathcal{E}$ is (in the limit of long distance) equal to $c\mathcal{B}$, are composed of actual photons. Actual and virtual photons are mixed near an antenna, with the virtual photons responsible only for the 'extra' magnetic-inductive and transient electric-dipole effects, which cause any imbalance between $\mathcal{E}$ and $c\mathcal{B}$. As distance from the antenna grows, the near-field effects (as dipole fields) die out more quickly, and only the 'radiative' effects that are due to actual photons remain as important effects. Although virtual effects extend to infinity, they drop off in field strength as $1/r^2$ rather than the field of EM waves composed of actual photons, which drop as $1/r$. The electrical power in the fields, respectively, decrease as $1/r^4$ and $1/r^2$.

- Quantum tunneling and evanescent waves may be considered a manifestation of virtual particle exchanges. The range of forces carried by virtual particles is limited by the uncertainty principle, which regards energy and time as conjugate variables; thus, virtual particles of larger mass have more limited range.

- The strong nuclear force between quarks is the result of interaction of virtual gluons. The residual of this force outside of quark triplets (neutron and proton) holds neutrons and protons together in nuclei, and is due to virtual mesons such as the π meson and ρ meson. The weak nuclear force is the result of exchange by virtual W and Z bosons.

- The spontaneous emission of a photon due to the decay of an excited atom or nucleus can be traced back to the quantization of the electromagnetic field.

- The Casimir effect, where the ground state of the quantized electromagnetic field causes attraction between a pair of electrically neutral metal plates, and the van der Waals force, which is partly due to a (relativistic) Casimir effect between two atoms, are consequences of vacuum fluctuations.

- Vacuum polarization, which involves pair production or the decay of the vacuum, which is the spontaneous production of particle-antiparticle pairs (such as electron-positron).

- The Lamb shift of energies of atomic levels.

The calculation of scattering amplitudes in theoretical particle physics requires the use of some rather large and complicated integrals over a large number of variables. These integrals do, however, have a regular structure, and may be represented as Feynman diagrams. The appeal of the Feynman diagrams is strong, as it allows for a simple visual presentation of what would otherwise be a rather arcane and abstract formula. In particular, part of the appeal is that the outgoing legs of a Feynman diagram can be associated with actual, on-shell particles. Thus, it is natural to

associate the other lines in the diagram with particles as well, called the 'virtual particles'. In mathematical terms, they correspond to the propagators appearing in the diagram.

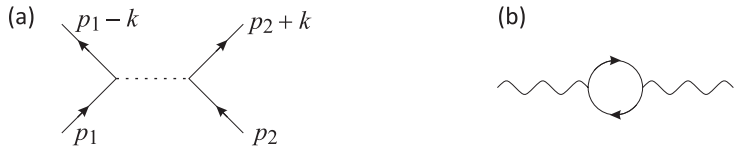

Figure 39.25: (a) Feynman diagram for one particle exchange scattering. The solid lines correspond to real particles, e.g. electrons (of momentum p_1 and so on), while the dotted line corresponds to a virtual particle carrying momentum k, e.g. a virtual photon. (b) One-loop diagram with fermion propagator. Virtual particles may be mesons or vector bosons, as in the example above; they may also be fermions. However, in order to preserve quantum numbers, most simple diagrams involving fermion exchange are prohibited. The image to the right shows an allowed diagram, a one-loop diagram. The solid lines correspond to a fermion propagator, the wavy lines to bosons.

In formal terms, a particle is considered to be an eigenstate of the particle number operator $\hat{a}^\dagger \hat{a}$. In many cases, the particle number operator does not commute with the Hamiltonian of the system, which implies that the particle number in an area of space is not a well-defined quantity. Instead, like other quantum observables, it must be represented by a probability distribution. Since these particles are not certain to exist, they are called virtual particles or vacuum fluctuations of vacuum energy. In a certain sense, they can be understood to be a manifestation of the time-energy uncertainty principle in a vacuum.

An important example of the 'presence' of virtual particles in a vacuum is the Casimir effect. Here, the explanation of the effect requires that the total energy of all of the virtual particles in a vacuum can be added together. Thus, although the virtual particles themselves are not directly observable, they do leave an observable effect: Their zero-point energy results in forces acting on suitably arranged metal plates or dielectrics.

Virtual particles are often popularly described as coming in pairs, a particle and antiparticle which can be of any kind. These pairs exist for an extremely short time, and then mutually annihilate, or in some cases, the pair may be boosted apart using external energy so that they avoid annihilation and become real particles. This may occur in one of two ways. In an accelerating frame of reference, the virtual particles may appear to be real to the accelerated observer; this is known as the Unruh effect. In short, the vacuum of a stationary frame appears to the accelerated observer, to be a warm gas of real particles in thermodynamic equilibrium.

39.3.1.2 Collective Lamb-shift

The *Lamb shift* results from the interaction of a (bound) valence electron with fluctuations of the electromagnetic vacuum. The fluctuations smear out the electronic orbit inside the Coulombian potential, thus leading to a shift. In the same time, if the electron is on an excited orbit, they incite radiative decay, thus leading to *spontaneous*

emission. The interaction takes place as an emission-reabsorption cycle of a *virtual photon* associated to a *transverse radiation field* [16].

The Lamb shift can be manipulated by tailoring the vacuum's mode structure, e.g. by a cavity or by the presence of antennas such as other atoms. The impact of a cavity on the Lamb shift and the spontaneous emission rate has been measured [596].

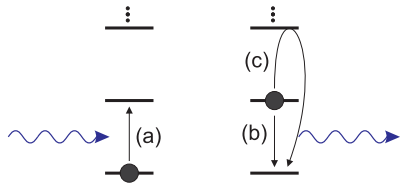

Figure 39.26: Scheme of collective Lamb shift.

Can we measure the collective Lamb-shift (impact of virtual photon processes)? Perhaps mixing the input and the scattered light using heterodyne techniques. Measure the collective Lamb shift in an ordered lattice, as Desy scientists do? A problem would be inhomogeneous light-shifts induced by the trapping potential and dipole-dipole interactions of the atoms excited by the lattice beams. Our calculations and simulations show that the impact of the exponential kernel decreases dramatically for large σ. How can [1112] have seen an effect in the X-ray regime? What distinguishes the collective Lamb-shift (impact of virtual photon processes) from shifts induced by atomic dipole interactions responsible for ground state collisions. After all all these are also mediated by virtual photons. Obviously, the interatomic interactions require an additional term in the Hamiltonian.

Can we derive a Lorentz-Lorenz formula from our theory analogously to [1119]? How to distinguish Lorentz-Lorenz shifts from collective dipole interactions? How are they related to collective line shifts [922, 470]?

According to [470] the total collective Lamb shift is [1286, 1285],

$$\Delta\omega_{lmb} = \left(\frac{4}{3} \mp 1\right) \frac{\rho\pi}{\hbar} \wp^2 \ , \tag{39.144}$$

where $\wp \equiv d/\sqrt{4\pi\varepsilon_0}$ and $d = \sqrt{3\pi\varepsilon_0\hbar\Gamma/k^3}$. The minus sign holds for a homogeneous slab, the plus sign for a homogeneous sphere.

$$\Delta\omega_{lmb} = \left(\frac{4}{3} \mp 1\right) \frac{\rho\pi}{4\pi\varepsilon_0\hbar} d^2 = \left(\frac{4}{3} \mp 1\right) \frac{\rho}{4} \frac{3\pi\Gamma}{k^3} = \frac{\pi\rho\Gamma}{4k^3} \ . \tag{39.145}$$

The $\frac{4}{3}$ term accounts for the Lorentz-Lorenz shift

$$\Delta\omega_{LL} = \frac{\rho\pi\Gamma}{k^3} \ . \tag{39.146}$$

Fig. 39.27 shows the collective Lamb shift calculated numerically and approximated analytically.

[16] What is the relationship between the Lamb shift and the *Bloch-Siegert shift* for single atoms without RWA and the collective Lamb-shift and the Lorentz-Lorenz shift with many atoms?

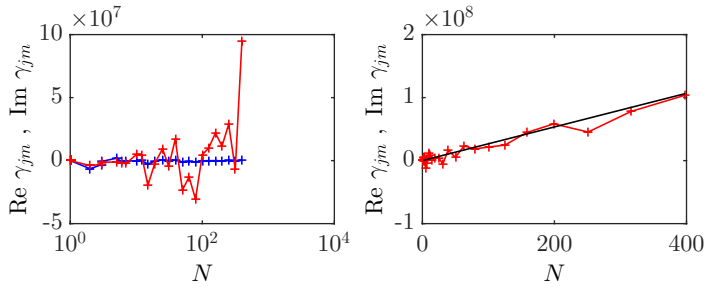

Figure 39.27: Collective Lamb shift.

39.3.1.3 Lorentz-Lorenz shift

The *Lorentz-Lorenz shift* follows from the *Clausius-Mossotti formula*[see Eqs. (14.28) and (16.29)],

$$n_{rfr}^2 - 1 = \frac{\frac{\rho\alpha_{pol}}{\varepsilon_0}}{1 - \frac{\rho\alpha_{pol}}{3\varepsilon_0}} \ . \tag{39.147}$$

The formula results from the fact that the polarization of a medium is induced by a local electric field resulting from a superposition of an external field and the field produced by the polarization of the neighboring atoms. In quantum optics near atomic resonances the polarisability can be approximated by [see (18.122)],

$$\alpha_{pol} = \frac{e^2}{m_e}\frac{1}{\omega_0^2 - \omega^2 - \imath\omega\gamma_\omega} = \frac{6\pi\varepsilon_0}{k_0^3}\frac{\omega_0\gamma_{\omega_0}}{\omega_0^2 - \omega^2 - \imath\omega\gamma_\omega} \simeq \frac{6\pi\varepsilon_0}{k_0^3}\frac{\Gamma}{2\Delta + \imath\Gamma} \ , \tag{39.148}$$

with

$$\gamma_\omega = \frac{e^2\omega^2}{6\pi\varepsilon_0 m_e c^3} = \frac{\omega^2}{\omega_0^2}\Gamma \ . \tag{39.149}$$

Inserting this into the susceptibility,

$$\chi_\varepsilon = \frac{3\pi\rho}{k_0^3}\frac{1}{\Delta/\Gamma - \pi\rho/k_0^3 + \imath/2} \equiv \frac{3\pi\rho}{k_0^3}\frac{1}{(\Delta - \Delta\omega_{LL})/\Gamma + \imath/2} \ , \tag{39.150}$$

defining the *Lorentz-Lorenz shift*

$$\boxed{\Delta\omega_{LL} = -\frac{\pi\rho}{k_0^3}\Gamma} \ . \tag{39.151}$$

For typical densities $\rho \simeq 10^{12}\,\mathrm{cm}^{-3}$, $\lambda = 780\,\mathrm{nm}$ and $\Gamma = (2\pi)\ 6\,\mathrm{MHz}$, we expect,

$$\Delta\omega_{LL} = (2\pi)\ 9\,\mathrm{kHz} \ . \tag{39.152}$$

In scalar approximation

$$\Delta\omega_{lmb} = \mp\frac{\rho\pi\Gamma}{2k^3} \approx \frac{N\Gamma}{R^3k^3} = \frac{N\Gamma}{\sigma^3} \ , \tag{39.153}$$

and there is no Lorentz-Lorenz contribution.

The Lorentz-Lorenz shift is due to static dipole-dipole interaction, not to virtual photon exchange.

39.3.1.4 Vectorial light

The procedure can be generalized to the vectorial case [1215, 1214, 859], where we get a similar steady-state solution as in (39.37),

$$\boxed{\vec{\beta}_j = (M_{jm})^{-1}\ \hat{\epsilon}\ \tfrac{\imath}{2}\Omega_0(\mathbf{r}_m)}\ , \tag{39.154}$$

only that the dipole moment amplitudes and the incident light field are now considered as vectors. The expression for the matrix M_{jm} is the same as in (39.36). However, the vectorial kernel must be calculated in a different way. Using the abbreviations,

$$\mathbf{r}_{jm} = \mathbf{r}_j - \mathbf{r}_m \quad , \quad r_{jm} = |\mathbf{r}_j - \mathbf{r}_m| + \delta_{jm} \quad , \quad c_{jm} = \frac{\imath}{k_0 r_{jm}} - \frac{1}{(k_0 r_{jm})^2}\ , \tag{39.155}$$

the new vectorial kernel can be written,

$$\gamma^{(3)}_{jm} = \frac{3\gamma_{jm}}{2}\ \frac{(1+c_{jm})r_{jm}^2\delta_{mn} - (1+3c_{jm})\mathbf{r}_{jm}\mathbf{r}^{\intercal}_{jm}}{r_{jm}^2}\ . \tag{39.156}$$

The steady-state scattered light field and the total field are now,

$$\vec{\mathcal{E}}_{sct}(\mathbf{r}) = -\frac{\imath\Gamma}{2}\sum_{j=1}^{N}\frac{3\gamma_{oj}(\mathbf{r})}{2}\ \frac{(1+c_{oj}(\mathbf{r}))k_0^2|\mathbf{r}-\mathbf{r}_j|^2\vec{\beta}_j - (1+3c_{oj}(\mathbf{r}))[(\mathbf{r}-\mathbf{r}_j)\cdot\vec{\beta}_j](\mathbf{r}-\mathbf{r}_j)}{|\mathbf{r}-\mathbf{r}_j|^2}\ . \tag{39.157}$$

A movie can be assisted at (watch movie).

39.3.2 Propagation of light within an absorber

The passage of coherent light through an absorber follows the *Lambert-Beer law*,

$$\boxed{I = I_0 e^{-\alpha z} \qquad \text{satisfying} \qquad I(mz) = I(z)^m}\ . \tag{39.158}$$

The *diffuse scattering* follows a different law. Imagine that the photons homogeneously fill a given volume $V = Az$. Per unit time, a given amount of energy E is pumped to the volume. The thicker the volume, the lower the energy density $u = E/Az$ and fewer photons reach the end of the absorber. This is the *Ohm's law*. The diffusively transmitted energy is,

$$\boxed{I = I_0\frac{a}{z} \qquad \text{satisfying} \qquad I(mz) = I(z)/m}\ . \tag{39.159}$$

39.3.2.1 Coherent backscattering

Shining coherent light on a homogeneous cloud, we expect no coherent scattering (exception made of multiple-atom scattering in backward direction, CBS and of fluctuations like speckle patterns). Like radiation trapping, *coherent backscattering* (CBS) is a manifestation of interference in multiple scattering. Just like photon echoes it is *not* due to interatomic correlations. While in radiation trapping this leads to an energy storage inside the atomic cloud connected to destructive interference of the radiation emitted to the cloud's outside, when the coherent beam is reflected at a diffuse

scattered, one observes *speckle patterns*. This holds as well for laser light reflection as for atomic wave reflections at a rough surface. See also (watch talk).

The coherent backscattering is an effect of constructive interference between two light scattering paths having the exact time-reversed single scattering sequence,

$$I = \left| \sum_j \vec{\mathcal{E}}_j e^{\imath\varphi_j} \right|^2 = \sum_j \left| \vec{\mathcal{E}}_j \right|^2 + \sum_{j \neq k} \vec{\mathcal{E}}_j \vec{\mathcal{E}}_k^* e^{\imath(\varphi_j - \varphi_k)} \ . \tag{39.160}$$

Only the second term makes speckles. However, the atomic motion smoothes out the speckle pattern in all directions. Only in the presence of correlations in the atomic positions they do not. E.g. in crystals or in the backscattering directions. Therefore, the constructive interference depends strongly on the backscattering angle ϑ. Fast atomic motion internal excitations can dynamically break the time-reversal symmetry of the scattering path, esp. when the laser is close to resonance and the phase delay per scattering process is long. Coherent backscattering is a weak form of *Anderson localization* (also strong localization) of light.

39.3.3 Localization of light

For a long time, people tried to observe strong localization with light. Many problems have been identified, some have been circumvented: Path irreversibilities due to internal structure, accumulated frequency shifts upon multiple photonic recoil, retardation combined to Doppler shifts, inelastic scattering, collisions. Recent simulations, however, suggest that strong localization would be impossible with vectorial light [1215, 1214, 859].

The higher the scattering order (number of scattering atoms), the deeper you can probe the cloud, involve higher-order correlation functions.

Strong localization is the inhibition of light propagation due to interference between multiple scattering paths. In fact the concept of a path for photons looses its sense, since a scattered photon is reabsorbed before it has time to leave the atom: We are approaching a regime where a dipolar description is more suited. The strong localization has been interpreted as a metal-insulator transition. Thinking of CBS with matter waves one is reminded the Mott insulating phase.

39.3.3.1 Anderson localization

In a disordered gas, interference between incident and reflected beams is averaged out. In the absence of interference phenomena the total transmission of a disordered medium is inversely proportional to the sample thickness (Ohm's law). In contrast, long-range spatial order can tolerate interferences, which may have dramatic influence on the propagation of light, such as a vanishing diffusion constant: in this situation, the medium behaves like an insulator (*strong localization of light* or *Anderson localization* in analogy to phase transitions to insulating states due to interference of electron wavefunctions) and its total transmission decreases exponentially with the samples thickness. Localization means that the transmission coefficient T of a plane wave decays exponentially with the system length L. The decay length is measured

by a so-called localization length $\lambda(k) = -L/\langle \ln T \rangle$ ($\lambda(k)^{-1}$ is also called the *Lyapunov exponent*). For $T \to 0, 1$, the localization length tends to $\lambda \to 0, \infty$. Multiple scattering experiments on strong localization of microwaves and light have been performed [1372]. A more accessible experimental situation is the so-called weak *weak localization of light* regime which manifests as coherent backscattering [768].

In dilute gases, single photon scattering will predominate. If L is the size of the sample and $l = 1/n\sigma$ the mean free path, this regime where the Lambert-Beer law, $I \sim e^{-\alpha z}$, holds is delimited by $1 < kL < kl$. At higher densities, multiple scattering leads to random walk of photons inside the sample resulting in *radiation trapping*. In this regimedelimited by $1 < kl < kL$, Ohm's law, $I \sim 1/z$, rules diffusive propagation of light. Interference effects may come into play when the sample is so dense that the mean free path for a photon is no larger than its wavelength. This so-called *Ioffe-Regel criterion*,

$$kl < 1 \ , \tag{39.161}$$

describes the regime of strong localization in $3D$ disordered samples. In this regime, ray optics does not apply. The propagation of radiation must rather be described by field amplitudes, which can interfere. Closed paths lead to standing waves, i.e. constructive interference. This hinders light propagation out of small regions: *The light gets localized* and the law is again exponential, $I \sim e^{-\tilde{\alpha} z}$. In other words localization arises from interference corrections to optical transport.

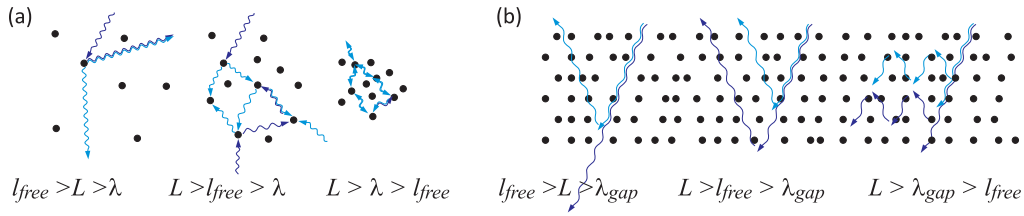

Figure 39.28: Illustration of the regime of single scattering, random walks, strong localization in (a) disordered gases and (b) photonic band gaps.

Now atoms have the important advantage that, due to their internal structure, the optical density can be tuned over wide ranges. However, for typical resonant cross sections σ the density must still be larger than $n > 10^{14}\,\mathrm{cm}^{-3}$, which is a lot.

Connection to superradiance [680], where directional bundling of radiation favors stimulated processes

Localization corresponds to a minimum in the density of states. E.g. PBGs arise from suppression of many states by destructive interference.

39.3.4 Exercises

39.3.4.1 Ex: The green flash

Discuss whether the '*green flash*' at sunset could be due to *superradiant extinction*. It can last seconds because refraction sweeps the ray through the spectrum (see the movie *Le rayon vert* by Éric Rohmer).

Solution:

39.3.4.2 Ex: Faraday effect with vectorial kernel in the coupled dipoles model

Try to simulate the pump laser phase shift and lensing by a small dense cloud by the coupled dipoles model for red and blue detuning. Discuss the influence of rescattering.

Solution:

39.4 Scattering from periodic structures and photonic bands

Long-range spatial ordering can have a dramatic influence on the propagation of light and the cooperativity of scattering, as we have already pointed out in the introduction of the structure factor in Sec. 39.1.1. This is true for the scattering of electronic waves in crystals. But atomic gases can also be arranged in periodic luminous potentials generated by dipolar forces (introduced in Sec. 38.2.2) exerted by counterpropagating laser beams. Such potentials, called *optical lattices*, can be realized with various geometries in 1, 2 or 3 dimensions. See also (watch talk).

Periodic structures are usually probed by Bragg scattering. This procedure can be applied to atoms ordered in optical lattices [146, 1361, 1219, 1221]: A test beam with wavevector $\mathbf{k}_{brg}$ and intensity I_{brg} is irradiated into the atomic cloud, and the power P_s of the first-order reflected beam by Bragg is detected under a solid angle Ω_s. Bragg diffraction is an interference effect of radiation patterns emitted by Rayleigh scattering from periodically aligned point-like antennas, the interference being constructive in only specified directions.

For optically dilute lattices, where multiple reflections can be neglected, the imaginary part of the atomic response is sufficient to describe Bragg reflection. For optically dense lattices, multiple reflections between consecutive atomic layers lead to interference phenomena between reflected and transmitted light fields and cause the emergence of frequency bands, inside which the propagation of light waves through the cloud is prohibited. These bands are known as *forbidden photonic bands*.

Photonic bands in optical lattices are interesting for several reasons:

1. They may facilitate the study of the phenomenon of Anderson localization. In fact, Anderson location of light in atomic gases requires very high densities or very large optical cross sections. Now, it is expected that, if the disorder is realized within periodic structures near the Bragg condition, the high density requirement is dramatically relaxed.

2. They modify the local density of states in a way to suppress spontaneous emission.

3. In optical lattices, unlike other systems, the scattering is very weak except when the light is tuned close to atomic resonances. Consequently, the expected forbidden bands are very narrow. This bears the advantage that we can adjust the optical density and tune the photon energy and the Bragg angle (i.e. the quasi-momentum) independently, which facilitates the mapping of the dispersion relation.

4. Crystals are always hampered by defects in the periodicity [733]. In latest-generation photonic crystals, the typical distance over which coherent light turns diffuse is limited to less than 20 μm. This limitation plays no role in optical lattices, where the delocalized photons rigorously guarantee perfect long-range order, even though the Debye-Waller factor may introduce local disorder.

Spectra of photonic bands in atomic clouds were detected experimentally [1158] in one-dimensional structures. Most of the above mentioned effects require omnidirectional photonic bands, but this is technically very difficult, mainly because of the narrow linewidth of the atomic transitions. We will develop this point in the course of this section. We also mention the prediction of forbidden photon bands in Bose condensates [852].

A presentation on this subject is available here (watch talk).

39.4.1 Bragg scattering

39.4.1.1 The reciprocal lattice

Let us consider a periodic *direct lattice* in real three-dimensional space whose elementary cells are located at positions,

$$\mathbf{R_n} = n_1\mathbf{a}_1 + n_2\mathbf{a}_2 + n_3\mathbf{a}_3 \ , \tag{39.162}$$

where $\mathbf{n} = (n_1, n_2, n_3)$ with $n_j \in \mathbb{Z}$ and $\mathbf{a}_j$ are linearly independent vectors describing the distance of two adjacent elementary cells [308]. Functions extended over the lattice, e.g. density distributions, are then supposed to be periodic,

$$n(\mathbf{r}) = n(\mathbf{r} + \mathbf{R_n}) \ , \tag{39.163}$$

such that they can be expanded in Fourier series similarly as we did for the introduction of the Bloch waves in Sec. 26.1,

$$n(\mathbf{r}) = \tfrac{1}{V}\sum_{\mathbf{m}} \rho_{\mathbf{m}} e^{\imath \mathbf{G_m}\cdot\mathbf{r}} \ , \tag{39.164}$$

where $\mathbf{m} = (m_1, m_2, m_3)$ with $m_j \in \mathbb{Z}$. The Fourier coefficients are [17],

$$\rho_{\mathbf{m}} = \int_0^{a_1}\int_0^{a_2}\int_0^{a_3} n(\mathbf{r}) e^{-2\pi\imath(m_1 x/a_1 + m_2 y/a_2 + m_3 z/a_3)} dxdydz = \int_0^1 n(\tilde{\mathbf{r}}) e^{2\pi\imath \mathbf{m}\cdot\tilde{\mathbf{r}}} d^3\tilde{r} \ . \tag{39.165}$$

[17] In crystallography $\rho_{\mathbf{m}}$ is called *structure factor*, but it is not to be confused with the structure factor defined in (39.5).

The condition (39.163) then yields,

$$n(\mathbf{r}) = \tfrac{1}{V}\sum_{\mathbf{m}} \rho_{\mathbf{m}} e^{\imath \mathbf{G_m}\cdot\mathbf{r}} = \tfrac{1}{V}\sum_{\mathbf{m}} \rho_{\mathbf{m}} e^{\imath \mathbf{G_m}\cdot\mathbf{r}} e^{\imath \mathbf{G_m}\cdot\mathbf{R_n}} = n(\mathbf{r}+\mathbf{R_n}) \ , \tag{39.166}$$

from which we conclude that the vectors $\mathbf{G_n}$ of the reciprocal lattice must satisfy,

$$\tfrac{1}{2\pi}\mathbf{G_m}\cdot\mathbf{R_n} \in \mathbb{Z} \ . \tag{39.167}$$

Example 232 (*The reciprocal lattice in crystallography*): In three dimensions the reciprocal lattice can be constructed by,

$$\begin{aligned} &\mathbf{G_m} = m_1\mathbf{b}_1 + m_2\mathbf{b}_2 + m_3\mathbf{b}_3 \qquad (39.168)\\ &\text{with} \quad \mathbf{b}_1 \equiv \frac{\mathbf{a}_2\times\mathbf{a}_3}{V} \quad , \quad \mathbf{b}_2 \equiv \frac{\mathbf{a}_3\times\mathbf{a}}{V} \quad , \quad \mathbf{b}_3 \equiv \frac{\mathbf{a}_1\times\mathbf{a}_2}{V} \\ &\text{and} \quad V \equiv \mathbf{a}_1\cdot(\mathbf{a}_2\times\mathbf{a}_3) \ . \end{aligned}$$

Knowing the density $n_1(\mathbf{r})$ within a single cell, which is often the case when the overlap between the density distributions of adjacent cells is negligible, we can write the global density distribution as,

$$\boxed{n(\mathbf{r}) = n_1(\mathbf{r}) \star \sum_{\mathbf{m}} \delta^{(3)}(\mathbf{r}-\mathbf{R_m})} \ . \tag{39.169}$$

Example 233 (*Elementary cell with Gaussian distribution*): With the ansatz $n_1(\mathbf{r}) = n_0 e^{-r^2/2\bar{r}^2}$, such that $\int n_1(\mathbf{r})d^3r = n_0(2\pi)^{3/2}\bar{r}^3 = N_1$,

$$\begin{aligned} \rho(\Delta\mathbf{k}) &= \sum_m e^{\imath m\Delta\mathbf{k}\cdot\mathbf{R}} \int_V n_1(\mathbf{r}) e^{\imath\Delta\mathbf{k}\cdot\mathbf{r}} d^3\mathbf{r} \qquad (39.170)\\ &= \frac{1-e^{\imath N_s\Delta kR}}{1-e^{\imath\Delta kR}} \times n_0 \int_V e^{-x^2/2\bar{r}^2} e^{-y^2/2\bar{r}^2} e^{-z^2/2\bar{r}^2} e^{\imath\Delta\mathbf{k}\cdot\mathbf{r}} d^3\mathbf{r} \\ &\approx N_s\delta(\Delta k - 2\pi/R) n_0 (2\pi)^{3/2}\bar{r}^3 e^{-6\Delta k^2\bar{r}^2} = N\delta(\Delta k - 2\pi/R) e^{-6\Delta k_x^2\bar{r}^2} \ . \end{aligned}$$

39.4.1.2 Impact of disorder in one-dimensional lattices

A wave be incident on a lattice in the direction $\mathbf{k}_0$ and scattered into the direction $\mathbf{k}_s \equiv \mathbf{k}_0 + \Delta\mathbf{k}$. The *structure coefficient* $\rho_{\mathbf{m}}$ describes the amplitude of radiation field scattered by the lattice,

$$\rho_{\mathbf{m}} = \int_V \rho(\mathbf{r}) e^{\imath\Delta\mathbf{k}\cdot\mathbf{r}} d^3\mathbf{r} \ . \tag{39.171}$$

Let the density distribution be,

$$n(\mathbf{r}) = \sum_j \rho_j(\mathbf{r}) \star \delta^{(3)}(\mathbf{r}-\mathbf{r}_j) = n_1(\mathbf{r}) \star \sum_j \delta(\mathbf{r} - j\hat{\mathbf{e}}_z \tfrac{\lambda_{dip}}{2}) \ , \tag{39.172}$$

that is, for perfect periodicity, introducing the density distribution of a unit cell and a $1D$ lattice.

The *Debye-Waller factor* describes the diffusion of the density over the sites of the lattice due to the thermal motion,

$$\begin{aligned}\overline{\rho_{\mathbf{m}}} &= \int_V n_1(\mathbf{r}) e^{\imath \Delta\mathbf{k}\cdot\mathbf{r}} d^3r \sum_j \overline{e^{\imath(j\hat{\mathbf{e}}_z\lambda_{dip}/2+\mathbf{u})\Delta\mathbf{k}}} \\ &= f_i \sum_j \overline{e^{\imath(j\hat{\mathbf{e}}_z\lambda_{dip}/2+\mathbf{u})\Delta\mathbf{k}}} = \rho_{\mathbf{m}} \overline{e^{\imath\mathbf{u}\Delta\mathbf{k}}} \ ,\end{aligned} \tag{39.173}$$

with

$$\overline{e^{\imath\mathbf{u}\Delta\mathbf{k}}} \approx e^{-|\mathbf{G}|^2\overline{u^2}/6} \ . \tag{39.174}$$

Example 234 (*Optical lattice*): The exponential distribution $e^{-6\Delta k_x^2 \bar{r}^2}$ is called Debye-Waller factor and describes the smearing out of the population over the lattice due to the thermal motion of the atoms. The δ-function sets the wavevector of emitted light. That is, the power of light is only emitted in particular directions given by the Bragg condition. Here, the solid angle $\Delta\Omega_s$ does not depend on the thermal distribution (as long as the atoms are within the Lamb-Dicke regime), but on the lattice size, which determines the goodness of the approximation of the Airy function (the sum in the above equation) by a Dirac δ-function. The width of the Airy function for a lattice of size w_0 is approximately $\Delta k = 2\sqrt{3}/w_0$. With this the solid angle is,

$$\Delta\Omega_s = \frac{12}{k^2 w_0^2} \ . \tag{39.175}$$

We can also estimate the solid angle from the diameter d of the Gaussian beam at a distance x away from a scattering medium of size w_0,

$$\begin{aligned} d &= w_0 \sqrt{1 + \left(\frac{\lambda x}{\pi w_0^2}\right)^2} \\ \Delta\Omega_s &= \frac{\pi d^2}{x^2} = \frac{\lambda^2}{\pi w_0^2} = \frac{4\pi}{k^2 w_0^2} \ . \end{aligned} \tag{39.176}$$

The power scattered into this solid angle is,

$$P_s = |A_s|^2 F^2 \Delta\Omega_s = |A_s|^2 e^{-2W} N^2 \Delta\Omega_s \ . \tag{39.177}$$

It depends quadratically on the number of atoms. Strictly speaking, the derivation only applies to perfectly ordered lattices, i.e. all the lattice sites are equally occupied. Defects lead to diffuse scattering, i.e. a background of isotropically distributed power at the expense of Bragg scattering. The sharpness of the Bragg radiation distribution remains intact.

We parametrize the density in an optical $1D$ lattice as follows:

$$\begin{aligned} n_l(\mathbf{r}) &= n_0 e^{(-x^2-y^2)/2\sigma_r^2} e^{-z^2/2\sigma_z^2} \\ n_a(\mathbf{r}) &= \sum_{m=1}^{N_s} \delta(\mathbf{r} - md\hat{\mathbf{e}}_z) \star n_l(\mathbf{r}) = \sum_{m=1}^{N_s} n_l(\mathbf{r} - md\hat{\mathbf{e}}_z) \ . \end{aligned} \tag{39.178}$$

We will show in Exc. 39.4.4.1, that the structure factor is then,

$$\boxed{\mathcal{S}_{\mathbf{k}_0}(\mathbf{k}) = \frac{n_0}{N}\frac{1-e^{\imath N_s dq_z}}{e^{-\imath dq_z}-1}e^{-q_x^2\sigma_r^2/2}e^{-q_y^2\sigma_r^2/2}e^{-q_z^2\sigma_z^2/2}} \ . \tag{39.179}$$

In Exc. 39.4.4.2 we derive the structure factor in spherical coordinates.

Some comments are needed:

1. The structure factor treatment assumes low optical density, which is not necessarily guaranteed when the laser is tuned close to a resonance [1219].

2. As the structure factor is independent of the laser detuning, it will not reveal any spectral structure, such as a band-gap or dip due to diffuse scattering. Also, absorption is not incorporated into the model.

39.4.1.3 The structure factor and the Bragg condition

The reciprocal space, obtained by Fourier transformation of the periodic density distribution, also adopts the shape of a periodic lattice. The Bragg condition requires that the difference between the incident and emitted wavevectors, $\Delta\mathbf{k} \equiv \mathbf{k}_s - \mathbf{k}_i$, matches a vector of the reciprocal lattice, $\mathbf{r}_j = j\mathbf{G}$. The Bragg condition is thus automatically incorporated into the structure factor (39.216).

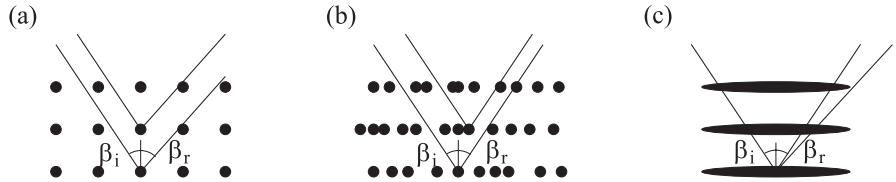

Figure 39.29: Several Bragg lattices.

With the lattice constant $d = \frac{1}{2}\lambda_{dip}$ the interference is constructive when the difference of the paths of two beams reflected by different layers is a multiple of the wavelength,

$$\tfrac{1}{2}\lambda_{dip}\cos\beta_i + \tfrac{1}{2}\lambda_{dip}\cos\beta_s = \lambda \ . \tag{39.180}$$

This is illustrated in Fig. 39.29(a). If the transverse distribution can be considered as homogeneous, as shown in Fig. 39.29(b), we have as second condition,

$$\beta_i = -\beta_s \ . \tag{39.181}$$

That is, the angles of incidence and reflection must be the same, as if we were dealing with a dielectric mirror. In contrast, if the transverse extent of the atomic layers gets smaller (until converging to the limit of a one-dimensional chain of point-scatterers, $\mathbf{G} \equiv 2k_{dip}\hat{\mathbf{e}}_z$), we return to the condition (39.180). In intermediate situations, illustrated in Fig. 39.29(c), and for $\lambda_{dip}\cos\beta_i \neq \lambda$ the reflection angle does not follow any of the relations (39.180) and (39.181).

39.4.1.4 Incoherent background

A finite size or defects in the periodic ordering of the atoms may lead to an isotropic background of Rayleigh-scattered light,

$$\frac{dP_s}{d\Omega_s} = |A_s|^2 \left[e^{-2W}|F|^2 + N_1 N(1 - e^{-2W})\right] \ . \tag{39.182}$$

The amount of photons scattered into the *same solid angle* as the one of Bragg scattering is typically for $1D$ lattices,

$$\frac{(1 - e^{-2W})N_1 N}{e^{-2W}|F|^2} = (e^{2W} - 1)\frac{N_1}{N} \approx 0.002 \ . \tag{39.183}$$

However, if we compare the total amount of coherently Bragg-scattered light, we obtain,

$$\frac{(1 - e^{-2W})N_1 N}{e^{-2W}|F|^2}\frac{4\pi}{d\Omega_s} \approx 2500 \ . \tag{39.184}$$

39.4.2 Transfer matrices calculation for $1D$-lattices

For one-dimensional optical lattices, that is, when the atoms are trapped in a potential dipole generated by a stationary light wave, we may consider applying the transfer matrix formalism developed in Secs. 18.1.7 and 24.3. The premisses of this model are the homogeneity and the infinite extent of the cloud in a direction transverse to the optical axis.

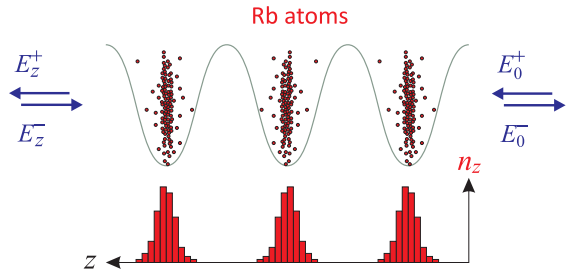

Figure 39.30: Scheme for transfer matrices calculations on $1D$-lattices.

With the notation introduced in Fig. 39.30 we find the equations relating the incident electric fields with the transmitted and reflected ones. If the T-matrix and the S-matrix are defined by [361],

$$\boxed{\begin{pmatrix} \mathcal{E}_z^+ \\ \mathcal{E}_0^- \end{pmatrix} = \mathcal{S}\begin{pmatrix} \mathcal{E}_0^+ \\ \mathcal{E}_z^- \end{pmatrix} \qquad \text{and} \qquad \begin{pmatrix} \mathcal{E}_z^+ \\ \mathcal{E}_z^- \end{pmatrix} = \mathcal{T}\begin{pmatrix} \mathcal{E}_0^+ \\ \mathcal{E}_0^- \end{pmatrix}}\ , \tag{39.185}$$

they are connected by,

$$\mathcal{S} = \begin{pmatrix} S_{11} & S_{12} \\ S_{21} & S_{22} \end{pmatrix} = \begin{pmatrix} T_{11} - \frac{T_{12}T_{21}}{T_{22}} & \frac{T_{12}}{T_{22}} \\ -\frac{T_{21}}{T_{22}} & \frac{1}{T_{22}} \end{pmatrix} \tag{39.186}$$

$$\text{and} \qquad \mathcal{T} = \begin{pmatrix} T_{11} & T_{12} \\ T_{21} & T_{22} \end{pmatrix} = \begin{pmatrix} S_{11} - \frac{S_{12}S_{21}}{S_{22}} & \frac{S_{12}}{S_{22}} \\ -\frac{S_{21}}{S_{22}} & \frac{1}{S_{22}} \end{pmatrix} .$$

From this follows,

$$\boxed{\mathcal{S} = \begin{pmatrix} t & r \\ r & t \end{pmatrix} \qquad \text{then} \qquad \mathcal{T} = \begin{pmatrix} t - \frac{r^2}{t} & \frac{r}{t} \\ -\frac{r}{t} & \frac{1}{t} \end{pmatrix}} , \tag{39.187}$$

satisfying by construction $\det \mathcal{S} = t^2 - r^2 \neq 1$ and $\det \mathcal{T} = 1$.

We calculate the reflection coefficient β of a classical polarizable sample from the microscopic polarizability (18.122) and the optical density (depth) of a thin layer, $n\delta z \sigma_0$, where σ_0 is the resonant optical cross section,

$$\beta = n\frac{k_{brg}\delta z}{2}\frac{\alpha_{pol}}{\varepsilon_0} = \frac{n\delta z}{2}\frac{6\pi}{k_{brg}^2}\frac{-1}{\imath + 2\Delta_{brg}/\Gamma} = \frac{n\delta z\sigma_0}{2}\frac{-1}{\imath + 2\Delta_{brg}/\Gamma} . \tag{39.188}$$

We remember that the polarizability is linked to the macroscopic susceptibility $\chi_e = n\alpha_{pol}/\varepsilon_0$ [18]. With

$$r = \frac{\imath\beta}{1 - \imath\beta} \qquad \text{and} \qquad t = \frac{1}{1 - \imath\beta} , \tag{39.189}$$

satisfying by construction $|t|^2 + |r|^2 = 1 = t - r$ and $rt^* + r^*t = 0$, we get

$$\boxed{\mathcal{S}_\beta = \frac{1}{1 - \imath\beta}\begin{pmatrix} 1 & \imath\beta \\ \imath\beta & 1 \end{pmatrix} \qquad \text{and} \qquad \mathcal{T}_\beta = \begin{pmatrix} 1 + \imath\beta & \imath\beta \\ -\imath\beta & 1 - \imath\beta \end{pmatrix}} . \tag{39.190}$$

We note that the employed model is classical, since we describe the gas by a sequence of layers, each characterized by a refractive index. Applying the transfer matrix model, we calculate how the incident and reflected light fields transform from one layer to another. The intrinsically 1D model allows to calculate the reflection, transmission, and absorption by the atomic lattice as a function of the incident laser frequency.

We still need to multiply with the transfer matrix describing the propagation of the incident beam through the layer,

$$\mathcal{T}_d = \begin{pmatrix} e^{\imath\mathbf{k}\cdot\mathbf{d}} & 0 \\ 0 & e^{-\imath\mathbf{k}\cdot\mathbf{d}} \end{pmatrix} , \tag{39.191}$$

[18] Note the analogy to the calculation (40.113) made for the reflection coefficient of an atom in a cavity in Sec. 40.2.2,

$$\beta = \frac{k}{\pi w^2}\frac{\alpha_{pol}}{\varepsilon_0} = \frac{6}{k^2w^2}\frac{-1}{2\Delta/\Gamma + \imath} = \frac{\sigma_0}{\pi w^2}\frac{-1}{2\Delta/\Gamma + \imath} .$$

such that the transfer matrix for passing the beam through an atomic layer is,

$$\mathcal{T} = \mathcal{T}_\beta \mathcal{T}_d \ . \tag{39.192}$$

For N_s layers we must obviously concatenate the matrices $\mathcal{M}^{N_s}$. The reflection coefficient is now simply,

$$r_{N_s} = \frac{(\mathcal{T}^{N_s})_{12}}{(\mathcal{T}^{N_s})_{22}} \ , \tag{39.193}$$

and can be evaluated numerically or analytically [361]. If the incident beam hits the cloud under an angle, $\mathbf{k}\cdot\mathbf{d} = kd\cos\theta = k_z d$, and furthermore, as shown in [363] Eq. (A10), the theory must be generalized by replacing,

$$\beta \to \frac{\beta}{2}(\cos^{-1}\theta + \cos\theta) \ . \tag{39.194}$$

However, for $\theta < 60^\circ$ the correction is small.

39.4.2.1 Limit of optically dilute clouds

For optically dilute clouds, $r \ll 1$, we expect standard Bragg scattering as described by equation (39.190),

$$\boxed{\mathcal{T} = \mathcal{T}_\beta \mathcal{T}_d \simeq \begin{pmatrix} e^{\imath k_z d} & \imath\beta e^{-\imath k_z d} \\ -\imath\beta e^{\imath k_z d} & e^{-\imath k_z d} \end{pmatrix}} \ , \tag{39.195}$$

with $\mathbf{k}\cdot\mathbf{d} = kd\cos\theta = k_z d$. Near the Bragg angle we have $\cos\theta \simeq \cos\theta_{brg} = \lambda_{sp}/\lambda_{dip}$ and near resonance we have $2\pi/k = \lambda \simeq \lambda_{sp}$, so that, with $d = \lambda_{dip}/2$, we obtain $k_z d \simeq \pi$ and,

$$\mathcal{T}^{N_s} \simeq \begin{pmatrix} e^{\imath\pi} & \imath\beta e^{-\imath\pi} \\ -\imath\beta e^{\imath\pi} & e^{-\imath\pi} \end{pmatrix}^{N_s} = \begin{pmatrix} -1 & -\imath\beta \\ \imath\beta & -1 \end{pmatrix}^{N_s} = (-1)^{N_s} \begin{pmatrix} 1 & N_s\imath\beta \\ -N_s\imath\beta & 1 \end{pmatrix} \ , \tag{39.196}$$

which we will verify in Exc. 39.4.4.3. The total reflectivity being $r_{N_s} \simeq N_s\imath\beta$, we get the reflection,

$$|r_{N_s}|^2 \simeq \frac{N_s^2\beta_{sp}^2\Gamma_{sp}^2}{4\Delta^2 + \Gamma_{sp}^2} \ . \tag{39.197}$$

Thus, the profile of the reflection curve is Lorentzian.

> **Example 235 (*Estimation of the reflectivity in the dilute cloud limit*):** In resonance we estimate for typical experimental values $N_s = 1000$, $n = 10^{17}\,\mathrm{cm}^3$, $\lambda_{dip} = 797\,\mathrm{nm}$, and $\Lambda_{brg} = 422\,\mathrm{nm}$,
>
> $$|r_{N_s}| = N_s\frac{nd\sigma_{sp}}{2} = N_s n\lambda_{dip}\frac{3\lambda_{sp}^2}{8\pi} \approx 1.7 \ .$$
>
> The high reflectivity is not physical, which shows that the assumption of optically diluted clouds is not necessarily satisfied in experimentally achievable parameter regimes. On the contrary we can expect to reach regimes, where the clouds are optically so dense, that photonic bands can be expected. That is, if the goal is to detect a band gap, it helps to have 1. many layers filled with atoms, 2. high atomic densities per layer.

39.4.2.2 Limit of optically dense clouds

In order to obtain analytical expressions in the regime of dense clouds, we write the transfer matrix for a single layer, using the expressions (39.190) and (39.191), as follows [363],

$$\boxed{\mathcal{T} = \mathcal{T}_\beta \mathcal{T}_d = \begin{pmatrix} (1+\imath\beta)e^{\imath \mathbf{k}\cdot\mathbf{d}} & \imath\beta e^{-\imath\mathbf{k}\cdot\mathbf{d}} \\ -\imath\beta e^{\imath\mathbf{k}\cdot\mathbf{d}} & (1-\imath\beta)e^{-\imath\mathbf{k}\cdot\mathbf{d}} \end{pmatrix}} \; . \tag{39.198}$$

Given that $\det \mathcal{T} = 1$, the matrix represents a unitary transformation and the eigenvalues can be cast into the form $e^{\pm\imath\phi}$. Letting,

$$\cos\Theta \equiv \tfrac{1}{2}\mathrm{Tr}\ \mathcal{T} = \cos k_z d - \beta \sin k_z d \; , \tag{39.199}$$

we can write the matrix,

$$\mathcal{T} = \mathbb{I}\cos\Theta + \imath A \sin\Theta = e^{\imath\Theta A} \tag{39.200}$$

with

$$A = \frac{1}{\sin\Theta}\begin{pmatrix} \beta\cos k_z d + \sin k_z d & \beta e^{-\imath k_z d} \\ -\beta e^{\imath k_z d} & -\beta\cos k_z d - \sin k_z d \end{pmatrix} \tag{39.201}$$

The eigenvectors of $\mathcal{T}$, and therefore of each power of $\mathcal{T}$, are *Bloch states of the periodic lattice*. We verify in Exc. 39.4.4.4, that the following relationships are satisfied,

$$\mathrm{Tr}\ A = 0 \quad , \quad A^2 = 1 \quad , \quad \det A = 1 \; . \tag{39.202}$$

The eigenvalues of $A\sin\Theta$ are $\lambda_A \pm 1$. The eigenvalues of the transfer matrix are,

$$\begin{aligned} \lambda &= \cos k_z d - \beta \sin k_z d \pm \imath\sqrt{1-(\cos k_z d - \beta\sin k_z d)^2} = \cos\Theta \pm \imath\sin\Theta \\ &= e^{\pm\imath \arccos(\cos k_z d - \beta \sin k_z d)} = e^{\pm\imath\theta} \; . \end{aligned} \tag{39.203}$$

This decomposition allows us to calculate the transfer matrix for a succession of μ layers. We get,

$$\begin{aligned} \mathcal{T}^\mu &= e^{\imath\mu\theta A} = \mathbb{I}\cos(\mu\theta) + \imath A \sin(\mu\theta) \\ &= \mathbb{I}\cos\left[\mu \arccos(\cos k_z d - \zeta \sin k_z d)\right] + iA\sin\left[\mu\arccos(\cos k_z d - \zeta\sin k_z d)\right] \; , \end{aligned} \tag{39.204}$$

which gives us the reflection coefficient,

$$\begin{aligned} r_\mu &= \frac{(\mathcal{T}^\mu)_{12}}{(\mathcal{T}^\mu)_{22}} = \frac{\imath\sin(\mu\theta)\mathcal{T}_{12}}{\cos(\mu\theta) + \imath\sin(\mu\theta)\mathcal{T}_{22}} \\ &= \frac{-\imath\beta e^{ik_z d}}{\sin\theta\cot(\mu\theta) - \imath\sin k_z d - \imath\beta\cos k_z d} \; . \end{aligned} \tag{39.205}$$

This is the final result. Near the Bragg angle, $\cos\theta \simeq 1$, we have,

$$\begin{aligned} r_{N_s} &= \frac{\imath\beta}{\sin\theta\cot(N_s\theta) - \imath\beta} \simeq \frac{\imath N_s\zeta}{1-\imath N_s\beta} \\ |r_{N_s}|^2 &\simeq \frac{N_s^2\beta_{sp}^2\Gamma_{sp}^2}{4\Delta^2 + (1+n\beta_{sp}^2)\Gamma_{sp}^2} \; . \end{aligned} \tag{39.206}$$

The intensity reflection profile, therefore, is a Lorentzian also in the limit of thick clouds. The additional condition for the occurrence of prohibited photonic bands is a large number of atomic layers, $N_s \gg 1$. We note that the model is an extension of the *Kronig-Penney model* introduced in Sec. 26.3.

39.4.2.3 Application of transfer matrices to real $1D$ optical lattices

The analytical treatment shown in the previous sections does not take account of possible lattice imperfections, since the atomic layers are assumed to be identical, infinitely thin, immobile and located at fixed periodic distances. Realistic optical lattices are different for several reasons:

1. Atomic clouds are not perfectly localized in ultra-thin layers, but distributed in a Gaussian way as a function of the cloud's temperature. The Debye-Waller factor (39.173) describes the impact of this distribution on the Bragg model.

2. The atoms are in thermal motion causing an inhomogeneous Doppler shift and are affected by the photonic recoil received in each scattering process. This causes a broadening of the reflection profiles and decreases the interference capability.

3. The number of atoms per layer may vary. Also, the global extent of the cloud is not infinite, that is, we have N_s layers filled with atoms with a gradual decrease at the confines of the cloud.

4. The atoms trapped in the optical potential are subjected to a dynamic Stark shift [19] causing an inhomogeneous broadening of the atomic transition as well.

5. The periodicity of the lattice is slightly modified because the refractive index experienced by the laser beams creating the dipole potential locally depends on the atomic density concentrated in the lattice's anti-nodes. The consequence is a local decrease of the lattice constant d [20].

All of the aforementioned imperfections may be included in a numerical treatment of the transfer matrices. For this we subdivide the atomic cloud into sufficiently thin sublayers, as shown in Fig. 39.30. Each sublayer, being characterized by its own 2D atomic density and its own shift from resonance, is described by an individual transfer matrix. The matrices are concatenated, and the reflection profile is computed, as shown in the expression (39.193) [1220]. Fig. 39.31 shows a numerical calculation of a photonic band in a rubidium optical lattice. The experimental variables are the incidence angle θ of the probe laser and its tuning Δ from a transition λ_{sp}. Δ determines σ and β via the polarizability (39.186) [21] and thus governs the propagation of light inside the layers. θ determines $k_z d$ and thus probes the periodicity *between* the layers.

Depending on the atomic density we can identify different behaviors [22]:

[19] Or 'light-shift', see Exc. 34.5.4.13.

[20] More correctly: If between λ_{dip} and λ_{D1} a photonic band were created for the laser beams that produce the optical lattice [363, 1360], these beams would be reflected without being able to penetrate the lattice. In fact, the periodicity changes in such a way, that the frequency of the beams is at the edge of the band gap. Deutsch *et al.* [363] showed that a self-consistent solution gives the modified lattice constant,

$$d' = \frac{\lambda_{dip}}{2}\left[1 + \frac{\phi_{dip}}{\pi}(1 - \mathrm{sign}\Delta_{dip})\right] ,$$

where $\phi_{dip} = \arctan\left(-\frac{\Delta_{dip}}{\Gamma} n d\, \sigma_{D1}(\Delta_{dip})\right)$.

[21] Δ also enters $k_z d$, but so weakly, that we can despise this dependence.

[22] The densities are assumed to be sufficiently low to eliminate collective effects such as, for example, superradiance.

1. At the limit of thin lattices, we do not expect multiple scattering. The absorptive (imaginary) part of polarizability dominates, $\beta \approx \mathfrak{Im}\ \beta$. Thus, the reflection coefficient is almost real, $re^{\imath\phi} \approx |r|$, the phase shifts are negligible, the profile of the reflection spectrum is symmetric. In this scheme, the interference of the radiation patterns of individual atoms is destructive in all directions, except under the Bragg angle. There are losses caused by scattering in non-paraxial modes. They are also due to elastic Rayleigh scattering but, because of the finite Debye-Waller factor, the radiation becomes diffuse and incoherent.

2. At the limit of thick lattices, we have multiple scattering. The (real) dispersive part of the polarizability is $\beta \approx \mathfrak{Re}\ \beta$. Thus, absorption is suppressed, we observe large phase shifts and the reflection spectrum profile is asymmetric. Multiple beam interference gives rise to global scattering.

Physically, the set parameters consistent of the quasi-momentum and the energy of the Bloch wave, (Θ, Δ), is more relevant because it allows analyzing the *dispersion relation* [23]. We observe the existence of energies Δ, where the real part of the quasi-momentum vanishes (modulo π). The 3D representation in Fig. 39.31(e) illustrates the occurrence of an *avoided crossing* due to the band gap at the edge of the Brillouin zone.

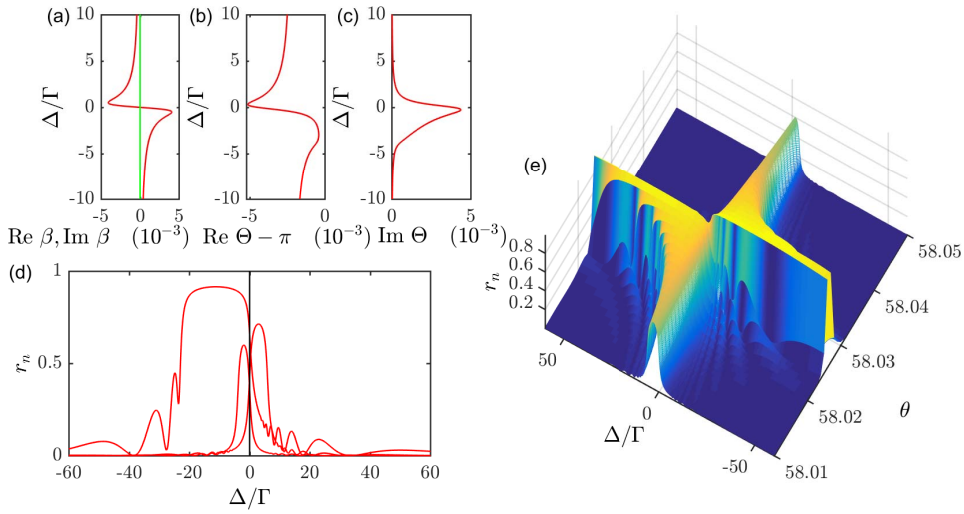

Figure 39.31: (code) Numerical calculation of a photonic band in a 1D optical lattice (wavelength $\Lambda_{dip} = 797$ nm) far-tuned from the rubidium D1 transition ($\lambda_{D1} = 795\,\text{nm}$). The probe laser exciting the Bragg resonance is tuned close to the rubidium resonance at $\lambda_{sp} = 422$ nm. We assume atomic densities of $n = 4 \cdot 10^{11}\,\text{cm}^{-3}$ and $N_s = 40000$ atomic layers. (a) Real and imaginary parts of the reflection index ($\propto$ polarizability) as a function of detuning Δ. (b,c) Real and imaginary parts of the quasi-momentum (x-axis) as a function of the detuning Δ. (d,e) 2D and 3D representation of the reflection coefficient.

[23] We note, that Θ via the relation (39.199) of the angle of incidence θ, but only weakly of the energy Δ.

In fact, Bragg resonances can be understood in reciprocal space as reflections at the edges of the Brillouin zone. Through the angle of incidence of the injected light beam, we adjust the quasi-momentum. The frequency of the light beam determines the energy. The forbidden photonic bands are caused by the formation of an energetic gap in the dispersion relation induced by the interaction of the atoms with the optical lattice.

39.4.2.4 Intensity distribution and LDOS within a lattice

The density matrix formalism outlined in Sec. 39.4.2 not only allows to calculate the overall reflectivity of the 1D optical lattice, but also the local intensity $I \propto |\mathcal{E}_a^+ + \mathcal{E}_a^-|^2$ at a point $z = a$ inside the lattice [1220].

To calculate this intensity we assume that the network is located between the points $z = 0$ and $z = b$ of the optical axis with $0 < a < b$. The transfer through the entire structure is given by,

$$\begin{pmatrix} \mathcal{E}_b^+ \\ \mathcal{E}_b^- \end{pmatrix} = \mathcal{T} \begin{pmatrix} \mathcal{E}_0^+ \\ \mathcal{E}_0^- \end{pmatrix} . \tag{39.207}$$

We use the boundary condition that, $\mathcal{E}_0^+$ being preset, there is no reflection of light behind the last layer, i.e., $\mathcal{E}_b^- = 0$. We obtain,

$$\mathcal{E}_0^- = -\frac{\mathcal{T}_{21}}{\mathcal{T}_{22}} \mathcal{E}_0^+ \qquad \text{and} \qquad \mathcal{E}_b^+ = \left(\mathcal{T}_{11} - \frac{\mathcal{T}_{12}\mathcal{T}_{21}}{\mathcal{T}_{22}} \right) \mathcal{E}_0^+ . \tag{39.208}$$

Now we separate the entire structure into two parts $\mathcal{T} = \mathcal{T}^{(b)}\mathcal{T}^{(a)}$, such that the field between the two parts is,

$$\begin{pmatrix} \mathcal{E}_1^+ \\ \mathcal{E}_1^- \end{pmatrix} = \mathcal{T}^{(a)} \begin{pmatrix} 1 \\ -\mathcal{T}_{21}/\mathcal{T}_{22} \end{pmatrix} \mathcal{E}_0^+ . \tag{39.209}$$

The sum gives,

$$\boxed{\mathcal{E}_1^+ + \mathcal{E}_1^- = \left(\mathcal{T}_{11}^{(a)} + \mathcal{T}_{21}^{(a)} - \frac{\mathcal{T}_{21}}{\mathcal{T}_{22}} (\mathcal{T}_{12}^{(a)} + \mathcal{T}_{22}^{(a)}) \right) \mathcal{E}_0^+} . \tag{39.210}$$

The *local density of states* (LDOS) in a photonic band can be evaluated from [1324, 507],

$$N(\omega) = 2\omega \sum_{\mathbf{k}} \delta(\omega^2 - \omega_{\mathbf{k}}^2) . \tag{39.211}$$

William found out:

$$k_{eff} = \frac{d\phi}{dz} , \tag{39.212}$$

with $\phi = \arctan(\mathfrak{Im}\ \mathcal{E}/\mathfrak{Re}\ \mathcal{E})$. The $\mathcal{E}$-field between two layers can be calculated using transfer matrices. The density of the states is given as the derivative of the inverse function of the dispersion relation:

$$N(\omega) = \frac{dk_{eff}(\omega)}{d\omega} . \tag{39.213}$$

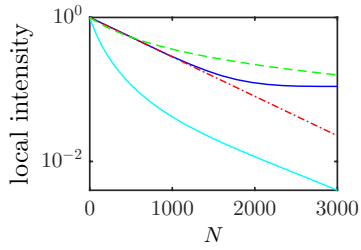

Figure 39.32: (code) The intensity decreases exponentially over a infinite lattice. For a finite lattice (here $N_s = 3000$), the intensity approaches a constant value at the end of the lattice. The graph shows in blue the intensity along the lattice, in red the exponential decay due to absorption in a homogeneous cloud (Lambert-Beer law), in green the hyperbolic decay following Ohm's law and in cyan the transmission assuming a lattice of N layers.

39.4.2.5 Suppression of spontaneous emission in forbidden photonic bands

The decrease in the LDOS is equivalent to the suppression of spontaneous emission [24], that is, an excited atom located inside the lattice will not be able to emit its photon. This is the condition for a forbidden photonic band to be *omnidimensional*. Omnidirectional bands need three-dimensional lattices. Nevertheless, the reduction of the spontaneous emission rate has already been observed in [596, 1387], which can be interpreted as $1D$ photonic crystals.

39.4.2.6 Impurities

The formula (39.210) allows the calculation of the impact of localized defects in numerical simulations. For example, it is instructive to look at the intensity profile along the structure in the presence of a localized lattice defect. In Fig. 39.33(c) we observe an intensity peak located at the 100-th atomic layer, exactly where the defect was introduced. This peak corresponds to a localized evanescent wave. Photons can not propagate freely through the lattice: they prefer to tunnel between lattice defects the rather than propagate by radiation.

The curves (a-b) of Fig. 39.33 illustrate how an empty photonic band fills up with localized states with well-defined energies when noise is added to the periodicity of the lattice. This situation is similar to that in semi-conductors doped by donor and acceptor states.

39.4.3 Photonic bands in the Bloch and the coupled dipoles models

The transfer matrix model is limited in several respects:

1. Firstly, being intrinsically 1D, the model does not apply to 2D or 3D lattices.

2. Also, it does not incorporate the possibility of transverse disorder or effects linked to the finite transverse extension of the atomic layers, for example, the

[24] For the same reason, resonant dipole-dipole interactions are suppressed [760].

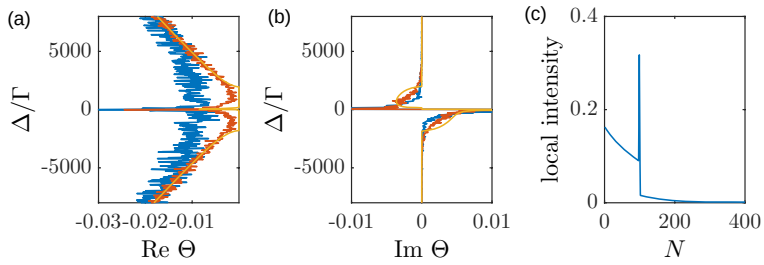

Figure 39.33: (code) (a,b) Dispersion relation as in Fig. 39.31, but in the presence of randomly distributed defects. (c) Intensity profile along the lattice with a defect located in the 100^{esima} atomic layer.

limitation of the number of layers participating in multiple reflection ('walk-off') [1221] or the impact of an imperfect mode matching [1219].

In contrast, the coupled dipoles model offers several advantages. An optical lattice is, after all, nothing more than a periodically ordered diluted sample of atoms. Hence, we can apply the coupled dipoles model introduced in Sec. 39.1.2 [1138, 1137]. The advantages of this model are its applicability to 3D systems and finite and disordered lattices. It also allows the inclusion of all kinds of inhomogeneities such as, for example, the spatial intensity distribution of a focused incident laser, or the deviation of the laser beam penetrating an atomic cloud due to refraction. On the other hand, the model only lends itself to heavy numerical simulations, limiting it to some 10000 atoms.

39.4.3.1 The Bloch model and forbidden electronic bands

The *Bloch model* is another model to describe 3D periodic systems [37]. It was introduced in Chp. 26 for 1D optical lattices. Its disadvantages are that it supposes infinite lattices and the absence of defects.

The Bloch model is commonly used to describe the scattering of electron waves in a solid, where the band gap originates from the Coulomb interaction of the electron with the atoms of the solid crystal. In contrast, in photonic crystals, the modes with high (low) frequency ω concentrate their energy in spatial regions with low (high) dielectric index ϵ. Close to geometric (Mie) resonances this causes a repulsion in the density distribution of photonic states, and the opening of a gap separating high frequency bands (air bands) from low frequency bands.

In optical lattices the photons interact with the atomic resonances. Photons and electrons are distinguished by their different dispersion relations and by the fact that electronic waves are scalar and photonic waves are vectorial. The electrons of a crystal are bound to an energy surface and follow the lines of the dispersion relation without leaving the metal. In contrast, photons are usually injected into the structure, which gives an additional degree of freedom. Therefore, any point in the phase diagram can be reached and the dispersion relation only informs, where at which point the transmission is stronger.

	photonic crystal	metal
lattice structure	atoms in a stationary wave	atoms in a crystal
particles	photons	electrons in a metal
equations of motion	Maxwell	Schrödinger
dispersion relation	$\hbar k/c$	$\hbar k^2/2m$
tune	Bragg angle and frequency	voltage
band gap origin	$\mathfrak{Im}\ \alpha$ absorption by atoms	e^- interacting with the atomic nuclei
band gap width	$< \omega_0 - \omega_{dip}$	interaction energy

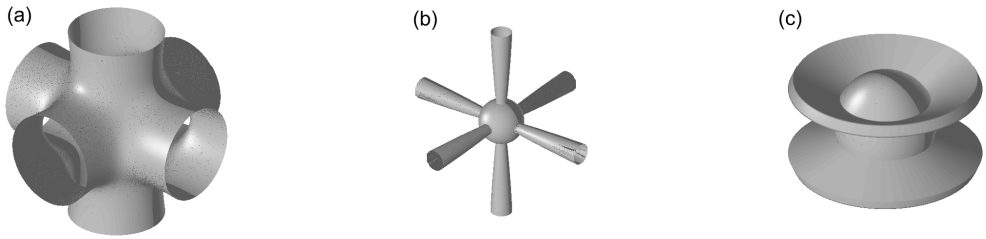

Figure 39.34: Attempt of an artistic illustration of the isoenergetic surfaces for electrons in a metal (left), photons in a 3D optical lattice (center), and photons in a 1D optical lattice (right). The interaction of atoms with the lattice is much weaker than the interaction of electrons with the metal, except close to resonances. Therefore, photonic bands are much narrower than electronic bands.

39.4.3.2 $3D$ photonic crystals

The reflection profile calculated in Fig. 39.31 resembles that of a dielectric mirror 18.6, for the calculation of which we also use the transfer matrix formalism. A dielectric coating consists of a periodic structure alternating high and low refractive index materials. Such structures are called *photonic crystals*.

The basic equation describing such material derives simply from Maxwell's equation, assuming macroscopic dielectric media, i.e., $\mathbf{D}(\mathbf{r}) = \varepsilon(\mathbf{r})\vec{\mathcal{E}}(\mathbf{r})$ with ε being real and scalar and $\mu \simeq 1$. After the expansion in $e^{\imath\omega t}$, we obtain a *master equation for dielectrics*,

$$\Theta\mathbf{H}(\mathbf{r}) \equiv \nabla \times \left(\frac{1}{\varepsilon(\mathbf{r})}\nabla \times \mathbf{H}(\mathbf{r})\right) = \frac{\omega^2}{c^2}\mathbf{H}(\mathbf{r}) \ , \tag{39.214}$$

with the condition of transversality $\nabla\mathbf{H}(\mathbf{r}) = 0 = \mathbf{D}(\mathbf{r})$ and $\vec{\mathcal{E}}(\mathbf{r}) = \left(\frac{-ic}{\omega\varepsilon(\mathbf{r})}\right)\nabla \times \mathbf{H}(\mathbf{r})$ [676]. The Θ operator is linear and Hermitian. We define the internal product analogously to quantum mechanics,

$$\langle \mathbf{F}|\mathbf{G}\rangle \equiv \int d\mathbf{r}\mathbf{F}(\mathbf{r})|\mathbf{G}(\mathbf{r}) \ . \tag{39.215}$$

The scalar product of modes with different frequencies vanishes, $\langle \mathbf{F}_{\omega_1}|\mathbf{G}_{\omega_2}\rangle = \delta_{\omega_1,\omega_2}$. The field can be found by minimizing the energy function $\frac{\langle \mathbf{H}|\Theta\mathbf{H}\rangle}{\langle \mathbf{H}|\mathbf{H}\rangle}$. We find that the displacement field $\langle \mathbf{D}\rangle$ is concentrated in regions, where $\epsilon(\mathbf{r})$ is large and is orthogonal to the lower frequency modes.

For periodic structures we can apply the reciprocal lattice theory in the same way as we do in solid-state physics or in optical lattices. But now, the state of Bloch is a vector: $\mathbf{H}_{\mathbf{k}}(\mathbf{r}) = e^{\imath \mathbf{k}\cdot\mathbf{r}} u_{\mathbf{k}}(\mathbf{r})$. Inserting in the master equation gives,

$$\Theta_{\mathbf{k}}\mathbf{u}_{\mathbf{k}}(\mathbf{r}) \equiv \left[(\imath\mathbf{k}+\nabla)\times\left(\frac{1}{\varepsilon(\mathbf{r})}(\imath\mathbf{k}+\nabla)\times\mathbf{u}_{\mathbf{k}}(\mathbf{r})\right)\right] = \frac{\omega(\mathbf{k})^2}{c^2}\mathbf{u}_{\mathbf{k}}(\mathbf{r}) \ , \tag{39.216}$$

together with $\mathbf{u}_{\mathbf{k}}(\mathbf{r}) = \mathbf{u}_{\mathbf{k}}(\mathbf{r}+\mathbf{r})$.

39.4.4 Exercises

39.4.4.1 Ex: Structure coefficient of a 1D lattice

Calculate the structure coefficient of the density distribution (39.178) and the square $|S_{\mathbf{k}_0}(\mathbf{k})|^2$.

Solution: *We calculate,*

$$\begin{aligned}
\mathcal{S}_{\mathbf{k}_0}(\mathbf{k}) &= \frac{1}{N}\int_{R^3} n_a(\mathbf{r}) e^{\imath(\mathbf{k}-\mathbf{k}_0)\cdot\mathbf{r}} d^3r \\
&= \frac{1}{N}\sum_{m=1}^{N_s} e^{\imath m d\mathbf{e}_z\cdot(k-\mathbf{k}_0)} \int_{R^3} n_l(\mathbf{r}) e^{\imath(\mathbf{k}-\mathbf{k}_0)\cdot\mathbf{r}} d^3r \\
&= \frac{1}{N} e^{\imath d\mathbf{e}_z\cdot(\mathbf{k}-\mathbf{k}_0)} \frac{1-e^{\imath N_s d\hat{\mathbf{e}}_z\cdot(\mathbf{k}-\mathbf{k}_0)}}{1-e^{\imath d\mathbf{e}_z\cdot(\mathbf{k}-\mathbf{k}_0)}} n_0 \int_{R^3} e^{(-x^2-y^2)/2\sigma_r^2} e^{-z^2/2\sigma_z^2} e^{\imath(\mathbf{k}-\mathbf{k}_0)\cdot\mathbf{r}} d^3r \\
&= \frac{n_0}{N}\frac{1-e^{\imath N_s dq_z}}{e^{-\imath dq_z}-1} \int_{-\infty}^{\infty} e^{-x^2/2\sigma_r^2} e^{\imath q_x x} dx \int_{-\infty}^{\infty} e^{-y^2/2\sigma_r^2} e^{\imath q_y y} dy \int_{-\infty}^{\infty} e^{-z^2/2\sigma_z^2} e^{\imath q_z z} dz \\
&= \frac{n_0}{N}\frac{1-e^{\imath N_s dq_z}}{e^{-\imath dq_z}-1} e^{-q_x^2\sigma_r^2/2} e^{-q_y^2\sigma_r^2/2} e^{-q_z^2\sigma_z^2/2} \ ,
\end{aligned}$$

and,

$$|\mathcal{S}_{\mathbf{k}_0}(\mathbf{k})|^2 = \frac{n_0^2}{N^2}\frac{1-\cos N_s(k_z-k_{0z})d}{1-\cos(k_z-k_{0z})d} e^{-(k_x-k_{0x})^2\sigma_r^2} e^{-(k_y-k_{0y})^2\sigma_r^2} e^{-(k_z-k_{0z})^2\sigma_z^2} \ .$$

39.4.4.2 Ex: Structure coefficient in spherical coordinates

Write the structure coefficient (39.178) in spherical coordinates.

Solution: *In spherical coordinates the structure coefficient can be written,*

$$\begin{aligned}
&\mathcal{S}_{k_0,\theta_0,0}(k_0,\theta,\phi)\\
&= \frac{1-e^{\imath N_s d(k_z-k_{0z})}}{1-e^{\imath d(k_z-k_{0z})}} e^{-(k_x-k_{0x})^2\sigma_r^2/2} e^{-(k_y-k_{0y})^2\sigma_r^2/2} e^{-(k_z-k_{0z})^2\sigma_z^2/2}\\
&= \frac{1-e^{\imath N_s d(k_0\cos\theta-k_0\cos\theta_0)}}{1-e^{\imath d(k_0\cos\theta-k_0\cos\theta_0)}} e^{-(k_0\cos\phi\sin\theta-k_0\cos\phi_0\sin\theta_0)^2\sigma_r^2/2}\times\\
&\quad\times e^{-(k_0\sin\phi\sin\theta-k_0\sin\phi_0\sin\theta_0)^2\sigma_r^2/2} e^{-(k_0\cos\theta-k_0\cos\theta_0)^2\sigma_z^2/2}\\
&= \frac{1-e^{\imath N_s dk_0(\cos\theta-\cos\theta_0)}}{1-e^{\imath dk_0(\cos\theta-\cos\theta_0)}} e^{-(\sin^2\theta-2\cos\phi\sin\theta\sin\theta_0+\sin^2\theta_0)k_0^2\sigma_r^2/2} e^{-(\cos\theta-\cos\theta_0)^2k_0^2\sigma_z^2/2} .
\end{aligned}$$

Assuming that we irradiate under the Bragg angle, $2dk_0\cos\theta_0 = 2\pi$, we obtain the solid angle into which light is scattered by,

$$\mathcal{S}_{k_0,\theta_{brg},0}(k_0,\theta,\phi) = \frac{1-e^{\imath N_s dk_0\cos\theta-\imath\pi N_s}}{1+e^{\imath dk_0\cos\theta}} \exp\left[-\left(\cos\theta-\frac{\pi}{dk_0}\right)^2\frac{k_0^2\sigma_z^2}{2}\right]\times$$
$$\times\exp\left[-\left(\sin^2\theta-2\cos\phi\sin\theta\sqrt{1-\left(\frac{\pi}{dk_0}\right)^2}+1-\left(\frac{\pi}{dk_0}\right)^2\right)\frac{k_0^2\sigma_r^2}{2}\right] .$$

39.4.4.3 Ex: Reflection in the dilute cloud limit

Verify the calculation (39.196).

Solution: *To calculate the total transfer matrix $\mathcal{T}^{N_s}$, we first diagonalize the matrix $\mathcal{T} = U\mathcal{D}U^{-1}$, where $\mathcal{D}$ is the matrix of eigenvalues and U a unitary transformation given by eigenvectors of $\mathcal{T}$. Under the Bragg angle this matrix adopts the form (39.190),*

$$\mathcal{T} = \begin{pmatrix} -1 & -\imath\beta \\ \imath\beta & -1 \end{pmatrix} .$$

We calculate,

$$U = \begin{pmatrix} -\imath & \imath \\ 1 & 1 \end{pmatrix} \qquad \textit{and} \qquad \mathcal{D} = \begin{pmatrix} -1+\beta & 0 \\ 0 & -1-\beta \end{pmatrix} .$$

We can now evaluate the transfer matrix for N_s layers,

$$\begin{aligned}
\mathcal{T}^{N_s} = U\mathcal{D}^{N_s}U^{-1} &\simeq (-1)^{N_s}\mathbf{U}\begin{pmatrix} 1-N_s\beta & 0 \\ 0 & 1+N_s\beta \end{pmatrix} U^{-1}\\
&= (-1)^{N_s}\begin{pmatrix} 1 & \imath N_s\beta \\ -\imath N_s\beta & 1 \end{pmatrix} .
\end{aligned}$$

For a finite Bragg angle we obtain,

$$\mathcal{T}^{N_s} = \begin{pmatrix} e^{\imath kd\cos\theta} & \imath\beta e^{-\imath kd\cos\theta} \\ -\imath\beta e^{\imath kd\cos\theta} & e^{-\imath kd\cos\theta} \end{pmatrix} ,$$

with the eigenvalues $\cos(kd\cos\theta) \pm \sqrt{\beta^2 - \sin^2(kd\cos\theta)}$.

39.4.4.4 Ex: Reflection in the dense cloud limit

Verify the representation (39.200).

Solution: *a. The expression (39.200) is composed of two parts. First, we compare the two sides of the equation,*

$$\begin{aligned}\mathcal{T} &= \begin{pmatrix} (1+\imath\beta)e^{\imath\mathbf{k}\cdot\mathbf{d}} & \imath\beta e^{-\imath\mathbf{k}\cdot\mathbf{d}} \\ -\imath\beta e^{\imath\mathbf{k}\cdot\mathbf{d}} & (1-\imath\beta)e^{-\imath\mathbf{k}\cdot\mathbf{d}} \end{pmatrix} \\ &= \begin{pmatrix} \cos k_z d - \beta\sin k_z d & 0 \\ 0 & \cos k_z d + \beta\sin k_z d \end{pmatrix} + \imath \begin{pmatrix} \beta\cos k_z d + \sin k_z d & \beta e^{-\imath k_z d} \\ -\beta e^{\imath k_z d} & -\beta\cos k_z d - \sin k_z d \end{pmatrix} \\ &= \mathbb{I}\cos\Theta + A\sin\Theta \ .\end{aligned}$$

Defining,

$$\begin{aligned}\cos\Theta &\equiv \cos k_z d - \beta\sin k_z d \\ \sin\Theta &= 1 - \cos\Theta = \sqrt{(\cos k_z d - \beta\sin k_z d)^2 - 1} \ ,\end{aligned}$$

it is easy to verify,

$$\begin{aligned} Tr\ A &= 0 \\ \det A &= -\frac{(1-\beta^2)\sin^2 k_z d + 2\beta\cos k_z d\sin k_z d}{\sin^2\Theta} = \frac{(\cos k_z d - \beta\sin k_z d)^2 - 1}{\sin^2\Theta} \equiv 1 \\ AA &= \frac{(1-\beta^2)\sin^2 k_z d + 2\beta\cos k_z d\sin k_z d}{\sin^2\Theta} \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} = \mathbb{I} \ .\end{aligned}$$

b. Since the A matrix is nilpotent, $AA = \mathbb{I}$*, we calculate,*

$$\begin{aligned}\sin(\Theta A) &= A\sin\Theta = \Theta A - \frac{(\Theta A)^3}{3!} + ... = \Theta A - \frac{\Theta^3 A}{3!} + ... = A\sin\Theta \\ \cos(\Theta A) &= A\cos\Theta = 1 - \frac{(\Theta A)^2}{2!} + ... = 1 - \frac{\Theta^2 I}{2!} + ... = \imath\cos\Theta \ .\end{aligned}$$

39.4.4.5 Ex: Photonic band spectra

Plot the 1D-photonic band gap spectrum in a standing wave as a function of Δ_{pr} and n.

39.4.4.10 Ex: Structure of a diamond lattice

A geometric configuration of point-like scatterers that can exhibit a broad omnidirectional photonic bandgap is the one of a diamond lattice [273, 1146, 37]. In this exercise we will study such a diamond-shaped lattice.
a. Produce a geometric representation of the primitive cell and a Wigner-Seitz cell.
b. Study the optical lattice generated by the following configuration of incident lasers,

$$\mathbf{k}_0 = \tfrac{\pi}{a}(0,-2,-1) \quad , \quad \mathbf{k}_1 = \tfrac{\pi}{a}(2,0,1) \quad , \quad \mathbf{k}_2 = \tfrac{\pi}{a}(0,2,-1) \quad , \quad \mathbf{k}_3 = \tfrac{\pi}{a}(-2,0,1)$$

with $k_{laser} = \omega_{laser}/c = \sqrt{5}\pi/a$.
c. Calculate the forbidden band according to [273, 1146, 37].

Solution: *a. This configuration is based on the superposition of two fcc lattices [37],*

$$\hat{\mathbf{a}}_{1,2,3} = \left(0, \tfrac{a}{2}, \tfrac{a}{2}\right), \left(\tfrac{a}{2}, 0, \tfrac{a}{2}\right), \left(\tfrac{a}{2}, \tfrac{a}{2}, 0\right) \quad \textit{and} \quad \hat{\mathbf{a}}_{4,5,6} = \hat{\mathbf{e}}_{1,2,3} + \left(\tfrac{a}{4}, \tfrac{a}{4}, \tfrac{a}{4}\right) \ . \tag{39.217}$$

The vectors of the reciprocal lattice are obtained via,

$$\begin{pmatrix} b_{1x} & b_{2x} & b_{3x} \\ b_{1y} & b_{2y} & b_{3y} \\ b_{1z} & b_{2z} & b_{3z} \end{pmatrix}^{\mathsf{T}} 2\pi = \begin{pmatrix} a_{1x} & a_{2x} & a_{3x} \\ a_{1y} & a_{2y} & a_{3y} \\ a_{1z} & a_{2z} & a_{3z} \end{pmatrix}^{-1} \quad , \tag{39.218}$$

yielding,

$$\hat{\mathbf{b}} = \left(-\tfrac{2\pi}{a}, \tfrac{2\pi}{a}, \tfrac{2\pi}{a}\right), \left(\tfrac{2\pi}{a}, -\tfrac{2\pi}{a}, \tfrac{2\pi}{a}\right), \left(\tfrac{2\pi}{a}, \tfrac{2\pi}{a}, -\tfrac{2\pi}{a}\right) \ . \tag{39.219}$$

The Wigner-Seitz cell of the reciprocal lattice, referred as the first Brillouin zone, is bordered by faces which can be given as,

$$|k_x|+|k_y|+|k_z| = \tfrac{3}{2}\frac{2\pi}{a} \quad , \quad |k_x| = \frac{2\pi}{a} \quad , \quad |k_y| = \frac{2\pi}{a} \quad , \quad |k_z| = \frac{2\pi}{a} \ . \tag{39.220}$$

b. The optical lattice obtained is illustrated in Fig. 39.40(c). For large forbidden bands we choose $k_0 a < 5$, i.e. $\omega_{laser} > 1.4\omega_0$. This gives the intensity distribution in the optical lattice,

$$I(\mathbf{r}) = I_0 + I_1 \left[-\cos\left(\sum_{\gamma=1}^{3} \hat{\mathbf{e}}_\gamma \cdot \mathbf{r} \right) + \sum_{\gamma=1}^{3} \cos(\hat{\mathbf{e}}_\gamma \cdot \mathbf{r}) \right] \ . \tag{39.221}$$

c.

Chapter 40

Coupling of atoms and optical cavities and the CQED regime

So far we have considered the coherent dynamics between atoms and radiation fields in free space, and we extended the theory to take into account the dissipative coupling to the electromagnetic vacuum by spontaneous emission and atomic motion. The vacuum represents a homogeneous and isotropic reservoir characterized by a continuous white energy spectrum. The situation changes completely when we place the atom inside an optical cavity which breaks the translational and rotational symmetries and imprints a resonance structure into the density of photonic states. Obviously, the cavity will profoundly change the atomic coupling to the electromagnetic vacuum, and hence the way in which the atom reacts to incident light, as much with respect to light scattering as with respect to optical forces.

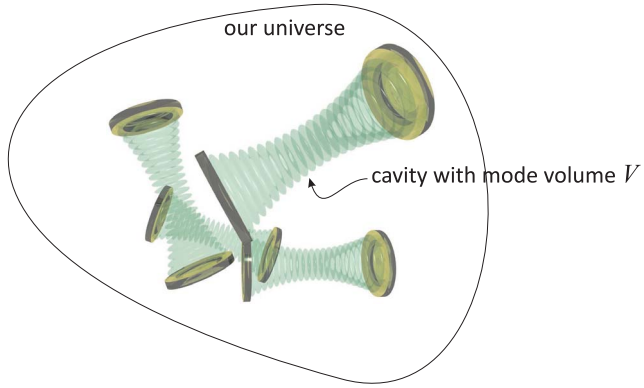

Figure 40.1: Illustration of the mode structure of empty space.

In this chapter we analyze the coupled dynamics of atoms interacting with the optical field modes of a cavity pumped by incident laser beams. We first concentrate in Sec. 40.1 on empty cavities. Then in Sec. 40.2 we turn our attention to the impact of atoms on the cavity dynamics, in particular its transmission spectrum. Cooperative and collective effects that may be induced by cavities will be discussed in Chps. 41

and 42.

40.1 Light fields in cavities without atoms

The quantization of the electromagnetic field has been introduced in Chp. 35. Nevertheless, we will consider the degree of freedom to be studied in this chapter, that is, the electric field amplitude of a light field developing in a mode of an optical cavity, as a classical entity. Therefore, there is no need to stress quantum mechanics to derive the fundamental equations of motion, and a classical derivation is shown in Sec. 40.2.5. Nevertheless, for reasons of consistency with later discussions, where quantization is required, we will reproduce here the standard procedure, which consists in constructing the Hamiltonian for the relevant degrees of freedom. The degree of freedom under study being a mode of a cavity, we will label it by the field operator $\hat{a}$ normalized to the electric field strength $\vec{\mathcal{E}}_1$ generated by a single photon, such that $|\langle\hat{a}\rangle|^2 = n$ represents the number of photons in the cavity.

In this first section of this chapter we will only consider a bare cavity not containing any matter which could interact with light. The mode of a linear cavity or the two counterpropagating modes of a ring cavity are pumped by incident laser light. We will first set up the equations of motion for the cavity fields and then discuss the main quantities characterizing a cavity, such as free spectral range, mode volume, decay rate, and single-photon field strength. Finally, we will calculate the density of states of cavities.

40.1.1 Master equation

The Hamiltonian of a laser-pumped linear cavity mode $\hat{a}$ coupled to the continuum of a heat bath represented by operators $\hat{a}_\omega$ is ($\hbar = 1$) (see Sec. 36.2.4 and Exc. 36.2.6.1),

$$\boxed{\begin{aligned}
\hat{H} &= \hat{H}_{cavity} + \hat{H}_{bath} + \hat{H}_{cavity:bath} + \hat{H}_{laser:cavity} \\
\hat{H}_{cavity} &= \omega_0 \hat{a}^\dagger \hat{a} \\
\hat{H}_{bath} &= \sum_\omega \omega \hat{a}^\dagger_\omega \hat{a}_\omega \\
\hat{H}_{cavity:bath} &= \sum_\omega g_{cavity:bath} \hat{a}^\dagger_\omega \hat{a} + h.c. \\
\hat{H}_{laser:cavity} &= \imath\eta \hat{a}^\dagger + h.c.
\end{aligned}} \quad , \tag{40.1}$$

with $[\hat{a}_\omega, \hat{a}^\dagger_{\omega'}] = \delta_{\omega,\omega'}$. The part of the Hamiltonian $\hat{H}_{laser:cavity}$ describes pumping of the cavity with an external light field matched to the cavity mode. The standard procedure consists in setting up the quantum Liouville equation for the total density operator $\hat{\rho}_{total} = \hat{\rho}_{cavity} \otimes \hat{\rho}_{bath}$ and tracing the over the bath's degrees of freedom [488, 283]. From this procedure, as shown in Sec. 36.2.4, we derive a master equation for the reduced density operator $\hat{\rho}_{cavity}$.

The inevitable coupling of the cavity to the environment, described by $\hat{H}_{cavity:bath}$, leads to irreversible losses. These losses can be described as spontaneous decay to the continuous vacuum heat bath. The irreversibility of the process is readily understood

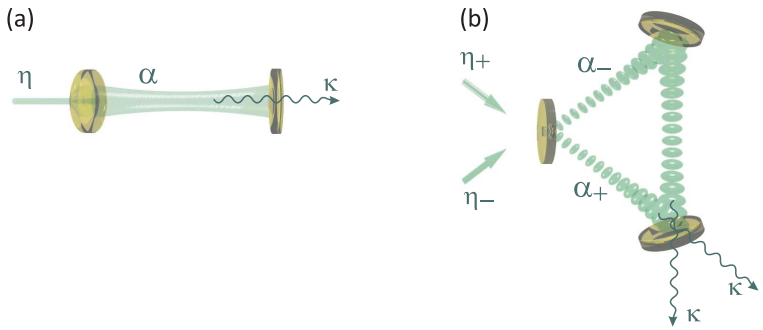

Figure 40.2: Scheme of (a) a linear cavity and (b) a ring cavity with optical modes $\alpha_\pm$ pumped by incident light fields $\eta_\pm$ and decaying into the void with rate κ.

in terms of the phase space offered by the vacuum being much larger. In fact, whenever discrete states are coupled to a continuum, the equilibrium is very much on the side of the continuum, that is, *discrete states decay*. Since an optical cavity can be considered a *temperature reservoir* T, where,

$$\bar{n} = \frac{1}{1 - e^{-\hbar\omega/k_B T)}} \ , \tag{40.2}$$

is the mean thermal photon number, the *Lindblad operator* is,

$$\begin{aligned} \mathcal{L}_{bath}\hat{\rho} = {} & \tfrac{\kappa}{2}(\bar{n}+1)(2\hat{a}\hat{\rho}\hat{a}^\dagger - \hat{a}^\dagger\hat{a}\hat{\rho} - \hat{\rho}\hat{a}^\dagger\hat{a}) + \tfrac{\kappa}{2}\bar{n}(2\hat{a}^\dagger\hat{\rho}\hat{a} - \hat{a}\hat{a}^\dagger\hat{\rho} - \hat{\rho}\hat{a}\hat{a}^\dagger) \\ & + \beta(2\bar{n}+1)(2\hat{a}^\dagger\hat{a}\hat{\rho}\hat{a}^\dagger\hat{a} - (\hat{a}^\dagger\hat{a})^2\hat{\rho} - \hat{\rho}(\hat{a}^\dagger\hat{a})^2) \ . \end{aligned} \tag{40.3}$$

We have already shown this in Exc. 36.2.6.1. The constants are the *cavity decay rate* κ and the pump rate β. Note that at room temperature in the microwave regime, $\bar{n}$ may be as large as a few hundred photons, whereas in the optical regime we may neglect the thermal excitation,

$$\boxed{\begin{aligned} \dot{\hat{\rho}} &= -\tfrac{\imath}{\hbar}[\hat{H},\hat{\rho}] + \mathcal{L}_{cav} \\ \mathcal{L}_{cav}\hat{\rho}(t) &= -\kappa\{\hat{a}^\dagger\hat{a}\hat{\rho}(t) - 2\hat{a}\rho(t)\hat{a}^\dagger + \hat{\rho}(t)\hat{a}^\dagger\hat{a}\} \end{aligned}} \ . \tag{40.4}$$

The expectation values are given by a *quantum Langevin equation* [283],

$$\boxed{\dot{\alpha} = \langle\dot{\hat{a}}\rangle = \frac{\imath}{\hbar}\langle[\hat{H},\hat{a}]\rangle - \kappa\langle\hat{a}\rangle = (-\kappa - \imath\Delta_c)\alpha + \eta} \ , \tag{40.5}$$

whose solution is easy to derive,

$$\boxed{\alpha(t) = \left(\alpha(0) - \frac{\eta}{\kappa + \imath\Delta_c}\right) e^{(-\kappa-\imath\Delta_c)t} + \frac{\eta}{\kappa + \imath\Delta_c}} \ , \tag{40.6}$$

or, using the electric field normalized to the amplitude of the field generated by a

single photon, $\vec{\mathcal{E}}^+_{cav} = \vec{\mathcal{E}}_1 \alpha$,

$$\begin{aligned}\vec{\mathcal{E}}_{cav}(z,t) &= \mathfrak{Re}\left[\vec{\mathcal{E}}_1 e^{\imath(kz-\omega t)}\alpha(t) + \vec{\mathcal{E}}_1 e^{\imath(-kz-\omega t)}\alpha(t)\right] \\ &= 2\vec{\mathcal{E}}_1 \cos kz \ \mathrm{Re}\left[e^{-\imath\omega t}\alpha(t)\right] \\ &= 2\vec{\mathcal{E}}_1 \cos kz \ \mathrm{Re}\left[\left(\alpha(0) - \frac{\eta}{\kappa + \imath\Delta_c}\right) e^{(-\kappa - \imath\omega_c)t} + \frac{\eta}{\kappa+\imath\Delta_c} e^{-\imath\omega t}\right] .\end{aligned} \tag{40.7}$$

The stationary solution is simply a Lorentzian,

$$|\alpha(\infty)|^2 = \frac{|\eta|^2}{\kappa^2 + \Delta_c^2} , \tag{40.8}$$

which represents an approximation of the Airy function(18.263).

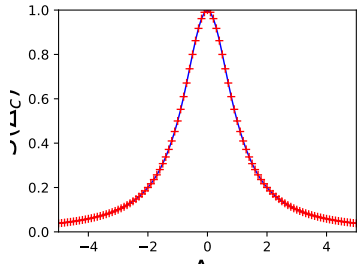

Figure 40.3: (code) Transmission spectrum of a cavity via numerical solution of the master equation (40.6) (solid line) and via the stationary solution (40.8) (crosses).

The result (40.7) shows that, letting $\eta = 0$, we see that the cavity field decays with the time constant κ from the stationary situation. κ also corresponds to the HWHM of the *field intensity*, $|\alpha(|\Delta_c| = \kappa)|^2 = \frac{1}{2}|\alpha(0)|^2$. Note, that the intensity decays as 2κ, and the HWHM of the *field amplitude* is $\left|\alpha(|\Delta_c| = \sqrt{3}\kappa)\right| = \frac{1}{2}|\alpha(0)|$.

> **Example 236 (*Evolution of the modes of a linear cavity*):** (40.7) also shows that a cavity initially filled with a strong resonant light field $|\alpha(0)| \gg \eta/\kappa$ begins to oscillate at its own frequency ω_c, before the pump dominates and imposes its own frequency ω. This is illustrated in Fig. 40.4. .

Frequently, we are interested in the light reflected from a cavity. The reflective response of the cavity to an incident pump beam E_{in} is,

$$\vec{\mathcal{E}}^+_{refl} = r_{in}\vec{\mathcal{E}}^+_{in} + t_{in}\vec{\mathcal{E}}^+_{cav} . \tag{40.9}$$

Also we may want to consider a temporal variation of the input field, for example of its detuning, $\Delta_c(t)$. In such cases, the equation (40.5) can not be integrated easily, and we need to resort to numerical methods. The simplest (and least convergent) method in a Newtonian iteration like,

$$\vec{\mathcal{E}}^+_{refl}(t+dt) = \vec{\mathcal{E}}^+_{refl}(t) + dt\ t_{in}\left[(-\kappa - \imath\Delta_c(t))\vec{\mathcal{E}}^+_{cav}(t) + \eta\vec{\mathcal{E}}^+_{in}(t)\right] . \tag{40.10}$$

We will study in Exc. 40.1.6.1 how a sudden change of the pump laser detuning may lead to *ringing* with a fixed frequency Δ_c. In Exc. 40.1.6.2 we will show, how it is possible to empty an optical cavity in times shorter than $1/\kappa$.

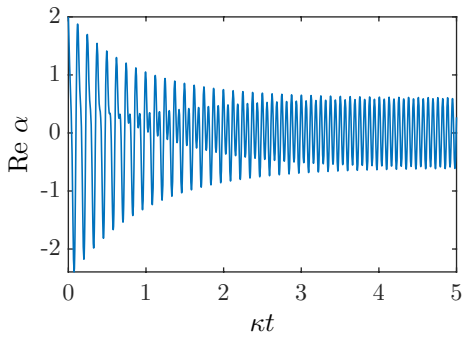

Figure 40.4: (code) Transient oscillations in a cavity pumped out of resonance.

40.1.2 Dynamics of an empty ring cavity

Linear cavities are characterized by the fact that they sustain standing light waves. That is, at every point of the mode volume, there are field components pointing into two counterpropagating orientations. In case of a ring cavity, we have two counterpropagating modes $\alpha_\pm$, which may be independently pumped by laser beams $\eta\pm$. Hence, the quantum Langevin equation (40.5) must be generalized to,

$$\boxed{\dot{\alpha}_\pm(t) = (-\kappa - \imath\Delta_c)\alpha_\pm + \eta_\pm} \,, \tag{40.11}$$

and the general solution (40.6) to,

$$\boxed{\alpha_\pm(t) = \left(\alpha_\pm(0) - \frac{\eta_\pm}{\kappa + \imath\Delta_c}\right) e^{(-\kappa-\imath\Delta_c)t} + \frac{\eta_\pm}{\kappa + \imath\Delta_c}} \,. \tag{40.12}$$

The two counterpropagating field modes will, provided they have the same polarization, interfere and form a standing light wave. In contrast to linear cavities, the phase of this standing wave is represents a degree of freedom, as it depends on the phases of the two field modes $\alpha_\pm$, which in turn can be controlled by the incident laser fields $\eta_\pm$. To better understand the behavior of the phase as a function of the pump beams, we analyze the interference of the two modes, which is described by,

$$\begin{aligned}\alpha_+\alpha_-^* = &\left(\alpha_+(0)\alpha_-^*(0) - \frac{\eta_-^*\alpha_+(0)}{\kappa - \imath\Delta_c} - \frac{\eta_+\alpha_-^*(0)}{\kappa + \imath\Delta_c} + \frac{\eta_+\eta_-^*}{\kappa^2 + \Delta_c^2}\right) e^{-2\kappa t} + \frac{\eta_+\eta_-^*}{\kappa^2 + \Delta_c^2} + \\ &+ \left(\alpha_+(0)\frac{\eta_-^*}{\kappa - \imath\Delta_c} - \frac{\eta_+\eta_-^*}{\kappa^2 + \Delta_c^2}\right) e^{(-\kappa-\imath\Delta_c)t} + \left(\alpha_-^*(0)\frac{\eta_+}{\kappa + \imath\Delta_c} - \frac{\eta_+\eta_-^*}{\kappa^2 + \Delta_c^2}\right) e^{(-\kappa+\imath\Delta_c)t} \,.\end{aligned} \tag{40.13}$$

To simplify this expression, we assume a symmetric pump, $\eta_\pm = \eta e^{\pm\imath\phi}$. We are interested in the reaction of the field's phase to a sudden change of ϕ. Now, we define the initial stationary conditions for $\phi = 0$ to be $\alpha_\pm(0) = \frac{\eta}{\kappa+\imath\Delta_c}$ and obtain,

$$\boxed{\alpha_+\alpha_-^* = \frac{\eta^2}{\kappa^2 + \Delta_c^2}\left[(1 - e^{\imath\phi})^2 e^{-2\kappa t} + e^{2\imath\phi} + 2e^{\imath\phi}(1 - e^{\imath\phi})e^{-\kappa t}\cos\Delta_c t\right]} \,. \tag{40.14}$$

In resonance, $\Delta_c = 0$, the expression (40.14) simplifies to,

$$\alpha_+\alpha_-^* = \frac{\eta^2}{\kappa^2}\left[(1 - e^{-\kappa t})e^{\imath\phi} + e^{-\kappa t}\right]^2 \,. \tag{40.15}$$

This results shows that the cavity phase adjusts itself to the pump field in exponential time κ^{-1}:

$$\tan\theta = \frac{\mathfrak{Im}\ \alpha_+\alpha_-^*}{\mathfrak{Re}\ \alpha_+\alpha_-^*} = \frac{(1-e^{-\kappa t})^2\sin 2\phi + 2(1-e^{-\kappa t})e^{-\kappa t}\sin\phi}{(1-e^{-\kappa t})^2\cos 2\phi + 2(1-e^{-\kappa t})e^{-\kappa t}\cos\phi + e^{-2\kappa t}} \ . \quad (40.16)$$

For small phase slips $\phi \ll \pi$, this reduces to,

$$\theta = 2\phi(1-e^{-\kappa t}) \quad , \quad \dot\theta \simeq \kappa(2\phi-\theta) \quad , \quad \ddot\theta \simeq -\kappa\dot\theta \ . \quad (40.17)$$

Hence, the pump represents a friction force for the phase.

Out of resonance but with negligible decay, $\kappa \simeq 0$, the expression (40.14) simplifies to,

$$\alpha_+\alpha_-^* = \frac{\eta^2}{\Delta_c^2}\left[1 + 2(e^{2\imath\phi} - e^{\imath\phi})(1-\cos\Delta_c t)\right] + \ , \quad (40.18)$$

such that,

$$\tan\theta = \frac{2(\sin 2\phi - \sin\phi)(1-\cos\Delta_c t)}{1 + 2(\cos 2\phi - \cos\phi)(1-\cos\Delta_c t)} \ , \quad (40.19)$$

which, for very small angles ϕ, reduces to,

$$\theta \simeq 4\phi\sin^2\frac{1}{2}\Delta_c t \ . \quad (40.20)$$

40.1.2.1 Transfer function of a ring cavity

Cavities have a finite response time to frequency or amplitude fluctuations of the pump light. To study this, we assume the light pumping a ring cavity to be subject to a phase modulation with frequency Ω and amplitude ϕ_0, that is, the quantum Langevin equation (40.5) is,

$$\boxed{(\partial_t + \kappa + \imath\Delta_c)\alpha_\pm = \eta e^{\pm\imath\phi_0\sin\Omega t}} \ , \quad (40.21)$$

and has the solution,

$$\alpha_\pm(t) = e^{(-\kappa-\imath\Delta_c)t}\left(\alpha_\pm(0) + \eta\int_0^T e^{(\kappa+\imath\Delta_c)\tau\pm\imath\phi_0\sin\Omega\tau}d\tau\right) \ . \quad (40.22)$$

For small amplitude oscillations, we can expand the pump term into a Fourier series of Bessel functions,

$$\begin{aligned}
\alpha_\pm(t) &= e^{(-\kappa-\imath\Delta_c)t}\left(\alpha_\pm(0) + \eta\int_0^T\left(e^{(\kappa+\imath\Delta_c)\tau} \pm \tfrac{\phi_0}{2}e^{(\kappa+\imath\Delta_c)\tau+\imath\Omega\tau} \mp \tfrac{\phi_0}{2}e^{(\kappa+\imath\Delta_c)\tau-\imath\Omega\tau}\right)d\tau\right) \\
&= e^{(-\kappa-\imath\Delta_c)t}\alpha_\pm(0) + \eta\frac{1-e^{(-\kappa-\imath\Delta_c)t}}{\kappa+\imath\Delta_c} \pm \tfrac{\phi_0}{2}\frac{e^{\imath\Omega t}-e^{(-\kappa-\imath\Delta_c)t}}{\kappa+\imath\Delta_c+\imath\Omega} \mp \tfrac{\phi_0}{2}\frac{e^{-\imath\Omega t}-e^{(-\kappa-\imath\Delta_c)t}}{\kappa+\imath\Delta_c-\imath\Omega} \\
&= \frac{\eta}{\kappa+\imath\Delta_c} \pm \tfrac{\phi_0\eta}{2}\frac{e^{\imath\Omega t}-e^{(-\kappa-\imath\Delta_c)t}}{\kappa+\imath\Delta_c+\imath\Omega} \mp \tfrac{\phi_0\eta}{2}\frac{e^{-\imath\Omega t}-e^{(-\kappa-\imath\Delta_c)t}}{\kappa+\imath\Delta_c-\imath\Omega} \\
&= \frac{\eta}{\kappa} \pm \imath\phi_0\eta\frac{\kappa\sin\Omega t - \Omega\cos\Omega t + \Omega e^{-\kappa t}}{\kappa^2+\Omega^2} \ .
\end{aligned} \quad (40.23)$$

In the last two steps, we defined for simplicity, $\alpha_\pm(0) = \frac{\eta}{\kappa + \imath\Delta_c}$ and set $\Delta_c = 0$. After some initial transients, when $t \gg \kappa^{-1}$, we can write,

$$\alpha_\pm \alpha_\pm^* = \frac{\eta^2}{\kappa^2} + \phi_0^2 \eta^2 \left(\frac{\kappa \sin \Omega t - \Omega \cos \Omega t}{\kappa^2 + \Omega^2} \right)^2 \tag{40.24}$$
$$\alpha_\pm \alpha_\mp^* = \left(\frac{\eta}{\kappa} \pm \imath \phi_0 \eta \frac{\kappa \sin \Omega t - \Omega \cos \Omega t}{\kappa^2 + \Omega^2} \right)^2 ,$$

giving in analogy to (40.16),

$$\theta = \arctan \frac{2\phi_0(\kappa^2 + \Omega^2)\left(\kappa^2 \sin \Omega t - \kappa\Omega \cos \Omega t\right)}{\left(\kappa^2 + \Omega^2\right)^2 - \phi_0^2 \left(\kappa^2 \sin \Omega t - \kappa\Omega \cos \Omega t\right)^2} \simeq 2\phi_0 \frac{\kappa^2 \sin \Omega t - \kappa\Omega \cos \Omega t}{\kappa^2 + \Omega^2} .$$

At low frequencies, $\Omega \ll \kappa$, the phase of the cavity field goes as, $\theta(\phi_0) \simeq 2\phi_0 \sin \Omega t$, and for high frequencies, $\Omega \gg \kappa$, as, $\theta(\phi_0) \simeq -2\phi_0 \frac{\kappa}{\Omega} \cos \Omega t$. Thus, we observe a low-pass behavior of the phase excursions of the cavity field with a cut-off frequency, κ^{-1}:

$$\boxed{\theta_m \simeq \frac{2\phi_0}{1 + \Omega/\kappa}} . \tag{40.25}$$

40.1.3 Characterization of the bare cavity

We first consider a linear cavity of length L pumped by a laser without any scatterer located inside the cavity. The cavity spectrum is an equidistant comb of eigenfrequencies separated by,

$$\delta_{fsr} \equiv \tau_{rt}^{-1} = \frac{c}{2L} . \tag{40.26}$$

The *free spectral range* δ_{fsr} is given in units of a real frequency. τ_{rt}^{-1} is the time for a photon to make a round trip in the cavity. The amplitude *decay rate of the cavity*,

$$\boxed{\kappa = \tau_\kappa^{-1} = \frac{\pi \delta_{fsr}}{F}} . \tag{40.27}$$

The intensity decay rate of the cavity, measured by 'cavity ring-down' is $\kappa_{int} = 2\kappa$. Note, that κ_{int} is also the FWHM width of the intensity transmission spectrum (see Exc. 18.3.7.18), such that the finesse

$$F = \frac{\delta_{fsr}}{\kappa_{int}/2\pi} \tag{40.28}$$

is simply the ratio between the free spectral range and the FWHM of the cavity intensity transmission curve, both measured in Hertz.

Example 237 (*Finesse of a cavity*): For example, for a cavity of length $L = 10$ cm an intensity decay time of $\tau_{int} = 20$ μs is measured, and we want to evaluate the finesse. We begin calculating the free spectral range $\delta_{fsr} = c/2L \approx 1.5$ GHz. Since the cavity field decays like $E(t) = E_0 e^{-\kappa t}$ and the intensity like $I(t) = E_0^2 e^{-2\kappa t}$, we get $\kappa = 1/\tau_\kappa = 1/2\tau_{int} \approx (2\pi)$ 4 kHz. Finally, the finesse is $F = \pi\delta_{fsr}/\kappa \approx 189000$.

For a cavity with a given geometry filled with a Gaussian mode of light with power P, the intensity is determined by Gaussian optics [1],

$$I(\mathbf{r}) = \frac{2P}{\pi w^2(z)} e^{-2\rho^2/w^2(z)} \qquad \text{and} \qquad w(z) = w_0\sqrt{1+\left(\frac{\lambda z}{\pi w_0^2}\right)^2} \ . \tag{40.29}$$

Defining the *mode volume* via $I(0)V_m \equiv \int I(\mathbf{r})dV$ and evaluating the spatial integral over the Gaussian mode along the cavity, we obtain,

$$\boxed{V_m = \frac{1}{I(0)}\int_0^L\int_0^\infty\int_0^{2\pi} \frac{2P}{\pi w^2(z)} e^{-2\rho^2/w^2(z)} d\phi\rho d\rho dz = \tfrac{\pi}{2} L w_0^2} \ . \tag{40.30}$$

Defining the amplitude of the electric field generated by a *single photon* via,

$$I(\mathbf{r}) = n\varepsilon_0 c\mathcal{E}_1^2(\mathbf{r}) \ , \tag{40.31}$$

where n is the number of photons in the cavity, we calculate for the energy stored in the cavity,

$$\frac{\hbar\omega}{2} = \int u_1(\mathbf{r})dV = \frac{1}{c}\int I_1(\mathbf{r})dV = \frac{1}{c} I_1(0)V_m \ . \tag{40.32}$$

Hence,

$$\boxed{|\vec{\mathcal{E}}_1(0)| = \sqrt{\frac{I_1(0)}{\varepsilon_0 c}} = \sqrt{\frac{\hbar\omega}{2\varepsilon_0 V_m}}} \ . \tag{40.33}$$

Resolve Exc. 18.4.4.2.The light power in the linear cavity can now be expressed using its free spectral range (40.26),

$$P = \frac{\pi w_0^2}{2} I(0) = \frac{2V_m}{L} n\varepsilon_0 c|\vec{\mathcal{E}}_1^2(0)| = 2V_m\delta_{fsr} n\varepsilon_0 \frac{\hbar\omega}{2\varepsilon_0 V_m} = \delta_{fsr} n\hbar\omega \ . \tag{40.34}$$

We assume that the cavity is pumped by a laser beam. To estimate the pump rate, we assume that the power P_{input} be measured in transmission. The coefficient η for resonant pumping is related to the number n of photons inside the cavity,

$$n = |\alpha|^2 = \frac{\eta^2}{\kappa^2} \ . \tag{40.35}$$

The intracavity field is resonantly amplified by the finesse,

$$\boxed{\alpha = \sqrt{\frac{F}{\pi}}\alpha_{input} = \sqrt{\frac{\delta_{fsr}}{\kappa}}\alpha_{input}} \ . \tag{40.36}$$

This gives,

$$\eta = \kappa\alpha = \kappa\sqrt{\frac{I}{c\hbar\omega}V_m} = \sqrt{\kappa\delta_{fsr}}\alpha_{input} = \sqrt{\kappa\delta_{fsr}}\sqrt{\frac{I_{input}}{c\hbar\omega}V_m} \ . \tag{40.37}$$

In practice, the pump rate will depend on the quality of the phase matching of the Gaussian beams and the impedance matching (in case of partially absorbing mirrors).

We will pursue the characterization of ring cavities including their interaction with scattering atoms in Sec. 40.2.2.

[1] See script on *Electrodynamics* (2023), Sec. 7.4.1 and Exc. 7.4.3.1.

40.1.3.1 The Schawlow-Townes limit

The *Schawlow-Townes limit* results from phase fluctuation of the standing light wave in the cavity demand $\Delta\phi = \frac{1}{n}$. Using the relationships (40.34) and (40.36), we find [1385],

$$\Delta\omega_{laser} = \frac{\kappa}{|\alpha|^2} = \kappa\frac{\delta_{fsr}\hbar\omega_{laser}}{P_{cav}} = \kappa\frac{\delta_{fsr}\hbar\omega_{laser}}{\frac{\delta_{fsr}}{\kappa}P_{out}} = \kappa^2\frac{\hbar\omega_{laser}}{P_{out}} \ . \tag{40.38}$$

Example 238 (*Schawlow-Townes limit of a HeNe laser*): For a typical HeNe laser, $F = 100$, $P_{out} = 1\,\mathrm{mW}$, $L = 20\,\mathrm{cm}$, we estimate,

$$\Delta\omega_{laser} = \left(\frac{\pi\delta_{fsr}}{F}\right)^2\frac{h\nu_{laser}}{P_{out}} = \left(\frac{\pi c}{2LF}\right)^2\frac{h\nu_{laser}}{P_{out}} \approx (2\pi)30\,\mathrm{mHz} \ .$$

40.1.4 Density of states in cavities

The density of states $\rho(\omega, \mathbf{k})$ of an optical cavity is defined by,

$$\int_{\mathcal{R}} \rho(\omega, \mathbf{k}) d\omega d\Omega = \frac{1}{(2\pi)^3}\int d^3\mathbf{x} d^3\mathbf{k} \ , \tag{40.39}$$

where $\mathcal{R}$ denotes the boundary imposed by the cavity. For free space photons we calculate (see Eq. (34.22)),

$$4\pi\int \rho_{free}(\omega, \mathbf{k}) d\omega = \frac{V}{(2\pi)^3}\int k^2 \sin\theta d\theta d\phi dk = \frac{Vk^3}{6\pi^2} = \frac{V\omega^3}{6\pi^2c^3} \ , \tag{40.40}$$

such that,

$$\rho_{free}(\omega, \mathbf{k}) = \rho_{free}(\omega) = \frac{V\omega^2}{(2\pi c)^3} \ , \tag{40.41}$$

is isotropic.

For light in a cavity, the density of states is modified with respect to free space, because it becomes frequency-dependent and anisotropic. The frequency dependence is expressed by the Airy formula,

$$\mathcal{L}(\omega) \equiv \frac{I_{cav}}{I_{in}} = \frac{\sqrt{1 + (2F/\pi)^2}}{1 + (2F/\pi)^2 \sin^2 kL} \ , \tag{40.42}$$

which will be derived in Excs. 40.1.6.3 and 40.1.6.4, and the anisotropy by,

$$\mathcal{R}(\hat{\mathbf{e}}_k) = 1 \qquad \forall \qquad \hat{\mathbf{e}}_k \in \Omega_{cav} \ , \tag{40.43}$$

where Ω_{cav} is the solid angle covered by the cavity mode. The formula,

$$\boxed{\rho_{cav}(\omega, \mathbf{k}) = \rho_{free}(\omega)[1 - \mathcal{R}(\hat{\mathbf{e}}_k)] + \rho_{free}(\omega)\mathcal{L}(\omega)\mathcal{R}(\hat{\mathbf{e}}_k)} \tag{40.44}$$

expresses that the density of states is nothing more than the *structure factor* of the cavity.

40.1.4.1 Confocal cavities

For a confocal cavity the solid angle is easy to calculate [596, 597]. Denoting by b is the clear aperture of the cavity mirrors, we get,

$$\Omega_{cav,con} = 2\int_0^{2\pi}\int_0^{\arcsin(2b/L)} \sin\theta d\theta d\phi = 4\pi\left(1-\sqrt{1-4\frac{b^2}{L^2}}\right) . \tag{40.45}$$

Expanding the root for small $b \ll L$, we get,

$$\boxed{\Omega_{cav,con} \simeq \frac{8\pi b^2}{L^2}} . \tag{40.46}$$

For non-degenerate geometries the functions $\mathcal{L}$ and $\mathcal{R}$ depend on the order mn of the transverse Gaussian modes:

$$\mathcal{L}_{mn}(\omega) = \frac{\sqrt{1+(2F/\pi)^2}}{1+(2F/\pi)^2\sin^2(kL+\varphi_{mn})} \qquad \text{and} \qquad \mathcal{R}_{mn}(\hat{\mathbf{e}}_k) = 1 \quad \forall \quad \hat{\mathbf{e}}_k \in \Omega_{mn} ,$$

where φ_{mn} is the frequency shift of the transverse modes.

40.1.4.2 Expansion into Hermite-Gaussian modes

More correctly, $\hat{\mathbf{e}}_k \in \Omega_{mn}$ means that we must weigh the density of states by the structure factor of the mode volume, which is nothing more than the Fourier transform of the cavity mode function,

$$\boxed{\mathcal{R}_{mn}(\hat{\mathbf{e}}_k) = \int_{\hat{\mathbf{e}}_k\in\Omega_{mn}} d^2k = \int_{\mathbb{R}^2} \mathcal{F}\left[\frac{u_{mn}(\mathbf{r})}{\hbar\omega}\right] d^2k} . \tag{40.47}$$

For a Hermite-Gaussian mode with waist $w(z)$ [see (18.313)],

$$u_{mn}(\mathbf{r}) = \hbar\omega\frac{w_0}{w}e^{-2(x^2+y^2)/w^2}H_m(\sqrt{2}x/w)^2H_n(\sqrt{2}y/w)^2 . \tag{40.48}$$

The Hermite polynomials are the eigenfunctions of the Fourier transform,

$$\mathcal{F}[e^{-x^2/2}H_n(x)] = (-\imath)^n e^{-k^2/2}H_n(k) . \tag{40.49}$$

Hence,

$$\begin{aligned}\mathcal{F}\left[\tfrac{1}{\hbar\omega}u_{mn}(\mathbf{r})\right] &= \frac{1}{\hbar\omega}\frac{w_0}{w}\mathcal{F}\left[e^{-2(x^2+y^2)/w^2}H_m(\sqrt{2}x/w)^2H_n(\sqrt{2}y/w)^2\right] \qquad (40.50)\\ &= \frac{1}{\hbar\omega}\frac{w_0}{w}\mathcal{F}\left[e^{-2x^2/w^2}H_m(\sqrt{2}x/w)^2\right]\mathcal{F}\left[e^{-2y^2/w^2}H_n(\sqrt{2}y/w)^2\right]\\ &= \frac{1}{\hbar\omega}\frac{w_0}{w}e^{-2k_x^2w^2}H_m(\sqrt{2}k_xw)^2e^{-2k_y^2w^2}H_n(\sqrt{2}k_yw)^2 \overset{m,n=0}{\longrightarrow} \frac{1}{\hbar\omega}\frac{w_0}{w}e^{-2\left(k_x^2+k_y^2\right)w^2} .\end{aligned}$$

Finally,

$$\begin{aligned}\mathcal{R}_{mn}(\hat{\mathbf{e}}_k) &= \int \mathcal{F}\left[\frac{u_{mn}(\mathbf{r})}{\hbar\omega}\right] d\left(\tfrac{k_x}{k}\right) d\left(\tfrac{k_y}{k}\right) \qquad (40.51)\\ &= \frac{1}{\hbar\omega}\frac{w_0}{w}\int e^{-2k_x^2w^2}H_m(\sqrt{2}k_xw)^2 d\left(\tfrac{k_x}{k}\right)\int e^{-2k_y^2w^2}H_n(\sqrt{2}k_yw)^2 d\left(\tfrac{k_y}{k}\right) .\end{aligned}$$

For the TEM_{00} mode, we get,

$$\mathcal{R}_{00}(\hat{\mathbf{e}}_k) = \frac{\pi}{2k^2w^2} \ , \tag{40.52}$$

using $P = \int I_{mn}(\mathbf{r})dxdy = \frac{1}{2}\pi w^2 I_0$. This coincides with the intuition, that for the TEM_{00}, the aperture is simply the divergence angle of the Gaussian mode.

The solid angle of a Gaussian mode in a non-degenerate cavity is calculated via,

$$\Omega_{cav} = 2 \cdot \frac{\pi w(z)^2}{z^2} = 2 \cdot \frac{\pi w_0^2}{z^2}\left(1 + \left(\frac{\lambda z}{\pi w_0^2}\right)^2\right) \ . \tag{40.53}$$

In the far field, we get,

$$\boxed{\Omega_{cav} \overset{z\to\infty}{\longrightarrow} \frac{8\pi}{k^2w_0^2}} \ . \tag{40.54}$$

Example 239 (*Solid angle for Hermite-Gaussian modes in a confocal cavity*): For confocal cavities, we must add $\sum_{mn}\mathcal{F}\left[\frac{1}{\hbar\omega}u_{mn}(\mathbf{r})\right]$ up to a limit, where the maximum $H_m(\sqrt{2}kw)$ is cut by the finite aperture of the mirrors of the cavity. Empirically, we find that $H_n(\xi)^2e^{-\xi^2}$ has its maximum at $\xi_{\max} = 13.7 \cdot n^{1/2}$. From the condition $u_{mn}(x, y, L) = 0$ for $xy > a^2$, we obtain,

$$x_{\max}y_{\max} < a^2$$
$$\left(13.7 \cdot n^{1/2}\right)^2 = \frac{\sqrt{2}x_{\max}}{w(L)}\frac{\sqrt{2}y_{\max}}{w(L)} < \frac{2a^2}{w(L)^2} \to \frac{a^2k^2w_0^2}{2L^2} \ ,$$

using $w(L) = w_0\sqrt{1 + \left(\frac{\lambda L}{\pi w_0^2}\right)^2} \to \frac{\lambda L}{\pi w_0}$. Finally,

$$\sum_{mn}\mathcal{F}\left[\frac{1}{\hbar\omega}u_{mn}(\mathbf{r})\right] = \frac{\pi}{2k^2w^2}\sum_{13.7^2 m,n<a^2k^2w_0^2/2L^2} = \frac{\pi}{2k^2w^2}\frac{1}{13.7^2}\frac{a^2k^2w_0^2}{2L^2} = \frac{1}{13.7^2}\frac{\pi a^2}{4L^2} \ .$$

40.1.5 Cumulant expansion of correlation functions and power spectra

40.1.5.1 Correlation functions

The evolution of the two-time correlation function of two operators $\hat{A}$ and $\hat{B}$ given by,

$$R(t,\tau) \equiv \langle\hat{A}(t+\tau)\hat{B}(t)\rangle \quad , \quad R(\tau) = \lim_{t\to\infty}\langle\hat{A}(t+\tau)\hat{B}(t)\rangle \ , \tag{40.55}$$

with respect to the time delay τ is determined by,

$$\frac{d}{d\tau}R(t,\tau) = \langle[\partial_\tau\hat{A}(t+\tau)]\hat{B}(t)\rangle \ . \tag{40.56}$$

Hence, the set of equations required to compute the correlation function can be derived from the equation of motion for the operator $\hat{A}$. The cumulant expansion of the correlation function then follows the same procedure as for a standard time evolution: the set of equations is expanded to a certain order and completed.

40.1.5.2 Steady state

If the original system is evolved up to a time t such that it is in steady state, i.e. expectation values no longer change after that time, the set of equations determining the correlation function has a special property. specifically, after the cumulant expansion has been performed, there can only be a single term in each product on the right-hand-side of the set of equations that depends on τ. All other terms depend on t alone, meaning that they are constant since they no longer change after the time t. Therefore, the system of equations from which the correlation function is computed is linear, in the sense that it can be written as,

$$\frac{d}{d\tau}\mathbf{y}(\tau) = \mathbf{M}\mathbf{y}(\tau) + \mathbf{d} \ , \tag{40.57}$$

where $\mathbf{y}(\tau)$ is the vector of τ-dependent variables. The elements of the matrix $\mathbf{M}$ as well as the vector $\mathbf{d}$ are given by steady-state expectation values and parameters, i.e. they are independent of τ.

40.1.5.3 Power spectra

According to the Wiener-Khinchin theorem. the spectral density associated with a correlation function is given by its Fourier transform,

$$S(t,\omega) = 2\mathfrak{Re} \int e^{-\imath\omega\tau} R(t,\tau) d\tau \ . \tag{40.58}$$

In order to compute this, we can solve the system of equations determining $R(t,\tau)$, subsequently taking the Fourier transform. However, if we are not interested in the temporal behavior of the correlation function, and if the system of which we want to compute the spectrum is in steady state, we can directly compute the spectrum from Eq. (40.57). To this end, we define

$$\mathbf{x}(s) = \mathcal{L}[y(\tau)] \ , \tag{40.59}$$

where $\mathcal{L}$ denotes the Laplace transform with respect to τ. Taking the Laplace transform of Eq. (40.57), we have,

$$(s\mathbb{I} - \mathbf{M})\mathbf{x}(s) = \mathbf{y}(0) + \frac{\mathbf{d}}{s} \ . \tag{40.60}$$

Note that the Laplace transform is equivalent to the Fourier transform at the point where $s = \imath\omega$, i.e. $S(\omega) = 2\mathfrak{Re}\ \mathbf{x}_1(\imath\omega)\}$. Hence, instead of computing the time evolution of the correlation function we can directly compute the spectrum by solving the linear equation,

$$\mathbf{x} = (\imath\omega\mathbb{I} - \mathbf{M})^{-1}[\mathbf{y}(0) + \tfrac{1}{\imath\omega}\mathbf{d}] \ . \tag{40.61}$$

For larger systems, the method using a Laplace transform is usually faster than integrating a system of equations of the same size. Additionally, it avoids numerical errors of the integration and the subsequent discrete Fourier transform.

40.1.6 Exercises

40.1.6.1 Ex: Quick ullage of an optical cavity

Consider a linear cavity resonantly pumped by a laser beam until a stationary state is reached. Suddenly, the phase of the incident light is changed by 180°. Based on equation (40.6), analyze the evolution of the light field inside the cavity.

Solution: *We have seen in class that the evolution of the light field in the cavity is given by (40.6). We now assume that the cavity is initially filled with the amplitude,*

$$\alpha(0) \equiv \frac{\eta_1}{\kappa + \imath\Delta_c} \ .$$

Suddenly, we change the phase and amplitude of the pumping wave, $\eta_1 \longrightarrow \eta_2$. The amplitude now evolves as,

$$\alpha(t) = (\alpha(0) - \frac{\eta_2}{\kappa + \imath\Delta_c})e^{(-\kappa - \imath\Delta_c)t} + \frac{\eta_2}{\kappa + \imath\Delta_c} = \frac{\eta_1 - \eta_2}{\kappa + \imath\Delta_c}e^{(-\kappa - \imath\Delta_c)t} + \frac{\eta_2}{\kappa + \imath\Delta_c} \ .$$

Therefore, the light amplitude vanishes at time,

$$t_0 = \frac{1}{\kappa + \imath\Delta_c} \ln \frac{\eta_2 - \eta_1}{\eta_2} \ .$$

Choosing $\eta_2 = -c\eta_1$ with large c we can minimize the time t_0.

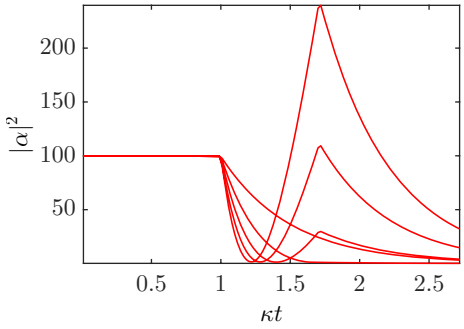

Figure 40.5: (code) Quick ullage of an optical cavity.

40.1.6.2 Ex: Ringing of an optical cavity

Consider a linear cavity with resonant frequency ω_c and the decay rate κ pumped by a laser beam whose frequency is swept linearly over a range $\omega \in [-10\kappa, 10\kappa]$. Prepare a numerical simulation varying the time Δt of the sweep.

Solution: *See Fig. 40.6.*

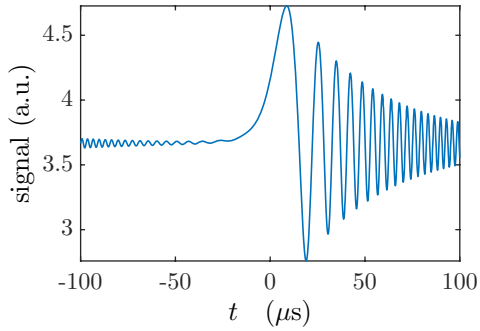

Figure 40.6: (code) Sweeping the laser frequency which pumps a cavity.

40.1.6.3 Ex: Derivation of the Airy formula

Derive the Airy formula (40.42).

Solution: *The electric field inside a cavity is,*

$$\mathcal{E}_{cav} = \mathcal{E}_{in} t_1 \frac{e^{\imath kx} - r_2 e^{\imath k(2L-x)}}{1 - r_1 r_2 e^{\imath k 2L}} \ .$$

This has been shown in Exc. 18.3.7.18. From this we calculate,

$$\mathcal{L}(\omega) = \frac{I_{cav}}{I_{in}} = t_1^2 \left| \frac{e^{\imath kx} - r_2 e^{\imath k(2L-x)}}{1 - r_1 r_2 e^{\imath k 2L}} \right|^2 = t_1^2 \frac{1 + r_2^2 - 2r_2 \cos(2k(L-x))}{1 + r_1^2 r_2^2 - 2r_1 r_2 \cos k2L} \ .$$

Averaging over the cavity field along the optical axis coordinate x, the cosine term in the numerator vanishes. Hence the expression simplifies to,

$$\mathcal{L}(\omega) = t_1^2 \frac{1 + r_2^2}{(1 - r_1 r_2)^2 + 4 r_1 r_2 \sin^2 kL} \ .$$

Assuming $r_1 = r_2 = \sqrt{R}$ and $t_1^2 = T = 1 - R$, we get,

$$\frac{I_{cav}}{I_{in}} = \frac{T}{1-R} \frac{\frac{1+R}{1-R}}{1 + \frac{4R}{(1-R)^2} \sin^2 kL} = \frac{\sqrt{1 + \left(\frac{2F}{\pi}\right)^2}}{1 + \left(\frac{2F}{\pi}\right)^2 \sin^2 kL} \ ,$$

using $F = \frac{\pi\sqrt{R}}{1-R}$. For sufficiently high finesse and close to resonance,

$$\frac{I_{cav}}{I_{in}} \simeq \frac{\frac{2F}{\pi}}{1 + \left(\frac{2F}{\pi}\right)^2 \sin^2 kL} \simeq \frac{\frac{2F}{\pi}}{1 + \left(\frac{2F}{\pi}\right)^2 (\frac{\Delta}{2\delta_{fsr}})^2} = \frac{\delta_{fsr} \kappa_{int}}{\Delta^2 + \left(\frac{\kappa_{int}}{2}\right)^2} \ ,$$

with

$$kL = \pi N + \frac{\Delta}{2\delta_{fsr}} \qquad \textit{and} \qquad F = \frac{\delta_{fsr}}{\kappa_{int}/2\pi} \ .$$

40.1.6.4 Ex: Airy formula for ring cavities

Derive the Airy formulas for a ring cavity laser-pumped through an incoupling mirror with reflectivity r_{ic} and comprising two more high-reflecting mirrors with reflectivity r_{hr}. Calculate (a) the intracavity intensity, (b) the intensity of the light reflected from the incoupler, and (c) the intensity of the light transmitted through the first encountered high reflector. For each for intensity study the cases that (i) the ring cavity is resonant and (ii) off-resonance. Also study the limit $r_{hr} \to 1$. Disregard absorption losses.

Solution: *a. The intracavity cavity field amplitude and intensity are,*

$$\frac{\mathcal{E}_{cav}(z)}{\mathcal{E}_{in}} = t_{ic}\sum_n (-r_{hr}^2 r_{ic})^n e^{\imath k(nL+x)} = t_{ic}\frac{e^{\imath kx}}{1+r_{ic}r_{hr}^2 e^{\imath kL}}$$
$$\frac{I_{cav}(z)}{I_{in}} = \frac{T_{ic}}{1+R_{hr}^2 R_{ic}+2R_{hr}\sqrt{R_{ic}}\cos kL} \ .$$

On resonance, $kL = \pi(2n+1)$,

$$\frac{I_{cav}^{(res)}(z)}{I_{in}} = \frac{1-R_{ic}}{(1-R_{hr}\sqrt{R_{ic}})^2} \overset{R_{hr}=1}{\longrightarrow} \frac{1+\sqrt{R_{ic}}}{1-\sqrt{R_{ic}}} \simeq \frac{2}{1-\sqrt{R_{ic}}} \gg 1 \ ,$$

and off resonance, $kL = \pi 2n$,

$$\frac{I_{cav}^{(off)}(z)}{I_{in}} = \frac{1-R_{ic}}{(1+R_{hr}\sqrt{R_{ic}})^2} \overset{R_{hr}=1}{\longrightarrow} \frac{1-\sqrt{R_{ic}}}{1+\sqrt{R_{ic}}} \simeq \frac{1-\sqrt{R_{ic}}}{2} \approx 0 \ .$$

b. The light amplitude and intensity reflected from the incoupler are,

$$\frac{\mathcal{E}_{rfl}(z)}{\mathcal{E}_{in}} = r_{ic} + t_{ic}r_{hr}^2 e^{\imath kL}\sum_n (-r_{ic}r_{hr}^2)^n e^{\imath nkL} t_{ic} = r_{ic} + \frac{t_{ic}^2 r_{hr}^2 e^{\imath kL}}{1+r_{ic}r_{hr}^2 e^{\imath kL}}$$
$$\frac{I_{rfl}(z)}{I_{in}} = \frac{R_{ic}+R_{hr}^2+2R_{hr}^2\sqrt{R_{ic}}\cos kL}{1+R_{hr}^2 R_{ic}+2R_{hr}\sqrt{R_{ic}}\cos kL} \ .$$

On resonance, $kL = \pi(2n+1)$,

$$\frac{I_{rfl}^{(res)}(z)}{I_{in}} = \frac{R_{ic}+R_{hr}^2-2R_{hr}^2\sqrt{R_{ic}}}{1+R_{hr}^2 R_{ic}-2R_{hr}\sqrt{R_{ic}}} \overset{R_{hr}=1}{\longrightarrow} 1 \ ,$$

and off resonance, $kL = \pi 2n$,

$$\frac{I_{rfl}^{(off)}(z)}{I_{in}} = \frac{R_{ic}+R_{hr}^2+2R_{hr}^2\sqrt{R_{ic}}}{1+R_{hr}^2 R_{ic}+2R_{hr}\sqrt{R_{ic}}} \overset{R_{hr}=1}{\longrightarrow} 1 \ .$$

c. The light amplitude and intensity transmitted through the first encountered high reflector are,

$$\frac{\mathcal{E}_{trns}(z)}{\mathcal{E}_{in}} = t_{ic}t_{hr}e^{\imath ka} + t_{ic}\sum_n (-r_{hr}^2 r_{ic})^n e^{\imath k(nL+a)} t_{hr} = t_{ic}t_{hr}e^{\imath ka}\left(1+\frac{1}{1+r_{ic}r_{hr}^2 e^{\imath kL}}\right)$$
$$\frac{I_{trns}(z)}{I_{in}} = T_{ic}T_{hr}\frac{4+R_{hr}^2 R_{ic}+4R_{hr}\sqrt{R_{ic}}\cos kL}{1+R_{hr}^2 R_{ic}+2R_{hr}\sqrt{R_{ic}}\cos kL} \ .$$

On resonance, $kL = \pi(2n+1)$,

$$\frac{I^{(res)}_{trns}(z)}{I_{in}} = T_{ic}T_{hr}\frac{R_{ic}+R^2_{hr}-2R^2_{hr}\sqrt{R_{ic}}}{1+R^2_{hr}R_{ic}-2R_{hr}\sqrt{R_{ic}}} \overset{R_{hr}=1}{\longrightarrow} T_{hr}\left(2-\sqrt{R_{ic}}\right)^2\frac{1+\sqrt{R_{ic}}}{1-\sqrt{R_{ic}}} \simeq T_{hr}\frac{I^{(res)}_{cav}(z)}{I_{in}} ,$$

and off resonance, $kL = \pi 2n$,

$$\frac{I^{(off)}_{trns}(z)}{I_{in}} = T_{ic}T_{hr}\frac{4+R^2_{hr}R_{ic}+4R_{hr}\sqrt{R_{ic}}}{1+R^2_{hr}R_{ic}+2R_{hr}\sqrt{R_{ic}}} \overset{R_{hr}=1}{\longrightarrow} \frac{9}{4}T_{ic}T_{hr} .$$

40.1.6.5 Ex: Filling rate for long cavities

Using the solution (40.6) try to calculate the transmission of a 15 km long cavity of finesse $F = 1000$ as a function of time, when it is pumped by a suddenly switched on laser. Analyze the results in the light of local causality.

Solution: *The free spectral range is $\delta_{fsr} = c/2L = 30\,\mathrm{kHz}$, the round-trip time $\tau_{rt} = \delta^{-1}_{fsr} = 0.33\,\mathrm{ms}$, the cavity linewidth $\kappa = \pi\delta_{fsr}/F = (2\pi)\ 15\,\mathrm{kHz}$, and the cavity decay time $\tau_\kappa = \kappa^{-1} = 10.6\,\mathrm{ms}$. Assuming resonance, $\Delta_c = 0$, the solution (40.6) predicts position-independent filling of the cavity at a rate $|\eta/\kappa|^2$. That is, we expect instantaneous transfer of information over a long distance, which is not possible. This means, that we must generalize the calculation leading to the solution (40.6).*
The problem is, that the single resonant mode assumption becomes invalid when the mode spacing is small and the step due to the sudden pump power increase so steep that is involves a large band of Fourier components, which can transiently excite several cavity modes.
The step response can be obtained as the Laplace transform of the frequency-dependent transfer function [1417, 489](see Sec. 56.2.1). The transfer function for transmission is just the Airy function, as shown in Exc. 18.3.7.18,

$$\mathcal{E}_{trns} = \mathcal{E}_{in}\frac{(1-R)e^{\imath kL}}{1-Re^{2\imath kL}} \simeq \mathcal{E}_{in}\sum_N \frac{1}{1+2\imath\Delta_c/\kappa} ,$$

with $\Delta_{c,N} \equiv \omega - \omega_N \equiv \omega - N2\pi\delta_{fsr}$ is the detuning from the N-th cavity ω_N. We describe the incident light by an oscillation suddenly switched on a time $t = 0$,

$$\mathcal{E}_{in}(t) = \mathcal{E}_0\theta(t)e^{\imath\omega t} .$$

Using the rules for the Laplace transform, $\mathcal{L}[\theta(t)] = \frac{1}{s}$ and $\mathcal{L}[e^{\imath\omega t}f(t)] = (\mathcal{L}f)(s-\imath\omega)]$, we get for the Laplace transform of this step signal,

$$\mathcal{L}[\mathcal{E}_{in}(t)] = \frac{\mathcal{E}_0}{s-\imath\omega} ,$$

showing that the sudden switch-on leads to a transient spectral broadening. In reality the broadening depends on the switching time constant γ^{-1}: the faster the switching, the larger the broadening. The general response of the cavity in transmission is,

$$\mathcal{E}_{trns}(t) = T_{Airy}(t) \star \mathcal{E}_{in}(t) ,$$

where the Laplace transform of the response function $T_{Airy}(t)$ is nothing else than the cavity's Airy function,

$$\mathcal{L}[T_{Airy}(t)] \equiv T_{Airy}(\omega) = \frac{\mathcal{E}_{trns}(\omega)}{\mathcal{E}_{in}(\omega)} \simeq \sum_N \frac{\kappa/2}{\kappa/2 + \imath\omega - \imath\omega_N} \ .$$

With these informations, we calculate,

$$\begin{aligned}\mathcal{E}_{trns}(t) &= \mathcal{L}^{-1}\left\{\mathcal{L}[T_{Airy}(t) \star \mathcal{E}_{in}(t)]\right\} = \mathcal{L}^{-1}\left\{\mathcal{L}[T_{Airy}(t)] \cdot \mathcal{L}[\mathcal{E}_{in}(t)]\right\} \\ &= \mathcal{E}_0 \sum_N \mathcal{L}^{-1}\left[\frac{\kappa/2}{\kappa/2 + s - \imath\omega_N} \cdot \frac{1}{s - \imath\omega_N}\right] \ .\end{aligned}$$

For simplicity, let us consider a single cavity mode labeled N_0 and resonant light, $\omega = \omega_{N_0}$. Then,

$$\begin{aligned}\mathcal{E}_{trns}(t) &= \mathcal{E}_0 \mathcal{L}^{-1}\left[\frac{\kappa/2}{\kappa/2 + s - \imath\omega_{N_0}} \frac{1}{s - \imath\omega_{N_0}}\right] \\ &= \mathcal{E}_0 e^{\imath\omega_{N_0} t} \mathcal{L}^{-1}\left[\frac{\kappa/2}{\kappa/2 + s} \frac{1}{s}\right] = \mathcal{E}_0 e^{\imath\omega_{N_0} t}(1 - e^{-\kappa t/2})\theta(t) \ ,\end{aligned}$$

which is exactly what we would expect for large mode spacing, $\delta_{fsr} \gg \gamma$. Otherwise, we need to consider the presence of non-resonant modes,

$$\begin{aligned}\mathcal{E}_{trns}(t) &= \mathcal{E}_0 \sum_N \mathcal{L}^{-1}\left[\frac{\kappa/2}{\kappa/2 + s - \imath\omega_N} \frac{1}{s - \imath\omega_{N_0}}\right] \\ &= \mathcal{E}_0 e^{\imath\omega_{N_0} t} \mathcal{L}^{-1}\left[\frac{\kappa/2}{\kappa/2 + s - \imath(N - N_0)2\pi\delta_{fsr}} \frac{1}{s}\right] \ .\end{aligned}$$

Introducing the abbreviation $\Delta_N \equiv (N - N_0)2\pi\delta_{fsr}$, we can also write,

$$\mathcal{E}_{trns}(t) = \mathcal{E}_0 e^{\imath\omega_{N_0} t} \sum_N \mathcal{L}^{-1}\left[\frac{\kappa/2}{(\kappa/2 - \imath\Delta_N)\, s + s^2}\right] = \mathcal{E}_0 e^{\imath\omega_{N_0} t} \sum_N \frac{\kappa/2}{(\kappa/2 - \imath\Delta_N)\, \partial_t + \partial_t^2} \ .$$

Hence,

$$\sum_N \ddot{\mathcal{E}}_{trns} + \left(\frac{\kappa}{2} - \imath\Delta_N\right) \dot{\mathcal{E}}_{trns} = \frac{\kappa}{2}\mathcal{E}_{in} \ .$$

Coming back to the case of large mode separation, we may approximate the differential equation by,

$$\ddot{\mathcal{E}}_{trns} + \frac{\kappa}{2}\dot{\mathcal{E}}_{trns} = \frac{\kappa}{2}\mathcal{E}_{in} \ ,$$

whose solution reproduces the previous result.

40.1.6.6 Ex: Fluorescence spectrum of an empty cavity

a. Calculate the fluorescence spectrum of an empty cavity pumped at a rate η classically via the autocorrelation function $\langle\alpha^*(t+\tau)\alpha(t)\rangle$.
b. Calculate the time evolution of the cumulants $\langle\hat{a}\rangle$, $\langle\hat{a}^\dagger\hat{a}\rangle$, $\langle\hat{a}^\dagger\hat{a}^\dagger\hat{a}\rangle$, $\langle\hat{a}\hat{a}^\dagger\hat{a}\rangle$, and

$\langle \hat{a}^\dagger \hat{a} \hat{a}^\dagger \hat{a} \rangle$ expanding up to forth order.
c. Based on the results obtained in (b) and applying the quantum regression theorem derive a set of linear differential equations for the autocorrelation functions $\langle \hat{a}(\tau) \rangle$, $\langle \hat{a}^\dagger(t+\tau)\hat{a}(t) \rangle$, $\langle \hat{a}^\dagger(t+\tau)\hat{a}^\dagger(t)\hat{a}(t) \rangle$, $\langle \hat{a}(t+\tau)\hat{a}^\dagger(t)\hat{a}(t) \rangle$, and $\langle \hat{a}^\dagger(t+\tau)\hat{a}(t+\tau)\hat{a}^\dagger(t)\hat{a}(t) \rangle$. Express them in matrix notation.
d. Calculate $g^{(1)}(\tau)$, the fluorescence spectrum, and $g^{(2)}(\tau)$ for the case $\eta = 0$.
e. Repeat the calculations in (c) to the case $\eta \neq 0$.

Solution: *a. The general solution of the inhomogeneous equation,*

$$[\partial_t + \kappa + \imath\Delta_c] f(t) = h \tag{40.62}$$

is,

$$\begin{aligned} f(t) &= [f(0) - f(\infty)] e^{-(\kappa+\imath\Delta_c)t} + f(\infty) \\ &= \left(f(0) - \tfrac{h}{\kappa+\imath\Delta_c} \right) e^{-(\kappa+\imath\Delta_c)t} + \tfrac{h}{\kappa+\imath\Delta_c} \ . \end{aligned} \tag{40.63}$$

Hence, the time-evolution according to (40.11) is,

$$\alpha e^{\imath\omega t} = \left(\alpha(0) e^{\imath\omega t} - \frac{\eta}{\kappa + \imath\Delta_c} \right) e^{(-\kappa+\imath\Delta_c)t} + \frac{\eta}{\kappa + \imath\Delta_c} \ , \tag{40.64}$$

or

$$\begin{aligned} \alpha(t) &= A e^{(-\kappa-\imath\omega_c)t} + B e^{-\imath\omega t} \\ \text{with} \quad A &= \alpha(0) - \frac{\eta}{\kappa + \imath\Delta_c} \qquad \text{and} \qquad B = \frac{\eta}{\kappa + \imath\Delta_c} \ . \end{aligned} \tag{40.65}$$

The autocorrelation is now,

$$\begin{aligned} \langle \alpha^*(t+\tau)\alpha(t) \rangle &= \lim_{t\to\infty} \frac{1}{t} \int_0^t \alpha^*(t'+\tau)\alpha(t') dt' \\ &= \lim_{t\to\infty} \frac{1}{t} \int_0^t \left(A^* e^{(-\kappa+\imath\omega_c)(t'+\tau)} + B^* e^{\imath\omega(t'+\tau)} \right) \left(A e^{(-\kappa-\imath\omega_c)t'} + B e^{-\imath\omega t'} \right) dt' \\ &= e^{(-\kappa+\imath\omega_c)\tau} \lim_{t\to\infty} \frac{1}{t} \int_0^t \left(|A|^2 e^{-2\kappa t'} + A^* B e^{(-\kappa-\imath\omega+\imath\omega_c)t'} \right) dt' \\ &\quad + e^{\imath\omega\tau} \lim_{t\to\infty} \frac{1}{t} \int_0^t \left(A B^* e^{(-\kappa+\imath\omega-\imath\omega_c)t'} + |B|^2 \right) dt' \\ &= \lim_{t\to\infty} \left[e^{(-\kappa+\imath\omega_c)\tau} \left(|A|^2 \frac{e^{-2\kappa t} - 1}{-2\kappa t} + A^* B \frac{e^{(-\kappa-\imath\omega+\imath\omega_c)t} - 1}{(-\kappa - \imath\omega + \imath\omega_c)t} \right) + \right. \\ &\quad \left. + e^{\imath\omega\tau} \left(A B^* \frac{e^{(-\kappa+\imath\omega-\imath\omega_c)t} - 1}{(-\kappa + \imath\omega - \imath\omega_c)t} + |B|^2 \right) \right] \\ &= \lim_{t\to\infty} \left[e^{(-\kappa+\imath\omega_c)\tau} (0+0) + e^{\imath\omega\tau} (0 + |B|^2) \right] = |B|^2 e^{\imath\omega\tau} \ . \end{aligned} \tag{40.66}$$

Hence, the $g^{(1)}(\tau)$ function is,

$$g^{(1)}(\tau) = \frac{\langle \alpha^*(t+\tau)\alpha(t) \rangle}{\langle \alpha^*(t)\alpha(t) \rangle} = e^{\imath\omega\tau} \ . \tag{40.67}$$

The spectrum should consist of an elastic peak at the Fourier frequency $\nu = \omega$. A broadened spectrum could only be observed as a transient at shorter times $t < \infty$.
b. From the Hamiltonian,

$$\hat{H} = -\Delta_c \hat{a}^\dagger \hat{a} + \imath\eta(\hat{a} - \hat{a}^\dagger) \ , \tag{40.68}$$

using the Heisenberg-Liouville equations, we derive the cumulant equations,

$$\begin{aligned}
[\partial_t + \kappa - \imath\Delta_c]\langle\hat{a}\rangle &= \eta \\
[\partial_t + 2\kappa]\langle\hat{a}^\dagger\hat{a}\rangle &= \eta(\langle\hat{a}^\dagger\rangle + \langle\hat{a}\rangle) \\
[\partial_t + 2\kappa + 2\imath\Delta_c]\langle\hat{a}^\dagger\hat{a}^\dagger\rangle &= 2\eta\langle\hat{a}^\dagger\rangle = 0 \\
[\partial_t + 3\kappa + \imath\Delta_c]\langle\hat{a}^\dagger\hat{a}^\dagger\hat{a}\rangle &= \eta\langle\hat{a}^\dagger\hat{a}^\dagger\rangle + 2\eta\langle\hat{a}^\dagger\hat{a}\rangle = 0 \\
[\partial_t + 4\kappa]\langle\hat{a}^\dagger\hat{a}^\dagger\hat{a}\hat{a}\rangle &= 2\eta(\langle\hat{a}^\dagger\hat{a}^\dagger\hat{a}\rangle + \langle\hat{a}^\dagger\hat{a}\hat{a}\rangle) = 0 \ .
\end{aligned} \tag{40.69}$$

The solution of the first equation (40.69) has already been derived in (40.64),

$$\begin{aligned}
\langle\hat{a}(t)\rangle &= (\langle\hat{a}_0\rangle - \langle\hat{a}_\infty\rangle)e^{-(\kappa+\imath\Delta_c)t} + \langle\hat{a}_\infty\rangle \\
&= \left(\langle\hat{a}_0\rangle - \tfrac{\eta}{\kappa+\imath\Delta_c}\right) e^{-(\kappa+\imath\Delta_c)t} + \tfrac{\eta}{\kappa+\imath\Delta_c} \ .
\end{aligned} \tag{40.70}$$

In matrix notation, $\partial_t \mathbf{y} = \mathcal{M}\mathbf{y} + \mathbf{d}$, with

$$\mathcal{M} = \begin{pmatrix}
\imath\Delta_c - \kappa & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & -\imath\Delta_c - \kappa & 0 & 0 & 0 & 0 & 0 \\
\eta & \eta & -2\kappa & 0 & 0 & 0 & 0 \\
0 & 2\tilde{\eta} & 0 & 2\imath\Delta_c - 2\kappa & 0 & 0 & 0 \\
0 & 0 & 2\tilde{\eta} & \tilde{\eta} & \imath\Delta_c - 3\kappa & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & -\imath\Delta_c - 3\kappa & 0 \\
0 & 0 & 0 & 0 & 2\tilde{\eta} & 2\tilde{\eta} & -4\kappa
\end{pmatrix}$$

$$\mathbf{y} = \begin{pmatrix}
\langle\hat{a}\rangle \\
\langle\hat{a}^\dagger\rangle \\
\langle\hat{a}^\dagger\hat{a}\rangle \\
\langle\hat{a}^\dagger\hat{a}^\dagger\rangle \\
\langle\hat{a}^\dagger\hat{a}^\dagger\hat{a}\rangle \\
\langle\hat{a}^\dagger\hat{a}\hat{a}\rangle \\
\langle\hat{a}^\dagger\hat{a}\hat{a}^\dagger\hat{a}\rangle
\end{pmatrix} \quad , \quad \mathbf{d} = \begin{pmatrix}
\eta \\ \eta \\ 0 \\ 0 \\ 0 \\ 0 \\ 0
\end{pmatrix} \ . \tag{40.71}$$

The steady-state solution can be obtained from $\mathbf{y} = -\mathcal{M}^{-1}\mathbf{d}$. Neglecting phase-invariant terms marked with $\tilde{\eta}$ vanish.
c. We can use the result to evaluate correlations such as $\langle\hat{a}^\dagger(t+\tau)\hat{a}(t)\rangle$. To this end we solve the second equation (40.69) using the quantum regression theorem, for example,

$$\begin{aligned}
\frac{d}{d\tau}\langle\hat{a}^\dagger(t+\tau)\hat{a}(t)\rangle &= \langle[\partial_\tau\hat{a}^\dagger(t+\tau)]\hat{a}(t)\rangle \\
&= \langle[\eta - (\kappa - \imath\Delta_c)\hat{a}^\dagger(t+\tau)]\hat{a}(t)\rangle \\
&= \eta\alpha(t) - (\kappa - \imath\Delta_c)\langle\hat{a}^\dagger(t+\tau)\hat{a}(t)\rangle \ .
\end{aligned} \tag{40.72}$$

The procedure can be extended to higher orders. Introducing the short-hand notation $\hat{a} \equiv \hat{a}(t+\tau)$ *and* $\hat{a}_0 \equiv \hat{a}(t)$ *we get,*

$$\begin{aligned}
[\partial_\tau + \kappa + \imath\Delta_c]\langle \hat{a}^\dagger \hat{a}_0\rangle &= \eta\langle \hat{a}_0\rangle = 0 \\
[\partial_\tau + \kappa + \imath\Delta_c]\langle \hat{a}^\dagger \hat{a}_0^\dagger \hat{a}_0\rangle &= \eta\langle \hat{a}_0^\dagger \hat{a}_0\rangle = 0 \\
[\partial_\tau + 2\kappa]\langle \hat{a}^\dagger \hat{a}\hat{a}_0^\dagger \hat{a}_0\rangle &= \eta(\langle \hat{a}^\dagger \hat{a}_0^\dagger \hat{a}_0\rangle + \langle \hat{a}\hat{a}_0^\dagger \hat{a}_0\rangle) = 0 \ .
\end{aligned} \tag{40.73}$$

In matrix notation, $\partial_\tau \mathbf{y} = \mathcal{M}\mathbf{y} + \mathbf{d}$*, with*

$$\mathcal{M} = \begin{pmatrix}
-\kappa + \imath\Delta_c & 0 & 0 & 0 & 0 \\
0 & -\kappa + \imath\Delta_c & 0 & 0 & 0 \\
0 & 0 & -\kappa + \imath\Delta_c & 0 & 0 \\
0 & 0 & 0 & -\kappa + \imath\Delta_c & 0 \\
0 & 0 & \eta & \eta & -2\kappa
\end{pmatrix} \tag{40.74}$$

$$\mathbf{y} = \begin{pmatrix}
\langle \hat{a}\rangle \\
\langle \hat{a}^\dagger \hat{a}_0\rangle \\
\langle \hat{a}^\dagger \hat{a}_0^\dagger \hat{a}_0\rangle \\
\langle \hat{a}\hat{a}_0^\dagger \hat{a}_0\rangle \\
\langle \hat{a}^\dagger \hat{a}\hat{a}_0^\dagger \hat{a}_0\rangle
\end{pmatrix} \quad , \quad \mathbf{d} = \eta \begin{pmatrix}
\langle \hat{a}_0\rangle \\
\langle \hat{a}_0^\dagger \hat{a}_0\rangle \\
\langle \hat{a}_0^\dagger \hat{a}_0^\dagger \hat{a}_0\rangle \\
\langle \hat{a}_0 \hat{a}_0^\dagger \hat{a}_0\rangle \\
\langle \hat{a}_0^\dagger \hat{a}_0 \hat{a}_0^\dagger \hat{a}_0\rangle
\end{pmatrix} \ .$$

d. Without pumping, $\eta = 0$*, the homogeneous equations are easy to solve,*

$$\begin{aligned}
\langle \hat{a}^\dagger \hat{a}_0\rangle &= \langle \hat{a}_0^\dagger \hat{a}_0\rangle e^{-(\imath\Delta_c + \kappa)\tau} \\
\langle \hat{a}^\dagger \hat{a}\hat{a}_0^\dagger \hat{a}_0\rangle &= \langle \hat{a}_0^\dagger \hat{a}_0 \hat{a}_0^\dagger \hat{a}_0\rangle e^{-(\imath\Delta_c + \kappa)\tau} \ ,
\end{aligned} \tag{40.75}$$

etc., so that,

$$g^{(1)}(\tau) = e^{-(\imath\Delta_c + \kappa)\tau} \qquad \textit{and} \qquad g^{(2)}(\tau) = e^{-(\imath\Delta_c + \kappa)\tau} \ . \tag{40.76}$$

The spectrum is a Lorentzian line,

$$\mathcal{F}(\langle \hat{a}^\dagger \hat{a}_0\rangle)(\omega) = \frac{1}{(\omega - \Delta_c)^2 + \kappa^2} \ . \tag{40.77}$$

e. In the presence of pumping, $\eta \neq 0$ *we get,*

$$\begin{aligned}
\langle \hat{a}_0\rangle &= \frac{\eta}{\kappa + \imath\Delta_c} \\
\langle \hat{a}^\dagger \hat{a}_0\rangle &= \left(\langle \hat{a}_0^\dagger \hat{a}_0\rangle - \eta\langle \hat{a}_0\rangle\right) e^{-(\kappa + \imath\Delta_c)\tau} + \eta\langle \hat{a}_0\rangle \\
&= \left(\langle \hat{a}_0^\dagger \hat{a}_0\rangle - \frac{\eta^2}{\kappa + \imath\Delta_c}\right) e^{-(\kappa + \imath\Delta_c)\tau} + \frac{\eta^2}{\kappa + \imath\Delta_c} \\
\langle \hat{a}^\dagger \hat{a}_0^\dagger \hat{a}_0\rangle &= \left(\langle \hat{a}_0^\dagger \hat{a}_0^\dagger \hat{a}_0\rangle - \eta\langle \hat{a}_0^\dagger \hat{a}_0\rangle\right) e^{-(\kappa + \imath\Delta_c)\tau} + \eta\langle \hat{a}_0^\dagger \hat{a}_0\rangle \\
\langle \hat{a}^\dagger \hat{a}\hat{a}_0^\dagger \hat{a}_0\rangle &= \left(\langle \hat{a}_0^\dagger \hat{a}_0 \hat{a}_0^\dagger \hat{a}_0\rangle - \eta(\langle \hat{a}^\dagger \hat{a}_0^\dagger \hat{a}_0\rangle + \langle \hat{a}\hat{a}_0^\dagger \hat{a}_0\rangle)\right) e^{-2\kappa\tau} + \eta(\langle \hat{a}^\dagger \hat{a}_0^\dagger \hat{a}_0\rangle + \langle \hat{a}\hat{a}_0^\dagger \hat{a}_0\rangle) \ .
\end{aligned} \tag{40.78}$$

40.2 Interaction of atoms with cavities

In Sec. 35.1 we have shown how to describe the dynamics of a single two-level atom driven by a quantized electromagnetic field and embedded in an electromagnetic vacuum under the assumption that the driving field be a plane wave and the vacuum be isotropic. In the following, we want to relax these conditions. We generalize Eq. (35.7) replacing the plane wave $e^{i\mathbf{k}\cdot\mathbf{r}}$ by a mode function $u_{\mathbf{k}}(\mathbf{r})$ and allowing the coupling constant (35.17) $g_{\mathbf{k}}$ to depend on $\mathbf{k}$. Such a situation corresponds to placing the atom inside an optical cavity whose macroscopic boundary conditions create a cooperative environment for the atom. We note that the role of the cavity can be understood as generating mirror images with which the atom interacts. Furthermore, both the atomic excitation and the radiation fields may decay. On the other hand, we restrict to non-interacting atoms, that is, free atoms or atoms trapped in external potentials that only interact with each other via re-scattering of an incident radiation field, i.e. no collisions and no properties requiring symmetrization of their wavefunctions.

In Sec. 40.2.1 we study a single atom or two atoms in a cooperative environment (e.g. a cavity). In particular, we will find that spontaneous emission is affected by the presence of a cavity. A wider discussion of scattering from correlated atoms is postponed to Sec. 41.1. Then, in Sec. 40.2.2 we will introduce some parameters characterizing the interaction between atoms and cavities. In particular, we will relate the important notions of the *cooperativity* of several atoms and the structure factor for light scattering introduced in 39.1.1 with the cavity-to-free space scattering ratio, the finesse and the density-of-states of a cavity, simply by pointing out that a cavity multiplies the number of atoms interacting with a light mode by the number of its mirror images. In Secs. 40.2.3, 40.2.4, and 40.2.6 we study the Hamiltonian governing the dynamics of a cavity mode interacting with a single immobile atom emphasizing the phenomenon of normal mode splitting. In Sec. 40.2.5 we simplify the equations of motion by adiabatically eliminating the internal atomic degree of freedom. Finally, in Secs. 40.2.7 and 40.2.8 we study the impact of the atomic center-of-mass degree of freedom (position and velocity) on the dynamics of the cavity fields. The discussion of backaction of the cavity fields on the atomic motion is postponed to Chp. 42.

40.2.1 Spontaneous emission in a cooperative environment

40.2.1.1 Atoms in a cooperative environment

The quantization of the electromagnetic field has been presented in Sec. 35.1.1 for the case of plane wave radiation modes. In the following, we want to generalize the treatment to arbitrary field modes characterized by mode functions $\mathbf{u}_{\mathbf{k}\lambda}(\mathbf{r})$ labeled by a wavevector and a polarization. These are classical vector functions satisfying the vector Helmholtz equation and the transversality condition,

$$[\nabla^2 + k_\lambda^2]\mathbf{u}_{\mathbf{k}\lambda}(\mathbf{r}) = 0 \qquad \text{and} \qquad \nabla\cdot\mathbf{u}_{\mathbf{k}\lambda}(\mathbf{r}) = 0\ , \tag{40.79}$$

with $k_\lambda = \omega_{\mathbf{k}\lambda}/c$ [897]. These classical functions are chosen to form an orthonormal set,

$$\int_V \mathbf{u}^*_{\mathbf{k}\lambda}(\mathbf{r})\cdot\mathbf{u}_{\mathbf{k}'\lambda'}(\mathbf{r})d^3r = \delta_{\mathbf{k}\mathbf{k}'}\delta_{\lambda,\lambda'}\ . \tag{40.80}$$

In free space, the plane wave approximation is generally good,

$$\mathbf{u}_{\mathbf{k}\lambda}^{free}(\mathbf{r}) = \frac{\vec{\epsilon}_\lambda}{\sqrt{V}} e^{\imath \mathbf{k}\cdot\mathbf{r}} \ , \tag{40.81}$$

where $\vec{\epsilon}_{\mathbf{k}\lambda}$ is a polarization vector such that $\mathbf{k}\cdot\vec{\epsilon}_{\mathbf{k}\lambda} = 0$ and V is the photon quantization volume.

Let us now rewrite the quantized transverse vector potential of the radiation field (35.7) as,

$$\boxed{\hat{\mathbf{A}}(\mathbf{r},t) = \sum_{\mathbf{k}\lambda} \sqrt{\tfrac{\hbar}{2\omega_{\mathbf{k}\lambda}\varepsilon_0}} [\mathbf{u}_{\mathbf{k}\lambda}(\mathbf{r})\hat{a}_{\mathbf{k}\lambda}(t) + \mathbf{u}^*_{\mathbf{k}\lambda}(\mathbf{r})\hat{a}^\dagger_{\mathbf{k}\lambda}(t)]} \ . \tag{40.82}$$

The quantum properties of the electric and magnetic field operators are determined by the bosonic annihilation and creation operators, $\hat{a}_{\mathbf{k}\lambda}(t)$ and $\hat{a}^\dagger_{\mathbf{k}\lambda}(t)$, respectively, with usual commutation relations: $[\hat{a}_{\mathbf{k}\lambda}(t), \hat{a}_{\mathbf{k}'\lambda'}(t)] = 0$ and $[\hat{a}_{\mathbf{k}\lambda}(t), \hat{a}^\dagger_{\mathbf{k}'\lambda'}(t)] = \delta_{\mathbf{k}\mathbf{k}'}\delta_{\lambda\lambda'}$.

For weak-coupling between the atoms and the field, one has the contributions to the Hamiltonian,

$$\boxed{\begin{aligned} \hat{H}_{atom} &= \hbar\omega_0 \hat{\sigma}^z \\ \hat{H}_{field} &= \sum_{\mathbf{k}} \hbar\omega_{\mathbf{k}} [\hat{a}^\dagger_{\mathbf{k}\lambda}(t)\hat{a}_{\mathbf{k}\lambda}(t) + \tfrac{1}{2}] \\ \hat{H}_{atom:field} &= -\imath\hbar \sum_{\mathbf{k},\lambda} (\hat{\sigma}^+ + \hat{\sigma}^-)[g_{\mathbf{k}\lambda}(\mathbf{r})\hat{a}_{\mathbf{k}\lambda} - g^*_{\mathbf{k}\lambda}(\mathbf{r})\hat{a}^\dagger_{\mathbf{k}\lambda}] \end{aligned}} \ , \tag{40.83}$$

and,

$$g_{\mathbf{k}\lambda}(\mathbf{r}) \equiv \sqrt{\frac{\omega_{\mathbf{k}}}{2\varepsilon_0\hbar}} \mathbf{d}\cdot\mathbf{u}_{\mathbf{k}\lambda}(\mathbf{r}) \tag{40.84}$$

is a complex function associated with the coupling strength between the atom and the field.

By solving the Heisenberg equations of motion for the atomic and field operators within the Born and Markov approximations (or using the procedure leading to the expression (35.234)), one obtains the spontaneous emission rate on a transition $|e\rangle \to |g\rangle$ of frequency ω_0:

$$\Gamma(\mathbf{r}) = 2\pi \sum_{\mathbf{k},\lambda} |g_{\mathbf{k}\lambda}(\mathbf{r})|^2 \delta(\omega_{\mathbf{k}} - \omega_0) \ . \tag{40.85}$$

which is the same result obtained by the Weisskopf-Wigner theory [897]. To evaluate the sum we need go to a continuous k-space via,

$$\sum_{\mathbf{k},\lambda} \longrightarrow \lim_{V\to\infty} \sum_\lambda \frac{V}{8\pi^3} \int d^3k \ . \tag{40.86}$$

Hence, in free space, inserting the mode function (40.82),

$$\begin{aligned}\Gamma(\mathbf{r}) &= \frac{\pi\omega_0}{\varepsilon_0\hbar}\sum_{\mathbf{k},\lambda}|\mathbf{d}\cdot\mathbf{u}_{\mathbf{k}\lambda}(\mathbf{r})|^2\delta(\omega_{\mathbf{k}}-\omega_0) \\ &= \frac{\hbar\omega_0}{8\pi^2\varepsilon_0\hbar^2}\lim_{V\to\infty}\sum_{\lambda}\int d^3k\ |\mathbf{d}\cdot\vec{\epsilon}_{\mathbf{k}\lambda}|^2\delta(\omega_{\mathbf{k}}-\omega_0) \\ &= \lim_{V\to\infty}\sum_{\lambda}\int\frac{|\mathbf{d}\cdot\vec{\epsilon}_{\mathbf{k}\lambda}|^2\vec{\mathcal{E}}_{\mathbf{k}}^2}{\hbar^2}2\pi\delta(\omega_{\mathbf{k}}-\omega_0)\frac{V}{8\pi^3c}k^2d\Omega_{\mathbf{k}}d\omega_{\mathbf{k}}\ .\end{aligned} \tag{40.87}$$

Plugging in the density of states for free space (22.53) and (34.23), we finally get,

$$\Gamma(\mathbf{r}) = \sum_{\lambda}\int\frac{|\mathbf{d}\cdot\vec{\epsilon}_{\mathbf{k}\lambda}|^2\vec{\mathcal{E}}_{\mathbf{k}}^2}{\hbar^2}2\pi\delta(\omega_{\mathbf{k}}-\omega_0)\rho(\omega_{\mathbf{k}},\mathbf{k})d\Omega_{\mathbf{k}}d\omega_{\mathbf{k}}\ , \tag{40.88}$$

where the density of states can now be arbitrarily shaped by the presence of boundary conditions, such as optical cavities or dielectric or metallic surfaces.

Example 240 (*Two atoms*): Let us now consider two excited atoms labeled by $q = 1, 2$, located at $\mathbf{r}_1$ and $\mathbf{r}_2$, and described by two of their eigenstates, $\{|g_q\rangle, |e_q\rangle\}$. As usual, $|g_q\rangle$ is the eigenstate with lowest energy ($E_{g_q} = -\frac{1}{2}\hbar\omega_q$) and longer lifetime, i.e. the ground state, whereas $|e_q\rangle$ is the eigenstate with highest energy ($E_{e_q} = +\frac{1}{2}\hbar\omega_q$). In presence of an external electromagnetic field, the Hamiltonian of the two atom-field system in the electric dipole approximation is,

$$\hat{H} = \sum_{q=1,2}[\hat{H}^{(q)}_{atom} + \hat{H}^{(q)}_{atom:field}] + \hat{H}_{field}\ ,$$

where $\hat{H}^{(q)}_{atom} \equiv \hbar\omega_q\hat{s}^z_q$ is the atomic Hamiltonian, with $\hat{s}^z_q \equiv \frac{1}{2}(|e_q\rangle\langle e_q| - |g_q\rangle\langle g_q|)$ being the energy operator of the q-th atom, and $\hat{H}^{(q)}_{atom:field} \equiv -\hat{\mathbf{d}}_q\cdot\hat{\vec{\mathcal{E}}}(\mathbf{r}_q)$ is the atom-field interaction Hamiltonian. The electric dipole moment operator satisfies $\langle e_q|\hat{\mathbf{d}}_q|e_q\rangle = \mathbf{0} = \langle g_q|\hat{\mathbf{d}}_q|g_q\rangle$ and has non-vanishing off-diagonal elements, i.e. the eigenstates have no permanent dipole moment. We define the dipole-moment matrix element as $\mathbf{d}_q \equiv \langle e_q|\hat{\mathbf{d}}_q|g_q\rangle$. The description of the field is identical to the case of one atom (40.81).
For weak-coupling between the atoms and the field, the interaction Hamiltonian becomes,

$$\hat{H}_{atom:field} = -\imath\hbar\sum_{\mathbf{k},\lambda}\sum_{q=1,2}(\hat{s}^+_q + \hat{s}^-_q)[g_{\mathbf{k}\lambda}(\mathbf{r}_q)\hat{a}_{\mathbf{k}\lambda} - g^*_{\mathbf{k}\lambda}(\mathbf{r}_q)\hat{a}^\dagger_{\mathbf{k}\lambda}]\ ,$$

where $\hat{s}^+_q \equiv |e_q\rangle\langle g_q|$ and $\hat{s}^-_q \equiv |g_q\rangle\langle e_q|$ are the electric dipole raising and lowering operators, respectively, satisfying the well-known commutation and anti-commutation relations: $[\hat{s}^+_q, \hat{s}^-_{q'}] = 2\hat{s}^z_q\delta_{qq'}$, $[\hat{s}^z_q, \hat{s}^\pm_{q'}] = \pm\hat{s}^\pm_q\delta_{qq'}$, and $[\hat{s}^+_q, \hat{s}^-_{q'}]_+ = 0$ with $(\hat{s}^\pm_q)^2 = 0$.
By solving the Heisenberg equations of motion for the atomic and field operators within the Born and Markov approximations, one obtains the spontaneous emission rate on a transition $|e_q\rangle \longrightarrow |g_q\rangle$ of frequency ω_q:

$$\Gamma_q = 2\pi\sum_{\mathbf{k},\lambda}|g_{\mathbf{k}\lambda}(\mathbf{r}_q)|^2\delta(\omega_{\mathbf{k}}-\omega_q) = \frac{\pi\omega_q}{\varepsilon_0\hbar}\sum_{\mathbf{k},\lambda}|\mathbf{d}_q\cdot\mathbf{u}_{\mathbf{k}\lambda}(\mathbf{r}_q)|^2\delta(\omega_{\mathbf{k}}-\omega_q)\ ,$$

which is the same result obtained by the Weisskopf-Wigner theory [897]. In addition, due to the coupling between the atoms through the vacuum field, one also has the cross-damping spontaneous emission rate:

$$\Gamma_q(\mathbf{r}_1,\mathbf{r}_2)=\Gamma_q(\mathbf{r}_2,\mathbf{r}_1)=\frac{\pi\omega_0}{\varepsilon_0\hbar}\sum_{\mathbf{k},\lambda}\Re\mathfrak{e}\ \left[\mathbf{d}_1\cdot\mathbf{u}_{\mathbf{k}\lambda}(\mathbf{r}_1)\mathbf{u}^*_{\mathbf{k}\lambda}(\mathbf{r}_2)\cdot\mathbf{d}_2^*\right]\delta(\omega_{\mathbf{k}}-\omega_q)\ ,$$

which shows explicitly the cooperative effect of the dipole-dipole interaction in the spontaneous emission rate.

40.2.1.2 Modification of the natural linewidth by cavities

The *cooperativity parameter* of a cavity is defined as the rate at which an atom emits into the volume of a cavity mode normalized to the rate at which it would scatter into free space,

$$\boxed{\Upsilon\equiv\frac{\Gamma_{cav}}{\Gamma_{free}}}\ . \tag{40.89}$$

In a cavity, spontaneous emission is strongly modified [596, 597, 598]. An atom interacting with a cavity will spontaneously emit into the cavity mode at an increased (reduced) rate, depending on whether the cavity is resonant or out of resonance. The natural width due to spontaneous decay and the line shift are calculated by integration over the coupling force between the atom and every available field mode [see (40.87)],

$$\boxed{\begin{aligned}\Gamma &= \iint\frac{|\mathbf{d}_{eg}\cdot\vec{\epsilon}_{\mathbf{k}}|^2|\vec{\mathcal{E}}_{\mathbf{k}}|^2}{\hbar^2}2\pi\delta(\omega_0-\omega_{\mathbf{k}})\rho(\omega_{\mathbf{k}},\mathbf{k})d\Omega_{\mathbf{k}}d\omega_{\mathbf{k}}\\ \Delta\omega &= \sum_i\iint\frac{|\mathbf{d}_{ei}\cdot\vec{\epsilon}_{\mathbf{k}}|^2|\vec{\mathcal{E}}_{\mathbf{k}}|^2}{\hbar^2}\frac{1}{\omega_{ei}-\omega_{\mathbf{k}}}\rho(\omega_{\mathbf{k}},\mathbf{k})d\Omega_{\mathbf{k}}d\omega_{\mathbf{k}}\end{aligned}}\ , \tag{40.90}$$

with the field amplitude per photon, $|\vec{\mathcal{E}}_{\mathbf{k}}|=\sqrt{\hbar\omega_{\mathbf{k}}/2\varepsilon_0 V}$, derived in (40.33), and the index i running over all internal atomic states. These formulas are simply applications of second-order perturbation theory (27.16) and of Fermi's golden rule (27.111) for transition probabilities both weighed with dynamic structure factor of the cavity.

We use the number of modes per unit of frequency range and per unit of solid angle in free space derived in (40.41) (ρ/V is the density of states),

$$\rho_{free}(\omega_{\mathbf{k}})=\frac{V\omega_{\mathbf{k}}^2}{(2\pi)^3c^3}\ . \tag{40.91}$$

Setting $\theta_{\mathbf{k}}$ as the angle between the atomic dipole moment and the cavity axis (which is not in place, yet, as we are still in free space), $\mathbf{d}\cdot\hat{\epsilon}_{\mathbf{k}}=d\cos\alpha_{\mathbf{k}}=d\cos(90^\circ-\theta_{\mathbf{k}})=d\sin\theta_{\mathbf{k}}$,

$$\begin{aligned}\Gamma_{free} &= \int\frac{d^2\sin^2\theta_{\mathbf{k}}}{\hbar^2}\frac{\hbar\omega_0}{2\varepsilon_0 V}2\pi\frac{V\omega_0^2}{(2\pi)^3c^3}\sin\theta d\theta d\phi\\ &= \frac{d^2k^3}{4\pi\varepsilon_0\hbar}\int_0^\pi\sin^3\theta d\theta=\frac{d^2k^3}{3\pi\varepsilon_0\hbar}\ .\end{aligned} \tag{40.92}$$

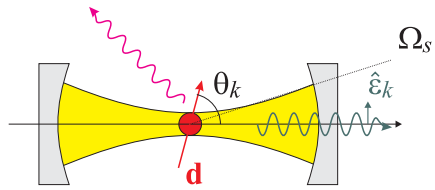

Figure 40.7: Illustration of cooperativity in a cavity. An excited atom can decay by emitting light into a cavity mode or into free space. Note that the cavity is not pumped directly by an incident laser beam.

Since the integration covers the whole solid angle of space 4π and the free space is isotropic, there is no preferred orientation, and we can perform the integration setting $\theta \equiv \theta_{\mathbf{k}}$. The result coincides with earlier calculations (34.46).

Now, we put the cavity in place, but tune it off resonance, such that no photons can be emitted into the solid angle covered by the cavity. That is, in the presence of the cavity, the solid angle of free space into which photons can be emitted is restricted. We repeat the calculation (40.92), but now we are not free to choose the axis of the coordinate system arbitrarily. Instead, we we assume that $\theta_{\mathbf{k}}(\theta,\phi) \simeq const$ over the small solid angle covered by the cavity, $\theta, \phi \in \Omega_{cav}$,

$$\begin{aligned}\Gamma_{free\notin cav} &= \int_{\hat{\mathbf{e}}_k \notin cav} \frac{d^2 \sin^2\theta_k}{\hbar^2} \frac{\hbar\omega_0}{2\varepsilon_0 V} 2\pi \frac{V\omega_0^2}{(2\pi)^3 c^3} \sin\theta d\theta d\phi \\ &\simeq \Gamma_{free} - \frac{d^2 k^3 \sin^2\theta_{\mathbf{k}}}{8\pi^2\varepsilon_0\hbar} \int_{\hat{\mathbf{e}}_k \in cav} \sin\theta d\theta d\phi = \Gamma_{free}\left(1 - \frac{3}{8\pi}\Omega_{cav}\sin^2\theta_{\mathbf{k}}\right) .\end{aligned} \tag{40.93}$$

Finally, we study the situation, when the cavity is in place but now tuned on resonance. Then the density of states in the photon emission directions $\mathbf{k} \in$ cavity is modulated by the Airy function (40.42),

$$\rho_{cav}(\omega_{\mathbf{k}}, \mathbf{k}) = \rho_{free}(\omega_{\mathbf{k}}) \mathcal{L}(\omega_{\mathbf{k}}) . \tag{40.94}$$

That is, photons can be emitted into the cavity mode with increased probability. Once again we repeat the calculation (40.92), but now inserting the density of states of the cavity,

$$\begin{aligned}\Gamma_{cav} &= \int_{\hat{\mathbf{e}}_k \in cav} \frac{d^2 \sin^2\theta_{\mathbf{k}}}{\hbar^2} \frac{\hbar\omega_0}{2\varepsilon_0 V} 2\pi \mathcal{L}(\omega_0) \frac{V\omega_0^2}{(2\pi)^3 c^3} \sin\theta d\theta d\phi \\ &\simeq \frac{d^2 k^3 \sin^2\theta_{\mathbf{k}}}{8\pi^2\varepsilon_0\hbar} \mathcal{L}(\omega_0) \int_{\hat{\mathbf{e}}_k \in cav} \sin\theta d\theta d\phi = \Gamma_{free}\mathcal{L}(\omega_0) \frac{3}{8\pi}\Omega_{cav}\sin^2\theta_{\mathbf{k}} ,\end{aligned} \tag{40.95}$$

where, in the last step, we substituted the free space decay rate (40.92). An analogous calculation for the *cooperative Lamb shift* $\Delta\omega_{cav}$ is left to the Exc. 40.2.9.1:

$$\boxed{\begin{aligned}\Gamma_{cav} &= \Gamma_{free} \tfrac{3}{8\pi}\Omega_{cav}\sin^2\theta_{\mathbf{k}} \mathcal{L}(\omega_0) \\ \Delta\omega_{cav} &= \Gamma_{free} \tfrac{3}{32\pi}\Omega_{cav}\sin^2\theta_{\mathbf{k}} \tfrac{\mathcal{L}'(\omega_0)}{\mathcal{L}(\omega_0)} 2\delta_{fsr}\end{aligned}} . \tag{40.96}$$

The quantities Γ_{cav} and $\Gamma_{free\in cav}$ are scattering rates into complementary solid angles. Now, the total spontaneous emission rate, which determines the lifetime of the radiating excited state and the spectral width of the transition is simply the sum of the partial scattering rates,

$$\begin{aligned}\Gamma &= \Gamma_{free\notin cav} + \Gamma_{cav} \\ &= \Gamma_{free}\left(1-\tfrac{3}{8\pi}\Omega_{cav}\right)\sin^2\theta_{\mathbf{k}} + \Gamma_{free}\mathcal{L}(\omega_0)\tfrac{3}{8\pi}\Omega_{cav}\sin^2\theta_{\mathbf{k}} \\ &= \Gamma_{free}\left[1+\left(\mathcal{L}(\omega_0)-1\right)\tfrac{3}{8\pi}\Omega_{cav}\right]\sin^2\theta_{\mathbf{k}}\ .\end{aligned} \tag{40.97}$$

Assuming for simplicity, $\theta_{\mathbf{k}} = \pi/2$, we find the extremes of the spontaneous emission rate, Γ_{enh} and Γ_{inh}, when the cavity is on or off resonance. With a resonant high finesse cavity the emission is obtained via $kL \to 0$,

$$\Gamma_{enh} = \Gamma_{free}\left[1+\left(\sqrt{1+\left(\tfrac{2F}{\pi}\right)^2}-1\right)\tfrac{3}{8\pi}\Omega_{cav}\right] \simeq \Gamma_{free}\left(1+\tfrac{3}{4\pi^2}F\Omega_{cav}\right)\ . \tag{40.98}$$

assuming high finesse, $F \gg 1$. With a non-resonant cavity, the emission is obtained via $kL \to \pi/2$,

$$\Gamma_{inh} = \Gamma_{free}\left[1+\left(\frac{1}{\sqrt{1+\left(\tfrac{2F}{\pi}\right)^2}}-1\right)\tfrac{3}{8\pi}\Omega_{cav}\right] \simeq \Gamma_{free}\left(1-\tfrac{3}{8\pi}\Omega_{cav}\right)\ . \tag{40.99}$$

For a small solid angle, we can expect a big increase of the scattering into the cavity, but without noticeable inhibition of the total decay, $\Gamma_{inh} \simeq \Gamma_{free}$.

If the atoms are saturated by an incident laser, they scatter light into the cavity at a rate (apart from a factor $\frac{1}{2}$),

$$\Gamma_{cav} = \Gamma_{free}\mathcal{L}(\omega_0)\tfrac{3}{8\pi}\Omega_{cav}\ . \tag{40.100}$$

Without cavity the emission into the same solid angle is obtained via $F \to 0$,

$$\Gamma_{free\in cav} = \Gamma_{free}\tfrac{3}{8\pi}\Omega_{cav}\ . \tag{40.101}$$

The scattering will fill the cavity with photons, until the leakage equalizes the pumping. When the balance is reached, Γ_{cav} will also be the rate at which photons are emitted by the cavity mode. We calculate an example in Exc. 40.2.9.2.

40.2.1.3 Purcell factor for confocal and concentric cavities

Using the solid angle of a confocal cavity (40.48), the cooperativity parameter is,

$$\Upsilon \simeq \frac{3F}{4\pi^2}\Omega_{cav} = \frac{3F}{4\pi^2}\frac{8\pi b^2}{L^2}\ , \tag{40.102}$$

where b is the clear aperture of the cavity mirrors. That is,

$$\boxed{\Upsilon = \frac{F}{\pi}\frac{6b^2}{L^2}\ .} \tag{40.103}$$

40.2.1.4 Purcell factor for the TEM_{00} cavity mode

With the solid angle (40.54) calculated for a this TEM_{00} cavity mode we calculate the *cooperativity parameter*,

$$\begin{aligned}\Upsilon \equiv \frac{\Gamma_{cav}}{\Gamma_{free}} &= \mathcal{L}(\omega_0)\tfrac{3}{8\pi}\Omega_{cav} = \sqrt{1+\left(\frac{2F}{\pi}\right)^2}\,\frac{3}{8\pi}\Omega_{cav} \\ &\simeq \frac{3F}{4\pi^2}\Omega_{cav} = \frac{\Gamma_{enh}}{\Gamma_{free}} - 1 = \frac{3F}{4\pi^2}\frac{8\pi}{k^2 w_0^2}\ ,\end{aligned} \tag{40.104}$$

that is,

$$\boxed{\Upsilon = \frac{F}{\pi}\frac{6}{k^2 w_0^2}}\ , \tag{40.105}$$

which is also called *Purcell factor*.

Now, exploiting the relationships (40.54), (40.105), and (40.27),

$$\Omega_{cav} = \frac{8\pi}{k^2 w_0^2} \quad , \quad \Upsilon = \frac{F}{\pi}\frac{6}{k^2 w_0^2} \quad , \quad \frac{F}{\pi} = \frac{\delta_{fsr}}{\kappa}\ , \tag{40.106}$$

and defining a new quantity,

$$g^2 = \Upsilon\kappa\Gamma_{free}\ , \tag{40.107}$$

which we will call the atom-field coupling strength, we may rewrite the prefactor $\Gamma_{free}\frac{3}{8\pi}\Omega_{cav}$ for the case of Gaussian cavity modes,

$$\Gamma_{free}\frac{3}{8\pi}\Omega_{cav} = \frac{g^2}{2\delta_{fsr}}\ . \tag{40.108}$$

Close to a cavity resonance, $kL = \omega/2\delta_{fsr} = (\omega_c + \Delta_c)/2\delta_{fsr} = 2\pi N + \Delta_c/2\delta_{fsr}$, the sine appearing in the Airy function (40.42) may be expanded $\sin kL = \sin \Delta_c/2\delta_{fsr} \simeq \Delta_c/2\delta_{fsr}$. Furthermore, assuming a high finesse, $F \gg 1$, the Airy function simplifies to,

$$\mathcal{L}(\omega_0) = \frac{\sqrt{1+(2F/\pi)^2}}{1+(2F/\pi)^2\sin^2\frac{\omega}{2\delta_{fsr}}} \simeq \frac{2F/\pi}{1+\Delta_a^2/\kappa^2}\ . \tag{40.109}$$

Inserting this into the formulae (40.96), where we set $\theta_{\mathbf{k}} = \frac{\pi}{2}$,

$$\boxed{\begin{aligned}\Gamma_{cav} &\simeq \tfrac{g^2\kappa}{\Delta_c^2+\kappa^2} \\ \Delta\omega_{cav} &\simeq \tfrac{-2g^2\Delta_c}{\Delta_c^2+\kappa^2}\end{aligned}}\ . \tag{40.110}$$

Obviously, the atom-field coupling strength g plays a central role in the modification of the emission spectra of atoms interaction with cavities. Therefore, we will have to study this quantity more deeply in the next sections.

Example 241 (*Cooperativity of non-degenerate and confocal cavities*): For example, for a non-degenerate linear cavity with finesse $F = 110000$ and waist $w_0 = 50\,\mu\mathrm{m}$ at 689 nm, the cooperativity is relatively weak, $\Upsilon \simeq 1$. Still, at this

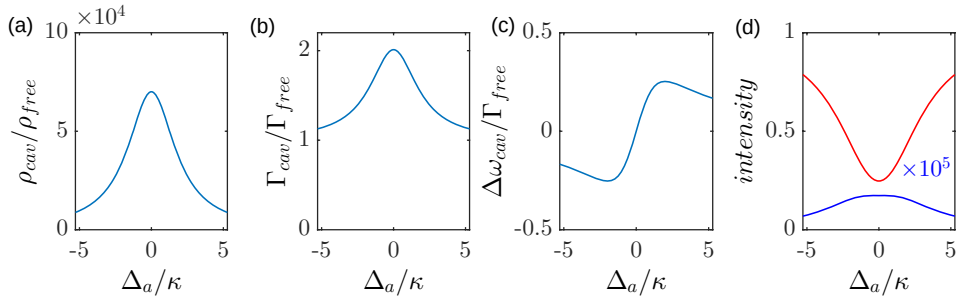

Figure 40.8: (code) Spontaneous emission on the strontium atom cooling transition ($\lambda = 689\,\text{nm}$, $\Gamma = (2\pi)\ 7.6\,\text{kHz}$) in a $L = 3.6\,\text{cm}$ long cavity with $F = 110000$ and $w_0 = 50\,\mu\text{m}$. (a) Cooperativity $\mathcal{L}(\omega)$ from Eq. (40.42) as a function of the detuning of the cavity. (b) Linewidth Γ_{cav} from (40.96)(ii) and (c) frequency shift of the strontium transition from Eq. (40.96)(ii). (d) Spontaneous emission into the cavity (blue) and into the open space (red).

cooperativity, half of the spontaneously emitted photons go into a tiny solid angle represented by the cavity. Confocal or concentric cavities may present more favorable geometries [596, 597, 598]. With $N_0 = 10^4$ saturated strontium atoms, the light power scattered into the cavity is $P_j = 20\,\text{fW}$. Estimation the cavity transmission by $T \simeq \pi/F$, we expect that a number of $T\frac{P_{cav}}{\hbar\omega} = 10^7\,\text{s}^{-1}$ photons can be detected by a photodetector recording the photon number leaking out of the cavity.

40.2.2 Characterization of the atom-field coupling

In Sec. 40.1.3 we started introducing a number of quantities characterizing empty cavities. We will now pursue this task including their interaction with atoms. In particular, we will introduce three important quantities allowing us to measure the degree of quantization of the system: the cooperativity Υ, the saturation parameter s, and the cavity resolution r.

40.2.2.1 The atomic dipole moment

As usual, the interaction strength of an atom with a light field is measured by the atom-field coupling constant, which is precisely HALF the single photon Rabi frequency. Using relationships derived in Sec. 40.1.3 and the expression (34.41) for the atomic dipole moment d, we find,

$$g \equiv \frac{d\mathcal{E}_1(0)}{\hbar} = \sqrt{\frac{3\pi\Gamma\omega}{2k^3V_m}} = \sqrt{\frac{3\Gamma\delta_{fsr}}{k^2w^2}}\ , \tag{40.111}$$

where $\mathcal{E}_1(0)$ the electric field produced by a single photon inside the cavity mode volume V_m calculated in (40.30) and Γ is the spontaneous decay rate. See also (watch talk).

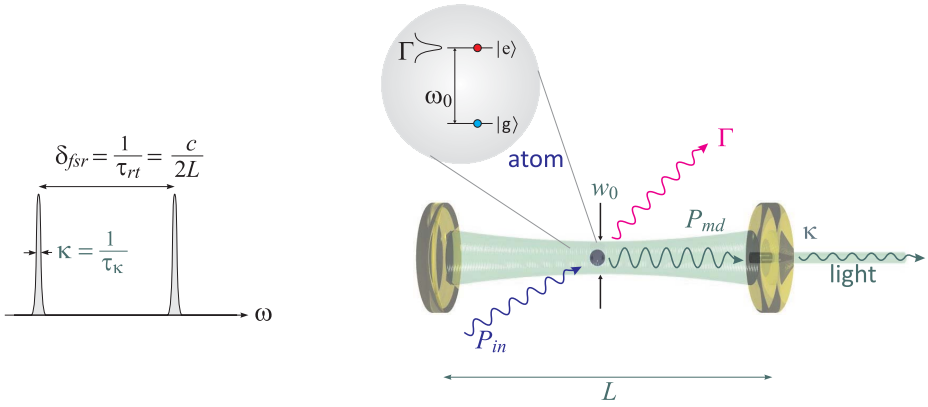

Figure 40.9: Relevant parameters for an atom interacting with a cavity.

40.2.2.2 Single atom reflection coefficient

Based on the complex atomic polarizability (18.122),

$$\frac{\alpha_{pol}}{\varepsilon_0} \simeq \frac{6\pi}{k^3} \frac{-1}{\imath + 2\Delta/\Gamma} \ , \tag{40.112}$$

the *single atom reflection coefficient* is defined as,

$$\beta_\Delta = \frac{k}{\pi w^2} \left| \frac{\mathfrak{Re}\ \alpha_{pol}}{\varepsilon_0} \right| = \frac{6}{k^2 w^2} \frac{2\Gamma|\Delta_a|}{4\Delta_a^2 + \Gamma} \overset{|\Delta| \gg \Gamma}{\longrightarrow} \frac{6}{k^2 w^2} \frac{\Gamma}{2|\Delta_a|} \ , \tag{40.113}$$

where $\Delta_a = \omega - \omega_0$. The resonant reflection coefficient can be interpreted in terms of a phase shift that depends on the matching between the resonant optical cross-section of the atom, $\sigma_0 = 3\lambda^2/2\pi$, and the cross section of the optical mode,

$$\beta_0 = \frac{\sigma_0}{\pi w^2} = \frac{6}{k^2 w^2} = \frac{2g^2}{\delta_{fsr}\Gamma} \ . \tag{40.114}$$

The total reflection coefficient is increased by the number of atoms N and the number of photon round trips F in the cavity, which gives out of resonance,

$$NF\beta_\Delta \simeq NF \frac{6}{k^2 w^2} \frac{\Gamma}{2\Delta_a} = NF \frac{g^2}{\Delta_a} \frac{kV}{\omega \pi w^2} = NU_0 \frac{L}{c} F = \frac{NU_0}{\kappa} \ , \tag{40.115}$$

where we introduced the *light-shift* produced by a single off-resonant photon and the Rayleigh scattering rate produced by a single photon,

$$U_0 \simeq \frac{g^2}{\Delta_a} \qquad \text{and} \qquad \gamma_0 \simeq \frac{g^2 \Gamma}{\Delta_a^2} \ . \tag{40.116}$$

Using the dipole moment $d = \sqrt{3\pi\varepsilon_0 \hbar \Gamma / k^3}$ and defining the electric field amplitude per photon $\mathcal{E}_1$ by the photon number n, the power P, and the intensity

$I = \varepsilon_0 c n_{ph} \mathcal{E}_1^2 = 2P/\pi w_0^2$, we calculate for the single-photon Rabi frequency (or atom-field coupling strength),

$$g = \frac{d\mathcal{E}_1}{\hbar} = \sqrt{\frac{1}{\hbar^2}\frac{3\pi\varepsilon_0\hbar\Gamma}{k^3}\frac{I}{\varepsilon_0 c n_{ph}}} = \sqrt{\frac{1}{\hbar^2}\frac{3\pi\varepsilon_0\hbar\Gamma}{k^3}\frac{1}{\varepsilon_0 c n_{ph}}\frac{2P}{\pi w_0^2}} = \sqrt{\frac{6}{k^2 w_0^2}\Gamma\frac{P}{n_{ph}\hbar\omega}} \ . \tag{40.117}$$

The single-photon light shift (or atom-atom coupling strength) is,

$$U_0 = \frac{g^2}{|\Delta_a|} = \frac{6}{k^2 w_0^2}\frac{\Gamma}{|\Delta_a|}\frac{P}{n_{ph}\hbar\omega} = \beta_\Delta \frac{P}{n_{ph}\hbar\omega} \ , \tag{40.118}$$

and the single-photon Rayleigh scattering rate,

$$\gamma_0 = \frac{g^2\Gamma}{\Delta_a^2} = \frac{6}{k^2 w_0^2}\frac{\Gamma^2}{\Delta_a^2}\frac{P}{n_{ph}\hbar\omega} \ . \tag{40.119}$$

In a cavity the flux $\delta_{fsr} = P/n_{ph}\hbar\omega$ is just the photon round trip rate (or free spectral range). $1/\delta_{fsr}$ is the time a photon interacts with an atom. In free space, this does not make sense to me, because I don't know how define the mode volume. I can however consider the interaction of a photon with an extended sample of length L. In this case, a photon interacts with the sample for the time L/c, so that,

$$U_0 = \frac{g^2}{|\Delta_a|} = \frac{6}{k^2 w_0^2}\frac{\Gamma}{|\Delta_a|}\frac{c}{L} = \beta_\Delta \frac{c}{L} \ , \tag{40.120}$$

and

$$\gamma_0 = \frac{g^2\Gamma}{\Delta_a^2} = \frac{6}{k^2 w_0^2}\frac{\Gamma^2}{\Delta_a^2}\frac{c}{L} \ . \tag{40.121}$$

This means, we can use the CARL equations derived for a ring cavity by just substituting $\kappa = \delta_{fsr} = c/L$, where L is now not the cavity but the sample length.

40.2.2.3 Optical density

Lambert-Beer's law relates the amplitude of the field transmitted to the incident (see also Eq. (43.140)),

$$\frac{\mathcal{E}_t}{\mathcal{E}_0} = \exp\left[\imath\sigma(\Delta_a)\left(\frac{\imath}{2} - \frac{\Delta_a}{\Gamma}\right)\int_{-\infty}^{\infty} n(\mathbf{r})dz\right] = e^{-b/2}e^{\imath\varphi} \ . \tag{40.122}$$

I.e. the field is shifted by an amount φ and absorbed by an amount b. The exponent (called optical density) can be rewritten, if we assume a number of N atoms homogeneously distributed over a cylinder with length L and radius $\bar{r} = w_0$,

$$\begin{aligned} OD &= \imath\sigma(\Delta_a)\left(\frac{\imath}{2} - \frac{\Delta_a}{\Gamma}\right)\int_{-\infty}^{\infty} n(\mathbf{r})dz = \sigma_0\frac{\Gamma^2}{\Delta_a^2}\left(-\frac{1}{2} - \frac{\imath\Delta_a}{\Gamma}\right)\int_0^L \frac{N}{\pi\bar{r}^2 L}dz \\ &= \sigma_0\frac{\Gamma^2}{\Delta_a^2}\left(-\frac{1}{2} - \frac{\imath\Delta_a}{\Gamma}\right)\frac{N}{\pi w_0^2} = \frac{6N}{k^2 w_0^2}\frac{\Gamma^2}{\Delta_a^2}\left(-\frac{1}{2} - \frac{\imath\Delta_a}{\Gamma}\right) \\ &= \frac{6N}{k^2 w_0^2}\left(-\frac{1}{2}\frac{\Gamma^2}{\Delta_a^2} - \frac{\imath\Gamma}{\Delta_a}\right) = N\frac{L}{c}(-\gamma_0 - \imath U_0) \ . \end{aligned} \tag{40.123}$$

Hence, the parameters $N\gamma_0$ and NU_0 are nothing else that the optical density per photon round trip time $\delta_{fsr} = c/L$,

$$\boxed{OD = \frac{-N(\gamma_0 + \imath U_0)}{\delta_{fsr}}} \,. \tag{40.124}$$

40.2.2.4 Collective cooperativity

The frequency shift accumulated during a round trip in the cavity, $\delta_{fsr}\beta_0$, becomes noticeable, when it exceeds the linewidth of the cavity κ. From this condition, we obtain the optical depth for a single passage through the atomic sample multiplied by the finesse of the cavity, which is precisely the *cooperativity parameter*,

$$\boxed{\Upsilon \equiv \frac{\delta_{fsr}\beta_0}{\kappa} = \frac{F}{\pi}\frac{6}{k^2 w^2} = \frac{2g^2}{\kappa\Gamma}} \,. \tag{40.125}$$

The sensitivity to the atom number can be measured in terms of a *critical atom number* N_{crt}, which the system can resolve,

$$N_{crt} = \frac{4\pi}{F\beta_0} = \frac{1}{\Upsilon} \,. \tag{40.126}$$

While the strong coupling regime of the CQED requires $\Upsilon > 1$ with a single atom, collective cooperativity is reached with N atoms if $N\Upsilon > 1$ [193, 285]. In this case, the atomic ensemble couples to the mode like a single 'super-atom', the coupling force being magnified to $g_N = g_1\sqrt{N}$. We have already obtained this result within the Jaynes-Cummings model for two indistinguishable atoms coupling to the same light mode and forming a *Dicke state* (see Sec. 41.1.1).

40.2.2.5 Saturation parameter in cavities

The *saturation parameter* for a single photon is given by,

$$\boxed{s = \frac{2\Omega_1^2}{\Gamma^2} = \frac{8g^2}{\Gamma^2}} \,, \tag{40.127}$$

where Ω_1 is the single photon Rabi frequency. Therefore, the number of photons needed to saturate an atomic transition is,

$$n_{sat} = \frac{1}{s} \,. \tag{40.128}$$

We see, that there is a *symmetry* between Υ and s, that is, between N_{crt} and n_{sat}. The regime $N\Upsilon > 1$ denotes the collective behavior of N atoms in the same way as $n_{sat} > 1$ indicates saturation. While Υ depends only on the phase matching between the atomic antenna and the cavity, s also depends on the cavity mode volume and the natural decay rate.

40.2.2.6 Cavity resolution parameter

Comparing the photonic recoil, which is given by,

$$\omega_{rec} = \frac{\hbar k^2}{2m} \ , \tag{40.129}$$

with the resolution power of a cavity κ, we can define the *resolution parameter*,

$$\boxed{r \equiv \frac{\omega_{rec}}{\kappa}} \ . \tag{40.130}$$

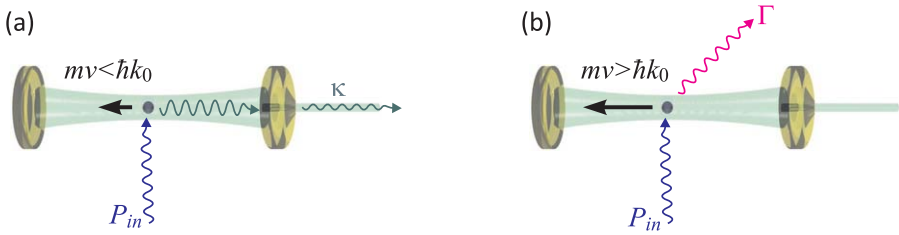

Figure 40.10: (a) If the recoil-induced Doppler shift of the atom moving along the cavity axis is smaller than the cavity linewidth, the light is preferentially scattered into the cavity mode. (b) Else it is scattered outside the mode.

With the three parameters defined in Eqs. (40.125), (40.127), and (40.130) we are able to measure the degree of quantization of the degrees of freedom involved in the matter-light interaction in a cavity. The cooperativity Υ measures the resolvability of single atoms in the atomic cloud, which depends on the phase matching between the atomic antenna (i.e. its optical cross section) and the focus of the optical mode. The saturation parameter s measures the resolvability of single photons in the cavity. And the cavity resolution parameter r measures the resolvability of the Doppler-shift due to the atomic center-of-mass motion caused by the absorption of a single photon. If one wants to operate in an environment, where all degrees of freedom involved in the atom-light interactions are fully quantized, the atoms need to be placed into a cavity whose characteristic quantities are all large, $\Upsilon, s, r \gg 1$.

In Exc. 40.2.9.3 we compare the coupling force and other characteristic parameters for various combinations of atomic species and optical cavities. In Exc. 40.2.9.4 we calculate the number of photons in a cavity pumped in or out of resonance.

40.2.3 Jaynes-Cummings model for one or two radiation modes

To study the dynamics of the coupled atom-cavity system, we consider the Jaynes-Cummings Hamiltonian (35.108) (or (40.83)), for a more concrete situation. That is, we allow for optical pumping and decay of internal states with the rates R and Γ, respectively, and we allow for inhomogeneous (however, mostly one-dimensional) mode functions $g(z) = ge^{\imath kz}$. On the other hand, we stick to a single atom (or N uncorrelated atoms), we disregard polarization and multi-mode excitation, and we will explicitly consider and compare two well distinct cases, linear and ring cavities.

40.2.3.1 Linear and ring cavities

From the Heisenberg equations with the Hamiltonian (40.83),

$$\boxed{\begin{aligned} \hat{H}_{atom} &= -\Delta_a \hat{\sigma}^+ \hat{\sigma}^- \\ \hat{H}_{cav} &= -\Delta_c \hat{a}^\dagger \hat{a} \\ \hat{H}_{atom:cav} &= g(z)\hat{a}^\dagger \hat{\sigma}^- + h.c. \\ \hat{H}_{laser:cav} &= -\imath\eta(\hat{a} - \hat{a}^\dagger) \end{aligned}} \; . \tag{40.131}$$

The Hamiltonian for a single motionless atom interacting with two cavity modes $|+\rangle$ and $|-\rangle$ (we may, for instance, consider the counterpropagating modes of a ring cavity) reads,

$$\boxed{\begin{aligned} \hat{H}_{atom} &= -\Delta_a \hat{\sigma}^+ \hat{\sigma}^- \\ \hat{H}_{cav} &= -\Delta_+ \hat{a}_+^\dagger \hat{a}_+ - \Delta_- \hat{a}_-^\dagger \hat{a}_- \\ \hat{H}_{atom:cav} &= g(z)\hat{a}_+^\dagger \hat{\sigma}^- + h.c. + g(z)\hat{a}_-^\dagger \hat{\sigma}^- + h.c. \\ \hat{H}_{laser:cav} &= -\imath\eta_+(\hat{a}_+ - \hat{a}_+^\dagger) - \imath\eta_-(\hat{a}_- - \hat{a}_-^\dagger) \end{aligned}} \; . \tag{40.132}$$

40.2.3.2 Time-evolution of an atom in a ring cavity

The coupling of the atom to the cavities $g(z)$ will, in general, depend on the atomic position. For simplicity let us, however, consider uniform and identical coupling, $g_+(z) = g_-(z) = g$, and furthermore assume that both cavities be on resonance, $\Delta_+ = \Delta_- = 0$. Finally, neglecting spontaneous emission and pumping, the total number of photons is conserved. With $\Delta_a = \omega - \omega_a$ we get,

$$\hat{H} = \omega \hat{a}_+^\dagger \hat{a}_+ + \omega \hat{a}_-^\dagger \hat{a}_- + \omega_0(\hat{\sigma}^+\hat{\sigma} - \tfrac{1}{2}) + g\hat{a}_+^\dagger \hat{\sigma}^- + g\hat{a}_-^\dagger \hat{\sigma}^- + h.c. \; . \tag{40.133}$$

Expanding the operators $\hat{a}_\pm = \sum_{n_\pm} |n_\pm - 1\rangle\langle n_\pm|$ and $\hat{\sigma}^- = |1\rangle\langle 2|$ we can, expand the state of the system like,

$$|\psi(t)\rangle = \sum_{k=0}^{n} c_{j,n_+,n_-} |j, n_+, n_-\rangle \; . \tag{40.134}$$

Alternatively, in analogy with Sec. 35.4.2, we may organize the Hilbert space in orthogonal subspaces, $\hat{H} = \bigoplus_n \hat{H}_n$, each one having $N \equiv j + n_+ + n_-$ energy units distributed over the atomic excitation state $j = 0, 1$ and the numbers of photons $n_\pm$ in each mode. Hence, every subspace is of dimension $2N + 1$. In this dressed states picture, introducing the photon imbalance $D \equiv n_+ - n_- = -N, ..., N$, we may expand the coupled state like,

$$\boxed{|\psi(t)\rangle = \sum_{N=0}^{\infty} \sum_{D=-N}^{N} \tilde{c}_{N,D} |N, D\rangle} \; . \tag{40.135}$$

Obviously, the set of three quantum numbers $\{j, n_+, n_-\}$ is equivalent to the set of two quantum numbers $\{N, D\}$ and can be recovered by,

$$j = 1 + (-1)^{N+D-1} \quad , \quad n_\pm = \tfrac{1}{2}(N \pm D - j) \ . \tag{40.136}$$

Hence, states with odd $N + D$ are excited atomic states, and states with even $N + D$ are ground states. We may now write down the Hamiltonian,

$$\hat{H}_N = (N - \tfrac{1}{2})\omega \mathbb{I}_{2N+1} + \tag{40.137}$$
$$+ \frac{1}{2} \begin{pmatrix} \Delta & g_+\sqrt{N} & & & & & & \\ g_+\sqrt{N} & -\Delta & g_-\sqrt{1} & & & & & \\ & g_-\sqrt{1} & \Delta & g_+\sqrt{N-1} & & & & \\ & & g_+\sqrt{N-1} & \ddots & g_-\sqrt{N-1} & & & \\ & & & g_-\sqrt{N-1} & \Delta & g_+\sqrt{1} & & \\ & & & & g_+\sqrt{1} & -\Delta & g_-\sqrt{N} & \\ & & & & & g_-\sqrt{N} & \Delta & \end{pmatrix} .$$

The subscripts of the coupling constants $g_+ = g_-$ are there only to clarify to which mode the photon belongs. Very far from resonance, where the interaction is dispersive, we may treat the light field perturbatively, as shown in (35.130),

$$\hat{H}_N = (N - \tfrac{1}{2})\omega \mathbb{I}_{2N+1} + \tag{40.138}$$
$$+ \begin{pmatrix} \frac{\Delta}{2} + \frac{Ng_+^2 + 0g_-^2}{4\Delta} & & & & \\ & -\frac{\Delta}{2} - \frac{Ng_+^2 + 1g_-^2}{4\Delta} & & & \\ & & \frac{\Delta}{2} + \frac{(N-1)g_+^2 + 1g_-^2}{4\Delta} & & \\ & & & -\frac{\Delta}{2} - \frac{(N-1)g_+^2 + 2g_-^2}{4\Delta} & \\ & & & & \ddots \end{pmatrix} ,$$

or with $g_+ = g_-$,

$$(\hat{H}_N)_{DD'} = \left[\left(N + \frac{1}{2} \right) \omega - \frac{1}{2} \frac{g^2}{4\Delta} + (-1)^{N+D} \left(\frac{\Delta}{2} + \left(N + \frac{1}{2} \right) \frac{g^2}{4\Delta} \right) \right] \delta_{DD'} \ . \tag{40.139}$$

If only the upper level of the atom interacts with both light fields, all terms with negative light shift disappear,

$$(\hat{H}_N)_{DD'} = \left[\left(N + \frac{1}{2} \right) \omega + \frac{1}{2} \frac{Ng^2}{4\Delta} + (-1)^{N+D} \left(\frac{\Delta}{2} + \frac{N}{2} \frac{g^2}{4\Delta} \right) \right] \delta_{DD'} \ . \tag{40.140}$$

As shown in Sec. 35.4.2, we propagate the evolution of the coupled state via $|\psi(t)\rangle = e^{-\imath \hat{H} t} |\psi(0)\rangle$. As the initial condition we may choose the atom to be in its ground state and the two field modes in uncorrelated Glauber states,

$$c_{j,n_+,n_-} = \langle j, n_+, n_- | \psi \rangle = e^{-|\alpha_+|^2/2 - |\alpha_-|^2/2} \frac{\alpha_+^{n_+} \alpha_-^{n_-}}{\sqrt{n_+! n_-!}} \delta_{j,0} \tag{40.141}$$
$$= \tilde{c}_{N,\delta} = e^{-|\alpha_+|^2/2 - |\alpha_-|^2/2} \frac{\alpha_+^{(N+\delta-j)/2} \alpha_-^{(N-\delta-j)/2}}{\sqrt{(\frac{N+\delta-j}{2})! (\frac{N-\delta-j}{2})!}} \delta_{1+(-1)^{N+\delta-1},0} \ .$$

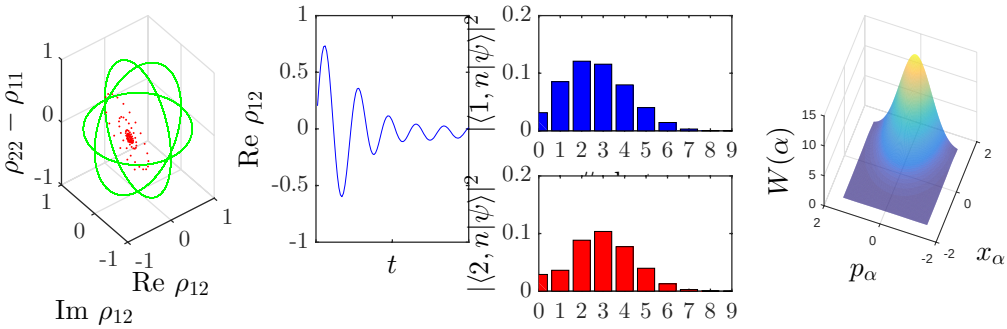

Figure 40.11: (code) Evolution of the coupled atom-ring cavity system. (a) Bloch vector, (b) photon distributions, and (c) Husimi function.

The observables of interest are the atomic Bloch vector (34.163), whose components are obtained from,

$$\rho_{ij} = \langle i|\mathrm{Tr}_{n_+,n_-}\hat{\rho}|j\rangle = \sum_{n_+,n_-}\langle i,n_+,n_-|\psi\rangle\langle\psi|j,n_+,n_-\rangle \tag{40.142}$$
$$= \sum_{n_+,n_-} c^*_{i,n_+,n_-}c_{j,n_+,n_-} = \sum_{n_+,n_-}\tilde{c}^*_{n_++n_-+i,n_+-n_-}\tilde{c}_{n_++n_-+j,n_+-n_-} \ ,$$

the photon statistics in each mode,

$$p_{n_+} = \langle n_+|\mathrm{Tr}_{i,n_-}\hat{\rho}|n_+\rangle = \sum_{j,n_-}\langle j,n_+,n_-|\psi\rangle\langle\psi|j,n_+,n_-\rangle \tag{40.143}$$
$$= \sum_{j,n_-}|c_{j,n_+,n_-}|^2 = \sum_{j,n_-}|\tilde{c}_{n_++n_-+j,n_+-n_-}|^2 \ ,$$

and analogously for p_{n_-}, and the field distribution functions, such as the Husimi function,

$$\pi Q_+(\alpha) \equiv \langle\alpha_+|\mathrm{Tr}_{\ i,n-}\hat{\rho}|\alpha_+\rangle \tag{40.144}$$
$$= e^{-|\alpha_+|^2}\sum_{n_-}\left(\left|\sum_{n_+}c_{1,n_+,n_-}\frac{\alpha^n}{\sqrt{n!}}\right|^2 + \left|\sum_{n_+}c_{2,n_+,n_-}\frac{\alpha^n}{\sqrt{n!}}\right|^2\right) \ ,$$

and analogously for $Q_-(\alpha)$, or the Wigner functions $W_\pm(\alpha)$ from the coefficients $\tilde{c}_{j,n_+,n_-}$, respectively, $\tilde{c}_{N,\delta}$, as shown in Secs. 35.2.2 and 35.4.3.

40.2.4 Normal-mode splitting in linear and ring cavities

The Jaynes-Cummings model introduced in Sec. 35.4 represents an idealized model of the interaction of a single cavity mode with a single atom. In this section we reconsider this model taking into account the facts that the coupling strength may vary in space

(via the introduction of mode functions) and that the cavity may interact with a reservoir (via the introduction of couplings to pump fields and losses.

We will also study the phenomenon of *normal mode splitting*, which is one of the most direct witnesses of an ongoing atom-cavity interaction (see the vacuum Rabi splitting discussed in Exc. 35.4.5.4).

40.2.4.1 Linear cavities

The starting point is the full Jaynes-Cummings Hamiltonian within the RWA (40.131) for an atom interacting with one mode of a linear optical cavity,

$$\boxed{\hat{H}_{JC} = -\Delta_a \hat{\sigma}^+\hat{\sigma}^- - \Delta_c \hat{a}^\dagger \hat{a} + g \sin kz(\hat{a}^\dagger\hat{\sigma}^- + \hat{a}\hat{\sigma}^+) - \imath\eta(\hat{a} - \hat{a}^\dagger)} \,. \tag{40.145}$$

For linear cavities normal mode splitting is derived in Exc. 40.2.9.5, where we compare the solution obtained by full numerical integration of the Jaynes-Cummings Hamiltonian (40.131) with an analytical approximation obtained in the weak excitation limit $g|\alpha|^2 \ll \Gamma, \Delta_a$ [2],

$$\alpha \simeq \frac{\eta}{\kappa - \imath\Delta_c + \frac{Ng^2}{\Gamma - \imath\Delta_a}} = \frac{\eta}{\kappa + N\gamma_0 + \imath(NU_0 - \Delta_c)} \,. \tag{40.146}$$

The solution coincides with one obtained for a system, where the atomic degree of freedom is adiabatically eliminated atom (see Sec. 40.2.5).

40.2.4.2 Ring cavities

The starting point is the full Jaynes-Cummings Hamiltonian within the RWA (40.132) for an atom interacting with two modes of an optical cavity. For two counter-propagating modes of a ring cavity it reads,

$$\boxed{\hat{H}_{JC} = -\Delta_a \hat{\sigma}^+\hat{\sigma}^- - \sum_{\pm} \Delta_c \hat{a}_\pm^\dagger \hat{a}_\pm + g(\hat{a}_\pm^\dagger \hat{\sigma}^- e^{\mp\imath kz} + \hat{a}_\pm \hat{\sigma}^+ e^{\pm\imath kz}) - \imath\eta_\pm(\hat{a}_\pm - \hat{a}_\pm^\dagger)} \,. \tag{40.147}$$

Note, that here, we do not treat the recoil $e^{\mp\imath kz}$ as a degree of freedom, but just as a parameter depending on the location of the atom. (We will come back to this in Chp. 42.) Decay processes can be considered in a master or in Heisenberg equations via jump operators $\hat{L}_k = \hat{\sigma}^-,\ \hat{\sigma}^+,\ \hat{a}_+, \hat{a}_-$ describing decay processes occurring, respectively, at rates $\gamma_k = 2\Gamma,\ 2R,\ 2\kappa,\ 2\kappa$.

40.2.4.3 (Anti-)Symmetric modes

Let us now introduce symmetric and anti-symmetric modes by,

$$\hat{b}_s = \tfrac{1}{\sqrt{2}}(\hat{a}_+ e^{\imath kz} + \hat{a}_- e^{-\imath kz}) \qquad \text{and} \qquad \hat{b}_a = \tfrac{1}{\sqrt{2}}(\hat{a}_+ e^{\imath kz} - \hat{a}_- e^{-\imath kz}) \,, \tag{40.148}$$

[2] Note that for N uncorrelated atoms, defining a bunching parameter via $b \equiv \frac{1}{N}\sum_j \sin kz_j$ and introducing the abbreviations $U_\gamma \equiv U_0 - \imath\gamma_0$ and $\Delta_\kappa \equiv \Delta_c + \imath\kappa$, the result (40.146) can be generalized to,

$$\alpha \simeq \frac{-\imath\eta}{NbU_\gamma - \Delta_\kappa} \,.$$

that is,

$$\hat{a}_+ = \frac{\hat{b}_s + \hat{b}_a}{\sqrt{2}e^{\imath kz}} \qquad \text{and} \qquad \hat{a}_- = \frac{\hat{b}_s - \hat{b}_a}{\sqrt{2}e^{-\imath kz}} \ , \tag{40.149}$$

which satisfy the commutations rules $[\hat{b}_s, \hat{b}_s^\dagger] = 1 = [\hat{b}_a, \hat{b}_a^\dagger]$. We can then rewrite the Hamiltonian,

$$\begin{aligned} \hat{H}_{JC} &= -\Delta_a \hat{\sigma}^+\hat{\sigma}^- + \sqrt{2}g(\hat{b}_s^\dagger\hat{\sigma}^- + \hat{b}_s\hat{\sigma}^+) - \sum_\pm \Delta_c \hat{a}_\pm^\dagger\hat{a}_\pm - \imath\eta_\pm(\hat{a}_\pm - \hat{a}_\pm^\dagger) \qquad (40.150) \\ &= \hat{H}_{atom} + \hat{H}_{atom:cav} + \hat{H}_{cav} + \hat{H}_{laser:cav} \ . \end{aligned}$$

We see that only the symmetric mode couples to the atom. On the other hand, both modes contribute to the field energy,

$$\hat{H}_{cav} = \Delta_c(\hat{a}_+^\dagger\hat{a}_+ + \hat{a}_-^\dagger\hat{a}) = \Delta_c(\hat{b}_s^\dagger\hat{b}_s + \hat{b}_a^\dagger\hat{b}_a) \ . \tag{40.151}$$

Now, let us check the pump terms,

$$\begin{aligned} \hat{H}_{laser:cav} &= \imath\eta_+(\hat{a}_+ - \hat{a}_+^\dagger) + \imath\eta_-(\hat{a}_- - \hat{a}_-^\dagger) \qquad (40.152) \\ &= \tfrac{\imath}{\sqrt{2}}\Big[(\eta_+e^{-\imath kz} + \eta_-e^{\imath kz})\hat{b}_s - (\eta_+e^{\imath kz} + \eta_-e^{-\imath kz})\hat{b}_s^\dagger \\ &\qquad +(\eta_+e^{-\imath kz} - \eta_-e^{\imath kz})\hat{b}_a - (\eta_+e^{\imath kz} - \eta_-e^{-\imath kz})\hat{b}_a^\dagger\Big] \ . \end{aligned}$$

For $\eta_+ = \eta_- = \eta$ we get,

$$\hat{H}_{laser:cav} = \eta\sqrt{2}\left[\imath(\hat{b}_s - \hat{b}_s^\dagger)\cos kz + (\hat{b}_a + \hat{b}_a^\dagger)\sin kz\right] \ . \tag{40.153}$$

Hence, for $kz = 0$ only the symmetric mode is pumped (no central peak). On the other hand, for $kz = \frac{\pi}{2}$ only the anti-symmetric mode is pumped, so that no normal-mode splitting is expected.

For $\eta_- = 0$ we get,

$$\hat{H}_{laser:cav} = \tfrac{\imath\eta_+}{\sqrt{2}}\left[e^{-\imath kz}(\hat{b}_s + \hat{b}_a) - e^{\imath kz}(\hat{b}_s^\dagger + \hat{b}_a^\dagger)\right] \ . \tag{40.154}$$

Hence, both modes are pumped and we observe three peaks. The normal-mode splitting can be observed in transmission spectra, as we will demonstrate in the following.

40.2.4.4 Normal modes of a ring cavity

We start from the Hamiltonian (40.147) and derive the Heisenberg equations,

$$\begin{aligned} \dot{\hat{\sigma}}^- &= (\imath\Delta_a - \tfrac{\Gamma}{2})\hat{\sigma}^- - \imath g(e^{\imath kz}\hat{a}_+ + e^{-\imath kz}\hat{a}_-)\hat{\sigma}^z \qquad (40.155) \\ \dot{\hat{\sigma}}^z &= 2\imath g(e^{\imath kz}\hat{a}_+ + e^{-\imath kz}\hat{a}_-)\hat{\sigma}^+ - 2\imath g\hat{\sigma}^-(e^{-\imath kz}\hat{a}_+^\dagger + e^{\imath kz}\hat{a}_-^\dagger) - \Gamma(\mathbb{I}_2 + \hat{\sigma}^z) \\ \dot{\hat{a}}_\pm &= (\imath\Delta_c - \kappa)\hat{a}_\pm - \imath g\hat{\sigma}^- e^{\mp\imath kz} + \eta_\pm \ . \end{aligned}$$

The stationary solution follows from the expectation values of these equations,

$$\begin{aligned} 0 &= (\imath\Delta_a - \tfrac{\Gamma}{2})\langle\hat{\sigma}^-\rangle + \imath g(e^{\imath kz}\langle\hat{a}_+\hat{\sigma}^z\rangle + e^{-\imath kz}\langle\hat{a}_-\hat{\sigma}^z\rangle) \qquad (40.156) \\ 0 &= 2\imath g(e^{\imath kz}\langle\hat{a}_+\hat{\sigma}^+\rangle + e^{-\imath kz}\langle\hat{a}_-\hat{\sigma}^+\rangle) - 2\imath g(e^{-\imath kz}\langle\hat{a}_+^\dagger\hat{\sigma}^-\rangle + e^{\imath kz}\langle\hat{a}_-^\dagger\hat{\sigma}^-\rangle) - \Gamma(1 + \langle\hat{\sigma}^z\rangle) \\ 0 &= (\imath\Delta_c - \kappa)\langle\hat{a}_\pm\rangle - \imath g\langle\hat{\sigma}^-\rangle e^{\mp\imath kz} + \eta_\pm \ . \end{aligned}$$

Neglecting all correlations, we derive from (40.156)(i),

$$\langle\hat{\sigma}^-\rangle = \frac{-\imath g}{\frac{\Gamma}{2}-\imath\Delta_a}(e^{\imath kz}\alpha_+ + e^{-\imath kz}\alpha_-)\langle\hat{\sigma}^z\rangle \ . \tag{40.157}$$

Substituting $\langle\hat{\sigma}^\pm\rangle$ in (40.156)(ii),

$$\left(1+\frac{2g^2}{\frac{\Gamma^2}{4}+\Delta_a^2}(|\alpha_+|^2+|\alpha_-|^2+e^{2\imath kz}\alpha_-^*\alpha_+ + e^{-2\imath kz}\alpha_+^*\alpha_-)\right)\langle\hat{\sigma}^z\rangle = -1 \ , \tag{40.158}$$

and in (40.156)(iii),

$$(\kappa-\imath\Delta_c)\alpha_\pm - \frac{g^2}{\frac{\Gamma}{2}-\imath\Delta_a}(e^{\imath kz\mp\imath kz}\alpha_+ + e^{-\imath kz\mp\imath kz}\alpha_-)\langle\hat{\sigma}^z\rangle = \eta_\pm \ . \tag{40.159}$$

Substituting $\langle\hat{\sigma}^z\rangle$ from (40.156) in (40.156),

$$(\kappa-\imath\Delta_c)\alpha_\pm - \frac{g^2(\frac{\Gamma}{2}+\imath\Delta_a)(\alpha_\pm + e^{\mp 2\imath kz}\alpha_\mp)}{\frac{\Gamma^2}{4}+\Delta_a^2+2g^2(|\alpha_+|^2+|\alpha_-|^2+e^{2\imath kz}\alpha_-^*\alpha_+ + e^{-2\imath kz}\alpha_+^*\alpha_-)} = \eta_\pm \ . \tag{40.160}$$

Assuming weak excitation, $g|\alpha_\pm|^2 \ll \Gamma, \Delta_a$, this last expression simplifies to,

$$\left(\kappa-\imath\Delta_c-\frac{g^2}{\frac{\Gamma}{2}-\imath\Delta_a}\right)\alpha_\pm - \frac{g^2}{\frac{\Gamma}{2}-\imath\Delta_a}e^{\mp 2\imath kz}\alpha_\mp \simeq \eta_\pm \ , \tag{40.161}$$

or, using the abbreviations,

$$U_\gamma \equiv U_0 - \imath\gamma_0 \equiv \frac{g^2}{\Delta_a+\imath\Gamma} = \frac{g^2(\Delta_a-\imath\frac{\Gamma}{2})}{\frac{\Gamma^2}{4}+\Delta_a^2} \ , \tag{40.162}$$

we write,

$$[\kappa+\imath(U_\gamma-\Delta_c)]\alpha_\pm + \imath U_\gamma e^{\mp 2\imath kz}\alpha_\mp \simeq \eta_\pm \ . \tag{40.163}$$

Resolving for $\alpha_\pm$,

$$\boxed{\alpha_\pm \simeq \frac{\eta_\pm\left[\kappa+\gamma_0+\imath(U_0-\Delta_c)\right]-\eta_\mp(\gamma_0+\imath U_0)e^{\mp 2\imath kz}}{\left[\kappa+\gamma_0+\imath(U_0-\Delta_c)\right]^2-(\gamma_0+\imath U_0)^2}} \ , \tag{40.164}$$

from which we can determine the transmission,

$$T_\pm = \left|\frac{\kappa\alpha_\pm}{\eta_\pm}\right|^2 \ . \tag{40.165}$$

This is illustrated in Fig. 40.12.

Example 242 (*Generalization for many atoms*): For N uncorrelated atoms, defining a bunching parameter via $b \equiv \frac{1}{N}\sum_j e^{2\imath kz_j}$ and introducing the abbreviations $U_\gamma \equiv U_0 - \imath\gamma_0$ and $\Delta_\kappa \equiv \Delta_c + \imath\kappa$, the result (40.146) can be generalized to,

$$\alpha_\pm \simeq -\imath\frac{\eta_\pm(NU_\gamma-\Delta_\kappa)-\eta_\mp NbU_\gamma}{(NU_\gamma-\Delta_\kappa)^2-(N|b|^2U_\gamma)^2} \ . \tag{40.166}$$

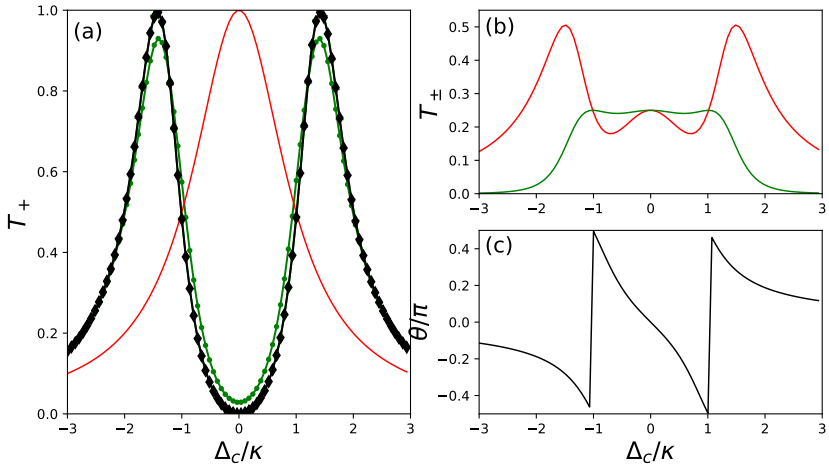

Figure 40.12: (code) Normal-mode splitting in a ring cavity observed in transmission spectra T_+ calculated from (40.165) with $g = \kappa$, $\eta_+ = 0.1\kappa$, and $\Gamma = R = 0$. (a) The blue curve is obtained for one-sided pumping ($\eta_- = 0$), the green curve for symmetric pumping ($\eta_- = \eta_+$ and $kz = 0$), and the red curve for anti-symmetric pumping ($\eta_- = \eta_+$ and $kz = \pi/2$). The green dots are obtained for symmetric pumping via numerical integration of the Hamiltonian (40.147). (b) Transmission spectra T_+ (green) and T_- (red) for one-sided pumping. (c) Phase of the standing wave formed by backscattering of probe light into the mode α_-.

Example 243 (*Level splitting for some limiting cases*): The first limiting case consists in setting $\eta_\pm = 0$ and assuming the light field to be classical. Then we obtain the Rabi Hamiltonian studied in previous sections,

$$\hat{H}_{Rabi} = -\Delta_a \hat{\sigma}^+\hat{\sigma}^- + \tfrac{1}{2}\Omega(\hat{\sigma}^+ + \hat{\sigma}^-) = \begin{pmatrix} 0 & \frac{1}{2}\Omega \\ \frac{1}{2}\Omega & -\Delta_a \end{pmatrix} .$$

Its eigenvalues: $E_{1,2} = -\frac{1}{2}\Delta_a \pm \sqrt{\Delta_a^2 + \Omega^2}$ exhibit the famous Autler-Townes splitting.
The second limiting case consists adiabatically eliminating the atomic states. This is valid if $|\Delta_a| \gg \Gamma$. Then we obtain the cavity Hamiltonian,

$$\hat{H}_{cav} = U_0(e^{-2\imath kz}\hat{a}_+^\dagger\hat{a}_- + e^{2\imath kz}\hat{a}_+\hat{a}_-^\dagger) + \sum_\pm (U_0 - \Delta_c)\hat{a}_\pm^\dagger\hat{a}_\pm - \imath\eta_\pm(\hat{a}_\pm - \hat{a}_\pm^\dagger) ,$$

with $L_k = \hat{a}_+, \hat{a}_-$ and $\gamma_k = 2\kappa, 2\kappa$, again for the case $z = \eta_\pm = 0$. The spectrum is asymmetric because $\Delta_a \neq 0$ [3,4]

[3] We note that, setting $z = \eta_\pm = 0$, the cavity Hamiltonian $\hat{H}_{cav} = U_0(\hat{a}_+^\dagger\hat{a}_- + \hat{a}_+\hat{a}_-^\dagger) - (\Delta_c - U_0)\sum_\pm \hat{a}_\pm^\dagger\hat{a}_\pm$ has the same structure as the Rabi Hamiltonian, which we can write, introducing annihilation and creation operators $\hat{\psi}_{g,e}$ and $\hat{\psi}_{g,e}^\dagger$ for atoms in ground and excited states, $\hat{H}_{Rabi} = \frac{1}{2}\Omega(\hat{\psi}_e^\dagger\hat{\psi}_g + \hat{\psi}_g^\dagger\hat{\psi}_e) - \Delta_a\sum_{j=g,e}\hat{\psi}_j^\dagger\hat{\psi}_j$. This emphasizes the analogy between Autler-Townes and normal-mode splitting.

[4] As the atomic degrees of freedom have been eliminated, spontaneous emission must be reintroduced by hand when required.

40.2.5 Adiabatic elimination of internal states

The equations of motion (40.11) describe the evolution of the light fields in counterpropagating modes of a ring cavity. Without scatterer located in the mode volume, the modes evolve independently. In contrast, a scatterer (e.g. an atom or a beam splitter) may redistribute photons between the modes, whose dynamics thereby becomes coupled.

We will in the following assume the scatterer as immobile, except for Sec. 40.5.1, where we consider a vibrating scatterer. Immobile scatterers can, for example, be heavy masses, such as imperfections on the surfaces of the mirrors of the cavity (scratches, dust particles, etc.), which can scatter light both, out of the cavity and into the reverse cavity mode. In *laser gyroscopes* this backscattering may induce a locking of counterpropagating modes and hamper their proper operation.

40.2.5.1 Classical derivation of coupled atom-ring cavity equations

The equations of motion (40.11) describe the light fields classically. Hence, it is not surprising that they can be derived with entirely classical arguments. Here, we will show this for a ring cavity in the presence of an atom sitting at a fixed position z on the cavity's optical axis. We understand the atom as a beamsplitter located within the mode volume of the resonator and partially reflecting and transmitting incident light with reflection and transmission coefficients $(r_\beta, t_\beta) = (\imath\beta, 1+\imath\beta)$ such that $r_\beta^2 + t_\beta^2 = 1$. Transmitted (forward scattered) photons may be phase-shifted, while reflected photons are backscattered into the counterpropagating mode of the resonator.

Similarly, we treat the incoupling mirror as a beam splitter with coefficients (r_{in}, t_{in}). The incident field E_{in} produces, in the cavity, field amplitudes of $\alpha_\pm$ for the co- and counterpropagating waves. As in (40.7), we normalize the amplitudes by the numbers of photons $n_\pm \equiv |\alpha_\pm|^2$. After a round-trip time $\tau = \delta_{fsr}^{-1}$ through the mode volume we have in the position of the incoupling mirror the field,

$$\begin{aligned}\alpha_+(t+\tau) &= r_{in}(1+\imath\beta)e^{\imath kL}\alpha_+(t) + \imath\beta r_{in}^2 e^{2\imath kL - 2\imath kz}\alpha_-(t) + t_{in}\alpha_+^{in}(t) \\ \alpha_-(t+\tau) &= r_{in}(1+\imath\beta)e^{\imath kL}\alpha_-(t) + \imath\beta e^{2\imath kz}\alpha_+(t) + t_{in}(1+\imath\beta)e^{\imath kL}\alpha_-^{in}(t)\ .\end{aligned} \tag{40.167}$$

L is the total length of the ring cavity. Obviously, we have $kL = \omega/\delta_{fsr}$. In the vicinity of a resonance we have, $\Delta_c \ll \delta_{fsr}$, and the quantity ω/δ_{fsr} is almost integer, $\omega \simeq 2\pi N\delta_{fsr} - \Delta_c$, such that we can expand the exponential, $e^{\imath kL} = 1 - \imath\Delta_c/\delta_{fsr}$. Thus, we obtain,

$$\begin{aligned}\tau\dot{\alpha}_+ &= -\left[1 - r_{in}(1+\imath\beta)e^{\imath kL}\right]\alpha_+ + \imath\beta r_{in}^2 e^{-2\imath kz}\alpha_- + t_{in}\alpha_+^{in} \\ \tau\dot{\alpha}_- &= -\left[1 - r_{in}(1+\imath\beta)e^{\imath kL}\right]\alpha_- + \imath\beta e^{2\imath kz}\alpha_+ + t_{in}(1+\imath\beta)\alpha_-^{in}\ .\end{aligned} \tag{40.168}$$

We now connect the transmission of the coupling mirror t_{in} with the decay constant κ assuming that the light can only leave the cavity through this mirror. We define,

$$\kappa \equiv \frac{T}{\tau} \tag{40.169}$$

as the part of the light lost during one round trip. Thus, $t_{in} = \sqrt{T} \simeq \sqrt{\pi/F} = \sqrt{\kappa/\delta_{fsr}}$. Besides that, t_{in} is very small, such that,

$$t_{in}^2 = 1 - r_{in}^2 \simeq 2(1 - r_{in}) \ . \tag{40.170}$$

Thus, the first factor is,

$$\begin{aligned} \delta_{fsr}\left[1 - r_{in}(1+\imath\beta)e^{\imath kL}\right] &\simeq \delta_{fsr} - \delta_{fsr}(1 - t_{in}^2/2)(1+\imath\beta)(1+\imath\Delta_c/\delta_{fsr}) \\ &\simeq \kappa/2 + \imath\beta - \imath\Delta_c \simeq -\kappa/2 \ . \end{aligned} \tag{40.171}$$

It gives the cavity losses for the two modes during one round trip. We assume here that losses can only occur via the coupling mirror. However, all losses can be included in a single appropriate κ. There are usually other losses due to scattering on the surface of the mirrors or absorption by the atoms. Finally, we obtain for weak atomic reflection and in resonance, that is, for $\beta \ll \kappa$ and $\Delta_c = 0$ the system of equations,

$$\begin{aligned} \dot{\alpha}_+ &= -\kappa\alpha_+ + \imath\delta_{fsr}\beta(1 - t_{in}^2)e^{-2\imath kz}\alpha_- + \sqrt{\kappa\delta_{fsr}}\alpha_+^{in} \\ \dot{\alpha}_- &= -\kappa\alpha_- + \imath\delta_{fsr}\beta e^{2\imath kz}\alpha_+ + (1+\imath\beta)\sqrt{\kappa\delta_{fsr}}\alpha_-^{in} \end{aligned} \tag{40.172}$$

To calculate the value of β, we need the reflection coefficient of a single atom. It depends on the polarizability,

$$r_\beta = \frac{k}{\pi w^2}\frac{\alpha_{pol}}{\varepsilon_0} \ \left(= \frac{\sigma_0}{\pi w^2}\frac{\Gamma}{2\Delta_a}\right) \ . \tag{40.173}$$

The optical potential to which the atom is exposed is,

$$\phi = \frac{I}{2c}\frac{\alpha_{pol}}{\varepsilon_0} \ , \tag{40.174}$$

where we write the intensity of light as,

$$I = 2\varepsilon_0 c\mathcal{E}_1^2|\alpha_+ e^{\imath kZ} + \alpha_- e^{-\imath kZ}| \ . \tag{40.175}$$

We normalize once more to the field generated by a single photon, $\mathcal{E}_1 = \sqrt{\hbar\omega/2\varepsilon_0 V_m}$ with the mode volume, $V_m = \frac{\pi}{2}Lw^2$. On the other hand, the potential can be determined directly through the Rabi frequency,

$$\phi(\mathbf{r}) = \frac{\hbar\Omega(\mathbf{r})^2}{4\Delta_a} \ , \tag{40.176}$$

The Rabi frequency $\Omega(\mathbf{r})^2 = 4g^2|\alpha_+ e^{\imath kZ} + \alpha_- e^{-\imath kZ}|^2$ is normalized to the frequency of Rabi generated by a photon g. Using the frequency shift (light-shift) by photon (40.116), $U_0 = \frac{g^2}{\Delta_a}$, we can also write,

$$\phi(\mathbf{r}) = \hbar U_0|\alpha_+ e^{\imath kZ} + \alpha_- e^{-\imath kZ}|^2 \ . \tag{40.177}$$

A comparison of the above equations gives,

$$r_\beta = \frac{\imath U_0}{\delta_{fsr}} \ . \tag{40.178}$$

With an atom in the resonator, we have,

$$\beta = \frac{\imath U_0}{\delta_{fsr}} \ . \tag{40.179}$$

We define for convenience, $\eta_\pm = \sqrt{\kappa\delta_{fsr}}\alpha_\pm^{in}$ and we suppose, that $t_{in} \ll 1$, $r_\beta \ll 1$ and $\beta \ll 1$. This ultimately leads to the result,

$$\dot{\alpha}_\pm = -\kappa\alpha_\pm - \imath U_0 e^{\mp 2\imath kz}\alpha_\mp + \eta_\pm \ . \tag{40.180}$$

Example 244 (*Classical CARL equations*): If we were to treat the atomic position z as a degree of freedom, we could calculate the classical potential of the stationary light wave, and therefore the dipole force,

$$F = -\nabla\phi = -\hbar U_0 \nabla_{Z=z} |\alpha_+ e^{\imath kZ} + \alpha_- e^{-\imath kZ}|^2 \ , \tag{40.181}$$

and, consequently, derive the dynamics of the scatterer via,

$$m\ddot{z} = -2\imath\hbar k U_0(\alpha_+\alpha_-^* e^{2\imath kz} - \alpha_+^*\alpha_- e^{-2\imath kz}) \ . \tag{40.182}$$

This will be studied in Chp. 42. In the remaining sections of this chapter we will assume the atom to be located at a fixed position.

In the above derivation we assumed, for simplicity, the pump laser on resonance with the cavity, $\Delta_c = 0$. Relaxing this condition, an analogous derivation yields [5],

$$\dot{\alpha}_\pm = (-\kappa + \imath\Delta_c - \imath U_0)\alpha_\pm - \imath U_0 e^{\mp 2\imath kz}\alpha_\mp + \eta_\pm \ . \tag{40.183}$$

40.2.5.2 Adiabatically simplified Hamiltonian

In a ring cavity, the simplified Hamiltonian,

$$\boxed{\hat{H} = (U_0 - \Delta_c)\sum_\pm \hat{a}_\pm^\dagger \hat{a}_\pm - \imath\eta_\pm(\hat{a}_\pm - \hat{a}_\pm^\dagger) + U_0(\hat{a}_+\hat{a}_-^\dagger e^{2\imath kz} + \hat{a}_+^\dagger \hat{a}_- e^{-2\imath kz})} \ , \tag{40.184}$$

which can be obtained from the full Hamiltonian via adiabatic elimination of the excited atomic state, already exhibits this phenomenon. With the above Hamiltonian we derive from the Heisenberg equation,

$$\dot{\hat{a}}_\pm = -\imath[\hat{a}_\pm, \hat{a}] - \kappa\hat{a}_\pm = (-\kappa + \imath\Delta_c - \imath U_0)\hat{a}_\pm - \imath U_0 e^{\mp 2\imath kz}\hat{a}_\mp + \eta_\pm \ , \tag{40.185}$$

which, after taking the expectation values and disregarding correlations, reproduces the equations of motion (40.183). Of course, as we eliminated the internal atomic degree of freedom, spontaneous emission is not accounted for. We may, however, include it phenomenologically via the substitution $U_0 \to U_\gamma \equiv U_0 - \imath\gamma_0$. The stationary solution of Eq. (40.185) is *exactly the same* as the one derived for the full Jaynes-Cummings model (40.164) under the assumption of weak excitation, $g|\alpha_\pm| \ll \Gamma, \Delta_a$,

$$\boxed{\alpha_\pm = -\imath\frac{\eta_\pm(U_\gamma - \Delta_\kappa) - U_\gamma e^{\mp 2\imath kz}\eta_\mp}{(U_\gamma - \Delta_\kappa)^2 - U_\gamma^2}} \tag{40.186}$$

[5] Note, that we have not allowed for spontaneous emission by the atomic scatterer out of the cavity mode. This approximation is only good far from resonance, $\Delta_a \gg \Gamma$. We will see in Sec. 42.1.3, how to generalize the equations of motion for near resonance cases.

with the abbreviations,

$$U_\gamma \equiv U_0 - \imath\gamma_0 \quad , \quad \Delta_\kappa \equiv \Delta_c + \imath\kappa \; . \tag{40.187}$$

Solve the Exc. 40.2.9.7.

40.2.6 Normal mode splitting induced by beam splitting

The fact that (in the weak excitation limit) normal mode splitting is fully described by the classical field equations (40.183) shows that the phenomenon clearly is *not a quantum effect*: a classical beam splitter inserted into the cavity does the same job. We will now discuss the normal mode splitting in detail based on the adiabatically simplified equations (40.187).

The equation (40.183) can be written as follows,

$$\imath\dot{\vec{\alpha}} = W\vec{\alpha} + \imath\vec{\eta} \; , \tag{40.188}$$

where $\vec{\alpha}$ and $\vec{\eta}$ regroup the amplitudes $\alpha_\pm$ and $\eta_\pm$. This equation takes the form of a Schrödinger equation, where,

$$W \equiv \begin{pmatrix} U_0 - \Delta_c - \imath\kappa & U_0 e^{-2\imath kz} \\ U_0 e^{2\imath kz} & U_0 - \Delta_c - \imath\kappa \end{pmatrix} \tag{40.189}$$

would be the Hamiltonian describing the coupling between counterpropagating modes. The eigenvalues of this matrix are,

$$W^{(1,2)} = 2U_0 - \Delta_c - \imath\kappa \quad , \quad -\Delta_c - \imath\kappa \; . \tag{40.190}$$

This *normal mode splitting* [6] of the cavity results from the coupling of the two cavity modes $\hat{a}_+^\dagger \hat{a}_-$. Obviously, the energies and widths of the eigenvalues do not depend neither on the pump intensities $\eta_\pm$ nor the z-position of the atom. On the other hand, the spectral behavior of $\alpha_\pm$, and hence the observable quantities, such as the transmission

$$T_\pm \equiv \left| \frac{\kappa\alpha_\pm}{\eta_\pm} \right|^2 \tag{40.191}$$

depend on these parameters. In the following, we will study normal mode splitting in a ring cavity by a discussion of the expression (40.164) for the cases of (i) anti-symmetric pumping, (ii) symmetric pumping, and (iii) uni-directional pumping.

(i) Assuming $\gamma_0 = 0$ and anti-symmetric pumping, $\eta_- = \eta_+$ and $kz = \pi/2$, the expression (40.164) becomes,

$$\begin{aligned} \alpha_+ &= \eta_+ \frac{\kappa - \imath(\Delta_c - 2U_0)}{[\kappa - \imath(\Delta_c - U_0)]^2 + U_0^2} \\ \Rightarrow \quad \left| \frac{\alpha_+}{\eta_+} \right|^2 &= \frac{1}{\kappa^2 + \Delta_c^2} \; . \end{aligned} \tag{40.192}$$

[6] The splitting is not exactly the *vacuum Rabi splitting*, which occurs when the excitation can not be eliminated adiabatically. The vacuum Rabi splitting results from the Jaynes-Cummings [1300, 312] and is caused by the coupling of internal and external states $\hat{a}^\dagger\hat{\sigma}$.

That is, the transmission profile is a Lorentzian.

(ii) For symmetric pumping, $\eta_- = \eta_+$ and $kz = 0$,

$$\alpha_+ = \eta_+ \frac{\kappa - \imath\Delta_c}{[\kappa - \imath(\Delta_c - U_0)]^2 + U_0^2} \qquad (40.193)$$
$$\Rightarrow \quad \left|\frac{\alpha_+}{\eta_+}\right|^2 = \frac{1}{\kappa^2 + (\Delta_c - 2U_0)^2} \ .$$

Setting $\Delta_c = \Delta_a$ we find from $0 \equiv \frac{d}{d\Delta_c}\left|\frac{\alpha_+}{\eta_+}\right|^2$ a minimum at $\Delta_c = 0$ and two maxima at $\Delta_c = 2U_0 = \sqrt{2}g$. This is the usual normal mode splitting for a ring cavity.

(iii) For uni-directional pumping, $\eta_- = 0$,

$$\alpha_+ = \eta_+ \frac{\kappa - \imath(\Delta_c - U_0)}{[\kappa - \imath(\Delta_c - U_0)]^2 + U_0^2} \qquad (40.194)$$
$$\Rightarrow \quad \left|\frac{\alpha_+}{\eta_+}\right|^2 = \frac{\kappa^2 + (\Delta_c - U_0)^2}{[\kappa^2 - \Delta_c(\Delta_c - 2U_0)]^2 + 4\kappa^2(\Delta_c - U_0)^2} \ .$$

That is, the transmission profile is a more complicated and may exhibit up to three peaks.

40.2.6.1 Unidirectional pumping

For unilateral pumping, $\eta_- = 0$, and approximating $\gamma_0 = 0$, the solution (40.164) simplifies to,

$$\alpha_+(\infty) = \eta_+ \frac{\chi}{\chi^2 + U_0^2} \qquad \text{and} \qquad \alpha_-(\infty) = \eta_+ \frac{\imath U_0 e^{2\imath kz}}{\chi^2 + U_0^2} \ . \qquad (40.195)$$

These formulas show that, for weak coupling, $U_0 \ll \kappa$, the counterpropagating mode receives little light. On the other side, for strong coupling (or very high finesse) and $\Delta_c = 0$, the intensity is equally distributed, $|\alpha_+|^2 = |\alpha_-|^2 = \frac{\eta_+}{2\kappa}$ [7]. We calculate the splitting of normal modes in Exc. 40.2.9.8.

The counterpropagating modes form, by interference, a standing light wave giving rise to a dipole potential in the form of a one-dimensional optical lattice. Defining the phase $\theta = \theta_1 - \theta_2$ through,

$$\alpha_+ \equiv |\alpha_+| e^{-\imath\theta_1} \qquad \text{and} \qquad \alpha_- \equiv |\alpha_-| e^{-\imath\theta_2} \ , \qquad (40.196)$$

we verify by the equation (40.7),

$$\mathcal{E}^+(\zeta, t) = \mathcal{E}_1 |\alpha_+(t)| e^{\imath k\zeta} + \mathcal{E}_1 |\alpha_-(t)| e^{-\imath\theta(t)} e^{-\imath k\zeta} \ , \qquad (40.197)$$

and,

$$\frac{1}{2\varepsilon_0 c \mathcal{E}_1^2} I(\zeta, t) = \frac{1}{\mathcal{E}_1^2} \mathcal{E}^+(\zeta, t) \mathcal{E}^-(\zeta, t) \qquad (40.198)$$
$$= |\alpha_+(t)|^2 + |\alpha_-(t)|^2 + 2|\alpha_+(t)||\alpha_-(t)| \cos(2k\zeta + \theta) \ .$$

[7] This observation explains why perturbing effects such as backscattering from mirrors imperfections are dramatically magnified when the finesse is high.

That is, the phase indicates the positions of the potential maxima. Inserting the stationary solution for unilateral pumping (40.195), we derive the expression,

$$\tan\theta = \frac{\mathfrak{Im}\ \alpha_+(\infty)\alpha_-^*(\infty)}{\mathfrak{Re}\ \alpha_+(\infty)\alpha_-^*(\infty)} = \frac{\mathfrak{Im}\ \chi\imath e^{-2\imath kz}}{\mathfrak{Re}\ \chi\imath e^{-2\imath kz}} = \frac{\kappa\cos 2kz + (U_0-\Delta_c)\sin 2kz}{\kappa\sin 2kz - (U_0-\Delta_c)\cos 2kz}\ . \tag{40.199}$$

Or in other words, the phase of light determines the equilibrium position of the atom (or vice versa). Two cases are interesting: (i) For $\Delta_c = 0$ and $U_0 \gg \kappa$ the condition (40.203) turns into $\tan\theta = -\tan 2kz$. In this case, the phase of the backscattered field adjusts in such a way, that the atom stays at the valleys of the anti-nodes. (ii) For $\Delta_c = U_0$ (or alternatively, when $\kappa \gg U_0, \Delta_c$) the condition (40.203) turns into $\tan\theta = -\tan(2kx + \frac{\pi}{2})$, such that the atom is at half height of the potential slope, exactly at the position, where it is able to backscatter the maximum of photons from the pumped mode α_+ to the mode α_-.

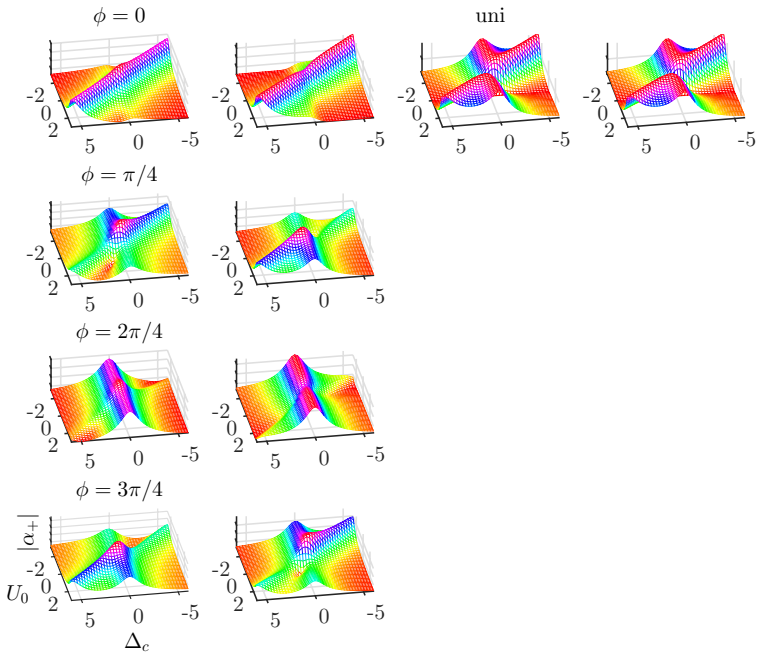

Figure 40.13: (code) (columns 1 and 2) Steady state field values according to (40.188) for bidirectional pumping with a single scatterer located at ϕ. (columns 3 and 4) Same for unidirectional pumping. Here the location of the scatterer does not matter.

40.2.6.2 (Anti-)Symmetric pumping

Let us assume equal intensities for the pumps, but variable phases, $\eta_\pm = \eta e^{\pm\imath\phi}$, such that $\xi = e^{-2\imath kz-\imath\phi}$. Then, equation (40.164) simplifies to,

$$\alpha_\pm(\infty) = \eta_\pm \frac{\chi - \imath U_\gamma \xi^\pm}{\chi^2 + U_\gamma^2} = \eta \frac{\chi - \imath U_\gamma e^{\mp 2\imath kz \mp \imath\phi}}{\chi^2 + U_\gamma^2}\ . \tag{40.200}$$

The potential is calculated in the same way as in (40.198). The coherences are,

$$\begin{aligned}
\alpha_\pm(\infty)\alpha_\pm^*(\infty) &= \eta^2 \tfrac{(\kappa-\imath\Delta_c\mp 2U_0 e^{\mp\imath kz}\sin kz)(\kappa+\imath\Delta_c\mp 2U_0 e^{\pm\imath kz}\sin kz)}{(\kappa^2+2U_0\Delta_c-\Delta_c^2)^2+4\kappa^2(U_0-\Delta_c)^2} \\
\alpha_\pm(\infty)\alpha_\mp^*(\infty) &= \eta^2 \tfrac{\kappa^2+(\Delta_c\mp 2\imath U_0 e^{\mp\imath kz}\sin kz)^2}{(\kappa^2+2U_0\Delta_c-\Delta_c^2)^2+4\kappa^2(U_0-\Delta_c)^2} \\
e^{\pm 2\imath kz} &= \tfrac{\alpha_\mp\alpha_\pm^*}{|\alpha_-\alpha_+^*|}
\end{aligned} \quad , \tag{40.201}$$

such that the relative phase of the counter-propagating waves adjusts itself to,

$$\tan\theta = \frac{\mathfrak{Im}\ \alpha_+(\infty)\alpha_-^*(\infty)}{\mathfrak{Re}\ \alpha_+(\infty)\alpha_-^*(\infty)} = \frac{\kappa^2\sin 2\phi + 4U_0^2\sin^2(kz+\phi)\sin 2kz}{\kappa^2\cos 2\phi - 4U_0^2\sin^2(kz+\phi)\cos 2kz} \ . \tag{40.202}$$

The quantity η^2/κ^2 denotes the number of intracavity photons. According to the formula (40.202), for a weak atom-field coupling, $U_0 \ll \kappa$, the phase adjusts itself to the external pumps, $\theta \to 2\phi$, while for strong coupling, it adjusts to the position of the atom, $\theta \to 2kz$.

Example 245 (*'Pulling' of the optical mode by the atom*): We study the case $U_0 \simeq \kappa$ considering $\gamma_0 = 0 = \Delta_c$ and a particular external phase [482], $\phi = \pi/2$,

$$\begin{aligned}
\alpha_\pm(\infty) &= \pm\imath\eta\frac{\kappa+\imath U_0 \pm U_0 e^{\mp 2\imath kz}}{\kappa^2+2\imath\kappa U_0} \\
\theta(\infty) &= \arctan\frac{-4U_0^2\cos^2 kz\sin 2kz}{\kappa^2+4U_0^2\cos^2 kz\cos 2kz} \simeq \arctan\frac{-8U_0^2}{\kappa^2+4U_0^2}kz \ ,
\end{aligned} \tag{40.203}$$

expanding the last formula around $kz = 0$. Fig. 40.14 shows how, with the increase in the coupling force between the field and the atoms, U_0, the phase tends to lock to the atomic position. However, the phase imposed by the external pump competes for this privilege. Curiously, this is independent of laser power, but depends only on the ratio between U_0 and κ.

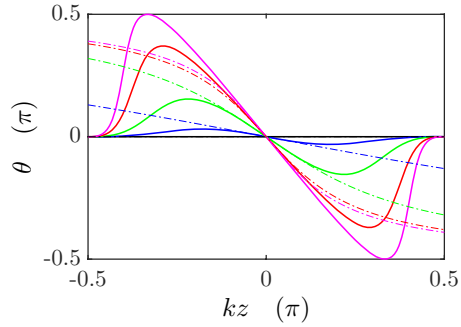

Figure 40.14: (code) 'Pulling' of the phase by the atoms for $U_0/\kappa = 0$, 0.2, 0.5, 1 and $\sqrt{2}$. The solid curves show the exact phase, the 'dash-dotted' curves the linear approximation (40.207).

Example 246 (*Resonant case*): Assuming that the cavity is in resonance, $\Delta_c = 0$, and pumped in a single direction, $\eta_- = 0$, neglecting spontaneous emission, $\gamma_0 = 0$, and assuming low backscattering rates, $U_s \ll \kappa$,

$$\alpha_+(\infty) \simeq \frac{\eta_+}{\kappa} \qquad \text{and} \qquad |\alpha_-(\infty)| = \frac{U_s}{\kappa}|\alpha_+(\infty)| \ .$$

Looking at short times, we find that the dynamics of the unpumped mode is delayed, since,

$$\dot\alpha_+(0) \simeq \eta_+ \qquad \text{and} \qquad \dot\alpha_-(0) \simeq -\imath U_s \alpha_+ e^{-2\imath k r_s} \ ,$$

giving,

$$\alpha_+(0) \simeq \eta_+ t \qquad \text{and} \qquad \alpha_-(0) \simeq -\imath U_s \eta_+ \frac{t^2}{2} e^{-2\imath k r_s} \ .$$

The complete solution of the equations (40.191) with unidirectional pumping, $\eta_- = 0$, will be derived in Exc. 40.2.9.9.

40.2.7 Time-dependent solutions

40.2.7.1 Time-dependent solution without pump

To calculate the homogeneous time-dependent solution of the equation of motion of the ring cavity with $\eta_\pm = 0$, we solve the Schrödinger equation (40.188) the way we learned in quantum mechanics. We start by diagonalizing the matrix (40.189),

$$\begin{aligned} W &= \begin{pmatrix} U_0 - \imath\kappa & U_0 e^{-2\imath kz} \\ U_0 e^{2\imath kz} & U_0 - \imath\kappa \end{pmatrix} \qquad (40.204) \\ &= \begin{pmatrix} e^{-2\imath kz} & -e^{-2\imath kz} \\ 1 & 1 \end{pmatrix} \begin{pmatrix} 2U_0 - \imath\kappa & 0 \\ 0 & -\imath\kappa \end{pmatrix} \begin{pmatrix} e^{-2\imath kz} & -e^{-2\imath kz} \\ 1 & 1 \end{pmatrix}^{-1} = U E_W U^{-1} \ , \end{aligned}$$

where E_W is the matrix of eigenvalues and U a unitary transformation. So,

$$\begin{aligned} \vec\alpha &= e^{-\imath W t}\vec\alpha_0 = U e^{-iE_W t} U^{-1}\vec\alpha_0 \qquad (40.205) \\ &= e^{-\kappa t - \imath U_0 t} \begin{pmatrix} \cos U_0 t & -\imath e^{-2\imath kz} \sin U_0 t \\ -\imath e^{2\imath kz} \sin U_0 t & \cos U_0 t \end{pmatrix} \vec\alpha_0 \ . \end{aligned}$$

In Exc. 40.2.9.7 we study the equation of motion numerically. We'll see an alternative calculation in Exc. 40.2.9.11. We calculate the coherence by,

$$\begin{aligned} \alpha_+(t)\alpha_-^*(t) &= e^{-2\kappa t}\left[\alpha_{0+}\alpha_{0-}(\cos^2 U_0 t + e^{-4\imath kz}\sin^2 U_0 t) + \tfrac{1}{2}(\alpha_{0+}^2 - \alpha_{0-}^2)\imath e^{-2\imath kz}\sin 2U_0 t\right] \\ &\xrightarrow{z\to 0} e^{-2\kappa t}\left[\alpha_{0+}\alpha_{0-} + \tfrac{1}{2}(\alpha_{0+}^2 - \alpha_{0-}^2)\imath \sin 2U_0 t\right] \ , \qquad (40.206) \end{aligned}$$

making the transition to the Lamb-Dicke regime by $z \to 0$. The phase of the standing wave is,

$$\tan\theta = \frac{\mathfrak{Im}\ \alpha_+(t)\alpha_-^*(t)}{\mathfrak{Re}\ \alpha_+(t)\alpha_-^*(t)} \xrightarrow{z\to 0} \frac{\alpha_{0+}^2 - \alpha_{0-}^2}{2\alpha_{0+}\alpha_{0-}} \sin 2U_0 t \ . \qquad (40.207)$$

We see that, in resonance and without pumping, the field adjusts its phase to the atom and also decays with the rate κ, while the atom redistributes the photons between

modes with the (Rabi-)frequency $2U_0$. The formula (40.207) does not show any damping of the phase dynamics in the Lamb-Dicke regime. Thus, in the absence of pumping, the cavity dissipation reduces only the field amplitudes, but does not damp the adjustment of the phase to the atomic position.

40.2.7.2 Time-dependent solution with fixed pump

To find the complete solution of the inhomogeneous Schrödinger equation (40.188), we first calculate the stationary solution,

$$\vec{\alpha}(\infty) = -\imath W^{-1}\vec{\eta}\ . \tag{40.208}$$

This particular solution of the inhomogeneous equation, added to the general solution of the homogeneous equation, gives the general solution of the inhomogeneous Schrödinger equation,

$$\vec{\alpha}(t) = e^{-\imath Wt}\vec{\alpha}(0) + (1 - e^{-\imath Wt})\vec{\alpha}(\infty)\ . \tag{40.209}$$

We derive and analyze this solution in the Exc. 40.2.9.12.

Analytical solutions only exist in particular cases. However, they allow a better understanding of the dynamics. So let's consider some limiting cases. In Exc. 40.2.9.13 we determine the steady state of an atom interacting with the modes of a unidirectionally pumped annular cavity and calculate the stationary position of the atom in a unidirectionally pumped ring cavity. In Exc. 40.2.9.14 we derive motion equations for the 'intensities' $\alpha_\pm\alpha_\pm^*$ and 'coherences' $\alpha_\pm\alpha_\mp^*$.

40.2.8 Forced atomic vibration in a ring cavity

We now assume, that the atom is forced to vibrate by an external force. The vibration is described by,

$$kz = kz_0 \sin\omega t\ . \tag{40.210}$$

We consider small modulation excursions, $1 \gtrsim kz_0 = \frac{kv}{\omega} = \frac{2\omega_{rec}}{\omega}$, which is equivalent to saying that the oscillation frequency should exceed to recoil shift. In this (Lamb-Dicke) regime the Bessel-expansion yields,

$$e^{\pm 2\imath kz_0 \sin\omega t} = \sum_n J_n(\pm 2kz_0)e^{\imath n\omega t} \simeq J_0(2kz_0) \pm 2\imath J_1(2kz_0)\sin\omega t \simeq 1 \pm 2\imath kz_0 \sin\omega t\ . \tag{40.211}$$

The differential equations for the two counterpropagating ring cavity-field (40.183) can then be written:

$$\boxed{\dot{\alpha}_\pm = (\mathbf{L} - 2\imath\mathbf{X}\sin\omega t)\alpha_\pm + \eta_\pm}\ , \tag{40.212}$$

where,

$$\mathbf{L} = \begin{pmatrix} -\kappa - \imath U_0 & -\imath U_0 J_0 \\ -\imath U_0 J_0 & -\kappa - \imath U_0 \end{pmatrix} \quad \text{and} \quad \mathbf{X} = \begin{pmatrix} 0 & -\imath U_0 J_1 \\ \imath U_0 J_1 & 0 \end{pmatrix}\ . \tag{40.213}$$

We insert the ansatz $\alpha_\pm = \sum_n \alpha_\pm^{(n)} e^{\imath n\omega t}$, where $\dot{\alpha}_\pm^{(n)} = 0$, into the equations and project onto the basis $e^{\imath n\omega t}$:

$$\begin{aligned} &\imath n\omega_x \sum_n \alpha_\pm^{(n)} e^{\imath n\omega t} = \big(\mathbf{L} - \mathbf{X}(e^{\imath\omega t} - e^{-\imath\omega t})\big) \sum_n \alpha_\pm^{(n)} e^{\imath n\omega t} + \eta_\pm \qquad (40.214)\\ &\Longrightarrow (\mathbf{L} - \imath n\omega)\alpha_\pm^{(n)} + \mathbf{X}(\alpha_\pm^{(n+1)} - \alpha_\pm^{(n-1)}) = -\eta_\pm \delta_{n0} \ . \end{aligned}$$

We define operators $\mathbf{S}_n^{\uparrow\downarrow}$ by $\alpha_\pm^{(n+1)} = \mathbf{S}_n^\uparrow \alpha_\pm^{(n)}$ for $n \geq 0$ and $\alpha_\pm^{(n-1)} = \mathbf{S}_n^\downarrow \alpha_\pm^{(n)}$ for $n \leq 0$ and obtain,

$$\big[\mathbf{L} - \imath n\omega + \mathbf{X}(\mathbf{S}_n^\uparrow - \mathbf{S}_n^\downarrow)\big]\, \alpha_\pm^{(n)} = -\eta_\pm \delta_{n0} \ . \qquad (40.215)$$

For $n = 0$, we get,

$$\alpha_\pm(\infty) = \alpha_\pm^{(0)} = -\left[\mathbf{L} + \mathbf{X}(\mathbf{S}_0^\uparrow - \mathbf{S}_0^\downarrow)\right]^{-1} \eta_\pm \ . \qquad (40.216)$$

If we substitute in equation (40.214) $\alpha_\pm^{(n)} = \mathbf{S}_{n-1}^\uparrow \alpha_\pm^{(n-1)} = \mathbf{S}_{n+1}^\downarrow \alpha_\pm^{(n+1)}$, we get for $n \gtrless 0$,

$$\mathbf{S}_{n-1}^\uparrow = \left[\mathbf{L} - \imath n\omega + \mathbf{X}\mathbf{S}_n^\uparrow\right]^{-1} \mathbf{X} \qquad \text{and} \qquad \mathbf{S}_{n+1}^\downarrow = \left[\mathbf{L} - \imath n\omega - \mathbf{X}\mathbf{S}_n^\downarrow\right]^{-1} \mathbf{X} \ . \quad (40.217)$$

By recursive substitution of the lower into the upper equation, the stationary solution can now be written by means of continued fractions,

$$\mathbf{S}_0^{\uparrow\downarrow} \equiv \frac{1}{\mathbf{L} - \imath\omega \pm \mathbf{X}\frac{1}{\mathbf{L} - 2\imath\omega \pm \mathbf{X}\frac{1}{\cdots}}\mathbf{X}}\mathbf{X} \ . \qquad (40.218)$$

$\alpha_\pm(\infty)$ in Eq. (40.216) gives us the stationary solution of the differential equation, time-averaged over an oscillation period.

If we are deep in the Lamb-Dicke regime, we need only consider the first order of the continued fractions. We set $\mathbf{S}_1^{\uparrow\downarrow} = \mathbf{1}$ and obtain the simplified equations,

$$\begin{aligned} &\mathbf{S}_0^\uparrow = [\mathbf{L} - \imath\omega + \mathbf{X}]^{-1}\mathbf{X} \qquad \text{and} \qquad \mathbf{S}_0^\downarrow = [\mathbf{L} - \imath\omega - \mathbf{X}]^{-1}\mathbf{X} \qquad (40.219)\\ &\alpha_\pm^{(0)} = -\left[\mathbf{L} + \mathbf{X}\left(\mathbf{S}_0^\uparrow - \mathbf{S}_0^\downarrow\right)\right]^{-1} \eta_\pm\\ &\alpha_\pm^{(1)} = \mathbf{S}_0^\uparrow \alpha_\pm^{(0)} \qquad \text{and} \qquad \alpha_\pm^{(-1)} = \mathbf{S}_0^\downarrow \alpha_\pm^{(0)} \ . \end{aligned}$$

Explicitly,

$$\begin{aligned} \mathbf{S}_0^{\uparrow\downarrow} &= \frac{U_0 k z_0}{(\kappa + \imath U_0 + \imath\omega)^2 + U_0^2(1 - k^2 x_0^2)} \begin{pmatrix} -U_0(1 \pm k z_0) & \imath(\kappa + \imath U_0 + \imath\omega) \\ -\imath(\kappa + \imath U_0 + \imath\omega) & -U_0(-1 \pm k z_0) \end{pmatrix}\\ \mathbf{S}_0^\uparrow - \mathbf{S}_0^\downarrow &= \frac{-2U_0^2 k^2 x_0^2}{(\kappa + \imath U_0 + \imath\omega)^2 + U_0^2(1 - k^2 x_0^2)} \mathbb{I}_2\\ \alpha_\pm &= \alpha_\pm^{(0)} + \alpha_\pm^{(1)} e^{\imath\omega t} + \alpha_\pm^{(-1)} e^{-\imath\omega t} \ . \qquad (40.220) \end{aligned}$$

Finally,

$$\boxed{\alpha_\pm = -[1 + \mathbf{S}_0^\uparrow e^{\imath\omega t} + \mathbf{S}_0^\downarrow e^{-\imath\omega t}][\mathbf{L} + \mathbf{X}(\mathbf{S}_0^\uparrow - \mathbf{S}_0^\downarrow)]^{-1}\eta_\pm} \ . \qquad (40.221)$$

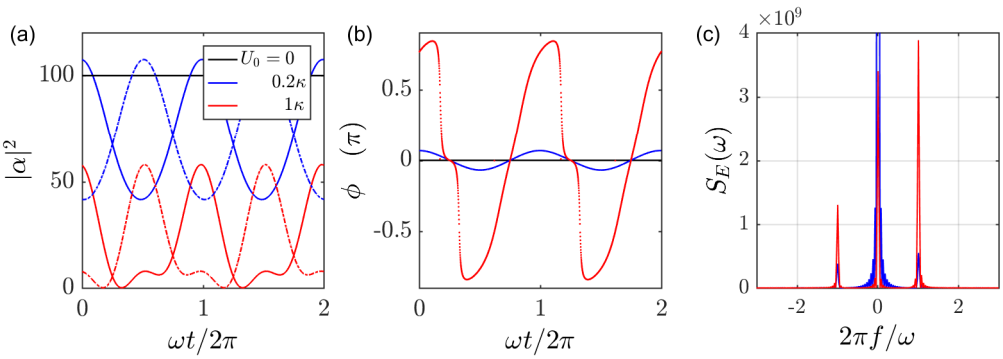

Figure 40.15: (code) (a) Photon number and (b) phase shift of the cavity in response to a modulated atomic position. The parameters are $kz_0 = 1$, $\kappa = (2\pi)\ 20\,\mathrm{kHz}$, $\omega = 2.5\kappa$, and $\eta_\pm = 10\kappa$. (c) Spectrum recorded behind a cavity mirror with the transmittivity t_{hr}. The spectrum is obtained as the Fourier transform of the $g^{(1)}(\tau)$ correlation function of the transmitted field $E_{out} = t_{hr}e^{\imath ka}E_{cav}$, where $e^{\imath ka}$ is a fixed phase factor depending on the mirror position a (see Sec. 35.5.2).

The Fig. 40.15 shows how the phase of the ring cavity behaves in time for various atom-field coupling constants.

It is interesting to study the oscillatory response of the cavity-field to a forced atomic vibration, because it yields information about the cavity backaction. In fact, as shown above, the vibrating atom imprints sidebands to the intracavity refractive index [1141, 9]. The sidebands appear in the cavity transmission spectrum. A more sophisticated method to detect the backaction could be to watch the response in the beat signal to a periodic modulation of the incoupled fields with a vibrating atom,

$$\dot{\alpha}_\pm = (-\kappa - \imath U_0)\alpha_\pm - \imath U_0 e^{\mp 2\imath k z_0 \sin\omega t}\alpha_\mp + \eta e^{\pm\imath\phi_0 \sin\omega_\phi t}\ . \tag{40.222}$$

We would expect a clear signature for resonance, $\omega_\phi = \omega$. The sidebands of the modulated pump would be coupled in, if they coincide. Instead of monitoring the cavity field, we could search the signature of the backaction in the atomic response. We will come back to this, when we discuss collective effects and the frequency shift of the center-of-mass motion. Do the Exc. 40.2.9.15. In Exc. 40.2.9.16 we study the spectrum of resonance fluorescence emitted by a ring cavity incorporating a beam splitter, and in Exc. 40.2.9.16 we study the spectrum of resonance fluorescence emitted by a linear cavity interacting with a single atom.

40.2.9 Exercises

40.2.9.1 Ex: Cooperative Lamb shift in a cavity

Calculate the cooperative Lamb shift in a cavity from the second formula (40.90) and plot the result as a function of the cavity detuning.

Solution: *The recipe to calculate the the cooperative Lamb shift is given by the second*

equation (40.90),

$$\Delta\omega = \sum_i \iint \frac{d^2 \sin^2\theta_{\mathbf{k}}}{\hbar^2} \frac{\hbar\omega_0}{2\varepsilon_0 V} \frac{1}{\omega_{ei} - \omega_{\mathbf{k}}} \rho(\omega_{\mathbf{k}}, \mathbf{k}) d\Omega_{\mathbf{k}} d\omega_{\mathbf{k}} \ .$$

Using previous results we can replace the density of states by (40.94), (40.91), and (40.42) and the integral over small solid angle by,

$$\int_{\hat{e}_k \in cav} \sin^2\theta_{\mathbf{k}} d\Omega_{\mathbf{k}} \simeq \tfrac{3}{8\pi}\Omega_{cav}$$

for $\theta_{\mathbf{k}} = \frac{\pi}{2}$. *Using the abbreviation (40.92), we obtain,*

$$\begin{aligned}\Delta\omega_{cav} &= \sum_i \Gamma_{free} \frac{3}{16\pi^2}\Omega_{cav} \int \frac{\mathcal{L}(\omega_{\mathbf{k}})}{\omega_{ei} - \omega_{\mathbf{k}}} d\omega_{\mathbf{k}} \\ &= \sum_i \Gamma_{free} \frac{3}{16\pi^2}\Omega_{cav} \int \frac{\sqrt{1 + (2F/\pi)^2}}{1 + (2F/\pi)^2 \sin^2 kL} \frac{1}{\omega_{ei} - \omega_{\mathbf{k}}} d\omega_{\mathbf{k}} \ .\end{aligned}$$

The only contribution to the difference in frequency shifts occurs near a resonance $\omega_{\mathbf{k}} \simeq \omega_{eg}$. *Therefore,*

$$\Delta\omega_{cav} \simeq \Gamma_{free} \frac{3}{32\pi}\Omega_{cav} \frac{\mathcal{L}'(\omega_{eg})}{\mathcal{L}(\omega_{eg})} 2\delta_{fsr} = \Gamma_{free} \frac{3}{32\pi}\Omega_{cav} \frac{(2F/\pi)^2 \sin(\omega_{eg}/\delta_{fsr})}{1 + (2F/\pi)^2 \sin^2(\omega_{eg}/2\delta_{fsr})} \ .$$

The spectrum is shown in Fig. 40.16

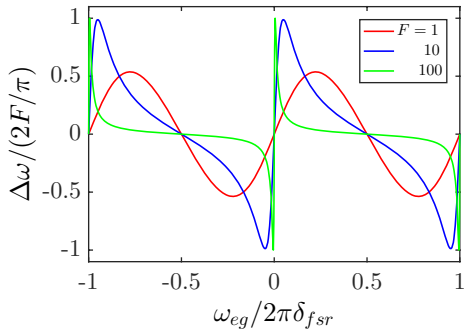

Figure 40.16: (code) Spectrum of the cooperative Lamb shift for three different finesses F.

40.2.9.2 Ex: Cooperative amplification for a rubidium gas in a cavity

Consider an non-degenerate cavity characterized by $\delta_{fsr} = 2\,\text{GHz}$, $F = 80$, and $w_0 = 6\,\mu\text{m}$. In order to benefit from the cooperativity of the cavity, the atoms must be within a volume axially delimited by the Rayleigh length and radially by the diameter of the mode near its waist.
a. Calculate the Rayleigh length for a wavelength of 780 nm and the mode volume.

b. For a given partial pressure of rubidium at room temperature of $p \approx 10^{-5}\,\mathrm{Pa}$, calculate the average number of atoms within the mode volume.
c. Of these atoms only those with an axial Doppler shift below $kv_z < \kappa$ emit resonantly into the cavity. Calculate the number of these atoms from the Maxwell-Boltzmann distribution.
d. Calculate the cooperative amplification of the emission rate into the cavity.

Solution: *a. The Rayleigh length is* $z_R = kw_0^2/2$. *This corresponds to a volume of* $V \simeq \pi w_0^2 z_R$.
b. The average number of atoms inside the mode volume is,

$$N_m = \frac{pV}{k_B T} \simeq 120 \ .$$

c. The number of atoms within the given velocity range is,

$$\begin{aligned} N_{kv_z} &= N_m \left(\frac{m}{2\pi k_B T}\right)^{3/2} \int e^{-m\mathbf{v}^2/2k_B T} d^3\mathbf{v} \\ &= N_m \left(\frac{\pi m}{2k_B T}\right)^{1/2} \int_0^{\kappa/k} e^{-mv_z^2/2k_B T} dv_z \\ &\simeq N_m \left(\frac{\pi m}{2k_B T}\right)^{1/2} \frac{\kappa}{k} = N_m \sqrt{\pi} \frac{\kappa}{k\bar{v}} \simeq 2 \ . \end{aligned}$$

Note that the interaction time of an atom transversely crossing the cavity mode is $w_0\sqrt{\frac{k_B T}{m}} \simeq 17\,\mathrm{ms}$.
d. The emission rate into the cavity is now,

$$R = \Gamma_{cav}|_{\hat{\mathbf{e}}_{\mathbf{k}} \in cav} \ N_{kv_z} = \Gamma_{free} \sqrt{1 + \left(\frac{2F}{\pi}\right)^2} \ \frac{3}{8\pi} \ \frac{8\pi}{k^2 w_0^2} \ N_m \sqrt{\pi} \frac{\kappa}{k\bar{v}} \ .$$

Without cavity,

$$R = \Gamma_{free} \cdot \frac{3}{8\pi} \cdot \frac{8\pi}{k^2 w_0^2} \cdot N_m \sqrt{\pi} \frac{\kappa}{k\bar{v}} \simeq 15000\,\mathrm{s}^{-1} \ .$$

With the cavity,

$$\Upsilon_{ndg} = \frac{F}{\pi} \cdot \frac{6}{k^2 w_0^2} \simeq 0.06 \ ,$$

we obtain,

$$R = \Gamma_{free} \cdot \eta \cdot N_m \sqrt{\pi} \frac{\kappa}{k\bar{v}} \simeq 780000 \ .$$

40.2.9.3 Ex: Characteristic parameters for various atom-cavity systems

Complete the following table calculating κ, V_m, ω_r, g_1, Υ, s, and r,

	rubidium	strontium
Γ	6 MHz	6.8 kHz
$\mathcal{F}$	250000	250000
L	100 μm	3 cm
w_0	20 μm	70 μm

Solution: *The completed table is,*

	rubidium	*strontium*
Γ	6 MHz	6.8 kHz
$\mathcal{F}$	250000	250000
L	100 μm	3 cm
w_0	20 μm	70 μm
κ	6 MHz	16 kHz
V_m	0.0002 mm^3	1 mm^3
ω_r	5 kHz	5 kHz
g_1	18 MHz	9 kHz
Υ	9	1
s	9	3
r	0.0008	0.3

40.2.9.4 Ex: Number of photons in a cavity

a. How many photons are in the mode of a cavity with finesse $F = 80000$ (i) in resonance and (ii) out of resonance resonantly pumped with a laser power of $P_{in} = 100\,\mu W$?
b. What power must be injected to produce 1 photon inside the cavity?
c. Resonant backscattering by the cavity mirrors can scatter photons into the reverse mode. Typically, $P_-/P_+ \simeq 0.005$. Hence, $n^{on}_{-,cav} = 1.5 \times 10^7$ and $n^{off}_{-,cav} = 0.01$. Using advanced techniques it is possible to reduce the number of backscattered photons by factor of > 20. Assuming that the losses due to backscattering are $S = 1$ ppm. Can the resonant backscattering by the mirrors destroy a BEC?
d. What is the amplitude of the output signal in terms of photons?

Solution: *a. The Airy formulas for the simplified case of a cavity with two identical mirrors give the intracavity intensity,*

$$\frac{P_{cav}}{P_{in}} = \frac{1}{T}\frac{(1-R)^2}{(1-R)^2 + 4R\sin^2\delta/2} \ ,$$

with $T = 1 - R$. For $\delta = 2\pi N$ and $\delta = 2\pi N + \pi$, we obtain respectively,

$$\frac{P^{on}_{cav}}{P_{in}} = \frac{1}{T} \qquad \textit{and} \qquad \frac{P^{off}_{cav}}{P_{in}} = \frac{1}{T}\frac{(1-R)^2}{(1+R)^2} \approx \frac{T}{2} \ .$$

From the finesse, $F = \pi\sqrt{R}/(1-R)$, we estimate the reflectivity of the mirrors $R \approx 1 - \pi/F$. Therefore, the fraction of the power injected in and out of resonance are, $P^{on}_{cav}/P_{in} \simeq 25000$ and $P^{off}_{cav}/P_{in} = 2 \times 10^{-5}$. Pumping the cavity mode with $P_{in} = 100\,\mu\mathrm{W}$ gives,

$$n^{on}_{+,cav} = \frac{P_{in}}{T\hbar\omega\delta_{fsr}} = 3 \times 10^9 \qquad \text{and} \qquad n^{off}_{+,cav} = 2.3 \ ,$$

photons.
b. We need $P_{in}/n^{on}_{+,cav} \simeq 0.3\,\mathrm{pW}$.
c. The photon number reflected from one mirror into the waist $(w_0/4L)^2 S n^{on}_{cav} \simeq 7 \times 10^{-3}$ into the cross section of a BEC $(\bar{r}/4L)^2 S n^{on}_{cav} \simeq 6 \times 10^{-6}$. The effect is negligible.
d. Assume an integration time of $\tau = 1\,\mu\mathrm{s}$. The count rate leaking out of the cavity is,

$$R = \frac{P_{-,out}}{\hbar\omega} = \frac{TP^{on}_{-,cav}}{\hbar\omega} = T\delta_{fsr} n^{on}_{-,cav} = \kappa n^{on}_{-,cav} \ .$$

Within τ we count $n_{-,out}\tau = \kappa n^{on}_{-,cav}\tau \simeq 2 \times 10^6$ photons. The photon counter can only count 10 photons per τ.

40.2.9.5 Ex: Saturation-induced bistability in a linear cavity

a. Derive the equations of motion for N immobile atoms located at positions z_j along the optical axis of and interacting with a linear cavity.
b. Assuming steady-state and doing the mean-field approximation isolate an equation for the cavity field $\alpha \equiv \langle \hat{a} \rangle$.
c. Simplify the equation for α for the case of perfect bunching $z_j = z$ and solve it analytically. Identify the instability.
d. Discuss the weak excitation limit.
e. Derive the transmission spectrum in the weak excitation limit.
f. Write down the equation for $n = |\alpha|^2$ for the resonant case, $\Delta_c = 0 = \Delta_a$, in terms of the single-atom cooperativity parameter $\Upsilon \equiv 4g^2/\gamma\Gamma$ and the single-photon saturation parameter $s_1 \equiv 8g^2/\Gamma^2$.

Solution: *a. The Hamiltonian for the open Dicke model applied to N atoms distributed over the mode volume of a ring cavity within the RWA is,*

$$\hat{H} = \hat{H}_{field} + \hat{H}_{pump} + \sum_{j=1}^{N} (\hat{H}^{(j)}_{atom} + \hat{H}^{(j)}_{atom:field}) \tag{40.223}$$

with

$$\begin{aligned} \hat{H}^{(j)}_{atom} &= -\Delta_a \hat{\sigma}^+_j \hat{\sigma}^-_j = -\tfrac{\Delta_a}{2}(\mathbb{I}_2 + \hat{\sigma}^z_j) \\ \hat{H}_{field} &= -\Delta_c \hat{a}^\dagger \hat{a} \\ \hat{H}_{pump} &= -\imath\eta(\hat{a} - \hat{a}^\dagger) \\ \hat{H}^{(j)}_{atom:field} &= g \sin kz_j (\hat{a}\hat{\sigma}^+_j + \hat{a}^\dagger \hat{\sigma}^-_j) \ . \end{aligned} \tag{40.224}$$

Using this Hamiltonian we derive the equations of motion for the individual atomic operators,

$$\begin{aligned}\dot{\hat{\sigma}}_i^- &= -\imath[\hat{\sigma}_i^-, \hat{H}] + \mathcal{L}_\Gamma \hat{\sigma}_i^- \\ &= \imath\Delta_a \sum_j [\hat{\sigma}_i^-, \hat{\sigma}_j^+]\hat{\sigma}_j^- - \imath g \sum_j \hat{a} \sin kz_j [\hat{\sigma}_i^-, \hat{\sigma}_j^+] - \tfrac{\Gamma}{2}\hat{\sigma}_i^- \\ &= (\imath\Delta_a - \tfrac{\Gamma}{2})\hat{\sigma}_i^- + \imath g \hat{a}\hat{\sigma}_i^z \sin kz_i \ ,\end{aligned} \tag{40.225}$$

and

$$\begin{aligned}\dot{\hat{\sigma}}_i^z &= -\imath[\hat{\sigma}_i^z, \hat{H}] + \mathcal{L}_\Gamma \hat{\sigma}_i^z \\ &= -\imath g \sum_j \hat{a} \sin kz_j [\hat{\sigma}_i^z, \hat{\sigma}_j^+] - \imath g \sum_j \hat{a}^\dagger \sin kz_j [\hat{\sigma}_i^z, \hat{\sigma}_j^-] + 2\Gamma \hat{\sigma}_i^+ \hat{\sigma}_i^- \\ &= -2\imath g \sin kz_i (\hat{a}\hat{\sigma}_i^+ - \hat{a}_+^\dagger \hat{\sigma}_i^-) - \Gamma(\mathbb{I}_2 + \hat{\sigma}_i^z) \ ,\end{aligned} \tag{40.226}$$

and for the field operators,

$$\begin{aligned}\dot{\hat{a}} &= -\imath[\hat{a}, \hat{H}] + \mathcal{L}_\kappa \hat{a} \\ &= \imath\Delta_c [\hat{a}, \hat{a}^\dagger \hat{a}] + \eta[\hat{a}, \hat{a}^\dagger] - \imath g \sum_j \hat{\sigma}_j^- \sin kz_j [\hat{a}, \hat{a}^\dagger] - \kappa\hat{a} \\ &= (\imath\Delta_c - \kappa)\hat{a} - \imath g \sum_j \hat{\sigma}_j^- \sin kz_j + \eta \ .\end{aligned} \tag{40.227}$$

b. The stationary solution follows from the expectation values of the Eqs. (40.225), (40.226), and (40.227),

$$\begin{aligned}&(i) \qquad 0 = (\imath\Delta_a - \tfrac{\Gamma}{2})\langle\hat{\sigma}_i^-\rangle - \imath g \langle\hat{a}\hat{\sigma}_i^z\rangle \sin kz_i \\ &(ii) \qquad 0 = 2\imath g \sin kz_i (\langle\hat{a}\hat{\sigma}_i^+\rangle - \langle\hat{a}^\dagger\hat{\sigma}_i^-\rangle) + \Gamma(\mathbb{I}_2 - \langle\hat{\sigma}_i^z\rangle) \\ &(iii) \qquad 0 = (\imath\Delta_c - \kappa)\langle\hat{a}\rangle - \imath g \sum_j \langle\hat{\sigma}_j^-\rangle \sin kz_j + \eta \ .\end{aligned} \tag{40.228}$$

Neglecting all correlations, we derive from (i),

$$\langle\hat{\sigma}_i^-\rangle = \frac{-\imath g}{\frac{\Gamma}{2} - \imath\Delta_a} \alpha \sin kz_i \langle\hat{\sigma}_i^z\rangle \ . \tag{40.229}$$

Substituting $\langle\hat{\sigma}_i^\pm\rangle$ in (ii),

$$\left(1 + \frac{2g^2}{\frac{\Gamma^2}{4} + \Delta_a^2} |\alpha|^2 \sin^2 kz_i\right) \langle\hat{\sigma}_i^z\rangle = 1 \ , \tag{40.230}$$

and in (iii),

$$-(\imath\Delta_c - \kappa)\alpha + \sum_j \frac{g^2}{\frac{\Gamma}{2} - \imath\Delta_a} \alpha \sin^2 kz_j \langle\hat{\sigma}_j^z\rangle = \eta \ . \tag{40.231}$$

Substituting $\langle\hat{\sigma}_j^z\rangle$,

$$-(\imath\Delta_c - \kappa)\alpha + \sum_j \frac{g^2(\frac{\Gamma}{2} + \imath\Delta_a)\alpha \sin^2 kz_j}{\frac{\Gamma^2}{4} + \Delta_a^2 + 2g^2|\alpha|^2 \sin^2 kz_j} = \eta \ . \tag{40.232}$$

or, using the abbreviations $U_\gamma \equiv U_0 - \imath\gamma_0$ *and* $\Delta_\kappa \equiv \Delta_c + \imath\kappa$,

$$\boxed{\sum_j \frac{U_\gamma \alpha \sin^2 kz_j}{1 + 2|U_\gamma/g|^2|\alpha|^2 \sin^2 kz_j} = \Delta_\kappa \alpha - \imath\eta} \ . \tag{40.233}$$

c. From this in the case of perfect bunching, $z_j = z$, *we get,*

$$\alpha = \frac{\imath\eta}{\Delta_\kappa - \frac{NU_\gamma \sin^2 kz}{1+2|U_\gamma/g|^2|\alpha|^2 \sin^2 kz}} \ . \tag{40.234}$$

With the abbreviation $g \longrightarrow g \sin kz$,

$$\alpha = \frac{\imath\eta}{\Delta_\kappa - \frac{NU_\gamma}{1+2|U_\gamma/g|^2|\alpha|^2}} \ , \tag{40.235}$$

and defining $\tilde{U}_\gamma \equiv U_\gamma/g_1$, $\tilde{\Delta}_\kappa \equiv \Delta_\kappa/g_1$, $\tilde{\eta} \equiv \eta/g_1$, $\tilde{N} \equiv N \sin^2 kz$, *and* $n \equiv |\alpha|^2$,

$$\alpha = \frac{\imath\tilde{\eta}}{\tilde{\Delta}_\kappa - \frac{N\tilde{U}_\gamma}{1+2|\tilde{U}_\gamma|^2 n}}. \tag{40.236}$$

From this we calculate the photon number,

$$n = \frac{\tilde{\eta}^2(1 + 2|\tilde{U}_\gamma|^2 n)^2}{|\tilde{\Delta}_\kappa|^2(1 + 2|\tilde{U}_\gamma|^2 n)^2 - N\left(\tilde{\Delta}_\kappa \tilde{U}_\gamma^* + \tilde{\Delta}_\kappa^* \tilde{U}_\gamma\right)(1 + 2|\tilde{U}_\gamma|^2 n) + N^2|\tilde{U}_\gamma|^2} \ . \tag{40.237}$$

Sorting the terms by powers of photon numbers we obtain a cubic equation, $0 = An^3 + Bn^2 + Cn + D$, *with the coefficients,*

$$\begin{aligned} A &= 4|\tilde{\Delta}_\kappa|^2|\tilde{U}_\gamma|^4 \\ B &= 4|\tilde{\Delta}_\kappa|^2|\tilde{U}_\gamma|^2 - 2N\left(\tilde{\Delta}_\kappa \tilde{U}_\gamma^* + \tilde{\Delta}_\kappa^* \tilde{U}_\gamma\right)|\tilde{U}_\gamma|^2 - 4\tilde{\eta}^2|\tilde{U}_\gamma|^4 \\ C &= |\tilde{\Delta}_\kappa|^2 - N\left(\tilde{\Delta}_\kappa \tilde{U}_\gamma^* + \tilde{\Delta}_\kappa^* \tilde{U}_\gamma\right) + N^2|\tilde{U}_\gamma|^2 - 4\tilde{\eta}^2|\tilde{U}_\gamma|^2 \\ D &= -\tilde{\eta}^2 \ . \end{aligned} \tag{40.238}$$

The roots of the cubic equation are given by,

$$R \equiv \sqrt[3]{36CBA - 108DA^2 - 8B^3 + 12\sqrt{3}A\sqrt{4C^3A - C^2B^2 - 18CBAD + 27D^2A^2 + 4DB^3}} \tag{40.239}$$

and

$$X_\pm \equiv \frac{R}{6A} \pm \frac{6AC - 2B^2}{3AR} \tag{40.240}$$

so that,

$$n_0 = X_- - \frac{B}{3A} \quad , \quad n_\pm = -\frac{1}{2}X_- - \frac{B}{3A} \pm \frac{\imath\sqrt{3}}{2}X_+ \ . \tag{40.241}$$

From this expression we numerically find $n = |\alpha_+ + \alpha_-|^2$, *which we ca use to finally obtain* α.

d. Assuming weak excitation, $g|\alpha_\pm| \ll \Gamma, \Delta_a$, *expression (40.233) simplifies to,*

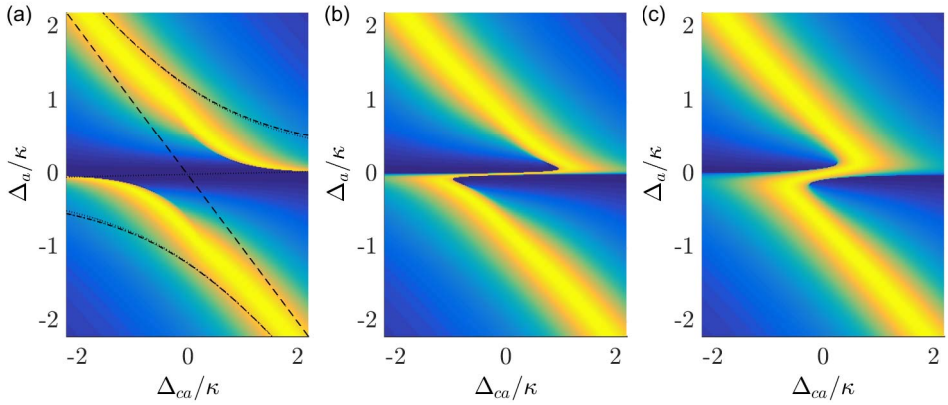

Figure 40.17: (code) Normal mode spectrum using the formula (40.244).

$$U_\gamma \alpha \sum_j \sin^2 kz_j = \Delta_\kappa \alpha - \imath\eta \ . \tag{40.242}$$

That is, defining the bunching parameter $b \equiv \frac{1}{N}\sum_j \sin^2 kz_j$,

$$NU_\gamma \alpha b = \Delta_\kappa \alpha - \imath\eta \ . \tag{40.243}$$

Resolving for α *we finally get,*

$$\alpha(\infty) \simeq \frac{-\imath\eta}{NU_\gamma b - \Delta_\kappa} = \frac{\eta}{\chi} = \frac{\eta}{\kappa + \imath(NbU_0 - \Delta_{ca} - \Delta_c)} \ , \tag{40.244}$$

defining $\chi \equiv \imath(NbU_\gamma - \Delta_\kappa)$ *and* $\Delta_{ca} \equiv \Delta_c - \Delta_a$. *Hence, finite bunching only effects the efficient number of atoms participating in the normal-mode splitting.*
e. The excitation spectrum for $\Gamma \simeq 0$ *is derived from the steady-state solution using the request,* $0 = \frac{d}{d\Delta_{ca}}|\alpha(\infty)|^2$. *We get,*

$$\Delta_{ca} = NbU_0 - \Delta_a = \frac{Nbg^2}{\Delta_a} - \Delta_a \ . \tag{40.245}$$

Assuming, $\Delta_{ca} = 0$, *we have the normal-mode splitting,*

$$\Delta_a = \pm g\sqrt{Nb} \ . \tag{40.246}$$

The transmission is illustrated in Fig. 40.18.
f. From Eq. (40.234) we get,

$$n = \frac{\eta^2}{\left|\Delta_\kappa - \frac{NU_\gamma}{1+2|U_\gamma/g|^2 n}\right|^2} \ , \tag{40.247}$$

and thus,

$$n = \frac{\eta^2}{\kappa^2}\left(\frac{1+s_1 n}{1+s_1 n + \frac{N\Upsilon}{2}}\right)^2 \ . \tag{40.248}$$

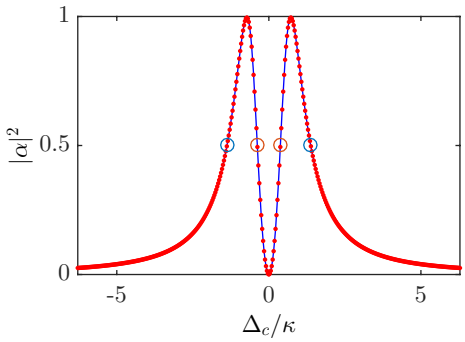

Figure 40.18: (code) Normal mode spectrum using the formula (40.244).

40.2.9.6 Ex: Emission spectrum of atoms in a linear cavity below saturation

a. Derive the mean-field evolution equation for the intracavity field $\alpha(t) = \langle \hat{a}(t) \rangle$ for a linear cavity driven below saturation.
b. Is it possible to calculate the autocorrelation spectrum and the emission spectrum of the cavity from $\langle \alpha^*(t+\tau)\alpha(t) \rangle$ [226, 1039]?
c. Calculate numerically the emission spectrum of a linear cavity interacting with many atoms using for the cavity mode a Fock state expansion up to a cut-off photon number of $n_{\rm cutoff} = 10$. Assume $(\eta, \Gamma, N, g_1, \Delta) = (0.1\kappa, 0.002\kappa, 100000, 0.002\kappa, 0)$. Interpret the result [949, 497].

Solution: *a. We use the steady-state solution, Eqs. (40.229) and (40.230), for the atomic state derived from the Maxwell-Bloch equations in Exc. 40.2.9.5,*

$$\langle \hat{\sigma}_i^- \rangle = \frac{-\imath g}{\frac{\Gamma}{2} - \imath \Delta_a} \alpha \sin kz_i \langle \hat{\sigma}_i^z \rangle = \frac{U_\gamma}{g} \alpha \sin kz_i \langle \hat{\sigma}_i^z \rangle \tag{40.249}$$

$$1 = \left(1 + \frac{2g^2 \sin^2 kz_i}{\frac{\Gamma^2}{4} + \Delta_a^2} |\alpha|^2 \right) \langle \hat{\sigma}_i^z \rangle = \left(1 + 2 \sin^2 kz_i \left| \frac{U_\gamma}{g} \right|^2 |\alpha|^2 \right) \langle \hat{\sigma}_i^z \rangle \ . \tag{40.250}$$

However, instead of inserting them into the steady-state equation of the field amplitude (40.228)(iii), we insert them into time-dependent mean-field equation (40.227),

$$\dot{\hat{a}} = \imath \Delta_\kappa \hat{a} - \imath g \sum_j \hat{\sigma}_j \sin kz_j + \eta \ . \tag{40.251}$$

This yields,

$$\dot{\alpha} = \imath \Delta_\kappa \alpha - \imath U_\gamma \alpha \sum_j \sin^2 kz_j \langle \hat{\sigma}_j^z \rangle + \eta \tag{40.252}$$

$$= \left(\imath \Delta_\kappa - \imath U_\gamma \sum_j \frac{\sin^2 kz_j}{1 + 2 \sin^2 kz_i |U_\gamma/g|^2 |\alpha|^2} \right) \alpha + \eta \ .$$

Below saturation, the denominator simplifies dramatically, and with $b \equiv \frac{1}{N}\sum_j \sin^2 kz_j$ *we obtain,*

$$\dot{\alpha} \simeq \imath(\Delta_\kappa - NbU_\gamma)\alpha + \eta = -\chi\alpha + \eta \ , \tag{40.253}$$

with $\chi \equiv \imath(NbU_\gamma - \Delta_\kappa) = \kappa + \imath(NbU_0 - \Delta_c)$*. For the initial condition* $\alpha(t) = 0$ *it is easy to see that this equation is solved by,*

$$\alpha(t) = \frac{\eta}{\chi}(1 - e^{-\chi t}) \ . \tag{40.254}$$

b. Naively, one might think that the autocorrelation function and the spectrum are given, respectively by,

$$g^{(1)}(\tau) \equiv \frac{\langle \alpha^*(t+\tau)e^{\imath\omega\tau}\alpha(t)\rangle}{\langle \alpha^*(t)\alpha(t)\rangle} \qquad with \qquad \langle ...\rangle \equiv \lim_{t\to\infty}\frac{1}{t}\int_0^t ...dt' \tag{40.255}$$
$$and \qquad S(\nu) = \mathcal{F}g^{(1)}(\tau) \ .$$

The autocorrelation function strongly dominated by an elastic peak, since,

$$\langle \alpha^*(t+\tau)e^{\imath\omega\tau}\alpha(t)\rangle = \frac{\eta^2}{|\chi|^2}e^{\imath\omega\tau}\lim_{t\to\infty}\frac{1}{t}\int_0^t (1 - e^{-\chi^*(t'+\tau)})(1 - e^{-\chi t'})dt' = \frac{\eta^2}{|\chi|^2}e^{\imath\omega\tau} \ , \tag{40.256}$$

which is not what we expect, because the fluorescence spectrum should contain inelastic contributions from two normal-modes. The problem is due to the fact that, deriving the expression we approximated the cavity field by its first-order mean-field, $\alpha = \langle\hat{a}\rangle$*, while the spectrum requires evaluation of second-order correlations. That is,* $\langle \alpha^*(t+\tau)e^{\imath\omega\tau}\alpha(t)\rangle$ *is NOT the correct way to calculate the autocorrelation, but* $\langle \hat{a}^*(t+\tau)e^{\imath\omega\tau}\hat{a}(t)\rangle$*.*
Actually, using the Julia package 'QuantumCumulants.jl', we can derive the following closed set of equations for the expectation values of the observables and their correlations,

$$\begin{aligned}
[\partial - \imath\Delta_c + \kappa]\langle\hat{a}\rangle &= \eta \\
[\partial + 2\kappa]\langle\hat{a}^\dagger\hat{a}\rangle &= \imath N g_1(\langle\hat{a}\hat{\sigma}_{1,21}\rangle - \langle\hat{a}^\dagger\hat{\sigma}_{1,12}\rangle) + \eta(\langle\hat{a}^\dagger\rangle + \langle\hat{a}\rangle) \\
[\partial + \Gamma]\langle\hat{\sigma}_{1,22}\rangle &= \imath g_1(\langle\hat{a}^\dagger\hat{\sigma}_{1,12}\rangle - \langle\hat{a}\hat{\sigma}_{1,21}\rangle) \\
[\partial + \imath\Delta_c + \tfrac{\Gamma}{2} + \kappa]\langle\hat{a}^\dagger\hat{\sigma}_{1,12}\rangle &= \imath g_1\left[\langle\hat{\sigma}_{1,22}\rangle + (2\langle\hat{\sigma}_{1,22}\rangle - 1)\langle\hat{a}^\dagger\hat{a}\rangle - 4\langle\hat{a}^\dagger\rangle\langle\hat{a}\rangle\langle\hat{\sigma}_{1,22}\rangle\right. \\
&\qquad \left. + (N-1)\langle\hat{\sigma}_{1,21}\hat{\sigma}_{2,12}\rangle\right] \\
[\partial + \Gamma]\langle\hat{\sigma}_{1,21}\hat{\sigma}_{2,12}\rangle &= \imath g_1(\langle\hat{a}^\dagger\hat{\sigma}_{1,12}\rangle - \langle\hat{a}\hat{\sigma}_{1,21}\rangle)(1 - 2\langle\hat{\sigma}_{1,22}\rangle) \ ,
\end{aligned} \tag{40.257}$$

as well as for the two-times correlations,

$$\begin{aligned}
[\partial + \imath\Delta_c + \kappa]\langle\hat{a}^\dagger a_0\rangle &= \imath N g_1\langle\hat{\sigma}_{1,21}\hat{a}_0\rangle \\
[\partial + \tfrac{\Gamma}{2}]\langle\hat{\sigma}_{1,21}\hat{a}_0\rangle &= \imath g_1[1 - 2\langle\hat{\sigma}_{1,22}\rangle]\langle\hat{a}^\dagger\hat{a}_0\rangle \ .
\end{aligned} \tag{40.258}$$

Here, phase-invariant expectation values have been set to zero and interatomic correlations ignored by dropping sums over atom number $\sum_{i=1}^N$ *and substituting the single-atom coupling strength* g_1 *by a collective coupling strength* $g_N = g_1\sqrt{N}$*. A numerical*

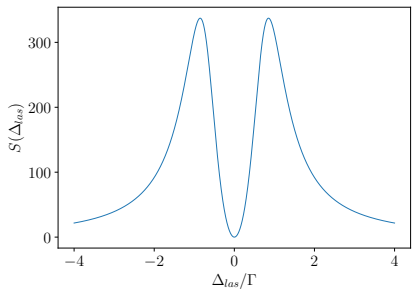

Figure 40.19: (code) Emission spectrum of a linear cavity driven below saturation using the quantum cumulants expansion.

calculation using the Julia 'QuantumCumulants.jl' package is shown in Fig. 40.19.

c. Alternatively, using the Julia package 'QuantumOptics.jl', we can numerically simulate the Hamiltonian for a single atom via a Fock state expansion of the cavity field up to a certain cut-off photon number. The result is exhibited in 40.21. It shows the appearance of an elastic peak and two Mollow triplets due to their beating with the normal modes. The normal modes are separated by g_N, Mollow sidebands are split by $g_N\sqrt{2}$.

The structure of the emission spectrum can be interpreted as follows. As we have already seen in Sec. 35.9.3, the Mollow splitting results from a modulation of spontaneous emission by Rabi flopping, whose frequency depends on the photon number as $g\sqrt{n}$. Similarly, normal-mode splitting would be modulation of cavity decay by Rabi-type flopping between counterpropagating modes. In a linear cavity this doesn't change n, hence we do not expect an n-dependence of normal mode splitting. In contrast the flopping between counterpropagating modes depends on the atom number as NU_0.

Transmission is modulated the collective Rabi oscillation of atoms.

The lowest eigen-energies of the Jaynes-Cummings ladder are,

$$\begin{aligned}\omega_0 &= 0\\ \omega_1 &= \omega \pm 2g\sqrt{1}\\ \omega_2 &= 2\omega \pm 2g\sqrt{2}\\ \omega_3 &= 3\omega \pm 2g\sqrt{3}\ ,\end{aligned}$$

as confirmed by the graph 40.21(b). Hence, the transition frequencies starting from the first excited state are,

$$\begin{aligned}\omega_1 - \omega_0 &= \omega + 2g\sqrt{1}\\ \omega_1 - \omega_0 &= \omega - 2g\sqrt{1}\ ,\end{aligned}$$

and including the second excited state,

$$\begin{aligned}
\omega_2 - \omega_1 &= \omega + 2g(\sqrt{2}+1) \\
\omega_2 - \omega_1 &= \omega + 2g \\
\omega_1 - \omega_0 &= \omega + 2g(\sqrt{2}-1) \\
\omega_1 - \omega_0 &= \omega + 2g(\sqrt{2}-1) \\
\omega_2 - \omega_1 &= \omega - 2g \\
\omega_2 - \omega_1 &= \omega - 2g(\sqrt{2}-1) \ .
\end{aligned}$$

In summary, Autler-Townes splitting is due to Rabi flopping of the degree of freedom

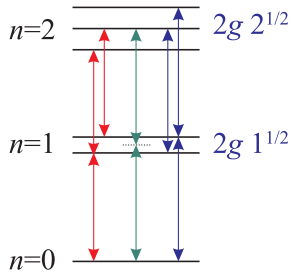

Figure 40.20: Eigenvalue spectrum of the Jaynes-Cummings model due to the first two excited states.

$\hat{\sigma}^-$ and depends on $\sqrt{n}$. Analogously, normal mode splitting is due to a flopping of α and depends on N. This might be interesting for calibrating $g\sqrt{N}$ via normal-mode splitting and, simultaneously $g\sqrt{n}$ via Mollow splitting.

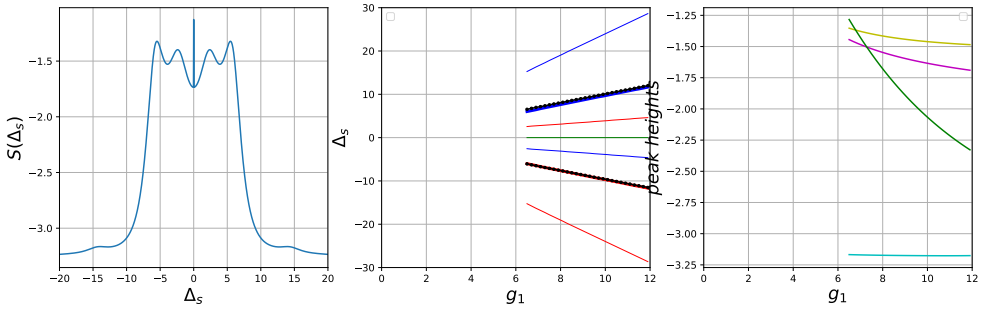

Figure 40.21: (code) (a) Emission spectrum of a linear cavity. (b) Dependence of the peaks's location observed in (a) on the atom-cavity coupling strength g. (thick red/blue lines) Lower and upper Mollow central peaks, respectively. They are separated by normal-mode splitting. (thin red/blue lines) Corresponding Mollow sidebands, (green) elastic peak due to cavity pumping, and (dotted) separations between Mollow central peaks and sidebands. (c) Dependence of the peaks' heights on g. (green) Elastic peak, (yellow) central Mollow peaks, (cyan) outer Mollow sideband, (magenta) inner Mollow sideband.

40.2.9.7 Ex: PDH-probing atoms in a ring cavity

Calculate the steady-state reflection of a phase-modulated laser beam from a ring cavity neglecting backscattering from the atoms. Demodulate the reflection signal with the modulation frequency.

Solution: *The steady-state solution (40.146) is,*

$$\alpha_+ = \frac{\eta_+ - \imath U_\gamma e^{-2\imath kz}\alpha_-}{\kappa - \imath(\Delta_c - U_\gamma)} \ ,$$

where we now neglect $\alpha_- \simeq 0$. Assuming that only the input coupler has finite transmission, with $\eta_+ = \sqrt{\kappa\delta_{fsr}}\beta_{in}$ from Eq. (40.37), the light leaking out of the cavity is then,

$$\beta_{out} = \sqrt{\frac{\kappa}{\delta_{fsr}}}\alpha_+ = \frac{\kappa\beta_{in}}{\kappa - \imath(\Delta_c - U_\gamma)} \ .$$

Note, that without atoms, $U_\gamma = 0$, we recover the Airy function derived in Exc. 18.3.7.18. If the incident light is described by,

$$\beta_{in} = \beta_{0,in}\left[J_0(M)e^{\imath\Delta_c t} + J_{+1}(M)e^{\imath(\Delta_c+\Omega)t} + J_{-1}(M)e^{\imath(\Delta_c-\Omega)t}\right] \ ,$$

the reflection signal becomes ($\Omega \gg \kappa$),

$$\beta_{refl} = \beta_{in} + \beta_{out} = \beta_{0,in}\sum_{n=0,\pm1} J_n(M)e^{\imath(\Delta_c+n\Omega)t}\left(1 + \frac{\kappa}{\kappa - \imath(\Delta_c + n\Omega - U_\gamma)}\right) \ .$$

Introducing the abbreviation,

$$L_n(\Delta_c, U_0) \equiv 1 + \frac{\kappa}{\kappa - \imath(\Delta_c + n\Omega - U_\gamma)} \ ,$$

the demodulated intensity is,

$$\begin{aligned}\mathfrak{Re}\ e^{\imath\Omega t+\imath\theta}\frac{|\beta_{refl}|^2}{\beta_{0,in}^2} &= \mathfrak{Re}\ e^{\imath\Omega t+\imath\theta}\left|\sum_{n=0,\pm1} J_n(M)e^{\imath n\Omega t}L_n(\Delta_c, U_0)\right|^2 \\ &= \mathfrak{Re}\ e^{\imath\theta}J_0(M)J_1(M)\left[L_0(\Delta_c, U_\gamma)L_1^*(\Delta_c, U_\gamma) - L_0^*(\Delta_c, U_\gamma)L_{-1}(\Delta_c, U_\gamma)\right] + \dots \ .\end{aligned}$$

After low-pass filtering, the oscillating terms disappear and we recover the standard PDH-signal, only that the error signal now is a measure for the one-photon light shift caused by the atoms.

40.2.9.8 Ex: Normal mode splitting of a ring cavity

Consider the stationary fields (40.166) developing in a ring cavity containing a homogeneous cloud of atoms and pumped in one direction, $\eta_- = 0$. For this system.
a. Calculate the transmission of the cavity in the direction of mode α_+ as a function of the detunings Δ_a and Δ_c and the number of atoms.

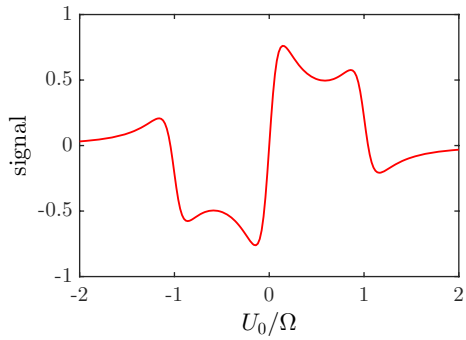

Figure 40.22: (code) PDH-signal induced by one-photon light shift. $\kappa = 0.1\Omega$, $\gamma_0 = 0.05\Omega$, and $\Delta_c = 0$.

Transmission spectra can be recorded under various boundary conditions. Calculate the transmission
b. keeping the laser at a fixed frequency ω and varying the cavity length ω_c;
c. tuning a cavity resonance to the atomic transition, $\omega_c = \omega_a$, and varying the laser frequency ω;
d. same as (d), but now calculate the detunings Δ_{ch} where the transmission drops to 1/2;
e. keeping the cavity constant at an *arbitrary* frequency ω_c and varying the laser frequency ω;
f. keeping the laser locked to the cavity, $\omega = \omega_c + NU_0$, and now ramping the cavity across the atomic resonance.

Solution: *a. The stationary solution for one-way pumping is,*

$$\alpha_+ \simeq -\imath \frac{\eta_+(NU_\gamma - \Delta_\kappa)}{(NU_\gamma - \Delta_\kappa)^2 - (N|b|^2 U_\gamma)^2} \ .$$

For a homogeneous cloud $b = \frac{1}{N}\sum_j e^{2\imath k z_j} = 0$, *so that,*

$$\alpha_+ \simeq \frac{-\imath\eta_+}{NU_\gamma - \Delta_\kappa} \ ,$$

or, substituting the abbreviations [312],

$$\boxed{\alpha_+ = \frac{\eta_+}{\kappa - \imath\Delta_c + \frac{g_N^2}{\Gamma - \imath\Delta_a}}} \ . \tag{40.259}$$

The transmission is given by (40.191),

$$\boxed{T_+ = \left|\frac{\kappa\alpha_+}{\eta_+}\right|^2 = \frac{\kappa^2(\Gamma^2 + \Delta_a^2)}{(\kappa\Gamma + g_N^2 - \Delta_c\Delta_a)^2 + (\Gamma\Delta_c + \kappa\Delta_a)^2}} \ . \tag{40.260}$$

Fig. 40.23 shows cavity transmission spectra.
Defining $\tilde{\Delta}_c \equiv \Delta_c/\kappa$ *and* $\tilde{\Delta}_a \equiv \Delta_a/\Gamma$ *and using the definition (40.125) of the*

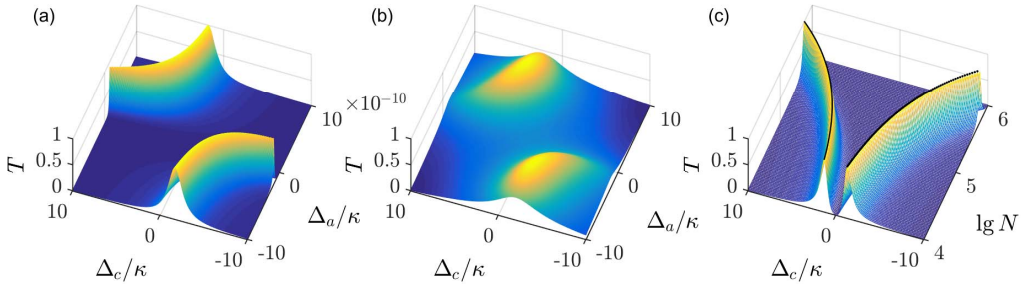

Figure 40.23: (code) Normal mode splitting of an annular cavity for the strontium intercombination line: $\kappa/2\pi = 690\,\mathrm{kHz}$, $\Gamma/2\pi = 7.6\,\mathrm{kHz}$ and $g/2\pi = 8.7\,\mathrm{kHz}$. (b) Convolution with a Lorentzian of 1 MHz width. (c) Dependence of the normal mode splitting on the atom number. The black lines are solutions of Eq. (40.262).

cooperativity, we can also write,

$$T_+ = \frac{1+\tilde{\Delta}_a^2}{\left(1+N\frac{\Upsilon}{2}-\tilde{\Delta}_c\tilde{\Delta}_a\right)^2+(\tilde{\Delta}_c+\tilde{\Delta}_a)^2} \ .$$

b. Keeping the laser at a fixed frequency ω (so that Δ_a is constant) and varying the cavity length Δ_c, we obtain from (40.260),

$$0 = \frac{\partial T_+}{\partial \Delta_c} = -\frac{[-2\Delta_a(\kappa\Gamma+g_N^2-\Delta_c\Delta_a)+2\Gamma(\kappa\Delta_a+\Gamma\Delta_c)]\kappa^2(\Gamma^2+\Delta_a^2)}{\cdots} \ ,$$

yielding,

$$\Delta_c = \frac{g_N^2\Delta_a}{\Gamma^2+\Delta_a^2} = U_0 \ . \tag{40.261}$$

c. Tuning a cavity resonance to the atomic transition, $\omega_c = \omega_a$, and varying the laser frequency, we obtain from (40.260),

$$\begin{aligned} 0 = \frac{\partial T_+}{\partial \Delta_a} &= \frac{\partial \Delta_a^2}{\partial \Delta_a}\frac{\partial T_+}{\partial \Delta_a^2} = 2\Delta_a \frac{\partial}{\partial \Delta_a^2}\frac{\kappa^2\Delta_a^2+\kappa^2\Gamma^2}{\Delta_a^4+(\kappa^2+\Gamma^2-2g_N^2)\Delta_a^2+(\kappa\Gamma+g^2)^2} \\ &= \frac{\kappa^2[\Delta_a^4+(\kappa^2+\Gamma^2-2g_N^2)\Delta_a^2+(\kappa\Gamma+g_N^2)^2]-[2\Delta_a^2+(\kappa^2+\Gamma^2-2g_N^2)][\kappa^2\Delta_a^2+\kappa^2\Gamma^2]}{\cdots} \ . \end{aligned}$$

The solution of this equation,

$$\Delta_a^2 = -\Gamma^2 \pm g_N\sqrt{2\Gamma^2+g_N^2+2\kappa\Gamma} \ , \tag{40.262}$$

is plotted in Fig. 40.23(c) as a black line. For cases of very narrow atomic resonances, $\kappa \gg \Gamma$, we may simplify,

$$\Delta_a^2 \simeq \pm g_N^2\sqrt{1+\frac{4\kappa\Gamma}{2g_N^2}} = \pm N g^2\sqrt{1+\frac{N_{crt}}{N}} \ , \tag{40.263}$$

where $N_{crt} = 4/\Upsilon$ is the critical atom number (40.126) and Υ the cooperativity (40.125).
d. For $\Delta_c = \Delta_a$ the transmission (40.260) simplifies to,

$$T(\Delta_a = \Delta_c) = \frac{\kappa^2(\Gamma^2 + \Delta_c^2)}{(\kappa\Gamma + g_N^2 - \Delta_c^2)^2 + (\Gamma + \kappa)^2\Delta_c^2} \ .$$

Then from $T(\Delta_{ch}) = \frac{1}{2}$ we get,

$$\begin{aligned}\Delta_{ch}^2 &= \tfrac{\kappa^2 - \Gamma^2 + 2g_N^2}{2} \pm \sqrt{\tfrac{(\kappa^2 - \Gamma^2 + 2g_N^2)^2}{4} + \kappa^2\Gamma^2 - 2\kappa\Gamma g_N^2 - g_N^4} \\ &\simeq \tfrac{\kappa^2}{2} + g_N^2 \pm \kappa\sqrt{\tfrac{\kappa^2}{4} + g_N^2} \ .\end{aligned}$$

The last approximation hold for $\Gamma \ll \kappa, g_N$. Now,

$$\Delta_{ch}^2 = \begin{cases} g_N^2 \pm \kappa g_N & for \ \ g_N \gg \kappa \\ \frac{\kappa^2}{2} + g_N^2 \pm \left(\frac{\kappa^2}{2} + g_N^2 - \frac{g_N^4}{\kappa^2}\right) & for \ \ g_N \ll \kappa \end{cases} \ .$$

such that for $g_N \ll \kappa$,

$$|\Delta_{ch}| = \kappa, \tfrac{g_N^2}{\kappa} \ .$$

The detunings are indicated as circles in Fig. 40.18.
e. Keeping the cavity constant at an arbitrary *frequency ω_c, and varying the laser frequency,*

$$0 = \frac{\partial T_+}{\partial \omega} = \frac{\partial}{\partial \omega} \frac{\kappa^2[\Gamma^2 + (\omega - \omega_a)^2]}{[\kappa\Gamma + g^2 - (\omega - \omega_c)(\omega - \omega_a)]^2 + [\kappa(\omega - \omega_a) + \Gamma(\omega - \omega_c)]^2} \ .$$

f. Typically, a locking electronics will maintain the pump laser locked to a cavity resonance, even if the cavity resonance is shifted by the refraction index imposed by atoms in the mode volume, that is,

$$\Delta_c = NU_0 = \omega - \omega_c = \frac{g_N^2\Delta_a}{\Gamma^2 + \Delta_a^2} \ .$$

Substituting the above boundary condition into the expression for the transmission,

$$T_+ = \frac{1}{\left(1 + \frac{g_N^2/\kappa\Gamma}{1 + \Delta_a^2/\Gamma^2}\right)^2} = \frac{1}{\left(1 + \frac{N\Upsilon/2}{1 + \Delta_a^2/\Gamma^2}\right)^2} \ .$$

We are now seeking transmission resonances upon varying the cavity length ω_c. However, we already see from the expression for T_+, that the transmission is maximized for $\Delta_a = 0$.

40.2.9.9 Ex: Time-dependent solution for a ring cavity pumped from one side below saturation

Derive the complete solution of the adiabatic field equations (40.183).

Solution: *For one-sided pumping with* $\chi \equiv \kappa + \imath(U_\gamma - \Delta_c)$ *the equations of motion read,*

$$\begin{aligned}\dot{\alpha}_+ &= -\chi\alpha_+ - \imath U_\gamma e^{-2\imath kz}\alpha_- + \eta_+ \\ \dot{\alpha}_- &= -\chi\alpha_- - \imath U_\gamma e^{2\imath kz}\alpha_+ \ .\end{aligned}$$

To decouple the differential equations from each other we derive one and insert the other,

$$\begin{aligned}\ddot{\alpha}_+ &= -\chi\dot{\alpha}_+ - \imath U_\gamma e^{-2\imath kz}\dot{\alpha}_- \\ &= -\chi\dot{\alpha}_+ + \imath U_\gamma e^{-2\imath kz}(\chi\alpha_- + \imath U_\gamma e^{2\imath kz}\alpha_+) \\ &= -\chi\dot{\alpha}_+ + \imath U_\gamma e^{-2\imath kz}\left(\chi\left[\frac{\dot{\alpha}_+ + \chi\alpha_+ - \eta_+}{-\imath U_\gamma e^{-2\imath kz}}\right] + \imath U_\gamma e^{2\imath kz}\alpha_+\right) \\ &= -2\chi\dot{\alpha}_+ - (U_\gamma^2 + \chi^2)\alpha_+ + \chi\eta_+\end{aligned}$$

and

$$\begin{aligned}\ddot{\alpha}_- &= -\chi\dot{\alpha}_- - \imath U_\gamma e^{2\imath kz}\dot{\alpha}_+ \\ &= -\chi\dot{\alpha}_- + \imath U_\gamma e^{2\imath kz}(\chi\alpha_+ + \imath U_\gamma e^{-2\imath kz}\alpha_- - \eta_+) \\ &= -\chi\dot{\alpha}_- + \imath U_\gamma e^{2\imath kz}\left(\chi\frac{\dot{\alpha}_- + \chi\alpha_-}{-\imath U_\gamma e^{2\imath kz}} + \imath U_\gamma e^{-2\imath kz}\alpha_- - \eta_+\right) \\ &= -2\chi\dot{\alpha}_- - (U_\gamma^2 + \chi^2)\alpha_- - \imath U_\gamma e^{2\imath kz}\eta_+ \ .\end{aligned}$$

This shows that we expect a damped oscillation tending toward the stationary solution. Making the ansatz,

$$\alpha_+ = e^{\lambda t} + \frac{\chi\eta_+}{\chi^2 + U_\gamma^2} \qquad \textit{and} \qquad \alpha_- = e^{\lambda t} + \frac{-\imath U_\gamma e^{2\imath kz}\eta_+}{\chi^2 + U_\gamma^2} \ ,$$

we obtain $\lambda = -\chi \pm \imath U_\gamma$*. Hence,*

$$\alpha_+ = e^{-\chi t}(A_+ e^{\imath U_\gamma t} + B_+ e^{-\imath U_\gamma t}) + \frac{\chi\eta_+}{\chi^2 + U_\gamma^2}$$

and

$$\alpha_- = e^{-\chi t}(A_- e^{\imath U_\gamma t} + B_- e^{-\imath U_\gamma t}) - \frac{\imath U_\gamma e^{2\imath kz}\eta_+}{\chi^2 + U_\gamma^2} \ .$$

Inserting the solutions into the original differential equations yields,

$$A_- = -A_+ e^{2\imath kz} \qquad \textit{and} \qquad B_- = B_+ e^{2\imath kz} \ .$$

$A_\pm$ *and* $B_\pm$ *depend on initial conditions. For example, setting* $\alpha_\pm(0) = 0$ *we get,*

$$A_+ = -\frac{1}{\chi - \imath U_\gamma}\frac{\eta_+}{2} \qquad \textit{and} \qquad B_+ = -\frac{1}{\chi + \imath U_\gamma}\frac{\eta_+}{2} \ ,$$

and finally,

$$\alpha_+(t) = \frac{\eta_+}{\chi^2 + U_\gamma^2}\left[\chi - e^{-\chi t}(\chi\cos U_\gamma t - U_\gamma \sin U_\gamma t)\right]$$
$$\alpha_-(t) = \frac{-\imath e^{2\imath kz}\eta_+}{\chi^2 + U_\gamma^2}\left[U_\gamma - e^{-\chi t}(U_\gamma\cos U_\gamma t + \chi \sin U_\gamma t)\right] \ .$$

Using the abbreviations,

$$U_\gamma \equiv U_0 - \imath\gamma_0 = \frac{g^2}{\Delta_a^2 + (\Gamma/2)^2} \quad , \quad \Delta_\kappa \equiv \Delta_c + \imath\kappa \quad , \quad \chi \equiv \imath(U_\gamma - \Delta_\kappa) \ ,$$

the time-dependent field amplitudes can also be written,

$$\boxed{\begin{array}{rcl} \frac{1}{\imath\eta_+}\alpha_+(t) & = & -\frac{\frac{1}{2}e^{\imath\Delta_\kappa t}}{\Delta_\kappa} + \frac{\frac{1}{2}e^{\imath(\Delta_\kappa - 2U_\gamma)t}}{2U_\gamma - \Delta_\kappa} + \frac{1}{\Delta_\kappa}\frac{U_\gamma - \Delta_\kappa}{2U_\gamma - \Delta_\kappa} \\ \frac{e^{-2\imath kz}}{\imath\eta_+}\alpha_-(t) & = & \frac{\frac{1}{2}e^{\imath\Delta_\kappa t}}{\Delta_\kappa} + \frac{\frac{1}{2}e^{\imath(\Delta_\kappa - 2U_\gamma)t}}{2U_\gamma - \Delta_\kappa} - \frac{1}{\Delta_\kappa}\frac{U_\gamma}{2U_\gamma - \Delta_\kappa} \end{array}} \ .$$

That is, we expect a sideband spectrum with frequency components at 0, Δ_c, *and* $\Delta_c - U_0$. *At long times,*

$$\frac{1}{\imath\eta_+}\begin{pmatrix}\alpha_+ \\ \alpha_-\end{pmatrix} \overset{t\to\infty}{\longrightarrow} \frac{1}{\Delta_\kappa(2U_\gamma - \Delta_\kappa)}\begin{pmatrix}U_\gamma - \Delta_\kappa \\ -U_\gamma e^{2\imath kz}\end{pmatrix} \ ,$$

we recover the usual steady-state solution. On resonance, $\Delta_c = 0 = \Delta_a$, *with the definition of the cooperativity,*

$$U_\gamma = \frac{-2\imath g^2}{\Gamma} \quad , \quad \Delta_\kappa = \imath\kappa \quad , \quad \Upsilon \equiv \frac{4g^2}{\kappa\Gamma}$$

we get,

$$\frac{\kappa}{\eta_+}\alpha_+(t) = -\frac{e^{-\kappa t}}{2} - \frac{\frac{1}{2}e^{-\kappa(1+\Upsilon)t}}{\Upsilon + 1} + \frac{\frac{1}{2}\Upsilon + 1}{\Upsilon + 1}$$
$$\frac{\kappa e^{-2\imath kz}}{\eta_+}\alpha_-(t) = \frac{e^{-\kappa t}}{2} - \frac{\frac{1}{2}e^{-\kappa(1+\Upsilon)t}}{\Upsilon + 1} - \frac{\frac{1}{2}\Upsilon}{\Upsilon + 1} \ .$$

40.2.9.10 Ex: Filling and drainage of a ring cavity with one fixed atom

Calculate by simulation of the classical cavity equations, how a laser-pumped ring cavity fills and looses photons in the presence of a single immobile atom.

Solution: *The result of the simulation is shown in Fig. 40.24. Only the mode* α_+ *is pumped until a time corresponding to* $\kappa t = 0.5$, *when it is switched off. The parameters are* $\kappa = (2\pi)\ 10\,\text{kHz}$, $U_0 = 2\kappa$, $\Delta_c = 0$, *and* $\eta = 10\kappa$. *We see that the intensities of the modes* $|\alpha_\pm|^2$ *do not depend on the atom's location, but the interference signal* $|\alpha_+ - \alpha_-|^2$ *does.*

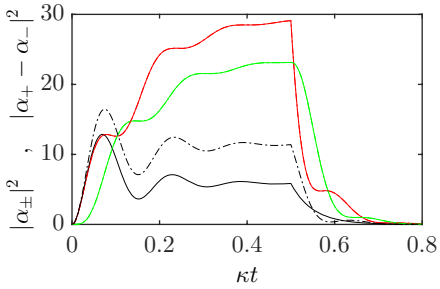

Figure 40.24: (code) Filling and drainage of the two counter-propagating modes of a laser-pumped ring cavity. Red curves show $|\alpha_+|^2$, green curves $|\alpha_-|^2$, and black curves $|\alpha_+ - \alpha_-|^2$. The atom is located at $kz = 0$ (solid line) and $kz = 0.1$ (dash-dotted line).

40.2.9.11 Ex: Position of the phase without pumping of the cavity

Solve the Schrödinger equation (40.189) by inserting ansatz,

$$\vec{\alpha} = \vec{\alpha}_1 e^{-\lambda_1 t} + \vec{\alpha}_2 e^{-\lambda_2 t} \ ,$$

where $\lambda_1 = \kappa + 2\imath U_0$ and $-\lambda_2 = \kappa$ are the eigenvalues of the matrix (40.189).

Solution: *We obtain,*

$$\begin{pmatrix} (-\kappa - 2\imath U_0)\alpha_{1+} e^{-\kappa t - 2\imath U_0 t} - \kappa \alpha_{2+} e^{-\kappa t} \\ (-\kappa - 2\imath U_0)\alpha_{1-} e^{-\kappa t - 2\imath U_0 t} - \kappa \alpha_{2-} e^{-\kappa t} \end{pmatrix}$$
$$= \begin{pmatrix} (-\imath U_0 - \kappa)(\alpha_{1+} e^{-\kappa t - 2\imath U_0 t} + \alpha_{2+} e^{-\kappa t}) - \imath U_0 e^{-2\imath kz}(\alpha_{1-} e^{-\kappa t - 2\imath U_0 t} + \alpha_{2-} e^{-\kappa t}) \\ -\imath U_0 e^{2\imath kz}(\alpha_{1+} e^{-\kappa t - 2\imath U_0 t} + \alpha_{2+} e^{-\kappa t}) + (-\imath U_0 - \kappa)(\alpha_{1-} e^{-\kappa t - 2\imath U_0 t} + \alpha_{2-} e^{-\kappa t}) \end{pmatrix} \ .$$

Separating the terms proportional to $e^{-\kappa t - 2\imath U_0 t}$ e $e^{-\kappa t}$, we obtain 4 relations,

$$\begin{pmatrix} \alpha_{1+} \\ \alpha_{2+} \\ \alpha_{1+} \\ \alpha_{2+} \end{pmatrix} = \begin{pmatrix} e^{-2\imath kz}\alpha_{1-} \\ -e^{-2\imath kz}\alpha_{2-} \\ e^{-2\imath kz}\alpha_{1-} \\ -e^{-2\imath kz}\alpha_{2-} \end{pmatrix} \ .$$

We can now write the solution as,

$$\vec{\alpha} = \begin{pmatrix} 1 \\ e^{2\imath kz} \end{pmatrix} \alpha_{1+} e^{-\kappa t - 2\imath U_0 t} + \begin{pmatrix} 1 \\ -e^{2\imath kz} \end{pmatrix} \alpha_{2+} e^{-\kappa t} \ ,$$

or, defining the abbreviation $\beta_n \equiv e^{\imath kz}\alpha_{n+}$,

$$\alpha_\pm = e^{\mp \imath kz}\beta_1 e^{-\kappa t - 2\imath U_0 t} \pm e^{-\imath kz}\beta_2 e^{-\kappa t} \ .$$

40.2.9.12 Ex: Dynamics of a standing wave in a symmetrically pumped ring cavity

Solve and discuss the equation (40.209).

Solution: *To obtain the inhomogeneous solution of the equation of motion for the ring cavity, we insert the general solution of the homogeneous equation into the equation of motion including a pump field, but assuming time-dependent coefficients $\beta_j(t)$. This gives,*

$$\dot{\beta}_1(t) = \tfrac{1}{2}e^{(\chi-\imath U_0)t}(\eta_+ e^{-\imath kz} - \eta_- e^{\imath kz}) = \imath\eta e^{(\chi-\imath U_0)t}\sin[-kz+\phi(t)] \ ,$$
$$\dot{\beta}_2(t) = \tfrac{1}{2}e^{(\chi+\imath U_0)t}(\eta_+ e^{-\imath kz} + \eta_- e^{\imath kz}) = \eta e^{(\chi+\imath U_0)t}\cos[-kz+\phi(t)] \ .$$

For a stationary pump, $\phi(t) = \phi$, a particular solution of the above differential equations is,

$$\beta_1(t) = \imath\frac{\eta}{\chi-\imath U_0}e^{(\chi-\imath U_0)t}\sin(-kz+\phi) \ ,$$
$$\beta_2(t) = \frac{\eta}{\chi+\imath U_0}e^{(\chi+\imath U_0)t}\cos(-kz+\phi) \ .$$

A particular solution of the inhomogeneous field equation is, therefore,

$$\begin{aligned} e^{\pm\imath kz}\alpha_\pm(t) &= \pm\beta_1(t)e^{-(\chi-\imath U_0)t} + \beta_2(t)e^{-(\chi+\imath U_0)t} \\ &= \pm\imath\frac{\eta}{\chi-\imath U_0}\sin(-kx+\phi) + \frac{\eta}{\chi+\imath U_0}\cos(-kz+\phi) \ . \end{aligned}$$

The general solution of the inhomogeneous equation is the sum of the general solution of the homogeneous equation and a particular solution of the inhomogeneous equation,

$$\begin{aligned} e^{\pm\imath kz}\alpha_\pm(t) &= \pm\beta_1(t)e^{-(\chi-\imath U_0)t} + \beta_2(t)e^{-(\chi+\imath U_0)t} \pm \beta_1 e^{-(\chi-\imath U_0)t} + \beta_2 e^{-(\chi+\imath U_0)t} \\ \alpha_\pm(t) &= \eta\frac{\pm\imath(\chi+\imath U_0)\sin(-kz+\phi) + (\chi-\imath U_0)\cos(-kz+\phi)}{\chi^2+U_0^2} \\ &\quad \pm \beta_1 e^{-(\chi-\imath U_0)t\mp\imath kz} + \beta_2 e^{-(\chi+\imath U_0)t\mp\imath kz} \ . \end{aligned}$$

Note that the specific initial condition, $\alpha_\pm(0) = \alpha_\pm(\infty)$, is realized for $\mp\beta_1 = \beta_2$. Further insight comes from the phase of the cavity field. The field adjusts to the atomic position by pulling its phase to the position of the atom, as long as the coupling is strong enough. Interestingly, the pumping force does not matter to the stationary situation. It only determines the speed of the self-adjustment process. This can be seen from a time-dependent analysis. We look at the phase $\phi = \pi/2$ and focus on $U_0 \ll \kappa$,

$$\begin{aligned} \alpha_\pm(t) &\simeq \imath\frac{\eta}{\kappa}\left(\pm 1 + \frac{2U_0}{\kappa}\sin(kz)e^{\mp\imath kz}\right) + (\beta_2 \pm \beta_1)e^{-\kappa t\mp\imath kz} \\ &\simeq \imath\frac{\eta}{\kappa}\left(\pm 1 + \frac{2U_0}{\kappa}kz\right) + (\beta_2 \pm \beta_1)e^{-\kappa t}(1 \mp \imath kz) \\ &\simeq \imath\frac{\eta}{\kappa}\left(\pm 1 + \frac{2U_0}{\kappa}kz\right) + (\beta_2 \pm \beta_1)e^{-\kappa t} \ . \end{aligned}$$

such that,

$$\alpha_+\alpha_-^* = \left(\imath\frac{\eta}{\kappa}\left(1+\frac{2U_0}{\kappa}kz\right)+(\beta_2+\beta_1)e^{-\kappa t}\right)\left(-\imath\frac{\eta}{\kappa}\left(1+\frac{2U_0}{\kappa}kz\right)+(\beta_2-\beta_1)e^{-\kappa t}\right)$$

$$\theta = \arctan\frac{-2\beta_1\frac{\eta}{\kappa}e^{-\kappa t}\left(1+\frac{2U_0}{\kappa}kz\right)}{(\beta_2^2-\beta_1^2)e^{-2\kappa t}+\frac{\eta^2}{\kappa^2}\left(1+\frac{2U_0}{\kappa}kz\right)^2} \ .$$

The time constant to reach the steady-state value is κ, and we retrieve the stationary formula for long times τ. During this period, small oscillations can occur with the period $2U_0$. To summarize, there is a competition between the phase of the field being defined by the coupling or by the atoms. The equilibrium depends on the ratio U_0/κ. Interestingly, the pump rate only matters during the transitional regime.

40.2.9.13 Ex: Stationary position of the atom in a unidirectionally pumped ring cavity

What is the steady state position of an atom interacting with the modes of a unidirectionally pumped ring cavity?

Solution: *To find the phase of the stationary wave we assume for simplicity, that the mode α_+ is stable, $\dot{\alpha}_+ = 0$. Also, we consider a scatterer fixed at a position Z, and look at the stationary solution,*

$$0 = -\kappa\alpha_- - \imath U_0 e^{2\imath kz}\alpha_+ \ ,$$

leading to,

$$|\alpha_+e^{\imath kZ}+\alpha_-e^{-\imath kZ}|^2 = \left|\alpha_+e^{\imath kZ}-\frac{\imath U_0}{\kappa}e^{-\imath kZ+2\imath kz}\alpha_+\right|^2 \sim 1+\frac{U_0^2}{\kappa^2}+\frac{2U_0}{\kappa}\sin 2k(z-Z) \ .$$

The slope of the standing wave is just where the sinus disappears, that is, $Z_{pente} = z$. Therefore, the scatterer is located right at the middle of the slope of the stationary wave, which it produced in the first place. The atoms are accelerated to the valley, that is, in the same direction as the wavevector of the pump field. Then, the standing wave again tries to regenerate itself at the new location of the scatterer. This means that the wave must continuously adjust its phase to the accelerated atoms. The atoms are always on the slope, etc. That is, the CARL starts running [8].

40.2.9.14 Ex: Equations of motion for intensities and coherences in a ring cavity

Derive from the equations (40.183) the equations of motion for intermodal coherences $\alpha_+\alpha_+^*$, $\alpha_-\alpha_-^*$, $\alpha_+\alpha_-^*$, and $\alpha_-\alpha_+^*$.

[8] Representations of numerical simulations can be contemplated here: http://www.ifsc.usp.br/~strontium/ → Research → Quantum Sensing → History of CARL → Children's corner.

Solution: *We obtain,*

$$\frac{d}{dt}(\alpha_\pm\alpha_\pm^* + 2\kappa) = \imath U_0(e^{\pm 2\imath kz}\alpha_\pm\alpha_\mp^* - e^{\mp 2\imath kz}\alpha_\mp\alpha_\pm^*) + \eta_\pm^*\alpha_\pm + \eta_\pm\alpha_\pm^*$$
$$\frac{d}{dt}(\alpha_\pm\alpha_\mp^* + 2\kappa) = (\alpha_\pm\alpha_\pm^* - \alpha_\mp\alpha_\mp^*) + \eta_\mp^*\alpha_\pm + \eta_\pm\alpha_\mp^* \ .$$

The quantities $\alpha_\pm\alpha_\mp^*$ describe a redistribution of photons between counterpropagating waves.

40.2.9.15 Ex: Backaction of atomic vibration on the modes of a symmetrically pumped ring cavity

a. Calculate the Lamb-Dicke parameter for gravitation-induced Bloch oscillations in a strontium gravimeter, as well as the modulation index. Is the continued fractions method applicable?
b. Study the dynamics of the counterpropagating light modes of a ring cavity in the presence of an atom whose position is periodically modulated with a given frequency by numerical integration of the equations of motion (40.183). Compare with the results obtained by the method of continued fractions proposed in Sec. 40.2.8.

Solution: *a. The recoil shift and the Bloch oscillation frequency are, respectively,*

$$\omega_{rec} = \frac{\hbar k^2}{2m} \quad , \quad \nu_{blo} = \frac{mg}{2\hbar k} \ .$$

With this we calculate for the gravitation-induced Bloch oscillations in a strontium gravimeter a Lamb-Dicke parameter of

$$\eta_{blo} = \sqrt{\frac{\omega_{rec}}{2\pi\nu_{ho}}} = \sqrt{\frac{\hbar k^2}{2m}\frac{\hbar k}{\pi mg}} \approx 2.4 \ .$$

The modulation index is,

$$kz_0 = \frac{kv}{2\pi\nu_{ho}} = \frac{2\omega_{rec}}{2\pi\nu_{ho}} = 2\eta_{blo}^2 \approx 12.5 \ .$$

Hence, the continued fractions method is NOT applicable. In contrast, the cavity linewidth does not matter.
b. The equations of motion (40.183), modified to account for the periodic vibration of the atom, are,

$$\dot\alpha_\pm = (-\kappa + \imath\Delta_c - \imath U_0)\alpha_\pm - \imath U_0 e^{\mp 2\imath kz_0 \sin\omega t}\alpha_\mp + \eta_\pm \ ,$$

ω being the vibration frequency and kz_0 the modulation excursion. The results of the simulation are exhibited in Fig. 40.25. Interestingly, we find that the cavity linewidth does not matter.

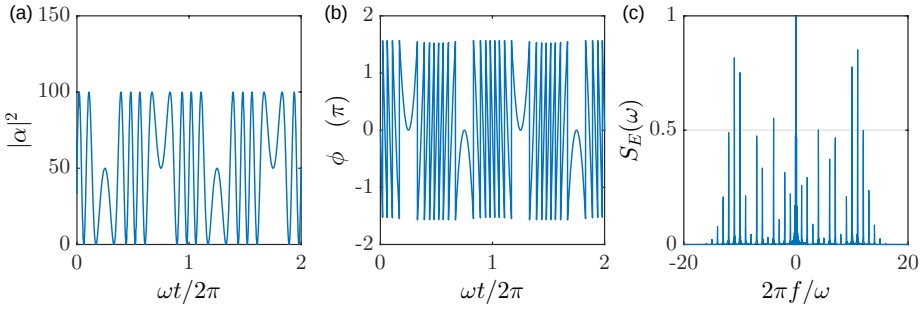

Figure 40.25: (code) (a) Photon number and (b) phase shift of the cavity in response to a modulated atomic position. The chosen parameters are $kz_0 = 2\pi$, $\kappa = (2\pi)\ 440\,\text{kHz}$, $\omega = (2\pi)\ 745\,\text{kHz}$, $\eta_\pm = 10\kappa$, $U_0 = -\kappa$. The initial photon number is $|\alpha|^2 = 16$. (c) Spectrum recorded behind a cavity mirror with the transmittivity t_{hr}. The spectrum is obtained as the Fourier transform of the $g^{(1)}(\tau)$ correlation function of the transmitted field $E_{out} = t_{hr}e^{\imath ka}E_{cav}$, where $e^{\imath ka}$ is a fixed phase factor depending on the mirror position a (see Sec. 35.5).

40.2.9.16 Ex: Fluorescent emission of a ring cavity for one-sided pumping in the adiabatic approximation

Based on the solution of the adiabatic field equations derived in Exc. 40.2.9.9 calculate the emission spectrum of the ring cavity driven below saturation (where the adiabatic approximation is good) from one side ($\eta_- = 0$) for both counter-propagating directions ($\alpha_\pm$). Compare with numerical solutions.

Solution: *In Exc. 40.2.9.9 we found,*

$$\begin{aligned}\alpha_\pm(t) &= A_\pm e^{(-\chi+\imath U_0)t} + B_\pm e^{(-\chi-\imath U_0)t} + C_\pm \\ &= A_\pm e^{(-\kappa+\imath\Delta_c)t} + B_\pm e^{[-\kappa+\imath(\Delta_c-2U_0)]t} + C_\pm\ ,\end{aligned}$$

where we assume $U_\gamma = U_0$ and $\chi = \kappa + \imath(U_0 - \Delta_c)$ and,

$$\begin{aligned}A_+ &= \frac{-\eta_+/2}{\chi - \imath U_0} \quad , \quad B_+ = \frac{-\eta_+/2}{\chi + \imath U_0} \quad , \quad C_+ = \frac{\chi\eta_+}{\chi^2 + U_\gamma^2} \\ A_- &= \frac{e^{2\imath kz}\eta_+/2}{\chi - \imath U_0} \quad , \quad B_+ = \frac{-e^{2\imath kz}\eta_+/2}{\chi + \imath U_0} \quad , \quad C_- = \frac{e^{2\imath kz}\imath U_0\eta_+}{\chi^2 + U_\gamma^2}\ .\end{aligned}$$

Now, we need to calculate the correlation function,

$$\langle t\alpha_+^*(t+\tau)e^{\imath\omega\tau}\alpha_+(t)\rangle = e^{\imath\omega\tau}\lim_{t\to\infty}\int_0^t \left[\begin{array}{c}\left(A_+^* e^{(-\kappa-\imath\Delta_c)(t+\tau)} + B_+^* e^{[-\kappa-\imath(\Delta_c-2U_0)](t+\tau)} + C_+^*\right)\times \\ \times\left(A_+ e^{(-\kappa+\imath\Delta_c)t} + B_+ e^{[-\kappa+\imath(\Delta_c-2U_0)]t} + C_+\right)\end{array}\right] dt'\ .$$

Using,

$$\lim_{t\to\infty}\int_0^t e^{-(a+\imath b)t}dt' = \lim_{t\to\infty}\frac{1-e^{-(a+\imath b)t}}{a+\imath b} = \frac{1}{a+\imath b}\ ,$$

we find,

$$\begin{aligned}
&\langle t\alpha_+^*(t+\tau)e^{\imath\omega\tau}\alpha_+(t)\rangle \\
&= e^{\imath\omega\tau}\begin{bmatrix} e^{(-\kappa-\imath\Delta_c)\tau}|A_+|^2\frac{1}{2\kappa}+e^{[-\kappa-\imath(\Delta_c-2U_0)]\tau}|B_+|^2\frac{1}{2\kappa}+|C_+|^2 t \\ +e^{(-\kappa-\imath\Delta_c)\tau}A_+^*B_+\frac{1}{2\kappa+2\imath U_0}+e^{[-\kappa-\imath(\Delta_c-2U_0)]\tau}A_+B_+^*\frac{1}{2\kappa-2\imath U_0} \\ +e^{(-\kappa-\imath\Delta_c)\tau}A_+^*C_+\frac{1}{\kappa+\imath\Delta_c}+A_+C_+^*\frac{1}{\kappa-\imath\Delta_c} \\ +e^{[-\kappa-\imath(\Delta_c-2U_0)]\tau}B_+^*C_+\frac{1}{\kappa+\imath(\Delta_c-2U_0)}+B_+C_+^*\frac{1}{\kappa-\imath(\Delta_c-2U_0)} \end{bmatrix} \\
&= e^{\imath\omega\tau}\begin{bmatrix} e^{(-\kappa-\imath\Delta_c)\tau}\left(\frac{|A_+|^2}{2\kappa}+\frac{A_+^*B_+}{2\kappa+2\imath U_0}+\frac{A_+^*C_+}{\kappa+\imath\Delta_c}\right) \\ +e^{[-\kappa-\imath(\Delta_c-2U_0)]\tau}\left(\frac{|B_+|^2}{2\kappa}+\frac{A_+B_+^*}{2\kappa-2\imath U_0}+\frac{B_+^*C_+}{\kappa+\imath(\Delta_c-2U_0)}\right) \\ +t|C_+|^2+\frac{A_+C_+^*}{\kappa-\imath\Delta_c}+\frac{B_+C_+^*}{\kappa-\imath(\Delta_c-2U_0)} \end{bmatrix}.
\end{aligned}$$

The autocorrelation function is now,

$$g^{(1)}(\tau)=\frac{\langle t\alpha_+^*(t+\tau)e^{\imath\omega\tau}\alpha_+(t)\rangle}{\langle t\alpha_+^*(t)\alpha_+(t)\rangle}=\frac{e^{-\kappa\tau}e^{\imath\omega\tau}\left(Xe^{-\imath\Delta_c\tau}+Ye^{\imath(2U_0-\Delta_c)\tau}+Z\right)}{X+Y+Z}$$

and the emission spectrum,

$$\begin{aligned}
S(\nu)&=\mathcal{F}g^{(1)}(\tau) \\
&=\frac{1}{X+Y+Z}\left(X\frac{\kappa}{(\nu-\omega+\Delta_c)^2+\kappa^2}+Y\frac{\kappa}{(\nu-\omega+2U_0-\Delta_c)^2+\kappa^2}+Z\delta(\nu-\omega)\right)
\end{aligned}$$

with $\Delta=\nu-\omega$ the detuning of the analyzing frequency filter.
The numerical solution is exhibited in Fig. 40.26.

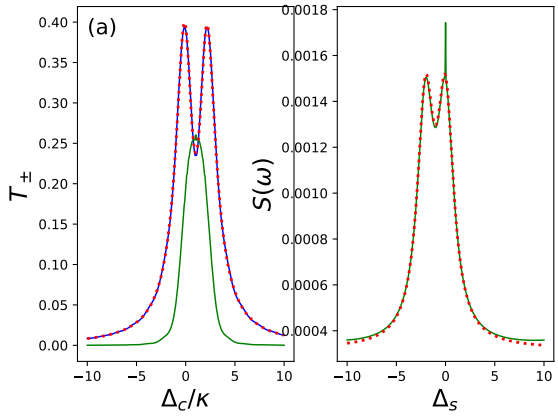

Figure 40.26: (code) (a) Transmission spectra and (b) emission spectra. The parameters are $\eta_+=0.1\kappa$, $\eta_-=0$, and $U_0=\kappa$.

40.3 Noise analysis of Bragg scattering in cavities

40.3.1 Fluorescence versus absorption

Consider a atoms in a cavity mode irradiated from the side [1295]. Every atom emits m photons, a fraction α of which goes into the cavity mode and is detected. Hence, $c = \alpha m a$ photons are counted, from which we infer the atom number and the noise,

$$a = \frac{c}{\alpha m} \tag{40.264}$$

$$\Delta a_f = a\frac{\Delta c}{c} = \frac{c}{\alpha m}\frac{\sqrt{c}}{c} = \sqrt{\frac{1}{\alpha m}a} \ . \tag{40.265}$$

For absorption $2\sigma/\pi w^2 = 4\alpha$ with $\sigma = 3\lambda^2/2\pi$. The photons missing in the transmitted beam are those scattered out of the cavity. If m_i photons come in, $ma = 4\alpha m_i a$ photons are scattered out. The main contribution to the absolute noise in the detected signal evidently comes from the shot noise of the incident probe beam, not from atom number fluctuations. Hence,

$$\Delta a_f = a\frac{\Delta c}{c} = \frac{c}{4\alpha m}\frac{\Delta c}{c} = \frac{1}{4\alpha m}\Delta c = \frac{1}{4\alpha m}\Delta m_i = \frac{1}{4\alpha m}\sqrt{4\alpha m} = \sqrt{1/4\alpha m} \ . \tag{40.266}$$

Consider a fluctuating number of atoms a. Each one scatters a fluctuating number of photons n, which are all detected. What information does the statistics of n containt about a? Let us first define the fluctuation and correlations function for the atom number,

$$\Delta a^2 = \langle a^2\rangle - \langle a\rangle^2 \tag{40.267}$$

$$g_{aa} \equiv \frac{\langle a^2\rangle - \langle a\rangle}{\langle a\rangle^2} = \frac{\Delta a^2 - \langle a\rangle}{\langle a\rangle^2} + 1 \ .$$

The probability to encounter a atoms is given by a distribution function $\rho(a)$. The probability to measure n_a photons at a fixed atom number is distribution according to $\varepsilon(n, a)$. Hence, the mean value of photon counts is,

$$\langle n\rangle = \sum_{a,n}\rho(a)\varepsilon(n,a)n = \sum_a \rho(a)\sum_n \varepsilon(n,a)n = \sum_a \rho(a)\langle n_a\rangle \ , \tag{40.268}$$

where $\langle n_a\rangle$ is the mean value of photon numbers at a fixed given atom number a and the fluctuation and correlations function are,

$$\Delta n_a^2 = \langle n_a^2\rangle - \langle n_a\rangle^2 \tag{40.269}$$

$$g_{nn} \equiv \frac{\langle n_a^2\rangle - \langle n_a\rangle}{\langle n_a\rangle^2} = \frac{\Delta n_a^2 - \langle n_a\rangle}{\langle n_a\rangle^2} + 1 \ .$$

It is reasonable to assume $\langle n_a\rangle = a\langle p\rangle$ where $\langle p\rangle$ is the mean number of photons scattered by an individual atom. We then get,

$$\langle n\rangle = \sum_a \rho(a)a\langle p\rangle = \langle p\rangle\sum_a \rho(a)a = \langle a\rangle\langle p\rangle \ . \tag{40.270}$$

Again we calculate the mean square of the counted photon numbers,

$$\begin{aligned}\langle n^2\rangle &= \sum_{a,n}\rho(a)\varepsilon(n,a)n^2 = \sum_a \rho(a)\langle n_a^2\rangle \\ &= \sum_a \rho(a)(\langle n_a\rangle^2 g_{nn} + \langle n_a\rangle) \\ &= \sum_a \rho(a)(\langle n_a\rangle^2 g_{nn} + a\langle p\rangle) = g_{nn}\sum_a \rho(a)\langle n_a\rangle^2 + \langle n\rangle \ .\end{aligned} \tag{40.271}$$

If the distribution $\varepsilon(n,a)$ is Poissonian with the mean value $a\langle p\rangle$,

$$\varepsilon(n,a) = e^{-a\langle p\rangle}\frac{(a\langle p\rangle)^n}{n!} \tag{40.272}$$

and the atom distribution is also Poissonian,

$$\rho(a) = e^{-\langle a\rangle}\frac{\langle a\rangle^n}{a!} \tag{40.273}$$

the total distribution is,

$$\kappa(n) = \sum_a \rho(a)\varepsilon(n,a) = \sum_a e^{-\langle a\rangle}\frac{\langle a\rangle^n}{a!}e^{-a\langle p\rangle}\frac{(a\langle p\rangle)^n}{n!} \ . \tag{40.274}$$

Hence

$$g_{nn} = g_{aa} + \frac{\langle p\rangle}{\langle n\rangle} \ . \tag{40.275}$$

40.3.2 Correlations in Bragg scattering

Light scattered from ultracold atoms arranged in a periodic optical lattice contains information about the quantum state of the system. The goal of the following calculations is to study the angular dependence and the coherence characteristics of the scattered light for the cases of propagating wave or cavity-enhanced input and output modes.

We consider a 1D grating with lattice constant d with N atoms distributed over M lattice sites. K of the lattice sites are illuminated by a pump laser. The full Hamiltonian for the problem of Bragg scattering at quantum correlated atoms is given in [870, 871, 873, 872]. The authors derive the Bose-Hubbard model and set up the Heisenberg equations of motion. Then however they dramatically simplify them by preventing tunneling. The correlations are then reintroduced ad hoc, when they assume particular wavefunctions, e.g. Mott insulator, superfluid or coherent states. The lattice is irradiated by a pump laser a_0, the scattered probe laser a_1 is detected. The angles of both modes with respect to the lattice can be chosen freely. The multiparticle Hamiltonian is, after adiabatic elimination of excited atomic states assumed to be valid for large detunings $\Delta_{la} = \omega_l - \omega_a$ between atomic resonance and light

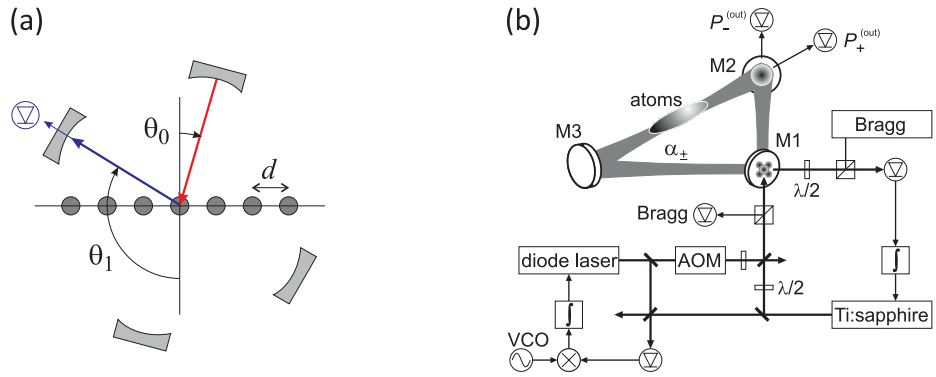

Figure 40.27: (a) Geometry of the scattering problem. (b) Possible experimental setup for measuring Bragg diffraction from CARL.

frequency,

$$\begin{aligned}
\hat{H} &= \hat{H}_f + \hat{H}_a \\
\text{with} \quad \hat{H}_f &= \sum_l \hbar\omega_l \hat{a}_l^\dagger \hat{a}_l - \imath\hbar \sum_l (\eta_l^* \hat{a}_l - \eta_l \hat{a}_l^\dagger) \\
\text{and} \quad \hat{H}_a &= \int d^3 r \hat{\Psi}^\dagger(\mathbf{r}) \hat{H}_{a_1} \hat{\Psi}(\mathbf{r}) + \frac{2\pi a_s \hbar^2}{m} \int d^3\mathbf{r} \hat{\Psi}^\dagger(\mathbf{r}) \hat{\Psi}^\dagger(\mathbf{r}) \hat{\Psi}(\mathbf{r}) \hat{\Psi}(\mathbf{r}) \\
\text{with} \quad \hat{h}_{a_1} &= \frac{\hat{p}^2}{2m_a} + V_{cl}(\mathbf{r}) + \hbar g_0^2 \sum_{l,m} \frac{u_l^*(\mathbf{r}) u_m(\mathbf{r}) \hat{a}_l^\dagger \hat{a}_m}{\Delta_{ma}} \; .
\end{aligned}$$

Here, $\hat{a}_i$ is the annihilation operator of mode i, η_l the pumping rate of mode 1, $\hat{\Psi}(\mathbf{r})$ the atomic field operator, a_s the s-wave scattering length, V_{cl} the lattice potential, and u_i the mode functions of the light fields.

For a strong potential and a weak pump, we derive the Bose-Hubbard-Hamiltonian with the ansatz of Wannier functions $\hat{\Psi}(\mathbf{r}) = \sum_i \hat{b}_i w(\mathbf{r} - \mathbf{r}_i)$,

$$\hat{H} = \hat{H}_f + \sum_{i,j=1}^{M} J_{i,j}^{cl} \hat{b}_i^\dagger \hat{b}_j + \hbar g_0^2 \sum_{l,m} \frac{\hat{a}_l^\dagger \hat{a}_m}{\Delta_{ma}} \left(\sum_{i,j=1}^{K} J_{i,j}^{lm} \hat{b}_i^\dagger \hat{b}_j \right) + \frac{U}{2} \sum_{i=1}^{M} \hat{b}_i^\dagger \hat{b}_i (\hat{b}_i^\dagger \hat{b}_i - 1) \quad (40.276)$$

and with the terms denoting the coefficients for the quantum motion of the atoms, the contribution of the light modes, and the interatomic interaction within a site, respectively

$$\begin{aligned}
J_{i,j}^{cl} &= \int d^3\mathbf{r} w(\mathbf{r} - \mathbf{r}_i) \left(-\frac{\hbar^2 \nabla^2}{2m} + V_{cl}(\mathbf{r}) \right) w(\mathbf{r} - \mathbf{r}_j) \qquad (40.277) \\
J_{i,j}^{lm} &= \int d^3\mathbf{r} w(\mathbf{r} - \mathbf{r}_i) u_l^*(\mathbf{r}) u_m(\mathbf{r}) w(\mathbf{r} - \mathbf{r}_j) \\
U &= \frac{4\pi a_s \hbar^2}{m_a} \int \mathrm{d}r |w(\mathbf{r})|^4 \; .
\end{aligned}$$

We now make the approximation that tunneling is only possible between nearest neighbors. Then the coefficients J^{cl} do not depend on index i of the potential site,

$$J^{cl}_{i,i} = J^{cl}_0 \quad , \quad J^{cl}_{i,i\pm1} = J^{cl} \ . \tag{40.278}$$

so that

$$\hat{H} = \hat{H}_f + J^{cl}_0 \hat{N} + J^{cl}\hat{B} + \hbar g_0^2 \sum_{l,m} \frac{\hat{a}^\dagger_l \hat{a}_m}{\Delta_{ma}} \left(\sum_{i=1}^{K} J^{lm}_{i,i} \hat{n}_i \right) \tag{40.279}$$
$$+ \hbar g_0^2 \sum_{l,m} \frac{\hat{a}^\dagger_l \hat{a}_m}{\Delta_{ma}} \left(\sum_{\langle i,j \rangle}^{K} J^{lm}_{i,j} \hat{b}^\dagger_i \hat{b}_j \right) + \frac{U}{2} \sum_{i=1}^{M} \hat{n}_i(\hat{n}_i - 1) \ .$$

where $\hat{n}_i = \hat{b}^\dagger_i \hat{b}_i$ is the atom number operator, $\hat{B} = \sum_{i=1}^{M} \hat{b}^\dagger_i \hat{b}_i + \text{h.c.}$, $\hat{N} = \sum_{i=1}^{K} \hat{n}_i$ the atom number is conserved g_0 is the atom-field coupling constant.

Let us calculate the Heisenberg equations from $\imath\hbar\dot{\hat{x}} = [\hat{x}, \hat{H}]$,

$$\dot{\hat{a}}_l = -\imath \left(\omega_l + \underbrace{\frac{g_0^2}{\Delta_{la}} \sum_{i=1}^{K} J^{ll}_{i,i} \hat{n}_i}_{\text{non-resonant dispersion}} + \underbrace{\frac{g_0^2}{\Delta_{la}} \sum_{\langle i,j \rangle}^{K} J^{ll}_{i,j} b^\dagger_i b_i}_{\text{tunneling}} \right) \hat{a}_l - \underbrace{i g_0^2 \sum_{m \neq l} \frac{a_m}{\Delta_{ma}} \left(\sum_{i=1}^{K} J^{lm}_{i,i} \hat{n}_i \right)}_{\text{scattering into } a_l}$$
$$- \underbrace{\imath g_0^2 \sum_{m \neq l} \frac{\hat{a}_m}{\Delta_{ma}} \left(\sum_{\langle i,j \rangle}^{K} J^{lm}_{i,j} \hat{b}^\dagger_i \hat{b}_i \right)}_{\text{correction to scattering due to tunneling}} + \eta_l \ . \tag{40.280}$$

and

$$\dot{\hat{b}}_i = -\frac{\imath}{\hbar} \left(J^{cl}_0 + \hbar g_0^2 \sum_{l,m} \frac{\hat{a}^\dagger_l \hat{a}_m}{\Delta_{ma}} J^{lm}_{i,i} + U \hat{n}_i \right) \hat{b}_i - \frac{\imath}{\hbar} \left(J^{cl} + \hbar g_0^2 \sum_{l,m} \frac{\hat{a}^\dagger_l \hat{a}_m}{\Delta_{ma}} J^{lm}_{i,i+1} \right) \hat{b}_{i+1}$$
$$- \frac{\imath}{\hbar} \left(J^{cl} + \hbar g_0^2 \sum_{l,m} \frac{\hat{a}^\dagger_l \hat{a}_m}{\Delta_{ma}} J^{lm}_{i,i-1} \right) \hat{b}_{i-1} \ . \tag{40.281}$$

The system contains additionally to the Bose-Hubbard model terms describing long-range interactions. This interaction is mediated by the light field.

40.3.3 Scattering from deep lattice

[873] derive the following Heisenberg equation for Bragg scattering reminiscent to the CARL model. The deep lattice is characterized by large V_{cl}, small overlap of Wannier functions, no tunneling ($J^{cl} = 0$, $J^{lm}_{i,j} = 0$ for $i \neq j$). With the approximation: $J^{lm}_{i,i} = u^*_l(r_i) u_m(r_i)$, neglect atomic localization,

$$\dot{\hat{a}}_1 = -\imath \left(\omega_1 + \frac{g_0^2}{\Delta_{1a}} \sum_{i=1}^{K} |u_1(r_i)|^2 \hat{n}_i \right) \hat{a}_1 - \imath \frac{g_0^2 a_0}{\Delta_{la}} \sum_{i=1}^{K} u^*_1(r_i) u_0(r_i) \hat{n}_i - \kappa \hat{a}_1 + \eta_1 \ . \tag{40.282}$$

In the equation for the matter wave only the first term doesn't vanish. This only concerns the phase, not the atom number operator. The term for dispersion $\frac{g_0^2}{\Delta_{1a}} \sum_{i=1}^{K} |u_1(r_i)|^2 \hat{n}_i$ be small compared to the the(weak coupling) rest. $\hat{a}_j \to a_j e^{-\imath\omega t}$ is a slowly varying envelope. A stationary solution is:

$$a_1 = C\hat{D} \tag{40.283}$$

with

$$\begin{aligned} C &\equiv -\frac{ig_0^2 a_0}{\Delta_{0a}(\kappa - \imath\Delta_{01})} \\ \hat{D} &\equiv \sum_{i=1}^{K} u_1^*(r_i) u_0(r_i) \hat{n}_i \equiv \sum_{i=1}^{K} A_i \hat{n}_i \ . \end{aligned} \tag{40.284}$$

Consider a 1D-lattice with sites at $x_m = m \cdot d$ $(m = 1, 2, ..., M)$. We scatter a running wave a_0 at the lattice and look at the expectation value of the scattered light field,

$$\begin{aligned} \langle a_1 \rangle = C\langle \hat{D} \rangle &= C \sum_{m=1}^{K} \mathrm{e}^{im\delta k_x d} \langle \hat{n}_m \rangle \\ &= Cn\mathrm{e}^{\imath(K+1)\alpha_-/2} \frac{\sin(K\alpha_-/2)}{\sin(\alpha_-/2)} \ . \end{aligned} \tag{40.285}$$

Here $\alpha_- = \delta k_x d$ and $\delta k_x = (k_0 - k_1)_x = k(\sin\Theta_0 - \sin\Theta_1)$. The above equation describes classical diffraction. The expectation value of the light field thus only depends of the atom number per lattice site n. The photon number and statistics however depend on higher moments of $\hat{n}_i$, i.e. on quantum correlations and quantum statistics.

The mode functions or traveling waves are

$$u_\beta(\mathbf{r}_m) = e^{\imath m k_{\beta x} d} \ , \tag{40.286}$$

where $\beta = 0, 1$. For standing waves

$$u_\beta(\mathbf{r}_m) = \cos(\imath m k_{\beta x} d) \ . \tag{40.287}$$

40.3.4 Correlations

We now assume all sites $\langle \hat{n}_i \rangle$ to be identical to an arbitrary specific site $\langle \hat{n}_a \rangle$, so that $\langle \hat{n}_i^2 \rangle = \langle \hat{n}_a^2 \rangle$. Furthermore, we assume a steep lattice, $\langle \hat{n}_i \hat{n}_{j \neq i} \rangle \equiv \langle \hat{n}_a \hat{n}_b \rangle$. The expectation value for the field is then,

$$\langle \hat{D} \rangle = \langle \hat{n}_a \rangle \sum_{i=1}^{K} A_i \equiv A \langle \hat{n}_a \rangle \ . \tag{40.288}$$

It can be measured by homodyne techniques. The photon count rate is,

$$\begin{aligned}\langle \hat{D}^* \hat{D} \rangle &= \sum_{i,j=1}^{K} A_i^* A_j \langle \hat{n}_i \hat{n}_j \rangle = \sum_{\imath \neq j}^{K} A_i^* A_j \langle \hat{n}_i \hat{n}_j \rangle + \sum_{i=1}^{K} |A_i|^2 \langle \hat{n}_i^2 \rangle \\ &= \langle \hat{n}_a \hat{n}_b \rangle \left(|A|^2 - \sum_{a}^{K} |A_a|^2 \right) + \langle \hat{n}_a^2 \rangle \sum_{i=1}^{K} |A_i|^2 \\ &= \langle \hat{n}_a \hat{n}_b \rangle |A|^2 + (\langle \hat{n}_a^2 \rangle - \langle \hat{n}_a \hat{n}_b \rangle) \sum_{i=1}^{K} |A_i|^2 \ ,\end{aligned} \tag{40.289}$$

and its variance is

$$\begin{aligned}\langle \hat{D}^* \hat{D} \rangle - |\langle \hat{D} \rangle|^2 &= \langle \hat{n}_a \hat{n}_b \rangle |A|^2 + (\langle \hat{n}_a^2 \rangle - \langle \hat{n}_a \hat{n}_b \rangle) \sum_{i=1}^{K} |A_i|^2 - \left| \sum_{i=1}^{K} A_i \langle \hat{n}_i \rangle \right|^2 \\ &= (\langle \hat{n}_a \hat{n}_b \rangle - \langle \hat{n}_a \rangle^2) |A|^2 + (\langle \hat{n}_a^2 \rangle - \langle \hat{n}_a \hat{n}_b \rangle) \sum_{i=1}^{K} |A_i|^2 \\ &= (\delta \hat{n}_a \delta \hat{n}_b) \, |A|^2 + (\langle \delta \hat{n}_a^2 \rangle - \langle \delta \hat{n}_a \delta \hat{n}_b \rangle) \sum_{i=1}^{K} |A_i|^2 \ .\end{aligned} \tag{40.290}$$

In the last equation we used the definition $\delta \hat{n}_i \equiv \hat{n}_i - \langle \hat{n}_i \rangle$ for which $\langle \delta \hat{n}_i \delta \hat{n}_j \rangle = \langle \hat{n}_i \hat{n}_j \rangle - \langle \hat{n}_a \rangle^2$ is easy to show.

40.3.4.1 Variance of photon number

The photon number variance is,

$$\begin{aligned}(\Delta n_{ph})^2 &= \langle n_{ph}^2 \rangle - \langle n_{ph} \rangle^2 = \langle \Delta n_{ph}^2 \rangle + \langle n_{ph} \rangle \\ &= |C|^4 (\langle \hat{D}^{*2} \hat{D}^2 \rangle - \langle \hat{D}^* \hat{D} \rangle) + |C|^2 \langle \hat{D}^* \hat{D} \rangle \ .\end{aligned}$$

40.3.5 Probing atomic correlations with traveling waves

Using the above relationships with traveling waves,

$$\langle a_1 \rangle = C \langle \hat{n}_a \rangle \sum_{i=1}^{K} u_1^*(\mathbf{r}_i) u_0(\mathbf{r}_i) = C \langle \hat{n}_a \rangle e^{i(K+1)d(k_{0x} - k_{1x})} \frac{\sin \frac{K}{2} d(k_{0x} - k_{1x})}{\sin \frac{1}{2} d(k_{0x} - k_{1x})} \ . \tag{40.291}$$

Analogously the correlation function gives,

$$\langle a_1^* a_1 \rangle = |C|^2 \left(\langle \hat{n}_a \hat{n}_b \rangle \left| \sum\nolimits_{m=1}^{K} u_1^*(\mathbf{r}_m) u_0(\mathbf{r}_m) \right|^2 + \left(\langle \hat{n}_a^2 \rangle - \langle \hat{n}_a \hat{n}_b \rangle \right) \sum\nolimits_{m=1}^{K} |u_0(\mathbf{r}_m)| |u_1(\mathbf{r}_m)| \right) \tag{40.292}$$

$$= |C|^2 \left(\frac{1 - \cos K d(k_{0x} - k_{1x})}{1 - \cos d(k_{0x} - k_{1x})} \langle \hat{n}_a \hat{n}_b \rangle + K \left(\langle \hat{n}_a^2 \rangle - \langle \hat{n}_a \hat{n}_b \rangle \right) \right) \ .$$

Its variance is

$$\langle a_1^* a_1\rangle - |\langle a_1\rangle|^2 = |C|^2 \left(\frac{1-\cos Kd(k_{0x}-k_{1x})}{1-\cos d(k_{0x}-k_{1x})} (\langle \hat{n}_a \hat{n}_b\rangle - |\langle \hat{n}_a\rangle|^2) + K(\langle \hat{n}_a^2\rangle - \langle \hat{n}_a \hat{n}_b\rangle) \right) . \tag{40.293}$$

Various techniques are possible, heterodyne or spectral measurements. Or one may tune the Bragg angle. The above Bragg technique may be applied to various types of quantum correlation [871, 873].

40.3.6 Quantum statistics for typical atomic distributions

If the number of illuminated lattice sites is much smaller than the total number of sites, then the coherent state is a good approximation for the calculation of the features of the scattered light in the limit $N, M \to \infty$ with finite $\frac{N}{M}$. Far from the diffraction maxima the approximation also holds for $M \propto K$. Now $n \equiv \frac{N}{M}$ is the expectation value of the atom number per potential site and $N_K \equiv K\frac{N}{M} = nK$.

40.3.6.1 Mott insulator

Products of Fock states at each lattice site, exactly n_i atoms per lattice site. The number of atoms per lattice site does not fluctuate $\hat{n}_i$, neither does the total number of atoms K. No quantum correlations between lattice sites.

The Mott insulating state is described by,

$$|\psi_{mi}\rangle = \prod_{m=1}^{N} |\psi_m\rangle_m . \tag{40.294}$$

Hence the atom numbers per site are uncorrelated. The correlation is,

$$\langle a_1^* a_1\rangle = |C|^2 \frac{1-\cos Kd(k_{0x}-k_{1x})}{1-\cos d(k_{0x}-k_{1x})} \langle \hat{n}_a\rangle^2 = |\langle a_1\rangle|^2 . \tag{40.295}$$

Its variance is $\langle a_1^* a_1\rangle - |\langle a_1\rangle|^2 = 0$. The behavior is identical to classical Bragg scattering,

$$\begin{aligned} \langle \hat{n}_a \hat{n}_b\rangle_{mi} &= \langle \hat{n}_a\rangle^2 \\ \langle \delta\hat{n}_a \delta\hat{n}_b\rangle_{mi} &= 0 \qquad \text{for} \qquad a \neq b \\ \langle \Delta\hat{n}_a\rangle_{mi} &= 0 . \end{aligned} \tag{40.296}$$

In $\langle \hat{D}^{*2}\hat{D}^2\rangle$, all terms with 2, 3, or 4 lattice sites factorize; are closest to the classical state. Consider uniform filling with $n = \frac{N}{M}$ atoms per lattice site.

40.3.6.2 Superfluid state

Every atom is delocalized over all sites. This causes fluctuating atom numbers in $K < M$ sites. All terms involving 2, 3, or 4 lattice sites do not factorize. The SF state is a superposition of all possible Fock states with N atoms in M sites.

The superfluid state,

$$|\psi_{sf}\rangle = \frac{1}{\sqrt{N!}}\left(\frac{1}{\sqrt{M}}\sum_{m=1}^{N} b_m^\dagger\right)^N |0\rangle \tag{40.297}$$

$$\hat{b}_i|\psi_{sf}(N,M)\rangle = \sqrt{\frac{N}{M}}|\psi_{sf}(N-1,M)\rangle_{sf}$$

$$\langle\psi_{sf}|\hat{b}_i^{\dagger m}\hat{b}_i^m|\psi_{sf}\rangle = \frac{N!}{M^m(N-m)!}\ .$$

In particular in the photon number variance there are terms like $\langle\hat{D}^{*2}\hat{D}^2\rangle$ containing contributions like $\langle n_a n_b n_c n_d\rangle$. With $[b_i, b_j^\dagger] = \delta_{ij}$ we find,

$$\begin{aligned}
\langle\hat{n}_i\rangle &= \langle b_i^\dagger b_i\rangle \qquad (40.298)\\
\langle\hat{n}_i^2\rangle &= \langle b_i^\dagger b_i b_i^\dagger b_i\rangle = \langle b_i^\dagger b_i\rangle + \langle b_i^\dagger 2 b_i^2\rangle\\
\langle\hat{n}_i^3\rangle &= \langle\hat{b}_i^\dagger\hat{b}_i\rangle 2 + \langle\hat{b}_i^{\dagger 2}\hat{b}_i^2\rangle + \langle\hat{b}_i^{\dagger 3}\hat{b}_i^3\rangle\\
\langle\hat{n}_i^4\rangle &= \langle b_i^\dagger b_i\rangle + 7\langle b_i^{\dagger 2} b_i^2\rangle + 6\langle b_i^{\dagger 3} b_i^3\rangle + \langle b_i^{\dagger 4} b_i^4\rangle\\
\langle\hat{n}_a\hat{n}_b\rangle &= \langle b_a^\dagger b_b^\dagger b_a b_b\rangle = \langle b_i^{\dagger 2} b_i^2\rangle\\
\langle\hat{n}_a\hat{n}_b\hat{n}_c\rangle &= \langle b_i^{\dagger 3} b_i^3\rangle\\
\langle\hat{n}_a\hat{n}_b\hat{n}_c\hat{n}_d\rangle &= \langle b_i^{\dagger 4} b_i^4\rangle\\
\langle\hat{n}_a^2\hat{n}_b\hat{n}_c\rangle &= \langle b_i^{\dagger 3} b_i^3\rangle + \langle b_i^{\dagger 4} b_i^4\rangle\\
\langle\hat{n}_a^3\hat{n}_b\rangle &= \langle b_i^{\dagger 2} b_i^2\rangle + 3\langle b_i^{\dagger 3} b_i^3\rangle + \langle b_i^{\dagger 4} b_i^4\rangle\\
\langle\hat{n}_a^2\hat{n}_b^2\rangle &= \langle b_i^{\dagger 2} b_i^2\rangle + 2\langle b_i^{\dagger 3} b_i^3\rangle + \langle b_i^{\dagger 4} b_i^4\rangle
\end{aligned}$$

This yields,

$$\begin{aligned}
2\langle\hat{n}_a\hat{n}_b\hat{n}_c\hat{n}_d\rangle - 3\langle\hat{n}_a^2\hat{n}_b\hat{n}_c\rangle + \langle\hat{n}_a^3\hat{n}_b\rangle &= N\frac{N-1}{M^2} \qquad (40.299)\\
-\langle\hat{n}_a\hat{n}_b\hat{n}_c\hat{n}_d\rangle + \langle\hat{n}_a^2\hat{n}_b\hat{n}_c\rangle &= N(N-1)\frac{N-2}{M^3}\\
\langle\hat{n}_a\hat{n}_b\hat{n}_c\hat{n}_d\rangle - 2\langle\hat{n}_a^2\hat{n}_b\hat{n}_c\rangle + \langle\hat{n}_a^2\hat{n}_b^2\rangle &= N\frac{N-1}{M^2}\\
-6\langle\hat{n}_a\hat{n}_b\hat{n}_c\hat{n}_d\rangle + 12\langle\hat{n}_a^2\hat{n}_b\hat{n}_c\rangle - 4\langle\hat{n}_a^3\hat{n}_b\rangle - 3\langle\hat{n}_a^2\hat{n}_b^2\rangle + \langle\hat{n}^4\rangle &= \frac{N}{M}
\end{aligned}$$

and hence the formula found by [873] simplifies to,

$$\begin{aligned}
\langle\hat{D}^{*2}\hat{D}^2\rangle = &\left|\sum_{i=1}^K A_i\right|^4 \frac{N!}{M^4(N-4)!} + \left[\left(\sum_{i=1}^K A_i^2\right)\left(\sum_{i=1}^K A_i^*\right)^2 + c.c. + 4\left|\sum_{i=1}^K A_i^2\right|^2 \sum_{i=1}^K |A_i|^2\right]\frac{N!}{M^3(N-3)!}\\
&+ 2\left[\left(\sum_{i=1}^K |A_i|^2\right)^2 + \frac{1}{2}\left|\sum_{i=1}^K A_i^2\right|^2\right]\frac{N!}{M^2(N-2)!} + 2\left[\left(\sum_{i=1}^K |A_i|^2 A_i\right)\sum_{i=1}^K A_i^* + c.c.\right]\frac{N!}{M(N-1)!}\\
&+ \sum_{i=1}^K |A_i|^4\frac{N}{M}\ . \qquad (40.300)
\end{aligned}$$

40.3.6.3 Coherent state

Approximation of the SF state. Product of local coherent states. Fluctuating atom numbers in $K \leq M$ sites, but also fluctuating total number (which is a drawback). No correlations between several different states. The approximation is good only for $K < M$.

Approximation to superfluid state,

$$|\psi_{co}\rangle = e^{-N/2} \prod_{m=1}^{N} e^{\hat{b}_i^\dagger \sqrt{N/M}} |0\rangle_m \tag{40.301}$$

$$\hat{b}_i |\psi_{co}(N,M)\rangle = \sqrt{\frac{N}{M}} |\psi_{co}(N-1,M)\rangle_{co}$$

$$\langle \psi_{co} | \hat{b}_i^{\dagger m} \hat{b}_i^m | \psi_{co} \rangle = \frac{N^m}{M^m} \ .$$

The correlation functions are derived analogously to the superfluid state.

	Mott insulator state	superfluid state	coherent state
$\langle \hat{n}_i^2 \rangle$	n^2	$n^2(1-\frac{1}{N})+n$	n^2+n
$(\Delta n_i)^2$	0	$n(1-\frac{1}{M})$	n
$\langle \hat{n}_K^2 \rangle$	N_K	$N_K^2(1-\frac{1}{N})+N_K$	$N_K^2+N_K$
$(\Delta \hat{n}_K)^2$	0	$N_K(1-\frac{K}{M})$	N_K
$\langle \hat{n}_a \hat{n}_b \rangle$	n^2	$n^2(1-\frac{1}{N})$	n^2
$\langle \delta\hat{n}_a \delta\hat{n}_b \rangle$	0	$-\frac{N}{M^2}$	0

40.3.6.4 Self-organized states

An interesting case occurs when self-organization populates only odd or even (Mott insulating) states as found by Vuletic. For us the more important cases are 1. thermal clouds with partial ordering into a lattice (CARL) and 2. arrays of BECs localized at different lattice sites. Try,

$$|\psi_{so}\rangle_{so} = \frac{1}{\sqrt{N!}} \prod_{m=1}^{M} \left(\frac{1}{\sqrt{N_m}} \sum_{i=1}^{N_m} b_i^\dagger \right) |0\rangle \ . \tag{40.302}$$

[1036] shows what correlations are building up under CARL action. Also Suppl. Carl, "Quantized motion" and "Coherence".

Let us interpret the observations: The expectation value of the field amplitude, $\langle a_1 \rangle$ only depends on the mean atom number. The angular dependence is like in for classical Bragg scattering.

Number of scattered photons $\langle a_1^* a_i \rangle$ (intensity depends for certain angles on the density correlation. From this one obtains the structure factor. Two terms contribute to the angular dependence of the intensity: the first one depends on $|A|^2$, i.e. it goes quadratically with the field amplitude. the second term is proportional to $\langle \hat{n}^2 \rangle - \langle \hat{n}_a \hat{n}_b \rangle$, i.e. contains quantum fluctuations.

Variance $R(\theta_0, \theta_1)$: the term with classical angular distribution $|A|^2$ only appears, when pair correlations $\langle \hat{n}_a \hat{n}_b \rangle$ do not vanish. So, not only the spatial structure of the lattice leads to diffraction, but also the distribution of the fluctuations. Here, the spatial distribution of the fluctuations $\langle \delta\hat{n}_a \delta\hat{n}_b \rangle$ can be either zero (MI) or identical with the density distribution. In the first case, only the fluctuation at each lattice site $\langle \delta\hat{n}^2 \rangle$ contributes to the noise, in the second case, pair correlations contribute to the classical distribution $|A|^2$.

The spatial distribution of the noise may differ from that of the average density. Additional peaks are obtained in the angular distribution.

40.3.7 Results and questions

40.3.7.1 1D optical lattice in transversely pumped cavity

System: Pump beam orthogonal to lattice ($\theta_0 = 0$), light scattered in the direction of the lattice $\left(\theta_1 = \frac{\pi}{2}\right)$, scattering into the resonator mode. Atoms at the distance $d = \lambda/2$ in the antinodes of a standing wave. Then:

$$\begin{aligned} \hat{D} &= \sum_{m=1}^{K} u_1^*(r_k) u_0(r_k) \hat{n}_k = \sum_{m=1}^{K} \cos(mdk_1 \sin\theta_1) \hat{n}_k \cos(mdk_0 \sin\theta_0) \hat{n}_k \\ &= \sum_{m=1}^{K} \cos(\pi m) \hat{n}_k = \sum_{m=1}^{K} (-1)^{2m-1} \hat{n}_k \ . \end{aligned} \tag{40.303}$$

$\langle \hat{D} \rangle$ disappears and thus also field amplitude (for both states). This corresponds to destructive interference (even K).

Photon number $\langle a_1^\dagger a_1 \rangle$ proportional to,

$$\langle \hat{D}^* \hat{D} \rangle = \langle \hat{n}_a \hat{n}_b \rangle |A|^2 + (\langle \hat{n}^2 \rangle - \langle \hat{n}_a \hat{n}_b \rangle) \sum_{i=1}^{K} |A_i|^2 = (\langle \hat{n}^2 \rangle - \langle \hat{n}_a \hat{n}_b \rangle) K \ . \tag{40.304}$$

for MI disappears $(\langle \hat{n}^2 \rangle - \langle \hat{n}_a \hat{n}_b \rangle)K$, for SF it becomes,

$$\begin{aligned} (\langle \hat{n}^2 \rangle - \langle \hat{n}_a \hat{n}_b \rangle) K &= \left(\frac{N^2}{M^2} - \frac{N}{M^2} + \frac{N}{M} - \frac{N^2}{M^2} + \frac{N}{M^2} \right) K \\ &= \frac{N}{M} K = N_K \ . \end{aligned} \tag{40.305}$$

The MI state does not scatter photons into resonator mode, SF state scatters a number of photons proportional to the atom number:

$$\begin{aligned} \langle a_i \rangle_{MI} &= 0 = \langle a_i \rangle_{SF} \\ \langle a_i^\dagger a_i \rangle_{MI} &= 0 \ , \ \langle a_i^\dagger a_i \rangle_{SF} = |C|^2 N_K \ . \end{aligned} \tag{40.306}$$

The mean photon number already yields information on the atomic quantum state.

40.3.7.2 Running waves

Running wave:

$$u_{0,1}(r) = \exp(\imath m k_{0,1} d) \ . \tag{40.307}$$

Then

$$\begin{aligned} A_m &= u_1^*(r_m) u_0(r_m) = e^{\imath m \alpha_-} \\ \alpha_- &= k_{0x} d \sin\Theta_0 - k_{1x} d \sin\Theta_1 \ . \end{aligned} \tag{40.308}$$

We obtain for the noise:

$$R = \langle \delta\hat{n}_a \delta\hat{n}_b \rangle \frac{\sin^2(K\alpha_-/2)}{\sin^2(\alpha_-/2)} + \left(\langle \delta\hat{n}^2 \rangle - \langle \delta\hat{n}_a \delta\hat{n}_b \rangle \right) K \ . \tag{40.309}$$

For the various states,

$$\begin{aligned} R_{MI} &= 0 \\ R_{CO} &= nK = N_K \\ R_{SF_K} &= -\frac{N}{M^2} \frac{\sin^2(K\alpha_-/2)}{\sin^2(\alpha_-/2)} + \frac{N}{M} K \ . \end{aligned} \tag{40.310}$$

Intensity of scattered light,

$$\langle \hat{D}^* \hat{D} \rangle = \langle \hat{n}_a \hat{n}_b \rangle |A|^2 + \left(\langle \hat{n}^2 \rangle - \langle \hat{n}_a \hat{n}_b \rangle \right) \sum_{i=1}^{K} |A_i|^2 \tag{40.311}$$

$$\begin{aligned} \langle \hat{D}^* \hat{D} \rangle_{MI} &= 0 \\ \langle \hat{D}^* \hat{D} \rangle_{Inc} &= K \langle \hat{n}^2 \rangle = nK \\ \langle \hat{D}^* \hat{D} \rangle_{SF} &= \left(\frac{N^2}{M^2} - \frac{N}{M^2} \right) \frac{\sin^2(K\alpha_-/2)}{\sin^2(\alpha_-/2)} + \frac{N}{M} K \ . \end{aligned}$$

MI and SF states are distinguishable in the diffraction minimum, and no distinction is possible in the maximum, because there are no fluctuations in the total number of atoms. Scattering at the maximum can be considered as a superradiance, since the intensity is proportional to N_K^2. At the minimum, scattering for MI is suppressed, scattering from SF proportional to N_K.

For even K the terms with $|A|^2$ disappear. Therefore, we only get a dependence from $\langle \hat{n}^2 \rangle - \langle \hat{n}_a \hat{n}_b \rangle$, i.e. the difference between local and non-local fluctuations. For running waves is the proportionality factor K.

40.3.7.3 Standing waves

If one of the two modes (pump or probe mode) is a standing wave in a resonator, the angular dependence of the noise becomes even stronger. We obtain new maxima in the classical diffraction (first terms in Eqs. (17, 18)) and the angular dependence of the second terms is no longer isotropic, $|A_i|^2$ returns a doubling of the lattice period or the frequency. This results in new peaks in the noise, where classically nothing is to be expected,

$$u_{0,1}(r) = \cos(m k_{0,1} d) \ . \tag{40.312}$$

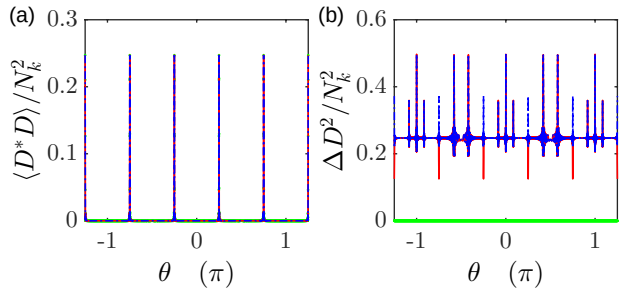

Figure 40.28: (code) For $\theta_1 = \frac{\pi}{2}$ (Probe light along lattice axis), different angles of the pump light, $P_+ = 1$ W, $\lambda_0 = \lambda_1 = 794$nm, $\lambda_G = 820$ nm. There are 150 filled lattice sites.

40.3.7.4 Questions

[871] assumes a classical incident light field, which means that the fluctuations in the Bragg-scattered light solely arise from quantum fluctuations in the atomic cloud. However, in reality the pump laser will have Poissonian fluctuations as well, $\langle \delta a_0 \rangle \neq 0$. How to treat conditional probabilities?

Binomial distribution,

$$P_n^{(m)} = \binom{m}{n} p^n (1-p)^{m-n} \ . \tag{40.313}$$

Poisson distribution,

$$P_n = \frac{\lambda^n}{n!} e^{-\lambda} \tag{40.314}$$

for large n small p we have $B_k^{(n)} \simeq P_k$ with $\lambda = np$. Thermal distribution,

$$P_n = \frac{\bar{n}^n}{(1+\bar{n})^{1+n}} \ . \tag{40.315}$$

Thermal distribution,

$$P_n = \frac{e^{\hbar\omega(n+1/2)k_B T}}{\sum_n e^{\hbar\omega(n+1/2)k_B T}} \ . \tag{40.316}$$

Photon noise at non-Bragg angles should disappear for $K \to \infty$?

In principle $g^{(2)}(\tau)$ can be determined in two ways: 1. Autocorrelation of a time-dependent intensity $I(t)$, 2. Normalized histogram of coincidences in a Hanbury-Brown-Twiss type experiment. In the first case, intensity trace can be gathered by a photon detector in current (i.e. integration) mode or by photon counting and summing up all counts within predefined time-intervals. This method is suitable to detect classical correlations or technical noise. However this method deletes the most interesting part of the information, which is photon statistics at short times. Furthermore, a photon counter has a finite bandwidth (in our case $\tau_{bw}^{-1} = 5\,\mathrm{MCnts/s}$). A single trace can thus only reproduce correctly the statistics of photons separated by $\tau_{dist} > \tau_{bw}$. If the coherence time τ_{coh} is shorter, quantum effects like antibunching will not become visible. This is why Hanbury-Brown-Twiss is needed [1171].

It is possible to generate arbitrary $g^{(2)}(\tau)$ by tailoring the waiting time distribution between photons. We have a 5 ns resolution photon arrival time trace (SR430) or a 5 μs resolution photon arrival time histogram (single-photon detector). In an experiment, we may couple the probe light leaking out of a cavity mirror through a fiber into a single-photon detector. A multi channel scaler counts the numbers of photons n_{ph} detected in subsequent time-intervals of given length τ. Now what is the noise Δn_{ph}? Is it the width of the histogram $H(n_{ph})$?

Maximum count rate: 5 counts/ µs. Time scale for CARL dynamics: 1 µs. Photon number in cavity for $P_+ = 1\,\mathrm{W}$ is $n_+ = 10^9$ and for $P_- = 1\,\mathrm{mW}$ is $n_- = 10^6$. Outcoupled power is $P_{out,-} = P_- \times 2\,\mathrm{ppm}$. Outcoming photons per second $n_{out,-} = P_-/\hbar\omega \times 1\,\mathrm{s} \simeq 10^{10}$.

Experimentally, superfluid lattices may correspond to condensates in shallow standing waves, where atoms can tunnel form site to site. Arrays of uncorrelated condensates in deep lattice would then be described by coherent states. What are the real quantum correlations in the cavity? What correlations does the CARL instability generate?

[871] assumes perfect ordering, even for the superfluid case. Superfluidity for him only means perfect mobility of the atoms between discrete, well-localized lattice sites. In practice however we will have a finite Debye-Waller factor. Can this have an impact on the quantum statistics of the scattered light?

[871] assumes the scattered light be stored in a cavity. Does the fact that we look at the outcoupled light modify the quantum statistics?

Is it possible to monitor the quantum correlations developing during CARL using the Bragg scattering noise analysis? Imagine we run a CARL experiment in high finesse and observe the superradiant ringing on a 100 µs time scale. We could use a weak collinear probe laser in low finesse to couple into the cavity short pulses (not limited by the cavity decay time). Hence, the CARL is quasi in steady state, when we detect the response of the Bragg scattering of the probe. The probe may be separated from other overlapping beams $\langle a_1 \rangle$ through homodyning, $\langle a_1^* a_1 \rangle$. The Bragg angle can be tuned by changing the wavelength.

The treatment only holds for optically dilute clouds, otherwise the scattering rate saturates. This means that only a small fraction of photons is scattered only the Bragg angles.

The portion of photons scattered into the cavity has to be integrated over the solid angle of the cavity mode. Far from the Rayleigh length we have $\tan\alpha \simeq \alpha = w(z)/w_0 = \lambda/\pi/w_0 \approx 0.13°$.

How about light Rayleigh-scattered out of the incidence plane?

40.4 Interaction of atoms with surfaces

40.4.1 Local density of states for atoms near surfaces

In the following sections we consider two-level atoms interacting with meta-materials. An atom consists of a discrete set of levels between which electric or magnetic transitions characterized by dipole moments $\mathbf{d}$ can be excited via vectorial laser light. The meta-material medium is defined by its spatially and frequency dependent relative

permittivity, $\varepsilon(\mathbf{r};\omega)$ and relative permeability, $\mu(\mathbf{r};\omega)$ [9].

The way how the atom and the medium interact can be understood introducing the notion of the photonic local density of states (LDOS). The medium shapes, via ε and μ, the LDOS for any radiation field the medium can sustain, assuming that the atom itself does not modify the LDOS. To calculate the density of states one must solve Maxwell equations and obtain the Green function $\mathcal{G}(\mathbf{r},\mathbf{r}';\omega)$, which completely describes the material. The density of states is proportional to the imaginary part of Green function. Furthermore, the Green function permits to calculate easily the propagation of an incident light field through the medium [10], and hence the local radiation intensity $\vec{\mathcal{E}}(\mathbf{r};\omega)$.

After this, one has to set up the Hamiltonian for the atom located at position $\mathbf{r}_a$ near the dielectric and solve, with a suitable ansatz, the Schrödinger equation. This yields the time evolution of the atomic state excitation probabilities [682, 41].

40.4.1.1 Density of states from Maxwell's equations

The density of states (DOS), the group velocity, and the distribution function are necessary for calculating various macroscopic quantities like specific heat, thermal conductivity, energy density, and radiation intensity. The local density of states (LDOS) is a generalization of the DOS and, unlike the DOS, a position dependent quantity. Like the DOS, the LDOS depends on the type of carrier - electron, phonon, or photon. It is generally related to the Green's function of the appropriate governing equation (Schrödinger equation for electrons, wave equation for long wavelength phonons, and Maxwell's equation for photons) and boundary conditions. Here, we are concerned with the photonic or electromagnetic LDOS [946].

The electromagnetic LDOS is related to the dyadic Green's function (DGF) of the vector Helmholtz equation. In free space the electric field and the magnetic field contributions are equal in the absence of scatterers. In other circumstances, however, there is a contribution to the LDOS from the magnetic field energy, and it is related to the magnetic DGF. Since the pioneering work of *Purcell* it is well known that the spontaneous emission rate of molecules is strongly affected by their vicinity to macroscopic objects. The LDOS (both electric and magnetic) also plays an important role in *Casimir* forces between objects. The Maxwell stress tensor in vacuum at thermal equilibrium can be expressed compactly in terms of the electric and magnetic DGF.

The spectral electric and magnetic fields are governed by the macroscopic Maxwell's equations (18.194). These equations can be converted to the vector Helmholtz equation for electric and magnetic fields (18.195). To invert these equations and express the electric and magnetic fields as integrals over the source regions, we make use of the dyadic Green's function (DGF) which also obeys the dyadic version of the vector Helmholtz equation (18.197). The electric field is obtained as a convolution integral (18.196).

[9] Note that the assumption of Drude type function is often a good one.

[10] Note that even without incident radiation the medium influences the atomic dynamics via the LDOS.

40.4.1.2 Local density of states (LDOS) and the decay rate

The concepts of density of states (DOS) and local density of states (LDOS) can be introduced starting from the situation of a non-absorbing and non-dispersive medium, $\varepsilon(\mathbf{r};\omega) = \varepsilon(\mathbf{r}) \in R^{>0}$, embedded in a closed cavity with volume $V = L^3$ assuming that $L \ll \lambda$, λ being the wavelength in vacuum). Then, a discrete set of eigenmodes of the vector Helmholtz equation can be obtained solving the eigenvalue equation [235],

$$\nabla \times \nabla \times \mathbf{e}_n(\mathbf{r}) = \varepsilon(\mathbf{r}) \frac{\omega_n^2}{c^2} \mathbf{e}_n(\mathbf{r}) \ , \tag{40.317}$$

yielding the eigenvalues ω_n/c as well as the eigenfunctions $\mathbf{e}_n(\mathbf{r})$. Since the differential operator is Hermitian, the eigenfunctions are orthogonal,

$$\int \varepsilon(\mathbf{r}) \mathbf{e}_m^*(\mathbf{r}) \cdot \mathbf{e}_n(\mathbf{r}) d^3r = \delta_{mn} \ . \tag{40.318}$$

The DOS $\rho(\omega)$ at a frequency ω counts the number of eigenmodes in an infinitely small frequency range and is defined as,

$$\rho(\omega) = \tfrac{1}{V} \sum_n \delta(\omega - \omega_n) \ . \tag{40.319}$$

This DOS is a global quantity that characterizes the spectral density of eigenmodes of the medium as a whole. A local quantity $\rho(\mathbf{r},\omega)$ (LDOS) can be introduced through a summation weighted by the amplitude of the eigenmodes at point $\mathbf{r}$,

$$\boxed{\rho(\mathbf{r},\omega) = \sum_n |\hat{\mathbf{e}}_n(\mathbf{r})|^2 \delta(\omega - \omega_n)} \ . \tag{40.320}$$

This relation defines the LDOS in the particular case of a medium for which a discrete set of eigenmodes can be introduced.

The (electric) LDOS (40.320) can be reformulated in terms of the electric Green function $\mathcal{G}(\mathbf{r},\mathbf{r}',\omega)$ being the solution of the vector Helmholtz equation (18.197) setting $\mu_r(\mathbf{r},\omega) = 1$. The solution can be cast into the shape,

$$\boxed{\mathcal{G}(\mathbf{r},\mathbf{r}',\omega) = c^2 \sum_n \hat{\mathbf{e}}_n^*(\mathbf{r}') \otimes \hat{\mathbf{e}}_n(\mathbf{r}) \left[\mathcal{PV}\left(\frac{1}{\omega_n^2 - \omega^2} \right) + \frac{\imath\pi}{2\omega_n} \delta(\omega - \omega_n) \right]} \ . \tag{40.321}$$

With this result, the LDOS can be written,

$$\begin{aligned} \rho(\mathbf{r},\omega) &= \frac{2\omega}{\pi c^2} \mathfrak{Im} \ \mathrm{Tr} \ \mathcal{G}(\mathbf{r},\mathbf{r},\omega) \qquad (40.322) \\ &= \frac{2\omega}{\pi c^2} \mathrm{Tr} \ c^2 \sum_n \mathbf{e}_n^*(\mathbf{r}) \otimes \mathbf{e}_n(\mathbf{r}) \frac{\pi}{2\omega_n} \delta(\omega - \omega_n) = \sum_n \mathbf{e}_n^*(\mathbf{r}) \cdot \mathbf{e}_n(\mathbf{r}) \delta(\omega - \omega_n) \ . \end{aligned}$$

This result shows that shows that the correct counting of eigenmodes is implicit in the Green function, although the latter can be computed by solving the Helmholtz equation without referring to any set of eigenmodes. In particular, the expression (40.322) even holds for lossy media, when a basis of eigenmodes cannot be defined [235].

40.4.1.3 Power radiated by a classical dipole

The Green tensor defined by (18.199) permits the calculation of the electric field generated by a current density according to (18.196).

For a classical point-dipole the solution can be given explicitly (see example 108). The radiated power is simply,

$$P = -\tfrac{1}{2}\mathfrak{Re} \int \mathbf{j}^*(\mathbf{r}) \cdot \vec{\mathcal{E}}(\mathbf{r}) d^3r \ . \tag{40.323}$$

With the current density parametrized as $\mathbf{j}(\mathbf{r}) = \dot{\mathbf{d}}_{eg}\delta(\mathbf{r}-\mathbf{r}_s) = -\imath\omega\mathbf{d}_{eg}\delta(\mathbf{r}-\mathbf{r}_s)$ we get,

$$P = \frac{\omega}{2}\mathfrak{Im}\ [\mathbf{d}_{eg}^* \cdot \vec{\mathcal{E}}(\mathbf{r}_s)] \ . \tag{40.324}$$

From (40.323) we obtain,

$$P = \frac{\mu_0\omega^3}{2}|\mathbf{d}_{eg}|^2\mathfrak{Im}\ [\hat{\mathbf{e}}_d\ \mathcal{G}(\mathbf{r},\mathbf{r}',\omega)\ \hat{\mathbf{e}}_d] \ , \tag{40.325}$$

where $\hat{\mathbf{e}}_d$ is the unit vector along the dipole. In this expression we assume that the source point $\mathbf{r}_s$ is located in vacuum, but the Green function $\mathcal{G}(\mathbf{r},\mathbf{r}_s,\omega)$ can describe an arbitrary environment surrounding the emitter. In particular, the emitted power calculated in this way accounts both for far-field radiation and absorption in the environment.

In the case of a dipole with a fixed orientation $\hat{\mathbf{e}}_d$, we can define a projected LDOS (sometimes called partial LDOS),

$$\rho_{\mathbf{d}}(\mathbf{r}_s,\omega) = \frac{2\omega}{\pi c^2}\mathfrak{Im}\ [\hat{\mathbf{e}}_d\ \mathcal{G}(\mathbf{r}_s,\mathbf{r}_s,\omega)\ \hat{\mathbf{e}}_d] \tag{40.326}$$

so that the full LDOS is,

$$\rho(\mathbf{r}_s,\omega) = \sum_{\hat{\mathbf{e}}_{dx},\hat{\mathbf{e}}_{dy},\hat{\mathbf{e}}_{dz}} \rho_{\mathbf{d}}(\mathbf{r}_s,\omega) = \frac{2\omega}{\pi c^2}\mathfrak{Im}\ \mathrm{Tr}\ \mathcal{G}(\mathbf{r}_s,\mathbf{r}_s,\omega) \ . \tag{40.327}$$

The projected LDOS accounts for radiation by an electric dipole with a given orientation,

$$\boxed{P = \frac{\pi\omega^2}{4\varepsilon_0}|\mathbf{d}_{eg}|^2\rho_{\mathbf{d}}(\mathbf{r}_s,\omega)} \ . \tag{40.328}$$

Example 247 (*LDOS in free space*): In the particular case of a dipole placed in 3D free space, the power transferred to the environment equals the power radiated to far-field radiation. It can be obtained from the free-space dyadic Green function $\mathcal{G}_0(\mathbf{r},\mathbf{r}_s,\omega)$, whose imaginary part at $\mathbf{r}=\mathbf{r}_s$ is obtained from the Green tensor (18.207)calculated for a bulk medium by setting $\mathbf{r}=\mathbf{r}'=\mathbf{r}_s$,

$$\mathfrak{Im}\ \mathcal{G}^{(0)}(\mathbf{r}_s,\mathbf{r}_s,\omega) = \frac{k_0}{6\pi}\mathbb{I} \ . \tag{40.329}$$

With this, the projected LDOS (40.326) along $\hat{\mathbf{e}}_d$ becomes,

$$\rho_{\mathbf{d}}^{(0)}(\mathbf{r}_s,\omega) = \frac{\omega^2}{3\pi^2c^3} \ , \tag{40.330}$$

and the full LDOS (40.327),

$$\rho^{(0)}(\mathbf{r}_s,\omega) = \frac{\omega^2}{\pi^2 c^3} \ . \tag{40.331}$$

The emitted power becomes,

$$P^{(0)} = \frac{\omega^4}{12\pi\varepsilon_0 c^3}|\mathbf{d}_{eg}|^2 \ . \tag{40.332}$$

40.4.1.4 Spontaneous emission by a quantum emitter in the weak coupling regime

In (18.126) we established a relationship between the power emitted by a classical radiator and a spontaneous emission by a quantized two-level system. The spontaneous emission rate can be evaluated in perturbation theory from Fermi's golden rule,

$$\frac{P}{\hbar\omega} \longrightarrow \frac{\pi\omega^2}{4\varepsilon_0}|\mathbf{d}|^2\rho_{\mathbf{d}}(\mathbf{r}_s,\omega) = \frac{\pi\omega_{eg}}{\hbar\varepsilon_0}|\hat{\mathbf{d}}_{eg}|^2\rho_{\mathbf{d}}(\mathbf{r}_s,\omega_{eg}) = \Gamma \ . \tag{40.333}$$

The correction factor comes from the fact that in quantum mechanics, unlike in in classical mechanics, positive and negative frequency components are treated separately as absorption resp. stimulated emission.

In free space, with the formula (40.330) we calculate for the relationship between spontaneous emission rate and the induced dipole moment,

$$\boxed{\Gamma^{(0)} = \frac{\omega_{eg}^3}{3\pi\hbar\varepsilon_0 c^3}|\mathbf{d}_{eg}|^2} \ , \tag{40.334}$$

which coincides with the expression (34.41).

40.4.1.5 Purcell factor and Lamb shift

The Purcell factor is defined as the ratio between the decay rates in the presence and in the absence of boundary conditions. It can this be evaluated from the expression (40.333) as,

$$\frac{\Gamma}{\Gamma^{(0)}} = \frac{\rho_{\mathbf{d}}(\mathbf{r}_s,\omega)}{\rho^{(0)}_{\mathbf{d}}(\mathbf{r}_s,\omega)} = \frac{6\pi c}{\omega_{eg}}\mathfrak{Im}\ \hat{\mathbf{e}}_d\ \mathcal{G}(\mathbf{r}_s,\mathbf{r}_s,\omega)\ \hat{\mathbf{e}}_d \ . \tag{40.335}$$

40.4.2 Interaction between atomic dipoles

Until now we concentrated on simple dipole in the environment of dielectric boundaries. We will now extend the formalism to interacting dipoles located at positions $\mathbf{r}_i$ and $\mathbf{r}_j$ continuing the discussion of Sec. 18.3.1.

Intermolecular energy transfer can occur through two mechanisms, namely, radiationless short-range transfer, also called *Förster transfer*, and radiative long-range transfer [399, 1151]. In the former the distance R between donor and acceptor is small compared with the electronic-energy-transfer wavelength $R \ll \lambda_A$. The free-space transfer rate behaves as R^{-6}, which can be explained by the instantaneous (longitudinal)

Coulomb interaction between the two molecules. In the latter the intermolecular distance substantially exceeds the transition wavelength, $R \gg \lambda_A$. The observed R^{-2} dependence of the transfer rate can be regarded as being the result of emission and reabsorption of real (transverse) photons, see Sec. 40.2.1 and example 240.

The Purcell factor (40.335) allows us to calculate the modification of the decay rate in the presence of a Green tensor. In the absence of boundaries we use the bulk medium Green tensor (18.214),

$$\begin{aligned}\Gamma_{ij}^{(b)} &= 3\lambda\Gamma^{(0)}\hat{\mathbf{e}}_d^* \,\mathfrak{Im}\, \mathcal{G}_b(\mathbf{r}_i,\mathbf{r}_j,\omega)\, \hat{\mathbf{e}}_d \\ &= \tfrac{3}{2}\Gamma^{(0)}\left[(1-(\hat{\mathbf{e}}_d\cdot\hat{\mathbf{e}}_R)^2)\frac{\sin kR}{kR} + (1-3(\hat{\mathbf{e}}_d\cdot\hat{\mathbf{e}}_R)^2)\left(\frac{\cos kR}{k^2R^2}-\frac{\sin kR}{k^3R^3}\right)\right] ,\end{aligned} \tag{40.336}$$

where $k^2=(\omega/c)^2\varepsilon\mu$ and $\mathbf{R}\equiv\mathbf{r}_i-\mathbf{r}_j$.

Similarly, the Lamb shift can be calculated,

$$\begin{aligned}\Delta_{ij}^{(b)} &= -\tfrac{3}{2}\lambda\Gamma^{(0)}\hat{\mathbf{e}}_d^* \,\mathfrak{Re}\, \mathcal{G}_b(\mathbf{r}_i,\mathbf{r}_j,\omega)\, \hat{\mathbf{e}}_d \\ &= \tfrac{3}{4}\Gamma^{(0)}\left[(1-(\hat{\mathbf{e}}_d\cdot\hat{\mathbf{e}}_R)^2)\frac{\cos kR}{kR} - (1-3(\hat{\mathbf{e}}_d\cdot\hat{\mathbf{e}}_R)^2)\left(\frac{\sin kR}{k^2R^2}+\frac{\cos kR}{k^3R^3}\right)\right]\end{aligned} \tag{40.337}$$

Again, the second line is obtained for free space using (18.214).

At long distances, $kR>1$, the results (40.336) and (40.337) simplify to,

$$\boxed{\begin{array}{rcl}\Delta_{ij}^{(b)} &\simeq& \tfrac{3}{4}\Gamma^{(0)}[1-(\hat{\mathbf{e}}_d\cdot\hat{\mathbf{e}}_R)^2]\frac{\cos kR}{kR}\\ \Gamma_{ij}^{(b)} &\simeq& \tfrac{3}{2}\Gamma^{(0)}[1-(\hat{\mathbf{e}}_d\cdot\hat{\mathbf{e}}_R)^2]\frac{\sin kR}{kR}\end{array}} , \tag{40.338}$$

and at very long distances, $kR\gg 1$, $\Delta_{ij}\to 0 \leftarrow \Gamma_{ij}$. This atomic dipole-dipole interaction interaction will play a role in the generation of interatomic correlations studied in Sec. 41.3.2. Do the Exc. 40.4.4.1.

40.4.2.1 Derivation of the Hamiltonian

First for one atom interacting with a dielectric then for two atoms,

$$\hat{H} = \int d^3r \int_0^\infty d\omega\hbar\omega\hat{\mathbf{f}}^\dagger(\mathbf{r},\omega)\hat{\mathbf{f}}(\mathbf{r},\omega) + \sum_{i=0}^{N}\hbar\omega_i\hat{\sigma}_i^+\hat{\sigma}_i - \sum_{i=0}^{N}\int_0^\infty d\omega\left[\hat{\mathbf{d}}_i\cdot\vec{\mathcal{E}}(\mathbf{r}_i,\omega)+H.c.\right] . \tag{40.339}$$

Here, $\hat{\mathbf{f}}(\mathbf{r},\omega)$ are polaritonic bosonic operators associated with the annihilation of the corresponding matter-light elementary excitations. The field operator is [474, 1211],

$$\vec{\mathcal{E}}(\mathbf{r},\omega) = i\vec{\epsilon}\sqrt{\frac{\hbar}{\pi\varepsilon_0}}\frac{\omega^2}{c^2}\int\sqrt{\mathfrak{Im}\;\varepsilon_r(\mathbf{r}',\omega)}\mathcal{G}(\mathbf{r},\mathbf{r}',\omega)\hat{\mathbf{f}}(\mathbf{r}',\omega)d^3r' . \tag{40.340}$$

40.4.3 Metamaterials

Ray optics (lenses, shadows, ..) for $a\gg\lambda$, photonic crystals for $a\simeq\lambda$, optical crystals and metamaterials for $a\ll\lambda$ [1190, 1045].

The permittivity ϵ and the permeability μ at *optical frequencies* are in general very different from the static values. E.g. for vacuum and electrically inactive media $\epsilon = 1$, for metals $\epsilon < 0$. For vacuum and magnetically inactive media $\mu = 1$, for resonant ferromagnets and antiferromagnets $\mu < 0$.

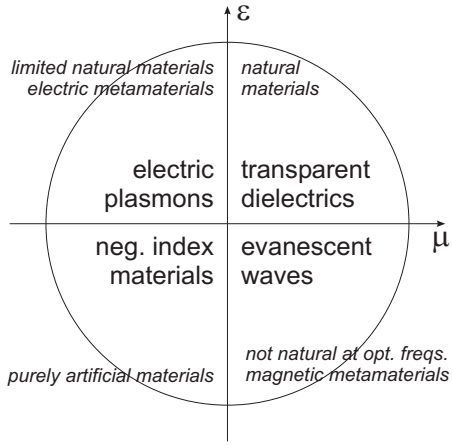

Figure 40.29: Metamaterials.

At low frequencies, conductors/metals are good as metamaterials, because they strongly respond to electromagnetic fields. At *optical frequencies* only the electric dipolemoment interacts with matter. Magnetic interaction is suppressed by the factor $(2\mu_B/ea_B)^2 = \alpha^2$. Therefore, resonant enhancement of optical magnetism is necessary, e.g. nanostructured $L-C$-circuits of wavelength-sized $\vec{\mathcal{E}}$ and $\vec{\mathcal{H}}$ guiding oscillations of a propagating light wave.

40.4.4 Exercises

40.4.4.1 Ex: Coupled dipoles model near dielectrics

Develop the vectorial coupled dipoles model in the vicinity of a dielectric using the Green tensor formalism.

Solution: *In free space the vectorial coupled dipoles model can be written (see Eq. (39.26)),*

$$\boxed{\frac{d\beta_i}{dt} = \sum_j \left(\delta_{ij}\imath\Delta - K_{ij}\right)\beta_j - \frac{\imath\Omega}{2}e^{\imath\mathbf{k}\cdot\mathbf{r}_i}} \ , \tag{40.341}$$

where the kernel is given by the projection of the Green tensor $\mathcal{G}(\mathbf{r}_i, \mathbf{r}_j, \omega_0)$ on the dipoles $\hat{\mathbf{e}}_{di}$ and $\hat{\mathbf{e}}_{dr}$ respectively located at $\mathbf{r}_i$ and $\mathbf{r}_j$,

$$K_{ij} = -\frac{3\pi\imath\Gamma}{k}\hat{\mathbf{e}}^*_{di}\ \mathcal{G}(\mathbf{r}_i, \mathbf{r}_j, \omega)\ \hat{\mathbf{e}}_{dj} \ . \tag{40.342}$$

In the absence of boundaries the Green tensor is simply the one derived for bulk media $\mathcal{G}_b(\mathbf{r}_i, \mathbf{r}_j, \omega_0)$ given by the expression (18.206). Let us first concentrate on this case.

Decomposing the kernel into real and imaginary parts,

$$K_{ij}^{(b)} = \frac{\Gamma_{ij}^{(b)}}{2} + \imath\Delta_{ij}^{(b)} = \frac{3\lambda\Gamma^{(0)}}{2}\hat{\mathbf{e}}_{di}^{*}\left[\mathfrak{Im}\ \mathcal{G}_b(\mathbf{r}_i,\mathbf{r}_j,\omega) - \imath\mathfrak{Re}\ \mathcal{G}_b(\mathbf{r}_i,\mathbf{r}_j,\omega)\right]\hat{\mathbf{e}}_{dj}\ . \quad (40.343)$$

We also find,

$$\Gamma_{ii}^{(b)} = \tfrac{3}{2}\Gamma^{(0)} \qquad \textit{and} \qquad \Delta_{ii}^{(b)} = 0\ . \quad (40.344)$$

Note, that in the scalar approximation the Green tensor reduces to the well known formula,

$$\mathcal{G}_b(\mathbf{r}_i,\mathbf{r}_j,\omega_0) \simeq \mathbb{I}\frac{e^{\imath k|\mathbf{r}_i-\mathbf{r}_j|}}{4\pi|\mathbf{r}_i-\mathbf{r}_j|}\ , \quad (40.345)$$

so that,

$$K_{ij}^{(b)} \simeq \frac{3\Gamma}{4}\frac{e^{\imath k|\mathbf{r}_i-\mathbf{r}_j|}}{\imath k|\mathbf{r}_i-\mathbf{r}_j|} \longrightarrow \frac{\Gamma}{2}e^{-\imath\mathbf{k}\cdot(\mathbf{r}_j-\mathbf{r}_m)}\frac{e^{\imath k|\mathbf{r}_j-\mathbf{r}_m|}}{\imath k|\mathbf{r}_j-\mathbf{r}_m|}\ . \quad (40.346)$$

Now, the only thing we need to do to account for boundaries is to generalize the Green tensor,

$$\mathcal{G} = \mathcal{G}_b + \mathcal{G}_d\ , \quad (40.347)$$

where G_d accounts for the presence of a dielectric. Then,

$$\frac{d\beta_i}{dt} = \left[\delta_{ij}\imath\Delta - \sum_j(K_{ij}^{(b)} + K_{ij}^{(d)})\right]\beta_j - \frac{\imath\Omega}{2}e^{\imath\mathbf{k}\cdot\mathbf{r}_i} \quad (40.348)$$

$$= \left[\imath(\Delta-\Delta_{ii}^{(d)}) - \left(\tfrac{\Gamma_{ii}^{(b)}}{2} + \tfrac{\Gamma_{ii}^{(d)}}{2}\right)\right]\beta_i - \sum_{j\neq i}\left(\tfrac{\Gamma_{ij}^{(b)}}{2} + \tfrac{\Gamma_{ij}^{(d)}}{2} + \imath\Delta_{ij}^{(b)} + \imath\Delta_{ij}^{(d)}\right)\beta_j - \tfrac{\imath\Omega}{2}e^{\imath\mathbf{k}\cdot\mathbf{r}_i}\ . \quad (40.349)$$

In particular, without dielectric,

$$\frac{d\beta_i}{dt} = \left(\imath\Delta - \frac{\Gamma_{ii}^{(b)}}{2}\right)\beta_i - \sum_{j\neq i}K_{ij}^{(b)}\beta_j - \frac{\imath\Omega}{2}e^{\imath\mathbf{k}\cdot\mathbf{r}_i}\ . \quad (40.350)$$

With a dielectric but for only a single atoms,

$$\frac{d\beta_i}{dt} = \left[\imath(\Delta-\Delta_{ii}^{(d)}) - \left(\frac{\Gamma_{ii}^{(b)}}{2} + \frac{\Gamma_{ii}^{(d)}}{2}\right)\right]\beta_i - \frac{\imath\Omega}{2}e^{\imath\mathbf{k}\cdot\mathbf{r}_i}\ . \quad (40.351)$$

40.4.4.2 Ex: Scattering Green tensor above a dielectric surface

In this exercise we calculate the Green tensor for two atomic dipoles above a homogeneous dielectric filling the $z < 0$ half space.
a. Formulate the problem.
b. Simplify the scattering Green tensor obtained by [682] for that situation.

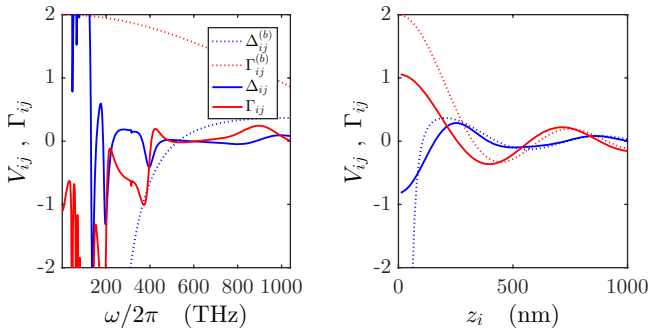

Figure 40.30: Scattering Green tensor for region-wise homogeneous dielectrics.

c. Simplify the Green tensor by assuming all atoms aligned along the y-axis at equal height from the dielectric.
d. Assume the atomic dipole moment to be aligned along the z-axis.
e. Derive the Green tensor for a single atom above the dielectric.

Solution: *a. We assume the environment composed of regions characterized by different locally homogeneous permittivities,*

$$\epsilon(\mathbf{r},\omega) = \epsilon(z,\omega) = \Theta(z) + \epsilon(\omega)\Theta(-z) = 1 + \chi_\varepsilon(\omega)\Theta(-z) \tag{40.352}$$
$$\mu(\mathbf{r},\omega) = 1 \ .$$

Supposing that the dipole sits in the region $z > 0$, the Green tensor is then,

$$\mathcal{G}(\mathbf{r},\mathbf{r}',\omega) = \begin{cases} \mathcal{G}_b(\mathbf{r},\mathbf{r}',\omega) + \mathcal{G}_d(\mathbf{r},\mathbf{r}',\omega) & \text{for} \quad z,z' > 0 \\ \mathcal{G}_d(\mathbf{r},\mathbf{r}',\omega) & \text{for} \quad z > 0 > z' \end{cases} \tag{40.353}$$

The bulk Green tensor $\mathcal{G}_b$ has been calculated in (18.206) under the assumption that whole space is homogeneous with permittivity $\epsilon(\omega) = 1$. $\mathcal{G}_d$ is scattering Green tensor. Now, we need to solve the inhomogeneous Helmholtz equation,

$$\left[\nabla_{\mathbf{r}} \times \nabla_{\mathbf{r}} \times -\tfrac{\omega^2}{c^2}\epsilon(\mathbf{r},\omega)\right](\mathcal{G}_b(\mathbf{r},\mathbf{r}',\omega) + \mathcal{G}_d(\mathbf{r},\mathbf{r}',\omega)) = \delta^{(3)}(\mathbf{r}-\mathbf{r}')\mathbb{I} \ . \tag{40.354}$$

Using (18.199) the bulk Green function can be removed and, for $\mathbf{r},\mathbf{r}' \in$ region 1, we are left with the scattering part of the Green function, which needs to satisfy the homogeneous Helmholtz equation [1313, 210],

$$\left[\nabla_{\mathbf{r}} \times \nabla_{\mathbf{r}} \times -\tfrac{\omega^2}{c^2}\chi_\varepsilon(\omega)\Theta(-z)\right]\mathcal{G}_d(\mathbf{r},\mathbf{r}',\omega) = 0 \ . \tag{40.355}$$

To deduce the Green tensor for a stratified background, it is convenient to expand it into plane waves. The Fourier transform of the Green tensor for a bulk medium (18.206) leads to [1002],

$$\mathcal{G}_b(\mathbf{r}_i,\mathbf{r}_j,\omega) = \frac{1}{(2\pi)^3 k^2}\int \frac{\mathbb{I}k^2 - \mathbf{k}'\otimes\mathbf{k}'}{k'^2 - k^2} e^{\imath\mathbf{k}'\cdot\mathbf{r}} d^3k' \ . \tag{40.356}$$

Exploiting the translational invariance of the system in the (x, y) plane, the expression can be simplified to,

$$\mathcal{G}_b(\mathbf{r}_i, \mathbf{r}_j, \omega) = \frac{\imath}{8\pi^2 k^2} \int \frac{\mathbb{I}k^2 - \mathbf{k}'\mathbf{k}'}{k'_z} e^{\imath \mathbf{k}' \cdot \mathbf{r}} dk'_x dk'_y - \frac{\hat{\mathbf{e}}_z \otimes \hat{\mathbf{e}}_z}{k^2} \delta^{(3)}(\mathbf{r}) \ , \tag{40.357}$$

using

$$k = \omega/c \quad , \quad k'_z \equiv \sqrt{k^2 - k'^2_x - k'^2_y} \quad , \quad \mathbf{k}' \equiv k'_x \hat{\mathbf{e}}_x + k'_y \hat{\mathbf{e}}_y + k'_z [\Theta(z) - \Theta(-z)] \hat{\mathbf{e}}_z \ . \tag{40.358}$$

We introduce a new coordinate system,

$$\hat{\mathbf{e}}_k \equiv \frac{\mathbf{k}'}{k'} \quad , \quad \hat{\mathbf{e}}_s \equiv \frac{\mathbf{k}' \times \hat{\mathbf{e}}_z}{|\mathbf{k}' \times \hat{\mathbf{e}}_z|} \quad , \quad \hat{\mathbf{e}}_p \equiv \hat{\mathbf{e}}_k \times \hat{\mathbf{e}}_l \ , \tag{40.359}$$

such that the direction $\hat{\mathbf{e}}_s$ corresponds to s-polarization and $\hat{\mathbf{e}}_p$ to p-polarization. Using $\mathbb{I} = \hat{\mathbf{e}}_x\hat{\mathbf{e}}_x + \hat{\mathbf{e}}_y\hat{\mathbf{e}}_y + \hat{\mathbf{e}}_z\hat{\mathbf{e}}_z = \hat{\mathbf{e}}_k\hat{\mathbf{e}}_k + \hat{\mathbf{e}}_s\hat{\mathbf{e}}_s + \hat{\mathbf{e}}_p\hat{\mathbf{e}}_p$, we find,

$$\mathcal{G}_b(\mathbf{r}_i, \mathbf{r}_j, \omega) = \frac{\imath}{8\pi^2} \int \frac{\hat{\mathbf{e}}_s\hat{\mathbf{e}}_s + \hat{\mathbf{e}}_p\hat{\mathbf{e}}_p}{k'_z} e^{\imath \mathbf{k}' \cdot \mathbf{r}} dk'_x dk'_y - \frac{\hat{\mathbf{e}}_z\hat{\mathbf{e}}_z}{k^2} \delta^{(3)}(\mathbf{r}) \ . \tag{40.360}$$

Now, we put the dielectric in the lower half space and extend the Green tensor. According to [1313, 1002, 210, 682] the scattering Green tensor for two dipole located above a homogeneous dielectric filling the $z < 0$ half space is given by,

$$\mathcal{G}_d(\mathbf{r}_i, \mathbf{r}_j, \omega) = \frac{\imath}{4\pi} \int_0^\infty \frac{k_\rho}{k_z} \left(\mathcal{G}^s(\rho, \phi, z_i, z_j, k_\rho, k_z) - \frac{k_z^2}{k^2} \mathcal{G}^p(\rho, \phi, z_i, z_j, k_\rho, k_z) \right) dk_\rho \ , \tag{40.361}$$

where $\rho \equiv \sqrt{x_{ij}^2 + y_{ij}^2}$, $\cos\phi \equiv x_{ij}/\rho$, and $k^2 = k_\rho^2 + k_z^2 \equiv k_x^2 + k_y^2 + k_z^2$.
b. The task can be performed by simply setting $\mu_i = \mu_{II} = 1$ and $\varepsilon_i = 1$ in the formulas presented by [682]. The Green tensor for s-polarization is then given by,

$$\mathcal{G}^s = \frac{r^s e^{\imath k_z (z_i + z_j)}}{2} \left[J_0(k_\rho \rho) \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \end{pmatrix} + J_2(k_\rho \rho) \begin{pmatrix} \cos 2\phi & -\sin 2\phi & 0 \\ -\sin 2\phi & -\cos 2\phi & 0 \\ 0 & 0 & 0 \end{pmatrix} \right] \ . \tag{40.362}$$

For p-polarization,

$$\begin{aligned} \mathcal{G}^p = \frac{r^p e^{\imath k_z (z_i + z_j)}}{2} & \left[J_0(k_\rho \rho) \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & -2k_\rho^2/k_z^2 \end{pmatrix} \right. \\ & \left. + \frac{2\imath k_\rho}{k_z} J_1(k_\rho \rho) \begin{pmatrix} 0 & 0 & \cos\phi \\ 0 & 0 & \sin\phi \\ -\cos\phi & -\sin\phi & 0 \end{pmatrix} + J_2(k_\rho \rho) \begin{pmatrix} -\cos 2\phi & \sin 2\phi & 0 \\ \sin 2\phi & \cos 2\phi & 0 \\ 0 & 0 & 0 \end{pmatrix} \right] \end{aligned} \tag{40.363}$$

with the Fresnel factors,

$$r^p = \frac{\varepsilon(\omega) k_z - k_z^d}{\varepsilon(\omega) k_z + k_z^d} \quad , \quad r^s = \frac{k_z - k_z^d}{k_z + k_z^d} \ , \tag{40.364}$$

and

$$k_z^d \equiv \sqrt{\varepsilon(\omega)k^2 - k_\rho^2} \qquad \textit{such that} \qquad \mathfrak{Re}\; k_z^d > 0\;, \tag{40.365}$$

and a suitable Drude-Lorentz model for $\varepsilon(\omega)$. Note that both matrices composing $\mathcal{G}^s$ describe a projection onto the xy-plane. The second matrix additionally describes a an azimuthal rotation around the z-axis. The first matrix composing $\mathcal{G}^p$ describes a stretching of the z-coordinate, the second ???, and the third is identical to the second component of $\mathcal{G}^s$.

c. Assuming all atoms aligned along the y-axis, we may set $\phi = 0$. The Green tensors then simplify to,

$$\mathcal{G}^s = \frac{r^s e^{2\imath k_z z_i}}{2} \begin{pmatrix} J_0(k_\rho\rho) + J_2(k_\rho\rho) & 0 & 0 \\ 0 & J_0(k_\rho\rho) - J_2(k_\rho\rho) & 0 \\ 0 & 0 & 0 \end{pmatrix} \tag{40.366}$$

$$\mathcal{G}^p = \frac{r^p e^{2\imath k_z z_i}}{2} \begin{pmatrix} J_0(k_\rho\rho) - J_2(k_\rho\rho) & 0 & \frac{2\imath k_\rho}{k_z} J_1(k_\rho\rho) \\ 0 & J_0(k_\rho\rho) + J_2(k_\rho\rho) & 0 \\ -\frac{2\imath k_\rho}{k_z} J_1(k_\rho\rho) & 0 & -\frac{2k_\rho^2}{k_z^2} J_0(k_\rho\rho) \end{pmatrix} .$$

d. Furthermore, if the dipoles are oriented long $\hat{\mathbf{e}}_d = d\hat{\mathbf{e}}_z$,

$$\hat{\mathbf{e}}_z^*\; \mathcal{G}^s\; \hat{\mathbf{e}}_z = 0 \qquad \textit{and} \qquad \hat{\mathbf{e}}_z^*\; \mathcal{G}^p\; \hat{\mathbf{e}}_z = -\frac{k_\rho^2}{k_z^2} r^p e^{2\imath k_z z_i} J_0(k_\rho\rho)\;. \tag{40.367}$$

e. The result is simply obtain from (40.353) and (40.354) by setting $\mathbf{r}_i = \mathbf{r}_j$ and

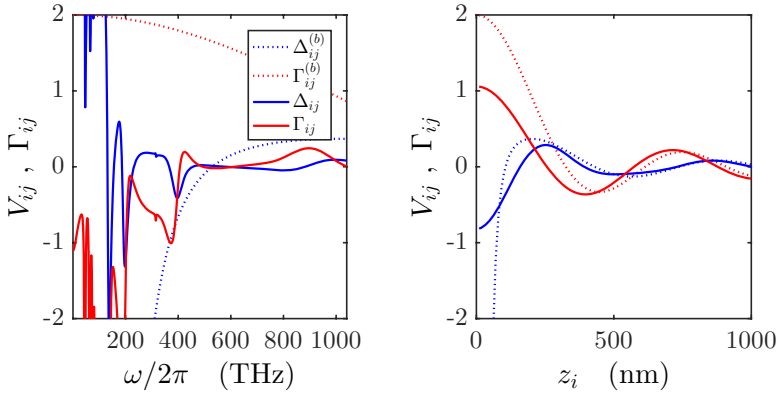

Figure 40.31: (code) Lamb-shift and Purcell factor.

using $J_0(0) = 1$ and $J_\nu(0) = 0$.

Chapter 41

Correlated atoms, entanglement and quantum gates

In Chps. 34 to 38 we concentrated on understanding the interaction of *single* atoms with light fields. In particular, we introduced the Rabi and the Jaynes-Cummings model. In Chp. 39 we introduced the coupled dipoles model for the interaction of many atoms with a single photon. In the following chapters, we will extend these models to several and many atoms and many photons [1].

model	RWA	symmetry	atom #	photon #	section
Rabi	no	$\mathcal{P}$	1	n	34.4
Jaynes-Cummings	yes	$U(1)$	1	n	35.4
Dicke	no	$\mathcal{P}$	>1	n	41.1
Tavis-Cummings	yes	$U(1)$	>1	n	41.2.2, 41.3.3

It does not come as a surprise that totally new phenomena arise from the collective interaction of several atoms with a single light mode. For instance, the atomic cloud can evolve toward a spin-squeezed or an entangled state, or it can emit light in a super- and subradiant way. The interplay between collective processes and processes favoring an individualization of the atom-light interaction is subtle, and the different models used to understand the processes only grasp partial aspects. The difficulty arises from the complexity of the task of describing the dynamics of N evolving in a Hilbert space of dimension 2^N. Approximations used to reduce the complexity of the Hilbert space come at the price of eventually loosing some interesting features. On the other hand, they may also help to crystallize fundamental symmetries, which allow us to deepen our intuition on the collective behavior of the many-body system.

Famous models used in the description of collective scattering are (among others) the Dicke model and the Tavis-Cummings model (see table above). The Dicke model (presented in Sec. 41.1) assumes a total indistinguishability of the atoms, the

[1] Other models, such as the Ising model, the Heisenberg model, or the Bose-Hubbard model are not treated here.
$\mathcal{P}$ is the parity operator defined in Eq. (41.79). The unitary group $U(1)$ corresponds to the circle group consisting of all complex numbers with absolute value 1 under multiplication.

Tavis-Cummings (discussed in Sec. 41.4 and used for the purpose of quantum computation) makes use of the rotating-wave approximation. Both models are based on the assumption of non-interacting atoms, neither by ground state collisions nor via radiation exchange, which certainly is a good assumption in the case of dilute atomic samples. On the other hand, we saw in the discussion of the coupled dipoles model in Chp. 39 that already the presence of a single photon in an atomic cloud leads noticeable interatomic interaction effects. In Sec. 41.3 we will extend the Dicke model to interacting atoms.

Finally, new phenomena arise from the presence of optical cavities shaping the spatial and spectral distribution of electromagnetic vacuum modes (see Chp. ??) and from the consideration of photonic recoil (see Chp. 42).

41.1 The Dicke model in the mean-field approximation

As we have seen in Sec. 23.3.9, the Hilbert space increases exponentially with the numbers of particles considered, the dimension of the Hilbert space of N particles being 2^N. This obviously presents a problem for numerical simulations, and simplifying models are needed. One of them is the *Dicke model*, where the N atoms are described as spin-$\frac{1}{2}$ particles and their collective interaction with a *single mode* light field via a single collective spin $\mathbf{S}$ with $S = N/2$. In this model, the dimension of the Hilbert space only scales polynomially as $2S + 1$.

In the next sections, we will introduce this model detailing its advantages and limitations and emphasizing its relations to super- and subradiance, spin squeezing and entanglement. In particular we will show that, when the coupling between the light and matter crosses a critical value, the Dicke model shows a mean-field phase transition to a superradiant phase.

41.1.1 Dicke states

The Hilbert space of the Dicke model [366, 610] is given by (the tensor product of) the states of the cavity and of the two-level atoms [2]. The Hilbert space of the cavity can be spanned by Fock states $|n\rangle$. Choosing the basis $|+\rangle \equiv \binom{0}{1}$ and $|-\rangle \equiv \binom{1}{0}$, the states of each two-level atom $j = 1, 2, .., N$ are defined through the spin operators $\hat{\mathbf{s}}_j = (\hat{s}_j^x, \hat{s}_j^y, \hat{s}_j^z)$ acting only an individual atom [3],

$$\begin{aligned} \hat{s}_j^x|... \pm ...\rangle &= \tfrac{1}{2}|... \mp ...\rangle \\ \hat{s}_j^y|... \pm ...\rangle &= \pm\imath\tfrac{1}{2}|... \mp ...\rangle \\ \hat{s}_j^z|... \pm ...\rangle &= \pm\tfrac{1}{2}|... \pm ...\rangle \ , \end{aligned} \tag{41.1}$$

and satisfying the spin algebra,

$$[\hat{s}_j^x, \hat{s}_k^y] = \imath\hat{s}_j^z\delta_{j,k} \ , \tag{41.2}$$

[2] Dicke states can also be introduced in the context of the Jaynes-Cummings model (see Sec. 41.1.1).

[3] Note, that here and in the following we set $\hbar \equiv 0$ for simplicity.

and related to the *Pauli spin matrices* (23.47) via,

$$\hat{\mathbf{s}} = \tfrac{1}{2}\vec{\hat{\sigma}} \quad , \quad \hat{s}^{\pm} = \hat{s}^x \pm \imath \hat{s}^y = \tfrac{1}{2}(\hat{\sigma}_x \pm \imath\hat{\sigma}_y) = \hat{\sigma}^{\pm} \ . \tag{41.3}$$

The Hamiltonian of the Dicke model is,

$$\hat{H} = -\Delta_c \hat{a}^\dagger \hat{a} + \sum_{j=1}^{N} \left(-\Delta_a \hat{s}_j^z + 2g(\hat{a} + \hat{a}^\dagger)\hat{s}_j^x + 2\imath g(\hat{a} - \hat{a}^\dagger)\hat{s}_j^y \right) \ . \tag{41.4}$$

Sometimes in literature the single-atom coupling strength (or half the single-atom single-photon Rabi frequency) is normalized to the atom number, $g \equiv \lambda/\sqrt{N}$. The coupling can be written as the sum of two terms: a co-rotating term that conserves the number of excitations and is proportional to $\hat{a}\hat{\sigma}^+ + \hat{a}^\dagger\hat{\sigma}^-$ and a counter-rotating term proportional to $\hat{a}\hat{\sigma}^- + \hat{a}^\dagger\hat{\sigma}^+$.

The above Hamiltonian assumes that all the spins are identical, i.e. they have the same transition frequency, they do not interact with each other, and they equally couple to the radiation field (e.g. a cavity mode). For the simple system of only two not mutually interacting spins, $\mathbf{s}_1$ and $\mathbf{s}_2$, simultaneously coupling to the same radiation field, the Dicke model has been introduced in Sec. 25.4.2. There, we have shown that the spin operators can be added, $\hat{\mathbf{S}} = \hat{\mathbf{s}}_1 + \hat{\mathbf{s}}_2$, and the total system be represented in a coupled basis, where $[\hat{s}_1 \cdot \hat{s}_2, \hat{\mathbf{S}}^2] = 0 = [\hat{s}_1 \cdot \hat{s}_2, \hat{S}_z^2]$. This concept can be generalized to an arbitrary number of spins, that is, under the above assumption, one can define macroscopic collective spin operators,

$$\hat{S}_\alpha \equiv \sum_{j=1}^{N} \hat{s}_j^\alpha \qquad \text{with} \qquad [\hat{S}_x, \hat{S}_y] = \imath \hat{S}_z \ , \tag{41.5}$$

and $\alpha = x, y, z$. Using these operators, one can rewrite the above Hamiltonian as

$$\boxed{\hat{H} = -\Delta_c \hat{a}^\dagger \hat{a} - \Delta_a \hat{S}_z + 2g\hat{a}_r \hat{S}_x - 2g\hat{a}_i \hat{S}_y} \tag{41.6}$$

with $\hat{a} = \hat{a}_r + \imath\hat{a}_i$, and it is easy to see that,

$$[\hat{H}, \hat{\mathbf{S}}^2] = 0 \neq [\hat{H}, \hat{S}_z] \ . \tag{41.7}$$

That is, the Dicke Hamiltonian preserves the spin $\langle \hat{\mathbf{S}}^2 \rangle$, but interaction with a light field can change the projection $\langle \hat{S}_z \rangle$. We will see in the following that this fact as important consequences for interaction dynamics of atomic ensembles coupled to a single light mode.

> **Example 248 (*Conservation of total spin under coherent interaction*):** More generally, a coherent interaction described by a Hamiltonian that only depends on collective spin components, $H = H(\hat{S}_x, \hat{S}_y, \hat{S}_z)$, cannot change the total spin $|\mathbf{S}|$. This is easy to see by doing a Taylor expansion of the Hamiltonian in the spin components and using $[\hat{\mathbf{S}}, \hat{\mathbf{S}}^2] = 0$. As a consequence a coherent (superradiant) spin state will stay coherent forever, unless individual atom-light interactions or decay processes occur.

41.1.1.1 Degeneracies of Dicke states

Let us now look at states having the same number N of energy packets counting free photons n and atomic excitations $N-n$. For example with $N=2$, the following states are possible. The normalization factors are simply the Clebsch-Gordan coefficients.

$\|S,M\rangle$ $\|n\rangle$	$\|\frac{N}{2},M\rangle$ $\#=1$	$\|\frac{N}{2}-1,M\rangle$ $\#=1$
0	$\|1,1\rangle = \|++\rangle$	
1	$\|1,0\rangle = \frac{1}{\sqrt{2}}(\|+-\rangle + \|-+\rangle)$	$\|0,0\rangle = \frac{1}{\sqrt{2}}(\|+-\rangle - \|-+\rangle)$
2	$\|1,-1\rangle = \|--\rangle$	

The right column of the above table contains a singlet state, which decouples from the triplet states (center column). The fact that it decouples from the deexcited triplet state makes the singlet state stable or *subradiant* [4]. See also Fig. 41.10.

For example with $N=3$ (see also Exc. 25.4.5.14),

$\|S,M\rangle$ n	$\|\frac{N}{2},M\rangle$ $\#=1$	$\|\frac{N}{2}-1,M\rangle$ $\#=2$
0	$\|\frac{3}{2},\frac{3}{2}\rangle = \|+++\rangle$	
1	$\|\frac{3}{2},\frac{1}{2}\rangle \sim \|++-\rangle + \|+-+\rangle + \|-++\rangle$	$\|\frac{1}{2},\frac{1}{2}\rangle$
2	$\|\frac{3}{2},-\frac{1}{2}\rangle \sim \|+--\rangle + \|-+-\rangle + \|--+\rangle$	$\|\frac{1}{2},-\frac{1}{2}\rangle$
3	$\|\frac{3}{2},-\frac{3}{2}\rangle = \|---\rangle$	

Example with N arbitrary,

$\|S,M\rangle$ $\|n\rangle$	$\|\frac{N}{2},M\rangle$ $\#=1$	$\|\frac{N}{2}-1,M\rangle$ $\#=N-1$	$\|\frac{N}{2}-2,M\rangle$ $\#=\frac{N(N-3)}{2}$
0	$\|\frac{N}{2},\frac{N}{2}\rangle = \|+++...\rangle$		
1	$\|\frac{N}{2},\frac{N}{2}-1\rangle \sim \sum_{perm.} \|-++...\rangle$	$\|\frac{N}{2}-1,\frac{N}{2}-1\rangle$	
2	$\|\frac{N}{2},\frac{N}{2}-2\rangle \sim \sum_{perm.} \|--+...\rangle$	$\|\frac{N}{2}-1,\frac{N}{2}-2\rangle$	$\|\frac{N}{2}-2,\frac{N}{2}-1\rangle$
$\vdots$	$\vdots$	$\vdots$	
N	$\|\frac{N}{2},-\frac{N}{2}\rangle = \|----..\rangle$		

We see that the Dicke states are not made to unambiguously label degenerate states. States $|S,M\rangle$ with $S<|M|$ are largely degenerate. The degeneracy of a Dicke state with $S\leq\frac{N}{2}$, that is, the number of states $|+\rangle^{N_+}|-\rangle^{N_-}$ composing a single Dicke state labeled by $|S,M\rangle$ is [492],

$$\# = \frac{(2S+1)N!}{(\frac{N}{2}+S+1)!(\frac{N}{2}-S)!}\ . \tag{41.8}$$

Transitions between energetically degenerate states $|S,M\rangle$ and $|S,M'\rangle$ with $M=M'$ but $S\neq S'$ are prohibited.

[4] Note that, while superradiance as well as subradiance can be explained by classical radiator models, such as the coupled dipoles model.

41.1.1.2 Mean-field approximation and light field elimination

The *mean-field approximation* consists in replacing the photonic operators by their expectation values, i.e. assuming classical light. This allows us to remove the light energy term from the Hamiltonian and replace the coupling strength by the n-photon Rabi frequency, $\Omega = 2g\sqrt{n}$. The Hamiltonian then becomes just a generalization of the semiclassical one-atom Hamiltonian (34.166) to large spins,

$$\boxed{\hat{H} = \hat{\mathbf{S}} \cdot \mathbf{G} = -\Delta_a \, \hat{S}_z + \mathfrak{Re}\, \Omega \, \hat{S}_x + \mathfrak{Im}\, \Omega \, \hat{S}_y} \,, \tag{41.9}$$

allowing for complex Rabi frequencies.

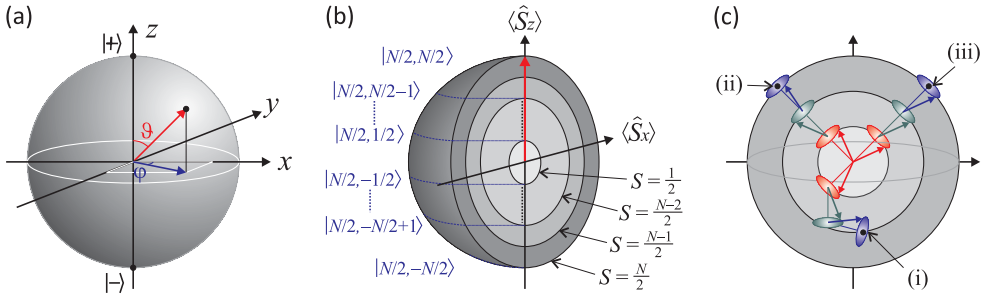

Figure 41.1: (a) Illustration of the Bloch sphere. (b) Bloch spheres of the various super/subradiant states with $N = 5$ atoms. (c) Illustration of (i) a subradiant state, (ii) a fully stretched coherent spin state, and (iii) a spin-correlated state for $N = 3$ atoms.

In the absence of spontaneous emission, any pure *single-atom* state is given by,

$$|\psi\rangle = |\vartheta, \varphi\rangle = \cos\tfrac{\vartheta}{2}|+\rangle + e^{\imath\varphi} \sin\tfrac{\vartheta}{2}|-\rangle \,, \tag{41.10}$$

where the angles ϑ and φ point to a location on the Bloch sphere characterizing the state of the atom. For example, a single initially deexcited atom having been subject to a $\frac{\pi}{2}$-pulse ends up in the state $|\frac{\pi}{2}, 0\rangle$. The expectation value of the spin operator in this state is simply obtained from,

$$\begin{aligned} \langle\vartheta,\varphi|\hat{S}_z|\vartheta,\varphi\rangle &= \cos^2\tfrac{\vartheta}{2}\langle+|\hat{S}_z|+\rangle + \sin^2\tfrac{\vartheta}{2}\langle-|\hat{S}_z|-\rangle = \tfrac{1}{2}\cos\vartheta \\ \langle\vartheta,\varphi|\hat{S}_+|\vartheta,\varphi\rangle &= e^{\imath\varphi}\sin\tfrac{\vartheta}{2}\cos\tfrac{\vartheta}{2}\langle+|\hat{S}_+|-\rangle = \tfrac{1}{2}e^{\imath\varphi}\sin\vartheta \,, \end{aligned} \tag{41.11}$$

yielding,

$$\langle\vartheta,\varphi|\hat{\mathbf{S}}|\vartheta,\varphi\rangle = \tfrac{1}{2}\begin{pmatrix} \cos\varphi\sin\vartheta \\ \sin\varphi\sin\vartheta \\ \cos\vartheta \end{pmatrix} \,. \tag{41.12}$$

We will also denote the probability of finding the system in state $|\pm\rangle$ by,

$$p_+ = \langle\hat{P}_\pm\rangle = |\langle+|\psi\rangle|^2 = \cos^2\tfrac{\vartheta}{2} = 1 - p_- \,. \tag{41.13}$$

41.1.1.3 Collective spin states

Let us now study the system obeying the Hamiltonian (41.9) in detail. The spin operators $\hat{\mathbf{S}}$ satisfy a SU(2) algebra explained in Sec. 25.3.2, i.e. $\hat{\mathbf{S}} \times \hat{\mathbf{S}} = \imath\hat{\mathbf{S}}$. The common eigenstates of $\hat{\mathbf{S}}^2$ and $\hat{S}_z$ are denoted by $|S, M\rangle$,

$$\begin{aligned} \hat{S}_z &= \hat{S}_+\hat{S}_- - \hat{S}_-\hat{S}_+ \qquad \text{with} \qquad \hat{S}_z|S,M\rangle = M|S,M\rangle \\ \hat{N}_\pm &\equiv \tfrac{1}{2}(N\mathbb{I} \pm \hat{S}_z) \qquad \text{with} \qquad \hat{N}_\pm|S,M\rangle = \tfrac{1}{2}(N \pm M)|S,M\rangle \ . \end{aligned} \tag{41.14}$$

From this we conclude that $S = N/2$ is half the number of atoms and M the inversion.

We consider an ensemble of $N = N_+ + N_-$ two-level atoms excited by a definite number of M photons, such that,

$$N = N_+ + N_- \qquad \text{and} \qquad 2M = N_+ - N_- \ . \tag{41.15}$$

Hence, $N_\pm = \frac{N}{2} \pm M$ is the number of atoms in each of the two states. The N atoms can occupy 2^N different collective states. However, when the atoms are identical and couple uniformly to the same light mode, all states where the same number of atoms is excited are energetically degenerate, and the total energy available to the system is,

$$E = M\omega_c \ . \tag{41.16}$$

The degeneracy of each many-body state with a given inversion M is given by the binomial coefficient,

$$\# = \binom{N}{\frac{N}{2}+M} = \binom{N}{N_+} = \binom{N}{N_-} \qquad \text{such that} \qquad \sum_{N_+=0}^{N} \binom{N}{N_+} = 2^N \ . \tag{41.17}$$

Therefore, we may set,

$$\boxed{|S,M\rangle \equiv |+\rangle^{N_+}|-\rangle^{N_-}} \ . \tag{41.18}$$

These states are called *Dicke states* [5].

For the special case $N = 2$ the transformation from the basis $|+\rangle^{N_+}|-\rangle^{N_-}$, used in the *Tavis-Cummings model*, to the basis $|S, M\rangle$, used in the Dicke model, is a unitary transformation. It has been extensively discussed in Sec. 25.4 at the example of two spins, whose complete Hilbert space can be expanded in the uncoupled or in the coupled basis. For $N > 2$ the situation is more complicated, since the degeneracies of both models are different. It is important to be aware that S is not simply half the atom number, but runs over $S = \frac{N}{2}, \frac{N}{2} - 1, ...$, depending on how the individual spins couple together. The degeneracy of an angular momentum state $|S, M\rangle$ with a specific inversion M but undefined orbital momentum S is determined by the condition $0 \leq S \leq M$, and given by,

$$\# = \tfrac{N}{2} - |M| + 1 \ . \tag{41.19}$$

[5] In Sec. 25.4.3 we used for the coupling of two spins the notation $|(s_1, s_2)s, m\rangle$. For coupling N spins, we should write in analogy,

$$|(\overbrace{\tfrac{1}{2}, .., \tfrac{1}{2}}^{N}), S, M\rangle \equiv |N, S, M\rangle \ .$$

Mostly, we will however drop the (constant) number N.

For example, for $N = 2$ the possible spin states are given by $|s_1 - s_2| \leq S \leq s_1 + s_2$, that is, $S = 0, 1$. And for $N = 5$, $M = \frac{3}{2}$ is supported by $S = \frac{3}{2}$ and $\frac{5}{2}$. Obviously, the degeneracy (41.19) is lower than (41.17) except for $N = 2$. Dicke states may be represented as vectors pointing to the surface of a so-called Bloch sphere of radius,

$$\|\langle N, S, M|\hat{\mathbf{S}}^2|N, S, M\rangle\| = S(S+1) \ , \tag{41.20}$$

as illustrated in Fig. 41.1(b).

41.1.1.4 Dicke Hamiltonian for 2 atoms from the Tavis-Cummings model

We start from the collective Dicke Hamiltonian (41.4) for two atoms assuming $\omega_{a1} = \omega_{a2}$ and $g_1 = g_2$, that is, both atoms are identical and inside the mode volume of the field to which they couple with equal strength, and apply the rotating wave approximation. The Hamiltonian then factorizes into a diagonal matrix of 4 by 4 blocks characterized by a given number of total excitations,

$$\hat{H}_n = \begin{pmatrix} (n+1)\omega_c - \omega_a & g\sqrt{n} & g\sqrt{n} & 0 \\ g\sqrt{n} & n\omega_c & 0 & g\sqrt{n} \\ g\sqrt{n} & 0 & n\omega_c & g\sqrt{n} \\ 0 & g\sqrt{n} & g\sqrt{n} & (n-1)\omega_c + \omega_a \end{pmatrix} . \tag{41.21}$$

Each block has two degenerate non-shifted eigenvalues and two non-degenerate shifted eigenvalues,

$$E = n\omega_c \quad \text{and} \quad E = n\omega_c \pm \varpi_n \quad \text{with} \quad \varpi_n \equiv \sqrt{(\omega_c + \omega_a)^2 - 4g^2 n} \ . \tag{41.22}$$

The description of the dynamics can be simplified by reducing the order of the matrix by calculating the average of the lines 2 and 3,

$$\hat{H}_D = \begin{pmatrix} (n+1)\omega_c - \omega_a & g\sqrt{2n} & 0 \\ g\sqrt{2n} & n\omega_c & g\sqrt{2n} \\ 0 & g\sqrt{2n} & (n-1)\omega_c + \omega_a \end{pmatrix} , \tag{41.23}$$

and opting for a new base defined by,

$$|\psi\rangle = \sum_n \begin{pmatrix} c_{22\ n-1} \\ c_{12\ n} \\ c_{11\ n+1} \end{pmatrix} |n\rangle \ , \tag{41.24}$$

with $c_{12\ n} = c_{21\ n}$. The new Hamiltonian (41.23) has exactly the same eigenvalues as the complete one (41.23), $\lambda = n\omega_c, n\omega_c \pm \varpi_n$, but without degeneracies. If we assume furthermore that the excitation is resonant, $\omega_c = \omega_a$, with high intensity, $n = |\alpha|^2$ for all n, defining the Rabi frequency $\Omega \equiv 2g\sqrt{n}$ our matrix becomes,

$$\hat{H}_D \simeq \begin{pmatrix} |\alpha|\omega & \frac{\Omega}{\sqrt{2}} & 0 \\ \frac{\Omega}{\sqrt{2}} & |\alpha|\omega & \frac{\Omega}{\sqrt{2}} \\ 0 & \frac{\Omega}{\sqrt{2}} & |\alpha|\omega \end{pmatrix} , \tag{41.25}$$

with the eigenvalue matrix,

$$E_n = U_n^\dagger \hat{H}_D U_n \simeq \begin{pmatrix} |\alpha|\omega - \Omega & & \\ & |\alpha|\omega & \\ & & |\alpha|\omega + \Omega \end{pmatrix} , \tag{41.26}$$

and the eigenvector matrix,

$$U_n \simeq \tfrac{1}{2} \begin{pmatrix} -1 & \sqrt{2} & 1 \\ \sqrt{2} & 0 & -\sqrt{2} \\ 1 & -\sqrt{2} & -1 \end{pmatrix} . \tag{41.27}$$

With this we can derive the propagator,

$$\begin{aligned} e^{-\imath \hat{H}_n t} =& \tfrac{1}{2} e^{-\imath \alpha^2 \omega \mathbf{t}} \begin{pmatrix} 1+\cos\alpha\Omega t & -\sqrt{2}\imath \sin\alpha\Omega t & -1+\cos\alpha\Omega t \\ -\sqrt{2}\imath\sin\alpha\Omega t & 2\cos\alpha\Omega t & -\sqrt{2}\imath\sin\alpha\Omega t \\ -1+\cos\alpha\Omega t & -\sqrt{2}\imath\sin\alpha\Omega t & 1+\cos\alpha\Omega t \end{pmatrix} \\ \overset{\alpha\Omega t=\pi/2}{\longrightarrow}& \tfrac{1}{2} e^{-\imath\pi/2\cdot\alpha\omega/\Omega} \begin{pmatrix} 1 & -\sqrt{2}\imath & -1 \\ -\sqrt{2}\imath & 0 & -\sqrt{2}\imath \\ -1 & -\sqrt{2}\imath & 1 \end{pmatrix} . \end{aligned}$$

The generalization to three atoms or N atoms is straightforward and will be left to Exc. 41.1.6.2.

41.1.2 Coherent spin states

By the fact that the individual spins are additive and the Hamiltonian linear in the spin operators, $\hat{H} \propto \hat{S}_z$, we know that the Schrödinger equation will be satisfied by *product states*,

$$|\Psi_N\rangle = \prod_{k=1}^{N} |\vartheta_k, \varphi_k\rangle_k , \tag{41.28}$$

where $|\vartheta_k, \varphi_k\rangle_k$ is the state of the k-the atom given by (41.10).

Coherent spin states now consist of N atoms, all being in the same state. In Exc. 41.1.6.3 we present another equivalent definition. Since the atoms are indistinguishable by the radiation field, we may as well drop the labeling index k,

$$|\Psi_N\rangle = |\vartheta, \varphi\rangle^N = \sum_{k=0}^{N} \sqrt{\binom{N}{k}} \cos^{N-k}\tfrac{\vartheta}{2} |+\rangle^{N-k} \, e^{\imath k\varphi} \sin^k \tfrac{\vartheta}{2} |-\rangle^k , \tag{41.29}$$

in agreement with (36.58), or equivalently, using the Dicke state notation (41.18),

$$\boxed{|\vartheta, \varphi\rangle^N = \sum_{k=0}^{2S} \sqrt{\binom{2S}{k}} \cos^{2S-k}\tfrac{\vartheta}{2} \, e^{\imath k\varphi} \sin^k \tfrac{\vartheta}{2} |S, S-k\rangle} . \tag{41.30}$$

Hence, similarly to the coherent state of a harmonic oscillator, which consists of a Poissonian distribution of number states, the coherent spin state consists of a binomial distribution of N_+ atoms in one state and $N - N_+$ in the other. Note also, that by construction, the coherent spin states are **stretched**, $S = N/2$. That is, they can be represented by a vector of length N equal to the radius of the (generalized) Bloch sphere [6]. In other words, S is a conserved quantum number as already shown in (41.7), and this feature does not change under the influence of the Hamiltonian (41.9). These states are called superradiant. Nevertheless, other states $|S, M\rangle$ are possible with $S \leq \frac{N}{2}$. These are squeezed, subradiant, or entangled states.

In the following we will study some of the properties of the coherent spin states. For instance, in Exc. 41.1.6.4(a) we calculate the expectation values of coherent spin states,

$$\langle \vartheta, \varphi|^N \hat{\mathbf{S}} |\vartheta, \varphi\rangle^N = S \begin{pmatrix} \cos\varphi \sin\vartheta \\ \sin\varphi \sin\vartheta \\ \cos\vartheta \end{pmatrix} . \tag{41.31}$$

Hence, the spin evolves on the surface of a Bloch sphere with radius,

$$\|\langle \vartheta, \varphi|^N \hat{\mathbf{S}} |\vartheta, \varphi\rangle^N\| = S \qquad \text{while still} \qquad \|\langle \vartheta, \varphi|^N \hat{\mathbf{S}}^2 |\vartheta, \varphi\rangle^N\| = S(S+1) . \tag{41.32}$$

For the number of atoms in each state we expect,

$$\langle \hat{N}_+ \rangle = \tfrac{N}{2} + \tfrac{1}{2}\langle \hat{S}_z \rangle = N \cos^2 \tfrac{\vartheta}{2} = N p_+ = N(1 - p_-) = N - \langle N_- \rangle . \tag{41.33}$$

41.1.3 Rotations, spin excitation and precession

We learn in quantum mechanics how to use Pauli matrices to describe rotations in the Bloch vector space (see Exc. 23.3.10.5). We will now extend this formalism to our collective spin space. A useful rule for the subsequent calculations, proved in Exc. 41.1.6.5, is the following,

$$e^{\imath F(\hat{S}_z)} \hat{S}_+ e^{-\imath F(\hat{S}_z)} = \hat{S}_+ e^{\imath[F(\hat{S}_z + \mathbb{I}) - F(\hat{S}_z)]} , \tag{41.34}$$

where F is an arbitrary function. For $F(\hat{S}_z) \equiv \phi \hat{S}_z$ the unitary transform $e^{\imath F(\hat{S}_z)}$ denotes a rotation about the z-axis, which we will study in the example below. For $F(\hat{S}_z) \equiv \zeta \hat{S}_z^2$ it generates squeezing along the z-axis, which we will study in the next section. Furthermore, we define the rotation matrices about the Cartesian axis,

$$R_x(\gamma) \equiv \begin{pmatrix} 1 & 0 & 0 \\ 0 & \cos\gamma & -\sin\gamma \\ 0 & \sin\gamma & \cos\gamma \end{pmatrix} , \qquad R_y(\gamma) \equiv \begin{pmatrix} \cos\gamma & 0 & -\sin\gamma \\ 0 & 1 & 0 \\ \sin\gamma & 0 & \cos\gamma \end{pmatrix} ,$$
$$R_z(\gamma) \equiv \begin{pmatrix} \cos\gamma & -\sin\gamma & 0 \\ \sin\gamma & \cos\gamma & 0 \\ 0 & 0 & 1 \end{pmatrix} , \tag{41.35}$$

for which it is possible to show (with $\alpha = x, y, z$),

$$\boxed{R_\alpha(\gamma) \hat{\mathbf{S}} = e^{\imath\gamma \hat{S}_\alpha} \hat{\mathbf{S}} e^{-\imath\gamma \hat{S}_\alpha}} . \tag{41.36}$$

[6] An illustration of the generalized Bloch sphere is attempted in Fig. 41.29.

Example 249 (*Rotation about* $\hat{S}_z$): Defining $F(\hat{S}_z) \equiv \phi \hat{S}_z$ the relationship (41.34) tells us,

$$e^{\imath\phi\hat{S}_z}\hat{S}_+ e^{-\imath\phi\hat{S}_z} = \hat{S}_+ e^{\imath\phi} \ ,$$

and consequently,

$$e^{\imath\phi\hat{S}_z}\hat{\mathbf{S}}e^{-\imath\phi\hat{S}_z} = \begin{pmatrix} \frac{1}{2}(e^{\imath\phi}\hat{S}_+ + e^{-\imath\phi}\hat{S}_-) \\ \frac{1}{2\imath}(e^{\imath\phi}\hat{S}_+ - e^{-\imath\phi}\hat{S}_-) \\ \hat{S}_z \end{pmatrix} = \begin{pmatrix} \cos\phi & -\sin\phi & 0 \\ \sin\phi & \cos\phi & 0 \\ 0 & 0 & 1 \end{pmatrix} \hat{\mathbf{S}} \equiv R_z(\phi)\hat{\mathbf{S}} \ .$$

Furthermore,

$$\begin{aligned} e^{-\imath\phi\hat{S}_z}|\vartheta,\varphi\rangle^N &= \sum_{k=0}^{2S} \sqrt{\binom{2S}{k}} \cos^{N-k}\tfrac{\vartheta}{2} e^{\imath k\varphi} \sin^k\tfrac{\vartheta}{2} e^{-\imath\phi(S-k)}|S,S-k\rangle \\ &= e^{-\imath\phi S}\left(e^{-\imath\phi}\cos\tfrac{\vartheta}{2}|+\rangle + e^{\imath(\varphi+\phi)}\sin\tfrac{\vartheta}{2}|-\rangle\right)^N = e^{-\imath\phi S}|\vartheta,\varphi+\phi\rangle^N \ . \end{aligned}$$

We also find,

$$\langle\vartheta,\varphi|^N R_z(\phi)\hat{\mathbf{S}}|\vartheta,\varphi\rangle^N = \tfrac{N}{2}\begin{pmatrix} \cos(\varphi+\phi)\sin\vartheta \\ \sin(\varphi+\phi)\sin\vartheta \\ \cos\vartheta \end{pmatrix} = \langle\vartheta,\varphi+\phi|^N\hat{\mathbf{S}}|\vartheta,\varphi+\phi\rangle^N \ .$$

To vary the polar angle ϑ of a coherent spin state $|\vartheta,\varphi\rangle$, we first rotate the coordinate system about the z-axis until $\varphi = 0$, then rotate about the y-axis by the desired angle θ, and finally rotate back about the z-axis to reach the initial azimuth φ,

$$\langle\vartheta,\varphi|^N R_z(\varphi)R_y^{-1}(\theta)R_z^{-1}(\varphi)\hat{\mathbf{S}}|\vartheta,\varphi\rangle^N = \tfrac{N}{2}\begin{pmatrix} \cos\varphi\sin(\theta+\vartheta) \\ \sin\varphi\sin(\theta+\vartheta) \\ \cos(\theta+\vartheta) \end{pmatrix} = \langle\vartheta+\theta,\varphi|^N\hat{\mathbf{S}}|\vartheta+\theta,\varphi\rangle^N \ .$$

The rotation about the x-axis is derived in Exc. 41.1.6.6, and in Exc. 41.1.6.7 we write down the explicit rotation matrix for two atoms.

Rotations such as the ones described by $R_\alpha(\gamma)$ are generated by the Dicke Hamiltonian (41.9), since the solution of the Schrödinger equation is,

$$\boxed{|\Psi(t)\rangle = e^{-\imath\hat{H}t}|\Psi(0)\rangle = e^{-\imath t\hat{S}_x\mathfrak{Re}\ \Omega_x - \imath t\hat{S}_y\mathfrak{Im}\ \Omega_y - \imath t\hat{S}_z\Delta}|\Psi(0)\rangle} \ . \tag{41.37}$$

That is, the Dicke Hamiltonian generates rotations $R_x(\mathfrak{Re}\ \Omega_x t)$, $R_y(\mathfrak{Im}\ \Omega_y t)$, and $R_z(\Delta t)$. This confirms that rotations do only transform coherent states into each other. Nevertheless, there are other unitary operations that transform coherent states into states that cannot be represented by coherent states. One example for this is squeezing.

41.1.3.1 Rotation algebra

The example 249 shows that rotations from an initial towards an arbitrary coherent spin states can be parametrized by a pair of Euler angles. Using (23.200) [328],

$$\begin{aligned} &U_{rt}(\vartheta,\varphi) = e^{\imath\varphi\hat{S}_z}e^{\imath\vartheta\hat{S}_y} = e^{-\imath\vartheta\hat{\mathbf{e}}_\varphi\cdot\hat{\mathbf{S}}} = e^{-\imath\vartheta(-\hat{S}_x\sin\varphi+\hat{S}_y\cos\varphi)} = e^{-\frac{\vartheta}{2}(\hat{S}_+e^{-\imath\varphi}-\hat{S}_-e^{\imath\varphi})} \\ &R(\vartheta,\varphi)\hat{\mathbf{S}} \equiv U_{rt}^\dagger(\vartheta,\varphi)\hat{\mathbf{S}}U_{rt}(\vartheta,\varphi) \end{aligned} \tag{41.38}$$

with $\hat{\mathbf{e}}_\varphi = -\hat{\mathbf{e}}_x \sin\varphi + \hat{\mathbf{e}}_y \cos\varphi$. With this we find,

$$|\vartheta,\varphi\rangle^N = U_{rt}(\vartheta,\varphi)|S,S\rangle \ . \tag{41.39}$$

41.1.4 Uncertainties, quantum projection noise and spin squeezing

Measuring the population of a coherently excited two-level system by projecting it onto an energy eigenstate introduces *quantum projection noise*. Although this inherent noise spoils the determination of the resonance frequency, it can to some extent be surpassed by *spin squeezing* [1380]. The projection noise limit has been observed with ions [653, 642] and with atomic clouds [1143]. The reduction of the noise by spin squeezing has been observed with ions [1127], micromasers [1074], and atomic clouds [572, 763]. Also, a weakly entangled state of two modes was observed for continuous spin variables [689]. Very strong squeezing spin can be obtained in a *Mott insulator* state, as demonstrated by [537].

First, we want to show that the Heisenberg uncertainty of a coherent spin state is nothing else than the quantum projection noise studied in Sec. 36.3.2. On one hand, we have,

$$\begin{aligned}
\langle\vartheta,\varphi|^N(\Delta\hat{S}_z)^2|\vartheta,\varphi\rangle^N &= \langle\vartheta,\varphi|^N\hat{S}_z^2|\vartheta,\varphi\rangle^N - (\langle\vartheta,\varphi|^N\hat{S}_z|\vartheta,\varphi\rangle^N)^2 \\
&= \sum_{k=0}^{N}\binom{N}{k}(\tfrac{N}{2}-k)^2 p_+^{N-k}p_-^k - \left(\sum_{k=0}^{N}\binom{N}{k}(\tfrac{N}{2}-k)p_+^{N-k}p_-^k\right)^2 \\
&= \left(\tfrac{N^2}{4} - N^2 p_+p_- + Np_+p_-\right) - \left(\tfrac{N}{2}(p_+-p_-)\right)^2 = Np_+p_- \ .
\end{aligned} \tag{41.40}$$

On the other hand, we have seen in (36.57) that this results corresponds to the variance of quantum projection noise,

$$\begin{aligned}
(\Delta r)^2 &= \sum_{r=0}^{N}(r-Np_\pm)^2 P_{N,r,\pm} \\
&= \sum_{k=0}^{N}(\tfrac{N}{2}-k+\tfrac{N}{2}(p_+-p_-))^2\binom{N}{k}p_+^{N-k}p_-^k = Np_+p_- \ .
\end{aligned} \tag{41.41}$$

The Heisenberg uncertainty relation (23.91) applied to angular momentum operator satisfying $[\hat{S}_x,\hat{S}_y] = \imath\hat{S}_z$ states,

$$\Delta\hat{S}_x\Delta\hat{S}_y \geq \tfrac{1}{2}|\hat{S}_z| \ . \tag{41.42}$$

Since there are no quantum correlations between the particles, the uncertainty of coherent spin states is additive (see Exc. 25.3.4.5),

$$(\Delta\hat{S}_\alpha)^2 = \sum_{k=0}^{N}(\Delta\hat{s}_k^\alpha)^2 \ . \tag{41.43}$$

For a coherent spin state we can calculate explicitly [see Exc. 41.1.6.4(b)],

$$\langle\vartheta,\varphi|^N \begin{pmatrix} \Delta\hat{S}_x^2 \\ \Delta\hat{S}_y^2 \\ \Delta\hat{S}_z^2 \end{pmatrix} |\vartheta,\varphi\rangle^N = \tfrac{N}{4} \begin{pmatrix} 1-\sin^2\vartheta\cos^2\varphi \\ 1-\sin^2\vartheta\sin^2\varphi \\ \sin^2\vartheta \end{pmatrix} . \tag{41.44}$$

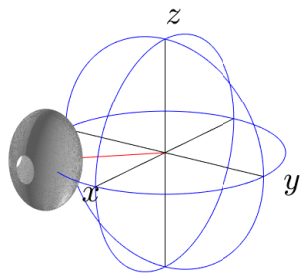

Figure 41.2: Illustration of the uncertainty of the spin components of a coherent spin state.

Example 250 (*Uncertainty of a coherent spin state after a $\frac{\pi}{2}$-pulse*): A $\frac{\pi}{2}$-pulse applied to a cloud in the collective ground state generates the state $|\vartheta,\varphi\rangle = |\frac{\pi}{2},0\rangle$. This is somewhat analogous to the beam splitting of a photonic Fock state discussed in Sec. 35.8. Interestingly, a Fock state seems more natural for an atomic cloud, while the Glauber state is more natural for a photonic mode. For example, for the particular state $|\frac{\pi}{2},0\rangle$ we find from (41.44),

$$(\Delta\hat{S}_x)^2 = 0 \qquad \text{and} \qquad (\Delta\hat{S}_y)^2 = (\Delta\hat{S}_z)^2 = \tfrac{S}{2} .$$

Note, that spin squeezing along the z-axis could be obtained by quantum non-demolition measurement of the inversion, that is, by measuring $\hat{S}_z$ without influencing the populations of the ground and excited state.

41.1.4.1 Spin squeezing by one-axis twisting

We have seen in the last section, that rotations influence the distribution of the uncertainty among the Cartesian coordinates in a specific way. It is, however, possible to manipulate the uncertainty distribution without rotating the collective spin state. An example with great practical importance is the concept of spin squeezing. It consists in establishing appropriate quantum correlations are between the individual spins, such as to partly cancel out fluctuations in one direction augmenting them in the other direction.

Squeezing of spin is not as straightforward as squeezing of bosons, since the uncertainty relations are essentially different [724]. To study spin-squeezing along the z-axis let as analyze the unitary transformation,

$$\boxed{Q_z(\zeta)\hat{\mathbf{S}} \equiv e^{\imath\zeta\hat{S}_z^2}\hat{\mathbf{S}}e^{-\imath\zeta\hat{S}_z^2}} . \tag{41.45}$$

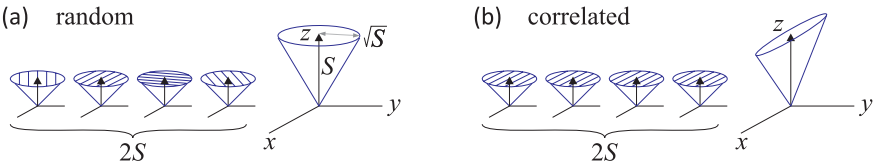

Figure 41.3: Illustration of the uncertainty in (a) a coherent state and (b) a spin-squeezed state.

Specifying the rule (41.34) for the particular case $F(\hat{S}_z) \equiv \zeta \hat{S}_z^2$, we get,

$$e^{\imath\zeta\hat{S}_z^2}\hat{S}_+ e^{-\imath\zeta\hat{S}_z^2} = \hat{S}_+ e^{2\imath\zeta(\hat{S}_z+1/2)} \ , \tag{41.46}$$

and hence,

$$Q_z(\zeta)\hat{\mathbf{S}} = e^{\imath\zeta\hat{S}_z^2}\hat{\mathbf{S}}e^{-\imath\zeta\hat{S}_z^2} = \begin{pmatrix} \frac{1}{2}(\hat{S}_+ e^{2\imath\zeta(\hat{S}_z+1/2)} + e^{-2\imath\zeta(\hat{S}_z+1/2)}\hat{S}_-) \\ \frac{1}{2\imath}(\hat{S}_+ e^{2\imath\zeta(\hat{S}_z+1/2)} - e^{-2\imath\zeta(\hat{S}_z+1/2)}\hat{S}_-) \\ \hat{S}_z \end{pmatrix} \ . \tag{41.47}$$

Let us now apply the *squeezing operator* to the state $|\frac{\pi}{2}, 0\rangle$. In Exc. 41.1.6.8 we show that,

$$\langle\tfrac{\pi}{2}, 0|^N e^{\imath\zeta\hat{S}_z^2}\hat{\mathbf{S}}e^{-\imath\zeta\hat{S}_z^2}|\tfrac{\pi}{2}, 0\rangle^N = \begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix} \tfrac{N}{2}\cos^{N-1}\zeta \tag{41.48}$$

$$\langle\tfrac{\pi}{2}, 0|^N e^{\imath\zeta\hat{S}_z^2}\begin{pmatrix} \hat{S}_x^2 \\ \hat{S}_y^2 \\ \hat{S}_z^2 \end{pmatrix} e^{-\imath\zeta\hat{S}_z^2}|\tfrac{\pi}{2}, 0\rangle^N = \begin{pmatrix} N+1 \\ N+1 \\ 2 \end{pmatrix} \tfrac{N}{8} + \begin{pmatrix} 1 \\ -1 \\ 0 \end{pmatrix} \tfrac{N(N-1)}{8}\cos^{N-2} 2\zeta \ .$$

The dependencies of the uncertainties as a function of the squeezing parameter are plotted in Fig. 41.4. We see that the uncertainties never get smaller than the unsqueezed value. The reason is that, since the unitary transform $e^{\imath\zeta\hat{S}_z^2}$ commutes with $\hat{S}_z$, the prescription (41.45) does not immediately lead to squeezing along the z-axis.

Nevertheless, the prescription does generate quantum correlations in $\hat{S}_x$ and $\hat{S}_y$, which can be transformed to squeezing by subsequently rotating the collective spin about the x-axis [724]. As shown in Exc. 41.1.6.9, a rotation by an angle ν does not modify the x-component,

$$\begin{aligned} &\langle\tfrac{\pi}{2}, 0|^N e^{\imath\nu\hat{S}_x} e^{\imath\zeta\hat{S}_z^2}\Delta\hat{S}_x^2 e^{-\imath\zeta\hat{S}_z^2} e^{-\imath\nu\hat{S}_x}|\tfrac{\pi}{2}, 0\rangle^N \\ &\qquad = \tfrac{N(N+1)}{8} + \tfrac{N(N-1)}{8}\cos^{N-2} 2\zeta - \tfrac{N^2}{4}\cos^{2N-2}\zeta \ , \end{aligned} \tag{41.49}$$

but it modifies the other ones,

$$\begin{aligned} &\langle\tfrac{\pi}{2}, 0|^N e^{\imath\nu\hat{S}_x} e^{\imath\zeta\hat{S}_z^2}\Delta\hat{S}_{y,z}^2 e^{-\imath\zeta\hat{S}_z^2} e^{-\imath\nu\hat{S}_x}|\tfrac{\pi}{2}, 0\rangle^N \\ &\qquad = \tfrac{N}{4}\{1 + \tfrac{N-1}{4}[A \pm \sqrt{A^2+B^2}\cos(2\nu + \arctan\tfrac{B}{A})]\} \ , \end{aligned} \tag{41.50}$$

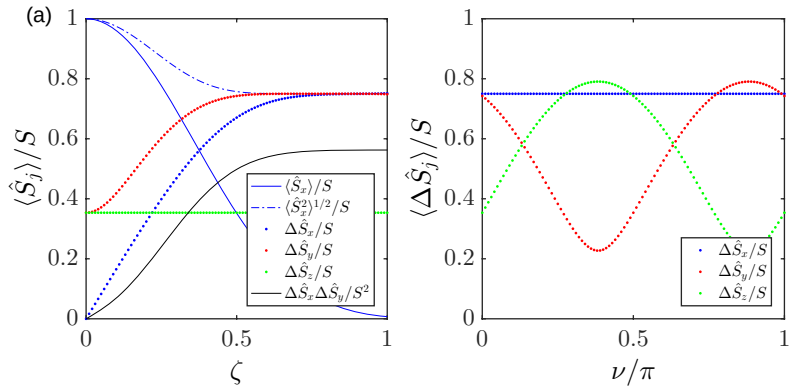

Figure 41.4: (code) (a) Uncertainties calculated in (41.48) as a function of the squeezing parameter. (b) Uncertainties after application of squeezing operator as a function of the rotation angle ν about the x-axis.

with $A \equiv 1 - \cos^{N-2} 2\zeta$ and $B \equiv 4 \sin\zeta \cos^{N-2}\zeta$. We study spin squeezing in Exc. 41.1.6.10 to 41.1.6.13. In Exc. 41.1.6.14 we investigate, whether double Fock states can lead to Heisenberg-limited interferometry, and in Exc. 41.1.6.15 we study entanglement witnesses with coherent spin states.

Obviously, since squeezed states are obtained from coherent states by unitary transform, they are still normalized,

$$\langle\vartheta,\varphi|^N e^{-\imath\zeta\hat{S}_z^2} e^{\imath\zeta\hat{S}_z^2} |\vartheta,\varphi\rangle^N = 1 \; . \tag{41.51}$$

Example 251 (*Conditional spin-squeezing by non-demolition measurement*): Technically, spin-squeezed states can be generated in experiments by quantum non-demolition measurements [163, 309, 1135]. Another idea would be to arrange for totally uniform spin-spin coupling, since this generates terms like,

$$H_{ss} = \sum_{i,j\neq i}^{N} \kappa_{ij} \hat{s}_i^z \hat{s}_j^z \simeq \kappa \sum_{i,j\neq i}^{N} \hat{s}_i^z \hat{s}_j^z = \kappa \hat{S}_z^2 \; . \tag{41.52}$$

In a cloud this latter idea is not realizable, because the interatomic coupling strength depends on the distance between the atoms, but if the atoms are coupled via their interaction with a common mode of an optical cavity it should be feasible.

41.1.5 Bosonic modes: Analogy between harmonic oscillators and collective spin states

Owing to the equidistant spectrum of their excitation levels, harmonic oscillator modes and collective spin states share many particularities, which will allow us to transfer various notions from the well-known harmonic oscillator studied in Sec. 24.6 to the spin ensembles. Respectively expanded on Fock states and Dicke states, the oscillator operators and the spin operators are approximately linked by the Holstein-Primakoff prescription, which will be worked out below. Also, we appreciated in

Sec. 35.2 the utility of quasi-probability distributions for the estimation of quantum correlations in light modes, which we will apply to spin systems below. Light fields and spin systems are examples of what is called a *bosonic mode*.

41.1.5.1 Mapping Fock and Dicke states

The operators $\hat{a}, \hat{a}^\dagger$ contain all information on a light mode. Similarly, $\hat{S}_+, \hat{S}_-, \hat{S}_z$ contain all information on a collective spin state. In the Heisenberg picture their unitary evolution under some operation (displacement, rotation, squeezing, etc.) is obtained from,

$$\hat{a}^\pm(t) = U(t)\hat{a}^\pm(0)U^\dagger(t) \qquad \text{versus} \qquad \hat{\mathbf{S}}(t) = U(t)\hat{\mathbf{S}}(0)U^\dagger(t) \; . \tag{41.53}$$

While the state of a light mode is given by an expectation value corresponding to a point in an infinite two-dimensional quadrature phase space, the state of a spin ensemble is represented as a vector in a generalized Bloch sphere,

$$\alpha(t) = \langle\psi(0)|\hat{a}^\pm(t)|\psi(0) \qquad \text{versus} \qquad \mathbf{S}(t) = \langle\Psi_N(0)|\hat{\mathbf{S}}(t)|\Psi_N(0)\rangle \; . \tag{41.54}$$

By the fact that the light mode is represented by a 2D complex plane, the commutation rule involves two field operators, while for the Bloch sphere, which is embedded in 3D space, with respect to a fixed coordinate system the commutation rule involves three field operators,

$$[\hat{a}, \hat{a}^\dagger] = 1 \qquad \text{versus} \qquad [\hat{S}_+, \hat{S}_-] = 2\hat{S}_z \; . \tag{41.55}$$

This has consequences for the uncertainty relations,

$$[\hat{x}, \hat{p}^\dagger] \geq \tfrac{1}{2} \qquad \text{versus} \qquad [\hat{S}_x, \hat{S}_y] \geq \tfrac{1}{2}|\langle S_z\rangle| \; . \tag{41.56}$$

On the other hand, as long as we are only interested in coherent evolutions, as shown in the example 248, the total angular momentum is a constant of motion. This means that an initially fully stretched collective spin state is restricted to evolve on the outer (superradiant) shell of the generalized Bloch sphere, which is a two-dimensional surface,

$$|\alpha\rangle = |\mathfrak{Re}\ \alpha, \mathfrak{Im}\ \alpha\rangle \qquad \text{versus} \qquad |\Psi_N\rangle = |\vartheta, \varphi\rangle^N \; . \tag{41.57}$$

As shown in Sec. 41.1.3, rotations do not influence any spin correlations. Therefore, we may as well introduce a local Cartesian coordinate system, rotated such that $\hat{S}_z$ is diagonal on this basis, and calculate its expectation value $\langle S_z\rangle = M$. We immediately see that the commutation rules (41.55) then become equivalent,

$$[\hat{a}, \hat{a}^\dagger] = 1 \qquad \text{versus} \qquad [\hat{S}_+, \hat{S}_-] = 2M \; , \tag{41.58}$$

as well as the corresponding uncertainty relations. In this basis the correlations can be expanded on a 2D phase space parametrized by the angles ϑ and φ.

41.1.5.2 The Holstein-Primakoff prescription

In the limit of large atom numbers the Dicke Hamiltonian can be approximated by a system of two coupled quantum oscillators. The mapping is done via the so-called *Holstein-Primakoff transformation*. The transformation is a mapping of the spin operators to boson creation and annihilation operators, effectively truncating their infinite-dimensional Fock space to finite-dimensional subspaces. Let us consider a spin operator $\hat{\mathbf{S}}$ defined by its commutation behavior $[\hat{S}_x, \hat{S}_y] = \imath \hat{S}_z$ and characterized by its eigenvectors $|S, M\rangle$,

$$\hat{\mathbf{S}}^2|S, M\rangle = S(S+1)|S, M\rangle \quad , \quad \hat{S}_z|S, M\rangle = M|S, M\rangle \ , \tag{41.59}$$

with the projection quantum number $M = -S, -S+1, \ldots, S-1, S$. We consider a single particle of spin S and take the state $|S, M = +S\rangle$ as a vacuum for a set of boson operators, and each subsequent state with lower projection quantum number as a boson excitation of the previous one,

$$|S, S-n\rangle \mapsto \frac{1}{\sqrt{n!}}(\hat{b}^\dagger)^n|0\rangle \ . \tag{41.60}$$

Each additional boson then corresponds to a decrease of M in the spin projection. Thus, the spin raising and lowering operators $\hat{S}_\pm = \hat{S}_x \pm \imath \hat{S}_y$ satisfying so that $[\hat{S}_+, \hat{S}_-] = 2\hat{S}_z$ correspond to bosonic annihilation and creation operators, respectively. The precise relations between the operators must be chosen to ensure the correct commutation relations for the spin operators. The resulting Holstein-Primakoff transformation can be written as,

$$\boxed{\hat{S}_+ = \sqrt{2S}\sqrt{1 - \tfrac{\hat{b}^\dagger \hat{b}}{2S}}\ \hat{b} \quad , \quad \hat{S}_- = \sqrt{2S}\ \hat{b}^\dagger \sqrt{1 - \tfrac{\hat{b}^\dagger \hat{b}}{2S}} \quad , \quad \hat{S}_z = (S - \hat{b}^\dagger \hat{b})} \ . \tag{41.61}$$

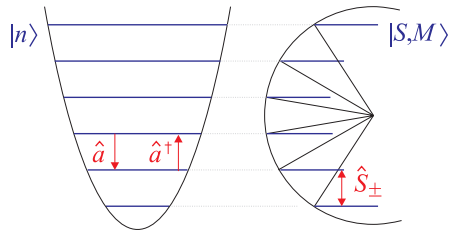

Figure 41.5: Illustration of the Holstein-Primakoff transformation.

The transformation is particularly useful in the case where S is large, when the square roots can be expanded as Taylor series, to give an expansion in decreasing powers of S [1278, 145]. We will verify the commutation relations in Exc. 41.1.6.16. The Holstein-Primakoff approximation allows us to rewrite the Hamiltonian (41.6)

as,

$$\begin{aligned}\hat{H}_{HP} &= -\Delta_c \hat{a}^\dagger \hat{a} - \Delta_a \hat{S}_z + 2g(\hat{a}+\hat{a}^\dagger)\hat{S}_x \\ &= -\Delta_c \hat{a}^\dagger \hat{a} - \Delta_a (S - \hat{b}^\dagger \hat{b}) + 2g(\hat{a}+\hat{a}^\dagger)\sqrt{2S}\left(\sqrt{1-\tfrac{\hat{b}^\dagger\hat{b}}{2S}}\;\hat{b} + \hat{b}^\dagger\sqrt{1-\tfrac{\hat{b}^\dagger\hat{b}}{2S}}\right) \\ &\simeq -\Delta_c \hat{a}^\dagger \hat{a} - \tfrac{1}{2}\Delta_a \hat{b}^\dagger\hat{b} + 2g_N(\hat{a}+\hat{a}^\dagger)(\hat{b}+\hat{b}^\dagger)\ ,\end{aligned} \tag{41.62}$$

with the collective coupling strength $g_N \equiv g\sqrt{N}$. The Hamiltonian (41.62) describes two coupled quantum oscillators without rotating-wave approximation [426] [7], a system which has already been discussed in Sec. 35.8.8 in the context of beamsplitters.

41.1.5.3 Quasi-probability distributions on the Bloch sphere

The operators contain all information on possible quantum correlations, and it is now interesting to quantify and illustrate the formation of such correlations under some manipulation. This is the purpose of the quasi-probability distributions.

The evolution of collective states and operators of a harmonic oscillator (resp. spin system) under the influence of a Hamiltonian is conveniently calculated by expanding them on a Fock (resp. Dicke) basis and evaluating propagators via unitary transformations, as in Eq. (41.53). On the other hand, quantum correlations become more visible on a Glauber (resp. coherent spin state) basis.

Now, the close analogy between harmonic oscillators and spin systems allows us to apply concepts elaborated for the harmonic oscillator to collective spin states. One example is the notion of quasi-probability distributions introduced in Sec. 35.2 for Glauber states, which we will apply to collective spin states below. In quantum optics a frequently used distribution function is the Wigner function $W_\rho(\alpha,\alpha^*)$ characterizing a light mode via an expansion into a coherent states basis $|\alpha\rangle$ spanning the complex quadrature plane. The purpose of this section is to derive an analogous function for collective spin states $W_\rho(\vartheta,\varphi)$.

We proceed by expanding an arbitrary state of a light mode on the Fock basis (24.115), which is similar to expanding coherent spin states on the Dicke basis (41.30),

$$|\psi\rangle = \sum_{n=0}^{\infty} c_n |n\rangle \qquad \text{versus} \qquad |\Psi_N\rangle = \sum_{M=+S,..,-S} c_{S,M}|S,M\rangle \tag{41.63}$$

with

$$c_n(t) = \langle n|e^{-\imath\hat{H}t}\psi(0)\rangle \qquad \text{versus} \qquad c_{S,M}(t) = \langle n|e^{-\imath\hat{H}t}\Psi_N(0)\rangle\ . \tag{41.64}$$

In particular for coherent states (resp. spin states),

$$|\alpha\rangle = \sum_{n=0}^{\infty} \frac{e^{-|\alpha|^2/2}\alpha^n}{\sqrt{n!}}|n\rangle \tag{41.65}$$

$$\text{versus} \qquad |\vartheta,\varphi\rangle^N = \sum_{M=+S,..,-S}\sqrt{\binom{N}{S+M}}\cos^{S-M}\tfrac{\vartheta}{2}e^{\imath(S+M)\varphi}\sin^{S+M}\tfrac{\vartheta}{2}|S,M\rangle\ .$$

[7] The Jaynes-Cummings model describes coupling of an atom to a harmonic oscillator mode [426]. In contrast (see 4.4).

We note that both Fock and Dicke states have no phase in phase space. Phases are generated by summing Fock (resp. Dicke) states with different dynamical phase factors corresponding to their energies.

For numerical simulations we also expand operators on the Fock (resp. Dicke) basis,

$$\begin{aligned} \hat{a} &= \sum_{n,n'=0}^{\infty} \delta_{n',n-1}\sqrt{n}|n'\rangle\langle n| \quad , \quad \hat{a}^\dagger = \sum_{n,n'=0}^{\infty} \delta_{n',n+1}\sqrt{n+1}|n'\rangle\langle n| \\ \text{versus} \quad \hat{S}_\pm &= \sum_{M,M'=+S,..,-S} \delta_{M',M\pm1}\sqrt{S(S+1)-M(M\pm1)}|S,M'\rangle\langle S,M| \\ \hat{S}_z &= \sum_{M,M'=+S,..,-S} \delta_{M',M} M|S,M'\rangle\langle S,M| \ . \end{aligned} \tag{41.66}$$

In the case of light modes, any point in phase space is reached via a displacement operator (see Eq. (24.111)). Similarly, any point on the Bloch sphere is reached via rotations about two axes [732, 328],

$$\begin{aligned} |\alpha\rangle &= D(\alpha)|0\rangle \qquad \text{versus} \quad |\vartheta,\varphi\rangle^N &= U_{rt}(\vartheta,\varphi)|S,-S\rangle \\ &= e^{\alpha\hat{a}^\dagger-\alpha^*\hat{a}}|0\rangle &= e^{\imath\varphi\hat{S}_z}e^{\imath\vartheta\hat{S}_y}|0,0\rangle^N \ . \end{aligned} \tag{41.67}$$

The Fock (resp. Dicke) basis may not the best one to reveal the existence of quantum correlations. The purpose of quasi-probability distributions defined on a basis of Glauber (resp. coherent spin) states is to provide a better characterization, in particular, on non-Gaussian collective states.

Example 252 (*Distributions for Gaussian spin states (coherent and squeezed)*): Let us now define proper quasi-probability distributions in analogy to those introduced for Glauber space in Sec. 35.2 [8]. In analogy to the example 207 we may, based on the rotation operator $R(\vartheta,\varphi)|S,S\rangle = e^{\imath\vartheta(\hat{S}_x\sin\varphi-\hat{S}_y\cos\varphi)}|S,S\rangle|\vartheta,\varphi\rangle^N$ introduced in (41.38) and the parity operator for rotations given by [732],

$$M_s = \frac{1}{R}\sum_{\ell=0}^{2S}\sqrt{\frac{2\ell+1}{4\pi}}(\gamma_\ell)^{-s}\mathbf{T}_{\ell 0} \qquad \text{with} \qquad \gamma_\ell = \frac{R\sqrt{4\pi}(2S)!}{\sqrt{(2S+\ell+1)!}\sqrt{(2S-\ell)!}} \tag{41.68}$$

$$\text{and} \qquad \mathbf{T}_{\ell m} = \sqrt{\frac{2\ell+1}{2S+1}}\sum_{M,M'=-S}^{S}\begin{pmatrix} S & \ell & S \\ M' & m & M \end{pmatrix}|S,M'\rangle\langle S,M|$$

with $R=\sqrt{S/2\pi}$ define a generalized probability distribution,

$$X_\rho(\vartheta,\varphi,s) = \text{Tr}\ \hat{\rho}U_{rt}(\vartheta,\varphi)M_sU_{rt}^\dagger(\vartheta,\varphi) \longrightarrow \langle\Psi_N|U_{rt}(\vartheta,\varphi)M_sU_{rt}^\dagger(\vartheta,\varphi)|\Psi_N\rangle \ , \tag{41.69}$$

where the second expression holds for pure states. The displacement operator from (35.56) is here replaced by a rotation parametrized by two Euler angles. From (41.69) the usual probability distributions follow as,

$$Q_\rho(\vartheta,\varphi) \equiv X_\rho(\vartheta,\varphi,-1) \quad , \quad W_\rho(\vartheta,\varphi) \equiv X_\rho(\vartheta,\varphi,0) \quad , \quad P_\rho(\vartheta,\varphi) \equiv X_\rho(\vartheta,\varphi,1) \tag{41.70}$$

[8] Compare (35.65) to (24.142).

The parity operator is expanded on the Dicke basis according to the recipe (41.68). To visualize a distribution function, we evaluate (41.69) for every point (ϑ, φ) of the Bloch sphere.
With increasing spin number S, the parity operators M_s converge to the infinite-dimensional operators Π_s of (35.57), while rotations transform into translations along the tangent of a sphere. For pure states the Wigner function is thus given by a rotation of the parity operator.

41.1.5.4 Expansion of non-Gaussian spin states

As long as a collective spin state can be expanded on a collective Dicke basis of superradiant states or reached by coherent evolution from such a state, it remains pure and can be represented by a probability distribution using the procedure outlined in the example 252. The states $|S,S\rangle$, $|S,M\rangle$, the $|\mathrm{W}\rangle$-state, and $|\vartheta,\varphi\rangle^N$ are illustrated in Fig. 41.6. Other non-Gaussian spin states can be reached, and are also shown, e.g. the $|\mathrm{N00N}\rangle$-state, the Greenberger-Horne-Zeilinger state $|\mathrm{GHZ}\rangle$, or the generalized spin cat state $|\mathrm{cat}\rangle$,

$$
\begin{aligned}
|\mathrm{W}\rangle &= |S,S-1\rangle \qquad (41.71)\\
|\mathrm{GHZ}\rangle &= \tfrac{1}{\sqrt{2}}(|\uparrow\rangle^{2S}|\downarrow\rangle^0 + |\uparrow\rangle^0|\downarrow\rangle^{2S}) = \tfrac{1}{\sqrt{2}}(|S,S\rangle + |S,-S\rangle)\\
|\mathrm{N00N}\rangle &= \tfrac{1}{\sqrt{2}}(|\uparrow\rangle^{2S}|\downarrow\rangle^0 + e^{\imath N\vartheta}|\uparrow\rangle^0|\downarrow\rangle^{2S}) = \tfrac{1}{\sqrt{2}}(|S,S\rangle + e^{\imath 2S\vartheta}|S,-S\rangle)\\
|\mathrm{cat}\rangle &= \cos\tfrac{\vartheta}{2}|S,S\rangle + e^{\imath\varphi}\sin\tfrac{\vartheta}{2}|S,-S\rangle\\
|\mathrm{squeezed}\rangle &= e^{-\imath\zeta\hat{S}_y^2/2}|S,S\rangle\ .
\end{aligned}
$$

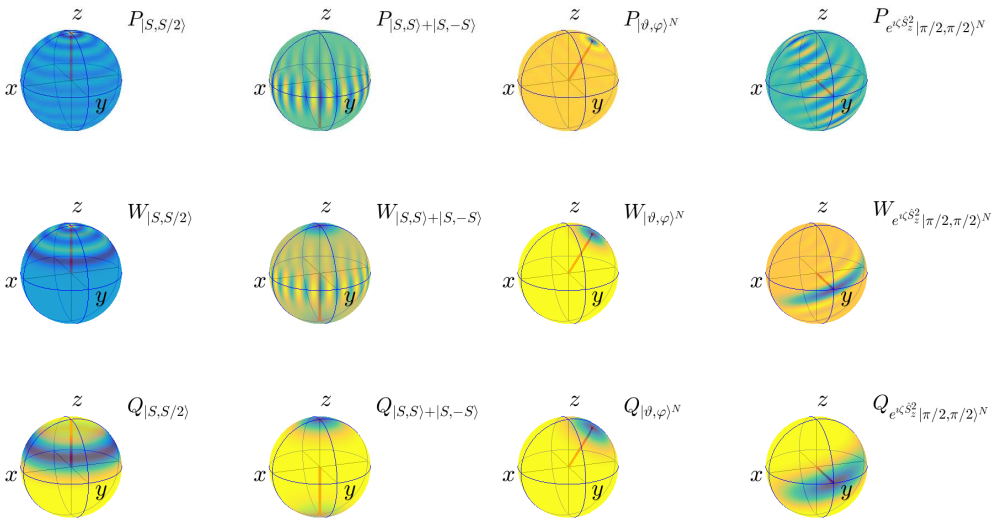

Figure 41.6: (code) P, W, and Q-distributions on the Bloch sphere for various states.

41.1.5.5 Continuous variable quantum information

Continuous variable quantum information is the area of quantum information science that makes use of physical observables with continuous spectra, like the strength of an electromagnetic field. Continuous-variable quantum computation is performed on infinite-dimensional Hilbert spaces and may be called "analog", while qubit quantum computation is performed on finite-dimensional Hilbert spaces (2^N with N the number of qubits) and may be called "digital".

Bosonic modes are examples of systems being studied for the implementation of continuous-variable quantum information. By modeling each mode of the electromagnetic field as a quantum harmonic oscillator with its associated field operators, one defines a canonically conjugate pair of variables for each mode, the so-called *quadratures*, which span a phase space on which Wigner quasi-probability distributions can be defined. Quantum measurements on such a system can be performed using homodyne and heterodyne detectors. Interestingly, qubits can be encoded into a continuous variable [530]. The procedure is easily understood at the example of a two-level atom dispersively interacting with a cavity mode studied within the Jaynes-Cummings model in Sec. 35.4.2 and illustrated in Fig. ?? and in the Exc. 35.4.5.6. See also Sec. 41.5.1.

In all approaches to quantum computing, it is important to know whether a task under consideration can be carried out efficiently by a classical computer. An algorithm might be described in the language of quantum mechanics, but upon closer analysis, reveals to be implementable using only classical resources [529], even if making use of quantum entanglement. When the Wigner quasi-probability representations of all the quantities (states, time evolutions and measurements) involved in a computation are non-negative, then they can be interpreted as ordinary probability distributions, indicating that the computation can be modeled as an essentially classical one [876].

41.1.6 Exercises

41.1.6.1 Ex: Dicke states and Clebsch-Gordan coefficients

Discuss the relationship between coherent Dicke states and Clebsch-Gordan coefficients at the example of two coupled spins.

Solution: *Note, that only fully stretched Dicke states are considered. For $N = 2 = 2S$, we have in the coupled basis,*

$$\begin{aligned}|\vartheta,\varphi\rangle^2 &= (\cos\tfrac{\vartheta}{2}|+\rangle + e^{\imath\varphi}\sin\tfrac{\vartheta}{2}|-\rangle)^2 \\ &= \cos^2\tfrac{\vartheta}{2}|+\rangle|+\rangle + e^{2\imath\varphi}\sin^2\tfrac{\vartheta}{2}|-\rangle|-\rangle + e^{\imath\varphi}\cos\tfrac{\vartheta}{2}\sin\tfrac{\vartheta}{2}(|+\rangle|-\rangle + |-\rangle|+\rangle)\ ,\end{aligned}$$

and in the uncoupled basis,

$$\begin{aligned}|\vartheta,\varphi\rangle^2 &= \sum_{k=0}^{N}\sqrt{\binom{2}{k}}\cos^{N-k}\tfrac{\vartheta}{2}e^{\imath k\varphi}\sin^k\tfrac{\vartheta}{2}|S,S-k\rangle \\ &= \cos^2\tfrac{\vartheta}{2}|1,1\rangle + \sqrt{2}e^{\imath\varphi}\cos\tfrac{\vartheta}{2}\sin\tfrac{\vartheta}{2}|1,0\rangle + e^{2\imath\varphi}\sin^2\tfrac{\vartheta}{2}|1,-1\rangle\ .\end{aligned}$$

Comparing both basis for $\varphi = 0$,

$$\begin{aligned}
&\cos^2\tfrac{\vartheta}{2}|+\rangle|+\rangle + \sin^2\tfrac{\vartheta}{2}|-\rangle|-\rangle + \cos\tfrac{\vartheta}{2}\sin\tfrac{\vartheta}{2}(|+\rangle|-\rangle + |-\rangle|+\rangle) \\
&= |\vartheta, 0\rangle^2 \\
&= \cos^2\tfrac{\vartheta}{2}|1,1\rangle + \sqrt{2}\cos\tfrac{\vartheta}{2}\sin\tfrac{\vartheta}{2}|1,0\rangle + \sin^2\tfrac{\vartheta}{2}|1,-1\rangle \ ,
\end{aligned}$$

and for $\vartheta = 0, \frac{\pi}{2}, \pi$,

$$\begin{aligned}
|+\rangle|+\rangle &= |0,0\rangle^2 = |1,1\rangle \\
\tfrac{1}{2}|+\rangle|+\rangle + \tfrac{1}{2}|-\rangle|-\rangle + \tfrac{1}{2}(|+\rangle|-\rangle + |-\rangle|+\rangle) &= |\tfrac{\pi}{2}, 0\rangle^2 = \tfrac{1}{2}|1,1\rangle + \tfrac{1}{\sqrt{2}}|1,0\rangle + \tfrac{1}{2}|1,-1\rangle \\
|-\rangle|-\rangle &= |\pi, 0\rangle^2 = |1,-1\rangle \ ,
\end{aligned}$$

from which we deduce,

$$\begin{pmatrix} |+,+\rangle \\ \frac{1}{\sqrt{2}}(|-,+\rangle + |+,-\rangle) \\ |-,-\rangle \end{pmatrix} = \begin{pmatrix} |1,1\rangle \\ |1,0\rangle \\ |1,-1\rangle \end{pmatrix} \ .$$

The same relationship is obtained by eliminating the singlet state from the unitary Clebsch-Gordan transformation between basis vectors from a coupled and an uncoupled basis,

$$\begin{pmatrix} |+,+\rangle \\ |-,+\rangle \\ |+,-\rangle \\ |-,-\rangle \end{pmatrix} = U_{CGC} \begin{pmatrix} |1,1\rangle \\ |1,0\rangle \\ |0,0\rangle \\ |1,-1\rangle \end{pmatrix} \quad \textit{with} \quad U_{CGC} = (U_{CGC}^\dagger)^{-1} = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & \frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}} & 0 \\ 0 & \frac{1}{\sqrt{2}} & -\frac{1}{\sqrt{2}} & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix} .$$

41.1.6.2 Ex: Dicke Hamiltonian for 3 atoms

Generalize the Dicke Hamiltonian (41.23) to 3 atoms.

Solution:

41.1.6.3 Ex: Coherent spin states

Show that the coherent spin state is an eigenstate of the operator $\hat{S}_{\vartheta,\varphi} \equiv \hat{S}_x \sin\vartheta\cos\varphi + \hat{S}_y \sin\vartheta\sin\varphi + \hat{S}_z\cos\vartheta$.

Solution: *Using,*

$$\langle\vartheta,\varphi|^N \hat{\mathbf{S}} |\vartheta,\varphi\rangle^N = \tfrac{N}{2}\begin{pmatrix} \sin\vartheta\cos\varphi \\ \sin\vartheta\sin\varphi \\ \cos\vartheta \end{pmatrix} \ ,$$

we immediately see,

$$\begin{aligned}\langle\vartheta,\varphi|^N \hat{S}_{\vartheta,\varphi}|\vartheta,\varphi\rangle^N &= \langle\vartheta,\varphi|^N \left(\hat{S}_x \sin\vartheta\cos\varphi + \hat{S}_y \sin\vartheta\sin\varphi + \hat{S}_z\cos\vartheta\right)|\vartheta,\varphi\rangle^N \\ &= \tfrac{N}{2}\langle\vartheta,\varphi|^N|\vartheta,\varphi\rangle^N = \tfrac{N}{2}\ .\end{aligned}$$

41.1.6.4 Ex: Collective spin of a coherent spin state

a. Calculate the expectation values for all spin components of the collective spin $\hat{\mathbf{S}}$ in a coherent spin state see also Exc. 25.3.4.8.
b. Calculate the uncertainties for all spin components of the collective spin $\hat{\mathbf{S}}$ in a coherent spin state and check the uncertainty relation.

Solution: *a. Let us first remember,*

$$\begin{aligned}&\hat{S}_x = \tfrac{1}{2}(\hat{S}_+ + \hat{S}_-) \quad , \quad \hat{S}_y = \tfrac{1}{2\imath}(\hat{S}_+ - \hat{S}_-) \quad , \quad \hat{S}_z = \tfrac{1}{2}[\hat{S}_+, \hat{S}_-] \\ &\hat{S}_x^2 = \tfrac{1}{4}(\hat{S}_+^2 + \hat{S}_-^2 + \hat{S}_+\hat{S}_- + \hat{S}_-\hat{S}_+) \quad , \quad \hat{S}_y^2 = -\tfrac{1}{4}(\hat{S}_+^2 + \hat{S}_-^2 - \hat{S}_+\hat{S}_- - \hat{S}_-\hat{S}_+)\ .\end{aligned}$$

For the sake of notational compactness we introduce the abbreviations,

$$p_+ \equiv \cos^2\tfrac{\vartheta}{2} \quad \textit{and} \quad p_- \equiv \sin^2\tfrac{\vartheta}{2} \quad \textit{so that} \quad \sqrt{p_+p_-} = \tfrac{1}{2}\sin\vartheta\ .$$

With the expression (41.31) for a coherent spin state we calculate, with a little help from MAPLE,

$$\begin{aligned}\langle\vartheta,\varphi|^N \hat{S}_+|\vartheta,\varphi\rangle^N &= \sum_{k,l=0}^{2S}\sqrt{\binom{2S}{l}\binom{2S}{k}}p_+^{2S-l/2-k/2}e^{-\imath(l-k)\varphi}p_-^{l/2+k/2}\langle S, S-l|\hat{S}_+|S, S-k\rangle \\ &= e^{\imath\varphi}\sum_{k=0}^{2S}\binom{2S}{k}k\cos^{4S-2k+1}\tfrac{\vartheta}{2}\sin^{2k-1}\tfrac{\vartheta}{2} = N\sqrt{p_+p_-} = Se^{\imath\varphi}\sin\vartheta\ ,\end{aligned}$$

and analogously,

$$\langle\vartheta,\varphi|^N \hat{S}_z|\vartheta,\varphi\rangle^N = \sum_{k=0}^{N}\binom{N}{k}(S-k)p_+^{2S-k}p_-^k = \tfrac{N}{2} - Np_- = S\cos\vartheta\ .$$

Hence, as expected, the total spin is just the sum of the individual spins calculated in 25.3.4.8,

$$\langle\Psi_N|\hat{\mathbf{S}}|\Psi_N\rangle = \langle\vartheta,\varphi|^N\hat{\mathbf{S}}|\vartheta,\varphi\rangle^N = S\begin{pmatrix}\cos\varphi\sin\vartheta\\ \sin\varphi\sin\vartheta\\ \cos\vartheta\end{pmatrix}\ .$$

b. Now, we calculate the higher orders,

$$\begin{aligned}\langle\vartheta,\varphi|^N\hat{S}_+^2|\vartheta,\varphi\rangle^N &= \overline{\langle\vartheta,\varphi|^N\hat{S}_-^2|\vartheta,\varphi\rangle^N}\\ &= \sum_{k,l=0}^{N}\sqrt{\binom{N}{l}\binom{N}{k}}p_+^{N-k/2-l/2}e^{\imath(k-l)\varphi}p_-^{k/2+l/2}\langle S,S-l|\hat{S}_+^2|S,S-k\rangle\\ &= \sum_{k,l=0}^{N}\sqrt{\binom{N}{l}\binom{N}{k}}\sqrt{k(2S-k+1)(k-1)(2S-k+2)}p_+^{N-k/2-l/2}e^{\imath(k-l)\varphi}p_-^{k/2+l/2}\delta_{l,k-2}\\ &= e^{2\imath\varphi}\sum_{k=0}^{N}\frac{N!p_+^{N-k+1}p_-^{k-1}}{(k-2)!(N-k)!} = e^{2\imath\varphi}(N-1)Np_+p_- \ ,\end{aligned}$$

and

$$\begin{aligned}\langle\vartheta,\varphi|^N\hat{S}_+\hat{S}_-|\vartheta,\varphi\rangle^N &= \sum_{k,l=0}^{N}\sqrt{\binom{N}{l}\binom{N}{k}}p_+^{N-k/2-l/2}e^{\imath(k-l)\varphi}p_-^{k/2+l/2}\langle S,S-l|\hat{S}_+\hat{S}_-|S,S-k\rangle\\ &= \sum_{k,l=0}^{N}\sqrt{\binom{N}{l}\binom{N}{k}}(2S+2Sk-k^2-k)p_+^{N-k/2-l/2}e^{\imath(k-l)\varphi}p_-^{k/2+l/2}\delta_{l,k}\\ &= \sum_{k=0}^{N}\binom{N}{k}(N+Nk-k^2-k)p_+^{N-k}p_-^k = Np_+^2+N^2p_+p_- \ ,\end{aligned}$$

and

$$\begin{aligned}\langle\vartheta,\varphi|^N\hat{S}_-\hat{S}_+|\vartheta,\varphi\rangle^N &= \sum_{k,l=0}^{N}\sqrt{\binom{N}{l}\binom{N}{k}}p_+^{N-k/2-l/2}e^{\imath(k-l)\varphi}p_-^{k/2+l/2}\langle S,S-l|\hat{S}_-\hat{S}_+|S,S-k\rangle\\ &= \sum_{k,l=0}^{N}\sqrt{\binom{N}{l}\binom{N}{k}}(2Sk-k^2+k)p_+^{N-k/2-l/2}e^{\imath(k-l)\varphi}p_-^{k/2+l/2}\delta_{l,k}\\ &= \sum_{k=0}^{N}\binom{N}{k}(Nk-k^2+k)p_+^{N-k}p_-^k = Np_-^2+N^2p_+p_- \ .\end{aligned}$$

From this we cross-check,

$$\langle\vartheta,\varphi|^N\hat{S}_z|\vartheta,\varphi\rangle^N = \tfrac{1}{2}\langle\vartheta,\varphi|^N\hat{S}_+\hat{S}_- - \hat{S}_-\hat{S}_+|\vartheta,\varphi\rangle^N = \tfrac{N}{2}(p_+^2-Np_-^2) = \tfrac{N}{2}\cos\vartheta \ .$$

Also,

$$\begin{aligned}\langle\vartheta,\varphi|^N\hat{S}_z^2|\vartheta,\varphi\rangle^N &= \sum_{k,l=0}^{N}\sqrt{\binom{N}{l}\binom{N}{k}}p_+^{N-k/2-l/2}e^{\imath(k-l)\varphi}p_-^{k/2+l/2}\langle S,S-l|\hat{S}_z^2|S,S-k\rangle\\ &= \sum_{k,l=0}^{N}\sqrt{\binom{N}{l}\binom{N}{k}}(\tfrac{N}{2}-k)^2p_+^{N-k/2-l/2}e^{\imath(k-l)\varphi}p_-^{k/2+l/2}\langle S,S-l|S,S-k\rangle\\ &= \sum_{k=0}^{N}\binom{N}{k}(\tfrac{N}{2}-k)^2p_+^{N-k}p_-^k = \tfrac{N^2}{4}+N(1-N)p_+p_- \ ,\end{aligned}$$

and

$$\begin{aligned}\langle\vartheta,\varphi|^N\hat{S}_x^2|\vartheta,\varphi\rangle^N &= \langle\vartheta,\varphi|^N\tfrac{1}{4}\left[\hat{S}_+\hat{S}_- + \hat{S}_-\hat{S}_+ + \hat{S}_+^2 + (\hat{S}_+^2)^\dagger\right]|\vartheta,\varphi\rangle^N \\ &= \tfrac{1}{4}[Np_+^2 + Np_-^2 + 2N^2p_+p_- + 2N(N-1)p_+p_-\cos 2\varphi] \\ &= \tfrac{1}{4}[N + N(N-1)\sin^2\vartheta\cos^2\varphi]\ ,\end{aligned}$$

and

$$\begin{aligned}\langle\vartheta,\varphi|^N\hat{S}_y^2|\vartheta,\varphi\rangle^N &= \langle\vartheta,\varphi|^N\tfrac{1}{4}\left[\hat{S}_+\hat{S}_- + \hat{S}_-\hat{S}_+ - \hat{S}_+^2 - (\hat{S}_+^2)^\dagger\right]|\vartheta,\varphi\rangle^N \\ &= \tfrac{1}{4}[Np_+^2 + Np_-^2 + 2N^2p_+p_- - 2N(N-1)p_+p_-\cos 2\varphi] \\ &= \tfrac{1}{4}[N + N(N-1)\sin^2\vartheta\sin^2\varphi]\ .\end{aligned}$$

In summary,

$$\begin{aligned}\langle\vartheta,\varphi|^N\hat{S}_x^2|\vartheta,\varphi\rangle^N &= \tfrac{1}{4}[N + N(N-1)\sin^2\vartheta\cos^2\varphi] \\ \langle\vartheta,\varphi|^N\hat{S}_y^2|\vartheta,\varphi\rangle^N &= \tfrac{1}{4}[N + N(N-1)\sin^2\vartheta\sin^2\varphi] \\ \langle\vartheta,\varphi|^N\hat{S}_z^2|\vartheta,\varphi\rangle^N &= \tfrac{1}{4}[N^2 - N(N-1)\sin^2\vartheta]\ ,\end{aligned}$$

confirming,

$$\langle\vartheta,\varphi|^N\hat{S}_x^2 + \hat{S}_y^2 + \hat{S}_z^2|\vartheta,\varphi\rangle^N = \tfrac{N(N+1)}{4} = S(S+1)\ .$$

Also,

$$\begin{aligned}\langle\vartheta,\varphi|^N\Delta\hat{S}_x^2|\vartheta,\varphi\rangle^N &= \tfrac{1}{4}[N + N(N-1)\sin^2\vartheta\cos^2\varphi] - \tfrac{N^2}{4}\sin^2\vartheta\cos^2\varphi = \tfrac{N}{4}[1 - \sin^2\vartheta\cos^2\varphi] \\ \langle\vartheta,\varphi|^N\Delta\hat{S}_y^2|\vartheta,\varphi\rangle^N &= \tfrac{1}{4}[N + N(N-1)\sin^2\vartheta\sin^2\varphi] - \tfrac{N^2}{4}\sin^2\vartheta\sin^2\varphi = \tfrac{N}{4}[1 - \sin^2\vartheta\sin^2\varphi] \\ \langle\vartheta,\varphi|^N\Delta\hat{S}_z^2|\vartheta,\varphi\rangle^N &= \tfrac{1}{4}[N^2 - N(N-1)\sin^2\vartheta] - \tfrac{N^2}{4}\cos^2\varphi = \tfrac{N}{4}\sin^2\vartheta = N\sin^2\tfrac{\vartheta}{2}\cos^2\tfrac{\vartheta}{2}\ .\end{aligned}$$

Interestingly, we find, $\Delta\hat{S}_x^2 + \Delta\hat{S}_y^2 + \Delta\hat{S}_z^2 = \frac{N}{2}$. *Finally,*

$$\begin{aligned}\langle\vartheta,\varphi|^N\Delta\hat{S}_x^2|\vartheta,\varphi\rangle^N\langle\vartheta,\varphi|^N\Delta\hat{S}_y^2|\vartheta,\varphi\rangle^N &= \tfrac{N^2}{16}\left(1 - \sin^2\vartheta\cos^2\varphi\right)\left(1 - \sin^2\vartheta\sin^2\varphi\right) \\ &= \tfrac{N^2}{16}\left(\cos^2\vartheta + \sin^4\vartheta\cos^2\varphi\sin^2\varphi\right)\ ,\end{aligned}$$

which is obviously larger than $(\langle\vartheta,\varphi|^N\frac{1}{2}\hat{S}_z|\vartheta,\varphi\rangle^N)^2$.

41.1.6.5 Ex: Unitary spin transformations

Prove the relationship $e^{\imath F(\hat{S}_z)}\hat{S}_+e^{-\imath F(\hat{S}_z)} = \hat{S}_+e^{\imath[F(\hat{S}_z+\mathbb{I})-F(\hat{S}_z)]}$.

Solution: *First we remember* ($\hbar = 1$),

$$\begin{aligned}[\hat{S}_z,\hat{S}_+] = [\hat{S}_z,\hat{S}_x + \imath\hat{S}_y] &= \hat{S}_x + \imath\hat{S}_y = \hat{S}_+ \\ [\hat{S}_z,[\hat{S}_z,\hat{S}_+]] &= \hat{S}_+\ .\end{aligned}$$

keeping in mind, that $[\hat{S}_+,[\hat{S}_z,\hat{S}_+]]=0\neq[\hat{S}_z,[\hat{S}_z,\hat{S}_+]]$. *First choosing* $F(\hat{S}_z)\equiv t\hat{S}_z$, *we apply the transformation* $U=e^{-\imath t\hat{S}_z}$ *to the rising ladder operator,*

$$\begin{aligned}U^\dagger\hat{S}_+U&=e^{\imath t\hat{S}_z}\hat{S}_+e^{-\imath t\hat{S}_z}=\hat{S}_++(\imath t)[\hat{S}_z,\hat{S}_+]+\tfrac{(\imath t)^2}{2!}[\hat{S}_z,[\hat{S}_z,\hat{S}_+]]+...\\&=\hat{S}_++(\imath t)\hat{S}_++\tfrac{(\imath t)^2}{2!}\hat{S}_++...\\&=\hat{S}_+\sum_{k=0}^{\infty}\tfrac{(\imath t)^k}{k!}\mathbb{I}^k=\hat{S}_+e^{\imath t\mathbb{I}}=\hat{S}_+e^{\imath t[\hat{S}_z+\mathbb{I}-\hat{S}_z]}\ .\end{aligned}$$

Second, we can show that,

$$\begin{aligned}[\hat{S}_z^2,\hat{S}_+]&=\hat{S}_z\hat{S}_++\hat{S}_+\hat{S}_z=\hat{S}_+(\mathbb{I}+2\hat{S}_z)\\[\hat{S}_z^2,[\hat{S}_z^2,\hat{S}_+]]&=[\hat{S}_z^2,\hat{S}_+](\mathbb{I}+2\hat{S}_z)\ .\end{aligned}$$

Now, choosing $F(\hat{S}_z)\equiv t\hat{S}_z^2$, *we apply the transformation* $U=e^{-\imath t\hat{S}_z^2}$ *to the rising ladder operator,*

$$\begin{aligned}U^\dagger\hat{S}_+U&=e^{\imath t\hat{S}_z^2}\hat{S}_+e^{-\imath t\hat{S}_z^2}=\hat{S}_++(\imath t)[\hat{S}_z^2,\hat{S}_+]+\tfrac{(\imath t)^2}{2!}[\hat{S}_z^2,[\hat{S}_z^2,\hat{S}_+]]+...\\&=\hat{S}_++\imath t\hat{S}_+(\mathbb{I}+2\hat{S}_z)+\tfrac{(\imath t)^2}{2!}\hat{S}_+(\mathbb{I}+2\hat{S}_z)(\mathbb{I}+2\hat{S}_z)+...\\&=\hat{S}_+\sum_{k=0}^{\infty}\tfrac{(\imath t)^k}{k!}(\mathbb{I}+2\hat{S}_z)^k=\hat{S}_+e^{\imath t(\mathbb{I}+2\hat{S}_z)}=\hat{S}_+e^{\imath t[(\hat{S}_z+\mathbb{I})^2-\hat{S}_z^2]}\ .\end{aligned}$$

Third, we can show,

$$\begin{aligned}[\hat{S}_z^n,\hat{S}_+]&=\hat{S}_+\hat{S}_z^{n-1}+\hat{S}_z[\hat{S}_z^{n-1},\hat{S}_+]=\sum_{k=1}^{n}\hat{S}_z^{k-1}\hat{S}_+\hat{S}_z^{n-k}\\[\hat{S}_z^n,[\hat{S}_z^n,\hat{S}_+]]&=...\ .\end{aligned}$$

Now, choosing $F(\hat{S}_z)\equiv t\hat{S}_z^n$, *we apply the transformation* $U=e^{-\imath t\hat{S}_z^n}$ *to the rising ladder operator,*

$$\begin{aligned}U^\dagger\hat{S}_+U&=e^{\imath t\hat{S}_z^n}\hat{S}_+(0)e^{-\imath t\hat{S}_z^n}=\hat{S}_++\imath t[\hat{S}_z^n,\hat{S}_+]+\tfrac{(\imath t)^2}{2!}[\hat{S}_z^n,[\hat{S}_z^n,\hat{S}_+]]+...\\&=...\ .\end{aligned}$$

41.1.6.6 Ex: Rotation about the x-axis

How does the collective spin transform under rotation about the x-axis?

Solution: *First we remember,*

$$\begin{aligned}&[\hat{S}_x,\hat{S}_+]=-\hat{S}_z\quad,\quad[\hat{S}_x,[\hat{S}_x,\hat{S}_+]]=\imath\hat{S}_y\quad,\quad[\hat{S}_x,[\hat{S}_x,[\hat{S}_x,\hat{S}_+]]]=-\hat{S}_z\\&[\hat{S}_x,\hat{S}_y]=\imath\hat{S}_z\quad,\quad[\hat{S}_x,[\hat{S}_x,\hat{S}_y]]=\hat{S}_y\quad,\quad[\hat{S}_x,[\hat{S}_x,[\hat{S}_x,\hat{S}_y]]]=\imath\hat{S}_z\\&[\hat{S}_x,\hat{S}_z]=-\imath\hat{S}_y\quad,\quad[\hat{S}_x,[\hat{S}_x,\hat{S}_z]]=\hat{S}_z\quad,\quad[\hat{S}_x,[\hat{S}_x,[\hat{S}_x,\hat{S}_z]]]=-\imath\hat{S}_y\ .\end{aligned}$$

With this,

$$R_x(\theta)\hat{S}_\alpha \equiv e^{\imath\theta\hat{S}_x}\hat{S}_\alpha e^{-\imath\theta\hat{S}_x} = \hat{S}_+ + (\imath\theta)[\hat{S}_x,\hat{S}_\alpha] + \frac{(\imath\theta)^2}{2!}[\hat{S}_x,[\hat{S}_x,\hat{S}_\alpha]] + ...$$

$$R_x(\theta)\hat{S}_+ \equiv \hat{S}_+ - (\imath\theta)\hat{S}_z + \frac{(\imath\theta)^2}{2!}\imath\hat{S}_y + ... = \hat{S}_x + \imath\hat{S}_y\cos\theta - \imath\hat{S}_z\sin\theta$$

$$e^{\imath\theta\hat{S}_x}\hat{\mathbf{S}}e^{-\imath\theta\hat{S}_x} = \begin{pmatrix} \hat{S}_x \\ \hat{S}_y\cos\theta - \hat{S}_z\sin\theta \\ \hat{S}_y\sin\theta + \hat{S}_z\cos\theta \end{pmatrix} = \begin{pmatrix} 1 & 0 & 0 \\ 0 & \cos\theta & -\sin\theta \\ 0 & \sin\theta & \cos\theta \end{pmatrix}\hat{\mathbf{S}} \equiv R_x(\theta)\hat{\mathbf{S}}\ .$$

41.1.6.7 Ex: Spin operators for two atoms

Calculate explicitly for the case of two atoms the rotation matrices $e^{\imath\gamma\hat{S}_\alpha}$ for $\alpha = x, y, z$. Check the relationship $e^{\imath\gamma\hat{S}_\alpha}\hat{\mathbf{S}}e^{-\imath\gamma\hat{S}_\alpha} = R_\alpha(\gamma)\hat{\mathbf{S}}$ by explicit calculation.

Solution: *In the case of two atoms we have $S = 1$. The spin ladder operators are explicitly,*

$$\hat{S}_+ = \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{pmatrix} \quad , \quad \hat{S}_- = \begin{pmatrix} 0 & 0 & 0 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{pmatrix} \ ,$$

so that the spin matrices become,

$$\hat{S}_x = \tfrac{1}{2}\begin{pmatrix} 0 & 1 & 0 \\ 1 & 0 & 1 \\ 0 & 1 & 0 \end{pmatrix} \quad , \quad \hat{S}_y = \tfrac{1}{2}\begin{pmatrix} 0 & -\imath & 0 \\ \imath & 0 & -\imath \\ 0 & \imath & 0 \end{pmatrix} \quad , \quad \hat{S}_z = \tfrac{1}{2}\begin{pmatrix} 1 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & -1 \end{pmatrix} \ ,$$

and their squares,

$$\hat{S}_x^2 = \tfrac{1}{4}\begin{pmatrix} 1 & 0 & 1 \\ 0 & 2 & 0 \\ 1 & 0 & 1 \end{pmatrix} \quad , \quad \hat{S}_y^2 = \tfrac{1}{4}\begin{pmatrix} 1 & 0 & -1 \\ 0 & 2 & 0 \\ -1 & 0 & 1 \end{pmatrix} \quad , \quad \hat{S}_z^2 = \tfrac{1}{4}\begin{pmatrix} 1 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix} \ .$$

The transformation matrix $e^{\imath\gamma\hat{S}_z}$ is easy to calculate,

$$e^{\imath\gamma\hat{S}_z} = \begin{pmatrix} e^{\imath\gamma/2} & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & e^{-\imath\gamma/2} \end{pmatrix} \ .$$

For the other transformations we need to diagonalize the spin operators. For $e^{\imath\gamma\hat{S}_x}$ the eigenvalue and eigenvector matrices are,

$$U_x = \begin{pmatrix} \frac{1}{2} & -\frac{1}{\sqrt{2}} & \frac{1}{2} \\ \frac{1}{\sqrt{2}} & 0 & -\frac{1}{\sqrt{2}} \\ \frac{1}{2} & \frac{1}{\sqrt{2}} & \frac{1}{2} \end{pmatrix} \quad , \quad \hat{E}_x = \begin{pmatrix} \frac{1}{\sqrt{2}} & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & -\frac{1}{\sqrt{2}} \end{pmatrix}$$

$$e^{\imath\gamma\hat{S}_x} = U_x e^{\imath\gamma\hat{E}_x} U_x^{-1} = \frac{1}{2}\begin{pmatrix} \cos\frac{\gamma}{\sqrt{2}}+1 & \imath\sqrt{2}\sin\frac{\gamma}{\sqrt{2}} & \cos\frac{\gamma}{\sqrt{2}}-1 \\ \imath\sqrt{2}\sin\frac{\gamma}{\sqrt{2}} & 2\cos\frac{\gamma}{\sqrt{2}} & \imath\sqrt{2}\sin\frac{\gamma}{\sqrt{2}} \\ \cos\frac{\gamma}{\sqrt{2}}-1 & \imath\sqrt{2}\sin\frac{\gamma}{\sqrt{2}} & \cos\frac{\gamma}{\sqrt{2}}+1 \end{pmatrix} .$$

and for $e^{\imath\gamma\hat{S}_y}$,

$$U_y = \begin{pmatrix} -\frac{1}{2} & \frac{1}{\sqrt{2}} & -\frac{1}{2} \\ -\frac{\imath}{\sqrt{2}} & 0 & \frac{\imath}{\sqrt{2}} \\ \frac{1}{2} & \frac{1}{\sqrt{2}} & \frac{1}{2} \end{pmatrix} \quad , \quad \hat{E}_y = \begin{pmatrix} \frac{1}{\sqrt{2}} & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & -\frac{1}{\sqrt{2}} \end{pmatrix}$$

$$e^{\imath\gamma\hat{S}_y} = U_y e^{\imath\gamma\hat{E}_y} U_y^{-1} = \frac{1}{2}\begin{pmatrix} \cos\frac{\gamma}{\sqrt{2}}+1 & \sqrt{2}\sin\frac{\gamma}{\sqrt{2}} & -\cos\frac{\gamma}{\sqrt{2}}+1 \\ -\sqrt{2}\sin\frac{\gamma}{\sqrt{2}} & 2\cos\frac{\gamma}{\sqrt{2}} & \sqrt{2}\sin\frac{\gamma}{\sqrt{2}} \\ -\cos\frac{\gamma}{\sqrt{2}}+1 & -\sqrt{2}\sin\frac{\gamma}{\sqrt{2}} & \cos\frac{\gamma}{\sqrt{2}}+1 \end{pmatrix} .$$

We check the relationship by showing that,

$$e^{\imath\gamma\hat{S}_z}\hat{S}_x e^{-\imath\gamma\hat{S}_z} = \frac{1}{2}\begin{pmatrix} 0 & e^{\imath\gamma/2} & 0 \\ e^{-\imath\gamma/2} & 0 & e^{\imath\gamma/2} \\ 0 & e^{-\imath\gamma/2} & 0 \end{pmatrix} = \hat{S}_x\cos\gamma - \hat{S}_y\sin\gamma = [R_z(\gamma)\hat{\mathbf{S}}]_x \ ,$$

and analogously for the other components.

41.1.6.8 Ex: Spin squeezing

a. Calculate $\langle\frac{\pi}{2},0|^N e^{\imath\zeta\hat{S}_z^2}\hat{\mathbf{S}}e^{-\imath\zeta\hat{S}_z^2}|\frac{\pi}{2},0\rangle^N$.
b. Calculate $\langle\frac{\pi}{2},0|^N e^{\imath\zeta\hat{S}_z^2}\Delta\hat{S}^2_{x,y,z}e^{-\imath\zeta\hat{S}_z^2}|\frac{\pi}{2},0\rangle^N$.

Solution: *a. We calculate,*

$$\begin{aligned}
&\langle\tfrac{\pi}{2},0|^N e^{\imath\zeta\hat{S}_z^2}\hat{S}_x e^{-\imath\zeta\hat{S}_z^2}|\tfrac{\pi}{2},0\rangle^N \\
&= \tfrac{1}{2^{2S}}\sum_{k,l=0}^{2S}\sqrt{\binom{2S}{l}\binom{2S}{k}}\langle S,S-l|\tfrac{1}{2}\left(\hat{S}_+ e^{2\imath\zeta(\hat{S}_z+1/2)} + e^{-2\imath\zeta(\hat{S}_z+1/2)}\hat{S}_-\right)|S,S-k\rangle \\
&= \tfrac{1}{2}\tfrac{1}{2^{2S}}\sum_{k,l=0}^{2S}\begin{pmatrix} \sqrt{\binom{2S}{l}\binom{2S}{k}}\sqrt{S(S+1)-(S-k)(S-k+1)}e^{2\imath\zeta(S-k+1/2)}\delta_{l,k-1} \\ +\sqrt{\binom{2S}{l}\binom{2S}{k}}e^{-2\imath\zeta(S-k-1+1/2)}\sqrt{S(S+1)-(S-k)(S-k-1)}\delta_{l,k+1}\end{pmatrix} \\
&= \tfrac{1}{2^{N+1}}\sum_{k=0}^{N}\left(\frac{N!e^{\imath\zeta(N-2k+1)}}{(k-1)!(N-k)!} + \frac{N!e^{-\imath\zeta(N-2k-1)}}{k!(N-k-1)!}\right) = \tfrac{N}{2}\cos^{N-1}\zeta \ .
\end{aligned}$$

Analogously,

$$\langle\tfrac{\pi}{2},0|^N e^{\imath\zeta\hat{S}_z^2}\hat{S}_y e^{-\imath\zeta\hat{S}_z^2}|\tfrac{\pi}{2},0\rangle^N = \tfrac{-\imath}{2^{N+1}}\sum_{k=0}^{N}\left(\frac{N!e^{\imath\zeta(N-2k+1)}}{(k-1)!(N-k)!}-\frac{N!e^{-\imath\zeta(N-2k-1)}}{k!(N-k-1)!}\right)=0\ ,$$

and,

$$\langle\tfrac{\pi}{2},0|^N e^{\imath\zeta\hat{S}_z^2}\hat{S}_z e^{-\imath\zeta\hat{S}_z^2}|\tfrac{\pi}{2},0\rangle^N = \langle\tfrac{\pi}{2},0|^N\hat{S}_z|\tfrac{\pi}{2},0\rangle^N = 0\ .$$

b. Now, from (41.47) we have,

$$\hat{\mathbf{S}}' \equiv e^{\imath\zeta\hat{S}_z^2}\hat{\mathbf{S}}e^{-\imath\zeta\hat{S}_z^2} = \begin{pmatrix} \frac{1}{2}\left(\hat{S}_+e^{2\imath\zeta(\hat{S}_z+1/2)}+e^{-2\imath\zeta(\hat{S}_z+1/2)}\hat{S}_-\right)\\ \frac{1}{2\imath}\left(\hat{S}_+e^{2\imath\zeta(\hat{S}_z+1/2)}-e^{-2\imath\zeta(\hat{S}_z+1/2)}\hat{S}_-\right)\\ \hat{S}_z\ . \end{pmatrix}$$

The square of the x-component is, using $[\hat{S}_+\hat{S}_-,\hat{S}_z]=0$,

$$\hat{S}_x'^2 = \tfrac{1}{4}\left(\hat{S}_+e^{2\imath\zeta(\hat{S}_z+1/2)}\hat{S}_+e^{2\imath\zeta(\hat{S}_z+1/2)}+e^{-2\imath\zeta(\hat{S}_z+1/2)}\hat{S}_-e^{-2\imath\zeta(\hat{S}_z+1/2)}\hat{S}_-+\hat{S}_+\hat{S}_-+\hat{S}_-\hat{S}_+\right)\ .$$

Evaluating it for an atomic cloud having suffered a $\frac{\pi}{2}$-pulse,

$$\langle\tfrac{\pi}{2},0|^N\hat{S}_x'^2|\tfrac{\pi}{2},0\rangle^N = \tfrac{1}{2^{2S+2}}\sum_{k,l=0}^{2S}\sqrt{\binom{2S}{k}\binom{2S}{l}}\langle S,S-l|\hat{S}_x'^2|S,S-k\rangle$$

$$= \tfrac{1}{2^{2S+2}}\sum_{k,l=0}^{2S}\sqrt{\binom{2S}{k}\binom{2S}{l}}\begin{pmatrix}\langle S,S-l|\hat{S}_+e^{2\imath\zeta(\hat{S}_z+1/2)}\hat{S}_+e^{2\imath\zeta(\hat{S}_z+1/2)}|S,S-k\rangle\\ +\langle S,S-l|e^{-2\imath\zeta(\hat{S}_z+1/2)}\hat{S}_-e^{-2\imath\zeta(\hat{S}_z+1/2)}\hat{S}_-|S,S-k\rangle\\ +\langle S,S-l|\hat{S}_+\hat{S}_-+\hat{S}_-\hat{S}_+|S,S-k\rangle\end{pmatrix}$$

$$= \tfrac{1}{2^{N+2}}\sum_{k=0}^{N}\begin{pmatrix}e^{2\imath\zeta(N-2k+2)}\sqrt{\frac{N!}{k!(N-k)!}\frac{N!}{(k-2)!(N-k+2)!}}\sqrt{k-1}\sqrt{N-k+2}\sqrt{k}\sqrt{N-k+1}\\ +e^{-2\imath\zeta(N-2k-2)}\sqrt{\frac{N!}{k!(N-k)!}\frac{N!}{(k+2)!(N-k-2)!}}\sqrt{k+2}\sqrt{N-k-1}\sqrt{k+1}\sqrt{N-k}\\ +\frac{N!}{k!(N-k)!}(k+1)(N-k)+\frac{N!}{k!(N-k)!}k(N-k+1)\end{pmatrix}$$

$$= \tfrac{1}{2^{N+2}}\sum_{k=0}^{N}\left(\frac{e^{4\imath\zeta}N!x^ky^{N-k}}{(k-2)!(N-k)!}+\frac{e^{4\imath\zeta}N!y^kx^{N-k}}{k!(N-k-2)!}+\frac{N!(k+1)}{k!(N-k-1)!}+\frac{N!(N-k+1)}{(k-1)!(N-k)!}\right)$$

$$= \tfrac{e^{4\imath\zeta}}{2^{N+2}}(N-1)Nx^2(x+y)^{N-2}\times 2+\tfrac{N(N+1)}{8}\ ,$$

where we used the abbreviations $x\equiv e^{-2\imath\zeta}$ and $y\equiv e^{2\imath\zeta}$. Now,

$$\langle\tfrac{\pi}{2},0|^N\hat{S}_x'^2|\tfrac{\pi}{2},0\rangle^N = \tfrac{N(N+1)}{8}+\tfrac{N(N-1)}{8}\cos^{N-2}2\zeta\ .$$

For $\zeta=0$ we recover the result from Exc. 41.1.6.4,

$$\langle\vartheta,\varphi|^N\hat{S}_x^2|\vartheta,\varphi\rangle^N = \tfrac{1}{4}\left[N+N(N-1)\sin^2\tfrac{\pi}{2}\cos^2 0\right] = \tfrac{N^2}{4}\ .$$

Analogously, we find,

$$\langle\tfrac{\pi}{2},0|^N\hat{S}_y'^2|\tfrac{\pi}{2},0\rangle^N = \tfrac{N(N+1)}{8}-\tfrac{N(N-1)}{8}\cos^{N-2}2\zeta\ .$$

41.1.6.9 Ex: Rotation of spin squeezed states

Calculate $\langle \frac{\pi}{2},0|^N e^{\imath\nu\hat{S}_x} e^{\imath\zeta\hat{S}_z^2} \Delta\hat{S}^2_{x,y,z} e^{-\imath\zeta\hat{S}_z^2} e^{-\imath\nu\hat{S}_x} |\frac{\pi}{2},0\rangle^N$.

Solution: *For the x-coordinate the calculation is easy, because,*

$$\langle \tfrac{\pi}{2},0|^N e^{\imath\nu\hat{S}_x} e^{\imath\zeta\hat{S}_z^2} \Delta\hat{S}^2_{x} e^{-\imath\zeta\hat{S}_z^2} e^{-\imath\nu\hat{S}_x} |\tfrac{\pi}{2},0\rangle^N = \langle \tfrac{\pi}{2},0|^N e^{\imath\zeta\hat{S}_z^2} \Delta\hat{S}^2_{x} e^{-\imath\zeta\hat{S}_z^2} |\tfrac{\pi}{2},0\rangle^N \ ,$$

where we can exploit the result of Exc. 41.1.6.8, yielding,

$$\langle \tfrac{\pi}{2},0|^N e^{\imath\nu\hat{S}_x} e^{\imath\zeta\hat{S}_z^2} \Delta\hat{S}^2_{x} e^{-\imath\zeta\hat{S}_z^2} e^{-\imath\nu\hat{S}_x} |\tfrac{\pi}{2},0\rangle^N = \tfrac{N(N+1)}{8} + \tfrac{N(N-1)}{8} \cos^{N-2} 2\zeta - \tfrac{N^2}{4} \cos^{2N-2}\zeta \ .$$

For the x- and y-coordinates, we note,

$$\langle \tfrac{\pi}{2},0|^N e^{\imath\nu\hat{S}_x} e^{\imath\zeta\hat{S}_z^2} \hat{S}_{y,z} e^{-\imath\zeta\hat{S}_z^2} e^{-\imath\nu\hat{S}_x} |\tfrac{\pi}{2},0\rangle^N = 0 \ .$$

Hence, we get for the y-coordinate,

$$\begin{aligned}
&\langle \tfrac{\pi}{2},0|^N e^{\imath\nu\hat{S}_x} e^{\imath\zeta\hat{S}_z^2} \Delta\hat{S}^2_{y} e^{-\imath\zeta\hat{S}_z^2} e^{-\imath\nu\hat{S}_x} |\tfrac{\pi}{2},0\rangle^N = \langle \tfrac{\pi}{2},0|^N e^{\imath\nu\hat{S}_x} e^{\imath\zeta\hat{S}_z^2} \Delta\hat{S}^2_{y} e^{-\imath\zeta\hat{S}_z^2} e^{-\imath\nu\hat{S}_x} |\tfrac{\pi}{2},0\rangle^N \\
&= \langle \tfrac{\pi}{2},0|^N e^{\imath\nu\hat{S}_x} e^{\imath\zeta\hat{S}_z^2} \hat{S}^2_{y} e^{-\imath\zeta\hat{S}_z^2} e^{-\imath\nu\hat{S}_x} |\tfrac{\pi}{2},0\rangle^N \\
&= \langle \tfrac{\pi}{2},0|^N e^{\imath\nu\hat{S}_x} \tfrac{-1}{4} \left(\hat{S}_+ e^{2\imath\zeta(\hat{S}_z+1/2)} - e^{-2\imath\zeta(\hat{S}_z+1/2)} \hat{S}_- \right)^2 e^{-\imath\nu\hat{S}_x} |\tfrac{\pi}{2},0\rangle^N \\
&= \tfrac{-1}{4} \langle \tfrac{\pi}{2},0|^N e^{\imath\nu\hat{S}_x} \left(e^{2\imath\zeta\hat{S}_z} \hat{S}_+ e^{2\imath\zeta\hat{S}_z} \hat{S}_+ e^{2\imath\zeta\hat{S}_z} + e^{-2\imath\zeta\hat{S}_z} e^{-2\imath\zeta\hat{S}_z} \hat{S}_- e^{-2\imath\zeta\hat{S}_z} \hat{S}_- - 2\hat{\mathbf{S}}^2 - 2\hat{S}_z^2 \right) e^{-\imath\nu\hat{S}_x} |\tfrac{\pi}{2},0\rangle^N \\
&= \tfrac{-1}{4} \langle \tfrac{\pi}{2},0|^N e^{\imath\nu\hat{S}_x} \left(\hat{S}_+^2 e^{6\imath\zeta(\hat{S}_z+1)} + e^{-6\imath\zeta(\hat{S}_z+1)} \hat{S}_-^2 - 2\hat{\mathbf{S}}^2 - 2\hat{S}_z^2 \right) e^{-\imath\nu\hat{S}_x} |\tfrac{\pi}{2},0\rangle^N
\end{aligned}$$

??? .

And for the z-coordinate,

$$\begin{aligned}
&\langle \tfrac{\pi}{2},0|^N e^{\imath\nu\hat{S}_x} e^{\imath\zeta\hat{S}_z^2} \Delta\hat{S}^2_{z} e^{-\imath\zeta\hat{S}_z^2} e^{-\imath\nu\hat{S}_x} |\tfrac{\pi}{2},0\rangle^N = \langle \tfrac{\pi}{2},0|^N e^{\imath\nu\hat{S}_x} \hat{S}^2_{z} e^{-\imath\nu\hat{S}_x} |\tfrac{\pi}{2},0\rangle^N \\
&= \langle \tfrac{\pi}{2},0|^N e^{\imath\nu\hat{S}_x} \hat{S}_z e^{-\imath\nu\hat{S}_x} e^{\imath\nu\hat{S}_x} \hat{S}_z e^{-\imath\nu\hat{S}_x} |\tfrac{\pi}{2},0\rangle^N = \langle \tfrac{\pi}{2},0|^N (\hat{S}_y \sin\nu + \hat{S}_z \cos\nu)^2 |\tfrac{\pi}{2},0\rangle^N \\
&= \frac{1}{2^{2S}} \sum_{k,l=0}^{N} \sqrt{\binom{N}{k}\binom{N}{l}} \langle S, S-l| \left(\tfrac{1}{2\imath} \hat{S}_+ \sin\nu - \tfrac{1}{2\imath} \hat{S}_- \sin\nu + \hat{S}_z \cos\nu \right)^2 |S, S-k\rangle \\
&= \frac{1}{2^N} \sum_{k,l=0}^{N} \sqrt{\binom{N}{k}\binom{N}{l}} \begin{pmatrix} -\frac{\sin^2\nu}{4} \sqrt{k-1}\sqrt{2S-k+2}\sqrt{k}\sqrt{2S-k+1}\delta_{l,k-2} \\ +\frac{\sin^2\nu}{4}(k+1)(2S-k)\delta_{l,k} + \frac{\sin^2\nu}{4} k(2S-k+1)\delta_{l,k} \\ -\frac{\sin^2\nu}{4} \sqrt{k+2}\sqrt{2S-k-1}\sqrt{k+1}\sqrt{2S-k}\delta_{l,k+2} \\ +\cos^2\nu (S-k)^2 \delta_{l,k} \end{pmatrix} ,
\end{aligned}$$

discarding all imaginary terms. Carrying out the calculations,

$$\langle \tfrac{\pi}{2},0|^N e^{\imath\nu\hat{S}_x} e^{\imath\zeta\hat{S}_z^2} \Delta\hat{S}^2_{z} e^{-\imath\zeta\hat{S}_z^2} e^{-\imath\nu\hat{S}_x} |\tfrac{\pi}{2},0\rangle^N = \tfrac{N}{4} \ .$$

41.1.6.10 Ex: Spin squeezing with two atoms

a. For a system of two atoms, write down the coherent state $|\vartheta,\varphi\rangle^2 = |\frac{\pi}{2},0\rangle^2$ in the Tavis-Cummings basis and in the Dicke state basis.
b. Derive the matrix representation for the squeezing operator along the z-axis and apply this operator to the above coherent spin state.
c. Compare spin squeezing with entanglement.

Solution: *a. We get in the Tavis-Cummings basis,*

$$\begin{aligned}|\vartheta,\varphi\rangle^2 &= \left(\cos\tfrac{\vartheta}{2}|+\rangle + e^{\imath\varphi}\sin\tfrac{\vartheta}{2}|-\rangle\right)^2 \\ &= \cos^2\tfrac{\vartheta}{2}|++\rangle + e^{\imath\varphi}\sin\tfrac{\vartheta}{2}\cos\tfrac{\vartheta}{2}(|+-\rangle + |+-\rangle) + e^{2\imath\varphi}\sin^2\tfrac{\vartheta}{2}|--\rangle\ ,\end{aligned}$$

such that,

$$|\tfrac{\pi}{2},0\rangle^2 = \tfrac{1}{2}(|+\rangle + |-\rangle)^2 = \tfrac{1}{2}(|++\rangle + |+-\rangle + |-+\rangle + |--\rangle)\ ,$$

while in the Dicke state basis, using

$$\begin{aligned}|\vartheta,\varphi\rangle^2 &= \sum_{k=0}^{N}\sqrt{\binom{N}{k}}\cos^k\tfrac{\vartheta}{2}e^{\imath(N-k)\varphi}\sin^{N-k}\tfrac{\vartheta}{2}|S,M\rangle \qquad \textit{with} \qquad N=2 \\ &= \cos^2\tfrac{\vartheta}{2}|1,1\rangle + 2e^{\imath\varphi}\sin\tfrac{\vartheta}{2}\cos\tfrac{\vartheta}{2}|1,0\rangle + e^{2\imath\varphi}\sin^2\tfrac{\vartheta}{2}|1,-1\rangle\ ,\end{aligned}$$

such that,

$$|\tfrac{\pi}{2},0\rangle = \tfrac{1}{2}|1,1\rangle + |1,0\rangle + \tfrac{1}{2}|1,-1\rangle\ . \tag{41.72}$$

b. Using the matrix representation of the spin operator,

$$\hat{S}_z = \begin{pmatrix}\frac{1}{2} & 0 & 0\\ 0 & 0 & 0\\ 0 & 0 & -\frac{1}{2}\end{pmatrix} \qquad \textit{and} \qquad \hat{S}_z^2 = \begin{pmatrix}\frac{1}{4} & 0 & 0\\ 0 & 0 & 0\\ 0 & 0 & \frac{1}{4}\end{pmatrix}\ ,$$

we find,

$$e^{\imath\zeta\hat{S}_z^2} = \begin{pmatrix}e^{\imath\zeta/4} & 0 & 0\\ 0 & 1 & 0\\ 0 & 0 & e^{\imath\zeta/4}\end{pmatrix}$$

Applying this operator to the coherent spin state, we get,

$$e^{\imath\zeta\hat{S}_z^2}|\vartheta,\varphi\rangle^N = \sum_{k=0}^{N}\sqrt{\binom{N}{k}}\cos^k\tfrac{\vartheta}{2}e^{\imath(N-k)\varphi}\sin^{N-k}\tfrac{\vartheta}{2}e^{\imath\zeta(S-k)^2}|S,S-k\rangle\ ,$$

such that,

$$\begin{aligned}e^{\imath\zeta\hat{S}_z^2}|\tfrac{\pi}{2},0\rangle^2 &= e^{\imath 2\varphi+\imath\zeta}\sin^2\tfrac{\vartheta}{2}|1,1\rangle + \sqrt{2}\cos\tfrac{\vartheta}{2}e^{\imath\varphi}\sin\tfrac{\vartheta}{2}|1,0\rangle + \cos^2\tfrac{\vartheta}{2}e^{\imath\zeta}|1,-1\rangle \\ &= \tfrac{e^{\imath\zeta}}{2}|1,1\rangle + \tfrac{1}{\sqrt{2}}|1,0\rangle + \tfrac{e^{\imath\zeta}}{2}|1,-1\rangle\ .\end{aligned}$$

Obviously, this state cannot be represented by a (stretched) coherent state (41.72).
c. In the Tavis-Cummings basis we calculate,

$$\hat{S}_z = \begin{pmatrix} 1 & & & \\ & 0 & & \\ & & 0 & \\ & & & -1 \end{pmatrix} \quad , \quad \hat{S}_z^2 = \begin{pmatrix} 1 & & & \\ & 0 & & \\ & & 0 & \\ & & & 1 \end{pmatrix} \quad , \quad e^{\imath\zeta\hat{S}_z^2} = \begin{pmatrix} e^{\imath\zeta} & & & \\ & 1 & & \\ & & 1 & \\ & & & e^{\imath\zeta} \end{pmatrix} .$$

Hence,

$$e^{\imath\zeta\hat{S}_z^2}\tfrac{1}{2}\begin{pmatrix} 1 \\ 1 \\ 1 \\ 1 \end{pmatrix} = \tfrac{1}{2}\begin{pmatrix} e^{\imath\zeta} \\ 1 \\ 1 \\ e^{\imath\zeta} \end{pmatrix} ,$$

only the stretched states are influenced by the squeezing operator. In a Ramsey interferometer this may be exploited to generate entanglement, $|++\rangle + |--\rangle$.

41.1.6.11 Ex: Mølmer-Sørensen gate

Derive the matrix representation for the two-qubit Mølmer-Sørensen gate $e^{\imath\zeta\hat{S}_x^2}$.

Solution: *With the definition (25.77),*

$$\hat{S}_k = \tfrac{1}{2}(\hat{\sigma}_k \otimes \mathbb{I}_2 + \mathbb{I}_2 \otimes \hat{\sigma}_k)$$

we can verify,

$$\hat{S}_x = e^{-\imath\pi\hat{S}_y/2}\hat{S}_z e^{\imath\pi\hat{S}_y/2} .$$

Using (24.153),

$$e^{\imath\zeta\hat{S}_x^2} = e^{\imath\zeta e^{-\imath\pi\hat{S}_y/2}\hat{S}_z e^{\imath\pi\hat{S}_y/2} e^{-\imath\pi\hat{S}_y/2}\hat{S}_z e^{\imath\pi\hat{S}_y/2}} = e^{e^{-\imath\pi\hat{S}_y/2}\imath\zeta\hat{S}_z^2 e^{\imath\pi\hat{S}_y/2}} = e^{-\imath\pi\hat{S}_y/2} e^{\imath\zeta\hat{S}_z^2} e^{\imath\pi\hat{S}_y/2}$$

$$= \left[\tfrac{1}{2}\begin{pmatrix} 1 & 1 & 1 & 1 \\ -1 & 1 & -1 & 1 \\ -1 & -1 & 1 & 1 \\ 1 & -1 & -1 & 1 \end{pmatrix}\right]^{-1} \begin{pmatrix} e^{\imath\zeta} & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & e^{\imath\zeta} \end{pmatrix} \tfrac{1}{2}\begin{pmatrix} 1 & 1 & 1 & 1 \\ -1 & 1 & -1 & 1 \\ -1 & -1 & 1 & 1 \\ 1 & -1 & -1 & 1 \end{pmatrix}$$

$$= \tfrac{1}{2} e^{\imath\zeta}\begin{pmatrix} 1 & 0 & 0 & 1 \\ 0 & 1 & 1 & 0 \\ 0 & 1 & 1 & 0 \\ 1 & 0 & 0 & 1 \end{pmatrix} .$$

Alternatively, we can search the eigenvalue matrix $\hat{E}$ and the eigenvector matrix U of the operator $\hat{S}_x^2 = U^{-1}EU$ and calculate $e^{\imath\zeta\hat{S}_x^2} = e^{\imath\zeta U^{-1}EU} = U^{-1}e^{\imath\zeta E}U$, which yields the same result. Applying the gate to the two-qubit ground state we generate the fully entangled EPR state.

41.1.6.12 Ex: Spin-squeezing via one-axis twisting

For a Dicke state with $N = 8$ atoms, program the matrix representations of the operators $\hat{S}_\pm$, $\hat{\mathbf{S}}$, $R_\alpha(\theta)$, and $Q_\alpha(\zeta)$ for $\alpha = x, y, z$ defined in the script, as well as the vector representation of the state $|\vartheta, \varphi\rangle$.
a. Starting from the ground state $|\vartheta, \varphi\rangle = |0, 0\rangle$, simulate the following time evolution: (i) $\frac{\pi}{2}$-pulse with the Hamiltonian $\hat{H} = \Omega \hat{S}_x$, where Ω is the Rabi frequency, (ii) interaction-free precession with the Hamiltonian $\hat{H} = \Delta \hat{S}_z$ where Δ is the detuning during a time T, (iii) $\frac{\pi}{2}$-pulse with the Hamiltonian $\hat{H} = \Omega \hat{S}_x$, (iv) projection of the energy axis. Plot the time evolution of the expectation values $\langle \hat{S}_\alpha \rangle$ and $\Delta \hat{S}_\alpha$.
b. Starting from the ground state $|\vartheta, \varphi\rangle = |0, 0\rangle$, simulate the following time evolution: (i) $\frac{\pi}{2}$-pulse with the Hamiltonian $\hat{H} = \Omega \hat{S}_y$, where Ω is the Rabi frequency, (ii) squeezing pulse along the z-axis with the squeezing parameter $\zeta = 0.6$, (iii) $\frac{\pi}{2}$-pulse with the Hamiltonian $\hat{H} = \Omega \hat{S}_x$. Plot the time evolution of the expectation values $\langle \hat{S}_\alpha \rangle$ and $\Delta \hat{S}_\alpha$. A movie can be seen at (watch movie).

Solution: *a. See plots of Fig. 41.7.*

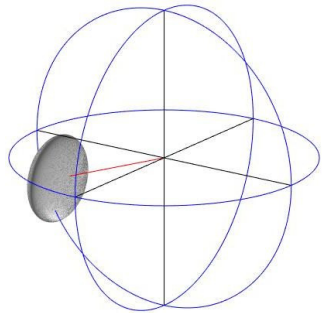

Figure 41.7: (code) Ramsey sequence.

b. See plots of Fig. 41.8.

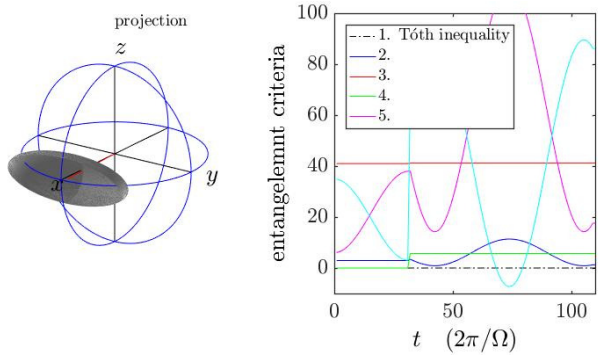

Figure 41.8: (code) Squeezing sequence.

41.1.6.13 Ex: Two-axis countertwisting

Study the Hamiltonian,

$$\hat{H} = \zeta(\hat{S}^2_{\pi/2,\pi/4} - \hat{S}^2_{\pi/2,-\pi/4}) = \tfrac{\zeta}{2\imath}(\hat{S}^2_+ - \hat{S}^2_-)$$

with $\hat{S}_{\vartheta,\varphi}$ defined in Exc. 41.1.6.3 in view of its squeezing features of an initial coherent spin state $|0,\varphi\rangle$ [724].

Solution: *The squeezing propagator generated by the Hamiltonian,*

$$\hat{H} = \zeta(\hat{S}_x + \imath\hat{S}_y)^2 - (\hat{S}_x - \imath\hat{S}_y)^2 = \zeta(\hat{S}_x\hat{S}_y + \hat{S}_y\hat{S}_x)$$

is

$$Q_z(\zeta) = e^{\imath\hat{H}t} = e^{\imath\zeta t(\hat{S}_x\hat{S}_y + \hat{S}_y\hat{S}_x)}$$

and we want to know

$$\langle\vartheta,\varphi|^N e^{\imath\zeta t(\hat{S}_x\hat{S}_y+\hat{S}_y\hat{S}_x)}\Delta\hat{S}^2_{x,y,z}e^{-\imath\zeta t(\hat{S}_x\hat{S}_y+\hat{S}_y\hat{S}_x)}|\vartheta,\varphi\rangle^N \ .$$

Note also,

$$\begin{aligned}\hat{S}_x\hat{S}_y, \hat{S}_y\hat{S}_x] &= \hat{S}_x\hat{S}_y[\hat{S}_y,\hat{S}_x] + [\hat{S}_x,\hat{S}_y]\hat{S}_x\hat{S}_y = 0\\ e^{\imath\zeta t(\hat{S}_x\hat{S}_y+\hat{S}_y\hat{S}_x)} &= e^{\imath\zeta t\hat{S}_x\hat{S}_y}e^{\imath\zeta t\hat{S}_y\hat{S}_x}\\ \hat{S}^2_x - \hat{S}^2_y &= \imath[\hat{S}_z,\hat{S}_x\hat{S}_y] \ .\end{aligned}$$

41.1.6.14 Ex: Interferometry with double Fock states

Discuss numerically whether, assuming as the initial state a double spin Fock state of the form $|+\rangle^{N_1}|-\rangle^{N_2}$, Heisenberg limited interferometry can be done within the Dicke model [184].

Solution: *Here, we want to study a product of two coherent spin states (in analogy to the superposition of two Glauber modes),*

$$\begin{aligned}|\psi\rangle = |\psi_1\rangle|\psi_2\rangle &= |\vartheta_1,\varphi_1\rangle^{N_1}|\vartheta_2,\varphi_2\rangle^{N_2} = (p_{1+}|+\rangle + p_{1-}|-\rangle)^{N_1}(p_{1+}|+\rangle + p_{1-}|-\rangle)^{N_1}\\ &= \sum_{k=0}^{2S_1}\sqrt{\binom{2S_1}{k}}p_{1+}^{S_1-k/2}p_{1-}^{k/2}\sum_{l=0}^{2S_2}\sqrt{\binom{2S_2}{l}}p_{2+}^{S_2-l/2}p_{2-}^{l/2}|S_1,M_1;S_2,M_2\rangle \ .\end{aligned}$$

Now, we construct operators acting on the whole Hilbert space,

$$|\psi\rangle \equiv |\psi_1\rangle\otimes|\psi_2\rangle \qquad , \qquad \hat{J}_\alpha \equiv \hat{S}^{(1)}_\alpha \oplus \hat{S}^{(2)}_\alpha = (\hat{S}^{(1)}_\alpha\otimes\mathbb{I}) + (\mathbb{I}\otimes\hat{S}^{(2)}_\alpha) \ ,$$

for all $\alpha = x,y,z,\pm$. The partial operators themselves are sums,

$$\hat{S}^{(\mu)}_\alpha = \sum_{k=1}^{N}\hat{S}^{(1)}_{k,\alpha} \ ,$$

with $\mu = 1, 2$. E.g. for two particles, one in each group μ, defining the basis $\{|--\rangle, |-+\rangle, |+-\rangle, |++\rangle\}$, we have,

$$\hat{J}_x = (\hat{S}_x \otimes \mathbb{I}) + (\mathbb{I} \otimes \hat{S}_x)$$
$$\hat{J}_x^2 = (\hat{S}_x \otimes \mathbb{I})^2 + (\mathbb{I} \otimes \hat{S}_x)^2 + (\hat{S}_x \otimes \mathbb{I})(\mathbb{I} \otimes \hat{S}_x) + (\hat{S}_x \otimes \mathbb{I})(\mathbb{I} \otimes \hat{S}_x) \ .$$

For the general case,

$$\begin{aligned}\hat{J}_\pm|S_1, M_1; S_2, M_2\rangle &= \sqrt{S_1(S_1+1) - M_1(M_1 \pm 1)}|S_1, M_1 \pm 1; S_2, M_2\rangle \\ &+ \sqrt{S_2(S_2+1) - M_2(M_2 \pm 1)}|S_1, M_1; S_2, M_2 \pm 1\rangle \\ \hat{J}_z|S_1, M_1; S_2, M_2\rangle &= M_1|S_1, M_1; S_2, M_2\rangle + M_2|S_1, M_1; S_2, M_2\rangle \ .\end{aligned}$$

The linear expectation values are easy to calculate,

$$\begin{aligned}&\langle\vartheta_1, \varphi_1|^{N_1}\langle\vartheta_2, \varphi_2|^{N_2}\hat{J}_+|\vartheta_1, \varphi_1\rangle^{N_1}|\vartheta_2, \varphi_2\rangle^{N_2} \\ &\qquad = \langle\vartheta_1, \varphi_1|^{N_1}\hat{S}_+^{(1)}|\vartheta_1, \varphi_1\rangle^{N_1} + \langle\vartheta_2, \varphi_2|^{N_2}\hat{S}_+^{(2)}|\vartheta_2, \varphi_2\rangle^{N_2} \\ &\qquad = S_1 e^{\imath\varphi_1}\sin\vartheta_1 + S_2 e^{\imath\varphi_2}\sin\vartheta_2 \ ,\end{aligned}$$

and so on. However, the situation is more complicated for higher momenta, such as,

$$\langle\vartheta_1, \varphi_1|^{N_1}\langle\vartheta_2, \varphi_2|^{N_2}\hat{J}_+^2|\vartheta_1, \varphi_1\rangle^{N_1}|\vartheta_2, \varphi_2\rangle^{N_2} \ ,$$

which have to be calculated numerically.
We consider the initial state,

$$|+\rangle^{N_1}|-\rangle^{N_2} = |N_1, S_1, M_1; N_2, S_2, M_2\rangle = |N_1, \tfrac{N_1}{2}, -\tfrac{N_1}{2}; N_2, \tfrac{N_2}{2}, +\tfrac{N_2}{2}\rangle \ .$$

It's like making a $\frac{\pi}{2}$-pulse and doing a complete spin-squeezing by measuring the atom number difference. The resulting state is NOT a coherent spin state, and the one-cloud Dicke model does not apply. This is analogous to combining two photonic Fock states at a beamsplitter and may be an example of sub SQL without entanglement [191]. See plots of Fig. 41.9.

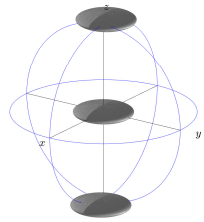

Figure 41.9: (code) Heisenberg-limited interferometry with two initial Fock states.

41.1.6.15 Ex: Entanglement criteria

A sufficient entanglement criterion for an N-qubit state is, that it violates one of the following inequalities [1315, 1316],

$$\begin{aligned}
\frac{\langle\Delta\hat{S}_z^2\rangle}{\langle\hat{S}_x\rangle^2+\langle\hat{S}_y\rangle^2} &\geq \frac{1}{N}\\
\langle\hat{S}_x^2\rangle+\langle\hat{S}_y^2\rangle+\langle\hat{S}_z^2\rangle &\leq \tfrac{N(N+2)}{4}\\
\langle\Delta\hat{S}_x^2\rangle+\langle\Delta\hat{S}_y^2\rangle+\langle\Delta\hat{S}_z^2\rangle &\geq \tfrac{N}{2}\\
\langle\hat{S}_k^2\rangle+\langle\hat{S}_m^2\rangle-\tfrac{N}{2} &\leq (N-1)\langle\Delta\hat{S}_n^2\rangle\\
(N-1)[\langle\Delta\hat{S}_k^2\rangle+\langle\Delta\hat{S}_m^2\rangle] &\geq \langle\hat{S}_k^2\rangle+\tfrac{N(N-2)}{4}\ ,
\end{aligned}$$

for $(kmn)=(123)$. Verify that, according to these criteria, coherent Dicke states are not entangled.

Solution: *With the results of Excs. 41.1.6.3 and 41.1.6.4 we find for coherent Dicke states immediately,*

$$\begin{aligned}
\frac{\langle\Delta\hat{S}_z^2\rangle}{\langle\hat{S}_x\rangle^2+\langle\hat{S}_y\rangle^2} &= \frac{1}{N\sin^2\varphi}\geq\frac{1}{N}\\
\langle\hat{S}_x^2\rangle+\langle\hat{S}_y^2\rangle+\langle\hat{S}_z^2\rangle &= \tfrac{N}{2}+\tfrac{N^4}{4}\\
\langle\Delta\hat{S}_x^2\rangle+\langle\Delta\hat{S}_y^2\rangle+\langle\Delta\hat{S}_z^2\rangle &= \tfrac{N}{2}\\
\langle\hat{S}_x^2\rangle+\langle\hat{S}_y^2\rangle-\tfrac{N}{2}-(N-1)\langle\Delta\hat{S}_z^2\rangle &= -\tfrac{N}{2}+\tfrac{N}{4}\sin^2\vartheta\leq 0\\
(N-1)[\langle\Delta\hat{S}_x^2\rangle+\langle\Delta\hat{S}_y^2\rangle]-\langle\hat{S}_z^2\rangle-\tfrac{N(N-2)}{4} &= 0\ .
\end{aligned}$$

41.1.6.16 Ex: Consistency of the Holstein-Primakoff transform

Verify that the relations (41.61) satisfy $[\hat{S}_+,\hat{S}_-]\simeq 2\hat{S}_z$ and $[\hat{S}_x,\hat{S}_y]\simeq\frac{\imath}{2}\hat{S}_z$.

Solution: *Using* $[\hat{b},\hat{b}^\dagger]=1$ *we find,*

$$\begin{aligned}
[\hat{S}_+,\hat{S}_-] &= 2S\left[\sqrt{1-\tfrac{\hat{b}^\dagger\hat{b}}{2S}}\ \hat{b},\hat{b}^\dagger\sqrt{1-\tfrac{\hat{b}^\dagger\hat{b}}{2S}}\right]\simeq 2S\left[\left(1-\tfrac{\hat{b}^\dagger\hat{b}}{4S}\right)\hat{b},\hat{b}^\dagger\left(1-\tfrac{\hat{b}^\dagger\hat{b}}{4S}\right)\right]\\
&= 2\left(S-\hat{b}^\dagger\hat{b}+\tfrac{1}{16S}\left[\hat{b}^\dagger\hat{b}\hat{a},\hat{b}^\dagger\hat{b}^\dagger\hat{b}\right]\right)\simeq 2\hat{S}_z\ ,
\end{aligned}$$

and

$$[\hat{S}_x,\hat{S}_y]=\left[\tfrac{1}{2}(\hat{S}_++\hat{S}_-),\tfrac{1}{2\imath}(\hat{S}_+-\hat{S}_-)\right]=\tfrac{-1}{4\imath}[\hat{S}_+,\hat{S}_-]\simeq\tfrac{\imath}{2}\hat{S}_z\ .$$

41.1.6.17 Ex: Dicke model of Bloch oscillations in the two-mode approximation

In the limit where Bloch oscillations can be modeled by a two-level system [1139] we may try a representation within the Dicke model and illustrate the dynamics on a Bloch sphere [1135]. The gravitational acceleration corresponds to a modification of kinetic energy without modification of the momentum state populations and without excitation of quantum coherences between them. Since the kinetic energy is represented by the vertical axis of the Bloch sphere, we may visualize acceleration via a rotation of the Bloch sphere, e.g. about the y-axis. The interpretation of the rotated Bloch sphere remains the same: the xy-plane shows the coherences and the z-axis the populations. Once this works, we can treat the thermal atomic cloud as a coherent spin state, e.g. squeeze it [724] or simulate trajectory of individual atoms inhomogeneously [345] [9,10].

Solution: *Assuming that, at any time, at most two discrete momentum states n and $n+1$ are coupled, the Hamiltonian (26.70) becomes,*

$$\begin{aligned}\tilde{H} &= 4\hbar\omega_{rec}n^2|2n\hbar k\rangle\langle 2n\hbar k| + 4\hbar\omega_{rec}(n+1)^2|2(n+1)\hbar k\rangle\langle 2(n+1)\hbar k| \\ &\quad + \tfrac{V_0}{4}\left(|2(n+1)\hbar k\rangle\langle 2n\hbar k| + |2n\hbar k\rangle\langle 2(n+1)\hbar k|\right) \ .\end{aligned}$$

Introducing spin operators for every single motional two-level atom,

$$\begin{aligned}\hat{\sigma}^+ &\equiv |p+2\hbar k\rangle\langle p| \quad , \quad \hat{\sigma}^x \equiv \hat{\sigma}^+ + \hat{\sigma}^- \quad , \quad \hat{\sigma}^z \equiv [\hat{\sigma}^+, \hat{\sigma}^-]_- \\ 2\hat{\sigma}^+\hat{\sigma}^- &= |p+2\hbar k\rangle\langle p+2\hbar k| = [\hat{\sigma}^-, \hat{\sigma}^+]_+ - [\hat{\sigma}^-, \hat{\sigma}^+]_- = \mathbb{I} + \hat{\sigma}^z \\ 2\hat{\sigma}^-\hat{\sigma}^+ &= |p\rangle\langle p| = [\hat{\sigma}^-, \hat{\sigma}^+]_+ + [\hat{\sigma}^-, \hat{\sigma}^+]_- = \mathbb{I} - \hat{\sigma}^z \ ,\end{aligned}$$

we get,

$$\begin{aligned}\tilde{H} &= 4\hbar\omega_{rec}n^2\hat{\sigma}^-\hat{\sigma}^+ + 4\hbar\omega_{rec}(n+1)^2\hat{\sigma}^+\hat{\sigma}^- + \tfrac{V_0}{4}(\hat{\sigma}^+ + \hat{\sigma}^-) \\ &= 8\hbar\omega_{rec}(n+\tfrac{1}{2})\hat{\sigma}^z + 8\hbar\omega_{rec}(n^2+n+\tfrac{1}{2}) + \tfrac{V_0}{4}\hat{\sigma}^x \ .\end{aligned}$$

Finally, we go to the collective Dicke Hamiltonian,

$$\hat{H} = \sum_j \tilde{H}_j = 8\hbar\omega_{rec}(n+\tfrac{1}{2})\hat{S}^z + 8\hbar\omega_{rec}(n^2+n+\tfrac{1}{2}) + \tfrac{V_0}{4}\hat{S}^x \ .$$

41.1.6.18 Ex: Uncertainty relation in different bases

In Exc. 41.1.6.4 the principal axes of the uncertainty ellipsoid of a coherent spin state have been derived for a fixed Cartesian coordinate system. Now, express the uncertainty ellipsoid in a local Cartesian basis anchored to spherical coordinates by $\hat{\mathbf{e}}'_x = \hat{\mathbf{e}}_r$, $\hat{\mathbf{e}}'_y = \hat{\mathbf{e}}_\theta$, and $\hat{\mathbf{e}}'_z = \hat{\mathbf{e}}_\phi$. Why is the radial projection onto the surface of the

[9] Note that, In order to simulate a series of Bloch oscillations, we must change the basis by hand after each Bragg reflection.

[10] An interesting question is, whether the Dicke picture can be extended to CARL (see Sec. 42.3.5).

generalized Bloch sphere invariant upon rotation? Interprete the projection of the uncertainty ellipsoid onto the radial axis and its dependency on rotation.

Solution: *According to Exc. 25.3.4.8 the commutation rules for an angular momentum satisfying* $[\hat{S}_x, \hat{S}_y] = \imath\hat{S}_z$ *is xxx. If now the system is in an eigenstate of* $\hat{S}_z$*, xxx. That is, the uncertainty relation describes a 2D disk tangential to the surface of the Bloch sphere, very similar to the situation in a 2D phase space, e.g. of a 1D harmonic oscillator.*

41.2 Super- and subradiance in open systems

The abstract spin formalism developed in the last sections revealed propagators allowing us to rotate and squeeze coherent spin states, but it did not tell us how to implement them physically. For this, we need to solve equations of motion derived from Hamiltonians realizable in the laboratory. In the following sections, we will set up the fundamental equations of motion (master or Heisenberg-Liouville) for open systems of N atoms subject to spontaneous emission collectively interacting with a single light mode subject to cavity decay and pumped by an external source.

We will discuss constants of motion of the Dicke and of the Tavis-Cummings model and phase transitions to superradiant states in the mean-field and in the Holstein-Primakoff approximation. Finally, we will present recent experimental realizations of Dicke phase transitions, namely superradiant self-ordering and superradiant lasing.

41.2.1 Models for open systems and phase transitions

We have already seen, that the spin quantum number S is preserved under the effect of the Dicke Hamiltonian (41.6). The spherical harmonics $|S, M\rangle$ are orthonormal and the spin operators $\hat{S}_\pm$ and $\hat{S}_{x,y,z}$ or their combinations do not allow for transitions between states with different S,

$$[\hat{H}, \hat{\mathbf{S}}^2] = 0 \quad \text{with} \quad \hat{\mathbf{S}}^2 = \tfrac{1}{2}(\hat{S}_+\hat{S}_- + \hat{S}_-\hat{S}_+) + \hat{S}_z^2 \tag{41.73}$$
$$\text{but} \quad [\hat{H}, \hat{S}_z] = \imath(\mathfrak{Im}\ \Omega\ \hat{S}_x - \mathfrak{Re}\ \Omega\ \hat{S}_y) \neq 0\ .$$

Hence, under the effect of the Dicke Hamiltonian an initial state $|N, S, M\rangle$ can only change its magnetic quantum number $|N, S, M\rangle \longrightarrow |N, S, M'\rangle$, and the manifolds with a given S form closed sub-spaces (see Exc. 41.2.4.1). In other words, once we start in a superradiant state $|N, S, M\rangle = |N, \frac{N}{2}, +\frac{N}{2}\rangle$, spin conservation excludes subradiant states, which allowed us to restrict to the superradiant Dicke subspace. Transitions between Dicke subspaces are only possible via physical processes that act on individual atoms, e.g. decay or phase fluctuation processes, as we will see later [498, 1429].

41.2.1.1 The generalized open Dicke model

In the presence of spontaneous decay or dephasing, superradiant spin conservation is no longer guaranteed. Let us have a look at the master equation for a set of N atoms

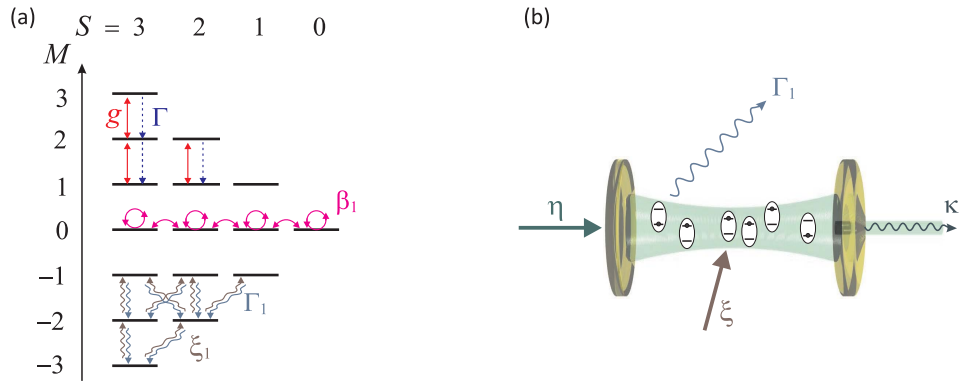

Figure 41.10: (a) Illustration of the Dicke states for $N = 6$. Hamiltonian interactions are in depicted in red. Superradiant decay occurs through a cascade from state $M = S$ to state $M = -S$. Spontaneous emission and phase noise leads to transitions along the blue arrows. The lowest states in each S subspace are dark and can only decay through a (subradiant) dark states cascade. (b) Scheme of the Dicke model.

coupled with the strength g to the mode of a cavity and additionally pumped by a classical laser field η [137, 723] (see (36.48)). After transformation into the rotating frame we have,

$$\boxed{\begin{aligned}
&\dot{\hat{\rho}} = \imath[\hat{\rho}, \hat{H}_{gD}] + \textstyle\sum_\gamma \mathcal{L}_{\gamma,\hat{L}}\hat{\rho} \qquad \text{or} \qquad \dot{\hat{A}} = -\imath[\hat{A}, \hat{H}_{gD}] + \textstyle\sum_\gamma \mathcal{L}^\dagger_{\gamma,\hat{L}}\hat{A} \\
&\hat{H}_{gD} = -\Delta_c \hat{a}^\dagger\hat{a} - \Delta_a \hat{S}_z + g(\hat{a}\hat{S}_+ + \hat{S}_-\hat{a}^\dagger) + g'(\hat{a}\hat{S}_- + \hat{S}_+\hat{a}^\dagger) - \imath\eta(\hat{a} - \hat{a}^\dagger) \\
&\text{and} \quad \mathcal{L}_{\gamma,\hat{L}}\hat{\rho} \equiv \gamma(2\hat{L}\hat{\rho}\hat{L}^\dagger - \hat{L}^\dagger\hat{L}\hat{\rho} - \hat{\rho}\hat{L}^\dagger\hat{L}) \\
&\text{and} \quad \mathcal{L}^\dagger_{\gamma,\hat{L}}\hat{A} \equiv \gamma(2\hat{L}^\dagger\hat{A}\hat{L} - \hat{L}^\dagger\hat{L}\hat{A} - \hat{A}\hat{L}^\dagger\hat{L})
\end{aligned}} \,. \tag{41.74}$$

The different coupling strengths g and g' allow us to isolate the counter-rotating terms, in order to discuss their relevance. The usual *open Dicke model* is obtained from the generalized Dicke Hamiltonian $\hat{H}_{gD}$ by setting $g' \equiv g$, while the rotating wave approximation is done by setting $g' \equiv 0$. The rates γ describe possible decay processes to which the degrees of freedom $\hat{L}$ are subject. The most relevant decay processes are listed in the following table:

decay rate γ	dissipative operator $\hat{L}$	physical process
κ	$\hat{a}$	cavity decay
ϕ	$\hat{a}^\dagger\hat{a}$	cavity phase jitter
$\gamma = \Gamma/2$	$\hat{S}_- = \sum_j \hat{s}_j^-$	collective (superradiant) atomic decay
$\gamma_1 = \Gamma_1/2$	$\hat{s}_j^-$	(transverse) single-atom decay
ξ_1	$\hat{s}_j^+$	single-atom optical pumping
β_1	$\hat{s}_j^z$	single-atom dephasing

$\Gamma = 2\gamma$ is the collective longitudinal atomic decay, κ and ϕ describe collective decay respectively collective phase noise of the cavity, while $\Gamma_1 = 2\gamma_1$, ξ_1, and β_1 stand for spontaneous emission, optical pumping via higher-lying levels, and phase fluctuation of individual atoms. The latter decay processes are described by sums of Lindbladians over all atoms. In Exc. 41.2.4.2 we derive the Heisenberg equations for the relevant degrees of freedom,

$$\begin{aligned}
\dot{\hat{a}} &= (\imath\Delta_c - \kappa - \phi)\hat{a} - \imath(g\hat{S}_- + g'\hat{S}_+) + \eta \\
\dot{\hat{S}}_- &= (\imath\Delta_a - \gamma_1 - \xi_1 - \beta_1 + \Gamma\hat{S}_z)\hat{S}_- + 2\imath\hat{S}_z(g\hat{a} + g'\hat{a}^\dagger) \\
\dot{\hat{S}}_z &= -\imath\hat{S}_+(g\hat{a} + g'\hat{a}^\dagger) + \imath(g\hat{a}^\dagger + g'\hat{a})\hat{S}_- - \Gamma\hat{S}_+\hat{S}_- - N(\gamma_1 - \xi_1)\mathbb{I} - 2(\gamma_1 + \xi_1)\hat{S}_z \\
\dot{\hat{s}}_j^- &= (\imath\Delta_a - \gamma_1 - \xi_1 - \beta_1)\hat{s}_j^- + 2\imath(g\hat{a} + g'\hat{a}^\dagger)\hat{s}_j^z \\
\dot{\hat{s}}_j^z &= -\imath(g\hat{a} + g'\hat{a}^\dagger)\hat{s}_j^+ + \imath(g\hat{a}^\dagger + g'\hat{a})\hat{s}_j^- - \gamma_1(\mathbb{I} - 2\hat{s}_j^z) + \xi_1(\mathbb{I} + 2\hat{s}_j^z) \ .
\end{aligned} \tag{41.75}$$

In Exc. 41.2.4.3 we verify that these equations of motion do not change the spin $\hat{\mathbf{S}}$. Neglecting all dissipation processes but Γ, the Eqs. (41.75) can be rewritten in terms of observables as,

$$\dot{\hat{\mathbf{S}}} = \begin{pmatrix} (g+g')(\hat{a}+\hat{a}^\dagger) \\ \imath(g-g')(\hat{a}-\hat{a}^\dagger) \\ -\Delta_a \end{pmatrix} \times \hat{\mathbf{S}} + \tfrac{\Gamma}{2} \begin{pmatrix} -\hat{S}_x + \{\hat{S}_x, \hat{S}_z\} \\ -\hat{S}_y + \{\hat{S}_y, \hat{S}_z\} \\ -2\hat{S}_z - 2\hat{S}_x^2 - 2\hat{S}_y^2 \end{pmatrix} \ . \tag{41.76}$$

Only the terms $\mathcal{L}_{\gamma_1}$, $\mathcal{L}_{\xi_1}$, and $\mathcal{L}_{\beta_1}$ can change $\hat{\mathbf{S}}^2$. The $\hat{\mathbf{S}}^2$ and $\hat{S}_z$ eigenvalues determine the coupling strength of the many-atom (Dicke) state to the cavity mode and the coherent, external drive. This coupling determines the rate of cavity photon generation as well as the pumping strength. The magnitude of the coupling strength distinguishes between superradiance and subradiance. For superradiant states the coupling strength scales superlinear in N, while for subradiant states the scaling is sublinear in N, and some subradiant states are dark. Dark means that the collective coupling to the cavity and the coherent, external drive of these states vanishes, meaning these states cannot decay via collective interactions e.g. by creating a cavity photon. However these states still decay into other states via the decay and dephasing processes $\mathcal{L}_{\gamma_1}$ and $\mathcal{L}_{\beta_1}$ acting individually on the emitters, see Fig. 41.10. Hence, spontaneous decay is an individualization process [498]. Generally, the spin preserving contributions in the master equation (41.78) generate quantum correlations leading to collective behavior (both super- and subradiance are collective effects) and the non-preserving terms destroy correlations leading to individualization (all properties scale exactly linear in N). However only the spin non-preserving contributions introduce coupling between superradiant and subradiant states, thus in order to prepare subradiant states an interplay of collectivity and individualization is necessary. Based on these considerations, we may distinguish between collective versus individual behavior and superradiant versus subradiant behavior. The latter are special cases of collective behavior. This twofold distinction seems crucial when investigating super- and subradiance in the presence of dephasing and individual decay. In Exc. 41.2.4.4 we study superradiant decay.

41.2.1.2 Symmetries of the Dicke and the Tavis-Cummings model

The total number of excitations,

$$\hat{N}_{ex} \equiv \hat{a}^\dagger \hat{a} + \hat{S}_z \tag{41.77}$$

is a constant of motion only for the Tavis-Cummings Hamiltonian, i.e. the Dicke Hamiltonian with RWA, $g' = 0$, and in the absence of pumping, $\eta = 0$,

$$[\hat{H}_{gD}, \hat{N}_{ex}] = \eta(\hat{a} - \hat{a}^\dagger) + 2g'(\hat{S}_- \hat{a} - \hat{S}_+ \hat{a}^\dagger) \ . \tag{41.78}$$

That is, the Dicke Hamiltonian preserves the excitation number, except for the counter-rotating terms, which can only change the excitation number by ± 2.

The Dicke model without RWA, $g' = g$, has one global symmetry [11],

$$\mathcal{P} : (\hat{a}, \hat{\sigma}^\pm) \to (-\hat{a}, -\hat{\sigma}^\pm) \ . \tag{41.79}$$

Because $\mathcal{P}$ squares to unity, it has two eigenvalues, 1 and -1. This symmetry is associated with a conserved quantity: the parity of the total number of excitations, $\mathcal{P} = (-1)^{N_{ex}}$. This parity conservation is a consequence of the preserved excitation number. A state of the Dicke model is said to be normal when this symmetry is preserved, and superradiant when this symmetry is spontaneously broken.

41.2.2 Superradiant Dicke phase transition

The interesting feature of the set of equations (41.75) is, that the degrees of freedom are macroscopically populated, yet, they follow the rules of quantum mechanics. For instance, we may expect them to behave as order parameters for macroscopic phase transitions. We will study one such example in the following.

41.2.2.1 Equilibrium Dicke phase transition

The Dicke model predicts a phase transition to a superradiant state, when the coupling strength g exceeds a certain critical value. To see this we simplify the Hamiltonian (41.6) by the mean-field approximation,

$$\omega_c \hat{a}^\dagger \hat{a} = \omega_c \alpha^2 \ , \tag{41.80}$$

where the field amplitude α is a real number, and calculate the free energy as a function of α,

$$\begin{aligned} F(\alpha) \equiv -\tfrac{1}{\beta} \ln Z(\alpha) \qquad \text{with} \qquad & Z(\alpha) = \mathrm{Tr}\ e^{-\beta \hat{H}} \\ \text{and} \qquad & \hat{H} = \omega_c \alpha^2 + \sum\nolimits_j \hat{h}_j \\ \text{and} \qquad & \hat{h}_j = \omega_a \hat{s}_j^z + 4g\alpha \hat{s}_j^x \ . \end{aligned} \tag{41.81}$$

[11] For a Dicke picture of CARL see Exc. 42.5.7.1.

$Z(\alpha)$ is the partition function, $\hat{h}_j$ the single-atom Hamiltonian, and $\beta \equiv 1/k_B T$. Carried out in Exc. 41.2.4.5, the calculation results in,

$$F(\alpha) = \omega_c \alpha^2 - \tfrac{N}{\beta} \ln(2 \cosh \beta E) \tag{41.82}$$

$$\text{where} \qquad \pm E \equiv \langle \hat{h}_j \rangle = \pm \sqrt{\left(\tfrac{\omega_a}{2}\right)^2 + (g\alpha)^2}$$

are the single-atom energy eigenvalues. The minimum of the free energy as a function of the field amplitude, $F'(\alpha) = 0$, yields a critical coupling strength g_c,

$$g_c \sqrt{N} = \tfrac{1}{2} \sqrt{\omega_c \omega_a \coth \tfrac{\beta \omega_a}{2}} \ , \tag{41.83}$$

Below g_c the free energy minimizes for $\alpha = 0$, and beyond g_c it minimizes for $\alpha > 0$, as seen in Fig. 41.11.

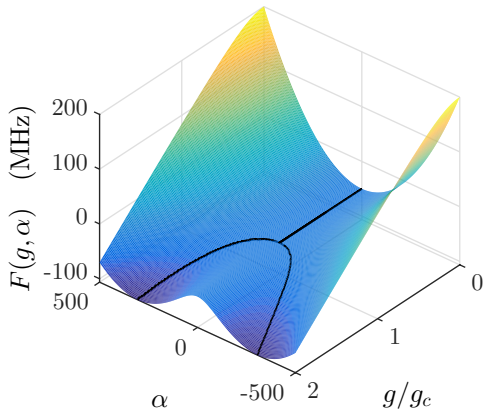

Figure 41.11: (code) Free energy as a function of coupling strength and photon number. Beyond the critical coupling strength g_c the minimum of the free energy splits opening the way for two possible equilibrium states of the mean-field phase.

Note that the critical coupling smoothly evolves down to zero temperature ($\beta \to 0$), where one obtains $g_c = \sqrt{\omega_c \omega_a / 2N}$ [12].

41.2.3 Beyond mean-field

We already applied the mean-field approximation in the derivation of the semiclassical Dicke Hamiltonian (41.9) and the Dicke phase transition (41.80). Some effects, however, are intrinsically to the existence of interatomic correlations, as for example, superradiant lasing [13]

[12] Note, that in the thermodynamic limit, $N \to \infty$, the operators can be replaced by [723]:

$$\hat{S}_x \overset{N\to\infty}{\longrightarrow} \tfrac{1}{2} \hat{N} \cos\hat{\varphi} \qquad \text{and} \qquad \hat{S}_y \overset{N\to\infty}{\longrightarrow} \tfrac{1}{2} \hat{N} \sin\hat{\varphi} \ .$$

In this case, the operators commute $[\hat{S}_x, \hat{S}_y] \to 0$.

[13] Interestingly, spin-squeezing, which is also based on interatomic correlations, can be described within the mean-field approximation.

41.2.3.1 Cumulant expansion

Often we are interested in quantum correlations rather than in the mean-field behavior of an operator. The *cumulant expansion* allows to study higher-order correlations by gradually removing lower-order ones. We introduce the correlation or cumulant expectation value between operators $\hat{A}$ and $\hat{B}$ [756, 1140],

$$\begin{aligned} \langle \hat{A} \rangle &\equiv \langle \hat{A} \rangle_c \\ \langle \hat{A}\hat{B} \rangle &\equiv \langle \hat{A} \rangle \langle \hat{B} \rangle + \langle \hat{A}\hat{B} \rangle_c \\ \langle \hat{A}\hat{B}\hat{C} \rangle &\equiv \langle \hat{A} \rangle \langle \hat{B} \rangle \langle \hat{C} \rangle + \langle \hat{A} \rangle \langle \hat{B}\hat{C} \rangle_c + \langle \hat{B} \rangle \langle \hat{A}\hat{C} \rangle_c + \langle \hat{C} \rangle \langle \hat{A}\hat{B} \rangle_c + \langle \hat{A}\hat{B}\hat{C} \rangle_c \ . \end{aligned} \tag{41.84}$$

The lowest order mean-field approximation consists in neglecting $\langle \hat{A}\hat{B} \rangle_c \simeq 0$.

Example 253 (*Superradiant lasing*): In a conventional laser amplification and optical phase coherence are established by stimulated photon emission from a population-inverted medium. This results in the Schawlow-Townes spectral linewidth, proportional to the square of the cavity decay width and inversely proportional to the photon number in the cavity. As Dicke showed, the coherence can also be stored in the emitters that constitute the gain medium provided they interact collectively with common radiation field modes [341]. If the spontaneous decay rate is much smaller than the cavity decay rate very narrow emission bandwidths far below the cavity decay width can be achieved. In Exc. 41.2.4.6 we study *superradiant lasing* in the Dicke model [868]. Cavity-mediated superradiance can also be described within the *Tavis-Cummings model* [226]. It represents an extension of the Jaynes-Cummings model for several atoms. We discussed such systems in Sec. 41.5.

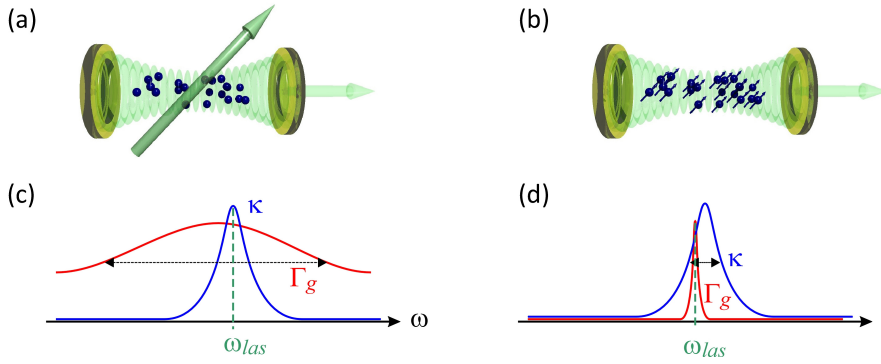

Figure 41.12: (a) Principle scheme of standard lasing. Here, the coherence is stored in the cavity field. The gain profile is much larger than the cavity width (good-cavity limit, $\kappa \ll \frac{1}{2}\Gamma_g$), as shown in (c). The laser frequency follows any (technical) cavity fluctuation: $\omega_{las} = \omega_{cav} + \omega_g \frac{2\kappa}{\Gamma_g}$. (b) *Superradiant lasing*. Here, the coherence is stored in the gain. We are in the bad-cavity limit, $\kappa \gg \Gamma_g$, as shown in (d). The laser frequency is robust to cavity fluctuations: $\omega_{las} = \omega_g + \omega_{cav} \frac{\Gamma_g}{2\kappa}$.

41.2.3.2 Superradiant lasing in the Holstein-Primakoff approximation

The superradiant phase transition was originally predicted by the Dicke model [366, 610]. It occurs when the strength of the interaction between the atoms and the field is greater than the energy of the non-interacting part of the system [14]. The collective Lamb shift, relating to the system of atoms interacting with the vacuum fluctuations, becomes comparable to the energies of atoms alone, and the vacuum fluctuations cause the spontaneous self-excitation of matter.

The transition can be readily understood by the use of the Holstein-Primakoff transformation applied to an ensemble of two-level atoms, as shown in Sec. ??, as a result of which the atoms become harmonic oscillators with frequencies equal to the difference between the energy levels. If the interaction between the atomic and the field oscillator is so strong that the system collapses in a ferroelectric-like phase transition. In Exc. 41.2.4.8 we will derive the Heisenberg equations for the open Dicke model in the Holstein-Primakoff approximation.

Example 254 (*Finding instabilities via retarded Green's functions*): Let us consider a set of linear Heisenberg equations,

$$\dot{v}_i(t) = M_{ij} v_j(t) \qquad \text{and} \qquad \dot{v}_i^\dagger(t) = M_{ij}^\dagger v_j^\dagger(t) \ .$$

The retarded *Green's function* is defined by,

$$G_{ij}(t) \equiv -\imath \langle [v_i(t), v_j^\dagger(0)] \rangle \theta(t) \ .$$

Its time derivative is,

$$\dot{G}_{ij}(t) \equiv -\imath \langle [v_i(t), v_j^\dagger(0)] \rangle \delta(t) - \imath \langle \dot{v}_i(t) v_j^\dagger(t) \rangle \theta(t) + \imath \langle v_j^\dagger(t) \dot{v}_i(t) \rangle \theta(t) \ .$$

Defining the equal-time correlation function by,

$$S_{ij} \equiv \langle [v_i(0), v_j^\dagger(0)] \rangle \ ,$$

we get,

$$\begin{aligned} \dot{G}_{ij}(t) &= -\imath S_{ij} \delta(t) - \imath M_{ik} \langle v_k(t) v_j^\dagger(t) \rangle \theta(t) + \imath M_{ik} \langle v_j^\dagger(t) v_k(t) \rangle \theta(t) \\ &= -\imath S_{ij} \delta(t) - \imath M_{ik} \langle [v_k(t), v_j^\dagger(t)] \rangle \theta(t) = -\imath S_{ij} \delta(t) + M_{ik} G_{kj}(t) \ . \end{aligned}$$

With the Fourier transform $f(\omega) = \int_{-\infty}^{\infty} dt e^{\imath \omega t} f(t)$ we finally get,

$$G(\omega) = (M + \imath \omega \mathbb{I})^{-1} \imath S \ .$$

For example, we may consider the system of two coupled oscillators studied in Sec. 35.8.8. In this case,

$$\mathbf{v} \equiv \begin{pmatrix} \hat{a} \\ \hat{a}^\dagger \\ \hat{b} \\ \hat{b}^\dagger \end{pmatrix} \qquad \text{such that} \qquad S = \text{diag}\ (1, -1, 1, -1) \ .$$

[14] This is similar to the case of superconductivity in ferromagnetism, which leads to the dynamic interaction between ferromagnetic atoms and the spontaneous ordering of excitations below the critical temperature.

In Exc. ?? we have shown that (setting $\Omega' \equiv \Omega$),

$$M = \begin{pmatrix} -\imath\omega - \kappa_a & 0 & -\frac{\imath\Omega}{2} & -\frac{\imath\Omega}{2} \\ 0 & \imath\omega - \kappa_a & \frac{\imath\Omega}{2} & \frac{\imath\Omega}{2} \\ -\frac{\imath\Omega}{2} & -\frac{\imath\Omega}{2} & -\imath\omega - \kappa_b & 0 \\ \frac{\imath\Omega}{2} & \frac{\imath\Omega}{2} & 0 & \imath\omega - \kappa_b \end{pmatrix} .$$

Thus,

$$G^R(\omega)^{-1} = S^{-1}(\omega\mathbb{I} - \imath M) = \begin{pmatrix} \omega - \omega_a + \imath\kappa_a & 0 & -\frac{\Omega}{2} & -\frac{\Omega}{2} \\ 0 & -\omega - \omega_a - \imath\kappa_a & -\frac{\Omega}{2} & -\frac{\Omega}{2} \\ -\frac{\Omega}{2} & -\frac{\Omega}{2} & \omega - \omega_b + \imath\kappa_b & 0 \\ -\frac{\Omega}{2} & -\frac{\Omega}{2} & 0 & -\omega - \omega_b - \imath\kappa_b \end{pmatrix} .$$

The superradiant transition corresponds to the requirement that one of the eigenvalues of M goes to zero [341, 723], or equivalently,

$$0 = \det G^R(\omega)^{-1} = \omega_a^2\omega_b^2 + \omega_a^2\kappa_b^2 - \omega_a\Omega^2\omega_b + \kappa_a^2\omega_b^2 + \kappa_a^2\kappa_b^2 ,$$

yielding,

$$\Omega = \sqrt{\frac{(\omega_a^2 + \kappa_a^2)(\omega_b^2 + \kappa_b^2)}{\omega_a\omega_b}} .$$

Example 255 (*Dicke phase transition with a superfluid gas in an optical cavity*): [105]

41.2.4 Exercises

41.2.4.1 Ex: Relationship between super- and subradiance and cooperativity

a. Discuss whether super- and subradiant states can be transformed into each other via unitary transformations.
b. Seek an interpretation of super- and subradiance as a modification of the structure factor by cooperativity.

Solution:

41.2.4.2 Ex: Heisenberg equation for the open Dicke model

Derive the Heisenberg equation for the open Dicke model.

Solution: *We start from the generalized Dicke Hamiltonian and the general form of the Lindbladian (41.74) to derive the Heisenberg equation,*

$$\frac{d}{dt}\hat{A} = -\imath[\hat{A}, \hat{H}_{gH}] + \mathcal{L}^\dagger_{\kappa,\hat{a}}\hat{A} + \mathcal{L}^\dagger_{\Gamma,\hat{S}_-}\hat{A} + \mathcal{L}^\dagger_{\gamma_1,\hat{s}^-}\hat{A} + \mathcal{L}^\dagger_{\xi_1,\hat{s}^+}\hat{A} + \mathcal{L}^\dagger_{\beta_1,\hat{s}^z}\hat{A} ,$$

considering the dissipation processes,

$$\begin{aligned}
\mathcal{L}^\dagger_{\kappa,\hat{a}}\hat{A} &= \kappa(\hat{a}^\dagger[\hat{A},\hat{a}] + [\hat{a}^\dagger,\hat{A}]\hat{a}) \\
\mathcal{L}^\dagger_{\phi,\hat{a}^\dagger\hat{a}}\hat{A} &= \phi(\hat{a}^\dagger\hat{a}[\hat{A},\hat{a}^\dagger\hat{a}] + [\hat{a}^\dagger\hat{a},\hat{A}]\hat{a}^\dagger\hat{a}) \\
\mathcal{L}^\dagger_{\Gamma,\hat{S}_-}\hat{A} &= \Gamma(\hat{S}_+[\hat{A},\hat{S}_-] + [\hat{S}_+,\hat{A}]\hat{S}_-) \\
\mathcal{L}^\dagger_{\gamma_1,\hat{s}^-}\hat{A} &= \gamma_1 \sum\nolimits_j (\hat{s}_i^+[\hat{A},\hat{s}_i^-] + [\hat{s}_i^+,\hat{A}]\hat{s}_i^-) \\
\mathcal{L}^\dagger_{\xi_1,\hat{s}^+}\hat{A} &= \xi_1 \sum\nolimits_j (\hat{s}_i^-[\hat{A},\hat{s}_i^+] + [\hat{s}_i^-,\hat{A}]\hat{s}_i^+) \\
\mathcal{L}^\dagger_{\beta_1,\hat{s}^z}\hat{A} &= \beta_1 \sum\nolimits_j (\hat{s}_i^z[\hat{A},\hat{s}_i^z] + [\hat{s}_i^z,\hat{A}]\hat{s}_i^z) \ ,
\end{aligned}$$

describing respectively the decay and phase jitter of the cavity field and superradiant decay, which are collective processes, and the single atom processes spontaneous decay, optical pumping, and phase noise. Using the commutation rules,

$$[\hat{s}_i^z,\hat{s}_j^\pm] = \pm\hat{s}_j^\pm\delta_{ij} \qquad \textit{and} \qquad [\hat{s}_i^+,\hat{s}_j^-] = 2\hat{s}_j^z\delta_{ij} \ ,$$

and the relationships $\hat{s}^{x,y,z} = \frac{1}{2}\hat{\sigma}^{x,y,z}$ *and* $\hat{s}^\pm = \hat{\sigma}^\pm$*, yielding,*

$$\hat{s}_j^z\hat{s}_j^\pm = \tfrac{1}{2}[\hat{s}_j^+,\hat{s}_j^-]\hat{s}_j^+ = \pm\tfrac{1}{2}\hat{s}_j^\pm = -\hat{s}_j^\pm\hat{s}_j^z \qquad \textit{and} \qquad \hat{s}_j^\pm\hat{s}_j^\mp = \tfrac{1}{2}(\mathbb{I} \mp 2\hat{s}_j^z) \ ,$$

we find,

$$\begin{aligned}
\dot{\hat{a}} &= -\imath[\hat{a},\hat{H}_{gH}] + \mathcal{L}^\dagger_{\kappa,\hat{a}}\hat{a} + \mathcal{L}^\dagger_{\phi,\hat{a}^\dagger\hat{a}}\hat{a} \\
&= \imath\Delta_c[\hat{a},\hat{a}^\dagger]\hat{a} - 2\imath g[\hat{a},\hat{a}^\dagger]\hat{S}_- - 2\imath g'\hat{S}_+[\hat{a},\hat{a}^\dagger] \\
&\qquad + \eta[\hat{a},\hat{a}^\dagger] + \kappa(\hat{a}^\dagger[\hat{a},\hat{a}] + [\hat{a}^\dagger,\hat{a}]\hat{a}) + \phi(\hat{a}^\dagger\hat{a}[\hat{a},\hat{a}^\dagger]\hat{a} + [\hat{a}^\dagger,\hat{a}]\hat{a}\hat{a}^\dagger\hat{a}) \\
&= (\imath\Delta_c - \kappa - \phi)\hat{a} - 2\imath(g\hat{S}_- + g'\hat{S}_+) + \eta \ ,
\end{aligned}$$

and,

$$\begin{aligned}
\dot{\hat{S}}_- &= -\imath[\hat{S}_-,\hat{H}_{gH}] + \mathcal{L}^\dagger_{\Gamma,\hat{S}_-}\hat{S}_- + \mathcal{L}^\dagger_{\gamma_1,\hat{s}^-}\hat{S}_- + \mathcal{L}^\dagger_{\xi_1,\hat{s}^+}\hat{S}_- + \mathcal{L}^\dagger_{\beta_1,\hat{s}^z}\hat{S}_- \\
&= \imath\Delta_a[\hat{S}_-,\hat{S}_z] - 2\imath g[\hat{S}_-,\hat{S}_+]\hat{a} - 2\imath g'[\hat{S}_-,\hat{S}_+]\hat{a}^\dagger + \Gamma[\hat{S}_+,\hat{S}_-]\hat{S}_- \\
&\qquad + \gamma_1\sum\nolimits_j[\hat{s}_j^+,\hat{s}_j^-]\hat{s}_j^- + \xi_1\sum\nolimits_j \hat{s}_j^-[\hat{s}_j^-,\hat{s}_j^+] + \beta_1\sum\nolimits_j(\hat{s}_i^z[\hat{s}_j^-,\hat{s}_i^z] + [\hat{s}_i^z,\hat{s}_j^-]\hat{s}_i^z) \\
&= (\imath\Delta_a - \gamma_1 - \xi_1 - \beta_1 + 2\Gamma\hat{S}_z)\hat{S}_- + 4\imath\hat{S}_z(g\hat{a} + g'\hat{a}^\dagger) \ .
\end{aligned}$$

and,

$$\begin{aligned}
\dot{\hat{S}}_z &= -\imath[\hat{S}_z,\hat{H}_{gH}] + \mathcal{L}^\dagger_{\Gamma,\hat{S}_-}\hat{S}_z + \mathcal{L}^\dagger_{\gamma_1,\hat{s}^-}\hat{S}_z + \mathcal{L}^\dagger_{\xi_1,\hat{s}^+}\hat{S}_z + \mathcal{L}^\dagger_{\beta_1,\hat{s}^z}\hat{S}_z \\
&= -2\imath g[\hat{S}_z,\hat{S}_+]\hat{a} - 2\imath g\hat{a}^\dagger[\hat{S}_z,\hat{S}_-] - 2\imath g'\hat{a}[\hat{S}_z,\hat{S}_-] - 2\imath g'[\hat{S}_z,\hat{S}_+]\hat{a}^\dagger + \Gamma(\hat{S}_+[\hat{S}_z,\hat{S}_-] + [\hat{S}_+,\hat{S}_z]\hat{S}_-) \\
&\qquad + \gamma_1\sum\nolimits_j(\hat{s}_j^+[\hat{s}_j^z,\hat{s}_j^-] + [\hat{s}_j^+,\hat{s}_j^z]\hat{s}_j^-) + \xi_1\sum\nolimits_j(\hat{s}_j^-[\hat{s}_j^z,\hat{s}_j^+] + [\hat{s}_j^-,\hat{s}_j^z]\hat{s}_j^+) \\
&\qquad + \beta_1\sum\nolimits_j(\hat{s}_j^z[\hat{s}_j^z,\hat{s}_j^z] + [\hat{s}_j^z,\hat{s}_j^z]\hat{s}_j^z) \\
&= -2\imath\hat{S}_+(g\hat{a} + g'\hat{a}^\dagger) + 2\imath(g\hat{a}^\dagger + g'\hat{a})\hat{S}_- - 2\Gamma\hat{S}_+\hat{S}_- - 2\sum\nolimits_j(\gamma_1\hat{s}_j^+\hat{s}_j^- - \xi_1\hat{s}_j^-\hat{s}_j^+) \\
&= -2\imath\hat{S}_+(g\hat{a} + g'\hat{a}^\dagger) + 2\imath(g\hat{a}^\dagger + g'\hat{a})\hat{S}_- - 2\Gamma(\hat{S}_+^2 - \hat{S}_z^2 + \hat{S}_z) - N(\gamma_1 - \xi_1)\mathbb{I} - 2(\gamma_1 + \xi_1)\hat{S}_z \ .
\end{aligned}$$

and,

$$\begin{aligned}\dot{\hat{s}}_j^- &= -\imath[\hat{s}_j^-, \hat{H}_{gH}] + \mathcal{L}^\dagger_{\Gamma,\hat{S}_-}\hat{s}_j^- + \mathcal{L}^\dagger_{\gamma_1,\hat{s}^-}\hat{s}_j^- + \mathcal{L}^\dagger_{\xi_1,\hat{s}^+}\hat{s}_j^- + \mathcal{L}^\dagger_{\beta_1,\hat{s}^z}\hat{s}_j^- \\ &= \Delta_a\imath[\hat{s}_j^-, \hat{s}_j^z] - 2\imath g\hat{a}[\hat{s}_j^-, \hat{s}_j^+] - 2g'\imath[\hat{s}_j^-, \hat{s}_j^+]\hat{a}^\dagger - \gamma_1[\hat{s}_j^+, \hat{s}_j^-]\hat{s}_j^- + \xi_1\hat{s}_j^-[\hat{s}_j^-, \hat{s}_j^+] \\ &\quad + \beta_1(\hat{s}_j^z[\hat{s}_j^-, \hat{s}_j^z] + [\hat{s}_j^z, \hat{s}_j^-]\hat{s}_i^z) \\ &= (\imath\Delta_a - \gamma_1 - \xi_1 - \beta_1)\hat{s}_j^- + 4\imath(g\hat{a} + g'\hat{a}^\dagger)\hat{s}_j^z \ ,\end{aligned}$$

and,

$$\begin{aligned}\dot{\hat{s}}_j^z &= -\imath[\hat{s}_j^z, \hat{H}_{gH}] + \mathcal{L}^\dagger_{\Gamma,\hat{S}_-}\hat{s}_j^z + \mathcal{L}^\dagger_{\gamma_1,\hat{s}^-}\hat{s}_j^z + \mathcal{L}^\dagger_{\xi_1,\hat{s}^+}\hat{s}_j^z + \mathcal{L}^\dagger_{\beta_1,\hat{s}^z}\hat{s}_j^z \\ &= -2\imath g(\hat{a}[\hat{s}_j^z, \hat{s}_j^+] + [\hat{s}_j^z, \hat{s}_j^-]\hat{a}^\dagger) - 2\imath g'(\hat{a}[\hat{s}_j^z, \hat{s}_j^-] + [\hat{s}_j^z, \hat{s}_j^+]\hat{a}^\dagger) + \gamma_1(\hat{s}_j^+[\hat{s}_j^z, \hat{s}_j^-] - [\hat{s}_j^+, \hat{s}_j^z]\hat{s}_j^-) \\ &\quad + \xi_1(\hat{s}_j^-[\hat{s}_j^z, \hat{s}_j^+] - [\hat{s}_j^-, \hat{s}_j^z]\hat{s}_j^+) + \beta_1(\hat{s}_j^z[\hat{s}_j^z, \hat{s}_j^z] + [\hat{s}_j^z, \hat{s}_j^z]\hat{s}_i^z) \\ &= -2\imath(g\hat{a} + g'\hat{a}^\dagger)\hat{s}_j^+ + 2\imath(g\hat{a}^\dagger + g'\hat{a})\hat{s}_j^- - 2\gamma_1\hat{s}_j^+\hat{s}_j^- + 2\xi_1\hat{s}_j^-\hat{s}_j^+ \\ &= -2\imath(g\hat{a} + g'\hat{a}^\dagger)\hat{s}_j^+ + 2\imath(g\hat{a}^\dagger + g'\hat{a})\hat{s}_j^- - \gamma_1(\mathbb{I} - 2\hat{s}_j^z) + \xi_1(\mathbb{I} + 2\hat{s}_j^z) \ .\end{aligned}$$

41.2.4.3 Ex: Spin conservation in the open Dicke model

a. Show that the Dicke Hamiltonian (41.74) with $g' = g$ preserves the spin $\hat{\mathbf{S}}^2$.
b. Show that the Dicke Hamiltonian (41.74) with $g' = 0$ preserves the spin $\hat{\mathbf{S}}^2$.
c. Verify whether the dissipative terms of the open Dicke model preserve the spin $\hat{\mathbf{S}}^2$.

Solution: *a. For the coherent part of the Dicke Hamiltonian with $g' = g$ it is easy to see,*

$$-\imath[\hat{\mathbf{S}}, \hat{H}] = -\imath[\hat{\mathbf{S}}, \omega_a\hat{S}_z + 4g(\hat{a} + \hat{a}^\dagger)\hat{S}_x] = \begin{pmatrix} -\omega_a\hat{S}_y \\ \omega_a\hat{S}_x - 4g(\hat{a} + \hat{a}^\dagger)\hat{S}_z \\ 4g(\hat{a} + \hat{a}^\dagger)\hat{S}_y \end{pmatrix} \ ,$$

so that $\frac{d}{dt}\hat{\mathbf{S}}^2 = \dot{\mathbf{S}}\cdot\hat{\mathbf{S}} + \hat{\mathbf{S}}\cdot\dot{\mathbf{S}} = 0$.
b. For the coherent part of the Dicke Hamiltonian with $g' = 0$ it is easy to see,

$$-\imath[\hat{\mathbf{S}}, \hat{H}] = -\imath[\hat{\mathbf{S}}, \omega_a\hat{S}_z + 2g(\hat{a}\hat{S}_+ + \hat{a}^\dagger S_-)] = \begin{pmatrix} -\omega_a\hat{S}_y + 2\imath g(\hat{a} - \hat{a}^\dagger)\hat{S}_z \\ \omega_a\hat{S}_x - 2g(\hat{a} + \hat{a}^\dagger)\hat{S}_z \\ 2g(\hat{a} + \hat{a}^\dagger)\hat{S}_y - 2\imath g(\hat{a} - \hat{a}^\dagger)\hat{S}_x \end{pmatrix} \ ,$$

so that $\frac{d}{dt}\hat{\mathbf{S}}^2 = \dot{\mathbf{S}}\cdot\hat{\mathbf{S}} + \hat{\mathbf{S}}\cdot\dot{\mathbf{S}} = 0$. The results are expected, since we know that $[\hat{\mathbf{S}}^2, \hat{H}] = 0$ for both Hamiltonians.
c. Using the results of Exc. 41.2.4.2,

$$\mathcal{L}\hat{\mathbf{S}} = \begin{pmatrix} \frac{1}{2}\mathcal{L}\hat{S}_+ + \frac{1}{2}\mathcal{L}\hat{S}_- \\ \frac{1}{2\imath}\mathcal{L}\hat{S}_+ - \frac{1}{2\imath}\mathcal{L}\hat{S}_- \\ \mathcal{L}\hat{S}_z \end{pmatrix} = \begin{pmatrix} \Gamma(\hat{S}_+\hat{S}_z + \hat{S}_z\hat{S}_-) \\ -\imath\Gamma(\hat{S}_+\hat{S}_z - \hat{S}_z\hat{S}_-) \\ -2\Gamma\hat{S}_+\hat{S}_- \end{pmatrix} \ ,$$

Finally, we find after elementary algebra,

$$\tfrac{d}{dt}\hat{\mathbf{S}}^2 = \mathcal{L}\hat{\mathbf{S}}\cdot\hat{\mathbf{S}} + \hat{\mathbf{S}}\cdot\mathcal{L}\hat{\mathbf{S}} = -2\Gamma(\hat{S}_+\hat{S}_- + 2\hat{S}_z^2) \neq 0 \ .$$

Note, that for a single atom, $\hat{S}_z = 1$, we get $\mathcal{L}\hat{\mathbf{S}}^2 = 0$.

41.2.4.4 Ex: Superradiant enhancement

For the open Dicke model consider the Heisenberg equations (41.75) without coherent mean-field, $\hat{a} = 0$, and disregarding single-atom decoherence, $\gamma_1 = \xi_1 = \beta_1 = 0$. Solve the equation of motion for the collective spin projection $\hat{S}_z$ for an arbitrary coherent spin state $|S, M\rangle$ and discuss the collective decay rate as a function of the collective inversion $\langle\hat{S}_z\rangle$.

Solution: *The equation of motion is,*

$$\dot{\hat{S}}_z = -2\Gamma\hat{S}_+\hat{S}_- \ .$$

Hence,

$$\begin{aligned}\langle\dot{S}_z\rangle &= -2\Gamma\langle S, M|\hat{S}_+\hat{S}_-|S, M\rangle \\ &= -2\Gamma\sqrt{(S-M+1)(S+M)}\sqrt{(S+M)(S-M+1)} \\ &= -2\Gamma(S+M)(S-M+1) \ .\end{aligned}$$

Hence, the decay rate depends on the instantaneous collective inversion $\langle\hat{S}_z\rangle = M$,

$$\begin{aligned}\langle S, S|\dot{S}_z|S, S\rangle &= -2N\Gamma \\ \langle S, 0|\dot{S}_z|S, 0\rangle &= -(\tfrac{N^2}{2} + N)\Gamma \\ \langle S, -S|\dot{S}_z|S, -S\rangle &= -2\Gamma(S-S)(S+S+1) = 0 \ .\end{aligned}$$

It is superradiantly enhanced when $M = 0$.

41.2.4.5 Ex: Equilibrium phase transition

a. Calculate the free energy of the Hamiltonian (41.6) in the mean-field approximation.
b. Minimize the free energy as a function of the field amplitude α for various coupling strengths g. **Help:** Expand the expression for $F'(\alpha)$ for small values of α. Derive the expression for the critical coupling strength.

Solution: *a. We perform the mean-field approximation via,*

$$\omega_c\hat{a}^\dagger\hat{a} = \omega_c\alpha^2 \ ,$$

where α is a real variational parameter. The Hamiltonian then reads,

$$\hat{H} = \omega_c\alpha^2 + \sum_j \hat{h}_j \qquad \textit{with} \qquad \hat{h}_j = \omega_a\hat{s}_j^z + 4g\alpha\hat{s}_j^x \ .$$

The matrix representation of the single-particle Hamiltonian is,

$$\langle s', m'|\hat{h}_j|s, m\rangle = \omega_a\langle\tfrac{1}{2}, m'|\hat{s}_j^z|\tfrac{1}{2}, m\rangle + 2g\alpha\langle\tfrac{1}{2}, m'|\hat{s}_j^+ + \hat{s}_j^-|\tfrac{1}{2}, m\rangle = \begin{pmatrix} \frac{1}{2}\omega_a & 2g\alpha \\ 2g\alpha & -\frac{1}{2}\omega_a \end{pmatrix} ,$$

with the eigenvalues,

$$E_\pm = \pm\sqrt{\tfrac{\omega_a^2}{4} + 4g^2\alpha^2} \equiv E ,$$

and the trace of the propagator,

$$Tr\; e^{-\beta\hat{h}_j} = \sum_{j=\pm}\langle j|e^{-\beta\hat{h}_j}|j\rangle = \langle +|e^{-\beta\hat{h}}|+\rangle + \langle -|e^{-\beta\hat{h}}|-\rangle = e^{-\beta E} + e^{\beta E} = 2\cosh\beta E .$$

The partition function is now,

$$Z(\alpha) = Tr\; e^{-\beta\hat{H}} = e^{-\beta\omega_c\alpha^2}\left(Tr\; e^{-\beta\hat{h}_j}\right)^N = e^{-\beta\omega_c\alpha^2}(2\cosh\beta E)^N ,$$

and the free energy,

$$\begin{aligned} F(\alpha) &\equiv -\tfrac{1}{\beta}\ln Z(\alpha) = \omega_c\alpha^2 - \tfrac{N}{\beta}\ln(2\cosh\beta E) \\ &= \omega_c\alpha^2 - \tfrac{N}{\beta}\ln\left(2\cosh\sqrt{\left(\tfrac{\beta\omega_a}{2}\right)^2 + (2\beta g\alpha)^2}\right) . \end{aligned}$$

b. The minimum of the free energy is obtained via,

$$\begin{aligned} 0 \stackrel{!}{=} F'(\alpha) &= 2\omega_c\alpha - N\beta\alpha(2g)^2\frac{\tanh\sqrt{\left(\frac{\beta\omega_a}{2}\right)^2 + (2\beta g\alpha)^2}}{\sqrt{\left(\frac{\beta\omega_a}{2}\right)^2 + (2\beta g\alpha)^2}} \\ &\simeq 2\omega_c\alpha - 2N\beta\alpha(2g)^2\frac{\tanh\beta\omega_a}{\beta\omega_a} , \end{aligned}$$

after a Taylor expansion in α. Hence, resolving for the critical coupling strength g_c,

$$g_c\sqrt{N} = \frac{1}{2}\sqrt{\omega_a\omega_c\coth\tfrac{\beta\omega_a}{2}} .$$

41.2.4.6 Ex: Superradiant lasing

a. Consider the generalized open Dicke model Hamiltonian (41.74) neglecting counter-rotating terms, $g' \equiv 0$, as well as pumping and phase fluctuations of the cavity modes, $\eta = \phi \equiv 0$. Derive the Heisenberg equations for the operators $\hat{a}$, $\hat{s}_j^-$, $\hat{s}_j^z$, $\hat{a}^\dagger\hat{s}_j^-$, $\hat{s}_i^+\hat{s}_j^-$, and $\hat{a}^\dagger\hat{a}$.
b. Calculate the expectation values of the equations of motion for all degrees of freedom and for the products specified in (a) assuming that all atoms are equal. Now, assume that the phase-invariance is not broken, $\langle\hat{a}\rangle = \langle\hat{a}^\dagger\rangle = \langle\hat{s}_1^\pm\rangle = 0$, and apply a

cumulant expansion up to second order.
c. Assuming the system to be in steady state solve the system of equations for the operators and products specified in (a) analytically. Assume $\gamma_1 \ll g \ll \kappa$ and plot $\hat{a}^\dagger\hat{a}$ as a function of the atom number N and the optical pumping rate ξ_1.
d. In which parameter regimes do you observe superradiant lasing?
e. Express $\langle \hat{\mathbf{S}}^2 \rangle$ and $\langle S_z \rangle$ in terms of single particle spin operators.
f. Evaluating $\langle \mathbf{S}^2 \rangle$ and $\langle S_z \rangle$ via the solution of the equations of motion, we find the steady-state quantum numbers always around $M \simeq \pm S$ [341]. Explain how this fact can induce squeezing, once $\langle S_z \rangle > 0$.

Solution: *a. For the specified case the Dicke Hamiltonian is [868, 341],*

$$\hat{H} = -\Delta_c \hat{a}^\dagger\hat{a} - \Delta_a \hat{S}_z + 2g(\hat{a}\hat{S}_+ + \hat{S}_-\hat{a}^\dagger) \ .$$

The equations of motion for the degrees of freedom are simply obtained from (41.75),

$$\begin{aligned}
\dot{\hat{a}} &= (\imath\Delta_c - \kappa)\hat{a} - 2\imath g \Sigma_j \hat{s}_j^- \\
\dot{\hat{s}}_j^- &= (\imath\Delta_a - \gamma_1 - \xi_1 - \beta_1)\hat{s}_j^- + 4\imath g \hat{a}\hat{s}_j^z \\
\dot{\hat{s}}_j^z &= -\gamma_1(\mathbb{I} - 2\hat{s}_j^z) + \xi_1(\mathbb{I} + 2\hat{s}_j^z) - 2\imath g \hat{a}\hat{s}_j^+ + 2\imath g \hat{a}^\dagger \hat{s}_j^- \ .
\end{aligned}$$

For the operator products we get,

$$\begin{aligned}
\frac{d}{dt}(\hat{a}^\dagger\hat{a}) &= \hat{a}^\dagger\dot{\hat{a}} + \dot{\hat{a}}^\dagger\hat{a} \\
&= \hat{a}^\dagger[(\imath\Delta_c - \kappa - \phi)\hat{a} - 2\imath g\Sigma_j \hat{s}_j^-] + [(-\imath\Delta_c - \kappa - \phi)\hat{a}^\dagger + 2\imath g \Sigma_j \hat{s}_j^+]\hat{a} \\
&= 2\kappa \hat{a}^\dagger\hat{a} + 2\imath g \Sigma_j (\hat{s}_j^+\hat{a} - \hat{a}^\dagger \hat{s}_j^-) \ ,
\end{aligned}$$

and,

$$\begin{aligned}
\frac{d}{dt}(\hat{a}^\dagger\hat{s}_j^-) &= \hat{a}^\dagger\dot{\hat{s}}_j^- + \dot{\hat{a}}^\dagger\hat{s}_j^- \\
&= \hat{a}^\dagger\left[(\imath\Delta_a - \gamma_1 - \xi_1 - \beta_1)\hat{s}_j^- + 4\imath g\hat{a}\hat{s}_j^z\right] + \left[(-\imath\Delta_c - \kappa)\hat{a}^\dagger + 2\imath g\Sigma_i \hat{s}_i^+\right]\hat{s}_j^- \\
&= (\imath\Delta_a - \gamma_1 - \xi_1 - \beta_1 - \imath\Delta_c - \kappa)\hat{a}^\dagger\hat{s}_j^- + 2\imath g\left[2\hat{a}^\dagger\hat{a}\hat{s}_j^z + \tfrac{1}{2}(N\mathbb{I} - 2\Sigma_i\hat{s}_z) + \Sigma_{i\neq j}\hat{s}_i^+\hat{s}_j^-\right] \ ,
\end{aligned}$$

and with $i \neq j$,

$$\begin{aligned}
\frac{d}{dt}(\hat{s}_i^+\hat{s}_j^-) &= \hat{s}_i^+\dot{\hat{s}}_j^- + \dot{\hat{s}}_i^+\hat{s}_j^- \\
&= \hat{s}_i^+\left[(\imath\Delta_a - \gamma_1 - \xi_1 - \beta_1)\hat{s}_j^- + 4\imath g\hat{a}\hat{s}_j^z\right] + \left[(-\imath\Delta_a - \gamma_1 - \xi_1 - \beta_1)\hat{s}_i^+ - 4\imath g\hat{s}_i^z\hat{a}^\dagger\right]\hat{s}_j^- \\
&= -2(\gamma_1 + \xi_1 + \beta_1)\hat{s}_i^+\hat{s}_j^- + 4\imath g(\hat{s}_i^+\hat{s}_j^z\hat{a} - \hat{a}^\dagger\hat{s}_i^z\hat{s}_j^-) \ .
\end{aligned}$$

b. The expectation values of the above equations are, assuming that all atoms are equal, $\langle \hat{s}_j \rangle = \langle \hat{s}_1 \rangle$, and setting for simplicity the cavity on resonance with the atoms,

$\Delta_c = \Delta_a = 0$,

$$
\begin{aligned}
\langle \dot{\hat{a}} \rangle &= -\kappa \langle \hat{a} \rangle - 2\imath g N \langle \hat{s}_1^- \rangle = 0 \\
\langle \dot{\hat{s}}_1^- \rangle &= -(\gamma_1 + \xi_1 + \beta_1) \langle \hat{s}_j^- \rangle + 4\imath g \langle \hat{a} \hat{s}_1^z \rangle = 0 \\
\langle \dot{\hat{s}}_1^z \rangle &= \xi_1 - \gamma_1 + 2(\xi_1 + \gamma_1) \langle \hat{s}_1^z \rangle - 4g \Im\mathrm{m}\ \langle \hat{a}^\dagger \hat{s}_1^- \rangle \\
\partial_t \langle \hat{a}^\dagger \hat{a} \rangle &= -2\kappa \langle \hat{a}^\dagger \hat{a} \rangle + 4Ng \Im\mathrm{m}\ \langle \hat{a}^\dagger \hat{s}_1^- \rangle \\
\partial_t \Im\mathrm{m}\ \langle \hat{a}^\dagger \hat{s}_1^- \rangle &= -(\gamma_1 - \xi_1 + \beta_1 + \kappa) \Im\mathrm{m}\ \langle \hat{a}^\dagger \hat{s}_j^- \rangle + 2g[2\langle \hat{s}_j^z \hat{a}^\dagger \hat{a} \rangle + \tfrac{1}{2}(N - 2\Sigma_i \langle \hat{s}_z \rangle) + (N-1)\langle \hat{s}_2^+ \hat{s}_1^- \rangle] \\
\partial_t \langle \hat{s}_2^+ \hat{s}_1^- \rangle &= -2(\gamma_1 + \xi_1 + \beta_1) \langle \hat{s}_2^+ \hat{s}_1^- \rangle + 4\imath g (\langle \hat{s}_2^+ \hat{a} \hat{s}_1^z \rangle - \langle \hat{s}_2^z \hat{a}^\dagger \hat{s}_1^- \rangle) \ .
\end{aligned}
$$

Now we apply the cumulant expansion (41.84) setting $\langle \hat{a} \rangle = \langle \hat{a}^\dagger \rangle = \langle \hat{s}_1^\pm \rangle = 0$ *and neglecting third-order correlations, e.g.* $\langle \hat{s}_i^z \hat{s}_i^+ \hat{s}_j^- \rangle = 0$. *That is,*

$$
\langle \hat{s}_j^z \hat{a}^\dagger \hat{a} \rangle_c = \langle \hat{s}_j^z \rangle \langle \hat{a}^\dagger \hat{a} \rangle_c \qquad \textit{and} \qquad \langle \hat{s}_i^z \hat{s}_j^+ \hat{a} \rangle_c = \langle \hat{s}_i^z \rangle \langle \hat{s}_j^+ \hat{a} \rangle_c \ .
$$

c. Postulating the system to be in steady state we set all derivatives $= 0$. *Then above system of equations can then be solved analytically. If* $N \simeq N - 1$,

$$
\begin{aligned}
4g \Im\mathrm{m}\ \langle \hat{a}^\dagger \hat{s}_1^- \rangle_c &= \xi_1 (1 - 2\langle \hat{s}_1^z \rangle) - \gamma_1 (1 + 2\langle \hat{s}_1^z \rangle) \\
2Ng \Im\mathrm{m}\ \langle \hat{a}^\dagger \hat{s}_1^- \rangle_c &= \kappa \langle \hat{a}^\dagger \hat{a} \rangle_c \\
(\beta_1 + \kappa + \xi_1 + \gamma_1) \Im\mathrm{m}\ \langle \hat{a}^\dagger \hat{s}_1^- \rangle_c &= g \left[1 + 2(1 + 2\langle \hat{a}^\dagger \hat{a} \rangle_c) \langle \hat{s}_1^z \rangle + 2N \langle \hat{s}_2^+ \hat{s}_1^- \rangle_c \right] \\
8g \langle \hat{s}_1^z \rangle_c \Im\mathrm{m}\ \langle \hat{a}^\dagger \hat{s}_1^- \rangle_c &= 2(\xi_1 + \beta_1 + \gamma_1) \langle \hat{s}_1^+ \hat{s}_2^- \rangle_c \ .
\end{aligned}
$$

Introducing the abbreviations $d_0 \equiv \frac{\xi_1 - \gamma_1}{\xi_1 + \gamma_1}$ *and* $n_c \equiv \frac{\kappa}{2Ng} \langle \hat{a}^\dagger \hat{a} \rangle_c$,

$$
\begin{aligned}
\Im\mathrm{m}\ \langle \hat{a}^\dagger \hat{s}_1^- \rangle_c &= n_c \qquad \textit{from (ii)} \\
2\langle \hat{s}_1^z \rangle &= d_0 - \frac{4g}{\xi_1 + \gamma_1} n_c \qquad \textit{from (i)} \\
\langle \hat{s}_1^+ \hat{s}_2^- \rangle_c &= \frac{4g}{\xi_1 + \beta_1 + \gamma_1} \langle \hat{s}_1^z \rangle_c \Im\mathrm{m}\ \langle \hat{a}^\dagger \hat{s}_1^- \rangle_c \\
&= \frac{2g}{\xi_1 + \beta_1 + \gamma_1} \left(d_0 - \frac{4g}{\xi_1 + \gamma_1} n_c \right) n_c \qquad \textit{from (iv)} \\
\frac{\beta_1 + \kappa + \xi_1 + \gamma_1}{g} n_c &= 1 + 2 \left(1 + 2 \frac{2Ng}{\kappa} n_c \right) \langle \hat{s}_1^z \rangle + 2N \langle \hat{s}_2^+ \hat{s}_1^- \rangle_c \qquad \textit{from (iii)} \ .
\end{aligned}
$$

Inserting the first three expressions into the last equation,

$$
0 = -\frac{\beta_1 + \kappa + \xi_1 + \gamma_1}{g} n_c + 1 + \left(1 + \frac{4Ng}{\kappa} n_c + \frac{4Ng}{\xi_1 + \beta_1 + \gamma_1} n_c \right) \left(d_0 - \frac{4g}{\xi_1 + \gamma_1} n_c \right) \ ,
$$

we obtain a quadratic equation in n_c, *namely* $0 = An_c^2 + Bn_c + C$, *with the coefficients,*

$$
\begin{aligned}
A &= -\frac{16Ng^2}{\xi_1 + \gamma_1} \left(\frac{1}{\kappa} + \frac{1}{\xi_1 + \beta_1 + \gamma_1} \right) \\
B &= -\frac{\beta_1 + \kappa + \xi_1 + \gamma_1}{g} - \frac{4g}{\xi_1 + \gamma_1} + 4Ngd_0 \left(\frac{1}{\kappa} + \frac{1}{\xi_1 + \beta_1 + \gamma_1} \right) \\
C &= 1 + d_0 \ .
\end{aligned}
$$

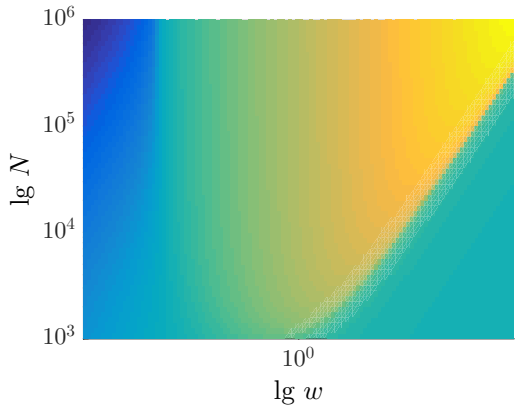

Figure 41.13: Superradiant lasing for the parameters $g = (2\pi)\ 3\,\mathrm{Hz}$, $\kappa = (2\pi)\ 150\,\mathrm{kHz}$, $\gamma_1 = (2\pi)\ 1.6\,\mathrm{mHz}$, $\beta_1 = (2\pi)\ 0.16\,\mathrm{Hz}$, and $\Delta_c = \Delta_a$.

Fig. 41.13 plots the intracavity photon number $\hat{a}^\dagger\hat{a}$ as a function of the atom number N and the optical pumping rate ξ_1. d. The superradiant laser spectrum can be calculated as the Fourier transform of the first-order correlation from,

$$\frac{d}{dt}[\hat{a}^\dagger(t)\hat{a}(0)] = \left[-\kappa\hat{a}^\dagger(t) + 2\imath g\Sigma_j \hat{s}_j^+(t)\right]\hat{a}(0)$$
$$\frac{d}{dt}[\hat{s}_j^+(t)\hat{a}(0)] = \left[-\beta_1\hat{s}_j^+(t) - 4\imath g\hat{s}_j^z(t)\hat{a}^\dagger(t) + 2\gamma_1\hat{s}_j^+(t)\hat{s}_j^z(t) - 2\xi_1\hat{s}_j^z(t)\hat{s}_j^+(t)\right]\hat{a}(0)\ .$$

Neglecting higher than second-order correlations, we get the expectation values,

$$\frac{d}{dt}\begin{pmatrix}\langle\hat{a}^\dagger(t)\hat{a}(0)\rangle\\ \langle\hat{s}_j^+(t)\hat{a}(0)\rangle\end{pmatrix} \simeq \begin{pmatrix}-\kappa & 2\imath Ng\\ -4\imath g\langle\hat{s}_j^z(t)\rangle & -\beta_1 - 2\gamma_1 - 2\xi_1\end{pmatrix}\begin{pmatrix}\langle\hat{a}^\dagger(t)\hat{a}(0)\rangle\\ \langle\hat{s}_j^+(t)\hat{a}(0)\rangle\end{pmatrix}\ .$$

e. We find,

$$\mathbf{S}^2 = \tfrac{1}{4}\sum_{i,j=1}^{N}\hat{\vec{\sigma}}_i\cdot\hat{\vec{\sigma}}_j = \tfrac{1}{4}\sum_{j=1}^{N}\hat{\vec{\sigma}}_j^2 + \tfrac{1}{4}\sum_{i\neq j}^{N}(\hat{\sigma}_i^x\hat{\sigma}_j^x + \hat{\sigma}_i^y\hat{\sigma}_j^y + \hat{\sigma}_i^z\hat{\sigma}_j^z)$$
$$= \tfrac{N}{4}\hat{\vec{\sigma}}_1^2 + \tfrac{1}{4}\sum_{i\neq j}^{N}[(\hat{\sigma}_i^+ + \hat{\sigma}_i^-)(\hat{\sigma}_j^+ + \hat{\sigma}_j^-) - (\hat{\sigma}_i^+ - \hat{\sigma}_i^-)(\hat{\sigma}_j^+ - \hat{\sigma}_j^-) + \hat{\sigma}_i^z\hat{\sigma}_j^z]$$
$$= \tfrac{N}{4}\left[(\hat{\sigma}^x)^2 + (\hat{\sigma}^y)^2 + (\hat{\sigma}^z)^2\right] + \tfrac{1}{4}\sum_{i\neq j}^{N}(4\hat{\sigma}_i^-\hat{\sigma}_j^+ + \hat{\sigma}_i^z\hat{\sigma}_j^z) = \tfrac{N}{4}3I + \sum_{i\neq j}^{N}(\hat{s}_i^-\,\hat{s}_j^+ + \hat{s}_i^z\hat{s}_j^z)\ .$$

Hence,

$$S(S+1) = \langle\mathbf{S}^2\rangle = \tfrac{3N}{4} + \sum_{i\neq j}^{N}\langle\hat{s}_i^-\,\hat{s}_j^+\rangle + \langle\hat{s}_i^z\hat{s}_j^z\rangle \qquad \textit{and} \qquad M = \langle S_z\rangle = \sum_{j=1}^{N}\langle\hat{s}_j^z\rangle\ .$$

Evaluating $\langle\mathbf{S}^2\rangle$ and $\langle S_z\rangle$ via the solution of the equations of motion, we the steady-state quantum numbers always around $M \simeq \pm S$ [341].

f. Upon superradiant lasing [1429, 341] finds strong optical pumping to subradiant states, in particular $|S,\pm S\rangle$. This is similarly to [263], only that the interatomic coupling is mediated by a cavity rather than interatomic interaction. Assuming the bulk part of the population in $|S,\pm S\rangle$ we may simplify the problem. From,

$$\hat{S}_\pm|S,M\rangle = \sqrt{S(S+1)-M(M\pm 1)}|S,M\pm 1\rangle$$

for dominating subradiant states $|S_{\simeq|M|},M\rangle$ for $M\simeq S\geq 0$,

$$\hat{S}_+|S,M\rangle = 0 \quad \textit{and} \quad \hat{S}_-|S,M\rangle = \sqrt{|M|(|M|+1)-M(M-1)}|S,M{-}1\rangle \simeq \sqrt{2S}|S,M{-}1\rangle \ ,$$

and for $M\simeq -S\leq 0$

$$\hat{S}_-|S,M\rangle = 0 \quad \textit{and} \quad \hat{S}_+|S,M\rangle = \sqrt{|M|(|M|+1)-M(M+1)}|S,M{+}1\rangle \simeq \sqrt{2S}|S,M{+}1\rangle \ .$$

That is, when the atoms are individually pumped to $M=-S\leq 0$ states $|S,-S\rangle$, subsequent coherent coupling may only drive transitions to higher states $|S,S+1\rangle$. Hence, we may define a Holstein-Primakoff approximation using $|S,-S\rangle$ as the ground state from which higher-lying oscillator states can be reached via creation operators,

$$\hat{S}_+ = \sqrt{2S}\hat{b}^\dagger \ .$$

In contrast, when the atoms are individually pumped to $M=S\geq 0$ states $|S,S\rangle$ subsequent coherent coupling may only drive transitions to lower states $|S,S-1\rangle$, so that the corresponding Holstein-Primakoff approximation uses $|S,S\rangle$ as the ground state from which lower-lying oscillator states can be reached via creation operators,

$$\hat{S}_- = \sqrt{2S}\hat{b}^\dagger \ .$$

Therefore, the Hamiltonian can be simplified as,

$$\hat{H} = g(\hat{a}^\dagger\hat{S}_- + \hat{a}\hat{S}_+) = \begin{cases} g(\hat{a}^\dagger\hat{b}^\dagger + \hat{a}\hat{b}) & \textit{for } M\geq 0 \\ g(\hat{a}^\dagger\hat{b} + \hat{a}\hat{b}^\dagger) & \textit{for } M\leq 0 \end{cases}$$

For $M\geq 0$ the Hamiltonian describes squeezing.

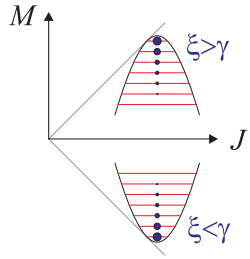

Figure 41.14: Illustration of the normal (below) and inverted (above) population of the harmonic oscillator levels in the Holstein Primakoff approximation (see also Sec. 36.2.4).

41.2.4.7 Ex: Superradiant lasing and the Schawlow-Townes limit

Discuss whether superradiant lasing beats the Schawlow-Townes limit.

Solution:

41.2.4.8 Ex: Heisenberg equation for the open Dicke model in the Holstein-Primakoff approximation

Derive the Heisenberg equations for the open Dicke model in the Holstein-Primakoff approximation.

Solution: *Starting from the Hamiltonian,*

$$\hat{H}_{HP} = -\Delta_c \hat{a}^\dagger \hat{a} - \Delta_a \hat{b}^\dagger \hat{b} + 2g_N(\hat{a} + \hat{a}^\dagger)(\hat{b} + \hat{b}^\dagger)$$

we readily derive,

$$\dot{\hat{a}} = \imath\Delta_c \hat{a} - 2\imath g_N(\hat{b} + \hat{b}^\dagger) \qquad \textit{and} \qquad \dot{\hat{b}} = \imath\Delta_a \hat{b} - 2\imath g_N(\hat{a} + \hat{a}^\dagger) \ .$$

41.3 Interacting atoms

When two atoms excited to an internal level of energy hc/λ are so close together that the range of their dipole moments overlap without forming a molecular bonding, $a_B \ll R \ll \lambda$, they may exhibit cooperative relaxation. The atoms are coupled via the radiation that they are susceptible to emit into the same continuum. The coupled atomic dipoles oscillate and decay in phase. The decays is accelerated one leads to an intense burst of coherent and spatially directional radiation. This phenomenon is termed *superradiance* [366, 1085]. We may view superradiance as destructive interference of the dipolar radiation patterns of all atoms in all but one direction of space triggered by the first spontaneous decay. The superradiant enhancement is largest when half of the atoms are deexcited. The correlated atoms can be in a Dicke state (then the total dipole moment is always zero) or in a product state (then the net dipole moment is non-zero at half-deexcitation). In the second case, we also talk about *superfluorescence*. In this case, an excited initially incoherent sample develops correlations due to the emission process. One can also imagine the case that the emission patterns pairwise cancel, and the decay is thus inhibited. This is called *subradiance*. Superradiance has been used in the microwave domain as a spectroscopic method in the observation of photon echoes.

Correlated quantum jumps are, in a sense, the few-atoms precursors of superradiance. Accelerated spontaneous decay has been predicted for atoms whose distance is shorter than the wavelength of the decaying transition [1174, 797]. Super- and subradiance has been observed in a system of two ion trapped in a Paul trap [364].

41.3.1 Rydberg blockade

Rydberg atoms (i.e. atoms in excited Rydberg states) exhibit huge polarizabilities inducing large interaction energies even at relatively modest densities. These can be so strong, that the presence of a single Rydberg-excited atom can drive out of resonance the frequencies of transitions connected to the Rydberg state for several neighboring atoms once the exciting laser is sufficiently narrow-band. This effect called *Rydberg blockade* can be described by the following interaction Hamiltonian [1110, 1243],

$$\hat{H}_{Rydberg} = \sum_{i>j} \kappa_{ij} \tfrac{1}{2}(\hat{\sigma}_i^z - 1)\tfrac{1}{2}(\hat{\sigma}_j^z - 1) \qquad \text{with} \qquad \kappa_{ij}/2\pi = \frac{C_6}{r_{ij}^6} \,, \tag{41.85}$$

where $\frac{1}{2}(\hat{\sigma}_i^z - 1) = |e\rangle_i\langle e|$ is the probability of finding the i-th atom in an excited state and C_6 interatomic van der Waals interaction coefficient of the transition.

Example 256 (*Two interacting Rydberg atoms*): In this example we study Rydberg blockade for two interacting Rydberg atoms. In this case, the Hamiltonian can be cast into the matrix form,

$$\hat{H} = -\Delta_a \hat{S}_z + \Omega \hat{S}_+ + \Omega^* \hat{S}_- + \hat{H}_{Rydberg} = \begin{pmatrix} \Delta_a & \frac{1}{2}\Omega & \frac{1}{2}\Omega^* & 0 \\ \frac{1}{2}\Omega^* & 0 & 0 & \frac{1}{2}\Omega^* \\ \frac{1}{2}\Omega & 0 & 0 & \frac{1}{2}\Omega \\ 0 & \frac{1}{2}\Omega & \frac{1}{2}\Omega^* & -\Delta_a + \kappa_{12} \end{pmatrix} .$$

The master equation can be numerically solved using the procedure outlined in example 257. The result of such a simulation is shown in Fig. 41.15. Comparing

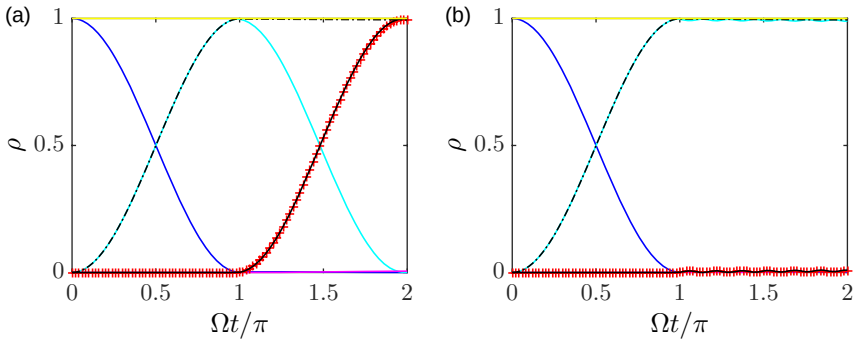

Figure 41.15: (code) Populations in a system of two two-level atoms interaction via van der Waals forces. Initially ($\Omega t < \pi$) only one atom is driven, after that only the other. We assume $\Omega \gg \Gamma$ and $C_6 = 4 \cdot 10^7$. The interatomic distance is (a) $kr_{12} = 0.5$, respectively, (a) $kr_{12} = 5$. (blue) $\rho_{11,11}$, (cyan) $\rho_{12,12}$, (magenta) $\rho_{21,21}$, (red) $\rho_{22,22}$, (black dotted) $\rho_{22}^{(1)}$, and (black) $\rho_{22}^{(2)}$.

the evolutions calculated in Fig. 41.15 for large and small interatomic distances, we see that the excitation of the first atom impedes the excitation of the second one when the interaction is strong.

Note, that an interesting situation occurs when the coupling is completely uniform (e.g. mediated by a cavity), $\kappa_{ij} \simeq \kappa$,

$$\hat{H}_{Rb} \simeq \tfrac{1}{8}\kappa(\hat{S}_z^2 - 2\hat{S}_z + 1) \ , \tag{41.86}$$

as pointed out in Eq. (41.52). Such Hamiltonians may be interesting for the generation of spin-squeezing.

41.3.2 Dipole-dipole interactions in the non-linear optics regime

The mean-field Dicke model totally neglects interactions between the atoms due to the exchange of real or virtual photons, i.e. neither resonant dipole-dipole interactions nor van der Waals interactions are considered [50, 137, 383, 416, 1099, 1110, 1197]. That is, interaction terms such as,

$$\hat{H}_{Ising} = -\sum_{i,j\neq i}^{N} \Delta_{ij}\hat{\sigma}_j^+\hat{\sigma}_i^- \tag{41.87}$$

are absent from the Hamiltonian. Spin-spin interactions are studied in the so-called *Ising model*, which is interesting in the context of (anti-)*ferromagnetism* [479, 480, 499, 723, 1434]. The negligence of interaction was, of course, the reason for the simplicity of the Dicke model and its manageability for large atom numbers. On the other hand, in Sec. 39.1.2 we have studied dipole-dipole interactions in the linear optics regime allowing for at most a single photon to interact with the cloud.

In this section, we will consider dipole-dipole interactions in very small dilute clouds interacting with an arbitrary number of photons. The possibility for the cloud of storing as many photons as there are atoms is common to the Dicke model. Here, we will call it the *non-linear optics* regime, as several photons may team up to excite higher Dicke excitations states. In particular, we will study two interacting atoms as done by the milestone experiment of DeVoe and Brewer [364]. Do the Exc. 41.3.4.1.

The starting point is the collective many-atoms Hamiltonian (39.9) of the scalar coupled dipoles model. After tracing over the vacuum modes, one obtains the master equation [15] [1090],

$$\boxed{\begin{aligned}
\hat{H} &= \tfrac{1}{2}\textstyle\sum_j \left[\Omega(\mathbf{r}_j)\hat{\sigma}_j^+ + h.c.\right] - \sum_{i,j}\Delta_{ji}\hat{\sigma}_j^+\hat{\sigma}_i^- \\
\mathcal{L}[\hat{\rho}] &= \tfrac{1}{2}\textstyle\sum_{i,j}\Gamma_{ij}\left(2\hat{\sigma}_j^-\hat{\rho}\hat{\sigma}_i^+ - \hat{\sigma}_i^+\hat{\sigma}_j^-\hat{\rho} - \hat{\rho}\hat{\sigma}_i^+\hat{\sigma}_j^-\right) \\
\mathcal{L}^\dagger[\hat{A}] &= \tfrac{1}{2}\textstyle\sum_{i,j}\Gamma_{ij}\left(2\hat{\sigma}_i^+\hat{A}\hat{\sigma}_j^- - \hat{\sigma}_i^+\hat{\sigma}_j^-\hat{A} - \hat{A}\hat{\sigma}_i^+\hat{\sigma}_j^-\right) \\
\Delta_{i\neq j} &\equiv -\tfrac{3\lambda\Gamma}{2}\,\hat{\mathbf{e}}_d^*\,\mathfrak{Re}\,G(\mathbf{r}_i,\mathbf{r}_j,\omega_0)\,\hat{\mathbf{e}}_d \quad \text{and} \quad \Delta_{jj}\equiv\Delta_a \\
\Gamma_{i\neq j} &\equiv 3\lambda\Gamma\,\hat{\mathbf{e}}_d^*\,\mathfrak{Im}\,G(\mathbf{r}_i,\mathbf{r}_j,\omega_0)\,\hat{\mathbf{e}}_d \quad \text{and} \quad \Gamma_{jj}\equiv\Gamma
\end{aligned}} \tag{41.88}$$

The expression for the line shifts Δ_{ij} and the decay rates Γ_{ij} have been derived in Sec. 40.4.1 from the bulk Green's tensor in free space. Assuming $\Delta_{ji} = 0 = \Gamma_{ji}$

[15] In return, the equations of motion (39.26) for the excitation amplitude should follow as the Heisenberg equation with the above Hamiltonian.

and $\Omega(\mathbf{r}_j) = \Omega$ we recover the mean-field Dicke model, where interaction terms are completely neglected,

$$\hat{H} = \tfrac{1}{2}\Omega \sum_j (\hat{\sigma}_j^+ + h.c.) - \Delta_a \sum_j \hat{\sigma}_j^+ \hat{\sigma}_j^- \ . \tag{41.89}$$

With (41.88) we set up either the master or the Heisenberg-Liouville equations,

$$\begin{aligned} \dot{\hat{\rho}} &= -\imath[\hat{H}, \hat{\rho}] + \mathcal{L}[\hat{\rho}] \\ \dot{\hat{A}} &= -\imath[\hat{A}, \hat{H}] + \mathcal{L}^\dagger[\hat{A}] \ . \end{aligned} \tag{41.90}$$

Note that in principle, the collective many-atom system (41.88) can be mapped to a single-atom multilevel system,

$$\frac{d}{dt}\vec{\hat{\varrho}} = \mathcal{M}\vec{\varrho} \ , \tag{41.91}$$

which is more amenable to numeric simulation using the methods presented in Sec. 34.7. However, analytically this is only simple to do in the case of two atoms, which can be mapped to a four-level system. This will be shown in Exc. 41.3.4.2.

Example 257 (*Diagonalizing collective decay*): The Lindbladian describing collective decay in (41.88) can be recast into a standard form by diagonalizing the real matrix $\mathbf{\Gamma} \equiv (\Gamma_{ij})$ [1090], that is, we define a unitary transformation $T = (T^\intercal)^{-1} \equiv (T_{jk})$,

$$D = T^\intercal \mathbf{\Gamma} T \Longrightarrow \tilde{\Gamma}_k \delta_{kj} = \sum_j T^\intercal_{ik} \Gamma_{ij} T_{jk}$$

$$\text{or} \qquad \mathbf{\Gamma} = T D T^\intercal \Longrightarrow \Gamma_{ij} = \sum_k T_{jk} \tilde{\Gamma}_k \delta_{kj} T^\intercal_{jk} \ .$$

Note that all coefficients not ornamented by a 'hat' can be moved around freely. Now, substituting the Γ_{ij},

$$\mathcal{L}[\hat{\rho}] = \tfrac{1}{2} \sum_{k,i,j} \left[2\hat{\sigma}_i^- T_{ik} \tilde{\Gamma}_k \delta_{ki} T^\intercal_{jk} \hat{\rho} \hat{\sigma}_j^+ - \hat{\sigma}_i^+ T_{ik} \tilde{\Gamma}_k \delta_{ki} T^\intercal_{jk} \hat{\sigma}_j^- \hat{\rho} - \hat{\rho} \hat{\sigma}_i^+ T_{ik} \tilde{\Gamma}_k \delta_{ki} T^\intercal_{jk} \hat{\sigma}_j^- \right] \ .$$

Now, defining new composite decay channels,

$$\hat{\Pi}_k^- = \sum_j T_{kj} \hat{\sigma}_j^- \qquad , \qquad \hat{\Pi}_k^+ = \sum_j \hat{\sigma}_j^+ T^\intercal_{kj} \ ,$$

we find,

$$\mathcal{L}[\hat{\rho}] = \tfrac{1}{2} \sum_k \tilde{\Gamma}_k [2\hat{\Pi}_k^+ \hat{\rho} \hat{\Pi}_k^- - \hat{\Pi}_k^+ \hat{\Pi}_k^- \hat{\rho} - \hat{\rho} \hat{\Pi}_k^+ \hat{\Pi}_k^-] \ .$$

Single-atom spontaneous emission simply follows from the assumption that $\Gamma_{ij} = \Gamma_1 \delta_{ij}$,

$$\mathcal{L}[\rho] = \tfrac{1}{2} \sum_j \Gamma [2\hat{\sigma}_j^- \hat{\rho} \hat{\sigma}_j^+ - \hat{\sigma}_j^+ \hat{\sigma}_j^- \hat{\rho} - \hat{\rho} \hat{\sigma}_j^+ \hat{\sigma}_j^-] \ .$$

On the other hand, Dicke superradiance follows from the assumption that $\Gamma_{ij} = \Gamma$. Introducing the collective spin operator, $\hat{S}^\pm \equiv \sum_j \hat{\sigma}_j^\pm$,

$$\begin{aligned} \mathcal{L}[\rho] &= \tfrac{1}{2} \sum_{i,j} \Gamma [2\hat{\sigma}_i^- \hat{\rho} \hat{\sigma}_j^+ - \hat{\sigma}_i^+ \hat{\sigma}_j^- \hat{\rho} - \hat{\rho} \hat{\sigma}_i^+ \hat{\sigma}_j^-] \\ &= \tfrac{1}{2} \Gamma [2\hat{S}^- \hat{\rho} \hat{S}^+ - \hat{S}^+ \hat{S}^- \hat{\rho} - \hat{\rho} \hat{S}^+ \hat{S}^-] \ . \end{aligned}$$

The uniform all-to-all coupling required for Dicke superradiance can be realized, when the atoms are localized in an area of space smaller than λ^3 or in a cavity.

41.3.2.1 Equations of motion in the presence of dipole-dipole coupling

We start from the Hamiltonian and jump operators (41.88) and derive the Heisenberg-Liouville equation (41.90),

$$\begin{aligned}\dot{\hat{\sigma}}_k^- &= -\imath[\hat{\sigma}_k^-, \hat{H}] + \mathcal{L}[\hat{\sigma}_k^-] \\ &= \tfrac{\imath}{2}\Omega(\mathbf{r}_k)\hat{\sigma}_k^z - \imath\Delta_a\hat{\sigma}_k^z\hat{\sigma}_k^- - \imath\sum_{j\neq k}^{N}\Delta_{kj}\hat{\sigma}_k^z\hat{\sigma}_j^- + \tfrac{\Gamma}{2}\hat{\sigma}_k^z\hat{\sigma}_k^- + \sum_{j\neq k}^{N}\tfrac{\Gamma_{kj}}{2}\hat{\sigma}_k^z\hat{\sigma}_j^- \ .\end{aligned} \tag{41.92}$$

Now, we assume low atomic excitation, $\langle\hat{\sigma}_k^z\rangle \simeq -1$, that is, most atoms are in the ground state. Then we may neglect correlations and find,

$$\dot{\hat{\sigma}}_k^- \simeq \left(\imath\Delta_a - \tfrac{\Gamma}{2}\right)\hat{\sigma}_k^- - \tfrac{\imath}{2}\Omega(\mathbf{r}_k) + \sum_{j\neq k}^{N}\left(\imath\Delta_{kj} - \tfrac{\Gamma_{kj}}{2}\right)\hat{\sigma}_j^- \tag{41.93}$$

or taking the expectation values,

$$\boxed{\dot{\beta}_k \simeq \left(\imath\Delta_a - \tfrac{\Gamma}{2}\right)\beta_k - \tfrac{\imath}{2}\Omega(\mathbf{r}_k) + \sum_{j\neq k}^{N}\left(\imath\Delta_{kj} - \tfrac{\Gamma_{kj}}{2}\right)\beta_j} \ . \tag{41.94}$$

These are just the equations of motion of the coupled dipoles model derived in Sec. 39.1.2. Evaluation of the coeffficients (41.88)(iv-v) yields the exponential kernel postulated in (39.29).

In Exc. 41.3.4.3 we derive them from the linear optics scalar coupled dipoles model,

$$\Delta_{j\neq i} \equiv -\frac{\Gamma\cos kr_{ji}}{kr_{ji}} \qquad \text{and} \qquad \Gamma_{j\neq i} \equiv \frac{\Gamma\sin kr_{ji}}{kr_{ji}} \tag{41.95}$$

with $r_{ji} = |\mathbf{r}_j - \mathbf{r}_i|$. These terms arise from the so-called scalar approximation of (40.338), where we neglect $1/R^2$ and $1/R^3$ terms and set $(\hat{\mathbf{e}}_d \cdot \hat{\mathbf{e}}_R) = 0$.

Example 258 (*Two atoms with dipole-dipole interactions*): For the case of only two atoms located at $\mathbf{r}_j$, using the basis defined in (25.75), we find the Hamiltonian [263],

$$\hat{H} = \begin{pmatrix} 0 & \frac{1}{2}\Omega^*(\mathbf{r}_2) & \frac{1}{2}\Omega^*(\mathbf{r}_1) & 0 \\ \frac{1}{2}\Omega(\mathbf{r}_2) & -\Delta_a & \frac{1}{2}\Delta_{21} & \frac{1}{2}\Omega^*(\mathbf{r}_1) \\ \frac{1}{2}\Omega(\mathbf{r}_1) & \frac{1}{2}\Delta_{12} & -\Delta_a & \frac{1}{2}\Omega^*(\mathbf{r}_2) \\ 0 & \frac{1}{2}\Omega(\mathbf{r}_1) & \frac{1}{2}\Omega(\mathbf{r}_2) & -2\Delta_a \end{pmatrix} , \tag{41.96}$$

with $\Omega(\mathbf{r}) = \Omega_0 e^{\imath\mathbf{k}\cdot\mathbf{r}_j}$. For two atoms the master equations (41.88) can easily be solved numerically by setting [16],

$$\hat{\sigma}_1^{\pm} = \hat{\sigma}^{\pm} \otimes \mathbb{I} \qquad \text{and} \qquad \hat{\sigma}_2^{\pm} = \mathbb{I} \otimes \hat{\sigma}^{\pm} \ , \tag{41.97}$$

as usual and,

$$\langle i, j|\hat{\rho}|m, n\rangle = \rho_{ij,mn} \ , \tag{41.98}$$

[16] Remember, that the formal solution of coherent part of the master equation can be written as $\hat{\rho}(t) = \mathcal{L}(t)\hat{\rho}(0) = e^{-\imath\hat{H}t}\hat{\rho}(0)e^{\imath\hat{H}t}$.

where the indices $i, m = 1, 2$ refer to the first atom and the indices $j, n = 1, 2$ to the second. The populations of the Dicke states $|11\rangle$, $|12\rangle$, $|21\rangle$, and $|22\rangle$ are then given by $\rho_{ij,ij}$, and the populations of the (anti-)symmetric states $|\psi\rangle^{(s,a)} = \frac{1}{\sqrt{2}}(|1,2\rangle \pm |2,1\rangle)$ are calculated via,

$$\langle\psi|^{(s,a)}\hat{\rho}|\psi\rangle^{(s,a)} = \tfrac{1}{2}(\rho_{12,12} \pm \rho_{12,21} \pm \rho_{21,12} + \rho_{21,21}) \ . \tag{41.99}$$

The temporal evolution of the populations in one and two atom systems, initially driven by a laser field which is then suddenly switched off, is shown in Fig. 41.16. Note that super and subradiance do occur for $\Delta_{12} = 0 = \Delta_a$ but necessitate $\Gamma_{ij} \neq 0$.

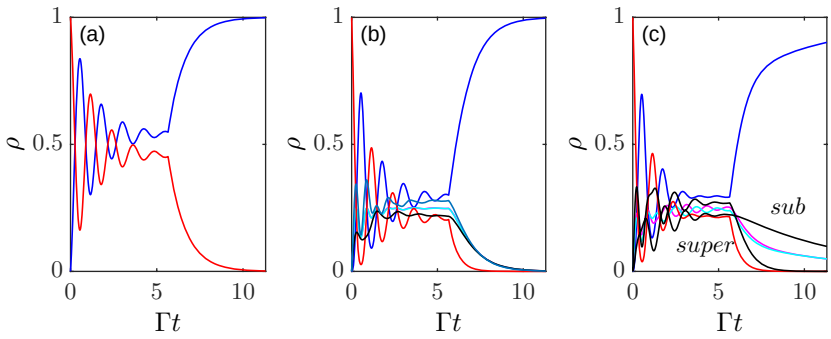

Figure 41.16: (code) (a) Response of a single two-level atom driven by a laser light with $\Omega = 5\Gamma$, $\Delta = -\Gamma$. The curves show (blue) the ground state and (red) the excited state populations. The light is switched off at $\Gamma t = 0.5$. (b) Response of two atoms $j = 1, 2$ located at $kz_j = \pm 5$ driven by the same laser light as in (a). (cyan and magenta) populations of the states $|eg\rangle$ and $|ge\rangle$. The two black lines show the populations of the (anti-)symmetric states $\frac{1}{\sqrt{2}}(|eg\rangle \pm |ge\rangle)$. (c) Same as (c) but with $kz_j = \pm 0.5$.

In Excs. 41.3.4.4 to 41.3.4.6 we study the impact of dipole-dipole interactions on super- and subradiance. In Exc. 41.3.4.7 we study three interacting two-level atoms, and in Exc. 41.3.4.8 we study two non-interacting three-level atoms.

Example 259 (*Blackbody radiation-induced superradiance*): In Exc. 34.6.7.9 we studied blackbody radiation-induced transitions in a single atom. The procedure can be generalized to several atoms [1359]. For two atoms the Liouvillean reads,

$$\begin{aligned}\dot{\hat{\rho}} &= \mathcal{L}_{bb}\hat{\rho} \\ &= -\tfrac{1}{2}\sum_{i,j=1,2}\Gamma_{ij}\left([\hat{\rho}\hat{\sigma}_i, \hat{\sigma}_j^\dagger] + [\hat{\sigma}_i, \hat{\sigma}_j^\dagger\hat{\rho}]\right) - \tfrac{1}{2}\sum_{i,j=1,2}(\Gamma_{ij} + \gamma\delta_{ij})\left([\hat{\rho}\hat{\sigma}_j^\dagger, \hat{\sigma}_i] + [\hat{\sigma}_j^\dagger, \hat{\sigma}_i\hat{\rho}]\right) \ ,\end{aligned}$$

with $\Gamma_{ij}\delta(t-t') \propto \langle\hat{E}_i(t)\hat{E}_j(t')\rangle$ containing both the real and the virtual photon exchange.

41.3.3 Cavity-mediated spin-exchange interactions

In the preceding sections we got to know two fundamentally different types of interatomic interactions, that is, Rydberg and dipole-dipole type interactions. Both are

generally nearest neighbor interactions and thus inhomogeneous. Let us nevertheless make the assumption of uniform coupling to simplify the discussion. Then the Rydberg blockade term (41.85) reads,

$$\hat{H} = \tfrac{1}{2}\sum_{i\neq j}\kappa_{ij}\hat{\sigma}_j^z\hat{\sigma}_i^z \simeq \kappa\hat{S}_z^2 \ , \tag{41.100}$$

and the Ising interaction term (41.87) becomes,

$$\hat{H}_{Ising} = -\sum_{i\neq j}\Delta_{ij}\hat{\sigma}_j^+\hat{\sigma}_i^- \simeq -\Delta_{Ising}\hat{S}_+\hat{S}_- \ . \tag{41.101}$$

A way of achieving uniform coupling consists in coupling all atoms with the same strength to the same cavity mode. This is what we will discuss in the next subsection. Do the Exc. 41.3.4.9.

In the full open system Dicke model κ and, Γ_1 describe physical processes, namely cavity decay and atomic spontaneous emission, while Γ is introduced as a mere collective decay rate, not rooted in a physical process. In reality, collective decay processes may be caused by interatomic contact interactions, but as we will see in the following, they can also be induced by coupling of the atoms to a common light mode.

Indeed, in the bad cavity limit, upon adiabatic elimination of the light mode, the cavity parameters Δ_c and κ are replaced by U_c and κ_c, which take over the role of a collective shift and decay process. This is seen in the Hamiltonian and the Lindbladian, after adiabatic elimination of the light mode, by the fact that the terms depending on κ_c have exactly the same structure as those for which collective decay at a rate Γ had been postulated in the full open Dicke model.

The systems do not differ in concept, but only in details: uniform coupling versus nearest neighbors, inhomogeneities of the light field versus disordered clouds, etc..

41.3.3.1 Adiabatic elimination of the modes of a bad high-finesse cavity

The collective Jaynes-Cummings Hamiltonian for a linear cavity (see Exc. 40.2.9.5),

$$\hat{H}_{JC} = -\Delta_c\hat{a}^\dagger\hat{a} - \imath\eta(\hat{a}-\hat{a}^\dagger) + \sum_{i=1}^{N}\left[-\tfrac{\Delta_a}{2}(\mathbb{I}_2+\hat{\sigma}_i^z) + g\sin kz_i(\hat{\sigma}_i^+\hat{a}+\hat{a}^\dagger\hat{\sigma}_i^-)\right] \ , \tag{41.102}$$

becomes in the case of perfect bunching, $z_i = z$, introducing the abbreviation $g \longrightarrow g\sin kz$,

$$\boxed{\hat{H}_{JC} = -\Delta_c\hat{a}^\dagger\hat{a} - \imath\eta(\hat{a}-\hat{a}^\dagger) - \Delta_a(\tfrac{N}{2}\mathbb{I}_2+\hat{S}_z) + g(\hat{S}_+\hat{a}+\hat{a}^\dagger\hat{S}_-)} \ , \tag{41.103}$$

where we introduced collective operators, $\hat{S}_\alpha \equiv \frac{1}{2}\sum_{i=1}^N\hat{\sigma}_i^\alpha$ for $\alpha = x, y, z$. Disregarding collective decay, $\Gamma = 0$, the Heisenberg equations become,

$$\begin{aligned}
\dot{\hat{a}} &= (\imath\Delta_c - \kappa)\hat{a} - \imath g\hat{S}_- + \eta \\
\dot{\hat{S}}_- &= (\imath\Delta_a - \tfrac{\Gamma_1}{2})\hat{S}_- + 2\imath g\hat{S}_z\hat{a} \\
\dot{\hat{S}}_z &= -\Gamma_1(\tfrac{N}{2}\mathbb{I}_2+\hat{S}_z) - \imath g(\hat{S}_+\hat{a}-\hat{a}^\dagger\hat{S}_-) \ .
\end{aligned} \tag{41.104}$$

Using $\eta \equiv \eta_r + \imath\eta_i$ we can reshape (41.104) in a real notation,

$$\begin{aligned}
\dot{\hat{a}}_r &= \tfrac{1}{2}(\dot{\hat{a}} + \dot{\hat{a}}^\dagger) &&= -\kappa\hat{a}_r - \Delta_c\hat{a}_i - g\hat{S}_y + \eta_r \\
\dot{\hat{a}}_i &= \tfrac{1}{2\imath}(\dot{\hat{a}} - \dot{\hat{a}}^\dagger) &&= -\kappa\hat{a}_i + \Delta_c\hat{a}_r - g\hat{S}_x + \eta_i \\
\dot{\hat{S}}_x &= \tfrac{1}{2}(\dot{\hat{S}}_- + \dot{\hat{S}}_+) &&= -\tfrac{\Gamma_1}{2}\hat{S}_x + \Delta_a\hat{S}_y - g\{\hat{a}_i, \hat{S}_z\} - \imath g[\hat{a}_r, \hat{S}_z] \\
\dot{\hat{S}}_y &= \tfrac{\imath}{2}(\dot{\hat{S}}_- - \dot{\hat{S}}_+) &&= -\tfrac{\Gamma_1}{2}\hat{S}_y - \Delta_a\hat{S}_x - g\{\hat{a}_r, \hat{S}_z\} + \imath g[\hat{a}_i, \hat{S}_z] \\
\dot{\hat{S}}_z &= \partial_t\tfrac{1}{2}[\hat{S}_+, \hat{S}_-] &&= -\Gamma_1(\tfrac{N}{2}\mathbb{I}_2 + \hat{S}_z) + g(\{\hat{a}_i, \hat{S}_x\} + \{\hat{a}_r, \hat{S}_y\} + \imath[\hat{a}_r, \hat{S}_x] - \imath[\hat{a}_i, \hat{S}_y])
\end{aligned} \tag{41.105}$$

The equations are equivalent to those derived by [805].

Example 260 (*Simplification for independent $\hat{a}$ and $\hat{\mathbf{S}}$*): As long as $\hat{a}$ and $\hat{\mathbf{S}}$ are independent, we may simply set $\{\hat{a}, \hat{\mathbf{S}}\} = 2\hat{a}\hat{\mathbf{S}}$ and $[\hat{a}, \hat{\mathbf{S}}] = 0$. The equations (41.105) can then be written in compact matrix notation,

$$\dot{\hat{\mathbf{S}}} = -\imath[\hat{\mathbf{S}}, \hat{H}] + \mathcal{L}_{\Gamma_1/2}\hat{\mathbf{S}} = \begin{pmatrix} -\frac{1}{2}\Gamma_1 & \Delta_a & -2g\hat{a}_i \\ -\Delta_a & -\frac{1}{2}\Gamma_1 & -2g\hat{a}_r \\ 2g\hat{a}_r & 2g\hat{a}_i & -\Gamma_1 \end{pmatrix} \begin{pmatrix} \hat{S}_x \\ \hat{S}_y \\ \hat{S}_z \end{pmatrix} - \begin{pmatrix} 0 \\ 0 \\ \Gamma_1\frac{N}{2}\mathbb{I}_2 \end{pmatrix} \tag{41.106}$$

$$= \begin{pmatrix} 2g\hat{a}_r \\ -2g\hat{a}_i \\ -\Delta_a \end{pmatrix} \times \begin{pmatrix} \hat{S}_x \\ \hat{S}_y \\ \hat{S}_z \end{pmatrix} - \Gamma_1 \begin{pmatrix} \frac{1}{2}\hat{S}_x \\ \frac{1}{2}\hat{S}_y \\ \frac{N}{2}\mathbb{I}_2 + \hat{S}_z \end{pmatrix} .$$

The equations (41.105) are just the Heisenberg-Liouville equations (41.76) derived from the open Dicke model and the open Tavis-Cummings model Hamiltonian, restricting to many immobile atoms and a single cavity mode. In the bad cavity limit, $\kappa \gg g$, the cavity field is effectively slaved to the internal atomic dynamics. Hence, we may assume $\dot{\hat{a}} \equiv 0$ and adiabatically eliminate the field. Setting $\dot{\hat{a}}_r = 0 = \dot{\hat{a}}_i$ in Eq. (41.105)(i-ii) we calculate,

$$\begin{aligned}
\hat{\Omega}_r &\equiv 2g\hat{a}_r = 2U_c(\hat{S}_x - \eta_i/g) - 2\kappa_c(\hat{S}_y - \eta_r/g) \\
\hat{\Omega}_i &\equiv 2g\hat{a}_i = -2\kappa_c(\hat{S}_x - \eta_i/g) - 2U_c(\hat{S}_y - \eta_r/g) \ ,
\end{aligned} \tag{41.107}$$

where we introduced the abbreviations,

$$U_\kappa \equiv U_c - \imath\kappa_c \qquad \text{with} \qquad U_c \equiv \frac{g^2\Delta_c}{\Delta_c^2 + \kappa^2} \qquad \text{and} \qquad \kappa_c \equiv \frac{g^2\kappa}{\Delta_c^2 + \kappa^2} \ . \tag{41.108}$$

U_c is the cooperative cavity Lamb-shift and κ_c is the Purcell-enhanced atomic decay

rate. Substituting (41.107) in the Eqs. (41.105)(iii-v) leads to [17],

$$\boxed{\begin{aligned}
\dot{\hat{S}}_x &= -(\tfrac{\Gamma_1}{2}+\kappa_c)\hat{S}_x + (\Delta_a - U_c)\hat{S}_y - 2(U_c\tilde{\eta}_r + \kappa_c\tilde{\eta}_i)\hat{S}_z + \kappa_c\{\hat{S}_x,\hat{S}_z\} + U_c\{\hat{S}_y,\hat{S}_z\} \\
\dot{\hat{S}}_y &= -(\Delta_a - U_c)\hat{S}_x - (\tfrac{\Gamma_1}{2}+\kappa_c)\hat{S}_y + 2(U_c\tilde{\eta}_i - \kappa_c\tilde{\eta}_r)\hat{S}_z - U_c\{\hat{S}_x,\hat{S}_z\} + \kappa_c\{\hat{S}_y,\hat{S}_z\} \\
\dot{\hat{S}}_z &= 2(\kappa_c\tilde{\eta}_i + U_c\tilde{\eta}_r)\hat{S}_x - 2(U_c\tilde{\eta}_i - \kappa_c\tilde{\eta}_r)\hat{S}_y - \Gamma_1(\tfrac{N}{2}\mathbb{I} + \hat{S}_z) - 2\kappa_c\hat{S}_z - 2\kappa_c(\hat{S}_x^2 + \hat{S}_y^2)
\end{aligned}} \quad . \tag{41.109}$$

Assuming $[\hat{S}_k, \hat{S}_l] = 0$ these equations simplify to the form (41.106). The number of intracavity photons is found via,

$$\hat{n} = \tfrac{1}{2g}(\hat{\Omega}_r^2 + \hat{\Omega}_i^2) = 2|U_\kappa/g|^2[(g\hat{S}_x - \eta_i)^2 + (g\hat{S}_y - \eta_r)^2] \; . \tag{41.110}$$

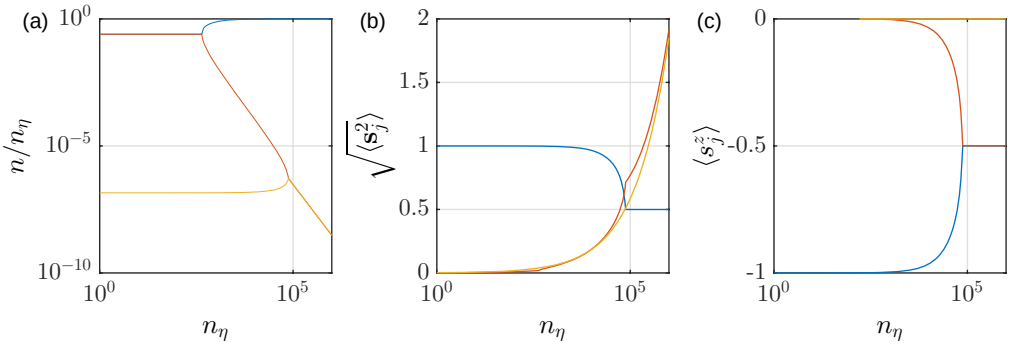

Figure 41.17: (code) Pump power dependence of (a) the intracavity photon number, (b) the total atomic spin, and (c) its projection onto the population axis.

It is interesting to consider some special cases. For example, for small $\hat{S}_{x,y} \ll \eta$, the collective dynamics will be externally controlled and the atomic spins may be considered as decorrelated. Close to the cavity resonance, $\Delta_c \ll \kappa$, Eq. (41.107) becomes,

$$\begin{aligned}
\hat{\Omega}_r &\simeq \tfrac{2}{g}(\kappa_c\eta_r - U_c\eta_i) = \frac{2g(\kappa_c\eta_r - \Delta_c\eta_i)}{\Delta_c^2 + \kappa^2} \longrightarrow \frac{2g\eta_r}{\kappa} \\
\hat{\Omega}_i &\simeq \tfrac{2}{g}(\kappa_c\eta_i + U_c\eta_r) = \frac{2g(\kappa\eta_i + \Delta_c\eta_r)}{\Delta_c^2 + \kappa^2} \longrightarrow \frac{2g\eta_i}{\kappa} \; .
\end{aligned} \tag{41.111}$$

I.e. the operators $\hat{\Omega}_{r,i}$ become real and the *cavity feedback* disappears. such that we recover the linear collective Dicke model.

[17] Equivalently, in complex notation,

$$\begin{aligned}
\Delta_\kappa\hat{a} &= g\hat{S}_- + \imath\eta \\
(\partial_t + \tfrac{\Gamma_1}{2})\dot{\hat{S}}_- &= \imath\Delta_a\hat{S}_- + 2U_\kappa(\imath\hat{S}_- - \tfrac{1}{g}\eta)\hat{S}_z \\
(\partial_t + \Gamma_1)S_z &= -\Gamma_1\tfrac{N}{2}I_2 - \kappa_c\{\hat{S}_+,\hat{S}_-\} + \tfrac{1}{g}\eta U_\kappa\hat{S}_+ + \tfrac{1}{g}\eta^* U_\kappa^*\hat{S}_- \; .
\end{aligned}$$

41.3.3.2 Hamiltonian for the Tavis-Cummings model after adiabatic elimination of the modes

Alternatively, we can try to derive a simplified Hamiltonian from which the Heisenberg-Liouville equations under adiabatic elimination of the cavity mode can be derived directly.

We have seen in Sec. 34.5.3, using the effective Hamiltonian approach, that the Heisenberg equation decomposes in a commutator and an anti-commutator. The complete Heisenberg-Liouville equation reads,

$$\boxed{\begin{aligned} \dot{\hat{\mathbf{S}}} &= -\imath[\hat{\mathbf{S}}, \hat{H}] + \mathcal{L}_{\kappa_c,\hat{S}_-}\hat{\mathbf{S}} + \sum_j \mathcal{L}_{\Gamma_1/2,\hat{s}_j^-}\hat{\mathbf{S}} \\ \text{with} \quad \hat{H} &= -2\Im\mathfrak{m}\,(\tilde{\eta}U_\kappa)\hat{S}_x - 2\Re\mathfrak{e}\,(\tilde{\eta}U_\kappa)\hat{S}_y - \Delta_a\hat{S}_z + U_c\hat{S}_+\hat{S}_- \end{aligned}} \quad . \tag{41.112}$$

As shown in Exc. 41.3.4.10, we recover exactly the equations of motion (41.109). The complete absence of the field from the equations of motion shows that, in the bad cavity limit, any coherence of the coupled atom-cavity system is entirely contained in the atomic cloud.

Comparing this model to the one of the open system Dicke model (41.74), we notice that the cavity decay plays the role of a collective decay mechanism.

41.3.3.3 The XX-Heisenberg model

Without pumping and neglecting spontaneous emission, $\eta = \Gamma_1 = 0$, we obtain the simplified Hamiltonian of the Tavis-Cummings model (41.76) with RWA, $g' = 0$,

$$\hat{H}_{TC} = -\Delta_a\hat{S}_z + U_c\hat{S}_+\hat{S}_- \ , \tag{41.113}$$

also known as the effective Hamiltonian of the *XX-Heisenberg model*. For large $N \gg 1$ the second term can safely be approximated by $\frac{1}{2}U_c\{\hat{S}_+, \hat{S}_-\}$ [956]. The Heisenberg-Liouville equations can then be written,

$$\dot{\hat{\mathbf{S}}} = \begin{pmatrix} 2U_c\hat{S}_x - 2\kappa_c\hat{S}_y \\ 2U_c\hat{S}_y + 2\kappa_c\hat{S}_x \\ -\Delta_a \end{pmatrix} \times \hat{\mathbf{S}} \ . \tag{41.114}$$

Analogously, inserting (41.107) into the above Heisenberg-Liouville equations of the Dicke model (41.76) without RWA, $g' = g$, we obtain neglecting $\eta = \Gamma = 0$,

$$\dot{\hat{\mathbf{S}}} = \begin{pmatrix} 4U_c\hat{S}_x - 4\kappa_c\hat{S}_y \\ 0 \\ -\Delta_a \end{pmatrix} \times \hat{\mathbf{S}} \ . \tag{41.115}$$

Example 261 (*One-axis twisting in the XX-Heisenberg model*): The coupling strength $\sqrt{N_+N_-} \leq \frac{N}{2}$ between the cavity mode and the atoms depends on the inversion. Hence, this leads to an inversion-dependent frequency shift known as *one-axis twisting* [18]. In the mean field treatment we simply replace

[18] This is somewhat analogous to the photon number-dependent phase shift observed in dispersive interaction in the Jaynes-Cummings model.

the operators by their expectation values. Setting $\Delta_a = 0$ in the Heisenberg-Liouville equations (41.114) and neglecting terms $\dot{\hat{S}}_z \propto \hat{S}_z$, we get,

$$\dot{\hat{\mathbf{S}}} \simeq \begin{pmatrix} 2(\kappa_c \hat{S}_x + U_c \hat{S}_y)\hat{S}_z \\ 2(\kappa_c \hat{S}_y - U_c \hat{S}_x)\hat{S}_z \\ -2\kappa_c(\hat{S}_x^2 + \hat{S}_y^2) \end{pmatrix} .$$

Starting from the initial condition, $\vec{S} = (0, 0, N/2)$, we see that the instantaneous collective dipole moment $\hat{S}_x^2 + \hat{S}_y^2$ determines the decay of the inversion, while the inversion $\hat{S}_z$ twists the dipole moment [868, 835, 959, 957, 956]. Collective decay occurs at a rate $\hat{S}_- \sqrt{\kappa_c/2}$. It is easy to see that $\partial_t \hat{\mathbf{S}}^2 = \hat{\mathbf{S}} \cdot \dot{\hat{\mathbf{S}}} + \dot{\hat{\mathbf{S}}} \cdot \hat{\mathbf{S}} = 0$.

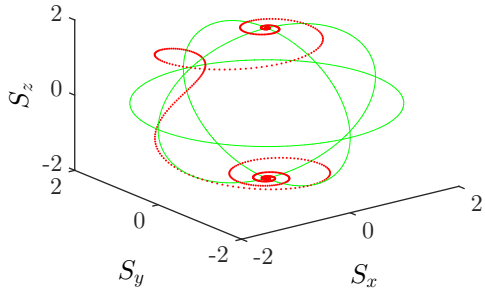

Figure 41.18: (code) One-axis twisting.

41.3.4 Exercises

41.3.4.1 Ex: Calculating with collective operators

The collective spin operators for an ensemble of J atoms with M internal levels are defined as,

$$\hat{S} = \sum_{j=1}^{J} \hat{\sigma}_j = \hat{\sigma} \otimes \mathbb{I}_M \otimes \mathbb{I}_M \otimes ... + \mathbb{I}_M \otimes \hat{\sigma} \otimes \mathbb{I}_M \otimes + ... \ ,$$

or more explicitly,

$$\hat{S}_{kl} = \sum_{j=1}^{J} \hat{\sigma}_j^{kl} = |k\rangle\langle l| \otimes \mathbb{I}_M \otimes \mathbb{I}_M \otimes ... + \mathbb{I}_M \otimes |k\rangle\langle l| \otimes \mathbb{I}_M \otimes + ... \ ,$$

with the spin matrices satisfying,

$$\hat{\sigma}_j^{kl}\hat{\sigma}_j^{mn} = \delta_{lm}\hat{\sigma}_j^{kn} \quad \text{and} \quad [\hat{\sigma}_i^{kl}, \hat{\sigma}_j^{mn}] = \delta_{ij}(\delta_{lm}\hat{\sigma}_j^{kn} - \delta_{kn}\hat{\sigma}_j^{ml})$$

$$\textstyle\sum_{m=1}^{M} \hat{\sigma}_j^{mm} = \mathbb{I}_M \quad \text{and} \quad \sum_{j=1}^{J}\sum_{m=1}^{M} \hat{\sigma}_j^{mm} = N\mathbb{I}_M \ .$$

Verify that for the case of atoms subject to spin-spin interaction,

$$\hat{H} \neq \sum_{j,m} \hat{\sigma}_j^{mm} \hat{H} \hat{\sigma}_j^{mm} \ .$$

Solution: *We calculate,*

$$\hat{S}_{kl}\hat{S}_{mn} = \sum_{i,j}\hat{\sigma}_i^{kl}\hat{\sigma}_j^{mn} = \sum_j \delta_{lm}\hat{\sigma}_j^{kn} + \sum_{i\neq j}\hat{\sigma}_i^{kl}\hat{\sigma}_j^{mn} = \delta_{lm}\hat{S}_{kn} + \sum_{i\neq j}\hat{\sigma}_i^{kl}\hat{\sigma}_j^{mn}$$
$$[\hat{S}_{kl},\hat{S}_{mn}] = \sum_{i,j}[\hat{\sigma}_i^{kl},\hat{\sigma}_j^{mn}] = \sum_{i,j}\delta_{ij}(\delta_{lm}\hat{\sigma}_j^{kn} - \delta_{kn}\hat{\sigma}_j^{ml}) = \delta_{lm}\hat{S}_{kn} - \delta_{kn}\hat{S}_{ml} \ .$$

A Hamiltonian with spin-spin interactions is generally composed of a sum of terms such as,

$$\hat{H} = a\hat{\sigma}_k^{mn} + b\hat{\sigma}_k^{mn}\hat{\sigma}_l^{pq} \ .$$

With this,

$$\begin{aligned}\sum_{j,r}\hat{\sigma}_j^{rr}\hat{H}\hat{\sigma}_j^{rr} &= a\sum_{j,r}\hat{\sigma}_j^{rr}\hat{\sigma}_k^{m,n}\hat{\sigma}_j^{rr} + b\sum_{j,r}\hat{\sigma}_j^{rr}\hat{\sigma}_k^{m,n}\hat{\sigma}_l^{p,q}\hat{\sigma}_j^{rr}\\ &= a\hat{\sigma}_k^{m,n}\delta_{kj} + a\sum_j\hat{\sigma}_k^{m,n}(1-\delta_{kj}) + b\sum_{j,r}\hat{\sigma}_j^{rr}\hat{\sigma}_k^{m,n}\hat{\sigma}_l^{p,q}\hat{\sigma}_j^{rr}\\ &\neq a\hat{\sigma}_k^{m,n} + b\hat{\sigma}_k^{mn}\hat{\sigma}_l^{pq} \ .\end{aligned}$$

41.3.4.2 Ex: Liouvillean for two dipole-coupled atoms

a. From the master equation (41.88) set up the Liouvillean $\mathcal{M}$ for a system of two atoms coupled via dipolar radiation allowing to write the master equation as $\dot{\vec{\varrho}} = \mathcal{M}\vec{\varrho}$.
b. Discuss the Lindblad term in the limit, $kr_{12} \to 0$.
c. We have seen in Exc. 34.6.7.9, how to write down the master equation for a two-level atom whose levels are coupled by blackbody radiation. Extend the procedure to two dipole-coupled two-level atoms whose levels are only coupled by blackbody radiation.

Solution: *a. We have already introduced master equations for two- and three-level systems in Secs. 34.5.2 and 34.7.1. This concept can be extended to two coupled two-level systems [110], which can be mapped as a four-level system. We start from the master equation,*

$$\frac{d\hat{\rho}}{dt} = -\imath[\hat{H},\hat{\rho}] + \mathcal{L}_{incoh}\hat{\rho} \quad \text{with} \quad \mathcal{L}_{incoh}\hat{\rho} = \tfrac{1}{2}\sum_{i,j=1}^{2}\Gamma_{ij}(2\hat{\sigma}_j^-\rho\hat{\sigma}_i^+ - \hat{\sigma}_i^+\hat{\sigma}_j^-\hat{\rho} - \hat{\rho}\hat{\sigma}_i^+\hat{\sigma}_j^-) \ ,$$

first concentrating on the coherent part,

$$\mathcal{L}_{coh}\hat{\rho} = -\imath[\hat{H},\hat{\rho}] \ .$$

The Hamiltonian and the density operator are given by,

$$\hat{H} = \begin{pmatrix}\Delta_a & \frac{1}{2}\Omega & \frac{1}{2}\Omega^* & 0\\ \frac{1}{2}\Omega^* & 0 & \frac{1}{2}\Delta_{21} & \frac{1}{2}\Omega^*\\ \frac{1}{2}\Omega & \frac{1}{2}\Delta_{12} & 0 & \frac{1}{2}\Omega\\ 0 & \frac{1}{2}\Omega & \frac{1}{2}\Omega^* & -\Delta_a\end{pmatrix} \quad \textit{and} \quad \hat{\rho} = \hat{\rho}^\dagger = \begin{pmatrix}\rho_{11,11} & \rho_{11,12} & \rho_{11,21} & \rho_{11,22}\\ \rho_{12,11} & \rho_{12,12} & \rho_{12,21} & \rho_{12,22}\\ \rho_{21,11} & \rho_{21,12} & \rho_{21,21} & \rho_{21,22}\\ \rho_{22,11} & \rho_{22,12} & \rho_{22,21} & \rho_{22,22}\end{pmatrix} \ ,$$

with the abbreviations,

$$\Delta_{12} = \Delta_{21} \equiv -\Gamma \frac{\cos kr_{12}}{kr_{12}} \qquad \textit{and} \qquad \Gamma_{12} = \Gamma_{21} \equiv \Gamma \frac{\sin kr_{12}}{kr_{12}} \qquad \textit{and} \qquad \Gamma_{11} = \Gamma_{22} = \Gamma \ ,$$

Thus, we have 16 equations to describe the evolutions of the 16 components of the total density matrix (ρ_{ij})*. After rearranging the density operator like,*

$$\begin{aligned}\hat{\vec{\varrho}} = (&\rho_{11,11} \ , \ \rho_{11,12} \ , \ \rho_{11,21} \ , \ \rho_{11,22} \ , \ \rho_{12,11} \ , \ \rho_{12,12} \ , \ \rho_{12,21} \ , \ \rho_{12,22} \ , \ \cdots \\ &\cdots \ , \ \rho_{21,11} \ , \ \rho_{21,12} \ , \ \rho_{21,21} \ , \ \rho_{21,22} \ , \ \rho_{22,11} \ , \ \rho_{22,12} \ , \ \rho_{22,21} \ , \ \rho_{22,22}) \ ,\end{aligned}$$

the coherent Liouvillean can be cast into the form (see also Sec. 34.7.1),

$$\boxed{\mathcal{L}_{coh}\hat{\rho} = -\imath[\hat{H},\hat{\rho}] \ \triangleq \ -\imath(\hat{H}\otimes\mathbb{I}_4 - \mathbb{I}_4\otimes\hat{H}^*)\hat{\vec{\varrho}} = \mathcal{M}_{coh}\hat{\vec{\varrho}}} \ ,$$

or explicitly,

$$\mathcal{M}_{coh} = -\imath \begin{pmatrix} -\hat{H}^* + \Delta_a\mathbb{I}_4 & \frac{1}{2}\Omega\mathbb{I}_4 & \frac{1}{2}\Omega^*\mathbb{I}_4 & 0 \\ \frac{1}{2}\Omega^*\mathbb{I}_4 & -\hat{H}^* & \frac{1}{2}\Delta_{12}\mathbb{I}_4 & \frac{1}{2}\Omega^*\mathbb{I}_4 \\ \frac{1}{2}\Omega\mathbb{I}_4 & \frac{1}{2}\Delta_{12}\mathbb{I}_4 & -\hat{H}^* & \frac{1}{2}\Omega\mathbb{I}_4 \\ 0 & \frac{1}{2}\Omega\mathbb{I}_4 & \frac{1}{2}\Omega^*\mathbb{I}_4 & -\hat{H}^* - \Delta_a\mathbb{I}_4 \end{pmatrix} \ .$$

For the incoherent part, where the two spins operators are,

$$\hat{\sigma}_1^{\pm} \equiv \sigma^{\pm}\otimes\mathbb{I} \qquad \textit{and} \qquad \hat{\sigma}_2^{\pm} \equiv \mathbb{I}\otimes\hat{\sigma}^{\pm} \ .$$

we express the Lindblad operator,

$$\begin{aligned}\mathcal{L}_{incoh}\hat{\rho} &= \tfrac{1}{2}\Gamma\left(2\sigma_1^-\hat{\rho}\hat{\sigma}_1^+ - \hat{\sigma}_1^+\sigma_1^-\hat{\rho} - \hat{\rho}\hat{\sigma}_1^+\sigma_1^-\right) + \tfrac{1}{2}\Gamma\left(2\sigma_2^-\hat{\rho}\hat{\sigma}_2^+ - \hat{\sigma}_2^+\sigma_2^-\hat{\rho} - \hat{\rho}\hat{\sigma}_2^+\sigma_2^-\right) \\ &\quad + \tfrac{1}{2}\Gamma_{12}\left(2\sigma_2^-\hat{\rho}\hat{\sigma}_1^+ - \hat{\sigma}_1^+\sigma_2^-\hat{\rho} - \hat{\rho}\hat{\sigma}_1^+\sigma_2^-\right) + \tfrac{1}{2}\Gamma_{12}\left(2\sigma_1^-\hat{\rho}\hat{\sigma}_2^+ - \hat{\sigma}_2^+\sigma_1^-\hat{\rho} - \hat{\rho}\hat{\sigma}_2^+\sigma_1^-\right) \\ &= \mathcal{L}_{\Gamma} + \mathcal{L}_{\Gamma_{12}} \ ,\end{aligned}$$

with

$$\mathcal{L}_{\Gamma} \equiv \tfrac{\Gamma}{2}\begin{pmatrix} 2\rho_{21,21}+2\rho_{12,12} & 2\rho_{21,22}-\rho_{11,12} & 2\rho_{12,22}-\rho_{11,21} & -2\rho_{11,22} \\ 2\rho_{22,21}-\rho_{12,11} & 2\rho_{22,22}-2\rho_{12,12} & -2\rho_{12,21} & -3\rho_{12,22} \\ 2\rho_{22,12}-\rho_{21,11} & -2\rho_{21,12} & -2\rho_{21,21}+2\rho_{22,22} & -3\rho_{21,22} \\ -2\rho_{22,11} & -3\rho_{22,12} & -3\rho_{22,21} & -4\rho_{22,22} \end{pmatrix} \ ,$$

and

$$\mathcal{L}_{\Gamma_{12}} \equiv \tfrac{\Gamma_{12}}{2}\begin{pmatrix} 2\rho_{12,21}+2\rho_{21,12} & 2\rho_{12,22}-\rho_{11,21} & 2\rho_{21,22}-\rho_{11,12} & 0 \\ 2\rho_{22,12}-\rho_{21,11} & -\rho_{12,21}-\rho_{21,12} & 2\rho_{22,22}-\rho_{12,12}-\rho_{21,21} & -\rho_{21,22} \\ 2\rho_{22,21}-\rho_{12,11} & 2\rho_{22,22}-\rho_{12,12}-\rho_{21,21} & -\rho_{12,21}-\rho_{21,12} & -\rho_{12,22} \\ 0 & -\rho_{22,21} & -\rho_{22,12} & 0 \end{pmatrix} \ ,$$

as

$$\mathcal{M}_{incoh} = \begin{pmatrix} \mathcal{G} & \mathcal{F}_1 & \mathcal{F}_2 & 0 \\ 0 & \mathcal{G} - \frac{1}{2}\Gamma\mathbb{I}_4 & -\frac{1}{2}\Gamma_{12}\mathbb{I}_4 & \mathcal{F}_2 \\ 0 & -\frac{1}{2}\Gamma_{12}\mathbb{I}_4 & \mathcal{G} - \frac{1}{2}\Gamma\mathbb{I}_4 & \mathcal{F}_1 \\ 0 & 0 & 0 & \mathcal{G} - \Gamma\mathbb{I}_4 \end{pmatrix} \quad with \quad \mathcal{G} = -\frac{1}{2}\begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & \Gamma & \Gamma_{12} & 0 \\ 0 & \Gamma_{12} & \Gamma & 0 \\ 0 & 0 & 0 & 2\Gamma \end{pmatrix}$$

$$with \quad \mathcal{F}_1 = \begin{pmatrix} 0 & \Gamma & \Gamma_{12} & 0 \\ 0 & 0 & 0 & \Gamma_{12} \\ 0 & 0 & 0 & \Gamma \\ 0 & 0 & 0 & 0 \end{pmatrix} \quad and \quad \mathcal{F}_2 = \begin{pmatrix} 0 & \Gamma_{12} & \Gamma & 0 \\ 0 & 0 & 0 & \Gamma \\ 0 & 0 & 0 & \Gamma_{12} \\ 0 & 0 & 0 & 0 \end{pmatrix} .$$

The master equation is now solved as,

$$\vec{\varrho}(t) = e^{(\mathcal{M}_{coh}+\mathcal{M}_{incoh})t}\vec{\varrho}(0) \ .$$

b. In the limit $kr_{12} \to 0$ we get for the Lindblad term,

$$\mathcal{M} = -i[\hat{H}, \vec{\rho}] = -\imath\times$$

$$\begin{pmatrix}
\rho_{11,11} & \rho_{11,12} & \rho_{11,21} & \rho_{11,22} & \rho_{12,11} & \rho_{12,12} & \rho_{12,21} & \rho_{12,22} & \rho_{21,11} & \rho_{21,12} & \rho_{21,21} & \rho_{21,22} & \rho_{22,11} & \rho_{22,12} & \rho_{22,21} & \rho_{22,22} & \\
0 & -\frac{1}{2}\Omega^* & 0 & \frac{1}{2}\Omega & \Gamma & \Gamma_{12} & 0 & \frac{1}{2}\Omega^* & \Gamma_{12} & \Gamma & 0 & 0 & 0 & 0 & 0 & \rho_{11,11} \\

0 & 0 & 0 & 0 & 0 & 0 & 0 & \frac{1}{2}\Omega & 0 & 0 & 0 & \frac{1}{2}\Omega^* & 0 & -\frac{1}{2}\Omega^* & -\frac{1}{2}\Omega & -2\Gamma & \rho_{22,22}
\end{pmatrix}$$

Figure 41.19: Liouvillean for two dipole-coupled atoms.

$$\Gamma_{12} \to \Gamma \qquad and \qquad |\Delta_{12}| \to \infty \ ,$$

and consequently,

$$\begin{aligned}\mathcal{L}_{incoh}\hat{\rho} &= \tfrac{1}{2}\Gamma\left[2(\hat{\sigma}_1^- + \hat{\sigma}_2^-)\hat{\rho}(\hat{\sigma}_1^+ + \hat{\sigma}_2^+) - (\hat{\sigma}_1^+ + \hat{\sigma}_2^+)(\hat{\sigma}_1^- + \hat{\sigma}_2^-)\hat{\rho} - \hat{\rho}(\hat{\sigma}_1^+ + \hat{\sigma}_2^+)(\hat{\sigma}_1^- + \hat{\sigma}_2^-)\right] \\ &= \Gamma[2\hat{S}^-\hat{\rho}\hat{S}^+ - \hat{S}^+\hat{S}^-\hat{\rho} - \hat{\rho}\hat{S}^+\hat{S}^-] \ .\end{aligned}$$

That is, in this limit the single-atom decay mentioned in (41.74) turns into a collective decay.
c. The master equation is [1359],

$$\begin{aligned}\frac{d\hat{\rho}}{dt} &= \mathcal{L}_{bb}\hat{\rho} \\ &= -\tfrac{1}{2}\sum_{i,j=1,2}\left(\Gamma_{ij} + R_{ij}\right)\left([\hat{\rho}\hat{\sigma}_j^+, \hat{\sigma}_i^-] + [\hat{\sigma}_j^+, \hat{\sigma}_i^-\hat{\rho}]\right) - \tfrac{1}{2}\sum_{i,j=1,2} R_{ij}\left([\hat{\rho}\hat{\sigma}_j^-, \hat{\sigma}_i^+] + [\hat{\sigma}_j^-, \hat{\sigma}_i^+\hat{\rho}]\right) \ ,\end{aligned}$$

with $R_{ij}\delta(t-t') \propto \langle \hat{E}_i(t)\hat{E}_j(t')\rangle$ containing both the real and the virtual photon exchange. With $\Gamma = \Gamma_{ii}$, $\Gamma_{12} = \Gamma_{21}$, $R = R_{ii}$, and $R_{12} = R_{21}$, we find,

$$\begin{aligned}\dot{\hat{\rho}} &= \tfrac{\Gamma}{2}\sum_{i=1,2}\left(2\hat{\sigma}_i^-\hat{\rho}\hat{\sigma}_i^+ - \hat{\rho}\hat{\sigma}_i^+\hat{\sigma}_i^- - \hat{\sigma}_i^+\hat{\sigma}_i^-\hat{\rho}\right) + \tfrac{\Gamma_{12}}{2}\sum_{i\neq j}\left(2\hat{\sigma}_j^-\hat{\rho}\hat{\sigma}_i^+ - \hat{\rho}\hat{\sigma}_i^+\hat{\sigma}_j^- - \hat{\sigma}_i^+\hat{\sigma}_j^-\hat{\rho}\right)\\ &+ R\sum_{i=1,2}\left(\hat{\sigma}_i^+\hat{\rho}\hat{\sigma}_i^- + \hat{\sigma}_i^-\hat{\rho}\hat{\sigma}_i^+ - \hat{\rho}\right) + \tfrac{R_{12}}{2}\sum_{i\neq j}\left(2\hat{\sigma}_i^+\hat{\rho}\hat{\sigma}_j^- + 2\hat{\sigma}_j^-\hat{\rho}\hat{\sigma}_i^+ - \hat{\rho}\{\hat{\sigma}_j^-,\hat{\sigma}_i^+\} - \{\hat{\sigma}_j^-,\hat{\sigma}_i^+\}\hat{\rho}\right)\\ &= \mathcal{L}_\Gamma + \mathcal{L}_{\Gamma_{12}} + \mathcal{L}_R + \mathcal{L}_{R_{12}}\ .\end{aligned}$$

with $\mathcal{L}_\Gamma$ and $\mathcal{L}_{\Gamma_{12}}$ derived in part (b) and

$$\mathcal{L}_R = R\begin{pmatrix}\rho_{12,12}-\rho_{11,11}+\rho_{21,21} & \rho_{21,22}-\rho_{11,12} & \rho_{12,22}-\rho_{11,21} & -\rho_{11,22}\\ \rho_{22,21}-\rho_{12,11} & \rho_{11,11}-\rho_{12,12}+\rho_{22,22} & -\rho_{12,21} & -\rho_{12,22}+\rho_{11,21}\\ \rho_{22,12}-\rho_{21,11} & -\rho_{21,12} & \rho_{11,11}-\rho_{21,21}+\rho_{22,22} & \rho_{11,12}-\rho_{21,22}\\ -\rho_{22,11} & -\rho_{22,12}+\rho_{21,11} & \rho_{12,11}-\rho_{22,21} & \rho_{12,12}+\rho_{21,21}-\rho_{22,22}\end{pmatrix},$$

and

$$\mathcal{L}_{R_{12}} = R_{12}\begin{pmatrix}\rho_{21,12}+\rho_{12,21} & \rho_{12,22}-\rho_{11,21} & \rho_{21,22}-\rho_{11,12} & 0\\ \rho_{22,12}-\rho_{21,11} & -\rho_{12,21}-\rho_{21,12} & \rho_{11,11}+\rho_{22,22}-\rho_{12,12}-\rho_{21,21} & \rho_{11,12}-\rho_{21,22}\\ \rho_{22,21}-\rho_{12,11} & \rho_{11,11}+\rho_{22,22}-\rho_{12,12}-\rho_{21,21} & -\rho_{12,21}-\rho_{21,12} & \rho_{11,21}-\rho_{12,22}\\ 0 & \rho_{12,11}-\rho_{22,21} & \rho_{21,11}-\rho_{22,12} & \rho_{21,12}+\rho_{12,21}\end{pmatrix}.$$

41.3.4.3 Ex: Super- and subradiant linewidth and decay rates from the coupled dipoles model

Calculate super- and subradiance linewidth and lineshifts for two atoms interacting via dipole-dipole interaction using the linear optics scalar coupled dipoles model culminating in Eq. (39.26) using the exponential kernel (39.29).

Solution: *We consider two atoms located next to each other at positions $\pm\frac{r_{12}}{2}$ of the z-axis, i.e. [1090],*

$$\mathbf{r}_1 = \tfrac{r_{12}}{2}\hat{\mathbf{e}}_z \quad , \quad \mathbf{r}_2 = -\tfrac{r_{12}}{2}\hat{\mathbf{e}}_z \quad \text{with} \quad |\mathbf{r}_1-\mathbf{r}_2| = r_{12} \ll \lambda\ .$$

We also set $\hat{\mathbf{e}}_z \perp \mathbf{k}_0$. Then, the Rabi frequencies $\Omega(\mathbf{r}_j) = \Omega_0 e^{\imath\mathbf{k}_0\cdot\mathbf{r}_j}$ at the atomic positions can be written,

$$\Omega(\mathbf{r}_1) = \Omega_0 e^{\imath k r_{12}/2} = \Omega^*(\mathbf{r}_2) \simeq \Omega_0\ .$$

Using the linear optics ansatz (39.11) yields for the amplitudes $\beta_j = \langle j|\psi\rangle$ and $\beta_j = \bar{\beta}_j e^{-\imath\Delta_0 t+\imath\mathbf{k}_0\cdot\mathbf{r}_j}$ the equation of motion (39.26),

$$\frac{d}{dt}\bar{\beta}_j = \left(\imath\Delta_0 - \frac{\Gamma}{2}\right)\bar{\beta}_j - \frac{\imath\Omega_0}{2} - \frac{\Gamma}{2}\sum_{m\neq j} e^{-\imath\mathbf{k}_0\cdot(\mathbf{r}_j-\mathbf{r}_m)}\frac{e^{\imath k_0|\mathbf{r}_j-\mathbf{r}_m|}}{\imath k_0|\mathbf{r}_j-\mathbf{r}_m|}\bar{\beta}_m\ ,$$

which for the case of two atoms reads, for $\hat{\mathbf{e}}_z \parallel \mathbf{k}_0$,

$$\frac{d}{dt}\bar{\beta}_1 = \left(\imath\Delta_0 - \frac{\Gamma}{2}\right)\bar{\beta}_1 - \frac{\imath\Omega_0}{2} - \Gamma\frac{1}{\imath k_0 r_{12}}\bar{\beta}_2\ ,$$

and for $\hat{\mathbf{e}}_z \perp \mathbf{k}_0$,

$$\begin{aligned}\frac{d}{dt}\bar{\beta}_1 &= \left(\imath\Delta_0 - \frac{\Gamma}{2}\right)\bar{\beta}_1 - \frac{\imath\Omega_0}{2} - \Gamma\frac{e^{\imath k_0 r_{12}}}{\imath k_0 r_{12}}\bar{\beta}_2 \\ &= \left(\imath\Delta_0 - \frac{\Gamma}{2}\right)\bar{\beta}_1 - \frac{\imath\Omega_0}{2} - \Gamma\left(\frac{\cos k_0 r_{12}}{\imath k_0 r_{12}} + \frac{\sin k_0 r_{12}}{k_0 r_{12}}\right)\bar{\beta}_2 \ .\end{aligned}$$

That is,

$$\begin{aligned}&\frac{d}{dt}\begin{pmatrix}\bar{\beta}_1\\ \bar{\beta}_2\end{pmatrix} = \imath\hat{H}_{eff}\begin{pmatrix}\bar{\beta}_1\\ \bar{\beta}_2\end{pmatrix} - \frac{\imath\Omega_0}{2} \\ &\textit{with} \qquad \hat{H}_{eff} = \begin{pmatrix}\Delta_0 + \frac{\imath\Gamma}{2} & \imath\Gamma\left(\frac{\cos k_0 r_{12}}{\imath k_0 r_{12}} + \frac{\sin k_0 r_{12}}{k_0 r_{12}}\right) \\ \imath\Gamma\left(\frac{\cos k_0 r_{12}}{\imath k_0 r_{12}} + \frac{\sin k_0 r_{12}}{k_0 r_{12}}\right) & \Delta_0 + \frac{\imath\Gamma}{2}\end{pmatrix} \ .\end{aligned}$$

The eigenvalues of the effective Hamitonian are then,

$$E = \Delta_0 \pm \Gamma\frac{\cos k_0 r_{12}}{k_0 r_{12}} + \imath\Gamma\left(\frac{1}{2} \pm \frac{\sin k_0 r_{12}}{k_0 r_{12}}\right) \ .$$

Hence, for $r_{12} \ll \lambda$ *the super/sub-radiant lifetimes and energy shifts are,*

$$\Gamma_\pm = \Gamma\left(1 \pm \frac{\sin kr_{12}}{kr_{12}}\right) \gtrless \Gamma \qquad \textit{and} \qquad \Delta_\pm = \pm\Gamma\frac{\cos kr_{12}}{2kr_{12}} \ .$$

41.3.4.4 Ex: Super- and subradiance in a two atom system

Calculate the temporal behavior of the (anti-)symmetric states $\rho_{S,A} = \frac{1}{2}(\rho_{12,12} + \rho_{21,21} \pm \rho_{12,21} \pm \rho_{21,12})$ from the master equation (41.88) or the Liouville equation (41.90). Consider in particular the case of absent driving, $\Omega = 0$.

Solution: *With the Rabi frequency,* $\Omega = \Omega_0 e^{\imath kr_{12}/2}$ *and the abbreviations,*

$$\begin{aligned}&\Omega_+ \equiv \sqrt{2}\Omega_0\cos\tfrac{kr_{12}}{2} \qquad \textit{and} \qquad \Omega_- \equiv \sqrt{2}\Omega_0\sin\tfrac{kr_{12}}{2} \\ &\textit{and} \qquad \Gamma_\pm \equiv \Gamma \pm \Gamma_{12} = \Gamma\left(1 \pm \tfrac{\sin kr_{12}}{r_{12}}\right) \ ,\end{aligned}$$

we obtain for the antisymmetric state,

$$\begin{aligned}2\frac{d}{dt}\rho_A &= \frac{d}{dt}(\rho_{12,12} + \rho_{21,21} - \rho_{12,21} - \rho_{21,12}) \\ &= \Omega_0\sin\tfrac{kr_{12}}{2}(-\rho_{11,12} - \rho_{12,11} + \rho_{11,21} + \rho_{21,11} - \rho_{22,12} - \rho_{12,22} + \rho_{22,21} + \rho_{21,22}) \\ &\quad + \imath(\Gamma - \Gamma_{12})(\rho_{12,12} + \rho_{21,21} - \rho_{12,21} - \rho_{21,12} + \rho_{22,22}) \\ &= \sqrt{2}\Omega_-\mathfrak{Re}\,(-\rho_{11,12} + \rho_{11,21} - \rho_{22,12} + \rho_{22,21}) + \imath\Gamma_-(2\rho_A + \rho_{22,22})\end{aligned}$$

and for the symmetric state,

$$\begin{aligned}
2\frac{d}{dt}\rho_S &= \frac{d}{dt}(\rho_{12,12}+\rho_{21,21}+\rho_{12,21}+\rho_{21,12}) \\
&= -\imath\Omega_0\cos\tfrac{kr_{12}}{2}(\rho_{11,12}-\rho_{12,11}+\rho_{11,21}-\rho_{21,11}+\rho_{22,12}-\rho_{12,22}+\rho_{22,21}-\rho_{21,22}) \\
&\quad +\imath(\Gamma+\Gamma_{12})(\rho_{12,12}+\rho_{12,21}+\rho_{21,12}+\rho_{21,21}-\rho_{22,22}) \\
&= \sqrt{2}\Omega_+\,\mathfrak{Im}\,(\rho_{11,12}+\rho_{11,21}+\rho_{22,12}+\rho_{22,21})+\imath\Gamma_+(2\rho_S-\rho_{22,22})\ .
\end{aligned}$$

Hence, after switching off the light, $\Omega=0$,

$$\frac{d}{dt}\rho_{S,A}=\imath\Gamma_\pm(\rho_{S,A}\mp\tfrac{1}{2}\rho_{22,22})\ .$$

41.3.4.5 Ex: Two-atom toy model for super- and subradiance

Calculate the eigenvalues and eigenvectors of the Hamiltonian (41.100) for two two-level atoms located at $\mathbf{r}_j=\pm\frac{r_{12}}{2}\hat{\mathbf{e}}_z$ with $r_{ji}=|\mathbf{r}_j-\mathbf{r}_i|\ll\lambda$ [364]. Consider the limits (a) absent coupling, $\Delta_{12}=0$, (b) resonant driving, $\Delta_a=0$, and (c) absent driving, $\Omega=0$. (d) Analyze the full Hamiltonian.

Solution: *The two atoms are subject to the Rabi frequencies,* $\Omega(\mathbf{r}_1)=\Omega_0 e^{\imath kr_{12}/2}=\Omega^*(\mathbf{r}_2)$*, so that,*

$$\hat{H}'\equiv\hat{H}-\Delta_a\mathbb{I}=\begin{pmatrix}\Delta_a & \frac{1}{2}\Omega & \frac{1}{2}\Omega^* & 0\\ \frac{1}{2}\Omega^* & 0 & \frac{1}{2}\Delta_{12} & \frac{1}{2}\Omega^*\\ \frac{1}{2}\Omega & \frac{1}{2}\Delta_{12} & 0 & \frac{1}{2}\Omega\\ 0 & \frac{1}{2}\Omega & \frac{1}{2}\Omega^* & -\Delta_a\end{pmatrix}\ , \tag{41.116}$$

with $\Delta_{12}=-\Gamma\frac{\cos kr_{12}}{kr_{12}}$.
a. In the limit of absent coupling, $\Delta_{12}=0$*, we obtain,*

$$\hat{H}'\equiv\hat{H}-\Delta_a\mathbb{I}=\begin{pmatrix}\Delta_a & \frac{1}{2}\Omega & \frac{1}{2}\Omega^* & 0\\ \frac{1}{2}\Omega^* & 0 & 0 & \frac{1}{2}\Omega^*\\ \frac{1}{2}\Omega & 0 & 0 & \frac{1}{2}\Omega\\ 0 & \frac{1}{2}\Omega & \frac{1}{2}\Omega^* & -\Delta_a\end{pmatrix}\ .$$

The eigenvalue and the eigenvector matrices are, with the abbreviations $G\equiv\sqrt{\Delta_a^2+|\Omega|^2}$*,*

$$\hat{E}'\equiv\hat{E}+\Delta_a=\begin{pmatrix}-G & 0 & 0 & 0\\ 0 & 0 & 0 & 0\\ 0 & 0 & 0 & 0\\ 0 & 0 & 0 & G\end{pmatrix}\quad\textit{and}\quad U=\begin{pmatrix}\frac{-G+\Delta_a}{\Omega} & 0 & 1 & \frac{G+\Delta_a}{\Omega}\\ \frac{\Omega^*}{\Omega} & -\frac{\Omega^*}{\Omega} & -\frac{2\Delta_a}{\Omega} & \frac{\Omega^*}{\Omega}\\ 1 & 1 & 0 & 1\\ \frac{-G-\Delta_a}{\Omega} & 0 & -1 & \frac{G-\Delta_a}{\Omega}\end{pmatrix}\ .$$

We easily verify $U\hat{E}'U^{-1} = H'$ *and propagate* $Ue^{\imath\hat{E}'t}U^{-1}$ *numerically.*
b. On resonance, $\Delta_a = 0$*, and additionally assuming* $\Omega = \Omega^*$ *we obtain,*

$$\hat{H} - \Delta_a \mathbb{I} \simeq \begin{pmatrix} 0 & \frac{1}{2}\Omega & \frac{1}{2}\Omega & 0 \\ \frac{1}{2}\Omega & 0 & \frac{1}{2}\Delta_{12} & \frac{1}{2}\Omega \\ \frac{1}{2}\Omega & \frac{1}{2}\Delta_{12} & 0 & \frac{1}{2}\Omega \\ 0 & \frac{1}{2}\Omega & \frac{1}{2}\Omega & 0 \end{pmatrix} ,$$

with the eigenvalues, $E_1 = -\frac{1}{2}\Delta_{12}$*,* $E_2 = 0$*, and* $E_{3,4} = \frac{1}{4}\Delta_{12} \pm \frac{1}{4}\sqrt{16\Omega^2 + \Delta_{12}^2}$*.*
c. In the absence of driving, $\Omega = 0$*, we obtain,*

$$\hat{H} - \Delta_a \mathbb{I} \simeq \begin{pmatrix} \Delta_a & 0 & 0 & 0 \\ 0 & 0 & \frac{1}{2}\Delta_{12} & 0 \\ 0 & \frac{1}{2}\Delta_{12} & 0 & 0 \\ 0 & 0 & 0 & -\Delta_a \end{pmatrix} .$$

The eigenvalue and the eigenvector matrices are,

$$\hat{E}' \equiv \hat{E} + \Delta_a = \begin{pmatrix} \Delta_a & 0 & 0 & 0 \\ 0 & \frac{1}{2}\Delta_{12} & 0 & 0 \\ 0 & 0 & -\frac{1}{2}\Delta_{12} & 0 \\ 0 & 0 & 0 & -\Delta_a \end{pmatrix} \quad \textit{and} \quad U = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & \frac{1}{\sqrt{2}} & -\frac{1}{\sqrt{2}} & 0 \\ 0 & \frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}} & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix} . \tag{41.117}$$

d. Applying the unitary transformation (41.117) to the full Hamiltonian (41.116), we find,

$$U^{-1}(\hat{H} - \Delta_a \mathbb{I})U = \begin{pmatrix} \Delta_a & \frac{1}{2}\Omega_+ & -\frac{\imath}{2}\Omega_- & 0 \\ \frac{1}{2}\Omega_+ & \frac{1}{2}\Delta_{12} & 0 & \frac{1}{2}\Omega_+ \\ -\frac{\imath}{2}\Omega_- & 0 & -\frac{1}{2}\Delta_{12} & -\frac{\imath}{2}\Omega_- \\ 0 & \frac{1}{2}\Omega_+ & -\frac{\imath}{2}\Omega_- & -\Delta_a \end{pmatrix} ,$$

introducing the effective Rabi frequencies for the two single-excitation modes,

$$\Omega_+ \equiv \sqrt{2}\Omega_0 \cos\tfrac{kr_{12}}{2} \qquad \textit{and} \qquad \Omega_- \equiv \sqrt{2}\Omega_0 \sin\tfrac{kr_{12}}{2}$$
$$\textit{and} \qquad \Delta_\pm \equiv \mp\tfrac{1}{2}\Delta_{12} = \pm\Gamma\tfrac{\cos kr_{12}}{2r_{12}} .$$

Hence, we see that the dipole-dipole interaction generates two collective 0,1,2-photon eigenstates $|gg\rangle$*,* $|\pm\rangle = \frac{1}{\sqrt{2}}(|eg\rangle \pm |ge\rangle)$*, and* $|ee\rangle$*. The pump efficiently couples to the superradiant state, but only very weakly to the long-lived (subradiant) state. The steady-state population of the long-lived mode then presents three typical regimes, depending on the pump strength. First, for the lowest intensities (linear-optics regime), the population of* $|ee\rangle$ *is negligible and the single-excitation modes* $|\pm\rangle$ *are driven only directly from the pump, so one obtains the following scaling for their population:*

$$P_\pm \simeq \tfrac{s_\pm}{2} \propto s \qquad \textit{with} \qquad s_\pm = \frac{2\Omega_\pm^2}{\Gamma_\pm^2 + 4(\Delta_a \mp \frac{1}{2}\Delta_\pm)^2}$$

the effective saturation parameter for each mode, and

$$s_0 = \frac{2\Omega_0^2}{\Gamma^2 + 4\Delta_a^2} \ ,$$

the single-atom one. This single-excitation regime holds for $s_\pm \ll 1$, i.e. $\Omega_+ \ll \Delta$. As the drive strength is increased, the doubly-excited state $|ee\rangle$ is substantially populated thanks to the strong coupling of the drive to the superradiant state:

$$P_+ \simeq \tfrac{s_+}{2} \propto s \qquad \text{and} \qquad P_{ee} \propto s^2 \ .$$

Then, the $|-\rangle$ state gets an additional population by decay from $|ee\rangle$, at rate Γ_-, leading to a long-lived population that grows quadratically with the saturation parameter: $P_{ee} \propto s^2$. Finally, for the largest values of the saturation parameter, i.e. with a Rabi frequency such that the dynamics of each atom is dominated by the drive ($\Omega_0 \gg \Delta \gg \Gamma, |\Delta_\pm|$), the system is cast into a separable state described by the density matrix,

$$\hat{\rho} = \tfrac{1}{2} \bigotimes_{j=1,2} \left(|g_j\rangle\langle g_j| + |e_j\rangle\langle e_j| \right) \ .$$

This mixed state projects equally on the states $|gg\rangle$, $|+\rangle$, $|-\rangle$, and $|ee\rangle$, resulting in $P_- \simeq \frac{1}{4}$. Hence, the strong pump overcomes the weak coupling of subradiant modes which, in the linear-optics regime, prevents one to populate them efficiently. The present mechanism is analogous to optical pumping, where an excited state (here $|ee\rangle$) is directly driven by the laser, and induces a population in the long-lived state (here $|-\rangle$) by incoherent decay.

41.3.4.6 Ex: Impact of dipole-dipole interactions on super- and subradiance

Here, we use the two-atom toy model studied in Fig. 41.16 to demonstrate the emergence of subradiant modes as a consequence of dipole-dipole interaction [364]. Calculate numerically the anti-symmetric state population $\hat{\rho}_A$ given in Eq. (41.99) at very long times as a function of the saturation parameter s and the interatomic distance kr_{ij}. Interpret the results.

Solution: *Fig. 41.20 shows the dependence of the decay rate of the subradiant anti-symmetric states of two atoms interacting via dipole-dipole coupling on the saturation parameter $s = \frac{2\Omega_0^2}{\Gamma^2+4\Delta^2}$ and their distance.*

41.3.4.7 Ex: Three interacting atoms

Numerically integrate the master equation (41.88) for three atoms.

Solution: *We simply extend the procedure demonstrated in the example 257 to three atoms,*

$$\hat{\sigma}_1^\pm = \hat{\sigma}^\pm \otimes \mathbb{I} \otimes \mathbb{I} \quad , \quad \hat{\sigma}_2^\pm = \mathbb{I} \otimes \hat{\sigma}^\pm \otimes \mathbb{I} \quad , \quad \hat{\sigma}_3^\pm = \mathbb{I} \otimes \mathbb{I} \otimes \hat{\sigma}^\pm \ .$$

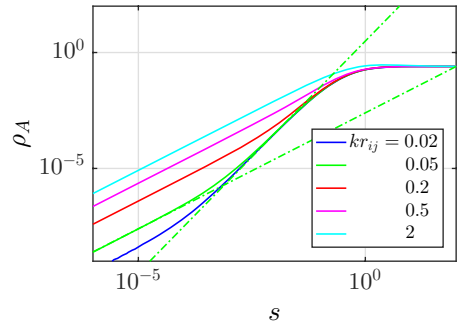

Figure 41.20: (code) Dependence of the population of the subradiant anti-symmetric state of two atoms interacting via dipole-dipole coupling on the saturation parameter and their distance.

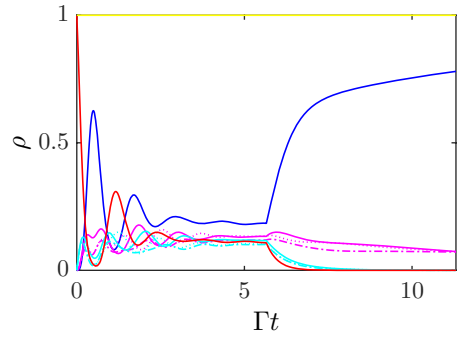

Figure 41.21: (code) Populations in a system of three interacting two-level atoms.

The result of such a simulation is shown in Fig. 41.21.

41.3.4.8 Ex: Two non-interacting three-level atoms

Extend the two two-level atoms toy model of example 257 to two non-interacting three level atoms $|1\rangle$-$|2\rangle$-$|3\rangle$ in cascade configuration.
a. Write down the total Hamiltonian and its matrix representation chosing an appropriate basis.
b. Write down the Lindbladian and numerically solve the master equation.

Solution: *a. The total Hamiltonian is,*

$$\hat{H} = \sum_{j=1,2} \left[-\Delta_a \hat{\sigma}_j^{22} + \tfrac{1}{2}\Omega_a(\hat{\sigma}_j^{12} + \hat{\sigma}_j^{21}) - \Delta_b \hat{\sigma}_j^{32}\hat{\sigma}_j^{23} + \tfrac{1}{2}\Omega_s(\hat{\sigma}_j^{23} + \hat{\sigma}_j^{32}) \right] \ .$$

Choosing the one-atom basis as,

$$|1\rangle = \begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix} \quad , \quad |2\rangle = \begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix} \quad , \quad |3\rangle = \begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix}$$

the single-atom Hamiltonian can be expressed as,

$$\hat{h} = \begin{pmatrix} 0 & \frac{1}{2}\Omega_a & 0 \\ \frac{1}{2}\Omega_a & -\Delta_a & \frac{1}{2}\Omega_b \\ 0 & \frac{1}{2}\Omega_b & -\Delta_b \end{pmatrix} .$$

The collective operators can be constructed via,

$$\hat{\sigma}_1^{mn} = |m\rangle\langle n| \otimes \mathbb{I}_3 \quad , \quad \hat{\sigma}_2^{mn} = \mathbb{I}_3 \otimes |m\rangle\langle n|$$
$$\rho_1^{kk} = \rho^{k\cdot,k\cdot}(\rho^{\cdot 1,\cdot 1} + \rho^{\cdot 2,\cdot 2} + \rho^{\cdot 3,\cdot 3}) \quad , \quad \rho_2^{kk} = (\rho^{1\cdot,1\cdot} + \rho^{2\cdot,2\cdot} + \rho^{3\cdot,3\cdot})\rho^{\cdot k,\cdot k} ,$$

yielding the two-atom collective Hamiltonian,

$$\hat{H} = \hat{H}_1 + \hat{H}_2 = \hat{h} \otimes \mathbb{I}_3 + \mathbb{I}_3 \otimes \hat{h}$$
$$= \begin{pmatrix} 0 & \frac{1}{2}\Omega_a & 0 & \frac{1}{2}\Omega_a & 0 & 0 & 0 & 0 & 0 \\ \frac{1}{2}\Omega_a & -\Delta_a & \frac{1}{2}\Omega_b & 0 & \frac{1}{2}\Omega_a & 0 & 0 & 0 & 0 \\ 0 & \frac{1}{2}\Omega_b & -\Delta_b & 0 & 0 & \frac{1}{2}\Omega_a & 0 & 0 & 0 \\ \frac{1}{2}\Omega_a & 0 & 0 & -\Delta_a & \frac{1}{2}\Omega_a & 0 & \frac{1}{2}\Omega_b & 0 & 0 \\ 0 & \frac{1}{2}\Omega_a & 0 & \frac{1}{2}\Omega_a & -\Delta_a - \Delta_a & \frac{1}{2}\Omega_b & 0 & \frac{1}{2}\Omega_b & 0 \\ 0 & 0 & \frac{1}{2}\Omega_a & 0 & \frac{1}{2}\Omega_b & -\Delta_a - \Delta_b & 0 & 0 & \frac{1}{2}\Omega_b \\ 0 & 0 & 0 & \frac{1}{2}\Omega_b & 0 & 0 & -\Delta_b & \frac{1}{2}\Omega_a & 0 \\ 0 & 0 & 0 & 0 & \frac{1}{2}\Omega_b & 0 & \frac{1}{2}\Omega_a & -\Delta_a - \Delta_b & \frac{1}{2}\Omega_b \\ 0 & 0 & 0 & 0 & 0 & \frac{1}{2}\Omega_b & 0 & \frac{1}{2}\Omega_b & -\Delta_b - \Delta_b \end{pmatrix} .$$

b. With the Lindbladian,

$$\mathcal{L}\hat{\rho} = \tfrac{1}{2}\Gamma_{12} \sum_{j=1,2} (2\hat{\sigma}_j^{12}\hat{\rho}\hat{\sigma}_j^{21} - \hat{\sigma}_j^{21}\hat{\sigma}_j^{12}\hat{\rho} - \hat{\rho}\hat{\sigma}_j^{21}\hat{\sigma}_j^{12}) + \tfrac{1}{2}\Gamma_{13}(2\hat{\sigma}_j^{23}\hat{\rho}\hat{\sigma}_j^{32} - \hat{\sigma}_j^{32}\hat{\sigma}_j^{23}\hat{\rho} - \hat{\rho}\hat{\sigma}_j^{32}\hat{\sigma}_j^{23}) ,$$

the extended master equation is readily set up and can be numerically solved using the procedure outlined in example 257. The result of such a simulation is shown in Fig. 41.22.

41.3.4.9 Ex: Rydberg blockade versus spin-spin interaction

a. Direct interactions (e.g. dipole-dipole coupling or van der Waals interaction) generate collective energy shifts Δ_{ij} and collective decay Γ_{ij} (see Sec. 41.3.2 or examples 257 and 258). Discuss why these terms are not observed in Hamiltonians describing Rydberg blockade.
b. Verify whether the operators $\hat{S}_z\hat{S}_z$ or $\hat{S}_+\hat{S}_-$ generate anti-diagonal terms in the Hamiltonian [956].

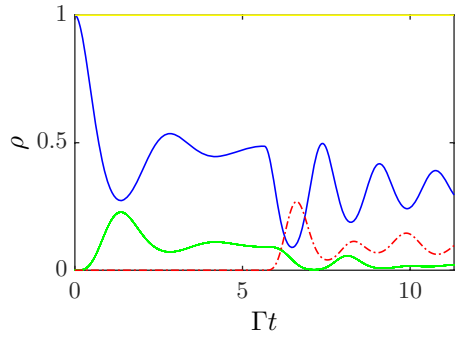

Figure 41.22: (code) Populations in a system of two interacting three-level atoms.

Solution: *Spin-spin interactions introduce collective energy shifts Δ_{ij} in the Hamiltonian and collective decay terms Γ_{ij} in the Lindbladian, which come additionally to single-atom detunings Δ and spontaneous emission Γ. Spin-spin interaction terms typically have the shape,*

$$\hat{H} \propto \hat{\sigma}_1^m \hat{\sigma}_2^n = \hat{\sigma}^m \otimes \hat{\sigma}^n = (\hat{\sigma}^m \oplus \mathbb{I})(\mathbb{I} \oplus \hat{\sigma}^n)$$
$$= \begin{pmatrix} \sigma_1^{11}\sigma_2^{11} & \sigma_1^{11}\sigma_2^{12} & \sigma_1^{12}\sigma_2^{11} & \sigma_1^{12}\sigma_2^{12} \\ \sigma_1^{11}\sigma_2^{21} & \sigma_1^{11}\sigma_2^{22} & \sigma_1^{12}\sigma_2^{21} & \sigma_1^{12}\sigma_2^{22} \\ \sigma_1^{21}\sigma_2^{11} & \sigma_1^{21}\sigma_2^{12} & \sigma_1^{22}\sigma_2^{11} & \sigma_1^{22}\sigma_2^{12} \\ \sigma_1^{21}\sigma_2^{21} & \sigma_1^{21}\sigma_2^{22} & \sigma_1^{22}\sigma_2^{21} & \sigma_1^{22}\sigma_2^{22} \end{pmatrix},$$

where,

$$\hat{\sigma}_1^m = \begin{pmatrix} \sigma_1^{11} & \sigma_1^{12} \\ \sigma_1^{21} & \sigma_1^{22} \end{pmatrix} \qquad \textit{and} \qquad \hat{\sigma}_2^n = \begin{pmatrix} \sigma_2^{11} & \sigma_2^{12} \\ \sigma_2^{21} & \sigma_2^{22} \end{pmatrix}$$

can be arbitrary Pauli matrices. The Hamiltonians for Rydberg blockade do not provide anti-diagonal terms *in contrast to spin-spin interactions,*

$$\hat{H} \propto \hat{\sigma}_1^m + \hat{\sigma}_2^n = \hat{\sigma}^m \oplus \hat{\sigma}^n = (\hat{\sigma}^m \oplus \mathbb{I}) + (\mathbb{I} \oplus \hat{\sigma}^n)$$
$$= \begin{pmatrix} \sigma_1^{11} + \sigma_2^{11} & \sigma_2^{12} & \sigma_1^{12} & 0 \\ \sigma_2^{21} & \sigma_1^{11} + \sigma_2^{22} & 0 & \sigma_1^{12} \\ \sigma_1^{21} & 0 & \sigma_1^{22} + \sigma_2^{11} & \sigma_2^{12} \\ 0 & \sigma_1^{21} & \sigma_2^{21} & \sigma_1^{22} + \sigma_2^{22} \end{pmatrix}.$$

The main difference is, however, that van der Waals interactions are essentially coherent, while dipole-dipole coupling generates correltaions via spontaneous decay Γ_{ij}.

b. We find (see also Sec. 41.3.3),

$$\hat{S}_z^2 = (\hat{\sigma}_1^z + \hat{\sigma}_2^z)(\hat{\sigma}_1^z + \hat{\sigma}_2^z) = (\hat{\sigma}^z \otimes \mathbb{I} + \mathbb{I} \otimes \hat{\sigma}^z)(\hat{\sigma}^z \otimes \mathbb{I} + \mathbb{I} \otimes \hat{\sigma}^z)$$
$$= \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix} ,$$

but

$$\hat{S}_+\hat{S}_- = (\hat{\sigma}_1^+ + \hat{\sigma}_2^+)(\hat{\sigma}_1^- + \hat{\sigma}_2^-) = (\hat{\sigma}^+ \otimes \mathbb{I} + \mathbb{I} \otimes \hat{\sigma}^+)(\hat{\sigma}^- \otimes \mathbb{I} + \mathbb{I} \otimes \hat{\sigma}^-)$$
$$= \hat{\mathbf{S}}^2 - \hat{S}_z^2 - \hat{S}_z = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 1 & 1 & 0 \\ 0 & 1 & 1 & 0 \\ 0 & 0 & 0 & 2 \end{pmatrix} .$$

41.3.4.10 Ex: Adiabatic elimination of the cavity mode, general case

Derive the equations of motion (41.109) for a system consisting of many atoms interacting with a single cavity mode after adiabatic elimination of the cavity mode.

Solution: *We start from the Heisenberg-Liouville equation (41.112) including collective and single-atom decay,*

$$\dot{\hat{\mathbf{S}}} = -\imath[\hat{\mathbf{S}}, \hat{H}] + \mathcal{L}_{\kappa_c, \hat{S}_-}\hat{\mathbf{S}} + \tfrac{1}{2}(\mathcal{L}_{\Gamma_1/2, \hat{S}_+} + \mathcal{L}_{\Gamma_1/2, \hat{S}_-})\hat{\mathbf{S}} \ , \tag{41.118}$$

with the Hamiltonian ($\tilde{\eta} \equiv \eta/g$),

$$\hat{H} = -2\mathfrak{Im}\ (\tilde{\eta}U_\gamma)\hat{S}_x - 2\mathfrak{Re}\ (\tilde{\eta}U_\gamma)\hat{S}_y - \Delta_a\hat{S}_z + U_c\hat{S}_+\hat{S}_- \ , \tag{41.119}$$

where

$$\begin{aligned} \mathfrak{Re}\ \tilde{\eta}U_\gamma &= \mathfrak{Re}\ (\tilde{\eta}_r + \imath\tilde{\eta}_i)(U_c - \imath\kappa_c) = U_c\tilde{\eta}_r + \kappa_c\tilde{\eta}_i \\ \mathfrak{Im}\ \tilde{\eta}U_\gamma &= \mathfrak{Re}\ (\tilde{\eta}_r + \imath\tilde{\eta}_i)(U_c - \imath\kappa_c) = U_c\tilde{\eta}_i - \kappa_c\tilde{\eta}_r \ , \end{aligned} \tag{41.120}$$

with $U_\kappa \equiv U_c - \imath\kappa_c$. To prepare the calculations we first set up tables of useful expressions. The Heisenberg equation $\dot{\hat{S}}_\alpha = -\imath[\hat{S}_\alpha, \hat{H}]$ leads to the following relationships

between Hamiltonian terms and equations of motion:

$\hat{H}=$	$-\imath[\hat{S}_x,\hat{H}]=$	$-\imath[\hat{S}_y,\hat{H}]=$	$-\imath[\hat{S}_z,\hat{H}]=$	$-\imath[\hat{S}_+,\hat{H}]=$	$-\imath[\hat{S}_-,\hat{H}]=$
$\hat{S}_x$	0	$-\hat{S}_z$	$\hat{S}_y$	$-\imath\hat{S}_z$	$\imath\hat{S}_z$
$\hat{S}_y$	$\hat{S}_z$	0	$-\hat{S}_x$	$\hat{S}_z$	$\hat{S}_z$
$\hat{S}_z$	$-\hat{S}_y$	$\hat{S}_x$	0	0	0

(41.121)

Exploiting the rules (41.121) and,

$$\hat{S}_\pm=\hat{S}_x\pm\imath\hat{S}_y\quad,\quad \hat{S}_+\hat{S}_-=\hat{S}_x^2+\hat{S}_y^2+\hat{S}_z\quad,\quad \hat{\mathbf{S}}^2=\hat{S}_x^2+\hat{S}_y^2+\hat{S}_z^2\ , \tag{41.122}$$

for the coupled atom-cavity system we arrive at,

$$-\imath[\hat{\mathbf{S}},\hat{H}]=\begin{pmatrix}0\\ 2(U_c\tilde{\eta}_i-\kappa_c\tilde{\eta}_r)\hat{S}_z\\ -2(U_c\tilde{\eta}_i-\kappa_c\tilde{\eta}_r)\hat{S}_y\end{pmatrix}+\begin{pmatrix}-2(U_c\tilde{\eta}_r+\kappa_c\tilde{\eta}_i)\hat{S}_z\\ 0\\ 2(U_c\tilde{\eta}_r+\kappa_c\tilde{\eta}_i)\hat{S}_x\end{pmatrix}+\begin{pmatrix}(\Delta_a-U_c)\hat{S}_y\\ (U_c-\Delta_a)\hat{S}_x\\ 0\end{pmatrix}+\begin{pmatrix}U_c\{\hat{S}_y,\hat{S}_z\}\\ -U_c\{\hat{S}_x,\hat{S}_z\}\\ 0\end{pmatrix}\ . \tag{41.123}$$

On the other hand, the Lindbladian $\mathcal{L}_{\hat{L}}\hat{X}=\hat{L}^\dagger[\hat{X},\hat{L}]+[\hat{L}^\dagger,\hat{X}]\hat{L}$ applied to collective spin operator yields:

$\hat{L}=$	$\mathcal{L}_{\hat{L}}\hat{S}_x=$	$\mathcal{L}_{\hat{L}}\hat{S}_y=$	$\mathcal{L}_{\hat{L}}\hat{S}_z=$	$\mathcal{L}_{\hat{L}}\hat{S}_+=$	$\mathcal{L}_{\hat{L}}\hat{S}_-=$
$\hat{S}_+$	$-\{\hat{S}_x,\hat{S}_z\}-\hat{S}_x$	$-\{\hat{S}_y,\hat{S}_z\}-\hat{S}_y$	$2\hat{S}_-\hat{S}_+$	$-\{\hat{S}_+,\hat{S}_z\}-\hat{S}_+$	$-\{\hat{S}_-,\hat{S}_z\}-\hat{S}_-$
$\hat{S}_-$	$\{\hat{S}_x,\hat{S}_z\}-\hat{S}_x$	$\{\hat{S}_y,\hat{S}_z\}-\hat{S}_y$	$-2\hat{S}_+\hat{S}_-$	$\{\hat{S}_+,\hat{S}_z\}-\hat{S}_+$	$\{\hat{S}_-,\hat{S}_z\}-\hat{S}_-$
$\hat{S}_z$	$-\hat{S}_x$	$-\hat{S}_y$	0	$-\hat{S}_+$	$-\hat{S}_-$

(41.124)

Exploiting the rules (41.123) and,

$$\mathcal{L}_{\hat{L}}(\hat{X}+\hat{Y})=\mathcal{L}_{\hat{L}}\hat{X}+\mathcal{L}_{\hat{L}}\hat{Y}\ , \tag{41.125}$$

we arrive at,

$$\mathcal{L}_{\hat{S}_+}\hat{\mathbf{S}} = \begin{pmatrix} -\{\hat{S}_x,\hat{S}_z\} - \hat{S}_x \\ -\{\hat{S}_y,\hat{S}_z\} - \hat{S}_y \\ 2\hat{S}_-\hat{S}_+ \end{pmatrix} \quad , \quad \mathcal{L}_{\hat{S}_-}\hat{\mathbf{S}} = \begin{pmatrix} \{\hat{S}_x,\hat{S}_z\} - \hat{S}_x \\ \{\hat{S}_y,\hat{S}_z\} - \hat{S}_y \\ -2\hat{S}_+\hat{S}_- \end{pmatrix} \quad , \quad \mathcal{L}_{\hat{S}_z}\hat{\mathbf{S}} = \begin{pmatrix} -\hat{S}_x \\ -\hat{S}_y \\ 0 \end{pmatrix} , \tag{41.126}$$

and consequently, for the coupled atom-cavity system,

$$\mathcal{L}_{\kappa_c,\hat{S}_-}\hat{\mathbf{S}} = \kappa_c \begin{pmatrix} \{\hat{S}_x,\hat{S}_z\} - \hat{S}_x \\ \{\hat{S}_y,\hat{S}_z\} - \hat{S}_y \\ -2\hat{S}_+\hat{S}_- \end{pmatrix} \quad , \quad \tfrac{1}{2}\sum_j (\mathcal{L}_{\Gamma_1/2,\hat{s}_j^-} + \mathcal{L}_{\Gamma_1/2,\hat{s}_j^+})\hat{\mathbf{S}} = \tfrac{\Gamma_1}{2} \begin{pmatrix} -\hat{S}_x \\ -\hat{S}_y \\ -(N\mathbb{I}_2 + 2\hat{S}_z) \end{pmatrix} . \tag{41.127}$$

Putting everything together we obtain the equations of motion,

$$\begin{aligned} \dot{\hat{\mathbf{S}}} = & \begin{pmatrix} -\kappa_c - \frac{\Gamma_1}{2} & \Delta_a - U_c & -2\kappa_c\tilde{\eta}_i - 2U_c\tilde{\eta}_r) \\ U_c - \Delta_a & -\kappa_c - \frac{\Gamma_1}{2} & 2U_c\tilde{\eta}_i - 2\kappa_c\tilde{\eta}_r \\ 2\kappa_c\tilde{\eta}_i + 2U_c\tilde{\eta}_r & -2U_c\tilde{\eta}_i + 2\kappa_c\tilde{\eta}_r & -2\kappa_c - \frac{\Gamma_1}{2} \end{pmatrix} \begin{pmatrix} \hat{S}_x \\ \hat{S}_y \\ \hat{S}_z \end{pmatrix} \\ & + 2U_c \begin{pmatrix} \{\hat{S}_y,\hat{S}_z\} \\ \{\hat{S}_x,\hat{S}_z\} \\ 0 \end{pmatrix} + 2\kappa_c \begin{pmatrix} \{\hat{S}_x,\hat{S}_z\} \\ \{\hat{S}_y,\hat{S}_z\} \\ -2(\hat{S}_x^2 + \hat{S}_y^2) \end{pmatrix} - \tfrac{\Gamma_1}{2} \begin{pmatrix} 0 \\ 0 \\ N\mathbb{I}_2 \end{pmatrix} . \end{aligned} \tag{41.128}$$

Approximating $\{\hat{S}_\alpha,\hat{S}_\beta\} \simeq 2\hat{S}_\alpha\hat{S}_\beta$,

$$\dot{\hat{\mathbf{S}}} \simeq \begin{pmatrix} -\frac{\Gamma_1}{2} & \Delta_a & -\hat{\Omega}_i \\ -\Delta_a & -\frac{\Gamma_1}{2} & -\hat{\Omega}_r \\ \hat{\Omega}_i & \hat{\Omega}_r & -\Gamma_1 \end{pmatrix} \begin{pmatrix} \hat{S}_x \\ \hat{S}_y \\ \hat{S}_z \end{pmatrix} - \begin{pmatrix} 0 \\ 0 \\ \Gamma_1 \frac{N}{2}\mathbb{I}_2 \end{pmatrix} , \tag{41.129}$$

with the abbreviations,

$$\begin{aligned} \hat{\Omega}_r &\equiv 2g\hat{a}_r = 2U_c(\hat{S}_x - \eta_i/g) - 2\kappa_c(\hat{S}_y - \eta_r/g) \\ \hat{\Omega}_i &\equiv 2g\hat{a}_i = -2\kappa_c(\hat{S}_x - \eta_i/g) - 2U_c(\hat{S}_y - \eta_r/g) \ , \end{aligned} \tag{41.130}$$

41.4 Quantum correlations and entanglement

The concept of *entanglement* arose in quantum mechanics by Einstein, Podolski and Rosen's famous Gedankenexperiment, today called the *EPR paradox* [411]. In his Gedankenexperiment, Einstein tried to prove the necessity of hidden variables for quantum mechanics to be a complete theory. Consequently, we begin this chapter by introducing the notion of entangled particles and recapitulating the discussion of the EPR paradox.

Since Feynman discovered the utility of entangled states for quantum computation [1009, 268], this area of research exploded with thousands of theoretical researchers, but few experiments, due to the enormous technical difficulties of creating and controlling these states. On the other side, states of entangled photons already play an

important role in *quantum cryptography* [123]. And in the context of metrology, *spin-squeezed* correlated quantum states offer the possibility of quantum noise reduction in frequency standards [1380].

Among the various systems proposed for the realization of entangled states and quantum computing gates we will only discuss one idea, which is based on the mutual coupling of atoms through a Jaynes-Cummings-like interaction mediated by an optical mode.

41.4.1 The EPR paradox and GHZ states

Let us imagine two maximally correlated particles produced by a suitable source, which fly freely without interaction in opposite directions along the y-axis toward two detectors a and b. The particles have an internal degree of freedom (spin) $|\pm\rangle_{a,b}$, which can be measured in various directions, for example, z or x by operators $\hat{\sigma}_z^{a,b}$ or $\hat{\sigma}_x^{a,b}$. Since the particles are completely entangled, the result of a measurement on the first particle $\hat{\sigma}_z^a$ allows the prediction of the result of another measurement $\hat{\sigma}_z^b$ performed on the second particle, and similarly for $\hat{\sigma}_x^a$ and $\hat{\sigma}_x^b$. Why is that?

The theory of *hidden variables* proposed by Einstein, Podolsky and Rosen [411] postulates, that the total state describing the two particles contains all information about the way, how the particles should behave at the detectors. The information was imprinted on each one of the two particle's when they were created in the source, i.e. the total state must be of the type,

$$|\psi\rangle = \begin{pmatrix} \pm_z^a & \pm_z^b \\ \pm_x^a & \pm_x^b \end{pmatrix} , \tag{41.131}$$

where the notation should be read as a decision table.

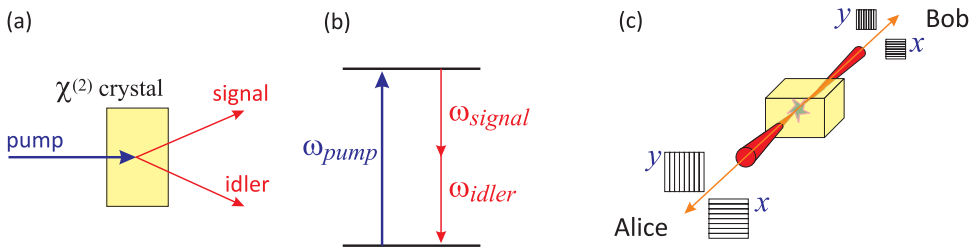

Figure 41.23: (a) Generation of entangled photon via parametric down-conversion. (b) Energy conservation upon parametric down-conversion. (c) Illustration of the EPR paradox.

On the other hand, quantum mechanics postulates that the reduction of the wavepacket describing the particle at detector a decides *spontaneously* on the result of the measurement at detector b. This decision *has no physical cause*. If the particles move with the speed of light, this decision is not restricted by *local causality* [601]. The state, also called *Bell state*, can be given in the form,

$$|\psi\rangle = |+_a \ +_b\rangle + |-_a \ -_b\rangle \ . \tag{41.132}$$

In Exc. 41.4.4.1 we check that this state cannot be expressed as a product state. Let us have a closer look at the EPR state (41.132) and imagine that particle 'a' (the one

that will later be analyzed by detector a) is embarked with Alice on a starship, while particle 'b' flies with Bob in opposite direction.

We introduce a basis choosing z as the quantization axis, that is, the basis vectors

$$|+\rangle_z = \begin{pmatrix} 1 \\ 0 \end{pmatrix} \quad , \quad |-\rangle_z = \begin{pmatrix} 0 \\ 1 \end{pmatrix} \tag{41.133}$$

are eigenvectors of the Pauli matrix $\hat{\sigma}_z$. On the other hand,

$$|+\rangle_x = \tfrac{1}{\sqrt{2}} \begin{pmatrix} 1 \\ 1 \end{pmatrix} \quad , \quad |-\rangle_x = \tfrac{1}{\sqrt{2}} \begin{pmatrix} 1 \\ -1 \end{pmatrix} \tag{41.134}$$

are eigenvectors of the Pauli matrix $\hat{\sigma}_x$. Quantum mechanics now tells us that, before any measurement, the wavefunction is in a superposition of states $|+\rangle$ and $|-\rangle$. That is, in the z-basis, using the tensor notation, we may write the entangled state (41.132) as,

$$\boxed{|\psi\rangle = \tfrac{1}{\sqrt{2}} \left(|+\rangle_z \otimes |+\rangle_z + |-\rangle_z \otimes |-\rangle_z \right)} \, . \tag{41.135}$$

But we can also express it in the x-basis,

$$\begin{aligned} |\psi\rangle &= \tfrac{1}{\sqrt{2}} \left(\tfrac{|+\rangle_x + |-\rangle_x}{\sqrt{2}} \otimes \tfrac{|+\rangle_x + |-\rangle_x}{\sqrt{2}} + \tfrac{|+\rangle_x - |-\rangle_x}{\sqrt{2}} \otimes \tfrac{|+\rangle_x - |-\rangle_x}{\sqrt{2}} \right) \\ &= \tfrac{1}{2\sqrt{2}} \begin{pmatrix} |+\rangle_x \otimes |+\rangle_x + |+\rangle_x \otimes |-\rangle_x + |-\rangle_x \otimes |+\rangle_x + |-\rangle_x \otimes |-\rangle_x \\ +|+\rangle_x \otimes |+\rangle_x - |+\rangle_x \otimes |-\rangle_x - |-\rangle_x \otimes |+\rangle_x + |-\rangle_x \otimes |-\rangle_x \end{pmatrix} \\ &= \tfrac{1}{\sqrt{2}} \left(|+\rangle_x \otimes |+\rangle_x + |-\rangle_x \otimes |-\rangle_x \right) \, . \end{aligned} \tag{41.136}$$

A generalization of this calculation to arbitrary rotations of the detector will be studied in Exc. 41.4.4.2.

After some time, Alice measures her spin in z-direction, i.e. performs a measurement of $\hat{\sigma}_z$. Her measurement not only collapses the wavefunction of Alice's spin a in either one of the states $|\pm\rangle_z$, but it instantaneously also collapses the wavefunction of Bob's spin along the z-direction,

$$|\psi\rangle \curvearrowright \begin{cases} |+\rangle_z \otimes |+\rangle_z = |+\rangle_z \otimes \frac{|+\rangle_x + |-\rangle_x}{\sqrt{2}} \\ |-\rangle_z \otimes |-\rangle_z = |+\rangle_z \otimes \frac{|+\rangle_x - |-\rangle_x}{\sqrt{2}} \end{cases} \tag{41.137}$$

Hence, if Bob measures along the z-axis, his measurement will be predefined by Alice's measurement. On the other hand, if tries to measure along the x-axis, he will find a random result with a probability of $\frac{1}{2}$ for each outcome [19]. That is, the direction of measurement in Alice's experiment fixes the quantization axis for Bob's experiment.

Two hypotheses have been put forward: The first one is that Alice's experiment sends information to Bob's experiment. Alice's particle told Bob's particle which spin

[19] Due to Bob's measurement along the x-axis Alice's wavefunction should collapse along the x-axis, as well. But according to quantum mechanics, Alice should be unable to know the spin value in x-direction, since she already knows the spin the z-direction, which is not allowed by the commutation rules,

$$[\hat{\sigma}_z^a, \hat{\sigma}_x^a] = \imath\hbar\hat{\sigma}_y^a \quad , \quad [\hat{\sigma}_z^b, \hat{\sigma}_x^b] = \imath\hbar\hat{\sigma}_y^b \, .$$

state he should be in. But this hypothesis violates the locality requirement of special relativity claiming that information cannot travel faster than light. Einstein called it 'spooky action at a distance'. The second hypothesis is to assume that quantum mechanics does not violate locality, but that the particles carry with them 'local hidden variables' [20] (like a proper DNA) whose values would be set right from the moment of the separation of the particles and which would determine the outcomes of any future spin measurement. Then, quantum mechanics would not be a complete theory, because it has nothing to say about these hidden variables.

41.4.1.1 Bell's inequality

In 1964 John S. Bell suggested an experimental test for the EPR paradox [114]. He proposed a theorem formulated as an inequality, the famous *Bell's inequality*, stating that *if the local hidden variables hypothesis proposed by Einstein is correct, then the inequality must be satisfied by experiment.*

There are many versions of Bell's inequality, all of them are equivalent. Let us follow Bell's argumentation and assume Alice and Bob to use Stern-Gerlach magnets oriented in arbitrary directions $\mathbf{a} \equiv \hat{\mathbf{e}}_{\vartheta,\varphi}$, respectively, $\mathbf{b} \equiv \hat{\mathbf{e}}_{\vartheta',\varphi'}$ to measure the expectation values,

$$\langle\psi|\hat{\vec{\sigma}}\cdot\mathbf{a}\otimes\mathbb{I}|\psi\rangle \qquad \text{and} \qquad \langle\psi|\mathbb{I}\otimes\hat{\vec{\sigma}}\cdot\mathbf{b}|\psi\rangle \tag{41.138}$$

respectively, on an anti-symmetric entangled two-spin state [21],

$$\boxed{|\psi\rangle = \tfrac{1}{\sqrt{2}}(|+\rangle_z\otimes|-\rangle_z - |+\rangle_z\otimes|-\rangle_z)} \; . \tag{41.139}$$

Let us first do the quantum calculation. Using the rules for Pauli matrices and the anti-symmetry of the entangled state,

$$\hat{\sigma}_x|\pm\rangle_z = |\mp\rangle_z \quad , \quad \hat{\sigma}_y|\pm\rangle_z = \pm\imath|\mp\rangle_z \quad , \quad \hat{\sigma}_z|\pm\rangle_z = \pm|\pm\rangle_z \; , \tag{41.140}$$

we derive in Excs. 41.4.4.3 and 41.4.4.4 the general relationship,

$$\langle\psi|\hat{\vec{\sigma}}\cdot\mathbf{a}\otimes\hat{\vec{\sigma}}\cdot\mathbf{b}|\psi\rangle = -\mathbf{a}\cdot\mathbf{b} \; , \tag{41.141}$$

which is the quantum mechanical correlation function for a joined measurement of Alice and Bob.

On the other hand, if local hidden variables exist, Alice's measurement is determined by the orientation $\mathbf{a}$ of her magnets and a (set of) hidden variable(s) λ, which are also available to Bob, whose measurement is determined by the orientation $\mathbf{b}$ of his magnets,

$$A(\mathbf{a},\lambda) \equiv \langle\psi|\hat{\vec{\sigma}}\cdot\mathbf{a}\otimes\mathbb{I}|\psi\rangle = \pm 1 \qquad \text{and} \qquad B(\mathbf{b},\lambda) \equiv \langle\psi|\mathbb{I}\otimes\hat{\vec{\sigma}}\cdot\mathbf{b}|\psi\rangle = \pm 1 \; , \tag{41.142}$$

with the crucial assumption that A does not depend on $\mathbf{b}$ and B not $\mathbf{a}$. Let us assume a probability distribution $\rho(\lambda)$ for the hidden variable satisfying $\int \rho(\lambda)d\lambda = 1$. Then the

[20] Note the difference to *non-local hidden variables* assumed by de Broglie and David Bohm in their formulation of quantum mechanics.

[21] The anti-symmetric state is chosen here for symmetry reasons facilitating the quantum calculation, but the arguments hold for any entangled state.

joint probability distribution $P(\mathbf{a},\mathbf{b})$ should coincide with the quantum mechanical correlation function,

$$P(\mathbf{a},\mathbf{b}) = \int A(\mathbf{a},\lambda)B(\mathbf{b},\lambda)\rho(\lambda)d\lambda = \langle\psi|\hat{\vec{\sigma}}\cdot\mathbf{a}\otimes\hat{\vec{\sigma}}\cdot\mathbf{b}|\psi\rangle \geq -1 \ . \tag{41.143}$$

For example, let the hidden variable now be unit vector $\vec{\lambda}$ with uniform probability distribution over all directions, such that,

$$A(\mathbf{a},\lambda) = \text{sign}(\mathbf{a}\cdot\vec{\lambda}) \qquad \text{and} \qquad B(\mathbf{b},\lambda) = -\text{sign}(\mathbf{b}\cdot\vec{\lambda}) \ . \tag{41.144}$$

Then,

$$\begin{aligned} P(\mathbf{a},\mathbf{b}) &= -\int \text{sign}(\cos\vartheta_{a\lambda})\text{sign}(\cos\vartheta_{b\lambda})\rho(\vartheta_\lambda)d\vartheta_\lambda \\ &= -\int_{\vartheta_a}^{\vartheta_b} \text{sign}(\cos\vartheta_\lambda)d\vartheta_\lambda = -1 + \tfrac{2}{\pi}\angle(\mathbf{a},\mathbf{b}) \ . \end{aligned} \tag{41.145}$$

This probability distribution clearly deviates from the quantum prediction, in particular at angles $\angle(\mathbf{a},\mathbf{b}) = \frac{\pi}{2}$, as seen in Fig. 41.24(a).

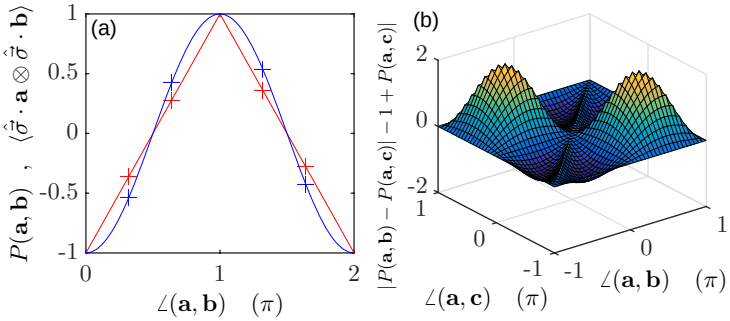

Figure 41.24: (code) (a) Joint probability distribution $P(\mathbf{a},\mathbf{b})$ in local hidden variables theory (red) and correlation function $\langle\psi|\vec{\sigma}\cdot\mathbf{a}\otimes\vec{\sigma}\cdot\mathbf{b}|\psi\rangle$ in quantum mechanics (blue). (b) Verification of Bell's inequality.

Let us finally derive Bell's inequality. Because of (41.142) for the anti-symmetric state we have the relation $B(\mathbf{b},\lambda) = -A(\mathbf{b},\lambda)$ and $A(\mathbf{a},\lambda) = A(\mathbf{a},\lambda)^{-1}$ allowing us to derive,

$$\begin{aligned} P(\mathbf{a},\mathbf{b}) - P(\mathbf{a},\mathbf{c}) &= -\int \left[A(\mathbf{a},\lambda)A(\mathbf{b},\lambda) - A(\mathbf{a},\lambda)A(\mathbf{c},\lambda)\right]\rho(\lambda)d\lambda \\ &= \int A(\mathbf{a},\lambda)A(\mathbf{b},\lambda)\left[A(\mathbf{b},\lambda)A(\mathbf{c},\lambda) - 1\right]\rho(\lambda)d\lambda \ , \end{aligned} \tag{41.146}$$

and

$$|P(\mathbf{a},\mathbf{b}) - P(\mathbf{a},\mathbf{c})| \leq \int |A(\mathbf{a},\lambda)A(\mathbf{b},\lambda)\left[A(\mathbf{b},\lambda)A(\mathbf{c},\lambda) - 1\right]|\rho(\lambda)d\lambda \tag{41.147}$$
$$\leq \int [1 - A(\mathbf{b},\lambda)A(\mathbf{c},\lambda)]\rho(\lambda)d\lambda$$
$$= \int \rho(\lambda)d\lambda + \int A(\mathbf{b},\lambda)B(\mathbf{c},\lambda)\rho(\lambda)d\lambda = 1 + P(\mathbf{b},\mathbf{c}) \ .$$

This inequality derived from the local hidden variables assumption is violated by quantum mechanics, since,

$$|\langle\hat{\vec{\sigma}}\cdot\mathbf{a}\otimes\hat{\vec{\sigma}}\cdot\mathbf{b}\rangle - \langle\hat{\vec{\sigma}}\cdot\mathbf{a}\otimes\hat{\vec{\sigma}}\cdot\mathbf{c}\rangle| = |-\mathbf{a}\cdot\mathbf{b} + \mathbf{a}\cdot\mathbf{c}| \tag{41.148}$$
$$\leq 1 - \mathbf{b}\cdot\mathbf{c} = 1 + \langle\hat{\vec{\sigma}}\cdot\mathbf{b}\otimes\hat{\vec{\sigma}}\cdot c\rangle$$

is not satisfied for arbitrary choices of $\mathbf{a}$, $\mathbf{b}$, and $\mathbf{c}$. To see this we plot in Fig. 41.24(b),

$$1 - \cos\angle(\mathbf{b},\mathbf{c}) - |\cos\angle(\mathbf{a},\mathbf{b}) - \cos\angle(\mathbf{a},\mathbf{c})| \ , \tag{41.149}$$

finding that this quantity becomes negative for some choices of the projection vectors.

Example 262 (*EPR paradox using GHZ states*): Here, we show a modified version of the EPR experiment proposed by Greenberger, Horne and Zeilinger (GHZ) based on the *GHZ state* [535]. They imagined a source creating three correlated non-interacting spin $\frac{1}{2}$ particles labeled a, b, and c flying toward three Stern-Gerlach type magnetic detectors, which measure the spins in x or in y-direction. The correct state is either quantum,

$$|\psi\rangle = |+_a \ +_b \ +_c\rangle_z - |-_a \ -_b \ -_c\rangle_z \ , \tag{41.150}$$

or

$$\boxed{|\psi\rangle = |+\rangle_z\otimes|+\rangle_z\otimes|+\rangle_z - |-\rangle_z\otimes|-\rangle_z\otimes|-\rangle_z} \ , \tag{41.151}$$

in tensor notation, or it contains hidden variables, that is, instructions telling the detectors which measurement result to exhibit upon arrival of a particle,

$$|\psi\rangle = \begin{pmatrix} \pm_x^a \ \pm_x^b \ \pm_x^c \\ \pm_y^a \ \pm_y^b \ \pm_y^c \end{pmatrix} . \tag{41.152}$$

Now, using the quantum mechanical rules (41.140), we obtain,

$$\hat{\sigma}_x\otimes\hat{\sigma}_x\otimes\hat{\sigma}_x|\psi\rangle \equiv \hat{\sigma}_x^a\hat{\sigma}_x^b\hat{\sigma}_x^c|\psi\rangle = -|\psi\rangle \ , \tag{41.153}$$

but also,

$$\hat{\sigma}_x^a\hat{\sigma}_y^b\hat{\sigma}_y^c|\psi\rangle = \hat{\sigma}_y^a\hat{\sigma}_x^b\hat{\sigma}_y^c|\psi\rangle = \hat{\sigma}_y^a\hat{\sigma}_y^b\hat{\sigma}_x^c|\psi\rangle = |\psi\rangle \ . \tag{41.154}$$

Hidden variables in a state $|\psi\rangle$ that *is not a coherent superposition* should at least be able to predict how each particle will behave in its respective detector, when we measure each one of the two spin components. From all possible combination only eight combinations can satisfy the requirement (41.154) written as,

$$\langle\hat{\sigma}_x^a\rangle\langle\hat{\sigma}_y^b\rangle\langle\hat{\sigma}_y^c\rangle = \langle\hat{\sigma}_y^a\rangle\langle\hat{\sigma}_x^b\rangle\langle\hat{\sigma}_y^c\rangle = \langle\hat{\sigma}_y^a\rangle\langle\hat{\sigma}_y^b\rangle\langle\hat{\sigma}_x^c\rangle = 1 \ . \tag{41.155}$$

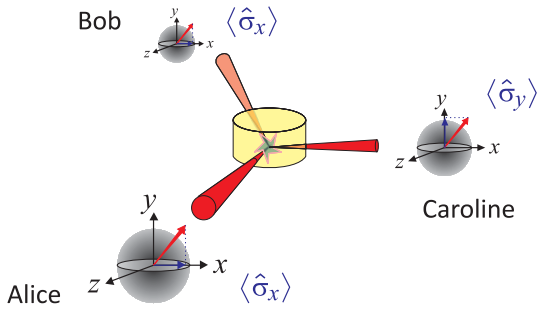

Figure 41.25: Scheme of the EPR experiment proposed by Greenberger, Horne and Zeilinger.

These are,

$$\begin{pmatrix} \langle\sigma_x^a\rangle & \langle\sigma_x^b\rangle & \langle\sigma_x^c\rangle \\ \langle\sigma_y^a\rangle & \langle\sigma_y^b\rangle & \langle\sigma_y^c\rangle \end{pmatrix} = \tag{41.156}$$
$$\begin{pmatrix} +++ \\ +++ \end{pmatrix}\begin{pmatrix} +-- \\ +-- \end{pmatrix}\begin{pmatrix} -+- \\ -+- \end{pmatrix}\begin{pmatrix} --+ \\ --+ \end{pmatrix}\begin{pmatrix} +++ \\ --- \end{pmatrix}\begin{pmatrix} +-- \\ -++ \end{pmatrix}\begin{pmatrix} -+- \\ +-+ \end{pmatrix}$$

but none of them satisfies (41.153) written as,

$$\langle\hat{\sigma}_x^a\rangle\langle\hat{\sigma}_x^b\rangle\langle\hat{\sigma}_x^c\rangle = -1 \ . \tag{41.157}$$

Therefore, the local hidden variables assumption is incompatible with quantum mechanics, and the EPR critique of quantum mechanics regarding its incompleteness must be refuted [22].

Which one of the two pictures is correct, the local hidden variables assumption or quantum mechanics, can actually be tested by Wheeler's *delayed choice* experiment. It consists of using pairs of correlated photons emitted in different directions, where they are expected by photodetectors. Polarizers located in front of the detectors fix the quantization axis to $\hat{\mathbf{e}}_x$ or $\hat{\mathbf{e}}_y$, but the choice of the axis is made only after the photons were created by the source, in order to avoid possible backactions of the polarizers on the source [23]. Bell's inequality condition [114] predicts a statistics for the results of repeated measurements where the orientation of the polarizers is randomly varied. The experiment run by Aspect [56, 54] showed that the assumption of local hidden variables violates *local realism* and thus confirmed quantum mechanics as being a complete theory.

[22] Note that the coupling of different degrees of freedom *is not* an entanglement, but it is the *condition* for being able to generate entanglement.

[23] We note that first attempts to demonstrate wave-particle duality with single photons in dilute laser beams are not really conclusive, because the attenuation of a coherent state does NOT result in a single photon states (non-classical Fock state). Even if on average only less than one photon is in the interferometer, this may still be a Glauber state. Nonetheless, real single photon experiments involving the deexcitation of individual atoms by emission of two photons, produced the same result.

41.4.2 Information entropy

According to von Neumann, we can define the *von Neumann entropy*, also called quantum *information entropy* as,

$$\boxed{S \equiv -\langle \log_2 \hat{\rho} \rangle = \mathrm{Tr}\ (\hat{\rho} \log_2 \hat{\rho}) = -\sum_n \hat{\rho}_n \log_2 \hat{\rho}_n} \ , \tag{41.158}$$

where $\rho_n \equiv \langle n|\hat{\rho}|n\rangle$. For statistically independent systems the density operator is $\hat{\rho} = \hat{\rho}_1 \otimes \hat{\rho}_2$ and the entropy is additive $S = S_1 + S_2$. The entropy is observable, that is, independent of the basis and invariant with respect to unitary transformations. Therefore, $\hat{\rho}$ can be diagonalized and can be assumed diagonal in the following examples. For N independent qubits the density operator $\hat{\rho}^{(N)}$ and the entropy $S^{(N)}$ are:

$$\begin{aligned}
&\hat{\rho}^{(0)} = |+\rangle\langle+| && , \quad S^{(0)} = 0 \text{ bit} \\
&\hat{\rho}^{(1)} = \tfrac{1}{2}(|+\rangle\langle+| + |-\rangle\langle-|) && , \quad S^{(1)} = 1 \text{ bits} \\
&\hat{\rho}^{(2)} = \tfrac{1}{4}(|++\rangle\langle++| + |+-\rangle\langle+-| + |-+\rangle\langle-+| + |--\rangle\langle--|) && , \quad S^{(2)} = 2 \text{ bits} \\
&\hat{\rho}^{(N)} = \tfrac{1}{2^N}(|++...\rangle\langle++...| + ...) && , \quad S^{(N)} = N \text{ bits} \ .
\end{aligned} \tag{41.159}$$

The set is canonical and the entropy maximal. On the other hand, if the states are entangled, the entropy is always less than $S^{(N)} = N$ bits. For the state of maximally entangled spins, we have,

$$\rho^{(N)}_{corr} = \tfrac{1}{2^N}(|++...+\rangle\langle++...+| + |--...-\rangle\langle--...-|) \quad , \quad S^{(N)}_{corr} = 1 \text{ bit} \ . \tag{41.160}$$

Entropy is a measure for the degree of entanglement of a system. For a Dicke state $|J, M\rangle$ the entropy is,

$$S_{JM} = -\log_2 \binom{2J}{J+M} \ . \tag{41.161}$$

For beam splitters, the information entropy is calculated as follows: A Fock state $|N\rangle = |+\rangle^N$ divided by a beam splitter is described by,

$$\begin{aligned}
2^{-N/2}(|+\rangle + |-\rangle)^N &= \tfrac{1}{2^{N/2}} \sum_{n=0}^{N} \binom{N}{n} |+\rangle^{N-n}|-\rangle^n \\
\rho^{(N)}_{split} &= \tfrac{1}{2^N} \sum_{n,m=0}^{N} \binom{N}{n}\binom{N}{m} |+\rangle^{N-n}|-\rangle^n\langle+|^{N-m}\langle-|^m \\
\rho^{(N)}_{split} &= \tfrac{1}{2^N} \sum_{n=0}^{N} \binom{N}{n}\binom{N}{n} |+\rangle^{N-n}|-\rangle^n\langle+|^{N-n}\langle-|^n \ .
\end{aligned} \tag{41.162}$$

For the information entropy, we obtain,

$$S^{(N)}_{split} = N + \tfrac{1}{2^N} \sum_{n=0}^{N} \binom{N}{n} \log_2 \binom{N}{n} \ . \tag{41.163}$$

The division of a beam is an incoherent process in the sense that it increases the entropy. The process is *irreversible*. The divided beams can not be recombined by a coherent process. For example, an interferometer always has two output ports. However, the phase is preserved.

The *quantum information content* is defined by the deviation from maximum entropy,

$$Q = S_{mx} - S_{actual} \ . \tag{41.164}$$

If the system is in a mixed state, the entropy measures deviations from a pure state behavior [99].

41.4.3 Classical and quantum correlations

Correlation is described by a system of coupled differential equations, each one describing another degree of freedom. The correlation between a degree of freedom and the rest of the system is lost, if their dynamics decouples. In quantum mechanics, this translates into the impossibility of factorizing the full density matrix of the correlated states. The *correlation index* is defined as the informational content of the correlation between two systems,

$$\begin{aligned} I &= Q - (Q_a + Q_b) \\ &= S_{mx,tot} - S_{actual,tot} - (S_{mx,a} - S_{actual,a} + S_{mx,b} - S_{actual,b}) \\ &= S_{actual,a} + S_{actual,b} - S_{actual,tot} \ . \end{aligned} \tag{41.165}$$

Classical correlations are those which are allowed by a local realistic theory, whereas quantum correlations are incompatible with the classical notion of local realism [99].

A measure for the entanglement of two modes is the *cross-correlation* of their intensity at equal times,

$$g^{(2)}_{a,b}(0) = \frac{\langle \hat{a}^\dagger(t)\hat{a}(t)\hat{b}^\dagger(t)\hat{b}(t)\rangle}{\langle \hat{a}^\dagger(t)\hat{a}(t)\rangle\langle \hat{b}^\dagger(t)\hat{b}(t)\rangle} \ . \tag{41.166}$$

The *Cauchy-Schwartz relation*,

$$g^{(2)}_{a,b}(\tau) \leq \sqrt{g^{(2)}_{a,a}(\tau)}\sqrt{g^{(2)}_{b,b}(\tau)} \tag{41.167}$$

only applies to classical states. Quantum states satisfy,

$$g^{(2)}_{a,b}(\tau) \leq \sqrt{\left[g^{(2)}_{a,a}(\tau) + \frac{1}{I_a(\tau)}\right]}\sqrt{\left[g^{(2)}_{b,b}(\tau) + \frac{1}{I_b(\tau)}\right]} \ , \tag{41.168}$$

where $I_k(\tau) = \langle \hat{k}^\dagger(t)\hat{k}(t)\rangle$.

Example 263 (*Classical versus quantum correlations*): A simple example for a *classical correlation* is the following: Imagine a white and a red billiard ball. Both are put in black boxes and embarked on star-ships heading off at light speed in opposite directions without letting the commanders know their color. When after one year of travel they open the boxes and verify the color of

their respective balls, they immediately know the color of the ball on the other star-ship. This 'measurement' is not limited by the speed of light, which would take two years to pass information between the star-ships.
A *quantum correlation* is more tricky than that. To get closer to the essence of quantum correlations, let us refine the classical example: Now, we assume that the billiard balls are made of different materials, so that we have one *heavy* white or red ball and one *light* white or red ball. Again they are embarked on star-ships. The commanders are now advised to open the boxes and EITHER sense the weights of the balls OR look at them to acknowledge their colors.
The difference of the quantum world begin here already: If the billiard balls were quantum particles, e.g. photons, the measurements of their properties would be exclusive.
Now, assume furthermore that instead of one box the star-ships embark 10 boxes, each one receiving one of two balls.

41.4.4 Exercises

41.4.4.1 Ex: Bell states

Show that the Bell states cannot be written as products of two states.

Solution: *In the product state,*

$$(c_+|+\rangle + c_-|-\rangle)^2 = c_+^2|++\rangle + c_-^2|--\rangle + c_+c_-|+-\rangle + c_-c_+|-+\rangle$$

the coefficients must satisfy $c_+c_- = 0$ *in order to have a Bell state, which is only possible if either* c_+ *or* c_- *is zero.*

41.4.4.2 Ex: Behavior of entanglement upon rotation of the quantization axis

Show that the anti-symmetric entangle Bell state remains entangled upon rotation of the quantization axis, that is,

$$|+\rangle_{\vartheta,\varphi} \otimes |-\rangle_{\vartheta,\varphi} - |-\rangle_{\vartheta,\varphi} \otimes |+\rangle_{\vartheta,\varphi} \;\propto\; |+\rangle_z \otimes |-\rangle_z - |-\rangle_z \otimes |+\rangle_z \;,$$

where $|\pm\rangle_{\vartheta,\varphi}$ are the eigenstates of the Pauli spin operator $\hat{\vec{\sigma}}$.

Solution: *Choosing the eigenstates of the rotated basis as,*

$$\begin{aligned}
|+\rangle_{\vartheta,\varphi} &\equiv |\vartheta,\varphi\rangle = \cos\tfrac{\vartheta}{2}|+\rangle_z + e^{\imath\varphi}\sin\tfrac{\vartheta}{2}|-\rangle_z \\
|-\rangle_{\vartheta,\varphi} &\equiv |\pi-\vartheta,\varphi+\pi\rangle = \sin\tfrac{\vartheta}{2}|+\rangle_z - e^{\imath\varphi}\cos\tfrac{\vartheta}{2}|-\rangle_z \;.
\end{aligned}$$

we see,

$$\begin{aligned}
|\psi\rangle &= \tfrac{1}{\sqrt{2}}\left[|\vartheta,\varphi\rangle \otimes |\pi-\vartheta,\varphi+\pi\rangle - |\pi-\vartheta,\varphi+\pi\rangle \otimes |\vartheta,\varphi\rangle\right] \\
&= \tfrac{1}{\sqrt{2}}\Big[\big(\cos\tfrac{\vartheta}{2}|+\rangle_z + e^{\imath\varphi}\sin\tfrac{\vartheta}{2}|-\rangle_z\big) \otimes \big(\sin\tfrac{\vartheta}{2}|+\rangle_z - e^{\imath\varphi}\cos\tfrac{\vartheta}{2}|-\rangle_z\big) \\
&\qquad - \big(\sin\tfrac{\vartheta}{2}|+\rangle_z - e^{\imath\varphi}\cos\tfrac{\vartheta}{2}|-\rangle_z\big) \otimes \big(\cos\tfrac{\vartheta}{2}|+\rangle_z + e^{\imath\varphi}\sin\tfrac{\vartheta}{2}|-\rangle_z\big)\Big] \\
&= -\tfrac{-e^{\imath\varphi}}{\sqrt{2}}\left[|+\rangle_z \otimes |-\rangle_z - |-\rangle_z \otimes |+\rangle_z\right] \;.
\end{aligned}$$

41.4.4.3 Ex: Rotations with Pauli matrices

a. Verify,

$$e^{-\imath(\pi/4)\hat{\sigma}_k}\hat{\sigma}_m e^{\imath(\pi/4)\hat{\sigma}_k} = \epsilon_{kmn}\hat{\sigma}_n + \delta_{km}\hat{\sigma}_k \qquad \text{with} \qquad (kmn) = (xyz) \ .$$

b. Prove,

$$|\vartheta,\varphi\rangle = e^{-\imath\varphi(\hat{\sigma}_z - I)/2}e^{-\imath\vartheta\hat{\sigma}_y/2}|0,0\rangle = e^{\imath\varphi/2}e^{-\imath\varphi\hat{\sigma}_z/2}e^{-\imath\vartheta\hat{\sigma}_y/2}|+\rangle \ .$$

c. Solve the eigenvalue equations,

$$\hat{\vec{\sigma}}\cdot\hat{\mathbf{e}}_z|\vartheta,\varphi\rangle = m|\vartheta,\varphi\rangle \qquad \text{and} \qquad \hat{\vec{\sigma}}\cdot\hat{\mathbf{e}}_\rho|\vartheta,\varphi\rangle = m|\vartheta,\varphi\rangle \ ,$$

with $\hat{\mathbf{e}}_\rho \equiv \hat{\mathbf{e}}_x\cos\phi + \hat{\mathbf{e}}_y\sin\phi$.

Solution: *a. This follows as a generalization of Exc. 23.3.10.5 with the definition of the Pauli matrices.*
b. We show,

$$|\vartheta,\varphi\rangle = \cos\tfrac{\vartheta}{2}|+\rangle + e^{\imath\varphi}\sin\tfrac{\vartheta}{2}|-\rangle = ...$$

c. The eigenvalue equation for polar quantization axis is,

$$\begin{aligned}\vec{\sigma}\cdot\hat{\mathbf{e}}_z|\vartheta,\varphi\rangle = \hat{\sigma}_z|\vartheta,\varphi\rangle &= \begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix}\left(\cos\tfrac{\vartheta}{2}|+\rangle + e^{\imath\varphi}\sin\tfrac{\vartheta}{2}|-\rangle\right)\\ &= \cos\tfrac{\vartheta}{2}|+\rangle - e^{\imath\varphi}\sin\tfrac{\vartheta}{2}|-\rangle \equiv m\left(\cos\tfrac{\vartheta}{2}|+\rangle + e^{\imath\varphi}\sin\tfrac{\vartheta}{2}|-\rangle\right) \ ,\end{aligned}$$

which can only be true for $m = 1$ with $|\vartheta,\varphi\rangle = |0,\varphi\rangle = |+\rangle$ or $m = -1$ with $|\vartheta,\varphi\rangle = |\pi,\varphi\rangle = |-\rangle$. Hence,

$$P_{m=1} = \langle\vartheta,\varphi|0,\varphi\rangle\langle 0,\varphi|\vartheta,\varphi\rangle = \tfrac{1}{2} = \langle\vartheta,\varphi|\pi,\varphi\rangle\langle\pi,\varphi|\vartheta,\varphi\rangle = P_{m=-1}$$
$$\langle\vartheta,\varphi|\vec{\sigma}\cdot\hat{\mathbf{e}}_z|\vartheta,\varphi\rangle = \cos\vartheta = \pm 1 = m \ .$$

For the azimuthal quantization axis,

$$\begin{aligned}\vec{\sigma}\cdot\hat{\mathbf{e}}_\rho|\vartheta,\varphi\rangle = (\hat{\sigma}_x\cos\phi + \hat{\sigma}_y\sin\phi)|\vartheta,\varphi\rangle &= \begin{pmatrix}0 & e^{-\imath\phi}\\ e^{\imath\phi} & 0\end{pmatrix}\left(\cos\tfrac{\vartheta}{2}|+\rangle + e^{\imath\varphi}\sin\tfrac{\vartheta}{2}|-\rangle\right)\\ &= e^{\imath\phi}\cos\tfrac{\vartheta}{2}|-\rangle + e^{-\imath\phi}e^{\imath\varphi}\sin\tfrac{\vartheta}{2}|+\rangle \equiv m\left(\cos\tfrac{\vartheta}{2}|+\rangle + e^{\imath\varphi}\sin\tfrac{\vartheta}{2}|-\rangle\right) \ ,\end{aligned}$$

which can only be true for $m = 1$ with $|\vartheta,\varphi\rangle = |\frac{\pi}{2},\phi\rangle$ or $m = -1$ with $|\vartheta,\varphi\rangle = |\frac{\pi}{2},\pi+\phi\rangle$. Hence,

$$P_{m=1} = \langle\vartheta,\varphi|\tfrac{\pi}{2},\phi\rangle\langle\tfrac{\pi}{2},\phi|\vartheta,\varphi\rangle = \tfrac{1}{2} = \langle\vartheta,\varphi|\tfrac{\pi}{2},\pi+\phi\rangle\langle\tfrac{\pi}{2},\pi+\phi|\vartheta,\varphi\rangle = P_{m=-1}$$
$$\langle\vartheta,\varphi|\vec{\sigma}\cdot\hat{\mathbf{e}}_\rho|\vartheta,\varphi\rangle = \cos(\varphi-\phi)\sin\vartheta = \pm 1 = m \ .$$

41.4.4.4 Ex: Projections of single-atom spins and their correlations

a. Calculate explicitly $\langle\vartheta,\varphi|\hat{\vec{\sigma}}|\vartheta,\varphi\rangle$ and $\langle\vartheta',\varphi'|\hat{\vec{\sigma}}\cdot\hat{\mathbf{e}}_{\vartheta,\varphi}|\vartheta',\varphi'\rangle$, where $|\vartheta,\varphi\rangle$ are the states defined in (41.10), using the basis ${}_z\langle+| = (1\ 0)$ and ${}_z\langle-| = (0\ 1)$.
b. For the anti-symmetric entangled two-atom spin state defined in (41.139) calculate the spin projection correlations $\langle\psi|\hat{\vec{\sigma}}\cdot\hat{\mathbf{e}}_{\vartheta,\varphi}\otimes\hat{\vec{\sigma}}\cdot\hat{\mathbf{e}}'_{\vartheta,\varphi}|\psi\rangle$.

Solution: *Using the rules (41.140) for Pauli matrices on the anti-symmetric entangled two-spin state, we can readily show,*

$$\langle\psi|\hat{\sigma}_x\otimes\hat{\sigma}_x|\psi\rangle = \langle\psi|\hat{\sigma}_y\otimes\hat{\sigma}_y|\psi\rangle = \langle\psi|\hat{\sigma}_z\otimes\hat{\sigma}_z|\psi\rangle = -1$$
$$\langle\psi|\hat{\sigma}_x\otimes\hat{\sigma}_y|\psi\rangle = \langle\psi|\hat{\sigma}_y\otimes\hat{\sigma}_z|\psi\rangle = \langle\psi|\hat{\sigma}_z\otimes\hat{\sigma}_x|\psi\rangle = 0\ .$$

a. The choice of the basis sets z as the quantization axis for which the Pauli matrices are defined. We consider an arbitrary projection axis given by the vector $|\vartheta,\varphi\rangle$. From now on dropping the subscript z, using the Pauli matrix rules, it is easy to see,

$$\langle\vartheta,\varphi|\hat{\vec{\sigma}}|\vartheta,\varphi\rangle = R_z(\varphi)R_y(\vartheta)\hat{\mathbf{e}}_z = \begin{pmatrix}\sin\vartheta\cos\varphi\\ \sin\vartheta\sin\varphi\\ \cos\vartheta\end{pmatrix} = \hat{\mathbf{e}}_{\vartheta,\varphi}\ .$$

Likewise,

$$\begin{aligned}&\langle\vartheta',\varphi'|\hat{\vec{\sigma}}\cdot\hat{\mathbf{e}}_{\vartheta,\varphi}|\vartheta',\varphi'\rangle\\ &= \left(\cos\tfrac{\vartheta'}{2}\langle+| + e^{-\imath\varphi'}\sin\tfrac{\vartheta'}{2}\langle-|\right)(\hat{\sigma}_x\sin\vartheta\cos\varphi + \hat{\sigma}_y\sin\vartheta\sin\varphi + \hat{\sigma}_z\cos\vartheta)\left(\cos\tfrac{\vartheta'}{2}|+\rangle + e^{\imath\varphi'}\sin\tfrac{\vartheta'}{2}|-\rangle\right)\\ &= \hat{\mathbf{e}}_{\vartheta,\varphi}\cdot\hat{\mathbf{e}}_{\vartheta',\varphi'}\ .\end{aligned}$$

Also,

$$|\pi-\vartheta,-\varphi\rangle = \cos\tfrac{\pi-\vartheta}{2}|+\rangle + e^{-\imath\varphi}\sin\tfrac{\pi-\vartheta}{2}|-\rangle = \sin\tfrac{\vartheta}{2}|+\rangle + e^{-\imath\varphi}\cos\tfrac{\vartheta}{2}|-\rangle = e^{-\imath\varphi}\hat{\sigma}_x|\vartheta,\varphi\rangle\ ,$$

and,

$$\hat{\sigma}_z\hat{\sigma}_y\hat{\sigma}_x|\vartheta,\varphi\rangle = \hat{\sigma}_z\hat{\sigma}_y\hat{\sigma}_x\left(\cos\tfrac{\vartheta}{2}|+\rangle + e^{\imath\varphi}\sin\tfrac{\vartheta}{2}|-\rangle\right) = -\imath|\vartheta,\varphi\rangle\ .$$

b. The correlations are,

$$\begin{aligned}&\langle\psi|\hat{\vec{\sigma}}\cdot\hat{\mathbf{e}}_{\vartheta,\varphi}\otimes\hat{\vec{\sigma}}\cdot\hat{\mathbf{e}}'_{\vartheta,\varphi})|\psi\rangle\\ &= \langle\psi|\begin{pmatrix}\hat{\sigma}_x\otimes\hat{\sigma}_x\sin\vartheta\cos\varphi\sin\vartheta'\cos\varphi' + \hat{\sigma}_x\otimes\hat{\sigma}_y\sin\vartheta\cos\varphi\sin\vartheta'\sin\varphi'\\ +\hat{\sigma}_x\otimes\hat{\sigma}_z\sin\vartheta\cos\varphi\cos\vartheta' + \hat{\sigma}_y\otimes\hat{\sigma}_x\sin\vartheta\sin\varphi\sin\vartheta'\cos\varphi'\\ +\hat{\sigma}_y\otimes\hat{\sigma}_y\sin\vartheta\sin\varphi\sin\vartheta'\sin\varphi' + \hat{\sigma}_y\otimes\hat{\sigma}_z\sin\vartheta\sin\varphi\cos\vartheta'\\ +\hat{\sigma}_z\otimes\hat{\sigma}_x\cos\vartheta\sin\vartheta'\cos\varphi' + \hat{\sigma}_z\otimes\hat{\sigma}_y\cos\vartheta\sin\vartheta'\sin\varphi'\\ +\hat{\sigma}_z\otimes\hat{\sigma}_z\cos\vartheta\cos\vartheta'\end{pmatrix}|\psi\rangle\\ &= -\begin{pmatrix}\sin\vartheta\cos\varphi\\ \sin\vartheta\sin\varphi\\ \cos\vartheta\end{pmatrix}\begin{pmatrix}\sin\vartheta'\cos\varphi'\\ \sin\vartheta'\sin\varphi'\\ \cos\vartheta'\end{pmatrix} = -\hat{\mathbf{e}}_{\vartheta,\varphi}\cdot\hat{\mathbf{e}}'_{\vartheta,\varphi} = -\cos\measuredangle(\hat{\mathbf{e}}_{\vartheta,\varphi},\hat{\mathbf{e}}'_{\vartheta,\varphi})\ .\end{aligned}$$

41.4.4.5 Ex: Entanglement

Upon detecting the polarization of one photon in an entangled photon pair the polarization of the other photon gets determined. Does this lead to a faster than light communication? Justify your answer. How would you demonstrate the no-cloning theorem from the assumption that relativistic causality should prevail.

Solution:

41.4.4.6 Ex: Entanglement

Three photon are prepared in the GHZ state defined as,

$$|\psi\rangle = \tfrac{1}{\sqrt{3}}\left(|h\rangle_1|h\rangle_2|h\rangle_3 + |v\rangle_1|v\rangle_2|v\rangle_3\right) \ .$$

Show that, when the components of polarization are measured along the axes that have an angle of 45° with respect to the original axes, corresponding to the states,

$$|h'\rangle = \tfrac{1}{\sqrt{2}}(|h\rangle + |v\rangle) \qquad \text{and} \qquad |v'\rangle = \tfrac{1}{\sqrt{2}}(|h\rangle - |v\rangle) \ ,$$

one gets necessarily an even number of photons with vertical polarization v'.

Solution: *Inserting the basis transform,*

$$|h\rangle = \tfrac{1}{\sqrt{2}}(|h'\rangle + |v'\rangle) \qquad , \qquad |v\rangle = \tfrac{1}{\sqrt{2}}(|h'\rangle - |v'\rangle)$$

in to the GHZ state, we get,

$$\begin{aligned}|\psi\rangle &= \tfrac{1}{\sqrt{3}}\tfrac{1}{\sqrt{2}^3}\left[(|h'\rangle + |v'\rangle)\otimes(|h'\rangle + |v'\rangle)\otimes(|h'\rangle + |v'\rangle) + (|h'\rangle - |v'\rangle)\otimes(|h'\rangle - |v'\rangle)\otimes(|h'\rangle - |v'\rangle)\right] \\ &= \tfrac{1}{\sqrt{6}}\left[|h'\rangle\otimes|h'\rangle\otimes|h'\rangle + |h'\rangle\otimes|v'\rangle\otimes|v'\rangle + |v'\rangle\otimes|v'\rangle\otimes|h'\rangle + |v'\rangle\otimes|h'\rangle\otimes|v'\rangle\right] \ ,\end{aligned}$$

which confirms the assertion.

41.4.4.7 Ex: NOON state

A *NOON state* is a quantum-mechanical many-body entangled state:

$$|\psi_{\text{NOON}}\rangle = \frac{|N\rangle_a|0\rangle_b + e^{\imath N\theta}|0\rangle_a|N\rangle_b}{\sqrt{2}} \ , \tag{41.169}$$

which represents a superposition of N particles in mode a with zero particles in mode b, and vice versa. Usually, the particles are photons, but in principle any bosonic field can support NOON states.
Two-photon NOON states, where $N = 2$, can be created deterministically from two identical photons and a 50:50 beam splitter. This is called the Hong-Ou-Mandel effect in quantum optics. Three- and four-photon NOON states cannot be created deterministically from single-photon states, but they have been created probabilistically via post-selection using spontaneous parametric down-conversion.

Solution: *NOON states are an important concept in quantum metrology and quantum sensing for their ability to make precision phase measurements when used in an optical interferometer. For example, consider the observable,*

$$A = |N,0\rangle\langle 0,N| + |0,N\rangle\langle N,0| \ , \tag{41.170}$$

The expectation value of A for a system in a NOON state switches between $+1$ and -1 when the phase changes from 0 to π/N. Moreover, the error in the phase measurement becomes,

$$\Delta\theta = \frac{\Delta A}{|d\langle A\rangle/d\theta|} = \frac{1}{N} \ . \tag{41.171}$$

This is the so-called Heisenberg limit, and gives a quadratic improvement over the standard quantum limit.

41.5 Creating quantum correlations

Since the experimental verification of *Bell's inequality* [57] numerous ideas were proposed for the creation and application of correlated states in distant particles. Realistic proposals on how to create such states are often based on a Jaynes-Cummings type coupling between states of atomic excitation and the degrees of freedom of a harmonic oscillator. The Jaynes-Cummings dynamics has been extensively studied in micromasers, where the non-resonant interaction of an atomic transition with the TEM_{00} mode of a stored radiation field generates quantum coherences. In very high finesse cavities, light field states with sub-Poissonian photon statistics can be generated and stored for macroscopic times, and schemes for the creation of Fock states and Schrödinger cat states were proposed and tested. Furthermore, the electronic excitation states of atoms successively traversing a micromaser can be correlated under suitable conditions. The availability of fundamental techniques motivated proposals for the investigation of phenomena such as EPR correlations, quantum teleportation, and quantum switching [382]. On the other hand, quantum coherences are very fragile to dissipation and rapidly decay when exposed to perturbations.

Jaynes-Cummings type dynamics can also be realized with a single ion stored in a Paul trap, where the interaction of its mechanical motion with an electronic transition [157] can induce very stable quantum coherences in the vibrational degrees of freedom. Schrödinger cat states have already been demonstrated in this system [866], as well as fundamental parts of a quantum computer, the quantum *controlled not gate* [866] and the quantum *phase gate* [1320]. In Sec. 41.5.1 we present a possible extension of these ideas to several atoms in a collective Jaynes-Cummings type interaction (also called Tavis-Cummings model) with a single harmonic oscillator mode.

In order to correlate particles, they must be able to exchange information, that is, they must interact in some way. One method uses ions trapped in a linear Paul trap, where they form a straight chain, individually driven by laser beams and coupled to each other via their vibrational degrees of freedom mediated through Coulomb repulsion [268]. We present this idea in Sec. 41.5.2. Such scenarios have been implemented

to create the first quantum computers. Another way consists in trapping neutral atoms in a dual optical lattice and let them undergo *controlled collisions* [661], as will be discussed in Sec. 41.5.3.

Alternative approaches to realizing quantum gates use dipole-dipole interactions [194], conditional Raman adiabatic passages by laser-induced excitation of interatomic dipole-dipole interactions [823], or interactions between permanent dipoles of atoms in Rydberg states [662] [24]

41.5.1 Correlating atoms in the Jaynes-Cummings model

In Sec. 35.4 we showed already that the Jaynes-Cummings model is able to perform coherent operations on a two-level system –which from now on we will call *qubit*–, such as the *population inversion* (NOT-gate) and the controlled dephasing of an excited dipole moment (phase gate). These operations are fundamental for applications in quantum information, however, we still lack essential ingredients allowing us to entangle states of two, three or more qubits in order to perform a *quantum register* of *qubits*. Once these register are realized, we must define coherent quantum operations called *quantum gates*.

41.5.1.1 Tavis-Cummings model for 2 atoms

In Sec. 35.4 we showed, how a Jaynes-Cummings interaction between an atom and a radiation field can exchange quantum correlations. It is reasonable to expect that, when we have two (or more) atoms interacting with the same radiation field, we can exchange correlations between atoms via the field. This would allow the implementation of entanglement protocols and quantum gates. We will disregard spontaneous processes, such that all couplings are then coherent and the processes reversible.

In Sec. 23.3.9 we learned, how to span a Hilbert space of various particles. We will now apply these notions in the scope of generalizing the Jaynes-Cummings model to *two atoms interacting with the same optical mode*, without spontaneous decay processes considered. The system is often referred to as the *Tavis-Cummings model*. The Hamiltonian of the system, which consists of two non-interacting atoms, both coupled in the same optical mode, is,

$$\boxed{\hat{H} = \omega \hat{a}^\dagger \hat{a} + \sum_{i=1,2} \omega_{ai} (\hat{\sigma}_i^+ \hat{\sigma}_i^- - \tfrac{1}{2}) + \sum_{i=1,2} \tfrac{1}{2} g_i(t) (\hat{a}\hat{\sigma}_i^+ + \hat{a}^+ \hat{\sigma}_i^-)} \,. \tag{41.172}$$

The suffix denotes the individual atoms. Note that the coupling constant $g_i(t)$ can be considered as time dependent, which may be useful for modeling radiation pulse envelopes. In matrix representation the Hamiltonian acting on the subspace of n photons is,

$$|\psi\rangle = \sum_n \begin{pmatrix} c_{11\ n+1} \\ c_{12\ n} \\ c_{21\ n} \\ c_{22\ n-1} \end{pmatrix} |n\rangle \qquad \text{where} \qquad c_{ij} \equiv_1 \langle j|_2 \langle i|\langle n|\psi\rangle \tag{41.173}$$

[24] A system to create quantum correlations is the *optical parametric oscillator* (OPO).

for example, $\langle n| \otimes \langle 1| \otimes \langle 1| = \langle n|(1\ 0\ 0\ 0)$, $\langle n| \otimes \langle 2| \otimes \langle 1| = \langle n|(0\ 1\ 0\ 0)$, and so on. The atomic transition operators are generalized to,

$$\hat{\sigma}_1^- = \sum_n |n\rangle\hat{\sigma}^- \otimes \mathbb{I}\langle n| = \sum_n |n\rangle \begin{pmatrix} & & 1 & \\ & & & 1 \\ 0 & & & \\ & 0 & & \end{pmatrix} \langle n| \tag{41.174}$$

$$\hat{\sigma}_2^- = \sum_n |n\rangle\mathbb{I} \otimes \hat{\sigma}^- \langle n| = \sum_n |n\rangle \begin{pmatrix} & 1 & & \\ 0 & & & \\ & & & 1 \\ & & 0 & \end{pmatrix} \langle n| \quad , \text{etc. .}$$

The Hamiltonian is, on this basis,

$$\hat{H} = \sum_n |n\rangle \begin{pmatrix} n\omega - \frac{\omega_{a1}}{2} - \frac{\omega_{a2}}{2} & & & \\ & n\omega - \frac{\omega_{a1}}{2} + \frac{\omega_{a2}}{2} & & \\ & & n\omega + \frac{\omega_{a1}}{2} - \frac{\omega_{a2}}{2} & \\ & & & n\omega + \frac{\omega_{a1}}{2} + \frac{\omega_{a2}}{2} \end{pmatrix} \langle n| + \sum_n |n-1\rangle\sqrt{n} \begin{pmatrix} 0 & & & \\ g_2 & & & \\ g_1 & & & \\ 0 & g_1 & g_2 & 0 \end{pmatrix} \langle n| + \sum_n |n+1\rangle\sqrt{n+1} \begin{pmatrix} 0 & g_2 & g_1 & 0 \\ & & & g_1 \\ & & & g_2 \\ & & & 0 \end{pmatrix} \langle n| \ . \tag{41.175}$$

Now, we can rearrange the subspaces and finally get,

$$\hat{H} = \sum_n |n\rangle \begin{pmatrix} (n+1)\omega - \frac{\omega_{a1}}{2} - \frac{\omega_{a2}}{2} & g_1\sqrt{n} & g_2\sqrt{n} & \\ g_1\sqrt{n} & n\omega + \frac{\omega_{a1}}{2} - \frac{\omega_{a2}}{2} & & g_2\sqrt{n+1} \\ g_2\sqrt{n} & & n\omega - \frac{\omega_{a1}}{2} + \frac{\omega_{a2}}{2} & g_1\sqrt{n+1} \\ & g_2\sqrt{n+1} & g_1\sqrt{n+1} & (n-1)\omega + \frac{\omega_{a1}}{2} + \frac{\omega_{a2}}{2} \end{pmatrix} \langle n| \ . \tag{41.176}$$

The density operator for the subspace is,

$$\hat{\rho} = \begin{pmatrix} |n+1\rangle|1\rangle_1|1\rangle_2\ {}_1\langle 1|_2\langle 1|\langle n+1| & |n+1\rangle|1\rangle_1|1\rangle_2\ {}_1\langle 1|_2\langle 2|\langle n| & \dots \\ |n\rangle|1\rangle_2|1\rangle_2\ {}_1\langle 1|_2\langle 1|\langle n+1| & \dots & \\ |n\rangle|2\rangle_1|2\rangle_2\ {}_1\langle 1|_2\langle 1|\langle n+1| & \dots & \\ |n-1\rangle|2\rangle_1|2\rangle_2\ {}_1\langle 1|_2\langle 1|\langle n+1| & \dots & \end{pmatrix} , \tag{41.177}$$

if the basis is again defined by equation (41.174).

41.5.1.2 Resonant excitation

To discuss the case of resonant excitation, $\Delta_1 = \Delta_2 = 0$, let us assume identical atoms, $\omega_{a1} = \omega_{a2} \equiv \omega_0$, and equal Rabi frequencies, $g_1 = g_2 \equiv g$. Assuming dipolarly

forbidden strongly saturated transition, $n = \alpha^2$ for all n, the Hamiltonian simplifies considerably,

$$\hat{H}_n = \begin{pmatrix} n\omega & g\sqrt{n} & g\sqrt{n} & \\ g\sqrt{n} & n\omega & & g\sqrt{n} \\ g\sqrt{n} & & n\omega & g\sqrt{n} \\ & g\sqrt{n} & g\sqrt{n} & n\omega \end{pmatrix} ,$$

the eigenvalues can be calculated and the time evolution matrix becomes, using the abbreviation $\varphi \equiv gt\sqrt{n}$,

$$\boxed{e^{-\imath\hat{H}_n t} = e^{-\imath\hat{H}_n^{A1}t} e^{-\imath\hat{H}_n^{A2}t} = \begin{pmatrix} \cos^2\varphi & \imath\sin\varphi\cos\varphi & \imath\sin\varphi\cos\varphi & -\sin^2\varphi \\ \imath\sin\varphi\cos\varphi & \cos^2\varphi & -\sin^2\varphi & \imath\sin\varphi\cos\varphi \\ \imath\sin\varphi\cos\varphi & -\sin^2\varphi & \cos^2\varphi & \imath\sin\varphi\cos\varphi \\ -\sin^2\varphi & \imath\sin\varphi\cos\varphi & \imath\sin\varphi\cos\varphi & \cos^2\varphi \end{pmatrix}} . \tag{41.178}$$

For a π-pulse, we get,

$$e^{-\imath\hat{H}_n t} \xrightarrow{\pi/2} \frac{1}{2}\begin{pmatrix} 1 & \imath & \imath & -1 \\ \imath & 1 & -1 & \imath \\ \imath & -1 & 1 & \imath \\ -1 & \imath & \imath & 1 \end{pmatrix} . \tag{41.179}$$

It is interesting to note that some superposition states completely separate from the optical mode,

$$e^{-\imath\hat{H}_n t}\begin{pmatrix} 0 \\ 1 \\ -1 \\ 0 \end{pmatrix} = \begin{pmatrix} 0 \\ 1 \\ -1 \\ 0 \end{pmatrix} \quad \text{and} \quad e^{-\imath\hat{H}_n t}\begin{pmatrix} 1 \\ 0 \\ 0 \\ -1 \end{pmatrix} = \begin{pmatrix} 1 \\ 0 \\ 0 \\ -1 \end{pmatrix} . \tag{41.180}$$

41.5.1.3 Dispersive excitation

In the dispersive limit, $\Delta_i \gg n^{1/2} g_i$, the dynamic evolution can be evaluated from a first order perturbative approach, analogous to the one already made for the standard JCM model. In this approach, the off-diagonal matrix elements (41.176) generate a light-shift of the energy levels appearing on the diagonal of the approximated matrix. Using the abbreviation $\Lambda_i \equiv g_i^2/\Delta_i$, the temporal evolution matrix $e^{-\imath\hat{H}_n t}$ can now be evaluated from,

$$\hat{H}_n = -\frac{\Delta_1 + \Delta_2}{2}\mathbb{I}_4 + \begin{pmatrix} n\Lambda_1 + n\Lambda_2 & & & \\ & -n\Lambda_1 + (n+1)\Lambda_2 & & \\ & & (n+1)\Lambda_1 - n\Lambda_2 & \\ & & & -(n+1)\Lambda_1 - (n+1)\Lambda_2 \end{pmatrix} . \tag{41.181}$$

We now assume that the light field only interacts with the upper level, as in the case of the dual resonance configuration studied in Exc. 35.4.5.4. This can be taken into account, neglecting those terms in the matrix (41.180) rotating with a positive Rabi frequency. Letting, moreover, $\Delta_1 = \Delta_2$ and $\Omega_1 = \Omega_2$, we obtain,

$$\hat{H}_n^{(1)} = \begin{pmatrix} 0 & & & \\ & -n\Lambda & & \\ & & -n\Lambda & \\ & & & -2(n+1)\Lambda \end{pmatrix} . \tag{41.182}$$

Thus, the temporal evolution is,

$$\boxed{e^{-\imath \hat{H}_n t} = \begin{pmatrix} 1 & & & \\ & e^{-n\Lambda} & & \\ & & e^{-n\Lambda} & \\ & & & e^{-2(n+1)\Lambda} \end{pmatrix}} . \tag{41.183}$$

For $\Lambda = \pi$,

$$e^{-\imath \hat{H}_n t} \xrightarrow{\pi} \begin{pmatrix} 1 & & & \\ & -1 & & \\ & & -1 & \\ & & & 1 \end{pmatrix} . \tag{41.184}$$

41.5.1.4 Bloch vector and the Q-function in the JC model with 2 atoms

Despite the more complex structure of the Hilbert space, the Bloch vectors of the individual atoms and the Q-function can be evaluated in analogy to Sec. 35.4.2. The Bloch vector is,

$$\vec{\rho}_{A1} = \frac{1}{\sqrt{2}} \begin{pmatrix} \sqrt{2}\ \mathfrak{Re}\ \rho_{12(A1)} \\ \sqrt{2}\ \mathfrak{Im}\ \rho_{12(A1)} \\ \rho_{22(A1)} - \rho_{11(A1)} \end{pmatrix} \qquad \text{where} \qquad \rho_{ij(A1)} = \mathrm{Tr}\ |i\rangle_1\langle j|\psi\rangle\langle\psi| \ . \tag{41.185}$$

In particular we have,

$$\begin{aligned} \rho_{22(A1)} &= \sum_{i,j,n} {}_2\langle j|_1\langle i|\langle n|1\rangle_1\langle 2|\psi\rangle\langle\psi|n\rangle|i\rangle_1|j\rangle_2 \qquad (41.186) \\ &= \sum_{j,n} {}_2\langle j|_1\langle 2|\langle n|\psi\rangle\langle\psi|n\rangle|1\rangle_1|j\rangle_2 \\ &= \sum_{n,m,m'} \langle n| \left(c_{2,1,m}|m\rangle\langle m'+1|c^*_{1,1,m'+1} + c_{2,2,m}|m'-1\rangle\langle m'|c^*_{1,2,m'}\rangle \right) |n\rangle \\ &= \sum_n (c^*_{1,1,n}c_{2,1,n} + c^*_{1,2,n}c_{2,2,n}) \ . \end{aligned}$$

Summarizing,

$$\begin{array}{lcl} \rho_{12(Ai\neq Aj)} & = & \sum_n (c^*_{1,1,n}c_{j,i,n} + c^*_{i,j,n}c_{2,2,n}) \\ \rho_{11(Ai\neq Aj)} & = & \sum_n (|c_{1,1,n}|^2 + |c_{i,j,n}|^2) \\ \rho_{22(Ai\neq Aj)} & = & \sum_n (|c_{j,i,n}|^2 + |c_{2,2,n}|^2) \end{array} \quad . \tag{41.187}$$

The function $Q(\alpha)$ for the JC dynamics of 2 atoms is,

$$\begin{aligned} Q(\alpha) &= \tfrac{1}{\pi}\langle\alpha|\hat{\rho}_{field}|\alpha\rangle = \tfrac{1}{\pi}\langle\alpha|\sum_{i,j} {}_2\langle j|_1\langle i|\psi\rangle\langle\psi|i\rangle_1|j\rangle_2|\alpha\rangle \qquad (41.188)\\ &= \tfrac{1}{\pi}\langle\alpha|\sum_{m,n}(c^*_{2,2,m-1}c_{2,2,n-1}|n-1\rangle\langle m-1| + c^*_{1,2,m}c_{1,2,n}|n\rangle\langle m| \\ &+ c^*_{2,1,m}c_{2,1,n}|n\rangle\langle m| + c^*_{1,1,m+1}c_{1,1,n+1}|n+1\rangle\langle m+1|)|n\rangle|\alpha\rangle \\ &= e^{-|\alpha|^2}\left[\left|\sum_n c_{2,2,n-1}\frac{\alpha^n}{\sqrt{n!}}\right|^2 + \left|\sum_n c_{1,2,n}\frac{\alpha^n}{\sqrt{n!}}\right|^2 + \left|\sum_n c_{2,1,n}\frac{\alpha^n}{\sqrt{n!}}\right|^2 + \left|\sum_n c_{2,2,n+1}\frac{\alpha^n}{\sqrt{n!}}\right|^2\right] . \end{aligned}$$

41.5.1.5 Correlating 2 atoms in the JC model

The investigations of the last section can be applied to describe the transfer of quantum coherence from one atom to another. The size of our system is now increased by the additional degrees of freedom, provided by internal states of the second atom. A suitable basis was defined in equation (23.124). Now, we imagine the following Gedankenexperiment: Starting from the initial condition that two adjacent atoms are in their respective electronic ground states, we assume a microwave $\pi/2$-pulse to create *simultaneously, but independently* on both atoms, a superposition of the HFS levels. Then, a non-resonant optical π-pulse interacts with the upper HFS level of the first atom $|1\rangle_{A1}$, and afterward the second atom $|2\rangle_{A2}$. Instead of reducing the atomic states and preparing a Schrödinger cat state in the optical field, (as we did in Sec. 35.4), we now project the field state onto the coherent state $|\beta\rangle$ and leave the atoms in a correlated state. The total procedure can be resumed by tracing the evolution of the whole state in the following suggestive way [64, 509]:

$$\begin{pmatrix} |\beta\rangle \\ 0 \\ 0 \\ 0 \end{pmatrix} \overset{\pi/2 \text{ microwave}}{\curvearrowright} \tfrac{1}{4}\begin{pmatrix} 1 \\ \imath \\ \imath \\ -1 \end{pmatrix}|\beta\rangle \overset{\pi \text{ opt+atom1}}{\curvearrowright} \tfrac{1}{4}\begin{pmatrix} |\beta\rangle \\ -\imath|-\beta\rangle \\ \imath|\beta\rangle \\ |-\beta\rangle \end{pmatrix} \overset{\pi \text{ opt+atom2}}{\curvearrowright} \tfrac{1}{4}\begin{pmatrix} |\beta\rangle \\ -\imath|-\beta\rangle \\ -\imath|-\beta\rangle \\ -|\beta\rangle \end{pmatrix}$$

$$\overset{\pi/2 \text{ microwave}}{\curvearrowright} \tfrac{1}{4}\begin{pmatrix} 1 \\ 0 \\ 0 \\ 1 \end{pmatrix}|\beta\rangle + \frac{1}{4}\begin{pmatrix} 1 \\ 0 \\ 0 \\ -1 \end{pmatrix}|-\beta\rangle \overset{\text{reduction}}{\curvearrowright} \tfrac{1}{2}\begin{pmatrix} 1 \\ 0 \\ 0 \\ -1 \end{pmatrix}|\beta\rangle \ . \tag{41.189}$$

If this procedure is extended to an arbitrary number of atoms, obviously all atoms being excited by the same optical mode before its projection in a coherent state $|\beta\rangle$

are included in the entangled state,

$$|\psi\rangle = \tfrac{1}{4}\begin{pmatrix}1\\:\\1\end{pmatrix}|\beta\rangle + \tfrac{1}{4}\begin{pmatrix}1\\:\\-1\end{pmatrix}|-\beta\rangle\ . \tag{41.190}$$

Finally, the correlation of the spin orientation of the atoms must be probed with additional laser light fields, which are selectively irradiated onto the atoms and resonantly tuned to a rapidly decaying optical transition. The states correlated in this way show a relatively low order entanglement, the von Neumann information entropy only being $S' = -\langle \log_2 \rho\rangle = N - 1$.

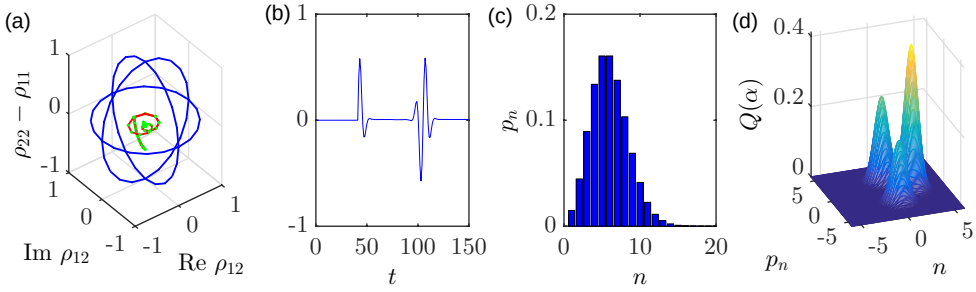

Figure 41.26: (code) Evolution of the state during a Jaynes-Cummings interaction with 2 atoms: (a) Bloch vector for the two atoms, (b) time evolution of the coherence ρ_{12} showing the phenomenon of collapse and revival, (c) distribution of photons, and (d) $Q(\alpha)$-function.

In a matricial notation the entangling gate can be expressed defining the state,

$$\begin{aligned}\langle\psi| &= \begin{pmatrix} c_{+\beta 11} & c_{+\beta 12} & c_{+\beta 21} & c_{+\beta 22} & c_{-\beta 11} & c_{-\beta 12} & c_{-\beta 21} & c_{-\beta 22}\end{pmatrix} \\ &= \langle\beta| \otimes \langle \text{atom}_1| \otimes \langle \text{atom}_2|\ .\end{aligned} \tag{41.191}$$

In this basis, the dispersive π-pulse is represented by,

$$U_{disp} \equiv \begin{pmatrix} 1 & & & & & & & \\ & & & & -1 & & & \\ & & & & & -1 & & \\ & & & 1 & & & & \\ & & & & 1 & & & \\ & -1 & & & & & & \\ & & -1 & & & & & \\ & & & & & & & 1 \end{pmatrix}\ . \tag{41.192}$$

A resonant $\pi/2$-pulse acting on the *both atoms simultaneously* does,

$$U_{reson} \equiv \mathbb{I} \otimes U^{(2)}_{\pi/2} \otimes \mathbb{I} = \frac{1}{\sqrt{2}} \begin{pmatrix} 1 & \imath & \imath & -1 & & & & \\ \imath & 1 & -1 & \imath & & & & \\ \imath & -1 & 1 & \imath & & & & \\ -1 & \imath & \imath & 1 & & & & \\ & & & & 1 & \imath & \imath & -1 \\ & & & & \imath & 1 & -1 & \imath \\ & & & & \imath & -1 & 1 & \imath \\ & & & & -1 & \imath & \imath & 1 \end{pmatrix} . \tag{41.193}$$

Now, concatenating and projecting on the Glauber state $|\beta\rangle$ we obtain, a posteriori, a unitary entangling gate,

$$U_{entangl} \equiv \mathrm{Tr}_\beta \; |\beta\rangle\langle\beta| U_{reson} U_{disp} U_{reson} |\beta\rangle\langle\beta| = \frac{1}{\sqrt{2}} \begin{pmatrix} 1 & 0 & 0 & -1 \\ 0 & -1 & -1 & 0 \\ 0 & -1 & -1 & 0 \\ -1 & 0 & 0 & 1 \end{pmatrix} \tag{41.194}$$

$$\text{such that} \quad \begin{pmatrix} 1 \\ 0 \\ 0 \\ -1 \end{pmatrix} = U_{entangl} \begin{pmatrix} 1 \\ 0 \\ 0 \\ 0 \end{pmatrix} .$$

41.5.2 Phononic quantum gate

The normal mode coupling can be used to create *quantum entanglement*. A suggested procedure to correlate two atoms '1' and '2' is shown in Fig. 41.27 [269, 606]. The atoms are regarded as qubits with the possible states of excitation $|g\rangle$ and $|e\rangle$. Additionally, the atoms are trapped (either they are ions in a linear ion trap or atoms in standing light wave sustained by a ring cavity). The are assumed to be cooled to the vibrational ground state $|0\rangle$, from which they can be coherently excited to the second collective vibrational mode $|1\rangle$ by means of a Raman transition, as illustrated in Fig. 41.27.

The sequence reads,

$$\begin{array}{cccccccc} |g_1\rangle|g_2\rangle|0\rangle & & |g_1\rangle|g_2\rangle|0\rangle & & |g_1\rangle|g_2\rangle|0\rangle & & |g_1\rangle|g_2\rangle|0\rangle \\ |g_1\rangle|e_2\rangle|0\rangle & \overset{\text{step 1}}{\curvearrowright} & |g_1\rangle|e_2\rangle|0\rangle & \overset{\text{step 2}}{\curvearrowright} & |g_1\rangle|e_2\rangle|0\rangle & \overset{\text{step 3}}{\curvearrowright} & |g_1\rangle|e_2\rangle|0\rangle \\ |e_1\rangle|g_2\rangle|0\rangle & & -\imath|g_1\rangle|g_2\rangle|1\rangle & & +\imath|g_1\rangle|g_2\rangle|1\rangle & & |e_1\rangle|g_2\rangle|0\rangle \\ |e_1\rangle|e_2\rangle|0\rangle & & -\imath|g_1\rangle|e_2\rangle|1\rangle & & -\imath|g_1\rangle|e_2\rangle|1\rangle & & -|e_1\rangle|e_2\rangle|0\rangle \end{array} . \tag{41.195}$$

Using the tensor notation $|\psi\rangle \otimes |\psi\rangle \equiv |\psi_1\rangle|\psi_2\rangle$ and introducing a matrix notation by

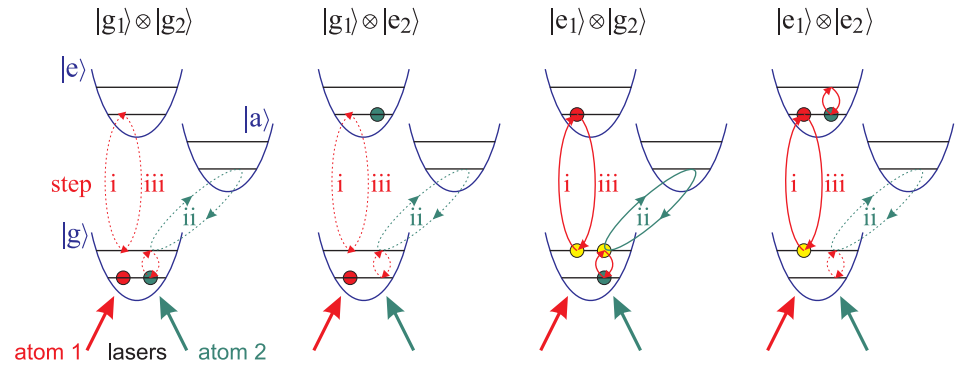

Figure 41.27: Scheme for an XOR-gate in an ion trap or a ring-cavity (see text for explanation). The four possible initial collective states respond differently to a predefined laser pulse sequence. Possible transitions are represented by solid lines, impossible transitions by dashed lines. $|a\rangle$ is an auxiliary excited level.

defining a basis as,

$$|g\rangle\otimes|g\rangle=\begin{pmatrix}1\\0\\0\\0\end{pmatrix}\ ,\ |g\rangle\otimes|e\rangle=\begin{pmatrix}0\\1\\0\\0\end{pmatrix}\ ,\ |e\rangle\otimes|g\rangle=\begin{pmatrix}0\\0\\1\\0\end{pmatrix}\ ,\ |e\rangle\otimes|e\rangle=\begin{pmatrix}0\\0\\0\\1\end{pmatrix}\ , \quad (41.196)$$

we can set up the truth table for this gate, also known as Cirac-Zoller gate, as,

$\|\psi\rangle$	$\|\psi\rangle$	$\|\psi\rangle\otimes\|\psi\rangle$	
$\|g\rangle$	$\|g\rangle$	$\|g\rangle\otimes\|g\rangle$	1
$\|g\rangle$	$\|e\rangle$	$\|g\rangle\otimes\|e\rangle$	1
$\|e\rangle$	$\|g\rangle$	$\|e\rangle\otimes\|g\rangle$	1
$\|e\rangle$	$\|e\rangle$	$-\|e\rangle\otimes\|e\rangle$	-1

$$\Longrightarrow \qquad U_{CZ}=\begin{pmatrix}1&0&0&0\\0&1&0&0\\0&0&1&0\\0&0&0&-1\end{pmatrix}\ . \quad (41.197)$$

We now define a new basis for the second atom only via $|a_2\rangle=\frac{1}{\sqrt{2}}(|g_2\rangle+|e_2\rangle)$ and $|b_2\rangle=\frac{1}{\sqrt{2}}(|g_2\rangle-|e_2\rangle)$. The basis transform corresponds to,

$$\begin{pmatrix}|g\rangle\otimes|a\rangle\\|g\rangle\otimes|b\rangle\\|g\rangle\otimes|a\rangle\\|g\rangle\otimes|b\rangle\end{pmatrix}=\tfrac{1}{\sqrt{2}}\mathbb{I}\otimes H\begin{pmatrix}|g\rangle\otimes|g\rangle\\|g\rangle\otimes|e\rangle\\|g\rangle\otimes|g\rangle\\|g\rangle\otimes|e\rangle\end{pmatrix}\quad\text{where}\quad \mathbb{I}\otimes H=\tfrac{1}{\sqrt{2}}\begin{pmatrix}1&1&0&0\\1&-1&0&0\\0&0&1&1\\0&0&1&-1\end{pmatrix} \quad (41.198)$$

is the Hadamard gate applied to the second qubit. Finally, we obtain the *controlled NOT* gate,

$$U_{XOR}=(\mathbb{I}\otimes H)U_{CZ}(\mathbb{I}\otimes H)^{-1}=\begin{pmatrix}1&0&0&0\\0&1&0&0\\0&0&0&1\\0&0&1&0\end{pmatrix}\ . \quad (41.199)$$

In particular, if $|\psi_1\rangle$ is initially in a superposition state, the states $|\psi_1\rangle$ and $|\psi_2\rangle$ end up entangled,

$$U_{XOR}(|g\rangle + |e\rangle) \otimes \mathbb{I} = \tfrac{1}{\sqrt{2}}(|g\rangle \otimes |g\rangle + |e\rangle \otimes |e\rangle) \ . \tag{41.200}$$

41.5.3 Quantum gates via controlled collisions

The proposed conditional quantum operation is based on a conditional collisional phase shift, the condition being that the atoms are in a particular state of excitation. In a suggestive notation for the Bloch vector of a particle subject to a resonant radiation pulse, the interaction is described by,

$$|\downarrow\rangle \xrightarrow{\pi/2} |\downarrow\rangle + \imath|\uparrow\rangle \xrightarrow{\pi/2} |\uparrow\rangle \xrightarrow{\pi/2} |\downarrow\rangle - \imath|\uparrow\rangle \xrightarrow{\pi/2} |\downarrow\rangle \ . \tag{41.201}$$

Jaksch demonstrated the following *phase gate*,

$$\begin{matrix} \downarrow\downarrow \\ \uparrow\downarrow \\ \downarrow\uparrow \\ \uparrow\uparrow \end{matrix} \longrightarrow \begin{matrix} \downarrow\downarrow \\ -\downarrow\uparrow \\ \uparrow\downarrow \\ \uparrow\uparrow \end{matrix} \ . \tag{41.202}$$

This gate is equivalent to the *XOR* port for the qubits defined by $\downarrow$ and $\downarrow \pm \uparrow$, since,

$$\begin{matrix} \downarrow(\downarrow \pm \uparrow) \\ \uparrow(\downarrow \pm \uparrow) \end{matrix} \longrightarrow \begin{matrix} \downarrow(\downarrow \mp \uparrow) \\ \uparrow(\downarrow \pm \uparrow) \end{matrix} \ . \tag{41.203}$$

41.5.4 Exercises

41.5.4.1 Ex: Generating a Bell state

Show that the operation $\overset{c}{X}_{01}(H_0 \otimes \mathbb{I})$, where H_0 is the Hadamard gate acting on the first qu-bit and $\overset{c}{X}_{01}$ the controlled NOT acting on the second qubit, applied to the 2-qubit ground state generates entanglement.

Solution: *We find,*

$$\overset{c}{X}_{01}(H_0 \otimes \mathbb{I}) = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \end{pmatrix} \left[\tfrac{1}{\sqrt{2}} \begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix} \otimes \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \right] \begin{pmatrix} 1 \\ 0 \\ 0 \\ 0 \end{pmatrix} = \tfrac{1}{\sqrt{2}} \begin{pmatrix} 1 \\ 0 \\ 0 \\ 1 \end{pmatrix} \ .$$

41.6 Quantum gates

In *quantum information* we use the notions introduced in the preceding sections and formalize the calculation. In this section, we present a brief formal introduction to

the field of *quantum computation with qubit matrices*. The formalism is abstract, but we may keep in mind a chain of entangled ions confined in a linear Paul trap. We will show how the electronic states of the ions are correlated to form a single collective state, and how quantum gates can be realized on such correlated particles. With three ions, an arbitrary quantum gate can be implemented, which includes and generalizes the three-bit Toffoli gate.

> **Example 264 (*Boolean versus linear algebra*):** The mathematical formalism underlying *classical computing* is the *Boolean algebra*, while the formalism underlying *quantum computing* is the *linear algebra*. It is important to stress that *everything you can do on a classical computer, can you do on a quantum computer, and vice versa*. The question is simply whether you can do it in due time.

To construct a quantum gate, we need at least two qubits spanning a 4-dimensional Hilbert space, since $\mathcal{H}^2 \otimes \mathcal{H}^2$ and $\mathcal{H}^1 \otimes \mathcal{H}^4$ are isomorph, that is,

$$\begin{aligned} |\varepsilon\rangle_0|\mu\rangle_1 &= (|0\rangle_0 + \imath|1\rangle_0)(|0\rangle_1 + \imath|1\rangle_1) &&= \begin{pmatrix} |0\rangle_0|0\rangle_1 \\ \imath|0\rangle_0|1\rangle_1 \\ \imath|1\rangle_0|0\rangle_1 \\ -|1\rangle_0|1\rangle_1 \end{pmatrix} \\ \triangleq \quad |0\rangle_0|\varepsilon\mu\rangle_1 &= |00\rangle_1 + \imath|01\rangle_1 + \imath|10\rangle_1 - |11\rangle_1 &&= \begin{pmatrix} |00\rangle_1 \\ \imath|01\rangle_1 \\ \imath|10\rangle_1 \\ -|11\rangle_1 \end{pmatrix} . \end{aligned} \tag{41.204}$$

A presentation on the subject is available at (watch talk). See also the websites IBM Circuit Composer, Qiskit, Cirq, and Pennylane.

41.6.1 The qubit

As we have seen above, the two principle ways a light mode acts on a two-level system are the resonant interaction and the dispersive interaction. From the Jaynes-Cummings model (35.125) and (35.132),

$$\begin{aligned} R(\tau) &\equiv \begin{pmatrix} \cos\frac{\pi}{2}\tau & \imath\sin\frac{\pi}{2}\tau \\ \imath\sin\frac{\pi}{2}\tau & \cos\frac{\pi}{2}\tau \end{pmatrix} \overset{\tau\to 1}{\longrightarrow} \begin{pmatrix} & \imath \\ \imath & \end{pmatrix} , \\ D(\tau) &\equiv \begin{pmatrix} e^{\imath\pi\tau} & 0 \\ 0 & 1 \end{pmatrix} \overset{\tau\to 1}{\longrightarrow} \begin{pmatrix} -1 & \\ & 1 \end{pmatrix} . \end{aligned} \tag{41.205}$$

These two gates are particular cases of the most fundamental single qubit quantum gate, which can be written as,

$$\boxed{U_3(\vartheta,\varphi,\lambda) = \begin{pmatrix} \cos\frac{\vartheta}{2} & -e^{\imath\lambda}\sin\frac{\vartheta}{2} \\ e^{\imath\varphi}\sin\frac{\vartheta}{2} & e^{\imath\lambda+\imath\varphi}\cos\frac{\vartheta}{2} \end{pmatrix}} , \tag{41.206}$$

which is a unitary operation since $\det U_3(\vartheta,\varphi,\lambda) = e^{\imath(\lambda+\varphi)}$. Special cases are the *Hadamard gate*,

$$H \equiv U_3(\tfrac{\pi}{2},0,\pi) = \tfrac{1}{\sqrt{2}}\begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix} , \tag{41.207}$$

and the *phase gate*,

$$U_1(\varphi) \equiv U_3(0,\varphi,0) = \begin{pmatrix} 1 & 0 \\ 0 & e^{\imath\varphi} \end{pmatrix} . \tag{41.208}$$

Phase rotations about particular angles receive specific names. For example,

$$\boxed{Z \equiv -\hat{\sigma}_z = U_1(\pi)} = |-q_0\rangle\langle q_0| , \tag{41.209}$$

is simply the negative Pauli z-matrix defined in (23.47). The *negation* in the Hilbert space $\mathcal{H}^2$,

$$\boxed{X \equiv \hat{\sigma}_x = U_3(\pi,0,\pi) = |\bar{q_0}\rangle\langle q_0|} , \tag{41.210}$$

is simply the Pauli x-matrix.

The general state of a qubit is a quantum superposition in the Hilbert space $\mathcal{H}^2$,

$$|\varepsilon\rangle = \alpha|0\rangle + \imath\beta|1\rangle = \begin{pmatrix} \alpha \\ \imath\beta \end{pmatrix} . \tag{41.211}$$

The possible outcomes of a measurement of its state are represented by a classical truth table,

$$\begin{matrix} |q_0\rangle \\ |0\rangle \\ |1\rangle \end{matrix} \quad \text{, for example} \quad |01\rangle = \begin{pmatrix} 0 \\ 1 \end{pmatrix} . \tag{41.212}$$

The only difference is, that now the possible values are not restricted to the binaries 0 or 1, but can be anything between 0 and 1, provide the total wavefunction stays normalized.

Analogously to to classical logic circuits, which can be represented by concatenated symbols, quantum circuits can be composed by concatenations of unitary operations. This is illustrated in Fig. 41.28.

41.6.2 Quantum gates of 2 qubits, the 'controlled NOT' gate

We can generalize the single-qubit algebra to arbitrary registers using the *direct* sum and the *external product* defined in (23.124) and (23.126),

$$\begin{matrix} |q_1 & q_0\rangle \\ |0 & 0\rangle \\ |0 & 1\rangle \\ |1 & 0\rangle \\ |1 & 1\rangle \end{matrix} \quad \text{, for example} \quad |01\rangle = \begin{pmatrix} 0 \\ 1 \\ 0 \\ 0 \end{pmatrix} . \tag{41.213}$$

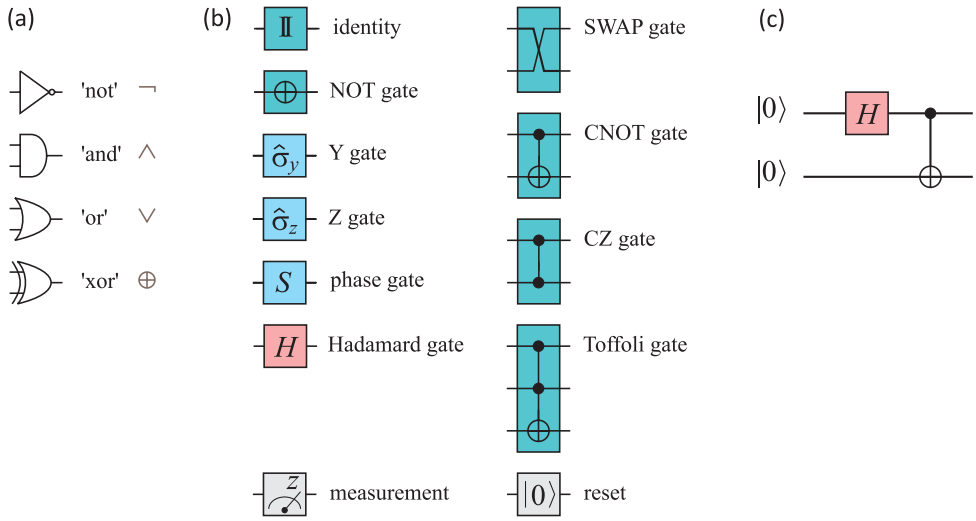

Figure 41.28: (a) Common symbols for fundamental classical gates and (b) for quantum gates. (c) Example of a quantum circuit generating Bell type entanglement.

Single qubit gates can be embedded in multi qubit registers. For example, the *negation* of 'NOT' gate in $\mathcal{H}^4$ can be applied either to the first or the second qubit [25],

$$\boxed{\begin{aligned} X_0 &\hat{=} \mathbb{I} \otimes \hat{X} = |q_1, \bar{q_0}\rangle\langle q_1, q_0| \\ X_1 &\hat{=} \hat{X} \otimes \mathbb{I} = |\bar{q_1}, q_0\rangle\langle q_1, q_0| \end{aligned}} \,. \tag{41.214}$$

The most interesting two-qubit quantum gate is the 'controlled NOT' gate or *antivalence*, which we will now discuss in detail. This gate is originally defined on $\mathcal{H}^2 \otimes \mathcal{H}^2$. The quantum operation is implemented by first going to the Hilbert space $\mathcal{H}^1 \otimes \mathcal{H}^4$, applying the unitary transform,

$$\mathbb{I} \oplus X = \begin{pmatrix} \mathbb{I}_2 & \\ & X \end{pmatrix} \,, \tag{41.215}$$

where X has been defined in Eq. (41.210), and finally returning to $\mathcal{H}^2 \otimes \mathcal{H}^2$:

$$\begin{aligned} |\varepsilon\rangle_0|\mu\rangle_1 \;\triangleq\; |0\rangle_0|\varepsilon\mu\rangle_1 \;\xrightarrow{\hat{N}}\; \delta_{\varepsilon=0}|\varepsilon\rangle_0|\mu\rangle_1 + \delta_{\varepsilon=1}|\varepsilon\rangle_1 \begin{pmatrix} 1 & \imath \\ \imath & 1 \end{pmatrix}^2 |\mu\rangle_1 \;\triangleq\; |\varepsilon\rangle_0|\varepsilon \oplus \mu\rangle_1 \\ \begin{pmatrix} |0\rangle_0|0\rangle_1 \\ \imath|0\rangle_0|1\rangle_1 \\ \imath|1\rangle_0|0\rangle_1 \\ -|1\rangle_0|1\rangle_1 \end{pmatrix} \triangleq \begin{pmatrix} |00\rangle_1 \\ \imath|01\rangle_1 \\ \imath|10\rangle_1 \\ -|11\rangle_1 \end{pmatrix} \xrightarrow{\hat{N}} \begin{pmatrix} |00\rangle_1 \\ \imath|01\rangle_1 \\ \imath|11\rangle_1 \\ -|10\rangle_1 \end{pmatrix} \triangleq \begin{pmatrix} |0\rangle_0|0\rangle_1 \\ \imath|0\rangle_0|1\rangle_1 \\ \imath|1\rangle_0|1\rangle_1 \\ -|1\rangle_0|0\rangle_1 \end{pmatrix} \end{aligned} \,. \tag{41.216}$$

[25] Note that we call 'first' the rightmost qubit.

The short-hand notation of the 'controlled NOT' operation on $\mathcal{H}^4$ can be written as,

$$\boxed{\begin{array}{lll} \overset{c}{X}_{10} & \hat{=}\, \mathbb{I}\oplus X & = |q_1, q_1\oplus q_0\rangle\langle q_1, q_0| \\ \overset{c}{X}_{01} & \hat{=}\, \mathbb{S}(\mathbb{I}\oplus X)\mathbb{S} & = |q_0\oplus q_1, q_0\rangle\langle q_1, q_0| \end{array}} \quad . \tag{41.217}$$

where the 'SWAP' operator $\mathbb{S}$ has been defined in (23.130). When the qubits addressed by a gate are not identified from their position in the tensor product, an index at the gate symbol indicates which qubits are involved. For example, X_0 inverts the first qubit q_0, and $\overset{c}{X}_{0\to 1} = \overset{c}{X}_{01}$ controls the state of the second qubit q_1 by the first one.

Example 265 (*Controlled NOT gate*): We can easily verify,

$$\begin{aligned} \overset{c}{X}_{10} &= |0\rangle\langle 0|\otimes\mathbb{I} + |1\rangle\langle 1|\otimes X \\ &= \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}\otimes\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} + \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix}\otimes\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} = \begin{pmatrix} \mathbb{I} & 0 \\ 0 & X \end{pmatrix} , \end{aligned} \tag{41.218}$$

and

$$\begin{aligned} \overset{c}{X}_{01} &= \mathbb{I}|\otimes|0\rangle\langle 0| + X\otimes|1\rangle\langle 1| \\ &= \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}\otimes\begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix} + \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}\otimes\begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix} = S\overset{c}{X}_{10}S . \end{aligned} \tag{41.219}$$

41.6.3 Fundamental and universal quantum gates of 3 qubits and more

We now consider three qubits in $\mathcal{H}^8 \equiv \mathcal{H}^2\otimes\mathcal{H}^2\otimes\mathcal{H}^2$. The *truth table* has the shape,

$$\begin{array}{ccc|c} |q_2 & q_1 & q_0\rangle & \\ |0 & 0 & 0\rangle & \\ |0 & 0 & 1\rangle & \\ |0 & 1 & 0\rangle & \\ |0 & 1 & 1\rangle & \text{, for example} \\ |1 & 0 & 0\rangle & \\ |1 & 0 & 1\rangle & \\ |1 & 1 & 0\rangle & \\ |1 & 1 & 1\rangle & \end{array} \qquad |010\rangle = \begin{pmatrix} 0 \\ 0 \\ 1 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{pmatrix} . \tag{41.220}$$

We choose $\mathbb{I}_8$ as the basis of $\mathcal{H}^8$. We assume that the number represented by the state $|q_2, q_1, q_0\rangle$ is $[q_2q_1q_0]_{binary} = [2^2q_2 + 2^1q_1 + 2^0q_0]_{decimal}$.

The unitary transform implemented by a quantum gate can be understood as a permutation of the basis vectors in the truth table. We can generalize the permutation rules (23.130) to 3D Hilbert spaces $\mathcal{H}^2\otimes\mathcal{H}^2\otimes\mathcal{H}^2$, where $M\otimes N\otimes R = \mathbb{S}_{01}(N\otimes M\otimes R)\mathbb{S}_{01} = \mathbb{S}_{12}(M\otimes R\otimes N)\mathbb{S}_{12} = \mathbb{S}_{01}(R\otimes N\otimes M)\mathbb{S}_{02}$, with the transformation matrices,

$$\mathbb{S}_{01} = \mathbb{I}\otimes\mathbb{S} \quad , \quad \mathbb{S}_{12} = \mathbb{S}\otimes\mathbb{I} \quad , \quad \mathbb{S}_{02} = \mathbb{S}_{01}\mathbb{S}_{12}\mathbb{S}_{01} , \tag{41.221}$$

where the operator $\mathbb{S}$ has again been taken from (23.130). In Exc. 41.6.6.4 we derive the explicit matricial forms of $\mathbb{S}_{ij}$.

Examples of fundamental three-qubits gates are, in short notation, the *negation* in $\mathcal{H}^8$,

$$\begin{aligned} X_0 &\hat{=} \mathbb{I}\otimes\mathbb{I}\otimes X = |q_2,q_1,\bar{q_0}\rangle\langle q_2,q_1,q_0| \\ X_1 &\hat{=} \mathbb{I}\otimes X\otimes\mathbb{I} = |q_2,\bar{q_1},q_0\rangle\langle q_2,q_1,q_0| \\ X_2 &\hat{=} X\otimes\mathbb{I}\otimes\mathbb{I} = |\bar{q_2},q_1,q_0\rangle\langle q_2,q_1,q_0| \ , \end{aligned} \tag{41.222}$$

the *antivalence*,

$$\begin{aligned} \overset{c}{X}_{10} &\equiv \mathbb{I}\otimes(\mathbb{I}\oplus X) &&= |q_2,q_1,q_1\oplus q_0\rangle\langle q_2,q_1,q_0| \\ \overset{c}{X}_{01} &\equiv \mathbb{S}_{01}\overset{c}{X}_{10}\mathbb{S}_{01} &&= |q_2,q_0\oplus q_1,q_0\rangle\langle q_2,q_1,q_0| \\ \overset{c}{X}_{02} &\equiv \mathbb{S}_{12}\overset{c}{X}_{01}\mathbb{S}_{12} &&= |q_0\oplus q_2,q_1,q_0\rangle\langle q_2,q_1,q_0| \\ \overset{c}{X}_{20} &\equiv \mathbb{S}_{02}\overset{c}{X}_{02}\mathbb{S}_{02} &&= |q_2,q_1,q_2\oplus q_0\rangle\langle q_2,q_1,q_0| \\ \overset{c}{X}_{21} &\equiv \mathbb{S}_{02}\overset{c}{X}_{01}\mathbb{S}_{02} &&= |q_2,q_2\oplus q_1,q_0\rangle\langle q_2,q_1,q_0| \\ \overset{c}{X}_{12} &\equiv \mathbb{S}_{12}\overset{c}{X}_{21}\mathbb{S}_{12} &&= |q_1\oplus q_2,q_1,q_0\rangle\langle q_2,q_1,q_0| \ , \end{aligned} \tag{41.223}$$

from which we get explicitly, as verified in Exc. 41.6.6.5,

$$\overset{c}{X}_{10} = \begin{pmatrix} \mathbb{I} & & & \\ & X & & \\ & & \mathbb{I} & \\ & & & X \end{pmatrix} \quad , \quad \overset{c}{X}_{20} = \begin{pmatrix} \mathbb{I} & & & \\ & \mathbb{I} & & \\ & & X & \\ & & & X \end{pmatrix} \quad , \quad \overset{c}{X}_{21} = \begin{pmatrix} \mathbb{I} & & & \\ & \mathbb{I} & & \\ & & & X\otimes\mathbb{I} \end{pmatrix} . \tag{41.224}$$

It is possible to show that all quantum logic gates can be reduced to a universal so-called *Toffoli gate* [95],

$$\begin{aligned} \mathcal{H}^8 &\xrightarrow{U} \mathcal{H}^8 \\ |q_2,q_1,q_0\rangle &\xrightarrow{U} |q_2,q_1,(q_2\wedge q_1)\oplus q_0\rangle \\ \mathbb{I}_8 &\xrightarrow{U} U \ , \end{aligned} \tag{41.225}$$

or in short-hand notation,

$$\boxed{\overset{cc}{X}_{210} = \mathbb{I}\oplus\mathbb{I}\oplus X = |q_2,q_1,(q_2\wedge q_1)\oplus q_0\rangle\langle q_2,q_1,q_0| = \begin{pmatrix} \mathbb{I}_6 & \\ & \hat{\sigma}_x \end{pmatrix}} \ , \tag{41.226}$$

as will be shown in Exc. 41.6.6.6 and 41.6.6.7.

Obviously, to perform quantum calculations, we need at least two qubits and operations acting simultaneous on both. Do the Excs. 41.6.6.8 to 41.6.6.9.

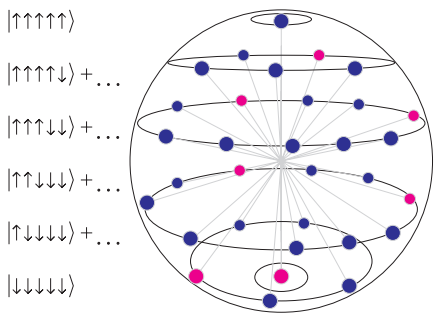

Figure 41.29: Illustration of the possible states of a 5-qubit system.

Until now, we restricted to pure states $|\psi_f\rangle = \bigotimes_k [\alpha_k|0\rangle_k + \beta_k|1\rangle_k]$ generated from an initial eigenstate $|\psi_i\rangle = \bigotimes_k |0\rangle_k$ by reversible quantum computing. The density operator can then be written,

$$\boxed{\hat{\rho} = |\psi_f\rangle\langle\psi_f| = U|\psi_i\rangle\langle\psi_i|U^\dagger} \,. \tag{41.227}$$

In the next section, following up on Sec. 34.3.3, we will discuss how projective measurements introduce irreversibility into the evolution of the density operator.

41.6.4 State propagation and projective measurements

The measurement of a qubit projects the Hilbert space on its two possible outcomes. For example, measuring the first out of three qubits means,

$$\mathcal{H}\otimes\mathcal{H}\otimes\mathcal{H}\overset{measure}{\longrightarrow}\begin{cases}|0\rangle\otimes\mathcal{H}\otimes\mathcal{H}\\ |1\rangle\otimes\mathcal{H}\otimes\mathcal{H}\end{cases}. \tag{41.228}$$

We consider a density matrix $\hat{\rho}$ operating on the entire Hilbert space and define projectors,

$$\hat{P}_j^{(n)}=\mathbb{I}\otimes...\otimes|n\rangle_j\langle n|\otimes...\otimes\mathbb{I}\qquad\text{with}\qquad n=0,1\ . \tag{41.229}$$

that, applied to a specific qubit q_j, project its state onto the eigenstate $|0\rangle$ or $|1\rangle$, respectively. A projective measurement of the j-th qubit with two possible outcomes $|q_j\rangle=|0\rangle,|1\rangle$ with the respective probabilities $p_j^{(0)},p_j^{(1)}$, generates the mixed states reduced density operator,

$$\boxed{\hat{\rho}_j^{red}=\sum_{n=0,1}p_j^{(n)}\frac{\hat{P}_j^{(n)}\hat{\rho}\hat{P}_j^{(n)}}{\text{Tr }\hat{\rho}\hat{P}_j^{(n)}}}\ . \tag{41.230}$$

Note that, a priori, $\hat{\rho}_j^{red}$ has the same rank as $\hat{\rho}$, but a more diagonal structure, since some coherences have been traced out.

41.6.4.1 Quantum state tomography

Any density operator of a pure or mixed state of an individual qubit can be expanded as,

$$\hat{\rho}_j=\tfrac{1}{2}\left(\mathbb{I}+a_j\hat{\sigma}_j^x+b_j\hat{\sigma}_j^y+c_j\hat{\sigma}_j^z\right)=\tfrac{1}{2}\begin{pmatrix}1+c_j & a_j-\imath b_j\\ a_j+\imath b_j & 1-c_j\end{pmatrix}\ , \tag{41.231}$$

where,

$$\hat{\sigma}_j^k=\mathbb{I}\otimes...\otimes\hat{\sigma}^k\otimes...\otimes\mathbb{I}\ , \tag{41.232}$$

and $\hat{\sigma}^k$ are the Pauli matrices. The parameters a_j, b_j, and c_j can be determined by measurements,

$$\boxed{\langle\hat{\vec{\sigma}}_j\rangle=\text{Tr }\hat{\rho}\hat{\vec{\sigma}}_j=\begin{pmatrix}a_j\\ b_j\\ c_j\end{pmatrix}}\ , \tag{41.233}$$

where $\hat{\rho}$ is the density matrix of the whole system.

41.6.4.2 Measurements on a single qubit

A single qubit $|\psi\rangle=\alpha|0\rangle+\beta|1\rangle$, normalized as $|\alpha|^2+|\beta|^2=1$, is described by the density operator,

$$\hat{\rho}=\begin{pmatrix}\rho_{00} & \rho_{01}\\ \rho_{10} & \rho_{11}\end{pmatrix}=|\psi\rangle\langle\psi|=\begin{pmatrix}|\alpha|^2 & \alpha\beta^*\\ \alpha^*\beta & |\beta|^2\end{pmatrix}\ . \tag{41.234}$$

A projective measurement of the qubit with two possible outcomes, $|q\rangle = |0\rangle, |1\rangle$ with the respective probabilities $p^{(0)} = |\alpha|^2$ and $p^{(1)} = |\beta|^2$, generates the mixed states reduced density operator,

$$\hat{\rho}^{red} = p^{(0)} \frac{|0\rangle\langle 0|\hat{\rho}|0\rangle\langle 0|}{\text{Tr}\ \hat{\rho}|0\rangle\langle 0|} + p^{(1)} \frac{|1\rangle\langle 1|\hat{\rho}|1\rangle\langle 1|}{\text{Tr}\ \hat{\rho}|1\rangle\langle 1|} = |\alpha|^2|0\rangle\langle 0| + |\beta|^2|1\rangle\langle 1| \ . \tag{41.235}$$

Some physical processes may not only project the density operator onto a specific basis, but onto a particular eigenstate,

$$\hat{\rho} \longrightarrow \hat{\rho}^{prj} = |0\rangle\langle 0|\hat{\rho}|0\rangle\langle 0| \ . \tag{41.236}$$

Example 266 (*Quantum Zeno effect on a single qubit*): As an example, let us express the quantum Zeno effect in quantum computing language. Starting from a two-level system in its ground state,

$$\hat{\rho}^{in} = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix} \quad , \quad U_3(\vartheta, 0, 0) = \begin{pmatrix} \cos\vartheta & -\sin\vartheta \\ \sin\vartheta & \cos\vartheta \end{pmatrix} \ ,$$

we perform small rotations,

$$\hat{\rho}^{rot} = U_3(\vartheta,0,0)\hat{\rho}^{in}U_3(\vartheta,0,0)^\dagger = \begin{pmatrix} \cos^2\vartheta & \cos\vartheta\sin\vartheta \\ \cos\vartheta\sin\vartheta & \sin^2\vartheta \end{pmatrix} \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix} \ ,$$

before measuring the system,

$$\hat{\rho}^{red} = \cos^2\vartheta \frac{|0\rangle\langle 0|\hat{\rho}^{rot}|0\rangle\langle 0|}{\text{Tr}\ \hat{\rho}^{rot}|0\rangle\langle 0|} + \sin^2\vartheta \frac{|1\rangle\langle 1|\hat{\rho}^{rot}|1\rangle\langle 1|}{\text{Tr}\ \hat{\rho}^{rot}|1\rangle\langle 1|} = \begin{pmatrix} \cos^2\vartheta & 0 \\ 0 & \sin^2\vartheta \end{pmatrix} \ .$$

Discarding the possibility that the system be excited, we project it system onto the ground state,

$$\hat{\rho}^{fin} = |0\rangle\langle 0|\hat{\rho}^{red}|0\rangle\langle 0| = |0\rangle\langle 0|U_3(\vartheta,0,0)\hat{\rho}^{in}U_3(\vartheta,0,0)^\dagger|0\rangle\langle 0| = \begin{pmatrix} \cos^2\vartheta & 0 \\ 0 & 0 \end{pmatrix} \ .$$

On the other hand, repeating the procedure n times with $\vartheta = \frac{\pi}{2n}$ and $n \to \infty$, we find,

$$\hat{\rho}^{fin} = \lim_{n\to\infty} \left(|0\rangle\langle 0|U_3(\tfrac{\pi}{2n},0,0)\hat{\rho}^{in}U_3(\tfrac{\pi}{2n},0,0)^\dagger|0\rangle\langle 0| \right)^n = \begin{pmatrix} \lim_{n\to\infty}\cos^{2n}\frac{\pi}{2n} & 0 \\ 0 & 0 \end{pmatrix} = \hat{\rho}^{in} \ .$$

That is, the evolution of the system is frozen by too many measurements.

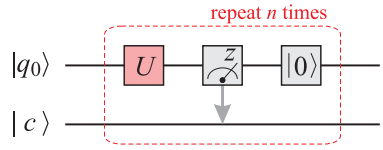

Figure 41.30: Quantum Zeno effect on a single qubit.

41.6.4.3 Measurements in two qubit systems

Let us now consider a two-qubit system $q_1 \otimes q_0$ described by the initial density matrix,

$$\hat{\rho} = \hat{\rho}_1 \otimes \hat{\rho}_0 = \begin{pmatrix} |\alpha_1|^2 & \alpha_1\beta_1^* \\ \alpha_1^*\beta_1 & |\beta_1|^2 \end{pmatrix} \otimes \begin{pmatrix} |\alpha_0|^2 & \alpha_0\beta_0^* \\ \alpha_0^*\beta_0 & |\beta_0|^2 \end{pmatrix} \tag{41.237}$$

$$= \begin{pmatrix} (\rho_1)_{00} & (\rho_1)_{01} \\ (\rho_1)_{10} & (\rho_1)_1 \end{pmatrix} \otimes \begin{pmatrix} (\rho_0)_{00} & (\rho_0)_{01} \\ (\rho_0)_{10} & (\rho_0)_1 \end{pmatrix} = \begin{pmatrix} \rho_{00\otimes 00} & \rho_{00\otimes 01} & \rho_{10\otimes 00} & \rho_{01\otimes 01} \\ \rho_{00\otimes 10} & \rho_{00\otimes 11} & \rho_{01\otimes 10} & \rho_{01\otimes 11} \\ \rho_{10\otimes 00} & \rho_{10\otimes 01} & \rho_{11\otimes 00} & \rho_{11\otimes 01} \\ \rho_{10\otimes 10} & \rho_{10\otimes 11} & \rho_{11\otimes 10} & \rho_{11\otimes 11} \end{pmatrix},$$

where we defined $\rho_{kl\otimes mn} \equiv (\rho_1)_{kl}(\rho_0)_{mn}$. Projective measurements of qubit q_1 with two possible outcomes, $|q_1\rangle = |0\rangle, |1\rangle$, with the respective probabilities $p^{(0)} = |\alpha_1|^2$ and $p^{(1)} = |\beta_1|^2$, yields the reduced density operator,

$$\hat{\rho}_1^{red} = p^{(0)} \frac{[|0\rangle\langle 0| \otimes \mathbb{I}]\hat{\rho}[|0\rangle\langle 0| \otimes \mathbb{I}]}{\text{Tr } \hat{\rho}[|0\rangle\langle 0| \otimes \mathbb{I}]} + p^{(1)} \frac{[|1\rangle\langle 1| \otimes \mathbb{I}]\hat{\rho}[|1\rangle\langle 1| \otimes \mathbb{I}]}{\text{Tr } \hat{\rho}[|1\rangle\langle 1| \otimes \mathbb{I}]} \tag{41.238}$$

$$= \frac{|\alpha_1|^2}{\rho_{00\otimes 00} + \rho_{01\otimes 01}} \begin{pmatrix} \rho_{00\otimes 00} & \rho_{00\otimes 01} & 0 & 0 \\ \rho_{01\otimes 00} & \rho_{01\otimes 01} & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix} + \frac{|\beta_1|^2}{\rho_{10,10} + \rho_{11,11}} \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & \rho_{10\otimes 10} & \rho_{10\otimes 11} \\ 0 & 0 & \rho_{11\otimes 10} & \rho_{11\otimes 11} \end{pmatrix}.$$

The inversion of qubit q_1 is,

$$\langle \hat{\sigma}_1^z \rangle = \text{Tr } \hat{\rho}\,[\hat{\sigma}^z \otimes \mathbb{I}] = \rho_{00,00} + \rho_{01,01} - \rho_{10,10} - \rho_{11,11}\ . \tag{41.239}$$

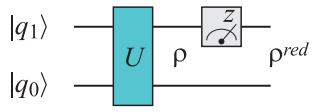

Figure 41.31: Projective measurement. After an operation U, two qubits remain in an entangled state $\hat{\rho}$. Measurement of qubit q_1 reduces the state to $\hat{\rho}^{red}$, while transferring the information to a classical channel c.

Example 267 (*Measurements on disentangled qubits*): As a particular case, let us first consider two disentangled qubits $|\psi\rangle = |q_1\rangle \otimes |q_0\rangle = [\alpha_1|0\rangle + \beta_1|1\rangle] \otimes [\alpha_0|0\rangle + \beta_0|1\rangle]$, such that,

$$\hat{\rho} = \begin{pmatrix} \alpha_1\alpha_0 \\ \alpha_1\beta_0 \\ \beta_1\alpha_0 \\ \beta_1\beta_0 \end{pmatrix} \begin{pmatrix} \alpha_1^*\alpha_0^* & \alpha_1^*\beta_0^* & \beta_1^*\alpha_0^* & \beta_1^*\beta_0^* \end{pmatrix} \tag{41.240}$$

$$= \begin{pmatrix} |\alpha_1|^2|\alpha_0|^2 & |\alpha_1|\alpha_0^*\beta_0^* & \alpha_1\beta_1^*|\alpha_0|^2 & \alpha_1\beta_1^*\alpha_0\beta_0^* \\ |\alpha_1|^2\alpha_0^*\beta_0 & |\alpha_1|^2|\beta_0|^2 & \alpha_1\beta_1^*\alpha_0^*\beta_0 & \alpha_1\beta_1^*|\beta_0|^2 \\ \alpha_1^*\beta_1|\alpha_0|^2 & \beta_1\alpha_1^*\alpha_0\beta_0^* & |\beta_1|^2|\alpha_0|^2 & |\beta_1|^2\alpha_0\beta_0^* \\ \alpha_1^*\beta_1\alpha_0^*\beta_0 & \alpha_1^*\beta_1|\beta_0|^2 & |\beta_1|^2\alpha_0^*\beta_0 & |\beta_1|^2|\beta_0|^2 \end{pmatrix}.$$

A projective measurements of qubit q_1 with two possible outcomes, $|q_1\rangle = |0\rangle_1, |1\rangle_1$ with the respective probabilities $p_0 = |\alpha_1|^2$ and $p_1 = |\beta_1|^2$, yields the reduced density operator,

$$\hat{\rho}_1^{red} = p^{(0)} \frac{[|0\rangle\langle 0| \otimes \mathbb{I}]\hat{\rho}[|0\rangle\langle 0| \otimes \mathbb{I}]}{\text{Tr } \hat{\rho}[|0\rangle\langle 0| \otimes \mathbb{I}]} + p^{(1)} \frac{[|1\rangle\langle 1| \otimes \mathbb{I}]\hat{\rho}[|1\rangle\langle 1| \otimes \mathbb{I}]}{\text{Tr } \hat{\rho}[|1\rangle\langle 1| \otimes \mathbb{I}]} \tag{41.241}$$

$$= |\alpha_1|^2 \begin{pmatrix} |\alpha_0|^2 & \alpha_0\beta_0^* & 0 & 0 \\ \alpha_0^*\beta_0 & |\beta_0|^2 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix} + |\beta_1|^2 \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & |\alpha_0|^2 & \alpha_0\beta_0^* \\ 0 & 0 & \alpha_0^*\beta_0 & |\beta_0|^2 \end{pmatrix}$$

$$= [|\alpha_1|^2|0\rangle\langle 0| + |\beta_1|^2|1\rangle\langle 1|] \otimes \hat{\rho}_0 \ .$$

The inversion of qubit q_1 is,

$$\langle \hat{\sigma}_1^z \rangle = |\alpha_1|^2 - |\beta_1|^2 \ . \tag{41.242}$$

That is, we are left with a mixture of two product states, $|0\rangle \otimes [\alpha_0|0\rangle + \beta_0|1\rangle]$ or $|1\rangle \otimes [\alpha_0|0\rangle + \beta_0|1\rangle]$. Analogically, a projective measurements of qubit q_0 yields,

$$\hat{\rho}_0^{red} = |\alpha_0|^2\hat{\rho}_1 \otimes |0\rangle\langle 0| + |\beta_0|^2\hat{\rho}_1 \otimes |1\rangle\langle 1| \tag{41.243}$$

and $\langle \hat{\sigma}_0^z \rangle = |\alpha_0|^2 - |\beta_0|^2$.

Example 268 (*Measurements on entangled qubits*): Now, we consider two entangled qubits $|\psi\rangle = \alpha[|0\rangle \otimes |0\rangle] + \beta[|1\rangle \otimes |1\rangle]$, with $|\alpha|^2 + |\beta|^2 = 1$, such that,

$$\hat{\rho} = \begin{pmatrix} \alpha \\ 0 \\ 0 \\ \beta \end{pmatrix} \begin{pmatrix} \alpha^* & 0 & 0 & \beta^* \end{pmatrix} = \begin{pmatrix} |\alpha|^2 & 0 & 0 & \alpha\beta^* \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ \alpha^*\beta & 0 & 0 & |\beta|^2 \end{pmatrix} \ . \tag{41.244}$$

Projective measurements of qubit q_1 with two possible outcomes yields in both of the two cases, $|q_1\rangle = |0\rangle, |1\rangle$, the reduced density operator,

$$\hat{\rho}_1^{red} = p^{(0)} \frac{[|0\rangle\langle 0| \otimes \mathbb{I}]\,\hat{\rho}[|0\rangle\langle 0| \otimes \mathbb{I}]}{\text{Tr } \hat{\rho}[|0\rangle\langle 0| \otimes \mathbb{I}]} + p_1 \frac{[|1\rangle\langle 1| \otimes \mathbb{I}]\hat{\rho}[|1\rangle\langle 1| \otimes \mathbb{I}]}{\text{Tr } \hat{\rho}[|1\rangle\langle 1| \otimes \mathbb{I}]} \tag{41.245}$$

$$= \begin{pmatrix} |\alpha|^2 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & |\beta|^2 \end{pmatrix} = |\alpha|^2[|0\rangle\langle 0| \otimes |0\rangle\langle 0|] + |\beta|^2[|1\rangle\langle 1| \otimes |1\rangle\langle 1|] \ .$$

A projective measurements of qubit q_1 would yield exactly the same result.

41.6.5 The field of quantum information

The possibility to experimentally control, manipulate and read out individual qubits gave birth to a new field of physics in the past two decades now called *quantum information*. This fields includes the more specific areas of *quantum processing* (which itself splits into the subareas of *quantum computing* and *quantum simulation*), *quantum communication*, and *quantum sensing* (see Sec. 36.5).

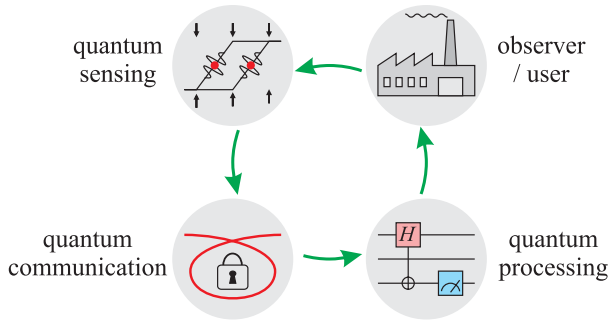

Figure 41.32: Key technologies of the second quantum revolution.

The fundamental epitomic systems on which the quantum information technologies are based are listed in the table below. Although the correspondence is oversimplified, it gives a coarse idea of the involved areas of quantum mechanics. Technological revolutions have often been triggered by paradigmatic 'paradoxes' which, in fact, were mostly dramatized juxtapositions of classical and innovative concepts and stop being paradoxical, once they have been resolved by a more complete theory. The table also lists the cornerstone paradoxes of quantum information technologies.

area	quantum computing	communication	sensing
system	two-level atom / spin	harmonic oscillator	propagation of free atom
device	qubit	photon	interferometer
phenomenon	quantum entanglement		superposition & measurement
paradox	EPR paradox		Schrödinger cat

41.6.5.1 Physical implementation of quantum computers

Quantum entanglement and information processing protocols for quantum computing have been implemented with various technologies (see table below for a non-exhaustive list), some of them pursued by private companies. Every approach has its advantages and disadvantages, the main figures of merit being the *qubit number*, the *qubit connectivity*, and the *gate fidelity*. Other important factors are *scalability*, *qubit homogeneity*, and *ease of fabrication and use*.

physical system	description	companies	publications
ions	trapped ion array	IonQ, AQT	[915, 840]
neutral atoms	optical lattice	-	[28]
transmons	superconducting JJ arrays	IBM, Google, ...	[49]
molecules	NMR on bonds in molecules	-	[1401]
NV centers	color centers in diamond	-	[1025]
quantum dots	quantum dots arrays	diraq	[814]
photons	polarization or timing	-	[1268]

Example 269 (*Quantum volume of perfect processor*): The *quantum volume* of an N-qubit quantum processor is a metric invented by IBM that characterizes the largest random quantum circuit that the device can efficiently

simulate. The formula for quantum volume is given by:

$$\text{quantum volume} = N^2 \times \text{maximal depth} \ . \tag{41.246}$$

In the case of a perfect N-qubit processor, the maximal depth is equal to N since each gate can be applied in parallel on all qubits, and there are N such layers. Therefore, the quantum volume of a perfect N-qubit processor is quantum volume $= N^3$. This means that a perfect N-qubit quantum processor can efficiently simulate random quantum circuits of up to N^3 gates. However, in reality, quantum processors suffer from errors due to various sources such as decoherence and imperfect gate operations, and as a result, their quantum volume is typically much lower than this theoretical limit.

41.6.5.2 Quantum sensing 2.0

Many sensors are based on interferometry, as explained in Sec. 36.5.3. The circuit exhibited in Fig. 41.33 visualizes the basic principle of an interferometer. The two Hadamard gates correspond to Ramsey pulses, and the controlled U gate realizes the interaction, which transfers information from the U gate to the sensing qubit.

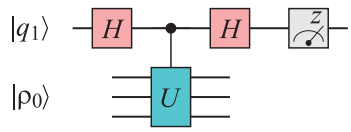

Figure 41.33: Quantum interferometry.

As mentioned in Sec. 36.3.2 and in Sec. 41.1.4, the sensitivity of interferometers can be enhanced when correlated particles are used. In Exc. 41.6.6.13 we show how the interferometer of Fig. 41.33 can be modified in order to benefit from correlated particles.

41.6.5.3 Quantum Fourier transform

The *quantum Fourier transform* (QFT) is a linear transformation on qubits and the quantum analogue of the inverse discrete Fourier transform. The quantum Fourier transform is a part of many quantum algorithms, notably Shor's algorithm for factoring and computing the discrete logarithm or the quantum phase estimation algorithm for estimating the eigenvalues of a unitary operator.

The quantum Fourier transform can be performed efficiently on a quantum computer, with a particular decomposition into a product of simpler unitary matrices. Using a simple decomposition, the discrete Fourier transform on 2^n amplitudes can be implemented as a quantum circuit consisting of only $O(n^2)$ Hadamard gates and controlled phase shift gates, where n is the number of qubits. This can be compared with the classical discrete Fourier transform, which takes $O(2^n)$ gates, which is exponentially more than in the classical case. However, the quantum Fourier transform acts on a quantum state, whereas the classical Fourier transform acts on a vector, so not every task that uses the classical Fourier transform can take advantage of this exponential speedup.

The quantum Fourier transform is the classical discrete Fourier transform applied to the vector of amplitudes of a quantum state, where we usually consider vectors of length $N = 2^n$. The classical Fourier transform acts on a vector $(x_0, x_1, \ldots, x_{N-1}) \in \mathbb{C}^N$ and maps it to the vector $(y_0, y_1, \ldots, y_{N-1}) \in \mathbb{C}^N$ according to the formula:

$$\boxed{y_k = \frac{1}{\sqrt{N}} \sum_{n=0}^{N-1} x_n \omega_N^{\mp kn} \ ,} \tag{41.247}$$

where $k = 0, 1, \ldots, N-1$ and $\omega_N = e^{2\pi\imath/N}$ and ω_N^n is an N^{th} root of unity. The lower sign holds for the *inverse* FT.

Similarly, the quantum Fourier transform acts on a quantum state $|x\rangle = \sum_{i=0}^{N-1} x_i |i\rangle$ and maps it to a quantum state $\sum_{i=0}^{N-1} y_i |i\rangle$ according to the same formula (41.247). In case that $|x\rangle$ is a basis state, the quantum Fourier Transform can also be expressed as the map,

$$|x\rangle \mapsto \frac{1}{\sqrt{N}} \sum_{k=0}^{N-1} \omega_n^{xk} |k\rangle \ . \tag{41.248}$$

Equivalently, the quantum Fourier transform can be viewed as a unitary matrix (or a quantum gate, similar to a Boolean logic gate for classical computers) acting on quantum state vectors, where the unitary matrix is given by,

$$F_N = \frac{1}{\sqrt{N}} \begin{pmatrix} 1 & 1 & 1 & 1 & \cdots & 1 \\ 1 & \omega & \omega^2 & \omega^3 & \cdots & \omega^{N-1} \\ 1 & \omega^2 & \omega^4 & \omega^6 & \cdots & \omega^{2(N-1)} \\ 1 & \omega^3 & \omega^6 & \omega^9 & \cdots & \omega^{3(N-1)} \\ \vdots & \vdots & \vdots & \vdots & & \vdots \\ 1 & \omega^{N-1} & \omega^{2(N-1)} & \omega^{3(N-1)} & \ldots & \omega^{(N-1)(N-1)} \end{pmatrix} \tag{41.249}$$

where $\omega = \omega_N$. Do the Excs. 41.6.6.10 and 41.6.6.11.

The QFT is unitary,

$$\boxed{FF^\dagger = \mathbb{I} \ ,} \tag{41.250}$$

and can be efficiently performed on a quantum computer. The quantum gates used in the circuit are the Hadamard gate and the controlled phase gate R_m,

$$H = \tfrac{1}{\sqrt{2}} \begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix} \qquad \text{and} \qquad R_m = \begin{pmatrix} 1 & 0 \\ 0 & e^{2\pi\imath/2^m} \end{pmatrix} \ , \tag{41.251}$$

with $e^{2\pi\imath/2^m} = \omega_{(2^m)}$ the primitive 2^m-th root of unity. The circuit is composed of H gates and the controlled version of R_m.

All quantum operations must be linear, so it suffices to describe the function on each one of the basis states and let the mixed states be defined by linearity. This is in contrast to how Fourier transforms are usually described. We normally describe Fourier transforms in terms of how the components of the results are calculated on an arbitrary input. This is how you would calculate the path integral or show BQP is

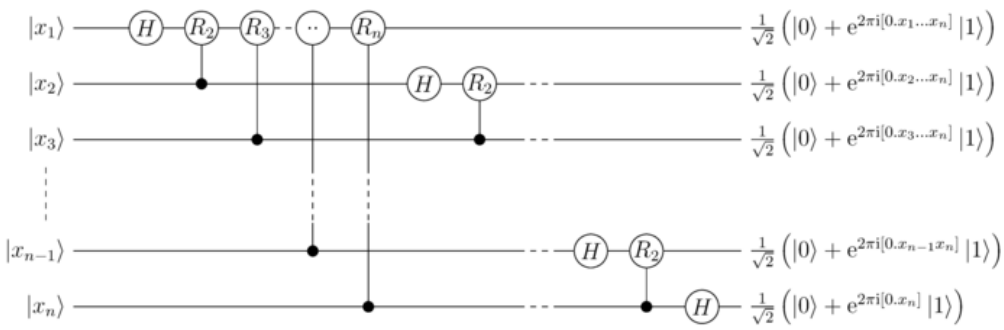

Figure 41.34: Quantum circuit for QFT with n qubits (without rearranging the order of output states).

in PP. But it is much simpler here (and in many cases) to just explain what happens to a specific arbitrary basis state, and the total result can be found by linearity.

The quantum Fourier transform can be approximately implemented for any N; however, the implementation for the case where N is a power of 2 is much simpler. As already stated, we assume $N = 2^n$. We have the orthonormal basis consisting of the vectors $|0\rangle, \ldots, |2^n - 1\rangle$. The basis states enumerate all the possible states of the qubits, $|x\rangle = |x_1 x_2 \ldots x_n\rangle = |x_1\rangle \otimes |x_2\rangle \otimes \cdots \otimes |x_n\rangle$, where $|x_j\rangle$ indicates that qubit j is in state x_j, with x_j either 0 or 1. By convention, the basis state index x orders the possible states of the qubits lexicographically, i.e. by converting from binary to decimal in this way:

$$x = x_1 2^{n-1} + x_2 2^{n-2} + \cdots + x_n 2^0 \ . \tag{41.252}$$

It is also useful to borrow fractional binary notation:

$$[0.x_1 \ldots x_m] = \sum_{k=1}^{m} x_k 2^{-k} \ . \tag{41.253}$$

For instance, $[0.x_1] = \frac{x_1}{2}$ and $[0.x_1 x_2] = \frac{x_1}{2} + \frac{x_2}{2^2}$. With this notation, the action of the quantum Fourier transform can be expressed in a compact manner:

$$\begin{aligned} \mathrm{QFT}(|x_1 x_2 \ldots x_n\rangle) = \frac{1}{\sqrt{N}} \left(|0\rangle + e^{2\pi\imath\ [0.x_n]}|1\rangle\right) \otimes \left(|0\rangle + e^{2\pi\imath\ [0.x_{n-1}x_n]}|1\rangle\right) \otimes \cdots \\ \otimes \left(|0\rangle + e^{2\pi\imath\ [0.x_1 x_2 \ldots x_n]}|1\rangle\right) \ , \end{aligned} \tag{41.254}$$

where we have used $[0.x_1 x_2 ... x_m] = [x_1 x_2 ... x_n]/2^m$. This can be seen by rewriting the formula for the Fourier transform in the binary expansion:

$$\mathrm{QFT}(|x\rangle) = \frac{1}{\sqrt{N}} \sum_{k=0}^{2^n-1} \omega_n^{xk} |k\rangle = \ldots = \frac{1}{\sqrt{N}} \bigotimes_{j=1}^{n} \left(|0\rangle + \omega_n^{x 2^{n-j}}|1\rangle\right) \ . \tag{41.255}$$

Now, we have $\omega_n^{x2^{n-j}} = e^{\frac{2\pi\imath}{2^n}x2^{n-j}} = e^{2\pi\imath(x2^{-j})}$. Let,

$$f(j) = x2^{-j} = 2^{-j}\sum_{r=1}^{n} x_r 2^{n-r} = \sum_{r=1}^{n} x_r 2^{n-j-r} \tag{41.256}$$
$$= \sum_{r=1}^{n-j} x_r 2^{n-j-r} + \sum_{r=n-j+1}^{n} x_r 2^{n-j-r} = a(j) + b(j) \ .$$

then $a(j) \in \mathbb{N}_0$, because $2^{n-j-r} \geq 0$, for $n-j-r \geq 0$, and $b(j) = 0.x_{n-j+1}x_{n-j+2}\dots x_n$, thus the (2) becomes:

$$e^{2\pi\imath f(j)} = e^{2\pi\imath(a(j)+b(j))} = e^{2\pi\imath a(j)} \cdot e^{2\pi\imath b(j)} = e^{2\pi\imath[0.x_{n-j+1}x_{n-j+2}\cdots x_n]} \ , \tag{41.257}$$

since $e^{2\pi\imath a(j)} = 1$ for all j. Then we can write:

$$\mathrm{QFT}(|x_1x_2\dots x_n\rangle) = \frac{1}{\sqrt{N}}\bigotimes_{j=1}^{n}\left(|0\rangle + \omega_n^{x2^{n-j}}|1\rangle\right) \tag{41.258}$$
$$= \frac{1}{\sqrt{N}}\bigotimes_{j=1}^{n}\left(|0\rangle + e^{2\pi\imath[0.x_{n-j+1}x_{n-j+2}\dots x_n]}|1\rangle\right)$$
$$= \frac{1}{\sqrt{N}}\left(|0\rangle + e^{2\pi\imath[0.x_n]}|1\rangle\right)\otimes\left(|0\rangle + e^{2\pi\imath[0.x_{n-1}x_n]}|1\rangle\right)\otimes\cdots\otimes\left(|0\rangle + e^{2\pi\imath[0.x_1x_2\dots x_n]}|1\rangle\right) \ .$$

To obtain this state from the circuit depicted above, a swap operations of the qubits must be performed to reverse their order. After the reversal, the n-th output qubit will be in a superposition state of $|0\rangle$ and $e^{2\pi\imath\ [0.x_1\dots x_n]}|1\rangle$, and similarly the other qubits before that (take a second look at the sketch of the circuit above).

In other words, the discrete Fourier transform, an operation on n qubits, can be factored into the tensor product of n single-qubit operations, suggesting it is easily represented as a quantum circuit (up to an order reversal of the output). In fact, each of those single-qubit operations can be implemented efficiently using a Hadamard gate and controlled phase gates. The first term requires one Hadamard gate and $(n-1)$ controlled phase gates, the next one requires a Hadamard gate and $(n-2)$ controlled phase gate, and each following term requires one fewer controlled phase gate. Summing up the number of gates, excluding the ones needed for the output reversal, gives $n + (n-1) + \cdots + 1 = n(n+1)/2 = O(n^2)$ gates, which is quadratic polynomial in the number of qubits.

The QFT is useful in the simulation of Hamiltonian evolution governed by conjugate variables,

$$e^{-\hat{H}t/\hbar} \qquad \text{where} \qquad \hat{H} = \frac{\hat{p}}{2m} + \frac{m}{2}\omega^2\hat{x}^2 \ , \tag{41.259}$$

where, similar to the *time-splitting spectral algorithm*, we may replace differential operators,

$$\hat{p} = F^{-1}\ \hat{x}\ F \ . \tag{41.260}$$

41.6.5.4 Boson sampling

A qubit is not necessarily a single (quasi-)particle, such as an atom or a photon. More generally any system which can interfere, that is be in superposition states, may qualify. F.ex. a laser pulse with squeezing/polarization as the degree of freedom can be used for *boson sampling* [1, 578, 1063, 1432].

41.6.6 Exercises

41.6.6.1 Ex: Controlled Z-gate

Check that the CZ gate is invariant under spin exchange. This fact justifies the symmetry of the symbol with respect to the two coupled qubits.

Solution: *Using,*

$$Z = -\hat{\sigma}_z = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}$$

and the `SWAP`*-gate introduced in (23.130) we just need to show,*

$$\overset{c}{Z}_{10} = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & -1 \end{pmatrix} = \mathbb{S}\overset{c}{Z}_{01}\mathbb{S} \equiv \overset{c}{Z}_{01} \ .$$

41.6.6.2 Ex: Quantum computing code for spin-squeezing

Express spin-squeezing of 2, respectively, 3 qubits by a quantum circuit.

Solution: *Check [1144]!*

41.6.6.3 Ex: Two-bit SWAP gate

Represent the two-qubit SWAP gate by a succession of three CNOT gates.

Solution: *From (41.217) we know* $\overset{c}{X}_{01} = \mathbb{S}\overset{c}{X}_{10}\mathbb{S}$. *With,*

$$\overset{c}{X}_{10} = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \end{pmatrix} \quad , \quad \overset{c}{X}_{01} = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 \end{pmatrix}$$

it is easy to show that,

$$\mathbb{S} = \overset{c}{X}_{01}\overset{c}{X}_{10}\overset{c}{X}_{01} = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix} ,$$

as illustrated in Fig. 41.35.

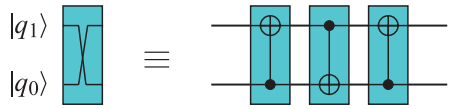

Figure 41.35: Swapping two qubits via three controlled NOT gates.

41.6.6.4 Ex: Three-bit SWAP gate

a. Convince yourself that the SWAP gates defined by (41.221) have the explicit matrix form,

$$\mathbb{S}_{ij}(k, k_{ij}) \equiv 1 \qquad \text{where} \qquad \begin{cases} k = [0, ..., 7] \\ k_{12} = [0, 1, 4, 5, 2, 3, 6, 7] \\ k_{01} = [0, 2, 1, 3, 4, 6, 5, 7] \\ k_{02} = [0, 4, 2, 6, 1, 5, 3, 7] \end{cases} ,$$

the index k indicating the column and k_{ij} the row where the matrix has an entry.
b. Verify,

$$\mathbb{S}^{-1} = \mathbb{S} \qquad , \qquad \mathbb{S}_{ij}^{-1} = \mathbb{S}_{ij} \ .$$

Solution:

41.6.6.5 Ex: Quantum gates

Verify the formulae (41.223).

Solution:

41.6.6.6 Ex: Toffoli gate

Check that the quantum circuit sketched in Fig. 41.36, which only envolves two-qubit quantum gates realizes a Toffoli gate.

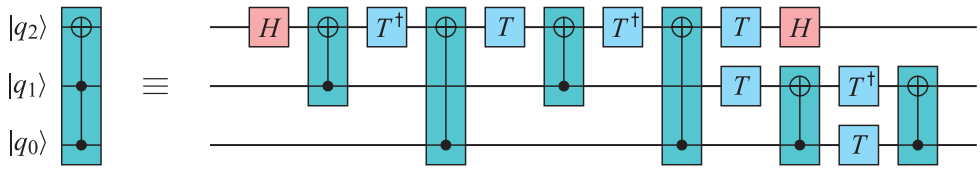

Figure 41.36: Quantum circuit realizing a Toffoli gate.

Solution: *The circuit diagram represents the operation,*

$$\overset{cc}{X}_{012} = \overset{c}{X}_{01} T_0 T_1^\dagger \overset{c}{X}_{01} T_1 H_2 T_2 \overset{c}{X}_{02} T_2^\dagger \overset{c}{X}_{12} T_2 \overset{c}{X}_{02} T_2^\dagger \overset{c}{X}_{12} H_2 = \begin{pmatrix} 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 \end{pmatrix},$$

or inverting the order of the significant qubits,

$$\overset{cc}{X}_{210} = S_{01} S_{12} S_{01} \overset{cc}{X}_{012} S_{01} S_{12} S_{01} = \begin{pmatrix} 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 \end{pmatrix}.$$

41.6.6.7 Ex: Classical and quantum logic

a. Verify $\neg(A \vee B) = \neg A \wedge \neg B$ and $A \oplus B = (\neg A \wedge B) \vee (A \wedge \neg B)$.
b. How would you realize the classical logical operations AND, OR, and XOR on a quantum computer?

Solution: *a. Trivial by comparing the truth tables.*
b. The classical logic operations AND and OR involve three bits, two at the input and one at the output. Because the corresponding quantum logic operation must be reversible, we must specify the state of all three qubits before and after the operation. That is, we are looking for a unitary transform in $\mathcal{H}^{2^3}$. *Classically, we determine the*

following truth tables,

$$|\psi\rangle_{in} = \begin{array}{c} |q_2,q_1,q_0\rangle \\ \left(\begin{array}{cc|c} 0&0&0\\ 0&0&1\\ 0&1&0\\ 0&1&1\\ 1&0&0\\ 1&0&1\\ 1&1&0\\ 1&1&1 \end{array}\right) \end{array} \quad , \quad |\psi\rangle_{out}^{AND-NOR} = \begin{array}{c} |q_2,q_1,(q_2\wedge q_1)\oplus q_0\rangle \\ \left(\begin{array}{cc|c} 0&0&0\\ 0&0&1\\ 0&1&0\\ 0&1&1\\ 1&0&0\\ 1&0&1\\ 1&1&1\\ 1&1&0 \end{array}\right) \end{array} \quad ,$$

$$|\psi\rangle_{out}^{OR-NAND} = \begin{array}{c} |q_2,q_1,(q_2\vee q_1)\oplus q_0\rangle \\ \left(\begin{array}{cc|c} 0&0&0\\ 0&0&1\\ 0&1&1\\ 0&1&0\\ 1&0&1\\ 1&0&0\\ 1&1&1\\ 1&1&0 \end{array}\right) \end{array} \quad , \quad |\psi\rangle_{out}^{XOR-NXOR} = \begin{array}{c} |q_2,q_1,(q_2\oplus q_1)\oplus q_0\rangle \\ \left(\begin{array}{cc|c} 0&0&0\\ 0&0&1\\ 0&1&1\\ 0&1&0\\ 1&0&1\\ 1&0&0\\ 1&1&0\\ 1&1&1 \end{array}\right) \end{array} \quad .$$

The classical gates are recovered by projecting the $q_0^{(out)}$ output bit on either the $q_0^{(in)} = 0$ or 1 input bit. In quantum logic, we use the relations (41.223) to construct the quantum AND (and simultaneously NOR) via the Toffoli gate,

$$U_{AND} = \overset{cc}{X}_{210} = |q_2,q_1,(q_2\wedge q_1)\oplus q_0\rangle\langle q_2,q_1,q_0| \ ,$$

or using the above defined basis,

$$\begin{array}{c} AND-NOR \\ \begin{pmatrix} |000\rangle \\ |001\rangle \\ |010\rangle \\ |011\rangle \\ |100\rangle \\ |101\rangle \\ |111\rangle \\ |110\rangle \end{pmatrix} \end{array} = \begin{pmatrix} 1&0&0&0&0&0&0&0\\ 0&1&0&0&0&0&0&0\\ 0&0&1&0&0&0&0&0\\ 0&0&0&1&0&0&0&0\\ 0&0&0&0&1&0&0&0\\ 0&0&0&0&0&1&0&0\\ 0&0&0&0&0&0&0&1\\ 0&0&0&0&0&0&1&0 \end{pmatrix} \begin{array}{c} |q_2,q_1,q_0\rangle \\ \begin{pmatrix} |000\rangle \\ |001\rangle \\ |010\rangle \\ |011\rangle \\ |100\rangle \\ |101\rangle \\ |110\rangle \\ |111\rangle \end{pmatrix} \end{array}$$

Similarly, for the quantum OR (and simultaneously NAND),

$$U_{OR} = X_2X_1X_0\overset{cc}{X}_{012}X_0X_1 = |q_2,q_1,(q_2\vee q_1)\oplus q_0\rangle\langle q_2,q_1,q_0| \ ,$$

or using the above defined basis,

$$\overset{OR-NAND}{\begin{pmatrix} |000\rangle \\ |001\rangle \\ |011\rangle \\ |010\rangle \\ |101\rangle \\ |100\rangle \\ |111\rangle \\ |110\rangle \end{pmatrix}} = \begin{pmatrix} 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 \end{pmatrix} \overset{|q_2,q_1,q_0\rangle}{\begin{pmatrix} |000\rangle \\ |001\rangle \\ |010\rangle \\ |011\rangle \\ |100\rangle \\ |101\rangle \\ |110\rangle \\ |111\rangle \end{pmatrix}}$$

Similarly, for the quantum XOR (and simultaneously NXOR),

$$U_{XOR} = \overset{c}{X}_{12}\overset{c}{X}_{02} = |q_2, q_1, (q_2 \oplus q_1) \oplus q_0\rangle\langle q_2, q_1, q_0| \ ,$$

or using the above defined basis,

$$\overset{XOR-NXOR}{\begin{pmatrix} |000\rangle \\ |001\rangle \\ |011\rangle \\ |010\rangle \\ |101\rangle \\ |100\rangle \\ |110\rangle \\ |111\rangle \end{pmatrix}} = \begin{pmatrix} 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \end{pmatrix} \overset{|q_2,q_1,q_0\rangle}{\begin{pmatrix} |000\rangle \\ |001\rangle \\ |010\rangle \\ |011\rangle \\ |100\rangle \\ |101\rangle \\ |110\rangle \\ |111\rangle \end{pmatrix}}$$

41.6.6.8 Ex: Quantum composer

Show that the following diagrams describe identical unitary operations:

Solution: *The diagrams can easily be verified after having translated them into a matricial language as,*

a.

$$\overset{c}{X}_{01} = (\mathbb{I} \otimes H)\overset{c}{Z}_{01}(\mathbb{I} \otimes H) \ .$$

b.

$$(H \otimes H)\overset{c}{X}_{01}(H \otimes H) = \overset{c}{X}_{10} \ .$$

c.

$$(\overset{cc}{U}_{012})^2 = (\mathbb{I} \otimes \mathbb{I} \otimes \overset{c}{U}_{12})(\overset{c}{X}_{01} \otimes \mathbb{I})(\mathbb{I} \otimes \mathbb{I} \otimes (\overset{c}{U}_{12})^\dagger)(\overset{c}{X}_{01} \otimes \mathbb{I})(\mathbb{I} \otimes \mathbb{I} \otimes \overset{c}{U}_{12}) \ .$$

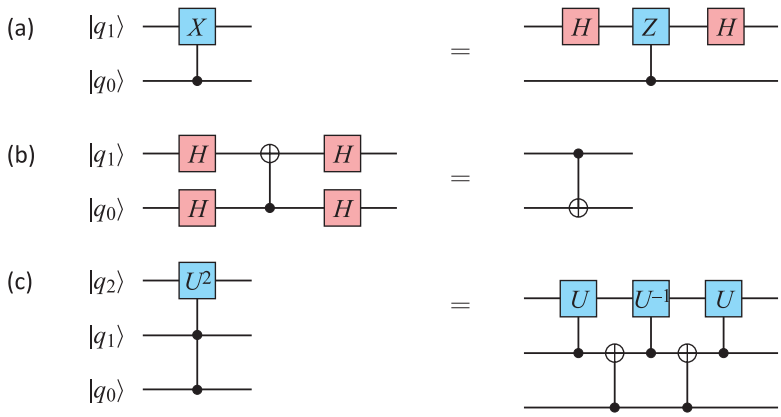

Figure 41.37:

41.6.6.9 Ex: Classical addition of two qubits

Design a quantum algorithm for the classical addition of up to 8 qubits.

Solution: *In the binary system the operation is given by the equation,*

$$\sum_{k=0}^{7} q_k = 4p_2 + 2p_1 + p_0 \ .$$

Using just XOR gates we find the scheme exhibited in Fig.41.38.

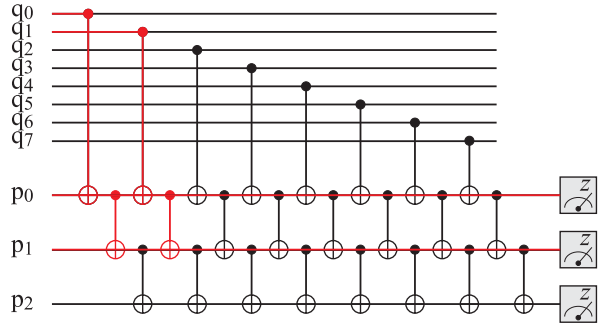

Figure 41.38: Quantum algorithm simulating the classical sum of up to 7 qubits (black lines) or up to 3 qubits (red lines).

41.6.6.10 Ex: CARL simulation on a quantum computer

Try to recast the so-called CARL Hamiltonian,

$$\hat{H} = U_0(\hat{a}_+^\dagger \hat{a}_- e^{-\imath k\hat{r}} + \hat{a}_+ \hat{a}_-^\dagger e^{\imath k\hat{r}})$$

such that it can be simulated by a sequence of quantum gates.

Solution: *We first truncate the admitted numbers of photons to some value and use the Holstein-Primakoff transformation. We must define a linear multi-qubit gate, each qubit standing for a photon. The motion is described as a 1D lattice in momentum space.*

41.6.6.11 Ex: Quantum Fourier transform on a quantum computer

Write down the QF transformation matrix for the case of $N = 4 = 2^2$ and phase $\omega = \imath$.

Solution: *The matrix reads,*

$$F_4 = \frac{1}{2}\begin{pmatrix} 1 & 1 & 1 & 1 \\ 1 & \imath & -1 & -\imath \\ 1 & -1 & 1 & -1 \\ 1 & -\imath & -1 & \imath \end{pmatrix} .$$

41.6.6.12 Ex: Three entangled qubits

a. Imagine a three-qubit quantum gate or a sequence of gates generating from the ground state the three partite states [400]:

$$|GHZ\rangle \equiv \frac{1}{\sqrt{2}}(|000\rangle + |111\rangle \qquad \text{and} \qquad |W\rangle \equiv \frac{1}{\sqrt{3}}(|001\rangle + |010\rangle + |100\rangle) .$$

b. Show how the procedure for the generation of the $|GHZ\rangle$ state can be easily extended to N entangled particles.

Solution: *a. In extension of the calculation of Exc. 41.5.4.1 it is easy to show that*

$$\overset{c}{X}_{12}\overset{c}{X}_{01}(H \otimes \mathbb{I} \otimes \mathbb{I}) \begin{pmatrix} 1 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{pmatrix} = \frac{1}{\sqrt{2}} \begin{pmatrix} 1 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 1 \end{pmatrix}$$

generates a GHZ state. The W state is obtained via

$$X_0 \overset{c}{X}_{01} \overset{c}{X}_{12} \overset{c}{H}_{01} U_3(\arccos(-\tfrac{1}{3}), 0, 0) \begin{pmatrix} 1 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{pmatrix} = \tfrac{1}{\sqrt{3}} \begin{pmatrix} 0 \\ 1 \\ 1 \\ 0 \\ 1 \\ 0 \\ 0 \\ 0 \\ 0 \end{pmatrix} .$$

b. We just have to continue the protocol like,

$$\overset{c}{X}_{N-1\ N} \overset{c}{X}_{N-2\ N-1} ... \overset{c}{X}_{01} (H \otimes \mathbb{I} \otimes \mathbb{I}) .$$

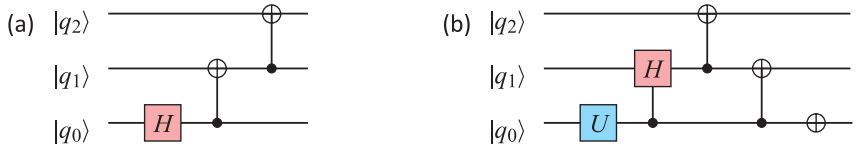

Figure 41.39: Quantum circuit generating (a) a GHZ state and (b) a W state.

41.6.6.13 Ex: Scattering circuit

a. Consider the controlled U gate given by,

$$\overset{c}{U}_{10} = |0\rangle\langle 0| \otimes \mathbb{I} + |1\rangle\langle 1| \otimes U ,$$

where U is an arbitrary unitary operation, and the quantum circuit given by,

$$M = [H \otimes \mathbb{I}] \overset{c}{U}_{10} [H \otimes \mathbb{I}]$$

and depicted in Fig. 41.33. Starting from an initial state $|0\rangle\langle 0| \otimes \hat{\rho}_0$, show, that a measurement of the first qubit $|q_1\rangle$ of the final state,

$$\hat{\rho}_f = M[|0\rangle\langle 0| \otimes \hat{\rho}_0] M^\dagger$$

yields,

$$\langle \hat{\sigma}_1^z \rangle = \mathfrak{Re}\ [\mathrm{Tr}_0\ \hat{\rho}_0 U] \qquad \text{and} \qquad \langle \hat{\sigma}_1^y \rangle = \mathfrak{Im}\ [\mathrm{Tr}_0\ \hat{\rho}_0 U] .$$

b. Calculate $\langle \vec{\hat{\sigma}}_1 \rangle$ for the case that U is a one-qubit phase gate given by (41.208).
c. Calculate $\langle \vec{\hat{\sigma}}_1 \rangle$ for the case that $U = X$ is a one-qubit `NOT` gate given by (41.210).

Solution: *a. The Hamamard gates applied to qubits q_1 and q_0 are, respectively [686],*

$$H_1 = H \otimes \mathbb{I} = \tfrac{1}{\sqrt{2}} \begin{pmatrix} \mathbb{I} & \mathbb{I} \\ \mathbb{I} & -\mathbb{I} \end{pmatrix} \qquad , \qquad H_0 = \mathbb{I} \otimes H = \tfrac{1}{\sqrt{2}} \begin{pmatrix} H & 0 \\ 0 & H \end{pmatrix} .$$

The controlled U gate is given by,

$$\overset{c}{U}_{10} = |0\rangle\langle 0| \otimes \mathbb{I} + |1\rangle\langle 1| \otimes U = \begin{pmatrix} \mathbb{I} & 0 \\ 0 & U \end{pmatrix} ,$$

so that the quantum circuit can be written as,

$$M = [H \otimes \mathbb{I}]\overset{c}{U}_{10}[H \otimes \mathbb{I}] = \tfrac{1}{2}\begin{pmatrix} \mathbb{I} & \mathbb{I} \\ \mathbb{I} & -\mathbb{I} \end{pmatrix}\begin{pmatrix} I & 0 \\ 0 & U \end{pmatrix}\begin{pmatrix} \mathbb{I} & \mathbb{I} \\ \mathbb{I} & -\mathbb{I} \end{pmatrix} = \tfrac{1}{2}\begin{pmatrix} \mathbb{I}+U & \mathbb{I}-U \\ \mathbb{I}-U & \mathbb{I}+U \end{pmatrix} .$$

Starting from an initial state

$$|0\rangle\langle 0| \otimes \hat{\rho}_0 = \begin{pmatrix} \hat{\rho}_0 & 0 \\ 0 & 0 \end{pmatrix} ,$$

we see, that the final state becomes,

$$\hat{\rho}_f = M[|0\rangle\langle 0| \otimes \hat{\rho}_0]M^\dagger = \tfrac{1}{4}\begin{pmatrix} \hat{\rho}_0 + U\rho_0 U^\dagger + (U\hat{\rho}_0 + \hat{\rho}_0 U^\dagger) & \hat{\rho}_0 - U\hat{\rho}_0 U^\dagger + (U\hat{\rho}_0 - \hat{\rho}_0 U^\dagger) \\ \hat{\rho}_0 - U\hat{\rho}_0 U^\dagger - (U\hat{\rho}_0 - \hat{\rho}_0 U^\dagger) & \hat{\rho}_0 + U\hat{\rho}_0 U^\dagger - (U\hat{\rho}_0 + \hat{\rho}_0 U^\dagger) \end{pmatrix} .$$

Tracing over the second qubit $|q_0\rangle$ yields the reduced density matrix of the probe qubit q_1,

$$\begin{aligned} \hat{\rho}^{red} = Tr_0\ \hat{\rho}_f &= \tfrac{1}{2}\begin{pmatrix} 1 + \frac{1}{2}Tr_0\ (U\hat{\rho}_0 + \hat{\rho}_0 U^\dagger) & \frac{1}{2}Tr_0\ (U\hat{\rho}_0 - \hat{\rho}_0 U^\dagger) \\ -\frac{1}{2}Tr_0\ (U\hat{\rho}_0 - \hat{\rho}_0 U^\dagger) & 1 - \frac{1}{2}Tr_0\ (U\hat{\rho}_0 + \hat{\rho}_0 U^\dagger) \end{pmatrix} \\ &= \tfrac{1}{2}\begin{pmatrix} 1 + \mathfrak{Re}\ [Tr_0\ U\hat{\rho}_0] & \imath\mathfrak{Im}\ [Tr_0\ U\hat{\rho}_0] \\ -\imath\mathfrak{Im}\ [Tr_0\ U\hat{\rho}_0] & 1 - \mathfrak{Re}\ [Tr_0\ U\hat{\rho}_0] \end{pmatrix} . \end{aligned}$$

Finally, we get for the observables of the probe qubit,

$$\begin{aligned} \langle\hat{\sigma}_1^x\rangle &= \langle 0|\hat{\rho}^{red}|1\rangle + \langle 1|\hat{\rho}^{red}|0\rangle = 0 \\ \langle\hat{\sigma}_1^y\rangle &= \imath\langle 0|\hat{\rho}^{red}|1\rangle - \imath\langle 1|\hat{\rho}^{red}|0\rangle = -\mathfrak{Im}\ [Tr_0\ \hat{\rho}_0 U] \\ \langle\hat{\sigma}_1^z\rangle &= \langle 0|\hat{\rho}^{red}|0\rangle - \langle 1|\hat{\rho}^{red}|1\rangle = \mathfrak{Re}\ [Tr_0\ \hat{\rho}_0 U] . \end{aligned}$$

b. If U is given by,

$$U = \begin{pmatrix} 1 & 0 \\ 0 & e^{\imath\varphi} \end{pmatrix} ,$$

we find,

$$\langle\vec{\hat{\sigma}}_1\rangle = \begin{pmatrix} 0 \\ \mathfrak{Im}\ (\rho_{00} + \rho_{11}e^{\imath\phi}) \\ \mathfrak{Re}\ (\rho_{00} + \rho_{11}e^{\imath\phi}) \end{pmatrix} = \begin{pmatrix} 0 \\ \rho_{11}\sin\phi \\ \rho_{00} + \rho_{11}\cos\phi \end{pmatrix} .$$

c. If $U = X$ is the inversion of a qubit, we find,

$$\langle\vec{\hat{\sigma}}_1\rangle = \begin{pmatrix} 0 \\ -\mathfrak{Im}\ (\rho_{01} + \rho_{10}) \\ \mathfrak{Re}\ (\rho_{01} + \rho_{10}) \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \\ \rho_{01} + \rho_{10} \end{pmatrix} .$$

41.6.6.14 Ex: Heisenberg-limited quantum sensing

This exercise aims at showing that entangled qubits allow for phase measurements beyond the standard quantum limit. Proceed as follows:
a. Express standard Ramsey interferometry for a single qubit as a sequence of quantum gates and calculate the uncertainty of the final Bloch vector component $\Delta\hat{S}_z/||\hat{S}_z||$.
b. Repeat (a) with a product state of two qubits.
c. Plot the relative uncertainty of the inversion $(\Delta\hat{S}_z^2/\langle\hat{S}_z^2\rangle)^{1/2}$ after the Ramsey cycle as a function of the precession phase for the cases (a) and (b), as well as the spin squeezing parameter $\sqrt{N}\langle\Delta\hat{S}_y\rangle/|\langle\hat{S}_z\rangle|$ [1380, 343].
d. Repeat (b) with two entangled qubits and interpret your observations.

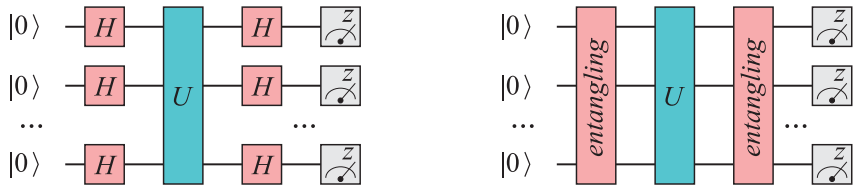

Figure 41.40: Scheme for Heisenberg-limited quantum sensing.

Solution: *a. Using the definitions of the Hadamard gate and the phase shift gate, Ramsey interferometry with a single qubit,*

$$H = \tfrac{1}{\sqrt{2}}\begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix} \quad , \quad U = \begin{pmatrix} e^{\imath\varphi/2} & 0 \\ 0 & e^{-\imath\varphi/2} \end{pmatrix} \ ,$$

we easily see, with $M \equiv HUH$,

$$\hat{\rho}_f = M|0\rangle\langle 0|M^\dagger = \begin{pmatrix} \cos^2\frac{\varphi}{2} & -\imath\cos\frac{\varphi}{2}\sin\frac{\varphi}{2} \\ \imath\cos\frac{\varphi}{2}\sin\frac{\varphi}{2} & \sin^2\frac{\varphi}{2} \end{pmatrix} \ .$$

This allows us to calculate,

$$\langle\hat{\mathbf{S}}\rangle = \tfrac{1}{2}\langle\vec{\hat{\sigma}}\rangle = \tfrac{1}{2}\,Tr\,\hat{\rho}_f\begin{pmatrix}\hat{\sigma}_x \\ \hat{\sigma}_y \\ \hat{\sigma}_z\end{pmatrix} = \tfrac{1}{2}\begin{pmatrix} 0 \\ \sin\varphi \\ \cos\varphi \end{pmatrix}$$

$$\langle\hat{S}_\alpha^2\rangle = \tfrac{1}{4}\,Tr\,\hat{\rho}_f\hat{\sigma}_\alpha^2 = \tfrac{1}{4} \quad for \quad \alpha = x, y, z$$

$$\Delta\hat{S}_\alpha^2 = \tfrac{1}{4}\begin{cases} 1 & for \quad \alpha = x \\ \cos^2\varphi & for \quad \alpha = y \\ \sin^2\varphi & for \quad \alpha = z \end{cases} \ ,$$

so that $\|\langle\mathbf{S}\rangle\| = \frac{1}{2}$ *and* $\langle\hat{S}_x^2\rangle + \langle\hat{S}_y^2\rangle + \langle\hat{S}_z^2\rangle = \frac{3}{4} = S(S+1)$. *The relative uncertainty of the inversion and the spin squeezing parameter are, respectively,*

$$\sqrt{\frac{\Delta\hat{S}_z^2}{\langle\hat{S}_z^2\rangle}} = \sin\varphi \qquad and \qquad \frac{\sqrt{N}\langle\Delta\hat{S}_y\rangle}{|\langle\hat{S}_z\rangle|} = 1 \ .$$

b. For two qubits, the same calculation with $M \equiv (H \otimes H)(U \otimes U)(H \otimes H)$ *and* $\hat{\rho}_f = M|0\rangle\langle 0|M^\dagger$ *allows us to calculate (with the help of MAPLE),*

$$\langle \hat{\mathbf{S}} \rangle = \tfrac{1}{2}\langle \vec{\hat{\sigma}} \otimes \mathbb{I} + \mathbb{I} \otimes \vec{\hat{\sigma}} \rangle = \tfrac{1}{2}\, Tr\, \hat{\rho}_f \begin{pmatrix} \hat{\sigma}^x \\ \hat{\sigma}^y \\ \hat{\sigma}^z \end{pmatrix} \otimes \mathbb{I} + \tfrac{1}{2}\, Tr\, \hat{\rho}_f \mathbb{I} \otimes \begin{pmatrix} \hat{\sigma}^x \\ \hat{\sigma}^y \\ \hat{\sigma}^z \end{pmatrix} = \begin{pmatrix} 0 \\ \sin\varphi \\ \cos\varphi \end{pmatrix}$$

$$\langle \hat{S}_\alpha^2 \rangle = \tfrac{1}{4}\, Tr\, \hat{\rho}_f [\hat{\sigma}_\alpha \otimes \mathbb{I} + \mathbb{I} \otimes \hat{\sigma}_\alpha]^2 = \tfrac{1}{2} \begin{cases} 1 & for \;\; \alpha = x \\ 2 - \cos^2\varphi & for \;\; \alpha = y \\ 1 + \cos^2\varphi & for \;\; \alpha = z \end{cases}$$

$$\Delta \hat{S}_\alpha^2 = \tfrac{1}{2} \begin{cases} 1 & for \;\; \alpha = x \\ \cos^2\varphi & for \;\; \alpha = y \\ \sin^2\varphi & for \;\; \alpha = z \end{cases} ,$$

so that $\|\langle \mathbf{S} \rangle\| = 1$ *and* $\langle \hat{S}_x^2 \rangle + \langle \hat{S}_y^2 \rangle + \langle \hat{S}_z^2 \rangle = 2 = S(S+1)$. *The relative uncertainty of the inversion is,*

$$\sqrt{\frac{\Delta \hat{S}_z^2}{\langle \hat{S}_z^2 \rangle}} = \frac{\sin\varphi}{\sqrt{1 + \cos^2\varphi}} \qquad and \qquad \frac{\sqrt{N}\langle \Delta \hat{S}_y \rangle}{|\langle \hat{S}_z \rangle|} = 1 \; .$$

c. Fig. 41.41(a) shows the relative uncertainty of the inversion (dotted) for the cases (a) and (b), as well as numerical calculation for the cases of up to 4 qubits.

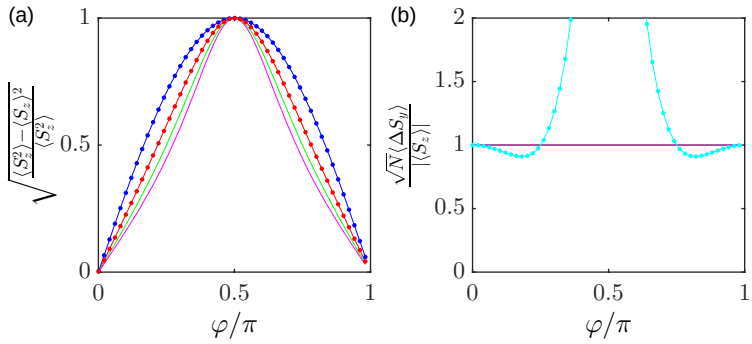

Figure 41.41: (code) (a) Relative uncertainty of the z-component as a function of the precession angle φ for various numbers of non-entangled qubits analytically (dots) and numerically (solid). (b) Metrology squeezing parameter.

d. For two entangled qubits, we replace the two-qubit Hadamard gate $H \otimes H$, *corresponding to a Ramsey pulse, by the entangling gate* $(H_1 \otimes \mathbb{I})\overset{c}{X}_{10}(H_1 \otimes \mathbb{I})$, *that is,*

$$M = (H_1 \otimes \mathbb{I})\overset{c}{X}_{10}(H_1 \otimes \mathbb{I})\; (U \otimes U)\; (H_1 \otimes \mathbb{I})\overset{c}{X}_{10}(H_1 \otimes \mathbb{I}) \; .$$

We again calculate $\hat{\rho}_f = M|0\rangle\langle 0|M^\dagger$ *and obtain,*

$$\langle \hat{\mathbf{S}} \rangle = \tfrac{1}{2}\langle \vec{\hat{\sigma}} \otimes \mathbb{I} + \mathbb{I} \otimes \vec{\hat{\sigma}} \rangle = \tfrac{1}{2}\, Tr\, \hat{\rho}_f \begin{pmatrix} \hat{\sigma}^x \\ \hat{\sigma}^y \\ \hat{\sigma}^z \end{pmatrix} \otimes \mathbb{I} + \tfrac{1}{2}\, Tr\, \hat{\rho}_f \mathbb{I} \otimes \begin{pmatrix} \hat{\sigma}^x \\ \hat{\sigma}^y \\ \hat{\sigma}^z \end{pmatrix} = \begin{pmatrix} 0 \\ \sin\varphi\cos\varphi \\ \cos\varphi \end{pmatrix}$$

$$\langle \hat{S}_\alpha^2 \rangle = \tfrac{1}{4}\, Tr\, \hat{\rho}_f [\hat{\sigma}_\alpha \otimes \mathbb{I} + \mathbb{I} \otimes \hat{\sigma}_\alpha]^2 = \tfrac{1}{2} \begin{cases} 2 - \cos^2\varphi & for \quad \alpha = x \\ 1 & for \quad \alpha = y \\ 1 + \cos^2\varphi & for \quad \alpha = z \end{cases}$$

$$\Delta \hat{S}_\alpha^2 = \tfrac{1}{2} \begin{cases} 2 - \cos^2\varphi & for \quad \alpha = x \\ 1 - 2\sin^2\varphi\cos^2\varphi & for \quad \alpha = y \\ 1 - \cos^2\varphi & for \quad \alpha = z \end{cases} .$$

The relative uncertainty of the inversion is,

$$\sqrt{\frac{\Delta \hat{S}_z^2}{\langle \hat{S}_z^2 \rangle}} = \sin\varphi \qquad and \qquad \frac{\sqrt{N}\langle \Delta \hat{S}_y \rangle}{|\langle \hat{S}_z \rangle|} = \frac{\sqrt{1 - 2\cos^2\phi \sin^2\phi}}{|\cos\phi|} .$$

In Fig. 41.41(b) we observe a reduce of the spin squeezing parameter below the classical limit. For example, for $\varphi = \pi/8$ *we get* 0.94.

Chapter 42

Atomic motion in optical cavities

In the preceding chapter we concentrated on the dynamics of the field modes of laser-pumped cavities. We devoted a particular attention to the role of scatterers, e.g. atoms, located in the mode volume and coupling the dynamics of counterpropagating modes. We assumed the atoms to be fixed in space, or at most subject to an external force constraining their motion. We have also seen that the coupling of counterpropagating modes critically depends on the position of the atom. Now, the cavity fields are expected to exert light forces on the atoms eventually leading to their displacement. As we will see in the following, this fact can have enormous impact on the coupling dynamics and even induce macroscopic instabilities.

We devote Sec. 42.1 to the derivation of the complete equations of motion for the case of a single atom, allowing for all degrees of freedom to be treated as quantized: the atomic excitation, the motion of its center of mass, and the radiation field in the cavity. We will provide a simple recipe for finding the suitable equations of motion depending on which degree of freedom s to be treated as quantized and which dissipation process to be taken into account. We will also show how and under which circumstances the atomic excitation may be adiabatically eliminated.

In Sec. 42.2 we generalize the equations of motion of many atoms, but treating all degrees of freedom as classical. This leads us to the paradigmatic Collective Atomic Recoil Laser (CARL), a self-organization phenomenon whose relationship to other such instabilities will be discussed in Sec. 42.3.

Finally, in Secs. 42.4 and 42.5 we will treat the light field, respectively, the atomic motion quantum mechanically and show in which sense the obtained dynamics are different.

42.1 Cavity interacting with a single atom

Here, we consider atoms interacting with the modes of an optical cavity pumped by lasers. As we saw in the previous chapter, the density of the modes in a cavity is concentrated around the optical axis, such that a scatterer located within the mode emits preferentially within the cavity, where the light is recycled. Therefore, we can in many situations treat the system as one-dimensional.

In free space, as discussed in Chp. 38, the force of light has two components: the radiation pressure, which scatters photons isotropically into space, and the dipole

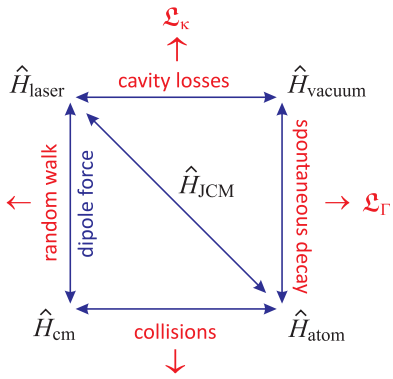

Figure 42.1: Hamiltonian in quantum optics.

force, which can be interpreted in terms of a redistribution of photons between light modes. In cavities, where the isotropic scattering is much reduced, radiative pressure can often be neglected. In contrast, if light is tuned away from atomic resonances, the atom will feel a dipole force originating from the backscattering of photons between counterpropagating modes.

42.1.1 Linear and ring cavities

We must distinguish two types of cavities with very different behaviors: The linear cavity or (*Fabry-Pérot etalon*), where counterpropagating modes form a single mode, and the ring cavity, where counterpropagating modes have independent photon budgets.

For a *linear cavity*, boundary conditions imposed by the surfaces of the cavity mirrors determine the possible spatial mode functions, which are necessarily standing waves. The amplitudes of the electric field are in second quantization (35.8),

$$\hat{\mathcal{E}}(z,t) = \hat{\mathcal{E}}^+(z,t)e^{-\imath\omega t} + \hat{\mathcal{E}}^-(z,t)e^{\imath\omega t} \qquad (42.1)$$
$$\text{with} \quad \hat{\mathcal{E}}^+(z,t) = \hat{\mathcal{E}}_1\hat{a}(t)e^{\imath kz} = (\hat{\mathcal{E}}^-(z,t))^\dagger \ .$$

with $[\hat{a},\hat{a}^\dagger] = 1$. With this we obtain, for a single atom coupled to the mode of the cavity pumped by a laser, within the dipolar approximation and the RWA [1], the following relevant contributions to the Hamiltonian ($\hbar = 1$),

$$\begin{aligned} \hat{H}_{atom} &= -\Delta_a\hat{\sigma}^+\hat{\sigma}^- + \tfrac{\hat{p}^2}{2m} \qquad (42.2)\\ \hat{H}_{cav} &= -\Delta_c\hat{a}^\dagger\hat{a} \\ \hat{H}_{atom:cav} &= g\hat{a}^\dagger\hat{\sigma}^- e^{-\imath k\hat{z}} + h.c. \\ \hat{H}_{laser:cav} &= \imath\eta\hat{a}^\dagger + h.c. \ , \end{aligned}$$

neglecting the dynamics of the pump field, which is supposed to be classical, $\eta = \delta_{fsr}\langle\hat{a}_{in}^\dagger\rangle$. Note that the propagator $e^{-\imath\hat{H}_{laser:cav}t}$ corresponds to a coherent state

[1] For the transformation into the rotating frame see the derivation of Sec. 34.4.2.

displacement operator. Δ_a is the detuning between the light and the atomic resonance, Δ_c between the light and cavity resonance and g is the light-atom coupling force, also called the single-photon Rabi frequency. Neglecting the kinetic energy term $\hat{p}^2/2m$, the photonic recoil $e^{-\imath k v \hat{z}}$, and the pumping η we recover the *Jaynes-Cummings model*. Do the Excs. 42.1.7.1 and 42.1.7.2.

For a *ring cavity*, we must distinguish the counterpropagating modes $\hat{a}_\pm$,

$$\hat{\mathcal{E}}^+(z,t) = \hat{\mathcal{E}}_1 \hat{a}_+(t) e^{\imath k z} + \hat{\mathcal{E}}_1 \hat{a}_-(t) e^{-\imath k z} = (\hat{\mathcal{E}}^-(z,t))^\dagger \ . \tag{42.3}$$

such that the total Hamiltonian $\hat{H}$ consists of the following parts [2],

$$\boxed{\begin{aligned} \hat{H}_{atom} &= \hat{H}_{electron} + \hat{H}_{motion} = -\Delta_a \hat{\sigma}^+ \hat{\sigma}^- + \frac{\hat{p}^2}{2m} \\ \hat{H}_{cav} &= -\Delta_c \hat{a}_+^\dagger \hat{a}_+ - \Delta_c \hat{a}_-^\dagger \hat{a}_- \\ \hat{H}_{atom:cav} &= g \hat{a}_+^\dagger \hat{\sigma}^- e^{-\imath k \hat{z}} + h.c. + g \hat{a}_-^\dagger \hat{\sigma}^- e^{\imath k \hat{z}} + h.c. \\ \hat{H}_{laser:cav} &= -\imath \eta_+ (\hat{a}_+ - \hat{a}_+^\dagger) - \imath \eta_- (\hat{a}_- - \hat{a}_-^\dagger) \end{aligned}} \ . \tag{42.4}$$

We identify the degrees of freedom of the system through the quantum observables appearing in the Hamiltonian: the counterpropagating modes of light with the amplitudes ($\hat{a}_\pm$), the internal degrees of freedom ($\hat{\sigma}^z, \hat{\sigma}^\pm$), and the spatial coordinates of the atom ($\hat{z}, \hat{p}$).

In contrast to linear cavities, ring cavities have the following particularities: 1. The phase of the standing wave is free to move; 2. the counterpropagating modes of the cavity have independent photon budgets, each backscattering event conserves momentum; 3. the backscattering acts on the phase of the standing wave. Atoms can be trapped by the dipole force within the cavity mode volume. The dipole force corresponds to a backscattering of photons between modes.

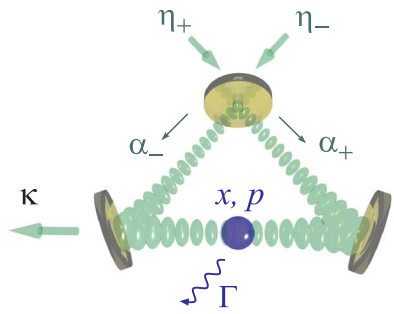

Figure 42.2: Scheme of an atom interacting with a ring cavity showing the relevant degrees of freedom ($\hat{x}$, $\hat{p}$, $\hat{a}_\pm$) and the possible decay processes (κ, Γ) for the derivation of the field equations.

[2] Throughout this chapter we will sometimes emphasize the motional degree of freedom in green color, photonic states in blue, electronic excitation states in pink.

42.1.2 Eliminating spontaneous emission and cavity decay

In fact, there are more degrees of freedom involved in the dynamics of atoms moving in a laser-pumped ring cavity, because of the atoms may scatter light into directions other than the cavity modes by spontaneous emission, and the cavity modes may decay by transmission through the mirrors. Therefore, we need to treat the respective vacuum field modes receiving the photons, $\hat{a}_{\mathbf{k}}$ and $\hat{a}_{\omega}$, quantum mechanically and include the respective Hamiltonians,

$$\begin{aligned} \hat{H}_{atom:vacuum} &= \sum_{\mathbf{k}} g_{atom:vacuum} \hat{a}^{\dagger}_{\mathbf{k}} \hat{\sigma}^{-} e^{-\imath \mathbf{k}\cdot\hat{\mathbf{r}}} + h.c. \\ \hat{H}_{cav:bath} &= \sum_{\omega} g_{cav:bath} \hat{a}^{\dagger}_{\omega} \hat{a}_{+} + g_{cav:bath} \hat{a}^{\dagger}_{\omega} \hat{a}_{-} + h.c. \ , \end{aligned} \tag{42.5}$$

in the description of the coupled dynamics. Here, $g_{atom:vacuum}$ denotes the vacuum Rabi frequency, that is, the coupling strength between the atomic dipole and the electromagnetic vacuum into which spontaneously emitted photons may escape. On the other hand, $g_{cav:bath}$ denotes the coupling strength between the cavity mode and the spectrum of electromagnetic modes into which cavity photons can escape and which we will from now on call *heat bath* to facilitate its semantic distinction from the spontaneous vacuum. The total density operator, the Hamiltonian and the equation of motion are, consequently,

$$\begin{aligned} \bar{\rho} &= \hat{\rho}_{atom} \otimes \hat{\rho}_{electron} \otimes \hat{\rho}_{cav} \otimes \hat{\rho}_{vacuum} \otimes \hat{\rho}_{bath} \\ \bar{H} &= \hat{H}_{motion} + \hat{H}_{electron} + \hat{H}_{cav} + \hat{H}_{atom:cav} + \hat{H}_{laser:cav} + \hat{H}_{atom:vacuum} + \hat{H}_{cav:bath} \\ \dot{\bar{\rho}} &= -\imath[\bar{H}, \bar{\rho}] \ . \end{aligned} \tag{42.6}$$

With the inclusion of the vacuum field modes $\hat{a}_{\omega}$ and $\hat{a}_{\mathbf{k}}$ the number of degrees of freedom to be treated literally explodes, and we have to find a way to eliminate them from the equation of motion. We do this by partially tracing the density operator over the vacuum field modes using the Weisskopf-Wigner theory,

$$\tilde{\rho} \equiv \mathrm{Tr}_{vacuum} \ \mathrm{Tr}_{bath} \ \bar{\rho} = \hat{\rho}_{atom} \otimes \hat{\rho}_{electron} \otimes \hat{\rho}_{cav} \ . \tag{42.7}$$

This allows us to reduce the Hamiltonian $\hat{H} = \bar{H} - \hat{H}_{atom:vacuum} - \hat{H}_{cav:bath}$. The price to pay is, that the equation of motion for this receives dissipative terms: The Liouville equation turns into a *master equation* with the following form,

$$\boxed{\begin{aligned} \dot{\hat{\rho}} = -\imath[\hat{H}, \hat{\rho}] \quad &+ \quad \mathcal{L}_{atom:vacuum} + \mathcal{L}_{cav:vacuum,+} + \mathcal{L}_{cav:vacuum,-} \\ \mathcal{L}_{atom:vacuum}\hat{\rho}(t) \quad &= \quad -\gamma\{\hat{\sigma}^{+}\hat{\sigma}^{-}\hat{\rho}(t) - 2\hat{\sigma}^{-}\hat{\rho}(t)\hat{\sigma}^{+} + \hat{\rho}(t)\hat{\sigma}^{+}\hat{\sigma}^{-}\} \\ \mathcal{L}_{cav:bath,\pm}\hat{\rho}(t) \quad &= \quad -\kappa\{\hat{a}^{\dagger}_{\pm}\hat{a}_{\pm}\hat{\rho}(t) - 2\hat{a}_{\pm}\hat{\rho}(t)\hat{a}^{\dagger}_{\pm} + \hat{\rho}(t)\hat{a}^{\dagger}_{\pm}\hat{a}_{\pm}\} \end{aligned}} \ , \tag{42.8}$$

where $\hat{H}$ is the Hamiltonian from (42.4). We see that each degree of freedom has its own loss mechanism. κ for the finite transmission of the resonator mirrors [283, 488] [3], Γ for the spontaneous emission, and γ_{frc}, when we exert a frictional force on the atoms.

[3] Here, we only consider cavity decay into a zero temperature reservoir without quantum phase fluctuations.

42.1.2.1 The problem with spontaneous emission in cavities

The above treatment still is incomplete, if we regard $\hat{\rho}$ as the atomic Bloch vector. The reason is that we know what the dissipative Lindbladt terms $\mathcal{L}_{vacuum}\tilde{\rho}$ generated by spontaneous emission look like for the atomic excitation $\hat{\rho}_{atom}$, but the Hamiltonian $\hat{H}_{atom:vacuum}$ also *contains the motional degree of freedom* $e^{-\imath\mathbf{k}\cdot\hat{\mathbf{r}}}$, which is intrinsically three-dimensional. That is, the dissipative terms also need to describe, how the motion diffuses in momentum space.

The inclusion of dissipative terms, however, is difficult, because unavoidable photonic recoil violates the supposed one-dimensionality of the atomic motion along the optical axis. Omnidirectional photonic recoil is also incompatible with the assumption that the momentum is quantized in multiples of $2\hbar k$ in the direction of the optical axis. And finally, if we consider degenerate matter waves, photonic recoil will eject atoms from a BEC. Even if, neglecting the emission process, we only consider absorption, we would need a quantization in multiples of $1\hbar k$ instead of $2\hbar k$. In the following, in order to keep the problem 1D, we will neglect momentum diffusion, i.e. we consider the simplified Hamiltonian $\tilde{H}$ and discard motional terms from the term $\mathcal{L}_{vacuum}\hat{\rho}$.

42.1.2.2 Quantum derivation of the CARL equations

To obtain the equations of motion we insert the Hamiltonian (42.4) into the equations for the field operators, for which the following commutation rules hold, $[\hat{a}_\pm, \hat{a}_\pm^\dagger] = 1$ and $[\hat{a}_\pm, \hat{a}_\mp^\dagger] = 0 = [\hat{a}_\pm, \hat{a}_\pm]$,

$$\begin{aligned}\dot{\hat{a}}_+ &= \imath[\hat{H}, \hat{a}_+] - \kappa\hat{a}_+ \\ &= -\imath\Delta_c[\hat{a}_+^\dagger\hat{a}_+, \hat{a}_+] + \imath g e^{-\imath k\hat{z}}\hat{\sigma}^-[\hat{a}_+^\dagger, \hat{a}_+] + \imath g e^{\imath k\hat{z}}\hat{\sigma}^+[\hat{a}_+, \hat{a}_+] + \eta_+[\hat{a}_+ - \hat{a}_+^\dagger, \hat{a}_+] - \kappa\hat{a}_+ \\ &= (-\kappa + \imath\Delta_c)\hat{a}_+ - \imath g\hat{\sigma}^- e^{-\imath kx} + \eta_+ \ ,\end{aligned} \tag{42.9}$$

and similarly for $\hat{a}_-$. For the Pauli deexcitation matrix, using the usual commutation rules for the *Pauli spin matrices* (23.47), that is $[\hat{\sigma}^+, \hat{\sigma}^-] = \hat{\sigma}_z$, $\hat{\sigma}_z\hat{\sigma}^\pm = \pm\hat{\sigma}^\pm$, and $[\hat{\sigma}^-, \hat{\sigma}^-] = 0$, we calculate,

$$\begin{aligned}\dot{\hat{\sigma}}^- &= \imath[\hat{H}, \hat{\sigma}^-] - \gamma\hat{\sigma}^- \\ &= -\imath\Delta_a[\hat{\sigma}^+\hat{\sigma}^-, \hat{\sigma}^-] + \imath g e^{\imath k\hat{z}}\hat{a}_+[\hat{\sigma}^+, \sigma^-] + \imath g e^{-\imath k\hat{z}}\hat{a}_-[\hat{\sigma}^+, \sigma^-] - \gamma\hat{\sigma}^- \\ &= (-\gamma + \imath\Delta_a)\hat{\sigma}^- + \imath g e^{\imath k\hat{z}}\hat{a}_+\hat{\sigma}_z + \imath g e^{-\imath k\hat{z}}\hat{a}_-\hat{\sigma}_z \ .\end{aligned} \tag{42.10}$$

For the Pauli inversion matrix, using the following commutation rules, $[\hat{\sigma}_z, \hat{\sigma}^+\hat{\sigma}^+] = 0$ and $[\hat{\sigma}_z, \hat{\sigma}^\pm] = \pm 2\hat{\sigma}^\pm$, we calculate,

$$\begin{aligned}\dot{\hat{\sigma}}_z &= \imath[\hat{H}, \hat{\sigma}_z] - 2\gamma - 2\gamma\hat{\sigma}_z \\ &= \imath g e^{-\imath k\hat{z}}\hat{a}_+^\dagger[\hat{\sigma}^-, \hat{\sigma}_z] + \imath g e^{\imath k\hat{z}}\hat{a}_-^\dagger[\hat{\sigma}^-, \hat{\sigma}_z] + \imath g e^{\imath k\hat{z}}\hat{a}_+[\hat{\sigma}^+, \hat{\sigma}_z] + \imath g e^{-\imath k\hat{z}}\hat{a}_-[\hat{\sigma}^+, \hat{\sigma}_z] - 2\gamma\hat{\sigma}_z \\ &= -2\gamma - 2\gamma\hat{\sigma}_z + 2\imath g e^{-\imath k\hat{z}}\hat{a}_+^\dagger\hat{\sigma}^- + 2\imath g e^{\imath k\hat{z}}\hat{a}_-^\dagger\hat{\sigma}^- - 2\imath g e^{\imath k\hat{z}}\hat{a}_+\hat{\sigma}^+ - 2\imath g e^{-\imath k\hat{z}}\hat{a}_-\hat{\sigma}^+ \ .\end{aligned} \tag{42.11}$$

Finally, we need to derive the equations governing the motion of atoms. For the position we obtain,

$$\dot{\hat{z}} = \imath[\hat{H}, \hat{z}] = \imath[\tfrac{\hat{p}^2}{2m}, \hat{z}] = \tfrac{1}{m}\hat{p} \ . \tag{42.12}$$

In order to calculate the momentum, we need to do a small auxiliary calculation. With the commutator $[\hat{z},\hat{p}] = \imath$ we derive,

$$[\hat{z}^n,\hat{p}] = \imath\frac{\delta\hat{z}^n}{\delta\hat{z}} = \imath n\hat{z}^{n-1} \tag{42.13}$$
$$[e^{\imath k\hat{z}},\hat{p}] = \sum_{n=0}^{\infty}\frac{(\imath k)^n}{n!}[\hat{z}^n,\hat{p}] = -k\sum_{n=0}^{\infty}\frac{(\imath k)^{n-1}}{(n-1)!}\hat{z}^{n-1} = -ke^{\imath k\hat{z}} \ ,$$

and with this result,

$$\begin{aligned}\dot{\hat{p}} &= \imath[\hat{H},\hat{p}] \\ &= \imath g\hat{a}_+^\dagger\hat{\sigma}^-[e^{-\imath k\hat{z}},\hat{p}] + c.c. + \imath g\hat{a}_-^\dagger\hat{\sigma}^-[e^{\imath k\hat{z}},\hat{p}] + c.c. \\ &= -\imath gk\hat{a}_+^\dagger\hat{\sigma}^-e^{-\imath k\hat{z}} + c.c. + \imath gk\hat{a}_-^\dagger\hat{\sigma}^-e^{\imath k\hat{z}} + c.c. \ .\end{aligned} \tag{42.14}$$

The *quantum Langevin equations* [283] describing the dynamics of the internal and external degrees of freedom of the atom and the field are coupled,

$$\boxed{\begin{aligned}\dot{\hat{a}}_\pm &= (-\kappa+\imath\Delta_c)\hat{a}_\pm - \imath g\hat{\sigma}^-e^{\mp\imath k\hat{z}} + \eta_\pm \\ \dot{\hat{\sigma}}^- &= (-\gamma+\imath\Delta_a)\hat{\sigma}^- + \imath g(e^{\imath k\hat{z}}\hat{a}_+ + e^{-\imath kz}\hat{a}_-)\hat{\sigma}_z \\ \dot{\hat{\sigma}}_z &= -2\gamma\hat{\sigma}_z + 2\imath g(e^{-\imath k\hat{z}}\hat{a}_+^\dagger + e^{\imath k\hat{z}}\hat{a}_-^\dagger)\hat{\sigma}^- - 2\imath g(e^{\imath k\hat{z}}\hat{a}_+ + e^{-\imath k\hat{z}}\hat{a}_-)\hat{\sigma}^+ \\ \dot{\hat{z}} &= \hat{p}/m \\ \dot{\hat{p}} &= \imath g\hbar k\hat{\sigma}^-(\hat{a}_+^\dagger e^{-\imath k\hat{z}} - \hat{a}_-^\dagger e^{\imath k\hat{z}}) + c.c.\end{aligned}} \ . \tag{42.15}$$

We may also verify,

$$\begin{aligned}\dot{\hat{n}}_+ &= \imath[\hat{H},\hat{n}_+] \\ &= \imath[-\Delta_c\hat{a}_+^\dagger\hat{a}_+ + g\hat{a}_+^\dagger\hat{\sigma}^-e^{-\imath k\hat{z}} + g\hat{a}_+\hat{\sigma}^+e^{\imath k\hat{z}} - \imath\eta_+(\hat{a}_+ - \hat{a}_+^\dagger),\hat{a}_+^\dagger\hat{a}_+] \\ &= (\eta_+ - \imath ge^{-\imath k\hat{z}}\hat{\sigma}^-)\hat{a}_+^\dagger + (\eta_+ + \imath g\hat{\sigma}^+e^{\imath k\hat{z}})\hat{a}_+ \ ,\end{aligned} \tag{42.16}$$

and hence conservation of momentum,

$$[\hat{H},\hbar k(\hat{n}_+ - \hat{n}_-) - \hat{p}] = \hbar k\eta_+(\hat{a}_+^\dagger + \hat{a}_+) - \hbar k\eta_-(\hat{a}_-^\dagger + \hat{a}_-) \ , \tag{42.17}$$

in the absence of pumping, $\eta_+ = 0 = \eta_-$.

42.1.3 Adiabatic elimination of the excited state

Under certain conditions, however, the internal and external dynamics occur at very different time scales, which allows a decoupling of the differential equations [4]. When the light fields are very detuned from atomic resonances, $\Delta_a \gg \Gamma$, the internal dynamics of the atoms is very fast, that is, the internal state adapts very rapidly to the boundary conditions defined by the external state and the state of the light field.

[4] In good cavity the limit the degrees of freedom of atomic excitation $\hat{\sigma}^\pm$ drop out of the dynamics, in the bad cavity limit, the fields $\hat{a}^\pm$ drop out of the dynamics.

Therefore, the internal state has no separate dynamics of its own, and we can adiabatically eliminate the internal degrees of freedom. Thus, we can neglect correlations between degrees of freedom, $\langle \hat{a}_\pm \hat{\sigma}^\pm \rangle = \langle \hat{a}_\pm \rangle \langle \hat{\sigma}^\pm \rangle$ etc. [1016, 481]. The adiabatic elimination of the excited state comes down to treating the atom as a classical antenna.

We obtain the stationary solutions for $t \to \infty$ in the same way as for the optical Bloch equations [see Eq. (34.188)], assuming in Eq. (42.15),

$$\dot{\hat{\sigma}}^- = 0 = \dot{\hat{\sigma}}_z \tag{42.18}$$

where $\langle \hat{\sigma}^- \rangle = \rho_{21}$. Introducing the position-dependent Rabi frequency of the atom in the standing wave [5],

$$\hat{\Omega}(z) = 2g(e^{\imath k\hat{z}}\hat{a}_+ + e^{-\imath k\hat{z}}\hat{a}_-) \ , \tag{42.19}$$

we write,

$$\begin{aligned} 0 &= (-\gamma + \imath\Delta_a)\hat{\sigma}^- + \tfrac{1}{2}\imath\hat{\Omega}\hat{\sigma}_z \\ 0 &= -2\gamma - 2\gamma\hat{\sigma}_z + \imath\hat{\Omega}^\dagger\hat{\sigma}^- - \imath\hat{\Omega}\hat{\sigma}^+ \ . \end{aligned} \tag{42.20}$$

These equations are solved by,

$$\begin{aligned} \hat{\sigma}_z(\infty) &= \frac{-2(\gamma^2 + \Delta_a^2)}{2(\gamma^2 + \Delta_a^2) + \hat{\Omega}^\dagger\hat{\Omega}} \\ \text{and} \quad \hat{\sigma}^-(\infty) &= \frac{-\imath(\gamma + \imath\Delta_a)\hat{\Omega}}{2(\gamma^2 + \Delta_a^2) + \hat{\Omega}^\dagger\hat{\Omega}} \simeq \frac{-\imath(\gamma + \imath\Delta_a)}{2\Delta_a^2}\hat{\Omega} \ . \end{aligned} \tag{42.21}$$

Inserting the approximated expression for $\hat{\sigma}^-(\infty)$ into the equation of motion (42.15) for the light modes,

$$\begin{aligned} \dot{\hat{a}}_\pm &= (-\kappa + \imath\Delta_c)\hat{a}_\pm - \imath g\hat{\sigma}^-(\infty)e^{\mp\imath k\hat{z}} + \eta_\pm \\ &= \left(-\kappa + \imath\Delta_c - \frac{g^2\gamma}{\Delta_a^2} - \frac{\imath g^2}{\Delta_a}\right)\hat{a}_\pm - \left(\frac{g^2\gamma}{\Delta_a^2} + \frac{\imath g^2}{\Delta_a}\right)e^{\mp 2\imath k\hat{z}}\hat{a}_\mp + \eta_\pm \ , \end{aligned} \tag{42.22}$$

and for the atomic momentum,

$$\begin{aligned} \dot{\hat{p}} &= \imath g\hbar k\hat{\sigma}^-(\infty)(\hat{a}_+^\dagger e^{-\imath k\hat{z}} - \hat{a}_-^\dagger e^{\imath k\hat{z}}) - \imath g\hbar k\hat{\sigma}^+(\infty)(\hat{a}_+ e^{\imath k\hat{z}} - \hat{a}_- e^{-\imath k\hat{z}}) \\ &= \frac{2\hbar k\gamma g^2}{\Delta_a^2}(\hat{a}_+^\dagger\hat{a}_+ - \hat{a}_-^\dagger\hat{a}_-) - \frac{2\imath\hbar k g^2}{\Delta_a}(e^{2\imath k\hat{z}}\hat{a}_+\hat{a}_-^\dagger - e^{-2\imath k\hat{z}}\hat{a}_+^\dagger\hat{a}_-) \ . \end{aligned} \tag{42.23}$$

Defining the light-shift U_0 caused by only one photon and the scattering rate γ_0 by,

$$U_0 \equiv \frac{g^2}{\Delta_a} \qquad \text{and} \qquad \gamma_0 \equiv \frac{\Gamma g^2}{\Delta_a^2} \ , \tag{42.24}$$

with $\Gamma = 2\gamma$, we finally get a set of equations, where the internal degree of freedom of the atom has been eliminated,

$$\boxed{\begin{aligned} \dot{\hat{a}}_\pm &= (-\kappa - \gamma_0 + \imath\Delta_c - \imath U_0)\hat{a}_\pm - (\gamma_0 + \imath U_0)e^{\mp 2\imath k\hat{z}}\hat{a}_\mp + \eta_\pm \\ \dot{\hat{p}} &= 2\hbar k\gamma_0(\hat{a}_+^\dagger\hat{a}_+ - \hat{a}_-^\dagger\hat{a}_-) + 2\imath\hbar k U_0(e^{-2\imath k\hat{z}}\hat{a}_+^\dagger\hat{a}_- - e^{2\imath k\hat{z}}\hat{a}_+\hat{a}_-^\dagger) \end{aligned}} \ . \tag{42.25}$$

[5] Note that the factor of 2 ensure consistency with previous definitions of the Rabi frequency, such as in (35.111). Note also, that $[\hat{\Omega}, \hat{\Omega}^\dagger] = 8g^2 \neq 0$, but this is negligible when the fields are large enough to be considered as classical. On the other hand the quadratic terms $\Omega^\dagger\Omega$ are negligible when they are small compared to γ^2 or Δ_a^2.

42.1.3.1 Radiation pressure and the adiabatically approximated Hamiltonian

The impact of radiation pressure should be considered when the pumping laser is close to a resonance. Then $\gamma_0 \ll U_0$ is no longer satisfied [481], and we get one more term from the equation for the atomic force: $\propto \hbar\gamma_0(|\alpha_+|^2 - |\alpha_-|^2)$.

For the adiabatically approximated Hamiltonian we get immediately from (42.4) [870],

$$\boxed{\begin{aligned}\hat{H} = \frac{\hat{p}^2}{2m} &+ \sum_{\pm}(U_0 - \Delta_c)\hat{a}_\pm^\dagger\hat{a}_\pm \\ &+ U_0(e^{-2\imath k\hat{z}}\hat{a}_+^\dagger\hat{a}_- + e^{2\imath k\hat{z}}\hat{a}_+\hat{a}_-^\dagger) - \imath\sum_{\pm}\eta_\pm(\hat{a}_\pm - \hat{a}_\pm^\dagger)\end{aligned}} \quad , \tag{42.26}$$

as shown in Exc. 42.1.7.3. Note that dissipative terms are (naturally) absent from this Hamiltonian, so that it shall not be used for the description of radiation pressure. On the other hand, all coherent terms of the equations of motion can be derived from this Hamiltonian (42.26), and we can verify momentum conservation (42.17) and deduce transformation properties. Solve the Exc. 42.1.7.4.

These equations, which we will call CARL equations for reasons that we will become clear in Sec. 42.2, describe the coupled dynamics of atoms being accelerated by the *kick* $e^{\imath k\hat{z}}$ imparted by the photonic recoil received upon scattering a photon from one mode into the counterpropagating one. In the same time, the backscattering *annihilates* a photon $\hat{a}_\pm$ in one mode and *creates* a photon $\hat{a}_\mp^\dagger$ in the counterpropagating mode. From now on we will exclusively use the CARL equations.

Finally, let us summarize, how the operators act on states and observables of the coupled system, noting that the same transformation rules as for free and trapped atoms (??) also hold for the optical lattice,

$$\boxed{\begin{array}{rclcrcl} e^{\imath k\hat{z}}|z\rangle &=& |z\rangle & , & e^{-\imath k\hat{z}}\hat{z}e^{\imath k\hat{z}} &=& \hat{z} \\ e^{\imath k\hat{z}}|p\rangle &=& |p+\hbar k\rangle & , & e^{-\imath k\hat{z}}\hat{p}e^{\imath k\hat{z}} &=& \hat{p}+\hbar k \\ \hat{a}_\pm|n\rangle &=& \sqrt{n}|n-1\rangle & , & e^{-\imath k\hat{z}}\hat{H}(\hat{z},\hat{p})e^{\imath k\hat{z}} &=& \hat{H}(\hat{z},\hat{p}-\hbar k) \\ \hat{a}_\pm^\dagger|n\rangle &=& \sqrt{n+1}|n+1\rangle & , & e^{\imath a\hat{p}/\hbar}\hat{H}(\hat{z},\hat{p})e^{-\imath a\hat{p}/\hbar} &=& \hat{H}(\hat{z}-a,\hat{p}) \end{array}} \quad . \tag{42.27}$$

For $ka = \pi$ the phase shift vanishes: $[e^{\imath\pi\hat{p}/\hbar k}, \hat{H}(\hat{z},\hat{p})] = 0$.

The dynamics is given by the time evolutions,

$$e^{-(\imath/\hbar)\hat{H}t}\hat{z}(0)e^{(\imath/\hbar)\hat{H}t} \quad , \quad e^{-(\imath/\hbar)\hat{H}t}\hat{p}(0)e^{(\imath/\hbar)\hat{H}t} \quad , \quad e^{-(\imath/\hbar)\hat{H}t}\hat{n}(0)e^{(\imath/\hbar)\hat{H}t} \; . \tag{42.28}$$

In Exc. 42.1.7.5 we calculate the photon number superposition state resulting from a kick $e^{\imath k_{kck}\hat{z}}$.

42.1.4 Adiabatic elimination of the cavity modes

We have seen in Sec. 42.1.3 how to eliminate the internal atomic degrees of freedom, once the condition $|\Delta_a| \gg \Gamma$ is satisfied. We may try an analogous treatment accounting for the limit $|\Delta_c| \gg \kappa$. In this case, the cavity fields evolve on a fast time

scale, adiabatically following the evolution of the other degrees of freedom. Hence, we set,

$$\dot{\hat{a}}_\pm = 0 \ , \tag{42.29}$$

and obtain from the first Heisenberg equation (42.15),

$$\hat{a}_\pm(\infty) = \frac{\imath g \hat{\sigma}^- e^{\mp \imath k \hat{z}} - \eta_\pm}{-\kappa + \imath \Delta_c} \ . \tag{42.30}$$

Defining,

$$U_c \equiv \frac{g^2 \Delta_c}{\kappa^2 + \Delta_c^2} \qquad \text{and} \qquad \kappa_c \equiv \frac{g^2 \kappa}{\kappa^2 + \Delta_c^2} \ , \tag{42.31}$$

we can write the position-dependent Rabi frequency (42.19) as,

$$\begin{aligned} \Omega(z) = 2g(e^{\imath k \hat{z}} \hat{a}_+ + e^{-\imath k \hat{z}} \hat{a}_-) \quad &= 2(\kappa_c + \imath U_c) \left(\frac{\eta_+ e^{\imath k \hat{z}} + \eta_- e^{-\imath k \hat{z}}}{g} - 2\imath \hat{\sigma}^- \right) \\ &\overset{\eta_\pm = 0}{\longrightarrow} -4\imath(\kappa_c + \imath U_c)\hat{\sigma}^- \ , \end{aligned} \tag{42.32}$$

in the limit of no pumping $\eta_\pm = 0$. Inserting this into the other Heisenberg equations (42.15), we immediately get,

$$\dot{\hat{\sigma}}^- = (-\gamma + \imath \Delta_a)\hat{\sigma}^- + \tfrac{\imath}{2}\Omega(z)\hat{\sigma}_z \overset{\eta_\pm = 0}{\longrightarrow} (-\gamma + \imath \Delta_a)\hat{\sigma}^- + 2(\kappa_c + \imath U_c)\hat{\sigma}^- \hat{\sigma}_z \ , \tag{42.33}$$

and

$$\dot{\hat{\sigma}}_z = -2\gamma \hat{\sigma}_z + \imath \Omega^\dagger(z)\hat{\sigma}^- - \imath \hat{\sigma}^+ \Omega(z) \overset{\eta_\pm = 0}{\longrightarrow} -2\gamma \hat{\sigma}_z - 4\kappa_c \hat{\mathbb{I}} \ , \tag{42.34}$$

as well as, $\dot{\hat{z}} = \hat{p}/m$ and

$$\dot{\hat{p}} = \imath g \hbar k \hat{\sigma}^- (e^{-\imath k \hat{z}} \hat{a}_+^\dagger - e^{\imath k \hat{z}} \hat{a}_-^\dagger) - \imath g \hbar k \hat{\sigma}^+ (e^{\imath k \hat{z}} \hat{a}_+ - e^{-\imath k \hat{z}} \hat{a}_-) \overset{\eta_\pm = 0}{\longrightarrow} 0 \ . \tag{42.35}$$

That is, in summary,

$$\boxed{\begin{array}{rcl} \dot{\hat{\sigma}}^- & = & (-\gamma - 2\kappa_c + \imath \Delta_a - 2\imath U_c)\hat{\sigma}^- \\ \dot{\hat{\sigma}}_z & = & -2\gamma \hat{\sigma}_z - 4\kappa_c \hat{\mathbb{I}} \\ \dot{\hat{p}} & = & 0 \end{array}} \ . \tag{42.36}$$

Alternatively, the coherent part of these equations can be derived by insert $\hat{a}_\pm(\infty)$ directly in the Hamiltonian (42.4). This will be done in Exc. 42.1.7.6. The equations (42.36) tell us that, in the absence of cavity decay and spontaneous emission, the atomic population will not undergo nutation, but the dipole moment will rotate with a velocity which depends on the inversion. The dynamics becomes interesting in the presence of several atoms, as studied in 41.3.3.

42.1.5 General rules for deriving equations of motion

We have, in the previous sections, derived Heisenberg equations (42.15), respectively (42.25) which, together with the Schrödinger equation for the system's state $|\psi(t)\rangle$

or the master equation for the density operator $\hat{\rho}(t)$ form an *over-complete* set. This section aims at providing a general recipe for choosing the right set of equations depending on two basic criteria for the nature of the degrees of freedom involved in the dynamics: (i) Do judge it necessary to treat the degree of freedom as quantum or may a classical description be sufficient; and (ii) Is the degree of freedom subject to dissipation (e.g. spontaneous emission of the electronic excitation, cavity decay of the field mode, or collisions messing up the center-of-mass motion), or not. The procedure, which will be applied throughout the remaining part of this chapter, leads to very different descriptions of the system depending on the specific parameter regime.

1. The procedure is generally applicable to coupled systems: We first need to *identify all relevant degrees of freedom and set up the Hamiltonian*, possibly eliminating irrelevant degrees of freedom, e.g. via adiabatic elimination or by tracing over them, if they contribute to dissipation. In the context of atoms coupled to a ring cavity, we assume our system to be in some state [6],

$$|\psi(t)\rangle = |\mathbf{r}\rangle \otimes |\alpha_+\rangle \otimes |\alpha_-\rangle \otimes |i\rangle \ , \tag{42.37}$$

   coupling the atomic motion, the light fields and the electronic excitation, although the electronic excitation $|i\rangle$ is often eliminated adiabatically. The dissipative degrees of freedom related to vacuum modes leading to spontaneous emission and cavity decay, as well as collisions between moving atoms are traced away, but may be considered in the master equation for the density operator and in the Heisenberg equations, where the corresponding decay rates are added phenomenologically.

   This first item has already been solved in the previous sections and led us to the Hamiltonian (42.4) and the corresponding Heisenberg equations (42.15), or the adiabatically approximated Hamiltonian (42.26) and the corresponding Heisenberg equations (42.25).

2. Now, we must decide which degrees of freedom B can be treated as *classical*. Typically, those are highly excited degrees of freedom (e.g. fast velocities of many photons in a mode). The corresponding operators can be substituted by their expectation value. Purely classical energy terms in the Hamiltonian can be ignored and removed. For the degrees of freedom $\hat{A}$ we want to treat as *quantum*, we chose an appropriate common basis, which can be discrete $\{|m\rangle\}$ where m is a complete set of quantum numbers. It can also be continuous $\{|\mathbf{r}\rangle\}$ or a combination of both $\{|\mathbf{r}, m\rangle\}$. Now, we need to expand all operators on the chosen basis.

3. For the quantized degrees of freedom must now decide, whether they all evolve coherently or whether they are subject to dissipation. In the first case, perform steps A4 to A7, in the second case, perform steps B4 to B7.

[6] Throughout this chapter we will denote momentum states by the Greek letters $|\mu\rangle$ or $\nu\rangle$. Photonic states will be labeled by the Latin letters $|n\rangle$ or $|m\rangle$. Electronic excitation states will be labeled by the Latin letters $|i\rangle$ or $|j\rangle$. Finally, expansion coefficients c_{ν,i,n_+,n_-} of the state or of the density matrix elements will sometimes be emphasized in red.

A4. In the case of coherent dynamics, we *expand the state* of the system $|\psi(t)\rangle$ on the whole basis. For example, expanded on a partially continuous basis, the coupled atom-ring cavity state may read,

$$|\psi(t)\rangle = \sum_{n_+,n_-,i} \int d^3r \; c_{n_+,n_-,i}(\mathbf{r},t)|\mathbf{r}\rangle \otimes |n_+\rangle \otimes |n_-\rangle \otimes |i\rangle \; , \tag{42.38}$$

where $\langle \mathbf{r}, \alpha_+, \alpha_-, i|\psi(t)\rangle = c_{n_+,n_-,i}(\mathbf{r},t)$ are the expansion coefficients depending on photon numbers $n_\pm$ in the counterpropagating light modes, the electronic excitation state i, and the atomic position $\mathbf{r}$ treated in terms of a continuous wavefunction in space [7]. When we want to treat the atomic motion as being quantized in discrete momentum states labeled by some integer number μ, we adopt the notation,

$$|\psi(t)\rangle = \sum_{\nu,n_+,n_-,i} c_{\nu,n_+,n_-,i}(t)|\nu\rangle \otimes |n_+\rangle \otimes |n_-\rangle \otimes |i\rangle \; , \tag{42.39}$$

where $\langle \nu, \alpha_+, \alpha_-, i|\psi(t)\rangle = c_{\nu,n_+,n_-,i}(t)$ are the new expansion coefficients.

A5. Next, we write down the *Schrödinger equation* for the state $|\psi(t)\rangle$, insert the expansion on the basis, and we derive a linear set of equation of motion for the expansion coefficients $\dot{c}_{\{m\}}(\mathbf{r})$. This set governs the dynamics of the quantum degrees of freedom.

A6. The dynamics of the classical degrees of freedom B is obtained by taking the expectation values of the *Heisenberg equations*. Here, we need to take care that the quantum degrees of freedom appearing in the Heisenberg equations are expressed by their expansions.

A7. The coupled set of equations for the expectation values of projectors of the system into a particular state, that is, $\dot{c}_{\{m\}}$ (respectively, $\dot{c}_{\{m\}}(\mathbf{r})$), and of observables B really represents all we need to describe the system dynamics and to simulate it numerically. Hack everything into your PC, pronto!

B4. In the case of dissipative dynamics, derive the master equation obeying commutation rules for all quantized degrees of freedom including the Lindbladt terms and expand every quantized degrees of freedom on the common basis, we do the same expansions, but,

$$\hat{\rho}(t) = |\psi(t)\rangle\langle\psi(t)| \; . \tag{42.40}$$

B5. Derive the linear set of equation of motion for the matrix elements $\dot{\rho}_{\{m\},\{n\}}$.

B6. Take the expectation values $\mathrm{Tr}\; \hat{\rho}\hat{B}$ of the Heisenberg equations for all degrees of freedom to be handled classical as expanding the quantized degrees of freedom on their basis.

B7. The coupled set of equations for $\dot{\rho}_{\{m\},\{n\}}$ and $\dot{B}$ is sufficient to describe the dynamics of the system, hack everything into your PC, pronto!

[7] Note that, in the absence of other quantum numbers, we rather use to write $c(\mathbf{r}) = \psi(\mathbf{r})$.

Let us apply the procedure to the simplest case that the electronic excitation has been adiabatically eliminated and *all* remaining degrees of freedom can be treated classical. Then we do not require a Hamiltonian, nor the Schrödinger equation. We just take the expectation value of the Heisenberg equations (42.25) for all degrees of freedom which is easy to do, because there is no quantum state to be expanded: we just can replace the operators by c-numbers,

$$\boxed{\begin{aligned} \dot{\alpha}_\pm &= (-\kappa + \imath\Delta_c - \imath U_0)\alpha_\pm - \imath U_0 e^{\mp 2\imath k z}\alpha_\mp + \eta_\pm \\ \dot{p} &= 2\imath\hbar k U_0(e^{-2\imath k z}\alpha_+^\dagger\alpha_- - e^{2\imath k z}\alpha_+\alpha_-^\dagger) \end{aligned}} \,. \tag{42.41}$$

These *totally classical* equations, called CARL equations, will be studied in the subsequent sections, while a thorough discussion of partially quantized equations of motion is postponed to Sec. 42.4.

42.1.5.1 CARL as a beam splitter

Neglecting spontaneous emission, $\gamma_0 = 0$, cavity pumping, $\eta = 0$, cavity decay, $\kappa = 0$, and cavity detuning, $\Delta_c = 0$, the CARL equations in the adiabatic approximation can be derived from the following Hamiltonian,

$$\hat{H} = \frac{\hat{p}^2}{2m} + \sum_\pm U_0\hat{a}_\pm^\dagger\hat{a}_\pm + U_0(e^{-2\imath k\hat{z}}\hat{a}_+^\dagger\hat{a}_- + e^{2\imath k\hat{z}}\hat{a}_+\hat{a}_-^\dagger) \,, \tag{42.42}$$

and read,

$$\begin{aligned} \dot{\hat{a}}_\pm &= -\imath U_0\hat{a}_\pm - \imath U_0 e^{\mp 2\imath k\hat{z}}\hat{a}_\mp \\ \dot{\hat{p}} &= 2\imath\hbar k U_0(e^{-2\imath k\hat{z}}\hat{a}_+^\dagger\hat{a}_- - e^{2\imath k\hat{z}}\hat{a}_+\hat{a}_-^\dagger) \,, \end{aligned} \tag{42.43}$$

or with the substitution $\hat{b}_\pm \equiv \hat{a}_\pm e^{\imath U_0 t}$,

$$\begin{aligned} \dot{\hat{b}}_\pm &= -\imath U_0 e^{\mp 2\imath k\hat{z}}\hat{b}_\mp \\ \ddot{\hat{b}}_\pm &= -U_0^2\hat{b}_\pm - 2k\dot{\hat{z}}U_0 e^{\mp 2\imath k\hat{z}}\hat{b}_\mp \,, \end{aligned} \tag{42.44}$$

we see that, if the motion weren't a dynamic variable, $\dot{\hat{z}} = 0$, the field amplitudes would just perform harmonic oscillations.

On the other hand, with the substitution $\hat{c} \equiv \hat{a}_+ e^{\imath k\hat{z}} + \hat{a}_- e^{-\imath k\hat{z}}$ [8], the complete Hamiltonian rephrased as,

$$\boxed{\hat{H} = \frac{\hat{p}^2}{2m} + U_0\hat{c}^\dagger\hat{c}} \,. \tag{42.45}$$

Here, we see that, if the motion described by $(\hat{z}, \hat{p})$ weren't a dynamic variable, our system would simply be a harmonic oscillator vibrating with the frequency U_0.

[8] Provided we are allowed to commute the operators $\hat{z}$ and $\hat{a}_\pm$.

42.1.5.2 Classical limit of the equations of motion

For atoms much hotter than the recoil limit and macroscopic light intensities we may replace the quantum operators by complex numbers $z \equiv \hat{z}$, $\alpha_\pm \equiv \hat{a}_\pm$ and $\rho_{21} = \hat{\sigma}^-$. The classical equations of motion (42.41) for the coupled system of a single atom confined at the position $r = z$ of the dipolar potential of a ring cavity can be cast into the form,

$$\boxed{\begin{aligned}\begin{pmatrix}\dot{\alpha}_+\\ \dot{\alpha}_-\end{pmatrix} &= \begin{pmatrix}-\kappa-\gamma_0+\imath(\Delta_c-U_0) & -(\gamma_0+\imath U_0)e^{-2\imath kz}\\ -(\gamma_0+\imath U_0)e^{2\imath kz} & -\kappa-\gamma_0+\imath(\Delta_c-U_0)\end{pmatrix}\begin{pmatrix}\alpha_+\\ \alpha_-\end{pmatrix}+\begin{pmatrix}\eta_+\\ \eta_-\end{pmatrix}\\ \dot{p} &= 2\hbar k\gamma_0(\alpha_+\alpha_+^*-\alpha_-\alpha_-^*)+2\imath\hbar kU_0(\alpha_+^*\alpha_-e^{-2\imath kz}-\alpha_+\alpha_-^*e^{2\imath kz})\end{aligned}} \,. \tag{42.46}$$

Recalling that $\alpha_\pm^*\alpha_\pm$ is the number of photons in the respective mode, we can interpret this equation as a rate equation: The number of photons in a mode α_+ changes by photon losses at a rate κ from resonator, or by gain due to backscattering from the counterpropagating mode, or by pumping with an external incident light field at rate η_+.

The equations (42.46) completely describe our coupled atom-cavity system. They are totally classical and work for both, atoms and macroscopic particles.

42.1.6 Cumulant expansion for CARL

The dynamics of quantum correlations such as $\hat{a}_+^\dagger\hat{a}_-$ or $\hat{a}_+\sigma^+$ can be derived from Heisenberg equations, as well. As an example, let us consider the adiabatically eliminated Hamiltonian (42.26) and ignore the quantized nature of the atomic motion, the relevant first-order field-field correlations are then $\hat{a}_+^2$, $\hat{a}_+^\dagger\hat{a}_+$, $\hat{a}_+^{\dagger 2}$, $\hat{a}_-^2$, $\hat{a}_-^\dagger\hat{a}_-$, $\hat{a}_-^{\dagger 2}$, $\hat{a}_+\hat{a}_-$, $\hat{a}_+\hat{a}_-^\dagger$, $\hat{a}_+^\dagger\hat{a}_-$, $\hat{a}_+^\dagger\hat{a}_-^\dagger$. From the Heisenberg equation we get, for instance,

$$\begin{aligned}\frac{d}{dt}\hat{a}_+^2 &= \imath[\hat{H},\hat{a}_+^2] \\ &= -2\imath(U_0-\Delta_c)\hat{a}_+^2+2U_0\left(e^{2\imath k\hat{z}}\hat{a}_+\hat{a}_-^\dagger-e^{-2\imath k\hat{z}}\hat{a}_+\hat{a}_-\right)-2\imath\eta_+\hat{a}_+ \,.\end{aligned} \tag{42.47}$$

This is the lowest order *cumulant expansion*. The expectation values form a system of 10 linear first order differential equations [226] from which we can calculate the steady-state of the system.

The correlation functions and spectra are obtained directly from the CARL equation for the cavity fields (42.25) using the Wiener-Khinchin theorem (35.176) and the quantum regression theorem (35.253). With the substitutions, $t \to 0$, $\hat{B} \to 1$, $\hat{A} \to d\hat{A}_k/d\tau$, and $\xi_i(\tau)\hat{A}_i(0) \to \zeta_i\hat{A}_i(\tau)$, the quantum regression theorem can be written in the form,

$$\boxed{\frac{d}{d\tau}\langle\hat{A}_k(\tau)\rangle = \sum_i \zeta_i\langle\hat{A}_i(\tau)\rangle \qquad \Longrightarrow \qquad \frac{d}{d\tau}\langle\hat{A}_k(\tau)\hat{C}(0)\rangle = \sum_i \zeta_i\langle\hat{A}_i(\tau)\hat{C}(0)\rangle} \,. \tag{42.48}$$

Applied, for example, to the correlation function (42.47), we obtain from the CARL equation (42.25), with $\gamma_0 = 0$ and $\Delta_c = 0$,

$$\frac{d}{d\tau}\langle\hat{a}_+(\tau)\hat{a}_+(0)\rangle = (-\kappa - \imath U_0)\langle\hat{a}_+(\tau)\hat{a}_+(0)\rangle - \imath U_0 e^{-2\imath k\hat{z}}\langle\hat{a}_-(0)\hat{a}_+(0)\rangle + \eta_+\langle\hat{a}_+(0)\rangle \ . \tag{42.49}$$

Repeating this calculation for the other first-order correlations functions we obtain a system of 10 linear first order differential equations, which can be solved via Laplace transform.

42.1.7 Exercises

42.1.7.1 Ex: Origin of quantum correlations

Derive the Hamiltonian (42.2) from the JCM Hamiltonian (35.111) transforming it into the co-rotating frame.

Solution: *We write the JCM Hamiltonian,*

$$\hat{H} = \omega_c\hat{a}^\dagger\hat{a} + \omega_a(\hat{\sigma}^+\hat{\sigma}^- - \tfrac{1}{2}) + \tfrac{1}{2}\Omega(\hat{a}\hat{\sigma}^+ + \hat{a}^\dagger\hat{\sigma}^-)$$

in matrix form as,

$$\hat{H}_n = \begin{pmatrix} (n-1)\omega_c & \frac{\Omega}{2}\sqrt{n} \\ \frac{\Omega}{2}\sqrt{n} & n\omega_c - \omega_a \end{pmatrix} \ .$$

Now, applying the unitary transform,

$$\hat{U} = \begin{pmatrix} e^{-\imath n\omega t} & 0 \\ 0 & e^{-\imath n\omega t} \end{pmatrix} \ ,$$

we get,

$$\tilde{H} = \hat{U}^\dagger\hat{H}\hat{U} + \imath\hbar\dot{\hat{U}}^\dagger\hat{U} = \begin{pmatrix} (n-1)(\omega_c - \omega) + \omega_a - \omega & \frac{\Omega}{2}\sqrt{n} \\ \frac{\Omega}{2}\sqrt{n} & n(\omega_c - \omega) \end{pmatrix} \ ,$$

and hence, introducing the detunings $\Delta_a \equiv \omega - \omega_a$ and $\Delta_c \equiv \omega - \omega_c$,

$$\hat{H} = -\Delta_c\hat{a}^\dagger\hat{a} - \Delta_a(\hat{\sigma}^+\hat{\sigma}^- - \tfrac{1}{2}) + \tfrac{1}{2}\Omega(\hat{a}\hat{\sigma}^+ + \hat{a}^\dagger\hat{\sigma}^-) \ .$$

42.1.7.2 Ex: Linear pumping of a cavity mode

Study how the Hamiltonian $\hat{H}_{pmp} = \imath\eta^*\hat{a} - \imath\eta\hat{a}^\dagger$, describing linear pumping of a cavity mode, fills the cavity with photons in the absence of dissipation (see also (40.2)).

Solution: *We can define a displacement operator $D(\eta t) \equiv e^{-\imath\hat{H}_{pmp}t} = e^{\eta^* t\hat{a} - \eta t\hat{a}^\dagger}$. The*

$$\begin{aligned}\langle 0|D^\dagger(\eta t)\hat{n}D(\eta t)|0\rangle &= \langle 0|D^\dagger(\eta t)\hat{a}^\dagger D(\eta t)D^\dagger(\eta t)\hat{a}D(\eta t)|0\rangle \\ &= \langle 0|(\hat{a}^\dagger + \eta^* t)(\hat{a} + \eta t)|0\rangle = \langle 0|\hat{n} + \eta^* t\hat{a} + \eta t\hat{a}^\dagger + |\eta t|^2|0\rangle = |\eta t|^2 \ .\end{aligned}$$

42.1.7.3 Ex: The adiabatically approximated Hamiltonian

a. Derive the adiabatically approximated Hamiltonian (42.26) from the total Hamiltonian (42.4).
b. Derive the CARL equations (42.25) directly from the adiabatically approximated Hamiltonian.
c. Show that, in the absence of pumping, the energy stored in the light fields is conserved separately from the mechanical energy of the atom.
d. Verify momentum conservation.

Solution: *a. With the definition of the Rabi frequency (42.19)* $\hat{\Omega} = 2g(e^{\imath k\hat{z}}\hat{a}_+ + e^{-\imath k\hat{z}}\hat{a}_-)$ *we can rewrite the Hamiltonian (42.4) as,*

$$\hat{H} = \frac{\hat{p}^2}{2m} - \Delta_a\hat{\sigma}^+\hat{\sigma}^- + \tfrac{1}{2}\hat{\Omega}^\dagger\hat{\sigma}^- + \tfrac{1}{2}\hat{\sigma}^+\hat{\Omega} - \sum_\pm \left[\Delta_c\hat{a}_\pm^\dagger\hat{a}_\pm + \imath\eta_\pm(\hat{a}_\pm - \hat{a}_\pm^\dagger)\right] ,$$

inserting the stationary solution (42.21): $\hat{\sigma}^-(\infty) = \hat{\Omega}/2\Delta_a$ *and setting* $\gamma = 0$*, we get,*

$$\begin{aligned}\hat{H} &\simeq \frac{\hat{p}^2}{2m} - \frac{\hat{\Omega}^\dagger\hat{\Omega}}{4\Delta_a} - \sum_\pm \left[\Delta_c\hat{a}_\pm^\dagger\hat{a}_\pm + \imath\eta_\pm(\hat{a}_\pm - \hat{a}_\pm^\dagger)\right] \\ &= \frac{\hat{p}^2}{2m} + \sum_\pm (U_0 - \Delta_c)\hat{a}_\pm^\dagger\hat{a}_\pm + U_0(e^{-2\imath k\hat{z}}\hat{a}_+^\dagger\hat{a}_- + e^{2\imath k\hat{z}}\hat{a}_+\hat{a}_-^\dagger) - \imath\sum_\pm \eta_\pm(\hat{a}_\pm - \hat{a}_\pm^\dagger) ,\end{aligned}$$

with $U_0 = \frac{g^2}{\Delta_a}$.
b. From this we derive,

$$\dot{\hat{a}}_+ = \imath[\hat{H}, \hat{a}_+] = (\imath\Delta_c - \imath U_0)\hat{a}_+ - \imath U_0\hat{a}_- e^{-2\imath k\hat{z}} + \eta_+ ,$$

where we used, $[\hat{a}_+^\dagger\hat{a}_+, \hat{a}_+] = -\hat{a}_+$*,* $[\hat{a}_-^\dagger\hat{a}_-, \hat{a}_+] = 0$*, and* $[\hat{a}_+^\dagger\hat{a}_-, \hat{a}_+] = -\hat{a}_-$ *and,*

$$\dot{\hat{p}} = \imath[\hat{H}, \hat{p}] = 2\imath U_0 k\left(e^{-2\imath k\hat{z}}\hat{a}_+^\dagger\hat{a}_- - e^{2\imath k\hat{z}}\hat{a}_+\hat{a}_-^\dagger\right) ,$$

where we used, $[e^{\imath k\hat{z}}, \hat{p}] = -ke^{\imath k\hat{z}}$.
c. Using the derived Hamiltonian without pumping terms and setting for simplicity $\Delta_c = 0$ *and using the commutation rules* $[\hat{a}_\pm, \hat{n}_\pm] = \hat{a}_\pm$ *and* $[\hat{a}_\pm^\dagger, \hat{n}_\pm] = -\hat{a}_\pm^\dagger$ *it is easy to show,*

$$[\hat{H}, \hat{n}_+ + \hat{n}_-] = 0 ,$$

such that kinetic energy can only be converted into potential energy,

$$[\hat{H}, \tfrac{\hat{p}^2}{2m}] = -[\hat{H}, U_0\left(\hat{a}_+^\dagger\hat{a}_- e^{-2\imath k\hat{z}} + \hat{a}_-^\dagger\hat{a}_+ e^{2\imath k\hat{z}}\right)] = 4\omega_{rec}U_0\left(\hat{a}_+^\dagger\hat{a}_- e^{-2\imath k\hat{z}} + \hat{a}_-^\dagger\hat{a}_+ e^{2\imath k\hat{z}}\right) .$$

d. Momentum conservation,

$$[\hat{H}, \hbar k(\hat{n}_+ - \hat{n}_-) - \hat{p}] = 0 .$$

42.1.7.4 Ex: Hamiltonian after adiabatic elimination of internal states for a linear cavity including counter-rotating terms

Repeat the adiabatic elimination of Sec. 42.1.4 for a linear cavity including counter-rotating terms.

Solution: *The Hamiltonian is,*

$$\begin{aligned}\hat{H} &= \frac{\hat{p}^2}{2m} - \Delta_a \hat{\sigma}^+\hat{\sigma}^- - \Delta_c \hat{a}^\dagger \hat{a} + g(\hat{a}^\dagger + \hat{a})(e^{\imath k\hat{z}} + e^{-\imath k\hat{z}})(\hat{\sigma}^- + \hat{\sigma}^+) \\ &= \frac{\hat{p}^2}{2m} - \Delta_a \hat{\sigma}^+\hat{\sigma}^- - \Delta_c \hat{a}^\dagger \hat{a} + \tfrac{\hat{\Omega}(z)}{2}(\hat{\sigma}^- + \hat{\sigma}^+) \ ,\end{aligned}$$

defining,

$$\hat{\Omega}(z) \equiv g(\hat{a}^\dagger + \hat{a}) \cos k\hat{z} = \hat{\Omega}(z)^\dagger \ .$$

The Heisenberg equations yield,

$$\begin{aligned}\dot{\sigma}^- &= -\gamma\hat{\sigma}^- + \imath[\hat{H}, \hat{\sigma}^-] = (-\gamma + \imath\Delta_a)\hat{\sigma}^- - \tfrac{\imath\Omega(z)}{2}\hat{\sigma}_z \\ \dot{\sigma}_z &= \imath[\hat{H}, \hat{\sigma}_z] - 2\gamma - 2\gamma\hat{\sigma}_z = -2\gamma - 2\gamma\hat{\sigma}_z + \imath\Omega(z)(\hat{\sigma}^+ - \hat{\sigma}^-) \ .\end{aligned}$$

In steady state,

$$\begin{aligned}\hat{\sigma}^-(\infty) &= \frac{\imath\Omega(z)}{2(-\gamma + \imath\Delta_a)}\hat{\sigma}_z(\infty) \simeq \frac{-\Omega(z)}{2\Delta_a} \\ \hat{\sigma}_z(\infty) &= \frac{-2(\gamma^2 + \Delta_a^2)}{2(\gamma^2 + \Delta_a^2) + \Omega(z)^2} \simeq -1 \\ \hat{\sigma}^+\hat{\sigma}^- &= \frac{\Omega(z)^2}{2(\gamma^2 + \Delta_a^2)} \simeq 0 \ .\end{aligned}$$

Using classical light $[\hat{a}, \hat{a}^\dagger] = 0$,

$$\hat{\Omega}^2 = g(\hat{a}^\dagger + \hat{a})^2 \cos^2 kz = 2g\hat{a}^\dagger\hat{a}\cos^2 kz + const \ ,$$

the Hamiltonian finally becomes,

$$\begin{aligned}\hat{H} &= \frac{\hat{p}^2}{2m} - \Delta_c \hat{a}^\dagger\hat{a} - \frac{\Omega(z)^2}{2\Delta_a} \\ &= \frac{\hat{p}^2}{2m} - \Delta_c \hat{a}^\dagger\hat{a} - \frac{g}{\Delta_a}\hat{a}^\dagger\hat{a}\cos^2 kz + const \ .\end{aligned}$$

42.1.7.5 Ex: Periodicity of a lattice

Assume a symmetrically pumped ring cavity in equilibrium with an atom initially at rest. What photonic states are generated in the counterpropagating light modes, when the atom is kicked by an external force imparting a sudden recoil of $\hbar k_{kck}$.

Solution:

42.1.7.6 Ex: Adiabatic elimination of the cavity modes

Derive the coherent part of the equations of motion (42.36) directly from the Hamiltonian (42.4) in the absence of pumping, $\eta_\pm = 0$, and in the limit of large cavity detunings, $|\Delta_c| \gg \kappa$.

Solution: *The Hamiltonian becomes,*

$$\hat{H}_{atom:field} = -\Delta_a \hat{\sigma}^+\hat{\sigma}^- + \frac{\hat{p}^2}{2m} - \sum_\pm \Delta_c \hat{a}_\pm^\dagger \hat{a}_\pm - \imath\eta_\pm(\hat{a}_\pm - \hat{a}_\pm^\dagger) + \tfrac{1}{2}\Omega^\dagger(z)\hat{\sigma}^- + \tfrac{1}{2}\hat{\sigma}^+\Omega(z)$$

$$\stackrel{\eta_\pm=0}{\longrightarrow} \frac{\hat{p}^2}{2m} + (2U_c - \Delta_a)\hat{\sigma}^+\hat{\sigma}^- \ .$$

Now, the equations of motion are,

$$\dot{\hat{\sigma}}^- = \imath[\hat{H}_{atom:field}, \hat{\sigma}^-] = \imath(2U_c - \Delta_a)[\hat{\sigma}^+\hat{\sigma}^-, \hat{\sigma}^-] = \imath(\Delta_a - 2U_c)\hat{\sigma}_z\hat{\sigma}^-$$
$$\dot{\hat{\sigma}}_z = \imath[\hat{H}_{atom:field}, \hat{\sigma}_z] = \imath(2U_c - \Delta_a)[\hat{\sigma}^+\hat{\sigma}^-, \hat{\sigma}_z] = 0 \ ,$$

which coincides with the coherent part of (42.36).

42.2 CARL: The collective atomic recoil laser

The *collective atomic recoil laser* (*CARL*) was first predicted in 1994 [173] as an atomic analog of FEL. The idea consists of a monochromatic homogeneous beam of moving two-level atoms (all atoms have the same velocity), a strong counterpropagating pump laser beam, and a weak copropagating probe beam tuned to the blue side of the resonance. The lasers form a standing light wave that moves in the same direction as the atoms. Atoms that are faster than the velocity of the standing wave are rejected by the maxima of the dipolar potential created by the standing wave and feel a repulsive force. Atoms that are slower than the standing wave velocity are pushed by the dipole potential maxima and feel an accelerating force. These forces can be interpreted as backscattering of photons from the pump wave into the probe wave. This redistribution of energy amplifies the contrast of the stationary wave, which in turn amplifies the backscattering efficiency, etc. Therefore, the CARL converts kinetic energy into coherent radiation (or more precisely, into an increase of the energy difference between probe and pump) mediated by atomic bunching. It is a self-amplifying mechanism. The CARL signature is a transient exponential amplification for the incident probe, which defines the frequency of the 'CARL laser'. The first experimental realization of CARL used a ring cavity [755].

42.2.1 Classical CARL equations for many mobile atoms

The preceding sections dealt with a single atom in a ring cavity. More interesting dynamics, however, emerge in the presence of several atoms, because their motion can be become correlated via their simultaneous interaction with the same two counter-propagating modes of the cavity, as illustrated in the following movie (watch movie). A talk on CARL can be assisted at (watch talk).

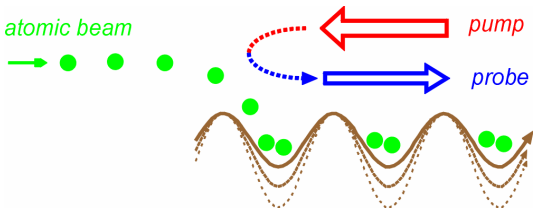

Figure 42.3: Collective atomic recoil laser.

To describe experiments dealing with many atoms, we have to extend the equations of motion (42.26) to N atoms via $z \longrightarrow z_j$ and $p \longrightarrow p_j$, where $j = 1, N$,

$$\boxed{\begin{aligned} \dot{\alpha}_\pm &= (-\kappa - \imath N U_0)\alpha_\pm - \imath U_0 \sum_{j=1}^{N} e^{\mp 2\imath k z_j}\alpha_\mp + \eta_\pm \\ \dot{p}_j &= -2\imath\hbar k U_0(\alpha_+\alpha_-^* e^{2\imath k z_j} - \alpha_-\alpha_+^* e^{-2\imath k z_j}) \end{aligned}} \quad . \tag{42.50}$$

with the kinetic and potential energies [9],

$$E_{kin} = \sum_j \frac{p_j^2}{2m} \quad , \quad E_{pot} = \sum_j U_0 |\alpha_+ e^{\imath k z_j} + \alpha_- e^{-\imath k z_j}|^2 \ . \tag{42.51}$$

If the atomic density distribution is homogeneous, the phases of randomly scattered photons destructively interfere and the quantity,

$$b \equiv \tfrac{1}{N} \sum_j e^{-2\imath k z_j} \ , \tag{42.52}$$

called *bunching parameter*, vanishes. That is, the impact of the scatterers on the light modes cancels out, as we will see in Exc. 42.2.7.1 for the case of two atoms. If on the other hand, atoms accumulate in the antinodes of the standing wave, it increases the contrast of it can spread more efficiently collectively by Bragg scattering. The particularity of the CARL is that during the temporal evolution the bunching process can amplify itself leading to an exponential growth of the counterpropagating mode, accompanied by an increasingly pronounced self-bunching.

In general, the equations can not be solved analytically, especially when the pump varies over time. A first approach consists in iterating them numerically,

$$\begin{aligned} \alpha_\pm(t+dt) &= \alpha_\pm(t) + dt\ [-(\kappa + \imath N U_0 - \imath\Delta_c)\alpha_\pm - \imath N U_0 b \alpha_\mp + \eta_\pm(t)] \\ z_j(t+dt) &= z_j + dt\ \tfrac{1}{m} p_j \\ p_j(t+dt) &= p_j - dt\ 2\imath\hbar k U_0(\alpha_+\alpha_-^* e^{2\imath k z_j} - \alpha_-\alpha_+^* e^{-2\imath k z_j}) \ . \end{aligned} \tag{42.53}$$

In Exc. 42.2.7.2 we will extend the equations (42.50) to the presence of two atomic species, and in Exc. 42.2.7.3 we will use them to describe the response of the light fields to an inertially moving atom supposing that is does not feel the CARL force.

[9] Note, that there is also a radial motion of the atom coupled to the axial movement. The coupling happens, because the axial motion influences the number of intracavity photons of the radiation field which, in turn, determines the depth of the dipole potential.

42.2.1.1 Locking of the pump laser

In practice the resonant frequency of a cavity fluctuates due to ambient noise. Hence, it is easier, experimentally, to lock the pump laser on a cavity mode, e.g. using the Pound-Drever-Hall method. This means,

$$\alpha_+ = \frac{\eta_+}{\kappa} \ . \tag{42.54}$$

In the presence of atoms, however, the resonant frequency can be shifted due to the refractive index of the atomic cloud [415]. Moreover, the shift depends on the atomic bunching and consequently varies during the dynamics of the CARL. The way the locking circuit works, is to continuously adjust the detuning between the laser and the cavity Δ_c (defined for the empty cavity) such as to maximize the amplitude of the field $|\alpha_+|$ and, hence, the transmission of the cavity filled with atoms. The dynamics of the detuning must be incorporated by an additional equation modeling the action of locking. Now that we know the effect, which an ideal lock should have, we can apply the boundary condition (42.54) and eliminate the pump mode α_+ from the dynamics of the system. That is, the following equations are usually sufficient to describe the CARL:

$$\boxed{\begin{aligned} \dot{\alpha}_- &= (-\kappa + \imath\Delta_c - \imath U_0)\alpha_- - \imath U_0 e^{-2\imath kz}\alpha_+ + \eta_- \\ m\ddot{z} &= 2\imath\hbar k U_0 \alpha_+ (\alpha_- e^{-2\imath kz} - \alpha_-^* e^{2\imath kz}) \end{aligned}} \ . \tag{42.55}$$

The frequency offset of the cavity resonances caused by the atom, U_0, can exceed the width of the cavity κ. From equation (40.146) we know,

$$|\alpha_+(\infty)|^2 = \frac{\chi\chi^*}{(\chi^2 + U_0^2)(\chi^{*2} + U_0^2)}\eta_+^2 \ .$$

The maxima of $|\alpha_+(\infty)|^2$ as a function of Δ_c give the shifted resonances of the modes.

Example 270 (*Locking on transverse modes*): We already mentioned that as the CARL accelerates, the frequency of the light which is backscattered to the probe shifts to the red until it escapes from the resonant mode. What happens if we provide another resonant mode that can receive photons? We will show in the following calculation, that CARL simply picks up the closest mode to dump the photons. The starting point is generalized CARL equations to accommodate a second reverse mode labeled β_-,

$$\begin{aligned} \dot{\alpha}_+ &= -(\kappa - \imath\Delta_c)\alpha_+ - \imath U_0(u_+^* u_+ \alpha_+ + u_+^* u_- \alpha_- + u_+^* u_\beta \beta_-) + \eta_+ \\ \dot{\alpha}_- &= -(\kappa - \imath\Delta_c)\alpha_- - \imath U_0(u_-^* u_- \alpha_- + u_-^* u_+ \alpha_+ + u_-^* u_\beta \beta_-) \\ \dot{\beta}_- &= -(\kappa - \imath\Delta_\beta)\beta_- - \imath U_0(u_\beta^* u_\beta \beta_- + u_\beta^* u_+ \alpha_+ + u_\beta^* u_- \alpha_-) \\ m\ddot{x} &= -U_0 \nabla |\alpha_+ u_+ + \alpha_- u_- + \beta_- u_\beta|^2 \ , \end{aligned} \tag{42.56}$$

com $u_\pm = e^{\pm \imath k z}$ and $u_\beta = e^{-\imath k_\beta x}$. We obtain,

$$\begin{aligned}
\dot{\alpha}_+ &= -(\kappa - \imath\Delta_c + \imath N U_0)\alpha_+ - \imath U_0 e^{-2\imath k z}\alpha_- - \imath U_1 e^{-\imath(k+k_\beta)x}\beta_- + \eta_+ \quad (42.57)\\
\dot{\alpha}_- &= -(\kappa - \imath\Delta_c + \imath N U_0)\alpha_- - \imath U_0 e^{2\imath k z}\alpha_+ - \imath U_1 e^{\imath(k-k_\beta)x}\beta_-\\
\dot{\beta}_- &= -(\kappa - \imath\Delta_\beta + \imath N U_1)\beta_- - \imath U_1 e^{\imath(k+k_\beta)x}\alpha_+ - \imath U_1 e^{-\imath(k-k_\beta)x}\beta_-\\
m\ddot{x} &= -U_0(2\imath k e^{2\imath k z}\alpha_-^*\alpha_+ - 2\imath k e^{-2\imath k z}\alpha_+^*\alpha_-)\\
&\quad - U_1(\imath(k+k_\beta)e^{\imath(k+k_\beta)x}\beta_-^*\alpha_+ - \imath(k+k_\beta)e^{-\imath(k+k_\beta)x}\alpha_+^*\beta_-)\\
&\quad - U_1(\imath(k-k_\beta)e^{\imath(k-k_\beta)x}\alpha_-^*\beta_- - \imath(k-k_\beta)e^{-\imath(k-k_\beta)x}\beta_-^*\alpha_-)\ .
\end{aligned}$$

Note that $k - k_\beta \approx 0$ and $k + k_\beta \approx 2k$. The result of the simulation is displayed in Fig. 42.4.

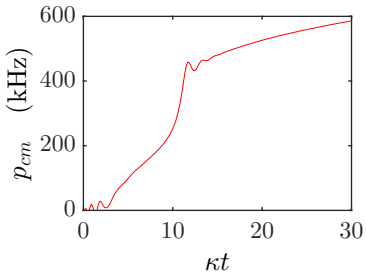

Figure 42.4: (code) The CARL locks to other modes of the cavity.

42.2.1.2 Analytic approximations for one-sided pumping and perfect bunching

Here, we will assume for simplicity, that the atoms are perfectly bunched, $z_j = z$ and $p_j = p$, i.e. they have *zero temperature*. This means that we only need to consider a single equation of motion for the atoms. However, their coupling to the cavity modes is N times stronger, which means that we have to substitute $U_0 \longrightarrow U_N \equiv N U_0$ in the equation of motion for the cavity fields.

When only one atom is in the cavity or when the atoms are perfectly bunched together, it is possible to derive analytical solutions. Particularly interesting is the following situation: We pump the cavity from one side. The pump is supposed to be dominant and locked to a resonance, such that we can neglect the feedback of the system on the pump, that is, we can assume, $\alpha_+ = \eta/\kappa$. Using the abbreviations $\chi \equiv \kappa + \imath U_0 - \imath\Delta_c$ and the photon recoil shift [481],

$$\omega_{rec} \equiv \frac{\hbar k^2}{2m}\ , \tag{42.58}$$

the equations (42.26) then become,

$$\boxed{\begin{aligned}
\dot{\alpha}_- &= -\chi\alpha_- - \imath U_N \alpha_+ e^{2\imath k z}\\
k\dot{v} &= 4\omega_{rec}\imath U_0 \alpha_+(\alpha_- e^{-2\imath k z} - \alpha_-^* e^{2\imath k z})
\end{aligned}}\ . \tag{42.59}$$

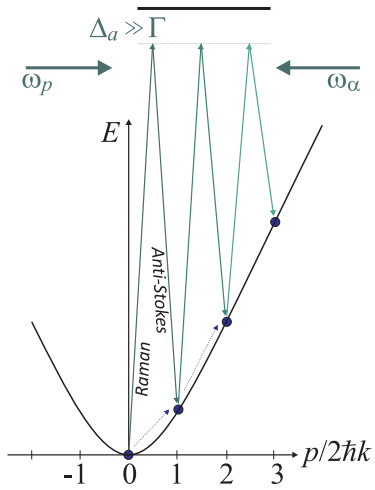

Figure 42.5: In the momentum picture the CARL acceleration process occurs as Raman-anti-Stokes processes along the free-particle dispersion relation.

We consider the stationary case (42.26). Doing the ansatz,

$$\alpha_- \equiv \beta e^{2\imath kx} \qquad \text{where} \qquad \dot{\beta} = 0 \tag{42.60}$$

we assume that the atom and the standing wave have the same velocity, that is, they move in phase. We obtain as solution,

$$\beta = \frac{-\imath U_N \alpha_+}{\kappa + 2\imath kv} \quad , \quad k\dot{v} = 8\omega_{rec} U_0^2 \alpha_+^2 \frac{2\kappa}{\kappa^2 + 4k^2 v^2} \ . \tag{42.61}$$

If $\kappa \ll 2kv$, then the differential equation is approximately solved by,

$$(kv)^3 = 3\varepsilon\kappa U_0^2 \alpha_+^2 t \ . \tag{42.62}$$

This means that the CARL frequency, that is, the frequency difference between the emitted probe wave and the incident light, increases temporarily. The frequency corresponds to the double Doppler shift. As the frequency of the probe light gradually shifts away from the cavity resonance, the probe light finally stops being amplified, and the amplitude of the probe field decreases: CARL is only a transient phenomenon. In fact, the behavior described by the equation (42.61) was observed in experiments [755].

Example 271 (*Universal scaling*): Our formula describing CARL,

$$\begin{aligned} \dot{\alpha}_- &= -\frac{\imath U_0 \eta_+}{\chi} \sum\nolimits_j e^{2\imath k z_j} - \chi \alpha_- \\ k\dot{v}_j &= -4\omega_{rec} \imath U_0 \eta_+ \left(\frac{\alpha_-}{\chi^*} e^{-2\imath k z_j} - \frac{\alpha_-^*}{\chi} e^{2\imath k z_j} \right) - \gamma_{fric} k v_j \ , \end{aligned} \tag{42.63}$$

where $\chi = \kappa + \imath N U_0 - \imath\Delta_c$, can be rewritten in terms of a universal 'scaling' if we define,

$$\tau = 4\omega_{rec}\rho t \quad \text{and} \quad \bar{\gamma} = \frac{\gamma_{fric}}{4\omega_{rec}\rho} \tag{42.64}$$
$$\theta_j = 2kz_j \quad \text{and} \quad P_j = \frac{2kv_j}{4\omega_{rec}\rho}$$
$$A = \frac{\imath|\chi|}{\chi^*\sqrt{\rho N}}\alpha_- \quad \text{and} \quad \bar{\chi} = \frac{\chi}{4\omega_{rec}\rho} \ .$$

We obtain,

$$\dot{A} = \frac{1}{N}\sum\nolimits_j e^{\imath\theta_j} - \bar{\chi}A \tag{42.65}$$
$$\dot{\theta} = P_j$$
$$\dot{P}_j = -2(A^* e^{-\imath\theta_j} + A e^{\imath\theta_j}) - \bar{\gamma}P_j \ .$$

provided that the universal scaling parameter ρ is set to,

$$\rho \equiv \left(\frac{NU_0^2\eta_+^2}{8\omega_{rec}^2|\chi|^2}\right)^{1/3} \ . \tag{42.66}$$

The meaning of the ρ parameter can be gathered by rewriting it in terms of the number of photons of the pump $|\alpha_+|^2 = \eta_+^2/\kappa^2$ and the depth of the dipolar potential $U_d = U_0|\alpha_+|^2$,

$$\rho^3 = \frac{N}{\alpha_+^2}\frac{U_d^2}{8\omega_{rec}^2} \ . \tag{42.67}$$

The ρ parameter therefore indicates the number of atoms per photon and the ratio between the depth of the dipolar trap and the photonic recoil energy.

42.2.2 Observation of CARL in ring cavities

The first observation of CARL was achieved with a cloud of 100 µK cold rubidium atoms interacting with a high finesse ring cavity [755]. In a thermal cloud the atomic motion prevents bunching, i.e. $b = 0$ so that according to Eq. (42.50) the cavity fields do not couple to the atoms. Density fluctuations that could seed CARL dynamics are rapidly washed out by thermal motion.

This problem can be circumvented by applying a robust *pre-bunching*, which can be done by subjecting the atoms to a periodic potential, e.g. via a standing wave formed by two counterpropagating cavity modes. The atoms then arrange themselves into a periodic lattice, so that the bunching parameter is initially $b \simeq 1$. If one cavity is then extinguished, a CARL dynamics can take place, until thermal motion succeeds in washing out the periodic lattice. This dynamics is illustrated in the simulation exhibited in Fig. 42.6 for the case of strontium atoms. The finite temperature of the cloud is accounted for via an initial density and momentum distribution for the atoms given by,

$$p_{0,j} = \sqrt{mk_BT}\ \zeta_j \quad \text{and} \quad z_{0,j} = \frac{\sqrt{2}}{k}\sqrt{\frac{k_BT}{U_0}}\ \zeta_j \ , \tag{42.68}$$

where ζ_j is a normally distributed random variable.

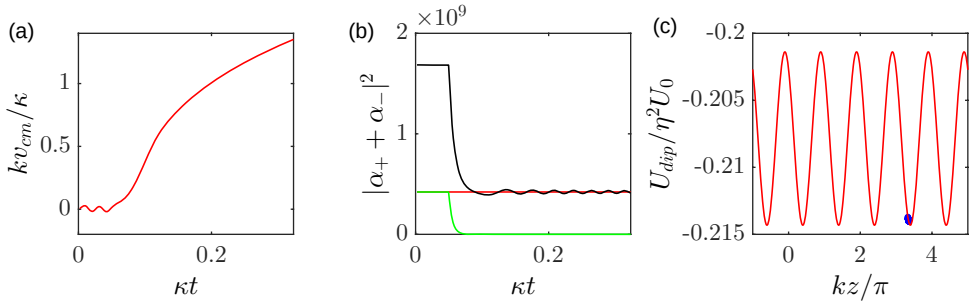

Figure 42.6: (code) Simulation for $N = 10^5$ strontium atoms at $T = 10\,\mu\text{K}$ temperature interacting via their $\Gamma = (2\pi)$ kHz narrow intercombination line at $\lambda = 689\,\text{nm}$ with a ring cavity (decay rate $\kappa = (2\pi)\ 1.7\,\text{MHz}$ and waist $w_0 = 68.4\,\mu\text{m}$). CARL dynamics is triggered by switching off one of two pump lasers whose intracavity power is $P = 1\,\text{W}$. (a) Doppler shift of the CARL-accelerated atoms, (b) interference signal between the two cavity light modes, and (c) atomic distribution in the standing wave potential.

Example 272 (*Curiosities: Atomic transport around mirrors*): Displacement of the atomic cloud in a unidirectionally pumped ring-cavity. The left and right image in Fig. 42.7 are taken for different pumping directions α. The upper cloud shows atoms trapped in the main focus of the ring-cavity. The lower traces stem from atoms transported from the focus passed the mirrors T_1 and T_2 towards the incoupling mirror located at the place where the lower traces intersect. The lower trace are imaged twice, because the imaging beam is reflected from the incoupling mirror surface, before it is sent to a photodiode.

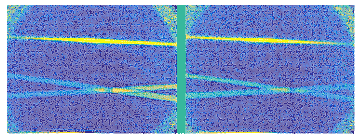

Figure 42.7: Displacement of the atomic cloud in a unidirectionally pumped ring-cavity. The left and right figures are taken for different pumping directions α. The upper cloud shows atoms trapped in the main focus of the ring-cavity. The lower traces stem from atoms transported from the focus passed the mirrors T_1 and T_2 towards the incoupling mirror located at the place where the lower traces intersect. The lower trace are imaged twice, because the imaging beam is reflected from the incoupling mirror surface, before it is sent to a photodiode.

42.2.2.1 CARL in the presence of friction forces

A feature of CARL, as it has been detected in Fig. 42.6 is, that it does not lead to a stationary state: the atoms are monotonically accelerated and the Doppler-shift of the backscattered probe light increases at the same pace. After a while, the frequency of the probe light runs out of the cavity resonance, so that the CARL dynamics starts to be suppressed. This led to a reduction of the oscillation amplitude of the interference signal observed in Fig. 42.6(b).

In order to maintain CARL strong we can think of limiting the acceleration by a friction force. How this works is illustrated in Fig. 42.8, where by subject the atoms to an optical molasses switched on at time $\kappa t = 0.3$. The friction can be incorporated into the CARl equations (42.50) via an additional force,

$$F_{frc} = -\beta_{frc} p \ . \tag{42.69}$$

We observe that the frequency shift of the backscattered light stabilizes at a lower value and that the oscillation amplitude of the interference signal is stronger than without molasses [1343].

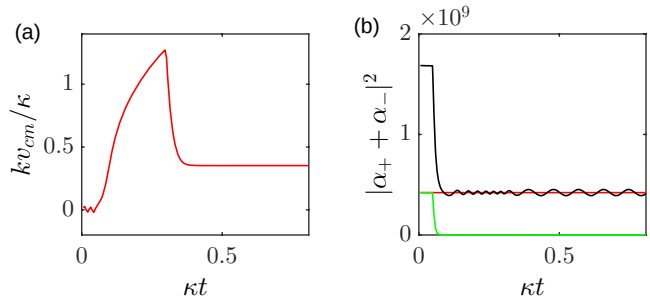

Figure 42.8: (code) Influence of an external friction force (switched on at $\kappa t = 0.3$) proportional to $\beta_{frc} = 3.8 \cdot 10^6\,\mathrm{s}^{-1}$. Other parameters are the same as in Fig. 42.6.

Let us note that, while provide a nice intuition, the description of the impact of an optical molasses force is incomplete, because it disregards heating effects caused by random photon scattering processes. The temperature of the atomic cloud is given by an equilibrium between friction and heating processes. The correct inclusion of optical molasses in the CARL dynamics will be studied in Sec. 42.6.1.

42.2.2.2 CARL in the presence of injected probe light

It is also interesting to study the impact of a weak injected probe light on the CARL dynamics. This light may have the same frequency as the pump light, $\eta_-/|\eta_-| = \eta_+/|\eta_+|$. This is for example the case, when light is backscattered from imperfection of the cavity mirror surfaces. Or may have a different frequency (provided the probe frequency is resonant to a cavity mode),

$$\eta_- = e^{\imath \Delta\nu t} \ . \tag{42.70}$$

The injected light fields η_+ and η_- create a standing light wave potential, in which the atoms move as being subject to an array of hurdles. The CARL force is too weak, the atoms will get stuck. We study this in Exc. 42.2.7.4. In Exc. 42.2.7.5 we study CARL dynamics for the case that the atoms are subject to an additional harmonic potential.

42.2.2.3 Impact of radiation pressure on CARL

CARL is a coherent force resulting from a coupling of only two counterpropagating modes of the cavity. As such, it can be derived from a potential. However, photons

may also be scattered out of the cavity and get lost for the system. These processes give rise to an additional radiation pressure force, which has been given in Eq. (42.46),

$$F_{rp} = 2\hbar k\gamma_0(\alpha_+\alpha_-^* - \alpha_-\alpha_+^*) \ . \tag{42.71}$$

But this force is weak when the laser is tuned far enough from the atomic resonance.

Fig. 42.9 shows a simulation of the impact of radiation pressure for the same system as in Fig. 42.6. For clarity the radiation pressure force has been exaggerated by a factor of 100.

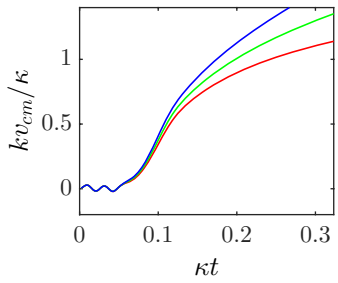

Figure 42.9: (code) Influence of radiation pressure on CARL.

42.2.3 CARL without cavity, propagation effects

Propagation effects are neglected in most treatments. An exception is [1439], who emphasize the important role of light intensity variations along the volume filled by the atomic cloud, within the SVEA, but ignoring interactions and external potentials. The approximation consists in setting $\vec{\mathcal{E}}(\mathbf{r}) = \vec{\mathcal{E}}$, i.e. assuming a uniform coupling strength $g = \frac{\Omega_1\Omega_2}{\hbar\Delta_a}$.

We assume the pump field detuning from the atomic resonance is large enough to neglect radiation pressure and to adiabatically eliminate the internal degrees of freedom. With the single-photon light shift $U_0 = \frac{g^2}{\Delta_a}$, the atomic positions z_n, the probe light field amplitude (scaled to the single-photon field amplitude) α_- and the

pump field α_+ taken as real [10],

$$\frac{\partial^2 R_n}{\partial T^2} = \frac{2\hbar k}{m}\imath U_0\alpha_+\left(\alpha_- e^{-2\imath kR_n} - \alpha_-^* e^{2\imath kR_n}\right)$$
$$\frac{\partial\alpha_-}{\partial T} + c\frac{\partial\alpha_-}{\partial Z} = -\imath U_0\alpha_+\sum_n e^{2\imath kR_n} \ .$$

In scaled units $r_n = 2kR_n$ and $p_n = P_n/\hbar k$ and $t = \omega_r T$ and $z = \omega_r Z/c$ where $\omega_r = 2\hbar k^2/m$,

$$\frac{\partial r_n}{\partial t} = p_n$$
$$\frac{\partial p_n}{\partial t} = \frac{2\imath U_0\alpha_+}{\omega_r}\left(\alpha_- e^{-\imath r_n} - \alpha_-^* e^{\imath r_n}\right)$$
$$\frac{\partial\alpha_-}{\partial t} + \frac{\partial\alpha_-}{\partial z} = -\frac{\imath U_0\alpha_+}{\omega_r}\sum_n e^{ir_n} \ .$$

Introducing the change of variables $\tau = (t-z)\sqrt{z}$ and $r_n(t) = \tilde{r}_n(\tau)$ and $p_n(t) = \sqrt{z}\tilde{p}_n(\tau)$ and $\alpha_-(t,z) = z\tilde{\alpha}_-(\tau)$, and using,

$$\frac{\tau}{2}\frac{\partial\tilde{\alpha}_-(\tau)}{\partial\tau} + \tilde{\alpha}_-(\tau) = \left(\sqrt{z} + \frac{t}{2\sqrt{z}} - \frac{3\sqrt{z}}{2}\right)z\frac{\partial\tilde{\alpha}_-(\tau)}{\partial\tau} + \tilde{\alpha}_-(\tau)$$
$$= \left(\frac{\partial\tau}{\partial t} + \frac{\partial\tau}{\partial z}\right)z\frac{\partial\tilde{\alpha}_-(\tau)}{\partial\tau} + \tilde{\alpha}_-(\tau)$$
$$= z\frac{\partial\tilde{\alpha}_-(\tau)}{\partial t} + z\frac{\partial\tilde{\alpha}_-(\tau)}{\partial z} + \tilde{\alpha}_-(\tau) = \frac{\partial\alpha_-(t,z)}{\partial t} + \frac{\partial\alpha_-(t,z)}{\partial z} \ .$$

[10] Here is a comment that Wolfgang Ketterle made on our papers [1217, 1218]:

> Regarding optical stimulation vs. atomic stimulation: There are two regimes, depending whether the atomic or optical coherences last longer. Indeed, you write: This implies that scattered photons have left the interaction volume before subsequent photons are scattered. In other terms the coherence time of the light modes is too small for the build-up of an optical interference pattern. Therefore the atomic density grating occurring in SRyS is not formed optical dipole forces but arises from the matter wave interference between different momentum states. This explains, why it is important that the thermal energy of the atoms be smaller than the recoil energy $k_BT < 2\hbar^2 2k^2/m$. Otherwise, the Doppler broadening leads to decoherence of the momentum states and consequently to a reduction of the contrast of the matter wave grating. For CARL the situation is reversed. CARL has been observed with temperatures much higher than the recoil temperature, i.e. in a regime where interferences between atoms in Raman superpositions of momentum states are smeared out by Doppler broadening. Here, the optical cavity plays a crucial role, because it stores the scattered light for such long times, that the atoms experience the force of the periodic dipole potential emerging from the interference of the probe with the pump mode. In our experiment, $c/2L = 20\,\mathrm{kHz}$, so that the lifetime is 7 orders of magnitude larger than without cavity. The gain can be varied over wide ranges, $G = 10^3 - 10^9\,\mathrm{s}^{-1}$. I disagree that you can really distinguish between optical dipole forces scattering atoms or matter wave gratings scattering light. This has confused us in earlier work, but in our 2003 Science paper (Schneble et al.) we clearly showed that even the extreme case of SRyS where the photon leaves immediately, can be described as atoms being Bragg scattered by the photons on their way out, in other words, there is a dipole force description even in this case.

it is easy to show,

$$\begin{aligned}\frac{\partial\tilde{r}_n}{\partial\tau} &= \tilde{p}_n \\ \frac{\partial\tilde{p}_n}{\partial\tau} &= \frac{2\imath U_0\alpha_+}{\omega_r}\left(\tilde{\alpha}_- e^{-\imath\tilde{r}_n} - \tilde{\alpha}_-^* e^{\imath\tilde{r}_n}\right) \\ \frac{\tau}{2}\frac{\partial\tilde{\alpha}_-}{\partial\tau} &= -\tilde{\alpha}_- - \frac{\imath N U_0\alpha_+}{\omega_r} b \ .\end{aligned}$$

In Exc. 42.2.7.6 we try a numerical approach.

42.2.4 Optical instability in ring cavities
