$$2\imath \mathbf{k}_0 \cdot \nabla \mathcal{E}_0 + 2\imath \omega_0 \mu_0 \varepsilon_0 \frac{\partial \mathcal{E}_0}{\partial t} - (k_0^2 - \omega_0^2 \mu_0 \varepsilon_0)\mathcal{E}_0 = 0 \ . \tag{18.36}$$

It is convenient to choose k_0 and ω_0 such that they satisfy the dispersion relation, $k_0^2 - \omega_0^2 \mu_0 \varepsilon_0 = 0$. This gives the following approximation to the wave equation,

$$\mathbf{k}_0 \cdot \nabla \mathcal{E}_0 + \omega_0 \mu_0 \varepsilon_0 \frac{\partial \mathcal{E}_0}{\partial t} = 0 \ . \tag{18.37}$$

This is a hyperbolic partial differential equation, like the original wave equation, but now of first-order instead of second-order. It is valid for coherent forward-propagating

waves in directions near the k_0-direction. The space and time scales over which $\mathcal{E}_0$ varies are generally much longer than the spatial wavelength and temporal period of the carrier wave. A numerical solution of the envelope equation thus can use much larger space and time steps, resulting in significantly less computational effort.

Example 98 (*Parabolic SVEA approximation*): Assuming that the wave propagation is dominantly in z-direction, and k_0 is taken in this direction. The SVEA is only applied to the second-order spatial derivatives in the z-direction and time. If $\nabla_\perp = \hat{\mathbf{e}}_x\partial/\partial x + \hat{\mathbf{e}}_y\partial/\partial y$ is the gradient in the x-y plane, the result is [1281],

$$k_0\frac{\partial\mathcal{E}_0}{\partial z} + \omega_0\mu_0\varepsilon_0\frac{\partial\mathcal{E}_0}{\partial t} - \tfrac{1}{2}\imath\nabla_\perp^2\mathcal{E}_0 = 0\ .$$

This is a parabolic partial differential equation. This equation has enhanced validity as compared to the full SVEA: it represents waves propagating in directions significantly different from the z-direction. It is the starting point of the theory of Gaussian beams, which will be studied in Sec. 18.4.1.

18.1.5 Plane waves in linear dielectrics and the refractive index

In dielectric (non-conducting) media we have $\varrho = 0$ and $\mathbf{j} = 0$ but $\dot{\vec{\mathcal{E}}}, \dot{\vec{\mathcal{B}}} \neq 0$. If the medium is linear and homogeneous, the permittivity ε and the permeability μ are constant, and we can substitute $\vec{\mathcal{D}} = \varepsilon\vec{\mathcal{E}}$ and $\vec{\mathcal{H}} = \mu^{-1}\vec{\mathcal{B}}$. Thus, Maxwell's equations (17.56) become equal to those holding for vacuum (17.6) but with the generalizations $\varepsilon_0 \to \varepsilon$ and $\mu_0 \to \mu$. Therefore, the wave equations remain valid,

$$\left(\frac{1}{c_n^2}\frac{\partial^2}{\partial t^2} - \nabla^2\right)\vec{\mathcal{E}} = 0 = \left(\frac{1}{c_n^2}\frac{\partial^2}{\partial t^2} - \nabla^2\right)\vec{\mathcal{B}}\ , \tag{18.38}$$

with the propagation velocity now reading,

$$c_n = \frac{1}{\sqrt{\varepsilon\mu}} = \frac{c}{n}\ , \tag{18.39}$$

where we defined the index of refraction,

$$n \equiv \sqrt{\frac{\varepsilon\mu}{\varepsilon_0\mu_0}}\ . \tag{18.40}$$

In dielectric media, we must use the original definitions for the energy and momentum densities and flows (17.58). The polarization and magnetization of the medium may cause new phenomena. For example, in anisotropic optical media the Poynting vector is not necessarily parallel to the wave vector. Resolve the Excs. 18.1.8.17 to 18.1.8.22.

18.1.6 Reflection and transmission by interfaces and Fresnel's formulas

So far we have considered homogenous media. An interesting question is, what happens when a field traverses regions characterized by different ε and μ. The boundary

conditions can be discussed from the integral form of the Maxwell equations, which follow immediately from the differential form via the theorems of Gauss and Stokes:

$$\begin{array}{lrcl} \text{(i)} & \oint_{\partial\mathcal{S}} \vec{\mathcal{H}} \cdot d\mathbf{l} & = & \frac{d}{dt}\int_{\mathcal{S}} \vec{\mathcal{D}} \cdot d\mathbf{S} + I_{enc} \\ \text{(ii)} & \oint_{\partial\mathcal{S}} \vec{\mathcal{E}} \cdot d\mathbf{l} & = & -\frac{d}{dt}\int_{\mathcal{S}} \vec{\mathcal{B}} \cdot d\mathbf{S} \\ \text{(iii)} & \oint_{\partial\mathcal{V}} \vec{\mathcal{D}} \cdot d\mathbf{S} & = & Q_{enc} \\ \text{(iv)} & \oint_{\partial\mathcal{V}} \vec{\mathcal{B}} \cdot d\mathbf{S} & = & 0 \end{array} \quad . \tag{18.41}$$

Let us consider two media with different permittivities $\varepsilon_{1,2}$ and permeabilities $\mu_{1,2}$ joined together at an interface. The closed path $\partial\mathcal{S}$ around a surface $\mathcal{S}$ and the closed surface $\partial\mathcal{V}$ around a volume $\mathcal{V}$ are chosen such as to cross the interface, as illustrated in Figs. 13.12 and 15.17. The surface integrals in equations (i) and (ii) vanish in the limit, where we choose the path $\partial\mathcal{S}$ very close to the interface.

From these equations, and as already shown in the derivations of the static equations (13.37), (13.39), (15.30), and (15.32), we have for linear media and in the absence of free surface charges σ_f and free surface currents $\mathbf{k}_f$,

$$\begin{array}{lrcl} \text{(i)} & \frac{1}{\mu_1}\vec{\mathcal{B}}_1^{\parallel} - \frac{1}{\mu_2}\vec{\mathcal{B}}_2^{\parallel} & = & |\mathbf{k}_f \times \hat{\mathbf{e}}_n| \longrightarrow 0 \\ \text{(ii)} & \vec{\mathcal{E}}_1^{\parallel} - \vec{\mathcal{E}}_2^{\parallel} & = & 0 \\ \text{(iii)} & \varepsilon_1\vec{\mathcal{E}}_1^{\perp} - \varepsilon_2\vec{\mathcal{E}}_2^{\perp} & = & \sigma_f \longrightarrow 0 \\ \text{(iv)} & \vec{\mathcal{B}}_1^{\perp} - \vec{\mathcal{B}}_2^{\perp} & = & 0 \end{array} \quad . \tag{18.42}$$

We will use these equations to establish the theory of reflection and refraction.

18.1.6.1 Normal incidence

Electromagnetic waves can be guided by interfaces (waveguides). From Maxwell's equations we can deduce useful rules for the behavior of waves near interfaces. First, we consider a plane wave propagating in the direction z within a dielectric medium characterized by the refraction index n_1,

$$\vec{\mathcal{E}}_i(z,t) = \hat{\mathbf{e}}_x \mathcal{E}_i e^{\imath(k_{z1}z - \omega t)} \quad , \quad \vec{\mathcal{B}}_i(z,t) = \hat{\mathbf{e}}_y \frac{n_1 \mathcal{E}_i}{c} e^{\imath(k_{z1}z - \omega t)} \; . \tag{18.43}$$

At position $z = 0$ there be a partially reflecting interface, as shown in Fig. 18.2(a). The reflected part is,

$$\vec{\mathcal{E}}_r(z,t) = \hat{\mathbf{e}}_x \mathcal{E}_r e^{\imath(-k_{z1}z - \omega t)} \quad , \quad \vec{\mathcal{B}}_r(z,t) = -\hat{\mathbf{e}}_y \frac{n_1 \mathcal{E}_r}{c} e^{\imath(-k_{z1}z - \omega t)} \; . \tag{18.44}$$

The negative sign comes from the relation $\vec{\mathcal{B}}(\mathbf{r},t) = \frac{1}{c}\mathbf{k} \times \vec{\mathcal{E}}(\mathbf{r},t)$. The transmitted part is,

$$\vec{\mathcal{E}}_t(z,t) = \hat{\mathbf{e}}_x \mathcal{E}_t e^{\imath(k_{z2}z - \omega t)} \quad , \quad \vec{\mathcal{B}}_r(z,t) = \hat{\mathbf{e}}_y \frac{n_2 \mathcal{E}_t}{c} e^{\imath(k_{z2}z - \omega t)} \; . \tag{18.45}$$

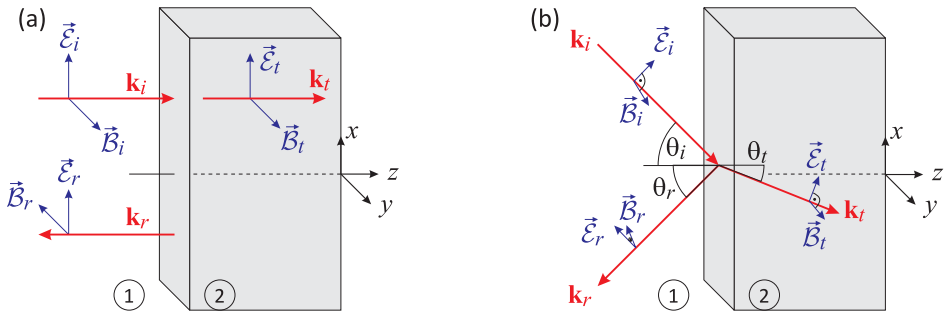

Figure 18.2: Electric and magnetic fields reflected and transmitted at an interface under (a) normal and (b) inclined incidence.

At the position $z = 0$ the total radiation must satisfy the boundary conditions. Since under normal incidence, there are only parallel components,

$$\vec{\mathcal{E}}_i(0,t) + \vec{\mathcal{E}}_r(0,t) = \vec{\mathcal{E}}_t(0,t) \quad , \quad \tfrac{1}{\mu_1}[\vec{\mathcal{B}}_i(0,t) + \vec{\mathcal{B}}_r(0,t)] = \tfrac{1}{\mu_2}\vec{\mathcal{B}}_t(0,t) \ . \tag{18.46}$$

Dividing all terms by $e^{-\imath\omega t}$,

$$\mathcal{E}_i + \mathcal{E}_r = \mathcal{E}_t \quad , \quad \tfrac{n_1}{\mu_1 c}[\mathcal{E}_i - \mathcal{E}_r] = \tfrac{n_2}{\mu_2 c}\mathcal{E}_t \ . \tag{18.47}$$

Solving the system of equations,

$$\boxed{\frac{\mathcal{E}_r}{\mathcal{E}_i} = \frac{1-\beta}{1+\beta} \quad , \quad \frac{\mathcal{E}_t}{\mathcal{E}_i} = \frac{2}{1+\beta}} \ , \tag{18.48}$$

defining

$$\beta \equiv \frac{\mu_1 n_2}{\mu_2 n_1} \ . \tag{18.49}$$

Example 99 (*Reflection on an air-glass interface*): We consider an air-glass interface, $n_1 = 1$ and $n_2 = 1.5$. Taking $\mu_1 = \mu_2 = \mu_0$ we have $\beta = 1.5$, and we calculate that the interface reflects the energy,

$$R \equiv \frac{I_r}{I_i} = \frac{\varepsilon_1 c_1 |\vec{\mathcal{E}}_r|^2}{\varepsilon_1 c_1 |\vec{\mathcal{E}}_i|^2} = \left(\frac{1-\beta}{1+\beta}\right)^2 = 0.04 \ ,$$

and transmits the energy,

$$T \equiv \frac{I_t}{I_i} = \frac{\varepsilon_2 c_2 |\vec{\mathcal{E}}_t|^2}{\varepsilon_1 c_1 |\vec{\mathcal{E}}_i|^2} = \frac{\varepsilon_2 c_2}{\varepsilon_1 c_1}\left(\frac{2}{1+\beta}\right)^2 = 0.96 \ .$$

We check $R + T = 1$.

18.1.6.2 Inclined incidence and geometric optics

When the wave strikes perpendicular to the interface, the polarization of the light is irrelevant. This is no longer true for inclined incidence, as shown in Fig. 18.2(b). In this case the Eqs. (18.43)-(18.45) must be generalized,

$$\vec{\mathcal{E}}_m(\mathbf{r},t) = \vec{\mathcal{E}}_{0m} e^{\imath(\mathbf{k}_m \cdot \mathbf{r} - \omega t)} \quad , \quad \vec{\mathcal{B}}_m(\mathbf{r},t) = \frac{n_m}{c}\hat{\mathbf{k}}_m \times \vec{\mathcal{E}}_m(\mathbf{r},t) \ , \tag{18.50}$$

for $m = i, r, t$. Obviously the frequency is the same for all waves, such that by inserting each wave into the wave equation we find,

$$k_i c_i = k_r c_r = k_t c_t = \omega \ , \tag{18.51}$$

with $c_m \equiv c/n_m$ and $c_i = c_r \equiv c_1$ and $c_t \equiv c_2$. We now need to join the fields $\vec{\mathcal{E}}_i + \vec{\mathcal{E}}_r$ and $\vec{\mathcal{B}}_i + \vec{\mathcal{B}}_r$ of one side of the interface with the fields $\vec{\mathcal{E}}_t$ and $\vec{\mathcal{B}}_t$ of the other side at the plane $z = 0$, respecting the boundary conditions (18.42). We get generic expressions,

$$(\cdot) e^{\imath(\mathbf{k}_i \cdot \mathbf{r} - \omega t)} + (\cdot) e^{\imath(\mathbf{k}_r \cdot \mathbf{r} - \omega t)} = (\cdot) e^{\imath(\mathbf{k}_t \cdot \mathbf{r} - \omega t)} \qquad \text{at} \qquad z = 0 \tag{18.52}$$

at all times t, where $(\cdot) \equiv \varepsilon_m \vec{\mathcal{E}}_m^{\perp}, \vec{\mathcal{E}}_m^{\parallel}, \vec{\mathcal{B}}_m^{\perp}, \frac{1}{\mu_m} \vec{\mathcal{B}}_m^{\parallel}$. Since the equation (18.52) must be valid at any point (x, y) of the plane $z = 0$, the exponential factors must be equal,

$$e^{\imath \mathbf{k}_i \cdot \mathbf{r}} = e^{\imath \mathbf{k}_r \cdot \mathbf{r}} = e^{\imath \mathbf{k}_t \cdot \mathbf{r}} \ , \tag{18.53}$$

that is,

$$\boxed{\mathbf{k}_i \cdot \hat{\mathbf{e}}_x = \mathbf{k}_r \cdot \hat{\mathbf{e}}_x = \mathbf{k}_t \cdot \hat{\mathbf{e}}_x \qquad \text{and} \qquad \mathbf{k}_i \cdot \hat{\mathbf{e}}_y = \mathbf{k}_r \cdot \hat{\mathbf{e}}_y = \mathbf{k}_t \cdot \hat{\mathbf{e}}_y} \ , \tag{18.54}$$

that is, the wavevectors $\mathbf{k}_i$, $\mathbf{k}_r$, $\mathbf{k}_t$ and the normal vector $\hat{\mathbf{e}}_z$ of the interface are in the same plane. We can orient the coordinate system such that $\mathbf{k}_i \cdot \hat{\mathbf{e}}_y \equiv 0$ (see Fig. 18.2). Defining the angles of incidence, reflection and refraction, we find,

$$\mathbf{k}_m \cdot \hat{\mathbf{e}}_x = k_i \sin\theta_i = k_r \sin\theta_r = k_t \sin\theta_t \ . \tag{18.55}$$

With (18.51) we deduce the *law of reflection*:

$$\boxed{\theta_i = \theta_r} \ , \tag{18.56}$$

and the *law of refraction* or *Snell's law*:

$$\boxed{\frac{\sin\theta_t}{\sin\theta_i} = \frac{n_1}{n_2}} \ . \tag{18.57}$$

The equations (18.54), (18.56), and (18.57) form the basis of geometric optics.

18.1.6.3 Polarization behavior and Fresnel's formulas

Going back to the condition (18.52) and eliminating the exponentials, we get,

$$\begin{aligned}
\text{for } \vec{\mathcal{B}}_m^{\parallel} \ : \quad & \tfrac{1}{\mu_1} \vec{\mathcal{B}}_i \cdot \hat{\mathbf{e}}_{x,y} + \tfrac{1}{\mu_1} \vec{\mathcal{B}}_r \cdot \hat{\mathbf{e}}_{x,y} &&= \tfrac{1}{\mu_2} \vec{\mathcal{B}}_t \cdot \hat{\mathbf{e}}_{x,y} \\
\text{for } \vec{\mathcal{E}}_m^{\parallel} \ : \quad & \vec{\mathcal{E}}_i \cdot \hat{\mathbf{e}}_{x,y} + \vec{\mathcal{E}}_r \cdot \hat{\mathbf{e}}_{x,y} &&= \vec{\mathcal{E}}_t \cdot \hat{\mathbf{e}}_{x,y} \\
\text{for } \vec{\mathcal{E}}_m^{\perp} \ : \quad & \varepsilon_1 \vec{\mathcal{E}}_i \cdot \hat{\mathbf{e}}_z + \varepsilon_1 \vec{\mathcal{E}}_r \cdot \hat{\mathbf{e}}_z &&= \varepsilon_2 \vec{\mathcal{E}}_t \cdot \hat{\mathbf{e}}_z \\
\text{for } \vec{\mathcal{B}}_m^{\perp} \ : \quad & \vec{\mathcal{B}}_i \cdot \hat{\mathbf{e}}_z + \vec{\mathcal{B}}_r \cdot \hat{\mathbf{e}}_z &&= \vec{\mathcal{B}}_t \cdot \hat{\mathbf{e}}_z \ .
\end{aligned} \tag{18.58}$$

We again orient the coordinate system such that $\mathbf{k}_i \cdot \hat{\mathbf{e}}_y \equiv 0$. We first assume, that the polarization of the incident field is within the plane of incidence (that is, the

plane spanned by the vectors $\mathbf{k}_i$ and $\mathbf{k}_r$), that is, $\vec{\mathcal{E}}_i \cdot \hat{\mathbf{e}}_y = 0 = \vec{\mathcal{B}}_i \cdot \hat{\mathbf{e}}_x$. This is called *p-polarization*. In this case, the conditions (18.58) become,

$$\begin{aligned}
\tfrac{1}{\mu_1}\vec{\mathcal{B}}_i \cdot \hat{\mathbf{e}}_y + \tfrac{1}{\mu_1}\vec{\mathcal{B}}_r \cdot \hat{\mathbf{e}}_y = \tfrac{1}{\mu_1}\mathcal{B}_i + \tfrac{1}{\mu_1}\mathcal{B}_r = \tfrac{1}{\mu_1 c_1}(\mathcal{E}_i - \mathcal{E}_r) &\stackrel{!}{=} \tfrac{1}{\mu_2 c_2}\mathcal{E}_t = \tfrac{1}{\mu_2}\mathcal{B}_t = \tfrac{1}{\mu_2}\vec{\mathcal{B}}_t \cdot \hat{\mathbf{e}}_y \\
\vec{\mathcal{E}}_i \cdot \hat{\mathbf{e}}_x + \vec{\mathcal{E}}_r \cdot \hat{\mathbf{e}}_x = \mathcal{E}_i \cos\theta_i + \mathcal{E}_r \cos\theta_r = (\mathcal{E}_i + \mathcal{E}_r)\cos\theta_r &\stackrel{!}{=} \mathcal{E}_t \cos\theta_t = \vec{\mathcal{E}}_t \cdot \hat{\mathbf{e}}_x \\
\varepsilon_1 \mathcal{E}_i \sin\theta_i + \varepsilon_1 \mathcal{E}_r \sin\theta_r = \varepsilon_1(\mathcal{E}_i - \mathcal{E}_r)\sin\theta_i &\stackrel{!}{=} \varepsilon_2 \mathcal{E}_t \sin\theta_t \\
0 &\stackrel{!}{=} 0 \ .
\end{aligned} \tag{18.59}$$

Using the abbreviation (18.49) and introducing another abbreviation,

$$\alpha \equiv \frac{\cos\theta_t}{\cos\theta_i} = \frac{\sqrt{1 - (n_1/n_2)^2 \sin^2\theta_i}}{\cos\theta_i} \ , \tag{18.60}$$

and solving the system of equations (18.59), we find *Fresnel's formula* for p-polarization [4],

$$\boxed{r_p \equiv \left.\frac{\mathcal{E}_r}{\mathcal{E}_i}\right|_p = \frac{\alpha - \beta}{\alpha + \beta} = \frac{n_1 \cos\theta_t - n_2 \cos\theta_i}{n_1 \cos\theta_t + n_2 \cos\theta_i} \quad \text{and} \quad t_p \equiv \left.\frac{\mathcal{E}_t}{\mathcal{E}_i}\right|_p = \frac{2}{\alpha + \beta}} \ . \tag{18.61}$$

We now assume that the polarization of the incident field is perpendicular to the plane of incidence, $\vec{\mathcal{E}}_i \cdot \hat{\mathbf{e}}_x = 0 = \vec{\mathcal{B}}_i \cdot \hat{\mathbf{e}}_y$. This is called *s-polarization*. In this case the equations (18.58) yield,

$$\begin{aligned}
\tfrac{1}{\mu_1}\vec{\mathcal{B}}_i \cdot \hat{\mathbf{e}}_x + \tfrac{1}{\mu_1}\vec{\mathcal{B}}_r \cdot \hat{\mathbf{e}}_x = \tfrac{1}{\mu_1 c_1}(\mathcal{E}_i \cos\theta_i - \mathcal{E}_r \cos\theta_r) &\stackrel{!}{=} \tfrac{1}{\mu_2 c_2}\mathcal{E}_t \cos\theta_t = \tfrac{1}{\mu_2}\vec{\mathcal{B}}_t \cdot \hat{\mathbf{e}}_x \\
\vec{\mathcal{E}}_i \cdot \hat{\mathbf{e}}_y + \vec{\mathcal{E}}_r \cdot \hat{\mathbf{e}}_y = \mathcal{E}_i + \mathcal{E}_r &\stackrel{!}{=} \mathcal{E}_t = \vec{\mathcal{E}}_t \cdot \hat{\mathbf{e}}_y \\
0 &\stackrel{!}{=} 0 \\
\mathcal{B}_i \sin\theta_i + \mathcal{B}_r \sin\theta_r = \tfrac{1}{c_1}(\mathcal{E}_i - \mathcal{E}_r)\sin\theta_i &\stackrel{!}{=} \tfrac{1}{c_2}\mathcal{E}_t \sin\theta_t = \mathcal{B}_t \sin\theta_t \ .
\end{aligned} \tag{18.62}$$

Similar to the case of p-polarization we obtain the Fresnel formulas for s-polarization,

$$\boxed{r_s \equiv \left.\frac{\mathcal{E}_r}{\mathcal{E}_i}\right|_s = -\frac{1 - \alpha\beta}{1 + \alpha\beta} = -\frac{n_1 \cos\theta_i - n_2 \cos\theta_t}{n_1 \cos\theta_i + n_2 \cos\theta_t} \quad \text{and} \quad t_s \equiv \left.\frac{\mathcal{E}_t}{\mathcal{E}_i}\right|_s = \frac{\sqrt{\alpha\beta}}{1 + \alpha\beta}} \ . \tag{18.63}$$

See also Exc. 18.1.8.23.

The power flux density incident on the interface is the projection of the intensity, $\vec{\mathcal{S}} \cdot \hat{\mathbf{e}}_z$. Therefore the intensities are,

$$I_m = \tfrac{1}{2}\varepsilon_1 c_m \mathcal{E}_m^2 \cos\theta_m \ , \tag{18.64}$$

[4] Using Snell's law (18.57) the Fresnel formulas can also be written as,

$$\begin{aligned}
r_p^2 &= \frac{\tan^2(\theta_i - \theta_t)}{\tan^2(\theta_i \theta_t)} \quad \text{and} \quad r_s^2 = \frac{\sin^2(\theta_i - \theta_t)}{\sin^2(\theta_i + \theta_t)} \\
t_p^2 &= \frac{\sin 2\theta_i \sin 2\theta_t}{\sin^2(\theta_i + \theta_t)\cos^2(\theta_i - \theta_t)} \quad \text{and} \quad t_s^2 = \frac{\sin 2\theta_i \sin 2\theta_t}{\sin^2(\theta_i + \theta_t)} \ .
\end{aligned}$$

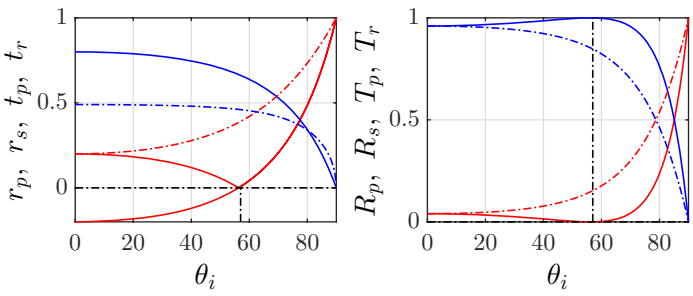

Figure 18.3: (code) Fresnel formulas for the transmitted (blue) and reflected (red) amplitude (left) and intensity (right). The dotted curve holds for s-polarization and the solid curve for p-polarization.

with $m = i, r, t$. Thus the reflection and the transmission are for p-polarization,

$$R_p = \left(\frac{\mathcal{E}_r}{\mathcal{E}_i}\right)_p^2 = \left(\frac{\alpha-\beta}{\alpha+\beta}\right)^2 \qquad \text{and} \qquad T_p = \frac{\varepsilon_2 c_2}{\varepsilon_1 c_1}\frac{\cos\theta_t}{\cos\theta_i}\left(\frac{\mathcal{E}_t}{\mathcal{E}_i}\right)_p^2 = \alpha\beta\left(\frac{2}{\alpha+\beta}\right)^2 = 1 - R_p \ . \tag{18.65}$$

For s-polarization we have,

$$R_s = \left(\frac{\mathcal{E}_r}{\mathcal{E}_i}\right)_s^2 = \left(\frac{1-\alpha\beta}{1+\alpha\beta}\right)^2 \qquad \text{and} \qquad T_s = \frac{\varepsilon_2 c_2}{\varepsilon_1 c_1}\frac{\cos\theta_t}{\cos\theta_i}\left(\frac{\mathcal{E}_t}{\mathcal{E}_i}\right)_s^2 = \alpha\beta\left(\frac{2}{1+\alpha\beta}\right)^2 = 1 - R_s \ . \tag{18.66}$$

18.1.6.4 The Brewster angle

For an angle of incidence of $\theta_i = 0°$ ($\alpha = 1$) we recover the expressions (18.48). For $\theta_i = 90°$ ($\alpha \to \infty$), all light is reflected. Looking at the formula (18.61) it is interesting to note the existence of an angle, where the reflection vanishes for the case of the s-polarization. It is given by $\alpha = \beta$, that is,

$$\sin^2\theta_{i,B} \equiv \sin^2\theta_i = \frac{1-\beta^2}{(n_1/n_2)^2 - \beta^2} \ . \tag{18.67}$$

θ_B is the *Brewster angle*. When $\mu_1 \simeq \mu_2$ we can simplify to,

$$\boxed{\theta_{i,B} = \arcsin\frac{1-\beta^2}{(n_1/n_2)^2-\beta^2} \simeq \arctan\frac{n_2}{n_1}} \ . \tag{18.68}$$

That is, a p-polarized beam of light traveling in a vacuum and encountering a dielectric with refractive index $n_2 = 1.5$ under the angle of $\theta_{i,B} \approx 56.3°$ is fully transmitted. This is seen in Fig. 18.3(right), where the reflected intensity I_r/I_0 of p-polarized light vanishes at a specific angle, and illustrated in Fig. 18.4(a).

18.1.6.5 Internal total reflection and the Goos-Hänchen shift

We now consider a light beam traveling in a dielectric with refractive index n_1 and encountering an interface to an optically less dense medium, $n_2 < n_1$, as illustrated

in Fig. 18.4(b). Increasing the angle of incidence θ_i, according to Snell's law (18.57) we will come to a point, where the outgoing angle reaches $\theta_t = 90°$. Snell's law gives the critical angle for this to happen,

$$\boxed{\theta_{i,tot} = \arcsin \frac{n_2}{n_1}} \ . \tag{18.69}$$

For an index of refraction $n_1 = 1.5$ this angle is $\theta_{i,tot} \approx 41.8°$. Above this angle, $\theta_i > \theta_{i,tot}$, all energy is reflected by the optically denser medium. This phenomenon of *total internal reflection* is used e.g. to guide light in optical fibers. Nevertheless, the fields do not completely disappear in the medium 2 but form, a so-called *evanescent wave*, which is exponentially attenuated and does not carry energy into the medium 2. A quick way to construct the evanescent wave consists in simply extending to the complex domain the formulas obtained for inclined incidence of light on interfaces. For $\theta_i > \theta_{i,tot}$,

$$\sin\theta_t = \frac{n_1}{n_2}\sin\theta_i > \frac{n_1}{n_2}\sin\theta_{i,tot} = \sin\theta_{t,tot} = 1 \ , \tag{18.70}$$

Obviously θ_t can no longer be interpreted as an angle! We will show in Exc. 18.1.8.24 that, for the geometry illustrated in Fig. 18.4(b), the electric field generated in region 2 is given by,

$$\vec{\mathcal{E}}_t(\mathbf{r},t) = \vec{\mathcal{E}}_0 e^{-\kappa z} e^{\imath(kx-\omega t)} \ , \tag{18.71}$$

where

$$\kappa \equiv \tfrac{\omega}{c}\sqrt{(n_1\sin\theta_i)^2 - n_2^2} \qquad \text{and} \qquad k \equiv \tfrac{\omega n_1}{c}\sin\theta_i \ . \tag{18.72}$$

(18.71) is a wave propagating in x-direction, parallel to the interface, and being

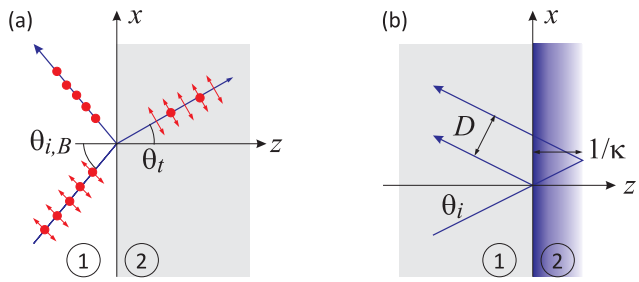

Figure 18.4: (a) Illustration of the effect of the Brewster angle on the polarization of light. (b) Illustration of the Goos-Hänchen shift.

attenuated in z-direction. The penetration depth of is κ^{-1}. Also in Exc. 18.1.8.24 we will show that for both polarizations p and s the reflection coefficient is 1, which confirms that there is no energy transported into the medium 2.

Example 100 (*The Goos-Hänchen shift*): The fact that the light wave penetrates region 2 up to a depth of κ^{-1} causes a transverse displacement of the wave known as *Goos-Hänchen shift* named after *Gustav Goos* and *Hilda Hänchen*. From Fig. 18.4 it is easy to verify that this displacement is of the order of magnitude $D \simeq \frac{2}{\kappa}\sin\theta_i$. It can be measured taking a beam of light with finite radial extent.

18.1.7 Transfer matrix formalism

For a propagating wave the amplitude of the field at a point $z = 0$ can be related to another point z via $\vec{\mathcal{E}}_z = M\vec{\mathcal{E}}_0$, where M is a phase factor of the type $e^{\imath kz}$. A counter-propagating wave (e.g. generated by partial reflection at an interface) suffers, over the same distance, a phase shift of $e^{-\imath kz}$. Since both waves interfere, it is useful to set up a model describing in a compact manner the amplitude and phase variations of the two counterpropagating waves along the optical axis. The *transfer matrix formalism* represents such a model.

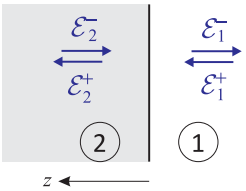

Figure 18.5: Illustration of the transfer matrix formalism.

18.1.7.1 The $\mathcal{T}$-matrix

Let us consider a beam of light propagating along the z-axis toward $+\infty$ through an inhomogeneous dielectric medium described by the refractive index $n(z)$. Each interface where the refractive index varies causes a partial reflection of the beam into the opposite direction. The fields reflected at different positions z interfere constructively or destructively depending on the accumulated phase. To address the problem mathematically, we divide the medium into layers treated as homogeneous and delimited by interfaces located at positions z, as shown in Fig. 18.5. We define the complex transfer matrix $\mathcal{T}_{12}$ describing the transition between from medium 1 to medium 2 by,

$$\boxed{\begin{pmatrix}\mathcal{E}_2^+\\ \mathcal{E}_2^-\end{pmatrix} = \mathcal{T}_{12}\begin{pmatrix}\mathcal{E}_1^+\\ \mathcal{E}_1^-\end{pmatrix}}\,. \tag{18.73}$$

Here, the fields $\mathcal{E}^\pm$ propagate toward $\pm\infty$. That is, the fields $\mathcal{E}_1^+$ and $\mathcal{E}_2^-$ move toward the interface and the fields $\mathcal{E}_1^-$ and $\mathcal{E}_2^+$ move away from the interface. In (18.48) we showed that the reflectivity and the transmissivity of the interface for a transition from region 1 to region 2 are given by,

$$r_{12} = \frac{n_1 - n_2}{n_1 + n_2} \qquad \text{and} \qquad t_{12} = \frac{2n_1}{n_1 + n_2}\,. \tag{18.74}$$

Obviously, we have $r_{21} = -r_{12}$ and $t_{21} = \frac{n_2}{n_1}t_{12}$. Therefore,

$$\mathcal{E}_2^+ = t_{12}\mathcal{E}_1^+ + r_{21}\mathcal{E}_2^- \qquad \text{and} \qquad \mathcal{E}_1^- = t_{21}\mathcal{E}_2^- + r_{12}\mathcal{E}_1^+\,, \tag{18.75}$$

that is,

$$\mathcal{E}_2^+ = \left(t_{12} - \tfrac{r_{12}r_{21}}{t_{21}}\right)\mathcal{E}_1^+ + \tfrac{r_{21}}{t_{21}}\mathcal{E}_1^- \qquad \text{and} \qquad \mathcal{E}_2^- = -\tfrac{r_{12}}{t_{21}}\mathcal{E}_1^+ + \tfrac{1}{t_{21}}\mathcal{E}_1^-\,. \tag{18.76}$$

The matrix, therefore, is,

$$\boxed{\mathcal{T}_{12} = \begin{pmatrix} t_{12} - \frac{r_{12}r_{21}}{t_{21}} & \frac{r_{21}}{t_{21}} \\ -\frac{r_{12}}{t_{21}} & \frac{1}{t_{21}} \end{pmatrix} = \frac{1}{2n_2}\begin{pmatrix} n_2+n_1 & n_2-n_1 \\ n_2-n_1 & n_2+n_1 \end{pmatrix}} \,. \tag{18.77}$$

The determinant is $\det \mathcal{T} = \frac{t_{12}}{t_{21}} = \frac{n_1}{n_2}$.

The simple propagation over a distance Δz through a homogeneous medium simply causes a phase shift, since $\mathcal{E}_z^+ = e^{\imath kz}\mathcal{E}_0^+$ and $\mathcal{E}_0^- = e^{\imath kz}\mathcal{E}_z^-$. The corresponding transfer matrix is,

$$\boxed{\mathcal{T}_{\Delta z} = \begin{pmatrix} e^{\imath k\Delta z} & 0 \\ 0 & e^{-\imath k\Delta z} \end{pmatrix}} \,. \tag{18.78}$$

Absorption losses can attenuate the beam. This can be taken into account via an absorption coefficient α in the matrix,

$$\boxed{\mathcal{T}_{abs} = \begin{pmatrix} e^{-\alpha} & 0 \\ 0 & e^{\alpha} \end{pmatrix}} \,. \tag{18.79}$$

satisfying $\det \mathcal{T} = 1$.

18.1.7.2 AR and HR coating

Concatenating the matrices (18.77) and (18.78), $\mathcal{M} = \mathcal{T}_{\Delta z}\mathcal{T}_{12}\mathcal{T}_{abs}$, we can now describe the transmission of a light beam through a dielectric layer with refractive index n_2 and thickness Δz.

Example 101 (*Anti-reflection coating*): Here we consider the transition between a medium n_0 through a thin layer n_1 of thickness $\lambda/4$ to a medium n_2. The transition is described by the concatenation of three matrices,

$$\begin{pmatrix} \mathcal{E}_2^+ \\ 0 \end{pmatrix} = \mathcal{T}_{12}\mathcal{T}_{\lambda/4}\mathcal{T}_{01}\begin{pmatrix} \mathcal{E}_0^+ \\ \mathcal{E}_0^- \end{pmatrix} = \begin{pmatrix} M_{11} & M_{12} \\ M_{21} & M_{22} \end{pmatrix}\begin{pmatrix} \mathcal{E}_0^+ \\ \mathcal{E}_0^- \end{pmatrix} = \begin{pmatrix} M_{11} - \frac{M_{12}M_{21}}{M_{22}} \\ 0 \end{pmatrix}\mathcal{E}_0^+ \,.$$

The total matrix is,

$$\begin{aligned} \mathcal{M} &= \frac{1}{2n_2}\begin{pmatrix} n_2+n_1 & n_2-n_1 \\ n_2-n_1 & n_2+n_1 \end{pmatrix}\begin{pmatrix} e^{\imath\pi/2} & 0 \\ 0 & e^{-\imath\pi/2} \end{pmatrix}\frac{1}{2n_1}\begin{pmatrix} n_1+n_0 & n_1-n_0 \\ n_1-n_0 & n_1+n_0 \end{pmatrix} \\ &= \frac{\imath}{2n_1n_2}\begin{pmatrix} n_1^2+n_0n_2 & n_1^2-n_0n_2 \\ -n_1^2+n_0n_2 & -n_1^2-n_0n_2 \end{pmatrix} \,. \end{aligned}$$

Finally, we obtain the fields,

$$\begin{aligned} \mathcal{E}_2^+ &= M_{11} - \frac{M_{12}M_{21}}{M_{22}}\mathcal{E}_0^+ = \frac{2in_0n_1}{n_1^2+n_0n_2}\mathcal{E}_0^+ \overset{n_1^2\equiv n_0n_2}{\longrightarrow} \frac{in_0}{n_1}\mathcal{E}_0^+ \\ \mathcal{E}_0^- &= -\frac{M_{21}}{M_{22}}\mathcal{E}_0^+ = \frac{n_1^2-n_0n_2}{n_1^2+n_0n_2}\mathcal{E}_0^+ \overset{n_1^2\equiv n_0n_2}{\longrightarrow} 0 \,. \end{aligned}$$

Choosing $n_1^2 \equiv n_0 n_2$ we can cancel out the reflection and maximize the transmission. We check,

$$T = \frac{I_t}{I_i} = \frac{\varepsilon_2 c_2 |\mathcal{E}_2^+|^2}{\varepsilon_0 c_0 |\mathcal{E}_0^+|^2} = \frac{\frac{n_2^2}{c^2}\frac{c}{n_2}\left|\frac{2\imath n_0 n_1}{n_1^2+n_0 n_2}\right|^2}{\frac{n_0^2}{c^2}\frac{c}{n_0}} = \frac{4 n_0 n_1^2 n_2}{(n_1^2+n_0 n_2)^2}$$

$$R = \frac{I_r}{I_i} = \frac{\varepsilon_0 c_0 |\mathcal{E}_0^-|^2}{\varepsilon_0 c_0 |\mathcal{E}_0^+|^2} = \left|\frac{n_1^2 - n_0 n_2}{n_1^2 + n_0 n_2}\right|^2 = 1 - T \ .$$

Fig. 18.6 shows the transmission through a stack of dielectric layers. The transfer matrix is,

$$\mathcal{M} = (\mathcal{T}_{21}\mathcal{T}_{\Delta z_2}\mathcal{T}_{abs}\mathcal{T}_{12}\mathcal{T}_{\Delta z_1}\mathcal{T}_{abs})^N \mathcal{T}_{01} \ . \tag{18.80}$$

We observe a large reflection band (600..660 nm) called one-dimensional *photonic band gap*. Dielectric mirrors can, nowadays, achieve reflections up to $R = 99.9995\%$, while the reflectivity of metal mirrors is always limited by losses.

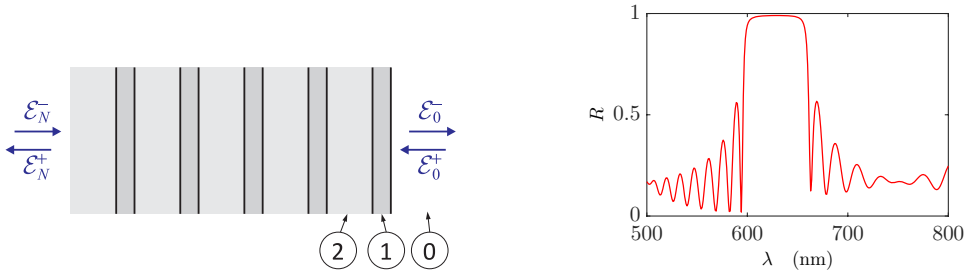

Figure 18.6: (code) Reflection by a high reflecting mirror made of 10 layers with $n_1 = 2.4$ and $\Delta z_1 = 80$ nm alternating with 10 layers with $n_2 = 1.5$ and $\Delta z_2 = 500$ nm. The absorption coefficient for each layer is supposed to be $\alpha = 0.2\%$. The beam impinges from vacuum, $n_0 = 1$.

Example 102 (*Use of transfer matrices in cavities*): The transfer matrix formalism can be used for *impedance matching* the reflection of optical cavities [5]. In order to deserve the label *mode*, a geometric configuration of a cavity must be self-consistent, that is, any field $\mathcal{E}^{\pm}(z)$ wanting to fill the mode must be the same after a round-trip around the cavity.
We proceed to calculating the real and imaginary parts of the transfer matrices,

$$\begin{pmatrix} \mathcal{E}_z^+ + \mathcal{E}_z^- \\ \mathcal{E}_z^+ - \mathcal{E}_z^- \end{pmatrix} = \mathcal{M} \begin{pmatrix} \mathcal{E}_0^+ + \mathcal{E}_0^- \\ \mathcal{E}_0^+ - \mathcal{E}_0^- \end{pmatrix} \ .$$

For example, the phase shift due to free space propagation is described by the matrix,

$$\mathcal{M}_{phase} = \begin{pmatrix} \cos kz & \imath \sin kz \\ \imath \sin kz & \cos kz \end{pmatrix} \ .$$

[5] Not to be confused with *phase matching* of optical cavities, which is an important requirement for coupling light efficiently into a cavity, but must be treated within the theory of Gaussian optics.

Reflection and transmission from a classical object with can be written as, $\vec{\mathcal{E}}_z^+ = t_a\mathcal{E}_0^+ + r_a\vec{\mathcal{E}}_z^-$ and $\mathcal{E}_0^- = t_a\vec{\mathcal{E}}_z^- - r_a\mathcal{E}_0^+$, where $r_a^2 + t_a^2 = 1$. Transforming to the basis $\mathcal{E}_j^+ \pm \mathcal{E}_j^-$, we obtain,

$$\mathcal{M}_{pump} = \begin{pmatrix} \frac{1+r_a}{t_a} & 0 \\ 0 & \frac{1-r_a}{t_a} \end{pmatrix} .$$

Let us assume that the cavity is pumped from one side by the field $\mathcal{E}_{in}$. We get after a round-trip,

$$\begin{pmatrix} \mathcal{E}^+ + \mathcal{E}^- \\ \mathcal{E}^+ - \mathcal{E}^- \end{pmatrix} = \mathcal{M} \begin{pmatrix} \mathcal{E}^+ + \mathcal{E}^- \\ \mathcal{E}^+ - \mathcal{E}^- \end{pmatrix} + t_{in} \begin{pmatrix} \mathcal{E}_{in}^+ + \mathcal{E}_{in}^- \\ \mathcal{E}_{in}^+ - \mathcal{E}_{in}^- \end{pmatrix} = t_{in}(1-\mathcal{M})^{-1} \begin{pmatrix} \mathcal{E}_{in}^+ + \mathcal{E}_{in}^- \\ \mathcal{E}_{in}^+ - \mathcal{E}_{in}^- \end{pmatrix} .$$

The phase minimum of the determinant $\det(1-\mathcal{M})$ determines the eigenvalues of the cavity. For a round-trip with losses in the mirrors the determinant is $\det(1 - \mathcal{M}_{phase}\mathcal{M}_{loss}) = 2 - (t_c + t_c^{-1})\cos\phi$, where t_c is the total transmission coefficient of the cavity. Phase minima always occur when $\phi = 2\pi n$. The amplification of the intensity at theses phases is given by,

$$\frac{I_{cav}}{I_{in}} = \frac{|\mathcal{E}^+ + \mathcal{E}^-|^2}{|\mathcal{E}_{in}^+ + \mathcal{E}_{in}^-|^2} = \frac{t_{in}^2}{(1-t_c)^2} .$$

Exc. 18.1.8.25 can be solved using transfer matrices.

The transfer matrix formalism can also be applied to modeling the passage of a laser beam through a gas of two levels atoms periodically organized in one dimension like a stack of pancakes [1220, 1158]. One only has to consider that the variation of the density of the gas along the optical axis generates a spatial modulation of the refractive index [6].

18.1.8 Exercises

18.1.8.1 Ex: Wave equation and Galilei transform

Show that any function of the form $y(x,t) = f(x-vt)$ or $y(x,t) = g(x+vt)$ satisfies the wave equation.

Solution: *We have,*

$$\frac{1}{v^2}\frac{\partial^2 y}{\partial t^2} + \frac{\partial^2 y}{\partial x^2} = \frac{1}{v^2}\frac{\partial^2 f(x-vt)}{\partial t^2} + \frac{\partial^2 f(x-vt)}{\partial x^2} = \frac{1}{v^2}\frac{\partial}{\partial t}(-v)f' + \frac{\partial}{\partial x}f' = \frac{1}{v^2}(-v)^2 f'' + f'' = 0 .$$

[6] We will discuss this system in Sec. 39.4.2 .

18.1.8.2 Ex: Plane waves

Consider a set of solutions for plane electromagnetic waves in vacuum, whose fields (electric or magnetic) are described by the real part of the functions $\mathbf{u}(\mathbf{r},t) = \mathbf{A}e^{\imath(\mathbf{k}\cdot\mathbf{r}-\omega t)}$, with constant phase $(\mathbf{k}\cdot\mathbf{r}-\omega t)$. In these expressions, $\mathbf{k}$ is the wavevector (determining the propagation direction of the wave) and $\omega = vk$ is the angular frequency, where $v = 1/\sqrt{\varepsilon\mu}$ is the propagation velocity of the waves.
a. Show that the divergent $\mathbf{u}(x,t)$ satisfies: $\nabla\cdot\mathbf{u} = \imath\mathbf{k}\cdot\mathbf{u}$;
b. Show that the rotation $\mathbf{u}(x,t)$ satisfies: $\nabla\times\mathbf{u} = \imath\mathbf{k}\times\mathbf{u}$;
c. Show that the waves are transverse and that the vectors $\vec{\mathcal{E}}$, $\vec{\mathcal{B}}$, and $\mathbf{k}$ are mutually perpendicular.

Solution: *a. First, we note that* $\mathbf{u}(\mathbf{r},t) = \mathbf{A}e^{\imath(k_x x+k_y y+k_z z-\omega t)}$. *Hence,*

$$\begin{aligned}\frac{\partial}{\partial x}\mathbf{u}(\mathbf{r},t) &= \imath k_x\mathbf{A}e^{\imath(k_x x+k_y y+k_z z-\omega t)}\\ \frac{\partial}{\partial y}\mathbf{u}(\mathbf{r},t) &= \imath k_y\mathbf{A}e^{\imath(k_x x+k_y y+k_z z-\omega t)}\\ \frac{\partial}{\partial z}\mathbf{u}(\mathbf{r},t) &= \imath k_z\mathbf{A}e^{\imath(k_x x+k_y y+k_z z-\omega t)}\ ,\end{aligned}$$

which can be generalized in the form:

$$\frac{\partial}{\partial x_j}\mathbf{u}(\mathbf{r},t) = \imath k_j\mathbf{A}e^{\imath(\sum_j k_j x_j-\omega t)}\ .$$

thus, the divergent is:

$$\nabla\cdot\mathbf{u} = \sum_j \frac{\partial}{\partial x_j}u_j(\mathbf{r},t) = \imath k_x A_x e^{\imath(\mathbf{k}\cdot\mathbf{r}-\omega t)} + \imath k_y A_y e^{\imath(\mathbf{k}\cdot\mathbf{r}-\omega t)} + \imath k_z A_z e^{\imath(\mathbf{k}\cdot\mathbf{r}-\omega t)} = \imath\mathbf{k}\cdot\mathbf{u}\ .$$

Therefore,

$$\nabla\cdot\mathbf{u} = \imath\mathbf{k}\cdot\mathbf{u}\ .$$

b. This can be proved analogously by calculating the determinant or the properties of the Levi-Civita tensor:

$$(\nabla\times\mathbf{u})_i = \epsilon_{ijk}\frac{\partial}{\partial x_j}u_k = \epsilon_{ijk}\frac{\partial}{\partial x_j}A_k e^{\imath(\mathbf{k}\cdot\mathbf{r}-\omega t)} = \epsilon_{ijk}(\imath k_j)A_k e^{\imath(\mathbf{k}\cdot\mathbf{r}-\omega t)} = \imath\epsilon_{ijk}k_j u_k = \imath(\mathbf{k}\times\mathbf{u})_i\ .$$

If it holds for the component i, it holds for every component:

$$\nabla\times\mathbf{u} = \imath\mathbf{k}\times\mathbf{u}\ .$$

c. Since $\vec{\mathcal{E}}(\mathbf{r},t)$ *and* $\vec{\mathcal{B}}(\mathbf{r},t)$ *are described by the real part of* $\mathbf{u}(\mathbf{r},t)$, *we get,*

$$\begin{aligned}\vec{\mathcal{E}}(\mathbf{r},t) &= \mathfrak{Re}\ [\hat{\mathbf{e}}_0 e^{\imath(\mathbf{k}\cdot x-\omega t)}]\\ \vec{\mathcal{B}}(\mathbf{r},t) &= \mathfrak{Re}\ [\vec{\mathcal{B}}_0 e^{\imath(\mathbf{k}\cdot x-\omega t)}]\ .\end{aligned}$$

Thus, using the result of item (a) and the divergence equations, we have:

$$\nabla \cdot \vec{\mathcal{E}}(\mathbf{r},t) = 0 \implies \mathbf{k} \cdot \vec{\mathcal{E}} = 0$$
$$\nabla \cdot \vec{\mathcal{B}}(\mathbf{r},t) = 0 \implies \mathbf{k} \cdot \vec{\mathcal{B}} = 0 \ .$$

from what we conclude, that the waves are transverse, that is, $\vec{\mathcal{E}}$ and $\vec{\mathcal{B}}$ are perpendicular to $\mathbf{k}$. We also verify that the time derivative of $\mathbf{u}(\mathbf{r},t)$ satisfies:

$$\frac{\partial}{\partial t}\mathbf{u}(\mathbf{r},t) = -\imath\omega\mathbf{A}e^{\imath(k_x x + k_y y + k_z z - \omega t)} = -\imath\omega\mathbf{u}(\mathbf{r},t) \ .$$

(Just do one of the following options:)
And, similarly, using the result of item (b) and Ampère's equation, we have:

$$\nabla \times \vec{\mathcal{B}}(\mathbf{r},t) = \mu\varepsilon\frac{\partial}{\partial t}\vec{\mathcal{E}}(\mathbf{r},t) \implies \imath\mathbf{k} \times \vec{\mathcal{B}} = -\imath\omega\mu\varepsilon\vec{\mathcal{E}} \implies \vec{\mathcal{E}} = -\frac{\mathbf{k} \times \vec{\mathcal{B}}}{k\sqrt{\mu\varepsilon}} \ .$$

And, similarly, using the result of item (b) and Faraday's equation, we have:

$$\nabla \times \vec{\mathcal{E}}(\mathbf{r},t) = -\frac{\partial}{\partial t}\vec{\mathcal{B}}(\mathbf{r},t) \implies \imath\mathbf{k} \times \vec{\mathcal{E}} = \imath\omega\vec{\mathcal{B}} \implies \vec{\mathcal{B}} = \frac{\mathbf{k} \times \vec{\mathcal{E}}}{k/\sqrt{\mu\varepsilon}} \ .$$

which demonstrates that the vectors $\vec{\mathcal{E}}$, $\vec{\mathcal{B}}$, and $\mathbf{k}$ are mutually perpendicular.

18.1.8.3 Ex: Polarization of a wave in vacuum

A transverse electromagnetic wave propagates through an isotropic, non-conducting medium without charges (vacuum) in positive z-direction. The projection of the vector of the electric field on the plane x-y has the form,

$$\vec{\mathcal{E}} = \vec{\mathcal{E}}_0 \sin(kz - \omega t) = (\mathcal{E}_{0x}, \mathcal{E}_{0y}, 0)\sin(kz - \omega t) \ .$$

a. Illustrate the motion of the electric field vector by a scheme. How is the wave polarized?
b. Show from Maxwell's equations, that the magnetic field vector can be written as,

$$\vec{\mathcal{B}}(\mathbf{r},t) = \frac{1}{\omega}(\mathbf{k} \times \vec{\mathcal{E}})$$

with the wavevector $\mathbf{k} = k\hat{\mathbf{e}}_z$.
c. Calculate the energy flux of the wave (Poynting vector) $\vec{\mathcal{S}}(\mathbf{r},t)$ as a function of the (phase) velocity of the wave c_0. How does the phase change in other media ($\mu \neq \mu_0$ and $\varepsilon \neq \varepsilon_0$)? What does this mean for $\vec{\mathcal{S}}(\mathbf{r},t)$.

Solution: *a. The wave is linearly polarized in the plane $\vec{\mathcal{E}}_0 = \vec{\mathcal{E}}_{0x}\hat{\mathbf{e}}_x + \vec{\mathcal{E}}_{0y}\hat{\mathbf{e}}_y$.*
b. We insert the electric field into Maxwell's second law,

$$\nabla \times \vec{\mathcal{E}} = \begin{pmatrix} -\partial_z\vec{\mathcal{E}}_y \\ \partial_z\vec{\mathcal{E}}_x \\ 0 \end{pmatrix} = \begin{pmatrix} -k\vec{\mathcal{E}}_{0y} \\ k\vec{\mathcal{E}}_{0x} \\ 0 \end{pmatrix} \cos(kz - \omega t) = k\hat{\mathbf{e}}_z \times \vec{\mathcal{E}}_0 \cos(kz - \omega t) \ .$$

Integrated in time we obtain the magnetic field,

$$\vec{\mathcal{B}} = -\int_0^t \nabla\times\vec{\mathcal{E}}dt' = -k\hat{\mathbf{e}}_z\times\vec{\mathcal{E}}_0\int_0^t \cos(kz-\omega t)dt' = \frac{k}{\omega}\hat{\mathbf{e}}_z\times\vec{\mathcal{E}}_0\sin(kz-\omega t) = \frac{k}{\omega}\hat{\mathbf{e}}_z\times\vec{\mathcal{E}}\ .$$

c. The Poynting vector then becomes,

$$\vec{\mathcal{S}} = \frac{1}{\mu}\vec{\mathcal{E}}\times\vec{\mathcal{B}} = \frac{1}{\mu}\vec{\mathcal{E}}\times\frac{1}{c}(\hat{\mathbf{e}}_z\times\vec{\mathcal{E}}) = \sqrt{\frac{\varepsilon}{\mu}}\vec{\mathcal{E}}^2\hat{\mathbf{e}}_k\ .$$

The intensity is,

$$I = |\vec{\mathcal{S}}| = \sqrt{\frac{\varepsilon\mu_0}{\varepsilon_0\mu}}I_{vac}\ .$$

Apparently, part of the energy transported by an electromagnetic wave through a dielectric is due to a polarization wave $\vec{\mathcal{P}}(\mathbf{r},t)$.

18.1.8.4 Ex: Jones matrices for a three-beam MOT

A three-beam magneto-optical trap (MOT) is characterized by the fact that each of three linearly polarized laser beams passes through a $\lambda/4$-waveplate rotated in a way to leave them circularly polarized. Then the beam traverses the MOT a first time, behind the MOT it passes through a second waveplate, and being finally reflected by a mirror, it makes all the way back, as shown in the figure. Show that the polarization of the laser beam at the position of the mirror is always *linear* independently of the rotation angle of the second waveplate.

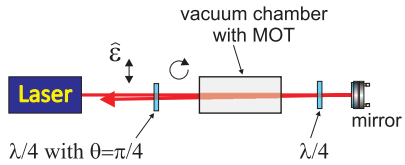

Figure 18.7: One of three retroreflected beams of a MOT.

Solution: *We use the Jones matrices for the $\lambda/4$ and $\lambda/2$-waveplates. To obtain the polarizations $\sigma^{\mp}$, the $\lambda/4$-waveplate must be rotated by $\pm 45°$:*

$$M_{\lambda/4}(\pm\tfrac{\pi}{4})\begin{pmatrix}1\\0\end{pmatrix} = \frac{e^{\imath\pi/4}}{\sqrt{2}}\begin{pmatrix}1\\ e^{\mp\imath\pi/2}\end{pmatrix} \propto \begin{pmatrix}1\\ \mp\imath\end{pmatrix}\ .$$

Now, passing through two $\lambda/4$-waveplates, we get,

$$M_{\lambda/4}(\phi)M_{\lambda/4}(\tfrac{\pi}{4})\begin{pmatrix}1\\0\end{pmatrix} = \begin{pmatrix}-\frac{1}{2}+\frac{\imath}{2}+\cos^2\phi-\imath\sin\phi\cos\phi\\ -\imath\left(-\frac{1}{2}-\frac{\imath}{2}+\cos^2\phi-\imath\sin\phi\cos\phi\right)\end{pmatrix} = -\tfrac{1}{2}(\imath+e^{-2\imath\phi})\begin{pmatrix}1\\ \frac{1+\sin 2\phi}{\cos 2\phi}\end{pmatrix}\ .$$

That is, the light is linearly polarized independently on the rotation angle ϕ. After the second passage through the second $\lambda/4$-waveplate, we get,

$$M_{\lambda/4}(\phi)^2 M_{\lambda/4}(\tfrac{\pi}{4}) \begin{pmatrix} 1 \\ 0 \end{pmatrix} = \begin{pmatrix} (\frac{1}{2}+\frac{\imath}{2})\cos 2\phi + (\frac{1}{2}-\frac{\imath}{2})\sin 2\phi \\ (\frac{1}{2}-\frac{\imath}{2})\cos 2\phi - (\frac{1}{2}+\frac{\imath}{2})\sin 2\phi \end{pmatrix} = \tfrac{1}{\sqrt{2}}(e^{\imath\pi/4}\cos 2\phi + e^{-\imath\pi/4}\sin 2\phi) \begin{pmatrix} 1 \\ -\imath \end{pmatrix} .$$

That is, the light is circularly polarized independently on the rotation angle ϕ. Finally, after the second passage through the first $\lambda/4$-waveplate, we get,

$$M_{\lambda/4}(\tfrac{\pi}{4}) M_{\lambda/4}(\phi) M_{\lambda/4}(\phi) M_{\lambda/4}\left(\tfrac{\pi}{4}\right) \begin{pmatrix} 1 \\ 0 \end{pmatrix} = \begin{pmatrix} \imath e^{-2\imath\phi} \\ 0 \end{pmatrix} .$$

Hence, after the fourth transmission, we always have linearly polarized light with the same polarization as the incident beam, and we see that the norm is preserved.

18.1.8.5 Ex: Temporal average of waves in complex notation

In complex notation there is a practical recipe for finding the temporal average of a product of waves. Consider $f(\mathbf{r},t) = \cos(\mathbf{k}\cdot\mathbf{r} - \omega t + \delta_a)$ and $g(\mathbf{r},t) = \cos(\mathbf{k}\cdot\mathbf{r} - \omega t + \delta_b)$. Show $\overline{fg} = \frac{1}{2}\mathfrak{Re}\,(\tilde{f}\tilde{g}^*)$. Note, that this only works, when the two waves have the same wavevector $\mathbf{k}$ and the same frequency ω, but they may have arbitrary amplitudes and phases. For example,

$$\langle u \rangle = \tfrac{1}{4}\mathfrak{Re}\,(\varepsilon_0 \vec{\tilde{\mathcal{E}}}\cdot\vec{\tilde{\mathcal{E}}}^* + \tfrac{1}{\mu_0}\vec{\tilde{\mathcal{B}}}\cdot\vec{\tilde{\mathcal{B}}}^*) \qquad \text{and} \qquad \langle \vec{\mathcal{S}} \rangle = \tfrac{1}{2\mu_0}\mathfrak{Re}\,(\vec{\tilde{\mathcal{E}}}\times\vec{\tilde{\mathcal{B}}}^*) .$$

Solution: *In complex notation,*

$$\tilde{f}(\mathbf{r},t) = e^{\imath(\mathbf{k}\cdot\mathbf{r}-\omega t+\delta_a)} \qquad \textit{and} \qquad \tilde{g}(\mathbf{r},t) = e^{\imath(\mathbf{k}\cdot\mathbf{r}-\omega t+\delta_b)} ,$$

we calculate on one hand,

$$\begin{aligned} \overline{fg} &= \frac{\omega}{2\pi}\int_0^{2\pi/\omega} \cos(\mathbf{k}\cdot\mathbf{r}-\omega t+\delta_a)\cos(\mathbf{k}\cdot\mathbf{r}-\omega t+\delta_b)dt \\ &= \frac{\omega}{2\pi}\int_0^{2\pi/\omega} \left[\tfrac{1}{2}\cos(\delta_a-\delta_b) + \tfrac{1}{2}\cos(2\mathbf{k}\cdot\mathbf{r}-2\omega t+\delta_a+\delta_b)\right] dt = \tfrac{1}{2}\cos(\delta_a-\delta_b) . \end{aligned}$$

On the other hand, we have,

$$\tfrac{1}{2}\mathfrak{Re}\,(\tilde{f}\tilde{g}^*) = \tfrac{1}{2}\mathfrak{Re}\,\left[e^{\imath(\mathbf{k}\cdot\mathbf{r}-\omega t+\delta_a)}e^{-\imath(\mathbf{k}\cdot\mathbf{r}-\omega t+\delta_b)}\right] = \tfrac{1}{2}\mathfrak{Re}\; e^{\imath(\delta_a-\delta_b)} = \tfrac{1}{2}\cos(\delta_a-\delta_b) .$$

18.1.8.6 Ex: Radiation pressure of a plane wave

A plane electromagnetic wave impinges vertically on a plane.
a. Show that the radiation pressure exerted on a surface is equal to the energy density in the incident beam. Does this ratio depend on the reflected part of the radiation?
b. Now consider a beam of small massive balls of mass m incident on a plane. What is the relationship between the mean pressure on the surface and the kinetic energy in this case?

Solution: *a. We calculate the radiative pressure as,*

$$P = \frac{1}{A}\frac{\Delta p}{\Delta t} = \frac{\varepsilon_0}{2}\mathcal{E}_0^2 = \frac{I}{c} = u \ ,$$

when light is fully absorbed.
b. Let N be the number of balls beating the plane per unit time. In the case of inelastic collisions,

$$P = \frac{Nmv}{A} = \frac{Nm}{A}\sqrt{\frac{2}{m}E_{kin}} = \frac{N}{A}\sqrt{2mE_{kin}} \ .$$

For elastically reflected collisions, the pressure will double. Unlike the radiative pressure of light, the pressure exerted by the balls goes with the root of the energy of the beam. This is due to the different dispersion relations for photons and massive particles.

18.1.8.7 Ex: Radiation pressure of solar light

Estimate the radiation pressure force exerted by the Sun on the Earth, and compare this force to the gravitational force on Earth and at the atmospheric pressure. (The intensity of sunlight at the Earth's orbit is $I = 1.37\,\mathrm{kW/m^2}$).
b. Repeat part (a) for Mars, which has an average distance of $2.28 \cdot 10^8\,\mathrm{km}$ from the Sun and has a radius of 3400 km.
c. What is the exerted radiation pressure when light strikes a perfect absorber (reflector)?

Solution: *a. The radiation pressure of the sun on the Earth is,*

$$\tfrac{I_{earth}}{c} = 4.5 \cdot 10^{-6}\,\mathrm{Pa} \ ,$$

which is small compared to the atmospheric pressure of $10^{13}\,\mathrm{hPa}$. The total force of the solar radiation on the Earth is,

$$F_{rad,earth} = \int_{earth} \tfrac{I}{c} \cdot d\mathbf{a} = \tfrac{I}{c}\pi r_{earth}^2 = 5.83 \cdot 10^8\,\mathrm{N} \ .$$

In comparison, $F_{g,earth} = 1.65 \cdot 10^{-14} F_{rad,earth}$.
b. The intensity decreases with the square of the distance of the source, such that,

$$\frac{I_{mars}}{c} \propto \frac{d_{sun-earth}^2}{d_{sol-mars}^2}\frac{I_{earth}}{c} = \left(\frac{149\ 600\ 000}{249\ 200\ 000}\right)^2 \tfrac{I_{earth}}{c} \ ,$$

which is still small compared to the atmospheric pressure on Mars, which is $0.6\% \cdot 10^{13}\,\mathrm{hPa}$. *Also,*

$$\frac{F_{rad,mars}}{F_{rad,earth}} = \frac{d_{sun-earth}^2 r_{mars}^2}{d_{sun-mars}^2 r_{earth}^2} \ .$$

c. The radiative pressure hitting a perfect reflector is twice the pressure when hitting a perfect absorber of the same size.
Gabarite: $F_{rad,mars} = 7.18 \cdot 10^7\,\mathrm{N}$, $F_{g,mars} = 4.27 \cdot 10^{-14}\,\mathrm{F_{rad,mars}}$.

18.1.8.8 Ex: Radiation pressure of a point-like emitter onto a plane

A punctual and intense source of light isotropically radiates 1.0 MW. The source is located 1.0 m above an infinite and perfectly reflecting plane. Determine the force that the radiation pressure exerts on the plane.

Solution: *The force is*

$$F = \int \mathbf{p} \cdot d\mathbf{A} = \int_0^\infty \int_0^{2\pi} \frac{I(\sqrt{a^2+r^2})}{c} \cos\theta r dr d\phi = \int_0^\infty \int_0^{2\pi} \frac{P}{c4\pi(a^2+r^2)} \frac{a}{\sqrt{r^2+a^2}} r dr d\phi$$
$$= \frac{aP}{2c} \int_0^\infty \frac{r dr}{(a^2+r^2)^{3/2}} = \frac{aP}{2c} \left. \frac{-1}{\sqrt{a^2+r^2}} \right|_0^\infty = \frac{P}{2c} = 3.3\,\mathrm{mN} \ .$$

18.1.8.9 Ex: Maxwell's tensor for a plane wave

Find all the elements of Maxwell's stress tensor for a monochromatic plane wave traveling in z-direction and being linearly polarized in y-direction. Interpret the result remembering that $\overleftrightarrow{T}$ represents a momentum flux density. How is $\overleftrightarrow{T}$ related to the energy density in this case?

Solution: *With the electric field,*

$$\vec{\mathcal{E}} = \mathcal{E}_0 \hat{\mathbf{e}}_x \sin(kz - \omega t) \ ,$$

the magnetic field is,

$$\vec{\mathcal{B}} = \tfrac{1}{c} \mathcal{E}_0 \hat{\mathbf{e}}_y \sin(kz - \omega t) \ .$$

For the tensor we calculate,

$$\begin{aligned} T_{ij} &= \varepsilon_0 (\mathcal{E}_i \mathcal{E}_j - \tfrac{1}{2}\delta_{ij}\mathcal{E}^2) + \tfrac{1}{\mu_0}(\mathcal{B}_i \mathcal{B}_j - \tfrac{1}{2}\delta_{ij}\mathcal{B}^2) \\ &= \tfrac{\varepsilon_0}{2}(\mathcal{E}^2\delta_{ix} - \mathcal{E}^2\delta_{iy} - \mathcal{E}^2\delta_{iz})\delta_{ij} + \tfrac{1}{\mu_0 c^2}(-\mathcal{E}^2\delta_{ix} + \mathcal{E}^2\delta_{iy} - \mathcal{E}^2\delta_{iz}) \\ &= -\varepsilon_0 \mathcal{E}^2 \delta_{iz}\delta_{jz} = -u\delta_{iz}\delta_{jz} \ . \end{aligned}$$

For the Poynting vector we calculate,

$$\vec{\mathcal{S}} = \tfrac{1}{\mu_0} \vec{\mathcal{E}} \times \vec{\mathcal{B}} = \varepsilon_0 \mathcal{E}^2 \hat{\mathbf{e}}_z \ ,$$

concluding that $s = T_{zz}$.

18.1.8.10 Ex: Superposition of waves

Suppose $Ae^{\imath ax} + Be^{\imath bx} = Ce^{\imath cx}\ \forall x$. Prove that $a = b = c$ and $A + B = C$.

Solution: *Obviously, the relation must also be valid at $x = 0$, which proves immediately,*

$$A + B = C \ .$$

Evaluating the derivative of the equation, $\imath aAe^{\imath ax} + \imath bBe^{\imath bx} = \imath c(A + B)e^{\imath cx}$, also at the point $x = 0$, we conclude,

$$aA + bB = c(A + B) \ ,$$

and evaluating the second derivative, $-a^2Ae^{\imath ax} - b^2Be^{\imath bx} = -c^2(A + B)e^{\imath cx}$, also at the point $x = 0$, we conclude,

$$a^2A + b^2B = c^2(A + B) \ .$$

Solving the second relation by c and substituting into the third,

$$a^2A + b^2B = \left(\frac{aA + bB}{A + B}\right)^2 (A + B) \ ,$$

which simplifies to,

$$a^2 + b^2 = 2ab \ ,$$

which requires $a = b$. Then $a = c$ is obvious.

18.1.8.11 Ex: Poynting vector of a superposition of two waves

The electric fields of two harmonic electromagnetic waves of angular frequencies ω_1 and ω_2 are given by $\vec{\mathcal{E}}_1 = \mathcal{E}_{10}\cos(k_1x - \omega_1t)\hat{\mathbf{e}}_y$ and by $\vec{\mathcal{E}}_2 = \mathcal{E}_{20}\cos(k_2x - \omega_2t + \delta)\hat{\mathbf{e}}_y$. For the superposition of these two waves, determine
a. the instantaneous Poynting vector and
b. the temporal average of the Poynting vector.
c. Repeat parts (a) and (b) for an inverted propagation direction of the second wave, i.e. $\vec{\mathcal{E}}_2 = \mathcal{E}_{20}\cos(k_2x + \omega_2t + \delta)\hat{\mathbf{e}}_y$.

Solution: *a. The instantaneous Poynting vector is,*

$$\begin{aligned}\vec{\mathcal{S}} &= \tfrac{1}{\mu_0}\vec{\mathcal{E}} \times \vec{\mathcal{B}} = \tfrac{1}{\mu_0}(\vec{\mathcal{E}}_1 + \vec{\mathcal{E}}_2) \times (\vec{\mathcal{B}}_1 + \vec{\mathcal{B}}_2) \\ &= \tfrac{1}{\mu_0}\hat{\mathbf{e}}_x[\mathcal{E}_{10}\mathcal{B}_{10}\cos^2(k_1x - \omega_1t) \\ &+ \mathcal{E}_{20}\mathcal{B}_{20}\cos^2(k_2x - \omega_2t + \delta) + (\mathcal{E}_{10}\mathcal{B}_{20} + \mathcal{E}_{20}\mathcal{B}_{10})\cos(k_1x - \omega_1t)\cos(k_2x - \omega_2t + \delta)] \ .\end{aligned}$$

b. Using the trigonometric formula $\cos a \cos b = \frac{1}{2}[\cos(a-b) + \cos(a+b)]$, we calculate the temporal average of the Poynting vector,

$$\begin{aligned}\langle\vec{\mathcal{S}}\rangle &= \tfrac{1}{\mu_0}\hat{\mathbf{e}}_x\left\langle\mathcal{E}_{10}\mathcal{B}_{10}\cos^2(k_1x - \omega_1t) + \mathcal{E}_{20}\mathcal{B}_{20}\cos^2(k_2x - \omega_2t + \delta)\right. \\ &\quad \left. + \tfrac{\mathcal{E}_{10}B_{20} + \mathcal{E}_{20}\mathcal{B}_{10}}{2}[\cos(\Delta kx - \Delta\omega t - \delta) + \cos(Kx - \Omega t + \delta)]\right\rangle \\ &= \tfrac{1}{\mu_0}\hat{\mathbf{e}}_x\left[\tfrac{\mathcal{E}_{10}\mathcal{B}_{10} + \mathcal{E}_{20}\mathcal{B}_{20}}{2} + \tfrac{\mathcal{E}_{10}\mathcal{B}_{20} + \mathcal{E}_{20}\mathcal{B}_{10}}{2}\langle\cos(\Delta kx - \Delta\omega t - \delta)\rangle\right] \\ &\overset{T\to\infty}{\longrightarrow} \tfrac{1}{\mu_0}\hat{\mathbf{e}}_x\left[\tfrac{\mathcal{E}_{10}\mathcal{B}_{10} + \mathcal{E}_{20}\mathcal{B}_{20}}{2} + \tfrac{\mathcal{E}_{10}\mathcal{B}_{20} + \mathcal{E}_{20}\mathcal{B}_{10}}{2}\cos\delta\ \delta_{k_1\neq k_2}\right] \ .\end{aligned}$$

c. In the case of counterpropagating beams,

$$\vec{\mathcal{S}} = \tfrac{1}{\mu_0}\hat{\mathbf{e}}_x[\mathcal{E}_{10}^2\cos^2(k_1x-\omega_1t) - \mathcal{E}_{20}^2\cos^2(k_2x+\omega_2t+\delta)] \ ,$$

and

$$\langle\vec{\mathcal{S}}\rangle = \tfrac{1}{2\mu_0}\hat{\mathbf{e}}_x\tfrac{\mathcal{E}_{10}^2+\mathcal{E}_{20}^2}{2} \ .$$

18.1.8.12 Ex: Poynting vector of a standing wave

The electric field $\vec{\mathcal{E}}(\mathbf{r},t)$ of a standing electromagnetic wave in vacuum be given by,

$$\vec{\mathcal{E}}(\mathbf{r},t) = \mathfrak{Re}\ \left(\mathcal{E}_0\hat{\mathbf{e}}_x e^{\imath(kz-\omega t)} - \mathcal{E}_0\hat{\mathbf{e}}_x e^{\imath(-kz-\omega t)}\right) = 2\mathcal{E}_0\sin kz\sin\omega t\hat{\mathbf{e}}_x$$

with $\mathcal{E}_0 \in \mathbb{R}$.
a. Determine the corresponding magnetic field $\vec{\mathcal{B}}(\mathbf{r},t)$.
b. Calculate the Poynting vector $\vec{\mathcal{S}}(\mathbf{r},t)$. What follows for the energy flow $\bar{s}$ of the standing electromagnetic wave in the temporal average, that is, calculate

$$\bar{s} = \frac{\int dt\ s}{\int dt} \ ,$$

where both integrals should be evaluated between $t=0$ and $t=2\pi/\omega$.

Solution: *a. With* $\nabla\times\vec{\mathcal{E}} = -\frac{\partial}{\partial t}\vec{\mathcal{B}}$ *follows,*

$$\hat{\mathbf{e}}_y\frac{\partial}{\partial z}\vec{\mathcal{E}}_x = -\frac{\partial}{\partial t}\vec{\mathcal{B}}_y\hat{\mathbf{e}}_y \ .$$

With $-2\mathcal{E}_0k\cos kz\sin\omega t = \frac{\partial}{\partial t}\vec{\mathcal{B}}_y$ *we obtain,*

$$\vec{\mathcal{B}} = \hat{\mathbf{e}}_y\mathcal{B}_0\cos kz\cos\omega t$$

with $\mathcal{B}_0 = \frac{2\mathcal{E}_0k}{\omega} = \frac{2\mathcal{E}_0}{c}$.
b. The Poynting vector is,

$$\begin{aligned}\vec{\mathcal{S}} &= \vec{\mathcal{E}}\times\vec{\mathcal{H}} = \varepsilon_0c^2\vec{\mathcal{E}}\times\vec{\mathcal{B}} = \varepsilon_0c\hat{\mathbf{e}}_z4\mathcal{E}_0^2\sin kz\cos kz\sin\omega t\cos\omega t \\ &= \varepsilon_0c\hat{\mathbf{e}}_z\mathcal{E}_0^2\sin 2kz\sin 2\omega t \ .\end{aligned}$$

In the temporal average,

$$\int_0^{2\pi/\omega}\sin 2\omega t\ dt = -\frac{1}{2\omega}\cos 2\omega t\Big|_0^{2\pi/\omega} = -\frac{1}{2\omega}[\cos 4\pi - \cos 0] = 0 \ .$$

Hence, $\bar{s}=0$.

18.1.8.13 Ex: Phase fronts of planar and spherical waves

Describes the phase front for (a) a plane wave and (b) a spherical wave.

Solution: *a. A plane wave is defined by,*

$$\psi(\mathbf{r},t) = A_0 e^{\imath(\mathbf{k}\cdot\mathbf{r}-\omega t)} \ .$$

Inserting into the wave equation (18.1) yields $|\mathbf{k}| = \omega/c$ *when* A_0 *is constant. The phase front is given by,*

$$\mathbf{k}\cdot\mathbf{r} - \omega t = const.$$

That is, for a given time t*, all points* $\mathbf{r}$ *satisfying the above equation form a surface perpendicular to* $\mathbf{k}$*. Since* $\phi = \mathbf{k}\cdot\mathbf{r}$*, we have* $\nabla\phi = \mathbf{k}$ *and the phase velocity is* $c \equiv \omega/|\nabla\phi|$*. Along the direction* $\mathbf{k}$*, the wave is periodic in space. The periodicity, called wavelength* λ*, is given by* $|\mathbf{k}| = 2\pi/\lambda$*.*
b. A spherical wave is defined by,

$$\psi(\mathbf{r},t) = \frac{A_0}{r} e^{\imath(kr-\omega t)} \ .$$

We notice that the expression is in spherical coordinates, and $\phi = kr$ *is not a scalar product of two vectors, but a product of two scalar quantities. Once again,* $k = \omega/c = 2\pi/\lambda$*, but* $\nabla\phi = k\hat{r}$*. The inverse dependence of the amplitude of* r *is a result of energy conservation.*

18.1.8.14 Ex: Fake spherical wave

We verified in class, that spherical waves of the form

$$\vec{\mathcal{E}}_\pm(\mathbf{r},t) = \vec{\mathcal{E}}_0 \frac{1}{r} e^{\imath(kr\pm\omega t)} \qquad \text{and} \qquad \vec{\mathcal{B}}_\pm(\mathbf{r},t) = \vec{\mathcal{B}}_0 \frac{1}{r} e^{\imath(kr\pm\omega t)}$$

with $\omega = ck$, $c^2 = 1/(\varepsilon_0\mu_0)$ satisfy the Helmholtz equation. Argue, why nevertheless, they can not be electromagnetic waves. Check whether such waves satisfy the homogeneous Maxwell equations.

Solution: *A spherical wave can not have homogeneous polarization.*
To verify Maxwell's equations in vacuum, we first calculate the gradient,

$$\nabla \frac{e^{\imath(kr\pm\omega t)}}{r} = \frac{e^{\imath(kr\pm\omega t)}}{r^3}(-1+\imath kr)\mathbf{r} \ .$$

With this the third equation gives the result,

$$0 = \nabla\cdot\vec{\mathcal{E}}_\pm = \vec{\mathcal{E}}_0\cdot\mathbf{r}\frac{e^{\imath(kr\pm\omega t)}}{r^3}(-1+\imath kr) = \vec{\mathcal{E}}_0\cdot\mathbf{r}\frac{e^{\imath(kr\pm\omega t)}}{r^3}(-1+\imath kr) = \frac{-1+\imath kr}{r^2}\vec{\mathcal{E}}_\pm\cdot\mathbf{r} \ ,$$

and the forth,

$$0 = \nabla\cdot\vec{\mathcal{B}}_\pm = \frac{-1+\imath kr}{r^2}\vec{\mathcal{B}}_\pm\cdot\mathbf{r} \ .$$

Thus, the equations for the divergences confirm that the polarizations of the fields must be perpendicular to the radial propagation direction. But this contradicts the fixed polarization assumed in the ansatz. Now, we check the first homogeneous Maxwell equation:

$$0 = \nabla \times \vec{\mathcal{B}}_\pm - \frac{\partial \vec{\mathcal{E}}_\pm}{c^2 \partial t} = \frac{e^{\imath(kr \pm \omega t)}}{r} \nabla \times \vec{\mathcal{B}}_0 + \left(\nabla \frac{e^{\imath(kr \pm \omega t)}}{r} \right) \times \vec{\mathcal{B}}_0 - \frac{\partial}{\partial t} \frac{e^{\imath(kr \pm \omega t)}}{c^2 r} \vec{\mathcal{E}}_0$$
$$= \frac{e^{\imath(kr \pm \omega t)}}{r^3} (-1 + \imath kr) \mathbf{r} \times \vec{\mathcal{B}}_0 \mp \frac{\imath\omega}{c^2} \frac{e^{\imath(kr \pm \omega t)}}{r} \vec{\mathcal{E}}_0 = \frac{-1 + \imath kr}{r} \hat{\mathbf{e}}_r \times \vec{\mathcal{B}} \mp \frac{\imath\omega}{c^2} \vec{\mathcal{E}} \ .$$

The second one gives,

$$0 = \nabla \times \vec{\mathcal{E}}_\pm + \frac{\partial \vec{\mathcal{B}}_\pm}{\partial t} = \frac{-1 + \imath kr}{r} \hat{\mathbf{e}}_r \times \vec{\mathcal{E}} \pm \imath\omega \vec{\mathcal{B}} \ ,$$

which must be satisfied for all r. Thus, the equations for the rotations also violate Maxwell's equations.

18.1.8.15 Ex: Spherical wave

Consider a spherical electromagnetic wave,

$$\vec{\mathcal{E}}(\mathbf{r}, t) = \vec{\mathcal{E}}_0(r, \theta) e^{\imath(kr - \omega t)} \qquad \text{and} \qquad \vec{\mathcal{B}}(\mathbf{r}, t) = \vec{\mathcal{B}}_0(r, \theta) e^{\imath(kr - \omega t)} \ .$$

Show that the validity of Maxwell's equations for $\nabla \cdot \vec{\mathcal{E}} = 0 = \nabla \cdot \vec{\mathcal{B}}$ for the case of vanishing charge and current densities implies that $\vec{\mathcal{E}}$, $\vec{\mathcal{B}}$, and $\hat{\mathbf{e}}_r$ are mutually orthogonal (transversality).

Solution: *Inserting the electric field into Maxwell's equations,*

$$\nabla \cdot \vec{\mathcal{E}}(\mathbf{r}, t) = e^{\imath(kr - \omega t)} [\nabla \cdot \vec{\mathcal{E}}_0(r, \theta) + \imath k \hat{\mathbf{e}}_r \cdot \vec{\mathcal{E}}_0(r, \theta)] = 0$$
$$\nabla \times \vec{\mathcal{E}}(\mathbf{r}, t) = e^{\imath(kr - \omega t)} [\nabla \times \vec{\mathcal{E}}_0(r, \theta) + \imath k \hat{\mathbf{e}}_r \times \vec{\mathcal{E}}_0(r, \theta)] = \imath\omega \vec{\mathcal{B}}_0(r, \theta) e^{\imath(kr - \omega t)} = -\frac{\partial \vec{\mathcal{B}}}{\partial t} \ .$$

Now, we divide by $e^{\imath(kr - \omega t)}$ and separate the real and imaginary parts,

$$\begin{aligned}
\nabla \cdot \vec{\mathcal{E}}_0(r, \theta) = 0 \qquad & \textit{and} \qquad \hat{\mathbf{e}}_r \cdot \vec{\mathcal{E}}_0(r, \theta) = 0 \\
\nabla \times \vec{\mathcal{E}}_0(r, \theta) = 0 \qquad & \textit{and} \qquad k \hat{\mathbf{e}}_r \times \vec{\mathcal{E}}_0(r, \theta) = \omega \vec{\mathcal{B}}_0(r, \theta) \\
\nabla \cdot \vec{\mathcal{B}}_0(r, \theta) = 0 \qquad & \textit{and} \qquad \hat{\mathbf{e}}_r \cdot \vec{\mathcal{B}}_0(r, \theta) = 0 \\
\nabla \times \vec{\mathcal{B}}_0(r, \theta) = 0 \qquad & \textit{and} \qquad k \hat{\mathbf{e}}_r \times \vec{\mathcal{B}}_0(r, \theta) = -\tfrac{\omega}{c^2} \vec{\mathcal{E}}_0(r, \theta) \ .
\end{aligned}$$

where we included the results of similar calculations for the magnetic field. We conclude that $\vec{\mathcal{E}}$, $\vec{\mathcal{B}}$, and $\hat{\mathbf{e}}_r$ are mutually orthogonal.

18.1.8.16 Ex: Spherical wave in a neutral dielectric medium

a. Show that spherical waves $\vec{\mathcal{E}}(\mathbf{r},t) = \frac{\vec{\mathcal{E}}_0}{r} e^{\imath(kr-\omega t)}$ solve the wave equation in a vacuum, when $\omega = ck$. The Laplace operator in spherical coordinates is,

$$\nabla^2 = \frac{1}{r^2}\frac{\partial}{\partial r}\left(r^2\frac{\partial}{\partial r}\right) + \frac{1}{r^2}\Delta_{\theta,\phi} \ .$$

The second term only acts on the parts that depend on the angles. Verify that $\Delta_{\theta,\phi}\vec{\mathcal{E}} \equiv 0$.
b. Show that the wave equations have the form,

$$\nabla^2\vec{\mathcal{E}} - \frac{1}{c^2}\frac{\partial^2\vec{\mathcal{E}}}{\partial t^2} = \frac{1}{\varepsilon_0 c^2}\frac{\partial^2\vec{\mathcal{P}}}{\partial t^2} \ ,$$

when the wave does not propagate in a vacuum, but in a neutral dielectric medium (i.e. without free charges). Assume the simple case that the dielectric displacement $\vec{\mathcal{D}} = \varepsilon_0\vec{\mathcal{E}} + \vec{\mathcal{P}}$ has the form,

$$\vec{\mathcal{P}} = \varepsilon_0\chi\vec{\mathcal{E}} \ .$$

What is the form of the wave equations in this case? How do you change the phase velocity c of the wave? You can identify the meaning of the quantity $n \equiv \sqrt{1+\chi}$?

Solution: *a. Inserting the ansatz for the spherical wave into the differential equation,*

$$\frac{1}{r^2}\frac{\partial}{\partial r}\left(r^2\frac{\partial\vec{\mathcal{E}}}{\partial r}\right) - \frac{1}{c^2}\frac{\partial^2\vec{\mathcal{E}}}{\partial t^2} = 0 \ ,$$

we find,

$$\omega = ck \ .$$

b. From the Maxwell equations for a dielectric ($\varrho = 0$, $\mathbf{j} = 0$, $\varepsilon \neq \varepsilon_0$, $\mu = \mu_0$),

$$\begin{aligned} \nabla\times\vec{\mathcal{B}} = \varepsilon_0\mu_0\partial_t\vec{\mathcal{E}} + \mu_0\partial_t\vec{\mathcal{P}} \quad &, \quad \nabla\cdot\vec{\mathcal{B}} = 0 \\ \nabla\times\vec{\mathcal{E}} = -\partial_t\vec{\mathcal{B}} \quad &, \quad \nabla\cdot\vec{\mathcal{E}} = -\tfrac{1}{\varepsilon_0}\nabla\cdot\vec{\mathcal{P}} \ . \end{aligned}$$

Hence,

$$\begin{aligned} \nabla^2\vec{\mathcal{E}} &= \nabla^2\vec{\mathcal{E}} + \tfrac{1}{\varepsilon_0}\nabla(-\nabla\cdot\vec{\mathcal{D}} + \nabla\cdot\vec{\mathcal{P}}) = \nabla^2\vec{\mathcal{E}} - \nabla(\nabla\cdot\vec{\mathcal{E}}) = -\nabla\times(\nabla\times\vec{\mathcal{E}}) \\ &= \nabla\times\partial_t\vec{\mathcal{B}} = \partial_t(\varepsilon_0\mu_0\partial_t\vec{\mathcal{E}} + \mu_0\partial_t\vec{\mathcal{P}}) \ . \end{aligned}$$

This is only valid when $\vec{\mathcal{P}} \propto \vec{\mathcal{E}}$, such that we can use $\nabla\cdot\vec{\mathcal{P}} = 0$. (We note, that generally $\vec{\mathcal{P}}(\mathbf{r},t) = \chi^{(1)}\vec{\mathcal{E}}(\mathbf{r},t) + \vec{\mathcal{P}}_{nl}(\mathbf{r},t)$.) Now inserting the ansatz, $\vec{\mathcal{E}}(\mathbf{r},t) = \vec{\mathcal{E}}_0 e^{\imath(\mathbf{k}\cdot\mathbf{r}-\omega t)} + c.c.$, and separating the susceptibility into a real part and an imaginary part, $\chi^{(1)} = \mathfrak{Re}\ \chi^{(1)} + \imath\mathfrak{Im}\ \chi^{(1)}$, we obtain,

$$\frac{\partial^2\vec{\mathcal{E}}(z,t)}{\partial z^2} + k^2(1+\mathfrak{Re}\ \chi^{(1)})\vec{\mathcal{E}}(z,t) + \imath k^2\mathfrak{Im}\ \chi^{(1)}\vec{\mathcal{E}}(z,t) = 0 \ .$$

Thus, we find that $n = \sqrt{1+\mathfrak{Re}\ \chi^{(1)}}$ is the refractive index. With this, the wave is,

$$\vec{\mathcal{E}}(z,t) = \vec{\mathcal{E}}_0 e^{-(k/2)\mathfrak{Im}\ \chi^{(1)}z} e^{\imath(knz-\omega t)}\hat{\mathbf{e}}(\theta,\varepsilon) + c.c. \ .$$

18.1.8.17 Ex: Refraction in a bath of water

An observer stands at the edge of a basin filled with water down to a depth of $h = 2.81$ m. He looks at an object lying on the bottom. At what depth h' appears the image of the object, if the direction of observation in which the observer perceives the image forms with the normal direction to the water surface an angle of $\alpha = 60°$? Prepare a scheme.

Solution: *According to the scheme we have,*

$$h' \tan\alpha = h \tan\beta \ .$$

Thus, using Snell's law, $n_{water} = \frac{\sin\alpha}{\sin\beta} = 1.3325$,

$$h' = h\frac{\tan\beta}{\tan\alpha} = h\frac{\cos\alpha\sin\beta}{\sin\alpha\sqrt{1-\sin^2\beta}} = h\frac{\cos\alpha}{\sqrt{n_{water}^2 - \sin^2\alpha}} \approx 0.49h \ .$$

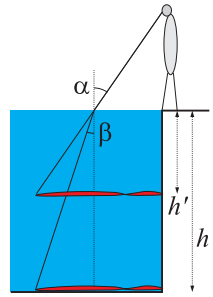

Figure 18.8: Refraction in a bath of water.

18.1.8.18 Ex: Poynting vector of a partially reflected wave

A plane wave $\vec{\mathcal{E}}_{in}(z,t)$ which is linearly polarized in x-direction runs along the z-axis from $-\infty$ towards an interface ($z = 0$-plane). At the interface, a part r of the wave is reflected without phase shift.
a. Give the amplitudes of the electric and the magnetic field in the half-space $z < 0$ in real numbers.
b. Give the Poynting vector $\vec{\mathcal{S}}(z,t)$ and its time average.

Solution: *a. The total amplitude of the electric field follows as a superposition,*

$$\begin{aligned}\vec{\mathcal{E}}(z,t) &= \vec{\mathcal{E}}_{in}(z,t) + r\vec{\mathcal{E}}_{in}(-z,t) = \mathcal{E}_0\hat{\mathbf{e}}_x e^{\imath(\omega t - kz)} + r\mathcal{E}_0\hat{\mathbf{e}}_x e^{\imath(\omega t + kz)} \\ &= \mathcal{E}_0\hat{\mathbf{e}}_x e^{\imath\omega t}[(1-r)e^{-\imath kz} + 2r\cos kz] \ .\end{aligned}$$

Magnetic field follows from $\nabla \times \vec{\mathcal{E}} = -\partial_t \vec{\mathcal{B}}$ *and is,*

$$\vec{\mathcal{B}}_{in}(z,t) = -\int dt\ \nabla \times \mathcal{E}_0 \hat{\mathbf{e}}_x e^{\imath(\omega t - kz)} = -\mathcal{E}_0 \int dt\ \nabla \times \hat{\mathbf{e}}_x e^{\imath(\omega t - kz)} = \mathcal{E}_0 \int dt\ \imath k e^{\imath(\omega t - kz)} \hat{\mathbf{e}}_y$$
$$= \mathcal{E}_0 \imath k \frac{1}{\imath\omega} e^{\imath(\omega t - kz)} \hat{\mathbf{e}}_y = \frac{1}{c} \mathcal{E}_0 \hat{\mathbf{e}}_y e^{\imath(\omega t - kz)}$$

hence,

$$\vec{\mathcal{B}}(z,t) = \vec{\mathcal{B}}_{in}(z,t) + r\vec{\mathcal{B}}_{in}(-z,t) = \frac{1}{c}\mathcal{E}_0 \hat{\mathbf{e}}_y e^{\imath(\omega t - kz)} - \frac{1}{c} r \mathcal{E}_0 \hat{\mathbf{e}}_y e^{\imath(\omega t + kz)}$$
$$= \frac{1}{c}\mathcal{E}_0 \hat{\mathbf{e}}_y e^{\imath\omega t}[(1-r)e^{-\imath kz} - 2\imath r \sin kz] \ .$$

b. The Poynting vector is now,

$$\vec{\mathcal{S}}(z,t) = \varepsilon_0 c^2 (\mathfrak{Re}\ \vec{\mathcal{E}} \times \mathfrak{Re}\ \vec{\mathcal{B}})$$
$$= \varepsilon_0 c^2 \left([\mathcal{E}_0 \hat{\mathbf{e}}_x \cos(\omega t - kz) + r\mathcal{E}_0 \hat{\mathbf{e}}_x \cos(\omega t + kz)] \times \right.$$
$$\left. \times \left[\tfrac{1}{c}\mathcal{E}_0 \hat{\mathbf{e}}_y \cos(\omega t - kz) - \tfrac{1}{c} r \mathcal{E}_0 \hat{\mathbf{e}}_y \cos(\omega t + kz) \right] \right)$$
$$= \varepsilon_0 c 2 \mathcal{E}_0^2 \hat{\mathbf{e}}_z [\cos(\omega t - kz) + r\cos(\omega t + kz)][\cos(\omega t - kz) - r\cos(\omega t + kz)]$$
$$= \varepsilon_0 c^2 \tfrac{1}{c} \mathcal{E}_0^2 \hat{\mathbf{e}}_z [\cos^2(\omega t - kz) - r^2 \cos^2(\omega t + kz)] \ .$$

The temporal average of the Poynting vector is,

$$\mathbf{I}(z) = \frac{\omega}{2\pi} \int_0^{2\pi/\omega} \vec{\mathcal{S}}(z,t) dt = \varepsilon_0 c \mathcal{E}_0^2 \hat{\mathbf{e}}_z \frac{\omega}{2\pi} \int_0^{2\pi/\omega} [\cos^2(\omega t - kz) - r^2 \cos^2(\omega t + kz)] dt$$
$$= \varepsilon_0 c \mathcal{E}_0^2 \hat{\mathbf{e}}_z \frac{\omega}{2\pi} \left[\frac{\pi}{\omega} - r^2 \frac{\pi}{\omega} \right] = \frac{1}{2} \varepsilon_0 c \mathcal{E}_0^2 \hat{\mathbf{e}}_z (1 - r^2) \ .$$

18.1.8.19 Ex: Energy flow upon refraction

Two infinitely extended media with relative dielectric constants ϵ_1 and ϵ_2 and permeabilities $\mu_1 = \mu_2 = \mu_0$, that is, with refraction indices $n_1 = \sqrt{\epsilon_1}$ and $n_2 = \sqrt{\epsilon_2}$, be separated by the $z = 0$-plane. Coming from the medium n_1 traveling in x-direction a linearly polarized plane wave with frequency ω and wavenumber k_1 hits the interface perpendicularly. The amplitude is $\mathcal{E}_0$.
a. Use the continuity of the normal components of $\vec{\mathcal{D}}$ and $\vec{\mathcal{B}}$, as well as of the tangential components of $\vec{\mathcal{E}}$ and $\vec{\mathcal{H}}$, at the interface to calculate the amplitudes of refracted part and the reflected part of the incident wave.
b. The energy flux is defined by the temporal average of the real part of the Poynting vector $\vec{\mathcal{S}}$: $\vec{\varphi} \equiv \mathfrak{Re}\ [\vec{\mathcal{E}} \times \vec{\mathcal{H}}^*]$. Calculate the incident, reflected, and refracted energy fluxes. What is the total flux in front and behind of the interface?
c. Determine the reflection coefficient r (the ratio between the absolute values of the reflected and incident fluxes) and the transmission coefficient t (the ratio between the absolute values of the transmitted and incident fluxes).

Solution: *a. Because of* $\mu_1 = \mu_2 = \mu_0$ *we have* $\vec{\mathcal{B}}_i = \mu_0 \vec{\mathcal{H}}_i$ *and* $n_i = \sqrt{\epsilon_i}$ *for* $i = 1, 2$. *Therefore, in front of the interface,*

$$\vec{\mathcal{E}}_1 = \hat{\mathbf{e}}_x \mathcal{E}_0 e^{-\imath\omega t} \left[e^{\imath k_1 z} + c_1 e^{-\imath k_1 z} \right]$$
$$\vec{\mathcal{B}}_1 = \hat{\mathbf{e}}_y \tfrac{\mathcal{E}_0}{c} e^{-\imath\omega t} n_1 \left[e^{\imath k_1 z} - c_1 e^{-\imath k_1 z} \right] \ ,$$

where the terms proportional to $e^{\imath k_1 z}$ *represent the incident part of the wave and the terms* $e^{-\imath k_1 z}$ *the reflected part. Behind the interface there is only a transmitted part, which is given by,*

$$\vec{\mathcal{E}}_2 = \hat{\mathbf{e}}_x \mathcal{E}_0 e^{-\imath\omega t} c_2 e^{\imath k_2 z}$$
$$\vec{\mathcal{B}}_2 = \hat{\mathbf{e}}_y \tfrac{\mathcal{E}_0}{c} e^{-\imath\omega t} n_2 c_2 e^{\imath k_2 z} \ .$$

Now, in the interface (that is, at $z = 0$*) the tangential component of* $\vec{\mathcal{E}}$ *(and hence, because of the linear polarization* $\vec{\mathcal{E}}$ *as well) and the tangential component of* $\vec{\mathcal{H}}$ *(and hence* $\vec{\mathcal{B}}$ *as well) are continuous. From this follows,*

$$1 + c_1 = c_2 \qquad \textit{continuity of } \vec{\mathcal{E}}_t$$
$$n_1(1 - c_1) = n_2 c_2 \qquad \textit{continuity of } \vec{\mathcal{H}}_t \ .$$

We obtain thus,

$$n_1(1 - c_1) = n_2 c_2 = n_2(1 + c_1)$$

and hence,

$$c_1 = \frac{n_1 - n_2}{n_1 + n_2} \qquad \textit{and} \qquad c_2 = \frac{2n_1}{n_1 + n_2} \ .$$

For the amplitudes of the reflected ($\mathcal{E}_{0r}$) *and refracted* ($\mathcal{E}_{0g}$) *parts we obtain thus,*

$$\mathcal{E}_{0r} = \frac{n_1 - n_2}{n_1 + n_2} \mathcal{E}_0 \qquad \textit{and} \qquad \mathcal{E}_{0g} = \frac{2n_1}{n_1 + n_2} \mathcal{E}_0 \ .$$

Upon reflection from an optically denser medium ($n_2 > n_1$) *the wave exhibits a phase jump with respect to the incident wave* ($n_1 - n_2 < 0$). *This is not the case for reflection by a less dense medium* ($n_2 < n_1$).
b. We get,

$$\vec{\varphi}_e = \mathfrak{Re}\ \vec{\mathcal{S}}_e = \tfrac{1}{\mu_0} \mathfrak{Re}\ (\vec{\mathcal{E}}_e \times \vec{\mathcal{B}}_e^*) = \tfrac{1}{\mu_0} \mathcal{E}_0^2 n_1 \hat{\mathbf{e}}_z$$
$$\vec{\varphi}_g = \mathfrak{Re}\ \vec{\mathcal{S}}_g = \tfrac{1}{\mu_0} \mathfrak{Re}\ (\vec{\mathcal{E}}_g \times \vec{\mathcal{B}}_g^*) = \tfrac{1}{\mu_0} \mathcal{E}_0^2 n_2 \left(\frac{2n_1}{n_1 + n_2} \right)^2 \hat{\mathbf{e}}_z$$
$$\vec{\varphi}_r = \mathfrak{Re}\ \vec{\mathcal{S}}_r = \tfrac{1}{\mu_0} \mathfrak{Re}\ (\vec{\mathcal{E}}_r \times \vec{\mathcal{B}}_r^*) = \tfrac{1}{\mu_0} \mathcal{E}_0^2 n_1 \left(\frac{n_1 - n_2}{n_1 + n_2} \right)^2 \hat{\mathbf{e}}_z \ .$$

For the total flux in front of the interface we have,

$$\vec{\varphi}_1 = \tfrac{1}{\mu_0} \mathfrak{Re}\ (\vec{\mathcal{E}}_1 \times \vec{\mathcal{B}}_1^*) = \tfrac{1}{\mu_0} \mathfrak{Re}\ \left((\vec{\mathcal{E}}_e + \vec{\mathcal{E}}_r) \times (\vec{\mathcal{B}}_e + \vec{\mathcal{B}}_r)^* \right)$$
$$= \tfrac{1}{\mu_0} \mathfrak{Re}\ \left((\vec{\mathcal{E}}_e \times \vec{\mathcal{B}}_e^*) + (\vec{\mathcal{E}}_r \times \vec{\mathcal{B}}_r^*) + (\vec{\mathcal{E}}_r \times \vec{\mathcal{B}}_e^* + \vec{\mathcal{E}}_e \times \vec{\mathcal{B}}_r^*) \right)$$
$$= \vec{\varphi}_e + \vec{\varphi}_r + \tfrac{1}{\mu_0} \mathcal{E}_0^2 n_1 \frac{n_1 - n_2}{n_1 + n_2} \mathfrak{Re}\ \left[e^{-\imath 2 k_1 z} - e^{\imath 2 k_1 z} \right] = \vec{\varphi}_e + \vec{\varphi}_r \ .$$

Behind the interface, obviously, we get,

$$\vec{\varphi}_2 = \vec{\varphi}_g \ .$$

Now,

$$\begin{aligned}\vec{\varphi}_e + \vec{\varphi}_r &= \tfrac{1}{\mu_0}\mathcal{E}_0^2 n_1 \left[1 - \left(\frac{n_1 - n_2}{n_1 + n_2}\right)^2\right] \hat{\mathbf{e}}_z \\ &= \tfrac{1}{\mu_0}\mathcal{E}_0^2 n_1 \frac{n_1^2 + n_2^2 + 2n_1 n_2 - n_1^2 - n_2^2 + 2n_1 n_2}{(n_1 + n_2)^2}\hat{\mathbf{e}}_z = \tfrac{1}{\mu_0}\mathcal{E}_0^2 n_2 \left(\frac{2n_1}{n_1 + n_2}\right)^2 \hat{\mathbf{e}}_z = \vec{\varphi}_g \ .\end{aligned}$$

Therefore, the flow of energy is continuous,

$$\vec{\varphi}_1 = \vec{\varphi}_e + \vec{\varphi}_r = \vec{\varphi}_g = \vec{\varphi}_2 \ .$$

c. The coefficients for reflection and transmissions are,

$$R \equiv \frac{|\vec{\varphi}_r|}{|\vec{\varphi}_e|} = \left(\frac{n_1 - n_2}{n_1 + n_2}\right)^2 \qquad \textit{and} \qquad T \equiv \frac{|\vec{\varphi}_g|}{|\vec{\varphi}_e|} = \frac{n_2}{n_1}\left(\frac{2n_1}{n_1 + n_2}\right)^2 \ .$$

It is easy to check,

$$R + T = 1 \ .$$

18.1.8.20 Ex: Birefringent crystal

An optically anisotropic crystal has in the x-direction the dielectric constant ε_1 (that is, the refractive index $n_1 = c\sqrt{\varepsilon_1 \mu_1}$) and in the y-direction ε_2, respectively, n_2. A linearly polarized plane wave with frequency ω propagating in z-direction impinges, coming from the vacuum, at normal incidence on a disc of thickness d of this material in such a way, that the plane of the polarization forms with the x and y-axes an angle of 45°. What is the polarization of the plane wave after the transition through the disk? How should we choose d, so that the wave is circularly polarized? Express this thickness in terms of the vacuum wavelength.

Solution: *For the incident wave we have,*

$$\vec{\mathcal{E}} = \mathcal{E}_0 e^{\imath(kz - \omega t)}(\hat{\mathbf{e}}_x + \hat{\mathbf{e}}_y) \ .$$

Furthermore, we have for the wavevector in transmission through the medium,

$$k = \frac{\omega}{v} = \omega\sqrt{\varepsilon\mu} = n\frac{\omega}{c} = \frac{2\pi}{\lambda} \ .$$

After the transmission through the disc, we obtain,

$$\begin{aligned}\vec{\mathcal{E}}_x &= \mathcal{E}_0 e^{\imath(kz + k_1 d - \omega t)} \qquad \textit{with} \qquad k_1 = n_1\frac{\omega}{c} \\ \vec{\mathcal{E}}_y &= \mathcal{E}_0 e^{\imath(kz + k_2 d - \omega t)} \qquad \textit{with} \qquad k_2 = n_2\frac{\omega}{c} \\ &= e^{\imath(k_2 d - k_1 d)}\vec{\mathcal{E}}_x \ .\end{aligned}$$

The components, therefore, have a phase difference of $k_2 d - k_1 d$ after transmission through the disk. In general, the wave is elliptically polarized. For circular polarization, the phase difference must be $\pi/2$ (depending on whether we want the light to be circularly polarized to the left or to the right). With this follows,

$$d = \pm\frac{\pi}{2}\,\frac{1}{k_2 - k_1} = \pm\frac{\pi}{2}\frac{c}{\omega}\,\frac{1}{n_2 - n_1}\ .$$

or with the wavelength in vacuum $\lambda = 2\pi c/\omega$

$$d(n_2 - n_1) = \pm\frac{\lambda}{4}\ ,$$

where the left-hand side gives the optical path difference. Therefore, we also speak of $\lambda/4$-waveplates.

18.1.8.21 Ex: Glass cube

At the center of a glass cube of length $d = 10\,\mathrm{mm}$ with the refractive index $n = 1.5$ there is a small spot. Which parts should the surfaces be covered so that the spot is invisible from outside the cube regardless of the direction of vision? Neglect the light refracted out of the cube after a first reflection inside the cube.

Solution: *The total internal reflection angle is $\theta_{i,tot} = \arcsin 1/n = 41.8°$. Thus, covering a centered area of,*

$$A = \pi\left(\tfrac{d}{2}\sin\theta_{i,tot}\right)^2 = \pi\left(\tfrac{d}{2n}\right)^2 \approx 0.35\,\mathrm{cm}^2\ .$$

18.1.8.22 Ex: Total internal reflection

a. We consider the transition of a beam of light from an optically dense medium (1) to a more dilute medium (2). Extending the theory of light refraction at interfaces beyond the angle of total internal reflection (18.70), derive the expression for the electric field in the medium (2).
b. Noting that α [from Eq. (18.60)] is now imaginary, use the equation (18.61) to calculate the reflection coefficient for the polarization parallel to the plane of incidence [7].
c. Do the same for polarization that is perpendicular to the plane of incidence.
d. In case of perpendicular polarization, show that the (real) evanescent fields are,

$$\vec{\mathcal{E}}(\mathbf{r},t) = \mathcal{E}_0 e^{-\kappa z}\cos(kx-\omega t)\hat{\mathbf{e}}_y \quad , \quad \vec{\mathcal{B}}(\mathbf{r},t) = \mathcal{E}_0 e^{-\kappa z}[\kappa\sin(kx-\omega t)\hat{\mathbf{e}}_x + k\cos(kx-\omega t)\hat{\mathbf{e}}_z]\ .$$

e. Verify that the fields in (d) satisfy all Maxwell equations without sources.
f. For the fields in (d), construct the Poynting vector and show that, on average, no energy is transmitted in z-direction.

[7] We observe 100% reflection, which is better than on a conductive surface.

Solution: *a. We choose the geometry such that the interface is in the $z = 0$ plane and all the beams lie within the $y = 0$ plane, that is,*

$$\mathbf{k}_t = k_t(\hat{\mathbf{e}}_x \sin\theta_t + \hat{\mathbf{e}}_z \cos\theta_t) \qquad with \qquad k_t = \omega n_2/c \ .$$

We now assume that $\theta_i > \theta_{i,total}$. In this case,

$$\cos\theta_t = \sqrt{1-\sin^2\theta_t} = \imath\sqrt{\sin^2\theta_t - 1} = \imath\sqrt{\tfrac{n_1^2}{n_2^2}\sin^2\theta_i - 1} \ ,$$

applying Snell's law. Inserting this into the equation for $\mathbf{k}_t$,

$$\mathbf{k}_t = k_t\left(\frac{n_1}{n_2}\hat{\mathbf{e}}_x \sin\theta_i + \imath\hat{\mathbf{e}}_z\sqrt{\frac{n_1^2}{n_2^2}\sin^2\theta_i - 1}\right) \equiv k\hat{\mathbf{e}}_x + \imath\kappa\hat{\mathbf{e}}_z \ ,$$

where

$$k \equiv \frac{\omega n_1}{c}\sin\theta_i \qquad and \qquad \kappa = \frac{\omega}{c}\sqrt{n_1^2\sin^2\theta_i - n_2^2} \ .$$

That is, we venture into the realm of complex variables, where θ_t can no longer be interpreted as a geometric angle. Nevertheless, we will continue with the analysis and see what happens. First, we look at the electric field, which has the general form,

$$\vec{\tilde{\mathcal{E}}}_t(\mathbf{r},t) = \vec{\tilde{\mathcal{E}}}_{0t}e^{\imath(\mathbf{k}_t\cdot\mathbf{r}-\omega t)} \ .$$

Replacing the wavevector, we obtain,

$$\vec{\tilde{\mathcal{E}}}_t(\mathbf{r},t) = \vec{\tilde{\mathcal{E}}}_{0t}e^{-\kappa z}e^{\imath(kx-\omega t)} \ .$$

That is, the transmitted wave propagates in x-direction (parallel to the interface) and is attenuated in z-direction.
b. How much of the wave is reflected in this case? For a wave polarized parallel to the incident plane (i.e. $\vec{\mathcal{E}}$ has only a x-component), we previously found that the reflected amplitude is,

$$\mathcal{E}_r = \frac{\alpha-\beta}{\alpha+\beta}\mathcal{E}_i \ ,$$

where,

$$\alpha \equiv \frac{\cos\theta_t}{\cos\theta_i} \qquad , \qquad \beta \equiv \frac{\mu_1\nu_1}{\mu_2\nu_2} = \frac{\mu_1 n_2}{\mu_2 n_1} \ .$$

In this case, α is purely imaginary and β is real, so the reflection coefficient is,

$$R = \left|\frac{\mathcal{E}_r}{\mathcal{E}_i}\right|^2 = \left|\frac{\alpha-\beta}{\alpha+\beta}\right|^2 = 1 \ ,$$

since,

$$|\alpha-\beta|^2 = |\alpha|^2 + \beta^2 = |\alpha+\beta|^2 \ .$$

c. For perpendicular polarization, we have,

$$\mathcal{E}_r = \frac{1-\alpha\beta}{1+\alpha\beta}\mathcal{E}_i \ ,$$

and once again, since 1 is real and $\alpha\beta$ is purely imaginary,

$$R = \left|\frac{1-\alpha\beta}{1+\alpha\beta}\right|^2 = 1 \ .$$

Thus, the reflection is, in fact, total for both polarizations.
d. Still with perpendicular polarization, the electric field lies entirely in y-direction, so,

$$\vec{\tilde{\mathcal{E}}}_t = \vec{\tilde{\mathcal{E}}}_0 e^{-\kappa z} e^{\imath(kx-\omega t)} \hat{\mathbf{e}}_y \ .$$

The magnetic field is (replacing the wavevector and with $\mathbf{k}_t = \frac{\omega n_2}{c}\hat{\mathbf{e}}_{k_t}$ and $\nu_2 = c/n_2$),

$$\vec{\tilde{\mathcal{B}}}_t = \frac{1}{\nu_2}\mathbf{k}_t \times \vec{\tilde{\mathcal{E}}}_t = \frac{1}{\nu_2}\frac{c}{\omega n_2}\tilde{\mathcal{E}}_0 e^{-\kappa z} e^{\imath(kx-\omega t)}(k\hat{\mathbf{e}}_z - \imath\kappa\hat{\mathbf{e}}_x) = \frac{\tilde{\mathcal{E}}_0}{\omega} e^{-\kappa z} e^{\imath(kx-\omega t)}(k\hat{\mathbf{e}}_z - \imath\kappa\hat{\mathbf{e}}_x) \ .$$

Taking the real parts to get the real fields, we have,

$$\vec{\mathcal{E}}_t = \mathcal{E}_0 e^{-\kappa z}\cos(kx-\omega t)\hat{\mathbf{e}}_y \quad , \quad \vec{\mathcal{B}}_t = \frac{\mathcal{E}_0}{\omega} e^{-\kappa z}[k\cos(kx-\omega t)\hat{\mathbf{e}}_z + \kappa\sin(kx-\omega t)\hat{\mathbf{e}}_x] \ .$$

e. To verify whether these fields satisfy the Maxwell equations, we first calculate the divergences,

$$\nabla\cdot\vec{\mathcal{E}}_t = 0 = \nabla\cdot\vec{\mathcal{B}}_t \ .$$

The rotations yield,

$$\nabla\times\vec{\mathcal{E}}_t = \mathcal{E}_0 e^{-\kappa z}[-k\sin(kx-\omega t)\hat{\mathbf{e}}_z + \kappa\cos(kx-\omega t)\hat{\mathbf{e}}_x = -\frac{\partial\vec{\mathcal{B}}_t}{\partial t}$$

$$\nabla\times\vec{\mathcal{B}}_t = \frac{\mathcal{E}_0}{\omega}e^{-\kappa z}\sin(kx-\omega t)\hat{\mathbf{e}}_y(k^2-\kappa^2) = \frac{n_2^2}{c^2}\omega\mathcal{E}_0 e^{-\kappa z}\sin(kx-\omega t)\hat{\mathbf{e}}_y = \frac{1}{\nu_2^2}\frac{\partial\vec{\mathcal{E}}_t}{\partial t} \ .$$

Thus, all four Maxwell equations are satisfied.
f. The Poynting vector is,

$$\vec{\mathcal{S}} = \tfrac{1}{\mu_0}\vec{\mathcal{E}}_t\times\vec{\mathcal{B}}_t = \frac{\mathcal{E}_0^2 e^{-2\kappa z}}{\mu_0\omega}[k\cos^2(kx-\omega t)\hat{\mathbf{e}}_x - \kappa\sin(kx-\omega t)\cos(kx-\omega t)\hat{\mathbf{e}}_z] \ .$$

Integrating this over a cycle ($t = 0$ to $2\pi/\omega$) Gives zero for the component z, so no energy is transmitted perpendicular to the interface, and all energy flows in x-direction, parallel to the interface.

18.1.8.23 Ex: Fresnel formulae

Rewrite the Fresnel formulae (18.61) and (18.63) in terms of the wavevectors of the incident, reflected and transmitted waves.

Solution: *Exploiting,*

$$\frac{k_2}{k_1} = \frac{c_1}{c_2} = \frac{n_2}{n_1} = \sqrt{\frac{\varepsilon_2\mu_2}{\varepsilon_1\mu_1}}$$

and with $k_{zm} = k_m \cos\theta_m$ for $m = i, r, t$, Eq. (18.61) for p-polarization can be rewritten as,

$$r^p = \frac{\varepsilon_1\mu_1 k_{zt} - \varepsilon_2\mu_2 k_{zi}}{\varepsilon_1\mu_1 k_{zt} + \varepsilon_2\mu_2 k_{zi}} \ ,$$

and Eq. (18.63) for s-polarization as,

$$r^s = \frac{k_{zt} - k_{zi}}{k_{zi} + k_{zt}} \ .$$

18.1.8.24 Ex: The Goos-Hänchen effect

The Goos-Hänchen shift is an optical phenomenon in which a linearly polarized light beam with finite transverse extension suffers, under total internal reflection from a plane interface, a small lateral displacement within the plane of incidence. The effect is due to an interference of the partial waves composing the finite-sized beam, hitting the interface under different angles and thus undergoing different phase shifts upon reflection. The sum of the reflected waves with different phase shifts form an interference pattern transverse to the mean propagation direction leading to a lateral displacement of the beam. Thus, the Goos-Hänchen effect is a coherence phenomenon [522, 523, 659].

To describe this phenomenon quantitatively, we consider a linearly polarized light beam of wavelength λ, with finite transverse size. This beam is fully internally reflected at the interface between two non-permeable media with refractive indices n_1 and $n_2 < n_1$. The relationship between the reflected and incident amplitudes is a complex number, which can be expressed by $\mathcal{E}_0''/\mathcal{E}_0 = e^{\imath\phi(\theta_i,\theta_{i,total})}$ for the angle of incidence $\theta_i > \theta_{i,total}$, where $\sin\theta_{i,total} = \frac{n_2}{n_1}$.

a. Show that for a beam of 'monochromatic' radiation in z-direction with an electric field amplitude of $\mathcal{E}(x)e^{\imath kz - \imath\omega t}$, where $\mathcal{E}(x)$ is smooth and finite in transverse direction (albeit extending over many wavelengths), the first approximation in terms of plane waves is,

$$\vec{\mathcal{E}}(x,z,t) = \hat{\epsilon}\int A(\kappa)e^{\imath\kappa x + \imath kz - \imath\omega t}d\kappa \ ,$$

where $\hat{\epsilon}$ is a polarization vector and $A(\kappa)$ is the Fourier transform of $\mathcal{E}(x)$ with respect to κ around $\kappa = 0$ small compared to k. The finite-sized beam consists of plane waves with a small range of angles of incidence centered around the valor predicted by geometric optics.

b. Consider the reflected beam and show that for $\theta_i > \theta_{i,total}$ the electric field can be expressed approximately as,

$$\vec{\mathcal{E}}_r(x,z,t) = \hat{\epsilon}_r\mathcal{E}(\xi - \delta\xi)e^{\imath\mathbf{k}_r\cdot\mathbf{r} - \imath\omega t + \imath\phi(\theta_i)} \ ,$$

where $\hat{\epsilon}_r$ is a polarization vector, ξ is the coordinate perpendicular to $\mathbf{k}_r$, which is the reflected wavevector and $\delta\xi = -\frac{1}{k}\frac{d\phi(\theta_i)}{d\theta_i}$.

c. With the Fresnel expressions for the phases $\phi(\theta_i)$ and for the two polarization states

of the plane, show that the lateral displacements of the beams with respect to the position predicted by geometric optics are,

$$\mathcal{D}_s = \frac{\lambda}{\pi}\frac{\sin\theta_i}{\sqrt{\sin^2\theta_i - \sin^2\theta_{i,total}}} \qquad \text{and} \qquad \mathcal{D}_p = \mathcal{D}_s \frac{\sin^2\theta_{i,total}}{\sin^2\theta_i - \cos^2\theta_i \sin^2\theta_{i,total}} \ .$$

Solution: *a. The purpose of this part is to show that, when a light beam has a finite diameter, it can be expanded into a superposition of partial planes wave of infinite radial extent. We therefore write the finite beam as,* $\vec{\mathcal{E}}(x,z,t) = \hat{\epsilon}E(x)e^{\imath kz-\imath\omega t}$ *with* $k = \frac{\omega}{c}n_1$*, and we insert this ansatz into the wavefunction,*

$$-\frac{\omega^2}{c^2}\vec{\mathcal{E}} = \frac{1}{c^2}\frac{\partial^2\vec{\mathcal{E}}}{\partial t^2} = \nabla^2\vec{\mathcal{E}} = -k^2\hat{\epsilon}\mathcal{E}(x)e^{\imath kz-\imath\omega t} + \hat{\epsilon}\frac{d^2\mathcal{E}(x)}{dx^2}e^{\imath kz-\imath\omega t}$$
$$= \hat{\epsilon}e^{\imath kz-\imath\omega t}\left(-k^2\mathcal{E}(x) + \frac{d^2\mathcal{E}(x)}{dx^2}\right) \ .$$

Now, we express $\mathcal{E}(x)$ *by its Fourier transform,* $A(\kappa) = \frac{1}{2\pi}\int \mathcal{E}(x)e^{-\imath\kappa x}dx$*. Thus* [8]*,*

$$-\frac{\omega^2}{c^2}\vec{\mathcal{E}} = \hat{\epsilon}e^{\imath kz-\imath\omega t}\mathcal{F}\left[-k^2\widetilde{\mathcal{E}(x)} + \widetilde{\frac{d^2\mathcal{E}(x)}{dx^2}}\right] = \hat{\epsilon}e^{\imath kz-\imath\omega t}\mathcal{F}\left[-k^2A(\kappa) + (\imath\kappa)^nA(\kappa)\right]$$
$$= \hat{\epsilon}e^{\imath kz-\imath\omega t}\int(-k^2-\kappa^2)A(\kappa)e^{\imath\kappa x}d\kappa$$
$$= \hat{\epsilon}\nabla^2\int A(\kappa)e^{\imath\kappa x+\imath kz-\imath\omega t}d\kappa = \hat{\epsilon}\nabla^2\left[\mathcal{E}(x)e^{\imath kz-\imath\omega t}\right] = \nabla^2\vec{\mathcal{E}} \ .$$

That is, the wave equation is satisfied under the condition $\mathcal{E}(x) = \int A(\kappa)e^{\imath\kappa x}dx$*, that is,* $\mathcal{E}(x)$ *can be understood as a distribution of partial wave amplitudes with wavevectors* κ*.*

b. Taking into account the angular distribution of the partial waves composing the light beam, the incident wave can be written as,

$$\vec{\mathcal{E}}_i(x,z,t) = \hat{\epsilon}\int A(\kappa)e^{\imath(\mathbf{k}_i+\vec{\kappa}_i)\cdot\mathbf{r}-\imath\omega t}d\kappa \qquad \textit{with} \qquad \begin{cases}\mathbf{k}_i = k(\hat{\mathbf{e}}_x\sin\theta_i + \hat{\mathbf{e}}_z\cos\theta_i)\\ \vec{\kappa}_i = \kappa(\hat{\mathbf{e}}_x\cos\theta_i - \hat{\mathbf{e}}_z\sin\theta_i)\end{cases}$$
$$= \hat{\epsilon}\int A(\kappa)e^{\imath k\zeta+\imath\kappa\xi-\imath\omega t}d\kappa \qquad \textit{with} \qquad \begin{cases}\zeta = x\sin\theta_i + z\cos\theta_i\\ \xi = x\cos\theta_i - z\sin\theta_i\end{cases} \ .$$

For a narrow distribution of partial waves we can approximate $\kappa \simeq k\delta\theta$*. Consequently, taking account of a phase shift* $\phi_i \equiv \phi(\theta_i+\delta\theta)$*, which depends on the angle of incidence,*

[8] A property of the Fourier transform defined by $\tilde{f}(\kappa) = \frac{1}{\sqrt{2\pi}}\int f(x)e^{-\imath\kappa x}dx$ is,

$$\left[\widetilde{\frac{d^nf}{dx^n}}\right](\kappa) = \frac{1}{\sqrt{2\pi}}\int\frac{d^nf(x)}{dx^n}e^{-\imath\kappa x}dx = \frac{(\imath\kappa)^n}{\sqrt{2\pi}}\int f(x)e^{-\imath\kappa x}dx = (\imath\kappa)^n\tilde{f}(\kappa) \ .$$

the reflected wave can be written as,

$$\begin{aligned}
\vec{\mathcal{E}}_r(x,z,t) &= \hat{\epsilon}\int A(\kappa)e^{\imath(\mathbf{k}_r+\vec{\kappa}_r)\cdot\mathbf{r}-\imath\omega t+\imath\phi_i}d\kappa \qquad with \qquad \begin{cases}\mathbf{k}_r = k(\hat{\mathbf{e}}_x\sin\theta_i - \hat{\mathbf{e}}_z\cos\theta_i)\\ \vec{\kappa}_r = \kappa(\hat{\mathbf{e}}_x\cos\theta_i + \hat{\mathbf{e}}_z\sin\theta_i)\end{cases}\\
&= \hat{\epsilon}\int A(\kappa)e^{\imath\kappa\xi+\imath k\zeta-\imath\omega t+\imath\phi_i}d\kappa \qquad with \qquad \begin{cases}\zeta = x\sin\theta_i - z\cos\theta_i\\ \xi = x\cos\theta_i + z\sin\theta_i\end{cases}\\
&= \hat{\epsilon}e^{\imath k(x\sin\theta_i - z\cos\theta_i)-\imath\omega t+\imath\phi_i}\int A(\kappa)e^{\imath\kappa(x\cos\theta_i+z\sin\theta_i)}d\kappa\\
&= \hat{\epsilon}e^{\imath k\zeta-\imath\omega t}\int A(\kappa)e^{\imath\kappa\xi+\imath\phi_i}d\kappa\ .
\end{aligned}$$

We expand the phase shift [9]*,*

$$\phi_i = \phi(\theta_i+\delta\theta) = \phi(\theta_i) + \delta\theta\frac{d\phi(\theta_i)}{d\theta_i} = \phi(\theta_i) - \kappa\delta\xi \qquad with \qquad \delta\xi \equiv -\frac{1}{k}\frac{d\phi(\theta_i)}{d\theta_i}\ ,$$

and insert it into the expression for the reflected field,

$$\vec{\mathcal{E}}_r(x,z,t) = \hat{\epsilon}e^{\imath k\zeta-\imath\omega t+\phi(\theta_i)}\int A(\kappa)e^{\imath\kappa\xi-\imath\kappa\delta\xi}d\kappa = \hat{\epsilon}e^{\imath k\zeta-\imath\omega t}\mathcal{E}(\xi-\delta\xi)\ .$$

c. Now we just need to calculate the transverse displacements,

$$\mathcal{D}_{s,p} \equiv d\xi_{s,p} = -\frac{1}{k}\frac{d\phi_{s,p}(\theta_i)}{d\theta_i}\ .$$

To do this, using the definitions,

$$\alpha \equiv \frac{\cos\theta_t}{\cos\theta_i} \qquad with \qquad \cos\theta_t = \imath\sqrt{\frac{n_1^2}{n_2^2}\sin^2\theta_i - 1} \qquad and \qquad \beta \equiv \frac{n_2}{n_1}\ ,$$

we first calculate the reflection coefficient for s-polarization,

$$r_s = \frac{1-\alpha\beta}{1-\alpha\beta} = \frac{1-\frac{\imath\sin\theta_{i,total}}{\cos\theta_i}\sqrt{\frac{n_1^2}{n_2^2}\sin^2\theta_i-1}}{1+\frac{\imath\sin\theta_{i,total}}{\cos\theta_i}\sqrt{\frac{n_1^2}{n_2^2}\sin^2\theta_i-1}} = \frac{\cos\theta_i - \imath\sqrt{\sin^2\theta_i-\sin^2\theta_{i,total}}}{\cos\theta_i+\imath\sqrt{\sin^2\theta_i-\sin^2\theta_{i,total}}}\ .$$

The imaginary and real parts are,

$$\mathfrak{Im}\ r_s = \frac{-2\cos\theta_i\sqrt{\sin^2\theta_i-\sin^2\theta_{i,total}}}{1-\sin^2\theta_{i,total}} \quad , \quad \mathfrak{Re}\ r_p = \frac{\cos^2\theta_i - \sin^2\theta_i + \sin^2\theta_{i,total}}{1-\sin^2\theta_{i,total}}\ ,$$

[9] Other properties of the Fourier transform are,

$$\widetilde{[fg]}(\kappa) = \frac{1}{\sqrt{2\pi}}\int f(x)g(x)e^{-\imath\kappa x}dx = \frac{1}{2\pi}\int\int\int f(x')e^{-\imath\kappa' x'}g(x)e^{-\imath(\kappa-\kappa')x}d\kappa' dx dx' = \frac{1}{\sqrt{2\pi}}[\tilde{f}\star\tilde{g}](\kappa)$$

$$\widetilde{[e^{iqx}]}(\kappa) = \frac{1}{\sqrt{2\pi}}\int e^{iqx}e^{-\imath\kappa x}dx = \sqrt{2\pi}\delta(q-\kappa)$$

$$\widetilde{[fe^{iqx}]}(\kappa) = \frac{1}{\sqrt{2\pi}}\int f(x)e^{iqx}e^{-\imath\kappa x}dx = \frac{1}{\sqrt{2\pi}}\int f(x)e^{\imath(q-\kappa)x}dx = f(q-\kappa)\ .$$

and the phase shift,

$$\phi_s = \arctan \frac{\mathfrak{Im}\ r_s}{\mathfrak{Re}\ r_s} = \arctan \frac{-2\cos\theta_i \sqrt{\sin^2\theta_i - \sin^2\theta_{i,total}}}{\cos^2\theta_i - \sin^2\theta_i + \sin^2\theta_{i,total}} \ .$$

Finally, the transverse displacement is,

$$\mathcal{D}_s = -\frac{1}{k}\frac{d\phi_s}{d\theta_i} = \frac{2}{k}\frac{\sin\theta}{\sqrt{\sin^2\theta - \sin^2\theta_{i,total}}} \ .$$

An analogous calculation for p-polarization gives the reflection coefficient,

$$r_p = \frac{\alpha - \beta}{\alpha + \beta} = \frac{\frac{\cos\theta_t}{\cos\theta_i} - \frac{n_2}{n_1}}{\frac{\cos\theta_t}{\cos\theta_i} + \frac{n_2}{n_1}} = \frac{\imath\sqrt{\sin^2\theta_i - \sin^2\theta_{i,total}} - \cos\theta_i \sin^2\theta_{i,total}}{\imath\sqrt{\sin^2\theta_i - \sin^2\theta_{i,total}} + \cos\theta_i \sin^2\theta_{i,total}} \ .$$

The imaginary and real parts are,

$$\mathfrak{Im}\ r_p = \frac{2\cos\theta_i \sin^2\theta_{i,total}\sqrt{\sin^2\theta_i - \sin^2\theta_{i,total}}}{\sin^2\theta_i - \sin^2\theta_{i,total} + \cos^2\theta_i \sin^4\theta_{i,total}} \ ,$$

$$\mathfrak{Re}\ r_p = \frac{\sin^2\theta_i - \sin^2\theta_{i,total} - \cos^2\theta_i \sin^4\theta_{i,total}}{\sin^2\theta_i - \sin^2\theta_{i,total} + \cos^2\theta_i \sin^4\theta_{i,total}} \ ,$$

and the phase shift,

$$\phi_p = \arctan \frac{\mathfrak{Im}\ r_p}{\mathfrak{Re}\ r_p} = \arctan \frac{2\cos\theta_i \sin^2\theta_{i,total}\sqrt{\sin^2\theta_i - \sin^2\theta_{i,total}}}{\sin^2\theta_i - \sin^2\theta_{i,total} - \cos^2\theta_i \sin^4\theta_{i,total}} \ .$$

Finally, the transverse displacement is,

$$\begin{aligned}\mathcal{D}_p = -\frac{1}{k}\frac{d\phi_p}{d\theta_i} &= -\frac{1}{k}\frac{2\sin\theta\sin^2\theta_{i,total}}{\left(\cos^2\theta\sin^2\theta_{i,total} - \sin^2\theta\right)\sqrt{\sin^2\theta - \sin^2\theta_{i,total}}} \\ &= \frac{\mathcal{D}_s \sin^2\theta_{i,total}}{\sin^2\theta - \cos^2\theta\sin^2\theta_{i,total}} \ .\end{aligned}$$

18.1.8.25 Ex: Interfaces

A light field of angular frequency ω passes from a medium (1), through a slab of thickness d representing a medium (2), to a medium (3). All three media are linear and homogeneous. Calculate the transmission coefficient between the media 1 and 3 for normal incidence.

Solution: *The transfer of the electric field through a system characterized by a matrix* $\mathcal{M}_{13}$ *is given by,*

$$\begin{pmatrix} \mathcal{E}_3^+ \\ 0 \end{pmatrix} = M_{13} \begin{pmatrix} \mathcal{E}_1^+ \\ \mathcal{E}_1^- \end{pmatrix} = M_{23} M_d M_{12} \begin{pmatrix} \mathcal{E}_1^+ \\ \mathcal{E}_1^- \end{pmatrix} ,$$

or equivalently,

$$\begin{pmatrix} \mathcal{E}_1^+ \\ \mathcal{E}_1^- \end{pmatrix} = M_{13}^{-1} \begin{pmatrix} \mathcal{E}_3^+ \\ 0 \end{pmatrix} = M_{12}^{-1} M_d^{-1} M_{23}^{-1} \begin{pmatrix} \mathcal{E}_3^+ \\ 0 \end{pmatrix} = M_{21} M_d M_{32} \begin{pmatrix} \mathcal{E}_3^+ \\ 0 \end{pmatrix} ,$$

exploiting the simple fact that $M_{12}^{-1} = M_{21}$*. Now, we find,*

$$\begin{aligned} \begin{pmatrix} \mathcal{E}_1^+ \\ \mathcal{E}_1^- \end{pmatrix} &= \frac{1}{2n_1} \begin{pmatrix} n_1+n_2 & n_1-n_2 \\ n_1-n_2 & n_1+n_2 \end{pmatrix} \begin{pmatrix} e^{-\imath k_2 d} & 0 \\ 0 & e^{\imath k_2 d} \end{pmatrix} \frac{1}{2n_2} \begin{pmatrix} n_2+n_3 & n_2-n_3 \\ n_2-n_3 & n_2+n_3 \end{pmatrix} \begin{pmatrix} \mathcal{E}_3^+ \\ 0 \end{pmatrix} \\ &= \frac{1}{4n_2 n_1} \begin{pmatrix} (n_2+n_1)e^{-\imath k_2 d}(n_2+n_3) + (n_1-n_2)e^{\imath k_2 d}(n_2-n_3) \\ (n_1-n_2)e^{-\imath k_2 d}(n_2+n_3) + (n_2+n_1)e^{\imath k_2 d}(n_2-n_3) \end{pmatrix} \mathcal{E}_3^+ , \end{aligned}$$

such that the transmission becomes,

$$\begin{aligned} T = \frac{I_3}{I_1} &= \frac{\varepsilon_3 c_3 |\mathcal{E}_3^+|^2}{\varepsilon_1 c_1 |\mathcal{E}_1^+|^2} = \frac{n_3}{n_1} \frac{|\mathcal{E}_3^+|^2}{|\mathcal{E}_1^+|^2} \\ &= \frac{n_3}{n_1} \frac{(4n_2 n_1)^2}{\left|(n_2+n_1)e^{-\imath k_2 d}(n_2+n_3) + (n_1-n_2)e^{\imath k_2 d}(n_2-n_3)\right|^2} \\ &= \frac{4n_1 n_2^2 n_3}{n_2^2(n_1+n_3)^2 + (n_1^2-n_2^2)(n_3^2-n_2^2)\sin^2 k_2 d} . \end{aligned}$$

18.2 Optical dispersion in material media

18.2.1 Plane waves in conductive media

When there are free charges in the propagation medium, we can not neglect neither ϱ_f nor $\mathbf{j}_f$ in the Maxwell equations used to describe the wave propagation, because the electric field of the wave will itself generate a current $\mathbf{j}_f = \varsigma \vec{\mathcal{E}}$, where ς is the conductivity introduced in Eq. (14.42). Thus, for linear media we must use the complete equations (17.6).

For a homogeneous and linear medium, the continuity equation gives,

$$\frac{\partial \varrho_f}{\partial t} = -\nabla \cdot \mathbf{j}_f = -\varsigma \nabla \cdot \vec{\mathcal{E}} = -\frac{\varsigma}{\varepsilon} \varrho_f , \tag{18.81}$$

with the solution

$$\varrho_f(t) = e^{-(\varsigma/\varepsilon)t} \varrho_f(0) . \tag{18.82}$$

Therefore, every initial free charge density $\varrho_f(0)$ diffuses within a characteristic time $\tau = \varepsilon/\varsigma$. This reflects the familiar fact that free charges in a conductor migrate to its edges with a speed that depends on the conductivity ς. For a good conductor, the relaxation time is much shorter than other characteristic times of the system, e.g. for oscillatory systems $\tau \ll \omega^{-1}$. In stationary situations we can assume, $\varrho = 0$, such that the relevant Maxwell equations,

$$\begin{array}{lrcl} \text{(i)} & \nabla \times \vec{\mathcal{B}} - \varepsilon\mu\partial_t\vec{\mathcal{E}} &=& \mu\varsigma\vec{\mathcal{E}} \\ \text{(ii)} & \nabla \times \vec{\mathcal{E}} + \partial_t\vec{\mathcal{B}} &=& 0 \\ \text{(iii)} & \nabla \cdot \vec{\mathcal{E}} &=& 0 \\ \text{(iv)} & \nabla \cdot \vec{\mathcal{B}} &=& 0 \end{array} \quad , \tag{18.83}$$

only differ from the Maxwell equations for dielectric media by the existence of the term $\mu\varsigma\vec{\mathcal{E}}$.

Letting the rotation operator act on equations (i) and (ii) and exploiting the disappearance of the field divergences we obtain generalized wave equations,

$$\nabla^2\vec{\mathcal{E}} = \varepsilon\mu\frac{\partial^2\vec{\mathcal{E}}}{\partial t^2} + \varsigma\mu\frac{\partial\vec{\mathcal{E}}}{\partial t} \qquad \text{and} \qquad \nabla^2\vec{\mathcal{B}} = \varepsilon\mu\frac{\partial^2\vec{\mathcal{B}}}{\partial t^2} + \varsigma\mu\frac{\partial\vec{\mathcal{B}}}{\partial t} \ . \tag{18.84}$$

These equations still accept plane wave solutions,

$$\vec{\mathcal{E}}(z,t) = \vec{\mathcal{E}}_0 e^{\imath(\tilde{k}z-\omega t)} \qquad \text{and} \qquad \vec{\mathcal{B}}(z,t) = \vec{\mathcal{B}}_0 e^{\imath(\tilde{k}z-\omega t)} \ , \tag{18.85}$$

but this time the wavevector is complex,

$$\tilde{k}^2 = \varepsilon\mu\omega^2 + \imath\varsigma\mu\omega \ , \tag{18.86}$$

which can easily be verified by inserting a plane wave into the wave equations (18.84). The root of this expression gives,

$$\boxed{\begin{array}{lllll} \tilde{k} = k + \imath\kappa & \text{with} & k & \equiv \omega\sqrt{\frac{\varepsilon\mu}{2}}\left(\sqrt{1+\left(\frac{\varsigma}{\varepsilon\omega}\right)^2}+1\right)^{1/2} \\ & \text{and} & \kappa & \equiv \omega\sqrt{\frac{\varepsilon\mu}{2}}\left(\sqrt{1+\left(\frac{\varsigma}{\varepsilon\omega}\right)^2}-1\right)^{1/2} \end{array}} \ . \tag{18.87}$$

The imaginary part results in an attenuation of the wave in z-direction:

$$\vec{\tilde{\mathcal{E}}}(z,t) = \vec{\tilde{\mathcal{E}}}_0 e^{-\kappa z} e^{\imath(kz-\omega t)} \qquad \text{and} \qquad \vec{\tilde{\mathcal{B}}}(z,t) = \vec{\tilde{\mathcal{B}}}_0 e^{-\kappa z} e^{\imath(kz-\omega t)} \ . \tag{18.88}$$

The typical attenuation distance, κ^{-1}, called *skin depth*, measures the penetration depth of the wave in a conductor, while the real part k determines the propagation of the wave. As before, the equations (18.83)(iii) and (iv) exclude components perpendicular to the interface. The wave only has transverse components, that is, parallel to the interface, so that we can let the electric field be along $\hat{\mathbf{e}}_x$,

$$\vec{\tilde{\mathcal{E}}}(z,t) = \tilde{\mathcal{E}}_0\hat{\mathbf{e}}_x e^{-\kappa z} e^{\imath(kz-\omega t)} \qquad \text{and} \qquad \vec{\tilde{\mathcal{B}}}(z,t) = \tilde{\mathcal{B}}_0\hat{\mathbf{e}}_y e^{-\kappa z} e^{\imath(kz-\omega t)} \ . \tag{18.89}$$

By the equation (18.83)(ii) we verify,

$$\tilde{\mathcal{B}}_0 = \frac{\tilde{k}}{\omega}\tilde{\mathcal{E}}_0 \ . \tag{18.90}$$

Expressing the wavevector and the complex amplitudes by phase factors,

$$\tilde{k} = Ke^{\imath\phi} \quad , \quad \tilde{\mathcal{E}}_0 = \mathcal{E}_0 e^{\imath\delta_E} \quad , \quad \tilde{\mathcal{B}}_0 = \mathcal{B}_0 e^{\imath\delta_B} \ , \tag{18.91}$$

with $K, \mathcal{E}_0, \mathcal{B}_0 \in \mathbb{R}$, we finally find,

$$\mathcal{B}_0 e^{\imath\delta_B} = \frac{Ke^{\imath\phi}}{\omega}\mathcal{E}_0 e^{\imath\delta_E} \ , \tag{18.92}$$

that is,

$$\frac{\mathcal{B}_0}{\mathcal{E}_0} = \frac{K}{\omega} = \frac{\sqrt{k^2+\kappa^2}}{\omega} = \sqrt{\varepsilon\mu\sqrt{1+\left(\frac{\varsigma}{\varepsilon\omega}\right)^2}} \tag{18.93}$$

and

$$\begin{aligned} \vec{\mathcal{E}}(z,t) &= \mathcal{E}_0\hat{\mathbf{e}}_x e^{-\kappa z}\cos(kz-\omega t+\delta_E) \\ \vec{\mathcal{B}}(z,t) &= \mathcal{B}_0\hat{\mathbf{e}}_y e^{-\kappa z}\cos(kz-\omega t+\delta_E+\phi) \ , \end{aligned} \tag{18.94}$$

as illustrated in Fig. 18.9. Such a wave is called *evanescent wave*. From Eqs. (18.93) and (18.87) we immediately deduce,

$$\begin{aligned} K &\overset{\varsigma\to 0}{\longrightarrow} \frac{\omega}{c_n} \quad \text{and} \quad \phi = \arctan\frac{\kappa}{k} \overset{\varsigma\to 0}{\longrightarrow} 0 \\ K &\overset{\varsigma\to\infty}{\longrightarrow} \infty \quad \text{and} \quad \phi \overset{\varsigma\to\infty}{\longrightarrow} \tfrac{\pi}{4} \ . \end{aligned} \tag{18.95}$$

Do the Exc. 18.2.7.1 and 18.2.7.2.

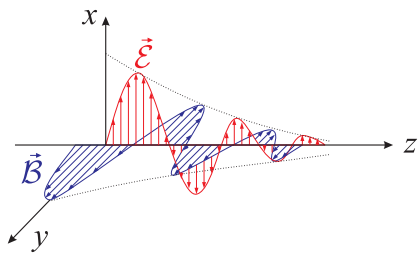

Figure 18.9: Attenuation of a wave by a conducting medium.

18.2.1.1 Reflection by a conductive surface

In the presence of free charges and currents the boundary conditions derived in (18.42) must be generalized,

$$\begin{array}{lrcl} \text{(i)} & \frac{1}{\mu_1}\vec{\mathcal{B}}_1^{\parallel} - \frac{1}{\mu_2}\vec{\mathcal{B}}_2^{\parallel} &=& \mathbf{k}_f \times \hat{\mathbf{e}}_n \\ \text{(ii)} & \vec{\mathcal{E}}_1^{\parallel} - \vec{\mathcal{E}}_2^{\parallel} &=& 0 \\ \text{(iii)} & \varepsilon_1\vec{\mathcal{E}}_1^{\perp} - \varepsilon_2\vec{\mathcal{E}}_2^{\perp} &=& \sigma_f \\ \text{(iv)} & \vec{\mathcal{B}}_1^{\perp} - \vec{\mathcal{B}}_1^{\perp} &=& 0 \end{array} \quad , \tag{18.96}$$

where σ_f is the density of free surface charges, $\mathbf{k}_f$ is the density of free surface currents, and $\hat{\mathbf{e}}_n$ the normal vector of the surface pointing into the direction of medium 1 (compare with Fig. 15.17).

We now assume that the interface at $z = 0$ separates the dielectric medium 1 from the conductive medium 2. A monochromatic plane wave is partially reflected and transmitted, as discussed above,

$$\begin{array}{lcl} \vec{\tilde{\mathcal{E}}}_i(z,t) = \tilde{\mathcal{E}}_{0i}\hat{\mathbf{e}}_x e^{\imath(k_1 z - \omega t)} & , & \vec{\tilde{\mathcal{B}}}_i(z,t) = -\frac{1}{c_1}\tilde{\mathcal{E}}_{0i}\hat{\mathbf{e}}_y e^{\imath(k_1 z - \omega t)} \\ \vec{\tilde{\mathcal{E}}}_r(z,t) = \tilde{\mathcal{E}}_{0r}\hat{\mathbf{e}}_x e^{\imath(-k_1 z - \omega t)} & , & \vec{\tilde{\mathcal{B}}}_r(z,t) = \frac{1}{c_1}\tilde{\mathcal{E}}_{0r}\hat{\mathbf{e}}_y e^{\imath(k_1 z - \omega t)} \\ \vec{\tilde{\mathcal{E}}}_t(z,t) = \tilde{\mathcal{E}}_{0t}\hat{\mathbf{e}}_x e^{\imath(\tilde{k}_2 z - \omega t)} & , & \vec{\tilde{\mathcal{B}}}_t(z,t) = \frac{\tilde{k}_2}{\omega}\tilde{\mathcal{E}}_{0t}\hat{\mathbf{e}}_y e^{\imath(\tilde{k}_2 z - \omega t)} \end{array} \quad , \tag{18.97}$$

Obviously, the transmitted wave penetrating the conductive medium is attenuated.

The boundary conditions at $z = 0$ become, for the considered case ($\vec{\mathcal{E}}^{\perp} = 0 = \vec{\mathcal{B}}^{\perp}$) and with $\mathbf{k}_f = 0$,

$$\begin{array}{lrcl} \text{(i)} & \frac{1}{\mu_1 c_1}(\mathcal{E}_{0i} - \mathcal{E}_{0r}) &=& \frac{\tilde{k}_2}{\mu_2\omega}\mathcal{E}_{0t} \\ \text{(ii)} & \tilde{\mathcal{E}}_{0i} + \tilde{\mathcal{E}}_{0r} &=& \tilde{\mathcal{E}}_{0t} \\ \text{(iii)} & 0 &=& \sigma_f \\ \text{(iv)} & 0 &=& 0\ . \end{array} \quad , \tag{18.98}$$

Defining,

$$\tilde{\beta} \equiv \frac{\mu_1\tilde{k}_2}{\mu_2 k_1}\ , \tag{18.99}$$

we derive,

$$\frac{\tilde{\mathcal{E}}_{0r}}{\tilde{\mathcal{E}}_{0i}} = \frac{1-\tilde{\beta}}{1+\tilde{\beta}} \quad \text{and} \quad \frac{\tilde{\mathcal{E}}_{0t}}{\tilde{\mathcal{E}}_{0i}} = \frac{2}{1+\tilde{\beta}}\ . \tag{18.100}$$

The formulas are formally similar to (18.48), but they are complex. For a bad conductor ($\varsigma = 0 \quad \rightarrow \quad \kappa = 0$) we recover the equation (18.48). For a perfect conductor ($\varsigma = \infty \quad \rightarrow \quad \kappa = \infty \quad \rightarrow \quad \tilde{\beta} = \imath\infty$) we find $\tilde{\mathcal{E}}_{0r} = -\tilde{\mathcal{E}}_{0i}$ and $\tilde{\mathcal{E}}_{0t} = 0$. That is, the wave is fully reflected with a phase change of 180° [10].

[10] The 'skin depth' in silver (for optical frequencies) is in the order of 10 nm. For this reason, thin layers of good conductors already represent good mirrors.

18.2.2 Linear and quadratic dispersion

The refractive index may depend on the wavelength. Even the *refractive index of air* exhibits dispersion, as shown in Fig. 18.10 [11].

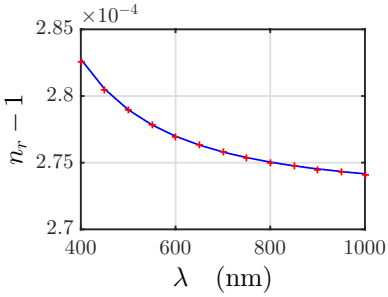

Figure 18.10: (code) Refractive index of air. The crosses were calculated by the Cauchy formula (18.146), with $A = 0.0002725$ and $B = 0.0059$.

We consider a superposition of two waves,

$$\begin{aligned} Y_1(x,t) + Y_2(x,t) &= a\cos(k_1 x - \omega_1 t) + a\cos(k_2 x - \omega_2 t) \\ &= 2a\cos\left[\tfrac{(k_1-k_2)x}{2} - \tfrac{(\omega_1-\omega_2)t}{2}\right]\cos\left[\tfrac{(k_1+k_2)x}{2} - \tfrac{(\omega_1+\omega_2)t}{2}\right] . \end{aligned} \tag{18.101}$$

The resulting wave can be seen as a wave of frequency $\frac{1}{2}(\omega_1+\omega_2)t$ and wavelength $\frac{1}{2}(k_1+k_2)$ whose amplitude is modulated by an envelope of frequency $\frac{1}{2}(\omega_1-\omega_2)t$ and wavelength $\frac{1}{2}(k_1-k_2)x$.

In the absence of dispersion the *phase velocities* of the two waves and the propagation velocity of the envelope, called *group velocity*, are equal,

$$c = \frac{\omega_1}{k_1} = \frac{\omega_2}{k_2} = \frac{\omega_1-\omega_2}{k_1-k_2} = \frac{\Delta\omega}{\Delta k} = v_g \ . \tag{18.102}$$

But the phase velocities of the two harmonic waves may be different, $c = c(k)$, such that the frequency depends on the wavelength, $\omega = \omega(k)$. In this case, the group velocity also varies with the wavelength,

$$v_g = \frac{d\omega}{dk} = \frac{d}{dk}(kc) = c + k\frac{dc}{dk} \ . \tag{18.103}$$

Often, this variation is not very strong, such that it is possible to expand around an average value ω_0 of the spectral region of interest,

$$\boxed{\begin{aligned} \omega(k) &= \omega_0 + \left.\frac{d\omega}{dk}\right|_{k_0}\cdot(k-k_0) + \frac{1}{2}\left.\frac{d^2\omega}{dk^2}\right|_{k_0}\cdot(k-k_0)^2 \\ &\equiv \omega_0 + v_g(k-k_0) + \beta(k-k_0)^2 \end{aligned}} \ . \tag{18.104}$$

[11] The refractive index of air can be calculated by the formula $n = 1 + (n_s - 1)\frac{0.00185097\ P}{1+0.003661\ T}$ with $n_s = \sqrt{1 + \frac{4.334446\cdot10^{-4}\lambda^2}{\lambda^2 - 3.470339\cdot10^{-3}} + \frac{1.118728\cdot10^{-4}\lambda^2}{\lambda^2 - 1.394001\cdot10^{-2}}}$, where T is the temperature in Celsius and P the atmospheric pressure in mbar.

Generally, $v_g < c$, in which situation we speak of *normal dispersion*. But there are situations of *anomalous dispersion*, where $v_g > c$, e.g. close to resonances or when the wave under study is a *matter wave* characterized by quadratic dispersion [12], $\hbar\omega = (\hbar k)^2/2m$.

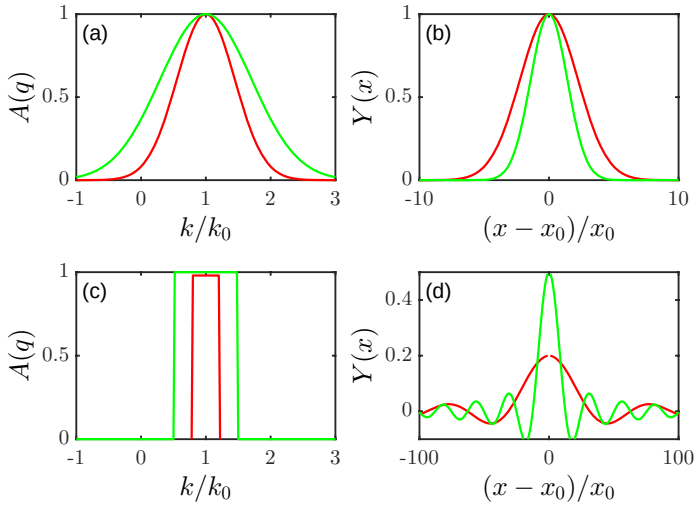

Figure 18.11: (code) Gaussian amplitude distribution (a,b) and rectangular distribution (c,d) in momentum space (a,c) and in position space (b,d).

Example 103 (*Rectangular wave packet with linear dispersion*): As an example we determine the shape of the wavepacket for a rectangular amplitude distribution, $A(k) = A_0\chi_{[k_0-\Delta k/2, k_0+\Delta k/2]}$, subject to linear dispersion (expansion up to the linear term in Eq. (18.104)). Via the Fourier theorem,

$$
\begin{aligned}
Y(x,t) &= \int_{-\infty}^{\infty} A(k) e^{\imath(kx-\omega t)} dk = A_0 \int_{k_0-\Delta k/2}^{k_0+\Delta k/2} e^{\imath(kx-\omega_0 t + v_g(k-k_0)t)} dk \\
&= A_0 e^{\imath(k_0 x-\omega_0 t)} \int_{k_0-\Delta k/2}^{k_0+\Delta k/2} e^{\imath(k-k_0)(x-v_g t)} dk \\
&= A_0 e^{\imath(k_0 x-\omega_0 t)} \int_{-\Delta k/2}^{\Delta k/2} e^{\imath k(\cancel{x - v_g t}^{\,u})} dk \\
&= A_0 \frac{e^{\imath u \Delta k/2} - e^{-\imath u \Delta k/2}}{\imath u} e^{\imath(k_0 x-\omega_0 t)} = 2A_0 \frac{\sin\frac{u\Delta k}{2}}{u} e^{\imath(k_0 x-\omega_0 t)} \equiv A(x,t) e^{\imath(k_0 x-\omega_0 t)} \,.
\end{aligned}
$$

The envelope $A(x,t)$ has the shape of a 'sinc' function, such that the wave intensity is,

$$|Y(x,t)|^2 = A_0^2 \Delta k^2 \ \mathrm{sinc}^2\left[\tfrac{\Delta k}{2}(x - v_g t)\right] \,.$$

Obviously, the *wave packet* is at any time t localized in space, as illustrated by the lower graphs of Figs. 18.11. It *moves with group velocity*, v_g, but it does not spread.

[12] Since $c = \frac{\omega}{c} = \frac{\hbar k}{2m} < \frac{\hbar k}{m} = v_g$.

The last example showed, that linear dispersion does not lead to spreading (or diffusion) of a wavepacket, as opposed to quadratic dispersion, which we will show in the following example.

Example 104 (*Dispersion of a Gaussian wavepacket subject to quadratic dispersion*): Quadratic dispersion causes spreading of wavepackets. We show this at the example of the Gaussian wavepacket, $A(k) = A_0 e^{-\alpha(k-k_0)^2}$, expanding the dispersion relation (18.104) up to the quadratic term. Via the Fourier theorem,

$$\begin{aligned} Y(x,t) &= \int_{-\infty}^{\infty} A(k) e^{\imath(kx-\omega t)} dk = A_0 e^{\imath(k_0 x - \omega_0 t)} \int_{-\infty}^{\infty} e^{\imath(k-k_0)(x-v_g t) - (\alpha + \imath\beta t)(k-k_0)^2} dk \\ &= A_0 e^{\imath(k_0 x - \omega_0 t)} \int_{-\infty}^{\infty} e^{\imath k(\cancel{x - v_g t}^{\,u}) - (\cancel{\alpha + \imath\beta t}^{\,v})k^2} dk \\ &\equiv A_0 e^{\imath(k_0 x - \omega_0 t)} \int_{-\infty}^{\infty} e^{\imath k u - v k^2} dk = A_0 \sqrt{\frac{\pi}{v}} e^{\imath(k_0 x - \omega_0 t)} e^{-u^2/4v} \ . \end{aligned}$$

The absolute square of the solution describes the spatial energy distribution of the packet,

$$|Y(x,t)|^2 = A_0^2 \frac{\pi}{\sqrt{v v^*}} e^{-u^2/4v - u^2/4v^*} = A_0^2 \frac{\pi}{x_0 \sqrt{\alpha/2}} e^{-(x-v_g t)^2/x_0^2} \ ,$$

with $x_0 \equiv \sqrt{2\alpha}\sqrt{1 + \frac{\beta^2}{\alpha^2} t^2}$. Obviously, for long times the pulse spreads with constant velocity. Since the constant α gives the initial width of the pulse, we realize that an initially compressed pulse spreads faster. Therefore, the angular coefficient of the dispersion relation determines the group velocity, while the curvature determines the spreading velocity. See upper graphs of Figs. 18.11.

Resolve the Excs. 18.2.7.3 to 18.2.7.5.

18.2.3 Microscopic dispersion and the Lorentz model

Obviously, the structure that we assume for the matter also influences its reaction to electromagnetic waves, which interact differently with the charged components of the matter. The planetary model proposed by *E. Rutherford* considers matter to be made of atoms, which in turn are composed of *bound electrons* orbiting small positively charged nuclei. On the other side, metals have free electrons. The inertia of the charged particles (free or bound electrons, ions) being accelerated by incident electromagnetic waves is the reason for the dispersion phenomena that we will treat in the following sections.

Thomson scattering is the elastic scattering of light (photons) by free or quasi-free electrically charged particles (that is, weakly bound as compared to photon energies). A charged particle is prompted by the field of an electromagnetic wave to perform harmonic oscillations within the plane spanned by the electric and the magnetic field vectors. As the oscillation is an accelerated motion, the particle simultaneously re-emits energy in the form of an electromagnetic wave with the same frequency (dipole radiation). Thomson scattering does not consider photonic recoil, that is, there is no transfer of momentum from the photon to the electron, which is only a good assumption when the energy of the incident photons is small enough, that is, $\hbar\omega \ll$

$m_e c^2$, so that the wavelength of the electromagnetic radiation is much longer than the Compton wavelength $\lambda \gg \lambda_C = h/mc \simeq 2.4\,\text{pm}$ of the electron (which is the case for optical wavelengths). For higher energies, it is necessary to take the recoil of the electron into consideration (as done in the case of Compton scattering) [13].

18.2.3.1 Lorentz model

In classical physics the scattering of light by charges is described by the *Lorentz model* [547]. Assuming a harmonic electric field, $\vec{\mathcal{E}}(t) = \vec{\mathcal{E}}_0 e^{-\imath\omega t}$, we derive a force acting on an electron harmonically bound to a potential [14],

$$\mathbf{F} = -e\vec{\mathcal{E}}(t) \tag{18.105}$$

with e the elementary charge. The equation of motion is that of a damped harmonic oscillator:

$$m_e\ddot{\mathbf{r}} + m_e\gamma_\omega\dot{\mathbf{r}} + m_e\omega_0^2\mathbf{r} = -e\vec{\mathcal{E}}(t) \tag{18.106}$$

with the mass m_e of the electron, the damping γ_ω (by collisions, radiative losses, etc.), and a resonance frequency ω_0. We note, that the damping may depend on the excitation frequency.

After some time, when the transient processes are damped out, the electrons oscillate with the angular frequency ω of the external field. For this inhomogeneous solution we make the ansatz:

$$\mathbf{r}(t) = \mathbf{r}_e e^{-\imath\omega t} \tag{18.107}$$

with the constant complex amplitude $\mathbf{r}_e$. Inserting this into the equation of motion, we obtain for the atomic dipole moment induced by the electromagnetic field [15]:

$$\boxed{\mathbf{d}(t) \equiv -e\mathbf{r}(t) = \frac{e^2/m_e}{\omega_0^2 - \omega^2 - \imath\gamma_\omega\omega}\vec{\mathcal{E}}(t) \equiv \alpha_{pol}(\omega)\vec{\mathcal{E}}(t)}\,, \tag{18.108}$$

where we used the *electric polarizability* α_{pol} introduced in (14.6) and relating the amplitudes of the field and the dipole moment. The imaginary term in the denominator means that the oscillation of $\mathbf{d}$ is out of phase with $\vec{\mathcal{E}}$ being delayed by an angle

$$\varphi = \arctan\frac{\gamma_\omega\omega}{\omega_0^2 - \omega^2}\,, \tag{18.109}$$

which is very small when $\omega \ll \omega_0$ and approaches π when $\omega \gg \omega_0$ [1219]. This is illustrated in Fig. 18.14(left).

[13] Thomson scattering can be considered the limiting case of *Compton scattering* for small photon energies. The Thomson model holds for free electrons in a metal, whose resonant frequency tends, due to the absence of restoring forces, to zero. Scattering by bound electrons is called *Rayleigh scattering*.
In practice, Thomson scattering is used to determine the electron density through the intensity and temperature of the spectral distribution of scattered radiation assuming a Maxwell distribution for the electron velocities.

[14] Let us imagine for the sake of illustration that the displacement of the electron from its equilibrium position generates (to first order) an elastic restoring force with resonances at certain frequencies.

[15] See Sec. 4.3.

The temporal average of the dipole moment is,

$$\sqrt{\overline{d^2}} = \alpha_{pol}\mathcal{E}_0\sqrt{\tfrac{1}{T}\int_0^T \cos^2\omega t dt} = \alpha_{pol}\mathcal{E}_0\sqrt{\tfrac{1}{2}} \equiv d_0\sqrt{\tfrac{1}{2}} \ . \tag{18.110}$$

To calculate the emitted radiation we must borrow a result from future lessons: From the electromagnetic fields (19.40) of an oscillating dipole we will derive the expression for the Poynting vector (19.44),

$$\langle\vec{\mathcal{S}}\rangle = \tfrac{1}{\mu_0}\langle\vec{\mathcal{E}}\times\vec{\mathcal{B}}\rangle = \frac{\mu_0 d_0^2\omega^4}{16\pi^2 c}\frac{\sin^2\theta}{r^2}\hat{\mathbf{e}}_r = \frac{d_0^2\omega^4}{32\pi^2\varepsilon_0 c^3}\frac{\sin^2\theta}{r^2}\hat{\mathbf{e}}_r \ . \tag{18.111}$$

Obviously, the radiation is not isotropic, but concentrated in directions perpendicular to the dipole moment. In fact, the spherical harmonic function ($\sin\theta$), responsible for this toroidal angular distribution, is precisely the p-wave [16]. The total power radiated by the dipole can be derived from the Poynting vector,

$$\boxed{P = \int_0^{2\pi}\int_0^{\pi}\langle\vec{\mathcal{S}}\rangle\cdot\hat{\mathbf{e}}_r r^2\sin\theta d\theta d\phi = \frac{\mu_0 d_0^2\omega^4}{32\pi^2 c}\ 2\pi\int_0^{\pi}\sin^3\theta d\theta = \frac{\mu_0\omega^4 d_0^2}{12\pi c}} \ , \tag{18.112}$$

knowing $\int_0^{\pi}\sin^3 x dx = \frac{4}{3}$. This result is known as the *Larmor formula*.

18.2.3.2 Thompson and Rayleigh scattering

We now imagine that the dipole is excited by an incident wave of intensity,

$$I = \tfrac{1}{2}\varepsilon_0 c\vec{\mathcal{E}}_0^2 \ , \tag{18.113}$$

and scatters the radiation to a solid angle $d\Omega$, such that the angular distribution of scattered power is,

$$\frac{dP}{d\Omega} = |\langle\vec{\mathcal{S}}\rangle| r^2 \ . \tag{18.114}$$

We can now calculate the differential *scattering cross section* inserting the polarizability (18.108),

$$\begin{aligned}\frac{d\sigma}{d\Omega} = \frac{dP/d\Omega}{I} &= \frac{d_0^2\omega^4\sin^2\theta}{32\pi^2\varepsilon_0 c^3 r^2}r^2\frac{1}{\frac{1}{2}\varepsilon_0 c\mathcal{E}_0^2} = \frac{|\alpha_{pol}|^2\mathcal{E}_0^2\omega^4\sin^2\theta}{16\pi^2\varepsilon_0^2 c^4\mathcal{E}_0^2} \\ &= \left|\frac{e^2/m_e}{\omega_0^2-\omega^2-\imath\gamma_\omega\omega}\right|^2\frac{\omega^4\sin^2\theta}{16\pi^2\varepsilon_0^2 c^4} = \frac{r_e^2\omega^4\sin^2\theta}{(\omega_0^2-\omega^2)^2+\gamma_\omega^2\omega^2} \ ,\end{aligned} \tag{18.115}$$

where we defined the abbreviation,

$$r_e \equiv \frac{1}{4\pi\varepsilon_0}\frac{e^2}{m_e c^2} \approx 2.8\cdot 10^{-15}\,\mathrm{m} \tag{18.116}$$

being the *classical electron radius*. The total cross section,

$$\boxed{\sigma(\omega) = \int_{\mathbb{R}^2}\frac{d\sigma}{d\Omega}d\Omega = \frac{8\pi}{3}r_e^2\frac{\omega^4}{(\omega_0^2-\omega^2)^2+\gamma_\omega^2\omega^2}} \ , \tag{18.117}$$

describes a resonance of Lorentzian profile.

We have the following limiting cases:

[16] $Y_1^{\pm 1}(\theta,\phi) = \mp\frac{1}{2}\sqrt{\frac{3}{2\pi}}e^{\pm\imath\phi}\sin\theta$.

- $\omega \gg \omega_0$ Thomson scattering ,
- $\omega = \omega_0$ resonance fluorescence ,
- $\omega \ll \omega_0$ Rayleigh scattering .

A *Thomson cross section* follows in the limit of high energies in comparison with the eigenfrequency, $\omega \gg \omega_0 \gg \gamma_\omega$ from the Lorentz model [17],

$$\sigma_{Thom} = \frac{8\pi}{3} r_e^2 \approx 6.65 \cdot 10^{-29}\,\mathrm{m}^2 \quad . \tag{18.118}$$

Example 105 (*Rayleigh scattering and the blue sky*): We consider the scattering cross section (18.117). For $\omega \to \omega_0$ we obtain a resonant amplification of the cross session of ω^2/γ_ω^2. The resonances of the particles in the atmosphere are in the blue region of the electromagnetic spectrum. Therefore, the visible frequencies are $\omega \ll \omega_0$, and the cross session is $\propto \omega^4$. For this reason, the blue region dominates. The sky just does not look violet, because the eyes are not sensitive for these colors.
The dependence on the observation angle $\propto \sin^2\theta$, where $\theta = \angle(\hat{\epsilon}, \mathbf{k}_s)$ is only valid for polarized light. For non-polarized light, which can be understood as a superposition of two waves with orthogonal polarization, the dependence is $\propto 1 + \cos^2\vartheta$, where $\vartheta = \angle(\mathbf{k}, \mathbf{k}_s)$.

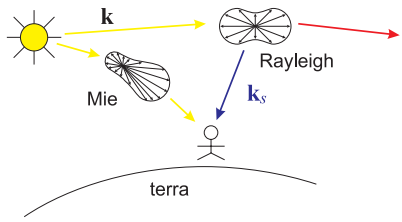

Figure 18.12: Dependence of the Rayleigh and Mie scattering on the observation angle.

Rayleigh scattering dominates for molecules and small scattering objects, $< \lambda/10$. *Mie scattering* is more important for $> \lambda/10$, e.g. water drops. This type of scattering is governed by boundary conditions defined by the surfaces of objects. The angular distributions are strongly oriented in forward direction, particularly when the objects are large. Therefore, this type of scattering only dominates at small angles with respect to the sun, where we observe a bleaching of the blue color of the sky).

18.2.3.3 Atomic polarizability

In atoms, the damping rate γ_ω is due to the radiative energy loss (given by Larmor's formula). It is calculated as the ratio between the classically radiated power and the

[17] A better approximation for small energies is obtained by expansion of the Klein-Nishina formula,

$$\sigma(\nu) = \sigma_{Thom}\left(1 - 2\alpha + \tfrac{56}{5}\alpha^2 + \dots\right)$$

with the factor $\alpha = \frac{h\nu}{m_e c^2}$.

kinetic energy of the electron orbiting the nucleus,

$$\gamma_\omega = \frac{P}{E_{kin}} = \frac{\mu_0 e^2 a^2/12\pi c}{m_e \omega^2 r^2/2} \ , \tag{18.119}$$

where $a = \omega^2 r$ is the acceleration of the electron. We get [547] [18],

$$\boxed{\gamma_\omega = \frac{e^2\omega^2}{6\pi\varepsilon_0 m_e c^3}} \ . \tag{18.120}$$

Defining $\Gamma \equiv \gamma_{\omega_0}$ and inserting into equation (18.108), we can calculate the polarizability within the Lorentz model,

$$\alpha_{pol} = 6\pi\varepsilon_0 c^3 \frac{\Gamma/\omega_0^2}{\omega_0^2 - \omega^2 - \imath(\omega^3/\omega_0^2)\Gamma} \ . \tag{18.121}$$

Close to narrow resonances we can approximate $(\omega_0 + \omega) \to 2\omega_0$ and $(\omega^3/\omega_0^2)\Gamma \to \omega_0\Gamma$ in the denominator of the formula (18.121). Hence, the *polarizability* simplifies to,

$$\boxed{\frac{\alpha_{pol}}{\varepsilon_0} \simeq \frac{6\pi}{k_0^3} \frac{-1}{\imath + 2\Delta/\Gamma}} \ , \tag{18.122}$$

defining the detuning $\Delta \equiv \omega - \omega_0$. Resolve the Excs. 18.2.7.6 to 18.2.7.9.

18.2.4 Classical theory of radiative forces

The Lorentz model permits a classical calculation of the forces exerted by a radiation wave on an electric dipole moment oscillating with the excitation frequency ω [659, 547] [19]. With the dipole moment given by equation (18.108) and the polarizability given by equation (18.121) we can write the dipolar interaction potential as the time-average,

$$\boxed{U_{dip}(\mathbf{r}) = -\frac{1}{2}\overline{\mathbf{d}\cdot\vec{\mathcal{E}}} = -\frac{1}{2\varepsilon_0 c} I(\mathbf{r}) \mathfrak{Re}\ \alpha_{pol}} \ , \tag{18.123}$$

with the field intensity $I = 2\varepsilon_0 c|\vec{\mathcal{E}}|^2$. The factor $\frac{1}{2}$ takes into account the fact, that the dipole moment is induced rather than permanent, as shown in equation (14.10).

Therefore, the potential energy of the atom in the field is proportional to the intensity $I(\mathbf{r})$ and the real part of the polarizability, which describes the *in-phase* component of the dipolar oscillation, being responsible for the dispersive properties of the interaction. The dipole force comes from the gradient of the interaction potential,

$$\mathbf{F}_{dip}(\mathbf{r}) = -\nabla U_{dip}(\mathbf{r}) = \frac{1}{\varepsilon_0 c} \nabla I(\mathbf{r}) \mathfrak{Re}\ \alpha_{pol} \ . \tag{18.124}$$

[18] In quantum mechanics we learn, that the rate for spontaneous emission is, $\Gamma = d^2k^3/3\pi\varepsilon_0\hbar$. This rate coincides with Eq. (18.120) when we assume an amplitude for the electron's oscillation equal to the size of the ground state of a harmonic oscillator,

$$d_0 = er = e\sqrt{\frac{\hbar}{m_e\omega}} = \overline{d^2}\sqrt{2} \ .$$

[19] In principle, we could also use Maxwell's stress tensor.

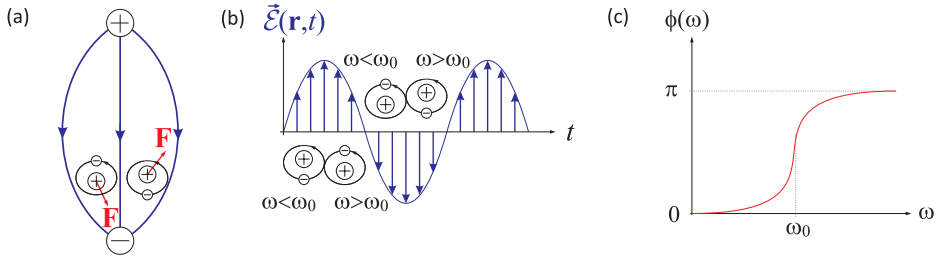

Figure 18.13: (a) Lorentz force on electric dipoles in an electrostatic field gradient. (b) Orientation of induced dipoles in an electromagnetic field. (c) Phase-shift of a harmonic oscillator with a resonance frequency at ω_0 driven at frequency ω.

It is a conservative force proportional to the intensity gradient of the light field. As illustrated in Fig. 18.13, below resonance ($\omega < \omega_0$) the induced electric dipole will be oriented parallel to the electric field such as to minimize its energy by seeking strong field regions. Above resonance ($\omega > \omega_0$) the orientation is reversed so that the dipole can minimize its energy by seeking low field regions.

The power of the field absorbed by the dipolar oscillator (and reemitted as dipolar radiation) is given by,

$$P_{abs} = \overline{\dot{\mathbf{d}} \cdot \vec{\mathcal{E}}} = 2\omega \mathfrak{Im}\ \tilde{\mathbf{d}} \cdot \vec{\tilde{\mathcal{E}}} = -\frac{\omega}{\varepsilon_0 c} I(\mathbf{r}) \mathfrak{Im}\ \alpha_{pol}\ . \tag{18.125}$$

The absorption results from the imaginary part of the polarizability, which describes the *out of phase* component of the dipolar oscillation. Considering the light as a stream of photons with energy $\hbar\omega$, the absorptive part can be interpreted in terms of photon absorption processes followed by spontaneous reemission. The corresponding scattering rate is,

$$\boxed{\Gamma_{sct}(\mathbf{r}) = \frac{P_{abs}}{\hbar\omega} = \frac{1}{\hbar\varepsilon_0 c} I(\mathbf{r}) \mathfrak{Im}\ \alpha_{pol}}\ . \tag{18.126}$$

We emphasize that these expressions are valid for any polarizable neutral particle exposed to an oscillating electric field, provided that saturation effects can be neglected. That it, the expressions hold for atoms and molecules excited near or far from resonances, as well as for a classical antenna [20].

Inserting the polarizability (18.121) in the expressions (18.123) for the dipolar potential and (18.126) for the (Rayleigh) scattering rate we obtain, for the case of large detunings in comparison to the transition linewidth, $\Delta \gg \Gamma$, and negligible saturation,

$$\begin{aligned} U_{dip}(\mathbf{r}) &= -\frac{1}{2\varepsilon_0 c} I(r) \mathfrak{Re}\ \frac{6\pi\varepsilon_0 c^3 \Gamma/\omega_0^2}{\omega_0^2 - \omega^2 - \imath(\omega^3/\omega_0^2)\Gamma} \\ &\simeq -\frac{3\pi c^2}{\omega_0^2} I(\mathbf{r}) \frac{\Gamma}{\omega_0^2 - \omega^2} = -\frac{3\pi c^2}{2\omega_0^3} I(\mathbf{r}) \left(\frac{\Gamma}{\omega_0 - \omega} + \frac{\Gamma}{\omega_0 + \omega} \right)\ , \end{aligned} \tag{18.127}$$

[20] An important difference between quantum and classical oscillators is the possible occurrence of saturation. When the intensity of the driving field is too high, the excited state becomes strongly populated and the derived results are no longer valid. However, for large detunings we are far below the saturation, such that the expressions can be used even for quantum oscillators.

and

$$\hbar\Gamma_{sct}(\mathbf{r}) = \frac{1}{\varepsilon_0 c} I(\mathbf{r}) \Im\mathfrak{m} \, \frac{6\pi\varepsilon_0 c^3 \Gamma/\omega_0^2}{\omega_0^2 - \omega^2 - \imath(\omega^3/\omega_0^2)\Gamma} \tag{18.128}$$
$$\simeq \frac{-6\pi c^2 \Gamma^2 \omega^3}{\omega_0^4} I(\mathbf{r}) \frac{1}{(\omega_0^2 - \omega^2)^2} = \frac{-3\pi c^2}{2\omega_0^3} \left(\frac{\omega}{\omega_0}\right)^3 I(\mathbf{r}) \left(\frac{\Gamma}{\omega_0 - \omega} + \frac{\Gamma}{\omega_0 + \omega}\right)^2 .$$

These expressions exhibit two resonant contributions: In addition to the usual resonance at $\omega = \omega_0$, there is a so-called *counter-rotating* term resonant at $\omega = -\omega_0$. In most applications the radiation source is tuned relatively close to the resonance at ω_0, such that the counter-rotating term can be neglected, which simplifies the expressions to,

$$\boxed{U_{dip}(\mathbf{r}) = \frac{3\pi c^2}{2\omega_0^3} \frac{\Gamma}{\Delta} I(\mathbf{r}) \qquad \text{and} \qquad \hbar\Gamma_{sct}(\mathbf{r}) = \frac{3\pi c^2}{2\omega_0^3} \frac{\Gamma^2}{\Delta^2} I(\mathbf{r})} \, . \tag{18.129}$$

The obvious relationship between the scattering rate and the dipolar potential,

$$\hbar\Gamma_{sct} = \frac{\Gamma}{\Delta} U_{dip} \, , \tag{18.130}$$

is a direct consequence of the profound relationship between the absorptive and dispersive responses of the oscillator. We furthermore emphasize the following relevant points:

- The sign of the detuning: Below an atomic resonance ('red detuning', $\Delta < 0$) the dipolar potential is negative and the interaction attracts the atom to regions of high intensity, e.g. toward the optical axis of a Gaussian light beam or towards the anti-nodes of a standing light wave. Above the atomic resonance ('blue detuning', $\Delta > 0$) is the opposite; the atom is repelled out of high-intensity regions.
- Intensity and detuning-dependence: The dipolar potential is $\propto I/\Delta$, while the scattering rate is $\propto I/\Delta^2$. Therefore, dipolar optical traps are generally realized at large detunings and high intensities in order to reduce the scattering rate while maintaining the potential depth.

18.2.4.1 Microscopic model of the susceptibility, anomalous dispersion

Until now we considered a single valence electron bound to a nucleus. If there are several electrons, the relationship (18.108) must be generalized. Electrons located at different orbitals of a molecule feel different spring constants f_j, natural frequencies ω_j, and damping coefficients γ_j. In the presence of several electrons per molecule and N molecules per volume unit, the polarization $\vec{\mathcal{P}}$ is given by the real part of (14.12),

$$\vec{\tilde{\mathcal{P}}} = \frac{Nq^2}{m} \left(\sum_j \frac{f_j}{\omega_j^2 - \omega^2 - \imath\gamma_j\omega} \right) \vec{\tilde{\mathcal{E}}} \, . \tag{18.131}$$

In equation (14.20) we defined the electric susceptibility χ_ε as proportionality constant between the electric field and the polarization. In the case considered here, $\vec{\mathcal{P}}$ *is not*

proportional to $\vec{\mathcal{E}}$ (strictly speaking, it is not a linear medium), because there is a phase shift between $\vec{\mathcal{P}}$ and $\vec{\mathcal{E}}$. But at least the *complex* polarization $\tilde{\vec{\mathcal{P}}}$ *is proportional to the complex field* $\tilde{\vec{\mathcal{E}}}$, which suggests the introduction of a *complex susceptibility* $\tilde{\chi}_\varepsilon$,

$$\tilde{\vec{\mathcal{P}}} = \varepsilon_0 \tilde{\chi}_\varepsilon \tilde{\vec{\mathcal{E}}} \ . \tag{18.132}$$

All manipulations made so far remain valid, if we assume that the physical polarization is the real part of $\tilde{\vec{\mathcal{P}}}$, in the same way as the physical field is the real part of $\tilde{\vec{\mathcal{E}}}$. In particular, the proportionality between $\tilde{\vec{\mathcal{D}}}$ and $\tilde{\vec{\mathcal{E}}}$ is the complex permittivity $\tilde{\varepsilon} = \varepsilon_0(1+\tilde{\chi}_\varepsilon)$, and the complex dielectric constant (in this model) is,

$$\tilde{\epsilon} \equiv \frac{\tilde{\varepsilon}}{\varepsilon_0} = 1 + \frac{Nq^2}{m\varepsilon_0} \sum_j \frac{f_j}{\omega_j^2 - \omega^2 - \imath\gamma_j\omega} \ . \tag{18.133}$$

Generally, the imaginary part is despicable; however, when ω is very close to one of the resonant frequencies ω_j, it will play a crucial role, as we shall see later.

In a dispersive medium the wave equation for a given frequency is,

$$\nabla^2 \tilde{\vec{\mathcal{E}}} = \tilde{\varepsilon}\mu_0 \frac{\partial^2 \tilde{\vec{\mathcal{E}}}}{\partial t^2} \ . \tag{18.134}$$

It admits plane wave solutions as before,

$$\tilde{\vec{\mathcal{E}}}(z,t) = \tilde{\vec{\mathcal{E}}}_0 e^{\imath(\tilde{k}z - \omega t)} \ , \tag{18.135}$$

with the complex wavenumber,

$$\tilde{k} = \omega\sqrt{\tilde{\varepsilon}\mu_0} = \tfrac{\omega}{c}\sqrt{\tilde{\epsilon}} \ . \tag{18.136}$$

Writing $\tilde{k}$ in terms of its real and imaginary parts, $\tilde{k} = k + \imath\kappa$, the plane wave becomes,

$$\tilde{\vec{\mathcal{E}}}(z,t) = \tilde{\vec{\mathcal{E}}}_0 e^{-\kappa z} e^{\imath(kz - \omega t)} \ . \tag{18.137}$$

Obviously, the wave is attenuated (this is not surprising, since the damping absorbs energy). Since the intensity is proportional to $\vec{\mathcal{E}}^2$ (and consequently to $e^{-2\kappa z}$), the quantity,

$$\alpha \equiv 2\kappa \tag{18.138}$$

is called *absorption coefficient*. The relationship,

$$I \propto e^{-\alpha z} \tag{18.139}$$

is called the *Lambert-Beer law*. However, the velocity of the wave is ω/k, and the *refraction index* is,

$$n = \frac{ck}{\omega} \ . \tag{18.140}$$

In the present case k and κ have nothing to do with conductivity, as in the case of Eq. (18.87); but they are determined by the parameters of our damped harmonic

oscillator. For gases, the second term in (18.133) is small, and we can approximate the square root (18.136) by the first term of the binomial expansion $\sqrt{1+\tilde{\chi}_\varepsilon} \simeq 1 + \frac{1}{2}\tilde{\chi}_\varepsilon$. Hence,

$$\tilde{k} = \frac{\omega}{c}\sqrt{\tilde{\epsilon}} \simeq \frac{\omega}{c}\left(1+\frac{\tilde{\chi}_\varepsilon}{2}\right) = \frac{\omega}{c}\left(1+\frac{Nq^2}{2m\varepsilon_0}\sum_j \frac{f_j}{\omega_j^2-\omega^2-\imath\gamma_j\omega}\right) . \tag{18.141}$$

therefore,

$$\boxed{\begin{array}{rcccl} n & = & \mathfrak{Re}\,\sqrt{\epsilon} & \simeq & 1+\dfrac{Nq^2}{2m\varepsilon_0}\displaystyle\sum_j \frac{f_j(\omega_j^2-\omega^2)}{(\omega_j^2-\omega^2)^2+\gamma_j^2\omega^2} \\ \alpha & = & \dfrac{2\omega}{c}\mathfrak{Im}\,\sqrt{\epsilon} & \simeq & \dfrac{Nq^2\omega^2}{m\varepsilon_0 c}\displaystyle\sum_j \frac{f_j\gamma_j}{(\omega_j^2-\omega^2)^2+\gamma_j^2\omega^2} \end{array}} . \tag{18.142}$$

In Fig. 18.14 we plot the refractive index and the absorption coefficient in the neighborhood of one of the resonances $\omega_0 = \omega_j$. In most cases the refractive index gradually increases with frequency, which is consistent with our experience in optics (Fig. 18.10). However, near a resonance the refraction index drops abruptly. Being atypical, this behavior is called *anomalous dispersion*. We observe that the region of anomalous dispersion ($\omega_1 < \omega < \omega_2$ in the figure) coincides with the region of maximum absorption. In fact, the material can be almost opaque in this spectral region. The reason is, we now excite the electrons on their 'preferred' frequency; the amplitude of their oscillation is relatively large, and therefore much energy is dissipated by the damping mechanism.

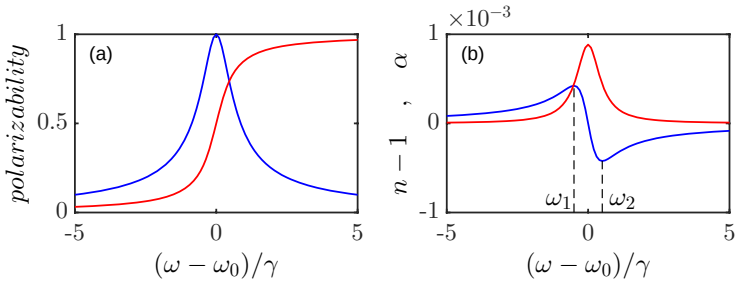

Figure 18.14: (code) (a) Profile of the polarizability $|\alpha_{pol}|$ (blue curve) and of the phase shift $\arctan \frac{\mathfrak{Im}\ \alpha_{pol}}{\pi \mathfrak{Re}\ \alpha_{pol}}$ (red curve). (b) Refractive index (blue curve) and the absorption (red curve). In the spectral region between ω_1 and ω_2 we have anomalous dispersion.

The refractive index n plotted in Fig. 18.14 may be below 1 above the resonance, suggesting that the *velocity of the wave exceeds* c. But we must remember that energy propagates at the group velocity, which is always below c. The graph does not include the contributions of other terms in the sum, because they are negligible when the resonances are narrow or distant from each other. Out of the resonances, the damping can be ignored, and the formula for the refractive index simplifies:

$$n = 1 + \frac{Nq^2}{2m\varepsilon_0}\sum_j \frac{f_j}{\omega_j^2-\omega^2} . \tag{18.143}$$

For most substances the natural frequencies ω_j are distributed across the spectrum in a chaotic way. In transparent materials, the resonances are in the ultraviolet regime, such that the visible frequencies ω are far below the resonances, $\omega \ll \omega_j$. In this case,

$$\frac{1}{\omega_j^2 - \omega^2} \simeq \frac{1}{\omega_j^2}\left(1 + \frac{\omega^2}{\omega_j^2}\right) . \tag{18.144}$$

and (18.143) adopts the form,

$$n = 1 + \frac{Nq^2}{2m\varepsilon_0}\sum_j \frac{f_j}{\omega_j^2} + \omega^2 \frac{Nq^2}{2m\varepsilon_0}\sum_j \frac{f_j}{\omega_j^4} . \tag{18.145}$$

Or, in terms of vacuum wavelengths ($\lambda = 2\pi c/\omega$):

$$\boxed{n = 1 + A\left(1 + \frac{B}{\lambda^2}\right)} . \tag{18.146}$$

This is the *Cauchy formula*; the constant A is called the *refraction coefficient* and B is called *dispersion coefficient*. The Cauchy equation applies reasonably well to most gases in the optical regime. Fig. 18.10 shows the example of the refractive index of air.

The Lorentz model certainly does not account for all dispersion phenomena in non-conductive media. But at least, it indicates how the damped harmonic motion of electrons can generate a dispersive refractive index, and it also explains why n is usually a slowly increasing function of ω with occasional 'anomalous' regions.

Example 106 (*Energy density and Poynting vector in a dielectric medium*): The energy density in vacuum, $\bar{u} = \frac{\varepsilon_0}{4}|\vec{\mathcal{E}}|^2 + \frac{1}{4\mu_0}|\vec{\mathcal{B}}|^2$, becomes in a dielectric medium,

$$\begin{aligned}\bar{u}^{(\chi)} &= \frac{1}{4}\mathfrak{Re}\,(\varepsilon\vec{\mathcal{E}}\cdot\vec{\mathcal{E}}^* + \frac{1}{\mu_0}\vec{\mathcal{B}}\cdot\vec{\mathcal{B}}^*) = \frac{\mathfrak{Re}\,\varepsilon}{4}|\vec{\mathcal{E}}|^2 + \frac{1}{4\mu_0}\left|\frac{k+\imath\kappa}{\omega}\vec{\mathcal{E}}\right|^2 \\ &= \frac{\varepsilon_0}{4}(1+\chi_e')\mathcal{E}_0^2 + \frac{\varepsilon_0}{4\omega^2}|k+\imath\kappa|^2\mathcal{E}_0^2 = (k^2-\kappa^2+k^2+\kappa^2)\frac{\varepsilon_0}{4}\mathcal{E}_0^2 = \frac{\varepsilon_0}{2}\frac{k^2}{\omega^2}\mathcal{E}_0^2 ,\end{aligned}$$

where we only consider the real part of the susceptibility χ_ε. On the other hand, the Poynting vector is,

$$\bar{I} = \frac{1}{2\mu_0}\mathfrak{Re}\,[\vec{\mathcal{E}}\times\vec{\mathcal{B}}^*] = \frac{\varepsilon_0 c^2}{2}\mathcal{E}_0^2\left[e^{-2\omega\kappa z/c}\mathfrak{Re}\,\frac{k+\imath\kappa}{\omega}\right] = \frac{\varepsilon_0 c^2}{2}\frac{k}{\omega}\mathcal{E}_0^2 e^{-2\omega\kappa z/c} .$$

18.2.4.2 The Fresnel-Fizeau effect

Naively, the index of refraction is due to a finite time lag between photon absorption and emission. The time spend in an excited state slows down the light propagation velocity. If during this time the atom travels, the atomic velocity adds to (or reduces) the light propagation velocity. This effect which is known as *Fresnel-Fizeau effect* is an internal degrees of freedom effect. Consider a medium with the index of refraction n

(measured in the moving frame) which is moving with velocity v. The copropagation velocity of light is for $v \ll c$,

$$c_v = \frac{c}{n_{rf}} \frac{c + n_{rf} v}{c + v/n_{rf}} \approx \frac{c}{n_{rf}} + v \left(1 - \frac{1}{n_{rf}^2}\right) . \tag{18.147}$$

This is the Fresnel 'drag' coefficient. In particular, it is easy to show that,

$$c_{-v} < c/n_{rf} < c_v < c . \tag{18.148}$$

Expressing the refraction index by the susceptibility, $n_{rf} = \sqrt{1 + \chi_\varepsilon} \approx 1 + \frac{1}{2}\chi_\varepsilon$, we get,

$$\frac{c_v - c_{-v}}{2v} = 1 - \frac{1}{n_{rf}^2} = \frac{\chi_\varepsilon}{1 + \chi_\varepsilon} . \tag{18.149}$$

Knowing that,

$$\chi_\varepsilon = \frac{2nd^2}{3\varepsilon_0 \hbar} \frac{\Delta + \imath\Gamma}{4\Delta^2 + 2\Omega^2 + \Gamma^2} \qquad \text{and} \qquad d = \sqrt{\frac{3\pi\varepsilon_0 \hbar \Gamma}{k^3}} \tag{18.150}$$

$$\mathfrak{Re}\ \chi_\varepsilon = \frac{2\pi\Gamma n}{k^3} \frac{\Delta}{4\Delta^2 + 2\Omega^2 + \Gamma^2}$$

it follows,

$$\frac{c_v - c_{-v}}{2v} = \frac{1}{1 + \left(\frac{2\pi\Gamma n}{k^3} \frac{\Delta}{4\Delta^2 + 2\Omega^2 + \Gamma^2}\right)^{-1}} . \tag{18.151}$$

For small detunings within the natural linewidth,

$$\frac{c_v - c_{-v}}{2v} \approx \frac{1}{1 + \frac{k^3}{2\pi n} \frac{\Gamma}{\Delta}} , \tag{18.152}$$

a long excited state lifetime is advantageous. For very large detunings and $\Omega \to 0$,

$$\frac{c_v - c_{-v}}{2v} \approx \frac{1}{1 + \frac{2k^3}{\pi n} \frac{\Delta}{\Gamma}} . \tag{18.153}$$

This shows that (far from resonance) the effect increases for large densities, broad linewidths and smaller detunings. For example, the *Rb* D_1 line for typical conditions the coefficient is $\frac{2k^3}{\pi n} \approx 1000$ [21].

18.2.5 Light interaction with metals and the Drude model

The *Drude model* is based on a classical kinetic theory of non-interacting electrons in a metal. Since the conduction electrons are considered to be free, the Drude oscillator is

[21] For the high-finesse ring-cavity CARL experiment this means that the Fresnel-Fizeau effect is negligible. Far from resonance the atoms do not spend time in the excited state. The adiabatic elimination of the internal degrees of freedom removes the effect from the theoretical model. It also means that the counter-propagating modes of the ring-cavity do not split because of the atomic velocity, $n_{rf+} = n_{rf-}$. The calculation shows that the back-scattered light is not perfectly resonant, but that this shift is negligibly small.

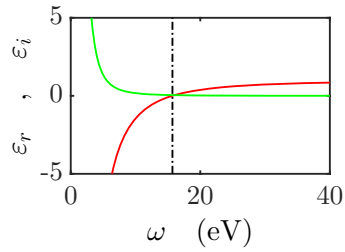

Figure 18.15: (code) Real (red) and imaginary (green) parts of the dielectric function as a function of the excitation frequency.

an extension of the Lorentz model of a single oscillator to the case, when the restoring force and the atomic resonance frequency are zero, $\Gamma_0 = \omega_0 = 0$. The equation of motion is,

$$m\frac{d\mathbf{v}}{dt} + m\Gamma_d\mathbf{v} = -e\vec{\mathcal{E}}\ , \tag{18.154}$$

where $m\frac{d\mathbf{v}}{dt}$ is the force accelerating the electron, $m\Gamma_d\mathbf{v}$ is the friction due to collisions with ions of the crystalline lattice and $-e\vec{\mathcal{E}} = -e\vec{\mathcal{E}}_0 e^{\imath\omega t}$ is the Coulomb force exerted by the oscillating field. We find,

$$\mathbf{v} = \mathbf{v}_0 e^{\imath\omega t} = -\frac{e}{m}\frac{\vec{\mathcal{E}}_0}{\imath\omega + \Gamma_d}e^{\imath\omega t}\ . \tag{18.155}$$

The current density corresponding to the motion of n electrons per unit volume is,

$$\mathbf{j}_c(\omega) = -ne\mathbf{v} = \frac{ne^2}{m(\Gamma_d + \imath\omega)}\vec{\mathcal{E}}\ . \tag{18.156}$$

In addition we have the current that corresponds to the electric displacement in vacuum,

$$\mathbf{j}_d(\omega) = \frac{\partial\vec{\mathcal{D}}}{\partial t} = \imath\omega\varepsilon_0\vec{\mathcal{E}}\ , \tag{18.157}$$

where $\vec{\mathcal{D}} = \varepsilon_0\vec{\mathcal{E}}$. The total current density is given by,

$$\mathbf{j}(\omega) = \mathbf{j}_c(\omega) + \mathbf{j}_d(\omega) = \left[\frac{ne^2}{m(\Gamma_d + \imath\omega)} + \imath\omega\varepsilon_0\right]\vec{\mathcal{E}}\ . \tag{18.158}$$

Assuming the total current as being created by a total electric displacement, $\vec{\mathcal{D}}_{tot} = \tilde{\varepsilon}\vec{\mathcal{E}}$, where again the electric field and the displacement are related by a complex permittivity, we find,

$$\mathbf{j}(\omega) = \frac{\partial\vec{\mathcal{D}}_{tot}}{\partial t} = \imath\omega\tilde{\varepsilon}\vec{\mathcal{E}}\ , \tag{18.159}$$

and comparing the last two expressions,

$$\left[\frac{ne^2}{m(\Gamma_d + \imath\omega)} + \imath\omega\varepsilon_0\right]\vec{\mathcal{E}} = \imath\omega\tilde{\varepsilon}(\omega)\vec{\mathcal{E}}\ . \tag{18.160}$$

Resolving by $\tilde{\varepsilon}$,

$$\boxed{\tilde{\epsilon}(\omega) = 1 - \frac{\omega_p^2}{i\omega\Gamma_d - \omega^2}} \ , \tag{18.161}$$

where

$$\omega_p \equiv \sqrt{\frac{ne^2}{m\varepsilon_0}} \tag{18.162}$$

is called the *plasma frequency*, which corresponds to the energy, where $\epsilon(\omega_p) \simeq 0$. Separated into real and imaginary parts,

$$\epsilon'(\omega) = 1 - \frac{\omega_p^2}{\Gamma_d^2 + \omega^2} \quad , \quad \epsilon''(\omega) = \frac{\omega_p^2 \Gamma_d}{\omega(\Gamma_d^2 + \omega^2)} \tag{18.163}$$

For $\omega < \omega_p$ and small Γ_d, the real part ϵ' is negative. No electric field can penetrate the metal, which therefore becomes fully reflecting.
For $\omega = \omega_p$, the real part ϵ' is zero. That is, the electrons oscillate in phase with the field along the propagation distance in the metal.
For $\omega \gg \omega_p$, the imaginary (absorptive) part ε'' disappears at high frequencies.

For metals, usually we have $\omega_p = (2\pi)\ 1000...4000\,\mathrm{THz}$ and $\Gamma_d \approx 100\,\mathrm{s}^{-1}$. Note that the model can not describe semiconductors.

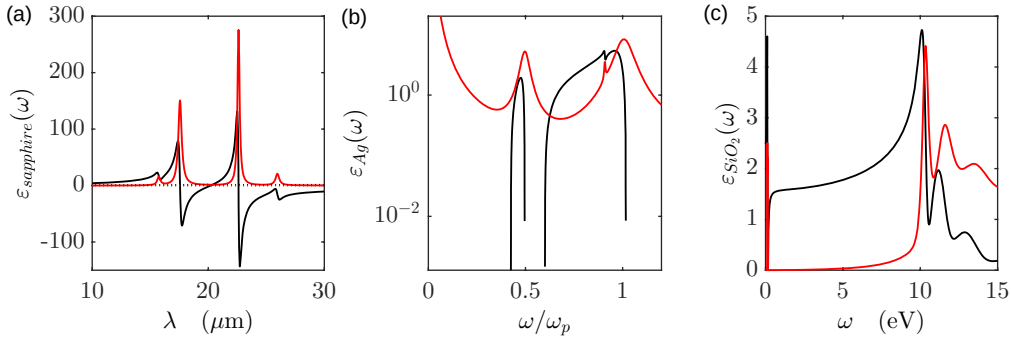

Figure 18.16: (code) Examples of frequency-dependent permittivities for (a) sapphire [444, **?**], (b) silver [1070], and (c) amorphous glas [375].

18.2.6 Causality connecting $\vec{\mathcal{D}}$ with $\vec{\mathcal{E}}$ and the Kramers-Kronig relations

A consequence of the dispersion of $\varepsilon(\omega)$ is the temporarily nonlocal connection between the displacement $\vec{\mathcal{D}}$ and the electric field $\vec{\mathcal{E}}$. Calculating the Fourier transform of,

$$\vec{\mathcal{D}}(\mathbf{r},\omega) = \varepsilon(\omega)\vec{\mathcal{E}}(\mathbf{r},\omega) = \varepsilon_0[1 + \chi_\varepsilon(\omega)]\vec{\mathcal{E}}(\mathbf{r},\omega) \ , \tag{18.164}$$

we obtain, using the convolution theorem,

$$\begin{aligned}\vec{\mathcal{D}}(\mathbf{r},t) &= \frac{1}{\sqrt{2\pi}}\int_{-\infty}^{\infty}\varepsilon(\omega)\vec{\mathcal{E}}(\mathbf{r},\omega)e^{-\imath\omega t}d\omega \\ &= \varepsilon_0\vec{\mathcal{E}}(\mathbf{r},t) + \frac{\varepsilon_0}{\sqrt{2\pi}}\int_{-\infty}^{\infty}\chi_\varepsilon(\omega)\vec{\mathcal{E}}(\mathbf{r},\omega)e^{-\imath\omega t}d\omega \\ &= \varepsilon_0\vec{\mathcal{E}}(\mathbf{r},t) + \frac{\varepsilon_0}{\sqrt{2\pi}}\int_{-\infty}^{\infty}\chi_\varepsilon(\tau)\vec{\mathcal{E}}(\mathbf{r},t-\tau)d\tau\ ,\end{aligned} \tag{18.165}$$

where $\chi_\varepsilon(\tau)$ is the Fourier transform of the electric susceptibility. This results shows that the displacement field $\vec{\mathcal{D}}$ depends on all values the incident electric field $\vec{\mathcal{E}}$ had at all times. Only if $\chi_\varepsilon(\omega)$ were independent of ω would we have $\chi_\varepsilon(\tau) \propto \delta(\tau)$.

Example 107 (*Simple model of the susceptibility*): To illustrate the implications of equation (18.165) we consider a permittivity of the following form,

$$\frac{\varepsilon(\omega)}{\varepsilon_0} = \frac{\omega_p}{\omega_0^2 - \omega^2 - \imath\gamma\omega}\ . \tag{18.166}$$

The kernel related to the susceptibility,

$$\chi_\varepsilon(\tau) = \frac{\omega_p^2}{2\pi}\int_{-\infty}^{\infty}\frac{e^{-\imath\omega\tau}d\tau}{\omega_0^2 - \omega^2 - \imath\gamma\omega}\ , \tag{18.167}$$

can be evaluated by contour integration, the result being,

$$\chi_\varepsilon(\tau) = \omega_p^2 e^{-\gamma\tau/2}\frac{\sin\tau\sqrt{\omega_0^2 - (\gamma/2)^2}}{\sqrt{\omega_0^2 - (\gamma/2)^2}}\Theta(\tau)\ , \tag{18.168}$$

where $\Theta(\tau)$ is the Heaviside function.

This example shows that the displacement field $\vec{\mathcal{D}}$ only depends on the electric field at *past times*, which is fortunate as it allows causality to be respected.

18.2.6.1 The Kramers-Kronig relations

The *Kramers-Kronig relations* are bidirectional mathematical relations, connecting the real and imaginary parts of any complex function that is an *analytic function* on the upper half-plane [22]. These relationships are often used to calculate the real part of response functions in physical systems from the imaginary part (or vice versa). This works because, in stable physical systems, *causality and analyticity* are equivalent conditions. Be $\chi(\omega)$ a complex function of the complex variable ω. We assume this function to be analytic in the upper closed half-plane of ω and to disappear as $1/|\omega|$ or faster for $|\omega| \to \infty$. The Kramers-Kronig relations are given by,

$$\boxed{\mathfrak{Re}\ \chi(\omega) = \frac{1}{\pi}\mathcal{P}\int_{-\infty}^{\infty}\frac{\mathfrak{Im}\ \chi(\omega')}{\omega'-\omega}d\omega' \quad \text{and} \quad \mathfrak{Im}\ \chi(\omega) = -\frac{1}{\pi}\mathcal{P}\int_{-\infty}^{\infty}\frac{\mathfrak{Re}\ \chi(\omega')}{\omega'-\omega}d\omega'}\ , \tag{18.169}$$

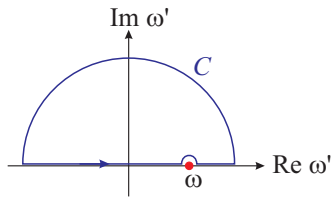

Figure 18.17: Path of the contour integral illustrating Cauchy's theorem.

where $\mathcal{P}$ denotes the *Cauchy principal value*. Thus, the real and imaginary parts of such a function are not independent, and the complete function can be reconstructed from only one of its parts.

For any analytic function χ defined on the upper closed half-plane, the function $\omega' \to \chi(\omega')/(\omega' - \omega)$ where $\omega \in \mathbb{R}$, will also be analytic in the upper half-plane. The *Cauchy's residue theorem* for integration consequently says, that

$$\oint \frac{\chi(\omega')}{\omega' - \omega} d\omega' = 0 \ . \tag{18.170}$$

We chose the contour to follow the real axis, making a loop around the pole at $\omega' = \omega$, and a large semicircle in the upper half-plane, as shown in Fig. 18.17. We now decompose the integral into its contributions along each one of these three paths and then evaluate the limits. The length of the semicircular path increases proportionally to $|\omega'|$, but the integral along it disappears in this limit, since $\chi(\omega')$ disappears at least as fast as $1/|\omega'|$. Letting the size of the semicircle go to zero we get,

$$0 = \oint \frac{\chi(\omega')}{\omega' - \omega} d\omega' = \mathcal{P} \int_{-\infty}^{\infty} \frac{\chi(\omega')}{\omega' - \omega} d\omega' - \imath\pi\chi(\omega) \ . \tag{18.171}$$

The second term in the last expression is obtained using the Sokhotski-Plemelj theorem of residues. After rearrangement we arrive at the compact form of the Kramers-Kronig relations,

$$\chi(\omega) = \frac{1}{\imath\pi} \mathcal{P} \int_{-\infty}^{\infty} \frac{\chi(\omega')}{\omega' - \omega} d\omega' \ . \tag{18.172}$$

The imaginary unit in the denominator makes the connection between the real and the imaginary components. Finally, we separate $\chi(\omega)$ and the equation (18.172) into their real and imaginary parts, and we get the expressions from above (18.169).

18.2.6.2 Physical interpretation in terms of causality

We can apply the Kramers-Kronig formalism to response functions. In certain linear and time-invariant physical systems or signal processing applications, the response function $h(t)$ describes, how some time-dependent property of the system, responds to a force $F(t')$ pulsed during a time t'. For example, the property of the system can be the angle of a pendulum and the force applied by a motor kicking the pendulum.

[22] A function is analytic if and only if its Taylor series about a point $\mathbf{r}_0$ converges to the function in some neighborhood for every $\mathbf{r}_0$ in its domain. Hence, analytic functions must be infinitely differentiable.

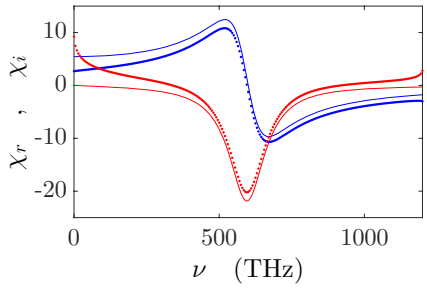

Figure 18.18: (code) Real (blue) and imaginary (red) parts of the susceptibility. The dashed curves are calculated by the Kramers-Kronig formulas.

The response function must be zero for $t < 0$, since the system can not respond to the force before it has been applied. It can be shown that this request for causality *in time domain* implies *in frequency domain*, that the Fourier transform $\chi(\omega)$ of $h(t)$ is analytical inside the upper half-plane. Furthermore, if we subject the system to an oscillating force with a frequency much higher than its highest resonance frequency, there will be almost no time for the system to respond before the forcing has alternated the direction, and hence the frequency response $\chi(\omega)$ converges to zero, when ω becomes very large. From these physical considerations, we see that $\chi(\omega)$ will normally satisfy the conditions necessary for the Kramers-Kronig relations to apply.

The frequency response of a system forced to generate an impulse response $h(t)$ is given by the Fourier-transform,

$$\chi(\omega) = \tfrac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} h(t) e^{-\imath\omega t} dt = \mathcal{F}[h(t)] \ , \tag{18.173}$$

which for an electrical system corresponds to its impedance. Now, the boundary condition of causality can be implemented with the use of the Heaviside step function $\Theta(t)$,

$$\chi(\omega) = \tfrac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} h(t)\Theta(t) e^{-\imath\omega t} dt = \mathcal{F}[h(t)\Theta(t)] = \mathcal{F}[h(t)\Theta(t)\Theta(t)] \ . \tag{18.174}$$

Note that the implementation of causality via the Heaviside step function is directly implemented when replacing the Fourier transform by the *Laplace transform*. Applying the convolution theorem to the Fourier transform and using the Fourier transform of the Heaviside function we get [23],

$$\boxed{\chi(\omega) = \mathcal{F}[h(t)\Theta(t)] \star \mathcal{F}[\Theta(t)] = \chi(\omega) \star (\mathcal{F}\Theta)(\omega) = \chi(\omega) \star \left(\tfrac{1}{2\pi\imath\omega} + \tfrac{1}{2}\delta(\omega)\right)} \ . \tag{18.175}$$

This equality can be considered an early or raw form of the Kramers-Kronig relations and will turn out to be equivalent to them. To see this, we carry out the convolution explicitly,

$$\chi(\omega) = \frac{1}{2\pi} \int_{-\infty}^{\infty} \frac{\chi(\omega')d\omega'}{\imath(\omega - \omega')} + \frac{1}{2}\chi(\omega) \ , \tag{18.176}$$

[23] $\mathcal{F}[\Theta(t)] = \frac{1}{\imath\sqrt{2\pi}\omega} + \sqrt{\frac{\pi}{2}}\delta(\omega)$

or isolating $\chi(\omega)$,

$$\chi(\omega) = \frac{1}{\pi}\int_{-\infty}^{\infty} \frac{\chi(\omega')d\omega'}{\imath(\omega-\omega')} \ . \tag{18.177}$$

This is the frequency response of causal systems being invariant under a Hilbert-transform. It is equivalent to the Kramers-Kronig relations (18.169). Rewriting it for only positive integration limits, the integral splits up like,

$$\chi(\omega) = \frac{1}{\pi}\int_{0}^{\infty} \frac{\chi(\omega')d\omega'}{\imath(\omega-\omega')} + \frac{1}{\pi}\int_{0}^{\infty} \frac{\chi(-\omega')d\omega'}{\imath(\omega+\omega')} \ . \tag{18.178}$$

From the definition of the Fourier integral of the real quantity $h(t)$ follows directly $\chi(-\omega) = \chi^*(\omega)$, that is, the positive frequency response determines the negative frequency response. Therefore,

$$\begin{aligned}\chi(\omega) &= \frac{1}{\pi}\int_{0}^{\infty} \frac{\chi(\omega')(\omega+\omega') + \chi^*(\omega')(\omega-\omega')}{\imath(\omega^2-\omega'^2)}d\omega' \\ &= \frac{1}{\pi}\int_{0}^{\infty} \frac{\omega'\mathfrak{Im}\ \chi(\omega') - \imath\omega\mathfrak{Re}\ \chi^*(\omega')}{\omega^2-\omega'^2}d\omega' \ .\end{aligned} \tag{18.179}$$

from which we obtain the Kramers-Kronig relations for the real and imaginary parts in a format, where they are useful for physically realistic response functions,

$$\boxed{\mathfrak{Re}\ \chi(\omega) = \frac{2}{\pi}\int_{0}^{\infty} \frac{\omega'\mathfrak{Im}\ \chi(\omega')}{\omega^2-\omega'^2}d\omega' \quad \text{and} \quad \mathfrak{Im}\ \chi(\omega) = \frac{-2}{\pi}\int_{0}^{\infty} \frac{\omega\mathfrak{Re}\ \chi(\omega')}{\omega^2-\omega'^2}d\omega'} \ . \tag{18.180}$$

The imaginary part of a response function describes, being *out of phase* with the driving force, how a system dissipates energy. The Kramers-Kronig relations imply that observing the *dissipative* response of a system is sufficient to determine its (reactive) *in-phase* response, and vice versa.

18.2.7 Exercises

18.2.7.1 Ex: Skin depth

a. Consider a piece of glass containing some free charges. How long does it take for the charges to migrate to the surface?
b. Suppose you were designing a microwave experiment at a frequency of 10^{10} Hz. How thick would you make a silver coating?
c. Find the wavelength and propagation velocity in copper for radio waves at 1 MHz. Compare with the corresponding values in air (or vacuum).

Solution: *a. The continuity equation tells us that in a conductor,*

$$\frac{\partial \varrho_f}{\partial t} = -\nabla\cdot\mathbf{j}_f = -\nabla\cdot\sigma\vec{\mathcal{E}} = -\sigma\frac{\varrho_f}{\varepsilon_0} \ .$$

The solution of the differential equation is,

$$\varrho_f(t) = \varrho_f(0)e^{-\sigma t/\varepsilon_0} \ .$$

With a conductivity of glass of $\sigma = 10^{-11}\,\mathrm{Sm}^{-1}$ *and a permittivity of* $\varepsilon = 4.7\varepsilon_0$ *we find a time constant for the drift of* $\tau \approx 4.16\,\mathrm{s}$.
b. Skin depth was derived in class,

$$d = \frac{1}{\kappa} = \frac{1}{\omega}\left[\frac{\mu\varepsilon}{2}\sqrt{1+\left(\frac{\sigma}{\varepsilon\omega}\right)^2}\right]^{-1/2} .$$

The conductivity of silver is $\sigma \approx 6.30\cdot 10^7\,\mathrm{Sm}^{-1}$. *Since it represents an excellent conductor,* $\varepsilon \simeq \varepsilon_0$. *Also, we have* $\mu \simeq \mu_0$. *Thus, at the given microwave frequency,*

$$d \simeq \sqrt{\frac{2}{\omega\mu_0\sigma}} \approx 634\,\mathrm{nm} .$$

c. For copper ($\sigma \approx 5.96\cdot 10^7\,\mathrm{Sm}^{-1}$*) we evaluate, at the given radiofrequency, the wavelength from the real part of* $\tilde{k}$,

$$\lambda = 2\pi/k \simeq 2\pi\sqrt{\frac{2}{\omega\mu_0\sigma}} \approx 4.1\cdot 10^{-4}\,\mathrm{m} ,$$

which is much shorter than radiofrequency wavelengths in free space. The propagation velocity,

$$v = \omega/k = \frac{\omega\lambda}{2\pi} \approx 410\,\mathrm{m/s}$$

and obviously much slower than the speed of light in free space, which points to large refraction index, $n = ck/\omega$.

18.2.7.2 Ex: Complex refractive index

A light wave described by the electric field $\mathcal{E}_i = \mathcal{E}_0 e^{\imath k_0 z}$ comes from the vacuum and impinges on a metal surface characterized by the complex refractive index $n = n' + \imath n''$. Determine from the relation $n = \sqrt{\epsilon}$ the relative dielectric constant ϵ.
a. At what depth the field falls to e^{-1}, if $\mathcal{E}_{met} \simeq 0.05\mathcal{E}_0$ and $k_{met} = nk_0$.
b. Now despise the penetrating field, $|\mathcal{E}_{met}| \simeq 0$, and consider the reflected field $\mathcal{E}_r = \mathcal{E}_0 e^{-\imath kx + \imath\Delta\phi}$. Calculate the intensity resulting from the superposition of $\mathcal{E}_i$ and $\mathcal{E}_r$.

Solution: *a. The wavefunction on the metal is,*

$$\mathcal{E}_{met} e^{\imath n k_0 x} = \mathcal{E}_{met} e^{-n'' k_0 x} e^{\imath n' k_0 x} .$$

Hence, $l_{1/2} = 1/(n'' k_0)$.
b. Factorizing $e^{\imath\Delta\phi/2}$ *we obtain,*

$$\begin{aligned} I &= \varepsilon_0 c|\mathcal{E}_i + \mathcal{E}_r|^2 = \varepsilon_0 c|\mathcal{E}_0 e^{\imath k_0 x} + \mathcal{E}_0 e^{\imath k_0 x + \imath\Delta\phi}|^2 \\ &= \varepsilon_0 c|e^{\imath\Delta\phi/2}|\cdot|\mathcal{E}_0 e^{\imath k_0 x - \imath\Delta\phi/2} + \mathcal{E}_0 e^{\imath k_0 x + \imath\Delta\phi/2}|^2 = \cos^2(kx - \Delta/2) . \end{aligned}$$

18.2.7.3 Ex: Fourier expansion

The Fourier inversion theorem says that,

$$f(z) = \int_{-\infty}^{\infty} A(k) e^{\imath kz} dk \qquad \Longleftrightarrow \qquad A(k) = \tfrac{1}{2\pi} \int_{-\infty}^{\infty} f(z) e^{-\imath kz} dz \ .$$

Use the theorem to determine $A(k)$ for the wavepacket given by $f(z,t) = \int_{-\infty}^{\infty} A(k) e^{\imath[kz - \omega(k)t]} dk$ as a function of the real parts $\mathfrak{Re}\ f(z,0)$ and $\mathfrak{Re}\ \dot{f}(z,0)$.

Solution: *The time derivative of the packet is,*

$$\dot{f}(z,t) = -\imath \int_{-\infty}^{\infty} \omega A(k) e^{\imath(kz - \omega t)} dk \ .$$

With this we calculate,

$$f(z,0) = \int_{-\infty}^{\infty} A(k) e^{\imath kz} dk \qquad \textit{and} \qquad \dot{f}(z,0) = -\imath \int_{-\infty}^{\infty} \omega A(k) e^{\imath kz} dk \ ,$$

that is,

$$A(k) = \tfrac{1}{2\pi} \int_{-\infty}^{\infty} f(z,0) e^{-\imath kz} dz \qquad \textit{and} \qquad -\imath\omega A(k) = \tfrac{1}{2\pi} \int_{-\infty}^{\infty} \dot{f}(z,0) e^{-\imath kz} dz \ .$$

Now, we decompose, $f = f_r + \imath f_i$, to get,

$$A(k) = \tfrac{1}{2\pi} \int_{-\infty}^{\infty} f(z,0) e^{-\imath kz} dz = \frac{1}{2\pi} \int_{-\infty}^{\infty} (f_r + \imath f_i) e^{-\imath kz} dz \stackrel{!}{=} \tfrac{1}{2\pi} \int_{-\infty}^{\infty} \frac{\dot{f}_r + \imath \dot{f}_i}{-\imath\omega} e^{-\imath kz} dz \ .$$

Since obviously $f_r = -\dot{f}_i/\omega$ and $f_i = \dot{f}_r/\omega$, we obtain,

$$A(k) = \tfrac{1}{2\pi} \int_{-\infty}^{\infty} \left[f_r(z,0) + \tfrac{\imath \dot{f}_r(z,0)}{\omega} \right] e^{-\imath kz} dz \ .$$

18.2.7.4 Ex: Electromagnetic wave

In a dispersionless medium ($\varepsilon = \varepsilon_0$ and $\mu = \mu_0$) we have for a component $u(x,t)$ of an electromagnetic wave (here without dimension),

$$u(x,t) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} dk A(k) e^{\imath kx - \imath\omega(k)t} \qquad \text{with} \qquad \omega(k) = ck \ ,$$

and

$$A(k) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} dx u(x,0) e^{-\imath kx} \ .$$

a. Show that $u(x,t)$ satisfies the one-dimensional wave equation for vacuum.
b. Calculate the spectral distribution $A(k)$ for $u(x,t) = e^{\imath k_0 x - \imath\omega_0 t}$.
c. Calculate the spectral distribution $A(k)$ for $\{u(x,t) = e^{\imath k_0 x - \imath\omega_0 t}$ for $-L < x - (\omega_0/k_0)t < L$ and 0 else$\}$.
d. Calculate $u(x,t)$, when $u(x,0) = \int_{-a}^{+a} \delta(x-a)da$.
e. Try to understand in an elementary way the relation of part (c) between the bandwidth and the length of the wavepacket. Perform the transition to the limit $L \to \infty$ explicitly. For the case (d) discuss the propagation of the wavepacket in space.
Formulas:

$$\delta(k_0 - k) = \frac{1}{2\pi} \int_{-\infty}^{\infty} dx e^{\imath(k_0-k)x} = \frac{1}{\pi} \lim_{L\to\infty} \frac{\sin(k_0-k)}{k_0-k}$$

$$\Theta(a) = \frac{1}{2\pi\imath} \int_{-\infty}^{\infty} dk \frac{e^{\imath k a}}{k} = \begin{cases} 1 & \text{for } a > 0 \\ 0 & \text{else} \end{cases} .$$

Solution: *a. Integration and differentiation are interchangeable.* $u(x,t)$ *therefore satisfies the one-dimensional wave equation,*

$$\left(\frac{\partial^2}{\partial x^2} - \frac{1}{c^2} \frac{\partial^2}{\partial t^2} \right) u(x,t) = 0$$

provided, as requested in the problem, $\omega(k) = ck$.
b. With the given formula we find,

$$A(k) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} dx\ e^{\imath(k_0-k)x} = \sqrt{2\pi}\delta(k_0 - k) .$$

c. We obtain,

$$A(k) = \frac{1}{\sqrt{2\pi}} \int_{-L}^{+L} dx\ e^{\imath(k_0-k)x} = \frac{1}{\sqrt{2\pi}} \frac{1}{\imath(k_0-k)} [e^{\imath(k_0-k)L} - e^{-\imath(k_0-k)L}]$$
$$= \frac{2L}{\sqrt{2\pi}} \frac{\sin([k_0-k]L)}{[k_0-k]L} .$$

d. We derive,

$$A(k) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} dx \int_{-a}^{+a} da\ \delta(x-a) e^{-\imath k x} = \frac{1}{\sqrt{2\pi}} \int_{-a}^{+a} dx\ e^{-\imath k x}$$
$$= \frac{1}{\sqrt{2\pi}} \frac{1}{\imath k} [e^{\imath k a} - e^{-\imath k x}] = \frac{2}{\sqrt{2\pi}} \frac{\sin ka}{k} ,$$

and hence,

$$u(x,t) = \frac{1}{2\pi\imath}\int_{-\infty}^{+\infty} dk\ \frac{e^{\imath ka} - e^{-\imath ka}}{k} e^{\imath k(x-ct)}$$
$$= \frac{1}{2\pi\imath}\int_{-\infty}^{+\infty} dk\ \frac{1}{k}(e^{\imath k(a+x)} - e^{\imath k(x-a)})e^{-\imath kct}$$
$$= \frac{1}{2\pi\imath}\int_{-\infty}^{+\infty} dk\ \left(\frac{e^{\imath k(x+a-ct)}}{k} - \frac{e^{\imath k(x-a-ct)}}{k}\right) = \Theta(x+a-ct) - \Theta(x-a-ct)\ .$$

From this follows that $u(x,t) = 1$ within the range $ct - a < x < ct + a$ and $u(x,t) = 0$ outside.
e. We had in part (c),

$$A(k) = \frac{2L}{\sqrt{2\pi}} \frac{\sin([k_0 - k]L)}{[k_0 - k]L}\ .$$

The main maximum is in $k = k_0$. Here, $A(k_0) = 2L/\sqrt{2\pi}$. It follows immediately,

$$\|A\left(k_0 \pm \tfrac{2n\pi}{L} \pm \tfrac{\pi}{2L}\right)\| = \frac{2L}{\sqrt{2\pi}(2n\pi \pm \pi/2)}$$

The bandwidth of the spectral distribution is twice the distance between two consecutive maxima, i.e. here, $\Delta k = 2\pi/L$. The spatial extent of the wavepacket is $\Delta x = 2L$. From this immediately follows a kind of 'uncertainty relationship' $\Delta k \Delta x = 4\pi > 1$. In the limit $L \to \infty$ follows immediately,

$$\lim_{L\to\infty} A(k) = \sqrt{2\pi}\frac{1}{\pi}\lim_{L\to\infty} \frac{\sin([k_0 - k)]L}{[k_0 - k]L} = \sqrt{2\pi}\delta(k_0 - k)$$

18.2.7.5 Ex: Phase and group velocity

Let us study the one-dimensional motion of a wavepacket in x-direction, which spreads in infinite space. The law of dispersion is given by $\omega = \omega(k)$. The motion of a wavepacket is then described by,

$$u(x,t) = \frac{1}{\sqrt{2\pi}}\int_{-\infty}^{\infty} dk A(k) e^{\imath kx - \imath\omega(k)t}\ ,$$

where the spectral distribution $A(k)$ is given by shape of the wavepacket at time $t = 0$:

$$A(k) = \frac{1}{\sqrt{2\pi}}\int_{-\infty}^{\infty} dx u(x,0) e^{-\imath kx}\ .$$

The maximum of $A(k)$ be at $k = k_0$. We call $v_{ph} = \omega(k)/k$ the *phase velocity* and $v_{gr} = [d\omega(k)/dk]_{k_0}$ the *group velocity*, because in specific idealized situations a

wavepacket propagates precisely at this speed. In the following we consider a propagation of the wavepacket given by,

$$u(x,0) = c\exp\left\{-\frac{x^2}{2a^2} + \imath k_0 x\right\}$$

for a medium characterized by the dispersion relation $\omega(k) = b^2k^2$ (for a de Broglie matter wave).
a. Plot the shape of the wavepacket at time $t = 0$ via the intensity distribution $|u(x,0)|^2$. The 'width' of a Gaussian profile is given by the points, where the profile fell to $(1/e)$ of the maximum value. Calculate the width $\triangle x(t=0)$ of the intensity distribution.
b. Calculate the spectral distribution $A(k)$ and the width $\triangle k$ of the corresponding intensity distribution $|A(k)|^2$.
c. Now calculate $u(x,t)$ at a later time t. Express $u(x,t)$ in the form
$u(x,t) = \alpha e^{-(x-\beta t)^2/\gamma} e^{\imath(k_0 x - \omega(k_0)t)} e^{\imath\phi}$, where α, β, γ, and ϕ are real quantities which, nevertheless, may depend on t and x.
d. Calculate the intensity distribution $|u(x,t)|^2$ at time t. At what speed does the maximum move? Calculate the width $\triangle x(t)$ of the intensity distribution. What is the temporal evolution of $\triangle x(t)\triangle k$?
e. Compare $|u(x,t)|^2$ width $|u(x,0)|^2$.
Help:

$$\int_{-\infty}^{+\infty} dx\ e^{-ax^2+bx+c} = \sqrt{\tfrac{\pi}{a}}\exp\left[\tfrac{b^2+4ac}{4a}\right]\ .$$

Solution: *a. We have,*

$$u(x,0) = e^{-x^2/2a^2}e^{\imath k_0 x} \qquad \textit{and hence} \qquad |u(x,0)|^2 = c^2 e^{-x^2/a^2}\ .$$

The intensity distribution reaches the fraction $(1/e)$ of the maximum value (at $x=0$), when $x^2/a^2 = 1$, that is, $x = \pm a$. Therefore, its width is precisely given by $\Delta x(t=0) = 2a$. It describes the spatial extent of the wavepacket at time $t = 0$.
b. With the help of the given formula we obtain immediately,

$$\begin{aligned} A(k) &= \frac{1}{\sqrt{2\pi}}\int_{-\infty}^{+\infty} dx u(x,0)\exp[-\imath kx] = \frac{c}{\sqrt{2\pi}}\int_{-\infty}^{+\infty} dx\exp\left\{-\frac{x^2}{2a^2} + \imath(k_0-k)x\right\} \\ &= \frac{c}{\sqrt{2\pi}}\sqrt{2\pi a^2}\exp\left\{-\frac{a^2}{2}(k_0-k)^2\right\} = ac\exp\left\{-\frac{a^2}{2}(k_0-k)^2\right\}\ . \end{aligned}$$

With this, we obtain for the corresponding intensity distribution,

$$|A(k)|^2 = a^2c^2e^{-a^2(k_0-k)^2}\ .$$

It is independent of time, has its maximum value at $k = k_0$ and reaches at $k_0 - k = \pm 1/a$ the fraction $(1/e)$ of this value. Its width, therefore, is $\Delta k(t=0) = 2/a$. The larger the spatial extent, the narrower the momentum distribution, and vice versa.
c. We have,

$$u(x,t) = \frac{1}{\sqrt{2\pi}}\int_{-\infty}^{+\infty} dk A(k) e^{\imath kx - \imath\omega(k)t}\ .$$

With $A(k)$ of part (b) and $\omega(k) = b^2k^2$ we consecutively get,

$$\begin{aligned}
u(x,t) &= \frac{ac}{\sqrt{2\pi}} \int_{-\infty}^{+\infty} dk \exp\left\{ -\left[\frac{a^2}{2} + \imath b^2 t\right] k^2 + [a^2 k_0 + \imath x]k - \frac{a^2}{2}k_0^2 \right\} \\
&= \frac{ac}{\sqrt{2\pi}} \frac{\sqrt{\pi}}{\sqrt{\frac{a^2}{2} + \imath b^2 t}} \exp\left\{ \frac{a^4 k_0^2 + \imath 2a^2 k_0 x - x^2 - a^2 k_0^2 (a^2 + 2\imath b^2 t)}{2a^2 + 4\imath b^2 t} \right\} \\
&= \frac{c}{\sqrt{1 + \imath 2\frac{b^2}{a^2}t}} \exp\left\{ \frac{\imath 2a^2 k_0 x - \imath 2a^2 b^2 k_0^2 t - x^2}{2a^2\left(1 + \imath 2\frac{b^2}{a^2}t\right)} \right\} \\
&= \frac{c}{\sqrt{1 + \imath 2\frac{b^2}{a^2}t}} \exp\left\{ -\frac{(x^2 - \imath 2a^2[k_0 x - b^2 k_0^2 t])\left(1 - \imath 2\frac{b^2}{a^2}t\right)}{2a^2\left(1 + \left(2\frac{b^2}{a^2}t\right)^2\right)} \right\} \\
&= \frac{c}{\sqrt{1 + \imath 2\frac{b^2}{a^2}t}} \exp\left\{ -\frac{x^2 - 4b^2 t[k_0 x - b^2 k_0^2 t] - 2a^2 \imath[k_0 x - b^2 k_0^2 t] - \imath 2\frac{b^2}{a^2} t x^2}{2a^2\left(1 + \left(2\frac{b^2}{a^2}t\right)^2\right)} \right\} .
\end{aligned}$$

Regrouping provides,

$$u(x,t) = \frac{c}{\sqrt{1 + \imath 2\frac{b^2}{a^2}t}} \exp\left\{ -\frac{(x - 2b^2 k_0 t)^2}{2a^2\left(1 + \left(2\frac{b^2}{a^2}t\right)^2\right)} \right\} \cdot$$

$$\cdot \exp\left\{ \imath \frac{2a^2[k_0 x - b^2 k_0^2 t] + 2\frac{b^2}{a^2}t + 2a^2\left(2\frac{b^2}{a^2}t\right)^2 [k_0 x - b^2 k_0^2 t] - 2a^2\left(2\frac{b^2}{a^2}t\right)^2 [k_0 x - b^2 k_0^2 t]}{2a^2\left(1 + \left(2\frac{b^2}{a^2}t\right)^2\right)} \right\}$$

$$= \frac{c}{\sqrt{1 + \imath 2\frac{b^2}{a^2}t}} \exp\left\{ -\frac{(x - 2b^2 k_0 t)^2}{2a^2\left(1 + \left(2\frac{b^2}{a^2}t\right)^2\right)} \right\} e^{\imath(k_0 x - b^2 k_0^2 t)} \cdot \exp\left\{ \imath \frac{2\frac{b^2}{a^2}t(x^2 - 4b^2 k_0 x t + 4b^4 k_0^2 t^2)}{2a^2\left(1 + \left(2\frac{b^2}{a^2}t\right)^2\right)} \right\}$$

$$= \frac{c}{\sqrt{1 + \imath 2\frac{b^2}{a^2}t}} \exp\left\{ -\frac{(x - 2b^2 k_0 t)^2}{2a^2\left(1 + \left(2\frac{b^2}{a^2}t\right)^2\right)} \right\} e^{\imath(k_0 x - b^2 k_0^2 t)} \cdot \exp\left\{ \imath \frac{2\frac{b^2}{a^2}t(x - 2b^2 k_0^t)^2}{2a^2\left(1 + \left(2\frac{b^2}{a^2}t\right)^2\right)} \right\} .$$

Now,

$$1 + \imath 2\frac{b^2}{a^2}t = \sqrt{1 + \left(2\frac{b^2}{a^2}t\right)^2} \exp\left\{ \imath \text{arctg}\left[\frac{2b^2}{a^2}t\right] \right\} ,$$

and hence,

$$u(x,t) = \frac{c}{\left[1 + \left(2\frac{b^2}{a^2}t\right)^2\right]^{-1/4}} \exp\left\{ -\frac{(x - 2b^2 k_0 t)^2}{2a^2\left(1 + \left(2\frac{b^2}{a^2}t\right)^2\right)} \right\} \exp\left\{\imath[k_0 x - b^2 k_0^2 t]\right\} \cdot$$

$$\cdot \exp\left\{ \imath \left[\frac{2\frac{b^2}{a^2}t(x - 2b^2 k_0 t)^2}{2a^2\left(1 + \left(2\frac{b^2}{a^2}t\right)^2\right)} - \frac{1}{2}\text{arcctg}\left(\frac{2b^2}{a^2}t\right) + n\pi \right] \right\} .$$

where the additional phase $\imath n\pi$ was introduced to remove the phase ambiguity of the arctan.
d. With part (c) immediately follows,

$$|u(x,t)|^2 = \frac{c^2}{\sqrt{1+\left(2\frac{b^2}{a^2}t\right)^2}} \exp\left\{-\frac{(x-2b^2k_0t)^2}{a^2\left(1+\left(2\frac{b^2}{a^2}t\right)^2\right)}\right\} .$$

The spatial intensity distribution has its maximum at,

$$x_m(t) = 2b^2k_0t .$$

This maximum propagates with the speed,

$$2b^2k_0 = \left[\frac{d\omega(k)}{dk}\right]_{k_0} \equiv v_{gr} .$$

The decay to $(1/e)$ happens, when

$$(x-v_{gr}t)^2 = a^2\left(1+\left(2\frac{b^2}{a^2}t\right)^2\right) .$$

This follows the width (spatial extent) at time t,

$$\Delta x(t) = 2a\sqrt{1+\left(2\frac{b^2}{a^2}t\right)^2} .$$

Since, on the other hand, $\Delta k = \frac{2}{a}$ is independent of time, we get an 'uncertainty relation' of the form,

$$\Delta x(t)\Delta k = 4\sqrt{1+\left(2\frac{b^2}{a^2}t\right)^2} \geq 4 .$$

e. The maximum of the spatial intensity distribution moves at group velocity, the width increases in the manner calculated in (d). The wave packet 'spreads'. For long t we obtain,

$$\Delta x(t) \to \frac{4b^2}{a}t \sim t .$$

Width increases linearly over time.

18.2.7.6 Ex: Radiation force acting on a small dielectric particle

The polarizability of a small ($a \ll \lambda$) dielectric particle with complex refraction index $n_p = \mathfrak{Re}\ n_p - \imath\frac{\alpha\lambda}{4\pi}$ immersed in a medium of refraction index n_m is given by,

$$\alpha_{rad} = \frac{4\pi a^3 \frac{n_p^2-n_m^2}{n_p^2+2n_m^2} n_m^2\varepsilon_0}{1-\frac{n_p^2-n_m^2}{n_p^2+2n_m^2}\left[\left(\frac{n_m\omega_0}{c}a\right)^2 - \frac{2}{3}\imath\left(\frac{n_m\omega_0}{c}a\right)^3\right]} .$$

Calculate the total force acting on it when subject to an electromagnetic field.

Solution: *Let us assume the particle to be in the Rayleigh regime of dipolar approximation, $a \ll \lambda$, where a small dielectric particle behaves like an induced electric dipole,*

$$\vec{\mathcal{P}}(\mathbf{r},t) = \alpha_{rad}\vec{\mathcal{E}}(\mathbf{r},t) \ .$$

The Lorentz force is,

$$\begin{aligned}\mathbf{F}(\mathbf{r}) &= [\vec{\mathcal{P}}(\mathbf{r})\cdot\nabla]\vec{\mathcal{E}}(\mathbf{r}) + \imath\frac{n_m\omega_0}{c}\vec{\mathcal{P}}(\mathbf{r})\times\vec{\mathcal{B}}(\mathbf{r}) \\ &= \alpha_{rad}\left\{[\vec{\mathcal{E}}(\mathbf{r})\cdot\nabla]\vec{\mathcal{E}}(\mathbf{r}) + \vec{\mathcal{E}}(\mathbf{r})\times[\nabla\times\vec{\mathcal{E}}(\mathbf{r})]\right\} = \tfrac{1}{2}\alpha_{rad}\nabla\vec{\mathcal{E}}^2(\mathbf{r}) \ .\end{aligned}$$

Time-averaged,

$$\begin{aligned}\langle\mathbf{F}(\mathbf{r})\rangle &= \tfrac{1}{2}\mathfrak{Re}\ \left[\alpha_{rad}\left\{[\vec{\mathcal{E}}(\mathbf{r})\cdot\nabla]\vec{\mathcal{E}}^*(\mathbf{r}) + \vec{\mathcal{E}}(\mathbf{r})\times\left[\nabla\times\vec{\mathcal{E}}^*(\mathbf{r})\right]\right\}\right] \\ \langle\mathbf{F}^i\rangle &= \tfrac{1}{2}\mathfrak{Re}\ \left[\alpha_{rad}E_j\partial^i(E^j)^*\right] \ .\end{aligned}$$

18.2.7.7 Ex: Lorentz model

Based on the Lorentz model, derive the differential equation for the oscillation amplitude of the electrons and calculate the response of the matter reacting via a polarization $P = Nex$, where N is the number of electrons and x their oscillation amplitude. Calculate the absorptive part $\mathfrak{Im}\ \chi$ and the dispersive part $\mathfrak{Re}\ \chi$ of the susceptibility $\chi \equiv P/\varepsilon_0\mathcal{E}$.
With this calculate the index of refraction n and the coefficient of absorption α in the Lorentz model.

Solution: *Differently from the Thomson model, the Lorentz model considers electrons bound to an atom. Of course, this bond influences the electronic motion. Let the light wave be $\mathcal{E} = \mathcal{E}_0 e^{\imath\omega t}$. The differential equation is,*

$$\ddot{x} + \gamma_\omega\dot{x} + \omega_0^2 = \frac{e}{m_e}\mathcal{E}_0 e^{\imath\omega t} \ .$$

The ansatz $x \equiv x_0 e^{\imath\omega t}$ leads to the oscillation amplitude,

$$x_0 = \frac{e\mathcal{E}_0}{m_e}\frac{1}{\omega_0^2 - \omega^2 - \imath\gamma_\omega\omega} \ .$$

For small detunings $\Delta = \omega - \omega_0 \ll \omega$ we get,

$$x_0 \simeq \frac{1}{2\omega}\frac{-\Delta + \imath\gamma_\omega/2}{\Delta^2 + (\gamma_\omega/2)^2} \ .$$

Hence,

$$\chi = \frac{Ne^2}{\varepsilon_0 m_e 2\omega}\frac{-\Delta + \imath\gamma_\omega/2}{\Delta^2 + (\gamma_\omega/2)^2} \ .$$

Writing the intensity as $I = I_0 e^{\imath\alpha z}$, we find the refraction index and the absorption coefficient,

$$n = 1 + \mathfrak{Im}\ \chi \qquad \text{and} \qquad \alpha = \mathfrak{Re}\ \chi\ .$$

We also have,

$$\phi(\omega) = \frac{\mathfrak{Im}\ \alpha}{\mathfrak{Re}\ \alpha} = \frac{-\gamma_\omega \omega^2}{\omega^2 - \omega_0^2} \overset{\omega\to\omega_0}{\to} \frac{\gamma_\omega}{2\Delta}\ .$$

18.2.7.8 Ex: Lorentz force on a single atomic dipole

Calculate the Lorentz force on a single atom within the dipole approximation from the expression [619],

$$\mathbf{F} = \int d^3r [\varrho(\mathbf{r})\vec{\mathcal{E}}(\mathbf{r}) + \mathbf{j}(\mathbf{r}) \times \vec{\mathcal{B}}(\mathbf{r})]\ .$$

Solution: *With the given formula, understanding the atom as a permanent dipole, $\mathbf{d} = -e(\mathbf{r}_1 - \mathbf{r}_2)$, we find the parametrization,*

$$\varrho(\mathbf{r}) \equiv -e\delta(\mathbf{r} - \mathbf{r}_1) + e\delta\mathbf{r} - \mathbf{r}_2) \qquad \text{and} \qquad \mathbf{j}(\mathbf{r}) \equiv -e\dot{\mathbf{r}}\delta(\mathbf{r} - \mathbf{r}_1) + e\dot{\mathbf{r}}\delta(\mathbf{r} - \mathbf{r}_2)\ .$$

The force then becomes,

$$\begin{aligned}
\mathbf{F} &= -e\vec{\mathcal{E}}(\mathbf{r}_1) + e\vec{\mathcal{E}}(\mathbf{r}_2) - e\dot{\mathbf{r}}_1 \times \vec{\mathcal{B}}(\mathbf{r}_1) + e\dot{\mathbf{r}}_2 \times \vec{\mathcal{B}}(\mathbf{r}_2) \\
&= (\mathbf{d}\cdot\nabla)\vec{\mathcal{E}} + \dot{\mathbf{d}} \times \vec{\mathcal{B}} \\
&= (\mathbf{d}\cdot\nabla)\vec{\mathcal{E}} + \frac{d}{dt}(\mathbf{d} \times \vec{\mathcal{B}}) - \mathbf{d} \times \dot{\vec{\mathcal{B}}} \\
&= (\mathbf{d}\cdot\nabla)\vec{\mathcal{E}} + \frac{d}{dt}(\mathbf{d} \times \vec{\mathcal{B}}) + \mathbf{d} \times (\nabla \times \tilde{\mathcal{E}})\ .
\end{aligned}$$

Use a plane wave $\vec{\mathcal{E}}(\mathbf{r}, t) = \mathcal{E}(kz - \omega t)\cos(kz - \omega t)\hat{\mathbf{e}}$. Then, $\nabla \times \vec{\mathcal{E}} = 0$.

18.2.7.9 Ex: The Faraday effect

Derive the *Faraday effect* from the Lorentz model using the following procedure:
a. Formulate the equation of motion for the position $\mathbf{s}$ of a bound electron according to (18.106) in the presence of a homogeneous magnetic field $\vec{\mathcal{B}} = \mathcal{B}\hat{\mathbf{e}}_z$ and an electromagnetic wave characterized by $\vec{\mathcal{E}}(z,t) = \mathcal{E}(z)\hat{\epsilon}e^{-\imath\omega t}$ and assumed to be initially linearly polarized in x-direction.
b. Express the motion of the electron in the xy-plane in a new basis given by $\hat{\mathbf{e}}_\pm = \frac{1}{\sqrt{2}}(\hat{\mathbf{e}}_x \pm \imath\hat{\mathbf{e}}_y)$.
c. Solve the equations of motion for the decoupled components $s_\pm(z,t) \equiv s_x \mp \imath s_y$ and determine the susceptibility.
d. Calculate the electric field and the angle by which the linear polarization vector is

rotated as a function of z.

Solution: *a. We write the equations for an electron at position* $\mathbf{s}$ *bound to a molecule in a dielectric medium subject to an electric and a magnetic field as,*

$$m_e\ddot{\mathbf{s}} + m_e\gamma_\omega\dot{\mathbf{s}} + m_e\omega_0^2\vec{\mathcal{S}} = -e(\vec{\mathcal{E}} + \dot{\mathbf{s}} \times \vec{\mathcal{B}}) \ . \tag{18.181}$$

Now, we describe the electric field as a plane wave propagating in z*-direction and being, at* $z = 0$*, linearly polarized in* x*-direction,* $\vec{\mathcal{E}}(0,t) = \mathcal{E}(0)\hat{\mathbf{e}}_x e^{-\imath\omega t}$*. In the internal region of the dielectric, the electric field will acquire components along* $\hat{\mathbf{e}}_x$ *and* $\hat{\mathbf{e}}_y$*. Thus we have to allow for a general ansatz,*

$$\vec{\mathcal{E}}(z,t) = \mathcal{E}_x(z)\hat{\mathbf{e}}_x + \mathcal{E}_y(z)\hat{\mathbf{e}}_y \ . \tag{18.182}$$

In the equation of motion (18.181), due to the construction of the plane wave, the force applied to the electron is contained in the xy*-plane, thus leading to a harmonic motion confined to this plane. Thus, the evolution of the components* $\mathcal{E}_{x,y}$ *under the action of the fields* $\vec{\mathcal{E}}$ *and* $\vec{\mathcal{B}}$ *must be determined.*

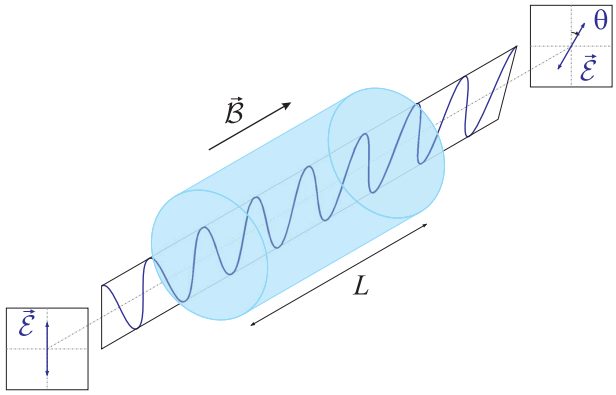

Figure 18.19: Scheme of the Faraday effect.

b. The position of the electron $\mathbf{s}$ *is obtained as the response of the medium to the action of the wave's electric field. That is, the wave induces a movement of the electron, so we can write* $\mathbf{s}(z,t) = s_x(z,t)\hat{\mathbf{e}}_x + s_y(z,t)\hat{\mathbf{e}}_y$*. Replacing* $\mathbf{s}(z,t)$*,* $\vec{\mathcal{E}}(z,t)$*, and* $\vec{\mathcal{B}}$ *in Eq. (18.181) we obtain,*

$$\begin{aligned} &m_e(\ddot{s}_x\hat{\mathbf{e}}_x + \ddot{s}_y\hat{\mathbf{e}}_y) + m_e\gamma_\omega(\dot{s}_x\hat{\mathbf{e}}_x + \dot{s}_y\hat{\mathbf{e}}_y) + m_e\omega_0^2(s_x\hat{\mathbf{e}}_x + s_y\hat{\mathbf{e}}_y) \\ &\quad = -e(\mathcal{E}_x\hat{\mathbf{e}}_x + \mathcal{E}_y\hat{\mathbf{e}}_y) + e(\dot{s}_x\mathcal{B}\hat{\mathbf{e}}_y - \dot{s}_y\mathcal{B}\hat{\mathbf{e}}_x) \ . \end{aligned} \tag{18.183}$$

Eq. (18.182) represents a system of coupled equations. We now replace the base formed by $\hat{\mathbf{e}}_x$ *and* $\hat{\mathbf{e}}_y$ *with the base formed by the circular polarization vectors* $\hat{\mathbf{e}}_\pm = \frac{1}{\sqrt{2}}(\hat{\mathbf{e}}_x \pm \imath\hat{\mathbf{e}}_y)$*. Separating the terms of this equation by components we get,*

$$\begin{aligned} &(\ddot{s}_x + \imath\ddot{s}_y) + (\gamma_\omega - \imath\Omega)(\dot{s}_x + \imath\dot{s}_y) + \omega_0^2(s_x + \imath s_y) = -\tfrac{e}{m_e}(\mathcal{E}_x + \imath\mathcal{E}_y) \\ &(\ddot{s}_x - \imath\ddot{s}_y) + (\gamma_\omega + \imath\Omega)(\dot{s}_x - \imath\dot{s}_y) + \omega_0^2(s_x - \imath s_y) = -\tfrac{e}{m_e}(\mathcal{E}_x - \imath\mathcal{E}_y) \ , \end{aligned} \tag{18.184}$$

where $\Omega = e\mathcal{B}/m_e$ is the cyclotron frequency. Defining new variables,

$$s_\pm(z,t) \equiv s_x(z,t) \mp \imath s_y(z,t) \quad , \quad \mathcal{E}_\pm(z,t) = [\mathcal{E}_x(z) \mp \imath \mathcal{E}_y(z)]e^{-\imath\omega t} = \mathcal{E}_0 e^{\imath(k_\pm z - \omega t)} \ , \tag{18.185}$$

a new system of equations is obtained from (18.184),

$$\begin{aligned} \ddot{s}_+ + (\gamma_\omega + \imath\Omega)\dot{s}_+ + \omega_0^2 s_+ &= -\tfrac{e}{m_e}\mathcal{E}_0 e^{\imath(k_+ z - \omega t)} \\ \ddot{s}_- + (\gamma_\omega - \imath\Omega)\dot{s}_- + \omega_0^2 s_- &= -\tfrac{e}{m_e}\mathcal{E}_0 e^{\imath(k_- z - \omega t)} \ . \end{aligned} \tag{18.186}$$

In doing so, we allowed for the possibility that the two circularly polarized plane waves may have different propagation velocities and thus phase shifts.
c. Neglecting γ_ω the solutions for $s_\pm$ are as follows:

$$s_\pm(z,t) = \frac{-e\mathcal{E}_0}{m_e(\omega_0^2 - \omega^2 \pm \omega\Omega)} e^{\imath(k_\pm z - \omega t)} = \frac{-e\mathcal{E}_\pm(z,t)}{m_e(\omega_0^2 - \omega^2 \pm \omega\Omega)} \ . \tag{18.187}$$

With these equations, the components of the electric dipole moment, $d_\pm(z,t) = -es_\pm(z,t)$ and the total polarization vector, $\mathcal{P}_\pm(z,t) = Nd_\pm(z,t)$ are, in the case of a linear dielectric,

$$\mathcal{P}_\pm(z,t) = \varepsilon_0 \chi_\varepsilon \mathcal{E}_\pm(z,t) = \frac{-Ne^2\mathcal{E}_\pm(z,t)}{m_e(\omega_0^2 - \omega^2 \pm \omega\Omega)} \ . \tag{18.188}$$

Thus the susceptibility in the circular basis is,

$$\chi_{\varepsilon\pm} = \frac{Ne^2}{m_e\varepsilon_0(\omega_0^2 - \omega^2 \pm \omega\Omega)} \tag{18.189}$$

d. Physically, this result represents the difference between the refraction indices n_+ and n_- obtained through the application of the magnetic field. The electric field (18.185) at a position z inside the dielectric becomes in the Cartesian basis, making the substitutions $k_\pm = n_\pm k_0$, $\bar{n} = (n_+ + n_-)/2$, and $\delta n = n_+ - n_-$,

$$\vec{\mathcal{E}}(z,t) = \mathcal{E}_0 e^{\imath(\bar{n}k_0 z - \omega t)}[\hat{\mathbf{e}}_x \cos\tfrac{\delta n\ k_0 z}{2} - \hat{\mathbf{e}}_y \sin\tfrac{\delta n\ k_0 z}{2}] \ . \tag{18.190}$$

The angular rotation of the polarization is,

$$\phi(z) = -\tfrac{1}{2}\delta n\ k_0 z \ . \tag{18.191}$$

Since $n_\pm^2 = 1 + \chi_{\varepsilon\pm}$ for a linear dielectric, expanding in Ω up to first order, we obtain,

$$\delta n = -\frac{Ne^2\omega\Omega}{m_e\varepsilon_0(\omega_0^2 - \omega^2)} \qquad \text{and} \qquad \bar{n} = \sqrt{1 + \frac{Ne^2}{m_e\varepsilon_0(\omega_0^2 - \omega^2)}} \ . \tag{18.192}$$

Substituting $k_0 = \omega/c$,

$$\boxed{\phi(z) = -\frac{Ne^3\omega^2}{m_e^2\varepsilon_0 2c(\omega_0^2 - \omega^2)^2}\mathcal{B}z \equiv V\mathcal{B}z} \ . \tag{18.193}$$

V it is called Verdet constant and is characteristic for the medium and also depends on the wavelength on the incident light [132, 767].

18.2.7.10 Ex: Complex refraction index and extinction coefficient

a. Derive the relations $n'^2 - n''^2 = 1 + \chi'_\varepsilon$ and $2n'n'' = \chi_\varepsilon$. **Note:** In a transparent dielectric medium there is no absorption, such that, $n'^2 = 1 + \chi'_\varepsilon = \frac{\varepsilon}{\varepsilon_0}$.
b. Calculate the *absorption coefficient* for a light field traversing a dielectric medium.

Solution: *a. From,*

$$n' = \mathfrak{Re}\ \sqrt{\epsilon} = \mathfrak{Re}\ \sqrt{1+\tilde{\chi}_\varepsilon} = \mathfrak{Re}\ \sqrt{1+\chi'_\varepsilon+\imath\chi''_\varepsilon} = \sqrt{\tfrac{1}{2}}\sqrt{\sqrt{(1+\chi'_\varepsilon)^2+\chi''^2_\varepsilon}+(1+\chi'_\varepsilon)}$$
$$n'' = \mathfrak{Im}\ \sqrt{\epsilon} = \mathfrak{Im}\ \sqrt{1+\tilde{\chi}_\varepsilon} = \mathfrak{Im}\ \sqrt{1+\chi'_\varepsilon+\imath\chi''_\varepsilon} = \sqrt{\tfrac{1}{2}}\sqrt{\sqrt{(1+\chi'_\varepsilon)^2+\chi''^2_\varepsilon}-(1+\chi'_\varepsilon)}\ ,$$

we calculate,

$$n'^2 - n''^2 = \left(\mathfrak{Re}\ \sqrt{1+\chi'_\varepsilon+\imath\chi''_\varepsilon}\right)^2 - \left(\mathfrak{Im}\ \sqrt{1+\chi'_\varepsilon+\imath\chi''_\varepsilon}\right)^2 = 1+\chi'_\varepsilon$$
$$2n'n'' = 2\mathfrak{Re}\ \sqrt{1+\chi'_\varepsilon+\imath\chi''_\varepsilon}\mathfrak{Im}\ \sqrt{1+\chi'_\varepsilon+\imath\chi''_\varepsilon} = \chi''_\varepsilon\ .$$

b. Within a dielectric medium, we obtain the propagating wave solutions of Maxwell's equations by substituting k with $\tilde{k}$,

$$\vec{\mathcal{E}} = \vec{\mathcal{E}}_0 e^{\imath\omega(\frac{n'z}{c}-t)-\omega\frac{n''}{c}z}\ .$$

The relationship between the amplitudes of the electric and magnetic fields is [24],

$$\mathcal{B}_0^{(\chi)} = \sqrt{\varepsilon\mu}\mathcal{E}_0 = \sqrt{\varepsilon_0\mu_0}\sqrt{1+\tilde{\chi}_\varepsilon}\ \mathcal{E}_0 = \frac{1}{c}(n'+\imath n'')\mathcal{E}_0 = (n'+\imath n'')\mathcal{B}_0\ .$$

We use the subscript (χ) to mark quantities within the dielectric medium. The average energy density is,

$$\bar{u}^{(\chi)} = \tfrac{1}{2}\varepsilon_0 n'^2|\vec{\mathcal{E}}|^2 = n'^2\bar{u}\ .$$

Now, the intensity of the light beam in a dielectric medium is attenuated,

$$\bar{I}^{(\chi)} = \tfrac{1}{\mu_0}|\vec{\mathcal{E}}\times\vec{\mathcal{B}}| = \tfrac{1}{2}\varepsilon_0 cn'|\vec{\mathcal{E}}|^2 = \tfrac{1}{2}\varepsilon_0 cn'\vec{\mathcal{E}}_0^2 e^{-2\omega n''z/c} = \bar{I}_0^{(\chi)}e^{-Kz}\ ,$$

where

$$\bar{I}_0^{(\chi)} = \tfrac{1}{2}\varepsilon_0 cn'\vec{\mathcal{E}}_0^2$$

is the intensity at the point, where the light enters the medium, and

$$K = 2\frac{\omega n''}{c} = \frac{\omega}{n'c}\chi''_\varepsilon$$

is called absorption coefficient. Note, that the energy flow $\bar{I}^{(\chi)}$ in the dielectric medium is always the product of energy density and propagation velocity c/n'. Note also, since the frequency ω of the light propagating through the dielectric remains the same, the wavelength shrinks like $\lambda = \frac{c/n'}{\nu}$ [816].

[24] In a dielectric medium, $\mu \simeq \mu_0$.

18.3 Plasmons, waveguides and resonant cavities

18.3.1 Green's tensor for wave propagation in dielectric media

The electromagnetic field in the presence of macroscopic dielectrics is governed by an inhomogeneous vector Helmholtz equation. Defining the permittivity and the permeability as tensor fields $\vec{\mathcal{D}}(\mathbf{r},\omega) = \epsilon(\mathbf{r},\omega)\varepsilon_0\vec{\mathcal{E}}(\mathbf{r},\omega)$ and $\vec{\mathcal{B}}(\mathbf{r},\omega) = \mu(\mathbf{r},\omega)\mu_0\vec{\mathcal{H}}(\mathbf{r},\omega)$ the Maxwell equations (17.6), become after a temporal Fourier transform,

$$\begin{aligned} \nabla\times\vec{\mathcal{H}} &= -\imath\omega\epsilon\varepsilon_0\vec{\mathcal{E}} + \mathbf{j} \\ \nabla\times\vec{\mathcal{E}} &= \imath\omega\mu\mu_0\vec{\mathcal{H}} \\ \nabla\cdot\epsilon\varepsilon_0\vec{\mathcal{E}} &= \varrho \\ \nabla\cdot\mu\mu_0\vec{\mathcal{H}} &= 0\ . \end{aligned} \tag{18.194}$$

It is easy to see, that the *inhomogeneous Helmholtz equation* [786, 946, 210],

$$\boxed{\left[\nabla\times\frac{1}{\mu(\mathbf{r},\omega)}\nabla\times - \frac{\omega^2}{c^2}\epsilon(\mathbf{r},\omega)\right]\vec{\mathcal{E}}(\mathbf{r},\omega) = \imath\omega\mu_0\mathbf{j}(\mathbf{r},\omega)} \tag{18.195}$$

satisfies the above Maxwell equations with $\vec{\mathcal{E}}(\mathbf{r},\omega)\to 0$ for $r\to\infty$. Using the Green's function formalism, the solution to the Helmholtz equation can be given by,

$$\vec{\mathcal{E}}(\mathbf{r},\omega) = \imath\omega\mu_0\int_V d^3r'\mathcal{G}(\mathbf{r},\mathbf{r}',\omega)\cdot\mathbf{j}(\mathbf{r}',\omega)\ , \tag{18.196}$$

where the *Green's tensor* is the solution to

$$\boxed{\left[\nabla_{\mathbf{r}}\times\frac{1}{\mu(\mathbf{r},\omega)}\nabla_{\mathbf{r}}\times - \frac{\omega^2}{c^2}\epsilon(\mathbf{r},\omega)\right]\mathcal{G}(\mathbf{r},\mathbf{r}',\omega) = \delta^{(3)}(\mathbf{r}-\mathbf{r}')\mathbb{I}} \tag{18.197}$$

together with the boundary condition $\mathcal{G}(\mathbf{r},\mathbf{r}',\omega)\to 0$ for $|\mathbf{r}-\mathbf{r}'|\to\infty$. The volume of integration V is a small volume surrounding the point $\mathbf{r}=\mathbf{r}'$ in order to avoid the singularity.

The Green's tensor represents the electric field radiated at position $\mathbf{r}$ by three orthogonal dipoles located at $\mathbf{r}'$.

18.3.1.1 Bulk medium

Let us now consider the simplest case of a bulk medium, i.e. an infinitely extended, homogeneous dielectric independent of $\mathbf{r}$, that is, $\epsilon(\mathbf{r},\omega)=\epsilon(\omega)$ and $\mu(\mathbf{r},\omega)=\mu(\omega)$. In this case, the Helmholtz equation further simplifies to,

$$[\nabla_{\mathbf{r}}\times\nabla_{\mathbf{r}}\times -k(\omega)^2]\vec{\mathcal{E}}_b(\mathbf{r},\omega) = \imath\omega\mu_0\mathbf{j}(\mathbf{r},\omega) \tag{18.198}$$

with $k(\omega)^2 = \frac{\omega^2}{c^2}\mu(\omega)\epsilon(\omega)$ defined at $\mathbf{r}$. The Green tensor is then the solution to,

$$\nabla_{\mathbf{r}}\times\nabla_{\mathbf{r}}\times\mathcal{G}_b(\mathbf{r},\mathbf{r}',\omega) - k^2\mathcal{G}_b(\mathbf{r},\mathbf{r}',\omega) = \delta^{(3)}(\mathbf{r}-\mathbf{r}')\mathbb{I}\ . \tag{18.199}$$

18.3.1.2 The scalar Helmholtz equation

The bulk medium vector Helmholtz equation (18.199) can be reduced to a scalar Helmholtz equation. To that end, we take its divergence and find,

$$\nabla \cdot \mathcal{G}_b(\mathbf{r},\mathbf{r}',\omega) = -\tfrac{1}{k^2}\nabla\delta^{(3)}(\mathbf{r}-\mathbf{r}') \ . \tag{18.200}$$

Using this identity and expanding,

$$\nabla_{\mathbf{r}}\times\nabla_{\mathbf{r}}\times\mathcal{G}_b = \begin{pmatrix} \partial_x^2-\triangle & \partial_x\partial_y & \partial_x\partial_z \\ \partial_x\partial_y & \partial_y^2-\triangle & \partial_y\partial_z \\ \partial_x\partial_z & \partial_y\partial_z & \partial_z^2-\triangle \end{pmatrix} \begin{pmatrix} G_{xx} & G_{xy} & G_{xz} \\ G_{yx} & G_{yy} & G_{yz} \\ G_{zx} & G_{zy} & G_{zz} \end{pmatrix} = (\nabla\otimes\nabla - \mathbb{I}\triangle)\,\mathcal{G}_b \ , \tag{18.201}$$

we may write,

$$\begin{aligned} [\Delta + k^2]\mathcal{G}_b(\mathbf{r},\mathbf{r}',\omega) &= \nabla\nabla\cdot\mathcal{G}_b(\mathbf{r},\mathbf{r}',\omega) - \nabla\times\nabla\times\mathcal{G}_b(\mathbf{r},\mathbf{r}',\omega) + k^2\mathcal{G}_b(\mathbf{r},\mathbf{r}',\omega) \\ &= \nabla\nabla\cdot\mathcal{G}_b(\mathbf{r},\mathbf{r}',\omega) - \delta^{(3)}(\mathbf{r}-\mathbf{r}')\mathbb{I} \\ &= -\tfrac{1}{k^2}\nabla\nabla\delta^{(3)}(\mathbf{r}-\mathbf{r}') - \delta^{(3)}(\mathbf{r}-\mathbf{r}')\mathbb{I} = -\left[\mathbb{I} + \tfrac{1}{k^2}\nabla\nabla\right]\delta^{(3)}(\mathbf{r}-\mathbf{r}') \ . \end{aligned} \tag{18.202}$$

The vector Helmholtz equation can hence be solved by writing,

$$\mathcal{G}_b(\mathbf{r},\mathbf{r}',\omega) = \left[\mathbb{I} + \tfrac{1}{k^2}\nabla\nabla\right] g(\mathbf{r},\mathbf{r}',\omega) \ , \tag{18.203}$$

where the scalar Green function g obeys the scalar Helmholtz equation,

$$\boxed{[\triangle + k^2]g(\mathbf{r},\mathbf{r}',\omega) = -\delta^{(3)}(\mathbf{r}-\mathbf{r}')} \ , \tag{18.204}$$

the solution of which is simply,

$$g(\mathbf{r},\mathbf{r}',\omega) = \frac{e^{\imath k|\mathbf{r}-\mathbf{r}'|}}{4\pi|\mathbf{r}-\mathbf{r}'|} \ , \tag{18.205}$$

where the boundary condition at infinity implies that k must have a positive imaginary part, $k = \sqrt{\varepsilon(\omega)}\frac{\omega}{c}$ with $\mathfrak{Im}\ k > 0$. Combining these results, we obtain the Green tensor of a bulk medium [994, 210],

$$\begin{aligned} \mathcal{G}_b(\mathbf{r},\mathbf{r}',\omega) &= \left[\mathbb{I} + \tfrac{1}{k^2}\nabla\nabla\right]\frac{e^{\imath k|\mathbf{r}-\mathbf{r}'|}}{4\pi|\mathbf{r}-\mathbf{r}'|} \\ &= \frac{\delta^{(3)}(\mathbf{R})\mathbb{I}}{3k^2} - \frac{e^{\imath kR}}{4\pi k^2R^3}\left\{[1-\imath kR-(kR)^2]\mathbb{I} - [3-3\imath kR-(kR)^2]\hat{\mathbf{e}}_R\otimes\hat{\mathbf{e}}_R\right\} \ , \end{aligned} \tag{18.206}$$

with $\mathbf{R} \equiv \mathbf{r}-\mathbf{r}'$, as will be shown in Exc. 18.3.7.1. The real and imaginary part are (for $\mathbf{R}\neq 0$),

$$\begin{aligned} \tfrac{4\pi}{k}\mathfrak{Re}\ \mathcal{G}_b(\mathbf{r},\mathbf{r}',\omega_0) &= (\mathbb{I}-\hat{\mathbf{e}}_R\otimes\hat{\mathbf{e}}_R)\frac{\cos kR}{kR} - (\mathbb{I}-3\hat{\mathbf{e}}_R\otimes\hat{\mathbf{e}}_R)\left(\frac{\sin kR}{k^2R^2} - \frac{\cos kR}{k^3R^3}\right) \\ \tfrac{4\pi}{k}\mathfrak{Im}\ \mathcal{G}_b(\mathbf{r},\mathbf{r}',\omega_0) &= (\mathbb{I}-\hat{\mathbf{e}}_R\otimes\hat{\mathbf{e}}_R)\frac{\sin kR}{kR} + (\mathbb{I}-3\hat{\mathbf{e}}_R\otimes\hat{\mathbf{e}}_R)\left(\frac{\cos kR}{k^2R^2} - \frac{\sin kR}{k^3R^3}\right) \ . \end{aligned} \tag{18.207}$$

Furthermore is is possible to show [210],

$$\mathfrak{Re}\ \mathcal{G}_b(\mathbf{r},\mathbf{r},\omega)=0 \qquad \text{and} \qquad \mathfrak{Im}\ \mathcal{G}_b(\mathbf{r},\mathbf{r},\omega)=\frac{k}{6\pi}\mathbb{I}\ . \tag{18.208}$$

Example 108 (*Electric field of a point dipole in an inhomogeneous dielectric*): Parametrizing the current generated by a point dipole located at $\mathbf{r}=\mathbf{r}_s$ by

$$\mathbf{j}(\mathbf{r},\omega)=-\imath\omega\mathbf{d}_s\delta^{(3)}(\mathbf{r}-\mathbf{r}_s)\ , \tag{18.209}$$

the generated electric field in an environment characterized by the Green function $\mathcal{G}(\mathbf{r},\mathbf{r}_s,\omega)$ can be evaluated from Eq. (18.196),

$$\vec{\mathcal{E}}(\mathbf{r},\mathbf{r}_s,\omega)=\omega^2\mu_0\mathcal{G}(\mathbf{r},\mathbf{r}_s)\cdot\mathbf{d}_s\ . \tag{18.210}$$

Using the solution (18.206) for bulk media we find,

$$\vec{\mathcal{E}}_b(\mathbf{r},\mathbf{r}_s,\omega)=\omega^2\mu_0\left[-\frac{e^{\imath kR}}{4\pi k^2R^3}\left\{[1-\imath kR-(kR)^2]\mathbb{I}-[3-3\imath kR-(kR)^2]\hat{\mathbf{e}}_R\otimes\hat{\mathbf{e}}_R\right\}\right]\cdot\mathbf{d}_s\ . \tag{18.211}$$

with $k=k(\omega)$.

18.3.1.3 Bulk medium Green tensor projected on particular orientations

The Green tensor can be used to relate two dipoles $\hat{\mathbf{e}}_d$ and $\hat{\mathbf{e}}'_d$ respectively located at $\mathbf{r}$ and $\mathbf{r}'$. Using the identity,

$$R^2\hat{\mathbf{e}}'^*_d(\hat{\mathbf{e}}_R\otimes\hat{\mathbf{e}}_R)\hat{\mathbf{e}}_d=\begin{pmatrix}d'_x & d'_y & d'_z\end{pmatrix}\begin{pmatrix}x^2 & xy & xz\\ xy & y^2 & yz\\ xz & yz & z^2\end{pmatrix}\begin{pmatrix}d_x\\ d_y\\ d_z\end{pmatrix}=(\hat{\mathbf{e}}'_d\cdot\hat{\mathbf{e}}_R)(\hat{\mathbf{e}}_d\cdot\hat{\mathbf{e}}_R)\ , \tag{18.212}$$

we calculate from (18.207),

$$\begin{aligned}&\tfrac{4\pi}{k}\hat{\mathbf{e}}'^*_d\ \mathfrak{Re}\ \mathcal{G}_b(\mathbf{r},\mathbf{r}',\omega)\ \hat{\mathbf{e}}_d \qquad (18.213)\\ &=[\hat{\mathbf{e}}'_d\cdot\hat{\mathbf{e}}_d-(\hat{\mathbf{e}}'_d\cdot\hat{\mathbf{e}}_R)(\hat{\mathbf{e}}_R\cdot\hat{\mathbf{e}}_d)]\frac{\cos kR}{kR}-[\hat{\mathbf{e}}'_d\cdot\hat{\mathbf{e}}_d-3(\hat{\mathbf{e}}'_d\cdot\hat{\mathbf{e}}_R)(\hat{\mathbf{e}}_R\cdot\hat{\mathbf{e}}_d)]\left(\frac{\sin kR}{k^2R^2}-\frac{\cos kR}{k^3R^3}\right)\\ &\tfrac{4\pi}{k}\hat{\mathbf{e}}'^*_d\ \mathfrak{Im}\ \mathcal{G}_b(\mathbf{r},\mathbf{r}',\omega)\ \hat{\mathbf{e}}_d\\ &=[\hat{\mathbf{e}}'_d\cdot\hat{\mathbf{e}}_d-(\hat{\mathbf{e}}'_d\cdot\hat{\mathbf{e}}_R)(\hat{\mathbf{e}}_R\cdot\hat{\mathbf{e}}_d)]\frac{\sin kR}{kR}+[\hat{\mathbf{e}}'_d\cdot\hat{\mathbf{e}}_d-3(\hat{\mathbf{e}}'_d\cdot\hat{\mathbf{e}}_R)(\hat{\mathbf{e}}_R\cdot\hat{\mathbf{e}}_d)]\left(\frac{\cos kR}{k^2R^2}-\frac{\sin kR}{k^3R^3}\right)\ .\end{aligned}$$

Note that dipole moment is complex in the case of circular polarization. The formula (18.213) simplifies when the dipoles are parallel,

$$\begin{aligned}&\tfrac{4\pi}{k}\hat{\mathbf{e}}^*_d\ \mathfrak{Re}\ \mathcal{G}_b(\mathbf{r},\mathbf{r}',\omega)\ \hat{\mathbf{e}}_d=[1-(\hat{\mathbf{e}}_d\cdot\hat{\mathbf{e}}_R)^2]\frac{\cos kR}{kR}-[1-3(\hat{\mathbf{e}}_d\cdot\hat{\mathbf{e}}_R)^2]\left(\frac{\sin kR}{k^2R^2}+\frac{\cos kR}{k^3R^3}\right)\\ &\tfrac{4\pi}{k}\hat{\mathbf{e}}^*_d\ \mathfrak{Im}\ \mathcal{G}_b(\mathbf{r},\mathbf{r}',\omega)\ \hat{\mathbf{e}}_d=[1-(\hat{\mathbf{e}}_d\cdot\hat{\mathbf{e}}_R)^2]\frac{\sin kR}{kR}+[1-3(\hat{\mathbf{e}}_d\cdot\hat{\mathbf{e}}_R)^2]\left(\frac{\cos kR}{k^2R^2}-\frac{\sin kR}{k^3R^3}\right)\ .\end{aligned} \tag{18.214}$$

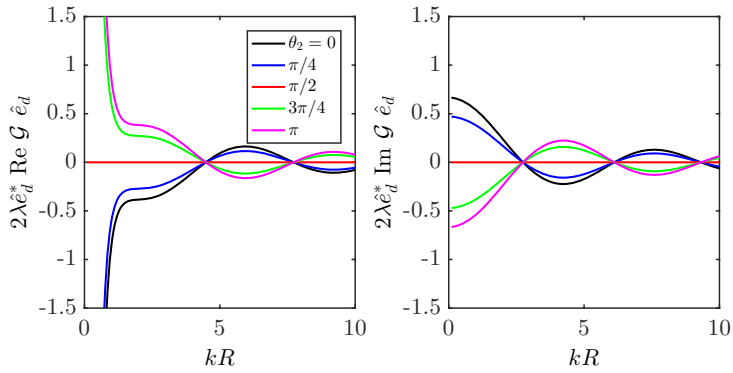

Figure 18.20: (code) Real and imaginary part of the bulk Green tensor for various orientations of the dipoles: $\hat{\mathbf{e}}_d'^* = \hat{\mathbf{e}}_x$ and $\hat{\mathbf{e}}_d$ as indicated in the legend.

18.3.1.4 Dispersion relation in anisotropic media

A homogeneous medium can still be anisotropic if,

$$\epsilon(\mathbf{r},\omega) = \epsilon(\omega) \qquad \text{although} \qquad \epsilon(\omega)\cdot\hat{\mathbf{e}}_r \neq const\ . \tag{18.215}$$

Then, $\epsilon(\omega)$ and $\mu(\omega)$ still need to be represented by tensors, which however do not depend on coordinates. The Helmholtz equation then simplifies to,

$$\left[\nabla_{\mathbf{r}} \times \nabla_{\mathbf{r}} \times -\frac{\omega^2}{c^2}\mu(\omega)\epsilon(\omega)\right] \vec{\mathcal{E}}_b(\mathbf{r},\omega) = \imath\omega\mu_0 \mathbf{j}(\mathbf{r},\omega)\ , \tag{18.216}$$

in analogy to (18.198). Assuming no currents, $\mathbf{j}(\mathbf{r},\omega) = 0$, and plane electromagnetic waves, $\vec{\mathcal{E}}_b(\mathbf{r},\omega) = \vec{\mathcal{E}}_0(\omega) e^{\imath\mathbf{k}\cdot(\mathbf{r}-\mathbf{r}')}$, we obtain with the identity (18.201),

$$\begin{aligned} 0 &= \left[\nabla_{\mathbf{r}} \otimes \nabla_{\mathbf{r}} - \mathbb{I}\triangle - \frac{\omega^2}{c^2}\mu\epsilon\right] \vec{\mathcal{E}}_0 e^{\imath\mathbf{k}\cdot(\mathbf{r}-\mathbf{r}')} \\ &= \left[-\mathbf{k}\otimes\mathbf{k} + k^2 - \frac{\omega^2}{c^2}\mu\epsilon\right] \vec{\mathcal{E}}_0 e^{\imath\mathbf{k}\cdot(\mathbf{r}-\mathbf{r}')}\ , \end{aligned} \tag{18.217}$$

where $\mu\epsilon$ is to be understood as a product between two matrices. From this we derive the dispersion relation,

$$0 = \left| -k_i k_j + k^2\delta_{ij} - \frac{\omega^2}{c^2}(\mu)_{il}(\epsilon)_{lj} \right|\ , \tag{18.218}$$

for $i,j = x,y,z$.

We will discuss anisotropic homogeneous media in the context of hyperbolic metamaterials in Sec. 18.3.3.

18.3.1.5 Interaction between dipoles near dielectric media

The vector Green tensor describes the interaction between two points in space via an electromagnetic field. It can be used to solve a variety of problems, for example,

- the interaction between dipoles in free space;
- the modification of a dipole due to the presence of a dielectric boundary (Purcell effect);
- the modification of the interaction between dipoles due to the presence of a dielectric boundary.

The linearity of Maxwell's equations allows us to exploit the superposition principle applying it to the Green tensor. For example, we can express the interaction between two point dipoles $\mathbf{r}_1$ and $\mathbf{r}_2$ near a dielectric boundary by simply adding to the bulk tensor for their interaction in free space $\mathcal{G}_b(\mathbf{r}_1, \mathbf{r}_2, \omega)$ a tensor $\mathcal{G}_d(\mathbf{r}_1, \mathbf{r}_2, \omega)$ accounting for the presence of the dielectric,

$$\boxed{\mathcal{G} = \mathcal{G}_b + \mathcal{G}_d} \,. \tag{18.219}$$

18.3.2 Plasmons at metal-dielectric interfaces

A *surface plasmon polariton* (SPP) or simply *plasmon* is an electromagnetic wave in the infrared or visible spectral regime, which propagates along a metal-dielectric or metal-air interface. The term SPP explains that the wave involves both, the motion of charges in the metal and electromagnetic waves in the air or the dielectric.

SPPs are a type surface waves, guided along the interface in a similar way as light can be guided by an optical fiber. The wavelengths of SPPs are shorter than that of the incident light, which created them. Thus, they can be more localized and more intense. Perpendicularly to the interface, they are confined to the scale of a wavelength. The propagation of SPPs along the interface is limited by absorption losses in the metal or by photon scattering into other directions, e.g. into free space.

SPPs can be excited by electronic or photonic bombardment. For a photon to excite an SPP, both must have the same frequency and the same momentum. However, at a given frequency, a free space photon has less momentum than an SPP because the two have different dispersion relations (see below). Therefore, a photon coming from free space can not directly couple to an SPP. For the same reason, an SPP (on a perfectly smooth metal surface) can not emit photons into free space (assumed uniform). This incompatibility is analogous to the absence of transmission at total internal reflection.

However, the coupling of photons to SPPs can be achieved using a coupling medium, such as a dielectric or a grating, designed to match the wavevectors of photons and SPPs, until their momenta coincide. For example, a glass prism may be positioned against a thin metal film in Kretschmann configuration, as shown in Fig. 18.21(a). Single insulated surface defects, such as isolated or periodic grooves, slits or elevations, provide a mechanism coupling free space radiation and SPPs, which then can exchange energy.

18.3.2.1 Fields and plasmonic dispersion relation

The properties of a SPP can be derived from Maxwell's equations. Let $z > 0$ be the space occupied by the dielectric and $z < 0$ the space occupied by the metal. The electric and magnetic fields must obey Maxwell's equations and, in particular, the

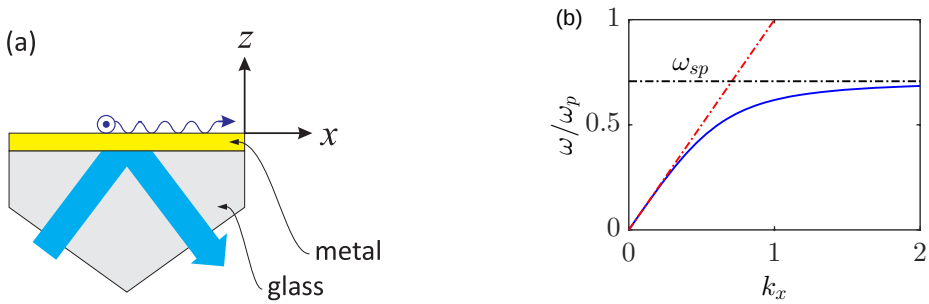

Figure 18.21: (code) (a) Kretschmann configuration of attenuated total reflection for the coupling of surface plasmons. The component of the scattered wavevector parallel to the surface forms SPPs, which then propagate along the metal-dielectric interface. (b) Dispersion curve for a SPP (blue). At low k_x it approaches the photonic dispersion curve (red).

boundary conditions (18.42)(i-iv) at the interface. We will show in Exc. 18.3.7.2, that the fields must have the following form:

$$\vec{\mathcal{H}}_n(\mathbf{r},t) = \begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix} \mathcal{H}_0 e^{\imath k_x x + \imath k_{z,n}|z| - \imath\omega t} \quad , \quad \vec{\mathcal{E}}_n(\mathbf{r},t) = \begin{pmatrix} \pm k_{z,n} \\ 0 \\ -k_x \end{pmatrix} \frac{\mathcal{H}_0}{\omega\varepsilon_n} e^{\imath k_x x + \imath k_{z,n}|z| - \imath\omega t} \,, \tag{18.220}$$

under the condition that,

$$\frac{k_{z,\mathrm{m}}}{\varepsilon_\mathrm{m}} = -\frac{k_{z,\mathrm{d}}}{\varepsilon_\mathrm{d}} \,, \tag{18.221}$$

where n indicates the material ($n = \mathrm{m}$ for the metal and $n = \mathrm{d}$ for the dielectric). This condition guarantees the continuity of the electric field parallel to the boundary. Upper signs apply to the dielectric region ($z > 0$) and lower signs to the metallic region ($z < 0$). That is, SPPs are always transverse magnetic waves (TM). The wavevector $\mathbf{k}$ is complex. In case of a lossless SPP, the k_x component is real and the k_z component imaginary,

$$k_{z,m} = \imath\kappa_{z,\mathrm{m}} \,, \tag{18.222}$$

such that the wave propagates along the x-direction and decays exponentially toward $\pm z$. While k_x is always the same in both materials, $k_{z,\mathrm{m}}$ is generally different from $k_{z,\mathrm{d}}$. Entering the fields (18.220) in the wave equation,

$$\nabla^2\vec{\mathcal{H}}_n = \varepsilon_n\mu_n\frac{\partial^2\vec{\mathcal{H}}_n}{\partial t^2} \,, \tag{18.223}$$

we easily verify that,

$$k_x^2 + k_{z,n}^2 = \omega^2\varepsilon_n\mu_n = \epsilon_n\left(\frac{\omega}{c}\right)^2 \,, \tag{18.224}$$

where we assume $\mu_n = \mu_0$ and $\varepsilon_n = \varepsilon_0\epsilon_n$, where the 'breve' denotes relative permittivities. Solving the two equations (18.224) for $n = \mathrm{m}, \mathrm{d}$ together with the relationship

(18.221), we obtain the dispersion relation for a plasmon wave propagating on the surface,

$$\boxed{k_x = \frac{\omega}{c}\sqrt{\frac{\epsilon_\mathrm{d}\epsilon_\mathrm{m}}{\epsilon_\mathrm{d}+\epsilon_\mathrm{m}}}} \,. \tag{18.225}$$

To apply this relation in practice, we must specify the two permittivities ϵ_n. For simplicity, we assume $\epsilon_\mathrm{d} = 1$, and for ϵ_m we resort to the *Drude model* using (18.161), where for now we despise the attenuation $\Gamma_d = 0$,

$$\epsilon_m(\omega) = 1 - \frac{\omega_p^2}{\omega^2} \,, \tag{18.226}$$

where ω_p is the plasma frequency (18.162). Joining the expressions (18.225) and (18.226) we obtain,

$$ck_x = \sqrt{\frac{\omega^2-\omega_p^2}{2\omega^2-\omega_p^2}} \,. \tag{18.227}$$

This relationship is plotted in Fig. 18.21(b).

At low k_x, the SPP behaves like a photon, but as k_x increases, the dispersion relation becomes flatter and reaches an asymptotic limit ω_{sp} called 'surface plasma frequency'. If $\omega < \omega_{sp}$, the SPP has a shorter wavelength than the radiation in the free space, such that the components $k_{z,\mathrm{m}}$ are purely imaginary and exhibit evanescent decay. The plasma frequency at the surface ($\epsilon_\mathrm{d} = 1$) is,

$$\omega_{sp} = \lim_{k_x\to\infty} \omega = \frac{\omega_p}{\sqrt{2}} \,. \tag{18.228}$$

18.3.2.2 Absorption of plasmons

The formula (18.226) predicts $\varepsilon_\mathrm{m} < 0$ below the plasmon frequency. Electromagnetic waves propagating in metals suffer damping due to ohmic losses and interactions between the electrons and the atoms of the metallic lattice. These effects appear as an imaginary component of the dielectric function. To take this into account, we express the dielectric function of a metal in the complex plane,

$$\epsilon_\mathrm{m} = \epsilon'_\mathrm{m} + \imath\epsilon''_\mathrm{m} \,. \tag{18.229}$$

Generally, we have, $|\epsilon'_\mathrm{m}| \gg \epsilon''_\mathrm{m}$, such that the wavevector can be expressed in terms of its real and imaginary components as (see Exc. 18.3.7.3),

$$k_x = k'_x + \imath k''_x = \frac{\omega}{c}\sqrt{\frac{\epsilon_d\epsilon'_\mathrm{m}}{\epsilon_\mathrm{d}+\epsilon'_\mathrm{m}}} + \imath\frac{\omega}{c}\sqrt{\frac{\epsilon_d\epsilon'_\mathrm{m}}{\epsilon_\mathrm{d}+\epsilon'_\mathrm{m}}}^3 \frac{\epsilon''_\mathrm{m}}{2(\epsilon'_\mathrm{m})^2} \,. \tag{18.230}$$

The wavevector gives us insight into the physically significant properties of the electromagnetic wave, such as its spatial extent and mode matching conditions.

18.3.2.3 Distance of propagation and depth of penetration

As an SPP propagates along the surface, it loses energy to the metal due to absorption. The intensity of the surface plasmon decays with the square of the electric field, therefore, over a distance x, the intensity decreases by a factor of $e^{-2k_x x}$. The propagation length is defined as the distance, where the SPP intensity has decreased by a factor of $1/e$. This condition is satisfied at a length $L = \frac{1}{2k''_x}$.

Likewise, the electric field decays perpendicular to the surface of the metal. At low frequencies, the penetration depth of the SPP into the metal is commonly approximated using the skin depth formula. In a dielectric, the field will decay much more slowly. The decay depth in the metal and the dielectric medium can be expressed as

$$z_n = \frac{\lambda}{2\pi}\left(\frac{|\epsilon'_{\rm m}| + \epsilon_{\rm d}}{\epsilon_n^2}\right)^{1/2} , \tag{18.231}$$

where n indicates the propagation medium. SPPs are very sensitive to small perturbations within the skin depth and, therefore, are often used to probe surface inhomogeneities. Resolve the Exc. 18.3.7.4.

18.3.3 Negative refraction and metamaterials

The general dispersion relation for anisotropic media has been derived in (18.218),

$$\boxed{\left|\tfrac{\omega^2}{c^2}\epsilon_{il}\mu_{lj} - k^2\delta_{ij} + k_i k_j\right| = 0} , \tag{18.232}$$

which, for isotropic media simplifies to $\frac{\omega^2}{c^2}n^2 = k^2$, where $n^2 = \epsilon\mu$. Apparently, inverting the signs of both, the permittivity and the permeability, $\varepsilon, \mu < 0$ has no effect on the equations. However, one can show [1335], that inserting into the first and second Maxwell equations,

$$\begin{aligned} \nabla\times\vec{\mathcal{H}} = \partial_t\vec{\mathcal{D}} \quad &, \quad \nabla\times\vec{\mathcal{E}} = -\partial_t\vec{\mathcal{B}} \\ \text{with} \quad \vec{\mathcal{D}} = \varepsilon\vec{\mathcal{E}} \quad &, \quad \vec{\mathcal{B}} = \mu\vec{\mathcal{H}} \end{aligned} \tag{18.233}$$

a plane wave, $\vec{\mathcal{E}}, \vec{\mathcal{D}}, \vec{\mathcal{B}}, \vec{\mathcal{H}} \propto e^{\imath(\mathbf{k}\cdot\mathbf{r}-\omega t)}$,

$$\mathbf{k}\times\vec{\mathcal{H}}_0 = -\omega\varepsilon\vec{\mathcal{E}}_0 \quad , \quad \mathbf{k}\times\vec{\mathcal{E}}_0 = \omega\mu\vec{\mathcal{H}}_0 , \tag{18.234}$$

one obtains for $\varepsilon, \mu > 0$, a right-handed triplet of vectors $\mathbf{k}$, $\vec{\mathcal{E}}$, $\vec{\mathcal{H}}$, whereas for $\varepsilon, \mu < 0$ one obtains a left-handed triplet. Defining the handedness via,

$$p \equiv \frac{(\mathbf{k}\times\vec{\mathcal{E}})\cdot\vec{\mathcal{H}}}{|(\mathbf{k}\times\vec{\mathcal{E}})\cdot\vec{\mathcal{H}}|} , \tag{18.235}$$

if $p = \pm 1$, we call the material is right(left)-handed. The energy flux,

$$\vec{\mathcal{S}} = \vec{\mathcal{E}}\times\vec{\mathcal{H}} \tag{18.236}$$

is parallel to $\mathbf{k}$ for right-handed materials and anti-parallel for left-handed, which means that phase and group velocities are reversed. Also, in left-handed materials we expect a reversed Doppler effect.

At the interface between two materials with different handednesses, $\varepsilon_1, \mu_1 > 0$ and $\varepsilon_2, \mu_2 < 0$, the equations (18.42) must still hold,

$$\begin{array}{ll} \text{(i)} & \vec{\mathcal{H}}_1^{\parallel} = \vec{\mathcal{H}}_2^{\parallel} \\ \text{(ii)} & \vec{\mathcal{E}}_1^{\parallel} = \vec{\mathcal{E}}_2^{\parallel} \\ \text{(iii)} & \varepsilon_1 \vec{\mathcal{E}}_1^{\perp} = \varepsilon_2 \vec{\mathcal{E}}_2^{\perp} \\ \text{(iv)} & \mu_1 \vec{\mathcal{H}}_1^{\perp} = \mu_2 \vec{\mathcal{H}}_2^{\perp} \end{array} \quad . \tag{18.237}$$

but now, the signs of $\mathcal{E}_2^{\perp}$ and $\mathcal{H}_2^{\perp}$ are inverted. We calculate,

$$\vec{\mathcal{E}}_0 \times \vec{\mathcal{H}}_0 = \frac{1}{\omega\mu} \vec{\mathcal{E}}_0 \times (\mathbf{k} \times \vec{\mathcal{E}}_0) = \frac{1}{\omega\mu} [\mathbf{k}(\vec{\mathcal{E}}_0 \cdot \vec{\mathcal{E}}_0) - \vec{\mathcal{E}}_0(\mathbf{k} \cdot \vec{\mathcal{E}}_0)] = \frac{\mathcal{E}_0^2}{\omega\mu} \mathbf{k} \uparrow\uparrow -\vec{\mathcal{S}} \; . \tag{18.238}$$

As a consequence Snell's law (18.57) must be corrected,

$$\frac{\sin\theta_t}{\sin\theta_i} = \frac{n_1}{n_2} = \frac{p_2}{p_1} \left| \sqrt{\frac{\varepsilon_2 \mu_2}{\varepsilon_1 \mu_1}} \right| \; . \tag{18.239}$$

The *complex refractive index*,

$$n = n' + \imath n'' = c\sqrt{\varepsilon\mu} = c\sqrt{(\varepsilon' + \imath\varepsilon'')(\mu' + \imath\mu'')} = c\sqrt{|\varepsilon\mu|} e^{\imath\phi/2} \tag{18.240}$$

can have negative real part, $\mathfrak{Re}\; n < 0$, if the angle is $\phi > \pi$, that is, if,

$$\sin\phi = \frac{\mathfrak{Im}\; \varepsilon\mu}{|\varepsilon\mu|} = \frac{\varepsilon''\mu' + \varepsilon'\mu''}{|\varepsilon\mu|} < 0 \; . \tag{18.241}$$

Since the absorption is necessarily $\varepsilon'', \mu'' > 0$, the condition (18.241) is satisfied if $\varepsilon', \mu' < 0$. More generally, a sufficient but not necessary condition for *negative refraction* is,

$$\varepsilon'|\mu' + \imath\mu''| + \mu'|\varepsilon' + \imath\varepsilon''| < 0 \; . \tag{18.242}$$

The direction of the phase velocity is $\mathbf{k}$, while the energy flows along $\vec{\mathcal{S}} = \vec{\mathcal{E}} \times \vec{\mathcal{H}}$. For $n' > 0$ the dispersive medium is called *right-handed*, because $\mathbf{k}$, $\vec{\mathcal{E}}$ and $\vec{\mathcal{H}}$ form a tripod. For $n' < 0$ the medium is called *left-handed*, because $-\mathbf{k}$, $\vec{\mathcal{E}}$ and $\vec{\mathcal{H}}$ form a tripod, that is, $\mathbf{k}$ and $\vec{\mathcal{S}}$ are contrary. We will check this in Exc. 18.3.7.5. Such media are always very dispersive.

Left-handed media have attracted much attention, because of the theoretical possibility of performing *perfect lenses* with a focusing power not being limited by diffraction. Left-handed media are studied in non-homogeneous and non-isotropic *metamaterials* [25], but there are also ideas on how to design them in homogeneous and isotropic atomic gases [26]

[25] See [1010, 1011, 1193, 824, 825, 827, 826, 1013, 62, 1291, 252, 211, 820, 1187, 790].
[26] See Sec. 34.7 and Excs. 34.8.4.11 and 34.8.4.12 .

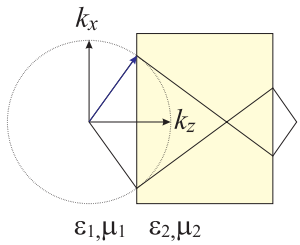

Figure 18.22: Refraction at the interface between 'right-handed' and 'left-handed' media.

18.3.3.1 Hyperbolic metamaterials

Hyperbolic metamaterials (HMM) are artificial media with sub-optical-wavelength nano-structuring, which exhibit unusual optical properties. In particular, they are characterized by extreme anisotropy, behaving like dielectrics when illuminated from one side and like metals when illuminated from another. As already mentioned in Sec. 18.3.1, in a hyperbolic metamaterial the dispersion relation is anisotropic, corresponding to permittivity and permeability tensors of the form,

$$\varepsilon = \begin{pmatrix} \varepsilon_\perp & & \\ & \varepsilon_\perp & \\ & & \varepsilon_{\shortparallel} \end{pmatrix} \quad \text{and} \quad \mu = \begin{pmatrix} \mu_\perp & & \\ & \mu_\perp & \\ & & \mu_{\shortparallel} \end{pmatrix} . \tag{18.243}$$

In the case $\varepsilon_\perp \varepsilon_{\shortparallel} < 0$ or $\mu_\perp \mu_{\shortparallel} < 0$ the dispersion relation,

$$\frac{k_x^2 + k_y^2}{\varepsilon_{\shortparallel}} + \frac{k_z^2}{\varepsilon_\perp} = \frac{(\omega/c)^2}{\varepsilon_0} , \tag{18.244}$$

becomes hyperbolic [27]. In Exc. 18.3.7.7 we derive from the Maxwell equations, allowing for an anisotropic (but homogeneous) permittivity tensor, the hyperbolic dispersion relation.

> **Example 109 (*Interest of hyperbolic metamaterials*):** Hyperbolic metamaterials are investigated for their potential interest in engineering the decay routes of quantum emitters by manipulating the local density-of-states. The reason is, that HMMs allow for the propagation of modes with wavevectors (known as high-k modes) much higher than the free-space wavevector. Thus, the evanescent waves (also with high-k) of an emitter couple more easily to a sufficiently close HMM, and thus emitting their photons faster.
> The elementary cells of a metamaterial are often complicated, and a stratification is helpful to describe its response to incident light. For example, many features of an HMM can be grasped by frequency-dependent effective permittivity and permeability tensors.

[27] Note that a more correct treatment would need to account for the polarizations of the electric and magnetic fields. We leave this to an upcoming version of the script.

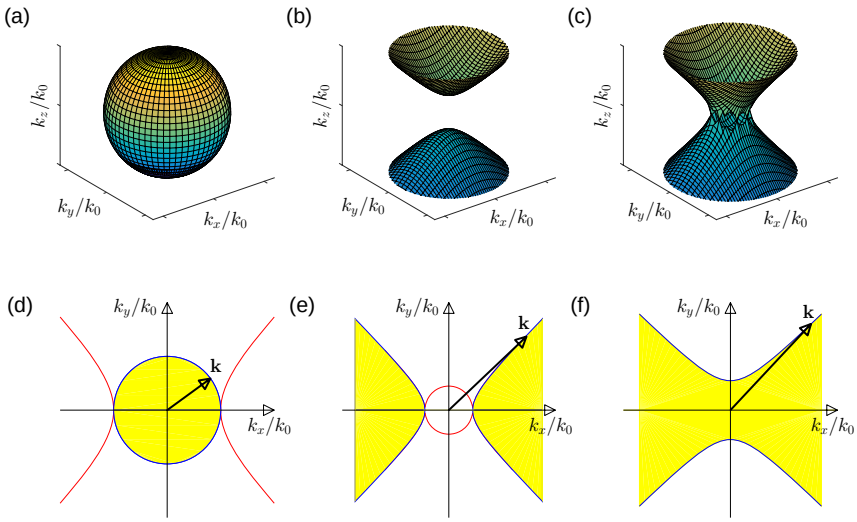

Figure 18.23: Isofrequency surfaces of hyperbolic dispersion relations. (a) Isotropic dielectric ($\varepsilon_\perp = \varepsilon_{\shortparallel}$); (b) two-sheeted hyperboloid ($\varepsilon_\perp < 0$ and $\varepsilon_{\shortparallel} > 0$); (c) one-sheeted hyperboloid ($\varepsilon_\perp > 0$ and $\varepsilon_{\shortparallel} < 0$). (d-f) Projection of the two-dimensional isofrequency surfaces shown in (a-c) on the $k_y = 0$ plane. The yellow-shaded areas correspond to lossy regions (real parts).

In Exc. 18.3.7.8 we show, that the effective permittivity of a nanostructure having the shape of a stack of alternating intrinsically homogeneous layers with permittivities ε_d and ε_m and thicknesses $d_\mathrm{d}, d_\mathrm{m} \ll \lambda$ [see Fig. 18.24(b)] is given by [1123],

$$\varepsilon_{\shortparallel} = \frac{\varepsilon_\mathrm{d} d_\mathrm{d} + \varepsilon_\mathrm{m} d_\mathrm{m}}{d_\mathrm{d} + d_\mathrm{m}} \qquad \text{and} \qquad \frac{1}{\varepsilon_\perp} = \frac{d_\mathrm{d}/\varepsilon_\mathrm{d} + d_\mathrm{m}/\varepsilon_\mathrm{m}}{d_\mathrm{d} + d_\mathrm{m}} \ . \tag{18.245}$$

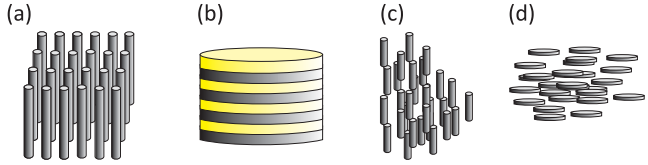

Figure 18.24: Hyperbolic dispersion materials. In order to achieve a negative permittivity in a given direction, the electrons must move freely along it, like in a metal.

Example 110 (*Anisotropy of a metamaterial*): For example, choosing $d_\mathrm{m} = d_\mathrm{d}$, $\varepsilon_\mathrm{d} = 1$ and $\varepsilon_\mathrm{m} = -2$, we obtain $\varepsilon_{\shortparallel} = \frac{1}{4}$ and $\varepsilon_\perp = -\frac{1}{2}$.

In Exc. 18.3.7.9 we discuss, whether it is possible to realize a hyperbolic dispersion relation in an atomic gas.

18.3.4 Wave guides

The presence of conductive interfaces influences the propagation of electromagnetic waves. Interfaces, which influence the propagation direction of electromagnetic waves are called *waveguides*. Let us consider a waveguide such as the one illustrated in Figs. 18.25. In the volume enclosed by the waveguide, supposedly perfectly conductive ($\vec{\mathcal{E}} = 0 = \vec{\mathcal{B}}$ inside the wave guide material), every electromagnetic field must satisfy the boundary conditions (18.42), that is, we have,

$$\boxed{\vec{\mathcal{E}}^{\parallel} = 0 \qquad \text{and} \qquad \vec{\mathcal{B}}^{\perp} = 0} \tag{18.246}$$

on all interior surfaces of the waveguide. Free surface charges and currents will automatically be generated in such a way as to endorse these conditions, and all conclusions derived in the following sections are basically corollaries of these boundary conditions.

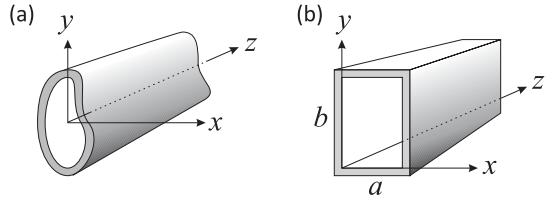

Figure 18.25: Waveguides of arbitrarily (i) and rectangular (ii) shape.

Let us now consider monochromatic waves propagating along a tube oriented in z-direction,

$$\vec{\mathcal{E}}(x,y,z,t) = \vec{\mathcal{E}}(x,y)e^{\imath(k_z z-\omega t)} \qquad \text{and} \qquad \vec{\mathcal{B}}(x,y,z,t) = \vec{\mathcal{B}}(x,y)e^{\imath(k_z z-\omega t)} \,. \tag{18.247}$$

Obviously, the $\vec{\mathcal{E}}$ and $\vec{\mathcal{B}}$ fields must simultaneously satisfy the vacuum Maxwell equations (17.6) inside the guide and the boundary conditions (18.246). To implement these conditions, we reformulate Maxwell's equations. We insert (18.247) and the expansions $\vec{\mathcal{E}}(x,y) = \sum_{k=x,y,z} \mathcal{E}_k(x,y)\hat{\mathbf{e}}_k$ and $\vec{\mathcal{B}}(x,y) = \sum_{k=x,y,z} \mathcal{B}_k(x,y)\hat{\mathbf{e}}_k$ in the Maxwell equations (17.6)(i) and (ii) and obtain,

$$\begin{aligned}
&\text{(i)} \quad \partial_y\mathcal{E}_z - \imath k_z\mathcal{E}_y = \imath\omega\mathcal{B}_x && \text{(ii)} \quad \partial_y\mathcal{B}_z - \imath k_z\mathcal{B}_y = -\imath\tfrac{\omega}{c^2}\mathcal{E}_x \\
&\text{(iii)} \quad \imath k_z\mathcal{E}_x - \partial_x\mathcal{E}_z = \imath\omega\mathcal{B}_y && \text{(iv)} \quad \imath k_z\mathcal{B}_x - \partial_x\mathcal{B}_z = -\imath\tfrac{\omega}{c^2}\mathcal{E}_y \\
&\text{(v)} \quad \partial_x\mathcal{E}_y - \partial_y\mathcal{E}_x = \imath\omega\mathcal{B}_z && \text{(vi)} \quad \partial_x\mathcal{B}_y - \partial_y\mathcal{B}_x = -\imath\tfrac{\omega}{c^2}\mathcal{E}_z \,.
\end{aligned} \tag{18.248}$$

Inserting the component $\mathcal{B}_y$ of the third into the second equation, the $\mathcal{B}_x$ of the first into the fourth equation, the $\mathcal{E}_y$ of the fourth into the first equation, and the $\mathcal{E}_x$ of the second in the third equation, we arrive at,

$$\begin{aligned}
&\text{(i)} \quad \mathcal{E}_x = \tfrac{\imath}{(\omega/c)^2-k_z^2}(k_z\partial_x\mathcal{E}_z + \omega\partial_y\mathcal{B}_z) \\
&\text{(ii)} \quad \mathcal{E}_y = \tfrac{\imath}{(\omega/c)^2-k_z^2}(k_z\partial_y\mathcal{E}_z - \omega\partial_x\mathcal{B}_z) \\
&\text{(iii)} \quad \mathcal{B}_x = \tfrac{\imath}{(\omega/c)^2-k_z^2}(k_z\partial_x\mathcal{B}_z - \tfrac{\omega}{c^2}\partial_y\mathcal{E}_z) \\
&\text{(iv)} \quad \mathcal{B}_y = \tfrac{\imath}{(\omega/c)^2-k_z^2}(k_z\partial_y\mathcal{B}_z + \tfrac{\omega}{c^2}\partial_x\mathcal{E}_z) \,.
\end{aligned} \tag{18.249}$$

And inserting these equations into Maxwell's equations (iii) and (iv), we arrive at,

$$\left[\frac{\partial^2}{\partial x^2}+\frac{\partial^2}{\partial y^2}+(\omega/c)^2-k_z^2\right]\mathcal{E}_z=0=\left[\frac{\partial^2}{\partial x^2}+\frac{\partial^2}{\partial y^2}+(\omega/c)^2-k_z^2\right]\mathcal{B}_z\ . \tag{18.250}$$

Hence, we can solve the waveguide problem by first solving the wave equations for the components $\mathcal{E}_z$ and $\mathcal{B}_z$ and then inserting the solutions into Eqs. (18.249) in order to obtain the other field components.

When $\mathcal{E}_z = 0$ we call these waves *transverse electric waves* (TE), when $\mathcal{B}_z = 0$ we call them *transverse magnetic waves* (TM), and when $\mathcal{E}_z = 0 = \mathcal{B}_z$ we call them *transverse electro-magnetic waves* (TEM). TEM waves can not exist in a hollow waveguide, as we will show in Exc. 18.3.7.10.

18.3.4.1 Waveguide with constant rectangular cross section

Here, we consider the transmission of TE waves through a waveguide of constant rectangular cross-section, as shown in Fig. 18.25(ii). Similarly to the procedure for solving the Laplace equation in electrostatics, we make a separation ansatz for the variables in a way suggested by the symmetry of the problem, that is, we assume the existence of two functions X and Y, such that inserting the ansatz

$$\mathcal{E}_z=0 \qquad \text{and} \qquad \mathcal{B}_z=X(x)Y(y)\ , \tag{18.251}$$

in the wave equation,

$$Y\frac{d^2X}{dx^2}+X\frac{d^2Y}{dy^2}+[(\omega/c)^2-k_z^2]=0\ , \tag{18.252}$$

leaves us with,

$$\frac{1}{X}\frac{d^2X}{dx^2}=-k_x^2 \quad \text{and} \quad \frac{1}{Y}\frac{d^2Y}{dy^2}=-k_y^2 \quad \text{with} \quad -k_x^2-k_y^2+(\omega/c)^2-k_z^2=0\ . \tag{18.253}$$

$\mathcal{B}_x$ must vanish on the surfaces at $x = 0, a$ and, because of (18.249)(iii) $\partial_x\mathcal{B}_z$ as well, such that $dX/dx = 0$, that is, X is a cosine. In the same way, $\mathcal{B}_y$ must vanish on the surfaces at $y = 0, b$, such that Y is a cosine. Therefore, the solution is,

$$\mathcal{B}_z=\mathcal{B}_0\cos k_x x\cos k_y y \qquad \text{with} \qquad k_x=\tfrac{m\pi}{a} \qquad \text{and} \qquad k_y=\tfrac{n\pi}{b}\ . \tag{18.254}$$

With this, the wavevector becomes,

$$k_z=\sqrt{(\omega/c)^2-\pi^2[(m/a)^2+(n/b)^2]}\ . \tag{18.255}$$

Consequently, the frequency must be higher than,

$$\omega>c\pi\sqrt{(m/a)^2+(n/b)^2}\equiv\omega_{mn}\ , \tag{18.256}$$

to avoid exponentially attenuated fields. The frequency ω_{mn} is called *cut-off frequency*. The components $\mathcal{B}_x$ and $\mathcal{B}_y$ can be determined from (18.249)(iii) and (iv),

$$\boxed{\begin{aligned}\vec{\mathcal{E}} &= \mathcal{E}_0 \begin{pmatrix} \frac{\imath\omega k_y}{k_x^2+k_y^2}\cos k_x x \sin k_y y \\ \frac{-\imath\omega k_x}{k_x^2+k_y^2}\sin k_x x \cos k_y y \\ 0 \end{pmatrix} e^{\imath(k_z z-\omega t)} \\ \vec{\mathcal{B}} &= \mathcal{B}_0 \begin{pmatrix} \frac{\imath k_z k_x}{k_x^2+k_y^2}\sin k_x x \cos k_y y \\ \frac{\imath k_z k_y}{k_x^2+k_y^2}\cos k_x x \sin k_y y \\ \cos k_x x \cos k_y y \end{pmatrix} e^{\imath(k_z z-\omega t)} \end{aligned}} \quad . \tag{18.257}$$

Inserting ω_{mn} in the dispersion relation (18.255), we notice that the formula for the phase propagation velocity,

$$c = \frac{\omega}{k_z} = \frac{c}{\sqrt{1-(\omega_{mn}/\omega)^2}} > c \ , \tag{18.258}$$

predicts a velocity above the speed of light. However, the group velocity,

$$v_g = \frac{1}{dk_z/d\omega} = c\sqrt{1-(\omega_{mn}/\omega)^2} < c \ , \tag{18.259}$$

is slower. Resolve Exc. 18.3.7.11 and 18.3.7.12 [28].

18.3.5 The coaxial line

We have already mentioned the possibility of TEM waves in a *coaxial waveguide*, as shown in Fig. 18.26. Inserting $\mathcal{E}_z = 0 = \mathcal{B}_z$ in the equations (18.248) we obtain,

$$\begin{aligned} c\mathcal{B}_y = \mathcal{E}_x \qquad & \text{and} \qquad c\mathcal{B}_x = -\mathcal{E}_y \\ \partial_x\mathcal{E}_y - \partial_y\mathcal{E}_x = 0 \quad & = \partial_x\mathcal{B}_y - \partial_y\mathcal{B}_x \\ \partial_x\mathcal{E}_x + \partial_y\mathcal{E}_y = 0 \quad & = \partial_x\mathcal{B}_x + \partial_y\mathcal{B}_y \end{aligned} \ , \tag{18.260}$$

where we join the Maxwell equations (iii) and (iv) in the last line. In Exc. 18.3.7.13 we will show that,

$$\vec{\mathcal{E}}(\rho,\phi,z,t) = \frac{A\cos(k_z z-\omega t)}{\rho}\hat{\mathbf{e}}_\rho \qquad \text{and} \qquad \vec{\mathcal{B}}(\rho,\phi,z,t) = \frac{A\cos(k_z z-\omega t)}{c\rho}\hat{\mathbf{e}}_\phi \ , \tag{18.261}$$

satisfies Maxwell's equations. Solve Exc. 18.3.7.14.

[28] Rectangular waveguides are used, for example, in radio detection and ranging (RADAR) systems to guide microwave signals from a synthesizer to an antenna.

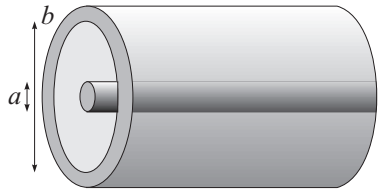

Figure 18.26: Guia de onda coaxial.

18.3.6 Cavities

An *optical resonator* consists of an arrangement of mirrors reflecting light beams in such a way as to form a closed path. Light which entered the cavity carries out many round-trips before it is transmitted again through a (partially reflecting) mirror, scattered out of the cavity mode or absorbed by impurities in the mirrors. Thus, the light power is considerably increased. That is, cavities can store light. Do Exc. 18.3.7.15 to 18.3.7.17.

In order to resonate in a cavity, a light beam must satisfy the boundary condition, that the mirror surfaces coincide with nodes of the standing light wave formed by the beam and its reflections at the mirrors. Therefore, in a cavity of length L, only a discrete spectrum of wavelengths $N\lambda/2 = L$ can be resonantly amplified, where N is a natural number. Because of this property, cavities are often used as frequency filters or optical spectrum analyzers: Only frequencies close to $\nu = N\delta_{fsr}$ are transmitted, where $\delta_{fsr} = c/2L$ is the called the *free spectral range* of the cavity.

A cavity is characterized on one hand by its geometry, that is, the curvature and the distance of its mirrors, and on the other hand by its finesse, which is given by the reflectivity of its mirrors. Let us first study the finesse and postpone the discussion of its geometry to Sec. 18.4.1. Treating the cavity as a multiple path interferometer (or *Fabry-Perot cavity*), we can derive an expression for the reflected and transmitted intensity as a function of frequency,

$$(k + \Delta k)L = \frac{(\omega_c + \Delta)L}{c} = \frac{\omega_c + \Delta}{2\delta_{fsr}} = \pi N + \frac{\Delta}{2\delta_{fsr}} . \tag{18.262}$$

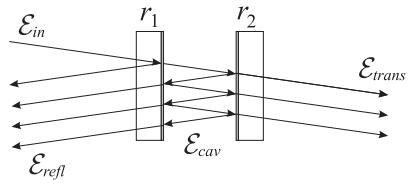

Figure 18.27: Multiple interference in an optical cavity of two mirrors characterized by reflectivities $r_{1,2}$.

The so-called *Airy formulas* for reflection and transmission are,

$$\boxed{\begin{aligned} I_{refl} &= I_{in}\frac{(2F/\pi)^2\sin^2(\Delta/2\delta_{fsr})}{1+(2F/\pi)^2\sin^2(\Delta/2\delta_{fsr})} \\ I_{trns} &= I_{in}\frac{1}{1+(2F/\pi)^2\sin^2(\Delta/2\delta_{fsr})} \end{aligned}}\ , \tag{18.263}$$

where $R=|r|^2$ is the reflectivity of a mirror and Δ the detuning between the laser and the cavity (in radians/s). We will derive the formulas in Exc. 18.3.7.18. The transmission curve of the cavity has a finite bandwidth κ_{int}, which depends on the reflectivity of the mirrors. The *finesse* of the cavity is defined by,

$$F \equiv \frac{2\pi\delta_{fsr}}{\kappa_{int}} = \frac{\pi\sqrt{R}}{1-R}\ . \tag{18.264}$$

Note that δ_{fsr} is given in terms of a real frequency, while κ_{int} is a radiant [29].

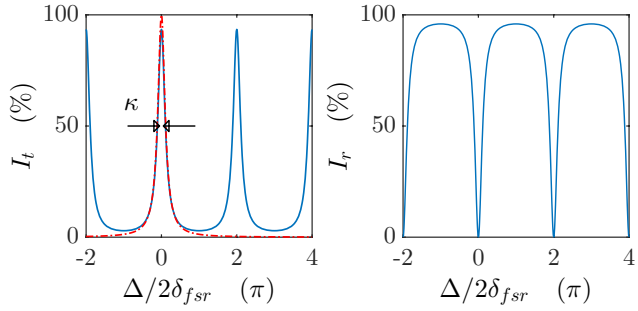

Figure 18.28: (code) Transmission and reflection of a resonator. The chosen mirror reflectivities are $R=70\%$, the absorption losses $S=1\%$. The red dash-dotted line is the Lorentzian approximation. Apparently, it fails off resonance.

The Airy formula was derived under the assumption of plane waves, but this assumption is not always realistic. Indeed, as we will show in Sec. 18.4.1, light propagates in transversely delimited modes and is subject to diffraction. We will see, that the resonance of a cavity not only depends on the order number N of the *longitudinal mode*, but also on the order of the *transverse mode*. The free space modes are TEM-modes.

18.3.6.1 Damping of the cavity

The decay time τ of the cavity is defined by the number of 'round-trips' with reflections at both mirrors R_1 and R_2, that a light beam can do before its intensity falls to e^{-1} of its original value [1407](p.148):

$$I(\tau) = I_0\sqrt{R_1R_2}^{c\tau/2L} \stackrel{!}{=} e^{-1}I_0\ . \tag{18.265}$$

[29] Note, that κ_{int} is defined as the FWHM of the intensity transmission curve.

Letting $R_1 = R_2 = 1 - T$, this yields,

$$\begin{aligned}\tau &= \frac{2L}{c}\frac{\ln e^{-1}}{\ln R_1 R_2} = \frac{1}{\delta_{fsr}}\frac{-1}{\ln(1-T)^2} \simeq \frac{1}{\delta_{fsr}}\frac{1}{2T} \\ &= \frac{1}{2\delta_{fsr}}\frac{1}{1-\sqrt{R_1 R_2}} \simeq \frac{F}{2\pi\delta_{fsr}} = \frac{1}{\kappa_{int}}\ ,\end{aligned} \tag{18.266}$$

approximating $\sqrt{R} \simeq 1$. Hence, κ_{int} has also the meaning of a intensity decay constant [30].

18.3.7 Exercises

18.3.7.1 Ex: Green function for vector Helmholtz equation

Derive the expression (18.206) in Cartesian coordinates.

Solution: *To evaluate,*

$$\left[\mathbb{I} + \tfrac{1}{k^2}\nabla\nabla^{\intercal}\right]\frac{e^{\imath kR}}{4\pi kR}\ ,$$

we first calculate the first and second derivatives in Cartesian coordinates,

$$\begin{aligned}\frac{\partial}{\partial x}\frac{e^{\imath kR}}{4\pi kR} &= (-1+\imath kR)x\frac{e^{\imath kR}}{4\pi kR^3} \\ \frac{\partial}{\partial x}\left((-1+\imath kR)x\frac{e^{\imath kR}}{4\pi kR^3}\right) &= [(-3+\imath kR)x^2 + R^2](-1+\imath kR)\frac{e^{\imath kR}}{4\pi kR^5} \\ \frac{\partial}{\partial y}\left((-1+\imath kR)x\frac{e^{\imath kR}}{4\pi kR^3}\right) &= (-3+\imath kR)xy(-1+\imath kR)\frac{e^{\imath kR}}{4\pi kR^5}\ .\end{aligned}$$

With this,

$$\left[\mathbb{I} + \frac{1}{k^2}\nabla\nabla\right]\frac{e^{\imath kR}}{4\pi kR} = \begin{pmatrix}1&0&0\\0&1&0\\0&0&1\end{pmatrix}\frac{e^{\imath kR}}{4\pi kR} + \begin{pmatrix}\partial_x^2 & \partial_x\partial_y & \partial_x\partial_z \\ \partial_y\partial_x & \partial_y^2 & \partial_y\partial_z \\ \partial_z\partial_x & \partial_z\partial_y & \partial_z^2\end{pmatrix}\frac{(-1+\imath kR)e^{\imath kR}}{4\pi k^3R^5}$$

$$= \frac{e^{\imath kR}\mathbb{I}}{4\pi kR} + \begin{pmatrix}(-3+\imath kR)x^2+R^2 & (-3+\imath kR)xy & (-3+\imath kR)xz \\ (-3+\imath kR)xy & (-3+\imath kR)y^2+R^2 & (-3+\imath kR)yz \\ (-3+\imath kR)xz & (-3+\imath kR)yz & (-3+\imath kR)z^2+R^2\end{pmatrix}\frac{(-1+\imath kR)e^{\imath kR}}{4\pi k^3R^5}$$

$$= -\frac{e^{\imath kR}}{4\pi k^3R^3}\left\{[1-\imath kR-(kR)^2]\mathbb{I} + (3-4\imath kR-(kR)^2)\hat{\mathbf{e}}_R\otimes\hat{\mathbf{e}}_R\right\}\ .$$

See also [210].

[30] It should not be confused with the electric field *amplitude* decay rate defined as $\kappa = \kappa_{int}/2$.

18.3.7.2 Ex: The fields of a plasmon

From the ansatz,

$$\vec{\mathcal{H}}_n(\mathbf{r},t) = \begin{pmatrix} 0 \\ \mathcal{H}_{y,n} \\ 0 \end{pmatrix} e^{\imath k_x x + \imath k_{z,n}|z| - \imath\omega t}$$

for a plasmonic wave, with $n = \mathrm{m}$ in the metallic region ($z < 0$) and $n = \mathrm{d}$ in the dielectric region ($z > 0$), construct the electric and magnetic fields on both sides of a metal-dielectric interface.

Solution: *From Maxwell's first equation we know, $\vec{\mathcal{E}}_n \propto \nabla \times \vec{\mathcal{H}}_n$, such that the fields have the generic form,*

$$\vec{\mathcal{H}}_n(\mathbf{r},t) = \begin{pmatrix} 0 \\ \mathcal{H}_{y,n} \\ 0 \end{pmatrix} e^{\imath k_x x + \imath k_{z,n}|z| - \imath\omega t} \quad , \quad \vec{\mathcal{E}}_n(\mathbf{r},t) = \begin{pmatrix} \mathcal{E}_{x,n} \\ 0 \\ \mathcal{E}_{z,n} \end{pmatrix} e^{\imath k_x x + \imath k_{z,n}|z| - \imath\omega t} \ .$$

In the interface, the fields must meet the conditions (18.98)(i-iv), giving,

$$\mathcal{H}_{y,m} = \mathcal{H}_{y,d} \equiv \mathcal{H}_0 \quad , \quad \mathcal{E}_{x,m} = \mathcal{E}_{x,d} \equiv \mathcal{E}_0 \quad , \quad \varepsilon_m \mathcal{E}_{z,m} = \varepsilon_d \mathcal{E}_{z,d} \ .$$

Inserting $\vec{\mathcal{H}}_n(\mathbf{r},t)$ in Maxwell's first equation,

$$\nabla \times \vec{\mathcal{H}}_n = \begin{pmatrix} -\partial_z \mathcal{H}_0 \\ 0 \\ \partial_x \mathcal{H}_0 \end{pmatrix} = \begin{pmatrix} \mp \imath k_{z,n} \\ 0 \\ \imath k_x \end{pmatrix} \mathcal{H}_0 e^{\imath k_x x + \imath k_{z,n}|z| - \imath\omega t}$$

$$= \varepsilon_n \begin{pmatrix} \mathcal{E}_0 \\ 0 \\ \mathcal{E}_{z,n} \end{pmatrix} \partial_t e^{\imath k_x x + \imath k_{z,n}|z| - \imath\omega t} = \partial_t \varepsilon_n \vec{\mathcal{E}}_n \ ,$$

where the upper signs hold for the dielectric region ($z > 0$), we can determine,

$$\mp \imath k_{z,n} \mathcal{H}_0 = -\imath\omega\varepsilon_n \mathcal{E}_0 \quad \textit{and} \quad \imath k_x \mathcal{H}_0 = -\imath\omega\varepsilon_n \mathcal{E}_{z,n} \ ,$$

such that,

$$\vec{\mathcal{H}}_n(\mathbf{r},t) = \begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix} \mathcal{H}_0 e^{\imath k_x x + \imath k_{z,n}|z| - \imath\omega t} \quad , \quad \vec{\mathcal{E}}_n(\mathbf{r},t) = \begin{pmatrix} \pm k_{z,n} \\ 0 \\ -k_x \end{pmatrix} \frac{\mathcal{H}_0}{\omega\varepsilon_n} e^{\imath k_x x + \imath k_{z,n}|z| - \imath\omega t} \ ,$$

under the condition that,

$$\frac{k_{z,m}}{\varepsilon_m} = -\frac{k_{z,d}}{\varepsilon_d} \ .$$

For metals, as we know from Eqs. (18.87) and (18.161), the wavevector and the permittivity can be complex. For lossless plasmons, according to (18.222) the wavevector in z-direction is purely imaginary, such that fields stick to the surface and propagate along it.

18.3.7.3 Ex: Absorption of plasmons

Derive the expression (18.230).

Solution: *The complex dispersion relation is,*

$$ck_x = c(k'_x + \imath k''_x) = \omega\sqrt{\frac{\hat{\varepsilon}_d(\hat{\varepsilon}'_m + \imath\hat{\varepsilon}''_m)}{\hat{\varepsilon}_d + \hat{\varepsilon}'_m + \imath\hat{\varepsilon}''_m}}$$
$$= \omega\sqrt{\hat{\varepsilon}_d}\sqrt{\frac{\hat{\varepsilon}'_m(\hat{\varepsilon}_d + \hat{\varepsilon}'_m) + (\hat{\varepsilon}''_m)^2}{(\hat{\varepsilon}_d + \hat{\varepsilon}'_m)^2 + (\hat{\varepsilon}''_m)^2} + \imath\frac{\hat{\varepsilon}''_m(\hat{\varepsilon}_d + \hat{\varepsilon}'_m) - (\hat{\varepsilon}''_m)^2}{(\hat{\varepsilon}_d + \hat{\varepsilon}'_m)^2 + (\hat{\varepsilon}''_m)^2}} \ .$$

neglecting quadratic terms and expanding for small $\hat{\varepsilon}''_m$,

$$ck_x \simeq \omega\sqrt{\frac{\hat{\varepsilon}_d}{\hat{\varepsilon}_d + \hat{\varepsilon}'_m}}\sqrt{\hat{\varepsilon}'_m + \imath\hat{\varepsilon}''_m} = \omega\sqrt{\frac{\hat{\varepsilon}_d\hat{\varepsilon}'_m}{\hat{\varepsilon}_d + \hat{\varepsilon}'_m}}\left(1 + \frac{\imath\hat{\varepsilon}''_m}{2\hat{\varepsilon}'_m} + ..\right) = ck_x\left(1 + \frac{\imath\hat{\varepsilon}''_m}{2\hat{\varepsilon}'_m} + ..\right) \ .$$

18.3.7.4 Ex: Poynting vector of plasmons

At the interface between the vacuum and a metal surface there live solutions of the Maxwell equations, which decay exponentially in z-direction. We consider in this exercise only those parts of the waves, which live on the vacuum side $z > 0$, as illustrated in Fig. 18.21(a). The magnetic field, in this scheme, takes the following form:

$$\vec{\mathcal{H}}(\mathbf{r}, t) = \begin{pmatrix} 0 \\ \mathcal{H}_0 \\ 0 \end{pmatrix} \cos(kx - \omega t)e^{-\kappa z} \ (z > 0) \ .$$

a. Derive with the help of Maxwell's equation $\nabla \times \vec{\mathcal{H}} - \frac{\partial\vec{\mathcal{D}}}{\partial t} = \mathbf{j}$ the corresponding electric field $\vec{\mathcal{E}}(\mathbf{r}, t)$ in the half-space $z > 0$.
b. Calculate the Poynting vector $\vec{\mathcal{S}}(\mathbf{r}, t)$ in the half-space $z > 0$.
c. Calculate the total energy flow in x-direction. To do this, calculate the average over an oscillation period and integrate over the half-space $z > 0$.

Solution: *a. The electric field follows with $\mathbf{j} = 0$ and $\vec{\mathcal{D}} = \varepsilon_0\vec{\mathcal{E}}$ from,*

$$\nabla \times \vec{\mathcal{H}} = \begin{pmatrix} -\partial_z\mathcal{H}_y \\ 0 \\ \partial_x\mathcal{H}_y \end{pmatrix} = \begin{pmatrix} \mathcal{H}_0\kappa\cos(kx - \omega t)e^{-\kappa z} \\ 0 \\ -\mathcal{H}_0 k\sin(kx - \omega t)e^{-\kappa z} \end{pmatrix} = \partial_t\varepsilon_0\mathcal{E} \ .$$

We now integrate the result by t:

$$\int dt \begin{pmatrix} \mathcal{H}_0\kappa\cos(kx-\omega t)e^{-\kappa z} \\ 0 \\ -\mathcal{H}_0 k\sin(kx-\omega t)e^{-\kappa z}\end{pmatrix} = \begin{pmatrix} \frac{-\mathcal{H}_0\kappa}{\omega}\sin(kx-\omega t)e^{-\kappa z} \\ 0 \\ \frac{-\mathcal{H}_0 k}{\omega}\cos(kx-\omega t)e^{-\kappa z}\end{pmatrix} .$$

With this, we obtain:

$$\vec{\mathcal{E}} = \frac{-\mathcal{H}_0}{\omega\varepsilon_0}e^{-\kappa z}\begin{pmatrix} \kappa\sin(kx-\omega t) \\ 0 \\ k\cos(kx-\omega t)\end{pmatrix} .$$

b. The Poynting vector is,

$$\begin{aligned}\vec{\mathcal{S}} = \vec{\mathcal{E}}\times\vec{\mathcal{H}} &= -\frac{\mathcal{H}_0^2}{\omega\varepsilon_0}e^{-2\kappa z}\begin{pmatrix} \kappa\sin(kx-\omega t) \\ 0 \\ k\cos(kx-\omega t)\end{pmatrix}\times\begin{pmatrix} 0 \\ \cos(kx-\omega t) \\ 0\end{pmatrix} \\ &= -\frac{\mathcal{H}_0^2}{\omega\varepsilon_0}e^{-2\kappa z}\begin{pmatrix} -k\cos^2(kx-\omega t) \\ 0 \\ \kappa\sin(kx-\omega t)\cos(kx-\omega t)\end{pmatrix} .\end{aligned}$$

c. In x-direction we must take the time average of $\cos^2$, which gives the factor $1/2$. The integral over z gives:

$$\int_0^\infty dz e^{-2\kappa z} = \frac{1}{2\kappa}e^{-2\kappa z}\Big|_0^\infty = \frac{1}{2\kappa} .$$

Therefore, the total energy flux is,

$$\bar{s}_1^{tot} = \frac{\mathcal{H}_0^2 k}{4\omega\varepsilon_0\kappa} .$$

18.3.7.5 Ex: Negative refraction

Show that a medium with negative refractive index is left-handed and allows for perfect focusing.

Solution: *Let us look more closely at the reasons for limitation in performance [1011]. Consider an infinitesimal dipole of frequency ω in front of a lens. The electric component of the field will be given by some 2D Fourier expansion,*

$$\mathcal{E}(\mathbf{r},t) = \sum_{\sigma,k_x,k_y}\mathcal{E}_\sigma(k_x,k_y)e^{\imath k_z+\imath k_x+\imath k_y-\imath\omega t} ,$$

where we choose the axis of the lens to be the z axis. Maxwell's equations tell us that,

$$k_z = \sqrt{\omega^2/c^2 - k_x^2 - k_y^2}$$

the lens is to apply a phase correction to each of the Fourier components, so that at some distance beyond the lens the fields reassemble to a focus, and an image of the dipole source appears. However, for larger values of the transverse wave vector, $\omega^2/c^2 < k_x^2 + k_y^2$, k_z turns imaginary. These evanescent waves decay exponentially with z and no phase correction will restore them to their proper amplitude. They are effectively removed from the image, which generally comprises only the propagating waves. Since the propagating waves are limited to,

$$\omega^2/c^2 > k_x^2 + k_y^2$$

the maximum resolution in the image can never be greater than

$$res = \frac{2\pi}{k_{max}} = \frac{2\pi c}{\omega} = \lambda \ ,$$

and this is true however perfect the lens and however large the aperture.
There is an unconventional alternative to a lens. Material with negative refractive index ($\varepsilon, \mu < 0$) will focus light even when the lens consists of a parallel-sided dielectric slab. Fig. 18.22 sketches the focusing of such a slab, assuming that the refractive index is $n = -1$. Still the propagation of light at the interfaces obeys Snell's laws of refraction, as light inside the medium makes a negative angle with the surface normal. The other characteristic of the system is the double focusing effect revealed by a simple ray diagram. Light transmitted through a slab of thickness d_2 located a distance d_1 from the source comes to a second focus when, $z = d_2 - d_1$.

18.3.7.6 Ex: Negative refraction in chiral media

In a *chiral medium* the electric polarization $\vec{\mathcal{P}}$ couples to the magnetic field $\vec{\mathcal{H}}$ of an electromagnetic wave and the magnetization $\vec{\mathcal{M}}$ couples to the electric field $\vec{\mathcal{E}}$ like,

$$\vec{\mathcal{P}} = \varepsilon_0 \chi_\varepsilon \vec{\mathcal{E}} + \tfrac{1}{c}\xi_{EH}\vec{\mathcal{H}} \qquad \text{and} \qquad \vec{\mathcal{M}} = \tfrac{1}{c}\xi_{HE}\vec{\mathcal{E}} + \chi_m \vec{\mathcal{H}} \ ,$$

where ξ_{EH} and ξ_{HE} are the complex chirality coefficients. Show that a chiral medium allows for a negative refraction coefficient.

Solution: *The chirality coefficients lead to additional contributions to the refractive index for one circular polarization,*

$$n = \sqrt{\varepsilon\mu - \tfrac{1}{4}(\xi_{EH} + \xi_{HE})^2} + \tfrac{\imath}{2}(\xi_{EH} - \xi_{HE}) \ .$$

Such a chiral medium allows $n < 0$ without requiring $\mu < 0$ if there is a positive imaginary part of $\xi_{EH} - \xi_{HE}$ of sufficiently large magnitude. For example, choosing the phases of the complex chirality coefficients such that $\xi_{EH} = -\xi_{HE} = \imath\xi$, with $\xi, \varepsilon, \mu > 0$, the index of refraction becomes $n = \sqrt{\varepsilon\mu} - \xi$, and $n < 0$ when $\xi > \sqrt{\varepsilon\mu}$ [1012].

18.3.7.7 Ex: Hyperbolic metamaterials

Hyperbolic metamaterials are artificial media with sub-wavelength nanostructuring below exhibiting uncommon optical properties, such as an extreme anisotropy giving rise to permittivity and permeability tensors of the form,

$$\epsilon = \begin{pmatrix} \varepsilon_\perp & & \\ & \varepsilon_\perp & \\ & & \varepsilon_{\shortparallel} \end{pmatrix} \quad \text{and} \quad \mu = \begin{pmatrix} \mu_\perp & & \\ & \mu_\perp & \\ & & \mu_{\shortparallel} \end{pmatrix} .$$

In the case $\varepsilon_\perp \varepsilon_{\shortparallel} < 0$ or $\mu_\perp \mu_{\shortparallel} < 0$ the dispersion relation,

$$\frac{k_x^2 + k_y^2}{\varepsilon_{\shortparallel}} + \frac{k_z^2}{\varepsilon_\perp} = \frac{(\omega/c)^2}{\varepsilon_0} ,$$

becomes hyperbolic.
Derive from the Maxwell equations, allowing for an anisotropic (but homogeneous) permittivity tensor, the hyperbolic dispersion relation.

Solution: *Inserting the first into the second Maxwell equation, we derive, accounting for the anisotropy of the permittivity tensor, the equation,*

$$\frac{\partial^2 \epsilon \vec{\mathcal{E}}}{\partial t^2} = \frac{\partial^2 \vec{\mathcal{D}}}{\partial t^2} = \frac{\partial}{\partial t} \nabla \times \vec{\mathcal{H}} = \nabla \times \frac{\partial}{\partial t} \frac{\vec{\mathcal{B}}}{\mu} = -\frac{1}{\mu} \nabla \times (\nabla \times \vec{\mathcal{E}}) = -\frac{1}{\mu} [\nabla (\nabla \cdot \vec{\mathcal{E}}) - \nabla^2 \vec{\mathcal{E}}] .$$

Inserting plane waves, $\vec{\mathcal{E}} = \vec{\mathcal{E}}_0 e^{\imath(\mathbf{k}\cdot\mathbf{r} - \omega t)}$, we calculate,

$$-\omega^2 \begin{pmatrix} \varepsilon_\perp \mathcal{E}_{0x} \\ \varepsilon_\perp \mathcal{E}_{0y} \\ \varepsilon_{\shortparallel} \mathcal{E}_{0z} \end{pmatrix} e^{\imath(\mathbf{k}\cdot\mathbf{r} - \omega t)} = -\frac{1}{\mu} \nabla (\imath k_x \mathcal{E}_{0x} + \imath k_y \mathcal{E}_{0y} + \imath k_z \mathcal{E}_{0z} e^{\imath(\mathbf{k}\cdot\mathbf{r} - \omega t)} + \frac{1}{\mu} \mathbf{k}^2 \begin{pmatrix} \mathcal{E}_{0x} \\ \mathcal{E}_{0y} \\ \mathcal{E}_{0z} \end{pmatrix} e^{\imath(\mathbf{k}\cdot\mathbf{r} - \omega t)}$$

$$= -\frac{1}{\mu} \begin{pmatrix} -k_x^2 \mathcal{E}_{0x} - k_x k_y \mathcal{E}_{0y} - k_x k_z \mathcal{E}_{0z} \\ -k_x k_y \mathcal{E}_{0x} - k_y^2 \mathcal{E}_{0y} - k_y k_z \mathcal{E}_{0z} \\ -k_x k_z \mathcal{E}_{0x} - k_y k_z \mathcal{E}_{0y} - k_z^2 \mathcal{E}_{0z} \end{pmatrix} e^{\imath(\mathbf{k}\cdot\mathbf{r} - \omega t)} + \frac{1}{\mu} \mathbf{k}^2 \begin{pmatrix} \mathcal{E}_{0x} \\ \mathcal{E}_{0y} \\ \mathcal{E}_{0z} \end{pmatrix} e^{\imath(\mathbf{k}\cdot\mathbf{r} - \omega t)} .$$

That is,

$$0 = \begin{pmatrix} \omega^2 \mu \varepsilon_\perp - k_y^2 - k_z^2 & k_x k_y & k_x k_z \\ k_x k_y & \omega^2 \mu \varepsilon_\perp - k_z^2 - k_x^2 & k_y k_z \\ k_x k_z & k_y k_z & \omega^2 \mu \varepsilon_{\shortparallel} - k_x^2 - k_y^2 \end{pmatrix} \begin{pmatrix} \mathcal{E}_{0x} \\ \mathcal{E}_{0y} \\ \mathcal{E}_{0z} \end{pmatrix} .$$

The determinant must vanish in order to obtain non-trivial solutions,

$$\begin{aligned} 0 = {} & \mu^3 \varepsilon_\perp^2 \varepsilon_{\shortparallel} \omega^6 - \mu^2 \varepsilon_\perp \varepsilon_{\shortparallel} k_x^2 \omega^4 - \mu^2 \varepsilon_\perp \varepsilon_{\shortparallel} k_y^2 \omega^4 - 2\mu^2 \varepsilon_\perp \varepsilon_{\shortparallel} k_z^2 \omega^4 - \mu^2 \varepsilon_\perp^2 k_x^2 \omega^4 - \mu^2 \varepsilon_\perp^2 k_y^2 \omega^4 \\ & + \mu \varepsilon_\perp k_x^4 \omega^2 + \mu \varepsilon_\perp k_y^4 \omega^2 + \mu \varepsilon_{\shortparallel} k_z^4 \omega^2 + \mu \varepsilon_\perp k_x^2 k_z^2 \omega^2 + \mu \varepsilon_\perp k_y^2 k_z^2 \omega^2 + 2\mu \varepsilon_\perp k_x^2 k_y^2 \omega^2 \\ & + \mu \varepsilon_{\shortparallel} k_x^2 k_z^2 \omega^2 + \mu \varepsilon_{\shortparallel} k_y^2 k_z^2 \omega^2 . \end{aligned}$$

Apart from the trivial solution $\omega = 0$, we get,

$$0 = \omega^4 - \left(\frac{k_x^2}{\varepsilon_{\shortparallel}} + \frac{k_y^2}{\varepsilon_{\shortparallel}} + \frac{k_z^2}{\varepsilon_{\perp}} + \frac{k^2}{\varepsilon_{\perp}} \right) \frac{\omega^2}{\mu} + \frac{k^2}{\mu^2 \varepsilon_{\perp}} \left(\frac{k_x^2}{\varepsilon_{\shortparallel}} + \frac{k_y^2}{\varepsilon_{\shortparallel}} + \frac{k_z^2}{\varepsilon_{\perp}} \right) \ .$$

Which is satisfied provided the dispersion relation is, $c^2 = \frac{1}{\varepsilon_0 \mu}$.

18.3.7.8 Ex: Stacked layer metamaterial

Show that the effective permittivity of a nanostructure having the shape of an alternating stack of two different but intrinsically homogenous layers with the permittivity ε_d and ε_m and thicknesses $d_d, d_m \ll \lambda$ is given by,

$$\varepsilon_{\perp} = \frac{\varepsilon_d d_d + \varepsilon_m d_m}{d_d + d_m} \qquad \text{and} \qquad \varepsilon_{\shortparallel} = \frac{d_d/\varepsilon_d + d_m/\varepsilon_m}{d_d + d_m} \ .$$

Solution: *Apply the Fresnel equations and calculate the $\mathcal{T}$-matrix of an infinite stack as done in [1123].*

18.3.7.9 Ex: Hyperbolic dispersion relation in gases

Discuss, whether it is possible to realize a hyperbolic dispersion relation in an atomic gas.

Solution: *How to induce anisotropy on the atomic level? Via electric or magnetic fields? Dispersion relation of a gas which can only do π transitions along a predefined axis?*
For hyperbolic, we need negative ε, i.e. EIT.
What are the signatures of negative ε.

18.3.7.10 Ex: TEM waves in a hollow wave guide

Verify that TEM waves can not occur in hollow waveguides. Do not use the already derived results (18.249).

Solution: *We define the TEM wave with respect to the z-axis, such that $\vec{\mathcal{E}}_z = 0$ and $\vec{\mathcal{E}} = \vec{\mathcal{E}}_x(x,y)\hat{\mathbf{e}}_x + \vec{\mathcal{E}}_y(x,y)\hat{\mathbf{e}}_y$ and analogously for $\vec{\mathcal{B}}$. The third and second Maxwell equations then require,*

$$\frac{\partial \vec{\mathcal{E}}_x}{\partial x} + \frac{\partial \vec{\mathcal{E}}_y}{\partial y} = 0 = \frac{\partial \vec{\mathcal{E}}_y}{\partial x} - \frac{\partial \vec{\mathcal{E}}_x}{\partial y} \ ,$$

that is, $\nabla \cdot \vec{\mathcal{E}} = 0 = \nabla \times \vec{\mathcal{E}}$. Since the rotation is zero, there exists a gradient, such that $\vec{\mathcal{E}} = -\nabla\Phi$, e

$$0 = \nabla \cdot \vec{\mathcal{E}} = -\nabla \cdot (\nabla\Phi) = -\nabla^2\Phi \ .$$

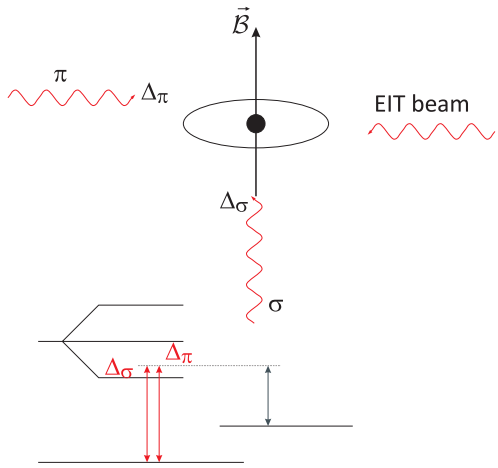

Figure 18.29: Hyperbolic dispersion materials.

The boundary condition of a waveguide is an equipotential surface, but since the Laplace equation does not admit local maximums or minimums, the potential has to be $\Phi = const$, that is $\vec{\mathcal{E}} = 0$.
Note that this argument only applies to a completely empty waveguide. Placing another conductor in the middle of the guide, the potential on its inner surface does not have to be the same as on the outer surface, and therefore a non-trivial potential is possible.

18.3.7.11 Ex: The TE_{00} mode in the rectangular waveguide

Show that the TE_{00} mode can not occur in a rectangular waveguide.

Solution: *For a hollow waveguide the dispersion relation simplifies to $\omega/c = k$. For TE_{00} modes we have $\mathcal{E}_z = 0$. Maxwell's equations then yield,*

$$\begin{aligned} \partial_x\mathcal{E}_y - \partial_y\mathcal{E}_x = \imath\omega\mathcal{B}_z \qquad & and \qquad \partial_x\mathcal{B}_y - \partial_y\mathcal{B}_x = 0 \\ -\imath k\mathcal{E}_y = \imath\omega\mathcal{B}_x \qquad & and \qquad \partial_y\mathcal{B}_z - \imath k\mathcal{B}_y = -\tfrac{\imath\omega}{c^2}\mathcal{E}_x \\ \imath k\mathcal{E}_x = \imath\omega\mathcal{B}_y \qquad & and \qquad \imath k\mathcal{B}_x - \partial_x\mathcal{B}_z = -\tfrac{\imath\omega}{c^2}\mathcal{E}_y \ . \end{aligned}$$

Solving the third equation by $\mathcal{E}_y$ and substituting it into the last equation,

$$\imath k\mathcal{B}_x - \partial_x\mathcal{B}_z = -\tfrac{\imath\omega}{c^2}\tfrac{-\omega}{k}\mathcal{B}_x \ ,$$

we find $\partial_x\mathcal{B}_z = 0$. Solving the fifth equation by $\mathcal{E}_x$ and substituting it into the fourth equation,

$$\partial_y\mathcal{B}_z - \imath k\mathcal{B}_y = -\tfrac{\imath\omega}{c^2}\tfrac{\omega}{k}\mathcal{B}_y \ ,$$

we find $\partial_y\mathcal{B}_z = 0$, that is, the field $\mathcal{B}_z(x,y) = \mathcal{B}_0$ is constant, that is,

$$\vec{\mathcal{B}} = \vec{\mathcal{B}}_0 e^{\imath(kz-\omega t)} \qquad and \qquad \frac{\partial\vec{\mathcal{B}}}{\partial t} = -\imath\omega\vec{\mathcal{B}}_0 e^{\imath(kz-\omega t)} \ .$$

Applying Faraday's law in the integral form to the cross-section of the waveguide ($S = ab$),

$$\oint \vec{\mathcal{E}}^{\parallel} dl = \oint \vec{\mathcal{E}} \cdot d\mathbf{l} = -\int \frac{\partial \vec{\mathcal{B}}}{\partial t} \cdot d\mathbf{S} = \int \imath\omega \vec{\mathcal{B}}_0 e^{\imath(kz-\omega t)} \cdot d\mathbf{S} = \imath\omega \mathcal{B}_0 e^{\imath(kz-\omega t)} ab \ .$$

The integration path follows the inner edges of the waveguide, where $\mathcal{E}^{\parallel} = 0$,

$$\oint \vec{\mathcal{E}} \cdot d\mathbf{l} = \oint \vec{\mathcal{E}}^{\parallel} dl = 0 \ .$$

such that $\mathcal{B}_0 = 0$. Then it would be a TEM_{00} mode, for which we already have shown in class that it does not exist in a hollow waveguide.

18.3.7.12 Ex: Cut-off frequency

Calculate the radial size of a hollow rectangular wave guide capable of guiding a (i) 60 Hz signal, (ii) a 10 MHz signal, and (iii) a 9.1 GHz signal.

Solution: *The frequency of the guided signal must be higher than the cut-off frequency. For a TE_{10} mode we get from Eq. (18.256) the condition $\omega > c\pi/a$, or $a > \lambda/2$. Hence, $\lambda_i = 2.5km$, $\lambda_{ii} = 15m$, and $\lambda_{iii} = 1.65cm$.*

18.3.7.13 Ex: Cylindrical waveguide

Show that the fields (18.261) satisfy the Maxwell equations with the boundary conditions (18.246) [545](p.411).

Solution: *The fields are,*

$$\vec{\mathcal{E}} = \frac{A\cos(kz-\omega t)}{\rho}\hat{\mathbf{e}}_\rho \equiv A_\rho \hat{\mathbf{e}}_\rho \qquad \text{and} \qquad \vec{\mathcal{B}} = \frac{A\cos(kz-\omega t)}{c\rho}\hat{\mathbf{e}}_\phi \equiv A_\phi \hat{\mathbf{e}}_\phi \ .$$

Obviously they satisfy the boundary conditions on the surface of the waveguide,

$$\vec{\mathcal{E}}^{\parallel} = 0 \qquad \text{and} \qquad \vec{\mathcal{B}}^{\perp} = 0 \ .$$

By inserting them into the second Maxwell equation with the rotational written in cylindrical coordinates (12.72),

$$\begin{aligned}\nabla \times \vec{\mathcal{E}} + \frac{\partial \vec{\mathcal{B}}}{\partial t} &= \hat{\mathbf{e}}_\phi \frac{\partial}{\partial z} A_\rho - \hat{\mathbf{e}}_z \frac{1}{\rho}\frac{\partial}{\partial \phi} A_\rho + \hat{\mathbf{e}}_\rho \frac{\partial}{\partial t} A_\rho \\ &= \hat{\mathbf{e}}_\phi \frac{\partial}{\partial z}\frac{A\cos(kz-\omega t)}{\rho} + \hat{\mathbf{e}}_\phi \frac{\partial}{\partial t}\frac{A\cos(kz-\omega t)}{c\rho} = \hat{\mathbf{e}}_\phi \frac{A\sin(kz-\omega t)}{\rho}\left(-k + \frac{\omega}{c}\right) = 0 \ .\end{aligned}$$

The third Maxwell equation with the divergence written in cylindrical coordinates (12.71) gives,

$$\nabla \cdot \vec{\mathcal{E}} = \frac{1}{\rho}\frac{\partial}{\partial \rho}(\rho A_\rho) + \frac{1}{\rho}\frac{\partial}{\partial \rho} A_\phi + \frac{\partial}{\partial z} A_z = \frac{1}{\rho}\frac{\partial}{\partial \rho}(\rho A_\rho) = \frac{1}{\rho} A \frac{\partial}{\partial \rho}\cos(kz-\omega t) = 0 \ .$$

The calculations for Maxwell's first and fourth equations are analogous.

18.3.7.14 Ex: Propagation of a TEM mode along a coaxial cable

A transmission line made of two concentric circular metallic cylinders with conductivity ρ and skin depth δ is filled with a lossless uniform dielectric (ε, μ). A TEM mode propagates along this line.
a. Show that the time averaged energy flux along the line is,

$$P = \sqrt{\frac{\mu}{\varepsilon}} \pi a^2 |\mathcal{H}_0|^2 \ln \frac{b}{a} \ ,$$

where H_0 is the maximum value of the azimuthal magnetic field on the surface of the inner conductor.
b. Show that the transmitted power is attenuated along the line like,

$$P(z) = P_0 e^{-2\gamma z} \ ,$$

where,

$$\gamma = \frac{1}{2\sigma\delta} \sqrt{\frac{\varepsilon}{\mu}} \frac{a^{-1} + b^{-1}}{ln(b/a)} \ .$$

c. The characteristic impedance Z_0 of the line is defined as the ratio between the voltage between the cylinders and the current flowing in axial direction inside one of the cylinders at any position z. Show that for this line,

$$Z_0 = \frac{1}{2\pi} \sqrt{\frac{\mu}{\varepsilon}} \ln \frac{b}{a} \ .$$

d. Show that the resistance and the serial inductance per unit length of the line are,

$$R = \frac{1}{2\pi\sigma\delta} \left(\frac{1}{a} + \frac{1}{b} \right) \quad , \quad L = \frac{\mu}{2\pi} \ln \frac{b}{a} + \frac{\mu_c \delta}{4\pi} \left(\frac{1}{a} + \frac{1}{b} \right) \ ,$$

where μ_c is the permeability of the conductor. The correction for the inductance comes from the penetration of the flux into the conductors by the distance of the order δ.

Solution:

18.3.7.15 Ex: Resonant cavity

Consider a perfectly conducting resonant cavity having the shape of a 3D rectangular box with the volume defined by $x \in [0, L_x]$, $y \in [0, L_y]$, and $z \in [0, L_z]$. Show that the resonant frequencies for both the TE and TM modes are given by $\omega_{n_x,n_y,n_z} = c\pi\sqrt{(n_x/L_x)^2 + (n_y/L_y)^2 + (n_z/L_z)^2}$ for integers n_i. Find the associated electric and magnetic fields.

Solution: *The rectangular symmetry of the problem allows us to separate the Cartesian variables, as shown in equation (13.76). For every component of the vector* $\vec{\mathcal{E}}$,

e.g. the $\mathcal{E}_x$ component, we can make an ansatz $\mathcal{E}_x = X_x(x)Y_x(y)Z_x(z)$ which, inserted in the wave equation gives,

$$\begin{aligned} X_x(x) &= A_{xx}\sin k_{xx}x + C_{xx}\cos k_{xx}x \\ Y_x(y) &= A_{xy}\sin k_{xy}y + C_{xy}\cos k_{xy}y \\ Z_x(z) &= A_{xz}\sin k_{xz}z + C_{xz}\cos k_{xz}z \ , \end{aligned}$$

and similarly for the components $\mathcal{E}_y$ and $\mathcal{E}_z$. The lengths being fixed by the boundary conditions,

$$\vec{\mathcal{E}}^{\parallel} = 0 \qquad \textit{and} \qquad \vec{\mathcal{B}}^{\perp} = 0 \ ,$$

for the $\mathcal{E}_x$ component we get on the surfaces $y = 0, L_y$ and $z = 0, L_z$,

$$C_{xy} = C_{xz} = 0 \qquad \textit{and} \qquad k_{xy} = \pi\tfrac{n_y}{L_y} \qquad , \qquad k_{xz} = \pi\tfrac{n_z}{L_z} \ .$$

We let $A_{xy} = 1 = A_{xz}$ and obtain, extending the procedure to the other components,

$$\begin{aligned} \mathcal{E}_x &= (A_{xx}\sin k_{xx}x + C_{xx}\cos k_{xx}x)\sin\tfrac{\pi n_y y}{L_y}\sin\tfrac{\pi n_z z}{L_z} \\ \mathcal{E}_y &= (A_{yy}\sin k_{yy}y + C_{yy}\cos k_{yy}y)\sin\tfrac{\pi n_x y}{L_x}\sin\tfrac{\pi n_z z}{L_z} \\ \mathcal{E}_z &= (A_{zz}\sin k_{zz}z + C_{zz}\cos k_{zz}z)\sin\tfrac{\pi n_x y}{L_x}\sin\tfrac{\pi n_y y}{L_y} \ . \end{aligned}$$

Now, we invoke Gauss's law,

$$\begin{aligned} 0 = \nabla\cdot\vec{\mathcal{E}} = {} & k_{xx}(A_{xx}\cos k_{xx}x - C_{xx}\sin k_{xx}x)\sin\tfrac{\pi n_y y}{L_y}\sin\tfrac{\pi n_z z}{L_z} \\ & + k_{yy}(A_{yy}\cos k_{yy}y - C_{yy}\sin k_{yy}y)\sin\tfrac{\pi n_x y}{L_x}\sin\tfrac{\pi n_z z}{L_z} \\ & + k_{zz}(A_{zz}\cos k_{zz}z - C_{zz}\sin k_{zz}z)\sin\tfrac{\pi n_x y}{L_x}\sin\tfrac{\pi n_y y}{L_y} \ . \end{aligned}$$

This equation must be valid in every point (x, y, z), hence also at $x = 0$, which is only possible when $A_{xx} = 0$. By symmetry, we must also set $A_{yy} = 0 = A_{zz}$, yielding,

$$\begin{aligned} 0 = \nabla\cdot\vec{\mathcal{E}} = {} & - k_{xx}C_{xx}\sin k_{xx}x\sin\tfrac{\pi n_y y}{L_y}\sin\tfrac{\pi n_z z}{L_z} \\ & - k_{yy}C_{yy}\sin k_{yy}y\sin\tfrac{\pi n_x y}{L_x}\sin\tfrac{\pi n_z z}{L_z} \\ & - k_{zz}C_{zz}\sin k_{zz}z\sin\tfrac{\pi n_x y}{L_x}\sin\tfrac{\pi n_y y}{L_y} \ . \end{aligned}$$

Finally, introducing the abbreviations $k_j = \pi n_j/L_j$, we get the electric field,

$$\begin{aligned} \vec{\tilde{\mathcal{E}}} = {} & C_{xx}e^{-\imath\omega t}\hat{\mathbf{e}}_x\cos k_x x\sin k_y y\sin k_z z \\ & + C_{yy}e^{-\imath\omega t}\hat{\mathbf{e}}_y\sin k_x x\cos k_y y\sin k_z z \\ & + C_{zz}e^{-\imath\omega t}\hat{\mathbf{e}}_z\sin k_x x\sin k_y y\cos k_z z \ . \end{aligned}$$

The magnetic field is obtained by Maxwell's equation,

$$\begin{aligned} -\imath\omega\vec{\tilde{\mathcal{B}}} = \frac{\partial\vec{\tilde{\mathcal{B}}}}{\partial t} = -\nabla\times\vec{\tilde{\mathcal{E}}} = {} & -(C_{zz}k_y - C_{yy}k_z)e^{-\imath\omega t}\hat{\mathbf{e}}_x\sin k_x x\cos k_y y\cos k_z z \\ & -(C_{xx}k_z - C_{zz}k_x)e^{-\imath\omega t}\hat{\mathbf{e}}_y\cos k_x x\sin k_y y\cos k_z z \\ & -(C_{yy}k_x - C_{xx}k_y)e^{-\imath\omega t}\hat{\mathbf{e}}_z\cos k_x x\cos k_y y\sin k_z z \ . \end{aligned}$$

The resonant frequency for the mode (n_x, n_y, n_z) *is,*

$$\omega_{n_x,n_y,n_z} = c\pi\sqrt{k_x^2 + k_y^2 + k_z^2} \ .$$

18.3.7.16 Ex: Spherical holes in conductors such as cavities

A spherical hole of radius a in a conductive medium may serve as an electromagnetic resonant cavity.
a. Assuming infinite conductivity, determine the transcendental equations for the characteristic frequencies $\omega_{\ell m}$ of the cavity for TE and TM modes.
b. Calculate numerical values for the wavelength $\lambda_{\ell m}$ in units of the radius a for the four lowest modes for TE and TM waves.
c. Explicitly calculate the electric and magnetic fields inside the cavity for the lowest TE mode and the lowest TM mode.

Solution:

18.3.7.17 Ex: Schumann resonances

A resonant cavity consists of the void space between two perfectly conducting and concentric spherical layers. The smaller one has the external radius a, the larger one the internal radius b. The azimuthal magnetic field has a radial dependence given by spherical Bessel functions, $j_\ell(kr)$ and $n_\ell(kr)$, where $k = \omega/c$.
a. Write the transcendental equation for the characteristic frequencies of the cavity for arbitrary ℓ.
b. For $\ell = 1$ use the explicit forms of the spherical Bessel functions to show that the characteristic frequencies are given by,

$$\frac{\tan kh}{kh} = \frac{k^2 + (ab)^{-1}}{k^2 + ab(k^2 - a^{-2})(k^2 - b^{-2})} \ ,$$

where $h = b - a$.
c. For $h/a \ll 1$, verify that the result of part (b) reproduces the frequency found in [659], Sec. 8.9, and determine the first-order corrections in h/a.
Now, we apply this cavity as a model for the atmosphere enclosed by the Earth's surface and its ionosphere.
d. For the Schumann resonances of Sec. 8.9 calculate the values Q under the assumption that the Earth has the conductivity σ_e and the ionosphere the conductivity σ_i with corresponding skin depths δ_e and δ_i. Show that in the lowest order in h/a the value Q is given by $Q = Nh/(\delta_e + \delta_i)$ and determine the numerical factor N for all ℓ.
e. For the lowest Schumann resonance evaluate the value Q assuming $\sigma_e = 0.1\ (\Omega m)^{-1}$, $\sigma_e = 10^{-5}\ (\Omega m)^{-1}$, $h = 100$ km.
f. Discuss the validity of the approximations used in part (a) for the parameter regime used in part (b).

Solution:

18.3.7.18 Ex: Airy formula

To derive the *Airy formulas*, consider a light field described by $\mathcal{E}_{in}$ incident on a Fabry-Pérot cavity of length L. The cavity mirrors are glass substrates having a surface with dielectric coating. The surfaces of the two mirrors are characterized by the transmission rates t_1, t_2 and reflection rates r_1, r_2. Note, that the reflected wave suffers a phase shift of π, when the reflection occurs at a denser medium $n > 1$. Disregard energy losses by absorption.

Solution: *The wave is reflected several times. For the field inside the cavity we find,*

$$\begin{aligned}\mathcal{E}_{cav}(z) &= \mathcal{E}_{in}t_1 \sum_n \left[(r_1r_2)^n e^{\imath k[2nL+z]} - r_2(r_1r_2)^n e^{\imath k[(2n+2)L-z]}\right] \\ &= \mathcal{E}_{in}t_1 \frac{e^{\imath kz} - r_2 e^{\imath k(2L-z)}}{1 - r_1r_2e^{\imath k2L}} \ ,\end{aligned} \tag{18.267}$$

using the Fourier expansion of $(1-s)^{-1} = \sum_n s^n$. *The reflected and transmitted fields are,*

$$\begin{aligned}\mathcal{E}_{rfl} &= r_1\mathcal{E}_{in} + \mathcal{E}_{in}\sum_{n=0}^{\infty} t_1(-r_2)(r_1r_2)^n t_1 e^{\imath k2(n+1)L} = \mathcal{E}_{in}\left(r_1 - \frac{e^{\imath k2L}t_1^2 r_2}{1 - r_1r_2e^{2\imath kL}}\right) \\ \mathcal{E}_{trns} &= \mathcal{E}_{in}\sum_{n=0}^{\infty} t_1(r_1r_2)^n t_2 e^{\imath k(2n+1)L} = \mathcal{E}_{in}\frac{t_1t_2e^{\imath kL}}{1 - r_1r_2e^{2\imath kL}} \ .\end{aligned} \tag{18.268}$$

Assuming $r_1 = r_2$, $t_1 = t_2$ *and* $T + R = 1$, *the formulas simplify to,*

$$\begin{aligned}\frac{\mathcal{E}_{cav}(z)}{\mathcal{E}_{in}} &= t_1\frac{e^{\imath kz} - r_2e^{\imath k(2L-z)}}{1 - r_1r_2e^{\imath k2L}} \\ \frac{\mathcal{E}_{rfl}}{\mathcal{E}_{in}} &= \sqrt{R}\frac{1 - e^{\imath k2L}}{1 - Re^{2\imath kL}} \\ \frac{\mathcal{E}_{trns}}{\mathcal{E}_{in}} &= \frac{(1-R)e^{\imath kL}}{1 - Re^{2\imath kL}} \ ,\end{aligned} \tag{18.269}$$

The intensities are,

$$\begin{aligned}I_{cav} &= I_{in}(1-R)\frac{(1-\sqrt{R})^2 + 4\sqrt{R}\sin^2 k(L-z)}{(1-R)^2 + 4R\sin^2 kL} \\ I_{refl} &= I_{in}R\frac{4\sin^2 kL}{(1-R)^2 + 4R\sin^2 kL} \\ I_{trns} &= I_{in}\frac{(1-R)^2}{(1-R)^2 + 4R\sin^2 kL} = 1 - I_{refl} \ .\end{aligned} \tag{18.270}$$

These are the Airy formulas. Using the free spectral range, we can write,

$$\omega = N2\pi\delta_{fsr} + \Delta \tag{18.271}$$
$$kL = kc/2\delta_{fsr} = \omega/2\delta_{fsr} = \pi N + \frac{\Delta}{2\delta_{fsr}} \ ,$$

and we obtain the form (18.263). Note that the free spectral range δ_{fsr} is given in terms of real frequencies.
Let us investigate the transmission spectrum close to resonance, that is $kL = N\pi$ or $|\Delta| \ll 2\pi\delta_{fsr}$. We can expand the sine,

$$I_{trns} = I_{in}\frac{(1-R)^2}{(1-R)^2 + 4R\sin^2\frac{\Delta}{2\delta_{fsr}}} = I_{in}\frac{(1-R)^2}{(1-R)^2 + 4R\left(\frac{\Delta}{2\delta_{fsr}}\right)^2 + ...} \tag{18.272}$$
$$\simeq I_{in}\frac{\delta_{fsr}^2\frac{(1-R)^2}{R}}{\delta_{fsr}^2\frac{(1-R)^2}{R} + \Delta^2} \equiv I_{in}\frac{\left(\frac{\kappa_{int}}{2}\right)^2}{\left(\frac{\kappa_{int}}{2}\right)^2 + \Delta^2} \ ,$$

utilizing

$$F = \frac{2\pi\delta_{fsr}}{\kappa_{int}} = \frac{\pi\sqrt{R}}{1-R} \simeq \frac{\pi}{1-R} \ . \tag{18.273}$$

We obtain a Lorentzian function.
Repeating the procedure for the intracavity field at the location of an antinode, $z = \lambda/4$,

$$\frac{I_{cav}}{I_{in}} = (1-R)\frac{(1-\sqrt{R})^2 + 4\sqrt{R}\sin^2\left(\frac{\Delta}{2\delta_{fsr}} - \frac{\pi}{2}\right)}{(1-R)^2 + 4R\sin^2\frac{\Delta}{2\delta_{fsr}}} = \frac{\frac{(1+\sqrt{R})^2}{1-R} - \frac{4\sqrt{R}}{1-R}\sin^2\frac{\Delta}{2\delta_{fsr}}}{1 + \left(\frac{2\sqrt{R}}{1-R}\right)^2\sin^2\frac{\Delta}{2\delta_{fsr}}} \ . \tag{18.274}$$

For large finesse, $1 + \sqrt{R} \simeq 2\sqrt{R}$, we find,

$$\frac{I_{cav}}{I_{in}} \simeq \frac{4F}{\pi}\frac{\cos^2\frac{\Delta}{2\delta_{fsr}}}{1 + \left(\frac{2F}{\pi}\right)^2\sin^2\frac{\Delta}{2\delta_{fsr}}} < \frac{4F}{\pi} \ . \tag{18.275}$$

Expanding the trigonometric functions,

$$\frac{I_{cav}}{I_{in}} \simeq \frac{4F}{\pi}\frac{1}{1 + (\Delta/\kappa)^2} < \frac{4F}{\pi} \ . \tag{18.276}$$

Alternatively, we can derive the Airy formulas from a self-consistency condition. The field at position x is,

$$\mathcal{E}_{cav}(x) = e^{\imath kx}t_1\mathcal{E}_{in} + e^{\imath k(L-x)}(-r_2)e^{\imath kL}t_1\mathcal{E}_{in} + r_1r_2e^{2\imath kL}\mathcal{E}_{cav}(x) \tag{18.277}$$
$$= \mathcal{E}_{in}t_1\frac{e^{\imath kx} - r_2e^{\imath k(2L-x)}}{1 - r_1r_2e^{2\imath kL}} \ ,$$

giving the same result as in (18.267).
Repeating the procedure for the intracavity field, but now averaging over the cavity

mode volume, $\frac{1}{2\pi}\int_0^{2\pi}\sin^2 x dx = \frac{1}{2}$*, the intracavity intensity from Eq. (18.270) yields,*

$$\frac{I_{cav}}{I_{in}} \to \frac{\frac{1+R}{1-R}}{1+\frac{4R}{(1-R)^2}\sin^2\frac{\Delta}{2\delta_{fsr}}} = \frac{\sqrt{1+\left(\frac{2F}{\pi}\right)^2}}{1+\left(\frac{2F}{\pi}\right)^2\sin^2\frac{\Delta}{2\delta_{fsr}}} \tag{18.278}$$
$$\simeq \frac{\sqrt{1+\left(\frac{2F}{\pi}\right)^2}}{1+(\Delta/\kappa)^2} \simeq \frac{2F}{\pi}\frac{1}{1+(\Delta/\kappa)^2} < \frac{2F}{\pi} .$$

The result can be generalized to cavities with more than two mirrors having the reflection coefficients $R_i = r_i^2$*, the transmission coefficients* $T_i = t_i^2$*, and the absorption coefficients* $S_i = 1 - R_i - T_i$*. In resonance we expect:*

$$I_{cav}(\delta = 0) = I_{in}\frac{4t_1\left(1 - S_{in} - \sum_i (S_i + T_i)\right)}{\left(t_1 + S_{in} + \sum_i (S_i + T_i)\right)^2} , \tag{18.279}$$

giving the factor of power amplification *of the cavity. The optimization of* I_{cav} *as a function of* R *is called impedance matching.*

18.4 Beam and wave optics

While the propagation of high wavelength radiation is dominated by diffraction effects, we observe that visible light tends to form bundles that apparently propagate (in homogeneous media) in a straight line. With the invention of the laser, the optical regime has become the preferred spectral regime for many spectroscopic applications. Therefore, we will dedicate the following section to the propagation of laser beams, which is understood within the theory of Gaussian optics.

18.4.1 Gaussian optics

At first glance, one might think that the propagation of laser light is well described by the laws of geometrical optics. Closer inspection, however, shows that a laser beam in many ways behaves more like a wave, although its energy is concentrated near an optical axis. The fields satisfy the wave equation. By inserting the propagating wave $u = \psi_z(x, y)e^{\imath(kz-\omega t)}$, we obtain an equation similar to the Schrödinger equation [734],

$$0 = \left[\frac{1}{c^2}\frac{\partial^2}{\partial t^2} - \nabla^2\right]\psi e^{\imath(kz-\omega t)} = e^{\imath(kz-\omega t)}\left(2\imath k\frac{\partial\psi}{\partial z} - \nabla^2\psi\right) . \tag{18.280}$$

Neglecting the second derivative for z, we obtain,

$$\left[2\imath k\frac{\partial}{\partial z} - \left(\frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2}\right)\right]\psi = 0 . \tag{18.281}$$

To describe a Gaussian beam, we choose an exponential ansatz and introduce two parameters that may vary along the propagation axis z: $\varphi(z)$ is a complex phase shift

and $q(z)$ a complex parameter, whose imaginary part describes the diameter of the beam. Inserting the ansatz

$$\psi = e^{-\imath\left[\varphi(z)+k(x^2+y^2)/2q(z)\right]} \tag{18.282}$$

into the Schrödinger equation, we obtain,

$$\begin{aligned} 0 = {} & 2\imath k e^{-\imath[\varphi+k(x^2+y^2)/2q]}\left(-\imath\frac{\partial\varphi}{\partial z}+\frac{\imath k(x^2+y^2)}{2q^2}\frac{\partial q}{\partial z}\right) - 2e^{-\imath[\varphi+k(x^2+y^2)/2q]}\frac{-\imath k}{q} \\ & - e^{-\imath[\varphi+k(x^2+y^2)/2q]}\left(\frac{-\imath kx}{q}\right)^2 - e^{-\imath[\varphi+k(x^2+y^2)/2q]}\left(\frac{-\imath ky}{q}\right)^2 . \end{aligned} \tag{18.283}$$

This leads directly to the equation,

$$0 = (q'-1)\frac{\imath k(x^2+y^2)}{q^2} - 2\imath\varphi' + \frac{2}{q} . \tag{18.284}$$

For Eq. (18.284) to be valid at all x and y, we need $q' = 1$ and $\varphi' = \frac{-\imath}{q}$. Integrating q', we find,

$$q(z) = q_0 + z . \tag{18.285}$$

It is practical to introduce real beam parameters

$$\boxed{\frac{1}{q} \equiv \frac{1}{R} - \imath\frac{\lambda}{\pi w^2}} . \tag{18.286}$$

Inserting this into the ansatz (18.282),

$$\psi = e^{-\imath\varphi - \imath\frac{k(x^2+y^2)}{2R^2} - \frac{(x^2+y^2)}{w^2}} , \tag{18.287}$$

it becomes clear that $R(z)$ is the radius of curvature and $w(z)$ is the diameter of the beam. Evaluating q_0 at the position of the focus (beam waist), where $R = \infty$, we get from (18.285) along with the definition (18.286),

$$\frac{1}{\frac{1}{R_z} - \imath\frac{\lambda}{\pi w_z^2}} = q(z) = q_0 + z = \frac{1}{\frac{1}{\infty} - \imath\frac{\lambda}{\pi w_0^2}} + z = \imath\frac{\pi w_0^2}{\lambda} + z , \tag{18.288}$$

The separation of this result into a real part and an imaginary part gives,

$$\frac{z}{R} + \frac{w_0^2}{w^2} = 1 \qquad \text{and} \qquad \frac{\pi w^2}{\lambda R} = \frac{\lambda z}{\pi w_0^2} . \tag{18.289}$$

Solving the second equation for $1/R$ and replacing this in the first equation gives an equation for w,

$$\boxed{w^2 = w_0^2\left[1 + \left(\frac{\lambda z}{\pi w_0^2}\right)^2\right]} . \tag{18.290}$$

This expression can now be replaced in the second equation,

$$\boxed{R = z\left[1 + \left(\frac{\pi w_0^2}{\lambda z}\right)^2\right]} . \tag{18.291}$$

We call $z_R \equiv q_0$ the *Rayleigh length*. Now we integrate φ',

$$\varphi = \int_0^z \frac{-\imath}{q} dz = \int_0^z \frac{-\imath dz}{\imath z_R + z} = -\imath \int_0^z \frac{z dz}{z_R^2 + z^2} - \int_0^z \frac{z_R dz}{z_R^2 + z^2} \tag{18.292}$$
$$= -\frac{\imath}{2} \ln \frac{z_R^2 + z^2}{z_R^2} - \arctan \frac{z}{z_R} = -\imath \ln \frac{w}{w_0} - \arctan \frac{\lambda z}{\pi w_0^2} \, .$$

Hence,

$$\boxed{\psi(\mathbf{r}) = \frac{w_0}{w} e^{\imath \arctan(-z/q_0) - \imath k(x^2+y^2)/2q}} \, . \tag{18.293}$$

We note that the function $|\psi|^2$ is normalized by the radial integral,

$$\int |\psi|^2 dx dy = \frac{w_0^2}{w^2} \int |e^{-k(x^2+y^2)/2q(z)}|^2 dx dy \tag{18.294}$$
$$= \frac{w^2}{w_0^2} \left(\int_{-\infty}^{\infty} e^{-2x^2/w^2} dx \right)^2 = \frac{\pi w_0^2}{2} \, ,$$

which is independent of z and thus ensures conservation of energy along the beam. The intensity profile of a Gaussian beam is proportional to $|\psi|^2$ and normalized to the total power P, that is,

$$\boxed{I(\mathbf{r}) = \frac{2P}{\pi w_0^2} |\psi(\mathbf{r})|^2 = \frac{2P}{\pi w(z)^2} e^{-2(x^2+y^2)/w(z)^2}} \, . \tag{18.295}$$

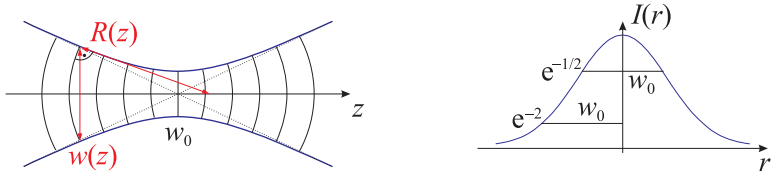

Figure 18.30: (Left) Propagation of the beam along the optical axis. (Right) Cross section of the Gaussian beam.

The above treatment shows that modes do not only exist in cavities but also in free space. In Excs. 18.4.4.1 and 18.4.4.2 we are dealing with modes of Gaussian light beams that are often used in laser beam optics.

Example 111 (*Gaussian optics*): The expansion of the Gaussian beam $\mathcal{E}(\mathbf{r}) = \mathcal{E}_0 e^{-(x^2+y^2)/w(z)^2 - z^2/z_R^2}$ into plane waves simply is,

$$\mathcal{E}(\mathbf{k}) = \int \mathcal{E}(\mathbf{r}) e^{\imath \mathbf{k}\cdot\mathbf{r}} d^3 r = \mathcal{E}_0 e^{-(k_x^2+k_y^2)w(z)^2 - k_z^2 z_R^2} \, .$$

18.4.1.1 Optical components

In *geometrical optics* (or ray optics) we work a lot with *transfer matrices* $\mathcal{M}$ defined by their feature of transforming the two-component vector, which consists of the distance of a ray from the optical axis $y(z)$ and its divergence $y'(z)$ [31]:

$$\begin{pmatrix} y(z) \\ y'(z) \end{pmatrix} = \mathcal{M} \begin{pmatrix} y(0) \\ y'(0) \end{pmatrix} . \tag{18.296}$$

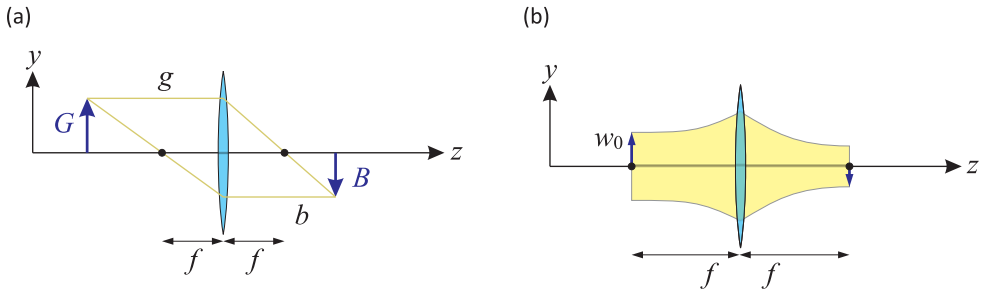

Figure 18.31: (a) Image formation through a lens with ray optics. (b) Focusing a laser beam with Gaussian optics.

Now, it is possible to show that the same matrix $\mathcal{M}$ can describe the transformation of a Gaussian beam through optical components along the optical axis, provided that we apply the transformation to the beam parameter q in the following way:

$$\boxed{q(z) = \frac{M_{11}q(0) + M_{12}}{M_{21}q(0) + M_{22}}} . \tag{18.297}$$

Hence, the transfer matrices allow us to calculate, how the parameters R and w transform along the optical axis through optical elements or in free propagation. The most common optical elements are lenses, crystals, prisms, mirrors, and cavities. For example, the matrix for free propagation of a beam over a distance d is,

$$\mathcal{M}_{dist} = \begin{pmatrix} 1 & d \\ 0 & 1 \end{pmatrix} , \tag{18.298}$$

and the matrix describing the passage through a thin lens with focal length f,

$$\mathcal{M}_{lens} = \begin{pmatrix} 1 & 0 \\ -1/f & 1 \end{pmatrix} . \tag{18.299}$$

In Exc. 18.4.4.3 we use these matrices to derive the lens equations in ray optics and Gaussian optics.

[31] Note that these matrices have nothing to do with the matrices describing the transmission and reflection of electric and magnetic fields by interfaces.

18.4.1.2 Modes of a linear cavity

We will now apply the formalism of the transfer matrices to calculate the modal structure of a linear cavity. Let $\mathcal{M}$ be the matrix describing the round-trip of a beam of light in the cavity. For the cavity to be stable, the fields must be stationary. This is only possible if the mode geometry is self-consistent. That is, at any position z, the beam parameter $q(z) = q_z$ must satisfy [734],

$$q_z = \frac{M_{11}q_z + M_{12}}{M_{21}q_z + M_{22}} \ . \tag{18.300}$$

Using, $M_{11}M_{22} - M_{12}M_{21} = 1$, the condition (18.300) can be solved by,

$$\frac{1}{q_z} = \frac{M_{22} - M_{11}}{2M_{12}} \pm \frac{\imath}{2M_{12}}\sqrt{4 - (M_{11} + M_{22})^2} \ , \tag{18.301}$$

or separating the real part from the imaginary part according to the definition (18.286) of the beam parameter,

$$w_z^2 = \frac{2\lambda M_{12}}{\pi\sqrt{4 - (M_{11} + M_{22})^2}} \qquad \text{and} \qquad R_z = \frac{2M_{12}}{M_{22} - M_{11}} \ . \tag{18.302}$$

Figure 18.32: (code) (Left) Scheme of a linear cavity. (Right) Radial profiles of the lowest order transverse Hermite-Gaussian modes TEM_{mn} of a linear cavity.

We now consider the cavity of length L schematized in Fig. 18.32. It consists of two mirrors with radii of curvature ρ_a and ρ_b. The transfer matrix for a round-trip beginning and ending at the position of mirror 'a' is,

$$\begin{aligned}\mathcal{M} &= \begin{pmatrix} 1 & 0 \\ -1/f_a & 1 \end{pmatrix}\begin{pmatrix} 1 & L \\ 0 & 1 \end{pmatrix}\begin{pmatrix} 1 & 0 \\ -1/f_b & 1 \end{pmatrix}\begin{pmatrix} 1 & L \\ 0 & 1 \end{pmatrix} \\ &= \frac{1}{f_a f_b}\begin{pmatrix} f_a(f_b - L) & f_a L(2f_b - L) \\ L - f_b - f_a & L(L - 2f_b) + f_a(f_b - L) \end{pmatrix} \ ,\end{aligned} \tag{18.303}$$

where $f_k = -\rho_k/2$ are the focal lengths of the mirrors. With (18.302) we obtain the diameter w_a and the radius of curvature R_a of the beam at the position of the mirror 'a',

$$w_a^2 = \frac{2\lambda f_a L(2f_b - L)}{\pi\sqrt{4f_a^2 f_b^2 - (L^2 - 2f_a L - 2f_b L + 2f_a f_b)^2}} \qquad \text{and} \qquad R_a = -2f_a \ . \tag{18.304}$$

Applying the second equation (18.289), we find,

$$\frac{\lambda a}{\pi w_0^2} = \frac{\pi w_a^2}{\lambda R_a} = \frac{L(2f_b - L)}{\sqrt{4f_a^2 f_b^2 - (L^2 - 2f_a L - 2f_b L + 2f_a f_b)^2}} \,, \tag{18.305}$$

and analogously for $\lambda b/\pi w_0^2$. We replace $f_k = \rho_k/2$ and introduce the abbreviation,

$$x_a \equiv \frac{\pi w_a^2}{\lambda R_a} = \frac{\frac{2L}{\rho_a}\left(1 - \frac{L}{\rho_b}\right)}{\sqrt{1 - \left(1 - \frac{2L}{\rho_a} - \frac{2L}{\rho_b} + \frac{2L^2}{\rho_a \rho_b}\right)^2}} \,, \tag{18.306}$$

and analogously for x_b. With the help of MAPLE we calculate,

$$\frac{x_a x_b - 1}{\sqrt{(1 + x_a^2)(1 + x_b^2)}} = \sqrt{1 - \frac{L}{\rho_a}}\sqrt{1 - \frac{L}{\rho_b}} \,. \tag{18.307}$$

The phase shift between the waist of the beam and mirror 'a' is given by the real part of the formula (18.292). The phase shift accumulated between the mirrors 'a' and 'b' is,

$$\begin{aligned} \varphi &= \varphi_a + \varphi_b = \arctan x_a + \arctan x_b \\ &= \pi - \arccos \frac{x_a x_b - 1}{\sqrt{1 + x_a^2}\sqrt{1 + x_b^2}} = \pi - \arccos \sqrt{1 - \frac{L}{\rho_a}}\sqrt{1 - \frac{L}{\rho_b}} \,, \end{aligned} \tag{18.308}$$

where we used tabulated trigonometric relationships to convert the arctan into a arccos.

The spectrum of transverse modes follows from the condition, that the total phase is a multiple of π, i.e.,

$$N = \frac{kL + \varphi}{\pi} = \frac{2L\nu}{c} + \frac{\varphi}{\pi} \,, \tag{18.309}$$

that is,

$$\boxed{\frac{\nu}{\delta_{fsr}} = N - 1 + \frac{1}{\pi} \arccos \sqrt{\left(1 - \frac{L}{\rho_a}\right)\left(1 - \frac{L}{\rho_b}\right)}} \,, \tag{18.310}$$

where we used the *free spectral range* $\delta_{fsr} \equiv c/2L$. This formula represents a generalization of the previously derived formula (18.262), which only holds in the limit of plane waves, $\rho_k \to \infty$.

The diameter of the beam waist in the cavity is,

$$w_0 = \sqrt[4]{\left(\frac{\lambda}{\pi}\right)^2 \frac{L(\rho_a - L)(\rho_b - L)(\rho_a + \rho_b - L)}{(\rho_a + \rho_b - 2L)^2}} \,. \tag{18.311}$$

For optimum coupling, the geometries of the Gaussian light beam and of the cavity must be matched, i.e. the diameter and divergence of the laser beam must be adjusted to the cavity mode, e.g. using a suitable arrangement of lenses. In Exc. 18.4.4.4, we will extend the calculation to ring cavities.

18.4.1.3 Hermite-Gaussian transverse modes

We can generalize the ansatz (18.282) to allow for more complicated radial intensity distributions described by the functions g and h,

$$\psi = g\left(\frac{x}{w}\right) h\left(\frac{y}{w}\right) e^{-\imath\left[\varphi(z)+k(x^2+y^2)/2q(z)\right]} \,. \tag{18.312}$$

Inserting the ansatz into the equation (18.281), we will show in Exc. 18.4.4.5, that the solution is given by,

$$\psi(x,y,z) = \frac{w_0}{w} H_m\left(\frac{\sqrt{2}x}{w}\right) H_n\left(\frac{\sqrt{2}y}{w}\right) e^{\imath(m+n+1)\arctan\frac{2z}{kw_0^2} - r^2\left(\frac{1}{w^2}+\frac{\imath k}{2R}\right)} \,. \tag{18.313}$$

Fig. 18.32(right) shows radial profiles of the lowest order transverse Hermite-Gaussian modes TEM_{mn} of a linear cavity.

In the presence of higher-order transverse modes TEM_{mn} the cavity spectrum becomes,

$$\boxed{\frac{\nu}{\delta_{fsr}} = N - 1 + \frac{m+n+1}{\pi} \arccos\sqrt{\left(1-\frac{L}{\rho_a}\right)\left(1-\frac{L}{\rho_b}\right)}} \,. \tag{18.314}$$

This formula can be derived using the self-consistency requirement for the light beam circulating inside the cavity. It represents yet another generalization of the formula (18.262) and lifts the degeneracy of the longitudinal modes described by the Airy formula and exhibited in Fig. 18.28. On the other hand, a *confocal cavity* with degenerate transverse modes, $\rho_a = \rho_b = L$, is particularly suited to work as a spectrum analyzer, as we will show in Exc. 53.1.10.8.

18.4.1.4 Splitting of TEM_{mn} modes having the same $m+n$

In a cylindrically symmetric mode, all modes TEM_{mn} with the same $m+n$ are degenerate. If however cylindrical symmetry is broken, e.g. due to alignment imperfection or in the case of a ring cavity, the degeneracy is lifted [1203]. If the problem of tilted incidence of the beams onto a mirror surface can be boiled down to assuming elliptically shaped mirrors, i.e. mirrors having different radii of curvatures in two orthogonal axis, the different phase shifts for the two axis can be calculated, as discussed in Exc. 18.4.4.4 and in Ref. [430]:

$$\nu/\delta_{fsr} = (q+1) + 2\frac{2m+1}{2\pi}\phi_h + 2\frac{2n+1}{2\pi}\phi_v \,. \tag{18.315}$$

where $\phi_k = \arccos\sqrt{\left(1-\frac{2a}{\rho_k}\right)\left(1-\frac{b}{\rho_k}\right)}$ for $k = h, v$. The splitting between the TEM_{01} and TEM_{10} modes is,

$$\tfrac{2}{\pi}\arccos\sqrt{\left(1-\tfrac{2a}{\rho_h}\right)\left(1-\tfrac{b}{\rho_h}\right)} - \tfrac{2}{\pi}\arccos\sqrt{\left(1-\tfrac{2a}{\rho_v}\right)\left(1-\tfrac{b}{\rho_v}\right)} \,. \tag{18.316}$$

The splitting observed for ring cavities is on the same order as the free spectra range.

Furthermore, different phase shifts in the dielectric surfaces lead to different resonance conditions [800]. Since, according to Fresnel's formulas, s and p-polarized light fields have different reflectivities under inclined incidence on mirrors, they also suffer different phase shifts and, hence, exhibit different eigenfrequencies of the cavity. In high-finesse ring cavities this leads to a dramatic splitting of s and p-polarized modes, which can be on the order of the free spectral range itself.

18.4.2 Non-Gaussian beams

The Hermite-Gaussian ansatz (18.312) to solve the wave equation represents only one possibility. But we nowadays know a large variety of beams with different transverse distributions of intensity, polarization and angular momentum. Examples are transverse Gaussian modes with Cartesian or circular symmetry, Bessel modes, Laguerre-Gaussian modes with angular momentum, and modes with radial or azimuthal polarization.

18.4.2.1 Bessel beams

Ideally, a *Bessel beam* (BB) is a non-diffracting monochromatic solution to the scalar wave equation in cylindrical coordinates carrying an infinite amount of energy [401, 863]. Inserting into the wave equation,

$$\left(\frac{1}{c^2}\frac{\partial^2}{\partial t^2} - \nabla^2\right)\psi(\mathbf{r},t) = 0 \tag{18.317}$$

the ansatz,

$$\psi(\mathbf{r},t) = e^{\imath(\beta z-\omega t)}\int_0^{2\pi} A(\phi)e^{\imath\alpha(x\cos\phi+y\sin\phi)}d\phi \ , \tag{18.318}$$

we get the dispersion relation,

$$\alpha^2+\beta^2 = \frac{\omega^2}{c^2} \ . \tag{18.319}$$

For β real the intensity profile does not vary along the z-axis,

$$|\psi(\mathbf{r},t)|^2 = \left|\int_0^{2\pi} A(\phi)e^{\imath\alpha(x\cos\phi+y\sin\phi)}d\phi\right|^2 = |\psi(x,y,z=0,t)|^2 \ . \tag{18.320}$$

For axial symmetry $A(\phi)=A$, we get what is called the 2^{st} type 0-order Bessel beam,

$$\psi(\mathbf{r},t) = Ae^{\imath(\beta z-\omega t)}\int_0^{2\pi} e^{\imath\alpha(x\cos\phi+y\sin\phi)}d\phi = Ae^{\imath(\beta z-\omega t)}J_0(\alpha\rho) \ . \tag{18.321}$$

For $0<\alpha\leq\omega/c$ we get a non-trivial solution decaying like $(\alpha\rho)^{-1}$.

In its simplest form, the electric field of an arbitrary ν-th order BB with wavelength λ can be written as,

$$\mathcal{E}(\rho,\phi,z) = A_0\exp(\imath k_z z)J_\nu(k_\rho\rho)\exp(\imath\nu\phi) \ , \tag{18.322}$$

where A_0 is the electric field strength and J_ν is the ν-th order Bessel function of the first kind. In Eq. (18.322), k_z and k_ρ are the longitudinal and transverse wave numbers satisfying the dispersion relation $k^2 = k_z^2 + k_\rho^2 = (2\pi/\lambda)^2$, such that $k_z = k\cos\theta$ and $k_\rho = k\sin\theta$, being θ the axicon angle associated to the tilted plane of waves propagating along the surface of a cone of half-angle θ in the angular spectrum decomposition. Cylindrical coordinates (ρ, ϕ, z) have been adopted, and a time harmonic factor $e^{\imath\omega t}$ has been omitted for brevity. For our purposes, the Rayleigh range is an essential parameter to be considered since the non-diffracting beam must propagate through a 20 cm long differential vacuum tube to minimize losses of atoms during their guidance to the science chamber. The maximum propagation distance up to which a BB can overcome diffraction is given by $Z_{max} = 2\pi R\bar{r}/\lambda$, where R is the aperture radius and $\bar{r}$ is the beam radius [401]. It should be noticed that, in general, Z_{max} is much greater than the Rayleigh range of a Gaussian beam with an equivalent beam waist radius $w_g = \bar{r}$.

Example 112 (*Frozen Bessel beams*): Certain superposition of these non-diffracting Bessel beams have interesting properties,

$$\psi(\mathbf{r}, t) = e^{-\imath\omega t} \sum_{n=-N}^{N} A_n J_0(k_{\rho n}\rho) e^{\imath\beta_n z} \ . \tag{18.323}$$

A *frozen Bessel beam* can be constructed by a continuous superposition of 0^{th}-order scalar BBs over the longitudinal wavenumber k_z, as given by the following integral solution of the scalar Helmholtz equation with azimuthal symmetry,

$$\Psi_0(\rho, z, t) = e^{-\imath\omega t} \int_{-k}^{k} S(k_z) J_0(\rho\sqrt{k^2 - k_z^2}) e^{-\imath k_z z} dk_z \ , \tag{18.324}$$

where $k \equiv \omega/c$ and $k_\rho^2 \equiv \omega^2/c^2 - k_z$ is the transverse wave number. The quantity k_ρ^2 must be positive since evanescent waves do come into play.
Higher-order Bessel beams can be constructed via [1422, 1421],

$$\Psi_1(\rho, \phi, z) = \mathcal{U}\Psi_0(\rho, z) \qquad \text{with} \qquad \mathcal{U} \equiv e^{\imath\phi}\left(\frac{\partial}{\partial\rho} + \frac{\imath}{\rho}\frac{\partial}{\partial\phi}\right) \ , \tag{18.325}$$

Apparently, they can carry angular orbital momentum.

18.4.3 Fourier optics

We have derived in Sec. 5.3.5 the Fresnel integral for the description of the propagation of phase fronts. In the following sections we will show that the expression can also be derived from the more general Huygens principle, and how they can be used for numerical calculations of phase front propagation. We will also show how it can be used for numerical calculations of phase front propagation.

18.4.3.1 Rayleigh-Sommerfeld solution

We consider the propagation of monochromatic light from a 2D planar source of area Σ indicated by the coordinates ξ and η, as illustrated in Fig. 18.33. The field distribution in the source plane is given by $\psi_0(\xi, \eta)$, and the field $\psi_z(x, y)$ in a distant

observation plane can be predicted using the first Rayleigh-Sommerfeld diffraction solution [521, 1338],

$$\boxed{\psi_z(x,y) = \frac{1}{\imath\lambda}\iint_\Sigma \frac{z}{r_{12}}\frac{e^{\imath k r_{12}}}{r_{12}}\psi_0(\xi,\eta)d\xi d\eta} \ . \tag{18.326}$$

The formula will be derived from the wave equation in Exc. 18.4.4.6. Here, z is the distance between the centers of the source and observation coordinate systems and

$$r_{12} = \sqrt{z^2 + (x-\xi)^2 + (y-\eta)^2} \tag{18.327}$$

is the distance between a position on the source plane and a position in the observation plane, with the planes assumed to be parallel.

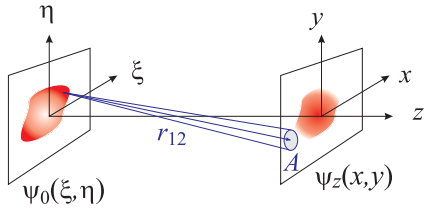

Figure 18.33: Propagation geometry for parallel source and observation planes. Every point of the source plane generates a spherical wave $\propto e^{\imath k r_{12}}/r_{12}$. The projection of the field within a solid angle element onto the xy-plane, which is proportional to z/r_{12} generates a new spherical wave propagating further along the z optical axis.

Expression (18.326) is a statement of the *Huygens-Fresnel principle*, which supposes that the source acts as an infinite collection of fictitious point sources located at (ξ,η), each one producing a spherical wave. The interference of the spherical waves at any observation position (x,y), expressed by the projection onto the propagation axis z in (18.326), can be written as a two-dimensional convolution integral,

$$\psi_z(x,y) = \iint_\Sigma h_z(x-\xi, y-\eta)\psi_0(\xi,\eta)d\xi d\eta = (h_z * \psi_0)(x,y) \ , \tag{18.328}$$

where the general form of the *Rayleigh-Sommerfeld impulse response*,

$$h_z(x,y) = \frac{z}{\imath\lambda}\frac{e^{\imath k r}}{r^2} \ , \tag{18.329}$$

where $r = \sqrt{z^2+x^2+y^2}$ is simply the field distribution $\psi_z(x,y)$ observed in case of a point-like source $\psi_0(\xi,\eta) = \delta(\xi)\delta(\eta)$.

The Fourier convolution theorem allows to write Eq. (18.328) as,

$$\psi_z(x,y) = \mathcal{F}^{-1}\{\mathcal{F}[h_z * \psi_0](x,y)\} = \mathcal{F}^{-1}\{\mathcal{F}[h_z(x,y)]\mathcal{F}[\psi_0(x,y)]\} \ , \tag{18.330}$$

where $\mathcal{F}$ denotes the two-dimensional Fourier transform. Introducing the *Rayleigh-Sommerfeld transfer function* H_z, we may also write,

$$\boxed{\begin{array}{rcl} \psi_z(x,y) & = & \mathcal{F}^{-1}\{H_z(f_x,f_y)\cdot\mathcal{F}[\psi_0(x,y)]\} \\ \text{where} \quad H_z(f_x,f_y) & = & e^{\imath k z\sqrt{1-(\lambda f_x)^2-(\lambda f_y)^2}} \end{array}} \ . \tag{18.331}$$

Strictly speaking, $\sqrt{f_x^2 + f_y^2} < \lambda^{-1}$ must be satisfied for propagating field components. The Rayleigh-Sommerfeld expression is the most accurate diffraction solution as, other than the assumption of scalar diffraction, this solution only requires that $r \gg \lambda$, the distance between the source and the observation position, be much greater than a wavelength.

18.4.3.2 Fresnel approximation

Let us simplify the transfer function by expanding the distance (18.327),

$$r_{12} \simeq z + \tfrac{1}{2}\tfrac{(x-\xi)^2}{z} + \tfrac{1}{2}\tfrac{(y-\eta)^2}{z} \ , \tag{18.332}$$

which amounts to assuming a parabolic radiation wave rather than a spherical wave for the fictitious point sources. Furthermore, we use the approximation $r_{12} \simeq z$ in the denominator of Eq. (18.326) to arrive at the Fresnel diffraction expression:

$$\boxed{\psi_z(x,y) = \frac{e^{\imath kz}}{\imath\lambda z} \iint\limits_{\Sigma} e^{\imath k[(x-\xi)^2+(y-\eta)^2]/2z} \psi_0(\xi,\eta) d\xi d\eta} \ . \tag{18.333}$$

This expression is also a convolution of the form in Eq. (18.328), where the impulse response is,

$$h_z(x,y) = \frac{e^{\imath kz}}{\imath\lambda z} e^{\imath k\rho^2/2z} \ , \tag{18.334}$$

and the transfer function is,

$$H_z(f_x, f_y) = e^{\imath kz} e^{-\imath\pi z\lambda(f_x^2+f_y^2)} \ . \tag{18.335}$$

The expressions in Eqs. (18.331) are again applicable in this case for computing diffraction results.

Another useful form of the Fresnel diffraction expression is obtained by moving the quadratic phase term in x and y outside the integrals:

$$\psi_z(x,y) = \frac{e^{\imath kz}}{\imath\lambda z} e^{\imath k(x^2+y^2)/2z} \iint\limits_{\Sigma} e^{\imath k(\xi^2+\eta^2)/2z} e^{-\imath k(x\xi+y\eta)/z} \psi_0(\xi,\eta) d\xi d\eta \ . \tag{18.336}$$

18.4.3.3 Fraunhofer approximation

Fraunhofer diffraction, which refers to diffraction patterns in a regime that is commonly known as the 'far field', is arrived at by approximating the chirp term multiplying the initial field within the integrals of Eq. (18.336) as unity. The assumption involved is,

$$z \gg \max[\tfrac{k}{2}(\xi^2 + \eta^2)] \tag{18.337}$$

and results in the Fraunhofer diffraction expression:

$$\boxed{\begin{aligned} \psi_z(x,y) &= \frac{e^{\imath kz}}{\imath\lambda z} e^{\imath k\rho^2/2z} \iint\limits_{\Sigma} e^{-\imath k(x\xi+y\eta)/z} \psi_0(\xi,\eta) d\xi d\eta \\ &= \frac{e^{\imath kz}}{\imath\lambda z} e^{\imath\frac{k}{2z}\rho^2} (\mathcal{F}\psi_0)(\tfrac{kx}{z}, \tfrac{ky}{z}) \end{aligned}} \ . \tag{18.338}$$

Along with multiplicative factors out front, the Fraunhofer expression can be recognized simply as a Fourier transform of the source field. The condition of Eq. (18.337), typically, requires very long propagation distances relative to the source support size. However, a form of the Fraunhofer pattern also appears in the propagation analysis involving lenses. The Fraunhofer diffraction expression is a powerful tool and finds use in many applications such as laser beam propagation, image analysis, and spectroscopy.

The Fraunhofer expression cannot be written as a convolution integral, so there is no impulse response or transfer function. But, since it is a scaled version of the Fourier transform of the initial field, it can be relatively easy to calculate, and as with the Fresnel expression, the Fraunhofer approximation is often used with success in situations where Eq. (18.337) is not satisfied. For simple source structures such as a plane-wave illuminated aperture, the Fraunhofer result can be useful even when Eq. (18.337) is violated by more than a factor of 10, particularly if the main quantity of interest is the irradiance pattern at the receiving plane. Using the *Fresnel number* defined as,

$$N_F = \frac{\max(\xi^2 + \eta^2)}{z\lambda} \ , \tag{18.339}$$

the commonly accepted requirement for the Fraunhofer region is $N_F \ll 1$.

18.4.3.4 Propagation of phase fronts across optical elements

To propagate an optical phase front located at z_0, we conveniently start from a Gaussian laser beam,

$$\psi_{Gauss}(\rho) = e^{-\rho^2/w_0^2} \ . \tag{18.340}$$

with $\rho = \sqrt{x^2 + y^2}$ the distance from the optical axis. For a given total power the electric field is obtained via normalization,

$$\mathcal{E}_0 = \sqrt{\frac{P}{\frac{1}{2}\varepsilon_0 c \int |u|^2 d^2\rho}} \ , \tag{18.341}$$

where $\eta \equiv \sqrt{\mu_0/\varepsilon_0} = 1/(\varepsilon_0 c)$ is the vacuum impedance.

Optical elements can shape the phase front of a light beam by phase shift or absorption. If the element can be assumed to be thin we may neglect the axial displacement, $\Delta z \simeq 0$, and simply multiply the phase front with an xy-matrix,

$$\boxed{\psi'_z(x,y) = e^{-\alpha_{component}(x,y)}\psi_z(x,y)} \ , \tag{18.342}$$

where $\alpha(x,y) = \sigma(x,y) + \imath\delta(x,y)$. For instance, a *pinhole* with radius R will transform a phase front like,

$$\alpha_{pinhole}(\rho) = \infty\Theta(\rho - R) \ , \tag{18.343}$$

where Θ is the Heavyside function. A *thin lens* with focal distance f will transform a phase front like,

$$\alpha_{lens}(\rho) = \imath\tfrac{k}{R}\rho^2 = \imath\tfrac{k}{2f}\rho^2 \ , \tag{18.344}$$

where R is the radius of the spherical lens. For an *axicon* of base angle α made of material with refractive index n_{refr},

$$\alpha_{axicon}(\rho) = \imath k(n_{refr} - 1)\rho \tan\alpha \ . \tag{18.345}$$

In Exc. 18.4.4.9 we will derive the phase front transformation matrices for other interesting optical components. We will do a numerical simulation in 18.4.4.10.

18.4.4 Exercises

18.4.4.1 Ex: Gaussian light mode

The light of a laser propagates in light modes called Gaussian. A beam propagating along $\hat{\mathbf{e}}_z$ and linearly polarized along $\hat{\mathbf{e}}_x$ is described by the potential vector, $\mathbf{A}(\mathbf{r},t) = \hat{\mathbf{e}}_x u(\mathbf{r}) e^{\imath(\omega t - kz)}$, where $u(\mathbf{r}) = \frac{u_0}{w(z)} e^{-(x^2+y^2)/w(z)^2}$ is the energy density and $w(z) = w_0\sqrt{1 + (\lambda z/\pi w_0^2)^2}$ the diameter of the beam at the position z. Calculate the Poynting vector in the Lorentz gauge, $\Phi = -\frac{c^2}{\imath\omega}\nabla\cdot\mathbf{A}$.

Solution: *First, we define as an abbreviation the Rayleigh length, $z_R \equiv \pi w_0^2/\lambda$. With this, we calculate the derivative of the waist $w = w(z)$,*

$$\frac{\partial w}{\partial z} = w_0 \frac{\partial}{\partial z}\sqrt{1 + (z/z_R)^2} = \frac{w_0}{\sqrt{1 + (z/z_R)^2}} \frac{z}{z_R^2} = \frac{w_0^2 z}{w z_R^2} = \frac{2z}{k w z_R} \equiv \mathcal{D} \ .$$

The gradient of the mode $u = u(x,y,z)$ now is,

$$\nabla u = \begin{pmatrix} \partial_x \\ \partial_y \\ \partial_z \end{pmatrix} \frac{u_0}{w} e^{-(x^2+y^2)/w^2} = \begin{pmatrix} \frac{-2x}{w^2}\frac{u_0}{w} e^{-\rho^2/w^2} \\ \frac{-2y}{w^2}\frac{u_0}{w} e^{-\rho^2/w^2} \\ u_0 e^{-\rho^2/w^2}\frac{-1}{w^2}\mathcal{D} + \frac{u_0}{w} e^{-\rho^2/w^2}\rho^2\frac{2}{w^3}\mathcal{D} \end{pmatrix} = -\begin{pmatrix} 2\tilde{x}\tilde{u} \\ 2\tilde{y}\tilde{u} \\ \mathcal{D}(1 - 2\tilde{\rho}^2)\tilde{u} \end{pmatrix} ,$$

where we defined normalized coordinates $\tilde{\rho} \equiv \rho/w$, $\tilde{u} \equiv u/w$ and $\tilde{z} \equiv z/z_R$. Within the Lorentz gauge we can calculate the scalar potential,

$$\Phi = -\frac{c^2}{\imath\omega}\nabla\cdot\mathbf{A} = -\frac{c^2}{\imath\omega}\nabla\cdot[\hat{\mathbf{e}}_x u e^{\imath(\omega t - kz)}] = -\frac{c^2}{\imath\omega} e^{\imath(\omega t - kz)}\frac{\partial u}{\partial x} = \frac{c^2}{\imath\omega} 2\tilde{x}\tilde{u} e^{\imath(\omega t - kz)} \ .$$

The magnetic field is,

$$\vec{\mathcal{B}} = \nabla\times\mathbf{A} = \begin{pmatrix} 0 \\ \frac{\partial}{\partial z}[u e^{\imath(\omega t - kz)}] \\ -\frac{\partial}{\partial y}[u e^{\imath(\omega t - kz)}] \end{pmatrix} = \begin{pmatrix} 0 \\ -\imath k w - \mathcal{D}(1 - 2\tilde{\rho}^2) \\ 2\tilde{y} \end{pmatrix} \tilde{u} e^{\imath(\omega t - kz)} \ .$$

The electric field is,

$$\begin{aligned}\vec{\mathcal{E}} &= -\nabla\Phi = -\frac{c^2}{\imath\omega}\begin{pmatrix}\partial_x\\ \partial_y\\ \partial_z\end{pmatrix}\frac{2xu}{w^2}e^{\imath(\omega t-kz)}\\ &= -\frac{c^2}{\imath\omega}\begin{pmatrix}\frac{e^{\imath(\omega t-kz)}}{w^2}\left(2u+2x\frac{\partial u}{\partial x}\right)\\ \frac{e^{\imath(\omega t-kz)}}{w^2}2x\frac{\partial u}{\partial y}\\ 2x\left(\frac{1}{w^2}u\frac{\partial}{\partial z}e^{\imath(\omega t-kz)}+\frac{e^{\imath(\omega t-kz)}}{w^2}\frac{\partial u}{\partial z}+ue^{\imath(\omega t-kz)}\frac{\partial}{\partial z}\frac{1}{w^2}\right)\end{pmatrix}\\ &= -\frac{c^2}{\imath\omega}\frac{2\tilde{u}e^{\imath(\omega t-kz)}}{w}\begin{pmatrix}1-2\tilde{x}^2\\ -2\tilde{x}\tilde{y}\\ -\imath kx-\tilde{x}(3-2\tilde{\rho}^2)\mathcal{D}\end{pmatrix}.\end{aligned}$$

Finally, we can derive the vector of Poynting,

$$\vec{\mathcal{S}} = \tfrac{1}{\mu_0}\vec{\mathcal{E}}\times\vec{\mathcal{B}}^* = -\frac{1}{\mu_0}\frac{c^2}{\imath\omega}2\tilde{u}^2\begin{pmatrix}-4xy^2-[-\imath kx-x(3-2\rho^2)\mathcal{D}][-\imath kw-\mathcal{D}(1-2\rho^2)]\\ -2(1-2x^2)y\\ (1-2x^2)[-\imath kw-\mathcal{D}(1-2\rho^2)]\end{pmatrix}.$$

On the optical axis,

$$\vec{\mathcal{S}} = -\hat{\mathbf{e}}_z\frac{1}{\mu_0}\frac{c^2}{\imath\omega}2\tilde{u}^2\imath kw \xrightarrow{z=0} -\hat{\mathbf{e}}_z\frac{c}{\mu_0}2\tilde{u}^2w\ .$$

In the focal plane,

$$\vec{\mathcal{S}} = -\frac{1}{\mu_0}\frac{c^2}{\imath\omega}2\tilde{u}^2\begin{pmatrix}-4xy^2+k^2xw\\ -2(1-2x^2)y\\ (1-2x^2)(-\imath kw)\end{pmatrix}.$$

We integrate radially,

$$P = \int_{\mathbb{R}^2}\vec{\mathcal{S}}\cdot d\mathbf{A} = xxx\ .$$

18.4.4.2 Ex: Volume and power of a Gaussian beam mode

a. Derive the expression for the mode volume V_m of a Gaussian beam of length L from the definition $I(0)V_m = \int I(\mathbf{r})dV$.
b. In quantum mechanics we learn, that the zero point energy of the harmonic oscillator is $\hbar\omega/2$. Use this notion to calculate the maximum electric field amplitude $\mathcal{E}_1(0)$ created by a single photon in terms of the mode volume.
c. A linear cavity of length L has the free spectral range $\delta_{fsr} = c/2L$. Express the

power of the beam in terms of the number of photons contained in the cavity.

Solution: *a. The intensity distribution in a Gaussian mode is,*

$$I(\mathbf{r}) = \frac{2P}{\pi w^2(z)} e^{-2\rho^2/w^2(z)} \qquad with \qquad w(z) = w_0 \sqrt{1 + \left(\frac{\lambda z}{\pi w_0^2}\right)^2} \ .$$

With this, we calculate,

$$V_m = \frac{1}{I(0)} \int I(r) dV = \int_0^L \int_0^\infty \frac{w_0^2}{w^2(z)} e^{-2\rho^2/w^2(z)} 2\pi\rho d\rho dz = \frac{\pi}{2} L w_0^2 \ .$$

b. The intensity is related to the electric field $\vec{\mathcal{E}}_1$ generated by a single photon and to the number of photons n by,

$$I(\mathbf{r}) = n\varepsilon_0 c \vec{\mathcal{E}}_1^2(\mathbf{r}) \ .$$

With this, we calculate the zero point energy,

$$\frac{\hbar\omega}{2} = \int u_1(\mathbf{r}) dV = \int \frac{I_1(\mathbf{r})}{c} dV = \frac{1}{c} I_1(0) V_m \ .$$

Hence,

$$\mathcal{E}_1(0) = \sqrt{\frac{I_1(0)}{\varepsilon_0 c}} = \sqrt{\frac{1}{\varepsilon_0 c} \frac{\hbar\omega}{2} \frac{c}{V_m}} = \sqrt{\frac{\hbar\omega}{2\varepsilon_0 V_m}} \ .$$

c. We get,

$$P = \frac{\pi w_0^2 I(0)}{2} = \frac{\pi w_0^2}{2} n\varepsilon_0 c \mathcal{E}_1(0)^2 = \frac{\pi w_0^2}{2} n\varepsilon_0 c \frac{\hbar\omega}{2\varepsilon_0 V_m} = \frac{\pi w_0^2}{2} n\varepsilon_0 c \frac{\hbar\omega}{2\varepsilon_0} \frac{2}{L\pi w_0^2} = n\hbar\omega\delta_{fsr} \ .$$

18.4.4.3 Ex: The lens in ray and wave optics

a. Use the transfer matrices (18.298) and (18.299) to derive the lens equations of geometric optics from the relation (18.296).
b. Now, use the transfer matrices (18.298) and (18.299) to derive, from the relation (18.296), the transformation of a Gaussian beam. How do the waists behave upon transformation?
c. You have a laser of $\lambda = 632\,\text{nm}$ wavelength producing a Gaussian beam of diameter $w_1 = 1\,\text{mm}$ in its waist. Now, you want to match the beam into a cavity, whose mode (defined by the radii of curvature of the mirrors) has a waist of diameter $w_2 = 100\,\mu\text{m}$. To do this, you have at your disposal a lens of $f = 500\,\text{mm}$ focal distance. Using the formulas derived in (b), determine, how the distances d_1 (between the location of the waist of the laser beam and the lens) and d_2 (between the lens and the location of the waist of the cavity) must be chosen.

Solution: *a. We concatenate the matrices for free propagation by a distance d_1,*

for the transformation of the beam by a lens with focal distance f, and another free propagation by a distance d_2,

$$\mathcal{M} = \begin{pmatrix} 1 & d_2 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ -1/f & 1 \end{pmatrix} \begin{pmatrix} 1 & d_1 \\ 0 & 1 \end{pmatrix} = \begin{pmatrix} 1 - d_2/f & d_1 + d_2 - d_1 d_2/f \\ -1/f & 1 - d_1/f \end{pmatrix} .$$

An image forms when the element M_{12} vanishes,

$$\mathcal{M} = \begin{pmatrix} -d_2/d_1 & 0 \\ -1/f & -d_1/d_2 \end{pmatrix} ,$$

implying,

$$\boxed{\frac{1}{f} = \frac{1}{d_1} + \frac{1}{d_2} \qquad \textit{and} \qquad \frac{y_2}{y_1} = -\frac{d_2}{d_1}} .$$

b. We concatenate the same matrices as in (a), but now we consider the beam parameter, which transforms like,

$$q_2 = \frac{M_{11} q_1 + M_{12}}{M_{21} q_1 + M_{22}} = \frac{(1 - d_2/f) q_1 + d_1 + d_2 - d_1 d_2/f}{-q_1/f + 1 - d_1/f} .$$

We assume that at the positions $d_{1,2}$ the beam has waists, such that $R_{1,2} = \infty$,

$$q_{1,2} = \frac{\imath \pi w_{1,2}^2}{\lambda} .$$

With this we obtain the condition,

$$\frac{\imath \pi w_2^2}{\lambda} \left(-\frac{\imath \pi w_1^2}{\lambda f} + 1 - \frac{d_1}{f} \right) = \left(1 - \frac{d_2}{f} \right) \frac{\imath \pi w_1^2}{\lambda} + d_1 + d_2 - \frac{d_1 d_2}{f} ,$$

or separating the real and imaginary parts,

$$\boxed{\frac{k^2 w_1^2 w_2^2}{4 f d_1 d_2} = \frac{1}{d_1} + \frac{1}{d_2} - \frac{1}{f} \qquad \textit{and} \qquad \frac{w_2^2}{w_1^2} = \frac{d_2 - f}{d_1 - f}} .$$

c. Solving the two formulas derived in (b) by d_2,

$$d_2 = \frac{k^2 w_1^2 w_2^2 - 4 f d_1}{4 f - 4 d_1} \qquad \textit{and} \qquad d_2 = f + (d_1 - f) \frac{w_2^2}{w_1^2} .$$

Solving the difference between the two formulas by d_1 and inserting this in the first formula,

$$(d_1 - f)^2 \frac{w_2^2}{w_1^2} = f^2 - \frac{k^2 w_1^2 w_2^2}{4} = (d_2 - f)^2 \frac{w_1^2}{w_2^2} .$$

For the given values we calculate,

$$d_1 = 1039\,\mathrm{mm} \qquad \textit{and} \qquad d_2 = 505\,\mathrm{mm} .$$

18.4.4.4 Ex: Transverse modes of a ring cavity

In this exercise we consider a ring cavity made of a plane input coupler and two identical curved high-reflectors (radius of curvature $\rho = 2f$) forming an isosceles triangle. Let $a = L/(2+\sqrt{2})$ be the two short distances and $b = L/(1+\sqrt{2})$ the long one, so that $L = 2a + b$.
a. How many waists does the cavity modes have, and where are they located?
b. Derive the round-trip matrix starting from the location of any one of the waists.
c. Calculate the waists.
d. Calculate the transverse mode spectrum, and prepare a plot for $\rho = 30\,\mathrm{cm}$ and $L = 8.7\,\mathrm{cm}$.
e. The above results presume cylindrical symmetry. However, incidence on curved mirrors under a tilted angle θ produces astigmatism. This can be accounted for by assuming different radii of curvature for the horizontal and vertical axis:

$$R_h = R\cos\theta \qquad \text{and} \qquad R_v = R/\cos\theta\ . \tag{18.346}$$

Calculate the impact waist sizes in the horizontal and vertical axis.

Solution: *a. The cavity has two waists, one at the input coupler, w_a, the other in free space, w_b.*
b. When we start from the input coupler, the round-trip matrix is,

$$\begin{pmatrix} 1 & a \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ -1/f & 1 \end{pmatrix} \begin{pmatrix} 1 & b \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ -1/f & 1 \end{pmatrix} \begin{pmatrix} 1 & a \\ 0 & 1 \end{pmatrix}\ . \tag{18.347}$$

From it we determine the beam radius and the radius of curvature at the input coupler,

$$w_a^2 = \frac{2\lambda B}{\pi\sqrt{4-(A+D)^2}} = \frac{\lambda(2af^2-2abf-2a^2f+ba^2+bf^2)}{\pi\sqrt{f^4-(f^2-bf-2af+ba)^2}} \quad \textit{and} \quad R = \frac{2B}{D-A} = \infty\ . \tag{18.348}$$

One the other hand, when we start from the free space waist, the round-trip matrix is

$$\begin{pmatrix} 1 & b/2 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ -1/f & 1 \end{pmatrix} \begin{pmatrix} 1 & 2a \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ -1/f & 1 \end{pmatrix} \begin{pmatrix} 1 & b/2 \\ 0 & 1 \end{pmatrix}\ . \tag{18.349}$$

c. The beam radius and the radius of curvature in free space is given by

$$w_b^2 = \frac{2\lambda B}{\pi\sqrt{4-(A+D)^2}} = \frac{\lambda(2bf^2-b^2f-4abf+b^2a+4af^2)}{2\pi\sqrt{f^4-(f^2-bf-2af+ba)^2}} \quad \textit{and} \quad R = \frac{2B}{D-A} = \infty\ . \tag{18.350}$$

d. The round-trip phase shift is given by twice the phase shift between the input coupler and the free space waist,

$$\begin{aligned} \nu/\delta_{fsr} &= (q+1) + 2\phi_{mn}(a)/\pi + 2\phi_{mn}(b)/\pi \\ &= (q+1) + \frac{m+n+1}{\pi}\left(2\arctan\frac{\lambda a}{\pi w_a^2} + 2\arctan\frac{\lambda b/2}{\pi w_b^2}\right)\ , \end{aligned} \tag{18.351}$$

Using the identity

$$\arctan x + \arctan y = \arccos \frac{1 - xy}{\sqrt{(1+x^2)(1+y^2)}} \ , \tag{18.352}$$

after some algebraic manipulations aided by MAPLE be arrive at

$$\nu/\delta_{fsr} = (q+1) + 2\frac{m+n+1}{\pi} \arccos \sqrt{\left(1 - \frac{2a}{R}\right)\left(1 - \frac{b}{R}\right)} \ . \tag{18.353}$$

For $R = 30\,\mathrm{cm}$ and $L = 8.7\,\mathrm{cm}$ the transverse mode splitting in terms of the free

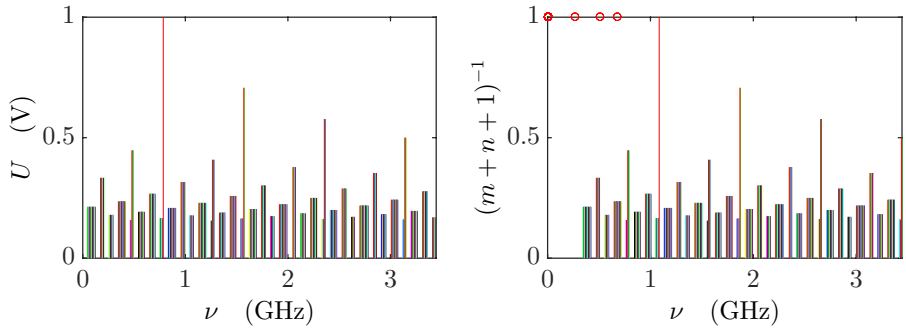

Figure 18.34: Transverse modes of a ring cavity. Top: high finesse, bottom: low finesse. The lifting of the $m+n$ degeneracy is indicated by a small (underestimated splitting).

spectral range is

$$\frac{2}{\pi} \arccos \sqrt{\left(1 - \frac{2a}{R}\right)\left(1 - \frac{b}{R}\right)} = 0.34 \ . \tag{18.354}$$

e.

18.4.4.5 Ex: Transverse Hermite-Gauss modes

Derive the spectrum of Hermite-Gauss transverse modes.

Solution: *We choose the ansatz,*

$$\psi = g\left(\frac{x}{w(z)}\right) h\left(\frac{y}{w(z)}\right) e^{-\imath[\varphi(z) + k(x^2+y^2)/2q(z)]} \ .$$

First, we note that the solution should work for $g = h = 1$, a case which has already been studied. The obtained results,

$$q' = 1 \qquad \textit{and} \qquad \varphi' = \frac{-\imath}{q} \ ,$$

can not depend on the choice of g and h and therefore can be used in the following. Inserting the ansatz into the equation (18.281) we calculate the derivatives,

$$\begin{aligned}
2\imath k\frac{\partial\psi}{\partial z} &= \left[2\imath k\left(-x\frac{g'}{g}-y\frac{h'}{h}\right)\frac{w'}{w^2}-\frac{2\imath k}{q}-\frac{k^2(x^2+y^2)}{q^2}\right]ghe^{-\imath[.]}\\
\frac{\partial}{\partial x}\psi &= \left(\frac{1}{w}g'-\frac{\imath kx}{q}g\right)he^{-\imath[.]}\\
\frac{\partial^2}{\partial x^2}\psi &= \left[\frac{1}{w^2}\frac{g''}{g}-\frac{2\imath kx}{qw}\frac{g'}{g}-\frac{k^2x^2}{q^2}-\frac{\imath k}{q}\right]ghe^{-\imath[.]}\ .
\end{aligned}$$

Now,

$$\begin{aligned}
0 &= 2\imath k\frac{\partial\psi}{\partial z}-\frac{\partial^2}{\partial x^2}\psi-\frac{\partial^2}{\partial y^2}\psi\\
&= \left[2\imath k\left(-x\frac{g'}{g}-y\frac{h'}{h}\right)\frac{w'}{w^2}-\frac{2\imath k}{q}-\frac{k^2(x^2+y^2)}{q^2}\right]-\left[\frac{1}{w^2}\frac{g''}{g}-\frac{2\imath kx}{qw}\frac{g'}{g}-\frac{k^2x^2}{q^2}-\frac{\imath k}{q}\right]-[...]\\
&= -\frac{1}{w^2}\frac{g''}{g}+\frac{2\imath kx}{w}\left(\frac{1}{q}-\frac{w'}{w}\right)\frac{g'}{g}-[...]\ .
\end{aligned}$$

hence we stay with,

$$C=-\frac{1}{w^2}\frac{g''}{g}+\frac{2\imath kx}{w}\left(\frac{1}{q}-\frac{w'}{w}\right)\frac{g'}{g}=-\frac{dg}{gdx}+2\imath kx\left(\frac{1}{q}-\frac{w'}{w}\right)\frac{dg}{gdx}\ ,$$

which must be valid for $z=0$, where $w=w_0$ and $w'=0$,

$$\frac{d^2g}{dx^2}-\frac{\imath k}{q_0}2x\frac{dg}{dx}+gC=\frac{d^2g}{dx^2}-\frac{2}{w_0^2}2x\frac{dg}{dx}+Cg=0\ .$$

This is already (almost) the differential equation of the Hermite polynomials,

$$\frac{d^2H_m(u)}{du^2}-2u\frac{dH_m(u)}{du}+2mH_m(u)=0\ ,$$

with $gh=H_m(\sqrt{2}x/w)H_m(\sqrt{2}y/w)$.

18.4.4.6 Ex: Derivation of the Rayleigh-Sommerfeld formula

Derive the Rayleigh-Sommerfeld formula (18.326).

Solution: *For any point $\mathbf{r}$ of an aperture we know that the function $\psi(\mathbf{r})$ satisfies the Helmholtz equation,*

$$(\nabla^2+k^2)\psi(\mathbf{r})=0\ .$$

There will also be a Green function that in a region $V=\{(x,y,z)|z>0\}$ which satisfies the equation:

$$(\nabla^2+k^2)G(\mathbf{r}-\mathbf{r}')=\delta^3(\mathbf{r}-\mathbf{r}')\ ,$$

where $\mathbf{r}'$ is an observation point in V. The solution of the latter equation is given by,

$$G(\mathbf{r}-\mathbf{r}') = -\frac{1}{4\pi}\frac{e^{\imath k|\mathbf{r}-\mathbf{r}'|}}{|\mathbf{r}-\mathbf{r}'|} \ . \tag{18.355}$$

Know we can write,

$$\psi(\mathbf{r}') = \int_V \psi(\mathbf{r})\delta^3(\mathbf{r}-\mathbf{r}')d^3r = \int_V \psi(\mathbf{r})(\nabla^2+k^2)G(\mathbf{r}-\mathbf{r}')d^3r \ .$$

We integrate the first term of the sum by parts,

$$\begin{aligned}\int_V \psi(\mathbf{r})\nabla^2 G d^3r &= \int_{\partial V}\psi(\mathbf{r})\nabla G\cdot d\mathbf{S} - \int_V \nabla\psi(\mathbf{r})\cdot\nabla G d^3r \\ &= \int_{\partial V}\psi(\mathbf{r})\nabla G\cdot d\mathbf{S} - \left[\int_{\partial V}\nabla\psi(\mathbf{r})\cdot G d\mathbf{S} - \int_V \nabla^2\psi(\mathbf{r})G d^3r\right] \ .\end{aligned}$$

Substituting this integral in the previous equation, we are left with,

$$\psi(\mathbf{r}') = \int_{\partial V}[\psi(\mathbf{r})\nabla G - \nabla\psi(\mathbf{r})]\cdot d\mathbf{S} + \cancelto{0}{\int_V(\nabla^2+k^2)\psi(\mathbf{r})G d^3r} \ .$$

Since $\nabla\psi$ is unknown and the integral is not null except at $z=0$, we look out for a Green function that is zero for $z\neq 0$, so that there is no need to worry about $\nabla\psi$, and the second term in the above equation vanishes. Defining a vector $\tilde{\mathbf{r}}' = (x', y', -z')$ outside the region V, we can write $G(\mathbf{r}-\mathbf{r}')$:

$$G(\mathbf{r}-\mathbf{r}') = -\frac{1}{4\pi}\frac{e^{\imath k|\mathbf{r}-\mathbf{r}'|}}{|\mathbf{r}-\mathbf{r}'|} + \frac{1}{4\pi}\frac{e^{\imath k|\mathbf{r}-\tilde{\mathbf{r}}'|}}{|\mathbf{r}-\tilde{\mathbf{r}}'|} \ .$$

Which is also a solution of the Eq. (18.355). Hence, at $z=0$, we get $|\mathbf{r}-\mathbf{r}'| = |\mathbf{r}-\tilde{\mathbf{r}}'|$, and therefore $G=0$ at $z=0$. The integral at the aperture Σ at $z=0$ becomes,

$$\psi(\mathbf{r}') = \int_\Sigma \psi(\mathbf{r})\partial_z G dS \ .$$

Knowing that the derivative is given by,

$$\frac{\partial G}{\partial z} = -\frac{1}{2\pi}\left(\imath k - \frac{1}{R}\right)\left(\frac{z}{R}\right)\frac{e^{\imath kR}}{R} \ .$$

We finally find the wave $\psi(\mathbf{r}')$,

$$\psi(\mathbf{r}') = -\frac{\imath k}{2\pi}\int_\Sigma \psi_{z=0}\left(\imath k - \frac{1}{R}\right)\frac{z}{R}\frac{e^{\imath kR}}{R}dS \ .$$

Using the approximation that $R \gg k$,

$$\psi(\mathbf{r}') \simeq -\frac{\imath k}{2\pi}\int_\Sigma \psi_0\frac{z}{R}\frac{e^{\imath kR}}{R}dS \ ,$$

and so we managed to propagate the beam given the initial beam for the entire V region.

18.4.4.7 Ex: Phasefront distorsion by an axicon and a thin lens

Calculate the phasefront distorsion suffered by a plane wave upon traversing (a) an axicon with base angle α and (b) a thin lens with focal length f.

Solution: *a. We consider an axicon with base angle α made of glas with refraction index n_{rfr} illuminated by a phase front of light with wavelength λ. The width w of the axicon depends on the distance r from the symmetry axis as,*

$$w = w_{max} - r\tan\alpha \ .$$

In a given time interval Δt the phase front travels by a distance depending on where

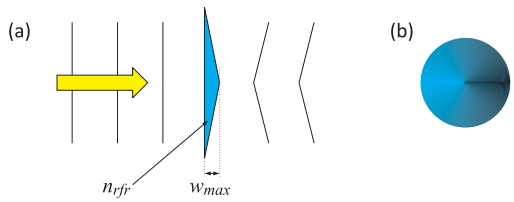

Figure 18.35: (a) Phase shift of a phase front passing through an axicon. (b) Top view of an axicon lens.

the beam hits the lens surface,

$$\Delta z = c\Delta t_1 + c_n(\Delta t - \Delta t_1) \ ,$$

with $\Delta t_1 \equiv w/c_n$. Choosing the time long enough for the phase front to cross the lens, $\Delta t = w_{max}/c_n$, the phase shift is,

$$\Delta\phi(r) = \frac{2\pi\Delta z}{\lambda} = 2\pi\frac{(n_{rfr}-1)w + w_{max}}{\lambda} \ .$$

That is,

$$\boxed{\Delta\phi(r) = -(n_{rfr}-1)kr\tan\alpha = -2\pi\frac{r}{r_{2\pi}}} \ ,$$

where $r_{2\pi}$ is the distance from the optical axis, where the phase shift is just 2π.
b. Thin lenses with focal length f have spherical surfaces with radius of curvature,

$$R = \frac{f}{2} \ .$$

The width Δw of a spherical segment depends on the distance r from the symmetry axis as,

$$\Delta w = R - \sqrt{R^2 - r^2} \ .$$

Hence, the width of the lens is,

$$w = w_{max} - \left(R - \sqrt{R^2 - r^2}\right) \simeq w_{\max} - \frac{r^2}{2R} \ .$$

In a given time interval Δt the phase front travels by a distance depending on where the beam hits the lens surface,

$$\Delta z = c\Delta t_1 + c_n(\Delta t - \Delta t_1) \ ,$$

with $\Delta t_1 = w/c_n$. Choosing the time long enough for the phase front to cross the lens, $\Delta t = w_{\max}/c_n$, the phase shift is,

$$\Delta\phi(r) = 2\pi\frac{\Delta z}{\lambda} = 2\pi\frac{(n_{rfr}-1)w + w_{max}}{\lambda} \ .$$

That is,

$$\boxed{\Delta\phi(r) = -(n_{rfr}-1)k\frac{r^2}{f} = -2\pi\frac{r^2}{r_{2\pi}^2}} \ ,$$

where $r_{2\pi}$ is the distance from the optical axis, where the phase shift is just 2π.

18.4.4.8 Ex: Transmission through a pinhole

Calculate the light field distribution after a circular pinhole of radius a.

Solution: *We now calculate the light field distribution after a pinhole. Conveniently switching to polar coordinates,*

$$\begin{aligned} k_x = k\cos\theta \quad &, \quad k_y = k\sin\theta \\ x = r\cos\phi \quad &, \quad y = r\sin\phi \\ k_x x + k_y y &= kr(\cos\phi\cos\theta + \sin\phi\sin\theta) = kr\cos(\phi-\theta) \\ 1-(\lambda k_x)^2 - (\lambda k_y)^2 &= 1-\lambda^2k^2 \ , \end{aligned}$$

we expect

$$\begin{aligned} u_{prop} &= \mathcal{F}^{-1}\{H\cdot\mathcal{F}\{[\min(a,\sqrt{x^2+y^2})]\} \\ &= \int dk_x dk_y e^{-\imath k_x x - \imath k_y y}\left(e^{\imath kz\sqrt{1-(\lambda k_x)^2-(\lambda k_y)^2}}\int dxdy e^{\imath k_x x+\imath k_y y}\min(a,\sqrt{x^2+y^2})\right) \\ &= \int\left(e^{-\imath kr\cos(\phi-\theta)}e^{\imath kz\sqrt{1-\lambda^2k^2}}\int_0^a\int_0^{2\pi} r' e^{\imath kr'\cos(\phi'-\theta)}d\phi' dr'\right)kdkd\theta \ . \end{aligned}$$

Introducing the Bessel function via $J_n(z) = \frac{1}{2\pi}\int_{-\pi}^{\pi} e^{\imath(z\sin\tau - n\tau)}d\tau$, it is possible to show that,

$$\frac{I(\theta)}{I_0} = \left(\frac{2J_1(ka\sin\theta)}{ka\sin\theta}\right)^2 \ .$$

The first ring of destructive interference is expected for $J_1(ka\sin\theta) = 0 = J_1(3.83205..)$,

$$\theta_0 \simeq \boxed{\sin\theta_0 = 1.22\frac{\lambda}{2a}} \simeq 3.83\frac{\lambda}{2\pi a} \ .$$

The angle under which the intensity is reduced to its rms*-value,*

$$\frac{I(\theta_e)}{I_0} = \frac{1}{\sqrt{e}} = 0.6065..$$

is given by $J_1(ka\sin\theta_e) = 0.6065 = J_1(1.3845..)$ *and has the value,*

$$\theta_e \simeq \sin\theta_e = 1.3845\frac{\lambda}{2\pi a} \ .$$

This is similar to a Gaussian beam with waist w_0*, since according to formula (18.290) we have,*

$$\frac{w^2 - w_0^2}{z^2} = \frac{w_0^2}{z_R^2} \ ,$$

hence, for large distances from the pinhole,

$$\theta \simeq \frac{w}{z} \simeq \frac{w_0}{z_R} = \frac{\lambda}{\pi w_0} \ .$$

This means, that the beam transmitted through a pinhole approximately behaves like a Gaussian beam with waist $w_0 = 2a/1.3845$*.*

Chapter 19

Radiation

In the previous sections we discussed the propagation of electromagnetic waves, but we do not say how these waves were produced in the first place. For now, we only know, that it need's accelerated charges or varying currents. Now, we will show how such 'sources' can emit energy by 'radiating' electromagnetic waves.

To begin with, let us consider sources located near the origin and confined within a sphere of radius r. The total power crossing the sphere's surface is the integral of the Poynting vector,

$$P(r) = \oint \vec{\mathcal{S}} \cdot d\mathbf{a} = \tfrac{1}{\mu_0} \oint (\vec{\mathcal{E}} \times \vec{\mathcal{B}}) \cdot d\mathbf{a} \ . \tag{19.1}$$

The radiated power is then the energy per unit area transported to infinity without ever returning,

$$P_{rad} = \lim_{r\to\infty} P(r) \ . \tag{19.2}$$

Now, the area of the sphere's surface is $4\pi r^2$ such that, in order to have non-vanishing radiation, the Poynting vector must decrease (for large r) no faster than as $1/r^2$. Following the Coulomb law, electrostatic fields decrease like $1/r^2$ or faster, when the total enclosed charge is zero. And Biot-Savart's law states that magnetostatic fields decrease at least as fast as $1/r^2$, such that $|\vec{\mathcal{S}}| \propto 1/r^4$, for static configurations. Hence, static sources do not radiate. On the other hand, Jefimenko's equations (17.109) and (17.112) indicate the existence of time-dependent terms (involving $\dot{\varrho}$ and $\dot{\mathbf{j}}$), which are proportional to $1/r$. These are the terms responsible for electromagnetic radiation. To study the radiation we choose the parts of $\vec{\mathcal{E}}$ and $\vec{\mathcal{B}}$ going as $1/r$ at large distances from the source, combine them to terms going as $1/r^2$ in the Poynting vector $\vec{\mathcal{S}}$, and integrate $\vec{\mathcal{S}}$ on a large spherical surface taking the limit $r \to \infty$.

19.1 Multipolar expansion of the radiation

19.1.1 The radiation of an arbitrary charge distribution

In this section we will calculate the radiation emitted by arbitrary time-dependent variations of charge and current distributions, but which are confined within a small volume near the origin. The retarded scalar potential is according to (17.106),

$$\Phi(\mathbf{r}, t) = \frac{1}{4\pi\varepsilon_0} \int \frac{\varrho(\mathbf{r}', t - R/c)}{R} d^3r' \ , \tag{19.3}$$

where $R = \sqrt{r^2 + r'^2 - 2\mathbf{r}\cdot\mathbf{r}'}$, as illustrated in Fig. 17.11. Within the small source approximation, $r' \ll r$, we have,

$$R \simeq r\left(1 - \frac{\mathbf{r}\cdot\mathbf{r}'}{r^2}\right) \qquad \text{and} \qquad \frac{1}{R} \simeq \frac{1}{r}\left(1 + \frac{\mathbf{r}\cdot\mathbf{r}'}{r^2}\right) , \tag{19.4}$$

such that, defining,

$$t_0 \equiv t - \tfrac{r}{c} , \tag{19.5}$$

we obtain,

$$\varrho(\mathbf{r}', t - R/c) \simeq \varrho(\mathbf{r}', t - \tfrac{r}{c} + \tfrac{\hat{\mathbf{e}}_r\cdot\mathbf{r}'}{c}) \equiv \varrho(\mathbf{r}', t_0 + \tfrac{\hat{\mathbf{e}}_r\cdot\mathbf{r}'}{c}) . \tag{19.6}$$

Expanding ϱ in a Taylor series around the retarded time at the origin t_0, we get,

$$\varrho(\mathbf{r}', t - R/c) \simeq \varrho(\mathbf{r}', t_0) + \dot{\varrho}(\mathbf{r}', t_0)\tfrac{\hat{\mathbf{e}}_r\cdot\mathbf{r}'}{c} + ... \tag{19.7}$$

Substituting the numerator and denominator in the formula (19.3) by the expansions (19.4) and (19.7) we get up to the first order,

$$\Phi(\mathbf{r}, t) = \frac{1}{4\pi\varepsilon_0 r}\left[\int \varrho(\mathbf{r}', t_0)d^3r' + \frac{\hat{\mathbf{e}}_r}{r}\cdot\int \mathbf{r}'\varrho(\mathbf{r}', t_0)d^3r' + \frac{\hat{\mathbf{e}}_r}{c}\cdot\frac{d}{dt}\int \mathbf{r}'\varrho(\mathbf{r}', t_0)d^3r'\right] . \tag{19.8}$$

The first integral is simply the charge [1], the other two represent the electric dipole at time t_0,

$$\Phi(\mathbf{r}, t) = \frac{1}{4\pi\varepsilon_0}\left[\frac{Q}{r} + \frac{\hat{\mathbf{e}}_r\cdot\mathbf{d}(t_0)}{r^2} + \frac{\hat{\mathbf{e}}_r\cdot\dot{\mathbf{d}}(t_0)}{cr}\right] . \tag{19.9}$$

In the static case, the first two terms are the contributions of the monopole and dipole to the multipolar expansion of Φ, the third term would not be present.

The vector potential,

$$\mathbf{A}(\mathbf{r}, t) = \frac{\mu_0}{4\pi}\int \frac{\mathbf{j}(\mathbf{r}', t - R/c)}{R}d^3r' , \tag{19.10}$$

is easily expanded up to first order by,

$$\mathbf{A}(\mathbf{r}, t) \simeq \frac{\mu_0}{4\pi r}\int \mathbf{j}(\mathbf{r}', t_0)d^3r' , \tag{19.11}$$

since, as we will show in Exc. 19.1.6.1,

$$\boxed{\mathbf{A}(\mathbf{r}, t) \simeq \frac{\mu_0}{4\pi}\frac{\dot{\mathbf{d}}(t_0)}{r}} , \tag{19.12}$$

that is, $\mathbf{d} \sim \mathbf{r}'$ is already of first order in $\mathbf{r}'$.

Now we must calculate the fields. Again, we are interested in the radiation zone (that is, in fields surviving great distances from the source), discarding all terms in $\vec{\mathcal{E}}$ and $\vec{\mathcal{B}}$ which decrease like $1/r^2$ or faster, which will not be the case for the first term

[1] The charge is evaluated at time t_0, but since it is conserved, it stays the same at all times.

(Coulomb) and the second term in (19.9). Therefore, considering the abbreviation (19.5), we obtain,

$$\nabla\Phi \simeq \frac{1}{4\pi\varepsilon_0}\nabla\frac{\hat{\mathbf{e}}_r\cdot\dot{\mathbf{d}}(t_0)}{rc} = \frac{1}{4\pi\varepsilon_0}\left[\cancelto{0}{\frac{\dot{\mathbf{d}}(t_0)}{cr^2}} + \frac{\hat{\mathbf{e}}_r\cdot\ddot{\mathbf{d}}(t_0)}{cr}\nabla t_0 - \cancelto{0}{\frac{2\hat{\mathbf{e}}_r\cdot\dot{\mathbf{d}}(t_0)}{cr^2}\hat{\mathbf{e}}_r}\right]$$
$$\simeq \frac{1}{4\pi\varepsilon_0}\frac{\hat{\mathbf{e}}_r\cdot\ddot{\mathbf{d}}(t_0)}{cr}\left(-\frac{\hat{\mathbf{e}}_r}{c}\right) . \tag{19.13}$$

Similarly,

$$\nabla\times\mathbf{A} = \nabla\times\frac{\mu_0}{4\pi}\frac{\dot{\mathbf{d}}(t_0)}{r} = \frac{\mu_0}{4\pi}\left[\frac{1}{r}\nabla\times\dot{\mathbf{d}}(t_0) + \left(\nabla\frac{1}{r}\right)\times\dot{\mathbf{d}}(t_0)\right] \tag{19.14}$$
$$= \frac{\mu_0}{4\pi}\left[-\frac{\ddot{\mathbf{d}}(t_0)}{r}\times\nabla t_0 - \cancelto{0}{\frac{\hat{\mathbf{e}}_r\times\dot{\mathbf{d}}(t_0)}{r^2}}\right] = -\frac{\mu_0}{4\pi}\frac{\ddot{\mathbf{d}}(t_0)}{r}\times\left(\frac{-\hat{\mathbf{e}}_r}{c}\right) = -\frac{\mu_0}{4\pi}\frac{\hat{\mathbf{e}}_r\times\ddot{\mathbf{d}}(t_0)}{cr} .$$

and,

$$\frac{\partial\mathbf{A}}{\partial t} \simeq \frac{\mu_0}{4\pi}\frac{\ddot{\mathbf{d}}(t_0)}{r} . \tag{19.15}$$

Hence, the Eqs. (17.78) tell us,

$$\vec{\mathcal{E}}(\mathbf{r},t) \simeq \frac{\mu_0}{4\pi r}[(\hat{\mathbf{e}}_r\cdot\ddot{\mathbf{d}}(t_0))\hat{\mathbf{e}}_r - \ddot{\mathbf{d}}(t_0)] = \frac{\mu_0}{4\pi r}[\hat{\mathbf{e}}_r\times(\hat{\mathbf{e}}_r\times\ddot{\mathbf{d}}(t_0)] \tag{19.16}$$
$$\vec{\mathcal{B}}(\mathbf{r},t) \simeq -\frac{\mu_0}{4\pi cr}[\hat{\mathbf{e}}_r\times\ddot{\mathbf{d}}(t_0)] .$$

In spherical coordinates,

$$\vec{\mathcal{E}}(r,\theta,\phi,t) \simeq \frac{\mu_0\ddot{d}(t_0)}{4\pi}\frac{\sin\theta}{r}\hat{\mathbf{e}}_\theta \quad \text{and} \quad \vec{\mathcal{B}}(r,\theta,\phi,t) \simeq \frac{\mu_0\ddot{d}(t_0)}{4\pi c}\frac{\sin\theta}{r}\hat{\mathbf{e}}_\phi . \tag{19.17}$$

The Poynting vector is,

$$\boxed{\vec{\mathcal{S}} \simeq \tfrac{1}{\mu_0}\vec{\mathcal{E}}\times\vec{\mathcal{B}} = \frac{\mu_0\ddot{d}(t_0)^2}{16\pi^2 c}\frac{\sin^2\theta}{r^2}\hat{\mathbf{e}}_r} , \tag{19.18}$$

which is a result that we already used in (18.111). And for total radiated power we get the *Larmor formula*,

$$P \simeq \oint\vec{\mathcal{S}}\cdot d\mathbf{a} = \frac{\mu_0\ddot{d}(t_0)}{6\pi c} . \tag{19.19}$$

The calculation is equivalent to a multipolar expansion of the retarded potentials up to the lowest order in r' which can still radiate, and which turns out to be an electric dipole radiation. Multipolar orders of radiation usually only come into play, when for some reason (e.g. a selection rule) the electric dipole radiation cancels. The next multipolar order will be, as we will soon see, a combination of magnetic dipole and quadrupolar electric radiation.

19.1.2 Multipolar expansion of retarded potentials

In order to simplify the multipolar treatment, we use the superposition principle, allowing us to decompose any temporal oscillation of a charge distribution into harmonic oscillations,

$$\varrho(\mathbf{r},t_r)=\varrho(\mathbf{r})e^{-\imath\omega t_r} \qquad \text{and} \qquad \mathbf{j}(\mathbf{r},t_r)=\mathbf{j}(\mathbf{r})e^{-\imath\omega t_r}\ . \tag{19.20}$$

By inserting these dependencies into the *retarded potentials* (17.106), we obtain with $t_r = t - |\mathbf{r}-\mathbf{r}'|/c$,

$$\Phi(\mathbf{r})=\frac{1}{4\pi\varepsilon_0}\int \varrho(\mathbf{r}_r)\frac{e^{\imath k|\mathbf{r}-\mathbf{r}'|}}{|\mathbf{r}-\mathbf{r}'|}d^3r' \qquad \text{and} \qquad \mathbf{A}(\mathbf{r})=\frac{\mu_0}{4\pi}\int \mathbf{j}(\mathbf{r}')\frac{e^{\imath k|\mathbf{r}-\mathbf{r}'|}}{|\mathbf{r}-\mathbf{r}'|}d^3r'\ , \tag{19.21}$$

with $k=\omega/c$ and implying $\Phi(\mathbf{r},t)=\Phi(\mathbf{r})e^{-\imath\omega t}$ and $\mathbf{A}(\mathbf{r},t)=\mathbf{A}(\mathbf{r})e^{-\imath\omega t}$.

From these expressions we can, knowing the sources (19.20), calculate the fields via the expressions (17.78) or alternatively (based only on the vector potential) via,

$$\vec{\mathcal{B}}=\nabla\times\mathbf{A} \qquad \text{and} \qquad \vec{\mathcal{E}}=\tfrac{\imath c^2}{\omega}\nabla\times\vec{\mathcal{B}} \qquad \text{and} \qquad \vec{\mathcal{B}}=\tfrac{-\imath}{\omega}\nabla\times\vec{\mathcal{E}}\ , \tag{19.22}$$

where $\vec{\mathcal{E}}$ is evaluated outside the source. We will consider sources which are small (size d) compared to the wavelength λ and distinguish three regions characterized by fields with very different properties:

• near-field (or static) zone	$r' < d \ll r \ll \lambda$
• intermediate (or inductive) zone	$r' < d \ll r \sim \lambda$
• far-field (or radiative) zone	$r' < d \ll \lambda \ll r$

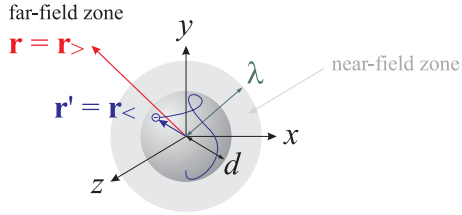

Figure 19.1: Geometry of source ($r' < d$) and observer ($r > d$) coordinates.

To handle the expression (19.21) we expand the Green function into spherical harmonics,

$$\frac{e^{\imath k|\mathbf{r}-\mathbf{r}'|}}{4\pi|\mathbf{r}-\mathbf{r}'|}=\imath k\sum_{\ell=0}^{\infty}h_\ell^{(1)}(kr_>)j_\ell(kr_<)\sum_{m=-\ell}^{\ell}Y^*_{\ell m}(\theta',\phi')Y_{\ell m}(\theta,\phi)\ , \tag{19.23}$$

where (placing the observer out of the source region) $r_< \equiv \min(r,r') = r'$ and $r_> \equiv \max(r,r') = r$. j_ℓ and $h_\ell^{(1)}$ are the *Bessel functions* and *Hankel functions* of the first type. This formula can be simplified by the sum rule,

$$\sum_{m=-\ell}^{\ell}Y^*_{\ell m}(\hat{\mathbf{e}}_{r'})Y_{\ell m}(\hat{\mathbf{e}}_r)=\frac{2\ell+1}{4\pi}P_\ell(\hat{\mathbf{e}}_{r'}\cdot\hat{\mathbf{e}}_r)\ , \tag{19.24}$$

where P_ℓ are *Legendre polynomials*. We write,

$$\frac{e^{\imath k|\mathbf{r}-\mathbf{r}'|}}{|\mathbf{r}-\mathbf{r}'|} = \imath k \sum_{\ell=0}^{\infty} (2\ell+1) h_\ell^{(1)}(kr) j_\ell(kr') P_\ell(\hat{\mathbf{e}}_{r'} \cdot \hat{\mathbf{e}}_r) \ . \tag{19.25}$$

For observation points $\mathbf{r}$ out of the source (which is certainly satisfied in the limit $r' \ll r$) the Eq. (19.21) becomes,

$$\mathbf{A}(\mathbf{r}) = \frac{\mu_0}{4\pi} (2\ell+1) \imath k \sum_{\ell=0}^{\infty} h_\ell^{(1)}(kr) \int \mathbf{j}(\mathbf{r}') j_\ell(kr') P_\ell(\hat{\mathbf{e}}_{r'} \cdot \hat{\mathbf{e}}_r) d^3r' \ . \tag{19.26}$$

Since we will always be considering the limit $kr' \ll 1$, we can expand the Bessel function for small arguments,

$$j_\ell(x) \overset{x\to 0}{\longrightarrow} \frac{x^\ell}{(2\ell+1)!!} \left(1 - \frac{x^2}{2(2\ell+3)} + ... \right) \ . \tag{19.27}$$

We obtain for the vector potential,

$$\boxed{\mathbf{A}(\mathbf{r}) \simeq \frac{\mu_0}{4\pi} \imath k \sum_{\ell=0}^{\infty} \frac{1}{(2\ell-1)!!} h_\ell^{(1)}(kr) \int \mathbf{j}(\mathbf{r}') (kr')^\ell P_\ell(\hat{\mathbf{e}}_{r'} \cdot \hat{\mathbf{e}}_r) d^3r'} \ . \tag{19.28}$$

Now, let us discuss the limiting cases by comparing the observation distance r with the wavelength. In the *near-field zone*, where $kr \ll 1$, we can also expand the Bessel function for small arguments,

$$n_\ell(x) \overset{x\to 0}{\longrightarrow} -\frac{(2\ell-1)!!}{x^{\ell+1}} \left(1 - \frac{x^2}{2(1-2\ell)} + ... \right) \tag{19.29}$$

$$\text{and} \qquad h_\ell^{(1)}(x) = j_\ell(x) + \imath n_\ell(x) \overset{x\to 0}{\longrightarrow} \imath n_\ell(x) \ ,$$

resulting in the vector potential,

$$\boxed{\mathbf{A}(\mathbf{r}) \overset{kr\to 0}{\longrightarrow} \frac{\mu_0}{4\pi} k \sum_{\ell=0}^{\infty} \frac{1}{(kr)^{\ell+1}} \int \mathbf{j}(\mathbf{r}') (kr')^\ell P_\ell(\hat{\mathbf{e}}_{r'} \cdot \hat{\mathbf{e}}_r) d^3r'} \ . \tag{19.30}$$

This formula could already have been derived by approximating the exponential of the formula (19.21) by $e^{\imath k|\mathbf{r}-\mathbf{r}'|} \simeq 1$ and expanding the following Green function into spherical harmonics [2],

$$\frac{1}{4\pi|\mathbf{r}-\mathbf{r}'|} = \sum_{\ell=0}^{\infty} \sum_{m=-\ell}^{\ell} \frac{1}{2\ell+1} \frac{r_<^\ell}{r_>^{\ell+1}} Y_{\ell m}^*(\theta', \phi') Y_{\ell m}(\theta, \phi) \ . \tag{19.31}$$

[2] This expansion is obtained by expanding the Legendre polynomials in the expansion (13.91),

$$\frac{1}{|\mathbf{r}-\mathbf{r}'|} = \frac{1}{r} \sum_{\ell=0}^{\infty} \frac{r_<^\ell}{r_>^{\ell+1}} P_\ell(\cos\theta') \qquad \text{with} \qquad P_\ell(\cos\theta') = \frac{4\pi}{2\ell+1} \sum_{m=\ell}^{\ell} Y_{\ell m}^*(\theta', \phi') Y_{\ell m}(\theta, \phi) \ ,$$

.

The absence of propagating terms in the expression (19.30) (the wave vector k can be eliminated from the expression (19.30)) demonstrates the *quasi-static* character of the fields within the near zone, that is, apart from a uniform and harmonic oscillation described by $e^{-\imath\omega t}$. The radial components depend on the details of the source's geometry. The scalar and vector potentials are of the form already derived in electrostatics (13.92) and magnetostatics (15.39).

On the other hand, in *far-field zone*, where $kr \gg 1$, the exponential in (19.21) oscillates rapidly and determines the behavior of vector potential. Here, we must resort to the complete expression (19.28), but we can expand the Hankel functions like,

$$h_\ell^{(1)}(x) = (-\imath)^{\ell+1}\frac{e^{\imath x}}{x}\sum_{m=0}^{\ell}\frac{\imath^m}{m!(2x)^m}\frac{(\ell+m)!}{(\ell-m)!} \ . \tag{19.32}$$

Knowing,

$$\begin{aligned} h_0^{(1)}(x) &= -\imath\tfrac{e^{\imath x}}{x} \quad , \quad P_0(x) = 1 \\ h_1^{(1)}(x) &= -\tfrac{e^{\imath x}}{x}\left(1-\tfrac{1}{\imath x}\right) \quad , \quad P_1(x) = x \ . \end{aligned} \tag{19.33}$$

we calculate the potentials,

$$\begin{aligned} \mathbf{A}_{\ell=0}(\mathbf{r}) &\simeq \frac{\mu_0}{4\pi}\frac{e^{\imath kr}}{r}\int \mathbf{j}(\mathbf{r}')d^3r' \\ \mathbf{A}_{\ell=1}(\mathbf{r}) &\simeq -\frac{\mu_0}{4\pi}\imath k\frac{e^{\imath kr}}{r}\left(1-\frac{1}{\imath kr}\right)\int \mathbf{j}(\mathbf{r}')\mathbf{r}'\cdot\hat{\mathbf{e}}_r d^3r' \ , \end{aligned} \tag{19.34}$$

We will see in the following sections that $\mathbf{A}_{\ell=0}$ is the potential for electric dipole radiation and $\mathbf{A}_{\ell=1}$ the potential for magnetic dipole radiation and electric quadrupolar radiation.

Example 113 (*The far-field limit*): Assuming that the spatial extent of the radiation source is small, $r' \lesssim d \ll r$, it is sufficient to approximate directly in the expression (19.21),

$$|\mathbf{r}-\mathbf{r}'| \simeq r - \hat{\mathbf{e}}_r\cdot\mathbf{r}' \ .$$

Moreover, if only the principal term in kr is desired [3], the inverse distance in (19.21) can be replaced by r. Then, the vector potential is,

$$\lim_{kr\to\infty}\mathbf{A}(\mathbf{r}) = \frac{\mu_0}{4\pi}\frac{e^{\imath kr}}{r}\int \mathbf{j}(\mathbf{r}')e^{-\imath k\hat{\mathbf{e}}_r\cdot\mathbf{r}'}d^3r' \ .$$

This shows that, in the far-field zone, the vector potential behaves like a spherically expanding wave modulated by an angular coefficient. It is easy to show, that the fields calculated from (19.22) are transverse to the radius vector and fall off as $1/r$. They correspond thus to the radiation fields. If the size of the source

[3] The expansion by $\frac{1}{kr}$ gives,

$$\frac{e^{-\imath k\hat{\mathbf{e}}_r\cdot r'}}{kr-k\hat{\mathbf{e}}_r\cdot r'} = \frac{e^{-\imath k\hat{\mathbf{e}}_r\cdot r'}}{kr}\left[\frac{\hat{\mathbf{e}}_r\cdot r'}{r}+\left(\frac{\hat{\mathbf{e}}_r\cdot r'}{r}\right)^2+\ldots\right] \simeq \frac{e^{-\imath k\hat{\mathbf{e}}_r\cdot r'}}{kr} \ .$$

is small compared to a wavelength, it is appropriate to expand the exponential in the integral in (19.25) in powers of k,

$$\lim_{kr\to\infty}\mathbf{A}(\mathbf{r})=\frac{\mu_0 k}{4\pi}\sum_n\frac{(-\imath)^n}{n!}\frac{e^{\imath kr}}{kr}\int\mathbf{j}(\mathbf{r}')(\hat{\mathbf{e}}_r\cdot k\mathbf{r}')^n d^3r' \ .$$

The magnitude of the n-th term is given by $\frac{1}{n!}\int\mathbf{j}(\mathbf{r}')(\hat{\mathbf{e}}_r\cdot k\mathbf{r}')^n d^3r'$. Since the order of magnitude of $\mathbf{r}'$ is d, and since we assumed $kr'\ll 1$, consecutive terms decrease rapidly with n. Consequently, the radiation emitted from the source comes mainly from the first terms of the expansion (19.26).

19.1.2.1 The electric monopole

We notice that the lowest order radiation found in the expansion of $\mathbf{A}$ is dipolar. How about monopolar fields? Let us examine the issue of electric monopole fields, when the sources vary in time. The contribution of the electric monopole is obtained by substituting $|\mathbf{r}-\mathbf{r}'|\to|\mathbf{r}|=r$ in the integral (19.21) for the potential Φ. The result is,

$$\Phi_{monopole}(\mathbf{r},t)=\frac{1}{4\pi\varepsilon_0}\frac{e^{\imath kr}}{r}\int\rho(\mathbf{r}')d^3r'=\frac{Q}{4\pi\varepsilon_0}\frac{e^{\imath kr}}{r} \ . \tag{19.35}$$

where $q(t)$ is the total charge of the source. Since the charge is localized in the source (and therefore conserved), the total charge q is independent of time. Thus, the electrical monopole part of the potential of a localized source is necessarily static. Radiation with harmonic temporal dependence, $e^{-\imath\omega t}$, does not have monopolar terms in the fields.

Now let us go back to multipolar fields. Since these fields can be calculated from the vector potential via (19.23), we omit explicit references to the scalar potential in the following.

19.1.3 Radiation of an oscillating electric dipole

Keeping only the first term in (19.30) we get the potential vector (19.33),

$$\mathbf{A}(\mathbf{r})=\frac{\mu_0}{4\pi}\frac{e^{\imath kr}}{r}\int\mathbf{j}(\mathbf{r}')d^3r' \ . \tag{19.36}$$

which is valid everywhere outside the source. Using the continuity equation we can rewrite it, using a result from Exc. 19.1.6.1,

$$\mathbf{A}(\mathbf{r})=-\frac{\mu_0}{4\pi}\frac{e^{\imath kr}}{r}\int\mathbf{r}'(\nabla'\cdot\mathbf{j})d^3r'=-\frac{\mu_0}{4\pi}\frac{e^{\imath kr}}{r}\imath\omega\int\mathbf{r}'\varrho(\mathbf{r}')d^3r' \ . \tag{19.37}$$

With the *electric dipole moment*,

$$\mathbf{d}\equiv\int\mathbf{r}'\varrho(\mathbf{r}')d^3r' \ , \tag{19.38}$$

defined in electrostatics we write,

$$\boxed{\mathbf{A}(\mathbf{r})=-\frac{\mu_0}{4\pi}\frac{e^{\imath kr}}{r}\imath\omega\mathbf{d}} \ . \tag{19.39}$$

We obtain the fields via the equations (19.22),

$$\boxed{\begin{aligned}\vec{\mathcal{B}} &= -\frac{ck^3\mu_0}{4\pi}(\hat{\mathbf{e}}_r \times \mathbf{d})\frac{e^{\imath kr}}{kr}\left(1-\frac{1}{\imath kr}\right)\\ \vec{\mathcal{E}} &= \frac{k^3}{4\pi\varepsilon_0}\left\{(\hat{\mathbf{e}}_r \times \mathbf{d})\times\hat{\mathbf{e}}_r\frac{e^{\imath kr}}{kr} + [3\hat{\mathbf{e}}_r(\hat{\mathbf{e}}_r\cdot\mathbf{d})-\mathbf{d}]\left(\frac{1}{(kr)^3}-\frac{\imath}{(kr)^2}\right)e^{\imath kr}\right\}\end{aligned}} \; . \tag{19.40}$$

We observe that the magnetic field is transverse to the radius vector $\hat{\mathbf{e}}_r$ at all distances, but that the electric field has components parallel and perpendicular to $\hat{\mathbf{e}}_r$. In Exc. 19.1.6.2 we will derive the fields (19.40) directly from the potentials.

In the radiation zone $kr \gg 1$ the fields adopt the typical behavior,

$$\vec{\mathcal{B}} = -\frac{ck^3\mu_0}{4\pi}(\hat{\mathbf{e}}_r \times \mathbf{d})\frac{e^{\imath kr}}{kr} \quad \text{and} \quad \vec{\mathcal{E}} = \frac{k^3}{4\pi\varepsilon_0}(\hat{\mathbf{e}}_r \times \mathbf{d})\times\hat{\mathbf{e}}_r\frac{e^{\imath kr}}{kr} \; . \tag{19.41}$$

In the near-field zone $kr \ll 1$,

$$\vec{\mathcal{B}} = \frac{\imath\omega\mu_0}{4\pi}(\hat{\mathbf{e}}_r \times \mathbf{d})\frac{1}{r^2} \quad \text{and} \quad \vec{\mathcal{E}} = \frac{1}{4\pi\varepsilon_0}[3\hat{\mathbf{e}}_r(\hat{\mathbf{e}}_r\cdot\mathbf{d})-\mathbf{d}]\frac{1}{r^3} \; , \tag{19.42}$$

does not have the propagation term $e^{\imath kr}$. The electric field, apart from its temporal oscillations, is just a static electric dipole. The magnetic field is, apart from a constant $Z_0 \equiv \sqrt{\mu_0/\varepsilon_0}$ called *vacuum impedance*, smaller by a factor kr than the electric field in the region where $kr \ll 1$. Thus, the fields in the near-field zone are of predominantly electrical nature. The magnetic field disappears, obviously, in the static limit $k \to 0$. In this case, the near-field zone extends to infinity.

The Poynting vector in the far-field due to the oscillation of the dipole moment $\mathbf{d}$ is, inserting (19.41),

$$\begin{aligned}\vec{\mathcal{S}} &= \frac{1}{2\mu_0}\vec{\mathcal{E}}\times\vec{\mathcal{B}}^* = -\frac{ck^4}{32\pi^2\varepsilon_0 r^2}\{[\hat{\mathbf{e}}_r \times \mathbf{d})\times\hat{\mathbf{e}}_r]\times(\hat{\mathbf{e}}_r \times \mathbf{d})\} \qquad (19.43)\\ &= -\frac{ck^4}{32\pi^2\varepsilon_0 r^2}(d^2-d_r^2)\hat{\mathbf{e}}_r = -\frac{ck^4}{32\pi^2\varepsilon_0 r^2}\hat{\mathbf{e}}_r d^2\sin^2\theta \; .\end{aligned}$$

The radiated power is given by the absolute value of (19.43) per solid angle element [4]. If the components of $\mathbf{d}$ all have the same phase, the angular distribution is a typical dipole pattern,

$$\frac{dP}{d\Omega} = \frac{c}{32\pi^2\varepsilon_0}k^4|\mathbf{d}|^2\sin^2\theta \; . \tag{19.44}$$

where the angle θ is measured from the direction of $\mathbf{d}$. The total radiated power, regardless of the relative phases of the components of $\mathbf{d}$, is,

$$P = \frac{cZ_0}{12\pi\varepsilon_0}|\mathbf{d}|^2 = \frac{\mu_0}{12\pi c}|\mathbf{d}|^2 \; , \tag{19.45}$$

[4] When writing angular distributions of radiation, we will always exhibit the polarization explicitly by writing the absolute square of a vector that is proportional to the electric field. If the angular distribution of a particular polarization is desired, it can then be obtained by taking the scalar product of the vector with the appropriate polarization vector before the square.

which is half of the value calculated in the derivation of the Larmor formula (19.19), because in (19.43) we choose to calculate directly the temporal average of the Poynting vector.

Resolve the 19.1.6.3. In Exc. 19.1.6.4 we will verify the gauge of the dipolar potential and in Exc. 19.1.6.5 we calculate the fields of a linear antenna.

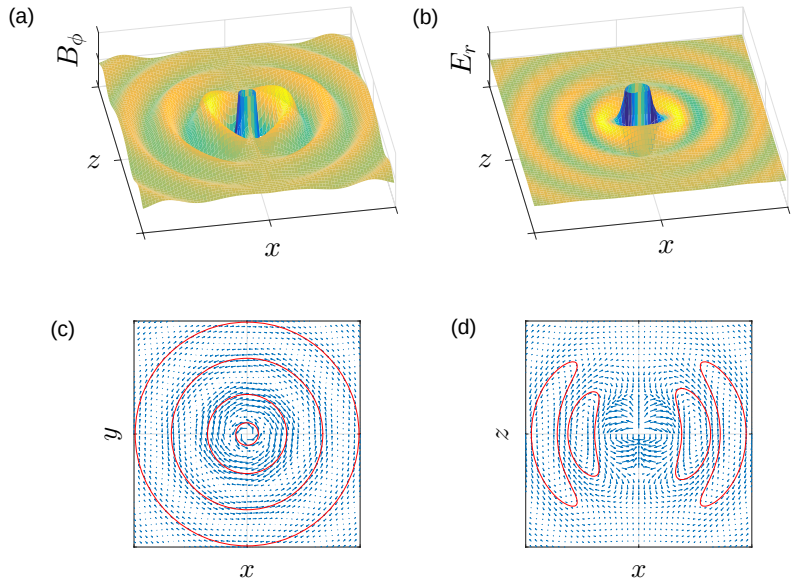

Figure 19.2: (code) Electric dipole radiation patterns. (a) Cut through $\vec{\mathcal{B}}_\phi$, (b) cut through $\vec{\mathcal{E}}_r$, (c) field lines of $\vec{\mathcal{B}}$ in the xy-plane, and (d) field lines of $\vec{\mathcal{E}}$ in the xz-plane. A movie can be seen at (watch movie).

Example 114 (*Linear antenna*): As an example, we calculate the power radiated by an oscillating charge $\varrho(\mathbf{r},t) = Q\delta(x)\delta(y)\delta(z - z_0 e^{-\imath\omega t})$. The dipole moment is,

$$\mathbf{d} = \int \mathbf{r}'\varrho(\mathbf{r}',t)dV' = Q\hat{\mathbf{e}}_z z_0 e^{-\imath\omega t} \ .$$

Inserted into the formula (19.45),

$$P = \frac{cZ_0 Q^2 z_0^2}{12\pi\varepsilon_0} \ .$$

Example 115 (*Linear antenna*): As another example we calculate the power radiated by a simple linear antenna, characterized by a current distribution $\mathbf{j}(\mathbf{r},t) = I_0\hat{\mathbf{e}}_z\delta(x)\delta(y)(1 - 2|z|/a)e^{-\imath\omega t}$. The dipole moment is,

$$\mathbf{d} = \frac{\imath}{\omega}\int \mathbf{j}dV' = \frac{\imath}{\omega} I_0\hat{\mathbf{e}}_z e^{-\imath\omega t}\int_{-a/2}^{a/2}\mathbf{j}dV'\left(1 - \frac{2|z'|}{a}\right)dz' = \frac{\imath I_0 a}{2\omega}\hat{\mathbf{e}}_z e^{-\imath\omega t} \ .$$

Inserted into the formula (19.45),

$$P = \frac{Z_0 I_0^2 (ka)^2}{48\pi} \ .$$

19.1.4 Magnetic dipole and electric quadrupole radiation

The term $\ell = 1$ in the expansion (19.28) leads to the second vector potential (19.34),

$$\mathbf{A}(\mathbf{r}) = -\imath\frac{\mu_0}{4\pi}\imath k h_1^{(1)} \int \mathbf{j}(\mathbf{r}')(\hat{\mathbf{e}}_r \cdot \mathbf{r}')d^3r' = \frac{\mu_0}{4\pi}\frac{e^{\imath kr}}{r}\left(\frac{1}{r} - \imath k\right)\int \mathbf{j}(\mathbf{r}')(\hat{\mathbf{e}}_r \cdot \mathbf{r}')d^3r' \ . \tag{19.46}$$

This vector potential can be written as the sum of two terms: one gives a transverse magnetic field and the other gives a transverse electric field. These physically distinct contributions can be separated by rewriting the integrand in (19.46) as the sum of a part, which is symmetric about an exchange of $\mathbf{j}$ and $\mathbf{r}'$, and an antisymmetric part. Therefore,

$$(\hat{\mathbf{e}}_r \cdot \mathbf{r}')\mathbf{j} = \tfrac{1}{2}[(\hat{\mathbf{e}}_r \cdot \mathbf{r}')\mathbf{j} + (\hat{\mathbf{e}}_r \cdot \mathbf{j})\mathbf{r}'] - \hat{\mathbf{e}}_r \times \tfrac{1}{2}(\mathbf{r}' \times \mathbf{j}) \ , \tag{19.47}$$

using the rule $B(AC) - C(AB)$. The second (antisymmetric) part is recognizable as the magnetization due to the current $\mathbf{j}$:

$$\vec{\mathcal{M}} = \tfrac{1}{2}(\mathbf{r}' \times \mathbf{j}) \ . \tag{19.48}$$

We will see, that the first (symmetric) term is related to the electric quadrupole moment density.

19.1.4.1 Magnetic dipole radiation

Considering, for the moment, only the magnetization term, we get the vector potential,

$$\boxed{\mathbf{A}(\mathbf{r}) = \frac{\imath k\mu_0}{4\pi}(\hat{\mathbf{e}}_r \times \mathbf{m})\frac{e^{\imath kr}}{r}\left(1 - \frac{1}{\imath kr}\right)} \ , \tag{19.49}$$

where $\mathbf{m}$ is the *magnetic dipole moment*,

$$\mathbf{m} = \int \vec{\mathcal{M}} d^3r = \tfrac{1}{2}\int (\mathbf{r} \times \mathbf{j})d^3r \ . \tag{19.50}$$

The fields can be determined by observing that the vector potential (19.49) is proportional to the magnetic field (19.40) of an electric dipole (except that we have to exchange the electric by the magnetic dipole moment). Thus, we can use the calculations we already made and transfer the results to the fields of a magnetic dipole via Eqs. (19.22):

$$\boxed{\begin{aligned} \vec{\mathcal{B}} &= \frac{k^3\mu_0}{4\pi}\left\{(\hat{\mathbf{e}}_r \times \mathbf{m}) \times \hat{\mathbf{e}}_r \frac{e^{\imath kr}}{kr} + [3\hat{\mathbf{e}}_r(\hat{\mathbf{e}}_r \cdot \mathbf{m}) - \mathbf{m}]\left(\frac{1}{(kr)^3} - \frac{\imath}{(kr)^2}\right)e^{\imath kr}\right\} \\ \vec{\mathcal{E}} &= -\frac{ck^3\mu_0}{4\pi}(\hat{\mathbf{e}}_r \times \mathbf{m})\frac{e^{\imath kr}}{kr}\left(1 - \frac{1}{\imath kr}\right) \end{aligned}} \ . \tag{19.51}$$

In Exc. 19.1.6.6 we will derive the fields (19.51) directly from the potentials.

All arguments concerning the behavior of the fields in the near-field and far-field regions are the same as those proposed for the electric dipole radiation with the modifications,

$$\begin{aligned} \vec{\mathcal{E}}^{(M1)} &\overset{\mathbf{m}\leftrightarrow c\mathbf{d}}{\longleftrightarrow} c\vec{\mathcal{B}}^{(E1)} \\ c\vec{\mathcal{B}}^{(M1)} &\overset{\mathbf{m}\leftrightarrow c\mathbf{d}}{\longleftrightarrow} \vec{\mathcal{E}}^{(E1)} \ . \end{aligned} \tag{19.52}$$

Likewise, the radiation pattern and the total radiated power are the same for the two types of dipole. The only difference in the radiation fields are their polarizations. For an electric dipole, the electric field vector lies in the plane defined by $\hat{\mathbf{e}}_r$ and $\mathbf{d}$, whereas for a magnetic dipole, it is perpendicular to the plane defined by $\hat{\mathbf{e}}_r$ and $\mathbf{m}$.

19.1.4.2 Electric quadrupole radiation

The integral of the symmetric term in (19.47) can be transformed using the continuity equation and integrating by parts:

$$\tfrac{1}{2}\int[(\hat{\mathbf{e}}_r\cdot\mathbf{r}')\mathbf{j}+(\hat{\mathbf{e}}_r\cdot\mathbf{j})\mathbf{r}']d^3r' = -\tfrac{\imath\omega}{2}\int\mathbf{r}'(\hat{\mathbf{e}}_r\cdot\mathbf{r}')\varrho(\mathbf{r}')d^3r' \ . \tag{19.53}$$

This will be demonstrated in Exc. 19.1.6.1. Since this integral involves the second moments of charge density, it corresponds to a quadrupolar electric radiation source. The potential vector is,

$$\boxed{\mathbf{A}(\mathbf{r}) = -\frac{\mu_0 ck^2}{8\pi}\frac{e^{\imath kr}}{r}\left(1-\frac{1}{\imath kr}\right)\int\mathbf{r}'(\hat{\mathbf{e}}_r\cdot\mathbf{r}')\varrho(\mathbf{r}')d^3r'} \ . \tag{19.54}$$

The expressions for the fields are a bit complicated, such that we focus on the radiation zone, where it is easy to verify that,

$$\vec{\mathcal{B}} = \nabla\times\mathbf{A} = \imath k\hat{\mathbf{e}}_r\times\mathbf{A} \quad , \quad \vec{\mathcal{E}} = \imath ck(\hat{\mathbf{e}}_r\times\mathbf{A})\times\hat{\mathbf{e}}_r \ . \tag{19.55}$$

Consequently, the magnetic field is,

$$\vec{\mathcal{B}} = -\frac{\imath ck^3\mu_0}{8\pi}\frac{e^{\imath kr}}{r}\int(\hat{\mathbf{e}}_r\times\mathbf{r}')(\hat{\mathbf{e}}_r\cdot\mathbf{r}')\varrho(\mathbf{r}')d^3re' \ . \tag{19.56}$$

With the definition of the tensor of the quadrupolar moment,

$$Q_{\alpha\beta} \equiv \int(3x_\alpha x_\beta - r^2\delta_{\alpha\beta})\varrho(\mathbf{r}')d^3r' \ , \tag{19.57}$$

the integral (19.56) can be written as,

$$\hat{\mathbf{e}}_r\times\int\mathbf{r}'(\hat{\mathbf{e}}_r\cdot\mathbf{r}')\varrho(\mathbf{r}')d^3\mathbf{r}' = \tfrac{1}{3}\hat{\mathbf{e}}_r\times\mathbf{Q}(\hat{\mathbf{e}}_r) \ , \tag{19.58}$$

where the vector $\mathbf{Q}(\hat{\mathbf{e}}_r)$ is defined via its components,

$$Q_\alpha = \sum_{\alpha\beta} Q_{\alpha\beta}\hat{\mathbf{e}}_\beta \ . \tag{19.59}$$

We note that its magnitude and direction depend on the direction of observation as well as on the properties of the source. With these definitions, we get the magnetic field,

$$\vec{\mathcal{B}} = -\frac{\imath c k^3 \mu_0}{24\pi} \frac{e^{\imath kr}}{r} \hat{\mathbf{e}}_r \times \mathbf{Q}(\hat{\mathbf{e}}_r) \ , \tag{19.60}$$

and the time-averaged power radiated into a solid angle,

$$\frac{dP}{d\Omega} = \frac{c^2 Z_0}{1152\pi^2} k^6 |[\hat{\mathbf{e}}_r \times \mathbf{Q}(\hat{\mathbf{e}}_r)] \times \hat{\mathbf{e}}_r|^2 \ . \tag{19.61}$$

The final expressions are complicated [659], but for the example of a ellipsoidal charge distribution periodically changing its 'aspect ratio', it is possible to show that the angular distribution of the radiation pattern exhibits four lobes,

$$\frac{dP}{d\Omega} = \frac{c^2 Z_0 k^6}{512\pi^2} Q_0^2 \sin^2\theta \cos^2\theta \ , \tag{19.62}$$

and the total radiated power is,

$$P = \frac{c^2 Z_0 k^6}{960\pi} Q_0^2 \ . \tag{19.63}$$

For multipoles of higher order the formulas become more and more complicated. Other techniques based on the multipolar expansion of the wave equation, rather than deriving the radiation patterns directly from the retarded potentials, are more suitable. Resolve the Exc. 19.1.6.7.

19.1.5 Multipolar expansion of the wave equation

The radiation from sources which are small in comparison with the observation distance exhibits a symmetry suggesting a reformulation of the wave equation in spherical coordinates, as we have already done in Sec. 13.6.3. In short, we consider a scalar field $\psi(\mathbf{r}, t)$ satisfying the wave equation,

$$\nabla^2 \psi - \frac{1}{c^2} \frac{\partial^2 \psi}{\partial t^2} = 0 \ . \tag{19.64}$$

The temporal dependency is separated by a Fourier transform,

$$\psi(\mathbf{r}, t) = \int_{-\infty}^{\infty} \phi(\mathbf{r}, \omega) e^{-\imath\omega t} d\omega \ , \tag{19.65}$$

yielding a distribution of the amplitudes which satisfying the Poisson equation,

$$(\nabla^2 + k^2)\phi(\mathbf{r}, \omega) = 0 \ , \tag{19.66}$$

with $\omega^2 = c^2 k^2$. Expanding into spherical harmonics by the ansatz,

$$\phi(\mathbf{r}, \omega) = \sum_{\ell, m} f_\ell(r) Y_{\ell,m}(\theta, \phi) \ , \tag{19.67}$$

we transform (19.66), where the Laplacian is expressed in spherical coordinates, into a differential equation which is independent of m,

$$\left[\frac{d^2}{dr^2} + \frac{2}{r}\frac{d}{dr} + k^2 - \frac{\ell(\ell+1)}{r^2}\right] f_\ell(r) = 0 \ . \tag{19.68}$$

This equation is precisely the spherical Bessel equation, whose solutions are linear combinations of spherical Bessel and von Neumann functions,

$$A_\ell j_\ell(kr) + B_\ell n_\ell(kr) \ . \tag{19.69}$$

With respect to the spherical part, we note that the spherical harmonics are the eigenfunctions of the square of an angular momentum operator $\hat{\mathbf{L}}$, which can be identified with the angular part of the Laplacian in spherical coordinates,

$$\hat{\mathbf{L}}^2 = -\left[\frac{1}{\sin\theta}\frac{\partial}{\partial \sin\theta}\left(\sin\theta\frac{\partial}{\partial \sin\theta}\right) + \frac{1}{\sin^2\theta}\frac{\partial}{\partial\phi}\right] \ , \tag{19.70}$$

and has as eigenvalues the integer numbers $\ell(\ell+1)$,

$$\hat{\mathbf{L}}^2 Y_{\ell m} = \ell(\ell+1) Y_{\ell m} \ . \tag{19.71}$$

The Lie algebra ruling the calculation with angular momentum operators will not be reproduced here [5].

Clearly, the simplicity of the multipolar expansion of the wave equation (19.64) into spherical coordinates is due to its scalar nature, and a similar procedure is used to solve the scalar Schrödinger equation for the hydrogen atom. Electromagnetic fields, however, are vectorial which complicates the calculus, as we will see in the following.

19.1.5.1 Multipolar expansion of the fields

Assuming a time dependence as $e^{-\imath\omega t}$ and combining the Maxwell equations for the field rotations to derive the Helmholtz equation, we obtain a set of equations, which is equivalent to the Maxwell equations,

$$(\nabla^2 + k^2)\vec{\mathcal{B}} = 0 \qquad \text{and} \qquad \nabla\cdot\vec{\mathcal{B}} = 0 \qquad \text{with} \qquad \vec{\mathcal{E}} = \imath\frac{c}{k}\nabla\times\vec{\mathcal{B}} \ , \tag{19.72}$$

or alternatively,

$$(\nabla^2 + k^2)\vec{\mathcal{E}} = 0 \qquad \text{and} \qquad \nabla\cdot\vec{\mathcal{E}} = 0 \qquad \text{with} \qquad \vec{\mathcal{B}} = \imath\frac{1}{ck}\nabla\times\vec{\mathcal{E}} \ . \tag{19.73}$$

Now, we have for any well-behaved vector field $\mathbf{X}$,

$$\nabla^2(\mathbf{r}\cdot\mathbf{X}) = \mathbf{r}\cdot(\nabla^2\mathbf{X}) + 2\nabla\cdot\mathbf{X} \ . \tag{19.74}$$

Applying this relation to the electromagnetic fields, we find,

$$\boxed{(\nabla^2 + k^2)(\mathbf{r}\cdot\vec{\mathcal{B}}) = 0 \qquad \text{and} \qquad (\nabla^2 + k^2)(\mathbf{r}\cdot\vec{\mathcal{E}}) = 0} \ . \tag{19.75}$$

[5] See the treatment of spherical potentials in Sec. 23.3.1 .

The *transverse magnetic field* and the *transverse electric field* can be rewritten by the rotation of the equations (19.72) respectively (19.73),

$$\begin{aligned} \mathbf{r}\cdot\vec{\mathcal{B}} &= \tfrac{\imath}{ck}\mathbf{r}\cdot(\nabla\times\vec{\mathcal{E}}) = \tfrac{\imath}{ck}(\mathbf{r}\times\nabla)\cdot\vec{\mathcal{E}} \equiv \tfrac{1}{ck}\mathbf{L}\cdot\vec{\mathcal{E}} \\ \mathbf{r}\cdot\vec{\mathcal{E}} &= \tfrac{\imath c}{k}\mathbf{r}\cdot(\nabla\times\vec{\mathcal{B}}) = \tfrac{\imath c}{k}(\mathbf{r}\times\nabla)\cdot\vec{\mathcal{B}} \equiv \tfrac{c}{k}\mathbf{L}\cdot\vec{\mathcal{B}} \end{aligned} \quad , \tag{19.76}$$

defining in this way the operator for the orbital angular momentum $\mathbf{L}$.

These scalar fields can now be expanded as demonstrated in (19.67) and (19.69). That is, we can expand the transverse parts of electric and magnetic fields into magnetic (electric) multipoles as,

$$\begin{aligned} \mathbf{r}\cdot\vec{\mathcal{B}}^{(M)}_{\ell m} &= \tfrac{\ell(\ell+1)}{k} g_\ell(kr) Y_{\ell m}(\theta,\phi) = \tfrac{1}{ck}\mathbf{L}\cdot\vec{\mathcal{E}}^{(M)}_{\ell m} \quad \text{and} \quad \mathbf{r}\cdot\vec{\mathcal{E}}^{(M)}_{\ell m} = 0 \\ \mathbf{r}\cdot\vec{\mathcal{E}}^{(E)}_{\ell m} &= -Z_0\tfrac{\ell(\ell+1)}{k} f_\ell(kr) Y_{\ell m}(\theta,\phi) = \tfrac{c}{k}\mathbf{L}\cdot\vec{\mathcal{B}}^{(E)}_{\ell m} \quad \text{and} \quad \mathbf{r}\cdot\vec{\mathcal{B}}^{(E)}_{\ell m} = 0 \end{aligned} \quad . \tag{19.77}$$

where g_ℓ is a linear combination of Bessel and Hankel functions and $\ell(\ell+1)/k$ a convenient normalization factor.

We can see (by simplifying the argument a bit) that, by comparing (19.77) with the equation (19.71) the field $\vec{\mathcal{E}}^{(M)}$ must contain the operator $\mathbf{L}$,

$$\boxed{\begin{aligned} \vec{\mathcal{E}}^{(M)} &= c g_\ell(kr)\mathbf{L}Y_{\ell m}(\theta,\phi) \quad \text{with} \quad \vec{\mathcal{B}}^{(M)} = -\tfrac{\imath}{ck}\nabla\times\vec{\mathcal{E}}^{(M)}_{\ell m} \\ \vec{\mathcal{B}}^{(E)} &= \mu_0 g_\ell(kr)\mathbf{L}Y_{\ell m}(\theta,\phi) \quad \text{with} \quad \vec{\mathcal{E}}^{(E)} = -\tfrac{\imath c}{k}\nabla\times\vec{\mathcal{B}}^{(E)}_{\ell m} \end{aligned}} \quad . \tag{19.78}$$

The functions,

$$\mathbf{X}_{\ell m}(\theta,\phi) = \frac{1}{\sqrt{\ell(\ell+1)}}\mathbf{L}Y_{\ell m}(\theta,\phi) \ , \tag{19.79}$$

are known as *vector spherical harmonics*. Combining the expansions into electric and magnetic multipoles we obtain,

$$\begin{aligned} \vec{\mathcal{B}} &= \sum_{\ell m}\left[a^{(E)}_{\ell,m} f_\ell(kr)\mathbf{X}_{\ell,m} - \tfrac{\imath}{k}a^{(M)}_{\ell,m}\nabla\times g_\ell(kr)\mathbf{X}_{\ell m}\right] \\ \vec{\mathcal{E}} &= \sum_{\ell m}\left[\tfrac{\imath}{k}a^{(E)}_{\ell,m}\nabla\times f_\ell(kr)\mathbf{X}_{\ell,m} - a^{(M)}_{\ell,m} g_\ell(kr)\mathbf{X}_{\ell m}\right] \ . \end{aligned} \tag{19.80}$$

The coefficients can be determined from the radial projections of the fields.

19.1.5.2 Vector spherical harmonics

The *vector spherical harmonics* defined above are a particular case of those defined for the coupling of two spins $\mathbf{L}$ and $\mathbf{S}$ with $S=1$ in the following sense,

$$\boxed{\mathbf{Y}_{j\ell m} = \sum_q \begin{pmatrix} J & 1 & L \\ -m & q & m-q \end{pmatrix} Y^{(\ell)}_{m-q}\hat{\mathbf{e}}_q} \ , \tag{19.81}$$

where the basis is in Cartesian coordinates,

$$\hat{\mathbf{e}}_0 = \hat{\mathbf{e}}_z \qquad \text{and} \qquad \hat{\mathbf{e}}_\pm = -\tfrac{1}{\sqrt{2}}(\hat{\mathbf{e}}_x \pm \imath\hat{\mathbf{e}}_y) \ . \tag{19.82}$$

These functions are tensor operators of rank $(1,\ell)$, since $\mathbf{Y}_{j\ell m} = (Y^{(\ell)} \otimes \hat{\mathbf{e}}^{(1)})^{(j)}_m$. This means they have vectorial properties via $\hat{\mathbf{e}}^{(1)}_q$ and, at the same time, are tensor operators just like the spherical harmonics $Y^{(\ell)}_m$. It is possible to check the following expressions,

$$\begin{aligned}
\mathbf{J}^2\mathbf{Y}_{j\ell m} &= j(j+1)\mathbf{Y}_{j\ell m} \\
\mathbf{L}^2\mathbf{Y}_{j\ell m} &= \ell(\ell+1)\mathbf{Y}_{j\ell m} \\
\mathbf{S}^2\mathbf{Y}_{j\ell m} &= 2\mathbf{Y}_{j\ell m} \\
\mathbf{J}_z\mathbf{Y}_{j\ell m} &= m\mathbf{Y}_{j\ell m} \ .
\end{aligned} \tag{19.83}$$

Furthermore, comparing (19.83) and (19.79),

$$\begin{aligned}
\frac{\mathbf{L}}{\sqrt{\ell(\ell+1)}}Y^{(\ell)}_m = -\imath\mathbf{Y}_{\ell\ell m} &= \mathbf{X}_{\ell m} \\
\frac{\mathbf{r}}{r}Y^{(\ell)}_m = \imath\sqrt{\frac{\ell+1}{2\ell+1}}\mathbf{Y}_{\ell\ \ell+1\ m} &- \imath\sqrt{\frac{l}{2\ell+1}}\mathbf{Y}_{\ell\ \ell-1\ m} \\
0 = \mathbf{r}\cdot\mathbf{Y}_{\ell\ell m} &= \mathbf{p}\cdot\mathbf{Y}_{\ell\ell m} \ .
\end{aligned} \tag{19.84}$$

In 19.1.6.8 we calculate the following examples, $\mathbf{Y}_{000} = 0$ and,

$$r\mathbf{Y}_{110} = \sqrt{\tfrac{3}{16\pi}}\begin{pmatrix} -\imath y \\ \imath x \\ 0 \end{pmatrix} \quad , \quad r\mathbf{Y}_{11\pm1} = \sqrt{\tfrac{3}{16\pi}}\begin{pmatrix} z \\ \pm\imath \\ -(x\pm\imath y) \end{pmatrix} \quad , \quad r\mathbf{Y}_{10\pm1} = -\sqrt{\tfrac{1}{24\pi}}\begin{pmatrix} x \\ \pm\imath y \\ 0 \end{pmatrix} \ . \tag{19.85}$$

Also,

$$\mathbf{Y}^2_{\kappa\kappa m} = [\kappa(\kappa+1)-m(m+1)]|Y_{\kappa\ m+1}|^2+2m^2|Y_{\kappa\ m}|^2+[\kappa(\kappa+1)-m(m-1)]|Y_{\kappa\ m-1}|^2 \ . \tag{19.86}$$

Applying the formulas [1368](Chp. 10.1) to scalar and vector products of vector spherical harmonics, it is possible to derive the energy density $\frac{\varepsilon_0}{2}\vec{\mathcal{E}}^2_{jm\tau} + \frac{1}{2\mu_0}\vec{\mathcal{B}}^2_{jm\tau}$ and the Poynting vector $\varepsilon_0|\vec{\mathcal{E}}_{jm\tau}\times\vec{\mathcal{B}}_{jm\tau}|$. The calculation is complicated, because we must calculate $(3j)$, $\{6j\}$, and $\{9j\}$ coefficients. Considering that the angular distribution is the same for electric and magnetic multipolar radiation, we obtain,

$$u_{jm\tau}(\mathbf{r}) = \frac{1}{2\mu_0}\vec{\mathcal{B}}^2_{jm\tau}(\mathbf{r}) = -\frac{\hbar\omega}{4V}\left(\frac{j+1}{2j+1}\right)^2\frac{(kr)^{2j}}{(2j+1)!!^2}\mathbf{Y}^2_{jjm} \ , \tag{19.87}$$

The question now is, with what polarization ε and under what angle of incidence $\mathbf{k}$ can we excite a particular multipolar transition. The transition can only be excited by a mode, to which it couples and, therefore, into which it can radiate light. Therefore, it is sufficient to analyze the angular distribution and the polarization of spontaneously

emitted radiation. In the far-field of a point source the electric and magnetic fields satisfy the Helmholtz equation [1368],

$$(\triangle + \mathbf{k}^2)\vec{\mathcal{E}}(\mathbf{r},t) = 0 \ , \tag{19.88}$$

and similarly for the magnetic field $\vec{\mathcal{B}}(\mathbf{r},t)$. An atomic transition $|J,m_J\rangle \leftrightarrow |J+\kappa, m_J+m\rangle$ interacts with the electric or magnetic multipolar part κ of the radiation field. The general solution of the Helmholtz equation, therefore, is expanded into spherical harmonics $Y_{\kappa m}(\theta,\phi)$:

$$\vec{\mathcal{E}} = \sum_{\kappa=0}^{\infty}\sum_{m=-\kappa}^{\kappa}\left(\vec{\mathcal{E}}_m^{(E\kappa)} + \vec{\mathcal{E}}_m^{(M\kappa)}\right) \tag{19.89}$$

and similarly for the magnetic field. The angular distributions of the multipolar electric field components are calculated by,

$$\vec{\mathcal{E}}_m^{(E\kappa)} = -\imath k^{-1}\nabla\times\vec{\mathcal{B}}_m^{(E\kappa)} \tag{19.90}$$

$$\vec{\mathcal{B}}_m^{(E\kappa)} = -\imath\left(\mathbf{k}\times\nabla\right)Y_{\kappa m}(\theta,\phi) \equiv \sqrt{\kappa(\kappa+1)}\mathbf{Y}_{\kappa\kappa m}(\theta,\phi) \ , \tag{19.91}$$

and similarly for the magnetic field. The field components can be expressed by the vector spherical harmonics $\mathbf{Y}_{\kappa\kappa m}$. The angular distribution of the radiated intensity follows from the absolute value of the Poynting vector,

$$I_m^{(E\kappa)}(\mathbf{r}) = \mu_0^{-1}\left|\vec{\mathcal{E}}_m^{(E\kappa)}(\mathbf{r})\times\vec{\mathcal{B}}_m^{(E\kappa)}(\mathbf{r})\right| = \mu_0^{-1}\left|\vec{\mathcal{B}}_m^{(E\kappa)}(\mathbf{r})\right|^2 \propto \mathbf{Y}_{\kappa\kappa m}(\theta,\phi)^2 \ . \tag{19.92}$$

The multipolar order of a radiation can, in principle, be determined by measuring its angular distribution. The above distribution integrate over all possible polarizations. If polarized light is used, in order to excite transitions between selected Zeeman levels, the angular intensity distribution of *polarized radiation* must be calculated. The transition rate between two levels $|a\rangle$ and $|b\rangle$ for light incident from a given direction $\mathbf{r}$ with a given polarization $\hat{\varepsilon}$ is, $|\langle b|\hat{\varepsilon}\vec{\mathcal{E}}_m^{(E\kappa)}(\mathbf{r})|a\rangle|^2$, where $\vec{\mathcal{E}}_m^{(E\kappa)}(\mathbf{r}) = -\imath k^{-1}\nabla\times\vec{\mathcal{B}}_m^{(E\kappa)}(\mathbf{r})$. The cases of linear polar polarization (respectively axial) of the light field in relation to the quantization axis are expressed by the fractions $\hat{\varepsilon}_{polar}\cdot\mathbf{Y}_{\kappa\kappa m}$, respectively, $\hat{\varepsilon}_{axial}\cdot\mathbf{Y}_{\kappa\kappa m}$, the absolute square values of which add up to the angular intensity distribution,

$$\begin{aligned}
u_{10} &\sim 4|Y_1^{(1)}|^2 &&= \tfrac{3}{4\pi}2\sin^2\theta \\
u_{1\pm1} &\sim 2|Y_1^{(1)}|^2 + 2|Y_0^{(1)}|^2 &&= \tfrac{3}{4\pi}(1+\cos^2) \\
u_{20} &\sim 12|Y_1^{(2)}|^2 &&= \tfrac{5}{4\pi}18\sin^2\cos^2 \\
u_{2\pm1} &\sim 4|Y_2^{(2)}|^2 + 2|Y_1^{(2)}|^2 + 6|Y_0^{(2)}|^2 &&= \tfrac{5}{4\pi}3(4\cos^2 -3\cos^2 +1) \\
u_{2\pm2} &\sim 8|Y_2^{(2)}|^2 + 4|Y_1^{(2)}|^2 &&= \tfrac{5}{4\pi}3\sin^2(1+\cos^2) \\
u_{30} &\sim 24|Y_1^{(3)}|^2 &&= \tfrac{7}{4\pi}\tfrac{9}{2}\sin^2(5\cos^2 -1)^2 \\
u_{3\pm1} &\sim 10|Y_2^{(3)}|^2 + 2|Y_1^{(3)}|^2 + 12|Y_0^{(3)}|^2 &&= \tfrac{7}{4\pi}\tfrac{3}{8}(225\cos^6 -305\cos^4 +111\cos^2 +1) \\
u_{3\pm2} &\sim 6|Y_3^{(3)}|^2 + 8|Y_2^{(3)}|^2 + 10|Y_1^{(3)}|^2 &&= \tfrac{7}{4\pi}\tfrac{15}{4}\sin^2(9\cos^4 -2\cos^2 +1) \\
u_{3\pm3} &\sim 18|Y_3^{(3)}|^2 + 6|Y_2^{(3)}|^2 &&= \tfrac{7}{4\pi}\tfrac{45}{8}\sin^4(1+\cos^2) \ .
\end{aligned} \tag{19.93}$$

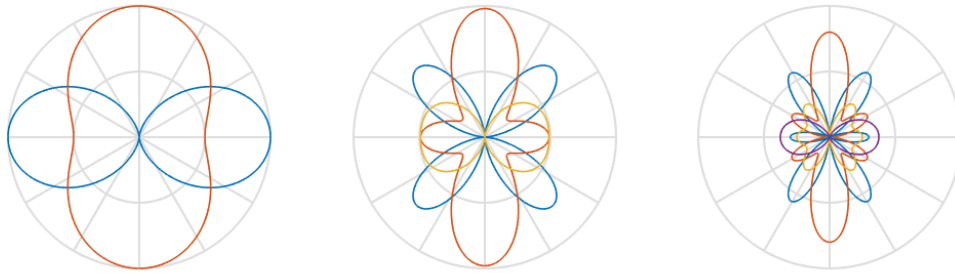

Figure 19.3: (code) Angular dependence of dipolar radiation u_{1m} (left), quadrupolar u_{2m} (center) and u_{3m} octupolar (right) with their respective contributions $m = 0$ (blue), $m = \pm 1$ (red), $m = \pm 2$ (yellow) and $m = \pm 3$ (magenta).

In the equatorial plane, only the parts $u_{j\pm 1}$ contribute; but these disappear in polar direction. All other components lie in the equatorial plane. For non-polarized radiation the angular distribution is uniform,

$$\sum_{m=-j}^{j} u_{jm} \sim \tfrac{2j+1}{4\pi} 2(j+1)! \; . \tag{19.94}$$

19.1.5.3 Distribution of the polarization of multipolar radiation

The axial and polar components of the vector spherical harmonics $\mathbf{Y}_{j\ell m}(\theta, \phi)$ at the observation point $\mathbf{r}$ can be determined as follows: First, we orient the coordinate system via the application of two rotation matrices $M_z(\phi)$ and $M_y(\theta)$ such that the observation point lies on top of the x axis. Then, we project the vector spherical harmonic via the application of a projection matrix $M_p(\lambda)$ on a straight line, which is perpendicular to the x-axis and forms with the y-axis an angle λ, as illustrated in Fig. 19.4. Finally, the coordinate system is rotated back to the original position:

$$\mathbf{Y}^{\lambda}_{jlm}(\theta, \phi) = M_z(\phi)^{-1} M_y(\theta)^{-1} M_p(\lambda) M_y(\theta) M_z(\phi) \mathbf{Y}_{jlm}(\theta, \phi) \tag{19.95}$$

with

$$M_p(\lambda) = \begin{pmatrix} 1 & 0 & 0 \\ 0 & \sin\lambda & 0 \\ 0 & 0 & \cos\lambda \end{pmatrix} \quad , \quad M_y(\theta) = \begin{pmatrix} \cos\theta & 0 & -\sin\theta \\ 0 & 1 & 0 \\ \sin\theta & 0 & \cos\theta \end{pmatrix} \quad , \tag{19.96}$$

$$M_z(\phi) = \begin{pmatrix} \cos\phi & -\sin\phi & 0 \\ \sin\phi & \cos\phi & 0 \\ 0 & 0 & 1 \end{pmatrix} \; . \tag{19.97}$$

The projection of the vector spherical harmonics $\mathbf{Y}_{jlm}(\theta, \phi)$ onto the vector field $\mathbf{Y}^{\lambda}_{j\ell m}(\theta, \phi)$ describes, how the light emitted by the multipolar transition is modified by transmission through a polarizer, whose main axis is rotated about the quantization axis by an angle λ.

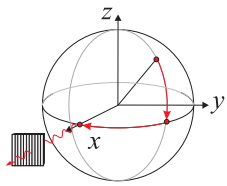

Figure 19.4: Illustration of the measurement of $\mathbf{Y}_{j\ell m}(\vartheta,\varphi)$.

19.1.5.4 Coupling of multipolar fields to radiation sources

We consider distributions of charges, currents, and *intrinsic magnetization*, e.g. the electron spin.

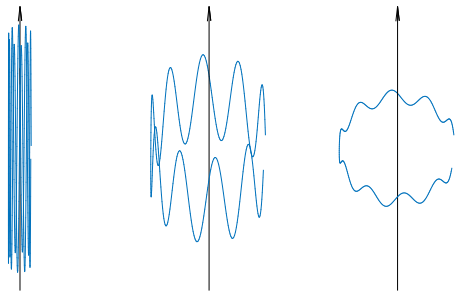

Figure 19.5: Classical picture of the electronic motion excited by (a) π-light, (c) $\sigma^{\pm}$-light, and (b) both.

19.1.5.5 Atomic multipoles

Here, we consider the electric charges and currents of an atom interacting with electromagnetic fields. We borrow the parametrization of the charges (17.25) and currents (17.39) in the atomic layer from the microscopic model of Maxwell's equations,

$$\varrho_{mic}(\mathbf{r}) = Ze\delta(\mathbf{r}) - \sum_j e\delta(\mathbf{r}-\mathbf{r}_j) \quad , \quad \mathbf{j}_{mic}(\mathbf{r}) = \sum_j e\dot{\mathbf{r}}_j\delta(\mathbf{r}-\mathbf{r}_j) \ . \tag{19.98}$$

We derive a polarization (17.34) and a magnetization (17.50) which, in the absence of free charges and currents, are given by,

$$\varrho_{mic}(\mathbf{r}) = -\nabla\cdot\vec{\mathcal{P}}(\mathbf{r}) \quad , \quad \mathbf{j}_{mic}(\mathbf{r}) = \dot{\mathbf{P}}(\mathbf{r}) + \nabla\times\vec{\mathcal{M}}(\mathbf{r}) \ . \tag{19.99}$$

Interacting with radiation fields $\vec{\mathcal{E}}$ and $\vec{\mathcal{B}}$, the interaction energy is,

$$W = -\int \vec{\mathcal{E}}(\mathbf{r})\cdot\vec{\mathcal{P}}(\mathbf{r})\ d^3r - \int \vec{\mathcal{M}}(\mathbf{r})\cdot\vec{\mathcal{B}}(\mathbf{r})\ d^3r \ . \tag{19.100}$$

The multipolar expansion using the above five equations gives,

$$\begin{aligned} W = e\sum\nolimits_j \left[1 + \tfrac{1}{2!}(\mathbf{r}_j\cdot\nabla) + \tfrac{1}{3!}(\mathbf{r}_j\cdot\nabla)^2 + ..\right]\mathbf{r}_j\cdot\vec{\mathcal{E}}(0) + \\ + \tfrac{e}{m}\sum\nolimits_j \left[\tfrac{1}{2!} + \tfrac{2}{3!}(\mathbf{r}_j\cdot\nabla) + \tfrac{3}{4!}(\mathbf{r}_j\cdot\nabla)^2 + ..\right]\mathbf{l}_j\cdot\vec{\mathcal{B}}(0) \ , \end{aligned} \tag{19.101}$$

where $\mathbf{l}_j \equiv m\mathbf{r}_j \times \dot{\mathbf{r}}_j$. Introducing dipole, quadrupole, and octupolar electric and magnetic moments,

$$\begin{array}{ll} \mathbf{d}_E = \sum_j \mathbf{r}_j & \mathbf{d}_M = \frac{1}{2!}\frac{1}{cm}\sum_j \mathbf{l}_j \\ \mathbf{q}_E = \frac{1}{2!}\sum_j \mathbf{r}_j \otimes \mathbf{r}_j & \mathbf{q}_M = \frac{2}{3!}\frac{1}{cm}\sum_j \mathbf{l}_j \otimes \mathbf{r}_j \\ \mathbf{o}_E = \frac{1}{2!}\sum_j \mathbf{r}_j \otimes \mathbf{r}_j \otimes \mathbf{r}_j & \mathbf{o}_M = \frac{3}{4!}\frac{1}{cm}\sum_j \mathbf{l}_j \otimes \mathbf{r}_j \otimes \mathbf{r}_j \end{array} \tag{19.102}$$

and making the ansatz for the fields $\vec{\mathcal{E}}(\mathbf{r}) = \hat{\epsilon}\vec{\mathcal{E}}_0 e^{\imath \mathbf{k}\cdot\mathbf{r}}$ and $\vec{\mathcal{B}}(\mathbf{r}) = (\mathbf{k}\times\hat{\epsilon})\vec{\mathcal{B}}_0 e^{\imath\mathbf{k}\cdot\mathbf{r}}$, where $\vec{\mathcal{B}}_0 = \vec{\mathcal{E}}_0/c$ we obtain,

$$\begin{aligned} W = {} & e\vec{\mathcal{E}}_0\hat{\varepsilon}[\mathbf{d}_E + \mathbf{q}_E\nabla + \mathbf{o}_E(\nabla\otimes\nabla) + ..]\; e^{\imath\mathbf{k}\cdot\mathbf{r}}\big|_{\mathbf{r}=0} \\ & + e\vec{\mathcal{E}}_0(\mathbf{k}\times\hat{\varepsilon})[\mathbf{d}_M + \mathbf{q}_M\nabla + \mathbf{o}_M(\nabla\otimes\nabla) + ..]\; e^{\imath\mathbf{k}\cdot\mathbf{r}}\big|_{\mathbf{r}=0}\ . \end{aligned} \tag{19.103}$$

The gradient only acts on the coordinate $\mathbf{r}$,

$$W = e\vec{\mathcal{E}}_0\hat{\varepsilon}[\mathbf{d}_E + \mathbf{q}_E\imath\mathbf{k} - \mathbf{o}_E(\mathbf{k}\otimes\mathbf{k}) + ..] + e\vec{\mathcal{E}}_0(\hat{\mathbf{k}}\times\hat{\varepsilon})[\mathbf{d}_M + \mathbf{q}_M\imath\mathbf{k} - \mathbf{o}_M(\mathbf{k}\otimes\mathbf{k}) + ..]\ . \tag{19.104}$$

To render irreducible multipolar component we replace,

$$\mathbf{q}_E \to \mathbf{q}_E - \tfrac{1}{3}\vec{\mathcal{E}}_3 \mathrm{Tr}\ \mathbf{q}_E = \tfrac{1}{2!}\left(\mathbf{r}\otimes\mathbf{r} - \tfrac{1}{3}\vec{\mathcal{E}}_3 r^2\right)\ . \tag{19.105}$$

19.1.5.6 Multipolar expansion of the vector potential

When the radiation has a small wavelength, or when dipolar transitions are prohibited by selection rules, higher multipolar orders can enter the game [718]. Then we expand the plane waves into spherical waves,

$$e^{\imath\mathbf{k}\cdot\mathbf{r}} = 4\pi\sum_{\ell=0}^{\infty}\sum_{m=-\ell}^{\ell}\imath^\ell j_\ell(kr)Y_\ell^m(\hat{\mathbf{e}}_k)Y_\ell^{m*}(\hat{\mathbf{e}}_r) = \sum_{\ell=0}^{\infty}(2\ell+1)\imath^\ell j_\ell(kr)P_\ell(\hat{\mathbf{e}}_k\cdot\hat{\mathbf{e}}_r)\ . \tag{19.106}$$

The quantum operator for the vector potential is,

$$\boxed{\begin{array}{lll} \hat{\mathbf{A}}^-(\mathbf{r}) = \sqrt{\frac{\hbar\omega}{2\varepsilon_0 V}}\hat{\epsilon}e^{\imath\mathbf{k}\cdot\mathbf{r}}\hat{a} & = \sum_{j=0}^{\infty}\sum_{m=-j}^{j}\sum_{\tau=\pm(-1)^j}\hat{\mathbf{A}}^-_{jm\tau}(\mathbf{r}) & \\ \quad \text{onde} \quad \hat{\mathbf{A}}^-_{jm(-1)^j}(\mathbf{r}) & = \sqrt{\frac{\hbar\omega}{2\varepsilon_0 V}}\frac{1}{\sqrt{j(j+1)}}\frac{-\imath}{k}\nabla\times(\nabla\times\mathbf{r})Y_{jm}(\theta,\phi)j_j(kr)\hat{a}_{jm\tau} & . \\ \quad \text{and} \quad \hat{\mathbf{A}}^-_{jm(-1)^{j+1}}(\mathbf{r}) & = \sqrt{\frac{\hbar\omega}{2\varepsilon_0 V}}\frac{1}{\sqrt{j(j+1)}}\nabla\times\mathbf{r}Y_{jm}(\theta,\phi)j_j(kr)\hat{a}_{jm\tau} & \end{array}} \tag{19.107}$$

Multipolar electric radiation has the parity $\tau = (-1)^j$ and magnetic radiation the parity $\tau = -(-1)^j$,

$$\Pi\hat{\mathbf{A}}_{jm\tau}(\mathbf{r}) = -\hat{\mathbf{A}}_{jm\tau}(-\mathbf{r}) = \tau\hat{\mathbf{A}}_{jm\tau}(\mathbf{r})\ . \tag{19.108}$$

The partial fields $\hat{\mathbf{A}}_{jm\tau}$ are irreducible tensor fields of order j:

$$U_R \hat{\mathbf{A}}_{jm\tau}(\mathbf{r}) U_R^* = \hat{\mathbf{A}}_{jm\tau}(R^{-1}\mathbf{r}) = \sum_{m'} \hat{\mathbf{A}}_{jm'\tau}(\mathbf{r}) D^j_{mm'} \ . \tag{19.109}$$

As a result, the elements of the transition matrix are,

$$\langle j_f m_f \tau_f | \imath \hat{\mathbf{A}}_{jm\tau}(\mathbf{r}) \hat{p} | j_i m_i \tau_i \rangle \ . \tag{19.110}$$

19.1.5.7 Representation in terms of vector spherical harmonics

The electric vector potential can be written as,

$$\begin{aligned}
\hat{\mathbf{A}}^{(E)}_{jm\tau}(\mathbf{r}) &= \sqrt{\frac{\hbar}{2\varepsilon_0 V\omega}} \frac{1}{\sqrt{j(j+1)}} \frac{-\imath}{k} \nabla \times \mathbf{j} Y^{(j)}_m(\Omega) j_j(kr) \qquad (19.111)\\
&= \sqrt{\frac{\hbar}{2\varepsilon_0 V\omega}} \frac{-\imath}{k} \nabla \times Y_{jjm}(\Omega) j_j(kr) \\
&= \sqrt{\frac{\hbar}{2\varepsilon_0 V\omega}} \left[-\sqrt{j} 2j+1 \cancelto{0}{j_{j+1}(kr)} Y_{jj+1m}(\Omega) + \sqrt{\frac{j+1}{2j+1}} j_{j-1}(kr) Y_{jj-1m}(\Omega) \right] \ ,
\end{aligned}$$

because for a small source sizes we can approximate, $j_j(kr) \simeq (kr)^j/(2j+1)!!$. We obtain,

$$\boxed{\begin{aligned}
\hat{\mathbf{A}}^{(E)}_{jm\tau}(\mathbf{r}) &= \sqrt{\tfrac{\hbar}{2\varepsilon_0 V\omega}} \sqrt{\tfrac{j+1}{2j+1}} \tfrac{(kr)^{j-1}}{(2j-1)!!} Y_{jj-1m} \\
\hat{\vec{\mathcal{E}}}^{(E)}_{jm\tau}(\mathbf{r}) &= -\tfrac{\partial \hat{\mathbf{A}}^{(E)}_{jm\tau}}{\partial t} = \imath \sqrt{\tfrac{\hbar\omega}{2\varepsilon_0 V}} \sqrt{\tfrac{j+1}{2j+1}} \tfrac{(kr)^{j-1}}{(2j-1)!!} Y_{jj-1m} \\
\hat{\vec{\mathcal{B}}}^{(E)}_{jm\tau}(\mathbf{r}) &= \nabla \times \hat{\mathbf{A}}^{(E)}_{jm\tau} = -\imath \sqrt{\tfrac{\mu_0 \hbar\omega}{2V}} \tfrac{j+1}{2j+1} \tfrac{(kr)^j}{(2j+1)!!} Y_{jjm} \ .
\end{aligned}} \tag{19.112}$$

Similarly we obtain for the magnetic vector potential,

$$\hat{\mathbf{A}}^{(M)}_{jm\tau}(\mathbf{r}) = -\imath \sqrt{\frac{\hbar}{2\varepsilon_0 V\omega}} \frac{1}{\sqrt{j(j+1)}} \mathbf{j} Y^{(j)}_m(\Omega) j_j(kr) = -\imath \sqrt{\frac{\hbar}{2\varepsilon_0 V\omega}} j_j(kr) Y_{jjm}(\Omega) \ , \tag{19.113}$$

and for a small source sizes,

$$\boxed{\begin{aligned}
\hat{\mathbf{A}}^{(M)}_{jm\tau}(\mathbf{r}) &= -\imath \sqrt{\tfrac{\hbar}{2\varepsilon_0 V\omega}} \tfrac{(kr)^j}{(2j+1)!!} Y_{jjm} \\
\hat{\vec{\mathcal{E}}}^{(M)}_{jm\tau}(\mathbf{r}) &= \sqrt{\tfrac{\hbar\omega}{2\varepsilon_0 V}} \tfrac{(kr)^j}{(2j+1)!!} Y_{jjm} \\
\hat{\vec{\mathcal{B}}}^{(M)}_{jm\tau}(\mathbf{r}) &= \sqrt{\tfrac{\mu_0 \hbar\omega}{2V}} \sqrt{\tfrac{j+1}{2j+1}} \tfrac{(kr)^{j-1}}{(2j-1)!!} Y_{jj-1m} \ .
\end{aligned}} \tag{19.114}$$

19.1.5.8 Interaction with light fields

The interaction energy is expressed by insertion of the field operators for $\vec{\mathcal{E}}$ and $\vec{\mathcal{B}}$,

$$\hat{\vec{\mathcal{E}}}(\mathbf{r})^- = \hat{\vec{\mathcal{E}}}_0^- \hat{\epsilon} e^{\imath \mathbf{k}\cdot\mathbf{r}} \quad \text{and} \quad \hat{\vec{\mathcal{B}}}(\mathbf{r})^- = \hat{\vec{\mathcal{E}}}_0^- \tfrac{1}{\omega} \mathbf{k} \times \hat{\epsilon} e^{\imath \mathbf{k}\cdot\mathbf{r}} \quad \text{with} \quad \hat{\vec{\mathcal{E}}}_0^- \equiv \imath \sqrt{\frac{\hbar\omega}{2\varepsilon_0 V}} \hat{a} \ . \tag{19.115}$$

Here, $\hat{\vec{\mathcal{E}}}_0^+$ creates a photon, while $\hat{\vec{\mathcal{E}}}_0^-$ annihilates a photon. Considering first order processes (RWA), we obtain for the matrix element $\langle f|\hat{H}_{ww}|i\rangle$ for the emission of a photon (and similarly for absorption),

$$\langle g, n+1|\hat{H}_{ww}|e, n\rangle = -ie\sqrt{\frac{\hbar\omega}{2\varepsilon_0 V}}\langle n+1|\hat{a}^\dagger|n\rangle\left[\hat{\epsilon}\langle g|\mathbf{d}_E + ...|e\rangle + (\hat{\mathbf{e}}_k \times \hat{\epsilon})\langle g|\mathbf{d}_M + ...|e\rangle)\right] . \tag{19.116}$$

Finally, the matrix elements for the first three multipolar orders are,

$$\begin{aligned}\langle f|\hat{H}_{ww}|i\rangle = -ie\sqrt{\frac{\hbar\omega}{2\varepsilon_0 V}}\sqrt{\cdot}\,[\hat{\epsilon}(\langle g|\mathbf{d}_E|e\rangle + \imath\langle g|\mathbf{q}_E|e\rangle\mathbf{k} - \langle g|\mathbf{o}_E|e\rangle\mathbf{k}\times\mathbf{k} + ...) \\ +(\hat{\mathbf{e}}_k \times \hat{\epsilon})(\langle g|\mathbf{d}_M|e\rangle + \imath\langle g|\mathbf{q}_M|e\rangle\mathbf{k} - \langle g|\mathbf{o}_M|e\rangle\mathbf{k}\times\mathbf{k} + ...)] .\end{aligned} \tag{19.117}$$

For $\sqrt{\cdot} = \sqrt{n+1}$ this formula describes induced and spontaneous emission and for $\sqrt{\cdot} = \sqrt{n}$ absorption.

19.1.5.9 Matrix element for electromagnetic transitions

The matrix element is a tensor product between the vector operator $\hat{\mathbf{p}}$ and a vector spherical harmonic $\mathbf{Y}_{j\ell m}$. Therefore,

$$\begin{aligned}\hat{\mathbf{A}}^{(E)}_{jm\tau}(\mathbf{r})\cdot\hat{\mathbf{p}} &= \imath\sqrt{\frac{\hbar}{2\varepsilon_0 V\omega}}\frac{\sqrt{j+1}}{(2j+1)!!}\langle j||p^{(1)}||j-1\rangle(kr)^{j-1}Y^{(j)}_m \\ \hat{\mathbf{A}}^{(M)}_{jm\tau}(\mathbf{r})\cdot\hat{\mathbf{p}} &= -\imath\sqrt{\frac{\hbar}{2\varepsilon_0 V\omega}}\frac{1}{\sqrt{j+1}(2j+1)!!}\langle j||p^{(1)}||j\rangle(kr)^{j}Y^{(j)}_m .\end{aligned} \tag{19.118}$$

In addition, we have $Y^{(j)}_m = \imath^{-j}\langle\Omega|jm\rangle$, and therefore,

$$\langle j_f m_f|Y^{(j)}_m|j_i m_i\rangle = \imath^{j_j - j_i}\frac{\sqrt{2j+1}\sqrt{2j_i+1}}{\sqrt{4\pi}\sqrt{2j_f+1}}\left(\begin{array}{c|ccc} j_f & j & j_i \\ m_f & m & m_i\end{array}\right)\left(\begin{array}{c|ccc} j_f & j & j_i \\ 0 & 0 & 0\end{array}\right) . \tag{19.119}$$

This relation contains the selection rules for the matrix element $\langle j_j m_j \tau_f|\hat{\mathbf{A}}_{jm\tau}(\mathbf{r})\cdot\hat{\mathbf{p}}|j_i m_i \tau_i\rangle$, i.e. the conservation laws for angular momentum and parity:

$$|j_f - j_i| \le j \le j_f + j_i \qquad \text{and} \qquad (-)^{j_j+j_i} = \tau . \tag{19.120}$$

19.1.5.10 Matrix element without hyperfine and fine structure

This matrix element relates the initial state to the final state by,

$$\langle\alpha L m|\hat{\mathbf{T}}^{(k)}_q|\alpha' L' m'\rangle . \tag{19.121}$$

The angular momentum of the electronic layer is not split any more. Following the Wigner-Eckart theorem we have,

$$\langle Lm|\hat{\mathbf{T}}^{(k)}_q|L'm'\rangle = (-)^{L-m_L}\begin{pmatrix} L' & k & L \\ m'_L & q & -m_L\end{pmatrix}\langle L||\hat{\mathbf{T}}^{(k)}_q||L'\rangle . \tag{19.122}$$

With the $(3j)$-symbol being $(3j) \sim \delta(L'kL)\delta_{m'_L+q,m_L}$ the following selection rules apply,

$$|L - L'| \leq k \leq L + L \qquad \text{and} \qquad m'_L + q = m_L \ . \tag{19.123}$$

The Zeeman splitting is normalized by,

$$\sum_{m_L, m'_L} |\langle Lm|\hat{\mathbf{T}}^{(k)}_q|L'm'\rangle|^2 = |\langle L||\hat{\mathbf{T}}^{(k)}_q||L'\rangle|^2 \ . \tag{19.124}$$

With this, we obtain for the relative oscillator strengths,

$$\left| \frac{\langle Lm|\hat{\mathbf{T}}^{(k)}_q|L'm'\rangle}{\langle L||\hat{\mathbf{T}}^{(k)}_q||L'\rangle} \right|^2 = \begin{pmatrix} L' & k & L \\ m'_L & q & -m_L \end{pmatrix}^2 \ . \tag{19.125}$$

However, electric multipole radiation does not act on $\mathbf{L}$, but on $\mathbf{J}$. For example, in the ion Yb^+ the transition ${}^2D_{5/2} - {}^2P_{1/2}$ is dipolarly prohibited, but not ${}^2D_{3/2} - {}^2P_{1/2}$.

19.1.5.11 Fermi's golden rule

A *Fermi's Golden rule* (first perturbative order) allows us to make a gross estimation of the transition rate,

$$\frac{1}{\tau} = \frac{2\pi}{\hbar^2}|\langle f|\hat{H}_{ww}|i\rangle|^2\delta(\omega - \omega_0) \ . \tag{19.126}$$

For spontaneous emission we have,

$$\frac{1}{\tau} = \frac{2\pi}{\hbar^2}\frac{e^2}{m^2}\frac{\hbar}{\omega 2\varepsilon_0 V}|\langle g|e^{\imath\mathbf{k}\cdot\mathbf{r}}\hat{H}_{ww}|i\rangle|^2 \ . \tag{19.127}$$

Approximating $p/m \simeq c$ and $V \simeq \lambda^3$ and using $\alpha \equiv e^2/(4\pi\varepsilon_0\hbar c)$ and $r \simeq a_B$, we obtain,

$$\frac{1}{\tau} = \frac{\alpha}{2\pi}\omega^2|\langle e^{\imath k a_B}\rangle|^2\delta(\omega) \ . \tag{19.128}$$

Now, expanding the exponential function into plane waves (19.106) and using the limit $kr \ll \ell$, where the Bessel function is well approximated by (19.27), we obtain,

$$\frac{1}{\tau} = \frac{2\pi\alpha}{(2\ell+1)!!^2}(ka_B)^{2\ell}\omega|\langle||\rangle|^2 \ . \tag{19.129}$$

19.1.6 Exercises

19.1.6.1 Ex: Relationship between current density and electric dipole moment

a. For a charge and current configuration contained in a volume $\mathcal{V}$ show that, $\int_{\mathcal{V}} \mathbf{j} dV = \frac{d\mathbf{d}}{dt}$, where $\mathbf{d}$ is the total dipolar moment.
b. Demonstrate the relationship, $\int \mathbf{r}'(\hat{\mathbf{e}}_r\cdot\mathbf{r}')\dot{\varrho}(\mathbf{r}')d^3r' = \int \{\mathbf{j}(\mathbf{r}')(\hat{\mathbf{e}}_r\cdot\mathbf{r}') + \mathbf{r}'[\hat{\mathbf{e}}_r\cdot\mathbf{j}(\mathbf{r}')]\}\, d^3r'$.

Solution: *a. We first calculate,*

$$0 = \oint_{\partial\mathcal{V}} x\mathbf{j}\cdot d\mathbf{S} = \int_{\mathcal{V}} \nabla\cdot(x\mathbf{j})dV = \int_{\mathcal{V}} (\nabla x\cdot\mathbf{j} + x\nabla\cdot\mathbf{j})dV$$
$$= \int_{\mathcal{V}} (j_x + x\nabla\cdot\mathbf{j})dV = \int_{\mathcal{V}} \left(j_x - x\frac{\partial\varrho}{\partial t}\right) dV \ ,$$

where we used the continuity equation. By choosing the volume large enough, the surface integral vanishes. Generalizing to 3D, we get,

$$\int_{\mathcal{V}} \mathbf{j}dV = \int_{\mathcal{V}} \mathbf{r}\frac{\partial\varrho}{\partial t}dV \equiv \frac{d\mathbf{d}}{dt} \ ,$$

which is the definition of the dipole moment.
b. The continuity equation allows us to replace $\imath\omega\varrho(\mathbf{r}')$ *by* $\nabla\cdot\mathbf{j}(\mathbf{r}')$*,*

$$-\tfrac{\imath\omega}{2}\int \mathbf{r}'(\hat{\mathbf{e}}_r\cdot\mathbf{r}')\varrho(\mathbf{r}')d^3r' = -\tfrac{1}{2}\int \mathbf{r}'(\hat{\mathbf{e}}_r\cdot\mathbf{r}')\nabla\cdot\mathbf{j}(\mathbf{r}')d^3r' \ .$$

Considering only one coordinate, we can apply the rule of integration by parts,

$$0 = \oint (\psi\mathbf{j})\cdot d\mathbf{S} = \int \nabla(\psi\mathbf{j})d^3r' = \int (\mathbf{j}\cdot\nabla\psi + \psi\nabla\cdot\mathbf{j})d^3r' \ .$$

In the following way,

$$-\int x'(\hat{\mathbf{e}}_r\cdot\mathbf{r}')\nabla\cdot\mathbf{j}(\mathbf{r}')d^3r' = \int \mathbf{j}(\mathbf{r}')\cdot\nabla[x'(\hat{\mathbf{e}}_r\cdot\mathbf{r}')]d^3r'$$
$$= \int \mathbf{j}(\mathbf{r}')\cdot[(\hat{\mathbf{e}}_r\cdot\mathbf{r}')\nabla x' + x'\nabla(\hat{\mathbf{e}}_r\cdot\mathbf{r}')]d^3r'$$
$$= \int \mathbf{j}(\mathbf{r}')\cdot[(\hat{\mathbf{e}}_r\cdot\mathbf{r}')\hat{\mathbf{e}}_x + x'\hat{\mathbf{e}}_r]d^3r' = \int \{j_x(\mathbf{r}')(\hat{\mathbf{e}}_r\cdot\mathbf{r}') + x'[\hat{\mathbf{e}}_r\cdot\mathbf{j}(\mathbf{r}')]\}\, d^3r' \ .$$

Such that finally,

$$-\tfrac{\imath\omega}{2}\int \mathbf{r}'(\hat{\mathbf{e}}_r\cdot\mathbf{r}')\varrho(\mathbf{r}')d^3r' = \int \{\mathbf{j}(\mathbf{r}')(\hat{\mathbf{e}}_r\cdot\mathbf{r}') + \mathbf{r}'[\hat{\mathbf{e}}_r\cdot\mathbf{j}(\mathbf{r}')]\}\, d^3r' \ .$$

19.1.6.2 Ex: Hertz dipole

A Hertz dipole with vertical orientation is in the focus of a parabolic antenna PA1 and emits electromagnetic radiation with a frequency of 3 GHz. The shape of the antenna is such that the electromagnetic radiation is reflected forming a 'parallel' beam with diameter $d = 3\,\mathrm{m}$. The electric field within the beam can be roughly described by the following formula:

$$\vec{\mathcal{E}}_1(\mathbf{r},t) = \vec{\mathcal{E}}_0\cos(\mathbf{k}_1\cdot\mathbf{r} - \omega t)\ \hat{\mathbf{e}}_z \qquad \text{where} \qquad \mathbf{k}_1 = -k\hat{\mathbf{e}}_x\sin\alpha + k\hat{\mathbf{e}}_y\cos\alpha \ .$$

a. Determine the parameter k using the wave equation.
b. What is the amplitude $\vec{\mathcal{E}}_0$ of the electric field assuming that the parabolic antenna emits a power of 5 W?
c. There is a second Hertz dipole, acting as a detector, oriented orthogonal to $\mathbf{k}_1$. The maximum amplitude of the electric field detected by D2 is around 0.1 V/m. Estimate the angle of the orientation of the dipole with respect to the vertical axis (without calculation, but with a short justification).
d. Now, the emitter dipole D1 is also rotated in such a way that, regardless of the orientation of the dipole D2, it does not receive signals. What is the orientation of the dipole emitter? Give a short justification.
e. The dipole emitter is again oriented vertically. Another parabolic antenna PA2, identical to PA1, is now integrated into the experiment, as shown in the figure. Calculate the power density S on the axis x in the time average. ($\alpha = 5°$)
Help: Addition theorems:

$$\cos(\alpha \pm \beta) = \cos\alpha\cos\beta \mp \sin\alpha\sin\beta \qquad \text{and} \qquad \cos 2\alpha = \cos^2\alpha - \sin^2\alpha$$

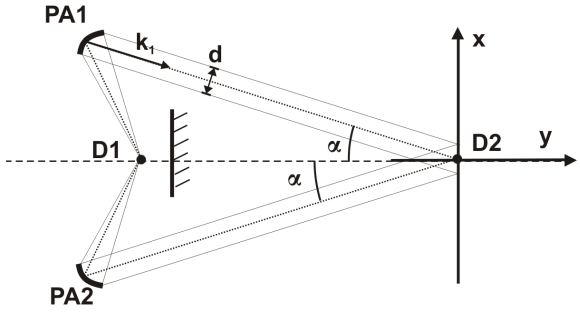

Figure 19.6: Hertz dipole.

Solution: *a. The wave equation gives,*

$$0 = \frac{1}{c^2}\frac{\partial^2\vec{\mathcal{E}}_1}{\partial t^2} - \nabla^2\vec{\mathcal{E}}_1 = \frac{-\omega^2}{c^2}\vec{\mathcal{E}}_1 - \frac{\partial^2}{\partial x^2}\vec{\mathcal{E}}_1 - \frac{\partial^2}{\partial y^2}\vec{\mathcal{E}}_1 - \cancelto{0}{\frac{\partial^2}{\partial z^2}\vec{\mathcal{E}}_1}$$
$$= \frac{-\omega^2}{c^2}\vec{\mathcal{E}}_1 + k^2\vec{\mathcal{E}}_1\sin^2\alpha + k^2\vec{\mathcal{E}}_1\cos^2\alpha = \frac{-\omega^2}{c^2}\vec{\mathcal{E}}_1 + k^2\vec{\mathcal{E}}_1 \ ,$$

such that, $k = \omega/c$.
b. The power being,

$$P = I\pi\frac{d^2}{4} = c\varepsilon_0\vec{\mathcal{E}}_0^2\pi\frac{d^2}{4} = 5\,\mathrm{W} \ ,$$

we calculate $\vec{\mathcal{E}}_0 \approx 23\,\mathrm{V/m}$. c. The dipole D2 is oriented in the direction ???
d. The dipole D2 is oriented such as to oscillate along the line D1-PA1.
e.

19.1.6.3 Ex: Dipolar spherical waves

We derived in class, starting from the relations $\vec{\mathcal{B}} = \nabla \times \mathbf{A}$ and $\vec{\mathcal{E}} = \frac{\imath c}{k}\nabla \times \vec{\mathcal{B}}$, the expressions (19.40) for the magnetic and electric fields of a electric dipole radiation produced by the dipole moment $\mathbf{d} = d\hat{\mathbf{e}}_z$.
a. Show that the magnetic field can be expressed in the form $\vec{\mathcal{B}} = \vec{\mathcal{B}}_\phi(r,\theta)\hat{\mathbf{e}}_\phi$.
b. Show that the electric field can be expressed in the form $\vec{\mathcal{E}} = \vec{\mathcal{E}}_r(r,\theta)\hat{\mathbf{e}}_r + \vec{\mathcal{E}}_\theta(r,\theta)\hat{\mathbf{e}}_\theta$.
c. The purpose of this exercise is to check in spherical coordinates, where the divergence and rotation are given by (12.79) and (12.80), that these fields satisfy Maxwell's equations.

Solution: *a. We calculate,*

$$\begin{aligned}\vec{\mathcal{B}} = \frac{ck^3\mu_0}{4\pi}\mathfrak{Re}\left[\hat{\mathbf{e}}_r \times \mathbf{d}\frac{e^{\imath(kr-\omega t)}}{kr}\left(1-\frac{1}{\imath kr}\right)\right] &= -\frac{ck^3 d\mu_0}{4\pi}\sin\theta\hat{\mathbf{e}}_\phi Re\left[\frac{e^{\imath u}}{kr}\left(1-\frac{1}{\imath kr}\right)\right] \\ &= -\frac{ck^3 d\mu_0}{4\pi}\sin\theta\left[\frac{\cos u}{kr}-\frac{\sin u}{(kr)^2}\right]\hat{\mathbf{e}}_\phi \\ &\equiv \vec{\mathcal{B}}_\phi\hat{\mathbf{e}}_\phi \ ,\end{aligned}$$

where we introduced the abbreviation $u \equiv kr - \omega t$ and used $\hat{\mathbf{e}}_r \times \hat{\mathbf{e}}_z = -\hat{\mathbf{e}}_\phi$.
b. We calculate,

$$\begin{aligned}\vec{\mathcal{E}} &= \frac{k^3}{4\pi\varepsilon_0}\mathfrak{Re}\left[(\hat{\mathbf{e}}_r\times\mathbf{d})\times\hat{\mathbf{e}}_r\frac{e^{\imath(kr-\omega t)}}{kr} + [3\hat{\mathbf{e}}_r(\hat{\mathbf{e}}_r\cdot\mathbf{d})-\mathbf{d}]\left(\frac{1}{(kr)^2}+\frac{1}{\imath kr}\right)\frac{e^{\imath(kr-\omega t)}}{kr}\right] \\ &= \frac{k^3 d}{4\pi\varepsilon_0}\mathfrak{Re}\left[-\sin\theta\hat{\mathbf{e}}_\theta\frac{e^{\imath(kr-\omega t)}}{kr} + [2\cos\theta\hat{\mathbf{e}}_r+\sin\theta\hat{\mathbf{e}}_\theta]\left(\frac{1}{(kr)^2}+\frac{1}{\imath kr}\right)\frac{e^{\imath(kr-\omega t)}}{kr}\right] \\ &= \frac{k^3 d}{4\pi\varepsilon_0}Re\left[2\cos\theta\left(\frac{1}{(kr)^2}+\frac{1}{\imath kr}\right)\frac{e^{\imath u}}{kr}\hat{\mathbf{e}}_r + \sin\theta\left(\frac{1}{(kr)^2}+\frac{1}{\imath kr}-1\right)\frac{e^{\imath u}}{kr}\hat{\mathbf{e}}_\theta\right] \\ &= \frac{k^3 d}{4\pi\varepsilon_0}\left[2\cos\theta\left(\frac{\cos u}{(kr)^2}+\frac{\sin u}{kr}\right)\frac{1}{kr}\hat{\mathbf{e}}_r + \sin\theta\left(\frac{\cos u}{(kr)^2}+\frac{\sin u}{kr}-\cos u\right)\frac{1}{kr}\hat{\mathbf{e}}_\theta\right] \\ &\equiv \vec{\mathcal{E}}_r\hat{\mathbf{e}}_r + \vec{\mathcal{E}}_\theta\hat{\mathbf{e}}_\theta \ ,\end{aligned}$$

where we used $\hat{\mathbf{e}}_\phi \times \hat{\mathbf{e}}_r = \hat{\mathbf{e}}_\theta$ and $\hat{\mathbf{e}}_z = \hat{\mathbf{e}}_r\cos\theta - \hat{\mathbf{e}}_\theta\sin\theta$.
c. Maxwell's fourth equation is obvious,

$$\nabla\cdot\vec{\mathcal{B}} = \frac{1}{r\sin\theta}\frac{\partial}{\partial\phi}[\vec{\mathcal{B}}_\phi] = 0 \ .$$

The third gives,

$$\begin{aligned}\nabla\cdot\vec{\mathcal{E}} &= \frac{1}{r^2}\frac{\partial}{\partial r}[r^2\vec{\mathcal{E}}_r] + \frac{1}{r\sin\theta}\frac{\partial}{\partial\theta}(\sin\theta\vec{\mathcal{E}}_\theta) \\ &= \frac{k^3 d}{4\pi\varepsilon_0}2\cos\theta\frac{1}{(kr)^2}\frac{\partial}{\partial r}\left[\left(\frac{1}{kr}+\frac{1}{\imath}\right)e^{iu}\right] + \frac{k^3 d}{4\pi\varepsilon_0}\left(\frac{1}{(kr)^2}+\frac{1}{\imath kr}-1\right)\frac{e^{\imath u}}{kr}\frac{1}{r\sin\theta}\frac{\partial}{\partial\theta}\sin^2\theta \\ &= 0 \ .\end{aligned}$$

The second gives,

$$\begin{aligned}
\nabla\times\vec{\mathcal{E}} &= \frac{k^3 d}{4\pi\varepsilon_0}\frac{1}{r}\left[\frac{\partial}{\partial r}(r\vec{\mathcal{E}}_\theta)-\frac{\partial}{\partial\theta}(\vec{\mathcal{E}}_r)\right]\hat{\mathbf{e}}_\phi \\
&= \frac{k^3 d}{4\pi\varepsilon_0}\frac{1}{r}\left[\frac{1}{k}\sin\theta\frac{\partial}{\partial r}\left\{\left(\frac{1}{(kr)^2}+\frac{1}{\imath kr}-1\right)e^{\imath u}\right\}-\left(\frac{1}{(kr)^3}+\frac{1}{\imath(kr)^2}\right)e^{\imath u}\frac{\partial}{\partial\theta}2\cos\theta\right]\hat{\mathbf{e}}_\phi \\
&= -\imath\omega\frac{ck^3 d\mu_0}{4\pi}\sin\theta\left[\left(1-\frac{1}{\imath kr}\right)\frac{e^{\imath u}}{kr}\right]\hat{\mathbf{e}}_\phi = \frac{ck^3 p\mu_0}{4\pi}\frac{\partial}{\partial t}\sin\theta\left[\left(1-\frac{1}{\imath kr}\right)\frac{e^{\imath u}}{kr}\right]\hat{\mathbf{e}}_\phi \\
&= -\frac{\partial\vec{\mathcal{B}}}{\partial t}\ .
\end{aligned}$$

Finally, the first one gives,

$$\begin{aligned}
\nabla\times\vec{\mathcal{B}} &= \hat{\mathbf{e}}_r\frac{1}{r\sin\theta}\left[\frac{\partial}{\partial\theta}(\vec{\mathcal{B}}_\phi\sin\theta)\right]+\hat{\mathbf{e}}_\theta\frac{1}{r\sin\theta}\left[-\sin\theta\frac{\partial}{\partial r}(r\vec{\mathcal{B}}_\phi)\right] \\
&= -\frac{ck^3 d\mu_0}{4\pi}\left[\frac{1}{r\sin\theta}\left(\frac{1}{kr}-\frac{1}{\imath(kr)^2}\right)e^{\imath u}\frac{\partial}{\partial\theta}\sin^2\theta\hat{\mathbf{e}}_r-\frac{\sin\theta}{kr}\frac{\partial}{\partial r}\left(1-\frac{1}{\imath kr}\right)e^{\imath u}\hat{\mathbf{e}}_\theta\right] \\
&= -\imath\omega\frac{k^3 d\mu_0}{4\pi}\left[2\cos\theta\left(\frac{1}{(kr)^2}+\frac{1}{\imath kr}\right)\frac{e^{\imath u}}{kr}\hat{\mathbf{e}}_r+\sin\theta\left(\frac{1}{(kr)^2}+\frac{1}{\imath kr}-1\right)\frac{e^{\imath u}}{kr}\hat{\mathbf{e}}_\theta\right] \\
&= \frac{k^3 d}{4\pi\varepsilon_0}\frac{\partial}{c^2\partial t}\left[2\cos\theta\left(\frac{1}{(kr)^2}+\frac{1}{\imath kr}\right)\frac{e^{\imath u}}{kr}\hat{\mathbf{e}}_r+\sin\theta\left(\frac{1}{(kr)^2}+\frac{1}{\imath kr}-1\right)\frac{e^{\imath u}}{kr}\hat{\mathbf{e}}_\theta\right] \\
&= \frac{\partial\vec{\mathcal{E}}}{c^2\partial t}\ .
\end{aligned}$$

For an illustration see Fig. 19.2.

19.1.6.4 Ex: Gauges of dipolar potentials

Verify that the retarded potentials of an oscillating dipole,

$$\begin{aligned}
\Phi(r,\theta,t) &= \frac{p_0\cos\theta}{4\pi\varepsilon_0 r}\left\{-\frac{\omega}{c}\sin[\omega(t-r/c)]+\frac{1}{r}\cos[\omega(t-r/c)]\right\} \\
\mathbf{A}(r,\theta,t) &= -\frac{\mu_0 p_0\omega}{4\pi r}\sin[\omega(t-r/c)]\hat{\mathbf{e}}_z\ ,
\end{aligned}$$

satisfy the Lorentz gauge.

Solution: *With* $\hat{\mathbf{e}}_z = \cos\theta\hat{\mathbf{e}}_r - \sin\theta\hat{\mathbf{e}}_\theta$, *we calculate,*

$$\begin{aligned}
\nabla\cdot\mathbf{A} &= \frac{1}{r^2}\frac{\partial}{\partial r}[r^2 A_r] + \frac{1}{r\sin\theta}\frac{\partial}{\partial\theta}[\sin\theta A_\theta] + \frac{1}{r\sin\theta}\frac{\partial}{\partial\phi}[A_\phi] \\
&= -\frac{\mu_0 p_0\omega}{4\pi}\left\{\frac{1}{r^2}\frac{\partial}{\partial r}\frac{r^2\cos\theta\sin(\omega t-\omega r/c)}{r} + \frac{1}{r\sin\theta}\frac{\partial}{\partial\theta}\frac{-\sin^2\theta\sin(\omega t-\omega r/c)}{r}\right\} \\
&= -\frac{\mu_0 p_0\omega}{4\pi}\left\{-\cos\theta\frac{-c\sin(\omega t-\omega r/c)+r\omega\cos(\omega t-\omega r/c)}{cr^2} - \frac{2\cos\theta\sin(\omega t-\omega r/c)}{r^2}\right\} \\
&= -\frac{\mu_0 p_0\omega\cos\theta}{4\pi r}\left\{-\frac{\omega\cos[\omega(t-r/c)]}{c} - \frac{\sin[\omega(t-r/c)]}{r}\right\} \\
&= -\frac{1}{c^2}\frac{p_0\cos\theta}{4\pi\varepsilon_0 r}\frac{\partial}{\partial t}\left\{-\frac{\omega}{c}\sin[\omega(t-r/c)] + \frac{1}{r}\cos[\omega(t-r/c)]\right\} = -\frac{\partial\Phi}{c^2\partial t}\ .
\end{aligned}$$

19.1.6.5 Ex: Electric and magnetic fields of an oscillating electric dipole

Calculate the electric and magnetic fields of an oscillating electric dipole in the dipolar approximation ($kr' \ll 1$) but for arbitrary distances ($kr \lesseqgtr 1$) directly from the retarded potentials in spherical coordinates. Find the Poynting vector and show that the radiation intensity is exactly the same, as the one derived within the far-field approximation ($kr \gg 1$).

Solution: *To create an electric dipole, we imagine a charge oscillating between the two ends of a linear antenna of length* b, *such that* $Q(t) = Q_0\cos\omega t$. *The electric dipole moment is,*

$$\mathbf{d} = Q\mathbf{b} = Q_0 b\hat{\mathbf{e}}_z\cos\omega t\ ,$$

the oscillating charge distribution can be parametrized by [6],

$$\varrho(\mathbf{r}', t_r) = Q_0\cos\omega t_r\left[\delta^{(3)}(z'-b) - \delta^{(3)}(z'+b)\right]\ .$$

The retarded scalar potential is,

$$\Phi(\mathbf{r},t) = \frac{1}{4\pi\varepsilon_0}\int\frac{\varrho(\mathbf{r}',t_r)}{R}d^3r' = \frac{1}{4\pi\varepsilon_0}\left(\frac{Q_0\cos\omega t}{R_+} - \frac{Q_0\cos\omega t}{R_-}\right)\ ,$$

with $t_r = t - R/c$. *We parametrize the extremities by* $\mathbf{b} = b\hat{\mathbf{e}}_z$ *and concentrate on a point in the* $y = 0$ *plane, such that* $\mathbf{r} = r\hat{\mathbf{e}}_x\sin\theta + r\hat{\mathbf{e}}_z\cos\theta$. *Then the distances are,*

$$R_\pm = \sqrt{(\mathbf{r}-\mathbf{b})^2} = \sqrt{r^2 + (b/2)^2 \mp 2rb\cos\theta}\ .$$

For a perfect dipole we require a small antenna size, $b \ll r$. *This allows us to approximate, to first order in* b,

$$R_\pm \simeq r\left(1 \mp \frac{b}{2r}\cos\theta\right) \qquad \textit{and} \qquad \frac{1}{R_\pm} \simeq \left(1 \pm \frac{b}{2r}\cos\theta\right)\ , \tag{19.130}$$

[6] Note that these oscillations do not presuppose the existence of a current. We could also have assumed an oscillating current parametrized by $\varrho(\mathbf{r}', t_r) = Q_0\delta^{(3)}(kz' - b\cos\omega t_r)$.

such that,

$$\begin{aligned}\cos[\omega(t-\tfrac{R_\pm}{c})] &\simeq \cos\left[\omega(t-\tfrac{r}{c}) \pm \tfrac{\omega b}{2c}\cos\theta\right] \\ &= \cos[\omega(t-\tfrac{r}{c})]\cos\left(\tfrac{\omega b}{2c}\cos\theta\right) \mp \sin[\omega(t-\tfrac{r}{c})]\sin\left(\tfrac{\omega b}{2c}\cos\theta\right) \ .\end{aligned}$$

In the dipolar approximation we assume, $b \ll c/\omega$, such that,

$$\cos[\omega(t-\tfrac{R}{c})] \simeq \cos[\omega(t-\tfrac{r}{c})] \mp \tfrac{\omega b}{2c}\cos\theta\sin[\omega(t-\tfrac{r}{c})] \ . \tag{19.131}$$

Inserting the approximations (19.130) and (19.131) in the expression for the vector potential and introducing the abbreviation $X \equiv \omega(t-\frac{r}{c})$, we obtain,

$$\boxed{\Phi(\mathbf{r},t) = \frac{p_0 b}{4\pi\varepsilon_0}\cos\theta\left(\frac{\cos X}{r^2} - \frac{\omega\sin X}{cr}\right)} \ .$$

The oscillation of the charges is necessarily due to a current, $I(t)\hat{\mathbf{e}}_z = \dot{Q}(t)\hat{\mathbf{e}}_z = -Q_0\omega\hat{\mathbf{e}}_z\sin\omega t$,

$$\mathbf{A}(\mathbf{r},t) = \frac{\mu_0}{4\pi}\int\frac{\mathbf{j}(\mathbf{r}',t_r)}{R}d^3r' = \frac{\mu_0}{4\pi}\int_{antenna}\frac{-Q_0\omega\hat{\mathbf{e}}_z\sin\omega t}{R}d\vec{\mathcal{S}}' \ ,$$

such that,

$$\boxed{\mathbf{A}(\mathbf{r},t) = -\frac{\mu_0 p_0\omega}{4\pi r}\hat{\mathbf{e}}_z\sin X} \ .$$

The derivatives are,

$$\begin{aligned}\nabla\Phi &= \hat{\mathbf{e}}_r\frac{\partial\Phi}{\partial t} + \hat{\mathbf{e}}_\theta\frac{1}{r}\frac{\partial\Phi}{\partial\theta} = \frac{p_0\omega}{4\pi\varepsilon_0 c}\hat{\mathbf{e}}_r\cos\theta\left(\frac{\omega\cos X}{cr} + \frac{\sin X}{r^2}\right) + \frac{p_0\omega}{4\pi\varepsilon_0 c}\hat{\mathbf{e}}_\theta\sin\theta\frac{\sin X}{r^2} \\ \frac{\partial\mathbf{A}}{\partial t} &= -\frac{p_0\omega^2}{4\pi\varepsilon_0 c^2}(\hat{\mathbf{e}}_r\cos\theta - \hat{\mathbf{e}}_\theta\sin\theta)\frac{\cos X}{r} \\ \nabla\times\mathbf{A} &= \frac{1}{r}\frac{\partial(rA_\theta)}{\partial r} - \frac{1}{r}\frac{\partial A_r}{\partial\theta} = -\frac{\mu_0 p_0\omega}{4\pi}\hat{\mathbf{e}}_\phi\sin\theta\left(\frac{\omega\cos X}{cr} + \frac{\sin X}{r^2}\right) \ .\end{aligned}$$

With this, the fields are,

$$\begin{aligned}\vec{\mathcal{E}} &= -\nabla\Phi - \frac{\partial\mathbf{A}}{\partial t} = -\frac{p_0\omega}{4\pi\varepsilon_0 c}\hat{\mathbf{e}}_r\cos\theta\frac{\sin X}{r^2} - \frac{p_0\omega}{4\pi\varepsilon_0 c}\hat{\mathbf{e}}_\theta\sin\theta\left(\frac{\omega\cos X}{cr} + \frac{\sin X}{r^2}\right) \\ \vec{\mathcal{B}} &= \nabla\times\mathbf{A} = -\frac{\mu_0 p_0\omega}{4\pi}\hat{\mathbf{e}}_\phi\sin\theta\left(\frac{\omega\cos X}{cr} + \frac{\sin X}{r^2}\right) \ .\end{aligned}$$

The Poynting vector is ...

19.1.6.6 Ex: Electric and magnetic fields of an oscillating magnetic dipole

Calculate the electric and magnetic fields of an oscillating magnetic dipole in the dipolar approximation ($kr' \ll 1$), but for arbitrary distances ($kr \lesseqgtr 1$) directly from the

retarded potentials in spherical coordinates. Compare with the fields of an oscillating electric dipole. Find the Poynting vector and show that the intensity of the radiation is exactly the same, as the one derived within the far-field approximation ($kr \gg 1$).

Solution: *To create a magnetic dipole, we imagine a circular loop of radius b traversed by a current $I(t) = I_0 \cos\omega t$. The magnetic dipole moment is,*

$$\mathbf{m} = I\mathbf{a} = \pi b^2 I_0 \hat{\mathbf{e}}_z \cos\omega t \ .$$

If the loop is electrically neutral, the retarded potentials are,

$$\Phi = 0 \qquad \textit{and}$$

$$\mathbf{A}(\mathbf{r},t) = \frac{\mu_0}{4\pi}\int \frac{\mathbf{j}(\mathbf{r}',t_r)}{R} d^3r' = \frac{\mu_0}{4\pi}\int_{loop} \frac{I_0\cos\omega t_r}{R} d\vec{\mathcal{S}}' = \frac{\mu_0 I_0 b}{4\pi}\hat{\mathbf{e}}_y \int_0^{2\pi} \frac{\cos\omega t_r}{R}\cos\phi' d\phi' \ ,$$

with $t_r = t - R/c$. To evaluate the integral we parametrize any point of the loop as $\mathbf{b} = b\hat{\mathbf{e}}_x\cos\phi' + b\hat{\mathbf{e}}_y \sin\phi'$ and concentrate on a point in the $y = 0$ plane, such that $\mathbf{r} = r\hat{\mathbf{e}}_x \sin\theta + r\hat{\mathbf{e}}_z\cos\theta$,

$$R = \sqrt{(\mathbf{r}-\mathbf{b})^2} = \sqrt{r^2 + b^2 - 2rb\sin\theta\cos\phi'} \ .$$

For a perfect dipole we require a small size of the loop, $b \ll r$. This allows us to approximate, to first order in b,

$$R \simeq r\left(1 - \frac{b}{r}\sin\theta\cos\phi'\right) \qquad \textit{and} \qquad \frac{1}{R} \simeq \left(1 + \frac{b}{r}\sin\theta\cos\phi'\right) \ , \tag{19.132}$$

such that,

$$\begin{aligned}\cos[\omega(t - \tfrac{R}{c})] &\simeq \cos\left[\omega(t-\tfrac{r}{c}) + \tfrac{\omega b}{c}\sin\theta\cos\phi'\right] \\ &= \cos[\omega(t-\tfrac{r}{c})]\cos\left(\tfrac{\omega b}{c}\sin\theta\cos\phi'\right) - \sin[\omega(t-\tfrac{r}{c})]\sin\left(\tfrac{\omega b}{c}\sin\theta\cos\phi'\right) \ .\end{aligned}$$

In the dipolar approximation we assume, $b \ll c/\omega$, such that,

$$\cos[\omega(t - \tfrac{R}{c})] \simeq \cos[\omega(t-\tfrac{r}{c})] - \tfrac{\omega b}{c}\sin\theta\cos\phi'\sin[\omega(t-\tfrac{r}{c})] \ . \tag{19.133}$$

Inserting the approximations (19.132) and (19.133) in the expression for the vector potential and introducing the abbreviation $X \equiv \omega(t - \frac{r}{c})$, we obtain,

$$\mathbf{A}(\mathbf{r},t) = \frac{\mu_0 I_0 b}{4\pi r}\hat{\mathbf{e}}_y \int_0^{2\pi}\left\{\cos X + b\sin\theta\cos\phi'\left(\frac{\cos X}{r} - \frac{\omega\sin X}{c}\right)\right\}\cos\phi' d\phi' \ .$$

The first term gives zero because $\int_0^{2\pi}\cos\phi' d\phi' = 0$. For the second we use $\int_0^{2\pi}\cos^2\phi' d\phi' = \pi$, such that,

$$\boxed{\mathbf{A}(\mathbf{r},t) = \frac{\mu_0 m_0}{4\pi}\hat{\mathbf{e}}_\phi \sin\theta\left(\frac{\cos X}{r^2} - \frac{\omega\sin X}{cr}\right)} \ ,$$

with $m_0 \equiv \pi b^2 I_0$. Here, we relax the specialization on the y-axis by replacing e_y by $\hat{\mathbf{e}}_\phi$. The derivatives are,

$$\nabla\times\mathbf{A} = \hat{\mathbf{e}}_r \frac{1}{r\sin\theta}\frac{\partial}{\partial\theta}(A_\phi\sin\theta) - \hat{\mathbf{e}}_\theta\frac{1}{r}\frac{\partial}{\partial r}(rA_\phi) \ .$$

The fields are,

$$\vec{\mathcal{E}} = -\frac{\partial \mathbf{A}}{\partial t} = \frac{\mu_0 m_0 \omega}{4\pi} \hat{\mathbf{e}}_\phi \sin\theta \left(\frac{\omega \cos X}{cr} + \frac{\sin X}{r^2} \right)$$

$$\vec{\mathcal{B}} = \nabla \times \mathbf{A}$$

$$= \frac{\mu_0 m_0}{2\pi} \hat{\mathbf{e}}_r \cos\theta \left(\frac{\cos X}{r^3} - \frac{\omega \sin X}{cr^2} \right) + \frac{\mu_0 m_0}{4\pi} \hat{\mathbf{e}}_\theta \sin\theta \left[\left(\frac{1}{r^3} - \frac{\omega^2}{c^2 r} \right) \cos X - \frac{\omega \sin X}{cr^2} \right] .$$

The Poynting vector is,

$$\vec{\mathcal{S}} = \tfrac{1}{\mu_0} \vec{\mathcal{E}} \times \vec{\mathcal{B}} = ...$$

The time average is,

$$\overline{\vec{\mathcal{S}}} = \frac{\mu_0 m_0^2 \omega^4 \sin^2\theta}{32\pi^2 c^3 r^2} .$$

19.1.6.7 Ex: Spherical harmonics

The spherical harmonic function for $\ell = 2$ and $m = 1$ has the form,

$$Y_{21}(\vartheta, \varphi) = \sqrt{\tfrac{15}{8\pi}} \sin\vartheta \cos\vartheta (\cos\varphi + \imath \sin\varphi) .$$

Express the quadrupolar momentum q_{21} as a linear combination in Cartesian coordinates,

$$Q_{ij} = \int \rho(\mathbf{r})(3x_i x_j - \delta_{ij} r^2)\, dr^3 .$$

Solution:

19.1.6.8 Ex: Vector spherical harmonics

Calculate the angular distribution of $E1$ and $M1$ radiation.Derive Eq. (19.85).

Solution: *The general formula is given by (19.129),*

$$\mathbf{Y}_{jlm} = \sum_q \begin{pmatrix} J & 1 & L \\ -m & q & m-q \end{pmatrix} Y^{(\ell)}_{m-q} \hat{\mathbf{e}}_q ,$$

where $\hat{\mathbf{e}}_q$ is given by $\hat{\mathbf{e}}_\pm \equiv -\frac{1}{\sqrt{2}}(\hat{\mathbf{e}}_x \pm \imath \hat{\mathbf{e}}_y)$ and $\hat{\mathbf{e}}_0 = \hat{\mathbf{e}}_z$. For $E1$ and $M1$ radiation we have to calculate the vector spherical harmonics $\mathbf{Y}_{11m}$ and $\mathbf{Y}_{10m}$. Using the tabulated spherical harmonics, we find,

$$r\mathbf{Y}_{100} = \begin{pmatrix} 1 & 1 & 0 \\ 0 & 0 & 0 \end{pmatrix} Y^{(0)}_m \hat{\mathbf{e}}_0 = \sqrt{\tfrac{1}{3}} \sqrt{\tfrac{1}{4\pi}} r \hat{\mathbf{e}}_0 = -\sqrt{\tfrac{1}{12\pi}} \begin{pmatrix} 0 \\ 0 \\ r \end{pmatrix} ,$$

and

$$r\mathbf{Y}_{10\pm1} = \begin{pmatrix} 1 & 1 & 0 \\ \mp 1 & 1 & 0 \end{pmatrix} rY_0^{(0)}\hat{\mathbf{e}}_1 + \begin{pmatrix} 1 & 1 & 0 \\ \mp 1 & -1 & 0 \end{pmatrix} rY_0^{(0)}\hat{\mathbf{e}}_{-1} \quad = \sqrt{\tfrac{1}{3}}\sqrt{\tfrac{1}{4\pi}}r\hat{\mathbf{e}}_{\pm1} = -\sqrt{\tfrac{1}{24\pi}}\begin{pmatrix} x \\ \pm\imath y \\ 0 \end{pmatrix} ,$$

and

$$\begin{aligned} r\mathbf{Y}_{110} &= \begin{pmatrix} 1 & 1 & 1 \\ 0 & 1 & -1 \end{pmatrix} rY_{-1}^{(1)}\hat{\mathbf{e}}_1 + \begin{pmatrix} 1 & 1 & 1 \\ 0 & 0 & 0 \end{pmatrix} rY_0^{(1)}\hat{\mathbf{e}}_0 + \begin{pmatrix} 1 & 1 & 1 \\ 0 & -1 & 1 \end{pmatrix} rY_1^{(1)}\hat{\mathbf{e}}_{-1} \\ &= -\sqrt{\tfrac{1}{2}}\left(rY_{-1}^{(1)}\hat{\mathbf{e}}_1 + rY_1^{(1)}\hat{\mathbf{e}}_{-1}\right) = \frac{1}{2}r\begin{pmatrix} Y_{-1}^{(1)} + Y_1^{(1)} \\ \imath(Y_{-1}^{(1)} - iY_1^{(1)}) \\ 0 \end{pmatrix} \\ &= \tfrac{1}{2}\imath\sqrt{\tfrac{3}{2\pi}}\begin{pmatrix} -\sin\theta\sin\phi \\ \sin\theta\cos\phi \\ 0 \end{pmatrix} = \tfrac{1}{2}\imath\sqrt{\tfrac{3}{2\pi}}\begin{pmatrix} -y \\ x \\ 0 \end{pmatrix} , \end{aligned}$$

and

$$\begin{aligned} r\mathbf{Y}_{11\pm1} &= \begin{pmatrix} 1 & 1 & 1 \\ \mp 1 & 1 & \pm 1 - 1 \end{pmatrix} rY_{\pm1-1}^{(1)}\hat{\mathbf{e}}_1 + \begin{pmatrix} 1 & 1 & 1 \\ \mp 1 & 0 & \pm 1 - 0 \end{pmatrix} rY_{\pm1-0}^{(1)}\hat{\mathbf{e}}_0 + \begin{pmatrix} 1 & 1 & 1 \\ \mp 1 & -1 & \pm 1 + 1 \end{pmatrix} rY_{\pm1+1}^{(1)}\hat{\mathbf{e}}_{-1} \\ &= \sqrt{\tfrac{1}{2}}\left(rY_0^{(1)}\hat{\mathbf{e}}_1 + rY_{\pm1}^{(1)}\hat{\mathbf{e}}_0 + rY_0^{(1)}\hat{\mathbf{e}}_{-1}\right) = \tfrac{1}{2}r\begin{pmatrix} Y_0^{(1)} \\ \pm iY_0^{(1)} \\ \pm\sqrt{2}Y_{\pm1}^{(1)} \end{pmatrix} \\ &= \tfrac{1}{4}\sqrt{\tfrac{3}{\pi}}r\begin{pmatrix} \cos\theta \\ \pm\imath\cos\theta \\ \sin\theta e^{\pm\imath\phi} \end{pmatrix} = \tfrac{1}{4}\sqrt{\tfrac{3}{\pi}}\begin{pmatrix} z \\ \pm iz \\ -(x \pm \imath y) \end{pmatrix} . \end{aligned}$$

19.2 Radiation of point charges

The fundamental structure of matter is based on electromagnetic forces: Electrons are bound to nuclei by the Coulomb-Lorentz force, the orbital motion of the electrons produces magnetic fields, which can interact with the intrinsic spins of electrons and nuclei, external electromagnetic fields can influence the motion of electrons. Therefore, it is of primary interest to understand the radiation emitted by accelerated point-like electric charges.

19.2.1 Power radiated by an accelerated point charge

We derived in an earlier chapter the fields (17.140) and (17.141) produced by an arbitrary moving charge,

$$\begin{aligned} \vec{\mathcal{E}}(\mathbf{r},t) &= \frac{q}{4\pi\varepsilon_0}\frac{R}{(\mathbf{R}\cdot\mathbf{u})^3}[(c^2-v^2)\mathbf{u} + \mathbf{R}\times(\mathbf{u}\times\mathbf{a})] \\ \vec{\mathcal{B}}(\mathbf{r},t) &= \tfrac{1}{c}\mathbf{R}\times\vec{\mathcal{E}}(\mathbf{r},t) , \end{aligned} \tag{19.134}$$

with $\mathbf{u} = c\hat{\mathbf{e}}_r - \mathbf{v}$. We call the first term in (19.134) *velocity field* and the second *acceleration field*. The Poynting vector is,

$$\vec{\mathcal{S}} = \tfrac{1}{\mu_0}(\vec{\mathcal{E}} \times \vec{\mathcal{B}}) = \tfrac{1}{\mu_0 c}[\vec{\mathcal{E}} \times (\mathbf{R} \times \vec{\mathcal{E}})] = \tfrac{1}{\mu_0 c}[\mathcal{E}^2 \hat{\mathbf{e}}_r - (\hat{\mathbf{e}}_r \cdot \vec{\mathcal{E}})\vec{\mathcal{E}}] \ . \tag{19.135}$$

However, not all of this energy flow constitutes radiation; part of it is field energy *transported* by the particle as it moves. The *radiated* energy is the part that separates from the charge and propagates to infinity. To calculate the total power radiated by the particle at time t_r we draw a large sphere of radius R, centered on the position of the particle at time t_r, we wait for the appropriate interval,

$$t - t_r \equiv \frac{R}{c} \ , \tag{19.136}$$

for the radiation to reach the sphere and, at that moment, we integrate the Poynting vector on the surface. The notation t_r points to the fact, that this is the retarded time for all points on the sphere at time t. Now, the area of the sphere is proportional to R^2, hence any term in $\vec{\mathcal{S}}$ that goes like $1/R^2$ will produce a finite response, but terms like $1/R^3$ or $1/R^4$ will not contribute in the limit $R \to \infty$. For this reason, only the acceleration field truly radiates:

$$\vec{\mathcal{E}}_{rad} = \frac{q}{4\pi\varepsilon_0} \frac{R}{(\mathbf{R} \cdot \mathbf{u})^3} [\mathbf{R} \times (\mathbf{u} \times \mathbf{a})] \ . \tag{19.137}$$

Since $\vec{\mathcal{E}}_{rad} \perp \mathbf{R}$, the second term in Eq. (19.135) disappears:

$$\vec{\mathcal{S}}_{rad} = \frac{1}{\mu_0 c} \vec{\mathcal{E}}^2_{rad} \hat{\mathbf{e}}_r \ . \tag{19.138}$$

Example 116 (*Radiation at the turning point*): If at time t_r the charge is instantaneously at rest, $\mathbf{v}(t_r) = 0$, for example at the turning points of a harmonic oscillation, then $\mathbf{u} = c\hat{\mathbf{e}}_r$, and,

$$\vec{\mathcal{E}}_{rad} = \frac{q}{4\pi\varepsilon_0 c^2 R} [\hat{\mathbf{e}}_r \times (\hat{\mathbf{e}}_r \times \mathbf{a})] = \frac{\mu_0 q}{4\pi R} [(\hat{\mathbf{e}}_r \cdot \mathbf{a})\hat{\mathbf{e}}_r - \mathbf{a}] \ . \tag{19.139}$$

In this case,

$$\vec{\mathcal{S}}_{rad} = \frac{1}{\mu_0 c} \left(\frac{\mu_0 q}{4\pi R} \right)^2 [a^2 - (\hat{\mathbf{e}}_r \cdot \mathbf{a})^2] \hat{\mathbf{e}}_r = \frac{\mu_0 q^2 a^2}{16\pi^2 c} \frac{\sin^2\theta}{R^2} \ , \tag{19.140}$$

where θ is the angle between $\hat{\mathbf{e}}_r$ and $\mathbf{a}$. No power is radiated in forward or backward directions. Instead, it is emitted in a torus around the instantaneous acceleration, as shown in Fig. 19.7(a).
The total radiated power is evidently,

$$P = \oint \vec{\mathcal{S}}_{rad} \cdot d\mathbf{S} = \frac{\mu_0 q^2 a^2}{16\pi^2 c} \int \frac{\sin^2\theta}{R^2} R^2 \sin\theta d\theta d\phi = \frac{\mu_0 q^2 a^2}{6\pi c} \ . \tag{19.141}$$

This, again, is the *Larmor formula*, which we previously obtained via another route (19.19). Although derived under the assumption that $v = 0$, the equations (19.140) and (19.141) represent a good approximation, since $v \ll c$.

An exact treatment of the case $v \neq 0$ is more difficult for two reasons. The first obvious reason is, that $\vec{\mathcal{E}}_{rad}$ is more complicated, and the second more subtle reason is that $\vec{\mathcal{S}}_{rad}$, which is the rate at which energy passes through the sphere, is not equal to the rate at which the energy separated from the particle. Suppose someone is throwing a stream of bullets through the window of a moving car. The rate N_t at which the bullets hit a stationary target is not the same as the rate N_g at which they left the weapon, because of the movement of the car. In fact, we can easily verify that $N_g = (1 - v/c)N_t$, if the car is moving toward the target, and,

$$N_g = \left(1 - \tfrac{\hat{\mathbf{e}}_r \cdot \mathbf{v}}{c}\right) N_t \tag{19.142}$$

for arbitrary directions (here v is the speed of the car, c is the velocity of the bullets, and $\mathbf{R}$ is a unit vector pointing from the car towards the target). In our case, if dW/dt is the rate at which energy passes through the sphere of radius R, then the rate at which the energy separated from the charge was,

$$\frac{dW}{dt_r} = \frac{dW/dt}{\partial t_r/\partial t} \ . \tag{19.143}$$

We calculate the denominator from the relation (19.136),

$$\begin{aligned} \frac{\partial t_r}{\partial t} = 1 - \frac{\partial\sqrt{[\mathbf{r} - \mathbf{w}(t_r)]^2}}{c\partial t} &= 1 - \frac{-2[\mathbf{r} - \mathbf{w}(t_r)]}{2c\sqrt{[\mathbf{r} - \mathbf{w}(t_r)]^2}} \cdot \frac{\partial \mathbf{w}(t_r)}{\partial t_r}\frac{\partial t_r}{\partial t} \\ &= 1 + \frac{\mathbf{R}}{cR} \cdot \mathbf{v}\frac{\partial t_r}{\partial t} = \frac{1}{1 - \hat{\mathbf{e}}_R \cdot \mathbf{v}/c} = \frac{cR}{\mathbf{R} \cdot \mathbf{u}} \ . \end{aligned} \tag{19.144}$$

This factor is precisely that of the relation (19.142) between N_g and N_t; is a purely geometric factor (the same as in the Doppler effect).

Therefore, the power radiated by the particle into an area element, $R^2 \sin\theta d\theta d\phi = R^2 d\Omega$ of the sphere is, using the Poynting vector (19.138) and the radiated field (19.137), given by,

$$\frac{dP}{d\Omega} = \frac{\vec{\mathcal{S}}_{rad}}{\partial t_r/\partial t} = \frac{\mathbf{R} \cdot \mathbf{u}}{Rc}\frac{1}{\mu_0 c}\vec{\mathcal{E}}^2_{rad}R^2 = \frac{q^2}{16\pi^2\varepsilon_0}\frac{|\hat{\mathbf{e}}_r \times (\mathbf{u} \times \mathbf{a})|^2}{(\hat{\mathbf{e}}_r \cdot \mathbf{u})^5} \ , \tag{19.145}$$

where $d\Omega = \sin\theta d\theta d\phi$ is the solid angle at which this energy is radiated. Integrating over θ and ϕ to obtain the total radiated power is not easy, such that we simply quote the answer:

$$\boxed{P = \frac{\mu_0 q^2 \gamma^6}{6\pi c}\left(a^2 - \left|\frac{\mathbf{v} \times \mathbf{a}}{c}\right|^2\right)} \ , \tag{19.146}$$

where $\gamma \equiv 1/\sqrt{1 - v^2/c^2}$. This is *Liénard's generalization* of Larmor's formula, to which it reduces when $v \ll c$. The factor γ^6 means that the radiated power increases enormously as the velocity of the particle approaches the speed of light.

Resolve the Excs. 19.2.3.1 to 19.2.3.5.

19.2.1.1 Bremstrahlung

Suppose that $\mathbf{v}$ and $\mathbf{a}$ be instantaneously collinear (at time t_r), such as for a motion on a straight line. In this case $\mathbf{u} \times \mathbf{a} = (c\hat{\mathbf{e}}_r - \boldsymbol{\mathcal{V}}^0) \times \mathbf{a}$, then the angular distribution of radiation (19.145) gives,

$$\frac{dP}{d\Omega} = \frac{q^2 c^2}{16\pi^2 \varepsilon_0} \frac{|\hat{\mathbf{e}}_r \times (\hat{\mathbf{e}}_r \times \mathbf{a})|^2}{(c - \hat{\mathbf{e}}_r \cdot \mathbf{v})^5} \ . \tag{19.147}$$

Now with $|\hat{\mathbf{e}}_r \times (\hat{\mathbf{e}}_r \times \mathbf{a})| = a \sin\theta$ and letting $\mathbf{v} \equiv v\hat{\mathbf{e}}_z$,

$$\frac{dP}{d\Omega} = \frac{\mu_0 q^2 a^2}{16\pi^2 c} \frac{\sin^2\theta}{(1 - \beta\cos\theta)^5} \ , \tag{19.148}$$

where $\beta \equiv v/c$. This is consistent with the result (19.140), in the case $v = 0$. However, for very large v ($\beta \approx 1$), the torus of the radiation illustrated in Fig. 19.7(a) is stretched and pushed forward by a factor $(1-\beta\cos\theta)^{-5}$, as indicated in Fig. 19.7(b). Although there is still no radiation in the exact forward direction, most of the radiation is concentrated in an increasingly narrow cone around the forward direction.

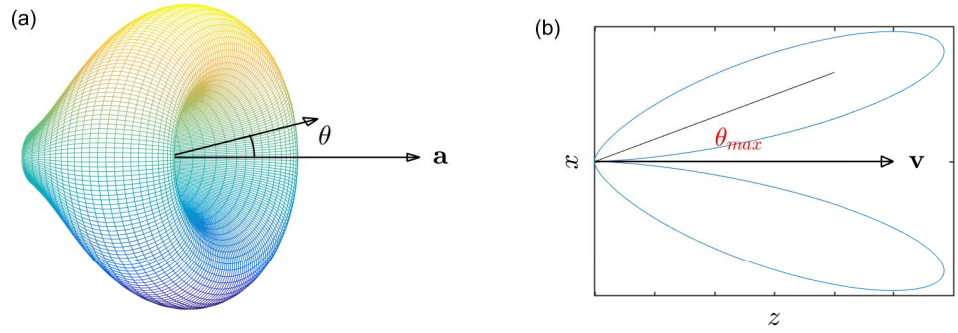

Figure 19.7: (code) (a) Radiation pattern of an accelerated charge. (b) Angular distribution of the bremsstrahlung.

The total emitted power is found by integrating equation (19.149) over all angles:

$$\begin{aligned} P &= \int \frac{dP}{d\Omega} d\Omega = \frac{\mu_0 q^2 a^2}{16\pi^2 c} \int \frac{\sin^2\theta}{(1-\beta\cos\theta)^5} \sin\theta d\theta d\phi \\ &= \frac{\mu_0 q^2 a^2}{8\pi c} \int_{-1}^{+1} \frac{1-x^2}{(1-\beta x)^5} dx = \frac{\mu_0 q^2 a^2}{8\pi c} \tfrac{4}{3}(1-\beta^2)^{-3} = \frac{\mu_0 q^2 a^2 \gamma^6}{6\pi c} \ . \end{aligned} \tag{19.149}$$

This result is consistent with the Liénard's formula (19.146), for the case when $\mathbf{v}$ and $\mathbf{a}$ are collinear. Note that the angular distribution of radiation is the same, whether the particle is accelerating or decelerating; it does not depend on $\mathbf{a}$, but only on velocity being concentrated in forward direction (with respect to the velocity) in both cases. When a high-speed electron hits a metal target, it decelerates rapidly, releasing what is called bremsstrahlung. This example is essentially the classical theory of *bremsstrahlung*.

We will calculate the *synchrotron radiation* in Exc. 19.2.3.6 and the *Cherenkov radiation* in Exc. 19.2.3.7. A movie illustrating the Cherenkov radiation emission can be viewed at (watch movie).

Example 117 (*Bremsstrahlung of thermal electrons*): The power lost by bremsstrahlung for not extremely relativistic velocities is,

$$P = \frac{\mu_0 q^2 a^2 \gamma^2}{6\pi c} \simeq \frac{\mu_0 q^2 a^2}{6\pi c} \ ,$$

such that,

$$\vec{\mathcal{E}}_{rad} = \int_0^t P dt = \frac{\mu_0 q^2 a^2}{6\pi c} \int_{v_0}^0 \frac{dv}{\dot{v}} = \frac{\mu_0 q^2 a}{6\pi c} \int_{v_0}^0 dv = \frac{\mu_0 q^2 a}{6\pi c} v_0 \ .$$

For an electron in a metal with a free path of $d \approx 3$ nm and a thermal velocity $v_0 = 100000$ m/s the deceleration $a = \frac{v_0^2}{2d}$ leads to a negligible radiated fraction,

$$\frac{\vec{\mathcal{E}}_{rad}}{E_{kin}} = \frac{\frac{\mu_0 q^2 a}{6\pi c} v_0}{\frac{m}{2} v_0^2} = \frac{\mu_0 q^2 a}{3\pi c m v_0} = \frac{\mu_0 q^2}{3\pi c m} \frac{v_0}{2d} \approx 2 \cdot 10^{-10} \ .$$

19.2.2 Radiation reaction

According to the laws of classical electrodynamics, an accelerated charge radiates. This radiation takes energy, which must come at the expense of the particle's kinetic energy. Under the influence of a given force, therefore, a charged particle accelerates less than a neutral particle of the same mass. The radiation evidently exerts a reactive force $\mathbf{F}_{rad}$ corresponding to a recoil. We will now derive the *radiation reaction* force from energy conservation.

For a non-relativistic particle ($v \ll c$), the total radiated power P is given by the *Larmor formula* (19.141). The conservation of energy suggests that this is also the rate at which the particle loses energy, under the influence of the radiative reaction force $\mathbf{F}_{rad}$:

$$\mathbf{F}_{rad} \cdot \mathbf{v} \stackrel{?}{=} -\frac{\mu_0 q^2 a^2}{6\pi c} = -P \ . \tag{19.150}$$

However, this equation is really wrong. For, to derive Larmor's formula, we calculated the radiated power by integrating the Poynting vector on a sphere of 'infinite' radius; in this calculation the velocity fields *did not contribute*, since they fall off very rapidly as a function of R. However, the velocity fields *carry* energy; they simply do not carry it to infinity. As the particle accelerates and decelerates, it exchanges energy with the velocity fields, while another part of the energy is irremediably radiated away by the acceleration fields. The equation (19.150) only takes into account this lost energy, but if we want to know the recoil force exerted by the fields on the charge, we must consider the power lost at each instant of time, not only the radiatively escaping power. (In this sense the term 'radiation reaction' is misleading and should be replaced by 'field reaction'.) In fact, we shall see shortly that F_{rad} is determined by the time derivative of the acceleration and can be nonzero, even if the acceleration is instantaneously zero, such that the particle does not radiate.

The energy lost by the particle during a given time interval, therefore, must equal the energy carried away by radiation plus the extra energy that has been pumped into the velocity fields. However, if we agree to consider only time intervals $[t_1, t_2]$ over which the *system returns to its initial state*, then the energy in the velocity fields is the same at both times, and the only loss is through radiation. Thus, equation (19.150), while instantly incorrect, is valid on average:

$$\int_{t_1}^{t_2} \mathbf{F}_{rad} \cdot \mathbf{v} dt = -\frac{\mu_0 q^2}{6\pi c} \int_{t_1}^{t_2} a^2 dt \ , \tag{19.151}$$

with the stipulation that the state of the system is identical at times t_1 and t_2. In the case of periodic movements, for example, we must integrate over a total number of complete cycles. Now, the right-hand side of the equation (19.151) can be integrated by parts:

$$\int_{t_1}^{t_2} \mathbf{a}^2 dt = \mathbf{v} \cdot \frac{d\mathbf{v}}{dt}\bigg|_{t_1}^{t_2} - \int_{t_1}^{t_2} \frac{d^2\mathbf{v}}{dt^2} \cdot \mathbf{v} dt \ . \tag{19.152}$$

The boundary term cancels, since the velocities and accelerations are identical at t_1 and t_2, then the equation (19.151) can be written in an equivalent way as,

$$\int_{t_1}^{t_2} \left(\mathbf{F}_{rad} - \frac{\mu_0 q^2}{6\pi c} \dot{\mathbf{a}} \right) \cdot \mathbf{v} dt = 0 \ . \tag{19.153}$$

This equation will certainly be satisfied if,

$$\boxed{\mathbf{F}_{rad} = \frac{\mu_0 q^2}{6\pi c} \dot{\mathbf{a}}} \ . \tag{19.154}$$

This is the *Abraham-Lorentz formula* for the radiation reaction force. Obviously, the equation (19.153) does not prove (19.154), because it does not say anything about the component of $\mathbf{F}_{rad}$ perpendicular to $\mathbf{v}$; and only informs us on the time-average of the parallel component for, moreover, very special time intervals.

The Abraham-Lorentz formula has disturbing implications, which are not fully understood nearly a century after the law was first proposed. Let us assume that a particle is not subject to external forces; then Newton's second law tells us,

$$F_{rad} = \frac{\mu_0 q^2}{6\pi c} \dot{a} = ma \ , \tag{19.155}$$

yielding,

$$a(t) = a_0 e^{t/\tau} \qquad \text{with} \qquad \tau = \frac{\mu_0 q^2}{6\pi mc} \ . \tag{19.156}$$

In the case of an electron, $\tau = 6 \cdot 10^{-24}$ s. The acceleration increases spontaneously exponentially with time! This absurd conclusion can be avoided, if we insist that $a_0 = 0$. But it turns out, that the systematic exclusion of such catastrophic solutions has an even more unpleasant consequence: if we now *switch on* an external force, the particle begins to respond to it *before it actually has been switch on* (see Exc. 19.2.3.8 and 19.2.3.9).

Example 118 (*Radiative damping*): Here, we calculate the radiative damping rate τ of a charged particle fixed to a spring by solving the equation of motion,

$$m\ddot{x} = F_{sprng} + F_{rad} + F_{excit} = -m\omega_0^2 x + m\tau\dddot{x} + F_{excit} \ .$$

With the oscillating system, $x(t) = x_0\cos(\omega t + \delta)$, we have,

$$\dddot{x} = -\omega^2\dot{x} \ .$$

Therefore,

$$m\ddot{x} + m\omega^2\tau\dot{x} + m\omega_0^2 x = F_{excit} \ ,$$

and the damping factor is given by $\omega^2\tau$.

Example 119 (*Radiation reaction*): In previous chapters, the problems of electrodynamics were divided into two classes: one class in which the charge and current sources are specified and the resulting electromagnetic fields are calculated, and the other class in which external electromagnetic fields are specified and the motion of charged particles of currents are calculated. Occasionally, as in the discussion of the bremsstrahlung, the two problems are combined. But the treatment is recursive: first, the motion of a charged particle in an external field is determined neglecting the radiation it emits; then the radiation of the particle is calculated from its (accelerated) trajectory treating the particle as a source of charge and current.
Obviously, this way of dealing with electrodynamical problems can only be approximate. The (accelerated) motion of charged particles within force fields necessarily involves the emission of radiation, removing energy, angular momentum, and momentum from the particles and thus influencing their subsequent motion. Consequently, the motion of radiation sources is (partially) determined by the emission of radiation, and a correct treatment must take account of the reaction of the radiation onto the motion of the sources. Fortunately, for many problems of electrodynamics the radiative reaction is negligibly small. On the other hand, there exists no completely satisfactory classical treatment. The difficulties presented by this problem touch upon fundamental aspects of physics, such as the nature of elementary particles. Nevertheless, there are viable partial solutions with limited regimes of validity. In quantum mechanics, the introduction of renormalization techniques was able to solve the divergences within the theory of *quantum electrodynamics* (QED).
In order to give a gross idea of 'radiative reaction', let us consider a charge q of a point particle distributed in space. For simplicity we choose 'sub-charges' $\frac{q}{2}$ located at two positions $\mathbf{d}_{1,2} = \pm\frac{d}{2}\hat{\mathbf{e}}_y$ and moving in an accelerated way in x-direction, that is, $\mathbf{a} = a\hat{\mathbf{e}}_x$. Only after the calculations will we go to the limit $d \to 0$. So with (17.140) we obtain for the electric field generated by the charge 2 at the place of the charge 1,

$$\begin{aligned}\vec{\mathcal{E}}_1(\mathbf{r},t) &= \frac{q/2}{4\pi\varepsilon_0}\frac{R}{(\mathbf{R}\cdot\mathbf{u})^3}[(c^2-v^2)\mathbf{u} + \mathbf{R}\times(\mathbf{u}\times\mathbf{a})] \\ &= \frac{q/2}{4\pi\varepsilon_0}\frac{R}{(\mathbf{R}\cdot\mathbf{u})^3}[(c^2-v^2+\mathbf{R}\cdot\mathbf{a})\mathbf{u} - \mathbf{a}(\mathbf{R}\cdot\mathbf{u})] \ .\end{aligned}$$

Now, we assume that the charge be instantly at rest, $\mathbf{v} = 0$, that is, $\mathbf{u} \equiv c\hat{\mathbf{e}}_r - \mathbf{v} = c\hat{\mathbf{e}}_r$. In Cartesian coordinates, $\mathbf{R} \equiv l\hat{\mathbf{e}}_x + d\hat{\mathbf{e}}_y$, where $l \equiv x(t) - x(t_r)$

is the distance between the actual position and the retarded position, we can write the x-component of the electric field as,

$$\vec{\mathcal{E}}_{x,1} = \frac{q/2}{4\pi\varepsilon_0}\frac{R}{c^3R^3}[(c^2 + \mathbf{R}\cdot\mathbf{a})u_x - (\mathbf{R}\cdot\mathbf{u})a_x] = \frac{q}{8\pi\varepsilon_0 c^2}\frac{c^2 l - d^2 a}{\sqrt{l^2+d^2}^3} \ .$$

By symmetry, $\vec{\mathcal{E}}_{x,1} = \vec{\mathcal{E}}_{x,2}$, such that the force on the dumbbell is,

$$\mathbf{F}_{self} = \frac{q}{2}(\vec{\mathcal{E}}_1 + \vec{\mathcal{E}}_2) = \frac{q}{8\pi\varepsilon_0 c^2}\frac{c^2 l - d^2 a}{\sqrt{l^2+d^2}^3}\hat{\mathbf{e}}_x \ .$$

Now, we expand l in terms of the retarded time,

$$l = x(t_r + T) - x(t_r) = \cancelto{0}{v\mathcal{T}} + \tfrac{1}{2}aT^2 + \tfrac{1}{6}\dot{a}T^3 + \dots \ ,$$

such that,

$$d = \sqrt{(cT)^2 - l^2} = cT\sqrt{1 - \left(\tfrac{aT}{2c} + \tfrac{\dot{a}T^2}{6c} + \dots\right)^2} = cT - \frac{a^2}{8c}T^3 + \dots \simeq cT - \frac{a^2}{8c}\left(\frac{d}{c}\right)^3 + \dots \ ,$$

where we replaced, in the last step, the first order solution in the expansion, $T \simeq d/c$, for the third order. Resolving by T,

$$T \simeq \frac{d}{c} + \frac{a^2 d^3}{8c^5} \ .$$

and inserting into the expansion of l,

$$l \simeq \frac{1}{2}a\left(\frac{d}{c} + \frac{a^2d^3}{8c^5}\right)^2 + \frac{1}{6}\dot{a}\left(\frac{d}{c} + \frac{a^2d^3}{8c^5}\right)^3 + \dots \simeq \frac{1}{2}a\left(\frac{d}{c}\right)^2 + \frac{1}{6}\dot{a}\left(\frac{d}{c}\right)^3 \ .$$

With this we obtain for reaction force,

$$\begin{aligned}\mathbf{F}_{self} \simeq \frac{q}{8\pi\varepsilon_0 c^2}\frac{c^2 l - d^2 a}{\sqrt{l^2+d^2}^3}\hat{\mathbf{e}}_x &\simeq \frac{q}{8\pi\varepsilon_0 c^2}\frac{c^2\left(\frac{1}{2}a\left(\frac{d}{c}\right)^2 + \frac{1}{6}\dot{a}\left(\frac{d}{c}\right)^3\right) - d^2 a}{\sqrt{(..)d^4 + d^2}^3}\hat{\mathbf{e}}_x \\ &\simeq \frac{q}{4\pi\varepsilon_0 c^2}\left(-\frac{a}{4d} + \frac{\dot{a}}{12c}\right)\hat{\mathbf{e}}_x \ ,\end{aligned}$$

considering that d is small. The acceleration is still expressed in terms of the retarded time, but this is easily remedied by,

$$a(t_r) = a(t) + \dot{a}(t)(t - t_r) = a(t) - \dot{a}(t)\frac{d}{c} \ .$$

Inserting into the force,

$$\begin{aligned}\mathbf{F}_{self} \simeq \frac{q}{4\pi\varepsilon_0 c^2}\left(-\frac{a}{4d} + \frac{\dot{a}}{12c}\right)\hat{\mathbf{e}}_x &= \frac{q}{4\pi\varepsilon_0}\left(-\frac{a(t)}{4c^2 d} - \frac{-\dot{a}(t)}{4c^3} + \frac{\dot{a}(t)}{12c^3}\right)\hat{\mathbf{e}}_x \\ &= \frac{q}{4\pi\varepsilon_0}\left(\frac{a(t)}{4c^2 d} + \frac{\dot{a}(t)}{3c^3}\right)\hat{\mathbf{e}}_x \ .\end{aligned}$$

Finally,

$$\mathbf{F} = m_{tot}a + \mathbf{F}_{rad} = \left(m_0 + \frac{1}{4\pi\varepsilon_0}\frac{q^2}{4dc^2}\right)\mathbf{a} + \frac{\mu_0 q^2 \dot{\mathbf{a}}}{12\pi c} \ ,$$

where m_0 is the sum of the two partial masses. We retrieve the Abraham-Lorentz formula by the second term. The missing factor of 2, when compared to (19.155), comes from the fact that we only consider the mutual reactions of partial charges. The expression in the parentheses corresponds to a correction of the inertial mass of the particle due to the Coulombian repulsion between the charges.

19.2.2.1 Radiation of a charge exposed to a gravitational field

Generalize Larmor's formula. Needs relative movement of charge and field [552].

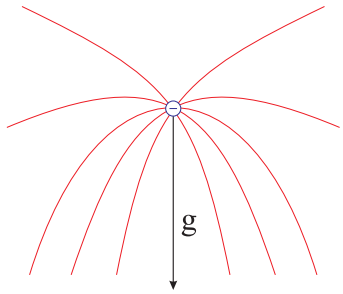

Figure 19.8: Illustration of the radiation field of a charge suspended in the Earth's gravitational field.

19.2.3 Exercises

19.2.3.1 Ex: Radiation emitted by a rotating electron

A particle with charge q moves with constant angular velocity ω in a circular orbit with radius R around the origin in the plane x-y. Its trajectory therefore is,

$$\mathbf{R}'(t) = R(\hat{\mathbf{e}}'_x \cos\omega t + \hat{\mathbf{e}}'_y \sin\omega t) \ .$$

a. Calculate the associated (temporary) charge density $\varrho(\mathbf{r}', t)$ and the dipole moment using the general rule,

$$\mathbf{d}(t) = \int \mathbf{r}' \varrho(\mathbf{r}', t) d^3\mathbf{r}' \ .$$

b. The rotating particle can be seen as a source of radiation. At a point $\mathbf{r}$ far from this source, in the dipole approximation, the associated electromagnetic fields are given by,

$$\vec{\mathcal{B}} = \tfrac{\mu_0}{4\pi c r} \hat{\mathbf{e}}_r \times \ddot{\mathbf{d}} \qquad \text{respectively} \qquad \vec{\mathcal{E}} = c\vec{\mathcal{B}} \times \hat{\mathbf{e}}_r \ .$$

Calculate the Poynting vector,

$$\vec{\mathcal{S}} = \tfrac{1}{\mu_0} \vec{\mathcal{E}} \times \vec{\mathcal{B}}$$

as well as its component $\mathcal{S}_n \equiv \hat{\mathbf{e}}_r \cdot \vec{\mathcal{S}}$ in the direction of the point $\mathbf{r}$. **Help:** Use the formula $\mathbf{a} \times \mathbf{b} \times \mathbf{c} = \mathbf{b}(\mathbf{a} \cdot \mathbf{c}) - \mathbf{c}(\mathbf{a} \cdot \mathbf{b})$.
c. Now calculate the time average of $\mathcal{S}_n$ over an orbit of the particle, that is, calculate $\bar{\mathcal{S}}_n = \int dt \mathcal{S}_n \ / \ \int dt$ with the two integrals taken between $t = 0$ and $t = 2\pi/\omega$. Express the result in spherical coordinates, so that $r^2 \bar{\mathcal{S}}_n$ is precisely the average power radiated to the solid angle element $d\Omega$ in the direction $\mathbf{r}$. Now integrate over the entire solid angle and evaluate the total emitted power P.

Solution: *a. The time-dependent charge density is in Cartesian coordinates,*

$$\varrho(\mathbf{r}', t) = q\delta(x' - R\cos\omega t)\delta(y' - R\sin\omega t)\delta(z') \ .$$

It is easy check that the volume integral over this charge density is, at all times, equal to the total existing charge. The electric dipole moment of our charge distribution is now,

$$\begin{aligned}\mathbf{d}(t) &= \int_{-\infty}^{\infty} dx' \int_{-\infty}^{\infty} dy' \int_{-\infty}^{\infty} dz' [x'\hat{\mathbf{e}}_x + y'\hat{\mathbf{e}}_y + z'\hat{\mathbf{e}}_z]\varrho(x', y', z', t) \\ &= qR(\hat{\mathbf{e}}_x \cos\omega t + \hat{\mathbf{e}}_y \sin\omega t) = q\mathbf{R}(t) \ .\end{aligned}$$

b. Using the result of part (a),

$$\ddot{\mathbf{d}} = -\omega^2 \mathbf{d} \ .$$

Thus, at a point $\mathbf{r}$ *very far from the radiation source, oscillating here at a frequency* ω*, the electromagnetic fields are given in the dipolar approximation by,*

$$\vec{\mathcal{B}} = -\frac{\mu_0\omega^2}{4\pi cr}[\hat{\mathbf{e}}_r \times \mathbf{d}] \qquad \textit{as well as} \qquad \vec{\mathcal{E}} = -\frac{\mu_0\omega^2}{4\pi r}\hat{\mathbf{e}}_r \times [\hat{\mathbf{e}}_r \times \mathbf{d}] \ .$$

With the given formulas the electric field can also be written,

$$\vec{\mathcal{E}} = \frac{\mu_0\omega^2}{4\pi r}[\mathbf{d} - \hat{\mathbf{e}}_r(\hat{\mathbf{e}}_r \cdot \mathbf{d})] \ .$$

For the Poynting vector we get in this way [7]*,*

$$\begin{aligned}\vec{\mathcal{S}} &= \frac{\mu_0}{c}\left(\frac{\omega^2}{4\pi r}\right)^2 [\mathbf{d} - \hat{\mathbf{e}}_r(\hat{\mathbf{e}}_r \cdot \mathbf{d})] \times [\hat{\mathbf{e}}_r \times \mathbf{d}] \\ &= \frac{\mu_0}{c}\left(\frac{\omega^2}{4\pi r}\right)^2 [\mathbf{d} \times [\hat{\mathbf{e}}_r \times \mathbf{d}] - (\hat{\mathbf{e}}_r \cdot \mathbf{d})\hat{\mathbf{e}}_r \times [\hat{\mathbf{e}}_r \times \mathbf{d}]] \\ &= \frac{\mu_0}{c}\left(\frac{\omega^2}{4\pi r}\right)^2 [\hat{\mathbf{e}}_r(\mathbf{d} \cdot \mathbf{d}) - \mathbf{d}(\hat{\mathbf{e}}_r \cdot \mathbf{d}) - (\hat{\mathbf{e}}_r \cdot \mathbf{d})^2\hat{\mathbf{e}}_r + \mathbf{d}(\hat{\mathbf{e}}_r \cdot \mathbf{d})] \\ &= \frac{\mu_0}{c}\left(\frac{\omega^2}{4\pi r}\right)^2 \hat{\mathbf{e}}_r[(\mathbf{d} \cdot \mathbf{d}) - (\hat{\mathbf{e}}_r \cdot \mathbf{d})^2] \ .\end{aligned}$$

[7] For time-dependent sinusoidal electromagnetic fields, the average power flux per unit time is often more useful. It can be found by using the analytical representation of the electric and magnetic fields as follows,

$$\begin{aligned}\vec{\mathcal{S}} &= \vec{\mathcal{E}} \times \vec{\mathcal{H}} = \mathfrak{Re}\ (\vec{\mathcal{E}}_0 e^{\imath\omega t}) \times \mathfrak{Re}\ (\vec{\mathcal{H}}_0 e^{\imath\omega t}) = \tfrac{1}{2}(\vec{\mathcal{E}}_0 e^{\imath\omega t} + \vec{\mathcal{E}}_0^* e^{-\imath\omega t}) \times \tfrac{1}{2}(\mathcal{H}_0 e^{\imath\omega t} + \vec{\mathcal{H}}_0^* e^{-\imath\omega t}) \\ &= \tfrac{1}{4}(\vec{\mathcal{E}}_0 \times \vec{\mathcal{H}}_0^* + \vec{\mathcal{E}}_0^* \times \vec{\mathcal{H}}_0 + \vec{\mathcal{E}}_0 \times \vec{\mathcal{H}}_0 e^{2\imath\omega t} + \mathcal{E}_0^* \times \vec{\mathcal{H}}_0^* e^{-2\imath\omega t}) \\ &= \tfrac{1}{4}[\vec{\mathcal{E}}_0 \times \vec{\mathcal{H}}_0^* + (\vec{\mathcal{E}}_0 \times \vec{\mathcal{H}}_0^*)^* + \vec{\mathcal{E}}_0 \times \vec{\mathcal{H}}_0 e^{2\imath\omega t} + (\vec{\mathcal{E}}_0 \times \vec{\mathcal{H}}_0^* e^{2\imath\omega t})^*] \\ &= \tfrac{1}{2}\mathfrak{Re}\ (\vec{\mathcal{E}}_0 \times \vec{\mathcal{H}}_0^*) + \tfrac{1}{2}\mathfrak{Re}\ (\vec{\mathcal{E}}_0 \times \vec{\mathcal{H}}_0 e^{2\imath\omega t}) \ .\end{aligned}$$

The temporal average is given by,

$$\langle\vec{\mathcal{S}}\rangle = \frac{1}{T}\int_0^T \vec{\mathcal{S}}(t)dt = \frac{1}{T}\int_0^T [\tfrac{1}{2}\mathfrak{Re}\ (\vec{\mathcal{E}}_0 \times \vec{\mathcal{H}}_0^*) + \tfrac{1}{2}\mathfrak{Re}\ (\vec{\mathcal{E}}_0 \times \vec{\mathcal{H}}_0^* e^{2\imath\omega t})]dt \ .$$

The second term is a sinusoidal curve, $\mathfrak{Re}\ e^{2\imath\omega t} = \cos 2\omega t$, and its average is zero, giving

$$\langle\vec{\mathcal{S}}\rangle = \frac{1}{2}\mathfrak{Re}\ (\vec{\mathcal{E}}_0 \times \vec{\mathcal{H}}_0^*) = \tfrac{1}{2}\mathfrak{Re}\ (\vec{\mathcal{E}}_0 e^{\imath\omega t} \times \vec{\mathcal{H}}_0^* e^{-\imath\omega t}) \ .$$

The component of Poynting vector in $\mathbf{r}$*-direction is, hence,*

$$\mathcal{S}_n = \hat{\mathbf{e}}_r \cdot \vec{\mathcal{S}} = \frac{\mu_0}{c}\left(\frac{\omega^2}{4\pi r}\right)^2 [(\mathbf{d}\cdot\mathbf{d}) - (\hat{\mathbf{e}}_r\cdot\mathbf{d})^2] \ .$$

For our example we obtain,

$$\begin{aligned}\mathcal{S}_n &= \frac{\mu_0}{c}\left(\frac{\omega^2 q}{4\pi r}\right)^2 (R^2 - [x\cos\omega t + y\sin\omega t]^2) \\ &= \frac{\mu_0}{c}\left(\frac{\omega^2 q}{4\pi r}\right)^2 (R^2 - x^2\cos^2\omega t - y^2\sin^2\omega t - 2xy\sin\omega t\cos\omega t) \ .\end{aligned}$$

c. The temporal average of $\mathcal{S}_n$ *over the period of an orbit gives, using*

$$\frac{\omega}{2\pi}\int_0^{2\pi/\omega} dt\cos^2\omega t = \frac{\omega}{2\pi}\int_0^{2\pi/\omega} dt\sin^2\omega t = \frac{1}{2}$$

and

$$\frac{\omega}{2\pi}\int_0^{2\pi/\omega} dt\cos\omega t\sin\omega t = 0$$

the result,

$$\bar{\mathcal{S}}_n = \frac{\mu_0}{c}\left(\frac{\omega^2 qR}{4\pi r}\right)^2 [R^2 - \frac{1}{2}(x^2+y^2)] = \frac{\mu_0}{2c}\left(\frac{\omega^2 q}{4\pi r}\right)^2 (1+\cos^2\theta) \ ,$$

where we moved in the last line to spherical coordinates. For the solid angle element $d\Omega$ *pointing in* $\mathbf{r}$*-direction we obtain the power radiated by the source,*

$$\frac{dP_n}{d\Omega} = r^2\bar{\mathcal{S}}_n = \frac{\mu_0}{2c}\left(\frac{\omega^2 q}{4\pi}\right)^2 (1+\cos^2\theta) \ .$$

Integration over $d\Omega = d\phi\sin\theta d\theta$ *gives the total radiated power,*

$$P = \frac{\mu_0}{2c}\left(\frac{\omega^2 q}{4\pi}\right)^2 \int_{-1}^{+1} dx(1+x^2) = \frac{\mu_0\omega^4 q^2 R^2}{6\pi c} \ .$$

19.2.3.2 Ex: Rutherford's atom model

In Rutherford's 'classical' atom model a hydrogen atom is described by an electron (charge $-e$) orbiting a nucleus (charge $+e$) in a circular trajectory with constant angular velocity ω. The equilibrium condition is chosen so that the Coulomb force and the centrifugal force compensate each other. However, according to the Exc. 19.2.3.1, such an electron represents a source of radiation. The radiated power decreased the energy of the electron [$dE/dt = -P$ with P taken from Exc. 19.2.3.1(c)]. Derive a differential equation for the temporal variation of the radius $R(t)$ of the electronic orbit, and integrate it with the boundary conditions $t_0 = 0$ and $R(t_0) = a_B$, where

$a_B = 0.53 \times 10^{-8}$ cm is the Bohr radius. After what time T do we get $R(T) = 0$?

Solution: *The equilibrium condition requires,*

$$m\omega^2 R = \frac{e^2}{R^2} \ .$$

The kinetic energy of the electron is then,

$$E_{kin} = \frac{1}{2}mv^2 = \frac{1}{2}m\omega^2 R^2 = \frac{1}{2}\frac{e^2}{R} \ ,$$

and its potential energy,

$$E_{pot} = -\frac{e^2}{R} \ .$$

Hence,

$$E = E_{kin} + E_{pot} = -\frac{1}{2}\frac{e^2}{R} \ .$$

The energy loss is, according to the Exc. 19.2.3.1,

$$\frac{dE}{dt} = -P = -\frac{2\omega^4 e^2 R^2}{3c^3} \ .$$

Now, understanding R as a function of time t, we obtain,

$$\frac{dE}{dt} = \frac{d}{dt}\left(-\frac{1}{2}\frac{e^2}{R}\right) = \frac{e^2}{R^2}\frac{dR}{dt} = -\frac{2\omega^4 e^2 R^2}{3c^3} \ ,$$

and with this, once again using the equilibrium condition, the differential equation,

$$\frac{dR}{dt} = -\frac{4}{3}\frac{e^4}{c^3 m^2}\frac{1}{R^2} \ .$$

Integration of this equation gives,

$$t - t_0 = -\frac{1}{4}\frac{c^3 m^2}{e^4}(R^3 - R^3(t_0)) \ .$$

Inserting $t_0 = 0$ and for $R(t_0) = a_B$ the Bohr radius, we obtain,

$$t = (a_B^3 - R^3)\frac{m^2 c^3}{4e^4} \ .$$

The time T when, due to the loss of energy, the radius of the electron's orbit becomes $R = 0$, is therefore,

$$T = \frac{m^2 c^3 a_B^3}{4e^4} \ .$$

Insertion of given values yields,

$$T \sim 1.6 \times 10^{-11}\,\mathrm{s} \ .$$

This is the radiation catastrophe of the classical model of the hydrogen atom.

19.2.3.3 Ex: Dynamics of charged point particles

Consider a point particle with charge q and mass m and general electromagnetic fields in vacuum, $\vec{\mathcal{E}}(\mathbf{r},t)$ and $\vec{\mathcal{B}}(\mathbf{r},t)$, which are not perturbed neither by the charge nor the current resulting from the particle's motion. On the particle acts the Coulomb-Lorentz force.
a. What are the equations of motion for the particle? What is the temporal variation of its total kinetic energy? What condition must be satisfied to ensure that the kinetic energy of the particle is temporally constant?
b. We now consider homogeneous fields $\vec{\mathcal{E}}(\mathbf{r},t) = \mathcal{E}_0\hat{\mathbf{e}}_z$ and $\vec{\mathcal{B}}(\mathbf{r},t) = \mathcal{B}_0\hat{\mathbf{e}}_z$. What are the equations of motion now?
c. The particle is at time $t = 0$ at the origin of the coordinate system and has the velocity $\mathbf{v}_0$. Solve the equations of motion. **Help:** Use the complex variable $\eta = x + \imath y$ and add the equations of motion to obtain a complex equation motion for η of the type $\ddot{\eta} = -\imath\omega\dot{\eta}$ with $\omega = q\vec{\mathcal{B}}_0/(mc)$.
d. How does the kinetic energy of the particle vary over time?

Solution: *a. From the specified force we derive, for the charged particle, Newton's equation of motion:*

$$m\ddot{\mathbf{r}} = \mathbf{F} = q(\vec{\mathcal{E}} + \mathbf{v}\times\vec{\mathcal{B}}) \ .$$

The temporal variation of the kinetic energy is given by,

$$\dot{W} \equiv \frac{d}{dt}\left(\frac{m}{2}\mathbf{v}^2\right) = m\mathbf{v}\cdot\dot{\mathbf{v}} = \mathbf{v}\cdot\mathbf{F} = q\mathbf{v}\cdot\vec{\mathcal{E}} \ .$$

For energy to remain constant, we need to guarantee,

$$\dot{W} = q\mathbf{v}\cdot\vec{\mathcal{E}} = 0 = q\dot{\mathbf{r}}\cdot\vec{\mathcal{E}} \ .$$

b. For time-independent and homogeneous fields, $\vec{\mathcal{E}}(\mathbf{r},t) = \vec{\mathcal{E}}_0\hat{\mathbf{e}}_z$ and $\vec{\mathcal{B}}(\mathbf{r},t) = \vec{\mathcal{B}}_0\hat{\mathbf{e}}_z$, we calculate for the force,

$$\mathbf{F} = q\vec{\mathcal{E}}_0\hat{\mathbf{e}}_z + \vec{\mathcal{B}}_0(v_x\hat{\mathbf{e}}_x + v_y\hat{\mathbf{e}}_y + v_z\hat{\mathbf{e}}_z)\times\hat{\mathbf{e}}_z = q\vec{\mathcal{E}}_0\hat{\mathbf{e}}_z + q\vec{\mathcal{B}}_0(-v_x\hat{\mathbf{e}}_y + v_y\hat{\mathbf{e}}_x) \ ,$$

and therefore for the equations of motion by components,

$$\ddot{x} = \frac{q\vec{\mathcal{B}}_0}{m}\dot{y} \quad , \quad \ddot{y} = -\frac{q\vec{\mathcal{B}}_0}{m}\dot{x} \quad , \quad \ddot{z} = \frac{q\vec{\mathcal{E}}_0}{m} \ .$$

c. The third equation can be integrated immediately. With the boundary conditions $z(0) = 0$ and $\dot{z}(0) = v_{0z}$ follows the 'free fall',

$$z(t) = \frac{q\vec{\mathcal{E}}_0}{2m}t^2 + v_{0z}t \ .$$

For the other two (coupled) equations we use a standard trick: we add $\imath$ times the second equation to the first one, and get,

$$\ddot{x} + \imath\ddot{y} = -\imath\frac{q\vec{\mathcal{B}}_0}{mc}\ (\dot{x} + \imath\dot{y}) \ .$$

that is, with the abbreviations $\eta = x + \imath y$ *and* $\omega = q\vec{\mathcal{B}}_0/(mc)$

$$\ddot{\eta} = -\imath\omega\dot{\eta} \ ,$$

we use that $\dot{\eta}(0) = v_{0x} + \imath v_{0y}$. *From this follows immediately,*

$$\dot{\eta}(t) = \dot{x} + \imath\dot{y} = (v_{0x} + \imath v_{0y})e^{-\imath\omega t} \ .$$

This equation can also be directly integrated,

$$\begin{aligned}\eta(t) = x + \imath y &= \frac{\imath}{\omega}e^{-\imath\omega t} + c \\ &= \left(\frac{v_{0x}}{\omega}\sin\omega t - \frac{v_{0y}}{\omega}\cos\omega t + \mathfrak{Re}\ c\right) + \imath\left(\frac{v_{0x}}{\omega}\cos\omega t + \frac{v_{0y}}{\omega}\sin\omega t + \mathfrak{Im}\ c\right) \ .\end{aligned}$$

Inserting the initial conditions,

$$\begin{aligned}x(t) &= \frac{v_{0x}}{\omega}\sin\omega t - \frac{v_{0y}}{\omega}(\cos\omega t - 1) \\ y(t) &= \frac{v_{0x}}{\omega}(\cos\omega t - 1) + \frac{v_{0y}}{\omega}\sin\omega t \ .\end{aligned}$$

d. From (c) follows,

$$\dot{x}^2 + \dot{y}^2 = v_{0x}^2 + v_{0y}^2 = constant \ .$$

Calling T_0 *the kinetic energy at time* $t = 0$ *we get,*

$$T(t) = \tfrac{m}{2}(\dot{x}^2 + \dot{y}^2 + \dot{z}^2) = T_0 + \tfrac{m}{2}q\vec{\mathcal{E}}_0 t(q\vec{\mathcal{E}}_0 t + 2v_{0z}) \ .$$

19.2.3.4 Ex: Excitation of an electron by circularly polarized light

Derive the expression for the dipole radiation from the Maxwell equations proceeding in the following way:
a. Derive the equation of motion of a point particle of charge q and mass m in an electromagnetic field $(\vec{\mathcal{E}},\ \vec{\mathcal{B}})$ neglecting the emission of radiation by the moving charge. Determine the temporal variation of the particle's energy W inside the external field.
b. A circularly polarized monochromatic wave in vacuum is described by the electric field, $\vec{\mathcal{E}}(\mathbf{r},t) = \mathcal{E}[\cos(kz - \omega t)\hat{\mathbf{e}}_x + \sin(kz - \omega t)\hat{\mathbf{e}}_y]$. Calculate the corresponding magnetic field $\vec{\mathcal{B}}(\mathbf{r},t)$.
c. Calculate the Poynting vector $\vec{\mathcal{S}}(\mathbf{r},t)$.
d. For an energy flux of the electromagnetic wave of $10\,\mathrm{W/m^2}$ calculate the amplitudes of the electric and the magnetic field.
e. For the particle of part (a) moving in the fields of part (b) establish the equation of motion.
f. Initially $(t = 0)$ the particle is at the origin of the coordinate system. How should the initial condition for the velocity be chosen in order to obtain a constant energy for the particle?
g. Determine the momentum $\mathbf{p}$ of the particle and verify that $\mathbf{p}_\perp = p_x\hat{\mathbf{e}}_x + p_y\hat{\mathbf{e}}_y$

coincides at every instant of time with the direction of $\vec{\mathcal{B}}$.
h. Solve the equation of motion with the initial conditions of part (d).
i. What is the form of the particle's trajectory in the x-y plane?

Solution: *a. The Lorentz force is,*

$$\mathbf{F} = q\vec{\mathcal{E}} + q(\mathbf{v} \times \vec{\mathcal{B}}) \ .$$

With Newton immediately follows the equation of motion,

$$\ddot{\mathbf{r}} = \tfrac{q}{m}\vec{\mathcal{E}} + \tfrac{q}{m}(\dot{\mathbf{r}} \times \vec{\mathcal{B}}) \ .$$

For the temporal variation of the particle's energy we obtain,

$$\dot{W} = \mathbf{v} \cdot \mathbf{F} = q\mathbf{v} \cdot \vec{\mathcal{E}} \ .$$

b. We have

$$\vec{\mathcal{B}} = \tfrac{1}{\omega}(\mathbf{k} \times \vec{\mathcal{E}}) \ ,$$

with $\mathbf{k} = k\hat{\mathbf{e}}_z$.
c. The Poynting vector is,

$$\vec{\mathcal{S}}(\mathbf{r}, t) = \varepsilon_0 c^2 (\vec{\mathcal{E}} \times \vec{\mathcal{B}}) = \varepsilon_0 c^2 \frac{\vec{\mathcal{E}}_0^2}{c} \left[\hat{\mathbf{e}}_z \sin^2(kz - \omega t) + \hat{\mathbf{e}}_z \cos^2(kz - \omega t)\right] = \varepsilon_0 c \vec{\mathcal{E}}_0^2 \hat{\mathbf{e}}_z \ ,$$

that is, we have a constant flow in the direction of the k vector.
d. The amplitudes are $\mathcal{E}_0 = \sqrt{s/\varepsilon_0 c} \approx 61\,\mathrm{V/m}$ *and* $\mathcal{B}_0 = \mathcal{E}_0/c \approx 2.1 \cdot 10^{-7}\,\mathrm{T}$.
e. Inserting the derived magnetic field into the equation of motion,

$$\ddot{\mathbf{r}} = \tfrac{q}{m}\vec{\mathcal{E}} + \tfrac{q}{m\omega}\mathbf{v} \times (\mathbf{k} \times \vec{\mathcal{E}}) = \tfrac{q}{m}\vec{\mathcal{E}} + \tfrac{q}{m\omega}(\mathbf{k}(\mathbf{v} \cdot \vec{\mathcal{E}}) - \vec{\mathcal{E}}(\mathbf{v} \cdot \mathbf{k})) \ .$$

Using one more time $\mathbf{k} = k\hat{\mathbf{e}}_z$ *and* $\omega = ck$, *we obtain by components,*

$$\begin{aligned}
\ddot{x} &= \frac{q}{m}\mathcal{E}_x \left(1 - \frac{\dot{z}}{c}\right) = \frac{q}{m}\mathcal{E} \left(1 - \frac{\dot{z}}{c}\right) \cos(kz - \omega t) \\
\ddot{y} &= \frac{q}{m}\mathcal{E}_y \left(1 - \frac{\dot{z}}{c}\right) = \frac{q}{m}\mathcal{E} \left(1 - \frac{\dot{z}}{c}\right) \sin(kz - \omega t) \\
\ddot{z} &= \frac{q}{mc}(\dot{\mathbf{r}} \cdot \vec{\mathcal{E}}) \ .
\end{aligned}$$

f. If we want $\dot{W} = 0$ *at all times, from (a) we get immediately that* $\dot{\mathbf{r}} \cdot \vec{\mathcal{E}} = 0$ *must always be satisfied. With the last equation of part (e) this implies* $\ddot{z} = 0$, *that is* $\dot{z} = \mathrm{const} = v_0$. *Insertion in the other two equations of motion provides,*

$$\begin{aligned}
\ddot{x} &= \frac{q\mathcal{E}}{m} \left(1 - \frac{v_0}{c}\right) \cos(kz - \omega t) \\
\ddot{y} &= \frac{q\mathcal{E}}{m} \left(1 - \frac{v_0}{c}\right) \sin(kz - \omega t) \ .
\end{aligned}$$

Integration gives,

$$\begin{aligned}
\dot{x} &= -\frac{q\mathcal{E}}{m\omega} \left(1 - \frac{v_0}{c}\right) \sin(kz - \omega t) + \dot{x}_0 \\
\dot{y} &= \frac{q\mathcal{E}}{m\omega} \left(1 - \frac{v_0}{c}\right) \cos(kz - \omega t) + \dot{y}_0 \ .
\end{aligned}$$

With this follows,

$$\begin{aligned} 0 = \dot{\mathbf{r}} \cdot \vec{\mathcal{E}} &= \left[-\frac{q\mathcal{E}}{m\omega} \left(1 - \frac{v_0}{c}\right) \sin(kz - \omega t) + \dot{x}_0 \right] \mathcal{E} \cos(kz - \omega t) \\ &+ \left[\frac{q\mathcal{E}}{m\omega} \left(1 - \frac{v_0}{c}\right) \cos(kz - \omega t) + \dot{y}_0 \right] \mathcal{E} \sin(kz - \omega t) \\ &= \dot{x}_0 \mathcal{E} \cos(kz - \omega t) + \dot{y}_0 \mathcal{E} \sin(kz - \omega t) \dot{\mathbf{r}}_0 \cdot \vec{\mathcal{E}} = \mathcal{E}_x \dot{x}_0 + \mathcal{E}_y \dot{y}_0 \ . \end{aligned}$$

For this expression to be zero at all times, we need $\dot{x}_0 = \dot{y}_0 = 0$. *Since* $z(t = 0) = 0$, *we obtain for the initial conditions we were looking for,*

$$\mathbf{v}(t = 0) = \begin{pmatrix} 0 & \frac{q\mathcal{E}}{m\omega} \left(1 - \frac{v_0}{c}\right) & 0 \end{pmatrix} \qquad \textit{with} \qquad v_0 \quad \textit{arbitrary} \ .$$

g. For the momentum we get,

$$\mathbf{p} = \begin{pmatrix} -\frac{q\mathcal{E}}{\omega} \left(1 - \frac{v_0}{c}\right) \sin(kz - \omega t) \\ \frac{q\mathcal{E}}{\omega} \left(1 - \frac{v_0}{c}\right) \cos(kz - \omega t) \\ m v_0 \end{pmatrix} \ .$$

A comparison with the magnetic field $\vec{\mathcal{E}}(\mathbf{r}, t) = \frac{\mathcal{E}}{c}[-\sin(kz - \omega t)\hat{\mathbf{e}}_x + \cos(kz - \omega t)\hat{\mathbf{e}}_y]$ *calculated in (b) shows that,*

$$\mathbf{p}_\perp = \frac{q}{ck} \left(1 - \frac{v_0}{c}\right) \vec{\mathcal{B}} \ .$$

h. Integration

$$\begin{aligned} x &= -\frac{q\mathcal{E}}{m\omega^2} \left(1 - \frac{v_0}{c}\right) \cos(kz - \omega t) \ + \ x_0 \\ y &= -\frac{q\mathcal{E}}{m\omega^2} \left(1 - \frac{v_0}{c}\right) \sin(kz - \omega t) \ + \ y_0 \\ z &= v_0 t \ + \ z_0 \ . \end{aligned}$$

With $x(t = 0) = y(t = 0) = z(t = 0) = 0$ *follows the solution,*

$$\begin{aligned} x(t) &= \frac{q\mathcal{E}}{m\omega^2} \left(1 - \frac{v_0}{c}\right) [1 - \cos(kz - \omega t)] \\ y(t) &= -\frac{q\mathcal{E}}{m\omega^2} \left(1 - \frac{v_0}{c}\right) \sin(kz - \omega t) \\ z(t) &= v_0 t \ . \end{aligned}$$

i. We define,

$$R \equiv \frac{q\mathcal{E}}{m\omega^2} \left(1 - \frac{v_0}{c}\right) \ .$$

We see immediately with part (f), that,

$$(x(t) - R)^2 + y^2(t) = R^2 \ .$$

Therefore, the trajectory is a circle with the radius R *and the center* $(R, 0)$.

19.2.3.5 Ex: Charge and current densities for radiative atomic transitions

The charge and current densities for radiative atomic transitions from the state $m = 0$, $2p$ of hydrogen to the ground state $1s$, are (neglecting the spin),

$$\varrho(r,\theta,\phi,t) = \frac{2e}{\sqrt{6}a_B^4} r e^{-3r/2a_B} Y_{00} Y_{10} e^{-\imath\omega_0 t} \quad , \quad \mathbf{j}(r,\theta,\phi,t) = -\imath v_0 \left(\frac{\hat{\mathbf{e}}_r}{2} + \frac{a_B}{z}\hat{\mathbf{e}}_z \right) \varrho(r,\theta,\phi,t) \ ,$$

where $v_0 = \alpha c$ is the orbital velocity of the electron, a_B the Bohr radius, and α the Sommerfeld constant.
a. Show that the effective transitional orbital 'magnetization' is,

$$\vec{\mathcal{M}}_{ef}(r,\theta,\phi,t) = -\imath \frac{\alpha c a_B}{2} \tan\theta (\hat{\mathbf{e}}_x \sin\phi - \hat{\mathbf{e}}_y \cos\phi) \varrho(r,\theta,\phi,t) \ .$$

Calculate $\nabla \cdot \vec{\mathcal{M}}_{ef}$ and evaluate the electric and magnetic dipole moments.
b. In the electric dipole approximation, calculate the temporal average of the total radiated power. Express your response in units of $(\hbar\omega_0)(\alpha^4 c/a_B)$.
c. Interpreting the classically calculated power as the energy of a photon ($\hbar\omega_0$) times the transition probability, numerically evaluate the transition probability in units of reciprocal seconds.
d. If, instead of the semiclassic charge density used above, the electron in the $2p$ state is described by a circular Bohr orbit of radius $2a_B$, rotating with the transition frequency ω_0, what would be the radiated power? Express your answer in the same units as in part (b), and evaluate the ratio of the two powers numerically.

Solution: *a. The magnetization is,*

$$\begin{aligned}
\vec{\mathcal{M}} = \tfrac{1}{2}\mathbf{r}\times\mathbf{j} &= \tfrac{1}{2}\mathbf{r}\times\left[-iv_0\left(\cancelto{0}{\frac{\hat{\mathbf{e}}_z}{2}} + \frac{a_B}{z}\hat{\mathbf{e}}_z\right)\varrho\right] = -\imath v_0 a_B \tfrac{1}{2}\hat{\mathbf{e}}_r \times \hat{\mathbf{e}}_z \tfrac{r}{z}\varrho \\
&= -\imath v_0 a_B \tfrac{1}{2}(-\hat{\mathbf{e}}_y \sin\theta\cos\phi + \hat{\mathbf{e}}_x \sin\theta \sin\phi)\tfrac{r}{z}\varrho \\
&= -\imath c\alpha a_B \tfrac{1}{2}\tan\theta(\hat{\mathbf{e}}_x \sin\phi - \hat{\mathbf{e}}_y\cos\phi)\varrho \equiv \mathbf{X}\varrho \ ,
\end{aligned}$$

defining $\mathbf{X} = -\imath c\alpha a_B \frac{1}{2}\left(\hat{\mathbf{e}}_x \frac{y}{r} - \hat{\mathbf{e}}_y \frac{x}{r}\right)\frac{r}{z}$. *We find* $Y_{00} = \sqrt{1/(4\pi)}$ *and* $Y_{10} = \sqrt{3/(4\pi)}z$ *in tables of mathematical formulas and introduce the abbreviation* $\kappa \equiv \frac{2q}{\sqrt{6}a_B^4}\frac{1}{\sqrt{4\pi}}\sqrt{\frac{3}{4\pi}}$. *With this the charge density becomes,*

$$\varrho = \kappa z e^{-3r/a_B} \ .$$

The divergence of magnetization is,

$$\begin{aligned}
\nabla\cdot\vec{\mathcal{M}} &= \varrho\nabla\cdot\mathbf{X} + \mathbf{X}\cdot\nabla\varrho = \varrho\cancelto{0}{\nabla\cdot\mathbf{X}} + \kappa\mathbf{X}\cdot\nabla z e^{-3r/2a_B} \\
&= \mathbf{X}\cdot\left\{ z e^{-3r/2a_B}\left[\frac{-3x}{2a_B r}\hat{\mathbf{e}}_x + \frac{-3y}{2a_B r}\hat{\mathbf{e}}_y + \left(\frac{1}{z} - \frac{3z}{2a_B r}\right)\hat{\mathbf{e}}_z\right]\right\} = 0 \ .
\end{aligned}$$

We can write the electric dipole moment as,

$$\mathbf{d} = \int (x\hat{\mathbf{e}}_x + y\hat{\mathbf{e}}_y + z\hat{\mathbf{e}}_z)\varrho(\mathbf{r})d^3r = \int (\cancelto{0}{x\hat{\mathbf{e}}_x + y\hat{\mathbf{e}}_y} + z\hat{\mathbf{e}}_z)\kappa z e^{\frac{-3}{2a_B}\sqrt{x^2+y^2+z^2}}\varrho(\mathbf{r})d^3r \ ,$$

because integrals of odd functions vanish. Now,

$$\mathbf{d} = \kappa\hat{\mathbf{e}}_z \int z^2 e^{\frac{-3}{2a_B}\sqrt{x^2+y^2+z^2}} \varrho(\mathbf{r}) d^3r = 2\pi\kappa\hat{\mathbf{e}}_z \left(\int_0^\infty r^4 e^{-3r/2a_B} dr\right)\left(\int_{-1}^1 \cos^2\theta d(\cos\theta)\right) .$$

Using $\int_0^\infty r^n e^{-\beta r} dr = \frac{n!}{\beta^{n+1}}$ *we finally get,*

$$\mathbf{d} = 2\pi\kappa\hat{\mathbf{e}}_z \left(\frac{4!}{(3/2a_B)^5}\right)\left(\frac{2}{3}\right)\mathbf{d} = \pi\kappa\hat{\mathbf{e}}_z \left(\frac{4a_B}{3}\right)^5 = \frac{2^9}{\sqrt{2}3^5} e a_B \approx 1.49 e a_B \hat{\mathbf{e}}_z .$$

Now we calculate the magnetic dipole moment,

$$\mathbf{m} = \int \vec{\mathcal{M}} d^3r = -\frac{-\imath a_B v_0}{2} \int \left(\frac{y}{z}\hat{\mathbf{e}}_x - \frac{x}{z}\hat{\mathbf{e}}_y\right) \varrho d^3r = 0 ,$$

because integrals of odd functions vanish, ϱ *being even in* x *and* y*.*
b. The time-averaged total radiated power is given by,

$$P_{Jackson} = \frac{\mu_0 c^3 k^4}{12\pi} \bar{p}^2 \approx 0.039\ (\hbar\omega_0)\left(\frac{\alpha^4 c}{a_B}\right) .$$

c. We obtain,

$$\Gamma = \frac{P}{\hbar\omega} \approx 6.3 \cdot 10^8\,\mathrm{s}^{-1} \approx (2\pi)\ 100\,\mathrm{MHz} .$$

d. For a Bohr transition from the state $2p$ *having the radius* $r = 2a_B$ *to the state* $2s$ *having the radius* aB*,*

$$\mathbf{d} = q(2a_B - a_B)\hat{\mathbf{e}}_z e^{-\imath\omega t} = q a_B e^{-\imath\omega t}\hat{\mathbf{e}}_z ,$$

gives an emitted power of,

$$P_{Bohr} = 0.018\ (\hbar\omega_0)\left(\frac{\alpha^4 c}{a_B}\right) \approx 0.45\ P_{Jackson} .$$

19.2.3.6 Ex: Synchrotron radiation

In the discussion of the Bremsstrahlung in class we assumed that the velocity and the acceleration were (at least instantaneously) *collinear*. Do the same analysis for the case, that they are *perpendicular*. Choose your axes so that v is along the z-axis and a along the x-axis (see Fig. 19.7), such that $\mathbf{v} = v\hat{\mathbf{e}}_z$, $\mathbf{a} = \hat{\mathbf{e}}_x$ and $\mathbf{R} = \sin\theta\cos\phi\hat{\mathbf{e}}_x + \sin\theta\sin\phi\hat{\mathbf{e}}_y + \cos\theta\hat{\mathbf{e}}_z$. Verify whether P is consistent with the Liénard formula.

Solution: *We start from the Liénard's generalization of Larmor's formula (19.146),*

$$\frac{dP}{d\Omega} = \frac{q}{16\pi\varepsilon_0} \frac{|\hat{\mathbf{e}}_r \times (\mathbf{u}\times\mathbf{a})|^2}{(c - \hat{\mathbf{e}}_r\cdot\mathbf{v})^5} ,$$

inserting boundary conditions, which are specific to the problem,

$$\mathbf{v} = v\hat{\mathbf{e}}_z \qquad \textit{and} \qquad \mathbf{a} = a\hat{\mathbf{e}}_x \qquad \textit{such that} \qquad \mathbf{u} = c\hat{\mathbf{e}}_r - \mathbf{v} = c\hat{\mathbf{e}}_r - v\hat{\mathbf{e}}_z \ .$$

Using $\hat{\mathbf{e}}_r = \hat{\mathbf{e}}_x \sin\theta\cos\phi + \hat{\mathbf{e}}_y \sin\theta\sin\phi + \hat{\mathbf{e}}_z\cos\theta$ *to calculate,*

$$\begin{aligned}
\frac{dP}{d\Omega} &= \frac{q^2}{16\pi\varepsilon_0}\frac{|\hat{\mathbf{e}}_r \times [(c\hat{\mathbf{e}}_r - v\hat{\mathbf{e}}_z)\times a\hat{\mathbf{e}}_x]|^2}{(c-\hat{\mathbf{e}}_r\cdot v\hat{\mathbf{e}}_z)^5} = \frac{q^2a^2}{16\pi\varepsilon_0 c^3}\frac{|\hat{\mathbf{e}}_r\times(\hat{\mathbf{e}}_r\times\hat{\mathbf{e}}_x) - \beta\hat{\mathbf{e}}_r\times(\hat{\mathbf{e}}_z\times\hat{\mathbf{e}}_x)|^2}{(1-\beta\hat{\mathbf{e}}_r\cdot\hat{\mathbf{e}}_z)^5} \\
&= \frac{q^2a^2}{16\pi\varepsilon_0 c^3}\frac{|\hat{\mathbf{e}}_r(\hat{\mathbf{e}}_r\cdot\hat{\mathbf{e}}_x) - \hat{\mathbf{e}}_x(\hat{\mathbf{e}}_r\cdot\hat{\mathbf{e}}_r) - \beta\hat{\mathbf{e}}_z(\hat{\mathbf{e}}_r\cdot\hat{\mathbf{e}}_x) + \beta\hat{\mathbf{e}}_x(\hat{\mathbf{e}}_r\cdot\hat{\mathbf{e}}_z)|^2}{(1-\beta\hat{\mathbf{e}}_r\cdot\hat{\mathbf{e}}_z)^5} \\
&= \frac{\mu_0 q^2a^2}{16\pi c}\frac{(\hat{\mathbf{e}}_r\sin\theta\cos\phi - \hat{\mathbf{e}}_x - \beta\hat{\mathbf{e}}_z\sin\theta\cos\phi + \beta\hat{\mathbf{e}}_x\cos\theta)^2}{(1-\beta\cos\theta)^5} \\
&= \frac{\mu_0 q^2a^2}{16\pi c}\frac{(\hat{\mathbf{e}}_r - \beta\hat{\mathbf{e}}_z)^2\sin^2\theta\cos^2\phi + (1-\beta\cos\theta)^2 - 2(\hat{\mathbf{e}}_r - \beta\hat{\mathbf{e}}_z)\cdot\hat{\mathbf{e}}_x\sin\theta\cos\phi(1-\beta\cos\theta)}{(1-\beta\cos\theta)^5} \\
&= \frac{\mu_0 q^2a^2}{16\pi c}\frac{(1+\beta^2-2\beta\cos\theta)\sin^2\theta\cos^2\phi + (1-\beta\cos\theta)^2 - 2\sin\theta\cos\phi(1-\beta\cos\theta)}{(1-\beta\cos\theta)^5} \\
&= \frac{\mu_0 q^2a^2}{16\pi c}\frac{(1-\beta\cos\theta)^2 - (1-\beta)^2\sin^2\theta\cos^2\phi}{(1-\beta\cos\theta)^5} \ .
\end{aligned}$$

The integral is,

$$\begin{aligned}
P &= \int\frac{dP}{d\Omega}d\Omega = \frac{\mu_0 q^2a^2}{16\pi c}\int_0^\pi\int_0^{2\pi}\frac{(1-\beta\cos\theta)^2 - (1-\beta)^2\sin^2\theta\cos^2\phi}{(1-\beta\cos\theta)^5}\sin\theta d\phi d\theta \\
&= \frac{\mu_0 q^2a^2}{16\pi^2 c}\frac{8}{3}\frac{\pi}{(1-\beta^2)^2} = \frac{\mu_0 q^2a^2\gamma^4}{6\pi c} \ .
\end{aligned}$$

For the relativistic velocities ($\simeq c$), the radiation is again accentuated in forward direction. The most important application of these formulas is the case of a circular movement. In this case the radiation is called synchrotron radiation. For a relativistic electron, the radiation sweeps like a locomotive beacon, as the particle moves.

19.2.3.7 Ex: Cherenkov radiation

Cherenkov radiation is observed, when a charge moves with relativistic velocity within a dielectric medium, which reduces the speed of light below the velocity of the particle. A blue superluminal shock wave is then formed.
a. Calculate the angle θ_c between the propagation direction of the charge and the propagation direction of the shock wavefront.
b. We now imagine the deceleration process of the charge inside the dielectric as being due to a collision with a heavy molecule of the dielectric material. The collision creates a photon emitted under the angle θ_c and the momentum of charge is deflected. We despise the recoil of the molecule. Based on relativistic energy and momentum conservation, calculate the angle θ_c in terms of the momenta of charge before and after the collision and of the radiated frequency.
c. Comparing the results obtained in (a) and (b), calculate the rest mass of the charge.
d. Calculate the retarded Liénard-Wiechert potentials inside and outside of the cone.

Solution: *a. From the diagram we can easily see,*

$$\cos\theta_c = \frac{1}{\beta_n} \qquad with \qquad \beta_n = \frac{nv}{c} \ .$$

b. Relativistic momentum and energy conservation,

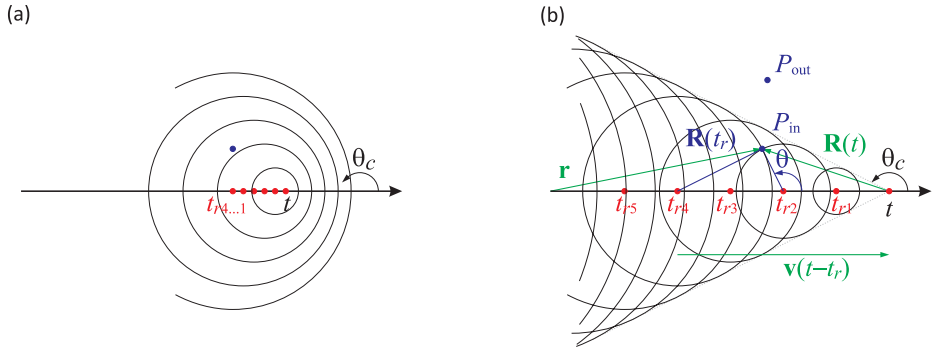

Figure 19.9: Scheme for Cherenkov radiation. (a) Charge moving at subluminal velocity, (b) at superluminal velocity.

$$\begin{pmatrix} \sqrt{c^2 p_{befor}^2 + m^2 c^4} \\ \mathbf{p}_{befor} \end{pmatrix} = \begin{pmatrix} \sqrt{c^2 p_{aftr}^2 + m^2 c^4} + \hbar\omega \\ \mathbf{p}_{aftr} + n\hbar\mathbf{k} \end{pmatrix} \ .$$

Momentum conservation,

$$p_{aftr}^2 = p_{befor}^2 + (n\hbar k)^2 - 2n\hbar k p_{antes})\cos\theta_c \qquad \Longrightarrow \qquad \cos\theta_c = \frac{p_{aftr}^2 - p_{befor}^2 + (n\hbar k)^2}{-2n\hbar k p_{befor}} \ .$$

Resolving the momentum conservation by p_{after}*,*

$$c^2 p_{aftr}^2 = \left(\sqrt{c^2 p_{antes}^2 + m^2 c^4} - \hbar\omega\right)^2 - m^2 c^4 = c^2 p_{befor}^2 + \hbar^2\omega^2 - 2\hbar\omega\sqrt{c^2 p_{before}^2 + m^2 c^4} \ ,$$

and replacing this in the formula for $\cos\theta_c$*,*

$$\begin{aligned} \cos\theta_c &= \frac{p_{before}^2 + \frac{\hbar^2\omega^2}{c^2} - \frac{2\hbar\omega}{c^2}\sqrt{c^2 p_{befor}^2 + m^2 c^4} - p_{befor}^2 + (n\hbar k)^2}{-2n\hbar k p_{befor}} \\ &= \frac{2\sqrt{c^2 p_{before}^2 + m^2 c^4} + (n^2 - 1)c\hbar k}{2cnp_{befor}} \ . \end{aligned}$$

c. Substituting $\cos\theta_c$ *by* $\frac{1}{\beta_n}$*,*

$$v = \frac{c^2 p_{befor}}{\sqrt{c^2 p_{befor}^2 + m^2 c^4} + (n^2 - 1)c\hbar k} \ .$$

d. From Fig. 19.9 we read,

$$\Delta t = t - t_r = \frac{|\mathbf{r} - \mathbf{w}(t_r)|}{c_n} \quad , \quad \mathbf{r} - \mathbf{w}(t_r) = \mathbf{R}(t_r) \quad , \quad \mathbf{v}\Delta t = \mathbf{R}(t_r) - \mathbf{R}(t) \quad , \quad \mathbf{w}(t) = \mathbf{r} - \mathbf{R}(t)$$

which allows us to calculate,

$$c_n \Delta t = R(t_r) = |\mathbf{v}\Delta t + \mathbf{R}(t)| = \sqrt{v^2\Delta t^2 + R^2(t) + 2v\Delta t R(t)\cos\theta} \ ,$$

which has two solution for Δt,

$$\Delta t = \frac{R(t)}{c_n^2 - v^2}\left(v\cos\theta \pm \sqrt{c_n^2 - v^2\sin^2\theta}\right) \ .$$

Since, only real solutions are possible, we get a condition for θ,

$$|\sin\theta| < \frac{c_n}{v} \equiv \sin\theta_C \ ,$$

where θ_C is the Cherenkov angle.
The Liénard-Wiechert potentials are now, using the Heaviside function,

$$\Phi(\mathbf{r},t) = \frac{1}{4\pi\varepsilon_0}\frac{qc_n}{R(t_r)c_n - \mathbf{R}(t_r)\cdot\mathbf{v}}\Theta(\cos\theta_C - \cos\theta) \qquad \textit{and} \qquad \mathbf{A}(\mathbf{r},t) = \frac{\mathbf{v}}{c_n^2}\Phi(\mathbf{r},t) \ .$$

The denominator of the potentials is,

$$\begin{aligned} R(t_r)c_n - \mathbf{R}(t_r)\cdot\mathbf{v} &= c_n^2\Delta t - [\mathbf{v}\Delta t + \mathbf{R}(t)]\cdot\mathbf{v} \\ &= (c_n^2 - v^2)\Delta t - vR(t)\cos\theta = \pm R(t)\sqrt{c_n^2 - v^2\sin^2\theta} \ , \end{aligned}$$

such that,

$$\Phi(\mathbf{r},t) = \pm\frac{q}{4\pi\varepsilon_0}\frac{\Theta(\cos\theta_C - \cos\theta)}{R(t)\sqrt{1 - \frac{v^2}{c_n^2}\sin^2\theta}} \ .$$

19.2.3.8 Ex: Electron subject to gravity

An electron is released from rest and falls under the influence of gravity. Within the first centimeter, what fraction of the lost potential energy is radiated?

Solution: *Accelerates by gravity the charge radiates. This means that not all lost potential energy is converted into kinetic energy, but also into radiation. Therefore, a charged object falls more slowly than an electrically neutral object. The dipole moment of the electron will be,*

$$\mathbf{p} = ez\hat{\mathbf{e}}_z \ .$$

The radiated power was derived in class,

$$P \simeq \frac{\mu_0\ddot{p}}{6\pi c} = \frac{\mu_0 eg}{6\pi c} \approx 5.7\cdot 10^{-52}\,\mathrm{Js}^{-1} \ .$$

To find out how much energy is radiated during the fall of the electron, we need to know, how long it takes the electron to drop by 1 cm. *If all lost potential energy were transformed into kinetic energy, we would have,* $v = gt$ *and* $d = \frac{1}{2}gt^2$. *Since the radiated power is very small, we can safely assume the validity of these expressions and verify that the response is consistent,*

$$t = \sqrt{\frac{2d}{g}} \approx 0.045\,\mathrm{s} \ ,$$

such that the radiated energy is,

$$Pt = 2.46 \cdot 10^{-53}\,\mathrm{J} \ .$$

The lost potential energy is,

$$V = mgh \approx 8.92 \cdot 10^{-32}\,\mathrm{J} \ ,$$

such as the fraction of potential energy lost by radiation is xxx.

19.2.3.9 Ex: Radiation reaction

Including the radiative reaction force (19.154), Newton's second law for a charged particle becomes,

$$a = \tau \dot{a} + \frac{F}{m} \ ,$$

where F is an external force acting on the particle.
a. In contrast to the case of an uncharged particle ($a = F/m$), the acceleration (in the same way as position and velocity) must be a continuous function of time, even when the force changes abruptly. (Physically, the radiative reaction dampens out any rapid variation in a.) Show that a is continuous at any time t by integrating the given equation of motion between $(t - \epsilon)$ and $(t + \epsilon)$ and evaluating the limit $\epsilon \to 0$.
b. A particle be subjected to a constant force F, beginning at time $t = 0$ and remaining until the time T. Find the most general solution $a(t)$ of the equation of motion in each of the three stages: (i) $t < 0$; (ii) $0 < t < T$; and (iii) $t > T$.
c. Impose the continuity condition (a) at times $t = 0$ and $t = T$. Show, that it is possible to *either* eliminate 'runaway-acceleration' in region (iii) *or* avoid 'pre-acceleration' in region (i), but not both.
d. Choosing to eliminate the runaway-acceleration, what will be the acceleration, as a function of time, in each stage (i-iii)? How will the velocity behave, which obviously must be continuous at $t = 0$ and $t = T$. Assume, that the particle was initially at rest: $v(-\infty) = 0$. Prepare schemes of $a(t)$ and $v(t)$ and compare with the behavior of a neutral particle.
e. Repeat (d) choosing the option to eliminate pre-acceleration.

Solution: *a. Including the radiative reaction force, Newton's second law for a charged particle becomes,*

$$a = \tau \dot{a} + \frac{F}{m} \qquad \textit{with} \qquad \tau \equiv \frac{\mu_0 Q^2}{6\pi c}\dot{a} \ .$$

For an electrically neutral particle, the reaction term disappears, which means that if F is discontinuous (as in the case of a suddenly applied force), then a also is. However, it turns out that adding the term $\tau\dot{a}$ guarantees that the acceleration is always continuous, even if the force is not. Suppose that we integrate this equation in a small time interval between $t-\epsilon$ and $t+\epsilon$,

$$\int_{t-\epsilon}^{t+\epsilon} a dt' = \int_{t-\epsilon}^{t+\epsilon} \left(\tau\dot{a} + \frac{F}{m}\right) dt' = \tau a(t+\epsilon) - \tau a(t-\epsilon) + \frac{1}{m}\int_{t-\epsilon}^{t+\epsilon} F dt' \ .$$

Given that both a and F are finite over the time interval (there are no divergences, such as delta functions), then both integrals, the one of the acceleration and the one of the force, should tend to zero as $\epsilon \to 0$. This is true, even F being discontinuous. The consequence is,

$$\lim_{\epsilon\to 0}[(a(t+\epsilon) - a(t-\epsilon)] = 0 \ ,$$

that is, a is continuous. In the case of the neutral particle, $Q=0$ and therefore $\tau = 0$ as well, such that $a(t+\epsilon) - a(t-\epsilon)$ vanishes in any case, and the argument fails.
b. Now, we consider the following example:

$$a(t) = \begin{cases} \tau\dot{a} & for \ \ t<0 \\ \tau\dot{a} + F/m & for \ \ 0<t<T \\ \tau\dot{a} & for \ \ T<t \end{cases} \ .$$

The partial solutions are,

$$a(t) = \begin{cases} a_0 e^{t/\tau} & for \ \ t<0 \\ a_1 e^{t/\tau} + F/m & for \ \ 0<t<T \\ a_2 e^{t/\tau} & for \ \ T<t \end{cases} \ .$$

c. The continuity of the acceleration at the times $t=0$ and $t=T$ requires,

$$a_0 = a_1 + F/m \qquad and \qquad a_1 e^{T/\tau} + F/m = a_2 e^{T/\tau} \ .$$

Eliminating t_1,

$$a_2 = \tfrac{F}{m}(e^{-T/\tau} - 1) + a_0 \ .$$

Since there were no forces before $t=0$, we let $a_0 = 0$. But this means, that we accept a constant (and negative, for $a_2 < 0$) acceleration in the third period without external force. Alternatively, we can let $a_2 = 0$, but that means that we accept a pre-acceleration in the first period, when the force has not yet come into action.
d. Accepting the condition $a_2 = 0$, we obtain the solutions,

$$a(t) = \begin{cases} \frac{F}{m}(1 - e^{-T/\tau})e^{t/\tau} & for \ \ t<0 \\ \frac{F}{m}(1 - e^{(t-T)/\tau}) & for \ \ 0<t<T \\ 0 & for \ \ T<t \end{cases} \ .$$

and

$$v(t) = \begin{cases} \frac{F\tau}{m}(1 - e^{-T/\tau})e^{t/\tau} & for \ \ t<0 \\ \frac{F}{m}(t - \tau e^{(t-T)/\tau}) + \frac{F\tau}{m} & for \ \ 0<t<T \\ \frac{FT}{m} & for \ \ T<t \end{cases} \ .$$

e. Accepting the condition $a_0 = 0$, we obtain the solutions,

$$a(t) = \begin{cases} 0 & \text{for } t < 0 \\ \frac{F}{m}(1 - e^{t/\tau}) & \text{for } 0 < t < T \\ \frac{F}{m}(e^{-T/\tau} - 1)e^{t/\tau} & \text{for } T < t \end{cases} .$$

and

$$v(t) = \begin{cases} 0 & \text{for } t < 0 \\ \frac{F}{m}(t - \tau e^{t/\tau}) + \frac{F\tau}{m} & \text{for } 0 < t < T \\ \frac{F\tau}{m}(e^{-T/\tau} - 1)e^{t/\tau} + \frac{FT}{m} & \text{for } T < t \end{cases} .$$

It is interesting to note that, changing the sign of $\tau \to -\tau$, behavior makes sense.

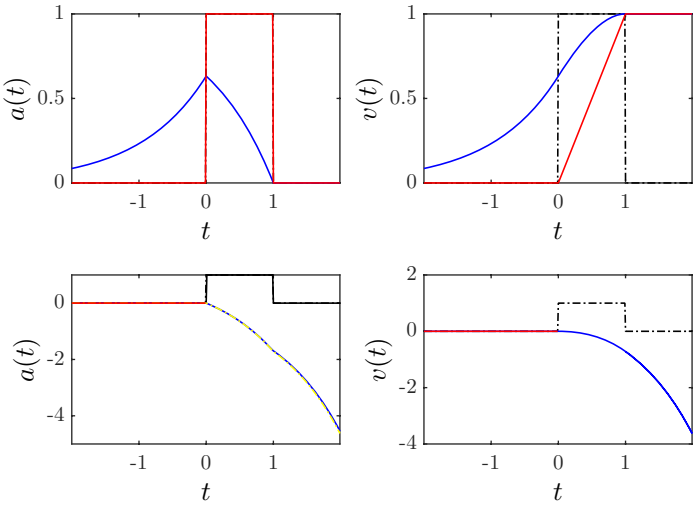

Figure 19.10: (code) Radiation reaction.

19.3 Diffraction and scattering

Radiation (let us call it 'light' for simplicity) incident on a target (e.g. a charge and current distribution, a dielectric body, an atomic cloud, or anything else) will be absorbed, diffracted or scattered. In the absence of absorption, the entire incident energy must be re-emitted. Whether the re-emission process is best described by *diffraction* or *scattering* models depends on the wavelength λ of light in relation to the size of the target and its structure. When the target is small, we can treat the problem in the lowest (usually dipolar) multipolar order; for a target of comparable size with λ, a complete multipolar treatment is required, and in the limit of a large target, we can resort to semi-geometrical methods to explain deviations from geometric optics caused by diffraction.

The topic of diffraction and scattering is well covered in the literature [659]. Rather than reproducing these theories here, we will give in this course a brief introduction

to the *coupled-dipoles model*. This model, which has received much attention in recent years, has proven capable, albeit renouncing of notions such as the refraction index, to give a microscopic view of many macroscopic scattering and diffraction phenomena.

19.3.1 Coupled dipoles model

The electrodynamics contained in Maxwell's macroscopic equations describes the interaction of light with matter characterized by a refractive index $n(\mathbf{r})$. The refractive index is understood as a continuous field, which fully describes the reaction of the target to incident light. On the other hand, we know how the microscopic constituents, that is, the atoms and molecules of the target material, react individually to incident light. In the simplest case, a two-level atom will absorb a photon carrying an electron to a higher orbit, and when the electron returns to the original state, it will emit a photon into an arbitrary direction, that is, isotropically in the time average.

The difficulty now resides in the linking of the macro- and microscopic images, illustrated in Fig. 19.11, to a complete theory. Indeed, all atoms or molecules in the crystal must *cooperate* in some way to generate a refractive index and macroscopic scattering phenomena described by the laws of Snellius, Lambert-Beer, or Ewald-Oseen [180]. The details of how this cooperation works are being studied in several laboratories around the world [1180, 1182, 298].

Figure 19.11: (Left) Macroscopic refraction and (right) microscopic scattering. See also (watch talk).

From a microscopic point of view, the refractive index is an artifact; it does not exist like an atom exists! Since Democritus' reflections on the nature of matter 350 years before Christ, we know that what does exist are 'atoms and empty space, the remainder is mere opinion'. The index of refraction can help us to simplify the description of how light interacts with macroscopic objects. But this does not always work, and in some circumstances even leads to paradoxical results, that are difficult to resolve within Maxwell's theory of electromagnetism. This is, for example, the case of the famous Abraham and Minkowski dilemma, which since 1909, when these two physicists proposed different calculations for the photonic momentum inside a dielectric medium leading to different results, still gives rise to debates. But there are also other situations, where microscopic theory is able to describe phenomena beyond the macroscopic approximation of continuous media. These are phenomena due to disorder, such as Anderson's localization of light or the spontaneous synchronization of atomic dipoles in superradiance.

In the simplest version of the coupled-dipoles model we imagine the target as a (more or less dense) sample of point-like two-level atoms, so that the radiation of the atoms can be described in the dipolar limit, $a_B \ll \lambda$, where the Bohr radius gives a

typical scale for the extension of the radiation source. We will not reproduce integrally the derivation of the coupled-dipoles model here, which borrows from the theory of quantum mechanics. Instead, we will superficially trace the line of argumentation and justify the results by showing that, in the limit of a smooth distribution of the atomic scatterers, we recover the classical laws of Maxwell's theory.

19.3.1.1 Rayleigh scattering

To describe the Rayleigh scattering from an atom, we need to understand the phenomenon of spontaneous emission. This is usually achieved by the *Weisskopf-Wigner theory* starting from the Hamiltonian describing the interaction of a single two-level atom of the sample (labeled j) interacting with an incident laser,

$$\hat{H}_j = \hbar g_{\mathbf{k}_0}\left(\hat{\sigma}_j e^{-\imath\omega_a t} + \hat{\sigma}_j^\dagger e^{\imath\omega_a t}\right)\left(\hat{a}_{\mathbf{k}_0}^\dagger e^{\imath\omega_0 t - \imath\mathbf{k}_0\cdot\mathbf{r}_j} + \hat{a}_{\mathbf{k}_0} e^{-\imath\omega_0 t + \imath\mathbf{k}_0\cdot\mathbf{r}_j}\right) + \sum_{\mathbf{k}} \hbar g_{\mathbf{k}}\left(\hat{\sigma}_j e^{-\imath\omega_a t} + \hat{\sigma}_j^\dagger e^{\imath\omega_a t}\right)\left(\hat{a}_{\mathbf{k}}^\dagger e^{\imath\omega_k t - \imath\mathbf{k}\cdot\mathbf{r}_j} + \hat{a}_{\mathbf{k}} e^{-\imath\omega_k t + \imath\mathbf{k}\cdot\mathbf{r}_j}\right) . \tag{19.157}$$

Here, ω_0, ω_a, and ω_k are, respectively, the frequencies of the incident laser, the atomic resonance and the scattered light [8]. $g_{\mathbf{k}_0}$ is the coupling strength between the atom and the incident light mode and $g_k = d\sqrt{\omega/(\hbar\varepsilon_0 V)}$ describes the coupling between the atom and a vacuum mode with the volume V. $\hat{\sigma}_j = |g\rangle\langle e|$ is the lowering operator of the atomic excitation, that is, it describes the transition of the j^{th} atom from the excited state $|e\rangle$ to the ground state $|g\rangle$. $\hat{a}_{\mathbf{k}}$ is the annihilation operator of a photon in the mode $\mathbf{k}$.

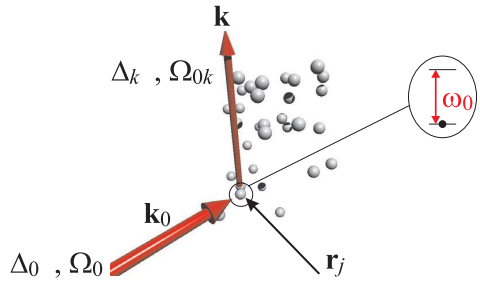

Figure 19.12: Scheme of the interaction of a light beam with a sample of atoms.

Now, considering an incident light mode (e.g. a laser beam) with high power,

$$\hat{a}_{\mathbf{k}_0}|n_0\rangle_{\mathbf{k}_0} = \sqrt{n_0}|n_0 - 1\rangle_{\mathbf{k}_0} \simeq \alpha_0|n_0\rangle_{\mathbf{k}_0} , \tag{19.158}$$

$\hat{a}_{\mathbf{k}_0}$ is approximately an observable, whose amplitude is proportional to the root of the intensity. As $[\hat{a}_{\mathbf{k}_0}, \hat{a}_{\mathbf{k}_0}^\dagger] \simeq 0$, we can disregard the quantum nature and treat the incident light as a classical field by replacing $\Omega_0 \equiv 2\alpha_0 g_{k_0}$, where Ω_0 is the Rabi frequency. The *rotating wave approximation* (RWA) allows us to neglect those terms

[8] We are only considering fixed atoms in space, that is, we do not allow acceleration by photonic recoil.

of the Hamiltonian, which (in the first perturbative order) do not conserve energy, that is, terms proportional to $\hat{\sigma}_j^- \hat{a}$ and $\hat{\sigma}_j^+ \hat{a}^\dagger$. Introducing the abbreviations,

$$\Delta_0 \equiv \omega_0 - \omega_a \qquad \text{and} \qquad \Delta_k \equiv \omega_k - \omega_a \ . \tag{19.159}$$

the Hamiltonian becomes,

$$\hat{H} = \tfrac{\hbar}{2}\Omega_0 \left(\hat{\sigma} \hat{a}_{\mathbf{k}_0}^\dagger e^{\imath \Delta_0 t} + h.c. \right) + \hbar \sum_{\mathbf{k}} \left(g_k \hat{\sigma} \hat{a}_{\mathbf{k}}^\dagger e^{\imath \Delta_k t} + h.c. \right) \ . \tag{19.160}$$

The system can be found in three states,

$$|\Psi(t)\rangle = \alpha(t)|0\rangle_a|0\rangle_{\mathbf{k}} + \beta(t)|1\rangle_a|0\rangle_{\mathbf{k}} + \sum_{\mathbf{k}} \gamma_{\mathbf{k}}(t)|0\rangle_a|1\rangle_{\mathbf{k}} \ . \tag{19.161}$$

Before the scattering the system is, with the probability amplitude α, in the state $|0\rangle_a|0\rangle_{\mathbf{k}}$. After the absorption of a photon, with the probability amplitude β, the atom is excited $|1\rangle_a|0\rangle_{\mathbf{k}}$. Finally, after the reemission of the photon to a mode $\mathbf{k}$, with the probability amplitude $\gamma_{\mathbf{k}}$, the state of the system is $|0\rangle_a|1\rangle_{\mathbf{k}}$. The temporal evolution of the probability amplitudes is obtained by inserting the Hamiltonian (19.160) and the ansatz (19.161) into the Schrödinger equation,

$$\frac{d}{dt}|\Psi(t)\rangle = -\frac{\imath}{\hbar}\hat{H}|\Psi(t)\rangle \ . \tag{19.162}$$

We get, after a calculation which is not reproduced here [9] and which makes use of the so-called *Markov approximation* postulating that the variation of the amplitudes $\beta_j(t)$ is slower than the evolution of the system given by $e^{\imath(\omega_k - \omega_0)t}$, the following equation of motion for the amplitudes β_j,

$$\boxed{\dot{\beta}_j = \left(\imath\Delta_0 - \frac{\Gamma}{2} \right) \beta_j - \frac{\imath\Omega_0}{2} e^{\imath \mathbf{k}_0 \cdot \mathbf{r}_j}} \ . \tag{19.163}$$

This equation correctly describes the dynamics of the probability amplitude of finding an atom exposed to a laser beam and subject to spontaneous emission of its excited state.

19.3.1.2 Collective scattering

In the presence of several atoms, the full Hamiltonian for the atomic cloud is simply obtained by summing over the N atoms [10],

$$\hat{H} = \sum_{j=1}^{N} \hat{H}_j \ . \tag{19.164}$$

Following the same scheme as in the last section, the Schrödinger equation with the Hamiltonian (19.164) where (19.157) can be resolved to the limit of weak excitation:

[9] See Sec. 39.1.2 .

[10] We do not consider in this Hamiltonian collisional interactions between the atoms, for example, of the van der Waals type, which can have a great impact at high densities $n \gg \lambda^{-3}$.

Let us restrict to the situation in which at most a single photon or a single atomic excitation can be in the system. This assumption is realistic, when the time for reemitting a photon is short. The state created by the passage of a single photon is a collective state, because the atomic sample can either be entirely in the ground state before a scattering event, $|g_1,..,g_N\rangle|0\rangle_{\mathbf{k}}$, or after a scattering event, $|g_1,..,g_N\rangle|1\rangle_{\mathbf{k}}$, or else any one of the atoms j can be excited, $|g_1,..,e_j,..,g_N\rangle|0\rangle_{\mathbf{k}}$, during the scattering event. All information on the system is coded in the temporal dependencies of the probability amplitudes for these states, which we obtain through the insertion of the wavefunction [11],

$$|\Psi\rangle = \alpha(t)|g_1\dots g_N\rangle|0\rangle_{\mathbf{k}} + e^{-\imath\Delta_0 t}\sum_{j=1}^{N}\beta_j(t)|g_1\dots e_j\dots g_N\rangle|0\rangle_{\mathbf{k}} \tag{19.165}$$
$$+\sum_{\mathbf{k}}\gamma_{\mathbf{k}}(t)|g_1\dots g_N\rangle|1\rangle_{\mathbf{k}} + \sum_{m,n=1}^{N}\epsilon_{m<n,\mathbf{k}}(t)|g_1\dots e_m\dots e_n\dots g_N\rangle|1\rangle_{\mathbf{k}}\ .$$

within the Schrödinger equation. What we get is a set of integro-differential equations for the amplitudes α, β, and $\gamma_{\mathbf{k}}$, which can be solved within the Markov approximation,

$$\boxed{\dot{\beta}_j = \left(\imath\Delta_0 - \frac{\Gamma}{2}\right)\beta_j - \frac{\imath\Omega_0}{2}e^{\imath\mathbf{k}_0\cdot\mathbf{r}_j} - \frac{\Gamma}{2}\sum_{m\neq j}\frac{e^{\imath k_0|\mathbf{r}_j-\mathbf{r}_m|}}{\imath k_0|\mathbf{r}_j-\mathbf{r}_m|}\beta_m}\ . \tag{19.166}$$

We note, that the first two terms of this equation correspond to the equation describing the dynamics of a single atom (19.163). The third term corresponds to processes, where photons scattered at an atom are reabsorbed by another atom.

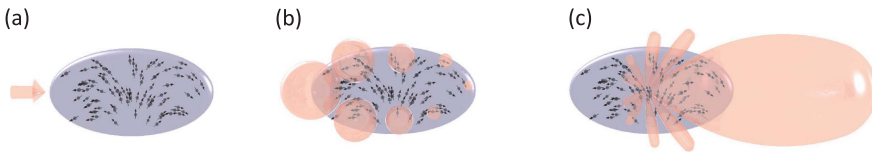

Figure 19.13: Illustration of cooperative scattering: From (a) to (c) a photon traversing an atomic cloud first excites the upstream dipoles, which immediately begin to radiate. The downstream dipoles are excited later on. The phase lag of the reemission processes leads to a radiative emission pattern being strongly peaked into forward direction.

The claim is now that equation (19.166) (or at least its generalization to level systems allowing to take account of the vectorial nature of light) is capable of reproducing all phenomena of macroscopic scattering, usually described by Maxwell's theory, for example, refraction, diffraction, Mie and Bragg scattering, etc. In addition, it correctly describes microscopic scattering phenomena, such as cooperative Rayleigh scattering, Anderson location, photonic band gaps, etc.

[11] The fourth term corresponds to the presence of two simultaneously excited atoms plus a (virtual) photon with 'negative' energy. These states need to be taken into account, if we do not want to make use ofthe RWA approximation.

19.3.2 The limit of the Mie scattering and the role of the refractive index

In practice, the exploitation of the N coupled equations (19.166) (one for each atom), which needs to be done numerically, is limited by computer capacity to some 100 000 atoms. On the other hand, at least, in the limit of high densities, we may hope, that the atomic cloud be well described by a continuous density distribution,

$$\sum_j \beta_j \to \int \beta(\mathbf{r}')\rho(\mathbf{r}')dV' \ . \tag{19.167}$$

Considering the stationary case, $\dot{\beta}_j = 0$, we arrive at,

$$\frac{\Omega_0}{2} e^{\imath \mathbf{k}_0 \cdot \mathbf{r}} = (\Delta_0 + \imath\Gamma)\beta(\mathbf{r}) + \frac{\Gamma}{2}\int \frac{e^{\imath k_0|\mathbf{r}-\mathbf{r}'|}}{k_0|\mathbf{r}-\mathbf{r}'|}\beta(\mathbf{r}')\rho(\mathbf{r}')dV' \ . \tag{19.168}$$

We note that the kernel of the above equation is the Green function of the Helmholtz equation, since,

$$[\nabla^2 + k_0^2]\frac{e^{\imath k_0|\mathbf{r}-\mathbf{r}'|}}{4\pi|\mathbf{r}-\mathbf{r}'|} = -\delta^{(3)}(\mathbf{r}-\mathbf{r}') \ . \tag{19.169}$$

Now, by applying the operator $[\nabla^2 + k_0^2]$ to both sides of equation (19.168), we arrive at,

$$0 = (\Delta_0 + \imath\Gamma)[\nabla^2 + k_0^2]\beta(\mathbf{r}) - 2\pi\Gamma\frac{\beta(\mathbf{r})\rho(\mathbf{r})}{k_0} \ , \tag{19.170}$$

that is [458, 66, 67],

$$\boxed{[\nabla^2 + k_0^2 n(\mathbf{r})^2]\beta(\mathbf{r}) = 0 \qquad \text{defining} \qquad n^2(\mathbf{r}) \equiv 1 - \frac{4\pi\rho(\mathbf{r})}{k_0^3(2\Delta_0/\Gamma + \imath)}} \ . \tag{19.171}$$

This is the *Helmholtz equation* of Maxwell's theory. The reappearance of the refractive index $n(\mathbf{r})$ is the price to pay for smoothing the density distribution, and with it we lose all effects related to discretization and cloud disorder. In Exc. 19.3.3.1 we compare the result of the smoothed coupled-dipole model (19.171) to the macroscopic susceptibility derived from the Lorentz model (18.142), and to the Clausius-Mossotti formula (14.28).

Example 120 (*Bragg scattering by partially disordered clouds*): Fig. 19.14 shows the example of Bragg scattering by an atomic cloud. Without disorder we would expect an incident laser beam to be partially reflected and partially transmitted. The simulation of the stationary version of equation (19.166) for the scattering of the cloud illustrated in (a) shows, in addition to transmission and reflection, a random pattern of specular scattering in all directions, which can be attributed to disorder.

Example 121 (*Collective radiative pressure*): The internal and the global structure of an atomic cloud both dramatically influence the radiative pressure force exerted on its center of mass. We compare two limiting cases [298]: (a) For

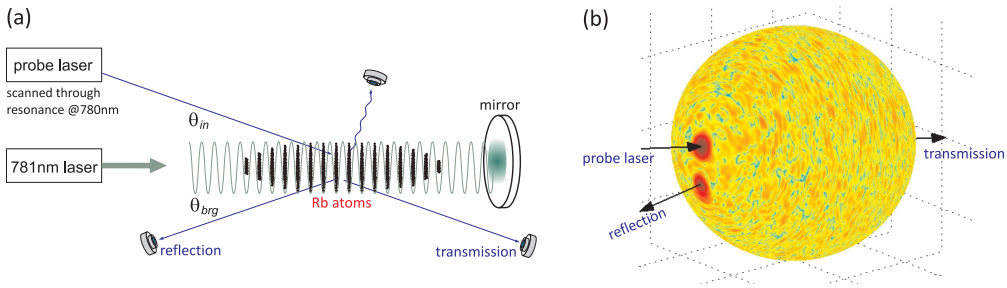

Figure 19.14: (a) Experimental scheme for Bragg reflection by an ordered atomic cloud in a periodic pile of pancakes. (b) Simulation of the stationary cloud scattering equation schematized in (a).

large dilute clouds, scattering by intrinsic disorder prevails. The more atoms are in the cloud, the more pronounced is the forward scattering of the light. Therefore, the radiative pressure force *per atom* exerted by the incident light decreases with N. (b) For small dense clouds, the scattering is rather governed by the global inhomogeneous shape of the cloud. The more atoms are in the cloud, the greater the variation of the refractive index and the greater the refractive deflection of photons off the optical axis [120]. Therefore, the radiation pressure force per atom exerted by the incident light increases with N, as shown in Fig. 19.15(c).

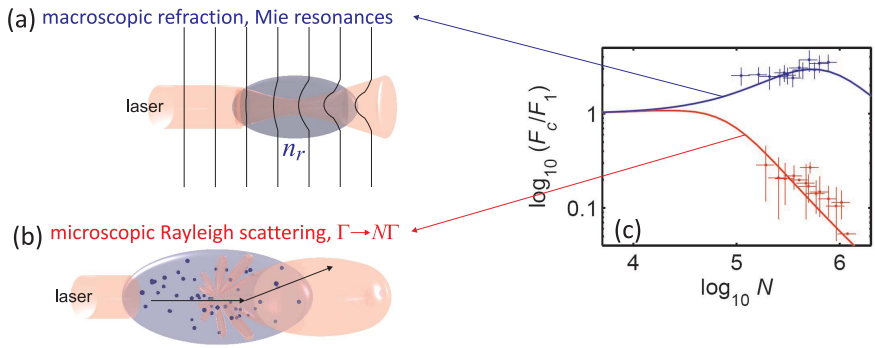

Figure 19.15: (a) Rayleigh scattering by a disordered cloud. (b) Mie scattering via wavefront deformation by the refractive index of an optically dense cloud. (c) Dependence of the radiation pressure force on the number of atoms for the two cases (a) and (b).

Microscopic collective scattering depends on one hand on the internal spatial distribution of the scatterers, that is, the intrinsic disorder, and on the other hand on the global distribution, i.e. the shape and the size of the cloud and its density distribution near the edges, which may be smooth or abrupt. In the limit of despicable disorder,

we have seen that the theory of collective scattering is equivalent to Maxwell's macroscopic theory. In this limit, we can describe the cloud of scatterers as a (locally) homogeneous sphere characterized by a refractive index $n(\mathbf{r})$, which varies spatially with the density of the scatterers. Let us assume, for simplicity, a spherical cloud with a homogeneous refraction index $n(\mathbf{r}) = n_0$ inside the cloud and $n(\mathbf{r}) = 1$ outside. The scattering of a plane wave of radiation by a dielectric sphere is known as *Mie scattering* . In Mie's theory we expand the incident plane wave into partial spherical waves,

$$e^{\imath \mathbf{k}\cdot\mathbf{r}} = \sqrt{4\pi} \sum_{\ell=0}^{\infty} \sqrt{2\ell+1}\imath^{\ell} j_{\ell}(kr) Y_{\ell 0}(\hat{\mathbf{e}}_r) \ , \tag{19.172}$$

which must satisfy the boundary condition for electromagnetic waves at the outer edge of the sphere. This is illustrated in Fig. 19.16. Theoretically it should be possible to observe Mie resonances with atomic clouds, albeit strictly speaking, they do not have a surface which could act like an abrupt boundary condition.

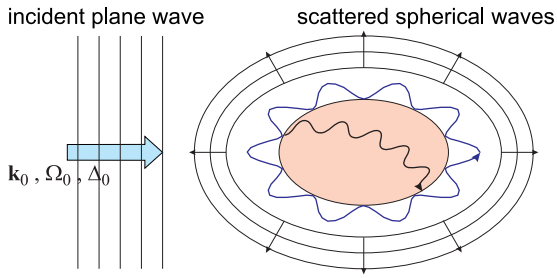

Figure 19.16: Two types of Mie resonances are possible: (i) Waves propagating in the interior of the body and form a stationary wave bounded by the surface and (ii) evanescent waves that propagate on the surface of the body (whispering gallery modes). The resonances of type (ii) require abrupt boundary conditions.

19.3.3 Exercises

19.3.3.1 Ex: Coupled dipoles versus Clausius-Mossotti

Compare the result of the smoothed coupled-dipole model (19.171) to the macroscopic susceptibility derived from the Lorentz model (18.142), and to the Clausius-Mossotti formula (14.28).

Chapter 20

Theory of special relativity

Until the end of the nineteenth century people believed in the existence of an 'ether', that is, a medium capable of carrying oscillations of the electromagnetic field in a similar way as water transports surface waves or the air propagates the sound. The propagation velocity of the light must then have a certain value c in this ether. But when measured in another inertial system, according to the Galilei transformation, propagation velocity should be the sum of c and the velocity v of the inertial system through the ether. This ether would be fixed to the universe, and the earth would have a velocity v with respect to this ether.

With the objective of measuring the relative velocity between a fixed laboratory and the ether, *Michelson* and *Morley* did an experiment known as *Michelson-Morley experiment*, and which now represents one of the foundations of the theory of special relativity. It consists of a *Michelson interferometer*, which can be rotated in space. If an 'ether' existed, which is not fixed to the Earth, the speed of light must be anisotropic and the interference fringes observed in the interferometer must move when the interferometer is rotated. This was not observed.

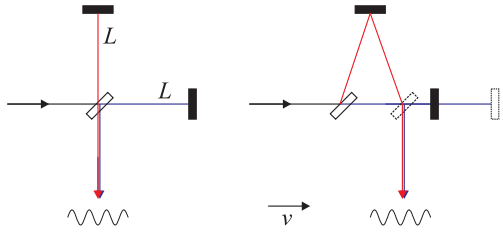

Figure 20.1: Scheme of the Michelson-Morley experiment.

Within the resting system (the ether) the times required for light to travel through each of the interferometer arms are,

$$t_{1,2} = \frac{2L}{c} \ . \tag{20.1}$$

In a frame moving in the direction of one of the arms these times would be,

$$t_1 = \frac{2L}{c}\frac{1}{\sqrt{1-\beta^2}} \qquad \text{and} \qquad t_2 = \frac{L}{c+v} + \frac{L}{c-v} = \frac{2L}{c}\frac{1}{1-\beta^2} \ . \tag{20.2}$$

The experiment confirms the result (20.1) *regardless of the rotation of the interferometer.*

Guided by Michelson's observation it was *Poincaré*, who first proposed the absence of an ether, which motivated *Einstein* to formulate the following postulates:

Law A: *The laws of physics do not depend on a translatory motion of the system as a whole. There is no particular system, in which the 'ether' would be at rest.*

Law B: *The speed of light is constant in all inertial systems and regardless of the speed of the emitting source.*

These postulates revolutionized classical mechanics. The new theory, called the theory of *special relativity*, still contains classical mechanics in the limit of slow velocities, but extends its validity to the limit of velocities approaching the speed of light. Moreover, special relativity reconciles mechanics with electrodynamics in a natural way, as we will show in the following sections.

20.1 Relativistic metric and Lorentz transform

In the theory of relativity, the space represented by the vector $\mathbf{r}$ and the time represented by the scalar ct (where we multiply the universal speed of light for dimensionality reasons) are treated on equal footing. There are other combinations of scalar and vectorial physical quantities such as energy E/c and linear momentum $\mathbf{p}$ which, when combined to a four-dimensional entity, allow for a more symmetrical representation of the fundamental laws of physics. Let us, in the following, set the foundations of this new formalism developed by Poincaré, Lorentz, Einstein, and Minkowski.

20.1.1 Ricci's calculus, Minkowski's metric, and space-time tensors

In the notation of 4-dimensional space-time vectors the physical quantities are described (or combined) by tensors of rank k, e.g. scalars A, vectors A^μ, matrices $A^{\mu\nu}$, and tensors of higher ranks $A^{\mu\nu\lambda\cdots}$. Tensors can be *contravariant*, A^μ, or *covariant*, A_μ, with respect to an index, depending on their behavior regarding the Lorentz transform (as we shall see shortly). Co- (or contra-) variant scalars are independent of the inertial system and, therefore, called *Lorentz invariants*. The contra- and covariant tensors are related by the *Minkowski metric* defined by (see also Sec. 12.4),

$$\boxed{(g^{\mu\nu}) \equiv \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \\ 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & -1 \end{pmatrix}} \,, \tag{20.3}$$

using the *sum rule of Einstein*, which consists in summing over all pairs of co- and contravariant indices,

$$a^\mu a_\mu \equiv \sum\nolimits_\mu a^\mu a_\mu \,, \tag{20.4}$$

via

$$a^\mu = g^{\mu\nu} a_\nu \,. \tag{20.5}$$

We note that the first index in a matrix counts the columns and the second index the rows. For flat space-time (that is, without curvature),

$$g_{\mu}{}^{\nu} = g_{\mu\alpha}g^{\alpha\nu} = \delta_{\mu}^{\nu} \quad , \quad g_{\mu\nu} = g^{\mu\nu} \quad \text{that is} \quad \check{g}^{-1} = \check{g} = \check{g}^{\intercal} \ , \tag{20.6}$$

where δ_{μ}^{ν} is the *Kronecker symbol* and the decoration '$\vee$' denotes a matrix, $\check{a} \equiv (a_{\mu\nu})$. Thus, the identity and the metric are the two faces of the same tensor, $\check{\delta} = \check{g}$. The norm is defined by,

$$\|(a^{\mu})\| \equiv \sqrt{a_{\mu}a^{\mu}} = \sqrt{a^{\mu}g_{\mu\nu}a^{\nu}} \ . \tag{20.7}$$

The product between two contravariant vectors is given by,

$$a^{\mu}b^{\mu} \equiv a^{\mu}g_{\mu\nu}b^{\nu} \ . \tag{20.8}$$

The tensors are represented by scalars, vectors and matrices. The vector symbol is used for the contravariant column vector,

$$\vec{a} \equiv (a^{\mu}) = \begin{pmatrix} a^0 \\ \mathbf{a} \end{pmatrix} \quad , \quad \check{a} \equiv (a^{\mu\nu}) = \begin{pmatrix} a^0 & (a^{m0}) \\ (a^{0n}) & (a^{mn}) \end{pmatrix} \ . \tag{20.9}$$

The covariant vector is also represented by a column,

$$\check{g}\vec{a} = (a_{\mu}) = (g_{\mu\nu}a^{\nu}) = \begin{pmatrix} a^0 \\ -\mathbf{a} \end{pmatrix} \ . \tag{20.10}$$

Often, Greek letters are used as indices for space-time tensors, while Roman letters are used as indices for spatial components. In order to work with vectors within Minkowski's formalism, we must interpret them as two-dimensional 1×4 matrices,

$$\vec{a} \equiv (a^{\mu 1}) \ , \tag{20.11}$$

where the '1' indicates the number of columns of the matrix. Introducing the *transposition*, denoted by the symbol '$\intercal$', as an exchange of the indices labeling rows and columns,

$$F_{\mu\nu} = (F^{\intercal})_{\nu\mu} \ , \tag{20.12}$$

we can represent the transposition of a vector by a 4×1 matrix,

$$\vec{a}^{\intercal} = (a^{\mu 1})^{\intercal} = (a^{1\mu}) = \begin{pmatrix} a^0 & \mathbf{a} \end{pmatrix} \ , \tag{20.13}$$

and define the scalar product between vectors in terms of the product between matrices as,

$$\begin{aligned} \vec{a} \cdot \vec{b} \equiv (a^{\mu 1}b_{\mu 1}) = (a^{\intercal})^{1\mu}(b_{\mu 1}) = (a^{\intercal})^{1\mu}g_{\mu\nu}(b^{\nu 1}) = \check{a}^{\intercal}\check{g}\check{b} \\ = \begin{pmatrix} a^0 & (a^m) \end{pmatrix} \begin{pmatrix} 1 & 0 \\ 0 & (-\delta^{mn}) \end{pmatrix} \begin{pmatrix} a^0 \\ (a^n) \end{pmatrix} \ . \end{aligned} \tag{20.14}$$

We conclude emphasizing that, to be able to multiply tensores as matrices, the indices to be contracted must be adjacent. If necessary, the tensors must be transposed,

$$A^{\mu\alpha}B^{\nu}{}_{\alpha} = A^{\mu\alpha}(B^{\intercal})_{\alpha}{}^{\nu} \ . \tag{20.15}$$

One has to be very careful, because in general $A^{\mu\alpha} \neq A^{\alpha\mu} \neq A_{\alpha\mu} \neq A_{\mu\alpha} \neq A_{\alpha}{}^{\mu} \neq A_{\mu}{}^{\alpha} \neq A^{\mu}{}_{\alpha} \neq A^{\alpha}{}_{\mu}$.

20.1.2 Lorentz transform

We are now in the shape to officially introduce our first explicit space-time vector by combining the physical quantities time and position,

$$\boxed{(r^\mu) \equiv \begin{pmatrix} ct \\ \mathbf{r} \end{pmatrix}} \,. \tag{20.16}$$

In classical mechanics the transformation to a system moving at velocity $\beta = v/c$ is described by the *Galilei transform* given by,

$$(G^\mu{}_\nu) \equiv \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ -\beta & 0 & 0 & 1 \end{pmatrix} \quad , \quad (G^\mu{}_\nu)^{-1} = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ \beta & 0 & 0 & 1 \end{pmatrix} \,. \tag{20.17}$$

Example 122 (*Galilei transform*): Let us try out the Galilei transform on the space-time vector (20.16):

$$\begin{pmatrix} ct' \\ x' \\ y' \\ z' \end{pmatrix} = (r'^\mu) = (G^\mu{}_\nu)(r_\nu) = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ -\beta & 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} ct \\ x \\ y \\ z \end{pmatrix} = \begin{pmatrix} ct \\ x \\ y \\ z - vt \end{pmatrix} \,.$$

In classical mechanics wave propagation is conditioned to the existence of a medium. Consequently, different inertial systems are not equivalent and, as will be shown in a later section, the wave equation *is not invariant* to the Galilei transform. Let us therefore look for another transformation, which preserves the shape of the wave equation. We may, for example, request the transformation to ensure that the propagation of the phase fronts of a spherical wave is independent of the inertial system: $c^2 t'^2 - \mathbf{r}'^2 = c^2 t^2 - \mathbf{r}^2$.

The story of the *Lorentz transform* begins with Poincaré, who introduced the idea of local time: According to him, simultaneity depends on the reference system. Voigt attempted in 1897 for the first time to find a transformation that would conserve the value of c, but it was Lorentz who found a transformation leaving Maxwell's equations invariant and, consequently, Helmholtz's wave equation as well. The Lorentz transform is linear with respect to the preservation of space-time intervals in Minkowski space and, as we will see shortly, it removes the contradictions between classical mechanics and electrodynamics.

Consider a system S' moving through our lab S at a velocity $\mathbf{v} = v\hat{\mathbf{e}}_z$. We define,

$$\beta = \frac{v}{c} \qquad \text{and} \qquad \gamma = \frac{1}{\sqrt{1-\beta^2}} \,. \tag{20.18}$$

The matrix describing the Lorentz transform from system S to system S' is,

$$\boxed{\check{\Lambda} = (\Lambda^{\mu}{}_{\nu}) \equiv \begin{pmatrix} \gamma & 0 & 0 & -\gamma\beta \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ -\gamma\beta & 0 & 0 & \gamma \end{pmatrix}} \quad , \quad \check{\Lambda}^{-1} = (\Lambda^{\mu}{}_{\nu})^{-1} = \begin{pmatrix} \gamma & 0 & 0 & \gamma\beta \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ \gamma\beta & 0 & 0 & \gamma \end{pmatrix} \tag{20.19}$$

that is, the inverse of the transformation matrix is obtained by changing the sign of the velocity, $v \to -v$. For the Lorentz transform tensor we can show,

$$\begin{aligned} (\Lambda^{\mu}{}_{\nu})^{-1} = g_{\mu\omega}\Lambda^{\omega}{}_{\kappa}g^{\kappa\nu} = \Lambda_{\mu}{}^{\nu} \qquad \text{that is} \qquad \check{\Lambda}^{-1} = \check{g}\check{\Lambda}\check{g} \\ \text{and} \qquad \Lambda^{\omega}{}_{\mu}g_{\omega\kappa}\Lambda^{\kappa}{}_{\nu} = g_{\mu\nu} \qquad \text{that is} \qquad \check{\Lambda}^{\intercal}\check{g}\check{\Lambda} = \check{g} \ . \end{aligned} \tag{20.20}$$

The transformation from a laboratory reference frame S into a rest frame S' is done by,

$$A'^{\mu} = \Lambda^{\mu}{}_{\nu}A^{\nu} \ . \tag{20.21}$$

Time-space scalars are always Lorentz invariant. We consider, for example,

$$x'_{\mu}x'^{\mu} = \Lambda_{\mu}{}^{\nu}x_{\nu}\Lambda^{\mu}{}_{\omega}x^{\omega} = (\check{\Lambda}^{-1}\check{\Lambda})^{\nu}{}_{\omega}x_{\nu}x^{\omega} = \mathbb{I}\ x^{\omega}x_{\omega} \ . \tag{20.22}$$

For space-time differentials, since,

$$dx'^{\mu} = \frac{\partial x'^{\mu}}{\partial x^{\nu}}dx^{\nu} \ , \tag{20.23}$$

comparing with the relationship (20.21), we can identify,

$$\Lambda^{\mu}{}_{\nu} = \frac{\partial x'^{\mu}}{\partial x^{\nu}} \ . \tag{20.24}$$

Contra- and covariant tensors are defined by their different behavior under arbitrary coordinate transformation. For example, in the case of Lorentz transforms,

$$A'_{\mu} = \frac{\partial x^{\nu}}{\partial x'^{\mu}}A_{\nu} \quad , \quad A'^{\mu} = \frac{\partial x'^{\mu}}{\partial x^{\nu}}A^{\nu} \ . \tag{20.25}$$

Similarly, tensors or higher rank satisfy,

$$A'_{\mu\nu} = \frac{\partial x^{\mu}}{\partial x'^{\nu}}\frac{\partial x^{\nu}}{\partial x'^{\beta}}A_{\nu\beta} \quad , \quad A'^{\mu\nu} = \frac{\partial x'^{\mu}}{\partial x^{\nu}}\frac{\partial x'^{\nu}}{\partial x^{\beta}}A^{\nu\beta} \ , \tag{20.26}$$

and also,

$$A'^{\mu_1..\mu_n}{}_{\nu_1..\nu_m} = \Lambda^{\mu_1}{}_{\omega_1}..\Lambda^{\mu_n}{}_{\omega_n}\Lambda_{\nu_1}{}^{\kappa_1}..\Lambda_{\nu_n}{}^{\kappa_n}A^{\omega_1..\omega_n}{}_{\kappa_1..\kappa_m} \ . \tag{20.27}$$

In Exc. 20.1.7.1 we show that the derivative by a covariant coordinate is contravariant.

Example 123 (*Lorentz transform*): In the limit of slow velocities, $v \ll c$, the Lorentz transform converges to the Galilei transform. This can be seen rewriting the Lorentz transform as,

$$\begin{pmatrix} t' \\ z' \end{pmatrix} = \begin{pmatrix} \gamma & -\frac{\gamma\beta}{c} \\ -\gamma\beta & \gamma \end{pmatrix} \begin{pmatrix} t \\ z \end{pmatrix} \simeq \begin{pmatrix} 1 & 0 \\ -\beta & 1 \end{pmatrix} \begin{pmatrix} t \\ z \end{pmatrix} \ .$$

Example 124 (*Lorentz transform*): We have,

$$\Lambda^{\mu}{}_{\nu} = \frac{\partial x'^{\mu}}{\partial x^{\nu}} = \left(\frac{\partial x'_{\mu}}{\partial x_{\nu}}\right)^{-1} = \left(\frac{\partial x^{\nu}}{\partial x'^{\mu}}\right)^{-1} = (\Lambda_{\mu}{}^{\nu})^{-1} \ .$$

20.1.3 Contraction of space

Einstein's theory has important consequences, such as the *contraction of space* and the *dilatation of time*. Let us consider a rod moving through the lab S with velocity v. The rod delimits two points $j = 1, 2$ in space-time for which we measure in the lab (at time $t = t_1 = t_2$) the distance $z_2 - z_1$. The spatio-temporal points are Lorentz-transformed to the system S', in which the rod is at rest (neglecting transverse spatial dimensions), by,

$$\begin{pmatrix} ct'_j \\ z'_j \end{pmatrix} = (\Lambda^{\mu}{}_{\nu}) \begin{pmatrix} ct \\ z_j \end{pmatrix} = \begin{pmatrix} \gamma ct - \gamma\beta z_j \\ -\gamma\beta ct + \gamma z_j \end{pmatrix} \ . \tag{20.28}$$

Hence,

$$z'_2 - z'_1 = -\gamma\beta ct + \gamma z_2 + \gamma\beta ct - \gamma z_1 = \gamma(z_2 - z_1) \ . \tag{20.29}$$

Consequently, in the lab the distance seems smaller than in the rest frame [1].

20.1.4 Dilatation of time

We consider a clock flying through the lab S at a velocity v. The clock produces regular time intervals, for which we measure in the lab the duration $t_2 - t_1$. The spatio-temporal points are Lorentz-transformed to the system S' in which the clock is at rest ($z' = z'_1 = z'_2$) via,

$$\begin{pmatrix} ct'_j \\ z' \end{pmatrix} = (\Lambda^{\mu}{}_{\nu}) \begin{pmatrix} ct_j \\ z_j \end{pmatrix} = \begin{pmatrix} \gamma ct_j - \gamma\beta z_j \\ -\gamma\beta ct_j + \gamma z_j \end{pmatrix} \ . \tag{20.30}$$

Hence,

$$\begin{aligned} t'_2 - t'_1 &= \gamma t_2 - \gamma\beta\frac{z_2}{c} - \gamma t_1 + \gamma\beta\frac{z_1}{c} \\ &= \gamma t_2 - \beta\left(\frac{z'}{c} + \gamma\beta t_2\right) - \gamma t_1 + \beta\left(\frac{z'}{c} + \gamma\beta t_1\right) = \gamma^{-1}(t_2 - t_1) \ . \end{aligned} \tag{20.31}$$

Consequently, in the lab the time interval seems longer than in the rest frame.

A good illustration of the effect of time dilatation is the *twin paradox*. A twin begins an interstellar voyage aboard a space ship traveling at a constant velocity. Twin B, who remained on Earth calculates, that the time elapsed for his twin A is smaller than his own time. Twin B calculates that the elapsed time for his twin A is shorter. Who's right? Twin A is wrong, because his system must be accelerated when taking off from Earth. Note that only special relativity is required to understand

[1] Alternatively, we can measure the instants of time t_j when the ends of the rod pass by a certain point z of the lab, such that $l = v(t_2 - t_1)$.

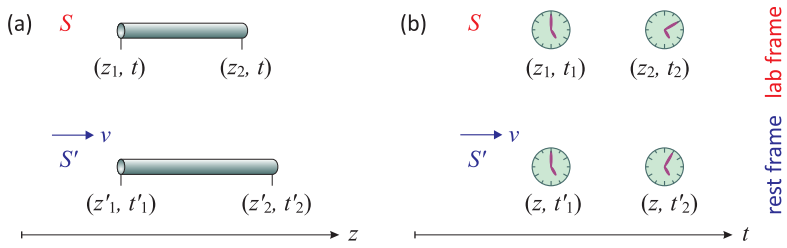

Figure 20.2: Illustration of (a) contraction of space and (b) dilatation of time.

the effect [2]: Take for example, a third person traveling back to Earth after having synchronized its clock with twin A. We calculate in Excs. 20.1.7.2 to 20.1.7.5 examples of temporal dilatation.

20.1.5 Transformational behavior of the wave equation

In the previous section we have seen that the relativistic metric is based on the covariant formulation of mechanics with the definition of relativistic space-time vectors. We introduced the *quadri-vectors* of the displacement Δr^μ, of the position (r^μ), and of the gradient (∂^μ),

$$\boxed{(\Delta r^\mu) \equiv \begin{pmatrix} c\Delta t \\ \Delta \mathbf{r} \end{pmatrix} \quad , \quad (r^\mu) \equiv \begin{pmatrix} ct \\ \mathbf{r} \end{pmatrix} \quad , \quad (\partial^\mu) \equiv \begin{pmatrix} \frac{1}{c}\frac{\partial}{\partial t} \\ -\nabla \end{pmatrix}} \; . \tag{20.32}$$

The contraction of quadri-vectors produces Lorentz invariants, such as the *quadri-scalars* of space-time intervals Δs^2, of proper time $\Delta\tau$, of proper distance $|\Delta\vec{\mathcal{S}}|$, or of the d'Alembertian $\Box$, given by,

$$\begin{aligned} \Delta s^2 &\equiv \Delta r_\mu \Delta r^\mu = c^2\Delta t^2 - \Delta \mathbf{r}^2 \; , \\ \Delta\tau &\equiv \sqrt{\tfrac{\Delta s^2}{c^2}} \qquad \text{for 'time'-like intervals} \qquad \Delta s^2 > 0 \; , \\ |\Delta \mathbf{s}| &\equiv \sqrt{-\Delta s^2} \qquad \text{for 'space'-like intervals} \qquad \Delta s^2 < 0 \; , \\ \Box &\equiv \partial_\mu \partial^\mu = \tfrac{1}{c^2}\tfrac{\partial^2}{\partial t^2} - \nabla^2 \; . \end{aligned} \tag{20.33}$$

With these definitions we can write the wave equation in the absence of sources,

$$\boxed{\Box\psi = \partial^\mu \partial_\mu \psi = 0} \; . \tag{20.34}$$

The covariant form of the wave equation already shows its compatibility with the Lorentz transform. Nevertheless, we will discuss the transformation properties in the following. These are fundamental, since the propagation of light, whose invariant velocity triggered the theory of relativity, is an undulatory phenomenon.

[2] [http://de.wikipedia.org/wiki/Zwillingsparadox]

20.1.5.1 Wave equation under Galilei transformation

The Galilei transformation claims that we obtain the coordinates of an object in a system S' simply by substituting $z \to z'$ and $t \to t'$ with [3],

$$\begin{aligned} t' \equiv t \quad & \text{and} \quad z' \equiv z - v_0 t \quad \text{or} \\ t \equiv t' \quad & \text{and} \quad z \equiv z' + v_0 t \ , \end{aligned} \tag{20.35}$$

which implies

$$v' = \frac{\partial z'}{\partial t'} = \frac{\partial z}{\partial t} - v_0 = v - v_0 \ . \tag{20.36}$$

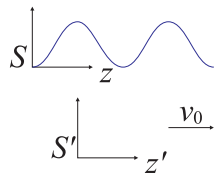

Figure 20.3: Wave in the inertial system S as seen by an observer in the system S' moving at a velocity u.

Newton's classical mechanics is *Galilei invariant*, which means that the fundamental equations of the type,

$$m\dot{v}_i = -\nabla_{x_i} \sum_j V_{ij}(|x_i - x_j|) \ , \tag{20.37}$$

do not change their shape under the *Galilei transform*. In contrast, the wave equation is *not* Galilei invariant. To see this, we consider a wave in the inertial system S, which is resting with respect to the propagation medium, being described by $Y(z,t)$ and satisfying the wave equation,

$$\frac{\partial^2 Y(z,t)}{\partial t^2} = c^2 \frac{\partial^2 Y(z,t)}{\partial z^2} \ . \tag{20.38}$$

An observer sits in the inertial system S' moving with respect to S with the speed v_0, such that $z' = z - v_0 t$. The question now is, what is the equation of motion for this wave described by $Y'(z',t')$, that is, we want to check the validity of

$$\frac{\partial^2 Y'(z',t')}{\partial t'^2} \stackrel{?}{=} c^2 \frac{\partial^2 Y'(z',t')}{\partial z'^2} \ . \tag{20.39}$$

For example, the wave $Y(z,t) = \sin k(z - ct)$ traveling to the right is perceived in the system S', which is also traveling to the right, as $Y'(z',t') = \sin k[z' - (c - v_0)t'] = Y(z,t)$ applying the Galilei transform. Therefore,

$$Y'(z',t') = Y(z,t) \ , \tag{20.40}$$

[3]Note that the Galilei transform (20.17) is unitary because $\det G = 1$.

that is, we expect that the laws valid in S are also valid in S'. We calculate the partial derivatives,

$$\frac{\partial Y'(z',t')}{\partial t'} = \frac{\partial Y(z,t)}{\partial t'} = \frac{\partial t}{\partial t'}\frac{\partial Y(z,t)}{\partial t}\bigg|_{z=const} + \frac{\partial z}{\partial t'}\frac{\partial Y(z,t)}{\partial z}\bigg|_{t=const} = \frac{\partial Y(z,t)}{\partial t} + v_0\frac{\partial Y(z,t)}{\partial z}$$
$$\frac{\partial Y'(z',t')}{\partial z'} = \frac{\partial Y(z,t)}{\partial z'} = \frac{\partial t}{\partial z'}\frac{\partial Y(z,t)}{\partial t}\bigg|_{z=const} + \frac{\partial z}{\partial z'}\frac{\partial Y(z,t)}{\partial z}\bigg|_{t=const} = \frac{\partial Y(z,t)}{\partial z} \ . \quad (20.41)$$

Therefore, we conclude that the wave equation in the propagating system is modified:

$$\begin{aligned}\frac{\partial^2 Y'(z',t')}{\partial t'^2} &\overset{\rightarrow}{=} \frac{\partial^2 Y(z,t)}{\partial t^2} + v_0^2\frac{\partial^2 Y(z,t)}{\partial z^2} + 2v_0\frac{\partial^2 Y(z,t)}{\partial t\partial z} \\ &\overset{\text{eq.onda}}{=} c^2\frac{\partial^2 Y(z,t)}{\partial z^2} + v_0^2\frac{\partial^2 Y(z,t)}{\partial z^2} + 2v_0\frac{\partial^2 Y(z,t)}{\partial t\partial z} \\ &\overset{\leftarrow}{=} (c^2 - v_0^2)\frac{\partial^2 Y'(z',t')}{\partial z'^2} + 2v_0\frac{\partial^2 Y'(z',t')}{\partial t'\partial z'} \ .\end{aligned} \quad (20.42)$$

Only in cases where the wave function can be written as $Y(z,t) = f(z-ct) = f(z'-(c-v_0)t') = f'(z'-ct') = Y'(z',t')$, will we obtain a similar wave equation to that of the system S, but with a modified propagation velocity. We calculate,

$$\frac{\partial f'(z'-ct')}{\partial t'} = \frac{\partial f(z'-(c-v_0)t')}{\partial t'} = (v_0-c)\frac{\partial f(z'-(c-v_0)t')}{\partial z'} = (v_0-c)\frac{\partial f'(z'-ct')}{\partial z'} \ , \quad (20.43)$$

and the second derivative,

$$\frac{\partial^2 f'(z'-ct')}{\partial t'^2} = (c-v_0)^2\frac{\partial^2 f'(z'-ct')}{\partial z'^2} \ . \quad (20.44)$$

The observation that the wave equation is not Galilei invariant expresses the fact, that there is a preferential system for the wave to propagate, which is simply the system in which the propagation medium is at rest. Only in this inertial system will a spherical wave propagate isotropically.

Example 125 (*Wave equation under Galilei transformation*): Let us now verify the correctness of the wave equation in the propagating system S' using the example of a sine wave,

$$\begin{aligned}&(c^2 - v_0^2)\frac{\partial^2 \sin k[z'-(c-v_0)t']}{\partial z'^2} + 2v_0\frac{\partial^2 \sin k[z'-(c-v_0)t']}{\partial z'\partial t'} \\ &= -k^2(c^2-v_0^2)\sin k[z'-(c-v_0)t'] + 2uk^2(c-v_0)\sin k[z'-(c-v_0)t'] \\ &= -k^2(c-v_0)^2\sin k[z'-(c-v_0)t'] = \frac{\partial^2 \sin k[z'-(c-v_0)t']}{\partial t'^2} \ .\end{aligned}$$

20.1.5.2 Wave equation under Lorentz transformation

The question now is, how to deal with electromagnetic waves which are lacking a propagation medium, as we have already noted and as has been verified by Michelson's famous experiment. If there is no propagation medium, all inertial systems should be equivalent, and the wave equation should be the same in all systems, and so should

be the propagation velocity, i.e. the speed of light. These were the consideration of *Henry Poincaré*. To solve the problem we need another transformation than that of *Galileo Galilei*. It was *Hendrik Antoon Lorentz* who found the solution, but the biggest intellectual challenge was to accept all consequences of this new transformation. *Albert Einstein* accepted the challenge and created a new mechanics, which he called *relativistic mechanics*. The wave equation for electromagnetic waves, called the *Helmholtz equation*, being a direct consequence of Maxwell's theory, it is not surprising that the relativistic theory proved not only compatible with electrodynamic theory, but provides a much deeper understanding of the latter.

We begin with the ansatz of a general transformation connecting temporal and spatial coordinates via four unknown parameters, γ, $\tilde{\gamma}$, β, and $\tilde{\beta}$,

$$ct = \gamma(ct' + \beta z') \qquad \text{and} \qquad z = \tilde{\gamma}(z' + \tilde{\beta}ct') \; . \tag{20.45}$$

A similar calculation as the one made for the Galilei transformation now gives the first derivatives,

$$\frac{\partial Y'(z',t')}{c\partial t'} = \frac{\partial Y(z,t)}{c\partial t'} = \frac{\partial t}{\partial t'}\,\frac{\partial Y(z,t)}{c\partial t}\bigg|_{z=const} + \frac{\partial z}{c\partial t'}\,\frac{\partial Y(z,t)}{\partial z}\bigg|_{t=const} = \gamma\frac{\partial Y(z,t)}{c\partial t} + \tilde{\gamma}\tilde{\beta}\frac{\partial Y(z,t)}{\partial z} \tag{20.46}$$

$$\frac{\partial Y'(z',t')}{\partial z'} = \frac{\partial Y(z,t)}{\partial z'} = \frac{c\partial t}{\partial z'}\,\frac{\partial Y(z,t)}{c\partial t}\bigg|_{z=const} + \frac{\partial z}{\partial z'}\,\frac{\partial Y(z,t)}{\partial z}\bigg|_{t=const} = \gamma\beta\frac{\partial Y(z,t)}{c\partial t} + \tilde{\gamma}\frac{\partial Y(z,t)}{\partial z} \; .$$

The second derivatives and the application of the wave equation in the system S give,

$$\begin{aligned}
\frac{\partial^2 Y'(z',t')}{c^2\partial t'^2} &\overset{\rightarrow}{=} \gamma^2\frac{\partial^2 Y(z,t)}{c^2\partial t^2} + 2\gamma\tilde{\gamma}\tilde{\beta}\frac{\partial^2 Y(z,t)}{c\partial t\partial z} + (\tilde{\gamma}\tilde{\beta})^2\frac{\partial^2 Y(z,t)}{\partial z^2} \\
&\overset{\text{wave eq.}}{=} \gamma^2\frac{\partial^2 Y(z,t)}{\partial z^2} + 2\gamma\tilde{\gamma}\tilde{\beta}\frac{\partial^2 Y(z,t)}{c\partial t\partial z} + (\tilde{\gamma}\tilde{\beta})^2\frac{\partial^2 Y(z,t)}{c^2\partial t^2} \\
&\overset{!}{=} (\gamma\beta)^2\frac{\partial^2 Y(z,t)}{c^2\partial t^2} + 2\gamma\tilde{\gamma}\beta\frac{\partial^2 Y(z,t)}{c\partial t\partial z} + \tilde{\gamma}^2\frac{\partial^2 Y(z,t)}{\partial z^2} \overset{\leftarrow}{=} \frac{\partial^2 Y'(z',t')}{\partial z'^2} \; .
\end{aligned} \tag{20.47}$$

That is, the wave equation in the system S' has the same form [4], under the condition that,

$$\gamma = \tilde{\gamma} \qquad \text{and} \qquad (\gamma\beta)^2 = (\tilde{\gamma}\tilde{\beta})^2 \qquad \text{and} \qquad \beta = \tilde{\beta} \; . \tag{20.48}$$

In addition, the transformation

$$\begin{pmatrix} ct' \\ z' \end{pmatrix} = \Lambda \begin{pmatrix} ct \\ z \end{pmatrix} \qquad \text{with} \qquad \Lambda \equiv \begin{pmatrix} \gamma & \gamma\beta \\ \gamma\beta & \gamma \end{pmatrix} \tag{20.49}$$

has to be unitary, that is,

$$1 = \det\Lambda = \gamma\tilde{\gamma} - \gamma\tilde{\gamma}\beta\tilde{\beta} = \gamma^2(1-\beta^2) \; , \tag{20.50}$$

which allows to relate the parameters γ and β by,

$$\gamma = \frac{1}{\sqrt{1-\beta^2}} \; . \tag{20.51}$$

[4] Note that the computation is dramatically simplified in the covariant formalism of 4-dimensional *space-time vectors* introduced by *Hermann Minkowski* and *Gregory Ricci-Curbastro*.

Finally and obviously, we expect to recover the Galilei transformation at low velocities,

$$ct = \gamma(ct' + \beta z') \to ct' \qquad \text{and} \qquad z = \gamma(z' + \beta ct') \to z' + v_0 t' \ . \tag{20.52}$$

That is, the limit is obtained by $\gamma \to 1$ and $\gamma\beta c \to v_0$, such that,

$$\beta = \frac{v_0}{c} \ . \tag{20.53}$$

The *Lorentz transform* from an inertial system S to another S' is,

$$\begin{aligned} t' &= \gamma\left(t - \tfrac{v_0}{c^2} z\right) \qquad \text{and} \qquad z' = \gamma(z - v_0 t) \qquad \text{or} \\ t &= \gamma\left(t' + \tfrac{v_0}{c^2} z'\right) \qquad \text{and} \qquad z = \gamma(z' + v_0 t') \ . \end{aligned} \tag{20.54}$$

20.1.6 The Lorentz boost

In this section we will construct the Lorentz transform from *infinitesimal generators* [659]. To begin with we introduce 6 fundamental matrices. The matrices,

$$K_k \equiv \begin{pmatrix} 0 & \hat{\mathbf{e}}_k \\ \hat{\mathbf{e}}_k & \mathbf{0}_3 \end{pmatrix} \ , \tag{20.55}$$

with the unit vectors $\hat{\mathbf{e}}_k = \hat{\mathbf{e}}_x, \hat{\mathbf{e}}_y, \hat{\mathbf{e}}_z$ generate linear boosts and the matrices,

$$S_k \equiv \begin{pmatrix} 0 & \mathbf{0} \\ \mathbf{0} & \mathbf{S}_k \end{pmatrix} \quad \text{with} \quad \mathbf{S}_x \equiv \hat{\mathbf{e}}_z\hat{\mathbf{e}}_y^\dagger - \hat{\mathbf{e}}_y\hat{\mathbf{e}}_z^\dagger \ , \ \mathbf{S}_y \equiv \hat{\mathbf{e}}_x\hat{\mathbf{e}}_z^\dagger - \hat{\mathbf{e}}_z\hat{\mathbf{e}}_x^\dagger \ , \ \mathbf{S}_z \equiv \hat{\mathbf{e}}_y\hat{\mathbf{e}}_x^\dagger - \hat{\mathbf{e}}_x\hat{\mathbf{e}}_y^\dagger \ , \tag{20.56}$$

generate spatial rotations around the 3 Cartesian axes. We note that the squares of all matrices S_k and K_k are diagonal and that,

$$[S_i, S_j] = \epsilon_{ijk} S_k \qquad , \qquad [S_i, K_j] = \epsilon_{ijk} K_k \qquad , \qquad [K_i, K_j] = -\epsilon_{ijk} S_k \ . \tag{20.57}$$

Example 126 (*Actions of the matrices K_k and S_k*): For example, the operation

$$(x'^\mu) = (\mathbb{I}_4 + K_z)^\mu{}_\nu (x^\nu) = \begin{pmatrix} 1 & \hat{\mathbf{e}}_z \\ \hat{\mathbf{e}}_z & \mathbb{I}_3 \end{pmatrix} \begin{pmatrix} ct \\ \mathbf{r} \end{pmatrix}$$

transports a space-time point $(ct, \mathbf{r})$ with light velocity along the z-axis to another point, $(ct', \mathbf{r}') = (ct + z, \mathbf{r} + ct\hat{\mathbf{e}}_z)$. And the operation

$$(x'^\mu) = (\mathbb{I}_4 + S_z)^\mu{}_\nu (x^\nu) = \begin{pmatrix} 1 & \mathbf{0} \\ \mathbf{0} & \mathbb{I}_3 + S_z \end{pmatrix} \begin{pmatrix} ct \\ \mathbf{r} \end{pmatrix} = \begin{pmatrix} ct \\ \begin{pmatrix} 1 & -1 & 0 \\ 1 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix} \mathbf{r} \end{pmatrix} = \begin{pmatrix} ct \\ x - y \\ y + x \\ z \end{pmatrix}$$

transports a space-time point $(ct, \mathbf{r})$ around the z-axis to another point, $(ct', \mathbf{r}') = (ct, x - y, y + x, z)$.

The *Lorentz boost* can now be written as,

$$\boxed{\begin{array}{llll} \Lambda = e^{L} & \text{with} & L & = -\vec{\omega}\cdot\mathbf{S} - \vec{\zeta}\cdot\mathbf{K} \\ & \text{where} & \mathbf{S} & \equiv \begin{pmatrix} S_x & S_y & S_z \end{pmatrix} \\ & \text{and} & \mathbf{K} & \equiv \begin{pmatrix} K_x & K_y & K_z \end{pmatrix} \end{array}} \quad . \tag{20.58}$$

We verify that,

$$\det \Lambda = \det e^{L} = e^{\mathrm{Tr}\ L} = \pm 1 \ . \tag{20.59}$$

Example 127 (*Lorentz-boost without rotation*): For a Lorentz-boost without rotation,

$$\Lambda = e^{-\vec{\zeta}\cdot\mathbf{K}} \qquad \text{with} \qquad \vec{\zeta} = \hat{\mathbf{e}}_\beta \ \tanh^{-1}\beta \ ,$$

we get,

$$\Lambda = \begin{pmatrix} \gamma & -\gamma\beta_x & -\gamma\beta_y & -\gamma\beta_z \\ -\gamma\beta_x & 1+\frac{(\gamma-1)\beta_x^2}{\beta^2} & \frac{(\gamma-1)\beta_x\beta_y}{\beta^2} & \frac{(\gamma-1)\beta_x\beta_z}{\beta^2} \\ -\gamma\beta_y & \frac{(\gamma-1)\beta_x\beta_y}{\beta^2} & 1+\frac{(\gamma-1)\beta_y^2}{\beta^2} & \frac{(\gamma-1)\beta_y\beta_z}{\beta^2} \\ -\gamma\beta_z & \frac{(\gamma-1)\beta_x\beta_z}{\beta^2} & \frac{(\gamma-1)\beta_y\beta_z}{\beta^2} & 1+\frac{(\gamma-1)\beta_z^2}{\beta^2} \end{pmatrix} = \begin{pmatrix} \gamma & -\gamma\vec{\beta} \\ -\gamma\vec{\beta} & \mathbb{I}_3 + (\gamma-1)\hat{\beta}_i\hat{\beta}_j \end{pmatrix} , \tag{20.60}$$

as will be shown in Exc. 20.1.7.6. The Lorentz transform (20.19) into a system moving along the z-axis follows immediately with $\beta_x = \beta_y = 0$.

20.1.6.1 The Thomas precession

We consider the circular motion of an electron around a nucleus about the z-axis subject to a centripetal (Coulombian) force. The nucleus is fixed in the lab frame S, the electron's rest frame S' moves with respect to the lab frame at the instantaneous velocity $\mathbf{v}(t) = c\vec{\beta}(t)$, as illustrated in Fig. 20.4.

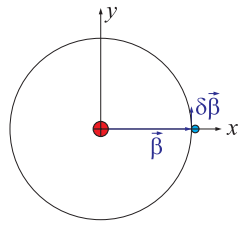

Figure 20.4: Circular motion of an electron around a nucleus.

At time t, when the electron's velocity is $\vec{\beta}(t)$, the Lorentz transform from S to S' is described by [659],

$$x'(t) = \Lambda_{boost}(\vec{\beta})x \ , \tag{20.61}$$

Note, that the nucleus' position does not change in the frame S, $x(t+\delta t) = x(t) = x$. At a later time $t+\delta t$, when the electron's velocity is $\vec{\beta}(t+\delta t) = \vec{\beta}(t) + \delta\vec{\beta}(t)$, the

Lorentz transform,

$$x'(t+\delta t) = \Lambda_{boost}(\vec{\beta}+\delta\vec{\beta})x = \Lambda_{boost}(\vec{\beta}+\delta\vec{\beta})\Lambda^{-1}_{boost}(\vec{\beta})x'(t) \tag{20.62}$$

can be expressed as a Lorentz transform from the electron's system S' at time t to the same S' at time $t+\delta t$. From the expression (20.60) for a Lorentz-boost without rotation, setting $\beta_z = 0$, we get for Lorentz-boost in the xy-plane,

$$\Lambda^{\pm 1}_{boost}(\beta_x\hat{\mathbf{e}}_x + \beta_y\hat{\mathbf{e}}_y) = \begin{pmatrix} \gamma & \mp\gamma\beta_x & \mp\gamma\beta_y & 0 \\ \mp\gamma\beta_x & 1+\frac{(\gamma-1)\beta_x^2}{\beta^2} & \frac{(\gamma-1)\beta_x\beta_y}{\beta^2} & 0 \\ \mp\gamma\beta_y & \frac{(\gamma-1)\beta_x\beta_y}{\beta^2} & 1+\frac{(\gamma-1)\beta_y^2}{\beta^2} & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix} . \tag{20.63}$$

Now, setting the initial position of the electron along the direction $\vec{\beta}(t) = \beta\hat{\mathbf{e}}_x$, as shown in Fig. 20.4, we get,

$$\Lambda^{-1}_{boost}(\vec{\beta}) = \begin{pmatrix} \gamma & \gamma\beta & 0 & 0 \\ \gamma\beta & \gamma & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix} , \tag{20.64}$$

and, expanding γ for small velocity changes like,

$$\gamma + \delta\gamma = \frac{1}{\sqrt{1-(\beta+\delta\beta)^2}} \simeq \gamma + \gamma^3\beta\delta\beta , \tag{20.65}$$

we find,

$$\begin{aligned} \Lambda_{boost}(\vec{\beta}+\delta\vec{\beta}) &= \begin{pmatrix} \gamma+\delta\gamma & -(\gamma+\delta\gamma)(\beta+\delta\beta_x) & -(\gamma+\delta\gamma)\delta\beta_y & 0 \\ -(\gamma+\delta\gamma)(\beta+\delta\beta_x) & 1+\frac{(\gamma+\delta\gamma-1)(\beta+\delta\beta_x)^2}{(\beta+\delta\beta_x)^2} & \frac{(\gamma+\delta\gamma-1)(\beta+\delta\beta_x)\delta\beta_y}{(\beta+\delta\beta_x)^2} & 0 \\ -(\gamma+\delta\gamma)\delta\beta_y & \frac{(\gamma+\delta\gamma-1)(\beta+\delta\beta_x)\delta\beta_y}{(\beta+\delta\beta_x)^2} & 1+\frac{(\gamma+\delta\gamma-1)(\delta\beta_y)^2}{(\beta+\delta\beta_x)^2} & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix} \\ &\simeq \begin{pmatrix} \gamma+\gamma^3\beta\delta\beta_x & -\gamma\beta-\gamma^3\delta\beta_x & -\gamma\delta\beta_y & 0 \\ -\gamma\beta-\gamma^3\delta\beta_x & \gamma+\gamma^3\beta\delta\beta_x & \frac{\gamma-1}{\beta}\delta\beta_y & 0 \\ -\gamma\delta\beta_y & \frac{\gamma-1}{\beta}\delta\beta_y & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix} . \end{aligned} \tag{20.66}$$

Multiplying the matrices (20.65) and (20.66) we get,

$$\Lambda_{Th}(\vec{\beta}+\delta\vec{\beta}) = \Lambda_{boost}(\vec{\beta}+\delta\vec{\beta})\Lambda^{-1}_{boost}(\vec{\beta}) \simeq \begin{pmatrix} 1 & -\gamma^2\delta\beta_x & -\gamma\delta\beta_y & 0 \\ -\gamma^2\delta\beta_x & 1 & \frac{\gamma-1}{\beta}\delta\beta_y & 0 \\ -\gamma\delta\beta_y & -\frac{\gamma-1}{\beta}\delta\beta_y & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix} . \tag{20.67}$$

This represents an infinitesimal Lorentz transformation that, expressing the components of $\delta\vec{\beta}$ parallel and perpendicular to β by,

$$\delta\vec{\beta}_{\|} = \tfrac{\delta\vec{\beta}\cdot\vec{\beta}}{\beta^2}\vec{\beta} \qquad \text{and} \qquad \delta\vec{\beta}_{\perp} = \delta\vec{\beta} - \tfrac{\delta\vec{\beta}\cdot\vec{\beta}}{\beta^2}\vec{\beta} \tag{20.68}$$

can be written in terms of the matrices $\mathbf{S}$ and $\mathbf{K}$ as [5],

$$\boxed{\begin{aligned}\Lambda_{Th}(\vec{\beta}+\delta\vec{\beta}) &= \mathbb{I} - \tfrac{\gamma-1}{\beta^2}(\vec{\beta}\times\delta\vec{\beta})\cdot\mathbf{S} - (\gamma^2\delta\vec{\beta}_{\|} + \gamma\delta\vec{\beta}_{\perp})\cdot\mathbf{K} \\ &\simeq R(\Delta\vec{\Omega})\ \Lambda_{boost}(\Delta\vec{\beta})\end{aligned}} \ . \tag{20.69}$$

Here, we defined the *commuting* infinitesimal boosts and rotations called *Wigner rotations*,

$$\Lambda_{boost}(\Delta\vec{\beta}) \equiv \mathbb{I} - \Delta\vec{\beta}\cdot\mathbf{K} \qquad \text{and} \qquad R(\Delta\vec{\Omega}) \equiv \mathbb{I} - \Delta\vec{\Omega}\cdot\mathbf{S} \tag{20.70}$$

in terms of velocity and rotation angle,

$$\Delta\vec{\beta} \equiv \gamma^2\delta\vec{\beta}_{\|} + \gamma\delta\vec{\beta}_{\perp} \qquad \text{and} \qquad \Delta\vec{\Omega} \equiv \frac{\gamma-1}{\beta^2}\vec{\beta}\times\delta\vec{\beta}\ . \tag{20.71}$$

Clearly, the second line of (20.69) holds to first order in $\delta\vec{\beta}$. Thus, the pure Lorentz boost (20.62) to the frame with velocity $c(\vec{\beta}+\delta\vec{\beta})$ is equivalent to a boost (20.61) to a frame moving with velocity $c\vec{\beta}$, followed by an infinitesimal Lorentz transformation consisting of a boost with velocity $c\vec{\Delta}\beta$ and a rotation $\Delta\vec{\Omega}$.

In summary, we got,

$$\begin{aligned} x'(t+\delta t) &= \Lambda_{boost}(\vec{\beta}+\delta\vec{\beta})x = \Lambda_{boost}(\vec{\beta}+\delta\vec{\beta})\Lambda^{-1}_{boost}(\vec{\beta})x'(t) \\ &= \Lambda_{Th}(\vec{\beta}+\delta\vec{\beta})x'(t) = R(\Delta\Omega)\Lambda_{boost}(\Delta\vec{\beta})x'(t)\ . \end{aligned} \tag{20.72}$$

In terms of the interpretation of the moving frames as successive rest frames of the electron we do not want rotations as well as boosts. Non-relativistic equations of motion can be expected to hold provided the evolution of the rest frame is described by infinitesimal boosts without rotations. We are thus led to consider the rest-frame coordinates at time $t+\delta t$ that are given from those at time t by the boost $\Lambda_{boost}(\Delta\vec{\beta})$ instead of Λ_{Th}. Denoting these coordinates by $\tilde{x}'$ we have,

$$\begin{aligned} \tilde{x}'(t+\delta t) &= \Lambda_{boost}(\Delta\vec{\beta})x'(t) \\ &= R(-\Delta\vec{\Omega})x'(t+\delta t) = R(-\Delta\vec{\Omega})\Lambda_{boost}(\vec{\beta}+\delta\vec{\beta})x\ . \end{aligned} \tag{20.73}$$

The rest system of coordinates defined by $\tilde{x}'$ is rotated by $R(-\Delta\vec{\Omega})$ relative to the boosted laboratory axes x'. If a physical vector $\mathbf{G}$ has a (proper) time rate of change $(d\mathbf{G}/d\tau)$ in the rest frame, the precession of the rest-frame axes with respect to the

[5] We note that, for the case $\vec{\beta}(t) = \beta\hat{\mathbf{e}}_x$ Eq. (20.69) can be written as,

$$\Lambda_{Th} = \mathbb{I} - \frac{\gamma-1}{\beta}S_z\delta\beta_y - \gamma^2 K_x\delta\beta_x - \gamma K_y\delta\beta_y\ ,$$

which reproduces exactly Eq. (20.67).

laboratory makes the vector have a total time rate of change with respect to the laboratory axes of,

$$\left(\frac{d\mathbf{G}}{dt}\right)_{non-rot} = \left(\frac{d\mathbf{G}}{dt}\right)_{rest} + \vec{\omega}_{Th} \times \mathbf{G} \ . \tag{20.74}$$

with

$$\vec{\omega}_{Th} = -\lim_{\delta t \to 0} \frac{\Delta\Omega}{\delta t} = \frac{\gamma^2}{\gamma+1}\frac{\mathbf{a}\times\mathbf{v}}{c^2} \ , \tag{20.75}$$

where $\mathbf{a}$ is the acceleration in the laboratory frame and, to be precise,

$$\left(\frac{d\mathbf{G}}{dt}\right)_{rest} = \gamma^{-1}\left(\frac{d\mathbf{G}}{d\tau}\right)_{rest} \ . \tag{20.76}$$

The *Thomas precession* is purely kinematical in origin. If a component of acceleration exists perpendicular to $\mathbf{v}$, for whatever reason, then there is a Thomas precession, independent of other effects such as precession of the magnetic moment in a magnetic field.

Example 128 (*Circular motion*): Assuming a constant circular motion about the z-axis, as parametrized by $\mathbf{v} = r\dot{\theta}\hat{\mathbf{e}}_\theta$ and $\mathbf{a} = -r\dot{\theta}^2\hat{\mathbf{e}}_r = -\dot{\theta}v\hat{\mathbf{e}}_r$ with $\dot{\theta} = const$, we find,

$$\vec{\omega}_{Th} = \frac{\gamma^2}{\gamma+1}\frac{\mathbf{a}\times\mathbf{v}}{c^2} = \frac{\gamma^2}{\gamma+1}\frac{-\dot{\theta}v^2}{c^2}\hat{\mathbf{e}}_z = -\frac{\gamma^2\beta^2}{\gamma+1}\dot{\theta}\hat{\mathbf{e}}_z = -(\gamma-1)\dot{\theta}\hat{\mathbf{e}}_z \ .$$

20.1.6.2 Spin-Orbit coupling

For electrons in atoms the acceleration is caused by the screened Coulomb field. Thus the Thomas angular velocity is,

$$\vec{\omega}_{Th} \simeq -\frac{1}{2c^2}\frac{\mathbf{r}\times\mathbf{v}}{m}\frac{1}{r}\frac{dV}{dr} = -\frac{1}{2m^2c^2}\mathbf{L}\frac{1}{r}\frac{dV}{dr} \ . \tag{20.77}$$

It is evident that the extra contribution to the energy from the Thomas precession reduces the spin-orbit coupling, yielding,

$$U = \frac{-ge}{2mc}\vec{\mathcal{S}}\cdot\vec{\mathcal{B}} + \frac{(g-1)}{2m^2c^2}\vec{\mathcal{S}}\cdot\mathbf{L}\frac{1}{r}\frac{dV}{dr} \ . \tag{20.78}$$

20.1.7 Exercises

20.1.7.1 Ex: Contravariant partial derivation

Show that the partial derivative by the contravariant coordinate x^μ is covariant.

Solution: *Contravariance of x^μ means,*

$$x'^\mu = \Lambda^\mu{}_\nu x^\nu = \frac{\partial x'^\mu}{\partial x^\nu}x^\nu \ .$$

With this, we obtain the covariant transformation,

$$\partial'_\mu \equiv \frac{\partial}{\partial x'^\mu} = \frac{\partial x^\nu}{\partial x'^\mu}\frac{\partial}{\partial x^\nu} = (\Lambda^{-1})^\nu{}_\mu \partial_\nu = \Lambda_\mu{}^\nu \partial_\nu \ .$$

20.1.7.2 Ex: Time dilatation

Proxima Centauri, which is the closest star to our solar system with a distance of 4.22 light-years from Earth, is a so-called Red Dwarf of class M. At its 34th anniversary, Peter embarks on a journey from Earth to this star. His spaceship flies with a speed of 250000 km/s. How old is Peter when he arrives? What is the age of Peter's twin brother, who remained on Earth at this time?

Solution: *The elapsed time seen from the Earth is,*

$$T = \frac{s}{t} \Longleftrightarrow t = \frac{s}{v} = \frac{4.22\ Lj}{250000\,\mathrm{km/s}} = 5.064\,\mathrm{a} \ .$$

The time elapsed for the astronaut is, due to the smaller time dilatation:

$$T' = \frac{t}{\gamma(v)} = \frac{5.064\ a}{\sqrt{1-\frac{(250000\,\mathrm{km/s})^2}{(300000\,\mathrm{km/s})^2}}} \approx 2.8\,\mathrm{a} \ .$$

Therefore, Peter arrives at Proxima Centauri at the age of 36.8, while his twin brother is 39.1 years old.

20.1.7.3 Ex: The twin paradox

Explain the twin paradox by applying the Lorentz transform to the twin traveling on a round-trip to α-Centauri assuming a fixed distance between Earth and α-Centauri.

Solution: *Let us denote by (t_0, z_0) the coordinates of the Earth S at the instant when the twin takes off with a space ship S' and by (t_1, z_1) the position of α-Centauri and the arrival time as indicated by the Earth-bound clock. The flying twin calculates his own coordinates via,*

$$\begin{pmatrix} ct'_j \\ z'_j \end{pmatrix} = \begin{pmatrix} \gamma c t_j - \gamma\beta z_j \\ -\gamma\beta c t_j + \gamma z_j \end{pmatrix} \qquad with \qquad j = 0, 1 \ .$$

Inserting the take-off and arrival time coordinates the Earth-bound team gets,

$$t_1 - t_0 = \frac{1}{\gamma\beta c}(\gamma z_1 - z'_1) - \frac{1}{\gamma\beta c}(\gamma z_0 - z'_0) = \frac{1}{v}(z_1 - z_0) \ ,$$

while the twin located in his space ship at $z'_1 = z'_0$ reads on his clock,

$$\begin{aligned} t'_1 - t'_0 &= \left(\gamma t_1 - \frac{\gamma\beta}{c} z_1\right) - \left(\gamma t_0 - \frac{\gamma\beta}{c} z_0\right) \\ &= \gamma t_1 - \frac{\beta}{c}(z'_1 + \gamma\beta c t_1) - \gamma t_0 + \frac{\beta}{c}(z'_0 + \gamma\beta c t_0) = \frac{1}{\gamma}(t_1 - t_0) \ . \end{aligned}$$

On α-Centauri the traveling twin encounters another space ship S'' flying in opposite direction $v \to -v$. The crews of both ships quickly synchronize their clocks before continuing their trip through space. Space ship S'' calculates for its coordinates with respect to the Terrestrian coordinates,

$$\begin{pmatrix} ct_j'' \\ z_j'' \end{pmatrix} = \begin{pmatrix} \gamma ct_j + \gamma\beta z_j \\ \gamma\beta ct_j + \gamma z_j \end{pmatrix} \qquad \text{with} \qquad j = 1, 2 \ .$$

After a long voyage S'' arrives on Earth at the coordinates $(t_2, z_2 = z_0)$ according to the Earth-bound clock. Inserting the encounter and arrival time coordinates and knowing $z_2'' = z_1''$,

$$t_2 - t_1 = \frac{1}{v}(z_1 - z_2) \qquad \text{and} \qquad t_2'' - t_1'' = \frac{1}{\gamma}(t_2 - t_1) \ ,$$

in the same way as on the outbound flight. Hence, $t_2'' - t_0'' = \frac{2}{\gamma}(t_2 - t_0)$.

20.1.7.4 Ex: Muons

In the upper layers of the atmosphere (at 20 km altitude) about 250 muons are generated per square meter and second. After that they move with 99.98% of the speed of light towards the surface of the Earth. Muons at rest have a lifetime of 1.52 µs.
a. Assuming that there were no time dilatation, how many muons would arrive per square meter and second at the surface of the Earth?
b. How many muons actually reach the surface of the Earth?

Solution: *a. The number is,*

$$N = N_0 \cdot 0.5^{t/T_H} = N_0 \cdot 0.5^{s/(vT_H)} = 250 \cdot 0.5^{20\,\mathrm{km}\,/(0.9998 \cdot 300000\,\mathrm{km/s} \cdot 1.52 \cdot 10^{-6}\,\mathrm{s})} \approx 1.6 \cdot 10^{-11} \ .$$

Therefore, to observe on average a single muon, we would need to wait around 2000 years.
b. In fact, because of their high velocity, they decay much slower. At a speed of 99.98% of the speed of light the time dilatation factor is γ close to 50. Hence the lifetime increases to 76 µs.

$$N = N_0 \cdot 0.5^{t/T_H} = N_0 \cdot 0.5^{s/(vT_H)} = 250 \cdot 0.5^{20\,\mathrm{km}\,/(0.9998 \cdot 300000\,\mathrm{km/s} \cdot 50 \cdot 1.52 \cdot 10^{-6}\,\mathrm{s})} \approx 136 \ .$$

Consequently, we expect around 136 muons.

20.1.7.5 Ex: Atomic clocks

In 1971 atomic clocks were taken by a high-speed aircraft to measure time dilatation directly. How long must an aircraft fly at a speed of 3000 km/h, so that the airplane's clock and a clock fixed on Earth show, due to time dilatation, a difference of one second?

Solution: *We have,*

$$t - \frac{t}{\gamma} = \Delta t \Longrightarrow t = \frac{\Delta t}{1 - \frac{1}{\gamma}} = \frac{1\,\mathrm{s}}{1 - \sqrt{1 - \frac{3000:3.6}{3\cdot 10^8}}} \approx 8200\,\mathrm{a} \ .$$

20.1.7.6 Ex: Lorentz-boost without rotation

Derive the matrix (20.60) for the Lorentz-boost without rotation to a system moving in arbitrary direction.

Solution: *To find the Lorentz-boost to an arbitrary direction $\vec{\beta}$ we proceed as follows. We first rotate the vector $\vec{\beta}$ about the z-axis until its y-components vanishes,*

$$U_z = \begin{pmatrix} \cos\phi & \sin\phi & 0 \\ -\sin\phi & \cos\phi & 0 \\ 0 & 0 & 1 \end{pmatrix} = \frac{1}{\beta_\rho} \begin{pmatrix} \beta_x & \beta_y & 0 \\ -\beta_y & \beta_x & 0 \\ 0 & 0 & \beta_\rho \end{pmatrix} \ ,$$

where $\beta_\rho = \sqrt{\beta_x^2 + \beta_y^2}$. Then we rotate the resulting vector about the y-axis until it lies on the z-axis,

$$U_y = \begin{pmatrix} \cos\theta & 0 & \sin\theta \\ 0 & 1 & 0 \\ -\sin\theta & 0 & \cos\theta \end{pmatrix} = \frac{1}{\beta} \begin{pmatrix} \beta_z & 0 & -\beta_\rho \\ 0 & \beta & 0 \\ \beta_\rho & 0 & \beta_z \end{pmatrix} \ .$$

It is easy to verify,

$$U_y U_z \vec{\beta} = \beta \hat{\mathbf{e}}_z \ .$$

Now, we extend the total rotation matrix into space-time,

$$U = \frac{1}{\beta_\rho \beta} \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & \beta_x\beta_z & \beta_y\beta_z & -\beta_\rho^2 \\ 0 & -\beta_y\beta & \beta_x\beta & 0 \\ 0 & \beta_x\beta_\rho & \beta_y\beta_\rho & \beta_z\beta_\rho \end{pmatrix} \ ,$$

apply the Lorentz-boost along the z-axis according to (20.19) and finally rotate back. The result is,

$$\Lambda_{\vec{\beta}} = U^{-1}\Lambda_z U = \begin{pmatrix} \gamma & -\gamma\beta_x & -\gamma\beta_y & -\gamma\beta_z \\ -\gamma\beta_x & 1 + \frac{(\gamma-1)\beta_x^2}{\beta^2} & \frac{(\gamma-1)\beta_x\beta_y}{\beta^2} & \frac{(\gamma-1)\beta_x\beta_z}{\beta^2} \\ -\gamma\beta_y & \frac{(\gamma-1)\beta_x\beta_y}{\beta^2} & 1 + \frac{(\gamma-1)\beta_y^2}{\beta^2} & \frac{\gamma-1}{\beta^2}\beta_y\beta_z \\ -\gamma\beta_z & \frac{(\gamma-1)\beta_x\beta_z}{\beta^2} & \frac{(\gamma-1)\beta_y\beta_z}{\beta^2} & 1 + \frac{(\gamma-1)\beta_z^2}{\beta^2} \end{pmatrix} \ ,$$

which is just the wanted formula (20.60).

20.2 Relativistic mechanics

20.2.1 The inherent time of an inertial system

The key to constructing relativistic theories is to find the quantities behaving well under Lorentz transformations. We have already defined some quantities in (20.32) and (20.33). But we need more to establish a *relativistic mechanics*. In the following sections we will analyze how other kinematic variables (velocity, momentum, and acceleration) fit into four-vectors. Since these variables are defined through time derivatives, an accurate characterization of the notion of *time intervals* is necessary.

We consider an object following a space-time trajectory. As the evaluation of traveled distances and elapsed time intervals depends on the observer's inertial system, there is no universal parametrization. But there is at least one 'natural' parametrization that all observers can agree on, which is the proper time τ, which is the duration of time felt by the object itself. Due to time dilatation, an observer sitting in some inertial system and measuring the motion of the object with the old-fashioned Newtonian tri-velocity $\mathbf{v}(t)$ infers, that the relation between his own time t and the proper time τ of the particle is given by,

$$\boxed{\frac{dt}{d\tau} = \gamma_v \equiv \frac{1}{\sqrt{1 - v^2/c^2}} > 1} \,. \tag{20.79}$$

Example 129 (*Common velocity under Lorentz transformation*): We could define the *common velocity* of a body via the distance $\mathbf{r}$ covered in a time interval t measured in the laboratory system (in relation to which the body travels with this velocity),

$$(v^\mu) \equiv \frac{d(r^\mu)}{dt} = \begin{pmatrix} c \\ \mathbf{v} \end{pmatrix}$$

However, the contraction of this 4-vector is not a Lorentz invariant because,

$$v_\mu v^\mu = c^2 - v^2 \neq c^2 - v'^2 = v'_\mu v'^\mu \,.$$

On the other hand, the notion of *proper time* allows us to define a true quadri-velocity. We assume that in some inertial system, the body follows the trajectory $r^\mu(\tau)$. Then the quantity,

$$\boxed{u^\mu \equiv \gamma_v v^\mu = \gamma_v \frac{dr^\mu}{dt} = \gamma_v \frac{d\tau}{dt}\frac{dr^\mu}{d\tau} = \frac{dr^\mu}{d\tau} \qquad \text{that is} \qquad (u^\mu) = \begin{pmatrix} \gamma_v c \\ \gamma_v \mathbf{v} \end{pmatrix}} \,, \tag{20.80}$$

called *proper velocity* is a Lorentz invariant, since,

$$u_\mu u^\mu = c^2 \,. \tag{20.81}$$

A useful illustration of the relation between space and time, as proposed by Minkowski, is exhibited in Fig. 20.5. The inner region of the cone represents the space-time points in a lab frame that a moving body can reach within a given time interval. The cone's surface are the points that can be reaches traveling at light speed, and the outer region remains inaccessible.

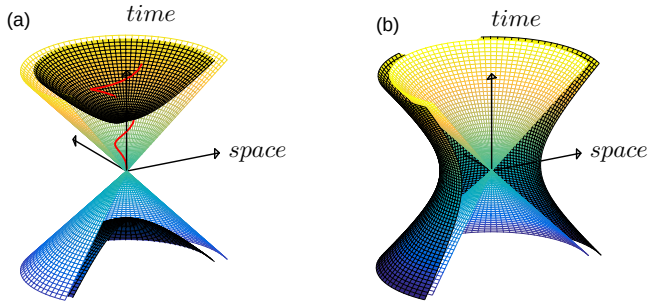

Figure 20.5: Two-dimensional illustration of Minkowski space-time. The cones delimits accessible (inside) from inaccessible (outside) regions. The red curve in (a) represents a possible trajectory for a moving body. The hyperboloid in (a) represents the hyperspace where a system S' with its *proper velocity* v is found after a time τ elapsed in the system S'. The hyperboloid in (b) represents the hyperspace of 'space'-like intervals according to (20.33).

20.2.2 Adding velocities

The Lorentz transformation from system S' moving with respect to another system S with the relative velocity v_0 must be applied to the proper velocity,

$$\begin{pmatrix} \gamma_{v'}c \\ \gamma_{v'}v' \end{pmatrix} = (\Lambda^{\mu}_{\ \nu}) \begin{pmatrix} \gamma_v c \\ \gamma_v v \end{pmatrix} = \begin{pmatrix} \gamma & -\gamma\beta \\ -\gamma\beta & \gamma \end{pmatrix} \begin{pmatrix} \gamma_v c \\ \gamma_v v \end{pmatrix} = \gamma_v\gamma \begin{pmatrix} c-\beta v \\ -\beta c + v \end{pmatrix} , \quad (20.82)$$

where we denote $\gamma \equiv \gamma_{v_0}$. Eliminating $\gamma_{v'}$ and resolving by v' we get,

$$\boxed{v' = \frac{v - v_0}{1 - v_0 v/c^2}} . \quad (20.83)$$

Obviously, the speed of light can not be exceeded. The velocity in the system S' is limited to $-c \leq v' \leq c$, even if $v = c$. Similar calculations can be made for the two transverse directions, and we obtain the general formula reproduced here without proof,

$$\mathbf{v} = \frac{\mathbf{v}' + \mathbf{v}_0 \left[\gamma(1 + \mathbf{v_0}\cdot\mathbf{v}'/v_0^2) - \mathbf{v}_0\cdot\mathbf{v}'/v_0^2\right]}{\gamma(1 + \mathbf{v}_0\cdot\mathbf{v}'/c^2)} . \quad (20.84)$$

We calculate in Exc. 20.2.6.1 an example of relativistic addition of velocities.

20.2.3 Relativistic momentum and rest energy

The *relativistic linear momentum* is given by,

$$\boxed{p^\mu \equiv mu^\mu = m\gamma_v v^\mu \qquad \text{or} \qquad (p^\mu) = \begin{pmatrix} E/c \\ \mathbf{p} \end{pmatrix}} \ . \tag{20.85}$$

We will show in Exc. 20.2.6.2 that an identification of the momentum p^μ with mv^μ would be inconsistent with the principle of momentum conservation and the principle of relativity. For zero velocity of the particle, $\mathbf{v} = 0$, the first line of the expression (20.85) is the famous Einstein equation on the equivalence of mass and energy,

$$E = mc^2 \ . \tag{20.86}$$

Thus, the mass is nothing more than the energy of the particle in its rest frame.

Transforming into the rest frame, we have:

$$p'_\mu p'^\mu = \left\| \begin{pmatrix} E/c \\ \mathbf{p} \end{pmatrix} \right\|^2 = \left\| \begin{pmatrix} mc \\ \mathbf{0} \end{pmatrix} \right\|^2 = p_\mu p^\mu \ , \tag{20.87}$$

yielding,

$$E = \sqrt{m^2c^4 + c^2\mathbf{p}^2} = mc^2\sqrt{1 + \gamma_v^2 \frac{\mathbf{v}^2}{c^2}} = \gamma_v mc^2 \ . \tag{20.88}$$

The kinetic energy in the non-relativistic limit follows from a Taylor expansion of the expression (20.88) for low velocities,

$$E_{kin} \equiv E - mc^2 = mc^2(\gamma_v - 1) \simeq \frac{p^2}{2m} - \frac{p^4}{8m^3c^2} \ . \tag{20.89}$$

Example 130 (*Compton scattering*): Here we consider the interaction of a photon with an electron. The electron has the rest mass m_e. Thus, transforming to the rest frame, we find its energy via, $(p_e)_\mu (p_e)^\mu = E_e^2/c^2 - \mathbf{p}^2 = m_e^2 c^4$. The photon has no rest mass. Thus, transforming to the rest frame, we find its energy via, $(p_\gamma)_\mu (p_\gamma)^\mu = (\hbar k)^2 = (\hbar\omega)^2/c^2$.

Now we let the photon with energy $\hbar\omega_i$ bounce off an electron initially at rest. After the collision the photon and the electron move away under angles of $\sin\theta_\gamma$, respectively, $\sin\theta_e$, with respect to the collision axis. As shown in Fig. 20.6, we can choose the collision axis along the z-axis and within the xy-plane. The photon has changed its energy to $\hbar\omega_f$ and its momentum to $\hbar k_f$, the

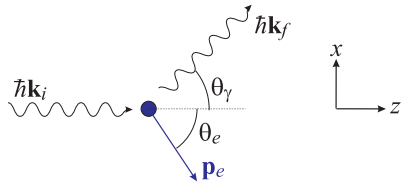

Figure 20.6: Scattering of a photon from an electron.

electron now has the momentum $\mathbf{p}_f$. For an elastic collision, energy and linear momentum conservation request,

$$p_i^\mu \equiv \begin{pmatrix} E_i/c \\ p_i^x \\ p_i^y \\ p_i^z \end{pmatrix} = \begin{pmatrix} \hbar\omega_i/c + m_e c \\ 0 \\ 0 \\ \hbar k_i \end{pmatrix} \stackrel{!}{=} \begin{pmatrix} \hbar\omega_f/c + \sqrt{m_e^2 c^2 + p_f^2} \\ -\hbar k_f \sin\theta_\gamma + p_f \sin\theta_e \\ 0 \\ \hbar k_f \cos\theta_\gamma + p_f \cos\theta_e \end{pmatrix} = \begin{pmatrix} E_f/c \\ p_f^x \\ p_f^y \\ p_f^z \end{pmatrix} \equiv p_f^\mu \ .$$

Solving the second line by θ_e and substituting into the fourth,

$$\begin{aligned} \frac{\hbar\omega_i}{c} = \hbar k_i &= p_f \cos\theta_e + \hbar k_f \cos\theta_\gamma = p_f \sqrt{1 - \sin^2\theta_e} + \hbar k_f \cos\theta_\gamma \\ &= p_f \sqrt{1 - \left(\frac{\hbar k_f}{p_f}\right)^2 \sin^2\theta_\gamma} + \hbar k_f \cos\theta_\gamma \ . \end{aligned}$$

Solving this by p_f,

$$\begin{aligned} c^2 p_f^2 &= (\hbar\omega_i - c\hbar k_f \cos\theta_\gamma)^2 - (c\hbar k_f)^2 \sin^2\theta_\gamma = (\hbar\omega_i)^2 - 2\hbar\omega_i c\hbar k_f \cos\theta_\gamma + (c\hbar k_f)^2 \\ &= (\hbar\omega_i)^2 - 2\hbar\omega_i \hbar\omega_f \cos\theta_\gamma + (\hbar\omega_f)^2 \ . \end{aligned}$$

Inserting this result into energy conservation,

$$\hbar\omega_i + m_e c^2 = \hbar\omega_f + \sqrt{m_e^2 c^4 + c^2 p_f^2} = \hbar\omega_f + \sqrt{m_e^2 c^4 + (\hbar\omega_i)^2 - 2\hbar\omega_i \hbar\omega_f \cos\theta_\gamma + (\hbar\omega_f)^2} \ .$$

Solving this by ω_f,

$$\frac{hc}{\lambda_f} = \hbar\omega_f = \frac{1}{(1 - \cos\theta_\gamma)/m_e c^2 + 1/\hbar\omega_i} \ ,$$

or defining the *Compton wavelength* of the electron,

$$\lambda_C \equiv \frac{h}{m_e c}$$

we find for the wavelength of the scattered photon,

$$\lambda_f = \lambda_i + \lambda_C (1 - \cos\theta_\gamma) \ .$$

Other examples of relativistic collisions will be studied in Excs. 20.2.6.3 to 20.2.6.5.

20.2.4 Relativistic Doppler effect

We have seen at the example of sonic waves, that the magnitude of the Doppler effect depends on who moves with respect to the *medium*: the source or the receiver. Electromagnetic waves, however, propagate in empty space, that is, there is no material medium, ether, or wind. According to Einstein's theory of relativity, there is no absolute motion and the propagation velocity of light is the same for all inertial systems. Therefore, the classical theory of the Doppler effect can not apply to electromagnetic waves.

By the fact that the vector k_μ given by,

$$\boxed{k^\mu \equiv \frac{p^\mu}{\hbar} \qquad \text{that is} \qquad (k^\mu) = \begin{pmatrix} \omega/c \\ \mathbf{k} \end{pmatrix}} \tag{20.90}$$

is a space-time vector,

$$k_\mu k^\mu = \omega^2/c^2 - k^2 = 0 \ , \tag{20.91}$$

we know that this vector transforms like,

$$\begin{aligned} \begin{pmatrix} \omega/c \\ k \end{pmatrix} = (\Lambda_{\mu\nu})^{-1} \begin{pmatrix} \omega'/c \\ k' \end{pmatrix} = \begin{pmatrix} \gamma & \gamma\beta \\ \gamma\beta & \gamma \end{pmatrix} \begin{pmatrix} \omega'/c \\ k' \end{pmatrix} \\ = \begin{pmatrix} \gamma\frac{\omega'}{c} + \gamma\beta k' \\ \gamma\beta\frac{\omega'}{c} + \gamma k' \end{pmatrix} = \frac{\omega'}{c}\gamma(1+\beta)\begin{pmatrix} 1 \\ 1 \end{pmatrix} \ , \end{aligned} \tag{20.92}$$

such that,

$$\boxed{\omega = ck = \omega'\sqrt{\frac{1+\beta}{1-\beta}} = \gamma\omega'(1+\beta)} \ . \tag{20.93}$$

Including the transverse motion, we obtain

$$\omega = \gamma\omega'\left(1 + \frac{\mathbf{v}_0 \cdot \mathbf{v}}{vc}\right) \ , \tag{20.94}$$

where $\mathbf{v}_0$ is the speed of the source. It is interesting to note that, even in case of a purely transverse motion $\mathbf{v}_0 \cdot \mathbf{v} = 0$, we observe a Doppler shift.

Example 131 (*Doppler effect on a moving laser*): We now consider a light source flying through the lab S, for example, a laser operating at a frequency ω', which is well-defined by an atomic transition of the active medium. A spectrometer installed in the same rest frame S' as the laser will measure just this frequency. We now ask, what frequency would be measured by a spectrometer installed in the lab frame. The classical response has already been derived for a moving sound source,

$$\omega' = \omega - kv = \omega - \frac{\omega}{c}v = \frac{\omega}{1+\frac{v}{c}} \ ,$$

with $k = \omega/c$. Because of time dilatation, we need to multiply by γ,

$$\omega' = \frac{\gamma^{-1}\omega}{1+\frac{v}{c}} = \omega\sqrt{\frac{1-\beta}{1+\beta}} \simeq \omega\left(1 \pm \frac{v}{c} + \frac{v^2}{2c^2}\right) \ .$$

The above example shows that, for non-relativistic velocities, one can distinguish the *first-order Doppler effect* from the *relativistic Doppler effect* due to time dilatation,

$$\boxed{\omega' \simeq \omega \pm kv + \tfrac{1}{2}\omega\beta^2} \ . \tag{20.95}$$

We will study the Doppler effect for the case of ultracold atoms in Excs. 20.2.6.6 to 20.2.6.8.

20.2.5 Relativistic Newton's law

The relativistic form of *Newton's law*,

$$\mathbf{F} = \frac{d\mathbf{p}}{dt} \ , \tag{20.96}$$

with the momentum given by (20.85) defines the *common* relativistic force. However, because it is derived from the momentum with respect to common time, the common force $\mathbf{F}$ *can not* be extended to a Lorentz invariant of the type F^μ. In contrast, *Minkowski force* defined as,

$$\boxed{K_\mu = \frac{dp_\mu}{d\tau} = \frac{\gamma_v dp_\mu}{dt} \qquad \text{that is} \qquad (K^\mu) = \begin{pmatrix} \gamma_v P/c \\ \gamma_v \mathbf{F} \end{pmatrix}} \ , \tag{20.97}$$

is covariant. Nevertheless, we will often be interested in the common force $\mathbf{F}$ acting on moving bodies as measured in a laboratory frame.

The work exerted on a particle increases its kinetic energy, such that,

$$\begin{aligned} W \equiv \int \mathbf{F}\cdot d\mathbf{l} &= \int \frac{d\mathbf{p}}{dt}\cdot d\mathbf{l} = \int \frac{d\mathbf{p}}{dt}\cdot \mathbf{v}\ dt = \int \frac{d}{dt}(\gamma_v m\mathbf{v})\cdot \mathbf{v}\ dt \\ &= \int (\gamma_v^3 m\dot{\mathbf{v}})\cdot \mathbf{v}\ dt = \int mc^2 \frac{d\gamma_v}{dt} dt = \int \frac{dE}{dt} dt = E_{final} - E_{initial} \ . \end{aligned} \tag{20.98}$$

Unlike the first two Newton laws, the third one (actio = reactio) does *not* apply in the relativistic regime. Indeed, the simultaneity of 'actions' and reactions' in the forces that two distant bodies A and B exert on each other depends on the velocity of the observer.

20.2.6 Exercises

20.2.6.1 Ex: Adding velocities

Imagine an array of flash lamps at rest in the system S. The lamps are aligned at distances of $\Delta s = 10\,\text{m}$ from each other. The array extends over a distance of many light-years. Now, the lamps are flashed successively (from left to right), so that the light seems to move to the right.
a. At what time interval Δt two adjacent lamps need to flash in order to generate an apparent velocity of $v_1 = 1.2c$?
b. An inertial system S' moves relative to S with velocity $v_2 = -0.56c$ in opposite direction to that of the motion of the flashes. At what velocity the flashes seem to be moving in the system S'?

Solution: *a. We have*

$$\Delta t = \frac{\Delta s}{v} = \frac{10\,\text{m}}{1.2c} = 2.78\cdot 10^{-8}\,\text{s} \ .$$

b. We consider the array of lamps at the instant in which the first lamp flashes, and we call this instant $t = 0$. In system S the distance of the lamps is $\Delta s = 10$ m. In

S' the situation is obviously different: the distance of the lamps is shortened and the clocks (fixed to the lamps) go more slowly and not in a synchronized way. We label the flash-lamps with an integer number j and parametrize the 'flashes' in the system S by,

$$z_j = j\Delta s = j \cdot 10\,\mathrm{m}$$
$$t_j = j\Delta t = j\frac{\Delta s}{v_1} = j\frac{10\,\mathrm{m}}{1.2c} \approx 2.89 \cdot 10^{-8}\,\mathrm{s}\ ,$$

and we transform to the system S',

$$z'_j = \gamma z_j - \gamma v_2 t_j = \gamma j\Delta s - \gamma v_2 j\frac{\Delta s}{v_1} = \left(1 - \frac{v_2}{v_1}\right)\gamma j\Delta s$$
$$t'_j = \gamma t_j - \gamma\frac{v_2}{c^2}z_j = \gamma j\frac{\Delta s}{v_1} - \gamma\frac{v_2}{c^2}j\Delta s = \left(\frac{1}{v_1} - \frac{v_2}{c^2}\right)\gamma j\Delta s\ .$$

Now, we can calculate the apparent velocity in the system S':

$$v'_2 = \frac{z'_j - z'_{j-1}}{t'_j - t'_{j-1}} = \frac{1 - \frac{v_2}{v_1}}{\frac{1}{v_1} - \frac{v_2}{c^2}} = \frac{v_1 - v_2}{1 - v_1 v_2/c^2} = \frac{1.2c + 0.56c}{1 + 1.2 \cdot 0.56} \approx 1.053c\ .$$

Surprisingly, the apparent velocity gets smaller, although we move in the direction opposite to the motion. We find the same value, when we simply apply Einstein's formula for the addition of velocities.
The term 'apparent velocity' means that, seen from far, the array looks like a single flashing light propagating in space. Traveling at a certain speed v_1 we would be at the position of every lamp of the array exactly when it flashes. If $v_1 > c$ this is of course not possible to realize. Note that there is no contradiction of relativity, because no information is transmitted through the flashing array. The flash lamps are assumed to have been programmed a long time ago and brought into their position afterward. Relativity does not impede events to occur at positions so distant that they cannot influence each other even by messengers traveling at the speed of light.

20.2.6.2 Ex: Covariant momentum

Show that an identification of the momentum p^μ with mv^μ would be inconsistent with the principle of momentum conservation and the principle of relativity.

Solution:

20.2.6.3 Ex: Inelastic collision

A particle of mass m whose total energy is twice its rest energy collides with an identical particle at rest. If they stick together, what is the mass of the resulting particle compound? What is its velocity?

Solution: *Conservation of energy and momentum requires,*

$$(p^{\mu}_{before}) = \begin{pmatrix} E_{before}/c \\ p^{z}_{before} \end{pmatrix} = \begin{pmatrix} 2mc + mc \\ \sqrt{3}mc \end{pmatrix} \stackrel{!}{=} \begin{pmatrix} \sqrt{m_{12}^2c^2 + p_{12}^2} \\ p_{12} \end{pmatrix} = (p^{\mu}_{after}) \ .$$

This gives,

$$2mc + mc = \sqrt{m_{12}^2c^2 + 3m^2c^2} \ .$$

Solving by m_{12},

$$m_{12} = \sqrt{6}m \ .$$

The time dilatation factor is,

$$\gamma = \frac{\gamma m}{m} = \frac{E/c^2}{m} = \frac{2m}{m} = 2 \ .$$

With this, the velocity in the lab frame is before the collision,

$$v = \frac{u}{\gamma} = \frac{p}{\gamma m} = \frac{\sqrt{3}mc}{\gamma m} = \sqrt{\frac{3}{4}}c \ ,$$

and after the collision,

$$v_{12} = \frac{u_{12}}{\gamma} = \frac{p_{12}}{\gamma m_{12}} = \frac{\sqrt{3}mc}{2m_{12}} = \frac{\sqrt{3}mc}{2\sqrt{6}m} = \sqrt{\frac{1}{8}}c = \sqrt{\frac{1}{6}}v \ .$$

20.2.6.4 Ex: Relativistic collision

Consider a relativistic completely inelastic frontal collision of two particles moving along the x-axis. Both particles have mass m. Before the collision, an observer A sitting in an inertial frame, notices that the masses move with the same constant velocities but in the opposite direction, that is, the particle 1 moves with velocity v and the particle 2 moves with velocity $-v$. According to another observer B, however, particle 1 is initially at rest.
a. Determine the velocity v'_x of particle 2 measured by observer B before collision.
b. Find the velocities v_A and v'_B of the particle resulting from the collision, measured, respectively, by the observers A and B.
c. Use the relativistic mass-energy conservation and calculate the mass M of the particle resulting from the collision.

Solution: *a. We can conclude that the observer B has the same velocity as the particle 1. Therefore, $v_B = v$, where v_B is the velocity of the observer B. The observer A, at rest, measures for the particle 2 the velocity $u_2 = -v$. From the Lorentz transformations, we see that particle 2 has the following velocity*

$$u'_2 = \frac{u_2 - v_B}{1 - \frac{u_2 v_B}{c^2}} \ .$$

Therefore, the velocity of the particle measured by the observer B is,

$$u_2' = \frac{-v - v}{1 - \frac{(-v)v}{c^2}} = \frac{-2v}{1 + v^2/c^2} \ .$$

b. After the collision, the observer A verifies that the final velocity is zero, $u_A = 0$. Considering again the Lorentz transform, the moving observer detects the following velocity for the particle resulting from the collision,

$$u_B' = \frac{u_A - v_B}{1 - \frac{u_A v_B}{c^2}} = -v \ .$$

c. The total energy of the system is equal to the sum of the energies of the particles,

$$\begin{aligned} E_{before} = E_1 + E_2 &= \frac{mc^2}{\sqrt{1 - u_1^2/c^2}} + \frac{mc^2}{\sqrt{1 - u_2^2/c^2}} \\ &= \frac{mc^2}{\sqrt{1 - v^2/c^2}} + \frac{mc^2}{\sqrt{1 - (-v)^2/c^2}} = \frac{2mc^2}{\sqrt{1 - u_1^2/c^2}} \ . \end{aligned}$$

Let's call M the mass of the compound after the collision and keep in mind that M is not necessarily $2m$:

$$E_{after} = \frac{Mc^2}{\sqrt{1 - u_A^2/c^2}} \ .$$

Since $u_A = 0$, it results $E_{after} = Mc^2$. In order to satisfy mass-energy conservation, we have $E_{before} = E_{after}$, that is,

$$\frac{2mc^2}{\sqrt{1 - v^2/c^2}} = Mc^2 \ .$$

Hence,

$$M = \frac{2m}{\sqrt{1 - v^2/c^2}} \ .$$

This is the mass of the resulting particle.

20.2.6.5 Ex: γ-rays

γ-rays produced by paired annihilation exhibit considerable Compton scattering. Consider a photon produced with the energy m_0c^2 by the annihilation of an electron and a positron, where m_0 is the rest mass of the electron. Suppose that this photon be scattered by a free electron and that the scattering angle is θ_γ, as shown in Fig. 20.6.

a. Find the maximum possible kinetic energy for the recoiling electron.

b. If the scattering angle were $\theta_\gamma = 120°$, determine the photon energy and the kinetic energy of the electron after the scattering.

c. If $\theta_\gamma = 120°$, what is the direction of motion of the electron after the scattering with respect to the direction of the incident photon?

Solution: *a. Given the expression for Compton scattering, where the apostrophe indicates the scattered photon,*

$$\lambda' - \lambda = \frac{h}{m_0 c}(1 - \cos\theta_\gamma) \ .$$

Multiplying it with $1/hc$*, we have,*

$$\frac{\lambda'}{hc} - \frac{\lambda}{hc} = \frac{1}{mc^2}(1 - \cos\theta_\gamma) \ .$$

But $E = hc/\lambda$*, and the initial photon energy is* $m_0 c^2$*, hence,*

$$\frac{1}{E'} - \frac{1}{m_0 c^2} = \frac{1}{m_0 c^2}(1 - \cos\theta_\gamma) \ .$$

The maximum momentum transfer to the electron occurs at,

$$\theta_\gamma = 180^\circ \ ,$$

then we can obtain the energy of the scattered photon,

$$E' = \frac{m_0 c^2}{3} \ .$$

By energy conservation, we have that the maximum kinetic energy is,

$$E_c^{max} = \frac{2m_0 c^2}{3} \ .$$

b. From the second expression, considering that $\cos 120^\circ = -\cos 60^\circ = -1/2$*, we have that,*

$$E' = \frac{2m_0 c^2}{5}$$

By energy conservation,

$$E_c = \frac{3m_0 c^2}{5} \ .$$

c. Because of momentum conservation, we have the following components (θ_e *is the angle of the electron with respect to the direction of the incident photon).*
In vertical direction (y), we have $p_e \sin\theta_e = p' \sin\theta_\gamma$*.*
In horizontal direction (x), we have $p_e \cos\theta_e = p - p' \cos\theta_\gamma$*.*
By dividing one expression by the other, we eliminate the variable p_e *and get,*

$$\tan\theta_e = \frac{p' \sin\theta_\gamma}{p - p' \cos\theta_\gamma} \ .$$

But for the photon, $E = pc$*, hence:* $\tan\theta_e = \frac{E' \sin\theta_\gamma}{E - E' \cos\theta_\gamma}$*, but since* $\cos 120^\circ = -\cos 60^\circ = -1/2$ *and* $\sin 120^\circ = \cos 30^\circ = \sqrt{3}/2$ *and given the values of* E *and* E'*, we arrive at,*

$$\tan\theta_e = \frac{\sqrt{3}}{6} \ .$$

20.2.6.6 Ex: Second order Doppler shift

The *second order Doppler shift* comes from the relativistic dilation of time. Periodic events occurring in a moving inertial system appear dilated to an observer in another system. Consider a strontium atom, which has a resonance at the wavelength $\lambda = 461\,\text{nm}$, located inside a resonant laser beam from which it absorbs and reemits photons.
a. Assume the atom initially at rest. What will be it's velocity after having absorbed a single photon?
b. Calculate the first and second order Doppler shift for the remitted photon as a function of the emission direction.

Solution: *a. The atomic mass of strontium is* $88u$. *The atomic velocity due to photonic recoil is,*

$$v = \frac{p}{m} = \frac{\hbar k}{m} = \frac{h}{m\lambda} = 9.9\,\text{mm/s} \ .$$

b. The first order Doppler shift is,

$$\mathbf{k}\cdot\mathbf{v} = kv\cos\theta = \frac{2\pi}{\lambda}\frac{h}{m\lambda}\cos\theta = (2\pi)\ 21259\,\text{Hz}\ \ \cos\theta \ ,$$

and the second order Doppler shift is,

$$\Delta\omega = \frac{\omega\beta^2}{2} = \frac{\pi v^2}{\lambda c} = (2\pi)\ 3.5\cdot 10^{-7}\,\text{Hz} \ .$$

20.2.6.7 Ex: Recoil- and Doppler-shift upon photon absorption

Derive the expressions for the recoil- and Doppler-shift upon the absorption of a photon of frequency ω_i by an atom with the initial velocity $\mathbf{v}_i$ using relativistic mechanics.

Solution: *Conservation of energy and linear momentum require that the photon absorption process* $i \to a$ *satisfies,*

$$p_i^\mu = \begin{pmatrix} \hbar\omega_i/c + E_i/c \\ \hbar\mathbf{k}_i + \mathbf{p}_i \end{pmatrix} = \begin{pmatrix} E_a/c + E^*/c \\ \mathbf{p}_a \end{pmatrix} = p_a^\mu \ .$$

The resonance frequency for the absorption of a photon of frequency $\omega = ck$ *by an atom traveling at velocity* $\mathbf{v} = \mathbf{p}/m$ *must be calculated relativistically,*

$$\begin{aligned} E^* - \hbar\omega_i = E_i - E_a &= \sqrt{m^2c^4 + c^2p_i^2} - \sqrt{m^2c^4 + c^2p_a^2} \\ &\simeq mc^2\left(1 + \frac{p_i^2}{2m^2c^2}\right) - mc^2\left(1 + \frac{(\hbar\mathbf{k}_i + \mathbf{p}_i)^2}{2m^2c^2}\right) \\ &\simeq -\frac{\hbar^2k_i^2}{2m} - \frac{\hbar\mathbf{k}_i\cdot\mathbf{p}_i}{m} = -\frac{\hbar^2\omega_i^2}{2mc^2} - \hbar\mathbf{k}_i\cdot\mathbf{v}_i \ . \end{aligned}$$

The first correction term accounts for photonic recoil, the second describes the linear Doppler effect.

20.2.6.8 Ex: Recoil- and Doppler-shift upon photon scattering in relativistic mechanics

Derive the expression for the recoil- and Doppler-shift upon the absorption and reemission of a photon of frequency ω_i by an atom with the initial velocity $\mathbf{v}_i$ using relativistic mechanics. Discuss the particular case, $\mathbf{v}_i = 0$.

Solution: *Conservation of energy and linear momentum require that the photon absorption process $i \to a$ and the reemission process $a \to f$ satisfy,*

$$p_i^\mu = \begin{pmatrix} \hbar\omega_i/c + E_i/c \\ \hbar\mathbf{k}_i + \mathbf{p}_i \end{pmatrix} = p_a^\mu = \begin{pmatrix} E_a/c + E^*/c \\ \mathbf{p}_a \end{pmatrix} = p_f^\mu = \begin{pmatrix} \hbar\omega_f/c + E_f/c \\ \hbar\mathbf{k}_f + \mathbf{p}_f \end{pmatrix} ,$$

where E^* is the excitation energy of the atom and,

$$m^2c^2 = (E_i/c)^2 - \mathbf{p}_i^2 = (E_a/c)^2 - \mathbf{p}_a^2 = (E_f/c)^2 - \mathbf{p}_f^2 ,$$

the atom's energy in its rest system. Hence,

$$\hbar\omega_i + \sqrt{m^2c^4 + c^2p_i^2} = \hbar\omega_f + \sqrt{m^2c^4 + c^2p_f^2}$$
$$\hbar\mathbf{k}_i + \mathbf{p}_i = \hbar\mathbf{k}_f + \mathbf{p}_f$$

from which we now aim at calculating the emission frequency ω_f as a function of the scattering angle $\vartheta \equiv \sphericalangle(\mathbf{k}_i, \mathbf{k}_f)$ and the initial atomic momentum $\mathbf{p}_i$in a similar way as we did in Sec. 38.3.1. Defining $\Delta\omega \equiv \omega_f - \omega_i$ and $\Delta\mathbf{k} \equiv \mathbf{k}_f - \mathbf{k}_i$, we get,

$$\hbar\Delta\omega = \sqrt{m^2c^4 + c^2p_i^2} - \sqrt{m^2c^4 + c^2(\mathbf{p}_i - \hbar\Delta\mathbf{k})^2} .$$

Let us consider the particular cases when $p_i = 0$ and introduce the recoil-frequency,

$$\omega_{rec} = \frac{\hbar\omega_i^2}{2mc^2} \simeq \frac{\hbar\omega_f^2}{2mc^2} ,$$

we recover the non-relativistic result (38.40) in first order,

$$\hbar\Delta\omega = mc^2 - \sqrt{m^2c^4 + \hbar^2c^2\Delta\mathbf{k}^2} \simeq -\frac{\hbar^2(\omega_f^2 + \omega_i^2 - 2\omega_f\omega_i\cos\vartheta)}{2mc^2} \simeq 2\omega_{rec}(-1+\cos\vartheta) .$$

20.3 Relativistic electrodynamics

20.3.1 Relativistic current and magnetism

To begin with, we introduce the space-time current density by,

$$\boxed{(j^\mu) \equiv \begin{pmatrix} c\varrho \\ \mathbf{j} \end{pmatrix}} \,. \tag{20.99}$$

This notation allows us to formulate the continuity equation as,

$$\boxed{\partial_\mu j^\mu = 0} \,. \tag{20.100}$$

Example 132 (*Electric charge under Lorentz transformation*): In order to convince ourselves that it makes sense to combine charge density and current as quadri-vectors, we consider a situation in which there are only static charges with density ϱ_0 and has no current: $j_\mu = (c\varrho_0 \; \mathbf{0})$. Now, in an inertial system moving at velocity $\mathbf{v}$, the charge density will appear as a current,

$$(j'^\mu) = (\Lambda^\mu{}_\nu j^\nu) = \begin{pmatrix} \gamma c\varrho_0 \\ -c\gamma\beta\varrho_0 \hat{\mathbf{e}}_z \end{pmatrix} = \begin{pmatrix} \gamma\varrho \\ -\gamma\varrho\mathbf{v} \end{pmatrix} \,.$$

That is, different observers observe different charge densities. The current $-\gamma\varrho\mathbf{v}$ appears due to the motion of the charge being contrary to the motion of the observer. Moreover, as the charge density is defined per unit volume and the volume is compressed due to Lorentz contraction, the observed charge density $\gamma\varrho_0$ appears to be increased.

The observation that a moving charge gives rise to a current is not new. But the fact that we can transform charge into current through a Lorentz transform already points to the close connection between the phenomena of electricity and magnetism in the theory of relativity: moving electric fields must generate magnetic fields. We will study the details of how this happens shortly. But first, let us have a look at a simple example, where we re-derive the magnetic force purely from the Coulomb force and a Lorentz contraction.

Example 133 (*Electric current under Lorentz transform*): We consider a sample of positive charges $+q$ moving along a conducting wire with velocity $+v$ and a sample of negative charges $-q$ moving in opposite direction with velocity $-v$, as shown Fig. 20.7. If the densities n of positive and negative charges is equal, the total charge density vanishes, while the currents add up to $I = 2nAqv$, where A is the cross section of the wire. We now consider a test particle, also carrying a charge q, which moves parallel to the wire at some velocity v_0. This charge does not feel any electrical force, because the wire is neutral, but we know that it experiences a magnetic force. We will now show, how to find an expression for this force without ever invoking the phenomenon of magnetism. The trick is to go to the inertial system S' of the test particle, which means that we have to transform to a velocity v_0. The formula for summing relativistic velocities tells us, that the velocities of the positive and negative charges are now different,

$$v_\pm = \frac{v \mp v_0}{1 \mp v_0 v/c^2} \,.$$

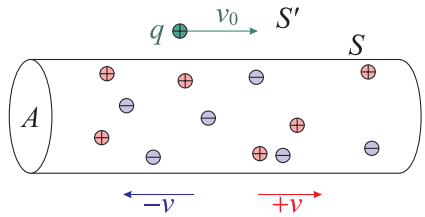

Figure 20.7: Illustration of the relativistic origin of the Lorentz force.

But with this transformation comes a Lorentz contraction modifying the density of the charges. In addition, the different velocities of the positive and negative charges cause that, seen from the system S' (rest frame of the test particle), the wire is no longer neutral. Let us see how this works: First, we introduce the density of positively (negatively) charged particles n_0 in the system S_+ (S_-) in which they are at rest. With this, the charge densities in the lab system S (rest frame of the wire) are,

$$\varrho_\pm = q n_\pm = \gamma_v q n_0 \ .$$

In the system S, the wire is neutral because the positive and negative charges travel at the same velocity, albeit in opposite directions, $\varrho_+ + \varrho_- = 0$. Now, in the system S', the charge densities are,

$$\begin{aligned}\varrho'_\pm = q\gamma_{v_\pm} n_0 &= \frac{1}{\sqrt{1-\left(\frac{v\mp v_0}{c\mp v v_0/c}\right)^2}} q n_0 \\ &= \frac{-c^2 \pm v v_0}{\sqrt{(c^2-v^2)(c^2-v_0^2)}} q n_0 = \left(1 \mp \frac{v_0 v}{c^2}\right)\gamma_{v_0}\gamma_v q n_0 \ ,\end{aligned}$$

Since $v_- > v_+$, we have $n'_- > n'_+$, and the wire carries negative charge. That is, the total charge density in the new system is,

$$\varrho' = q(n'_+ - n'_-) = -\frac{2 v_0 v}{c^2}\gamma_{v_0} q n_\pm \ .$$

But we know that a line of electric charges creates an electric field (using Gauß' law) of,

$$\vec{\mathcal{E}}'(r) = \frac{\varrho' A}{2\pi\varepsilon_0 r}\hat{\mathbf{e}}_r = -\frac{2 v_0 v}{c^2}\gamma_{v_0} q n_\pm \frac{A}{2\pi\varepsilon_0 r}\hat{\mathbf{e}}_r \ ,$$

where r is the radial direction perpendicular to the wire. This means that in its rest frame, the particle experiences a force,

$$F' = q\mathcal{E}'(r) = -v_0\gamma_{v_0}\frac{n_\pm A q^2 v}{\pi\varepsilon_0 c^2 r} \ ,$$

where the negative sign tells us, that the force is in radial direction toward the center of the wire for $v_0 > 0$. But if there is a force in one system, there must also be a force in the other one. Transforming back to the lab system S, we conclude that even when the wire is neutral, there will be a force,

$$F = \frac{F'}{\gamma_{v_0}} = -v_0\frac{n_\pm A q^2 v}{\pi\varepsilon_0 c^2 r} = -v_0 q\frac{\mu_0 I}{2\pi r} \ .$$

But this agrees precisely with the Lorentz force attracting or repelling two neutral current-carrying wires.

This analysis provides an explicit demonstration of how an electric force in one reference system is interpreted as a magnetic force in another. Another surprising observation is the following. We are accustomed to think of Lorentz contraction as an exotic result, which is only important, when we approach the speed of light. However, the electrons traveling on a wire are very slow, taking about an hour to travel a meter! Nevertheless, we can easily detect the magnetic force between two wires which, as we have seen above, can be directly attributed to the length contraction of the electronic density [6].

20.3.2 Electromagnetic potential and tensor

The shape of the *scalar and vector relativistic potentials* (17.104), as expressed by the laws of Coulomb and Biot-Savart, suggests their combination to a quadri-vector,

$$\boxed{(A^\mu) \equiv \begin{pmatrix} \frac{1}{c}\Phi \\ \mathbf{A} \end{pmatrix}} \,. \tag{20.101}$$

with this the *gauge transform* defined in (17.85) adopts the form,

$$\boxed{A^\mu \to A^\mu - \partial^\mu \chi} \,. \tag{20.102}$$

In particular, the *Lorentz gauge* (17.86) becomes,

$$\boxed{\partial_\mu A^\mu = 0} \,. \tag{20.103}$$

Now, let us have a look at the following antisymmetric construction,

$$\boxed{F^{\mu\nu} \equiv \partial^\mu A^\nu - \partial^\nu A^\mu} \,. \tag{20.104}$$

Obviously, this tensor is invariant under gauge transformation, since,

$$F^{\mu\nu} \to \partial^\mu (A^\nu - \partial^\nu \chi) - \partial^\nu (A^\mu - \partial^\mu \chi) = F^{\mu\nu} - \partial^\mu \partial^\nu \chi + \partial^\nu \partial^\mu \chi \,. \tag{20.105}$$

which already suggests, that the components of $F^{\mu\nu}$ have something to do with electromagnetic fields.

In fact, analyzing each component of (20.104) in the light of the equations (17.78), we find the so-called *electromagnetic field tensor*,

$$\check{F} = (F^{\mu\nu}) = \begin{pmatrix} 0 & -\frac{1}{c}\mathcal{E}_x & -\frac{1}{c}\mathcal{E}_y & -\frac{1}{c}\mathcal{E}_z \\ \frac{1}{c}\mathcal{E}_x & 0 & -\mathcal{B}_z & \mathcal{B}_y \\ \frac{1}{c}\mathcal{E}_y & \mathcal{B}_z & 0 & -\mathcal{B}_x \\ \frac{1}{c}\mathcal{E}_z & -\mathcal{B}_y & \mathcal{B}_x & 0 \end{pmatrix} = \begin{pmatrix} 0 & -\frac{1}{c}\vec{\mathcal{E}} \\ \frac{1}{c}\vec{\mathcal{E}} & (-\epsilon_{mnk}\mathcal{B}_k) \end{pmatrix} \,. \tag{20.106}$$

where ϵ_{mnk} it is the Levi-Civita tensor.

[6] The above discussion needs a small adjustment for real wires. In the rest frame of the wire the positive charges, which are ions, are fixed while the electrons move. According to the above explanation, we might think that this will lead to an imbalance of the charge densities. But this is not correct. The current is due to electrons injected by the battery into one end of the battery and drained at the other end in such a way, that the wire remains neutral in the rest frame, with the electron density accurately compensating the ionic density. In contrast, if we moved to a system in which ions and electrons had equal and opposite speeds, the wire would appear charged.

20.3.2.1 Maxwell's equations

The dual tensor is,

$$\check{\mathcal{F}} = (\mathcal{F}^{\mu\nu}) = (\tfrac{1}{2}\epsilon^{\mu\nu\alpha\beta}F_{\alpha\beta}) = \begin{pmatrix} 0 & -\mathcal{B}_x & -\mathcal{B}_y & -\mathcal{B}_z \\ \mathcal{B}_x & 0 & \frac{1}{c}\mathcal{E}_z & -\frac{1}{c}\mathcal{E}_y \\ \mathcal{B}_y & -\frac{1}{c}\mathcal{E}_z & 0 & \frac{1}{c}\mathcal{E}_x \\ \mathcal{B}_z & \frac{1}{c}\mathcal{E}_y & -\frac{1}{c}\mathcal{E}_x & 0 \end{pmatrix} = \begin{pmatrix} 0 & -\vec{\mathcal{B}} \\ \vec{\mathcal{B}} & (\frac{1}{c}\epsilon_{mnk}\mathcal{E}_k) \end{pmatrix} . \tag{20.107}$$

The spatio-temporal *Maxwell equations* are written,

$$\boxed{\partial_\mu F^{\mu\nu} = \mu_0 j^\nu \quad , \quad \partial_\mu \mathcal{F}^{\mu\nu} = 0} \, . \tag{20.108}$$

The first space-time Maxwell equation incorporates the familiar form of Maxwell's first and third equations,

$$\begin{aligned} (\partial_\mu F^{\mu\nu}) &= \begin{pmatrix} \frac{\partial}{c\partial t} & \nabla \end{pmatrix} \begin{pmatrix} 0 & -\frac{1}{c}\vec{\mathcal{E}} \\ \frac{1}{c}\vec{\mathcal{E}} & (-\epsilon_{mnk}\mathcal{B}_k) \end{pmatrix} = \begin{pmatrix} \frac{1}{c}\nabla\cdot\vec{\mathcal{E}} \\ -\frac{1}{c^2}\frac{\partial}{\partial t}\vec{\mathcal{E}} - \nabla\cdot(\epsilon_{mnk}B_k) \end{pmatrix}^\intercal \\ &= \begin{pmatrix} \frac{1}{c}\nabla\cdot\vec{\mathcal{E}} \\ -\frac{1}{c^2}\frac{\partial}{\partial t}\vec{\mathcal{E}} + \left(\epsilon_{mkn}\frac{\partial}{\partial x^m}\mathcal{B}_k\right) \end{pmatrix}^\intercal = \begin{pmatrix} \frac{1}{c}\nabla\cdot\vec{\mathcal{E}} \\ -\frac{1}{c^2}\frac{\partial}{\partial t}\vec{\mathcal{E}} + \nabla\times\vec{\mathcal{B}} \end{pmatrix}^\intercal = \mu_0 \begin{pmatrix} c\rho \\ \mathbf{j} \end{pmatrix}^\intercal = (\mu_0 j^\nu) \, , \end{aligned} \tag{20.109}$$

using the definition of the vector product,

$$(\mathbf{a}\times\mathbf{b})_k = \epsilon_{mnk}a_m b_n \, . \tag{20.110}$$

The second space-time Maxwell equation incorporates Maxwell's second and fourth equations. With the definition of the Levi-Civita tensor, we can rewrite the equation as,

$$\epsilon^{\mu\nu\kappa\lambda}\partial_\kappa F_{\mu\nu} = \partial_\kappa F_{\mu\nu} + \partial_\mu F_{\nu\kappa} + \partial_\nu F_{\kappa\mu} = 0 \, . \tag{20.111}$$

This form satisfies the requirement of cyclical permutability and also takes into account the fact, that all indexes must be different. If two indexes are equal, for example, $\mu = \kappa$, we would have $\partial_\kappa F_{\mu\mu} + \partial_\mu F_{\mu\kappa} + \partial_\mu F_{\kappa\mu}$. This expression is certainly zero because the field tensor is antisymmetric, $F^{\mu\nu} = -F^{\nu\mu}$.

20.3.3 Lorentz transformation of electromagnetic fields

The rapid motion of the electron within the electrostatic field $\vec{\mathcal{E}}$ of the nucleus produces, according to the theory of relativity, a magnetic field $\vec{\mathcal{B}}'$ in the reference frame of the electron. In atomic physics [7] we learn that this field can interact with the spin of the electron, thus giving rise to a considerable energy shift called the fine structure of the atomic spectrum. We calculate the interaction energy in the following.

[7] See script on *Quantum mechanics* (2023).

In the relativistic mechanics defined by the metric (20.3) and the Lorentz transform (20.19) the Maxwell field tensor is given by (20.106). With this we can calculate the field transformed into an inertial system propagating along the z-axis,

$$F'^{\mu\nu} = \Lambda^{\mu}{}_{\alpha} F^{\alpha\beta} \Lambda_{\beta}{}^{\nu} = \begin{pmatrix} 0 & -\frac{\gamma}{c}\mathcal{E}_x + \gamma\beta\mathcal{B}_y & -\frac{\gamma}{c}\mathcal{E}_y - \gamma\beta\mathcal{B}_x & -\frac{1}{c}\mathcal{E}_z \\ \frac{\gamma}{c}\mathcal{E}_x - \gamma\beta\mathcal{B}_y & 0 & -\mathcal{B}_z & -\gamma\frac{\beta}{c}\mathcal{E}_x + \gamma\mathcal{B}_y \\ \frac{\gamma}{c}\mathcal{E}_y + \gamma\beta\mathcal{B}_x & \mathcal{B}_z & 0 & -\gamma\frac{\beta}{c}\mathcal{E}_y - \gamma\mathcal{B}_x \\ \frac{1}{c}\mathcal{E}_z & \gamma\frac{\beta}{c}\mathcal{E}_x - \gamma B_y & \gamma\frac{\beta}{c}\mathcal{E}_y + \gamma B_x & 0 \end{pmatrix} . \tag{20.112}$$

Using $\mathbf{v} = v_z \hat{\mathbf{e}}_z$, that is $\beta_x = 0 = \beta_y$ and $\beta_z = \beta$, we find,

$$\vec{\mathcal{E}}' = \begin{pmatrix} \mathcal{E}'_x \\ \mathcal{E}'_y \\ \mathcal{E}'_z \end{pmatrix} = \begin{pmatrix} \gamma\mathcal{E}_x - \beta_z c\gamma\mathcal{B}_y \\ \gamma\mathcal{E}_y + \beta_z c\gamma\mathcal{B}_x \\ \mathcal{E}_z \end{pmatrix} = \begin{pmatrix} \gamma\mathcal{E}_x + \gamma c\beta_y\mathcal{B}_z - \gamma c\beta_z\mathcal{B}_y - \frac{\gamma^2}{\gamma+1}\beta_x\vec{\beta}\cdot\mathcal{E} \\ \gamma\mathcal{E}_y + \gamma c\beta_z\mathcal{B}_x - \gamma c\beta_x\mathcal{B}_z - \frac{\gamma^2}{\gamma+1}\beta_y\vec{\beta}\cdot\mathcal{E} \\ \gamma\mathcal{E}_z + \gamma c\beta_x\mathcal{B}_y - \gamma c\beta_y\mathcal{B}_x - \frac{\gamma^2}{\gamma+1}\beta_z\vec{\beta}\cdot\mathcal{E} \end{pmatrix} \tag{20.113}$$

$$\vec{\mathcal{B}}' = \begin{pmatrix} \mathcal{B}'_x \\ \mathcal{B}'_y \\ \mathcal{B}'_z \end{pmatrix} = \begin{pmatrix} \gamma\mathcal{B}_x + \frac{\beta_z}{c}\gamma\mathcal{E}_y \\ \gamma\mathcal{B}_y - \frac{\beta_z}{c}\gamma\mathcal{E}_x \\ \mathcal{B}_z \end{pmatrix} = \begin{pmatrix} \gamma\mathcal{B}_x - \gamma\frac{\beta_y}{c}\mathcal{E}_z + \gamma\frac{\beta_z}{c}\mathcal{E}_y - \frac{\gamma^2}{\gamma+1}\beta_x\vec{\beta}\cdot\mathcal{B} \\ \gamma\mathcal{B}_y - \gamma\frac{\beta_z}{c}\mathcal{E}_x + \gamma\frac{\beta_x}{c}\mathcal{E}_z - \frac{\gamma^2}{\gamma+1}\beta_y\vec{\beta}\cdot\mathcal{B} \\ \gamma\mathcal{B}_z - \gamma\frac{\beta_x}{c}\mathcal{E}_y + \gamma\frac{\beta_y}{c}\mathcal{E}_x - \frac{\gamma^2}{\gamma+1}\beta_z\vec{\beta}\cdot\mathcal{B} \end{pmatrix} .$$

yielding,

$$\boxed{\begin{aligned} \vec{\mathcal{E}}' &= \gamma(\vec{\mathcal{E}} + c\vec{\beta}\times\vec{\mathcal{B}}) - \frac{\gamma^2}{\gamma+1}\vec{\beta}(\vec{\beta}\cdot\vec{\mathcal{E}}) \\ \vec{\mathcal{B}}' &= \gamma(\vec{\mathcal{B}} - \tfrac{1}{c}\vec{\beta}\times\vec{\mathcal{E}}) - \frac{\gamma^2}{\gamma+1}\vec{\beta}(\vec{\beta}\cdot\vec{\mathcal{B}}) \end{aligned}} . \tag{20.114}$$

Although having been derived for the special case $\vec{\beta} = \beta\hat{\mathbf{e}}_z$, this result holds for arbitrary velocities, $\gamma \to 1$, in any direction $\vec{\beta}$. At lower velocities the result simplifies to,

$$\vec{\mathcal{E}}' \simeq \vec{\mathcal{E}} + c\vec{\beta}\times\vec{\mathcal{B}} \qquad \text{and} \qquad \vec{\mathcal{B}}' = \vec{\mathcal{B}} - \tfrac{1}{c}\vec{\beta}\times\vec{\mathcal{E}} . \tag{20.115}$$

The first of these equations is the Coulomb-Lorentz force: In the charge's rest frame the Lorentz part of the force has to disappear. The second equation becomes important only for relativistic velocities. Let us consider, for example, the orbital motion of an electron within the Colombian field generated by a proton. From the point of view of the proton, the motion of the electron corresponds to a circular current producing a magnetic field in the place of the proton, which can be approximated to first order in v/c by [8],

$$\vec{\mathcal{B}}' \simeq -\frac{\mathbf{v}}{c^2}\times\vec{\mathcal{E}} . \tag{20.116}$$

We conclude that magnetism can be seen as a relativistic electrical phenomenon. Do the Exc. 20.3.6.2.

[8] Note, however, that this derivation does not account for the rotation of electrons reference system giving rise to the so-called Thomas precession.

20.3.3.1 Lorentz force

The spatio-temporal *Lorentz force* is,

$$\boxed{K^\mu = \frac{dp^\mu}{d\tau} = qF^{\mu\nu}u_\nu} \,, \tag{20.117}$$

using the definition of the proper velocity (20.80) and of the proper momentum (20.85). Being covariant it is a Minkowski force of the type (20.97). Extracting the spatial components,

$$\mathbf{F} = \frac{d\mathbf{p}}{dt} = \frac{d\mathbf{p}}{\gamma d\tau} = q(\vec{\mathcal{E}} + \mathbf{v} \times \vec{\mathcal{B}}) \,, \tag{20.118}$$

Remembering that $\mathbf{p} = m\gamma\mathbf{v}$ is the relativistic momentum.

The temporal component of the Lorentz force,

$$\frac{dE/c}{dt} = \frac{dE/c}{\gamma d\tau} = \frac{q}{c}\vec{\mathcal{E}} \cdot \mathbf{v} \,, \tag{20.119}$$

simply informs us, that the kinetic energy $m\gamma c^2 - mc^2$ increases under the action of work.

The spatio-temporal *Lorentz force density* is,

$$\boxed{f^u = F^{\mu\nu}j_\nu} \,. \tag{20.120}$$

From this we obtain the equations,

$$\begin{aligned} f^u = F^{\mu\nu}j_\nu &= \begin{pmatrix} 0 & -\frac{1}{c}\vec{\mathcal{E}} \\ \frac{1}{c}\vec{\mathcal{E}} & (-\epsilon_{mnk}\mathcal{B}_k) \end{pmatrix} \begin{pmatrix} c\varrho \\ \mathbf{j} \end{pmatrix} = \begin{pmatrix} -\frac{1}{c}\vec{\mathcal{E}} \cdot \mathbf{j} \\ \varrho\vec{\mathcal{E}} - (\epsilon_{mnk}j_m\mathcal{B}_k) \end{pmatrix} \\ &= \begin{pmatrix} -\frac{1}{c}\vec{\mathcal{E}} \cdot \mathbf{j} \\ \varrho\vec{\mathcal{E}} + \mathbf{j} \times \vec{\mathcal{B}} \end{pmatrix} = \begin{pmatrix} \frac{1}{c}P \\ \mathbf{f} \end{pmatrix} \,. \end{aligned} \tag{20.121}$$

20.3.4 Energy and momentum tensor

The meaning of the 4-dimensional energy-momentum tensor is illustrated with the following matrix,

$$T^{\alpha\beta} = \begin{pmatrix} density & flux & flux & flux \\ flux & pressure & shear & shear \\ fluxo & shear & pressure & shear \\ flux & shear & shear & pressure \end{pmatrix} \,. \tag{20.122}$$

The *Maxwell stress tensor* for an electromagnetic field in the absence of sources is defined by,

$$T^{\mu\nu} = \frac{1}{\mu_0}\left(F^\mu_{\ \alpha}F^{\alpha\nu} + \frac{1}{4}F_{\alpha\beta}F^{\alpha\beta}g^{\mu\nu}\right) \,. \tag{20.123}$$

In matrix notation this gives,

$$(T^{\mu\nu}) = \tfrac{1}{\mu_0}\left(F^{\mu\gamma}g_{\gamma\alpha}F^{\alpha\nu} + \tfrac{1}{4}g_{\alpha\gamma}F^{\gamma\delta}g_{\delta\beta}F^{\alpha\beta}g^{\mu\nu}\right) = \tfrac{1}{\mu_0}\check{F}\check{g}\check{F} + \tfrac{1}{4\mu_0}\left\|\check{F}(\check{g}\check{F}\check{g})\right\|\check{g} \tag{20.124}$$

$$= \begin{pmatrix} u & \frac{1}{c}\vec{\mathcal{S}} \\ \frac{1}{c}\vec{\mathcal{S}} & -(T_{mn}) \end{pmatrix}$$

$$= \begin{pmatrix} \varepsilon_0\mathcal{E}^2 & \frac{1}{c}\mathcal{S}_x & \frac{1}{c}\mathcal{S}_y & \frac{1}{c}\mathcal{S}_z \\ \frac{1}{c}\mathcal{S}_x & -\varepsilon_0\mathcal{E}_x^2 - \frac{1}{\mu_0}\mathcal{B}_x^2 + \frac{1}{\mu_0}\mathcal{B}^2 & -\varepsilon_0\mathcal{E}_x\mathcal{E}_y - \frac{1}{\mu_0}\mathcal{B}_y\mathcal{B}_x & -\varepsilon_0\mathcal{E}_x\mathcal{E}_z - \frac{1}{\mu_0}\mathcal{B}_z\mathcal{B}_x \\ \frac{1}{c}\mathcal{S}_y & -\varepsilon_0\mathcal{E}_x\mathcal{E}_y - \frac{1}{\mu_0}\mathcal{B}_y\mathcal{B}_x & -\varepsilon_0\mathcal{E}_y^2 - \frac{1}{\mu_0}\mathcal{B}_y^2 + \frac{1}{\mu_0}\mathcal{B}^2 & -\varepsilon_0\mathcal{E}_y\mathcal{E}_z - \frac{1}{\mu_0}\mathcal{B}_z\mathcal{B}_y \\ \frac{1}{c}\mathcal{S}_z & -\varepsilon_0\mathcal{E}_x\mathcal{E}_z - \frac{1}{\mu_0}\mathcal{B}_z\mathcal{B}_x & -\varepsilon_0\mathcal{E}_y\mathcal{E}_z - \frac{1}{\mu_0}\mathcal{B}_z\mathcal{B}_y & -\varepsilon_0\mathcal{E}_z^2 - \frac{1}{\mu_0}\mathcal{B}_z^2 + \frac{1}{\mu_0}\mathcal{B}^2 \end{pmatrix}$$
$$+ \left(\tfrac{\varepsilon_0}{2}\mathcal{E}^2 - \tfrac{1}{2\mu_0}\mathcal{B}^2\right)(g^{\mu\nu}) \ ,$$

with the energy density $u = \frac{\varepsilon_0}{2}\mathcal{E}^2 + \frac{1}{2\mu_0}\mathcal{B}^2$, the Poynting vector $\vec{\mathcal{S}} = \frac{1}{\mu_0}\vec{\mathcal{E}} \times \vec{\mathcal{B}}$, the Maxwell stress tensor $\overleftrightarrow{\mathbf{T}} = \varepsilon_0\mathcal{E}_m\mathcal{E}_n + \frac{1}{\mu_0}\mathcal{B}_m\mathcal{B}_n - u\delta_{mn}$.

20.3.4.1 Energy and momentum conservation

Using the space-time formalism the energy and momentum conservation laws can be summarized by,

$$f^\mu + \partial_\nu T^{\mu\nu} = 0 \qquad \text{and} \qquad T^{\mu\nu} = T^{\nu\mu} \ . \tag{20.125}$$

This can be seen by applying Maxwell's equations,

$$F^{\mu\nu}j_v + \tfrac{1}{\mu_0}\partial_\nu\left(F^\mu{}_\alpha F^{\alpha\nu} + \tfrac{1}{4}F_{\alpha\beta}F^{\alpha\beta}g^{\mu\nu}\right) = 0 \ . \tag{20.126}$$

In matrix notation we obtain,

$$\begin{pmatrix} 0 & -\frac{1}{c}\vec{\mathcal{E}} \\ \frac{1}{c}\vec{\mathcal{E}} & -(\epsilon_{mnk}\mathcal{B}_k) \end{pmatrix} + \begin{pmatrix} \frac{\partial}{c\partial t}u + \frac{1}{c}\nabla\cdot\vec{\mathcal{S}} \\ \varepsilon_0\mu_0\frac{\partial}{\partial t}\vec{\mathcal{S}} - \nabla(T_{mn}) \end{pmatrix} = 0 \ , \tag{20.127}$$

and therefore,

$$\left(P/c \quad \mathbf{f}\right) + \left(\tfrac{\partial}{c\partial t} \quad \nabla\right)\begin{pmatrix} u & \frac{1}{c}\vec{\mathcal{S}} \\ \frac{1}{c}\vec{\mathcal{S}} & -(T_{mn}) \end{pmatrix} = \begin{pmatrix} \frac{P}{c} + \frac{\partial}{c\partial t}u + \frac{1}{c}\nabla\cdot\vec{\mathcal{S}} \\ \mathbf{f} + \frac{1}{c}\frac{\partial}{c\partial t}\vec{\mathcal{S}} - \nabla(T_{mn}) \end{pmatrix}^{\mathsf{T}} \tag{20.128}$$

$$= \begin{pmatrix} -\frac{1}{c}\mathbf{j}\cdot\vec{\mathcal{E}} + \frac{\partial}{c\partial t}u + \frac{1}{c}\nabla\cdot\vec{\mathcal{S}} \\ \rho\vec{\mathcal{E}} + \mathbf{j}\times\vec{\mathcal{B}} + \varepsilon_0\mu_0\frac{\partial}{\partial t}\vec{\mathcal{S}} - \nabla(T_{mn}) \end{pmatrix}^{\mathsf{T}} = 0 \ .$$

20.3.4.2 Properties of the energy and momentum tensor

Note however, that in a dielectric medium, the matrix elements can be decomposed into separate contributions of the radiation field and the medium. Taken by parts the contributions do not necessarily satisfy the symmetry requirements [9].

[9] See the Abraham-Minkowski controversy.

Defining the angular momentum density of the shear via,

$$M^{\mu\nu g} = T^{\mu\nu}x^g - T^{\mu g}x^\nu \ . \tag{20.129}$$

Conservation of angular momentum means,

$$\partial_\mu M^{\mu\nu g} = 0 \ . \tag{20.130}$$

20.3.5 Solution of the covariant wave equation

Inserting into Maxwell's equations (20.108) the representation of the fields in terms of potentials (20.104), we calculate,

$$\mu_0 j^\mu = \partial_\mu F^{\mu\nu} = \partial_\mu(\partial^\mu A^\nu - \partial^\nu A^\mu) = \Box A^\nu + \partial^\nu \underbrace{(\partial_\mu A^\mu)}_{\to 0} \ . \tag{20.131}$$

The second term disappears in the Lorentz gauge (20.103). Then, the inhomogeneous wave equation is,

$$\boxed{\Box A^\mu = \mu_0 j^\mu} \ . \tag{20.132}$$

Analogously to the three-dimensional Green function (17.99) we can define a four-dimensional one,

$$\Box D(x) \equiv \delta^{(4)}(x) \tag{20.133}$$

with $x = r - r'$. With the representation of the Dirac function,

$$\delta^{(4)}(x) = \tfrac{1}{(2\pi)^4} \int d^4k e^{-\imath k\cdot x} \ , \tag{20.134}$$

where $k \cdot x = k^\mu x_\mu = \omega t - \mathbf{k}\cdot\mathbf{r}$, and the Fourier transform of the Green function,

$$D(x) = \tfrac{1}{(2\pi)^4} \int d^4k \tilde{D}(k) e^{-\imath k\cdot x} \ , \tag{20.135}$$

the equation (20.132) becomes,

$$\begin{aligned}\left[\frac{1}{c^2}\frac{\partial^2}{\partial t^2} - \nabla^2\right] \frac{1}{(2\pi)^4} \int d^4k \tilde{D}(k) e^{-\imath k\cdot x} &= \frac{1}{(2\pi)^4} \int d^4k \tilde{D}(k) \left(-\frac{\omega^2}{c^2} + \mathbf{k}^2\right) e^{-\imath k\cdot x} \\ &= \frac{1}{(2\pi)^4} \int d^4k e^{-\imath k\cdot x} = \delta^{(4)}(x) \ , \end{aligned} \tag{20.136}$$

that is,

$$\tilde{D}(k) = -\frac{1}{k\cdot k} \ . \tag{20.137}$$

With this, the Green function becomes,

$$D(x) = \tfrac{-1}{(2\pi)^4} \int d^4k \frac{e^{-\imath k\cdot x}}{k\cdot k} \ . \tag{20.138}$$

The integral can be solved by contour integration [659], yielding,

$$D_{r,a}(r - r') = \tfrac{1}{2\pi}\theta(\pm ct \mp ct')\delta[(r - r')^2] \ , \tag{20.139}$$

where the index 'r' refers to *retarded* and 'a' to *advanced*. Finally the solution of inhomogeneous wave equation is,

$$\boxed{A^\mu(r) = A^\mu_{r,a}(r) + \mu_0 \int d^4r' D_{r,a}(r-r') j^\mu(r')} \ , \tag{20.140}$$

where $A^\mu_{r,a}(r)$ are the solutions of the homogeneous wave equation for an incoming, respectively, outgoing wave.

The radiation fields are defined by the difference of the incident and outgoing fields. Thus, the vector potential of the radiation is,

$$A^\mu_{rad}(r) = A^\mu_{out}(r) - A^\mu_{in}(r) = \mu_0 \int d^4r' D(r-r') j^\mu(r') \ , \tag{20.141}$$

with $D(x) \equiv D_r(x) - D_a(x)$.

We can generalize the parametrization of 4-current by,

$$j^\mu(r) = ec \int d\tau u^\mu(\tau) \delta^{(4)}[r - r'(\tau)] \ . \tag{20.142}$$

By inserting this current into (20.140) we obtain the Liénard-Wiechert potentials.

20.3.6 Exercises

20.3.6.1 Ex: Motion in constant fields

In the Newtonian world, electric fields accelerate particles on straight lines and magnetic fields make the particles move in circles. Here, we will re-analyze the Coulomb-Lorentz force in the relativistic framework. The force remains the same, but the momentum is now $\mathbf{p} = m\gamma\mathbf{u}$.
a. Consider a constant electric field $\vec{\mathcal{E}} = \mathcal{E}\hat{\mathbf{e}}_x$ without magnetic field.
b. Consider a constant magnetic field $\vec{\mathcal{B}} = \mathcal{B}\hat{\mathbf{e}}_z$ without electric field.

Solution: *a. The equation of motion for a charged particle with velocity* $\mathbf{u} = (u, 0, 0)$ *is,*

$$m\frac{d(\gamma u)}{dt} = q\mathcal{E} \qquad \Longrightarrow \qquad m\gamma u = q\mathcal{E}t \ ,$$

where we assume implicitly, that the particle starts at rest at $t = 0$*. Reorganizing, we get,*

$$u = \frac{dx}{dt} = \frac{q\mathcal{E}t}{\sqrt{m^2 + q^2\mathcal{E}^2t^2/c^2}} \overset{t\to\infty}{\longrightarrow} c \ .$$

If the particle starts at the origin, we have,

$$x = \frac{mc^2}{eQ}\left(\sqrt{1 + \frac{q^2\mathcal{E}^2t^2}{m^2c^2}} - 1\right) \ .$$

At the beginning, when the velocities are not very high, yet, this reduces to,

$$mx \simeq \tfrac{1}{2}q\mathcal{E}t^2 + \ldots \ ,$$

which is the usual non-relativistic result for particles undergoing a constant acceleration on a straight line.
b. Now, let's turn off the electric field and look at the case of the constant magnetic field $\vec{\mathcal{B}} = \mathcal{B}\hat{\mathbf{e}}_z$. *In the non-relativistic world we know that the particles rotate with the cyclotron frequency* $\omega = q\mathcal{B}/m$. *Looking at the temporal component of the force equation, we find, in the absence of an electric field,*

$$\frac{dP^0}{d\tau} = 0 \ .$$

This tells us that, as in the classical world, magnetic fields do not do work *in relativistic situations. We conclude, then, that the energy* $E = m\gamma c^2$, *is constant. Consequently, the (magnitude) of the velocity remains constant. In other words, the velocity, and therefore the position, continue to rotate in circles. The equation of motion is now,*

$$m\frac{d(\gamma\mathbf{u})}{dt} = q\mathbf{u} \times \vec{\mathcal{B}} \ .$$

Since γ *is constant, the equation adopts the same form as in the non-relativistic case and the solutions are circles. The only difference is, that the frequency with which the particle moves on a circle, now depends on how fast the particle is moving,*

$$\omega = \frac{q\mathcal{B}}{m\gamma} \ .$$

We can interpret this as being due to the relativistic increase of the mass of the moving particle.
So far, we have analyzed situations, where $\vec{\mathcal{E}} = 0$ *or* $\vec{\mathcal{B}} = 0$. *On the other hand, we have already seen that* $\vec{\mathcal{E}}\cdot\vec{\mathcal{B}} = 0$ *and* $\vec{\mathcal{E}}^2 - \vec{\mathcal{B}}^2$ *are two Lorentz-invariant quantities. This means that the solutions described above can be generalized to apply to any situation, where* $\vec{\mathcal{E}}\cdot\vec{\mathcal{B}} = 0$ *and* $\vec{\mathcal{E}}^2 - \vec{\mathcal{B}}^2$ *is* > 0 *or* < 0.

20.3.6.2 Ex: Electric and magnetic dipole moment of moving dipoles

The electric dipole moment $\mathbf{d}$ and the magnetic dipole moment $\vec{\mu}$ of a particle in its rest frame will appear in a lab frame through which the particle is moving with velocity $\mathbf{v}$ as,

$$\boxed{\mathbf{d}' = \mathbf{d} + \tfrac{1}{c^2}\mathbf{v}\times\vec{\mu} \qquad \text{and} \qquad \vec{\mu}' = \vec{\mu} - \tfrac{1}{2}\mathbf{v}\times\mathbf{d}} \ .$$

Verify this for a particle with a purely magnetic dipole moment via a Lorentz transform using by the following procedure:
a. Derive the Lorentz transform from a rest frame S, flying through the lab frame S' into arbitrary direction $\vec{\beta}$, back into the lab frame for (i) the charge-current density quadrivector, (ii) the time-position quadrivector, and (iii) a volume element using the generalized Lorentz boost (20.60).
b. Parametrize the electric and magnetic dipole moment by appropriate charge and current densities, e.g. assuming two equal charges dislocated in opposite directions of the z-axis, respectively, a circular current in the xy-plane.
c. Apply the Lorentz transform to the electric dipole moment by transforming all

quantities of the defining formula. (It is convenient to choose $\beta_y = 0$.)

Solution: *a. The Lorentz transform of the charge-current density quadrivector into a frame moving S' into arbitrary direction $\vec{\beta}$ is given by [448],*

$$\begin{pmatrix} c\varrho' \\ \mathbf{j}' \end{pmatrix} = (\Lambda^\mu_\nu)^{-1} \begin{pmatrix} c\varrho \\ \mathbf{j} \end{pmatrix} = \begin{pmatrix} \gamma & \gamma\vec{\beta} \\ \gamma\vec{\beta} & \mathbb{I}_3 + (\gamma-1)\hat{\beta}_i\hat{\beta}_j \end{pmatrix} \begin{pmatrix} c\varrho \\ \mathbf{j} \end{pmatrix}$$
$$= \begin{pmatrix} \gamma c\varrho + \gamma\vec{\beta}\cdot\mathbf{j} \\ \gamma c\vec{\beta}\varrho + \left(\mathbf{j} + \frac{\gamma-1}{\beta^2}\beta_i\beta_j\right) j_j \end{pmatrix} = \begin{pmatrix} \gamma c\varrho + \gamma\vec{\beta}\cdot\mathbf{j} \\ \mathbf{j} + \left(\gamma c\varrho + \frac{\gamma-1}{\beta^2}\vec{\beta}\cdot\mathbf{j}\right)\vec{\beta} \end{pmatrix} .$$

The same transformation of the position vector yields,

$$\begin{pmatrix} ct' \\ \mathbf{r}' \end{pmatrix} = (\Lambda^\mu_\nu)^{-1} \begin{pmatrix} ct \\ \mathbf{r} \end{pmatrix} = \begin{pmatrix} \gamma ct + \gamma\vec{\beta}\cdot\mathbf{r} \\ \mathbf{r} + \left(\gamma ct + \frac{\gamma-1}{\beta^2}\vec{\beta}\cdot\mathbf{r}\right)\vec{\beta} \end{pmatrix} .$$

Evaluating in the lab frame at $t' = 0$,

$$\mathbf{r}' = \mathbf{r} + \left(\gamma ct + \frac{\gamma-1}{\beta^2}\vec{\beta}\cdot\mathbf{r}\right)\vec{\beta} = \mathbf{r} + \left(-\gamma\vec{\beta}\cdot\mathbf{r} + \frac{\gamma-1}{\beta^2}\vec{\beta}\cdot\mathbf{r}\right)\vec{\beta} = \mathbf{r} - \frac{\gamma}{\gamma+1}\vec{\beta}\cdot\mathbf{r}\vec{\beta} .$$

And a volume element will always be contracted by,

$$d^3r' = \frac{1}{\gamma}d^3r .$$

b. For convenience, we assume that the electric dipole moment $\mathbf{d}$ is generated by two point charges displaced from the center along the z-axis by an amount b, and the magnetic dipole moment $\vec{\mu}$ is generated by a current line in the xy-plane at a distance R from the center,

$$\varrho(\mathbf{r}) = q\delta^3(\mathbf{r}) + \frac{d}{2b}[\delta^3(\mathbf{r}-b\hat{\mathbf{e}}_z) - \delta^3(\mathbf{r}+b\hat{\mathbf{e}}_z)] \quad \textit{and} \quad \mathbf{j}(\mathbf{r}) = \frac{1}{\pi R^4}\vec{\mu}\times\mathbf{r}\,\delta(\theta-\tfrac{\pi}{2})\delta(r-R) .$$

With this it is easy to verify the electric and magnetic dipole moments,

$$\mathbf{d} \equiv \int \mathbf{r}\varrho(\mathbf{r})d^3r \qquad \textit{and} \qquad \vec{\mu} \equiv \tfrac{1}{2}\int \mathbf{r}\times\mathbf{j}(\mathbf{r})d^3r ,$$

as can easily be verified.
c. The transformed dipole moment now reads, assuming $\varrho = 0$,

$$\mathbf{d}' = \int \mathbf{r}'\varrho' d^3r' = \int \left[\mathbf{r} - \frac{\gamma}{\gamma+1}(\vec{\beta}\cdot\mathbf{r})\vec{\beta}\right]\left[\gamma\vec{\beta}\cdot\mathbf{j}\right]\frac{1}{\gamma}d^3r$$
$$= \frac{1}{\pi R^4}\int \left[\mathbf{r} - \frac{\gamma}{\gamma+1}(\vec{\beta}\cdot\mathbf{r})\vec{\beta}\right]\left[\gamma\vec{\beta}\cdot(\vec{\mu}\times\mathbf{r})\delta(\theta-\tfrac{\pi}{2})\delta(r-R)\right]\frac{1}{\gamma}r^2\sin\theta dr d\theta d\phi ,$$

after inserting the current density parametrization. With,

$$\vec{\beta} = \beta_x\hat{\mathbf{e}}_x + \beta_z\hat{\mathbf{e}}_z \quad , \quad \vec{\mu} = \mu\hat{\mathbf{e}}_z \quad , \quad \mathbf{r} = r\hat{\mathbf{e}}_r \quad , \quad \mathbf{R} = R\hat{\mathbf{e}}_x\cos\phi + R\hat{\mathbf{e}}_z\sin\phi ,$$

we calculate,

$$\mathbf{d}' = \frac{-\beta_x \mu}{\pi R^4} \int \begin{pmatrix} \sin\theta\cos\phi - \frac{\gamma\beta_x}{\gamma+1}\left(\beta_x \sin\theta\cos\phi + \beta_z\cos\theta\right) \\ \sin\theta\sin\phi \\ \cos\theta - \frac{\gamma\beta_z}{\gamma+1}\left(\beta_x \sin\theta\cos\phi + \beta_z\cos\theta\right) \end{pmatrix} \sin\phi\delta(\theta - \tfrac{\pi}{2})\delta(r-R) r^4 \sin\theta dr d\theta d\phi$$

$$= \frac{-\beta_x \mu}{\pi} \int \begin{pmatrix} \sin\phi\cos\phi - \frac{\gamma}{\gamma+1}\beta_x^2 \sin\phi\cos\phi \\ \sin^2\phi \\ -\frac{\gamma}{\gamma+1}\beta_x\beta_z \sin\phi\cos\phi \end{pmatrix} d\phi = -\beta_x \mu \hat{\mathbf{e}}_y = \tfrac{1}{c}\vec{\beta} \times \vec{\mu} \ .$$

20.4 Lagrangian formulation of electrodynamics

20.4.1 Relation with quantum mechanics

In classical and relativistic mechanics we learn to deal with *masses* and in electrodynamics with *charges* and with fields and electromagnetic waves. We will show in Sec. 20.4.2.1 how electrodynamics can be integrated into the classical and relativistic mechanics by the prescription of *minimal coupling*,

$$\boxed{p^\mu \to p^\mu - qA^\mu} \ . \tag{20.143}$$

Revolutionary discoveries in the early twentieth century culminated in the development of quantum mechanics, where we learned to accept that the microscopic world works differently. On one hand, massive particles have undulating properties; they can diffract and interfere. On the other side, light has corpuscular properties; it consists of indivisible energy packets called *photons*. Fortunately, classical theories can be incorporated into quantum mechanics by canonical procedures called first and second quantization.

20.4.1.1 Treatment of massive particles in quantum mechanics

In quantum mechanics we learn [10] that matter propagates like a scalar wave (in contrast to electromagnetic waves, which are vectorial). Consequently, in quantum mechanics, massive particles are described by wavefunctions obeying wave equations. Slow particles obey the Schrödinger equation, whereas bosonic relativistic particles obey a wave equation called *Klein-Gordon equation* and fermions obey the *Dirac equation*. The Schrödinger and Klein-Gordon equations are obtained from a simple prescription for canonical quantization:

$$\boxed{p^\mu \to \imath\hbar\partial^\mu} \ . \tag{20.144}$$

Obtaining the Dirac equation is a bit more involved.

[10] See script on *Quantum mechanics* (2023).

20.4.1.2 Quantization of the electromagnetic field

We also learn in quantum mechanics [11] that light consists of indivisible energy packets. This fact is taken into account, by dividing space into modes that can be filled with discrete numbers of photons. Each mode is treated as a harmonic oscillator. Quantum field theories explain, how we must quantize non-radiative electric and magnetic fields.

These topics will not be covered in this course.

20.4.2 Classical mechanics of a point particle in a field

For a system with m degrees of freedom specified by generalized coordinates $q_1, .., q_m$ and the generalized velocities $\dot{q}_1, .., \dot{q}_m$ the classical action is determined by the *Lagrangian* $\mathcal{L}(q_i, \dot{q}_i)$ via,

$$\mathcal{S}[q_i, \dot{q}_i] = \int dt \mathcal{L}(q_i, \dot{q}_i, t) \ . \tag{20.145}$$

Thus, the action is a functional of the generalized coordinates. According to Hamilton's *least action principle*, the dynamics of a classical system is described by equations that minimize the action, $\delta\mathcal{S} = 0$. These equations of motion can be expressed by the Lagrangian in the form of *Euler-Lagrange equations*,

$$\frac{d}{dt}\frac{\partial \mathcal{L}}{\partial \dot{q}_i} - \frac{\partial \mathcal{L}}{\partial q_i} = 0 \ . \tag{20.146}$$

The *canonical momentum* is given by equation,

$$p_i(q_i, \dot{q}_i, t) = \frac{\partial \mathcal{L}}{\partial \dot{q}_i} \ , \tag{20.147}$$

and the Hamiltonian is defined by the *Legendre transform*,

$$\mathcal{H}(q_i, p_i) = \dot{q}_i \frac{\partial \mathcal{L}}{\partial \dot{q}_i} - \mathcal{L} = p_i \dot{q}_i - \mathcal{L}(q_i, \dot{q}_i) \ . \tag{20.148}$$

using Einstein's summing convention. Comparing the differential of both sides of this equation,

$$\left[\frac{\partial \mathcal{H}}{\partial q_i} dq_i + \frac{\partial \mathcal{H}}{\partial p_i} dp_i\right] + \frac{\partial \mathcal{H}}{\partial t} = d\mathcal{H} = \left[\dot{q}_i dp_i + p_i d\dot{q}_i - \frac{\partial \mathcal{L}}{\partial q_i} dq_i - \frac{\partial \mathcal{H}}{\partial \dot{q}_i} d\dot{q}_i\right] - \frac{\partial \mathcal{L}}{\partial t} \ , \tag{20.149}$$

we obtain Hamilton's equations of motion,

$$\dot{q}_i = \frac{\partial \mathcal{H}}{\partial p_i} \quad , \quad \dot{p}_i = -\frac{\partial \mathcal{H}}{\partial q_i} \quad , \quad \frac{\partial \mathcal{H}}{\partial t} = -\frac{\partial \mathcal{L}}{\partial t} \ . \tag{20.150}$$

From these equations it follows, that if the Hamiltonian is independent of a particular coordinate q_i, the corresponding moment p_i is constant. For conservative forces, the Lagrangian and the Hamiltonian can be written as $\mathcal{L} = T - V$ and $\mathcal{H} = T + V$, with T the kinetic energy and V the potential energy [12].

[11] See script on *Quantum mechanics* (2023).

[12] Thus, a particle chooses its trajectory in a way to minimize the conversion between kinetic and potential energy.

20.4.2.1 Electrodynamic Lagrangian

So far we have focused on free particles or particles confined by scalar potentials. In what follows, we will address the influence of a magnetic field on a charged particle. Classically, the force on a charged particle in electric and magnetic fields is given by the Lorentz force law and the exerted work by Ohm's law:

$$\frac{dW}{dt} = e\mathbf{v} \times \vec{\mathcal{E}} \qquad \text{and} \qquad \mathbf{F} = q(\vec{\mathcal{E}} + \mathbf{v} \times \vec{\mathcal{B}}) \ , \tag{20.151}$$

where q denotes the charge and v the velocity. In this case, the generalized coordinates $q_i \equiv r_i \equiv (r_1, r_2, r_3)$ are precisely the Cartesian coordinates specifying the position, and $\dot{q}_i = \dot{r}_i = (\dot{r}_1, \dot{r}_2, \dot{r}_3)$ the velocity of the particles. These equations of motion are sufficient to describe the dynamics of a system. The force which depends on the velocity and is associated with the magnetic field is quite different from the conservative forces associated with scalar potentials. Let us now study, how the Lorentz force appears in the Lagrange formulation of classical mechanics.

With revised these foundations, we will return to the problem of the influence of an electromagnetic field on the dynamics of a charged particle. Since the Lorentz force depends on velocity, it can not simply be expressed as a gradient of some potential. However, the classical trajectory of the particle is still specific to the least action principle.

The electric and magnetic fields can be expressed in terms of a scalar and a vector potential as,

$$\vec{\mathcal{E}} = -\nabla\Phi - \partial_t \mathbf{A} \qquad \text{and} \qquad \vec{\mathcal{B}} = \nabla \times \mathbf{A} \ . \tag{20.152}$$

The Lorentz force is,

$$\mathbf{F} = q\left[-\nabla\Phi - \frac{\partial \mathbf{A}}{\partial t} + \mathbf{v} \times (\nabla \times \mathbf{A})\right] \ . \tag{20.153}$$

We now analyze the x-component,

$$\begin{aligned} F_x &= q\left[-\frac{\partial\Phi}{\partial x} - \frac{\partial A_x}{\partial t} + v_y\left(\frac{\partial A_y}{\partial x} - \frac{\partial A_x}{\partial y}\right) - v_z\left(\frac{\partial A_x}{\partial z} - \frac{\partial A_z}{\partial x}\right) + v_x\frac{\partial A_x}{\partial x} - v_x\frac{\partial A_x}{\partial x}\right] \\ &= q\left[-\frac{\partial\Phi}{\partial x} + \mathbf{v}\cdot\frac{\partial \mathbf{A}}{\partial x} - \frac{dA_x}{dt}\right] \ , \end{aligned} \tag{20.154}$$

where we used,

$$\frac{d}{dt} = \frac{\partial}{\partial t} + v_i\frac{\partial}{\partial x_i} \ . \tag{20.155}$$

Since the potentials do not depend on the velocity, we can also write,

$$F_x = q\left[-\frac{\partial\Phi}{\partial x} + \frac{\partial \mathbf{v}\cdot\mathbf{A}}{\partial x} - \frac{d}{dt}\frac{\partial \mathbf{v}\cdot\mathbf{A}}{\partial v_x}\right] = -\frac{\partial U}{\partial x} + \frac{d}{dt}\frac{\partial U}{\partial v_x} \ , \tag{20.156}$$

introducing the generalized potential,

$$U \equiv q\Phi - q\mathbf{A}\cdot\mathbf{v} \ . \tag{20.157}$$

The corresponding Lagrangian takes the form:

$$\boxed{\mathcal{L}(r_i,\dot{r}_i) = \tfrac{m}{2}\dot{\mathbf{r}}^2 - q\Phi + q\dot{\mathbf{r}}\cdot\mathbf{A} = \tfrac{m}{2}\dot{r}_i\dot{r}_i - q\Phi + q\dot{r}_iA_i} \,. \tag{20.158}$$

The important point is that the *canonical momentum*

$$\boxed{p_i = \frac{\partial\mathcal{L}}{\partial\dot{r}_i} = m\dot{r}_i + qA_i} \tag{20.159}$$

is no longer equal to velocity times the mass, $mv_i \neq p_i$, because there is an extra term!

Using the definition of the corresponding Hamiltonian,

$$\begin{aligned}\mathcal{H}(r_i,p_i) &= (m\dot{r}_i + qA_i)\dot{r}_i - \tfrac{m}{2}\dot{r}_i\dot{r}_i + q\Phi - q\sum_i \dot{r}_iA_i \\ &= \left(\tfrac{m}{2}\dot{r}_i + qA_i\right)\dot{r}_i + q\Phi = \tfrac{m}{2}\mathbf{v}^2 + q\Phi \,.\end{aligned} \tag{20.160}$$

Obviously, the Hamiltonian has just the familiar form of the sum of kinetic and potential energies. However, to obtain Hamilton's equations of motion, the Hamiltonian must be expressed only in terms of the coordinates and the canonical momenta, that is,

$$\boxed{\mathcal{H}(r_i,p_i) = \frac{1}{2m}(\mathbf{p} - q\mathbf{A})^2 + q\Phi = qv_j\frac{\partial A_j}{\partial r_i} - q\frac{\partial\Phi}{\partial r_i}} \,. \tag{20.161}$$

Let us now consider Hamilton's equations of motion,

$$\begin{aligned}\dot{r}_i &= \frac{\partial\mathcal{H}}{\partial p_i} = \frac{1}{m}(p_i - qA_i) \\ \dot{p}_i &= -\frac{\partial\mathcal{H}}{\partial r_i} = -\frac{1}{2m}\frac{\partial}{\partial r_i}(p_j - qA_j)^2 - q\frac{\partial\Phi}{\partial r_i} \,.\end{aligned} \tag{20.162}$$

The first equation reproduces the canonical momentum (20.158), while the second gives the Lorentz force. To understand how, we need to remember that dp/dt *is not the acceleration*: The term dependent on $\mathbf{A}$ also varies over time in a rather complicated way, since it is the field seen by the moving particle.

Example 134 (*Lorentz force from the Lagrangian*): Obviously, we can recover the Lorentz force from the Hamiltonian: Differentiating the canonical momentum (20.158),

$$\begin{aligned}m\ddot{r}_i &= -q\dot{A}_i + \dot{p}_i = -q\dot{A}_i - \frac{\partial\mathcal{H}}{\partial r_i} \\ &= -q\dot{A}_i - \frac{\partial}{\partial r_i}q\left(\sum_j v_j\frac{\partial A_j}{\partial r_i} - \frac{\partial\Phi}{\partial r_i}\right) = -q\dot{A}_i + q\nabla_i(\mathbf{A}\cdot\mathbf{v}) - q\nabla_i\Phi \,.\end{aligned}$$

that is,

$$\begin{aligned}m\ddot{\mathbf{r}} &= -q\nabla\Phi + q\mathbf{v}\times(\nabla\times\mathbf{A}) + q(\mathbf{v}\cdot\nabla)\mathbf{A} - q\frac{d\mathbf{A}}{dt} \\ &= -q\nabla\Phi + q\mathbf{v}\times(\nabla\times\mathbf{A}) - q\frac{\partial\mathbf{A}}{\partial t} = q\vec{\mathcal{E}} + q\mathbf{v}\times\vec{\mathcal{B}}\end{aligned}$$

using the rules (20.155) and $\mathbf{v}\times(\nabla\times\mathbf{A}) = \nabla(\mathbf{A}\cdot\mathbf{v}) - (\nabla\cdot\mathbf{v})\mathbf{A}$.

Using the Coulomb gauge $\nabla \cdot \mathbf{A} = 0$ the Coulomb-Lorentz force can be derived from the Lagrangian via the equation (20.158) or from the Hamiltonian via the second equation (20.162).

20.4.3 Generalization to relativistic mechanics

We now want to generalize the Lagrangian treatment of a particle to relativistic mechanics. Not all forces known in classical mechanics can be put into a covariant form. One example is the Newtonian gravitational force, understood as a force acting at a distance, which is incompatible with the theory of relativity. On the other side, electrodynamics is automatically Lorentz-invariant. Therefore, let us discuss the Lagrangian only for two examples: 1. a totally free particle and 2. a particle under the influence of electromagnetic forces.

Analogously to the classical case, we want to derive, from the principle of minimum action (20.145) Euler-Lagrange type equations (20.146). To put the action into a Lorentz-invariant form, we go to the particle's rest frame via $t = \gamma\tau$,

$$\mathcal{S}[r^\mu, u^\mu] = \int \gamma \mathcal{L}(q^\mu, u^\mu, \tau) d\tau \ . \tag{20.163}$$

We note, however, that we must now distinguish co- and contravariant indices to take account of non-Euclidean metrics. Since $\mathcal{S}$ is an invariant scalar, $\gamma\mathcal{L}$ must be an invariant scalar as well. The Euler-Lagrange equations are now,

$$\frac{d}{d\tau}\frac{\partial \mathcal{L}}{\partial u_\mu} - \frac{\partial \mathcal{L}}{\partial x_\mu} = 0 \ . \tag{20.164}$$

The ansatz for the Lagrangian,

$$\mathcal{L} \equiv \tfrac{m}{2} u_\mu u^\mu \tag{20.165}$$

inserted into the Euler-Lagrange equation gives,

$$\frac{d}{d\tau} m u^\mu - 0 = \frac{d}{d\tau} p^\mu = 0 \ , \tag{20.166}$$

which makes sense in the absence of external forces [13].

20.4.3.1 Lagrangian relativistic electrodynamics

We now consider a charged particle interacting with an external electromagnetic field [659]. In relativistic notation the Lorentz force and the Ohm's law (20.145) become [compare (20.117)],

$$\frac{m du^\mu}{d\tau} = q F^{\mu\nu} u_\nu \ , \tag{20.167}$$

where m is the resting mass, τ the proper time in the particle's system, and $(u^\mu) = (\gamma c, \gamma \mathbf{u}) = (p^\mu/m)$ its 4-velocity. Following the classical model (20.157) we can make for the Lagrangian the covariant ansatz [519],

$$\boxed{\mathcal{L} = \mathcal{L}_{free} + \mathcal{L}_{int} = \tfrac{m}{2} u_\mu u^\mu + q u_\mu A^\mu} \ . \tag{20.168}$$

[13] We note, that any ansatz $\mathcal{L}(z) \equiv \mathcal{L}(u_\mu u^\mu)$ satisfying $\partial_z \mathcal{L} = \frac{m}{2}$ is possible. We will show this in Exc. 20.4.5.1.

The canonical momenta are,

$$p_\mu = \frac{\partial \mathcal{L}}{\partial u^\mu} = m u_\mu + q A_\mu \ , \tag{20.169}$$

such that the Euler-Lagrange equations (20.164) result in,

$$\frac{d}{d\tau}(m u_\mu + q A_\mu) - \frac{\partial}{\partial x_\mu}(q u_\nu A^\nu) = 0 \ . \tag{20.170}$$

That is,

$$K_\mu = \frac{d}{d\tau} m u_\mu = \frac{\partial}{\partial x_\mu}(q u_\nu A^\nu) - \frac{d}{d\tau}(q A_\mu) \ , \tag{20.171}$$

which is precisely the Minkowski type Lorentz force.

The total energy is,

$$E_{tot} = c p^0 = c(E + q\Phi) \ , \tag{20.172}$$

where E is the kinetic energy including the rest mass (20.88). We calculate,

$$m^2 u_\mu u^\mu = m^2 c^2 = (p_\mu - q A_\mu)(p^\mu - q A^\mu) = m^2 u_0 u^0 - (\mathbf{p} - q\mathbf{A})^2 = E^2/c^2 - (\mathbf{p} - q\mathbf{A})^2 \ . \tag{20.173}$$

That is,

$$E^2 = (\mathbf{p} - q\mathbf{A})^2 - m^2 c^2 \ . \tag{20.174}$$

In Exc. 20.4.5.3 we show an example for the application of the relativistic electrodynamic Lagrangian.

20.4.3.2 Charges and currents interacting with an electromagnetic field

In the case of continuous variables we use Lagrangian densities,

$$\mathcal{L} = \sum_i \mathcal{L}_i(q_i, \dot{q}_i) \longrightarrow \int \mathcal{L}(\phi_k, \partial^\alpha \phi_k) d^3x \ . \tag{20.175}$$

For example, the Lagrangian of the electromagnetic field is [520],

$$\mathcal{L} = T - V = \mathcal{L}_{field} + \mathcal{L}_{int} = -\tfrac{1}{4\mu_0} F^{\mu\nu} F_{\mu\nu} - A_\mu j^\mu \ , \tag{20.176}$$

but we will not deepen this here.

20.4.4 Symmetries and conservation laws

> *Symmetry* is a feature of a system conserving specific properties under some transformation.

For example, the geometry of a system does not change, when we apply a reflection and the interaction energy between two charges does not change when we switch their coordinates.

In the Lagrangian formalism we call a quantity (or generalized momentum) *conserved*, when the Lagrangian does not depend on the associated coordinate,

$$\mathcal{L} \neq \mathcal{L}(q_k) \qquad \Longrightarrow \qquad p_k \ \text{ is conserved} \ . \tag{20.177}$$

We can see this by the Euler-Lagrange equation,

$$\frac{dp_k}{dt} = \frac{d}{dt}\frac{\partial \mathcal{L}}{\partial \dot{q}_k} = \frac{\partial \mathcal{L}}{\partial q_k} = 0 \ . \tag{20.178}$$

Emmy Noether formulated the theorem, that a *symmetry transformation*, that is, a transformation that does not change the action,

$$t \to t + \delta t \qquad \text{and} \qquad \mathbf{q} \to \mathbf{q} + \delta \mathbf{q} \ , \tag{20.179}$$

conserves the following quantities:

$$\boxed{\left(\dot{\mathbf{q}} \cdot \frac{\partial \mathcal{L}}{\partial \dot{\mathbf{q}}} - \mathcal{L}\right) \delta t - \frac{\partial \mathcal{L}}{\partial \dot{\mathbf{q}}} \cdot \delta \mathbf{q}} \ . \tag{20.180}$$

For example, a *temporal translation*, $\delta t \neq 0$ without another transformed coordinate $\delta q_\alpha = 0 \ , \ \forall \alpha$, leaves the *total energy*,

$$\dot{\mathbf{q}} \frac{\partial \mathcal{L}}{\partial \dot{\mathbf{q}}} - \mathcal{L} = \mathcal{H} \ , \tag{20.181}$$

(known by the Legendre transform) unchanged. The *spatial translation*, $\delta q_\alpha = 0$ but $\delta t \neq 0$, leave the *linear momentum*,

$$\frac{\partial \mathcal{L}}{\partial \dot{q}_\alpha} = p_\alpha \ , \tag{20.182}$$

unchanged. We note that in relativistic theory, these two conservation laws are related. *Spatial rotation* around an axis $\hat{\mathbf{e}}_n$, defined in Cartesian coordinates by,

$$\mathbf{r} \to \mathbf{r} + \delta \vec{\theta} = \mathbf{r} + \delta(\hat{\mathbf{e}}_n \times \mathbf{r}) \ , \tag{20.183}$$

with $\delta t \neq 0$, leaves the angular momentum,

$$\frac{\partial \mathcal{L}}{\partial \dot{\mathbf{q}}} \cdot \delta(\hat{\mathbf{e}}_n \times \mathbf{r}) = \mathbf{p} \cdot (\hat{\mathbf{e}}_n \times \mathbf{r}) = \hat{\mathbf{e}}_n \cdot (\mathbf{r} \times \mathbf{p}) = \hat{\mathbf{e}}_n \cdot \mathbf{L} = 0 \ , \tag{20.184}$$

unchanged.

20.4.5 Exercises

20.4.5.1 Ex: Lagrangian relativistic of a free particle

Show that the Lagrangian $\mathcal{L}(z) = \mathcal{L}(u_\mu u^\mu)$ with $\mathcal{L}' = \frac{m}{2}$ satisfies the Euler-Lagrange equation.

Solution: *We calculate,*

$$\frac{d}{d\tau}\frac{\partial \mathcal{L}}{\partial u_\mu} - \frac{\partial \mathcal{L}}{\partial x_\mu} = \frac{d}{d\tau} 2u_\mu \frac{\partial \mathcal{L}}{\partial z} = \frac{d}{d\tau} m u_\mu = 0 \ .$$

20.4.5.2 Ex: Motion of charged particles in a magnetic field

A non-relativistic particle with mass m and charge q be in a static magnetic field,

$$\vec{\mathcal{B}}(\mathbf{r}) = \mathcal{B}_x(x,y,z)\hat{\mathbf{e}}_x + \mathcal{B}_y(x,y,z)\hat{\mathbf{e}}_y + \mathcal{B}_z(x,y,z)\hat{\mathbf{e}}_z \ .$$

Its Lagrange function is then,

$$\mathcal{L} = \frac{1}{2}m\mathbf{v}^2 + \frac{q}{c}\mathbf{v}\cdot\mathbf{A} \ ,$$

where $\mathbf{v}$ is the velocity of the particle and $\mathbf{A}$ the vector potential corresponding to the magnetic field $\vec{\mathcal{B}}$.
a. If $\mathbf{A} = A_x(x,y,z)\hat{\mathbf{e}}_x + A_y(x,y,z)\hat{\mathbf{e}}_y + A_z(x,y,z)\hat{\mathbf{e}}_z$ is given, what are the Cartesian components of $\vec{\mathcal{B}}$?
b. Using the formula $\frac{d}{dt}\frac{\partial L}{\partial \dot{q}} = \frac{\partial L}{\partial q}$ derive the equations of motion for the Cartesian components of $\mathbf{v}$.
c. What is the condition for $\mathcal{B}_x = \mathcal{B}_y = 0$ and $\mathcal{B}_z = \mathcal{B}_0$ to be constant?
d. Now, consider $A_x = A_y = 0$ and $A_y = \mathcal{B}_0 x$. What equations of motion for v_x, v_y, and v_z follow from this?
e. Calculate $v_x(t)$, $v_y(t)$, and $v_z(t)$. Contour conditions be given by $v_z(t=0) = v_0^{(\|)}$, $v_y(t=0) = 0$ and $v_x(t=0) = v_0^{(\perp)}$. Use the abbreviation $\omega_0 = \frac{q\mathcal{B}_0}{mc}$.
f. Calculate $x(t)$, $y(t)$, and $z(t)$ choosing $x(t=0) = y(t=0) = z(t=0) = 0$. What is the form of the trajectory that corresponds to this motion?
g. Suppose now that $A_x = A_y = 0$ and $A_y = \mathcal{B}(z)x$. What is the consequence of this for $\mathcal{B}_x$, $\mathcal{B}_y$, and $\mathcal{B}_z$? What are the corresponding equations of motion for v_x, v_y, and v_z ?
h. Now, let $\frac{\partial \mathcal{B}(z)}{\partial z} = \mathcal{B}' =$constant. Discuss the motion equation for v_z, inserting as an approximation for $v_y(t)$ and $x(t)$ the solutions of parts (e) and (f). What, under this circumstance, is the consequence for $v_z(t)$?

Solution: *a. We have* $\vec{\mathcal{B}} = \nabla \times \mathbf{A}$ *and hence,*

$$\mathcal{B}_x = \frac{\partial A_z}{\partial y} - \frac{\partial A_y}{\partial z} \quad , \quad \mathcal{B}_y = \frac{\partial A_x}{\partial z} - \frac{\partial A_z}{\partial x} \quad , \quad \mathcal{B}_z = \frac{\partial A_y}{\partial x} - \frac{\partial A_x}{\partial y} \ .$$

b. The Lagrange function is,

$$\mathcal{L} = \tfrac{m}{2}(v_x^2 + v_y^2 + v_z^2) + \tfrac{q}{c}(v_x A_x + v_y A_y + v_z A_z) \ .$$

Therefore we get for $k = (x, y, z)$,

$$\frac{\partial \mathcal{L}}{\partial v_k} = m v_k + \frac{q}{c} A_k \qquad \textit{and} \qquad \frac{\partial \mathcal{L}}{\partial x_k} = \frac{q}{c}\left(v_x \frac{\partial A_x}{\partial x_k} + v_y \frac{\partial A_y}{\partial x_k} + v_z \frac{\partial A_z}{\partial x_k} \right) \ .$$

The Lagrange equations,

$$\frac{d}{dt}\frac{\partial \mathcal{L}}{\partial v_k} = \frac{\partial \mathcal{L}}{\partial x_k} \ ,$$

therefore, give for the x*-component of the velocity,*

$$m\frac{dv_x}{dt} + \frac{q}{c}\left(v_x \frac{\partial A_x}{\partial x} + v_y \frac{\partial A_x}{\partial y} + v_z \frac{\partial A_x}{\partial z} \right) = \frac{q}{c}\left(v_x \frac{\partial A_x}{\partial x} + v_y \frac{\partial A_y}{\partial x} + v_z \frac{\partial A_z}{\partial x} \right) \ .$$

resp.

$$\begin{aligned} \frac{dv_x}{dt} &= \frac{q}{mc}\left(v_y \left[\frac{\partial A_y}{\partial x} - \frac{\partial A_x}{\partial y} \right] - v_z \left[\frac{\partial A_x}{\partial z} - \frac{\partial A_z}{\partial x} \right] \right) = \frac{q}{mc}(v_y \mathcal{B}_z - v_z \mathcal{B}_y) \\ &= \frac{q}{mc}(\mathbf{v} \times \vec{\mathcal{B}})_x \ . \end{aligned}$$

In the same way,

$$\frac{dv_y}{dt} = \frac{q}{mc}(\mathbf{v} \times \vec{\mathcal{B}})_y \ .$$

and

$$\frac{dv_z}{dt} = \frac{q}{mc}(\mathbf{v} \times \vec{\mathcal{B}})_z \ .$$

Finally,

$$\frac{d\mathbf{v}}{dt} = \frac{q}{mc}\mathbf{v} \times \vec{\mathcal{B}} \ .$$

are the expected equations of motion for a particle under the influence of the Lorentz force.

c. For $\mathcal{B}_x = \mathcal{B}_y = 0$ *we have everywhere,*

$$\frac{\partial A_z}{\partial y} = \frac{\partial A_y}{\partial z} \qquad \textit{and} \qquad \frac{\partial A_z}{\partial x} = \frac{\partial A_x}{\partial z} \ .$$

Since $\mathcal{B}_z = \textit{constant} = \mathcal{B}_0$ *we also have everywhere,*

$$\mathcal{B}_0 = \frac{\partial A_y}{\partial x} - \frac{\partial A_x}{\partial y} \ .$$

We make the ansatz,

$$A_y = c_1 x + c_1' \qquad \textit{and} \qquad A_x = c_2 y + c_2' \ .$$

From this immediately follows,

$$\mathcal{B}_0 = c_1 - c_2 \ .$$

d. We can now, without restricting the generality of the result, choose,

$$A_x = A_z = 0 \qquad \textit{and} \qquad A_y = B_0 x \ .$$

Hence,

$$\mathcal{B}_x = \mathcal{B}_y = 0 \qquad \textit{and} \qquad \mathcal{B}_z = \mathcal{B}_0 \ ,$$

and therefore,

$$\frac{dv_x}{dt} = \frac{q\mathcal{B}_0}{mc} v_y \qquad \textit{and} \qquad \frac{dv_y}{dt} = -\frac{q\mathcal{B}_0}{mc} v_x \qquad \textit{and} \qquad \frac{dv_z}{dt} = 0 \ .$$

e. Because of,

$$\frac{dv_z}{dt} = 0 \qquad \textit{follows} \qquad v_z = \text{constant} \equiv v_0^{(\|)} \ .$$

We also have,

$$\frac{d^2 v_x}{dt^2} = \frac{q\mathcal{B}_0}{mc}\frac{dv_y}{dt} = -\left(\frac{q\mathcal{B}_0}{mc}\right)^2 v_x \ .$$

resp.

$$\frac{d^2 v_x}{dt^2} = -\omega_0^2 v_x \ .$$

From this immediately follows,

$$\begin{aligned} v_x &= +v_0^{(\perp)}(\cos\omega_0 t + \alpha \sin\omega_0 t) \\ v_y &= -v_0^{(\perp)}(\sin\omega_0 t - \alpha \cos\omega_0 t) \\ v_z &= \text{constant} = v_0^{(\|)} \ . \end{aligned}$$

Considering also the boundary condition $v_y(t=0) = 0$, necessarily, $\alpha = 0$ and, hence,

$$v_x = v_0^{(\perp)} \cos\omega_0 t \qquad , \qquad v_y = -v_0^{(\perp)} \sin\omega_0 t \qquad , \qquad v_z = v_0^{(\|)} \ .$$

With this, we see,

$$v^2 = (v_0^{(\|)})^2 + (v_0^{(\perp)})^2 = \text{constant} \ .$$

f. We obtain successively,

$$\frac{dz}{dt} = v_0^{(\|)} \qquad \textit{hence} \qquad z(t) = v_0^{(\|)} t + z_0 \ .$$

$$\frac{dx}{dt} = v_0^{(\perp)} \cos\omega_0 t \qquad \textit{hence} \qquad x(t) = \frac{v_0^{(\perp)}}{\omega_0} \sin\omega_0 t + x_0 \ .$$

$$\frac{dy}{dt} = -v_0^{(\perp)} \sin\omega_0 t \qquad \textit{hence} \qquad y(t) = \frac{v_0^{(\perp)}}{\omega_0} \cos\omega_0 t + y_0 \ .$$

With $x(t=0) = y(t=0) = z(t=0) = 0$ now we get, $x_0 = z_0 = 0$ and $y_0 = -v_0^{(\perp)}/\omega_0$. Hence, we obtain,

$$x(t) = \frac{v_0^{(\perp)}}{\omega_0} \sin\omega_0 t \qquad , \qquad y(t) = \frac{v_0^{(\perp)}}{\omega_0} \cos\omega_0 t - \frac{v_0^{(\perp)}}{\omega_0} \qquad , \qquad z(t) = v_0^{(\|)} t \ .$$

Therefore, the trajectory is a spiral around the z-axis.
g. Let now be $A_x = A_z = 0$ as above, but $A_y = \mathcal{B}(z)x$. In this case, we have,

$$\mathcal{B}_z = \mathcal{B}(z) \quad , \quad \mathcal{B}_y = 0 \quad , \quad \mathcal{B}_x = -x\frac{\partial \mathcal{B}(z)}{\partial z} \ .$$

respectively. For the equation of motion (let $\omega_0 = q\mathcal{B}_0/mc$ again),

$$\begin{aligned}
\frac{dv_x}{dt} &= +\omega_0 v_y \frac{\mathcal{B}(z)}{\mathcal{B}_0} \\
\frac{dv_y}{dt} &= -\omega_0 \left(v_x \frac{\mathcal{B}(z)}{\mathcal{B}_0} + x v_z \frac{1}{\mathcal{B}_0}\frac{\partial \mathcal{B}(z)}{\partial z} \right) \\
\frac{dv_z}{dt} &= +\omega_0 x v_y \frac{1}{\mathcal{B}_0}\frac{\partial \mathcal{B}(z)}{\partial z} \ .
\end{aligned}$$

h. From (e) and (f) follows:

$$v_y x = -\frac{(v_0^{(\perp)})^2}{\omega_0}\sin^2\omega_0 t \ .$$

and hence,

$$\frac{dv_z}{dt} \approx -(v_0^{(\perp)})^2 \sin^2\omega_0 t \frac{1}{\mathcal{B}_0}\frac{\partial \mathcal{B}(z)}{\partial z} \ .$$

If the derivative of $\mathcal{B}(z)$ by z is constant ($= B'$), we obtain,

$$v_z(t) \approx \frac{1}{2}(v_0^{(\perp)})^2 \left\{ \sin\omega_0 t \cos\omega_0 t - \omega_0 t \right\} \frac{\mathcal{B}'}{\mathcal{B}_0} + v_0^{(\parallel)} \ .$$

Hence, for large $\mathcal{B}'$ and t large v_z can change sign.

20.4.5.3 Ex: Connection between kinetic and canonical momentum and the Abraham-Minkowski debate

The nonrelativistic Lagrangian that governs the interaction of a particle with electric and magnetic dipole moment with external electromagnetic fields can be written,

$$\mathcal{L} = \tfrac{m}{2}v^2 + \vec{\mathcal{E}} \cdot \mathbf{d} + \vec{\mathcal{B}} \cdot \vec{\mu} \ .$$

a. Based on the results of Exc. 20.3.6.2 calculate the kinetic and canonical momenta of a particle with flying at velocity $\mathbf{v}$ through a lab.
b. Now, average over a macroscopic number of particles introducing the polarization $\vec{\mathcal{P}} = \langle \sum_n \mathbf{d}_n \delta^3(\mathbf{r} - \vec{\mathcal{S}}_n)\rangle$ and the magnetization $\vec{\mathcal{M}} = \frac{1}{2}\langle \sum_n \vec{\mu}_n \delta^3(\mathbf{r} - \vec{\mathcal{S}}_n)\rangle$, and compare the kinetic and canonical momenta with the Abraham and Minkowski expressions for the linear momentum density.

Solution: *a. The kinetic momentum is simply [1132],*

$$\mathbf{p}^{kin} = m\mathbf{v} \ .$$

Inserting the electric and magnetic dipole moments, as they appear in the lab frame, the Lagrangian becomes,

$$\mathcal{L} = \tfrac{m}{2}v^2 + \vec{\mathcal{E}}\cdot(\mathbf{d} + \tfrac{1}{c^2}\mathbf{v}\times\vec{\mu}) + \vec{\mathcal{B}}\cdot(\vec{\mu} - \tfrac{1}{2}\mathbf{v}\times\mathbf{d}) \ ,$$

and its derivative,

$$\begin{aligned} p_i^{can} = \frac{\partial L}{\partial v_i} &= mv_i + \frac{1}{c^2}\frac{\partial}{\partial v_i}\mathcal{E}_j\epsilon_{jmn}v_m\mu_n - \frac{c}{2}\frac{\partial}{\partial v_i}\mathcal{B}_j\epsilon_{jmn}v_m d_n \\ &= mv_i + \tfrac{1}{c^2}\epsilon_{inj}\mu_n\mathcal{E}_j - \tfrac{1}{2}\epsilon_{inj}d_n\mathcal{B}_j \ , \end{aligned}$$

or

$$\mathbf{p}^{can} - \mathbf{p}^{kin} = \tfrac{1}{c^2}\vec{\mu}\times\vec{\mathcal{E}} - \tfrac{1}{2}\mathbf{d}\times\vec{\mathcal{B}} \ .$$

b. We get for the macroscopic kinetic and canonical momenta,

$$\mathbf{p}^{can} - \mathbf{p}^{kin} = \tfrac{1}{c^2}\vec{\mathcal{M}}\times\vec{\mathcal{E}} - \vec{\mathcal{P}}\times\vec{\mathcal{B}} \ ,$$

and for the Abraham and Minkowski expressions linear momentum densities,

$$\vec{\wp}^A = \tfrac{1}{c^2}\vec{\mathcal{E}}\times\vec{\mathcal{H}} = \tfrac{1}{c^2}\vec{\mathcal{E}}\times\left(\tfrac{1}{\mu_0}\vec{\mathcal{B}} - \vec{\mathcal{M}}\right) \quad \textit{and} \quad \vec{\wp}^M = \vec{\mathcal{D}}\times\vec{\mathcal{B}} = (\varepsilon_0\vec{\mathcal{E}} + \vec{\mathcal{P}})\times\vec{\mathcal{B}} \ .$$

Hence,

$$\vec{\wp}^A - \vec{\wp}^M = \tfrac{1}{c^2}\vec{\mathcal{M}}\times\vec{\mathcal{E}} - \vec{\mathcal{P}}\times\vec{\mathcal{B}} = \mathbf{p}^{can} - \mathbf{p}^{kin} \ .$$

20.5 Relativistic gravity

The starting point of Einstein's theory on *general relativity* is the famous *equivalence principle* stating that there is no difference in heavy mass and inert mass, that is, gravity and acceleration are fundamentally the same. Taking this axiom seriously, we must accept a series of astonishing corollaries, such as the fact that space-time is neither Euclidian, nor Minkowskian, but distorted by the presence of mass. Time and space coordinates are intertwined (see also Secs. 6.4 and 36.5.2).

In the following, we briefly recapitulate Minkowskian metrics in Cartesian and spherical coordinates before introducing Schwarzschild metrics as a special case.

20.5.1 Metric and geodesic equation in curved space-time

Minkowskian metrics in Cartesian coordinates has been introduced in Sec. 20.1.1. In the following sections, we will briefly recapitulate it and extend it to spherical coordinates before generalizing the metrics to curved space-time.

20.5.1.1 Minkowski metrics

In Cartesian coordinates the line element and tetrad are given by,

$$\begin{aligned} ds^2 &= c^2t^2 - dx^2 - dy^2 - dz^2 \\ \mathbf{e}_t &= \frac{1}{c}\partial_t \quad , \quad \mathbf{e}_x = \partial_x \quad , \quad \mathbf{e}_y = \partial_y \quad , \quad \mathbf{e}_z = \partial_z \\ \mathbf{e}^t &= cdt \quad , \quad \mathbf{e}^x = dx \quad , \quad \mathbf{e}^y = dy \quad , \quad \mathbf{e}^z = dz \ , \end{aligned} \tag{20.185}$$

and the metric tensor by,

$$g_{\mu\nu} = \frac{\partial x_\alpha}{\partial \xi^\mu}\frac{\partial x^\alpha}{\partial \xi^\nu} = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \\ 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & -1 \end{pmatrix} . \tag{20.186}$$

Note that the matrix representation of the metric is defined via,

$$\boxed{ds^2 = g^{\mu\nu}dx_\mu dx_\nu} \, . \tag{20.187}$$

In spherical coordinates,

$$\begin{pmatrix} t \\ x \\ y \\ z \end{pmatrix} = \begin{pmatrix} t \\ r\sin\theta\cos\phi \\ r\sin\theta\sin\phi \\ r\cos\theta \end{pmatrix} , \tag{20.188}$$

the line element and tetrad are given by,

$$\begin{aligned} ds^2 &= c^2t^2 - dr^2 - r^2d\theta^2 - r^2\sin^2\theta d\phi^2 \\ \mathbf{e}_t &= \frac{1}{c}\partial_t \quad , \quad \mathbf{e}_r = \partial_r \quad , \quad \mathbf{e}_\theta = \frac{1}{r}\partial_\theta \quad , \quad \mathbf{e}_\phi = \frac{1}{r\sin\theta}\partial_\phi \ , \end{aligned} \tag{20.189}$$

and the metric tensor,

$$g_{\mu\nu} = \frac{\partial x_\alpha}{\partial \xi^\mu}\frac{\partial x^\alpha}{\partial \xi^\nu} = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \\ 0 & 0 & -r^2 & 0 \\ 0 & 0 & 0 & -r^2\sin^2\theta \end{pmatrix} , \tag{20.190}$$

with $\xi^\mu, \xi^\nu = t, r, \theta, \phi$ and $x_\alpha = t, x, y, z$. The Minkowski metrics is a generalization of Euclidian metric to four-dimensional space-time.

20.5.2 Schwarzschild metric

General relativity breaks with the concept of Euclidian space allowing for space-time to be distorted. The simplest example is the *Schwarzschild metric* which assumes a distortion of time and space as a function of the distance from a heavy mass. Schwarzschild's solution was the first exact solution of Einstein's field equations. It holds on the outside of non-charged non-rotating masses.

Metric and tetrad of Schwarzschild coordinates (t, r, θ, ϕ) are given by,

$$c^2 d\tau^2 = \left(1 - \tfrac{r_s}{r}\right) c^2 dt^2 - \left(1 - \tfrac{r_s}{r}\right)^{-1} dr^2 - r^2 d\theta^2 - r^2 \sin^2\theta d\phi^2 \tag{20.191}$$

$$\mathbf{e}_t = \frac{1}{c\sqrt{1 - r_s/r}}\partial_t \quad , \quad \mathbf{r} = \sqrt{1 - \frac{r_s}{r}}\partial_r \quad , \quad \mathbf{e}_\theta = \frac{1}{r}\partial_\theta \quad , \quad \mathbf{e}_r = \frac{1}{r\sin\theta}\partial_\phi \ ,$$

where,

$$r_s \equiv \frac{2\gamma_N M}{c^2} \ , \tag{20.192}$$

is called the *Schwarzschild radius*. The metric tensor in free (massless) space is,

$$g_{\mu\nu} = \frac{\partial x_\alpha}{\partial \xi^\mu}\frac{\partial x^\alpha}{\partial \xi^\nu} = \begin{pmatrix} 1 - \frac{r_s}{r} & 0 & 0 & 0 \\ 0 & -(1 - \frac{r_s}{r})^{-1} & 0 & 0 \\ 0 & 0 & -r^2 & 0 \\ 0 & 0 & 0 & -r^2\sin^2\theta \end{pmatrix} . \tag{20.193}$$

For $r \gg r_s$ this reduces to the Minkowski metric.

20.5.3 Christoffel symbols for relativistic space-time and geodesic equation

The Christoffel symbols are defined by,

$$\Gamma^\mu_{\ \alpha\beta} \equiv \frac{\partial \mathbf{e}_\alpha}{\partial x^\beta} \cdot \mathbf{e}^\mu = \frac{\partial^2 \xi^\gamma}{\partial x^\alpha \partial x^\beta}\frac{\partial x^\mu}{\partial \xi^\gamma} \ . \tag{20.194}$$

They yields for spherical coordinates,

$$\Gamma^a_{\ it} = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix} \quad , \quad \Gamma^a_{\ ir} = \begin{pmatrix} 0 & 0 & -r & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix} \tag{20.195}$$

$$\Gamma^a_{\ i\theta} = \begin{pmatrix} 0 & 0 & -r & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix} \quad , \quad \Gamma^a_{\ i\phi} = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix} \ .$$

In relativistic space-time the *geodesic equation* is a curve representing in some sense the shortest path between two points in a surface. The geodesic line is obtained by solving the differential equation,

$$\boxed{\frac{d^2x^\mu}{d\tau^2} + \Gamma^\mu{}_{\alpha\beta}\frac{dx^\alpha}{d\tau}\frac{dx^\beta}{d\tau} = 0} \ . \tag{20.196}$$

Define *Einstein tensor*, *Ricci tensor* (see 12.4.3).

20.5.4 Exercises

20.5.4.1 Ex: Space-time metric in spherical coordinates

Write down the space-time metric for Earth in spherical coordinates.

Solution: *From Sec. 12.3.6 we derive,*

$$ds^2 = c^2dt^2 - dr^2 - r^2d\theta^2 - r^2\sin^2\theta d\phi^2 \ .$$

It is obtained from the Schwarzschild metric setting the Schwarzschild radius $r_s \simeq 0$. *For Earth* $r_s \approx 8.8\,\mathrm{mm}$.

D.J. Griffiths, *Introduction to Electrodynamics* [545]ISBN

Chapter 21

Appendices to 'Electrodynamics'

21.1 Special topic: Goos-Hänchen shift with light and matter waves

Newton's corpuscular light model predicts a lateral shift of a light beam when totally reflected from an interface to an optically thin medium. Photons leaving the optically dense medium are reattracted to it by gravitation. The lateral distance covered during their ballistic flight corresponds to the shift, called *Goos-Hänchen shift* (GHS). It seems as if the light beam was reflected at a plane lying behind the boundary within the region of the evanescent wave (EW). Although the underlying model is incorrect (although De Broglie himself conjectured that the effect could point towards a finite photon mass), newer model based on the Maxwell theory also predict an energy flux within the EW forming within the thin medium. Many unsuccessful attempts have been undertaken to observe this flux, and it has still not been directly observed nowadays. The problem is that any probe brought into the EW undermines it and vanishes the GHS. Goos and Hänchen circumvented the problem by measuring only the lateral shift in the optically dense medium [522, 523, 195]. The agreement of their observations with Maxwell theory gives confidence in the existence of the flux.

21.1.1 Evanescent wave potentials

A light field reflected at an angle θ ($= 52°$ for Landragin's dielectric prism) on a boundary to an optically thin medium is described by

$$\mathcal{E}(\mathbf{r}) = \mathcal{E}_0 e^{\imath q x - \kappa z} \ , \tag{21.1}$$

where $q = kn \sin\theta$ and $\kappa = k\sqrt{n^2 \sin^2\theta - 1}$. Introducing the Rabi frequency

$$\Omega(\mathbf{r}) = \sqrt{\frac{\sigma_0 \Gamma}{\hbar\omega} I(\mathbf{r})} = \sqrt{\frac{\epsilon_0 c^2 \sigma_0 \Gamma}{\hbar\omega}} \mathcal{E}_0 e^{-\kappa z} \ , \tag{21.2}$$

the interaction energy reads $\mathbf{d} \cdot \vec{\mathcal{E}} = \Omega(\mathbf{r}) e^{\imath q x}$. The force $\mathbf{F} = -\nabla \mathbf{d} \cdot \vec{\mathcal{E}}$ is made of two contributions. Using the optical Bloch equations, we find the stationary solutions for

the dipole and the dissipative forces [20]

$$\mathbf{F}_{dip} = -\frac{\hbar\Delta\Omega}{4\Delta^2 + 2\Omega(\mathbf{r})^2 + \Gamma^2}\nabla\Omega(\mathbf{r}) \ , \tag{21.3}$$
$$\mathbf{F}_{diss} = \frac{\hbar\Gamma\Omega^2}{4\Delta^2 + 2\Omega(\mathbf{r})^2 + \Gamma^2}\nabla\theta(\mathbf{r}) \ .$$

Treating the mechanical effects of light analogously to the Laguerre-Gaussian modes. For LGM the phase gradient is almost parallel with the Poynting vector except for higher order corrections for the axial component.

The dipole force can be derived from a conservative evanescent potential

$$V(z) = \frac{\Omega^2}{\Delta}e^{-2\kappa z} = \frac{\pi c^2\Gamma}{2\omega^3} \ I \ \left(\frac{1}{\Delta_{D1}} + \frac{2}{\Delta_{D2}}\right)e^{-2\kappa z} \ .$$

Apparently, radiation pressure accelerates the atoms not in the direction of the wavevector, but of the phase gradient [22]. Is this the same as the Poynting vector? This may lead to observable effects in evanescent waves. Hence, the observation of a transverse radiation pressure would already prove a Goos-Hänchen shift.

21.1.2 Energy flux in the evanescent wave

An incoming laser beam be expanded after phases

$$\mathcal{E}_i(x) = \mathcal{E}_{ip}\int f(\theta)e^{-\imath x k_{ix_0}\theta}d\theta \ . \tag{21.4}$$

The reflected beam then reads

$$\mathcal{E}_r(x) = \mathcal{E}_{ip}\int r(\theta)f(\theta)e^{-\imath x k_{ix_0}\theta}d\theta \ , \tag{21.5}$$

where $r(\theta) = \frac{a-\imath b}{a+\imath b}$ according to the Fresnel equations or $r = e^{i\varphi}$. We assume that we can linearize the phase $\varphi(\theta) = \varphi(\theta_0) + (\theta-\theta_0)\partial_\theta\varphi(\theta_0) \equiv \chi + \theta\partial_\theta\varphi(\theta_0)$. Then equation (21.5) can be written

$$\mathcal{E}_r(x) = \mathcal{E}_{ip}e^{-\imath\chi}\int f(\theta)e^{-\imath(x-\Delta x_{GH})k_{ix_0}\theta}d\theta = \mathcal{E}_i(x-\Delta x_{GH})e^{-\imath\chi} \ , \tag{21.6}$$

where $\Delta x_{GH} = \frac{2\cos\theta_0}{k_{ix_0}}\partial_\theta\varphi(\theta_0) = \frac{2}{k_i}\partial_\theta\varphi(\theta_0)$. The reflected laser beam is parallel shifted.

Calculations show [1091, 815] that the energy flux penetrates the thin medium only where the transverse profile of the beam shows a gradient. In the regions of constant intensity the flux is inside the plane of incidence and parallel to the surface. Hence, the Goos-Hänchen shift is only observable with spatially inhomogeneous beams.

21.1.2.1 Expression for the shift

Let us now estimate the GHS for a prism $n_1 = 1.5$, the Rb D_2-line for which $\lambda = 2\pi/k = 780$ nm. The EW penetration depth ζ is given by $k\zeta = \sqrt{n_1^2\sin^2\theta - n_2^2}^{-1}$

$$\frac{\Delta_{GH}}{2\zeta} = \frac{n_1^2n_2^2\sin\theta\cos^2\theta}{n_1^4\sin^2\theta + n_2^4\cos^2\theta - n_1^2n_2^2} \ . \tag{21.7}$$

We assume that the angle of incidence is close to the critical angle $\theta = \theta_c + \xi = \arcsin n_1^{-1} + \xi$. Near the critical angle the GHS diverges as does the penetration depth. Hence, the GHS should be measured very close to the critical angle. The expansion in ξ yields

$$\frac{\Delta_{GH}}{2\zeta} = \frac{n_1}{n_2}\left(1 + \xi\frac{n_2^2 n_1^2 - n_2^4 - 2n_1^4}{n_2^3\sqrt{n_1^2 - n_2^2}}\right) . \tag{21.8}$$

The Goos-Hänchen shift is proportional to the penetration depth of the evanescent wave. It has been measured by [195].

21.1.2.2 Goos-Hänchen shift with resonant absorbers

Resonant absorbers have an impact on the evanescent wave and hence on the Goos-Hänchen shift as has been measured by [1028]. Hence, we now consider the presence of an resonant gas with a small index of refraction, $n_2 = 1 + \bar{n}$, so that

$$\frac{k\Delta_{GH}}{2} = \frac{1}{\sqrt{n_1^2\sin^2\theta - (1+\bar{n})^2}}\frac{n_1^2(1+\bar{n})^2\sin\theta\cos^2\theta}{n_1^4\sin^2\theta + (1+\bar{n})^4\cos^2\theta - n_1^2(1+\bar{n})^2} . \tag{21.9}$$

To first order in $\bar{n}$ and ξ

$$\Delta_{GH}(\bar{n},\xi) \approx \frac{A\bar{n}}{\sqrt{\xi}\,(B\xi - \bar{n})} + \Delta_{GH}(\bar{n}=0,\xi) . \tag{21.10}$$

According to [953] (Eq. 4.6),

$$\begin{aligned} T &= -\frac{N|d\epsilon_1|^2}{\eta\varepsilon_0\hbar|\epsilon_1|^2}\int d\mathbf{v}W(\mathbf{v})\theta(v_z)\frac{1}{\Gamma + \eta k v_z - \imath\,(\Delta - \alpha k v_x)} \qquad (21.11)\\ &= -\frac{N|d|^2}{\eta\varepsilon_0\hbar}\left(\frac{3}{2\pi v_0^2}\right)^{3/2}\int_0^\infty dv_z e^{-3v_z^2/2v_0^2}\int_{-\infty}^\infty dv_y e^{-3v_y^2/2v_0^2}\int_{-\infty}^\infty dv_x e^{-3v_x^2/2v_0^2}\frac{1}{\Gamma - \imath\Delta}\\ &= -\frac{N|d|^2}{\eta\varepsilon_0\hbar}\frac{1}{\sqrt{2}}\frac{1}{\Gamma - \imath\Delta} . \end{aligned}$$

An effective refractive index variation may be define [953] (Eq. 3.16) with $\beta = i\eta$,

$$\delta n = -\beta T = \beta\frac{N|d|^2}{\sqrt{2}\eta\varepsilon_0\hbar}\frac{1}{\Gamma - \imath\Delta} = \imath\frac{N|d|^2}{\sqrt{2}\varepsilon_0\hbar}\frac{\Gamma + \imath\Delta}{\Gamma^2 + \Delta^2} . \tag{21.12}$$

The interesting question is, whether the energy flux in the evanescent wave is directly observable. The existence of an EW is not questionable. On the contrary it has become an important in quantum optics, where near-resonant EWs are used for *selective reflection spectroscopy*. In cold atom optics, far-off resonant EWs are used to repel ultracold atoms from surfaces. Does the energy flux related to the GHS leave any footprints in the atomic cloud (possibly a BEC)? Certainly, one has to stay at a detuning, where the flux in the evanescent wave satisfies $\mathfrak{Im}\,\mathbf{k} \perp \mathfrak{Re}\,\mathbf{k}$, so that there is no energy transfer. Think about phase shift of the de Broglie wave underneath a fixed envelope, analogy to geometric phases or the Aharonov-Bohm effect.

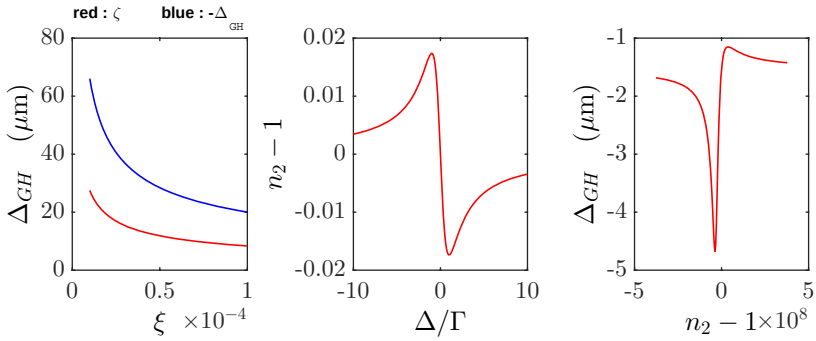

Figure 21.1: (code) Selective reflection Goos.

21.1.3 Imbert-Fedorov shift

A transverse shift should be expected for circularly polarized light or Laguerre-Gaussian modes. This shift called Imbert-Fedorov shift can be described with the flux method. The effect should be small, $\Delta x_{IF} \approx 0.1\ \Delta x_{GH}$. It has been observed with microwaves [307] and light [1034].

For this case it is interesting that the wavevector $\mathbf{k}$ and the flux $\mathbf{S}$ are both parallel to the surface, but orthogonal on each other. The flux is perpendicular to the plane of incidence.

The symmetry breaking (upward or downward flux) is inherent in the circularly polarized laser beam [23, 478, 975]. Here the Poynting vector describes a helix about the optical axis.

For matter waves the index of refraction can be tuned via the particle energy, which is not possible with light. E.g. if $E = V_2 > V_1$, the critical angle for total reflection is $\alpha = 0$. Do we expect a Imbert-Fedorov shift for spinor condensates? Is the plane wave approximation good or should be use real BEC wavefronts?

The total reflection of Laguerre-Gaussian beams has also been studied [969].

21.1.4 Matter wave Goos-Hänchen shift at a potential step

The phase of a BEC could be a sensitive probe for the Goos-Hänchen shift. Here, it is important that the de Broglie wavelength be longer than the edge of the potential. Otherwise, the effect is trivial even in the classical particle picture.

Matter waves behave analogously to optical waves, except that the Schrödinger equation must be used. Consider the situation of a particle moving towards a potential step at an angle α as shown in Fig. 21.2. The energy of the particle is $E > V_2 > V_1$. The incidence region V_1 corresponds to the atom optically thick medium (the de Broglie wavelength is shorter, the propagation velocity fast, $\hbar k_1 = \sqrt{2m(E - V_1)}$. V_2 is the atom optically thin medium.

Consequently we expect a critical angle α_c beyond which the matter wave is totally reflected,

$$\sin \alpha_c = \sqrt{\frac{E - V_2}{E - V_1}}\ . \tag{21.13}$$

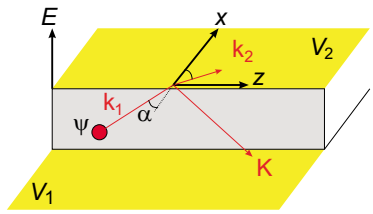

Figure 21.2: Matter wave refraction at a potential step.

For partial reflection, if the incident wave is described by [1091] $\psi_0 = e^{\imath x k_{x1} + \imath y k_{y1}}$, the reflected and refracted wave are

$$\psi_1 = \frac{\cos\alpha - \sqrt{\sin^2\alpha_c - \sin^2\alpha}}{\cos\alpha + \sqrt{\sin^2\alpha_c - \sin^2\alpha}} e^{-\imath x k_{x1} + \imath y k_{y1}} \tag{21.14}$$
$$\psi_2 = \frac{2\cos\alpha}{\cos\alpha + \sqrt{\sin^2\alpha_c - \sin^2\alpha}} e^{-\imath x \sqrt{k_2^2 - k_{y1}^2} + \imath y k_{y1}} \ .$$

For total reflection,

$$\psi_1 = \exp\left(-\imath 2 \arctan\sqrt{\frac{\sin^2\alpha - \sin^2\alpha_c}{1 - \sin^2\alpha}}\right) e^{-\imath x k_{x1} + \imath y k_{y1}} \tag{21.15}$$
$$\psi_2 = \frac{2\cos\alpha}{\cos\alpha + \imath\sqrt{\sin^2\alpha - \sin^2\alpha_c}} e^{-x\sqrt{k_{1y}^2 - k_2^2} + \imath y k_{y1}} \ .$$

The matter wave Goos-Hänchen shift Δ_{GH} can be estimated by comparing the matter wave flux $\mathbf{J} = -i\frac{\hbar}{2m}(\psi^*\nabla\psi - \psi\nabla\psi^*)$ in the evanescent wave with the flux in a Δ_{GH} wide strip of the reflected beam. The result [1091] is

$$\frac{\Delta_{GH}}{2} = \frac{\sin\alpha\cos^2\alpha}{k\cos^2\alpha_c\sqrt{\sin^2\alpha - \sin^2\alpha_c}} \ . \tag{21.16}$$

See [1091, 611].

The difficult question is now what the matter wave analogue of the Imbert-Fedorov shift would be. It is known for relativistic electrons that momentum and velocity must not necessarily be collinear [334]. How about particles with a real angular orbital momentum, e.g. the reflection of vortices?

21.2 Special topic: The dilemma of Abraham and Minkowski

If Minkowski is correct, then as a photon enters an atomic cloud with $n > 1$, then the cloud receives a collective momentum in the direction opposite to the photon propagation [230]. 'Momentum conservation requires then that the medium also has a mechanical momentum. When a pulse of light enters the medium, the particles in

the medium are accelerated by the leading edge of the pulse and decelerated by the trailing edge.' However, near resonance the refraction index is dispersive. I.e. for blue-detuning we should expect $n < 1$ and hence a collective momentum in the direction of photon propagation.

A picturesque interpretation would be, that the acceleration of the atoms by the leading or trailing edge of the light pulse is due to the dipole force (real part of susceptibility). For red (blue) detuning, the atoms are accelerated backwards (forwards) by the leading edge of the pulse and forwards (backwards) by the trailing edge. In case, that the cloud absorbs or diffracts photons, a net momentum should remain in the cloud: [817] "The propagation of an optical pulse through a transparent dielectric causes no transfer of momentum to the material, as a positive Lorentz force in the leading part of the pulse is exactly balanced by a negative Lorentz force in its trailing part. However, this balance is removed in the present problem because of the attenuation of the light by its interaction with the charge carriers. This causes the leading part of the pulse at a given time to be weaker than the trailing part and produces a net negative transfer of momentum to the bulk semiconductor."

Out side the medium, we know that the photon momentum is,

$$p_{out} = mc \ , \tag{21.17}$$

with $m = \hbar\omega/c^2$. Inside the medium, it is

$$p_{in} = m\frac{c}{\eta} = \frac{\hbar\omega}{\eta c} \ . \tag{21.18}$$

According to Minkowski, we must use $m = \hbar\omega/(c/\eta)^2$.

21.2.1 Calculation of the momentum of light in a dielectric medium

Let us consider [898] a plane light wave within a dielectric medium given by $\varepsilon = \eta^2\varepsilon_0$ and $\mu = \mu_0$,

$$\vec{\mathcal{E}}(\mathbf{r},t) = \hat{\mathbf{e}}_x\mathcal{E}_0\cos\omega\,(t - z/c) \qquad \text{and} \qquad \vec{\mathcal{H}}(\mathbf{r},t) = \hat{\mathbf{e}}_y\sqrt{\frac{\varepsilon}{\mu_0}}\mathcal{E}_0\cos\omega(t - z/c) \ , \tag{21.19}$$

The energy densities and the energy flows, called 'Poynting vector', are (taking the temporal average),

$$u = \frac{1}{2}(\vec{\mathcal{E}}\cdot\vec{\mathcal{D}} + \vec{\mathcal{B}}\cdot\vec{\mathcal{H}}) = \tfrac{1}{2}\varepsilon\mathcal{E}_0^2 \qquad \text{and} \qquad \mathbf{S} = \vec{\mathcal{E}}\times\vec{\mathcal{H}} = \tfrac{1}{2}\sqrt{\frac{\varepsilon}{\mu_0}}\mathcal{E}_0^2\hat{\mathbf{e}}_z = \frac{c}{\eta}u\hat{\mathbf{e}}_z \ . \tag{21.20}$$

Therefore, the intensity of a light field, $I = |\mathbf{S}|$, is increased by the dielectric. Rewriting this in terms of the average number of photons q in a volume V, we obtain for the energy,

$$\int u d^3r = \tfrac{1}{2}\varepsilon\mathcal{E}_0^2 V = N\hbar\omega \ . \tag{21.21}$$

The energy flow of a field of light is equal to the momentum carried by the photons. For a single photon, we have,

$$\mathbf{p}_{Abr} \equiv \frac{1}{N}\frac{1}{c^2}\int \mathbf{S}d^3r = \frac{\hbar\mathbf{k}_0}{\eta} \ . \tag{21.22}$$

However, Minkowski's point of view was,

$$\mathbf{p}_{Min} = \frac{1}{N}\int dV\vec{\mathcal{D}}\times\vec{\mathcal{B}} = \eta\hbar\mathbf{k}_0 \ . \tag{21.23}$$

The recoil frequency is modified from $\hbar\omega_{rec} = \frac{\hbar^2k^2}{2m}$ to $\hbar\omega_{rec}^{\eta} = \eta^2\omega_{rec}$ [230].

21.2.1.1 Kinetic versus canonical momentum

In reality, what is propagating in the medium is NOT a photon, but a photon interacting with atoms of the medium (otherwise we wouldn't need a refractive index to describe the propagation of light). The total momentum must, obviously, be conserved. Upon entering a medium, part of the radiation momentum is transferred to the medium [1132]:

$$\mathbf{p}^{tot} = \mathbf{p}^{med} + \mathbf{p}^{rad} \ . \tag{21.24}$$

But how this repartition is done is, as long as we do not attempt to measure one or the other component, arbitrary. We could chose $(\mathbf{p}^{med}, \mathbf{p}^{rad}) \rightarrow (\mathbf{p}^{med}_{kin}, \mathbf{p}^{rad}_{kin})$, and calling $\mathbf{p}_{Abr} \equiv \mathbf{p}^{rad}_{kin} = \frac{\varepsilon_0\mu_0}{N}\int\vec{\mathcal{E}}\times\vec{\mathcal{H}}dV$ the Abraham momentum, write,

$$\mathbf{p}^{tot} = \mathbf{p}^{med}_{kin} + \mathbf{p}_{Abr} \ . \tag{21.25}$$

We could also chose $(\mathbf{p}^{med}, \mathbf{p}^{rad}) \rightarrow (\mathbf{p}^{med}_{can}, \mathbf{p}^{rad}_{can})$, and calling $\mathbf{p}_{Min} \equiv \mathbf{p}^{rad}_{can} = \frac{1}{N}\int\vec{\mathcal{D}}\times\vec{\mathcal{B}}dV$ the Minkowski momentum, write,

$$\mathbf{p}^{tot} = \mathbf{p}^{med}_{can} + \mathbf{p}_{Min} \ . \tag{21.26}$$

We could also chose $(\mathbf{p}^{med}, \mathbf{p}^{rad}) \rightarrow (\mathbf{p}^{med}_{rel}, \mathbf{p}^{rad}_{rel})$, and calling $\mathbf{p}_{em} \equiv \mathbf{p}^{rad}_{rel} = \frac{\varepsilon_0}{N}\int\vec{\mathcal{E}}\times\vec{\mathcal{B}}dV$ the vacuum electromagnetic momentum, write,

$$\mathbf{p}^{tot} = \mathbf{p}^{med}_{rel} + \mathbf{p}_{em} \ . \tag{21.27}$$

$$\mathbf{p}_{rel} = \mathbf{p}_{kin} - \vec{\mathcal{E}}\times\tfrac{1}{c^2}\mathbf{m} \quad , \quad \mathbf{p}_{kin} = m\mathbf{v} \ . \tag{21.28}$$

21.2.1.2 Tentative explanations

People seem to agree on the interpretation that, as long as the propagation of the energy in a medium is concerned, the Abraham interpretation is valid. The kinetic momentum of a laser beam is given by the Abraham value p_{Abr}. But as soon as photons are localized by atoms, it is Minkowski? The scattering of a photon by an individual atom tears away the atoms from its neighbors. The difference p_{med} in the momentum p_{Min} imparted to the individual atom and the momentum carried by the photon p_{Abr} is imparted to neighboring atoms.

The total momentum transfer to bulk material, free of any boundary or surface effects, has the Abraham value of $\hbar\omega_0/\eta_g c$ but that the transfer to an attenuating subsystem within the bulk material has the Minkowski value of $\eta_p\hbar\omega_0/c$ [817].

The field carries a momentum p_{Abr} per photon, but that there is also a momentum p_{med} imparted by the field to the medium. An atom that absorbs or emits a photon of frequency ω in the medium therefore recoils with the momentum $p_{Abr} + p_{med} = p_{Min}$, as if the photon momentum were the Minkowski photon momentum p_{Min} [898].

A slide show about this topic can be visualized at (watch talk).

21.2.1.3 Energy and momentum tensor in a dielectric

In a dielectric,

$$T^{\alpha\beta} = \begin{pmatrix} g^0 & c\tilde{\mathbf{g}}^j_{rad} + c\tilde{\mathbf{g}}^j_{mat} \\ c\mathbf{g}^i_{rad} + c\mathbf{g}^i_{mat} & -\mathbf{T}^{ij}_{rad} - \mathbf{T}^{ij}_{mat} \end{pmatrix} . \tag{21.29}$$

We need $\mathbf{g}^i_{rad} + \mathbf{g}^i_{mat} = \tilde{\mathbf{g}}^i_{rad} + \tilde{\mathbf{g}}^i_{mat}$, but this does not necessarily imply, $\mathbf{g}^i_{rad} = \tilde{\mathbf{g}}^i_{rad}$. The Abraham form of the energy-momentum tensor is,

$$T^{\alpha\beta}_{Abr} = \begin{pmatrix} g^0 & c\mathbf{g}^j_{rad} + c\tilde{\mathbf{g}}^j_{mat} \\ c\mathbf{g}^i_{rad} + c\mathbf{g}^i_{mat} & -\mathbf{T}^{ij}_{rad} - \mathbf{T}^{ij}_{mat} \end{pmatrix} . \tag{21.30}$$

Obviously, the radiation term is symmetric. From the Minkowski form,

$$T^{\alpha\beta}_{Mkw} = \begin{pmatrix} g^0 & c^{-1}\vec{\mathcal{E}} \times \vec{\mathcal{H}} + c\tilde{\mathbf{g}}^j_{mat} \\ c\mathbf{D} \times \mathbf{B} + c\mathbf{g}^i_{mat} & -\mathbf{T}^{ij}_{rad} - \mathbf{T}^{ij}_{mat} \end{pmatrix} , \tag{21.31}$$

the radiation term is not symmetric. 'Every experiment is only sensitive to specific terms of the complete energy-momentum tensor. Every experiment involving only angular momentum will be insensitive to independently symmetric terms, and experiments involving only linear momentum will be insensitive to terms, which are divergence-free. ' [1027].

The total electromagnetic stress tensor contains the following components,

$$\begin{aligned} T^{\alpha\beta}_{(m)} &= \rho_0(c^2 + \epsilon_i)u^\alpha u^\beta + \phi\left(u^\alpha u^\beta + \delta^{\mu\nu}\right) \\ T^{\alpha\beta}_{(f)} &= \varepsilon_0 c^2\left(F^{\mu\gamma}F^{\nu}_{\ \gamma} - \tfrac{1}{4}F^2_{\gamma\delta}\delta^{\mu\nu}\right) \\ T^{\alpha\beta}_{(P)} &= \tfrac{1}{\varepsilon-\varepsilon_0}\left(P^{\mu\gamma}P^{\nu}_{\ \gamma} - \tfrac{1}{4}P^2_{\gamma\delta}\delta^{\mu\nu}\right) \\ T^{\alpha\beta}_{(M)} &= \tfrac{1}{\mu^{-1}-\mu_0^{-1}}\left(M^{\mu\gamma}M^{\nu}_{\ \gamma} - \tfrac{1}{4}M^2_{\gamma\delta}\delta^{\mu\nu}\right) - F^{*\mu\gamma}M^{\nu}_{\ \gamma} - F^{\mu\gamma}M^{*\nu}_{\ \ \gamma} , \end{aligned} \tag{21.32}$$

with

$$u^\beta = \begin{pmatrix} c \\ \mathbf{u} \end{pmatrix} \quad , \tag{21.33}$$

$$P^{\mu\nu} = \begin{pmatrix} 0 & \vec{\mathcal{P}} \\ \vec{\mathcal{P}} & \frac{1}{c}(v^a P^b - v^b P^a) \end{pmatrix} \quad , \quad M^{\mu\nu} = \begin{pmatrix} 0 & \vec{\mathcal{M}} \\ \vec{\mathcal{M}} & \frac{1}{c}(v^a M^b - v^b M^a) \end{pmatrix}$$

$$\vec{\mathcal{D}} = \varepsilon\vec{\mathcal{E}} = \varepsilon_0\vec{\mathcal{E}} + \vec{\mathcal{P}} + \tfrac{1}{c}\left(\tfrac{\mathbf{v}}{c} \times \vec{\mathcal{M}}\right) \quad , \quad \vec{\mathcal{H}} = \tfrac{1}{\mu}\vec{\mathcal{B}} = \tfrac{1}{\mu_0}\vec{\mathcal{B}} - \vec{\mathcal{M}} + c\left(\tfrac{\mathbf{v}}{c} \times \vec{\mathcal{P}}\right) .$$

Hence,

$$\begin{aligned} M^{\mu\nu\eta} &= T^{\mu\nu}x^\eta - T^{\mu\eta}x^\nu \\ 0 = \partial_\eta M^{\mu\nu\eta} &= T^{\mu\nu}\partial_\eta x^\eta - \partial_\eta T^{\mu\eta}x^\nu = 3T^{\mu\nu} . \end{aligned} \tag{21.34}$$

21.2.1.4 Discussion in the framework of cooperative scattering

- It seems to me that the problem does not even arise in our cooperative scattering theory, at least as long as we don't do the smooth density approximation. Cooperative scattering from a coarse-grained cloud's does not require the notion of a refractive index. The notion of refractive index is an artifact coming from the smooth density approximation. It is not surprising if its application to coarse-grained atomic clouds can lead to apparently paradox effects. The paradox disappears within a correct microscopic theory of cooperative scattering.

  On the other hand, the collective scattering theory may give some hints on sheer forces within the cloud. Coarse-grained atomic clouds do not have sharp boundaries. Thus, it is not essential, when the pulse enters the cloud, but when a photon is scattered by an individual atom. The Abraham momentum has never been measured really. If we measure p_m and p_{med} we could infer p_A from the difference.

- Timed Dicke state gives wrong results for photon momentum inside cloud...! Can we test this by manipulating the dispersive part of n?

- We can calculate the radiation pressure force. Can we also calculate the Poynting vector?

- Is the small displacement of the momentum halo ring into $-\hbar k_0$ direction real? They all assume that the bulk of the recoil is absorbed by a single atom, but that the other atoms also feel something. Perhaps, this holds for Bragg scattering, where the high cooperativity leave the atoms only with two choices: Be diffracted or stay in the cloud. In disordered clouds the situation may be not so clear.

21.2.1.5 Test using sub-recoil resolving cavities

Advantage: Due to high cavity cooperativity we can enforce backscattering, which facilitates the situation. If a single atom is backscattered from an atom inside the atomic cloud, the recoil imparted to rest of the atomic cloud should be $P = 2(\eta - 1)\hbar k_0$, or $p = P/N$ per atom. If many photons are scattered this should lead to an appreciable acceleration. The use of a sub-recoil resolving cavity could allow detecting the acceleration spectroscopically. Problem: How to distinguish this effect from the shift of the cavity eigenfrequencies due to η?

A cavity immersed in a dielectric medium with n changes its resonances to $\nu_0 = c/\eta\lambda$. This shows that the wavelength is altered in the medium. I.e. forward scattering with $\eta > 1$ shifts a cavity resonance to the red. What does it do to the atomic resonance? Is this the collective Lamb shift?

A microscopic quantum mechanical description, e.g. based on the coupled dipoles model detailed in Sec. 19.3.1 may lead to a deeper understanding of the interplay of radiation and matter in a dielectric medium [1027, 587, 495, 817, 506, 230].

21.2.1.6 Shared recoil?

Assume a BEC irradiated by two intersecting laser beams in Raman configuration tuned in a way as to generate Bragg diffraction. Applying a $\pi/2$ pulse, we observe

matter wave interference. What is the resulting N-body state [1]?

$$|\Psi\rangle = |\Psi_P\rangle \pm |-\Psi_P\rangle = |P, P, P...\rangle \pm |-P, -P, -P, ...\rangle \tag{21.35}$$

$$|\Phi\rangle = (|\psi_{1P}\rangle \pm |-\psi_{1P}\rangle)(|\psi_{2P}\rangle \pm |-\psi_{2P}\rangle)... \tag{21.36}$$

We know the answer: The second case is correct, and we do not create Schrödinger cat states. For every atom, the final state is completely independent of the presence of the other atoms, i.e. the scattering is NOT collective in the sense that the recoil momentum is distributed over several atoms.

Here are some question:

- Why does collective scattering seem to be negligible for Bragg diffraction? We believe that the state generated by a Bragg pulse is a product state (or Schrödinger kitten state): During the scattering process, every atom evolves by itself into a superposition of momentum states, which is shaped the the mean-field of other atoms.

- What does this mean for collective scattering? Is the final atomic state some intermediate situation between $|\Psi\rangle$ and $|\Phi\rangle$? Then there should be entanglement.

- How can we break down the N-body matter wave function we found for collective halos into the individual atoms?

- What is the correct ansatz for the state generated by a pump beam inside an atomic cloud: The timed Dicke ansatz or the product state? They are identical in the single-excited atom case, but different for higher excitations. Must the experiment decide?

  The $p = mc$ argument leads to Abraham, the $p = h/\lambda$ argument to Minkowski!

- 'Hidden' momentum discussion by Saldanha. Consider Amperian current loop in a uniform electric field: $S_{mat} = -I\mathcal{E}baN\hat{y} = \vec{\mathcal{M}} \times \vec{\mathcal{E}}$ There is a net material momentum up canceled by an el.mg. momentum down.

- No interfaces no surfaces in atomic clouds.

- To what might correspond the division into an el.mg. and a medium part in collective scattering?

21.2.2 Exercises

21.2.2.1 Ex: Einstein box Gedankenexperiment with a BEC

Estimate whether the Einstein box experiment is feasible with a BEC using EIT to cancel absorption?

[1] Same idea, assume a BEC in one of two possible hyperfine states. Apply a microwave $\pi/2$-pulse. Look at the internal degrees of freedom.

Solution: *Consider a transparent slab of thickness D and mass M traversed by a radiation pulse of wavevector $\hbar k_0$. The traversal time is,*

$$\tau = \frac{D + \Delta z}{c/\eta} \ , \tag{21.37}$$

where Δz is the displacement of the slab during the transit time. After the pulse entered the slab, the slab a velocity,

$$v_m = \frac{\hbar k_0 - \hbar k_M}{M} \ , \tag{21.38}$$

so that the displacement after the pulse left the slab is

$$\Delta z = v_m \tau = \frac{\hbar(k_0 - k_M)}{M} \frac{D + \Delta z}{c/\eta} \ , \tag{21.39}$$

or

$$Mc^2 = \hbar c(k_0 - k_M)\eta(D + \Delta z) = \hbar\omega(\eta - \eta\frac{k_M}{k_0})(D + \Delta z) \ . \tag{21.40}$$

Relativistic energy must be conserved, because the system is closed, i.e.

$$p_\mu p^\mu = E^2/c^2 - \mathbf{p} \cdot \mathbf{p} = Mc^2 \ . \tag{21.41}$$

Would such an experiment be able to yield one (or both) momenta: Abraham and Minkowski?

21.3 Special topic: Advanced Gaussian optics

The most common mode is a Gaussian laser beam, which is the lowest order Hermite-Gaussian mode. But other modes are possible.

21.3.1 Laguerre-Gaussian beams

Since several years, attention has been drawn on an unusual feature of light: The fact that it carries angular momentum when it is in special modes called a *Laguerre-Gaussian mode* [1208]. Furthermore, while it is well-known that the light polarization couples to the internal degrees of freedom of atoms, the light angular momentum has been predicted to couple to external degrees of freedom, i.e. light should be able to exert a torque to the atomic motion [21, 65, 22, 20, 23, 973]. The torque has been observed on macroscopic particles [1208]. For a hot atomic gas, the Doppler-effect precludes the direct observation of torsional effect. Recently, phase-conjugation by Non-Degenerate Four-Wave Mixing (ND4WM) in a Magneto-Optical Trap (MOT) has been used to indirectly proof that the atoms acquired angular momentum from light [1289]. Also, magneto-optical trap have been constructed based on laser beams [757, 1223]. Those experiments exploited the doonat-shaped intensity distribution of the LG modes, but did not demonstrate the effect of the torque. And frequency shift [302]. Most traps for neutral atoms are based on light forces, for example the MOT works with radiation pressure. Deliberate misalignement of the optical beams within a plane can give rise to vortex forces and set up a racetrack for the atoms [1351, 71].

Laguerre-Gaussian modes can be generated using a *Fresnel zone plate*.

21.3.1.1 Energy density in Laguerre-Gaussian modes

Besides plane and spherical waves, Gaussian beams and many other functions, the Laguerre-Gaussian modes (LGM) are a solution of Maxwell's equations, i.e. they satisfy $\nabla^2 u + k^2 u = 0$, where u is the scalar mode function of the beam [734]. The vector potential in the Lorentz gauge, $\Phi = -\frac{1}{\imath k}\nabla \cdot \mathbf{A}$, of those modes in the paraxial approximation [777] is given by [21],

$$\boxed{\begin{aligned} \mathbf{A}_{nm}(\mathbf{r}) &= \hat{\mathbf{e}}_x u_{nm}(\mathbf{r}) e^{-\imath kz} \\ u_{nm}(\mathbf{r}) &= u_{00}(\mathbf{r}) \left(\tfrac{r\sqrt{2}}{w(z)}\right)^{|l|} L_p^{|l|}\left(\tfrac{2r^2}{w(z)^2}\right) e^{-\imath l\phi}\, e^{\imath(2p+|l|)\arctan\frac{z}{z_R}} \\ u_{00}(\mathbf{r}) &= \tfrac{u_0}{\sqrt{z^2+z_R^2}}\, e^{-\frac{r^2}{w(z)^2}}\, e^{-\frac{\imath k r^2 z}{2(z^2+z_R^2)}}\, e^{\imath \arctan\frac{z}{z_R}} \end{aligned}} \quad , \tag{21.42}$$

where $l = n - m$ and $p = \min(n, m)$. In the following we will use the convenient cylindrical coordinate system defined in (12.43). Note that, for $l = p = 0$ we recover a Gaussian beam, as will be shown in Exc. 21.3.2.3.

21.3.1.2 Poynting vector in Laguerre-Gaussian modes

The energy flux is given by the Poynting vector $\vec{\mathcal{S}} = \mu_0^{-1}\vec{\mathcal{E}} \times \vec{\mathcal{B}} = c^2\mathbf{p}$. $|\vec{\mathcal{S}}|$ is the beam intensity. The energy density is $u = \frac{1}{2}(\varepsilon_0|\vec{\mathcal{E}}|^2 + \mu_0^{-1}|\vec{\mathcal{B}}|^2)$. The linear momentum and angular momentum densities and total momenta are defined as,

$$\begin{aligned} \mathbf{p} &= \int \vec{\wp} d^3r \qquad \text{with} \quad \vec{\wp} = \varepsilon_0 \vec{\mathcal{E}} \times \vec{\mathcal{B}} \\ \mathbf{L} &= \int \vec{\ell} d^3r \qquad \text{with} \quad \vec{\ell} = \mathbf{r} \times \vec{\wp} \end{aligned} \quad . \tag{21.43}$$

The cycle-average of the real part of the linear momentum density can in the paraxial approximation be traced back to the mode function u, respectively, the scalar potential Φ and the vector potential $\mathbf{A}$ using (17.78),

$$\begin{aligned} \langle \vec{\wp} \rangle &= \frac{\varepsilon_0}{2}(\vec{\mathcal{E}}^* \times \vec{\mathcal{B}} + \vec{\mathcal{E}} \times \vec{\mathcal{B}}^*) \\ &= \imath\omega\frac{\varepsilon_0}{2}(u^*\nabla u - u\nabla u^*) + \omega k \varepsilon_0 |u|^2 \hat{\mathbf{e}}_z + \omega\sigma\frac{\varepsilon_0}{2}\frac{\partial |u|^2}{\partial r}\hat{\mathbf{e}}_\phi \; . \end{aligned} \tag{21.44}$$

The components of the linear momentum density are [23],

$$\vec{\wp} = \varepsilon_0 \omega k |u|^2 \left[\hat{\mathbf{e}}_z + \frac{rz}{z^2 + z_r^2}\hat{\mathbf{e}}_r + \left(\frac{l}{kr} - \frac{\sigma}{2|u|^2}\frac{\partial |u|^2}{k\partial r}\right)\hat{\mathbf{e}}_\phi\right] \; . \tag{21.45}$$

The Poynting vector is in general not parallel to the wavevector $\mathbf{k}$, but spirals about the optical axis.

21.3.1.3 Poynting vector in Hermite-Gaussian modes

This holds even for Hermite-Gaussian beams, as we will show in the following. We start from the energy density of a LGM in Eq. (21.42). For a Gaussian mode $l = p = 0$,

$$|u_{00}(\mathbf{r})| = \frac{u_0 e^{-r^2/w(z)^2}}{w(z)} \ . \tag{21.46}$$

we find, as will be shown in Exc. 21.3.2.3,

$$\vec{\wp} = \varepsilon_0 \omega k |u|^2 \left[\hat{\mathbf{e}}_z + \frac{rz}{z^2 + z_r^2} \hat{\mathbf{e}}_r + \sigma \frac{r z_R}{z^2 + z_R^2} \hat{\mathbf{e}}_\phi \right] \ . \tag{21.47}$$

i.e. the radial component vanishes for small beam divergence, the azimuthal component is on the order $w_0/z_R \approx 500$ times smaller.

Inserting the full expression of the energy density of a LGM, one finds one term containing σ and hence predicting spin-orbit coupling. It can be shown that it results in a dissipative force proportional to $l\sigma$ [20].

21.3.1.4 Mechanical forces exerted by Laguerre-Gaussian modes

The Laguerre-Gaussian modes are labeled by n and m, where $l = n - m$ and $p = \min(n, m)$, such that $2p + |l| = m + n$. We should recover the Gaussian field for $l = 0$. The electric field $\mathcal{E}_{lp}(\mathbf{r}) = \varepsilon_{lp}(\mathbf{r}) e^{i\theta_{lp}(\mathbf{r})}$ is,

$$\begin{aligned} \varepsilon_{lp}(\mathbf{r}) &= \varepsilon_{00} \sqrt{\frac{p!}{(|l|+p)!}} \ \frac{e^{-r^2/w(z)^2}}{\sqrt{1 + z^2/z_R^2}} \ \left(\frac{r\sqrt{2}}{w(z)} \right)^{|l|} \ L_p^{|l|} \left(\tfrac{2r^2}{w(z)^2} \right) \ , \\ \theta_{lp}(\mathbf{r}) &= \frac{kr^2 z}{2\,(z^2 + z_R^2)} + l\phi + (2p + l + 1) \arctan \frac{z}{z_R} + kz \ . \end{aligned} \tag{21.48}$$

With the Rabi frequency defined through,

$$\Omega_{lp}(\mathbf{r}) = \Omega_0 \frac{w_0}{w(z)} \ e^{-r^2/w(z)^2} \ \left(\frac{r\sqrt{2}}{w(z)} \right)^{|n-m|} \ L_{\min(n,m)}^{|n-m|} \left(\tfrac{2r^2}{w(z)^2} \right) \ , \tag{21.49}$$

Using the optical Bloch equations, we find the stationary solutions for the dipole and the dissipative forces [20],

$$\begin{aligned} \mathbf{F}_{dip} &= -2\hbar \Omega_{lp}(\mathbf{r}) \ \frac{\Delta}{4\Delta^2 + 2\Omega_{lp}(\mathbf{r})^2 + \Gamma^2} \nabla \Omega_{lp}(\mathbf{r}) \ , \\ \mathbf{F}_{diss} &= 2\hbar \Omega_{lp}^2(\mathbf{r}) \ \frac{\Gamma}{4\Delta^2 + 2\Omega_{lp}(\mathbf{r})^2 + \Gamma^2} \nabla \theta_{lp}(\mathbf{r}) \ . \end{aligned} \tag{21.50}$$

where the gradients are,

$$\nabla \Omega_{lp}(\mathbf{r}) = ... \tag{21.51}$$

and,

$$\begin{aligned} \nabla \theta_{lp}(\mathbf{r}) &= -\nabla \left[-kz - l\phi - \frac{kr^2 z}{2(z^2 + z_R^2)} - (n + m + 1) \tan^{-1} \frac{z}{z_R} \right] \\ &= \left(k + \frac{kr^2}{2(z^2 + z_R^2)} \left(1 - \frac{2z^2}{z^2 + z_R^2} \right) + \frac{(n + m + 1) z_R}{z^2 + z_R^2} \right) \hat{\mathbf{e}}_z + \frac{krz}{z^2 + z_R^2} \hat{\mathbf{e}}_r + \frac{l}{r} \hat{\mathbf{e}}_\phi \ . \end{aligned} \tag{21.52}$$

Here we assume the velocity cold enough not to influence the detuning. Otherwise, we must substitute $\Delta \to \Delta - \mathbf{v}\nabla\theta$. At the waist $z = 0$ and for typical experimental conditions $r, k^{-1} \ll z_R$,

$$\nabla\theta_{lp}(\mathbf{r}) \approx k\hat{\mathbf{e}}_z + \frac{l}{r}\hat{\mathbf{e}}_\phi \ . \tag{21.53}$$

We can now write the azimuthal force and the torque in analogy to the radiation pressure,

$$\mathbf{F}_{az} = \hbar\frac{\mathbf{l}}{r}\ \frac{I}{\hbar\omega}\ \sigma(\Delta) \tag{21.54}$$

and,

$$\mathbf{T} = \hbar\frac{\mathbf{r}\times\mathbf{l}}{r}\ \frac{I}{\hbar\omega}\ \sigma(\Delta) \ . \tag{21.55}$$

If we further concentrate on the first Laguerre-Gaussian mode given by $l = 1$ and $p = 0$ or $n = 1$ and $m = 0$, and assume low saturation $\Omega \ll \Gamma$, we find the force,

$$\mathbf{F}_{diss} = -\hbar\Gamma\left[k\hat{\mathbf{e}}_z + \frac{\hat{\mathbf{e}}_\phi}{r}\right]\ e^{-2r^2/w_0^2}\ \frac{2r^2}{w_0^2}\ \frac{\Omega_0^2}{4\Delta^2+\Gamma^2} \ . \tag{21.56}$$

It consists of a rotational torque and a component in $\mathbf{k}$ direction. For a normal Gaussian field, $l = 0$. The LG modes have a ring-shaped intensity distribution $I^{(Lag)}(x, y)$. Therefore, the rotational force depends on the distance from the axis and has a maximum at the radius $r = w_0/2$. The dipole force contribution may be neglected close to resonance, and higher-order contributions from the LG mode as well.

21.3.1.5 Laguerre-Gaussian standing wave

Many experiments are performed within the Rayleigh range, $z \ll z_R$, where,

$$\begin{aligned} \mathcal{E}_{pl}(r,\phi) &= \mathcal{E}_0 f_{pl}(r)\ e^{-il\phi}e^{\imath(\omega t-kz)} \ , \\ f_{pl}(r) &= \frac{\Omega_{pl}(r)}{\Omega_0} = \frac{e^{-r_w^2/2}}{z_R}\ r_w^{|l|}\ L_p^{|l|}(r_w^2) \ . \end{aligned} \tag{21.57}$$

where we introduced the normalized paraxial distance $r_w \equiv r\sqrt{2}/w_0$. When such a Laguerre-Gaussian beam is reflected form a mirror reflected from a mirror it changes the signs of $k \longrightarrow -k$ but not $l \to l$. We obtain a standing wave, made of ring-shaped potentials,

$$\left|f_{pl}(r)\ e^{-\imath l\phi}e^{\imath(\omega t-kz)} + f_{pl}(r)\ e^{-\imath l\phi}e^{\imath(\omega t+kz)}\right|^2 = 4f_{pl}^2(r)\cos^2 kz \ . \tag{21.58}$$

At $z = 0$ the potential reads

$$U_{pl} = \frac{\Omega^2}{4\Delta} = \frac{\sigma_0\Gamma I(x,y)}{\hbar\omega 4\Delta} = \frac{\Omega_0^2}{4\Delta}4f_{pl}^2(r) \ , \tag{21.59}$$

If in contrast the counterpropagating beam has an inverse angular momentum,

$$\left|f_{pl}(r)\ e^{-\imath l\phi}e^{i(\omega t-kz)} + f_{pl}(r)\ e^{\imath l\phi}e^{\imath(\omega t+kz)}\right|^2 = 4f_{pl}^2(r)\cos^2(kz-l\phi) \ , \tag{21.60}$$

the superposition of a Laguerre-Gaussian beam with a reflected beam gives an azimuthally periodic modulation like a circular $1D$ lattice, which is twisted along the $\hat{z}$-axis. However there is no axial confinement. The intensity resembles a knot of l worms winding about the $\hat{z}$-axis at constant distance like helices. Axial modulation has to be obtained by an additional plane wave [27].

Let us calculate the dipole force via $\mathbf{F} = -\nabla U$,

$$\begin{aligned} \frac{\partial f_{pl}^2(r)}{\partial x} &= 2 f_{pl}(r) \frac{\partial r}{\partial x} \frac{\partial}{\partial r} \frac{e^{-r_w^2/2}}{z_R} \; r_w^{|l|} \; L_p^{|l|}(r_w^2) \\ &= f_{pl}(r)^2 \frac{8x}{w_0^2} \left[\frac{|l|}{2r_w^2} - \frac{1}{2} - \frac{L_{p-1}^{|l|+1}(r_w^2)}{L_p^{|l|}(r_w^2)} \right] \end{aligned} \tag{21.61}$$

using $\frac{d}{dx} L_n^{(m)}(x) = -L_{n-1}^{(m+1)}(x)$.

21.3.1.6 Creation of Laguerre-Gaussian modes

The polarization of light couples to the internal degrees of freedom of the atoms. But special light modes, i.e. the higher-order Laguerre-Gaussian (LG) modes, may carry orbital angular momentum. This angular momentum couples to the external degrees of freedom of the atoms [21, 65, 22, 20], i.e. the light exerts a torque onto the atoms. This light force is, however, very weak and in a gas cell with hot atoms, the Doppler-effect smears out the motional effect. Nevertheless, the torque has been observed with macroscopic particles [1208]. And in a Magneto-Optical Trap (MOT), phase-conjugation by nondegenerate four-wave mixing has been used to indirectly prove the transfer of angular momentum to the atoms [1289]. Finally, MOTs using Laguerre-Gaussian laser beams been constructed, however without demonstrating the effect of the torque [757, 1223].

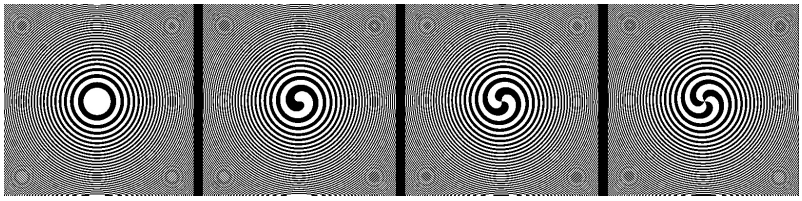

Figure 21.3: Masks for generating Laguerre-Gaussian beams.

The interference of such a mode with a plane wave v yields interference patterns proportional to,

$$u_{nm}(\mathbf{r}) e^{-ikz} + v_{nm}(\mathbf{r}) e^{-ikz} \propto \cos\left(-l\phi - \frac{kr^2 z}{2z_R^2} - (m+n+1) \arctan \frac{z}{z_R} \right) . \tag{21.62}$$

At some distance $z \neq 0$ and for $l \neq 0$ the patterns have Yin-Yang spiral shape. Inversely, like in holography, plane waves are *diffracted* at the spiral patterns in such a way that they generated a Laguerre-Gaussian mode. This is not an image. Images are also formed with undiffracted parts of the plane wave. The patterns form a fundamental focus at a distance f and subfoci at distances $f/2$, $f/3$, ... The fundamental

beam is separated from the undiffracted and higher-order Fresnel modes by a short focal length lens placed in the fundamental focus. A spiral mask can be generated by setting $z = z_R$ in Eq. (21.62) and filling black the region where r and ϕ satisfy [593],

$$\cos\left(-l\phi - \frac{kr^2}{2z_R} - \pi(n + 1/2)\right) > 0 \ . \tag{21.63}$$

A special case is defined by $l = 0$ which reproduces the *Fresnel zone plate*. The orbital momentum may be transferred to the atomic motion. Perhaps this also has an effect on the internal degrees of freedom: The higher-order orbital angular momentum may couple to higher multipole moments. At reflection on a mirror, the symmetry of the LG mode is inverted. Therefore, we can build a standing wave LG beam with no axial force (if the intensities are balanced and the waists matched) and twice the torque. LG modes can also be created from normal Gaussian modes with an arrangement of cylindrical lenses.

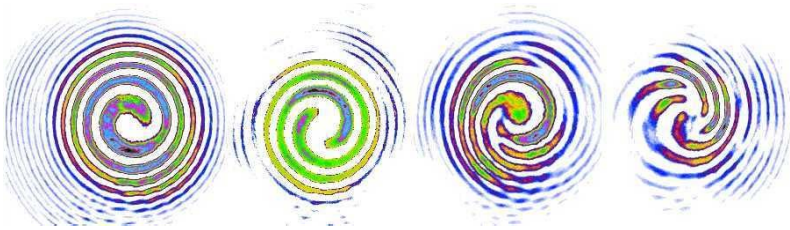

Figure 21.4: Laguerre-Gaussian beams with various charges.

21.3.1.7 Optical signatures

The interference of a Laguerre-Gaussian mode (LGM) with a phase-matched plane wave Gaussian beam yields interference patterns shown in the above figure. In the far-field, the laser beam forms a ring-shaped LGM. Higher-order topological charges are easily detected in the interference patterns through the occurrence of bifurcations or by the number of arms spiraling into the center.

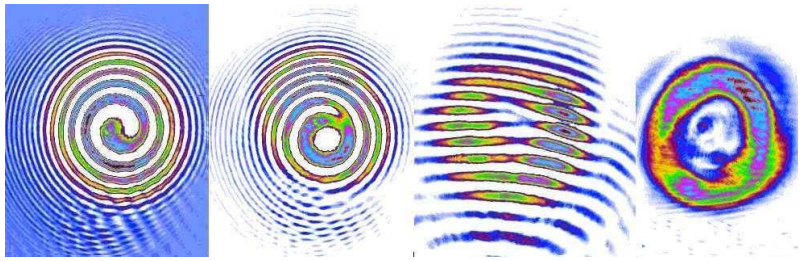

Figure 21.5: Bifurcations in a Laguerre-Gaussian beam.

21.3.1.8 Detection of photon torque in ion traps

The general force of a light beam on an atom consists of the dipole force which depends on the intensity gradient in the light beam and the radiation pressure which is proportional to the phase gradient. The dipole force has a neglegible contribution to the torque, so that we will concentrate on the radiation pressure.

The torque eventually accelerates a rotational motion of the irradiated atoms that may be directly detected by suitable velocimetric schemes (i.e. heterodyne beating [1371]). The methods are based either on the Doppler effect shifting the atomic resonance lines or on the spatial resolution of the coordinate ot momentum distribution of the atoms. We will discuss four possibilities: A. fluorescence spectra, B. excitation spectra, C. fluorescence imaging, D. absorption imaging.

For detection of the pure effect, one might consider either free atoms, optical molasses, atoms trapped in a MOT or ions confined in Penning or Paul traps. Ion traps are better suited for detecting the Doppler shift [1048]. The ion traps are very deep (several eV) so that they can stay trapped even when heated by laser beams. MOTs or molasses or cold atoms in free expansion might allow to detect the effect of redistribution of the atoms by the azimuthal force.

Hot gases have inhomogeneously Doppler broadened fluorescence spectra. For a Maxwell-Boltzmann velocity distribution, the line profile will be Gaussian. On the other hand, if the atoms are cold $k\bar{v} < \Gamma$, the inhomogeneous broadening disappears and the linewidth is given by the spontaneous decay of the upper level (Lamb-Dicke regime). If cold atoms are subject to a torque, the velocity distribution will exhibit a significant deviation from the Gaussian shape. The shape of the fluorescence spectrum also should strongly depend on the observation axis. In the simplest case of atoms rotating with a constant velocity of 12 m/s around the z-axis, watching perpendicularly to the z-axis the fluorescence spectrum should exhibit shoulders. Could also take stroboscopic TOF pictures. For sodium $\Gamma = 2\pi \times 10\,\mathrm{MHz}$ this corresponds to 6 m/s velocity or 40 μK temperature.

The excitation spectrum of a single oscillating two-level atom is easy to predict. For a sodium atom $\lambda = 589\,\mathrm{nm}$, rotating with $\omega_{rot} = 2\pi \times 10\,\mathrm{kHz}$ on an orbit with $r = 1\,\mathrm{mm}$, radius the excitation spectrum can be described by a convolution (figure). For multi-level systems, we have to solve the Bloch equations with an oscillating term using the method of infinite fractions. For sodium, the characteristics cannot be resolved because of the hyperfine splitting being smaller than $kv_{\max} \approx 2\pi \times 100\,\mathrm{MHz}$. Cesium might be better.

Experimentally, one could either analyze the *fluorescence spectrum* with homodyne beating or deduce the velocity distribution from the dependence of the optical cross section of the Doppler-induced detuning, i.e. by recording *excitation spectra* [2].

21.3.1.9 Detection of photon torque in atomic gases

Let us consider a cloud of 10^9 sodium atoms at densities around $10^9\,\mathrm{cm}^{-3}$ and temperatures around 300 μK. Then the magnetic field is suddenly switched off and the laser beams are detuned further from resonance and attenuated. This configuration consists a friction force for the atoms, but there is no restoring force. The atoms move

[2] An interesting question is whether there is coupling to higher multipole moments of internal transitions.

in this so-called *optical molasses* for 5 ms before the laser beams are switched off, too. After 15 ms, a time-of-flight image tells us the velocity distribution at the switch-off time. During the molasses period, we can irradiate two counterpropagating LG laser beams along the symmetry axis of the trap. This light is resonant to the $F = 2$ to $F' = 3$ transition of the $D2$ line.

Being released from the MOT, the atoms are initially inhomogeneously distributed in space as well as in velocity space. Then molasses, then atoms feel different $\Omega(\mathbf{r}, \Delta)$. Effects of optical pumping and repumping in a multi-level system? Problems with imbalanced z component in the standing wave LG beam? Consider collisions? Atoms get out of resonance when $kv \gg \Gamma, \Omega$.

Comparing the equations for radiation pressure and for the azimuthal force, we see that the relative strength of the forces is like k and r^{-1} which is on the order of 1:10000 for typical experimental conditions, and the wanted effect is rather small. The longitudinal radiation pressure can be compensated by taking two counterpropagating beams. Upon reflection on a mirror, the symmetry of the LG mode is inverted, so that it is easy to build a standing wave LG beam with no axial force (if the intensities are balanced and the waists matched) and twice the torque [3].

21.3.1.10 Monte-Carlo simulations

Numerical Monte-Carlo simulations of the motion of the atoms in a Laguerre-Gaussian beam can be performed by solving the deterministic Newton equations and adiabatically updating the initial conditions. This procedure disregards the stochastic recoil induced by spontaneous emission and therefore does not reproduce the random walk of the atoms. We start by generating a numeric atomic cloud trapped in a MOT with randomly distributed initial conditions in position and velocity space. The velocity distribution is chosen according to a temperature of 300 μK, the position distribution according to reproduce the experimentally observed size of the MOT, i.e. typically 3 mm. We sometimes arbitrarily distort the position distribution to make the influence of the torque more visible.

It is important to consider the cross saturation of both the molasses and the Laguerre beams $j = ML, LG$:

$$\sigma_{m=x,y,z}(\Delta^{(j)}) = \frac{\Gamma^2}{4(\Delta^{(j)} - k\hat{\mathbf{e}}_m\mathbf{v} - \mu_B/\hbar \cdot (\mathbf{r}\cdot\nabla)B)^2 + 2\sum_j \sum_{n=x,y,z} 2\Omega_n^{(j)}(\mathbf{r})^2 + \Gamma^2} , \tag{21.64}$$

where

$$\Omega^{(ML)}_{m=x,y,z}(\mathbf{r}) = \Omega^{(ML)} e^{-|\hat{\mathbf{e}}_m \times \mathbf{r}|^2/w^2_{mot}} \tag{21.65}$$

and

$$\Omega^{(LG)}_{m=x,y}(\mathbf{r}) = \Omega^{(LG)} e^{-|\hat{\mathbf{e}}_m \times \mathbf{r}|^2/w^2_{LG}} \sqrt{2}\frac{|\hat{\mathbf{e}}_m \times \mathbf{r}|}{w_{LG}} . \tag{21.66}$$

[3] An interesting question is whether LG beams can be coupled into linear cavities. If so, we expect ring-shaped intensity profiles, with axial standing wave modulation, having a constant angular momentum along axial direction. This would represent an ideal system to study torque, since the axial component is balanced *exactly*.

The forces of the molasses beams and the Laguerre-Gaussian beam are calculated in two dimensions by,

$$\mathbf{F} = \sum_{m=\pm x,\pm y,\pm z} \hat{\mathbf{e}}_m \hbar k \cdot \frac{\Omega_m^{(ML)}(\mathbf{r})}{\Gamma}^2 \cdot \frac{\sigma_m(\Delta^{(ML)})}{\sigma_0} + \sum_{m=\pm x,\pm y} \hat{\mathbf{e}}_\vartheta \hbar/r \cdot \frac{\Omega_m^{(LG)}(\mathbf{r})^2}{\Gamma} \cdot \frac{\sigma_m(\Delta^{(LG)})}{\sigma_0} \ . \tag{21.67}$$

Employing the Verlet algorithm for the Monte-Carlo iteration of the position and velocity of the atoms after each time step dt

$$\begin{aligned} \mathbf{r} &= \mathbf{r}_0 + \mathbf{v}_0 dt + \tfrac{1}{2m}\mathbf{F}_0 dt^2 \\ \mathbf{v} &= \mathbf{v}_0 + \tfrac{1}{2m}(\mathbf{F} + \mathbf{F}_0) dt \\ t &= t + dt \ . \end{aligned} \tag{21.68}$$

Here, Δ_{mot}, Ω_{mot}, and w_{mot} denote the detuning, Rabi frequency and waist of the molasses (and MOT) beams.

A more sophisticated method would simulate the random walk by including spontaneous emission either simultaneously doing Monte-Carlo wavefunction simulations of the optical Bloch equations or by simulating a random waiting time to the next absorption process.

The most obvious impact of the Laguerre-Gaussian beam on the atomic motion was seen when 1) a non-uniform spatial MOT distribution was generated, 2) the LG beam was strongly saturating and irradiated for several ms during the molasses period (that way, the velocity distribution was modified by the torque, but the viscous friction did not allow a radial acceleration), 3) the atoms were allowed to ballistically expand. This converted the velocity distribution into a position distribution and gave rise to a characteristic shape of the atomic cloud [478].

21.3.2 Exercises

21.3.2.1 Ex: Gaussian and Laguerre-Gaussian beams

Convince yourself that the Laguerre-Gaussian beam parametrized in (21.42) corresponds to the Gaussian beam of (18.293).

Solution: *The Gaussian beam is,*

$$\psi(\mathbf{r}) = \frac{w_0}{w} e^{\imath \arctan(-z/q_0) - \imath k(x^2+y^2)/2q} = \frac{w_0}{w} e^{-kr^2 z_R/2(z^2+z_R^2)} e^{\imath \arctan(-z/q_0) - \imath k r^2 z/2(z^2+z_R^2)} \ ,$$

using (18.288). On the other hand, the zero-order Laguerre-Gaussian beam is,

$$\begin{aligned} u_{00}(\mathbf{r}) &= \frac{u_0}{\sqrt{z^2+z_R^2}} e^{-kr^2 z_R/2(z^2+z_R^2)} e^{\imath \arctan(-z/q_0) - \imath k r^2 z/2(z^2+z_R^2} \\ &= \frac{u_0}{z_R}\frac{w_0}{w} e^{-kr^2 z_R/2(z^2+z_R^2)} e^{\imath \arctan(-z/q_0) - \imath k r^2 z/2(z^2+z_R^2)} = \frac{u_0}{z_R}\psi(\mathbf{r}) \ , \end{aligned}$$

using $L_0^0(x) = 1$.

21.3.2.2 Ex: Motion of atoms in Laguerre-Gaussian beams

Programs on the motion of atoms in Laguerre-Gaussian beams.

Solution: *LaguerreGaussian1*
LaguerreGaussian2 intensity and phase profile and force fields.
LaguerreGaussian3 beating with a plane wave.
LaguerreGaussian4 superposition with a reflected wave.
LaguerreExpansion Motion of a free atom in a MOT with Laguerre-Gaussian laser beam. Calculated trajectories and endpoints for several atoms, the force stops when Doppler shift ¿ linewidth.
LaguerreExpansion1 Only endpositions calculated.
LaguerreExpansion2 Makes a movie.
LaguerreExpansion3 Makes a movie, specializes on first order Laguerre beam.
LaguerreExpansion4 Nonlinearized molasses forces without random walk by spontaneous emission.
LaguerreExpansion5 Atomic motion in a ring built by counterpropagating LG beams with dipole force.

21.3.2.3 Ex: Linear momentum density for Hermite-Gaussian modes

Compare the linear momentum density for Hermite-Gaussian (18.293) and Laguerre-Gaussian (21.42) modes.

Solution: *Using (18.290) ...*

21.4 Special topic: Superconductivity

At low temperatures some metals completely give up electric resistance. This effect found by Kammerlingh-Onnes is called *superconductivity* and has been explained through Bose-Einstein condensation of electron pairs [290]. But before we outline this theory let us try a classical approach based on electrodynamics as proposed by Fritz and Heinz London.

21.4.1 London model of superconductivity and the Meissner effect

We learned in Sec. 14.3.2 that *Ohm's law* is explained within the Drude model by the fact that the accelerating Coulomb force of the electric field, $m\dot{\mathbf{v}} = q\vec{\mathcal{E}}$, is spoiled by collisions,

$$\mathbf{j} = \varsigma\vec{\mathcal{E}} \,. \tag{21.69}$$

Let us now suppose a perfect conductor, where collisions are absent. Then, if we want the current density $\mathbf{j} = \varrho\mathbf{v}$ to be constant,

$$0 = \dot{\mathbf{j}} = \varrho\dot{\mathbf{v}} = -\frac{q^2 n_e}{m}\vec{\mathcal{E}} \,, \tag{21.70}$$

where $\varrho = -en_e$ is the free electron charge density.

Let us now study the behavior of the magnetic field in a conductor with $\mu_0 = 0$. Maxwell's equations require,

$$\nabla \times \vec{\mathcal{E}} = -\dot{\vec{\mathcal{B}}} \quad \text{and} \quad \nabla \times \vec{\mathcal{B}} = \mu_0 \mathbf{j} + \dot{\vec{\mathcal{D}}} \,. \tag{21.71}$$

Assuming $\dot{\vec{\mathcal{D}}} = 0$ the above equations can easily be solved, yielding,

$$\boxed{\nabla^2 \dot{\vec{\mathcal{B}}} = \frac{\mu_0 n_e q^2}{m} \dot{\vec{\mathcal{B}}}} \,. \tag{21.72}$$

This equation describes the behavior of a magnetic field in and around a perfect conductor.

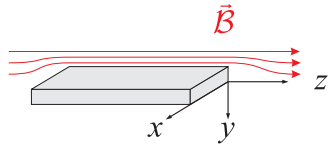

Figure 21.6: Scheme of the Meissner effect.

As we will see in Exc. 21.4.5.1, the solution of Eq. (21.72) predicts an expulsion of the magnetic field out of the conductor, as illustrated in Fig. 21.6. This effect is termed the *Meissner-Ochsenfeld effect*. That is, in the absence of resistivity, a conductor acts like a perfect diamagnetic (magnetic susceptibility $\chi_m = 1$). According to the Lenz rule, the electrons try to compensate any $\mathcal{B}$-field change by collectively rotating such as to counteract the change. The electrons rotate in such a way that the $\mathcal{B}$-field disappears inside the conductor, which leads to an amplification of the field near the surfaces. As a consequence, permanent magnets are repelled from superconducting surfaces.

The problem is that the discontinuity of the magnetic field at the periphery of the superconductor should violate the continuity equation. And in fact, it is experimentally observed, that the magnetic field is not completely expelled from thin superconducting films, because the magnetic field penetrates somewhat into the superconductor with the penetration depth λ_L. In order to understand this, it is necessary to replace the classical *Ohm's law* for the current density $\mathbf{j}$ and the electric field $\vec{\mathcal{E}}$, $\mathbf{j} = \varsigma \vec{\mathcal{E}}$, by the *London equation*.

The London brothers postulates that the magnetic field inside a superconductor would not only be constant, as predicted by Eq. (21.72) by vanish altogether,

$$\boxed{\nabla^2 \vec{\mathcal{B}} = \frac{\mu_0 n_e q^2}{m} \vec{\mathcal{B}}} \,. \tag{21.73}$$

We will study consequences of this equation in Exc. 21.4.5.2.

21.4.1.1 Derivation of the London equation

The London equation can be derived in the framework of quantum mechanics, considering the superconducting state as a macroscopically extended quantum state de-

scribed by the following wavefunction,

$$\psi(\mathbf{r}) = \psi_0 e^{\imath S(\mathbf{r})} \ , \tag{21.74}$$

where $S = S(\mathbf{r})$ is the phase of the macroscopic wavefunction. $\psi_0^2 = n_e$ corresponds to the density of the number of Cooper pairs in the superconductor. The implicit assumption of a homogeneous density of the Cooper pairs is reasonable, since the pairs are negatively charged and repel each other. Any imbalance of the density of pairs would therefore generate an electric field, which would be compensated immediately. The kinetic momentum operator in the presence of a magnetic field, $\mathbf{p} = -\imath\hbar\nabla - q\mathbf{A}$, where $\mathbf{A} = \mathbf{A}(\mathbf{r}, t)$ is the vector potential of the magnetic field, applied to the wavefunction ψ gives,

$$m\mathbf{v}\psi = \mathbf{p}\psi = (\hbar\nabla S - q\mathbf{A})\psi \ . \tag{21.75}$$

That is,

$$\mathbf{v} = \frac{\hbar}{m}\nabla S - \frac{q}{m}\mathbf{A} \ . \tag{21.76}$$

With $\mathbf{j} = qn_e\mathbf{v}$ follows immediately,

$$\boxed{\mathbf{j} = \frac{n_e q\hbar}{m}\nabla S - \frac{n_e q^2}{m}\mathbf{A}} \ . \tag{21.77}$$

This is the London equation.

There are two useful forms of this equation, sometimes referred to as the 1^{st} and the 2^{nd} London equation,

$$\partial_t \mathbf{j} = \frac{n_e q^2}{m}\vec{\mathcal{E}} \ , \tag{21.78}$$

and

$$\nabla \times \mathbf{j} = -\frac{n_e q^2}{m}\vec{\mathcal{B}} \ . \tag{21.79}$$

The phase S does not contribute to these two equations. It does not contribute to the first equation, because the phase is only dependent on the position and therefore constant in time, and it does not contribute to the second equation, because $\nabla \times \nabla S = 0$ [4]

21.4.2 BCS theory

Many-body effects like superconductivity are not explained by the free electron or the Bloch model. Superconductivity is characterized by two main features: The disappearance of electrical resistance in some metals at temperatures below roughly $T \simeq 10\,\mathrm{K}$, and the expulsion of magnetic flux lines out of the metals, known as Meissner-Ochsenfeld effect.

According to Bardeen-Cooper-Schrieffer near the edge of the Fermi surface induced by weak attractive interactions strong correlations in momentum space may build up.

[4] Note that, although the phase does not contribute to the last two formulas, it should not be neglected! If the phase component were not included, it would mean that the current density without magnetic field would have to be zero. In reality, however, the phase gradient can also contribute to the current density, which therefore need not necessarily be zero, i.e. the current density is not zero, although no magnetic field is applied.

Such interations can be mediated by local polarization traces, i.e. deformations of the lattice or phonons, imprinted by a moving electron into the metallic lattice and sensed by a second electron following at a reasonable distance [207, 244]. Thus Fermi gases are unstable with respect to formation of bound fermion pairs. However, fermion pairs are not bound in the ordinary sense, and the presence of a filled Fermi sea is essential. Rather, we have a many-body state. Hence, the interpretation as a Bose-condensate of Cooper pairs explains some characteristics like the existence of a delocalized macroscopic wavefunction and the superfluid-like behavior suppressing the electrical resistance. But it oversimplifies and does not account for the important role of fermionic statistics in the many-body state.

The requirements for Cooper pairing are 1. low temperature to rule out thermal phonons, 2. strong electron-lattice interaction, 3. many electrons just below E_F, 4. anti-parallel spins, and 5. antiparallel momentum of the electrons.

Below T_c the motions of the electrons and the ions in the lattice are highly correlated. Cooper pairs are weakly bound, in thermal equilibrium with unpaired electrons, and have a vanishing total momentum. The typical distance of the electrons in a pair is roughly 100 nm. Although the fraction of paired electrons is only 10^{-4}, their number within the volume occupied by a single pair is 10^6.

Cooper-pairs form through scattering processes. Since all states below the Fermi surface are occupied, the final momenta must be above k_F. In other words, the two electrons are excited from slightly below $E = E_F$ to slightly above $E + E_g/2 = E_F$, where they profit from the large amount of available empty states allowing for their high mobility and letting them transit into the strongly correlated pairing state. The pairs then have the binding energy E_g, because the increase in kinetic energy must be overcompensated by the potential energy. Such processes smooth out the Fermi edge even at $T = 0$, as if the temperature really were at $T \simeq T_c$.

An energy gap forms which has just the width E_g. Its origin is understood as follows: If an electron could slightly change its energy, the pair correlation would immediately break up and the binding energy E_g liberated. But this energy cannot be dissipated. Since the binding energy for Cooper pairs is roughly $E_g \simeq 3k_BT_c$, a thermal noise source must at least provide the energy $3k_BT_c$, which is not possible if $T < T_c$. At higher temperatures, the pairing gap narrows and vanishes at $T = T_c$. The gap can be spectroscopically probed with IR radiation.

Higher $\mathcal{B}$ fields require lower critical temperatures. The critical temperature drops with rising mass of the ions, $T_c m^{1/2} = const.$ This indicates that the vibration of the lattice ions is crucial for superconductivity.

Magnetic fields trying to penetrate superconducting wires perturb the superconductivity. This problem can be reduced in type II superconductors, where the size of the Cooper pairs are reduced and employing superconducting wires containing normal conducting channels.

The quantitative treatment starts with the two-body Schrödinger equation,

$$\left[-\frac{\hbar^2}{2m}(\nabla_1^2 + \nabla_2^2) + V(r_1 - r_2)\right] \Psi(r_1, r_2) = (E + 2E_F)\Psi(r_1, r_2) \ . \tag{21.80}$$

Here we assume singlet pairing s-wave collisions. Center-of-mass and relative coordinates are now separated, giving,

$$\left[-2\frac{\hbar^2}{2m}\nabla_r^2 + V(r)\right]\psi(r) = \left(E + 2E_F - \frac{\hbar^2 K^2}{4m}\right)\Psi(r) \ . \tag{21.81}$$

Transforming into momentum space, assuming that the Fourier transform $V(p,p') = V^{-1}\int e^{-\imath(p-p')r}V(r)d^3r$ is only nonzero, $= V_0$, inside an energy interval smaller than the Debye frequency $\hbar\omega_D$ close to the Fermi surface, we finally arrive at the binding energy of the Cooper-pair,

$$E = -\frac{2\hbar\omega_D}{e^{2/V_o D(E_F)} - 1} \ , \tag{21.82}$$

where $D(E_F) \propto k_F$ is the density of states at the Fermi surface. Estimating $V(r) \approx \hbar^2/ma^2$ the Fourier transform goes like $V_0 \propto a$, so that $k_B T_{BCS} \propto -e^{-\pi/2k_F|a_s|}$(see Sec. 49.4).

A full quantum treatment reveals the presence of a gap. This gap can also be understood in the following way. In the normal state the energy spectrum is twofold degenerate. A state with a hole in the Fermi surface has the same energy as a state with an electron above the Fermi surface. Cooper-pairing couples those states, which leads to energy splitting and introduces a *pairing gap*,

$$|u_k|^2 = \frac{1}{2}\left[1 + \frac{\epsilon_k - E_F}{\sqrt{\Delta_0^2 + (\epsilon_k - E_F)^2}}\right] = 1 - |v_k|^2 \tag{21.83}$$
$$\Delta = -\sum_k u_k v_k \ .$$

The product $u_k v_k$ only contributes near the Fermi surface. We get a density of states,

$$D_s(E) = D_n \frac{|E - E_F|}{\sqrt{-\Delta_0^2 + (\epsilon_k - E_F)^2}} \ , \tag{21.84}$$

which has a gap. The states are redistributed toward the edges of the gap.

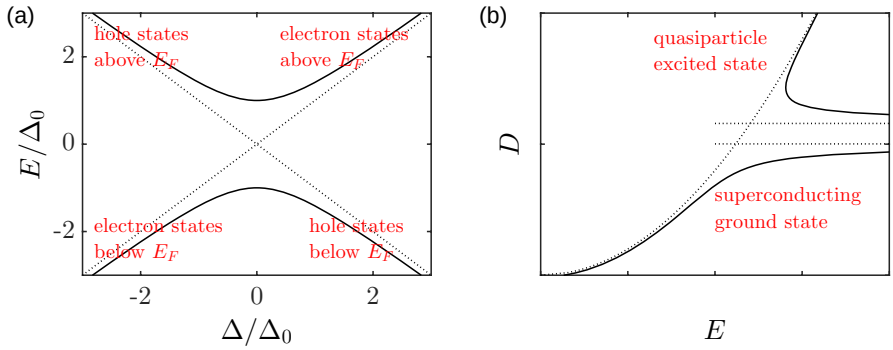

Figure 21.7: Pairing gap in the energy spectrum and the density of states.

21.4.3 Josephson junctions

Two superconductors that are joined by a nm thin isolating oxide layer build a *Josephson junction* (JJ) [685]. Cooper pairs may tunnel through the junction producing a current flow i_J. The basic JJ is described by,

$$i_J = I_c \sin\varphi \qquad \text{and} \qquad v = \frac{\Phi_0}{2\pi}\frac{d\varphi}{dt} \ , \tag{21.85}$$

where

$$\Phi_0 = \frac{h}{2e} \ . \tag{21.86}$$

I_c is the critical supercurrent of the junction, and v is the voltage at the JJ. φ is a dynamical variable describing the phase difference between the macroscopic wave functions on both sides of the junction. Note that for small φ we have $u \propto i$ similar to the situation in a magnetic coil. The *ac*-Josephson effect consists in applying a constant voltage. Then φ increases linearly in time and the Josephson-current oscillates at a given (microwave) frequency [505],

$$f_J = \frac{v}{\Phi_0} \ . \tag{21.87}$$

This allows a very precise measurement of h/e.

21.4.4 Synchronization of coupled Josephson junctions

The superconducting flux is quantized. A *superconducting quantum interference device* consist of two JJs connected in parallel. In that way the *supercurrent* is split and recombined.

21.4.4.1 Resistively shunted junctions

In a widely accepted model of nonideal *resistively shunted junctions* (RSJ) [1031] the junction current consists of three components: A superconducting current $i_J = I_c \sin\varphi$, a resistive current $i_R = v/R$, and a capacitance current $\dot{v}C$ (see Fig. 21.8). From Kirchhoff's laws using (21.85),

$$C\frac{\Phi_0}{2\pi}\frac{d^2\varphi}{dt^2} + \frac{1}{R}\frac{\Phi_0}{2\pi}\frac{d\varphi}{dt} + I_c \sin\varphi = i \ , \tag{21.88}$$

if the resistance is assumed independent of the applied voltage. Located in front of the term $\dot{\varphi}$ the resistivity is inversely proportional to the dissipation. The reason for this is that dissipation occurs via *single-particle tunneling*. Note that the equation is identical to that of an overdamped rotator or of a phase-locked loop.

Neglecting the resistance, the equation of motion can be derived from the Hamiltonian,

$$\hat{H} = \frac{p_\varphi^2}{2C\Phi_0/2\pi} - i\varphi - I_c \cos\varphi \ , \tag{21.89}$$

via $\dot{\varphi} = \frac{\partial H}{\partial p_\varphi}$ and $\dot{p}_\varphi = -\frac{\partial H}{\partial \varphi}$. The φ and p_φ are conjugate variables,

$$[\varphi, p_\varphi] = \imath \ . \tag{21.90}$$

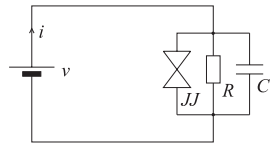

Figure 21.8: Resistively shunted Josephson junction.

Let us go to scaled variables via $\tilde{H} \equiv H/(C\Phi_0/2\pi)$, $\tilde{p_\varphi} \equiv p_\varphi/(C\Phi_0/2\pi)$, $K \equiv I_c/(C\Phi_0/2\pi)$, and $\lambda \equiv i/(C\Phi_0/2\pi)$,

$$\tilde{H} = \frac{\tilde{p}_\varphi^2}{2} - \lambda\varphi - K\cos\varphi \ , \tag{21.91}$$

In these units,

$$[\varphi, \tilde{p}_\varphi] = \imath\frac{e}{\hbar C} \ . \tag{21.92}$$

21.4.4.2 Response to *ac* driving sources

Let the applied voltage be $v(t) = V_0 + V_s\cos\omega_s t$. We may substitute the voltage in (21.85) and integrate,

$$\varphi = \varphi(0) + \frac{2\pi}{\Phi_0}V_0 t + \frac{2\pi}{\Phi_0}\frac{V_s}{\omega_s}\sin\omega_s t \ . \tag{21.93}$$

The resistive current is then,

$$i_R = \frac{V_0}{R} + \frac{V_s}{R}\cos\omega_s t \ , \tag{21.94}$$

and plugging (21.93) this into the Josephson current (21.85),

$$\begin{aligned} i_J &= I_c\sin\left(\varphi(0) + \frac{2\pi}{\Phi_0}V_0 t + \frac{2\pi V_s}{\Phi_0\omega_s}\sin\omega_s t\right) \\ &= I_c\sum_n (-1)^n J_n\left(\frac{2\pi V_s}{\Phi_0\omega_s}\right)\sin\left[(f_J - n\omega_s)t + \varphi(0)\right] \ , \end{aligned} \tag{21.95}$$

where we expanded the double sine into Bessel-functions. The time-averaged Josephson current disappears unless $f_J = n\omega_s$,

$$\bar{i}_J = I_c\sum_n (-1)^n J_n\left(\frac{2\pi V_s}{\Phi_0\omega_s}\right)\sin\left[\varphi(0)\right]\ \delta(f_J - n\omega_s) \ . \tag{21.96}$$

The averaged total current $\bar{i} = \bar{i}_R + \bar{i}_J$ as a function of the applied voltage v thus obtains a washboard-type characteristics,

$$\bar{i} = \frac{V_0}{R} + I_c\sum_n (-1)^n J_n\left(\frac{2\pi V_s}{\Phi_0\omega_s}\right)\sin\left[\varphi(0)\right]\ \delta(v - n\omega_s\Phi_0) \ . \tag{21.97}$$

The plateaus in the i-v characteristics are called *Shapiro steps*. They appear at voltages $n\hbar\omega_s/4\pi e$. In the case of arrays of m JJs, steps are also observed at voltages corresponding to rational fractions of frequencies $m\omega_j = n\omega_s$, provided the JJs are locked [249].

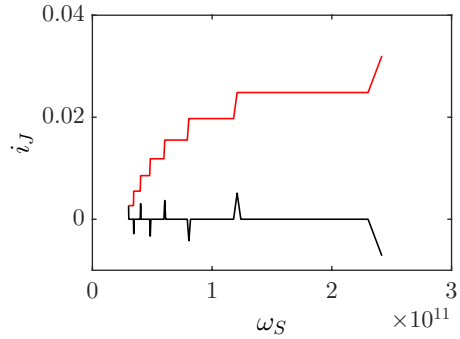

Figure 21.9: (code) Shapiro steps and their derivative.

21.4.4.3 Locking

To study the locking phenomenon we simplify the JJ equation by neglecting dissipation, $C = 0$,

$$\frac{\Phi_0}{2\pi}\frac{d\varphi}{dt} = Ri + RI_c \sin\varphi \ . \tag{21.98}$$

This is the so-called *Adler equation*,

$$\frac{d\psi}{dt} = -\nu + \varepsilon \sin\psi \ , \tag{21.99}$$

whose formal solution is [1031],

$$t = \int \frac{d\psi}{\varepsilon \sin\psi - \nu} \ . \tag{21.100}$$

The beat frequency is,

$$\Omega_\psi = 2\pi \left| \int \frac{d\psi}{\varepsilon\left(1 - \frac{\psi^2}{2}\right) - \nu} \right|^{-1} \ , \tag{21.101}$$

expanding around the maximum at $\psi = \pi/2$,

$$\Omega_\psi \simeq \pi\varepsilon \left| \int \frac{d\psi}{-\psi^2 - 2\frac{\nu}{\varepsilon} + 2} \right|^{-1} = \pi\sqrt{2\varepsilon}\sqrt{\varepsilon - \nu} \left| \int \frac{d\tilde{\psi}}{1 - \tilde{\psi}^2} \right|^{-1} \simeq \pi\sqrt{2\varepsilon}\sqrt{\nu - \varepsilon} \ . \tag{21.102}$$

This is due to a locking of the drive frequency and the frequency of the oscillators.

21.4.4.4 Devil's staircase

Locking can also happen between higher harmonics. To see this we chose an alternative treatment goes as follows. The equation of motion with a pure ac driving voltage without resistance is,

$$C\frac{\Phi_0}{2\pi}\frac{d^2\varphi}{dt^2} + I_c \sin\left(\varphi(0) + \frac{2\pi V_0}{\Phi_0}t + \frac{2\pi V_s}{\Phi_0\omega_s}\sin\omega_s t\right) = 0 \ . \tag{21.103}$$

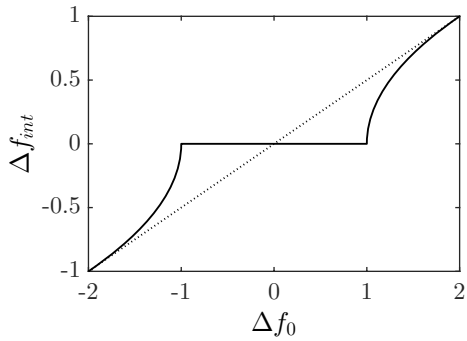

Figure 21.10: (code) Arnold tongue.

It can be derived from the Hamiltonian,

$$\hat{H} = \frac{p_\varphi^2}{2C\Phi_0/2\pi} - I_c \cos\left(\varphi(0) + \frac{2\pi V_0}{\Phi_0}t + \frac{2\pi V_s}{\Phi_0\omega_s}\sin\omega_s t\right) \ . \tag{21.104}$$

Substituting $\tilde{H} \equiv H/(C\Phi_0/2\pi)$, $\tilde{p_\varphi} \equiv p_\varphi/(C\Phi_0/2\pi)$, $K \equiv I_c/(\omega_s C\Phi_0/2\pi)$, and $\lambda \equiv \imath/(\omega_s C\Phi_0/2\pi)$, ...

We now go to the annulus map describing the Josephson junction. The JJ map can be interpreted as a δ-kicked rotor. The dissipative map [1431] predicts the occurrences of locking regions, known as Shapiro steps observed at all simple rational numbers m/n. They are equivalent to those of a *devil's staircase*.

21.4.4.5 Quantized JJ

The quantized energy levels of the JJ $\cos\psi$ potential result in a phase quantization. As a consequence, the energy exchange between an oscillating driving pump, ω_s, and the JJ, only occurs in multiples of ω_J.

To visualize quantum effects, one has to go to the quantum map $|\psi_{n+1}\rangle = \hat{U}\psi_n$.

21.4.5 Exercises

21.4.5.1 Ex: Perfect conductor

Calculate the magnetic field near a perfect conductor by solving equation (21.72).

Solution:

21.4.5.2 Ex: Perfect conductor

Quantify the Meissner effect for a thin layer by solving equation (21.73).

Solution:

21.4.5.3 Ex: Meissner-Ochsenfeld effect

Calculate the magnetic field inside a thin superconducting layer as a function of layer thickness and temperature.

Solution: *See Lucca 7300035/2020-2.*

21.5 Quantities and formulas in electromagnetism

21.5.1 Electromagnetic quantities

charge	Q	basic SI unit [C]
electric field (Coulomb law)	$\vec{\mathcal{E}}$	$d\vec{\mathcal{E}}(\mathbf{r}) = \frac{1}{4\pi\epsilon_0}\frac{dQ(\mathbf{r}-\mathbf{r}')}{\lvert\mathbf{r}-\mathbf{r}'\rvert^3}$
Coulomb law		$\vec{\mathcal{E}}(\mathbf{r}) = \frac{1}{4\pi\epsilon_0}\int_{\mathcal{V}}\frac{\rho(\mathbf{r}')(\mathbf{r}-\mathbf{r}')}{\lvert\mathbf{r}-\mathbf{r}'\rvert^3}d^3r'$

21.5.3 CGS units

Often used in electrodynamics are *CGS units*, also called *Gaussian units*. In this script we will use exclusively *SI units* of the *Système International d'Unités*. To do

the conversion between the unit systems, it is enough let,

$$\begin{aligned} e \to e_{CGS}\sqrt{4\pi\varepsilon_0} \quad &, \quad \mathbf{j} \to \mathbf{j}_{CGS}\sqrt{4\pi\varepsilon_0} \\ \vec{\mathcal{E}} \to \vec{\mathcal{E}}_{CGS}\sqrt{\tfrac{1}{4\pi\varepsilon_0}} \quad &, \quad \vec{\mathcal{B}} \to \vec{\mathcal{B}}_{CGS}\sqrt{\tfrac{\mu_0}{4\pi}} \\ \vec{\mathcal{D}} \to \vec{\mathcal{D}}_{CGS}\sqrt{\tfrac{\varepsilon_0}{4\pi}} \quad &, \quad \vec{\mathcal{H}} \to \vec{\mathcal{H}}_{CGS}\sqrt{\tfrac{1}{4\pi\mu_0}} \\ \vec{\mathcal{P}} \to \vec{\mathcal{P}}_{CGS}\sqrt{4\pi\varepsilon_0} \quad &, \quad \vec{\mathcal{M}} \to \vec{\mathcal{M}}_{CGS}\sqrt{\tfrac{4\pi}{\mu_0}} \ . \end{aligned} \tag{21.105}$$

Maxwell's equations in the irrational Gaussian system are,

$$\text{rot}\ \vec{\mathcal{H}} = \tfrac{1}{c}\partial_t\vec{\mathcal{D}} + \tfrac{4\pi}{c}\mathbf{j} \quad , \quad \text{div}\ \vec{\mathcal{D}} = 4\pi\varrho \ . \tag{21.106}$$

Moreover,

$$u = \tfrac{1}{8\pi}(\vec{\mathcal{E}}^2 + \vec{\mathcal{B}}^2) \quad , \quad \mathbf{S} = \tfrac{c}{4\pi}(\vec{\mathcal{E}} \times \vec{\mathcal{B}}) \ . \tag{21.107}$$

The material equations for dielectric media are,

$$\vec{\mathcal{D}} = \varepsilon\vec{\mathcal{E}} \quad , \quad \vec{\mathcal{P}} = \chi_\varepsilon\vec{\mathcal{E}} \quad , \quad \varepsilon = 1 + 4\pi\chi_\varepsilon \ , \tag{21.108}$$

and for dia- and paramagnetic media,

$$\vec{\mathcal{B}} = \mu\vec{\mathcal{H}} \quad , \quad \vec{\mathcal{M}} = \chi_\mu\vec{\mathcal{H}} \quad , \quad \mu = 1 + 4\pi\chi_\mu \ . \tag{21.109}$$

21.6 Rules of vector analysis

21.6.1 Basic rules

(i) $\mathbf{A}\cdot\mathbf{B} = \mathbf{B}\cdot\mathbf{A}$ but $\mathbf{A}\cdot\nabla \neq \nabla\cdot\mathbf{A}$, (21.110)

(ii) $\phi\mathbf{B} = \mathbf{B}\phi$ but $\phi\nabla \neq \nabla\phi$,

(iii) $\mathbf{A}\times\mathbf{B} = -\mathbf{B}\times\mathbf{A}$ but $\mathbf{A}\times\nabla \neq -\nabla\times\mathbf{A}$,

(iv) $\mathbf{A}\cdot(\mathbf{B}\times\mathbf{C}) = \mathbf{B}\cdot(\mathbf{C}\times\mathbf{A})$,

(v) $\mathbf{A}\times(\mathbf{B}\times\mathbf{C}) = \mathbf{B}(\mathbf{A}\cdot\mathbf{C}) - \mathbf{C}(\mathbf{A}\cdot\mathbf{B})$,

(vi) $\nabla f(\phi(\mathbf{r})) = \dfrac{\partial f}{\partial\phi}\nabla\phi(\mathbf{r})$ chain rule ,

(vii) $\nabla(\mathbf{A}\cdot\mathbf{B}) = \nabla(A\mathbf{B}) + \nabla(\mathbf{A}B)$ product rule for scalars and vectors .

21.6.2 Deduced rules

$$
\begin{aligned}
&\text{(i)} && \nabla(\phi+\psi) = \nabla\phi + \nabla\psi \ , && (21.111)\\
&\text{(ii)} && \nabla(\phi\psi) = \phi\nabla\psi + \psi\nabla\phi \ , \\
&\text{(iii)} && \nabla\cdot(\mathbf{A}+\mathbf{B}) = \nabla\cdot\mathbf{A} + \nabla\cdot\mathbf{B} \ , \\
&\text{(iv)} && \nabla\times(\mathbf{A}+\mathbf{B}) = \nabla\times\mathbf{A} + \nabla\times\mathbf{B} \ , \\
&\text{(v)} && \nabla\cdot(\phi\mathbf{A}) = \phi(\nabla\cdot\mathbf{A}) + (\nabla\phi)\cdot\mathbf{A} \ , \\
&\text{(vi)} && \nabla\times(\phi\mathbf{A}) = \phi(\nabla\times\mathbf{A}) + (\nabla\phi)\times\mathbf{A} \ , \\
&\text{(vii)} && \nabla\cdot(\mathbf{A}\times\mathbf{B}) = (\nabla\times\mathbf{A})\cdot\mathbf{B} - \mathbf{A}\cdot(\nabla\times\mathbf{B}) \ , \\
&\text{(viii)} && \nabla\times(\mathbf{A}\times\mathbf{B}) = (\mathbf{B}\cdot\nabla)\mathbf{A} - (\mathbf{A}\cdot\nabla)\mathbf{B} + \mathbf{A}(\nabla\cdot\mathbf{B}) - \mathbf{B}(\nabla\cdot\mathbf{A}) \ , \\
&\text{(ix)} && \nabla(\mathbf{A}\cdot\mathbf{B}) = \mathbf{A}\times(\nabla\times\mathbf{B}) + \mathbf{B}\times(\nabla\times\mathbf{A}) + (\mathbf{A}\cdot\nabla)\mathbf{B} + (\mathbf{B}\cdot\nabla)\mathbf{A} \ , \\
&\text{(x)} && \nabla\times(\nabla\phi) = 0 = \nabla\cdot(\nabla\times\mathbf{A}) \ , \\
&\text{(xi)} && \nabla\times(\nabla\times\mathbf{A}) = \nabla(\nabla\cdot\mathbf{A}) - \triangle\mathbf{A} \ , \\
&\text{(xii)} && \nabla\cdot(\nabla\phi) = \triangle\phi \ , \\
&\text{(xiii)} && \mathbf{A}\cdot(\nabla\phi) = (\mathbf{A}\cdot\nabla)\phi \ , \\
&\text{(xiv)} && \mathbf{A}\times(\nabla\phi) = (\mathbf{A}\times\nabla)\phi \ , \\
&\text{(xv)} && \nabla\phi = \frac{d\phi}{dr}\nabla r \qquad \text{chain rule} \ , \\
&\text{(xvi)} && \nabla\phi(\psi) = \frac{d\phi(\psi)}{d\psi}\nabla\psi \ , \\
&\text{(xvii)} && \nabla\cdot\mathbf{A}(\psi) = \frac{d\mathbf{A}(\psi)}{d\psi}\cdot\nabla\psi \ , \\
&\text{(xviii)} && \nabla\times\mathbf{A}(\psi) = -\frac{d\mathbf{A}(\psi)}{d\psi}\times\nabla\psi \ .
\end{aligned}
$$

21.6.3 Integral rules

(i) $$\int_{\mathcal{V}} \nabla\phi dV = \int_{\mathcal{S}} \phi d\mathbf{S}, \tag{21.112}$$

(ii) $$\int_{\mathcal{V}} \nabla\cdot\vec{\mathcal{E}} dV = \oint_{\partial\mathcal{V}} \vec{\mathcal{E}}\cdot d\mathbf{S} \qquad \text{Gauß' rule ,}$$

(iii) $$\int_{\mathbf{A}} \nabla\times\vec{\mathcal{E}}\cdot d\mathbf{S} = \oint_{\partial\mathcal{C}} \vec{\mathcal{E}}\cdot d\mathbf{l} \qquad \text{Stokes' rule ,}$$

(iv) $$\int_{\mathcal{V}} \phi(\nabla\psi) dV = \int_{\partial\mathcal{V}} \phi\psi d\mathbf{S} - \int_{\mathcal{V}} (\nabla\phi)\psi dV \qquad \text{Green's rule ,}$$

(v) $$\int_{\mathcal{V}} \left[\phi(\triangle\psi) - (\triangle\phi)\psi\right] dV = \int_{\partial V} \left[\phi(\nabla\psi) - (\nabla\phi)\psi\right]\cdot d\mathbf{S}$$

(vi) $$\int_{\mathcal{V}} \phi(\triangle\psi) dV = \int_{\mathcal{V}} (\triangle\phi)\psi dV \tag{21.113}$$

where $\triangle$ is hermitian, when $\lim_{r\to\infty} r\phi(r) = 0 = \lim_{r\to\infty} r\psi(r)$,

(vii) $$\frac{d}{dt}\int_{a(t)}^{b(t)} f(x,t)dx = \int_{a(t)}^{b(t)} \frac{\partial f}{\partial\tau}(x,t)dx + \frac{db(t)}{dt} f(b,t)dx - \frac{da(t)}{dt} f(a,t)dx \ .$$

Notation,

$$\nabla\phi\cdot d\mathbf{S} = \nabla\phi\cdot\mathbf{n}\ dS = \frac{\partial\phi}{\partial\mathbf{n}}\ dS \ . \tag{21.114}$$

21.7 Rules for Laplace and Fourier transforms

21.7.1 Laplace transform

Formulas for the *Laplace transform*:

(definition) $$(\mathcal{L}f)(p) = \int_0^\infty f(t)e^{-pt}dt \tag{21.115}$$

(inversion) $$\mathcal{L}^{-1}\mathcal{L}f = f \quad \text{where} \quad (\mathcal{L}^{-1}\mathcal{L}f)(t) = \int_{\varepsilon-\imath\omega}^{\varepsilon+\imath\omega} \mathcal{L}f(p)e^{pt}\frac{dp}{2\pi\imath}$$

(linearity) $$\mathcal{L}(af+bg) = a\mathcal{L}(f) + b\mathcal{L}(g)$$

(similarity) $$\mathcal{L}[f(at)] = a^{-1}\mathcal{L}f(a^{-1}p)$$

(translation) $$\mathcal{L}\mathcal{T}f = \mathcal{L}f \cdot e^{-pT} \quad \text{where} \quad \mathcal{T}f(t) = f(t-T)$$

$$\mathcal{L}\left(fe^{qt}\right) = \mathcal{T}\mathcal{L}f$$

(differentiation) $$\mathcal{L}\partial_t f = p\mathcal{L}f - f(0)$$

$$\mathcal{L}(-tf) = \partial_p\mathcal{L}f$$

(pulse response) $$\mathcal{L}\delta = 1 \quad \text{where} \quad \delta(t) = \mathcal{L}^{-1}1$$

(step response) $$\mathcal{L}\delta' = p^{-1}$$

(integration) $$\mathcal{L}\int_0^t dt\ f = p^{-1}\mathcal{L}f$$

$$\mathcal{L}(t^{-1}f) = \int_p^\infty dp\ \mathcal{L}f$$

(convolution) $$\mathcal{L}(f\star g) = \mathcal{L}f \cdot \mathcal{L}g$$

(periodic functions) $$\mathcal{L}(f = \mathcal{T}f) = \int_0^{-T} dt\ \frac{e^{-pt}f(t)}{1-e^{pT}}$$

(eigenfunctions) $$f\star e^{pt} = \mathcal{L}f \cdot e^{pt}\ .$$

21.7.2 Correlation

Formulas for the *correlation*:

(definition) $$(f\diamond g)(t) = \int_{-\infty}^\infty f(\tau)g(t+\tau)d\tau \tag{21.116}$$

(non-commutativity) $$(f\diamond g)(t) = (g\diamond f)^s$$

(complex autocorrelation) $$|f\diamond g^*| \le f\diamond g^*(0)\ .$$

21.7.3 Fourier transform

Formulas for the *Fourier transform*:

(definition) $$(\mathcal{F}f)(\omega) = \int_{-\infty}^{\infty} f(t)e^{-\imath\omega t}dt \tag{21.117}$$

(inversion) $$\mathcal{F}^{-1}\mathcal{F}f = f \quad \text{where} \quad (\mathcal{F}^{-1}\mathcal{F}f)(t) = \int_{-\infty}^{\infty} \mathcal{F}f(\omega)e^{\imath\omega t}d\omega$$

(linearity) $$\mathcal{F}(af + bg) = a\mathcal{F}(f) + b\mathcal{F}(g)$$

(similarity) $$?$$

(translation) $$\mathcal{F}\mathcal{T}f = \mathcal{F}f \cdot e^{-\imath\omega T} \quad \text{where} \quad \mathcal{T}f(t) = f(t-T)$$

$$\mathcal{F}\left(fe^{\imath\omega t}\right) = \mathcal{T}\mathcal{F}f$$

(differentiation) $$\mathcal{F}[tf(t)] = \imath\partial_\omega(Ff)(\omega)$$

$$\mathcal{F}[f'(t)] = \imath\omega(Ff)(\omega)$$

(pulse response) $$\mathcal{F}\delta = 1 \quad \text{where} \quad \delta(t) = \mathcal{F}^{-1}1$$

(step response) $$\mathcal{F}\delta' = ?$$

(duality) $$\mathcal{F}\mathcal{F}\ f = f^s \quad \text{where} \quad f^s(t) = f(-t)$$

$$\mathcal{F}\ f^* = (\mathcal{F}\ f)^{*s} \quad \text{where} \quad f^s(t) = f(-t)$$

(symmetry) $$f = f^s = f^* \quad \Leftrightarrow \quad \mathcal{F}\ f = (\mathcal{F}\ f)^s$$

$$f = -f^s = f^* \quad \Leftrightarrow \quad \mathcal{F}\ f = -(\mathcal{F}\ f)^*$$

$$f = f^* \quad \Leftrightarrow \quad \mathcal{F}\ f = (\mathcal{F}\ f)^{*s}$$

(convolution) $$\mathcal{F}(f \star g) = \mathcal{F}f \cdot \mathcal{F}g$$

$$\mathcal{F}(f \cdot g) = \mathcal{F}f \star \mathcal{F}g$$

(eigenfunctions) $$f \star e^{\imath\omega t} = \mathcal{F}f \cdot e^{\imath\omega t}\ .$$

21.7.3.1 Fast Fourier transform

The *discrete Fourier transform* is defined by,

$$\begin{aligned} H_n &= \sum_{k=0}^{N-1} e^{-2\pi\imath nk/N} h_k \\ &= \sum_{k=0}^{N-1} e^{-2\pi\imath nk/(N/2)} h_{2k} + e^{-2\pi\imath k/N} \sum_{k=0}^{N/2-1} e^{-2\pi\imath nk/(N/2)} h_{2k+1} \\ &= even + odd\ . \end{aligned} \tag{21.118}$$

The inverse transform is,

$$h_k = \frac{1}{N}\sum_{k=0}^{N-1} e^{2\pi\imath nk/N} H_n\ . \tag{21.119}$$

The sine transform of a real vector s_k is,

$$S_n = \frac{2}{N}\sum_{k=1}^{N-1} s_k \sin \pi nk/N\ . \tag{21.120}$$

In MATLAB the fast Fourier transform is defined by:

$$F(k+1) = \sum_{n=0}^{N-1} f(n+1) e^{-2\pi\imath/N \cdot kn} \ . \tag{21.121}$$

inversion:

$$f(n+1) = \frac{1}{N} \sum_{k=0}^{N-1} F(k+1) e^{2\pi\imath/N \cdot kn} \ . \tag{21.122}$$

symmetry,

$$\begin{aligned} & f(n+1) = f^*(n+1) \qquad (21.123) \\ & \Longrightarrow K(k+1) = \sum_{n=0}^{N-1} f^*(n+1) e^{-2\pi\imath/N \cdot kn} e^{-2\pi\imath/N \cdot Nn} = F^*(N-k+1) \ . \end{aligned}$$

and,

$$\begin{aligned} & f(N-n) = f(n+1) = f^*(n+1) \qquad (21.124) \\ & \Longrightarrow F(k+1) = \sum_{n=0}^{N-1} f^*(N-n) e^{-2\pi\imath/N \cdot kn} \\ & \qquad = \sum_{n=0}^{N-1} f^*(n'+1) e^{2\pi\imath/N \cdot kn'} e^{-2\pi\imath/N \cdot (N-1)} = F^*(k+1) e^{2\pi\imath/N} \ . \end{aligned}$$

and,

$$\begin{aligned} & -f(N-n) = f(n+1) = f^*(n+1) \qquad (21.125) \\ & \Longrightarrow F(k+1) = \sum_{n=0}^{N-1} -f^*(N-n) e^{-2\pi\imath/N \cdot kn} \\ & \qquad = \sum_{n=0}^{N-1} -f^*(n'+1) e^{2\pi\imath/N \cdot kn'} e^{-2\pi\imath/N \cdot (N-1)} = -F^*(k+1) e^{2\pi\imath/N} \ . \end{aligned}$$

Hence, we choose, $\mathcal{F} f(n+1) = F(k+1) e^{-\pi\imath/N}$.

21.7.3.2 Fourier expansion

The complex *Fourier expansion* is defined by,

$$\boxed{f_N(x) = \sum_{n=-N}^{N} c_n e^{\imath n x}} \ , \tag{21.126}$$

where

$$c_n \equiv \frac{1}{2\pi} \int_{2\pi} s(x) e^{-\imath n x} dx \ . \tag{21.127}$$

21.7.4 Convolution

Formulas for the *convolution*:

$$
\begin{aligned}
&\text{(definition)} && (f\star g)(t) = \int_{-\infty}^{\infty} f(\tau)g(t-\tau)d\tau && (21.128)\\
&\text{(neutral element)} && f\star\delta^{(n)} = f^{(n)}\\
&\text{(distributivity)} && (f+g)\star h = f\star h + g\star h\\
& && af\star g = f\star ag\\
&\text{(commutativity)} && f\star g = g\star f\\
&\text{(associativity)} && (f\star g)\star h = f\star(g\star h)\\
&\text{(translational invariance)} && \mathcal{T}(f\star g) = \mathcal{T}f\star g = f\star\mathcal{T}\\
&\text{(differentiation)} && \partial_x(f\star g) = \partial_x f\star g = f\star\partial_x g\\
&\text{(integration)} && \int_x (f\star g) = \int_x f\int_x g\\
&\text{(complexity)} && f = f_r + \imath f_i\\
&\text{(Dirac function)} && \mathcal{T}f = f\star\mathcal{T}\delta\\
& && f(T) = f\cdot\mathcal{T}\delta\ .
\end{aligned}
$$

Example 135 (*Convolution of two Lorentzians*): The convolution of two *Lorentzians*,

$$\mathcal{L}_a(x) \equiv \frac{a}{\pi}\frac{1}{x^2+a^2} \qquad \text{with} \qquad \int_{-\infty}^{\infty}\mathcal{L}_a(x)dx = 1\ ,$$

is simply another Lorentzian with the linewidth $a+b$,

$$\boxed{(\mathcal{L}_a\star\mathcal{L}_b)(x) = \mathcal{L}_{a+b}(x)}\ .$$

In order to demonstrate this, we first we apply the method of partial fractions to the expression,

$$
\begin{aligned}
&\frac{1}{y^2+a^2}\frac{1}{(x-y)^2+b^2} = \frac{A}{y^2+a^2} + \frac{B}{(x-y)^2+b^2}\\
&\text{with}\quad A = \frac{2xy+(x^2-a^2+b^2)}{(x^2+a^2+b^2)^2-4a^2b^2}\quad,\quad B = \frac{-2x(y-x)+(x^2+a^2-b^2)}{(x^2+a^2+b^2)^2-4a^2b^2}\ .
\end{aligned}
$$

Now, we calculate the convolution,

$$
\begin{aligned}
&(\mathcal{L}_a\star\mathcal{L}_b)(x) = \frac{ab}{\pi^2}\int_{-\infty}^{\infty}\frac{1}{y^2+a^2}\frac{1}{(x-y)^2+b^2}dy\\
&= \frac{ab}{\pi^2}\frac{1}{(x^2+a^2+b^2)^2-4a^2b^2}\left(\int_{-\infty}^{\infty}\frac{2xy+(x^2-a^2+b^2)}{y^2+a^2}dy + \int_{-\infty}^{\infty}\frac{-2x(y-x)+(x^2+a^2-b^2)}{(x-y)^2+b^2}dy\right)\\
&= \frac{ab}{\pi^2}\frac{1}{(x^2+a^2+b^2)^2-4a^2b^2}\left((x^2-a^2+b^2)\int_{-\infty}^{\infty}\frac{1}{y^2+a^2}dy + (x^2+a^2-b^2)\int_{-\infty}^{\infty}\frac{1}{(x-y)^2+b^2}dy\right)\\
&= \frac{ab}{\pi^2}\frac{(x^2-a^2+b^2)\frac{\pi}{a}+(x^2+a^2-b^2)\frac{\pi}{b}}{(x^2+a^2+b^2)^2-4a^2b^2} = \frac{a+b}{\pi}\frac{1}{x^2+(a+b)^2} = \mathcal{L}_{a+b}(x)\ .
\end{aligned}
$$

Example 136 (*Convolution of two Gaussians*): The convolution of two *Gaussians*,

$$\mathcal{G}_a(x) \equiv \sqrt{\frac{1}{\pi}}\frac{1}{a}e^{-x^2/a^2} \qquad \text{with} \qquad \int_{-\infty}^{\infty}\mathcal{G}_a(x)dx = 1 \ ,$$

is simply another Gaussian with the linewidth $\sqrt{a^2+b^2}$,

$$\boxed{(\mathcal{G}_a \star \mathcal{G}_b)(x) = \mathcal{G}_{\sqrt{a^2+b^2}}(x)} \ .$$

We demonstrate this by calculating,

$$\begin{aligned}
(\mathcal{G}_a \star \mathcal{G}_b)(x) &= \frac{1}{\pi ab}\int_{-\infty}^{\infty} e^{-y^2/a^2}e^{-(x-y)^2/b^2}dy = \frac{\sqrt{ab}}{\pi}\int_{-\infty}^{\infty} e^{-(a^{-2}+b^{-2})y^2+2b^{-2}xy-b^{-2}x^2}dy \\
&= \frac{1}{\pi ab\sqrt{(a^{-2}+b^{-2})}}\int_{-\infty}^{\infty} e^{-\tilde{y}^2+\frac{2x}{b^2\sqrt{a^{-2}+b^{-2}}}\tilde{y}-b^{-2}x^2}d\tilde{y} \\
&= \frac{1}{\pi\sqrt{a^2+b^2}}\int_{-\infty}^{\infty} e^{-\left(\tilde{y}-\frac{x}{\sqrt{b^4/a^2+b^2}}\right)^2-\frac{x^2}{a^2+b^2}}d\tilde{y} \\
&= \frac{1}{\pi\sqrt{a^2+b^2}}e^{-\frac{x^2}{a^2+b^2}}\int_{-\infty}^{\infty} e^{-\tilde{y}^2}d\tilde{y} = \frac{1}{\sqrt{\pi}\sqrt{a^2+b^2}}e^{-\frac{x^2}{a^2+b^2}} = \mathcal{G}_{\sqrt{a^2+b^2}}(x) \ .
\end{aligned}$$

21.7.5 Green's functions

If a differential operator $\mathcal{L}_x$ acting on a variable x admits a *Green's function* $\mathcal{G}$ such that,

$$\boxed{\mathcal{L}_x\mathcal{G}(x,x') = \delta(x-x')} \ , \tag{21.129}$$

The Green function can be used to solve any equation,

$$\mathcal{L}_x f(x) = \varrho(x) \tag{21.130}$$

by calculating,

$$f(x) = \int \mathcal{G}(x,x')\varrho)(x)dx \ . \tag{21.131}$$

21.7.5.1 List of Green functions

The following table provides a list of useful Green functions.

differential operator $\mathcal{L}$	Green function $\mathcal{G}$
∂_t^n	$\frac{t^{n-1}}{(n-1)!}\Theta(t)$
$\partial_t + \gamma$	$\Theta(t)e^{-\gamma t}$
$\triangle$	$-\frac{1}{4\pi r}$
$\nabla\cdot$	$-\frac{\mathbf{r}-\mathbf{r}'}{4\pi R^3}$
$\nabla\times$	$-\frac{(\mathbf{r}-\mathbf{r}')\times(\mathbf{r}-\mathbf{r}')}{4\pi R^3}$
$\Box$	$-\frac{1}{4\pi r}\delta(t \mp \frac{1}{c}r)$
$\triangle + k^2$	$-\frac{e^{ikr}}{4\pi r}$
$-\nabla\times\nabla\times + k^2$	see Sec. 18.3.1

Example 137 (*Green function for time derivation*): To solve the differential equation,

$$(\partial_t + \gamma) f(t) = c \ ,$$

we search the Green function for the equation,

$$(\partial_t + \gamma)\mathcal{G}(t,t') = \delta(t-t') \ .$$

From the above table, we get,

$$f(t) = \int_{-\infty}^{\infty} \mathcal{G}(t,t') \ c \ dt' = c\int_{-\infty}^{\infty} \Theta(t-t')e^{-\gamma(t-t')}dt' = \frac{c}{\gamma}e^{-\gamma t} \ .$$

Chapter 22

Antecedents of quantum mechanics

Developed at the beginning of the 20^{th} century, quantum mechanics is today the most fundamental and far-reaching theory in physics. It shaped our World more than any other science, as technologies based on quantum mechanical effects are the key to an industry representing today one third of the World's global domestic product. Boosted by the invention of the transistor and the laser, the industry today branches out in many areas including energy generation, electronics, optics, and photonics. Nevertheless and despite its long history and its incomparable success, quantum mechanics is far from being exhausted. The invention of novel techniques for quantum state manipulation and entanglement generation, awarded with various Nobel prizes in the past, and advances in information science during the past 25 years prepared the ground for a second wave of quantum-based technologies called Quantum Revolution 2.0. In terms of economic, military, and social advantages the stakes of this revolution are so important that they triggered a fierce international race for technological domination. This chapter traces briefly the historical conditions and the discoveries that led to the invention of quantum mechanics.

The fundamental idea of quantum mechanics is the assumption that there are entities which can not be subdivided beyond a certain limit. Examples are the mass of a body, the speed of an electron orbiting an atom, or the intensity of a beam of light. This idea was first uttered by *Leucippus* 500 years a.c. and his student *Democritus*, who imagined matter being made of smallest particles which they called *atoms*. These atoms move freely, collide, combine, and separate: 'There is nothing else than atoms and free space' they claimed. The microscopic atoms would have the same characteristics as the macroscopic objects they form when they combine, for example, color and shape. The idea of the atom resurfaced and was refined in the course of the 18^{th} century (see Tab. 1.1 below). Today, we know that the basic idea was good, but reality is a little more complicated.

Still, at the end of the 19^{th} century, the physical world seemed rather simple: matter and light was all that existed. Matter was made up of atoms and light was a wave. Therefore, to describe a real system, it was enough to calculate the trajectories of its elementary particles and the propagation of light between them. The way that light interacts with polarizable and magnetizable matter via electric and magnetic fields had been perfectly explained by laws discovered by Coulomb, Ampère, Faraday, and Maxwell.

Table 22.1: *Historical time line of the quantization of matter.*

500 a.c.	Democritus	invention of the atom
1800	Avogadro, Dalton	reinvention of the atom
1897	Thomson	charge transport, raisin-in-a-cake model
1909	Rutherford, Geiger, Marsden	α-scattering, charge localized in nuclei
1911	Rutherford	planetary model
1900	Bohr	quantized orbitals
1923	de Broglie	matter has characteristics of waves
1927	Davisson, Germer, Stern	electron and atoms diffraction

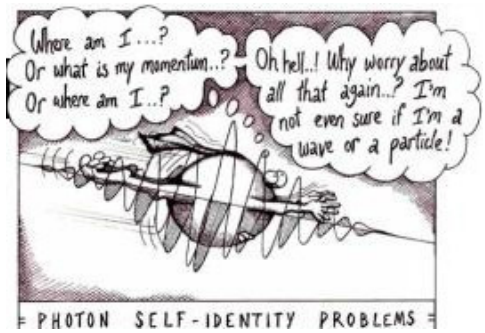

Figure 22.1: Particle-wave duality.

However, new experimental observations, such as the ultraviolet divergence of black-body radiation, that appeared in the late 19^{th} century, were incompatible with these traditional concepts. New ideas were pioneered by *Max Planck* who, in 1905, with a little help from Einstein quantized the electromagnetic field, and therefore the light, into small harmonic oscillators. This was the starting point for the development of a new theory called 'quantum mechanics'. Soon, this theory was applied to explain the photoelectric effect. The second important step was initialized by *Niels Bohr*, who quantized the hydrogen atom in 1913 into discrete excitation levels.

Table 22.2: *Historical time line of the quantization of light.*

1801	Young	light is diffracted like a wave
1860	Maxwell	unified theory of electrodynamics including light
1888	Hertz	detection of radio waves
$\sim$ 1890		accurate measurements of black-body radiation spectra
1900	Planck	quantum hypothesis: $E = h\nu$
1905	Einstein	photoelectric effect, light behaves like a particle

Nowadays we know that our universe is not as simple as classical mechanics sug-

gested, and that atoms are also waves and light also behaves like particles. This *duality principle* is one of the fundamental ideas of quantum mechanics. The appearance of an object as a wave or as a particle depends on the situation in which it is observed. While the wave nature of light was well established in classical physics since a long time, Louis de Broglie was the first in 1924 to apply the duality principle also to massive particles and to predict that particles, under certain conditions, behave like waves the wavelengths of which increase as their velocity decreases. Each particle (or body) is delocalized along a distance corresponding to this 'de Broglie wavelength'. This feature of matter was soon discovered experimentally in electron beams and is still used today in commercial devices, for example in electron microscopes.

22.1 The discovery of the atom

22.1.1 Democrit's model

'The principles of reality are atoms and emptiness while other things are mere opinions.' This is a quotation from the Greek philosopher *Democritus* 400 years before Christ and before Socrates. Together with his teacher Leucippus, he formed the first idea of indivisible particles: atoms.

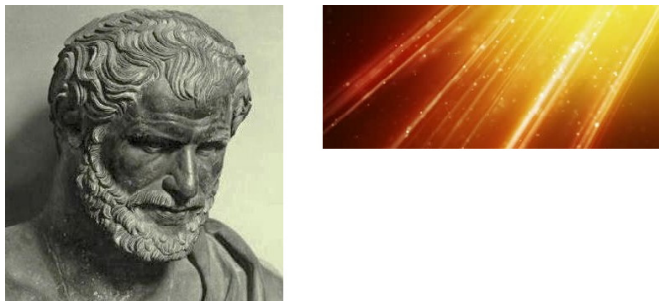

Figure 22.2: Democritus and dust in a sun ray.

Democritus' work only survived as second-hand accounts, the major part of it having been written down by *Aristotle*, who also, defending the idea of the continuum, was the greatest critic of Democritus' theory. Aristotle said that the reasoning that guided Democritus to affirm the existence of atoms was as follows. For a body to change its shape, it is necessary that its parts can move. This presupposes an emptiness (or vacuum) in which the matter moves. But if matter were divided infinitely into ever smaller parts, it would loose its consistency. Nothing could be formed because nothing could arise from the ever more infinitely deep dilution of matter into emptiness. Hence, he concluded that the division of matter can not be infinite, that is, there is an indivisible limit: the atom. 'There is only atoms and emptiness', he said.

Observing dust particles in a whirling motion within a ray of sunlight, Democritus was led to the idea that atoms would behave in the same way, randomly colliding, some crowding, others dispersing, others never yet joining with another atom.

The consistency of clusters of atoms, which makes something look solid, liquid, gaseous, or animated (which is the state of the soul) would then be determined by the shape of the atoms involved and their spatial arrangement. In this sense, water atoms are smooth and slippery; the atoms of steel have shapes with sharp edges that hold them solidly together; the atoms of salt, as their taste shows, are harsh and pointed; the atoms of air are small and little connected, penetrating all other materials; and the atoms of soul and fire are spherical and very delicate.

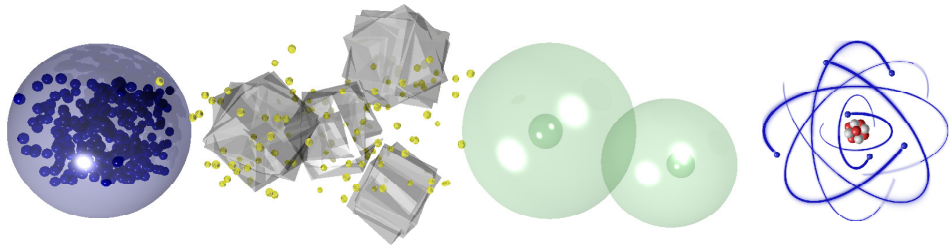

Figure 22.3: Atoms of steel and air, atoms of the soul, and Bohr's atom model.

We know nowadays that Democritus' first theory of the structure of matter was very close to the truth: There really are indivisible particles called atoms composed of a nucleus and an electronic shell, and the space between the atomic nuclei is, in fact, quite empty.

The atomic hypothesis came to be reborn in the modern age with the scientists Boyle, Clausius, Maxwell, and Boltzmann due to their successful explanations of the properties of gases based on the so-called kinetic theory, where they assumed a gas being constituted of identical molecules that collided elastically with each other and with the walls of the recipient containing them. The discovery of the atom through the *laws of proportions* in chemistry and the establishment of Avogadro's number considerably strengthened the atomic hypothesis. The hypothesis was definitely consecrated with the various experiments that established the charge of the electron and the mass ratio between electrons and protons.

By the beginning of the 19^{th} century the atomic nature of matter had definitely been established, and the basic composition of the atoms was already relatively well known. It was known, through experiments, that electrons could be removed from neutral atoms thus creating positively charged ions and that only a certain number of electrons could be removed from each atom. This number proved to be dependent on the atomic species and was called the atomic number Z. This information was fundamental for establishing the basic composition of atoms. The question that arose at this point concerned the dimensions and configurations of the atomic system. How would loads and masses be distributed in this entity?

22.1.2 Thomson's model and Rutherford's experiment

The internal structure of a body can be studied by throwing beams of small particles against it. The detection of the angular distribution of the scattered particles gives access to the structure factor of the body. In crystallography we throw X-rays

into super-complicated molecules to learn the architecture e.g. of proteins. And in medicine, X-rays reveal the internal structure of the human body. Obviously, the scattering technique is an extremely powerful tool, used in many areas of modern physics.

In a series of experiments done before 1911, *Ernest Rutherford* analyzed the internal structure of gold atoms using α-particles, i.e., He^{2+} atoms. The experiments carried out by Geiger, Marsden, and Rutherford consisted of observing the deflection of particles from a collimated beam when scattered by a thin metallic sheet (gold of thickness $\sim 1\,\mu m$) carefully obtained by electroplating [see Fig. 22.4(cd)].

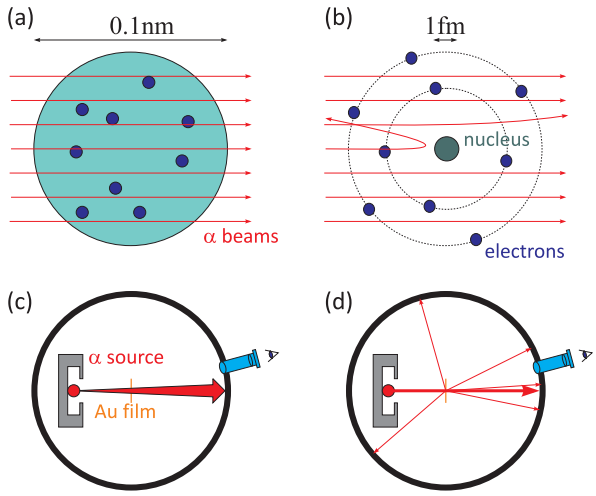

Figure 22.4: Comparison of Rutherford scattering by free electrons and electrons strongly bound to small nuclei. (a) Thomson's 'raisin-in-a-pudding' type atom; (b) Rutherford's 'planetary' atom. (c) Rutherford scattering by a raisin pudding atom and (d) by a planetary atom.

The atomic model proposed by *Joseph John Thomson* suggests a structure resembling a *pudding with raisins*: the electrons would be homogeneously distributed within an extended nucleus (size 0.1 nm) of positive charge thus compensating for the negative charge of the electrons. The α-particles would penetrate the gold nucleus, perceived as almost homogeneous, but would suffer multiple deflections due to collisions with the disordered electrons within the nucleus. Since electrons are very light, the angle of deflection θ would be small, even after many collisions. For this model we expect a Gaussian dependence of the particles' deflection angle given by the *scattering cross section* [see Fig. 22.4(a-b)],

$$\frac{d\sigma}{d\Omega} \propto e^{-\theta^2/\theta_0^2} \,, \tag{22.1}$$

where θ_0 is a small angle.

However, the measurements performed on this *Rutherford scattering* showed different results:

- For a fixed scattering angle, the amount of particles scattered into a solid angle element $d\Omega$ is proportional to the thickness of the metal foil.

- For a given fixed angle and a given metal sheet the amount of scattered particles in $d\Omega$ varies inversely with E_{kin}^2, where E_{kin} is the kinetic energy of the α-particles.
- For a given energy and a given metal sheet, the number of particles scattered into $d\Omega$ is proportional to $(\sin\frac{\theta}{2})^{-4}$.
- For a given energy and sheet thickness, the number of particles scattered into $d\Omega$ in a given direction is proportional to Z_{tg}^2, where Z_{tg} is the atomic number of the element that constitutes the sheet.

The extremely rare deflection of α-particles and their angular distribution can be understood by the assumption that the positive charge is concentrated in a very small volume (~ 1 fm, that is 10000 times less than the size of the atom itself). This volume is called the atomic nucleus, hence the denomination of *nuclear model*. Since most of the particles pass through the gold sheet without hindrance, there must be a large gap between the nuclei. The electrons, which move within a large (in comparison with the diameter of the nucleus) empty space (the vacuum) around the nucleus, shield the positive nuclear charge, so that the atom appears outwardly neutral.

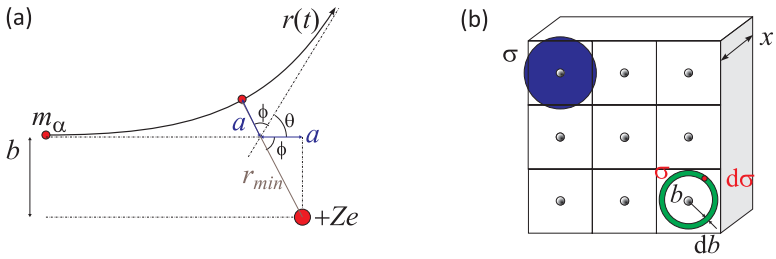

Figure 22.5: (a) Trajectory of an α-particle. (b) Illustration of the scattering cross section.

We now derive Rutherford's scattering formula from the hypothesis of a point-like nucleus. Due to the repulsive action of the Coulomb force,

$$F = \frac{Z_\alpha Z_{tg} e^2}{4\pi\varepsilon_0 r^2} \ , \tag{22.2}$$

we have for the trajectory of the α-particle ($Z_\alpha = 2$) a hyperbola [see Fig. 22.5(a)]. The large half-axis of the hyperbola can be determined from the following ansatz,

$$E_{\rm kin} = \frac{Z_\alpha Z_{tg} e^2}{4\pi\varepsilon_0}\frac{1}{2a} \ , \tag{22.3}$$

where $2a$ is the minimum distance of the particle α, when it collides with the nucleus in a central collision [1]. The distance a depends on the kinetic energy and can also be used for non-central collisions. The collision parameter b is the minimum distance of the α-particle to the nucleus, if it continued to fly in a straight line. In fact the

[1] In a central collision, when the α-particle reaches the minimum distance $2a$, its initial kinetic energy, $E_{\rm kin}$ is fully converted into potential energy.

α-particle will be deflected by an angle θ. From the geometry of the hyperbola, as $2\phi + \theta = 180°$, we obtain the following equation:

$$\tan\phi = \tfrac{b}{a} = \tan\left(90° - \tfrac{\theta}{2}\right) = \cot\tfrac{\theta}{2} \ , \tag{22.4}$$

and therefore

$$\cot\tfrac{\theta}{2} = \frac{b}{a} = \frac{8\pi\varepsilon_0 E_{\text{kin}}}{Z_\alpha Z_{tg} e^2} b \ , \tag{22.5}$$

replacing a with the formula (22.3). Taking the derivative of this latter formula, we obtain a relation between the width db of the hollow cone and the pertinent width $d\theta$ of the deflection angle θ,

$$-\frac{1}{2\sin^2\frac{\theta}{2}} d\theta = \frac{8\pi\varepsilon_0 E_{\text{kin}}}{Z_\alpha Z_{tg} e^2} db \ . \tag{22.6}$$

Let $n_{tg} = \frac{N_{tg}}{V}$ be the density of the particles in the target (N_{tg} atoms per volume V) and x the film thickness. Then $\sigma = \frac{A}{N_{tg}} = \frac{V/x}{N_{tg}} = \frac{1}{n_{tg}x}$ is the average cross-section per atom sensed by the α-particle on its way through the film. The probability $P(\theta)d\theta$ for the α-particle of being within a ring at distance b from the nucleus (whose area is $2\pi bdb$) and being scattered into the angle θ is then given by,

$$P(\theta)d\theta = \frac{2\pi bdb}{\sigma} = n_{tg} x 2\pi bdb \ . \tag{22.7}$$

These particles, i.e., dN of the N particles, are deflected into the hollow cone with the probability,

$$\begin{aligned} \frac{dN}{N} = P(\theta)d\theta &= n_{tg} x 2\pi \frac{Z_\alpha Z_{tg} e^2}{8\pi\varepsilon_0 E_{\text{kin}}} \cot\frac{\theta}{2} \cdot \frac{Z_\alpha Z_{tg} e^2}{8\pi\varepsilon_0 E_{\text{kin}}} \cdot \frac{1}{2\sin^2\frac{\theta}{2}} d\theta \\ &= n_{tg} x \frac{Z_\alpha^2 Z_{tg}^2 e^4}{64\pi\varepsilon_0^2 E_{\text{kin}}^2} \cdot \frac{\cos\frac{\theta}{2}}{\sin^3\frac{\theta}{2}} d\theta \ , \end{aligned} \tag{22.8}$$

where we replaced the parameters b and db with the expressions (22.5) and (22.6). The solid angle of the cone can be expressed by,

$$d\Omega = 2\pi \sin\theta d\theta = 4\pi \sin\tfrac{\theta}{2} \cos\tfrac{\theta}{2} d\theta \ . \tag{22.9}$$

Thus, the number dN of particles scattered to the solid angle $d\Omega$ remains,

$$\boxed{\frac{dN}{N} = n_{tg} x \frac{Z_\alpha^2 Z_{tg}^2 e^4}{256\pi^2\varepsilon_0^2 E_{\text{kin}}^2} \cdot \frac{1}{\sin^4\frac{\theta}{2}} d\Omega} \ . \tag{22.10}$$

That is Rutherford's scattering formula. Often, the formula is expressed with the *differential* cross section $\frac{d\sigma}{d\Omega}$. We get,

$$\frac{dN}{N} = \frac{d\sigma}{\sigma} = n_{tg} x d\sigma \ , \tag{22.11}$$

and therefore

$$\frac{d\sigma}{d\Omega} = \frac{dN}{N n_{tg} x d\Omega} = \left(\frac{Z_\alpha Z_{tg} e^2}{4\pi\varepsilon_0 \cdot 4E_{\text{kin}}}\right)^2 \frac{1}{\sin^4\frac{\theta}{2}} \ . \tag{22.12}$$

Here, we have to make some comments:

- The angle $\theta = 0$ is not defined, since there exists a minimum deflection angle $\theta_{\min}$. This angle is reached, when the α-particle moves at the distance $b = b_{\max}$ from the atom, that is, at the edge of the circular area of the cross section. For a greater collision parameter b, the α-particle traverses the field of the next neighboring atom, and the deflection angle increases again. We have:

$$\sigma = \frac{A}{N_{tg}} = \pi b_{\max}^2 \qquad \text{and} \qquad \frac{\theta_{\min}}{2} \simeq \tan\frac{\theta_{\min}}{2} = \frac{Z_\alpha Z_{tg} e^2}{8\pi\varepsilon_0 E_{\text{kin}} \cdot b_{\max}} \ , \tag{22.13}$$

  simply by inverting the formula (22.5). For very large impact parameters, that is, when the α-particle passes the atom outside its electronic layer, the electrons of the atom shield the charge of the nucleus, an effect called *screening*.

- For very high energies, the distribution of the nuclear charge over a finite volume influences the scattering, calling for corrections in the Rutherford formula. Moreover, at short internuclear distances, nuclear forces appear additionally to the electromagnetic interaction.

- The integral over the probability distribution $P(\theta)d\theta$ is normalized,

$$\int_{\theta_{\min}}^{\pi} P(\theta)d\theta = 1 \ . \tag{22.14}$$

  Similarly, we have for the surface integrals,

$$\int_{\theta \geqslant \theta_{\min}} \frac{d\sigma}{d\Omega} d\Omega = \sigma \ . \tag{22.15}$$

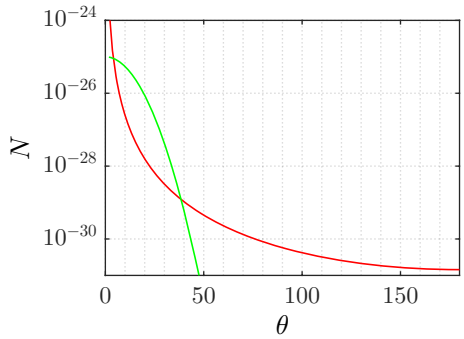

Figure 22.6: (code) Angular dependence of the cross-section corresponding to Thomson's (green) and Rutherford's (red) models.

Rutherford derived the formula (22.12) describing the scattering of α-particles within classical physics. A derivation from the laws governing quantum mechanics using the *Born approximation* shows that Rutherford's formula describes scattering correctly in first order, and that purely quantum effects present only minor corrections. We will review the Rutherford scattering in Excs. 22.1.6.1 and 22.1.6.2 and discuss the screening effect in Exc. 22.1.6.3.

22.1.3 Emission of radiation in the planetary model

The *planetary model* proposed by Rutherford suggests electrons spinning around a positively charged nucleus in circular orbits [2]. This motion of electrons should obey the laws of Maxwell's electrodynamic theory. Let us now calculate some consequences of this picture.

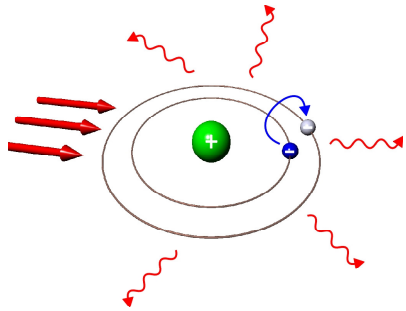

Figure 22.7: Light-induced transitions between orbits in the planetary model.

We now treat the atom as a rotor where the negative particle, the electron, orbits the positive particle. The dipole moment is,

$$p_0 = -er \ . \tag{22.16}$$

We calculate in the Exc. 22.1.6.4 the power emitted by the acceleration $a = \omega^2 r$ of the electron on its circular trajectory,

$$P = \frac{\mu_0 \omega^4 p_0^2}{12\pi c} \ . \tag{22.17}$$

The initial energy of the electron spinning around the nucleus (for a hydrogen atom $Z = 1$),

$$E = \frac{p^2}{2m_e} - \frac{e^2}{4\pi\varepsilon_0 r} = \frac{m_e \omega^2 r^2}{2} - \frac{e^2}{4\pi\varepsilon_0 r} \ , \tag{22.18}$$

is dissipated by radiation of the power (22.17), i.e.,

$$-P = \frac{dE}{dt} = m_e \omega^2 r \frac{dr}{dt} + \frac{e^2}{4\pi\varepsilon_0 r^2}\frac{dr}{dt} = 2m_e \omega^2 r \frac{dr}{dt} \ . \tag{22.19}$$

The latter equation supposes an equilibrium between the centrifugal force and the Coulomb force,

$$m_e \omega^2 r = \frac{e^2}{4\pi\varepsilon_0 r^2} \ , \tag{22.20}$$

allowing to link the revolution frequency ω to the instantaneous radius of the orbit $r(t)$. Resolving the Eq. (22.19) by $\dot{r}$ and replacing the power by the relation (22.17)

[2] This type of model had already been proposed by Jean Perrin in 1901 and by Hantaro Nagaoka in 1903, around the same time when Thompson developed his model. The planetary model was later on rescued by John William Nicholson in 1911.

and the frequency ω by the relation (22.20), we obtain,

$$\frac{dr}{dt} = -\frac{P}{2m_e\omega^2 r} = -\frac{\mu_0\omega^2 e^2}{24\pi m_e c} r = -\frac{e^4}{96\pi^2\varepsilon_0^2 m_e^2 c^3}\frac{1}{r^2} \ . \tag{22.21}$$

Integration of this equation gives,

$$t - t_0 = -\frac{32\pi^2\varepsilon_0^2 m_e^2 c^3}{e^4}[r^3 - r^3(t_0)] \ . \tag{22.22}$$

Now inserting $t_0 = 0$ and assuming $r(t_0) = a_B$, the time τ within which the loss of energy due to radiation emission decreases the radius of the electronic orbit to $r = 0$, is,

$$t = \tau = \frac{32\pi^2\varepsilon_0^2 m_e^2 c^3 a_B^3}{e^4} \ . \tag{22.23}$$

Insertion of the numerical values gives the decay time $\tau \sim 10^{-10}$ s. This is the effect called *radiation collapse* of the classical atomic model.

22.1.4 Zeeman effect in the planetary model

The orbital motion of the electron generates a ring current $I = e/T = e\omega/2\pi$, which produces an *orbital magnetic moment* which, as shown in Exc. 22.1.6.5, can be calculated following the laws of electromagnetism,

$$\vec{\mu}_\ell = IA\hat{\mathbf{n}} = \frac{e\omega}{2\pi}\pi r^2\hat{\mathbf{n}} \ , \tag{22.24}$$

where $A = \pi r^2$ is the area of the trajectory. Introducing the angular momentum $\mathbf{L} = m_e\omega r^2\hat{\mathbf{n}}$ we get in vector notation,

$$\vec{\mu}_\ell = \frac{e}{2m_e}\mathbf{L} \ . \tag{22.25}$$

We now imagine this atom in the presence of a magnetic field $\vec{\mathcal{B}}$ oriented in the direction that we will call z. This results in a precession of the magnetic moment around the field (similar to the precession of a spinning top in the presence of a gravitational field) governed by the equation,

$$\frac{d\mathbf{L}}{dt} = \vec{\mu}_\ell \times \vec{\mathcal{B}} = \frac{e}{2m_e}\mathbf{L} \times \vec{\mathcal{B}} = -\mathbf{\Omega}_L \times \mathbf{L} \ ,$$

with $\mathbf{\Omega}_L = \frac{e}{2m_e}\vec{\mathcal{B}}$ representing the precession frequency and being called *Larmor frequency*. It is evident that the presence of the magnetic field considerably alters the state of the atom, even producing profound modifications in the frequency of the orbit of the electron ω_0 and therefore in the energetic state of the atom. This change is called *Zeeman effect*.

The Zeeman effect can be calculated by imagining that the field has an arbitrary direction with respect to $\mathbf{L}$. In this case, the equation describing the electronic motion as resulting from an equilibrium between the centrifugal force and the Coulomb force needs to be complemented by a Lorentz force,

$$m_e\ddot{\mathbf{r}} + m_e\omega_0^2\mathbf{r} = \mathbf{F}_L = -e\mathbf{v} \times \vec{\mathcal{B}} \ . \tag{22.26}$$

where $m\ddot{\mathbf{r}}$ is the centrifugal force due to the circular motion of the electron and $m_e\omega_0^2\mathbf{r}$ the centripetal force due to the Coulomb attraction exerted by the nucleus. Assuming the direction of the magnetic field given by $\vec{\mathcal{B}} = \mathcal{B}\hat{\mathbf{e}}_z$ with $\mathcal{B} = 2m_e\Omega_L/e$, the equations of motion can be decomposed into,

$$\begin{aligned} \ddot{x} + \omega_0^2 x + 2\Omega_L \dot{y} &= 0 \\ \ddot{y} + \omega_0^2 y - 2\Omega_L \dot{x} &= 0 \\ \ddot{z} + \omega_0^2 z &= 0 \ . \end{aligned} \tag{22.27}$$

The z-direction is not influenced. With the ansatz $x = ae^{\imath\omega t}$ and $y = be^{\imath\omega t}$ we obtain the system of equations,

$$\begin{aligned} a(\omega_0^2 - \omega^2) + 2\imath\Omega_L\omega b &= 0 \\ b(\omega_0^2 - \omega^2) - 2\imath\Omega_L\omega a &= 0 \ , \end{aligned} \tag{22.28}$$

which has a non-trivial solution for a and b only when the determinant of the coefficients of a and b vanishes:

$$0 = \begin{vmatrix} \omega_0^2 - \omega^2 & 2\imath\Omega_L\omega \\ -2\imath\Omega_L\omega & \omega_0^2 - \omega^2 \end{vmatrix} = \omega^4 - (2\omega_0^2 + 4\Omega_L^2)\omega^2 + \omega_0^4 \ . \tag{22.29}$$

We get,

$$\omega = \omega_{1,2} = \sqrt{\omega_0^2 + 2\Omega_L^2 \pm 2\Omega_L\sqrt{\omega_0^2 + \Omega_L^2}} = \omega_0 \pm \Omega_L + \frac{1}{2}\frac{\Omega_L^2}{\omega_0} + \ldots \ , \tag{22.30}$$

or, as $\Omega_L \ll \omega$, we get $\omega_{1,2} = \omega_0 \mp \Omega_L$. The result is a splitting of the energy levels proportional to the magnetic field,

$$\Delta E = 2\hbar\Omega_L = \frac{\hbar e}{m_e}\mathcal{B} = 2\mu_B\mathcal{B} \ , \tag{22.31}$$

where the abbreviation $\mu_B = e\hbar/2m_e \simeq 9.27\cdot 10^{-24}\,\mathrm{JT}^{-1}$ is called the *magneton Bohr*.

Although the classical derivation shows quantitative deviations from experimental observations, it is quite interesting, as it illustrates several aspects which have a quantum mechanical equivalence.

Example 138 (*Stern-Gerlach experiment*): Among several historical experiments carried out to unravel the atomic structure, one of the most important is the experiment carried out by *Otto Stern* and *Walther Gerlach* in 1922 to measure the magnetic moment of atoms. The results of this experiment once again demonstrated the need for new concepts to explain the observations.
Using Bohr's quantization rule, $L = n\hbar$, within the formula (22.25) we get,

$$\vec{\mu} = -\mu_B\frac{\mathbf{L}}{\hbar} \ .$$

In the presence of a magnetic field the dipole undergoes an interaction $W = -\vec{\mu}\cdot\vec{\mathcal{B}}$, and therefore a feels a force,

$$\mathbf{F} = -\vec{\mu}\cdot\nabla\vec{\mathcal{B}} \ .$$

By subjecting beams of atoms to the gradient of a magnetic field and detecting this force, Stern and Gerlach were able to measure the magnetic moment produced by the rotation of the electrons around the atomic nuclei.

22.1.5 Bohr's theory and its limitations

The classical model of the planetary atom provides a mechanical illustration of the microscopic world but fails to quantitatively explain experimental observations such as the discrete nature of atomic spectra.

The radiation emitted by hydrogen atoms is characterized by discrete, spectrally very thin lines. The observed lines are grouped in series named after Lyman, Ballmer and others,

$$\frac{1}{\lambda} = R_H \frac{\mu}{m_e} \left(\frac{1}{m^2} - \frac{1}{n^2} \right) , \tag{22.32}$$

where m and n are integers. $R_H = (1/4\pi\epsilon)^2(m_e e^4/4\pi\hbar^3 c)$ is the Rydberg constant and $\mu = m_e m_{at}/(m_e + m_{at})$ the reduced mass.

The discrete nature of spectral lines and the problem of the radiation collapse led *Niels Bohr* to formulate the following *postulates*:

1. There are specific stationary orbits, where electrons do not emit energy.

2. Each emission or absorption of radiation energy by electrons comes with a transition between stationary orbits. The radiation emitted during this transition is homogeneous.

3. The laws of mechanics can describe the dynamic equilibrium of electrons in stationary states, but fails to describe the transition of electrons *between* stationary orbits.

Thus, Bohr's model predicts the quantization of energy levels, known as *first quantization* of quantum mechanics. The radii of the possible orbits can be calculated from the postulate that the orbital angular momentum be quantized in units of $\hbar$, that is, the electrons form stationary de Broglie waves along the orbits [3]. We discuss Bohr's model in Excs. 22.1.6.6 and 22.1.6.7.

In the picture proposed by Bohr, the radiative decay happens as an abrupt transition of an electron between an outer (more energetic) orbit and an inner (less energetic) orbit. Since the energies of stationary orbits are very well defined, the emitted radiation is mono-energetic, i.e., the spectrum consists of discrete characteristic lines.

We note here that the picture of an abrupt transition of electrons between discrete states, called the *quantum jump*, did not receive Schrödinger's blessing. He rather imagined for electrons, within his theory of quantum wave mechanics, wave-shaped orbitals instead of planetary trajectories, thus avoiding the problem of radiation due to charge deceleration and the quantum jump concept. According to him, during a transition between electronic orbits, the energy is transformed into radiation *gradually* [4].

[3] A generalization of Bohr's theory was provided by *Arnold Johannes Wilhelm Sommerfeld*. Assuming elliptical orbits for the electrons he managed to explain some features of the fine structure, provided the motion of the electron was treated relativistically. The basic premises were 1. stable orbits when the Coulomb attraction is balanced by the centrifugal force, 2. quantization of phase space $\int r_q dq = n_q \hbar$, and 3. quantization of angular momentum $\int L d\theta = n_\theta \hbar$.

[4] We note here, that quantum jumps were observed much later!

22.1.6 Exercises

22.1.6.1 Ex: Analysis of Rutherford scattering

a. What conclusions can be drawn from the observation that Rutherford's formula describes well the scattering of charged particles traveling through matter over a wide range of parameters?
b. Why do we see a deviation from Rutherford's formula for large energies?
c. The scattering of protons with energy E crossing a thin film of thorium is well described up to energies of $E = 4.3\,\mathrm{MeV}$ by Rutherford's formula. Estimate for this case the range of nuclear forces.
d. For small scattering angles θ we observe large deviations from Rutherford's formula. Explain why?
e. Assume the thorium atoms of item (c) to form a periodic crystal with the lattice constant $d = 10a_B$. At which minimum angle θ Rutherford's formula loses its validity.

Solution: *a. Thomson's assumption of a heavy nuclear charge distributed across the atom is false. Instead they are the light-weighted electrons distributed through the atom.*
b. For large energies, i.e., small distances, the proton can feel the finite extension of the nucleus as well as nuclear forces.
c. When the shock parameter b tends to zero, the distance $2a$ between the proton and the nucleus depends on the kinetic energy as,

$$E_{\mathrm{kin}} = \frac{Z_p Z_{tg} e^2}{4\pi\varepsilon_0}\frac{1}{2a} \ .$$

With $Z_p = 1$, $Z_{tg} = 90$ and the given energy limit we obtain $2a = 15\,\mathrm{fm}$.
d. When the collision parameter b is large, we need to take into account the proximity of other nuclei as well as screening effects.
e. For this case we set $b = 5a_B$. From Eq. (22.5) we find,

$$\cot\tfrac{\theta}{2} = \frac{8\pi\varepsilon_0 E}{Z_\alpha Z_{thorium} e^2} b \ ,$$

yielding $\theta = 1.14 \cdot 10^{-4}\,\mathrm{rad} = 6.5 \cdot 10^{-3}\ ^\circ$.

22.1.6.2 Ex: Rutherford scattering

a. A beam of α-particles with energy $E_{\mathrm{kin}} = 3\,\mathrm{MeV}$ and flux $I = 5 \cdot 10^3\,\mathrm{s}^{-1}$ impinges on a thick gold film $x = 1\,\mu\mathrm{m}$. Using Rutherford's formula, calculate how many particles are scattered in $\Delta t = 10\,\mathrm{minutes}$ in the range of angles $10^\circ \le \theta \le 30^\circ$.
b. Now, the gold film is replaced with an aluminum film of the same thickness. How many α-particles are scattered under equal circumstances?

Solution: *a. The atomic mass of gold $^{197}_{79}Au$ being $m_{Au} = 196.966570\ u$ contains and its density being $\rho_{Au} = 19.3\,\mathrm{g/cm^3}$, we expect $n_{tg} = \rho_{Au}/m_{Au} = 5.9 \cdot 10^{28}\,\mathrm{m^3}$*

atoms per volume. With this we calculate,

$$N_{Au} = I\Delta t \int_{10^\circ \le 30^\circ} \frac{dN}{N} = I\Delta t n_{tg} x \frac{Z_\alpha^2 Z_{tg}^2 e^4}{256\pi^2 \varepsilon_0^2 E_{\text{kin}}^2} \int_0^{2\pi} \int_{10^\circ}^{30^\circ} \frac{1}{\sin^4 \frac{\theta}{2}} \sin\theta d\theta d\phi$$
$$= 63.6 \cdot \frac{-4\pi}{\sin^2 \frac{\theta}{2}} \Bigg|_{10^\circ}^{30^\circ} = 105000 \ .$$

b. Aluminum $^{27}_{13}Al$ *has about the same number of atoms per volume. With this we calculate,*

$$N_{Al} = \frac{Z_{Al}^2}{Z_{Au}^2} N_{Au} = 3885 \ .$$

22.1.6.3 Ex: Screening of electrons

Consider thin layer of charge $-Z_{tg}e$ with radius R. This screening causes a scattering angle,

$$\tan\tfrac{\theta}{2} = \frac{D}{2b} \frac{\sqrt{1-(b/R)^2}}{1+D/2R} \ ,$$

with $D \equiv \frac{3Ze^2}{m_2 v^2/2}$ for $b < R$. Verify how the screening changes the differential cross section $\frac{d\sigma}{d\Omega}$.

Solution:

22.1.6.4 Ex: Radiation of an oscillating dipole

Calculate the angular distribution of the power radiated by an oscillating electric or magnetic dipole from expressions for the emitted electric and magnetic fields found in literature.

Solution: *We consider* [5] *an electric dipole with the dipole moment* p_0 *harmonically oscillating with the angular frequency* ω *along the direction* $\hat{\mathbf{e}}_z$*,*

$$\mathbf{p}(\mathbf{r},t) = \mathbf{p}(\mathbf{r}) e^{-\imath\omega t} = p_0 \hat{\mathbf{e}}_z e^{-\imath\omega t} \ .$$

In vacuum, the generated field can be derived exactly using the retarded potentials as,

$$\mathbf{E} = \frac{1}{4\pi\varepsilon_0} \left\{ \frac{\omega^2}{c^2 r} (\hat{\mathbf{e}}_r \times \mathbf{p}) \times \hat{\mathbf{e}}_r + \left(\frac{1}{r^3} - \frac{\imath\omega}{cr^2} \right) [3\hat{\mathbf{e}}_r (\hat{\mathbf{e}}_r \cdot \mathbf{p}) - \mathbf{p}] \right\} e^{\imath\omega r/c} e^{-\imath\omega t}$$
$$\mathbf{B} = \frac{\omega^2}{4\pi\varepsilon_0 c^3} \hat{\mathbf{e}}_r \times \mathbf{p} \left(1 - \frac{c}{\imath\omega r} \right) \frac{e^{\imath\omega r/c}}{r} e^{-\imath\omega t} \ .$$

[5] See script on *Electrodynamics* (2023), Excs. 7.6.1.2 and 8.2.1.2.

For $r\omega/c \gg 1$, the far field adopts the simplest form of a radiating spherical wave, but with the angular dependence incorporated in the vector product:

$$\mathbf{B} = \frac{\omega^2}{4\pi\varepsilon_0 c^3}(\hat{\mathbf{e}}_r \times \mathbf{p})\frac{e^{i\omega(r/c-t)}}{r} = \frac{\omega^2\mu_0 p_0}{4\pi c}(\hat{\mathbf{e}}_r \times \hat{\mathbf{e}}_z)\frac{e^{i\omega(r/c-t)}}{r} = -\frac{\omega^2\mu_0 p_0}{4\pi c}\sin\theta\frac{e^{i\omega(r/c-t)}}{r}\hat{\mathbf{e}}_\phi$$

$$\mathbf{E} = c\mathbf{B}\times\hat{\mathbf{e}}_r = -\frac{\omega^2\mu_0 p_0}{4\pi}\sin\theta(\hat{\mathbf{e}}_\phi\times\hat{\mathbf{e}}_r)\frac{e^{i\omega(r/c-t)}}{r} = -\frac{\omega^2\mu_0 p_0}{4\pi}\sin\theta\frac{e^{i\omega(r/c-t)}}{r}\hat{\mathbf{e}}_\theta \ .$$

In the temporal average, $\frac{\omega}{2\pi}\int_0^{2\pi}\cos^2\omega t dt = \frac{1}{2}$, the Poynting vector,

$$\langle\mathbf{S}\rangle = \frac{1}{\mu_0}\langle\mathbf{E}\times\mathbf{B}\rangle = \frac{\mu_0 p_0^2\omega^4}{32\pi^2 c}\frac{\sin^2\theta}{r^2}\hat{\mathbf{e}}_r$$

In the temporal average, it is not isotropically distributed, but concentrated in the directions perpendicular to the dipolar moment, as a result of the non-spherical nature of the electrical and magnetic waves. In fact, the spherical harmonic function ($\sin\theta$) responsible for this toroidal angular distribution is just the p-wave ($\ell = 1$). The total power radiated by the field can be derived from the vector Poynting vector as being,

$$P = \int_0^{2\pi}\int_0^{\pi}\langle\mathbf{S}\rangle\cdot\hat{\mathbf{e}}_r r^2\sin\theta d\theta d\phi = \frac{\mu_0 p_0^2\omega^4}{32\pi^2 c}\ 2\pi\ \int_0^{\pi}\sin^3\theta d\theta = \frac{\mu_0\omega^4 p_0^2}{12\pi c} \ .$$

22.1.6.5 Ex: Magnetic moments

a. Derive from the expression $\vec{\mu}_L = \frac{1}{2}\int_{\mathbb{R}^3}\mathbf{r}\times\mathbf{j}(\mathbf{r}')d^3r'$ of classical electrodynamics and an appropriate parametrization of the current density $\mathbf{j}$ the relation between the magnetic dipole moment $\vec{\mu}$ due to the orbiting electron and the angular momentum $\mathbf{L}$.
b. The length of the angular momentum vector being given by $|\mathbf{L}| = \hbar$, calculate the magnetic moment for an electron and for a proton.

Solution: *a. The rotational motion of a charge, $-e$, creates a current $I = -e/2\pi r$, corresponding to a current density,*

$$\mathbf{j}(\mathbf{r}') = I\hat{\mathbf{e}}_\phi\delta(r-r')\delta(z') = -e\frac{\mathbf{v}}{2\pi r}\delta(r-r')\delta(z') \ .$$

The dipole moment caused by a circular motion of an electron is,

$$\vec{\mu}_L = \frac{1}{2}\int_{\mathbb{R}^3}\mathbf{r}\times\mathbf{j}(\mathbf{r}')d^3r' = \frac{1}{4\pi}\mathbf{r}\times\int_0^{2\pi}d\phi'\int_{-\infty}^{\infty}dz'\int_0^{\infty}r'dr'\frac{-e\mathbf{v}}{r}\delta(r-r')\delta(z')$$
$$= \frac{-1}{2}e\mathbf{r}\times\mathbf{v} = \frac{-e}{2m_e}\mathbf{L} \ ,$$

with the angular momentum $\mathbf{L} = \mathbf{r}\times m_e\mathbf{v}$. The quotient $\gamma_e \equiv -e/2m_e$ is called the gyromagnetic ratio of the electron. We often use the Bohr magneton, $\mu_B \equiv \hbar e/2m_e$, which represents the elementary unit of angular momentum,

$$\vec{\mu}_L = -\frac{\mu_B}{\hbar}g_L\mathbf{L} \ ,$$

where $g_L \equiv \mu_L/L = 1$ is a factor taking into account possible corrections between the classical derivation and quantum mechanics.
b. We have,

$$\mu_e = \mu_B \quad , \quad \mu_p = \mu_K \ .$$

22.1.6.6 Ex: Bohr's atom

In 1913, Niels Bohr presented his atomic model adapting Rutherford's model to the quantization ideas proposed by Max Planck.
a. Impose the quantization rule for the angular momentum ($L = n\hbar$) of an electron orbiting an atom of atomic number Z to find an expression for the radii of the allowed orbits.
b. According to Bohr's model, the transition between different orbits is accompanied by the emission (or absorption) of a photon. Determine the energy of a photon emitted during a transition between the first excited state and the ground state of a hydrogen atom.
c. Consider an electron trapped in an infinite one-dimensional box potential of width a. Determine an expression for the electronic energy levels.
d. What should be the width a of this potential, in terms of the Bohr radius, so to ensure that a photon emitted during a transition between the first excited state and the ground state equals that obtained in item (b)?

Solution: *a. In equilibrium, the centrifugal force and the Culombian force between the electron and the Z positive charges of the nucleus must compensate. Hence,*

$$F_{cf} = F_{cou} \qquad \textit{therefore} \qquad \frac{m_e v^2}{r} = \frac{1}{4\pi\varepsilon_0}\frac{Ze^2}{r^2} \ .$$

But the quantization condition is $L = n\hbar$, which by the definition of angular momentum leads us to:

$$v = \frac{n\hbar}{m_e r} \ .$$

By replacing the velocity in centripetal force, we will have:

$$r_n = \frac{(4\pi\varepsilon_0)\hbar^2}{m_e e^2}\frac{n^2}{Z} = a_B\frac{n^2}{Z} \ ,$$

where we defined the radius of Bohr a_B.
b. The energy of the electron is $E = E_c + E_p = \frac{m_e}{2}v^2 - \frac{1}{4\pi\epsilon_0}\frac{Ze^2}{r}$. With the Coulomb force, we have,

$$E = -\frac{1}{2}\frac{1}{4\pi\varepsilon_0}\frac{Ze^2}{r} \ .$$

Inserting the possible radii r_n, we get:

$$E_n = -\frac{1}{2}\frac{1}{4\pi\varepsilon_0}\frac{Z^2e^2}{a_B n^2} = -\frac{m_e}{2}\left(\frac{1}{4\pi\varepsilon_0}\right)^2\frac{Z^2e^2}{\hbar^2 n^2} \ .$$

The energy E_f of the photon emitted is,

$$E_2 - E_1 = -\frac{1}{2}\left(\frac{1}{4\pi\varepsilon_0}\right)^2 \frac{m_e Z^2 e^2}{\hbar^2}\left[\frac{1}{4} - 1\right] \ .$$

Hence,

$$E_f = \frac{3}{8}\left(\frac{1}{4\pi\varepsilon_0}\right)^2 \frac{m_e e^2}{\hbar^2} \ .$$

c. Considering that the potential $V(x)$ is zero for $0 < x < a$ and infinity outside this region, we have the Schrödinger equation $-\frac{\hbar^2}{2m}\frac{d}{dx}\psi = E\psi$ which leads us to the solution:

$$\psi(x) = A\cos(kx) + B\sin(kx) \qquad \text{where} \qquad k^2 = \frac{2m_e E}{\hbar^2}$$

The boundary condition, $\psi(0) = 0$ leads to $A = 0$ and $\psi(a) = 0$ leads to $ka = n\pi$. With ansatz above, we conclude that

$$E_n = \frac{n^2\pi^2\hbar^2}{2ma^2} \ .$$

d. The energy of the emitted photon is,

$$E_f = E_2 - E_1 = \frac{\hbar^2\pi^2}{2ma^2}[4-1] = \frac{3\hbar^2\pi^2}{2ma^2} \ .$$

Thus, equating with the expression for E_f for the Bohr atom, we have

$$\frac{3\hbar^2\pi^2}{2m_e a^2} = \frac{3}{8}\left(\frac{1}{4\pi\varepsilon_0}\right)^2 \frac{me^2}{\hbar^2} \ .$$

Hence,

$$a = \frac{4\pi\varepsilon_0\hbar^2}{m_e e^2}2\pi \ .$$

But the Bohr radius a_B is just the orbit in which $n = 1$ in the expression of the Bohr radius. Then

$$a = 2\pi a_B \ .$$

That is, the width of the potential has the same order of magnitude as the diameter of a hydrogen atom (around $0.1\,\text{nm}$).

22.1.6.7 Ex: The hydrogen atom

The hydrogen atom can be seen as a point-like proton and an electron distributed over space with charge density $\rho = Ae^{-2r/a_B}$ around the proton that is in the center. Here, A is a constant and r is the distance from the center.
a. Calculate A considering the fact that the atom is electrically neutral.
b. Calculate the amplitude of the electric field at a radius $r = a_B$.

Solution: *a. The total charge of the electronic layer must give one unit of negative elementary charge,*

$$\begin{aligned}\frac{-e}{A} &= \int_{\mathbb{R}^3} e^{-2r/a_B} dV = 4\pi \int_0^\infty r^2 e^{-2r/a_B} dr \\ &= 4\pi \left(-\frac{1}{2} a_B e^{-2\frac{R}{a_B}} R^2 - \frac{1}{2} a_B^2 e^{-2\frac{R}{a_B}} R - \frac{1}{4} a_B^3 e^{-2\frac{R}{a_B}} + \frac{1}{4} a_B^3 \right) \Big|_0^\infty = \pi a_B^3 \ .\end{aligned}$$

Hence, $A = -e/\pi a_B^3$.
b. For a sphere with volume V *and surface* ∂V *we have according to Gauß' law,*

$$\oint_{\partial V} \vec{E} \cdot d\vec{f} = \frac{1}{\varepsilon_0} \int_V \frac{-e}{\pi a_B^3} e^{-2r/a_B} dV \ .$$

The surface integral in spherical coordinates is,

$$\oint_{\partial V} \vec{E} \cdot d\vec{f} = \oint_{\partial V} \vec{E} \cdot \hat{e}_r R^2 \sin\theta d\theta d\phi = 4\pi E_r R^2 \ .$$

The charge inside the sphere (including the proton) is,

$$\begin{aligned} e + \int_V \frac{-e}{\pi a_B^3} e^{-2r/a_B} dV &= e + \frac{-e}{\pi a_B^3} 4\pi \int_0^R r^2 e^{-2r/a_B} dr \\ &= e + \frac{-e}{\pi a_B^3} 4\pi \frac{-1}{2} a_B \left(e^{-2\frac{R}{a_B}} R^2 + a_B e^{-2\frac{R}{a_B}} R + \frac{1}{2} a_B^2 e^{-2\frac{R}{a_B}} - \frac{1}{2} a_B^2 \right) \\ &= \frac{2e}{a_B^2} \left(e^{-2\frac{R}{a_B}} R^2 + a_B e^{-2\frac{R}{a_B}} R + \frac{1}{2} a_B^2 e^{-2\frac{R}{a_B}} \right) \ . \end{aligned}$$

Hence,

$$\begin{aligned} E_r(R) &= \frac{e}{2\pi\varepsilon_0 a_B^2} \left(e^{-2\frac{R}{a_B}} + \frac{a_B}{R} e^{-2\frac{R}{a_B}} + \frac{1}{2} \frac{a_B^2}{R^2} e^{-2\frac{R}{a_B}} \right) \\ &\overset{R \to a_B}{\longrightarrow} \frac{e}{4\pi\varepsilon_0 a_B^2} \ 5e^{-2} \simeq 350\,\mathrm{GV/m} \ . \end{aligned}$$

22.2 The discovery of the photon

The concept of the nature of light has a variable history. Newton proposed around ~ 1650 a corpuscular model to explain Snellius' law on the refraction of a light beam penetrating a crystal. Around the same time Huygens found a wave-based interpretation. The two models predicted different speeds of light within the dense medium. Newton found, that the speed of light is greater in the medium than outside, while Huygens found the opposite [6]. In the late 1800's the wave nature of light was established through observations of interference effects confirming Huygens' hypothesis.

[6] Note that until today there remain doubts about the correct value of the momentum of light in dielectric media [898].

However, some observations made were incompatible with this simplistic ideas, for example, the spectrum of blackbody radiation, the Compton effect, the specific heat of the solid, the radiation pressure, and the photoelectric effect. All these observations are readily understood by assuming a corpuscular nature of the light [7].

Nowadays, knowing the theory of quantum mechanics, we are aware that both ideas have their range of validity and that the electromagnetic radiation is dual: In general, propagation and interference effects are best described by waves. However, when interacting with matter, light tends to localize into small energy packets that we call *photons*.

22.2.1 Radiation in a conductive cavity

In the age of lasers a classical treatment of the emission and absorption of light may seem an atavism. However, even with coherent and monochromatic radiation sources, the most commonly used physical picture is that of a classical optical field interacting with an atom or a molecule whose energetic structure is treated quantum mechanically. And even the atomic or molecular dipole is often treated like a classical oscillator. The exposition of such a dipole to simple boundary conditions prepares the analogous development of a quantum oscillator and provides a direct path to quantization of the radiation field.

Even if we rarely do experiments by throwing light into a small hole in a metallic box, the electromagnetic fields obtained by solving Maxwell's equation are particularly simple for boundary conditions, where the fields disappear on the inner surfaces of the box. Before discussing the physics of radiation in a perfectly conducting cavity, we have to introduce some basic relations between electromagnetic amplitudes, stored energy, and intensity.

The electric field of a plane wave oscillating with frequency ω and propagating through vacuum in the direction of propagation defined by the *wave vector*,

$$\mathbf{k} = \frac{2\pi}{\lambda}\hat{\mathbf{k}} \ , \tag{22.33}$$

can be written,

$$\vec{\mathcal{E}} = \vec{\mathcal{E}}_0 e^{\imath(\mathbf{k}\cdot\mathbf{r}-\omega t)} \ , \tag{22.34}$$

where $\vec{\mathcal{E}}_0 = \mathcal{E}_0\hat{\mathbf{e}}$ consists of an amplitude $\mathcal{E}_0$ and a polarization $\hat{\mathbf{e}}$. Since the field $\vec{\mathcal{E}}_0$ is transverse to the direction of propagation, the polarization has two components perpendicular to $\mathbf{k}$. The magnetic induction field associated with the wave is,

$$\mathcal{B}_0 = \tfrac{1}{c}\mathcal{E}_0 \ . \tag{22.35}$$

For a propagating wave $\vec{\mathcal{E}}$ and $\vec{\mathcal{B}}$ are in phase, while for a standing wave they are out of phase.

For a given cavity mode we can express the standing wave in this mode as,

$$\vec{\mathcal{E}} = \vec{\mathcal{E}}_0(\mathbf{r})e^{-\imath\omega t} \ . \tag{22.36}$$

[7] The corpuscular hypothesis is now called the second quantization of quantum theory or quantization of the electromagnetic field.

The energy of the electromagnetic field of a standing wave, averaged over one oscillation of the frequency ω is,

$$\bar{U} = \frac{1}{2}\int \left(\frac{\varepsilon_0}{2}|\vec{\mathcal{E}}|^2 + \frac{1}{2\mu_0}|\vec{\mathcal{B}}|^2\right) dV \ . \tag{22.37}$$

Now, the *energy density* of the oscillating electromagnetic field is given by,

$$\boxed{\bar{u} = \frac{d\bar{U}}{dV} = \frac{1}{4}\left(\varepsilon_0|\vec{\mathcal{E}}|^2 + \frac{1}{\mu_0}|\vec{\mathcal{B}}|^2\right)} \ . \tag{22.38}$$

From the equation (22.35) we can see that the contributions of the electric and magnetic fields are equal. Therefore,

$$\bar{U} = \tfrac{1}{2}\int \varepsilon_0|\vec{\mathcal{E}}|^2 dV \qquad \text{and} \qquad \bar{u} = \tfrac{1}{2}\varepsilon_0|\vec{\mathcal{E}}|^2 \ . \tag{22.39}$$

Another important quantity is the *flux of electromagnetic energy* through a surface. The *Poynting vector* describing this flux is defined by,

$$\mathbf{I} = \tfrac{1}{\mu_0}\vec{\mathcal{E}} \times \vec{\mathcal{B}} \ . \tag{22.40}$$

Again using the equation (22.35), we find the value averaged over a time period,

$$\boxed{\bar{I} = \tfrac{1}{2}\varepsilon_0 c|\vec{\mathcal{E}}|^2} \ . \tag{22.41}$$

This quantity, called *intensity*, describes the fact that the flux is a density of energy multiplied with the velocity of propagation in vacuum,

$$\bar{u}c = \tfrac{1}{2}\varepsilon_0 c|\vec{\mathcal{E}}|^2 = \bar{I} \ . \tag{22.42}$$

The intensity can also be written,

$$\bar{I} = \frac{1}{2}\sqrt{\frac{\varepsilon_0}{\mu_0}}|\vec{\mathcal{E}}|^2 \ . \tag{22.43}$$

where the factor $\sqrt{\mu_0/\varepsilon_0}$ is called *impedance of free space*, because it has the unit of a resistance and the last equation has the same form as the power dissipated in a resistor,

$$W = \frac{1}{2}\frac{V^2}{R} \ . \tag{22.44}$$

22.2.2 Black body radiation

We now want to calculate the energy density inside the cavity before using the result to describe the interaction between light and a sample of two-level atoms located inside the cavity. The basic idea is to say that the electrons inside the conducting surface of the cavity oscillate because of thermal motion. The oscillation generates a dipolar radiation leading to stationary waves developing within the cavity. As the walls of the cavity are conducting, the electric field $\vec{\mathcal{E}}$ must disappear inside the wall and on its

surfaces. The task is now twofold: first count the number of possible standing waves, which satisfy the boundary conditions as a function of frequency; second, determine the energy for each wave and then calculate the spectral distribution of the energy within the cavity.

The equations describing the radiated energy in free space are,

$$\nabla^2\vec{\mathcal{E}} = \frac{1}{c^2}\frac{\partial^2\vec{\mathcal{E}}}{\partial t^2} \qquad \text{and} \qquad \nabla\cdot\vec{\mathcal{E}} = 0\ . \tag{22.45}$$

The stationary waves solutions separate into terms oscillating in time and in space.

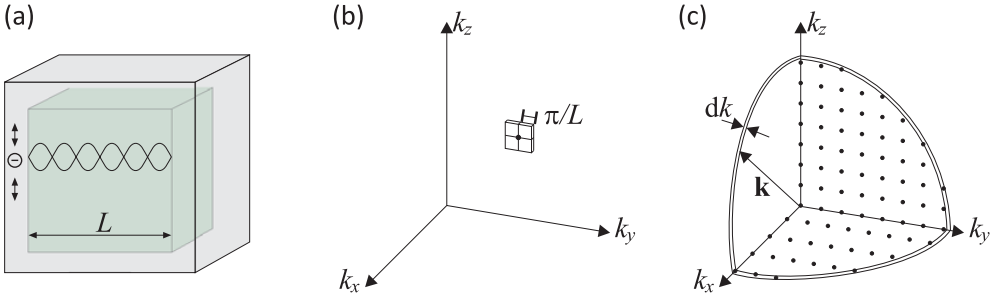

Figure 22.8: (a) Cavity in position space showing the thermal motion of the electrons inside the walls. (b and c) Density-of-states in a cavity in momentum space.

Now, respecting the boundary conditions for a three-dimensional box of length L, we have for the components of $\vec{\mathcal{E}}$ [8],

$$\begin{aligned}\vec{\mathcal{E}}(\mathbf{r},t) = e^{-\imath\omega t}[&\hat{\mathbf{e}}_x\cos(k_x x)\sin(k_y y)\sin(k_z z)\\ &+\hat{\mathbf{e}}_y\sin(k_x x)\cos(k_y y)\sin(k_z z)\\ &+\hat{\mathbf{e}}_z\sin(k_x x)\sin(k_y y)\cos(k_z z)]\ ,\end{aligned} \tag{22.46}$$

with the components,

$$k_x = \frac{\pi n_x}{L} \qquad \text{for} \qquad n_x = 0, 1, 2, ... \tag{22.47}$$

and similar for k_y and k_z. Note, that for each component $\mathcal{E}_{x,y,z}$ the transverse amplitudes disappear in 0 and L. By inserting this solution into Helmholtz's equation (22.45), we obtain,

$$k_x^2 + k_y^2 + k_z^2 = \frac{\omega^2}{c^2}\ . \tag{22.48}$$

The states $k_{x,y,z}$ (enumerated by integer numbers $n_{x,y,z}$) form a three-dimensional orthogonal lattice of points in space $\mathbf{k}$ separated by a distance along the axes k_x, k_y, k_z of $\frac{\pi}{L}$, as shown in Fig. 22.8. In principle, the number of states that can be placed within a sphere of radius k in the momentum space is,

$$N = \int_{\text{sphere}} dn_x dn_y dn_z\ . \tag{22.49}$$

[8] See script on *Electrodynamics* (2023).

However, the periodic boundary conditions for $|\mathbf{k}|$ limit the components k_x, k_y, k_z to positive values ($n \geq 0$), that is, the volume under consideration is limited to an octant. On the other hand, we must multiply the number of states by two because of the degeneracy of polarizations. Hence,

$$4N = \int_0^n 4\pi n^2 dn = \left(\frac{L}{\pi}\right)^3 \int_0^k 4\pi k^2 dk = \frac{4L^3}{\pi^2}\frac{k^3}{3} = \frac{4L^3\omega^3}{3\pi^2 c^3} \ . \tag{22.50}$$

With this, we obtain the *mode density*,

$$\frac{N}{L^3} = \frac{\omega^3}{3\pi^2 c^3} \ . \tag{22.51}$$

The *spectral density of modes* ϱ can be given in several units,

$$\int \varrho(n)dn = \int \varrho(k)dk = \int \varrho(\omega)d\omega = \frac{N}{L^3} \ , \tag{22.52}$$

such that,

$$\boxed{\varrho(n) = \frac{\pi n^2}{L^3} \quad \text{or} \quad \varrho(k) = \frac{k^2}{\pi^2} \quad \text{or} \quad \varrho(\omega) = \frac{\omega^2}{\pi^2 c^3}} \ . \tag{22.53}$$

The density of oscillating modes within the cavity grows like the square of the frequency. Now, the mean energy per mode in a sample of oscillators in thermal equilibrium is, following the equipartition law, equal to,

$$\bar{E} = k_B T \ , \tag{22.54}$$

where k_B is the Boltzmann constant. We conclude that the *spectral energy density* $u_{RJ}(\omega)$ in the cavity is,

$$\boxed{u_{RJ}(\omega)d\omega = k_B T \varrho(\omega)d\omega = k_B T \frac{\omega^2}{\pi^2 c^3}d\omega} \ . \tag{22.55}$$

This law is known as the *Rayleigh-Jeans law* of *black-body radiation*. As seen in Fig. 22.9, this law suggests the physically impossible fact, called *ultraviolet catastrophe*, that the energy storage in the cavity grows without limits like the square of frequency.

22.2.3 Planck's distribution of modes

We obtained the result (22.54) by multiplying the number of modes with the mean energy per mode. As there is no doubt about our method of counting the modes, the problem with the ultraviolet catastrophe can only root in the use of the equipartition principle for assigning energy to the oscillators.

Planck's idea to solve this problem was to first consider the probability distribution for exciting the modes (thermal states) for a sample of oscillators in thermal equilibrium at temperature T. This probability distribution p comes from mechanical

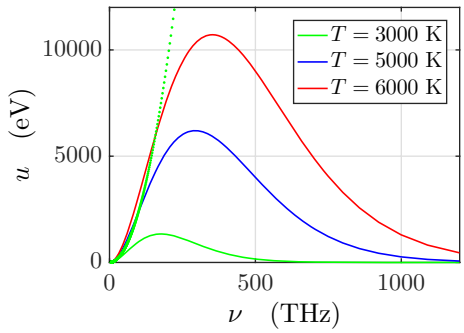

Figure 22.9: (code) Spectral energy density following Rayleigh-Jeans' and Planck's laws.

statistics and can be written in terms of the *Boltzmann factor*, e^{-E_n/k_BT}, and the partition function $q = \sum_{n=0}^{\infty} e^{-E_n/k_BT}$ as,

$$p_n = \frac{e^{-E_n/k_BT}}{q} \ . \tag{22.56}$$

Now Planck hypothesized that the energy be quantized, that is, it must be assigned in discrete portions, proportional to the frequency, such that,

$$\boxed{E_n = n\hbar\omega} \ , \tag{22.57}$$

where $n = 0, 1, 2, ..$ and the proportionality constant $\hbar$ is called *Planck's constant*. With the abbreviation $Z \equiv e^{-\hbar\omega/k_BT}$ and using the rule $\sum_{n=0}^{\infty} Z^n = (1-Z)^{-1}$, we find the average number,

$$\bar{n} = \sum_n n p_n = (1-Z)\sum_n n Z^n = (1-Z)Z\frac{\partial}{\partial Z}\sum_n Z^n = \frac{Z}{1-Z} = \frac{1}{e^{\hbar\omega/k_BT}-1} \ . \tag{22.58}$$

The probability of occupancy of state n is,

$$p_n = (1-Z)Z^n = \frac{\bar{n}^n}{(1+\bar{n})^{1+n}} \ , \tag{22.59}$$

and the average energy is,

$$\bar{E} = \sum_n E_n p_n = \sum_n n\hbar\omega e^{-n\hbar\omega/k_BT} = \frac{\hbar\omega}{e^{\hbar\omega/k_BT}-1} \ , \tag{22.60}$$

in contrast to the initial assumption (22.55).

Finally, we obtain Planck's expression for the energy density inside the cavity by replacing the energy (22.60) for the factor k_BT in Rayleigh-Jeans' law (22.55),

$$\boxed{u_P(\omega)d\omega = \bar{E}\varrho(\omega)d\omega = \frac{\omega^2}{\pi^2c^3}\frac{\hbar\omega}{e^{\hbar\omega/k_BT}-1}d\omega} \ . \tag{22.61}$$

This result, drawn in Fig. 22.9, is much more satisfactory, because now the energy density has an upper bound, and it coincides with the results of experiments. For high

temperatures or low excitation energies, $\hbar\omega \ll k_B T$, Planck's distribution converges to that of Rayleigh-Jeans', $u_P(\omega) \to u_{RJ}(\omega)$.

Note, that the form of the expression for the energy depends on the parametrization and must be derived respecting $u(\omega)d\omega = u(\lambda)d\lambda$, etc.. Often the blackbody radiation is expressed in terms of the *spectral radiance*,

$$L(\omega) \equiv \frac{c}{4\pi} u(\omega) \ , \tag{22.62}$$

which can be understood as the (isotropic) energy flux into all directions of space. Solve the Excs. 22.2.10.1 to 22.2.10.7.

22.2.4 The corpuscular nature of the photon

22.2.4.1 The photoelectric effect

Light incident on a metallic surface can expel electrons. For this to occur, the light must have a *minimum frequency*. If the frequency is below this value, there is no point in increasing the light intensity: the electrons won't be expelled. The main experimental observations are: 1. Electrons are ejected without apparent delay, i.e. it is not necessary (and it doesn't help) to accumulate a certain amount of energy. 2. Higher light intensities increase the number of electrons, but not their kinetic energy after expulsion. 3. Red light does not eject electrons, even at high intensities. 4. Weak ultraviolet light only ejects few electrons, but with high kinetic energy.

These observations challenge the classical electromagnetic model according to which the Lorentz acceleration of the electrons should be proportional to the field *amplitude*. The observations were explained by Einstein's theory of the *photoelectric effect*, which assumes the light to be quantized (unlike Planck, who preferred to quantize the process of light absorption),

$$E = h\nu \ . \tag{22.63}$$

Assuming a fixed exit work A for the extraction of an electron, we can measure the constant $\hbar$:

$$h\nu = A + \tfrac{mv^2}{2} = A + eV \qquad \to \qquad h = \frac{eV}{\nu - \nu_g} \ . \tag{22.64}$$

The energy of the fastest electrons is measured through the decelerating voltage by varying ν and I. We will discuss the photoelectric effect quantitatively later in the Exc. 27.4.5.7.

22.2.4.2 Bremsstrahlung and the Franck-Hertz experiment

Bremsstrahlung is, in a way, the inverse process of the photoelectric effect. Here, electrons are accelerated toward a cathode. Finding a target they are rapidly decelerated, a process in which they emit a continuous spectrum of X-rays (in addition to characteristic lines attributed to electronic transitions in the target atoms). For any given kinetic energy the spectra have a red threshold corresponding to photons that receive the entire energy of the electron.

In the *Franck-Hertz experiment* free electrons produced in a plasma are accelerated by a strong electric field. Having traveled a sufficiently long distance they have

acquired enough kinetic energy to excite electronic transitions in the atoms of the plasma. When an excitation occurs, the electron suddenly loses all its energy and must be accelerated again, starting from rest, before it can excite another atom.

22.2.4.3 Radiative pressure and Compton scattering

When light is scattered from a particle, it transfers momentum to it called *photonic recoil*. This effect, known as *radiation pressure*, occurs for example in *Compton scattering*.

X-rays scattered by the electrons of a carbon target are red-shifted by an amount, which increases with the scattering angle. This is the *Compton effect*. The data are understood assuming a corpuscular nature of light and applying the laws of conservation of energy and momentum to the collision processes between photons and electrons. The scattered photon sees its energy reduced and therefore its wavelength increased, as we have already seen in Sec. 20.2.3.

In a material where there are free electrons, this effect will occur at all photon energies. In other materials, it is only observed with high energy photons. For high energy photons, exceeding the atomic binding energy, the electrons can be considered free such that, in the scattering process, the photon is able to eject the electron from its atom. The photon receives the remaining energy and is deviated, such that the overall momentum of the system is conserved. The loss of energy for the photon results in a spectral shift to the red during its passage through the material.

Photons of visible light, on the other hand, do not have enough energy to eject bound electrons. In this case, the mass in the Compton formula must be replaced by the atomic mass, such that the spectral displacement becomes much smaller. This limit, which involves bound electrons, is that of Thomson and Rayleigh scattering.

The relevance of this effect lies in the fact that it shows that light exhibits properties commonly attributed to corpuscles, since Thomson's scattering model, based on the classical theory of charged particles accelerated by electromagnetic fields, can not explain any spectral shift. Compton scattering is discussed quantitatively in Exc. 20.2.6.5.

22.2.5 Einstein's transitions rates

Bohr's atom model explained for the first, time how light interacts with matter: Atoms have discrete excitation levels, and they absorb and emit discrete energy packets $\hbar\omega$. Unfortunately, Bohr's model can not predict transition rates. Here, Einstein helped out by developing a useful theory (see Fig. 22.10).

Figure 22.10: Bohr model and Einstein rate diagram.

We consider a two-level atom or a sample of atoms within a conducting cavity. We have N_1 atoms in the lower energy state E_1 and N_2 in the upper state E_2. Light interacts with these atoms through stimulated resonant absorption and emission. The rates, $B_{12}u(\omega)$ and $B_{21}u(\omega)$ are proportional to the energy spectral density $u(\omega)$ of the cavity modes. The central idea of Einstein is to postulate that atoms in the higher state can emit light spontaneously at a rate A_{21}, which depends only on the density of modes of the cavity, i.e. the volume of the cavity, but not the energy of the field of radiation. With the Einstein coefficients we can formulate valid rate equations in situations, where the spectral distribution of the radiation is wider than the spectral width of the atomic transition and where the spectral distribution of the light flux from the source, $\bar{I}(\omega)$, is weak compared to the saturation intensity of the atomic transition. Even if modern light sources generally have very narrow and intense spectral emission bands, Einstein's coefficients are often used in the spectroscopic literature to characterize the light-matter interaction with atoms and molecules.

The Einstein rate equations describe the energy flux between atoms and the optical modes of the cavity,

$$\begin{aligned} \frac{dN_1}{dt} = -\frac{dN_2}{dt} &= -R_{1\to 2} + R_{2\to 1} + \mathcal{S}_{2\to 1} \\ &= -N_1 B_{12} u(\omega) + N_2 B_{21} u(\omega) + N_2 A_{21} \ . \end{aligned} \tag{22.65}$$

$R_{1\to 2}$ is the *absorption rate*, $R_{2\to 1}$ the *stimulated emission rate* and $\mathcal{S}_{2\to 1}$ the *spontaneous emission rate*. The assumption of a third type of transition, called spontaneous emission, is necessary, if $B_{12} = B_{21}$ but $N_1 > N_2$ in thermal equilibrium. In thermal equilibrium we have the condition of stationarity, $\frac{dN_1}{dt} = -\frac{dN_2}{dt} = 0$ for a given energy density value $u(\omega) = u_{th}(\omega)$, such that,

$$u_{th}(\omega) = \frac{A_{21}}{\left(\frac{N_1}{N_2}\right) B_{12} - B_{21}} \ . \tag{22.66}$$

The *Boltzmann distribution law* controlling the distribution of the number of atoms in the lower and upper states is given by,

$$\frac{N_1}{N_2} = \frac{g_1}{g_2} e^{-(E_1 - E_2)/k_B T} \ , \tag{22.67}$$

where $g_{1,2}$ are the degeneracies of the lower and upper states and $E_2 - E_1 = \hbar\omega_0$. We find,

$$u_{th}(\omega) = \frac{A_{21}}{\frac{g_1}{g_2} e^{\hbar\omega_0/k_B T} B_{12} - B_{21}} \ . \tag{22.68}$$

But this result must be consistent with Planck's distribution (22.61). Therefore, by comparing this equation with the equation (22.68), it must be that,

$$\frac{g_1}{g_2}\frac{B_{12}}{B_{21}} = 1 \ . \tag{22.69}$$

and also,

$$\frac{A_{21}}{B_{21}} = \frac{\hbar\omega_0^3}{\pi^2 c^3} \ . \tag{22.70}$$

This equation shows that, once we know one of the three transition rates, we can always calculate the others.

It is useful to compare the rate A_{21} with B_{21} from the equation (22.68) inserting the equation (22.69),

$$\frac{A_{21}}{B_{21}u_{th}(\omega)} = e^{\hbar\omega_0/k_BT} - 1 \ . \tag{22.71}$$

This expression shows that, when $E_2 - E_1 \gg k_BT$, that is, for optical, UV, or X-ray frequencies, spontaneous emission dominates. But in low-frequency regimes, that is, IR, microwave, or radio waves, stimulated emission is more important. Note that even when stimulated emission dominates, spontaneous emission is always present and plays an important role, for example, in processes ultimately limiting the emission bandwidth of lasers.

22.2.6 Absorption spectrum for a single atom

Every light source has a certain spectral width. Conventional light sources, such as incandescent bulbs or plasmas have relatively broad emission bands compared to atomic or molecular absorbers, at least when the latter ones are studied in dilute gases. Even when we use pure spectral sources, such as a laser tuned to the peak of a resonance, the transition line always exhibits an intrinsic width associated with the interruption of the phase evolution of the excited state. Phase interruptions such as spontaneous or stimulated emission and collisions are common examples of line broadening mechanisms. The emission or absorption of radiation occurs within a frequency distribution centered about $\omega_0 \equiv \omega_2 - \omega_1$, and we must account for this spectral distribution in our calculation of the energy transfer.

On the other hand, as we will see in Sec. 34.1.3 and Sec. 34.5.1, spontaneous decay at a rate Γ of the excited level causes a finite linewidth for the atomic transition. Consequently, even perfectly monochromatic light will be absorbed according to a probability distribution given by the spectral absorption profile of the atomic transition. This profile is called the frequency-dependent *optical cross section* and reads [9],

$$\boxed{\sigma(\omega) = \frac{g_2}{g_1}\lambda^2\frac{\Gamma}{2\pi}\frac{\frac{1}{4}\Gamma}{(\omega-\omega_0)^2+\frac{1}{4}\Gamma^2} = \frac{g_2}{g_1}\lambda^2\frac{\Gamma}{4}\mathcal{L}_\Gamma(\omega-\omega_0)\ ,} \tag{22.72}$$

where we defined the Lorentzian profile as,

$$\mathcal{L}_\beta(\Delta) \equiv \frac{\beta}{2\pi}\frac{1}{\Delta^2+(\beta/2)^2} \qquad \text{with} \qquad \int_{-\infty}^{\infty}\mathcal{L}_\beta(\Delta)d\Delta = 1\ . \tag{22.73}$$

The total power P absorbed by a two-level atom with resonance frequency ω_0 from a radiation field with the spectral intensity distribution $I(\omega)$ and with the total intensity of the laser beam $\bar{I} = \int I(\omega)d\omega$ can now be expressed as the integral,

$$\boxed{P = \int \sigma(\omega)I(\omega)d\omega}\ , \tag{22.74}$$

[9] At low saturation.

Example 139 (*Limiting cases*): Let us analyze the two limiting cases when either one of the spectral distributions $I(\omega)$ or $\sigma(\omega)$ is much narrower than the other.
For a *narrow laser*, we may assume a δ-peaked spectral intensity distribution,

$$I(\omega) = \bar{I}\delta(\omega - \omega_L) \ . \tag{22.75}$$

When it drives a *broad transition* described by an optical cross section given by (22.72), the scattered power is,

$$P = \bar{I}\sigma(\omega_L) \ . \tag{22.76}$$

For a *narrow transition*, we may substitute the Lorentzian in (22.72) by a Dirac δ-function,

$$\sigma(\omega) \overset{\Gamma\to 0}{\longrightarrow} \frac{g_2}{g_1}\lambda^2\frac{\Gamma}{4}\delta(\Delta) \ . \tag{22.77}$$

When it is driven by a *broad laser*, for which we assume a spectral intensity distribution,

$$I(\omega) = \bar{I}\mathcal{L}_\beta(\omega - \omega_L) \qquad \text{with} \qquad \bar{I} = \int I(\omega)d\omega = \frac{I(\omega_L)}{\mathcal{L}_\beta(0)} = \frac{\pi\beta}{2}I(\omega_L) \tag{22.78}$$

we obtain for the scattered power,

$$P = \int \frac{g_2}{g_1}\lambda^2\frac{\Gamma}{4}\delta(\omega - \omega_0)\bar{I}\mathcal{L}_\beta(\omega - \omega_L)d\omega = \frac{g_2}{g_1}\lambda^2\frac{\Gamma}{4}\bar{I}\mathcal{L}_\beta(\omega_0 - \omega_L) \ . \tag{22.79}$$

22.2.6.1 Broad laser driving a broad transition

Until now we assumed a fixed laser frequency ω_L (with finite emission bandwidth) driving a fixed resonance frequency ω_0. What we call *absorption spectrum* is what we obtain when we tune either the laser frequency or when we (somehow) vary the resonance frequency, such that $\Delta \equiv \omega_L - \omega_0$ is ramped. Assuming Lorentzian profiles with finite linewidths for both, $\bar{I}$ and σ, we get,

$$\begin{aligned} P(\Delta) = P(\omega_L - \omega_0) &= \int \sigma(\omega)I(\omega)d\omega = \int \frac{g_2}{g_1}\frac{\lambda^2\Gamma}{4}\mathcal{L}_\Gamma(\omega - \omega_L)\bar{I}\mathcal{L}_\beta(\omega - \omega_0)d\omega \\ &= \frac{g_2}{g_1}\frac{\lambda^2\Gamma}{4}\bar{I}\int \mathcal{L}_\Gamma(\omega' + \omega_0 - \omega_L)\mathcal{L}_\beta(\omega')d\omega' \ . \end{aligned} \tag{22.80}$$

That is, the absorption spectrum is obtained as a convolution of both profiles,

$$\boxed{P(\Delta) = \frac{g_2}{g_1}\frac{\lambda^2\Gamma\bar{I}}{4}(\mathcal{L}_\Gamma \star \mathcal{L}_\beta)(\Delta)} \ . \tag{22.81}$$

This result reproduces the two limiting cases discussed in the above example, since for narrow transitions, $\Gamma \to 0$, that is $\mathcal{L}_\Gamma \to \delta$, we recover the results (22.79), and for narrow lasers, $\beta \to 0$, that is, $\mathcal{L}_\beta \to \delta$, we recover (22.76). Obviously, this formula holds for other line profiles e.g. when the resonance is broadened by some perturbations [10].

[10] Let us here remind the following identities holding for Lorentzian and Gaussian line profiles:

$$(\mathcal{L}_\gamma \star \mathcal{L}_\beta)(\Delta) = \mathcal{L}_{\gamma+\beta}(\Delta) \qquad \text{and} \qquad (\mathcal{G}_\Gamma \star \mathcal{G}_\beta)(\Delta) = \mathcal{G}_{\sqrt{\gamma^2+\beta^2}}(\Delta) \ .$$

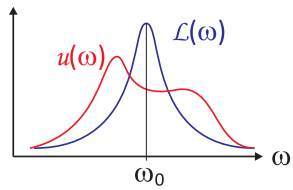

Figure 22.11: Absorption spectrum (blue) and spectral energy distribution of the source (red).

22.2.6.2 Two-level atom in a blackbody radiation field

When considering a two-level atom interacting with a blackbody a radiation field, we describe the spectral intensity distribution by (22.61),

$$I(\omega) = \frac{\omega^2}{\pi^2 c^2} \frac{\hbar\omega}{e^{\hbar\omega/k_B T} - 1} \tag{22.82}$$

$$\text{with} \qquad \bar{I} = \int I(\omega) d\omega = \frac{\hbar}{\pi^2 c^2} \left(\frac{k_B T}{\hbar}\right)^4 \int_0^\infty \frac{x^3 dx}{e^x - 1} = \frac{\pi^2}{15 c^2 \hbar^3} (k_B T)^4 \ .$$

Since the width of the transition is negligibly small in comparison with the blackbody spectrum, $\Gamma \to 0$, we may evaluate the scattered power as,

$$P = \int \frac{g_2}{g_1} \frac{\lambda^2 \Gamma}{4} \mathcal{L}_\Gamma(\omega - \omega_0) \frac{\omega^2}{\pi^2 c^2} \frac{\hbar\omega}{e^{\hbar\omega/k_B T} - 1} d\omega \tag{22.83}$$

$$\xrightarrow{\Gamma \to 0} \frac{g_2}{g_1} \frac{\lambda^2 \Gamma}{4} \frac{\omega_0^2}{\pi^2 c^2} \frac{\hbar\omega_0}{e^{\hbar\omega_0/k_B T} - 1} \ .$$

22.2.7 Absorption in a gas

We are often interested in the attenuation of the intensity of a beam of light traversing a dilute gas of resonant scattering atoms. The Einstein rate equation yields the *temporal* transition rates, but does not say how they relate to the *spatial* attenuation length of the light beam. Let us now generalize the previous results to a gas of two-level atoms. As long as the transition linewidth is narrow [case (22.77)], the power is removed from the system only by spontaneous emission; absorption only converts radiation into atomic excitation which, subsequently, can be returned to the radiation field by stimulated emission. At steady-state the Einstein rate equation (22.65) reads,

$$0 = -N_1 B_{12} u(\omega_0) + N_2 B_{21} u(\omega_0) + N_2 A_{21} \ . \tag{22.84}$$

Using the result (22.69), we can write the amount of power removed from the system by spontaneous emission as,

$$P = N_2 A_{21} \hbar\omega_0 = u(\omega_0) B_{12} (N_1 - \tfrac{g_1}{g_2} N_2) \hbar\omega_0 \ . \tag{22.85}$$

The second part of the equation describes the energy loss of the beam, i.e. the difference between energy removed by absorption and energy returned to the beam by stimulated emission.

On the other hand, the power absorbed from the radiation field $u(\omega_0)$ by atoms whose transition is described by the cross section (22.72), is given by,

$$P = \int (N_1 - \tfrac{g_1}{g_2} N_2)\sigma(\omega) I(\omega) d\omega \ . \tag{22.86}$$

Remembering $I(\omega) = cu(\omega)$ and assuming a *large radiation spectrum*, $I(\omega) \simeq I(\omega_0)$, a comparison of equations (22.85) and (22.86) yields,

$$\boxed{B_{12} = \frac{c}{\hbar\omega_0} \int \sigma(\omega) d\omega} \ . \tag{22.87}$$

22.2.7.1 Lambert-Beer law

In the expression (22.86) the absorption probability distribution $\sigma(\omega)$ is convoluted with the spectral energy distribution of the light source, $u(\omega) = d\bar{u}/d\omega$, which in turn is related to the energy *density* via, $\bar{U} = V\bar{u}$, where V is the mode volume of the light field. Considering a thin slab of the absorber with volume ΔV, we have $d\bar{U} = \Delta V d\bar{u}$. Assuming that the light propagates in z-direction across the absorber and converting the time dependence into a spatial dependence, we have on one hand,

$$P = -\frac{d\bar{U}}{dt} = -\frac{d\bar{u}}{dt}\Delta V = -c\frac{d\bar{u}}{dz}\Delta V = -\frac{d\bar{I}}{dz}\Delta V \ . \tag{22.88}$$

On the other hand, assuming that the light field be a *laser with narrow emission bandwidth*, $I(\omega) = \bar{I}\delta(\omega - \omega_L)$, we get from (22.86),

$$P = \int (N_1 - \tfrac{g_1}{g_2} N_2)\sigma(\omega) I(\omega) d\omega = \bar{I}(N_1 - \tfrac{g_1}{g_2} N_2)\sigma(\omega_L) \ , \tag{22.89}$$

Now comparing both results,

$$\frac{d\bar{I}}{\bar{I}} = -\frac{N_1 - \frac{g_1}{g_2} N_2}{\Delta V}\sigma(\omega_L) dz \simeq -n\sigma(\omega_L) dz \ , \tag{22.90}$$

where the approximation holds for low saturation, that it, if $N_1 \gg N_2$. The solution of this differential equation is,

$$\boxed{\bar{I} = \bar{I}_0 e^{-\sigma(\omega_L) n z}} \ . \tag{22.91}$$

Here, z is the total distance, over which absorption takes place. The last equation is the *Lambert-Beer law* for light absorption. It is very useful for measuring atomic densities in gas cells or of atomic beams [860, 816, 1364]. Solve the Excs. 22.2.10.9 to 22.2.10.11.

22.2.8 Saturation

Strong driving of a transition leads to its saturation and causes line broadening. To see this, we go back to Einstein's rate equations in steady-state (22.65) additionally

simplified by assuming $g_1 = 1 = g_2$, such that $B_{12} = B_{21}$. Resolving these equations by N_1 and N_2 and using $N_1 + N_2 = N$ and $N_1 - N_2 \equiv \Delta N$, we get,

$$N_1 = N\frac{B_{21}u(\omega) + A_{21}}{2B_{21}u(\omega) + A_{21}} \qquad \text{and} \qquad N_2 = N\frac{B_{12}u(\omega)}{2B_{21}u(\omega) + A_{21}} \ . \tag{22.92}$$

For vanishing pump rate we expect, $N_1 \overset{u\to 0}{\longrightarrow} N$ and $N_2 \overset{u\to 0}{\longrightarrow} 0$. In contrast, when the pump rate becomes much larger than the relaxation rates, $N_1, N_2 \overset{u\to\infty}{\longrightarrow} \frac{1}{2}$. This means that the absorption coefficient $\alpha = \sigma(N_1 - N_2)$ goes to zero, and the medium becomes completely transparent. The difference in the populations of the ground and excited states,

$$\Delta N = N\frac{A_{21}}{2B_{21}u(\omega) + A_{21}} = \frac{N}{1 + s(\omega)} \ , \tag{22.93}$$

can be expressed via a *saturation parameter*

$$s(\omega) \equiv \frac{2B_{12}u(\omega)}{A_{21}} \ , \tag{22.94}$$

which represents the ratio of pump rate to the relaxation rate. The pump rate due to a monochromatic wave with intensity $\bar{I}$ is obtained by comparing (22.85) with (22.89),

$$B_{12}u(\omega) = \frac{\sigma(\omega)\bar{I}}{\hbar\omega} \ . \tag{22.95}$$

We obtain for the saturation parameter,

$$s(\omega) = \frac{2\sigma(\omega)\bar{I}}{\hbar\omega A_{21}} \ . \tag{22.96}$$

According to (22.85) and (22.93) the power absorbed per unit volume on the transition by atoms with the populations $N_{1,2}$ in a radiation field with a broad spectral profile and spectral energy density $u(\omega)$ is,

$$P = \hbar\omega B_{12}u(\omega)\Delta N = \hbar\omega B_{12}u(\omega)\frac{N}{1 + s(\omega)} \ . \tag{22.97}$$

With (22.94) this can be written as,

$$P = \hbar\omega\frac{A_{21}}{2}\frac{N}{1 + s(\omega)^{-1}} \ . \tag{22.98}$$

Let us now remember that the absorption cross section (22.72) of a homogeneously broadened line is Lorentzian. This means that the saturation parameter (22.96) itself becomes Lorentzian. We can assume that the relaxation rate A_{21} is independent of ω within the frequency range of the line profile,

$$\boxed{s(\omega) = s(\omega_0)\frac{(\Gamma/2)^2}{\Delta^2 + (\Gamma/2)^2}} \ . \tag{22.99}$$

Substituting this into (22.98) yields the frequency dependence of the absorbed radiation power per unit frequency interval $d\omega$,

$$P = \hbar\omega \frac{A_{21}N}{2} \frac{s(\omega_0)(\Gamma/2)^2}{(\omega-\omega_0)^2 + (\Gamma/2)^2[1+s(\omega_0)]} = N\bar{I}\sigma(\omega_0)\frac{(\Gamma/2)^2}{\Delta^2 + (\gamma_s/2)^2} \ , \tag{22.100}$$

where we introduced the increased halfwidth of the Lorentzian profile,

$$\boxed{\gamma_s \equiv \Gamma\sqrt{1+s(\omega_0)}} \ . \tag{22.101}$$

Apparently, the halfwidth of the saturation-broadened line increases with the resonant saturation parameter $s(\omega_0)$. If according to (22.94) the induced transition rate at resonance equals the total relaxation rate $A_{21}/2$, the resonant saturation parameter becomes $s(\omega_0) = 1$, which increases the linewidth by a factor $\sqrt{2}$, compared to the unsaturated linewidth Γ for weak radiation fields. Starting from (22.100) we can define a *saturated* absorption cross section,

$$\boxed{\sigma_s(\omega) = \sigma_s(\omega_0)\frac{(\gamma_s/2)^2}{\Delta^2 + (\gamma_s/2)^2} = \sigma(\omega_0)\frac{(\Gamma/2)^2}{\Delta^2 + (\gamma_s/2)^2} = \sigma(\omega)\frac{1}{1+s(\omega)}} \ , \tag{22.102}$$

where the unsaturated absorption profile is,

$$\sigma(\omega) = \sigma(\omega_0)\frac{(\Gamma/2)^2}{\Delta^2 + (\Gamma/2)^2} \ . \tag{22.103}$$

This shows that the saturation decreases the absorption coefficient by the factor $1 + s(\omega)$. At the line center, this factor has its maximum value $1 + s(\omega_0)$, while it decreases to 1 for increasing $|\Delta|$, see (22.101), see Fig. 22.12. This is the reason why the line broadens.

From (22.96) we see, that unity saturation, $s(\omega_0) = 1$, corresponds to a light intensity of,

$$\bar{I}_{sat} \equiv \frac{\hbar\omega}{2\sigma(\omega_0)}\Gamma = \frac{2\pi^2 c\hbar}{3\lambda^3}\Gamma \ . \tag{22.104}$$

This intensity is called *saturation intensity*. Taking account of the degeneracies g_j of the levels the saturation intensity becomes [11],

$$\boxed{I_{sat} = \frac{g_1}{g_2}\frac{2\pi^2 c\hbar}{3\lambda_0^3}\Gamma} \ . \tag{22.105}$$

Finally, we anticipate that the resonant saturation parameter is basically a measure for the ratio between the stimulated population transfer rate, given by a quantity called *Rabi frequency* Ω, which will be thoroughly introduced in Secs. 27.4.3 and 34.4.2, and the spontaneous decay rate Γ,

$$s(\omega_0) = \frac{2\Omega^2}{\Gamma^2} \ . \tag{22.106}$$

We thus obtain the important relationship between laser intensity and Rabi frequency,

$$\boxed{\Omega^2 = \sigma(\omega_0)\frac{\bar{I}}{\hbar\omega_0}\Gamma} \ . \tag{22.107}$$

[11] Some authors define the saturation for $s = 2$, as happens when $\Omega = \Gamma$.

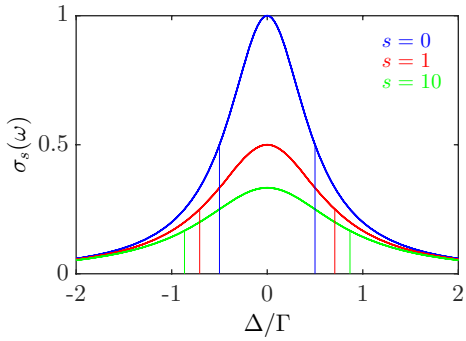

Figure 22.12: (code) Optical cross section for absorption at various saturation parameters. The reduction of absorption is understood by considerable depletion of the ground state at the profit of the excited state, $N_1, N_2 \overset{s\to\infty}{\longrightarrow} \frac{1}{2}$, in which case absorption is totally compensated by stimulated emission.

22.2.9 Specific heat of solids

The *Debye model* applies Planck's law on the distribution of energy in electromagnetic radiation, which treats radiation as a gas of *photons*, to the energy distribution of atomic vibrations in a solid, treating them as a gas of *phonons* in a box (the box being the solid). Most of the steps of the calculation are identical, as both are examples of a massless bosonic gas with linear dispersion relation.

According to the equipartition theorem, every atom has 3 degrees of freedom due to its translational motion. Thus, in a crystal lattice with N atoms, we expect the total energy $E = 3Nk_BT$ and the *specific heat* should be, following the *Dulong-Petit law*,

$$C_V = \left(\frac{\partial E}{\partial T}\right)_V = 3Nk_B \ , \tag{22.108}$$

for all solids regardless of temperature.

It was observed, however, that the specific heat of solids decreases like $C_V \propto T^3$ as T approaches zero. It was Einstein's idea to apply Planck's formula by treating the N atoms as three-dimensional harmonic oscillators vibrating in a lattice. The discrete energies $n\hbar\omega$ are identified with quasi-particles called *phonons*. The quantum nature of atoms does not matter, they just provide the medium supporting the phonons. Following the Bose-Einstein statistics, we must replace,

$$k_BT \to \hbar\omega/(e^{\hbar\omega/k_BT} - 1) \ , \tag{22.109}$$

such that the derivative of the energy,

$$C_V = \left(\frac{\partial}{\partial T}\frac{3Nk_B\hbar\omega}{e^{\hbar\omega/k_BT} - 1}\right)_V = 3Nk_B\left(\frac{\hbar\omega}{k_BT}\right)^2\frac{e^{\hbar\omega/k_BT}}{(e^{\hbar\omega/k_BT} - 1)^2} \ , \tag{22.110}$$

gives the specific heat. The disappearance of the specific heat at low temperatures,

$$C_V \simeq \frac{3N(\hbar\omega)^2}{k_BT^2}e^{-\hbar\omega/(k_BT)} \ , \tag{22.111}$$

which is related to the finite localization energy of harmonic oscillators, does not describe experimental observations very well, and the model had to be refined by Debye, later on.

22.2.9.1 Debye model for the specific heat

While Einstein assumed monochromatic lattice vibrations, Debye's approach was to allow a *spectrum* of vibrational frequencies. With the density of states,

$$\rho(\nu)d\nu = (4\pi V v^3)\nu^2 d\nu \ , \tag{22.112}$$

where v is the velocity of sound propagation, the formula is totally equivalent to the density-of-states for photons in a cavity. Assuming that there is an upper bound ν_m for the vibrational frequencies, we normalize as $3N_0 = \int_0^{\nu_m} \rho(\nu)d\nu$. The energy now is [12],

$$E = \int_0^{\nu_m} \frac{\hbar\omega}{e^{\hbar\omega/k_B T} - 1} \frac{4\pi V}{v^3} \nu d\nu = 9Nk_B \frac{T^4}{\theta^3} \int_0^{\theta/T} \frac{x^3 dx}{e^x - 1} \ . \tag{22.113}$$

The *Debye temperature* $\theta = h\nu_m/k_B$ is characteristic for the metal. The derivative is then,

$$C_V = 9Nk_B \left[4\left(\frac{T}{\theta}\right)^3 \int_0^{\theta/T} \frac{x^3 dx}{e^x - 1} - \frac{\theta}{T} \frac{1}{e^{\theta/T} - 1} \right] \ . \tag{22.114}$$

At low temperatures this formula reproduces the *Debye law*,

$$C_V = \frac{12\pi^4}{5} Nk_B \left(T/\theta\right)^3 \ . \tag{22.115}$$

22.2.10 Exercises

22.2.10.1 Ex: Resistance of vacuum

Show that $\sqrt{\mu_0/\varepsilon_0}$ has the dimension of a resistance and the value of $376.7\,\Omega$.

Solution: *Using the expressions* $\nabla \cdot \vec{\mathcal{E}} = \varrho/\varepsilon_0$, $\int \vec{\mathcal{E}} \cdot d\mathbf{l} = U$, $\dot{Q} = I$, *and* $U = RI$, *dimensional considerations yield,*

$$\left[\sqrt{\frac{\mu_0}{\varepsilon_0}}\right] = \left[\frac{1}{\varepsilon_0 c}\right] = \left[\frac{|\vec{\mathcal{E}}|}{l\varrho c}\right] = \left[\frac{Ul^3}{Ql^2 c}\right] = \left[\frac{U}{I}\right] = [R] = \Omega \ .$$

$\varepsilon_0 = 8.8542 \cdot 10^{12}\,\mathrm{As/Vm}$ *and* $\mu_0 = 4\pi \cdot 10^{-7}\,\mathrm{Vs/Am}$.

[12] The fact that the electron gas also has a heat capacity is neglected.

22.2.10.2 Ex: The laws of Planck and Rayleigh-Jeans

Show that Planck's law reproduces the Rayleigh-Jeans law in the low-frequency limit.

Solution: *Taylor Expansion of Planck's law:*

$$u_\omega^{Pl} = \frac{\omega^2}{\pi^2 c^3}\frac{\hbar\omega}{e^{\hbar\omega/k_B T}-1} = \frac{\omega^2}{\pi^2 c^3}\frac{\hbar\omega}{(1+\hbar\omega/k_B T+...)-1} \simeq \frac{\omega^2}{\pi^2 c^3}k_B T \ .$$

22.2.10.3 Ex: The laws of Wien and Stefan-Boltzmann

a. Derive the parametrization of Planck's law in terms of frequency ν and wavelength λ.
b. Derive the law of *Stefan-Boltzmann* according to which the total power radiated per unit surface area of a black body across all wavelengths (also known as the black-body radiant emittance) is given by σT^4, where $\sigma \equiv \pi^2 k_B^4/60c^2\hbar^3$ is called the Stefan-Boltzmann constant.
c. Derive *Wien's displacement law* according to which the maximum emission of a blackbody spectrum occurs at $\lambda_{\max} T = 2.898\times10^{-3}\,\mathrm{Km}$ in the wavelength parametrization and $\nu_{\max}/T = 0.0588\,\mathrm{THz/K}$ in the frequency parametrization. Determine the frequency of the maximum emission for the 2.7 K background radiation of the universe.

Solution: *a. The spectral energy density of a blackbody according to Planck's law is in the various parametrizations,*

$$\begin{aligned} u_{Pl}(\omega)d\omega &= \frac{\omega^2}{\pi^2 c^3}\frac{\hbar\omega}{e^{\beta\hbar\omega}-1}d\omega \\ = u_{Pl}(\nu)d\nu &= \frac{8\pi h\nu^3}{c^3}\frac{1}{e^{\beta h\nu}-1}d\nu \\ = u_{Pl}(\lambda)d\lambda &= \frac{8\pi ch}{\lambda^5}\frac{1}{e^{\beta hc/\lambda}-1}d\lambda \end{aligned}$$

b. The intensity of the light emitted from the blackbody surface is given by,

$$L_{Pl}(\omega) = \frac{c}{4\pi}u_{Pl}(\omega) = \frac{2h\nu^3}{c^2}\frac{1}{e^{\beta\hbar\omega}-1} \ .$$

The power emitted per unit area of the emitting body is,

$$\begin{aligned} \frac{P}{A} &= \int_{half\ sphere}\cos\theta d\Omega\int_0^\infty L_{Pl}(\nu)d\nu = \int_0^{2\pi}\int_0^{\pi/2}\cos\theta\sin\theta d\theta d\phi\int_0^\infty \frac{2h\nu^3}{c^2}\frac{1}{e^{\beta\hbar\omega}-1}d\nu \\ &= \pi\int_0^\infty \frac{2h}{c^2}\frac{1}{(\beta h)^4}\frac{x^3}{e^x-1}dx = \pi\frac{2h}{c^2}\frac{1}{(\beta h)^4}\frac{\pi^4}{15} = \frac{\pi^2 k_B^4}{60\hbar^3 c^2}T^4 \equiv \sigma T^4 \ . \end{aligned}$$

c. The spectral radiance in wavelength parametrization is

$$L_{Pl}(\lambda)d\lambda = \frac{c}{4\pi}u_{Pl}(\lambda)d\lambda = \frac{2c^2 h}{\lambda^5}\frac{1}{e^{\beta hc/\lambda}-1}d\lambda \ .$$

The peak follows from,

$$0 = \frac{\partial L(\lambda)}{\partial \lambda} = 2c^2 h \frac{-5\lambda e^{\beta h \frac{c}{\lambda}} + 5\lambda + ch\beta e^{\beta h \frac{c}{\lambda}}}{\lambda^7 \left(e^{\beta h \frac{c}{\lambda}} - 1\right)^2} \ .$$

Defining $x \equiv \beta h \frac{c}{\lambda}$ *we find the condition,*

$$0 = (x-5)e^x + 5$$

with the numerical solution $x = 4.965....$ *Hence,*

$$\lambda_{peak} = \frac{hc}{xk_B} \frac{1}{T} \ .$$

For $2.7\,\mathrm{K}$ *we expect* $\lambda_{peak} = 966\,\mu\mathrm{m}$*, or* $\nu_{peak} = 310\,\mathrm{GHz}$*.*
The spectral radiance in frequency parametrization is,

$$L(\nu)d\nu = \frac{c}{4\pi} u_{Pl}(\nu)d\nu = \frac{2h\nu^3}{c^2} \frac{1}{e^{\beta h\nu} - 1} d\nu \ .$$

The peak follows from,

$$0 = \frac{\partial L(\nu)}{\partial \nu} = 2h\nu^2 \frac{3e^{\beta h\nu} - 3 - \nu\beta h e^{\beta h\nu}}{c^2 \left(e^{\beta h\nu} - 1\right)^2} \ .$$

Defining $x \equiv \beta h\nu$ *we find the condition,*

$$0 = (x-3)e^x + 3$$

with the numerical solution $x = 4.965....$ *Hence,*

$$\nu_{peak} = \frac{xk_B}{h} T \ .$$

For $2.7\,\mathrm{K}$ *we expect* $\nu_{peak} = 280\,\mathrm{GHz}$*.*

22.2.10.4 Ex: Radiometric thermometry

Modern radiometric thermometers measure the blackbody radiation emitted by a hot body. Calculate the variation of the blackbody radiant emittance of a person having fever (40° instead of 37° body temperature). How much does the maximum emission wavelength change? In which spectral range should the thermometer be sensitive?

Solution: *The Stefan-Boltzmann law reads,*

$$\frac{P}{A} = \sigma T^4 \qquad with \qquad \sigma = \frac{\pi^2 k_B^4}{60c^2\hbar^3} \approx 5.67 \cdot 10^{-8} \frac{\mathrm{W}}{\mathrm{m^2 K^4}} \ .$$

Hence, around $T = (273 + 37)\,\mathrm{K}$ *and with* $\Delta T = 3\,\mathrm{K}$*,*

$$\frac{\Delta(P/A)}{P/A} = \frac{4\sigma T^3 \Delta T}{\sigma T^4} = \frac{4\Delta T}{T} \approx 0.0387 \ .$$

Wien's law reads,

$$\lambda_{max} T = C_{Wien} \qquad with \qquad C_{Wien} \approx 2.898 \cdot 10^{-3}\,\mathrm{Km} \ .$$

Hence, around $T = (273 + 37)\,\mathrm{K}$,

$$\lambda_{max} = \frac{C_{Wien}}{T} \approx 9.348\,\mu\mathrm{m} \ ,$$

and with $\Delta T = 3\,\mathrm{K}$,

$$\frac{\Delta\lambda_{max}}{\lambda_{max}} = -\frac{\Delta T}{T} \approx 0.0097 \ .$$

The thermometer should be sensitive in the infrared range around $10\,\mu\mathrm{m}$.

22.2.10.5 Ex: Photons in a resonator

a. The light power emitted by a laser ($\lambda = 633\,\mathrm{nm}$) be $P = 1\,\mathrm{nW}$. How many photons does the laser emit per second? How many photons of the emitted laser beam are in a mode volume of $L = 10\,\mathrm{cm}$ length?
b. How many photons on average are inside an optical cavity having the same mode volume at ambient temperature, when there is no incident light?

Solution: *a. The number of emitted photons per second is,*

$$\# = \frac{P}{h\nu} = \frac{\lambda P}{hc} \approx 3.2 \cdot 10^{9}\,\mathrm{s^{-1}} \ .$$

Using the expressions $I = 2P/\pi w^2$ *and* $V_m = \frac{\pi}{2} w^2 L$, *we get for the number of photons in the mode,*

$$n = \frac{E}{\hbar\omega} = \frac{uV_m}{\hbar\omega} = \frac{IV_m}{c\hbar\omega} = \frac{2P}{\pi w^2}\,\frac{V_m}{c\hbar\omega} = \frac{LP}{c\hbar\omega} = 1.06 \ photons \ .$$

b. The back-body radiation puts

$$\bar{n} = \frac{1}{e^{\hbar\omega/k_B T} - 1} = 10^{-33} \ photons$$

into the mode volume.

22.2.10.6 Ex: Number of modes in a cavity

a. How many modes do fit into a cubical box of $10\,\mathrm{cm}$ size for a frequency interval of $1000\,\mathrm{Hz}$ centered at a wavelength of $500\,\mathrm{nm}$?
b. How many photons are in the box supposing it has a temperature of $T = 300\,\mathrm{K}$, respectively, $T = 6000\,\mathrm{K}$?

Solution: *a. From Eq. (22.51) we get the total number of modes with frequencies between 0 and* ν,

$$N = \frac{\omega^3}{3\pi^2 c^3} L^3 = \frac{8\pi\nu^3}{3c^3} L^3 \ .$$

Hence, for the given range,

$$N = L^3 \int_{\nu-\Delta\nu/2}^{\nu+\Delta\nu/2} \varrho(\nu)d\nu = L^3 \int_{\nu-\Delta\nu/2}^{\nu+\Delta\nu/2} \frac{8\pi\nu^2}{c^3}d\nu$$
$$= \frac{8\pi L^3}{3c^3}\left[(\nu+\Delta\nu/2)^3 - (\nu-\Delta\nu/2)^3\right] \simeq \frac{8\pi L^3}{3c^3}6\nu^2\frac{\Delta\nu}{2} = \frac{8\pi L^3}{c\lambda^2}\Delta\nu = 335100 \ .$$

b. The number of photons follows from the spectral energy density Eq. (22.61),

$$N_{ph} = L^3 \int_{\nu-\Delta\nu/2}^{\nu+\Delta\nu/2} \frac{u(\nu)}{h\nu}d\nu = L^3 \int_{\nu-\Delta\nu/2}^{\nu+\Delta\nu/2} \varrho(\nu)\frac{h\nu}{e^{\beta h\nu}-1}d\nu$$
$$= L^3 \int_{\nu-\Delta\nu/2}^{\nu+\Delta\nu/2} \frac{4\nu^2}{c^3}\frac{1}{e^{\beta h\nu}-1}d\nu \simeq \frac{4L^3}{c\lambda^2}\Delta\nu\frac{1}{e^{\beta h\nu}-1} \ .$$

For $T = 300\,\mathrm{K}$ we expect only $4.6 \cdot 10^{-36}$ photons, but for $T = 6000\,\mathrm{K}$ we expect $1.8 \cdot 10^4$ photons. Integrated over all frequencies we would have,

$$N_{ph} = L^3 \int \frac{4\nu^2}{c^3}\frac{1}{e^{\beta h\nu}-1}d\nu = L^3\frac{1}{(\beta h)^3}\frac{4}{c^3}\int_0^\infty \frac{x^2}{e^x-1}dx = \left(\frac{2Lk_BT}{ch}\right)^3 \zeta(3) \ ,$$

hence $N_{ph} \approx 8.7 \cdot 10^{10}$ photons at $300\,\mathrm{K}$ and $N_{ph} \approx 7 \cdot 10^{14}$ photons at $6000\,\mathrm{K}$.

22.2.10.7 Ex: Number of photons emitted from lasers and blackbodies

a. Calculate the total number of photons per area per unit time emitted by a blackbody at temperature T.
b. The linewidth of a helium-neon laser is $\Delta\nu = 1000\,\mathrm{Hz}$. The operating wavelength is $\lambda = 632.8\,\mathrm{nm}$, the power is $P = 1\,\mathrm{mW}$, and the beam size $w_0 = 1\,\mathrm{mm}$. How many photons are emitted per second?
c. What would be the temperature of a blackbody radiator emitting the same number of photons from an equal area and over the same frequency interval as the laser?

Solution: *a. According to Wien's law the total radiance is,*

$$I = \sigma T^4 = \frac{2\pi^5 k_B^4}{15c^2h^3}T^4 \ .$$

The total number of photons per area per unit time is,

$$\frac{\partial N}{\partial A\partial t} = \int \frac{I_\nu}{h\nu}d\nu = \int_0^\infty \frac{2\pi\nu^2}{c^2}\frac{1}{e^{\beta h\nu}-1}d\nu$$
$$= \frac{2\pi}{c^2(\beta h)^3}\int_0^\infty \frac{x^2}{e^x-1}dx = \frac{2\pi(k_BT)^3}{c^2h^3}2\zeta(3) \ .$$

with $\zeta(3) = 1.202$.
b. The photon flux for the HeNe laser is,

$$\frac{\partial N_{HeNe}}{\partial t} = \frac{P}{h\nu} \approx 3.2 \cdot 10^{15}\,\mathrm{s^{-1}} \ .$$

c. The photon flux from the blackbody within the specified bandwidth is ($I_\nu = \frac{c}{4\pi} u_\nu$),

$$\frac{\partial N}{\partial A \partial t} = \int_\nu^{\nu+\Delta\nu} \frac{I_\nu}{h\nu} d\nu \simeq \frac{I_\nu}{h\nu}\Delta\nu = \frac{2}{\lambda^2}\frac{\Delta\nu}{e^{\beta h\nu}-1}$$
$$\Longrightarrow \frac{\partial N}{\partial t} = \frac{2}{\lambda^2}\frac{\Delta\nu}{e^{\beta h\nu}-1}\pi w_0^2 \ .$$

Hence,

$$T = \frac{h\nu/k_B}{\ln\left(1+\frac{2\pi w_0^2}{\lambda^2}\frac{\Delta\nu}{\partial_t N_{HeNe}}\right)} \approx 4.6\cdot 10^9\,\mathrm{K} \ .$$

22.2.10.8 Ex: Number of photons per radiation mode

Assume the isotropic emission of a pulsed flashlamp with spectral bandwidth $\Delta\lambda = 100\,\mathrm{nm}$ around $\lambda = 400\,\mathrm{nm}$ amounts to $P_0 = 100\,\mathrm{W}$ peak power out of a volume of $1\,\mathrm{cm}^3$. Calculate the spectral power density $u(\nu)$ and the spectral intensity $I(\nu)$ through a spherical surface $r = 2\,\mathrm{cm}$ away from the center of the emitting sphere. How many photons per mode are contained in the radiation field?

Solution: *The total intensity is,*

$$I = \frac{P_0}{4\pi r^2} \approx 2\cdot 10^4\,\mathrm{W/m^2} \ .$$

The spectral intensity is,

$$I(\nu) = \frac{I}{|\Delta\nu|} = \frac{I}{(c/\lambda^2)\Delta\lambda} \approx 1.1\cdot 10^{-10}\,\mathrm{J/m^2} \ ,$$

the spectral power density is,

$$u(\nu) = \frac{I(\nu)}{c} = 3.6\cdot 10^{-19}\,\mathrm{Js/m^2} \ ,$$

and the spectral mode density is,

$$\varrho(\nu) = \frac{8\pi\nu^2}{c^3} \ .$$

Within the volume of the sphere with radius r there are

$$N = \varrho(\nu)V\Delta\nu = \varrho(\nu)\tfrac{4}{3}\pi r^3\Delta\nu \approx 3\cdot 10^{15}$$

modes. The energy per mode is

$$W_m = \frac{u(\nu)V\Delta\nu}{N} \approx 7\cdot 10^{-25}\,\mathrm{J/mode} \ .$$

With the energy of a photon at λ *of* $E = h\nu = hc/\lambda \approx 3.1\,\mathrm{eV}$, *the average number of photons per mode is,*

$$n_{ph} = \frac{W_m}{h\nu} = \frac{u(\nu)}{\varrho(\nu)} = \approx 1.5\cdot 10^{-6} \ .$$

The average number of photons per mode is therefore very small.

22.2.10.9 Ex: Atoms in an optical cavity

a. Consider a closed optical cavity at $T = 600^\circ$ C. The cavity has the shape of a $L = 1$ m-long and $d = 3$ cm-diameter tube. Calculate the total energy of the black-body radiation inside the cavity.
b. Inside the cavity there is a gas with strontium atoms (1 fundamental level and 3 degenerate excited levels, $\lambda = 461$ nm). Using the expression (22.67), assuming thermal equilibrium, calculate the number of excited atoms for a partial pressure of the strontium gas of 10^{-3} mbar.
c. Calculate the optical density for a laser in resonance with the transition traversing the cavity along the symmetry axis.

Solution: *a. Following Planck's law the spectral energy density is,*

$$u_P(\omega) = \frac{\omega^2}{\pi^2 c^3} \frac{\hbar\omega}{e^{\hbar\omega/k_B T - 1}} \ .$$

The energy density is,

$$\begin{aligned} \bar{u}_P &= \int_0^\infty u_E^{Pl}(\omega) d\omega = \frac{k_B T}{\pi^2 c^3} \left(\frac{k_B T}{\hbar}\right)^3 \int_0^\infty \frac{x^3}{e^x - 1} dx \\ &= \frac{k_B T}{\pi^2 c^3} \left(\frac{k_B T}{\hbar}\right)^3 \frac{\pi^4}{15} = \frac{\pi^2}{15\hbar^3 c^3} (k_B T)^4 = \tfrac{4}{c}\sigma T^4 = 4.3 \cdot 10^{-4}\,\mathrm{J/m^3} \ , \end{aligned}$$

where $\sigma = 5.67 \cdot 10^{-8}\,\mathrm{W/m^2\ K^4}$ is the Stefan-Boltzmann constant. With the cavity volume $V = \pi L d^2/4$ the energy is,

$$\bar{u}_P V = 3 \cdot 10^{-7}\,\mathrm{J} \ .$$

b. In equilibrium the Einstein rate equation gives,

$$\frac{N_1}{N_2} = \frac{g_1}{g_2} e^{-(E_1 - E_2)/k_B T} \ .$$

Hence,

$$\frac{N_2}{N} = \frac{1}{N_1/N_2 + 1} = \frac{1}{\frac{g_1}{g_2} e^{-(E_1 - E_2)/k_B T} - 1} = 9.9 \cdot 10^{-16} \ .$$

At the pressure $p = 10^{-1}$ Pa, the total number of atoms is $N = \frac{pV}{k_B T} \simeq 5.8 \cdot 10^{15}$. Therefore, we expect $N = 57$ atoms.
c. With the density of the strontium gas $n = N/V \simeq 8.3 \cdot 10^{13}$ cm^{-3}, we obtain for optical density,

$$b_0 = \sigma_0 n L = \frac{g_2}{g_1} \frac{\lambda^2}{2\pi} n L \simeq 8.4 \cdot 10^5 \ .$$

22.2.10.10 Ex: Sodium atoms in an optical cavity

A sodium atom is placed in a cavity of volume $V = 1\,\mathrm{cm}^3$ with walls at the temperature T, producing a thermal radiation field with spectral energy density $u_P(\nu)$. At what temperature T are the spontaneous and induced transition probabilities equal
a. for the transition $3P \to 3S$ with the transition wavelength $\lambda = 589\,\mathrm{nm}$ and the excited state lifetime $\tau_{3P} = 16\,\mathrm{ns}$;
b. for the hyperfine transition $3S$ $(F = 3 \to F = 2)$ with the transition frequency $\nu = 1772\,\mathrm{MHz}$ and the excited state lifetime $\tau_{3F} \simeq 1\,\mathrm{s}$?

Solution: *Induced and spontaneous transition probabilities are equal when the radiation field contains one photon per mode. This means:*

$$\bar{n} = \frac{1}{e^{h\nu/k_B T} - 1} = 1 \ ,$$

hence $e^{h\nu/k_B T} = 2$ *and hence,*

$$T = \frac{hc}{\lambda k \ln 2} \ .$$

a. For $\lambda = 589\,\mathrm{nm}$ *we obtain for a thermal radiation field* $T = 35300\,\mathrm{K}$. *If a laser beam is sent through the cavity, the condition* $B_{ik}\rho = A_{ik}$ *can be fulfilled at modest laser intensities. This can be estimated as follows: The number of modes in the cavity within the frequency interval* $\Delta\nu = [2\pi\tau_{3P}]^{-1} \approx 10\,\mathrm{MHz}$, *which is the natural linewidth of the* $3P \to 3S$ *transition of Na, is,*

$$\varrho(\nu)\Delta\nu = \frac{8\pi}{c\lambda^2}\Delta\nu \approx 2.4 \cdot 10^6\,\mathrm{cm}^{-3} \ .$$

The energy of a photon at the transition wavelength is $h\nu$. *With 1 photon per mode, the radiation density in the cavity is,*

$$\bar{u} = \varrho_\nu h\nu\Delta\nu \approx 8 \cdot 10^{-8}\,\mathrm{J/cm}^{-13} \ .$$

The intensity of a laser beam with a spectral width equal to $\Delta\nu$ *is then inside the cavity* $I = c\bar{u} \approx 24\,\mathrm{mW/cm}^2$.
b. For $\nu = 1.772\,\mathrm{MHz}$ *we obtain* $T = 0.12\,\mathrm{K}$. *The energy density* $\bar{u}$ *of the thermal field within the natural linewidth* $\Delta\nu = [2\pi\tau_{3F}]^{-1} \approx 0.16\,\mathrm{s}^{-1}$ *is,*

$$\bar{u} = u_\nu\Delta\nu = \varrho_\nu h\nu\Delta\nu = \frac{8\pi\nu^2}{c^3}h\nu\Delta\nu \ .$$

With this we get, $\bar{u} = 5 \cdot 10^{-37}\,\mathrm{Ws/cm}^3$, *which is 24 orders of magnitude smaller than the visible radiation in (a).*

22.2.10.11 Ex: Applying the Lambert-Beer law

The beam of a monochromatic laser passes through an absorbing atomic vapor with path length $L = 5\,\mathrm{cm}$. If the laser frequency is tuned to the center of an absorbing transition $|i\rangle \to |k\rangle$ with absorption cross section $\sigma_0 = 10^{-14}\,\mathrm{cm}^2$, the attenuation

of the transmitted intensity is 10%. Assuming low saturation calculate the atomic density n_i in the absorbing level $|i\rangle$.

Solution: *The transmitted intensity is,*

$$I = I_0 e^{-\alpha L} = 0.9 I_0 \ .$$

Hence, $\alpha L = 0.1$. *With* $L = 5\,\mathrm{cm}$ *we expect* $\alpha = 0.02\,\mathrm{cm}^{-1}$. *Now with* $\alpha = n_i \sigma$,

$$n_i = \frac{\alpha}{\sigma} = 2 \cdot 10^{12}\,\mathrm{cm}^{-3} \ .$$

Chapter 23

Foundations and mathematical tools

As we have seen in the precedent section, the important message of quantum mechanics is that matter propagates as a wave and light, when localized, only changes its energy in discrete units. Once we understand (or at least accept) this fact, a large part of quantum mechanics follows just as a corollary. The idea expressed by de Brogie, that matter would be a wave led to the first quantization. Interestingly, the concept of light underwent a reverse evolution. Classically described as a wave, it was divided by Planck and Einstein into quantized corpuscles, today called 'photons'.

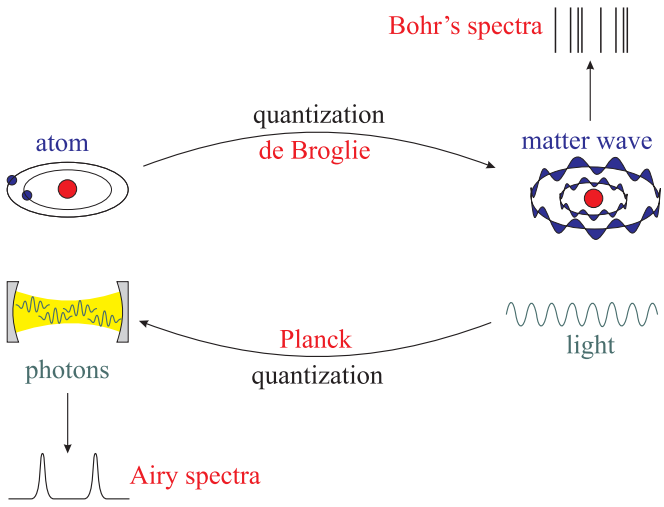

Figure 23.1: Illustration of particle-wave duality for matter and light.

In this chapter, we will introduce step by step the formalism of quantum mechanics by gradually increasing the degree of abstraction. Applications of the formalism will be shown in consecutive chapters (watch talk).

23.1 Basic notions

The aim of this section is to give 'feeling' for the new concepts introduced and used by quantum mechanics. We will first motivate the fundamental quantum equations of motion by linking them to classical dispersion relations and then spend some time to discuss the probabilistic concept proposed by Max Born.

23.1.1 Dispersion relation and Schrödinger equation

A fundamental problem in physics is the issue of the propagation of physical entities. On one hand, we have the light, whose propagation in the vacuum is described by the dispersion relation $\omega = ck$ or,

$$\omega^2 - c^2k^2 = 0 \ . \tag{23.1}$$

Since light is a wave, in the most general form, assuming the validity of the superposition principle, it can be described by a wave packet, $A(\mathbf{r},t) = \int e^{\imath(\mathbf{k}\cdot\mathbf{r}-\omega t)}a(\mathbf{k})d^3k$. It is easy to verify that the *wave equation*,

$$\frac{\partial^2}{\partial t^2}A - c^2\nabla^2 A = 0 \ , \tag{23.2}$$

reproduces the dispersion relation.

On the other hand, we have slow massive particles possessing kinetic energy,

$$E = \frac{p^2}{2m} \ . \tag{23.3}$$

With the hypothesis of de Broglie that even a massive particle has wave quality, we can try an *ansatz* [1] of a wave equation satisfying the dispersion relation (23.3). From Planck's formula, $E = \hbar\omega$, and the formula of *Louis de Broglie*, $\mathbf{p} = \hbar\mathbf{k}$, describing the particle by a wave packet $\psi(\mathbf{r},t) = \int e^{\imath(\mathbf{k}\cdot\mathbf{r}-\omega t)}\varphi(\mathbf{k})d^3k$ not subject to external forces, it is easy to verify that the equation,

$$\imath\hbar\frac{\partial}{\partial t}\psi = \left(-\frac{\hbar^2}{2m}\nabla^2\right)\psi \ , \tag{23.4}$$

reproduces the dispersion relation. If the particle is subject to a potential, its total energy is $E = \mathbf{p}^2/2m + V(\mathbf{r},t)$. This dispersion relation corresponds to the famous *Schrödinger equation*,

$$\imath\hbar\frac{\partial}{\partial t}\psi = \left(-\frac{\hbar^2}{2m}\nabla^2 + V(\mathbf{r},t)\right)\psi \ . \tag{23.5}$$

23.1.2 Relativistic particle waves

Despite the similarities between light particles and material particles, there are notable differences: The photon is a relativistic particle with no rest mass. How can we establish a relationship between such different objects?

[1] Trial, working hypothesis.

To clarify this relationship we now consider particles that are similar to light in the sense that they have high velocities, that is, relativistic particles. From the relativistic principle of the equivalence of mass and energy, we obtain for a massive particle $E^2 = m^2c^4 + c^2p^2$ or,

$$\omega^2 - c^2k^2 = \frac{m^2c^4}{\hbar^2} \ . \tag{23.6}$$

This dispersion relation can be obtained from the differential equation,

$$\frac{\partial^2}{\partial t^2}A - c^2\nabla^2 A = -\frac{m^2c^4}{\hbar^2}A \ , \tag{23.7}$$

inserting, for example, the already proposed wave packet $A(\mathbf{r},t) = \int e^{\imath(\mathbf{k}\cdot\mathbf{r}-\omega t)}a(\mathbf{k})d^3k$, supposed not to be subject to external forces. The equation (23.7) is a wave equation called *Klein-Gordon equation*. For particles without rest mass, as in the case of photons, the equation is reduced to the wave equation of light (23.2).

Now, making the transition to non-relativistic velocities, $v \ll c$, we can expand the dispersion relation,

$$E = \sqrt{m^2c^4 + c^2m^2v^2} = mc^2\left(1 + \frac{v^2}{2c^2} + ..\right) \qquad \text{or} \qquad \hbar\omega \simeq mc^2 + \frac{\hbar^2k^2}{2m} \ . \tag{23.8}$$

In analogy with the Klein-Gordon equation we can derive the approximate dispersion relation (23.8) from a wave equation,

$$\imath\hbar\frac{\partial}{\partial t}A = \left(mc^2 - \frac{\hbar^2}{2m}\nabla^2\right)A \ . \tag{23.9}$$

With the transformation $\psi = e^{-\imath mc^2t/\hbar}A$, we rediscover the Schrödinger equation (23.4),

$$\imath\hbar\frac{\partial}{\partial t}\psi = -\frac{\hbar^2}{2m}\nabla^2\psi \tag{23.10}$$

as the non-relativistic limit of the Klein-Gordon equation.

It is interesting to note that in all cases discussed, obviously the dispersion relations and the differential equations can be interconverted by the substitutions,

$$E \longrightarrow \imath\hbar\frac{\partial}{\partial t} \qquad \text{and} \qquad \mathbf{p} \longrightarrow -\imath\hbar\nabla \ . \tag{23.11}$$

We will discuss this later in the context of Ehrenfest's theorem in Secs. 23.1.6, 23.1.7, and 23.4.6.

> **Example 140 (*Demystifying Quantum Mechanics 1.0*):** The essence of quantum mechanics can be boiled down to the particle-wave duality. That is the fact that the building blocks of matter must be considered as de Broglie waves. Once this fact is understood and assimilated, quantum mechanics loses much of its mystery. For example delocalization of an atom, that is, the fact that it can be at two locations at the same time irritates us only as long as we try to imagine it as an indivisible solid block. In contrast we are not surprised

to encounter the same ocean wave or tsunami in different continents.
The misconception is already rooted in the statement that *a quantum particle can be simultaneously in two places*. What we really mean when we say a particle is delocalized is, that the way it is embedded in space-time (which is the frame in which we can (or cannot) attribute locations and velocities to it) resembles a wave, and that the way this wave evolves or propagates in space is wave-like and described by a Schrödinger equation. Note that position-velocity is just one property that a particle can have. Spin is another one, and the appropriate space in which a spin is embedded is not necessarily position space, but can be an abstract configuration space. An atom can have an internal structure, whose dynamics is totally independent of how the atom moves as a whole. Thus, a particle IS not a wave, but PROPAGATES like one in space-time. Still, its evolution will follow a Schrödinger-type equation.
At first the Schrödinger equation seems weird, because it is complex and thus rules the behavior of an unphysical quantity, the wave function. But we should keep in mind the Schrödinger equation is the non-relativistic approximation of the Klein-Gordon equation, which resembles much more a classical wave equation, and applies also to particles propagating at velocities nearly as fast as light.
With regard to these facts, a terminology that suits much better the features of quantum mechanics is simply wave mechanics, how Schrödinger termed it. This terminology also has the advantage of avoiding confusion with light wave effects erroneously attributed to quantum mechanics, such as light tunneling which is totally understood within Maxwell's theory.
We must however be aware that the simple wave picture is not sufficient to understand all of quantum mechanics. As we will see in the next sections, it is necessary to complement wave mechanics with a measurement theory, and phenomena genuine to what today is called Quantum Mechanics 2.0, in particular, entanglement are difficult to understand in wave mechanics.

23.1.3 Born's interpretation

The first part of this script is devoted to *individual particles* or systems of distinguishable *massive particles*, and we will only turn our attention to *light* and *indistinguishable particles* when discussing the (second) *quantization of fields*.

According to our current conviction, the complete reality (neglecting relativistic effects) on any system is contained in the Schrödinger equation (23.5). That statement does not make us smarter without having to explaining the meaning of the *wavefunction* ψ. In an attempt to marry the concepts of particles and waves, *Max Born* proposed in 1926 the interpretation of the quantity

$$\int_V |\psi(\mathbf{r},t)|^2 d^3r \tag{23.12}$$

as probability of finding the particle inside the volume V.

If $|\psi(\mathbf{r},t)|^2$ has the meaning of a *probability density* or *probability distribution*, the square of the wavefunction must be integrable,

$$\|\psi(\mathbf{r},t)\|^2 \equiv \int_{\mathbb{R}^3} |\psi(\mathbf{r},t)|^2 d^3r < \infty \ . \tag{23.13}$$

This allows us to proceed to a *normalization* of the wave function,

$$\tilde{\psi}(\mathbf{r},t) \equiv \frac{\psi(\mathbf{r},t)}{\sqrt{\int_{\mathbb{R}^3} |\psi(\mathbf{r},t)|^2 d^3r}} \ , \tag{23.14}$$

such that $\|\tilde{\psi}(\mathbf{r},t)\| = 1$.

23.1.4 Continuity equation

In quantum mechanics we associate the wavefunction that describes a quantum system to a *probability wave*. As the Schrödinger equation describes a time evolution, in order to be useful, the wavefunction must allow for probability flows. We define the probability density and the probability flow by,

$$\begin{aligned} \rho(\mathbf{r},t) &\equiv \psi^*(\mathbf{r},t)\psi(\mathbf{r},t) \ , \\ \mathbf{j}(\mathbf{r},t) &\equiv \frac{\hbar}{2m\imath} \left[\psi^*(\mathbf{r},t)\nabla\psi(\mathbf{r},t) - \psi(\mathbf{r},t)\nabla\psi^*(\mathbf{r},t)\right] \ . \end{aligned} \tag{23.15}$$

Starting from the Schrödinger equation we can easily derive the *continuity equation* (see Exc. 23.1.8.1),

$$\dot{\rho}(\mathbf{r},t) + \nabla\cdot\mathbf{j}(\mathbf{r},t) = 0 \ , \tag{23.16}$$

or in the integral form,

$$-\frac{d}{dt}\int_V \rho d^3r = \int_V \nabla\cdot\mathbf{j} d^3r = \oint_{\partial V} \mathbf{j}\cdot d\mathbf{S} \ , \tag{23.17}$$

using Gauß' law. With $I \equiv \int_S \mathbf{j}\cdot d\mathbf{S}$, the *probability current* which flows through the surface S delimiting the *probability charge* $Q \equiv \int_V \rho(\mathbf{r},t)d^3r$, we obtain,

$$-\dot{Q} = I \ . \tag{23.18}$$

The continuity equation is obviously similar to that of electromagnetism.

23.1.5 Distributions in space and time

So far we only spoke of spatial distributions, $\psi(\mathbf{r},t)$. But we could also consider velocity or moment distributions. In classical mechanics, a particle has a well-defined position and velocity. Knowing the position and velocity, Newton's equations allow predicting its coordinates at future times. Let us now investigate whether the Schrödinger equation allows this as well.

The more general solution of the Schrödinger equation can be written as a superposition of plane waves $e^{\imath(\mathbf{r}\cdot\mathbf{k}-\omega t)}$ with frequencies $\omega = \mathbf{p}^2/2\hbar m$ and wave vectors $\mathbf{k} = \mathbf{p}/\hbar$. Each plane wave has an individual amplitude $\varphi(\mathbf{p})$, such that,

$$\psi(\mathbf{r},t) = \tfrac{1}{h^{3/2}} \int d^3p\varphi(\mathbf{p})e^{\imath(\mathbf{r}\cdot\mathbf{k}-\omega t)} = \int d^3p \tfrac{1}{h^{3/2}}\varphi(\mathbf{p})e^{\imath(\mathbf{r}\cdot\mathbf{p}/\hbar - \mathbf{p}^2 t/2m\hbar)} \ , \tag{23.19}$$

with $h \equiv 2\pi\hbar$. At time $t = 0$, this expansion is nothing more than a Fourier transform,

$$\psi(\mathbf{r},0) = \tfrac{1}{h^{3/2}} \int d^3p\varphi(\mathbf{p})e^{\imath\mathbf{r}\cdot\mathbf{k}} \ , \tag{23.20}$$

that we can reverse,

$$\varphi(\mathbf{p}) = \tfrac{1}{h^{3/2}} \int d^3r \psi(\mathbf{r},0) e^{-\imath \mathbf{r}\cdot\mathbf{k}} \ . \tag{23.21}$$

In the absence of forces the momentum distribution becomes stationary. We can now use the momentum distribution $\varphi(\mathbf{p})$ as coefficients of the expansion of the temporal wavefunction $\psi(\mathbf{r},t)$, as shown above. Thus, the expansion represents a general solution of the time-dependent Schrödinger equation. The magnitude $|\varphi(\mathbf{p})|^2$ is the probability density in *momentum space*.

Example 141 (*Normalization of the wave function in momentum space*): It is easy to show that the probability density in momentum space is also normalized:

$$\begin{aligned}\int |\varphi(\mathbf{p})|^2 d^3p &= \tfrac{1}{h^3} \int d^3p \int d^3r \psi^*(\mathbf{r}) e^{\imath \mathbf{r}\cdot\mathbf{k}} \int d^3r' \psi(\mathbf{r}') e^{-\imath \mathbf{r}'\cdot\mathbf{k}} \\ &= \int d^3r \int d^3r' \psi^*(\mathbf{r}) \psi(\mathbf{r}') \tfrac{1}{(2\pi)^3} \int d^3k e^{\imath \mathbf{k}\cdot(\mathbf{r}-\mathbf{r}')} \\ &= \int d^3r \int d^3r' \psi^*(\mathbf{r}) \psi(\mathbf{r}') \delta^3(\mathbf{r}-\mathbf{r}') = \int |\psi(\mathbf{r})|^2 d^3r = 1 \ ,\end{aligned}$$

knowing that the Fourier transform of a plane wave is nothing more than the Dirac distribution.

Since the probability distributions $|\psi(\mathbf{r})|^2$ and $|\varphi(\mathbf{p})|^2$ are interconnected by Fourier transform, we already know that we can not localize [2] both simultaneously. If one is well localized, the other is necessarily delocalized. Do the Exc. 23.1.8.2.

23.1.6 Eigenvalues

We have already seen that the position and momentum distributions of a particle are spread. We calculate the mean values of these distributions, denoted by $\langle \mathbf{r} \rangle$ and $\langle \mathbf{p} \rangle$, as *first moments* of the respective distributions:

$$\langle \mathbf{r} \rangle = \int d^3r |\psi(\mathbf{r},t)|^2 \mathbf{r} \qquad \text{and} \qquad \langle \mathbf{p} \rangle = \int d^3p |\varphi(\mathbf{p},t)|^2 \mathbf{p} \ . \tag{23.22}$$

Using the expansions (23.19) and (23.20), we can calculate,

$$\begin{aligned}\langle \mathbf{p} \rangle = \int \varphi^*(\mathbf{p}) \mathbf{p} \varphi(\mathbf{p}) d^3p &= \int \tfrac{1}{h^{3/2}} \int \psi^*(\mathbf{r}) e^{\imath \mathbf{k}\cdot\mathbf{r}} d^3r \mathbf{p} \varphi(\mathbf{p}) d^3p \\ &= \tfrac{1}{h^{3/2}} \int \psi^*(\mathbf{r}) \int \varphi(\mathbf{p}) \mathbf{p} e^{\imath \mathbf{k}\cdot\mathbf{r}} d^3p d^3r \\ &= \tfrac{1}{h^{3/2}} \int \psi^*(\mathbf{r}) \tfrac{\hbar}{\imath} \nabla \int \varphi(\mathbf{p}) e^{\imath \mathbf{k}\cdot\mathbf{r}} d^3p d^3r = \int \psi^*(\mathbf{r}) \tfrac{\hbar}{\imath} \nabla \psi(\mathbf{r}) d^3r \ .\end{aligned}$$

This calculation shows that the expectation value, called *eigenvalue*, of the momentum can be expressed through an operator $\hat{p} \equiv (\hbar/\imath)\nabla$ acting on the wavefunction [3,4].

[2] Localize: Restrict the distribution volume indefinitely.

[3] From now on, the hat over a physical magnitude will denote quantum operators.

[4] We note here that the rules $\langle \psi | \hat{x} | \psi \rangle \leftrightarrow \langle \phi | - \tfrac{\hbar}{\imath} \nabla_p | \phi \rangle$ and $\langle \psi | \tfrac{\hbar}{\imath} \nabla_{\mathbf{r}} | \psi \rangle \leftrightarrow \langle \phi | \hat{p} | \phi \rangle$ from the Fourier transformation are useful for numerical simulations of the Schrödinger equation: Instead of calculating the spatial derivative $\left(\tfrac{\hbar}{\imath}\nabla\right)^2$ of the wavefunction, one makes a Fast Fourier Transform (FFT) to momentum space, multiplies with $\mathbf{p}$, and transforms back.

More generally, we can compute the eigenvalue of a function in $\mathbf{r}$ and $\mathbf{p}$ via,

$$\langle f(\hat{\mathbf{r}},\hat{\mathbf{p}})\rangle = \int d^3r\psi^*(\mathbf{r})f(\mathbf{r},\hat{\mathbf{p}})\psi(\mathbf{r}) \ . \tag{23.23}$$

However, it is important to note that the operators $\hat{\mathbf{r}}$ and $\hat{\mathbf{p}}$ do not necessarily commute.

Example 142 (*Non-commutation of space and momentum*): Considering a one-dimensional motion, we verify,

$$\hat{p}_x x\psi = \frac{\hbar}{\imath}\frac{d}{dx}x\psi = \frac{\hbar}{\imath}\psi + x\frac{\hbar}{\imath}\frac{d}{dx}\psi \neq x\frac{\hbar}{\imath}\frac{d}{dx}\psi = x\hat{p}_x\psi \ .$$

23.1.7 Temporal evolution of eigenvalues

We now consider the temporal evolution of the position of a particle. We will use in the following the partial integration rule $\int_V \psi\nabla\xi = \oint_{\partial V}\psi\xi - \int_V \nabla\psi\xi = -\int_V(\nabla\psi)\xi$, assuming that at least one of the functions, ψ or ξ, disappears at the edge of the volume, which can be guaranteed by choosing the volume large enough. To begin with, we will concentrate on the x-component of the position, the time derivative of which is computed using the continuity equation (23.16),

$$\frac{d}{dt}\langle\hat{x}\rangle = \int d^3r\frac{d}{dt}|\psi|^2 x = -\int d^3r\ x\nabla\cdot\mathbf{j} = -\cancelto{0}{\int d\mathbf{S}\cdot\mathbf{j}\,x} + \int d^3r\ \mathbf{j}\cdot\nabla x = \int d^3r\ \mathbf{j}_x \ , \tag{23.24}$$

Generalizing to three dimensions, we can write,

$$\begin{aligned}\frac{d}{dt}\langle m\hat{\mathbf{r}}\rangle &= m\int d^3r\ \mathbf{j} = m\int d^3r\frac{\hbar}{2m\imath}[\psi^*\nabla\psi - \psi\nabla\psi^*] \\ &= \tfrac{1}{2}\int d^3r[\psi^*\hat{\mathbf{p}}\psi + \psi\hat{\mathbf{p}}\psi^*] = \int d^3r\psi^*\hat{\mathbf{p}}\psi = \langle\hat{\mathbf{p}}\rangle \ ,\end{aligned} \tag{23.25}$$

since the eigenvalue of $\hat{\mathbf{p}}$ is a real quantity.

Now, we define the abbreviation:

$$\hat{H} \equiv -\frac{\hbar^2}{2m}\nabla^2 + V(\hat{\mathbf{r}},t) \ , \tag{23.26}$$

called the *Hamilton operator* or *Hamiltonian* and we calculate the second derivative of the position using the Schrödinger equation (23.5),

$$\frac{d}{dt}\langle\hat{\mathbf{p}}\rangle = \int d^3r\left[\left(\tfrac{1}{\imath\hbar}\hat{H}\psi\right)^*\hat{\mathbf{p}}\psi + \psi^*\hat{\mathbf{p}}\tfrac{1}{\imath\hbar}\hat{H}\psi\right] = \tfrac{\imath}{\hbar}\int d^3r\ \psi^*(\hat{H}\hat{\mathbf{p}} - \hat{\mathbf{p}}\hat{H})\psi = \tfrac{\imath}{\hbar}\langle[\hat{H},\hat{\mathbf{p}}]\rangle \ , \tag{23.27}$$

introducing the *commutator* $[\hat{a},\hat{b}] \equiv \hat{a}\hat{b} - \hat{b}\hat{a}$ as an abbreviation. After that,

$$\tfrac{\imath}{\hbar}\langle[\hat{H},\hat{\mathbf{p}}]\rangle = \tfrac{\imath}{\hbar}\langle[\hat{V},\hat{\mathbf{p}}]\rangle = \tfrac{\imath}{\hbar}\int d^3r\psi^*\left[\hat{V}\tfrac{\hbar}{\imath}\nabla\psi - \tfrac{\hbar}{\imath}\nabla(V\psi)\right] = -\int d^3r\psi^*\psi\nabla V = \langle\hat{\mathbf{F}}\rangle \ . \tag{23.28}$$

In summary, we found a law,

$$\langle \hat{\mathbf{F}} \rangle = \frac{d^2}{dt^2} \langle m\hat{\mathbf{r}} \rangle \ , \tag{23.29}$$

much like *Newton's law*, but instead of applying to localized particles, the law applies to the eigenvalues of probability distributions. Similar laws can be derived for angular momentum and energy conservation.

The observation made by *Paul Ehrenfest*, that in quantum mechanics the mean values follow the same laws of classical mechanics, is called *Ehrenfest theorem*.

23.1.8 Exercises

23.1.8.1 Ex: Conservation of probability

Demonstrate the conservation of local probability through the definitions of probability densities, $\rho(\mathbf{r}, t)$, and probability current $\mathbf{j}(\mathbf{r}, t)$.

Solution: *Assuming the validity of the Schrödinger equation, we obtain,*

$$\begin{aligned} \dot{\rho} &= \psi^* \dot{\psi} + \dot{\psi}^* \psi = \psi^* \frac{1}{\imath\hbar} \left(\frac{-\hbar^2}{2m} \nabla^2 \right) \psi + \left(\frac{1}{\imath\hbar} \frac{-\hbar^2}{2m} \nabla^2 \psi \right)^* \psi \\ &= -\frac{\hbar}{2mi} \nabla \cdot [\psi^* \nabla \psi - (\nabla \psi)^* \psi] = -\nabla \cdot \mathbf{j} \ . \end{aligned}$$

23.1.8.2 Ex: Fourier theorem

The spatial distribution of a particle is given by a Gaussian function with the width Δx. Calculate the momentum distribution and its width Δp. Just consider one spatial dimension. Show that $\Delta x \Delta p = \hbar$ using the *rms* definition for the widths.

Solution: *The distribution of the particle is given by* $\psi(x, 0) = Ae^{-x^2/2\Delta x^2}$. *The constant* A *is determined from the normalization condition,*

$$1 = \int_{-\infty}^{\infty} |\psi(x,0)|^2 dx = \int_{-\infty}^{\infty} A^2 e^{-x^2/\Delta x^2} dx = A^2 \sqrt{\pi} \Delta x \quad \Longrightarrow \quad A = \left(\frac{1}{\pi \Delta x^2} \right)^{1/4} .$$

Therefore, the momentum distribution is,

$$\varphi(p) = \frac{1}{(2\pi\hbar)^{1/2}} \int_{-\infty}^{\infty} \psi(x,0) e^{-\imath x k} dx = \frac{1}{(2\pi\hbar)^{1/2} \pi^{1/4}} \frac{1}{\sqrt{\Delta x}} \int_{-\infty}^{\infty} e^{-x^2/2\Delta x^2} e^{-\imath x k} dx \ .$$

With the definition of the Fourier transform,

$$g(k) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} f(x) e^{-\imath k x} dx \ ,$$

the transformation of $f(x) = \frac{1}{\sqrt{2\pi}} \frac{1}{\sqrt{\Delta x}} e^{-x^2/2\Delta x^2}$ *is* $g(k) = \frac{1}{\sqrt{2\pi}} \sqrt{\Delta x} e^{-\Delta x^2 k^2/2}$. *Hence,*

$$\varphi(p) = \frac{1}{(2\pi\hbar)^{1/2} \pi^{1/4}} \sqrt{\Delta x} e^{-\Delta x^2 k^2/2} \ .$$

The width of this momentum distribution is $\Delta k \equiv \Delta x^{-1}$, which shows that position and momentum distributions can not be narrow simultaneously. The equation

$$\Delta x \Delta p = \hbar$$

corresponds to the Heisenberg uncertainty relation.

23.2 Postulates of quantum mechanics

In this section we will introduce the fundamentals and main methods of quantum mechanics. We will learn what are observables and get to know the postulates which establish the foundation of quantum mechanics, as well as Heisenberg's famous principle of uncertainty.

23.2.1 Superposition principle (1. postulate)

A physical system can be found in several states. For example, a particle may be at rest or in motion, an atom may be excited or deexcited. In quantum mechanics, every possible state is described by a *wavefunction* ψ. Wavefunctions can be functions of various types of coordinates, for example, of position $\psi = \psi(\mathbf{r})$, of momentum $\psi = \psi(\mathbf{p})$, or of energy $\psi = \psi(E)$. The choice of the coordinates is called *representation*.

One peculiarity of quantum systems is that they may be in a *superposition of states*. That is, if $\psi_1, \psi_2, ..., \psi_k$ are possible states with amplitudes c_k, automatically the functions,

$$\psi = \sum_k c_k \psi_k \qquad \text{or} \qquad \psi = \int dk\ c(k)\phi(k) \tag{23.30}$$

are possible states as well. This is called *superposition principle*, and means, for example, that a particle may be *simultaneously* in several places or that an atom may be *at the same time* excited and deexcited.

There are systems that can only exist in a *restricted number* of states, such as the two-level atom. Others may exist in an *infinite number* of states or even in a *continuous distribution* of states.

23.2.2 Interpretation of the wave function (2. postulate)

A *state function* (or wavefunction) characterizes a system of which we may calculate various properties. The function can adopt complex values devoid of immediate physical interpretation. In fact, the wavefunction is above all a mathematical construct. On the other hand, the norm $|\psi|^2$ has the meaning of a probability of the system to be in the state ψ. This is the famous interpretation of *Max Born* of the wave function (see Sec. 23.1.3).

If ψ_k with $k = 1, 2, \ldots$ are all possible states of a system, the interpretation as a probability requires,

$$\sum_k |\psi_k|^2 = 1\ . \tag{23.31}$$

Analogically, for a continuous distribution, for example, in spatial representation,

$$\int_{-\infty}^{\infty} |\psi(x)|^2 dx = 1 \ . \tag{23.32}$$

That is, the probability needs *normalization*.

23.2.3 Dirac bra-ket notation and vector representation

In order to distinguish more easily the amplitudes (which are complex numbers) and the wavefunctions we will now use the Bra-Ket notation introduced by *Paul Dirac*. The functions are represented by *kets*,

$$|\psi\rangle = \sum_k c_k |k\rangle \ . \tag{23.33}$$

The complex transpositions of these states are represented by *bras*,

$$\langle\psi| = |\psi\rangle^\dagger = \sum_k c_k^* \langle k| \ . \tag{23.34}$$

But the notation has other advantages. For example, let us suppose that we know the three possible states of a system, $|1\rangle$, $|2\rangle$, and $|3\rangle$, which are linearly independent. Then we can define the states as vectors:

$$|1\rangle = \begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix} \quad , \quad |2\rangle = \begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix} \quad , \quad |3\rangle = \begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix} \ . \tag{23.35}$$

These three states can be interpreted as the basis of a *vector space* representing the system. Now, each wavefunction can be expanded on this basis and expressed by a vector. An arbitrary ket state of this system will then be,

$$|\psi\rangle = \begin{pmatrix} c_1 \\ c_2 \\ c_3 \end{pmatrix} \ . \tag{23.36}$$

The corresponding bra state will be,

$$\langle\psi| = \begin{pmatrix} c_1^* & c_2^* & c_3^* \end{pmatrix} \ . \tag{23.37}$$

Now we can easily calculate the probability for a system to be in a state $|\psi\rangle$,

$$||\psi\rangle|^2 = \langle\psi|\psi\rangle = \begin{pmatrix} c_1^* & c_2^* & c_3^* \end{pmatrix} \cdot \begin{pmatrix} c_1 \\ c_2 \\ c_3 \end{pmatrix} = |c_1|^2 + |c_2|^2 + |c_3|^2 \ . \tag{23.38}$$

23.2.4 Observables (3. postulate)

The only way to get information about a system is to *measure* the values of characteristic quantities of the system, e.g. energy or linear momentum. In classical mechanics we have learned that a system can be completely characterized by a set of measurable physical quantities. For example, the motion of a rigid body of mass m and inertial moment $\mathbf{I}$ is defined by its position $\mathbf{r}$, its moment $\mathbf{p}$, and its angular momentum $\mathbf{L}$. In quantum mechanics we describe observable physical quantities by *operators* acting on the *Hilbert space* of wavefunctions, $|\psi\rangle \mapsto \hat{\mathbf{p}}|\psi\rangle$, where $\hat{p}$ would be the operator of the linear momentum. To better distinguish the observables, we decorate their symbols with a hat. We will see more ahead (see Sec. 23.3.5) that every quantum system is completely described by a complete set of observables.

To find the current values a_ψ of any *observable* $\hat{A}$ in a specific situation given by a wave function ψ, we need to solve an equation of eigenvalues,

$$\hat{A}|\psi\rangle = a_\psi|\psi\rangle \ . \tag{23.39}$$

We can rewrite the equation as $a_\psi = \langle\psi|\hat{A}|\psi\rangle$. The values a_n are real numbers, if the observable is a *Hermitian operator*, that is,

$$\hat{A} = \hat{A}^\dagger \quad \Longrightarrow \quad a_\psi = a_\psi^* \ . \tag{23.40}$$

We leave proof of this for the Exc. 23.2.9.1.

Thus, we postulate the substitution of the *dynamic variables* characterizing a classical system by abstract objects called operators. These operators can be understood as mathematical prescriptions, e.g., differential operators acting on a state of the system. The expectation value of any operator $\hat{A}$ characterizing a system in a state $|\psi\rangle$ is $a_\psi \equiv \langle\hat{A}\rangle_\psi \equiv \langle\psi|\hat{A}|\psi\rangle/\langle\psi|\psi\rangle$. Such operators are specific for a system, but independent of its state. The dynamical variables for a specific state are obtained as eigenvalues of the respective variable in that specific state. The temporal evolution of the operators or of the states is governed by equations of motion (see Sec. 23.4) [5].

23.2.5 Representation of operators as matrices

In the same way as we already represented wavefunctions by vectors, we can also represent operators by matrices,

$$\hat{A} \equiv \sum_{i,j} |i\rangle a_{ij} \langle j| = \begin{pmatrix} & \vdots & \\ .. & a_{ij} & .. \\ & \vdots & \end{pmatrix} = \begin{pmatrix} & \vdots & \\ .. & \langle j|\hat{A}|i\rangle & .. \\ & \vdots & \end{pmatrix} \ . \tag{23.41}$$

To extract components from a matrix we do, $\langle i|\hat{A}|j\rangle$, for example,

$$\langle 1|\hat{A}|1\rangle = \begin{pmatrix} 1 & 0 & .. \end{pmatrix} \cdot \hat{A} \cdot \begin{pmatrix} 1 \\ 0 \\ \vdots \end{pmatrix} = a_{11} \ . \tag{23.42}$$

[5] Note that there are theoretical attempts to generalize the concept of observables to non-Hermitian operators [117, 118] only displaying $\mathcal{PT}$-symmetry.

Projectors are particular operators defined by,

$$\hat{P}_k \equiv |k\rangle\langle k| = \begin{pmatrix} 0 & : & 0 \\ .. & 1 & .. \\ 0 & : & 0 \end{pmatrix} \quad . \tag{23.43}$$

The eigenvalue of a projector, $\langle \hat{P}_k \rangle = \langle \psi | \hat{P}_k | \psi \rangle = |\langle k|\psi\rangle|^2$, is nothing more than the probability of finding a system, whose general state is $|\psi\rangle$, in the particular state, since expanding as done in (23.33), we have,

$$\langle \hat{P}_k \rangle = \sum_{m,n} c_m^* c_n \langle m|k\rangle\langle k|n\rangle = |c_k|^2 \ . \tag{23.44}$$

Using the matrix formalism we can define other interesting operators and verify their properties. For example, choosing the basis,

$$|1\rangle = \begin{pmatrix} 1 \\ 0 \end{pmatrix} \quad , \quad |2\rangle = \begin{pmatrix} 0 \\ 1 \end{pmatrix} \ , \tag{23.45}$$

we find,

$$\begin{array}{rclcrcl} |1\rangle\langle 1| & = & \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix} & , & |2\rangle\langle 2| & = & \begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix} \\ |1\rangle\langle 2| & = & \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix} & , & |2\rangle\langle 1| & = & \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix} \end{array} \quad . \tag{23.46}$$

Obviously, these matrices can be used to expand any 2×2 matrix. An equivalent set of matrices are the *Pauli spin matrices*,

$$\boxed{\mathbb{I} \equiv \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \quad , \quad \hat{\sigma}^x \equiv \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \quad , \quad \hat{\sigma}^y \equiv \begin{pmatrix} 0 & \imath \\ -\imath & 0 \end{pmatrix} \quad , \quad \hat{\sigma}^z \equiv \begin{pmatrix} -1 & 0 \\ 0 & 1 \end{pmatrix}} \ . \tag{23.47}$$

An important property of the Pauli matrices is their behavior under commutation and anti-commutation,

$$\begin{aligned} [\hat{\sigma}_k, \hat{\sigma}_m]_- &\equiv \hat{\sigma}_k \hat{\sigma}_m - \hat{\sigma}_k \hat{\sigma}_m = \imath \epsilon_{kmn} \hat{\sigma}_n \\ [\hat{\sigma}_k, \hat{\sigma}_m]_+ &\equiv \hat{\sigma}_k \hat{\sigma}_m + \hat{\sigma}_k \hat{\sigma}_m = 2\delta_{km} \ . \end{aligned} \tag{23.48}$$

Defining so-called ladder operators or rising, respectively, lowering operators, depending on the arrangement of the level system via,

$$\boxed{\hat{\sigma}^{\pm} = \tfrac{1}{2}(\hat{\sigma}_x \pm \imath \hat{\sigma}_y)} \ , \tag{23.49}$$

we may represent the matrices as,

$$\begin{array}{rclcrcl} |1\rangle\langle 1| & = & \tfrac{1}{2}(\mathbb{I}_2 - \hat{\sigma}^z) = \hat{\sigma}^- \hat{\sigma}^+ & , & |2\rangle\langle 2| & = & \tfrac{1}{2}(\mathbb{I}_2 + \hat{\sigma}^z) = \hat{\sigma}^+ \hat{\sigma}^- \\ |2\rangle\langle 1| & = & \tfrac{1}{2}(\hat{\sigma}^x + \imath \hat{\sigma}^y) = \hat{\sigma}^+ & , & |1\rangle\langle 2| & = & \tfrac{1}{2}(\hat{\sigma}^x - \imath \hat{\sigma}^y) = \hat{\sigma}^- \end{array} \ , \tag{23.50}$$

and write down the *Pauli vector* [6],

$$\hat{\vec{\sigma}} \equiv \begin{pmatrix} \hat{\sigma}_x \\ \hat{\sigma}_y \\ \hat{\sigma}_z \end{pmatrix} = \begin{pmatrix} \hat{\sigma}^- + \hat{\sigma}^+ \\ \imath(\hat{\sigma}^- - \hat{\sigma}^+) \\ [\hat{\sigma}^+, \hat{\sigma}^-] \end{pmatrix} \tag{23.51}$$

and the vector

$$\vec{\rho} \equiv \begin{pmatrix} \langle\hat{\sigma}_x\rangle \\ \langle\hat{\sigma}_y\rangle \\ \langle\hat{\sigma}_z\rangle \end{pmatrix} , \tag{23.52}$$

which is called *Bloch vector* [7,8]. The eigenvalue of the Bloch vector has a fixed length (see Exc. 23.2.9.2).

The representation of physical quantities by matrices is essential for the description of quantum superposition states.

23.2.6 Correspondence principle (4. postulate)

Operators do not necessarily commute. We have already seen in Sec. 23.1.6, that in one dimension the position and the momentum operators do not commute. We can generalize to three dimensions via,

$$[\hat{p}_j, \hat{x}_k] = -\imath\hbar\delta_{jk} \qquad \text{and} \qquad [\hat{p}_j, \hat{p}_k] = 0 = [\hat{x}_j, \hat{x}_k] \ , \tag{23.53}$$

which is easily verified by replacing the operators with $\hat{x}_k = x_k$ and $\hat{p}_k = \frac{\hbar}{\imath}\nabla$ and allowing the commutators to act on a wavefunction $\psi(x)$.

Conversely, quantum mechanics follows from classical mechanics with the prescription [9], $A(q_k, p_k, t) \longrightarrow A(\hat{q}_k, \hat{p}_k, t) = \hat{A}$. Letting the smallest amount of energy possible go to zero, $\hbar \longrightarrow 0$, the commutator disappears, the energy spectrum becomes continuous, and we recover classical mechanics.

23.2.7 Schrödinger equation and quantum measurements (5. postulate)

The time evolution is given by the Schrödinger equation,

$$\boxed{\imath\hbar\frac{\partial}{\partial t}|\psi\rangle = \hat{H}|\psi\rangle} \ . \tag{23.54}$$

A closed system, disconnected from the rest of the world (we will now call the rest of the world *reservoir*) is not subject to dissipation, i.e., it does not lose energy

[6] Note that other definitions of the Pauli matrices, e.g. $\hat{\sigma}^y \to -\hat{\sigma}^y$ and $\hat{\sigma}^z \to -\hat{\sigma}^z$ are also found in literature. They simply correspond to a change of basis $|1\rangle \leftrightarrow |2\rangle$.

[7] The Bloch vector is widely used in describing the interaction of a two-level system with a light field.

[8] Schrödinger invented the *wave mechanics* when he derived his wave equation from the dispersion relation for massive particles. Heisenberg invented a mechanics (detailed in later sections), which he called *mechanics of matrices*. Later, he showed the formal equivalence of both theories.

[9] Considering the Weyl order.

to the reservoir. Such a system is always described by a hermitian Hamiltonian. Unfortunately, this system also does not allow information leakage, that is, we can not measure the system. This is reflected in the fact that the Schrödinger equation does not allow to describe the process of a *quantum measurement*. This is because before the measurement, the system can be in several states or even in a superposition of states, while after the measurement we know exactly the state. This amounts to a reduction of entropy, which is not allowed in a closed system.

The famous *postulate* of *state reduction* or *projection of the wavefunction* formulated by *John von Neumann* describes the quantum measurement process as a sequence of two distinct steps [10]. In a first step, the measuring apparatus projects the measured operator $\hat{A}$ on an eigenvector basis. That is, if the measurement is compatible with the operator [11], we obtain a distribution of probability amplitudes of the results,

$$\hat{A} \quad \curvearrowright \quad \langle \hat{A} \rangle = \langle \psi | \hat{A} | \psi \rangle = \langle \psi | \hat{A} | \sum_k c_k |k\rangle = \sum_k a_k c_k \langle \psi | k \rangle = \sum_k a_k |c_k|^2 \ , \quad (23.55)$$

with $\langle \psi | \psi \rangle = \sum_k |a_k|^2 = 1$. Therefore, we can understand $|\langle k | \psi \rangle|^2$ as the probability of the system to be in the eigenstate $|k\rangle$. In other words, this first step of the measurement process removes in an irreversible manner all coherences from the observable, $\hat{A} \curvearrowright \sum_k |k\rangle\langle k|\hat{A}|k\rangle\langle k|$.

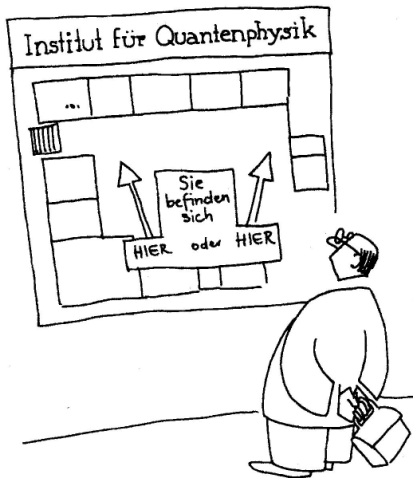

Figure 23.2: Superposition.

In a second step, the observing scientist will *read* the measuring device and note the result, which will necessarily be one of the possible a_k,

$$\langle \hat{A} \rangle \quad \curvearrowright \quad a_k \ . \quad (23.56)$$

If the state is stationary, it will never change any more. That is, each subsequent measurement will yield the same result. The Exc. 23.2.9.3 illustrates the process of

[10] For simplicity, we only consider pure state, here.

[11] To understand the meaning of *compatible*, we must establish a more complete theory of measurement including the reservoir in the quantum description.

quantum measurement at the example of a measurement of the excitation energy of a two-level atom.

23.2.8 Stationary Schrödinger equation

The general form of the Schrödinger equation in one dimension is,

$$\hat{H}\Psi(t,x) = \imath\hbar\frac{\partial}{\partial t}\Psi(t,x) \ , \tag{23.57}$$

with $\hat{H} \equiv \frac{\hat{p}^2}{2m} + V(x,t)$ and $\hat{p} \equiv -\imath\hbar\frac{\partial}{\partial x}$. If the potential is independent of time, $V(x,t) = V(x)$, we can do the following ansatz, $\Psi(x,t) \equiv \psi(x)f(t)$. Insertion into the Schrödinger equation yields,

$$\frac{1}{\psi(x)}\left(-\frac{\hbar^2}{2m}\frac{d^2}{dx^2} + V(x)\right)\psi(x) = \frac{\imath\hbar}{f(t)}\frac{d}{dt}f(t) = const. \equiv E \ . \tag{23.58}$$

The solution of the right-hand side of the equation is $\imath\hbar(\ln f - \ln f_0) = E(t - t_0)$. Hence,

$$f(t) = f(0)e^{-\imath E(t-t_0)/\hbar} \ . \tag{23.59}$$

Obviously, $|\Psi(x,t)|^2 = |\psi(x)|^2$.

Now, we can see that the stationary Schrödinger equation,

$$\hat{H}\psi(x) = E\psi(x) \ , \tag{23.60}$$

is nothing more than an eigenvalue equation. This means that the Schrödinger wave mechanics is equivalent to the mechanics of the Heisenberg matrices. The Excs. 23.2.9.4 and 23.2.9.5 are first simple calculations of the eigenvalues and eigenvectors of a two-level system.

23.2.9 Exercises

23.2.9.1 Ex: Reality of eigenvalues

Show that the eigenvalues of an observable are real.

Solution:

$$a_\psi = \langle\psi|\hat{A}|\psi\rangle = \langle\psi|\hat{A}^\dagger|\psi\rangle = (\langle\psi|\hat{A}|\psi\rangle)^* = a_\psi^* \ .$$

23.2.9.2 Ex: Normalization of the Bloch vector

Calculate the expectation value of the length of the Pauli vector and the length of the Bloch vector (23.49).

Solution: *With* $|\psi\rangle = a_1|1\rangle + a_2|2\rangle$ *the expectation value of the length of the Pauli vector is,*

$$\langle\hat{\vec{\sigma}}^\dagger\hat{\vec{\sigma}}\rangle = \langle\psi|\hat{\sigma}_x^2 + \hat{\sigma}_y^2 + \hat{\sigma}_z^2|\psi\rangle = 3\langle\psi|\mathbb{I}_2|\psi\rangle = 3 \ .$$

In contrast, the expectation value of the length of the Bloch vector is,

$$\begin{aligned}\vec{\rho}^{\dagger}\vec{\rho} &= \langle\psi|\hat{\sigma}_x|\psi\rangle^2 + \langle\psi|\hat{\sigma}_y|\psi\rangle^2 + \langle\psi|\hat{\sigma}_z|\psi\rangle^2 \\ &= (a_1^* a_2 + a_1 a_2^*)^2 - (a_1^* a_2 - a_1 a_2^*)^2 + (a_1^* a_1 - a_2^* a_2)^2 = |a_1|^2 + |a_2|^2 = 1 \ .\end{aligned}$$

23.2.9.3 Ex: Quantum measurement

Explain the idea of quantum measurement at the example of a measurement of the excitation energy of a two-level atom.

Solution: *With the general wavefunction* $|\psi(t)\rangle \equiv c_1(t)|1\rangle + c_2(t)|2\rangle$*, we obtain*

$$\langle\psi|\hat{H}|\psi\rangle = |c_1|^2 E_1 + |c_2|^2 E_2 \ .$$

Normalization requires $\langle\psi|\psi\rangle = |c_1|^2 + |c_2|^2 = 1$*. The measuring apparatus will give the result* E_1 *with the probability* $|c_1|^2$ *and the result* E_2 *with the probability* $|c_2|^2$*, even if in reality the system was in a superposition of the two states* [12]*.*

23.2.9.4 Ex: Two-level atom

Consider a two-level atom. The Hamiltonian is given by,

$$\hat{H} = \begin{pmatrix} 0 & 0 \\ 0 & \hbar\omega_0 \end{pmatrix} \ .$$

Using the stationary Schrödinger equation, calculate the eigenvalues and eigenvectors.

Solution: *The Hamiltonian has the eigenvalues,*

$$\det \begin{pmatrix} -E & 0 \\ 0 & \hbar\omega_0 - E \end{pmatrix} = -E(\hbar\omega_0 - E) = 0 \qquad \Longrightarrow \qquad E = 0, \hbar\omega_0 \ .$$

Solving the Schrödinger equation, $\hat{H}|\psi\rangle = E|\psi\rangle$*, we get the eigenvectors,*

$$\begin{pmatrix} 0 & 0 \\ 0 & \hbar\omega_0 \end{pmatrix} \begin{pmatrix} c_1 \\ c_2 \end{pmatrix} = 0 \begin{pmatrix} c_1 \\ c_2 \end{pmatrix} \Longrightarrow |1\rangle = \begin{pmatrix} 1 \\ 0 \end{pmatrix} \ ,$$

$$\begin{pmatrix} 0 & 0 \\ 0 & \hbar\omega_0 \end{pmatrix} \begin{pmatrix} c_1 \\ c_2 \end{pmatrix} = \hbar\omega_0 \begin{pmatrix} c_1 \\ c_2 \end{pmatrix} \Longrightarrow |2\rangle = \begin{pmatrix} 0 \\ 1 \end{pmatrix} \ .$$

[12] The quantum Monte Carlo wavefunction simulation method provides a useful picture of what happens in the process of projecting a wavefunction by a quantum measurement.

23.2.9.5 Ex: The ammonium molecule

Consider the two states $|1\rangle$ and $|2\rangle$ of the ammonium molecule outlined in the figure. Suppose they are orthonormal, $\langle i|j\rangle = \delta_{ij}$, and that only these two states are accessible to the system, so that we can describe it using the basis formed by $|1\rangle$ and $|2\rangle$. On this basis the Hamiltonian $\hat{H}$ of the system is given by,

$$\hat{H} = \begin{pmatrix} E_0 & -E_1 \\ -E_1 & E_0 \end{pmatrix} .$$

a. If the system is initially in state $|1\rangle$, will it remain in that state at a later time? How about if the initial state is $|2\rangle$?
b. Obtain the eigenvalues E_I and E_{II} and the respective eigenvectors $|I\rangle$ and $|II\rangle$ of $\hat{H}$, expressing them in terms of $|1\rangle$ and $|2\rangle$.
c. What is the probability of measuring an energy E_I in the following state,

$$|\psi\rangle = \tfrac{1}{\sqrt{5}}|1\rangle - \tfrac{2}{\sqrt{5}}|2\rangle \ ?$$

d. Based on the above result, we can predict at least one possible electromagnetic radiation emission frequency for an ammonia sample. What is this frequency?

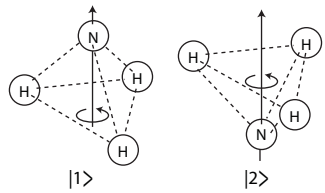

Figure 23.3: The two states of the ammonium molecule.

Solution: *a. No, because these states are not eigenstates of the Hamiltonian. The temporal evolution of the system mixes the two, and we have two specific combinations with well-defined energy, the eigenstates of $\hat{H}$. Starting in $|1\rangle$ or $|2\rangle$ we will be able to measure either one of the two possible energies depending of the time we wait, that is, $\langle 2|\hat{H}|1\rangle \neq 0$.*
b. We write

$$|1\rangle = \begin{pmatrix} 1 \\ 0 \end{pmatrix} \quad \textit{and} \quad |2\rangle = \begin{pmatrix} 0 \\ 1 \end{pmatrix} \quad \textit{and} \quad |\psi\rangle = \begin{pmatrix} c_1 \\ c_2 \end{pmatrix} .$$

With this,

$$0 = \hat{H}\begin{pmatrix} c_1 \\ c_2 \end{pmatrix} - \lambda \begin{pmatrix} c_1 \\ c_2 \end{pmatrix} = \begin{pmatrix} E_0 - \lambda - E_1 & \\ -E_1 & E_0 - \lambda \end{pmatrix} \begin{pmatrix} c_1 \\ c_2 \end{pmatrix} .$$

Hence,

$$\begin{vmatrix} E_0 - \lambda - E_1 & \\ -E_1 & E_0 - \lambda \end{vmatrix} = (E_0 - \lambda)^2 - E_1^2 = 0 \ ,$$

giving the eigenvalues

$$\lambda = E_{I,II} = E_0 \pm E_1 \ .$$

The eigenvectors follow from,

$$\hat{H}\begin{pmatrix} c_1 \\ c_2 \end{pmatrix} = E_I \begin{pmatrix} c_1 \\ c_2 \end{pmatrix} \Longrightarrow \begin{pmatrix} E_0 c_1 - E_1 c_2 \\ -E_1 c_1 + E_0 c_2 \end{pmatrix} = \begin{pmatrix} E_0 c_1 - E_1 c_1 \\ E_0 c_2 - E_1 c_2 \end{pmatrix} \Longrightarrow c_1 = c_2 \ .$$

Along with the normalization condition $\langle I|I\rangle = 1$ *this gives* $c_1 = c_2 = 1/\sqrt{2}$ *and*

$$|I\rangle = \tfrac{1}{\sqrt{2}}|1\rangle + \tfrac{1}{\sqrt{2}}|2\rangle \ .$$

Also,

$$\hat{H}\begin{pmatrix} c_1 \\ c_2 \end{pmatrix} = E_{II} \begin{pmatrix} c_1 \\ c_2 \end{pmatrix} \Longrightarrow \begin{pmatrix} E_0 c_1 - E_1 c_2 \\ -E_1 c_1 + E_0 c_2 \end{pmatrix} = \begin{pmatrix} E_0 c_1 + E_1 c_1 \\ E_0 c_2 + E_1 c_2 \end{pmatrix} \Longrightarrow c_1 = -c_2 \ .$$

Along with the normalization condition $\langle II|II\rangle = 1$ *this gives* $c_1 = -c_2 = 1/\sqrt{2}$ *and*

$$|II\rangle = \tfrac{1}{\sqrt{2}}|1\rangle - \tfrac{1}{\sqrt{2}}|2\rangle \ .$$

c. We calculate the superposition

$$\begin{aligned} P_{E_I} = |\langle I|\psi\rangle|^2 &= \left|\left(\tfrac{1}{\sqrt{2}}\langle 1| + \tfrac{1}{\sqrt{2}}\langle 2|\right)\left(\tfrac{1}{\sqrt{5}}|1\rangle - \tfrac{2}{\sqrt{5}}|2\rangle\right)\right|^2 \\ &= \left|\tfrac{1}{\sqrt{10}}\langle 1|1\rangle - \tfrac{2}{\sqrt{10}}\langle 2|2\rangle\right|^2 = \left|-\tfrac{1}{\sqrt{10}}\right|^2 = 10\% \ . \end{aligned}$$

d. The emission is due to the transition from E_{II} *to* E_I*, hence the emitted energy is:*

$$E_{II} - E_I = E_0 + E_1 - (E_0 - E_1) = 2E_1 \ .$$

Therefore the frequency of the emitted photons is $\nu = \frac{2E_1}{h}$.

23.3 Abstract formalism of quantum mechanics

The formal development of quantum mechanics will be the subject of this section. We will learn how to find a complete set of observables characterizing a system, discuss the role of symmetries in quantum mechanics and show how to switch between several representations of the same system.

23.3.1 Lie algebra

The quantum mechanical operators form a *Lie algebra* $\mathcal{L}^2$. This means that $\mathcal{L}^2$ is at the same time a complex and linear *vector space* with respect to addition and scalar multiplication and a *non-commutative ring* with scalar internal product. In

particular, $\mathcal{L}^2$ is unitary, normalized, and complete and acts on a *Hilbert space* of quantum states,

$$\begin{aligned}(\hat{A}+\hat{B})|\psi\rangle &= \hat{A}|\psi\rangle + \hat{B}|\psi\rangle, \\ (\alpha\hat{A})|\psi\rangle &= \alpha(\hat{A}|\psi\rangle)\ , \\ (\hat{A}\hat{B})|\psi\rangle &= \hat{A}(\hat{B}|\psi\rangle)\ .\end{aligned} \tag{23.61}$$

The properties of the Hilbert space are,

$$\begin{aligned}\hat{A}|\psi+\varphi\rangle &= \hat{A}|\psi\rangle + \hat{A}|\varphi\rangle\ , \\ \hat{A}|a\psi\rangle &= a\hat{A}|\psi\rangle\ .\end{aligned} \tag{23.62}$$

For a *Hermitian operator*, $\hat{A} = \hat{A}^\dagger$, we have $\langle\psi|\hat{A}|\psi\rangle = \langle\hat{A}\psi|\psi\rangle$ or $\langle\hat{A}\rangle \equiv \langle\psi|\hat{A}|\psi\rangle = \langle\hat{A}\rangle^*$, using the Dirac bra-ket notation,

$$\langle\psi|^\dagger \equiv |\psi\rangle\ . \tag{23.63}$$

There are identity and nullity operators,

$$\hat{1}|\psi\rangle = |\psi\rangle \qquad \text{and} \qquad \hat{0}|\psi\rangle = 0\ . \tag{23.64}$$

We define the *(anti-)commutator* as,

$$[\hat{A},\hat{B}]_\mp \equiv \hat{A}\hat{B} \pm \hat{B}\hat{A}\ , \tag{23.65}$$

which can be $\neq 0$. The sum of two Hermitian operators is Hermitian, but the product is not, since,

$$(\hat{A}+\hat{B})^\dagger = \hat{A}^\dagger + \hat{B}^\dagger = \hat{A}+\hat{B} \qquad \text{but} \qquad (\hat{A}\hat{B})^\dagger = \hat{B}^\dagger\hat{A}^\dagger = \hat{B}\hat{A} \neq \hat{A}\hat{B}\ . \tag{23.66}$$

On the other hand, the following relations of Hermitian operators are always Hermitian,

$$\hat{A}\hat{B} + \hat{B}\hat{A} \qquad \text{and} \qquad \imath(\hat{A}\hat{B} - \hat{B}\hat{A})\ . \tag{23.67}$$

We define the *scalar product* as,

$$\langle\psi|\varphi\rangle\ . \tag{23.68}$$

Two states are called *orthogonal*, if $\langle\psi|\varphi\rangle = 0$. The norm is written as,

$$|\psi|^2 = \langle\psi|\psi\rangle\ , \tag{23.69}$$

the deviation is,

$$\Delta A \equiv \sqrt{\langle\hat{A}^2\rangle - \langle\hat{A}\rangle^2}\ . \tag{23.70}$$

A *unitary operator* is defined by $\hat{A}^{-1} = \hat{A}^\dagger$.

23.3.2 Complete bases

If it is impossible to find a set of amplitudes c_n,

$$\nexists\{c_n\} \quad \text{such that} \quad \sum_n c_n|n\rangle = 0 \ , \tag{23.71}$$

the functions are called *linearly independent*. A set of linearly independent functions may form a *basis*. The space opened by a set of linearly independent functions is called *Hilbert space*.

An operator $\hat{A}$ is completely characterized by its *eigenvalues* and *eigenfunctions*. If a set of eigenfunctions $|n\rangle$ is *complete*, every allowed state of the system can be expanded in these eigenfunctions,

$$|\psi\rangle = \sum_n c_n|n\rangle \qquad \text{and} \qquad \hat{A}|n\rangle = a_n|n\rangle \ . \tag{23.72}$$

To calculate properties of a specific system, we often want to find a matrix representation for the operator $\hat{A}$. For this, we solve the stationary Schrödinger equation, that is, we calculate the eigenvalues and *eigenvectors*. When all eigenvalues are different, $a_n \neq a_m$, we know that the corresponding eigenvectors are orthogonal, $\langle n|m\rangle = 0$,

$$\begin{aligned} &\hat{A}|n\rangle = a_n|n\rangle \quad , \quad \hat{A}|m\rangle = a_n|m\rangle \quad , \quad \forall\{n,m\}\ a_n \neq a_m \\ \Longrightarrow\ &\forall\{n,m\}\ \langle n|m\rangle = \delta_{m,n} \ . \end{aligned} \tag{23.73}$$

Exc. 23.3.10.1 asks for demonstrating this.

Frequently, for example, in the case of a particle confined to a potential, there exist discrete eigenvalues (for $E < 0$) simultaneously with continuous eigenvalues (for $E > 0$). Assuming $\langle m|m'\rangle = \delta_{m,m'}$, $\langle m|\mathbf{k}\rangle = 0$ and $\langle \mathbf{k}|\mathbf{k'}\rangle = \delta^{(3)}(\mathbf{k}-\mathbf{k'})$, with a complete base,

$$\sum_m |m\rangle\langle m| + \int d^3k|\mathbf{k}\rangle\langle\mathbf{k}| = \hat{\mathbf{1}} \ , \tag{23.74}$$

an arbitrary vector can be expanded on an orthogonal basis,

$$|\psi\rangle = \sum_m |m\rangle\langle m|\psi\rangle + \int d^3k\ |\mathbf{k}\rangle\langle\mathbf{k}|\psi\rangle \ . \tag{23.75}$$

This also applies to observables,

$$\hat{A} = \sum_{m,n} |m\rangle\langle m|\hat{A}|n\rangle\langle n| + \int d^3k d^3l\ |\mathbf{k}\rangle\langle\mathbf{k}|\hat{A}|\mathbf{l}\rangle\langle\mathbf{l}| \ , \tag{23.76}$$

and functions of observables,

$$f(\hat{A}) = \sum_{m,n} |m\rangle f(\langle m|\hat{A}|n\rangle)\langle n| + \int d^3k d^3l\ |\mathbf{k}\rangle f(\langle\mathbf{k}|\hat{A}|\mathbf{l}\rangle)\langle\mathbf{l}| \ . \tag{23.77}$$

23.3.3 Degeneracy

The eigenvectors form a natural basis for the Hilbert space. However, a problem arises in the case of *degeneracy*, that is, when some eigenvalues are equal, $a_n = a_m$. In this case, the eigenvectors that correspond to degenerate eigenvalues are not completely defined, and we have to construct a basis verifying that all constructed eigenvectors are orthogonal. For this, there exists the method of *orthogonalization by Schmidt*, which works like this: We assume that we have already solved the eigenvalue equation, that we found a degenerate eigenvalue, $\hat{A}|a_k\rangle = a|a_k\rangle$ for every $k = 1, .., g_k$, where g_k is the degree of degeneracy, and that we also found a complete basis of eigenvalues $|a_m\rangle$, but which is not orthogonal, that is, $\exists\{m, n\}$ with $\langle a_n|a_m\rangle \neq 0$. The task is to build another basis $|b_m\rangle$ satisfying $\langle b_n|b_m\rangle = \delta_{n,m}$.

The first vector of the orthogonal base can be chosen freely, e.g.,

$$|b_1\rangle \equiv |a_1\rangle \ . \tag{23.78}$$

Since the basis $\{|a_k\rangle\}$ is assumed to be complete, the second vector is necessarily a linear combination of vectors $|a_k\rangle$, that is, $|b_2\rangle = |a_2\rangle + \lambda|b_1\rangle$. With the condition $\langle b_1|b_2\rangle = 0 = \langle b_1|a_2\rangle + \lambda\langle b_1|b_1\rangle$ we can determine the parameter λ, and obtain for the second vector,

$$|b_2\rangle \equiv |a_2\rangle - |b_1\rangle \frac{\langle b_1|a_2\rangle}{\langle b_1|b_1\rangle} \ . \tag{23.79}$$

In the same way, we can derive for a third vector, $|b_3\rangle = |a_3\rangle + \mu|b_1\rangle + \nu|b_2\rangle$, the conditions, $\langle b_1|b_3\rangle = 0 = \langle b_1|a_3\rangle + \mu\langle b_1|b_1\rangle$ and $\langle b_2|b_3\rangle = 0 = \langle b_2|a_3\rangle + \nu\langle b_2|b_2\rangle$, and obtain,

$$|b_3\rangle \equiv |a_3\rangle - |b_1\rangle \frac{\langle b_1|a_3\rangle}{\langle b_1|b_1\rangle} - |b_2\rangle \frac{\langle b_2|a_3\rangle}{\langle b_2|b_2\rangle} \ . \tag{23.80}$$

An overall way of writing this down is,

$$|b_k\rangle \equiv \left(1 - \frac{|b_1\rangle\langle b_1|}{\langle b_1|b_1\rangle} - \frac{|b_2\rangle\langle b_2|}{\langle b_2|b_2\rangle} - ... - \frac{|b_{k-1}\rangle\langle b_{k-1}|}{\langle b_{k-1}|b_{k-1}\rangle}\right)|a_k\rangle \ . \tag{23.81}$$

In the Exc. 23.3.10.2 we practice the orthogonalization of a set of three linearly independent but non-orthogonal vectors, and in the Exc. 23.3.10.3 we find an orthogonal basis for a partially degenerate three-level system.

23.3.4 Bases as unitary operators

One way to formulate the eigenvalue problem is as follows: Let $|n\rangle$ be an orthonormal basis with the respective eigenvalues a_n of an operator $\hat{A}$:

$$\hat{A}|n\rangle = a_n|n\rangle \qquad \text{with} \qquad \langle n|m\rangle = \delta_{mn} \ . \tag{23.82}$$

We construct the matrices,

$$U \equiv \begin{pmatrix} |1\rangle & |2\rangle & \cdots \end{pmatrix} \qquad \text{and} \qquad \hat{E} \equiv \begin{pmatrix} a_1 & 0 & \cdots \\ 0 & a_2 & \\ \vdots & & \ddots \end{pmatrix} \ . \tag{23.83}$$

With the definition of $U^\dagger$ we have,

$$U^\dagger = \begin{pmatrix} \langle 1| \\ \langle 2| \\ \vdots \end{pmatrix} \quad \text{and} \quad U^\dagger U = \begin{pmatrix} \langle 1|1\rangle & \langle 1|2\rangle & \cdots \\ \langle 2|1\rangle & \langle 2|2\rangle & \cdots \\ \vdots & \vdots & \ddots \end{pmatrix} = \hat{\mathbf{1}} \, . \tag{23.84}$$

Therefore,

$$\begin{aligned} U^\dagger U = \hat{\mathbf{1}} \quad &\Longrightarrow \quad U^\dagger U U^{-1} = \hat{1} U^{-1} \quad \Longrightarrow \quad U^\dagger = U^{-1} \\ U^\dagger U = \hat{\mathbf{1}} \quad &\Longrightarrow \quad U U^\dagger U U^{-1} = U \hat{1} U^{-1} \quad \Longrightarrow \quad U U^\dagger = \hat{\mathbf{1}} \, . \end{aligned} \tag{23.85}$$

Also,

$$\hat{A}|n\rangle = \hat{E}|n\rangle \quad \text{and} \quad \hat{A}U = U\hat{E} \, . \tag{23.86}$$

That is, by knowing the unitary matrix (or *transformation matrix*) U, we can solve the eigenvalue problem simply by $\hat{E} = U^{-1}\hat{A}U$.

Note, that this does not apply to a non-orthonormal basis. In this case, we need to do a Schmidt orthogonalization and use the condition $\det U = 1$. We apply the technique detailed in this section to solve Excs. 23.3.10.4, 23.3.10.5, and 23.3.10.6.

23.3.5 Complete set of commuting operators

Even for simple systems, we can ask various types of questions (measurements). Considering, for example, a particle flying freely in space, we can gather its position or its velocity. Let a be the result of a measurement of the observable $\hat{A}$, that is, $a = \langle\psi_a|\hat{A}|\psi_a\rangle$. Due to the measurement we know that the system is in the state $|\psi_a\rangle$. Immediately after this first measurement we perform another measurement of *another* observable $\hat{B}$ giving $\langle\psi_a|\hat{B}|\psi_a\rangle$. The result of this measurement can only yield an eigenstate, $b = \langle\psi_a|\hat{B}|\psi_a\rangle$, if the operators commute, $[\hat{A}, \hat{B}] = 0$. That is, *if two operators $\hat{A}$ and $\hat{B}$ commute, and if $|\psi\rangle$ is an eigenvector of $\hat{A}$, then $\hat{B}|\psi\rangle$ is also an eigenvector of $\hat{A}$ with the same eigenvalue*:

$$\begin{aligned} &[\hat{A}, \hat{B}] = 0 \quad , \quad a = \langle\psi|\hat{A}|\psi\rangle \\ \Longrightarrow \; &\hat{A}(\hat{B}|\psi\rangle) = a(\hat{B}|\psi\rangle) \quad \text{and} \quad \langle\psi|\hat{B}|\psi\rangle \in \mathbb{R} \, . \end{aligned} \tag{23.87}$$

In addition, we observe that, if two operators commute, the orthonormal basis constructed for one of the operators is also orthonormal for the other. That is, *if two operators $\hat{A}$ and $\hat{B}$ commute and if $|\psi_1\rangle$ and $|\psi_2\rangle$ are two eigenvectors of $\hat{A}$ with different eigenvalues, then the matrix element $\langle\psi_1|\hat{B}|\psi_2\rangle$ is equal to zero:*

$$\begin{aligned} &[\hat{A}, \hat{B}] = 0 \quad , \quad a_1 = \langle\psi_1|\hat{A}|\psi_1\rangle \neq \langle\psi_2|\hat{A}|\psi_2\rangle = a_2 \\ \Longrightarrow \; &\langle\psi_1|\hat{B}|\psi_2\rangle = 0 \, . \end{aligned} \tag{23.88}$$

Finally, we affirm that, *if two operators $\hat{A}$ and $\hat{B}$ commute, we can construct an orthonormal basis $\{|\psi_{a,b}\rangle\}$ with common eigenvectors of $\hat{A}$ and $\hat{B}$*:

$$\begin{aligned} &[\hat{A}, \hat{B}] = 0 \\ \Longrightarrow \; &\exists \, \{|\psi_{a,b}\rangle\} \quad \text{tal que} \quad \hat{A}|\psi_{a,b}\rangle = a|\psi_{a,b}\rangle \quad \text{and} \quad \hat{B}|\psi_{a,b}\rangle = b|\psi_{a,b}\rangle \, . \end{aligned} \tag{23.89}$$

The statements (23.87) to (23.89) are verified in Exc. 23.3.10.7.

The fact that commuting operators have a common system of eigenvectors authorizing sharp eigenvalues can be used to construct and characterize a state.

Example 143 (*Measuring momenta in orthogonal directions*): For example, the obvious solutions of the eigenvalue equations,

$$\hat{p}_x|\psi_{p_x}\rangle = \frac{\hbar}{\imath}\frac{d}{dx}|\psi_{p_x}\rangle = p_x|\psi_{p_x}\rangle \qquad \text{and} \qquad \hat{p}_y|\psi_{p_y}\rangle = \frac{\hbar}{\imath}\frac{d}{dy}|\psi_{p_y}\rangle = p_y|\psi_{p_y}\rangle$$

are the plane waves $e^{\imath p_x x/\hbar}$ and $e^{\imath p_y y/\hbar}$. Therefore, the total state of the particle can be described by,

$$|\psi_{p_x,p_y,p_z}\rangle = |\psi_{p_x}\rangle|\psi_{p_y}\rangle = e^{(\imath/\hbar)(p_x x+p_y y)} f(z) \ .$$

However, these eigenfunctions are infinitely degenerate, since the linear momentum in z-direction is not specified. A third operator $\hat{p}_z|\psi\rangle = p_z|\psi\rangle$ commutes with the others,

$$[\hat{p}_k, \hat{p}_m] = 0 \ .$$

Hence,

$$|\psi_{p_x,p_y,p_z}\rangle = e^{(\imath/\hbar)(p_x x+p_y y+p_z z)} \ ,$$

is a possible state of the system.
On the other hand, choosing $\hat{p}_z^2 = -\hbar^2\frac{\partial^2}{\partial z^2}$ as the third operator, giving the eigenvalues p_z^2, the state would have been,

$$|\psi_{p_x,p_y,p_z^2}\rangle = e^{(\imath/\hbar)(p_x x+p_y y)}\cos\tfrac{p_z z}{\hbar} \qquad \text{or} \qquad |\psi_{p_x,p_y,p_z^2}\rangle = e^{(\imath/\hbar)(p_x x+p_y y)}\sin\tfrac{p_z z}{\hbar} \ . \tag{23.90}$$

Therefore, there are two solutions with the same eigenvalues, p_x, p_y, p_z^2. To lift this degeneracy, we need to introduce yet another observable. This observable can be, for example, the *parity* $\hat{P}$, that is, the behavior of the wave function upon mirroring $z \longrightarrow -z$ in the x-y plane. The fact that the set of operators p_x, p_y, p_z on one hand and p_x, p_y, p_z^2, $\hat{P}$ on the other are equivalent, shows that the required number of observables for a complete characterization depends on their judicious choice.

Also, the number needed for a *complete set of commuting operators* (*CSCO*) depends on the number of *degrees of freedom* and the symmetry of the system. In the case of the free particle in one dimension it is enough to consider one observable only, for example, $\hat{x}$ or $\hat{p}$. In three dimensions, we already need at least three commuting observables. In Exc. 23.3.10.8 we will try to find a CSCO for a matrix with partially degenerate eigenvalues.

23.3.6 Uncertainty relation

We have already learned that observables that do not commute can not be measured with arbitrary precision. This principle can be quantified as follows: If $\hat{A}$ and $\hat{B}$ are two observables, then,

$$\boxed{\Delta\hat{A}\Delta\hat{B} \geq \tfrac{1}{2}|\langle[\hat{A},\hat{B}]\rangle|} \ . \tag{23.91}$$

This is Heisenberg's famous *uncertainty principle*. For example, $[\hat{p},\hat{x}] = -\imath\hbar$, and hence, $\Delta p\Delta x \geq \hbar/2$. We will see later (see Sec. 25.3.1), that $[\hat{l}_x,\hat{l}_y] = \imath\hbar\hat{l}_z$ such that $\Delta l_x \Delta l_y \geq \hbar|\langle l_z\rangle|/2$. More difficult to show, since time has no simple quantum operator, is $\Delta E\Delta t \geq \hbar/2$. In the Exc. 23.3.10.9 we will show the *Schwartz inequality*, and in the Exc. 23.3.10.10 we ask for a formal derivation of Heisenberg's uncertainty principle.

23.3.7 Representations

23.3.7.1 Spatial representation

A Hilbert space can be discrete or, as in the case of the momentum of a free particle, continuous. In this latter case, the eigenvalues are continuously distributed, since the equation,

$$-\imath\hbar\nabla_{\mathbf{r}}\psi(\mathbf{r}) = \mathbf{p}\psi(\mathbf{r}) \ , \tag{23.92}$$

has solutions for each value of E. The eigenfunctions are $\psi(\mathbf{r}) = ae^{\imath\mathbf{p}\cdot\mathbf{r}/\hbar}$. Eq. (23.92) clearly has the form of an eigenvalue equation, for which we have already introduced the Heisenberg matrix formalism. The question now is how these descriptions combine.

Observables that do not commute correspond to expansions on different bases and generate alternative representations. For example, we can represent quantum mechanics in *position space* or *linear momentum space*. If $|\mathbf{r}\rangle$ is a basis of the space of the particles' state,

$$\hat{\mathbf{r}}|\mathbf{r}\rangle = \mathbf{r}|\mathbf{r}\rangle \quad , \quad \langle\mathbf{r}'|\mathbf{r}\rangle = \delta^3(\mathbf{r}'-\mathbf{r}) \quad , \quad \int_{\mathbb{R}^3}|\mathbf{r}\rangle\langle\mathbf{r}|d^3r = \hat{\mathbf{1}} \ , \tag{23.93}$$

we can expand the position operator on a position basis as,

$$\hat{\mathbf{r}} = \int_{\mathbb{R}^3}\mathbf{r}|\mathbf{r}\rangle\langle\mathbf{r}|d^3r \ , \tag{23.94}$$

and any state vector as,

$$\boxed{|\psi(t)\rangle = \int_{\mathbb{R}^3}|\mathbf{r}\rangle\psi(t,\mathbf{r})d^3r} \ . \tag{23.95}$$

The quantities $\langle\mathbf{r}|\psi(t)\rangle = \psi(t,\mathbf{r})$ Schrödinger wave functions. We can also say that the wavefunctions are the coordinates of the state in the particular base $|\mathbf{r}\rangle$. Consequently,

$$\begin{aligned}\langle\mathbf{r}|\hat{\mathbf{r}}|\mathbf{r}'\rangle &= \mathbf{r}\delta^3(\mathbf{r}-\mathbf{r}') \\ \langle\mathbf{r}|f(\hat{\mathbf{r}})|\mathbf{r}'\rangle &= f(\mathbf{r})\delta^3(\mathbf{r}-\mathbf{r}') \ .\end{aligned} \tag{23.96}$$

It is also true that,

$$\boxed{\langle\mathbf{r}|\hat{A}|\psi(t)\rangle = \int_{\mathbb{R}^3}A(\mathbf{r},\mathbf{r}')\psi(t,\mathbf{r}')d^3r'} \ , \tag{23.97}$$

where the quantity $A(\mathbf{r},\mathbf{r}') \equiv \langle\mathbf{r}|\hat{A}|\mathbf{r}'\rangle$ is called *kernel* of the operator. The transition from Heisenberg's abstract mechanics to Schrödinger's wave mechanics is done by the substitutions $|\psi(t)\rangle \to \psi(t,\mathbf{r})$ and $\hat{A} \to A(\mathbf{r},\mathbf{r}')$.

23.3.7.2 Momentum representation

The uncertainty relation is symmetric in $\hat{\mathbf{r}}$ and $\hat{\mathbf{p}}$. Nothing prevents us from choosing as a basis,

$$\hat{\mathbf{p}}|\mathbf{p}\rangle = \mathbf{p}|\mathbf{p}\rangle \quad , \quad \langle\mathbf{p}'|\mathbf{p}\rangle = \delta^3(\mathbf{p}'-\mathbf{p}) \quad , \quad \int_{\mathbb{R}^3} |\mathbf{p}\rangle\langle\mathbf{p}|d^3p = \hat{\mathbf{1}} \ , \tag{23.98}$$

in which we can expand the momentum operator on a momentum basis as,

$$\hat{\mathbf{p}} = \int_{\mathbb{R}^3} \mathbf{p}|\mathbf{p}\rangle\langle\mathbf{p}|d^3p \ , \tag{23.99}$$

with the wavefunctions,

$$\boxed{|\psi(t)\rangle = \int_{R^3} |\mathbf{p}\rangle\varphi(\mathbf{p},t)d^3p} \ , \tag{23.100}$$

where $\langle\mathbf{p}|\psi(t)\rangle = \varphi(t,\mathbf{p})$. The formulas are analogous to the ones in the spatial representation. In particular, in the momentum representation the position operator is $\mathbf{r} = \imath\hbar\nabla_{\mathbf{p}}$.

The representations follow from one another by Fourier transformation. Since $-\imath\hbar\nabla_{\mathbf{r}}\langle\mathbf{r}|\mathbf{p}\rangle = \mathbf{p}\langle\mathbf{r}|\mathbf{p}\rangle$, we know,

$$\boxed{\langle\mathbf{r}|\mathbf{p}\rangle = \tfrac{1}{\hbar^{3/2}}\exp(\tfrac{\imath}{\hbar}\mathbf{r}\cdot\mathbf{p})} \ , \tag{23.101}$$

where the prefactor $\hbar^{-3/2}$ is introduced to take account of the unit of the states [13]. ψ and φ are different representations of the same quantum state related by,

$$\langle\mathbf{r}|\psi(t)\rangle = \int_{\mathbb{R}^3} \langle\mathbf{r}|\mathbf{p}\rangle\langle\mathbf{p}|\psi(t)\rangle d^3p = \tfrac{1}{h^{3/2}}\int_{\mathbb{R}^3} e^{\imath\mathbf{r}\cdot\mathbf{p}/\hbar}\varphi(\mathbf{p},t)d^3p = \psi(\mathbf{r},t) \tag{23.102}$$

$$\langle\mathbf{p}|\psi(t)\rangle = \int_{\mathbb{R}^3} \langle\mathbf{p}|\mathbf{r}\rangle\langle\mathbf{r}|\psi(t)\rangle d^3r = \tfrac{1}{h^{3/2}}\int_{\mathbb{R}^3} e^{-\imath\mathbf{r}\cdot\mathbf{p}/\hbar}\psi(\mathbf{r},t)d^3r = \varphi(\mathbf{p},t) \ .$$

Normalization ensures that $\psi = \mathcal{F}^{-1}\mathcal{F}\psi$ with the relation,

$$\delta(x) = \lim_{t\to\infty}\tfrac{1}{2\pi}\int_{-t}^{t} e^{\imath kx}dk \ . \tag{23.103}$$

Using the wavevector $\hbar\mathbf{k} = \mathbf{p}$ we can also write,

$$\psi(\mathbf{r}) = \tfrac{1}{(2\pi)^{3/2}}\int_{\mathbb{R}^3} e^{\imath\mathbf{r}\cdot\mathbf{k}}\tilde{\varphi}(\mathbf{k})d^3k \quad \text{and} \quad \tilde{\varphi}(\mathbf{k}) = \tfrac{1}{(2\pi)^{3/2}}\int_{\mathbb{R}^3} e^{-\imath\mathbf{r}\cdot\mathbf{k}}\psi(\mathbf{r})d^3r \ , \tag{23.104}$$

defining the function $\tilde{\varphi}(\mathbf{k}) \equiv \hbar^{3/2}\varphi(\mathbf{p})$. Applying the Fourier transform to functions of operator we can calculate,

$$\begin{aligned}\langle\mathbf{r}|G(\hat{\mathbf{p}})|\mathbf{r}'\rangle &= \int d^3p\langle\mathbf{r}|G(\hat{\mathbf{p}})|\mathbf{p}\rangle\langle\mathbf{p}|\mathbf{r}'\rangle = \int d^3pG(\mathbf{p})\langle\mathbf{r}|\mathbf{p}\rangle\langle\mathbf{p}|\mathbf{r}'\rangle \\ &= \tfrac{1}{\hbar^{3/2}}\int d^3pG(\mathbf{p})e^{\imath\mathbf{k}\cdot(\mathbf{r}-\mathbf{r}')} = \tfrac{1}{\hbar^3}(\mathcal{F}G)(\mathbf{r}-\mathbf{r}') \ .\end{aligned} \tag{23.105}$$

[13] Note that the units of the wavefunctions are defined by normalization: $\langle\mathbf{r}'|\mathbf{r}\rangle = \delta^3(\mathbf{r}-\mathbf{r}')$. Introducing the parenthesis [...] to extract the unit of a physical quantity, we find, $[|\mathbf{r}\rangle] = [\psi(\mathbf{r})] = [r^{-3/2}]$ and $[|\mathbf{p}\rangle] = [\varphi(\mathbf{p})] = [p^{-3/2}]$. We do not assign a unit to the abstract state $|\psi\rangle$, that is, $[|\psi\rangle] = 1$.

In Exc. 23.3.10.11 we will show $\langle \mathbf{r}|\hat{\mathbf{p}}|\psi\rangle = (\hbar/\imath)\nabla_{\mathbf{r}}\langle \mathbf{r}|\psi\rangle$, thus justifying that we can understand an operator as a rule to determine what happens to a function. For example, the rule $\hat{p}_x$ asks for a derivation of the wavefunction by x.

23.3.8 Quasi-classical approximation (WKB)

We can express the correspondence between classical and quantum mechanics by the following analogy between (i) the density matrices and observables depending on (ii) discrete variables and (iii) continuous variables,

$$\begin{array}{rclcrcl} \varrho(p,q) & = & \frac{1}{I}\sum_{i=1}^{I}\delta(p-p_i)\delta(q-q_i) & \text{(i)} & \hat{\varrho} & = & \frac{1}{I}\sum_{i=1}^{I}|p_iq_i\rangle\langle q_ip_i| \\ \langle A\rangle(p,q) & = & \frac{1}{I}\sum_{i=1}^{I}A(p_i,q_i) & \text{(ii)} & \langle\hat{A}\rangle & = & \frac{1}{I}\sum_{i=1}^{I}\langle p_iq_i|\hat{A}|q_ip_i\rangle \\ \Rightarrow \langle A\rangle(p,q) & = & \int A(p,q)\varrho(p,q)dpdq & \text{(iii)} & \langle\hat{A}\rangle & = & \sum_{i=1}^{I}\langle p_iq_i|\hat{\varrho}\hat{A}|q_ip_i\rangle \end{array} . \tag{23.106}$$

The objective is to bring this analogy to the point of assigning to the quantum functions $\hat{A}$ unequivocally corresponding classical functions $A(p,q)$ satisfying classical formula. We achieve this by,

$$\boxed{A(p,q) \equiv \langle p|\hat{A}|q\rangle\langle q|p\rangle \qquad \text{that is} \qquad \hat{A} \equiv \int |p\rangle\langle p|A(p,\hat{q})dp = \int A(\hat{p},q)|q\rangle\langle q|dp} \, , \tag{23.107}$$

with the normalization,

$$\langle q|q'\rangle = h^{I/2}\delta(q-q') \qquad \text{and} \qquad \langle p|p'\rangle = h^{I/2}\delta(p-p') \tag{23.108}$$
$$\text{as well as} \qquad \langle p|q\rangle = h^{-I/2}e^{ipq/\hbar} \qquad \text{and} \qquad \int |q\rangle\langle q|dq = \mathbb{I} = \int |p\rangle\langle p|dp \, ,$$

with $p,q \in \mathbb{R}^I$ and $|p\rangle = |p_1\rangle|p_2\rangle..|p_I\rangle$. We obtain for classical distributions for position and momentum,

$$\int \varrho(p,q)dpdq = 1 \tag{23.109}$$
$$\int \varrho(p,q)dp = \langle q|\hat{\varrho}|q\rangle = w(q) = \frac{1}{I}\sum_{i=1}^{I}\langle\delta(\hat{q}-q_i)$$
$$\int \varrho(p,q)dq = \langle p|\hat{\varrho}|p\rangle = w(p) = \frac{1}{I}\sum_{i=1}^{I}\langle\delta(\hat{p}-p_i) \, .$$

Now we expand the commutator $[\hat{A},\hat{B}]$ in powers of $\hbar$:

$$\begin{aligned}(AB)(p,q) &= \langle p|\hat{A}\hat{B}|q\rangle\langle q|p\rangle \\ &= \langle p|\int |p'\rangle\langle p'|A(p',\hat{q})dp'\int B(\hat{p},q')|q'\rangle\langle q'|dq'|q\rangle\langle q|p\rangle = \langle p|A(p,\hat{q})B(\hat{p},q)\langle q|p\rangle \, .\end{aligned} \tag{23.110}$$

We expand,

$$A(p,\hat{q}) = A|_q + \left.\frac{\partial A}{\partial q}\right|_q (\hat{q}-q) + ... + \frac{1}{n!}\frac{\partial^n A}{\partial q^n}(\hat{q}-q)^n + ... \tag{23.111}$$
$$B(\hat{p},q) = B|_p + \left.\frac{\partial B}{\partial p}\right|_p (\hat{p}-p) + ... + \frac{1}{m!}\frac{\partial^m B}{\partial p^m}(\hat{p}-p)^m + ... \ .$$

Now,

$$(AB)(p,q) = AB + A\frac{\partial B}{\partial p}\langle p|\hat{p}-p|q\rangle\langle q|p\rangle + \frac{\partial A}{\partial q}B\langle p|\hat{q}-q|q\rangle\langle q|p\rangle + ... \tag{23.112}$$
$$+ \frac{1}{m!n!}\frac{\partial^n A}{\partial q^n}\frac{\partial^m B}{\partial p^m}\langle p|(\hat{q}-q)^n(\hat{p}-p)^m|q\rangle\langle q|p\rangle + ... \ .$$

But now we have, $[(\hat{p}-p),(\hat{q}-q)] = [\hat{p},\hat{q}] = \hbar/\imath$ with the consequence,

$$[(\hat{p}-p),(\hat{q}-q)^n] = \frac{\hbar}{\imath}\frac{\partial(\hat{q}-q)^n}{\partial(\hat{q}-q)} = \frac{\hbar}{\imath}(\hat{q}-q)^{n-1}n \ . \tag{23.113}$$

Also,

$$[(\hat{q}-q)^n,(\hat{p}-p)^m] = (\hat{p}-p)[(\hat{q}-q)^n,(\hat{p}-p)^{m-1}]+[(\hat{q}-q)^n,(\hat{p}-p)](\hat{p}-p)^{m-1} \ . \tag{23.114}$$

Because of $\langle p|\hat{p}-p = 0$ all terms with $\hat{p}-p$ vanish,

$$(\hat{q}-q)^n(\hat{p}-p)^m = [(\hat{q}-q)^n,(\hat{p}-p)](\hat{p}-p)^{m-1} = \hbar\imath n(\hat{q}-q)^{n-1}(\hat{p}-p)^{m-1} \tag{23.115}$$
$$= \left\{ \begin{pmatrix} (\hbar\imath)^n n!(\hat{p}-p)^{m-n} & \text{for} & m \geq n \\ (\hbar\imath)^n m!(\hat{q}-q)^{n-m} & \text{for} & n \geq m \end{pmatrix} \right. = (\hbar\imath)^n n!\delta_{nm} \ .$$

Finally,

$$(AB)(p,q) = (\hbar\imath)^n n!\frac{\partial^n A}{\partial q^n}\frac{\partial^n B}{\partial p^n} \ . \tag{23.116}$$

23.3.9 Spanning a Hilbert space with several degrees of freedom

All systems analyzed up to this point were characterized by a single degree of freedom (e.g., energy, momentum, or angular momentum), which could have a continuous or discrete spectrum. Even when we treated systems exhibiting various degrees of freedom (motion of a particle in 3D space, electron orbitals in the hydrogen atom), we always found a way to separate the degrees of freedom into orthogonal Hilbert spaces, which allowed us to treat the dynamics of the degrees of freedom separately. In this chapter, we will establish the theoretical foundations allowing us to analyze systems, where degrees of freedom can not be separated because they are entangled or interact. In particular, we will consider the system of two spins and the coupling of angular momenta in general.

23.3.9.1 Projection and internal sum

A *projector* is an operator which *reduces* the domain of an operator, originally acting on a Hilbert space $\mathcal{H}$ to the *subspace* defined by the projector. We consider an operator $\hat{A}$ with the matrix representation,

$$\hat{A} \equiv \sum_{\substack{i,j \\ |i\rangle,|j\rangle\in\mathcal{H}}} |i\rangle A_{ij}\langle j| = \begin{pmatrix} & \vdots & \\ .. & A_{ij} & .. \\ & \vdots & \end{pmatrix} , \tag{23.117}$$

acting on wavefunctions $|\psi\rangle \in \mathcal{H}$ which can be expanded on a basis $|i\rangle$ of $\mathcal{H}$. Now, we consider a subspace $\mathcal{R} \subset \mathcal{H}$ defined by the base $|k\rangle$. Then the projector $\hat{P}_\mathcal{R}$ can be represented by,

$$\boxed{\hat{P}_\mathcal{R} \equiv \sum_{\substack{k \\ |k\rangle\in\mathcal{R}}} |k\rangle\langle k| = \begin{pmatrix} 0 & & 0 & & 0 \\ & 1 & & & \\ 0 & & .. & & 0 \\ & & & 1 & \\ 0 & & 0 & & 0 \end{pmatrix}} . \tag{23.118}$$

Applied to the operator $\hat{A}$,

$$\hat{A}_\mathcal{R} \equiv \hat{P}_\mathcal{R}\hat{A} = \hat{P}_\mathcal{R}\hat{A}_\mathcal{R} = \sum_{k,l} |k\rangle A_{kl}\langle l| = \begin{pmatrix} 0 & & 0 & & 0 \\ & & \vdots & & \\ 0 & .. & A_{kl} & .. & 0 \\ & & \vdots & & \\ 0 & & 0 & & 0 \end{pmatrix} . \tag{23.119}$$

Applied to a state $|i\rangle$,

$$|\psi\rangle_\mathcal{R} = \hat{P}_\mathcal{R}|\psi\rangle = \hat{P}_\mathcal{R}|\psi\rangle_\mathcal{R} = \sum_k c_k|k\rangle = \begin{pmatrix} 0 \\ \begin{pmatrix} \vdots \\ c_k \\ \vdots \end{pmatrix} \\ 0 \end{pmatrix} . \tag{23.120}$$

We study an example in the 23.3.10.12

Consequently, we can understand the Hilbert space as the sum of its subspaces,

$$\hat{A} = \bigoplus_\mathcal{R} \hat{A}_\mathcal{R} \qquad \text{and} \qquad \bigoplus_\mathcal{R} \hat{P}_\mathcal{R} = \mathbb{I} . \tag{23.121}$$

The dimensions of the subspaces are additive,

$$\dim \hat{A} = \sum_\mathcal{R} \dim \hat{A}_\mathcal{R} .$$

Example 144 (*Projection for a three-level atom*): The Hamiltonian of a three-level atom with excitation of two transitions is given by,

$$\hat{H} = \begin{pmatrix} \omega_1 & \Omega_{12} & 0 \\ \Omega_{12} & \omega_2 & \Omega_{23} \\ 0 & \Omega_{23} & \omega_3 \end{pmatrix} .$$

The projector,

$$\hat{P} = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \end{pmatrix}$$

reduces the Hamiltonian to a two-level transition,

$$\hat{H}_{\mathcal{R}} = \begin{pmatrix} \omega_1 & \Omega_{12} & 0 \\ \Omega_{12} & \omega_2 & 0 \\ 0 & 0 & 0 \end{pmatrix} .$$

Obviously, the concatenation (23.121) only serves to increase the Hilbert space of a given degree of freedom described by a given observable, e.g., when we add one more level of energy to the spectrum of an atom described by a Hamiltonian. If, in contrast, we want to add another degree of freedom, we need the external sum or external product discussed below.

23.3.9.2 Tensorial product

We have previously worked with systems exhibiting more than one degree of freedom and therefore having to be characterized by more than one observable with its spectrum of eigenstates. One example are the electronic orbitals of the hydrogen atom $|n\ell m\rangle$, which need three quantum numbers to be labeled unambiguously. Obviously, each quantum number increases the dimensionality of the Hilbert space. Another example is the system $|\alpha\beta\rangle$ of two particles with spin $\frac{1}{2}$, each spin being defined on its respective space,

$$|\alpha\rangle = \begin{pmatrix} \alpha_1 \\ \alpha_2 \end{pmatrix} = (\alpha_i)_i \in \mathcal{H}_A \qquad \text{and} \qquad |\beta\rangle = \begin{pmatrix} \beta_1 \\ \beta_2 \end{pmatrix} = (\beta_k)_k \in \mathcal{H}_B \ . \tag{23.122}$$

The combined state is,

$$|\alpha\beta\rangle \in \mathcal{H}_A \otimes \mathcal{H}_B \qquad \text{with} \qquad \dim \mathcal{H}_A \otimes \mathcal{H}_B = \dim \mathcal{H}_A \dim \mathcal{H}_B \ . \tag{23.123}$$

The symbol $\otimes$ denotes the *outer tensorial product* of two vectors (states) [14]. Now, in order to represent the multidimensional space $\mathcal{H}_A \otimes \mathcal{H}_B$ by a matrix, we use the fact

[14] The tensorial product of two states should not be confused with other definitions of products, such as the inner (or scalar) product of two states,

$$\langle\alpha|\beta\rangle \equiv \alpha_1\beta_1 + \alpha_2\beta_2 \ ,$$

that it is isomorphic to the space $\mathcal{H}_{\mathbb{I}} \otimes \mathcal{H}_{A\otimes B}$, that is, we proceed to a reorganization of the quantum numbers identifying,

$$|\gamma\rangle \equiv |\alpha\rangle|\beta\rangle = |\alpha\rangle \otimes |\beta\rangle = |\alpha\beta\rangle = \begin{pmatrix} \alpha_1|\beta\rangle \\ \alpha_2|\beta\rangle \end{pmatrix} = \begin{pmatrix} \alpha_1\beta_1 \\ \alpha_1\beta_2 \\ \alpha_2\beta_1 \\ \alpha_2\beta_2 \end{pmatrix} = (\gamma_m)_m \in \mathcal{H}_A \otimes \mathcal{H}_B \ , \tag{23.124}$$

where $m = 1, 2, 3, 4$ is identified with $(i, k) = (1, 1), (1, 2), (2, 1), (2, 2)$. The new vector is element of the 4-dimensional vector space $\mathcal{H}_A \otimes \mathcal{H}_B$. If $\{|\alpha\rangle_i\}$ and $\{|\beta\rangle_k\}$ are bases in their respective spaces $\mathcal{H}_A$ and $\mathcal{H}_B$, then $\{|\gamma\rangle_m\}$ is a basis of the product space $\mathcal{H}_A \otimes \mathcal{H}_B$.

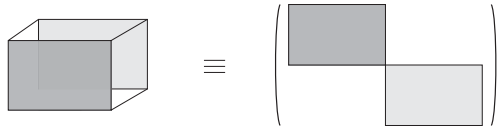

Figure 23.4: Illustration of the isomorphism between $\mathcal{H}_A \otimes \mathcal{H}_B$ and $\mathcal{H}_{\mathbb{I}} \otimes \mathcal{H}_{A\otimes B}$ for matrices of rank 2.

For observables we proceed in the same way: The external product of two commutators spans a Hilbert product space with the dimension corresponding to product of the dimensions of the sub-spaces. Assuming that,

$$\hat{A} \equiv \sum\nolimits_{i,j} |i\rangle A_{ij} \langle j| \quad \text{and} \quad \hat{B} \equiv \sum\nolimits_{k,l} |k\rangle B_{kl} \langle l| \ . \tag{23.125}$$

then

$$\hat{A} \otimes \hat{B} \equiv \sum_{(ik)(jl)} |ik\rangle A_{ij} B_{kl} \langle jl| \ , \tag{23.126}$$

---

the outer product,

$$|\alpha\rangle\langle\beta| \equiv \begin{pmatrix} \alpha_1\beta_1 & \alpha_1\beta_2 \\ \alpha_2\beta_1 & \alpha_2\beta_2 \end{pmatrix}$$

$$\begin{pmatrix} A_{11} \\ A_{12} \\ A_{21} \\ A_{22} \end{pmatrix} \begin{pmatrix} B_{11} \\ B_{12} \\ B_{21} \\ B_{22} \end{pmatrix}^{\dagger} = \begin{pmatrix} A_{11}B_{11} & A_{11}B_{12} & A_{11}B_{21} & A_{11}B_{22} \\ A_{12}B_{11} & A_{12}B_{12} & A_{12}B_{21} & A_{12}B_{22} \\ A_{21}B_{11} & A_{21}B_{12} & A_{21}B_{21} & A_{21}B_{22} \\ A_{22}B_{11} & A_{22}B_{12} & A_{22}B_{21} & A_{22}B_{22} \end{pmatrix} \ ,$$

the exterior (cross) product,

$$|\alpha\rangle \times |\beta\rangle = \begin{pmatrix} \alpha_2\beta_3 - \alpha_3\beta_2 \\ \alpha_3\beta_1 - \alpha_1\beta_3 \\ \alpha_1\beta_2 - \alpha_2\beta_1 \end{pmatrix} \ ,$$

nor the point-wise or *Hadamard product*,

$$\hat{A} \circ \hat{B} \equiv \begin{pmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{pmatrix} \circ \begin{pmatrix} B_{11} & B_{12} \\ B_{21} & B_{22} \end{pmatrix} = \begin{pmatrix} A_{11}B_{11} & A_{12}B_{12} \\ A_{21}B_{21} & A_{22}B_{22} \end{pmatrix} \ .$$

such that

$$\dim \hat{A} \otimes \hat{B} = \dim \hat{A} \dim \hat{B} \ .$$

For example, $|i\rangle\langle j| \otimes |k\rangle\langle l| = |ik\rangle\langle jl|$.

For two two-dimensional operators $\hat{A}$ and $\hat{B}$, the *tensorial external product* is defined by,

$$\hat{A} \otimes \hat{B} = \begin{pmatrix} A_{11}B_{11} & A_{11}B_{12} & A_{12}B_{11} & A_{12}B_{12} \\ A_{11}B_{21} & A_{11}B_{22} & A_{12}B_{21} & A_{12}B_{22} \\ A_{21}B_{11} & A_{21}B_{12} & A_{22}B_{11} & A_{22}B_{12} \\ A_{21}B_{21} & A_{21}B_{22} & A_{22}B_{21} & A_{22}B_{22} \end{pmatrix} \ , \tag{23.127}$$

and can be decomposed as,

$$\boxed{\hat{A} \otimes \hat{B} = (\hat{A} \otimes \mathbb{I})(\mathbb{I} \otimes \hat{B}) = \begin{pmatrix} A_{11} & & A_{12} & \\ & A_{11} & & A_{12} \\ A_{21} & & A_{22} & \\ & A_{21} & & A_{22} \end{pmatrix} \begin{pmatrix} B_{11} & B_{12} & & \\ B_{21} & B_{22} & & \\ & & B_{11} & B_{12} \\ & & B_{21} & B_{22} \end{pmatrix} .} \tag{23.128}$$

The concept (23.126) can be generalized to more degrees of freedom like,

$$\hat{A} \otimes \hat{B} \otimes \hat{C} \equiv \sum_{(ikm)(jln)} |ikm\rangle A_{ij} B_{kl} C_{mn} \langle jln| \ , \tag{23.129}$$

Obviously, the external product is associative $(\hat{A} \otimes \hat{B}) \otimes C = \hat{A} \otimes (\hat{B} \otimes C)$, but does not commute, even though the operators acting on different spaces do commute, $[\hat{A}, \hat{B}] = 0$. Nevertheless, we can reverse the order of the product of two operators using,

$$\hat{A} \otimes \hat{B} = \mathbb{S}(\hat{B} \otimes \hat{A})\mathbb{S} \qquad \text{with} \qquad \mathbb{S} \equiv \begin{pmatrix} 1 & & & \\ & 0 & 1 & \\ & 1 & 0 & \\ & & & 1 \end{pmatrix} \ . \tag{23.130}$$

The operator $\mathbb{S}$ is also called *SWAP-gate*.

We note, that it is important to distinguish from what space the vector came from. In our notation, the vector *before* the symbol of the tensorial product ($\otimes$) is belongs to the space $\mathcal{H}_A$, and the one *after* the $\otimes$ belongs to the space $\mathcal{H}_B$. With the definition (23.125) we can verify that the operators only act on their respective states:

$$(A \otimes B)(|\alpha\rangle \otimes |\beta\rangle) = A|\alpha\rangle \otimes B|\beta\rangle \ . \tag{23.131}$$

Example 145 (*Tensorial product*): We can check the relationship (23.131)

by the definitions (23.124) and (23.127) of the external product,

$$\left[\begin{pmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{pmatrix} \otimes \begin{pmatrix} B_{11} & B_{12} \\ B_{21} & B_{22} \end{pmatrix}\right]\left[\begin{pmatrix} \alpha_1 \\ \alpha_2 \end{pmatrix} \otimes \begin{pmatrix} \beta_1 \\ \beta_2 \end{pmatrix}\right] \tag{23.132}$$

$$= \begin{pmatrix} A_{11}B_{11} & A_{11}B_{12} & A_{12}B_{11} & A_{11}B_{12} \\ A_{11}B_{21} & A_{11}B_{22} & A_{12}B_{21} & A_{11}B_{22} \\ A_{21}B_{11} & A_{11}B_{12} & A_{22}B_{11} & A_{22}B_{12} \\ A_{21}B_{21} & A_{11}B_{22} & A_{22}B_{21} & A_{22}B_{22} \end{pmatrix} \begin{pmatrix} \alpha_{11}\beta_{11} \\ \alpha_{11}\beta_{21} \\ \alpha_{21}\beta_{11} \\ \alpha_{21}\beta_{21} \end{pmatrix}$$

$$= \begin{pmatrix} A_{11}B_{11}\alpha_{11}\beta_{11} + A_{11}B_{12}\alpha_{11}\beta_{21} + A_{12}B_{11}\alpha_{21}\beta_{11} + A_{11}B_{12}\alpha_{21}\beta_{21} \\ A_{11}B_{21}\alpha_{11}\beta_{11} + A_{11}B_{22}\alpha_{11}\beta_{21} + A_{12}B_{21}\alpha_{21}\beta_{11} + A_{11}B_{22}\alpha_{21}\beta_{21} \\ A_{21}B_{11}\alpha_{11}\beta_{11} + A_{11}B_{12}\alpha_{11}\beta_{21} + A_{22}B_{11}\alpha_{21}\beta_{11} + A_{22}B_{12}\alpha_{21}\beta_{21} \\ A_{21}B_{21}\alpha_{11}\beta_{11} + A_{11}B_{22}\alpha_{11}\beta_{21} + A_{22}B_{21}\alpha_{21}\beta_{11} + A_{22}B_{22}\alpha_{21}\beta_{21} \end{pmatrix}$$

$$= \begin{pmatrix} (A_{11}\alpha_1 + A_{12}\alpha_2)(B_{11}\beta_1 + B_{12}\beta_2) \\ (A_{11}\alpha_1 + A_{12}\alpha_2)(B_{21}\beta_1 + B_{22}\beta_2) \\ (A_{21}\alpha_1 + A_{22}\alpha_2)(B_{11}\beta_1 + B_{12}\beta_2) \\ (A_{21}\alpha_1 + A_{22}\alpha_2)(B_{21}\beta_1 + B_{22}\beta_2) \end{pmatrix}$$

$$= \begin{pmatrix} A_{11}\alpha_1 + A_{12}\alpha_2 \\ A_{21}\alpha_1 + A_{22}\alpha_2 \end{pmatrix} \otimes \begin{pmatrix} B_{11}\beta_1 + B_{12}\beta_2 \\ B_{21}\beta_1 + B_{22}\beta_2 \end{pmatrix} = \begin{pmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{pmatrix} \begin{pmatrix} \alpha_1 \\ \alpha_2 \end{pmatrix} \otimes \begin{pmatrix} B_{11} & B_{12} \\ B_{21} & B_{22} \end{pmatrix} \begin{pmatrix} \beta_1 \\ \beta_2 \end{pmatrix} .$$

Example 146 (*Mathematical definition of the tensor product*): If α belongs to the Hilbert space $\mathcal{H}_\alpha$ and β belongs to $\mathcal{H}_\beta$, then the equivalence class of (α, β) is denoted by $\alpha \otimes \beta$ and called the tensor product of α with β. This use of the $\otimes$-symbol refers specifically to the outer product operation. An element of $\mathcal{H}_\alpha \otimes \mathcal{H}_\beta$ that can be written in the form $\alpha \otimes \beta$ is called a pure tensor. In general, an element of the tensor product space is not a pure tensor, but rather a finite linear combination of pure tensors. For example, if α_1 and α_2 are linearly independent, and β_1 and β_2 are also linearly independent, then $\alpha_1 \otimes \beta_1 + \alpha_2 \otimes \beta_2$ cannot be written as a pure tensor. The number of pure tensors required to express an element of a tensor product is called the tensor rank. The rank should not be confused with the tensor order, which is the number of spaces one has taken the product of (in this case two), and which corresponds to the number of indices. For linear operators or matrices, thought of as $(1,1)$ tensors (elements of the space $\mathcal{H}_\alpha \otimes \mathcal{H}_\alpha^*$), the tensor rank agrees with matrix rank.
Given bases $\{\alpha_i\}$ and $\{\beta_j\}$ for $\mathcal{H}_\alpha$ and $\mathcal{H}_\beta$ respectively, the tensors $\{\alpha_i \otimes \beta_j\}$ form a basis for $\mathcal{H}_\alpha \otimes \mathcal{H}_\beta$. Therefore, if $\mathcal{H}_\alpha$ and $\mathcal{H}_\beta$ are finite-dimensional, the dimension of the tensor product is the product of dimensions of the original spaces; for instance $\mathbb{R}^m \otimes \mathbb{R}^n$ is isomorphic to $\mathbb{R}^{nm}$.
The tensor product also operates on linear maps (called operators in quantum mechanics) between vector spaces. Specifically, given two linear maps $\hat{A} : \mathcal{H}_\alpha \to \mathcal{H}'_\alpha$ and $\hat{B} : \mathcal{H}_\beta \to \mathcal{H}'_\beta$ between vector spaces, the tensor product of the two linear maps $\hat{A}$ and $\hat{B}$ is a linear map,

$$\hat{A} \otimes \hat{B} : \mathcal{H}_\alpha \otimes \mathcal{H}_\beta \to \mathcal{H}'_\alpha \otimes \mathcal{H}'_\beta ,$$

defined by,

$$(\hat{A} \otimes \hat{B})(\alpha \otimes \beta) = \hat{A}(\alpha) \otimes \hat{B}(\beta) .$$

In this way, the tensor product becomes a bifunctor from the category of vector spaces to itself, covariant in both arguments. If $\hat{A}$ and $\hat{B}$ are both injective, surjective or (in the case that $\mathcal{H}_\alpha$, $\mathcal{H}'_\alpha$, $\mathcal{H}_\beta$, and $\mathcal{H}'_\beta$ are normed vector spaces or topological vector spaces) continuous, then $\hat{A} \otimes \hat{B}$ is injective, surjective or continuous, respectively.
By choosing bases of all vector spaces involved, the linear maps $\hat{A}$ and $\hat{B}$ can be represented by matrices. Then, depending on how the tensor $\alpha \otimes \beta$ is vectorized, the matrix describing the tensor product $\hat{A} \otimes \hat{B}$ is the Kronecker product of the two matrices. For example, if $\mathcal{H}_\alpha$, $\mathcal{H}'_\alpha$, $\mathcal{H}_\beta$, and $\mathcal{H}'_\beta$ above are all two-dimensional and bases have been fixed for all of them, and $\hat{A}$ and $\hat{B}$ are given by the matrices,

$$\hat{A} = \begin{pmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{pmatrix} \quad , \quad \hat{B} = \begin{pmatrix} B_{11} & B_{12} \\ B_{21} & B_{22} \end{pmatrix}$$

respectively, then the tensor product of these two matrices is,

$$\begin{pmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{pmatrix} \otimes \begin{pmatrix} B_{11} & B_{12} \\ B_{21} & B_{22} \end{pmatrix} = \begin{pmatrix} A_{11} \begin{pmatrix} B_{11} & B_{12} \\ B_{21} & B_{22} \end{pmatrix} & A_{12} \begin{pmatrix} B_{11} & B_{12} \\ B_{21} & B_{22} \end{pmatrix} \\ A_{21} \begin{pmatrix} B_{11} & B_{12} \\ B_{21} & B_{22} \end{pmatrix} & A_{22} \begin{pmatrix} B_{11} & B_{12} \\ B_{21} & B_{22} \end{pmatrix} \end{pmatrix} .$$

The resultant rank is at most 4, and thus the resultant dimension is 4. Note that rank here denotes the tensor rank i.e. the number of requisite indices (while the matrix rank counts the number of degrees of freedom in the resulting array). Note $\mathrm{Tr}\ \hat{A} \otimes \hat{B} = \mathrm{Tr}\ \hat{A} \times \mathrm{Tr}\ \hat{B}$.
A dyadic product is the special case of the tensor product between two vectors of the same dimension.

23.3.9.3 Direct external sum

Using the nomenclature (23.125) we define the external direct sum by,

$$\hat{A} \oplus \hat{B} \equiv \sum_{(ik)(jl)} |ik\rangle (A_{ij} + B_{kl}) \langle jl| \ , \tag{23.133}$$

that is,

$$\hat{A} \oplus \hat{B} = \begin{pmatrix} A_{11} + B_{11} & A_{11} + B_{12} & A_{12} + B_{11} & A_{12} + B_{12} \\ A_{11} + B_{21} & A_{11} + B_{22} & A_{12} + B_{21} & A_{12} + B_{22} \\ A_{21} + B_{11} & A_{21} + B_{12} & A_{22} + B_{11} & A_{22} + B_{12} \\ A_{21} + B_{21} & A_{21} + B_{22} & A_{22} + B_{21} & A_{22} + B_{22} \end{pmatrix} . \tag{23.134}$$

It can be decomposed as,

$$\boxed{\hat{A} \oplus \hat{B} = \hat{A} \oplus \mathbb{O} + \mathbb{O} \oplus \hat{B} = \hat{A} \otimes \begin{pmatrix} 1 & 1 \\ 1 & 1 \end{pmatrix} + \begin{pmatrix} 1 & 1 \\ 1 & 1 \end{pmatrix} \otimes \hat{A} \ .} \tag{23.135}$$

Again, using the definition (23.130) of the unitary operator $\mathbb{S}$, we can reverse the order of the operator by,

$$\hat{A} \oplus \hat{B} = \mathbb{S}(\hat{B} \oplus \hat{A})\mathbb{S} \ . \tag{23.136}$$

Example 147 (*Direct external sum of two diagonal Hamiltonians*): As an example we consider a two-level atom excited by radiation and trapped in an external harmonic potential. We assume that the degrees of freedom do not interact. As the Hamiltonian of the HO is diagonal, the total Hamiltonian is organized into a diagonal matrix of quadratic subspaces,

$$\hat{H} = \hbar\omega(n+\tfrac{1}{2}) \oplus \begin{pmatrix} 0 & \hbar\Omega \\ \hbar\Omega & \hbar\Delta \end{pmatrix} = \begin{pmatrix} \frac{\hbar\omega}{2} & \frac{\hbar\omega}{2}+\hbar\Omega & 0 & 0 & \vdots \\ \frac{\hbar\omega}{2}+\hbar\Omega & \frac{\hbar\omega}{2}+\hbar\Delta & 0 & 0 & \vdots \\ 0 & 0 & \frac{3\hbar\omega}{2} & \frac{3\hbar\omega}{2}+\hbar\Omega & \vdots \\ 0 & 0 & \frac{3\hbar\omega}{2}+\hbar\Omega & \frac{3\hbar\omega}{2}+\hbar\Delta & \vdots \\ \cdots & \cdots & \cdots & \cdots & \ddots \end{pmatrix} .$$

It acts on the product state $|n\rangle|i\rangle$, where the first ket denotes the vibrational level and the second ket the electronic excitation of the atom.

Other examples are studied in 23.3.10.13 and 23.3.10.14.

23.3.9.4 Trace

The *trace* of an operator over a subspace reduces its domain to the remaining dimensions (the $\cdot$ -symbol is a place holder for the dimension over which we do NOT want to trace):

$$\mathrm{Tr}_B \hat{A}\otimes\hat{B} = \sum_{(ik)(jl)(\cdot m)} \langle \cdot\, m|ik\rangle A_{ij}B_{kl}\langle jl|\cdot m\rangle = \sum_{(ik)(jl)(\cdot m)} |i\rangle A_{ij}B_{kl}\langle j|\delta_{km}\delta_{lm}$$

$$= \sum_{(i)(j)(m)} |i\rangle A_{ij}B_{mm}\langle j| = \hat{A}\sum_m B_{mm} = \hat{A}\,\mathrm{Tr}_B\hat{B} \,. \tag{23.137}$$

For example, $\mathrm{Tr}_\rho \hat{A}\otimes\hat{\rho} = \hat{A}$. See the Excs. 23.3.10.15 and 23.3.10.16.

It can be shown,

$$\mathrm{Tr}\ \hat{A}\hat{B} = \mathrm{Tr}\ \hat{B}\hat{A} \,. \tag{23.138}$$

23.3.10 Exercises

23.3.10.1 Ex: Orthogonality

Show that two eigenvectors of a Hermitian operator associated with two different eigenvalues are orthogonal.

Solution:

$$\begin{aligned} &\hat{A}|1\rangle = a_1|1\rangle \quad , \quad \hat{A}|2\rangle = a_2|2\rangle \\ \Longrightarrow \quad &\langle 2|a_2|1\rangle = \langle 2|\hat{A}^\dagger|1\rangle = \langle 2|\hat{A}|1\rangle = \langle 2|a_1|1\rangle \\ \Longrightarrow \quad &\langle 2|1\rangle = \delta_{a_1,a_2} \,. \end{aligned}$$

23.3.10.2 Ex: Orthonormalization

Orthonormalize the base $\langle a_1| = \begin{pmatrix} 1 & -1 & 0 \end{pmatrix}$, $\langle a_2| = \begin{pmatrix} 0 & 1 & 0 \end{pmatrix}$, $\langle a_3| = \begin{pmatrix} 0 & 1 & 1 \end{pmatrix}$.

Solution: *The new base is,*

$$|b_1\rangle = \frac{|a_1\rangle}{||a_1\rangle|} = \tfrac{1}{\sqrt{2}}|a_1\rangle = \tfrac{1}{\sqrt{2}} \begin{pmatrix} 1 \\ -1 \\ 0 \end{pmatrix}$$

$$|b_2\rangle = \frac{(1 - |b_1\rangle\langle b_1|)|a_2\rangle}{|(1 - |b_1\rangle\langle b_1|)|a_2\rangle|} = \frac{1}{|.|} \left[1 - \tfrac{1}{2} \begin{pmatrix} 1 \\ -1 \\ 0 \end{pmatrix} \begin{pmatrix} 1 \\ -1 \\ 0 \end{pmatrix}^\dagger \right] \begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix} = \tfrac{1}{\sqrt{2}} \begin{pmatrix} 1 \\ 1 \\ 0 \end{pmatrix}$$

$$|b_3\rangle = \frac{(1 - |b_1\rangle\langle b_1| - |b_2\rangle\langle b_2|)|a_3\rangle}{|(1 - |b_1\rangle\langle b_1| - |b_2\rangle\langle b_2|)|a_3\rangle|} = \frac{1}{|.|} \left[1 - \tfrac{1}{2} \begin{pmatrix} 1 \\ -1 \\ 0 \end{pmatrix} \begin{pmatrix} 1 \\ -1 \\ 0 \end{pmatrix}^\dagger - \begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix} \begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix}^\dagger \right] \begin{pmatrix} 0 \\ 1 \\ 1 \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix} .$$

23.3.10.3 Ex: Orthonormal base

Construct an orthonormal basis for the following operator describing a partially degenerate three-level system,

$$\hat{A} = \begin{pmatrix} 1 & 1 & 1 \\ 1 & 1 & 1 \\ 1 & 1 & 1 \end{pmatrix} .$$

Solution: *Obviously* $\langle a_1| = \begin{pmatrix} 1 & 1 & 1 \end{pmatrix}$ *is an eigenvector for the eigenvalue* $a = 3$ *without degeneracy. The other eigenvalue,* $a = 0$*, is twice degenerate, since it has the linearly independent eigenvectors* $\langle a_2| = \begin{pmatrix} 1 & -1 & 0 \end{pmatrix}$ *and* $\langle a_3| = \begin{pmatrix} 1 & 0 & -1 \end{pmatrix}$. *However,* $\langle a_2|$ *and* $\langle a_3|$ *are not orthonormal. But*

$$|b_1\rangle = \frac{|a_1\rangle}{\|\cdots\|} = \tfrac{1}{\sqrt{3}} \begin{pmatrix} 1 \\ 1 \\ 1 \end{pmatrix} \qquad \textit{and} \qquad |b_2\rangle = \frac{|a_2\rangle - |b_1\rangle\langle b_1|a_2\rangle}{\|\cdots\|} = \frac{|a_2\rangle}{\|\cdots\|} = \tfrac{1}{\sqrt{2}} \begin{pmatrix} 1 \\ -1 \\ 0 \end{pmatrix}$$

$$\textit{and} \qquad |b_3\rangle = \frac{|a_3\rangle - |b_1\rangle\langle b_1|a_3\rangle - |b_2\rangle\langle b_2|a_3\rangle}{\|\cdots\|} = \frac{|a_3\rangle - |b_2\rangle\frac{1}{\sqrt{2}}}{\|\cdots\|} = \tfrac{1}{\sqrt{6}} \begin{pmatrix} 1 \\ 1 \\ -2 \end{pmatrix} \qquad \textit{are.}$$

23.3.10.4 Ex: Eigenvalue equation

Calculate the unitary matrix U transforming the Hamiltonian $\hat{H} = \begin{pmatrix} 1 & -\imath \\ \imath & 1 \end{pmatrix}$ into a diagonal matrix $E = U^\dagger \hat{H} U$.

Solution: *The eigenvalue matrix is,*

$$E = \begin{pmatrix} 0 & 0 \\ 0 & 2 \end{pmatrix} .$$

The eigenvalue 0 *corresponds to the eigenvector* $\frac{1}{\sqrt{2}} \begin{pmatrix} \imath \\ 1 \end{pmatrix}$ *and the eigenvalue* 2 *to the eigenvector* $\frac{1}{\sqrt{2}} \begin{pmatrix} -\imath \\ 1 \end{pmatrix}$. *Hence,*

$$U = \frac{1}{\sqrt{2}} \begin{pmatrix} \imath & -\imath \\ 1 & 1 \end{pmatrix} .$$

This makes it easy to check $E = U^\dagger \hat{H} U$. *Note that the transformation matrix is not uniquely defined, since every matrix* $e^{\imath\phi} U$ *does the same job.*

23.3.10.5 Ex: Spin rotation operators

Prove the following relations for the spin rotation operator: $e^{-\imath\pi\hat{\sigma}_x/4} \hat{\sigma}_z e^{\imath\pi\hat{\sigma}_x/4} = -\hat{\sigma}_y$ and $e^{-\imath\pi\hat{\sigma}_x/4} \hat{\sigma}_y e^{\imath\pi\hat{\sigma}_x/4} = \hat{\sigma}_z$.

Solution: *The Hermitian operator* σ_x *can be diagonalized via,*

$$\hat{\sigma}_x = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} = \begin{pmatrix} -1 & 1 \\ 1 & 1 \end{pmatrix} \begin{pmatrix} -1 & 0 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} -1 & 1 \\ 1 & 1 \end{pmatrix}^{-1} = U(-\hat{\sigma}_z)U^{-1} .$$

Hence, the unitary transformation $e^{-\imath\pi\sigma_x/4}$ *reads,*

$$e^{-\imath\pi\hat{\sigma}_x/4} = U e^{\imath\pi\hat{\sigma}_z/4} U^{-1} = \begin{pmatrix} -1 & 1 \\ 1 & 1 \end{pmatrix} \begin{pmatrix} e^{\imath\pi/4} & 0 \\ 0 & e^{-\imath\pi/4} \end{pmatrix} \begin{pmatrix} -1 & 1 \\ 1 & 1 \end{pmatrix}^{-1} = \begin{pmatrix} \frac{1}{\sqrt{2}} & -\frac{\imath}{\sqrt{2}} \\ -\frac{\imath}{\sqrt{2}} & \frac{1}{\sqrt{2}} \end{pmatrix} .$$

And so,

$$e^{-\imath\pi\hat{\sigma}_x/4} \hat{\sigma}_z e^{\imath\pi\hat{\sigma}_x/4} = \begin{pmatrix} \frac{1}{\sqrt{2}} & -\frac{\imath}{\sqrt{2}} \\ -\frac{\imath}{\sqrt{2}} & \frac{1}{\sqrt{2}} \end{pmatrix} \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} \begin{pmatrix} \frac{1}{\sqrt{2}} & -\frac{\imath}{\sqrt{2}} \\ -\frac{\imath}{\sqrt{2}} & \frac{1}{\sqrt{2}} \end{pmatrix}^{-1} = \begin{pmatrix} 0 & \imath \\ -\imath & 0 \end{pmatrix} = \hat{\sigma}_y ,$$

and similar for the second expression.

23.3.10.6 Ex: Eigenvalues and eigenvectors

Find the eigenvalues and -vectors of the operator $\hat{A} = \begin{pmatrix} 1 & 1 & 1 \\ 1 & 1 & 1 \\ 1 & 1 & 1 \end{pmatrix}$ and construct the unitary matrix which transforms this operator into a diagonal matrix.

Solution: *The eigenvalues follow from,*

$$0 = \det(\hat{A} - E) = 3E^2 - E^3 \Longrightarrow E_1 = 0, E_2 = 3, E_3 = 0 \ .$$

The eigenvectors from,

$$\hat{A}\begin{pmatrix} a \\ b \\ c \end{pmatrix} = \begin{pmatrix} a+b+c \\ a+b+c \\ a+b+c \end{pmatrix} = 3\begin{pmatrix} a \\ b \\ c \end{pmatrix} \Longrightarrow \begin{array}{c} a = b = c \\ a^2+b^2+c^2 = 1 \end{array} \Longrightarrow u_2 = \begin{pmatrix} \frac{1}{\sqrt{3}} \\ \frac{1}{\sqrt{3}} \\ \frac{1}{\sqrt{3}} \end{pmatrix}$$

$$\hat{A}\begin{pmatrix} a \\ b \\ c \end{pmatrix} = \begin{pmatrix} a+b+c \\ a+b+c \\ a+b+c \end{pmatrix} = 0\begin{pmatrix} a \\ b \\ c \end{pmatrix} \Longrightarrow \begin{array}{c} b = -a-c \\ a^2+b^2+c^2 = 1 \end{array} \Longrightarrow c = -\frac{1}{2}\left(a \pm \sqrt{2-3a^2}\right)$$

$$\Longrightarrow u_1 = \begin{pmatrix} a \\ \frac{1}{2}\left(-a+\sqrt{2-3a^2}\right) \\ \frac{1}{2}\left(-a-\sqrt{2-3a^2}\right) \end{pmatrix} \ , u_3 = \begin{pmatrix} a \\ \frac{1}{2}\left(-a-\sqrt{2-3a^2}\right) \\ \frac{1}{2}\left(-a+\sqrt{2-3a^2}\right) \end{pmatrix} \ .$$

We define the unitary transformation matrix and the diagonal matrix of eigenvalues,

$$U \equiv \begin{pmatrix} |u_1\rangle & |u_2\rangle & |u_3\rangle \end{pmatrix} = \begin{pmatrix} a & \frac{1}{\sqrt{3}} & a \\ \frac{1}{2}\left(-a+\sqrt{2-3a^2}\right) & \frac{1}{\sqrt{3}} & \frac{1}{2}\left(-a-\sqrt{2-3a^2}\right) \\ \frac{1}{2}\left(-a-\sqrt{2-3a^2}\right) & \frac{1}{\sqrt{3}} & \frac{1}{2}\left(-a+\sqrt{2-3a^2}\right) \end{pmatrix}$$

$$E \equiv \begin{pmatrix} E_1 & 0 & 0 \\ 0 & E_2 & 0 \\ 0 & 0 & E_3 \end{pmatrix} = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 3 & 0 \\ 0 & 0 & 0 \end{pmatrix} \ .$$

For the transformation matrix to be unitary, we need

$$1 = \det U = a\sqrt{3}\sqrt{2-3a^2} \ ,$$

with the solution $a = \frac{1}{\sqrt{3}}$*, that is,*

$$U = \begin{pmatrix} \frac{1}{\sqrt{3}} & \frac{1}{\sqrt{3}} & \frac{1}{\sqrt{3}} \\ \frac{1}{2} - \frac{1}{2\sqrt{3}} & \frac{1}{\sqrt{3}} & -\frac{1}{2} - \frac{1}{2\sqrt{3}} \\ -\frac{1}{2} - \frac{1}{2\sqrt{3}} & \frac{1}{\sqrt{3}} & \frac{1}{2} - \frac{1}{2\sqrt{3}} \end{pmatrix} \ .$$

It is easy to show,

$$U^\dagger U = UU^\dagger = \hat{1} \qquad \textit{and} \qquad \hat{A}U = UE \ .$$

23.3.10.7 Ex: Commuting operators

a. Show that if two operators $\hat{A}$ and $\hat{B}$ commute and if $|\psi\rangle$ is an eigenvector of $\hat{A}$, $\hat{B}|\psi\rangle$ also is an eigenvector of $\hat{A}$ with the same eigenvalue.
b. Show that if two operators $\hat{A}$ and $\hat{B}$ commute and if $|\psi_1\rangle$ and $|\psi_2\rangle$ are two eigenvector of $\hat{A}$ with different eigenvalues, the matrix element $\langle\psi_1|\hat{B}|\psi_2\rangle$ is equal to zero.
c. Show that if two operators $\hat{A}$ and $\hat{B}$ commute, we can construct an orthonormal basis of eigenvectors common to $\hat{A}$ and $\hat{B}$.

Solution: *a. The operators $\hat{A}$ and $\hat{B}$ commute:*

$$\begin{aligned} [\hat{A},\hat{B}] = 0 \quad &, \quad \hat{A}|\psi\rangle = a|\psi\rangle \\ \Longrightarrow \quad & \hat{A}\hat{B}|\psi\rangle = \hat{B}\hat{A}|\psi\rangle = \hat{B}a|\psi\rangle = a\hat{B}|\psi\rangle \ . \end{aligned}$$

b. If furthermore $|\psi_1\rangle$ and $|\psi_2\rangle$ are eigenvectors of $\hat{A}$,

$$\begin{aligned} [\hat{A},\hat{B}] = 0 \quad &, \quad \hat{A}|\psi_1\rangle = a_1|\psi_1\rangle \quad , \quad \hat{A}|\psi_2\rangle = a_2|\psi_2\rangle \\ \Longrightarrow \quad & \langle\psi_1|a_1\hat{B}|\psi_2\rangle = \langle\psi_1|\hat{A}\hat{B}|\psi_2\rangle = \langle\psi_1|\hat{B}\hat{A}|\psi_2\rangle = \langle\psi_1|\hat{B}a_2|\psi_2\rangle \\ \Longrightarrow \quad & \langle\psi_1|\hat{B}|\psi_2\rangle = \langle\psi_1|\hat{B}|\psi_2\rangle\delta_{a_1,a_2} \ . \end{aligned}$$

The result can be generalized to,

$$\langle\psi_m|\hat{B}|\psi_n\rangle = \delta_{m,n}\langle\psi_m|\hat{B}|\psi_m\rangle \ .$$

c. Using the last result we can make the following calculation,

$$\hat{B} = \sum_{m,n} |m\rangle\langle m|\hat{B}|n\rangle\langle n| = \sum_m |m\rangle\langle m|\hat{B}|m\rangle\langle m| \ ,$$

and,

$$\hat{B}|n\rangle = \sum_m |m\rangle\langle m|\hat{B}|m\rangle\langle m|n\rangle = \langle n|\hat{B}|n\rangle|n\rangle = b_n|n\rangle \ .$$

This shows that $|n\rangle$ is an eigenvector of $\hat{B}$, too.
c Alternative. The opposite is easy to show, since $\hat{A}|\psi_n\rangle = \psi_n|u_n\rangle$ and $\hat{B}|\psi_n\rangle = b_n|\psi_n\rangle$ we see that $[\hat{A},\hat{B}]|\psi_n\rangle = 0$.
To prove that observable commutators $[\hat{A},\hat{B}] = 0$ have a complete set of common eigenfunctions, we first consider the case where the eigenvalues of $\hat{A}$ are all non-degenerate. We let $\{|\psi_n\rangle\}$ be a complete base of eigenvectors of $\hat{A}$ with the eigenvalues a_n,

$$\hat{A}|\phi_n\rangle = a_n|a_n\rangle \qquad with \qquad a_n \neq a_m \ .$$

We can now write,

$$\hat{A}(\hat{B}|\psi_n>) = \hat{B}\hat{A}|\psi_n\rangle = a_n(\hat{B}|\psi_n\rangle) \ ,$$

such that we can say that $\hat{B}|\psi_n\rangle$ is an eigenvector of $\hat{A}$ with the corresponding eigenvalue a_n. As both, $\hat{B}|\psi_n\rangle$ and $psi_n\rangle$ are eigenvectors associated with the same eigenvalue a_n, which is unique, they may only be differ by a multiplicative constant, which we will call b_n. That is,

$$\hat{B}|\phi_n\rangle = b_n|\psi_n\rangle \ .$$

Now we treat the case, where $\hat{A}$ has degenerate eigenvalues, for example, the eigenvalue a_n being g times degenerate. We let $|\psi_{nr}>$ with $r = 1, 2, .., g$ be linearly independent eigenvectors of the eigenvalue. Since $[\hat{A}, \hat{B}] = 0$, we reason as we did above to find that $\hat{B}|\psi_{nr}\rangle$ is an eigenvector of $\hat{A}$ corresponding to the degenerate eigenvalue a. Therefore, we can expand $\hat{B}|\psi_{nr}\rangle$ on the basis of degenerate eigenvectors of a_n:

$$\hat{B}|\psi_{nr}\rangle = \sum_{s=1}^{g} c_{rs}|\psi_{ns}\rangle \ ,$$

with the expansion coefficients of c_{rs}. Now we apply the sum $\sum_r d_r$ with constants d_r to this equation,

$$\hat{B}\sum_{r=1}^{g} d_r|\psi_{nr}\rangle = \sum_{r=1}^{g}\sum_{s=1}^{g} d_r c_{rs}|\psi_{ns}\rangle \ .$$

Hence, $\sum_r d_r|\psi_{nr}\rangle$ will be an eigenvalue of $\hat{B}$ with the eigenvalue b_n, under the condition that,

$$\sum_{r=1}^{g} d_r c_{rs} = b_n d_s \qquad with \qquad s = 1, 2, .., g \ .$$

This constitutes a system of g linear equations for d_r constants. A non-trivial solution requires,

$$\det[c_{rs} - b_n\delta_{rs}] = 0 \ .$$

This is an equation of order g in b_n with g roots. For each root, $b_n = b_n^{(k)}$ with $k = 1, 2, .., g$, we get a value d_r, for example, $d_r^{(k)}$. Now, the ket,

$$|\phi_n^{(k)}\rangle = \sum_{r=1}^{g} d_r^{(k)}|\psi_{nr}\rangle$$

is simultaneously an eigenvector of $\hat{A}$ and of $\hat{B}$ with their respective eigenvalues a_n and $b_n^{(k)}$.

23.3.10.8 Ex: Eigenvalues

a. Find the eigenvalues and eigenvectors of the operator $\hat{A} = \begin{pmatrix} 1 & 0 & 1 \\ 0 & \mu & 0 \\ 1 & 0 & 1 \end{pmatrix}$ for $0 < \mu < 2$.
b. Write down the unitary matrix U satisfying the eigenvalue equation: $\hat{A}U = UE_A$, where E_A is the matrix that has all eigenvalues of $\hat{A}$ in its diagonal.
c. Now consider the case $\mu = 0$. Find a complete set of commuting operators (CSCO). That is, calculate the components of a second operator $\hat{B}$, which commutes with $\hat{A}$, as a function of its eigenvalues λ_1, λ_2, and λ_3, and verify $[\hat{A}, \hat{B}] = 0$. Find the most general form of operator $\hat{B}$.

Solution: *a. The eigenvalues are,*

$$\det\begin{pmatrix}1-\lambda & 0 & 1\\ 0 & \mu-\lambda & 0\\ 1 & 0 & 1-\lambda\end{pmatrix} = -2\lambda\mu + 2\lambda^2 + \lambda^2\mu - \lambda^3 = 0 \Longrightarrow \lambda = 0, \mu, 2\ .$$

The eigenvectors are,

$$\begin{pmatrix}1 & 0 & 1\\ 0 & \mu & 0\\ 1 & 0 & 1\end{pmatrix}\begin{pmatrix}a\\ b\\ c\end{pmatrix} = 0\begin{pmatrix}a\\ b\\ c\end{pmatrix} \Longrightarrow \begin{array}{c} a+c=0\\ \mu b = 0\\ a+c=0\end{array} \Longrightarrow \begin{array}{c} c=-a\\ b=0\end{array} \Longrightarrow u_1 = \begin{pmatrix}1/\sqrt{2}\\ 0\\ -1/\sqrt{2}\end{pmatrix}\ ,$$

$$\begin{pmatrix}1 & 0 & 1\\ 0 & \mu & 0\\ 1 & 0 & 1\end{pmatrix}\begin{pmatrix}a\\ b\\ c\end{pmatrix} = \mu\begin{pmatrix}a\\ b\\ c\end{pmatrix} \Longrightarrow \begin{array}{c} a+c=\mu a\\ \mu b = \mu b\\ a+c=\mu c\end{array} \Longrightarrow a=b \Longrightarrow u_2 = \begin{pmatrix}0\\ 1\\ 0\end{pmatrix}\ ,$$

$$\begin{pmatrix}1 & 0 & 1\\ 0 & \mu & 0\\ 1 & 0 & 1\end{pmatrix}\begin{pmatrix}a\\ b\\ c\end{pmatrix} = 2\begin{pmatrix}a\\ b\\ c\end{pmatrix} \Longrightarrow \begin{array}{c} a+c=2a\\ \mu b = 2b\\ a+c=2c\end{array} \Longrightarrow \begin{array}{c} c=a\\ b=0\end{array} \Longrightarrow u_3 = \begin{pmatrix}1/\sqrt{2}\\ 0\\ 1/\sqrt{2}\end{pmatrix}\ .$$

They form an orthonormal basis.
b. The eigenvalue matrix and the unitary matrix are,

$$E_A = \begin{pmatrix}0 & 0 & 0\\ 0 & \mu & 0\\ 0 & 0 & 2\end{pmatrix} \qquad \textit{and} \qquad U = \begin{pmatrix}1/\sqrt{2} & 0 & 1/\sqrt{2}\\ 0 & 1 & 0\\ -1/\sqrt{2} & 0 & 1/\sqrt{2}\end{pmatrix}\ .$$

It is easy to check $\hat{A}U = UE_A$.
c. As long as, $\mu \neq 0, 2$ *the observable* $\hat{A}$ *is sufficient to characterize the system, but if for example* $\mu = 0$*, we need another observable* $\hat{B}$ *which commutes with* $\hat{A}$ *and satisfies the condition,* $\hat{B}U = U\hat{E}_B$*,*

$$\begin{pmatrix}b_{11} & b_{12} & b_{13}\\ b_{21} & b_{22} & b_{23}\\ b_{31} & b_{32} & b_{33}\end{pmatrix}U = \begin{pmatrix}b_{11}/\sqrt{2} - b_{13}/\sqrt{2} & b_{12} & b_{11}/\sqrt{2} + b_{13}/\sqrt{2}\\ b_{21}/\sqrt{2} - b_{23}/\sqrt{2} & b_{22} & b_{21}/\sqrt{2} + b_{23}/\sqrt{2}\\ b_{31}/\sqrt{2} - b_{33}/\sqrt{2} & b_{32} & b_{31}/\sqrt{2} + b_{33}/\sqrt{2}\end{pmatrix}$$

$$= \begin{pmatrix}\lambda_1/\sqrt{2} & 0 & \lambda_3/\sqrt{2}\\ 0 & \lambda_2 & 0\\ -\lambda_1/\sqrt{2} & 0 & \lambda_3/\sqrt{2}\end{pmatrix} = U\begin{pmatrix}\lambda_1 & 0 & 0\\ 0 & \lambda_2 & 0\\ 0 & 0 & \lambda_3\end{pmatrix}\ ,$$

where b_{ij} *are the components and* λ_i *the eigenvalues of* $\hat{B}$*. The result is,*

$$\hat{B} = \begin{pmatrix}\frac{1}{2}(\lambda_1+\lambda_3) & 0 & \frac{1}{2}(\lambda_3-\lambda_1)\\ 0 & \lambda_2 & 0\\ \frac{1}{2}(\lambda_3-\lambda_1) & 0 & \frac{1}{2}(\lambda_1+\lambda_3)\end{pmatrix}\ .$$

It's easy to check $[\hat{A},\hat{B}]=0$. *Of course, in order to lift the degeneracy of* $\hat{A}$ *regarding the eigenvectors* u_1 *and* u_2, *the eigenvalues of* $\hat{B}$ *belonging to the same eigenvectors must be different, that is,* $\lambda_1 \neq \lambda_2$. *Note that the trivial case* $\lambda_2=\lambda_3$ *represents a possible observable.*

23.3.10.9 Ex: Schwartz inequality

Demonstrate the Schwartz inequality $|\langle u|v\rangle|^2 \leq \langle u|u\rangle\langle v|v\rangle$.

Solution: *Defining the wavefunction* $|\phi\rangle \equiv |v\rangle\langle u|u\rangle - |u\rangle\langle u|v\rangle$,

$$\begin{aligned}
0 \leq \langle\phi|\phi\rangle &= (-\langle v|u\rangle\langle u| + \langle u|u\rangle\langle v|)(|v\rangle\langle u|u\rangle - |u\rangle\langle u|v\rangle) \\
&= -\langle v|u\rangle\langle u|v\rangle\langle u|u\rangle + \langle v|u\rangle\langle u|u\rangle\langle u|v\rangle + \langle u|u\rangle\langle v|v\rangle\langle u|u\rangle - \langle u|u\rangle\langle v|u\rangle\langle u|v\rangle \\
&= \langle u|u\rangle\langle v|v\rangle\langle u|u\rangle - \langle u|u\rangle\langle v|u\rangle\langle u|v\rangle = \langle u|u\rangle(\langle u|u\rangle\langle v|v\rangle - |\langle u|v\rangle|^2) \ .
\end{aligned}$$

23.3.10.10 Ex: Heisenberg's uncertainty principle

Develop the formal derivation of Heisenberg's uncertainty principle.

Solution: *First we show,*

$$\Delta A^2 = \langle A^2\rangle - \langle A\rangle^2 = \langle A^2 - 2\langle A\rangle A + \langle A\rangle^2\rangle = \langle (A-\langle A\rangle)(A-\langle A\rangle)\rangle = \langle \delta A \delta A\rangle \ .$$

Now we calculate,

$$\begin{aligned}
\Delta A^2 \Delta B^2 = \langle\psi|\delta\hat{A}\delta\hat{A}|\psi\rangle\langle\psi|\delta\hat{B}\delta\hat{B}|\psi\rangle &= \langle\delta\hat{A}\psi|\delta\hat{A}\psi\rangle\langle\delta\hat{B}\psi|\delta\hat{B}\psi\rangle \\
&\geq |\langle\delta\hat{A}\psi|\delta\hat{B}\psi\rangle|^2 = \Big|\langle\psi|\delta\hat{A}\delta\hat{B}|\psi\rangle\Big|^2 \ ,
\end{aligned}$$

using Schwartz's inequality. Separating the real and imaginary part,

$$\begin{aligned}
\Delta A^2\Delta B^2 &\geq \mathfrak{Re}\ ^2\langle\psi|\delta\hat{A}\delta\hat{B}|\psi\rangle + \mathfrak{Im}\ ^2\langle\psi|\delta\hat{A}\delta\hat{B}|\psi\rangle \geq \mathfrak{Im}\ ^2\langle\psi|\delta\hat{A}\delta\hat{B}|\psi\rangle \\
&= \left[\tfrac{1}{2\imath}\Big(\langle\psi|\delta\hat{A}\delta\hat{B}|\psi\rangle - \langle\psi|\delta\hat{B}\delta\hat{A}|\psi\rangle\Big)\right]^2 = \left[\tfrac{1}{2\imath}\langle\psi|[\delta\hat{A},\delta\hat{B}]|\psi\rangle\right]^2 = \left[\tfrac{1}{2\imath}\langle\psi|[\hat{A},\hat{B}]|\psi\rangle\right]^2 \ .
\end{aligned}$$

$\imath[\hat{A},\hat{B}]$ *is always real when* $\hat{A}$ *and* $\hat{B}$ *are observable. This inequality has two roots:* $\Delta A\Delta B \geq \pm\frac{1}{2}|\langle[\hat{A},\hat{B}]\rangle|$, *but as the result must be valid when we exchange* $\hat{A}$ *and* $\hat{B}$, *we finally obtain,*

$$\Delta A\Delta B \geq \tfrac{1}{2}|\langle[\hat{A},\hat{B}]\rangle| \ .$$

23.3.10.11 Ex: Fourier transform

Show that $\langle \mathbf{r}|\hat{\mathbf{P}}|\psi\rangle = \frac{\hbar}{\imath}\nabla\langle \mathbf{r}|\psi\rangle$ reproduces the Schrödinger equation in position representation.

Solution: *Using the result (23.105) we calculate,*

$$\begin{aligned}\langle \mathbf{r}|\hat{\mathbf{P}}|\psi\rangle &= \int d^3r'\langle \mathbf{r}|\hat{\mathbf{P}}|\mathbf{r}'\rangle\langle \mathbf{r}'|\psi\rangle = \tfrac{1}{\hbar^{3/2}}\int\int d^3r'd^3p\ \mathbf{p}e^{\imath\mathbf{p}\cdot(\mathbf{r}-\mathbf{r}')/\hbar}\psi(\mathbf{r}') \\ &= \tfrac{1}{\hbar^{3/2}}\int\int d^3r'd^3p\tfrac{\hbar}{\imath}\nabla_{\mathbf{r}}e^{\imath\mathbf{p}\cdot(\mathbf{r}-\mathbf{r}')/\hbar}\psi(\mathbf{r}') = \tfrac{\hbar}{\imath}\nabla_{\mathbf{r}}\int d^3r'\delta^3(\mathbf{r}-\mathbf{r}')\psi(\mathbf{r}') = \tfrac{\hbar}{\imath}\nabla_{\mathbf{r}}\psi(\mathbf{r})\ .\end{aligned}$$

Alternatively we can explore the property of the Fourier transform, $\mathcal{F}[x^n f(x)] = \imath^n\frac{d^n\mathcal{F}f(k)}{dk^n}$, giving

$$\langle \mathbf{r}|\hat{P}_x|\mathbf{r}'\rangle = \int d^3p\langle \mathbf{r}|\hat{P}_x|\mathbf{p}\rangle\langle \mathbf{p}|\mathbf{r}'\rangle = \tfrac{\hbar}{\imath}\delta'(x-x')\delta(y-y')\delta(z-z')\ .$$

to calculate,

$$\begin{aligned}\langle \mathbf{r}|\hat{P}_x|\psi\rangle &= \int d^3r'\langle \mathbf{r}|\hat{P}_x|\mathbf{r}'\rangle\langle \mathbf{r}'|\psi\rangle \\ &= \tfrac{\hbar}{\imath}\int dx'\delta'(x-x')\int dy'\delta(y-y')\int dz'\delta(z-z')\psi(\mathbf{r}') = \frac{\hbar}{\imath}\frac{\partial}{\partial x}\psi(x,y,z)\ .\end{aligned}$$

With this result and the Hamiltonian $\hat{H} \equiv \hat{\mathbf{P}}^2/2m + V(\hat{\mathbf{R}})$ it is easy to verify the Schrödinger equation in spatial representation,

$$\imath\hbar\frac{d}{dt}\langle \mathbf{r}|\psi(t)\rangle = \left[-\frac{\hbar^2}{2m}\nabla^2_{\mathbf{r}} + V(\mathbf{r})\right]\langle \mathbf{r}|\psi(t)\rangle\ .$$

It is interesting to note that the Schrödinger equation in momentum representation is given by,

$$\begin{aligned}\imath\hbar\frac{d}{dt}\langle \mathbf{p}|\psi(t)\rangle &= \langle \mathbf{p}|\frac{\hat{\mathbf{P}}^2}{2m}\psi(t)\rangle + \langle \mathbf{p}|V(\hat{\mathbf{R}})|\psi(t)\rangle \\ &= \frac{\mathbf{p}^2}{2m}\langle \mathbf{p}|\psi(t)\rangle + \int\int\langle \mathbf{p}|V(\hat{\mathbf{R}})|\mathbf{r}\rangle\langle \mathbf{r}|\mathbf{p}'\rangle\varphi(\mathbf{p}',t)d^3rd^3p' \\ &= \frac{\mathbf{p}^2}{2m}\langle \mathbf{p}|\psi(t)\rangle + \frac{1}{h^{3/2}}\int\int V(\mathbf{r})e^{(\imath/\hbar)(\mathbf{p}'-\mathbf{p})\cdot\mathbf{r}}\varphi(\mathbf{p}',t)d^3rd^3p' \\ &= \frac{\mathbf{p}^2}{2m}\langle \mathbf{p}|\psi(t)\rangle + \int\tilde{V}(\mathbf{p}-\mathbf{p}')\varphi(\mathbf{p}',t)d^3p'\ ,\end{aligned}$$

where $\tilde{V}(\mathbf{p}) = \hbar^{-3/2}\int V(\mathbf{r})e^{-\imath\mathbf{k}\cdot\mathbf{r}}d^3r$.

23.3.10.12 Ex: Projection of the motion of a particle

Project the Hamiltonian of the motion of a free particle onto the plane x-y at the position $z = z_0$ using the projection operator $\hat{P} = |z_0\rangle\langle z_0|$ and the trace defined in

(23.137) generalized to continuous variables.

Solution: *The particle's Hamiltonian is,*

$$\hat{H} = \frac{\hat{\mathbf{p}}^2}{2m} = \int d^3r d^3r' |\mathbf{r}'\rangle\langle\mathbf{r}'| \frac{\hat{\mathbf{p}}^2}{2m} |\mathbf{r}\rangle\langle\mathbf{r}| \ .$$

The projector $\hat{P} = |z_0\rangle\langle z_0|$ *projects the Hamiltonian onto,*

$$\begin{aligned}
\hat{H}_{\mathcal{R}} &= |z_0\rangle\langle z_0| \int d^3r d^3r' |x'y'z'\rangle\langle x'y'z'| \frac{\hat{\mathbf{p}}^2}{2m} |xyz\rangle\langle xyz|z_0\rangle\langle z_0| \\
&= \int d^3r d^3r' \delta(z'-z_0) |x'y'\rangle\langle x'y'| \frac{\hat{p}_x^2 + \hat{p}_y^2 + \hat{p}_z^2}{2m} |xy\rangle\langle xy| \delta(z-z_0) \\
&= \int dx dy dx' dy' |x'y'\rangle\langle x'y'| \frac{\hat{p}_x^2 + \hat{p}_y^2}{2m} |xy\rangle\langle xy| = \frac{\hat{p}_x^2 + \hat{p}_y^2}{2m} \ .
\end{aligned}$$

23.3.10.13 Ex: Complete system of commuting operators

Construct the Hilbert space of two independent two-level systems a and b. Consider observables $\hat{X}_a$ and $\hat{Y}_b$ acting on their respective systems. What will be their shapes $\hat{X}_{ab}$, respectively $\hat{Y}_{ab}$, in the total Hilbert space? Construct the expanded state $|\psi_{ab}\rangle$ from the basis of the individual systems. Verify $[\hat{X}_{ab}, \hat{Y}_{ab}] = 0$. Verify that the expanded observables obey the same eigenvalue equations as the original ones.

Solution: *Be* $\hat{X}_a$ *and* $\hat{Y}_b$ *two operators related to the two atoms a and b with the eigenvalue spectra,*

$$\hat{X}_a |k\rangle_a = a_k |k\rangle_a \quad , \quad \hat{Y}_b |k\rangle_b = b_k |k\rangle_b \ ,$$

with $k = 1, 2$ *such that the general states are* $|\psi_a\rangle = a_1|1\rangle_a + a_2|2\rangle_a$ *and* $|\psi_b\rangle = b_1|1\rangle_b + b_2|2\rangle_b$. *Since* $[\hat{X}_a, \hat{Y}_b] = 0$, *we can build the operators,*

$$\hat{X}_{ab} = \hat{X}_a \otimes 1_2 = \begin{pmatrix} \hat{X}_a & 0 \\ 0 & 1_2 \end{pmatrix} \quad , \quad \hat{Y}_{ab} = 1_2 \otimes \begin{pmatrix} 1_2 & 0 \\ 0 & \hat{Y}_a \end{pmatrix} \quad , \quad \hat{Z}_{ab} = \begin{pmatrix} \hat{X}_a & 0 \\ 0 & \hat{Y}_b \end{pmatrix} \ .$$

We verify that $[\hat{X}_{ab}, \hat{Y}_{ab}] = 0$ *simply because of the construction of the total matrix. Also, we build states*

$$|\psi_{ab}\rangle = c_1 \begin{pmatrix} |1\rangle_a \\ |1\rangle_b \end{pmatrix} + c_2 \begin{pmatrix} |2\rangle_a \\ |1\rangle_b \end{pmatrix} + c_3 \begin{pmatrix} |1\rangle_a \\ |2\rangle_b \end{pmatrix} + c_4 \begin{pmatrix} |2\rangle_a \\ |2\rangle_b \end{pmatrix} = c_1|1\rangle_{ab} + c_2|2\rangle_{ab} + c_3|3\rangle_{ab} + c_4|4\rangle_{ab} \ .$$

The expanded operators satisfy the same eigenvalue equations:

$$\hat{X}_{ab}|1_{ab}\rangle = \begin{pmatrix} \hat{X}_a & 0 \\ 0 & 1_2 \end{pmatrix} \begin{pmatrix} |1\rangle_a \\ |1\rangle_b \end{pmatrix} = \begin{pmatrix} \hat{X}_a|1\rangle_a \\ |1\rangle_b \end{pmatrix} = \begin{pmatrix} a_1|1\rangle_a \\ |1\rangle_b \end{pmatrix} = a_1|1_{ab}\rangle \ .$$

such that $\hat{X}_{ab}|\psi_{ab}\rangle = c_k|\psi_{ab}\rangle$.

23.3.10.14 Ex: Liouville equation

Show that $\begin{pmatrix}1 & 0\\ 0 & 0\end{pmatrix}\otimes\hat{A}+\begin{pmatrix}0 & 0\\ 0 & 1\end{pmatrix}\otimes\hat{B}=\hat{A}\oplus\hat{B}$.

Solution:

23.3.10.15 Ex: Liouville equation

Show at the example of a two-level system that the von Neumann equation, $\dot{\hat{\rho}}=-\frac{\imath}{\hbar}[\hat{H},\hat{\rho}]$, can be written, $\dot{\vec{\rho}}=-\frac{\imath}{\hbar}(\hat{H}\otimes\mathbb{I}-\mathbb{I}\otimes\hat{H})\vec{\rho}$, using the definition of the external product and $\vec{\rho}\equiv\begin{pmatrix}\rho_{11}\\ \rho_{12}\\ \rho_{21}\\ \rho_{22}\end{pmatrix}$. **Help:** For this exercise the physical interpretation of $\hat{\rho}$ as the density operator does not matter. It may be regarded as a common observable.

Solution: *On one hand we have,*

$$\begin{aligned}[\hat{H},\hat{\rho}] &= \begin{pmatrix}H_{11} & H_{12}\\ H_{21} & H_{22}\end{pmatrix}\begin{pmatrix}\rho_{11} & \rho_{12}\\ \rho_{21} & \rho_{22}\end{pmatrix}-\begin{pmatrix}\rho_{11} & \rho_{12}\\ \rho_{21} & \rho_{22}\end{pmatrix}\begin{pmatrix}H_{11} & H_{12}\\ H_{21} & H_{22}\end{pmatrix}\\ &= \begin{pmatrix}H_{12}\rho_{21}-H_{21}\rho_{12} & H_{11}\rho_{12}+H_{12}\rho_{22}-H_{12}\rho_{11}-H_{22}\rho_{12}\\ H_{21}\rho_{11}+H_{22}\rho_{21}-\rho_{21}H_{11}-\rho_{22}H_{21} & H_{21}\rho_{12}-H_{12}\rho_{21}\end{pmatrix}.\end{aligned}$$

On the other hand, knowing,

$$\hat{H}\otimes\mathbb{I}=\begin{pmatrix}H_{11} & H_{12} & 0 & 0\\ H_{21} & H_{22} & 0 & 0\\ 0 & 0 & H_{11} & H_{12}\\ 0 & 0 & H_{21} & H_{22}\end{pmatrix}\quad,\quad \mathbb{I}\otimes\hat{H}=\begin{pmatrix}H_{11} & 0 & H_{12} & 0\\ 0 & H_{11} & 0 & H_{12}\\ H_{21} & 0 & H_{22} & 0\\ 0 & H_{21} & 0 & H_{22}\end{pmatrix},$$

we have,

$$\begin{aligned}(\mathbb{I}\otimes\hat{H}-\hat{H}\otimes\mathbb{I})\vec{\rho} &= \begin{pmatrix}H_{11} & 0 & H_{12} & 0\\ 0 & H_{11} & 0 & H_{12}\\ H_{21} & 0 & H_{22} & 0\\ 0 & H_{21} & 0 & H_{22}\end{pmatrix}-\begin{pmatrix}H_{11} & H_{12} & 0 & 0\\ H_{21} & H_{22} & 0 & 0\\ 0 & 0 & H_{11} & H_{12}\\ 0 & 0 & H_{21} & H_{22}\end{pmatrix}\begin{pmatrix}\rho_{11}\\ \rho_{12}\\ \rho_{21}\\ \rho_{22}\end{pmatrix}\\ &= \begin{pmatrix}H_{12}\rho_{21}-H_{12}\rho_{12}\\ -H_{21}\rho_{11}+(H_{11}-H_{22})\rho_{12}+H_{12}\rho_{22}\\ H_{21}\rho_{11}+(H_{22}-H_{11})\rho_{21}-H_{12}\rho_{22}\\ H_{21}\rho_{12}-H_{21}\rho_{21}\end{pmatrix},\end{aligned}$$

given that $\hat{H}^\dagger=\hat{H}$.

23.3.10.16 Ex: Unitary transformation of singlet states

Consider two spins a and b that do not interact. Applying to each spin the same transformation to another base, show that the singlet state has in each base the following form: $|\psi\rangle = \frac{1}{\sqrt{2}}\left(|\uparrow\rangle_a|\downarrow\rangle_b - |\downarrow\rangle_a|\uparrow\rangle_b\right)$.

Solution: *The change of base corresponds to a unitary transformation* $U = \begin{pmatrix} a & b \\ c & d \end{pmatrix}$, *where* $\det U = 1$. *Hence,*

$$\begin{aligned}
|0,0\rangle &= \tfrac{1}{\sqrt{2}}[|\uparrow\rangle_a|\downarrow\rangle_b - |\downarrow\rangle_a|\uparrow\rangle_b] \\
&= \tfrac{1}{\sqrt{2}}\left[(a|1\rangle_a + b|2\rangle_a)(c|1\rangle_b + d|2\rangle_b) - (c|1\rangle_a + d|2\rangle_a)(a|1\rangle_b + b|2\rangle_b)\right] \\
&= \tfrac{1}{\sqrt{2}}\left[ad(|1\rangle_a|2\rangle_b - |2\rangle_a|1\rangle_b) + bc(|2\rangle_a|1\rangle_b - |1\rangle_a|2\rangle_b)\right] = \tfrac{1}{\sqrt{2}}\left(|1\rangle_a|2\rangle_b - |2\rangle_a|1\rangle_b\right) \ .
\end{aligned}$$

23.4 Time evolutions

Quantum systems may evolve in time, as predicted by the time-dependent Schrödinger equation (23.54). In this section we show different equivalent but complementary descriptions of the temporal evolution of quantum systems depending on whether the time dependence is attributed to the state function of to observables.

23.4.1 Unitary transformations

The best we can do to characterize a system is, obviously, to measure all its observables. However, neither the state functions nor the observables are fixed unambiguously, since defining a unitary operator, $U^\dagger = U^{-1}$, we can do,

$$\langle\psi|\hat{A}|\psi\rangle = \langle\psi|U^\dagger U\hat{A}U^\dagger U|\psi\rangle = \langle U\psi|U\hat{A}U^\dagger|U\psi\rangle \ . \tag{23.139}$$

That is, exchanging $|\psi\rangle$ by $U|\psi\rangle$ and at the same time $\hat{A}$ by $U\hat{A}U^\dagger$, we obtain quantities describing the same physical reality, since the eigenvalues are unchanged. This allows us to choose the best mathematical representation for a specific problem. As an example, we will apply the temporal unitary transformation to solve the dynamics of a coupled two-level system in Exc. 23.4.7.1.

23.4.2 Schrödinger picture

Important examples of how the same system can be represented in different ways (related by unitary transformations) are the Heisenberg, Schrödinger, and interaction pictures.

The *Schrödinger picture*, denoted by the subscript S, is defined by the choice of a Hamiltonian,

$$\hat{H}_S = \hat{H}(t, \hat{p}_S, \hat{r}_S) \qquad \text{with} \qquad \frac{d}{dt}\hat{p}_S = \frac{d}{dt}\hat{r}_S = 0 \ . \tag{23.140}$$

That is, the observables of the system $\hat{A}_S(t, \hat{p}_S, \hat{r}_S)$ can only depend *explicitly* on time, but not via other operators, for instance $\hat{p}_S$ and $\hat{r}_S$, which are stationary,

$$\frac{d}{dt}\hat{A}_S = \frac{\partial \hat{A}_S}{\partial t} + \cancelto{0}{\dot{\hat{p}}_S}\frac{\partial \hat{A}_S}{\partial p_S} + \cancelto{0}{\dot{\hat{r}}_S}\frac{\partial \hat{A}_S}{\partial r_S} \ . \tag{23.141}$$

This is,

$$\boxed{\frac{d}{dt}\hat{A}_S(t) = \frac{\partial}{\partial t}\hat{A}_S(t)} \ . \tag{23.142}$$

In the context of a moving particle, this means that the Hamiltonian $\frac{1}{2m}\hat{p}_S^2 + V(\hat{r}_S)$ is time-independent (unless the potential $V(\hat{r}_S, t)$ is itself time-dependent). In this case, the formal solution of the Schrödinger equation,

$$\boxed{\imath\hbar\frac{d}{dt}|\psi_S(t)\rangle = \hat{H}_S|\psi_S(t)\rangle} \ , \tag{23.143}$$

can be written,

$$|\psi_S(t)\rangle = e^{-(\imath/\hbar)\hat{H}_S t}|\psi_S(0)\rangle \equiv U(t)|\psi_S(0)\rangle \ . \tag{23.144}$$

Apparently, the temporal dynamics is completely within the wave functions.

Example 148 (*The time evolution operator*): Generalizing to an arbitrary initial time t_0 we write the temporal translation operator,

$$U(t, t_0)|\psi(t_0)\rangle = |\psi(t)\rangle \ . \tag{23.145}$$

By the expression (23.144) we find immediately, with $t_0 < t_1 < t_2$,

$$U(t_2, t_0) = U(t_2, t_1)U(t_1, t_0) \quad \text{and} \quad U(t_0, t) = U^\dagger(t, t_0) = U^{-1}(t, t_0) = U(t, t_0)^{-1} \ .$$

The conjugate operator of time evolution acts on the vector 'bra',

$$\langle\psi(t)| = \langle\psi(t_0)|U^\dagger(t, t_0) \ .$$

23.4.3 Heisenberg picture

As unitary transformations do not change the physics, the system described by,

$$|\psi_S(t)\rangle \longrightarrow U(t)^\dagger|\psi_S(t)\rangle \equiv |\psi_H\rangle \qquad \text{and} \qquad \hat{A}_S(t) \longrightarrow U(t)^\dagger\hat{A}_S(t)U(t) \equiv \hat{A}_H(t) \tag{23.146}$$

with the transformation defined by equation (23.144), is equivalent. The subscript H means the *Heisenberg picture*. In particular, we obviously have,

$$\hat{H}_S = \hat{H}_H \equiv \hat{H} \ . \tag{23.147}$$

Thus, the matrix element of the operator $\hat{A}_S$ in Schrödinger's picture with the time-dependent base $\{|\psi_S\rangle\}$ is equal to the matrix element of the operator $\hat{A}_H = U^\dagger\hat{A}_S U$

in Heisenberg's picture with the time-independent base $\{|\psi_H\rangle\}$. In this picture the wavefunctions are independent of time,

$$\boxed{\frac{d}{dt}|\psi_H\rangle = \frac{d}{dt}|\psi_S(0)\rangle = 0}\,, \tag{23.148}$$

but the operators depend *im- and explicitly* on time,

$$\begin{aligned}\frac{d}{dt}\hat{A}_H(t) &= \frac{d}{dt}\left(U(t)^\dagger \hat{A}_S(t) U(t)\right) = \frac{dU^\dagger}{dt}\hat{A}_S(t)U(t) + U(t)^\dagger \hat{A}_S(t)\frac{dU}{dt} + U(t)^\dagger \frac{\partial \hat{A}_S(t)}{\partial t}U(t) \\ &= \frac{\imath}{\hbar}\hat{H}^\dagger U(t)^\dagger \hat{A}_S U(t) + U(t)^\dagger \hat{A}_S \frac{-\imath}{\hbar}\hat{H}U(t) + U^\dagger(t)\frac{\partial \hat{A}_S(t)}{\partial t}U(t)\,. \end{aligned} \tag{23.149}$$

That is,

$$\boxed{\frac{d}{dt}\hat{A}_H(t) = \frac{\imath}{\hbar}[\hat{H}, \hat{A}_H(t)] + \frac{\partial \hat{A}_H(t)}{\partial t}}\,. \tag{23.150}$$

This so-called *Heisenberg equation*, which describes the temporal evolution of an operator acting on time-independent states in the Heisenberg picture, is equivalent to the Schrödinger equation, which expresses the temporal evolution of a quantum state in Schrödinger's picture.

According to equation (23.150), the rate of temporal variation of an operator in the Heisenberg representation is given by the commutator of that operator with the total Hamiltonian of the system. Note that if an operator representing a dynamic variable commutes with the Hamiltonian in the Schrödinger representation, it will also commute with the Hamiltonian in the Heisenberg representation and thus with the complete set of commutating observables,

$$[\hat{H}, \hat{A}_S] = 0 \qquad \Longleftrightarrow \qquad [\hat{H}, \hat{A}_H] = 0\,. \tag{23.151}$$

We will show this in the Exc. 23.4.7.2. Note that we could interpret Eq. (23.148) as a Schrödinger equation with a Hamiltonian $\tilde{H}_H = 0$. That is, *the Hamiltonian used in the Schrödinger equation differs from the one used in the Heisenberg equation.* We will study this in more detail in Secs. 23.4.4 and 23.4.5.

> **Example 149 (*Position and momentum operators in the Heisenberg picture*):** We know that in Schrödinger's picture (23.140), the operators $\hat{p}_S$ and $\hat{r}_S$ are stationary. Using this fact in derivation (23.149), we can show for example for the momentum operator,
>
> $$\frac{\partial}{\partial t}\hat{p}_S = 0 \qquad \Longrightarrow \qquad \frac{\partial}{\partial t}\hat{p}_H = 0 \qquad \Longrightarrow \qquad \frac{d}{dt}\hat{p}_H = \frac{\imath}{\hbar}[\hat{H}, \hat{p}_H]\,.$$

In the Exc. 23.4.7.3 we will use the Heisenberg picture to derive the equations of motion for a particle confined to a potential.

23.4.4 Interaction picture

The *interaction picture* deals with problems where the total Hamiltonian is composed of a time-independent part and a time-dependent part,

$$\hat{H} = \hat{H}_0 + \hat{V}(t) \ . \tag{23.152}$$

Analogously to Eq. (23.144), we define a time evolution operator in terms of the *time-independent* part of the total Hamiltonian,

$$\boxed{|\psi_I(t)\rangle = e^{\imath \hat{H}_0 t/\hbar}|\psi_S(t)\rangle \qquad \text{and} \qquad \hat{A}_I(t) = e^{\imath \hat{H}_0 t/\hbar}\hat{A}_S e^{-\imath \hat{H}_0 t/\hbar}} \ . \tag{23.153}$$

Now we are interested in the temporal dependence of quantum states and operators in the interaction picture. Replacing the inverse function $|\psi_S(t)\rangle = e^{-\imath \hat{H}_0 t/\hbar}|\psi_I(t)\rangle$ in the Schrödinger equation (23.143) we immediately see,

$$\boxed{\hat{V}(t)|\psi_I(t)\rangle = \imath\hbar \frac{\partial}{\partial t}|\psi_I(t)\rangle} \ . \tag{23.154}$$

Apparently, in the interaction picture, only the perturbative term in Hamiltonian controls the temporal evolution. Taking the time derivative of both sides of the equation (23.153) transforming an operator from the Schrödinger to the interaction picture results in,

$$\boxed{\frac{d\hat{A}_I}{dt} = \frac{\imath}{\hbar}[\hat{H}_0, \hat{A}_I] + \frac{\partial \hat{A}_I}{\partial t}} \ . \tag{23.155}$$

Therefore, we see that the time derivative can be expressed in the form of a commutator, resembling the Heisenberg equation (23.150), except that only the unperturbed term of the Hamiltonian appears in the argument of the commutation operator. As already state in Sec. 23.4.3, different Hamiltonians are used in the Schrödinger and in the Heisenberg equation.

> **Example 150 (*Schrieffer-Wolff transformation*):** The *Schrieffer-Wolff transformation* is a unitary transformation used to perturbatively diagonalize the system Hamiltonian to first order in the interaction. As such, the Schrieffer-Wolff transformation is an operator version of second-order perturbation theory. The Schrieffer-Wolff transformation is often used to project out the high energy excitations of a given quantum many-body Hamiltonian in order to obtain an effective low energy model. The Schrieffer-Wolff transformation thus provides a controlled perturbative way to study the strong coupling regime of quantum-many body Hamiltonians.
> Consider a quantum system evolving under the time-independent Hamiltonian operator $\hat{H}$ of the form $\hat{H} = \hat{H}_0 + \hat{V}$, where H_0 is a Hamiltonian with known eigenstates $|m\rangle$ and corresponding eigenvalues E_m, and where V is a small perturbation. Moreover, it is assumed without loss of generality that $\hat{V}$ is purely off-diagonal in the eigenbasis of $\hat{H}_0$, i.e.,
>
> $$\langle m|\hat{V}|m\rangle = 0 \tag{23.156}$$
>
> for all m. Indeed, this situation can always be arranged by absorbing the diagonal elements of $\hat{V}$ into $\hat{H}_0$, thus modifying its eigenvalues to,
>
> $$E'_m = E_m + \langle m|\hat{V}|m\rangle \ . \tag{23.157}$$

The Schrieffer-Wolff transformation is a unitary transformation which expresses the Hamiltonian in a basis (the 'dressed' basis) where it is diagonal to first order in the perturbation $\hat{V}$. This unitary transformation is conventionally written as:

$$\hat{H}' = e^{\imath S}\hat{H}e^{-\imath S} \ . \tag{23.158}$$

When $\hat{V}$ is small, the generator S of the transformation will likewise be small. The transformation can then be expanded in S using the Baker-Campbell-Haussdorf formula,

$$\hat{H}' = \hat{H} + [\imath S, \hat{H}] + \tfrac{1}{2}[\imath S, [\imath S, \hat{H}]] + \dots \ . \tag{23.159}$$

In terms of $\hat{H}_0$ and $\hat{V}$, the transformation becomes,

$$\hat{H}' = \hat{H}_0 + \hat{V} + [\imath S, \hat{H}_0] + [\imath S, \hat{V}] + \tfrac{1}{2}[\imath S, [\imath S, \hat{H}_0]] + \tfrac{1}{2}[\imath S, [\imath S, \hat{V}]] + \dots \ . \tag{23.160}$$

The Hamiltonian can be made diagonal to first order in $\hat{V}$ by choosing the generator S such that,

$$[\hat{H}_0, \imath S] = \hat{V} \ . \tag{23.161}$$

This equation always has a definite solution under the assumption that $\hat{V}$ is off-diagonal in the eigenbasis of $\hat{H}_0$. Substituting this choice in the previous transformation yields:

$$\hat{H}' = \hat{H}_0 + \tfrac{1}{2}[\imath S, \hat{V}] + O(\hat{V}^3) \ . \tag{23.162}$$

This expression is the standard form of the Schrieffer-Wolff transformation. Note that all the operators on the right-hand side are now expressed in a new basis 'dressed' by the interaction $\hat{V}$ to first order.

In the general case, the difficult step of the transformation is to find an explicit expression for the generator S. Once this is done, it is straightforward to compute the Schrieffer-Wolff Hamiltonian by computing the commutator $[S, \hat{V}]$. The Hamiltonian can then be projected on any subspace of interest to obtain an effective projected Hamiltonian for that subspace. In order for the transformation to be accurate, the eliminated subspaces must be energetically well separated from the subspace of interest, meaning that the strength of the interaction $\hat{V}$ must be much smaller than the energy difference between the subspaces. This is the same regime of validity as in standard second-order perturbation theory.

23.4.5 Hamiltonian under arbitrary unitary transformation

In the preceding section we have studied particular unitary transformations between the Schrödinger, Heisenberg, and interaction pictures. Let us now have a look at *arbitrary* unitary transformations.

We have seen that the unitary transformation,

$$|\psi_U\rangle = U^\dagger|\psi\rangle \qquad , \qquad \hat{A}_U = U^\dagger \hat{A} U \ , \tag{23.163}$$

leaves the physics of a system unchanged. The question is now, how the Schrödinger equation,

$$\hat{H}|\psi\rangle = \imath\hbar\frac{d}{dt}|\psi\rangle \tag{23.164}$$

transforms into the new system, that is, what will the Hamiltonian $\hat{H}_U$ look like in the transformed equation,

$$\hat{H}_U|\psi_U\rangle \stackrel{?}{=} \imath\hbar\frac{d}{dt}|\psi_U\rangle \ . \tag{23.165}$$

We calculate,

$$\begin{aligned}\imath\hbar\frac{d}{dt}|\psi_U\rangle &= \imath\hbar U^\dagger\frac{d}{dt}|\psi\rangle + \imath\hbar\dot{U}^\dagger|\psi\rangle = (U^\dagger\hat{H} + \imath\hbar\dot{U}^\dagger)|\psi\rangle \\ &= (U^\dagger\hat{H} + \imath\hbar\dot{U}^\dagger)U|\psi_U\rangle = (U^\dagger\hat{H}U + \imath\hbar\dot{U}^\dagger U)|\psi_U\rangle = \hat{H}_U|\psi_U\rangle \ .\end{aligned} \tag{23.166}$$

Hence,

$$\boxed{\hat{H}_U = U^\dagger\hat{H}U + \imath\hbar\dot{U}^\dagger U} \ . \tag{23.167}$$

We will apply this concept in Exc. 23.5.6.2 to a particle in the field of gravity.

Example 151 (*Interaction picture*): The above derivation is general and holds for any unitary transformation. We will now apply it to transform the Hamiltonian $\hat{H} = \hat{H}_0 + \hat{V}(t)$ into the interaction picture via the transformation $U = e^{-(\imath/\hbar)\hat{H}_0 t}$. From

$$\dot{U}^\dagger = \frac{\imath}{\hbar}\hat{H}_0 e^{(\imath/\hbar)\hat{H}_0 t} = \frac{\imath}{\hbar}\hat{H}_0 U^\dagger \tag{23.168}$$

we calculate,

$$\begin{aligned}\hat{H}_U &= U^\dagger\hat{H}U + \imath\hbar\dot{U}^\dagger U = U^\dagger[\hat{H}_0 + \hat{V}(t)]U + \imath\hbar\frac{\imath}{\hbar}\hat{H}_0 U^\dagger U \\ &= U^\dagger[\hat{H}_0 + \hat{V}(t)]U - \hat{H}_0 = U^\dagger\hat{V}(t)U \ ,\end{aligned} \tag{23.169}$$

which confirms the validity of the Schrödinger equation (23.154) in the interaction picture, provided the Hamiltonian is taken to be the perturbation part $\hat{V}(t)$, only. In the Heisenberg picture $\hat{V}(t) = 0$, such that,

$$\hat{H}_U = 0 \ , \tag{23.170}$$

which confirms Eq. (23.148).

23.4.6 Ehrenfest's theorem

For linear operators satisfying $[\hat{A}, \hat{B}] = \imath$ we can give a generalization of the commutation relation:

$$\boxed{[\hat{A}, F(\hat{A}, \hat{B})] = \imath\frac{\delta F(\hat{A}, \hat{B})}{\delta\hat{B}}} \ . \tag{23.171}$$

This can be verified by a Taylor expansion of $F(\hat{A}, \hat{B})$ by $\hat{B}$ around $\hat{B} = 0$, as will be shown in Exc. 23.4.7.4. An immediate consequence of $[\hat{p}, \hat{r}] = -\imath\hbar$ is,

$$[\hat{p}, F(\hat{r})] = -\imath\hbar\frac{\delta F(\hat{r})}{\delta\hat{r}} \ . \tag{23.172}$$

The momentum observable is not singularly defined by the commutation relation, because each unitarily transformed operator satisfies the relation as well. We

can expand a unitarily equivalent momentum as $\tilde{p} = UpU^\dagger = e^{\imath F(r)} p e^{-\imath F(r)} = p + \imath[F(r), p] + \frac{1}{2!}[F(r), [F(r), p]] + ...$ using the relation (23.172).

The observables in the Heisenberg picture follow the same equations of motion as the corresponding classical quantities. This *correspondence principle* is called *Ehrenfest theorem*. For example, when working with position and momentum variables $[\hat{r}, \hat{k}] = \imath$ and $\hat{H} = \frac{\hbar^2}{2m}\hat{k}^2 + V(\hat{r})$, we obtain,

$$[\hat{r}, \hat{H}] = \imath\hbar \frac{\delta \hat{H}}{\delta \hat{p}} \qquad \text{and} \qquad [\hat{p}, \hat{H}] = -\imath\hbar \frac{\delta \hat{H}}{\delta \hat{r}} \ , \tag{23.173}$$

and using the Heisenberg equation (23.150),

$$\dot{\hat{r}} = \frac{\delta \hat{H}}{\delta \hat{p}} \qquad \text{and} \qquad \dot{\hat{p}} = -\frac{\delta \hat{H}}{\delta \hat{r}} \ . \tag{23.174}$$

We will demonstrate this in Exc. 23.4.7.5 for the case of a harmonic potential.

In the Schrödinger picture the equation of motion for the eigenvalues of the observables takes the form,

$$\frac{d}{dt}\langle \hat{A}_S \rangle = \langle \partial_t \psi | \hat{A}_S | \psi \rangle + \langle \psi | \partial_t \hat{A}_S | \psi \rangle + \langle \psi | \hat{A}_S | \partial_t \psi \rangle = \frac{\partial}{\partial t}\langle \hat{A}_S \rangle + \frac{\imath}{\hbar}\langle [\hat{H}, \hat{A}_S] \rangle \ . \tag{23.175}$$

The eigenvalues behave as Heisenberg observables in Eq. (23.149), that is, they follow the laws of Hamilton's and Newton's mechanics.

The important result now is that the equations that govern the eigenvalues of the observables are identical in the both pictures, since from the Heisenberg picture we obtain with Eq. (23.149),

$$\frac{d}{dt}\langle \hat{A}_H \rangle = \frac{\partial}{\partial t}\langle \hat{A}_H \rangle + \frac{\imath}{\hbar}\langle [\hat{H}, \hat{A}_H] \rangle \ .$$

23.4.7 Exercises

23.4.7.1 Ex: Coupled two-level atom

Calculate the time evolution of an atom with two levels coupled by a light field using the Hamiltonian,

$$\hat{H} = \begin{pmatrix} 0 & \frac{1}{2}\hbar\Omega \\ \frac{1}{2}\hbar\Omega & -\hbar\Delta \end{pmatrix} \ ,$$

where $\Delta = \omega - \omega_0$ is the detuning between the frequency of the light and the frequency of the transition and Ω the Rabi frequency. **Help:** Determine the matrix of the eigenvalues $\hat{E}$ and the unitary transformation U given by $U^\dagger \hat{H} U = \hat{E}$ and use the formal solution of the Schrödinger equation: $|\psi(t)\rangle = e^{-\imath \hat{H} t/\hbar}|\psi_0\rangle = e^{-\imath U^\dagger \hat{E} U t/\hbar}|\psi_0\rangle = U^\dagger e^{-\imath \hat{E} t/\hbar} U |\psi_0\rangle$.

Solution: *We find the eigenvalues via,*

$$0 = \det(\hat{H} - E\hat{1}) = \det \begin{pmatrix} -E & \frac{1}{2}\Omega \\ \frac{1}{2}\Omega & -\Delta - E \end{pmatrix} = E\Delta + E^2 - \tfrac{1}{4}\Omega^2 \Longrightarrow E_{1,2} = -\tfrac{1}{2}\Delta \pm \tfrac{1}{2}\sqrt{\Delta^2 + \Omega^2} \ .$$

The eigenvectors follow, introducing the generalized Rabi frequency, $G \equiv \sqrt{\Delta^2+\Omega^2}$, from,

$$\hat{H}\begin{pmatrix} a \\ b \end{pmatrix} = \begin{pmatrix} \frac{1}{2}\Omega b \\ \frac{1}{2}\Omega a - \Delta b \end{pmatrix} = -\tfrac{1}{2}\Delta \pm \tfrac{1}{2}G \begin{pmatrix} a \\ b \end{pmatrix} \quad \Longrightarrow \quad \begin{matrix} \Omega b = a(-\Delta \pm G) \\ a^2+b^2 = 1 \end{matrix} .$$

The second equation allows us to introduce an angle ϑ such, that for the first eigenvalue, $a_1 = \cos\vartheta$ and $b_1 = \sin\vartheta$. We find

$$\tan\vartheta = \frac{b_1}{a_1} = \frac{G-\Delta}{\Omega} = \frac{\Omega}{G+\Delta} = \frac{-a_2}{b_2} \ .$$

Joining the eigenvectors to form a unitary matrix and the eigenvalues into a diagonal matrix,

$$U \equiv \begin{pmatrix} a_1 & a_2 \\ b_1 & b_2 \end{pmatrix} = \begin{pmatrix} \cos\vartheta & \sin\vartheta \\ -\sin\vartheta & \cos\vartheta \end{pmatrix} \quad , \quad E = \begin{pmatrix} -\frac{1}{2}\Delta + \frac{1}{2}G & 0 \\ 0 & -\frac{1}{2}\Delta - \frac{1}{2}G \end{pmatrix} .$$

It is easy to show

$$\det U = 1 \quad , \quad U^{-1} = U^\dagger \quad , \quad U^\dagger \hat{H} U = E \ .$$

With the Schrödinger equation, $\frac{d}{dt}|\psi(t)\rangle = \frac{1}{\imath\hbar}|\psi(t)\rangle$, through its formal solution, we can finally calculate the temporal evolution,

$$\begin{aligned} |\psi(t)\rangle &= e^{-\imath\hat{H}t/\hbar}|\psi_0\rangle = e^{-\imath U^\dagger \hat{E} U t/\hbar}|\psi_0\rangle = U^\dagger e^{-\imath\hat{E}t/\hbar} U|\psi_0\rangle \\ &= \begin{pmatrix} \cos\vartheta & -\sin\vartheta \\ \sin\vartheta & \cos\vartheta \end{pmatrix} \begin{pmatrix} e^{\frac{1}{2}\imath t(-\Delta+G)} & 0 \\ 0 & e^{\frac{1}{2}\imath t(-\Delta-G)} \end{pmatrix} \begin{pmatrix} \cos\vartheta & -\sin\vartheta \\ \sin\vartheta & \cos\vartheta \end{pmatrix} |\psi_0\rangle \\ &= \begin{pmatrix} \cos^2\vartheta e^{\frac{1}{2}\imath t(-\Delta+G)} + \sin^2\vartheta e^{\frac{1}{2}\imath t(-\Delta-G)} & \sin\vartheta\cos\vartheta\left(e^{\frac{1}{2}\imath t(-\Delta+G)} - e^{\frac{1}{2}\imath t(-\Delta-G)}\right) \\ \sin\vartheta\cos\vartheta\left(e^{\frac{1}{2}\imath t(-\Delta+G)} - e^{\frac{1}{2}\imath t(-\Delta-G)}\right) & \sin^2\vartheta e^{\frac{1}{2}\imath t(-\Delta+G)} + \cos^2\vartheta e^{\frac{1}{2}\imath t(-\Delta-G)} \end{pmatrix} |\psi_0\rangle \ . \end{aligned}$$

Assuming the two-level system to be initially in its ground state, $|\psi_0\rangle = \binom{1}{0}$, we

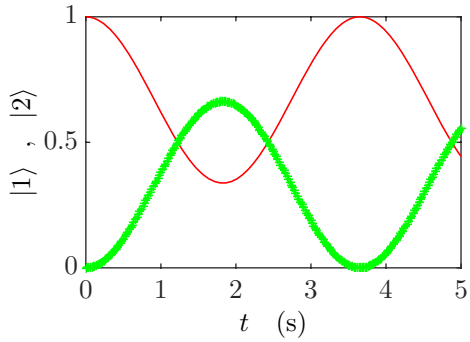

Figure 23.5: (code) Temporal evolution of the populations in a three-level system.

obtain,

$$a_1(t) = e^{-\imath t\Delta/2}\left(e^{\imath tG/2}\cos^2\vartheta + e^{-\imath tG/2}\sin^2\vartheta\right) = e^{-\imath t\Delta/2}\left[\cos\tfrac{Gt}{2} + \imath\left(\cos^2\vartheta - \sin^2\vartheta\right)\sin\tfrac{Gt}{2}\right]$$
$$a_2(t) = e^{-\frac{1}{2}\imath t\Delta}\sin\vartheta\cos\vartheta\left(e^{-\frac{1}{2}\imath tG} - e^{\frac{1}{2}\imath tG}\right) = 2ie^{-\imath t\Delta/2}\sin\vartheta\cos\vartheta\sin\tfrac{Gt}{2}\ .$$

With

$$\cos^2\vartheta - \sin^2\vartheta = \frac{1-\tan^2\vartheta}{1+\tan^2\vartheta} = \frac{\Omega^2-(G+\Delta)^2}{\Omega^2+(G+\Delta)^2} = -\frac{\Delta}{G}$$
$$\sin\vartheta\cos\vartheta = \frac{\tan\vartheta}{1+\tan^2\vartheta} = \frac{\Omega(G-\Delta)}{\Omega^2+(G-\Delta)^2} = \frac{\Omega}{2G}$$

we find

$$a_1(t) = e^{-\imath t\Delta/2}\left[\cos\tfrac{Gt}{2} - \imath\tfrac{\Delta}{G}\sin\tfrac{Gt}{2}\right] \qquad \textit{and} \qquad a_2(t) = \frac{\imath\Omega}{G}e^{-\imath t\Delta/2}\sin\tfrac{Gt}{2}$$

in accordance with the derivation of the Rabi formula (27.93).

23.4.7.2 Ex: Commutator in Schrödinger's and Heisenberg's picture

Show that operators which commute with the Hamiltonian in the Schrödinger picture also do it in the Heisenberg picture. Use the rule $[\hat{H}, \hat{A}\hat{B}] = \hat{A}[\hat{H},\hat{B}] + [\hat{H},\hat{A}]\hat{B}$.

Solution: *We calculate,*

$$0 = [\hat{H}, U\hat{A}_S U^\dagger] = U\hat{A}_S\cancelto{0}{[\hat{H},U^\dagger]} + U[\hat{H},\hat{A}_S]U^\dagger + \cancelto{0}{[\hat{H},U]}\hat{A}_S U^\dagger\ .$$

23.4.7.3 Ex: Motion in Heisenberg's picture

Consider the Hamiltonian $\hat{H} = \frac{\hat{p}^2}{2m} + \frac{m}{2}\omega^2\hat{r}^2$. Using the relation $[\hat{p},\hat{r}] = -\imath\hbar$ calculate in the Heisenberg picture the equations of motion for the observables $\hat{p}$, $\hat{r}$, and $\hat{p}\hat{r}$.

Solution: *a. We have*

$$\frac{d\hat{p}}{dt} = \frac{\imath}{\hbar}[\hat{H},\hat{p}] + \frac{\partial\hat{p}}{\partial t} = \frac{\imath}{\hbar}\left[\frac{\hat{p}^2}{2m} + \frac{m}{2}\omega^2\hat{r}^2, \hat{p}\right] = \frac{\imath m\omega^2}{2\hbar}[\hat{r}^2,\hat{p}] = \frac{\imath m\omega^2}{2\hbar}\left[\hat{r}\hat{r}\hat{p} - \left(\tfrac{\hbar}{\imath} + \hat{r}\hat{p}\right)\hat{r}\right] = -m\omega^2\hat{r}\ .$$

b. We have

$$\frac{d\hat{r}}{dt} = \frac{\imath}{\hbar}[\hat{H},\hat{r}] + \frac{\partial\hat{r}}{\partial t} = \frac{\imath}{\hbar}\left[\frac{\hat{p}^2}{2m} + \frac{m}{2}\omega^2\hat{r}^2, \hat{r}\right] = \frac{\imath}{2\hbar m}[\hat{p}^2,\hat{r}] = \frac{\imath}{2\hbar m}\left[\hat{p}\hat{p}\hat{r} - \left(\hat{p}\hat{r} - \tfrac{\hbar}{\imath}\right)\hat{p}\right] = \frac{\hat{p}}{m}\ .$$

c. We have

$$\frac{d(\hat{p}\hat{r})}{dt} = \frac{\imath}{\hbar}\left[\frac{\hat{p}^2}{2m} + \frac{m}{2}\omega^2\hat{r}^2, \hat{p}\hat{r}\right] + \frac{\partial(\hat{p}\hat{r})}{\partial t}$$
$$= \frac{\imath}{\hbar 2m}\left[\hat{p}\hat{p}\hat{p}\hat{r} - \hat{p}\left(\hat{p}\hat{r} - \tfrac{\hbar}{\imath}\right)\hat{p}\right] + \frac{\imath m\omega^2}{2\hbar}\left[\hat{r}\hat{r}\hat{p}\hat{r} - \left(\tfrac{\hbar}{\imath} + \hat{r}\hat{p}\right)\hat{r}\hat{r}\right] = \frac{\hat{p}^2}{m} - m\omega^2\hat{r}^2\ .$$

23.4.7.4 Ex: Commutator of a function of operators

Prove the relationship (23.171).

Solution: *We first calculate,*

$$\begin{aligned}
[\hat{A}, \hat{B}^n] &= \hat{B}^{n-1}[\hat{A}, \hat{B}] + [\hat{A}, \hat{B}^{n-1}]\hat{B} \\
&= \hat{B}^{n-1}[\hat{A}, \hat{B}] + \hat{B}^{n-2}[\hat{A}, \hat{B}]\hat{B} + [\hat{A}, \hat{B}^{n-2}]\hat{B}^2 \\
&= \hat{B}^{n-1}[\hat{A}, \hat{B}] + \hat{B}^{n-2}[\hat{A}, \hat{B}]\hat{B} + ... + [\hat{A}, \hat{B}]\hat{B}^{n-1} \\
&= \sum_{k=1}^{n} \hat{B}^{n-k}[\hat{A}, \hat{B}]\hat{B}^{k-1} = \imath n \hat{B}^{n-1} \ .
\end{aligned}$$

With this we can show,

$$\begin{aligned}
[\hat{A}, F(\hat{A}, \hat{B})] &= \left[\hat{A}, F(\hat{A}, 0) + \frac{\delta F(\hat{A}, 0)}{\delta \hat{B}}\hat{B} + ... + \frac{1}{n!}\frac{\delta^n F(\hat{A}, 0)}{\delta \hat{B}^n}\hat{B}^n + ...\right] \\
&= \frac{\delta F(\hat{A}, 0)}{\delta \hat{B}}[\hat{A}, \hat{B}] + ... + \frac{1}{n!}\frac{\delta^n F(\hat{A}, 0)}{\delta \hat{B}^n}[\hat{A}, \hat{B}^n] + ... \\
&= \imath\frac{\delta F(\hat{A}, 0)}{\delta \hat{B}} + ... + \imath\frac{1}{n!}\frac{\delta^n F(\hat{A}, 0)}{\delta \hat{B}^n}\imath n \hat{B}^{n-1} + ... \\
&= \imath\frac{\delta}{\delta \hat{B}}\left(1 + ... + \imath\frac{1}{(n-1)!}\frac{\delta^{n-1}}{\delta \hat{B}^{n-1}}\hat{B}^{n-1} + ...\right) F(\hat{A}, 0) = \imath\frac{\delta}{\delta \hat{B}}F(\hat{A}, B) \ .
\end{aligned}$$

23.4.7.5 Ex: Ehrenfest's theorem

Compare the equations of Ehrenfest's theorem with those of Hamilton-Jacobi for a classical particle subject to a time-independent potential. Discuss the classical limit, that is, when the Hamilton-Jacobi equations approach those of Ehrenfest.

Solution: *Are equivalent,*

$$\begin{aligned}
[\hat{r}, \hat{H}] &= \frac{1}{2m}\left(\hat{r}\hat{p}\hat{p} - \hat{p}\hat{p}\hat{r}\right) = \frac{1}{2m}\left((\hat{p}\hat{r} + \imath\hbar)\hat{p} - \hat{p}\left(-\imath\hbar + \hat{r}\hat{p}\right)\right) = \frac{\imath\hbar}{m}\hat{p} = \imath\hbar\frac{\delta \hat{H}}{\delta \hat{p}} \\
[\hat{p}, \hat{H}] &= \hat{p}V(\hat{r}) - V(\hat{r})\hat{p} = -\imath\hbar\frac{\delta \hat{H}}{\delta \hat{r}} \ .
\end{aligned}$$

For example, we take the harmonic potential, $V(\hat{r}) = \frac{m}{2}\omega^2\hat{r}^2$.

23.5 Symmetries in quantum mechanics

We already saw in Sec. 23.3.4 that, beyond observables, there is another category of operators that does not correspond to measurable physical quantities, but is very useful in the quantum formalism. These are the *unitary transformations*. In this section we will encounter some interesting examples.

23.5.1 Translation, rotation and momentum kick

23.5.1.1 Temporal translation operator

The temporal evolution of a system is described by the Schrödinger equation whose formal solution can be written as follows,

$$|\psi(t)\rangle = e^{-\imath\hat{H}t/\hbar}|\psi(0)\rangle \ . \tag{23.176}$$

With this we can define an *evolution operator* or temporal translation,

$$\boxed{U_{tp}(\tau) \equiv e^{-\imath\hat{H}t/\hbar} \qquad \text{such that} \qquad U_{tp}(\tau)|\psi(t)\rangle = |\psi(t+\tau)\rangle} \ . \tag{23.177}$$

The temporal evolution has already been discussed extensively in Sec. 23.4.

23.5.1.2 Spatial translation operator

In this section we look for a unitary *translation operator*,

$$\mathcal{T}_{tr}\mathbf{r} \equiv \mathbf{a} + \mathbf{r} \ . \tag{23.178}$$

Before this, we need to derive the following calculation rule for commutators, which will be done in Exc. 23.5.6.1:

$$e^{\hat{A}}\hat{B}e^{-\hat{A}} = \hat{B} + [\hat{A},\hat{B}] + \tfrac{1}{2!}[\hat{A},[\hat{A},\hat{B}]] + ... \ . \tag{23.179}$$

Applying this formula to the two operators $\hat{\mathbf{p}}$ and $\hat{\mathbf{r}}$ related by the commutation rule (23.53), we obtain,

$$e^{(\imath/\hbar)\mathbf{a}\cdot\hat{\mathbf{p}}}\hat{\mathbf{r}}e^{(-\imath/\hbar)\mathbf{a}\cdot\hat{\mathbf{p}}} = \hat{\mathbf{r}} + [(\imath/\hbar)\mathbf{a}\cdot\hat{\mathbf{p}},\hat{\mathbf{r}}] + \tfrac{1}{2!}\cancelto{0}{[(\imath/\hbar)\mathbf{a}\cdot\hat{\mathbf{p}},\mathbf{a}]} + ... = \hat{\mathbf{r}} + \mathbf{a} \ . \tag{23.180}$$

That is, the operator

$$\boxed{U_{tr}(\mathbf{a}) \equiv e^{(-\imath/\hbar)\mathbf{a}\cdot\hat{\mathbf{p}}}} \tag{23.181}$$

performs a spatial translation of the position operator. The operator is unitary,

$$U_{tr}(\mathbf{a})^{-1} = U_{tr}(\mathbf{a})^{\dagger} \ , \tag{23.182}$$

and forms a group since $U_{tr}(\mathbf{a})U_{tr}(\mathbf{b}) = U_{tr}(\mathbf{a}+\mathbf{b})$. Summarizing the impact of the translation on the operators of space,

$$\boxed{U_{tr}^{\dagger}(\mathbf{a})\hat{\mathbf{r}}U_{tr}(\mathbf{a}) = \hat{\mathbf{r}} + \mathbf{a} \qquad , \qquad U_{tr}^{\dagger}(\mathbf{a})\hat{\mathbf{p}}U_{tr}(\mathbf{a}) = \hat{\mathbf{p}}} \ , \tag{23.183}$$

where the second relation is obvious.

To demonstrate how the translation acts on a state, let us calculate,

$$\hat{\mathbf{r}} e^{(-\imath/\hbar)\mathbf{a}\cdot\hat{\mathbf{p}}}|\mathbf{r}\rangle = e^{(-\imath/\hbar)\mathbf{a}\cdot\hat{\mathbf{p}}}(\hat{\mathbf{r}}+\mathbf{a})|\mathbf{r}\rangle = (\mathbf{r}+\mathbf{a})e^{(-\imath/\hbar)\mathbf{a}\cdot\hat{\mathbf{p}}}|\mathbf{r}\rangle \ . \tag{23.184}$$

Hence,

$$\boxed{U_{tr}(\mathbf{a})|\mathbf{r}\rangle = e^{(-\imath/\hbar)\mathbf{a}\cdot\hat{\mathbf{p}}}|\mathbf{r}\rangle = |\mathbf{r}+\mathbf{a}\rangle} \ . \tag{23.185}$$

Therefore, if a particle is in an eigenstate $|\mathbf{r}\rangle$ of the position operator (i.e. located exactly at the position $\mathbf{r}$), then after $U_{tr}(\mathbf{a})$ acts on it, the particle is at the position $\mathbf{r}+\mathbf{a}$: The translation operator $U_{tr}(\mathbf{a})$ hence moves particles and fields by the distance $\mathbf{a}$.

Finally, we want to describe, how the translation operator acts on an arbitrary state $|\psi\rangle$ represented in position-space, remembering that the position-space wavefunction is obtained via $\psi(\mathbf{r}) \equiv \langle\mathbf{r}|\psi\rangle$, as already mentioned in Sec. 23.3.7. We get,

$$\psi'(\mathbf{r}) \equiv \mathcal{T}_{tr}\psi(\mathbf{r}) \equiv \langle\mathbf{r}|U_{tr}(\mathbf{a})|\psi\rangle = \langle U_{tr}^{\dagger}(\mathbf{a})\mathbf{r}|\psi\rangle = \langle\mathbf{r}-\mathbf{a}|\psi\rangle = \psi(\mathbf{r}-\mathbf{a}) \ . \tag{23.186}$$

This relation is easier to remember as $\psi'(\mathbf{r}+\mathbf{a}) = \psi(\mathbf{r})$, which can be read as: *The value of the new wavefunction at the new point equals the value of the old wavefunction at the old point.*

> **Example 152 (*Translation of spatial wavefunctions*):** Here is an example showing that these two descriptions (23.185) and (23.186) are equivalent. The state $|\mathbf{x}\rangle$ corresponds to the wavefunction $\psi(\mathbf{r}) = \delta^3(\mathbf{r}-\mathbf{x})$, while the state $U_{tr}(\mathbf{a})|\mathbf{x}\rangle = |\mathbf{x}+\mathbf{a}\rangle$ corresponds to the wavefunction $\psi'(\mathbf{r}) = \delta^3(\mathbf{r}-(\mathbf{x}+\mathbf{a}))$. These indeed satisfy $\psi'(\mathbf{r}) = \psi(\mathbf{r}-\mathbf{a})$.

Comparing the expansion of the translation operator,

$$\langle\mathbf{r}|U_{tr}(\mathbf{a})|\psi\rangle = \langle e^{(\imath/\hbar)\mathbf{a}\cdot\hat{\mathbf{p}}}\mathbf{r}|\psi\rangle = \left(1 + \frac{\imath}{\hbar}\mathbf{a}\cdot\hat{\mathbf{p}} - \frac{1}{\hbar^2}\frac{(\mathbf{a}\cdot\hat{\mathbf{p}})^2}{2!} + ..\right)\langle\mathbf{r}|\psi\rangle \ , \tag{23.187}$$

with the Taylor expansion of the wavefunction,

$$\langle\mathbf{r}+\mathbf{a}|\psi\rangle = \psi(\mathbf{r}+\mathbf{a}) = \left(1 + \mathbf{a}\cdot\nabla + \frac{(\mathbf{a}\cdot\nabla)^2}{2!} + ..\right)\psi(\mathbf{r}) \ . \tag{23.188}$$

we obtain

$$\hat{\mathbf{p}}|\mathbf{r}\rangle = \frac{\hbar}{\imath}\nabla|\mathbf{r}\rangle \ . \tag{23.189}$$

Finally, we note that the momentum operator can be defined via the translation operator,

$$\hat{\mathbf{p}} = \imath\hbar\,\nabla_{\mathbf{a}} U_{tr}(\mathbf{a})|_{\mathbf{a}=\mathbf{0}} \ . \tag{23.190}$$

23.5.1.3 Momentum kick operator

In this section we look for the unitary transformation into a frame moving a constant velocity $\mathbf{v}$,

$$\mathcal{T}_{kc}\mathbf{p} \equiv \mathbf{p} + m\mathbf{v} \ . \tag{23.191}$$

As this transformation corresponds to a 'translation' in momentum space, the form of the unitary transformation operator and the way it acts on operators and states are easy to derive by analogy to the spatial translation operator, simply interchanging the roles of the conjugate operators of space and momentum. The corresponding unitary operator in the so-called *kick operator*,

$$\boxed{U_{kc}(m\mathbf{v}) = e^{(\imath/\hbar)m\mathbf{v}\cdot\hat{\mathbf{r}}}} \ . \tag{23.192}$$

where $m\mathbf{v} = \mathbf{p} = \hbar\mathbf{k}$ is the gain in momentum due to the kick.

A common situation where such a kick occurs is the photonic recoil that an atom receives upon absorption of a photon. Using the relationship (23.179) derived in Exc. 23.5.6.1 it is easy to verify the following expressions of the left-hand panel,

$$\boxed{\begin{aligned} e^{\imath\mathbf{k}\cdot\hat{\mathbf{r}}}|\mathbf{r}\rangle &= e^{\imath\mathbf{k}\cdot\mathbf{r}}|\mathbf{r}\rangle \\ e^{\imath\mathbf{k}\cdot\hat{\mathbf{r}}}|\mathbf{p}\rangle &= |\mathbf{p}+\hbar\mathbf{k}\rangle \\ e^{-\imath\mathbf{k}\cdot\hat{\mathbf{r}}}\hat{\mathbf{r}}e^{\imath\mathbf{k}\cdot\hat{\mathbf{r}}} &= \hat{\mathbf{r}} \\ e^{-\imath\mathbf{k}\cdot\hat{\mathbf{r}}}\hat{\mathbf{p}}e^{\imath\mathbf{k}\cdot\hat{\mathbf{r}}} &= \hat{\mathbf{p}}+\hbar\mathbf{k} \\ e^{-\imath\mathbf{k}\cdot\hat{\mathbf{r}}}\frac{\hat{\mathbf{p}}^2}{2m}e^{\imath\mathbf{k}\cdot\hat{\mathbf{r}}} &= \frac{(\hat{\mathbf{p}}+\hbar\mathbf{k})^2}{2m} \end{aligned}} \quad , \quad \boxed{\begin{aligned} e^{-\imath\mathbf{b}\cdot\hat{\mathbf{p}}/\hbar}|\mathbf{r}\rangle &= |\mathbf{r}+\mathbf{b}\rangle \\ e^{-\imath\mathbf{b}\cdot\hat{\mathbf{p}}/\hbar}|\mathbf{p}\rangle &= e^{-\imath\mathbf{b}\cdot\mathbf{p}/\hbar}|\mathbf{p}\rangle \\ e^{\imath\mathbf{b}\cdot\hat{\mathbf{p}}/\hbar}\hat{\mathbf{r}}e^{-\imath\mathbf{b}\cdot\hat{\mathbf{p}}/\hbar} &= \hat{\mathbf{r}}+\mathbf{b} \\ e^{\imath\mathbf{b}\cdot\hat{\mathbf{p}}/\hbar}\hat{\mathbf{p}}e^{-\imath\mathbf{b}\cdot\hat{\mathbf{p}}/\hbar} &= \hat{\mathbf{p}} \\ e^{\imath\mathbf{b}\cdot\hat{\mathbf{p}}/\hbar}V(\hat{\mathbf{r}})e^{-\imath\mathbf{b}\cdot\hat{\mathbf{p}}/\hbar} &= V(\hat{\mathbf{r}}+\mathbf{b}) \end{aligned}} \tag{23.193}$$

The rule implies $[e^{\imath\mathbf{k}\cdot\hat{\mathbf{r}}}, \hat{\mathbf{p}}] \neq 0 \neq [e^{\imath\mathbf{k}\cdot\hat{\mathbf{r}}}, \hat{H}]$. That is, we describe the kick by simply adding the corresponding momentum $\hbar\mathbf{k}$ to the system and adjusting the kinetic energy accordingly.

The right-hand panel of Eq. (23.193) summarizes rules for calculating with the spatial *displacement operator*, $U_{tr}(\mathbf{b}) = e^{-\imath\mathbf{b}\cdot\hat{\mathbf{p}}/\hbar}$, introduced in Sec. 23.5.1. By analogy we find $[e^{-\imath\mathbf{b}\cdot\hat{\mathbf{p}}/\hbar}, \hat{\mathbf{r}}] \neq 0 \neq [e^{-\imath\mathbf{b}\cdot\hat{\mathbf{p}}/\hbar}, \hat{H}]$ when the particle is subject to a potential.

The 'kick' will play a prominent role in the discussion of photonic recoil (see Sec. 24.6.2). Of course the assumption of an infinitely fast transition is an idealization and the ultimate reason for the non-conservation of momentum and energy by the system. In real situations, such as in the case of photonic recoil, the dynamics should be described by a collision process which conserves momentum and energy.

23.5.1.4 Rotation operator

In this section we look for the unitary transformation corresponding to the *rotation operator* [1298],

$$\mathcal{T}_{rt}\mathbf{r} \equiv e^{\vec{\alpha}\times}\mathbf{r} \ . \tag{23.194}$$

We calculate,

$$\begin{aligned} e^{\vec{\alpha}\times}\mathbf{r} = \sum_n \frac{(\vec{\alpha}\times)^n}{n!}\mathbf{r} &= \mathbf{r} + \vec{\alpha}\times\mathbf{r} + \tfrac{1}{2}\vec{\alpha}\times(\vec{\alpha}\times\mathbf{r}) + .. \\ &= \hat{\mathbf{e}}_\alpha(\hat{\mathbf{e}}_\alpha\cdot\mathbf{r}) + \hat{\mathbf{e}}_\alpha\times\mathbf{r}\sin\alpha - \hat{\mathbf{e}}_\alpha\times(\hat{\mathbf{e}}_\alpha\times\mathbf{r})\cos\alpha \ , \end{aligned} \tag{23.195}$$

as we will see in Exc. 23.5.6.4. We define the unitary rotational transformation by,

$$\boxed{U_{rt}^\dagger(\vec{\alpha})\hat{\mathbf{r}}U_{rt}(\vec{\alpha}) = e^{\vec{\alpha}\times}\hat{\mathbf{r}} \quad , \quad U_{rt}(\vec{\alpha})|\mathbf{r}\rangle = |e^{\vec{\alpha}\times}\mathbf{r}\rangle} \ . \tag{23.196}$$

To derive the explicit form of the rotation operator, we consider two rotations about the same axis $\vec{\alpha} = \lambda_1 \hat{\mathbf{e}}_\alpha + \lambda_2 \hat{\mathbf{e}}_\alpha$, such that

$$U_{rt}(\lambda_1 \hat{\mathbf{e}}_\alpha) U_{rt}(\lambda_2 \hat{\mathbf{e}}_\alpha) = U_{rt}(\lambda_1 \hat{\mathbf{e}}_\alpha + \lambda_2 \hat{\mathbf{e}}_\alpha) \ . \tag{23.197}$$

Calculating the derivative of this equation by λ_1 and then setting $\lambda_1 = 0$, we have,

$$\begin{aligned} & \frac{dU_{rt}(\lambda_1 \hat{\mathbf{e}}_\alpha)}{d\lambda_1}\Big|_{\lambda_1=0} U_{rt}(\lambda_2 \hat{\mathbf{e}}_\alpha) &=& \frac{dU_{rt}(\lambda_1 \hat{\mathbf{e}}_\alpha + \lambda_2 \hat{\mathbf{e}}_\alpha)}{d(\lambda_1+\lambda_2)}\Big|_{\lambda_1=0} \frac{d(\lambda_1+\lambda_2)}{d\lambda_1}\Big|_{\lambda_1=0} \\ \Longrightarrow \quad & \frac{d\lambda_1 \hat{\mathbf{e}}_\alpha}{d\lambda_1}\Big|_{\lambda_1=0} \cdot \nabla_{\vec{\alpha}} U_{rt}(\vec{\alpha})|_{\vec{\alpha}=0} U_{rt}(\lambda_2 \hat{\mathbf{e}}_\alpha) &=& \frac{dU_{rt}(\lambda_2 \hat{\mathbf{e}}_\alpha)}{d\lambda_2} \\ \Longrightarrow \quad & \hat{\mathbf{e}}_\alpha \cdot \tfrac{\hat{\mathbf{L}}}{\imath\hbar} \ U_{rt}(\lambda_2 \hat{\mathbf{e}}_\alpha) &=& \frac{dU_{rt}(\lambda_2 \hat{\mathbf{e}}_\alpha)}{d\lambda_2} \end{aligned} \tag{23.198}$$

where we define the angular momentum operator,

$$\hat{\mathbf{L}} \equiv \imath\hbar \ \nabla_{\vec{\alpha}} U_{rt}(\vec{\alpha})|_{\vec{\alpha}=0} \ . \tag{23.199}$$

The solution of the last differential equation (23.198) is, with $\lambda_2 \hat{\mathbf{e}}_\alpha = \vec{\alpha}|_{\lambda_1=0}$,

$$\boxed{U_{rt}(\vec{\alpha}) = e^{(-\imath/\hbar)\hat{\mathbf{L}}\cdot\vec{\alpha}}} \ . \tag{23.200}$$

The explicit form of $\hat{\mathbf{L}}$ follows from its action on a state $|\psi\rangle$ projected into position space. In analogy with the derivation of the result (23.189), comparing the expansion of the operator (23.200),

$$\langle \mathbf{r}|U_{rt}(\vec{\alpha})|\psi\rangle = \langle e^{(\imath/\hbar)\vec{\alpha}\cdot\hat{\mathbf{L}}}\mathbf{r}|\psi\rangle = \left(1 + \frac{\imath}{\hbar}\vec{\alpha}\cdot\hat{\mathbf{L}} + ..\right)\langle \mathbf{r}|\psi\rangle \ , \tag{23.201}$$

with the Taylor expansion of the wavefunction,

$$\langle e^{\vec{\alpha}\times}\mathbf{r}|\psi\rangle = \psi(\mathbf{r} + \vec{\alpha}\times\mathbf{r} + ..) = [1 + (\vec{\alpha}\times\mathbf{r})\cdot\nabla_{\mathbf{r}} + ..]\,\psi(\mathbf{r}) \ , \tag{23.202}$$

we find,

$$\frac{\imath}{\hbar}\vec{\alpha}\cdot\hat{\mathbf{L}} = (\vec{\alpha}\times\mathbf{r})\cdot\nabla_{\mathbf{r}} = \vec{\alpha}\cdot(\mathbf{r}\times\nabla_{\mathbf{r}}) = \frac{\imath}{\hbar}\vec{\alpha}\cdot(\mathbf{r}\times\hat{\mathbf{p}}) \ , \tag{23.203}$$

that is,

$$\hat{\mathbf{L}} = \hat{\mathbf{r}}\times\hat{\mathbf{p}} \ . \tag{23.204}$$

Therefore, the observable $\hat{\mathbf{L}}$ is the *orbital angular momentum* of the particle producing the rotations.

Inserting the angular momentum expression (23.204) into the rotation operator (23.200) and using the rule (23.179) as well as the commutation relations for position and momentum operators, we can now verify the expression directly. Note also that the rotation transformation acts on the momentum operators and states in the same way as on position operators and states. This is not surprising, as the angular momentum operator is symmetric in $\mathbf{r}$ and $\mathbf{p}$.

23.5.2 Transformation to accelerated and rotating frames

23.5.2.1 Transformation to an accelerated frame

Transformation into a accelerated frame with acceleration $\mathbf{g}$ adds a homogeneous force term to the Hamiltonian. At non-relativistic velocities, the transformation can be performed via a unitary kick into a system instantaneously moving at velocity $\mathbf{g}t$,

$$\boxed{U_{ac}(\mathbf{g}) = e^{(\imath/\hbar)m\mathbf{g}t\cdot\hat{\mathbf{r}}}} \quad , \quad |\psi_{ac}\rangle = U_{ac}(\mathbf{g})|\psi\rangle \ . \tag{23.205}$$

This operator removes the force field from the Hamiltonian, since the Schrödinger equation,

$$\imath\hbar\frac{d}{dt}|\psi\rangle = \hat{H}|\psi\rangle \qquad \text{with} \qquad \hat{H} = \frac{\hat{\mathbf{p}}^2}{2m} + m\mathbf{g}\cdot\hat{\mathbf{r}} \ , \tag{23.206}$$

transforms into the Schrödiner equation,

$$\begin{aligned} \imath\hbar\frac{d}{dt}|\psi_{ac}\rangle &= \imath\hbar\frac{d}{dt}\left(e^{(\imath/\hbar)m\mathbf{g}t\cdot\hat{\mathbf{r}}}|\psi\rangle\right) \\ &= \imath\hbar e^{(\imath/\hbar)m\mathbf{g}t\cdot\hat{\mathbf{r}}}\frac{d}{dt}|\psi\rangle + \imath\hbar|\psi\rangle\frac{d}{dt}e^{(\imath/\hbar)m\mathbf{g}t\cdot\hat{\mathbf{r}}} \\ &= e^{(\imath/\hbar)m\mathbf{g}t\cdot\hat{\mathbf{r}}}\left(\frac{\hat{\mathbf{p}}^2}{2m} + m\mathbf{g}\cdot\hat{\mathbf{r}}\right)|\psi\rangle - m\mathbf{g}\cdot\hat{\mathbf{r}}e^{(\imath/\hbar)m\mathbf{g}t\cdot\hat{\mathbf{r}}}|\psi\rangle = \frac{\hat{\mathbf{p}}^2}{2m}|\psi_{ac}\rangle \ . \end{aligned} \tag{23.207}$$

23.5.2.2 Transformation to a rotating frame

Transformation into a frame rotating at angular velocity $\vec{\omega}$ adds ... to the Hamiltonian. At non-relativistic velocities, the transformation can be performed via a unitary rotation transformation into a system rotated by an angle $\vec{\omega}t$,

$$\boxed{U_{ar}(\vec{\omega}) = e^{(\imath/\hbar)m\vec{\omega}t\cdot\hat{\mathbf{L}}}} \quad , \quad |\psi_{ar}\rangle = U_{ar}(\vec{\omega})|\psi\rangle \ . \tag{23.208}$$

23.5.3 Composite transformations, Galilei boost

Some transformations are generated by several operators. The Galilei transform of a system into a moving frame, the displacement operator for coherent states (24.111), or the squeezing operator (35.88) are prominent examples. These transformations can be handled using Glauber's formula, which will be introduced below, before we turn our attention to the Galilei transform.

23.5.3.1 Glauber's and Baker-Campbell-Hausdorff's formulas

The *Baker-Campbell-Hausdorff formula* for operators $\hat{A}$ and $\hat{B}$ reads,

$$\ln(e^{\hat{A}}e^{\hat{B}}) = \hat{A} + \hat{B} + \tfrac{1}{2}[\hat{A},\hat{B}] + \tfrac{1}{12}[\hat{A},[\hat{A},\hat{B}]] - \tfrac{1}{12}[\hat{B},[\hat{A},\hat{B}]] + ... \ . \tag{23.209}$$

A useful special case called *Glauber's formula* follows when $\hat{A}$ and $\hat{B}$ commute with their commutator, i.e. $[\hat{A},[\hat{A},\hat{B}]] = [\hat{B},[\hat{A},\hat{B}]] = 0$,

$$\boxed{e^{[\hat{B},\hat{A}]/2}e^{\hat{A}}e^{\hat{B}} = e^{\hat{A}+\hat{B}} = e^{[\hat{A},\hat{B}]/2}e^{\hat{B}}e^{\hat{A}}} \ . \tag{23.210}$$

Example 153 (*The Baker-Hausdorff formula*): In order to prove the Baker-Hausdorff formula, we consider the operator,

$$\hat{G}(\tau) \equiv e^{\tau(\hat{A}+\hat{B})} e^{-\tau\hat{B}} e^{-\tau\hat{A}} \ .$$

The derivative is,

$$\begin{aligned}
\hat{G}'(\tau) &= (\hat{A}+\hat{B}) e^{\tau(\hat{A}+\hat{B})} e^{-\tau\hat{B}} e^{-\tau\hat{A}} - e^{\tau(\hat{A}+\hat{B})} \hat{B} e^{-\tau\hat{B}} e^{-\tau\hat{A}} - e^{\tau(\hat{A}+\hat{B})} e^{-\tau\hat{B}} \hat{A} e^{-\tau\hat{A}} \\
&= e^{\tau(\hat{A}+\hat{B})} \left[\hat{A} e^{-\tau\hat{B}} - e^{-\tau\hat{B}} \hat{A} \right] e^{-\tau\hat{A}} = e^{\tau(\hat{A}+\hat{B})} \left[\hat{A} - e^{-\tau\hat{B}} \hat{A} e^{\tau\hat{B}} \right] e^{-\tau\hat{B}} e^{-\tau\hat{A}} \\
&= e^{\tau(\hat{A}+\hat{B})} \left[\hat{A} - \left(\hat{A} + [-\tau\hat{B}, \hat{A}] + \tfrac{1}{2!}[-\tau\hat{B}, [-\tau\hat{B}, \hat{A}]] + .. \right) \right] e^{-\tau\hat{B}} e^{-\tau\hat{A}} \ ,
\end{aligned}$$

using the formula (23.179). If now $[\hat{A}, [\hat{A}, \hat{B}]] = 0 = [\hat{B}, [\hat{A}, \hat{B}]]$, then,

$$\hat{G}'(\tau) = e^{\tau(\hat{A}+\hat{B})} \tau [\hat{B}, \hat{A}] e^{-\tau\hat{B}} e^{-\tau\hat{A}} = -\tau [\hat{A}, \hat{B}] e^{\tau(\hat{A}+\hat{B})} e^{-\tau\hat{B}} e^{-\tau\hat{A}} = -\tau [\hat{A}, \hat{B}] \hat{G}(\tau) \ .$$

The solution of this differential equation is,

$$\hat{G}(\tau) \equiv e^{-(\tau^2/2)[\hat{A},\hat{B}]} \hat{G}(0) \ .$$

With $\hat{G}(0) = 1$ we obtain at the point $\tau = 1$,

$$e^{\hat{A}+\hat{B}} e^{-\hat{B}} e^{-\hat{A}} = e^{-(1/2)[\hat{A},\hat{B}]} \ .$$

23.5.3.2 Galilei and Lorentz boosts

The *Galilei transform* (or *Galilei boost*) is defined by,

$$\mathcal{T}_G \mathbf{r} = \mathbf{r} + \mathbf{v}t \qquad \text{and} \qquad \mathcal{T}_G \mathbf{p} = \mathbf{p} + m\mathbf{v} \ . \tag{23.211}$$

It describes the transformation of a system into a moving frame. Obviously, the Galilei transform must satisfy $\mathcal{T}_{\mathbf{v}_1} \mathcal{T}_{\mathbf{v}_2} = \mathcal{T}_{\mathbf{v}_1+\mathbf{v}_2}$, while this certainly does not hold for relativistic velocities.

In quantum mechanics we define,

$$\hat{\mathbf{G}} = \hat{\mathbf{p}}t - \hat{\mathbf{r}}m = \imath\hbar \nabla_{\mathbf{v}} U_G(\mathbf{v})|_{\mathbf{v}=0} \ , \tag{23.212}$$

with the Galilei boost,

$$\boxed{U_G(\mathbf{v}) = e^{(-\imath/\hbar)\mathbf{v}\cdot\hat{\mathbf{G}}}} \ . \tag{23.213}$$

We can simplify this unitary transform using Glauber's formula (23.210). To this end we first calculate the commutator,

$$[\mathbf{v}\cdot\hat{\mathbf{p}}, \mathbf{v}\cdot\hat{\mathbf{r}}] = -\imath\hbar\mathbf{v}^2 \ , \tag{23.214}$$

which does not depend on $\hat{\mathbf{p}}$ nor $\hat{\mathbf{r}}$, but may contribute a phase factors. With this we can rewrite the expression (23.213),

$$\begin{aligned}
U_G(\mathbf{v}) &= e^{(-\imath/\hbar)\mathbf{v}t\cdot\hat{\mathbf{p}} + (\imath/\hbar)\mathbf{v}m\cdot\hat{\mathbf{r}}} \qquad (23.215) \\
&= e^{(-\imath/\hbar)mt\mathbf{v}^2/2} e^{(\imath/\hbar)\mathbf{v}m\cdot\hat{\mathbf{r}}} e^{(-\imath/\hbar)\mathbf{v}t\cdot\hat{\mathbf{p}}} = e^{(\imath/\hbar)mt\mathbf{v}^2/2} e^{(-\imath/\hbar)\mathbf{v}t\cdot\hat{\mathbf{p}}} e^{(\imath/\hbar)\mathbf{v}m\cdot\hat{\mathbf{r}}} \\
U_G^\dagger(\mathbf{v}) &= e^{(\imath/\hbar)\mathbf{v}t\cdot\hat{\mathbf{p}} - (\imath/\hbar)\mathbf{v}m\cdot\hat{\mathbf{r}}} \\
&= e^{(-\imath/\hbar)mt\mathbf{v}^2/2} e^{(-\imath/\hbar)\mathbf{v}m\cdot\hat{\mathbf{r}}} e^{(\imath/\hbar)\mathbf{v}t\cdot\hat{\mathbf{p}}} = e^{(\imath/\hbar)mt\mathbf{v}^2/2} e^{(\imath/\hbar)\mathbf{v}t\cdot\hat{\mathbf{p}}} e^{(-\imath/\hbar)\mathbf{v}m\cdot\hat{\mathbf{r}}} \ .
\end{aligned}$$

We apply these expressions to transform the position and momentum operators,

$$\boxed{\begin{array}{rcl} U_G^\dagger(\mathbf{v})\hat{\mathbf{r}}U_G(\mathbf{v}) &=& e^{(\imath/\hbar)\mathbf{v}t\cdot\hat{\mathbf{p}}}\hat{\mathbf{r}}e^{(-\imath/\hbar)\mathbf{v}t\cdot\hat{\mathbf{p}}} = \hat{\mathbf{r}} + \mathbf{v}t \\ U_G^\dagger(\mathbf{v})\hat{\mathbf{p}}U_G(\mathbf{v}) &=& e^{(-\imath/\hbar)\mathbf{v}m\cdot\hat{\mathbf{r}}}\hat{\mathbf{p}}e^{(\imath/\hbar)\mathbf{v}m\cdot\hat{\mathbf{r}}} = \hat{\mathbf{p}} + m\mathbf{v} \end{array}} \ , \tag{23.216}$$

and consequently,

$$\begin{aligned} U_G^\dagger(\mathbf{v})\frac{\hat{\mathbf{p}}^2}{2m}U_G(\mathbf{v}) = \frac{\left[U_G^\dagger(\mathbf{v})\hat{\mathbf{p}}U_G(\mathbf{v})\right]^2}{2m} = \frac{(\hat{\mathbf{p}}+m\mathbf{v})^2}{2m} \\ U_G^\dagger(\mathbf{v})V(\hat{\mathbf{r}})U_G(\mathbf{v}) = V(U_G^\dagger(\mathbf{v})\hat{\mathbf{r}}U_G(\mathbf{v})) = V(\hat{\mathbf{r}}+\mathbf{v}t) \ . \end{aligned} \tag{23.217}$$

Setting $m = 0$ the Galilei boost simply reproduces a spatial translation by a vector $\mathbf{v}t$, and setting $t = 0$ the Galilei boost simply becomes the prescription for the momentum kick by an amount $m\mathbf{v}$.

Applying the Galilei boost expressions (23.215) to states, we find,

$$\boxed{\begin{array}{rcl} U_G(\mathbf{v})|\mathbf{r}\rangle &=& e^{(\imath/\hbar)m\mathbf{v}\cdot(\hat{\mathbf{r}}+\mathbf{v}t/2)}|\mathbf{r}+\mathbf{v}t\rangle \\ U_G(\mathbf{v})|\mathbf{p}\rangle &=& e^{-(\imath/\hbar)t\mathbf{v}\cdot(\hat{\mathbf{p}}+m\mathbf{v}/2)}|\mathbf{p}+m\mathbf{v}\rangle \end{array}} \ . \tag{23.218}$$

The prefactors do not shift the states, but only contribute irrelevant phase factors.

Finally, knowing the commutator of $\hat{\mathbf{p}}$ and $\hat{\mathbf{r}}$ we derive,

$$[\mathbf{G}\cdot\mathbf{a}, \mathbf{G}\cdot\mathbf{b}] = 0 \ , \tag{23.219}$$

for any vectors $\mathbf{a}$ and $\mathbf{b}$, and with that, using Glauber's formula (23.210), we verify,

$$U_G(\mathbf{v}_1)U_G(\mathbf{v}_2) = e^{(-\imath/\hbar)(\mathbf{v}_1+\mathbf{v}_2)\cdot\mathbf{G} - [\mathbf{v}_1\cdot\mathbf{G}, \mathbf{v}_2\cdot\mathbf{G}]/2\hbar^2} = U_G(\mathbf{v}_1+\mathbf{v}_2) \ . \tag{23.220}$$

Obviously, for very high velocities, the Galilei-boost should be replaced by the *Lorentz transform* (or *Lorentz boost*) [659]. Here, we only note, that the additivity of velocities expressed by equation (23.220) does not hold for non-collinear relativistic velocities (see Sec. 20.1.6).

23.5.4 Gauge transformations

We learn in electrodynamics [15], that the motion of a particle carrying the charge q and interacting with an electrical potential $\Phi(\mathbf{r}, t)$ and a magnetic vector potential $\mathbf{A}(\mathbf{r}, t)$ is governed by the electric and the magnetic field,

$$\vec{\mathcal{E}}(\mathbf{r}, t) = -\nabla\Phi - \partial_t\mathbf{A} \qquad \text{and} \qquad \vec{\mathcal{B}}(\mathbf{r}, t) = \nabla\times\mathbf{A} \ . \tag{23.221}$$

Also, we know that the fields are invariant under the substitution,

$$\Phi \to \Phi' \equiv \Phi - \partial_t\chi \qquad \text{and} \qquad \mathbf{A} \to \mathbf{A}' \equiv \mathbf{A} + \nabla\chi \ , \tag{23.222}$$

[15] See script on *Electrodynamics* (2023).

where $\chi(\mathbf{r},t)$ is a scalar field called *gauge field*.

In quantum mechanics the *gauge transformation* defined by,

$$\boxed{U_{gg}(\chi) = e^{-\imath q\chi(\mathbf{r},t)/\hbar}} \tag{23.223}$$

obviously must keep the Schrödinger equation invariant. However, since the gauge field may depend on time, as shown in Sec. 23.4.5, the Hamiltonian is different in the transformed system. Transforming operators and wave functions as,

$$\hat{H} \to U_{gg}\hat{H}U_{gg}^{-1} \equiv \hat{H}_U \qquad \text{and} \qquad |\psi\rangle \to U_{gg}|\psi\rangle \equiv |\psi_U\rangle \ , \tag{23.224}$$

we calculate for the energy,

$$\begin{aligned}\hat{H}_U|\psi_U\rangle = U_{gg}\imath\hbar\tfrac{d}{dt}U_{gg}^{-1}|\psi_U\rangle &= U_{gg}\imath\hbar U_{gg}^{-1}\tfrac{d}{dt}|\psi_U\rangle + U_{gg}\imath\hbar\left(\tfrac{-\imath q}{\hbar}U_{gg}^{-1}\tfrac{d\chi}{dt}\right)|\psi_U\rangle \\ &= \imath\hbar\left(\tfrac{d}{dt} - \tfrac{\imath q}{\hbar}\tfrac{d\chi}{dt}\right)|\psi_U\rangle \ ,\end{aligned} \tag{23.225}$$

in accordance with the transformation rule (23.167) for time-dependent unitary transformations. For the momentum, we get analogously,

$$\begin{aligned}\hat{\mathbf{p}}_U|\psi_U\rangle = U_{gg}(-\imath\hbar\nabla)U_{gg}^{-1}|\psi_U\rangle &= U_{gg}(-\imath\hbar)U_{gg}^{-1}(\nabla|\psi_U\rangle) + U_{gg}(-\imath\hbar)\left(\tfrac{-\imath q}{\hbar}U_{gg}^{-1}\nabla\chi\right)|\psi_U\rangle \\ &= (-\imath\hbar)\left[\nabla - \tfrac{\imath q}{\hbar}(\nabla\chi)\right]|\psi_U\rangle \ ,\end{aligned} \tag{23.226}$$

This corresponds to the substitutions [16],

$$\boxed{U_{gg}\imath\hbar\frac{d}{dt}U_{gg}^{-1} = \imath\hbar\frac{d}{dt} + q\frac{d\chi}{dt} \qquad \text{and} \qquad U_{gg}\hat{\mathbf{p}}U_{gg}^{-1} = \hat{\mathbf{p}} - q\nabla\chi} \ . \tag{23.227}$$

This shows that the gauge transformation applies to the *minimal coupling* rule (see Sec. 30.1.2),

$$\hat{H} = \hat{H}_{kin}+q\Phi \overset{U_{gg}}{\curvearrowright} \hat{H}_{kin}+q\Phi+q\partial_t\chi \quad \text{and} \quad m\hat{\mathbf{v}} = \hat{\mathbf{p}}-q\mathbf{A} \overset{U_{gg}}{\curvearrowright} \hat{\mathbf{p}}-q\mathbf{A}-q\nabla\chi \ , \tag{23.228}$$

confirming the rules (23.222). That is, the Hamiltonian of a particle carrying the charge q and interacting with an electric potential Φ and a magnetic vector potential $\mathbf{A}$ is,

$$\hat{H} = \tfrac{1}{2m}(\hat{\mathbf{p}} - q\mathbf{A} - q\nabla\chi)^2 + q\Phi + q\partial_t\chi \ . \tag{23.229}$$

23.5.5 Noether's theorem and conservation laws

The fundamental laws of physics are often expressed as symmetries. The knowledge of symmetries allows the characterization of a system and its behavior without the need to know its details. We can often deduce the differential equation of motion from the symmetries. The fundamental symmetries define the fundamental laws of physics. Following *Noether's theorem* each symmetry corresponds to a conserved quantity, that is, a quantities that remains invariant for all time. The invariance of a

[16] In quadrivetorial notation $\imath\hbar\partial_\mu \longrightarrow \imath\hbar\partial_\mu + q\partial_\mu\chi$.

system under symmetry transformation represents a *conservation law*. For example, the homogeneity of space corresponds to the conservation of linear momentum.

In quantum mechanics, a *symmetry transformation* is defined by,

$$|\psi\rangle \longrightarrow U|\psi\rangle \qquad \text{and} \qquad \hat{Q} \longrightarrow U\hat{Q}U^{\dagger} \ . \tag{23.230}$$

Therefore, to find a conservation law, i.e., an invariable observable (also called *constant of motion*), we must verify that the observable and the transformed wavefunctions simultaneously satisfy the same fundamental equations (that is, Schrödinger's or Heisenberg's equation) as the original observable and wavefunctions. For example, if the wavefunction $|\psi\rangle$ satisfies the Schrödinger equation, the wave function $U|\psi\rangle$ must do this too,

$$\hat{H}U|\psi\rangle \stackrel{!}{=} \imath\hbar\frac{d}{dt}U|\psi\rangle = \imath\hbar\frac{dU}{dt}|\psi\rangle + \imath\hbar U\frac{d}{dt}|\psi\rangle = \imath\hbar\frac{dU}{dt}|\psi\rangle + U\hat{H}|\psi\rangle \ . \tag{23.231}$$

Consequently, we obtain the relation,

$$[\hat{H}, U] = \imath\hbar\dot{U} \ . \tag{23.232}$$

As shown in (23.175) and (23.176), an operator that commutes with the Hamiltonian does not explicitly depend on time, that is, it is *conserved*.

23.5.5.1 Temporal homogeneity

Temporal homogeneity means invariance under translation in time by a fixed time interval τ, that is, under the unitary temporal transformation,

$$U(\tau) \equiv |\psi(\tau)\rangle\langle\psi(0)| = e^{(\imath/\hbar)\hat{E}\tau} \ . \tag{23.233}$$

Since $\frac{d}{dt}e^{(\imath/\hbar)\hat{E}\tau} = 0$, this means $[e^{(\imath/\hbar)\hat{E}\tau}, \hat{H}] = 0$, which implies conservation of energy $[\hat{E}, \hat{H}] = 0$. This will be verified in the Exc. 23.5.6.5.

> **Example 154 (*Homogeneity of time*):** We imagine the following mental experiment or *Gedankenexperiment*: We consider two attractive bodies that move away from each other until they reach the perihelia. At this point, before the bodies reapproach, we change the laws, for example, by modifying the force of attraction. As a consequence, when the bodies arrive at the initial point, the total energy is non-zero. Therefore, the conservation of energy indicates that the laws are invariant.

23.5.5.2 Temporal isotropy

The fundamental laws of classical physics and quantum mechanics are all symmetrical under *time reversal*. That is, they are remain invariant when we change the arrow of time, $t \to -t$.

23.5.5.3 Spatial homogeneity

Spatial homogeneity means invariance under spatial translation, that is, under the unitary translational transformation,

$$U_{tr}(\mathbf{a}) \equiv \int |\mathbf{r}+\mathbf{a}\rangle\langle\mathbf{r}| d^3r = e^{(-\imath/\hbar)\hat{\mathbf{p}}\cdot\mathbf{a}} \ . \tag{23.234}$$

This is equivalent to momentum conservation $[\hat{\mathbf{p}}, \hat{H}] = 0$ [17].

> **Example 155 (*Homogeneity of space*):** Ehrenfest's theorem says $[\hat{\mathbf{p}}, H] = -\imath\hbar\frac{\partial H}{\partial \hat{\mathbf{p}}}$. Therefore, the commutator is not zero when there is a potential, $\hat{H} = \hat{\mathbf{p}}^2/2m + V(\hat{\mathbf{r}})$. This is obvious, because the potential introduces an energy inhomogeneity to a particle interacting with the potential. However, this does not mean that the space itself is inhomogeneous, because in order to verify the translational invariance of space, we must displace the entire system, that is, the particle together with the potential. For example, if the potential is generated by another particle we must consider the Hamiltonian $\hat{H} = \hat{\mathbf{p}}_1^2/2m_1 + \hat{\mathbf{p}}_2^2/2m_2 + V(\hat{\mathbf{r}}_1 - \hat{\mathbf{r}}_2)$.

23.5.5.4 Spatial isotropy

Spatial isotropy means invariance under rotation, that is, under rotational unitary transformation,

$$U_{rt}(\phi) \equiv e^{(-\imath/\hbar)\hat{\mathbf{L}}\phi} \ . \tag{23.235}$$

This is equivalent to the conservation of angular momentum $[\hat{\mathbf{L}}, \hat{H}] = 0$.

23.5.5.5 Parity conservation

Besides continuous symmetry transformations there exist discrete transformations. Discrete symmetries are important in elementary particle physics. The *parity conservation* means invariance to spatial reflection: $\mathbf{r} \to -\mathbf{r}$. A parity transformation is defined by the mirroring of the wavefunction through a point in space, for example $\mathbf{r} = 0$,

$$\hat{P}|\psi(\mathbf{r})\rangle \equiv |\psi(-\mathbf{r})\rangle \ . \tag{23.236}$$

with

$$\hat{P}^2 = \hat{P} \ . \tag{23.237}$$

We talk about *even* parity when $\hat{P}|\psi(\mathbf{r})\rangle = |\psi(\mathbf{r})\rangle$ and *odd* parity when $\hat{P}|\psi(\mathbf{r})\rangle = -|\psi(\mathbf{r})\rangle$. See Exc. 23.5.6.6.

[17] Imagine that the forces attracting two bodies to each other are not equal: Contrary to Newton's third law, body A attracts body B, more than the body B attracts the body A. In that case after a while the two bodies have different momenta. With the unitary transformation $U_{tr}(\mathbf{a}) = e^{-\imath\hat{p}\cdot\mathbf{a}/\hbar} \simeq 1 - \imath\epsilon\mathbf{p}\cdot\mathbf{a}/\hbar + ...$ we have,

$$U_{tr}H|\psi\rangle = U_{tr}E_\psi|\psi\rangle = E_\psi U|\psi\rangle = H|\psi(\mathbf{r}+\mathbf{a})\rangle =? = H|\psi(\mathbf{r}\rangle \ .$$

Since, $[H, \hat{p}] = 0$, Heisenberg's equation yields,

$$\frac{\partial}{\partial t}\langle\psi|\hat{p}\cdot\mathbf{a}|\psi\rangle = \frac{1}{\imath\hbar}\langle\psi|[\hat{p}\cdot\mathbf{a}, \hat{H}]|\psi\rangle = 0 \ .$$

23.5.5.6 Invariance to the velocity of the inertial system

The *Galilei boost* asks for *Galilei invariance* regarding the transformation,

$$U_G(\mathbf{v}) \equiv \iint |\mathbf{r}+\mathbf{v}t, \mathbf{p}+m\mathbf{v}\rangle\langle \mathbf{r}, \mathbf{p}| d^3r d^3p \ , \tag{23.238}$$

that is, the equations of motion ruling the dynamics of the inertial system under consideration should not dependent on its velocity $\mathbf{v}$.

23.5.5.7 Charge conservation

Let us consider again the *gauge transform* (23.222). We know that the Lagrangian density in free space is given in terms of the potentials by,

$$\begin{aligned} \mathcal{L}(x^\mu) &= \tfrac{1}{4\mu_0} F^{\mu\nu}F_{\mu\nu} - A_\mu j^\mu = \tfrac{\varepsilon_0}{2}\vec{\mathcal{E}}^2 - \tfrac{1}{2\mu_0}\vec{\mathcal{B}}^2 - A_\mu j^\mu \\ &= \tfrac{\varepsilon_0}{2}[\nabla\Phi + \partial_t \mathbf{A}]^2 - \tfrac{1}{2\mu_0}[\nabla\times\mathbf{A}]^2 - \Phi\rho + \mathbf{A}\cdot\mathbf{j} \ , \end{aligned} \tag{23.239}$$

and the *action* is simply the fourth-dimensional integral,

$$S = \int \mathcal{L}(x^\mu) dV dt \ . \tag{23.240}$$

From the Lagrangian formulation, Maxwell's equations can be derived by requiring the action to be minimal, $\delta S = 0$, which yields the Euler-Lagrange equations. As the field equations do not change under gauge transformation, this implies that the action is also unchanged.

To find the relation with *charge conservation*, we simply have to compare the actions in different gauges. First, we express the Lagrangian transformed into the old gauge,

$$\begin{aligned} \mathcal{L}'(x^\mu) &= \tfrac{\varepsilon_0}{2}\{\nabla[\Phi - \cancel{\partial_t\chi}\,] + \partial_t[\mathbf{A} + \cancel{\nabla\chi}\,]\}^2 - \tfrac{1}{2\mu_0}\{\nabla\times[\mathbf{A} + \cancel{\nabla\chi}^{\,0}]\}^2 \\ &\quad - [\Phi - \partial_t\chi]\rho + [\mathbf{A}+\nabla\chi]\cdot\mathbf{j} \\ &= \mathcal{L} + (\partial_t\chi)\rho + \nabla\chi\cdot\mathbf{j} \ . \end{aligned} \tag{23.241}$$

With this result, we can calculate the difference between the actions under gauge transformation and recall, that they can not be different:

$$0 \stackrel{!}{=} S' - S = \int [(\partial_t\chi)\rho + \nabla\chi\cdot\mathbf{j}] dV dt = -\int \chi[\partial_t\rho + \nabla\cdot\mathbf{j}] dV dt \ , \tag{23.242}$$

using partial integration [18] and choosing volumes so large, that every charge is inside. This is the *continuity equation* derived from the gauge invariance of the action. The calculation really is nothing more than an application of Noether's theorem from which we could have derived directly the continuity equation, $\partial_\mu j^\mu = 0$.

In summary, the conservation of charge means invariance with respect to gauge transformations,

$$U_{cl}(\chi) \equiv e^{-\imath q\chi(\mathbf{r},t)/\hbar} \ , \tag{23.243}$$

[18] Think about the argument, because $\int \partial_t|\chi\rho dt = 0$!

where χ is the gauge field. We note that q and χ are conjugated observables. Therefore, if $[\chi, \hat{H}] = 0$, then the charge q is a conserved quantity.

Transformations can be combined. For example, we believe that nowadays all laws are invariant with respect to CPT transformation, that is, a combination of *charge conjugation*, *parity inversion*, and *θ-transform*.

23.5.6 Exercises

23.5.6.1 Ex: Calculus with commutator

Derive the rule (23.179) via a Taylor expansion of the operator $\hat{G}(\tau) \equiv e^{\tau\hat{A}}\hat{B}e^{-\tau\hat{A}}$.

Solution: *To derive the rule we make a Taylor expansion of the operator,*

$$\hat{G}(\tau) \equiv e^{\tau\hat{A}}\hat{B}e^{-\tau\hat{A}} = \sum_n \frac{\tau^n}{n!}\frac{d^n}{d\tau^n}\hat{G}(0) \ .$$

Derivatives are easily calculated,

$$\hat{G}'(\tau) = \hat{A}e^{\tau\hat{A}}\hat{B}e^{-\tau\hat{A}} - e^{\tau\hat{A}}\hat{B}\hat{A}e^{-\tau\hat{A}} = [\hat{A}, \hat{G}(\tau)] \ ,$$
$$\hat{G}''(\tau) = \hat{A}[\hat{A}, \hat{G}(\tau)] - [\hat{A}, \hat{G}(\tau)]\hat{A} = [\hat{A}, [\hat{A}, \hat{G}(\tau)]] \ .$$

At point $\tau = 1$ we get the result (23.179).

23.5.6.2 Ex: Particle in a homogenous gravitational field

a. Consider a particle free to move along the axis of gravity. Derive the time-dependent unitary operator describing the transformation into the particle's rest frame and check, whether the transformation satisfies the expression (23.167).
b. Solve the Schrödinger equation and derive the Heisenberg equations for $\hat{x}$ and $\hat{p}$.
c. Calculate the phase shift due to gravity from the solution of the Schrödinger equation.

Solution: *a. The force free-particle Schrödinger equation,*

$$\imath\hbar\frac{d}{dt}|\psi\rangle = \frac{\hat{p}^2}{2m}|\psi\rangle$$

describes the particle's evolution in the frame accelerated by gravity, where the particle does not sense external forces. With the time-dependent unitary transformation $|\tilde{\psi}\rangle = |\psi\rangle e^{-\imath mgzt/\hbar}$,

$$\begin{aligned}\imath\hbar\frac{d}{dt}|\tilde{\psi}\rangle &= \imath\hbar e^{-\imath mgzt/\hbar}\frac{d}{dt}|\psi\rangle + \imath\hbar|\psi\rangle\frac{d}{dt}e^{-\imath mgzt/\hbar} \\ &= \frac{\hat{p}^2}{2m}e^{-\imath mgzt/\hbar}|\psi\rangle + mgze^{-\imath mgzt/\hbar}|\psi\rangle = \left(\frac{\hat{p}^2}{2m} + mgz\right)|\tilde{\psi}\rangle = \hat{H}|\tilde{\psi}\rangle\end{aligned}$$

we transform back into the lab frame, where the particle is subject to a homogeneous potential.
b. Inserting into the Schrödinger equation,

$$\imath\hbar\frac{d}{dt}\tilde{\psi}(z,t) = \hat{H}\tilde{\psi}(z,t) = \left(-\frac{\hbar^2}{2m}\frac{d^2}{dz^2} + mg\hat{z}\right)\tilde{\psi}(z,t)$$

the ansatz,

$$\tilde{\psi}(z,t) \equiv \psi(z)e^{-\imath Et/\hbar}e^{-\imath mgzt/\hbar} \ ,$$

we get,

$$-\frac{d^2}{dz^2}\psi(z) = \frac{2mE}{\hbar^2}\psi(z) = k^2\psi(z) \ .$$

Hence,

$$\tilde{\psi}(z,t) = e^{-\imath Et/\hbar}e^{-\imath mgzt/\hbar}e^{\imath kz} \ .$$

The Heisenberg equations are,

$$\frac{d}{dt}\hat{z} = \frac{\imath}{\hbar}[\hat{H},\hat{z}] = \frac{\hat{p}}{m} \qquad \textit{and} \qquad \frac{d}{dt}\hat{p} = \frac{\imath}{\hbar}[\hat{H},\hat{p}] = mg \ .$$

c. The instantaneous phase is the exponent of the wavefunction,

$$\phi(t) = -\frac{Et}{\hbar} - \frac{mgzt}{\hbar} + kz = k\left(z - \frac{v}{2}t\right) - \frac{mgzt}{\hbar} \ ,$$

with $v = \hbar k/m$. Without gravity the de Broglie phase front would propagate with $z - \frac{v}{2}t = const$. Hence, the phase shift due to gravity depends quadratically on time,

$$\phi_{2z=vt}(t) = -\frac{mgvt^2}{2\hbar} = -\frac{kgt^2}{2} \ .$$

23.5.6.3 Ex: Phase shift in a Ramsey-Bordé interferometer

a. Calculate the time dependence of the dynamical phase accumulated by an atom in the field of gravity as a function of its initial momentum.
b. Derive the phase difference of a particle wavefunction passing through a *Ramsey-Bordé interferometer* [19].

Solution: *a. We assume plane waves. The momentum evolves as,*

$$p = mgt + p_0 \ .$$

Hence, the accumulated phase is,

$$\phi_{p_0} = \hbar^{-1}\int_0^t Edt = \hbar^{-1}\int_0^t \frac{p^2}{2m}dt = \frac{mg^2t^3}{6\hbar} + \frac{p_0gt^2}{2\hbar} + \frac{p_0^2t}{2m\hbar} \ .$$

[19] A Ramsey-Bordé interferometer consists of a $\pi/2$-π-$\pi/2$ laser pulse sequence (similar to photon echo in NMR) of Bragg diffraction pulses leading to a splitting and recombination of an atomic wavefunction in momentum space. Assume that every pulse transfers one unit of photonic recoil, $\hbar k$, to the atomic center-of-mass, where k is the wavevector of the laser light.

The phase difference with and without initial momentum is,

$$\Delta\phi = \phi_{p_0} - \phi_0 = \tfrac{1}{2\hbar}(p_0 g t^2 + \tfrac{1}{m} p_0^2 t) \ .$$

b. Using the obtained result, we calculate for each of the two arms of a Ramsey-Bordé interferometer, the upper and the lower one, two contributions: One phase shift accumulated between the first and second laser pulse and another phase shift accumulated between the second and third laser pulse,

$$\phi_{lower} = \phi_{p_0}|_{p_0=0} + \phi_{p_0}|_{p_0=\hbar k - mgt} \qquad \textit{and} \qquad \phi_{upper} = \phi_{p_0}|_{p_0=\hbar k} + \phi_{p_0}|_{p_0=\hbar k - mgt} \ ,$$

where t is the time interval between the first and second laser pulse. Apparently, the phase shifts accumulated during the time interval between the second and third laser pulse cancel out. Hence,

$$\Delta\phi = \phi_{upper} - \phi_{lower} = \phi_{p_0}|_{p_0=\hbar k} - \phi_{p_0}|_{p_0=0} = \frac{\hbar k g t^2}{2\hbar} + \frac{(\hbar k)^2 t}{2m\hbar} = \frac{k g t^2}{2} + \omega_{rec} t \ .$$

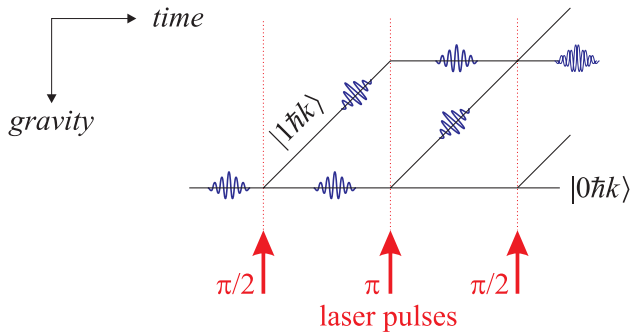

Figure 23.6: Scheme of a Ramsey-Bordé interferometer.

23.5.6.4 Ex: Rotation operator

Derive the rule $e^{\vec{\alpha}\times}\mathbf{r} = \sum_n \frac{(\vec{\alpha}\times)^n}{n!}\mathbf{r} = \hat{\mathbf{e}}_\alpha(\hat{\mathbf{e}}_\alpha\cdot\mathbf{r}) + \hat{\mathbf{e}}_\alpha\times\mathbf{r}\sin\alpha - \hat{\mathbf{e}}_\alpha\times(\hat{\mathbf{e}}_\alpha\times\mathbf{r})\cos\alpha$.

Solution: *We use,*

$$\begin{aligned}
&\vec{\alpha}\times(\vec{\alpha}\times\mathbf{r}) = \vec{\alpha}(\vec{\alpha}\cdot\mathbf{r}) - \alpha^2\mathbf{r} \\
&\vec{\alpha}\times[\vec{\alpha}\times(\vec{\alpha}\times\mathbf{r})] = -\alpha^2(\vec{\alpha}\cdot\mathbf{r}) \\
&\vec{\alpha}\times\{\vec{\alpha}\times[\vec{\alpha}\times(\vec{\alpha}\times\mathbf{r})]\} = -\alpha^2\vec{\alpha}\times(\vec{\alpha}\times\mathbf{r}) \ .
\end{aligned}$$

The odd terms of the sum give

$$\vec{\alpha}\times\mathbf{r} - \tfrac{\alpha^2}{3!}\vec{\alpha}\times\mathbf{r} + \tfrac{\alpha^4}{5!}\vec{\alpha}\times\mathbf{r} - ... = \vec{\alpha}\times\mathbf{r}\sin\alpha \ .$$

Even terms give

$$\mathbf{r} - \tfrac{1}{2!}\vec{\alpha}\times(\vec{\alpha}\times\mathbf{r}) - \tfrac{\alpha^2}{4!}\vec{\alpha}\times(\vec{\alpha}\times\mathbf{r}) - ... = \mathbf{r} + (1-\cos\alpha)\vec{\alpha}\times(\vec{\alpha}\times\mathbf{r}) \ .$$

Putting the terms together,

$$e^{\vec{\alpha}\times}\mathbf{r} = \mathbf{r} + \hat{\mathbf{e}}_\alpha \times \mathbf{r}\sin\alpha + \hat{\mathbf{e}}_\alpha \times (\hat{\mathbf{e}}_\alpha \times \mathbf{r})(1-\cos\alpha) \ ,$$

this is the equation we looked for.
The transformation represents a rotation about the angle $\vec{\alpha}$, which can be seen by separating $\mathbf{r}$ into vectors parallel or perpendicular to $\hat{\mathbf{e}}_\alpha$:

$$e^{\vec{\alpha}\times}\mathbf{r}_\parallel + e^{\vec{\alpha}\times}\mathbf{r}_\perp = \mathbf{r}_\parallel + \hat{\mathbf{e}}_\alpha \times \mathbf{r}_\perp \sin\alpha + \mathbf{r}_\perp \cos\alpha \ .$$

This equation is equivalent to,

$$e^{\vec{\alpha}\times}\mathbf{r}_\parallel = \mathbf{r}_\parallel \qquad \textit{and} \qquad e^{\vec{\alpha}\times}\mathbf{r}_\perp = \hat{\mathbf{e}}_\alpha \times \mathbf{r}_\perp \sin\alpha + \mathbf{r}_\perp \cos\alpha \ ,$$

the parallel component is conserved while for the perpendicular we have,

$$(e^{\vec{\alpha}\times}\mathbf{r}_\perp)^2 = \mathbf{r}_\perp^2 \sin^2\alpha + \mathbf{r}_\perp^2 \cos^2\alpha = \mathbf{r}_\perp^2 \qquad \textit{and} \qquad (e^{\vec{\alpha}\times}\mathbf{r}_\perp)\cdot\mathbf{r}_\perp - \cos\alpha \ .$$

23.5.6.5 Ex: Constants of motion

Show at the example of energy conservation using the relation (23.232), that energy commutes with the Hamiltonian if $\dot{E} = 0$.

Solution: *If $\dot{E} = 0$, we can deduce,*

$$0 = -e^{(\imath/\hbar)\hat{E}\tau}\frac{d\hat{E}}{dt} = \imath\hbar\frac{d}{dt}\left(e^{(\imath/\hbar)\hat{E}\tau}\right) = \imath\hbar\dot{U} = [\hat{H},U] = \left[\hat{H},\left(1+\frac{\imath\hat{E}\tau}{\hbar} - \frac{\hat{E}^2\tau^2}{2!\hbar^2} + ...\right)\right]$$
$$= \frac{\imath\tau}{\hbar}[\hat{H},\hat{E}] - \frac{\tau^2}{2!\hbar^2}[\hat{H},\hat{E}^2] + ... = \frac{\imath\tau}{\hbar}[\hat{H},\hat{E}] - \frac{\tau^2}{2!\hbar^2}\left[[\hat{H},\hat{E}]\hat{E} + \hat{E}[\hat{H},\hat{E}]\right] + ...,$$

which is valid when $[\hat{H},\hat{E}] = 0$.

23.5.6.6 Ex: Parity

Show that the eigenfunctions of the Hamiltonian $\hat{H} = -(\hbar/2m)(d^2/dx^2) + V(x)$ have well-defined parity, i.e., parity is a *good quantum number* in cases where the energy is an even function of position, $V(x) = V(-x)$.

Solution: *A state $|\psi\rangle$ has even parity when the wavefunction does not change under inversion of the position coordinate, $\hat{P}\langle x|\psi\rangle = \langle -x|\psi\rangle$. It has odd parity when*

$\hat{P}\langle x|\psi\rangle = \langle -x| - \psi\rangle$. *$\hat{P}$ is a* good quantum number *when is commutes with the Hamiltonian,*

$$0 = [\hat{P}, \hat{H}]\langle x|\psi\rangle = \left(-\frac{\hbar^2}{2m}\frac{d^2}{d(-x)^2} + V(-x)\right)\langle -x| \pm \psi\rangle - \left(-\frac{\hbar^2}{2m}\frac{d^2}{dx^2} + V(x)\right)\langle -x| \pm \psi\rangle$$
$$= [V(-x) - V(x)]\langle -x| \pm \psi\rangle \ .$$

That is, it should be, $V(x) = V(-x)$.

Chapter 24

Linear motion / Separable potentials

In this chapter we will analyze the translational and vibrational motion of a quantum particle. We will give special consideration to the rectangular potential and the harmonic oscillator.

24.1 Translational motion

In one dimension the Hamiltonian of a free particle is,

$$\hat{H} = -\frac{\hbar^2}{2m}\frac{d^2}{dx^2} \ . \tag{24.1}$$

Therefore, the general solution of the Schrödinger stationary equation,

$$\hat{H}\psi(x) = E\psi(x) \ , \tag{24.2}$$

is,

$$\psi(x) = Ae^{\imath kx} + Be^{-\imath kx} \qquad \text{with} \qquad k = \sqrt{\tfrac{2mE}{\hbar^2}} \ . \tag{24.3}$$

Note that the $e^{\imath kx}$ functions are not quadratically integrable, since $\int_{-\infty}^{\infty} |e^{\imath kx}|^2 dx = \int_{-\infty}^{\infty} dx \to \infty$. On the other side, they do not represent actual physical systems. In practice, we need to consider wave packets or specify a finite volume for the particle. Note also that the spectrum of eigenvalues is continuous. Do the Exc. 24.1.4.1.

24.1.1 Quadratic integrability

To allow for an interpretation as probability density we need to ask for quadratic integrability,

$$\int |\psi|^2 d^3r = 1 \ . \tag{24.4}$$

This means that the wavefunction can not be infinite inside a finite volume. But it can be infinite within an infinitely small volume. Also, since the Schrödinger equation contains the second derivative by position, the wavefunction must be continuous and have a continuous derivative.

24.1.2 Separation of dimensions

Frequently, a 3D potential can be written in the way,

$$V(x,y,z) = V_x(x) + V_y(y) + V_z(z) \ . \tag{24.5}$$

This is the case, for example, for a rectangular well with $V_x(x) = V_y(y) = V_z(z) = V_0/3$ inside the well and $V(x,y,z) = 0$ outside. It also holds for a harmonic potential,

$$V(\mathbf{r}) = \frac{m}{2}\left(\omega_x^2 x^2 + \omega_y^2 y^2 + \omega_z^2 z^2\right) \ . \tag{24.6}$$

In these cases, the following ansatz for the wavefunction is generally useful,

$$\psi(\mathbf{r}) = \psi_x(x)\psi_y(y)\psi_z(z) \ , \tag{24.7}$$

since inserting the ansatz into the Schrödinger equation,

$$\left[-\frac{\hbar^2}{2m}\left(\frac{d^2}{dx^2} + \frac{d^2}{dy^2} + \frac{d^2}{dz^2}\right) + V_x(x) + V_y(y) + V_z(z)\right]\psi_x(x)\psi_y(y)\psi_z(z) = E\psi_x(x)\psi_y(y)\psi_z(z) \ , \tag{24.8}$$

the equation separates into three independent one-dimensional equations,

$$-\frac{\hbar^2}{2m}\frac{\psi_x''(x)}{\psi_x(x)} + V_x(x) = const. \equiv E_x \ , \tag{24.9}$$

and the same for y and z. Since, $E = E_x + E_y + E_z$ may have the same value for different combinations of E_x, E_y and E_z, multidimensional systems are often degenerate.

24.1.3 Homogeneous force fields, gravity

The behavior of a wavefunction in a homogeneous force field has been studied in Excs. 23.5.6.2 and 23.5.6.3.

24.1.4 Exercises

24.1.4.1 Ex: Trapped particle

Consider the problem of a particle of mass m forced to move in a single direction and completely confined to a box, with walls placed at the positions $x = 0$ and $x = a$.
a. The particle be in the ground state, what is its energy and its wavefunction?
b. Suppose the particle has the following wavefunction:

$$\psi_I(x) = \frac{1}{\sqrt{7a}}\left[2\cos\left(\frac{\pi}{2a}(6x-a)\right) - 3\imath\sin\left(\frac{2\pi}{a}x\right) + \cos\left(\frac{\pi}{2a}(2x-a)\right)\right] \ ,$$

what is the probability that a measurement of the energy yields the result $E = \frac{2\pi^2\hbar^2}{ma^2}$?
c. Considering again the ground state of item (a), what is the probability distribution for the momentum of the particle in this state?
d. Still starting from the ground state, suppose we remove (instantaneously) the walls,

leaving the particle free ($\hat{H} = \hat{p}^2/2m$). What is the energy of this free particle?
Formulae:

$$\int_0^L e^{\imath Bx} \sin\left(\frac{n\pi x}{L}\right) dx = \frac{n\pi L[1-(-1)^n e^{\imath BL}]}{n^2\pi^2 - B^2L^2} \qquad \text{for} \qquad n = 1, 2, 3, ...$$
$$\int_{-\infty}^{\infty} \frac{x^2}{(1-x^2)^2} \cos^2 \tfrac{\pi x}{2} dx = \frac{\pi^2}{4}$$

Solution: *a. This is the classical problem of an infinite potential well in 1D:*

$$\left[-\frac{\hbar^2}{2m}\frac{\partial^2}{\partial x^2} + V(x)\right]\psi(x) = E\psi(x) \ .$$

with $V(x) = 0$ for $0 < x < a$ and $V(x) = \infty$ for $x > a$ or $x < 0$. For $0 < x < a$ the ansatz

$$\psi(x) = Ae^{\imath kx} + Be^{-\imath kx}$$

gives $k = \sqrt{2mE}/\hbar$. For $x > a$ or $x < 0$ we have $\psi(x) = 0$. Hence, $\psi(a) = \psi(0) = 0$ and $\psi(0) = A + B = 0$, that is, $A = -B$. Also, $\psi(a) = A(e^{\imath ka} - e^{-\imath ka}) = 0$, that is, $A\sin(ka) = 0$ or $k = n\pi/a$ for $n = 1, 2, ...$ The result is,

$$\psi_n(x) = A_n \sin\frac{n\pi x}{a} \ .$$

Normalization requires $1 = \int_0^a |\psi_n(x)|^2 dx$, hence,

$$A_n^2 \int_0^a \sin^2\frac{n\pi x}{a} dx = \frac{A_n^2 a}{2} = 1 \ ,$$

or $A_n = \sqrt{2/a}$. The final result is,

$$\psi_n(x) = \sqrt{\frac{2}{a}} \sin\frac{n\pi x}{a} \ ,$$

for $0 < x < a$. With $k = \frac{\sqrt{2mE}}{\hbar} = \frac{n\pi}{a}$ we have

$$E = \frac{n^2\pi^2\hbar^2}{2ma^2} \ ,$$

for $n = 1, 2, 3, ...$
b. We can rewrite the cosines as sines [they are only written as cosines to not immediately deliver the solution of item (a)],

$$\psi_I(x) = \frac{1}{\sqrt{7a}}\left[2\sin\frac{3\pi x}{a} - 3\imath\sin\frac{2\pi x}{a} + \sin\frac{\pi x}{a}\right] \ .$$

The energy $E = \frac{2\pi^2\hbar^2}{ma^2}$ corresponds to the state with $n = 2$ and the wavefunction: $\psi_a(x) = \sqrt{\frac{2}{a}}\sin\frac{2\pi x}{a}$ and the overlap between this state and $\psi_I(x)$ is given by the

scalar product between them (see the given formulae). Only the product with the same period does not result in zero when integrated:

$$\langle\psi_2(x)|\psi_I(x)\rangle = \int_{-\infty}^{\infty}\psi_2^*(x)\psi_I(x)dx = \sqrt{\frac{2}{a}}\frac{-3\imath}{\sqrt{7a}}\int_0^a \sin\frac{2\pi x}{a}\sin\frac{2\pi x}{a}dx = \frac{-3\imath}{\sqrt{14}}\ .$$

The probability is given by:

$$P = |\langle\psi_2(x)|\psi_I(x)\rangle|^2 = \frac{9}{14} \approx 64\%\ .$$

c. We can go from the original wavefunction to the momentum space distribution:

$$\begin{aligned}\psi(p) &= \frac{1}{\sqrt{2\pi\hbar}}\int_{-\infty}^{\infty}\psi(x)e^{\imath px/\hbar}dx = \frac{1}{\sqrt{2\pi\hbar}}\int_0^a\sqrt{\frac{2}{a}}\sin\frac{\pi x}{a}e^{\imath px/\hbar}dx \\ &= \frac{1}{\sqrt{a\pi\hbar}}\frac{\pi a[1+e^{\imath pa/\hbar}]}{\pi^2-p^2a^2/\hbar^2} = \sqrt{\frac{a\pi}{\hbar}}\frac{1+e^{\imath pa/\hbar}}{\pi^2-p^2a^2/\hbar^2}\ ,\end{aligned}$$

using the given formulae. The probability distribution for moments is,

$$\begin{aligned}|\psi(p)|^2 &= \frac{a\pi}{\hbar}\frac{(1+e^{\imath pa}/\hbar)(1+e^{-\imath pa}/\hbar)}{(\pi^2-p^2a^2/\hbar^2)^2} = \frac{a\pi\hbar^3}{(\pi^2\hbar^2-p^2a^2)^2}(2+e^{\imath pa/\hbar}+e^{-\imath pa/\hbar}) \\ &= \frac{2a\pi\hbar^3}{(\pi^2\hbar^2-p^2a^2)^2}(1+\cos pa/\hbar) = \frac{4a\pi\hbar^3}{(\pi^2\hbar^2-p^2a^2)^2}\cos^2 pa/\hbar\ .\end{aligned}$$

d. The 'smart' way to respond is simply to argue that the idealized walls (infinitely high and instantaneously withdrawn) do not interact with the particle. Then by conservation of energy, the energy is the same as in item (a):

$$E_0 = \frac{\pi^2\hbar^2}{2ma^2}\ .$$

Or we can do the calculation. The Hamiltonian of the free particle is $\hat{H} = p^2/2m$. We can calculate the energy using the state prior to the removal of walls, and the new Hamiltonian is,

$$\begin{aligned}E &= \int_{-\infty}^{\infty}\frac{p^2}{2m}|\psi(p)|^2dp = \frac{1}{2m}4a\pi\hbar^3\int_{-\infty}^{\infty}\frac{p^2}{(\hbar^2\pi^2-p^2a^2)^2}\cos^2\frac{pa}{2\hbar}dp \\ &= \frac{2\hbar^2}{ma^2}\int_{-\infty}^{\infty}\frac{y^2}{(1-y^2)^2}\cos^2\frac{\pi y}{2}dy = \frac{\pi^2\hbar^2}{2ma^2}\ ,\end{aligned}$$

using the given formulae.

24.2 Rectangular potentials

The continuity equation (23.16) teaches us that the probability flux of a moving particle cannot make abrupt changes. That is, even if the particle encounters an obstacle represented by a smooth or abrupt variation of the potential depth, the wavefunction and its derivative must remain continuous, unless the potential step is infinitely high.

24.2.1 Box potential

Let us now place the particle into a rectangular potential well, such that the Hamiltonian is,

$$\hat{H} = -\frac{\hbar^2}{2m}\frac{d^2}{dx^2} + V(x) \qquad \text{with} \qquad V(x) = \begin{cases} 0 & \text{for} \quad x \in [0, L] \\ \infty & \text{for} \quad x \notin [0, L] \end{cases} . \tag{24.10}$$

As the potential barriers are high, the walls are hard, that is, the particle, even being a quantum particle, can not penetrate. The wavefunction and the possible energy values are,

$$\boxed{\psi(x) = \sqrt{\frac{2}{L}} \sin\frac{n\pi x}{L} \qquad \text{and} \qquad E_n = \frac{n^2\hbar^2\pi^2}{2mL^2}} . \tag{24.11}$$

The Exc. 24.2.5.1 asks to demonstrate the result (24.11) illustrated in Fig. 24.1.

Obviously the spectrum of eigenvalues is now discrete. They can be enumerated by an integer n called *quantum number*. Note that the energy levels are not equidistant.

> **Example 156 (*Localization energy*):** There is a minimal *energy* $E_1 = \frac{\hbar^2\pi^2}{2mL^2}$ which is called *zero point energy* or *localization energy*. This energy can be understood as a consequence of Heisenberg's *uncertainty principle*. We can make the following gross estimation of the zero point energy. Obviously, the particle is localized with an uncertainty lower than $\Delta x < L$. Hence, $\Delta p > \hbar/\Delta x > \hbar/L$. The average kinetic energy is,
>
> $$\frac{\langle p^2\rangle}{2m} = \frac{\langle p\rangle^2 + \Delta p^2}{2m} = \frac{\Delta p^2}{2m} > \frac{\hbar^2}{2mL^2} .$$
>
> The fact that the numerical value is different from the value calculated by the formula (24.11) comes from the particular geometry of the box potential.

24.2.2 Multidimensional box potential

In a multidimensional well there can be degeneracy if the well exhibits symmetries. In the case of a 2D quadratic well $L_x = L_y$, the eigenenergies are doubly degenerate, since $E_{n_x,n_y} = E_{n_y,n_x}$. In the case of a 3D cubic well $L_x = L_y = L_z$, the eigenenergies are 6-fold degenerate, because $E_{n_x,n_y,n_z} = E_{n_y,n_z,n_x} = E_{n_z,n_x,n_y} = E_{n_z,n_y,n_x} = E_{n_y,n_x,n_z} = E_{n_x,n_z,n_y}$. The states and energies of the 2D well are calculated in Exc. 24.2.5.2.

24.2.3 Potentials with several sections of constant depths

To find the global wavefunction in potentials with several sections of constant depths, we solve Schrödinger's equations separately for each section,

$$\left(-\frac{\hbar^2}{2m}\frac{d^2}{dx^2} + V_a\right)\psi_a(x) = E\psi_a(x) . \tag{24.12}$$

The general solution for a section a with potential energy V_a is,

$$\boxed{\psi_a(x) = A_a e^{\imath k_a x} + B_a e^{-\imath k_a x}} , \tag{24.13}$$

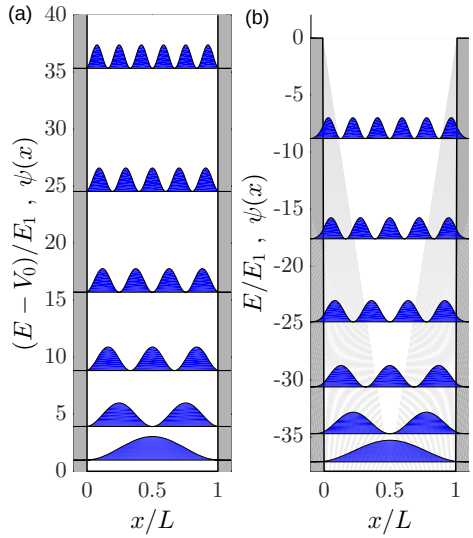

Figure 24.1: (code) (a) Wavefunctions and energies in the box potential. (b) The rectangular potential well with the reference energy set to the height of the well.

where $k_a = \frac{1}{\hbar}\sqrt{2m(E-V_a)}$. If $E > V_a$, the wave is propagating. k_a is the Broglie wavevector of the wave. If $E < V_a$, the wave is evanescent. That is, the wave decays within a distance $\kappa_a = -\imath k_a$.

If the particle is confined, that is, if $E < V(x \to \pm\infty)$, the possible energy levels are quantized and the spectrum is discrete.

For every transition between two sections $a = 1$ and $a = 2$ we require the boundary conditions,

$$\psi_1(x) = \psi_2(x) \qquad \text{and} \qquad \psi_1'(x) = \psi_2'(x)\ . \tag{24.14}$$

Together with the normalization, $1 = \int_{-\infty}^{\infty} |\psi|^2 dx$, these conditions are sufficient to determine the wavefunction unambiguously.

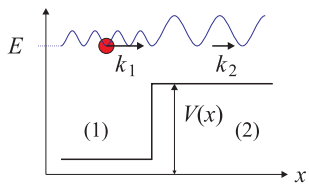

Figure 24.2: Scheme of a potential with several sections of constant depths.

24.2.4 Potential well

Consider a particle with energy E and a potential well of finite depth such that $V(x) = V_0 < 0$ for $-L/2 > x > L/2$ and $V(x) = 0$ otherwise, as illustrated in Fig. 24.3(a). The particle be confined, $E < 0$.

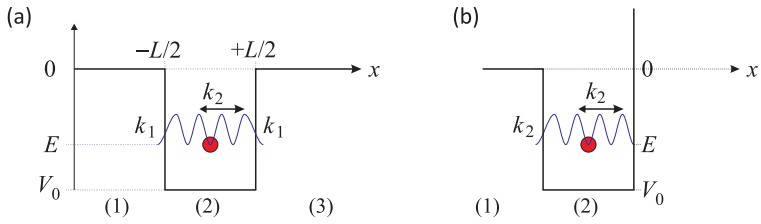

Figure 24.3: (a) Scheme of a two-sided and (b) one-sided potential well.

The wavevectors are

$$k_1 = k_3 = \tfrac{1}{\hbar}\sqrt{2mE} = \imath\tfrac{1}{\hbar}\sqrt{2m|E|} = \imath\kappa_1 \qquad \text{and} \qquad k_2 = \tfrac{1}{\hbar}\sqrt{2m(E-V_0)}\ . \tag{24.15}$$

with $\kappa_1 \in \mathbb{R}^+$. The boundary conditions yield,

$$\begin{aligned} A_1 e^{-\imath k_1 L/2} + B_1 e^{\imath k_1 L/2} &= A_2 e^{-\imath k_2 L/2} + B_2 e^{\imath k_2 L/2} \\ -\imath k_1 A_1 e^{-\imath k_1 L/2} + \imath k_1 B_1 e^{\imath k_1 L/2} &= -\imath k_2 A_2 e^{-\imath k_2 L/2} + \imath k_2 B_2 e^{\imath k_2 L/2} \\ A_2 e^{\imath k_2 L/2} + B_2 e^{-\imath k_2 L/2} &= A_3 e^{\imath k_1 L/2} + B_3 e^{-\imath k_1 L/2} \\ \imath k_2 A_2 e^{\imath k_2 L/2} - \imath k_2 B_2 e^{-\imath k_2 L/2} &= \imath k_1 A_3 e^{\imath k_1 L/2} - \imath k_1 B_3 e^{-\imath k_1 L/2}\ . \end{aligned} \tag{24.16}$$

For confined particles, $E < 0$, the problem is totally symmetric. In addition, the wavefunction must disappear for $x \to \pm\infty$. Therefore, we can simplify,

$$A_1 = 0 = B_3 \qquad \text{and} \qquad A_3 = B_1\ . \tag{24.17}$$

The first two equations (24.16) now give,

$$B_1 e^{\imath k_1 L/2} = A_2 e^{-\imath k_2 L/2} + B_2 e^{\imath k_2 L/2} = \frac{k_2}{k_1}\left(-A_2 e^{-\imath k_2 L/2} + B_2 e^{\imath k_2 L/2}\right)\ . \tag{24.18}$$

We now consider the quotient B_2/A_2. Using the right part of equation (24.18),

$$\frac{B_2}{A_2} = \frac{e^{-\imath k_2 L/2}(k_2 + k_1)}{e^{\imath k_2 L/2}(k_2 - k_1)} = \frac{e^{-\imath k_2 L}(k_2 + \imath\kappa_1)^2}{k_2^2 + \kappa_1^2}\ . \tag{24.19}$$

Since the amplitudes are real, the imaginary part of the quotient (24.19) should disappear, which is the case when,

$$\begin{aligned} 0 &= \mathfrak{Im}\ e^{-\imath k_2 L}(k_2 + \imath\kappa_1)^2 = 2\kappa_1 k_2 \cos k_2 L + (\kappa_1^2 - k_2^2)\sin k_2 L \\ &\Longrightarrow \tan k_2 L = \frac{2\kappa_1 k_2}{-\kappa_1^2 + k_2^2}\ . \end{aligned} \tag{24.20}$$

In order to construct graphically the values of the momenta k_2 of the particle associated with the allowed energy levels, we introduce a constant $\beta \equiv \hbar/(L\sqrt{2m|V_0|})$. Hence,

$$\tan k_2 L = \tan\frac{1}{\beta}\sqrt{1 - |E/V_0|} = \frac{2\sqrt{|E/V_0|}\sqrt{1-|E/V_0|}}{1 - 2|E/V_0|} = \frac{2\kappa_1 k_2}{-\kappa_1^2 + k_2^2}\ . \tag{24.21}$$

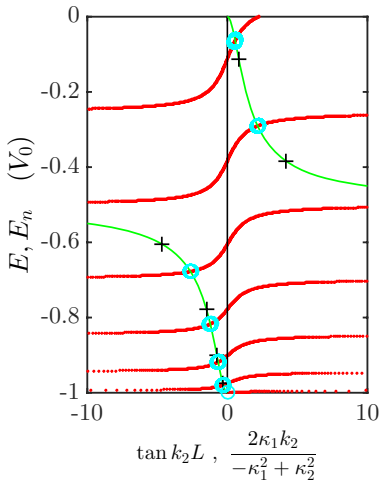

Figure 24.4: (code) Graphical solution for a finite bilateral potential well. The red dotted curves represent the tangents (left side of the equation (24.21)), the solid green curves the hyperbolas (right side of the equation), the circles in cyan are the eigenenergies. When $0 < E - V_0 \ll E$, they converge to the eigenenergies of the infinitely deep well (black crosses and vertical black line).

At the bottom of deep potentials, that is, when $0 < E - V_0 \ll E$, or equivalently, $E \simeq V_0$, we have $k_2 \ll \kappa_1$ and hence, $\tan k_2 L \to 0 \implies k_2 L = n\pi$. The energies are then,

$$E - V_0 = \frac{\hbar^2}{k_2^2} 2m = \frac{\hbar^2 \pi^2}{2mL^2} n^2 \ . \tag{24.22}$$

Apply the notions obtained in this section to solve Excs. 24.2.5.3 and 24.2.5.4.

24.2.5 Exercises

24.2.5.1 Ex: Particle in a box

Obtain the wavefunctions and associated energy levels of a particle confined in a box, where $V(x) = 0$ for $0 \leq x \leq l$ and $V(x) = \infty$ outside.

Solution: *In order to avoid abrupt variations near the walls, we require,*

$$\psi(0) = 0 = \psi(L) \ .$$

The general solution of the Schrödinger equation inside the well is,

$$\psi(t) = C \cos kx + D \sin kx \ .$$

With the boundary conditions,

$$C = 0 \qquad \textit{and} \qquad \sin kL = 0 \ .$$

The normalization condition results in,

$$1 = \int_0^L |\psi(x)|^2 dx = D^2 \int_0^L \sin^2 \frac{n\pi x}{L} dx = \frac{1}{2} L D^2 \ .$$

Therefore, the wave function and the possible values of energy are,

$$\psi(x) = \sqrt{\frac{2}{L}} \sin \frac{n\pi x}{L} \qquad \textit{and} \qquad E_n = \frac{n^2 \hbar^2 \pi^2}{2mL^2} \ .$$

24.2.5.2 Ex: Particle in a two-dimensional box

Obtain the wavefunctions and associated energy levels of a particle trapped in a two-dimensional box inside which the particle is confined to a rectangular surface with dimensions L_1 in x-direction and L_2 in y-direction, $V(x, y) = 0$ for $0 \le x \le L_1$ and $0 \le y \le L_2$ and $V(x, y) = \infty$ else.

Solution: *Since the dimensions of the potential separate, $V(x, y) = V_1(x) + V_2(y)$, we can simply use the solutions of the 1D problem,*

$$\langle n_1, n_2 | \psi \rangle \equiv \psi(x, y) = \frac{2}{\sqrt{L_1 L_2}} \sin \frac{n_1 \pi x}{L_1} \sin \frac{n_1 \pi x}{L_2} \qquad \textit{and} \qquad E_{n_1,n_2} = \frac{n_1^2 \hbar^2 \pi^2}{2mL_1^2} + \frac{n_2^2 \hbar^2 \pi^2}{2mL_2^2} \ .$$

In the case where $L_1 = L_2$, the eigenenergies are doubly degenerate, since $E_{n_1,n_2} = E_{n_2,n_1}$.

24.2.5.3 Ex: Particle in a well

Obtain the energies of the bound states of a particle in the potential well in which $V(x) = \infty$ for $x < 0$, $V(x) = -V_0$ for $0 \le x \le L/2$ and $V(x) = 0$ to $x > L/2$. Compare the obtained values with those of the symmetrical well discussed in Sec. 24.2.4 and the well with infinitely high walls discussed in Sec. 24.2.1.

Solution: *For the unilateral potential well we can simply apply the results of the bilateral potential well. However, with the condition $\psi(0) = 0$, even eigenfunctions are not allowed. That is, $n = 1, 3, ...$*

24.2.5.4 Ex: Least bound states and localization energy

Calculate, based on the discussion in Sec. 24.2.4, the minimum required potential depth V_0 of a three-dimensional finite rectangular well potential of size L to have a bound state capable of trapping an ^{87}Rb atom. Assuming a trap volume of $L = 10\,\text{nm}$, how deep should the trap be?

Solution: *We first consider the one-dimensional potential $V(r) = -V_0$ for $|x| < L/2$*

discussed in Sec. 24.2.4. When, varying the potential depth V_0, a bound state goes into the continuum, we have $E = 0$. With this condition Eq. (24.21) simplifies to,

$$\tan \tfrac{L}{\hbar}\sqrt{2mV_0} = 0 \qquad or \qquad V_0 = \frac{(n\hbar\pi)^2}{2mL^2} \ ,$$

which is just the energy spectrum (24.11) of an infinite box potential. In three dimensions,

$$E_{n_1,n_2,n_3} = \frac{\hbar^2\pi^2}{2mL^2}(n_1^2 + n_2^2 + n_3^2) \ .$$

Hence,

$$V_0 > \frac{3\hbar^2\pi^2}{2mL^2} \ .$$

That is, the more a particle is localized, the deeper must be the potential. For $L = 10\,\mathrm{nm}$, we get $V_0 > 17\,\mathrm{MHz} = 816\,\mu\mathrm{K}$.

24.3 Potential barrier

The linear momentum of a particle described by $\psi(x,t) = Ae^{\imath kx}$ is,

$$\langle\psi|\hat{p}|\psi\rangle = \langle\psi|\frac{\hbar}{\imath}\frac{d}{dx}|\psi\rangle = \hbar k \ . \tag{24.23}$$

Therefore, this particle propagates towards $+\infty$. On the contrary, the particle $Be^{-\imath kx}$ propagates towards $-\infty$. Thus, the two solutions (24.13) of the Schrödinger equation (24.12) correspond to propagating particle waves. From here on we will use the letter A (B) to denote the amplitudes of waves propagating in direction ∞ ($-\infty$).

In locations where the potential changes abruptly, the particle can be partially reflected.

24.3.1 $\mathcal{T}$-scattering matrix

As we have already shown in the previous section, we can write the transformation of the amplitudes due to a potential step at position L as,

$$\begin{aligned} A_2e^{\imath k_2L} + B_2e^{-\imath k_2L} &= A_1e^{\imath k_1L} + B_1e^{-\imath k_1L} \\ \imath k_2A_2e^{\imath k_2L} - \imath k_2B_2e^{-\imath k_2L} &= \imath k_1A_1e^{\imath k_1L} - \imath k_1B_1e^{-\imath k_1L} \ . \end{aligned} \tag{24.24}$$

We can summarize these two equations in a matrix formalism,

$$\boxed{\begin{pmatrix} A_2 \\ B_2 \end{pmatrix} = \mathcal{T}\begin{pmatrix} A_1 \\ B_1 \end{pmatrix}} \ , \tag{24.25}$$

with the *scattering matrix* $\mathcal{T}$ for a particle with energy E (see Fig. 24.2),

$$\begin{aligned}\mathcal{T} &= \frac{1}{2}\begin{pmatrix}\left(1+\frac{k_1}{k_2}\right)e^{\imath(k_1-k_2)L} & \left(1-\frac{k_1}{k_2}\right)e^{\imath(-k_1-k_2)L}\\ \left(1-\frac{k_1}{k_2}\right)e^{\imath(k_1+k_2)L} & \left(1+\frac{k_1}{k_2}\right)e^{\imath(-k_1+k_2)L}\end{pmatrix} \\ &= \frac{1}{2}\begin{pmatrix}e^{-\imath k_2 L} & 0\\ 0 & e^{\imath k_2 L}\end{pmatrix}\begin{pmatrix}1+\frac{k_1}{k_2} & 1-\frac{k_1}{k_2}\\ 1-\frac{k_1}{k_2} & 1+\frac{k_1}{k_2}\end{pmatrix}\begin{pmatrix}e^{\imath k_1 L} & 0\\ 0 & e^{-\imath k_1 L}\end{pmatrix} .\end{aligned} \tag{24.26}$$

If there are more zones with different depths, we may concatenate the scattering matrices. Denoting by $\mathcal{T}_{m\to n}$ the scattering matrix describing a transition at position $L_{m,n}$ of a potential of the depth V_m to another potential V_n, we write,

$$\mathcal{T} = \mathcal{T}_{2\to 3}\mathcal{T}_{1\to 2} . \tag{24.27}$$

24.3.2 $\mathcal{S}$-scattering matrix

Another common definition is the *scattering matrix* $\mathcal{S}$,

$$\boxed{\begin{pmatrix}A_2\\ B_1\end{pmatrix} = \mathcal{S}\begin{pmatrix}B_2\\ A_1\end{pmatrix}} . \tag{24.28}$$

To see how the scattering matrices are interconnected, we start with

$$\begin{pmatrix}A_2\\ B_2\end{pmatrix} = \mathcal{T}\begin{pmatrix}A_1\\ B_1\end{pmatrix} = \begin{pmatrix}\mathcal{T}_{11}A_1 + \mathcal{T}_{12}B_1\\ \mathcal{T}_{21}A_1 + \mathcal{T}_{22}B_1\end{pmatrix} , \tag{24.29}$$

Multiplying the first line with $\mathcal{T}_{22}$ and the second with $-\mathcal{T}_{12}$ and adding them,

$$\mathcal{T}_{22}A_2 - \mathcal{T}_{12}B_2 = \left(\mathcal{T}_{11}\mathcal{T}_{22} - \mathcal{T}_{12}\mathcal{T}_{21}\right)A_1 . \tag{24.30}$$

This equation resolved by A_2 along with the second equation (24.29) resolved by B_1 give,

$$\begin{pmatrix}A_2\\ B_1\end{pmatrix} = \mathcal{S}\begin{pmatrix}B_2\\ A_1\end{pmatrix} = \begin{pmatrix}\mathcal{T}_{12}/\mathcal{T}_{22} & \mathcal{T}_{11} - \mathcal{T}_{12}\mathcal{T}_{21}/\mathcal{T}_{22}\\ 1/\mathcal{T}_{22} & -\mathcal{T}_{21}/\mathcal{T}_{22}\end{pmatrix}\begin{pmatrix}B_2\\ A_1\end{pmatrix} . \tag{24.31}$$

The matrix $\mathcal{S}$ describes the causality of scattering process more adequately: The amplitude A_2 in region (2) results from the superposition of a wave B_2 being reflected by the barrier and a wave A_1 being transmitted by the barrier. The amplitude B_1 in region (1) results from the superposition of a wave A_1 being reflected by the barrier and a wave B_2 being transmitted by the barrier. Therefore, the matrix $\mathcal{S}$ is more appropriate for the description of the quantum reflection, as we will discuss in the next section. However, it has the disadvantage that it can not be concatenated in the same way as the $\mathcal{T}$ matrices.

Unlike the $\mathcal{T}$ matrix the $\mathcal{S}$ matrix is *unitary*, since

$$\det\mathcal{S} = \mathcal{S}_{11}\mathcal{S}_{22} - \mathcal{S}_{12}\mathcal{S}_{21} = -\frac{\mathcal{T}_{11}}{\mathcal{T}_{22}} = -e^{2\imath k_1 L} . \tag{24.32}$$

Also, it is possible to show,

$$\mathcal{S}^\dagger\mathcal{S} = \begin{pmatrix}\mathcal{S}_{11}^* & \mathcal{S}_{21}^*\\ \mathcal{S}_{12}^* & \mathcal{S}_{22}^*\end{pmatrix}\begin{pmatrix}\mathcal{S}_{11} & \mathcal{S}_{12}\\ \mathcal{S}_{21} & \mathcal{S}_{22}\end{pmatrix} = \begin{pmatrix}1 & 0\\ 0 & 1\end{pmatrix} . \tag{24.33}$$

24.3.3 Quantum reflection at a potential step

The *quantum reflection* is a non-classical property of the motion of a particle. An example is the *reflection* of a quantum particle by an *attractive* potential. To study this effect, we consider a plane wave $e^{\imath k_1 x}$ propagating in region (1) ($E_1 > V_1$) encountering a potential step up or down at position $x = 0$ leading to another region (2). Using the S matrix formalism introduced in the previous section,

$$\mathcal{S} = \frac{1}{k_1 + k_2} \begin{pmatrix} k_2 - k_1 & 2k_1 \\ 2k_2 & k_1 - k_2 \end{pmatrix} , \tag{24.34}$$

we find that one part of the wave is reflected into the region (1), another is transmitted into the region (2),

$$\begin{aligned} \begin{pmatrix} A_2 \\ B_1 \end{pmatrix} = \mathcal{S} \begin{pmatrix} 0 \\ 1 \end{pmatrix} = \begin{pmatrix} \mathcal{T}_{11} - \mathcal{T}_{12}\mathcal{T}_{21}/\mathcal{T}_{22} \\ -\mathcal{T}_{21}/\mathcal{T}_{22} \end{pmatrix} = \begin{pmatrix} \frac{(1+k_1/k_2)^2 - (1-k_1/k_2)^2}{2(1+k_1/k_2)} \\ -\frac{1-k_1/k_2}{1+k_1/k_2} \end{pmatrix} \\ = \frac{1}{k_1 + k_2} \begin{pmatrix} 2k_1 \\ k_1 - k_2 \end{pmatrix} . \end{aligned} \tag{24.35}$$

We use $B_2 = 0$, since no wave comes from the side of region (2), and $A_1 = 1$, because it simplifies the formulas and does not affect the generality of the results. The interesting results are:

- Even when $E_2 < V_2$, the particle enters the classically prohibited region: $\psi_2(x) \propto e^{-\kappa_2 x}$ with $\kappa_2 = \frac{1}{\hbar}\sqrt{2m(V_2 - E_2)}$, i.e. the transmission is non-zero, $|A_2| > 0$.

- Even with $E_2 > V_2$, the particle has a probability of being reflected at the step, $|B_1| > 0$.

Example 157 (*Contrast of a partially reflected wave*): Defining $K_\pm \equiv \frac{1}{2}\left(\max|\psi_1|^2 \pm \min|\psi_1|^2\right)$, the *contrast* of the wavefunction in region (1) is given by K_-/K_+. Writing the function as $\psi_1 = e^{\imath k_1 x} + B_1 e^{-\imath k_1 x}$ it is easy to show, that

$$|B_1| = \frac{\sqrt{K_+ + K_-} - \sqrt{K_+ - K_-}}{\sqrt{K_+ + K_-} + \sqrt{K_+ - K_-}} \simeq \frac{K_-}{2K_+} . \tag{24.36}$$

This formula can be understood as an analogue of *Fresnel formula* for matter waves [1].

In Exc. 24.3.7.1 we calculate the behavior of a Broglie wave passing through a potential step and entering a classically forbidden region. In Exc. 24.3.7.2 we investigate a model describing the collision between attracting or repelling particles via a partial reflection at a potential step.

[1] In this sense light reflection at an optical interface (with typical losses of 4% for glass) can be interpreted as quantum reflection of light

24.3.4 Continuity of probability flow

The continuity equation (23.16) requires that the *probability flux* be preserved in stationary situations,

$$0 = \frac{dj}{dx} = \frac{d}{dx}\frac{\hbar}{2m\imath}\left[\psi^*\left(\frac{d}{dx}\psi\right) - \left(\frac{d}{dx}\psi^*\right)\psi\right] \ . \tag{24.37}$$

Applying this to a potential step separating the regions $n = 1, 2$, we find,

$$\begin{aligned} j_n &= \frac{\hbar}{2mi}\left[\psi^*\frac{d}{dx}\psi - \psi\frac{d}{dx}\psi^*\right] \\ &= \frac{\hbar}{2m\imath}\left[(A_n^* e^{-\imath k_n x} + B_n^* e^{\imath k_n x})(\imath k_n A_n e^{\imath k_n x} - \imath k_n B_n e^{-\imath k_n x})\right. \\ &\quad \left. - (A_n e^{\imath k_n x} + B_n e^{-\imath k_n x})(-\imath k_n A_n^* e^{-\imath k_n x} + \imath k B_n^* e^{\imath k x})\right] \\ &= \frac{\hbar k_n}{m}(|A_n|^2 - |B_n|^2) \ . \end{aligned} \tag{24.38}$$

Hence, $j_1 = j_2$ implies $k_1|A_1|^2 - k_1|B_1|^2 = k_2|A_2|^2 - k_2|B_2|^2$. Assuming that the particle comes from side 1 and $B_2 = 0$, we have,

$$1 = |B_1|^2 + \tfrac{k_2}{k_1}|A_2|^2 = R + T \ , \tag{24.39}$$

defining the *transmission* T and the *reflection* R as,

$$T \equiv \tfrac{k_2}{k_1}|\mathcal{S}_{12}|^2 = \tfrac{k_2}{k_1}|A_2|^2 \qquad \text{and} \qquad R \equiv |\mathcal{S}_{22}|^2 = |B_1|^2 \ . \tag{24.40}$$

24.3.5 Tunneling and quantum reflection at a potential well

Particles thrown with a kinetic energy E against potential barriers can cross them even if $V_0 > E$ or be reflected even when $V_0 < E$, as illustrated in Fig. 24.5(a). This can be verified by considering a particle propagating from $x = -\infty$ towards $x = +\infty$ through a potential well located at $x \in [0, a]$. We determine the concatenation $\mathcal{T} = \mathcal{T}_{2\to3}\mathcal{T}_{1\to2}$. Then we find the $\mathcal{S}$ matrix that corresponds to the $\mathcal{T}$ matrix and solve the problem in the same way as in the previous section. For example, we can calculate the transmission and reflection probabilities. The formula is derived in Exc. 24.3.7.3,

$$\boxed{R = 1 - T = \left(1 + \frac{16E/V_0(1 - E/V_0)}{(e^{\kappa L} - e^{-\kappa L})^2}\right)^{-1}} \ , \tag{24.41}$$

and sketched in Fig. 24.5(b).

24.3.6 The delta-potential

In quantum mechanics the δ-potential can be used to simulate situations, where a particle is free to move in two regions of space with a barrier in between. For example, an electron can move almost freely in a conducting material, but when two conducting surfaces are put close together, the interface between them acts as a barrier for the electron that can be approximated by a δ-potential. The δ-potential is a limiting

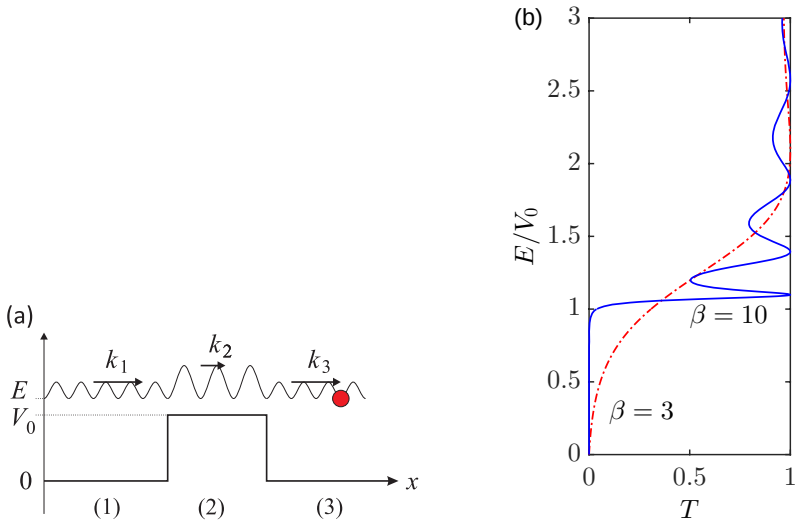

Figure 24.5: (code) (a) Tunnel effect and quantum transmission and reflection at a potential barrier. (b) Coefficients of transmission and reflection (horizontal) through the shown potential barrier as a function of the energy normalized to the height of the barrier E/V_0. The dashed red curve corresponds to a low barrier, $\beta \equiv \frac{1}{\hbar} L\sqrt{2mV_0} = 3$, the blue solid curve corresponds to a deep barrier $\beta = 10$.

case of the finite potential well when we decrease its width while maintained the product of its width and its depth constant. Here, for simplicity, we only consider a one-dimensional potential well, but the analysis can be expanded to more dimensions.

The time-independent Schrödinger equation for the wavefunction $\psi(x)$ of a particle in one dimension is,

$$-\frac{\hbar^2}{2m}\frac{d^2\psi(x)}{dx^2} + \alpha\delta(x)\psi(x) = E\psi(x) \ , \tag{24.42}$$

The potential is called a δ-potential well if α is negative and a δ-potential barrier if α is positive.

The potential splits the space in two parts ($x < 0$ and $x > 0$). In each of these parts the potential energy is zero, and the Schrödinger equation reduces to,

$$\frac{d^2\psi}{dx^2} = -\frac{2mE}{\hbar^2}\psi \ . \tag{24.43}$$

The solutions of this differential equation are linear combinations of $e^{\imath kx}$ and $e^{-\imath kx}$, where the wavenumber k is related to the energy by $k = \frac{\sqrt{2mE}}{\hbar}$. In general, due to the presence of the δ-potential in the origin, the coefficients of the solution need not be the same in both half-spaces:

$$\psi(x) = \begin{cases} \psi_1(x) = A_1 e^{\imath kx} + B_1 e^{-\imath kx} & \text{for } x < 0 \\ \psi_2(x) = A_2 e^{\imath kx} + B_2 e^{-\imath kx} & \text{for } x > 0 \end{cases} \ , \tag{24.44}$$

where, in the case of positive energies (real k), $e^{\imath kx}$ represents a wave traveling to the right, and $e^{-\imath kx}$ one traveling to the left. One obtains a relation between the coefficients by imposing that the wavefunction be continuous at the origin,

$$\psi(0) = \psi_1(0) = \psi_2(0) = A_1 + B_1 = A_2 + B_2 \ . \tag{24.45}$$

A second relation can be found by studying the derivative of the wavefunction. Normally, we could also impose differentiability at the origin, but this is not possible because of the δ-potential. However, if we integrate the Schrödinger equation around $x = 0$ over an interval $[-\epsilon, +\epsilon]$:

$$-\frac{\hbar^2}{2m}\int_{-\epsilon}^{+\epsilon}\psi''(x)dx + \int_{-\epsilon}^{+\epsilon}V(x)\psi(x)dx = E\int_{-\epsilon}^{+\epsilon}\psi(x)dx \ . \tag{24.46}$$

In the limit $\epsilon \to 0$ the right-hand side of this equation vanishes,

$$-\frac{\hbar^2}{2m}[\psi_2'(0) - \psi_1'(0)] + \alpha\psi(0) = 0 \ . \tag{24.47}$$

Substituting the definition of ψ into this expression, we obtain,

$$-\frac{\hbar^2}{2m}\imath k(A_1 - B_1 - A_2 + B_2) + \alpha(A_1 + B_1) = 0 \ . \tag{24.48}$$

The boundary conditions thus give the following restrictions on the coefficients,

$$\boxed{\begin{array}{rcl} A_1 + B_1 - A_2 - B_2 &=& 0 \\ A_1 - B_1 - A_2 + B_2 &=& \dfrac{2m\alpha}{\imath k\hbar^2}(A_1 + B_1) \end{array}} \ . \tag{24.49}$$

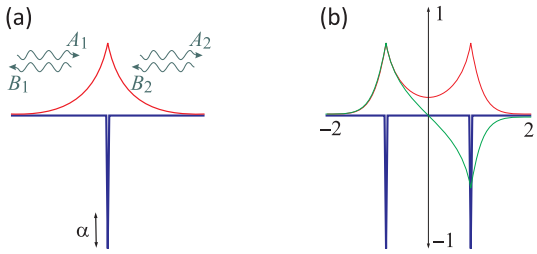

Figure 24.6: (a) The δ-potential (green) and the bound state wavefunction (blue). (b) Double δ-potential (green).

24.3.6.1 Bound states

The bound state wavefunction solution to the δ-function potential is continuous everywhere, but its derivative is not defined at $x = 0$.

In any one-dimensional attractive potential there will be a bound state. To find its energy, note that for negative energies, $E < 0$, the wavenumber $k = \imath\sqrt{2m|E|}/\hbar = \imath\kappa$

is imaginary and the wavefunctions are exponentially increasing or decreasing functions of x (see above). Requiring that the wavefunctions do not diverge at infinity eliminates half of the terms: $A_2 = B_1 = 0$. The wavefunction is then an evanescent wave,

$$\psi(x) = \begin{cases} \psi_1(x) = A_1 e^{\kappa x} & \text{for } x < 0 \\ \psi_2(x) = B_2 e^{-\kappa x} & \text{for } x > 0 \end{cases} . \tag{24.50}$$

From the boundary conditions and normalization conditions, it follows that,

$$A_1 = B_2 = \sqrt{\kappa} \quad \text{and} \quad \kappa = -\frac{m\alpha}{\hbar^2} , \tag{24.51}$$

from which follows that α must be negative, that is the bound state only exists for the well, and not for the barrier. The Fourier transform of this wavefunction is a Lorentzian function. The energy of the bound state is then,

$$E_b = -\frac{\hbar^2\kappa^2}{2m} = -\frac{m\alpha^2}{2\hbar^2} . \tag{24.52}$$

The δ-potential well and its wavefunction are exhibited in Fig. 24.6(a).

24.3.6.2 Scattering

For positive energies, the wavefunctions are oscillating functions of x. That is, the particle is free to move in either half-space: $x < 0$ or $x > 0$, but it may be scattered at the δ-potential. The quantum case can be studied in the following situation: a particle incident on the barrier from the left side (A_1) may be reflected (B_1) or transmitted (A_2). To find the amplitudes for reflection and transmission for incidence from the left, we set in the equations (24.49) $A_1 = 1$ (incoming particle), $B_1 = r$ (reflection), $B_2 = 0$ (no incoming particle from the right), and $A_2 = t$ (transmission), and solve for r and t,

$$t = \frac{1}{1 - \dfrac{m\alpha}{\imath\hbar^2 k}} \quad , \quad r = \frac{1}{\dfrac{\imath\hbar^2 k}{m\alpha} - 1} . \tag{24.53}$$

Due to the mirror symmetry of the model, the amplitudes for incidence from the right are the same as those from the left. The result is that there is a non-zero probability,

$$R = |r|^2 = \frac{1}{1 + \dfrac{\hbar^4 k^2}{m^2\alpha^2}} = \frac{1}{1 + \dfrac{2\hbar^2 E}{m\alpha^2}} . \tag{24.54}$$

for the particle to be reflected. This does not depend on the sign of α, that is, a barrier has the same probability of reflecting the particle as a well. This is a significant difference from classical mechanics, where the reflection probability would be 1 for the barrier (the particle simply bounces back), and 0 for the well (the particle passes through the well undisturbed). The probability for transmission is,

$$T = |t|^2 = 1 - R = \frac{1}{1 + \dfrac{m^2\alpha^2}{\hbar^4 k^2}} = \frac{1}{1 + \dfrac{m\alpha^2}{2\hbar^2 E}} . \tag{24.55}$$

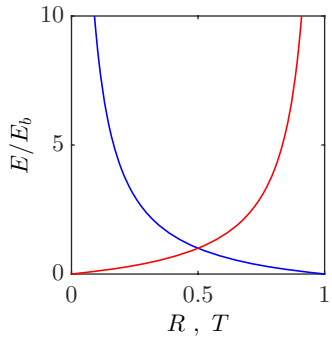

Figure 24.7: (code) Transmission (red) and reflection (blue) probability of a δ-potential well. The energy $E > 0$ is in units of $E_b = m\alpha^2/2\hbar^2$.

An application example regards the interfaces between two conducting materials. In the bulk of the materials, the motion of the electrons is quasi-free and can be described by the kinetic term in the above Hamiltonian with an effective mass m. Often, the surfaces of such materials are covered with oxide layers or are not ideal for other reasons. This thin, non-conducting layer may then be modeled by a local δ-function potential. Electrons may then tunnel from one material to the other giving rise to a current.

Example 158 (*Double delta potential*): The δ-function model is actually a one-dimensional version of the hydrogen atom. The model becomes particularly useful when applied to the hydrogen molecule ion, as shown in the following. The double-well δ-function models a diatomic hydrogen molecule by the corresponding Schrödinger equation:

$$-\frac{\hbar^2}{2m}\frac{d^2\psi}{dx^2}(x) + V(x)\psi(x) = E\psi(x) \ ,$$

where the potential is now:

$$V(x) = -q\lambda\left[\delta\left(x + \tfrac{R}{2}\right) + \delta\left(x - \tfrac{R}{2}\right)\right]$$

where $0 < R < \infty$ is the 'internuclear' distance with δ-function (negative) peaks located at $x = \pm R/2$ (shown in brown in the diagram). Keeping in mind the relationship of this model with its three-dimensional molecular counterpart, we use atomic units and set $\hbar = m = 1$. Here $0 < \lambda < 1$ is a formally adjustable parameter. From the single well case, we can infer the 'ansatz' for the solution to be:

$$\psi(x) = Ae^{-d\left|x+\frac{R}{2}\right|} + Be^{-d\left|x-\frac{R}{2}\right|} \ .$$

Matching of the wavefunction at the δ-function peaks yields the determinant:

$$\begin{vmatrix} q-d & qe^{-dR} \\ q\lambda e^{-dR} & q\lambda - d \end{vmatrix} = 0 \quad \text{where} \quad E = -\frac{d^2}{2} \ .$$

Thus, d is found to be governed by the pseudo-quadratic equation:

$$d_\pm(\lambda) = \tfrac{1}{2}q(\lambda+1) \pm \tfrac{1}{2}\left\{q^2(1+\lambda)^2 - 4\lambda q^2[1 - e^{-2d_\pm(\lambda)R}]\right\}^{1/2} \ ,$$

which has two solutions $d = d_{\pm}$. For the case of equal charges (symmetric homonuclear case), $\lambda = 1$ and the pseudo-quadratic reduces to:

$$d_{\pm} = q[1 \pm e^{-d_{\pm}R}] \ .$$

The '+' case corresponds to a wave function symmetric about the midpoint (shown in red in the diagram) where $A = B$ and is called gerade. Correspondingly, the '-' case is the wavefunction that is anti-symmetric about the midpoint where $A = -B$ is called ungerade (shown in green in the diagram). They represent an approximation of the two lowest discrete energy states of the three-dimensional H_2^+ and are useful in its analysis. Analytical solutions for the energy eigenvalues for the case of symmetric charges are given by:

$$d_{\pm} = q + W(\pm qRe^{-qR})/R \ ,$$

where W is the standard Lambert function. Note that the lowest energy corresponds to the symmetric solution d_+. In the case of unequal charges, and for that matter the three-dimensional molecular problem, the solutions are given by a generalization of the Lambert function (see section on generalization of Lambert function and references herein).
One of the most interesting cases is when $qR \leq 1$, which results in $d_- = 0$. Thus, one has a non-trivial bound state solution with $E = 0$. For these specific parameters, there are many interesting properties that occur, one of which is the unusual effect that the transmission coefficient is unity at zero energy.

24.3.7 Exercises

24.3.7.1 Ex: Tunneling

A rubidium-87 atom moves in free space (region 0) with velocity $v = 1\,\mathrm{cm/s}$ (see diagram). Suddenly it encounters a gap with depth $V_1 = -k_B \cdot 1\mu\mathrm{K}$.
a. What is the particle's Broglie wavelength in region 1?
b. Now the atom encounters a barrier of height $V_2 = -V_1$. What is the probability that the particle will enter region 2?
c. What is the probability of finding the particle inside region 2 up to a depth of $x_2 = 10\,\mathrm{nm}$?

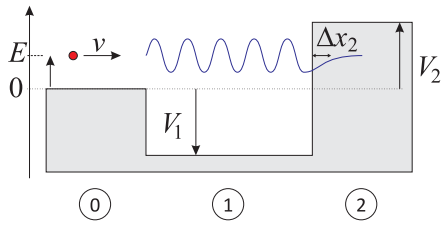

Figure 24.8: Particle in a potential landscape.

Solution: *a. The energy of the particle in region 0 is*

$$E = \frac{m}{2}v^2 = k_B \cdot 523\,\mathrm{nK} \ .$$

The wave vector in region 1 is

$$k_1 = \sqrt{\frac{2m}{\hbar^2}(E - V_1)} = \frac{\sqrt{m^2v^2 - 2mV_1}}{\hbar} \ ,$$

giving $\lambda = 2\pi/k_1 = 270\,\text{nm}$.
b. Writing the wavevector in region 2 as

$$k_2 = \sqrt{\frac{2m}{\hbar^2}(E - V_2)} = \imath\sqrt{\frac{2m}{\hbar^2}(V_2 - E)} = \imath\kappa_2 \ ,$$

we have $\kappa_2 = 2.34 \cdot 10^7\,\text{m}^{-1}$. *We have the conditions of continuity*

$$\psi_1(x) = Ae^{\imath k_1 x} + Be^{-\imath k_1 x} = Ce^{\imath k_2 x} + De^{-\imath k_2 x} = \psi_2(x)$$
$$\psi_1'(x) = \imath k_1 Ae^{\imath k_1 x} - \imath k_1 Be^{-\imath k_1 x} = \imath k_2 Ce^{\imath k_2 x} - \imath k_2 De^{-\imath k_2 x} = \psi_2'(x) \ .$$

Inserting $x = 0$ *and* $D = 0$,

$$A + B = C \quad , \quad \imath k_1 - \imath k_1 B = \imath k_2 C \ ,$$

giving

$$B = \frac{k_1 - k_2}{k_1 + k_2}A \quad , \quad C = \frac{2k_1}{k_1 + k_2}A \ .$$

We note that the dimension of the coefficients is that of a wavevector. The probability of finding the particle within region 2 is,

$$\int_0^\infty |\psi_2(x)|^2 dx = \int_0^\infty |Ce^{\imath k_2 x}|^2 dx = \left|\frac{2k_1}{k_1 + \imath\kappa_2}\right|^2 A^2 \int_0^\infty e^{-2\kappa_2 x} dx$$
$$= \frac{4k_1^2}{k_1^2 + \kappa_2^2}\frac{A^2}{-2\kappa_2}\, e^{-2\kappa_2 x}\Big|_0^\infty = \frac{4(E - V_1)}{-V_1 - V_1}\frac{A^2}{2\kappa_2} = 1.16 \cdot 10^{-7}\ A^2 \ .$$

c. The probability of finding the particle up to the depth x_2 *is,*

$$\int_0^{x_2} |\psi_2(x)|^2 dx = (1 - e^{-2\kappa_2 x_2}) \int_0^\infty |\psi(x_2)|^2 dx = 0.27 \cdot 10^{-7}\ A^2 \ .$$

24.3.7.2 Ex: Collisions

A *collision* between attractive or repulsive particles can be described by the Schrödinger equation as a one-dimensional scattering,

$$-\frac{\hbar^2}{2m}\psi''(x) + \alpha\delta(x)\psi(x) = E\psi(x) \ .$$

The energy spectrum may be a discrete spectrum of bound states and a continuum of free states.
a. Calculate the transmission coefficient for the case of a particle with energy E thrown against the potential energy barrier $V(x) = \alpha\delta(x)$. Does the result change for the

case when $V(x) = -\alpha\delta(x)$, with $\alpha > 0$?
b. For this last potential, find the energy of the bound state and its corresponding wavefunction.

Solution: *a. The general solution for $E > 0$ is simply,*

$$\psi_E(x) = \begin{cases} A_1 e^{\imath kx} + B_1 e^{-\imath kx} & for \quad x < 0 \\ A_2 e^{\imath kx} + B_2 e^{-\imath kx} & for \quad x > 0 \end{cases} \quad , \quad \frac{\hbar^2 k^2}{2m} = E \ .$$

The probability flow in the two regions 1 and 2,

$$\begin{aligned} j_n &= \frac{\hbar}{2m\imath}\left[\psi^* \frac{d}{dx}\psi - \psi \frac{d}{dx}\psi^*\right] \\ &= \frac{\hbar}{2m\imath}\left[(A_n^* e^{-\imath kx} + B_n^* e^{\imath kx})(\imath k A_n e^{\imath kx} - \imath k B_n e^{-\imath kx})\right. \\ &\quad \left. - (A_n e^{\imath kx} + B_n e^{-\imath kx})(-\imath k A_n^* e^{-\imath kx} + \imath k B_n^* e^{\imath kx})\right] \\ &= \frac{\hbar k}{m}(|A_n|^2 - |B_n|^2) \ , \end{aligned}$$

must be maintained, that is, $j_1 = j_2$, such that,

$$|A_1|^2 - |B_1|^2 = |A_2|^2 - |B_2|^2 \ .$$

Assuming that the particle comes from the region 1, $B_2 = 0$, we obtain,

$$\frac{|B_1|^2}{|A_1|^2} + \frac{|A_2|^2}{|A_1|^2} = R + T = 1 \ .$$

b.

24.3.7.3 Ex: Energy barrier

Consider a particle with energy E thrown (in the direction $\hat{\mathbf{e}}_x$) against a potential energy barrier of finite height and width, such that $V(x) = 0$ for $x < 0$ or $x > L$ and $V(x) = V_0$ for $0 \leq x \leq L$.
a. Obtain the reflection and transmission coefficients R and T for the case $E > V_0$. Discuss the result.
b. Do the same for the case $E < V_0$.

Solution: *We consider a particle with kinetic energy E moving from $x = -\infty$ to $x = \infty$ through a barrier (a well) of potential with the height (depth) $V(z) = V_0$ for $x \in [0, L]$. The wavevectors of the particle in the three zones are,*

$$k_1 = k_3 = \frac{1}{\hbar}\sqrt{2mE} \qquad and \qquad k_2 = \frac{1}{\hbar}\sqrt{2m(E - V_0)} \ . \tag{24.56}$$

The wavefunctions are,

$$\psi_1(x) = e^{\imath k_1 x} + B_1 e^{-\imath k_1 x} \quad and \quad \psi_2(x) = A_2 e^{\imath k_2 x} + B_2 e^{-\imath k_2 x} \quad and \quad \psi_3(x) = A_3 e^{\imath k_1 x} \ .$$

Boundary conditions must be met,

$$\begin{aligned}
\psi_1(0) = \psi_2(0) &\implies 1 + B_1 = A_2 + B_2 \\
\psi_1'(0) = \psi_2'(0) &\implies \imath k_1 - \imath k_1 B_1 = \imath k_2 A_2 - \imath k_2 B_2 \\
\psi_1(L) = \psi_2(L) &\implies A_2 e^{\imath k_2 L} + B_2 e^{-\imath k_2 L} = A_3 e^{\imath k_1 L} \\
\psi_1'(L) = \psi_2'(L) &\implies \imath k_2 A_2 e^{\imath k_2 L} - \imath k_2 B_2 e^{-\imath k_2 L} = \imath k_1 A_3 e^{\imath k_1 L} \ .
\end{aligned}$$

This gives,

$$1 + B_1 + \tfrac{k_1}{k_2}(1 - B_1) = 2A_2 \qquad \textit{and} \qquad 1 + B_1 - \tfrac{k_1}{k_2}(1 - B_1) = 2B_2$$

$$\textit{and} \qquad A_3 e^{\imath k_1 L} + \tfrac{k_1}{k_2} A_3 e^{\imath k_1 L} = 2A_2 e^{\imath k_2 L} \qquad \textit{and} \qquad A_3 e^{\imath k_1 L} - \tfrac{k_1}{k_2} A_3 e^{\imath k_1 L} = 2B_2 e^{-\imath k_2 L} \ .$$

And then

$$\begin{aligned}
1 + B_1 + \tfrac{k_1}{k_2}(1 - B_1) &= A_3 e^{\imath (k_1 - k_2) L} + \tfrac{k_1}{k_2} A_3 e^{\imath (k_1 - k_2) L} \\
1 + B_1 - \tfrac{k_1}{k_2}(1 - B_1) &= A_3 e^{\imath (k_1 + k_2) L} - \tfrac{k_1}{k_2} A_3 e^{\imath (k_1 + k_2) L} \ ,
\end{aligned}$$

yielding,

$$B_1 = \frac{(k_2^2 - k_1^2)(e^{2\imath k_2 L} - 1)}{(k_2 + k_1)^2 - (k_2 - k_1)^2 e^{2\imath k_2 L}} \qquad \textit{and} \qquad A_3 = \frac{(k_2 + k_1)^2 - (k_2 - k_1)^2}{(k_1 + k_2)^2 e^{\imath (k_2 - k_1) L} - (k_1 - k_2)^2 e^{\imath (k_2 + k_1) L}} \ .$$

From this we calculate the reflection,

$$R = |B_1|^2 = \frac{-(k_2^2 - k_1^2)^2 (e^{\imath k_2 L} - e^{-\imath k_2 L})^2}{2k_2^4 + 12 k_2^2 k_1^2 + 2k_1^4 - (k_2^2 - k_1^2)^2 (e^{2\imath k_2 L} + e^{-2\imath k_2 L})} = 1 - |A_3|^2 = 1 - T \ .$$

Substituting (24.56) and $\kappa \equiv \imath k_2$, we finally get,

$$R = 1 - T = \left(1 + \frac{16 E/V_0 (1 - E/V_0)}{(e^{\kappa L} - e^{-\kappa L})^2} \right)^{-1} \ .$$

The reflection $|B_1|^2$ and the transmission $|A_3|^2$ show resonances, when L or V_0 are varied. These are located at $2\kappa L = 2\pi \imath n$, where $n \in \mathbb{N}$.

24.3.7.4 Ex: Wavepacket reflected at a potential barrier

Simulate the reflection of a Gaussian wavepacket at a potential barrier for various kinetic energies using the Julia programming language.

Solution: *Fig. 24.9 shows the simulation.*

24.4 Numerical approaches for arbitrary potentials

In practice, many potentials are not box-shaped or harmonic, which renders an analytic treatment difficult or impossible. To some extend approximation methods can be

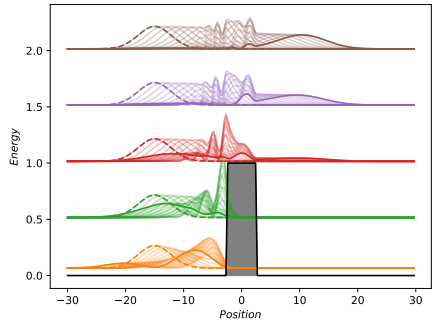

Figure 24.9: (code) Partial reflection of a wavepacket at a potential barrier.

used, as discussed in Sec. 27.5, but many problems can only be solved numerically. In Sec. 24.4.1 we will first show at the example of arbitrary one-dimensional potentials, how the Schrödinger equation can be solved numerically and how this allows one to determine the eigenenergies of bound states. In Sec. 24.4.2 we will introduce the very efficient Fourier grid method for calculating bound state energies and wavefunctions.

24.4.1 Calculation of free and bound states wavefunctions

Numerical routines or packages are available for solving ordinary differential equations (ODE). Generally it is advantageous to convert the one-dimensional second-order Schrödinger equation into two first-order differential equations via,

$$\varphi'(x) = \frac{2m}{\hbar^2}[E - V(x)]\psi(x) \qquad \text{and} \qquad \psi'(x) = \varphi(x)\ . \tag{24.57}$$

For free states, $E > V(x)$, we just solve equation (24.57) specifying the kinetic energy of the particle. The magenta curve in Fig 24.10(a) is an example of a collisional wavefunction in a Morse-type interatomic potential.

For bound states, we must additional satisfy the eigenvalue problem, since only specific discrete eigenenergies E are permitted. A possible procedure consists in guessing an eigenvalue E, calculating the associated wavefunction $\psi(x)$ using an ODE solver, check whether it diverges for $x \to \pm\infty$, and vary E until $\psi(x)$ no longer diverges. Then we repeat the procedure for are bound state energies, until we got them all. The red curve in Fig 24.10(a) shows the wavefunction of a vibrational state in a Morse-type potential obtained by solving the Schrödinger equation and adjusting the energy until the function stops diverging in the classically forbidden range. In this example the iteration process was stopped when the wavefunction diverged at around $R \approx 19a_B$. In Exc. 24.4.4.1 we will practice this technique at the example of Hermite's differential equation, and in Exc. 24.4.4.2 we will study the case of a potential whose depth linearly increases with the distance from origin.

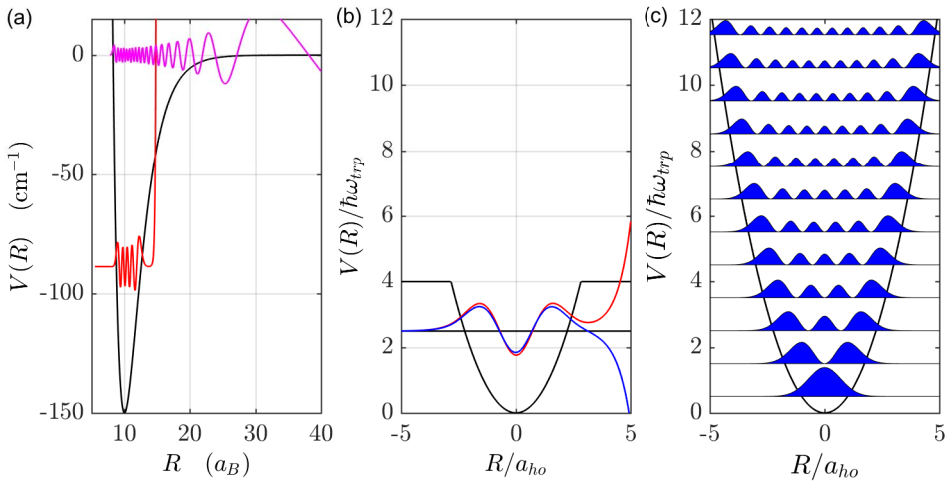

Figure 24.10: (code) (a) Free particle (magenta) and bound state wavefunction (red) calculated using a MATLAB ODE solver. (b) Bound state wavefunction of the harmonic oscillator calculated using a MATLAB ODE solver. For the red curve the eigenvalue has been slightly overestimated and for the blue curve underestimated. (c) Calculation of the harmonic oscillator energies and wave functions using the Fourier grid method.

24.4.2 The Fourier grid method for bound states

The objective of the *Fourier grid method* is to analytically solve the 1D Schrödinger equation with an arbitrary potential $V(r)$ on a grid of $2N+1$ equally spaced spatial points r_i, where $i = 0, \pm 1, ..., \pm N$. That is, we assume the potential $V(r_i)$ to be given at these points. Skaling by the spatial coordinate r by $r/L = x/2\pi$, we get for the dimensionless coordinate x the Schrödinger equation,

$$\left[-\frac{h^2}{2mL^2}\frac{d^2}{dx^2} + V(x)\right]\psi(x) = E\psi(x) \ , \tag{24.58}$$

with the grid given by,

$$x_i \equiv \frac{2\pi i}{2N+1} \ . \tag{24.59}$$

The main difficulty for numerically solving such eigenvalue equations is obviously the derivative. Numerical differentiation schemes can be cast into the following general form [884],

$$f'(x_i) = \sum_{j=-N}^{N} D_{ij} f(x_j) \ , \tag{24.60}$$

that is, they can be expressed as a multiplication of the discretized wavefunction represented as a vector $f(x_j)$ and a matrix D_{ij}. These schemes are usually based on interpolation polynomials and are the more accurate, the higher the order of these polynomials is chosen to be.

Instead of using interpolation polynomials, one may now consider over-all approximation of a function $f(x)$ by a Fourier series of N-th order, i.e. to assume (see

(21.126)),

$$f(x) = \sum_{k=-\infty}^{\infty} c_k e^{\imath kx} \simeq \sum_{k=-N}^{N} c_k e^{\imath kx} \ . \tag{24.61}$$

The highest harmonics of the Fourier expansion N is set by the distance between two grid points. The expansion coefficients are,

$$c_k = \frac{1}{2\pi}\int_0^{2\pi} f(x)e^{-\imath kx}dx \longrightarrow \frac{1}{2\pi}\sum_{j=-N}^{N} f(x_j)e^{-\imath kx_j}\Delta x = \frac{1}{2N+1}\sum_{j=-N}^{N} f(x_j)e^{-\imath kx_j} \ . \tag{24.62}$$

Now, substituting x by the discrete variable x_i, we take the derivative $f'(x_i)$ of the function (24.61), insert the expansion coefficients (24.62), and compare the resulting expression to the linear combination (24.60) of the functional values $f(x_j)$,

$$\begin{aligned} f'(x_i) &= \sum_{k=-N}^{N} \imath k c_k e^{\imath kx_i} = \frac{\imath}{2N+1}\sum_{k=-N}^{N} k \sum_{j=-N}^{N} f(x_j)e^{\imath k(x_i-x_j)} \\ &= \frac{2}{2N+1}\sum_{k=1}^{N} k \sum_{j=-N}^{N} f(x_j)\sin k(x_j-x_i) \equiv \sum_{j=-N}^{N} D_{ij}f(x_j) \ . \end{aligned} \tag{24.63}$$

From this we see, that the matrix elements $D_{j'j}$ are given by,

$$\boxed{D_{ij} = \frac{2}{2N+1}\sum_{k=1}^{N} k\sin k(x_j-x_i) = \frac{2}{2N+1}\sum_{k=1}^{N} k\sin\frac{2\pi k(i-j)}{2N+1}} \ . \tag{24.64}$$

The sum can be evaluated analytically, as shown in Exc. 24.4.4.3 [1244],

$$D_{ii} = 0 \qquad \text{and} \qquad D_{i\neq j} = \frac{(-1)^{i-j}}{2\sin\frac{x_i-x_j}{2}} = \frac{(-1)^{i-j}}{2\sin\frac{\pi(i-j)}{2N+1}} \ . \tag{24.65}$$

We may proceed similarly for the second derivative,

$$\begin{aligned} f''(x_i) &= -\sum_{k=-N}^{N} k^2 c_k e^{\imath kx_i} = \frac{-1}{2N+1}\sum_{k=-N}^{N} k^2 \sum_{j=-N}^{N} f(x_j)e^{\imath k(x_i-x_j)} \\ &= \frac{-2}{2N+1}\sum_{k=1}^{N} k^2 \sum_{j=-N}^{N} f(x_j)\cos k(x_j-x_i) \equiv \sum_{j=-N}^{N} (D^2)_{ij}f(x_j) \ , \end{aligned} \tag{24.66}$$

yielding,

$$\boxed{(D^2)_{ij} = \frac{-2}{2N+1}\sum_{k=1}^{N} k^2\cos k(x_j-x_i) = \frac{-2}{2N+1}\sum_{k=1}^{N} k^2\cos\frac{2\pi k(i-j)}{2N+1}} \ . \tag{24.67}$$

Again, the sum can be evaluated analytically, as shown in Exc. 24.4.4.3 [1244],

$$(D^2)_{ii} = -\frac{N^2+2}{12} \qquad \text{and} \qquad (D^2)_{i\neq j} = -\frac{(-1)^{i-j}}{2\sin^2\frac{\pi(i-j)}{2N+1}} \ . \tag{24.68}$$

With this scheme of differentiation, the set of difference equations representing the problem (24.68) is readily found to be [847, 395, 1244],

$$\boxed{\hat{H}\psi = E\psi \qquad \text{with} \qquad \hat{H}_{ij} = -\frac{h^2}{2mL^2}(D^2)_{ij} + V(x_j)\delta_{ij}} \ . \tag{24.69}$$

This eigenvalue problem can easily be solved on a computer, see Fig 24.10(b).

24.4.3 Steepest descent ot the ground state

The softwares 'Maple' or 'Mathematics' are useful for analytical calculations, that is, multiplying matrices or determining eigenvalues. For numerical calculations the software 'Matlab' is more adapted. For example, the time evolution of a Schrödinger equation,

$$|\psi(t)\rangle = e^{-\imath\hat{H}t/\hbar}|\psi(0)\rangle \ , \tag{24.70}$$

can be calculated in a single command line using the Matlab 'expm' function.

When the system varies temporally, $\hat{H}(t)$, we may divide time into small units dt and propagate the wavefunction as,

$$|\psi(t+dt)\rangle = e^{-\imath\hat{H}(t)dt/\hbar}|\psi(t)\rangle \simeq |\psi(t)\rangle\left(1 - \imath\frac{\hat{H}}{\hbar}dt\right) \ , \tag{24.71}$$

continuously reinserting the solution into the equation. This *Newton method* does not converge quickly (dt should be chosen small enough, when $\hat{H}(t)$ varies rapidly), but there are other more sophisticated methods like the *Runge-Kutta method*.

A variation of this method is called *steepest descent method*. This method is similar to the Newton Eq. (24.71), but replaces the time dt with an imaginary time. Thus, the coherent temporal evolution of the Schrödinger equation is replaced by a dissipative evolution. The loss of energy automatically takes the system to the ground state. However, in order to preserve the normalization of the wavefunction, it must be renormalized at each iteration step,

$$|\psi(t+dt)\rangle \to \frac{|\psi(t+dt)\rangle}{\sqrt{\langle\psi(t+dt)|\psi(t+dt)\rangle}} \ . \tag{24.72}$$

The method also applies to more complicated equations than the Schrödinger equation, for example, the *Gross-Pitaevskii equation*. We will deepen this technique in Sec. 45.3.3.

Another numerical method often used in quantum mechanics is the method called the quantum *Monte Carlo simulation* of the wavefunction [913]. This method simulates trajectories of quantum systems treating intrinsic quantum noise as random processes disrupting the uniformity of the trajectory. The advantage of this method is that it also applies to dissipative systems.

24.4.4 Exercises

24.4.4.1 Ex: Numerical resolution of the Hermite differential equation

Solve the Hermite differential equation (24.93) numerically for $n = 8$, e.g. using the 'ode45' ordinary differential equation solver of Matlab, or similar. Plot the wavefunction of the 8-th vibrational level of a harmonic oscillator.

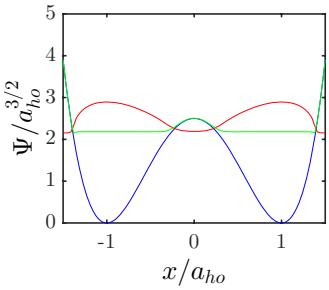

Figure 24.11: (code) Condensate wavefunction (red) in a double-well potential (blue) numerically calculated using the steepest descent method. Also shown is the chemical potential (green).

Solution: *The results are exhibited in Fig. 24.12.*

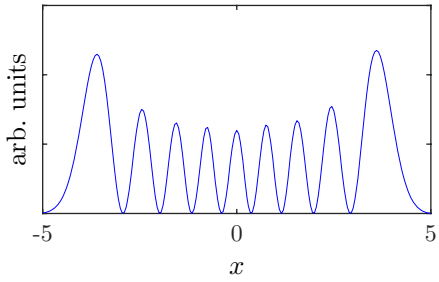

Figure 24.12: (code) Solution of the Hermite differential equation for $n = 8$.

24.4.4.2 Ex: Numerical resolution of the Schrödinger equation

Paramagnetic atoms, such as rubidium, can be confined in quadrupolar magnetic traps, which are characterized by a linear increase of the magnetic field in any direction of space. Let us consider one dimension of such a potential, given by $V(x) = \mu_B \partial_x B \, |x| - V_0$ wherever $V(x)$ is negative and $V(x) = 0$ else. Here μ_B is the Bohr magneton. Be $\partial_x B = 200\,\mathrm{G/cm}$ the magnetic field gradient and $V_0 = h\ 15\,\mathrm{kHz}$ the potential depth.
a. Calculate the energy and wavefunction of the lowest bound state of this potential by numerical integration of the stationary Schrödinger equation using Matlab or another software.
b. Obtain all bound state energies and wavefunctions using the Fourier grid method.

Solution: *The results are exhibited in Fig. 24.13.*

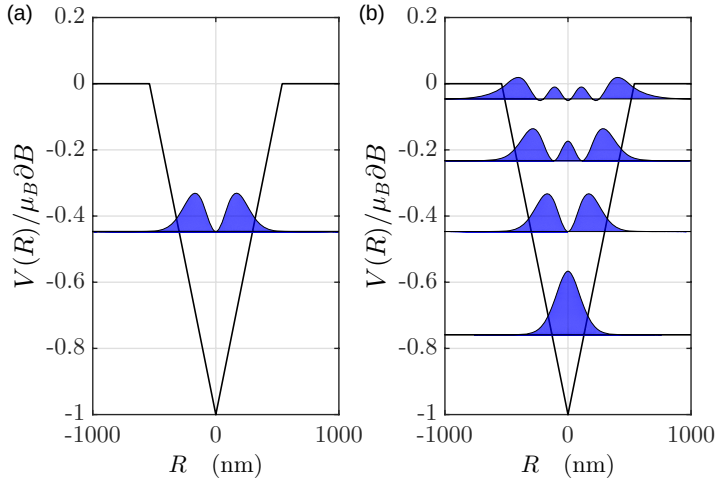

Figure 24.13: (code) Eigenenergies and wavefunctions of a quadrupolar potential.

24.4.4.3 Ex: The Fourier grid method

Derive (a) the formula (24.65) and (b) the formula (24.68) for $N \gg 1$ using the formula (1.352) from [532].

Solution: *a. Formula (1.352) [532] reads,*

$$\sum_{k=1}^{N} k \sin kx = \frac{\sin(N+1)x}{4\sin^2\frac{x}{2}} - \frac{(N+1)\cos\frac{2N+1}{2}x}{2\sin\frac{x}{2}} \ .$$

With this, inserting $x = \frac{2\pi(i-j)}{2N+1}$*, we find,*

$$D_{ij} = \frac{2}{2N+1}\sum_{k=1}^{N} k \sin\frac{2\pi k(i-j)}{2N+1} \ .$$

In particular we find,

$$D_{ii} = 0$$

$$D_{i\neq j} = \frac{2}{2N+1}\sum_{k=1}^{N} k \sin k\frac{2\pi(i-j)}{2N+1} = \frac{1}{2N+1}\left(\frac{\sin(N+1)\frac{2\pi(i-j)}{2N+1}}{2\sin^2\frac{\pi(i-j)}{2N+1}} - \frac{(N+1)\cos\pi(i-j)}{\sin\frac{\pi(i-j)}{2N+1}}\right) ,$$

in agreement with [1244]. Approximating $2N+1 \simeq 2N$*, we can simplify,*

$$D_{i\neq j} \simeq \frac{2}{2N+1}\left(\frac{\sin\pi(i-j)}{4\sin^2\frac{\pi(i-j)}{2N+1}} - \frac{(N+1)(-1)^{i-j}}{2\sin\frac{\pi(i-j)}{2N+1}}\right) = \frac{(-1)^{i-j}}{2\sin\frac{\pi(j-i)}{2N+1}} \ ,$$

recovering the result of [884].
b. Similarly,

$$(D^2)_{ij} = \frac{-2}{2N+1}\sum_{k=1}^{N} k^2 \cos\frac{2\pi k(i-j)}{2N+1} \ .$$

In particular we find [1244],

$$(D^2)_{ii} = \frac{-2}{2N+1}\sum_{k=1}^{N} k^2 = \frac{-2}{2N+1}\frac{N(N+1)(2N+1)}{6} = -\frac{N(N+1)}{3}$$

$$(D^2)_{i\neq j} = \frac{(-1)^{i-j}(N+1)\cos\frac{\pi(i-j)}{2N+1} + (N+1)\cos\frac{(N+1)2\pi(i-j)}{2N+1} - \sin\frac{(N+1)2\pi(i-j)}{2N+1}\cot\frac{\pi(i-j)}{2N+1}}{2(2N+1)\sin^2\frac{\pi(i-j)}{2N+1}} .$$

Approximating $2N+1 \simeq 2N$,

$$(D^2)_{i\neq j} \simeq (-1)^{i-j}\frac{\cos\frac{\pi(i-j)}{2N+1}+1}{4\sin^2\frac{\pi(i-j)}{2N+1}} .$$

24.4.4.4 Ex: Derivation of the Fourier grid method from the FFT

The Fast Fourier Transform (FFT) is defined by,

$$\begin{aligned} H_n &= \sum_{k=0}^{N-1} e^{-2\pi\imath nk/N} h_k \\ &= \sum_{k=0}^{N-1} e^{-2\pi\imath nk/(N/2)} h_{2k} + e^{-2\pi\imath k/N}\sum_{k=0}^{N/2-1} e^{-2\pi\imath nk/(N/2)} h_{2k+1} = even + odd . \end{aligned}$$

the inverse transform is,

$$h_k = \frac{1}{N}\sum\nolimits_{k=0}^{N-1} e^{2\pi\imath nk/N} H_n .$$

The sinus transform of a real vector s_k is,

$$S_n = \frac{2}{N}\sum\nolimits_{k=1}^{N-1} s_k \sin \pi nk/N .$$

Calculate the inverse transform of the matrix $T_{rs} = k_r^2\delta_{rs}$.

Solution: *See [884, 847, 395].*

24.4.4.5 Ex: Infinite rectangular double-well potential

a. Consider the rectangular double-well potential sketched in Fig. 24.14 and calculate the energy levels according to the procedure taught in Sec. 24.3.5.
b. For the same type of potential as in (a) prepare a numerical calculation of the wavefunctions, e.g. using the Fourier grid method introduced in Sec. 32.2.5, for ^{87}Rb using the following dimensions of the potential: $V_0 = h \times 15\,\text{MHz}$, $L = 40\,\text{nm}$, and $b = 3\,\text{nm}$.

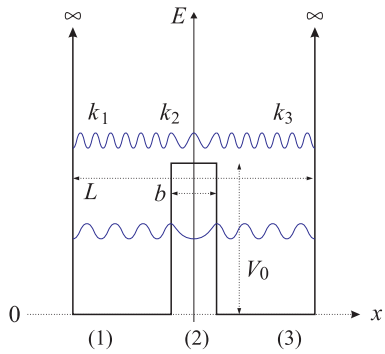

Figure 24.14: Scheme of the rectangular double-well potential.

Solution: *a. As usual, we set the wavefunctions in the various sections* $j = 1, 2, 3$ *as* $\psi_j(x) = A_j e^{\imath k_j x} + B_j e^{-\imath k_j x}$*, where for symmetry reasons* $k_1 = k_3$*, and* $\hbar k_1 = \sqrt{2mE}$ *and* $\hbar k_2 = \sqrt{2m(E - V_0)}$*. The boundary conditions are,*

$$\begin{aligned}
\psi_1(-\tfrac{L}{2}) = 0 = \psi_3(\tfrac{L}{2}) \\
\psi_1(-\tfrac{b}{2}) = \psi_2(-\tfrac{b}{2}) = \pm\psi_2(\tfrac{b}{2}) = \pm\psi_3(\tfrac{b}{2}) \\
\psi_1'(\tfrac{b}{2}) = \psi_2'(-\tfrac{b}{2}) = \pm\psi_2'(\tfrac{b}{2}) = \pm\psi_3'(\tfrac{b}{2}) \ .
\end{aligned}$$

Solving this system of equations, we get,

$$\begin{aligned}
\frac{B_1}{A_1} = -e^{\imath k_1 L} = \frac{A_3}{B_3} \\
\left(1 + \frac{k_1}{k_2}\right) A_1 e^{-\imath k_1 b/2} + \left(1 - \frac{k_1}{k_2}\right) B_1 e^{\imath k_1 b/2} = 2A_2 e^{-\imath k_2 b/2} \\
\left(1 - \frac{k_1}{k_2}\right) A_1 e^{-\imath k_1 b/2} + \left(1 + \frac{k_1}{k_2}\right) B_1 e^{\imath k_1 b/2} = 2B_2 e^{\imath k_2 b/2} \ ,
\end{aligned}$$

and from symmetry considerations,

$$A_1 = \pm B_3 \quad , \quad B_1 = \pm A_3 \quad , \quad A_2 = \pm B_2 \ .$$

After some algebra,

$$\pm \frac{e^{\imath k_1 (L+b/2) - \imath k_2 b/2} \pm e^{-\imath k_1 b/2 + \imath k_2 b/2}}{e^{\imath k_1 (L+b/2) + \imath k_2 b/2} \pm e^{-\imath k_1 b/2 - \imath k_2 b/2}} = \frac{k_2 - k_1}{k_2 + k_1} \ .$$

This equation must be solved numerically.
b. Fig. 24.15 shows the simulation.

24.4.4.6 Ex: Least bound states numerically

Calculate numerically the minimum required potential depth V_0 to have a bound state using the method detailed in Sec. 24.4.1 for the following three one-dimensional

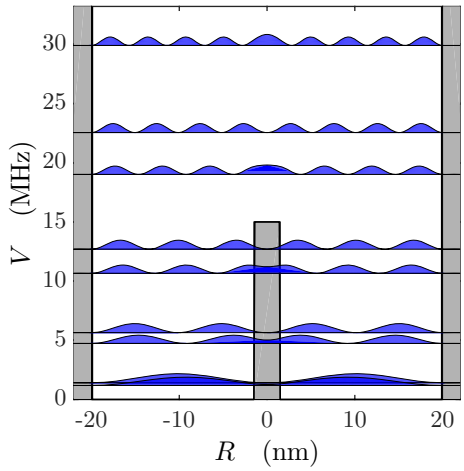

Figure 24.15: (code) Wavefunctions and energy levels of the rectangular double-well potential calculated by the Fourier grid method.

potentials (Θ is the Heavyside function):
a. For the square well potential $V(z) = -V_0\ \Theta(L-2|z|)$; compare with the calculated energy spectrum for the box potential and the square well potential of Secs. 24.2.1 and 24.2.4;
b. for the harmonic oscillator potential with given spill-over height V_0, that is, $V(z) = (\frac{m}{2}\omega_{ho}^2 z^2 - V_0)\ \Theta(2V_0 - m\omega_{ho}^2 z^2)$; compare with the calculated energy spectrum of an ordinary unlimited harmonic oscillator;
c. for the sinusoidal potential given by $V(z) = -V_0 \cos^2(kz)\ \Theta(\pi - 2k|z|)$; compare with the recoil energy $E_{rec} = \hbar^2 k^2/2m$.

Solution: *The results are exhibited in Fig. 24.16.*
a. The energy of the lowest bound state in a box potential with infinite walls is,

$$E_1 = \frac{\hbar^2 \pi^2}{2mL^2}\ .$$

We find that the square well potential must be deeper than $V_0 = 0.014E_1$ in order to support a bound state.
b. The energy of the lowest bound state in a harmonic potential is,

$$E_0 = \frac{\hbar\omega_{ho}}{2}\ .$$

We find that the spill-over height must be higher than $V_0 = 0.18\hbar\omega_{ho}$ in order to support a bound state.
c. The recoil energy is,

$$E_{rec} = \frac{\hbar^2 k^2}{2m}\ .$$

We find that the potential must be deeper than $V_0 = 0.54E_{rec}$.

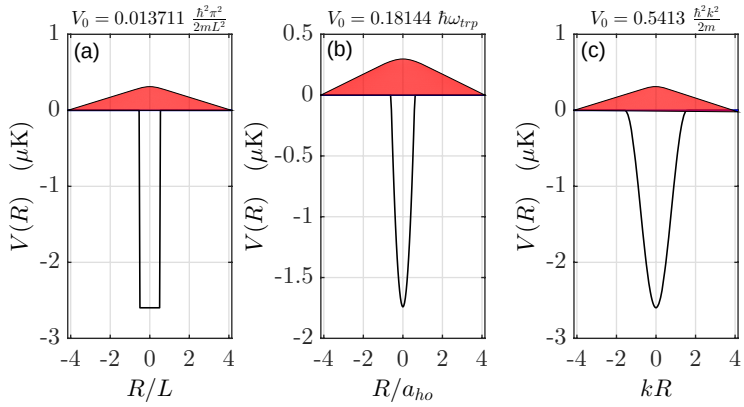

Figure 24.16: (code) Potential depth for having exactly one least bound state for (a) a square well, (b) a harmonic, and (c) a sine potential.

24.5 Harmonic oscillator

Many systems oscillate. Common examples are vibrations of atoms bound in a molecule or in a crystalline lattice, of particles trapped in applied electric or magnetic fields, or light in an electromagnetic mode. Most periodic movements are approximately harmonic for small amplitude vibrations and can be treated in a way that we will detail now.

We start with the unidimensional *harmonic oscillator* (OH),

$$\left[\frac{-\hbar^2}{2m}\frac{d^2}{dx^2} + V(x) - E\right]\psi(x) = 0 \qquad \text{where} \qquad V(x) = \frac{m}{2}\omega^2 x^2 \ . \tag{24.73}$$

24.5.1 Factorization of the Hamiltonian and Fock states

Respecting the fact that the operators $\hat{p}$ and $\hat{x}$ do not commute, $\frac{\imath}{\hbar}[\hat{p},\hat{x}] = 1$, we can rewrite the Hamiltonian of the harmonic oscillator in the following way,

$$\begin{aligned}\hat{H} &= -\frac{\hbar^2}{2m}\frac{d^2}{dx^2} + \frac{m}{2}\omega^2\hat{x}^2 = \hbar\omega\left[\left(\sqrt{\tfrac{m\omega}{2\hbar}}\hat{x} - \imath\sqrt{\tfrac{1}{2m\hbar\omega}}\hat{p}\right)\left(\sqrt{\tfrac{m\omega}{2\hbar}}\hat{x} + \imath\sqrt{\tfrac{1}{2m\hbar\omega}}\hat{p}\right) + \tfrac{1}{2}\right] \\ &= \hbar\omega\left(\hat{a}^\dagger\hat{a} + \tfrac{1}{2}\right) \ ,\end{aligned} \tag{24.74}$$

with the abbreviation

$$\hat{a} \equiv \sqrt{\frac{m\omega}{2\hbar}}\hat{x} + \imath\sqrt{\frac{1}{2m\hbar\omega}}\hat{p} \tag{24.75}$$

and its Hermitian transposition $\hat{a}^\dagger$. Now let's try to find out the properties of the operators $\hat{a}^\dagger$ and $\hat{a}$. First of all, the commutator is,

$$\begin{aligned}[\hat{a},\hat{a}^\dagger] &= \left[\sqrt{\frac{m\omega}{2\hbar}}\hat{x} + \imath\sqrt{\frac{1}{2m\hbar\omega}}\hat{p}, \sqrt{\frac{m\omega}{2\hbar}}\hat{x} - \imath\sqrt{\frac{1}{2m\hbar\omega}}\hat{p}\right] = \frac{\imath}{2\hbar}\left[\hat{x}+\hat{p}, \hat{x}-\hat{p}\right] \\ &= \tfrac{\imath}{\hbar}\left[\hat{p},\hat{x}\right] = 1 \ .\end{aligned} \tag{24.76}$$

Knowing $\hat{H}|\psi\rangle = E|\psi\rangle$ is it clear that $\hat{a}^\dagger\hat{a}$ is an observable with the eigenvalue $n \equiv \frac{E}{\hbar\omega} - \frac{1}{2}$,

$$\hat{a}^\dagger\hat{a}|\psi\rangle = \left(\tfrac{E}{\hbar\omega} - \tfrac{1}{2}\right)|\psi\rangle \equiv n|\psi\rangle \implies |\psi\rangle = |n\rangle \ . \tag{24.77}$$

Now, we show that the states $\hat{a}|\psi\rangle$ are eigenstates of the operator defined as $\hat{n} \equiv \hat{a}^\dagger\hat{a}$, since,

$$\begin{aligned}
\hat{a}^\dagger\hat{a}\hat{a}|\psi\rangle &= (\hat{a}\hat{a}^\dagger - [\hat{a},\hat{a}^\dagger])\hat{a}|\psi\rangle = (\hat{a}\hat{a}^\dagger\hat{a} - \hat{a})|\psi\rangle = \hat{a}(\hat{a}^\dagger\hat{a} - 1)|\psi\rangle = (n-1)\hat{a}|\psi\rangle \\
&\implies \hat{a}|\psi\rangle \propto |n-1\rangle \equiv C|n-1\rangle \\
&\implies n = \langle n|\hat{a}^\dagger\hat{a}|n\rangle = C^2\langle n-1|n-1\rangle \\
&\implies C = \sqrt{n} \ .
\end{aligned} \tag{24.78}$$

We note that the quantum number of the new $|n-1\rangle$ is decreased by 1. Similarly, we show for the state $\hat{a}^\dagger|\psi\rangle$,

$$\begin{aligned}
\hat{a}^\dagger\hat{a}\hat{a}^\dagger|\psi\rangle &= \hat{a}^\dagger([\hat{a},\hat{a}^\dagger] + \hat{a}^\dagger\hat{a})|\psi\rangle = \hat{a}^\dagger(1 + \hat{a}^\dagger\hat{a})|\psi\rangle = (n+1)\hat{a}^\dagger|\psi\rangle \\
&\implies \hat{a}^\dagger|\psi\rangle \propto |n+1\rangle \equiv C|n+1\rangle \\
&\implies n+1 = \langle n|\hat{a}^\dagger\hat{a} + [\hat{a},\hat{a}^\dagger]|n\rangle = C^2\langle n+1|n+1\rangle \\
&\implies C = \sqrt{n+1} \ .
\end{aligned} \tag{24.79}$$

Therefore, this new state is also an eigenvector $|n+1\rangle$, with a quantum number increased by one unit. $\hat{a}^\dagger$ and $\hat{a}$ are creation and annihilation operators of an energy packet,

$$\boxed{\hat{a}^\dagger|n\rangle = \sqrt{n+1}|n+1\rangle \qquad \text{and} \qquad \hat{a}|n\rangle = \sqrt{n}|n-1\rangle} \ . \tag{24.80}$$

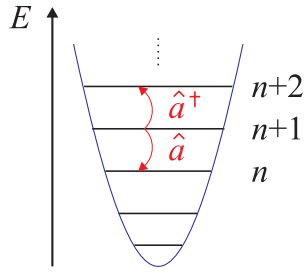

Figure 24.17: Equidistant ladder of vibrational levels showing the actions of the creation and the annihilation operator.

The matrix representation of the field operators is,

$$\hat{a}^\dagger = \sum_n \sqrt{n+1}|n+1\rangle\langle n| \qquad \text{and} \qquad \hat{a} = \sum_n \sqrt{n}|n-1\rangle\langle n| \ , \tag{24.81}$$

from which we deduce,

$$\hat{n} = \hat{a}^\dagger\hat{a} = \sum_n n|n\rangle\langle n| \qquad \text{and} \qquad \hat{H} = \hbar\omega\left(\hat{n} + \tfrac{1}{2}\right) \ . \tag{24.82}$$

Now it is clear, that $\hat{n}$ can be understood as a number operator [2]. The energy spectrum of the harmonic oscillator is equidistant,

$$\boxed{E_n = \hbar\omega\left(n + \tfrac{1}{2}\right)} \,. \tag{24.83}$$

The state with n quanta can be created from the vacuum,

$$|n\rangle = \frac{\hat{a}^\dagger}{\sqrt{n}}|n-1\rangle = \frac{\hat{a}^{\dagger n}}{\sqrt{n!}}|0\rangle \,. \tag{24.84}$$

The state $|n\rangle$ is called *number state* or *Fock state*.

24.5.1.1 Uncertainty in Fock states

We consider an OH of mass m and angular frequency ω prepared in the stationary state $|n\rangle$ which is an eigenstate of the Hamiltonian $\hat{H}$ with eigenvalue $(n+\frac{1}{2})\hbar\omega$. Defining the characteristic size of the OH, $a_{ho} = \sqrt{\hbar/m\omega}$, the annihilation and creation operators can be written,

$$\hat{a} = \frac{1}{\sqrt{2}}\left(\frac{\hat{x}}{a_{ho}} + \imath\frac{a_{ho}}{\hbar}\hat{p}\right) \qquad \text{and} \qquad \hat{a}^\dagger = \frac{1}{\sqrt{2}}\left(\frac{\hat{x}}{a_{ho}} - \imath\frac{a_{ho}}{\hbar}\hat{p}\right) \,. \tag{24.85}$$

Therefore, the position and momentum operators are,

$$\sqrt{2}\frac{1}{a_{ho}}\hat{x} = \hat{a} + \hat{a}^\dagger \qquad \text{and} \qquad \sqrt{2}\imath\frac{a_{ho}}{\hbar}\hat{p} = \hat{a} - \hat{a}^\dagger \,. \tag{24.86}$$

The mean squared deviations of the position $\hat{x}$ and the momentum $\hat{p}$ are,

$$\begin{aligned}
\Delta x^2 &= \langle n|\hat{x}^2|n\rangle = \frac{a_{ho}^2}{2}\langle n|\hat{a}\hat{a} + \hat{a}\hat{a}^\dagger + \hat{a}^\dagger\hat{a} + \hat{a}^\dagger\hat{a}^\dagger|n\rangle = \frac{a_{ho}^2}{2}\langle n|2\hat{n}+1|n\rangle \\
&= \frac{a_{ho}^2}{2}(2n+1) \qquad (24.87)\\
\Delta p^2 &= \langle n|\hat{p}^2|n\rangle = \frac{-\hbar^2}{2a_{ho}^2}\langle n|\hat{a}\hat{a} - \hat{a}\hat{a}^\dagger - \hat{a}^\dagger\hat{a} + \hat{a}^\dagger\hat{a}^\dagger|n\rangle = \frac{-\hbar^2}{2a_{ho}^2}\langle n| - 2\hat{n} - 1|n\rangle \\
&= \frac{\hbar^2}{2a_{ho}^2}(2n+1) \,.
\end{aligned}$$

From the results of the previous item we obtain the uncertainty relation $\Delta x\Delta p$ for the OH in the state $|n\rangle$,

$$\Delta p\Delta x = \tfrac{\hbar}{2}(2n+1) \,. \tag{24.88}$$

Example 159 (*Localization energy*): The non-vanishing energy of the fundamental state of the harmonic oscillator, $E_0 = \hbar\omega/2$, is an immediate consequence of the Heisenberg principle $\Delta x\Delta p \geq \hbar$, because in analogy with Example 156 we calculate,

$$\frac{\langle p^2\rangle}{2m} = \frac{\Delta p^2}{2m} > \frac{\hbar^2}{2m\Delta x^2} > \frac{\hbar^2}{2ma_{ho}^2} = \frac{\hbar\omega}{2} \,.$$

In the case of an electromagnetic field this energy is called *vacuum fluctuation*.

[2] Also, we can define phase operators by $\widehat{\exp}(\mp\imath\phi) = \sum_n |n \mp 1\rangle\langle n|$.

24.5.2 Harmonic oscillator in spatial representation

To simplify the Schrödinger equation in spatial representation,

$$\left[-\frac{\hbar^2}{2m}\frac{d^2}{dx^2}+\frac{m}{2}\omega^2 x^2\right]\psi(x)=\hbar\omega(n+\tfrac{1}{2})\psi(x)\ , \tag{24.89}$$

we use the scale $\tilde{x}\equiv x/a_{ho}$, where $a_{ho}=\sqrt{\hbar/m\omega}$ is the spatial extent of the ground state. Therefore,

$$\begin{aligned}\frac{2}{\hbar\omega}\left[-\frac{\hbar^2}{2m}\frac{d^2}{d(a_{ho}\tilde{x})^2}+\frac{m}{2}\omega^2(a_{ho}\tilde{x})^2\right]\tilde{\psi}(\tilde{x})&=\frac{2}{\hbar\omega}\left[-\frac{\hbar\omega}{2}\frac{d^2}{d\tilde{x}^2}+\frac{\hbar\omega}{2}\tilde{x}^2\right]\tilde{\psi}(\tilde{x})\\&=\left[-\frac{d^2}{d\tilde{x}^2}+\tilde{x}^2\right]\tilde{\psi}(\tilde{x})=(2n+1)\tilde{\psi}(\tilde{x})\ .\end{aligned}$$

Now we start looking for asymptotic solutions. For $\tilde{x}\to\pm\infty$, that is, when the particle enters the classically forbidden region, we can neglect the total energy of the particle,

$$\left[-\frac{d^2}{d\tilde{x}^2}+\tilde{x}^2\right]\tilde{\psi}_\infty(\tilde{x})\simeq 0\ . \tag{24.90}$$

The solution of this equation is $\tilde{\psi}_\infty(\tilde{x})=Ce^{-\tilde{x}^2/2}$, since

$$\begin{aligned}\left[-\frac{d^2}{d\tilde{x}^2}+\tilde{x}^2\right]e^{-\tilde{x}^2/2}&=-\frac{d}{d\tilde{x}}(-\tilde{x})e^{-\tilde{x}^2/2}+\tilde{x}^2e^{-\tilde{x}^2/2}\\&=-\tilde{x}^2e^{-\tilde{x}^2/2}+e^{-\tilde{x}^2/2}+\tilde{x}^2e^{-\tilde{x}^2/2}=e^{-\tilde{x}^2/2}\simeq 0\ .\end{aligned} \tag{24.91}$$

This motivates the ansatz $\tilde{\psi}(\tilde{x})\equiv e^{-\tilde{x}^2/2}H(\tilde{x})$ for the complete differential equation (24.89),

$$\begin{aligned}&\left[-\frac{d^2}{d\tilde{x}^2}+\tilde{x}^2\right]e^{-\tilde{x}^2/2}H(\tilde{x})=-e^{-\tilde{x}^2/2}\frac{d^2H(\tilde{x})}{d\tilde{x}^2}-2\frac{de^{-\tilde{x}^2/2}}{d\tilde{x}}\frac{dH(\tilde{x})}{d\tilde{x}}-\frac{d^2e^{-\tilde{x}^2/2}}{d\tilde{x}^2}H(\tilde{x})+\tilde{x}^2e^{-\tilde{x}^2/2}H(\tilde{x})\\&=-e^{-\tilde{x}^2/2}\frac{d^2H(\tilde{x})}{d\tilde{x}^2}-2(-x)e^{-\tilde{x}^2/2}\frac{dH(\tilde{x})}{d\tilde{x}}+\left[-\tilde{x}^2e^{-\tilde{x}^2/2}+e^{-\tilde{x}^2/2}\right]H(\tilde{x})+\tilde{x}^2e^{-\tilde{x}^2/2}H(\tilde{x})\\&\equiv(2n+1)e^{-\tilde{x}^2/2}H(\tilde{x})\ .\end{aligned} \tag{24.92}$$

Thus, the functions $H(\tilde{x})$ must satisfy the differential equation,

$$H''(\tilde{x})=2\tilde{x}H'(\tilde{x})-2nH(\tilde{x})\ . \tag{24.93}$$

We can verify that the Hermite polynomials defined by,

$$H_n(\tilde{x})=(-1)^ne^{\tilde{x}^2}\frac{d^n}{d\tilde{x}^n}e^{-\tilde{x}^2}\ , \tag{24.94}$$

transform the differential equation into a recursion formula,

$$H_{n+1}(\tilde{x})=2\tilde{x}H_n(\tilde{x})-2nH_{n-1}(\tilde{x})\ , \tag{24.95}$$

which allows us to easily calculate the polynomials,

$$H_0(\tilde{x})=1\quad,\quad H_1(\tilde{x})=2x\quad,\quad H_2(\tilde{x})=4x^2-2\quad,\quad ... \tag{24.96}$$

In summary, the eigenfunction of a harmonic oscillator in the state of excitation n is,

$$\boxed{\langle x|n\rangle = \psi_n(x) = C_n e^{-x^2/2a_{ho}^2} H_n(x/a_{ho})} \ , \tag{24.97}$$

where the constant C_n is determined by the normalization condition (28.22), $\langle \psi_m|\psi_n\rangle = \delta_{m,n}$,

$$C_n = \frac{1}{\sqrt{a_{ho}\sqrt{\pi}2^n n!}} \ . \tag{24.98}$$

The Hermite functions, H_n, are found in mathematical tables, see Sec. 28.3. The spatial and momentum wavefunctions for the vibrational ground state are,

$$\langle x|0\rangle = \frac{1}{\pi^{1/4}\sqrt{a_{ho}}} e^{-x^2/2a_{ho}^2} \quad \text{and} \quad \langle p|0\rangle = \frac{1}{\pi^{1/4}} \sqrt{\frac{a_{ho}}{\hbar}} e^{-a_{ho}^2 p^2/2\hbar^2} \ . \tag{24.99}$$

Here we will only show the graphical representation of $|\psi|^2$ in Fig. 24.18. The Exc. 24.5.6.1 asks to evaluate HO in a classically forbidden region and in Exc. 24.5.6.2 we will calculate the spectrum of a semi-harmonic HO.

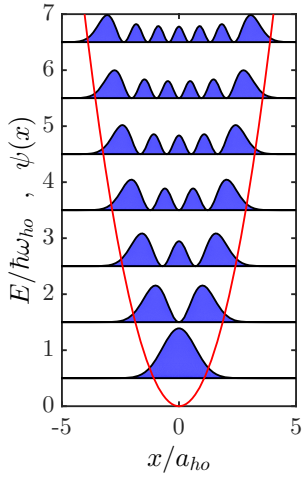

Figure 24.18: (code) Wavefunctions and energies for a harmonic potential.

24.5.3 Properties of the harmonic oscillator

We note that there are regions where $\psi(\tilde{x}) \neq 0$ even though $V(x) > E$. This effect is purely quantum. Classically, we can not find a particle in regions where its energy is below the potential.

We also note that for high quantum numbers, $n \to \infty$, we expect to recover the classical predictions, i.e.,

$$\lim_{n\to\infty} |\psi(x)|^2 = P_E(x) \ , \tag{24.100}$$

where P_E is the probability density of finding the oscillating particle at position x. The probability of finding the particle in a range dx close to the location x is easily

calculated,

$$E = \frac{m}{2}v^2 + \frac{m}{2}\omega^2 x^2 \tag{24.101}$$

$$\Rightarrow \qquad P_E(x)dx = \frac{t(x+dx)-t(x)}{T} = \frac{dx}{vT} = \frac{dx}{T}\frac{1}{\sqrt{2E/m-\omega^2x^2}} \ .$$

We see that for high energy values the wavefunction approaches the classical expectation.

We already mentioned that there exist solutions only for certain energies $E_n = \hbar\omega(2n+1)$. Consequently, the energy levels are equidistant, $E_{n+1} - E_n = \hbar\omega$, as if there were a box into which we add, one after the other, particles with the energy $\hbar\omega$ until we have accumulated n portions of energy. These particles are called *phonons* in the case of vibrations of massive particles, and *photons* in the case of a radiation field.

The fact that the energy distribution is the same as the one proposed by Planck for the black-body radiation suggests the use of the harmonic oscillator to describe the second quantization.

24.5.4 Time evolution of the unperturbed harmonic oscillator

Here we study the temporal evolution of a population distribution in a harmonic oscillator. The formal solution of the Schrödinger equation is,

$$|\psi(t)\rangle = e^{-\imath\hat{H}t/\hbar}|\psi(0)\rangle \ . \tag{24.102}$$

As the Hamiltonian is diagonal in the basis $|n\rangle$,

$$\hat{H} = \hbar\omega(\hat{n} + \tfrac{1}{2}) \ . \tag{24.103}$$

we can write,

$$e^{-\imath\hat{H}t/\hbar} = \sum_n |n\rangle e^{-\imath\omega t(n+1/2)}\langle n| \ . \tag{24.104}$$

If the initial state is $|\psi(0)\rangle = \sum_m c_m|m\rangle$, the final state and the eigenvalue of any observable will be,

$$|\psi(t)\rangle = \sum_n |n\rangle e^{-\imath\omega t(n+1/2)}\langle n|\psi(0)\rangle = \sum_n e^{-\imath\omega t(n+1/2)}c_n|n\rangle \tag{24.105}$$

$$\langle\psi(t)|\hat{A}|\psi(t)\rangle = \sum_m \langle m|e^{\imath\omega t(m+1/2)}c_m^*|\hat{A}|\sum_n e^{-\imath\omega t(n+1/2)}c_n|n\rangle = \sum_{m,n} c_m^* c_n e^{\imath\omega t(m-n)}\langle m|\hat{A}|n\rangle \ .$$

If the oscillator is initially in an eigenstate, $|\psi(0)\rangle = |k\rangle$, we obtain,

$$|\psi(t)\rangle = e^{-\imath\omega t(k+1/2)}|k\rangle \qquad \text{and} \qquad \langle\psi(t)|\hat{A}|\psi(t)\rangle = \langle k|\hat{A}|k\rangle \ , \tag{24.106}$$

that is, the *state remains stationary*. Motion needs non-diagonal elements of $\hat{A}$.

Another observation is that the populations do not change, even in the case of an initial superposition, since,

$$P_k(t) = |\langle k|\psi(t)\rangle|^2 = |e^{-\imath\omega t(k+1/2)}c_k|^2 = |c_k|^2 \ . \tag{24.107}$$

We conclude that

- movement of an observable $\hat{A}$ is possible, but only due to *variations of the phase factors*;
- to carry out transitions between the vibrational states is necessary to *perturb the oscillator*, e.g. by applying fields of electromagnetic radiation.

Example 160 (*Motion of a harmonic oscillator*): We now consider some specific examples. If the studied observable is the Hamiltonian and the initial state an arbitrary superposition, then

$$\langle\psi(t)|\hat{H}|\psi(t)\rangle = \hbar\omega \sum_{m,n} c_m^* c_n e^{\imath\omega t(m-n)} \langle m|\hat{n} + \tfrac{1}{2}|n\rangle = \hbar\omega \sum_n |c_n|^2 (n + \tfrac{1}{2}) \ .$$

That is, the total energy of the oscillator is the sum of the energies of the states weighted with the populations of those states. In the case of the position operator,

$$\begin{aligned}\langle\psi(t)|\hat{x}|\psi(t)\rangle &= \tfrac{a_{ho}}{\sqrt{2}} \sum_{m,n} c_m^* c_n e^{\imath\omega t(m-n)} \langle m|\hat{a} + \hat{a}^\dagger|n\rangle \\ &= \tfrac{a_{ho}}{\sqrt{2}} \sum_n \left(c_{n-1}^* c_n e^{-\imath\omega t}\sqrt{n} + c_{n+1}^* c_n e^{\imath\omega t}\sqrt{n+1}\right) \\ &\overset{m,n\to\infty}{\longrightarrow} a_{ho}\sqrt{2} \sum_n \sqrt{n}|c_n|^2 \cos\omega t \ .\end{aligned}$$

That is, *the particle can only oscillate, if there are populations in consecutive states*. If this is not the case, $\langle\psi(t)|\hat{x}|\psi(t)\rangle = 0$. The oscillation frequency is always ω, independent of the energy of the particle. We will study this in Excs. 24.5.6.3, leaving the discussion of the temporal evolution of perturbed oscillators to later sections.

24.5.5 Multidimensional harmonic oscillator

The 3D harmonic potential is given by

$$V_{ho}(\mathbf{r}) = \frac{m}{2}\omega_x^2 x^2 + \frac{m}{2}\omega_y^2 y^2 + \frac{m}{2}\omega_z^2 z^2 \ . \tag{24.108}$$

Making the ansatz

$$\psi(\mathbf{r}) = \psi_x(x)\psi_y(y)\psi_z(z) \ , \tag{24.109}$$

we can separate the spatial directions and obtain a one-dimensional equation for each coordinate, such that the coordinates can be considered separately. Each function $\psi_k(x_k)$ is of the form (24.97) and the energies are,

$$E_k = \hbar\omega_k(n_k + \tfrac{1}{2}) \ , \tag{24.110}$$

where $k = x, y, z$.

24.5.6 Exercises

24.5.6.1 Ex: Ground state of a harmonic oscillator

Equating the ground state energy of quantum HO to that of its classical analog, obtain the maximum elongation x_m. Now, knowing that the ground state wavefunction

is proportional to the Gaussian $\psi_0 \propto e^{-x^2/2x_m^2}$, obtain the expression for the probability of finding the HO outside the classical limits and estimate its value.

Solution: *The ground state energy is,*

$$\frac{1}{2}\hbar\omega = \frac{m}{2}\omega^2 x_m^2 \quad \Longrightarrow \quad x_m = \sqrt{\frac{\hbar}{m\omega}} = a_{ho} \ .$$

The ground state wave function is,

$$\psi_0(x) = Ce^{-x^2/2a_{ho}^2} H_0(x/a_{ho}) \ .$$

With the normalization,

$$1 = \int_{-\infty}^{\infty} |\psi_0(x)|^2 dx = C^2 a_{ho} \int_{-\infty}^{\infty} e^{-\tilde{x}^2} d\tilde{x} = C^2 a_{ho}\sqrt{\pi} \ ,$$

we get the probability of being in a classically forbidden region,

$$w = 1 - \int_{-a_{ho}}^{a_{ho}} |\psi_0(x)|^2 dx = 1 - \frac{1}{\sqrt{\pi}} \int_{-1}^{1} e^{-\tilde{x}^2} d\tilde{x} = 1 - erf(1) \approx 0.157 \ .$$

24.5.6.2 Ex: Particle in a semi-harmonic well

Find the energy levels of a particle in a potential energy well of the form $V(x) = \infty$ for $x < 0$ and $V(x) = \frac{m\omega^2 x^2}{2}$ for $x > 0$. What is the parity of the allowed states?

Solution: *They are simply states with $\psi_n(0) = 0$. That is, with n odd. Only states with odd parity are allowed.*

24.5.6.3 Ex: Vibration of a harmonic oscillator

Consider a HO of mass m and angular frequency ω. At time $t = 0$ the oscillator's state is $|\psi(0)\rangle = \sum_n c_n |n\rangle$, where $|n\rangle$ are the stationary states of the HO with energy $(n + 1/2)\hbar\omega$.
a. What is the probability P for measuring, at an arbitrary time $t > 0$, an energy of the HO higher than $2\hbar\omega$? For the case when $P = 0$, what are the non-zero coefficients c_n?
b. From now on, we assume that only c_0 and c_1 are nonzero. Write down the normalization condition for $|\psi(0)\rangle$ and the mean value $\langle\hat{H}\rangle$ of energy in terms of c_0 and c_1. With the additional requirement $\langle\hat{H}\rangle = \hbar\omega$, calculate $|c_0|^2$ and $|c_1|^2$.
c. Given that the normalized state vector $|\psi(0)\rangle$ is defined to less than an overall phase factor, we determine this factor by choosing the real and positive coefficients c_0 and $c_1 = |c_1|e^{\imath\theta}$. Assuming $\langle\hat{H}\rangle = \hbar\omega$ and $\langle\hat{x}\rangle = \frac{1}{2}\sqrt{\hbar/m\omega}$, calculate θ.
d. With $|\psi(0)\rangle$ determined (according to the previous item), write down $|\psi(t)\rangle$ for $t > 0$ and calculate the value θ at this time t. Deduce the average value $\langle\hat{x}\rangle(t)$ of the

position at time t.

Solution: *a. The probability is* $P_{n\geq 2}(t) = 1 - |c_0|^2 - |c_1|^2$. *For* $P = 0$ *we have* $c_n = c_0\delta_{n0} + c_1\delta_{n1}$.
b. Normalization requests $1 \equiv \langle\psi(0)|\psi(0)\rangle = |c_0|^2 + |c_1|^2$. *With the requirement*

$$\langle\hat{H}\rangle = \tfrac{1}{2}\hbar\omega|c_0|^2 + \tfrac{3}{2}\hbar\omega|c_1|^2 = \hbar\omega \ ,$$

we have the equations

$$|c_0|^2 + |c_1|^2 = 1 \qquad \textit{and} \qquad |c_0|^2 + 3|c_1|^2 = 2 \ ,$$

which gives $|c_0| = |c_1| = 2^{-1/2}$.
c. The expectation value for the position is,

$$\langle\hat{x}(t)\rangle = \tfrac{a_{ho}}{\sqrt{2}}\left(c_0^* c_1 e^{-\imath\omega t} + c_0 c_1^* e^{\imath\omega t}\right) \ .$$

Initially, $(t = 0)$ *we have the additional requirement,*

$$\langle\hat{x}(0)\rangle = a_{ho}\left(c_0^* c_1 + c_1^* c_0\right) \equiv \tfrac{1}{2}\sqrt{\tfrac{\hbar}{m\omega}} \ ,$$

setting $c_0 = |c_0|$ *and* $c_1 = |c_1|e^{\imath\theta}$ *we find,*

$$\cos\theta = \frac{1}{4c_0 c_1} = \frac{1}{\sqrt{2}} \ .$$

This means, $\theta = \pi/4$.
d. We can now write,

$$|\psi(t)\rangle = e^{-\imath\omega t/2}c_0|0\rangle + e^{-3\imath\omega t/2}c_1|1\rangle = \tfrac{1}{\sqrt{2}}e^{-\imath\omega t/2}\left(|0\rangle + e^{-\imath\omega t - \imath\pi/4}|1\rangle\right) \ .$$

The expectation value of the position is,

$$\begin{aligned}\langle\hat{x}(t)\rangle &= \tfrac{1}{2}\left(\langle 0| + e^{\imath\omega t + \imath\pi/4}\langle 1|\right)\tfrac{a_{ho}}{\sqrt{2}}(\hat{a}^\dagger + \hat{a})\left(|0\rangle + e^{-\imath\omega t - \imath\pi/4}|1\rangle\right) \\ &= \tfrac{a_{ho}}{\sqrt{2}}\cos(\omega t + \pi/4) \ .\end{aligned}$$

24.6 Superposition states of a harmonic oscillator

As any other quantum system, a harmonic oscillator does not need to be in a particular vibrational eigenstate. In fact, it is much more common to encounter them in superpositions of many states. In a system in thermal equilibrium, the energetic distribution of occupied states reflects the temperature of the system.

24.6.1 Coherent states

The most common superposition for a harmonic oscillation is a Poissonian probability distribution of occupied vibrational (Fock) states. This state, called coherent or Glauber state, has particular features that we will discuss in the following sections.

24.6.1.1 Displacement operator

We now consider the so-called *displacement operator*,

$$\boxed{D(\alpha) \equiv e^{\alpha\hat{a}^\dagger - \alpha^*\hat{a}}} \ , \tag{24.111}$$

which acts on the phase space of a harmonic oscillator spanned by the operators $\hat{a}$ and $\hat{a}^\dagger$, that is, $\hat{x} \propto \mathfrak{Re}\ \hat{a}$ and $\hat{p} \propto \mathfrak{Im}\ \hat{a}$, and try to discovers its features.

$D(\alpha)$ is a unitary operator, since using Glauber's formula (23.210) we get,

$$\begin{aligned} D^\dagger(\alpha)D(\alpha) &= e^{\alpha^*\hat{a}-\alpha\hat{a}^\dagger} e^{\alpha\hat{a}^\dagger-\alpha^*\hat{a}} = e^{\alpha^*\hat{a}-\alpha\hat{a}^\dagger+\alpha\hat{a}^\dagger-\alpha^*\hat{a}+[\alpha^*\hat{a}-\alpha\hat{a}^\dagger,\alpha\hat{a}^\dagger-\alpha^*\hat{a}]/2} \\ &= e^{[\alpha^*\hat{a}-\alpha\hat{a}^\dagger,\alpha\hat{a}^\dagger-\alpha^*\hat{a}]/2} = e^{[\alpha^*\hat{a},\alpha\hat{a}^\dagger]/2+[-\alpha\hat{a}^\dagger,\alpha\hat{a}^\dagger]/2+[\alpha^*\hat{a},-\alpha^*\hat{a}]/2+[-\alpha\hat{a}^\dagger,-\alpha^*\hat{a}]/2} \\ &= e^{|\alpha|^2[\hat{a},\hat{a}^\dagger]/2+|\alpha|^2[\hat{a}^\dagger,\hat{a}]/2} = e^0 = \hat{1} \ . \end{aligned} \tag{24.112}$$

We can rewrite the displacement operator using Glauber's formula:

$$\begin{aligned} D(\alpha) &= e^{\alpha\hat{a}^\dagger-\alpha^*\hat{a}} = e^{\alpha\hat{a}^\dagger} e^{-\alpha^*\hat{a}} e^{-[\alpha\hat{a}^\dagger,-\alpha^*\hat{a}]/2} = e^{\alpha\hat{a}^\dagger} e^{-\alpha^*\hat{a}} e^{|\alpha|^2[\hat{a}^\dagger,\hat{a}]/2} \\ &= e^{\alpha\hat{a}^\dagger} e^{-\alpha^*\hat{a}} e^{-|\alpha|^2/2} \ . \end{aligned} \tag{24.113}$$

The state resulting from the action of the operator $D(\alpha)$ onto the ground state of the HO is,

$$\begin{aligned} |\alpha\rangle \equiv D(\alpha)|0\rangle &= e^{-|\alpha|^2/2} e^{\alpha\hat{a}^\dagger} e^{-\alpha^*\hat{a}}|0\rangle = e^{-|\alpha|^2/2} \sum_{n=0}^{\infty} \frac{(\alpha\hat{a}^\dagger)^n}{n!}|0\rangle \\ &= e^{-|\alpha|^2/2} \left(1 + \alpha\hat{a}^\dagger + \frac{(\alpha\hat{a}^\dagger)^2}{2!} + ..\right)|0\rangle \\ &= e^{-|\alpha|^2/2} \left(|0\rangle + \frac{\alpha}{1!}\sqrt{1}|1\rangle + \frac{\alpha^2}{2!}\sqrt{2!}|2\rangle + ..\right) \ , \end{aligned} \tag{24.114}$$

that is, the state $|\alpha\rangle$ is a superposition distributed according to the *Poisson distribution*,

$$\boxed{|\alpha\rangle = e^{-|\alpha|^2/2} \sum_{n=0}^{\infty} \frac{\alpha^n}{\sqrt{n!}}|n\rangle} \ . \tag{24.115}$$

Applying the step-down operator $\hat{a}$ onto the state $|\alpha\rangle$, we find,

$$\begin{aligned} \hat{a}|\alpha\rangle &= e^{-|\alpha|^2/2} \sum_{n=0}^{\infty} \frac{\alpha^n}{\sqrt{n!}} \hat{a}|n\rangle = e^{-|\alpha|^2/2} \sum_{n=0}^{\infty} \frac{\alpha^n}{\sqrt{n!}} \sqrt{n}|n-1\rangle \\ &= e^{-|\alpha|^2/2} \sum_{n=0}^{\infty} \frac{\alpha^n}{\sqrt{(n-1)!}}|n-1\rangle \ , \end{aligned} \tag{24.116}$$

that is,

$$\boxed{\hat{a}|\alpha\rangle = \alpha|\alpha\rangle} \ . \tag{24.117}$$

We can also write,

$$\langle\alpha|\hat{a}^\dagger = (\hat{a}|\alpha\rangle)^\dagger = (\alpha|\alpha\rangle)^\dagger = \langle\alpha|\alpha^* \ . \tag{24.118}$$

The state $|\alpha\rangle$ is called *coherent state* or *Glauber state* [3]. We note that, in spite of its appearance, the equation (24.117) is not an eigenvalue equation, since $\hat{a}$ is not observable.

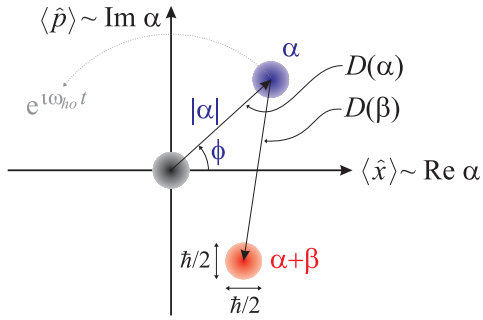

Figure 24.19: Illustration of the action of displacement operators $D(\alpha)$ and $D(\beta)$ on Glauber states in the phase space spanned by $\alpha = \mathfrak{Re}\ \alpha + \imath\, \mathfrak{Im}\ \alpha = |\alpha| e^{\imath\phi}$. The uncertainty of Glauber states Δx and Δp is represented by a finite distribution of the amplitude α in the phase space.

Using the formula (23.179), we verify immediately,

$$\boxed{D^\dagger(\alpha)\hat{a}D(\alpha) = \hat{a} + \alpha \quad , \quad D^\dagger(\alpha)\hat{a}^\dagger D(\alpha) = \hat{a}^\dagger + \alpha^*} \ . \tag{24.119}$$

Furthermore, the product of two displacement operators is, apart from a phase factor, another displacement operator satisfying,

$$\boxed{D(\alpha)D(\beta) = e^{(\alpha\beta^* - \alpha^*\beta)/2} D(\alpha+\beta)} \ , \tag{24.120}$$

as will be verified in Exc. 24.6.6.1. When acting on an eigenket, the phase factor $e^{(\alpha\beta^* - \alpha^*\beta)/2}$ appears in each term of the resulting state, which makes it physically irrelevant.

24.6.1.2 Uncertainty in Glauber states

Consider a HO prepared in a state $|\alpha\rangle$. The eigenvalues of the observables $\hat{x} \equiv \frac{a_{ho}}{\sqrt{2}}(\hat{a}^\dagger + \hat{a})$ and $\hat{p} \equiv \frac{\imath\hbar}{a_{ho}\sqrt{2}}(\hat{a}^\dagger - \hat{a})$ are,

$$\begin{aligned} \tfrac{\sqrt{2}}{a_{ho}}\langle\alpha|\hat{x}|\alpha\rangle &= \langle\alpha|\hat{a} + \hat{a}^\dagger|\alpha\rangle = \alpha + \alpha^* \\ \tfrac{\imath a_{ho}\sqrt{2}}{\hbar}\langle\alpha|\hat{p}|\alpha\rangle &= \langle\alpha|\hat{a} - \hat{a}^\dagger|\alpha\rangle = \alpha - \alpha^* . \end{aligned} \tag{24.121}$$

With this the eigenvalues of the quadratures become,

$$\begin{aligned} \tfrac{2}{a_{ho}^2}\langle\alpha|\hat{x}^2|\alpha\rangle &= \langle\alpha|(\hat{a}+\hat{a}^\dagger)^2|\alpha\rangle = \langle\alpha|\hat{a}\hat{a} + 1 + 2\hat{a}^\dagger\hat{a} + \hat{a}^\dagger\hat{a}^\dagger|\alpha\rangle \\ &= \alpha^2 + 1 + 2|\alpha|^2 + \alpha^{*2} = 1 + (\alpha+\alpha^*)^2 = 1 + \tfrac{2}{a_{ho}^2}\langle\alpha|\hat{x}|\alpha\rangle^2 \\ \tfrac{-a_{ho}^2}{\hbar^2}\langle\alpha|\hat{p}^2|\alpha\rangle &= \langle\alpha|(\hat{a}-\hat{a}^\dagger)^2|\alpha\rangle = \langle\alpha|\hat{a}\hat{a} - 1 - 2\hat{a}^\dagger\hat{a} + \hat{a}^\dagger\hat{a}^\dagger|\alpha\rangle \\ &= \alpha^2 - 1 - 2|\alpha|^2 + \alpha^{*2} = -1 + (\alpha-\alpha^*)^2 = -1 - \tfrac{2a_{ho}^2}{\hbar^2}\langle\alpha|\hat{p}|\alpha\rangle^2 \ . \end{aligned} \tag{24.122}$$

[3] We can also define a *Bargmann state* as the eigenstate corresponding to the step-up operator using the notation $\hat{a}^\dagger||\alpha\rangle = \alpha||\alpha\rangle$.

The uncertainties defined in (23.70) become,

$$\begin{aligned}\Delta x^2 &= \langle\alpha|\hat{x}^2|\alpha\rangle - \langle\alpha|\hat{x}|\alpha\rangle^2 = \tfrac{a_{ho}^2}{2} \\ \Delta p^2 &= \langle\alpha|\hat{p}^2|\alpha\rangle - \langle\alpha|\hat{p}|\alpha\rangle^2 = \tfrac{\hbar^2}{2a_{ho}^2}\ .\end{aligned} \tag{24.123}$$

And finally, we find the Heisenberg relation,

$$\Delta p \Delta x = \tfrac{\hbar}{2}\ . \tag{24.124}$$

Comparing with the uncertainty relation (24.88) derived for Fock states, we conclude that the uncertainty is always *smallest* for Glauber states. In this sense, the Glauber states are the ones which are closest to classical states characterized by the absence of uncertainty.

24.6.1.3 Orthogonality and completeness of Glauber states

Glauber are not orthogonal, since,

$$|\langle\alpha|\beta\rangle|^2 = e^{-|\alpha-\beta|^2}\ . \tag{24.125}$$

We leave the demonstration for Exc. 24.6.6.2, but we note here already that for $|\alpha-\beta| \gg 0$ the states are approximately orthogonal. The reason for this is, that the respective population distributions through the Fock states, $|\langle n|\alpha\rangle|^2$ and $|\langle n|\beta\rangle|^2$, do not overlap and hence do not interfere. Some more useful relationships are studied in Exc. 24.6.6.3. In Exc. 24.6.6.4 we show that the coherent state basis is not only complete,

$$\tfrac{1}{\pi}\int |\alpha\rangle\langle\alpha| d^2\alpha = \mathbb{I}\ , \tag{24.126}$$

but it is overcomplete. The state $|\alpha\rangle + |-\alpha\rangle$ is sometimes called *Schrödinger cat state*. In Exc. 24.6.6.5 we will show why such states are very difficult to detect.

24.6.2 Kicking a harmonic oscillator

Let us now study the dynamics of a harmonic oscillator subject to a *kick* or a dislocation or both in the same time. For this we need to remember the Galilei boost introduced in Sec. 23.5.3 and the unitary transformations corresponding to a spatial displacement (23.181) and to a kick (23.192),

$$U_{tr}(b) = e^{(-\imath/\hbar)b\hat{p}} \qquad \text{and} \qquad U_{kc}(k) = e^{\imath k\hat{x}}\ , \tag{24.127}$$

where we restrict to one dimension. The crucial point is that for a harmonic oscillator we know how to expand the operators $\hat{x}$ and $\hat{p}$ into linear combinations of the field operators $\hat{a}$ and $\hat{a}^\dagger$, which allows us to apply the whole formalism developed in the last sections to these transformation operators.

24.6.2.1 Transitions between vibrational states via momentum kick and dislocation

With the formalism developed in the last sections the displacement operator (24.114) can be decomposed in a combination of a spatial displacement and a kick operator (24.127). We can see this by simply substituting the field operators $\hat{a}$ and $\hat{a}^\dagger$ by linear combinations of position and momentum operators using (24.85),

$$\begin{aligned}\alpha\hat{a}^\dagger - \alpha^*\hat{a} &= \frac{\alpha}{\sqrt{2}}\left(\frac{\hat{x}}{a_{ho}} - \imath\frac{a_{ho}\hat{p}}{\hbar}\right) - \frac{\alpha^*}{\sqrt{2}}\left(\frac{\hat{x}}{a_{ho}} + \imath\frac{a_{ho}\hat{p}}{\hbar}\right) \\ &= -\imath\frac{\sqrt{2}a_{ho}\mathfrak{Re}\ \alpha}{\hbar}\ \hat{p} + \imath\frac{\sqrt{2}\mathfrak{Im}\ \alpha}{a_{ho}}\ \hat{x}\ .\end{aligned} \tag{24.128}$$

Using Glauber's rule,

$$D(\alpha) = e^{\alpha\hat{a}^\dagger - \alpha^*\hat{a}} = e^{\imath\ \mathfrak{Re}\ \alpha\mathfrak{Im}\ \alpha} e^{(-\imath a_{ho}\sqrt{2}/\hbar)\mathfrak{Re}\ \alpha\ \hat{p}} e^{(\imath\sqrt{2}/a_{ho})\mathfrak{Im}\ \alpha\ \hat{x}}\ . \tag{24.129}$$

Hence, similarly to the Galilei boost in time and space, the displacement operator $D(\alpha)$ transforms the state of a harmonic oscillator, for example the ground state, $|\alpha\rangle = D(\alpha)|0\rangle$, by kicking its momentum by an amount,

$$\hbar k = \frac{\hbar\sqrt{2}}{a_{ho}}\mathfrak{Im}\ \alpha\ , \tag{24.130}$$

and/or displacing its position suddenly by an amount,

$$b = \sqrt{2}a_{ho}\mathfrak{Re}\ \alpha\ , \tag{24.131}$$

such that,

$$\alpha = \frac{b}{\sqrt{2}a_{ho}} + \imath\frac{ka_{ho}}{\sqrt{2}}\ . \tag{24.132}$$

The real and imaginary parts of α decide which contribution predominates, the kick or the dislocation,

$$\boxed{D(\alpha) = e^{\imath\ \mathfrak{Re}\ \alpha\mathfrak{Im}\ \alpha}\ U_{tr}(\sqrt{2}a_{ho}\mathfrak{Re}\ \alpha)\ U_{kc}(\tfrac{\hbar\sqrt{2}}{a_{ho}}\mathfrak{Im}\ \alpha)}\ . \tag{24.133}$$

For example, if α is imaginary the operation describes a pure momentum kick by an amount $\hbar k$, which puts the harmonic oscillator into a coherent state with the mean occupation number,

$$n = |\alpha|^2 = |\mathfrak{Im}\ \alpha|^2 = \tfrac{1}{2}k^2a_{ho}^2\ , \tag{24.134}$$

On the other hand, if α is real the operation describes a pure dislocation by an amount b, which puts the harmonic oscillator into a coherent state with the mean occupation number,

$$n = |\alpha|^2 = |\mathfrak{Re}\ \alpha|^2 = \frac{b^2}{2a_{ho}^2}\ . \tag{24.135}$$

Now, let us focus on the kick operator and study how it acts on Fock states,

$$\begin{aligned}\langle n|e^{\imath k\hat{x}}|0\rangle = \langle n|\alpha\rangle &= \langle n|e^{-|\alpha|^2/2}\sum_{m=0}^{\infty}\frac{\alpha^m}{\sqrt{m!}}|m\rangle \\ &= e^{-|\alpha|^2/2}\frac{\alpha^n}{\sqrt{n!}} = e^{-|ka_{ho}|^2/4}\frac{(\imath k a_{ho})^n}{\sqrt{2^n n!}}\ ,\end{aligned} \tag{24.136}$$

using (24.132). This formula tells us that for small α, transitions may only occur to the vibrational states $|0\rangle$ and $|1\rangle$, since,

$$\langle n|e^{\imath k\hat{x}}|0\rangle \overset{ka_{ho}\to 0}{\longrightarrow} \frac{\alpha^n}{\sqrt{n!}} \simeq \delta_{n,0} + \alpha\delta_{n,1}\ . \tag{24.137}$$

On the other hand for very large α, the exponential in (24.136) pulls the transition rate to a particular vibrational state $|n\rangle$ to zero, but this is simply due to the fact that the population is redistributed over many states, since,

$$\sum_n |\langle n|e^{\imath k\hat{x}}|0\rangle|^2 = e^{-(ka_{ho})^2/2}\sum_{n=0}^{\infty}\frac{|\alpha|^{2n}}{n!} = e^{-(ka_{ho})^2/2}e^{|\alpha|^2} = 1\ . \tag{24.138}$$

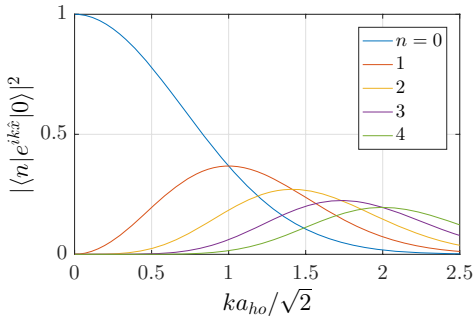

Figure 24.20: (code) Transition matrix element $|\langle n|e^{\imath k\hat{x}}|0\rangle|^2$ as a function of ka_{ho}. The curves are Poisson distributions of photon numbers in coherent states.

For small momentum kicks we may approximate the transition matrix elements by,

$$\begin{aligned}\langle m|e^{\imath k\hat{x}}|n\rangle &\simeq \langle m|1 + \imath k\tfrac{a_{ho}}{\sqrt{2}}(\hat{a}+\hat{a}^\dagger)|n\rangle \\ &= \delta_{m,n} + \tfrac{\imath k a_{ho}}{\sqrt{2}}(\sqrt{n}\delta_{m,n-1} + \sqrt{n+1}\delta_{m,n+1})\ ,\end{aligned} \tag{24.139}$$

such that,

$$\sum_{m\neq n}|\langle m|e^{\imath k\hat{x}}|n\rangle|^2 \simeq k^2 a_{ho}^2(n+\tfrac{1}{2})\ . \tag{24.140}$$

Formula (24.140) tell us that the probability for a transition between vibrational states depends on the parameter ka_{ho}, which we will discuss in the next section. For small ka_{ho} it gets increasingly more difficult for the system to leave the original

vibrational state $|n\rangle$ and to form a coherent state. After a momentum kick, the population is coherently distributed over several vibrational states in a way to fulfill momentum and energy conservation. Let us consider, for simplicity, an initial state $|0\rangle$. If the kick is weak or the trap strong (i.e. if $|\alpha| < 1$), the atom will stay in $|0\rangle$ with a high probability amplitude and go to $|1\rangle$ only with a small probability amplitude. We will derive in Exc. 24.6.6.6 the general expression for the transition matrix element for arbitrary values of α [4],

$$\boxed{\langle m|e^{\imath k\hat{x}}|n\rangle = e^{|\alpha|^2/2}\sum_{k=0}^{n}\sqrt{\binom{n}{k}\binom{m}{k}}\langle n-k|\alpha\rangle\langle m-k|\alpha\rangle} \ . \tag{24.141}$$

The formula satisfies,

$$\sum_m |\langle m|e^{\imath k\hat{x}}|n\rangle|^2 = \sum_m \langle n|e^{\imath kx}|m\rangle\langle m|e^{-\imath kx}|n\rangle = \langle n|e^{\imath kx}e^{-\imath kx}|n\rangle = 1 \ . \tag{24.142}$$

Kicking a harmonic oscillator initially in state $|0\rangle$ we obtain for the expectation value of position and momentum,

$$\boxed{\begin{array}{lcl} \langle\alpha|\hat{p}|\alpha\rangle & = & \langle 0|D(\alpha)^\dagger \hat{p} D(\alpha)|0\rangle = \langle 0|e^{\imath k\hat{x}}\hat{p}e^{-\imath k\hat{x}}|0\rangle = \langle 0|\hat{p}|0\rangle + \hbar k \\ \langle\alpha|\hat{x}|\alpha\rangle & = & \langle 0|\hat{x}|0\rangle \end{array}} \ .$$

24.6.2.2 Lamb-Dicke regime

We already introduced $|\alpha|$ as the amplitude (24.135) of the coherent vibrational state created by kicking a harmonic oscillator. Defined as,

$$\boxed{\eta \equiv |\alpha| = \tfrac{1}{\sqrt{2}} k a_{ho}} \qquad \text{with} \qquad a_{ho} \equiv \sqrt{\frac{\hbar}{m\omega_{ho}}} \ . \tag{24.143}$$

the so-called *Lamb-Dicke parameter* measures the *degree of confinement* of a particle in a harmonic trap with respect to the momentum kick. We say that we are in the *Lamb-Dicke regime*, when $\eta < 1$, that is when the particle is localized to a volume smaller than the wavelength, $2\pi x_0 \ll \lambda = 2\pi/k$, corresponding to the momentum change.

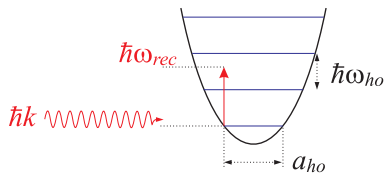

Figure 24.21: Illustration of the Lamb-Dicke parameter.

[4] See also 35.2.3.

We can also rewrite the Lamb-Dicke parameter in terms of the trap's secular frequency, ω_{ho}, and the recoil-shift,

$$\boxed{\eta = \sqrt{\frac{\omega_{rec}}{\omega_{ho}}}} \qquad \text{with} \qquad \omega_{rec} \equiv \frac{\hbar k^2}{2m} \ , \tag{24.144}$$

where we understand the recoil-energy $\hbar\omega_{rec}$ as the kinetic energy gained through the recoil acceleration. In this form the Lamb-Dicke parameter tells us that, in the Lamb-Dicke regime, the energy of the momentum kick is not sufficient to efficiently excite vibrational states,

$$(2n+1)\hbar k^2/m \ll \omega_{ho} \ . \tag{24.145}$$

That is, cold particles in low vibrational states n can not accommodate the recoil shift within the vibrational spectrum of the trap. Consequently, the recoil cannot be transferred to the particle itself, but must be absorbed by the entire trap. This is the case of the *strong binding regime* in ion traps, which is analogous to the *Mößbauer effect* discussed later in Sec. 38.3.3.

Finally, the Lamb-Dicke parameter can be rewritten in terms of the *inverse Doppler modulation index*,

$$\boxed{\eta = \frac{k v_{max}}{2\omega_{ho}}} \qquad \text{with} \qquad \frac{m}{2} v_{max}^2 = \hbar\omega_{ho} \ . \tag{24.146}$$

Accelerated by the momentum kick, the atom will execute harmonic oscillations with frequency ω_{ho} and with the maximum velocity-excursions v_{max}. Hence, any quantity depending on the atomic velocity, e.g. the Doppler-shift of light scattered from the atom, will be modulated. We will see in Sec. 38.3.3 that the modulation generates a spectrum of frequency sidebands which, in case of small $\eta < 1$, are restricted to first-order sidebands located at $\pm\omega_{ho}$ of the light frequency. Do the Exc. 24.6.6.7.

Example 161 (*Absorption of recoil by a molecular dimer*): To be able to discuss the validity of energy and momentum conservation in a kicked system, let us consider a molecule made of two atoms with masses m_1 and m_2 bound by a force obeying Hooke's law. Then we kick atom 1 via the momentum shift operator $e^{\imath k\hat{x}_1}$ (e.g. during a photon absorption process with the associated recoil) and analyze the motional dynamics of the whole system [5]. (We restrict ourselves to one dimension.)

The first step is to write down the Hamiltonian,

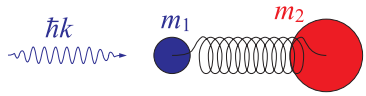

Figure 24.22: Illustration of a heteronuclear dimer kicked by photonic recoil.

$$\hat{H} = -\frac{\hbar^2}{2m_1}\frac{d^2}{dx_1^2} - \frac{\hbar^2}{2m_2}\frac{d^2}{dx_2^2} + \frac{\mu}{2}\omega_{ho}^2(x_1 - x_2)^2 \ ,$$

[5] The selective kicking is realistic if we image both atoms being of different species with different transitions responding differently to incident radiation.

We transform in the center-of-mass system via,

$$M \equiv m_1 + m_2 \quad \text{and} \quad \frac{1}{\mu} \equiv \frac{1}{m_1} + \frac{1}{m_2}$$
$$R = \frac{m_1 x_1 + m_2 x_2}{M} \quad \text{and} \quad r = x_1 - x_2 \ .$$

Applying the separation ansatz $\psi(x_1, x_2) = \Theta(R)\phi(r)$ to the Schrödinger equation,

$$\left[-\frac{\hbar^2}{2m_1}\frac{d^2}{dx_1^2} - \frac{\hbar^2}{2m_2}\frac{d^2}{dx_2^2} + \frac{\mu}{2}\omega_{ho}^2(\hat{x}_1 - \hat{x}_2)^2 \right] \psi(x_1, x_2) = E_{tot}\psi(x_1, x_2) \ ,$$

we calculate for $i = 1, 2$,

$$\frac{d}{dx_i} = \frac{dR}{dx_i}\frac{d}{dR} + \frac{dr}{dx_i}\frac{d}{dr} = \frac{m_i}{M}\frac{d}{dR} \pm \frac{d}{dr}$$
$$\frac{d^2}{dx_i^2} = \frac{m_i^2}{M^2}\frac{d^2}{dR^2} \pm 2\frac{m_i}{M}\frac{d}{dR}\frac{d}{dr} + \frac{d^2}{dr^2}$$
$$-\frac{\hbar^2}{2m_1}\frac{d^2}{dx_1^2} - \frac{\hbar^2}{2m_2}\frac{d^2}{dx_2^2} = -\frac{\hbar^2}{2M}\frac{d^2}{dR^2} - \frac{\hbar^2}{2\mu}\frac{d^2}{dr^2} \ .$$

Hence, we get,

$$-\frac{\hbar^2}{2M}\frac{d^2}{dR^2}\Theta(R) = (E_{tot} - E)\Theta(R) \quad , \quad \left[-\frac{\hbar^2}{2\mu}\frac{d^2}{dr^2} + \frac{\mu}{2}\omega_{ho}^2\hat{r}^2 \right] \phi(r) = E\phi(r) \ ,$$

with the vibrational energy E and the energy of the center-of-mass motion $E_{tot} - E$.
Now, we analyze the kick operator $e^{\imath k\hat{x}_1}$ with $\hat{x}_1 = \hat{R} - \frac{m_2}{M}\hat{r}$. We find that, because of $[\hat{R}, \hat{r}] = 0$,

$$e^{\imath k\hat{x}_1} = e^{\imath k\hat{R}} e^{-\imath k\frac{m_2}{M}\hat{r}} \ .$$

This means that the kick operator simultaneously acts on both: the center-of-mass receives a recoil accelerating it by an amount $p_{cm} = \hbar k$, and the vibrational relative motion receives a kick of an amount $p_{rl} = \hbar k m_2/M$ following the dynamics described in Sec. 24.6.2.
Obviously, the total system conserves momentum, which is imparted to the center-of-mass motion. Whether the kick also excites the relative motion depends on mass ratio. In the limit $m_1 \ll m_2$ we find $p_{rl} = \hbar k$, while in the limit $m_1 \gg m_2$ we get $p_{rl} \to 0$. In terms of the Lamb-Dicke parameter, we find,

$$\eta = \frac{p_{rl}a_{ho}}{\hbar\sqrt{2}} = \frac{km_2}{M\sqrt{2}}\sqrt{\frac{\hbar}{\mu\omega_{ho}}} = \frac{km_2}{m_1 + m_2}\sqrt{\frac{\hbar}{2\omega_{ho}}\left(\frac{1}{m_1} + \frac{1}{m_2}\right)} \ .$$

Hence, in the limit $m_1 \ll m_2$ we expect a much larger Lamb-Dicke parameter than for $m_1 \gg m_2$. In particular, considering the limit $m_2 \to \infty$, we recover the formula (24.144) holding for an atom confined in a harmonic potential,

$$\eta \overset{m_2\to\infty}{\longrightarrow} \sqrt{\frac{\hbar k^2}{\omega_{ho}2m_1}} = \sqrt{\frac{\omega_{rec}}{\omega_{ho}}} \ .$$

24.6.3 Shaking a harmonic oscillator

As we mentioned below the formulae (23.193), the transformation in momentum space is not a realistic concept for a *kick*. In practice, a kick will always be the results of a collision, which is understood here as a scattering of a free (massive or massless) particle at our harmonically trapped particle. And the scattering process will take a finite amount of time, e.g. the duration of a radiative π-pulse required to excite an atomic transition.

More realistic is to expose the harmonic oscillator to periodic forcing,

$$\boxed{\hat{H}(t) = \hat{H}^{(0)} + \hat{H}^{(1)} = -\frac{\hbar^2}{2m}\frac{d^2}{dx^2} + \frac{m}{2}\omega_{ho}^2\hat{x}^2 + \frac{\hbar\Omega}{2}(\hat{a}e^{\imath\nu t} + \hat{a}^\dagger e^{-\imath\nu t})} \,. \tag{24.147}$$

To study its time evolution we calculate,

$$|\psi(t)\rangle = e^{-(\imath/\hbar)\hat{H}t}\sum_n a_n|n\rangle \stackrel{a_n=\delta_{n,0}}{\longrightarrow} e^{-(\imath/\hbar)\hat{H}t}|0\rangle \,, \tag{24.148}$$

when the oscillator is initially in the state $|0\rangle$. We rewrite the time evolution propagator as,

$$e^{-(\imath/\hbar)\hat{H}t} = e^{-\imath\omega_{ho}t(\hat{n}+1/2)-(\imath\Omega t/2)(\hat{a}e^{\imath\nu t}+\hat{a}^\dagger e^{-\imath\nu t})} \,. \tag{24.149}$$

To simplify the propagator, we first have a closer look at the terms $\hat{a}e^{\imath\omega_{ho}t}$ and $\hat{a}^\dagger e^{-\imath\omega_{ho}t}$, which we evaluate through their action on the complete system of unperturbed eigenfunctions,

$$\begin{aligned} e^{-(\imath/\hbar)\hat{H}^{(0)}t}\hat{a}e^{(\imath/\hbar)\hat{H}^{(0)}t}|n\rangle &= e^{-(\imath/\hbar)\hat{H}^{(0)}t}\hat{a}e^{(\imath/\hbar)E_n^{(0)}t}|n\rangle \\ &= e^{-(\imath/\hbar)E_{n-1}^{(0)}t}e^{(\imath/\hbar)E_n^{(0)}t}\hat{a}|n\rangle = e^{\imath\omega_{ho}t}\hat{a}|n\rangle \,. \end{aligned} \tag{24.150}$$

Hence, defining the detuning $\Delta \equiv \nu - \omega_{ho}$,

$$\begin{array}{rcccl} \hat{a}e^{\imath\nu t} &=& e^{\imath\omega_{ho}t}\hat{a}e^{\imath\Delta t} &=& e^{-\imath\omega_{ho}t(\hat{n}+1/2)}\hat{a}e^{\imath\Delta t}e^{\imath\omega_{ho}t(\hat{n}+1/2)} \\ \hat{a}^\dagger e^{-\imath\nu t} &=& e^{-\imath\omega_{ho}t}\hat{a}^\dagger e^{-\imath\Delta t} &=& e^{-\imath\omega_{ho}t(\hat{n}+1/2)}\hat{a}^\dagger e^{-\imath\Delta t}e^{\imath\omega_{ho}t(\hat{n}+1/2)} \\ \hat{n} &=& & & e^{-\imath\omega_{ho}t(\hat{n}+1/2)}\hat{n}e^{\imath\omega_{ho}t(\hat{n}+1/2)} \end{array} \,. \tag{24.151}$$

Substituting these expression into the propagator (24.149) we get,

$$e^{-(\imath/\hbar)\hat{H}t} = e^{e^{-\imath\omega_{ho}t(\hat{n}+1/2)}\left[-\imath\omega_{ho}t(\hat{n}+1/2)-(\imath\Omega t/2)\hat{a}e^{\imath\Delta t}-(\imath\Omega t/2)\hat{a}^\dagger e^{-\imath\Delta t}\right]e^{\imath\omega_{ho}t(\hat{n}+1/2)}} \,. \tag{24.152}$$

Now, making use of the relationship,

$$e^{e^{-\hat{A}}\hat{B}e^{\hat{A}}} = \sum_n \frac{(e^{-\hat{A}}\hat{B}e^{\hat{A}})^n}{n!} = \sum_n \frac{e^{-\hat{A}}\hat{B}^n e^{\hat{A}}}{n!} = e^{-\hat{A}}e^{\hat{B}}e^{\hat{A}} \,, \tag{24.153}$$

which is easy to show by expansion of $e^{\hat{B}}$, we find [6],

$$e^{-(\imath/\hbar)\hat{H}t} = e^{-\imath\omega_{ho}t(\hat{n}+1/2)}e^{-\imath\omega_{ho}t(\hat{n}+1/2)-(\imath\Omega t/2)(\hat{a}e^{\imath\Delta t}+\hat{a}^\dagger e^{-\imath\Delta t})}e^{\imath\omega_{ho}t(\hat{n}+1/2)} \,. \tag{24.154}$$

[6] Note, that this formula can not be simplified using Glauber's formula, because $[\hat{n},[\hat{n},\hat{a}]] \neq 0$. Note also, that the unitary transformation corresponds to a transformation into Dirac's interaction picture, which will be studied in the context of quantized radiation fields in Sec. 35.4.

In particular, for $\Delta = 0$,

$$\boxed{\langle n|e^{-(\imath/\hbar)\hat{H}t}|0\rangle = e^{-n\imath\omega_{ho}t}\langle n|e^{-\imath\omega_{ho}t(\hat{n}+1/2)-(\imath\Omega t/2)(\hat{a}+\hat{a}^\dagger)}|0\rangle} \ . \tag{24.155}$$

The dynamics is illustrated in Fig. 24.23. Again, we notice that the state generated

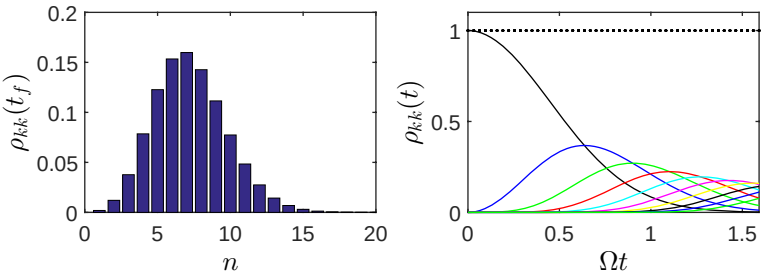

Figure 24.23: (code) (a) Populations of the vibrational states after a given interaction time. (b) Time evolution of the lowest populations.

is a coherent state. In Exc. 24.6.6.8 we will study how to generalize the problem to non-resonant excitation, $\Delta \neq 0$.

24.6.4 Forcing a harmonic oscillator

The transfer of momentum is the result of a (generally) constant force applied for a certain amount of time,

$$\hbar k = \int_{-\infty}^{\infty} mg\ \Theta_{[0,\Delta t]}(t)\ dt \ , \tag{24.156}$$

where g denotes the acceleration. That is, we expect that a harmonic oscillator,

$$\boxed{\hat{H}(t) = -\frac{\hbar^2}{2m}\frac{d^2}{dx^2} + \frac{m}{2}\omega_{ho}^2\hat{x}^2 - mg\hat{x}\ \Theta_{[0,\Delta t]}(t)} \ , \tag{24.157}$$

forced for a period of time Δt should have suffered a kick.

24.6.4.1 Displaced harmonic oscillator

To begin with, we will derive the dynamics of a harmonic oscillator suddenly exposed to a homogeneous constant force $F(t) = mg\ \Theta_{[0,\infty]}(t)$. It is easy to see, that the above perturbed Hamiltonian can be cast into the form,

$$\hat{H}(t) = -\frac{\hbar^2}{2m}\frac{d^2}{dx^2} + \frac{m}{2}\omega_{ho}^2\left(\hat{x} - \frac{g}{\omega_{ho}^2}\right)^2 - \frac{mg^2}{2\omega_{ho}^2} \ , \tag{24.158}$$

where the last constant term plays no role in the dynamics. That is, as we know from classical physics, the essential impact of a homogeneous force (e.g. gravity) on a harmonic oscillator consists in displacing its equilibrium position. Knowing the

eigenvalues and -states of the unperturbed Hamiltonian, the obvious solution of the perturbed eigenvalue problem is,

$$\begin{aligned} \hat{H}|\psi_n^{(1)}\rangle &= E_n^{(1)}|\psi_n^{(1)}\rangle \\ \text{with} \quad E_n^{(1)} &= E_n - \frac{mg^2}{2\omega_{ho}^2} \\ \text{and} \quad \langle x|\psi_n^{(1)}\rangle &= \psi_n^{(1)}(x) = \psi_n(x - \tfrac{g}{\omega_{ho}^2}) = \langle x - \tfrac{g}{\omega_{ho}^2}|n\rangle \ . \end{aligned} \tag{24.159}$$

Using the properties (23.181) and (23.183) we may write,

$$\langle x - \tfrac{g}{\omega_{ho}^2}|n\rangle = \langle x|U_{tr}^\dagger(-\tfrac{g}{\omega_{ho}^2})|n\rangle = \langle x|e^{-(\imath/\hbar)(g/\omega_{ho}^2)\hat{p}}|n\rangle \ , \tag{24.160}$$

and using the representation (24.86) of the momentum operator by the field operators and introducing the abbreviation $\beta \equiv \frac{g}{\omega_{ho}^2 a_{ho}\sqrt{2}}$ we can rewrite,

$$\langle x - \tfrac{g}{\omega_{ho}^2}|n\rangle = e^{-\beta(\hat{a}-\hat{a}^\dagger)}\langle x|n\rangle \ . \tag{24.161}$$

Note, that the transition from (24.157) to (24.159) can also be obtained by a redefinition of the field operators according to,

$$\hat{b} \equiv \hat{a} - \tfrac{mga_{ho}}{\hbar\omega_{ho}\sqrt{2}} \ , \tag{24.162}$$

since,

$$\hat{H} = \hbar\omega_{ho}(\hat{a}^\dagger\hat{a} + \tfrac{1}{2}) - \tfrac{mga_{ho}}{\sqrt{2}}(\hat{a} + \hat{a}^\dagger) = \hbar\omega_{ho}(\hat{b}^\dagger\hat{b} + \tfrac{1}{2}) - \tfrac{mg^2}{2\omega_{ho}^2} \tag{24.163}$$

and $\hat{a} - \hat{a}^\dagger = \hat{b} - \hat{b}^\dagger$.

The temporal evolution is given by the time-dependent Schrödinger equation. Since the jump is finite, the solution must be well behaved at time $t = 0$,

$$\begin{aligned} \langle x|\psi_n^{(1)}(t)\rangle &= \langle x|e^{-(\imath/\hbar)\hat{H}t}|\psi_n^{(1)}(0)\rangle \\ &= \langle x|e^{-(\imath/\hbar)\hat{H}t}e^{-\beta(\hat{a}-\hat{a}^\dagger)}|n\rangle \\ &= \langle x|e^{-(\imath/\hbar)\hat{H}t}e^{-\beta(\hat{a}-\hat{a}^\dagger)}e^{(\imath/\hbar)\hat{H}t}e^{-(\imath/\hbar)\hat{H}t}|n\rangle \ . \end{aligned} \tag{24.164}$$

To simplify the first three exponential functions, we use the relationships (24.153) and (24.150) [7],

$$e^{-(\imath/\hbar)\hat{H}t}e^{-\beta(\hat{a}-\hat{a}^\dagger)}e^{(\imath/\hbar)\hat{H}t} = e^{-\beta e^{-(\imath/\hbar)\hat{H}t}(\hat{a}-\hat{a}^\dagger)e^{(\imath/\hbar)\hat{H}t}} = e^{-\beta\left(e^{\imath\omega_{ho}t}\hat{a} - e^{-\imath\omega_{ho}t}\hat{a}^\dagger\right)} \ , \tag{24.165}$$

and write the temporal solution,

$$\begin{aligned} \psi_n^{(1)}(x,t) &= e^{-\beta(\hat{a}e^{\imath\omega_{ho}t} - \hat{a}^\dagger e^{-\imath\omega_{ho}t})}e^{-(\imath/\hbar)\hat{H}t}\psi_n(x) \\ &= e^{-\beta(\hat{a}-\hat{a}^\dagger)\cos\omega_{ho}t - \imath\beta(\hat{a}+\hat{a}^\dagger)\sin\omega_{ho}t}e^{-(\imath/\hbar)E_n^{(0)}t}\psi_n(x) \ . \end{aligned} \tag{24.166}$$

[7] We can use (24.150), because the shifted harmonic oscillator has, except from a constant offset the same eigenenergies.

Using Glauber's formula (23.210) we find,

$$\begin{aligned}\psi_n^{(1)}(x,t) &= e^{-\imath\beta(\hat{a}+\hat{a}^\dagger)\sin\omega_{ho}t}e^{-\beta(\hat{a}-\hat{a}^\dagger)\cos\omega_{ho}t}e^{\imath\beta^2\sin\omega_{ho}t\cos\omega_{ho}t}e^{-(\imath/\hbar)E_n^{(0)}t}\psi_n(x)\\ &= e^{-\imath(mg/\hbar\omega_{ho})\hat{x}\sin\omega_{ho}t}e^{-(\imath/\hbar)(g/\omega_{ho}^2)\hat{p}\cos\omega_{ho}t}e^{\imath\beta^2\sin\omega_{ho}t\cos\omega_{ho}t}e^{-(\imath/\hbar)E_n^{(0)}t}\psi_n(x)\\ &= e^{-\imath\beta(\hat{a}+\hat{a}^\dagger)\sin\omega_{ho}t}e^{\imath\beta^2\sin\omega_{ho}t\cos\omega_{ho}t}e^{-(\imath/\hbar)E_n^{(0)}t}\psi_n(x-b\cos\omega_{ho}t)\ . \end{aligned} \tag{24.167}$$

Finally,

$$\boxed{|\psi_n^{(1)}(x,t)|^2 = |\psi_n(x-\bar{x}(t))|^2 \qquad \text{where} \qquad \bar{x}(t)\equiv\tfrac{g}{\omega_{ho}^2}\cos\omega_{ho}t}\ . \tag{24.168}$$

This means that the spatial distribution of $\psi_n^{(1)}$ around $\bar{x}(t)$ is the same as of ψ_n around $\bar{x}=0$. The entire distribution oscillates without deformation. The momentum distribution follows from the Fourier transform,

$$\begin{aligned}\phi_n^{(1)}(p,t) &= \frac{1}{\sqrt{2\pi\hbar}}\int dx e^{-(\imath/\hbar)px}\psi_n^{(1)}(x,t)\\ &= \frac{1}{\sqrt{2\pi\hbar}}\int du\ e^{-(\imath/\hbar)pu}e^{-(\imath/\hbar)um\omega_{ho}\frac{g}{\omega_{ho}^2}\sin\omega_{ho}t}e^{\imath\gamma(p,t)}\psi_n\\ &= e^{\imath\gamma(p,t)}\phi_n(p+m\omega_{ho}\tfrac{g}{\omega_{ho}^2}\sin\omega_{ho}t)\ , \end{aligned} \tag{24.169}$$

where the abbreviation $\gamma=\gamma^*$ contains all unitary transformations of (24.167), that do not depend on x. We obtain,

$$\boxed{|\phi_n^{(1)}(p,t)|^2 = |\phi_n(p-\bar{p}(t))|^2 \qquad \text{where} \qquad \bar{p}(t)\equiv -m\tfrac{g}{\omega_{ho}}\sin\omega_{ho}t}\ . \tag{24.170}$$

24.6.4.2 Discussion of the kick dynamics

For the acceleration of the harmonic oscillator to resemble a 'kick', the time during which the perturbation is active must be much smaller than a trap oscillation period, $\omega_{ho}\Delta t \ll 1$. In this case, we may expand the oscillatory motion (24.168) and (24.170),

$$\bar{x}=\frac{g}{\omega_{ho}^2} \qquad \text{and} \qquad \bar{p}=-mg\Delta t\equiv-\hbar k\ , \tag{24.171}$$

which is consistent with the initial request (24.156). It is also clear that, for a given force mg, the maximum momentum that can be transmitted is limited, $\hbar k < mg/\omega_{ho}$.

As long as the kick-approximation $\omega_{ho}\Delta t \ll 1$ holds, we may simply describe the dynamics during the application of the force, via a time-dependent kick operator,

$$e^{\imath k(t)\hat{x}} = D(\alpha(t))\ , \tag{24.172}$$

where the acquired momentum increases linearly with time according to $k(t) = k\frac{\max(\min(t,\Delta t),0)}{\Delta t}$. I.e. the populations of the vibrational states evolve like (24.136) into a coherent state with increasing amplitude $|\alpha(t)|^2$. At the end of the kick, on a much slower time-scale ω_{ho}^{-1}, the wavefunctions will start to oscillate all in phase, according to (24.168).

The time-dependence of the states $|\alpha(t)\rangle$, as shown in Exc. 24.6.6.9 is given by,

$$|\alpha(t)\rangle = e^{-(\imath/\hbar)\hat{H}t}|\alpha(0)\rangle = \sum_n e^{-(\imath/\hbar)E_n t} e^{-|\alpha(0)|^2/2} \frac{\alpha(0)^n}{\sqrt{n!}}|n\rangle \tag{24.173}$$
$$= e^{-\imath\omega_{ho}t/2} \sum_n e^{-|\alpha(0)|^2/2} \frac{(\alpha(0)e^{-\imath\omega_{ho}t})^n}{\sqrt{n!}}|n\rangle = e^{-\imath\omega_{ho}t/2}|\alpha(0)e^{-\imath\omega_{ho}t}\rangle \ .$$

With (24.150) we find,

$$\hat{x}(t) = e^{-(\imath/\hbar)\hat{H}t}\hat{x}(0)e^{(\imath/\hbar)\hat{H}t} = \hat{x}(0)\cos\omega_{ho}t + \tfrac{\hat{p}(0)}{m\omega_{ho}}\sin\omega_{ho}t \qquad \text{and} \tag{24.174}$$
$$\hat{p}(t) = e^{-(\imath/\hbar)\hat{H}t}\hat{p}(0)e^{(\imath/\hbar)\hat{H}t} = m\omega_{ho}\hat{x}(0)\sin\omega_{ho}t + \hat{p}(0)\cos\omega_{ho}t \ ,$$

or with (24.173),

$$\boxed{\begin{array}{rcl} \langle\alpha(t)|\hat{x}|\alpha(t)\rangle & = & \langle\alpha(0)|\hat{x}|\alpha(0)\rangle\cos\omega_{ho}t + \frac{1}{m\omega_{ho}}\langle\alpha(0)|\hat{p}|\alpha(0)\rangle\sin\omega_{ho}t \\ \langle\alpha(t)|\hat{p}|\alpha(t)\rangle & = & m\omega_{ho}\langle\alpha(0)|\hat{x}|\alpha(0)\rangle\sin\omega_{ho}t + \langle\alpha(0)|\hat{p}|\alpha(0)\rangle\cos\omega_{ho}t \end{array}} \ . \tag{24.175}$$

We note, that the position and momentum wavefunctions $\langle x|n\rangle$ and $\langle p|n\rangle$ of the excited vibrational states are complicated Hermite polynomials, but we don't have to write them down explicitly to get to the last result. We will derive some further properties in Exc. 24.6.6.10.

24.6.4.3 Simulation of the displacement of a harmonic oscillator

The Hamiltonian of a harmonic oscillator subject to an external force can be cast into the form,

$$\hat{H}(t) = -\frac{\hbar^2}{2m}\frac{d^2}{dx^2} + \frac{m}{2}\omega_{ho}^2\hat{x}^2 + mg\hat{x} = \hbar\omega_{ho}(\hat{a}^\dagger\hat{a} + \tfrac{1}{2}) + mg\tfrac{a_{ho}}{\sqrt{2}}(\hat{a} + \hat{a}^\dagger)$$
$$= \begin{pmatrix} \ddots & \ddots & & 0 \\ \ddots & (n+\frac{1}{2})\hbar\omega_{ho} & mg\frac{a_{ho}}{\sqrt{2}}\sqrt{n+1} & \\ & mg\frac{a_{ho}}{\sqrt{2}}\sqrt{n+1} & (n+\frac{3}{2})\hbar\omega_{ho} & \ddots \\ 0 & & \ddots & \ddots \end{pmatrix} \ . \tag{24.176}$$

The temporal evolution of the state is given by,

$$|\psi(t)\rangle = e^{-(\imath/\hbar)\hat{H}t}|\psi(0)\rangle = e^{-(\imath/\hbar)\hat{H}t}\sum_n a_n|n\rangle \overset{a_n=\delta_{n,0}}{\longrightarrow} e^{-(\imath/\hbar)\hat{H}t}|0\rangle \ , \tag{24.177}$$

when the oscillator is initially in the state $|0\rangle$. Note that, without perturbation, $|\psi(t)\rangle = \sum_n e^{-\imath\omega_{ho}(\hat{n}+1/2)t}a_n|n\rangle$.

Various quantities now are interesting to plot as a function of time. Firstly, we calculate the populations $|\langle n|\psi(t)\rangle|^2$ of the various states and the total energy from,

$$\boxed{\begin{array}{rl} \langle n|\psi(t)\rangle & = \langle n|e^{-(\imath/\hbar)\hat{H}t}\sum_m a_m|m\rangle \\ E_{tot}(t) & = \sum_n \hbar\omega_{ho}(n+\frac{1}{2})|\langle n|\psi(t)\rangle|^2 \end{array}} \ . \tag{24.178}$$

Secondly, we get for the temporal evolution of the spatial wavefunction,

$$\langle x|\psi(t)\rangle = \sum_n \langle x|n\rangle\langle n|\psi(t)\rangle = \sum_n \langle x|n\rangle\langle n|e^{-(\imath/\hbar)\hat{H}t}\sum_m a_m|m\rangle \ , \tag{24.179}$$

where $|\langle x|n\rangle\langle n|\psi(t)\rangle|^2$ is the spatial representation of the wavefunction of the n-th eigenstate derived in (24.97),

$$\langle x|n\rangle = \frac{e^{-x^2/2a_{ho}^2}H_n(x/a_{ho})}{\sqrt{a_{ho}\sqrt{\pi}2^n n!}} \ , \tag{24.180}$$

weighed with instantaneous population (24.178) of this state. We thus obtain for the total wavefunction,

$$\boxed{\langle x|\psi(t)\rangle = \sum_n \frac{e^{-x^2/2a_{ho}^2}H_n(x/a_{ho})}{\sqrt{a_{ho}\sqrt{\pi}2^n n!}}\langle n|e^{-(\imath/\hbar)\hat{H}t}|n\rangle} \ . \tag{24.181}$$

Furthermore, we may calculate the expectation values of the position and the momentum of the harmonic oscillator from the total wavefunction $\langle x|\psi(t)\rangle$,

$$\begin{aligned} \langle\psi(t)|\hat{x}|\psi(t)\rangle &= \int\langle\psi(t)|\hat{x}|x\rangle\langle x|\psi(t)\rangle dx = \int x|\psi(x,t)|^2 dx \\ \langle\psi(t)|\hat{p}|\psi(t)\rangle &= \int\langle\psi(t)|\hat{p}|p\rangle\langle p|\psi(t)\rangle dp = \int p|\phi(p,t)|^2 dp \ , \end{aligned} \tag{24.182}$$

where $\phi(p,t)$ is the Fourier transform of $\psi(x,t)$ according to (23.102). In practice, it is however easier to calculate them from the populations $\langle n|\psi(t)\rangle$,

$$\boxed{\begin{array}{rl} \langle\psi(t)|\hat{x}|\psi(t)\rangle & = \frac{a_{ho}}{\sqrt{2}}\sum_n \langle\psi(t)|\hat{a}+\hat{a}^\dagger|n\rangle\langle n|\psi(t)\rangle \\ \langle\psi(t)|\hat{p}|\psi(t)\rangle & = \frac{\hbar}{\imath a_{ho}\sqrt{2}}\sum_n \langle\psi(t)|\hat{a}-\hat{a}^\dagger|n\rangle\langle n|\psi(t)\rangle \end{array}} \ . \tag{24.183}$$

The temporal evolution of the forced harmonic oscillator defined by (24.177) can be numerically propagated. In cases where the force varies in time, the propagation can be done iteratively by subdividing time in intervals $t_k - t_{k-1}$ for $k \in \mathbb{N}$ sufficiently small that the force can be considered constant within them,

$$|\psi(t_k)\rangle = e^{-(\imath/\hbar)\hat{H}(t_k-t_{k-1})}|\psi(t_{k-1})\rangle \ . \tag{24.184}$$

The results of such a simulation are illustrated in Fig. 24.24.

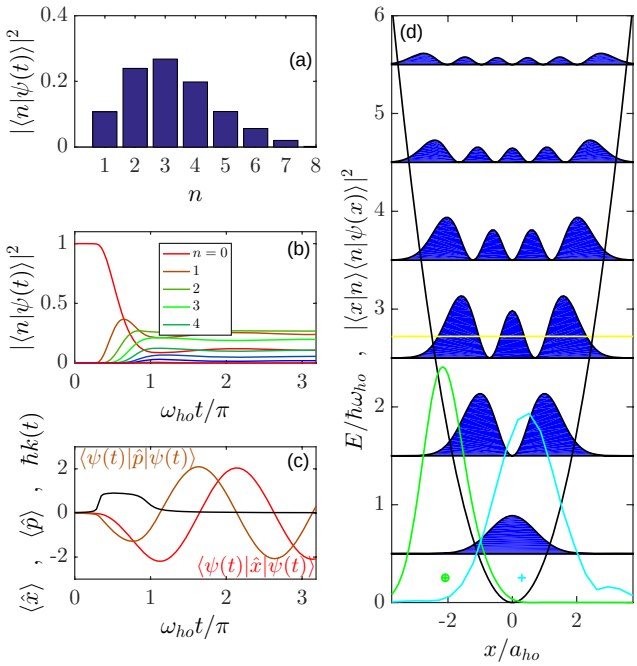

Figure 24.24: (code) Evolution of a harmonic oscillator subject to time-dependent forcing. (a) Histogram of the final population of the vibrational states. (b) Time evolution of the vibrational state populations. (c) Time evolution of the applied force (black) and of the expectation values of position (red) and momentum (brown). (d) Spatial wavefunctions $\langle n|\psi(x)\rangle|^2$ (Hermite polynomials) (blue) of the lowest vibrational states of the harmonic potential (black). The green Gaussian is the coherent sum of the spatial wavefunctions $|\sum_n\langle n|\psi(x)\rangle|^2$, and the cyan Gaussian the coherent sum of the momentum wavefunctions $|\sum_n\langle n|\psi(p)\rangle|^2$. The horizontal yellow line is the total energy of the system. You may also run a movie of the simulation clicking on (watch movie)! Furthermore, a presentation about the topic of recoil on trapped atoms is available at (watch talk)!

24.6.5 Quantization of the electromagnetic field

The quantization of light (also called *second quantization*) triggered by Max Planck's treatments of black-body radiation in 1905 resolved the problem of the ultraviolet divergence and explained the photoelectric effect. Twenty years later the quantization of the atom by Niels Bohr (also called *first quantization*) explained the internal structure of the atom.

The operator for the electric field of a laser mode is given by,

$$\hat{\mathcal{E}} = \imath\mathcal{E}_1[\hat{a}e^{\imath\mathbf{k}\cdot\mathbf{r}-\imath\omega t} - \hat{a}^\dagger e^{-\imath\mathbf{k}\cdot\mathbf{r}+\imath\omega t}] \,, \tag{24.185}$$

where $\mathcal{E}_1 = \sqrt{\hbar\omega/2\varepsilon_0 V}$ is the electric field generated by a single photon in the mode volume V. Exc. 24.6.6.11 asks to calculate the eigenvalues $\langle\hat{\mathcal{E}}\rangle$ and $\Delta\hat{\mathcal{E}}$.

It is sometimes convenient to represent the light field by its quadratures. With the definition $\hat{a} \equiv \hat{x}_1 + \imath\hat{x}_2$, where $\hat{x}_{1,2}$ are non-commuting observables ($[\hat{x}_1, \hat{x}_2] = \imath/2$),

we can write the field as,

$$\hat{\mathcal{E}} = -2\mathcal{E}_1[\hat{x}_1 \sin(\mathbf{k}\cdot\mathbf{r}-\omega t) + \hat{x}_2 \cos(\mathbf{k}\cdot\mathbf{r}-\omega t)] \ . \tag{24.186}$$

Heisenberg's uncertainty relations requires,

$$\Delta x_1 \Delta x_2 \geq \tfrac{1}{4} \ . \tag{24.187}$$

For coherent states, $\Delta x_1 = \Delta x_2 = \frac{1}{2}$.

24.6.6 Exercises

24.6.6.1 Ex: Sum of displacements operators

Prove formula (24.120). Find a geometric interpretation of the phase factor $(\alpha\beta^* - \alpha^*\beta)/2$ in the complex plane of Glauber states.

Solution: *The formula can be derived by utilizing the Baker-Campbell-Hausdorff formula,*

$$e^{\alpha\hat{a}^\dagger - \alpha^*\hat{a}} e^{\beta\hat{a}^\dagger - \beta^*\hat{a}} = e^{(\alpha+\beta)\hat{a}^\dagger - (\beta^*+\alpha^*)\hat{a}} e^{(\alpha\beta^* - \alpha^*\beta)/2} \ .$$

The phase factor measure the area in the Glauber plane enclosed by the amplitudes α, β, and $\alpha+\beta$. To see this we represent the amplitudes as vectors,

$$\alpha \to \begin{pmatrix} \mathfrak{Re}\ \alpha \\ \mathfrak{Im}\ \alpha \\ 0 \end{pmatrix} \qquad \textit{and} \qquad \beta \to \begin{pmatrix} \mathfrak{Re}\ \beta \\ \mathfrak{Im}\ \beta \\ 0 \end{pmatrix} \ .$$

Now, the area is given by,

$$A = \left| \begin{pmatrix} \mathfrak{Re}\ \alpha \\ \mathfrak{Im}\ \alpha \\ 0 \end{pmatrix} \times \begin{pmatrix} \mathfrak{Re}\ \beta \\ \mathfrak{Im}\ \beta \\ 0 \end{pmatrix} \right| = |\mathfrak{Re}\ \alpha \mathfrak{Im}\ \beta - \mathfrak{Im}\ \alpha \mathfrak{Re}\ \beta| = \left| \frac{\alpha^*\beta - \alpha\beta^*}{2\imath} \right| = |\mathfrak{Im}\ \alpha^*\beta| \ .$$

It has the meaning of a geometrical phase.

24.6.6.2 Ex: Harmonic oscillator and coherent states

a. Verify whether the Glauber states of a harmonic oscillator are orthogonal.
b. Show that $\langle\alpha|\hat{n}|\alpha\rangle = |\alpha|^2$, $\langle\alpha|\hat{n}^2|\alpha\rangle = |\alpha|^4 + |\alpha|^2$, and $\Delta\hat{n} = |\alpha|$.
c. What is the population of the state $|n\rangle$ of a harmonic oscillator in a Glauber state?

Solution: *a. This easily follows with*

$$\langle\alpha|\beta\rangle = e^{-|\alpha|^2/2 - |\beta|^2/2} \sum_n \frac{\alpha^{*n}\beta^n}{n!} = e^{-|\alpha|^2/2 - |\beta|^2/2 + \alpha^*\beta} \ ,$$

such that

$$|\langle\alpha|\beta\rangle|^2 = e^{-|\alpha-\beta|^2} \ .$$

b. We calculate

$$\langle\alpha|\hat{n}|\alpha\rangle = \langle\alpha|\hat{a}^\dagger\hat{a}|\alpha\rangle = |\alpha|^2 \ ,$$

and

$$\langle\alpha|\hat{n}^2|\alpha\rangle = \langle\alpha|\hat{a}^\dagger\hat{a}\hat{a}^\dagger\hat{a}|\alpha\rangle = \langle\alpha|\alpha^*\hat{a}\hat{a}^\dagger\alpha|\alpha\rangle = \langle\alpha|\alpha^*(1-\hat{a}^\dagger\hat{a})\alpha|\alpha\rangle = |\alpha|^2 + |\alpha|^4 \ ,$$

and

$$\Delta n = \sqrt{\langle n^2\rangle - \langle n\rangle^2} = |\alpha| \ .$$

c. The population is,

$$|\langle n|\alpha\rangle|^2 = e^{-|\alpha|^2}\frac{|\alpha|^{2n}}{n!} = e^{-\langle n\rangle}\frac{\langle n\rangle^n}{n!} \ .$$

This is a Poisson distribution which, for $\langle n\rangle$ very large, resembles a Gaussian.

24.6.6.3 Ex: Annihilation operator acting on Fock and Glauber states

Show that the annihilation operator $\hat{a}$ does not reduce the photon number of a Glauber state in contrast to a Fock state.

Solution: *We have,*

$$\frac{\langle n|\hat{a}^\dagger\hat{n}\hat{a}|n\rangle}{\langle n|\hat{n}|n\rangle} = n-1 \qquad \textit{but} \qquad \frac{\langle\alpha|\hat{a}^\dagger\hat{n}\hat{a}|\alpha\rangle}{\langle\alpha|\hat{n}|\alpha\rangle} = |\alpha|^2 = n \ .$$

24.6.6.4 Ex: Completeness of coherent states

a. Show,

$$\tfrac{1}{\pi}\int|\alpha\rangle\langle\alpha|d^2\alpha = \sum_{n=0}^{\infty}|n\rangle\langle n| = \mathbb{I} \ .$$

b. Show that coherent states can be expanded in terms of other coherent states and that, consequently, the coherent state basis is overcomplete.

Solution: *a. Using the expansion (24.115) of Glauber into Fock states and writing $\alpha = |\alpha|e^{\imath\theta}$ we find,*

$$\begin{aligned}\int|\alpha\rangle\langle\alpha|d^2\alpha &= \sum_{n,m=0}^{\infty}\frac{|n\rangle\langle m|}{\sqrt{m!}\sqrt{n!}}\int e^{-|\alpha|^2}\alpha^{*m}\alpha^n d^2\alpha \\ &= \sum_{n,m=0}^{\infty}\frac{|n\rangle\langle m|}{\sqrt{m!}\sqrt{n!}}\int_0^\infty e^{-|\alpha|^2}|\alpha|^{m+n+1}d|\alpha|\int_0^{2\pi}e^{\imath(n-m)\theta}d\theta \\ &= \sum_{n,m=0}^{\infty}\frac{|n\rangle\langle m|}{\sqrt{m!}\sqrt{n!}}\times\frac{n!}{2}\times 2\pi\delta_{nm} = \pi\sum_{n=0}^{\infty}|n\rangle\langle n| \ .\end{aligned}$$

b. [1184], p.55.

24.6.6.5 Ex: Schrödinger cat state

Calculate the probability of finding n photons in Schrödinger's cat state $|\psi\rangle = 2^{-1/2}(|\alpha\rangle \pm |-\alpha\rangle)$.

Solution: *The probability is,*

$$P_n = \left|\langle n|\tfrac{1}{\sqrt{2}}(|\alpha\rangle \pm |-\alpha\rangle)\right|^2 = \tfrac{1}{2}\left|e^{-|\alpha|^2/2}\frac{\alpha^n \pm (-\alpha)^n}{\sqrt{n!}}\right|^2 \ .$$

With this, for the sign $(+)$, we have $P_n^{cat} = 2P_n^{coherent}$ if n is even and $P_n^{cat} = 0$ if n is odd. But for the sign $(-)$ it is just the opposite. That is, the loss of a single photon turns the 'cat' $|\alpha\rangle + |-\alpha\rangle$ into a cat $|\alpha\rangle - |-\alpha\rangle$.

24.6.6.6 Ex: Transition elements for arbitrary Lamb-Dicke parameters

Calculate the general expression for $\langle m|e^{\imath k\hat{x}}|n\rangle$ with the abbreviation $\alpha \equiv \imath k a_{ho}/\sqrt{2}$ for arbitrary values of the Lamb-Dicke parameter using the following results of the discussion of the displacement operator $D(\alpha) = e^{\alpha\hat{a}^\dagger - \alpha^*\hat{a}} = e^{-|\alpha|^2/2}e^{\alpha\hat{a}^\dagger}e^{-\alpha^*\hat{a}}$ for Glauber states. The relations

$$|n\rangle = \frac{(\hat{a}^\dagger)^n}{\sqrt{n!}}|0\rangle \qquad \text{and} \qquad \langle n|\alpha\rangle = e^{-|\alpha|^2/2}\frac{\alpha^n}{\sqrt{n!}}$$

describe the relation between Fock and Glauber states. Furthermore,

$$D(-\alpha) = D^\dagger(\alpha) \qquad \text{and} \qquad D^\dagger(\alpha)\hat{a}^\dagger D(\alpha) = \hat{a}^\dagger + \alpha^* \ .$$

Solution: *From the rules for the displacement operator we immediately derive,*

$$D(\alpha)\hat{a}^\dagger = (\hat{a}^\dagger - \alpha^*)D(\alpha) = (\hat{a}^\dagger + \alpha)D(\alpha) \ ,$$

using that in this particular case $\alpha^* = -\alpha$. This allows us to do the following derivation,

$$e^{\imath k\hat{x}}|n\rangle = D(\alpha)|n\rangle = \tfrac{1}{\sqrt{n!}}D(\alpha)(\hat{a}^\dagger)^n|0\rangle = \tfrac{1}{\sqrt{n!}}(\hat{a}^\dagger + \alpha)^n D(\alpha)|0\rangle = \tfrac{1}{\sqrt{n!}}(\hat{a}^\dagger + \alpha)^n|\alpha\rangle \ .$$

Using the binomial expansion $(x+y)^n = \sum_{k=0}^n \binom{n}{k}x^k y^{n-k}$ we calculate,

$$e^{\imath k\hat{x}}|n\rangle = \frac{1}{\sqrt{n!}}\sum_{k=0}^{n}\binom{n}{k}\alpha^{n-k}(\hat{a}^\dagger)^k|\alpha\rangle \ ,$$

such that,

$$\begin{aligned}
\langle m|e^{\imath k\hat{x}}|n\rangle &= \frac{1}{\sqrt{n!}}\sum_{k=0}^{n}\binom{n}{k}\alpha^{n-k}\langle m|(\hat{a}^\dagger)^k|\alpha\rangle \\
&= \frac{1}{\sqrt{n!}}\sum_{k=0}^{n}\binom{n}{k}\alpha^{n-k}\left[\sqrt{m(m-1)}\hat{a}^{k-2}|m-2\rangle\right]^\dagger|\alpha\rangle \\
&= \frac{1}{\sqrt{n!}}\sum_{k=0}^{n}\binom{n}{k}\alpha^{n-k}\sqrt{\frac{m!}{[m-\min(k,m)]!}}\langle m-\min(k,m)|(\hat{a}^\dagger)^{k-\min(k,m)}|\alpha\rangle \ .
\end{aligned}$$

Let us restrict to the case $m \geq n$. Then necessarily $\min(k,m) = k$, *so that,*

$$\begin{aligned}\langle m|e^{\imath k\hat{x}}|n\rangle &= \frac{1}{\sqrt{n!}}\sum_{k=0}^{n}\binom{n}{k}\alpha^{n-k}\sqrt{\frac{m!}{(m-k)!}}\langle m-k|\alpha\rangle \\ &= \sum_{k=0}^{n}\sqrt{\binom{n}{k}}\frac{\alpha^{n-k}}{\sqrt{(n-k)!}}\sqrt{\binom{m}{k}}\langle m-k|\alpha\rangle \\ &= e^{|\alpha|^2/2}\sum_{k=0}^{n}\sqrt{\binom{n}{k}\binom{m}{k}}\langle n-k|\alpha\rangle\langle m-k|\alpha\rangle \ .\end{aligned}$$

The case $m \leq n$ can be calculated via,

$$\langle m|e^{\imath k\hat{x}}|n\rangle = \langle n|e^{-ik\hat{z}}|m\rangle^* = \langle n|D(-\alpha)|m\rangle^* = \langle n|D(\alpha)|m\rangle \ ,$$

which gives us the same formula.
With the last formula we recover the expression (24.136) for $\langle m|e^{-\imath k\hat{z}}|0\rangle$. We also recover the expressions (24.139),

$$\begin{aligned}\langle m|e^{\imath k\hat{x}}|m\rangle &\overset{\alpha\to 0}{\longrightarrow} \sum_{k=0}^{m}\frac{m!\alpha^{2m-2k}}{k!(m-k)!^2} \overset{\alpha\to 0}{\longrightarrow} 1 \\ \langle m|e^{\imath k\hat{x}}|m-1\rangle &\overset{\alpha\to 0}{\longrightarrow} \sum_{k=0}^{m-1}\frac{\sqrt{(m-1)!}\sqrt{m!}}{k!(m-1-k)!(m-k)!}\alpha^{2m-1-2k} \overset{\alpha\to 0}{\longrightarrow} \sqrt{m}\alpha \\ \langle m|e^{\imath k\hat{x}}|m+1\rangle &\overset{\alpha\to 0}{\longrightarrow} \sum_{k=0}^{m+1}\frac{\sqrt{(m+1)!}\sqrt{m!}}{k!(m+1-k)!(m-k)!}\alpha^{2m+1-2k} \overset{\alpha\to 0}{\longrightarrow} \sqrt{m+1}\alpha \ .\end{aligned}$$

24.6.6.7 Ex: Lamb-Dicke regime

A rubidium atom is trapped in an isotropic harmonic trap with secular frequency $\omega_{ho} = (2\pi)\ 1\,\text{kHz}$. Determine whether, driven on its D_2 line, it is within the Lamb-Dicke regime.

Solution: *The frequency of the D_2-line is* 780 nm. *Hence, the recoil frequency is,*

$$\omega_{rec} = \frac{\hbar k^2}{2m} \approx (2\pi)\ 3.54\,\text{kHz} \ ,$$

and the Lamb-Dicke parameter,

$$\eta = \sqrt{\frac{\omega_{rec}}{\omega_{ho}}} \approx 2 \ .$$

24.6.6.8 Ex: Resonantly excited harmonic oscillator

Write down the Hamiltonian of a harmonic oscillator subject to an oscillating homogenous force, and numerically simulate the evolution of the vibrational states starting from the ground state.

Solution: *Writing the force as,*

$$F = -\frac{d\hat{H}_F}{dx} = F_0 \cos\omega t \ ,$$

we see that it can be derived from the potential,

$$\hat{H}_F = -F_0 \hat{x} \cos\omega t \ .$$

Doing the RWA defining the Rabi frequency Ω as an abbreviation,

$$\hat{H}_F = -F_0 \tfrac{\sqrt{2}}{a_{ho}} (\hat{a} e^{\imath\omega t} + \hat{a}^\dagger e^{-\imath\omega t}) \equiv \tfrac{\hbar\Omega}{2} (\hat{a} e^{\imath\omega t} + \hat{a}^\dagger e^{-\imath\omega t}) \ .$$

In matrix formalism,

$$\begin{aligned}
\hat{H} &= \frac{\hat{p}^2}{2m} + V(\hat{x}) + \hat{H}_F \\
&= \sum_n \left[\hbar\omega_0 (n|n\rangle\langle n| + \tfrac{1}{2}) + \tfrac{\hbar\Omega}{2} e^{\imath\omega t} \sqrt{n} |n-1\rangle\langle n| + \tfrac{\hbar\Omega}{2} e^{-\imath\omega t} \sqrt{n+1} |n+1\rangle\langle n| \right] \\
&= \hbar \begin{pmatrix} \ddots & \ddots & & \\ \ddots & (n-1)\omega_0 & \frac{\Omega}{2} e^{\imath\omega t}\sqrt{n} & \\ & \frac{\Omega}{2} e^{-\imath\omega t}\sqrt{n} & n\omega_0 & \ddots \\ & & \ddots & \ddots \end{pmatrix} + \frac{\hbar\omega_0}{2} \mathcal{I} \ .
\end{aligned}$$

Transforming the eigenstates of the Schrödinger equation according to $|n'\rangle = e^{\imath n\omega t}|n\rangle$, or alternatively transforming the Hamiltonian according to,

$$\hat{H}' = U^\dagger \hat{H} U + i\hbar \dot{U}^\dagger U$$

with the unitary transformation,

$$U \equiv \begin{pmatrix} \ddots & \ddots & & \\ \ddots & e^{\imath(n-1)\omega t} & 0 & \\ & 0 & e^{\imath n\omega t} & \ddots \\ & & \ddots & \ddots \end{pmatrix} \ ,$$

we get,

$$\hat{H}' = \hbar \begin{pmatrix} \ddots & \ddots & & \\ \ddots & -(n-1)\Delta & \frac{\Omega}{2}\sqrt{n} & \\ & \frac{\Omega}{2}\sqrt{n} & -n\Delta & \ddots \\ & & \ddots & \ddots \end{pmatrix} + \frac{\hbar\omega_0}{2} \ ,$$

where we defined $\Delta \equiv \omega - \omega_0$.

24.6.6.9 Ex: Shifted harmonic oscillator

Consider a HO of mass m, angular frequency ω, and electric charge q immersed in a uniform electric field oriented parallel to the axis $\hat{\mathbf{e}}_x$ of the oscillator.
a. Get the energies of the stationary states of the HO and show how to get the corresponding eigenstates.
b. Calculate the expectation values $\langle x\rangle$ and $\langle p\rangle$ for the displaced oscillator now using Glauber states (or arbitrary superpositions of states) and taking advantage of the formulas (24.86), (24.119), and (23.179).
c. Now, the electric field is suddenly turned off. Calculate the time evolution of the oscillator.

Solution: *We consider an electron in a harmonic potential suddenly subject to an electric field,*

$$\hat{H} = \begin{cases} \hat{H}^{(1)} = \frac{p^2}{2m} + \frac{m}{2}\omega^2 x^2 + e\mathcal{E}x & for \quad t < 0 \\ \hat{H} = \frac{p^2}{2m} + \frac{m}{2}\omega^2 x^2 & for \quad t \geq 0 \end{cases} .$$

a. With the abbreviation $b \equiv \frac{e\mathcal{E}}{m\omega^2}$ *we can rewrite the Hamiltonian*

$$\hat{H}^{(1)} = \frac{p^2}{2m} + \frac{m}{2}\omega^2(x-b)^2 - \frac{m}{2}\omega^2 b^2 \ ,$$

with the obvious solution

$$\hat{H}^{(1)}|\psi_n^{(1)}\rangle = E_n^{(1)}|\psi_n^{(1)}\rangle \qquad , \qquad \psi_n^{(1)}(x) = \psi_n(x-b) \qquad , \qquad E_n^{(1)} = E_n - \frac{m}{2}\omega^2 b^2 \ .$$

b. With the Taylor expansion

$$\psi_n(x-b) = \psi_n(x) - b\psi_n'(x) + \frac{(-b)^2}{2!}\psi_n''(x) + .. = e^{-b(d/dx)}\psi_n(x) \ ,$$

and the abbreviation $\beta \equiv \frac{b}{a_{ho}\sqrt{2}}$ *we can rewrite,* $|\psi_n^{(1)}(x)\rangle = e^{-\beta(\hat{a}-\hat{a}^\dagger)}|\psi_n\rangle$. *The expectation value of* $\hat{a}$ *is therefore,*

$$\langle\psi_n^{(1)}|\hat{a}|\psi_n^{(1)}\rangle = \langle\psi_n|e^{-\beta(\hat{a}^\dagger-\hat{a})}\hat{a}e^{-\beta(\hat{a}-\hat{a}^\dagger)}|\psi_n\rangle \ .$$

Using the formula (23.179) we have

$$e^{-\beta(\hat{a}^\dagger-\hat{a})}\hat{a}e^{-\beta(\hat{a}-\hat{a}^\dagger)} = \hat{a} + \beta[\hat{a}-\hat{a}^\dagger, \hat{a}] = \hat{a} + \beta \ ,$$

which verifies the formula postulated in class (24.119). Hence, $\langle\psi_n^{(1)}|\hat{a}|\psi_n^{(1)}\rangle = \langle\psi_n|\hat{a}+\beta|\psi_n\rangle$ *and* $\langle\psi_n^{(1)}|\hat{a}^\dagger|\psi_n^{(1)}\rangle = \langle\psi_n|\hat{a}^\dagger+\beta|\psi_n\rangle$, *tal que,*

$$\langle\psi_n^{(1)}|\hat{x}|\psi_n^{(1)}\rangle = b \qquad and \qquad \langle\psi_n^{(1)}|\hat{p}|\psi_n^{(1)}\rangle = 0 \ .$$

c. The temporal evolution is given by the time-dependent Schrödinger equation. Since the jump is finite, the solution must be well behaved in time $t = 0$,

$$\psi_n^{(1)}(x,t) = \begin{cases} e^{-(\imath/\hbar)\hat{H}^{(1)}t}\psi_n^{(1)}(x) = e^{-(\imath/\hbar)E_n^{(1)}t}\psi_n^{(1)}(x) & \textit{for} \quad t < 0 \\ e^{-(\imath/\hbar)\hat{H}t}\psi_n^{(1)}(x) & \textit{for} \quad t \geq 0 \end{cases} .$$

For times $t \geq 0$ we write,

$$\psi_n^{(1)}(x,t) = e^{-(\imath/\hbar)Ht}e^{-\beta(\hat{a}-\hat{a}^\dagger)}\psi_n(x) = e^{-(\imath/\hbar)\hat{H}t}e^{-\beta(\hat{a}-\hat{a}^\dagger)}e^{(\imath/\hbar)\hat{H}t}e^{-(\imath/\hbar)\hat{H}t}\psi_n(x) .$$

We now use the relationship

$$e^{-\hat{A}}e^{\hat{B}}e^{\hat{A}} = \sum_n \frac{e^{-\hat{A}}\hat{B}^n e^{\hat{A}}}{n!} = \sum_n \frac{(e^{-\hat{A}}\hat{B}e^{\hat{A}})^n}{n!} = e^{e^{-\hat{A}}\hat{B}e^{\hat{A}}} ,$$

which is easy to show by expansion of $e^{\hat{B}}$. The expression $e^{-\hat{A}}\hat{B}e^{\hat{A}}$ can be evaluated through its action on the complete system of eigenfunctions,

$$e^{-(\imath/\hbar)\hat{H}t}\hat{a}e^{(\imath/\hbar)\hat{H}t}|\psi_n\rangle = e^{-(\imath/\hbar)\hat{H}t}\hat{a}e^{(\imath/\hbar)E_n^{(0)}t}|\psi_n\rangle = e^{-(\imath/\hbar)E_{n-1}^{(0)}t}e^{(\imath/\hbar)E_n^{(0)}t}\hat{a}|\psi_n\rangle .$$

Hence,

$$e^{-(\imath/\hbar)\hat{H}t}\hat{a}e^{(\imath/\hbar)\hat{H}t} = \hat{a}e^{\imath\omega t} \qquad \textit{and} \qquad e^{-(\imath/\hbar)\hat{H}t}\hat{a}^\dagger e^{(\imath/\hbar)\hat{H}t} = \hat{a}^\dagger e^{-\imath\omega t} .$$

Now we can write the temporal solution,

$$\psi_n^{(1)}(x,t) = e^{-\beta(\hat{a}e^{\imath\omega t}-\hat{a}^\dagger e^{-\imath\omega t})}e^{-(\imath/\hbar)\hat{H}t}\psi_n(x) = e^{-\beta\cos\omega t(\hat{a}-\hat{a}^\dagger)-\imath\beta\sin\omega t(\hat{a}+\hat{a}^\dagger)}e^{-(\imath/\hbar)E_n^{(0)}t}\psi_n(x) .$$

Using Glauber's formula (23.210) we find,

$$\begin{aligned}\psi_n^{(1)}(x,t) &= e^{-\imath\beta\sin\omega t(\hat{a}+\hat{a}^\dagger)}e^{-\beta\cos\omega t(\hat{a}-\hat{a}^\dagger)}e^{\imath\beta^2\sin\omega t\cos\omega t}e^{-(\imath/\hbar)E_n^{(0)}t}\psi_n(x) \\ &= e^{-\imath\beta\sin\omega t(\hat{a}+\hat{a}^\dagger)}e^{\imath\beta^2\sin\omega t\cos\omega t}e^{-(\imath/\hbar)E_n^{(0)}t}\psi_n(x - b\cos\omega t) .\end{aligned}$$

Finally,

$$|\psi_n^{(1)}(x,t)|^2 = |\psi_n(x - \bar{x}(t))|^2 ,$$

where $\bar{x}(t) \equiv b\cos\omega t$. This means that the spatial distribution of $\psi_n^{(1)}$ around $\bar{x}(t)$ is the same as of ψ_n around $\bar{x} = 0$. The entire distribution oscillates without deformation. The momentum distribution follows from the Fourier transform,

$$\begin{aligned}\phi_n^{(1)}(p,t) &= \frac{1}{\sqrt{2\pi\hbar}}\int dx e^{-(\imath/\hbar)px}\psi_n^{(1)} = \frac{1}{\sqrt{2\pi\hbar}}\int du\ e^{-(\imath/\hbar)pu}e^{-(\imath/\hbar)um\omega b\sin\omega t}e^{\imath\gamma(p,t)}\psi_n \\ &= e^{\imath\gamma(p,t)}\phi_n(p + m\omega b\sin\omega t) ,\end{aligned}$$

with $\gamma = \gamma^*$. We obtain,

$$|\phi_n^{(1)}(p,t)|^2 = |\phi_n(p - \bar{p}(t))|^2 ,$$

where $\bar{p}(t) \equiv -m\omega b\sin\omega t$.

24.6.6.10 Ex: Spatial wavefunction of a particle in a coherent state

a. Derive the following relations for the harmonic oscillator having received a recoil momentum,

$$\langle\psi_n^{(1)}|\hat{x}|\psi_n^{(1)}\rangle = 0 \qquad \text{and} \qquad \langle\psi_n^{(1)}|\hat{p}|\psi_n^{(1)}\rangle = \hbar k \ .$$

b. Calculate the temporal evolution of the oscillator after having received the recoil via,

$$\langle x|e^{-\imath\hat{H}t/\hbar}e^{-\imath k\hat{x}}|n\rangle \ .$$

c. Calculate the spatial wavefunction of a particle in a coherent state,

$$\langle x|\alpha\rangle = \sum_n e^{-|\alpha|^2/2}\frac{\alpha^n}{\sqrt{n!}}\langle x|n\rangle \ .$$

Solution: *a. We calculate,*

$$\begin{aligned}\langle\psi_n^{(1)}|\hat{x}|\psi_n^{(1)}\rangle &= \tfrac{a_{ho}}{\sqrt{2}}\langle n|e^{\imath k\hat{x}}(\hat{b}+\hat{b}^\dagger)e^{-\imath k\hat{x}}|n\rangle \\ &= \tfrac{a_{ho}}{\sqrt{2}}\langle\alpha|\hat{b}+\hat{b}^\dagger|\alpha\rangle = \tfrac{a_{ho}}{\sqrt{2}}(\alpha+\alpha^*)\langle\alpha|\alpha\rangle = 0 \ ,\end{aligned}$$

and,

$$\begin{aligned}\langle\psi_n^{(1)}|\hat{p}|\psi_n^{(1)}\rangle &= \tfrac{\hbar}{\imath\sqrt{2}a_{ho}}\langle n|e^{\imath k\hat{x}}(\hat{b}-\hat{b}^\dagger)e^{-\imath k\hat{x}}|n\rangle \\ &= \tfrac{\hbar}{\imath\sqrt{2}a_{ho}}(\alpha-\alpha^*)\langle\alpha|\alpha\rangle = -\hbar k \ .\end{aligned}$$

b.

24.6.6.11 Ex: Electric field amplitude and fluctuation

Calculate $\langle\hat{\mathcal{E}}\rangle$ and $\Delta\hat{\mathcal{E}}$ for a coherent state.

Solution: *The results are,*

$$\langle\hat{\mathcal{E}}\rangle = -2\hat{\mathcal{E}}_m|\alpha|\sin(\mathbf{k}\cdot\mathbf{r}-\omega t) \quad , \quad \langle\hat{\mathcal{E}}^2\rangle = \hat{\mathcal{E}}_m^2[4|\alpha|^2\sin(\mathbf{k}\cdot\mathbf{r}-\omega t)+1] \quad , \quad \Delta\hat{\mathcal{E}} = \hat{\mathcal{E}}_m \ .$$

24.6.6.12 Ex: Beam splitting a Fock state

A beam splitter is a device dividing an input mode (e.g. a laser beam) into two output modes 1 and 2. Assuming that a beam splitter sends every single photon with equal probability to one of the two output modes and that the input mode be a Fock state, what would be the photon statistics in the output mode? **Help:** Create the total output state $|n_1, n_2\rangle$ from vacuum by successive application of the photon creation operator $\hat{a}_1^\dagger + \hat{a}_2^\dagger$.

Solution: *See Sec. 35.8.2.*

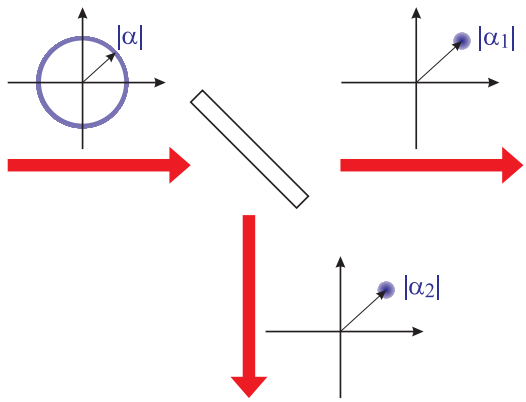

Figure 24.25: Beam splitting of a Fock state.

24.6.6.13 Ex: Wavefunction of a harmonic oscillator in a Glauber state

Derive the wavefunction for a harmonic oscillator in a coherent state using the exponential generating function of Hermite polynomials,

$$e^{2xt-t^2} = \sum_{n=0}^{\infty} \frac{t^n}{n!} H_n(x) \ .$$

Solution: *Starting from,*

$$\langle x|n\rangle = \frac{1}{\sqrt{a_{ho}\sqrt{\pi}2^n n!}} e^{-x^2/2a_{ho}^2} H_n(x/a_{ho}) \qquad \textit{and} \qquad |\alpha\rangle = e^{-|\alpha|^2/2} \sum_{n=0}^{\infty} \frac{\alpha^n}{\sqrt{n!}} |n\rangle$$

we obtain,

$$\langle x|\alpha\rangle = \frac{e^{-|\alpha|^2/2} e^{-x^2/2a_{ho}^2}}{\sqrt{a_{ho}\sqrt{\pi}}} \sum_{n=0}^{\infty} \frac{(\alpha/\sqrt{2})^n}{n!} H_n(x/a_{ho}) \ .$$

Using the given generating function we get,

$$\langle x|\alpha\rangle = \frac{1}{\sqrt{a_{ho}\sqrt{\pi}}} e^{-|\alpha|^2/2 - x^2/2a_{ho}^2 + \sqrt{2}\alpha x/a_{ho} - \alpha^2/2} \ ,$$

and,

$$|\langle x|\alpha\rangle|^2 = \frac{1}{a_{ho}\sqrt{\pi}} e^{-[(\alpha+\alpha^*)/\sqrt{2} + x/a_{ho}]^2} \ .$$

Chapter 25

Rotations / Central potentials

Rotations are, on the same rights as translations, symmetry operations in space. They are of fundamental importance for the discussion of composite particles, such as atoms because they help us to formulate appropriate boundary conditions facilitating the solution of the three-dimensional Schrödinger equation.

25.1 Particle in a central potential

Many potentials do not have Cartesian symmetry, but fortunately, many problems have *some* kind of symmetry, cylindrical, spherical or periodic. Those with cylindrical or spherical symmetry can be solved by separating the curvilinear coordinates, as we will show in the following. Particularly important are spherical potentials caused by central forces, for example, the Coulomb force between the proton and the electron in the hydrogen atom.

25.1.1 Transformation to relative coordinates

The hydrogen atom represents a *two-body problem*. We consider the two masses $m_{1,2}$ of a proton and an electron separated by a distance $\mathbf{r}$ and interacting through a potential $V(\mathbf{r})$. The Hamiltonian is

$$\hat{H} = \frac{-\hbar^2}{2m_1}\nabla_{r1}^2 + \frac{-\hbar^2}{2m_2}\nabla_{r2}^2 + V(\mathbf{r}_1 - \mathbf{r}_2) \ , \tag{25.1}$$

where $\mathbf{r}_{1,2}$ are the positions of the proton and the electron. With the ansatz $\Xi(t, \mathbf{r}_1, \mathbf{r}_2) = \Xi(\mathbf{r}_1, \mathbf{r}_2)e^{-\imath E_{tot}t/\hbar}$, the time-dependent Schrödinger equation

$$\hat{H}\Xi(t, \mathbf{r}_1, \mathbf{r}_2) = \imath\hbar\frac{d}{dt}\Xi(t, \mathbf{r}_1, \mathbf{r}_2) \ , \tag{25.2}$$

becomes stationary,

$$\left[\frac{-\hbar^2}{2m_1}\nabla_{r_1}^2 + \frac{-\hbar^2}{2m_2}\nabla_{r_2}^2 + V(\mathbf{r}_1 - \mathbf{r}_2)\right]\Xi(\mathbf{r}_1, \mathbf{r}_2) = E_{tot}\Xi(\mathbf{r}_1, \mathbf{r}_2) \ . \tag{25.3}$$

Now we transform into the center-of-mass system making for the total wavefunction the ansatz $\Xi(\mathbf{r}_1, \mathbf{r}_2) = e^{-\imath\mathbf{P}\cdot\mathbf{R}/\hbar}\Psi(\mathbf{r})$ with $\mathbf{R} \equiv \frac{m_1}{M}\mathbf{r}_1 + \frac{m_2}{M}\mathbf{r}_2$ and $\mathbf{r} \equiv \mathbf{r}_1 - \mathbf{r}_2$ and introducing the abbreviation $M = m_1 + m_2$. This corresponds to a product of a plane

wave, describing the linear motion of the center of the masses, and a radial wave function, which describes the relative motion of the atom. The kinetic energy of one mass is:

$$\begin{aligned}&\frac{-\hbar^2}{2m_1}\nabla_{r_1}^2 e^{-\imath\mathbf{P}\cdot\mathbf{R}/\hbar}\Psi(\mathbf{r}) \qquad (25.4)\\ &= \frac{-\hbar^2}{2m_1}\left[e^{-\imath\mathbf{P}\cdot\mathbf{R}/\hbar}\nabla_{r_1}^2\Psi(\mathbf{r}) + 2(-\tfrac{\imath m_1\mathbf{P}}{\hbar M})e^{-\imath\mathbf{P}\cdot\mathbf{R}/\hbar}\nabla_{r_1}\Psi(\mathbf{r}) + \Psi(\mathbf{r})(-\tfrac{\imath m_1}{\hbar^2 M}\mathbf{P})^2 e^{-\imath\mathbf{P}\cdot\mathbf{R}/\hbar}\right]\\ &= e^{-\imath\mathbf{P}\cdot\mathbf{R}/\hbar}\left[\frac{-\hbar^2}{2m_1}\nabla_{r_1}^2\Psi(\mathbf{r}) + \frac{\imath\hbar\mathbf{P}}{M}\nabla_{r_1}\Psi(\mathbf{r}) - \frac{m_1\mathbf{P}^2}{2M^2}\Psi(\mathbf{r})\right] .\end{aligned}$$

Hence, for two atoms,

$$\begin{aligned}&E_{tot}\Xi(\mathbf{r}_1,\mathbf{r}_2) - V(\mathbf{r})\Xi(\mathbf{r}_1,\mathbf{r}_2) \qquad (25.5)\\ &= e^{-\imath\mathbf{P}\cdot\mathbf{R}/\hbar}\left[\frac{-\hbar^2}{2m_1}\nabla_{r_1}^2\Psi(\mathbf{r}) + \frac{-\hbar^2}{2m_2}\nabla_{r_2}^2\Psi(\mathbf{r}) + \frac{\imath\hbar\mathbf{P}}{M}(\nabla_{r_1}+\nabla_{r_2})\Psi(\mathbf{r}) + \frac{\mathbf{P}^2}{2M}\Psi(\mathbf{r})\right] .\end{aligned}$$

Using $\nabla_{r_1} = -\nabla_{r_2} = \nabla_r$, we see that the third term cancels, such that,

$$\frac{P^2}{2M}\Psi(\mathbf{r}) + \frac{-\hbar^2}{2m_1}\nabla_r^2\Psi(\mathbf{r}) + \frac{-\hbar^2}{2m_2}\nabla_r^2\Psi(\mathbf{r}) + V(\mathbf{r})\Psi(\mathbf{r}) = E_{tot}\Psi(\mathbf{r}) . \qquad (25.6)$$

Subtracting the energy of the center-of-mass motion with $E = E_{tot} - \frac{P^2}{2M}$ and introducing the abbreviation $m^{-1} = m_1^{-1} + m_2^{-1}$, we finally get,

$$\boxed{\left[\frac{-\hbar^2}{2m}\nabla_r^2 + V(\mathbf{r})\right]\Psi(\mathbf{r}) = E\Psi(\mathbf{r})} . \qquad (25.7)$$

25.1.2 Particle in a cylindrical potential

The equation (25.7) is three-dimensional because $\Psi(\mathbf{r})$ is a *scalar field* and the momentum operator in Cartesian coordinates is given by,

$$\nabla_r^2 = \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} + \frac{\partial^2}{\partial z^2} . \qquad (25.8)$$

However, in some situations, the symmetry of the system allows to reduce dimensionality similarly to the cases of the box potential and the three-dimensional harmonic oscillator. Let us now discuss the cases of cylindrical and spherical symmetry.

Electrons in magnetic fields are subject to the Lorentz force, which keeps them in a rotating motion. We can rewrite the momentum operator in cylindrical coordinates,

$$x = \rho\cos\varphi \quad , \quad y = \rho\sin\varphi \quad , \quad z = z , \qquad (25.9)$$

as

$$\nabla_r^2 = \frac{\partial^2}{\partial\rho^2} + \frac{1}{\rho}\frac{\partial}{\partial\rho} + \frac{1}{\rho^2}\frac{\partial^2}{\partial\varphi^2} + \frac{\partial^2}{\partial z^2} . \qquad (25.10)$$

Now, with the assumption that the potential only depends on ρ, $V(\mathbf{r}) = V(\rho)$, we can try the ansatz,

$$\Psi(\mathbf{r}) = R(\rho)\xi(\varphi)\zeta(z) , \qquad (25.11)$$

and obtain,

$$\frac{1}{R(\rho)}\left[-\frac{\hbar^2}{2m}\left(\frac{\partial^2}{\partial\rho^2}+\frac{1}{\rho}\frac{\partial}{\partial\rho}+V(\rho)\right)\right]R(\rho)-\frac{\hbar^2}{2m}\frac{1}{\zeta(z)}\frac{\partial^2}{\partial z^2}\zeta(z)-\frac{\hbar^2}{2m\rho^2}\frac{1}{\xi(\varphi)}\frac{\partial^2}{\partial\varphi^2}\xi(\varphi)=E\,. \tag{25.12}$$

First, we separate the axial motion,

$$-\frac{\zeta''}{\zeta}=const\equiv\frac{2mE_z}{\hbar^2}\equiv k_z^2\,, \tag{25.13}$$

the solution of this equation being a superposition of two plane waves counterpropagating along the axis z, $\zeta(z)=Ae^{\imath k_z z}+Be^{-\imath k_z z}$. Now, we separate the azimuthal motion,

$$\frac{\rho^2}{R(\rho)}\frac{\partial R^2(\rho)}{\partial\rho^2}+\frac{\rho}{R(\rho)}\frac{\partial R(\rho)}{\partial\rho}+\frac{2m\rho^2}{\hbar^2}[E-V(\rho)]-\rho^2k_z^2=-\frac{\xi''}{\xi}=const\equiv m_\varphi^2\,. \tag{25.14}$$

The solution of the right-hand part of the equation is $\xi(\varphi)=Ce^{\imath m_\varphi\varphi}+De^{-\imath m_\varphi\varphi}$. Finally, we have the radial equation,

$$\frac{1}{R(\rho)}\frac{\partial R(\rho)^2}{\partial\rho^2}+\frac{1}{\rho R(\rho)}\frac{\partial R(\rho)}{\partial\rho}-\frac{2m}{\hbar^2}[E-V(\rho)]-k_z^2-\frac{m_\varphi^2}{\rho^2}=0\,, \tag{25.15}$$

with the effective potential $V_{eff}=V(\rho)+\frac{\hbar^2m_\varphi^2}{2m\rho^2}$. For a homogeneous potential, $V(\rho)=V_0$, the solution will be a superposition of Bessel functions.

Example 162 (*Rigid rotor in cylindrical coordinates*): To give an example, we disregard the potential, $V(\rho)=0$, and we consider for the particle an orbit with constant radius, $\rho=const$ such that $R(\rho)=\delta(\rho-\rho_0)$. In this case, we only need to treat the orbital motion described by the right part of Eq. (25.14). For the solution of this equation, $\xi(\varphi)=Ae^{\imath m_\varphi\varphi}$, to be well-defined, we need $\xi(\varphi)=\xi(\varphi+2\pi)$. This implies,

$$m_\varphi=0,\pm1,\pm2,..$$

and

$$E_\varphi=\frac{\hbar^2m_\varphi^2}{2m\rho^2}\,.$$

The allowed energies $E_{m_\varphi}=E_\varphi$ can be obtained by letting the Hamiltonian

$$\hat{H}=-\frac{\hbar^2}{2I}\frac{\partial^2}{\partial\varphi^2}\,,$$

with the moment of inertia $I=m\rho^2$ actuate on the azimuthal wavefunction $\xi(\varphi)$. We now define the operator,

$$\hat{l}_z=\frac{\hbar}{\imath}\frac{\partial}{\partial\varphi}\,.$$

This operator acts on the wavefunction ξ as follows,

$$\hat{l}_z\xi(\varphi)=\hbar m_\varphi\xi(\varphi)\,.$$

It is easy to show that wavefunctions with different values m_l are orthogonal.
Note: 1. The state $m_\varphi=0$ has zero energy; that is, it has no zero-point energy.
2. The particle is delocalized within a ring of radius r: $\Delta l_z\Delta\sin\varphi\geq\frac{\hbar}{2}|\langle\cos\varphi\rangle|$.

25.1.3 Hamiltonian in spherical coordinates

We can rewrite the momentum operator in spherical coordinates,

$$x = r\sin\vartheta\cos\varphi \quad , \quad y = r\sin\vartheta\sin\varphi \quad , \quad z = r\cos\vartheta \ , \tag{25.16}$$

as [1],

$$\nabla_r^2 = \frac{1}{r^2}\frac{\partial}{\partial r}\left(r^2\frac{\partial}{\partial r}\right) + \frac{1}{r^2}\frac{\hat{\mathbf{L}}^2}{\hbar^2} \qquad \text{where} \qquad \frac{\hat{\mathbf{L}}^2}{\hbar^2} \equiv \frac{1}{\sin\vartheta}\frac{\partial}{\partial\vartheta}\left(\sin\vartheta\frac{\partial}{\partial\vartheta}\right) + \frac{1}{\sin^2\vartheta}\frac{\partial^2}{\partial\varphi^2} \ , \tag{25.17}$$

is an abbreviation called *Legendre operator*. For an isotropic potential, $V(\mathbf{r}) = V(r)$, we can try the ansatz,

$$\Psi(\mathbf{r}) = R(r)Y(\vartheta,\varphi) \tag{25.18}$$

to solve the Schrödinger equation (23.60),

$$\frac{r^2}{R(r)}\left[-\frac{\hbar^2}{2m}\frac{1}{r^2}\frac{\partial}{\partial r}\left(r^2\frac{\partial}{\partial r}\right) + V(r) - E\right]R(r) = \frac{-1}{2m}\frac{\hat{\mathbf{L}}^2 Y(\vartheta,\varphi)}{Y(\vartheta,\varphi)} = const \equiv -\frac{\hbar^2}{2m}\ell(\ell{+}1) \ , \tag{25.19}$$

where we choose a separation constant, $\ell(\ell+1)$, the significance of which we shall soon learn. Considering only the angular part,

$$\boxed{\hat{\mathbf{L}}^2 Y(\vartheta,\varphi) = \hbar^2\ell(\ell+1)Y(\vartheta,\varphi)} \ , \tag{25.20}$$

and making another separation ansatz,

$$Y(\vartheta,\varphi) = \Theta(\vartheta)\Phi(\varphi) \ , \tag{25.21}$$

we obtain,

$$\sin^2\vartheta\left(\frac{1}{\Theta(\vartheta)}\frac{1}{\sin\vartheta}\frac{\partial}{\partial\vartheta}\sin\vartheta\frac{\partial}{\partial\vartheta}\Theta(\vartheta) + \ell(\ell+1)\right) = -\frac{1}{\Phi(\varphi)}\frac{\partial^2}{\partial\varphi^2}\Phi(\varphi) = const \equiv m^2 \ , \tag{25.22}$$

where we choose a separation constant, m^2. Introducing another abbreviation,

$$\hat{L}_z \equiv \frac{\hbar}{\imath}\frac{\partial}{\partial\varphi} \ , \tag{25.23}$$

the azimuthal equation takes the form

$$\boxed{\hat{L}_z\Phi(\varphi) = \hbar m\Phi(\varphi)} \ . \tag{25.24}$$

As in the case of the cylindrical potential, the solution of the *azimuthal equation* is, using the normalization,

$$\Phi(\varphi) = \tfrac{1}{\sqrt{2\pi}}e^{\imath m\varphi} \ , \tag{25.25}$$

with the *magnetic quantum number* $m = 0, \pm1, \pm2, ...$

[1] We may also write: $\mathbf{p}^2 = (\hat{\mathbf{e}}_r\cdot\mathbf{p})^2 + (\hat{\mathbf{e}}_r\times\mathbf{p})^2 = p_r^2 + \frac{\mathbf{L}^2}{r^2}$, where p_r^2 is the radial part of the Laplace operator and $\frac{\mathbf{L}^2}{r^2}$ the angular part.

The *polar equation*,

$$\frac{1}{\Theta(\vartheta)}\frac{1}{\sin\vartheta}\frac{\partial}{\partial\vartheta}\sin\vartheta\frac{\partial}{\partial\vartheta}\Theta(\vartheta)+\ell(\ell+1)=\frac{m^2}{\sin^2\vartheta}\ , \tag{25.26}$$

is called Legendre's differential equation and can be solved by a power series in $\cos^k\vartheta$. For $m=0$, the solutions are the *Legendre polynomials*, $P_\ell(\cos\vartheta)$ with

$$P_\ell(z)=\frac{1}{2^\ell\ell!}\frac{d^\ell}{dz^\ell}[(z^2-1)^\ell]\ . \tag{25.27}$$

The first polynomials are,

$$P_0(z)=1\quad,\quad P_1(z)=z\quad,\quad P_2(z)=\tfrac{1}{2}(3z^2-1)\quad,\quad P_3(z)=\tfrac{1}{2}(5z^3-3z)\ . \tag{25.28}$$

For $m>0$, the solutions are the associated polynomials,

$$P_\ell^m(z)=(-1)^m(1-z^2)^{m/2}\frac{d^m}{dz^m}P_\ell(z)=\frac{(-1)^m}{2^\ell\ell!}(1-z^2)^{m/2}\frac{d^{\ell+m}}{dz^{\ell+m}}[(z^2-1)^\ell] \tag{25.29}$$

$$P_\ell^{-m}(z)=(-1)^m\frac{(\ell-m)!}{(\ell+m)!}P_\ell^m(z)\ .$$

The polar function must still be normalized,

$$\Theta_\ell^m(\vartheta)=P_\ell^m(\cos\vartheta)\sqrt{\frac{2\ell+1}{2}\frac{(\ell-m)!}{(\ell+m)!}}\ . \tag{25.30}$$

The functions $Y_{\ell m}(\vartheta,\varphi)$ are the *spherical harmonics*. They form an orthonormal system,

$$\int_0^\pi\int_0^{2\pi}Y^*_{\ell'm'}(\vartheta,\varphi)Y_{\ell m}(\vartheta,\varphi)\sin\vartheta d\vartheta d\varphi=\delta_{\ell'\ell}\delta_{m'm}\ . \tag{25.31}$$

Finite solutions only exist when the *angular momentum quantum number* is $\ell=0,1,..$ and for $|m|\le\ell$.

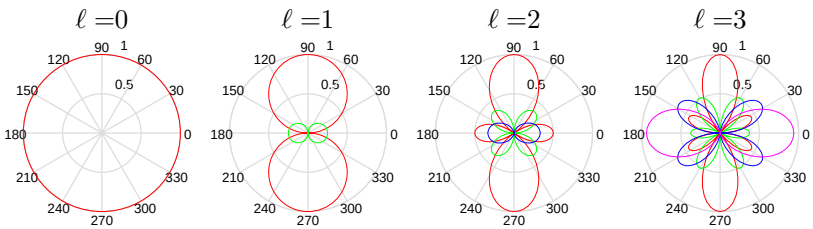

Figure 25.1: (code) Angular wavefunctions. Shown are the Legendre polynomials $P_\ell^m(\cos\vartheta)$ for $\ell=0,1,2,3$ and $m=0,..,\ell$. Red: $m=0$, green: $|m|=1$, blue: $|m|=2$, and magenta: $|m|=3$.

The solutions of the angular part of the Schrödinger equation for the hydrogen atom are finally,

$$\boxed{Y_{\ell m}(\vartheta,\varphi) = \frac{1}{\sqrt{2\pi}}\, P_\ell^m(\cos\vartheta)\sqrt{\frac{2\ell+1}{2}\frac{(\ell-m)!}{(\ell+m)!}}\, e^{\imath m\varphi}} \,. \tag{25.32}$$

The spherical harmonics are simultaneously eigenfunctions of the operators $\mathbf{L}^2$, as can be seen from Eq. (25.20), and of the operator L_z according to Eq. (25.24). The quantities represented by the quantum operators $\hat{H}, \hat{\mathbf{L}}^2, \hat{L}_z$ are conserved in the hydrogen system. The conservation of the angular momentum is due to the spherical symmetry of the Coulomb potential.

We will verify the parity of the spherical harmonics in Exc. 25.1.5.1.

25.1.4 Separation of radial motion

In Sec. 25.1.3 we derived, after having separated the motion of the center-of-mass (that is, of the heavy nucleus) and the angular coordinates, the radial equation (25.19) describing the radial component of the electronic motion,

$$\frac{1}{R(r)}\left[-\frac{\hbar^2}{2m}\frac{1}{r^2}\frac{\partial}{\partial r}\left(r^2\frac{\partial}{\partial r}\right) + V(r) - E\right] R(r) = -\frac{\hat{\mathbf{L}}^2}{2mr^2} \,, \tag{25.33}$$

Now, we make the substitution $R(r) = u(r)/r$ and the radial equation becomes,

$$\boxed{\left[-\frac{\hbar^2}{2m}\frac{\partial^2}{\partial r^2} + \frac{\hat{\mathbf{L}}^2}{2mr^2} + V(r)\right] u(r) = E u(r)} \,. \tag{25.34}$$

This equation is very similar to a one-dimensional Schrödinger equation, but there is an additional potential term called *centrifugal potential*,

$$V_\ell(r) \equiv \frac{\hat{\mathbf{L}}^2}{2mr^2} \,. \tag{25.35}$$

For example, for the potential of an electron orbiting a proton, we have,

$$\left[-\frac{\hbar^2}{2m}\frac{\partial^2}{\partial r^2} - \frac{Ze^2}{4\pi\epsilon_0 r} + \frac{\hbar^2\ell(\ell+1)}{2mr^2} - E\right] u_{E\ell}(r) = 0 \,. \tag{25.36}$$

We will discuss this equation intensely in the context of the hydrogen atom.

In Exc. 25.1.5.2 we derive the radial Gross-Pitaevskii equation for a Bose-Einstein condensate trapped in a spherical potential. In the Exc. 25.1.5.3 we will study particles inside a central potential of zero depth, in the Excs. 25.1.5.4 and 25.1.5.5 we consider 3D spherical box potentials and in Exc. 25.1.5.6 a spherical harmonic potential.

> **Example 163 (*Rigid rotor in spherical coordinates*):** We continue the discussion of the rigid rotor, now in spherical coordinates. In the case that the orbit of the particle is fixed to a radius R, we can neglect the kinetic energy due

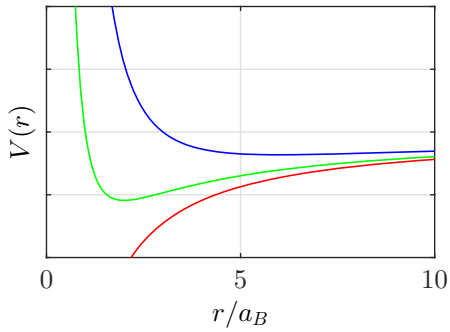

Figure 25.2: (code) Sum of a Coulomb potential and centrifugal potential for $\ell = 0$ (lower curve), $\ell = 1$ (center curve), and $\ell = 2$ (upper curve).

to the radial motion and the potential, both being constant. In this case the radial Schrödinger equation is,

$$\left[\frac{\hbar^2\ell(\ell+1)}{2mr^2}\right] u_{E\ell} = E_\ell u_{E\ell} \ .$$

The energies of the *rigid rotor* are

$$E_\ell = \frac{\hbar^2\ell(\ell+1)}{2I} \ ,$$

with the *momentum of inertia* $I = mR^2$.

25.1.5 Exercises

25.1.5.1 Ex: Parity of the spherical harmonic functions

We consider the parity transformation $\mathbf{P}$ with $(x, y, z) \xrightarrow{\mathbf{P}} (-x, -y, -z)$. Use spherical coordinates to show that $Y_{\ell m} \xrightarrow{\mathbf{P}} (-1)^\ell Y_{\ell m}$, and therefore that a spherical surface function has even parity when ℓ is even, and odd parity, when ℓ is odd.

Solution: *In spherical coordinates the parity transformation can be written* $(r, \theta, \phi) \xrightarrow{\mathbf{P}} (r, \pi-\theta, \pi+\phi)$. *On the azimuthal side, the spherical harmonics are* $\propto e^{im\phi}$. *Therefore, the transformation* $\phi \to \phi + \pi$ *yields a factor* $(-1)^m$. *On the polar side, the spherical harmonics are* $\propto P_\ell^m(\cos\theta)$. *The transformation* $\theta \to \pi - \theta$ *transforms* $z = \cos\theta$ *into* $-z$. *In the definition of polynomials via derivatives, (25.27) and (25.29), it is clear that this gives a factor* $(-1)^{\ell+m}$. *Therefore, we obtain,*

$$Y_{\ell m}(\pi - \theta, \pi + \phi) = (-1)^\ell Y_{\ell m}(\theta, \phi) \ .$$

That is, spherical harmonics are functions with well-defined parity.

25.1.5.2 Ex: Bose-Einstein condensate in an isotropic potential

The time-dependent Gross-Pitaevskii equation describing the wavefunction of a Bose-Einstein condensate reads,

$$\imath\hbar\frac{\partial\psi(\mathbf{r},t)}{\partial t} = \left(-\frac{\hbar^2}{2m}\nabla^2 + V_{trp}(r) + g|\psi(\mathbf{r},t)|^2\right)\psi(\mathbf{r},t) \ ,$$

where the factor g depends on the force of the interatomic interaction and V_{trp} is the potential trapping the atoms. Derive the stationary Gross-Pitaevskii equation via the transform $\psi(\mathbf{r},t) = \psi(\mathbf{r})e^{-\imath\mu t/\hbar}$, where the constant μ is called the chemical potential. For $V(\mathbf{r}) = V(r)$ the wavefunction will have radial symmetry, $\psi(\mathbf{r}) = \frac{\phi(r)}{r}$. Rewrite the Gross-Pitaevskii equation for the function ϕ.

Solution: *The transform immediately yields,*

$$\mu\psi(\mathbf{r}) = \left(-\frac{\hbar^2}{2m}\nabla^2 + V_{trp}(r) + g|\psi(\mathbf{r})|^2\right)\psi(\mathbf{r}) \ .$$

From this we obtain [626],

$$\mu\frac{\phi(r)}{r} = \left(-\frac{\hbar^2}{2m}\left[\frac{1}{r}\frac{\partial^2}{\partial r^2}r + \frac{1}{r^2\sin\vartheta}\frac{\partial}{\partial\vartheta}\left(\sin\vartheta\frac{\partial}{\partial\vartheta}\right) + \frac{1}{r^2\sin^2\vartheta}\frac{\partial^2}{\partial\varphi^2}\right] + V_{trp}(r) + g\left|\frac{\phi(r)}{r}\right|^2\right)\frac{\phi(r)}{r}$$

$$\mu\phi(r) = \left(-\frac{\hbar^2}{2m}\frac{\partial^2}{\partial r^2} + V_{trp}(r) + g\frac{|\phi(r)|^2}{r^2}\right)\phi(r) \ ,$$

with

$$\int|\psi(\mathbf{r})|^2 d^3r = 4\pi\int_0^\infty|\psi(\mathbf{r})|^2 r^2 dr = 4\pi\int_0^\infty|\phi(\rho,z)|^2 dr = 1 \ .$$

25.1.5.3 Ex: Motion of a free particle in spherical coordinates

Obtain the eigenfunctions of a free particle as the limiting case of its motion in a central force field with $V(r) \to 0$. Compare the derived eigenfunctions – associated with the complete set of observables $\hat{H}$, $\hat{L}^2$, and $\hat{L}_z$ – to those described by plane waves – associated with the motion characterized by the observables $\hat{p}_x$, $\hat{p}_y$, $\hat{p}_z$, and $\hat{H} = \hat{\mathbf{P}}^2/2m$ –, which also constitute a complete set of observables.

Solution: *The radial equation is,*

$$\left[-\frac{\hbar^2}{2mr^2}\frac{d}{dr}\left(r^2\frac{d}{dr}\right) + \frac{\hbar^2\ell(\ell+1)}{2mr^2} + V(r)\right]R(r) = ER(r) \ .$$

We consider $V(r) = 0$. Introducing a dimensionless variable $\rho \equiv kr$ with $k \equiv \sqrt{2mE/\hbar^2}$ the equation takes the form of a Bessel equation for $\mathcal{J}$ defined by $\mathcal{J}(\rho) \equiv \sqrt{\rho}R(r)$ (which motivates the choice of the notation $\mathcal{J}$):

$$\rho^2\frac{d^2\mathcal{J}}{d\rho^2} + \rho\frac{d\mathcal{J}}{d\rho} + \left[\rho^2 - (\ell+\tfrac{1}{2})^2\right]\mathcal{J} = 0 \ .$$

Regular solutions for positive energies are given by functions called Bessel functions of the first kind $\mathcal{J}_{\ell+1/2}(\rho)$ such that the solutions for R are the so-called spherical Bessel functions $R(r) = j_\ell(kr) \equiv \sqrt{\frac{\pi}{2kr}}\mathcal{J}_{\ell+1/2}(kr)$. The solutions of the Schrödinger equation in polar coordinates for a particle of mass m_0 in vacuum are enumerated by the discrete quantum numbers ℓ and m, while $k \in [0, \infty[$ varies continuously,

$$\psi(\mathbf{r}) = j_\ell(kr)Y_{\ell m}(\theta, \phi) \ ,$$

where $Y_{\ell m}$ are the spherical harmonics. These solutions represent states with defined angular momentum $\mathbf{L}$, contrary to the states corresponding to plane waves, $e^{\imath \mathbf{k}\cdot\mathbf{r}}$, which are characterized by defined linear momenta $\mathbf{p}$.
It is worth noting that plane waves can be expanded into spherical waves by,

$$e^{\imath \mathbf{k}\cdot\mathbf{r}} = \sum_{\ell=0}^{\infty}(2\ell+1)\imath^\ell j_\ell(kr)P_\ell(\hat{\mathbf{k}}\cdot\hat{\mathbf{r}}) = 4\pi\sum_{\ell=0}^{\infty}\sum_{m=-\ell}^{\ell}\imath^\ell j_\ell(kr)Y_{\ell m}(\hat{\mathbf{k}})Y^*_{\ell m}(\hat{\mathbf{r}}) \ .$$

25.1.5.4 Ex: Particle in a spherical box

Find the energy levels and wavefunctions of a particle confined in a spherical box described by potential energy, $V(r) = 0$ for $r < a$ and $V(r) = \infty$ for $r \geq a$ considering the angular momentum $\ell = 0$.

Solution: *The radial equation is,*

$$-\frac{\hbar^2}{2m}\frac{\partial^2}{\partial r^2}u = Eu \ .$$

This is a one-dimensional wave equation the general solution of which, $u(r) = Ae^{\imath kr} + Be^{-\imath kr}$, must meet the conditions,

$$u(0) = 0 = A + B \qquad \text{and} \qquad u(a) = 0 = Ae^{\imath ka} + Be^{-\imath ka} \ .$$

The first condition ensures that the radial function $R(r) = u(r)/r$ does not diverge in the center. We obtain, $ka = n\pi$ and, therefore, the energies,

$$E = \frac{\hbar^2 k^2}{2m} = \frac{\hbar^2\pi^2}{2ma^2}n^2 \ .$$

The wavefunctions are,

$$\psi(\mathbf{r}) = R_1(r)Y_{00}(\theta,\phi) = \frac{1}{\sqrt{4\pi}}\frac{u(r)}{r} = \frac{A}{\sqrt{4\pi}}\frac{e^{\imath kr} - e^{-\imath kr}}{r} = \frac{\imath A}{r\sqrt{\pi}}\sin\frac{n\pi r}{a} \ .$$

Normalization requests,

$$1 = \int|\psi(r)|^2 d^3r = 4\pi\frac{A^2}{\pi}\int_0^a \frac{\sin^2\frac{n\pi}{a}r}{r^2}r^2dr = 4A^2\int_0^a \sin^2\frac{n\pi r}{a}dr = 2aA^2 \ .$$

Finally,

$$\psi(\mathbf{r}) = \frac{\imath}{r\sqrt{2\pi a}}\sin\frac{n\pi r}{a} \ .$$

25.1.5.5 Ex: Finite spherical 3D potential well

a. Derive the possible energy levels and associated wavefunctions for a particle trapped in a spherical 3D potential well of depth V_0 and radius a. Note that this problem is analogous to *Mie scattering* of scalar waves.
b. Discuss the case of a well surrounded by infinitely high walls.

Solution: *a. We consider the potential $V(r) = V_0$ for $r < a$ and $V(r) = 0$ outside, and we first concentrate on bound states, that is, $E < 0$. We will see that there is a* discrete *number of such states (unlike for free states with $E > 0$ which form a continuous spectrum and describe the scattering of the particle by the sphere). Furthermore, the number of states is finite (unlike for Coulombian potentials). The resolution of this problem essentially follows that of free space with additionally a normalization of the total wave function. We solve two Schrödinger equations —inside and outside the sphere— with constant potential depths considering the following boundary conditions: 1. The wave function must be regular at the origin. 2. The wavefunction and its derivatives must be continuous at the potential discontinuity. 3. The wavefunction must converge at infinity.*
Inside the well, $r < a$, the radial Schrödinger equation

$$\left[-\frac{\hbar^2}{2m}\frac{1}{r^2}\frac{\partial}{\partial r}\left(r^2\frac{\partial}{\partial r}\right) + V(r) - E\right] R_{E\ell} = -\frac{\hbar^2\ell(\ell+1)}{2mr^2}R_{E\ell}$$

becomes with the substitutions $\rho \equiv kr$ and $k \equiv \frac{2m}{\hbar^2}(E - V_0)$,

$$R''_{E\ell} + \tfrac{2}{\rho}R'_{E\ell} + \left(1 - \tfrac{\ell(\ell+1)}{\rho^2}\right) R_{E\ell} = 0 \ .$$

Outside the radius, $r > a$, we obtain the same equation with the replacements $\rho \equiv \imath\kappa r$ and $\kappa \equiv \frac{2m}{\hbar^2}E$. The solutions are the spherical Bessel functions, the Hankel functions, and the Neumann functions [2]*. We note,*

$$j_\ell(\rho) = (-\rho)^\ell \left(\frac{1}{\rho}\frac{\partial}{\partial\rho}\right)^\ell \frac{\sin\rho}{\rho} \qquad \text{with} \qquad j_0(\rho) \overset{\rho\to 0}{\longrightarrow} 0$$

$$n_\ell(\rho) = -(-\rho)^\ell \left(\frac{1}{\rho}\frac{\partial}{\partial\rho}\right)^\ell \frac{\cos\rho}{\rho} \qquad \text{with} \qquad n_0(\rho) \overset{\rho\to 0}{\longrightarrow} \infty \ .$$

The first boundary condition excludes the Neumann and Hankel functions, which are singular at the origin. Therefore,

$$R_{E\ell}^{(r<a)} = A\ j_\ell\left(\sqrt{\tfrac{2m(E-V_0)}{\hbar^2}}r\right) \ ,$$

[2] The spherical Bessel and Neumann functions are related to the Bessel functions $\mathcal{J}$ by,

$$j_\ell(\rho) = \sqrt{\tfrac{\pi}{2\rho}}\mathcal{J}_{\ell+1/2}(\rho) \qquad \text{and} \qquad n_l(\rho) = (-1)^{\ell+1}\sqrt{\tfrac{\pi}{2\rho}}\mathcal{J}_{-\ell-1/2}(\rho) \ ,$$

where

$$\mathcal{J}''_\nu(\rho) + \tfrac{1}{\rho}\mathcal{J}'_\nu(\rho) + \left(1 - \tfrac{\nu^2}{\rho^2}\right)\mathcal{J}_\nu(\rho) = 0$$

is the differential Bessel equation.

with a constant A.
The fact that the energy of bound states is negative, together with the third boundary condition, selects the Hankel functions of the first type for the outside region, since they are those which converge at infinity,

$$R_{E\ell}^{(r>a)} = B\ h_\ell^{(1)}\left(\imath\sqrt{\tfrac{-2mE}{\hbar^2}}r\right)\ .$$

The possible energy values follow from the second boundary condition $R_{E\ell}^{(r<a)}(ka) = R_{E\ell}^{(r>a)}(\kappa a)$. That is, the continuity of the derivative (or conveniently of the logarithmic derivative) requires quantization of the energy. Along with the normalization, this condition allows the determination of the constants A and B.
b. The case of the well surrounded by infinite walls follows from the conditions $E - V_0 \ll -E, -V_0$. Obviously, $R_{E\ell}^{(r>a)} = 0$, such that we can impose the following boundary conditions to the Bessel functions,

$$R_{E\ell}(ka) = j_\ell(ka) = 0\ .$$

Each Bessel function with the index ℓ has several zero crossings corresponding to main quantum numbers n. We use zero crossings of the spherical Bessel functions to find

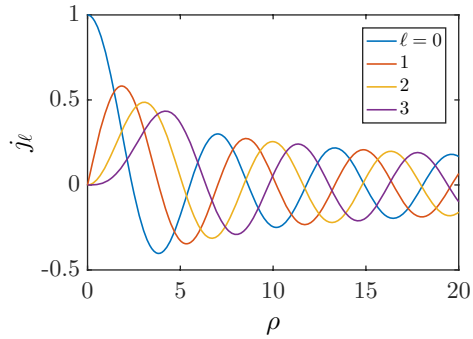

Figure 25.3: (code) Bessel functions.

the energy spectrum and the wavefunctions: Calling $u_{n,\ell}$ the n-th zero of j_ℓ we get,

$$E_{n\ell} = \frac{u_{n,\ell}^2\hbar^2}{2ma^2}\ .$$

The zero points generally have no analytical expression. However, for the particular case $\ell = 0$ (spherically symmetric orbitals), the spherical Bessel function is $j_0(x) = \frac{\sin x}{x}$, the zeros of which can easily be expressed by $u_{n,0} = k\pi$. The eigenenergies are consequently,

$$E_{n0} = \frac{(n\pi)^2\hbar^2}{2ma^2}\ .$$

25.1.5.6 Ex: Particle in a spherical harmonic potential

A quantum particle of mass m is subject to a potential

$$V = \tfrac{1}{2}m\omega^2(x^2+y^2+z^2) \ .$$

a. Obtain the energy levels of this particle. That is, determine the eigenvalues of

$$-\frac{\hbar^2}{2m}\nabla^2\psi + V\psi = E\psi \ .$$

b. Consider the fundamental level and the first two excited levels. Set up a table showing for each of these three levels the energy value, the degeneracy, and the respective states in terms of the quantum numbers.
c. Using

$$\nabla^2\psi = \left[\frac{1}{r^2}\frac{\partial}{\partial r}\left(r^2\frac{\partial}{\partial r}\right) - \frac{L^2}{\hbar^2 r^2}\right]\psi$$

and remembering $\hat{\mathbf{L}}^2 Y_{\ell m}(\theta,\phi) = \hbar^2\ell(\ell+1)Y_{\ell m}$, write down the differential equation of item (a) for the radial part of the wavefunction (it is not necessary to solve it). Identify in this equation the effective potential $V_{eff}(r)$.
d. Solve the differential equation of the previous item for the case where $\ell = 0$ and determine the corresponding eigenvalue. To do this, allow for a solution of the type $e^{-\alpha r^2}$ and determine α.

Solution: *a. The Hamiltonian with the harmonic potential is separable, that is, we can solve the one-dimensional equations,*

$$-\frac{\hbar^2}{2m}\frac{d^2}{dx^2}\psi_x(x) + \frac{m}{2}\omega^2\psi_x(x) = E\psi_x(x) \ .$$

and add the eigenenergies $E_x = \hbar\omega\left(n_x + \frac{1}{2}\right)$, giving

$$E = \hbar\omega\left(n_x + n_y + n_z + \frac{3}{2}\right) \ .$$

b. Sorting the states according to (n_x, n_y, n_z) under the condition $n_x + n_y + n_z = n$ we obtain,

level	*energy*	*states*	*degeneracy*
$n=0$	$E_0 = \frac{3\hbar\omega}{2}$	$(0,0,0)$	1
$n=1$	$E_1 = \frac{5\hbar\omega}{2}$	$(1,0,0);(0,1,0);(0,0,1)$	3
$n=2$	$E_2 = \frac{7\hbar\omega}{2}$	$(1,1,0);(1,0,1);(0,1,1);(2,0,0);(0,2,0);(0,0,2)$	6
n	$E_n = \frac{(2n+3)\hbar\omega}{2}$		$\frac{(n+1)(n+2)}{2}$

c. We can rewrite the Hamiltonian

$$H = \frac{\hat{p}^2}{2m} + \frac{m}{2}\omega^2 r^2 = -\frac{\hbar^2\nabla^2}{2m} + \frac{m}{2}\omega^2 r^2 \ .$$

Passing this expression into spherical coordinates and using $\psi(\mathbf{r}) = R_n(r)Y_{lm}(\theta,\phi)$, we have,

$$-\frac{\hbar^2}{2m}\left[\frac{1}{r^2}\frac{\partial}{\partial r}\left(r^2\frac{\partial}{\partial r}\psi(\mathbf{r})\right) - \frac{L^2}{\hbar^2 r^2}\psi(\mathbf{r})\right] + \frac{m}{2}\omega^2 r^2\psi(\mathbf{r}) = E\psi(\mathbf{r}) \ ,$$

from which,

$$Y_{\ell m}\left[-\frac{\hbar^2}{2m}\frac{1}{r^2}\frac{\partial}{\partial r}\left(r^2\frac{\partial}{\partial r}\right)+\frac{\hbar^2\ell(\ell+1)}{2mr^2}+\frac{m}{2}\omega^2r^2\right]R_n=ER_nY_{\ell m}\ ,$$

from where we can directly read the effective potential:

$$V_{eff}=\frac{m}{2}\omega^2r^2+\frac{\hbar^2\ell(\ell+1)}{2mr^2}\ .$$

The quantum numbers (n,ℓ,m) are equivalent to (n_x,n_y,n_z).
d. When $\ell=0$, the centrifugal term disappears, and we can eliminate the spherical functions from the differential equation:

$$\left[-\frac{\hbar^2}{2m}\frac{1}{r^2}\frac{\partial}{\partial r}\left(r^2\frac{\partial}{\partial r}\right)+\frac{m}{2}\omega^2r^2\right]R_n=ER_n\ .$$

Inserting the function $e^{-\alpha r^2}$ we obtain,

$$\begin{aligned}
&-\frac{\hbar^2}{2m}\frac{1}{r^2}\frac{\partial}{\partial r}\left(r^2\frac{\partial}{\partial r}\right)e^{-\alpha r^2}+\frac{m}{2}\omega^2r^2e^{-\alpha r^2}\\
&=-\frac{\hbar^2}{2m}\frac{1}{r^2}\frac{\partial}{\partial r}\left(-2\alpha r^3e^{-\alpha r^2}\right)+\frac{m}{2}\omega^2r^2e^{-\alpha r^2}\\
&=-\frac{\hbar^2}{2m}\frac{1}{r^2}\left(-2\alpha r^3\right)\left(-2\alpha re^{-\alpha r^2}\right)-\frac{\hbar^2}{2m}\frac{1}{r^2}e^{-\alpha r^2}\left(-6\alpha r^2\right)+\frac{m}{2}\omega^2r^2e^{-\alpha r^2}\\
&=-\frac{\hbar^2}{2m}\left[4\alpha^2r^2-6\alpha\right]e^{-\alpha r^2}+\frac{m}{2}\omega^2r^2e^{-\alpha r^2}=Ee^{-\alpha r^2}\ .
\end{aligned}$$

The constant α must satisfy the following equation for all values of r:

$$-\frac{\hbar^2}{2m}\left[4\alpha^2r^2-6\alpha\right]+\frac{m}{2}\omega^2r^2=E\ ,$$

which is only possible when

$$-\frac{\hbar^2}{2m}4\alpha^2+\frac{m}{2}\omega^2=0\ .$$

Hence,

$$\alpha=\pm\frac{m\omega}{2\hbar}\ ,$$

and eigenvalues are

$$E=\frac{3\hbar^2}{m}\alpha=\frac{3\hbar\omega}{2}\ .$$

25.2 Quantum treatment of hydrogen

According to Rutherford's and Bohr's planetary atomic model we may imagine an atom as a very heavy nucleus having a positive electric charge surrounded by a very light negatively charged charge electronic cloud. Since the nucleus is very small compared to the electronic cloud, we treat it as an entity with mass M and charge Ze, where Z is the number of protons and corresponds to the order of the element in the periodic system.

The canonical procedure for calculating all properties of an atom is to establish its Hamiltonian, that is, to determine the kinetic energies of all components and all interaction energies between them, and to solve the Schrödinger equation. For each component we write the kinetic energy,

$$T_{ncl} = \frac{P^2}{2M} \qquad \text{and} \qquad T_{ele} = \sum_{i=1}^{Z} \frac{p_i^2}{2m} \; . \tag{25.37}$$

Here, $(\mathbf{R}, \mathbf{P})$ are the nuclear coordinates and $(\mathbf{r}_i, \mathbf{p}_i)$ those of the electrons. The energies that corresponds to the interactions, that is, Coulombian attraction or repulsion, between the components of the atom are,

$$V_{ncl-ele} = -\sum_{i=1}^{Z} \frac{Ze^2}{4\pi\varepsilon_0 |\mathbf{R} - \mathbf{r}_i|} \qquad \text{and} \qquad V_{ele-ele} = \sum_{i \neq j=1}^{Z} \frac{e^2}{4\pi\varepsilon_0 |\mathbf{r}_i - \mathbf{r}_j|} \; . \tag{25.38}$$

There are also interactions due to the spin of the particles, which we will deal with later.

Obviously, the solution to this many-body problem is very complicated. For this reason, we will in this chapter, based on the Schrödinger equation, calculate the complete spectrum of the simplest possible atom, hydrogen. This atom consists of a proton and an electron, only.

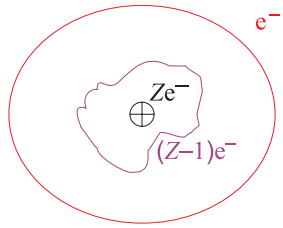

Figure 25.4: The hydrogen model applies to other atoms having a single valence electron occupying a sufficiently large space, that it sees the nucleus together with rest of the electrons shielding the nucleus as a single positive charge.

25.2.1 Bohr's model

Let us now turn our attention to the radial part of the Schrödinger equation describing a particle in a radial potential. We expect that the quantum solutions for the hydrogen atom are similar to the predictions of Bohr's model. Following this model, the orbit

is stable when the attraction force is equal to the centrifugal force. But in addition, Bohr postulated, that only certain energies are allowed. For the hydrogen atom he found,

$$E_n = -\frac{1}{2}\frac{Ze^2}{4\pi\varepsilon_0}\frac{1}{r_n} = -\frac{Z^2\hbar^2}{2ma_B^2}\frac{1}{n^2} = -\frac{Z^2e^2}{4\pi\varepsilon_0}\frac{1}{2a_Bn^2} = -\frac{Z^2}{n^2}\ 13.6\,\mathrm{eV}\ , \tag{25.39}$$

with the *Bohr radius*

$$a_B \equiv 4\pi\varepsilon_0\frac{\hbar^2}{me^2}\ . \tag{25.40}$$

With this equation he was able to explain the spectral observations. Electrons can only jump from one level to another, while emitting or absorbing a photon. The series observed in the hydrogen spectrum $(E_n - E_m)/\hbar$ are the Lyman ($m = 1$), the Balmer ($m = 2$), the Paschen ($m = 3$) an the Brackett series ($m = 4$).

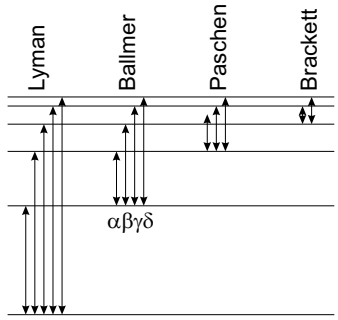

Figure 25.5: The hydrogen transitions.

The discussion of the hydrogen atom within quantum mechanics can start from the radial Schrödinger equation (25.36) with the Coulomb attraction potential,

$$\left[-\frac{\hbar^2}{2m}\frac{\partial^2}{\partial r^2} - \frac{Ze^2}{4\pi\varepsilon_0 r} + \frac{\hbar^2\ell(\ell+1)}{2mr^2} - E\right] u_{E\ell}(r) = 0\ . \tag{25.41}$$

In order to facilitate comparison with Bohr's classical model, let us express the energy in terms of Bohr's energy, $E \equiv E_n = E_1/n^2$, and write the radius in units of a_B, that is, $\tilde{r} \equiv Zr/a_B$. This yields,

$$u''_{n\ell}(\tilde{r}) + \left(-\frac{\ell(\ell+1)}{\tilde{r}^2} + \frac{2}{\tilde{r}} - \frac{1}{n^2}\right) u_{n\ell}(\tilde{r}) = 0\ . \tag{25.42}$$

To ensure that for large radii, $r \to \infty$, the solution is finite, we need an asymptotic behavior like $u_{n\ell}(\tilde{r} \to \infty) = e^{-\tilde{r}/n}$. To ensure that for small radii, $r \to 0$, the solution is finite, we need $u_{n\ell}(\tilde{r} \to 0) = \tilde{r}^{\ell+1}$. We derive the asymptotic solutions in Exc. 25.2.3.1. The resulting differential equation only has solutions for an integer and positive *main quantum number* n and when $\ell = 0, 1, .., n-1$. That is, in the relation $E = E_1/n^2$ the parameter n is integer and positive, such that energy levels remain

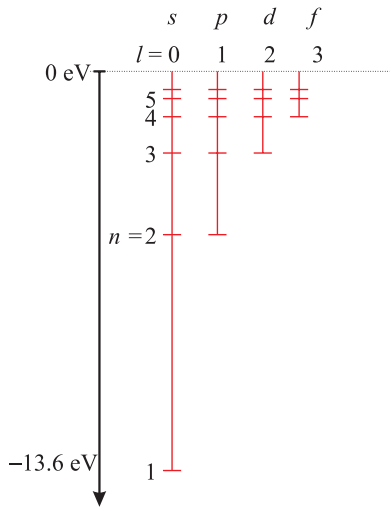

Figure 25.6: Level scheme.

degenerate in ℓ and m. This means that Bohr's postulate of discrete (i.e. quantized) energy levels is valid (uff!)

Substituting the ansatz,

$$u_{n\ell}(\tilde{r}) = D_{n\ell}\tilde{r}^{\ell+1}e^{-\tilde{r}/n}L(\tilde{r}) \ , \tag{25.43}$$

it's easy to show (see Exc. 25.2.3.2), that the differential equation (25.42) reduces to,

$$\tilde{r}L''(\tilde{r}) + 2\left[(\ell+1) - \tfrac{1}{n}\tilde{r}\right]L'(\tilde{r}) + 2\left[1 - \tfrac{1}{n}(\ell+1)\right]L(\tilde{r}) = 0 \ . \tag{25.44}$$

Still with the abbreviation $\rho \equiv 2\tilde{r}/n = 2Zr/na_B$ the ansatz

$$u_{n\ell}(\rho) = D_{n\ell}\rho^{\ell+1}e^{-\rho/2}L(\rho) \ , \tag{25.45}$$

leads to the differential equation [3]

$$\rho L''(\rho) + [2(\ell+1) - \rho]\,L'(\rho) + [n-\ell-1]L(\rho) = 0 \ . \tag{25.46}$$

The solutions of this differential equation, $L^{(2\ell+1)}_{n-\ell-1}(\rho)$, are the *Laguerre polynomials*. These polynomials are listed in mathematical tables. Using the properties of these polynomials it is possible to show that the radial functions are orthogonal and can be normalized (see Exc. 25.2.3.3). Fig. 25.7 shows the curves for the lowest orbitals.

[3] *Laguerre's associated differential equation* is,

$$\rho\partial_\rho^2 L^{(\alpha)}_\nu + (\alpha+1-\rho)\partial_\rho L^{(\alpha)}_\nu + \nu L^{(\alpha)}_\nu = 0 \ .$$

The Laguerre polynomials are generated by

$$L^{(\alpha)}_\nu(\rho) = \frac{e^\rho\rho^{-\alpha}}{\alpha!}\frac{d^\nu}{d\rho^\nu}\left(e^{-\rho}\rho^{\nu+\alpha}\right) \ .$$

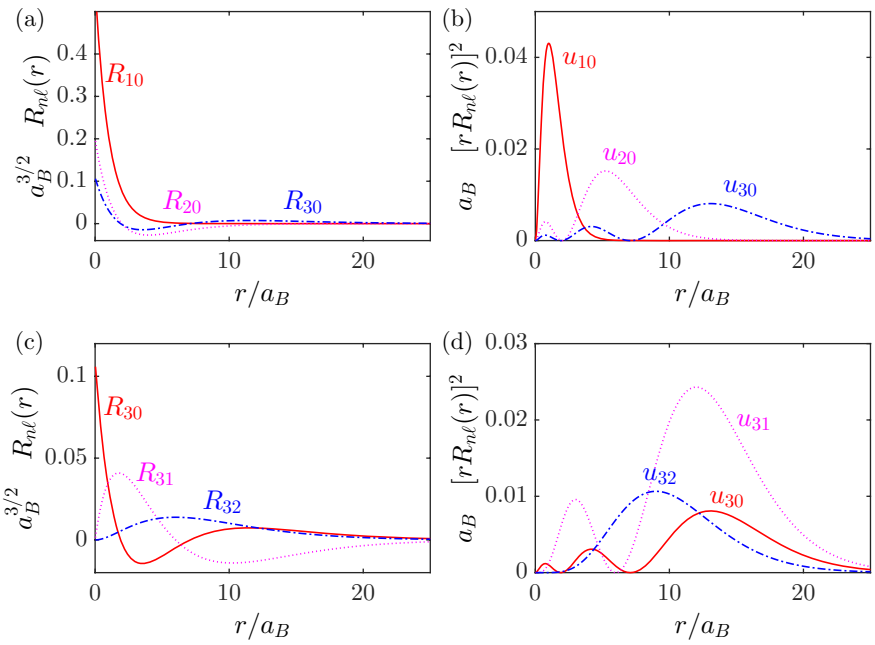

Figure 25.7: (code) (a,c) Radial wavefunctions $R_{n\ell}(r)$ and (b,d) square of the radial wavefunctions $u_{n\ell}(r)$ for various quantum numbers n and ℓ.

Finally, we can write the complete solutions of the Schrödinger equation $\hat{H}\psi = E\psi$,

$$\boxed{\psi_{n\ell m}(r,\theta,\phi) = \frac{u_{n\ell}(r)}{r} Y_{\ell m}(\theta,\phi) \qquad \text{and} \qquad E_n = -\frac{\hbar^2}{2ma_B^2}\frac{Z^2}{n^2}} \,, \tag{25.47}$$

where $n = 1, 2, 3, ..$ and $\ell = 0, 1, .., n-1$ and $m = -\ell, -\ell+1, .., \ell$. Of course, each energy level n is,

$$\sum_{\ell=0}^{n-1} (2\ell+1) = n^2 \tag{25.48}$$

times degenerate.

From the normalization condition,

$$\begin{aligned} 1 &= \int_{\mathbb{R}^3} |\psi_{n\ell m}(r,\theta,\phi)|^2 d^3r \\ &= \int_0^\infty |u_{n\ell}(r)|^2 dr \int_{\mathbb{R}^2} |Y_{\ell m}(\theta,\phi)|^2 \sin\theta d\theta d\phi = \int_0^\infty |u_{n\ell}(r)|^2 dr \,, \end{aligned} \tag{25.49}$$

we obtain the constants,

$$D_{n\ell} = \sqrt{\left(\frac{2Z}{na_B}\right)^3 \frac{(n-\ell-1)!}{2n(n+\ell)!}} \,, \tag{25.50}$$

and the radial wavefunctions finally read,

$$R_{n\ell}(r) = D_{n\ell}\left(\frac{2\tilde{r}}{n}\right)^{\ell} e^{-\tilde{r}/n} L_{n-\ell-1}^{(2\ell+1)}(\tfrac{2\tilde{r}}{n}) = D_{n\ell}\rho^{\ell}e^{-\rho/2}L_{n-\ell-1}^{(2\ell+1)}(\rho)\ , \tag{25.51}$$

using the previously introduced abbreviations.

Here is a list of the first wavefunctions of the hydrogen atom,

$$\begin{aligned}
\psi_{100} &= \tfrac{1}{\sqrt{\pi}}\left(\tfrac{Z}{a_B}\right)^{3/2} e^{-\tilde{r}} \\
\psi_{200} &= \tfrac{1}{4\sqrt{2\pi}}\left(\tfrac{Z}{a_B}\right)^{3/2} (2-\tilde{r})e^{-\tilde{r}/2} \\
\psi_{210} &= \tfrac{1}{4\sqrt{2\pi}}\left(\tfrac{Z}{a_B}\right)^{3/2} \tilde{r}e^{-\tilde{r}/2}\cos\theta \\
\psi_{21\pm1} &= \tfrac{1}{8\sqrt{\pi}}\left(\tfrac{Z}{a_B}\right)^{3/2} \tilde{r}e^{-\tilde{r}/2}\sin\theta e^{\pm\imath\varphi} \\
\psi_{300} &= \tfrac{1}{81\sqrt{3\pi}}\left(\tfrac{Z}{a_B}\right)^{3/2} (27-18\tilde{r}+2\tilde{r}^2)e^{-\tilde{r}/3} \\
\psi_{31\pm1} &= \tfrac{\sqrt{2}}{81\sqrt{3\pi}}\left(\tfrac{Z}{a_B}\right)^{3/2} (6-\tilde{r})\tilde{r}e^{-\tilde{r}/3}\sin\theta e^{\pm\imath\varphi} \\
\psi_{320} &= \tfrac{1}{81\sqrt{6\pi}}\left(\tfrac{Z}{a_B}\right)^{3/2} \tilde{r}^2e^{-\tilde{r}/3}(3\cos^2\theta-1)\ ,
\end{aligned} \tag{25.52}$$

where we use the abbreviation $\tilde{r} \equiv Zr/a_B$. Using these wavefunctions we can now calculate important eigenvalues such as, for example,

$$\begin{aligned}
\langle 1\rangle_{n\ell m} &= 1 \\
\langle \delta^{(3)}(\tilde{r})\rangle_{n\ell m} &= \frac{\delta_{\ell,0}}{\pi n^3} \\
\langle \tilde{r}\rangle_{n\ell m} &= n^2\left[1+\frac{1}{2}\left(1-\frac{\ell(\ell+1)}{n^2}\right)\right] \\
\langle \tilde{r}^2\rangle_{n\ell m} &= n^4\left[1+\frac{3}{2}\left(1-\frac{\ell(\ell+1)-\frac{1}{3}}{n^2}\right)\right] \\
\langle \tilde{r}^3\rangle_{n\ell m} &= n^6\left[\frac{35}{8}-\frac{35}{8n^2}-\frac{15}{4n^2}(\ell+2)(\ell-1)+\frac{3}{8n^4}(\ell+2)(\ell+1)\ell(\ell-1)\right] \\
\langle \tilde{r}^4\rangle_{n\ell m} &= n^8\left[\frac{63}{8}+\frac{35}{8n^2}(2\ell^2+2\ell-3)+\frac{5}{8n^4}5\ell(\ell+1)(3\ell^2+3\ell-10)+\frac{12}{n^8}\right] \\
\left\langle\frac{1}{\tilde{r}}\right\rangle_{n\ell m} &= \frac{1}{n^2} \\
\left\langle\frac{1}{\tilde{r}^2}\right\rangle_{n\ell m} &= \frac{1}{n^3(\ell+\frac{1}{2})} \\
\left\langle\frac{1}{\tilde{r}^3}\right\rangle_{n\ell m} &= \frac{n}{n^4\ell(\ell+\frac{1}{2})(\ell+1)} \\
\left\langle\frac{1}{\tilde{r}^4}\right\rangle_{n\ell m} &= \frac{\frac{3}{2}n^2-\frac{1}{2}\ell(\ell+1)}{n^5(\ell+\frac{3}{2})(\ell+1)(\ell+\frac{1}{2})\ell(\ell-\frac{1}{2})}\ .
\end{aligned} \tag{25.53}$$

These results will become important later. In Exc. 25.2.3.4 we will calculate the eigenvalue $\langle r \rangle$ for several orbitals $|\psi_{n\ell m}\rangle$.

25.2.2 The virial theorem

Originally derived for classical mechanics, the *virial theorem* also holds for quantum mechanics, as shown for the first time by *Fock*. We evaluate the commutator between the Hamiltonian

$$\hat{H} = \hat{\mathbf{p}}^2/2m + V(\hat{\mathbf{r}}) \ , \tag{25.54}$$

and the product of the position operator $\hat{\mathbf{r}}$ with the momentum operator $\hat{\mathbf{p}} = -\imath\hbar\nabla$ of the particle:

$$[\hat{H}, \hat{\mathbf{r}} \cdot \hat{\mathbf{p}}] = [\hat{H}, \hat{\mathbf{r}}] \cdot \hat{\mathbf{p}} + \hat{\mathbf{r}} \cdot [\hat{H}, \hat{\mathbf{p}}] = -\imath\hbar \frac{\hat{\mathbf{p}}^2}{m} + \imath\hbar \hat{\mathbf{r}} \cdot \nabla V \ , \tag{25.55}$$

using the theorems of Ehrenfest. Therefore, we find for the operator $\hat{Q} = \hat{\mathbf{r}} \cdot \hat{\mathbf{p}}$ the commutator,

$$\frac{\imath}{\hbar}[\hat{H}, \hat{Q}] = 2E_{kin} - \hat{\mathbf{r}} \cdot \nabla V \ . \tag{25.56}$$

The left side of this equation is precisely $-d\hat{Q}/dt$, following the Heisenberg equation of motion. The eigenvalue $\langle d\hat{Q}/dt \rangle$ of the temporal derivative vanishes in steady state, therefore we obtain the virial theorem,

$$2\langle E_{kin} \rangle = \langle \hat{\mathbf{r}} \cdot \nabla V \rangle \ . \tag{25.57}$$

Example 164 (*Virial theorem applied to a central potential*): For example, for a central potential $V(r) \propto r^s$ we obtain,

$$2\langle E_{kin} \rangle = \langle \hat{\mathbf{r}} \cdot \hat{\mathbf{e}}_r \frac{\partial V}{\partial r} \rangle = \langle r \frac{\partial V}{\partial r} \rangle = s\langle V \rangle \ .$$

In Exc. 25.2.3.5 we calculate the eigenvalues $\langle r^{-1} \rangle$ and $\langle p^2 \rangle$ and we verify the virial theorem. Finally, in Exc. 25.2.3.6 we calculate transition matrix elements between different orbitals.

25.2.3 Exercises

25.2.3.1 Ex: Asymptotes of Laguerre's polynomials

Derive the asymptotic solutions of equation (25.42).

Solution: *For $\tilde{r} \to 0$ the approximate equation is,*

$$u''_{n,\ell}(\tilde{r}) - \frac{\ell(\ell+1)}{\tilde{r}^2} u_{n,\ell}(\tilde{r}) = 0 \ .$$

The ansatz $u_{n,\ell} = \xi(\tilde{r})\tilde{r}^{\ell+1}$ transforms this equation into,

$$\xi''(\tilde{r})\tilde{r} + 2(\ell+1)\xi'(\tilde{r}) = 0 \ ,$$

which is satisfied in the center ($\tilde{r} \to 0$) for all polynomials $\xi(\tilde{r})$.
For $r \to \infty$ the equation becomes,

$$n^2 u''_{n,\ell}(\tilde{r}) - u_{n,\ell}(\tilde{r}) = 0 \ .$$

The solution of this differential equation is $u_{n,\ell} = e^{\pm\tilde{r}/n}$, the option with positive sign being non-normalized.

25.2.3.2 Ex: Laguerre equation

Show that the equation (25.42) transforms with the ansatz (25.43) into equation (25.44).

Solution: *The derivatives of the ansatz are,*

$$\begin{aligned}
\frac{\partial}{\partial\tilde{r}}\frac{u_{n\ell}(\tilde{r})}{D_{n\ell}} &= (\ell+1)\tilde{r}^{\ell}e^{-\tilde{r}/n}L(\tilde{r}) - \tfrac{1}{n}\tilde{r}^{\ell+1}e^{-\tilde{r}/n}L(\tilde{r}) + \tilde{r}^{\ell+1}e^{-\tilde{r}/n}L'(\tilde{r}) \\
\frac{\partial^2}{\partial\tilde{r}^2}\frac{u_{n\ell}(\tilde{r})}{D_{n\ell}} &= \tilde{r}^{\ell}e^{-\tilde{r}/n}\left[\tilde{r}L''(\tilde{r}) + 2(\ell+1)L'(\tilde{r}) - \tfrac{2}{n}\tilde{r}L'(\tilde{r}) + \ell(\ell+1)\tfrac{1}{\tilde{r}}L(\tilde{r})\right. \\
&\quad \left. -\tfrac{2}{n}(\ell+1)L(\tilde{r}) + \tfrac{1}{n^2}\tilde{r}L(\tilde{r})\right] \ .
\end{aligned}$$

With this,

$$0 = \tilde{r}\partial_{\tilde{r}}^2 L(\tilde{r}) + 2\left[(\ell+1) - \tfrac{1}{n}\tilde{r}\right]\partial_{\tilde{r}}L(\tilde{r}) + 2\left[1 - \tfrac{1}{n}(\ell+1)\right]L(\tilde{r}) \ .$$

25.2.3.3 Ex: Laguerre functions

Using the orthogonality relation of associated Laguerre polynomials,

$$\begin{aligned}
\int_0^\infty \rho^\alpha e^{-\rho}L_n^{(\alpha)}(\rho)L_m^{(\alpha)}(\rho)d\rho &= \frac{\Gamma(n+\alpha+1)}{n!}\delta_{n,m} \\
\int_0^\infty \rho^{\alpha+1}e^{-\rho}L_n^{(\alpha)}\rho^2 d\rho &= \frac{(n+\alpha)!}{n!}(2n+\alpha+1) \ ,
\end{aligned}$$

and the recursion formula,

$$\begin{aligned}
nL_n^{(\alpha+1)}(\rho) &= (n-\rho)L_{n-1}^{(\alpha+1)}(\rho r) + (n+\alpha)L_{n-1}^{(\alpha)}(\rho) \\
\rho L_n^{(\alpha+1)}(\rho) &= (n+\alpha)L_{n-1}^{(\alpha)}(\rho) - (n-\rho)L_n^{(\alpha)}(\rho) \ ,
\end{aligned}$$

a. calculate the normalization constant $D_{n,l}$ for a hydrogen-like atom with atomic number Z;
b. calculate the mean value

$$\langle r\rangle_{nlm} = \frac{n^2 a_B}{Z}\left[1 + \frac{1}{2}\left(1 - \frac{\ell(\ell+1)}{n^2}\right)\right] \ ;$$

c. calculate the mean value

$$\left\langle \frac{1}{r} \right\rangle_{n\ell m} = \frac{Z}{n^2 a_B} \ .$$

Solution: *a. To obtain the normalization, we write*

$$1 = \langle 1 \rangle_{n\ell m} = \int \psi^*_{n\ell m} \psi_{r\ell m} d^3r = \int R_{n\ell} Y^*_{\ell m} R_{n\ell} Y_{\ell m} r^2 \sin\theta dr d\theta d\phi$$
$$= \int |Y_{\ell m}|^2 d\Omega \int_0^\infty R^2_{n\ell} r^2 dr = \int_0^\infty u^2_{n\ell} dr = \frac{a_B}{2Z} \int_0^\infty \left(D_{n\ell} \rho^{\ell+1} e^{-\rho/2} L^{(2\ell+1)}_{n-\ell-1}(\rho) \right)^2 d\rho \ .$$

Using the orthogonality relation of the Laguerre polynomials,

$$1 = \frac{n a_B}{2} D^2_{n\ell} \int_0^\infty \rho^{(2l+1)+1} e^{-\rho} L^{(2\ell+1)}_{n-\ell-1}(\rho)^2 d\rho = \frac{n a_B}{2} D^2_{n\ell} \frac{(n+\ell)!}{(n-\ell-1)!} 2n \ ,$$

We find

$$D_{n\ell} = \left(\frac{2Z}{n a_B} \right)^3 \frac{(n-\ell-1)!}{2n(n+\ell)!^3} \ .$$

b. We write,

$$\langle r \rangle_{n\ell m} = \int \psi^*_{n\ell m} r \psi_{r\ell m} d^3r = \int R_{n\ell} Y^*_{\ell m} r R_{n\ell} Y_{\ell m} r^2 \sin\theta dr d\theta d\phi$$
$$= \int |Y_{\ell m}|^2 d\Omega \int_0^\infty R^2_{n\ell} r^3 dr = \int_0^\infty R^2_{n\ell} r^3 dr \ .$$

we find the normalization of the radial functions,

$$R_{n\ell}(r) = -\left(\frac{2Z}{n a_B} \right)^3 \frac{(n-\ell-1)!}{2n(n+\ell)!^3} \rho^\ell e^{-\rho/2} L^{2\ell+1}_{n+\ell}(\rho) \qquad \textit{with} \qquad \rho \equiv \frac{2Z}{n a_B} r \ .$$

With this we obtain,

$$\langle r \rangle_{n\ell m} = \left[\frac{2Z}{n a_B} \frac{(n-\ell-1)!}{2n(n+\ell)!^3} \right]^2 \int_0^\infty \rho^{2l+3} e^{-\rho} L^{2\ell+1}_{n+\ell}(\rho)^2 \ d\rho \ .$$

which is the desired result.
c. In the same way we write

$$\left\langle \frac{1}{r} \right\rangle_{n\ell m} = \int \psi^*_{n\ell m} \frac{1}{r} \psi_{r\ell m} d^3r = \int_0^\infty R^2_{n\ell} r d^3r \ .$$

25.2.3.4 Ex: Orbital radii in Bohr's model

Using the results of 25.2.3.3, obtain the expectation values $\langle r \rangle$ for the states ψ_{100}, ψ_{210} and ψ_{320} of the hydrogen atom. Compare the results with those of Bohr's model.

Solution: *We write,*

$$\langle r\rangle_{100} = \frac{a_0}{Z}\frac{3}{2} \quad , \quad \langle r\rangle_{210} = \frac{2^2 a_B}{Z}\frac{5}{4} \quad , \quad \langle r\rangle_{320} = \frac{3^2 a_B}{Z}\frac{7}{6} \ .$$

The values obtained from Bohr's model are,

$$r_n = \frac{n^2 a_B}{Z} \ .$$

That is, the second term containing the angular momentum represents a correction. But the correction diminishes when $n, l \to \infty$.

25.2.3.5 Ex: The virial theorem and Bohr's model

Calculate, for the state ψ_{320} of the hydrogen atom, the expectation values $\langle \frac{1}{r}\rangle$, $\langle \frac{\mathbf{L}^2}{r^2}\rangle$, and $\langle \mathbf{p}^2\rangle$.
From the results, obtain the expectation values for the kinetic and potential energies, $\langle T\rangle$ and $\langle V\rangle$, and show that, consistent with the virial theorem, $\langle T\rangle = -(1/2)\langle V\rangle$. Compare the results with Bohr's model.

Solution: *Using the formulas (25.53), we find,*

$$\left\langle \frac{1}{\tilde{r}} \right\rangle_{320} = \frac{1}{n^2} = \frac{1}{9} \ .$$

Thus, the expectation value of the potential is,

$$\langle V(r)\rangle_{320} = -\frac{Ze^2}{4\pi\epsilon_0}\frac{Z}{a_B}\left\langle \frac{1}{\tilde{r}} \right\rangle_{320} = -\frac{Z^2 e^2}{4\pi\epsilon_0 a_B}\frac{1}{9} = -\frac{Z^2\hbar}{m a_B^2}\frac{1}{9} \ .$$

Also we can rewrite the kinetic energy operator as the sum of a radial term and a centrifugal term,

$$\hat{\mathbf{p}}^2 = \hat{p}_r^2 + \frac{\hat{\mathbf{L}}^2}{r^2} \ .$$

The expectation value of the centrifugal term is,

$$\left\langle \frac{\hat{\mathbf{L}}^2}{\tilde{r}^2} \right\rangle_{320} = \left\langle \frac{1}{\tilde{r}^2} \right\rangle_{320} \hbar^2\ell(\ell+1) = \frac{6\hbar^2}{n^3(\ell+\frac{1}{2})} = \frac{4\hbar^2}{45} \ .$$

To evaluate the radial term we need the wavefunction,

$$\psi_{320} = \frac{1}{81\sqrt{6\pi}}\left(\frac{Z}{a_B}\right)^{3/2} \tilde{r}^2 e^{-\tilde{r}/3}(3\cos^2\vartheta - 1) \qquad \textit{with} \qquad \tilde{r} \equiv \frac{rZ}{a_B} \ .$$

We now calculate,

$$\begin{aligned}\langle p_{\tilde{r}}^2\rangle_{320} &= \int \psi_{320}^* p_{\tilde{r}}^2 \psi_{320} d^3r \\ &= \frac{1}{81^2 6\pi}\left(\frac{Z}{a_B}\right)^3 \int_0^{2\pi} d\varphi \int_0^{\pi} (3\cos^2\vartheta - 1)^2 \sin\vartheta d\vartheta \int_0^{\infty} \tilde{r}^2 e^{-\tilde{r}/3} p_r^2 \left[\tilde{r}^2 e^{-\tilde{r}/3}\right] r^2 dr \\ &= \frac{1}{81^2 6\pi}\cdot 2\pi \cdot \frac{8}{5}\cdot(-\hbar^2)\int_0^{\infty} \tilde{r}^4 e^{-\tilde{r}/3}\frac{1}{\tilde{r}}\left(\frac{\partial^2}{\partial\tilde{r}^2}\tilde{r}\tilde{r}^2 e^{-\tilde{r}/3}\right) d\tilde{r} = \frac{\hbar^2}{45} \ .\end{aligned}$$

Thus, the expectation value of the kinetic energy is

$$\langle E_{kin}\rangle_{320} = \frac{Z^2}{a_B^2}\frac{\langle p_{\tilde{r}}^2\rangle_{320}}{2m} + \frac{Z^2}{a_B^2}\frac{1}{2m}\left\langle\frac{L^2}{\tilde{r}^2}\right\rangle_{320} = \frac{Z^2\hbar^2}{2ma_B^2}\frac{1}{9} = -\frac{1}{2}\langle V(r)\rangle_{320} \ ,$$

in agreement with the virial theorem. We also check that, in agreement with Bohr's model,

$$\left\langle\frac{\hat{\mathbf{p}}^2}{2m}\right\rangle_{320} + \langle V(r)\rangle_{320} = -\frac{1}{2}\frac{Z^2e^2}{4\pi\epsilon_0 a_B}\frac{1}{3^2} = E_3 \ .$$

25.2.3.6 Ex: Transition matrix elements

Using the following (non-normalized) wavefunctions of hydrogen, $\psi_{100}(\mathbf{r}) = e^{-\tilde{r}}$, $\psi_{210}(\mathbf{r}) = \tilde{r}e^{-\tilde{r}/2}\cos\theta$ and $\psi_{21\pm1}(\mathbf{r}) = \tilde{r}e^{-\tilde{r}/2}\sin\theta e^{\pm\imath\phi}$, calculate the matrix elements (a) $\langle\psi_{100}|\tilde{z}|\psi_{210}\rangle$, (b) $\langle\psi_{100}|\tilde{z}|\psi_{211}\rangle$, (c) $\langle\psi_{100}|\tilde{x}-\imath\tilde{y}|\psi_{210}\rangle$, and (d) $\langle\psi_{100}|\tilde{x}-\imath\tilde{y}|\psi_{211}\rangle$ using the formulae:

$$\begin{aligned}&\int_0^{\infty} x^4 e^{-3x/2}dx = \tfrac{256}{81} \quad , \quad \int_0^{\pi}\sin^3 x dx = \tfrac{4}{3} \ , \\ &\int_0^{\pi}\cos x\sin^2 x dx = 0 \quad , \quad \int_0^{\pi}\cos^2 x\sin x dx = \tfrac{2}{3} \ .\end{aligned}$$

Try to interpret the results.

Solution: *a. With $\tilde{z} = \tilde{r}\cos\theta$ we calculate,*

$$\begin{aligned}\langle\psi_{100}|\tilde{z}|\psi_{210}\rangle &= \int e^{-\tilde{r}}\cdot\tilde{z}\cdot\tilde{r}e^{-\tilde{r}/2}\cos\theta d^3\tilde{r} \\ &= \int \tilde{z}\tilde{r}e^{-3\tilde{r}/2}\cos\theta\tilde{r}^2\sin\theta d\theta d\phi d\tilde{r} \\ &= \int_0^{\pi}\cos^2\theta\sin\theta d\theta\int_0^{2\pi} d\phi\int_0^{\infty}\tilde{r}^4 e^{-3\tilde{r}/2}d\tilde{r} = \tfrac{2}{3}\cdot 2\pi\cdot\tfrac{256}{81} = \tfrac{2^{10}}{3^5}\pi \ .\end{aligned}$$

b. With $\tilde{z} = \tilde{r}\cos\theta$ we calculate,

$$\begin{aligned}\langle\psi_{100}|\tilde{z}|\psi_{211}\rangle &= \int e^{-\tilde{r}}\cdot\tilde{z}\cdot\tilde{r}e^{-\tilde{r}/2}\sin\theta e^{\imath\phi}d^3\tilde{r}\\ &= \int \tilde{z}\tilde{r}e^{-3\tilde{r}/2}\sin\theta e^{\imath\phi}\tilde{r}^2\sin\theta d\theta d\phi d\tilde{r}\\ &= \int_0^\pi \cos\theta\sin^2\theta d\theta\int_0^{2\pi}e^{i\phi}d\phi\int_0^\infty \tilde{r}^4e^{-3\tilde{r}/2}d\tilde{r} = 0\ .\end{aligned}$$

c. With $\tilde{x}-\imath\tilde{y} = \tilde{r}\sin\theta e^{-\imath\phi}$ we calculate,

$$\begin{aligned}\langle\psi_{100}|\tilde{x}-\imath\tilde{y}|\psi_{210}\rangle &= \int e^{-\tilde{r}}\cdot(\tilde{x}-\imath\tilde{y})\cdot\tilde{r}e^{-\tilde{r}/2}\cos\theta d^3\tilde{r}\\ &= \int(\tilde{x}-\imath\tilde{y})\tilde{r}e^{-3\tilde{r}/2}\cos\theta\tilde{r}^2\sin\theta d\theta d\phi d\tilde{r}\\ &= \int_0^\pi \cos\theta\sin^2\theta d\theta\int_0^{2\pi}e^{-\imath\phi}d\phi\int_0^\infty \tilde{r}^4e^{-3\tilde{r}/2}d\tilde{r} = 0\ .\end{aligned}$$

d. With $\tilde{x}-\imath\tilde{y} = \tilde{r}\sin\theta e^{-\imath\phi}$ we calculate,

$$\begin{aligned}\langle\psi_{100}|\tilde{x}-\imath\tilde{y}|\psi_{211}\rangle &= \int e^{-\tilde{r}}\cdot(\tilde{x}-\imath\tilde{y})\cdot\tilde{r}e^{-\tilde{r}/2}\sin\theta e^{\imath\phi}d^3\tilde{r}\\ &= \int(\tilde{x}-\imath\tilde{y})\tilde{r}e^{-3\tilde{r}/2}\sin\theta e^{\imath\phi}\tilde{r}^2\sin\theta d\theta d\phi d\tilde{r}\\ &= \int_0^\pi \sin^3\theta d\theta\int_0^{2\pi}d\phi\int_0^\infty \tilde{r}^4e^{-3\tilde{r}/2}d\tilde{r} = \tfrac{4}{3}\cdot 2\pi\cdot\tfrac{256}{81} = \tfrac{2^{11}}{3^5}\pi\ .\end{aligned}$$

The matrix elements describe transitions between electronic states induced by dipole radiation. The selection rules are $|\Delta\ell| = 1$ and $\Delta m = 0$ for linear polarization and $\Delta m = \pm 1$ for circular polarization (always with respect to the $\hat{\mathbf{e}}_z$-axis). The linear polarization corresponds to the transition operator $\hat{z}$ and the circular polarization to the operator $\hat{x}-\imath\hat{y}$.

25.3 Angular momentum

25.3.1 The orbital angular momentum operator

The definition of *orbital angular momentum* is adopted from classical mechanics:

$$\hat{\mathbf{l}} = \hat{\mathbf{r}}\times\hat{\mathbf{p}} = -\imath\hbar\hat{\mathbf{r}}\times\hat{\nabla} = -\imath\hbar\begin{vmatrix}\hat{\mathbf{e}}_x & \hat{\mathbf{e}}_y & \hat{\mathbf{e}}_z\\ x & y & z\\ \partial_x & \partial_y & \partial_z\end{vmatrix}\ . \tag{25.58}$$

To better understand the properties of the angular momentum operator in quantum mechanics we will derive in the Excs. 25.3.4.1 and 25.3.4.2 some of its properties.

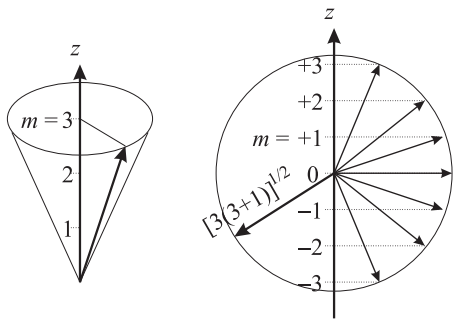

Figure 25.8: Illustration of angular momentum in quantum mechanics.

25.3.1.1 Constants of motion

The preceding chapter dealt with the resolution of the radial and angular equations for the case of a radial potential. The radial equation allowed to calculate the eigenenergies of the Hamiltonian $\hat{H}$,

$$\hat{H}|\psi\rangle = E_{n\ell}|\psi\rangle \ . \tag{25.59}$$

We also found the common eigenvalues and eigenfunctions of operators $\hat{\mathbf{l}}^2$ and $\hat{l}_z$ [see Eqs. (25.20) and (25.24)]. We now use the notation $|\ell, m\rangle \equiv Y_{\ell m}(\theta, \phi)$ for the eigenfunctions,

$$\hat{\mathbf{l}}^2|\ell, m\rangle = \hbar^2\ell(\ell+1)|\ell, m\rangle \qquad \text{and} \qquad \hat{l}_z|\ell, m\rangle = \hbar m|\ell, m\rangle \ . \tag{25.60}$$

With this we have,

$$\begin{aligned} & [\hat{H}, \hat{\mathbf{l}}^2]|\psi\rangle = \hat{H}\hbar^2\ell(\ell+1)|\psi\rangle - \hat{\mathbf{l}}^2 E|\psi\rangle = 0 \\ \text{and} \quad & [\hat{H}, \hat{l}_z]|\psi\rangle = \hat{H}\hbar m|\psi\rangle - \hat{l}_z E|\psi\rangle = 0 \ . \end{aligned} \tag{25.61}$$

Therefore, the operators $\hat{\mathbf{l}}^2$ and $\hat{l}_z$ are constants of motion,

$$[\hat{H}, \hat{l}_z] = 0 = [\hat{H}, \hat{\mathbf{l}}^2] \ . \tag{25.62}$$

Exc. 25.3.4.3 asks to show explicitly, at the example of an isotropic three-dimensional harmonic oscillator, that $\hat{\mathbf{l}}^2$ and $\hat{l}_z$ are constants of motion.

25.3.2 SU(2) algebra of angular momentum and spin

So far, we have solved the angular eigenvalue equation in the spatial representation for an orbital angular momentum, $\hat{\mathbf{l}} = \hat{\mathbf{r}} \times \hat{\mathbf{p}}$. But it is not clear, whether *every* angular momentum has this representation, which is derived from classical notions. Using the orbital angular momentum expression (25.58) it is easy to verify,

$$\hat{\mathbf{l}} \times \hat{\mathbf{l}} = \imath\hbar\hat{\mathbf{l}} \ . \tag{25.63}$$

However, it is not clear a priori, whether *any* quantity $\hat{\mathbf{j}}$ satisfying

$$\boxed{\hat{\mathbf{j}} \times \hat{\mathbf{j}} = \imath\hbar\hat{\mathbf{j}}} \qquad \text{or equivalently} \qquad [\hat{j}_m, \hat{j}_n] = \imath\hbar\epsilon_{kmn}\hat{j}_k \tag{25.64}$$

using the Levi-Civita symbol, can be represented like (25.58). In fact, we will see that the electron has an intrinsic spin with no orbiting charges, and cannot be represented as an orbital angular momentum. What needs to be done now is to show that (25.64) generates a consistent algebra even in cases beyond the representation (25.58).

Since $\hat{\mathbf{j}}^2$ and $\hat{j}_z$ commute (we show this from Eq. (25.64) in Exc. 25.3.4.4), they have common eigenfunctions $|j,m\rangle$. We can write the eigenvalues as,

$$\hat{\mathbf{j}}^2|j,m\rangle = \hbar^2 j(j+1)|j,m\rangle \qquad \text{and} \qquad \hat{j}_z|j,m\rangle = \hbar m|j,m\rangle \ , \tag{25.65}$$

where, for now, we only know that m is real and $j \geq 0$. But since $\langle j,m|\hat{\mathbf{j}}^2|j,m\rangle \geq \langle j,m|\hat{j}_z^2|j,m\rangle$, it is clear that $j(j+1) \geq m^2$.

25.3.2.1 Rising and lowering operator

Now we introduce the *rising operator* $\hat{j}_+$ and the *lowering operator* $\hat{j}_-$ via

$$\hat{j}_\pm \equiv \hat{j}_x \pm \imath \hat{j}_y \qquad \text{such that} \qquad \hat{j}_- = \hat{j}_+^\dagger \ . \tag{25.66}$$

It is easy to check the following relationships

$$[\hat{j}_z, \hat{j}_\pm] = \pm\hbar\hat{j}_\pm \qquad \text{and} \qquad [\hat{\mathbf{j}}^2, \hat{j}_\pm] = 0 \qquad \text{and} \qquad \hat{j}_\mp\hat{j}_\pm = \hat{\mathbf{j}}^2 - \hat{j}_z^2 \mp \hbar\hat{j}_z \ . \tag{25.67}$$

With this we find

$$\begin{aligned} &\hat{j}_z\hat{j}_\pm|j,m\rangle = ([\hat{j}_z,\hat{j}_\pm] + \hat{j}_\pm j_z)|j,m\rangle = \hbar(m\pm 1)\hat{j}_\pm|j,m\rangle \\ \text{and} \quad &\hat{\mathbf{j}}^2 j_\pm|j,m\rangle = \hat{j}_\pm\hat{\mathbf{j}}^2|j,m\rangle = \hbar^2 j(j+1)\hat{j}_\pm|j,m\rangle \ . \end{aligned} \tag{25.68}$$

That is, $\hat{j}_\pm|j,m\rangle$ is a eigenstate of $\hat{\mathbf{j}}^2$ and $\hat{j}_z$ with the eigenvalues j and $m \pm 1$, respectively, if $j_\pm|j,m\rangle \neq 0$. Hence,

$$\hat{j}_+|j,m\rangle \propto |j,m+1\rangle \ . \tag{25.69}$$

In order not to violate the condition $m^2 \leq j(j+1)$, we need to fix $\hat{j}_\pm|j,\pm j\rangle = 0$. Therefore, for a specified j, the m can have only one of the $2j+1$ possible values $m = -j, -j+1, .., j$. Since $2j+1$ is an integer, j can only have values $j = 0, \frac{1}{2}, 1, \frac{3}{2}, ...$ Thus, the eigenvalue equation of the observables $\hat{\mathbf{j}}^2$, $\hat{\mathbf{j}}$ is solved, since we could have chosen instead of $\hat{j}_z$ any one of the components of $\hat{\mathbf{j}}$, knowing that the others do not commute with the chosen one.

All spin components $\hat{j}_z$ and the scalar $\hat{\mathbf{j}}^2$ can only have discrete eigenvalues. The smallest unit is $\hbar/2$. With the normalization $\langle j,m|j',m'\rangle = \delta_{j,j'}\delta_{m,m'}$ we have,

$$\langle j,m|\hat{j}_\mp\hat{j}_\pm|j,m\rangle = \langle j,m|(\hat{\mathbf{j}}^2 - \hat{j}_z^2 \mp \hbar\hat{j}_z)|j,m\rangle = \hbar^2[j(j+1) - m(m\pm 1)] \ , \tag{25.70}$$

and

$$\boxed{\hat{j}_\pm|j,m\rangle = \hbar\sqrt{j(j+1) - m(m\pm 1)}|j,m\pm 1\rangle} \ . \tag{25.71}$$

In Exc. 25.3.4.5 we calculate the uncertainty of the angular momentum components, in Exc. 25.3.4.6 we write the operator $\hat{j}_x$ in a matrix form, and in Excs. 25.3.4.7 and 25.3.4.8 we calculate projections of the spin of the electron in different directions of the quantization axis.

25.3.3 The electron spin

Every angular momentum $\hat{\mathbf{l}}$ generates a *magnetic dipole moment* $\vec{\mu}_\ell \propto \hat{\mathbf{l}}$, which interacts with external magnetic fields, $V(\vec{\mathcal{B}}) = \vec{\mu}_\ell \cdot \vec{\mathcal{B}}$. *Inhomogeneous* magnetic fields exert forces on dipole moments, $\mathbf{F} = -\nabla(\vec{\mu}_\ell \cdot \vec{\mathcal{B}})$, which are detected by the *Stern-Gerlach experiment*. This experiment reveals not only the quantization of angular momentum, but also the presence of semi-integral values for the magnetic quantum number.

In 1925 Uhlenbeck and Goudsmit proposed that the electron could have an intrinsic angular momentum with the quantum number $s = 1/2$. This angular momentum, called *spin*, would not correspond to any orbiting mass or charge distribution within the classical radius of the electron of the type $\mathbf{l} = \mathbf{r} \times \mathbf{p}$. The spin is a purely quantum phenomenon because it disappears when $\hbar \to 0$. It is believed nowadays that the electron is actually point-like with no detectable deviation from Coulomb's law at any distance. The spin of the electron does not follow from the Schrödinger equation, but can be included, ad hoc. On the other hand, it is interesting that it is a necessary consequence of the stringent relativistic derivation of quantum mechanics by *Paul Dirac*.

To characterize the spin, we can use the whole SU(2) formalism of the quantum mechanics of angular momentum:

$$\hat{\mathbf{s}} \times \hat{\mathbf{s}} = \imath\hbar\hat{\mathbf{s}} \ , \tag{25.72}$$

and

$$\begin{aligned} &\hat{\mathbf{s}}^2|\tfrac{1}{2},\pm\tfrac{1}{2}\rangle = \hbar^2\tfrac{3}{4}|\tfrac{1}{2},\pm\tfrac{1}{2}\rangle \quad , \quad \hat{s}_z|\tfrac{1}{2},\pm\tfrac{1}{2}\rangle = \pm\tfrac{\hbar}{2}|\tfrac{1}{2},\pm\tfrac{1}{2}\rangle \quad , \\ &\hat{s}_\pm = \hbar\hat{\sigma}_\pm = \hbar|\tfrac{1}{2},\pm\tfrac{1}{2}\rangle\langle|\tfrac{1}{2},\mp\tfrac{1}{2}| \ . \end{aligned} \tag{25.73}$$

The operators $\hat{\sigma}_\pm$ are the *Pauli spin matrices* defined in (23.47) for the basis chosen as,

$$|\tfrac{1}{2},+\tfrac{1}{2}\rangle = \begin{pmatrix} 1 \\ 0 \end{pmatrix} \quad \text{and} \quad |\tfrac{1}{2},-\tfrac{1}{2}\rangle = -\tfrac{1}{2}\begin{pmatrix} 0 \\ 1 \end{pmatrix} \ . \tag{25.74}$$

25.3.4 Exercises

25.3.4.1 Ex: Properties of the angular orbital momentum

Show that $\hat{\mathbf{l}} \times \hat{\mathbf{l}} = \imath\hbar\hat{\mathbf{l}}$ and $[\hat{l}_x, \hat{l}_y] = \imath\hbar\hat{l}_z$.

Solution: *For the x-component we have,*

$$\begin{aligned} (\hat{\mathbf{l}} \times \hat{\mathbf{l}})_x = [\hat{l}_y, \hat{l}_z] &= (\hat{z}\hat{p}_x - \hat{x}\hat{p}_z)(\hat{x}\hat{p}_y - \hat{y}\hat{p}_x) - (\hat{x}\hat{p}_y - \hat{y}\hat{p}_x)(\hat{z}\hat{p}_x - \hat{x}\hat{p}_z) \\ &= (\hat{y}\hat{p}_z - \hat{z}\hat{p}_y)(\hat{x}\hat{p}_x - \hat{p}_x\hat{x}) = \imath\hbar\hat{l}_x \ , \end{aligned}$$

where we used $[\hat{p}_k, \hat{x}_m] = -\imath\hbar\delta_{km}$. For the other components we can do the same calculation.

25.3.4.2 Ex: Levi-Civita tensor

a. Demonstrate $[\hat{l}_k, \hat{r}_m] = \imath\hbar\hat{r}_n\epsilon_{kmn}$ where the Levi-Civita tensor is defined by $\epsilon_{kmn} = 1$ when (kmn) is an even permutation of (123), $\epsilon_{kmn} = -1$ for an odd permutation, and $\epsilon_{kmn} = 0$ when two of the indices are equal.
b. Verify $\hat{j}_m\hat{j}_n = \frac{1}{4}\delta_{mn} + \frac{\imath}{2}\epsilon_{kmn}\hat{j}_k$.

Solution: *a. Using*

$$\hat{l}_k = (\hat{r}\times\hat{p})_k = (\hat{r}_m\hat{p}_n - \hat{r}_n\hat{p}_m)\epsilon_{kmn} \qquad \textit{and} \qquad [\hat{p}_k, \hat{r}_m] = -\imath\hbar\delta_{km} \ ,$$

it is easy to show

$$\begin{aligned}[\hat{l}_k, \hat{r}_m] &= (\hat{r}_m\hat{p}_n - \hat{r}_n\hat{p}_m)\epsilon_{kmn}\hat{r}_m - \hat{r}_m(\hat{r}_m\hat{p}_n - \hat{r}_n\hat{p}_m)\epsilon_{kmn} \\ &= [\hat{r}_n\hat{r}_m\hat{p}_m - \hat{r}_n\hat{p}_m\hat{r}_m]\,\epsilon_{kmn} = \imath\hbar\hat{r}_n\epsilon_{kmn} \ .\end{aligned}$$

b.

25.3.4.3 Ex: Angular orbital momentum of a harmonic oscillator

Show for an isotropic three-dimensional harmonic oscillator: $[\hat{H}, \hat{\mathbf{l}}^2] = [\hat{H}, \hat{l}_z] = 0$. Make explicit calculations, that is, show

$$\left[\tfrac{\hat{p}^2}{2m}, \hat{l}_z\right] = 0 = \left[\frac{m}{2}\omega^2\hat{r}^2, \hat{l}_z\right] \qquad \text{and} \qquad \left[\tfrac{\hat{p}^2}{2m}, \hat{\mathbf{l}}^2\right] = 0 = \left[\frac{m}{2}\omega^2\hat{r}^2, \hat{\mathbf{l}}^2\right] \ .$$

Solution: *In general way, we can show*

$$\begin{aligned}\left[\tfrac{\hat{p}^2}{2m}, \hat{l}_z\right] &= \tfrac{1}{2m}[\hat{p}_x^2 + \hat{p}_y^2 + \hat{p}_z^2, \hat{x}\hat{p}_y - \hat{y}\hat{p}_x] = \tfrac{1}{2m}[\hat{p}_x^2, \hat{x}]\hat{p}_y - \frac{1}{2m}[\hat{p}_y^2, \hat{y}]\hat{p}_x \\ &= \tfrac{1}{2m}\left(\hat{p}_x\hat{p}_x\hat{x}\hat{p}_y - \hat{p}_x\hat{x}\hat{p}_x\hat{p}_y - \imath\hbar\hat{p}_x\hat{p}_y - [\hat{p}_y^2, \hat{y}\hat{p}_x]\right) = \tfrac{1}{2m}\left(-2\imath\hbar\hat{p}_x\hat{p}_y + 2\imath\hbar\hat{p}_x\hat{p}_y\right) = 0 \ ,\end{aligned}$$

and in the same way $\left[\tfrac{\hat{p}^2}{2m}, \hat{\mathbf{l}}^2\right] = 0$. *For a harmonic potential,*

$$\begin{aligned}\left[\frac{m}{2}\omega^2\hat{r}^2, \hat{l}_z\right] &= \frac{m}{2}\omega^2[\hat{x}^2 + \hat{y}^2 + \hat{z}^2, \hat{x}\hat{p}_y - \hat{y}\hat{p}_x] = \frac{m}{2}\omega^2[\hat{y}^2, \hat{p}_y]\hat{x} - \frac{m}{2}\omega^2[\hat{x}^2, \hat{p}_x]\hat{y} \\ &= \frac{m}{2}\omega^2(\hat{y}\hat{p}_y\hat{y}\hat{x} + \hat{y}\imath\hbar\hat{x} - \hat{p}_y\hat{y}\hat{y}\hat{x} - [\hat{x}^2, \hat{p}_x]\hat{y}) = \frac{m}{2}\omega^2(2\imath\hbar\hat{x}\hat{y} - 2\imath\hbar\hat{x}\hat{y}) = 0 \ .\end{aligned}$$

25.3.4.4 Ex: Commutation of the absolute value and the components of the orbital angular momentum

Show $[\hat{\mathbf{j}}^2, \hat{\mathbf{j}}] = 0$.

Solution: *With* $\hat{\mathbf{j}}^2 = \hat{j}_x^2 + \hat{j}_y^2 + \hat{j}_z^2$ *and* $[\hat{A}\hat{B}, \hat{C}] = \hat{A}[\hat{B}, \hat{C}] + [\hat{A}, \hat{C}]\hat{B}$ *we find, using the formal definition of angular momentum* $[\hat{j}_m, \hat{j}_n] = i\hbar\epsilon_{kmn}\hat{j}_k$, *that*

$$-[\hat{j}_x^2, \hat{j}_z] = \imath\hbar(\hat{j}_x\hat{j}_y + \hat{j}_y\hat{j}_x) = [\hat{j}_y^2, \hat{j}_z] \qquad \textit{and} \qquad [\hat{j}_z^2, \hat{j}_z] = 0 \ .$$

For the components $\hat{j}_x$ *and* $\hat{j}_y$ *we find the same results.*

25.3.4.5 Ex: Uncertainty of angular momentum components

Show that if $\hat{j}_z$ is precise, then $\hat{j}_x$ and $\hat{j}_y$ are imprecise.

Solution: *The definition of the operators* $\hat{j}_\pm \equiv \hat{j}_x \pm \imath\hat{j}_y$ *implies that* $\hat{j}_z$ *is an observable. Therefore,*

$$\begin{aligned}
(\Delta j_z)^2 &= \langle j,m|\hat{j}_z^2|j,m\rangle - \langle j,m|\hat{j}_z|j,m\rangle^2 = 0 \\
(\Delta j_x)^2 &= \langle j,m|\hat{j}_x^2|j,m\rangle - \langle j,m|\hat{j}_x|j,m\rangle^2 = \langle j,m|\hat{j}_x^2|j,m\rangle = \tfrac{1}{4}\langle j,m|(\hat{j}_+ + \hat{j}_-)^2|j,m\rangle \\
&= \tfrac{1}{4}\langle j,m|\hat{j}_+\hat{j}_- + \hat{j}_-\hat{j}_+|j,m\rangle = \tfrac{\hbar^2}{2}[j(j+1) - m^2] \geq \tfrac{\hbar^2}{2}j \ .
\end{aligned}$$

25.3.4.6 Ex: Matrix representation of the components of the angular momentum

Calculate the matrix elements of $\hat{j}_x$ and $\hat{j}_x^2$ in the basis where $\hat{j}_z$ is observable. Give the general formula and examples for $j = \frac{1}{2}$ and $j = 1$.

Solution: *We show,*

$$\begin{aligned}
\langle j',m'|\hat{j}_x|j,m\rangle &= \tfrac{1}{2}\langle j',m'|\hat{j}_+ + \hat{j}_-|j,m\rangle \\
&= \tfrac{\hbar}{2}\sqrt{j(j+1) - m(m+1)}\delta_{j',j}\delta_{m',m+1} + \tfrac{\hbar}{2}\sqrt{j(j+1) - m(m-1)}\delta_{j',j}\delta_{m',m-1} \ .
\end{aligned}$$

Similarly using $\hat{j}_x^2 = \frac{1}{4}(\hat{j}_+^2 + \hat{j}_-^2 + \hat{j}_+\hat{j}_- + \hat{j}_-\hat{j}_+) = \frac{1}{4}(\hat{j}_+^2 + \hat{j}_-^2 + 2\hat{\mathbf{j}}^2 - 2\hat{j}_z^2)$, *we get,*

$$\begin{aligned}
\langle j',m'|\hat{j}_x^2|j,m\rangle &= \tfrac{\hbar^2}{4}\sqrt{j(j+1) - (m+1)(m+2)}\sqrt{j(j+1) - m(m+1)}\delta_{j',j}\delta_{m',m+2} \\
&+ \tfrac{\hbar^2}{4}\sqrt{j(j+1) - (m-1)(m-2)}\sqrt{j(j+1) - m(m-1)}\delta_{j',j}\delta_{m',m-2} \\
&+ \tfrac{\hbar^2}{2}[j(j+1) - m^2]\delta_{j',j}\delta_{m',m} \ .
\end{aligned}$$

For example for $j = 1/2$ *we get,*

$$\hat{j}_x = \tfrac{\hbar}{\sqrt{2}}\hat{\sigma}_x \qquad \textit{and} \qquad \hat{j}_x^2 = \tfrac{\hbar^2}{2}\mathbb{I} \ .$$

And for $j = 1$ *we get,*

$$\hat{j}_x = \tfrac{\hbar}{2}\begin{pmatrix} 0 & 1 & 0 \\ 1 & 0 & 1 \\ 0 & 1 & 0 \end{pmatrix} \qquad \textit{and} \qquad \hat{j}_x^2 = \tfrac{\hbar^2}{4}\begin{pmatrix} 1 & 0 & 1 \\ 0 & 2 & 0 \\ 1 & 0 & 1 \end{pmatrix} \ .$$

25.3.4.7 Ex: Spin-1/2-particle in a magnetic field

Consider a spin-1/2-particle whose magnetic moment is $\vec{\mu} = \gamma \mathbf{s}$ (where γ is a constant). We can describe the quantum state of this particle in terms of the space generated by the eigenvectors $|+\rangle$ and $|-\rangle$ of the operator $\hat{s}_z$, which measures the spin projection in z-direction:

$$\hat{s}_z|+\rangle = \tfrac{\hbar}{2}|+\rangle \quad , \quad \hat{s}_z|-\rangle = -\tfrac{\hbar}{2}|-\rangle$$

Initially ($t = 0$) the particle is in the state $\psi(t=0)\rangle = |+\rangle$ and is subject to a uniform magnetic field $\vec{\mathcal{B}} = \mathcal{B}\hat{\mathbf{e}}_y$, so that:

$$\hat{H} = -\vec{\mu} \cdot \vec{\mathcal{B}} = -\gamma \mathcal{B} \hat{s}_y \ .$$

a. What are the possible measurements of the spin projection on the y-axis?
b. Find the eigenvectors of $\hat{s}_y$.
c. Get $|\psi(t)\rangle$ at $t > 0$ in terms of the eigenvectors $|+\rangle$ and $|-\rangle$ defined above.
d. Obtain the mean expectation values of the observables $\hat{s}_x$, $\hat{s}_y$ and $\hat{s}_z$ as a function of time.

Solution: *a. In any axis the possible projections are: $+\hbar/2$ and $-\hbar/2$.*
b. We have,

$$\hat{s}_y = \tfrac{\hbar}{2} \begin{pmatrix} 0 & -\imath \\ \imath & 0 \end{pmatrix} \ .$$

With this,

$$\hat{s}_y \begin{pmatrix} a \\ b \end{pmatrix} = \tfrac{\hbar}{2} \begin{pmatrix} -\imath b \\ \imath a \end{pmatrix} = \tfrac{\hbar}{2} \begin{pmatrix} a \\ b \end{pmatrix} \implies a = -\imath b \implies |+_y\rangle = b \begin{pmatrix} -\imath \\ 1 \end{pmatrix} \ .$$

Normalization, $|\langle +_y|+_y\rangle|^2 = 1$, requires,

$$|+_y\rangle = \tfrac{1}{\sqrt{2}} \begin{pmatrix} -\imath \\ 1 \end{pmatrix} \ .$$

Also,

$$\hat{s}_y \begin{pmatrix} a \\ b \end{pmatrix} = \frac{\hbar}{2} \begin{pmatrix} -\imath b \\ \imath a \end{pmatrix} = -\frac{\hbar}{2} \begin{pmatrix} a \\ b \end{pmatrix} \implies a = \imath b \implies |-_y\rangle = b \begin{pmatrix} \imath \\ 1 \end{pmatrix} \ .$$

Normalization, $|\langle -_y|-_y\rangle|^2 = 1$, requires,

$$|-_y\rangle = \tfrac{1}{\sqrt{2}} \begin{pmatrix} \imath \\ 1 \end{pmatrix} \ .$$

Finally,

$$|\pm_y\rangle = \mp \tfrac{\imath}{\sqrt{2}}|+\rangle + \tfrac{1}{\sqrt{2}}|-\rangle \ .$$

c. We have the solution,

$$|\psi(t)\rangle = e^{-\imath\hat{H}t/\hbar}|\psi(0)\rangle = e^{\imath\gamma\mathcal{B}\hat{s}_y t/\hbar}|+\rangle \ .$$

We can express $|+\rangle$ *in terms of the eigenvectors of* $\hat{s}_y$*:*

$$|+\rangle = \tfrac{\imath}{\sqrt{2}}(|+_y\rangle - |-_y\rangle) \ .$$

Finally, since $\hat{s}_y|\pm_y\rangle = \pm\frac{\hbar}{2}|\pm_y\rangle$ *engenders* $f(\hat{s}_y)|\pm_y\rangle = f(\pm\frac{\hbar}{2})|\pm_y\rangle$*,*

$$|\psi(t)\rangle = e^{\imath\gamma\mathcal{B}\hat{s}_y t/\hbar}\tfrac{\imath}{\sqrt{2}}(|+_y\rangle - |-_y\rangle) = \tfrac{\imath}{\sqrt{2}}(e^{\imath\gamma\mathcal{B}t/2}|+_y\rangle - e^{-\imath\gamma\mathcal{B}t/2}|-_y\rangle) \ .$$

Expressing the eigenvectors of $\hat{s}_y$ *by the eigenvectors of* $\hat{s}_z$*:*

$$\begin{aligned}|\psi(t)\rangle &= \tfrac{\imath}{\sqrt{2}}e^{\imath\gamma\mathcal{B}t/2}\left(\tfrac{-\imath}{\sqrt{2}}|+\rangle + \tfrac{1}{\sqrt{2}}|-\rangle\right) - e^{-\imath\gamma\mathcal{B}t/2}\left(\tfrac{\imath}{\sqrt{2}}|+\rangle + \tfrac{1}{\sqrt{2}}|-\rangle\right)\\ &= \tfrac{\imath}{2}\left[-2\imath\cos\tfrac{\gamma\mathcal{B}t}{2}|+\rangle + 2\imath\sin\tfrac{\gamma\mathcal{B}t}{2}|-\rangle\right] = \cos\tfrac{\gamma\mathcal{B}t}{2}|+\rangle - \sin\tfrac{\gamma\mathcal{B}t}{2}|-\rangle \ .\end{aligned}$$

d. We want $\langle\psi(t)|\hat{s}_i|\psi(t)\rangle$ *with* $i = x, y, z$*. We have,*

$$|\psi(t)\rangle = \begin{pmatrix}\cos\frac{\gamma\mathcal{B}t}{2}\\ -\sin\frac{\gamma\mathcal{B}t}{2}\end{pmatrix} \ .$$

Now,

$$\begin{aligned}\langle\hat{s}_x\rangle &= \begin{pmatrix}\cos & -\sin\end{pmatrix}\tfrac{\hbar}{2}\begin{pmatrix}0 & 1\\ 1 & 0\end{pmatrix}\begin{pmatrix}\cos\\ -\sin\end{pmatrix} = \tfrac{\hbar}{2}(-\cos\sin - \cos\sin) = -\tfrac{\hbar}{2}\sin(\gamma\mathcal{B}t)\\ \langle\hat{s}_y\rangle &= \begin{pmatrix}\cos & -\sin\end{pmatrix}\tfrac{\hbar}{2}\begin{pmatrix}0 & -\imath\\ \imath & 0\end{pmatrix}\begin{pmatrix}\cos\\ -\sin\end{pmatrix} = \tfrac{\hbar}{2}(\imath\cos\sin - \imath\cos\sin) = 0\\ \langle\hat{s}_z\rangle &= \begin{pmatrix}\cos & -\sin\end{pmatrix}\tfrac{\hbar}{2}\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix}\begin{pmatrix}\cos\\ -\sin\end{pmatrix} = \tfrac{\hbar}{2}(\cos^2 - \sin^2) = \tfrac{\hbar}{2}\cos(\gamma\mathcal{B}t) \ .\end{aligned}$$

25.3.4.8 Ex: Spin expectation value for a two-level system

Consider an arbitrary state of a two-level system $|\vartheta,\varphi\rangle = \cos\frac{\vartheta}{2}|+\rangle + e^{\imath\varphi}\sin\frac{\vartheta}{2}|-\rangle$ and calculate the expectation values of the ladder operators $\hat{s}_\pm$ and of the spin operator $\hat{\mathbf{s}}$. Also calculate the expectation values of $\hat{s}_\pm^2$, $\hat{s}_\pm\hat{s}_\mp$, $\hat{s}_\alpha^2$ with $\alpha = x, y, z$. Finally, calculate the uncertainties of $\hat{s}_\alpha$ and check the uncertainty relation.

Solution: *Using* $\hat{s}_\pm|\mp\rangle = |\pm\rangle$*,* $\hat{s}_\mp|\mp\rangle = 0$*, and* $\hat{s}_z|\pm\rangle = \pm\frac{1}{2}|\pm\rangle$*, we first calculate,*

$$\langle\vartheta,\varphi|\hat{s}_+|\vartheta,\varphi\rangle = \left(\langle+|\cos\tfrac{\vartheta}{2} + \langle-|e^{-\imath\varphi}\sin\tfrac{\vartheta}{2}\right)\hat{s}_+\left(\cos\tfrac{\vartheta}{2}|+\rangle + e^{\imath\varphi}\sin\tfrac{\vartheta}{2}|-\rangle\right) = \tfrac{1}{2}e^{\imath\varphi}\sin\vartheta$$

$$\langle\vartheta,\varphi|\hat{\mathbf{s}}|\vartheta,\varphi\rangle = \begin{pmatrix}\frac{1}{2}(\hat{s}_+ + \hat{s}_-)\\ \frac{1}{2\imath}(\hat{s}_+ - \hat{s}_-)\\ \frac{1}{2}[\hat{s}_+, \hat{s}_-]\end{pmatrix} = \begin{pmatrix}\frac{1}{2}\cos\varphi\sin\vartheta\\ \frac{1}{2}\sin\varphi\sin\vartheta\\ \frac{1}{2}\cos\vartheta\end{pmatrix} \ ,$$

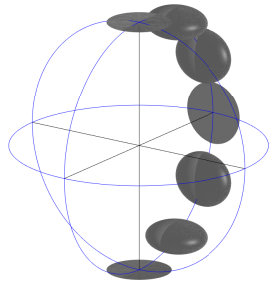

Figure 25.9: (code) Illustration of the uncertainties for various states on the Bloch sphere.

We also calculate,

$$\begin{aligned}
\langle\vartheta,\varphi|\hat{s}_+^2|\vartheta,\varphi\rangle &= 0 = \langle\vartheta,\varphi|\hat{s}_-^2|\vartheta,\varphi\rangle \\
\langle\vartheta,\varphi|\hat{s}_+\hat{s}_-|\vartheta,\varphi\rangle &= \left(\langle+|\cos\tfrac{\vartheta}{2} + \langle-|e^{-\imath\varphi}\sin\tfrac{\vartheta}{2}\right)\hat{s}_+\hat{s}_-\left(\cos\tfrac{\vartheta}{2}|+\rangle + e^{\imath\varphi}\sin\tfrac{\vartheta}{2}|-\rangle\right) = \cos^2\tfrac{\vartheta}{2} \\
\langle\vartheta,\varphi|\hat{s}_-\hat{s}_+|\vartheta,\varphi\rangle &= \sin^2\tfrac{\vartheta}{2} \\
\langle\vartheta,\varphi|\hat{s}_x^2|\vartheta,\varphi\rangle &= \tfrac{1}{4}\left(\hat{s}_+\hat{s}_- + \hat{s}_+\hat{s}_- + \hat{s}_+^2 + \hat{s}_-^2\right) = \tfrac{1}{4} \\
\langle\vartheta,\varphi|\hat{s}_y^2|\vartheta,\varphi\rangle &= \tfrac{1}{4}\left(\hat{s}_+\hat{s}_- + \hat{s}_+\hat{s}_- - \hat{s}_+^2 - \hat{s}_-^2\right) = \tfrac{1}{4} \\
\langle\vartheta,\varphi|\hat{s}_z^2|\vartheta,\varphi\rangle &= \left(\langle+|\cos\tfrac{\vartheta}{2} + \langle-|e^{-\imath\varphi}\sin\tfrac{\vartheta}{2}\right)\hat{s}_z^2\left(\cos\tfrac{\vartheta}{2}|+\rangle + e^{\imath\varphi}\sin\tfrac{\vartheta}{2}|-\rangle\right) = \tfrac{1}{4}\ ,
\end{aligned}$$

Finally,

$$\begin{aligned}
\langle\vartheta,\varphi|\Delta\hat{s}_x|\vartheta,\varphi\rangle &= \sqrt{\tfrac{1}{4} - \tfrac{1}{4}\cos^2\varphi\sin^2\vartheta} \\
\langle\vartheta,\varphi|\Delta\hat{s}_y|\vartheta,\varphi\rangle &= \sqrt{\tfrac{1}{4} - \tfrac{1}{4}\sin^2\varphi\sin^2\vartheta} \\
\langle\vartheta,\varphi|\Delta\hat{s}_z|\vartheta,\varphi\rangle &= \sqrt{\tfrac{1}{4} - \tfrac{1}{4}\cos^2\vartheta}\ .
\end{aligned}$$

The uncertainty relation demands,

$$\langle\vartheta,\varphi|\Delta\hat{s}_x|\vartheta,\varphi\rangle\langle\vartheta,\varphi|\Delta\hat{s}_y|\vartheta,\varphi\rangle \geq \tfrac{1}{4}|\cos\vartheta|\ ,$$

which can be verified by simple algebraic calculation. The uncertainties are illustrated in Fig. 25.9.

25.4 Coupling of angular momenta

25.4.1 Singlet and triplet states with two electrons

In this section we first consider the spin states of two electrons, which can be combined into two groups with well-defined total spin. With this we can understand the energy spectrum of helium, which is very much dominated by Pauli's principle and quantum statistics. The introduced concepts can be extended to atoms with many electrons.

Angular momentum is an important quantum number in the treatment of the internal structure of atoms. The two electrons in the helium electronic shell each

contribute a spin of $S = \frac{1}{2}$, which couple to a total angular momentum. Let us consider, for simplicity, two free electrons. The state of the two-particle system is an element of the product space of the two Hilbert spaces in which the individual electrons are described. We will now apply the formalism of Sec. 23.3.9 explicitly to a pair of electrons. The states that the two electrons can occupy are:

$$|\gamma_1\rangle = \begin{pmatrix}1\\0\end{pmatrix} \otimes \begin{pmatrix}1\\0\end{pmatrix} = \begin{pmatrix}1\\0\\0\\0\end{pmatrix} \equiv |\uparrow\uparrow\rangle \quad , \tag{25.75}$$

$$|\gamma_2\rangle = |\uparrow\downarrow\rangle \quad , \quad |\gamma_3\rangle = |\downarrow\uparrow\rangle \quad , \quad |\gamma_4\rangle = |\downarrow\downarrow\rangle \; .$$

The Pauli matrices act on the spin of the individual electrons. They can be extended to the product Hilbert space as follows,

$$\begin{aligned}
\tfrac{\hbar}{2}\hat{\sigma}_x \otimes \mathbb{I}_2 &= \tfrac{\hbar}{2}\begin{pmatrix}0 & \mathbb{I}_2\\ \mathbb{I}_2 & 0\end{pmatrix} \quad , \quad \tfrac{\hbar}{2}\mathbb{I}_2 \otimes \hat{\sigma}_x = \tfrac{\hbar}{2}\begin{pmatrix}\hat{\sigma}_x & 0\\ 0 & \hat{\sigma}_x\end{pmatrix} \\
\tfrac{\hbar}{2}\hat{\sigma}_y \otimes \mathbb{I}_2 &= \tfrac{\hbar}{2}\begin{pmatrix}0 & \imath\mathbb{I}_2\\ -\imath\mathbb{I}_2 & 0\end{pmatrix} \quad , \quad \tfrac{\hbar}{2}\mathbb{I}_2 \otimes \hat{\sigma}_y = \tfrac{\hbar}{2}\begin{pmatrix}\hat{\sigma}_y & 0\\ 0 & \hat{\sigma}_y\end{pmatrix} \\
\tfrac{\hbar}{2}\hat{\sigma}_z \otimes \mathbb{I}_2 &= \tfrac{\hbar}{2}\begin{pmatrix}-\mathbb{I}_2 & 0\\ 0 & \mathbb{I}_2\end{pmatrix} \quad , \quad \tfrac{\hbar}{2}\mathbb{I}_2 \otimes \hat{\sigma}_z = \tfrac{\hbar}{2}\begin{pmatrix}\hat{\sigma}_z & 0\\ 0 & \hat{\sigma}_z\end{pmatrix} \; .
\end{aligned} \tag{25.76}$$

With these operators we can now build other operators. We first consider the three components of the total angular momentum,

$$\hat{S}_k = \tfrac{\hbar}{2}(\hat{\sigma}_k \otimes \mathbb{I}_2 + \mathbb{I}_2 \otimes \hat{\sigma}_k) \qquad \text{such that} \tag{25.77}$$

$$\hat{S}_x = \tfrac{\hbar}{2}\begin{pmatrix}0&1&1&0\\1&0&0&1\\1&0&0&1\\0&1&1&0\end{pmatrix} \; , \; \hat{S}_y = \tfrac{\imath\hbar}{2}\begin{pmatrix}0&1&1&0\\-1&0&0&1\\-1&0&0&1\\0&-1&-1&0\end{pmatrix} \; , \; \hat{S}_z = \hbar\begin{pmatrix}-1&0&0&0\\0&0&0&0\\0&0&0&0\\0&0&0&1\end{pmatrix} \; .$$

The operator for the square of the absolute value of the total angular momentum is calculated as follows:

$$\hat{\mathbf{S}}^2 = \hat{S}_x^2 + \hat{S}_y^2 + \hat{S}_z^2 = \hbar^2\begin{pmatrix}2&0&0&0\\0&1&1&0\\0&1&1&0\\0&0&0&2\end{pmatrix} \; . \tag{25.78}$$

Now, we look for the eigenvalues of the total angular momentum. The equation for the eigenvalues of $\hat{S}_z$,

$$\hat{S}_z|\gamma_k\rangle = M_S|\gamma_k\rangle \; , \tag{25.79}$$

is already diagonal in the introduced basis $\{\gamma_k\}$ with the eigenvalues,

$$M_S = -\hbar, 0, 0, \hbar \ . \tag{25.80}$$

For $\hat{\mathbf{S}}^2$ the situation is more interesting: The states $|\gamma_1\rangle$ and $|\gamma_4\rangle$ *are* eigenstates of $\mathbf{S}^2$ for the eigenvalue $2\hbar^2$, but the states $|\gamma_2\rangle$ and $|\gamma_3\rangle$ are *not* eigenstates. On the other hand, we know that the linear combination of two eigenstates with the same eigenvalue is also a eigenstate. Therefore, the states

$$|\tilde{\gamma}_1\rangle \equiv |\gamma_1\rangle \quad , \quad |\tilde{\gamma}_4\rangle \equiv |\gamma_4\rangle \quad , \quad |\tilde{\gamma}_a\rangle \equiv \tfrac{1}{\sqrt{2}}(|\gamma_2\rangle - |\gamma_3\rangle) \quad , \quad |\tilde{\gamma}_s\rangle \equiv \tfrac{1}{\sqrt{2}}(|\gamma_2\rangle + |\gamma_3\rangle) \ , \tag{25.81}$$

are *still* eigenstates of $\hat{S}_z$, but they *also* are eigenstates of $\hat{\mathbf{S}}^2$, since we can easily verify,

$$\hat{\mathbf{S}}^2|\gamma_s\rangle = 2\hbar^2|\gamma_s\rangle \qquad \text{and} \qquad \hat{\mathbf{S}}^2|\gamma_a\rangle = 0\hbar^2|\gamma_a\rangle \ , \tag{25.82}$$

using the matrices (25.77). In summary, for the eigenvalue $\langle\hat{\mathbf{S}}^2\rangle = 2\hbar^2$ there exist the following three states:

$$\left.\begin{array}{ll} |\gamma_1\rangle & M_s = 1 \\ |\gamma_4\rangle & M_s = -1 \\ |\gamma_s\rangle & M_s = 0 \end{array}\right\} \qquad \text{triplet} \ , \ S = 1 \tag{25.83}$$

For $\langle\mathbf{S}^2\rangle = 0$ there is only one state:

$$|\gamma_a\rangle \quad M_s = 0 \qquad \text{singlet} \ , \ S = 0 \ . \tag{25.84}$$

By exchanging the two electrons, the vectors $|\gamma_1\rangle$ and $|\gamma_4\rangle$ retain their shape, while the mixed vectors change their shape: $\gamma_2 \longleftrightarrow \gamma_3$. Under particle exchange $|\gamma_a\rangle$ reverses its sign, that is, it is antisymmetric, while $|\gamma_1\rangle$, $|\gamma_4\rangle$ and $|\gamma_c\rangle$ conserve their signs, that is, they are symmetrical.

In summary, the triplet states have the quantum number of the total angular momentum (with the expected value for $\hat{\mathbf{S}}^2$ of $\hbar^2 S(S+1) = 2\hbar^2$), and they are symmetrical about the exchange of particles. The singlet state has the quantum number of the total angular momentum $S = 0$, and it is antisymmetric about the exchange of particles. The transition from the original basis $\{|\gamma_1\rangle, |\gamma_2\rangle, |\gamma_3\rangle, |\gamma_4\rangle\}$ to the new basis $\{|\tilde{\gamma}_1\rangle, |\tilde{\gamma}_s\rangle, |\tilde{\gamma}_a\rangle, |\tilde{\gamma}_4\rangle\}$ described by Eqs. (25.81) is done by a unitary transformation,

$$|\tilde{\gamma}\rangle = U_{CGC}|\gamma\rangle \qquad \text{with} \qquad U_{CGC} = \begin{pmatrix} 1 & & & \\ & \frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}} & \\ & \frac{1}{\sqrt{2}} & -\frac{1}{\sqrt{2}} & \\ & & & 1 \end{pmatrix} \ , \tag{25.85}$$

whose components are known as Clebsch-Gordan coefficients. A similar treatment can be done with bosons, as will be discussed in Sec. 31.1.

25.4.2 Coupling two spins

We now consider a perturbation of the system which, for some reason, only affects the first spin. In the absence of the second atom we would have,

$$\hat{H}_1 = \begin{pmatrix} 0 & \Omega^* \\ \Omega & 0 \end{pmatrix} . \tag{25.86}$$

Including the second atom,

$$\hat{H} = \hat{H}_1 \otimes \mathbb{I} = \begin{pmatrix} & & \Omega^* & \\ & & & \Omega^* \\ \Omega & & & \\ & \Omega & & \end{pmatrix} . \tag{25.87}$$

In this case, the perturbation Hamiltonian does not commute with the total angular momentum,

$$[\hat{\mathbf{S}}^2, \hat{H}] \neq 0 . \tag{25.88}$$

Another type of perturbation affects both spin symmetrically (e.g., Dicke superradiance with two atoms in the same radiative mode or two counterpropagating modes in a ring cavity). The interaction Hamiltonian is now the sum of the individual perturbations,

$$\hat{H} = \hat{H}_1 \otimes \mathbb{I} + \mathbb{I} \otimes \hat{H}_1 = \begin{pmatrix} & \Omega^* & \Omega^* & \\ \Omega & & & \Omega^* \\ \Omega & & & \Omega^* \\ & \Omega & \Omega & \end{pmatrix} . \tag{25.89}$$

This Hamiltonian commutes with the total angular momentum,

$$[\hat{\mathbf{S}}^2, \hat{H}] = 0 . \tag{25.90}$$

S now is a good quantum number. Singlet states do not couple with triplets. This is the idea behind Dicke's superradiance. The absolute value of the total angular momentum is conserved. The quantum number S is called *Dicke cooperativity* [366]. In Exc. 42.5.7.1 we will discuss the coupling of two counterpropagating modes in a ring cavity. In Sec. 41.1 we will discuss Dicke states.

Example 165 (*Two atoms interacting through their dipole moments*): As an example of a system exhibiting coupling of the type described in (25.89) we consider two two-level atoms $j = 1, 2$. As long as the atoms do not interact, the Hamiltonian will be,

$$\hat{H} = \hbar\omega_0 \hat{S}_z , \tag{25.91}$$

with $\hat{S}_z$ given by (25.77). Now, if the atoms interact via their dipole moments with an electromagnetic field assumed to be the same for both atoms,

$$\begin{aligned} \hat{H}_{int} = &- \tfrac{q}{m}\mathbf{A}(\mathbf{r}_1) \cdot (p_x \hat{\mathbf{e}}_x \hat{\sigma}^x \otimes \mathbb{I} + p_y \hat{\mathbf{e}}_y \hat{\sigma}^y \otimes \mathbb{I}) \\ &- \tfrac{q}{m}\mathbf{A}(\mathbf{r}_2) \cdot (p_x \hat{\mathbf{e}}_x \mathbb{I} \otimes \hat{\sigma}^x + p_y \hat{\mathbf{e}}_y \mathbb{I} \otimes \hat{\sigma}^y) , \end{aligned} \tag{25.92}$$

with $\mathbf{r}_1 \simeq \mathbf{r}_2$. By the rules (25.76) we find in matrix notation a Hamiltonian equivalent to (25.89). Using the abbreviations $\Omega_x \equiv \frac{q}{m} A_x p_x$, $\Omega_y \equiv \frac{q}{m} A_y p_y$, $\Omega_\pm \equiv \Omega_x \pm \imath\Omega_y$, and $\Omega \equiv \sqrt{\Omega_x^2 + \Omega_y^2}$,

$$\hat{H} = \begin{pmatrix} 0 & \Omega_- & \Omega_- & 0 \\ \Omega_+ & 0 & 0 & \Omega_- \\ \Omega_+ & 0 & 0 & \Omega_- \\ 0 & \Omega_+ & \Omega_+ & 0 \end{pmatrix} . \tag{25.93}$$

Using symbolic algebra software we find the eigenvector and eigenvalue matrices,

$$U = \begin{pmatrix} \frac{\Omega_-}{\Omega_+} & -\frac{\Omega_-}{\Omega_+} & 0 & \frac{\Omega_-}{\Omega_+} \\ -\sqrt{\frac{\Omega_-}{\Omega_+}} & 0 & -1 & \sqrt{\frac{\Omega_-}{\Omega_+}} \\ -\sqrt{\frac{\Omega_-}{\Omega_+}} & 0 & 1 & \sqrt{\frac{\Omega_-}{\Omega_+}} \\ 1 & 1 & 0 & 1 \end{pmatrix} \quad \text{and} \quad \hat{E} = \begin{pmatrix} -2\Omega & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 2\Omega \end{pmatrix} . \tag{25.94}$$

Now, we get for the evolution of the various states,

$$U e^{\imath \hat{E} t} U^{-1} \begin{pmatrix} 0 \\ 1 \\ 1 \\ 0 \end{pmatrix} = \begin{pmatrix} -\sqrt{\frac{-\Omega_-}{\Omega_+}} \sin 2\Omega t \\ \cos 2\Omega t \\ \cos 2\Omega t \\ \sqrt{\frac{\Omega_+}{-\Omega_-}} \sin 2\Omega t \end{pmatrix} \quad \text{and} \quad U e^{\imath \hat{E} t} U^{-1} \begin{pmatrix} 0 \\ 1 \\ -1 \\ 0 \end{pmatrix} = \begin{pmatrix} 0 \\ 1 \\ -1 \\ 0 \end{pmatrix} . \tag{25.95}$$

That is, the Hamiltonian (25.92) does not mix antisymmetric singlet states and symmetric triplet states.

25.4.3 Decoupled and coupled bases

Electrically charged orbiting particles produce a magnetic field. This field can influence the motion of other particles. In the same way, the spin of an electron can influence its own orbital motion. That is, angular momenta can couple and interact in a complicated way. Even to describe the behavior of an atom as simple as hydrogen in an external field, we need to construct the eigenstates of the total angular momentum resulting from a coupling of the electron's intrinsic spin and its orbital motion.

On the other side, we have hitherto considered predominantly hydrogen and hydrogen-like atoms, that is, atoms with a nucleus and a single (valence) electron. But in fact atoms can have more than 100 electrons, which complicates the exact description. In atoms with many electrons, one of the most common coupling schemes is when the angular momenta of all electrons couple to a *total angular momentum*, $\hat{\mathbf{L}} = \sum_k \hat{\mathbf{l}}_k$, which then couples to the *total spin*, $\hat{\mathbf{S}} = \sum_k \hat{\mathbf{s}}_k$, to form the complete total angular momentum, $\hat{\mathbf{J}} = \hat{\mathbf{L}} + \hat{\mathbf{S}}$. We generally assign total momenta to capital letters.

Adopting an unbiased notation we study some properties of the total angular momentum, $\hat{\mathbf{j}} \equiv \hat{\mathbf{j}}_1 + \hat{\mathbf{j}}_2$. In Exc. 25.4.5.1 we find that the addition of angular momenta produces a quantity which is also an angular momentum, but not the subtraction.

The angular momenta of two particles or two angular momenta of different origins in a single particle represent independent degrees of freedom, $[\mathbf{j}_1, \mathbf{j}_2] = 0$. Without

interaction between angular momenta the Hilbert spaces are orthogonal:

$$\mathcal{H}_1 \otimes \mathcal{H}_2 = \begin{pmatrix} \mathcal{H}_1 & 0 \\ 0 & \mathcal{H}_2 \end{pmatrix} . \tag{25.96}$$

The eigenfunctions act on a space of dimension, $\dim \mathcal{H}_1 \cdot \dim \mathcal{H}_2$:

$$|j_1, m_{j1}; j_2, m_{j2}\rangle . \tag{25.97}$$

That is, there is a complete set of commuting operators $\{\hat{\mathbf{j}}_1^2, \hat{j}_{1z}, \hat{\mathbf{j}}_2^2, \hat{j}_{2z}\}$. Therefore, we can specify quantum numbers j_1, j_2, m_{j1}, and m_{j2} simultaneously. On the other hand, the group $\{\hat{\mathbf{j}}_1^2, \hat{\mathbf{j}}_2^2, \hat{\mathbf{j}}^2, \hat{j}_z\}$ also represents a complete set of commuting operators, as shown in Exc. 25.4.5.2. It has the basis

$$|(j_1, j_2)j, m_j\rangle . \tag{25.98}$$

To describe the two angular momenta simultaneously, we must opt between the decoupled picture $|j_1, m_{j1}; j_2, m_{j1}\rangle$ and the coupled picture $|(j_1, j_2)j, m_j\rangle$. For now, the choice of the picture makes no difference, but we will see later that there may be an energy associated with the coupling [4]. In this case, as we will show, the choice of the coupled base is more natural, because generally the energy commutes like $[\hat{H}, \hat{\mathbf{j}}^2] = 0 = [\hat{H}, \hat{j}_z]$ and $[\hat{H}, \hat{\mathbf{j}}_1^2] = 0 = [\hat{H}, \hat{\mathbf{j}}_2^2]$, but $[\hat{H}, \hat{j}_{1z}] \neq 0 \neq [\hat{H}, \hat{j}_{2z}]$.

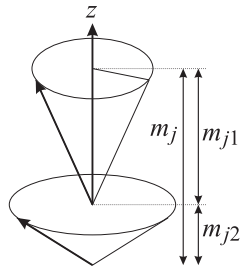

Figure 25.10: Illustration of the coupling of two angular momenta.

Example 166 (*Coupled basis*): For example, using the Hamiltonian (25.94) it is easy to see that,

$$[\hat{H}, (\hat{\sigma}_x \otimes \mathbb{I})^2 + (\hat{\sigma}_y \otimes \mathbb{I})^2 + (\hat{\sigma}_z \otimes \mathbb{I})^2] = 0 = [\hat{H}, (\mathbb{I} \otimes \hat{\sigma}_x)^2 + (\mathbb{I} \otimes \hat{\sigma}_y)^2 + (\mathbb{I} \otimes \hat{\sigma}_z)^2]$$
$$[\hat{H}, \hat{\sigma}_z \otimes \mathbb{I}] \neq 0 \neq [\hat{H}, \mathbb{I} \otimes \hat{\sigma}_z] .$$

25.4.3.1 Allowed values of total angular momentum

As long as we do not specify an interaction energy between the spins or between spins and external fields, all states are energetically degenerate. In the decoupled image

[4] That is, the Hamiltonian of the system does not contain terms of type $\hat{\mathbf{j}}_1 \cdot \hat{\mathbf{j}}_2$, but may have terms proportional to $\hat{\mathbf{j}}_1 + \hat{\mathbf{j}}_2$.

the degeneracy is easily calculated,

$$\# = \sum_{m_{j1}=-j_1}^{j_1} \sum_{m_{j2}=-j_2}^{j_2} 1 = (2j_1+1)(2j_2+1) \ . \tag{25.99}$$

Now, we want to find the possible values of j and m_j in the coupled picture. The values of m_j follow immediately from $\hat{\mathbf{j}}_1 + \hat{\mathbf{j}}_2 = \hat{\mathbf{j}}$,

$$m_j = m_{j1} + m_{j2} \ . \tag{25.100}$$

With $|m_{j1}| \leq j_1$ and $|m_{j2}| \leq j_2$ the values of m_j are limited to

$$|m_j| \leq j_1 + j_2 \ . \tag{25.101}$$

We often know the two angular momenta j_1 and j_2 and all their projections in the decoupled base,

$$|m_{j1}| \leq j_1 \qquad \text{and} \qquad |m_{j2}| \leq j_2 \ . \tag{25.102}$$

To find the quantum numbers in the coupled base, we arrange the states ordering them by their total magnetic quantum number m_j. We can, without loosing generality, concentrate on the situation $j_1 \geq j_2$. The following table reproduces the possible combinations. The x-symbols represent Clebsch-Gordan coefficients:

m_{j1} $+m_{j2}=$ m_j	j	j	$j-1$	j	$j-1$	$j-2$		j	$j-1$	j
		$j-1$	$j-1$	$j-2$	$j-2$	$j-2$		$-j+1$	$-j+1$	$-j$
j_1 j_2	x									
j_1 j_2-1		x	x							
j_1-1 j_2		x	x							
j_1 j_2-2				x	x	x				
j_1-1 j_2-1				x	x	x				
j_1-2 j_2				x	x	x				
							$\ddots$			
$-j_1+1$ $-j_2$								x	x	
$-j_1$ j_2+1								x	x	
$-j_1$ $-j_2$										x

The possible values for j are all those allowing for $j \geq |m_j| = |m_{j1} + m_{j2}|$, that is,

$$|j_1 - j_2| \leq j \leq j_1 + j_2 \ . \tag{25.103}$$

Each value of j has the degeneracy $2j+1$. Therefore, as will be verified in Exc. 25.4.5.3, the total degeneracy is,

$$\sum_{j=|j_1-j_2|}^{j_1+j_2} 2j+1 = (2j_1+1)(2j_2+1) \ . \tag{25.104}$$

Example 167 (*Spin states in the presence of* $\mathbf{L}\cdot\mathbf{S}$ *coupling*): As an example we consider two electrons occupying the $(5p)^2$ orbital. That is, both electrons have $s_i = \frac{1}{2}$ and $\ell_i = 1$. As illustrated in Fig. 25.11, the coupling first gives $S = s_1 + s_2 = 0, 1$ and $L = \ell_1 + \ell_2 = 0, 1, 2$. Then we determine the possible values of the total angular momentum $J = L + S = 0, 1, 2$ depending on the values of L and S.

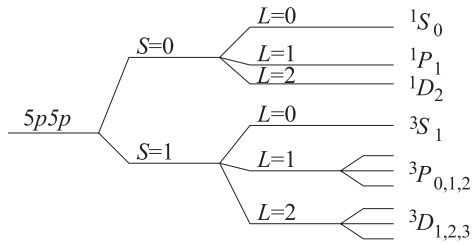

Figure 25.11: Possible spin states of two electrons occupying the $(5p)^2$ orbital. Spin-orbit coupling $\mathbf{L}\cdot\mathbf{S}$ leads to a splitting of the energy levels.

25.4.4 Clebsch-Gordan coefficients

Let us now describe how to add *two* angular momenta, $\hat{\mathbf{j}}_1$ and $\hat{\mathbf{j}}_2$. Since they act on different degrees of freedom,

$$[\vec{\alpha}_1\cdot\hat{\mathbf{j}}_1, \vec{\alpha}_2\cdot\hat{\mathbf{j}}_2] = 0 \tag{25.105}$$

for arbitrary vectors $\vec{\alpha}_1$ and $\vec{\alpha}_2$. We have a system of common eigenvectors, $|\eta, j_1, j_2, m_1, m_2\rangle$, where η are the eigenvalues of other observables commuting with $\hat{\mathbf{j}}_1$ and $\hat{\mathbf{j}}_2$. These eigenvectors give the values $\hbar^2 j_1(j_1+1)$ and $\hbar^2 j_2(j_2+1)$ for the observables $\hat{\mathbf{j}}_1^2$ and $\hat{\mathbf{j}}_2^2$, as well as $\hbar m_1$ and $\hbar m_2$ for the observables j_{z1} and j_{z2}. The number of states is $(2j_1+1)(2j_2+1)$. Now we want to construct the eigenstates of the total angular momentum $\hat{\mathbf{j}} = \hat{\mathbf{j}}_1 + \hat{\mathbf{j}}_2$. Since

$$[\hat{\mathbf{j}}, \hat{\mathbf{j}}_1^2] = 0 = [\hat{\mathbf{j}}, \hat{\mathbf{j}}_2^2]\ , \tag{25.106}$$

there exist common eigenstates $|j_1, j_2, j, m\rangle$ for the set of observables $\hat{\mathbf{j}}_1^2$, $\hat{\mathbf{j}}_2^2$, $\hat{\mathbf{j}}^2$ and $\hat{j}_z$. These eigenstates are linear combinations of the individual states,

$$\begin{aligned} |(j_1,j_2)j,m\rangle &= \sum_{m_1,m_2} |j_1,j_2,m_1,m_2\rangle\langle j_1,j_2,m_1,m_2|(j_1,j_2)j,m\rangle \\ &= \sum_{m_1,m_2} |j_1,j_2,m_1,m_2\rangle \left(\begin{array}{cc|c} j_1 & j_2 & j \\ m_1 & m_2 & m \end{array}\right)\ . \end{aligned} \tag{25.107}$$

The matrix coefficient is called *Clebsch-Gordan coefficient*. The Clebsch-Gordans disappear when the conditions [5]

$$|j_1-j_2| \le j \le j_1+j_2 \qquad \text{and} \qquad m = -j_1-j_2, -j_1-j_2+1, .., j_1+j_2 \tag{25.108}$$

are not satisfied.

The unitary transformation matrices between decoupled and coupled bases,

$$|(j_1,j_2)j,m\rangle = U_{CGC}|j_1,m_1;j_2,m_2\rangle\ , \tag{25.109}$$

are listed in tables of the Clebsch-Gordan coefficients.

[5] The Clebsch-Gordans are related to the $(3j)$ de Wigner symbols.

Example 168 (*Clebsch-Gordans for the coupling of two spins* $\frac{1}{2}$): For example, for the system consisting of two $\frac{1}{2}$ spins we have,

$$\begin{pmatrix} |(\frac{1}{2},\frac{1}{2})1,+1\rangle \\ |(\frac{1}{2},\frac{1}{2})1,0\rangle \\ |(\frac{1}{2},\frac{1}{2})0,0\rangle \\ |(\frac{1}{2},\frac{1}{2})1,-1\rangle \end{pmatrix} = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & \sqrt{\frac{1}{2}} & \sqrt{\frac{1}{2}} & 0 \\ 0 & \sqrt{\frac{1}{2}} & -\sqrt{\frac{1}{2}} & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} |\frac{1}{2},+\frac{1}{2};\frac{1}{2},+\frac{1}{2}\rangle \\ |\frac{1}{2},-\frac{1}{2};\frac{1}{2},+\frac{1}{2}\rangle \\ |\frac{1}{2},+\frac{1}{2};\frac{1}{2},-\frac{1}{2}\rangle \\ |\frac{1}{2},-\frac{1}{2};\frac{1}{2},-\frac{1}{2}\rangle \end{pmatrix} .$$

In the Excs. 25.4.5.4 and 25.4.5.5 we write all possible states of two angular momenta in decoupled and coupled bases. In Excs. 25.4.5.6, 25.4.5.7, we derive the matrix representation of two spins in the decoupled and the coupled base. In 25.4.5.8, and 25.4.5.9 we practice the transformation between decoupled and coupled bases, and in Exc. 25.4.5.10 we verify a rule guaranteeing the unitarity of the Clebsch-Gordan transformation. Finally in 25.4.5.11, 25.4.5.12, and 25.4.5.13 we study $\mathbf{L}\cdot\mathbf{S}$-coupling.

25.4.4.1 Coupling of three angular moments

Three angular momenta can be coupled in three different configurations: First j_1 with j_2, then the total spin $(j_1,j_2)j_{12}$ with the third one j_3. We use the notation $|[(j_1,j_2)j_{12},j_3]J\rangle$ or $|[(j_1,j_3)j_{13},j_2]J\rangle$ or $|[(j_2,j_3)j_{23},j_1]J\rangle$. The recoupling of three spins

$$\begin{array}{ccccc} \mathbf{j}_1 & + & \mathbf{j}_2 & = & \mathbf{j}_{12} \\ + & & & & + \\ \mathbf{j}_3 & & & & \mathbf{j}_3 \\ = & & & & = \\ \mathbf{j}_{13} & + & \mathbf{j}_2 & = & \mathbf{J} \end{array} \tag{25.110}$$

is described by $\{6j\} = \begin{Bmatrix} j_1 & j_3 & j_{13} \\ J & j_{12} & j_2 \end{Bmatrix}$-symbols, for example,

$$|[(j_1,j_2)j_{12},j_3]J\rangle = \sum_{j_{13}} \{6j\} |[(j_1,j_3)j_{13},j_2]J\rangle \ . \tag{25.111}$$

25.4.4.2 Notation for atomic states with LS-coupling

In an atom, the spins of the electrons often couple to a total spin, $\mathbf{S} = \sum_k \mathbf{s}_k$, and separately the orbital angular momenta to a total orbital angular momentum, $\mathbf{L} = \sum_k \mathbf{l}_k$. These two total spins now couple to a total angular momentum, $\mathbf{J} = \mathbf{L}+\mathbf{S}$. When this **LS**-*coupling* happens, the following notation is used to characterize the electronic states in atoms:

$$^{2S+1}L_J \ . \tag{25.112}$$

25.4.4.3 jj-coupling

There is also the case that for each electron its spin couples to its own orbital angular momentum, $\mathbf{j}_k = \mathbf{l}_k + \mathbf{s}_k$, before coupling to the total angular momenta of other

electrons, $\mathbf{J} = \sum_k \mathbf{j}_k$. This is called **jj**-*coupling*. In the case of two electrons the recoupling of the four involved spins

$$\begin{array}{ccccc} \mathbf{l}_1 & + & \mathbf{l}_2 & = & \mathbf{L} \\ + & & + & & + \\ \mathbf{s}_1 & + & \mathbf{s}_2 & = & \mathbf{S} \\ = & & = & & = \\ \mathbf{j}_1 & + & \mathbf{j}_2 & = & \mathbf{J} \end{array} \tag{25.113}$$

is described by $\{9j\} = \begin{Bmatrix} l_1 & l_2 & L \\ s_1 & s_2 & S \\ j_1 & j_2 & J \end{Bmatrix}$-symbols,

$$|[(l_1, s_1)j_1, (l_2, s_2)j_2]J\rangle = \sum_{L,S} \{9j\} |[(l_1, l_2)L, (s_1, s_2)S]J\rangle \ . \tag{25.114}$$

25.4.5 Exercises

25.4.5.1 Ex: Addition/subtraction of angular momenta

Show that $\hat{\mathbf{j}}_1 + \hat{\mathbf{j}}_2$ is an angular momentum, but not $\hat{\mathbf{j}}_1 - \hat{\mathbf{j}}_2$.

Solution: *We find on one hand,*

$$i\hbar\hat{\mathbf{j}} = i\hbar\hat{\mathbf{j}}_1 \pm i\hbar\hat{\mathbf{j}}_2 \ .$$

On the other hand, using $\hat{\mathbf{j}}_1 \times \hat{\mathbf{j}}_2 = -\hat{\mathbf{j}}_2 \times \hat{\mathbf{j}}_1$*, we find,*

$$i\hbar\hat{\mathbf{j}} = \hat{\mathbf{j}} \times \hat{\mathbf{j}} = (\hat{\mathbf{j}}_1 \pm \hat{\mathbf{j}}_2) \times (\hat{\mathbf{j}}_1 \pm \hat{\mathbf{j}}_2) = \hat{\mathbf{j}}_1 \times \hat{\mathbf{j}}_1 + \hat{\mathbf{j}}_2 \times \hat{\mathbf{j}}_2 + \hat{\mathbf{j}}_1 \times \hat{\mathbf{j}}_2 + \hat{\mathbf{j}}_2 \times \hat{\mathbf{j}}_1 = i\hbar\hat{\mathbf{j}}_1 + i\hbar\hat{\mathbf{j}}_2 \ .$$

Only for the upper signs do we obtain equality of the two above expressions and therefore a total angular momentum.

25.4.5.2 Ex: CSCO for coupled angular momenta

Be $\hat{\mathbf{j}} = \hat{\mathbf{j}}_1 + \hat{\mathbf{j}}_2$. Show that $\{\hat{\mathbf{j}}_1^2, \hat{\mathbf{j}}_2^2, \hat{\mathbf{j}}^2, \hat{j}_z\}$ is a CSCO; that is, show that
a. $\hat{\mathbf{j}}^2$ commutes with $\hat{\mathbf{j}}_1^2$ and $\hat{\mathbf{j}}_2^2$;
b. $\hat{\mathbf{j}}^2$ does not commute with $\hat{j}_{1z}$ or $\hat{j}_{2z}$ and that we can not specify m_{j1} or m_{j2} together with j.

Solution: *a. We have,*

$$[\mathbf{j}^2, \mathbf{j}_1^2] = [(\mathbf{j}_1 + \mathbf{j}_2)^2, \mathbf{j}_1^2] = [\mathbf{j}_1^2 + \mathbf{j}_2^2 + \mathbf{j}_1\mathbf{j}_2 + \mathbf{j}_2\mathbf{j}_1, \mathbf{j}_1^2] = [\mathbf{j}_1\mathbf{j}_2 + \mathbf{j}_2\mathbf{j}_1, \mathbf{j}_1^2] = 2\mathbf{j}_2[\mathbf{j}_1, \mathbf{j}_1^2] = 0.$$

b. We have,

$$[\hat{\mathbf{j}}^2, j_{1z}] = [\hat{\mathbf{j}}_1^2 + \hat{\mathbf{j}}_2^2 + 2\hat{\mathbf{j}}_1\hat{\mathbf{j}}_2, \hat{j}_{1z}] = 2\hat{\mathbf{j}}_2[\hat{\mathbf{j}}_1, \hat{j}_{1z}] \neq 0 \ .$$

Therefore, we can not specify m_{j1} *or* m_{j2} *together with* j*.*

25.4.5.3 Ex: Multiplicity of coupled angular momenta

Verify $\# = (2j_1+1)(2j_2+1)$ within the coupled representation.

Solution: *We have,*

$$2\sum_{j=a}^{b} j + \sum_{j=a}^{b} 1 = 2\tfrac{(b-a+1)(a+b)}{2} + (b-a+1) = (b-a+1)(a+b+1)$$

$$\sum_{j=|j_1-j_2|}^{j_1+j_2} 2j+1 = ([j_1+j_2]-[j_1-j_2]+1)([j_1-j_2]+[j_1+j_2]+1)$$

$$= (j_2+j_2+1)(j_1+j_1+1) \ .$$

25.4.5.4 Ex: Possible states of two (de-)coupled angular momenta

Find all possible states with the angular momenta $j_1 = 1$ and $j_2 = 1/2$ in decoupled and coupled pictures.

Solution: *In the decoupled image we have,*

$$|j_1, m_{j1}; j_2, m_{j2}\rangle = |1,+1;\tfrac{1}{2},\pm\tfrac{1}{2}\rangle, |1,0;\tfrac{1}{2},\pm\tfrac{1}{2}\rangle, |1,-1;\tfrac{1}{2},\pm\tfrac{1}{2}\rangle \ .$$

In the coupled image we have,

$$|(j_1,j_2)j, m_j\rangle = |\tfrac{3}{2}(1,\tfrac{1}{2}),\pm\tfrac{3}{2}\rangle, |\tfrac{3}{2}(1,\tfrac{1}{2}),\pm\tfrac{1}{2}\rangle, |\tfrac{1}{2}(1,\tfrac{1}{2}),\pm\tfrac{1}{2}\rangle \ .$$

25.4.5.5 Ex: Fine and hyperfine structure of the rubidium atom ^{85}Rb

1. The rubidium atom ^{85}Rb has one valence electron. In the first excited state this electron has the orbital angular momentum, $L = 1$. What are the possible states?
2. In the fundamental state of this atom the total electronic angular momentum J couples with the spin of the nucleus, $I = 5/2$, to form the total angular momentum $\mathbf{F} = \mathbf{J} + \mathbf{I}$. Determine the possible values for the angular momentum F and the magnetic quantum number m_F.

Solution: *a. The states are,*

$$^2P_{1/2} \ \ with \ \ m_j = \pm\tfrac{1}{2} \ \ and \ \ ^2P_{3/2} \ \ with \ \ m_j = \pm\tfrac{1}{2}, \pm\tfrac{3}{2} \ .$$

b. The states are,

$$F = 2 \ \ with \ \ m_F = -2,..,2 \ \ and \ \ F = 3 \ \ with \ \ m_F = -3,..3 \ .$$

25.4.5.6 Ex: Expansion of the hyperfine structure of the rubidium atom ^{87}Rb

Determine for the states $S_{1/2}$ and $P_{3/2}$ of an atom with nuclear spin $I = 3/2$ and hyperfine coupling $\hat{\mathbf{J}} \cdot \hat{\mathbf{I}}$ how the eigenstates of the coupled base expand into the decoupled base. Do not consider external magnetic fields.

Solution: *For the state $S_{1/2}$, we have $J = 1/2$ and $I = 3/2$ which coupled to $F = 1, 2$. The transformation is done via,*

$$|(J,I)F,m_F\rangle = |(\tfrac{1}{2},\tfrac{3}{2})2 \pm 2\rangle = U_{CGC}|\pm\tfrac{3}{2}\pm\tfrac{1}{2}\rangle = U_{CGC}\sum_{m_I,m_J}|I,m_I,J,m_J\rangle$$

that is,

$$\begin{pmatrix} |(\frac{3}{2},\frac{1}{2})2,\pm2\rangle \\ |(\frac{3}{2},\frac{1}{2})2,\pm1\rangle \\ |(\frac{3}{2},\frac{1}{2})1,\pm1\rangle \\ |(\frac{3}{2},\frac{1}{2})2,0\rangle \\ |(\frac{3}{2},\frac{1}{2})1,0\rangle \end{pmatrix} = \begin{pmatrix} 1 & & & & \\ & \sqrt{\frac{1}{4}} & \sqrt{\frac{3}{4}} & & \\ & \pm\sqrt{\frac{3}{4}} & \mp\sqrt{\frac{1}{4}} & & \\ & & & \sqrt{\frac{1}{2}} & \sqrt{\frac{1}{2}} \\ & & & \sqrt{\frac{1}{2}} & -\sqrt{\frac{1}{2}} \end{pmatrix} \begin{pmatrix} |\frac{3}{2},\pm\frac{3}{2},\frac{1}{2},\pm\frac{1}{2}\rangle \\ |\frac{3}{2},\pm\frac{3}{2},\frac{1}{2},\mp\frac{1}{2}\rangle \\ |\frac{3}{2},\pm\frac{1}{2},\frac{1}{2},\pm\frac{1}{2}\rangle \\ |\frac{3}{2},+\frac{1}{2},\frac{1}{2},-\frac{1}{2}\rangle \\ |\frac{3}{2},-\frac{1}{2},\frac{1}{2},+\frac{1}{2}\rangle \end{pmatrix}.$$

For the state $P_{3/2}$, the transformation is done by

$$\begin{aligned}
|3\pm3\rangle &= |\pm\tfrac{3}{2}\pm\tfrac{1}{2}\rangle \\
|3\pm2\rangle &= \sqrt{\tfrac{1}{2}}|\pm\tfrac{3}{2}\pm\tfrac{1}{2}\rangle + \sqrt{\tfrac{1}{2}}|\pm\tfrac{3}{2}\pm\tfrac{1}{2}\rangle \\
|3\pm1\rangle &= \sqrt{\tfrac{1}{5}}|\pm\tfrac{3}{2}\mp\tfrac{1}{2}\rangle + \sqrt{\tfrac{3}{5}}|\pm\tfrac{1}{2}\pm\tfrac{1}{2}\rangle + \sqrt{\tfrac{1}{5}}|\mp\tfrac{3}{2}\pm\tfrac{1}{2}\rangle \\
|30\rangle &= \sqrt{\tfrac{1}{20}}|\tfrac{3}{2}-\tfrac{3}{2}\rangle + \sqrt{\tfrac{9}{20}}|\tfrac{1}{2}-\tfrac{1}{2}\rangle + \sqrt{\tfrac{9}{20}}|-\tfrac{1}{2}\tfrac{1}{2}\rangle + \sqrt{\tfrac{1}{20}}|-\tfrac{3}{2}\tfrac{3}{2}\rangle \\
|2\pm2\rangle &= \sqrt{\tfrac{1}{2}}|\pm\tfrac{3}{2}\pm\tfrac{1}{2}\rangle - \sqrt{\tfrac{1}{2}}|\pm\tfrac{3}{2}\pm\tfrac{1}{2}\rangle \\
|2\pm1\rangle &= \mp\sqrt{\tfrac{3}{4}}|\mp\tfrac{1}{2}\pm\tfrac{3}{2}\rangle \pm \sqrt{\tfrac{1}{2}}|\pm\tfrac{3}{2}\mp\tfrac{1}{2}\rangle \\
|20\rangle &= \tfrac{1}{2}|\tfrac{3}{2}-\tfrac{3}{2}\rangle + \tfrac{1}{2}|\tfrac{1}{2}-\tfrac{1}{2}\rangle - \tfrac{1}{2}|-\tfrac{1}{2}\tfrac{1}{2}\rangle - \tfrac{1}{2}|-\tfrac{3}{2}\tfrac{3}{2}\rangle
\end{aligned}$$

25.4.5.7 Ex: Transition amplitudes between Zeeman sub-states

a. We consider the atom of ^{87}Rb having the nuclear angular momentum $I = 3/2$. What are the possible hyperfine states F resulting from a coupling of I with the total electronic state angular momentum of the ground state $^2S_{1/2}$? What are the possible Zeeman sub-states of F?
b. What are the possible hyperfine states F' resulting from a coupling of I with the total electronic angular momentum of the excited state $^2P_{3/2}$, $F' = 2$? What are the

possible Zeeman sub-states of F'?
c. A transition between a ground hyperfine state and an excited hyperfine state can be described by a coupling of the total angular momentum F with the angular momentum of the photon κ forming the angular momentum of the excited state F'. To see this, we now consider the levels $F = 1$ and $F' = 2$. Expand the coupled angular momentum $|(F, \kappa)F', m_{F'}\rangle = |(1, 1)2, m_{F'}\rangle$ on a decoupled basis for every possible value $m_{F'}$. Use the table in Fig. 25.13 to determine the Clebsch-Gordan coefficients.
Note: The Clebsch-Gordans only compare the oscillator strengths of transitions between Zeeman sub-states of a given set (F, F'). In order to compare the oscillator strengths to other transitions (F, F') it is necessary to calculate $6j$-coefficients.

Solution: *a. With $J = \frac{1}{2}$ we obtain $F = |J - I|, ..J + I = 1, 2$ and $m_F = -F, .. + F$*

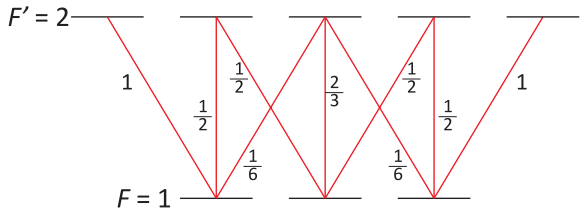

Figure 25.12: Transitions between hyperfine states.

for each F.
b. With $J' = 3/2$ we obtain $F' = 0, 1, 2, 3$ and $m_{F'} = -F', .. + F'$ for each F'.
c. We apply the formula (25.107),

$$|(F, \kappa)F', m_{F'}\rangle = \sum_{m_\kappa=-1}^{+1} |F, \kappa, m_{F'} - m_\kappa, m_\kappa\rangle \left(\begin{array}{cc|c} F & \kappa & F' \\ m_{F'} - m_\kappa & m_\kappa & m_{F'} \end{array}\right) .$$

Thereby,

$$|(1,1)2, \pm 2\rangle = \sum_{m_\kappa} |1, 1, \pm 2 - m_\kappa, m_\kappa\rangle \left(\begin{array}{cc|c} 1 & 1 & 2 \\ \pm 2 - m_\kappa & m_\kappa & \pm 2 \end{array}\right) = \sqrt{1}|1, 1, \pm 1, \pm 1\rangle$$

$$|(1,1)2, \pm 1\rangle = \sum_{m_\kappa} |1, 1, \pm 1 - m_\kappa, m_\kappa\rangle \left(\begin{array}{cc|c} 1 & 1 & 2 \\ \pm 1 - m_\kappa & m_\kappa & \pm 1 \end{array}\right) = \sqrt{\tfrac{1}{2}}|1, 1, \pm 1, 0\rangle + \sqrt{\tfrac{1}{2}}|1, 1, 0, \pm 1\rangle$$

$$\begin{aligned} |(1,1)2, 0\rangle &= \sum_{m_\kappa} |1, 1, 0 - m_\kappa, m_\kappa\rangle \left(\begin{array}{cc|c} 1 & 1 & 2 \\ -m_\kappa & m_\kappa & 0 \end{array}\right) \\ &= \sqrt{\tfrac{1}{6}}|1, 1, +1, -1\rangle + \sqrt{\tfrac{2}{3}}|1, 1, 0, 0\rangle + \sqrt{\tfrac{1}{6}}|1, 1, -1, +1\rangle \ . \end{aligned}$$

25.4.5.8 Ex: Gymnastics of angular momentum operators

Consider the problem of adding angular momenta $j_1 = 1$ and $j_2 = 1/2$:
a. What are the possible values of m and j, in which $\hat{j}^2|j, m\rangle = j(j + 1)\hbar^2|j, m\rangle$ and

$j_z|j,m\rangle = m\hbar|j,m\rangle$?
b. What are the degeneracy $g_{j_1,j_2}(m)$?
c. Find the base states $\{|j,m\rangle\}$, which are common to the operators $\mathbf{j}_1^2$, $\mathbf{j}_2^2$, $\mathbf{j}$, j_z, expanded in the base $\{|j_1,m_1\rangle \otimes |j_2,m_2\rangle\}$ of the eigenstates of $\mathbf{j}_1^2$, $\mathbf{j}_2^2$, j_{1z}, j_{2z}.

Solution: *a. The quantum numbers j and m can have the values,*

$$\begin{array}{lll} & j = 1/2 \quad & \textit{with} \quad m = \pm 1/2 \\ \textit{or} \quad & j = 3/2 \quad & \textit{with} \quad m = \pm 1/2, \pm 3/2 \ . \end{array}$$

*b. Every state m can be the result of several combinations of j_1 and j_2. The states with $m = \pm 3/2$ only correspond to $j = j_1 + j_2$ (*fully stretched *states), but the states $m = \pm 1/2$ correspond to $j = j_1 + j_2 = 3/2$ or $j = j_1 - j_2 = 1/2$. Hence, the degeneracies are $g_{1,1/2}(\pm 3/2) = 1$ and $g_{1,1/2}(\pm 1/2) = 2$.*
c. The states are

$$\left.\begin{array}{l} |(j_1,j_2)j = \frac{3}{2}, m = \pm\frac{3}{2}\rangle \\ |(j_1,j_2)j = \frac{3}{2}, m = \pm\frac{1}{2}\rangle \\ |(j_1,j_2)j = \frac{1}{2}, m = \pm\frac{1}{2}\rangle \end{array}\right\} = \left\{\begin{array}{c} |j_1 = 1, m_1 = \pm 1\rangle |j_2 = \frac{1}{2}, m_2 = \pm\frac{1}{2}\rangle \\ |j_1 = 1, m_1 = \pm 1\rangle |j_2 = \frac{1}{2}, m_2 = \mp\frac{1}{2}\rangle \\ |j_1 = 1, m_1 = 0\rangle |j_2 = \frac{1}{2}, m_2 = \pm\frac{1}{2}\rangle \end{array}\right. .$$

25.4.5.9 Ex: (Un-)coupled bases of the spherical harmonics

Expand the triplet state ${}^3P_J$ of strontium in a decoupled basis and write down the transformation matrix between the bases.

Solution: *We have*

$$|(L,S)J,M_J\rangle = \sum_{m_L,m_S} \left(\begin{array}{cc|c} L & S & J \\ m_L & m_S & m_J \end{array}\right) |L,m_L;S,m_S\rangle \ ,$$

such that,

$$\begin{pmatrix} |(1,1)2,+2\rangle \\ |(1,1)2,+1\rangle \\ |(1,1)1,+1\rangle \\ |(1,1)2,0\rangle \\ |(1,1)1,0\rangle \\ |(1,1)0,0\rangle \\ |(1,1)2,-1\rangle \\ |(1,1)1,-1\rangle \\ |(1,1)2,-2\rangle \end{pmatrix} = \begin{pmatrix} 1 & & & & & & & & \\ & \sqrt{1/2} & \sqrt{1/2} & & & & & & \\ & \sqrt{1/2} & -\sqrt{1/2} & & & & & & \\ & & & \sqrt{1/6} & \sqrt{1/2} & \sqrt{1/3} & & & \\ & & & \sqrt{2/3} & 0 & -\sqrt{1/3} & & & \\ & & & \sqrt{1/6} & -\sqrt{1/2} & \sqrt{1/3} & & & \\ & & & & & & \sqrt{1/2} & \sqrt{1/2} & \\ & & & & & & \sqrt{1/2} & -\sqrt{1/2} & \\ & & & & & & & & 1 \end{pmatrix} \begin{pmatrix} |1,+1;1,+1\rangle \\ |1,+1;1,0\rangle \\ |1,0;1,+1\rangle \\ |1,+1;1,-1\rangle \\ |1,0;1,0\rangle \\ |1,-1;1,+1\rangle \\ |1,0;1,-1\rangle \\ |1,-1;1,0\rangle \\ |1,-1;1,-1\rangle \end{pmatrix}$$

25.4.5.10 Ex: Properties of Clebsch-Gordan coefficients

Given the momenta j_1 and j_2, and C_{m_1,m_2} denoting the Clebsch-Gordan coefficients, prove that $\sum_{m_1,m_2} |C_{m_1,m_2}|^2 = 1$.

Solution: *The Clebsch-Gordans are defined by,*

$$|j,m\rangle = \sum_{m_1,m_2} |m_1,m_2\rangle\langle m_1,m_2|j,m\rangle \ ,$$

where we left out the $j_{1,2}$ to simplify the notation. Since the $|j,m\rangle$ and the $|m_1,m_2\rangle$ are orthogonal,

$$\begin{aligned} 1 = \langle j,m|j,m\rangle &= \sum_{m_1,m_2,m_1',m_2'} \langle j,m|m_1',m_2'\rangle\langle m_1',m_2'|m_1,m_2\rangle\langle m_1,m_2|j,m\rangle \\ &= \sum_{m_1,m_2} |\langle m_1,m_2|j,m\rangle|^2 \ . \end{aligned}$$

25.4.5.11 Ex: Spin-orbit coupling

a. Show that the operator $\hat{\mathbf{L}}\cdot\hat{\mathbf{S}}$ associated with the spin-orbit coupling, satisfies the relation $\hat{\mathbf{L}}\cdot\hat{\mathbf{S}} = \hat{L}_z\hat{S}_z + (\hat{L}_+\hat{S}_- + \hat{L}_-\hat{S}_+)/2$.
Obtain the matrix representation of the operator $\mathbf{L}\cdot\mathbf{S}$, considering the bases:
b. $\{|m_L\rangle\otimes|m_S\rangle\}$ of the eigenstates which are common to the operators $\hat{\mathbf{L}}^2$, $\hat{\mathbf{S}}^2$, $\hat{L}_z$, $\hat{S}_z$;
c. $\{|J,M\rangle\}$, which is associated with the operators $\hat{\mathbf{L}}^2$, $\hat{\mathbf{S}}^2$, $\hat{\mathbf{J}}^2$, $\hat{J}_z$.
d. Give the explicit matrices for the case $L=1$ and $S=\frac{1}{2}$ in the representations (b) and (c) and verify that the two representations yield the same eigenvalue spectrum.

Solution: *a. This is trivial using the definition, $\hat{L}_\pm \equiv \hat{L}_x \pm i\hat{L}_y$, and similarly for $\hat{S}$.*
b. In the decoupled base,

$$\begin{aligned} &\langle m_L'm_S'|\hat{\mathbf{L}}\cdot\hat{\mathbf{S}}|m_Lm_S\rangle \\ &= \langle m_L'm_S'|\hat{L}_z\hat{S}_z|m_Lm_S\rangle + \tfrac{1}{2}\langle m_L'm_S'|\hat{L}_+\hat{S}_-|m_Lm_S\rangle + \tfrac{1}{2}\langle m_L'm_S'|\hat{L}_-\hat{S}_+|m_Lm_S\rangle \\ &= \hbar^2 m_L m_S \delta_{m_L,m_L'}\delta_{m_S,m_S'} \\ &+ \tfrac{1}{2}\hbar^2\sqrt{L(L+1)+m_L(m_L+1)}\sqrt{S(S+1)+m_S(m_S-1)}\delta_{m_L+1,m_L'}\delta_{m_S-1,m_S'} \\ &+ \tfrac{1}{2}\hbar^2\sqrt{L(L+1)+m_L(m_L-1)}\sqrt{S(S+1)+m_S(m_S+1)}\delta_{m_L-1,m_L'}\delta_{m_S+1,m_S'} \ . \end{aligned}$$

c. In the coupled base,

$$\begin{aligned} \langle J'm_J|\hat{\mathbf{L}}\cdot\hat{\mathbf{S}}|Jm_J\rangle &= \tfrac{1}{2}\langle J'm_J|\hat{\mathbf{J}}^2 - \hat{\mathbf{L}}^2 - \hat{\mathbf{S}}^2|Jm_J\rangle \\ &= \tfrac{1}{2}\hbar^2\left[J(J+1) - L(L+1) - S(S+1)\right]\delta_{J',m_J,J,m_J} \ . \end{aligned}$$

To obtain the eigenvalues of the spin-orbit coupling in the decoupled base we must diagonalize the matrix. Doing so, we find exactly the eigenvalues resulting form a calculation in the coupled base.

d. The matrices are,

$$\langle m'_L m'_S|\hat{\mathbf{L}}\cdot\hat{\mathbf{S}}|m_L m_S\rangle = \frac{\hbar^2}{2}\begin{pmatrix} |+1,+\frac{1}{2}\rangle \\ |+1,-\frac{1}{2}\rangle \\ |0,+\frac{1}{2}\rangle \\ |0,-\frac{1}{2}\rangle \\ |-1,+\frac{1}{2}\rangle \\ |-1,-\frac{1}{2}\rangle \end{pmatrix}^t \begin{pmatrix} +1 & 0 & 0 & 0 & 0 & 0 \\ 0 & -1 & \sqrt{2} & 0 & 0 & 0 \\ 0 & \sqrt{2} & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & \sqrt{2} & 0 \\ 0 & 0 & 0 & \sqrt{2} & -1 & 0 \\ 0 & 0 & 0 & 0 & 0 & +1 \end{pmatrix} \begin{pmatrix} |+1,+\frac{1}{2}\rangle \\ |+1,-\frac{1}{2}\rangle \\ |0,+\frac{1}{2}\rangle \\ |0,-\frac{1}{2}\rangle \\ |-1,+\frac{1}{2}\rangle \\ |-1,-\frac{1}{2}\rangle \end{pmatrix}$$

and

$$\langle J' m_J|\hat{\mathbf{L}}\cdot\hat{\mathbf{S}}|J m_J\rangle = \frac{\hbar^2}{2}\begin{pmatrix} |\frac{1}{2},+\frac{1}{2}\rangle \\ |\frac{1}{2},-\frac{1}{2}\rangle \\ |\frac{3}{2},+\frac{3}{2}\rangle \\ |\frac{3}{2},+\frac{1}{2}\rangle \\ |\frac{3}{2},-\frac{1}{2}\rangle \\ |\frac{3}{2},-\frac{3}{2}\rangle \end{pmatrix}^t \begin{pmatrix} -2 & 0 & 0 & 0 & 0 & 0 \\ 0 & -2 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} |\frac{1}{2},+\frac{1}{2}\rangle \\ |\frac{1}{2},-\frac{1}{2}\rangle \\ |\frac{3}{2},+\frac{3}{2}\rangle \\ |\frac{3}{2},+\frac{1}{2}\rangle \\ |\frac{3}{2},-\frac{1}{2}\rangle \\ |\frac{3}{2},-\frac{3}{2}\rangle \end{pmatrix} .$$

The eigenvalues of the first matrix are $1, -2$.

25.4.5.12 Ex: Expansion of the spin-orbit coupling

Consider the problem of adding the orbital angular momentum ℓ and a spin $1/2$. Obtain the $2\ell+1$ states $|\ell+1/2, m_j\rangle$, in addition to the 2ℓ states $|\ell-1/2, m_j\rangle$ (which constitute a common basis for the operators $\mathbf{l}_1^2$, $\mathbf{s}_2^2$, $\mathbf{j}^2$, j_z), expanded in the base $|m_1, m_2\rangle$ of the eigenstates of the operators $\mathbf{l}^2$, $\mathbf{s}^2$, l_z, s_z. You can simplify the procedure by deriving two recurrence relationships from which the desired states follow [6].

Solution: *The states are, for all* $m_j = -(\ell \pm \frac{1}{2}), .., \ell \pm \frac{1}{2}$,

$$|(\ell,s)j,m_j\rangle = |(\ell,\tfrac{1}{2})\ell\mp\tfrac{1}{2},m_j\rangle = \sum_{m_s=\pm 1/2} |\ell,\tfrac{1}{2},m_j-m_s,m_s\rangle \left(\begin{array}{cc|c} \ell & \frac{1}{2} & \ell\mp\frac{1}{2} \\ m_j-m_s & m_s & m_j \end{array}\right)$$

$$= |\ell,\tfrac{1}{2},m_j+\tfrac{1}{2},-\tfrac{1}{2}\rangle \left(\begin{array}{cc|c} \ell & \frac{1}{2} & \ell\mp\frac{1}{2} \\ m_j+\frac{1}{2} & -\frac{1}{2} & m_j \end{array}\right) + |\ell,\tfrac{1}{2},m_j-\tfrac{1}{2},\tfrac{1}{2}\rangle \left(\begin{array}{cc|c} \ell & \frac{1}{2} & \ell\mp\frac{1}{2} \\ m_j-\frac{1}{2} & \frac{1}{2} & m_j \end{array}\right)$$

$$= |\ell,\tfrac{1}{2},m_j+\tfrac{1}{2},-\tfrac{1}{2}\rangle\sqrt{\frac{\ell\pm m+\frac{1}{2}}{2\ell+1}} + |\ell,\tfrac{1}{2},m_j-\tfrac{1}{2},\tfrac{1}{2}\rangle\sqrt{\frac{\ell\mp m+\frac{1}{2}}{2\ell+1}} ,$$

using the formulae (28.5).

25.4.5.13 Ex: External product of two spins

Derive the matrix representation of the spin-orbit coupling operator $\mathbf{L}\cdot\mathbf{S}$ for $L=1$ and $S=1/2$ from the definition of the outer product.

[6] See Cohen-Tannoudji, Vol.2, Complement A_X.

Solution: *Choosing the base* $\langle \ell m| = \begin{pmatrix} 1 & 0 & -1 \end{pmatrix}$ *the matrix representation of the rising and lowering operators,*

$$\hat{l}_+ = \hbar\sqrt{2}\begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{pmatrix} \quad , \quad \hat{l}_- = \hbar\sqrt{2}\begin{pmatrix} 0 & 0 & 0 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{pmatrix}$$

yields the matrix representation of the Cartesian coordinates of $\mathbf{l}$*,*

$$\hat{l}_x = \tfrac{\hat{l}_+ + \hat{l}_-}{2} = \tfrac{\hbar}{\sqrt{2}}\begin{pmatrix} 0 & 1 & 0 \\ 1 & 0 & 1 \\ 0 & 1 & 0 \end{pmatrix} \quad , \quad i\hat{l}_y = \tfrac{\hat{L}_+ - \hat{L}_-}{2} = \tfrac{\hbar}{\sqrt{2}}\begin{pmatrix} 0 & 1 & 0 \\ -1 & 0 & 1 \\ 0 & -1 & 0 \end{pmatrix} \quad ,$$

$$\hat{l}_z = \hbar\begin{pmatrix} 1 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & -1 \end{pmatrix} .$$

We can verify that $\hat{\mathbf{l}}^2 = \hat{l}_x^2 + \hat{l}_y^2 + \hat{l}_z^2 = \hbar^2 l(l+1) = 2\hbar^2 \mathbb{I}_3$*. The matrix representation of* $\hat{\mathbf{s}}$ *are simply the Pauli matrices,*

$$\hat{s}_x = \tfrac{1}{2}\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \quad , \quad \hat{s}_y = \tfrac{1}{2}\begin{pmatrix} 0 & -\imath \\ \imath & 0 \end{pmatrix} \quad , \quad \hat{s}_z = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}.$$

We can verify that $\hat{\mathbf{s}}^2 = \hat{s}_x^2 + \hat{s}_y^2 + \hat{s}_z^2 = \hbar^2 s(s+1) = \frac{3}{4}\hbar^2 \mathbb{I}_3$*. The spin-orbit coupling can now be written* $\hat{\mathbf{l}} \otimes \hat{\mathbf{s}} = \hat{l}_x \otimes \hat{s}_x + \hat{l}_y \otimes \hat{s}_y + \hat{l}_z \otimes \hat{s}_z$*. Choosing the base* $\langle \ell m| = \begin{pmatrix} 1,+\frac{1}{2} & 1,-\frac{1}{2} & 0,+\frac{1}{2} & 0,-\frac{1}{2} & -1,+\frac{1}{2} & -1,-\frac{1}{2} \end{pmatrix}$ *the matrix representation of* $\hat{L}_x\hat{S}_x$ *in the full Hilbert space reads,*

$$\hat{L}_x\hat{S}_x = \tfrac{\hbar}{\sqrt{2}}\begin{pmatrix} & & 1 & & & \\ & & & 1 & & \\ 1 & & & & 1 & \\ & 1 & & & & 1 \\ & & 1 & & & \\ & & & 1 & & \end{pmatrix} \tfrac{\hbar}{2}\begin{pmatrix} & 1 & & & & \\ 1 & & & & 1 & \\ & & & & & 1 \\ & & & & & \\ & & 1 & & & \\ & & & 1 & & \end{pmatrix} = \tfrac{\hbar^2}{2\sqrt{2}}\begin{pmatrix} & & 1 & & 1 & \\ & 1 & & & & 1 \\ 1 & & & & 1 & \\ & & & & & \\ & 1 & & & & \\ & & 1 & & & \end{pmatrix} .$$

Similarly,

$$\hat{L}_y\hat{S}_y = \tfrac{\hbar}{\sqrt{2}}\begin{pmatrix} & & -\imath & & & \\ & & & -\imath & & \\ \imath & & & & -\imath & \\ & \imath & & & & -\imath \\ & & \imath & & & \\ & & & \imath & & \end{pmatrix} \tfrac{\hbar}{2}\begin{pmatrix} & -\imath & & & & \\ \imath & & & & -\imath & \\ & & & & & -\imath \\ & & & & & \\ & & \imath & & & \\ & & & \imath & & \end{pmatrix} = \tfrac{\hbar^2}{2\sqrt{2}}\begin{pmatrix} & & 1 & & -1 & \\ & 1 & & & & -1 \\ -1 & & & & 1 & \\ & & & & & 1 \\ & & -1 & & & \\ & & & 1 & & \end{pmatrix} ,$$

and,

$$\hat{L}_z\hat{S}_z = \hbar\begin{pmatrix} 1 & & & & & \\ & 1 & & & & \\ & & 0 & & & \\ & & & 0 & & \\ & & & & -1 & \\ & & & & & -1 \end{pmatrix} \tfrac{\hbar}{2}\begin{pmatrix} 1 & & & & & \\ & -1 & & & & \\ & & 1 & & & \\ & & & -1 & & \\ & & & & 1 & \\ & & & & & -1 \end{pmatrix} = \tfrac{\hbar^2}{2}\begin{pmatrix} 1 & & & & & \\ & 1 & & & & \\ & & & & & \\ & & & & & \\ & & & & -1 & \\ & & & & & -1 \end{pmatrix} .$$

Finally,

$$\hat{\mathbf{L}}\cdot\hat{\mathbf{S}} = \begin{pmatrix} \frac{1}{2} & 0 & 0 & 0 & 0 & 0 \\ 0 & -\frac{1}{2} & \frac{1}{\sqrt{2}} & 0 & 0 & 0 \\ 0 & \frac{1}{\sqrt{2}} & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & \frac{1}{\sqrt{2}} & 0 \\ 0 & 0 & 0 & \frac{1}{\sqrt{2}} & -\frac{1}{2} & 0 \\ 0 & 0 & 0 & 0 & 0 & \frac{1}{2} \end{pmatrix} .$$

25.4.5.14 Ex: Coupling three spins

Express the states of three coupled $\frac{1}{2}$ spins in the uncoupled basis using the Clebsch-Gordan coefficients. Proceed by first coupling two spins and then coupling the result to the third spin. Compare the dimensions of the Hilbert spaces in both basis and discuss your findings.

Solution: *We first couple two spins and then couple the result to the third one. The general procedure is summarized by,*

$$\begin{aligned} |(j_1,j_2)j_{12},m_{12}\rangle &= \sum_{m_1,m_2} U_{CGC}^{(1/2\times 1/2)} |j_1,m_1,j_2m_2\rangle \\ |(j_1,j_2)j_{12},j_3)j,m\rangle &= \sum_{m_{12},m_3} U_{CGC}^{(1\times 1/2)} |(j_1,j_2)j_{12},m_{12},j_3,m_3\rangle \\ &= \sum_{m_1,m_2,m_3} U_{CGC}^{(1\times 1/2)} U_{CGC}^{(1/2\times 1/2)} |j_1,m_1,j_2m_2,j_3,m_3\rangle \ . \end{aligned}$$

For the particular case of spin $\frac{1}{2}$ systems, the coupling of spin j_1 with j_2, we have,

$$\begin{pmatrix} |1,+1\rangle \\ |1,0\rangle \\ |0,0\rangle \\ |1,-1\rangle \end{pmatrix} = \begin{pmatrix} 1 & & & \\ & \frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}} & \\ & \frac{1}{\sqrt{2}} & -\frac{1}{\sqrt{2}} & \\ & & & 1 \end{pmatrix} \begin{pmatrix} |+\frac{1}{2}\rangle|+\frac{1}{2}\rangle \\ |+\frac{1}{2}\rangle|-\frac{1}{2}\rangle \\ |-\frac{1}{2}\rangle|+\frac{1}{2}\rangle \\ |-\frac{1}{2}\rangle|-\frac{1}{2}\rangle \end{pmatrix} = \begin{pmatrix} |+\frac{1}{2}\rangle|+\frac{1}{2}\rangle \\ \frac{1}{\sqrt{2}}|+\frac{1}{2}\rangle|-\frac{1}{2}\rangle + \frac{1}{\sqrt{2}}|-\frac{1}{2}\rangle|+\frac{1}{2}\rangle \\ \frac{1}{\sqrt{2}}|+\frac{1}{2}\rangle|-\frac{1}{2}\rangle - \frac{1}{\sqrt{2}}|-\frac{1}{2}\rangle|+\frac{1}{2}\rangle \\ |-\frac{1}{2}\rangle|-\frac{1}{2}\rangle \end{pmatrix} .$$

Now, we couple the spin $(j_1, j_2)j_{12}$ with the spin j_3,

$$\begin{pmatrix} |((\frac{1}{2},\frac{1}{2})1,\frac{1}{2})\frac{3}{2}+\frac{3}{2}\rangle \\ |((\frac{1}{2},\frac{1}{2})1,\frac{1}{2})\frac{3}{2},+\frac{1}{2}\rangle \\ |((\frac{1}{2},\frac{1}{2})0,\frac{1}{2})\frac{1}{2},+\frac{1}{2}\rangle \\ |((\frac{1}{2},\frac{1}{2})0,\frac{1}{2})\frac{3}{2},-\frac{1}{2}\rangle \\ |((\frac{1}{2},\frac{1}{2})1,\frac{1}{2})\frac{1}{2},-\frac{1}{2}\rangle \\ |((\frac{1}{2},\frac{1}{2})1,\frac{1}{2})\frac{3}{2},-\frac{3}{2}\rangle \end{pmatrix} = \begin{pmatrix} 1 & & & & & \\ & \sqrt{\frac{1}{3}} & \sqrt{\frac{2}{3}} & & & \\ & \sqrt{\frac{2}{3}} & -\sqrt{\frac{1}{3}} & & & \\ & & & \sqrt{\frac{2}{3}} & \sqrt{\frac{1}{3}} & \\ & & & \sqrt{\frac{1}{3}} & -\sqrt{\frac{2}{3}} & \\ & & & & & 1 \end{pmatrix} \begin{pmatrix} |1,+1\rangle|+\frac{1}{2}\rangle \\ |1,+1\rangle|-\frac{1}{2}\rangle \\ |0,0\rangle|+\frac{1}{2}\rangle \\ |0,0\rangle|-\frac{1}{2}\rangle \\ |1,-1\rangle|+\frac{1}{2}\rangle \\ |1,-1\rangle|-\frac{1}{2}\rangle \end{pmatrix}$$

$$= \begin{pmatrix} |1,+1\rangle|+\frac{1}{2}\rangle \\ \sqrt{\frac{1}{3}}|1,+1\rangle|-\frac{1}{2}\rangle + \sqrt{\frac{2}{3}}|0,0\rangle|+\frac{1}{2}\rangle \\ \sqrt{\frac{1}{3}}|1,+1\rangle|-\frac{1}{2}\rangle - \sqrt{\frac{2}{3}}|0,0\rangle|+\frac{1}{2}\rangle \\ \sqrt{\frac{2}{3}}|0,0\rangle|-\frac{1}{2}\rangle + \sqrt{\frac{1}{3}}|1,-1\rangle|+\frac{1}{2}\rangle \\ \sqrt{\frac{2}{3}}|0,0\rangle|-\frac{1}{2}\rangle - \sqrt{\frac{1}{3}}|1,-1\rangle|+\frac{1}{2}\rangle \\ |1,-1\rangle|-\frac{1}{2}\rangle \end{pmatrix} = \begin{pmatrix} |+++\rangle \\ \sqrt{\frac{1}{3}}(|++-\rangle + |+-+\rangle - |-++\rangle) \\ \sqrt{\frac{1}{3}}(|++-\rangle - |+-+\rangle + |-++\rangle) \\ \sqrt{\frac{1}{3}}(|+--\rangle - |-+-\rangle + |--+\rangle) \\ \sqrt{\frac{1}{3}}(|+--\rangle - |-+-\rangle - |--+\rangle) \\ |---\rangle \end{pmatrix},$$

where we simplified the notation for the last vector. Apparently, the Hilbert space for three spins is larger (dimension 2^3) than the one of a spin $\frac{3}{2}$ state, whose dimension is 6,

$$\begin{pmatrix} |(\frac{1}{2},\frac{1}{2})1,\frac{1}{2})\frac{3}{2},+\frac{3}{2}\rangle \\ |(\frac{1}{2},\frac{1}{2})1,\frac{1}{2})\frac{3}{2},+\frac{1}{2}\rangle \\ |(\frac{1}{2},\frac{1}{2})0,\frac{1}{2})\frac{1}{2},+\frac{1}{2}\rangle \\ ? \\ ? \\ |(\frac{1}{2},\frac{1}{2})0,\frac{1}{2})\frac{3}{2},-\frac{1}{2}\rangle \\ |(\frac{1}{2},\frac{1}{2})1,\frac{1}{2})\frac{1}{2},-\frac{1}{2}\rangle \\ |(\frac{1}{2},\frac{1}{2})1,\frac{1}{2})\frac{3}{2},-\frac{3}{2}\rangle \end{pmatrix} = \begin{pmatrix} 1 & & & & & & & \\ & \sqrt{\frac{1}{3}} & \sqrt{\frac{1}{3}} & -\sqrt{\frac{1}{3}} & & & & \\ & \sqrt{\frac{1}{3}} & -\sqrt{\frac{1}{3}} & \sqrt{\frac{1}{3}} & & & & \\ & & & & \sqrt{\frac{1}{3}} & -\sqrt{\frac{1}{3}} & \sqrt{\frac{1}{3}} & \\ & & & & \sqrt{\frac{1}{3}} & -\sqrt{\frac{1}{3}} & -\sqrt{\frac{1}{3}} & \\ & & & & & & & 1 \end{pmatrix} \begin{pmatrix} |+++\rangle \\ |++-\rangle \\ |+-+\rangle \\ |-++\rangle \\ |+--\rangle \\ |-+-\rangle \\ |--+\rangle \\ |---\rangle \end{pmatrix}.$$

This it due to the fact that, apart from the particular coupling $((j_1, j_2)j_{12}, j_3)j$, there are two more coupling schemes, $((j_1, j_3)j_{13}, j_2)j$ and $((j_2, j_3)j_{23}, j_1)j$, which can be transformed into each other via $\{6j\}$-coefficients.

Chapter 26

Periodic systems

Many physical systems treat quantum particles in periodic potential. Examples are electrons in crystals or cold atoms in optical lattices. The periodicity gives rise to a wealth of new phenomena, such as Bragg scattering, the formation of energy bands, Mott insulators, or Bloch oscillations. Various theoretical approaches have been developed leading to a deep understanding of the features of crystals, metals, and optical lattices for atomic gases.

In the following sections we will mainly focus on the Bloch model, which is based on introducing periodic boundary conditions to the Schrödinger equation. In the Secs. 26.1 we will give a brief introduction into the Bloch model for electrons in solids, where the periodicity is imposed by the crystalline structure of the material. We will, however, no go into details leaving a comprehensive treatment to specialized textbooks [53, 726]. In the Secs. 26.2 we will concentrate on optical lattices for atomic gases formed by counterpropagating laser beams. The physical realization of these lattices, which can be realized with nearly perfect periodicity, have permitted the experimental observation of phenomena which had been elusive in solid state physics.

26.1 The Bloch model for electrons

The motion of an electron inside a crystal is ruled by a spatially periodic potential $V(\mathbf{r})$ originating from the positively charged crystal atoms and the mean field produced by the quasi-free electrons,

$$V(\mathbf{r}) = V(\mathbf{r} + \mathbf{R}) \ , \tag{26.1}$$

where $\mathbf{R}$ is a vector connecting two arbitrarily chosen atoms of the lattice. With the Hamiltonian

$$\hat{H} = -\frac{\hbar^2}{2m}\nabla^2 + V(\mathbf{r}) \tag{26.2}$$

we can write the Schrödinger equation,

$$[\hat{H} + V(\mathbf{r})]\psi(\mathbf{r}) = E\psi(\mathbf{r}) \ . \tag{26.3}$$

Since V and ∇ are invariant under translations $U_{tr}(\mathbf{R})\psi(\mathbf{r}) \equiv \psi(\mathbf{r} + \mathbf{R})$ by a fixed distance $\mathbf{R}$, where the translation operator has been defined in Eq. (23.181), we have,

$$\hat{H}U_{tr}(\mathbf{R})\psi(\mathbf{r}) = EU_{tr}(\mathbf{R})\psi(\mathbf{r}) \ . \tag{26.4}$$

That is, for a non-degenerate eigenvalue [1],

$$\psi(\mathbf{r}+\mathbf{R}) = f(\mathbf{R})\psi(\mathbf{r}) \ . \tag{26.5}$$

This relation holds for all vectors $\mathbf{R}$ of the lattice, such that,

$$f(\mathbf{R}_1+\mathbf{R}_2)\psi(\mathbf{r}) = \psi(\mathbf{r}+\mathbf{R}_1+\mathbf{R}_2) = f(\mathbf{R}_1)\psi(\mathbf{r}+\mathbf{R}_2) = f(\mathbf{R}_1)f(\mathbf{R}_2)\psi(\mathbf{r}) \ . \tag{26.6}$$

The relationship $f(\mathbf{R}_1+\mathbf{R}_2) = f(\mathbf{R}_1)f(\mathbf{R}_2)$ is satisfied by the ansatz $f(\mathbf{R}) \equiv e^{\imath\mathbf{k}\cdot\mathbf{R}}$, where $\mathbf{k}$ is an arbitrary vector of reciprocal space. We get the famous *Bloch theorem*,

$$\boxed{\psi_{\mathbf{k}}(\mathbf{r}+\mathbf{R}) = e^{\imath\mathbf{k}\cdot\mathbf{R}}\psi_{\mathbf{k}}(\mathbf{r})} \ , \tag{26.7}$$

which represents a necessary condition for any eigenfunction $\psi_{\mathbf{k}}$ of the Schrödinger equation with periodic potential. Bloch's theorem simply postulates that, apart from a phase factor, the wavefunction has the same periodicity as the potential.

The *Bloch function*,

$$\boxed{\psi_{\mathbf{k}}(\mathbf{r}) \equiv u_{\mathbf{k}}(\mathbf{r})e^{\imath\mathbf{k}\cdot\mathbf{r}} \qquad \text{with} \qquad u_{\mathbf{k}}(\mathbf{r}+\mathbf{R}) = u_{\mathbf{k}}(\mathbf{r})} \ , \tag{26.8}$$

automatically satisfies Bloch's theorem. That is, the wave function of the electron ψ is a plane wave $e^{\imath\mathbf{k}\cdot\mathbf{r}}$ modulated by a function $u_{\mathbf{k}}$ having the same periodicity as the lattice [741]. Although the vector of the electronic wave is arbitrary, it is possible (and useful) to restrict its value to the first *Brillouin zone* defined by $\mathbf{k} \in [-\pi/\mathbf{a}, \pi/\mathbf{a}]$, where $\mathbf{a}$ is an elementary vector of the lattice. The reason is that we can reduce a wavevector $\mathbf{k}$ in a wavefunction trespassing the first Brillouin zone by an appropriate vector $\mathbf{G}$ of *reciprocal lattice*,

$$\mathbf{k}' = \mathbf{k} + \mathbf{G} \ , \tag{26.9}$$

yielding,

$$\psi_{\mathbf{k}}(\mathbf{r}) = u_{\mathbf{k}}(\mathbf{r})e^{\imath\mathbf{k}\cdot\mathbf{r}} = u_{\mathbf{k}}(\mathbf{r})e^{-\imath\mathbf{G}\cdot\mathbf{r}}e^{\imath\mathbf{k}'\cdot\mathbf{r}} \ . \tag{26.10}$$

We now define another function $u_{\mathbf{k}'}(\mathbf{r}) \equiv u_{\mathbf{k}}(\mathbf{r})e^{-\imath\mathbf{G}\cdot\mathbf{r}}$, which also satisfies the requirement (26.8), knowing that $\mathbf{G}\cdot\mathbf{R} = n2\pi$, we see,

$$u_{\mathbf{k}'}(\mathbf{r}+\mathbf{R}) = u_{\mathbf{k}}(\mathbf{r}+\mathbf{R})e^{-\imath\mathbf{G}\cdot(\mathbf{r}+\mathbf{R})} = u_{\mathbf{k}}(\mathbf{r})e^{-\imath\mathbf{G}\cdot\mathbf{r}} = u_{\mathbf{k}'}(\mathbf{r}) \ . \tag{26.11}$$

Hence,

$$\psi_{\mathbf{k}}(\mathbf{r}) = u_{\mathbf{k}'}(\mathbf{r})e^{\imath\mathbf{k}'\cdot\mathbf{r}} = \psi_{\mathbf{k}'}(\mathbf{r}) \ . \tag{26.12}$$

26.1.1 Approximation for quasi-bound electrons

We now assume that the behavior of the electron near an atom is not influenced by atoms farther apart,

$$\psi_{\mathbf{k}}(\mathbf{r}) = \sum_{i\in\text{lattice}} c_i(\mathbf{k})\phi(\mathbf{r}-\mathbf{R}_i) \ . \tag{26.13}$$

That is, we neglect superposition states of the electron at various sites of the lattice. The atom is subject to a potential $U_{at}(\mathbf{r}-\mathbf{R}_i)$ located near the atom at the position

[1] This also holds true for degenerate eigenvalues if we choose suitable basis of eigenvectors.

$\mathbf{R}_i$, and it is described by the eigenfunction $\phi(\mathbf{r}-\mathbf{R}_i)$ (only defined for the site i) with energy E_0,

$$\left[-\frac{\hbar^2}{2m}\nabla^2 + U_{at}(\mathbf{r}-\mathbf{R}_i)\right]\phi(\mathbf{r}-\mathbf{R}_i) = E_0\phi(\mathbf{r}-\mathbf{R}_i)\ . \tag{26.14}$$

Even so, the function $\psi_{\mathbf{k}}(\mathbf{r})$ must satisfy Bloch's theorem. This is the case when $c_i(\mathbf{k}) = e^{\imath\mathbf{k}\cdot\mathbf{R}_i}$ and therefore,

$$\psi_{\mathbf{k}}(\mathbf{r}) = \sum_{i\in\text{lattice}} e^{\imath\mathbf{k}\cdot\mathbf{R}_i}\phi(\mathbf{r}-\mathbf{R}_i)\ . \tag{26.15}$$

Example 169 (*Ansatz for a quasi-bound electron wavefunction*): The ansatz (26.15) satisfies Bloch's theorem because,

$$\psi_{\mathbf{k}}(\mathbf{r}+\mathbf{R}_j) = \sum_i e^{\imath\mathbf{k}\cdot\mathbf{R}_i}\phi(\mathbf{r}-(\mathbf{R}_i-\mathbf{R}_j)) = e^{i\mathbf{k}\cdot\mathbf{R}_j}\sum_i e^{\imath\mathbf{k}\cdot(\mathbf{R}_i-\mathbf{R}_j)}\phi(\mathbf{r}-(\mathbf{R}_i-\mathbf{R}_j)) = e^{\imath\mathbf{k}\cdot\mathbf{R}_j}\psi_{\mathbf{k}}(\mathbf{r})\ .$$

We now calculate the energy $E(\mathbf{k})$ of an electron with the wavevector $\mathbf{k}$ inserting the function $\psi_{\mathbf{k}}(\mathbf{r})$ of (26.15) in the Schrödinger equation and obtain,

$$\left[-\frac{\hbar^2}{2m}\nabla^2 + U(\mathbf{r})\right]\sum_i e^{\imath\mathbf{k}\cdot\mathbf{R}_i}\phi(\mathbf{r}-\mathbf{R}_i) = E(\mathbf{k})\sum_i e^{\imath\mathbf{k}\cdot\mathbf{R}_i}\phi(\mathbf{r}-\mathbf{R}_i)\ . \tag{26.16}$$

$U(\mathbf{r})$ is the potential energy of the electron illustrated in Fig. 26.1 together with the energy $U_{at}(\mathbf{r}-\mathbf{R}_i)$ of a free electron.

Substituting the kinetic energy term of (26.16) by the kinetic energy of (26.14), we calculate,

$$\sum_i e^{\imath\mathbf{k}\cdot\mathbf{R}_i}[-U_{at}(\mathbf{r}-\mathbf{R}_i) + E_0 + U(\mathbf{r}) - E(\mathbf{k})]\phi(\mathbf{r}-\mathbf{R}_i) = 0\ . \tag{26.17}$$

Now, multiplying this equation with $\psi^*_{\mathbf{k}}(\mathbf{r}) = \sum_j e^{\imath\mathbf{k}\cdot\mathbf{R}_j}\phi^*(\mathbf{r}-\mathbf{R}_j)$ and integrating over the volume of the crystal, we obtain,

$$\begin{aligned}[E(\mathbf{k}) - E_0]\sum_{i,j} e^{\imath\mathbf{k}\cdot(\mathbf{R}_i-\mathbf{R}_j)}\int \phi^*(\mathbf{r}-\mathbf{R}_j)\phi(\mathbf{r}-\mathbf{R}_i)dV \\ = \sum_{i,j} e^{\imath\mathbf{k}\cdot(\mathbf{R}_i-\mathbf{R}_j)}\int \phi^*(\mathbf{r}-\mathbf{R}_j)[U(\mathbf{r}) - U_{at}(\mathbf{r}-\mathbf{R}_i)]\phi(\mathbf{r}-\mathbf{R}_i)dV\ .\end{aligned} \tag{26.18}$$

The functions $\phi^*(\mathbf{r}-\mathbf{R}_j)$ and $\phi(\mathbf{r}-\mathbf{R}_i)$ overlap only a little, even for adjacent atoms, such that we can neglect the terms $i \neq j$ on the left side. The sum then corresponds to the number N of sites in the lattice. On the right side we can not neglect the terms involving other sites, because even if the wavefunctions of adjacent sites overlap little, the contribution of the potential difference $|U(\mathbf{r}) - U_{at}(\mathbf{r}-\mathbf{R}_i)|$ is much lower for $\mathbf{r} = \mathbf{R}_i$ than for $\mathbf{r} = \mathbf{R}_j$. On the other hand, as the wavefunctions $\phi(\mathbf{r}-\mathbf{R}_i)$

disappear quickly when $|\mathbf{r}-\mathbf{R}_i| > |\mathbf{R}_m-\mathbf{R}_i|$, we can focus on adjacent sites (called $\mathbf{R}_m$),

$$N[E(\mathbf{k})-E_0] = N\int \phi^*(\mathbf{r}-\mathbf{R}_i)[U(\mathbf{r})-U_{at}(\mathbf{r}-\mathbf{R}_i)]\phi(\mathbf{r}-\mathbf{R}_i)dV \tag{26.19}$$
$$+N\sum_{m=\text{adjacent}} e^{\imath\mathbf{k}\cdot(\mathbf{R}_i-\mathbf{R}_m)}\int \phi^*(\mathbf{r}-\mathbf{R}_m)[U(\mathbf{r})-U_{at}(\mathbf{r}-\mathbf{R}_i)]\phi(\mathbf{r}-\mathbf{R}_i)dV\ .$$

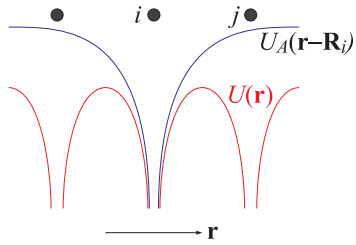

Figure 26.1: Potential energy $U(\mathbf{r})$ of a crystal electron (red) and potential energy $U_A(\mathbf{r}-\mathbf{R}_i)$ of the electron of a free atom (blue).

Now we further suppose that the eigenfunction ϕ exhibits radial symmetry corresponding to an s orbital. We obtain for the eigenvalues from the Schrödinger equation,

$$E(\mathbf{k}) = E_0-\alpha-\gamma\sum_{m\ \text{adjacent of}\ i} e^{\imath\mathbf{k}\cdot(\mathbf{R}_i-\mathbf{R}_m)} \tag{26.20}$$
$$\text{with}\quad \alpha = \int \phi^*(\mathbf{r}-\mathbf{R}_i)[U_{at}(\mathbf{r}-\mathbf{R}_i)-U(\mathbf{r})]\phi(\mathbf{r}-\mathbf{R}_i)dV$$
$$\text{and}\quad \gamma = \int \phi^*(\mathbf{r}-\mathbf{R}_m)[U_{at}(\mathbf{r}-\mathbf{R}_i)-U(\mathbf{r})]\phi(\mathbf{r}-\mathbf{R}_i)dV\ .$$

The interpretation is as follows: The combination of the atoms in a lattice produces an energy displacement α. In addition, it generates a spitting into a continuous band of energies as a function of reduced wavevector $\mathbf{k}$...

26.1.2 Approximation for quasi-free electrons

Here we assume an essentially homogeneous potential acting on the free electrons and consider the impact of the periodic lattice as a small perturbation. The periodic potential can be decomposed into a Fourier series by the vectors $\mathbf{G}$ of the reciprocal lattice,

$$U(\mathbf{r}) = \sum_{\mathbf{G}} U_{\mathbf{G}} e^{\imath\mathbf{G}\cdot\mathbf{r}}\ . \tag{26.21}$$

Consequently, we can make for Bloch functions (26.10) the following periodic ansatz,

$$\psi_{\mathbf{k}}(\mathbf{r}) = u_{\mathbf{k}}(\mathbf{r})e^{\imath\mathbf{k}\cdot\mathbf{r}} \qquad \text{with} \qquad u_{\mathbf{k}}(\mathbf{r}) = \tfrac{1}{\sqrt{V_c}}\sum_{\mathbf{G}} u_{\mathbf{G}}(\mathbf{k})e^{\imath\mathbf{G}\cdot\mathbf{r}}\ , \tag{26.22}$$

where V_c is the volume of the crystal.

Without periodic potential, the eigenfunctions would be those of a free particle,

$$\psi_{\mathbf{k}}(\mathbf{r}) = \tfrac{1}{V_c} e^{\imath \mathbf{k}\cdot\mathbf{r}} \tag{26.23}$$

with the eigenenergies

$$E_0(\mathbf{k}) = V_0 + \frac{\hbar^2 k^2}{2m} \ . \tag{26.24}$$

Inserting the functions (26.21) and (26.22) in the Schrödinger equation, we obtain,

$$\left[-\tfrac{\hbar^2}{2m}\nabla^2 + \sum_{\mathbf{G}''} U_{\mathbf{G}''} e^{\imath \mathbf{G}''\cdot\mathbf{r}} \right] \tfrac{1}{\sqrt{V_c}} e^{\imath \mathbf{k}\cdot\mathbf{r}} \sum_{\mathbf{G}'} u_{\mathbf{G}'}(\mathbf{k}) e^{\imath \mathbf{G}'\cdot\mathbf{r}} = E(\mathbf{k}) \tfrac{1}{\sqrt{V_c}} e^{\imath \mathbf{k}\cdot\mathbf{r}} \sum_{\mathbf{G}} u_{\mathbf{G}'}(\mathbf{k}) e^{\imath \mathbf{G}'\cdot\mathbf{r}} \ , \tag{26.25}$$

that is,

$$\tfrac{1}{\sqrt{V_c}} \sum_{\mathbf{G}'} \left[-\tfrac{\hbar^2}{2m}(\mathbf{k}+\mathbf{G}')^2 - E(\mathbf{k}) \right] u_{\mathbf{G}'}(\mathbf{k}) e^{\imath(\mathbf{k}+\mathbf{G}')\cdot\mathbf{r}} + \tfrac{1}{\sqrt{V_c}} \sum_{\mathbf{G}''} U_{\mathbf{G}''} e^{\imath \mathbf{G}''\cdot\mathbf{r}} \sum_{\mathbf{G}'} u_{\mathbf{G}'}(\mathbf{k}) e^{\imath(\mathbf{k}+\mathbf{G}')\cdot\mathbf{r}} = 0 \ . \tag{26.26}$$

Now multiplying with $\frac{1}{\sqrt{V_c}} e^{\imath(\mathbf{k}+\mathbf{G})\cdot\mathbf{r}}$ and integrating over the volume of the crystal (knowing $\frac{1}{V_c}\int_{V_c} e^{\imath \mathbf{G}\cdot\mathbf{r}} dV = \delta_{\mathbf{G},0}$), we obtain,

$$\left[\tfrac{\hbar^2}{2m}(\mathbf{k}+\mathbf{G})^2 - E(\mathbf{k}) \right] u_{\mathbf{G}}(\mathbf{k}) + \sum_{\mathbf{G}'} U_{\mathbf{G}-\mathbf{G}'} u_{\mathbf{G}'}(\mathbf{k}) = 0 \ , \tag{26.27}$$

for any value of $\mathbf{G}$.

To estimate the dependence of the Fourier components $u_{\mathbf{G}}(\mathbf{k})$ for $\mathbf{G} \neq 0$ we insert the unperturbed eigenenergies into the equation (26.27) only considering, in the sum over $\mathbf{G}'$, the terms of the first perturbative order, that is, those containing U_0 or $u_0(\mathbf{k})$,

$$\frac{\hbar^2}{2m}[(\mathbf{k}+\mathbf{G})^2 - k^2] u_{\mathbf{G}}(\mathbf{k}) - U_0 u_{\mathbf{G}}(\mathbf{k}) + U_0 u_{\mathbf{G}}(\mathbf{k}) + U_{\mathbf{G}} u_0(\mathbf{k}) = 0 \tag{26.28}$$

$$u_{\mathbf{G}}(\mathbf{k}) = \frac{U_{\mathbf{G}} u_0(\mathbf{k})}{\frac{\hbar^2}{2m}[k^2 - (\mathbf{k}+\mathbf{G})^2]} \ . \tag{26.29}$$

Since the Fourier coefficients $U_{\mathbf{G}}$ have, for $\mathbf{G} \neq 0$, small values, the function $u_{\mathbf{G}}(\mathbf{k})$ is not negligible only for $k^2 \simeq (\mathbf{k}+\mathbf{G})^2$ that is,

$$-2\mathbf{k}\cdot\mathbf{G} \simeq |\mathbf{G}|^2 \ . \tag{26.30}$$

We now want to find out the meaning of this condition ...

For the coefficients $u_0(\mathbf{k})$ and $u_{\mathbf{G}}(\mathbf{k})$ we obtain,

$$\left[\tfrac{\hbar^2}{2m} k^2 - E(\mathbf{k}) \right] u_0(\mathbf{k}) + U_0 u_0(\mathbf{k}) + U_{-\mathbf{G}}(\mathbf{k}) u_{\mathbf{G}}(\mathbf{k}) = 0 \tag{26.31}$$

$$\left[\tfrac{\hbar^2}{2m} k^2 - E(\mathbf{k}) \right] u_{\mathbf{G}}(\mathbf{k}) + U_{\mathbf{G}} u_0(\mathbf{k}) + U_0(\mathbf{k}) u_{\mathbf{G}}(\mathbf{k}) = 0 \ .$$

From this follows,

$$\left[\tfrac{\hbar^2}{2m} k^2 + U_0 - E(\mathbf{k}) \right]^2 = U_{\mathbf{G}} U_{-\mathbf{G}} = 0 \ . \tag{26.32}$$

Since the potential $U(\mathbf{r})$ is real, $U_{-\mathbf{G}} = U^*_{\mathbf{G}}$. Therefore, introducing the eigenenergies $E_0(\mathbf{k})$ of free electrons (26.24),

$$E(\mathbf{k}) = E_0(\mathbf{k}) \pm |U_{\mathbf{G}}| \ . \tag{26.33}$$

Under the influence of the periodic perturbation potential we find at the surfaces of a Brillouin zone an energy splitting developing a forbidden gap in the spectrum. We can understand this observation as follows: In the crystal all electronic waves with wavevectors ending on a surface of a Brillouin zone are reflected by Bragg reflection. In the example of a one-dimensional lattice we understand that the superposition of an incident wave ($k = n\pi/a$) with the reflected one ($k = -n\pi/a$) produces a standing electronic probability density wave ρ being proportional to $\rho_1 \propto \cos^2 n\pi/a$ or $\rho_2 \propto \sin^2 n\pi/a$. The charge density ρ_1 is maximal at the location of the atom in this site, which corresponds to an increased interaction energy; the density ρ_2 is minimal at the location of the atom. This explains the splitting.

The Bloch model can explain many properties of metals, semiconductors and insulators.

26.1.3 One-dimensional periodic potentials

In the following, we restrict ourselves to a one-dimensional potential, $V(z) = V(z+a)$, acting on (the center-of-mass of) atoms. How such potentials can be realized in practice will be shown in Sec. 26.2. For now, we just assume that we can write the potential as,

$$V(z) = -2V_0 \cos^2 Kz \ . \tag{26.34}$$

In the Fourier expansion, $V(z) = \sum_K U_K e^{\imath Kz}$, this potential corresponds to the Fourier coefficients $U_0 = -V_0$ and $U_{\pm K} = -\frac{V_0}{2}$,

$$V(z) = -V_0(1 + \tfrac{1}{2}e^{2\imath k_L z} + e^{-2\imath k_L z}) \ . \tag{26.35}$$

We also expand the wavefunction into plane waves,

$$\psi(z) = \sum_q c_q e^{\imath qz} \ , \tag{26.36}$$

and we insert these expansions into Schrödinger's stationary equation $\hat{H}\psi = \varepsilon\psi$, yielding,

$$\left[\frac{-\hbar^2}{2m}\frac{\partial^2}{\partial z^2} + \sum_K U_K e^{\imath Kz}\right] \sum_q c_q e^{\imath qz} = \varepsilon \sum_q c_q e^{\imath qz} \ . \tag{26.37}$$

Defining $q = k + nK$, where $k \in [-K/2, K/2]$ and $n \in \mathbb{Z}$,

$$\left[\tfrac{\hbar^2}{2m}(nK+k)^2 - V_0\right] c_{nK+k} - \tfrac{1}{2}V_0 c_{nK+k-K} - \tfrac{1}{2}V_0 c_{nK+k+K} = \varepsilon c_{nK+k} \ . \tag{26.38}$$

In matrix notation,

$$\hat{H}\mathbf{c} = \varepsilon\mathbf{c} \ . \tag{26.39}$$

where the matrix is around $n = .., -1, 0, +1, ..$:

$$\hat{H} = \begin{pmatrix} \ddots & & & & \\ & \frac{\hbar^2}{2m}(k-K)^2 - V_0 & -\frac{1}{2}V_0 & & \\ & -\frac{1}{2}V_0 & \frac{\hbar^2}{2m}k^2 - V_0 & -\frac{1}{2}V_0 & \\ & & -\frac{1}{2}V_0 & \frac{\hbar^2}{2m}(k+K)^2 - V_0 & \\ & & & & \ddots \end{pmatrix} \quad , \quad \mathbf{c} = \begin{pmatrix} \vdots \\ c_{k-K} \\ c_k \\ c_{k+K} \\ \vdots \end{pmatrix} . \tag{26.40}$$

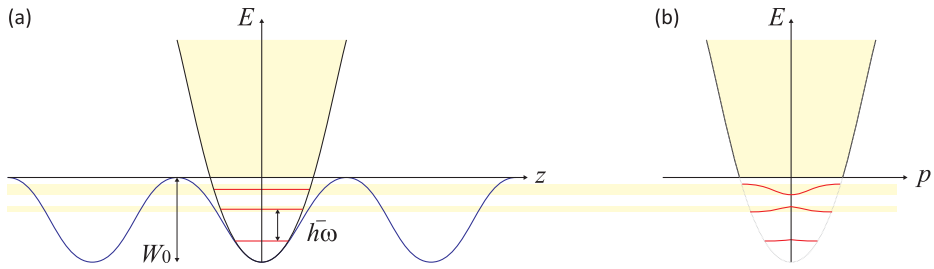

Figure 26.2: (a) Approximation of a periodic potential by a potential harmonic. (b) Dispersion relation in momentum space.

For shallow potentials, $V_0 \ll \hbar^2 K^2/2m$, we can neglect the coefficients V_0 in the Eq. (26.39) and we find,

$$\varepsilon \simeq \hbar^2 q^2/2m \ , \tag{26.41}$$

which corresponds to the dispersion relation for free particles. On the other hand, looking *at the bottom* of deep potentials, $V_0 \gg \hbar^2 K^2/2m$, we can harmonically approximate the cosine potential by $V(z) \approx -2V_0 + \frac{m}{2}\omega^2 z^2$ with $\omega = K\sqrt{V_0/m} = \hbar^{-1}\sqrt{2V_0 E_{rec}}$. For this case we expect,

$$\varepsilon \simeq -2V_0 + \hbar\omega\left(n + \tfrac{1}{2}\right) \ . \tag{26.42}$$

The exact spectrum of eigenvalues ε can be calculated by numerically determining the eigenvalues of the matrix (26.40) for the first Brillouin zone, $k \in [-K/2, K/2]$, and the above limits are confirmed.

To estimate the width of the forbidden band, we cut out a 2×2 matrix within the matrix $\hat{H}$ and neglect its coupling with the others submatrices,

$$\hat{H}_s = \begin{pmatrix} \frac{\hbar^2}{2m}(k-K)^2 - V_0 & -\frac{1}{2}V_0 \\ -\frac{1}{2}V_0 & \frac{\hbar^2}{2m}k^2 - V_0 \end{pmatrix} \ . \tag{26.43}$$

At the edges of the Brillouin zone, $k = \frac{1}{2}K$, we get the eigenvalues $\varepsilon = \frac{\hbar^2 K^2}{m} - V_0 \pm \frac{V_0}{2}$, that is, the band gap is $\Delta\varepsilon = V_0$. Bloch's theorem says that Schrödinger's equation can be solved for any *Bloch states*. These are superpositions of plane wave momentum states [53],

$$\psi_k(z) = e^{\imath kz} u_k(z) \ , \tag{26.44}$$

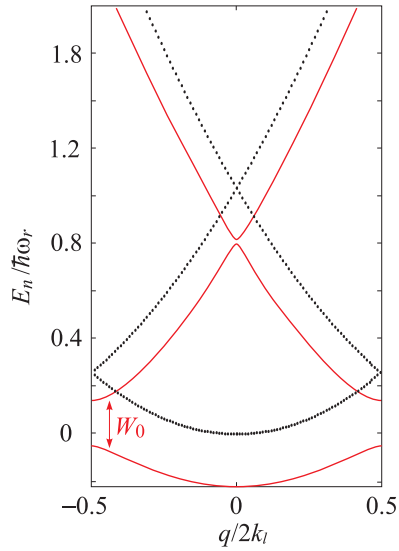

Figure 26.3: (code) Bloch bands with coupling potential (continuous red line) and without potential, $V_0 = 0$ (dotted black line). The parameters are $\omega_r = (2\pi)\ 20\,\text{kHz}$, $\omega_{ho} = (2\pi)\ 12\,\text{kHz}$, $\lambda_L = 689\,\text{nm}$, and $V_0 = 0.2\hbar\omega_r$.

with $u_k(z) = u_k(z + a)$.

The requirement that $\psi(z)$ satisfies the Schrödinger equation is equivalent to the condition that $\mathbf{c}$ satisfies an eigenvalue equation. Let U be the matrix of the eigenvectors of $\hat{H}$ and $\hat{E}$ the diagonal matrix of eigenvalues: $\hat{H} = U^{-1}\hat{E}U$ gives $\hat{E}U\mathbf{c} = \varepsilon U\mathbf{c}$, such that $U\mathbf{c}$ can be understood as eigenvectors.

Alternatively, we define $d_{nK+k} \equiv c_{nK+k+K}/c_{nK+k}$, consequently Eq. (26.39) becomes,

$$d_{nK+k-K} = \frac{V_0}{\frac{\hbar^2}{m}(nK+k)^2 - 2\varepsilon - V_0(2 + d_{nK+k})} \ . \tag{26.45}$$

26.1.4 Bloch oscillations

A *Bloch oscillation* is a phenomenon in solid state physics. It is the oscillation of a particle (e.g., an electron) confined to a periodic potential (e.g. a crystal), when a constant force (e.g., generated by a continuous electric field) acts on it. This phenomenon is very difficult to observe in solid crystals because, due to electron scattering by defects of the lattice [316, 1007], the coherent evolution is limited to a small fraction of the Brillouin zone. However, Bloch oscillations were observed in semiconducting superlattices, in ultrathin *Josephson junctions*, and with cold atoms in optical lattices [583, 851].

Let us first show a simple treatment for electrons subject to a constant electric field $\mathcal{E}$. The one-dimensional equation of motion is,

$$\hbar\frac{dk}{dt} = -e\mathcal{E} \ , \tag{26.46}$$

with the solution,

$$k(t) = k(0) - \frac{e\mathcal{E}}{\hbar} t \ . \tag{26.47}$$

The velocity v of the electron is given by,

$$v(k) = \frac{1}{\hbar} \frac{d\mathcal{E}}{dk} \ , \tag{26.48}$$

where $\mathcal{E}(k)$ denotes the *dispersion relation* for a given energy band. We now assume that it has the following form (tight-binding limit),

$$\mathcal{E} = A \cos ak \ , \tag{26.49}$$

where a is the lattice parameter and A a constant. Then, $v(k)$ is given by,

$$v(k) = -\frac{Aa}{\hbar} \sin ak \ , \tag{26.50}$$

and the position of the electron by,

$$x(t) = \int v(k(t))dt = -\frac{A}{e\mathcal{E}} \cos\left(\frac{ae\mathcal{E}}{\hbar} t\right) \ . \tag{26.51}$$

This shows, that the electron is oscillating in real space. The oscillation frequency, called *Bloch frequency* is given by,

$$\omega_{blo} = \frac{ae|\mathcal{E}|}{\hbar} \ . \tag{26.52}$$

26.1.5 Exercises

26.2 Optical lattices

Periodic potentials for quantum particles can be realized artificially. A prominent example are *optical lattices* formed by the interference patterns of intersecting laser beams. Tuned sufficiently far away from atomic resonances the periodically structured light field exerts optical forces on the atoms which can be derived from potentials being proportional to the local light intensity. As these forces are relatively weak, the kinetic energy of the atoms must be very low (typically μK) to allow for their impact to be relevant. In many cases, the depth of the optical lattice only allows for a small number of localized quantum states, so that the quantum nature of the atomic motion becomes highly relevant. Famous examples are the Bloch oscillations and the Mott insulating states.

We are not yet prepared to understand, how these potential arise from the light-atom interaction, as this topic will only be treated in the Secs. 38.2 and in Chp. 42.8.2. However, this is not necessary to understand many of the features of the atomic dynamics in optical lattices. We will thus simply impose a known periodic potential to a cold atomic cloud and study its energetic band structure and the atomic motion.

Various three-dimensional crystalline geometries have been realized and studied [673, 558, 153]. In the following, we will mainly focus on one-dimensional lattices, leaving a discussion of phenomena specific to three-dimensional lattices to future sections.

26.2.1 Atoms in 1D optical lattices

As already pointed out, a periodic optical potential can be generated by two counter-propagating plane wave laser beams, $e^{\pm \imath k_l z}$, with wavevectors k_l and $-k_l$ and tuned to the red side of an atomic transition. In this situation the atoms are attracted to the maxima of the light intensity, the antinodes,

$$V(z) = \tfrac{V_0}{4}|e^{\imath k_l z} + e^{-\imath k_l z}|^2 = \tfrac{V_0}{2}[1 + \cos(2k_l z)] \ . \tag{26.53}$$

Applying the procedure unfolded in Sec. 26.1.3 to the optical lattice, we expand the motional atomic wavefunction into plane (Bloch) waves,

$$\psi(z) = \sum_{n=-\infty}^{\infty} c_n e^{2\imath q z} e^{2\imath n k_l z} \ , \tag{26.54}$$

where $|c_n(t)|^2$ are the population of momentum states separated by $2k_l$ in momentum space. Inserting this expansion and the potential (26.53), after removing the constant energy $V_0/2$, into the stationary Schrödinger equation,

$$E\psi = -\frac{\hbar^2}{2m}\frac{\partial^2 \psi}{\partial z^2} + \frac{V_0}{2}\cos(2k_l z)\psi \ , \tag{26.55}$$

we obtain, collecting terms oscillating with the same exponential $e^{2\imath n k_l z}$,

$$\boxed{E_n c_n = 4\hbar\omega_{rec}\left(n + \frac{q}{k_l}\right)^2 c_n + \frac{V_0}{4}(c_{n+1} + c_{n-1})} \ , \tag{26.56}$$

where we defined an abbreviation,

$$\omega_{rec} = \frac{\hbar k_l^2}{2m} \tag{26.57}$$

called *recoil frequency* [2]. The eigenvalue problem (26.56) can be solved numerically for any value of q, yielding the dispersion relation already exhibited in Fig. 26.3.

To reproduce the dynamics of the matter wave, we start from the time-dependent Schrödinger equation with the same periodic potential. We again expand the time-dependent wavefunction into plane waves via,

$$\psi(z,t) = \sum_{n=-\infty}^{\infty} c_n(t) e^{2\imath n k_l z} \ , \tag{26.58}$$

and insert this ansatz into the Schrödinger equation,

$$\imath\hbar\frac{\partial \psi}{\partial t} = -\frac{\hbar^2}{2m}\frac{\partial^2 \psi}{\partial z^2} + \frac{V_0}{4}\cos(2k_l x)\psi \ , \tag{26.59}$$

obtaining a set of equations of motion for the expansion coefficients c_n,

$$\boxed{\dot{c}_n = -4\imath\omega_{rec} n^2 c_n + \frac{V_0}{4\imath\hbar}(c_{n+1} + c_{n-1})} \ . \tag{26.60}$$

The temporal evolution of the coefficients $c_n(t)$ can be simulated numerically.

[2] The reason of the terminology, which will become clear after a study of Sec. 38.2, is that the $\hbar\omega_{rec}$ is the kinetic energy of an atom having received two units of photonic momenta.

26.2.2 Bloch oscillations of atoms in 1D optical lattices

Neutral atoms in a vertical optical lattice are accelerated by gravity, and this accelerated motion leads to Bloch oscillations [316, 1007]. To treat this case, we could simply replace the electric force $-e\vec{\mathcal{E}}$ in the expression (26.52) by the gravitational force mg and obtain the result,

$$\omega_{blo} = \frac{mg\lambda_l}{2\hbar} \ , \tag{26.61}$$

with the wavelength $\lambda_l = 2a$ of the counterpropagating lasers generating the standing wave.

For didactic reasons, however, let us formulate the problem in the language introduced in the previous section extending the Hamiltonian by the gravitational potential [3] (see also Exc. 23.5.6.2),

$$\hat{H} = -\frac{\hbar^2}{2m}\frac{\partial^2}{\partial z^2} + \frac{V_0}{2}\cos 2k\hat{z} + mg\hat{z} \ . \tag{26.62}$$

We define the transformation $U \equiv e^{-\imath mg\hat{z}t/\hbar}$ and find with (23.167) and (23.213) the Hamiltonian in the accelerated frame,

$$\tilde{H} = U^\dagger \hat{H} U + \imath\hbar\dot{U}^\dagger U = \frac{\tilde{p}^2}{2m} + \frac{V_0}{4}\left(e^{2\imath k\hat{z}} + e^{-2\imath k\hat{z}}\right) \ . \tag{26.63}$$

with

$$\tilde{p} \equiv \hat{p} - mgt = U^\dagger \hat{p} U \ . \tag{26.64}$$

Now, we expand the operators using the rules (23.99) and (23.213) [4],

$$\begin{aligned} \tilde{p} &= \int p|p\rangle\langle p|dp \longrightarrow \sum_n (p + 2n\hbar k)|p + 2n\hbar k\rangle\langle p + 2n\hbar k| \\ e^{2\imath k\hat{z}} &= \int |p + 2\hbar k\rangle\langle p|dp \longrightarrow \sum_n |p + 2(n+1)\hbar k\rangle\langle p + 2n\hbar k| \ , \end{aligned} \tag{26.65}$$

based on the assumption that every atom can only exist in a superposition of discrete momentum states separated by $2\hbar k$, but can have an 'offset' momentum $p = mv$, e.g. due to thermal motion. Disregarding thermal motion, we may set in the accelerated frame $p = 0$. Then,

$$\tilde{p} = \sum_n 2n\hbar k|2n\hbar k\rangle\langle 2n\hbar k| \qquad \text{and} \qquad e^{2\imath k\hat{z}} = \sum_n |2n\hbar k + 2\hbar k\rangle\langle 2n\hbar k| \ , \tag{26.66}$$

such that,

$$\tilde{H} = \sum_n 4n^2\hbar\omega_{rec}|2n\hbar k\rangle\langle 2n\hbar k| + \tfrac{V_0}{4}\sum_n \left(|2n\hbar k + 2\hbar k\rangle\langle 2n\hbar k| + |2n\hbar k\rangle\langle 2n\hbar k + 2\hbar k|\right) \ . \tag{26.67}$$

[3] For Bose-Einstein condensates, the procedure should be generalized taking into account the energy of the mean field due to interatomic collisions.

[4] See also (42.149) and (42.156).

With the expansion of the wavefunction $|\tilde{\psi}\rangle = \sum_n c_n |2n\hbar k\rangle$ the Schrödinger equation becomes [1138, 1139],

$$\begin{aligned} \imath\hbar \frac{d}{dt}|\tilde{\psi}\rangle &= \imath\hbar \sum_n \dot{c}_n |2n\hbar k\rangle \\ &= \sum_n \left(4n^2\hbar\omega_{rec} c_n + \tfrac{V_0}{4}(c_{n-1} + c_{n+1})\right) |2n\hbar k\rangle = \tilde{H}|\tilde{\psi}\rangle \ , \end{aligned} \tag{26.68}$$

that is,

$$\dot{c}_n = -4\imath n^2 \omega_{rec} c_n + \frac{V_0}{4\imath\hbar}(c_{n-1} + c_{n+1}) \ . \tag{26.69}$$

In the lab frame the wavefunction reads,

$$\begin{aligned} |\psi\rangle = U|\tilde{\psi}\rangle &= e^{-\imath m g \hat{z} t/\hbar} \sum_n c_n |2n\hbar k\rangle \\ &= \sum_n c_n |2n\hbar k - mgt\rangle = \sum_n c_n |2\hbar k(n - \nu_{blo} t)\rangle \ , \end{aligned} \tag{26.70}$$

where we introduced the *Bloch frequency*,

$$\boxed{\nu_{blo} = \frac{mg}{2\hbar k}} \ . \tag{26.71}$$

Finally,

$$\boxed{\dot{c}_n = -4\imath (n - \nu_{blo} t)^2 \omega_{rec} c_n + \frac{V_0}{4\imath\hbar}(c_{n-1} + c_{n+1})} \ . \tag{26.72}$$

The center-of-the mass momentum of the atomic matter wave is,

$$\frac{\langle p \rangle_{lab}}{\hbar k_l} = \sum_n n |c_n(t)|^2 + \nu_{blo} t \ . \tag{26.73}$$

The Bloch oscillations can be understood in various pictures. The first one, illustrated in 26.4(a), is based on *Bragg reflection*: A resting atom has infinite de Broglie wavelength. Being constantly accelerated by gravity, the matter wave reduces its de Broglie wavelength from ∞ to a value, where it becomes commensurate with the periodicity of the standing light wave potential. At this moment Bragg scattering comes into play, reflecting the atomic motion back into upward direction, and the process starts over again. The atoms evolve like jumping on a trampoline with a frequency given by ν_{blo}.

To understand the second picture, we need to address a question we have left aside so far, as this requires a notion of optical forces. It is the question in which way the matter wave interacts with the standing light wave. For the present discussion, it is sufficient to know that the atom must have an internal transition capable of scattering photons from the light beams. As any absorption and emission process transfers a recoil momentum of $\hbar k_l$ to the atom, we can understand the Bragg scattering process as a so-called *Raman scattering* process: a photon of the laser beam generating the optical lattice coming from the left is absorbed and re-emitted to the left. This is best illustrated in the momentum domain sketched in Fig. 26.4(b). This Raman scattering

transfers twice the photonic recoil to the atom. The requirement for commensurability of the Broglie wavelength and wavelength of the standing light wave is equivalent to saying that the matter wave momentum is equal to the recoil of a single photon. In other words, the matter wave always Bragg-reflected at the edge of a Brillouin zone.

Finally, in the *Bloch state picture*, the dispersion relation of a free particle is distorted due to the periodicity of the potential generated by the standing light wave such as to open a forbidden band. As a consequence, instead of being accelerated without limits, the atom enters the second Brillouin zone, which is to say that it is reflected to the other side of the first Brillouin zone.

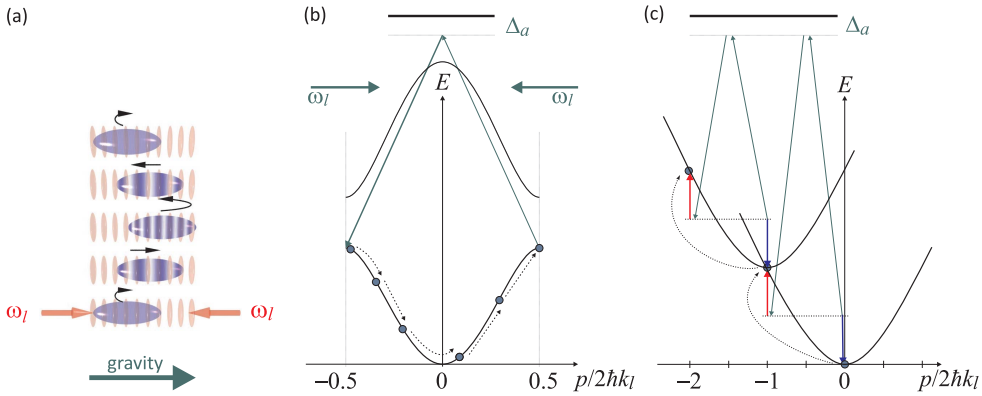

Figure 26.4: Illustration of Bloch oscillations (a) in real space, (b) in momentum space, and (c) in the moving frame. You may also run a movie of Bloch oscillations clicking on (watch movie)!

The additional term, which contains the frequency of the Bloch oscillation ν_{blo}, increases linearly over time. As time goes by, a resonance is crossed when $t = -n\tau_{blo}$, and the crossing is periodically repeated at every $n = -1, -2, 0, ...$ Tracing the matter wave evolution in the laboratory system, we see that whenever the resonance is crossed, the momentum undergoes a change of sign corresponding to a reflection of its motion. We expand the population of the momentum states into plane (Bloch) waves with $|c_n(t)|^2$.

Of course there are some conditions that need to be met to observe Bloch oscillations. The transfer of momentum is efficient only in the rapid adiabatic passage (ARP) regime characterized by the conditions $2(\nu_{blo}/\omega_{rec}) \ll (W_0/4\omega_{rec})^2 \ll 16$. The first condition requires that the force that drives the atoms to perform the Bloch oscillations must be weak enough to avoid transitions between Bloch bands, which guarantees the adiabaticity of the process. The other condition requires that the optical lattice be weak enough so that the dynamics involves only two adjacent momentum states at the same time and the transfer between the two is successful. A talk on this subject can be watched at (watch talk). Do the Exc. 26.2.3.1.

We will come back to the topic of optical lattices holding matter waves in Sec. 46.4.2 in the context of Mott insulating states of Bose-Einstein condensates.

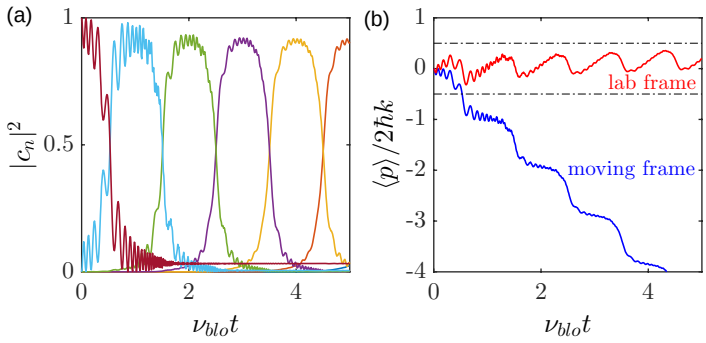

Figure 26.5: (code) Dynamics of Bloch's oscillations calculated from Eq. (26.57). (a) The colored curves show successively populated momentum states. (b) Center-of-mass motion of the wave packet in the lab frame (red) and in the moving frame (blue). The used parameters are $\omega_{rec} = (2\pi)\ 4.8\,\mathrm{kHz}$, $\nu_{blo} = 0.05\omega_{rec}$, and $W_0 = -0.7\omega_{rec}$.

26.2.3 Exercises

26.2.3.1 Ex: Purification of Bloch oscillations

Simulations of Bloch oscillations of atoms in an optical lattice for $W_0 = 0.4\omega_{rec}$ and $0.8\omega_{rec}$ produce the dynamics exhibited in Fig. 26.6. Interpret the different behaviors.

Solution: *(a-b) If the lattice is too shallow ($W_0 = 0.4\omega_{rec}$), the band gap is too narrow. The atom is then likely to tunnel into the next Bloch band staying inside its actual accelerated momentum state. I.e. stationary populations pile up in every c_n. Because the atom is not completely reflected at the edge of the Brillouin zone, its center of mass begins to drift.*
(e-f) If the lattice is too deep ($W_0 = 1.6\omega_{rec}$), the atom does not even reach the band gap. It stays confined to the standing wave potential oscillating like in a harmonic potential.
(c-d) If the lattice is just right ($W_0 = 0.8\omega_{rec}$), the atom is almost completely reflected. Fast initial oscillations damp out, because only the fastest atoms undergo Landau-Zener transitions confining them to the first momentum state c_0.
Approximating the lattice by a harmonic oscillator potential,

$$U_{dip}(z) = -\tfrac{\hbar W_0}{2}\cos 2kz \simeq -\tfrac{\hbar W_0}{2}(1 + k^2 z^2) \equiv \tfrac{m}{2}\omega_{ho}^2 z^2 \ ,$$

we expect the vibration frequency,

$$\omega_{ho} = \sqrt{2W_0\omega_{rec}} \ .$$

Using this formula it is possible to check that the fast vibrations observed in Figs. 26.6 have frequencies that correspond to $\omega_{ho}/2$.

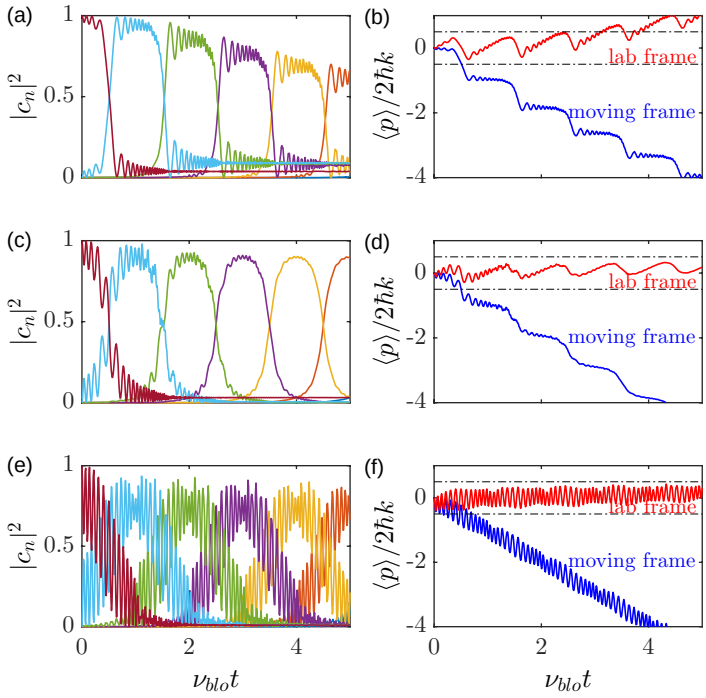

Figure 26.6: (code) Dynamics of Bloch oscillations (a-b) for $W_0 = 0.4\omega_{rec}$, (c-d) for $W_0 = 0.8\omega_{rec}$, and (e-f) for $W_0 = 1.6\omega_{rec}$. Furthermore, $\omega_{rec} = (2\pi)\ 4.8\,\mathrm{kHz}$ and $\nu_{blo} = 0.05\omega_{rec}$.

26.2.3.2 Ex: Gaussian approximation for Wannier function

Consider a standing light wave producing a dipolar potential of the shape $V(x) = W_0 \sin^2 kx = \frac{W_0}{2} - \frac{W_0}{2}\cos 2kx$ with $W_0 \gg E_{rec} = (\hbar k)^2/2m$.
a. Approximate the potential of a single lattice site around $x = 0$ by a harmonic potential. Calculate for which depth of the dipolar potential the approximated potential supports at least one bound state. What is the spacing of the levels and the characteristic size of the harmonic oscillator a_{ho}. Write down the normalized ground state wavefunction of the harmonic oscillator.
b. Now, let us consider a 3D cubic lattice made of three identical orthogonal standing light waves. Approximate the ground state Wannier function of a lattice site by appropriately normalized ground state wavefunctions of a harmonic oscillator. Derive the formula $U^{3d} = \frac{8}{\pi} k a_d \left(\frac{W_0}{E_{rec}}\right)^{3/4}$ starting from,

$$U^{3D} = g^{3D} \int \omega^4_{(0,0)}(x,y,z) d^3r$$

with $g^{3D} = \frac{4\pi\hbar a_d}{m}$.

Solution: *a. The harmonic approximation for the sinusoidal potential is,*

$$U(x) = W_0 (kx)^2 + \dots \ .$$

With $\omega \equiv \sqrt{\frac{2W_0k^2}{m}}$, *we can approximate the potential by,*

$$U_{ho}(x) = \frac{m}{2}\omega^2 x^2 \qquad for \qquad |x| \leq \sqrt{\frac{2\hbar U_0}{m\omega^2}} \qquad and \qquad U_{ho}(x) = 0 \qquad else\ .$$

The ground state of the harmonic oscillator is,

$$E_0 = \hbar\omega\left(0 + \frac{1}{2}\right) = \frac{\hbar\omega}{2}\ .$$

The condition of having at least one bound state, $E_0 < W_0$, *yields*

$$W_0 > E_0 = \frac{\hbar\omega}{2} = \frac{\hbar}{2}\sqrt{\frac{2W_0k^2}{m}} \qquad \Longrightarrow \qquad W_0 > \frac{\hbar k}{2m}\ .$$

This is precisely the energy of the photonic recoil of the light generating the standing wave. The spacing of the levels is $\hbar\omega$ *and the size of the harmonic oscillator is,*

$$a_{ho} = \sqrt{\frac{\hbar}{m\omega}}\ .$$

The normalized ground state wavefunction is given by,

$$\psi_{0,0}(x) = Ce^{-x^2/2a_{ho}^2} \qquad where \qquad C = \frac{1}{\sqrt{a_{ho}\sqrt{\pi}}}\ .$$

b. For the 3D harmonic oscillator the ground state wave function becomes simply,

$$\psi_{0,0}(\mathbf{r}) = C\psi_{0,0}(x)\psi_{0,0}(y)\psi_{0,0}(z)\ .$$

With the normalization condition,

$$1 = \int_{-\lambda/2}^{\lambda/2}\int_{-\lambda/2}^{\lambda/2}\int_{-\lambda/2}^{\lambda/2}\omega_{0,0}(\mathbf{r})d^3\mathbf{r} = \left(\int_{-\lambda/2}^{\lambda/2} C\sqrt{2}a_{ho}e^{-\tilde{x}^2}d\tilde{x}\right)^3$$
$$= (C\sqrt{2}a_{ho})^3\left(\int_{-\lambda/2}^{\lambda/2} e^{-\tilde{x}^2}d\tilde{x}\right)^3\ .$$

With this, ...

26.2.3.3 Ex: Perturbative treatment of a weak lattice

A weak lattice potential with $V_0 < E_{rec}$ can be treated in perturbation theory to motivate the resulting opening of a gap in the refolded energy parabola. The unperturbed Hamiltonian $\hat{H}_0 = p^2/2m$ contains only the kinetic energy and the perturbation is $V(x) = V_0\sin^2(kx) = \frac{1}{2}V_0 - \frac{1}{4}V_0(e^{2\imath kx} + e^{-2\imath kx})$.
a. Calculate $\hat{V}(x)\phi_p(x)$ and show that $\langle\phi_{p\pm\hbar k}|\hat{V}|\phi_p\rangle$ are the only non-zero matrix elements of the perturbation $V(x)$ between the eigenstates of $\hat{H}_0$ (which are the orthonormal plane waves $\phi_p = e^{\imath px/\hbar}$). Neglect the constant term of the potential,

which only yields a global energy shift.
b. This coupling is relevant around those momenta p, where ϕ_p has the same energy $\phi_{p+\hbar k}$ or $\phi_{p-\hbar k}$. Show that these momenta are $p = \mp\hbar k$.
c. Consider the perturbed system restricted to the basis $\{|p = -\hbar k\rangle, |p = +\hbar k\rangle\}$ and give the Hamiltonian as 2×2 matrix.
d. Diagonalize the matrix and consider the difference of the eigenenergies. Use them to estimate the size of the gap, that the lattice opens between the two lowest bands.
e. Calculate the eigenstates and interpret them by comparing the probability density to the lattice potential.

Solution:

26.3 The Kronig-Penney model

The *Kronig-Penney model* describes the band structure of a lattice. Let us assume a periodic potential of rectangular wells with valleys of widths a and peaks of widths b,

$$V(x) = U_0 \theta_{\mathrm{mod}(x,a+b)\in[a,a+b]} \ . \tag{26.74}$$

Inserting into the Schrödinger equation the plane wave ansatz $\psi = Ae^{\imath Kx} + Be^{-\imath Kx}$ for the wavefunction in the valley, $0 < x < a$, and $\psi = Ce^{Qx} + De^{-Qx}$ in the peak, $-b < x < 0$, we obtain $\varepsilon = \hbar^2 K^2/2m$ and $U_0 - \varepsilon = \hbar^2 Q^2/2m$. Choosing the constants A, B, C, D such that ψ and $\dot{\psi}$ are continuous in $x = 0, a$, we derive, using the periodicity of the Bloch wave $\psi(a < x < a + b) = \psi(-b < x < 0)e^{\imath k(a+b)}$,

$$\begin{pmatrix} 1 & 1 & -1 & -1 \\ \imath K & -\imath K & -Q & Q \\ e^{\imath Ka} & e^{-\imath Ka} & -e^{-Qb+\imath k(a+b)} & -e^{Qb+\imath k(a+b)} \\ \imath K e^{\imath Ka} & -\imath K e^{-\imath Ka} & -Qe^{-Qb+\imath k(a+b)} & Qe^{Qb+\imath k(a+b)} \end{pmatrix} \begin{pmatrix} A \\ B \\ C \\ D \end{pmatrix} = 0 \ . \tag{26.75}$$

The determinant of the matrix must be zero, or,

$$\frac{Q^2 - K^2}{2QK} \sinh Qb \sin Ka + \cosh Qb \cos Ka = \cos k(a + b) \ . \tag{26.76}$$

For δ-shaped peaks, we let $b = 0$ and $U_0 = \infty$ such that $Q^2 ba/2 = P$, this simplifies to,

$$\frac{P}{Ka} \sin Ka + \cos Ka = \cos ka \ . \tag{26.77}$$

The dispersion relation for light is different. According to [864],

$$-\frac{\sqrt{\varepsilon} + \sqrt{\varepsilon}^{-1}}{2} \sin(\sqrt{\varepsilon}\omega a/c) \sin(\omega a/c) + \cos(\sqrt{\varepsilon}\omega a/c) \cos(\omega a/c) = \cos ka \ . \tag{26.78}$$

For $\varepsilon = 1$ the equation simplifies to $ka = 2\omega a/c$.

26.3.1 Photonic density of states

The *photonic density of states* in free space in three dimensions is evaluated from [1324],

$$dN = 2\left(\frac{L}{2\pi}\right)^3 \int d^3k = 2\left(\frac{L}{2\pi}\right)^3 k^2 dk \int d\phi d\cos\theta = \frac{L^3\omega^2}{\pi^2 c^3} d\omega \equiv D(\omega)d\omega \ . \quad (26.79)$$

In one dimension,

$$dN = 2\frac{L}{2\pi}dk = \frac{L}{\pi c}d\omega \ . \quad (26.80)$$

The density is normalized $\int_0^{\pi c/L} D(\omega)d\omega = 1$ and the total energy, if all states are populated, is $E \equiv \int_0^{\pi c/L} \omega D(\omega)d\omega = \pi c/L$. However, this applies only if $\omega = ck$. If the dispersion relation is more complicated, for example, inside a cavity or a forbidden photonic band, $\omega = \omega(k)$, we must generalize,

$$D(\omega) = \frac{L}{\pi}\frac{dk}{d\omega} \ . \quad (26.81)$$

Assuming that the dispersion relation is given by the Kronig-Penney model, we obtain gaps in the density-of-states for those values of ω which do not belong to any k.

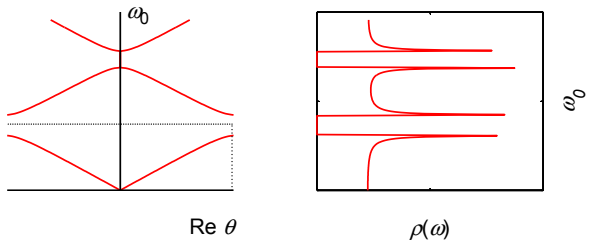

Figure 26.7: Dispersion ratio and state density for a one-dimensional optical lattice.

26.3.2 Exercises

26.3.2.1 Ex: Mass of photons in a lattice

The effective mass of particles in a lattice is defined as,

$$\frac{1}{m^*} = \frac{1}{\hbar^2}\frac{d^2E(k)}{dk^2} \ .$$

Calculate the effective mass of a rubidium atom in a far-detuned optical standing wave.

Solution: *For free electrons, $E = \hbar^2k^2/2m$, such that $1/m^* = 1/m$. For free photons $E = \hbar k/c$, such that $1/m^* = 0$!*

Chapter 27

Approximation methods

Virtually every problem going beyond the potential well, the harmonic oscillator, or the hydrogen atom without spin and external fields is impossible to solve analytically. In this chapter we will talk about techniques to solve approximately problems in more realistic situations. There are a number of methods of which we will discuss the only following: 1. The stationary or time-dependent perturbation method is useful for evaluating small perturbations of the system, for example, caused by external electric or magnetic fields; 2. the variational method, which serves to find and improve trial wavefunctions, the initial shapes of which are generally motivated by the symmetries of the system; 3. the semi-classical WKB method; 4. and finally the method of self-consistent fields, which is an iterative method of solving the Schrödinger equation.

27.1 Stationary perturbations

27.1.1 Time-independent perturbation theory

We first introduce *time-independent perturbation theory* (TIPT) for multilevel systems. We separate the Hamiltonian into an unperturbed part,

$$\hat{H}^{(0)}|\psi^{(0)}\rangle = E^{(0)}|\psi^{(0)}\rangle \ , \tag{27.1}$$

and perturbations, which are proportional to a small parameters λ,

$$\hat{H} = \hat{H}^{(0)} + \lambda\hat{H}^{(1)} + \lambda^2\hat{H}^{(2)} + .. \ . \tag{27.2}$$

The perturbed wavefunctions are,

$$|\psi\rangle = |\psi^{(0)}\rangle + \lambda|\psi^{(1)}\rangle + \lambda^2|\psi^{(2)}\rangle + .. \ , \tag{27.3}$$

and the energies

$$E = E^{(0)} + \lambda E^{(1)} + \lambda^2 E^{(2)} + .. \ . \tag{27.4}$$

The contributions $\propto \lambda^n$ are the *corrections* of order n. The equation we need to solve now is,

$$\hat{H}|\psi\rangle = E|\psi\rangle \ . \tag{27.5}$$

By inserting all the expansions above and segregating all orders of λ^k, we find the following system of equations,

$$\begin{aligned} \hat{H}^{(0)}|\psi^{(0)}\rangle &= E^{(0)}|\psi^{(0)}\rangle \\ (\hat{H}^{(0)} - E^{(0)})|\psi^{(1)}\rangle &= (E^{(1)} - \hat{H}^{(1)})|\psi^{(0)}\rangle \\ (\hat{H}^{(0)} - E^{(0)})|\psi^{(2)}\rangle &= (E^{(2)} - \hat{H}^{(2)})|\psi^{(0)}\rangle + (E^{(1)} - \hat{H}^{(1)})|\psi^{(1)}\rangle \\ &\dots \ . \end{aligned} \tag{27.6}$$

27.1.1.1 First order energy correction

We now consider eigenstates $|\psi_n^{(1)}\rangle$ of the perturbed system and expand the first-order correction of the wavefunction in a linear combination of unperturbed eigenvectors $|\psi_n^{(0)}\rangle \equiv |n\rangle$,

$$|\psi_n^{(1)}\rangle = \sum_m |m\rangle\langle m|\psi_n^{(1)}\rangle \ . \tag{27.7}$$

We insert this expansion into the second equation (27.6) and multiply with $\langle n|$,

$$\langle n|(\hat{H}^{(0)} - E_n^{(0)})\sum_m |m\rangle\langle m|\psi_n^{(1)}\rangle = 0 = \langle n|E_n^{(1)} - \hat{H}^{(1)}|n\rangle \ . \tag{27.8}$$

We obtain for the first order correction of the energy of unperturbed states,

$$\boxed{E_n^{(1)} = \langle n|\hat{H}^{(1)}|n\rangle} \ . \tag{27.9}$$

As a first example we will calculate in Exc. 27.1.3.1 the first order correction for the energy of a slightly deformed one-dimensional box potential.

27.1.1.2 First order correction for the wavefunction

Now let us have a look at the first-order correction for the wavefunction again considering the second equation (27.6),

$$\langle m|\hat{H}^{(0)} - E_n^{(0)}|\psi_n^{(1)}\rangle = \langle m|E_n^{(1)} - \hat{H}^{(1)}|n\rangle \ . \tag{27.10}$$

When $n = m$, the left side of this equation disappears. Therefore, $E_n^{(1)} - \langle n|\hat{H}^{(1)}|n\rangle = 0$, and we can restrict to the terms $n \neq m$ discarding the terms in $E_n^{(1)}$,

$$\langle m|\psi_n^{(1)}\rangle = \frac{E_n^{(1)}\delta_{mn} - \langle m|\hat{H}^{(1)}|n\rangle}{\hat{E}_m^{(0)} - E_n^{(0)}} = \frac{\langle m|\hat{H}^{(1)}|n\rangle}{E_n^{(0)} - E_m^{(0)}} \ . \tag{27.11}$$

We obtain for the first-order correction for the energy of the states,

$$\boxed{|\psi_n^{(1)}\rangle = \sum_m |m\rangle\langle m|\psi_n^{(1)}\rangle = \sum_{m\neq n} |m\rangle \frac{\langle m|\hat{H}^{(1)}|n\rangle}{\hat{E}_n^{(0)} - E_m^{(0)}}} \ . \tag{27.12}$$

This procedure simulates the distortion of the state by blending it with other states. The perturbation induces virtual transitions to other states. The perturbation is large when the blended levels are close.

See Exc. 27.1.3.2. In Exc. 27.1.3.3 we calculate the first order correction due to the finite extension of the hydrogen nucleus. In Exc. 27.1.3.4 we treat the coupling of the energy levels of a two-level system as a first order perturbation, and compare the result with the exact solution. The Stark effect for an electron confined in a box can be discussed (see Exc. 27.1.3.5) in first order TIPT.

27.1.1.3 Second order correction for the energy

To calculate the second order correction for the energy we expand the second order correction,

$$|\psi_n^{(2)}\rangle = \sum_m |m\rangle\langle m|\psi_n^{(2)}\rangle \ , \tag{27.13}$$

import it into the third equation (27.6) and multiply with $\langle n|$,

$$\langle n|(\hat{H}^{(0)}-E_n^{(0)})\sum_m |m\rangle\langle m|\psi_n^{(2)}\rangle = \langle n|(E_n^{(2)}-\hat{H}^{(2)})|n\rangle+\langle n|(E_n^{(1)}-\hat{H}^{(1)})\sum_m |m\rangle\langle m|\psi_n^{(1)}\rangle \ . \tag{27.14}$$

Now,

$$\sum_m \langle m|\psi_n^{(2)}\rangle(E_n^{(0)}-E_m^{(0)})\delta_{nm} = 0 = E_n^{(2)}-\langle n|\hat{H}^{(2)}|n\rangle+\sum_m \langle m|\psi_n^{(1)}\rangle\left(E_n^{(1)}\delta_{nm} - \langle n|\hat{H}^{(1)}|m\rangle\right) \ . \tag{27.15}$$

The left-hand side of this equation disappears. Also, on the right-hand side, for $n \neq m$, the term $E_n^{(1)}\delta_{nm}$ disappears, and for $n = m$ the whole parenthesis disappears. Therefore, we can discard the term $E_n^{(1)}$ and restrict the sum to terms with $n \neq m$. Inserting the coefficients $\langle m|\psi_n^{(1)}\rangle$ calculated in (27.11), we finally obtain,

$$\boxed{E_n^{(2)} = \langle n|\hat{H}^{(2)}|n\rangle + \sum_{m\neq n} \frac{\langle n|\hat{H}^{(1)}|m\rangle\langle m|\hat{H}^{(1)}|n\rangle}{E_n^{(0)} - E_m^{(0)}}} \ . \tag{27.16}$$

The first term is similar to the first order correction; the eigenvalue of the second order perturbation calculated in the base of the unperturbed states. The second term describes the shift of the energies through possible temporary transitions to other states.

In Exc. 27.1.3.6 we treat a system of three coupled levels up to the second perturbative order. The Stark effect discussed in Exc. 27.1.3.7 needs the TIPT calculation up to the second order.

27.1.2 TIPT with degenerate states

Exact calculations show that the effect of a perturbation is larger – but finite – for degenerate states. On the other hand, from the above expressions for the corrections of both energies and wavefunctions, we would infer that these corrections can become very large for small perturbations or even diverge.

Fortunately, the fact that every linear combination of degenerate wavefunctions is an eigenfunction of the Hamiltonian as well gives us the freedom to choose the combination, which is most similar to the final form of the perturbed wavefunctions.

For example, considering a perturbation by a magnetic field it may be advantageous to expand the spherical functions Y_{lm} on a basis of cylindrical coordinates [1]. We will see in the following that we can solve both problems, the selection of the initial combination and the prevention of divergent denominators at once, without explicitly specifying the expansion.

We consider eigenstates $|n,\nu\rangle$ with the energy $E_n^{(0)}$ being r times degenerate with respect to the quantum number ν, where $\nu = 1,..,r$. All states satisfy

$$\hat{H}^{(0)}|n,\nu\rangle = E_n^{(0)}|n,\nu\rangle \ . \tag{27.17}$$

We construct linear combinations that most resemble the perturbed states

$$|\psi_{n\mu}^{(0)}\rangle = \sum_{\nu=1}^{r} c_{\mu\nu}|n,\nu\rangle \ . \tag{27.18}$$

When the perturbation $\hat{H}^{(1)}$ is applied, we assume that the state $|\psi_{n\mu}^{(0)}\rangle$ is distorted towards the similar state $|\psi_{n\mu}\rangle$, and the energy changes from $E_n^{(0)}$ to $E_{n\mu}$. We now need the index μ to label the energy, since the degeneracy can be removed by the perturbation. As before, we write now,

$$\begin{aligned} \hat{H} &= \hat{H}^{(0)} + \lambda\hat{H}^{(1)} + .. \\ |\psi_{n\mu}\rangle &= |\psi_{n\mu}^{(0)}\rangle + \lambda|\psi_{n\mu}^{(1)}\rangle + .. \\ E_{n\mu} &= E_n^{(0)} + \lambda E_{n\mu}^{(1)} + .. \ . \end{aligned} \tag{27.19}$$

The replacement of these expansions in $\hat{H}|\psi_{n\mu}\rangle = E_{n\mu}|\psi_{n\mu}\rangle$, and a collection of the terms in λ up to first order gives,

$$\begin{aligned} \hat{H}^{(0)}|\psi_{n\mu}^{(0)}\rangle &= E_n^{(0)}|\psi_{n\mu}^{(0)}\rangle \\ (E_n^{(0)} - \hat{H}^{(0)})|\psi_{n\mu}^{(1)}\rangle &= (E_{n\mu}^{(1)} - \hat{H}^{(1)})|\psi_{n\mu}^{(0)}\rangle \ . \end{aligned} \tag{27.20}$$

As before, we try to express the first-order corrections for the wavefunctions through degenerate unperturbed wavefunctions $|\psi_{n\mu}^{(0)}\rangle$ and non-degenerate wavefunctions [2] $|\psi_m^{(0)}\rangle$:

$$|\psi_{n\mu}^{(1)}\rangle = \sum_{\nu} b_{\mu\nu}|\psi_{n\nu}^{(0)}\rangle + \sum_{m} a_{nm}|\psi_m^{(0)}\rangle \ . \tag{27.21}$$

Inserting this into the first-order equation (27.20), we obtain,

$$\sum_{\nu} b_{\mu\nu}(E_n^{(0)} - E_n^{(0)})|\psi_{n\nu}^{(0)}\rangle + \sum_{m} a_{nm}(E_m^{(0)} - E_n^{(0)})|\psi_m^{(0)}\rangle = (E_{n\mu}^{(1)} - \hat{H}^{(1)})|\psi_{n\mu}^{(0)}\rangle \ . \tag{27.22}$$

The first term disappears. Inserting the expansion (27.18),

$$\sum_{m} a_{nm}(E_m^{(0)} - E_n^{(0)})|\psi_m^{(0)}\rangle = (E_{n\mu}^{(1)} - \hat{H}^{(1)})\sum_{\nu} c_{\mu\nu}|n,\nu\rangle \ , \tag{27.23}$$

[1] Another example would be the preference for the coupled base $|(l,s)j,m_j\rangle$ in comparison to the decoupled base $|l,m_l,s,m_s\rangle$ knowing that the degeneracy in j is lifted, when there is an energy associated with interacting angular momenta and the degeneracy in m_j is lifted, when we apply a magnetic field.

[2] Note that we label all states *which are not degenerate with the state under investigation* $|\psi_{n\mu}^{(1)}\rangle$ with the index m, even if there are degeneracies between them.

and multiplying the two sides with $\langle n,\mu|$, we get zero on the left-hand side, since we can choose the non-degenerate states to be orthogonal $\langle n,\nu|m\rangle = \delta_{m,n}$. Hence,

$$\boxed{\sum_\nu c_{\mu\nu}\left[E^{(1)}_{n\mu}\langle n,\mu|n,\nu\rangle - \langle n,\mu|\hat{H}^{(1)}|n,\nu\rangle\right] = 0} \ . \tag{27.24}$$

This *secular equation* (one for each μ) represents, in fact, a set of r linear equations for the coefficients $c_{\mu\nu}$. The condition for having non-trivial solutions is,

$$\det\left(\langle n,\nu|\hat{H}^{(1)}|n,\mu\rangle - E^{(1)}_{n\mu}\delta_{\mu,\nu}\right)_{\mu,\nu} = 0 \ . \tag{27.25}$$

The solution of this *secular determinant* yields the solicited energies $E^{(1)}_\mu$. Now, the solution of the secular equation (27.24) *for each energy value* produces those coefficients, which represent the best linear combinations adapted to the perturbation. Unlike in previous calculations with degenerate states, here we consider linear combinations of vectors of the degenerate subspace prior to switching on the perturbation.

In practice, we apply perturbation theory only to the lowest relevant order. That is, we only calculate the second order correction if first order corrections vanish. One famous example is the *quadratic Stark effect* discussed in Sec. 30.3. In the case of eigenvalues, which are degenerate in the absence of perturbation, the first order will always produce a remarkable correction, as in the example of the *linear Stark effect*, also discussed in Sec. 30.3. For this reason, we need not discuss higher perturbation orders in the case of degenerate eigenvalues.

Example 170 (*Perturbation in a system with two degenerate states*): As an example, we consider the following Hamiltonian,

$$\hat{H} = \begin{pmatrix} \Delta & \Omega \\ \Omega & \Delta \end{pmatrix} \ .$$

The exact solution gives the eigenvalues and eigenvectors,

$$E_1 = \Delta+\Omega \quad , \quad E_2 = \Delta-\Omega \quad , \quad |\psi_1\rangle = \tfrac{1}{\sqrt{2}}\begin{pmatrix}1\\1\end{pmatrix} \quad , \quad |\psi_2\rangle = \tfrac{1}{\sqrt{2}}\begin{pmatrix}-1\\1\end{pmatrix} \ .$$

Now we divide the Hamiltonian into an unperturbed part and a perturbation,

$$\hat{H} \equiv \hat{H}^{(0)} + \hat{H}^{(1)} = \begin{pmatrix} \Delta & 0 \\ 0 & \Delta \end{pmatrix} + \begin{pmatrix} 0 & \Omega \\ \Omega & 0 \end{pmatrix} \ .$$

We get in zero order,

$$E^{(0)}_1 = \Delta = E^{(0)}_2 \quad , \quad |1\rangle = \begin{pmatrix}1\\0\end{pmatrix} \quad , \quad |2\rangle = \begin{pmatrix}0\\1\end{pmatrix} \ ,$$

The application of non-degenerate perturbation theory in first order would give,

$$\langle 1|\hat{H}^{(1)}|1\rangle = 0 = \langle 2|\hat{H}^{(1)}|2\rangle \quad , \quad |\psi^{(1)}_1\rangle = |1\rangle\frac{\langle 1|\hat{H}^{(1)}|2\rangle}{E^{(0)}_1 - E^{(0)}_2} \to \infty \leftarrow -|\psi^{(1)}_2\rangle \ .$$

That is, the correction of the energy vanishes in first order, while the correction of the wavefunction diverges. Obviously, the $|\nu\rangle$ obtained by the diagonalization of the matrix $\hat{H}^{(0)}$ is not adapted to the calculation of the matrix elements $\hat{H}^{(1)}$. Now, applying degenerate perturbation theory, we obtain by the secular determinant,

$$0 = \det\left[\langle\nu|\hat{H}^{(1)}|\mu\rangle - E_\mu^{(1)}\delta_{\mu,\nu}\right] = \det\begin{pmatrix} -E_\mu^{(1)} & \Omega \\ \Omega & -E_\mu^{(1)} \end{pmatrix} = (E_\mu^{(1)})^2 - \Omega^2 \ ,$$

eigenvalues are $E_1^{(1)} = \Omega$ and $E_2^{(1)} = -\Omega$ allowing the establishment of the secular equation,

$$c_{11}\left[E_1^{(1)} - \langle 1|\hat{H}^{(1)}|1\rangle\right] - c_{12}\langle 1|\hat{H}^{(1)}|2\rangle = c_{11}[\Omega - 0] - c_{12}\Omega = 0$$
$$-c_{21}\langle 2|\hat{H}^{(1)}|1\rangle + c_{22}\left[E_2^{(1)} - \langle 2|\hat{H}^{(1)}|2\rangle\right] = -c_{21}\Omega + c_{22}[-\Omega - 0] = 0 \ .$$

We obtain $c_{11} = c_{12}$ and $c_{21} = -c_{22}$ and with this,

$$|\psi_1^{(0)}\rangle = \sum_\nu c_{1\nu}|\nu\rangle = c_{11}|1\rangle + c_{12}|2\rangle = \tfrac{1}{\sqrt{2}}\begin{pmatrix}1\\1\end{pmatrix} \quad , \quad |\psi_2^{(0)}\rangle = c_{21}|1\rangle + c_{22}|2\rangle = \tfrac{1}{\sqrt{2}}\begin{pmatrix}-1\\1\end{pmatrix} \ .$$

Thus, we can verify that the corrections for the eigenenergies,

$$E_1 = E_1^{(0)} + \langle\psi_1^{(0)}|\hat{H}^{(1)}|\psi_1^{(0)}\rangle = \Delta + \Omega \quad , \quad E_2 = E_2^{(0)} + \langle\psi_2^{(0)}|\hat{H}^{(1)}|\psi_2^{(0)}\rangle = \Delta - \Omega \ ,$$

coincides with the exact calculation made at the beginning. The eigenfunctions $|\psi_1^{(0)}\rangle$ should be already corrected in zeroth order, which we verify by calculating,

$$|\psi_1^{(1)}\rangle = |\psi_1^{(0)}\rangle \frac{\langle\psi_1^{(0)}|\hat{H}^{(1)}|\psi_2^{(0)}\rangle}{E_1 - E_2} = 0 = |\psi_2^{(1)}\rangle \ .$$

In Exc. 27.1.3.8 we study a partially degenerate three-level system and the breakdown of the degeneracy due to a perturbation. And in Exc. 27.1.3.9 we will treat a perturbation in a box potential with degenerate energy levels.

27.1.3 Exercises

27.1.3.1 Ex: One-dimensional well with a deformation in the centre

Consider a one-dimensional potential well between $-L/2$ and $L/2$ with infinitely high walls. In the center of the well is a small deformation,

$$H^{(1)} = \begin{cases} \varepsilon \text{ for } \frac{-a}{2} \le x \le \frac{a}{2} \\ 0 \text{ outside that region} \ . \end{cases}$$

Calculate the correction for the eigenenergies in first order and discuss the limits $a \ll L$ and $a \to L$.

Solution: *The energies and wavefunctions for* $\varepsilon \longrightarrow 0$ *are,*

$$E_n^{(0)} = \frac{\pi^2\hbar^2 n^2}{2mL^2} \quad , \quad \psi^{(0)}_{n=impar}(x) = \sqrt{\frac{2}{L}}\cos\frac{n\pi x}{L} \quad , \quad \psi^{(0)}_{n=par}(x) = \sqrt{\frac{2}{L}}\sin\frac{n\pi x}{L} \ ,$$

because it is easy to check,

$$\psi_n^{(0)}(\pm L/2) = 0 \qquad \textit{and} \qquad \frac{2}{L}\int_{-L/2}^{L/2} \cos^2\frac{n\pi x}{L}dx = 1 = \frac{2}{L}\int_{-L/2}^{L/2} \sin^2\frac{n\pi x}{L}dx \ .$$

The first order correction is,

$$\begin{aligned} E_n^{(1)} = \langle n|H^{(1)}|n\rangle &= \int_0^L \psi_n^{*(0)}(x)H^{(1)}(x)\psi_n^{(0)}(x)dx = \frac{2}{L}\int_{-a/2}^{a/2} \varepsilon \begin{pmatrix} \cos^2\frac{n\pi x}{L} \\ \sin^2\frac{n\pi x}{L} \end{pmatrix} dx \\ &= \frac{4\varepsilon}{L}\int_0^{a/2}\left(\frac{1}{2} \pm \frac{1}{2}\cos\frac{2n\pi x}{L}\right)dx = \frac{2\varepsilon}{L}\frac{L}{2n\pi}\int_0^{n\pi a/L}(1 \pm \cos z)dz \\ &= \varepsilon\left(\frac{a}{L} - \frac{(-1)^n}{n\pi}\sin\frac{n\pi a}{L}\right) \ , \end{aligned}$$

where the upper (lower) signs correspond to the odd (even) n. When $a \ll L$, we can approximate by $E^{(1)}_{n=impar} \simeq \varepsilon 2a/L$ and $E^{(1)}_{n=par} \simeq 0$. Apparently, the perturbation is stronger when the wavefunction has a large overlap with the perturbation. By analogy we can consider the strings of a violin. When we perturb the strings near the nodes, we do not influence the vibration. When we perturb away from the nodes, the frequency is altered. When $a \to L$ but $\varepsilon \ll E_1^{(0)}$, we can approximate by $E_n^{(1)} \simeq \varepsilon$. In this case, all energies are shifted up by the same amount.

27.1.3.2 Ex: Perturbation

Show that the scalar product $\langle\psi_n^{(0)}|\psi_n^{(1)}\rangle$ (from the first-order correction to the state of the 'perturbed' system with the n-th state of the free Hamiltonian), cancels out when we impose that the 'perturbed' state $|\psi(\lambda)\rangle$ be normalized and the the product $\langle\psi_n^{(0)}|\psi(\lambda)\rangle$ be real.[3]

Solution:

27.1.3.3 Ex: Extended nucleus

The expression $V(r) = -e^2/4\pi\epsilon_0 r$ for the potential energy of an electron in the hydrogen atom implies that the nucleus (the proton) is treated as a point particle. Now suppose that, on the contrary, the charge of the proton $+e$ is evenly distributed over a sphere of radius $R = 10^{-13}$ cm.
a. Derive the modified potential V_m, which corresponds to this distribution of the nuclear charge.
b. Assume that the wavefunction of the hydrogen atom does not change much due to the modified potential. Calculate in lowest order in R/a_B the average energetic displacement $\langle\Delta V\rangle$ for the state $(n = 1, \ell = 0, m = 0)$. How will the energy displacement be in comparison to the states $(n = 2, \ell = 0, m = 0)$ and $(n = 2, \ell = 1, m = 0)$?
c. Calculate in the same way $\langle\Delta V\rangle$ for muonic hydrogen in the ground state.

[3] See [276], Cap XI, A-2.

Solution: *a. Using Gauss' law,*

$$\int_{\partial V} \mathbf{E}\cdot d\mathbf{S} = \tfrac{1}{\epsilon_0}\int_V \rho dV \qquad with \qquad \rho = \frac{e}{4\pi R^3/3}\ ,$$

we obtain for the electric field,

$$4\pi r^2 E_r = \begin{cases} \frac{1}{\varepsilon_0}4\pi\int_0^r \frac{e}{4\pi R^3/3} r'^2 dr' & for \quad r<R \\ \frac{e}{\varepsilon_0} & for \quad r>R \end{cases}\ .$$

Resolving by E_r,

$$E_r = \begin{cases} \frac{e}{4\pi\varepsilon_0}\frac{r}{R^3} & for \quad r<R \\ \frac{e}{4\pi\varepsilon_0 r^2} & for \quad r>R \end{cases}\ .$$

The potentials follow with,

$$V_m = e\int E_r dr = \begin{cases} \frac{e^2}{4\pi\varepsilon_0}\frac{r^2}{2R^3} + const & for \quad r<R \\ -\frac{e^2}{4\pi\varepsilon_0 r} & for \quad r>R \end{cases}\ .$$

Continuity at the position R requires, $const = \frac{3e^2}{4\pi\varepsilon_0 2R}$. Hence,

$$V_m = \begin{cases} \frac{-e^2}{8\pi\varepsilon_0 R}\left(3-\frac{r^2}{R^2}\right) & for \quad r<R \\ \frac{-e^2}{4\pi\varepsilon_0 r} & for \quad r>R \end{cases}\ .$$

b. We consider the difference of this potential from a Coulomb potential,

$$\Delta V(r) \equiv V_m(r) - V(r) = \begin{cases} -\frac{3e^2}{8\pi\epsilon_0 R} + \frac{e^2 r^2}{8\pi\epsilon_0 R^3} + \frac{e^2}{4\pi\epsilon_0 r} & for \ \ r<R \\ 0 \ \ for \ \ r>R \end{cases}\ .$$

being a perturbation of the Coulombian case, which has already been solved. Using perturbation theory we calculate the first-order correction of ground state energy,

$$\Delta E_1^{(1)} = \langle\psi_{100}|\Delta V(r)|\psi_{100}\rangle = 4\pi\int_0^R \psi_{100}^* \Delta V(r)\psi_{100} r^2 dr = \frac{4}{10}\frac{e^2}{4\pi\epsilon_0 a_B^3}R^2\ .$$

To solve the integral we can approximate the exponential appearing in the function ψ_{100} by $e^{-\tilde{r}} \simeq 1$, since the radius within which $\Delta V(r) \neq 0$ is very small: $R \approx a_B/10^4$. We obtain, $\frac{\Delta E_1^{(1)}}{E_1} \approx 10^{-8}$, which is a very small energy correction. Because of the smaller $\langle r\rangle$ and being consequently closer to the nucleus, the fundamental state (100) is most affected by the finite size of the nucleus. As the other states are further apart, they will have even smaller corrections of their energies.
The same calculation made for muonic hydrogen gives,

$$\frac{\Delta E_e}{\Delta E_\mu} = \left(\frac{a_\mu}{a_B}\right)^3 = \left(\frac{m_e}{m_\mu}\right)^3 \approx 1.25\cdot 10^{-7}\ .$$

27.1.3.4 Ex: Perturbation of a two-level system

We consider a two-level system. Without perturbation the system would have the Hamiltonian $H^{(0)}$, the eigenenergies $E^{(0)}_{1,2}$ and the eigenfunctions $\psi^{(0)}_{1,2}$. Now we switch on a stationary perturbation of the form $H^{(1)} = \epsilon(|1\rangle\langle 2| + |2\rangle\langle 1|)$.
a. Calculate the eigenenergies directly solving the perturbed Schrödinger equation.
b. Calculate the perturbed energies using TIPT and compare to the exact calculation of the eigenenergies.
c. Calculate the eigenstates directly solving the perturbed Schrödinger equation.
d. Calculate the perturbed states using TPIT and compare to the exact calculation of the eigenfunctions.

Solution: *a. We have already dealt with the two-level system with coupling in Exc. 23.4.7.1. Here we rephrase the problem assuming that the coupling represents a perturbation. The Hamiltonian is*

$$\hat{H} = \begin{pmatrix} H^{(0)}_{11} & 0 \\ 0 & H^{(0)}_{22} \end{pmatrix} + \begin{pmatrix} 0 & H^{(1)}_{12} \\ H^{(1)}_{21} & 0 \end{pmatrix} = \begin{pmatrix} E^{(0)}_1 & \varepsilon \\ \varepsilon & E^{(0)}_2 \end{pmatrix} .$$

To find the perturbed eigenvalues $E^{(1)}_{1,2}$ we solve the eigenvalue equation $\det(\hat{H} - E^{(1)}_{\pm}) = 0$, giving

$$E^{(1)}_{1,2} = \tfrac{1}{2}(E^{(0)}_1 + E^{(0)}_2) \pm \tfrac{1}{2}\sqrt{(E^{(0)}_1 - E^{(0)}_2)^2 + 4\varepsilon^2} .$$

Obviously, for $\varepsilon \to 0$ we get the unperturbed energies. If the distance from unperturbed levels, $\Delta E \equiv E^{(0)}_1 - E^{(0)}_2$, decreases, the perturbation gets more important and causes a minimum distance $E^{(1)}_1 - E^{(1)}_2 = 2\varepsilon$. That is, the perturbation drives the levels away from each other. This is called avoided crossing. For small perturbations we can expand,

$$E^{(1)}_{1,2} = \tfrac{1}{2}\left(E^{(0)}_1 + E^{(0)}_2\right) \pm \tfrac{1}{2}\left(E^{(0)}_1 - E^{(0)}_2\right)\left(1 + \frac{2\varepsilon^2}{\Delta E^2} + ...\right) \simeq E^{(0)}_{1,2} \pm \frac{\varepsilon^2}{\Delta E} .$$

b. Using first-order perturbation theory,

$$E^{(1)}_n = \langle\psi^{(0)}_n|\hat{H}^{(1)}|\psi^{(0)}_n\rangle = 0 ,$$

since $H^{(1)}$ has no diagonal components. In second order,

$$E^{(2)}_n = \langle\psi^{(0)}_n|\hat{H}^{(2)}|\psi^{(0)}_n\rangle + \sum_{m\neq n} \frac{\langle n|\hat{H}^{(1)}|m\rangle\langle m|\hat{H}^{(1)}|n\rangle}{E^{(0)}_n - E^{(0)}_m} = 0 \pm \frac{\varepsilon^2}{\Delta E} ,$$

giving the same result as in a Taylor expansion of the exact energies by the perturbation ε.
c. Now we take a look at the wavefunctions

$$\begin{pmatrix} E^{(0)}_1 & H^{(1)}_{12} \\ H^{(1)}_{21} & E^{(0)}_2 \end{pmatrix} \begin{pmatrix} \cos\zeta & \sin\zeta \\ -\sin\zeta & \cos\zeta \end{pmatrix} = \begin{pmatrix} \cos\zeta & \sin\zeta \\ -\sin\zeta & \cos\zeta \end{pmatrix} \begin{pmatrix} E^{(1)}_+ & 0 \\ 0 & E^{(1)}_- \end{pmatrix} .$$

We obtain

$$|\psi^{(1)}\rangle = \begin{pmatrix} \psi_+^{(1)} \\ \psi_-^{(1)} \end{pmatrix} = \begin{pmatrix} \cos\zeta & \sin\zeta \\ -\sin\zeta & \cos\zeta \end{pmatrix} \begin{pmatrix} \psi_1^{(0)} \\ \psi_2^{(0)} \end{pmatrix} = \begin{pmatrix} \psi_1^{(0)}\cos\zeta + \psi_2^{(0)}\sin\zeta \\ -\psi_1^{(0)}\sin\zeta + \psi_2^{(0)}\cos\zeta \end{pmatrix} ,$$

with $\tan\zeta = \frac{2|H_{12}^{(1)}|}{\Delta E} \simeq \zeta$. *In first order,*

$$\psi_+^{(1)} = \psi_1^{(0)}\cos\zeta + \psi_2^{(0)}\sin\zeta \simeq \psi_1^{(0)} + \zeta\psi_2^{(0)} \simeq \psi_1^{(0)} + \frac{\varepsilon}{\Delta E}\psi_2^{(0)}$$

and $$\psi_-^{(1)} = -\psi_1^{(0)}\sin\zeta + \psi_2^{(0)}\cos\zeta \simeq \psi_2^{(0)} - \zeta\psi_2^{(0)} \simeq \psi_2^{(0)} - \frac{\varepsilon}{\Delta E}\psi_1^{(0)} .$$

d. Using first-order perturbation theory,

$$|\psi_n^{(1)}\rangle = \sum_{m\neq n} |m\rangle \frac{\langle m|\hat{H}^{(1)}|n\rangle}{E_n^{(0)} - E_m^{(0)}} = \pm|m\rangle \frac{\varepsilon}{\Delta E} .$$

giving the same result as in a Taylor expansion of the exact energies by the perturbation ε.

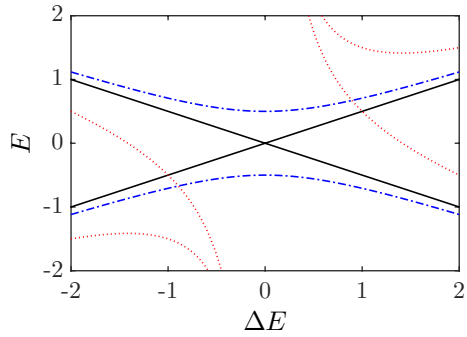

Figure 27.1: Avoided crossing of coupled two levels. Black solid: uncoupled states, blue dash-dotted: exact solution, red dotted: first order correction TIPT.

27.1.3.5 Ex: Stark effect for an electron in a box

Consider an electron in a one-dimensional box, that is, in a well inside the interval $x \in [0, a]$ delimited by infinite walls. When a uniform electric field $\mathcal{E}$ is applied, also in x-direction, the electron experiences a force equal to $-e\mathcal{E}$, being $-e$ the electron charge, so that the potential energy inside the box becomes $e\mathcal{E}x$.
a. What is the energy of the ground state of the electron (in first order approximation)? We can assume that $e\mathcal{E}a$ is much smaller than the ground state energy the electron would have in the absence of electric fields.
b. Use first-order TIPT to get an approximation for the ground state wavefunction by calculating the first term of the correction.

Solution: *a. In zeroth order we have,*

$$E_n^{(0)} = \frac{\pi^2\hbar^2 n^2}{2m_e a^2} \qquad \textit{and} \qquad \psi_n^{(0)}(x) = \sqrt{\frac{2}{a}} \sin\frac{n\pi x}{a} \ ,$$

with $n = 1$. *In the first order we obtain for the energy,*

$$E_n^{(1)} = \langle n|e\mathcal{E}x|n\rangle = \frac{2}{a} e\mathcal{E} \int_0^a x \sin^2\frac{n\pi x}{a} dx = \frac{2}{a} e\mathcal{E}\frac{a^2}{4} = \frac{a}{2} e\mathcal{E} \ .$$

b. In the first order we obtain the eigenfunctions,

$$\begin{aligned}
|\psi_n^{(1)}\rangle &= \sum_{m\neq n} |m\rangle \frac{\langle m|H^{(1)}|n\rangle}{E_n^{(0)} - E_m^{(0)}} = \sum_{m\neq n} |\psi_m^{(0)}\rangle \frac{\int\int \langle m|x\rangle\langle x|e\mathcal{E}x|x'\rangle\langle x'|n\rangle d^3x d^3x'}{E_n^{(0)} - E_m^{(0)}} \\
&= \sum_{m\neq n} |\psi_m^{(0)}\rangle \frac{1}{E_n^{(0)} - E_m^{(0)}} \frac{2}{a} e\mathcal{E} \int_0^a x \sin\frac{m\pi x}{a} \sin\frac{\pi x}{a} dx \\
&= \sum_{m\neq n} |\psi_m^{(0)}\rangle \frac{2m_e a^2}{\pi^2\hbar^2 n^2 - \pi^2\hbar^2 m^2} \frac{2}{a} e\mathcal{E} \frac{2mna^2}{\pi^2} \frac{(-1)^{m+n} - 1}{(m^2 - n^2)^2} \\
&= \sum_{m\neq n} |\psi_m^{(0)}\rangle \frac{8m_e a^3 e\mathcal{E}}{\pi^4\hbar^2} \frac{mn[1 - (-1)^{m+n}]}{(m^2 - n^2)^3} \ .
\end{aligned}$$

27.1.3.6 Ex: Perturbed 3-level system until second order TIPT

Consider the following perturbed Hamiltonian:

$$H = H_0 + H_\lambda = \begin{pmatrix} E_1 & 0 & 0 \\ 0 & E_2 & 0 \\ 0 & 0 & E_3 \end{pmatrix} + \begin{pmatrix} 0 & \lambda & 0 \\ \lambda & 0 & \lambda \\ 0 & \lambda & 0 \end{pmatrix} \ .$$

a. Determine the perturbed eigenvalues and eigenfunctions in first order TIPT.
b. Determine the eigenvalues in second order TIPT.

Solution: *a. In zeroth order,*

$$E_n^{(0)} = E_{1,2,3} \qquad \textit{and} \qquad |n\rangle = \hat{e}_n \ .$$

The eigenvalues in first order are,

$$E_n^{(1)} = \langle n|H_\lambda|n\rangle = \hat{e}_n^\dagger H_\lambda \hat{e}_n = 0 \ .$$

The perturbed eigenfunctions in first-order are $|\psi_n\rangle = |n\rangle + |\psi_n^{(1)}\rangle + ...$, *where*

$$|\psi_n^{(1)}\rangle = \sum_{m\neq n} |m\rangle \frac{\langle m|H_\lambda|n\rangle}{E_n - E_m}$$

$$|\psi_1^{(1)}\rangle = |2\rangle \frac{\hat{e}_2^\dagger H_\lambda \hat{e}_1}{E_1 - E_2} + |3\rangle \frac{\hat{e}_3^\dagger H_\lambda \hat{e}_1}{E_1 - E_3} = |2\rangle \frac{\lambda}{E_1 - E_2}$$

$$|\psi_2^{(1)}\rangle = |1\rangle \frac{\hat{e}_1^\dagger H_\lambda \hat{e}_2}{E_2 - E_1} + |3\rangle \frac{\hat{e}_3^\dagger H_\lambda \hat{e}_2}{E_2 - E_3} = |1\rangle \frac{\lambda}{E_2 - E_1} + |3\rangle \frac{\lambda}{E_2 - E_1}$$

$$|\psi_3^{(1)}\rangle = |1\rangle \frac{\hat{e}_1^\dagger H_\lambda \hat{e}_3}{E_3 - E_1} + |2\rangle \frac{\hat{e}_2^\dagger H_\lambda \hat{e}_3}{E_3 - E_2} = |2\rangle \frac{\lambda}{E_3 - E_2} \ .$$

b. The eigenvalues in second order are,

$$E_n^{(2)} = \sum_{m\neq n} \frac{\langle n|H_\lambda|m\rangle\langle m|H_\lambda|n\rangle}{E_n^{(0)} - E_m^{(0)}}$$

$$E_1^{(2)} = \frac{\langle 1|H_\lambda|2\rangle\langle 2|H_\lambda|1\rangle}{E_1^{(0)} - E_2^{(0)}} + \frac{\langle 1|H_\lambda|3\rangle\langle 3|H_\lambda|1\rangle}{E_1^{(0)} - E_3^{(0)}} = \frac{\lambda^2}{E_1^{(0)} - E_2^{(0)}} \ .$$

27.1.3.7 Ex: Stark effect for a charge in a harmonic oscillator

Consider a charged harmonic oscillator, immersed in a uniform electric field $\mathcal{E}$, described by the Hamiltonian $\hat{H}^{(1)} = \hat{H} + e\mathcal{E}\hat{x}$, being $\hat{H} = \hat{p}^2/2m + m\omega^2\hat{x}^2/2$ the Hamiltonian of the free one-dimensional oscillator, and e the charge of the oscillator.
a. Obtain, through TIPT, the eigenenergies (first and second order corrections). Compare the results obtained by TIPT with the analytical ones [4].
b. Same thing for a perturbation of the form $\rho m\omega^2\hat{x}^2/2$.
c. Same thing for a perturbation $\sigma\hbar\omega\hat{x}^3$.

Solution: *a. We already calculated in Exc. 24.6.6.9 the influence of a constant force on a harmonic oscillator,*

$$\hat{H}^{(1)}|\psi_n^{(1)}\rangle = E_n^{(1)}|\psi_n^{(1)}\rangle \quad , \quad |\psi_n^{(1)}(x)\rangle = |\psi_n(x-b)\rangle \quad , \quad E_n^{(1)} = E_n - \frac{m}{2}\omega^2 b^2 \ ,$$

with $b \equiv e\mathcal{E}/m\omega^2$. *With TIPT we calculate the first order correction,*

$$E_n^{(1)} = \langle n|\hat{H}^{(1)}|n\rangle = e\mathcal{E}\langle n|\hat{x}|n\rangle = 0 \ .$$

In second order,

$$E_n^{(2)} = \langle n|\hat{H}^{(2)}|n\rangle + \sum_{m\neq n} \frac{\langle m|\hat{H}^{(1)}|n\rangle\langle n|\hat{H}^{(1)}|m\rangle}{E_n^{(0)} - E_m^{(0)}} = e^2\mathbf{E}^2 \sum_{m\neq n} \frac{|\langle m|\hat{x}|n\rangle|^2}{\hbar\omega(n-m)} \ .$$

[4] See [276], Complement A_XI.

With

$$\langle m|\hat{x}|n\rangle = \frac{a_{ho}}{\sqrt{2}}\langle m|\hat{a}+\hat{a}^\dagger|n\rangle = \frac{a_{ho}}{\sqrt{2}}(\sqrt{n}\delta_{m,n-1}+\sqrt{n+1}\delta_{m,n+1}) \ ,$$

we find,

$$E_n^{(2)} = e^2\mathcal{E}^2\frac{a_{ho}^2}{\hbar\omega}\left[\frac{n}{2}+\frac{n+1}{-2}\right] = -\frac{1}{2}b^2m^2\omega^4\ \frac{\hbar}{m\omega}\frac{1}{\hbar\omega} = -\frac{m}{2}\omega^2b^2 \ .$$

This coincides with the exact result calculated above.
b. With a quadratic perturbation, the exact solutions will be,

$$E_n = \hbar\omega(1+\rho)(n+1/2) \ .$$

With TIPT, we calculate the first order correction,

$$E_n^{(1)} = \langle n|\hat{H}^{(1)}|n\rangle = \rho\frac{m}{2}\omega^2\langle n|\hat{x}^2|n\rangle = \rho\frac{m}{2}\omega^2a_{ho}^2(n+1/2) = \frac{\rho}{2}\hbar\omega(n+1/2) = \frac{\rho}{2}E_n^{(0)} \ .$$

In second order, with

$$\langle m|\hat{x}^2|n\rangle = \sqrt{n(n-1)}\delta_{m,n-2}+\sqrt{n^2}\delta_{m,n}+\sqrt{(n+1)(n+1)}\delta_{m,n}+\sqrt{(n+1)(n+2)}\delta_{m,n+2}$$

we find

$$\begin{aligned}
\langle m|\hat{x}^2|n\rangle &= \frac{a_{ho}^2}{2}\langle m|(\hat{a}+\hat{a}^\dagger)(\hat{a}+\hat{a}^\dagger)|n\rangle \\
&= \frac{a_{ho}^2}{2}\left(\sqrt{n(n-1)}\delta_{m,n-2}+n\delta_{m,n}+(n+1)\delta_{m,n}+\sqrt{(n+1)(n+2)}\delta_{m,n+2}\right) \\
E_n^{(2)} &= \langle n|\hat{H}^{(2)}|n\rangle + \sum_{m\neq n}\frac{\langle m|\hat{H}^{(1)}|n\rangle\langle n|\hat{H}^{(1)}|m\rangle}{E_n^{(0)}-E_m^{(0)}} = \frac{m^2}{4}\rho^2\omega^4\sum_{m\neq n}\frac{|\langle m|x^2|n\rangle|^2}{\hbar\omega(n-m)} \\
&= \frac{m^2}{4}\rho^2\omega^4\frac{a_{ho}^4}{4}\frac{1}{\hbar\omega}\left(\frac{n(n-1)}{n-(n-2)}+\frac{(n+1)(n+2)}{n-(n+2)}\right) = -\frac{\rho^2}{8}\hbar\omega(n+1/2) = -\frac{\rho^2}{8}E_n^{(0)} \ .
\end{aligned}$$

c. We calculate

$$E_n^{(1)} = \langle n|\hat{H}^{(1)}|n\rangle = \sigma\hbar\omega\langle n|\hat{x}^3|n\rangle \propto \langle n|(\hat{a}+\hat{a}^\dagger)^3|n\rangle = 0 \ ,$$

and

$$\begin{aligned}
E_n^{(2)} &= (\sigma\hbar\omega)^2\sum_{m\neq n}\frac{|\langle m|\hat{x}^3|n\rangle|^2}{E_n^{(0)}-E_m^{(0)}} \\
&= \frac{\sigma^2\hbar\omega}{2^3}a_{ho}^6\sum_{m\neq n}\frac{|\langle m|(\hat{a}^\dagger)^3+3(\hat{a}^\dagger)^2\hat{a}+3\hat{a}^\dagger-3\hat{a}+3\hat{a}^2\hat{a}^\dagger+\hat{a}^3|n\rangle|^2}{n-m} \\
&= \frac{\sigma^2\hbar^4}{8m^3\omega^2}\sum_{m\neq n}\frac{1}{n-m}\Big|\sqrt{(n+3)(n+2)(n+1)}\delta_{m,n+3}+\sqrt{n(n-1)(n-2)}\delta_{m,n-3}+ \\
&\qquad +3\sqrt{n^2(n+1)}\delta_{m,n+1}+\sqrt{n(n+1)^2}\delta_{m,n-1}\Big|^2 \\
&= \frac{\sigma^2\hbar^4}{8m^3\omega^2}\left[-\tfrac{1}{3}(n+3)(n+2)(n+1)+\tfrac{1}{3}n(n-1)(n-2)-3n^2(n+1)+3n(n+1)^2\right] \\
&= -\frac{\sigma^2\hbar^4}{4m^3\omega^2} \ .
\end{aligned}$$

27.1.3.8 Ex: Three-level system with degeneracy

Consider the following Hamiltonian $\hat{H}^{(0)}$ and its perturbation $\hat{H}^{(1)}$

$$\hat{H}^{(0)} + \hat{H}^{(1)} = \begin{pmatrix} \Delta & 0 & 0 \\ 0 & \Delta & 0 \\ 0 & 0 & \Delta' \end{pmatrix} + \begin{pmatrix} 0 & \Omega & 0 \\ \Omega & 0 & \Omega \\ 0 & \Omega & 0 \end{pmatrix} \ .$$

Calculate the corrections for the eigenvalues and eigenfunctions up to first order.

Solution: *For the unperturbed system we have* $(E_n^{(0)} - \hat{H}^{(0)})|n,\nu\rangle = 0$*, that is,*

$$\langle 1,1|\hat{H}^{(0)})|1,1\rangle = \langle 1,2|\hat{H}^{(0)}|1,2\rangle = \Delta \qquad \textit{and} \qquad \langle 2|\hat{H}^{(0)}|2\rangle = \Delta' \ ,$$

where ν *is the degenerate quantum number. Applying the non-degenerate TIPT, we would get* $(E_n^{(1)} - \hat{H}^{(1)})|n,\nu\rangle = 0$*,*

$$\langle 1,1|\hat{H}^{(1)})|1,1\rangle = \langle 1,2|\hat{H}^{(1)}|1,2\rangle = \langle 2|\hat{H}^{(0)}|2\rangle = 0 \ .$$

The first two eigenvalues are degenerate. To find the first-order corrections in this subspace, we calculate,

$$0 = \det\left[\langle n,\nu|\hat{H}^{(1)})|n,\mu\rangle - E_{n\mu}^{(1)}\delta_{\mu,\nu}\right] = \det\left[\begin{pmatrix} 0 & \Omega \\ \Omega & 0 \end{pmatrix} - \begin{pmatrix} E^{(1)} & 0 \\ 0 & E^{(1)} \end{pmatrix}\right] = (E^{(1)})^2 - \Omega^2 \ .$$

That is, the corrections for the eigenvalues are $E^{(1)} = \pm\Omega$*. The corrections for the eigenfunctions follow with* $\sum_n c_{\mu\nu}[E_{n\mu}^{(1)}\langle n,\mu|n,\nu\rangle - \langle n,\mu|\hat{H}^{(1)})|n,\nu\rangle] = 0$*, that is,*

$$\begin{aligned} c_{11}[\Omega - \langle 1|H^{(1)}|1\rangle] + c_{12}[-\langle 1|H^{(1)}|2\rangle] &= c_{11}\Omega - c_{12}\Omega = 0 \\ c_{21}[-\langle 2|H^{(1)}|1\rangle] + c_{22}[-\Omega - \langle 2|H^{(1)}|2\rangle] &= -c_{21}\Omega - c_{22}\Omega = 0 \ . \end{aligned}$$

Therefore, the normalized eigenfunctions are,

$$|\psi_1^{(0)}\rangle = c_{11}|1\rangle + c_{12}|2\rangle = \tfrac{1}{\sqrt{2}}\begin{pmatrix} 1 \\ 1 \\ 0 \end{pmatrix} \qquad \textit{and} \qquad |\psi_2^{(0)}\rangle = c_{21}|1\rangle + c_{22}|2\rangle = \tfrac{1}{\sqrt{2}}\begin{pmatrix} 1 \\ -1 \\ 0 \end{pmatrix} \ .$$

Finally we obtain the corrections for the eigenvalues $\langle\psi^{(0)}_{n,\mu}|H^{(1)}|\psi^{(0)}_{n,\mu}\rangle$,

$$\langle\psi^{(0)}_1|\hat{H}^{(1)}|\psi^{(0)}_1\rangle = \tfrac{1}{2}\begin{pmatrix}1\\1\\0\end{pmatrix}^T\begin{pmatrix}0&\Omega&0\\\Omega&0&\Omega\\0&\Omega&0\end{pmatrix}\begin{pmatrix}1\\1\\0\end{pmatrix} = \Omega$$

$$\langle\psi^{(0)}_2|\hat{H}^{(1)}|\psi^{(0)}_2\rangle = \frac{1}{2}\begin{pmatrix}1\\-1\\0\end{pmatrix}^T\begin{pmatrix}0&\Omega&0\\\Omega&0&\Omega\\0&\Omega&0\end{pmatrix}\begin{pmatrix}1\\-1\\0\end{pmatrix} = -\Omega$$

$$\langle\psi^{(0)}_3|\hat{H}^{(1)}|\psi^{(0)}_3\rangle = \begin{pmatrix}0\\0\\1\end{pmatrix}^T\begin{pmatrix}0&\Omega&0\\\Omega&0&\Omega\\0&\Omega&0\end{pmatrix}\begin{pmatrix}0\\0\\1\end{pmatrix} = 0\ .$$

Thus, the energies of the perturbed Hamiltonian are: $E^{(0)}_1 + E^{(1)}_1 = \Delta+\Omega, \Delta-\Omega, \Delta'$. *Finally, the wavefunctions are up to first order,*

$$|\psi^{(1)}_1\rangle = \sum_{m\neq 1}|\psi^{(0)}_1\rangle\frac{\langle\psi^{(0)}_m|\hat{H}^{(1)}|\psi^{(0)}_1\rangle}{E^{(0)}_1-E^{(0)}_m} = |\psi^{(0)}_1\rangle\frac{\langle\psi^{(0)}_2|\hat{H}^{(1)}|\psi^{(0)}_1\rangle}{E^{(0)}_1-E^{(0)}_2} + |\psi^{(0)}_1\rangle\frac{\langle\psi^{(0)}_3|\hat{H}^{(1)}|\psi^{(0)}_1\rangle}{E^{(0)}_1-E^{(0)}_3}$$

$$= \frac{1}{(\Delta+\Omega)-(\Delta-\Omega)}\tfrac{1}{\sqrt{2}}\begin{pmatrix}1\\1\\0\end{pmatrix}\tfrac{1}{\sqrt{2}}\begin{pmatrix}1\\-1\\0\end{pmatrix}\begin{pmatrix}0&\Omega&0\\\Omega&0&\Omega\\0&\Omega&0\end{pmatrix}\tfrac{1}{\sqrt{2}}\begin{pmatrix}1\\1\\0\end{pmatrix}$$

$$+\frac{1}{(\Delta+\Omega)-\Delta'}\tfrac{1}{\sqrt{2}}\begin{pmatrix}1\\1\\0\end{pmatrix}\begin{pmatrix}0\\0\\1\end{pmatrix}\begin{pmatrix}0&\Omega&0\\\Omega&0&\Omega\\0&\Omega&0\end{pmatrix}\tfrac{1}{\sqrt{2}}\begin{pmatrix}1\\1\\0\end{pmatrix} = \frac{\Omega}{2(\Delta-\Delta'+\Omega)}\begin{pmatrix}1\\1\\0\end{pmatrix}$$

$$|\psi^{(1)}_2\rangle = |\psi^{(0)}_2\rangle\frac{\langle\psi^{(0)}_1|\hat{H}^{(1)}|\psi^{(0)}_2\rangle}{E^{(0)}_2-E^{(0)}_1} + |\psi^{(0)}_2\rangle\frac{\langle\psi^{(0)}_3|\hat{H}^{(1)}|\psi^{(0)}_2\rangle}{E^{(0)}_2-E^{(0)}_3} = \frac{-\Omega}{2(\Delta-\Delta'-\Omega)}\begin{pmatrix}1\\-1\\0\end{pmatrix}$$

$$|\psi^{(1)}_3\rangle = |\psi^{(0)}_3\rangle\frac{\langle\psi^{(0)}_1|\hat{H}^{(1)}|\psi^{(0)}_3\rangle}{E^{(0)}_3-E^{(0)}_1} + |\psi^{(0)}_3\rangle\frac{\langle\psi^{(0)}_2|\hat{H}^{(1)}|\psi^{(0)}_3\rangle}{E^{(0)}_3-E^{(0)}_2} = \frac{-\sqrt{2}\Omega^2}{(\Delta'-\Delta)^2-\Omega^2}\begin{pmatrix}0\\0\\1\end{pmatrix}\ .$$

Note that we can alternatively separate the Hamiltonian as follows,

$$\hat{H}^{(0)}+\hat{H}^{(1)} = \begin{pmatrix}\Delta&\Omega&0\\\Omega&\Delta&0\\0&0&\Delta'\end{pmatrix} + \begin{pmatrix}0&0&0\\0&0&\Omega\\0&\Omega&0\end{pmatrix}\ .$$

the advantage being that, already without perturbation, the eigenvalues $E^{(0)}_n$ *are not degenerate:*

$$|1\rangle = \begin{pmatrix}1\\1\\0\end{pmatrix} \leftrightarrow E^{(0)}_1 = \Delta+\Omega \quad , \quad |2\rangle = \begin{pmatrix}1\\-1\\0\end{pmatrix} \leftrightarrow E^{(0)}_1 = \Delta-\Omega \quad , \quad |3\rangle = \begin{pmatrix}0\\0\\1\end{pmatrix} \leftrightarrow E^{(0)}_3 = \Delta'\ .$$

In this case none of the first order corrections contributes: $\langle n|\hat{H}^{(1)}|n\rangle = 0$.

27.1.3.9 Ex: Perturbation in a 3D well with degeneracy

Consider a particle confined to a three-dimensional, infinite cubic well described by the potential energy $V(x,y,z) = 0$ for $0 < x < a$, $0 < y < a$ and $0 < z < a$ and $V(x,y,z) = \infty$ outside this region. We know that the particle's stationary states are $\Psi^{(0)}_{n_x,n_y,n_z}(x,y,z) = \left(\frac{2}{a}\right)^{3/2} \sin\left(\frac{n_x\pi}{a}x\right) \sin\left(\frac{n_y\pi}{a}y\right) \sin\left(\frac{n_z\pi}{a}z\right)$, being n_x, n_y, n_z positive integers. The associated energies are $E^{(0)}_{n_x,n_y,n_z} = \frac{\pi^2\hbar^2}{2ma^2}(n_x^2 + n_y^2 + n_z^2)$. Note that the ground state is not degenerate while the first excited state is three times degenerate. Consider that the particle in this box is subject to a perturbation of the shape $H^{(1)} = V_0$ for $0 < x < a/2$ and $0 < y < a/2$ and $H^{(1)} = 0$ outside this region.
a. Obtain the first-order correction for the ground state energy.
b. Obtain the first-order correction for the (degenerate) energy of the first excited state, in addition to the *optimal base* (which follows from the linear combinations of degenerate states) which most closely approximates the perturbed states.

Solution: *a. The perturbation potential increases by* V_0 *in a quarter of the box. The ground state is not degenerate. Therefore, the first order correction for the ground state is simply,*

$$E^{(1)}_0 = \langle 111|H^{(1)}|111\rangle = \left(\tfrac{2}{a}\right)^3 V_0 \int_0^{a/2} \sin^2\tfrac{\pi x}{a}dx \int_0^{a/2} \sin^2\tfrac{\pi y}{a}dy \int_0^{a} \sin^2\tfrac{\pi z}{a}dz = \tfrac{V_0}{4} \ ,$$

such that the corrected value is,

$$E^{(1)}_0 = E^{(1)}_0 + \tfrac{V_0}{4} \ .$$

b. For the first excited state we need the complete degenerate TIPT machinery. We start by constructing the matrix, $W_{\mu\nu} = \langle\mu|H^{(1)}|\nu\rangle$*, com* $\mu,\nu \in \{(211),(121),(112)\}$*. We find,*

$$W_{211,211} = W_{121,121} = W_{112,112} = \tfrac{V_0}{4}$$
$$W_{121,112} = \left(\tfrac{2}{a}\right)^3 V_0 \int_0^{a/2} \sin^2\tfrac{\pi x}{a}dx \int_0^{a/2} \sin\tfrac{\pi y}{a}\sin\tfrac{2\pi y}{a}dy \int_0^{a} \sin\tfrac{2\pi z}{a}\sin\tfrac{\pi z}{a}dz = 0$$
$$W_{211,112} = 0 \ ,$$

because the integral in z *vanishes.*

$$W_{211,121} = \left(\tfrac{2}{a}\right)^3 V_0 \int_0^{a/2} \sin\tfrac{\pi x}{a}\sin\tfrac{2\pi x}{a}dx \int_0^{a/2} \sin\tfrac{\pi y}{a}\sin\tfrac{2\pi y}{a}dy \int_0^{a} \sin\tfrac{\pi z}{a}dz = \tfrac{16}{9\pi^2}V_0 \ .$$

Therefore,,

$$W = \tfrac{V_0}{4}\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & (8/3\pi)^2 \\ 0 & (8/3\pi)^2 & 1 \end{pmatrix} \ .$$

The characteristic equation in W/V_0 gives the eigenvalues

$$w_1 = 1 \quad , \quad w_{2,3} = 1 \pm (8/3\pi)^2 \ .$$

In first-order the corrected value for the first excited state, therefore, is

$$E_1^{(1)} = E_1^{(0)} + \frac{V_0}{4} w_k \ .$$

That is, the perturbation removes the degeneracy to three distinct levels. If we had applied non-degenerate TIPT, we would have concluded that the first-order correction would be the same for all three states. The non-persturbed 'good' states are linear combinations of the form

$$|\psi^{(0)}\rangle = \alpha|112\rangle + \beta|211\rangle + \gamma|121\rangle \ .$$

where the coefficients form the eigenvectors of the matrix W,

$$W|\psi^{(0)}\rangle = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & (8/3\pi)^2 \\ 0 & (8/3\pi)^2 & 1 \end{pmatrix} \begin{pmatrix} \alpha \\ \beta \\ \gamma \end{pmatrix} = w \begin{pmatrix} \alpha \\ \beta \\ \gamma \end{pmatrix} = w|\psi^{(0)}\rangle \ .$$

For $w = 1$, we obtain $\alpha = 1$, $\beta = \gamma = 0$ and for $w = 1 \pm (8/3\pi)^2$ we obtain $\alpha = 0$, $\beta = \pm\gamma = 1/\sqrt{2}$. Therefore the good states are,

$$|\psi^0\rangle = |112\rangle, \tfrac{1}{\sqrt{2}}(|211\rangle \pm |121\rangle) \ .$$

27.1.3.10 Ex: Vanishing perturbation orders

Show that it is impossible to design a perturbation Hamiltonian of the form,

$$\hat{H} = \hat{H}^{(0)} + \hat{H}^{(1)} = \begin{pmatrix} 0 & 0 & 0 \\ 0 & E_2 & 0 \\ 0 & 0 & E_3 \end{pmatrix} + \begin{pmatrix} 0 & \Omega_{12} & \Omega_{13} \\ \Omega_{12}^* & 0 & \Omega_{23} \\ \Omega_{13}^* & \Omega_{23}^* & 0 \end{pmatrix}$$

such that the first and second order corrections vanish.

Solution: *The first order corrections $E_n^{(1)} = \langle n|\hat{H}^{(1)}|n\rangle$ obviously vanishes. For the second order corrections to vanish,*

$$0 = E_n^{(2)} = \sum_{m \neq n} \frac{\langle n|\hat{H}^{(1)}|m\rangle\langle m|\hat{H}^{(1)}|n\rangle}{E_n^{(0)} - E_m^{(0)}} \ ,$$

we have to guarantee,

$$0 = \frac{|\Omega_{12}|^2}{-E_2} + \frac{|\Omega_{13}|^2}{-E_3} \quad , \quad 0 = \frac{|\Omega_{12}|^2}{E_2} + \frac{|\Omega_{23}|^2}{E_2 - E_3} \quad , \quad 0 = \frac{|\Omega_{13}|^2}{E_3} + \frac{|\Omega_{23}|^2}{E_3 - E_2} \ .$$

Resolving the first equation by E_3 and substituting into the third, we obtain,

$$E_3 = -\frac{|\Omega_{13}|^2}{|\Omega_{12}|^2} E_2 \quad , \quad 0 = |\Omega_{12}|^2 + |\Omega_{13}|^2 + |\Omega_{23}|^2 \ ,$$

which is impossible to satisfy.

27.2 Variational method

27.2.1 The Rayleigh fraction

Let us assume that we want to calculate the ground state energy E_g of a system described by a Hamiltonian $\hat{H}$, but we do not know the wavefunction, and we do not know how to solve the Schrödinger equation. If at least we had a good idea of the generic form of the solution (Gaussian, sinusoidal, ..), we could choose a trial function with a free parameter and optimize this parameter minimizing the energy, which ought to be minimal for the ground state. This is precisely the idea of the *variational method*. Note that the variational method only works for the ground state.

For any function ψ we know that the *Rayleigh fraction* $\mathcal{E}$ satisfies,

$$E_g \leq \frac{\langle\psi|\hat{H}|\psi\rangle}{\langle\psi|\psi\rangle} \equiv \mathcal{E} \ , \tag{27.26}$$

not only when ψ is the wavefunction of an excited state, but even when it represents a (imperfect) trial to the ground state. Assuming normalized wavefunctions we can discard the denominator $\langle\psi|\psi\rangle = 1$. To verify the theorem, we expand the function ψ into orthonormal (unknown) eigenfunctions, $|\psi\rangle = \sum_n c_n|\psi_n\rangle$. Since ψ is normalized,

$$1 = \langle\psi|\psi\rangle = \sum_{m,n}\langle\psi_m|c_m^* c_n|\psi_n\rangle = \sum_n |c_n|^2 \ . \tag{27.27}$$

In the same way,

$$\langle\psi|\hat{H}|\psi\rangle = \sum_{m,n}\langle\psi_m|c_m^* \hat{H} c_n|\psi_n\rangle = \sum_n E_n|c_n|^2 \ . \tag{27.28}$$

As the ground state is that of the lowest energy, $E_g \leq E_n$, we have demonstrated the relationship (27.26)

$$E_g = E_g \sum_n |c_n|^2 \leq \sum_n E_n|c_n|^2 = \langle\hat{H}\rangle \ . \tag{27.29}$$

In practice, the ansatz ψ_α for the ground state allows us to calculate an energy that must be minimized via

$$\boxed{\frac{\partial\langle\psi_\alpha|\hat{H}_\alpha|\psi_\alpha\rangle}{\partial\alpha} = 0} \ . \tag{27.30}$$

In the Excs. 27.2.3.1 and 27.2.3.2 we will approach the fundamental state of a quartic potential and a harmonic oscillator, respectively, by trying several trial wavefunctions and optimizing their free parameters.

27.2.2 Rayleigh-Ritz method

A modification of the variational method is the *Rayleigh-Ritz method*. Here, instead of using a trial function, we use a linear combination of eigenfunctions with variable coefficients: $|\psi\rangle = \sum_k c_k|k\rangle$. These variables are then optimized to minimize the Rayleigh fraction,

$$E_g \leq \frac{\sum_{k,m} c_k^* c_m \langle k|\hat{H}|m\rangle}{\sum_{k,m} c_k^* c_m \langle k|m\rangle} = \mathcal{E} \ , \tag{27.31}$$

where we assume real coefficients and eigenfunctions. For this, the derivatives with respect to all coefficients must vanish:

$$\begin{aligned} 0 \equiv \frac{\partial \mathcal{E}}{\partial c_q} &= \frac{\sum_{k,m} \frac{\partial}{\partial c_q} c_k^* c_m \langle k|\hat{H}|m\rangle}{\sum_{k,m} c_k^* c_m \langle k|m\rangle} - \frac{\sum_{k,m} c_k^* c_m \langle k|\hat{H}|m\rangle \sum_{k,m} \frac{\partial}{\partial c_q} c_k^* c_m \langle k|m\rangle}{\left(\sum_{k,m} c_k^* c_m \langle k|m\rangle\right)^2} \\ &= \frac{\sum_{k,m} c_k^* \delta_{qm} \langle k|\hat{H}|m\rangle}{\sum_{k,m} c_k^* c_m \delta_{km}} - \mathcal{E} \frac{\sum_{k,m} c_k^* \delta_{qm} \delta_{km}}{\sum_{k,m} c_k^* c_m \delta_{km}} = \sum_k c_k^* \langle k|\hat{H}|q\rangle - \mathcal{E} c_q^* \ , \end{aligned} \tag{27.32}$$

using the definition of $\mathcal{E}$ (27.31). For the expression $\partial\mathcal{E}/\partial c_q^*$ we get analogous results. Hence,

$$\boxed{0 = \sum_m c_m (\langle q|\hat{H}|m\rangle - \mathcal{E}\langle q|m\rangle)} \ . \tag{27.33}$$

The condition for the existence of solutions is that the secular determinant disappears,

$$0 = \det(\langle q|\hat{H}|m\rangle - \mathcal{E}\langle q|m\rangle) \ . \tag{27.34}$$

The solution of this equation leads to a set of values $\mathcal{E}$, and the lowest value, $\mathcal{E}_{min}$, is the best approximation for the ground state energy. The coefficients of the wavefunction are obtained by solving the eigenvalue equation (27.33) with $\mathcal{E}_{min}$.

In Exc. 27.2.3.3 we derive the regression formulas for a linear *least squares fit* from a Rayleigh-Ritz variational. In Exc. 27.2.3.4 we will use the Rayleigh-Ritz method to estimate the effect of a finite nuclear mass of the hydrogen atom on the energy levels. In Exc. 27.2.3.5 we will use the Rayleigh-Ritz method to find the maximum number of atoms allowing for a stable Bose-Einstein condensate made of atoms subject to an attractive interatomic force.

27.2.3 Exercises

27.2.3.1 Ex: Variational method applied to a quartic potential

Determine the ground state energy of the quartic potential $V(x) = bx^4$ making the variational ansatz $\psi_\alpha(x) = (\alpha/\pi)^{1/4} e^{-\alpha x^2/2}$. **Formulae**:

$$\int_{-\infty}^{\infty} e^{-x^2} dx = \sqrt{\pi} \quad , \quad \int_{-\infty}^{\infty} x^2 e^{-x^2} dx = \tfrac{1}{2}\sqrt{\pi} \quad , \quad \int_{-\infty}^{\infty} x^4 e^{-x^2} dx = \tfrac{3}{4}\sqrt{\pi}$$

Solution: *The ansatz is already normalized, since*

$$\langle\psi_\alpha|\psi_\alpha\rangle = \sqrt{\frac{\alpha}{\pi}}\int_{-\infty}^{\infty} e^{-\alpha x^2}dx = 1 \ .$$

The energy follows from,

$$\begin{aligned}\langle\psi_\alpha|\hat{H}|\psi_\alpha\rangle &= \sqrt{\frac{\alpha}{\pi}}\int_{-\infty}^{\infty} e^{-\alpha x^2/2}\left(-\frac{\hbar^2}{2m}\frac{d^2}{dx^2}+bx^4\right)e^{-\alpha x^2/2}dx \\ &= -\frac{\hbar^2}{2m}\sqrt{\frac{\alpha}{\pi}}\int_{-\infty}^{\infty}(-\alpha+\alpha^2x^2)e^{-\alpha x^2}dx + b\sqrt{\frac{\alpha}{\pi}}\int_{-\infty}^{\infty}x^4e^{-\alpha x^2}dx = \frac{\hbar^2\alpha}{4m}+\frac{3b}{4\alpha^2} \ .\end{aligned}$$

The energy is minimal when,

$$0 = \frac{d\langle\psi_\alpha|\hat{H}|\psi_\alpha\rangle}{d\alpha} = \frac{d}{d\alpha}\left(\frac{\hbar^2\alpha}{4m}+\frac{3b}{4\alpha^2}\right) = \frac{1}{4}\frac{\hbar^2\alpha^3-6bm}{m\alpha^3} \ .$$

Hence, $\alpha = \left(\frac{6bm}{\hbar^2}\right)^{1/3}$ *and,*

$$\langle\psi_\alpha|\hat{H}|\psi_\alpha\rangle = \frac{3}{4}\left(\frac{3b\hbar^2}{4m^2}\right)^{1/3} \ .$$

27.2.3.2 Ex: Variational method applied to the harmonic oscillator

Obtain, through the variational method, the ground state energy of the one-dimensional harmonic oscillator described by the Hamiltonian $\hat{H} = -\frac{\hbar^2}{2m}\frac{d^2}{dx^2}+\frac{1}{2}m\omega^2x^2$, and the corresponding wavefunction from the test functions
a. $\psi(x) = Ae^{-\alpha x^2}$ being α a constant;
b. $\psi(x) = A/(x^2+\beta^2)$ being β a constant;
c. $\psi(x) = A\cos(\pi x/a)$ between the limits $\pm a/2$ being a a constant.

Solution: *a. Normalization requires*

$$1 = |A|^2\int_{-\infty}^{\infty}e^{-2\alpha x^2}dxA = |A|^2\sqrt{\frac{\pi}{2\alpha}} \ .$$

Now,

$$\begin{aligned}\langle\hat{H}\rangle &= -\frac{\hbar^2}{2m}|A|^2\int_{-\infty}^{\infty}e^{-\alpha x^2}\frac{d^2}{dx^2}e^{-\alpha x^2}dx + \frac{m}{2}\omega^2|A|^2\int_{-\infty}^{\infty}e^{-\alpha x^2}x^2e^{-\alpha x^2}dx \\ &= -\frac{\hbar^2}{2m}\sqrt{\frac{2\alpha}{\pi}}\int_{-\infty}^{\infty}2\alpha e^{-2\alpha x^2}\left(-1+2\alpha x^2\right)dx + \frac{m}{2}\omega^2\sqrt{\frac{2\alpha}{\pi}}\int_{-\infty}^{\infty}e^{-2\alpha x^2}x^2dx \\ &= \frac{\hbar^2}{2m}\sqrt{\frac{2\alpha}{\pi}}(2\alpha)^{1/2}\int_{-\infty}^{\infty}e^{-x^2}dx + \left(-\frac{\hbar^2}{2m}\sqrt{\frac{2\alpha}{\pi}}(2\alpha)^2+\frac{m}{2}\omega^2\sqrt{\frac{2\alpha}{\pi}}\right)\frac{1}{(2\alpha)^{3/2}}\int_{-\infty}^{\infty}e^{-x^2}x^2dx \\ &= \frac{\hbar^2}{2m}\sqrt{\frac{2\alpha}{\pi}}(2\alpha)^{1/2}\sqrt{\pi} + \left(-\frac{\hbar^2}{2m}\sqrt{\frac{2\alpha}{\pi}}(2\alpha)^2+\frac{m}{2}\omega^2\sqrt{\frac{2\alpha}{\pi}}\right)\frac{1}{(2\alpha)^{3/2}}\frac{1}{2}\sqrt{\pi} = \frac{\hbar^2\alpha}{2m}+\frac{m\omega^2}{8\alpha} \ .\end{aligned}$$

Now we vary $\hat{H}$ by α,

$$0 = \frac{d}{d\alpha}\langle\hat{H}\rangle = \frac{d}{d\alpha}\left(\frac{\hbar^2\alpha}{2m} + \frac{m\omega^2}{8\alpha}\right) = \frac{\hbar^2}{2m} - \frac{m\omega^2}{8\alpha^2} \ ,$$

and we estimate $\langle\hat{H}\rangle$ at the position of the minimum, $\alpha = \frac{m\omega}{2\hbar}$,

$$\langle\hat{H}\rangle = \frac{\hbar\omega}{2} \ .$$

b. Normalization requires

$$1 = |A|^2 \int_{-\infty}^{\infty} \frac{1}{(x^2+\beta^2)^2} dx = |A|^2 \left[\frac{1}{2}\frac{x}{\beta^2(x^2+\beta^2)} + \frac{1}{2\beta^3}\arctan\frac{x}{\beta}\right]_{-\infty}^{\infty} = \frac{\pi}{2\beta^3} \ .$$

With this

$$\begin{aligned}
\langle\hat{H}\rangle &= -\frac{\hbar^2}{2m}|A|^2 \int_{-\infty}^{\infty} \frac{1}{x^2+\beta^2}\frac{d^2}{dx^2}\frac{1}{x^2+\beta^2} dx + \frac{m}{2}\omega^2|A|^2 \int_{-\infty}^{\infty} \frac{1}{x^2+\beta^2} x^2 \frac{1}{x^2+\beta^2} dx \\
&= -\frac{\hbar^2}{2m}\frac{2\beta^3}{\pi} \int_{-\infty}^{\infty} \frac{6x^2-2\beta^2}{(x^2+\beta^2)^4} dx + \frac{m}{2}\omega^2\frac{2\beta^3}{\pi} \int_{-\infty}^{\infty} \frac{x^2}{(x^2+\beta^2)^2} dx \\
&= -\frac{\hbar^2}{2m}\frac{2\beta^3}{\pi}\left[-\frac{4}{3}\frac{x}{(x^2+\beta^2)^3} - \frac{1}{6}\frac{x}{\beta^2(x^2+\beta^2)^2} - \frac{1}{4\beta^4}\frac{x}{x^2+\beta^2} - \frac{1}{4\beta^5}\arctan\frac{x}{\beta}\right]_{-\infty}^{\infty} \\
&+ \frac{m}{2}\omega^2\frac{2\beta^3}{\pi}\left[-\frac{1}{2}\frac{x}{x^2+\beta^2} + \frac{1}{2\beta}\arctan\frac{x}{\beta}\right]_{-\infty}^{\infty} \\
&= \frac{\hbar^2}{2m}\frac{2\beta^3}{\pi}\frac{\pi}{4\beta^5} + \frac{m}{2}\omega^2\frac{2\beta^3}{\pi}\frac{\pi}{2\beta} = \frac{\hbar^2}{m4\beta^2} + \frac{m}{2}\omega^2\beta^2 \ .
\end{aligned}$$

Now we vary $\hat{H}$ by β,

$$0 = \frac{d}{d\beta}\langle\hat{H}\rangle = \frac{d}{d\beta}\left(\frac{\hbar^2}{m4\beta^2} + \frac{m}{2}\omega^2\beta^2\right) = -\frac{1}{2}\frac{\hbar^2 - 2m^2\omega^2\beta^4}{m\beta^3} \ ,$$

and we estimate $\langle\hat{H}\rangle$ at the position of the minimum, $\beta^2 = \frac{\hbar}{\sqrt{2}m\omega}$,

$$\langle\hat{H}\rangle = \frac{\hbar\omega}{\sqrt{2}} \ .$$

This estimate is $\sqrt{2}$ times larger than the estimate using a Gaussian trial function, which indicates that the Gaussian ansatz be closer to the exact wavefunction than the Lorentzian.

c. Normalization requires

$$1 = |A|^2 \int_{-a/2}^{a/2} \cos\frac{\pi x}{a}\cos\frac{\pi x}{a} dx = |A|^2\frac{a}{2} \ .$$

With this

$$\begin{aligned}\langle\hat{H}\rangle &= -\frac{\hbar^2}{2m}|A|^2\int_{-a/2}^{a/2}\cos\frac{\pi x}{a}\frac{d^2}{dx^2}\cos\frac{\pi x}{a}dx + \frac{m}{2}\omega^2|A|^2\int_{-a/2}^{a/2}x^2\cos^2\frac{\pi x}{a}dx \\ &= \sqrt{\frac{2}{a}}^2\left(\frac{\hbar^2}{2m}\frac{\pi^2}{a^2}\int_{-a/2}^{a/2}\cos^2\frac{\pi x}{a}dx + \frac{m}{2}\omega^2\int_{-a/2}^{a/2}x^2\cos^2\frac{\pi x}{a}dx\right) \\ &= \frac{2}{a}\left(\frac{\hbar^2}{2m}\frac{\pi^2}{a^2}\frac{a}{2} + \frac{m}{2}\omega^2\frac{a^3}{24}\frac{\pi^2-6}{\pi^2}\right) = \frac{\hbar^2}{2m}\frac{\pi^2}{a^2} + \frac{m}{2}\omega^2\frac{a^2}{12}\frac{\pi^2-6}{\pi^2}\ .\end{aligned}$$

Now we vary $\hat{H}$ by a,

$$0 = \frac{d\langle\hat{H}\rangle}{da} = \frac{d}{da}\left(\frac{\hbar^2}{2m}\frac{\pi^2}{a^2} + \frac{m}{2}\omega^2\frac{a^2}{12}\frac{\pi^2-6}{\pi^2}\right) = \frac{1}{12}\frac{-12\hbar^2\pi^4 + m^2\omega^2a^4\pi^2 - 6m^2\omega^2a^4}{ma^3\pi^2}\ ,$$

and we estimate $\langle\hat{H}\rangle$ at the position of the minimum, $a^4 = a_{ho}^4\frac{12\pi^4}{\pi^2-6}$,

$$\langle\hat{H}\rangle = \frac{\hbar\omega}{2}\sqrt{\frac{\pi^2-6}{3}}\ .$$

This estimate is $\sqrt{(\pi^2-6)/3} \approx 1.14$ times larger than the estimate using a Gaussian trial function, which indicates that the Gaussian ansatz be closer to the exact wavefunction than the cosine.

27.2.3.3 Ex: Linear least squares

Use the Raleigh-Ritz method to derive the regression coefficients for a linear fit $f(x_k) = ax_k + b$ to a set of data points (x_k, y_k).

Solution: *The sum of the squared deviations is,*

$$\chi = \sum_{k=1}^{N}[f(x_k) - y_k]^2 = \sum_{k=1}^{N}[ax_k + b - y_k]^2\ .$$

Its minimum with respect to b is given by,

$$0 = \frac{\partial\chi}{\partial b} = \sum_k 2(ax_k + b - y_k)\ .$$

Hence,

$$b = \frac{1}{N}\sum_k y_k - \frac{a}{N}\sum_k x_k = \bar{y} - a\bar{x}\ .$$

Its minimum with respect to a is now given by,

$$0 = \frac{\partial\chi}{\partial a} = \sum_k \frac{\partial}{\partial a}(ax_k + b - y_k)^2 = \sum_k 2(ax_k - a\bar{x} - y_k + \bar{y})(x_k - \bar{x})\ .$$

Hence,

$$a = \frac{\sum_k (x_k - \bar{x})(y_k - \bar{y})}{\sum_k (x_k - \bar{x})(x_k - \bar{x})} = \frac{\sum_k (x_k - \bar{x}) y_k}{\sum_k (x_k - \bar{x})^2} \ .$$

27.2.3.4 Ex: Effect of finite nuclear mass on hydrogen via Rayleigh-Ritz

Use the Rayleigh-Ritz method to estimate the impact of the finite mass of the nucleus of the hydrogen atom. To do this, calculate the ground state energy using the exact Hamiltonian, but a basis of wavefunctions assuming an infinitely heavy nucleus. Only take into account the states ψ_{100} and ψ_{200}. **Help:** Express the exact Hamiltonian in terms of the infinite-mass Hamiltonian approximating for small corrections of the reduced mass: $m \equiv m_e/(1+\gamma) \simeq (1-\gamma)m_e$, where $\gamma \equiv m_e/m_p$.

Solution: *The exact radial Hamiltonian follows from the transformation to the center-of-mass system,*

$$\hat{H}_m = -\frac{\hbar^2}{2m}\frac{d^2}{dr^2} - \frac{e^2}{4\pi\epsilon_0 r} \ ,$$

where $m = (1/m_e + 1/m_p)^{-1} = m_e/(1+\gamma) \simeq (1-\gamma)m_e$, *where* $\gamma \equiv m_e/m_p$. *However, when we solve the Schrödinger equation for the hydrogen atom, we use the approximate Hamiltonian* $\hat{H}_{m_e}$ *substituting* m *by* m_e. *We can rewrite the exact Hamiltonian in terms of the approximate one:*

$$\hat{H}_m = (1+\gamma)\hat{H}_{m_e} + \gamma\frac{e^2}{4\pi\varepsilon_0 r} \ .$$

The functions of the $1s$ *and* $2s$ *orbitals were derived for the approximate Hamiltonian,*

$$\psi_{100} = \sqrt{\tfrac{1}{\pi a_B^3}} e^{-r/a_B} \qquad \textit{and} \qquad \psi_{200} = \sqrt{\tfrac{1}{32\pi a_B^3}} \left(2 - \tfrac{r}{a_B} e^{-r/2a_B}\right) \ ,$$

where $a_B = \frac{4\pi\epsilon_0\hbar^2}{m_e e^2}$. *That is, the Bohr radius is calculated with the* real *mass of the electron and not the* reduced *mass,*

$$\langle 2|\hat{H}_m|1\rangle = (1+\gamma)E_n + \gamma\frac{e^2}{4\pi\varepsilon_0}\langle 2|\tfrac{1}{r}|1\rangle = (1+\gamma)E_n + \gamma\frac{e^2}{4\pi\varepsilon_0} 4\pi \int \psi^*_{200} r \psi_{100} d^3r = \frac{16E_1}{27\sqrt{2}}\gamma \ .$$

The other elements of the matrix are,

$$\langle k|m\rangle = \delta_{k,m} \qquad \textit{and} \qquad \langle 1|\hat{H}_m|2\rangle = \langle 2|\hat{H}_m|1\rangle = \frac{16\gamma}{27\sqrt{2}}E_1$$
$$\langle 1|\hat{H}_m|1\rangle = (1-\gamma)\frac{E_1}{1^2} \qquad \textit{and} \qquad \langle 2|\hat{H}_m|2\rangle = (1-\gamma)\frac{E_1}{2^2} \ .$$

with $E_1 = -\frac{m_e e^4}{32\pi^2\epsilon_0^2\hbar^2} = -\frac{\hbar^2}{2m_e a_B^2}$ *and* $E_n = \frac{E_1}{n^2}$. *Now,*

$$0 = \det(\langle k|\hat{H}_m|m\rangle - \mathcal{E}\langle k|m\rangle) = \begin{vmatrix} \langle 1|\hat{H}_m|1\rangle - \mathcal{E} & \langle 1|\hat{H}_m|2\rangle \\ \langle 2|\hat{H}_m|1\rangle & \langle 1|\hat{H}_m|1\rangle - \mathcal{E} \end{vmatrix}$$
$$= \begin{vmatrix} (1-\gamma)E_1 - \mathcal{E} & \frac{16}{27\sqrt{2}}\gamma E_1 \\ \frac{16}{27\sqrt{2}}\gamma E_1 & (1-\gamma)\frac{1}{4}E_1 - \mathcal{E} \end{vmatrix}$$
$$= \frac{1}{4}E_1^2 - \frac{1}{2}E_1^2\gamma - \frac{5}{4}E_1\mathcal{E} + \frac{1}{4}E_1^2\gamma^2 + \frac{5}{4}E_1\gamma\mathcal{E} + \mathcal{E}^2 - \frac{2^7}{3^6}\gamma^2 E_1^2 \ ,$$

with the solutions,

$$\mathcal{E} = E_1\left(\frac{5}{8}(1-\gamma) \pm \frac{3}{8}\sqrt{(1-\gamma)^2 + \frac{2^{13}}{3^8}\gamma^2}\right) = -\frac{\hbar^2}{2ma_{B^2}}\begin{cases} 0.999\ 46 \\ 0.249\ 95 \end{cases} .$$

The solution with the lower energy is obtained for the + sign, because E_1 *is negative. Hence, expanding this solution,*

$$\mathcal{E} \simeq E_1\left(1 - \gamma + \frac{1}{2}\frac{2^{13}}{3^8}\gamma^2 + ...\right) .$$

With the proton nucleus, the lowest energy $\mathcal{E}$ *is just a bit above the energy* E_1 *of the infinitely heavy nucleus. The coefficients follow from,*

$$c_1^2 + c_2^2 = 1 \qquad \textit{and} \qquad c_1(\langle 1|\hat{H}_m|1\rangle - \mathcal{E}) + c_2\langle 2|\hat{H}_m|1\rangle = 0$$
$$\textit{and} \qquad c_1\langle 1|\hat{H}_m|2\rangle + c_2(\langle 2|\hat{H}_m|2\rangle - \mathcal{E}) = 0 \ .$$

We find the solutions $c_1 = 1.000\ 00$ *and* $c_2 = -0.000\ 54 \simeq -\gamma$. *The* $2s$ *orbital mixes a little into the* $1s$ *and reduces its amplitude near the nucleus because of the finite mass.*

27.2.3.5 Ex: Collapse of a condensate with attractive interactions

A Bose-Einstein condensate of ^{7}Li may become unstable due to attractive interatomic force, the scattering length being $a_s = -27.3a_B$. Consider the radial Gross-Pitaevskii Hamiltonian derived in Exc. 25.1.5.2 with an external harmonic potential with the oscillation frequency $\omega_{trp}/(2\pi) = 50$ Hz. Using the variational method to determine the maximum number of atoms allowing for a stable condensate. (Note that the derived minimization condition must be evaluated numerically.)

Solution: *We want to minimize the radial Gross-Pitaevskii Hamiltonian,*

$$\hat{H}_\alpha = -\frac{\hbar^2}{2m}\frac{d^2}{dr^2} + \frac{m}{2}\omega^2 r^2 + \frac{g|\phi_\alpha(r)|^2}{r^2} \ ,$$

with $\psi_\alpha(\mathbf{r}) = \frac{\phi_\alpha(r)}{r}$ *and* $g = N\frac{4\pi\hbar^2 a_s}{m}$ *doing the ansatz* $\psi_\alpha(\mathbf{r}) = Ae^{-\alpha r^2}$. *Normaliza-*

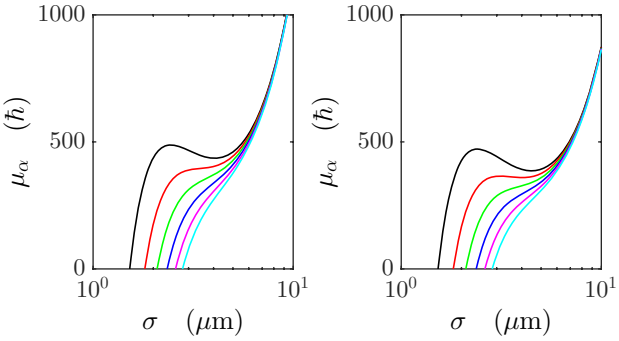

Figure 27.2: (code) Chemical potential as a function of the size of the BEC for various atom numbers between 1000 and 2000 calculated using the variational method (left) and by numerical integration (right).

tion requests,

$$1 = \langle\psi_\alpha|\psi_\alpha\rangle = 4\pi\int_0^\infty |\psi_\alpha(\mathbf{r})|^2 r^2 dr = 4\pi\int_0^\infty |\phi_\alpha(r)|^2 dr$$
$$= 4\pi\int_0^\infty A^2 e^{-2\alpha r^2} r^2 dr = A^2\sqrt{\frac{\pi}{2\alpha}}^3 .$$

Hence, $A^2 = \sqrt{2\alpha/\pi}^3$*. The ground state energy is now,*

$$\mu_\alpha = \langle\phi_\alpha|\hat{H}_\alpha|\phi_\alpha\rangle = 4\pi\int_0^\infty \phi_\alpha(r)\hat{H}_\alpha\phi_\alpha(r)dr$$
$$= 4\pi A^2\int_0^\infty re^{-\alpha r^2}\left[-\tfrac{\hbar^2}{2m}(-6\alpha+4r^2\alpha^2)+\tfrac{m}{2}\omega^2 r^2+gA^2e^{-2\alpha r^2}\right]re^{-\alpha r^2}dr$$
$$= \tfrac{4\pi A^2}{\alpha\sqrt{\alpha}}\tfrac{6\hbar^2\alpha}{2m}\int_0^\infty \zeta^2 e^{-2\zeta^2}d\zeta + \tfrac{4\pi A^2}{\alpha^2\sqrt{\alpha}}\left(-\tfrac{4\hbar^2\alpha^2}{2m}+\tfrac{m\omega^2}{2}\right)\int_0^\infty \zeta^4 e^{-2\zeta^2}d\zeta + \tfrac{4\pi A^2}{\alpha\sqrt{\alpha}}gA^2\int_0^\infty \zeta^2 e^{-4\zeta^2}d\zeta$$
$$= \tfrac{4\pi A^2}{\alpha\sqrt{\alpha}}\tfrac{6\hbar^2\alpha}{2m}\tfrac{1}{8}\sqrt{\tfrac{\pi}{2}} + \tfrac{4\pi A^2}{\alpha^2\sqrt{\alpha}}\left(-\tfrac{4\hbar^2\alpha^2}{2m}+\tfrac{m\omega^2}{2}\right)\tfrac{3}{32}\sqrt{\tfrac{\pi}{2}} + \tfrac{4\pi A^2}{\alpha\sqrt{\alpha}}gA^2\tfrac{\sqrt{\pi}}{32} = \tfrac{3\hbar^2\alpha}{2m}+\tfrac{m\omega^2}{2\alpha}+g\left(\tfrac{\alpha}{\pi}\right)^{3/2} .$$

Minimizing [262],

$$0 = \frac{\partial\mu_\alpha}{\partial\alpha} = \frac{\partial}{\partial\alpha}\left[\frac{3\hbar^2\alpha}{2m}+\frac{m\omega^2}{2\alpha}+g\left(\frac{\alpha}{\pi}\right)^{3/2}\right] = \frac{3\hbar^2\alpha^2 - m^2\omega^2 + 3\pi^{-3/2}g\alpha^{\frac{5}{2}}m}{2m\alpha^2}$$

we obtain

$$0 = 3\hbar^2\alpha^2 - m^2\omega^2 + 3\pi^{-3/2}g\alpha^{\frac{5}{2}}m .$$

This equation must be evaluated numerically. The challenge is to find the number of atoms for which μ_α *has no local minimum. Instead of doing this, here we simply trace some curves for various atom numbers. The figure above shows the chemical potential as a function of the size of the condensate* $\sigma = \alpha^{-1/2}$ *for atom numbers between 1000 (lower curve) and 2000 (upper curve).*

27.3 WKB approximation

The *WKB approximation* (from Wentzel-Kramers-Brillouin) [197, 751, 1370] is a method to find approximate solutions for linear differential equations with spatially variable coefficients. It is typically used for calculations in quantum mechanics where the wavefunction is reformulated as an exponential semi-classically expanded function, and then the amplitude or phase is slowly changed. In the following, we present the WKB approximation applied to the Schrödinger equation and exemplify it in some canonical systems.

27.3.1 WKB approximation applied to the Schrödinger equation

Starting from the time-independent Schrödinger equation,

$$-\frac{\hbar^2}{2m}\frac{d^2}{dx^2}\psi(x) + V(x)\psi(x) = E\psi(x) \ , \tag{27.35}$$

and rewrite it as follows,

$$\frac{d^2\psi}{dx^2} = k(x)\psi(x) \ . \tag{27.36}$$

with $k(x) = \sqrt{2m[E - V(x)]/\hbar^2}$. For now, we will restrict ourselves to energies $E > V(x)$. In this scheme, the wavefunctions are usually complex functions, so that we can write them in polar coordinates, containing an amplitude $A(x)$ and a phase $\phi(x)$, which are both real numbers:

$$\psi(x) = A(x)e^{\imath\phi(x)} \ . \tag{27.37}$$

Substituting this function into the Schrödinger equation we obtain a system of coupled equations in terms of $A(x)$ and $\phi(x)$,

$$A'' = A\Big[(\phi')^2 - k^2\Big] \qquad \text{and} \qquad (A^2\phi')' = 0 \ . \tag{27.38}$$

The equations (27.39) and (27.37) are completely equivalent to the Schrödinger equation. The second Eq. (27.38) is easy to solve,

$$A = \frac{C}{\sqrt{\phi'}} \ , \tag{27.39}$$

being C a real constant. We can not say the same thing about the solution of the first Eq. (27.38). In order to solve it we are going to use the WKB approach, assuming that A varies slowly, so the term $A'' \to 0$. By doing this approximation we can rewrite Eq. (27.39) in this way:

$$(\phi')^2 = k^2 \ . \tag{27.40}$$

Solving this last expression we obtain two linearly independent solutions, $\phi' = \pm k$. So we get the expression for the phase:

$$\phi(x) = \pm \int k(x)dx \ . \tag{27.41}$$

We write this indefinite integral, because the constant term can be absorbed by the constant C. Finally, we obtain the expression for the wavefunction in the WKB approximation:

$$\boxed{\psi(x) = \frac{C}{\sqrt{|k(x)|}} e^{\pm \int |k(x)| dx}} \ . \tag{27.42}$$

Here, taking the absolute value of the wavevector, we have already generalized for the case that the energy E of the particle is lower than the potential $V(x)$ (classically forbidden region).

Example 171 (*WKB approximation*): The WKB approach is a semiclassical method for the solution of the Schrödinger equation that does not require the potential to be a perturbation of a soluble problem. Instead, it only assumes that certain classical quantities having the dimension of an action (energy per time) are much larger than Planck's constant. Inserting the ansatz

$$\psi(x) = A e^{\imath S(x)/\hbar} \ ,$$

into the one-dimensional time-independent Schrödinger equation, we find,

$$-\tfrac{i\hbar}{2m} S''(x) + \tfrac{1}{2m} S'(x)^2 + V(x) - E = 0 \ .$$

Now we expand the exponent in orders of $\hbar$,

$$S(x) = S_0(x) + \hbar S_1(x) + \tfrac{\hbar^2}{2} S_2(x) + \dots \ ,$$

and insert it in the above equation. Collecting the orders in $\hbar$, we find in the first orders,

$$\begin{aligned} \left[\tfrac{1}{2m} S_0'(x)^2 + V(x) - E\right] \hbar^0 &= 0 \\ \left[-\tfrac{\imath\hbar}{2m} S_0''(x) + \tfrac{1}{m} S_0'(x) S_1'(x)\right] \hbar^1 &= 0 \\ \left[\tfrac{1}{2m} S_1'(x)^2 - \tfrac{\imath}{2m} S_1''(x)\right] \hbar^2 &= 0 \ . \end{aligned}$$

The solution of the zeroth order equation, $S_0(x) = \pm \int^x \sqrt{2m[E - V(x')}dx'$, gives

$$\psi(x) = A e^{\pm \frac{\imath}{\hbar} \int^x \sqrt{2m[E - V(x')}dx'} \ .$$

The WKB approximation can be used to describe continuous potentials (or barriers) by stepwise constant potentials. The transmission $|T|^2$ through these parts can be obtained by multiplying the individual tunneling probabilities,

$$\ln |T|^2 \simeq -2 \int_{barrier} \kappa(x) dx \ ,$$

with $\kappa(x) = \frac{1}{\hbar} \sqrt{2m[V(x) - E]}$.

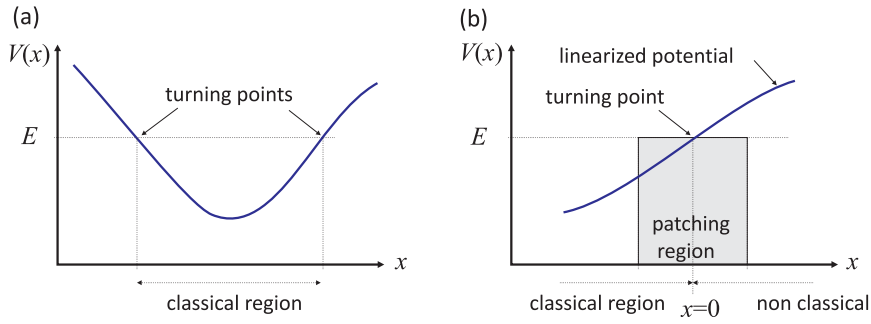

Figure 27.3: (a) Potential for which we want to obtain the connection formula. (b) Turning point.

27.3.2 Connection formulas

Now let us derive the connection formulas that interconnect solutions with E above and below $V(x)$ at the turning points, precisely those regions where WKB fails. We will apply the derivation to a generic confining potential shown in Fig. 27.3.

Let us start with the right turning point Fig. 27.3(a)]. First, we shift the coordinate system so that the turning point coincides with zero, as shown in Fig. 27.3(b). As seen above, the WKB solutions will be given by the following equations:

$$\psi(x) \approx \begin{cases} \frac{1}{\sqrt{k(x)}}\left[Be^{\imath\int_x^0 k(x')dx'} + Ce^{-\imath\int_x^0 k(x')dx'}\right] & \text{if} \quad x \leq 0 \\ \frac{1}{\sqrt{k(x)}} De^{-\int_0^x |k(x')|dx'} & \text{if} \quad x \geq 0 \end{cases} . \tag{27.43}$$

In the vicinity of the turning point we approximate the potential by a straight line (Taylor series expansion up to first order) with the following functional dependence,

$$V(x) \approx E + V'(0)x \ . \tag{27.44}$$

The Schrödinger equation for this potential acquires the following format,

$$\frac{d^2\psi_t}{dx^2} = \alpha^3 x\psi_t \ , \tag{27.45}$$

with $\alpha = [\frac{2m}{\hbar^2}V'(0)]^{1/3}$. Through a change of variables, $z = \alpha x$, we fall back on Airy's equation,

$$\frac{d^2\psi_t}{dz^2} = z\psi_t \ , \tag{27.46}$$

having as solution a linear combination of the two solutions of the Airy equation,

$$\psi_t(x) = a\text{Ai}(\alpha x) + b\text{Bi}(\alpha x) \ . \tag{27.47}$$

Now let's have a look at the WKB solutions in the two regions in the vicinity of the turning point. In the classically forbidden region we have $k(x) = \alpha^{3/2}\sqrt{-x}$, thus being $\int_0^x |k(x')|dx' = \frac{2}{3}(\alpha x)^{3/2}$. Thus, the WKB solution in the classically forbidden region near the turning point will be given by:

$$\psi(x) \approx \frac{D}{\sqrt{\hbar}\alpha^{3/4}x^{1/4}} e^{-\frac{2}{3}(\alpha x)^{3/2}} \ . \tag{27.48}$$

Using the asymptotic forms of Airy functions in the solution (27.47) we obtain the following expression for $\psi_t(x)$,

$$\psi_p(x) \approx \frac{a}{2\sqrt{\pi}(\alpha x)^{1/4}} e^{-\frac{2}{3}(\alpha x)^{3/2}} + \frac{b}{\sqrt{\pi}(\alpha x)^{1/4}} e^{\frac{2}{3}(\alpha x)^{3/2}} , \tag{27.49}$$

which when compared to equation (27.48) shows us that $a = \sqrt{\frac{4\pi}{\alpha\hbar}} D$ and $b = 0$. Repeating the previous steps in the negative region we see that the WKB solution in the asymptotic forms of the Airy solutions for approximately linear potentials takes the following format (with $b = 0$):

$$\psi(x) \approx \frac{1}{\sqrt{\hbar}\alpha^{3/4}(-x)^{1/4}} \left[B e^{\imath\frac{2}{3}(-\alpha x)^{3/2}} + C e^{-\imath\frac{2}{3}(-\alpha x)^{3/2}} \right] , \tag{27.50}$$

and

$$\psi_p(x) \approx \frac{a}{\sqrt{\pi}(-\alpha x)^{1/4}} \frac{1}{2\imath} \left[e^{\imath\pi/4} e^{\imath\frac{2}{3}(-\alpha x)^{3/2}} - e^{-\imath\pi/4} e^{-\imath\frac{2}{3}(-\alpha x)^{3/2}} \right] . \tag{27.51}$$

When compared, $\frac{a}{2\imath\sqrt{\pi}} e^{\imath\pi/4} = \frac{B}{\sqrt{\hbar\alpha}}$ and $-\frac{a}{2\imath\sqrt{\pi}} e^{-\imath\pi/4} = \frac{C}{\sqrt{\hbar\alpha}}$. Having all this information we can rewrite the WKB solutions for all positions in the potential, including the turning points [5]:

$$\psi(x) \approx \begin{cases} \frac{2D}{\sqrt{k(x)}} \sin\left[\int_x^{x_2} k(x')dx' + \frac{\pi}{4} \right] , & \text{if } x \le x_2 \\ \frac{D}{\sqrt{k(x)}} e^{-\int_{x_2}^{x} |k(x')|dx'} , & \text{if } x \ge x_2 \end{cases} . \tag{27.52}$$

Repeating the process for a decreasing turning point [left turning point of the potential of Fig. 27.3(a)], we obtain the following expression:

$$\psi(x) \approx \begin{cases} \frac{D'}{\sqrt{k(x)}} e^{-\int_{x}^{x_1} |k(x')|dx'} , & \text{if } x \le x_1 \\ \frac{2D'}{\sqrt{k(x)}} \sin\left[\int_{x_1}^{x} k(x')dx' + \frac{\pi}{4} \right] , & \text{if } x \ge x_1 \end{cases} . \tag{27.53}$$

Example 172 (*Harmonic oscillator*): Now we apply the WKB method to a well-known system: the harmonic oscillator. We will calculate its energy levels and the respective eigenfunctions.

Eigenenergies: First, note that for a confining potential, and more specifically in the region where $E \ge V(x)$, we have the solutions obtained for the left and right turning point, these two solutions must match each other, that is,

$$\frac{2D}{\sqrt{k(x)}} \sin\left[\int_x^{x_2} k(x')dx' + \frac{\pi}{4} \right] \simeq \frac{2D'}{\sqrt{k(x)}} \sin\left[\int_{x_1}^{x} k(x')dx' + \frac{\pi}{4} \right] ,$$

and hence the zeros of these functions, so the arguments of those sines must be equal (except for a multiple of π),

$$\begin{aligned} \int_x^{x_2} k dx' + \frac{\pi}{4} &= -\int_{x_1}^{x_1} k dx' - \frac{\pi}{4} + n\pi \qquad (27.54) \\ \left(\int_{x_1}^{x} + \int_x^{x_2} \right) k dx' &= \left(n - \frac{1}{2} \right)\pi \\ \int_{x_1}^{x_2} k dx' &= \left(n - \frac{1}{2} \right)\pi , \end{aligned}$$

[5] Note that we shifted the turning point to an arbitrary position x_2.

with $n = 1, 2...$ [6]. With this information we take a harmonic potential of the type $V(x) = \frac{1}{2}\kappa x^2$. In this case, the turning points for a given energy E will be at $-\sqrt{\frac{2E}{\kappa}}$ and $\sqrt{\frac{2E}{\kappa}}$. For this potential we will have that $k(x) = \sqrt{\frac{2m}{\hbar^2}(E - \frac{1}{2}\kappa x^2)}$. Calculating the integral of $k(x)$ between these two turning points we get,

$$\int_{x_1}^{x_2} k(x)dx = \frac{2m}{\hbar}\int_{-\sqrt{2E/k}}^{\sqrt{2E/k}} \sqrt{E - \frac{1}{2}\kappa x^2}dx = \pi E\frac{m}{\kappa} = \left(n - \frac{1}{2}\right)\pi\hbar \ ,$$

isolating E and taking $\omega = \sqrt{\kappa/m}$ we have,

$$E = (n - \tfrac{1}{2})\hbar\omega \ ,$$

with $n = 1, 2...$, the exact spectrum of the harmonic oscillator, but this is just a coincidence.

Eigenstates: Now we will calculate the eigenstates of the harmonic oscillator. The eigenfunctions were calculated on a computer. The first graph (Fig. 27.4) compares the first exact excited state with that obtained using the WKB method.

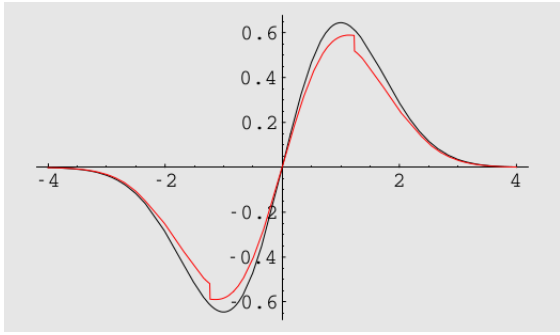

Figure 27.4: First excited state calculated accurately and through the WKB approximation.

Note that the WKB approach is very good when $x \to 0$ and $x \to \infty$, regions where the difference between the oscillator energy and the potential are large ($E \gg V(x \to 0)$ and $E \ll V(x \to \infty)$), because in these regions the wavelength $\lambda(x)$ acquires the lowest values, since it is proportional to $|1/\sqrt{E - V(x)}|$. Hence, the spatial region in which the potential needs to be practically constant is smaller, which explains why the approximation is closer to the exact solution. In the intermediate regions the difference between E and $V(x)$ begins to decrease, and the WKB approximation delivers its worst results.

As we increase the energy of the harmonic oscillator, the approximation becomes better (for the same reason as discussed in the previous paragraph). The following graph illustrates this effect for $n = 10$.

Example 173 (*Hydrogen atom*): Eigenenergies: For the hydrogen atom the effective potential is given by,

$$V(x) = -\frac{e^2}{4\pi\epsilon_0}\frac{1}{r} + \frac{\hbar^2}{2m}\frac{l(l+1)}{r^2} \ .$$

[6] Note that $n \neq 0$, because the integral (27.54) has to be greater than zero.

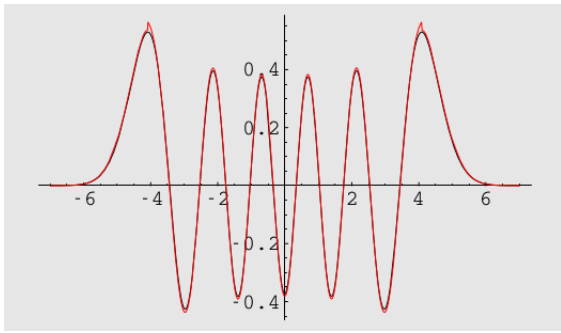

Figure 27.5: Wavefunction of the vibrational state $n = 10$ calculated exactly and using the WKB approximation.

Note that the WKB method for this case obeys the relation (27.54), hence we get,

$$\int_{r_1}^{r_2} p(r)dr = \sqrt{2m}\int_{r_1}^{r_2}\sqrt{E + \frac{e^2}{4\pi\epsilon_0}\frac{1}{r} - \frac{\hbar^2}{2m}\frac{l(l+1)}{r^2}}dr$$
$$= \sqrt{-2mE}\int_{r_1}^{r_2}\frac{1}{r}\sqrt{-r^2 - \frac{e^2}{4\pi\epsilon_0 E}r + \frac{\hbar^2}{2mE}l(l+1)}dr\ .$$

Notice that $E < 0$. Let us make the following substitution to facilitate algebraic manipulations,

$$B = -\frac{e^2}{4\pi\epsilon_0 E} \qquad \text{and} \qquad C = -\frac{\hbar^2}{2mE}l(l+1)\ .$$

The turning points r_1 and r_2 are given by the following expressions,

$$r_1 = \frac{B - \sqrt{B^2 - 4C}}{2} \qquad \text{and} \qquad r_2 = \frac{B + \sqrt{B^2 - 4C}}{2}\ .$$

Thus, returning to the integral we will have the following:

$$\int_{r_1}^{r_2} p(r)dr = \sqrt{-2mE}\int_{r_1}^{r_2}\frac{1}{r}\sqrt{(r-r_1)(r_2-r)}dr = \sqrt{-2mE}\frac{\pi}{2}(\sqrt{r_2} - \sqrt{r_1})^2$$
$$= \sqrt{-2mE}\frac{\pi}{2}(r_1 + r_2 - 2r_1r_2) = \sqrt{-2mE}\frac{\pi}{2}(B - 2\sqrt{C})$$
$$= \frac{\pi}{2}\Big(-\frac{e^2\sqrt{2m}}{4\pi\epsilon_0\sqrt{-E}} - 2\hbar\sqrt{l(l+1)}\Big) = \Big(n - \frac{1}{2}\Big)\pi\hbar\ .$$

Isolating E we obtain the energy spectrum of the hydrogen atom in the WKB approximation:

$$E = -\frac{m}{2\hbar}\Big(\frac{e^2}{4\pi\epsilon_0}\Big)^2\frac{1}{\Big[n - 1/2 + l(l+1)\Big]^2} = -\frac{13.6}{\Big[n - 1/2 + l(l+1)\Big]^2}eV\ .$$

For high energies ($n \gg l$), we recover Bohr's expression.

27.3.3 Exercises

27.3.3.1 Ex: Energy levels of hydrogen via WKB

Use the WKB approach to calculate the energy levels of the hydrogen atom.

Solution:

27.4 Time-dependent perturbations

Temporal perturbations typically occur when we suddenly switch on an external field that influences the motion or spin of the particles, or when the field varies over time, for example, an electromagnetic field. Let us first study a two-level system subject to a temporal perturbation.

27.4.1 Two-level systems

We write the perturbation as

$$\hat{H} = \hat{H}^{(0)} + \hat{H}^{(1)}(t) \ . \tag{27.55}$$

As in the case of a stationary perturbation, we write the eigenenergies and -functions of the unperturbed system as

$$\hat{H}^{(0)}|n\rangle = E_n|n\rangle \ . \tag{27.56}$$

Recalling that this stationary Schrödinger equation was obtained from the time-dependent Schrödinger equation via a separation ansatz (23.59), the temporal evolution of these eigenfunctions is given by,

$$|\psi_n^{(0)}(t)\rangle = |n\rangle e^{-\imath E_n t/\hbar} \ . \tag{27.57}$$

For small perturbations we can expect that the ansatz,

$$|\psi^{(1)}(t)\rangle = a_1(t)|\psi_1^{(0)}(t)\rangle + a_2(t)|\psi_2^{(0)}(t)\rangle \ , \tag{27.58}$$

be good. Note that not only do eigenfunctions oscillate, but the coefficients also depend on time, because the composition of the states can change. The instantaneous probability of finding the system in state n is $|a_n(t)|^2$. Importing the above linear combination into the Schrödinger equation,

$$\left[\hat{H}^{(0)} + \hat{H}^{(1)}(t)\right]|\psi^{(1)}(t)\rangle = \imath\hbar\frac{\partial}{\partial t}|\psi^{(1)}(t)\rangle \ , \tag{27.59}$$

we find,

$$\begin{aligned} &a_1\hat{H}^{(0)}|\psi_1^{(0)}\rangle + a_2\hat{H}^{(0)}|\psi_2^{(0)}\rangle + a_1\hat{H}^{(1)}|\psi_1^{(0)}\rangle + a_2\hat{H}^{(1)}|\psi_2^{(0)}\rangle \\ &\qquad = \imath\hbar\left[\frac{\partial a_1}{\partial t}|\psi_1^{(0)}\rangle + \frac{\partial a_2}{\partial t}|\psi_2^{(0)}\rangle + a_1\frac{\partial|\psi_1^{(0)}\rangle}{\partial t} + a_2\frac{\partial|\psi_2^{(0)}\rangle}{\partial t}\right] \\ \implies &a_1\hat{H}^{(1)}|\psi_1^{(0)}\rangle + a_2\hat{H}^{(1)}|\psi_2^{(0)}\rangle = \imath\hbar\dot{a}_1|\psi_1^{(0)}\rangle + \imath\hbar\dot{a}_2|\psi_2^{(0)}\rangle \ , \end{aligned} \tag{27.60}$$

because the other terms satisfy the Schrödinger equation of zero order. Replacing the stationary eigenfunctions,

$$a_1 e^{-\imath E_1 t/\hbar}\hat{H}^{(1)}|1\rangle + a_2 e^{-\imath E_2 t/\hbar}\hat{H}^{(1)}|2\rangle = \imath\hbar\dot{a}_1 e^{-\imath E_1 t/\hbar}|1\rangle + \imath\hbar\dot{a}_2 e^{-\imath E_2 t/\hbar}|2\rangle \ , \quad (27.61)$$

and multiplying this equation with $\langle 1|\times$ and $\langle 2|\times$, we find with the abbreviation $\hbar\omega_0 \equiv E_2 - E_1$,

$$\imath\hbar\dot{a}_1 = a_1\langle 1|\hat{H}^{(1)}|1\rangle + a_2 e^{-\imath\omega_0 t}\langle 1|\hat{H}^{(1)}|2\rangle \quad (27.62)$$

$$\text{and} \qquad \imath\hbar\dot{a}_2 = a_1 e^{\imath\omega_0 t}\langle 2|\hat{H}^{(1)}|1\rangle + a_2\langle 2|\hat{H}^{(1)}|2\rangle \ .$$

Frequently, the perturbation induces only a coupling, but does not directly influence the energies very much, $\langle n|\hat{H}^{(1)}|n\rangle \simeq 0$,

$$\boxed{\dot{a}_1 = a_2\frac{e^{-\imath\omega_0 t}}{\imath\hbar}\langle 1|\hat{H}^{(1)}|2\rangle \qquad \text{and} \qquad \dot{a}_2 = a_1\frac{e^{\imath\omega_0 t}}{\imath\hbar}\langle 2|\hat{H}^{(1)}|1\rangle} \ . \quad (27.63)$$

Without perturbation, $\langle m|\hat{H}^{(1)}|n\rangle = 0$, no dynamics develops; the eigenfunctions evolve independently.

27.4.2 The time-dependent perturbation method

Now, let us turn our attention to systems with many levels.

In *time-dependent perturbation theory* (TDPT) we separate the Hamiltonian into a stationary part and a time-dependent part [7,8],

$$\hat{H}(t) = \hat{H}^{(0)} + \lambda\hat{H}^{(1)}(t) \ . \quad (27.64)$$

As usual, this Hamiltonian satisfies the Schrödinger equation,

$$\imath\hbar\frac{\partial}{\partial t}|\psi(t)\rangle = \hat{H}(t)|\psi(t)\rangle \ . \quad (27.65)$$

Now, we do a unitary transformation into the *interaction picture* with $S(t) = e^{-\imath\hat{H}^{(0)}t/\hbar}$ substituting $|\psi(t)\rangle \equiv S(t)|\psi_I(t)\rangle$ and $\hat{H}^{(1)}(t) \equiv S(t)\hat{W}(t)S^{-1}(t)$ in the Schrödinger equation. This procedure removes the stationary part, as shown in Sec. 23.4.4,

$$\imath\hbar\frac{\partial}{\partial t}|\psi_I(t)\rangle = \lambda\hat{W}(t)|\psi_I(t)\rangle \ . \quad (27.66)$$

If $\hat{W}(t)$ is also independent of time, the solution simply is $|\psi_I(t)\rangle = e^{-\imath\hat{W}t/\hbar}|\psi_I(0)\rangle$. Otherwise, we integrate the equation,

$$|\psi_I(t)\rangle = |\psi_I(0)\rangle + \frac{\lambda}{\imath\hbar}\int_0^t \hat{W}(\tau)|\psi_I(\tau)\rangle d\tau \ . \quad (27.67)$$

[7] See Becker-Sauter II, p.118ff and [1298], p.104ff. An alternative treatment is found in [816], p.191ff or in Blochinzew, p.332ff.

[8] Note that by substituting $\hat{W}$ by $\hat{H}^{(1)}$, the equation (27.66), $\imath\hbar\partial_t|\psi_I(t)\rangle = \hat{H}^{(1)}(t)|\psi_I(t)\rangle$, corresponds to a first-order perturbative approximation, i.e., the perturbation eigenvalues $\hat{H}(1)$ are calculated with the eigenvectors of the unperturbed system. Thus, in first order TDPT we can substitute $\hat{W}$ for $\hat{H}^{(1)}$.

Substituting $|\psi_I(\tau)\rangle$ by $|\psi_I(t)\rangle$ we iterate this equation,

$$|\psi_I(t)\rangle = |\psi_I(0)\rangle + \frac{\lambda}{\imath\hbar}\int_0^t \hat{W}(\tau_1)\left(|\psi_I(0)\rangle + \frac{\lambda}{\imath\hbar}\int_0^{\tau_1}\hat{W}(\tau_2)|\psi_I(\tau_2)\rangle d\tau_2\right)d\tau_1 \tag{27.68}$$
$$= |\psi_I(0)\rangle + \frac{\lambda}{\imath\hbar}\int_0^t \hat{W}(\tau_1)d\tau_1|\psi_I(0)\rangle + \left(\frac{\lambda}{\imath\hbar}\right)^2\int_0^t\hat{W}(\tau_1)\int_0^{\tau_1}\hat{W}(\tau_2)|\psi_I(\tau_2)\rangle d\tau_2 d\tau_1\rangle$$
$$= \left[\sum\nolimits_{n=1}^{N}\left(\frac{\lambda}{\imath\hbar}\right)^n\int_0^t\hat{W}(\tau_1)\int_0^{\tau_1}\hat{W}(\tau_2)...\int_0^{\tau_{n-1}}\hat{W}(\tau_n)d\tau_1 d\tau_2...d\tau_n\right]|\psi_I(0)\rangle + o(\lambda^{N+1})\ .$$

This is called the *Dyson series*. For $N = 1$, we get the first order of the perturbation series [9],

$$|\psi_I(t)\rangle = \left(1 + \frac{\lambda}{\imath\hbar}\int_0^t\hat{W}(\tau)d\tau\right)|\psi_I(0)\rangle\ . \tag{27.69}$$

The stationary states of the unperturbed Hamiltonian are given by $\hat{H}^{(0)}|f\rangle = E_f|f\rangle$. Now, the perturbed states are expanded on this basis, $|\psi_I(t)\rangle = \sum_f |f\rangle a_f(t)$. The expansion coefficients are [10],

$$a_f(t) = \langle f|\psi_I(t)\rangle = \langle f|\psi_I(0)\rangle + \frac{\lambda}{\imath\hbar}\langle f|\int_0^t S^{-1}(\tau)\hat{H}^{(1)}(\tau)S(\tau)|\psi_I(0)\rangle d\tau\ . \tag{27.70}$$

Now, we assume that the system be initially in the eigenstate $|\psi_I(0)\rangle = |i\rangle$. The amplitudes then are,

$$a_{i\to f}(t) = \langle f|i\rangle + \frac{\lambda}{\imath\hbar}\int_0^t e^{\imath E_f\tau/\hbar}\langle f|\hat{H}^{(1)}(\tau)|i\rangle e^{-\imath E_i\tau/\hbar}d\tau \tag{27.71}$$
$$= \delta_{if} + \frac{\lambda}{\imath\hbar}\int_0^t\langle f|\hat{H}^{(1)}(\tau)|i\rangle e^{\imath\omega_{if}\tau}d\tau\ .$$

The time-varying potential generates a perturbation causing a variation of the system's state. As the energy is not conserved, $[\partial_t, \hat{H}(t)] \neq 0$, the time-dependence is not separable and the system exchanges energy with the potential. In first-order perturbation theory we only consider weak perturbations, i.e. the initial state is emptied only slowly, $a_{i\to i}(dt) \simeq a_{i\to i}(0) = 1$. On the other hand, for an initially empty state f the gain is obviously considerable. For $i \neq f$ we have,

$$\boxed{da_{i\to f}(t) = a_{i\to f}(t+dt) - a_{i\to f}(t) = \frac{\lambda}{\imath\hbar}\langle f|\hat{H}^{(1)}(t)|i\rangle e^{\imath\omega_{if}t}dt}\ . \tag{27.72}$$

This formula is nothing more than a generalization of the formula (27.63) obtained for a two-level system assuming that the initial state does not deplete considerably. In Exc. 27.4.5.1 we calculate the dynamics of a harmonic oscillator perturbed by a decaying force.

[9] For higher orders,

$$|\psi_I(t)\rangle \approx \left[\sum\nolimits_{n=1}^{N}\left(\frac{\lambda}{\imath\hbar}\right)^n\left(\int_0^t\hat{W}(\tau)d\tau\right)^n\right]|\psi_I(0)\rangle = T\left[\exp\left(\frac{\lambda}{\imath\hbar}\int_0^t\hat{W}(\tau)d\tau\right)\right]|\psi_I(0)\rangle\ .$$

[10] We could define the coefficients in Schrödinger's picture, $a_f \equiv \langle f|\psi\rangle$, but this would only introduce a phase factor, $a_{i\to f} \to a_{i\to f}e^{\imath(E_f-E_i)t/\hbar}$, which is unimportant for absolute values $|a_{i\to f}|^2$. This corresponds to a transformation to a rotating system, which will be discussed in Sec. 34.4.1.

27.4.3 Specific perturbations

27.4.3.1 Sudden switch-on of a constant perturbation

To begin with, we consider a constant perturbation $\hat{H}^{(1)}$ suddenly switched on at $t = 0$. In Schrödinger's picture we can rewrite Eq. (27.71),

$$a_{i\to f}(t) = \delta_{if} + \frac{\lambda}{\imath\hbar}\langle f|\hat{H}^{(1)}|i\rangle \int_0^t e^{\imath\omega_{if}\tau} d\tau = \delta_{if} + \frac{\lambda}{\imath\hbar}\langle f|\hat{H}^{(1)}|i\rangle \frac{-1+e^{\imath\omega_{if}t}}{\imath\omega_{if}} \ . \quad (27.73)$$

We obtain for $i \neq f$,

$$\boxed{|a_{i\to f}(t)|^2 = \frac{\lambda^2}{\hbar^2}|\langle f|\hat{H}^{(1)}|i\rangle|^2 \frac{\sin^2(\omega_{if}t/2)}{(\omega_{fi}/2)^2}} \ . \quad (27.74)$$

For long times we calculate the rate [11],

$$\frac{d}{dt}|a_{i\to f}(t)|^2 = \frac{\lambda^2}{\hbar^2}|\langle f|\hat{H}^{(1)}|i\rangle|^2 \frac{\sin\omega_{fi}t}{\omega_{fi}/2} \overset{t\to\infty}{\longrightarrow} \frac{2\pi\lambda^2}{\hbar^2}|\langle f|\hat{H}^{(1)}|i\rangle|^2 \delta(\omega_f - \omega_i) \ , \quad (27.75)$$

where we use the representation of the Dirac function,

$$\delta(x) = \lim_{t\to\infty} \tfrac{1}{2\pi} \int_{-t}^{t} e^{\imath kx} dk = \lim_{t\to\infty} \tfrac{t}{\pi} \mathrm{sinc}\ xt \ . \quad (27.76)$$

The δ-function in (27.75) ensures that, for infinitely sharp steps, transitions are impossible, unless the energy of the final state is the same as the one of the initial state. This points to the fact that infinitely sharp steps are not a realistic physical concept.

In practice, the changes applied to a system are often slow and the observation times are long, because the frequencies of the transitions are high $\omega_{fi}/2\pi \simeq$ THz. Let us assume that the perturbation be switched on within a time constant γ^{-1}. In Exc. 27.4.5.2 we will study how the rapidity of a perturbation influences the transition rate. We will see via a temporal analysis of $|a_{i\to f}(t)|^2$, that for slow variations, $\gamma \ll \omega_{fi}$, the system adiabatically approaches the final situation. For $\gamma \simeq \omega_{fi}$, the system receives a shock and exhibits oscillating transients. For $\gamma > \omega_{fi}$, we observe violent oscillations with largest amplitudes.

27.4.3.2 Periodic perturbations

We now consider the case of an oscillatory perturbation, for example an electromagnetic field. In principle, knowledge of the system's response to periodic perturbations allows us to treat arbitrary perturbations, since we can expand them in Fourier series. We first treat transitions between discrete levels, before considering states embedded in continua,

$$\hat{H}^{(1)}(t) = \begin{cases} 0 \quad \text{for} \quad t < 0 \\ 2\hbar\hat{\Omega}_0 \cos\omega t \quad \text{for} \quad t \geq 0 \end{cases} \ . \quad (27.77)$$

[11] We use the trigonometric rule $\sin x = 2\sin\frac{x}{2}\cos\frac{x}{2}$.

With the abbreviation $\Omega_{fi} \equiv \langle f|\hat{\Omega}_0|i\rangle$ the transition rate is,

$$a_{i\to f}(t) = -\imath\Omega_{fi}\int_0^t 2e^{\imath\omega_{fi}\tau}\cos\omega\tau d\tau \tag{27.78}$$
$$= -\imath\Omega_{fi}\left[\cancelto{0}{\frac{e^{\imath(\omega_{fi}+\omega)t}-1}{\imath(\omega_{fi}+\omega)}} + \frac{e^{\imath(\omega_{fi}-\omega)t}-1}{\imath(\omega_{fi}-\omega)}\right] .$$

The first term being small, we neglect it doing a so-called *rotating wave approximation* (RWA). We obtain,

$$|a_{i\to f}(t)|^2 = |\Omega_{fi}|^2\frac{\sin^2\frac{1}{2}(\omega_{fi}-\omega)t}{\frac{1}{4}(\omega_{fi}-\omega)^2} . \tag{27.79}$$

This result coincides with the formula (27.74), except that the energy difference between the states ω_{fi} is shifted by the frequency of the perturbation ω. The quantity $\Delta_{fi} \equiv \omega - \omega_{fi}$ is called a detuning. The transition probability is maximal, when we are at resonance, that is $\Delta_{fi} = 0$. In this case,

$$|a_{i\to f}(t)|^2 \longrightarrow |\Omega_{fi}|^2t^2 . \tag{27.80}$$

This can be seen by expanding the numerator in a Taylor series for small $(\omega_{fi}-\omega)t$.

Note, that the probability exceeds 1 for long times, which can not be. In fact, the restriction to the first order in the Taylor expansion used in the derivation of the last equation is no longer valid for long times, when $(\omega_{fi}-\omega)t > 1$, and we need to take into account higher orders.

Example 174 (*The Rabi formula*): Let us now come back to the two-level system studied in Sec. 27.4.1 and consider a periodic perturbation oscillating at frequency $\omega = \omega_0 + \Delta$, where Δ is called the *detuning* from the resonance whose frequency is ω_0,

$$H^{(1)} = -e\mathbf{E}(\mathbf{r},t)\cdot\mathbf{r} = -eE_0\hat{\varepsilon}\cos(kz-\omega t)\cdot\mathbf{r} . \tag{27.81}$$

Then,

$$\langle 2|H^{(1)}|1\rangle = -eE_0\cos(kz-\omega t)\langle 2|r|1\rangle = \hbar\Omega\cos(kz-\omega t) , \tag{27.82}$$

where we call

$$\Omega \equiv \frac{-eE_0\langle 2|r|1\rangle}{\hbar} \tag{27.83}$$

the *Rabi frequency*. With this abbreviation the Eqs. (27.63) become,

$$\dot{a}_1 = -\imath\Omega a_2e^{-\imath\omega_0t}\cos(kz-\omega t) \quad \text{and} \quad \dot{a}_2 = -\imath\Omega^*a_1e^{\imath\omega_0t}\cos(kz-\omega t) . \tag{27.84}$$

Neglecting fast-rotating terms doing the so-called *rotating wave approximation* (RWA) and choosing the position of the atom to be $z = 0$ we derive,

$$\dot{a}_1 \simeq -\frac{\imath\Omega}{2}a_2e^{\imath\Delta t} \quad \text{and} \quad \dot{a}_2 \simeq -\frac{\imath\Omega^*}{2}a_1e^{-\imath\Delta t} , \tag{27.85}$$

which coincides with the formulas derived in Sec. 27.4.1. With the equations of motion we can, starting from initial values for $a_1(0)$ and $a_2(0)$, calculate the temporal evolution.

We solve this system of differential equations by differentiating one and substituting the other,

$$\ddot{a}_2 = -\imath\dot{a}_1\frac{\Omega^*}{2}e^{-\imath\Delta t} - a_1\Delta\frac{\Omega^*}{2}e^{-\imath\Delta t} = -\frac{|\Omega|^2}{4}a_2 - \imath\Delta\dot{a}_2 \ . \tag{27.86}$$

We find solutions via the ansatz $a_2 = e^{-\imath\Delta t/2}(Ae^{\imath Gt/2}+Be^{-\imath Gt/2})$. The equation for a_2 yields,

$$\begin{aligned}(\tfrac{\imath}{2}G - \tfrac{\imath}{2}\Delta)^2 Ae^{\imath(G-\Delta)t/2} + (-\tfrac{\imath}{2}G - \tfrac{\imath}{2}\Delta)^2 Be^{\imath(-G-\Delta)t/2} \\ = -\tfrac{|\Omega|^2}{4}(Ae^{\imath(G-\Delta)t/2} + Be^{\imath(-G-\Delta)t/2} \\ - \imath\Delta\left[(\tfrac{\imath}{2}G - \tfrac{\imath}{2}\Delta)Ae^{\imath(G-\Delta)t/2} + (-\tfrac{\imath}{2}G - \tfrac{\imath}{2}\Delta)Be^{\imath(-G-\Delta)t/2}\right] \ .\end{aligned} \tag{27.87}$$

Separating the parts in A and in B we obtain two equations with the same result,

$$G^2 = |\Omega|^2 + \Delta^2 \ . \tag{27.88}$$

G is called the *generalized Rabi frequency*. Using the initial conditions, $a_1(0) = 1$ and $a_2(0) = 0$, we can fix one of the coefficients A and B, since $a_2(0) = A + B = 0$,

$$a_2 = 2\imath Ae^{-\imath\Delta t/2}\sin\tfrac{G}{2}t \ . \tag{27.89}$$

We now import this solution into the differential equation for a_1,

$$\dot{a}_1 = -\imath\frac{\Omega}{2}a_2e^{\imath\Delta t} = \Omega Ae^{\imath\Delta t/2}\sin\tfrac{G}{2}t \ . \tag{27.90}$$

The integral is,

$$a_1(t) = \int_0^t \Omega Ae^{\imath\Delta t'/2}\sin\tfrac{G}{2}t'dt' = -\frac{2A}{\Omega^*}e^{\imath\Delta t/2}\left(G\cos\tfrac{G}{2}t - \imath\Delta\sin\tfrac{G}{2}t\right) \ . \tag{27.91}$$

Using the normalization condition,

$$\begin{aligned}1 = |a_1|^2 + |a_2|^2 = \left|-\frac{2A}{\Omega^*}e^{\imath\Delta t/2}\left(G\cos Gt - \imath\Delta\sin\tfrac{G}{2}t\right)\right|^2 + \left|2\imath Ae^{-\imath\Delta t/2}\sin Gt\right|^2 \\ = \frac{4A^2}{|\Omega|^2}\left(G^2\cos^2\tfrac{G}{2}t + \Delta^2\sin^2\tfrac{G}{2}t\right) + 4A^2\sin^2\tfrac{G}{2}t = 4A^2\frac{G^2}{|\Omega|^2} \ .\end{aligned} \tag{27.92}$$

Hence, $A = |\Omega|/2G$. In general, we can choose Ω real, and the final solution is,

$$\boxed{a_1(t) = -e^{\imath\Delta t/2}\left(\cos\tfrac{G}{2}t + \tfrac{-\imath\Delta}{G}\sin\tfrac{G}{2}t\right) \quad \text{and} \quad a_2(t) = \tfrac{\imath\Omega}{G}e^{-\imath\Delta t/2}\sin\tfrac{G}{2}t} \ . \tag{27.93}$$

This results has already been obtained in Exc. 23.4.7.1 using an exact (i.e. not perturbative) calculus. When the energies E_n are degenerate, under the influence of the perturbation, the populations of the system oscillate with the Rabi frequency Ω. When the energies are different, the oscillation frequency G is higher, but the amplitude decreases as well. The initially empty state never reaches unitary population. In Exc. 27.4.5.3 we calculate the time required to allow the perturbation to invert the population of a two-level system, in Exc. 27.4.5.4 we study the maximum achievable inversion as a function of detuning, and in Exc. 27.4.5.5 we analyze the dynamics of a system subject to sequences of pulses.
In Exc. 27.4.5.6 we show a derivation using the Laplace transformation method.

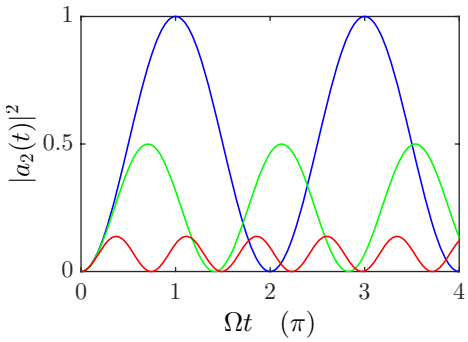

Figure 27.6: (code) Probability $|a_2(t)|^2$ for the atom to be in the excited state for $\Omega = \Gamma$ and $\Delta = 0$ (blue), $\Delta = \Gamma$ (green), and $\Delta = 2.5\Gamma$ (red). Time is in units of $1/\Gamma$.

27.4.3.3 Transitions to continuous levels

When there are several final states, $f \in F$, the formula (27.79) must be generalized. The total transition probability,

$$P_{i\to F}(t) = \sum_{f\in F} |a_{i\to f}(t)|^2 \ , \tag{27.94}$$

corresponds to the probability of the initial state $|i\rangle$ to be depleted. When the final state lies within a continuum, the sum in (27.94) must be replaced by an integral. With the *density of states* written in the form $\rho(E)$, where $\rho(E)dE$ is the number of states found in the energy range between E and $E + dE$, the transition probability is [12],

$$P_{i\to F}(t) = \int_{E_{min}}^{E_{max}} |a_{i\to f}(t)|^2 \rho(E_f) dE_f \ , \tag{27.95}$$

where $E \in [E_{min}, E_{max}]$ is the regime of energies within reach of the periodic perturbation. Now, plugging in the expression (27.79),

$$P_{i\to F}(t) = \int_{E_{min}}^{E_{max}} |\Omega_{fi}|^2 \frac{\sin^2 \frac{1}{2\hbar}(E_{fi} - E)t}{\frac{1}{4\hbar^2}(E_{fi} - E)^2} \rho(E_f) dE_f \ . \tag{27.96}$$

Again using the representation (27.76) of the Dirac function with the substitution $x \equiv (E_{fi} - E)/2\hbar$, we obtain after sufficiently long times [13],

$$P_{i\to F}(t) = \int_{E_{min}}^{E_{max}} |\Omega_{fi}|^2 t^2 \frac{\pi}{t} \delta(\tfrac{E_{fi}-E}{2\hbar}) \rho(E_f) dE_f = 2\pi\hbar t |\Omega_{fi}|^2 \rho(E_i + E) \ . \tag{27.97}$$

The transition rate is,

$$\frac{dP_{i\to F}(t)}{dt} = \pi\hbar |\Omega_{fi}|^2 \rho(E_i + E) \ . \tag{27.98}$$

[12] With $\rho(E) \equiv \sum_{f\in F} \delta(E_f - E)$ the integral is converted back into a sum.
[13] Remember $\delta(ax) = \frac{1}{a}\delta(x)$.

For a narrow distribution of final energies E centered around E_f we may substitute the density of states by a δ-distribution, $\rho(E) = \delta(E - E_f)$, so that,

$$\boxed{\frac{dP_{i\to F}}{dt} = \frac{2\pi}{\hbar}|\langle f|\hat{H}^{(1)}|i\rangle|^2\delta(E_{fi} - E)} \,, \tag{27.99}$$

where we went back to the definition of the perturbation Hamiltonian (27.77). This expression is called *Fermi's Golden rule*. In Exc. 27.4.5.7 we will calculate the *photoelectric effect*.

27.4.3.4 Continuous frequency distribution

To derive Eq. (27.79), we considered perturbations with fixed oscillation frequencies. To handle frequency distributions $\varrho(\omega)$, we must generalize this equation by calculating the integral,

$$\begin{aligned} |a_{i\to f}(t)|^2 &= |\Omega_{fi}|^2 \int \varrho(\omega)\frac{\sin^2\frac{1}{2}(\omega_{fi}-\omega)t}{\frac{1}{4}(\omega_{fi}-\omega)^2}d\omega \\ &\simeq |\Omega_{fi}|^2 t\varrho(\omega_{fi})\int_{-\infty}^{\infty}\mathrm{sinc}^2 x dx = \pi t|\Omega_{fi}|^2\varrho(\omega_{fi}-\omega) \,, \end{aligned} \tag{27.100}$$

again using the representation (27.76) of the Dirac function. The approximation $\varrho(\omega) = \varrho(\omega_{fi})$ can be used if the width of the sinc function is much narrower than the frequency distribution, which is the case for sufficiently long times, $t \gg \pi/2\Delta_{fi}$.

27.4.4 Transition rates for higher-order perturbations

The evolution from an initial state $|i\rangle$ that the system occupies at time t_0 to some final state $|\psi\rangle$, which may be a superposition, occupied at time t, is ruled by the solution of the Schrödinger equation,

$$|\psi\rangle = e^{-\imath\hat{H}(t-t_0)/\hbar}|i\rangle \,. \tag{27.101}$$

The probability to encounter $|\psi\rangle$ in a given state $|f\rangle$ is $|\langle f|\psi\rangle|^2$, and the *transition rate* is simply the derivative of this. The transition rate *out of the initial state* into any other final state is, consequently

$$\boxed{\frac{1}{\tau} = \sum_f \frac{d}{dt}|\langle f|e^{-\imath\hat{H}(t-t_0)/\hbar}|i\rangle|^2} \,. \tag{27.102}$$

From this formula we can already see, that at short times, when we can expand the exponential to first order, we will recover the results of (27.72).

Let us now consider a time-independent perturbation in the Schrödinger picture,

$$\hat{H}(t) = \hat{H}^{(0)} + \hat{H}^{(1)} \,, \tag{27.103}$$

where the time dependence is entirely left to the wavefunction. Now, we expand the propagator $e^{-\imath\hat{H}(t-t_0)}$ in a perturbative series [14]. Unfortunately, generally $[\hat{H}^{(0)}, \hat{H}^{(1)}] \neq$

[14] We drop the $\hbar = 1$ for the following calculation to simplify the notation.

0, so that we cannot simply assume $e^{-\imath\hat{H}t} \neq e^{-\imath\hat{H}^{(0)}t}e^{-\imath\hat{H}^{(1)}t}$. But we can calculate,

$$\imath\frac{d}{dt}e^{\imath\hat{H}^{(0)}t}e^{-\imath\hat{H}t} = -\hat{H}^{(0)}e^{\imath\hat{H}^{(0)}t}e^{-\imath\hat{H}t} + e^{\imath\hat{H}^{(0)}t}\hat{H}e^{-\imath\hat{H}t} = e^{\imath\hat{H}^{(0)}t}\hat{H}^{(1)}e^{-\imath\hat{H}t} \ . \quad (27.104)$$

Integrating both sides and resolving for $e^{-\imath\hat{H}t}$,

$$e^{-\imath\hat{H}t} = e^{-\imath\hat{H}^{(0)}t}\left\{e^{\imath\hat{H}^{(0)}t_0}e^{-\imath\hat{H}t_0} - \imath\int_{t_0}^{t} e^{\imath\hat{H}^{(0)}t_1}\hat{H}^{(1)}e^{-\imath\hat{H}t_1}dt_1\right\} \ . \quad (27.105)$$

We want to analyze a steady-state situation, that is, we assume that the interaction as gradually built up in an infinitely remote past. Hence, we can set $\hat{H} = \hat{H}^{(0)}$ for $t_0 \to -\infty$,

$$e^{-\imath\hat{H}t} = e^{-\imath\hat{H}^{(0)}t}\left\{1 - \imath\int_{-\infty}^{t} e^{\imath\hat{H}^{(0)}t_1}\hat{H}^{(1)}e^{\varepsilon t_1}e^{-\imath\hat{H}t_1}dt_1\right\} \ , \quad (27.106)$$

where the term $e^{\varepsilon t_1}$, with $\varepsilon \to 0$, is inserted to guarantee a smooth switch-on. We iterate,

$$\boxed{\begin{aligned} e^{-\imath\hat{H}t} &= e^{-\imath\hat{H}^{(0)}t}\left\{1 - \imath\int_{-\infty}^{t} e^{\imath\hat{H}^{(0)}t_1}\hat{H}^{(1)}e^{\varepsilon t_1}\times\right. \\ &\times \left. e^{-\imath\hat{H}^{(0)}t}\left[1 - \imath\int_{-\infty}^{t_1} e^{\imath\hat{H}^{(0)}t_2}\hat{H}^{(1)}e^{\varepsilon t_2}e^{-\imath\hat{H}t_2}dt_2\right]dt_1\right\} \end{aligned}} \ . \quad (27.107)$$

We calculate the matrix elements up to second order substituting $\hat{H}$ with $\hat{H}^{(0)}$ in the last integral,

$$\begin{aligned} &\langle f|e^{-\imath\hat{H}t}|i\rangle \quad (27.108)\\ &\simeq \langle f|e^{-\imath\hat{H}^{(0)}t}\left\{1 - \imath\int_{-\infty}^{t} e^{\imath\hat{H}^{(0)}t_1}\hat{H}^{(1)}e^{\varepsilon t_1}e^{-\imath\hat{H}^{(0)}t_1}\left[1 - \imath\int_{-\infty}^{t_1} e^{\imath\hat{H}^{(0)}t_2}\hat{H}^{(1)}e^{\varepsilon t_2}e^{-\imath\hat{H}^{(0)}t_2}dt_2\right]dt_1\right\}|i\rangle \\ &= e^{-\imath\omega_f t}\langle f|i\rangle - \imath e^{-\imath\omega_f t}\int_{-\infty}^{t} e^{\imath\omega_f t_1}\langle f|\hat{H}^{(1)}|i\rangle e^{\varepsilon t_1}e^{-\imath\omega_i t_1}dt_1 \\ &\quad - e^{-\imath\omega_f t_1}\int_{-\infty}^{t} e^{\imath\omega_f t_1}\langle f|\hat{H}^{(1)}e^{\varepsilon t_1}e^{-\imath\omega_i t_1}\sum_m |m\rangle\langle m|\int_{-\infty}^{t_1} e^{\imath\hat{H}^{(0)}t_2}\hat{H}^{(1)}|i\rangle e^{\varepsilon t_2}e^{-\imath\omega_i t_2}dt_2 dt_1 \ . \end{aligned}$$

where we separated the perturbation orders and inserted $\sum_m |m\rangle\langle m| = 1$ using the

closure relation. Using the time-independence of $\hat{H}^{(1)}$,

$$\begin{aligned}
\langle f|e^{-\imath\hat{H}t}|i\rangle &\simeq e^{-i\omega_{fi}t}\delta_{fi} - \imath e^{-\imath\omega_f t}\langle f|\hat{H}^{(1)}|i\rangle \int_{-\infty}^{t} e^{(\imath\omega_f - \imath\omega_i+\varepsilon)t_1}dt_1 \qquad (27.109)\\
&\quad - e^{-\imath\omega_f t}\sum_m \langle f|\hat{H}^{(1)}|m\rangle\langle m|\hat{H}^{(1)}|i\rangle \int_{-\infty}^{t} e^{(\imath\omega_f - \imath\omega_i+\varepsilon)t_1}\int_{-\infty}^{t_1} e^{(\imath\omega_m - \imath\omega_i+\varepsilon)t_2}dt_2dt_1\\
&= e^{-\imath\omega_{fi}t}\delta_{fi} - \imath e^{-\imath\omega_f t}\langle f|\hat{H}^{(1)}|i\rangle \frac{e^{(\imath\omega_f - \imath\omega_i+\varepsilon)t}}{\imath(\omega_f-\omega_i)+\varepsilon}\\
&\quad - e^{-\imath\omega_f t}\sum_m \langle f|\hat{H}^{(1)}|m\rangle\langle m|\hat{H}^{(1)}|i\rangle \int_{-\infty}^{t} e^{(\imath\omega_f - \imath\omega_m+\varepsilon)t_1}\frac{e^{(\imath\omega_m - \imath\omega_i+\varepsilon)t_1}}{\imath(\omega_m-\omega_i)+\varepsilon}dt_1\\
&= e^{-\imath\omega_{fi}t}\delta_{fi} - \imath\langle f|\hat{H}^{(1)}|i\rangle \frac{e^{(-\imath\omega_i+\varepsilon)t}}{\imath(\omega_f-\omega_i)+\varepsilon}\\
&\quad - e^{-\imath\omega_f t}\sum_m \frac{\langle f|\hat{H}^{(1)}|m\rangle\langle m|\hat{H}^{(1)}|i\rangle}{\imath(\omega_m-\omega_i)+\varepsilon}\int_{-\infty}^{t} e^{(\imath\omega_f - \imath\omega_i+2\varepsilon)t_1}dt_1\\
&= e^{-\imath\omega_{fi}t}\delta_{fi} - \imath\langle f|\hat{H}^{(1)}|i\rangle \frac{e^{(-\imath\omega_i+\varepsilon)t}}{\imath(\omega_f-\omega_i)+\varepsilon} - \sum_m \frac{\langle f|\hat{H}^{(1)}|m\rangle\langle m|\hat{H}^{(1)}|i\rangle}{\imath(\omega_m-\omega_i)+\varepsilon}\frac{e^{(-\imath\omega_i+2\varepsilon)t}}{\imath(\omega_f-\omega_i)+2\varepsilon}\,.
\end{aligned}$$

These three terms represent the zeroth, first, and second perturbation orders of the propagation operator (27.101). They are also called *Feynman propagators*. Now, we can calculate the transition rate up to second order,

$$\begin{aligned}
\frac{1}{\tau} &= \frac{d}{dt}\sum_f \left|\langle f|e^{-\imath\hat{H}t}|i\rangle\right|^2 \qquad (27.110)\\
&= \lim_{\varepsilon\to 0}\sum_f \left|\langle f|\hat{H}^{(1)}|i\rangle - \sum_m \frac{\langle f|\hat{H}^{(1)}|m\rangle\langle m|\hat{H}^{(1)}|i\rangle}{-\imath\imath(\omega_m-\omega_i)-\imath\varepsilon}\right|^2 \frac{d}{dt}\left|\frac{e^{(-\imath\omega_i+\varepsilon)t}}{\imath(\omega_f-\omega_i)+\varepsilon}\right|^2\\
&= \sum_f \left|\langle f|\hat{H}^{(1)}|i\rangle - \sum_m \frac{\langle f|\hat{H}^{(1)}|m\rangle\langle m|\hat{H}^{(1)}|i\rangle}{(\omega_m-\omega_i)}\right|^2 \lim_{\varepsilon\to 0}\frac{2\varepsilon e^{2\varepsilon t}}{(\omega_f-\omega_i)^2+\varepsilon^2}\,.
\end{aligned}$$

The last fraction is a representation of the δ-function. Reintroducing $\hbar$, we finally obtain,

$$\boxed{\frac{1}{\tau} = \frac{2\pi}{\hbar^2}\sum_f \left|\langle f|\hat{H}^{(1)}|i\rangle + \frac{1}{\hbar}\sum_m \frac{\langle f|\hat{H}^{(1)}|m\rangle\langle m|\hat{H}^{(1)}|i\rangle}{\omega_i-\omega_m}\right|^2 \delta(\omega_f-\omega_i)}\,. \qquad (27.111)$$

The first term is *Fermi's Golden rule*, the second order corresponds to the *Kramers-Heisenberg formula*, which serves to describe Thomson, Rayleigh and Raman scattering. The generalization of this transition rate to all perturbation orders can be written,

$$\begin{aligned}
\frac{1}{\tau} = \frac{2\pi}{\hbar^2}\sum_f \Bigg|\langle f|\Bigg(\hat{H}^{(1)} + \frac{1}{\hbar}\sum_m \frac{\hat{H}^{(1)}|m\rangle\langle m|\hat{H}^{(1)}}{\omega_i-\omega_m} + \ \ldots \qquad (27.112)\\
+\frac{1}{\hbar^{n-1}}\sum_{m_1,\ldots,m_{n-1}} \frac{\hat{H}^{(1)}|m_1\rangle\langle m_1|\ldots|m_{n-1}\rangle\langle m_{n-1}|\hat{H}^{(1)}}{(\omega_i-\omega_{m_1})\ldots(\omega_i-\omega_{m_{n-1}})}\Bigg)|i\rangle\Bigg|^2 \delta(\omega_{fi})\,.
\end{aligned}$$

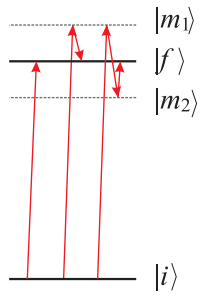

Figure 27.7: Graphical illustration of the various transitions orders. From left to right: absorption, Raman transition via an intermediate virtual state $|m_1\rangle$, three-photon process via two intermediate virtual states $|m_1\rangle$ and $|m_2\rangle$.

27.4.5 Exercises

27.4.5.1 Ex: Perturbed harmonic oscillator

Consider a one-dimensional harmonic oscillator (HO) initially prepared ($t = -\infty$) in the ground state $|0\rangle$ of the unperturbed Hamiltonian $H^{(0)} = \hbar\omega\hat{a}^\dagger\hat{a}$, such that $H^{(0)}|n\rangle = E_n|n\rangle$ with $E_n = n\hbar\omega$.
a. Through the expression, $a_f(t) \approx \frac{1}{i\hbar}\int_{t_i}^{t_f} W_{fi}e^{i\omega_{fi}t}dt$, and the perturbative Hamiltonian $W(t) = -e\mathcal{E}xe^{-t^2/\tau^2}$ (x is the position operator of the HO), applied between $t = -\infty$ and $t = +\infty$, calculate the probability of the system to be in the excited state $|n\rangle$, specifying n, at $t = +\infty$. Analyze the result.
b. Do the same for a shape-changing perturbation, $W(t) = \Lambda x^2 e^{-t^2/\tau^2}$.

Solution: *a. For this perturbation, the probability is,*

$$P_n = |\langle n|\psi\rangle|^2 = |a_{0\to n}(\infty)|^2 = \left|\delta_{0n} + \frac{1}{\imath\hbar}\int_{-\infty}^{\infty}\langle n|W|0\rangle e^{\imath\omega_{n0}t}dt\right|^2$$
$$= \left|\delta_{0n} - \frac{1}{\imath\hbar}e\mathcal{E}\int_{-\infty}^{\infty}\langle n|\hat{x}|0\rangle e^{-t^2/\tau^2}e^{\imath\omega_{n0}t}dt\right|^2 = \left|\delta_{0n} - \frac{e\mathcal{E}}{\imath\hbar}\frac{a_{ho}}{\sqrt{2}}\delta_{n1}\int_{-\infty}^{\infty}e^{-t^2/\tau^2}e^{\imath\omega t}dt\right|^2$$
$$= \left|\delta_{0n} - \frac{e\mathcal{E}}{\imath\hbar}\frac{a_{ho}}{\sqrt{2}}\delta_{n1}\sqrt{\pi}\tau e^{-\tau^2\omega^2/4}\right|^2 = \left|\delta_{0n} + \imath\delta_{n1}\frac{\sqrt{\pi}e\mathcal{E}\tau}{\sqrt{2m\hbar\omega}}e^{-\tau^2\omega^2/4}\right|^2 ,$$

such that,

$$P_{0\to 1} = \frac{\pi e^2\mathcal{E}^2\tau^2}{2m\hbar\omega}e^{-\tau^2\omega^2/2} .$$

To obtain transitions, the time scale τ of the perturbation must be adapted to provide Fourier components near the transition frequency. The rate is maximal for $\tau = \sqrt{2}/\omega$.

b. For this perturbation the probability is

$$\begin{aligned} P_n &= \left| \delta_{0n} + \frac{1}{\imath\hbar}\Lambda(1-\delta_{0n}) \int_{-\infty}^{\infty} \langle n|\hat{x}^2|0\rangle e^{-t^2/\tau^2} e^{\imath\omega_{n0}t} dt \right|^2 \\ &= \left| \delta_{0n} + \frac{\Lambda}{\imath\hbar} \frac{a_{ho}^2}{2} 2\delta_{n2} \int_{-\infty}^{\infty} e^{2i\omega t} e^{-t^2/\tau^2} dt \right|^2 \\ &= \left| \delta_{0n} + \frac{\Lambda}{\imath\hbar} \frac{a_{ho}^2}{2} 2\delta_{n2} \frac{\tau\sqrt{\pi}}{\sqrt{2}} e^{-\tau^2\omega^2} \right|^2 = \left| \delta_{0n} - \frac{\imath\sqrt{\pi}\Lambda\tau}{\sqrt{2}m\omega} \delta_{n2} e^{-\tau^2\omega^2} \right|^2 . \end{aligned}$$

such that,

$$P_{0\to 1} = \frac{\pi\Lambda^2\tau^2}{2m^2\omega^2} e^{-2\tau^2\omega^2} .$$

27.4.5.2 Ex: Impact of the rapidity of a perturbation

Here we consider a slow variation,

$$\hat{W}(t) = \begin{cases} 0 & \text{for} \quad t < 0 \\ W_0(1-e^{-\gamma t}) & \text{for} \quad t \geq 0 \end{cases} ,$$

with $\gamma \ll \omega_{fi}$.
a. Calculate the transition rate for long times, $t \gg \gamma^{-1}$.
b. Analyze the transition rate at a given time as a function of γ.

Solution: *Review this exercise!!!*
We calculate,

$$a_{i\to f}(t) = \frac{\langle f|\hat{W}_0|i\rangle}{\imath\hbar} \int_0^t (1-e^{-\gamma\tau}) e^{\imath\omega_{fi}\tau} d\tau = \frac{\langle f|\hat{W}_0|i\rangle}{\imath\hbar} \left[\frac{e^{\imath\omega_{fi}t}-1}{\imath\omega_{fi}} + \frac{e^{-\gamma t+\imath\omega_{fi}t}-1}{\gamma-\imath\omega_{fi}} \right] .$$

For $\gamma \ll \omega_{fi}$ we neglect the γ in the denominator,

$$a_{i\to f}(t) \simeq \frac{\langle f|\hat{W}_0|i\rangle}{\hbar\omega_{fi}} e^{\imath\omega_{fi}t} \left[-1+e^{-\gamma t}\right] .$$

a. For long times, $t \gg \gamma^{-1}$, we get,

$$a_{i\to f}(t) \overset{\gamma t\gg 0}{\longrightarrow} \frac{\langle f|\hat{W}_0|i\rangle}{\hbar\omega_{fi}} (-e^{\imath\omega_{fi}t}) ,$$

which joins the limit of the time-independent perturbation theory (27.12),

$$|a_{i\to f}(t)|^2 \overset{\gamma t\gg 0}{\longrightarrow} \left| \frac{\langle f|\hat{H}^{(1)}|i\rangle|}{\hbar\omega_{fi}} \right|^2 .$$

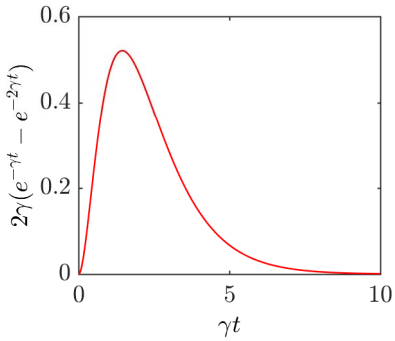

Figure 27.8: Transition rate for fixed $t = 1$ as a function of γ.

b. At a given time, the transition rate is,

$$\frac{d|a_{i\to f}|^2}{dt} = \left|\frac{\langle f|\hat{H}^{(1)}|i\rangle|}{\hbar\omega_{fi}}\right|^2 (2\gamma e^{-\gamma t} - 2\gamma e^{-2\gamma t}) \ .$$

27.4.5.3 Ex: Rabi oscillation

The population of a degenerate two-level system be initially in state $|1\rangle$. What should be the duration of a perturbation to transfer the population to state $|2\rangle$?

Solution: *Since $\omega_0 = 0$, the population of state $|2\rangle$ is,*

$$|a_2(t)|^2 = \frac{\Omega^2}{G^2}\sin^2 Gt = \sin^2 \Omega t \ .$$

For the sinus to reach 1, we need to wait for the time $t = \pi/2\Omega$ [15].

27.4.5.4 Ex: Rabi method

Free atoms be illuminated by light pulses characterized by the Rabi frequency Ω, whose pulse area is (i) $\int_0^t \Omega\ dt = \pi$ and (ii) $= 2\pi$. For which frequency tuning $\Delta = \omega - \omega_0$ the excited state population is maximum? Draw the spectral profile of the population in the range $-5 < \Delta/\Omega < 5$.

Solution: *The Schrödinger equation gives,*

$$\frac{\partial}{\partial t}|\psi\rangle = \begin{pmatrix} 0 & \frac{1}{2}\Omega \\ \frac{1}{2}\Omega & -\Delta \end{pmatrix} |\psi\rangle \ .$$

Deriving the second line and inserting it into the first one, we get,

[15] This is called π-*pulse*, because the frequency of Rabi is often defined as$\Omega/2$.

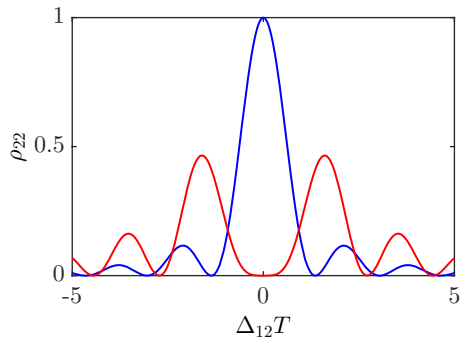

Figure 27.9: (code) Rabi fringes for (blue) a π-pulse and (red) a 2π-pulse.

$$\ddot{c}_2 = i\Delta\dot{c}_2 - \tfrac{1}{4}\Omega^2 c_2 \ .$$

The trial $c_2(t) = c_{20} + c_{2+}e^{\imath\chi t} + c_{2-}e^{-\imath\chi t}$ *gives the characteristic equation,*

$$-\chi^2 + \Delta\chi + \tfrac{1}{4}\Omega^2 = 0 \ .$$

With the initial conditions $c_2(0) = 0$ *the solution is,*

$$c_2(t) = c_2(0)e^{\imath\Delta t/2}(e^{\imath Gt/2} - e^{-\imath Gt/2}) \ ,$$

where $G \equiv \sqrt{\Delta^2 + \Omega^2}$*. Here,* $|c_2|^2 = \rho_{22}$ *is the population of the upper state. Therefore,*

$$|c_2|^2 \propto 2 - 2\cos(Gt) = 4\sin^2\tfrac{1}{2}Gt \ .$$

Considering, in particular, $n = \pi, 2\pi$*, the solution becomes,*

$$|c_2|^2 = \frac{\Omega^2}{G^2}\sin^2\tfrac{1}{2}G^2t = \frac{1}{1+(\Delta/\Omega)^2}\sin^2\frac{1}{2}\sqrt{1+(\Delta/\Omega)^2}n\pi \ .$$

27.4.5.5 Ex: Ramsey fringes

a. Consider a two-level atom illuminated by a $\frac{\pi}{2}$-pulse of nearly resonant light, $G \simeq \Omega$, and calculate the ground and excited state amplitudes.
b. How do the amplitudes evolve after the pulse if the detuning Δ is small but non-zero?
c. Derive the solution for $|a_2(t)|^2$ of the equations (27.63) for the resonant case ($\Delta = 0$) assuming the following initial conditions, $a_2(0) = \frac{e^{\imath\phi}}{\sqrt{2}}$ and $a_2(t = \frac{\pi}{2\Omega}) = 0$ if $\phi = 0$.
d. Discuss the case of two consecutive $\frac{\pi}{2}$-pulses separated by a time interval T.

Solution: *a. We exploit Eqs. (27.93), which holds for the initial condition that the atoms be in their ground state,*

$$a_1(t) = -e^{\imath\Delta t/2}\left(\cos\frac{G}{2}t + \frac{-\imath\Delta}{2G}\sin\frac{G}{2}t\right) \qquad \textit{and} \qquad a_2(t) = \frac{\imath\Omega}{G}e^{-\imath\Delta t/2}\sin\frac{G}{2}t \ .$$

Inserting $G \simeq \Omega = \frac{\pi}{2t}$ *we get after the first pulse,*

$$a_1(\tfrac{\pi}{2\Omega}) = -\frac{1}{\sqrt{2}} \qquad \text{and} \qquad a_2(\tfrac{\pi}{2\Omega}) = \frac{\imath}{\sqrt{2}} \ .$$

b. The coherence precesses according to,

$$a_1(t) = -\frac{1}{\sqrt{2}} e^{\imath \Delta T/2} \qquad \text{and} \qquad a_2(t) = \frac{\imath}{\sqrt{2}} e^{-\imath \Delta T/2} \ .$$

c. We use the same ansatz as in Eq. (27.87),

$$a_2 = e^{-\imath \Delta t/2}(A e^{\imath G t/2} + B e^{-\imath G t/2}) \ .$$

Inserting the first initial condition, $a_2(0) \equiv \frac{e^{\imath\phi}}{\sqrt{2}} = A + B$*, we get for the resonant case,*

$$a_2 = A e^{\imath \Omega t/2} + \left(\tfrac{e^{\imath\phi}}{\sqrt{2}} - A \right) e^{-\imath \Omega t/2} \ .$$

Now, we use the second initial condition setting $\phi = 0$*,*

$$0 \equiv a_2(t = \frac{\pi}{2\Omega}) = A e^{\imath \pi/4} + \left(\tfrac{1}{\sqrt{2}} - A \right) e^{-\imath \pi/4} \ ,$$

yielding $A = \frac{e^{\imath\pi/4}}{2}$*. Hence,*

$$a_2 \simeq \frac{e^{\imath\pi/4}}{2} e^{\imath \Omega t/2} + \left(\frac{e^{\imath\phi}}{\sqrt{2}} - \frac{e^{\imath\pi/4}}{2} \right) e^{-\imath \Omega t/2}$$

and

$$|a_2|^2 = 1 - \cos\phi \ .$$

d. Setting $\phi \equiv \Delta T$ *we see that the excited state population after the Ramsey pulse sequence oscillates with the free precession time period* T*.*

27.4.5.6 Ex: Two-level atom via Laplace transformation

Solve the problem of a two-level atom interacting with a laser using the Laplace transformation method.

Solution: *We consider the two-level system* $|\psi(t)\rangle = a(t)|1\rangle + b(t)|2\rangle$ *with the Hamiltonian in the rotating wave approximation,*

$$\hat{H} = \hat{H}^{(0)} + \hat{V} = \begin{pmatrix} 0 & c.c. \\ \frac{1}{2}\Omega e^{\imath\omega t} & \omega_0 \end{pmatrix} = \omega_0 |2\rangle\langle 2| + \tfrac{1}{2}\Omega e^{-\imath\omega t}|2\rangle\langle 1| + c.c. \ .$$

Entering into Schrödinger's equation, $|\dot{\psi}(t)\rangle = -\frac{\imath}{\hbar}\hat{H}(t)|\psi(t)\rangle$*, yields,*

$$\dot{a}|1\rangle + \dot{b}|2\rangle = -\frac{\imath}{\hbar}\left[\omega_0|2\rangle\langle 2| + \tfrac{1}{2}\Omega e^{-i\omega t}|2\rangle\langle 1| + \tfrac{1}{2}\Omega e^{\imath\omega t}|1\rangle\langle 2|\right]\left[a|1\rangle + b|2\rangle\right] \ .$$

Follows,

$$\dot{a} = -\tfrac{\imath\Omega}{2} e^{\imath\omega t} b \qquad \textit{and} \qquad \dot{b} = -\tfrac{\imath\Omega}{2} e^{-\imath\omega t} a - \imath\omega_0 b \ .$$

And by Laplace transformation,

$$p\tilde{a}(p) - a(t_0) = -\tfrac{\imath\Omega}{2}\tilde{b}(p-\imath\omega) \qquad \textit{and} \qquad p\tilde{b}(p) - b(t_0) = -\tfrac{\imath\Omega}{2}\tilde{a}(p+\imath\omega) - \imath\omega_0\tilde{b}(p) \ .$$

Now substitute $p \to p + \imath\omega$ and define $\Delta \equiv \omega - \omega_0$, $G = \sqrt{\Omega^2 + \Delta^2}$,

$$\tilde{b}(p) = \frac{(p+\imath\omega_0)b(t_0) - \frac{\imath\Omega}{2}a(t_0)}{(G/2)^2 + [p + \imath(\omega_0 + \Delta/2)]^2} \ .$$

The backward transformation is,

$$b(t) = e^{-\imath(\omega_0+\Delta/2)t}\left\{ b(0)\cos\frac{Gt}{2} - \frac{\imath}{G}\left[\Omega a(0) + \Delta b(0)\right]\sin\frac{Gt}{2}\right\} \ .$$

The population of the excited level is precisely $\rho_{22}(t) = |b(t)|^2$. In the same way we obtain the population of the ground level,

$$\tilde{a}(p) = \frac{(p-\imath\omega_0)a(t_0) - \frac{\imath\Omega}{2}b(t_0)}{(p-\imath\Delta)p + (\Omega/2)^2} \ ,$$

and

$$a(t) = e^{\imath(\Delta/2)t}\left\{ a(0)\cos\frac{Gt}{2} - \frac{\imath}{G}\left[\Omega b(0) + \Delta a(0)\right]\sin\frac{Gt}{2}\right\} \ .$$

We consider the particular case, $\Omega = 0$. The atom precedes in an unperturbed way,

$$a(t) = a(0) \qquad \textit{and} \qquad b(t) = b(0)e^{-\imath\omega t} \ .$$

27.4.5.7 Ex: Photoelectric effect

A hydrogen atom ground state in the ground state $1s$ is placed in an electric field $\mathbf{E}(t) = \mathbf{E}_0\cos\omega t$, such that $W(t) = -e\mathbf{r}\cdot\mathbf{E}(t) = W_0 e^{-\imath\omega t} + W_0^\dagger e^{\imath\omega t}$ with $W_0 = e\mathbf{r}\cdot\mathbf{E}_0/2$. Find, via Fermi's Golden rule,

$$R = \frac{2\pi}{\hbar}|\langle f|W(t)|i\rangle|^2\rho(E_f - E_i \mp \hbar\omega) \ ,$$

using the density of states $\rho(E_k)dE_k = V/(2\pi)^3 k^2 dk d\Omega$, the probability per unit of time for the atom to be ionized, by exciting from the ground state $\psi_{100}(\mathbf{r}) = e^{-r/a_B}/(\pi a_B^3)^{1/2}$ to the state described by the plane wave $\psi_{\mathbf{k}}(\mathbf{r}) = e^{-\imath\mathbf{k}\cdot\mathbf{r}}/V^{1/2}$. Simplify the calculation by assuming $\mathbf{E}_0 = E_0\hat{\mathbf{e}}_z$ and $\mathbf{k} = k\hat{\mathbf{e}}_z$.

Solution: *Transforming into the rotating system we realize that only one of the components $e^{\pm\imath\omega t}$ is resonant, such that we can discard the other:*

$$W(t) = W_0 e^{-\imath\omega t} \ .$$

Without loss of the generality we now choose $\mathbf{E}_0 = E_0\hat{\mathbf{e}}_z$,

$$\begin{aligned}\langle f|\hat{W}_0|i\rangle &= \int_{\mathbb{R}^3} d^3r' \frac{e^{\imath\mathbf{k}\cdot\mathbf{r}'}}{\sqrt{V}} \frac{e\mathcal{E}_0 z'}{2} \frac{1}{\sqrt{\pi a_B^3}} e^{-r'/a_B} \\ &= \frac{1}{\sqrt{V}} \frac{e\mathcal{E}_0}{2} \frac{1}{\sqrt{\pi a_B^3}} \int_0^\infty dr' r'^2 \int_{\mathbb{R}^2} d\Omega' e^{\imath\mathbf{k}\cdot\mathbf{r}'} r' \cos\theta' e^{-r'/a_B} \ .\end{aligned}$$

We need to expand the plane wave in terms of the spherical harmonics,

$$e^{\imath\mathbf{k}\cdot\mathbf{r}'} = 4\pi \sum_{\ell=0}^{\infty} \sum_{m=-\ell}^{\ell} \imath^\ell j_l kr' [Y_\ell^m(\theta,\phi)]^* Y_\ell^m(\theta',\phi') \ .$$

Inserting this above,

$$\langle f\hat{W}_0|i\rangle = \frac{4\pi e\mathcal{E}_0}{2(V\pi a_B^3)^{1/2}} \sum_{\ell=0}^{\infty} \imath^\ell \int_0^\infty dr' r'^3 e^{-r'/a_B} j_l(kr') \sum_{m=-\ell}^{\ell} [Y_\ell^m(\theta,\phi)]^* \int_{\mathbb{R}^2} d\Omega' Y_\ell^m(\theta',\phi') \cos\theta' \ .$$

Writing $\cos\theta'$ *as a function of the harmonics,* $\cos\theta' = \left(\frac{4\pi}{3}\right)^{1/2} [Y_1^0(\theta,\phi)]^*$, *due to the orthogonality of the spherical harmonics, we can simplify,*

$$\int_{\mathbb{R}^2} d\Omega' Y_\ell^m(\theta',\phi') \cos\theta' = \left(\tfrac{4\pi}{3}\right)^{1/2} \int_{\mathbb{R}^2} d\Omega' [Y_1^0(\theta,\phi)]^* Y_\ell^m(\theta',\phi') = \delta_{l,1}\delta_{m,0} \ .$$

This causes the matrix element to be,

$$\langle f\hat{W}_0|i\rangle = \frac{2\pi\imath e\mathcal{E}_0 \cos\theta}{(V\pi a_B^3)^{1/2}} \int_0^\infty dr' r'^3 e^{-r/a_B} \left(\frac{\sin kr'}{k^2 r'^2} - \frac{\cos kr'}{kr'} \right) \ .$$

We use the following tabulated integrals,

$$\int_0^\infty dr' r' e^{-r/a_B} \sin kr' = \frac{2ka_B^3}{(1+k^2a_B^2)^2} \quad \text{and} \quad \int_0^\infty dr' r'^2 e^{-r/a_B} \cos kr' = \frac{2a_B^3(1-3k^2a_B^2)}{(1+k^2a_B^2)^3} \ .$$

Therefore the radial integral is,

$$\int_0^\infty dr' r'^3 e^{-r/a_B} \left(\frac{\sin kr'}{k^2 r'^2} - \frac{\cos kr'}{kr'} \right) = \frac{8ka_B^5}{(1+k^2a_B^2)^3} \ ,$$

and the matrix element,

$$\langle f\hat{W}_0|i\rangle = 16\imath e\mathcal{E}_0 \cos\theta \left(\frac{\pi a_B^5}{V}\right)^{1/2} \frac{8ka_B}{(1+k^2a_B^2)^3} \ .$$

For the density of states we calculate, $\rho(E_k)dE_k = \rho(E_k)\frac{\hbar^2}{m}kdk \equiv \frac{V}{(2\pi)^3}k^2 dk d\Omega$, *yielding*

$$\rho(E_k) = \frac{V}{(2\pi)^3} \frac{m_e k}{\hbar^2} d\Omega \ .$$

The transition rate now becomes,

$$\frac{dR}{d\Omega} = \frac{2\pi}{\hbar^2}\frac{V}{(2\pi)^3}\frac{m_e k}{\hbar^2}\frac{256\pi e^2\mathcal{E}_0^2 a_B^5\cos^2\theta}{V}\frac{(ka_B)^2}{(1+(ka_B)^2)^6} = \frac{64\mathcal{E}_0^2 a_B^3\cos^2\theta}{\pi}\frac{(ka_B)^3}{(1+(ka_B)^2)^6} .$$

With the energy of the ground state of hydrogen,

$$E_1 = -\frac{\hbar^2}{2m_e a_B^2} \equiv \hbar\omega_0 ,$$

and energy conservation,

$$\hbar\omega = \frac{\hbar^2 k^2}{2m_e} + \hbar\omega_0 ,$$

we derive the abbreviation $(ka_B)^2 = \frac{\omega-\omega_0}{\omega_0}$ *which allows rewriting of the transition rate as,*

$$\frac{dR}{d\Omega} = \frac{4\pi\varepsilon_0 64\mathcal{E}_0^2 a_B^3}{\hbar}\frac{\omega_0^6}{\omega^6}\left(\frac{\omega}{\omega_0}-1\right)^{3/2}\cos^2\theta .$$

Only need to integrate over the solid angle, $\int d\Omega\cos^2\theta = 4\pi/3$,

$$R = \frac{256\mathcal{E}_0^2 a_B^3}{3\hbar}\frac{\omega_0^6}{\omega^6}\left(\frac{\omega}{\omega_0}-1\right)^{3/2} .$$

The frequency dependency is shown in the figure. Note, that the rate is zero directly above the ionization threshold. .

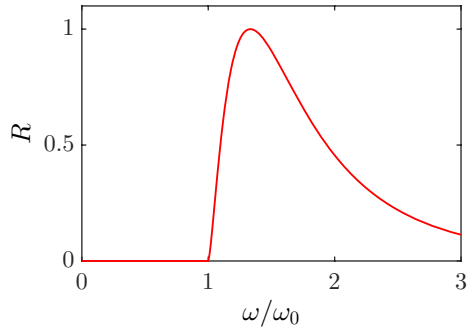

Figure 27.10: Photoelectric effect

27.4.5.8 Ex: Kicked harmonic oscillator in second order perturbation

Consider a one-dimensional harmonic oscillator initially in its ground state kicked via the $\hat{H}^{(1)}(t) = e^{\imath k\hat{x}}\Theta(t)$, as discussed in Sec. 24.6.2. Calculate the transition rate (27.102) to the final state $|f\rangle = |0\rangle$ in first and second order perturbation theory.

Solution: *The transition rate is given as,*

$$\frac{1}{\tau} = \frac{d}{dt}|\langle f|e^{-\imath\hat{H}(t-t_0)/\hbar}|0\rangle|^2 = \frac{2\pi}{\hbar^2}\left|\langle f|\hat{H}^{(1)}|0\rangle + \sum_m \frac{\langle f|\hat{H}^{(1)}|m\rangle\langle m|\hat{H}^{(1)}|0\rangle}{\omega_i - \omega_m}\right|^2 \delta(\omega_f - \omega_i) \ .$$

From (3.113) with $\alpha = \imath k a_{ho}/\sqrt{2}$,

$$\langle f|e^{ik\hat{x}}|0\rangle = \langle f|\alpha\rangle = e^{-|\alpha|^2/2}\frac{\alpha^f}{\sqrt{f!}} \ .$$

Hence, in first order,

$$\frac{1}{\tau_{0\to f}} = \frac{2\pi}{\hbar^2}|\langle f|e^{\imath k\hat{x}}|0\rangle|^2\delta(\omega_f - \omega_i) = \frac{2\pi}{\hbar^2}e^{-|\alpha|^2}\frac{|\alpha|^{2f}}{f!}\delta(\omega_f - \omega_i) \xrightarrow{f=0} \frac{2\pi}{\hbar^2}e^{-|\alpha|^2} \ .$$

In second order,

$$\begin{aligned}\frac{1}{\tau_{0\to f}} &= \frac{2\pi}{\hbar^2}\left|\sum_m \frac{\langle f|e^{\imath k\hat{x}}|m\rangle\langle m|e^{\imath k\hat{x}}|0\rangle}{\omega_i - \omega_m}\right|^2 \delta(\omega_f - \omega_i) \xrightarrow{f=0} \frac{2\pi}{\hbar^2}\left|\sum_m \frac{|\langle m|\alpha\rangle|^2}{\omega_i - \omega_m}\right|^2 \delta(0) \\ &= \frac{2\pi}{\hbar^2}e^{-2|\alpha|^2}\left|\sum_m \frac{|\alpha|^{2m}}{m!}\frac{1}{\omega_i - \omega_m}\right|^2 \delta(0) \ .\end{aligned}$$

27.4.5.9 Ex: Dynamic Stark shift induced by blackbody radiation

Calculate the dynamic Stark shift induced by blackbody radiation at $T = 300\,\mathrm{K}$ on the 1 mHz large strontium intercombination line at 698 nm.

Solution:

27.5 Further reading

C. Cohen-Tannoudji, B. Diu, F. Laloe, Wiley Interscience, *Quantum mechanics, vol. 1,2* [276]ISBN

Chapter 28

Appendices to 'Quantum Mechanics'

This chapter compiles some fundamental functions and polynomials, which are relevant in quantum theory.

28.1 Quantities and formulas in quantum mechanics

28.1.1 Atomic units

A system of units commonly used in atomic physics is the one of *atomic units*. This system is based on the system of Gaussian units (CGS) [1] defined by,

$$e_{cgs} = e/\sqrt{4\pi\varepsilon_0} \quad , \quad a_B = 1/\alpha \times \hbar/m_e c = \hbar^2/m_e e_{cgs}^2 \quad , \quad \hbar = 1 \ . \tag{28.1}$$

With this fixing we give the energy in terms of e_{cgs}^2/a_B, the wavevector in terms of $1/a_B$, the distance in terms of a_B and the mass in terms of m_e, such that,

$$\begin{aligned} \tilde{E} &= E/(e_{cgs}^2/a_B) \ , \\ \tilde{k} &= k a_B \ , \\ \tilde{R} &= R/a_B \ , \\ \tilde{\mu} &= \mu/m_e \ . \end{aligned} \tag{28.2}$$

This notation simplifies formulas in atomic physics. For example:

$$\begin{aligned} k = \sqrt{\tfrac{2\mu}{\hbar^2}(E-V)} \quad &\text{becomes} \quad \tilde{k} = \sqrt{2\tilde{\mu}(\tilde{E}-\tilde{V})} \ , \\ V = C_6 \tfrac{e_{cgs}^2 a_B^5}{R^6} \quad &\text{becomes} \quad \tilde{V} = \tfrac{C_6}{\tilde{R}^6} \ . \end{aligned} \tag{28.3}$$

[1] See script on *Electrodynamics* (2023).

28.2 Clebsch-Gordan and Wigner symbols

28.2.1 Clebsch-Gordan symbols

Clebsch-Gordan coefficients are used to describe spin coupling [2],

$$\langle j_1, m_1; j_2, m_2 | (j_1 j_2) j, m\rangle = \left(\begin{array}{cc|c} j_1 & j_2 & j \\ m_1 & m_2 & m \end{array}\right) = (-1)^{j_1 - j_2 + m}\sqrt{\Delta(j_1 j_2 j)}\times \tag{28.4}$$

$$\times \sqrt{(j_1+m_1)!(j_1-m_1)!(j_2+m_2)!(j_2-m_2)!(j+m)!(j-m)!}$$

$$\sum_t \frac{(-1)^t}{t!(-j_2+m_1+j+t)!(-j_1-m_2+j+t)!(j_1+j_2-j-t)!(j_1-m_1-t)!(j_2+m_2-t)!} .$$

28.2.2 $\{3j\}$-symbols

The Clebsch-Gordans are related to Wigner's *$\{3j\}$-symbols*,

$$\left(\begin{array}{cc|c} j_1 & j_2 & j \\ m_1 & m_2 & m \end{array}\right) = (-1)^{-j_1+j_2-m}\sqrt{2j+1}\begin{pmatrix} j_1 & j_2 & j \\ m_1 & m_2 & -m \end{pmatrix} , \tag{28.5}$$

with the abbreviation,

$$\Delta(j_1 j_2 j_3) \equiv \frac{(j_1+j_2-j_3)!(j_1-j_2+j_3)!(-j_1+j_2+j_3)!}{(j_1+j_2+j_3+1)!} . \tag{28.6}$$

Particular $\{3j\}$-symbols are,

$$\begin{pmatrix} j_1 & j_2 & j \\ 0 & 0 & 0 \end{pmatrix} = \frac{(-1)^{(j_1+j_2+j)/2}}{j_1/2+j_2/2+j/2+1}\frac{\sqrt{\Delta(j_1 j_2 j)}}{\Delta(\frac{j_1}{2}\frac{j_2}{2}\frac{j}{2})} , \tag{28.7}$$

and

$$\begin{pmatrix} 0 & j & j \\ 0 & 0 & 0 \end{pmatrix} = \frac{(-1)^j}{\sqrt{2j+1}} . \tag{28.8}$$

28.2.3 $\{6j\}$-symbols

$\{6j\}$-symbols describe the recoupling of two spins. They can be evaluated by,

$$\begin{Bmatrix} j_1 & j_2 & j_3 \\ J_1 & J_2 & J_3 \end{Bmatrix} = \sqrt{\Delta(j_1 j_2 j_3)\Delta(j_1 J_2 J_3)\Delta(J_1 j_2 J_3)\Delta(J_1 J_2 j_3)}\sum_t \frac{(-)^t(t+1)!}{f(t)} , \tag{28.9}$$

where,

$$f(t) = (t-j_1-j_2-j_3)!(t-j_1-J_2-J_3)!(t-J_1-j_2-J_3)!(t-J_1-J_2-j_3)! \tag{28.10}$$
$$(j_1+j_2+J_1+J_2-t)!(j_2+j_3+J_2+J_3-t)!(j_3+j_1+J_3+J_1-t)! .$$

[2] See [60], p.111 or [1298], p.119.

28.2.4 $\{9j\}$-symbols

$\{3j\}$-*symbols* describe the recoupling of three spins. They can be evaluated by,

$$\begin{Bmatrix} j_1 & j_2 & J_{12} \\ j_3 & j_4 & J_{34} \\ J_{13} & J_{24} & J \end{Bmatrix} = \sum_g (-)^{2g}(2g+1) \begin{Bmatrix} j_1 & j_2 & J_{12} \\ J_{34} & J & g \end{Bmatrix} \begin{Bmatrix} j_3 & j_4 & J_{34} \\ j_2 & g & J_{24} \end{Bmatrix} \begin{Bmatrix} J_{13} & J_{24} & J \\ g & j_1 & j_3 \end{Bmatrix} . \tag{28.11}$$

$\{9j\}$-symbols satisfy the following orthogonality relation,

$$\sum_{J_{12},J_{34}} \hat{J}_{12}\hat{J}_{34}\hat{H}_{13}\hat{H}_{24} \begin{Bmatrix} j_1 & j_2 & J_{12} \\ j_3 & j_4 & J_{34} \\ H_{13} & H_{24} & J \end{Bmatrix} \begin{Bmatrix} j_1 & j_2 & J_{12} \\ j_3 & j_4 & J_{34} \\ J_{13} & J_{24} & J \end{Bmatrix} = \delta_{J_{13}H_{13}}\delta_{J_{24}H_{24}} . \tag{28.12}$$

28.3 Functions and polynomials

28.3.1 The Gauss function

Indefinite integrals:

$$\int_{-\infty}^{\infty} e^{-ax^2} dx = \sqrt{\pi/a} \quad \text{and} \quad \int_0^{\infty} x^n e^{-ax^2} dx = \frac{\Gamma(\frac{n+1}{2})}{2a^{\frac{n+1}{2}}} . \tag{28.13}$$

Higher momenta:

$$\int_{x_0}^{x_1} e^{-ax^2} dx = xe^{-ax^2}\Big|_{x_0}^{x_1} + 2a\int_{x_0}^{x_1} x^2 e^{-ax^2} dx . \tag{28.14}$$

28.3.2 Bessel functions

The integral definition of the *Bessel function*, the *von Neumann function*, and the *Hankel function* of the first and second kind are:

$$\begin{aligned} J_k(x) &= \frac{1}{\pi}\int_0^{\pi} \cos(k\tau - x\sin\tau)d\tau = \frac{1}{2\pi}\int_{-\pi}^{\pi} e^{\imath(x\sin\tau - k\tau)} d\tau \\ N_k(x) &= ... \\ H_k^{(1,2)} &= J_k \pm \imath N_k . \end{aligned} \tag{28.15}$$

The derivative,

$$2\frac{dJ_k(x)}{dx} = J_{k-1}(x) - J_{k+1}(x) . \tag{28.16}$$

Sum rules (empirically found),

$$\sum_{k=-\infty}^{\infty} J_k(x) = \sum_{k=-\infty}^{\infty} J_k(x)^2 = 1 \neq \sum_{k=-\infty}^{\infty} |J_k(x)|^2 . \tag{28.17}$$

The *spherical Bessel function*, the *spherical von Neumann function*, and the *spherical Hankel function* of the first and second kind are defined by:

$$\begin{aligned} j_k(x) &= \sqrt{\frac{\pi}{2x}} J_{k+1/2}(x) \\ n_k(x) &= \sqrt{\frac{\pi}{2x}} N_{k+1/2}(x) = (-1)^{k+1} \sqrt{\frac{\pi}{2x}} J_{-k-1/2}(x) \\ h_k^{(1,2)} &= j_k \pm \imath n_k \ . \end{aligned} \tag{28.18}$$

The series,

$$j_k(x) = (-x)^k \left(\frac{1}{x} \frac{d}{dx} \right)^k \frac{\sin x}{x} \quad , \quad n_k(x) = -(-x)^k \left(\frac{1}{x} \frac{d}{dx} \right)^k \frac{\cos x}{x} \ . \tag{28.19}$$

The derivative,

$$j_k'(x) = \frac{k}{x} j_k(x) - j_{k+1}(x) \ . \tag{28.20}$$

28.3.3 Hermite polynomials

The definition of the *Hermite polynomials*:

$$\begin{aligned} H_n(x) &= \left(2x - \frac{d}{dx} \right)^n \cdot 1 = (-1)^n e^{x^2} \frac{d^n}{dx^n} e^{-x^2} = \frac{2^n}{\sqrt{\pi}} \int_{-\infty}^{\infty} (x + \imath t)^n e^{-t^2} dt \\ He_n(x) &\equiv 2^{-n/2} H_n(x) \ . \end{aligned} \tag{28.21}$$

Orthogonality and normalization:

$$\int_{-\infty}^{\infty} e^{-x^2} H_m(x) H_n(x) dx = \sqrt{\pi} 2^n n! \delta_{mn} \ . \tag{28.22}$$

Recursion:

$$\begin{aligned} \frac{d}{dx} H_n(x) &= 2 H_{n-1}(x) \\ \frac{d}{dx} e^{-x^2} H_n(x) &= e^{-x^2} H_{n+1}(x) \\ H_{n+1}(x) &= 2x H_n(x) - 2n H_{n-1}(x) \ . \end{aligned} \tag{28.23}$$

Particular values:

$$\begin{aligned} H_{2n+1}(0) &= 0 \\ H_{2n+1}(0) &= (-1)^n 2^n (2n-1)!! \end{aligned} \tag{28.24}$$

Series:

$$H_{2n}(x) = \sum_{k=0}^{\infty} \frac{(2n)!}{(2k)!} \frac{(-1)^{n-k}}{(n-k)!} (2x)^{2k} \tag{28.25}$$
$$H_{2n-1}(x) = \sum_{k=0}^{\infty} \frac{(2n+1)!}{(2k+1)!} \frac{(-1)^{n-k}}{(n-k)!} (2x)^{2k+1}$$
$$H_n(x) = n! \sum_{k=0}^{\text{int}(n/2)} \frac{1}{k!} \frac{(-1)^k}{(n-2k)!} (2x)^{n-2k} \ .$$

28.3.4 Laguerre polynomials

The definition of the *Laguerre polynomials* is:

$$L_n^{(m)}(x) \equiv \frac{e^x x^{-m}}{m!} \frac{d^n}{dx^n} (e^{-x} x^{n+m}) \tag{28.26}$$
$$L_n \equiv L_n^{(0)}(x) \ .$$

Series:

$$L_n^{(m)}(x) = \sum_{k=0}^{n} \binom{n+m}{n-k} \frac{(-x)^k}{k!} \ . \tag{28.27}$$

Recursion:

$$\frac{d}{dx} L_n^{(m)}(x) = -L_{n-1}^{(m+1)}(x) \ . \tag{28.28}$$

Related functions:

$$u_{mn}(\varepsilon) \equiv e^{-\varepsilon^2} \cdot (\imath\varepsilon)^{n-m} \cdot \sqrt{\tfrac{m!}{n!}} \cdot L_m^{n-m}(\varepsilon^2) \tag{28.29}$$
$$u_{mn}(0) \approx (\imath\varepsilon)^{n-m} \cdot \sqrt{\tfrac{n!}{m!(n-m)!^2}}$$
$$u_{n+1,n}(0) \approx \imath\varepsilon \cdot \sqrt{n+1} \ .$$

Fourier transforms:

$$\int_{-\infty}^{\infty} e^{-ax^2} x^{2k} \cos xp \cdot dx = \tfrac{(-1)^k \sqrt{\pi}}{2^k \sqrt{a^{2k+1}}} \cdot e^{p^2/4a} \cdot He_{2k}(p/\sqrt{2a}) \tag{28.30}$$
$$\int_{-\infty}^{\infty} e^{-x^2/2} x^{2m} L_n^{2m}(x^2) \cos xp \cdot dx = \tfrac{(-1)^m \sqrt{\pi}}{\sqrt{2}n!} \cdot e^{-p^2/2} \cdot He_n(p) He_{n+2m}(p)$$
$$\int_{-\infty}^{\infty} e^{-x^2/2} x^{2m+1} L_n^{2m+1}(x^2) \sin xp \cdot dx = \tfrac{(-1)^m \sqrt{\pi}}{\sqrt{2}n!} \cdot e^{-p^2/2} \cdot He_n(p) He_{n+2m+1}(p)$$
$$\int_{-\infty}^{\infty} e^{-ax-bp} f(|x-p|) \cdot dxdp = \tfrac{1}{a+b} \left[\int_{-\infty}^{\infty} e^{-ax} f(x) dx + \int_{-\infty}^{\infty} e^{-bp} f(p) dp \right] \ .$$

28.3.5 Legendre polynomials

The definition of *Legendre polynomials* is:

$$P_n(x) \equiv \frac{1}{2^n n!}\frac{d^n}{dx^n}(x^2-1)^n \tag{28.31}$$
$$P_n^{(-m)}(x) \equiv (1-x^2)^{m/2}\frac{d^m}{dx^m}P_l(x) \ .$$

Series:

$$P_n^{(m)}(x) = \frac{(-1)^m(n+m)!}{2^m m!(n-m)!}(1-x^2)^{m/2}\left[\begin{array}{c} 1-\frac{(n-m)!(m+n+1)!}{1!(m+1)!}\frac{1-x}{2}+ \\ +\frac{(n-m)!(n-m+1)!(m+n+1)!(m+n+2)!}{2!(m+1)!(m+2)!}\left(\frac{1-x}{2}\right)^2-...\end{array}\right] . \tag{28.32}$$

28.3.6 Spherical harmonics

The definition of *spherical harmonics* is [1368]:

$$Y_{\ell m}(\vartheta,\varphi) \equiv \sqrt{\frac{2\ell+1}{4\pi}}\sqrt{\frac{(\ell-|m|)!}{(\ell+|m|)!}}P_\ell^{|m|}(\cos(\vartheta)e^{im\varphi} \ . \tag{28.33}$$

The lowest *spherical harmonics* are:

$$\begin{array}{lcllcl} Y_0^{(0)} & = & \frac{1}{2}\sqrt{\frac{1}{\pi}} & Y_0^{(1)} & = & \frac{1}{2}\sqrt{\frac{3}{\pi}}\cos\theta \\ Y_{\pm1}^{(1)} & = & \mp\frac{1}{2}\sqrt{\frac{3}{2\pi}}\sin\theta e^{\pm i\phi} & Y_0^{(2)} & = & \frac{1}{4}\sqrt{\frac{5}{\pi}}(3\cos^2\theta-1) \\ Y_{\pm1}^{(2)} & = & \mp\frac{1}{2}\sqrt{\frac{15}{2\pi}}\sin\theta\cos\theta e^{\pm i\phi} & Y_{\pm2}^{(2)} & = & \frac{1}{4}\sqrt{\frac{15}{2\pi}}\sin^2\theta e^{\pm 2i\phi} \end{array} \tag{28.34}$$

28.3.7 Vector spherical harmonics

The definition of *vector spherical harmonics* is [1368]:

$$\mathbf{Y}_{j\ell m}(\mathbf{r}) \equiv (-1)^{1-\ell-m}\sqrt{2j+1}\sum_q \begin{pmatrix} \ell & 1 & j \\ m-q & q & -m \end{pmatrix} Y_{\ell\ m-q}(\vartheta,\varphi)\hat{\mathbf{e}}_q \ . \tag{28.35}$$

28.3.7.1 The Gamma function

The definition of the *Gamma function* is:

$$\Gamma(x+1) = x\Gamma(x) \quad , \quad \Gamma(1/2) = \sqrt{\pi} \ . \tag{28.36}$$

28.3.8 Riemann zeta-function

The definition of the *Riemann zeta-function* is,

$$g_\eta(1) = \zeta(\eta) \ , \tag{28.37}$$

where,

$$g_\eta(z) = \sum_{t=1}^{\infty} \pm \frac{(\pm z)^t}{t^\eta} = \frac{1}{\Gamma(\eta)} \int_0^\infty \frac{x^{\eta-1} dx}{z^{-1} e^x \pm 1} \ , \tag{28.38}$$

is also called the Bose/Fermi function. The upper sign holds for bosons, the lower for fermions. The *Sommerfeld expansion*,

$$\begin{aligned} \int_0^\infty \frac{g(x)dx}{e^{x-y}+1} &= \int_0^y g(x)dx + \int_0^\infty \frac{g(y+x)^{\eta-1}dx}{e^x+1} - \int_0^x \frac{g(y-x)^{\eta-1}dx}{e^x+1} \\ &\approx \int_0^y g(x)dx + \frac{\pi^2}{6} g'(x) + ... \end{aligned} \tag{28.39}$$

holds for $z \gg 1$ and yields,

$$f_\eta(e^y) \approx \frac{x^\eta}{\Gamma(\eta+1)} \left(1 + \frac{\pi^2 \eta(\eta-1)}{6x^2} + \frac{7\pi^4 \eta(\eta-1)(\eta-2)(\eta-3)}{360x^4} + ... \right) \ . \tag{28.40}$$

For small z both functions converge towards,

$$c_\eta(z) = \frac{1}{\Gamma(\eta)} \int_0^\infty \frac{x^{\eta-1} dx}{z^{-1} e^x} = c_{\eta-1}(z) = z \ . \tag{28.41}$$

The derivative is,

$$\frac{\partial f_\eta(Z)}{\partial Z} = \frac{\partial}{\partial Z} \sum_{t=1}^{\infty} -\frac{(-Z)^t}{t^\eta} = \sum_{t=1}^{\infty} \frac{(-Z)^{t-1}}{t^{\eta-1}} = \frac{1}{Z} \sum_{t=1}^{\infty} -\frac{(-Z)^t}{t^{\eta-1}} = \frac{f_{\eta-1}(Z)}{Z} \ , \tag{28.42}$$

or,

$$\begin{aligned} \frac{\partial f_\eta(Z)}{\partial Z} &= \frac{1}{\Gamma(\eta)} \frac{\partial}{\partial Z} \int_0^\infty \frac{x^{\eta-1} dx}{Z^{-1} e^x + 1} = \frac{1}{\Gamma(\eta)} \int_0^\infty \frac{x^{\eta-1} Z^{-2} e^x dx}{(Z^{-1} e^x + 1)^2} \\ &= \frac{1}{Z\Gamma(\eta)} \int_0^\infty x^{\eta-1} \frac{d}{dx} \frac{-1}{Z^{-1} e^x + 1} dx = \frac{\eta - 1}{Z\Gamma(\eta)} \int_0^\infty \frac{x^{\eta-2}}{Z^{-1} e^x + 1} dx = \frac{f_{\eta-1}(Z)}{Z} \ . \end{aligned} \tag{28.43}$$

Atomic and Molecular Physics

Chapter 29

Electron spin and the atomic fine structure

The energy structure of hydrogen calculated by Bohr's model from the non-relativistic Hamiltonian agrees very well with the experimental measurements. However, in high-resolution experiments, small deviations were observed as energy shifts and splittings of spectral lines. These deviations, called *fine structure*, were not predicted by theory, which suggests that there are weak additional effects that do not strongly affect the position of the spectral lines but remove the energy degeneracy of the orbital quantum number ℓ: $E = E_{n,\ell}$.

As a possible explanation we have the fact that the electrons present relativistic mass and momentum. In order to estimate the relevance of relativistic corrections let us estimate the electron velocity in the fundamental hydrogen states given by $E_1 = -\hbar^2/2m_e a_B^2$. Using the definitions of the Bohr radius, $a_B = 4\pi\varepsilon_0\hbar^2/(m_e e^2)$, and the *fine structure constant*

$$\alpha \equiv \frac{e^2}{4\pi\epsilon_0\hbar c} \simeq \frac{1}{137} \ , \tag{29.1}$$

we obtain,

$$v = \sqrt{\frac{2E_1}{m_e}} = \frac{\hbar}{m_e a_B} = \frac{e^2}{4\pi\varepsilon_0\hbar} = \alpha c \ , \tag{29.2}$$

which shows that the electron velocity is very high and that relativistic effects may indeed be *not negligible*.

29.1 The Dirac equation

29.1.1 The Klein-Gordon equation for bosons

The Schrödinger equation for a free particle is based on the non-relativistic energy-momentum dispersion relation,

$$E = \frac{p^2}{2m_e} \ . \tag{29.3}$$

and the definitions of the quantum operators for energy and momentum,

$$E = \imath\hbar\frac{\partial}{\partial t} \qquad \text{and} \qquad \mathbf{p} = -\imath\hbar\nabla \ . \tag{29.4}$$

As already discussed in Sec. 23.1.2 we can, in order to find a relativistic wave equation, try the approach of inserting the quantum operators into the relativistic energy-momentum relation [1].

$$E^2 = c^2p^2 + m_e^2c^4 \ . \tag{29.5}$$

We obtain,

$$\boxed{\left[\frac{1}{c^2}\frac{\partial^2}{\partial t^2} - \nabla^2 + \left(\frac{m_e c}{\hbar}\right)^2\right]\psi = 0} \ . \tag{29.6}$$

This is the *Klein-Gordon equation*. The stationary solution of this equation is a spherical wave,

$$\psi = \psi_0 \frac{1}{r} e^{-2\pi r/\lambda_C} \ , \tag{29.7}$$

where $\lambda_C = h/m_e c$ is the *Compton wavelength*. We show this in Exc. 29.1.5.1. For example, in the case of heavy bosonic particles, such as a field of π-mesons, ψ is the *Yukawa potential*.

In the framework of the *standard model*, it is believed that matter is composed of two fundamental types of particles, bosons and fermions. Bosons are exchanged between fermions conveying the interaction between them. A typical example is the one of two electrons whose Coulomb interaction is mediated by the exchange of photons. Bosons obey the Klein-Gordon equation, fermions the Dirac equation derived in the following section.

29.1.2 The Dirac equation for fermions

In 1928 Paul Dirac, at the age of 26, developed an approach to a relativistic wave equation which differed from the Klein-Gordon equation. Motivated by the observation that the photon, being the relativistic particle *par excellence*, obeys a linear energy-momentum relation of the form $\omega = ck$, he attempted to derive a linear dispersion relation in E and p for heavy particles via the following ansatz:

$$E = \alpha_0 m_e c^2 + \alpha_1 c p_x + \alpha_2 c p_y + \alpha_3 c p_z \ . \tag{29.8}$$

Replacing energy and momentum with their respective operators [2],

$$\imath\hbar\frac{\partial}{\partial t}\phi = \alpha_0 m_e c^2 \phi - \imath c\hbar\left(\alpha_1\frac{\partial}{\partial x} + \alpha_2\frac{\partial}{\partial y} + \alpha_3\frac{\partial}{\partial z}\right)\phi \ . \tag{29.9}$$

We must now ensure that the relativistic energy-momentum condition (29.5) be satisfied.

Example 175 (*Derivation of the Dirac equation*): Taking the square on the right-hand side of the equation (29.9),

$$\begin{aligned}
&[\alpha_0 m_e c^2 - \imath c\hbar(\alpha_1\partial_x + \alpha_2\partial_y + \alpha_3\partial_z)][\alpha_0 m_e c^2 - \imath c\hbar(\alpha_1\partial_x + \alpha_2\partial_y + \alpha_3\partial_z)] \\
&= m_e^2c^4\alpha_0^2 - ic\hbar m_e c^2[(\alpha_0\alpha_1 + \alpha_1\alpha_0)\partial_x + (\alpha_0\alpha_2 + \alpha_2\alpha_0)\partial_y + (\alpha_0\alpha_3 + \alpha_3\alpha_0)\partial_z] \\
&\quad - c^2\hbar^2[\alpha_1^2\partial_x^2 + \alpha_2^2\partial_y^2 + \alpha_3^2\partial_z^2] \\
&\quad - c^2\hbar^2[(\alpha_1\alpha_2\partial_x\partial_y + \alpha_2\alpha_1\partial_y\partial_x) + (\alpha_2\alpha_3\partial_y\partial_z + \alpha_3\alpha_2\partial_z\partial_y) + (\alpha_3\alpha_1\partial_z\partial_x + \alpha_1\alpha_3\partial_x\partial_z)] \ .
\end{aligned}$$

[1] Using the covariant notation with $p_\mu \equiv (E/c, \mathbf{p})$: $p_\mu p^\mu = E^2/c^2 - p^2 = m_e^2c^2$ is a Lorentz invariant.

[2] We introduce the abbreviation $\partial_k \equiv \frac{\partial}{\partial x_k}$

For this expression to be identical to the relativistic energy-momentum condition (29.5),

$$m_e^2c^4 - c^2\hbar^2[\partial_x^2 + \partial_y^2 + \partial_z^2] \ ,$$

we need to postulate for all $i = 0, .., 4$, that $\alpha_i\alpha_j + \alpha_j\alpha_i = 2\delta_{ij}$.

Obviously, the condition

$$[\alpha_i, \alpha_j]_+ = 2\delta_{ij} \tag{29.10}$$

can not be satisfied if the α_i are numbers. The idea of Dirac was to interpret the variables α_i as matrices. These matrices act as operators on appropriate states, which are no longer scalar wavefunctions but vectors. Each component of the vector is a wavefunction in the usual sense. The Hilbert space is extended to be the product space of the usual spatial wavefunctions and a finite-dimensional vector space.

Example 176 (*Calculation with matrices of operator*): To give an idea of how the algebra works we consider a general situation. As the operator we choose the product,

$$\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \frac{\partial}{\partial x}$$

and as the wavefunction vector we choose,

$$\begin{pmatrix} e^{\imath k_1 x} \\ e^{\imath k_2 x} \end{pmatrix} .$$

Applying the operator on the state vector we get,

$$\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \frac{\partial}{\partial x} \begin{pmatrix} e^{\imath k_1 x} \\ e^{\imath k_2 x} \end{pmatrix} = \begin{pmatrix} 0 & \frac{\partial}{\partial x} \\ \frac{\partial}{\partial x} & 0 \end{pmatrix} \begin{pmatrix} e^{\imath k_1 x} \\ e^{\imath k_2 x} \end{pmatrix} = \begin{pmatrix} 0 + \frac{\partial}{\partial x} e^{\imath k_2 x} \\ \frac{\partial}{\partial x} e^{\imath k_1 x} + 0 \end{pmatrix} = \begin{pmatrix} \imath k_2 e^{\imath k_2 x} \\ \imath k_1 e^{\imath k_1 x} \end{pmatrix} .$$

The matrices α_i must satisfy the condition (29.10). It is possible to show that this requires at least four-dimensional matrices of the following form:

$$\alpha_0 = \begin{pmatrix} -\mathbb{I} & 0 \\ 0 & \mathbb{I} \end{pmatrix} \quad \text{and} \quad \alpha_j = \begin{pmatrix} 0 & \sigma_j \\ \sigma_j & 0 \end{pmatrix} , \tag{29.11}$$

where $j = x, y, z = 1, 2, 3$. In this notation the components of the matrices are themselves matrices, i.e. the *Pauli spin matrices* defined in (23.47). The state vector must also have four dimensions,

$$\vec{\vec{\Phi}}(\mathbf{r}, t) = \begin{pmatrix} \vec{\phi}(\mathbf{r}, t) \\ \vec{\chi}(\mathbf{r}, t) \end{pmatrix} \quad \text{with} \quad \vec{\phi}(\mathbf{r}, t) = \begin{pmatrix} \phi_1(\mathbf{r}, t) \\ \phi_2(\mathbf{r}, t) \end{pmatrix} \quad \text{and} \quad \vec{\chi}(\mathbf{r}, t) = \begin{pmatrix} \chi_1(\mathbf{r}, t) \\ \chi_2(\mathbf{r}, t) \end{pmatrix} . \tag{29.12}$$

ϕ_j are called *large components*, χ_j are called *small components*. This designation is explained later. Combining the matrices α_j to a three-dimensional vector $\vec{\alpha}$, we can now write the Dirac equation (29.9) like,

$$\boxed{\imath\hbar\partial_t \vec{\vec{\Phi}}(\mathbf{r}, t) = \left(m_e c^2 \alpha_0 + c\vec{\alpha} \cdot \mathbf{p}\right) \vec{\vec{\Phi}}(\mathbf{r}, t)} \ . \tag{29.13}$$

Or, using the notation (29.11) and combining the Pauli matrices σ_j to a three-dimensional vector $\vec{\sigma}$, we can write the Dirac equation as:

$$\boxed{\imath\hbar\frac{\partial}{\partial t}\begin{pmatrix}\vec{\phi}\\ \vec{\chi}\end{pmatrix} = \left[m_e c^2\begin{pmatrix}-\mathbb{I} & 0\\ 0 & \mathbb{I}\end{pmatrix} + c\begin{pmatrix}0 & \vec{\sigma}\cdot\mathbf{p}\\ \vec{\sigma}\cdot\mathbf{p} & 0\end{pmatrix}\right]\begin{pmatrix}\vec{\phi}\\ \vec{\chi}\end{pmatrix}} \ . \tag{29.14}$$

The non-diagonal matrix,

$$\begin{pmatrix}0 & \vec{\sigma}\cdot\mathbf{p}\\ \vec{\sigma}\cdot\mathbf{p} & 0\end{pmatrix} \tag{29.15}$$

couples large and small components.

Example 177 (*Covariant and relativistically invariant form of Dirac's equation*): To demonstrate its relativistic invariance it is useful to rewrite the Dirac equation in a way in which time and space appear on equal footings. For this we introduce new matrices,

$$\gamma^0 \equiv \alpha_0 \qquad \text{and} \qquad \gamma^k = \gamma^0\alpha_k \ . \tag{29.16}$$

We obtain,

$$\gamma^0 = \begin{pmatrix}-\mathbb{I} & 0\\ 0 & \mathbb{I}\end{pmatrix} \qquad \text{and} \qquad \gamma^k = \begin{pmatrix}0 & \sigma_k\\ -\sigma_k & 0\end{pmatrix} \ . \tag{29.17}$$

We also define another important matrix by,

$$\gamma_5 \equiv \imath\gamma_0\gamma_1\gamma_2\gamma_3 = \begin{pmatrix}0 & \mathbb{I}\\ \mathbb{I} & 0\end{pmatrix} \ . \tag{29.18}$$

With this, using Einstein's notation [3], the Dirac equation (29.12) adopts the form,

$$\imath\hbar\gamma^\mu\partial_\mu\psi - mc\psi = 0 \ . \tag{29.19}$$

The complete system is summarized in the Minkowski metrics of time-space in the form,

$$[\gamma^\mu, \gamma^\nu]_+ = 2\eta^{\mu\nu} \ , \tag{29.20}$$

for $\mu, \nu = 0, .., 5$, that is, all matrices γ_k anticommute.
The Dirac equation can now be interpreted as an eigenvalue equation, where the rest mass is proportional to the eigenvalue of a momentum quadrivector, the proportionality constant being the speed of light:

$$P_{\text{op}}\psi = mc\psi \ , \tag{29.21}$$

Using $\not{\phi}$ in the Feynman slash notation, which includes the γ-matrices, as well as a summation over the components of the spinor in the derivative, the Dirac equation becomes:

$$\imath\hbar\not{\partial}\psi - mc\psi = 0 \ . \tag{29.22}$$

A fundamental theorem states that, if two distinct sets of matrices are given, which both satisfy Clifford's relations, then they are connected to each other by a similarity transformation:

$$\gamma'^\mu = S^{-1}\gamma^\mu S \ . \tag{29.23}$$

[3] $\partial_0 \equiv \frac{1}{c}\partial_t$

If, in addition, the matrices are all unitary, as is the case of Dirac's set, then S is unitary,

$$\gamma'^{\mu} = U^{\dagger}\gamma^{\mu}U \ . \tag{29.24}$$

29.1.2.1 Anti-particles

Disregarding for a moment the non-diagonal matrix, the Dirac equation separates into two independent equations,

$$\imath\hbar\frac{\partial\vec{\phi}}{\partial t} = m_e c^2\vec{\phi} \quad \text{and} \quad \imath\hbar\frac{\partial\vec{\chi}}{\partial t} = -m_e c^2\vec{\chi} \ . \tag{29.25}$$

These are eigenenergy equations with the eigenvalues $m_e c^2$ and $-m_e c^2$. The state with negative energy is interpreted as *anti-particle*. Therefore, the non-diagonal matrix mixes particles and anti-particles. We will study in Exc. 29.1.5.2 the so-called *Zitterbewegung* as a solution of the Dirac equation.

29.1.2.2 Particles and anti-particles in the non-relativistic limit

To reduce the Dirac equation to the non-relativistic Schrödinger equation, we first need to get rid of the rest energy. To do so, we separate a fast oscillation, whose frequency corresponds to the rest mass of the electron via the following ansatz, where $\mathbf{u}$ and $\mathbf{v}$ vary slowly in time:

$$\vec{\Phi}(\mathbf{r},t) = e^{-\imath\omega_0 t}\begin{pmatrix}\mathbf{u}(\mathbf{r},t)\\ \mathbf{v}(\mathbf{r},t)\end{pmatrix} \quad , \quad \hbar\omega_0 = m_e c^2 \ , \tag{29.26}$$

with the temporal derivative,

$$\imath\hbar\dot{\vec{\Phi}} = \left[m_e c^2\begin{pmatrix}\mathbf{u}\\ \mathbf{v}\end{pmatrix} + \imath\hbar\begin{pmatrix}\dot{\mathbf{u}}\\ \dot{\mathbf{v}}\end{pmatrix}\right] e^{-\imath\omega_0 t} \ . \tag{29.27}$$

We insert this into the Dirac equation,

$$\left[m_e c^2\begin{pmatrix}\mathbf{u}\\ \mathbf{v}\end{pmatrix} + \imath\hbar\begin{pmatrix}\dot{\mathbf{u}}\\ \dot{\mathbf{v}}\end{pmatrix}\right] e^{-\imath\omega_0 t} = \left[m_e c^2\begin{pmatrix}\mathbf{u}\\ -\mathbf{v}\end{pmatrix} + c\vec{\sigma}\cdot\mathbf{p}\begin{pmatrix}\mathbf{v}\\ \mathbf{u}\end{pmatrix}\right] e^{-\imath\omega_0 t} \tag{29.28}$$

finally obtaining,

$$\imath\hbar\dot{\mathbf{u}} = c(\vec{\sigma}\cdot\mathbf{p})\mathbf{v} \quad , \quad \imath\hbar\dot{\mathbf{v}} = c(\vec{\sigma}\cdot\mathbf{p})\mathbf{u} - 2m_e c^2\mathbf{v} \ . \tag{29.29}$$

Since $\mathbf{u}$ and $\mathbf{v}$ only vary slowly in time, the derivatives on the left-hand side are small quantities. However, the condition that both derivatives must zero is too strong, because it leads to the trivial solution $\mathbf{u} = 0$ and $\mathbf{v} = 0$. We find the first non-trivial solution by the condition $\dot{\mathbf{v}} = 0$. The second equation then becomes,

$$\mathbf{v} = \frac{1}{2m_e c}(\vec{\sigma}\cdot\mathbf{p})\mathbf{u} \ . \tag{29.30}$$

Inserted into the first equation,

$$\imath\hbar\dot{\mathbf{u}} = c\frac{(\vec{\sigma}\cdot\mathbf{p})^2}{2m_e c}\mathbf{u}\ . \tag{29.31}$$

We need, therefore, to evaluate the expression $(\vec{\sigma}\cdot\mathbf{p})^2$,

$$\vec{\sigma}\cdot\mathbf{p} = \begin{pmatrix} p_z & p_x - \imath p_y \\ p_x + \imath p_y & -p_z \end{pmatrix} \qquad \text{and} \qquad (\vec{\sigma}\cdot\mathbf{p})^2 = \mathbf{p}^2\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}\ . \tag{29.32}$$

Inserted into the differential equation (29.31) for $\mathbf{u}$ we obtain precisely the Schrödinger equation for a free particle,

$$\boxed{\imath\hbar\dot{\mathbf{u}} = \frac{\mathbf{p}^2}{2m_e}\mathbf{u}}\ . \tag{29.33}$$

Let us return to the question, why we call $\mathbf{u}$ the *strong* component. We have from the equation (29.30),

$$\mathbf{v}^\dagger\mathbf{v} = \frac{1}{(2m_e c)^2}(\vec{\sigma}\cdot\mathbf{p})^2\mathbf{u}^\dagger\mathbf{u} = \frac{1}{2m_e c^2}\frac{\mathbf{p}^2}{2m_e}\mathbf{u}^\dagger\mathbf{u}\ , \tag{29.34}$$

and since $\frac{\mathbf{p}^2}{2m_e} \ll m_e c^2$ follows immediately $\mathbf{v}^\dagger\mathbf{v} \ll \mathbf{u}^\dagger\mathbf{u}$.

In this non-relativistic approximation the components $\mathbf{u}$ are much larger than the components $\mathbf{v}$. The mixture between particles and antiparticles only matters when $\frac{\mathbf{p}^2}{2m_e} \simeq m_e c^2$, resp., $\frac{1}{2}m_e v^2 \simeq m_e c^2$ or $|v| \simeq c$. The electron only receives small positronic contributions as it approaches the speed of light. In the ground state of the hydrogen atom the electron has a velocity of of $v = \alpha c \simeq c/137$. That is, the contribution of the weak components is small, but present.

Example 178 (*Vanishing rest mass*): Let us note that for the case of vanishing rest mass, $m_e = 0$, the Dirac equation (29.14) dramatically simplifies. Taking the time derivative of the upper equation (29.14) and inserting the lower equation (29.14), we find,

$$\frac{1}{c^2}\frac{\partial^2}{\partial t^2}\vec{\phi} = \frac{1}{c^2}\frac{c\vec{\sigma}\cdot\mathbf{p}}{\imath\hbar}\frac{\partial}{\partial t}\vec{\chi} = -\frac{(\vec{\sigma}\cdot\mathbf{p})^2}{\hbar^2}\vec{\phi} = -\frac{\mathbf{p}^2}{\hbar^2}\vec{\phi} = \nabla^2\vec{\phi}\ . \tag{29.35}$$

I.e. we recover a Helmholtz type wave equation.

29.1.2.3 The spin

We consider the operator defined by [372, 373],

$$\hat{\mathbf{s}} \equiv \tfrac{\hbar}{2}\vec{\sigma}\ , \tag{29.36}$$

and we calculate the commutation relations between its components. From the definitions of the Pauli matrices (23.47) we obtain the rule,

$$[\hat{s}_x, \hat{s}_y] = \tfrac{\hbar^2}{4}\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}\begin{pmatrix} 0 & \imath \\ -\imath & 0 \end{pmatrix} - \tfrac{\hbar^2}{4}\begin{pmatrix} 0 & \imath \\ -\imath & 0 \end{pmatrix}\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} = \frac{\hbar^2}{4}\begin{pmatrix} -2\imath & 0 \\ 0 & 2\imath \end{pmatrix} = \imath\hbar\hat{s}_z\ . \tag{29.37}$$

In general terms the following holds true: $[s_i, s_j] = \epsilon_{ijk}\imath\hbar s_k$. It is interesting to compare this with the commutation relation for the orbital angular momentum $[\hat{l}_i, \hat{l}_j] = \epsilon_{ijk}\imath\hbar\hat{l}_k$. The coincidence suggests a generalization of the concept of angular momentum: We now call *angular momentum operator* every three-dimensional vector operator satisfying this commutation relation [4]. We consider the eigenvalue equation for $\hat{s}_z$, which is incorporated in the Dirac equation,

$$\hat{s}_z\vec{\phi} = \tfrac{\hbar}{2}\begin{pmatrix} -1 & 0 \\ 0 & 1 \end{pmatrix}\begin{pmatrix} \phi_1 \\ \phi_2 \end{pmatrix} = m_s\hbar\begin{pmatrix} \phi_1 \\ \phi_2 \end{pmatrix} . \tag{29.38}$$

The eigenvalues are obviously $m_s = \pm\frac{1}{2}$. The angular momentum related to the matrices $\mathbf{S}$ is obviously half-integer. We are dealing here with a new type of angular momentum, which is not included in the usual definition of *orbital* angular momentum $\mathbf{L} = \mathbf{r} \times \mathbf{p}$. The new angular momentum is called *intrinsic* angular momentum or *spin* of the particle. The spin represents a new structure or dimension additional to space comparable to the polarization of light. The photons of a circularly polarized light beam also contribute to an intrinsic angular momentum, which however in this case is integer.

In Exc. 29.1.5.3 we will see that neither $\hat{l}_z$ nor $\hat{s}_z$ are constants of motion of the Hamiltonian (29.14), but the sum $\hat{j}_z \equiv \hat{l}_z + \hat{s}_z$,

$$[\hat{j}_z, \hat{H}] = 0 . \tag{29.39}$$

29.1.2.4 The stationary Dirac equation

By a similar treatment as in the Schrödinger equation one can deduce a stationary Dirac equation (29.13) via a separation of the time variable. Making for the time an exponential ansatz,

$$\vec{\phi}(\mathbf{r}, t) = \vec{\phi}(\mathbf{r})e^{-\imath Et/\hbar} \quad \text{and} \quad \vec{\chi}(\mathbf{r}, t) = \vec{\chi}(\mathbf{r})e^{-\imath Et/\hbar} , \tag{29.40}$$

we obtain coupled stationary equations for the large and small components,

$$(E - m_e c^2)\vec{\phi}(\mathbf{r}) = c\sigma \cdot \mathbf{p}\vec{\chi}(\mathbf{r}) \quad \text{and} \quad (E + m_e c^2)\vec{\chi}(\mathbf{r}) = c\sigma \cdot \mathbf{p}\vec{\phi}(\mathbf{r}) . \tag{29.41}$$

29.1.3 The relativistic electron in a central Coulomb field

29.1.3.1 Minimal coupling

In atomic physics we are mainly interested in electrons bound to a potential (e.g., generated by an atomic nucleus), that is, we must introduce electromagnetic forces into the Dirac equation. Therefore, we now consider the interaction of a charged particle with an electromagnetic field given by the vector potential $\mathbf{A}$ and by the electrostatic potential U, such that the electric and magnetic fields,

$$\vec{\mathcal{E}} = -\nabla U - \frac{\partial \mathbf{A}}{\partial t} \quad \text{and} \quad \vec{\mathcal{B}} = \nabla \times \mathbf{A} , \tag{29.42}$$

[4] This concept can be derived from the requirement of symmetry under rotation of space as discussed in Sec. 23.5.

allow to calculate the Coulomb-Lorentz force. In the Hamiltonian formulation of electrodynamics the interaction can be described simply by the transition [5],

$$\boxed{\hat{\mathbf{p}} \longrightarrow \hat{\mathbf{p}} - q\mathbf{A} \equiv \vec{\pi} \quad \text{and} \quad \hat{H} \longrightarrow \hat{H} + qU} \ . \tag{29.43}$$

called the *minimal coupling*. We briefly mentioned this already in Sec. 23.5.4, and the rules will be derived in Sec. 30.1. In addition to the substitution of the momentum, we must add the scalar potential qU, and we obtain the Dirac equation for a particle inside an applied electromagnetic field,

$$\imath\hbar\dot{\vec{\Phi}} = \left(m_e c^2\alpha_0 + c\vec{\alpha}\cdot\vec{\pi} + qU\right)\vec{\Phi} \ , \tag{29.44}$$

in generalization of Eq. (29.13).

29.1.3.2 Solving the stationary Dirac equation

Let us, for now, disregard external magnetic fields, $\mathbf{A} = 0$. Then, the stationary Dirac equation (29.41) becomes,

$$\begin{aligned} [E - qU(\mathbf{r}) - m_e c^2]\vec{\phi}(\mathbf{r}) &= c\sigma\cdot\mathbf{p}\vec{\chi}(\mathbf{r}) \\ [E - qU(\mathbf{r}) + m_e c^2]\vec{\chi}(\mathbf{r}) &= c\sigma\cdot\mathbf{p}\vec{\phi}(\mathbf{r}) \ . \end{aligned} \tag{29.45}$$

For the Coulomb potential,

$$qU(r) = -\frac{1}{4\pi\epsilon_0}\frac{e^2}{r} \tag{29.46}$$

the Dirac equation can be solved algebraically [374, 541, 548, 471] [6]. The calculation is more complicated than the resolution of the Schrödinger equation for hydrogen derived in Secs. 25.1.4 and 25.2.1 and will be sketched in the following.

> **Example 179 (*Dirac equation in spherical coordinates*):** The goal of the following calculation is to express the Dirac equation for an electron in a central Coulomb field in spherical coordinates, i.e. r and $p_r = -\imath\hbar\partial_r$ instead of $\mathbf{p}$. The starting point is the Dirac equation (29.14),
>
> $$\imath\hbar\partial_t\vec{\Phi}(\mathbf{r},t) = \hat{H}\vec{\Phi}(\mathbf{r},t) \ , \tag{29.47}$$
>
> with the Hamiltonian in the minimal coupling (29.43),
>
> $$\hat{H} \equiv m_e c^2\alpha_0 + c\vec{\alpha}\cdot[\mathbf{p} - q\mathbf{A}(\mathbf{r})] + qU(\mathbf{r}) \tag{29.48}$$
> $$\text{with} \quad \mathbf{A} = 0 \quad \text{and} \quad U(\mathbf{r}) = -\frac{e^2}{4\pi\varepsilon_0 r} \ .$$
>
> We adopt the standard procedure from non-relativistic physics, which consists in rewriting the Hamiltonian in terms of observables, which commute with the Hamiltonian [7].

[5] In quadrivetorial notation: $\pi_\mu = p_\mu - qA_\mu$ with $p_\mu = \begin{pmatrix} E/c \\ \mathbf{p} \end{pmatrix}$ and $A_\mu = \begin{pmatrix} U/c \\ \mathbf{A} \end{pmatrix}$.

[6] See also http://einstein.drexel.edu/~bob/Term_Reports/Whitehead_3.pdf

[7] Typical examples are the Hamiltonian of the harmonic oscillator (24.75) written in terms of $\hat{n} \equiv \hat{a}^\dagger\hat{a}$ or the Hamiltonian of the hydrogen atom (25.34) written in terms of $\mathbf{L}^2$.

The goal is to calculate the quantity $\vec{\alpha}\cdot\mathbf{p}$ appearing in the above Hamiltonian. As a first steps we define the following quantities,

$$\boxed{\begin{array}{rcll} \mathbf{L} & \equiv & \mathbf{r}\times\mathbf{p} \quad \text{satisfying} & \mathbf{L}\times\mathbf{L} = \imath\hbar\mathbf{L} \\ \mathbf{S} & \equiv & \frac{\hbar}{2}\vec{\varsigma} \equiv \frac{\hbar}{2}\gamma_5\vec{\alpha} & \\ \mathbf{J} & \equiv & \mathbf{L}+\mathbf{S} & \\ \hbar j' & \equiv & \alpha_0(\gamma_5\vec{\alpha}\cdot\mathbf{L}+\hbar) & \\ r\varepsilon & \equiv & \vec{\alpha}\cdot\mathbf{r} & \end{array}} \ . \tag{29.49}$$

remembering that $\gamma_5 = -\imath\alpha_1\alpha_2\alpha_3 = \begin{pmatrix} 0 & \mathbb{I} \\ \mathbb{I} & 0 \end{pmatrix}$ is the transformation exchanging particles and anti-particles. The first important relationship we have to derive is,

$$(\vec{\alpha}\cdot\mathbf{B})(\vec{\alpha}\cdot\mathbf{C}) = (\mathbf{B}\cdot\mathbf{C}) + \imath\gamma_5\vec{\alpha}\cdot(\mathbf{B}\times\mathbf{C}) \ . \tag{29.50}$$

It holds for $[\vec{\alpha},\mathbf{B}] = 0 = [\vec{\alpha},\mathbf{C}]$ and will be proven in 29.1.5.4. Exploiting this relationship, we see that the scalar quantity ε satisfies,

$$\varepsilon^2 = \frac{1}{r^2}(\vec{\alpha}\cdot\mathbf{r})^2 = \frac{1}{r^2}[\mathbf{r}\cdot\mathbf{r} + \imath\vec{\alpha}\cdot(\mathbf{r}\times\mathbf{r})] = 1 \ . \tag{29.51}$$

Furthermore, with the definition of j' we show,

$$\begin{aligned} r\varepsilon\vec{\alpha}\cdot\mathbf{p} = (\vec{\alpha}\cdot\mathbf{r})(\vec{\alpha}\cdot\mathbf{p}) &= \mathbf{r}\cdot\mathbf{p} + \imath\gamma_5\vec{\alpha}\cdot(\mathbf{r}\times\mathbf{p}) \\ &= \mathbf{r}\cdot\mathbf{p} + \imath\gamma_5\vec{\alpha}\cdot\mathbf{L} = rp_r + \imath\alpha_0\hbar j' - \imath\hbar \ , \end{aligned} \tag{29.52}$$

where the relationship $\mathbf{r}\cdot\mathbf{p} = rp_r$ is verified in Exc. 29.1.5.5(c). Hence,

$$\vec{\alpha}\cdot\mathbf{p} = \varepsilon\left(p_r + \frac{\imath\hbar(\alpha_0 j' - 1)}{r}\right) \ , \tag{29.53}$$

The final radial Hamiltonian is,

$$\boxed{\hat{H} = m_e c^2\alpha_0 + c\varepsilon\left(p_r - \imath\frac{\hbar}{r}\right) + \frac{\imath c\varepsilon\alpha_0\hbar j'}{r} - \frac{e^2}{4\pi\varepsilon_0 r}} \ . \tag{29.54}$$

For now the choice of the quantities ε and j' must seem arbitrary, so we will have to discover their properties. We will see that j' is a non-zero integer related to the total angular momentum j. The following properties will be proven in Exc. 29.1.5.5(a) and (b),

$$\begin{aligned} (\hbar j')^2 &= \mathbf{J}^2 + \tfrac{\hbar^2}{4} \\ [\hbar j', \hat{H}]_- = [\varepsilon, \hat{H}]_- &= [\alpha_0, \hat{H}]_- = 0 \ . \end{aligned} \tag{29.55}$$

Hence, we got a collection of radial variables being constants of motion of the Dirac Hamiltonian.

Example 180 (*Resolving the spherical Dirac equation*): We will now search a solution to the spherical Dirac equation with the Hamiltonian (29.54). Noticing that the matrix α_0 is diagonal and the matrix ε counter-diagonal (just

like the Dirac matrices $\vec{\alpha}$), we may break down the stationary radial Dirac equation into 2 by 2 matrices. Using the fact that ε commutes with all other terms and anti-commutes with α_0 and that $\varepsilon^{-1} = \varepsilon^\dagger$ is a unitary transformation, we may go to a new basis via,

$$\begin{pmatrix} m_e c^2 - \frac{e^2}{4\pi\varepsilon_0 r} & -\imath c p_r - c\frac{\hbar}{r} - c\frac{\hbar j'}{r} \\ \imath c p_r + c\frac{\hbar}{r} - c\frac{\hbar j'}{r} & -m_e c^2 - \frac{e^2}{4\pi\varepsilon_0 r} \end{pmatrix} \begin{pmatrix} \vec{\phi} \\ \varepsilon\vec{\chi} \end{pmatrix} = E \begin{pmatrix} \vec{\phi} \\ \varepsilon\vec{\chi} \end{pmatrix} . \tag{29.56}$$

Substituting $\alpha = \frac{e^2}{4\pi\varepsilon_0\hbar c}$ and $a_\pm \equiv \frac{\hbar}{m_e c \mp E/c}$ (that is, $\pm m_e c^2 - E \equiv \pm\frac{\hbar c}{a_\pm}$), we find,

$$\begin{pmatrix} \frac{1}{a_+} - \frac{\alpha}{r} & -\frac{d}{dr} - \frac{j'+1}{r} \\ \frac{d}{dr} - \frac{j'-1}{r} & -\frac{1}{a_-} - \frac{\alpha}{r} \end{pmatrix} \begin{pmatrix} \vec{\phi} \\ \varepsilon\vec{\chi} \end{pmatrix} = 0 . \tag{29.57}$$

Assuming the existence of solutions of the form,

$$\begin{pmatrix} \vec{\phi} \\ \varepsilon\vec{\chi} \end{pmatrix} = \frac{e^{-r/a}}{r} \begin{pmatrix} \vec{f} \\ \vec{g} \end{pmatrix} , \tag{29.58}$$

where $a \equiv \sqrt{a_+ a_-} = \hbar\left(m_e^2 c^2 - \frac{E^2}{c^2}\right)^{-1}$ [that is, $\frac{d}{dr}\frac{e^{-r/a}}{r} = \frac{e^{-r/a}}{r}\left(-\frac{1}{a} - \frac{1}{r}\right)$], we find,

$$\begin{pmatrix} \frac{1}{a_+} - \frac{\alpha}{r} & -\frac{d}{dr} - \frac{1}{a} - \frac{j'}{r} \\ \frac{d}{dr} - \frac{1}{a} - \frac{j'}{r} & -\frac{1}{a_-} - \frac{\alpha}{r} \end{pmatrix} \begin{pmatrix} \vec{f} \\ \vec{g} \end{pmatrix} = 0 . \tag{29.59}$$

Next we expand the unknown function $\vec{f}$ and $\vec{g}$ as series,

$$\vec{f}(r) = \sum_{s=-\infty}^{\infty} f_s r^s \qquad \text{and} \qquad \vec{g}(r) = \sum_{s=-\infty}^{\infty} g_s r^s . \tag{29.60}$$

These are then substituted into our system of equations. In order for the equation to go to zero as required, each term in the resulting series must separately go to zero. The coefficient of the r_s terms are,

$$\begin{aligned} \frac{f_s}{a_+} - \alpha f_{s+1} - (s+1+j')g_{s+1} + \frac{g_s}{a} &= 0 \\ \frac{g_s}{a_-} - \alpha g_{s+1} - (s+1-j')f_{s+1} + \frac{f_s}{a} &= 0 . \end{aligned} \tag{29.61}$$

These can be combined by multiplying the first equation (29.61) by a and and the second by a_- and then subtracting the former from the latter. Exploiting $\frac{a}{a_+} = \frac{a_-}{a}$, this gives us an expression directly relating the f_s coefficients with the g_s coefficients,

$$[\alpha a - a_+(s-j')]f_s + [\alpha a_- + a(s+j')]g_s = 0 . \tag{29.62}$$

To obtain the values of the coefficients we consider the boundary conditions. The functions $\vec{f}(r)$ and $\vec{g}(r)$ must go to zero at $r = 0$, because the functions $\vec{\phi}$ and $\vec{\chi}$ would otherwise diverge there due to the r^{-1} term. This means that there is some smallest s below which the series does not continue. We call this s_0, and it has the property,

$$f_{s_0-1} = g_{s_0-1} = 0 . \tag{29.63}$$

Plugging this into the equations (29.61), we find,

$$\begin{aligned} \alpha f_{s_0} + (s_0 + j')g_{s_0} &= 0 \\ \alpha g_{s_0} - (s_0 - j')f_{s_0} &= 0 \ . \end{aligned} \tag{29.64}$$

Combining these equations we can write the value s_0 in a very simple form,

$$s_0 = \sqrt{j'^2 - \alpha^2} \ . \tag{29.65}$$

This places a lower bound on the series. Note that this bound becomes imaginary if $\alpha > j'$. This will be discussed in more detail shortly.
The upper bound of the series is also useful. It can be shown that the series must terminate if the energy eigenvalue is to be less than $m_e c^2$ [374]. The implication of this result is that if the series terminates at index s_1 such that,

$$f_{s_1+1} = g_{s_1+1} = 0 \ . \tag{29.66}$$

Then, using equations (29.61) and (29.62), we have,

$$\frac{s_1}{a} = \frac{1}{2}\left(\frac{1}{a_-} - \frac{1}{a_+}\right)\alpha = \frac{E}{\hbar c}\alpha \ , \tag{29.67}$$

where we have used the definitions of the coefficients $a_\pm$ to expand them. Squaring this expression and expanding a using its definition, we get,

$$s_1^2\left(m_e c^2 - \frac{E^2}{c^2}\right) = \alpha^2 \frac{E^2}{c^2} \ . \tag{29.68}$$

This can be solved for the energy eigenvalues,

$$E = \pm m_e c^2 \left(1 + \frac{\alpha^2}{s_1^2}\right)^{-1/2} \ . \tag{29.69}$$

Note that the 'negative energy' solution corresponds to positron energy levels. From here forward, we drop the negative root and look only at the electron solution.
The two end points of the series, the indices s_0 and s_1 are separated by an integer number of steps. Calling this integer n' we can write,

$$s_1 = n' + s_0 = n' + \sqrt{j'^2 - \alpha^2} \ . \tag{29.70}$$

Plugging this into (29.69) gives a result for the energy eigenvalues in terms of only the two quantum numbers n' and j',

$$E_{n',j'} = m_e c^2 \left[1 + \frac{\alpha^2}{\left(n' + \sqrt{j'^2 - \alpha^2}\right)^2}\right]^{-1/2} \ .$$

This is the final result quoted for the energy eigenvalues of the hydrogenic atom by Dirac [374]. It turns out that later developments in the field [541, 548] prefer to use an equivalent set of quantum numbers that maps more closely to the familiar ones. The number j' is closely related to the total angular momentum quantum number j. j' has the range 1, 2, 3, while j has the range $\frac{1}{2}$, $\frac{3}{2}$, $\frac{5}{2}$. It is natural, and in fact correct, to make the identifications,

$$j' = j + \tfrac{1}{2} \ , \tag{29.71}$$

and

$$n' = n - j' = n - j - \tfrac{1}{2} \ , \tag{29.72}$$

for the principal quantum number n [541]. Combining these two adjustments with equation (29.71), we get the *Sommerfeld fine-structure formula*,

$$\boxed{E_{n,j} = m_e c^2 \left[1 + \frac{\alpha^2}{\left(n - j - \frac{1}{2} + \sqrt{(j+\frac{1}{2})^2 - \alpha^2} \right)^2} \right]^{-1/2}} \ , \tag{29.73}$$

with $j = \left| \ell \pm \frac{1}{2} \right|$ and $\ell = 0, 1, ...$ The derivation of the form of the actual wave functions $\vec{\phi}(r)$ and $\vec{\chi}(r)$ is very tedious [541] and will not be reproduced here.

The energy predicted by the Sommerfeld fine-structure formula (29.73) depends on two quantum numbers. The degeneracy of the orbital angular momentum $\mathbf{j}$ is lifted, and the new quantum number besides the main quantum number n is that of the total angular momentum j. The intransparent expression can be expanded by α,

$$\boxed{E_{n,j} \simeq m_e c^2 \left[1 - \frac{\alpha^2}{2n^2} - \frac{\alpha^4}{2n^3} \left(\frac{1}{j+1/2} - \frac{3}{4n} \right) \right]} \ . \tag{29.74}$$

The second term reproduces the energy of Bohr's model, but there are correction terms proportional to α^4. We will show in Secs. 29.1.4, that the energy levels, called *fine structure*, result from several relativistic corrections of different origins.

In the expression (29.74) for the electron energy in the Coulomb potential, the last term is positive and proportional to $1/n^4$. It describes relaxation of the binding due to the contribution of weak components. The term containing the quantum number j is called the spin-orbit coupling. To better understand this contribution we must first analyze more deeply the matrices $\vec{\sigma}$.

29.1.3.3 Dirac's Hamiltonian in the sub-relativistic limit

Defining the energy $E' = E - m_e c^2$, the stationary Dirac equation (29.45) for an electron of charge $q = -e$ in an external electrostatic potential $U(\mathbf{r})$ can be written,

$$[E' - qU(\mathbf{r})]\vec{\phi} = c\vec{\sigma} \cdot \mathbf{p}\vec{\chi} \qquad \text{and} \qquad [E' - qU(\mathbf{r}) + 2m_e c^2]\vec{\chi} = c\vec{\sigma} \cdot \mathbf{p}\vec{\phi} \ . \tag{29.75}$$

resolving the second equation for the wavefunction $\vec{\chi}$ and substituting it into the first,

$$\boxed{E'\vec{\phi} = qU(\mathbf{r})\vec{\phi} + \vec{\sigma} \cdot \mathbf{p} \frac{1}{2m_e} \left(1 + \frac{E' - qU(\mathbf{r})}{2m_e c^2} \right)^{-1} \vec{\sigma} \cdot \mathbf{p}\vec{\phi}} \ . \tag{29.76}$$

In the non-relativistic limit,

$$E' - qU \simeq \frac{\mathbf{p}^2}{2m_e} \ll m_e c^2 \ , \tag{29.77}$$

we get by Taylor expansion of the second term in the bracket,

$$E'\vec{\phi} \simeq qU(\mathbf{r})\vec{\phi} + \vec{\sigma} \cdot \mathbf{p} \frac{1}{2m_e} \left(1 - \frac{E' - qU(\mathbf{r})}{2m_e c^2} \right) \vec{\sigma} \cdot \mathbf{p}\vec{\phi} \ . \tag{29.78}$$

Now, $\vec{\sigma}\cdot\mathbf{p}$ is an operator entity, which acts on the subsequent operators and wavefunctions. We thus have to apply the product rule, $(\vec{\sigma}\cdot\mathbf{p})V\psi = V(\vec{\sigma}\cdot\mathbf{p})\psi + [(\vec{\sigma}\cdot\mathbf{p})V]\psi$, to the first occurrence of operator this operator in equation (29.76),

$$E'\vec{\phi} \simeq qU(\mathbf{r})\vec{\phi} + \tfrac{1}{2m_e}\left(1 - \tfrac{E'-qU(\mathbf{r})}{2m_e c^2}\right)(\vec{\sigma}\cdot\mathbf{p})^2\,\vec{\phi} + \tfrac{q}{4m_e^2c^2}[(\vec{\sigma}\cdot\mathbf{p})U(\mathbf{r})](\vec{\sigma}\cdot\mathbf{p})\vec{\phi}\,. \quad (29.79)$$

In the following we will make use of a general relationship which is similar to (29.50),

$$(\vec{\sigma}\cdot\mathbf{B})(\vec{\sigma}\cdot\mathbf{C}) = (\mathbf{B}\cdot\mathbf{C}) + \imath\vec{\sigma}\cdot(\mathbf{B}\times\mathbf{C})\,. \quad (29.80)$$

It holds for $[\vec{\sigma},\mathbf{B}] = 0 = [\vec{\sigma},\mathbf{C}]$ and will be demonstrated in Exc. 29.1.5.4. The relationship yields,

$$(\vec{\sigma}\cdot\mathbf{p})^2 = \mathbf{p}^2 \qquad \text{and} \qquad [\vec{\sigma}\cdot\mathbf{p}U(\mathbf{r})](\vec{\sigma}\cdot\mathbf{p}) = \mathbf{p}U(\mathbf{r})\cdot\mathbf{p} + \imath\vec{\sigma}\cdot[\mathbf{p}U(\mathbf{r})\times\mathbf{p}]\,, \quad (29.81)$$

so that expressing the momentum operator by $\mathbf{p} = -\imath\hbar\nabla$ wherever it acts on the potential,

$$E'\vec{\phi} \simeq qU(\mathbf{r})\vec{\phi} + \tfrac{1}{2m_e}\left(1 - \tfrac{E'-qU(\mathbf{r})}{2m_e c^2}\right)\mathbf{p}^2\vec{\phi} - \tfrac{\hbar^2 q}{4m_e^2c^2}\nabla U(\mathbf{r})\cdot\nabla\vec{\phi} + \tfrac{\hbar}{4m_e^2c^2}\vec{\sigma}\cdot[\nabla U(\mathbf{r})\times\mathbf{p}]\vec{\phi}\,. \quad (29.82)$$

Also, with $U(\mathbf{r}) = U(r)$,

$$\nabla U(r) = \frac{\partial U}{\partial r}\nabla r = \frac{\partial U}{\partial r}\frac{\mathbf{r}}{r} \qquad \text{and} \qquad \nabla U(r)\cdot\nabla = \frac{\partial U}{\partial r}\hat{\mathbf{e}}_r\cdot\nabla = \frac{\partial U}{\partial r}\frac{\partial}{\partial r}\,. \quad (29.83)$$

We get,

$$\begin{aligned} E'\vec{\phi} &= qU(\mathbf{r})\vec{\phi} + \frac{1}{2m_e}\left(1 - \frac{E'-qU(\mathbf{r})}{2m_e c^2}\right)\mathbf{p}^2\vec{\phi} - \frac{\hbar^2}{4m_e^2c^2}\frac{\partial qU}{\partial r}\frac{\partial}{\partial r}\vec{\phi} + \frac{\hbar q}{4m_e^2c^2}\vec{\sigma}\cdot\left[\frac{1}{r}\frac{\partial U}{\partial r}\mathbf{r}\times\mathbf{p}\vec{\phi}\right] \\ &\simeq \left(\frac{\mathbf{p}^2}{2m_e} + qU(r) - \frac{\mathbf{p}^4}{8m_e^3c^2} + \frac{q}{2m_e^2c^2}\frac{1}{r}\frac{\partial U}{\partial r}\mathbf{s}\cdot\mathbf{l} - \frac{\hbar^2 q}{4m_e^2c^2}\frac{\partial U}{\partial r}\frac{\partial}{\partial r}\right)\vec{\phi}\,. \end{aligned} \quad (29.84)$$

where we again applied the non-relativistic approximation (29.77) in the second line and made use of the definitions $\mathbf{s} = \frac{\hbar}{2}\vec{\sigma}$ and $\mathbf{l} = \mathbf{r}\times\mathbf{p}$. The term in the bracket can be used as the Hamiltonian allowing to calculate the fine structure as first-order perturbations to the non-relativistic energy levels obtained from non-relativistic theory,

$$\boxed{\hat{H} \simeq \frac{\mathbf{p}^2}{2m_e} - \frac{1}{4\pi\varepsilon_0}\frac{e^2}{r} - \frac{\mathbf{p}^4}{8m_e^3c^2} - \frac{e}{2m_e^2c^2}\frac{1}{r}\frac{\partial U}{\partial r}\mathbf{s}\cdot\mathbf{l} - \frac{\hbar^2 e}{4m_e^2c^2}\frac{\partial U}{\partial r}\frac{\partial}{\partial r}}\,. \quad (29.85)$$

The first two terms are those arising from Bohr's atom model, the third one is a correction due to the relativistic velocity of the electron, the forth comes from the electron's spin-orbit coupling, and the fifth is called the Darwin term. All contributions represent perturbations to the non-relativistic Schrödinger theory of Bohr's atom and will be discussed extensively in Secs. 29.2. We will show in 29.1.5.6 that $\hat{\mathbf{l}}^2$, $\hat{\mathbf{s}}^2$, and $\hat{\mathbf{j}}^2$ are constants of motion of the above Hamiltonian.

29.1.4 The Pauli equation

When we calculated the electron's energy in the Coulomb potential (29.85), we only considered the electrostatic potential of the nucleus, letting the potential vector $\mathbf{A}$ be zero. As long as we do not apply an external magnetic field this is correct, because the internal magnetism of the atom is already completely enclosed in the Dirac equation. On the other hand, we know that the atom contains moving charges, that is, currents which generate magnetic fields [8]. Furthermore, the spins of the electron and of the proton produce magnetic moments, which ought to interact with the magnetic fields. Hence, the existence of magnetic effects in an atom is to be expected.

These magnetic effects can be discussed in a more transparent way applying a Schrödinger-like equation with minimal coupling to electromagnetic fields (29.43) to a two-component spinor $\vec{\phi}$. This Schrödinger-like equation can be obtained from Dirac's equation (29.75) via a stronger non-relativistic approximation, which consists in completely neglecting the weak component $[E' - qU(\mathbf{r})]\vec{\chi}$. On the other hand, we allow for the existence of magnetic fields via the substitution $\mathbf{p} \to \vec{\pi}$. The equation for the strong component (29.76) then becomes,

$$\boxed{E'\vec{\phi} = qU(\mathbf{r})\vec{\phi} + \frac{(\vec{\sigma}\cdot\vec{\pi})^2}{2m_e}\vec{\phi}} \,. \tag{29.86}$$

We can again apply the formula (29.80) to calculate,

$$\begin{aligned}(\vec{\sigma}\cdot\vec{\pi})^2\psi &= \vec{\pi}^2\psi + \imath\vec{\sigma}\cdot(\vec{\pi}\times\vec{\pi})\psi = \vec{\pi}^2\psi + \imath q\vec{\sigma}\cdot[-\mathbf{p}\times\mathbf{A}(\mathbf{r}) - \mathbf{A}(\mathbf{r})\times\mathbf{p}]\psi \\ &= \vec{\pi}^2\psi - \hbar q\vec{\sigma}\cdot\{\nabla\times[\mathbf{A}(\mathbf{r})\psi] + \mathbf{A}(\mathbf{r})\times\nabla\psi\} \\ &= \vec{\pi}^2\psi - \hbar q\vec{\sigma}\cdot[\nabla\times\mathbf{A}(\mathbf{r})]\psi = [\mathbf{p} - q\mathbf{A}(\mathbf{r})]^2\psi - \hbar q\vec{\sigma}\cdot\vec{\mathcal{B}}(\mathbf{r})\psi \,.\end{aligned} \tag{29.87}$$

In the case of an electron ($e = -q$) we obtain the so-called *Pauli equation*,

$$E'\vec{\phi} = \left[\frac{1}{2m_e}\left(-\imath\hbar\nabla + e\mathbf{A}\right)^2 + \frac{e\hbar}{2m_e}\vec{\sigma}\cdot\vec{\mathcal{B}} - eU(\mathbf{r})\right]\vec{\phi} \,, \tag{29.88}$$

which corresponds to a Schrödinger-like equation for a two-component spinor $\vec{\phi}$ with the Hamiltonian,

$$\boxed{\hat{H} \simeq \frac{\mathbf{p}^2}{2m_e} - \frac{1}{4\pi\varepsilon_0}\frac{e^2}{r} - \frac{\imath\hbar e}{2m_e}(\nabla\cdot\mathbf{A} + \mathbf{A}\cdot\nabla) + \frac{e}{m_e}\mathbf{s}\cdot\vec{\mathcal{B}}} \,, \tag{29.89}$$

neglecting terms in $\mathbf{A}^2$. Note however, that the kinetic energy is calculated with the *momentum projected onto the spin*, $\vec{\sigma}\cdot\vec{\pi}$. The third term can be simplified within the Coulomb gauge $\nabla\cdot\mathbf{A} = 0$ yielding,

$$\hat{H}_{int} = \frac{e}{m_e}(\mathbf{A}\cdot\mathbf{p}) \,. \tag{29.90}$$

The Pauli equation serves for a classical (non-relativistic) approach to the electron's spin-orbit coupling, as we will see below and in the discussion of the fine structure in Sec. 29.2.2.

[8] The spin of the electron does not generate a magnetic field, in contrast to the angular momentum caused by its *orbital motion*. It only interacts with the environment through the requirement of symmetrization for being a fermion.

29.1.4.1 Dipole moment of the orbital angular momentum

The rotational motion of a charge, $-e$, creates a current I, corresponding to a current density,

$$\mathbf{j}(\mathbf{r}') = I\hat{\mathbf{e}}_\phi \delta(r-r')\delta(z') = -e\frac{\mathbf{v}}{2\pi r}\delta(r-r')\delta(z') \ . \tag{29.91}$$

Hence, the dipole moment caused by the circular motion of an electron is,

$$\begin{aligned}\vec{\mu}_\ell &= \frac{1}{2}\int_V \mathbf{r}\times\mathbf{j}(\mathbf{r}')d^3r' \qquad (29.92)\\ &= \frac{1}{4\pi}\mathbf{r}\times\int_0^{2\pi}d\phi'\int_{-\infty}^{\infty}dz'\int_0^{\infty}r'dr'\frac{-e\mathbf{v}}{r}\delta(r-r')\delta(z') = \tfrac{-1}{2}e\mathbf{r}\times\mathbf{v} = \frac{-e}{2m_e}\mathbf{l}\ ,\end{aligned}$$

with the angular momentum $\mathbf{l} = \mathbf{r}\times m_e\mathbf{v}$. The quotient $\gamma_e \equiv -e/2m_e$ is called *gyromagnetic ratio* of the electron. We often use the *Bohr magneton*, $\mu_B \equiv \hbar e/2m_e$, which represents the elementary unit of spin,

$$\boxed{\frac{\vec{\mu}_\ell}{\mu_B} = -g_l\frac{\mathbf{l}}{\hbar}} \ . \tag{29.93}$$

The *g-factor* of a system having any angular momentum $\mathbf{l}$ is defined as a proportionality constant between the normalized dipole moment and the normalized angular momentum. $g_\ell \equiv \frac{\mu_\ell}{\ell\mu_B} = 1$ takes into account possible corrections between our classical derivation and quantum mechanics.

29.1.4.2 Pauli's model of spin-orbit coupling

The aim of this section is to demonstrate the relationship between the spin-orbit coupling term in Dirac's Hamiltonian (29.85) and the spin-magnetic field coupling term in Pauli's Hamiltonian (29.89).

A comparison of Pauli's expression with the energy of a magnetic moment in the field $\vec{\mathcal{B}}$,

$$\hat{H}_{\ell s} = -\vec{\mu}_s\cdot\vec{\mathcal{B}} \ , \tag{29.94}$$

suggests the following connection between the spin and the magnetic moment:

$$-\vec{\mu}_s\cdot\vec{\mathcal{B}} = \frac{e\hbar}{2m_e}\vec{\sigma}\cdot\vec{\mathcal{B}} = \frac{e}{m_e}\mathbf{s}\cdot\vec{\mathcal{B}} \ . \tag{29.95}$$

We conclude, that the electron carries, besides mass, charge and spin, also a magnetic dipole moment,

$$\boxed{\frac{\vec{\mu}_s}{\mu_B} = -\frac{e}{m_e\mu_B}\mathbf{s} = -2\frac{\mathbf{s}}{\hbar}} \ , \tag{29.96}$$

For the g-factor of the electron, we obtain $g_e = 2$ [9]. Neutron and proton are also fermions with spin $\frac{1}{2}$, but they do not obey the Dirac equation! Their g-factors are

[9] The exact value is $g_e \equiv \frac{\mu_s}{s\mu_B} = 2.002319314...$ The deviation $g_e - 2 \simeq \frac{\alpha}{\pi} - 0.164\frac{\alpha^2}{\pi^2}$ is due to the coupling of the spin to the fluctuations of the electromagnetic vacuum. We need to use quantum electrodynamical methods to calculate the corrections.

$g_{proton} = 5.5858$ and $g_{neutron} = -3.8261$. The large deviation from $g = 2$ points to the existence of an internal structure.

The rapid motion of the electron within the electrostatic field $\vec{\mathcal{E}}$ of the nucleus produces, following the theory of relativity, in the electron's reference frame a magnetic field $\vec{\mathcal{B}}'$ with which the electronic spin can interact. As we will show in Exc. 29.1.5.7, the field seen by the electron can be approximated in first order in v/c by,

$$\vec{\mathcal{B}}' \simeq \frac{\mathbf{v}}{c^2} \times \vec{\mathcal{E}} \, . \tag{29.97}$$

With this the interaction energy (29.94) becomes,

$$\begin{aligned} \hat{H}_{\ell s} = -\vec{\mu}_s \cdot \vec{\mathcal{B}}' = \frac{e}{m_e c^2} \mathbf{s} \cdot (\mathbf{v} \times \vec{\mathcal{E}}) = -\frac{e}{m_e^2 c^2} \mathbf{s} \cdot (\mathbf{p} \times \nabla U) \\ = -\frac{e}{m_e^2 c^2} \mathbf{s} \cdot \left(\mathbf{p} \times \frac{\mathbf{r}}{r} \frac{\partial U}{\partial r} \right) = -\frac{1}{m_e^2 c^2 r} \mathbf{s} \cdot \mathbf{l} \frac{\partial V(r)}{\partial r} \, , \end{aligned} \tag{29.98}$$

with $V(r) = -eU(r)$.

The resulting interaction energy coincides, apart from a factor $\frac{1}{2}$ [1299], with the one obtained in the from Dirac's equation (29.85). The deviation, called *Thomas factor*, is due to the necessity to transform back into the inertial system of the nucleus. This transformation, called *Thomas precession*, must be done by a Lorentz transformation, which is not trivial with electron continuously changing its propagation direction on its circular orbit. The transformation introduces the additional factor of $\frac{1}{2}$ [10].

29.1.5 Exercises

29.1.5.1 Ex: Yukawa potential

Show, that Yukawa's potential satisfies the Klein-Gordon equation.

Solution: *We have,*

$$\frac{1}{r^2} \frac{\partial}{\partial r} r^2 \frac{\partial}{\partial r} \frac{e^{mcr/\hbar}}{r} = \frac{m^2 c^2}{\hbar^2} \frac{e^{2\pi mcr/h}}{r} \, .$$

29.1.5.2 Ex: Zitterbewegung

Zitterbewegung is a hypothetical rapid motion of elementary particles, in particular electrons, that obey the Dirac equation. The existence of such motion was first proposed by Erwin Schrödinger in 1930 as a result of his analysis of the wave packet solutions of the Dirac equation for relativistic electrons in free space, in which an interference between positive and negative energy states produces what appears to be a fluctuation (at the speed of light) of the position of an electron around the median,

[10] This is a kinematic effect in space-time: the Lorentz transformations for systems moving with non-collinear velocities can not simply be concatenated, but must be rotated, too [471, 659].

with a frequency of $2m_ec^2/\hbar$, or approximately $1.6 \cdot 10^{21}$ rad/s. For the hydrogen atom, the Zitterbewegung produces the Darwin term which plays the role in the fine structure as a small correction of the energy level of the s-orbitals.
Use the Heisenberg equation to derive, from Dirac's Hamiltonian, equations of motion for the position operator $\hat{\mathbf{r}}$ and the 'velocity operator' $\hat{\vec{\alpha}}$. Solve the equation of motion and identify the Zitterbewegung.
Zitterbewegung of a free relativistic particle has never been observed experimentally. However, it has been simulated twice. First, with a trapped ion, by putting it in an environment such that the non-relativistic Schrödinger equation for the ion has the same mathematical form as the Dirac equation (although the physical situation is different) [503]. Then, in 2013, it was simulated in a setup with Bose-Einstein condensates [778].

Solution: *For a free electron, the time-dependent Dirac equation (29.13) is written as,*

$$\hat{H}\vec{\vec{\Phi}}(\mathbf{r},t) = \imath\hbar\frac{\partial\vec{\vec{\Phi}}}{\partial t}(\mathbf{r},t) \ ,$$

where $\vec{\vec{\Phi}}(\mathbf{r},t)$ is the wavefunction (bispinor) of the electron, and $\hat{H} = m_ec^2\alpha_0 + c\vec{\alpha}\cdot\mathbf{p}$ is Dirac's Hamiltonian. The Heisenberg picture implies that any operator $\hat{Q}$ obeys the equation,

$$-\imath\hbar\frac{\partial\hat{Q}}{\partial t} = [\hat{H},\hat{Q}] \ .$$

In particular, the time-dependence of the position operator is given by

$$\hbar\frac{\partial\mathbf{r}(t)}{\partial t} = \imath[\hat{H},\mathbf{r}] = \hbar c\vec{\alpha} \ ,$$

where $\mathbf{r}(t)$ is the position operator at time t. The above equation shows that the operator $\vec{\alpha}$ can be interpreted as a 'velocity operator'. To add time-dependence to $\vec{\alpha}$, one implements the Heisenberg picture, which says,

$$\vec{\alpha}(t) = e^{\imath\hat{H}t/\hbar}\vec{\alpha}e^{-\imath\hat{H}t/\hbar} \ .$$

The time-dependence of the velocity operator is given by

$$\hbar\frac{\partial\vec{\alpha}(t)}{\partial t} = \imath[\hat{H},\vec{\alpha}]_- = \imath m_ec^2[\alpha_0,\vec{\alpha}]_- + c[\vec{\alpha}\cdot\mathbf{p},\vec{\alpha}]_- \ .$$

This expression can be simplified using $[\alpha_m,\alpha_n]_+ = 2\delta_{mn}$ for all $m,n = 0,..,3$, since with $k = 1,..,3$,

$$\begin{aligned}
\imath[\hat{H},\alpha_k] &= \imath m_ec^2[\alpha_0,\alpha_k]_- + \imath c[\alpha_np_n,\alpha_k]_- \\
&= 2\imath m_ec^2\alpha_0\alpha_k + \imath cp_n[\alpha_n,\alpha_k]_- \\
&= 2\imath m_ec^2\alpha_0\alpha_k + 2\imath cp_n\alpha_n\alpha_k(1-\delta_{nk}) \\
&= -2\imath m_ec^2\alpha_k\alpha_0 + 2\imath cp_k - 2\imath c\alpha_k\alpha_np_n \\
&= 2\imath cp_k - 2\imath m_ec^2\alpha_k\alpha_0 - 2\imath c\alpha_k\vec{\alpha}\cdot\mathbf{p} \\
&= 2\imath\left[cp_k - \alpha_k(m_ec^2\alpha_0 + c\vec{\alpha}\cdot\mathbf{p})\right] = 2\imath(cp_k - \alpha_k\hat{H}) \ .
\end{aligned}$$

With this we get,

$$\hbar\frac{\partial\vec{\alpha}(t)}{\partial t} = 2\imath(c\mathbf{p} - \vec{\alpha}\hat{H}) \ .$$

Now, because both $\mathbf{p}$ *and* $\hat{H}$ *are time-independent, the above equation can easily be integrated twice to find the explicit time-dependence of the position operator. First:*

$$\vec{\alpha}(t) = \left(\vec{\alpha}(0) - c\mathbf{p}\hat{H}^{-1}\right)e^{-\frac{2\imath\hat{H}t}{\hbar}} + c\mathbf{p}\hat{H}^{-1} \ ,$$

and finally

$$\mathbf{r}(t) = \mathbf{r}(0) + c^2\mathbf{p}\hat{H}^{-1}t + \tfrac{1}{2}\imath\hbar c\hat{H}^{-1}(\vec{\alpha}(0) - c\mathbf{p}\hat{H}^{-1})\left(e^{-2\imath\hat{H}t/\hbar} - 1\right) \ .$$

The resulting expression consists of an initial position, a motion proportional to time, and an unexpected oscillation term with an amplitude equal to the Compton wavelength, $hc/\hat{H} \simeq h/m_e c \equiv \lambda_C$*. That oscillation term is the so-called Zitterbewegung. The Zitterbewegung term vanishes on taking expectation values for wave-packets that are made up entirely of positive- (or entirely of negative-) energy waves. This can be achieved by taking a Foldy-Wouthuysen transformation. Thus, we arrive at the interpretation of the Zitterbewegung as being caused by interference between positive- and negative-energy wave components.*

29.1.5.3 Ex: Constants of motion of Dirac's Hamiltonian 1

Show that $\hat{L}_z$ with $\hat{\mathbf{L}} \equiv \mathbf{r} \times \hat{\mathbf{p}}$ and $\hat{S}_z$ with $\hat{\mathbf{S}} \equiv \frac{\hbar}{2}\gamma_5\vec{\alpha}$ defining $\gamma_5 \equiv -\imath\alpha_1\alpha_2\alpha_3$ are not constants of motions, but $\hat{\mathbf{J}} = \hat{\mathbf{L}} + \hat{\mathbf{S}}$, that is,

$$[\hat{H}, \hat{J}_z] = [\hat{H}, \hat{L}_z + \hat{S}_z] = 0 \ . \tag{29.99}$$

Solution: *Explicitly we have* $\hat{S}_z = \frac{\hbar}{2}\begin{pmatrix}\sigma_z & 0\\ 0 & \sigma_z\end{pmatrix}$*. Now we calculate with Dirac's Hamiltonian (29.13),*

$$\begin{aligned}[\hat{H}, \hat{L}_z] &= [\cancelto{0}{m_e c^2\alpha_0} + c\vec{\alpha}\cdot\mathbf{p}, \hat{L}_z] = \sum_k c\alpha_k p_k(xp_y - yp_x) - c(xp_y - yp_x)\alpha_k p_k \\ &= c\alpha_1 p_x xp_y - cxp_y\alpha_1 p_x - c\alpha_2 p_y yp_x + cyp_x\alpha_2 p_y = -\imath\hbar c(\alpha_1 p_y - \alpha_2 p_x) \\ &= -\imath\hbar c(\vec{\alpha}\times\mathbf{p})_z \ .\end{aligned}$$

Hence, $[\hat{H}, \mathbf{L}] = -\imath\hbar c\vec{\alpha}\times\mathbf{p}$*. With* $\alpha_j = \alpha_j^{-1} = \alpha_j^\dagger$ *for all* $j = 1, .., 3$ *and for* γ_5 *it is obvious to verify,*

$$\gamma_5\alpha_3\alpha_1 = \imath\alpha_2 = -\alpha_1\gamma_5\alpha_3 \qquad , \qquad \alpha_2\gamma_5\alpha_3 = \imath\alpha_1 = -\gamma_5\alpha_3\alpha_2 \ .$$

With this,

$$\begin{aligned}[\hat{H}, \hat{S}_z] &= [\cancelto{0}{m_e c^2\alpha_0} + c\vec{\alpha}\cdot\mathbf{p}, \gamma_5\hat{S}_z] = \sum_k c\alpha_k p_k\tfrac{\hbar\gamma_5}{2}\alpha_3 - \tfrac{\hbar\gamma_5}{2}\alpha_3 c\alpha_k p_k \\ &= \tfrac{\hbar}{2}c(\alpha_1\gamma_5\alpha_3 - \gamma_5\alpha_3\alpha_1)p_x + \tfrac{\hbar}{2}c(\alpha_2\gamma_5\alpha_3 - \gamma_5\alpha_3\alpha_2)p_y \\ &= \tfrac{\hbar}{2}c(-\imath\alpha_2 - \imath\alpha_2)p_x + \tfrac{\hbar}{2}c(\imath\alpha_1 + \imath\alpha_1)p_y = \hbar c\imath\alpha_1 p_y - \imath\hbar c\alpha_2 p_x = \imath\hbar c(\vec{\alpha}\times\mathbf{p})_z \ .\end{aligned}$$

Comparing the results of the two calculations, we conclude,

$$[\hat{H}, \hat{J}_z] = [\hat{H}, \hat{L}_z + \hat{S}_z] = 0 \ .$$

29.1.5.4 Ex: Calculating with Dirac matrices

a. Prove that, if $[\mathbf{B}, \vec{\sigma}] = 0 = [\mathbf{C}, \vec{\sigma}]$ where $\vec{\sigma}$ are the Pauli matrices, then,

$$(\vec{\sigma} \cdot \mathbf{B})(\vec{\sigma} \cdot \mathbf{C}) = \mathbf{B} \cdot \mathbf{C} + \imath \vec{\sigma} \cdot (\mathbf{B} \times \mathbf{C}) \ . \tag{29.100}$$

b. Prove that, if $[\mathbf{B}, \vec{\alpha}] = 0 = [\mathbf{C}, \vec{\alpha}]$ where $\vec{\alpha}$ are the Dirac matrices, then,

$$(\vec{\alpha} \cdot \mathbf{B})(\vec{\alpha} \cdot \mathbf{C}) = \mathbf{B} \cdot \mathbf{C} + \imath\gamma_5 \vec{\alpha} \cdot (\mathbf{B} \times \mathbf{C}) \ . \tag{29.101}$$

c. Show that the spin defined as,

$$\mathbf{S} = \tfrac{\hbar}{2} \vec{\varsigma} \qquad \text{where} \qquad \vec{\varsigma} \equiv \gamma_5 \vec{\alpha} = \mathbb{I} \otimes \vec{\sigma} \tag{29.102}$$

obeys different commutation rules than the Dirac matrices.
d. Conclude that,

$$(\vec{\varsigma} \cdot \mathbf{B})(\vec{\varsigma} \cdot \mathbf{C}) = \mathbf{B} \cdot \mathbf{C} + \imath \vec{\varsigma} \cdot (\mathbf{B} \times \mathbf{C}) \ . \tag{29.103}$$

Solution: *a. Using* $[\sigma_k, \sigma_m]_+ = 2\delta_{km}$ *we derive,*

$$\begin{aligned}
&(\sigma_x B_x + \sigma_y B_y + \sigma_z B_z)(\sigma_x C_x + \sigma_y C_y + \sigma_z C_z) \\
&= \sum_j \sigma_j^2 B_j C_j + \sigma_y B_y \sigma_z C_z + \sigma_z B_z \sigma_y C_y + \sigma_z B_z \sigma_x C_x + \sigma_x B_x \sigma_z C_z + \sigma_x B_x \sigma_y C_y + \sigma_y B_y \sigma_x C_x \\
&= \mathbf{B} \cdot \mathbf{C} + \sigma_y \sigma_z (\mathbf{B} \times \mathbf{C})_x + \sigma_z \sigma_x (\mathbf{B} \times \mathbf{C})_y + \sigma_x \sigma_y (\mathbf{B} \times \mathbf{C})_z \\
&= \mathbf{B} \cdot \mathbf{C} + \imath \sigma_x (\mathbf{B} \times \mathbf{C})_x + \imath \sigma_y [(\mathbf{B} \times \mathbf{C})_y + \imath \sigma_z (\mathbf{B} \times \mathbf{C})_z \ .
\end{aligned}$$

b. Using $[\alpha_i, \alpha_j]_+ = 2\delta_{ij}$ *we derive,*

$$\begin{aligned}
&(\alpha_x B_x + \alpha_y B_y + \alpha_z B_z)(\alpha_x C_x + \alpha_y C_y + \alpha_z C_z) \\
&= \sum_j \alpha_j^2 B_j C_j + \alpha_y B_y \alpha_z C_z + \alpha_z B_z \alpha_y C_y + \alpha_z B_z \alpha_x C_x + \alpha_x B_x \alpha_z C_z + \alpha_x B_x \alpha_y C_y + \alpha_y B_y \alpha_x C_x \\
&= \mathbf{B} \cdot \mathbf{C} + \alpha_y \alpha_z (\mathbf{B} \times \mathbf{C})_x + \alpha_z \alpha_x (\mathbf{B} \times \mathbf{C})_y + \alpha_x \alpha_y (\mathbf{B} \times \mathbf{C})_z \\
&= \mathbf{B} \cdot \mathbf{C} + \imath\gamma_5 \alpha_x (\mathbf{B} \times \mathbf{C})_x + \imath\gamma_5 \alpha_y [(\mathbf{B} \times \mathbf{C})_y + \imath\gamma_5 \alpha_z (\mathbf{B} \times \mathbf{C})_z \ .
\end{aligned}$$

c. Using the commutation rules for $m, n = 0, .., 3$,

$$[\alpha_m, \alpha_n]_+ = 2\delta_{mn} \qquad \textit{and} \qquad [\gamma_5, \alpha_0]_+ = 0 = [\gamma_5, \vec{\alpha}]_- = 0 \ ,$$

we deduce for $m, n = 1, .., 3$,

$$[\varsigma_m, \varsigma_n]_+ = [\alpha_m, \alpha_n]_+ = 2\delta_{mn} \qquad \textit{and} \qquad [\vec{\varsigma}, \alpha_0]_- = 0 = [\vec{\alpha}, \alpha_0]_+ \ .$$

On the other hand,

$$\begin{aligned}[\varsigma_m, \varsigma_n]_- &= \imath\hbar(\mathbb{I}_2 \otimes \sigma_m)(\mathbb{I}_2 \otimes \sigma_n) - \imath\hbar(\mathbb{I}_2 \otimes \sigma_n)(\mathbb{I}_2 \otimes \sigma_m) \\ &= \imath\hbar(\mathbb{I}_2 \otimes \sigma_m\sigma_n) - \imath\hbar(\mathbb{I}_2 \otimes \sigma_n\sigma_m) = \imath\hbar I_2 \otimes [\sigma_m, \sigma_n] \\ &= \imath\hbar\epsilon_{kmn}(\mathbb{I}_2 \otimes \sigma_k) = \imath\hbar\epsilon_{kmn}\varsigma_k \ ,\end{aligned}$$

and

$$\begin{aligned}[\alpha_m, \alpha_n]_- &= [\gamma_5\varsigma_m, \gamma_5\varsigma_n]_- = [\varsigma_m, \varsigma_n]_- = \imath\hbar\epsilon_{kmn}\varsigma_k \\ &= \imath\hbar\epsilon_{kmn}\gamma_5\alpha_k \neq \imath\hbar\epsilon_{kmn}\alpha_k \ .\end{aligned}$$

d. Follows trivially from (b) and (c).

29.1.5.5 Ex: Constants of motion of Dirac's Hamiltonian 2

In this exercise we will prove the relationships (29.55):
a. Prove,

$$(\hbar j')^2 = \mathbf{J}^2 + \tfrac{\hbar^2}{4} \ . \tag{29.104}$$

b. Prove,

$$[\hbar j', \hat{H}]_- = 0 \ . \tag{29.105}$$

c. Prove,

$$\mathbf{r}\cdot\mathbf{p} = -\imath\hbar r\frac{\partial}{\partial r} \ . \tag{29.106}$$

d. Prove,

$$[\varepsilon, \hat{H}]_- = 0 \ . \tag{29.107}$$

Solution: *a. We start inserting the definition of* $\hbar j' \equiv [\alpha_0(\gamma_5\vec{\alpha}\cdot\mathbf{L} + \hbar)$,

$$\begin{aligned}(\hbar j')^2 &= [\alpha_0(\gamma_5\vec{\alpha}\cdot\mathbf{L} + \hbar)]^2 \\ &= (\alpha_0\gamma_5\vec{\alpha}\cdot\mathbf{L})(\alpha_0\gamma_5\vec{\alpha}\cdot\mathbf{L}) + (\alpha_0\hbar)(\alpha_0\gamma_5\vec{\alpha}\cdot\mathbf{L}) + (\alpha_0\gamma_5\vec{\alpha}\cdot\mathbf{L})(\alpha_0\hbar) + \hbar^2\alpha_0^2 \ .\end{aligned}$$

Using the commutation rules $[\alpha_m, \alpha_n]_+ = 2\delta_{mn}$ *for* $m, n = 0, .., 3$ *and* $[\gamma_5, \alpha_m]_- = 0$ *for* $m = 1, 2, 3$*, but* $[\gamma_5, \alpha_0]_+ = 0$*, we can simplify,*

$$\begin{aligned}(\hbar j')^2 &= (\vec{\alpha}\cdot\mathbf{L})(\vec{\alpha}\cdot\mathbf{L}) + 2\hbar\gamma_5\vec{\alpha}\cdot\mathbf{L} + \hbar^2 \\ &= \mathbf{L}\cdot\mathbf{L} + \imath\gamma_5\vec{\alpha}\cdot(\mathbf{L}\times\mathbf{L}) + 2\hbar\gamma_5\vec{\alpha}\cdot\mathbf{L} + \hbar^2\end{aligned}$$

using the formula (29.101). Using $\mathbf{L}\times\mathbf{L} = \imath\hbar\mathbf{L}$ *we find,*

$$(\hbar j')^2 = \mathbf{L}^2 + \hbar\gamma_5\vec{\alpha}\cdot\mathbf{L} + \hbar^2 = (\mathbf{L} + \hbar\gamma_5\vec{\alpha})\cdot\mathbf{L} + \hbar^2 \ ,$$

and substituting $\mathbf{J} = \mathbf{L} + \frac{\hbar}{2}\gamma_5\vec{\alpha}$*,*

$$(\hbar j')^2 = \left(\mathbf{J} + \tfrac{\hbar}{2}\gamma_5\vec{\alpha}\right)\cdot\left(\mathbf{J} - \tfrac{\hbar}{2}\gamma_5\vec{\alpha}\right) + \hbar^2 = \mathbf{J}^2 - \tfrac{\hbar^2}{4}\vec{\alpha}^2 + \hbar^2 = \mathbf{J}^2 + \tfrac{\hbar^2}{4} \ ,$$

where we finally used $\vec{\alpha}\cdot\vec{\alpha}=3$ [11].
b. Using the formula derived in 29.1.5.3 we find quickly,

$$(\vec{\alpha}\cdot\mathbf{p})(\vec{\alpha}\cdot\mathbf{L})=\cancelto{0}{\mathbf{p}\cdot\mathbf{L}}+\imath\vec{\alpha}\cdot(\mathbf{p}\times\mathbf{L})$$
$$(\vec{\alpha}\cdot\mathbf{L})(\vec{\alpha}\cdot\mathbf{p})=\cancelto{0}{\mathbf{L}\cdot\mathbf{p}}+\imath\vec{\alpha}\cdot(\mathbf{L}\times\mathbf{p})\ .$$

The premisses for the formula (29.100) to be applicable, $[\alpha_j,p_j]=0=[\alpha_j,L_j]$ *are satisfied, because* α_j *are constants and* p_j *and* L_j *are scalars. With this, respecting* $[x_k,p_m]=\imath\hbar\delta_{km}$*,*

$$\begin{aligned}
&(\vec{\alpha}\cdot\mathbf{p})(\vec{\alpha}\cdot\mathbf{L})+(\vec{\alpha}\cdot\mathbf{L})(\vec{\alpha}\cdot\mathbf{p})=\imath\vec{\alpha}\cdot(\mathbf{p}\times\mathbf{L})+\imath\vec{\alpha}\cdot(\mathbf{L}\times\mathbf{p})\\
&=\imath\alpha_x p_y L_z-\imath\alpha_x p_z L_y+\imath\alpha_x L_y p_z-\imath\alpha_x L_z p_y+\ldots\textit{terms in }\alpha_y\textit{ and }\alpha_z\\
&=\imath\alpha_x p_y(xp_y-yp_x)-\imath\alpha_x p_z(zp_x-xp_z)+\imath\alpha_x(zp_x-xp_z)p_z-\imath\alpha_x(xp_y-yp_x)p_y+\\
&\quad+\ldots\textit{terms in }\alpha_{y,z}\\
&=\imath\alpha_x xp_y^2-\imath\alpha_x xp_y^2+\imath\alpha_x xp_z^2-\imath\alpha_x xp_z^2-\imath\alpha_x p_y yp_x-\imath\alpha_x p_z zp_x+\imath\alpha_x zp_x p_z+\imath\alpha_x yp_x p_y+\\
&\quad+\ldots\textit{terms in }\alpha_{y,z}\\
&=\imath\alpha_x[y,p_y]p_x+\imath\alpha_x[z,p_z]p_x+\ldots\textit{terms in }\alpha_{y,z}\\
&=-2\hbar\alpha_x p_x+\ldots\textit{terms in }\alpha_{y,z}=-2\hbar\vec{\alpha}\cdot\mathbf{p}\ .
\end{aligned}$$

This result can be rewritten as,

$$[\vec{\alpha}\cdot\mathbf{p},\vec{\alpha}\cdot\mathbf{L}+\hbar]_+=0\ .$$

Consequently,

$$[\vec{\alpha}\cdot\mathbf{p},\alpha_0(\gamma_5\vec{\alpha}\cdot\mathbf{L}+\hbar)]_-=[\vec{\alpha}\cdot\mathbf{p},\hbar j']_-=0\ .$$

It is easy to see,

$$[\hbar j',m_e c^2\alpha_0]_-=0=\left[\hbar j',-\frac{e^2}{4\pi\varepsilon_0 r}\right]\ .$$

Finally, $[\hbar j',\hat{H}]_-=0$ *.*
c. Using the representation of the gradient in spherical coordinates,

$$\mathbf{r}\cdot\mathbf{p}=r\hat{\mathbf{e}}_r\cdot(-\imath\hbar)\left(\hat{\mathbf{e}}_r\frac{\partial}{\partial r}+\frac{\hat{\mathbf{e}}_\theta\vartheta}{r}\frac{\partial}{\partial\vartheta}+\frac{\hat{\mathbf{e}}_\theta\varphi}{r\sin\vartheta}\frac{\partial}{\partial\varphi}\right)=-\imath\hbar r\frac{\partial}{\partial r}\ .$$

d. It is easy to see,

$$r\varepsilon\alpha_0=\vec{\alpha}\cdot\mathbf{r}\alpha_0=\vec{\alpha}\alpha_0\cdot\mathbf{r}=-\alpha_0\vec{\alpha}\cdot\mathbf{r}=-\alpha_0\vec{\alpha}\cdot\mathbf{r}=-\alpha_0 r\varepsilon\ .$$

We also calculate,

$$[\vec{\alpha}\cdot\mathbf{r},\mathbf{r}\cdot\mathbf{p}]=(\vec{\alpha}\cdot\mathbf{r})(\mathbf{r}\cdot\mathbf{p})-(\mathbf{r}\cdot\mathbf{p})(\vec{\alpha}\cdot\mathbf{r})=\vec{\alpha}\cdot[\mathbf{r}(\mathbf{r}\cdot\mathbf{p})-(\mathbf{r}\cdot\mathbf{p})\mathbf{r}]=\vec{\alpha}\cdot[\mathbf{r},\mathbf{r}\cdot\mathbf{p}]=\vec{\alpha}\cdot(\mathbf{r}\cdot[\mathbf{r},\mathbf{p}])=\imath\hbar\vec{\alpha}\cdot\mathbf{r}\ ,$$

or $[r\varepsilon,rp_r]_-=\imath\hbar\varepsilon r$*. Hence,*

$$\left[\varepsilon,\varepsilon\left(p_r-\imath\frac{\hbar}{r}\right)\right]_-=0\ .$$

[11] Not to confuse with $\vec{\alpha}^\dagger\vec{\alpha}=1$.

29.1.5.6 Ex: Constants of motion in the $\mathbf{L}\cdot\mathbf{S}$-coupling

Consider a particle of mass μ described by the Hamiltonian $\hat{H} = -\frac{\hbar^2}{2\mu}\nabla^2 + V(r) + \xi(r)\mathbf{L}\cdot\mathbf{S}$, being $V(r)$ a central potential, $\mathbf{L}$ and $\mathbf{S}$ its orbital angular momentum and spin.
a. Obtain the commutation relations $[\mathbf{L}, \hat{H}]$, $[\mathbf{S}, \hat{H}]$ and $[\mathbf{L}+\mathbf{S}, \hat{H}]$ for the cases without and with spin-orbit interaction $\xi(r)\mathbf{L}\cdot\mathbf{S}$ introduced by relativistic corrections.
b. Calculate $[\mathbf{L}^2, \hat{H}]$, $[\mathbf{S}^2, \hat{H}]$ and $[\mathbf{J}^2, \hat{H}]$.

Solution: *a. Without spin-orbit interaction we have,*

$$[\mathbf{L}, -\tfrac{\hbar^2}{2\mu}\nabla^2 + V(r)] = [\mathbf{S}, -\tfrac{\hbar^2}{2\mu}\nabla^2 + V(r)] = [\mathbf{J}, -\tfrac{\hbar^2}{2\mu}\nabla^2 + V(r)] = 0 \ .$$

This is obvious, since we know $[L_z, \hat{H}_0] = 0$, and since without spin-orbit interaction the atom is completely round, the same has to be valid for any other axis: $[L_x, \hat{H}_0] = [L_y, \hat{H}] = 0$. With interaction,

$$[\mathbf{L}, H] = [\mathbf{L}, -\frac{\hbar^2}{2\mu}\nabla^2 + V(r) + \xi(r)\mathbf{L}\cdot\mathbf{S}] = \xi(r)[\mathbf{L}, L_xS_x + L_yS_y + L_zS_z]$$
$$= \xi(r)\left\{\left[\begin{pmatrix}L_x\\L_y\\L_z\end{pmatrix}, L_x\right]S_x + \left[\begin{pmatrix}L_x\\L_y\\L_z\end{pmatrix}, L_y\right]S_y + \left[\begin{pmatrix}L_x\\L_y\\L_z\end{pmatrix}, L_z\right]S_z\right\} = \imath\hbar\xi(r)\mathbf{S}\times\mathbf{L} \ ,$$

using $[L_x, L_y] = \imath\hbar L_z$. Analogously,

$$[\mathbf{S}, \hat{H}] = \imath\hbar\xi(r)\mathbf{L}\times\mathbf{S} \ .$$

Finally,

$$[\mathbf{J}, \hat{H}] = [\mathbf{J}, -\frac{\hbar^2}{2\mu}\nabla^2 + V(r) + \xi(r)\mathbf{L}\cdot\mathbf{S}] = \frac{\xi(r)}{2}[\mathbf{J}, \mathbf{J}^2 - \mathbf{L}^2 - \mathbf{S}^2] = 0 \ .$$

Using the results of Excs. 25.4.5.2 and 25.4.5.11.
b. In the same way,

$$[\mathbf{L}^2, \hat{H}] = \mathbf{L}\cdot[\mathbf{L}, \hat{H}] + [\mathbf{L}, \hat{H}]\cdot\mathbf{L} = \imath\hbar\xi(r)\mathbf{L}\cdot(\mathbf{S}\times\mathbf{L}) + \imath\hbar\xi(r)(\mathbf{S}\times\mathbf{L})\cdot\mathbf{L} = 0 \ .$$

In the same way,

$$[\mathbf{S}^2, \hat{H}] = 0 = [\mathbf{J}^2, \hat{H}] \ .$$

29.1.5.7 Ex: Magnetic field generated by the orbiting proton at the location of the electron

Calculate the magnetic field generated by the orbiting proton as it is perceived by the electron.

Solution: *In relativistic mechanics defined by the metric and Lorentz transform,*

$$\eta_{\mu\nu} \equiv \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \\ 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & -1 \end{pmatrix} \quad , \quad \Lambda_{\mu\nu} \equiv \begin{pmatrix} \gamma & 0 & 0 & -\gamma\beta \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ -\gamma\beta & 0 & 0 & \gamma \end{pmatrix}$$

where $\beta \equiv v/c$ *and* $\gamma \equiv 1/\sqrt{1-\beta^2}$*, the Maxwell field tensor is given by*

$$F_{\mu\nu} \equiv \begin{pmatrix} 0 & -\frac{1}{c}\vec{\mathcal{E}}_x & -\frac{1}{c}\vec{\mathcal{E}}_y & -\frac{1}{c}\vec{\mathcal{E}}_z \\ \frac{1}{c}\vec{\mathcal{E}}_x & 0 & -\vec{\mathcal{B}}_z & \vec{\mathcal{B}}_y \\ \frac{1}{c}\vec{\mathcal{E}}_y & \vec{\mathcal{B}}_z & 0 & -\vec{\mathcal{B}}_x \\ \frac{1}{c}\vec{\mathcal{E}}_z & -\vec{\mathcal{B}}_y & \vec{\mathcal{B}}_x & 0 \end{pmatrix} .$$

With this we can calculate the transformed field in an inertial system,

$$\begin{aligned} F'_{\mu\nu} &= \Lambda_\mu{}^\alpha F_{\alpha\beta}\Lambda^\beta{}_\nu = \eta_{\mu\eta}\Lambda^{\eta\alpha}F_{\alpha\beta}\Lambda^{\beta\kappa}\eta_{\kappa\nu} \\ &= \begin{pmatrix} 0 & -\frac{\gamma}{c}\vec{\mathcal{E}}_x + \gamma\beta\vec{\mathcal{B}}_y & -\frac{\gamma}{c}\vec{\mathcal{E}}_y - \gamma\beta\vec{\mathcal{B}}_x & -\frac{1}{c}\vec{\mathcal{E}}_z \\ \frac{\gamma}{c}\vec{\mathcal{E}}_x - \gamma\beta\vec{\mathcal{B}}_y & 0 & -\vec{\mathcal{B}}_z & -\gamma\frac{\beta}{c}\vec{\mathcal{E}}_x + \gamma\vec{\mathcal{B}}_y \\ \frac{\gamma}{c}\vec{\mathcal{E}}_y + \gamma\beta\vec{\mathcal{B}}_x & \vec{\mathcal{B}}_z & 0 & -\gamma\frac{\beta}{c}\vec{\mathcal{E}}_y - \gamma\vec{\mathcal{B}}_x \\ \frac{1}{c}\vec{\mathcal{E}}_z & \gamma\frac{\beta}{c}\vec{\mathcal{E}}_x - \gamma\vec{\mathcal{B}}_y & \gamma\frac{\beta}{c}\vec{\mathcal{E}}_y + \gamma\vec{\mathcal{B}}_x & 0 \end{pmatrix} , \end{aligned}$$

giving at low velocities ($\gamma \to 1$) *and knowing* $\mathbf{v} = v_z\hat{\mathbf{e}}_z$*,*

$$\begin{aligned} \vec{\mathcal{E}}' &= \begin{pmatrix} \vec{\mathcal{E}}'_x \\ \vec{\mathcal{E}}'_y \\ \vec{\mathcal{E}}'_z \end{pmatrix} = \begin{pmatrix} \vec{\mathcal{E}}_x - \beta c\vec{\mathcal{B}}_y \\ \vec{\mathcal{E}}_y + \beta c\vec{\mathcal{B}}_x \\ \vec{\mathcal{E}}_z \end{pmatrix} = \begin{pmatrix} \vec{\mathcal{E}}_y + v_y\vec{\mathcal{B}}_z - v_z\vec{\mathcal{B}}_y \\ \vec{\mathcal{E}}_y + v_z\vec{\mathcal{B}}_x - v_x\vec{\mathcal{B}}_z \\ \vec{\mathcal{E}}_z + v_x\vec{\mathcal{B}}_y - v_y\vec{\mathcal{B}}_x \end{pmatrix} = \vec{\mathcal{E}} + \mathbf{v}\times\vec{\mathcal{B}} \\ \vec{\mathcal{B}}' &= \begin{pmatrix} \vec{\mathcal{B}}'_x \\ \vec{\mathcal{B}}'_y \\ \vec{\mathcal{B}}'_z \end{pmatrix} = \begin{pmatrix} \vec{\mathcal{B}}_x + \frac{\beta}{c}\vec{\mathcal{E}}_y \\ \vec{\mathcal{B}}_y - \frac{\beta}{c}\vec{\mathcal{E}}_x \\ \vec{\mathcal{B}}_z \end{pmatrix} = \begin{pmatrix} \vec{\mathcal{B}}_x + \frac{1}{c^2}v_z\vec{\mathcal{E}}_y - \frac{1}{c^2}v_y\vec{\mathcal{E}}_z \\ \vec{\mathcal{B}}_y + \frac{1}{c^2}v_x\vec{\mathcal{E}}_z - \frac{1}{c^2}v_z\vec{\mathcal{E}}_x \\ \vec{\mathcal{B}}_z + \frac{1}{c^2}v_y\vec{\mathcal{E}}_x - \frac{1}{c^2}v_x\vec{\mathcal{E}}_y \end{pmatrix} = \vec{\mathcal{B}} + \frac{\mathbf{v}}{c^2}\times\vec{\mathcal{E}} . \end{aligned}$$

The first equation is the Lorentz force. The second only becomes important for relativistic velocities. Thus, the field seen by the electron can be approximated in first order in v/c *by,*

$$\vec{\mathcal{B}}' \simeq \frac{\mathbf{v}}{c^2}\times\vec{\mathcal{E}} .$$

29.2 Fine structure of hydrogen-like atoms via TIPT

The wave equation that simultaneously satisfies the requirements of quantum mechanics and special relativity is the *Dirac equation*. In free space including electromagnetic

interactions it describes all massive particles of semi-integer spin with parity as a symmetry, such as electrons and quarks. It was the first theory to fully explain special relativity in the context of quantum mechanics. The Dirac equation describes the fine structure of the hydrogen spectrum in a completely rigorous manner. The equation also implied the existence of a new form of matter, antimatter, previously unsuspected and unobserved. The equation also justifies a posteriori the introduction of spinors, that is, of the vector wavefunctions introduced by Pauli in a heuristic way. We have seen in the last section that, in the limit of high but non-relativistic velocities, the Dirac equation adopts the form of a Schrödinger equation with the modified Hamiltonian (29.85),

$$\begin{aligned}\hat{H} &= \hat{H}_0 + \hat{H}_{rl} + \hat{H}_{\ell s} + \hat{H}_{dw} + \hat{H}_{lamb} \\ &= \left(\frac{p^2}{2m_e} - \frac{Ze^2}{4\pi\varepsilon_0 r}\right) - \frac{p^4}{8m_e^3c^2} + \frac{1}{2m_e^2c^2}\frac{1}{r}\frac{dV}{dr}\mathbf{l}\cdot\mathbf{s} + \frac{\pi\hbar^2}{2m_e^2c^2}\frac{Ze^2}{4\pi\varepsilon_0}\delta^3(\mathbf{r}) + \hat{H}_{lamb}\ .\end{aligned} \tag{29.108}$$

We will discuss the various terms in the following sections. Note that the expression for the Darwin term differs from that of (29.85). We will see in Exc. 29.2.6.1, that they are, in fact, equivalent.

29.2.1 Correction for relativistic velocities

The first correction in the expression, $\hat{H}_{rl}$ in Eq. (29.108), comes from the expansion of the relativistic energy for small velocities up to second order,

$$E_{kin} = \sqrt{p^2c^2 + m_e^2c^4} \simeq m_ec^2 + \frac{p^2}{2m_e} - \frac{p^4}{8m_e^3c^2} + \dots\ . \tag{29.109}$$

The correction is of the order of magnitude,

$$\frac{H_{rl}}{H_0} = \frac{\frac{p^4}{8m_e^3c^2}}{\frac{p^2}{2m_e}} = \frac{v^2}{4c^2} \simeq \frac{\alpha^2}{4} \approx 0.01\%\ . \tag{29.110}$$

Due to the degeneracy of these states, it would be appropriate to use perturbation theory with degenerate states. However, as $\hat{H}_{rl}$ only depends on spatial coordinates commuting with $\mathbf{l}$ and $\mathbf{s}$, the degeneracy is not very important, since $\hat{H}_{rl}$ is already diagonal in the base $|n,\ell,m\rangle$, that is, $\langle n,\ell,m|n',\ell',m'\rangle = \delta_{\ell\ell'}\delta_{mm'}$. Starting from,

$$\begin{aligned}\hat{H}_{rl} &= -\frac{p^4}{8m_e^3c^2} = -\frac{1}{2m_ec^2}\left(\frac{p^2}{2m_e}\right)^2 = -\frac{1}{2m_ec^2}\left(\hat{H}_0 + \frac{Ze^2}{4\pi\varepsilon_0 r}\right)^2 \\ &= -\frac{1}{2m_ec^2}\left(\hat{H}_0 - \frac{2E_n n^2}{\tilde{r}}\right)^2\ ,\end{aligned} \tag{29.111}$$

with $\tilde{r} \equiv \frac{Zr}{a_B}$ and using as an abbreviation the energies of hydrogen following Bohr's model,

$$E_n = \langle n,\ell|\hat{H}_0|n,\ell\rangle = -\frac{Z^2e^2}{4\pi\varepsilon_0}\frac{1}{2a_Bn^2} = -\frac{m_ec^2}{2}\frac{Z^2\alpha^2}{n^2}\ . \tag{29.112}$$

We have

$$\begin{aligned}\Delta E_{rl} &= \langle n,\ell|\hat{H}_{rl}|n,\ell\rangle \qquad (29.113)\\ &= -\frac{1}{2m_ec^2}\left[\langle n,\ell|\hat{H}_0^2|n,\ell\rangle - \langle n,\ell|\frac{4E_nn}{\tilde{r}}\hat{H}_0|n,\ell\rangle + \langle n,\ell|\left(\frac{2E_nn}{\tilde{r}}\right)^2|n,\ell\rangle\right]\\ &= \frac{Z^2\alpha^2}{4E_nn^2}\left[E_n^2 - 4E_n^2n^2\frac{1}{n^2} + 4E_n^2n^4\frac{1}{n^3(\ell+\frac{1}{2})}\right]\ ,\end{aligned}$$

using the eigenvalues calculated in (25.53). Finally, we obtain the following relativistic correction,

$$\boxed{\Delta E_{rl} = E_n(Z\alpha)^2\left[\frac{1}{n(\ell+\frac{1}{2})} - \frac{3}{4n^2}\right]}\ . \qquad (29.114)$$

Obviously, the degeneracy with respect to the angular momentum ℓ is lifted by this correction.

29.2.2 Correction due to spin-orbit coupling

The second correction, $\hat{H}_{\ell s}$ in the expression (29.108), called *spin-orbit interaction*, is a relativistic correction due to the fact that the electron moves rapidly within the electrostatic field $\vec{\mathcal{E}}$ generated by the nucleus. Considering the fundamental orbit and the fact that the angular momenta are of the order of $\hbar$ we can estimate the importance of this effect,

$$\frac{H_{\ell s}}{H_0} = \frac{\frac{1}{2m_e^2c^2}\frac{1}{r}\frac{e^2}{4\pi\varepsilon_0 r^2}\mathbf{l}\cdot\mathbf{s}}{\frac{p^2}{2m_e}} \simeq \frac{\frac{1}{2m_e^2c^2}\frac{e^2}{4\pi\varepsilon_0}\frac{1}{a_B^3}\hbar^2}{\frac{e^2}{4\pi\varepsilon_0 a_B}} = \frac{1}{2m_e^2c^2}\frac{\hbar^2}{a_B^2} = \frac{\alpha^2}{2} \approx 0.01\%\ . \qquad (29.115)$$

Example 181 (*Classical derivation of the spin-orbit interaction*): In the following, we will derive the expression from classical arguments borrowed from electrodynamic theory. Seen from the rest system of the electron being at position $\mathbf{x} = 0$, it is the proton that orbits around the electron. This orbit creates a current, $-\mathbf{j}(\mathbf{r}')$, which generates a magnetic field. Following the *Biot-Savart's law* the potential vector and the amplitude of the field are,

$$\mathbf{A}(\mathbf{x}) = \frac{\mu_0}{4\pi}\int_V \frac{-\mathbf{j}(\mathbf{r}')d^3r'}{|\mathbf{x}-\mathbf{r}'|}\ , \qquad (29.116)$$

respectively,

$$\begin{aligned}\vec{\mathcal{B}}(\mathbf{x}) = \nabla_x\times\mathbf{A}(\mathbf{x}) &= \frac{\mu_0}{4\pi}\int_V\frac{(\mathbf{x}-\mathbf{r}')\times\mathbf{j}(\mathbf{r}')}{|\mathbf{x}-\mathbf{r}'|^3}d^3r' \qquad (29.117)\\ &= -\frac{\mu_0}{4\pi}\int_{-\infty}^{\infty}dz'\int_0^{\infty}r'dr'\int_0^{2\pi}d\phi\frac{(\mathbf{x}-\mathbf{r}')\times\mathbf{v}}{|\mathbf{x}-\mathbf{r}'|^3}\frac{Ze}{2\pi r}\delta(r-r')\delta(z')\\ &= \frac{Ze\mu_0}{4\pi}\frac{(\mathbf{x}-\mathbf{r})\times\mathbf{v}}{|\mathbf{x}-\mathbf{r}|^3}\ ,\end{aligned}$$

where we replaced the expression for the current density (29.91). With the expression for the *Coulomb potential* between the electron and the proton and its radial derivative,

$$V(r) = \frac{-Ze^2}{4\pi\varepsilon_0 r}\quad ,\quad \frac{1}{r}\frac{dV(r)}{dr} = \frac{Ze^2}{4\pi\varepsilon_0 r^3}\ , \qquad (29.118)$$

we have at the position of the electron,

$$\vec{\mathcal{B}}(\mathbf{0}) = \frac{Ze\mu_0}{4\pi}\frac{-\mathbf{r}\times\mathbf{v}}{r^3} = -\frac{\varepsilon_0\mu_0}{e}\frac{\mathbf{r}\times\mathbf{v}}{r}\frac{dV(r)}{dr} \qquad (29.119)$$
$$= -\frac{1}{ec^2}\frac{\mathbf{r}\times\mathbf{v}}{r}\frac{dV(r)}{dr} = -\frac{1}{em_e c^2 r}\frac{dV(r)}{dr}\mathbf{l}\ .$$

The advantage of introducing the potential V is, that this expression also holds for more complicated atoms with many electrons, where the potential may deviate considerably from the Coulombian potential. Note, that the magnetic field is very strong, $B \simeq \xi(a_B)\hbar/\mu_B \approx 5$ T. Inserting the magnetic field into Pauli's expression (29.94) together with the magnetic moment of the spin (29.96),

$$\hat{H}_{\ell s} = -\vec{\mu}_s\cdot\vec{\mathcal{B}}(\mathbf{0}) = \frac{1}{m_e^2c^2}\mathbf{s}\cdot\mathbf{l}\frac{1}{r}\frac{dV(r)}{dr}\ . \qquad (29.120)$$

where we still have to apply the corrective *Thomas factor* of $\frac{1}{2}$.

The interaction operator can be written,

$$\hat{H}_{\ell s} = \xi(r)\mathbf{l}\cdot\mathbf{s}\ , \qquad (29.121)$$

with the abbreviation,

$$\xi(r) \equiv \frac{-1}{2m_e^2c^2r}\frac{dV}{dr} = -\frac{Ze^2}{8\pi\varepsilon_0 m_e^2c^2}\frac{1}{r^3} = \frac{E_nZ^2\alpha^2n^2}{\hbar^2}\frac{1}{\tilde{r}^3}\ , \qquad (29.122)$$

with $\tilde{r} \equiv Zr/a_B$ and using the formulas (25.53).

After the introduction of the spin, the Hilbert space of the particles' wavefunctions must be extended. The wavefunctions are now products of spatial wavefunctions and spin eigenvectors:

$$|n,\ell,m_\ell,m_s\rangle = R_{n\ell}(r)Y_{\ell m}(\theta,\phi)\begin{pmatrix}s_1\\s_2\end{pmatrix}\ . \qquad (29.123)$$

The new Hilbert space is the tensorial product of position space and spin space. The *radial* Hamiltonian for the hydrogen atom including the centrifugal term and the spin-orbit coupling now takes the form:

$$\hat{H} = \frac{p^2}{2m} + V(r) + \frac{\mathbf{l}^2}{2m_e r^2} + \xi(r)\mathbf{l}\cdot\mathbf{s}\ . \qquad (29.124)$$

We may again consider the energy term $V_{\ell s}$ as a small perturbation, and calculate it using unperturbed wavefunctions,

$$\Delta E_{\ell s} = \langle n,\ell,s,m_\ell,m_s|V_{\ell s}|n,\ell,s,m_\ell,m_s\rangle = \langle n,\ell|\xi(r)|n,\ell\rangle\langle\ell,s,m_\ell,m_s|\mathbf{s}\cdot\mathbf{l}|\ell,s,m_\ell,m_s\rangle\ . \qquad (29.125)$$

Assuming a Coulombian potential, we first look at the radial part (29.122), which can easily be calculated using the formulae (25.53),

$$\langle n,\ell|\xi(r)|n,\ell\rangle = \frac{E_nZ^2\alpha^2n^2}{\hbar^2}\frac{1}{n^3\ell(\ell+\frac{1}{2})(\ell+1)}\ . \qquad (29.126)$$

To diagonalize the angular part of the Hamiltonian, we need the common wavefunctions of $\mathbf{l}^2$ and $\mathbf{l}\cdot\mathbf{s}$. We can rewrite the coupling term as:

$$\mathbf{l}\cdot\mathbf{s} = \tfrac{1}{2}(\mathbf{j}^2 - \mathbf{l}^2 - \mathbf{s}^2) \ . \tag{29.127}$$

In the common eigensystem of $\mathbf{j}^2$, $\mathbf{l}^2$, and $\mathbf{s}^2$ the Hamiltonian, therefore, is diagonal. We know the basis of this system from the theory of the addition of angular momenta. The states of the basis are linear combinations of the functions $|n,\ell,m_\ell,m_s\rangle$. Since the spins precess around each other, ℓ_z and s_z are not good observables, the non-coupled base is not appropriate. But $\mathbf{s}^2$, $\mathbf{l}^2$, and $\mathbf{j}^2$ are good observables. In the coupled basis $\{n,(\ell,s)j,m_j\}$,

$$\langle n,(\ell,s)j,m_j|\mathbf{s}\cdot\mathbf{l}|n,(\ell,s)j,m_j\rangle = \tfrac{\hbar^2}{2}[j(j+1)-\ell(\ell+1)-s(s+1)] \ . \tag{29.128}$$

Since $j=\ell\pm 1/2$, we find that every level splits into two levels, one with the energy $E_{n\ell}+\ell\zeta_{n\ell}$ and the degeneracy $2\ell+2$ and the other with the degeneracy $E_{n\ell}-(\ell+1)\zeta_{n\ell}$ with the degeneracy 2ℓ, where we introduced the abbreviation,

$$\zeta_{n\ell} \equiv \tfrac{\hbar^2}{2}\langle\xi(r)\rangle \ . \tag{29.129}$$

All in all, we get an energy correction due to the spin-orbit interaction of,

$$\boxed{\Delta E_{\ell s} = -E_n(Z\alpha)^2\frac{j(j+1)-\ell(\ell+1)-\frac{3}{4}}{2n\ell(\ell+1/2)(\ell+1)}} \ . \tag{29.130}$$

Note, that the coupling $\mathbf{l}\cdot\mathbf{s}$ lifts the degeneracy with respect to $\mathbf{l}$, but not with respect to ℓ_z (see Fig. 29.1). As we have already seen in Exc. 29.1.5.6, in the presence of an energy associated with the coupling $\mathbf{l}\cdot\mathbf{s}$, only the total angular momentum $\mathbf{l}+\mathbf{s}$ is a constant of motion.

29.2.3 Non-local electron-core interaction

Let us now discuss the third correction in the expression (29.108). The electron-nucleus interaction that we have considered so far is *local*, that is, the interaction at the point $\mathbf{r}$ sensed by the electron depends essentially on the field at that point in space. However, when relativistic theory is correctly applied, the electron-nucleus interaction becomes *non-local*, and the electron is then affected by all values of the nuclear field in a region around $\mathbf{r}$ [12]. The size of this region is of the order of the *Compton wavelength* of the electron, $\lambda_C/2\pi \equiv \hbar/m_e c$. This correction was introduced by *Sir Charles Galton Darwin* through a substitution in the Dirac equation that solved the problem of normalization of the wavefunction.

Imagine that instead of the potential $V(\mathbf{r})$, the potential of the electron is given by the integral,

$$\int f(r')V(\mathbf{r}+\mathbf{r}')d^3r' \ , \tag{29.131}$$

[12] The smearing out of the electron's position is also known as *Zitterbewegung*. See Exc. 29.1.5.2.

where $f(r')$ is a radially symmetric and normalized density-type function that takes significant values only in the vicinity of $\mathbf{r}$ within a volume $(\lambda_C/2\pi)^3$ centered at $\mathbf{r}' = 0$. Expanding the potential $V(\mathbf{r}+\mathbf{r}')$ near the origin,

$$V(\mathbf{r}+\mathbf{r}') = V(\mathbf{r}) + [\mathbf{r}'\cdot\nabla_r]V(\mathbf{r}) + \tfrac{1}{2!}[\mathbf{r}'\cdot\nabla_r]^2 V(\mathbf{r}) + \dots\ , \tag{29.132}$$

and inserting into the integral,

$$\begin{aligned}&\int f(r')V(\mathbf{r}+\mathbf{r}')d^3r' \\ &= V(\mathbf{r})\int f(r')d^3r' + \int \mathbf{r}' f(r')d^3r'\cdot\nabla_r V(\mathbf{r}) + \tfrac{1}{2!}\int r'^2 f(r')[\hat{\mathbf{e}}_{r'}\cdot\nabla_r]^2 d^3r' V(r) + \dots \\ &= V(\mathbf{r}) + 0 + \tfrac{1}{2!}\int r'^2 f(r')d^3r'\nabla^2 V(r) + \dots\ .\end{aligned} \tag{29.133}$$

The second term is null due to the parity of $f(r')$ and the third produces the Darwin correction using $V(\mathbf{r}) = V(r)$. Letting the function be constant within the volume, $f(\mathbf{r}) \simeq f_0$, and with the normalization,

$$1 = \int_{-\hbar/2m_ec}^{\hbar/2m_ec}\int_{-\hbar/2m_ec}^{\hbar/2m_ec}\int_{-\hbar/2m_ec}^{\hbar/2m_ec} f(r)dxdydz = f_0\left(\frac{\hbar}{m_ec}\right)^3\ , \tag{29.134}$$

we get the integral

$$\int r^2 f(r)d^3r = \int_{-\hbar/2m_ec}^{\hbar/2m_ec}\int_{-\hbar/2m_ec}^{\hbar/2m_ec}\int_{-\hbar/2m_ec}^{\hbar/2m_ec} f(r)r^2 dxdydz = \left(\frac{\hbar}{2m_ec}\right)^2\ . \tag{29.135}$$

Also,

$$\nabla^2 V(\mathbf{r}) = -e\nabla^2\frac{Ze}{4\pi\varepsilon_0 r} = -e\frac{\varrho(\mathbf{r})}{\varepsilon_0} = -\frac{Ze^2\delta^3(\mathbf{r})}{\varepsilon_0}\ . \tag{29.136}$$

Hence,

$$\int f(r')V(\mathbf{r}+\mathbf{r}')d^3r' = -\frac{Ze^2}{4\pi\varepsilon_0 r} + \frac{\pi\hbar^2}{2m_e^2c^2}\frac{Ze^2}{4\pi\varepsilon_0}\delta^3(\mathbf{r}) + \dots\ , \tag{29.137}$$

which is precisely the electrostatic energy with the Darwin correction in the expressions (29.85) and (29.108).

To estimate the importance of this effect we inserting the wavefunctions (25.52) evaluated at the origin,

$$\begin{aligned}\langle\hat{H}_{dw}\rangle &= \int d^3r\psi^*_{n\ell m}(\mathbf{r})\frac{\pi\hbar^2}{2m_e^2c^2}\frac{Ze^2}{4\pi\varepsilon_0}\delta^3(\mathbf{r})\psi_{n\ell m}(\mathbf{r}) \\ &= \frac{\pi\hbar^2}{2m_e^2c^2}\frac{Ze^2}{4\pi\varepsilon_0}|\psi_{n00}(0)|^2\delta_{\ell 0}\delta_{m0} = \frac{\pi\hbar^2}{2m_e^2c^2}\frac{Ze^2}{4\pi\varepsilon_0}\frac{Z^3}{\pi n^3 a_B^3}\delta_{\ell 0}\ .\end{aligned} \tag{29.138}$$

We obtain,

$$\frac{H_{dw}}{H_0} = \frac{\frac{\pi\hbar^2}{2m_e^2c^2}\frac{Ze^2}{4\pi\varepsilon_0}\frac{1}{\pi a_B^3}}{\frac{e^2}{4\pi\varepsilon_0 a_B}} = \frac{\hbar^2}{2m_e^2c^2}\frac{Z}{a_B^2} = \frac{\alpha^2}{2} \approx 0.01\%\ . \tag{29.139}$$

Darwin's correction vanishes for angular momentum $\mathbf{l} > 0$, such that,

$$\boxed{\Delta E_{dw} = \langle\hat{H}_{dw}\rangle = -E_n\frac{(Z\alpha)^2}{n}\delta_{\ell 0}\ .} \tag{29.140}$$

29.2.4 Summary of the corrections

Combining the $\mathbf{l}\cdot\mathbf{s}$ and relativistic corrections, we obtain,

$$\begin{aligned}\Delta E_{fs} &= \Delta E_{rl} + \Delta E_{\ell s} + \Delta E_{dw} \qquad (29.141)\\ &= E_n(Z\alpha)^2\left[\frac{1}{n(\ell+\frac{1}{2})} - \frac{3}{4n^2}\right] - E_n(Z\alpha)^2\frac{j(j+1)-\ell(\ell+1)-\frac{3}{4}}{2n\ell(\ell+\frac{1}{2})(\ell+1)} - E_n(Z\alpha)^2\\ &= E_n(Z\alpha)^2\begin{cases}\frac{1}{nj} - \frac{3}{4n^2} - \frac{j(j+1)-(j-\frac{1}{2})(j+\frac{1}{2})-\frac{3}{4}}{2n(j-\frac{1}{2})j(j+\frac{1}{2})} - 1 & \text{para} \quad \ell = j-\frac{1}{2}\\ \frac{1}{n(j+1)} - \frac{3}{4n^2} - \frac{j(j+1)-(j+\frac{1}{2})(j+\frac{3}{2})-\frac{3}{4}}{2n(j+\frac{1}{2})(j+1)(j+\frac{3}{2})} - 1 & \text{para} \quad \ell = j+\frac{1}{2}\end{cases}\\ &= E_n(Z\alpha)^2\left[\frac{1}{n(j+\frac{1}{2})} - \frac{3}{4n^2} - 1\right] .\end{aligned}$$

That is, the levels are now degenerate in j (see Fig. 29.1) [13]. Obviously the levels which are most affected by relativistic corrections are those with low values of n and ℓ.

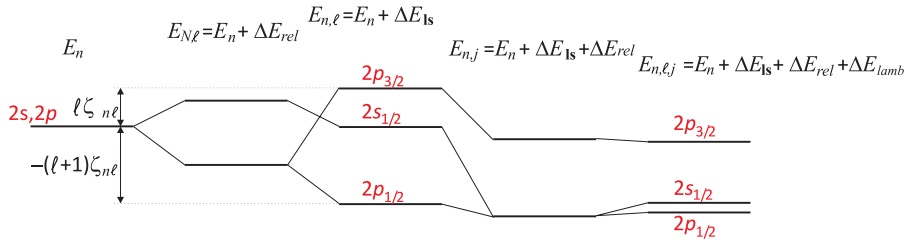

Figure 29.1: Hydrogen levels.

The levels are labeled by $n\ell_j$. For example, the state $3d_{5/2}$ has the main quantum number $n=3$, the orbital angular momentum $\ell=2$, and the total angular momentum $j=5/2$. For large n or j the fine structure disappears. The new energy scheme is shown in Fig. 29.1. We note that, taking into account all relativistic corrections (but without the Lamb shift), we still have a partial degeneracy of the quantum number j. For example, the states $^2s_{1/2}$ and $^2p_{1/2}$ have the same energy. This is a particularity of the hydrogen atom.

29.2.5 Lamb shift

Only remains to discuss the fourth correction, $\hat{H}_{lamb}$ in the expression (29.6). The origin of the *Lamb shift* lies in quantum electrodynamics. Being due to the quantum nature of the electromagnetic field, this correction is not predicted within the Dirac equation.

We may imagine the Coulomb force between charged particles being mediated by a continuous exchange of virtual photons. But each isolated charge also continuously emits and reabsorbs virtual photons, with the result that the position of the electron is smeared over a region of 0.1 fm. This reduces the overlap between the electronic

[13] It is interesting that the quantum treatment presented here, including relativistic corrections, coincidentally agrees with the corrections of *Arnold Johannes Wilhelm Sommerfeld*.

orbits and the nucleus. Hence, the Lamb shift causes corrections that are stronger for small n and small ℓ. For example in hydrogen, the $2p_{1/2}$ is $4.4 \cdot 10^{-6}\,\mathrm{eV} = 1\,\mathrm{GHz}$ below the $2s_{1/2}$ (see Fig. 29.1).

29.2.6 Exercises

29.2.6.1 Ex: The Darwin term

Show that the expressions for the Darwin correction (29.85) and (29.108) are equivalent.

Solution: *The Darwin term in (29.85) is given as,*

$$\hat{H}_{dw} = -\frac{\hbar^2 e}{4m_e^2c^2}\frac{\partial U(r)}{\partial r}\frac{\partial}{\partial r} = -\frac{\hbar^2 e}{4m_e^2c^2}\nabla U(r)\cdot\nabla \ .$$

The expectation value is,

$$\begin{aligned}\langle H_{dw}\rangle &= \int \psi^*(r)\nabla U(r)\cdot\nabla\psi(r)d^3r = \cancelto{0}{\int \nabla\psi^*(r)U(r)\psi(r)dS} - \int \nabla\left[\psi^*(r)\nabla U(r)\right]\psi(r)d^3r \\ &= -\int \left[\nabla\psi^*(r)\right]\nabla U(r)\psi(r)d^3r - \int \psi^*(r)\left[\nabla^2 U(r)\right]\psi(r)d^3r \ .\end{aligned}$$

Hence,

$$\int \psi^*(r)\nabla U(r)\cdot\nabla\psi(r)d^3r = -\tfrac{1}{2}\int \psi^*(r)\left[\nabla^2 U(r)\right]\psi(r)d^3r \ .$$

Therefore, we can rewrite the Darwin term as,

$$\hat{H}_{dw} = -\frac{1}{2}\frac{-\hbar^2}{4m_e^2c^2}\nabla^2 eU = \frac{\hbar^2}{8m_e^2c^2}\frac{-Ze^2}{\varepsilon_0}\delta^3(\mathbf{r}) = \frac{\pi\hbar^2}{2m_e^2c^2}\frac{Ze^2}{4\pi\varepsilon_0}\delta^3(\mathbf{r}) \ .$$

29.3 Hyperfine structure

Rutherford's measurements suggested a point-like and infinitely heavy atomic nucleus. In fact, the mass is finite and the nuclear charge is distributed over a finite volume and often in a non-isotropic manner, which leads to multipolar interactions with the electrons. In addition, many nuclei have a spin that can interact with the magnetic moment of the electrons. The energy corrections due to these effects are called *hyperfine structure* [14].

Because many of the following considerations will remain valid for many-electron systems to be discussed later, we will switch to a notation denoting by $\mathbf{L}$ the total orbital angular momentum of the electronic shell, $\mathbf{S}$ the total spin of the electronic shell, and $\mathbf{J}$ the total angular momentum of the electronic shell, remembering that for hydrogen $\mathbf{S} = \frac{\hbar}{2}\vec{\sigma}$.

[14] See [276] p. 1229 and [1329] p. 23 for further reading.

29.3.1 Coupling to the nuclear spin

29.3.1.1 Dipole moment of the nuclear spin

The nucleus may also have an angular momentum interacting with the angular momentum of the electrons. However, the momentum depends inversely on the masses. That is, the angular momentum of the nucleus is $\mu_N/\mu_B = m_e/m_p \simeq 10^{-3}$ times smaller, where $\mu_N = \hbar e/2m_p$ is an abbreviation called *nuclear magneton*. Thus, we can assume that the interaction between the nucleus and the electron will not interfere with the $\mathbf{L}\cdot\mathbf{S}$-coupling between the orbital angular momentum and the spin of the electron. The spin of the nucleus will be oriented along the total momentum of the electrons $\mathbf{J}$. However, this interaction will have the ability to lift the hydrogen degeneracy, even though the *splitting* will only be *hyperfine*. Indeed, the order of magnitude of *hyperfine splitting* is 10^{-6} eV.

Analogously to the expressions (29.93) and (29.96), we write the dipole moment of the nucleus,

$$\boxed{\frac{\vec{\mu}_I}{\mu_N} = \frac{e}{2m_p\mu_N} g_p \mathbf{I} = g_p \frac{\mathbf{I}}{\hbar}} \,, \tag{29.142}$$

where $g_p \equiv \mu_I/I$ is once again a factor taking into account possible corrections between the classical derivation and quantum mechanics [15].

29.3.1.2 Hyperfine splitting

In the derivation of the Pauli equation (29.89) from the Dirac equation (29.76) we discarded non-relativistic terms and reintroduced electronic spin-orbit coupling by hand allowing for $\mathbf{A}(\mathbf{r},t) \neq 0$. By an analogous calculation directly applied to the Dirac equation we may unravel the *hyperfine structure*. Instead of setting the vector potential to $\mathbf{A}(\mathbf{r},t) = 0$, as we did in (29.45), we now generalize the Dirac equation (29.76),

$$E'\vec{\phi} = qU(\mathbf{r})\vec{\phi} + \vec{\sigma}\cdot\vec{\pi}\frac{1}{2m_e}\left(1 + \frac{E'-U(\mathbf{r})}{2m_ec^2}\right)^{-1}\vec{\sigma}\cdot\vec{\pi}\vec{\phi} \,. \tag{29.143}$$

Assuming $\langle q\mathbf{A}\rangle \ll \langle \mathbf{p}\rangle$, we may only retain terms to the lowest order in $\mathbf{A}$ and neglect terms containing $q\mathbf{A}\frac{E'-U(\mathbf{r})}{2m_ec^2}$. Using the result of the calculation (29.87),

$$(\vec{\sigma}\cdot\vec{\pi})(\vec{\sigma}\cdot\vec{\pi}) = [\mathbf{p} - q\mathbf{A}]^2 - \hbar q\vec{\sigma}\cdot\vec{\mathcal{B}} \,, \tag{29.144}$$

we find the generalization of the total energy (29.85),

$$\hat{H} \simeq \frac{[\mathbf{p}-q\mathbf{A}(\mathbf{r})]^2}{2m_e} - \frac{1}{4\pi\varepsilon_0}\frac{e^2}{r} - \frac{\mathbf{p}^4}{8m_e^3c^2} - \frac{e}{2m_e^2c^2}\frac{1}{r}\frac{\partial U}{\partial r}\mathbf{S}\cdot\mathbf{L} - \frac{\hbar^2 e}{4m_e^2c^2}\frac{\partial U}{\partial r}\frac{\partial}{\partial r} - \frac{\hbar q}{2m_e}\vec{\sigma}\cdot\vec{\mathcal{B}}(\mathbf{r}) \,, \tag{29.145}$$

and expanding the bracket

$$[\mathbf{p}-q\mathbf{A}]^2 \simeq \mathbf{p}^2 - q\mathbf{p}\cdot\mathbf{A} - q\mathbf{A}\cdot\mathbf{p} = \mathbf{p}^2 - 2q\mathbf{A}\cdot\mathbf{p} \tag{29.146}$$

[15] In fact, the proton factor g is anomalous, $g_p = 5.58$, which reduces the fraction μ_l/μ_I. For the neutron we have: $g_n = -3.83$

in the Coulomb gauge, we see that two new terms are added to the energy called the hyperfine structure,

$$\boxed{\begin{array}{rcl} \hat{H} & = & \hat{H}_B + \hat{H}_{fs} + \hat{H}_{hfs} \\ \text{with} \quad \hat{H}_{hfs} & = & \hat{H}_{LI} + \hat{H}_{SI} = \frac{e}{m_e}\mathbf{A}(\mathbf{r})\cdot\mathbf{p} + \frac{2\mu_B}{\hbar}\mathbf{S}\cdot\vec{\mathcal{B}}(\mathbf{r}) \end{array}} \ , \tag{29.147}$$

with $\vec{\mu}_S = -\frac{e}{m_e}\mathbf{S}$.

Up to now we did not say anything about the origin of the magnetic field. We only notice that any magnetic field will interact with the electron's orbit and with its spin. We now make use of our knowledge that the proton has a spin of its own which produces, at the position of the electrons, a magnetic vector potential,

$$\mathbf{A}(\mathbf{r}) = \frac{\mu_0}{4\pi}\frac{\vec{\mu}_I \times \mathbf{r}}{r^3} \ , \tag{29.148}$$

interacting with the angular momentum of the electron $\mathbf{L}$ in the form,

$$\begin{aligned} \hat{H}_{LI} &= \frac{e}{m_e}\mathbf{A}\cdot\hat{\mathbf{p}} = \frac{e}{m_e}\frac{\mu_0}{4\pi r^3}(\vec{\mu}_I \times \mathbf{r})\cdot\mathbf{p} \\ &= \frac{e}{m_e}\frac{\mu_0}{4\pi r^3}\frac{\mu_N}{\hbar}g_p(\mathbf{I}\times\mathbf{r})\cdot\mathbf{p} = \frac{\mu_0}{2\pi r^3}\frac{\mu_B}{\hbar}\frac{\mu_N}{\hbar}g_p\mathbf{L}\cdot\mathbf{I} \ , \end{aligned} \tag{29.149}$$

using the definition of Bohr's magneton.

In addition, the potential vector (29.148) generated by the nuclear spin produces a magnetic field [659],

$$\vec{\mathcal{B}} = \nabla\times\mathbf{A} = \frac{\mu_0}{4\pi r^3}\left[3(\vec{\mu}_I\cdot\hat{\mathbf{r}})\hat{\mathbf{r}} - \vec{\mu}_I\right] + \tfrac{2}{3}\mu_0\vec{\mu}_I\delta^3(\mathbf{r}) \ , \tag{29.150}$$

as will be shown in Exc. 29.3.3.1. This field interacts with the spin of the electron $\mathbf{S}$ in the form,

$$\begin{aligned} \hat{H}_{SI} &= -\vec{\mu}_S\cdot\vec{\mathcal{B}} = -\frac{\mu_0}{4\pi r^3}\left[3(\vec{\mu}_I\cdot\hat{\mathbf{r}})(\vec{\mu}_S\cdot\hat{\mathbf{r}}) - (\vec{\mu}_S\cdot\vec{\mu}_I)\right] - \tfrac{2}{3}\mu_0\vec{\mu}_S\cdot\vec{\mu}_I\delta^3(\mathbf{r}) \\ &= \frac{\mu_0}{4\pi r^3}\frac{\mu_B}{\hbar}g_e\frac{\mu_N}{\hbar}g_p\left[3(\mathbf{I}\cdot\hat{\mathbf{r}})(\mathbf{S}\cdot\hat{\mathbf{r}}) - (\mathbf{S}\cdot\mathbf{I})\right] + \tfrac{2}{3}\mu_0 g_e\mu_B\frac{\mathbf{S}}{\hbar}\cdot g_p\mu_N\frac{\mathbf{I}}{\hbar}\delta^3(\mathbf{r}) \ , \end{aligned} \tag{29.151}$$

inserting the expressions (29.96) and (29.142). The first term gives the energy of the nuclear dipole in the field due to the electronic orbital angular momentum. The second term gives the energy of the 'finite distance' interaction of the nuclear dipole with the field due to the electron spin magnetic moments. The final term, often known as the *Fermi contact term* relates to the direct interaction of the nuclear dipole with the spin dipoles and is only non-zero for states with a finite electron spin density at the position of the nucleus (those with unpaired electrons in s-subshells).

We now discuss the two cases in which $L = 0$ or $L \neq 0$ separately in the following subsections [276, 1128, 659].

29.3.1.3 Orbital angular momentum $L = 0$

For vanishing orbital angular momenta, $L = 0$, we only need to consider the contribution $\hat{H}_{SI}$. Furthermore, this contribution will be dominated by the Dirac term,

because the s-orbitals have a high probability at the nuclear region, but fall off quickly at larger distances. Hence,

$$\hat{H}_{SI} \simeq \tfrac{2}{3}\mu_0 g_e \mu_B \frac{\mathbf{S}}{\hbar} \cdot g_p \mu_N \frac{\mathbf{I}}{\hbar} \delta^3(\mathbf{r}) \ . \tag{29.152}$$

Defining the complete total angular momentum of the atom,

$$\mathbf{F} \equiv \mathbf{I} + \mathbf{S} \ , \tag{29.153}$$

we calculate from (29.151),

$$\begin{aligned} \Delta E^{\ell=0}_{hfs} &= \langle (S,I)F, m_F | \hat{H}_{SI} | (S,I)F, m_F \rangle = \frac{2\mu_0 g_e g_p \mu_B \mu_N}{3\hbar^2} \langle \mathbf{S}\cdot\mathbf{I} \rangle \langle \delta^3(\mathbf{r}) \rangle \qquad (29.154) \\ &= \tfrac{2}{3}\mu_0 g_e g_p \mu_B \mu_N [F(F+1) - I(I+1) - S(S+1)] \int \psi^*_{n00}(\mathbf{r}) \delta^3(\mathbf{r}) \psi_{n00}(\mathbf{r}) d^3r \\ &= \tfrac{2}{3}\mu_0 g_e g_p \mu_B \mu_N [F(F+1) - I(I+1) - S(S+1)] \left| \tfrac{1}{\sqrt{\pi}} \left(\tfrac{Z}{n a_B} \right)^{3/2} \right|^2 \ . \end{aligned}$$

As an example consider the hyperfine structure of the state $1s_{1/2}$ of the hydrogen atom. With $J = I = \frac{1}{2}$ and $Z = n = 1$ we obtain (see Exc. 29.3.3.2),

$$\begin{aligned} \Delta E^{L=0}_{hfs}(F=1) - \Delta E^{\ell=0}_{hfs}(F=0) &= \tfrac{2}{3}\mu_0 g_e \mu_B g_p \mu_N \ 2 \ \tfrac{1}{\pi} \left(\tfrac{Z}{n a_B} \right)^3 \qquad (29.155) \\ &= \frac{2 g_e g_p m_e^2 c^2}{3 m_p} \alpha^4 \approx (2\pi\hbar) \cdot 1.420 \, \text{GHz} \ . \end{aligned}$$

The experimental value is 1.4204057518 GHz. This frequency corresponds to the spectral line used in radio astronomy, where the measurement of the angular distribution of this radiation allows the mapping of the spatial distribution of interstellar hydrogen.

29.3.1.4 Orbital angular momenta $L \neq 0$

In the case $L \neq 0$ both contributions, $\hat{H}_{SI}$ and $\hat{H}_{LI}$ have to be considered, however, we may neglect the Dirac term, because the orbitals with orbital angular momentum have vanishing probabilities at the nuclear region. Combining the two terms (29.149) and (29.151), we obtain,

$$\begin{aligned} \hat{H}_{JI} = \hat{H}_{LI} + \hat{H}_{SI} &= \frac{\mu_0}{4\pi r^3} \frac{\mu_B}{\hbar} g_e \frac{\mu_N}{\hbar} g_p \left[3(\mathbf{I}\cdot\hat{\mathbf{r}})(\mathbf{S}\cdot\hat{\mathbf{r}}) + \mathbf{L}\cdot\mathbf{I} - \mathbf{S}\cdot\mathbf{I} \right] \qquad (29.156) \\ &= \frac{\mu_0}{4\pi r^3} \frac{\mu_B}{\hbar} g_e \frac{\mu_N}{\hbar} g_p \mathbf{N}\cdot\mathbf{I} \ , \end{aligned}$$

introducing $\mathbf{N}$ as a quantity that only depends on the electronic shell:

$$\mathbf{N} \equiv 3(\mathbf{S}\cdot\hat{\mathbf{r}})\hat{\mathbf{r}} + \mathbf{L} - \mathbf{S} \ . \tag{29.157}$$

Generalizing the complete total angular momentum of the atom (29.153),

$$\mathbf{F} \equiv \mathbf{I} + \mathbf{J} \ , \tag{29.158}$$

is useful for calculating the coupling $\mathbf{I}\cdot\mathbf{J} = \frac{1}{2}(\mathbf{F}^2 - \mathbf{I}^2 - \mathbf{J}^2)$. Now, as the $\mathbf{L}\cdot\mathbf{S}$-coupling is strong, we project the two angular momenta onto the total electronic angular momentum $\mathbf{J}$,

$$\mathbf{N} \longrightarrow \frac{\mathbf{N}\cdot\mathbf{J}}{|\mathbf{J}|}\frac{\mathbf{J}}{|\mathbf{J}|} \quad , \qquad \mathbf{I} \longrightarrow \frac{\mathbf{I}\cdot\mathbf{J}}{|\mathbf{J}|}\frac{\mathbf{J}}{|\mathbf{J}|} \; . \tag{29.159}$$

We get for the coupling between the projected spins (29.159) of the electronic layer and the nucleus,

$$\mathbf{N}\cdot\mathbf{I} \longrightarrow \frac{(\mathbf{N}\cdot\mathbf{J})(\mathbf{I}\cdot\mathbf{J})}{|\mathbf{J}|^2} = \frac{(\mathbf{N}\cdot\mathbf{J})(\mathbf{F}^2 - \mathbf{I}^2 - \mathbf{J}^2)}{2|\mathbf{J}|^2} \; . \tag{29.160}$$

We calculate

$$\begin{aligned}\Delta E_{hfs}^{L\neq 0} &= \langle((L,S)J,I)F,m_F|\hat{H}_{JI}|((L,S)J,I)F,m_F\rangle \qquad (29.161)\\ &= \frac{\mu_0}{4\pi}\frac{\mu_B}{\hbar}g_e\frac{\mu_N}{\hbar}g_p\left\langle\frac{\mathbf{N}\cdot\mathbf{I}}{r^3}\right\rangle \\ &\longrightarrow \frac{\mu_0}{4\pi}\frac{\mu_B}{\hbar}g_e\frac{\mu_N}{\hbar}g_p\frac{\mathbf{N}\cdot\mathbf{J}[F(F+1)-I(I+1)-J(J+1)]}{2J(J+1)}\left(\frac{Z}{a_B}\right)^3\frac{n}{n^4L(L+\frac{1}{2})(L+1)} \; .\end{aligned}$$

Introducing the *interval factor*,

$$A_J \equiv \frac{\mu_0}{4\pi}\frac{\mu_B}{\hbar}g_e\frac{\mu_N}{\hbar}g_p\left(\frac{Z}{a_B}\right)^3\frac{\mathbf{N}\cdot\mathbf{J}}{2J(J+1)}\frac{n}{n^4L(L+\frac{1}{2})(L+1)} \; , \tag{29.162}$$

as a quantity that only depends on the electronic shell, we can write

$$\boxed{\Delta E_{hfs}^{L\neq 0} = \tfrac{A_J}{2}[F(F+1) - J(J+1) - I(I+1)]} \; . \tag{29.163}$$

Note, that the $\mathbf{J}\cdot\mathbf{I}$-coupling breaks the degeneracy of $\mathbf{J}$ in the hydrogen atom, but not of J_z. We can derive the following *interval rule*,

$$\Delta E_{F+1} - \Delta E_F = A_J(F+1) \; . \tag{29.164}$$

Besides the magnetic interaction between the angular momenta of the nucleus and the electronic shell there is an interaction between the nucleus, when it is not spherically symmetric, and the shell. This interaction causes deviations from the interval rule and an additional splitting of the hyperfine states.

29.3.2 Electric quadrupole interaction

The fact that the nucleus is not perfectly spherical gives rise to new electron-nucleus corrections that are called *quadrupolar interaction*. The starting point is,

$$\hat{H}_{qud} = -\frac{1}{4\pi\epsilon_0}\frac{e^2}{|\mathbf{r}_e - \mathbf{r}_N|} - \frac{1}{4\pi\epsilon_0}\frac{e^2}{|\mathbf{r}_e|} \; , \tag{29.165}$$

where $\mathbf{r}_e$ is the electronic coordinate and $\mathbf{r}_N$ is the nuclear coordinate, both having their origin in the center mass of the nucleus. For $\mathbf{r}_e > \mathbf{r}_N$ this interaction can be obtained after several mathematical steps as [860],

$$\hat{H}_{qud} = B_J \frac{3(\hat{\mathbf{I}}\cdot\hat{\mathbf{J}})(2\hat{\mathbf{I}}\cdot\hat{\mathbf{J}}+1) - 2\hat{\mathbf{I}}^2\hat{\mathbf{J}}^2}{2I(I-1)2J(J-1)} \ , \tag{29.166}$$

where B_J is called the *constant of the quadrupolar electron-nucleus interaction*. With this expression we can calculate,

$$\Delta E_{qud} = \langle IJKm_K|\hat{H}_{qud}|IJKm_K\rangle = B_J \frac{\frac{3}{2}K(K+1) - 2I(I+1)J(J+1)}{2I(2I-1)2J(2J-1)} \ , \tag{29.167}$$

where $K \equiv 2\langle\hat{\mathbf{J}}\cdot\hat{\mathbf{I}}\rangle = F(F+1) - I(I+1) - J(J+1)$. It is important to remember that a nucleus with $I = 0$ or $I = \frac{1}{2}$ has no quadrupole moment, $B_J = 0$. Also for $J = \frac{1}{2}$ there will be no contribution.

Joining the contributions $\hat{\mathbf{J}}\cdot\hat{\mathbf{I}}$ of Eq. (29.163) and the quadrupolar contribution (29.167), the hyperfine structure can be described by,

$$\begin{aligned}\Delta E_{hfs} &= \Delta E_{JI} + \Delta E_{qud} \\ &= \frac{A_J}{2}K + \frac{B_J}{8IJ(2I-1)(2J-1)}[3K(K+1) - 4I(I+1)J(J+1)] \ ,\end{aligned} \tag{29.168}$$

where the constants A_J and B_J depend on the atom and the total electronic angular momentum.

Table 29.1: List of atomic data [1245] showing the natural linewidth of the D_2 line, frequencies of the D_1 and D_2 lines, and the hyperfine splitting.

Element	$\gamma_{D2}/2\pi$	$D1$	$D2$	$\nu_{HFS}[S_{1/2}]$

^{135}Cs	5.18	11182.000	11737.000	

In Excs. 29.3.3.3 and 29.3.3.4 we determine the hyperfine structures of sodium and rubidium atoms.

29.3.3 Exercises

29.3.3.1 Ex: Field of a magnetic moment

a. Calculate the vector potential $\mathbf{A}(\mathbf{r})$ and the magnetic dipole moment $\vec{\mu}$ produced by an orbiting electron by Biot-Savart's law using the expansion of $|\mathbf{r}-\mathbf{r}'|^{-1}$ in Legendre polynomials.
b. Calculate the magnetic field $\vec{\mathcal{B}}(\mathbf{r})$.

Solution: *a. We parametrize the current of a loop around the z-axis by,*

$$\mathbf{j}(\mathbf{r}') = I\hat{e}_\phi \delta(z')\delta(\rho' - R) \ .$$

With this, the vector potential is,

$$\mathbf{A}(\mathbf{r}) = \frac{\mu_0}{4\pi}\int_V \frac{\mathbf{j}(\mathbf{r}')}{|\mathbf{r}-\mathbf{r}'|}d^3r' = \frac{\mu_0 I}{4\pi}\int_V \frac{\delta(z')\delta(\rho'-R)}{|\mathbf{r}-\mathbf{r}'|}d\rho'\hat{\mathbf{e}}_{\phi'}\rho' d\phi' dz' = \frac{\mu_0 I}{4\pi}\oint_C \frac{d\mathbf{s}'}{|\mathbf{r}-\mathbf{r}'|} \ ,$$

using $\hat{\mathbf{e}}_{\phi'}\rho' d\phi' = d\mathbf{s}'$. *We expand the integral in terms of Legendre polynomials,*

$$\frac{1}{|\mathbf{r}-\mathbf{r}'|} = \frac{1}{\sqrt{r^2+r'^2-2rr'\cos\theta'}} = \frac{1}{r\sqrt{1-2\frac{r'}{r}\cos\theta'+\frac{r'^2}{r^2}}} = \frac{1}{r}\sum_{n=0}^{\infty} P_n(\cos\theta')\left(\frac{r'}{r}\right)^n \ ,$$

Table 29.2: Hyperfine constants of some alkaline atoms.

atom	n	$A_J(n^2S_{1/2})$	$A_J(n^2P_{1/2})$	$A_J(n^2P_{3/2})$	$B_J(n^2P_{3/2})$
		[MHz·h]	[MHz·h]	[MHz·h]	[MHz·h]
^{1}H, $I=\frac{1}{2}$	1	1420	46.17	−3.07	−0.18
^{7}Li, $I=\frac{3}{2}$	2	401.75	46.17	−3.07	−0.18
	3		13.5	−0.96	
^{23}Na, $I=\frac{3}{2}$	3	885.82	94.3	18.65	2.82
	4	202	28.85	6.00	0.86
^{85}Rb, $I=\frac{5}{2}$	5	1011.9	120.7	25.029	26.03
	6	239.3	39.11	8.25	8.16
^{87}Rb, $I=\frac{3}{2}$	5	3417.3	409.1	84.852	12.510
	6	809.1	132.5	27.70	3.947

where θ' is the angle between the vectors $\mathbf{r}$ and $\mathbf{r}'$ and $r'=\rho'$. With this, the vector potential is,

$$\mathbf{A}(\mathbf{r})=\frac{\mu_0 I}{4\pi}\sum_{n=0}^{\infty}\frac{1}{r^{n+1}}\oint_C P_n(\cos\theta')r'^n d\mathbf{s}'=\frac{\mu_0 I}{4\pi r}\oint_C 1 d\mathbf{s}'+\frac{\mu_0 I}{4\pi r^2}\oint_C r'\cos\theta' d\mathbf{s}'+\dots\ .$$

The monopole term vanishes, while the dipole term is (considering a vector $\mathbf{r}$ within the x-y plane, such that $\theta'=\phi-\phi'$),

$$\mathbf{A}(\mathbf{r})=\frac{\mu_0 I}{4\pi}\frac{1}{r^2}\oint_C r'\cos(\phi-\phi')\hat{\mathbf{e}}_{\phi'}r'd\phi'=\frac{\mu_0 I}{4\pi r^2}R^2\oint_C\cos(\phi-\phi')\begin{pmatrix}-\sin\phi'\\ \cos\phi'\\ 0\end{pmatrix}d\phi'$$

$$=\frac{\mu_0}{4\pi}\frac{1}{r^3}I\pi R^2\begin{pmatrix}-r\sin\phi\\ r\cos\phi\\ 0\end{pmatrix}=\frac{\mu_0}{4\pi}\frac{\vec{\mu}\times\mathbf{r}}{r^3}\ ,$$

with

$$\mathbf{r}=\begin{pmatrix}r\sin\theta\cos\phi\\ r\sin\theta\sin\phi\\ r\cos\theta\end{pmatrix}\qquad\text{and}\qquad\vec{\mu}=I\pi R^2\hat{\mathbf{e}}_z\ .$$

b. The magnetic field is,

$$\vec{\mathcal{B}}=\nabla\times\mathbf{A}=\frac{\mu_0}{4\pi}\nabla\times\left(\vec{\mu}\times\frac{\mathbf{r}}{r^3}\right)=\tfrac{\mu_0}{4\pi}\left[\cancelto{0}{\left(\tfrac{\mathbf{r}}{r^3}\cdot\nabla\right)\vec{\mu}}-(\vec{\mu}\cdot\nabla)\tfrac{\mathbf{r}}{r^3}+\vec{\mu}\left(\nabla\cdot\tfrac{\mathbf{r}}{r^3}\right)-\cancelto{0}{\tfrac{\mathbf{r}}{r^3}(\nabla\cdot\vec{\mu})}\right]\ .$$

Now we calculate on one hand for the x-component of the first non-vanishing term,

$$(\vec{\mu}\cdot\nabla)\frac{x}{r^3}=\vec{\mu}\cdot\left(\nabla\frac{x}{r^3}\right)=\vec{\mu}\cdot\left(x\nabla\frac{1}{r^3}+\frac{1}{r^3}\nabla x\right)=\vec{\mu}\cdot\left(x\hat{\mathbf{e}}_r\frac{\partial}{\partial r}\frac{1}{r^3}+\frac{1}{r^3}\hat{\mathbf{e}}_x\right)=\vec{\mu}\cdot\left(x\hat{\mathbf{e}}_r\frac{-3}{r^4}+\frac{1}{r^3}\hat{\mathbf{e}}_x\right)\ ,$$

so that,

$$-(\vec{\mu}\cdot\nabla)\frac{\mathbf{r}}{r^3} = \frac{1}{r^3}\left[3(\vec{\mu}\cdot\hat{\mathbf{e}}_r)\hat{\mathbf{e}}_r - \vec{\mu}\right] \ .$$

However, this result only holds for $r > 0$, because the derivation only holds for this case. For $r > 0$ the other term vanishes,

$$\vec{\mu}\left(\nabla\cdot\frac{\mathbf{r}}{r^3}\right) = \vec{\mu}4\pi\delta^3(\mathbf{r}) \longrightarrow 0 \ .$$

The problem can be resolved by noticing that the average magnetic field on a finite sized sphere is known, and that the field must be obtained by volume integration of $\vec{\mathcal{B}}_{dip}(\mathbf{r})$ even in the limit of infinitesimally small r. This can be achieved by adding a δ-function term normalized such that,

$$\bar{\mathbf{B}} = \frac{2\mu_0\vec{\mu}}{4\pi R^3} = \frac{\frac{2}{3}\mu_0\vec{\mu}\int_{\mathbb{R}^3}\delta^3(\mathbf{r})d^3r}{\frac{4\pi}{3}R^3} \ .$$

With this we finally obtain (see 15.4.2.10),

$$\vec{\mathcal{B}} = \frac{\mu_0}{4\pi r^3}\left[3(\vec{\mu}\cdot\hat{\mathbf{r}})\hat{\mathbf{r}} - \vec{\mu}\right] + \frac{2}{3}\mu_0\vec{\mu}\delta^3(\mathbf{r}) \ .$$

29.3.3.2 Ex: Probability for finding the electron near the nucleus

Calculate the expectation value $\langle\delta^{(3)}(\mathbf{r})\rangle_{n\ell m}$ for encountering the electron of a hydrogen atom close to the nucleus.

Solution: *With,*

$$\begin{aligned}
\psi_{n\ell m}(r,\vartheta,\varphi) &= R_{n\ell}(r)Y_{\ell m}(\vartheta,\varphi)\\
R_{n\ell}(r) &= \sqrt{\left(\frac{2Z}{na_B}\right)^3\frac{(n-\ell-1)!}{2n(n+\ell)!}}\left(\frac{2\tilde{r}}{n}\right)^\ell e^{-\tilde{r}/n}L_{n-\ell-1}^{(2\ell+1)}(\tfrac{2\tilde{r}}{n})\\
Y_{\ell m}(\vartheta,\varphi) &= \frac{1}{\sqrt{2\pi}}P_\ell^m(\cos\vartheta)\sqrt{\frac{2\ell+1}{2}\frac{(\ell-m)!}{(\ell+m)!}}e^{\imath m\varphi} \ ,
\end{aligned}$$

we find, using the formula (28.27),

$$\begin{aligned}
R_{n0}(0) &= \sqrt{\left(\frac{Z}{na_B}\right)^3\left(\frac{2}{n}\right)^2}L_{n-1}^{(1)}(0)\delta_{\ell,0}\\
&= \sqrt{\frac{Z}{na_B}}^3\frac{2}{n}\sum_{k=0}^{n-1}\binom{n}{n-1-k}\frac{(-0)^k}{k!}\delta_{\ell,0} = \sqrt{\frac{Z}{na_B}}^3 2\delta_{\ell,0} \ ,
\end{aligned}$$

and

$$Y_{00}(\vartheta,\varphi) = \frac{P_0^0(\cos\vartheta)}{2\sqrt{\pi}} = \frac{1}{2\sqrt{\pi}} \ ,$$

and hence,

$$\langle \delta^{(3)}(\mathbf{r}) \rangle_{n\ell m} = |\psi_{n\ell m}(\mathbf{0})|^2 = \frac{1}{\pi} \left(\frac{Z}{n a_B} \right)^3 \delta_{\ell,0} \ .$$

29.3.3.3 Ex: Hyperfine structure of sodium

Determine the hyperfine structure of the ^2S and ^2P states of the sodium atom including energy shifts. See Tab. 34.1 for the hyperfine constants A_J and B_J.

Solution: *With $I = \frac{3}{2}$ the state $^2S_{1/2}$ has two hyperfine levels, $F = 1, 2$. The quadrupole coefficient vanishes,*

$$\Delta E_{hfs} = \frac{A_J}{2} K = \frac{885.82\,\mathrm{MHz}}{2} K \ ,$$

such that

$$\Delta E_{hfs}(^{23}Na,^2 S_{1/2}, F = 1) \stackrel{K=-5/2}{\longrightarrow} -\frac{5}{4} \cdot 885.82\,\mathrm{MHz}$$
$$\Delta E_{hfs}(^{23}Na,^2 S_{1/2}, F = 2) \stackrel{K=3/2}{\longrightarrow} \frac{3}{4} \cdot 885.82\,\mathrm{MHz}$$
$$\Delta E_{hfs}(^{23}Na,^2 S_{1/2}, F = 2) - \Delta E_{hfs}(^{23}Na,^2 S_{1/2}, F = 1) = 2A_J = 1771.64\,\mathrm{MHz} \ .$$

The state $^2P_{1/2}$ has two hyperfine levels, $F = 1, 2$. The quadrupole coefficient vanishes,

$$\Delta E_{hfs} = \frac{A_J}{2} K = \frac{94.3\,\mathrm{MHz}}{2} K \ ,$$

such that

$$\Delta E_{hfs}(^{23}Na,^2 P_{1/2}, F = 1) \stackrel{K=-5/2}{\longrightarrow} -\frac{5}{4} \cdot 94.3\,\mathrm{MHz}$$
$$\Delta E_{hfs}(^{23}Na,^2 P_{1/2}, F = 2) \stackrel{K=3/2}{\longrightarrow} \frac{3}{4} \cdot 94.3\,\mathrm{MHz}$$
$$\Delta E_{hfs}(^{23}Na,^2 P_{1/2}, F = 2) - \Delta E_{hfs}(^{23}Na,^2 S_{1/2}, F = 1) = 2A_J = 188.6\,\mathrm{MHz} \ .$$

The state $^2P_{3/2}$ has four hyperfine levels, $F = 0, 1, 2, 3$. The quadrupole coefficient does not vanish,

$$\begin{aligned} \Delta E_{hfs} &= \frac{A_J}{2} K + \frac{B_J[3K(K+1) - 4I(I+1)J(J+1)]}{8I(2I-1)(2J-1)} \\ &= \frac{18.65\,\mathrm{MHz}}{2} K + \frac{2.82\,\mathrm{MHz}[3K(K+1) - \frac{225}{4}]}{48} \ , \end{aligned}$$

such that

$$\Delta E_{hfs}(^{23}Na,^2P_{3/2},F=0) \overset{K=-15/2}{\longrightarrow} \frac{-15}{4}\cdot 18.65\,\text{MHz} - \frac{135}{256}\cdot 2.82\,\text{MHz}$$
$$\Delta E_{hfs}(^{23}Na,^2P_{3/2},F=1) \overset{K=-11/2}{\longrightarrow} \frac{-11}{4}\cdot 18.65\,\text{MHz} - \frac{223}{256}\cdot 2.82\,\text{MHz}$$
$$\Delta E_{hfs}(^{23}Na,^2P_{3/2},F=2) \overset{K=-3/2}{\longrightarrow} \frac{-3}{4}\cdot 18.65\,\text{MHz} - \frac{303}{256}\cdot 2.82\,\text{MHz}$$
$$\Delta E_{hfs}(^{23}Na,^2P_{3/2},F=3) \overset{K=9/2}{\longrightarrow} \frac{9}{4}\cdot 18.65\,\text{MHz} - \frac{209}{256}\cdot 2.82\,\text{MHz}\ .$$

We verify that $\sum_F (2F+1)\Delta E_{hfs}(^{23}Na,^{2S+1}L_J,F)=0$.

29.3.3.4 Ex: Hyperfine structure of rubidium

Given the following energy distances $\nu_{F,F'}$ of the hyperfine levels of the rubidium isotopes ^{87}Rb and ^{85}Rb [104],

^{87}Rb, $S_{1/2}$ splits into $\nu_{1,2}=6834.7\,\text{MHz}$
^{87}Rb, $P_{3/2}$ splits into $\nu_{0,1}=72.3\,\text{MHz}, \nu_{1,2}=157.1\,\text{MHz}, \nu_{2,3}=267.2\,\text{MHz}$
^{85}Rb, $S_{1/2}$ splits into $\nu_{1,2}=3035.7\,\text{MHz}$
^{85}Rb, $P_{3/2}$ splits into $\nu_{1,2}=29.4\,\text{MHz}, \nu_{2,3}=63.4\,\text{MHz}, \nu_{3,4}=120.7\,\text{MHz}$,

calculate the positions of the barycenters.

Solution: *The rubidium hyperfine structure is,*

^{87}Rb, $S_{1/2}$ *gives* $E_{bc}=\frac{\hat{1}+\hat{2}\nu_{1,2}}{\hat{1}+\hat{2}}=4272.1\,\text{MHz}$
^{87}Rb, $P_{3/2}$ *gives* $E_{bc}=\frac{\hat{0}+\hat{1}\nu_{0,1}+\hat{2}\nu_{0,2}+\hat{3}\nu_{0,3}}{\hat{0}+\hat{1}+\hat{2}+\hat{3}}=\frac{(\hat{1}+\hat{2}+\hat{3})\nu_{0,1}+(\hat{2}+\hat{3})\nu_{1,2}+\hat{3}\nu_{2,3}}{\hat{0}+\hat{1}+\hat{2}+\hat{3}}=302.5\,\text{MHz}$
^{85}Rb, $S_{1/2}$ *gives* $E_{bc}=\frac{\hat{2}+\hat{3}\nu_{2,3}}{\hat{2}+\hat{3}}=1771.2\,\text{MHz}$
^{85}Rb, $P_{3/2}$ *gives* $E_{bc}=\frac{\hat{1}+\hat{2}\nu_{1,2}+\hat{3}\nu_{1,3}+\hat{4}\nu_{1,4}}{\hat{1}+\hat{2}+\hat{3}+\hat{4}}=\frac{(\hat{2}+\hat{3}+\hat{4})\nu_{1,2}+(\hat{3}+\hat{4})\nu_{2,3}+\hat{4}\nu_{3,4}}{\hat{1}+\hat{2}+\hat{3}+\hat{4}}=113.3\,\text{MHz}$.

29.3.3.5 Ex: Two particles

Consider a two-particle system of masses μ_1 and μ_2, exposed to a central potential $V(r)$ and an interaction potential $V(|\mathbf{r}_1-\mathbf{r}_2|)$ which only depends on the distance between the particles. The Hamiltonian of the system in the interaction representation is $H=H_1+H_2+V(|\mathbf{r}_1-\mathbf{r}_2|)$ with $H_\ell=-\frac{\hbar^2}{2\mu_\ell}\nabla_\ell^2+V(r_\ell)$, $\ell=1,2,...$ Show that the individual angular momenta $\mathbf{L}_\ell$ are not, in general, constants of the motion, unlike the *total* angular momentum $\mathbf{L}=\mathbf{L}_1+\mathbf{L}_2$.

Solution: *We have,*

$$[\hat{H},\hat{\mathbf{L}}_\mathbf{1}^2]=[V(|\mathbf{r}_1-\mathbf{r}_2|),(\hat{\mathbf{r}}_\mathbf{1}\times\hat{\mathbf{p}}_\mathbf{1})^2]\neq 0\ .$$

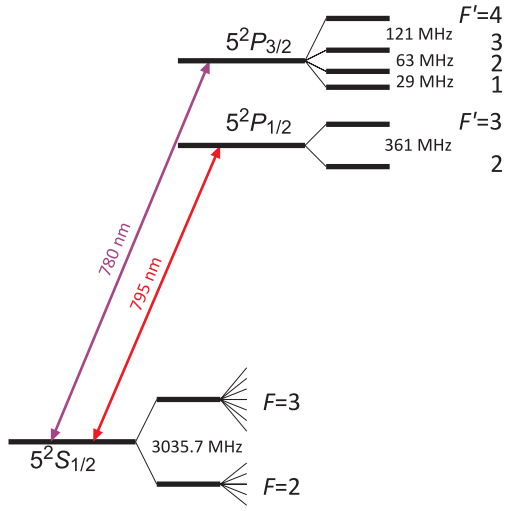

Figure 29.2: Rb hyperfine structure.

On the other side,

$$[\hat{H}, (\hat{\mathbf{L}}_\mathbf{1} + \hat{\mathbf{L}}_\mathbf{1})^2] = [V(|\mathbf{r}_1 - \mathbf{r}_2|), (\hat{\mathbf{r}}_\mathbf{1} \times \hat{\mathbf{p}}_\mathbf{1} + \hat{\mathbf{r}}_\mathbf{2} \times \hat{\mathbf{p}}_\mathbf{2})^2] \neq 0 \ .$$

We showed in the derivation of the radial Schrödinger equation (25.34), that the given Hamiltonian can be transformed into relative coordinates.

29.4 Exotic atoms

'Normal' atoms consist of a nucleus made of protons and neutrons and an electronic shell. But other two-particle systems are possible, e.g. where the nucleus or electron is replaced by another hadron or lepton (anti-proton, positron, muon, etc.). Such a system is called *exotic atom*. Atoms in Rydberg states also belong to this category.

29.4.1 Positronium and muonium

Positronium (e^+e^-) is a hydrogen-like system consisting of leptons, that is, an electron and a positron, which is the antiparticle of the electron. The muonium (μ^+e^-) is similar to positronium, except that here the positron is replaced by a muon whose mass is $m_{\mu^+} = 207m_e$. Leptons are, according to the present understanding, particles without internal structure. Both systems are unstable: the two particles annihilate each other producing γ-photons. The energy levels and orbits of the two particles are similar to that of the hydrogen atom. However, because of the reduced mass, the frequencies of the spectral lines are less than half of the corresponding hydrogen lines.

The fundamental state of positronium, like that of hydrogen, has two possible configurations depending on the relative orientation of the electron and positron spins.

The singlet state with antiparallel spins ($S = 0$, $M_s = 0$) is known as para-positronium (p-Ps) and denoted by $^1S_0$. It has an average lifetime of

$$\tau = \frac{2\hbar}{m_e c^2 \alpha^5} = 124.4\,\text{ps} \tag{29.169}$$

and decays preferably in two gamma rays with energy of 511 keV each (in the center-of-mass). The triplet state with parallel spins ($S = 1, M_s = -1, 0, 1$) is known as ortho-positronium (o-Ps) and denoted as $^3S_1$. It has an average life of 138.6 ns, and the most common form of decay produces three photons. Other forms of decay are negligible. For example, the decay channel producing five photons is 10^{-6} times less likely. Measurements of these lifetimes and the positronium energy levels have been used in precision tests of quantum electrodynamics.

While the precise calculation of the positronium energy levels is based on the Bethe-Salpeter equation, the similarity between positronium and hydrogen allows for an approximate estimate. In this approach, the energy levels are suppodsed to be different from those of hydrogen because of the difference in the value of the reduced mass μ, used in the energy equation. Since $\mu = m_e/2$ for positronium, we have

$$E_n = -\frac{\mu q_e^4}{8h^2\epsilon_0^2}\frac{1}{n^2} = -\frac{1}{2}\frac{m_e q_e^4}{8h^2\epsilon_0^2}\frac{1}{n^2} = \frac{-6.8\,\text{eV}}{n^2}\ . \tag{29.170}$$

A di-positronium molecule, that is, a system of two bound positronium atoms, has already been observed. Positronium in high energy states has been conjectured to become the dominant form of atomic matter in the universe in the very distant future if the proton decay becomes tangible.

29.4.2 Hadronic atoms

In contrast to *leptons* (such as the electron e^-, the positron e^+ and the muons μ^+ and μ^-) that participate only in electromagnetic interactions and weak interactions, *hadrons* also participate in strong (nuclear type) interactions. There are two types of hadrons, *baryons* (such as the proton p and antiproton $\bar{p}$, the neutron n and antineutron $\bar{n}$, hyperons Σ, Ξ, ...) that have semi-integer spin and behave like fermions and *mesons* (like the π-meson, K-meson, ...) that have an integer spin. Every negatively charged hadron can be used to form a hydrogen-type *hadronic atom*. These systems contain a nucleus and negative hyperon and are known as hyperonic atoms. All of these are unstable and due to the fact that they have a sufficiently long lifetime, some of their spectral lines have now been observed.

Since the hadrons interact strongly with the nucleus, the theory developed for hydrogen systems (in which only exist Coulomb interaction) can not be directly applied. In this way the values shown in Tab. 29.3 give only an estimate of the 'radius' and the ionization potential of the hadronic atoms $p\pi^-$, $p\kappa^-$, $p\bar{p}$ and $p\Sigma^-$.

29.4.3 Muonic hydrogen

The muon mass is $m_\mu = 207 m_e$. When a muon is attached to a proton we have *muonic hydrogen*. Its size is smaller because of the reduced mass $a_\mu = a_B \frac{1/m_e}{1/m_\mu + 1/m_p}$

Table 29.3: *Main features of some exotic atoms.*

system	reduced mass	radius 'a'	I_p
pe^-	$1836/1837 \approx 1$	$\approx a_B = 1$	$e^2/2a_B \approx 0.5$
e^+e^-	0.5	2	0.25
μ^+e^-	$207/208 \approx 1$	1	0.5
$p\mu^-$	≈ 186	$5.4 \cdot 10^{-3}$	93
$p\pi^-$	≈ 238	$4.2 \cdot 10^{-3}$	119
$p\kappa^-$	≈ 633	$1.6 \cdot 10^{-3}$	317
$p\bar{p}$	≈ 928	$1.1 \cdot 10^{-3}$	459
$p\Sigma^-$	≈ 1029	$9.7 \cdot 10^{-3}$	515

and the binding energy and the energies of excitation are greater for the same reason. F.ex. while for $H = p^+e^-$ the transition $2S - 2P_{1/2}$ is at 10 eV $\triangleq$ 121 nm, for $p^+\mu^-$ it is at 1900 eV. Muonic atoms are interesting because they have amplified Lamb shifts, hyperfine interactions, and quantum electrodynamical corrections. Therefore, the displacement due to the finite distribution of charges in the proton $r_p = 0.8$ fm should influence the spectrum. While in p^+e^- the $2S$ level is shifted upward by the Lamb shift by a value of 4.4×10^{-6} eV, in $p^+\mu^-$ it is shifted down by a value of 0.14 eV. In Exc. 29.4.5.2 we calculate the spectrum of the muonic hydrogen and in Exc. 27.1.3.3 we compare the energy corrections due to the finite extension of the nuclei for muonic and for standard hydrogen in first order TIPT.

29.4.4 Rydberg atoms

An atom excited to a state whose main quantum number is very high is called *Rydberg atom*. These atoms have a number of peculiar properties, including high sensitivity to electric and magnetic fields, long decay times, and wavefunctions that approximate classical electron orbits. The inner electrons protect the outer electron from the electric field of the nucleus such that, from a distance, the electric potential looks identical to that seen by the electron of a hydrogen atom.

Despite its flaws, Bohr's atom model is useful in explaining these properties. In Exc. 22.1.6.6 we derive Bohr's expression for the orbital radius in terms of the principal quantum number n:

$$r = \frac{4\pi\epsilon_0 n^2 \hbar^2}{e^2 m} \ . \tag{29.171}$$

Thus, it is clear why Rydberg atoms have peculiar properties: the radius goes as n^2 (such that for example the state with $n = 137$ of hydrogen has a radius of ~ 1 mm) and the geometric cross section goes as n^4. Thus, Rydberg atoms are extremely large, with loosely bound valence electrons that are easily perturbed or ionized by collisions or external fields.

Since the binding energy of a Rydberg electron is proportional to $1/r$, and therefore

falls as $1/n^2$, the spacing between energy levels falls as

$$\Delta E = E_1 \left(\frac{1}{(n+1)^2} - \frac{1}{n^2} \right) \stackrel{n\to\infty}{\longrightarrow} E_1 \left(-\frac{2}{n^3} + \frac{3}{n^4} + ... \right) \tag{29.172}$$

leading to less and less spaced levels. These Rydberg states form the *Rydberg series*.

29.4.4.1 Correspondence principle in Rydberg atoms

To calculate the oscillation frequency of an electron confined to a proton, we use the classical planetary model,

$$m\omega_n^2 = \frac{e^2}{4\pi\epsilon_0 r} \qquad \text{and} \qquad m\omega r^2 = n\hbar \ . \tag{29.173}$$

Eliminating r,

$$\omega_n = \frac{me^4}{(4\pi\epsilon_0)^2 n^3 \hbar^3} \ . \tag{29.174}$$

Radiation of this frequency will be emitted by an atomic antenna. On the other hand, the Bohr model predicts frequencies between orbitals,

$$\omega_n = \frac{E_{n+1} - E_n}{\hbar} = \frac{me^4}{2(4\pi\epsilon_0)^2\hbar^2} \left(\frac{1}{(n+1)^2} - \frac{1}{n^2} \right) \stackrel{n\to\infty}{\longrightarrow} \frac{me^4}{2(4\pi\epsilon_0)^2\hbar^2} \frac{2}{n^3} \ . \tag{29.175}$$

29.4.4.2 Production of Rydberg atoms

In the hydrogen atom only the ground state ($n = 1$) is actually stable. Other states must be excited by various techniques such as electron impact or charge exchange. In contrast to these methods, which produce a distribution of excited atoms at various levels, the optical excitation method allows to produce specific states, but only for alkali metals whose transitions fall into frequency regimes which are accessible to lasers.

29.4.4.3 Potential in a Rydberg atom

The valence electron in a Rydberg atom with Z protons in the nucleus and $Z - 1$ electrons in closed layers sees a spherically symmetric Coulomb potential:

$$U_{cou} = -\frac{e^2}{4\pi\varepsilon_0 r} \ . \tag{29.176}$$

The similarity of the effective potential 'seen' by the outer electron and the authentic hydrogen potential suggests a classical treatment within the planetary model. There are three notable exceptions:

- An atom can have two (or more) electrons in highly excited states with comparable orbital radii. In this case, the electron-electron interaction gives rise to a significant deviation from the hydrogen potential. For an atom in a multiple Rydberg state the additional term U_{ee} includes a sum over each pair of highly excited electrons:

$$U_{ee} = \frac{e^2}{4\pi\varepsilon_0} \sum_{i<j} \frac{1}{|\mathbf{r}_i - \mathbf{r}_j|} \ . \tag{29.177}$$

- If the valence electron has very low angular momentum (interpreted classically as an extremely eccentric elliptical orbit), it can pass close enough to the nucleus to polarize it, giving rise to an additional term,

$$U_{pol} = -\frac{e^2\alpha_d}{(4\pi\varepsilon_0)^2 r^4} \ . \tag{29.178}$$

- If the outer electron penetrates the inner electronic shells, it *sees* more of the charge of the nucleus and therefore feels a larger force. In general, the modification of the potential energy is not simple to calculate and should be based on some knowledge of the nucleus' geometry.

In hydrogen the binding energy is given by:

$$E_B = -\frac{E_1}{n^2} \ . \tag{29.179}$$

The binding energy is weak at high values of n, which explains the fragility of the Rydberg states that can easily be ionized, e.g. by collisions.

Additional terms modifying the potential energy of a Rydberg state require the introduction of a *quantum defect*, $\delta\ell$, in the expression for the binding energy:

$$E_B = -\frac{E_1}{(n-\delta_\ell)^2} \ . \tag{29.180}$$

The long lifetimes of Rydberg states with high orbital angular momentum can be explained in terms of overlapping wavefunctions. The wavefunction of an electron in a state with high ℓ (large angular momentum, 'circular orbit') has little overlap with the wavefunctions of the internal electrons and therefore stays relatively unperturbed. Also, the small energy difference between adjacent Rydberg states decreased the decay rate according to the result (34.40).

29.4.4.4 Rydberg atoms in external fields

The large distance between the electron and ionic nucleus in a Rydberg atom gives rise to an extremely large electric dipole moment d. There is an energy associated with the presence of an electric dipole in an electric field $\vec{\mathcal{E}}$, known as *Stark shift*,

$$E_S = -\mathbf{d}\cdot\vec{\mathcal{E}} \ . \tag{29.181}$$

Depending on the sign of the projection of the dipole moment onto the vector of the local electric field, the energy of a state increases or decreases with the intensity of the field. The narrow spacing between adjacent levels n in the Rydberg series means that the states can approach degeneracy even for relatively weak fields. Theoretically, the force of the field in which a level crossing would occur (assuming no coupling between the states) is given by the *Inglis-Teller limit*,

$$F_{IT} = \frac{e}{12\pi\varepsilon_0 a_0^2 n^5} \ . \tag{29.182}$$

In hydrogen the pure Coulomb potential does not couple the Stark states of an n level, which results in a *real crossover*. In other elements, deviations from the ideal $1/r$-potential allow for *avoided crossings*.

29.4.5 Exercises

29.4.5.1 Ex: Positronium

Calculate and compare the fine and hyperfine structure of positronium.

Solution: *The energy between states* $^1S_{1/2}, F = 0$ *and* $^1S_{1/2}, F = 1$ *is* $5.9 \cdot 10^{-6}\,\mathrm{eV}$. *The energy between states* $^3S_1$ *(ortho) and* $^1S_0$ *(para) is* $8.9 \cdot 10^{-4}\,\mathrm{eV}$.

29.4.5.2 Ex: Muonic hydrogen

Muonic hydrogen consists of a proton and a negatively charged muon. Calculate the binding energy of the ground state of muonic hydrogen in eV and write down the ground state's wavefunction.

Solution: *Following Bohr's model the hydrogen energy spectrum is,*

$$E_n = -\frac{\hbar^2}{2ma_B^2}\frac{1}{n^2} \qquad with \qquad a_B = 4\pi\epsilon_0\frac{\hbar^2}{me^2}\ ,$$

where m *is the reduced mass. In the case of the electron we have* $m = 0.9995m_e$. *The mass of the muon is approximately* $m_\mu = 207m_e$. *Thus, in the case of the muon we have* $m = 0.8981m_\mu$. *The ground state energy is,*

$$E_1^\mu \simeq -2.82\,\mathrm{keV} \qquad with \qquad a_B \simeq 2.56 \cdot 10^{-13}\,\mathrm{m}\ .$$

Chapter 30

Atoms with spin in external fields

The atomic fine structure was derived in the last chapter under the assumption that all electric and magnetic fields arise from the motion and spin of the electrons in the atomic shell and the nuclear spin. In this chapter, we will extend the treatment to include the reaction of the electrons to external electrostatic or electromagnetic fields. In this context, we will discuss the Zeeman and the Stark effect.

30.1 Charged particles in electromagnetic fields

30.1.1 Lagrangian and Hamiltonian of charged particles

A charge subject to an electromagnetic field feels the Lorentz force,

$$\mathbf{F} = q\vec{\mathcal{E}} + q\dot{\mathbf{r}} \times \vec{\mathcal{B}} \,, \tag{30.1}$$

where

$$\vec{\mathcal{E}} = -\nabla\Phi - \frac{\partial \mathbf{A}}{\partial t} \qquad \text{and} \qquad \vec{\mathcal{B}} = \nabla \times \mathbf{A} \,, \tag{30.2}$$

where Φ and $\mathbf{A}$ are called scalar and vector potential, respectively.

It is important to realize here, that the momentum $\mathbf{p}$ not only involves the momentum of the particle $m\mathbf{v}$, but the field also carries a momentum $q\mathbf{A}(\mathbf{r})$. As we learned in electrodynamics it is possible to derive the Lorentz force from a Lagrangian for the electronic motion,

$$\boxed{\mathcal{L}(r_i, \dot{r}_i) = \frac{m}{2}\dot{\mathbf{r}}^2 - q\Phi(\mathbf{r}) + q\dot{\mathbf{r}} \cdot \mathbf{A}(\mathbf{r})} \,. \tag{30.3}$$

With this aim we first determine the momentum by,

$$p_i = \frac{\partial \mathcal{L}}{\partial \dot{r}_i} = m\dot{r}_i + qA_i \,, \tag{30.4}$$

and the Hamiltonian by,

$$\mathcal{H} = \sum\nolimits_i p_i \dot{r}_i - \mathcal{L}(r_i, \dot{r}_i) = (m\mathbf{v} + q\mathbf{A}) \cdot \dot{\mathbf{r}} - \frac{m}{2}\dot{\mathbf{r}}^2 + q\Phi - q\dot{\mathbf{r}} \cdot \mathbf{A} = \frac{m}{2}\mathbf{v}^2 + q\Phi \,. \tag{30.5}$$

That is,

$$\boxed{\mathcal{H}(r_i, p_i) = \frac{1}{2m}(\mathbf{p} - q\mathbf{A})^2 + q\Phi} \ . \tag{30.6}$$

The following equations hold,

$$\dot{r}_i = \frac{\partial \mathcal{H}}{\partial p_i} \qquad \text{and} \qquad \dot{p}_i = -\frac{\partial \mathcal{H}}{\partial r_i} \ . \tag{30.7}$$

The first equation is easily verified by inserting the Hamiltonian (30.5). The second leads to the Lorentz force,

$$F_i = m\dot{v}_i = \dot{p}_i - q\dot{A}_i = -\frac{\partial \mathcal{H}}{\partial r_i} - q\dot{A}_i = q\mathcal{E}_i + q(\mathbf{v} \times \vec{\mathcal{B}})_i \ , \tag{30.8}$$

where the last step of the derivation will be shown in the Exc. 30.1.3.1 using the Coulomb gauge $\nabla \cdot \mathbf{A} = 0$.

30.1.2 Minimal coupling

Note that the same result (30.6) can be obtained by a canonical substitution,

$$m\mathbf{v} \longrightarrow \mathbf{p} - q\mathbf{A} \qquad \text{and} \qquad \mathcal{H} \longrightarrow \mathcal{H} + q\Phi \ . \tag{30.9}$$

This substitution rule, called *minimal coupling*, can be applied in quantum mechanics,

$$m\hat{\mathbf{v}} \longrightarrow -\imath\hbar\nabla - q\mathbf{A} \qquad \text{and} \qquad \hat{H} \longrightarrow \hat{H} + q\Phi \ . \tag{30.10}$$

In the case of the electron ($q = -e$) trapped in a central Coulomb potential $q\Phi = -\frac{Ze^2}{4\pi\varepsilon_0 r}$ and in the presence of any magnetic potential $\mathbf{A}$, we thus obtain,

$$\boxed{\hat{H} = \frac{m_e}{2}\hat{\mathbf{v}}^2 + q\Phi = \frac{-\hbar^2}{2m_e}\nabla^2 - \frac{\imath\hbar e}{2m_e}\mathbf{A}\cdot\nabla - \frac{\imath\hbar e}{2m_e}\nabla\cdot\mathbf{A} + \frac{e^2\mathbf{A}^2}{2m_e} + q\Phi} \ . \tag{30.11}$$

The fourth term called *diamagnetic term* is quadratic in $\mathbf{A}$ and usually so small that it can be neglected. The second and third terms describe the interaction of the electron through its momentum $\hat{\mathbf{p}}$ with the potential vector $\mathbf{A}$ produced by magnetic moments inside the atom or outer magnetic fields. Within the Coulomb gauge we have $(\nabla \cdot \mathbf{A})\psi = (\mathbf{A}\cdot\nabla)\psi + \psi(\nabla\cdot\mathbf{A}) = (\mathbf{A}\cdot\nabla)\psi$, such that,

$$\boxed{\hat{H}_{int} = \tfrac{e}{m_e}\mathbf{A}\cdot\hat{\mathbf{p}}} \ . \tag{30.12}$$

Example 182 (*Interaction Hamiltonian in dipolar approximation*): Note that the Hamiltonian (30.11) has been obtained from a gauge transformation in (23.229). With the particular choice for the gauge field,

$$\chi(\mathbf{r}, t) \equiv -\mathbf{A}(\mathbf{r}, t)\cdot\mathbf{r} \ ,$$

assuming that the potential only weakly varies in space, such that,

$$\nabla\chi(\mathbf{r}, t) \simeq -\mathbf{A}(\mathbf{r}, t) \qquad \textit{and} \qquad \frac{\partial\chi(\mathbf{r}, t)}{\partial t} = -\mathbf{r}\cdot\frac{\partial\mathbf{A}(\mathbf{r}, t)}{\partial t} = -\mathbf{r}\cdot\vec{\mathcal{E}}(\mathbf{r}, t) \ ,$$

we get with $\mathbf{d} \equiv q\mathbf{r}$,

$$\begin{aligned}\hat{H} &= \frac{1}{2m_e}(\hat{\mathbf{p}} - q\mathbf{A} + \nabla\chi)^2 + q\Phi + q\frac{\partial\chi(\mathbf{r},t)}{\partial t} \\ &\simeq \frac{\hat{\mathbf{p}}^2}{2m_e} + q\Phi - \mathbf{d}\cdot\vec{\mathcal{E}}(\mathbf{r},t)\ .\end{aligned} \tag{30.13}$$

This is the interaction Hamiltonian in the dipolar approximation.

30.1.3 Exercises

30.1.3.1 Ex: Lagrangian of an electron in the electromagnetic field

a. Show that the Lagrangian (30.3) reproduces the Lorentz force (30.1).
b. Show that the Hamiltonian (30.5) reproduces the Lorentz force (30.1).

Solution: *a. Starting from the Lagrangian (30.3) we derive,*

$$\frac{\partial\mathcal{L}}{\partial\dot{r}_i} = mv_i + qA_i \qquad \textit{and} \qquad \frac{\partial\mathcal{L}}{\partial r_i} = -q\partial_i\Phi + \partial_i\mathbf{v}\cdot\mathbf{A}\ .$$

Exploring the Lagrange equation,

$$\frac{d}{dt}\frac{\partial\mathcal{L}}{\partial\dot{r}_i} = \frac{\partial\mathcal{L}}{\partial r_i}$$

we calculate,

$$F_i = m\dot{v}_i = \frac{d}{dt}\frac{\partial\mathcal{L}}{\partial\dot{r}_i} - q\frac{dA_i}{dt} = \frac{\partial\mathcal{L}}{\partial r_i} - q\frac{dA_i}{dt} = -q\partial_i\Phi + \partial_i\mathbf{v}\cdot\mathbf{A} - q\frac{dA_i}{dt}\ .$$

Using,

$$\frac{d\mathbf{A}}{dt} = \frac{\partial\mathbf{A}}{\partial t} + (\mathbf{v}\cdot\nabla)\mathbf{A} \qquad \textit{and} \qquad \nabla(\mathbf{v}\cdot\mathbf{A}) = \mathbf{v}\times(\nabla\times\mathbf{A}) + (\mathbf{v}\cdot\nabla)\mathbf{A}\ ,$$

we obtain,

$$\mathbf{F} = m\dot{\mathbf{v}} = -q\nabla\Phi + q\mathbf{v}\times(\nabla\times\mathbf{A}) + q(\mathbf{v}\cdot\nabla)\mathbf{A} - q\frac{\partial\mathbf{A}}{\partial t} - q(\mathbf{v}\cdot\nabla)\mathbf{A} = q\vec{\mathcal{E}} + q\mathbf{v}\times\vec{\mathcal{B}}\ .$$

b. Inserting the Hamiltonian (30.5) into the equation (30.7) we obtain,

$$\begin{aligned}F_i &= -\frac{\partial}{\partial r_i}\left[\sum\nolimits_j \frac{1}{2m}(p_j - qA_j)^2 + q\Phi\right] - q\dot{A}_i = q\sum\nolimits_j \tfrac{1}{m}(p_j - qA_j)\partial_i A_j - q\partial_i\Phi - q\dot{A}_i \\ &= q\sum\nolimits_j v_j\partial_i A_j - q\partial_i\Phi - q\dot{A}_i\ .\end{aligned}$$

We derive using $\frac{d\mathbf{A}}{dt} = \frac{\partial \mathbf{A}}{\partial t} + (\mathbf{v}\cdot\nabla)\mathbf{A}$,

$$\begin{aligned}\mathbf{F} &= q\begin{pmatrix} v_2\partial_1 A_2 + v_3\partial_1 A_3 + v_1\partial_1 A_1 \\ v_3\partial_2 A_3 + v_1\partial_2 A_1 + v_2\partial_2 A_2 \\ v_1\partial_3 A_1 + v_2\partial_3 A_2 + v_3\partial_3 A_3 \end{pmatrix} - q\nabla\Phi - q\frac{\partial \mathbf{A}}{\partial t} - q(\mathbf{v}\cdot\nabla)\mathbf{A} \\ &= q\begin{pmatrix} -\partial_t A_1 + v_2(\partial_1 A_2 - \partial_2 A_1) - v_3(\partial_3 A_1 - \partial_1 A_3) \\ -\partial_t A_2 + v_3(\partial_2 A_3 - \partial_3 A_2) - v_1(\partial_1 A_2 - \partial_2 A_1) \\ -\partial_t A_3 + v_1(\partial_3 A_1 - \partial_1 A_3) - v_2(\partial_2 A_3 - \partial_3 A_2) \end{pmatrix} - q\nabla\Phi \\ &= -q\nabla\Phi - q\frac{\partial \mathbf{A}}{\partial t} + q\mathbf{v}\times(\nabla\times\mathbf{A}) = q\vec{\mathcal{E}} + q\mathbf{v}\times\vec{\mathcal{B}}\,.\end{aligned}$$

30.2 Interaction with magnetic fields

30.2.1 Normal Zeeman effect of the fine structure

The dipole moments of atoms can interact with external magnetic fields. The interaction leads to a shift of levels, which depends on the magnetic quantum number. Thus, the ultimate degeneracy in the energetic structure of the atom is lifted. This is called *Zeeman splitting*. We consider a uniform magnetic field $\vec{\mathcal{B}} = \mathcal{B}\hat{\mathbf{e}}_z$ with the potential vector,

$$\mathbf{A} = \tfrac{1}{2}\vec{\mathcal{B}}\times\mathbf{r} = -\tfrac{\mathcal{B}}{2}(-y\hat{\mathbf{e}}_x + x\hat{\mathbf{e}}_y)\,. \tag{30.14}$$

Thus the interaction energy between the electron and the field is given by the Hamiltonian (30.12),

$$\begin{aligned}\hat{V}_{zee}(B) &= -\frac{\imath\hbar e}{m_e}\mathbf{A}\cdot\nabla = -\frac{\imath\hbar e}{2m_e}(\vec{\mathcal{B}}\times\mathbf{r})\cdot\nabla = -\frac{\imath\hbar e}{2m_e}\vec{\mathcal{B}}\cdot(\mathbf{r}\times\nabla) \\ &= -\frac{e}{2m_e}\vec{\mathcal{B}}\cdot\hat{\mathbf{L}} = -\frac{\mu_B}{\hbar}g_L\hat{\mathbf{L}}\cdot\vec{\mathcal{B}} = -\vec{\mu}_L\cdot\vec{\mathcal{B}} = -\frac{\mu_B}{\hbar}\hat{L}_z\mathcal{B}\,,\end{aligned} \tag{30.15}$$

with $g_L = 1$ using the relation (29.93), $\vec{\mu}_L = \frac{e}{2m_e}\mathbf{L}$, between the angular momentum of the electron and the resulting magnetic moment. This relationship holds for an atom without spin (two electrons can couple their spins to a singlet state) and no hyperfine structure (or an unresolved hyperfine structure). The energies are therefore,

$$\boxed{\Delta E_{zee}(\mathcal{B}) = -\frac{\mu_B}{\hbar}\mathcal{B}\langle n,L,m_L|\hat{L}_z|n,L,m_L\rangle = -\mu_B m_L\mathcal{B}}\,. \tag{30.16}$$

In the Excs. 30.2.8.1 and 30.2.8.2 we represent the interaction between an atomic angular momentum and a magnetic field in different bases characterized by different quantization axes.

30.2.2 Anomalous Zeeman effect

The anomalous Zeeman effect occurs when the ensemble of electrons has a spin. Using the already known expressions for the dipole moments of the orbital momentum and

the spin of the electron, we obtain for the magnetic dipole moment,

$$\hat{\vec{\mu}}_J = \hat{\vec{\mu}}_L + \hat{\vec{\mu}}_S = \frac{\mu_B}{\hbar} g_L \hat{\mathbf{L}} + \frac{\mu_B}{\hbar} g_S \hat{\mathbf{S}} = \frac{\mu_B}{\hbar}(\hat{\mathbf{L}} + 2\hat{\mathbf{S}}) \ , \tag{30.17}$$

with $g_L = 1$ and $g_S = g_e = 2$. We can see that the dipole moment of the atom is not parallel to the total momentum, $\hat{\mathbf{J}} = \hat{\mathbf{L}} + \hat{\mathbf{S}}$.

When the magnetic field is weak, $\hat{V}_{ls} \gg \hat{V}_{zee}(\mathcal{B})$, the total momentum $\hat{\mathbf{J}}$ will be a good observable. Therefore, we must first project the momenta $\hat{\mathbf{L}}$ and $\hat{\mathbf{S}}$ onto $\hat{\mathbf{J}}$,

$$\hat{\mathbf{L}} \longrightarrow \left(\hat{\mathbf{L}} \cdot \tfrac{\hat{\mathbf{J}}}{|\hat{\mathbf{J}}|}\right) \tfrac{\hat{\mathbf{J}}}{|\hat{\mathbf{J}}|} \qquad \text{and} \qquad \hat{\mathbf{S}} \longrightarrow \left(\hat{\mathbf{S}} \cdot \tfrac{\hat{\mathbf{J}}}{|\hat{\mathbf{J}}|}\right) \tfrac{\hat{\mathbf{J}}}{|\hat{\mathbf{J}}|} \ , \tag{30.18}$$

before projecting the result onto the $\vec{\mathcal{B}}$-field. The potential is,

$$\begin{aligned}
\hat{V}_{zee}(\mathcal{B}) &= -\hat{\vec{\mu}}_J \cdot \vec{\mathcal{B}} = -\frac{\mu_B}{\hbar}(\hat{\mathbf{L}} + 2\hat{\mathbf{S}}) \cdot \vec{\mathcal{B}} \longrightarrow -\frac{\mu_B}{\hbar}\left[\left(\hat{\mathbf{L}} \cdot \tfrac{\hat{\mathbf{J}}}{|\hat{\mathbf{J}}|}\right)\tfrac{\hat{\mathbf{J}}}{|\hat{\mathbf{J}}|} \cdot \vec{\mathcal{B}} + 2\left(\hat{\mathbf{S}} \cdot \tfrac{\hat{\mathbf{J}}}{|\hat{\mathbf{J}}|}\right)\tfrac{\hat{\mathbf{J}}}{|\hat{\mathbf{J}}|} \cdot \vec{\mathcal{B}}\right] \\
&= -\frac{\mu_B}{\hbar|\mathbf{J}|^2}\left[\hat{\mathbf{L}} \cdot \hat{\mathbf{J}} + 2\hat{\mathbf{S}} \cdot \hat{\mathbf{J}}\right]\hat{\mathbf{J}} \cdot \vec{\mathcal{B}} = -\frac{\mu_B}{\hbar|\mathbf{J}|^2}\frac{1}{2}\left[\hat{\mathbf{J}}^2 + \hat{\mathbf{L}}^2 - \hat{\mathbf{S}}^2 + 2(\hat{\mathbf{J}}^2 + \hat{\mathbf{S}}^2 - \hat{\mathbf{L}}^2)\right]\hat{\mathbf{J}} \cdot \vec{\mathcal{B}} \\
&= -\frac{\mu_B}{\hbar}\frac{1}{2}\frac{3\hat{\mathbf{J}}^2 - \hat{\mathbf{L}}^2 + \hat{\mathbf{S}}^2}{|\hat{\mathbf{J}}|^2}\hat{\mathbf{J}} \cdot \vec{\mathcal{B}} \ .
\end{aligned} \tag{30.19}$$

And the energy is,

$$\Delta E_{zee}(\mathcal{B}) = \left\langle \frac{\mu_B}{\hbar}\left(1 + \frac{J(J+1) - L(L+1) + S(S+1)}{2J(J+1)}\right)\hat{\mathbf{J}} \cdot \vec{\mathcal{B}} \right\rangle \ . \tag{30.20}$$

Introducing the *Landé factor*,

$$g_J \equiv 1 + \frac{J(J+1) + S(S+1) - L(L+1)]}{2J(J+1)} \ , \tag{30.21}$$

we can write

$$\boxed{\Delta E_{zee}(\mathcal{B}) = -\frac{\mu_B}{\hbar} g_J \langle \hat{J}_z \rangle \mathcal{B} = -\mu_B g_J m_J \mathcal{B}} \ . \tag{30.22}$$

This expression describes the *anomalous Zeeman effect*, for which $S \neq 0$. For the *normal Zeeman effect*, for which the spin is zero, we find again $g_J = 1$.

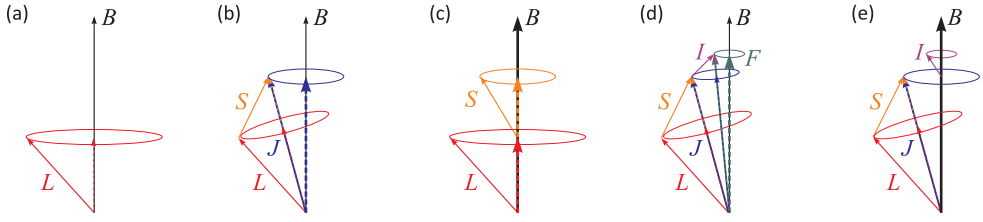

Figure 30.1: Coupling angular moments for the effect (a) Normal Zeeman effect, (b) anomalous Zeeman effect, (c) Paschen-Back effect, (d) Zeeman effect of the hyperfine structure, and (e) Paschen-Goudsmith effect.

30.2.3 Paschen-Back effect and intermediate magnetic fields

A very strong external magnetic field (> 1 T), such that $\hat{V}_{ls} \ll \hat{V}_{zee}(\mathcal{B})$, can break the $\hat{\mathbf{L}} \cdot \hat{\mathbf{S}}$-coupling. Both spins $\hat{\mathbf{L}}$ and $\hat{\mathbf{S}}$ now couple separately to the field,

$$\hat{\mathbf{L}} \longrightarrow \left(\hat{\mathbf{L}} \cdot \frac{\vec{\mathcal{B}}}{|\vec{\mathcal{B}}|}\right) \frac{\vec{\mathcal{B}}}{|\vec{\mathcal{B}}|} \qquad \text{and} \qquad \hat{\mathbf{S}} \longrightarrow \left(\hat{\mathbf{S}} \cdot \frac{\vec{\mathcal{B}}}{|\vec{\mathcal{B}}|}\right) \frac{\vec{\mathcal{B}}}{|\vec{\mathcal{B}}|} \ . \tag{30.23}$$

Therefore,

$$\hat{V}_{pb}(\mathcal{B}) = -\frac{\mu_B}{\hbar}(\hat{\mathbf{L}} + 2\hat{\mathbf{S}}) \cdot \vec{\mathcal{B}} \longrightarrow -\frac{\mu_B}{\hbar}\left[\left(\hat{\mathbf{L}} \cdot \frac{\vec{\mathcal{B}}}{|\vec{\mathcal{B}}|}\right) \frac{\vec{\mathcal{B}}}{|\vec{\mathcal{B}}|} + 2\left(\hat{\mathbf{S}} \cdot \frac{\vec{\mathcal{B}}}{|\vec{\mathcal{B}}|}\right) \frac{\vec{\mathcal{B}}}{|\vec{\mathcal{B}}|}\right] \cdot \vec{\mathcal{B}} \ , \tag{30.24}$$

such that

$$\boxed{\Delta E_{pb}(\mathcal{B}) = -\mu_B(m_L + 2m_S)\mathcal{B}} \ . \tag{30.25}$$

This is the *Paschen-Back effect*.

The derivations we have made so far have focused on simple situations well described by CSCOs in various coupling schemes. The projections on the different quantization axes [the total spin (30.18) in the Zeeman case or the applied magnetic field (30.23) in the Paschen-Back case] ensure that the Hamiltonians $\hat{V}_{ls}$ and $\hat{V}_{zee}(\mathcal{B})$ in these CSCOs are described by diagonal matrices. However, in regimes *intermediate* between Zeeman and Paschen-Back, $\hat{V}_{ls} \simeq \hat{V}_{zee}(\mathcal{B})$, it is generally not possible to find a diagonal representation.

In order to calculate the energy spectrum in intermediate regimes we must, therefore, determine all the components of the matrix,

$$\hat{V}_{ls} + \hat{V}_{zee}(\mathcal{B}) = \xi(r)\hat{\mathbf{L}} \cdot \hat{\mathbf{S}} + \frac{\mu_B}{\hbar}(\hat{\mathbf{L}} + 2\hat{\mathbf{S}}) \ . \tag{30.26}$$

Using $\hat{L}_\pm \equiv \hat{L}_x \pm \imath \hat{L}_y$ and $\hat{S}_\pm \equiv \hat{S}_x \pm \imath \hat{S}_y$, we can easily rewrite the energy in the following way,

$$\hat{V}_{ls} + \hat{V}_{zee}(\mathcal{B}) = \xi(r)\left(\hat{L}_z\hat{S}_z + \tfrac{1}{2}\hat{L}_+\hat{S}_- + \tfrac{1}{2}\hat{L}_-\hat{S}_+\right) + \frac{\mu_B}{\hbar}(\hat{\mathbf{L}} + 2\hat{\mathbf{S}}) \cdot \vec{\mathcal{B}} \ . \tag{30.27}$$

This operator acts on the uncoupled states,

$$\begin{aligned} &\Delta E_{ls} + \Delta E_{zee}(\mathcal{B}) \\ &= \langle L' m'_L; S' m'_S | \xi_{nl}(\hat{L}_z\hat{S}_z + \tfrac{1}{2}\hat{L}_+\hat{S}_- + \tfrac{1}{2}\hat{L}_-\hat{S}_+) + \mu_B(\hat{L}_z + 2\hat{S}_z)\mathcal{B} | L m_L; S m_S \rangle \\ &= \hbar^2 \xi_{nl}\left(m_L m_S \delta_{m_L,m'_L}\delta_{m_S,m'_S} + \tfrac{1}{2}L_+S_-\delta_{m_L,m'_L-1}\delta_{m_S-1,m'_S} + \tfrac{1}{2}L_-S_+\delta_{m_L-1,m'_L}\delta_{m_S,m'_S-1}\right) \\ &\quad + \hbar\mu_B(m_L + 2m_S)\mathcal{B}\delta_{m_L,m'_L}\delta_{m_S,m'_S} \ , \end{aligned} \tag{30.28}$$

with the abbreviations $L_\pm \equiv \sqrt{L(L+1) - m_L(m_L \pm 1)}$. The energies are now the eigenvalues of this matrix. The factor ξ_{nl} is usually determined experimentally by letting $\mathcal{B} = 0$. In Exc. 30.2.8.3 we calculate the re-coupling of the spins of two electrons in an external magnetic field.

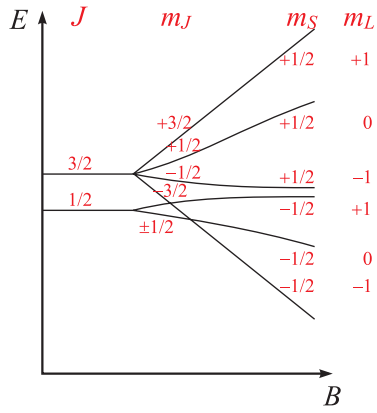

Figure 30.2: Transition between the Zeeman regime and the Paschen-Back regime for the case $L = 1$ and $S = 1/2$.

30.2.4 Zeeman effect of the hyperfine structure

When the energy of the interaction with the magnetic field is comparable to the hyperfine interactions, but much weaker than that of the fine interactions, the fields do not disturb the coupling between the total electronic momentum $\hat{\mathbf{J}}$ and the spin of the nucleus $\hat{\mathbf{I}}$. Hence, J, I, F, and m_F are good quantum numbers. Therefore, to calculate the interaction energy,

$$\hat{V}_{hfs} + \hat{V}_{zee}(\mathcal{B}) = \hat{V}_{hfs} - \hat{\vec{\mu}}_F \cdot \vec{\mathcal{B}} \,, \tag{30.29}$$

where $\hat{\vec{\mu}}_F$ is the total magnetic momentum,

$$\hat{\vec{\mu}}_F = \hat{\vec{\mu}}_J + \hat{\vec{\mu}}_I = -\frac{\mu_B}{\hbar} g_J \hat{\mathbf{J}} + \frac{\mu_N}{\hbar} g_p \hat{\mathbf{I}} \,. \tag{30.30}$$

we project the nuclear spin and the total electronic momentum separately in the direction of $\hat{\mathbf{F}}$,

$$\hat{\mathbf{J}} \longrightarrow \left(\hat{\mathbf{J}} \cdot \frac{\hat{\mathbf{F}}}{|\mathbf{F}|}\right) \frac{\hat{\mathbf{F}}}{|\mathbf{F}|} \qquad \text{and} \qquad \hat{\mathbf{I}} \longrightarrow \left(\hat{\mathbf{I}} \cdot \frac{\hat{\mathbf{F}}}{|\mathbf{F}|}\right) \frac{\hat{\mathbf{F}}}{|\mathbf{F}|} \,. \tag{30.31}$$

Note the negative sign in (30.30) due to the negative charge of the electron. The Landé factor g_J [see (30.21)] is the one caused by the coupling of the orbital angular momentum $\hat{\mathbf{L}}$ and the electron spin $\hat{\mathbf{S}}$ and depends on the state under consideration. Thereby,

$$\begin{aligned} \hat{V}_{zee}(\mathcal{B}) &= \left[-\frac{\mu_B}{\hbar} g_J \left(\hat{\mathbf{J}} \cdot \frac{\hat{\mathbf{F}}}{|\mathbf{F}|}\right) \frac{\hat{\mathbf{F}}}{|\mathbf{F}|} + \frac{\mu_N}{\hbar} g_p \left(\hat{\mathbf{I}} \cdot \frac{\hat{\mathbf{F}}}{|\mathbf{F}|}\right) \frac{\hat{\mathbf{F}}}{|\mathbf{F}|}\right] \vec{\mathcal{B}} \\ &= \left(-\frac{\mu_B}{\hbar |\hat{\mathbf{F}}|^2} g_J \hat{\mathbf{J}} \cdot \hat{\mathbf{F}} + \frac{\mu_N}{\hbar |\hat{\mathbf{F}}|^2} g_p \hat{\mathbf{I}} \cdot \hat{\mathbf{F}}\right) (\mathcal{B} \cdot \hat{F}_z) \,. \end{aligned} \tag{30.32}$$

Using $\hat{\mathbf{J}} \cdot \hat{\mathbf{F}} = \frac{1}{2}(\hat{\mathbf{F}}^2 + \hat{\mathbf{J}}^2 - \hat{\mathbf{I}}^2)$ and $\hat{\mathbf{I}} \cdot \hat{\mathbf{F}} = \frac{1}{2}(\hat{\mathbf{F}}^2 - \hat{\mathbf{J}}^2 + \hat{\mathbf{I}}^2)$ we write,

$$\hat{V}_{zee}(\mathcal{B}) = -\frac{\mu_B}{\hbar} g_J \frac{\hat{\mathbf{F}}^2 + \hat{\mathbf{J}}^2 - \hat{\mathbf{I}}^2}{2|\mathbf{F}|^2} \mathcal{B}\hat{F}_z + g_p \frac{\mu_N}{\hbar} \frac{\hat{\mathbf{F}}^2 - \hat{\mathbf{J}}^2 + \hat{\mathbf{I}}^2}{2|\hat{\mathbf{F}}|^2} \mathcal{B}\hat{F}_z \,, \tag{30.33}$$

such that

$$\boxed{\Delta E_{hfs} + \Delta E_{zee}(\mathcal{B}) \simeq \Delta E_{hfs} + \mu_B g_F m_F \mathcal{B}} \,, \tag{30.34}$$

using the *Landé factor* g_F for the state F,

$$g_F \simeq g_J \frac{F(F+1) + J(J+1) - I(I+1)}{2F(F+1)} - g_p \frac{\mu_N}{\mu_B} \frac{F(F+1) - J(J+1) + I(I+1)}{2F(F+1)} \,, \tag{30.35}$$

where the second term can be neglected.

The splitting of electronic states with the momentum $\hat{\mathbf{F}}$ into $2F+1$ sublevels $m_F = -F, .., F$ is called *Zeeman effect of the hyperfine structure*. The result (30.32) only applies to weak magnetic fields. For strong fields the Zeeman splitting becomes a Paschen-Back splitting of the hyperfine structure.

30.2.5 Paschen-Back effect of the hyperfine structure

When the interaction with the magnetic field exceeds the hyperfine interaction, the nuclear spin $\hat{\mathbf{I}}$ decouples from the total momentum $\hat{\mathbf{J}}$, and both couple separately to the external magnetic field,

$$\hat{\mathbf{J}} \longrightarrow \left(\hat{\mathbf{J}} \cdot \frac{\vec{\mathcal{B}}}{|\vec{\mathcal{B}}|}\right) \frac{\vec{\mathcal{B}}}{|\vec{\mathcal{B}}|} \qquad \text{and} \qquad \hat{\mathbf{I}} \longrightarrow \left(\hat{\mathbf{I}} \cdot \frac{\vec{\mathcal{B}}}{|\vec{\mathcal{B}}|}\right) \frac{\vec{\mathcal{B}}}{|\vec{\mathcal{B}}|} \,. \tag{30.36}$$

The Zeeman effect of the hyperfine structure becomes a hyperfine structure of the Zeeman effect, also called *Paschen-Back effect of the hyperfine structure* or *Paschen-Goudsmith effect*. We can diagonalize the potential on a basis, where I, m_I, J, and m_J are good quantum numbers. Using the expression (29.168) but disregarding the quadrupolar contribution to the hyperfine interaction, $B_J \simeq 0$, we obtain,

$$\begin{aligned} \hat{V}_{hfs} + \hat{V}_{zee}(\mathcal{B}) &= \hat{V}_{hfs} - (\hat{\vec{\mu}}_J + \cancelto{\simeq 0}{\hat{\vec{\mu}}_I}) \cdot \vec{\mathcal{B}} \simeq \frac{A_J}{\hbar^2} \hat{\mathbf{J}} \cdot \hat{\mathbf{I}} - \hat{\vec{\mu}}_J \cdot \vec{\mathcal{B}} \\ &\longrightarrow \frac{A_J}{\hbar^2} \left(\hat{\mathbf{J}} \cdot \frac{\vec{\mathcal{B}}}{\mathcal{B}}\right) \frac{\vec{\mathcal{B}}}{\mathcal{B}} \cdot \left(\hat{\mathbf{I}} \cdot \frac{\vec{\mathcal{B}}}{\mathcal{B}}\right) \frac{\vec{\mathcal{B}}}{\mathcal{B}} - \mu_{J_z} \mathcal{B} = \frac{A_J}{\hbar^2} \hat{J}_z \hat{I}_z + \frac{\mu_B}{\hbar} g_J \hat{J}_z \mathcal{B} \,, \end{aligned} \tag{30.37}$$

where we neglect the interaction of the dipole moment of the nucleus with the external magnetic field, $\vec{\mu}_I \simeq 0$. We obtain for strong magnetic fields,

$$\boxed{\Delta E_{hfs} + \Delta E_{zee}(\mathcal{B}) \simeq A_J m_J m_I + \mu_B g_J m_J \mathcal{B}} \,. \tag{30.38}$$

The re-coupling of the state $|F m_F\rangle$ to $|m_I m_J\rangle$ in strong magnetic fields is described by Clebsch-Gordan coefficients,

$$|F m_F\rangle = \sum\nolimits_{m_I + m_J = m_F} |m_I m_J\rangle \langle m_I m_J | F m_F\rangle \,. \tag{30.39}$$

Example 183 (*Nuclear magnetic resonance*): In Eq. (30.37) we have neglected the nuclear dipole moment for being small in comparison to the electronic one. Taking it into account, we get an additional term $\hat{V}_{nmr}$,

$$\hat{V}_{hfs} + \hat{V}_{zee} + \hat{V}_{nmr} = \frac{A_J}{\hbar^2} \hat{\mathbf{J}} \cdot \hat{\mathbf{I}} + \vec{\mu}_J \cdot \vec{\mathcal{B}} + \vec{\mu}_I \cdot \vec{\mathcal{B}} = \frac{A_J}{\hbar^2} \hat{J}_z \hat{I}_z + \mu_{J_z} \mathcal{B} + \mu_{I_z} \mathcal{B} \,. \tag{30.40}$$

Considering a hydrogen atom ^{1}H in a $\vec{\mathcal{B}} = 10\,\mathrm{T}$ strong magnetic field, we have the following hierarchy of energies:

$$\begin{aligned}\Delta E_{zee}(\mathcal{B}) &= \mu_B g_e m_J \simeq h \cdot 140\,\mathrm{GHz} \\ \Delta E_{hfs}(\mathcal{B}) &\simeq h \cdot 1.4\,\mathrm{GHz} \\ \Delta E_{nmr}(\mathcal{B}) &= \mu_N g_p m_I \simeq h \cdot 213\,\mathrm{MHz}\ ,\end{aligned} \tag{30.41}$$

where $g_e = 2.002..$ is the g-factor of the electron and $g_p = 5.586..$ of the proton. Now, in large molecules the most electrons are paired, such that $\hat{\mathbf{J}} = 0$. In that case, we are left with the interaction between the nuclear spin and the applied magnetic field,

$$\Delta E_{nmr}(\mathcal{B}) = \mu_N g_I m_I \mathcal{B}\ , \tag{30.42}$$

where the g-factor of the nucleus g_I must be looked up in data tables. This is the regime where *nuclear magnetic resonances* (NMR) can be excited with a large variety of applications in spectroscopy and imaging.

30.2.6 Hyperfine structure in the intermediate field regime

Knowing the dipolar magnetic A_J and quadrupolar B_J interval factors, it is possible to calculate the Zeeman shift of the hyperfine structure in magnetic fields intermediate between the Zeeman and Paschen-Back regimes. For this, we must determine all the components of the matrix $\hat{V}_{hfs} + \hat{V}_{zee}(B)$ and calculate the eigenvalues. The relevant terms of the Eqs. (29.168) and the Eq. (30.36) are,

$$\hat{V}_{hfs} + \hat{V}_{zee}(\mathcal{B}) = \frac{A_J}{\hbar^2}\hat{\mathbf{I}}\cdot\hat{\mathbf{J}} + \frac{B_J}{\hbar^2}\frac{6(\hat{\mathbf{I}}\cdot\hat{\mathbf{J}})^2 + 3\hat{\mathbf{I}}\cdot\hat{\mathbf{J}} - 2\hat{\mathbf{J}}^2\hat{\mathbf{I}}^2}{2I(2I-1)2J(2J-1)} + g_J\mu_B\vec{\mathcal{B}}\cdot\hat{\mathbf{J}} - g_I\mu_N\vec{\mathcal{B}}\cdot\hat{\mathbf{I}}\ . \tag{30.43}$$

We develop the complete matrix representation of this Hamiltonian within the uncoupled base, where m_J, m_I are good quantum numbers, introducing the abbreviations $I_\pm \equiv \sqrt{I(I+1) - m_I(m_I \pm 1)}$ and $I_{\pm\pm} \equiv \sqrt{I(I+1) - (m_I \pm 1)(m_I \pm 2)}$. The SU(2) algebra provides useful expressions, $\hat{\mathbf{I}}\cdot\hat{\mathbf{J}} = \hat{I}_z\hat{J}_z + \frac{1}{2}(\hat{I}_+\hat{J}_- + \hat{I}_-\hat{J}_+)$. The elements of the matrix are,

$$\begin{aligned}&\langle m_I' m_J'|H_{hfs} + H_B|m_I m_J\rangle = \left[A_J + \tfrac{3B_J}{2I(2I-1)2J(2J-1)}\right]\times \\ &\times\left\{m_I m_J \delta_{m_I'\ m_I}\delta_{m_J'\ m_J} + \tfrac{1}{2}I_+J_-\delta_{m_I'\ m_I+1}\delta_{m_J'\ m_J-1} + \tfrac{1}{2}I_-J_+\delta_{m_I'\ m_I-1}\delta_{m_J'\ m_J+1}\right\} \\ &+ \tfrac{6B_J}{2I(2I-1)2J(2J-1)}\langle m_I' m_J'|\left(\tfrac{\mathbf{I}\cdot\mathbf{J}}{\hbar}\right)^2|m_I m_J\rangle \\ &+ \left[-\tfrac{B_J 2I(I+1)J(J+1)}{2I(2I-1)2J(2J-1)} + (g_J m_J - g_I\mu_N m_I)\mu_B B\right]\delta_{m_I'\ m_I}\delta_{m_I'\ m_I}\end{aligned} \tag{30.44}$$

where

$$\begin{aligned}\langle m_I' m_J'|\left(\tfrac{\hat{\mathbf{I}}\cdot\hat{\mathbf{J}}}{\hbar}\right)^2|m_I m_J\rangle = &\left[(m_I m_J)^2 + \tfrac{1}{4}I_-^2J_+^2 + \tfrac{1}{4}I_+^2J_-^2\right]\delta_{m_I'\ m_I}\delta_{m_J'\ m_J} + \\ &+ \tfrac{1}{2}\left(m_I' m_J' + m_I m_J\right)I_+J_-\delta_{m_I'\ m_I+1}\delta_{m_J'\ m_J-1} + \\ &+ \tfrac{1}{2}\left(m_I' m_J' + m_I m_J\right)I_-J_+\delta_{m_I'\ m_I-1}\delta_{m_J'\ m_J+1} + \\ &+ \tfrac{1}{4}I_+J_-I_{++}J_{--}\delta_{m_I'\ m_I+2}\delta_{m_J'\ m_J-2} + \\ &+ \tfrac{1}{4}I_-J_+I_{--}J_{++}\delta_{m_I'\ m_I-2}\delta_{m_J'\ m_J+2}\ .\end{aligned} \tag{30.45}$$

The matrix $\langle m_I' m_J' | H_{hfs} + H_B | m_I m_J \rangle$ is divided into $2F+1$ diagonal blocks, each labeled m_F. The total number of levels is,

$$\sum_{F=|I-J|,..,I+J} 2F{+}1 = (2I{+}1)(2J{+}1) = \sum_{m_F=|-F,..,F|} \left(\sum_{m_I=|-I,..,I|,\ m_J=|-J,..,J|,\ m_I+m_J=m_F} 1 \right) .$$

In this form the matrix can be programmed, e.g. using computational software such as MATLAB, and all eigenvalues of the Hamiltonian for any state $^{2S+1}X_J$ and nuclear spin I can be calculated numerically. Obviously, the eigenvalues follow from a diagonalization of the matrix and do not depend on the chosen base. Fig. 30.3 shows the result obtained for ^{6}Li ($I = \frac{3}{2}$) in the state $2s\ ^2P_{3/2}$ knowing that $A_J/h = -1.17$ MHz and $B_J = 0$.

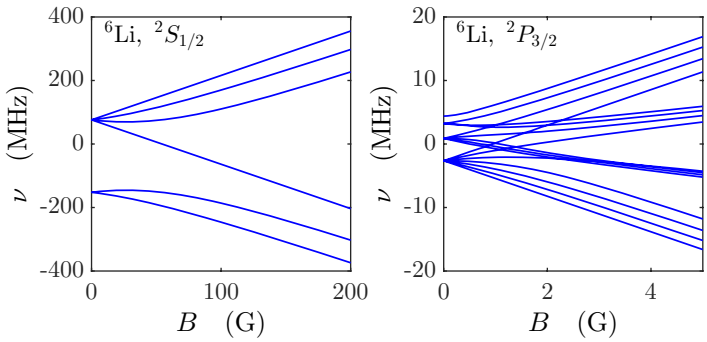

Figure 30.3: (code) Hyperfine and Zeeman structure of the state $^2P_{3/2}$ of ^{6}Li.

Example 184 (*Fully stretched states*): It is interesting to analyze the so-called *fully stretched Zeeman states* defined by $F = I + J$ and $|m_F| = F$. For these states, the spin K defined in (29.167) becomes,

$$\begin{aligned} K \equiv 2\langle \hat{\mathbf{J}} \cdot \hat{\mathbf{I}} \rangle &= F(F+1) - I(I+1) - J(J+1) \\ &= (I+J)(I+J+1) - I(I+1) - J(J+1) = 2JI \ , \end{aligned}$$

and the hyperfine structure (29.168) becomes,

$$\Delta E_{hfs} = \frac{A_J}{2} K + \frac{B_J}{8I(2I-1)J(2J-1)} [3K(K{+}1) - 4I(I{+}1)J(J{+}1)] = A_J IJ + \tfrac{B_J}{4} \ .$$

That is, the hyperfine structure does not depend on the F quantum number at any $\mathcal{B}$-field amplitude, which means that the m_J, m_I, and m_F will be good quantum numbers at arbitrary $\mathcal{B}$-field strengths. So see this, we calculate the Landé-factor (30.35),

$$g_F = g_J \frac{J}{F} - g_J \frac{\mu_N}{\mu_B} \frac{I}{F} \ ,$$

and consider the particular Zeeman state $m_F = F$, $m_J = J$, and $m_I = I$,

$$\begin{aligned} \hat{V}_{hfs} + \hat{V}_{zee}(\mathcal{B}) &= A_J IJ + \tfrac{B_J}{4} + g_J \mu_B \vec{\mathcal{B}} \cdot \hat{\mathbf{J}} - g_I \mu_N \vec{\mathcal{B}} \cdot \hat{\mathbf{I}} \\ &= A_J IJ + \tfrac{B_J}{4} + \mu_B g_F m_F \mathcal{B} = A_J IJ + \tfrac{B_J}{4} + (\mu_B g_J J - \mu_N g_J I)\mathcal{B} \ . \end{aligned}$$

The energy displacement of the fully stretched states is always linear in the magnetic field. We can also look at the matrix elements $I_+ = 0$ and $I_- = \sqrt{2I}$ and note that all non-diagonal terms vanish.

When one of the spins, J or I, is equal to $1/2$ only two possible hyperfine states exist: $F = I \pm J$. For this case there is an approximate analytic formula called the *Breit-Rabi formula* [81], which will be derived in Exc. 30.2.8.4,

$$\begin{aligned}\Delta E_{hfs} + \Delta E_{zee}(\mathcal{B}) &= \langle \tfrac{A_J}{\hbar^2}\hat{\mathbf{I}}\cdot\hat{\mathbf{J}} + g_J\mu_B\vec{\mathcal{B}}\cdot\hat{\mathbf{J}} - g_I\mu_N\vec{\mathcal{B}}\cdot\hat{\mathbf{I}}\rangle \\ &= -\frac{A_J}{4} + \mu_N g_N m_F \mathcal{B} \pm \frac{A_J(I+\frac{1}{2})}{2}\sqrt{1+\frac{4m_F}{2I+1}x+x^2}\ ,\end{aligned} \tag{30.46}$$

with the abbreviation $x \equiv \frac{2(\mu_B g_J - \mu_N g_I)\mathcal{B}}{A_J}$. Resolve also Exc. 30.2.8.5.

Atoms with paired electrons have no spin and therefore no magnetic dipole moment. For example, helium or strontium in their ground state $^1S_0$. These systems are diamagnetic due to the Hamiltonian term (30.11) being quadratic in $\vec{\mathcal{B}}$, as we shall see in Exc. 30.2.8.6.

30.2.7 Landau levels in two-dimensional systems subject to magnetic fields

Magnetic field can also have interesting effects in *artificial atoms*, e.g. quantum dots. An important example is the formation of *Landau levels*. We consider a two-dimensional system of non-interacting particles with charge q and spin S confined to an area $A = L_x L_y$ in the x-y plane. We apply a uniform magnetic field,

$$\vec{\mathcal{B}} = \mathcal{B}\hat{\mathbf{e}}_z \tag{30.47}$$

along the z axis. The Hamiltonian of this system is,

$$\hat{H} = \tfrac{1}{2m}(\hat{\mathbf{p}} - q\hat{\mathbf{A}})^2\ , \tag{30.48}$$

where $\hat{\mathbf{p}}$ is the operator of the canonical momentum and $\hat{\mathbf{A}}$ is the potential vector, related to the magnetic field by $\vec{\mathcal{B}} = \nabla\times\hat{\mathbf{A}}$. The vector potential,

$$\mathbf{A} = \tfrac{1}{2}\begin{pmatrix}-\mathcal{B}y\\ \mathcal{B}x\\ 0\end{pmatrix} \tag{30.49}$$

reproduces the field (30.47). However, we have the freedom in choosing the potential vector, given by the gauge transformation, to add the gradient of a scalar field, for example,

$$\chi \equiv \tfrac{1}{2}\mathcal{B}xy \quad\Longrightarrow\quad \nabla\chi = \tfrac{1}{2}\begin{pmatrix}\mathcal{B}y\\ \mathcal{B}x\\ 0\end{pmatrix} \quad\Longrightarrow\quad \mathbf{A}' \equiv \mathbf{A} + \nabla\chi = \mathcal{B}x\hat{\mathbf{e}}_y\ . \tag{30.50}$$

The potential vector $\mathbf{A}'$ gives the same magnetic field and only changes the general phase of the wavefunction, but the physical properties do not change. In this gauge, which is called *Landau gauge*, the Hamiltonian is,

$$\hat{H} = \frac{\hat{p}_x^2}{2m} + \frac{1}{2m}\left(\hat{p}_y - \frac{q\mathcal{B}}{c}\hat{x}\right)^2 . \tag{30.51}$$

The operator $\hat{p}_y$ commutes with this Hamiltonian, since the $\hat{y}$ operator is absent due to the choice of the gauge. Thus, the operator $\hat{p}_y$ can be replaced by its eigenvalue $\hbar k_y$. Hence, by introducing the *cyclotron frequency*,

$$\omega_c \equiv \frac{q\mathcal{B}}{mc} , \tag{30.52}$$

we obtain,

$$\boxed{\hat{H} = \frac{\hat{p}_x^2}{2m} + \frac{m\omega_c^2}{2}\left(\hat{x} - \frac{\hbar k_y}{m\omega_c}\right)^2} . \tag{30.53}$$

This is exactly the Hamiltonian of the quantum harmonic oscillator, except that the minimum of the potential is displaced in position space by the value,

$$x_0 \equiv \frac{\hbar k_y}{m\omega_c} . \tag{30.54}$$

To find the energies, we note that the translation of the potential of the harmonic oscillator does not affect the energies. The energies of this system are therefore identical to those of the standard quantum harmonic oscillator,

$$E_n = \hbar\omega_c\left(n + \tfrac{1}{2}\right) , \tag{30.55}$$

for $n \geq 0$. Since the energy does not depend on the quantum number k_y, we will have degeneracy. To derive the wavefunctions, we remember that $\hat{p}_y$ commutes with the Hamiltonian. Then the wavefunction splits into a product of eigenstates of the momentum in y-direction and eigenstates of the harmonic oscillator $|\phi_n\rangle$ shifted by a value x_0 in x-direction:

$$\Psi(x, y) = e^{\imath k_y y}\phi_n(x - x_0) . \tag{30.56}$$

That is, the state of the electron is characterized by two quantum numbers, n and k_y.

Each set of wavefunctions with the same n is called *Landau level*. Effects due to Landau levels are only observed, when the average thermal energy is lower than the separation of the energy levels, which means that low temperatures and strong magnetic fields are required. Each Landau level is degenerate, because of the second quantum number k_y, which can adopt the values,

$$k_y = \frac{2\pi N}{L_y} , \tag{30.57}$$

with $N \in \mathbb{N}$. The allowed values of N are further restricted by the condition that the center of mass of the oscillator, x_0, must be physically inside the system, $0 \leq x_0 < L_x$. Using (30.54) this gives the following range for N,

$$0 \leq N < \frac{m\omega_c L_x L_y}{2\pi\hbar} . \tag{30.58}$$

For particles with charge $q = Ze$, the upper limit in N can simply be written as a ratio of fluxes,

$$Z\frac{\Phi}{\Phi_0} = \frac{Z\mathcal{B}L_xL_y}{(hc/e)} = N_{max} \ , \tag{30.59}$$

where $\Phi_0 = h/2e$ is the fundamental *flux quantum* and $\Phi = \mathcal{B}A$ the flux through the system (with area $A = L_xL_y$). Thus, for particles with spin S, the maximum number of particles per Landau level is,

$$N_{max} = Z(2S+1)\frac{\Phi}{\Phi_0} \ . \tag{30.60}$$

30.2.7.1 Integer and fractional quantum Hall effect

In general, Landau levels are observed in electronic systems with $Z = 1$ and $S = 1/2$. As the magnetic field increases, more and more electrons can fit a certain Landau level. The occupation of the highest Landau level ranges from entirely full to entirely empty, leading to oscillations in various electronic properties (see *de Haas-van Alphen effect*, *Shubnikov-de Haas effect* and *quantum Hall effect*. The most direct observation of the

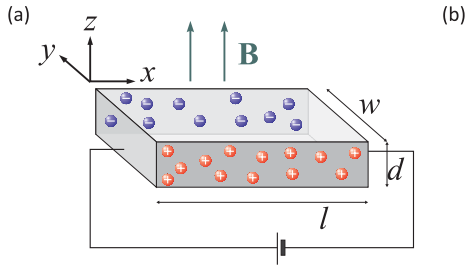

Figure 30.4: Scheme of the Quantum Hall effect.

Landau levels is done via the quantum Hall effect. To discuss this effect let us briefly recapitulate the Hall effectoriginally studied in Sec. 15.1.1. In the scheme of Fig. 30.4, charges are deviated by the Lorentz force exerted by an applied magnetic field $\vec{\mathcal{B}}$ from a driven current density j_x into a current density j_y until a sufficient amount of surface charge density has accumulated to generate an electric field exerting a Coulomb force on the charges which neutralizes the Lorentz force, $\mathbf{F} = q(\vec{\mathcal{E}} + \mathbf{v} \times \vec{\mathcal{B}}) = 0$. Resolving this condition by $\mathbf{v}$, we obtain for the current density,

$$\mathbf{j} = \varrho q\mathbf{v} = \varrho q\frac{\mathcal{E}}{\mathcal{B}}\hat{\mathbf{e}}_x = \varsigma\vec{\mathcal{E}} \ , \tag{30.61}$$

where the last equation is Ohm's law and

$$\varsigma = \begin{pmatrix} \varsigma_{xx} & \varsigma_{xy} \\ -\varsigma_{xy} & \varsigma_{yy} \end{pmatrix} \qquad \text{and} \qquad \varrho = \varsigma^{-1} = \frac{1}{\varsigma_{xx}^2 + \varsigma_{yy}^2}\begin{pmatrix} \varsigma_{xx} & -\varsigma_{xy} \\ \varsigma_{xy} & \varsigma_{yy} \end{pmatrix} \tag{30.62}$$

the conductivity and the resistivity, respectively. The Hall resistivity does therefore depend linearly on the magnetic field,

$$\varrho_{xy} = \frac{\mathcal{E}}{j} = \frac{\mathcal{B}}{\varrho q} \ . \tag{30.63}$$

In two-dimensional systems this is, however, not observed. Instead, plateaus emerge whenever the magnetic field is ramped across a value where a new Landau level is possible binding one more electron,

$$\varrho_{xy} = \frac{2\pi\hbar}{e^2}\frac{1}{\nu} \qquad \text{with} \qquad \nu \in \mathbb{Z} \ . \tag{30.64}$$

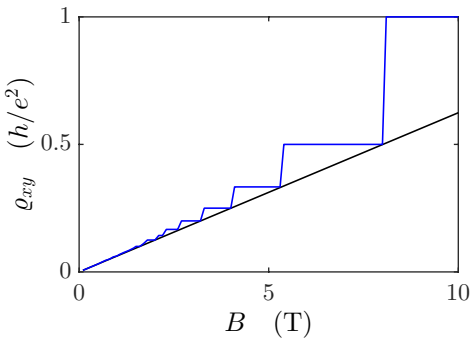

Figure 30.5: (code) Scheme of the quantum Hall effect.

30.2.8 Exercises

30.2.8.1 Ex: Zeeman effect with different quantization axes

The Zeeman effect can be described in several ways depending on the choice of the quantization axis. Consider a magnetic field $\vec{\mathcal{B}} = \mathcal{B}_x\hat{\mathbf{e}}_x$ and calculate the interaction Hamiltonian $V(\mathcal{B}) = -\vec{\mu}_J \cdot \vec{\mathcal{B}}$
a. choosing the quantization axis $\hat{\mathbf{e}}_x$ in the direction of the magnetic field,
b. choosing the quantization axis $\hat{\mathbf{e}}_z$ perpendicular to the direction of the magnetic field.

Solution: *a. Choosing the quantization axis* $\hat{\mathbf{e}}_x$ *in the direction of the magnetic field, the interaction Hamiltonian becomes,*

$$V(\mathcal{B}) = -\tfrac{1}{\hbar}\mu_B\mathcal{B}_x\hat{J}_x = -\tfrac{1}{\hbar}\mu_B\mathcal{B}_x\sum_{m_x,m_x'}|J,m_x'\rangle\langle J,m_x'|\hat{J}_x|J,m_x\rangle\langle J,m_x| \ ,$$

with the matrix elements,

$$\langle J,m_x'|\hat{J}_x|J,m_x\rangle = \hbar m_x\delta_{m_x',m_x} \ .$$

For the example of a spin $J = 1/2$*, we have,*

$$V(\mathcal{B}) = -\tfrac{1}{2}\mu_B\mathcal{B}_x\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix}$$

with the eigenvalues,

$$\langle V(\mathcal{B})\rangle = \mp\tfrac{1}{2}\mu_B\mathcal{B}_x \qquad for \qquad |\psi_\pm\rangle = |\tfrac{1}{2},\pm\tfrac{1}{2}\rangle_x \ .$$

b. Now we choose the quantization axis $\hat{\mathbf{e}}_z$ *perpendicular to the direction of the magnetic field,*

$$V(\mathcal{B}) = -\tfrac{1}{\hbar}\mu_B\mathcal{B}_x\hat{J}_x = -\tfrac{1}{\hbar}\mu_B\mathcal{B}_x\sum_{m_z,m_z'}|J,m_z'\rangle\langle J,m_z'|\hat{J}_+ + \hat{J}_-|J,m_z\rangle\langle J,m_z| \ ,$$

with the matrix elements,

$$\begin{aligned}&\langle J,m_z'|\hat{J}_+ + \hat{J}_-|J,m_z\rangle\\ &\quad = \hbar\sqrt{J(J+1)-m_z(m_z+1)}\delta_{m_z',m_z+1} + \hbar\sqrt{J(J+1)-m_z(m_z-1)}\delta_{m_z',m_z-1} \ .\end{aligned}$$

For the example of a spin $J = 1/2$*, we have,*

$$V(\mathcal{B}) = -\tfrac{1}{2}\mu_B\mathcal{B}_x\begin{pmatrix}0 & 1\\ 1 & 0\end{pmatrix}$$

with the eigenvalues $\langle V(\mathcal{B})\rangle = \mp\frac{1}{2}\mu_B\mathcal{B}_x$ *for the eigenvectors* $|\psi_\pm\rangle = \frac{1}{\sqrt{2}}|\frac{1}{2},\frac{1}{2}\rangle_z + \frac{1}{\sqrt{2}}|\frac{1}{2},-\frac{1}{2}\rangle_z$.

30.2.8.2 Ex: Zeeman shift and quantization axes

Choosing the fixed quantization axis $\hat{\mathbf{e}}_z$ and a magnetic field $\vec{\mathcal{B}}(\mathbf{r})$ in an arbitrary direction, calculate the Hamiltonian of the Zeeman interaction with an angular momentum $J = 1$ and show that the energy shift depends only on absolute value $|\vec{\mathcal{B}}(\mathbf{r})|$.

Solution: *The energy is,*

$$\begin{aligned}V(\mathcal{B}) &= -\vec{\mu}_J\cdot\vec{\mathcal{B}} = -\tfrac{1}{\hbar}\mu_B(\mathcal{B}_x\hat{J}_x + \mathcal{B}_y\hat{J}_y + \mathcal{B}_z\hat{J}_z)\\ &= -\tfrac{1}{\hbar}\mu_B\sum_{m_z,m_z'}|J,m_z'\rangle\Big[\tfrac{1}{2}\mathcal{B}_x\langle J,m_z'|(\hat{J}_+ + \hat{J}_-)|J,m_z\rangle\\ &\qquad +\tfrac{1}{2\imath}\mathcal{B}_y\langle J,m_z'|(\hat{J}_+ - \hat{J}_-)|J,m_z\rangle + \mathcal{B}_z\langle J,m_z'|\hat{J}_z|J,m_z\rangle\Big]\langle J,m_z|\\ &= -\mu_B\sum_{m_z,m_z'}|J,m_z'\rangle\Big[\tfrac{1}{2}(\mathcal{B}_x - \imath\mathcal{B}_y)\sqrt{J(J+1)-m_z(m_z+1)}\delta_{m_z',m_z+1}\\ &\qquad +\tfrac{1}{2}(\mathcal{B}_x + \imath\mathcal{B}_y)\sqrt{J(J+1)-m_z(m_z-1)}\delta_{m_z',m_z-1} + \mathcal{B}_z m_z\delta_{m_z',m_z}\Big]\langle J,m_z| \ .\end{aligned}$$

For an angular momentum $J = 1$ *we have,*

$$V(\mathcal{B}) = -\mu_B\begin{pmatrix}\mathcal{B}_z & \frac{1}{\sqrt{2}}(\mathcal{B}_x - \imath\mathcal{B}_y) & 0\\ \frac{1}{\sqrt{2}}(\mathcal{B}_x + \imath\mathcal{B}_y) & 0 & \frac{1}{\sqrt{2}}(\mathcal{B}_x - \imath\mathcal{B}_y)\\ 0 & \frac{1}{\sqrt{2}}(\mathcal{B}_x + \imath\mathcal{B}_y) & -B_z\end{pmatrix}$$

with the eigenvalues $\langle V(\mathcal{B})\rangle = 0, \mp\mu_B|\vec{\mathcal{B}}|$.

30.2.8.3 Ex: Coupling of two electrons

Consider a two-electron system.
a. Show that the operator $(\hbar A/\hbar^2)\hat{\mathbf{s}}_1 \cdot \hat{\mathbf{s}}_2$ distinguishes the triplet from the singlet states.
b. Consider now, that the electrons are exposed to a magnetic field B applied in the direction $\hat{\mathbf{e}}_z$, so that they acquire the interaction energies with the field $(\mu_B\mathcal{B}/\hbar)(g_1\hat{s}_{1z}+g_2\hat{s}_{2z})$. Obtain the matrix associated with the total Hamiltonian and demonstrate that in the regime $\hbar A \gg \mu_B\mathcal{B}$, the representation that favors the total momentum is more adequate.
c. Show that in the regime $\hbar A \ll \mu_B\mathcal{B}$, it is convenient to use the representation that privileges the *individual* spins of the total momentum.
d. Analyze the intermediate regime $\hbar A \simeq \mu_B\mathcal{B}$.

Solution: *a. We first deal with the case of strong spin-spin coupling, $\hbar A \gg \mu_B\mathcal{B}$. We have,*

$$V_{ss} = \tfrac{\hbar A}{\hbar^2}\hat{\mathbf{s}}_1 \cdot \hat{\mathbf{s}}_2 = \tfrac{\hbar A}{2\hbar^2}(\hat{\mathbf{S}}^2 - \hat{\mathbf{s}}_1^2 - \hat{\mathbf{s}}_2^2) \ .$$

This gives,

$$V_{ss}|(s_1,s_2)S,m_S\rangle = \tfrac{\hbar A}{2}[(s_1 \pm s_2)(s_1 \pm s_2 + 1) - s_1(s_1+1) - s_2(s_2+1)]|(s_1,s_2)S,m_S\rangle$$
$$= \hbar A \left\{ \begin{array}{c} +2s_1s_2 \\ -2(s_1+1)s_2 \end{array} \right\} |(s_1,s_2)S,m_S\rangle \ .$$

The upper line corresponds to the triplet state, the lower state to the singlet state.
b. The coupling of the spins to the magnetic field is analogous to the discussion of the Zeeman effect and the Paschen-Back effect. In the case of strong spin-spin coupling, the energy of the spin-spin coupling is unaffected, such that we obtain the Zeeman effect,

$$V_{zee}(\mathcal{B}) = -\hat{\vec{\mu}}_S \cdot \vec{\mathcal{B}} = -\frac{\mu_B}{\hbar}(g_1\hat{\mathbf{s}}_1 + g_2\hat{\mathbf{s}}_2)\cdot\vec{\mathcal{B}} = -\frac{\mu_B\mathcal{B}}{\hbar}\left(g_1\frac{\hat{\mathbf{s}}_1\cdot\hat{\mathbf{S}}}{\hat{\vec{S}}^2} + g_2\frac{\hat{\mathbf{s}}_2\cdot\hat{\mathbf{S}}}{\hat{\vec{S}}^2}\right)\hat{\mathbf{S}}\cdot\vec{\mathcal{B}}$$
$$= -\frac{\mu_B}{2\hbar}\frac{g_1(\mathbf{S}^2+\mathbf{s}_1^2-\mathbf{s}_2^2)+g_2(\mathbf{S}^2+\mathbf{s}_2^2-\mathbf{s}_1^2)}{\hat{\vec{S}}^2}\hat{\mathbf{S}}\cdot\vec{\mathcal{B}}$$
$$= -\frac{\mu_B}{2\hbar}\frac{(g_1+g_2)(s_1\pm s_2)(s_1\pm s_2+1)+(g_1-g_2)s_1(s_1+1)+(g_2-g_1)s_2(s_2+1)}{(s_1\pm s_2)(s_1\pm s_2+1)}\hat{\mathbf{S}}\cdot\vec{\mathcal{B}}$$
$$= -\frac{\mu_B\mathcal{B}}{2\hbar}4\hat{S}_z \ ,$$

using $g_1 = g_2 = 2$. This gives the total energy,

$$[V_{ss} + V_{zee}(\mathcal{B})]|(s_1,s_2)S,m_S\rangle = \left[\hbar A\left\{\begin{array}{c}+2s_1s_2\\-2(s_1+1)s_2\end{array}\right\} - 2\mu_B\mathcal{B}m_S\right]|(s_1,s_2)S,m_S\rangle \ .$$

c. For weak spin-spin coupling, $\hbar A \ll \mu_B\mathcal{B}$, we have,

$$V_{ss} = \frac{\hbar A}{\hbar^2}\hat{\mathbf{s}}_1\cdot\hat{\mathbf{s}}_2 = \frac{\hbar A}{2\hbar^2}\left(\frac{\hat{\mathbf{s}}_1\cdot\vec{\mathcal{B}}}{\mathcal{B}^2}\right)\vec{\mathcal{B}}\cdot\left(\frac{\hat{\mathbf{s}}_2\cdot\vec{\mathcal{B}}}{\mathcal{B}^2}\right)\vec{\mathcal{B}} = \frac{\hbar A}{2\hbar^2}\hat{s}_{1z}\hat{s}_{2z} \ ,$$

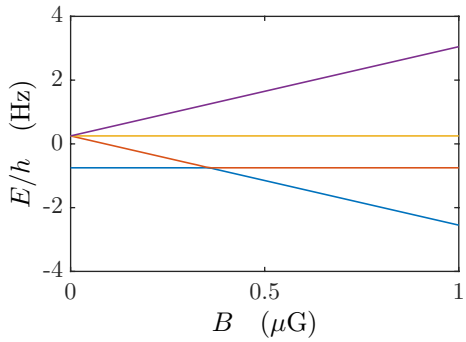

Figure 30.6: Zeeman splitting of coupled electrons.

giving

$$V_{ss}|s_1,m_1;s_2,m_2\rangle = \tfrac{\hbar A}{2} m_1 m_2 |s_1,m_1;s_2,m_2\rangle \ .$$

The reaction to a magnetic field is now that of the Paschen-Back effect,

$$V_{PB}(\mathcal{B}) = -\hat{\vec{\mu}}_S \cdot \vec{\mathcal{B}} = -\tfrac{\mu_B \mathcal{B}}{\hbar}(g_1 \hat{s}_{1z} + g_2 \hat{s}_{2z}) = -\tfrac{2\mu_B \mathcal{B}}{\hbar}(\hat{s}_{1z} + \hat{s}_{2z}) \ ,$$

using $g_1 = g_2 = 2$. *This gives,*

$$[V_{ss} + V_{zee}(\mathcal{B})]|s_1,m,1;s_2,m_2\rangle = \left[\tfrac{\hbar A}{2} m_1 m_2 - 2\mu_B \mathcal{B}(m_1+m_2)\right] |s_1,m_1;s_2,m_2\rangle \ .$$

d. For an intermediate spin-spin coupling, $\hbar A \simeq \mu_B \mathcal{B}$, *we have,*

$$\begin{aligned} V_{ss} + V_{zee}(\mathcal{B}) &= \tfrac{\hbar A}{\hbar^2} \hat{\mathbf{s}}_1 \cdot \hat{\mathbf{s}}_2 - \tfrac{\mu_B \mathcal{B}}{\hbar}(g_1 \hat{s}_{1z} + g_2 \hat{s}_{2z}) \\ &= \tfrac{\hbar A}{\hbar^2}\left(\hat{s}_{1z}\hat{s}_{2z} + \tfrac{1}{2}\hat{s}_{1+}\hat{s}_{2-} + \tfrac{1}{2}\hat{s}_{1-}\hat{s}_{2+}\right) - \tfrac{\mu_B \mathcal{B}}{\hbar}(g_1 \hat{s}_{1z} + g_2 \hat{s}_{2z}) \ . \end{aligned}$$

This gives,

$$\begin{aligned} &\langle s_1', m_1'; s_2', m_2' | [V_{ss} + V_{zee}(\mathcal{B})] | s_1, m_1; s_2, m_2 \rangle \\ &= \hbar A \left(m_1 m_2 \delta_{m_1,m_1'}\delta_{m_2,m_2'} + \tfrac{1}{2} s_{1+} s_{2-} \delta_{m_1,m_1'-1}\delta_{m_2-1,m_2'} + \tfrac{1}{2} s_{1-} s_{2+} \delta_{m_1-1,m_1'}\delta_{m_2,m_2'-1} \right) \\ &- \mu_B \mathcal{B}(g_1 m_1 + g_2 m_2)\delta_{m_1,m_1'}\delta_{m_2,m_2'} \ , \end{aligned}$$

with $s_{k\pm} \equiv \sqrt{s_k(s_k+1) - m_k(m_k \pm 1)}$. *Choosing the base* $|m_1, m_2\rangle = \begin{pmatrix} 1/2, 1/2 \\ 1/2, -1/2 \\ -1/2, 1/2 \\ -1/2, -1/2 \end{pmatrix}$

and with $g_k = 2$, $s_k = \frac{1}{2}$ *we find the following matrix representation,*

$$V_{ss} + V_{zee}(\mathcal{B}) = \begin{pmatrix} \frac{1}{4}\hbar A - 2\mu_B \mathcal{B} & 0 & 0 & 0 \\ 0 & -\frac{1}{4}\hbar A & \frac{1}{2}\hbar A s_{1-} s_{2+} & 0 \\ 0 & \frac{1}{2}\hbar A s_{1+} s_{2-} & -\frac{1}{4}\hbar A & 0 \\ 0 & 0 & 0 & \frac{1}{4}\hbar A + 2\mu_B \mathcal{B} \end{pmatrix} \ ,$$

with $s_{1-}s_{2+} = s_{1+}s_{2-} = 1$. The characteristic equation is,

$$0 = det\,[V_{ss}+V_{zee}(\mathcal{B})] = (\tfrac{1}{4}\hbar A-2\mu_B\mathcal{B}-E)(\tfrac{1}{4}\hbar A+2\mu_B\mathcal{B}-E)\left[(-\tfrac{1}{4}\hbar A-E)^2-(\tfrac{1}{2}\hbar A)^2\right] .$$

The eigenvalues are,

$$E = \tfrac{1}{4}\hbar A \pm 2\mu_B\mathcal{B}, -\tfrac{3}{4}\hbar A, \tfrac{1}{4}\hbar A .$$

This is nothing more than the Breit-Rabi formula for the specific case that both spin are $\frac{1}{2}$, that is, all states are fully stretched.

30.2.8.4 Ex: Breit-Rabi formula

Derive the analytical Breit-Rabi formula for the hyperfine structure (30.46) supposing $J = \frac{1}{2}$.

Solution: *The purpose is to diagonalize the following matrix,*

$$\begin{aligned}\langle m_I' m_J'|V_{hfs}+V_{zee}(\mathcal{B})|m_I m_J\rangle &= \langle m_I' m_J'|\tfrac{A_J}{\hbar^2}\mathbf{I}\cdot\mathbf{J}+g_J\mu_B\vec{\mathcal{B}}\cdot\mathbf{J}-g_I\mu_N\vec{\mathcal{B}}\cdot\mathbf{I}|m_I m_J\rangle \\ &= \langle m_I' m_J'|A_J(I_zJ_z+\left(\tfrac{1}{2}I_+J_-+\tfrac{1}{2}I_-J_+\right)+g_J\mu_B\mathcal{B}J_z-g_I\mu_N\mathcal{B}I_z|m_I m_J\rangle .\end{aligned}$$

Now, since $J = \frac{1}{2}$ we know that there are only two hyperfine states $F = I \pm J = I \pm \frac{1}{2}$. We also know $m_F = m_I + m_J$ and $m_J \pm \frac{1}{2}$. Using the formula,

$$\hat{J}_\pm|m_I, m_J\rangle = \hbar\sqrt{J(J+1)-m_J(m_J\pm 1)}|m_I, m_J\pm 1\rangle ,$$

we find,

$$\hat{J}_\pm|m_I, \pm\tfrac{1}{2}\rangle = 0 \qquad and \qquad \hat{J}_\pm|m_I, \mp\tfrac{1}{2}\rangle = |m_I, \mp\tfrac{1}{2}\rangle .$$

With this, we can calculate the components of the matrix:

$$\begin{aligned}\langle m_I', \tfrac{1}{2}|V_{hfs}+V_{zee}(B)|m_I, \tfrac{1}{2}\rangle &= (A_J m_I\tfrac{1}{2}+\hbar g_J\mu_B\mathcal{B}\tfrac{1}{2}-\hbar g_I\mu_N\mathcal{B}m_I)\delta_{m_I' m_I} \\ &= \left[\tfrac{A_J}{2}(m_F-\tfrac{1}{2})+\tfrac{\hbar}{2}(g_J\mu_B-g_I\mu_N)\mathcal{B}-\hbar g_I\mu_N\mathcal{B}m_F\right]\delta_{m_I' m_I} \\ \langle m_I', -\tfrac{1}{2}|V_{hfs}+V_{zee}(B)|m_I, -\tfrac{1}{2}\rangle &= (-A_J m_I\tfrac{1}{2}-\hbar g_J\mu_B\mathcal{B}\tfrac{1}{2}-\hbar g_I\mu_N\mathcal{B}m_I)\delta_{m_I' m_I} \\ &= \left[-\tfrac{A_J^2}{2}(m_F+\tfrac{1}{2})-\tfrac{\hbar}{2}(g_J\mu_B-g_I\mu_N)\mathcal{B}-\hbar g_I\mu_N\mathcal{B}m_F\right]\delta_{m_I' m_I} \\ \langle m_I', \tfrac{1}{2}|V_{hfs}+V_{zee}(\mathcal{B})|m_I, -\tfrac{1}{2}\rangle &= \tfrac{A_J}{2}\sqrt{I(I+1)+m_I(m_I-1)}\delta_{m_I' m_I-1} \\ &= \tfrac{A_J}{2}\sqrt{I(I+1)+(m_F^2-\tfrac{1}{4})}\delta_{m_I' m_I-1} \\ \langle m_I', -\tfrac{1}{2}|V_{hfs}+V_{zee}(\mathcal{B})|m_I, \tfrac{1}{2}\rangle &= \tfrac{A_J}{2}\sqrt{I(I+1)+m_I(m_I+1)}\delta_{m_I' m_I+1} \\ &= \tfrac{A_J}{2}\sqrt{I(I+1)+(m_F^2-\tfrac{1}{4})}\delta_{m_I' m_I+1} .\end{aligned}$$

The eigenvalues of this 2×2 matrix are,

$$\Delta E_{hfs}+\Delta E_{zee}(\mathcal{B}) = -\tfrac{A_J}{4}-g_I\mu_N\mathcal{B}m_F \pm \tfrac{A_J}{4}\sqrt{-1+8m_F^2+4A_J^2I(I+1)+4m_Fx+x^2} ,$$

with the abbreviation $x \equiv \frac{2(\mu_B g_J-\mu_N g_I)\mathcal{B}}{A_J}$. This is the Breit-Rabi formula. Note that the derivation can also be made in the base $|(I,J),F,m_F\rangle$ using the formula $\mathbf{I}\cdot\mathbf{J} = \frac{1}{2}(\mathbf{F}^2-\mathbf{J}^2-\mathbf{I}^2)$.

30.2.8.5 Ex: Reciprocal pollution of the Paschen-Back and Zeeman regimes

a. Determine the interaction matrix $\langle \tilde{m}_J \tilde{m}_I | \hat{V}_{hfs} + \hat{V}_{zee}(B) | m_J m_I \rangle$ of an atom with electron spin **J** and nuclear spin **J** in the decoupled base without considering the quadrupolar terms.
b. Determine the interaction matrix explicitly for the case of ^{6}Li ($I = 1$) in its ground state $^2S_{1/2}$ ($A_J = h \cdot 152.137$ MHz) for a magnetic field of $\mathcal{B} = 100$ G.
c. For the system defined in (b) determine the eigenvalues $E(\mathcal{B})$ of the interaction matrix and the eigenvectors $|\alpha(\mathcal{B})\rangle$ on the decoupled base $|m_J m_I\rangle$.
d. For the system defined in (c) determine the eigenvectors $|\alpha(\mathcal{B})\rangle$ in the coupled base $|F m_F\rangle$.
e. How good are the selection rules for transitions $S_{1/2} - P_{3/2}$ in the intermediate regime between Zeeman and Paschen-Back? We start by calculating the Zeeman shifts for both levels (s denotes the structure $S_{1/2}$, p the structure $P_{3/2}$)

$$
\begin{aligned}
{}_B\langle m_J^s m_I^s | H_{hfs} + H_B | m_J^s m_I^s \rangle_B &= E^s(\mathcal{B}) \\
{}_B\langle m_J^p m_I^p | H_{hfs} + H_B | m_J^p m_I^p \rangle_B &= E^p(\mathcal{B}) \ .
\end{aligned}
$$

For the level $P_{3/2}$ the interval factor is less. In particular for ^{6}Li it is so small that we are immediately in the Paschen-Back scheme. This means that the matrix $\overline{{}_\infty\langle \tilde{m}_J^p \tilde{m}_I^p | m_J^p m_I^p \rangle_B} = \delta_{m_J^p, \tilde{m}_J^p} \delta_{m_I^p, \tilde{m}_I^p}$ is diagonal. The element of the transition matrix is then,

$$
\begin{aligned}
&{}_B\langle m_J^p m_I^p | T_q^{(E\kappa)} | m_J^s m_I^s \rangle_B \\
&\quad = \sum_{\tilde{m}_J^s \tilde{m}_I^s} \sum_{\tilde{m}_J^p \tilde{m}_I^p} \overline{{}_\infty\langle \tilde{m}_J^p \tilde{m}_I^p | m_J^p m_I^p \rangle_B} \ {}_\infty\langle \tilde{m}_J^s \tilde{m}_I^s | m_J^s m_I^s \rangle_B \ {}_\infty\langle \tilde{m}_J^p \tilde{m}_I^p | T_q^{(E\kappa)} | \tilde{m}_J^s \tilde{m}_I^s \rangle_\infty \\
&\quad = \sum_{\tilde{m}_J^s \tilde{m}_I^s} {}_\infty\langle \tilde{m}_J^s \tilde{m}_I^s | m_J^s m_I^s \rangle_B \ {}_\infty\langle m_J^p m_I^p | T_q^{(E\kappa)} | \tilde{m}_J^s \tilde{m}_I^s \rangle_\infty \ .
\end{aligned}
$$

The matrix elements in the pure Zeeman regime can be expressed by [Deh07, unpublished],

$$
\begin{aligned}
\langle F^p m_F^p | T_q^{(E\kappa)} | F^s m_F^s \rangle &=_0 \langle m_J^p m_I^p | \, T_q^{(E\kappa)} \, | m_J^s m_I^s \rangle_0 \\
&= \begin{pmatrix} J^s & \kappa & J^p \\ m_J^s & \mathrm{sign}(m^p - m^s) & -m_J^p \end{pmatrix}^2 \begin{Bmatrix} J^p & J^s & \kappa \\ F^s & F^p & I \end{Bmatrix}^2 \frac{(2F^s+1)(2J^p+1)(2\kappa+1)}{2I+1} \ .
\end{aligned}
$$

Discuss the pure Paschen-Back regime via ${}_\infty\langle m_J^p m_I^p | T_q^{(E\kappa)} | m_J^s m_I^s \rangle_\infty$.

Solution: *a. The level shifts in a magnetic field are calculated in a regime, where m_J and m_I are good quantum numbers. Therefore, the diagonalization of the interaction matrix gives the eigenvalues (Zeeman shifts), and in strong magnetic fields, the corresponding eigenvectors are orthonormal. As the quadrupole interaction can usually be neglected, $B_J = 0$, we get,*

$$
\hat{H}_{hfs} + \hat{H}_B = \tfrac{A_J}{\hbar^2} \mathbf{I} \cdot \mathbf{J} + g_J \mu_B \vec{\mathcal{B}} \cdot \mathbf{J} - g_I \mu_N \vec{\mathcal{B}} \cdot \mathbf{I} \ .
$$

The elements of the matrix are,

$$
\begin{aligned}
&\langle \tilde{m}_I \tilde{m}_J | \hat{H}_{hfs} + \hat{H}_B | m_I m_J \rangle = (g_J m_J - g_I \mu_N m_I) \mu_B \mathcal{B} \delta_{\tilde{m}_I, m_I} \delta_{\tilde{m}_J, m_J} \\
&+ A_J \left\{ m_I m_J \delta_{\tilde{m}_I, m_I} \delta_{\tilde{m}_J, m_J} + \tfrac{1}{2} I_+ J_- \delta_{\tilde{m}_I, m_I+1} \delta_{\tilde{m}_J, m_J-1} + \tfrac{1}{2} I_- J_+ \delta_{\tilde{m}_I, m_I-1} \delta_{\tilde{m}_J, m_J+1} \right\} \ .
\end{aligned}
$$

b. In particular, for the given system we obtain,

$$\langle \tilde{m}_I \tilde{m}_J | \hat{H}_{hfs} + \hat{H}_B | m_I m_J \rangle = \begin{pmatrix} 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \end{pmatrix} ,$$

using the following base: $\{|m_J, m_I\rangle\} = \{|\frac{1}{2}, 1\rangle, |\frac{1}{2}, 0\rangle, |\frac{1}{2}, -1\rangle, |-\frac{1}{2}, 1\rangle, |-\frac{1}{2}, 0\rangle, |-\frac{1}{2}, -1\rangle\}$.
c. We express the eigenfunctions corresponding to the eigenvalues by,

$$|\alpha(\mathcal{B})\rangle = \sum_{m_J m_I} |m_J m_I\rangle\langle m_J m_I | \alpha(\mathcal{B})\rangle \ .$$

We find, for example, for the ground state $^6Li\ S_{1/2}$,

$$|\alpha_{PB,1}(150\,\mathrm{G})\rangle = 0.987|m_J = -\tfrac{1}{2}, m_I = 1\rangle + 0.162|m_J = \tfrac{1}{2}, m_I = 0\rangle$$
$$|\alpha_{PB,2}(500\,\mathrm{G})\rangle = 0.999|m_J = -\tfrac{1}{2}, m_I = 1\rangle + 0.055|m_J = \tfrac{1}{2}, m_I = 0\rangle \ .$$

d. We express the eigenfunctions corresponding to the eigenvalues by,

$$|\alpha(\mathcal{B})\rangle = \sum_{m_J m_I} |m_J m_I\rangle\langle m_J m_I | \alpha(\mathcal{B})\rangle = \sum_{m_J m_I} \sum_{F m_F} |F m_F\rangle\langle F m_F | m_J m_I\rangle\langle m_J m_I | \alpha(\mathcal{B})\rangle \ ,$$

where $\langle F m_F | m_J m_I\rangle$ *are the Clebsch-Gordans and the* $\langle m_J m_I | \alpha(\mathcal{B})\rangle$ *were determined in (c). We find, for example, for the ground state* $^6Li\ S_{1/2}$,

$$|\alpha_{Z,1}(150\,\mathrm{G})\rangle = 0.xxx|F = 0, m_F = 0\rangle + 0.yyy|F = 1, m_F = 0\rangle$$
$$|\alpha_{Z,1}(500\,\mathrm{G})\rangle = 0.xxx|F = 0, m_F = 0\rangle + 0.yyy|F = 1, m_F = 0\rangle \ .$$

e.

30.2.8.6 Ex: Diamagnetism of the ground states of H atoms

Calculate the quadratic Zeeman effect for the ground state of the hydrogen atom caused by the (usually neglected) diamagnetic term of the Hamiltonian in first order TPIT. Write down the energy shift as $\Delta E = -\frac{\chi}{2}\mathcal{B}^2$ assuming a constant magnetic field in order to obtain the diamagnetic susceptibility χ.

Solution: *The diamagnetic term of the interaction Hamiltonian with electromagnetic fields is,*

$$\hat{H}_{int} = \frac{e^2 \mathbf{A}^2}{2m} \ .$$

Assuming a homogeneous magnetic field, $\mathbf{A} = \frac{\mathcal{B}}{2}(y\hat{\mathbf{e}}_x - x\hat{\mathbf{e}}_y) = \frac{\mathcal{B}}{2}\rho\hat{\mathbf{e}}_\phi$ *with* $\rho = r\sin\theta$, *we make a first coarse approximation substituting* ρ *by* a_B,

$$\langle \hat{H}_{int}\rangle_{ap} \simeq \mathcal{B}^2 \frac{e^2 a_B^2}{8m} \approx h\mathcal{B}^2\ 96\,\mathrm{mHz/G}^2 \ .$$

The theoretical value is 5.5 mHz/G². For a better estimate based on the 1s orbital wavefunction, $\psi_{100} = \frac{1}{\sqrt{\pi}}(Z/a_B)^{3/2}e^{-Zr/a_B}$. *We get for the first electron,*

$$\begin{aligned}\langle\psi_{100}|\hat{H}_{int}|\psi_{100}\rangle &= \frac{e^2\mathcal{B}^2}{8m}\frac{Z^3}{\pi a_B^3}\int_{\mathbb{R}^3} e^{-Zr/a_B}\rho^2 e^{-Zr/a_B}d^3r \\ &= \frac{e^2\mathcal{B}^2}{8m}\frac{Z^3}{\pi a_B^3}2\pi\int_0^\pi \sin^3\theta d\theta\int_0^\infty e^{-u}u^4du\left(\frac{a_B}{2Z}\right)^5 \\ &= \frac{e^2\mathcal{B}^2}{8m}\frac{Z^3}{\pi a_B^3}2\pi\frac{4}{3}\ 24\ \left(\frac{a_B}{2Z}\right)^5 = \frac{8e^2\mathcal{B}^2a_B^2}{mZ^2} = \frac{64}{Z^2}\langle\hat{H}_{int}\rangle_{ap}\ .\end{aligned}$$

Hence,

$$\chi = -\frac{16e^2a_B^2}{mZ^2}\ .$$

30.3 Interaction with electric fields

30.3.1 Stark Effect

Electric fields interact with the electrons of the atom. Describing the atom by its dipole moment, according to (30.13), the interaction energy is,

$$\hat{V}_{stark} = -\hat{\mathbf{d}}\cdot\vec{\mathcal{E}}\ . \tag{30.65}$$

This is the *Stark effect*. This effect is usually weak, and its observation requires strong fields or high spectral resolution. Stationary perturbation theory TIPT gives,

$$E_n^{(1)} = \langle\psi_n^{(0)}|-\hat{\mathbf{d}}\cdot\mathcal{E}|\psi_n^{(0)}\rangle = e\mathcal{E}_z\int_{\mathbb{R}^3} z|\psi_n^{(0)}|^2d^3r = 0\ , \tag{30.66}$$

with $\mathbf{d} = -e\mathbf{r}$ and $\vec{\mathcal{E}}_z = \mathcal{E}_z\hat{\mathbf{e}}_z$. This only applies when the states have well-defined parity and are NOT degenerate in ℓ. When they ARE degenerate in ℓ, which is the case of hydrogen, the states have no defined parity $(-1)^\ell$. For example, the states s and p contributing to the same state $|\psi_{n,j}\rangle$ have different parities. In this case, the condition (30.66) is not automatically satisfied, and the first perturbation order yields a value. This is the case of the *linear Stark effect*. In the Excs. 30.3.2.1 and 30.3.2.2 we explicitly calculate the Stark energy shift for a hydrogen atom subject to an electric field.

Other atoms do not have this degeneracy, and we must calculate the *quadratic Stark effect* in second order TIPT,

$$|\psi_n^{(1)}\rangle = e\mathcal{E}_z\sum_{n'\neq n}|\psi_{n'}^{(0)}\rangle\frac{\langle\psi_{n'}^{(0)}|\hat{z}|\psi_n^{(0)}\rangle}{E_n-E_{n'}}\ . \tag{30.67}$$

and

$$E_n^{(2)} = e^2\mathcal{E}_z^2\sum_{n'\neq n}\frac{|\langle\psi_{n'}^{(0)}|\hat{z}|\psi_n^{(0)}\rangle|^2}{E_n-E_{n'}}\ . \tag{30.68}$$

To simplify the matrix elements, we separate the radial part from the angular part,

$$\langle\psi_{n'}^{(0)}|\hat{z}|\psi_n^{(0)}\rangle = \langle n'J'm'_J|\hat{z}|nJm_J\rangle = \int_0^\infty r^3 R_{n'J'}R_{nJ}dr \int Y^*_{J'm'_J}\tfrac{z}{r}Y_{Jm_J}d\Omega \ . \quad (30.69)$$

The radial part, written as

$$\langle n'_J J'||\hat{z}||n_J J\rangle \equiv \int_0^\infty r^3 R_{n'_J J'}R_{n_J J}dr \ , \quad (30.70)$$

and called the *irreducible matrix element*, no longer depends on the magnetic quantum number. On the other hand, the angular part may be expressed by Clebsch-Gordan coefficients, as will be discussed more extensively in Sec. 34.2.3. The result is called *Wigner-Eckart theorem*,

$$\boxed{\frac{\langle n'_J J'm'_J|\hat{z}|n_J Jm_J\rangle}{\langle n'_J J'||\hat{z}||n_J J\rangle} = \int Y^*_{J'm'_J}\tfrac{z}{r}Y_{Jm_J}d\Omega = \frac{1}{2J'+1}\begin{pmatrix} J & 1 & J' \\ m_J & 0 & -m'_J\end{pmatrix}} \ . \quad (30.71)$$

With $[\hat{z},\hat{L}_z]=0$, which was shown in Exc. 25.3.4.2, and obviously $[\hat{z},\hat{S}_z]=0$ we find,

$$0 = \langle J'm'_J|[\hat{z},\hat{J}_z]|Jm_J\rangle = (m_J - m'_J)\langle J'm'_J|\hat{z}|Jm_J\rangle \ . \quad (30.72)$$

This means that for $m_J \neq m'_J$, the matrix elements $\langle J'm'_J|\hat{z}|Jm_J\rangle$ should disappear. Therefore, the matrix is diagonal in m_J. We consider dipole transitions with $|J-J'| \leq 1$ [1],

$$\begin{pmatrix} J & 1 & J+1 \\ m_J & 0 & -m_J\end{pmatrix} = \frac{(J+1)^2-m_J^2}{(2J+1)(J+1)}, \quad (30.73)$$
$$\begin{pmatrix} J & 1 & J \\ m_J & 0 & -m_J\end{pmatrix} = \frac{m_J^2}{J(J+1)} \ ,$$
$$\begin{pmatrix} J & 1 & J-1 \\ m_J & 0 & -m_J\end{pmatrix} = \frac{J^2-m_J^2}{J(2J+1)} \ .$$

States with the same $|m_J|$ lead to the same quadratic Stark effect,

$$\Delta E \sim A + B|m_J|^2 \ . \quad (30.74)$$

The factors A and B depend on the main quantum number n and also on L,S,J. Moreover, they depend on the energy distance of all contributing levels, because of the denominator in the perturbation equation (30.67). Only levels with different parity $(-1)^L$ contribute. The formulae (30.73) will be derived explicitly in Exc. 30.3.2.3.

30.3.2 Exercises

30.3.2.1 Ex: Stark effect in hydrogen

Consider the hydrogen atom immersed in a uniform electric field $\vec{\mathcal{E}}$ applied along the $\hat{\mathbf{e}}_z$-direction. The term corresponding to this interaction in the total Hamiltonian

[1] For it is possible to show that $\langle n'_J J'||\hat{z}||n_J J\rangle = 0$ for $|J-J'|>1$.

is $\hat{H}^{(1)} = -e\vec{\mathcal{E}}\hat{z}$. For typical electric fields produced in laboratory, the condition $\hat{H}^{(1)} \ll \hat{H}_0$, which allows the use of TIPT, is satisfied. The effect of the perturbation $\hat{H}^{(1)}$, called Stark effect, is the removal of the degeneracy of some of the hydrogen atom states. Calculate the Stark effect for the state $n = 2$.

Solution: *Before explicitly calculating the elements of the perturbation matrix, we note that the perturbation matrix has nonzero components only between states of opposite parity. As we are considering the level $n = 2$, the relevant states are $\ell = 0$ and $\ell = 1$. Hence,*

$$\langle n'\ell'm'|\hat{z}|n\ell m\rangle = 0 \qquad for \qquad \ell = \ell' \ .$$

In addition, knowing

$$0 = \langle n'\ell'm'|[\hat{L}_z, \hat{z}]|n\ell m\rangle = (m - m')\langle n'\ell'm'|\hat{z}|n\ell m\rangle \ ,$$

we deduce that,

$$\langle n'\ell'm'|\hat{z}|n\ell m\rangle = 0 \qquad para \qquad m \neq m' \ .$$

Therefore, by choosing the basis as $\Big(2s \quad 2p, m = 0 \quad 2p, m = 1 \quad 2p, m = -1\Big)$, we obtain the matrix,

$$W_s = \begin{pmatrix} 0 & \langle 2s|W|2p, m = 0\rangle & 0 & 0 \\ \langle 2p, m = 0|W|2s\rangle & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix} \ .$$

We calculate explicitly,

$$\begin{aligned} \langle \phi_{200}|z|\phi_{100}\rangle &= \frac{a_B}{32\pi}\int_0^\infty \int_0^\pi \int_0^{2\pi} \tilde{r}e^{-\tilde{r}/2}\cos\theta \ \tilde{r}\cos\theta \ (2-\tilde{r})e^{-\tilde{r}/2}\tilde{r}^2\sin\theta d\theta d\phi d\tilde{r} \\ &= \frac{a_B}{16}\int_{-1}^1 \cos^2\theta d(\cos\theta)\int_0^\infty (2-\tilde{r})\tilde{r}^4 e^{-\tilde{r}}d\tilde{r} = \frac{a_B}{16}\frac{2}{3}(-72) = -3a_B \ . \end{aligned}$$

The characteristic equation for degenerate TIPT gives,

$$0 = \det(W_s - E\delta_{\ell\ell'}\delta_{mm'}) = E^2(E^2 - W_s^2) \ ,$$

such that we get four energies,

$$E = 0, \pm 3ea_B|\vec{\mathcal{E}}| \ .$$

Note that the matrix element is linear in $|\vec{\mathcal{E}}|$. Therefore, this correction is called the linear Stark effect. Transforming into the base diagonalizing the perturbation, we obtain the four vectors,

$$|2p, m = \pm 1\rangle \qquad and \qquad \tfrac{1}{\sqrt{2}}|2p, m = 0\rangle \pm |2s, m = 0\rangle \ .$$

30.3.2.2 Ex: Stark effect in the $1s$ hydrogen level

Calculate the Stark shift of the hydrogen ground state by taking into account the contributions of the excited states $n = 2, 3, ...$

Solution: *The energy term in second order perturbation theory for the* $1s$ *state of hydrogen is given by,*

$$E^{(2)} = e^2\mathcal{E}^2 \sum_{n\neq 1,\ell,m} \frac{|\langle 100|z|n\ell m\rangle|^2}{E_1 - E_n} \ ,$$

where E_n *is the eigenvalue associated with* $|n\ell m\rangle$ *taken from Bohr's model. As there are states* $|n\ell m\rangle$ *with parity opposite to* $|100\rangle$*, the term* $E^{(2)}$ *will not be zero and there will, in fact, be a quadratic contribution to the energy shift, which will be negative because* $E_1 - E_n < 0$*. An upper limit for the magnitude of this reduction can be obtained, noting that* $|E_1 - E_n| \geq \Delta E$*, where* $\Delta E \equiv |E_1 - E_2|$ *and hence,*

$$\begin{aligned} |E^{(2)}| &\leq \frac{e^2\mathcal{E}^2}{\Delta E} \sum_{n\neq 1,\ell,m} \langle 100|z|n\ell m\rangle\langle n\ell m|z|100\rangle \\ &= \frac{e^2\mathcal{E}^2}{\Delta E} \langle 100|z \left(\sum_{n\neq 1,\ell,m} |n\ell m\rangle\langle n\ell m| \right) z|100\rangle \ , \end{aligned}$$

Using the completeness relation for the base $|n\ell m\rangle$*,*

$$\sum_{n\neq 1,\ell,m} |n\ell m\rangle\langle n\ell m| = \mathbb{I} - |100\rangle\langle 100| \ ,$$

the inequality can be written in the form,

$$|E^{(2)}| \leq \frac{e^2\mathcal{E}^2}{\Delta E} [\langle 100|z^2|100\rangle - \langle 100|z|100\rangle^2] \ ,$$

As mentioned above, $\langle 100|z|100\rangle = 0$*, and the other term can be easily calculated,*

$$\langle 100|z^2|100\rangle = \int d\Omega \sin\theta \cos^2\theta \int dr r^4 \left(\frac{e^{-r/a_B}}{\sqrt{\pi a_B^3}} \right)^2 = a_B^2 \ .$$

Replacing the value $\Delta E = 3e^2/32\pi\epsilon_0 a_B$*, the limit for the reduction of energy is obtained,*

$$|E^{(2)}| \leq \frac{32\pi}{3} \epsilon_0 a_B^3 \mathcal{E}^2 \simeq 10.667\pi\epsilon_0 a_B^3 \mathcal{E}^2 \ .$$

To obtain the real energy correction from the starting equation, the matrix elements of z *must be calculated,*

$$\langle 100|z|n\ell m\rangle = \int d^3r R^*_{n\ell}(r) Y^*_{\ell m}(\theta,\phi)(r\cos\theta)\tfrac{1}{\sqrt{4\pi}} R_{10}(r) \ ,$$

where $\langle \mathbf{r}|n\ell m\rangle = R_{n\ell}(r)Y_{\ell m}(\theta,\phi)$. *Using* $\cos\theta = \sqrt{\frac{4\pi}{3}}Y_{10}(\theta,\phi)$, *we obtain,*

$$\langle 100|z|n\ell m\rangle = \int drr^3 R^*_{n\ell}(r)R_{10}(r)\int d\Omega Y^*_{\ell m}(\theta,\phi)\tfrac{1}{\sqrt{3}}Y_{10}(\theta,\phi)\ ,$$

and with the orthogonality relations for the spherical harmonics, the angular part is easily solved,

$$\langle 100|z|n\ell m\rangle = \frac{\delta_{\ell 1}\delta_{m0}}{\sqrt{3}}\int drr^3 R^*_{n\ell}(r)R_{10}(r)\ ,$$

Therefore, the second order energy correction is given by,

$$E^{(2)} = \frac{-8\pi\epsilon_0 a_B\mathcal{E}^2}{3}\sum_{n\neq 1}\left[\left(\int drr^3 R^*_{n\ell}(r)R_{10}(r)\right)^2\frac{n^2}{n^2-1}\right]\ .$$

The calculation of the radial integrals in general is not trivial, but the result for the sum can be estimated by taking the first terms. For example, for $n = 1,...,4$, *we have the radial wavefunctions,*

$$R_{10}(r) = \frac{2}{\sqrt{a_B^3}}e^{-r/a_B}\quad ,\quad R_{21}(r) = \frac{1}{2\sqrt{6a_B^3}}\frac{r}{a_B}e^{-r/2a_B}$$
$$R_{31}(r) = \frac{4}{81\sqrt{6a_B^3}}\left(6-\frac{r}{a_B}\right)\frac{r}{a_B}e^{-r/3a_B}\quad ,\quad R_{41}(r) = \frac{1}{8\sqrt{15a_B^3}}\left(\frac{r^2}{8a_B^2}-\frac{5r}{2a_B}+10\right)\ ,$$

and the integrals result in,

$$\int_0^\infty drr^3 R_{21}(r)R_{10}(r) = \frac{2^8}{3^4\sqrt{6}}a_B\quad ,\quad \int_0^\infty drr^3 R_{21}(r)R_{10}(r) = \frac{3^4}{2^6\sqrt{6}}a_B$$
$$\int_0^\infty drr^3 R_{21}(r)R_{10}(r) = \frac{2^8 3^3}{5^5\sqrt{15}}a_B\ .$$

With these terms, the energy shift is,

$$E^{(2)} = \frac{-8\pi\epsilon_0 a_B\mathcal{E}^2}{3}(2.220+0.300+0.157+..) \simeq -7.139\pi\epsilon a_B^3\mathcal{E}\ .$$

The exact result for this energy correction is $-9\pi\epsilon_0 a_B^3\mathcal{E}$ *[136].*

30.3.2.3 Ex: Stark effect

Derive the Eqs. (30.73) from the formula (28.5).

Solution: *We have*

$$\begin{pmatrix} J & 1 & J' \\ m_J & 0 & -m_J\end{pmatrix} = (-1)^{J-1+m_J}\sqrt{\frac{(J+1-J')!(J-1+J')!(-J+1+J')!}{(J+J'+2)!}}\times$$
$$\times\sum_t \frac{(-1)^t\sqrt{(J+m_J)!(J-m_J)!(J'-m_J)!(J'+m_J)!}}{t!(m_J-1+J'+t)!(-J+J'+t)!(J+1-J'-t)!(J-m_J-t)!(1-t)!}\ .$$

For $J' = J - 1$ we have

$$\begin{pmatrix} J & 1 & J-1 \\ m_J & 0 & -m_J \end{pmatrix} = (-1)^{J-1+m_J} \sqrt{\frac{2!(2J-2)!}{(2J+1)!}} \times \sum_t \frac{(-1)^t \sqrt{(J+m_J)!(J-m_J)!(J-1-m_J)!(J-1+m_J)!}}{t!(m_J-2+J+t)!(t-1)!(2-t)!(J-m_J-t)!(1-t)!} \times$$

$$\begin{pmatrix} J & 1 & J-1 \\ m_J & 0 & -m_J \end{pmatrix}^2 = \frac{2}{(2J+1)(2J)(2J-1)} \left[J^2 - m_J^2\right] \ .$$

For $J' = J$ we have

$$\begin{pmatrix} J & 1 & J \\ m_J & 0 & -m_J \end{pmatrix} = (-1)^{J-1+m_J} \sqrt{\frac{(2J-1)!}{(2J+2)!}} \sum_t \frac{(-1)^t (J+m_J)!(J-m_J)!}{t!^2(1-t)!^2(m_J-1+J+t)!(J-m_J-t)!}$$

$$\begin{pmatrix} J & 1 & J \\ m_J & 0 & -m_J \end{pmatrix}^2 = \frac{4}{(2J+2)(2J+1)2J} m_J^2 \ .$$

For $J' = J + 1$ we have

$$\begin{pmatrix} J & 1 & J+1 \\ m_J & 0 & -m_J \end{pmatrix} = (-1)^{J-1+m_J} \sqrt{\frac{(J+1-J')!(J-1+J')!(-J+1+J')!}{(J+J'+2)!}} \times \sum_t \frac{(-1)^t \sqrt{(J+m_J)!(J-m_J)!(J'-m_J)!(J'+m_J)!}}{t!(m_J-1+J'+t)!(-J+J'+t)!(J+1-J'-t)!(J-m_J-t)!(1-t)!}$$

$$\begin{pmatrix} J & 1 & J+1 \\ m_J & 0 & -m_J \end{pmatrix}^2 = \frac{2}{(2J+3)(2J+2)(2J+1)} \left[(J+1)^2 - m_J^2\right] \ .$$

Chapter 31

Atoms with many electrons

31.1 Symmetrization of bosons and fermions

Quantum mechanics must be formulated in a way to avoid any possibility of distinguishing identical particles. However, the language of mathematics automatically assigns a particle to a wavefunction; for example, $\psi_a(x_1)$ is the wavefunction a of particle 1 and $\psi_b(x_2)$ the wavefunction b of particle 2. In the absence of interactions, the total wavefunction, $\Psi = \psi_a(x_1)\psi_b(x_2)$, solves the Schrödinger equation of two particles. Now, by changing the coordinates of the particles we get a different state $\Psi' = \psi_a(x_2)\psi_b(x_1)$ [1]. This erroneously suggests that the wavefunction of a particle plays the role of a *label* (or 'soul') characterizing the particle beyond its set of quantum numbers. Why this is a problem, we will see in the following example [2].

Example 185 (*Indistinguishability of particles*): We consider a system of two non-interacting spinless particles in an infinite potential well. The total wavefunction is,

$$\Psi^{(1,2)} \equiv \psi_a(x_1)\psi_b(x_2) = C\cos\frac{n_a\pi x_1}{L}\cos\frac{n_b\pi x_2}{L} \tag{31.1}$$

with the energy,

$$E_{a,b} = \frac{\pi^2 n_a^2}{2mL^2} + \frac{\pi^2 n_b^2}{2mL^2} \ .$$

For observable quantities, such as $|\Psi^{(1,2)}|^2$, we must ensure, $|\Psi^{(1,2)}|^2 = |\Psi^{(2,1)}|^2$, that is,

$$C^2\cos^2\tfrac{n_a\pi x_1}{L}\cos^2\tfrac{n_b\pi x_2}{L} = C^2\cos^2\tfrac{n_a\pi x_2}{L}\cos^2\tfrac{n_b\pi x_1}{L} \ ,$$

[1] We note that the states are orthogonal, because

$$\int \Psi^{*(1,2)}\Psi^{(2,1)}dx_1dx_2 = \int \psi_a^*(x_1)\psi_b^*(x_2)\psi_a(x_2)\psi_b(x_1)dx_1dx_2$$
$$= \int \psi_a^*(x_1)\psi_b(x_1)dx_1 \int \psi_b^*(x_2)\psi_a(x_2)dx_2 = \delta_{n_a,n_b} \ .$$

[2] Ultimately, all this is simply a consequence of the uncertainty principle, which forbids us to specify a wavefunction as a function of two non-commuting coordinates: We have to choose one coordinate on which the wavefunction depends and treat the other as a quantum number, for example, $\psi_{\mathbf{k}}(\mathbf{r}) = e^{\imath\mathbf{k}\cdot\mathbf{r}}$ or $\psi_n(x) = \cos\frac{n\pi x}{L}$. When we now exchange the coordinates of two particles without changing their quantum numbers, we get obviously different states. In classical physics, the wavefunction of a particle would be written $\psi(x,p)$. If two classical particles are not distinct by any other mean, an exchange of *all* their coordinates would reproduce exactly the same state.

but this is not valid for $n_a \neq n_b$. If $n_a = n_b$, we have $\psi_a = \psi_b$. That is, the particles stay in the same state, and we do not need to worry about indistinguishability:

$$\Psi^{(2,1)} = \psi_a(x_2)\psi_b(x_1) = \Psi^{(1,2)} \qquad \text{and} \qquad E_{a,b} = E_{b,a} \ .$$

However, the fact that this state is never observed with two electrons shows, that theory must be corrected to allow a true description of reality. Will deepen this argument in Exc. 31.1.3.1.

We need to construct the total wavefunction in another way. Let us consider linear combinations of $\Psi^{(1,2)}$,

$$\Psi^{S,A} \equiv \tfrac{1}{\sqrt{2}}(\Psi^{(1,2)} \pm \Psi^{(2,1)}) = \tfrac{1}{\sqrt{2}}\left[\psi_a(x_1)\psi_b(x_2) \pm \psi_a(x_2)\psi_b(x_1)\right] \ . \tag{31.2}$$

This *symmetrized wavefunction* (or anti-symmetrized) represents a trick to eradicate the *label* sticking to the particles. For, under position exchange described by the operator $\mathcal{P}_x\psi_a(x_1)\psi_b(x_2) \equiv \psi_a(x_2)\psi_b(x_1)$, the (anti-)symmetrized functions behave like [3],

$$\mathcal{P}_x\Psi^{S,A} = \pm\Psi^{S,A} \qquad \text{while} \qquad \mathcal{P}_x\Psi^{(1,2)} = \Psi^{(2,1)} \neq \mp\Psi^{(1,2)} \ . \tag{31.3}$$

The (anti-)symmetrized function solves the Schrödinger equation, as well. As $[\hat{H}, \mathcal{P}_x] = 0$, we can say that the system exhibits an *exchange symmetry* or *exchange degeneracy* upon particle exchange. Observables such as $\Psi^{*S,A}\Psi^{S,A}$ stay conserved, for example, the probability

$$\begin{aligned} |\Psi^{S,A}|^2 &= \tfrac{1}{2}\left[|\psi_a(x_1)\psi_b(x_2)|^2 + |\psi_a(x_2)\psi_b(x_1)|^2\right] \\ &\pm \tfrac{1}{2}\left[\psi_a^*(x_1)\psi_b^*(x_2)\psi_a(x_2)\psi_b(x_1) + \psi_a^*(x_2)\psi_b^*(x_1)\psi_a(x_1)\psi_b(x_2)\right] = \mathcal{P}_x|\Psi^{S,A}|^2 \end{aligned} \tag{31.4}$$

does not change, when we exchange x_1 for x_2. For $x_1 = x_2$, we observe,

$$|\Psi^{S,A}|^2 = |\psi_a(x)\psi_b(x)|^2 \pm |\psi_a(x)\psi_b(x)|^2 \ . \tag{31.5}$$

That is, for a symmetric system, the probability of finding two particles at the same location is doubled, whereas for an anti-symmetric system, this probability is zero.

Wolfgang Pauli showed that the (anti-)symmetric character is related to the spin of the particles. Particles with *integer spin* called *bosons* must be symmetric. Particles with *semi-integer spin* called *fermions* must be anti-symmetric. Electrons are fermions. Therefore, in an atom, they can not be in the same state (location), but must be distributed over a complicated shell of orbitals. We note, that this applies not only to elementary particles, but also to composed particles such as, for example, atoms. We will determine in Exc. 31.1.3.2 the bosonic or fermionic character of several atomic species.

31.1.1 Pauli's Principle

Two electrons with anti-parallel spins can be separated by inhomogeneous magnetic fields, even if they are initially in the same place. Therefore, they are distinguishable

[3] To guarantee $|\mathcal{P}_x\Psi^{(1,2)}|^2 = |\Psi^{(1,2)}|^2$, we have $\mathcal{P}_x\Psi^{(1,2)} = e^{\imath\phi}\Psi^{(1,2)}$. From this, $\mathcal{P}_x\mathcal{P}_x\Psi^{(1,2)} = e^{2\imath\phi}\Psi^{(1,2)} = \Psi^{(1,2)}$. Hence, $\mathcal{P}_x\Psi^{(1,2)} = \pm\Psi^{(1,2)}$.

and the wavefunction need not be anti-symmetric. But if we exchange the spin along with the position, the particles must be indistinguishable. This must be taken into account in the wavefunction by assigning a spin coordinate, $\psi_a(x_1, s_1)$. The exchange operator should now be generalized,

$$\mathcal{P}_{x,s}\Psi^{(1,2)} \equiv \mathcal{P}_{x,s}\psi_a(x_1, s_1)\psi_b(x_2, s_2) = \psi_a(x_2, s_2)\psi_b(x_1, s_1) = \Psi^{(2,1)} \ . \tag{31.6}$$

We now assume that the electrons not only do *not* interact with each other, but there is also *no interaction* between the position and the spin of each electron. That is, for a while we will discard $\mathbf{L}\cdot\mathbf{S}$-coupling [4]. We can then write the total wavefunction of an electron as the *product* of a spatial function, $\psi(x)$, and a spin function, $\chi(s) = \alpha\uparrow + \beta\downarrow$, where α and β are probability amplitudes of finding the electron in the respective spin state, such that,

$$\psi(x, s) = \psi(x)\chi(s) \ . \tag{31.7}$$

For two particles, the total spin function is,

$$X^{(1,2)} = \chi_a(s_1)\chi_b(s_2) \ . \tag{31.8}$$

The (anti-)symmetrized version is

$$X^{S,A} = \tfrac{1}{\sqrt{2}}(X^{(1,2)} \pm X^{(2,1)}) = \tfrac{1}{\sqrt{2}}[\chi_a(s_1)\chi_b(s_2) \pm \chi_a(s_2)\chi_b(s_1)] \ , \tag{31.9}$$

as we have already seen in Sec. 25.4.1. Since there are only two spin directions, there are four possibilities to attribute the spins $\uparrow$ and $\downarrow$ to the functions $\chi_m(s_n)$,

$$X^S = \begin{cases} \uparrow\uparrow & = \chi_{1,1} \\ \frac{1}{\sqrt{2}}(\uparrow\downarrow + \downarrow\uparrow) & = \chi_{1,0} \\ \downarrow\downarrow & = \chi_{1,-1} \end{cases} \qquad \text{and} \qquad X^A = \tfrac{1}{\sqrt{2}}\,(\uparrow\downarrow - \downarrow\uparrow) = \chi_{0,0} \tag{31.10}$$

For the total wavefunction, which must be anti-symmetric for electrons, there are two possibilities,

$$\Theta^A = \begin{cases} \Psi^S X^A = \frac{1}{2}(\Psi^{(1,2)} + \Psi^{(2,1)})(X^{(1,2)} - X^{(2,1)}) = \frac{1}{\sqrt{2}}[\psi_a(x_1)\psi_b(x_2) + \psi_a(x_2)\psi_b(x_1)]\chi_{0,0} \\ \Psi^A X^S = \frac{1}{2}(\Psi^{(1,2)} - \Psi^{(2,1)})(X^{(1,2)} + X^{(2,1)}) = \frac{1}{\sqrt{2}}[\psi_a(x_1)\psi_b(x_2) - \psi_a(x_2)\psi_b(x_1)] \begin{cases} \chi_{1,1} \\ \chi_{1,0} \\ \chi_{1,-1} \end{cases} \end{cases} . \tag{31.11}$$

That is, the two electrons may be in a *triplet* state with the anti-symmetric spatial wavefunction, or in a *singlet* state with the symmetric spatial wavefunction [5].

How to generalize these considerations to N particles? The symmetric wavefunctions contain all permutations of the label a_k, where we understand by a_k the set of quantum numbers unambiguously specifying the state of the particle k,

$$\Theta^S = \mathcal{N} \sum_{\mathcal{P}_{x,s}a_k} \psi_{a_1}(x_1)...\psi_{a_N}(x_N) \ , \tag{31.12}$$

[4] In the case of $\mathbf{L}\cdot\mathbf{S}$-coupling, the total wavefunction can not be written as a product of spatial and spin functions, but it must be anti-symmetric anyway.

[5] In the coupled image, the total spin $\mathbf{S} = \mathbf{s}_1 + \mathbf{s}_2$ can have the following values $S = |s_1 - s_2|, .., s_1 + s_2 = 0, 1$. In the case $S = 0$ the magnetic quantum number can only have one value (singlet), $m_S = 0$. In the case $S = 1$ it can have three values $m_S = -1.0, +1$ (triplet) (see Exc. 30.2.8.3).

with a normalization factor $\mathcal{N}$ [6]. The (anti-)symmetrized wavefunction is obtained from the *Slater determinant*,

$$\Theta^A = \tfrac{1}{N!} \det \psi_{a_k}(x_n) = \tfrac{1}{N!} \begin{vmatrix} \psi_{a_1}(x_1) & \cdots & \psi_{a_1}(x_N) \\ \vdots & \ddots & \vdots \\ \psi_{a_N}(x_1) & \cdots & \psi_{a_N}(x_N) \end{vmatrix} . \tag{31.13}$$

This function satisfies

$$\mathcal{P}_{x,s}\Theta^{A,(1,..,i,j,..,N)} = \Theta^{A,(1,..,j,i,..,N)} = -\Theta^{A,(1,..,i,j,..,N)} . \tag{31.14}$$

The Slater determinant is zero, when two sets of quantum numbers are identical, $a_i = a_j$. For example, for two electrons in an electronic shell, $|n_i, l_i, m_i, s_i\rangle = |n_j, l_j, m_j, s_j\rangle$. This is *Pauli's strong exclusion principle*:

> *The total wavefunction must be antisymmetric with respect to the exchange of any pair of identical fermions and symmetrical with respect to exchange of any pair of identical bosons.*

Pauli's weak exclusion principle (usually sufficient for qualitative considerations) says that two fermions in identical states can not occupy the same region in space. That is, their Broglie waves interfere destructively, as if Pauli's principle exerted a repulsive interaction on the particles. This 'force' has a great impact on the phenomenology of the bonds between atoms, as we will discuss in the following sections.

31.1.2 Consequences for quantum statistics

The indistinguishability of quantum particles has interesting consequences on the statistical behavior of bosons and fermions. This becomes obvious when we consider two particles 1 and 2 being able to adopt two different states a and b. Distinguishable particles can be in one of the following four states,

$$\Psi = \{\psi_a(x_1)\psi_a(x_2), \psi_a(x_1)\psi_b(x_2), \psi_b(x_1)\psi_a(x_2), \psi_b(x_1)\psi_b(x_2)\} \tag{31.15}$$

with the same probability of $p = 1/4$. When the quantum particles approach each other, $x_1 \simeq x_2$, they must become indistinguishable. Bosonic indistinguishable particles can stay in one of the following three states,

$$\Psi = \{\psi_a(x_1)\psi_a(x_2), \tfrac{1}{\sqrt{2}}[\psi_a(x_1)\psi_b(x_2) + \psi_b(x_1)\psi_a(x_2)], \psi_b(x_1)\psi_b(x_2)\} \tag{31.16}$$

with the same probability of $p = 1/3$. Finally, fermionic indistinguishable particles can only be in one state,

$$\Psi = \{\tfrac{1}{\sqrt{2}}[\psi_a(x_1)\psi_b(x_2) - \psi_b(x_1)\psi_a(x_2)]\} \tag{31.17}$$

with the probability of $p = 1$. We see that a simple two-particle system already exhibits qualitative modifications of its statistical behavior. These differences generate

[6] It is possible to show $\mathcal{N} = \sqrt{\frac{\Pi_{k=1}^{m} n_k!}{N!}}$, where n_k is the population of state ψ_{a_k}, that is, the number of particles with the same set of quantum numbers a_k.

different physics as we deal with systems of large numbers of particles, as we can see in the cases of the free electron gas and the Bose-Einstein condensate.For a broader discussion, see Chap. 50.1.

We finally note a result of the standard model of particle physics assigning a fermionic character to all fundamental constituent particles of matter while the mediators of fundamental forces are always bosons.

31.1.3 Exercises

31.1.3.1 Ex: Indistinguishability of particles

Consider the observable quantity $\int_0^{L/2}\int_0^{L/4}|\Psi(x_1,x_2)|^2dx_1dx_2$ for the case of the wavefunction defined in (31.1) and show, that it *does* depend on particle exchange.

Solution: *We use the normalized wavefunctions* $\psi_k(x_m)=\sqrt{\frac{2}{L}}\cos\frac{n_k\pi x_m}{L}$ *with* $k=a,b$ *and* $m=1,2$*, and we consider the orbitals* $n_a=1$ *and* $n_b=2$*. The probability* $\int_0^{L/2}\int_0^{L/4}|\Psi^{(1,2)}|^2dx_1dx_2$ *is certainly an observable. However, because of,*

$$\int_0^{L/2}\int_0^{L/4}|\psi_a(x_1)\psi_b(x_2)|^2dx_1dx_2=\frac{2}{L}\int_0^{L/2}\int_0^{L/4}\cos^2\frac{\pi x_1}{L}\cos^2\frac{2\pi x_2}{L}dx_1dx_2=\frac{1}{16}\frac{2+\pi}{\pi}L$$
$$\neq\int_0^{L/2}\int_0^{L/4}|\psi_a(x_2)\psi_b(x_1)|^2dx_1dx_2=\frac{2}{L}\int_0^{L/2}\int_0^{L/4}\cos^2\frac{\pi x_2}{L}\cos^2\frac{2\pi x_1}{L}dx_1dx_2=\frac{1}{16}L\ ,$$

it is not equal to $\int_0^{L/2}\int_0^{L/4}|\Psi^{(2,1)}|^2dx_1dx_2$*.*

31.1.3.2 Ex: Bosonic and fermionic isotopes

Consulting an isotope table determine the bosonic or fermionic character of the following atomic species: ^{87}Sr, ^{86}Sr, ^{87}Rb, ^{39}K, and ^{40}K.

Solution:

31.1.3.3 Ex: Interference of bosons and fermions

a. Consider two clouds of ultracold bosonic atoms (BECs at temperature $T=0$) moving into opposite direction with velocities $v_\pm=\pm v$, respectively. Describe the matter wave interference pattern.
b. Repeat the consideration for the case of (i) fermionic clouds and (ii) only two counterpropagating atoms. Is matter wave interference possible at all for fermions?

Solution: *a. Neglecting the finite spatial extension and assuming the same number of atoms in both bosonic clouds, we describe the condensates as plane matter waves. We expect matter wave interference pattern with the periodicity* $2\pi\hbar/mv$*. Repeating the experiment the interference pattern will always have the same periodicity, but different phases. The total symmetrized wavefunction is* $\Psi(1,2)=\ldots\ \ldots$

Table 31.1: Nuclear spin, ground state, and quantum statistical nature of some atomic species.

atom	I	ground state	type
^{6}Li	0	$^{2}S_{1/2}$	fermion
^{7}Li	$\frac{3}{2}$	$^{2}S_{1/2}$	boson
^{23}Na	$\frac{3}{2}$	$^{2}S_{1/2}$	boson
^{39}K	$\frac{3}{2}$	$^{2}S_{1/2}$	boson
^{40}K	0	$^{2}S_{1/2}$	fermion
^{87}Sr	$\frac{7}{2}$	$^{1}S_{0}$	fermion
^{88}Sr	0	$^{1}S_{0}$	boson
^{85}Rb	$\frac{5}{2}$	$^{2}S_{1/2}$	boson
^{87}Rb	$\frac{3}{2}$	$^{2}S_{1/2}$	boson
^{133}Cs	$\frac{9}{2}$	$^{2}S_{1/2}$	boson

b. In the case of fermions, the total anti-symmetrized wavefunction is $\Psi(1,2) = ...$, hence, two fermions can interference. However, as the phase of the patterns for each pair of colliding atoms is arbitrary, no overall interference patterns will form. Nevertheless, fermions can interfere with themselves in matter wave interferometers [853, 344].

31.2 Helium

The simplest atom to discuss Pauli's principle is helium. The helium atom has a charged nucleus $Z = +2e$ and mass $m_{He} \approx 4m_H$.

31.2.1 The ground state

The ground state of the *helium* atom brings together the two electrons, that is, $(1s)^2$. To treat the helium atom, we can, as a first trial, describe the atom by the Bohr model, assuming independent electrons. Neglecting the electronic repulsion term (which depends on $r_{12} = |\mathbf{r}_1 - \mathbf{r}_2|$), we can separate the total wavefunction:

$$\Psi(\mathbf{r}_1, \mathbf{r}_2) = \Psi_1(\mathbf{r}_1)\Psi_2(\mathbf{r}_2) \ , \tag{31.18}$$

and we get two Schrödinger equations, the Hamiltonian being equal to the one of hydrogen-like atoms:

$$\left[-\frac{\hbar^2}{2\mu}\nabla_i^2 - \frac{e^2}{4\pi\varepsilon_0}\frac{Z}{r_i} \right] \Psi_i(\mathbf{r}_i) = E_n^{(i)}\Psi_i(\mathbf{r}_i) \ , \tag{31.19}$$

with $i = 1, 2$. For hydrogen-like atoms we have,

$$E = E_n^{(1)} + E_n^{(2)} = E_B Z^2 \left(\frac{1}{n_1^2} + \frac{1}{n_2^2} \right) \ , \tag{31.20}$$

with $E_B = -13.6\,\text{eV}$. With this, we get the energy for the ground state:

$$E_{He}(1s) = -2Z^2 E_B = -108.8\,\text{eV} \ . \tag{31.21}$$

The value predicted by Bohr's model is far from experimental reality: The ionization energy measured for the first electron is 24.6 eV, for the second 54.4 eV, totalizing a binding energy for two electrons of −78.983 eV . This corresponds to an error of about 38%. The lower energy of the first electron is due to the shielding of the nucleus by the second.

31.2.1.1 First-order perturbation of the energy

Treating the repulsion term between the electrons as a perturbation [60] and using the eigenfunctions of hydrogen atoms $|n, \ell, m_\ell\rangle$, the total wavefunction is $|n_1, \ell_1, m_{\ell_1}; n_2, \ell_2, m_{\ell_2}\rangle$, we obtain as first order TIPT correction for the energy:

$$\Delta E = \langle n_1, \ell_1, m_{\ell_1}; n_2, \ell_2, m_{\ell_2}| \frac{e^2}{4\pi\varepsilon_0 r_{12}} |n_1, \ell_1, m_{\ell_1}; n_2, \ell_2, m_{\ell_2}\rangle \ . \tag{31.22}$$

This correction is called the *Coulomb integral* and has the value:

$$\Delta E = \frac{e^2}{4\pi\varepsilon_0} \int |\Psi_{n_1,\ell_1,m_{\ell_1}}(\mathbf{r}_1)|^2 \left(\frac{1}{r_{12}}\right) |\Psi_{n_2,\ell_2,m_{\ell_2}}(\mathbf{r}_2)|^2 dV_1 dV_2 \ . \tag{31.23}$$

This integral is always positive. The term $|\Psi_{n_1,\ell_1,m_{\ell_1}}(\mathbf{r}_1)|^2 dV_1$ is the probability of finding the electron inside the volume element dV_1 and, when multiplied by $-e$, gives the charge associated with that region. Thus, the integral represents the Coulombian interaction energy of the confined charges within the two volume elements dV_1 and dV_2. ΔE is the total contribution to the potential energy. Calculating the Coulomb integral for the ground state, which will be done in Exc. 31.2.3.1, we obtain,

$$\Delta E = \frac{5Z}{4}\left(\frac{e^2}{4\pi\varepsilon_0 2a_B}\right) = \frac{5Z}{4} E_B \ , \tag{31.24}$$

with a_B the Bohr radius. ΔE corresponds to 34 eV. Thus, the ground state energy is $E_{He}(1s) = -108.8\,\text{eV} + 34\,\text{eV} = -74.8\,\text{eV}$. Comparing with the experimental value of $-78.983\,\text{eV}$ we have an error around 5.3%.

31.2.1.2 Shielding of the nuclear charge

We can make the approximation in which we consider that each electron moves in a Coulombian potential, with respect to the nucleus, shielded by the charge distribution of the other electron [352]. The resulting potential will be generated by an effective charge $\zeta e \equiv (Z - B)e$. The quantity $B \in [0, 1]$ is called the shielding constant.

The first electron feels a total nuclear charge Ze, while the second feels an effective nuclear charge ζe. We exchange Z for ζ in the energy term for hydrogen-like atoms,

$$E_n = -\zeta \frac{E_B}{n^2} \ , \tag{31.25}$$

and the energy for the ground state becomes, assuming total shielding, $B = 1$,

$$E = E_1 + E_2 = -Z^2 E_B - \zeta^2 E_B = -4E_B - E_B = -5E_B = -67.5\,\text{eV} \ . \qquad (31.26)$$

Comparing with the experimental value of -78.983 eV we have an error around 15%. For a shielding constant of around $B = 0.656$ the experimental value is reproduced. This means that the effective nuclear charge felt by the second electron is only *partly* shielded by the former. The TPIT method (31.22) and the shielding concept (31.25) can be combined in a variational calculation, where the effective charge ζ is the variational parameter. In Exc. 31.2.3.2 we study the reciprocal shielding of the electrons at the example of the helium-type ion H^-.

31.2.2 Excited states

Let us now investigate the excited states of helium, in particular those, where *only one electron* is excited, the other one being in the ground state, $(1s)^1(2s)^1$ and $(1s)^1(2p)^1$. All energies are considerably higher (weaker binding) than predicted by Bohr's model with $Z = 2$, because of the interaction with the other electron. Also, the $(2s)$ and $(2p)$ levels are no longer degenerate, because the electrostatic potential is no longer Coulombian (see Fig. 31.1).

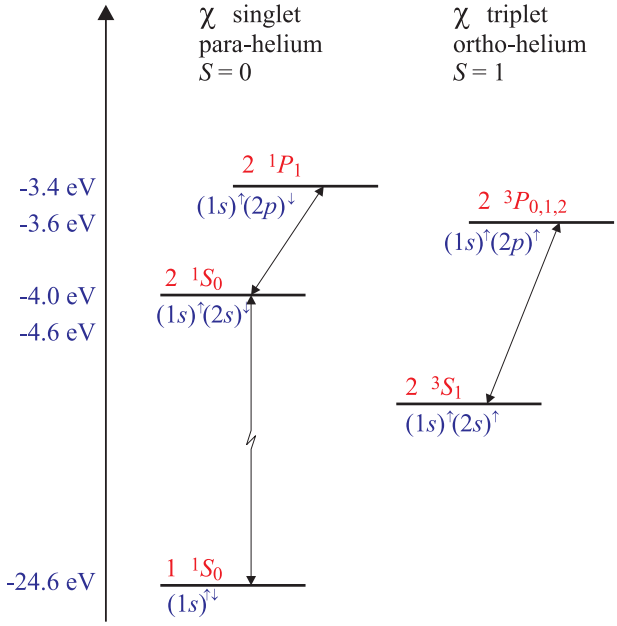

Figure 31.1: Helium levels for the excitation of the first electron and allowed singlet and triplet transitions. Note that the state $(1s)^{\uparrow\uparrow}$ does not exist.

As we have seen in the discussion of the fine structure of hydrogen, the energy of the $\mathbf{l} \cdot \mathbf{s}$-coupling given by (29.130) is $\propto E_n(Z\alpha)^2 \propto Z^4$. For helium which still has a small Z, the energy of the coupling is weak ($\sim 10^{-4}$ eV), so that we can count on a direct coupling of the spins of the two electrons. If in an excited state the

orbits of the electrons are different, we can construct combinations of symmetric **or** antisymmetric spatial wavefunctions $\Psi^{S,A}$, are therefore combinations $X^{A,S}$ of anti-parallel or parallel spins. When the spins are parallel ($S = 1$), the spatial wavefunction is antisymmetric, when they are antiparallel ($S = 0$), it is symmetric. From the symmetry of the wavefunction depends the energy of the Coulombian interelectronic interaction, because in the symmetric state the average distance of the electrons is much smaller than in the antisymmetric state, where *the total spatial function disappears for zero distance*. Consequently, the configuration $(1s)^1(2s)^1$ has two states with $S = 0$ and $S = 1$, with energy $E_{S=0} > E_{S=1}$. Likewise, all configurations are split, as shown in Fig. 31.1. The energy difference ($\sim 0.6\,\mathrm{eV}$) is considerable and larger than the energy of fine structure interaction. This explains why the two spins first couple to a total spin, $\mathbf{s}_1 + \mathbf{s}_2 = \mathbf{S}$, before this spin couples to the total orbital angular momentum, $\mathbf{S} + \mathbf{L} = \mathbf{J}$. This is the $\mathbf{L} \cdot \mathbf{S}$-coupling.

31.2.2.1 Exchange energy

The energy difference between the two states $S = 0$ and $S = 1$ is called *exchange energy*. It comes out of a first-order perturbation calculation. For example, for the two possible states $(1s)^1(2s)^1$, we write the total anti-symmetric wavefunctions,

$$\Theta^A_\pm = \tfrac{1}{\sqrt{2}} \left[\psi_{100}(\mathbf{r}_1)\psi_{200}(\mathbf{r}_2) \pm \psi_{100}(\mathbf{r}_2)\psi_{200}(\mathbf{r}_1)\right] \cdot \chi^{A,S} \ , \tag{31.27}$$

where the $(+)$ sign holds for χ^A $(S = 0)$ and the $(-)$ sign for χ^S $(S = 1)$. The energies are,

$$\begin{aligned} \Delta E^{S,A} &= \tfrac{1}{2} \int dr_1^3 \int dr_2^3 \Theta^{*A}_\pm \frac{e^2}{4\pi\varepsilon_0 |\mathbf{r}_1 - \mathbf{r}_2|} \Theta_p m^A \\ &= \tfrac{1}{2} \int dr_1^3 \int dr_2^3 \frac{e^2}{4\pi\varepsilon_0 |\mathbf{r}_1 - \mathbf{r}_2|} [|\psi_{100}(\mathbf{r}_1)|^2 |\psi_{200}(\mathbf{r}_2)|^2 + |\psi_{100}(\mathbf{r}_2)|^2 |\psi_{200}(\mathbf{r}_1)|^2] \\ &\quad \pm \tfrac{1}{2} \int dr_1^3 \int dr_2^3 \frac{e^2}{4\pi\varepsilon_0 |\mathbf{r}_1 - \mathbf{r}_2|} 2\psi^*_{100}(\mathbf{r}_1)\psi^*_{200}(\mathbf{r}_2)\psi_{100}(\mathbf{r}_2)\psi_{200}(\mathbf{r}_1) \\ &\equiv \Delta E_{coulomb} \pm \Delta E_{exchange} \ . \end{aligned} \tag{31.28}$$

The first integral,

$$\Delta E_{coulomb} = \int dr_1^3 \int dr_2^3 \frac{e^2}{4\pi\varepsilon_0 |\mathbf{r}_1 - \mathbf{r}_2|} |\psi_{100}(\mathbf{r}_1)|^2 |\psi_{200}(\mathbf{r}_2)|^2 \ , \tag{31.29}$$

is the Coulomb energy (31.23) between the electronic orbitals. We note that this part can be calculated from the Hamiltonian using *non-symmetrized* orbitals. The second integral,

$$\Delta E_{exchange} = \int dr_1^3 \int dr_2^3 \frac{e^2}{4\pi\varepsilon_0 |\mathbf{r}_1 - \mathbf{r}_2|} \psi^*_{100}(\mathbf{r}_1)\psi^*_{200}(\mathbf{r}_2)\psi_{100}(\mathbf{r}_2)\psi_{200}(\mathbf{r}_1) \ , \tag{31.30}$$

called *exchange energy* corresponds to the interference terms of the symmetrization and must be added or subtracted according to their symmetry character. It is interesting to note that up to this point the spin does not enter directly into the helium

Hamiltonian,

$$\hat{H}^{S,A} = \frac{p_1^2}{2m} + \frac{p_2^2}{2m} + V(r_1) + V(r_2) + V(|\mathbf{r}_1 - \mathbf{r}_2|) \pm \Delta E_{exchange} \ , \tag{31.31}$$

but only through the symmetry character of the spatial wavefunction. On the other hand, on a much smaller energy scale, the spin enters through the $\mathbf{L} \cdot \mathbf{S}$-interaction.

The potential is not spherically symmetric, the term r_{12} depends on the angle between $\mathbf{r}_1$ and $\mathbf{r}_2$. Thus, the total wavefunction $\Psi(\mathbf{r}_1, \mathbf{r}_2)$ is not separable into a radial and an angular part. By consequence, unlike for hydrogen, the Schrödinger equation with the Hamiltonian (31.21) has no analytical solution.

Example 186 (*TIPT for excited helium states*): We consider the two electrons of a helium atom occupying different orbits described by wavefunctions denoted by $\psi_a(1) \equiv \psi_{n_1,\ell_1,m_{\ell_1}}(\mathbf{r}_1)$ and $\psi_b(2) \equiv \psi_{n_2,\ell_2,m_{\ell_2}}(\mathbf{r}_2)$. Applying the Hamiltonian without the interelectronic interaction term, the total states $\Theta = \psi_a(1)\psi_b(2)$ and $\psi_a(2)\psi_b(1)$ have the same energy $E_a + E_b$. To calculate the energy correction, we use TIPT for degenerate states. We have to calculate the secular determinant $\det(\langle n, \nu | H^{(1)} | n, \mu \rangle - E^{(1)}_{n,\mu}\delta_{\mu,\nu})$. The terms of the perturbation matrix $H^{(1)}$ are:

$$\begin{aligned}
H^{(1)}_{11} &= \langle \psi_a(1)\psi_(2)| \frac{e^2}{4\pi\varepsilon_0 r_{12}} |\psi_a(1)\psi_b(2)\rangle \\
H^{(1)}_{22} &= \langle \psi_a(2)\psi_b(1)| \frac{e^2}{4\pi\varepsilon_0 r_{12}} |\psi_a(2)\psi_b(1)\rangle \\
H^{(1)}_{12} &= \langle \psi_a(1)\psi_b(2)| \frac{e^2}{4\pi\varepsilon_0 r_{12}} |\psi_a(2)\psi_b(1)\rangle = H^{(1)}_{21} \ .
\end{aligned}$$

The terms $J \equiv H^{(1)}_{11} = H^{(1)}_{22}$ are Coulomb integrals. The term $K \equiv H^{(1)}_{12}$ is called *exchange integral*:

$$K = \frac{e^2}{4\pi\varepsilon_0} \langle \psi_a(1)\psi_b(2)| \frac{1}{r_{12}} |\psi_a(2)\psi_b(1)\rangle \ .$$

Hence, as J and K are positive, the determinant is:

$$\begin{vmatrix} J - E & K \\ K & J - E \end{vmatrix} = 0 \ ,$$

yielding,

$$E^{(1)} = J \pm K \ .$$

That is, the states that were previously degenerate with energy $E = E_a + E_b$ are now split into two states with energies $E = E_a + E_b + J \pm K$. And the corresponding eigenfunctions are:

$$\Psi^{S,A}(1,2) = \frac{1}{\sqrt{2}} [\psi_a(1)\psi_b(2) \pm \psi_b(1)\psi_a(2)] \ .$$

This result shows that the repulsion between the two electrons breaks the degeneracy (of separable functions written in product form) into states with an energy difference $2K$. Note that the eigenfunctions are symmetric, which is discussed in the next section.

31.2.2.2 The spectrum of helium

So far we have seen that, if the electrons are in the same orbital, we have an energy term $E = 2E_a + J$ and, when they are in *different orbitals*, we have $E = E_a + E_b + J \pm K$, with a separation between levels of $2K$.

In practice, we consider only the excitation of *one* electron, because the energy to excite the two electrons exceeds the ionization energy of the helium atom. To find the selection rules for transitions between symmetric and antisymmetric states, we calculate the dipole moment of the transition. For a two-electron system the dipole moment is $\hat{\mathbf{d}} = -e\mathbf{r}_1 - e\mathbf{r}_2$, which is symmetric with respect to a permutation of the two electrons. The matrix element for the dipolar transition is:

$$\langle \Psi^A | \hat{\mathbf{d}} | \Psi^S \rangle = -e \int \Psi^{*A}(\mathbf{r}_1, \mathbf{r}_2)(\mathbf{r}_1 + \mathbf{r}_2)\Psi^S(\mathbf{r}_1, \mathbf{r}_2) dV_1 dV_2 \ . \tag{31.32}$$

If we exchange the electrons, the above integral changes sign, because $\Psi^A(\mathbf{r}_1, \mathbf{r}_2)$ changes sign. But the integral can not depend on the nomenclature of the integration variables, so *it must be zero*. The transition between a symmetric and an antisymmetric state can not occur. Looking at the spin wavefunction in $\Theta = \Psi^S\chi^A$ or $\Psi^A\chi^S$, we find that transitions are only allowed between singlet states or between triplet states. That is, there is a *selection rule* for the spin postulating $\Delta S = 0$ [7,8].

Because of the differences observed in the singlet and the triplet spectrum of helium, illustrated in Fig. 31.1, it was first believed that they belong to different atomic species, called *para-helium* and *ortho-helium*. A chemical analysis showed later that it was the same element.

31.2.3 Exercises

31.2.3.1 Ex: Helium atom

Compare the measured binding energy with the prediction of Bohr's model considering the inter-electronic interaction up to first order TIPT.

Solution: *Here, we consider the perturbation due to the Coulomb interaction between the electrons,*

$$V_{ee} = \frac{-e^2}{4\pi\varepsilon_0 |\mathbf{r}_1 - \mathbf{r}_2|} \ .$$

We focus on the ground state. As the total spatial wavefunction must necessarily be symmetrical (the orbitals of the electrons are identical), the total spin is antisymmet-

[7] Moreover, transitions between the states ${}^1S_0$ and ${}^3S_1$ are impossible, because they violate the selection rule for the angular momentum, $\Delta L = \pm 1$.

[8] We can understand the selection rules as follows: As long as the wavefunction can be written as a product, $\Theta = \Psi(x)\chi(s)$, the symmetry character is preserved for the two functions separately. The eigenvalues of the operators $\mathcal{P}_x$ and $\mathcal{P}_s$ are then good quantum numbers. But this only holds for weak $\mathbf{L}\cdot\mathbf{S}$-coupling. The electric dipole operator for the transition does not act on the spin (which prevents the recoupling $S = 1 \leftrightarrow S = 0$ via $E1$-radiation) and also does not act on the symmetry character of the orbitals (which prevents transitions $\Psi^S \leftrightarrow \Psi^A$).
In principle, this holds for any species of atoms with two valence electrons. In reality however, the influence of the $\mathbf{L}\cdot\mathbf{S}$-coupling grows with Z, which weakens the interdiction of the intercombination transition. In this case, only the operator $\mathcal{P}_{x,s}$ yields good eigenvalues.

ric. The list (25.52) gives us the radial wavefunction ψ_{100}*,*

$$\Theta^A = \psi_{100}(\mathbf{r}_1)\psi_{100}(\mathbf{r}_2)\chi_{00} = \frac{1}{\pi}\left(\frac{Z}{a_B}\right)^{3/2} e^{-Zr_1/a_B}\frac{1}{\pi}\left(\frac{Z}{a_B}\right)^{3/2} e^{-Zr_2/a_B}\times\uparrow\downarrow \ .$$

The perturbation energy calculated with unperturbed wavefunctions is,

$$\begin{aligned}
E_1^{(1)} &= \langle\Theta^A|V_{ee}|\Theta^A\rangle \\
&= \left\langle \frac{1}{\pi}\frac{Z^{3/2}}{a_B^{3/2}}e^{-Zr_1/a_B}\frac{1}{\pi}\frac{Z^{3/2}}{a_B^{3/2}}e^{-Zr_2/a_B}\right| \frac{e^2}{4\pi\varepsilon_0|\mathbf{r}_1-\mathbf{r}_2|}\left|\frac{1}{\pi}\frac{Z^{3/2}}{a_B^{3/2}}e^{-Zr_1/a_B}\frac{1}{\pi}\frac{Z^{3/2}}{a_B^{3/2}}e^{-Zr_2/a_B}\right\rangle \\
&= \frac{e^2}{4\pi\varepsilon_0}\frac{1}{\pi^4}\frac{Z^6}{a_B^6}\int\int\frac{e^{-2Z(r_1+r_2)/a_B}}{|\mathbf{r}_1-\mathbf{r}_2|}d^3r_1d^3r_2 = mc^2\alpha^2a_B\frac{1}{32\pi^4}\frac{Z}{a_B}\int\int\frac{e^{-\tilde{r}_1-\tilde{r}_2}}{|\tilde{\mathbf{r}}_1-\tilde{\mathbf{r}}_2|}d^3\tilde{r}_1d^3\tilde{r}_2 \\
&= \frac{mc^2\alpha^2Z}{32\pi^4}\int_0^{2\pi}d\varphi_2\int_0^\infty d\tilde{r}_2\tilde{r}_2^2\int_0^\pi d\vartheta_2\sin\vartheta_2\int_0^{2\pi}d\varphi_1\int_0^\infty d\tilde{r}_1\tilde{r}_1^2\int_0^\pi d\vartheta_1\sin\vartheta_1\frac{e^{-\tilde{r}_1-\tilde{r}_2}}{|\tilde{\mathbf{r}}_1-\tilde{\mathbf{r}}_2|} \ .
\end{aligned}$$

We write the distance between the electrons in spherical coordinates,

$$\begin{aligned}
&|\tilde{\mathbf{r}}_1-\tilde{\mathbf{r}}_2| \\
&= \sqrt{(\tilde{r}_1\sin\vartheta_1\cos\varphi_1-\tilde{r}_2\sin\vartheta_2\cos\varphi_2)^2+(\tilde{r}_1\sin\vartheta_1\sin\varphi_1-\tilde{r}_2\sin\vartheta_2\sin\varphi_2)^2+(\tilde{r}_1\cos\vartheta_1-\tilde{r}_2\cos\vartheta_2)^2} \\
&= \sqrt{\tilde{r}_1^2+\tilde{r}_2^2-2r_1r_2\left[\sin\vartheta_1\sin\vartheta_2\cos(\varphi_1-\varphi_2)+\cos\vartheta_1\cos\vartheta_2\right]} = R \ .
\end{aligned}$$

Since the two orbitals are spherical, we can solve the angular integrals in $\vartheta_2, \varphi_1, \varphi_2$ *letting* $\vartheta_2 = \varphi_1 = \varphi_2 = 0$ *at a distance*

$$R = \sqrt{\tilde{r}_1^2+\tilde{r}_2^2-2\tilde{r}_1\tilde{r}_2\cos\vartheta_1} \qquad \textit{with} \qquad \frac{dR}{d\vartheta_1} = \frac{\tilde{r}_1\tilde{r}_2\sin\vartheta_1}{R} \ .$$

Hence,

$$\begin{aligned}
E_1^{(1)} &= \frac{mc^2\alpha^2Z}{32\pi^4}8\pi^2\int_0^\infty d\tilde{r}_2\tilde{r}_2^2\int_0^\infty d\tilde{r}_1\tilde{r}_1^2\int_0^\pi d\vartheta_1\sin\vartheta_1\frac{e^{-\tilde{r}_1-\tilde{r}_2}}{R} \\
&= \frac{mc^2\alpha^2Z}{32\pi^4}8\pi^2\int_0^\infty d\tilde{r}_2\tilde{r}_2^2\int_0^\infty d\tilde{r}_1\tilde{r}_1^2\int_{\tilde{r}_1-\tilde{r}_2}^{\tilde{r}_1+\tilde{r}_2}dR\frac{e^{-\tilde{r}_1-\tilde{r}_2}}{\tilde{r}_1\tilde{r}_2} \\
&= \frac{mc^2\alpha^2Z}{4\pi^2}\int_0^\infty d\tilde{r}_2\tilde{r}_2e^{-\tilde{r}_1}\int_0^\infty d\tilde{r}_1\tilde{r}_1(\tilde{r}_1+\tilde{r}_2-\tilde{r}_1+\tilde{r}_2)e^{-\tilde{r}_2} = \frac{mc^2\alpha^2Z}{\pi^2} \\
&= .. = \frac{5}{4}\frac{m}{2}c^2\alpha^2Z = 34.0\,\text{eV} \ .
\end{aligned}$$

The corrected energy, $E_1 = (-108.8+34.0)\,\text{eV} = -74.8\,\text{eV}$ *is much closer to the measured value.*

31.2.3.2 Ex: Shielding in helium

The helium atom (or helium-like atoms such as H^-) has two interacting electrons in its composition, which means that these systems have no exact solution. To circumvent this problem we have to come up with a series of approximate methods for calculating their eigenstates and their respective eigenenergies. Among these methods, a widely

used one, due mainly to its ease and practicality, is the variational method, in which we calculate the fundamental state of a given problem through a test function that is not a solution of the original problem. This method, when applied to a helium atom, uses as test function the solution of the problem without coulombian interaction between the electrons, which only feel the interaction with the original charge of the nucleus. However, this method could be further improved if we considered an effective nuclear charge, due to its interaction with the electrons themselves, and then obtaining the test function. Apply this correction to the case of helium. Interpret the result. **Help:**

$$\int \frac{\sin\theta_2}{\sqrt{r_1^2+r_2^2-2r_1^2r_2^2\cos\theta_2}}d\theta_2 = \frac{\sqrt{r_1^2+r_2^2-2r_1^2r_2^2\cos\theta_2}}{r_1r_2} \qquad \text{and} \qquad \left\langle\frac{1}{r}\right\rangle = \frac{Z}{a_B}\ .$$

Solution: *This is the Hamiltonian of a helium-type atom (2 electrons) subjected to a nuclear charge of Z_0e:*

$$\hat{H} = -\frac{\hbar^2}{2m}(\nabla_1^2+\nabla_2^2) - \frac{e^2}{4\pi\varepsilon_0}\left(\frac{Z_0}{r_1}+\frac{Z_0}{r_2}-\frac{1}{|\mathbf{r}_1-\mathbf{r}_2|}\right)\ .$$

The term that prevents this problem from being calculated exactly is given by V_{ee}:

$$V_{ee} = \frac{e^2}{4\pi\varepsilon_0}\frac{1}{|\mathbf{r}_1-\mathbf{r}_2|}\ .$$

Applying the variational method in the traditional way, we would use the following test function:

$$\psi_{MV}(r_1,r_2) = \frac{Z_0^3}{\pi a_B^3}e^{-Z_0(r_1+r_2)/a_B}\ ,$$

which is the solution of the Hamiltonian with $V_{ee}=0$. But since we want to obtain the shielding effects in the problem, we will rewrite the Hamiltonian in the following format,

$$\hat{H} = -\frac{\hbar^2}{2m}(\nabla_1^2+\nabla_2^2) - \frac{e^2}{4\pi\varepsilon_0}\left(\frac{Z}{r_1}+\frac{Z}{r_2}\right) + \frac{e^2}{4\pi\varepsilon_0}\left[\frac{Z-Z_0}{r_1}+\frac{Z-Z_0}{r_2}+\frac{1}{|\mathbf{r}_1-\mathbf{r}_2|}\right]\ .$$

Now the test function of the variational method will be the solution of a problem of non-interacting electrons, but now with a nucleus having an effective charge different from the original one. The test function acquires a similar format as the previous one, but with Z_0 replaced by Z.

$$\psi_{MV}(r_1,r_2) = \frac{Z^3}{\pi a_B^3}e^{-Z(r_1+r_2)/a_B}\ .$$

Note that the adjustment parameter in this test function is Z, so we will minimize the energy in relation to Z. Once we have the test function at hand, we proceed with the variational method, calculating the mean value of H,

$$\langle H\rangle = 2Z^2E_1 + 2(Z-Z_0)\frac{e^2}{4\pi\varepsilon_0}\left\langle\frac{1}{r}\right\rangle + \langle V_{ee}\rangle\ ,$$

with $\langle 1/r\rangle$ being the expectation value of $1/r$ in the ground state ψ_{100} of a hydrogen-type atom with charge Z.

$$\frac{e^2}{4\pi\varepsilon_0}\Big\langle\frac{1}{r}\Big\rangle = \frac{e^2}{4\pi\varepsilon_0}\frac{Z}{a_B} = \langle V(r)\rangle = -2E_1 \ ,$$

and $E_1 = -13.6eV$. Now we have to calculate the mean value of V_{ee}:

$$\begin{aligned}\langle V_{ee}\rangle &= \frac{e^2}{4\pi\varepsilon_0}\Big(\frac{Z^3}{\pi a_B^3}\Big)^2\int\frac{e^{-2Z(r_1+r_2)/a_B}}{|\mathbf{r}_1-\mathbf{r}_2|}d^3r_1d^3r_2 \\ &= \frac{e^2}{4\pi\varepsilon_0}\Big(\frac{Z^3}{\pi a_B^3}\Big)^2\int\frac{e^{-2Z(r_1+r_2)/a_B}}{\sqrt{r_1^2+r_2^2-2r_1^2r_2^2\cos\theta_2}}d^3r_1d^3r_2 \ .\end{aligned}$$

Let us first calculate the integral in r_2. Without loss of generality we can rotate the coordinate system in r_2 such that its z-axis points along r_2, which facilitates integration. The integral in ϕ_2 is equal to 2π, the integral in θ_2 is given by,

$$\begin{aligned}\int_0^\pi\frac{\sin\theta_2}{\sqrt{r_1^2+r_2^2-2r_1^2r_2^2\cos\theta_2}}d\theta_2 &= \frac{1}{r_1r_2}\Big(\sqrt{r_1^2+r_2^2+2r_1^2r_2^2}-\sqrt{r_1^2+r_2^2-2r_1^2r_2^2}\Big) \\ &= \frac{1}{r_1r_2}[(r_1+r_2)-|r_1-r_2|] = \begin{cases}2/r_1, & \text{if } r_2<r_1\\ 2/r_2, & \text{if } r_2>r_1\end{cases} \ .\end{aligned}$$

Taking again the radial part r_2 we will have,

$$\begin{aligned}&= 4\pi\Big(\frac{1}{r_1}\int_0^{r_1}e^{-2Zr_2/a_B}r_2^2dr_2+\int_{r_1}^\infty e^{-2Zr_2/a_B}r_2dr_2\Big) \\ &= \frac{\pi a_B^3}{8Zr_1}\Big[1-\Big(1+\frac{2r_1}{a_B}\Big)e^{-4r_1/a_B}\Big] \ .\end{aligned}$$

Hence, $\langle V_{ee}\rangle$

$$\begin{aligned}\langle V_{ee}\rangle &= \frac{e^2}{4\pi\varepsilon_0}\frac{Z^2}{\pi a_B^3}\int\Big[1-\Big(1+\frac{2r_1}{a_B}\Big)e^{-4r_1/a_B}\Big]e^{-4r_1/a_B}r_1\sin\theta_1dr_1d\theta_1d\phi_1 \\ &= \frac{5Z}{8a_B}\frac{e^2}{4\pi\varepsilon_0} = -\frac{5Z}{4}E_1 \ .\end{aligned}$$

The average energy can then be written,

$$\langle H\rangle = [2Z^2-4Z(Z-Z_0)-\tfrac{5}{4}Z]E_1 = [-2Z^2+4ZZ_0-\tfrac{5}{4}Z]E_1 \ .$$

Minimizing $\langle H\rangle$ we obtain,

$$\frac{\partial\langle H\rangle}{\partial Z} = [-4Z+4Z_0-\tfrac{5}{4}]E_1 = 0 \ ,$$

yielding $Z = Z_0 - \frac{5}{16}$. Thus, for He, $Z_0 = 2$, the effective charge is $Z \approx 1.68$. This result seems to be correct, because it is the negatively charged electrons of the ion, which cause the effective charge to be less than the original charge. This phenomenon is known as core shielding.
The correction of the energy is,

$$E = \langle\Phi|\hat{H}|\Phi\rangle = -2E_0\left(Z-\tfrac{5}{16}\right)^2 = -77.46\,\text{eV} \ .$$

This gives an error around 1.9% compared to the experimental value of -78.983 eV.

31.3 Electronic shell structure

The interelectronic interaction and the need to antissimetrize the wavefunction of the electrons both contribute to excessively increase the complexity of multielectronic atoms. The Hamiltonian describing a multielectronic atom of atomic number Z,

$$\hat{H} = E_{kin} + V_{ncl-ele} + V_{ele-ele} = \sum_{i=1}^{Z} \frac{p_i^2}{2m} - \sum_{i=1}^{Z} \frac{Ze^2}{4\pi\varepsilon_0 |\mathbf{r}_i|} + \sum_{i<j=1}^{Z} \frac{e^2}{4\pi\varepsilon_0 |\mathbf{r}_i - \mathbf{r}_j|} \ , \quad (31.33)$$

is extremely complicated to solve, even for the simplest case ($Z = 2$) we must use approximation methods.

31.3.1 TIPT method

Note that, if we assume independent electrons ($V_{ele-ele} = 0$), that is, each electron moves independently of the others within the electrostatic potential generated by the nucleus and the other $Z-1$ electrons, the problem would be solvable: We could solve the Schrödinger equation for a product state of all the electronic wavefunctions, and we would know the eigenfunctions and individual eigenenergies of each electron (as for the hydrogen atom). In principle, we should use antisymmetric wavefunctions, but as a first approach we can choose to only respect Pauli's weak principle, that is, assign an *individual and unique* set of quantum numbers to each electron. The total energy would be the sum of the energy of every electron, and the associated physical eigenstates would be obtained by means of an antisymmetrization of the tensor product of the multielectronic state.

Thus, as a first approximation, we use the states of individual electrons (orbital approximation) and consider $V_{ele-ele}(|\mathbf{r}_i - \mathbf{r}_j|)$ as a perturbation making use of *time-independent perturbation theory*. However, this term is not small enough to justify this procedure, since approximating

$$V_{ncl-ele} \simeq \frac{Z^2 e^2}{a_B} \quad \text{and} \quad V_{ele-ele} \simeq \frac{Z(Z-1)e^2}{2a_B} \ , \quad (31.34)$$

we realize that $V_{ele-ele}/V_{ncl-ele}$ varies between $\frac{1}{4}$ for $Z = 2$ and $\frac{1}{2}$ for $Z \gg 1/2$. For this reason the use of alternative methods to describe multielectronic atoms is necessary. Nevertheless, the set of quantum numbers derived from Bohr's atomic model are still the same as those used for many-electron atoms, and the orbitals are used as starting points for more sophisticated methods.

To calculate most of the atomic properties we need reasonably realistic potentials. The most important terms of the Hamiltonian are the Coulombian potential between the nucleus and the electrons, V_{ne}, being naturally spherical, and the interaction potentials between the electrons, V_{ee}, which we will try to approximate by a spherical potential and treat the deviations caused by the approximation afterward. Knowing the effect of the shielding of the nucleus by electronic charges, we already know the asymptotes (see Fig. 31.2),

$$V_{eff} = -\frac{Ze^2}{4\pi\varepsilon_0 r} \quad \text{for} \quad r \to 0 \quad \text{and} \quad V_{eff} = -\frac{e^2}{4\pi\varepsilon_0 r} \quad \text{for} \quad r \to \infty. \quad (31.35)$$

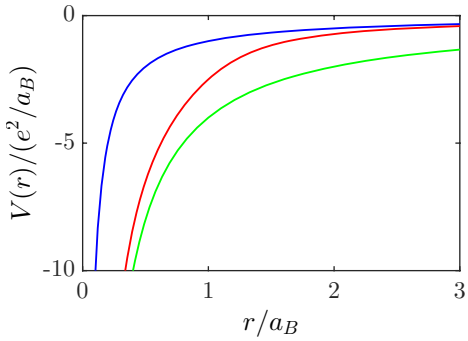

Figure 31.2: (code) External potential (shielded Coulombian) $V_{cl} \propto \frac{e^2}{r}$ (blue, upper curve), interior potential (non-shielded Coulombian for $Z = 4$) $V_{bl} \propto \frac{Ze^2}{r}$ (green, lower curve), and effective potential (red, middle curve).

31.3.2 Thomas-Fermi model for an electron gas

A first approach to getting a reasonable *effective potential* V_{eff} is provided by the *Thomas-Fermi model*. This is a semi-classical model that aims to roughly describe the total energy of the electrons as a *density functional* of atomic/molecular electrons. It serves as a basis for more sophisticated methods aiming at determining the electronic structure, such as *density functional theory* (DFT), and the wavefunctions determined by this method often serve as a starting point for the Hartree method discussed below. One of the important predictions of the *Thomas-Fermi model* is that the average radius of an atom depends on the nuclear charge as $\bar{R} \propto Z^{-1/3}$.

The Thomas-Fermi model allows us to understand the electronic configuration of the fundamental states and provides the basis for the periodic system of elements. In this model, the electrons are treated as independent particles, on one side forming an effective radial electric potential, on the other side being subjected to this potential. Instead of requiring anti-symmetry of the wavefunction, it is only necessary to ensure that all electrons are distinguished by at least one quantum number. The orbitals of complex atoms are similar to the wavefunctions of hydrogen. So, we can use these quantum numbers n, ℓ, m_ℓ, and m_s for every electron.

However, the effective radial potential depends very much on the species and is quite different from the Coulomb potential. So, the degeneracy in ℓ is lifted. In general, electrons with small ℓ are more strongly bound, because they have a higher probability of being near the nucleus, where the potential is deeper (see Fig. 31.2). The same argument explains why electrons with small n are more strongly bound. We will discuss these effects in more depth in Sec. 31.4.1 by comparing the excitation levels of the valence electron in different alkalis.

31.3.2.1 Density of states in the Fermi gas model

Even though the real potential sensed by the electrons bound to a nucleus is very different from the three-dimensional well, we can roughly imagine that the atom is subdivided into small volumes, understood as box potentials, all filled with electrons. From this we can calculate the distribution of the electronic charge, such that the

average local energy is homogeneous and the electronic cloud in equilibrium. The distribution, in turn, serves to determine the shape of the electrostatic potential which, when subdivided into small volumes filled with electrons, produces the same charge distribution. This principle is called *self-consistency*.

According to the Fermi gas model, we consider an infinite potential well, that we gradually fill up with electrons. The Pauli principle allows us to place at most two electrons in each orbital,

$$\Psi = \psi_{1,\uparrow}(x_1)\psi_{1,\downarrow}(x_2)\psi_{2,\uparrow}(x_3)\psi_{2,\downarrow}(x_4)\cdot\ldots\ . \tag{31.36}$$

This total wavefunction satisfies the weak Pauli principle, but is obviously not antisymmetric. The approximation is good, when the interaction between the electrons is negligible. Otherwise, we need to consider the exchange energy terms. This model, called *Fermi gas model*, is often used to describe the behavior of electrons that can freely move within the conductance band of a metal.

We divide the atom into small volumes (cells) containing uniformly distributed non-interacting electrons, whose total number is N, and we analyze each cell individually. The whole volume can be modeled by a box potential: $V(\mathbf{r}) = 0$ for $0 \le x, y, x \le L$ and $V(\mathbf{r}) = \infty$ in all other places. In this case we find the possible states $\{|n_x, n_y, n_z\rangle\}$ with $n_x, n_y, n_z = 1, 2, 3$ and the single electron energies,

$$E_{n_x,n_y,n_z} = \frac{\pi^2\hbar^2}{2m_eL^2}(n_x^2 + n_y^2 + n_z^2) = \frac{\hbar^2}{2m_e}\mathbf{k}^2_{n_x,n_y,n_z}\ , \tag{31.37}$$

where $\mathbf{k}^2_{n_x,n_y,n_z} = k_x^2 + k_y^2 + k_z^2 = (\frac{n_x\pi}{L})^2 + (\frac{n_y\pi}{L})^2 + (\frac{n_z\pi}{L})^2$. Each set of values $\mathbf{k} = (k_x, k_y, k_z)$ corresponds to an accessible state of the system, and each state is associated with a volume element $(\pi/L)^3$ in k-space. Defining the density of states $\eta(E)$, we can express the total number of states below a particular energy E by,

$$\begin{aligned} n(E) &= \int_0^E \eta(E')dE' \equiv \frac{1}{(2\pi)^3}\int d^3r d^3k = \frac{L^3}{(2\pi)^3}4\pi\int k^2dk \\ &= \frac{L^3}{(2\pi)^3}4\pi\left(\frac{2m_e}{\hbar^3}\right)^{3/2}\int_0^E\sqrt{E'}dE' = \frac{L^3}{3\pi^2}\left(\frac{2m_eE}{\hbar^3}\right)^{3/2}\ . \end{aligned} \tag{31.38}$$

$\eta(E)dE$ is the number of states with energies between E and $E + dE$.

At temperature $T = 0$ K all N electrons are in their energetically lowest available state, obeying the Pauli exclusion principle and considering the spin. The energy of the N-th electron (the most energetic one) is then called the *Fermi energy* E_F. That is, below E_F all states are occupied, and all states above E_F are unoccupied. The total energy is given by the sum of the energies of the N less energetic states, and the final physical state is given by the antisymmetrization of the corresponding wavefunction. With the formula (31.38), we can express the Fermi energy via $n(E_F) \equiv N$, such that,

$$E_F = \frac{\hbar^2}{2m_eL^2}(3\pi^2N)^{2/3}\ , \tag{31.39}$$

so that the density of states can be expressed as,

$$\boxed{\eta(E) = \frac{dn(E)}{dE} = \frac{L^3}{2\pi^2}\left(\frac{2m_e}{\hbar^2}\right)^{3/2}E^{1/2} = \frac{3N}{2}\frac{E^{1/2}}{E_F^{3/2}}}\ . \tag{31.40}$$

31.3.2.2 Thomas-Fermi energy

Fermi's box potential trick allowed us to model the impact of Pauli's principle on the spatial distribution of fermions in a restricted volume, but we did not take into account yet the fact that electrons are charged and will interact. Hence, the energy calculated so far is purely kinetic and will have to be complemented by potential energy.

The total kinetic energy of the electrons with the system in its ground state is,

$$\begin{aligned} E_{tot} &= \int_0^{E_F} E\eta(E)dE = \frac{L^3}{2\pi^2}\left(\frac{2m_e}{\hbar^2}\right)^{3/2}\int_0^{E_F} E^{3/2}dE \\ &= \frac{L^3}{5\pi^2}\left(\frac{2m_e}{\hbar^2}\right)^{3/2} E_F^{5/2} = \frac{\hbar^2 3^{5/3}\pi^{4/3}}{10m_e}L^3\left(\frac{N}{L^3}\right)^{5/3} = CL^3\rho^{5/3} \ , \end{aligned} \tag{31.41}$$

where $\rho \equiv N/L^3$ is the density of electrons per unit volume and C just a proportionality constant. Now understanding ρ as a quantity depending on position in space, we calculate the total number of electrons as,

$$N = \int_{\mathbb{R}^3} \rho(\mathbf{r})d^3r \ , \tag{31.42}$$

and the kinetic energy density by,

$$u_{kin}(\mathbf{r}) = C\rho^{5/3}(\mathbf{r}) \ , \tag{31.43}$$

such that the total kinetic energy of the electrons in the electronic shell is,

$$T[\rho] = C\int \rho^{5/3}(\mathbf{r})d^3r \ . \tag{31.44}$$

The potential associated with the electron-nucleus interaction is,

$$V_{ep}[\rho] = -\frac{Ze^2}{4\pi\varepsilon_0}\int \frac{\rho(\mathbf{r}')}{r'}d^3r' = \int V_p(\mathbf{r}')\rho(\mathbf{r}')d^3r' \ , \tag{31.45}$$

with the electrical potential generated by the nucleus,

$$\Phi_p(\mathbf{r}) = \frac{V_p(\mathbf{r})}{-e} = \frac{Ze}{4\pi\varepsilon_0}\frac{1}{r} \tag{31.46}$$

The potential associated with the electron-electron interaction is,

$$V_{ee}[\rho] = \frac{1}{2}\frac{e^2}{4\pi\varepsilon_0}\int \frac{\rho(\mathbf{r})\rho(\mathbf{r}')}{|\mathbf{r}-\mathbf{r}'|}d^3rd^3r' = \int V_e(\mathbf{r}')\rho(\mathbf{r}')d^3r' \ , \tag{31.47}$$

with the electrical potential generated by the electron cloud,

$$\Phi_e(\mathbf{r}) = \frac{V_e(\mathbf{r})}{-e} = -\frac{1}{2}\frac{e}{4\pi\varepsilon_0}\int \frac{\rho(\mathbf{r}')}{|\mathbf{r}-\mathbf{r}'|}d^3r' \tag{31.48}$$

Thus, the total energy (*Thomas-Fermi energy*) can be written as a functional of the electronic density of the atom,

$$\boxed{H_{TF}[\rho] = T[\rho] + V_{ep}[\rho] + V_{ee}[\rho]} \ . \tag{31.49}$$

31.3.2.3 Electronic density and the Thomas-Fermi equation

Exploiting the variational principle, we are interested in the electronic density $\rho(\mathbf{r})$ which minimizes the Thomas-Fermi energy. We can perform this process via Lagrange multipliers under the constraint, that the number of electrons remains constant in the atom. Thus,

$$0 = \delta \left\{ H_{TF}[\rho] - \mu \left(\int \rho(\mathbf{r}) d^3r - N \right) \right\} \ . \tag{31.50}$$

Inserting the Thomas-Fermi energy (31.49) we calculate,

$$\mu = \frac{\delta}{\delta\rho(\mathbf{r})} \left\{ C\rho^{5/3}(\mathbf{r}) + V_p(\mathbf{r})\rho(\mathbf{r}) + V_e(\mathbf{r})\rho(\mathbf{r}) \right\} = \tfrac{5}{3} C\rho^{2/3}(\mathbf{r}) + V_p(\mathbf{r}) + V_e(\mathbf{r}) \ . \tag{31.51}$$

Resolving for the electronic density,

$$\rho(\mathbf{r}) = \left(\frac{3}{5C} \right)^{3/2} [\mu - V_p(\mathbf{r}) - V_e(\mathbf{r})]^{3/2} \ . \tag{31.52}$$

The above expression is called the *Thomas-Fermi equation* and describes the electron density of the atom in its ground state. The expression (31.48) can be rewritten as a Poisson equation,

$$\nabla^2 V_e(\mathbf{r}) = \frac{e^2}{2\varepsilon_0} \rho(\mathbf{r}) \ , \tag{31.53}$$

so that,

$$\nabla^2 V_e(\mathbf{r}) = \frac{e^2}{2\varepsilon_0} \left(\frac{3}{5C} \right)^{3/2} [\mu - V_p(\mathbf{r}) - V_e(\mathbf{r})]^{3/2} \ . \tag{31.54}$$

For the effective potential introduced via $V_{eff} = V_p + V_e$, we find,

$$\begin{aligned} \nabla^2 V_{eff}(\mathbf{r}) &= \nabla^2 \left(-\frac{Ze^2}{4\pi\varepsilon_0} \frac{1}{r} \right) + \nabla^2 V_e(\mathbf{r}) \\ &= -\frac{Ze^2}{\varepsilon_0} \delta^3(\mathbf{r}) + \frac{e^2}{2\varepsilon_0} \left(\frac{3}{5C} \right)^{3/2} [\mu - V_{eff}(\mathbf{r})]^{3/2} \ . \end{aligned} \tag{31.55}$$

We note that, with (31.50), we can identify the Lagrange multiplier μ as a *chemical potential*. In particular, for non-interacting neutral atoms, we have $\mu = 0$. In addition, since for an atom both the potential and the electronic density must have spherical symmetry, we can write for $r \neq 0$,

$$\frac{1}{r} \frac{\partial^2}{\partial r^2} [r V_{eff}(r)] = \frac{e^2}{2\varepsilon_0} \left(\frac{3}{5C} \right)^{3/2} [-V_{eff}(\mathbf{r})]^{3/2} \ . \tag{31.56}$$

We now make the ansatz,

$$V_{eff}(r) \equiv -\frac{Z}{r} \chi(\alpha r) \qquad \text{setting} \qquad \alpha \equiv \frac{3e^{4/3}}{5C\varepsilon_0^{2/3}} Z^{1/3} \ . \tag{31.57}$$

This transforms the expression (31.56) into,

$$\frac{\partial^2}{\partial r^2} \chi(\alpha r) = -\frac{e^2}{Z\varepsilon_0} \left(\frac{3Z}{5C} \right)^{3/2} \frac{\chi^{3/2}(\alpha r)}{r^{1/2}} \ , \tag{31.58}$$

or, substituting $x \equiv \alpha r$,

$$\frac{d^2\chi}{dx^2} = -\frac{\chi^{3/2}}{x^{1/2}} \ . \tag{31.59}$$

It is important to note the last equation does not depend on the parameter Z, thus being a general result for any neutral atom. The function $\chi(x)$ is determined numerically, but we can analyze its asymptotic values given the expected behavior of the effective potential $V_{eff}(r)$: for $r \to 0$ we expect that $V_{eff}(r) = V_p(r)$, hence $\chi(0) = 1$. On the other hand, for $r \to \infty$, we expect $V_{eff}(r) = 0$, hence $\chi(\infty) = 0$. Do the Exc. 31.3.5.1.

With $\chi(x)$ known, we obtain the charge density $\rho(x)$, and hence we are able to calculate the total energy of the atom under investigation. Thus, it is possible to show that [60],

$$H_{TF}[\rho] = -0.7687\frac{e^2}{4\pi\varepsilon_0 a_B}Z^{7/3} \ . \tag{31.60}$$

It is important to highlight some points:

1. The result holds for neutral atoms.

2. There is no electronic shell structure assumed; apart from the fact that the kinetic energy was derived in a way as to respect Pauli's principle, the whole calculation was done within the laws of classical electromagnetism; no quantum mechanics was involved and, hence, no set of quantum numbers has been found.

3. Apart from the Pauli principle used to calculate the density of states (31.40), quantum statistical effects of identical particles (such as wavefunction anti-symmetrization) are not taken into account.

A more refined model which deals with third criticism and, in addition, is closer to density functional theory (DFT) is the Thomas-Fermi-Dirac model.

31.3.3 Hartree method

The effective potential obtained from the Thomas-Fermi model can serve as a starting point for quantum treatments. Assuming that all electrons are subject to the same effective potential V_{eff}, we numerically solve the Schrödinger equation for each electron independently,

$$\hat{H}_i = \left(-\frac{\hbar^2}{2m}\nabla_i^2 + V_{eff}\right)\psi_i(\mathbf{r}_i) = e_i\psi_i(\mathbf{r}_i) \ . \tag{31.61}$$

With this we calculate all energies and eigenfunctions (only the radial parts are of interest) minimizing the total energy and respecting the weak Pauli principle, that is, we classify the states in the order of increasing energies e_i and fill them successively with electrons. For the total wavefunction we obtain,

$$\left(\sum_{i=1}^{N}\hat{H}_i\right)\Psi_N = E_n\Psi_N \quad \text{with} \quad \Psi_N = \psi_1 \cdot .. \cdot \psi_N \quad \text{and} \quad E_n = \sum_{i=1}^{N} e_i \ . \tag{31.62}$$

With the eigenfunctions we calculate the charge densities $e|\psi_j(\mathbf{r}_j)|^2$. We integrate the interaction energy between these charge densities and the potentials exerted by the nucleus and all other electrons $j \neq i$ to obtain an effective potential that represents an improved estimation for the electronic mean field,

$$V_{eff} \longleftarrow -\frac{Ze^2}{4\pi\varepsilon_0 r_i} + \sum_{j\neq i} \int d^3r_j \frac{e^2}{4\pi\varepsilon_0|\mathbf{r}_i - \mathbf{r}_j|}|\psi_j(\mathbf{r}_j)|^2 \ . \tag{31.63}$$

We replace that potential in the Schrödinger equation, and repeat the whole process from the beginning, until the total energy $\sum_i e_i$ does not get any lower. This self-consistent method is called *Hartree method*. Fock improved these calculations using antisymmetric wavefunctions for the valence electrons. This method is called *Hartree-Fock method*.

31.3.4 Hartree-Fock method

The Hartree-Fock method used to treat atomic or molecular many-body systems aims at obtaining the electronic wavefunction of the system. Dealing with anti-symmetrized wavefunctions, it represents a refinement of the Hartree method. The method is based on the variational principle and on the assumption that we can write the global wavefunction as a Slater determinant, with each electron occupying a specific orbital state (spin-orbital) and interacting with an effective potential stemming from the electrons which occupy other orbitals. Instead of solving the Schrödinger equation, we must now solve a set of equations called Hartree-Fock equations of the type $\hat{F}\psi_k(1) = \epsilon_k\psi_k(1)$. The method is performed iteratively until convergence of the atomic orbitals and their respective energies is reached. The procedure is then called *self-consistent*: Starting from an initial trial global wavefunction we calculate the effective potential in each orbital and a new set of wavefunctions which, in turn, generate a new effective potential. This new potential is then used in a new set of Hartree-Fock equations.

31.3.4.1 Hartree-Fock equations

To start with, we write the Hamiltonian (31.33) of a multi-electronic atom as [60],

$$\hat{H} = \sum_{i=1}^{Z} \hat{h}_i + \tfrac{1}{2}\sum_{i\neq j} \hat{V}_{ij} \ , \tag{31.64}$$

where $\hat{h}_i$ is the Hamiltonian only of the electron i, and $\hat{V}_{ij}$ is the interaction term between the electrons i and j. To implement the method we must suppose that the multi-electronic state can be written as the product of the individual states of each electron:

$$\Psi'(1,...,Z) = \psi_1(1)\psi_2(2)...\psi_Z(Z) \ , \tag{31.65}$$

where $\psi_i(1) = \phi_i(r_1)\chi(\alpha) = \psi_i^\alpha(r_1)$ represents the spin-orbital state of electron 1, that is, the spatial wavefunction of the electron in the state i and with spin α. However, due to the symmetrization postulate, the physical state of the system must be expressed by a Slater determinant,

$$\Psi(1,...,Z) = \frac{1}{\sqrt{Z!}} \det\ [\psi_1(1)\psi_2(2)...\psi_Z(Z)] \ . \tag{31.66}$$

Now, we use the variational principle to minimize the expectation value of the ground state energy by varying the functions $\psi_k(n)$. In this way, the correct orbitals are those that minimize the energy. The expectation value is written as,

$$E = \langle\Psi|\hat{H}|\Psi\rangle = \langle\Psi|\sum_{i=1}^{Z}\hat{h}_i|\Psi\rangle + \langle\Psi|\tfrac{1}{2}\sum_{i\neq j}\hat{V}_{ij}|\Psi\rangle \ . \tag{31.67}$$

It is possible to show that,

$$\langle\Psi|\sum_{i=1}^{Z}\hat{h}_i|\Psi\rangle = \sum_{i=1}^{Z}\langle\psi_i|\hat{h}_i|\psi_i\rangle \qquad \text{and} \tag{31.68}$$

$$\langle\Psi|\tfrac{1}{2}\sum_{i\neq j}\hat{V}_{ij}|\Psi\rangle = \tfrac{1}{2}\sum_{i,j}^{Z}[\langle\psi_i\psi_j|\hat{V}_{ij}|\psi_i\psi_j\rangle - \langle\psi_j\psi_i|\hat{V}_{ij}|\psi_j\psi_i\rangle] \ .$$

Hence,

$$E = \sum_{i=1}^{Z}\langle\psi_i|\hat{h}_i|\psi_i\rangle + \tfrac{1}{2}\sum_{i,j}^{Z}[\langle\psi_i\psi_j|\hat{V}_{ij}|\psi_i\psi_j\rangle - \langle\psi_j\psi_i|\hat{V}_{ij}|\psi_j\psi_i\rangle] \ . \tag{31.69}$$

The above expression can be minimized via Lagrange multipliers under the constraint that the states are orthogonal $\langle\psi_i|\psi_j\rangle = \delta_{ij}$,

$$\delta\left\{\langle\Psi|\hat{H}|\Psi\rangle - \sum_{i,j}\epsilon_{ij}[\langle\psi_i\psi_j|\hat{V}_{ij}|\psi_i\psi_j\rangle - \langle\psi_j\psi_i|\hat{V}_{ij}|\psi_j\psi_i\rangle]\right\} \tag{31.70}$$

Thus, we obtain the following set of *Hartree-Fock equations*:

$$\hat{F}\psi_k(1) = \epsilon_k\psi_k(1) \qquad \text{where} \qquad \hat{F} = \hat{h}_1 + \sum_i(2\hat{J}_i - \hat{K}_i) \tag{31.71}$$

is the Fock operator and ϵ_k is the energy associated with the spin-orbital ψ_k. The operator $\hat{J}_i$, called *Coulomb operator*, represents the mean potential sensed by electron 1 in the orbital k due to the presence of electron 2 in the orbital i:

$$\hat{J}_i\psi_k(1) = \left\{\int \psi_i^*(2)V_{12}\psi_i(2)dr_2\right\}\psi_k(1) \ . \tag{31.72}$$

The operator $\hat{K}_i$, denominated *exchange operator*, is a consequence of the symmetrization process and therefore a purely quantum effect, that is, without classical analogue:

$$\hat{K}_i\psi_k(1) = \left\{\int \psi_i^*(2)V_{12}\psi_k(2)dr_2\right\}\psi_k(1) \ . \tag{31.73}$$

Once we know all wavefunctions, the energies of the orbitals can be obtained in the following way:

$$\int dr_1\psi_k^*(1)\left\{\hat{h}_1 + \sum_i(2\hat{J}_i - \hat{K}_i)\right\}\psi_k^*(1) = \epsilon_k\int dr_1\psi_k^*(1)\psi_k(1) = \epsilon_k \ , \tag{31.74}$$

that is,

$$\epsilon_k = \int dr_1 \psi_k^*(1)\hat{h}_1\psi_k^*(1) + \sum_i (2\hat{J}_{ki} - \hat{K}_{ki}) \ , \tag{31.75}$$

where,

$$\hat{J}_{ki} = \int dr_1 \psi_k^*(1)\hat{J}_i\psi_k(1) \qquad \text{is the Coulomb integral} \tag{31.76}$$

$$\hat{K}_{ki} = \int dr_1 \psi_k^*(1)\hat{K}_i\psi_k(1) \qquad \text{is the exchange integral .}$$

The total atomic energy can be calculated by,

$$E = 2\sum_k \epsilon_k - \sum_{k,i} (2\hat{J}_{ki} - \hat{K}_{ki}) \ . \tag{31.77}$$

Furthermore, if assuming that, taking an electron away from the orbital ψ_k the electronic distribution remains unchanged, it is possible to associate the energy ϵ_k with the ionization energy of the electron in this orbital, $I_k \simeq \epsilon_k$. This equality is known as *Koopman's theorem*.

31.3.5 Exercises

31.3.5.1 Ex: Effective potential in the Thomas-Fermi model

Calculate numerically and plot the effective potential in the Thomas-Fermi model from the differential equation (31.59) for $Z = 40$ [1419].

Solution: *We rewrite the equations as,*

$$\frac{d}{dt}\begin{pmatrix}\chi' \\ \chi\end{pmatrix} = \begin{pmatrix}-\chi^{3/2}/x^{1/2} \\ \chi'\end{pmatrix} \ .$$

Fig. 31.3 shows the calculated Thomas-Fermi potential and comparisons with the Coulombian nuclear and shielded potentials.

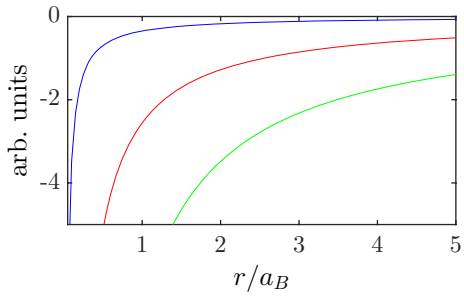

Figure 31.3: (code) (red) Effective potential in the Thomas-Fermi potential compared to the Coulombian nuclear (blue) and shielded (green) potentials.

31.4 The periodic system of elements

Completely filled principal layers n, ℓ are isotropic, $\Psi_N(\mathbf{r}) = \Psi(r)$, as we will show in Exc. 31.4.4.1. It is important to distinguish three different energetic sequences: 1. Tab. 31.6 shows, for a given atom, the excited orbitals of the *last electron*. 2. The energy sequence shown in Tab. 31.7 tells us in which orbital the next electron will be placed, when we go to the *next atom* in the periodic table 31.9 which has one more proton in the nucleus. 3. The inner electrons are subject to different potentials and, hence, follow a different sequence energetic sequence: While for the inner electrons we find,

$$E_{n,\ell} < E_{n,\ell+1} \ll E_{n+1,\ell} \ , \tag{31.78}$$

the sequence is partially inverted for the outermost electron. Note that it is the outermost electrons that determine the chemical reactivity of the atom. The sequence is illustrated in Fig. 31.5.

Noble gases have small radii, high excitation energies and high ionization energies. The outermost electrons in a noble gas atom must overcome a large energy gap to any higher quantum numbers. Halogens have strong electro-affinities, since the outer electron layer (n_{max}) is incomplete and therefore malleable, such that an electron approaching the halogen perceives the nuclear charge through a partially transparent shield. Alkalis are similar to hydrogen and have excitation energies in the optical regime. Their fundamental state $^2S_{1/2}$ is determined by a single valence electron in the $\ell = 0$ orbital. Unlike hydrogen, excitation energies are highly dependent on ℓ, since orbits with small ℓ correspond to eccentric ellipses and have higher probabilities to be in the unshielded region $-Z^2e^2/r$ than orbits with large ℓ, who spend more time in the shielded region $-e^2/r$. For the same reason, energies corresponding to larger n resemble more those of the hydrogen spectrum.

31.4.0.1 Inner shell electrons

The interior shell structure of the atoms can be analyzed by X-ray scattering. Electrons decelerated by atoms emit a continuous spectrum called *Bremsstrahlung*, but they can also expel electrons from the inner layers leaving a hole behind. When a hole is filled by cascades of electrons falling down from higher layers, the atom emits a specific X-ray spectrum ($\approx 10^4\,\mathrm{eV}$). The selection rules $\Delta\ell = \pm 1$ and $\Delta j = \pm 1$ split the lines in two components. X-ray spectra of neighboring elements in the periodic table are very similar, because the inner layers not being shielded, they see a potential close to $\propto Z^2/r$. Therefore, the Z-dependency of inner energy levels along a horizontal rows in the periodic table is more or less $\omega \propto Z^2$, as predicted by Bohr's atomic model.

31.4.1 Electronic shell model

In the Fermi gas model, each of the energy levels contains several states, and each of these states can be occupied by a single electron, according to the Pauli principle. In this way, we obtain the electronic configuration for the atoms of the periodic system. In this picture, the energies of the ground states of the elements, normalized by $1/Z^2$, can be arranged in the scheme of Fig. 31.4.

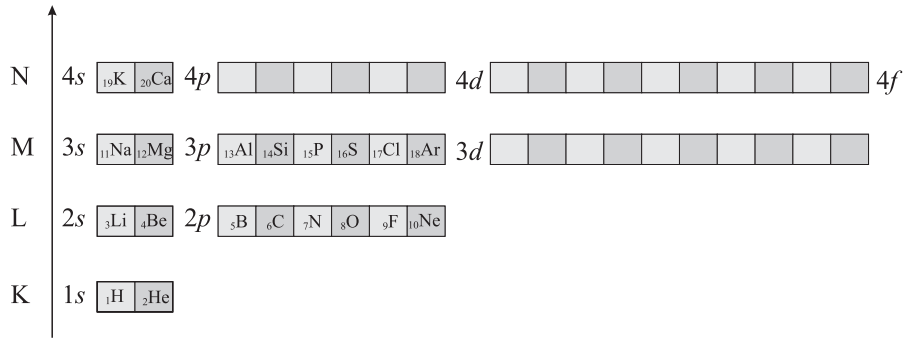

Figure 31.4: Periodic order.

This only works for atoms with up to 18 electrons. When the layer $3p$ is completely filled, the next to be occupied is not $3d$ but the $4s$. The new scheme is illustrated in Fig. 31.5. The anomalies beginning at $Z = 18$ arise due to electron-electron interaction. The real potential evolves from one to the other Coulombian potential, as distance from the nucleus is increased, as illustrated in Fig. 31.2. Near the nucleus, the electrons shield the positive charge less than for large distances r. Thus, those states that have a high probability near the nucleus are energetically lowered. That is,

$$E_{2s} < E_{2p} \qquad \text{and} \qquad E_{6s} < E_{6p} < E_{6d} \ . \tag{31.79}$$

The degeneracy of the orbital angular momentum in the Schrödinger model is thus lifted. The shielding is, as can be seen in the example of the excited states of lithium, a large effect in the range of some eV.

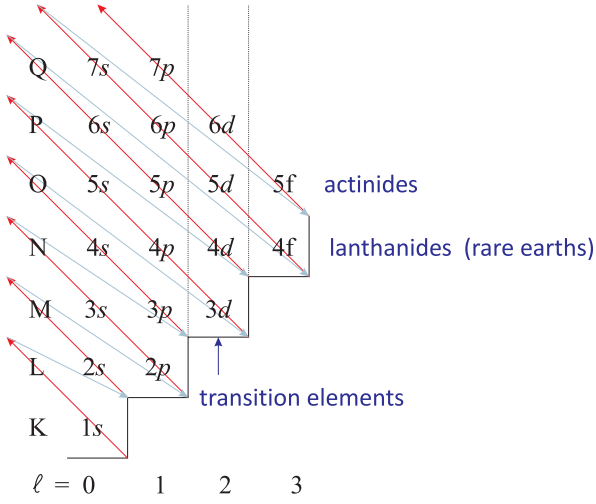

Figure 31.5: Illustration of the sequence of filling the orbitals with electrons.

The shielding also accounts for the anomalies in the periodic system, such as in K or Ca. Since $E_{4s} < E_{3d}$, the $4s$ state is filled before the $3d$. Similar anomalies

also occur in Rb ($5s$), Cs ($6s$), and Fr ($7s$). In rare earths the shielding effect is even more pronounced. Here, the energy of the state $6s$ is even below the energy of the $4f$, which means that the shells $6s$, $5s$, $5p$, and $5d$ protect the $4f$ shell very well [9]. Resolve Exc. 31.4.4.2.

31.4.1.1 Alkalines

The electronic shell structure of alkalines consists of a completed noble gas shell and an additional valence electron. Their spectrum is therefore very similar to hydrogen. An empirical approach can be stressed to describe this feature,

$$E_{n,\ell} = -\frac{\mu_{EG}c^2}{2}\frac{Z^2\alpha^2}{(n-\Delta_{n,\ell})^2} \ , \tag{31.80}$$

where μ_{EG} is the reduced mass relative to the noble gas shell and $\Delta_{n,\ell}$ is called *quantum defect*. The quantum defect is tabulated for most alkaline states and is particularly important for low energy states. For sodium, for example, the values are:

ℓ	$n=3$	$n=4$	$n=5$	$n=6$
s	1.37	1.36	1.35	1.34
p	0.88	0.87	0.86	0.86
d	0.10	0.11	0.13	0.11
f	-	0.00	-0.01	0.008

For states with a large angular momentum, the quantum defect disappears. In these states, the electron is far from the nucleus and the potential is similar to that of hydrogen. Alkalines are currently widely studied in quantum optics laboratories, for being comparatively simple, but having a sufficiently rich structure to be interesting. The fundamental electronic transitions typically lie in the visible and near-infrared spectral range and can be excited with comparatively simple laser sources. The lifetime of excited states is typically longer than 20 ns, which corresponds natural linewidths of approximately (2π) 10 MHz.

31.4.1.2 Excited states

The experimentally easiest and most precise approach to determining orbital energies consists in measuring excitation spectra of valence electrons. The diagram of Fig. 31.6 compares such excitation spectra for various alkaline atoms. Although this is not to be confused with the binding energies of valence electrons of different atoms, it gives us a qualitative idea of the impact of shielding and indicates, which orbital will be occupied by the additional valence electron of the next species in the periodic table.

[9] An example of this is Nd:YAG (Neodymium in Yttrium Aluminum Garnet). In this crystal, optical transitions can be excited within the $4f$ shell of the Nd. However, these transitions are only allowed due to perturbations of the crystalline field. The very strong shielding ensures a long life of the excited state. For this reason this crystal is an excellent laser material.

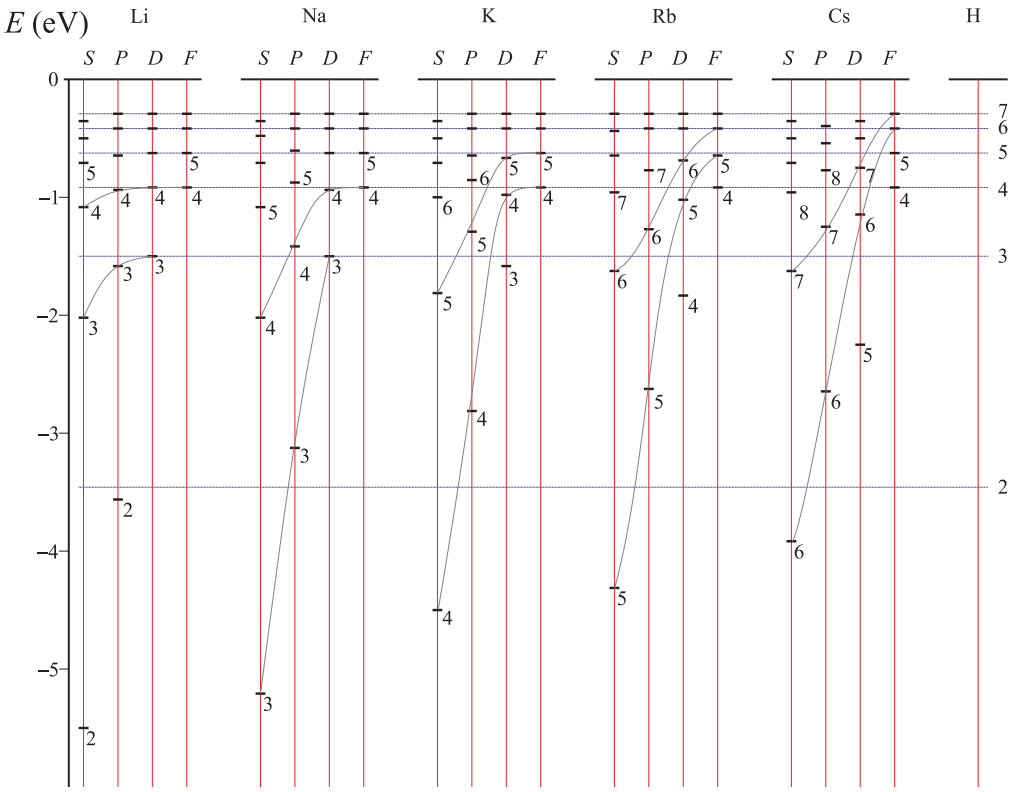

Figure 31.6: Comparison of the excitation energies of the *valence electron* for several alkaline atoms. Grey line are meant to guide the eye.

31.4.2 LS and jj-coupling

Following Hund's rule, the $\mathbf{L} \cdot \mathbf{S}$-coupling is energetically favorable compared to the $\mathbf{j} \cdot \mathbf{j}$-coupling, which means that the spins of the outermost electrons, that is, the electrons outside of filled subshells (n, ℓ), prefer to orient their spins in parallel in order to anti-symmetrize the spatial wavefunctions and thus maximize the distance between the electrons. Every sub-layer of the series shown in Fig. 31.5 must be filled in the listed order before placing new electrons in the next layer.

In the case of helium, we have seen that the Pauli principle first determines the relative orientation of the electron spins. The spins $\mathbf{s}_i$ of the individual electrons therefore add up to a total angular momentum $\mathbf{S}$. The *orbital* angular momenta $\mathbf{l}_i$ also adopt a relative orientation. It is determined by a residual spherically non-symmetric Coulomb interaction: A certain combination $\mathbf{L}$ of orbital angular momenta leads to a certain spatial distribution of the electrons and thus to a certain electrostatic energy distribution.

The total spin $\mathbf{S}$ and the total orbital angular momentum $\mathbf{L}$ subsequently couple to a total angular momentum $\mathbf{J}$ very similar to the $\mathbf{l} \cdot \mathbf{s}$ spin-orbit coupling in single electron systems. States with different $\mathbf{J}$ then have the respective energies that the

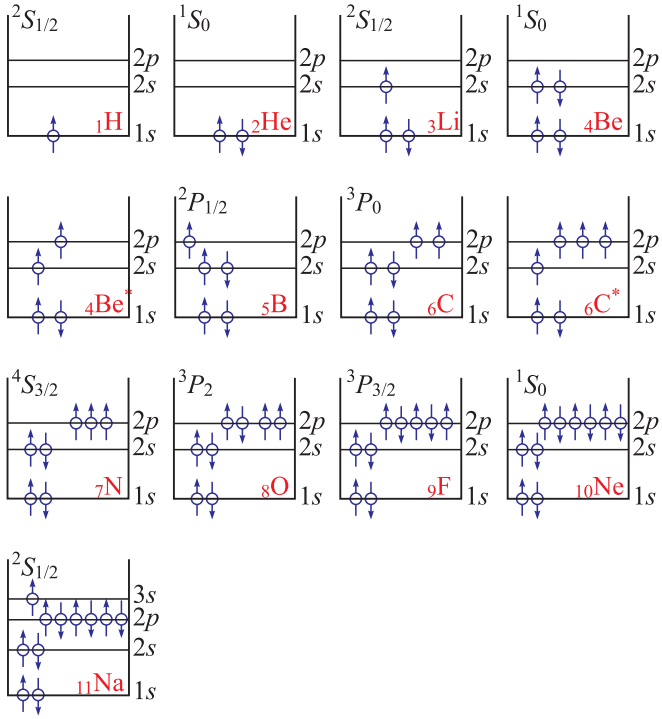

Figure 31.7: Illustration of Hund's rule.

total spin **S** adopts in the field generated by the total orbital angular momentum **L** [10].

The above coupling scheme is called *Russel-Saunders coupling* or *LS-coupling*. It works well when the spin-orbit coupling of individual electrons is small. In this case, intercombination is forbidden, which means that there can be no electromagnetic transition between states with different spins (see the case of metastable helium in Sec. 31.2.2).

Since $E_{LS} \simeq (Z\alpha)^4 \simeq Z^4$, as shown in (29.130), for heavy atoms, the coupling of an electronic spin to its own orbital momentum grows strongly with Z, as well as the symmetrization and the exchange energy, which mutually orient the spins, and the residual Coulomb interaction, which mutually couples the angular orbital momenta. In this case, the orientation of $\mathbf{L}_i$ relative to $\mathbf{S}_i$ delivers more energy than the exchange energy and the residual energy cost. Hence, the spin and the orbital angular momentum of an individual electron couple first,

$$\mathbf{j}_i = \mathbf{l}_i + \mathbf{s}_i \ . \tag{31.81}$$

We obtain a new Hamiltonian of fine structure of the form,

$$H_{FS} \propto \mathbf{j}_i \cdot \mathbf{j}_j \ . \tag{31.82}$$

[10] In addition, there are the small contributions due to $\mathbf{l}_i \cdot \mathbf{l}_j$-coupling and to $\mathbf{s}_i \cdot \mathbf{s}_j$-coupling, where $i \neq j$.

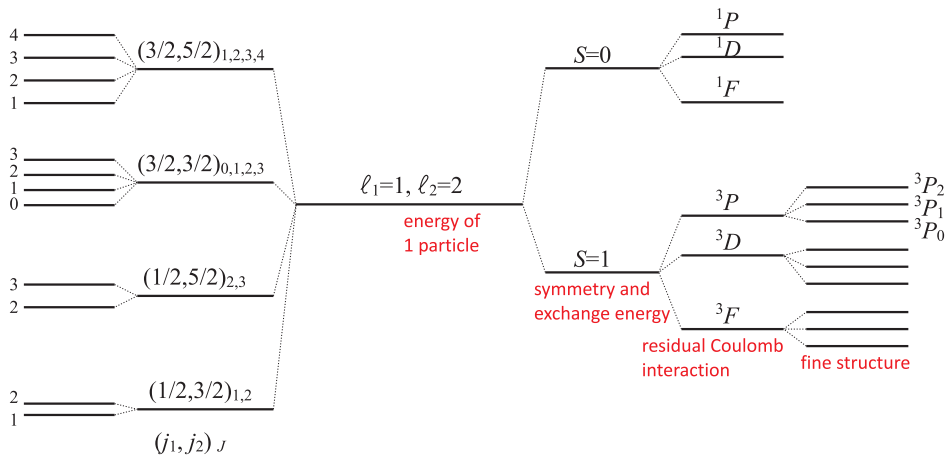

Figure 31.8: Hierarchy of coupling energies at the example of two electrons out of closed shells, $(2p)(3d)$, under the presumption of perfect jj-coupling (left) or LS-coupling (right).

Pure jj-coupling only exists for very heavy nuclei. Normally, we have a so-called *intermediate coupling*, which is a mixture of LS and jj-coupling. This can considerable relax the intercombination prohibition. When the coupling is pure, we have the following dipolar selection rules:

LS-coupling: $\Delta S = 0$, $\Delta L = \pm 1$, $\Delta \ell = \pm 1$

jj-coupling: $\Delta j = 0, \pm 1$ for one e^-, $\Delta j = 0$ for all others

In addition we have for the two couplings: $\Delta J = 0, \pm 1$, but $J, J' = 0$ is forbidden, $\Delta m_J = 0, \pm 1$ when $\Delta J = 0$ but $m_J, m_{J'} = 0$ is forbidden.

31.4.3 Summary of contributions to the atomic energy levels

The total Hamiltonian of a single atom is composed of the kinetic energy of the nucleus and the electrons, of various interaction potentials between the nucleus and the electrons, and of interactions with various types of external electromagnetic fields.

$$\hat{H} = -\frac{\hbar^2}{2m}\nabla_R^2 + \sum_{i=1}^{N}\left(-\frac{\hbar^2}{2m}\nabla_{r_i}^2\right) + V(\mathbf{r}_1, \mathbf{s}_1, .., \mathbf{r}_N, \mathbf{s}_N) + V_{ext} \ . \tag{31.83}$$

Of course, with the presence of other atoms, other interactions may generate other relevant contributions to the Hamiltonian.

The following interactions contribute to the potential V: The Coulomb interactions,

$$V_{ncl-ele} = -\sum_{i=1}^{Z}\frac{Ze^2}{4\pi\varepsilon_0|\mathbf{r} - \mathbf{r}_i|} \quad \text{and} \quad V_{ele-ele} = \sum_{i<j=1}^{Z}\frac{e^2}{4\pi\varepsilon_0|\mathbf{r}_i - \mathbf{r}_j|} \ , \tag{31.84}$$

the antisymmetry of the wavefunction, that is, exchange integrals,

$$V_{sym} \ , \tag{31.85}$$

the energies of spin-orbit couplings,

$$V_{ls} = -\sum_{i=1}^{Z} \frac{1}{e2m^2c^2} \frac{1}{|\mathbf{r}-\mathbf{r}_i|} \frac{dV_{cl}}{dr_i} (\mathbf{l}_i \cdot \mathbf{s}_i) \ , \tag{31.86}$$

the energies of spin-spin couplings,

$$V_{ss} = \sum_{i\neq j=1}^{Z} \frac{e^2}{m^2} \left[\frac{\sigma_\mathbf{i} \cdot \sigma_\mathbf{j}}{|r_i - r_j|^3} - 3\frac{[\sigma_\mathbf{i} \cdot (\mathbf{r}_i - \mathbf{r}_j)][\sigma_\mathbf{j} \cdot (\mathbf{r}_i - \mathbf{r}_j)]}{(\mathbf{r}_i - \mathbf{r}_j)^5} \right] \ , \tag{31.87}$$

the energies of orbit-orbit couplings,

$$V_{ll} = \sum_{i\neq j=1}^{Z} c_{ij} (\mathbf{l}_i \cdot \mathbf{l}_j) \ , \tag{31.88}$$

interactions between the spin of the electrons and the nuclear spin and between the orbital angular momentum of the electrons and the nuclear spin,

$$V_{hfs} = \frac{A}{\hbar^2} \mathbf{J} \cdot \mathbf{I} \ , \tag{31.89}$$

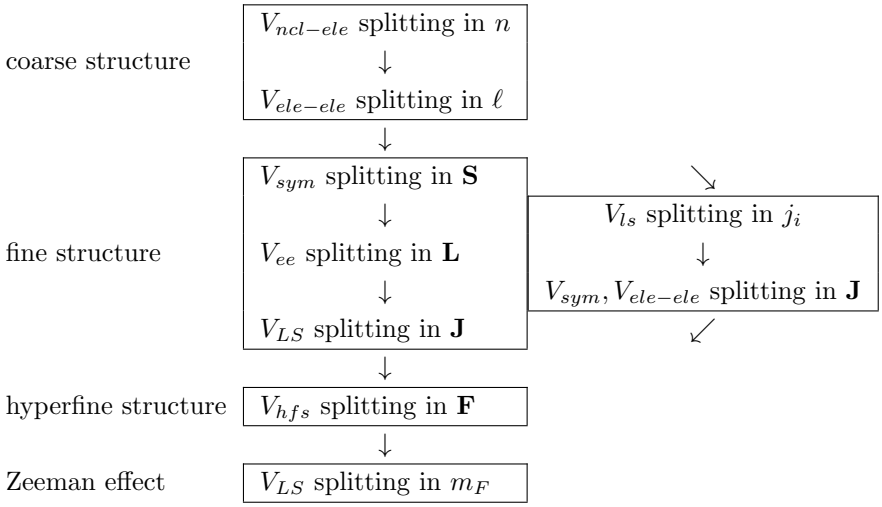
and relativistic corrections.

$$V_{rel} \ , \tag{31.90}$$

In addition, static external fields may displace energy levels and can influence the internal coupling of angular momenta and spins,

$$V_{ext} = -\mathbf{d} \cdot \vec{\mathcal{E}} \ , \ \ -\vec{\mu} \cdot \vec{\mathcal{B}} \ . \tag{31.91}$$

What quantum numbers are good depends on the relative amplitudes of intra-atomic interactions:
Case 1: fine structure with $\mathbf{L}\cdot\mathbf{S}$-coupling plus Zeeman splitting of hyperfine structure: $V_{ncl-ele}, V^r_{ele-ele} \gg V^a_{ele-ele}, V_{sym} \gg V_{\ell s} \gg V_{hfs} \gg V_B$ the quantum number are $|n_i, \ell_i, \mathbf{L}, \mathbf{S}, \mathbf{J}, \mathbf{F}, m_F\rangle$.
Case 2: fine structure with $\mathbf{j}\cdot\mathbf{j}$-coupling plus Zeeman splitting of hyperfine structure: $V_{ncl-ele}, V^r_{ele-ele} \gg V_{\ell s} \gg V^a_{ele-ele}, V_{sym} \gg V_{hfs} \gg V_B$ the quantum number are $|n_i, \ell_i, j_i, \mathbf{J}, \mathbf{F}, m_F\rangle$.
Case 3: fine structure with $\mathbf{L}\cdot\mathbf{S}$-coupling plus hyperfine structure of Zeeman splitting: $V_{ncl-ele}, V^r_{ele-ele} \gg V^a_{ele-ele}, V_{sym} \gg V_{\ell s} \gg V_B \gg V_{hfs}$ the quantum number are $|n_i, \ell_i, \mathbf{L}, \mathbf{S}, \mathbf{J}, m_J, m_I\rangle$.
Case 4: fine structure with $\mathbf{L}\cdot\mathbf{S}$-coupling plus Paschen-Back splitting of fine structure: $V_{ncl-ele}, V^r_{ele-ele} \gg V^a_{ele-ele}, V_{sym} \gg V_B \gg V_{\ell s} \gg V_{hfs}$ the quantum number are $|n_i, \ell_i, \mathbf{L}, \mathbf{S}, m_L, m_S, m_I\rangle$.



31.4.4 Exercises

31.4.4.1 Ex: Filled electronic shells

Show at the example of hydrogen that completely filled electronic layer are isotropic.

Solution: *An addition theorem for spherical harmonics states that,*

$$P_\ell(\hat{\mathbf{e}}_x \cdot \hat{\mathbf{e}}_y) = \frac{4\pi}{2\ell+1} \sum_{m=-\ell}^{\ell} Y_{\ell m}(\hat{\mathbf{e}}_y) Y^*_{\ell m}(\hat{\mathbf{e}}_x) \ ,$$

where P_ℓ is the Legendre polynomial of degree ℓ. In particular, for $\hat{\mathbf{e}}_y = \hat{\mathbf{e}}_x$,

$$\sum_{-\ell}^{\ell} |Y_{\ell m}|^2 d\Omega = \frac{2\ell+1}{4\pi} \ .$$

31.4.4.2 Ex: Electronic excitation levels of alkaline

Explain why
a. state [Li] $(2s)^2 S_{1/2}$ has lower energy than [H] $(2s)^2 S_{1/2}$;
b. state [Li] $(2s)^2 S_{1/2}$ has lower energy than [Li] $(2p)^2 P_J$;
c. state [Na] $(4s)^2 S_{1/2}$ has lower energy than [Na] $(3d)^2 D_J$.

Solution: *Looking at Fig. 31.6, we see:*
a. The nucleus is shielded by a filled $(1s)^2$ orbital, so that we could expect equivalence of both systems. However, the $(2s)$ valence electron still has a large probability of being near the nucleus, so that the shielding is only partial. The stronger attraction of the $Z = 3$ charge of the nucleus lowers the energy of the valence electron.

b. Higher orbital quantum numbers $\ell \gg 0$ have lower probabilities of near the nucleus, so that the shielding is more effective.
c. Same reason as in (b), only that the energy correction is now so large that the 'natural' ordering according to the main quantum number of Bohr's model is inverted.

Chapter 32

Molecular dimers

In systems of many particles (gases, fluids, or solids) interatomic interactions must be considered. These interactions usually have electrostatic origins, but generally can not be given in the form of closed expressions. For example, the collision of two atoms i and j can occur in a multitude of channels, that is, interaction potentials $V(\mathbf{r}_i - \mathbf{r}_j)$. Interatomic forces do not only govern collisions, but can sustain molecular bound states. This introduces new degrees of freedom in the systems of many particles through possible excitations of vibration or rotation movements.

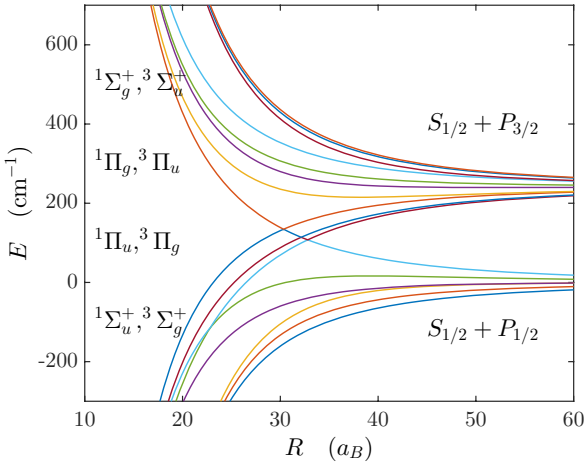

Figure 32.1: (code) Example of an interatomic potential spaghetti: The lowest states of the molecule $^{85}Rb_2$.

In this course, we will not go beyond homo- or heteronuclear dimers, that is, molecules consisting of two identical or different atoms.

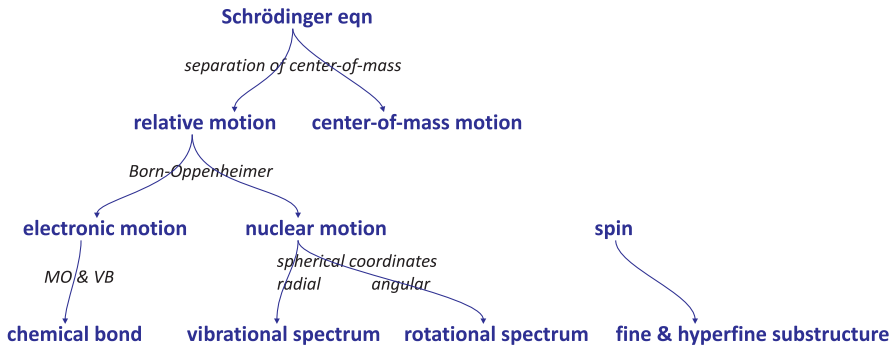

Figure 32.2: Approximations made in the molecular physics.

32.1 Molecular binding

32.1.1 Ionic and covalent binding

There are two fundamental ways of binding two atoms together, the ionic bond and the covalent bond [1]. The *ionic bond* is ruled by the quantities *electroaffinity* (EA), *electronegativity* (EN), and *ionization energy* (IE):

- **Ionization energy:** This energy is needed for the release of an electron by a neutral atom, e.g. $\mathrm{Na} + 5.1\,\mathrm{eV} \rightarrow \mathrm{Na}^+ + e^-$.
- **Electroaffinity**: This energy is released by the capture of an electron by a neutral atom, e.g. $\mathrm{Cl} + e^- \rightarrow \mathrm{Cl}^- + 3.8\,\mathrm{eV}$.
- **Electronegativity**: This quantity measures the stability of a valence orbital, e.g. that of fluorine (3.98) is more stable than that of cesium (0.79), such that fluorine holds its electrons tighter than cesium.

At short distances, the exchange of an electron between atoms can decrease energy. The so-called *ionic bond* is then sustained by the Coulombian attraction between two ions, and the binding energy can be estimated through electrostatic interaction.

Example 187 (*Ionic binding in NaCl*): For example, a sodium and a chlorine atom gain energy by forming a molecule,

$$\begin{aligned} \mathrm{Na} + 5.1\,\mathrm{eV} &\rightarrow \mathrm{Na}^+ + e^- \\ \mathrm{Cl} + e^- &\rightarrow \mathrm{Cl}^- + 3.8\,\mathrm{eV} \\ \mathrm{Na}^+ + \mathrm{Cl}^- &\rightarrow \mathrm{NaCl} + 4.9\,\mathrm{eV} \\ \hline \mathrm{Na} + \mathrm{Cl} &\rightarrow \mathrm{NaCl} + (-5.1 + 3.8 + 4.9)\,\mathrm{eV} \ . \end{aligned} \tag{32.1}$$

[1] We are not considering metallic bonds nor hydrogen bridge bonds, here.

The molecules are polar and, therefore, have a permanent electric dipole moment. The bond has no preferential direction, since each atom is perfectly isotropic. Therefore, this type is well suited for the construction of crystalline lattices.

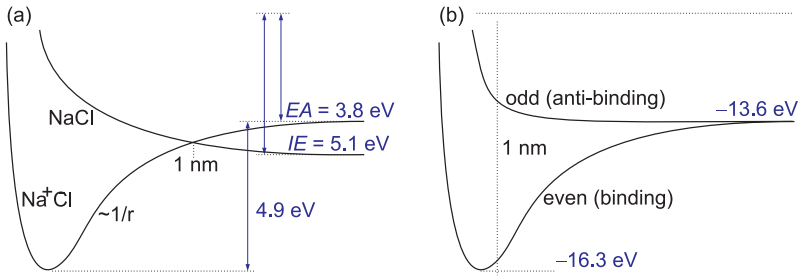

Figure 32.3: Scheme for (a) ionic binding of NaCl and (b) covalent binding of H_2.

To understand *covalent bond*, we consider the example H_2^+ and estimate the interaction energy for each distance R between the nuclei. In this case, in contrast to atoms, the spherical symmetry is broken, and therefore the energy degeneracy with respect to parity is abolished, that is, for wavefunctions $\psi(-x) = \pm\psi(x)$ the energies vary differently with R. The even wavefunction, which has an increased probability of the electron of being between the nuclei, is binding, which means that the interaction potential exhibits a minimum at a certain distance. The odd wavefunction, which disappears between the nuclei, is anti-binding, which means that the interaction potential is repulsive at all distances. In fact, an electron located at the center between two positive charges can overcome the Coulomb repulsion between the nuclei, whose mutual distance is twice. Obviously, the energy can not fall below that of the fundamental state of He^+, being approximately -4×13.6 eV. With two electrons, as in the case of the neutral molecule H_2, the anti-parallel orientation of the spins, $\uparrow\downarrow$, allows us to place the two electrons in the same orbital, while for parallel orientation, $\uparrow\uparrow$, we expect anti-binding. Each electron without a partner in an orbital can form a covalent bond, for example, phosphorus [P]=[Ne]$3s^2 3p^{\uparrow\uparrow\uparrow}$ has three available orbitals corresponding to different magnetic quantum numbers. The covalent bond is directional (sp^1, sp^2, or sp^3 hybridization), which is essential for the molecular structure such as in CH_4. Do the Exc. 32.1.6.1.

32.1.2 Born-Oppenheimer approximation and the H_2^+ molecule

The *Born-Oppenheimer approximation* in molecular physics consists in considering, at first, the positions of the nuclei as being fixed in space. This allows us to study the stationary states of the electrons subject to the potential created by the nuclei for a given internuclear distance R. Varying R, the electronic energies (computed for a fixed R) remain the same, because the electronic wavefunctions adjust instantaneously due to their mass being much lower than that of the nuclei. The non-varying electronic energies play the role of interaction potential energies between the nuclei [60].

32.1.2.1 Separation of the center-of-mass

Let us consider two heavy masses, $M_{a,b} = M$ separated by a distance R and interacting through a potential $V_{nn}(R)$. Furthermore, there is a light-weighted mass m_e interacting with the other masses through $V_{ne}(r)$. The Hamiltonian is,

$$\hat{H} = \frac{-\hbar^2}{2M}\nabla_a^2 + \frac{-\hbar^2}{2M}\nabla_b^2 + \frac{-\hbar^2}{2m_e}\nabla_e^2 + V_{nn}(|\mathbf{R}_a - \mathbf{R}_b|) + V_{ne}(|\mathbf{R}_a - \mathbf{R}_e|) + V_{ne}(|\mathbf{R}_b - \mathbf{R}_e|) \; . \tag{32.2}$$

We transform to the center-of-mass system of the two heavy masses anchored at

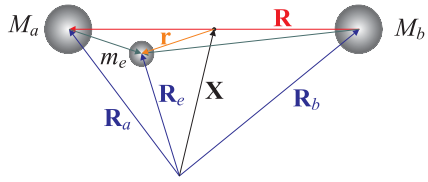

Figure 32.4: System with two heavy and one light mass.

$\mathbf{X} \equiv \frac{M_a\mathbf{R}_a + M_b\mathbf{R}_b}{M} = \frac{1}{2}(\mathbf{R}_a + \mathbf{R}_b)$. The distance of the *heavies* is $\mathbf{R} \equiv \mathbf{R}_a - \mathbf{R}_b$, and the coordinate of the light mass counting from the center-of-mass is $\mathbf{r} = \mathbf{R}_a - \frac{1}{2}\mathbf{R} - \mathbf{R}_e$. Introducing the reduced mass of the *heavies* $M_r = \frac{M}{2}$,

$$\left[\frac{-\hbar^2}{2M}\nabla_X^2 + \frac{-\hbar^2}{2M_r}\nabla_R^2 + V_{nn}(R) + \frac{-\hbar^2}{2m_e}\nabla_r^2 + V_{ne}(|\mathbf{r} + \tfrac{\mathbf{R}}{2}|) + V_{ne}(|\mathbf{r} - \tfrac{\mathbf{R}}{2}|)\right]\Theta(\mathbf{X})\Psi(\mathbf{R}, \mathbf{R}_e)$$
$$= E_{tot}\Theta(\mathbf{X})\Psi(\mathbf{R}, \mathbf{R}_e) \; , \tag{32.3}$$

Here, we made the ansatz for the total wavefunction $\Psi = \Theta(\mathbf{X})\Psi(\mathbf{R}, \mathbf{R}_e)$, assuming that the center-of-mass is only determined by the heavy masses,

$$\frac{-\hbar^2}{2M}\nabla_X^2\Theta(\mathbf{X}) = E_{cm}\Theta(\mathbf{X}) \tag{32.4}$$
$$\left[\frac{-\hbar^2}{2M_r}\nabla_R^2 + V_{nn}(R) + \frac{-\hbar^2}{2m_e}\nabla_r^2 + V_{ne}(|\mathbf{r} + \tfrac{1}{2}\mathbf{R}|) + V_{ne}(|\mathbf{r} - \tfrac{1}{2}\mathbf{R}|)\right]\Psi(\mathbf{R}, \mathbf{R}_e) = E\Psi(\mathbf{R}, \mathbf{R}_e) \; ,$$

where $E_{tot} = E_{cm} + E$.

32.1.2.2 Adiabatic approximation

The Born-Oppenheimer approximation now consists in assuming that the movement of the *heavies* is independent of the position of m_e, which allows us to separate the corresponding wavefunction ϕ via the ansatz $\Psi(\mathbf{R}, \mathbf{R}_e) = \psi(\mathbf{R}, \mathbf{r})\phi(\mathbf{R})$. On the other hand, the orbital ψ of the light mass m_e does not change much, when we vary the distance of the *heavies*, $\nabla_R\psi(\mathbf{R}, \mathbf{r}) \simeq 0$. This is only valid, as long as the *heavies* are inert on the time scale of the movement of m_e. Therefore, we can approximate the second derivative,

$$\nabla_R^2[\psi(\mathbf{R}, \mathbf{r})\phi(\mathbf{R})] = \phi(\mathbf{R})\nabla_R^2\psi(\mathbf{R}, \mathbf{r}) + 2[\nabla_R\phi(\mathbf{R})] \cdot [\nabla_R\psi(\mathbf{R}, \mathbf{r})] + \psi(\mathbf{R}, \mathbf{r})\nabla_R^2\phi(\mathbf{R})$$
$$\simeq \psi(\mathbf{R}, \mathbf{r})\nabla_R^2\phi(\mathbf{R}) \; , \tag{32.5}$$

postulating that the first two terms are negligible compared to the third. We can now separate the second equation (32.4) in two parts, the first being,

$$\boxed{\left[\frac{-\hbar^2}{2m_e}\nabla_r^2 + V_{ne}(|\mathbf{r}+\tfrac{1}{2}\mathbf{R}|) + V_{ne}(|\mathbf{r}-\tfrac{1}{2}\mathbf{R}|)\right]\psi(\mathbf{r},\mathbf{R}) = \varepsilon(R)\psi(\mathbf{r},\mathbf{R})}\,. \tag{32.6}$$

We solve this equation for the electronic degree of freedom $\mathbf{r}$ by choosing a fixed internuclear distance $\mathbf{R}$, and we substitute in the second expression (32.4), which gives,

$$\boxed{\left[\frac{-\hbar^2}{2M_r}\nabla_R^2 + V_{nn}(R) + \varepsilon(R)\right]\phi(\mathbf{R}) = E\phi(\mathbf{R})}\,. \tag{32.7}$$

Treating the interatomic distance R as a fixed parameter, the solution of Eq. (32.6) provides the electronic orbitals and their energies $\varepsilon(R)$. The *Born-Oppenheimer potential* is composed of the electrostatic repulsive potential of the nuclei and the kinetic energy of the electron, $V_{nn}(R) + \varepsilon(R)$. In other words, the presence of the electrons generates an additional interaction energy between the nuclei. By inserting this complete interatomic potential into Eq. (32.7), we can determine its vibrational structure $\phi_{vib}(\mathbf{R})$.

Fig. 32.5 shows an example of binary effective nuclear potentials, as a function of the distance R between the two nuclei. Each curve corresponds to a different solution of the electronic equation, that is, to a different electronic state. In many cases, such nuclear potentials have a stable equilibrium region. The bound states located in these regions are *molecular* bound states of two atoms.

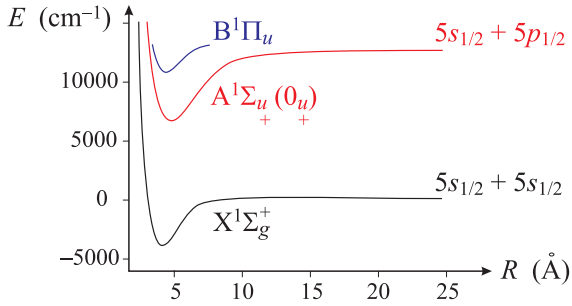

Figure 32.5: Effective nuclear potentials for the interaction between two rubidium atoms (Rb_2).

In practice, the calculation of adiabatic Born-Oppenheimer potentials is difficult and makes it the subject of sophisticated theories, such as the *molecular orbital model* or the *valence bond model* [2]. We study in Exc. 32.1.6.2 a generalization of the Born-Oppenheimer approximation.

[2] Note that the Born-Oppenheimer approximation is no longer good in the presence of relativistic or spin-orbit coupling effects.

32.1.3 Linear combination of orbitals and the H_2 molecule

In the following we will discuss the electronic structure of the simplest neutral molecule: H_2. For the low electron states of this molecule, the Born-Oppenheimer approximation is totally satisfactory, that is, we want to solve a Schrödinger type equation (32.6), but with two electrons. We are, therefore, interested in the electronic Hamiltonian,

$$\boxed{\hat{H} = -\frac{\hbar^2}{2m_e}(\nabla_1^2 + \nabla_2^2) + \frac{e^2}{4\pi\varepsilon_0}\left(\frac{1}{R_{ab}} - \frac{1}{|\mathbf{r}_1-\mathbf{R}_a|} - \frac{1}{|\mathbf{r}_1-\mathbf{R}_b|} - \frac{1}{|\mathbf{r}_2-\mathbf{R}_a|} - \frac{1}{|\mathbf{r}_2-\mathbf{R}_b|} + \frac{1}{r_{12}}\right)}\,, \tag{32.8}$$

where '1' and '2' denote the two electrons and 'a' and 'b' the nuclei.

This problem can not be solved analytically. The standard procedure begins with choosing a suitable basis, i.e. a very compact basis which does not depend on the configuration of the molecule. That is, we want the basis to be composed of functions that do not depend on the distance between the two nuclei, R_{ab}, to avoid calculations for different bond lengths.

The most natural basis functions are the available atomic orbitals of the individual hydrogen atoms. When the bond length is too large, the system approaches the limit of two non-interacting hydrogen atoms. In this case, the electron wavefunction can be approximated by the product of *atomic orbitals* (AO) of atom 'a' and atom 'b'. Therefore, the smallest basis that gives us a realistic picture of the fundamental state of the H_2 molecule must comprise two functions: $|1s_a\rangle$ and $|1s_b\rangle$. For finite bond lengths, it is advisable to allow the AOs to polarize and deform in response to the presence of the other electron (and the other nucleus). However, the $|1s_a\rangle$ and $|1s_b\rangle$ functions do not have to be exactly the hydrogenic eigenfunctions. It is sufficient to require them to be similar to the $1s$ orbitals and be centered on them. Since the actual shape of the orbitals is not yet fixed, we will give all the expressions in abstract matrix form, leaving the spatial integration for once the shape of the orbitals has been specified. This is the method of *linear combination of atomic orbitals* (LCAO).

32.1.4 Molecular orbital theory

We are now in a position to discuss the basic principles of the *molecular orbital method* (MO), which is the basis of the theory of the electronic structure of real molecules. The first step in any MO approach is to separate the Hamiltonian into two parts, one part describing the electrons '1' and '2' separately and one part counting for the interaction between them:

$$\hat{H} = \hat{h}(1) + \hat{h}(2) + \hat{V}_{12} + \frac{e^2}{4\pi\varepsilon_0}\frac{1}{R_{ab}} \qquad \text{with} \tag{32.9}$$

$$\hat{h}(i) = -\frac{\hbar^2\nabla_i}{2m_e} - \frac{e^2}{4\pi\varepsilon_0}\left(\frac{1}{|\mathbf{r}_i - \mathbf{R}_a|} + \frac{1}{|\mathbf{r}_i - \mathbf{R}_b|}\right) \qquad \text{and} \qquad \hat{V}_{12} = \frac{e^2}{4\pi\varepsilon_0}\frac{1}{r_{12}}\,,$$

where $i = 1, 2$. We must remember that, within the BO approximation, R_{ab} is just a number. We choose the Hamiltonian $h(i)$ as the one-electron part of the complete Hamiltonian in matrix representation on the minimum basis:

$$\begin{pmatrix} \langle 1s_a|\hat{h}|1s_a\rangle & \langle 1s_a|\hat{h}|1s_b\rangle \\ \langle 1s_b|\hat{h}|1s_a\rangle & \langle 1s_b|\hat{h}|1s_b\rangle \end{pmatrix} \equiv \begin{pmatrix} \epsilon & h_{ab} \\ h_{ab} & \epsilon \end{pmatrix}\,, \tag{32.10}$$

defining the average one-electron energy $\epsilon \equiv \langle 1s_a|\hat{h}|1s_a\rangle$ and the non-diagonal coupling (often called *resonance integral*) $h_{ab} \equiv \langle 1s_a|\hat{h}|1s_b\rangle = \langle 1s_a|\hat{h}|1s_b\rangle$. We can immediately diagonalize this matrix, the eigenvalues and the eigenvalues being:

$$\epsilon_\pm = \epsilon \pm h_{ab} \qquad \text{and} \qquad |\phi_\pm\rangle \propto \tfrac{1}{2}(|1s_a\rangle \pm |1s_b\rangle) \ . \tag{32.11}$$

The one-electron effective Hamiltonian eigenstates are called *molecular orbital* (MO). They are one-electron wavefunctions delocalized over the spatial regions of the molecule.

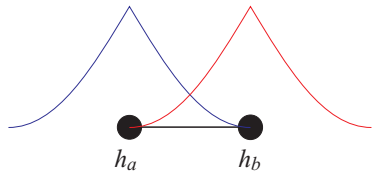

Figure 32.6: Illustration of the atomic orbitals.

We need to first normalize the MOs, which is more complicated than it might seem, because the AOs are not orthogonal. For example, when the atoms approach each other, their AOs may have the shape shown in Fig. 32.6. However, by defining the overlap integral by $S \equiv \langle 1s_a|1s_b\rangle$, we can normalize as follows:

$$|\phi_\pm\rangle = \tfrac{1}{\sqrt{2(1\pm S)}}(|1s_a\rangle \pm |1s_b\rangle) \ , \tag{32.12}$$

since,

$$\langle\phi_\pm|\phi_\pm\rangle = \tfrac{1}{2(1\pm S)}(\langle 1s_a|1s_a\rangle \pm \langle 1s_a|1s_b\rangle \pm \langle 1s_b|1s_a\rangle + \langle 1s_b|1s_b\rangle) = 1 \ . \tag{32.13}$$

These eigenfunctions merely show the symmetry of the molecule. The two hydrogen atoms are equivalent and, therefore, the eigenorbital must give equal weight to each $1s$ orbital. Thus, our choice of the one-electron Hamiltonian does not really matter that much, because every one-electron Hamiltonian exhibiting the symmetry of the molecule would give the same molecular orbitals. For historical reasons, $|\phi_+\rangle$ is denoted by $|\sigma\rangle$ and $|\phi_-\rangle$ by $|\sigma^*\rangle$.

The second step in MO theory consists of constructing the determinant from the MOs corresponding to the wanted states. For illustration we will look at the lowest singlet state constructed from molecular orbitals. We note that $h_{ab} < 0$, such that $|\sigma\rangle$ has an energy inferior to $|\sigma^*\rangle$. Neglecting the interaction, the lowest singlet state,

$$|\Phi_{MO}\rangle = |\sigma\rangle|\sigma^*\rangle \ , \tag{32.14}$$

is the molecular ground state of H_2. To estimate the validity of the approximation, we calculate the expectation value of the energy, $\left|\langle\sigma|\langle\sigma^*|\hat{H}|\sigma\rangle|\sigma^*\rangle\right|$, decomposing the wavefunction into spin and spatial parts, noting that the spin part is normalized:

$$\begin{aligned}\left|\langle\sigma|\langle\sigma^*|\hat{H}|\sigma\rangle|\sigma^*\rangle\right| &= \langle\sigma(1)|\langle\sigma(2)|\hat{H}|\sigma(1)\rangle|\sigma(2)\rangle\langle\Phi_{spin}|\Phi_{spin}\rangle \\ &= \langle\sigma(1)|\langle\sigma(2)|\hat{H}|\sigma(1)\rangle|\sigma(2)\rangle \ .\end{aligned} \tag{32.15}$$

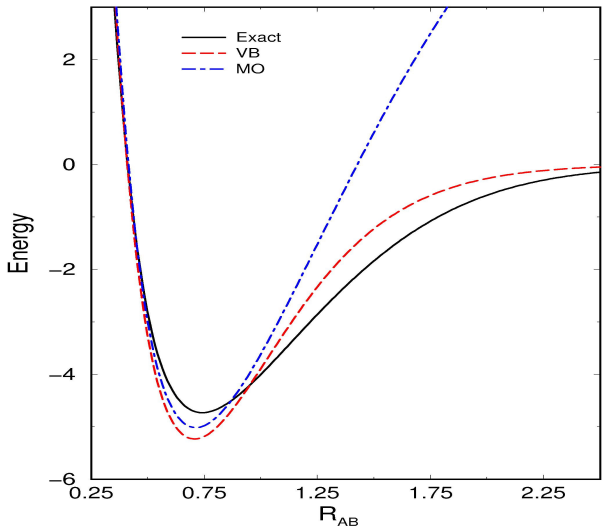

Figure 32.7: Total energy as a function of interatomic distance.

Hence, with (32.10) we get,

$$\begin{aligned}
\langle\sigma(1)|\langle\sigma(2)|\hat{h}(2)|\sigma(1)\rangle|\sigma(2)\rangle &= \langle\sigma(1)|\sigma(1)\rangle\langle\sigma(2)|h(2)|\sigma(2)\rangle = \langle\sigma(2)|h(2)|\sigma(2)\rangle \equiv \epsilon_\sigma \\
\langle\sigma(1)|\langle\sigma(2)|\hat{h}(1)|\sigma(1)\rangle|\sigma(2)\rangle &= \langle\sigma(1)|h(1)|\sigma(1)\rangle\langle\sigma(2)|\sigma(2)\rangle = \langle\sigma(1)|h(1)|\sigma(1)\rangle \equiv \epsilon_\sigma \\
\langle\sigma(1)|\langle\sigma(2)|\hat{V}_{12}|\sigma(1)\rangle|\sigma(2)\rangle &\equiv J_{\sigma\sigma} \ . \qquad (32.16)
\end{aligned}$$

Putting these facts together, we can write,

$$\begin{aligned}
\langle\Phi_{MO}|\hat{H}|\Phi_{MO}\rangle &= \langle\Phi_{MO}|\hat{h}_1|\Phi_{MO}\rangle + \langle\Phi_{MO}|\hat{h}_2|\Phi_{MO}\rangle + \langle\Phi_{MO}|\hat{V}_{12}|\Phi_{MO}\rangle + \frac{e^2}{4\pi\varepsilon_0 R_{ab}} \\
&= 2\epsilon_\sigma + J_{\sigma\sigma} + \frac{e^2}{4\pi\varepsilon_0 R_{ab}} \ . \qquad (32.17)
\end{aligned}$$

Each of the first two terms represents the energy of a single electron (either 1 or 2) in the field produced by both the nuclei ($\hat{h}$), while the third is the average repulsion between the two electrons. Note that the first and second term are both positive, such that the bond must come from the one-electron part. This is the MO energy for the ground state of the H_2. We can try a more reasonable ansatz for the $1s$-type basis functions [3] by determining the unknown quantities from above (ϵ_σ and $J_{\sigma\sigma}$) numerically and plot the total energy as a function of R_{ab} (blue dotted curve in Fig. 32.7). The exact adiabatic energy function determined from experimental data (solid black curve) agrees well at low energies. Summarizing the results with some key numbers, we note that MO theory predicts a bond distance of 0.072 nm in reasonable agreement with the exact value of 0.074 nm. We can also compare the

[3] It turns out that it is more convenient to adjust the exponential decomposition of the hydrogenic orbitals to a sum of Gaussians.

binding energies,

$$D_e = E_{H_2}(R_{equil}) - 2E_H \ . \tag{32.18}$$

MOs theory predicts a binding energy of 5.0 eV compared to the experimental value of 4.75 eV. In view of the simplicity of the wavefunction and the absence of adjustable parameters the agreement is not so bad. Unfortunately, far away from the equilibrium distance, we have an unpleasant surprise: the molecule does not dissociate into two hydrogen atoms!

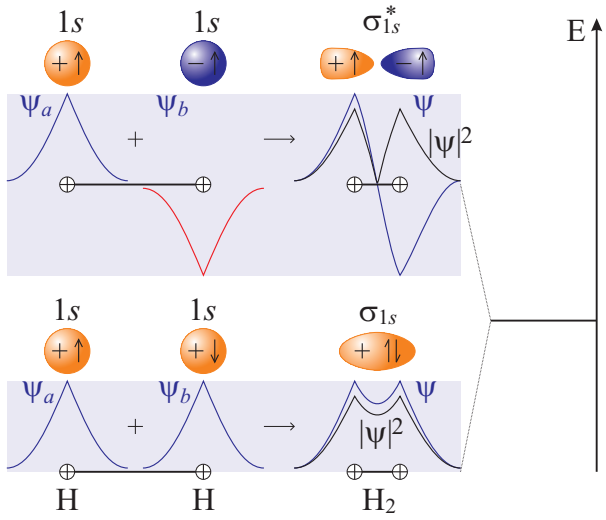

Figure 32.8: Illustration of MO theory for a dimer of two equal atoms, each one with a valence electron in the atomic 1s orbital: When the atoms approach, the atomic orbitals form new molecular binding and anti-biding orbitals.

To get an idea of what is happening near dissociation, we expand the fundamental MO state in terms of AO configurations:

$$\begin{aligned} |\Phi_{MO}\rangle &\propto |\sigma(1)\rangle|\sigma(2)\rangle|\Phi_{spin}\rangle \\ &= \tfrac{1}{2(1+S)}(|1s_a(1)\rangle + |1s_b(1)\rangle)(|1s_a(2)\rangle + |1s_b(2)\rangle)|\Phi_{spin}\rangle \\ &= \tfrac{1}{2(1+S)}(|1s_a(1)\rangle|1s_a(2)\rangle + |1s_a(1)\rangle|1s_b(2)\rangle + |1s_b(1)\rangle|1s_a(2)\rangle + |1s_b(1)\rangle|1s_b(2)\rangle)|\Phi_{spin}\rangle \ . \end{aligned} \tag{32.19}$$

The two terms in the middle of the last line, called *covalent configurations*, are exactly what we expect near dissociation: one electron in each hydrogen atom. However, the first and last term (which are called *ionic configurations*) correspond to having two electrons in one atom and none in the other, which gives us H^+ and H^- at dissociation! Since the weight of these terms is fixed, it is obvious that we got the wrong wavefunction (and therefore the wrong energy) when dissociating the molecule. Near the equilibrium point, the ionic terms contribute significantly to the true wavefunction, such that the MO theory is good at this point. But it is always terrible at dissociation.

32.1.5 Valence binding

An alternative to MO theory represents the *valence bond* theory (VB). Here, we use significantly more physical intuition and discard the ionic configurations from the MO wavefunction. Thus, the VB ground state wavefunction is:

$$\begin{aligned}|\Psi\rangle &\propto \frac{|1s_a(1)\rangle|1s_a(2)\rangle + |1s_b(1)\rangle|1s_a(2)\rangle}{\sqrt{2}} \frac{|\uparrow(1)\rangle|\downarrow(2)\rangle + |\downarrow(1)\rangle|\uparrow(2)\rangle}{\sqrt{2}} \\ &\equiv |\Psi_{space}\rangle|\Psi_{spin}\rangle \ . \end{aligned} \tag{32.20}$$

VB theory assumes that this wavefunction is a good approximation to the true wavefunction at *all* binding distances and not only at large distances R_{ab}. To verify this approximation, we can calculate the average energy for this VB state. First, we normalize the VB wavefunction,

$$\begin{aligned}\langle\Psi|\Psi\rangle &= \langle\Psi_{space}|\langle\Psi_{spin}|\Psi_{space}\rangle|\Psi_{spin}\rangle = \langle\Psi_{space}|\Psi_{space}\rangle \\ &= \tfrac{1}{2}\left(\langle 1s_a(1)|\langle 1s_b(2)| + \langle 1s_b(1)\langle 1s_a(2)|\right)\left(|1s_a(1)\rangle|1s_a(2)\rangle + |1s_b(1)\rangle|1s_a(2)\rangle\right) \\ &= \tfrac{1}{2}\left(\langle 1s_a(1)|1s_b(2)|1s_a(1)\rangle|1s_b(2)\rangle + \langle 1s_a(1)|1s_b(2)|1s_b(1)\rangle|1s_a(2)\rangle\right. \\ &\quad \left.+\langle 1s_b(1)|1s_a(2)|1s_a(1)\rangle|1s_b(2)\rangle + \langle 1s_b(1)|1s_a(2)|1s_b(1)\rangle|1s_a(2)\rangle\right) \\ &= \tfrac{1}{2}(1 + S^2 + S^2 + 1) = 1 + S^2 \ . \end{aligned} \tag{32.21}$$

Therefore, the correctly normalized VB wavefunction is:

$$|\Psi_{VB}\rangle = \frac{1}{2\sqrt{1+S^2}}\left(|1s_a(1)\rangle|1s_a(2)\rangle + |1s_b(1)\rangle|1s_a(2)\rangle\right)\left(|\uparrow(1)\rangle|\downarrow(2)\rangle - |\downarrow(1)\rangle|\uparrow(2)\rangle\right) \ . \tag{32.22}$$

Now we want to calculate $\langle\hat{H}_{el}\rangle$ for this state. We note that the spin part does not matter, since the Hamiltonian is independent of spin:

$$\begin{aligned}\langle\Psi_{VB}|\hat{H}|\Psi_{VB}\rangle &= \langle\Psi_{spin}|\langle\Psi_{space}|\hat{H}|\Psi_{space}\rangle|\Psi_{spin}\rangle \\ &= \langle\Psi_{space}|\hat{H}|\Psi_{space}\rangle\langle\Psi_{spin}|\Psi_{spin}\rangle = \langle\Psi_{space}|\hat{H}|\Psi_{space}\rangle \ . \end{aligned} \tag{32.23}$$

The only remnant of the spin state is the fact that the spatial wavefunction is symmetric, which is only possible when the spin part is antisymmetric. Treating each term in $\langle\hat{H}\rangle$ separately,

$$\begin{aligned}\langle\Psi|\hat{h}_1|\Psi\rangle &= \tfrac{1}{2}\left(\langle 1s_a(1)|\langle 1s_b(2)| + \langle 1s_b(1)|1s_a(2)|\right)\hat{h}_1\left(|1s_a(1)\rangle|1s_a(2)\rangle + |1s_b(1)\rangle|1s_a(2)\rangle\right) \\ &= \tfrac{1}{2}\Big(\langle 1s_a(1)|1s_b(2)|\hat{h}_1|1s_a(1)\rangle|1s_b(2)\rangle + \langle 1s_a(1)|1s_b(2)|\hat{h}_1|1s_b(1)\rangle|1s_a(2)\rangle \\ &\quad +\langle 1s_b(1)|1s_a(2)|\hat{h}_1|1s_a(1)\rangle|1s_b(2)\rangle + \langle 1s_b(1)|1s_a(2)|\hat{h}_1|1s_b(1)\rangle|1s_a(2)\rangle\Big) \\ &= \tfrac{1}{2}(\epsilon + Sh_{ab} + \epsilon + Sh_{ab}) \ , \end{aligned} \tag{32.24}$$

or,

$$\boxed{\langle\Psi_{VB}|\hat{h}_1|\Psi_{VB}\rangle = \frac{\epsilon + Sh_{ab}}{1+S^2}} \ . \tag{32.25}$$

Since the two electrons are identical, the elements of the $\hat{h}_2$ are the same as those of $\hat{h}_1$. The only remaining term is the average value of the interaction:

$$\langle\Psi|\hat{V}_{12}|\Psi\rangle = \tfrac{1}{2}\left(\langle 1s_a(1)|\langle 1s_b(2)| + \langle 1s_b(1)|1s_a(2)|\right)\hat{V}_{12}\left(|1s_a(1)\rangle|1s_a(2)\rangle + |1s_b(1)\rangle|1s_a(2)\rangle\right) \tag{32.26}$$

$$= \tfrac{1}{2}\Big(\langle 1s_a(1)|1s_b(2)|\hat{V}_{12}|1s_a(1)\rangle|1s_b(2)\rangle + \langle 1s_a(1)|1s_b(2)|\hat{V}_{12}|1s_b(1)\rangle|1s_a(2)\rangle$$
$$+ \langle 1s_b(1)|1s_a(2)|\hat{V}_{12}|1s_a(1)\rangle|1s_b(2)\rangle + \langle 1s_b(1)|1s_a(2)|\hat{V}_{12}|1s_b(1)\rangle|1s_a(2)\rangle\Big) \ .$$

The second and third terms are the same. They are called *exchange integrals*, because the 'bra' orbitals have switched order as compared to the 'kets':

$$K = \langle 1s_a(1)|1s_b(2)|\hat{V}_{12}|1s_b(1)\rangle|1s_a(2)\rangle = \langle 1s_b(1)|1s_a(2)|\hat{V}_{12}|1s_a(1)\rangle|1s_b(2)\rangle \ . \tag{32.27}$$

The first and forth terms are also the same. They are called *Coulomb integrals*, because they seem to be due to the Coulomb interaction between two charge densities:

$$J = \langle 1s_b(1)|1s_a(2)|\hat{V}_{12}|1s_a(1)\rangle|1s_b(2)\rangle = \langle 1s_a(1)|1s_b(2)|\hat{V}_{12}|1s_b(1)\rangle|1s_a(2)\rangle \ . \tag{32.28}$$

Therefore, we have the result,

$$\boxed{\langle\Psi_{VB}|\hat{V}_{12}|\Psi_{VB}\rangle = \frac{J+K}{1+S^2}} \ . \tag{32.29}$$

Adding all terms, we get:

$$\langle\Psi_{VB}|\hat{H}|\Psi_{VB}\rangle = \langle\Psi_{VB}|\hat{h}_1|\Psi_{VB}\rangle + \langle\Psi_{VB}|\hat{h}_2|\Psi_{VB}\rangle + \langle\Psi_{VB}|\hat{V}_{12}|\Psi_{VB}\rangle + \frac{1}{R_{ab}}$$
$$= 2\frac{\epsilon + Sh_{ab}}{1+S^2} + \frac{J+K}{1+S^2} + \frac{1}{R_{ab}} \ . \tag{32.30}$$

The Coulomb and exchange terms are positive. Nuclear repulsion is clearly positive. Thus, the only terms that lead to binding in this picture are the average energy of an electron ϵ and the resonance integral h_{ab}. If the first term is dominant, the bond is due to *electronic delocalization*, since an electron located near one of the atoms would only contribute the atomic value to ϵ, which does not imply a bound state. If h_{ab} is large, the bond involves some resonance character, which can be related to the familiar concept of resonance between different Lewis point structures.

A numerical evaluation of all integrals gives the potential curve presented in Fig. 32.7 for VB theory. As expected, this simple VB wavefunction gives the correct dissociation threshold, where MO theory fails. In addition, the accuracy of the simple VB result is surprisingly good even near the equilibrium distance: The VB predicts a bond distance of 0.071 nm (compared to the correct value of 0.074 nm) and $D_e = 5.2$ eV (compared to 4.75 eV). Thus, the VB wavefunction also gives a good agreement without adjustable parameters. But more importantly, it indicates a way of improving the wavefunction whenever we encounter an obvious error: in this case, we saw that the description of the dissociation was weak, and we constructed a VB ansatz curing the problem. This approach to VB is often generalized as follows

when dealing with polyatomic molecules. We write the wavefunction as a product of a spatial part and a spin:

$$|\Psi\rangle = |\Psi_{space}\rangle|\Psi_{spin}\rangle \ . \tag{32.31}$$

The main assumption in VB theory is that the spatial part can be well represented by a product of atomic-like functions. For example, for water, we would immediately write a spatial part as:

$$|\Psi_{space}\rangle \simeq |1s_{H_a}\rangle|1s_{H_b}\rangle|1s_O\rangle|1s_O\rangle|2s_O\rangle|2s_O\rangle|2p_{xO}\rangle|2p_{xO}\rangle|2p_{yO}\rangle|2p_{yO}\rangle \ . \tag{32.32}$$

However, there are two things wrong with this wavefunction. First, we know that atomic orbitals hybridize in a molecule. Therefore, we need to make appropriate linear combinations of AOs (in this case sp^3 hybrids) to obtain the hybridized AOs. In this case, the four sp^3 hybrids can be written symbolically as:

$$|sp^3\rangle = c_{s,i}|2s\rangle + c_{x,i}|2p_x\rangle + c_{y,i}|2p_y\rangle + c_{z,i}|2p_z\rangle \ . \tag{32.33}$$

and therefore, a more appropriate spatial configuration is:

$$|\Psi_{space}\rangle \simeq |1s_{H_a}\rangle|1s_{H_b}\rangle|1s_O\rangle|1s_O\rangle|sp^3_{1O}\rangle|sp^3_{1O}\rangle|sp^3_{2O}\rangle|sp^3_{2O}\rangle|sp^3_{3O}\rangle|sp^3_{4O}\rangle \ . \tag{32.34}$$

The other problem with this state is that it lacks the adequate symmetry to describe fermions; the general state must be antisymmetric. In the case of two electrons this concept is easy to apply - singlets have symmetric space parts and triplets antisymmetric ones. However, in the case of many electrons, the rules are not so simple; in fact, the time of numerical computation grows exponentially with the number of electrons.

Formally, we will leave the derivation at this point to defining an operator $\mathcal{A}$ which 'antisymmetrizes' the wavefunction. In this case,

$$|\Psi_{space}\rangle \simeq \mathcal{A}\left[|1s_{H_a}\rangle|1s_{H_b}\rangle|1s_O\rangle|1s_O\rangle|sp^3_{1O}\rangle|sp^3_{1O}\rangle|sp^3_{2O}\rangle|sp^3_{2O}\rangle|sp^3_{3O}\rangle|sp^3_{4O}\rangle\right] \ . \tag{32.35}$$

In general, the results of VB theory are very accurate for small systems, where it can be applied. The predicted bond lengths are rather short, and the binding energies tend to be too small, but the results are nevertheless qualitatively excellent. In addition, the correct hybridized atomic orbitals fall directly off the calculation, giving a good qualitative insight. Also, note that the atomic configurations should not change (or very little) when the geometry of the molecule changes (since the orbitals depend on the atom and not on the molecular structure). Therefore, these VB wavefunctions have a strong connection to the diabatic states discussed above. However, the exponential amount of time that one must invest to perform these calculations makes them impractical for most molecules of interest.

32.1.6 Exercises

32.1.6.1 Ex: Classical model of the covalent binding

Consider the molecule H_2^+ with the two nuclei separated by 1 nm and an electron located in the middle between the nuclei. Calculate the electrostatic force acting on the nuclei.

Solution:

32.1.6.2 Ex: Beyond the Born-Oppenheimer approximation for molecules

For molecules, the Born-Oppenheimer approximation may fail in some situations. Therefore, it is common to use another approach known as Born-Huang. To illustrate this approach, we consider a diatomic molecule in the laboratory frame.
a. Write down the many-body Hamiltonian of the molecule in atomic units.
b. If we change the coordinate system to the position of the center-of-mass of the nuclei of the molecule, we eliminate the dependency on the global translation of the molecule. The Hamiltonian is now given by,

$$-\frac{\nabla_R^2}{2\mu_{AB}} - \sum_{i,j}\frac{1}{2M}\nabla_i\nabla_j - \sum_i\frac{\nabla_i^2}{2} + V$$

where that the Coulombian interactions are included in the fifth term. Write down the time-independent Schrödinger equation for this molecule.
c. The Born-Huang approximation consists in assuming that the total wavefunction can be expanded on a basis of wavefunctions of the nuclei and the electrons, that is,

$$\Psi(\mathbf{r},\mathbf{R}) = \sum_k |\chi_k(\mathbf{R})\rangle|\phi_k(\mathbf{r},\mathbf{R})\rangle \ ,$$

where χ and ϕ are the wavefunctions of the nuclei and the electrons, respectively. For the Schrödinger equation calculated in the previous item, use the Born-Huang approximation and obtain the set of coupled equations

$$\left\{\sum_k\left[-\frac{1}{2\mu_{AB}}\left(\nabla_R^2 + \langle\phi_k|\nabla_R^2|\phi_k\rangle + 2\langle\phi_k|\nabla_R|\phi_k\rangle.\nabla_R|\right)\right] - \right.$$
$$\left.\sum_k\left[\frac{1}{2M}\left(\sum_{i,j}\langle\phi_i|\nabla_i.\nabla_j|\phi_k\rangle\right) + \frac{1}{2}\sum_i\langle\phi_i|\nabla_i^2|\phi_k\rangle - \langle\phi_i|V|\phi_k\rangle|\right]\right\}|\chi_k\rangle = E\sum_k|\chi_k\rangle$$

which includes, although approximately, the kinetic energy of nuclei and electrons.
Help: Use $\nabla^2(\alpha\beta) = \alpha\nabla^2\beta + \beta\nabla^2\alpha + 2\nabla\alpha\cdot\nabla\beta$.
d. Make a brief comparison between the Born-Huang approximation (and the coupled equations obtained in the previous equation) and the Born-Oppenheimer approximation.

Solution: *a. We have the kinetic energies of nucleus A, nucleus B and the electrons. We also consider the coulombian interaction nucleus-nucleus, nucleus-electron, and electron-electron. Therefore the Hamiltonian is given by,*

$$\hat{H} = -\frac{\nabla_A^2}{2M_A} - \frac{\nabla_B^2}{2M_B} - \sum_i\frac{\nabla_i^2}{2} + \frac{1}{2}\sum_{i\neq j}\frac{1}{|\mathbf{r_i}-\mathbf{r_j}|} + \sum_{i=A,B}\sum_j\frac{Z_i}{|\mathbf{r_j}-\mathbf{R_i}|} + \frac{Z_AZ_B}{\mathbf{R}} \ ,$$

being M_A and M_B the nuclear masses, Z_A e Z_B the charges of the nuclei, $\mathbf{R}$ the relative coordinate between the nuclei, and ∇_i the kinetic energy of the electron i.
b. The time-independent Schrödinger equation is given by,

$$\left[-\frac{\nabla_R^2}{2\mu_{AB}} - \sum_{i,j}\frac{1}{2M}\nabla_i\nabla_j - \sum_i\frac{\nabla_i^2}{2} + V\right]|\Psi(\mathbf{R},\mathbf{r})\rangle = E|\Psi(\mathbf{R},\mathbf{r})\rangle \ .$$

c. The Schrödinger equation obtained in the previous item is:

$$\left[-\frac{\nabla_R^2}{2\mu_{AB}} - \sum_{i,j}\frac{1}{2M}\nabla_i\nabla_j - \sum_i\frac{\nabla_i^2}{2} + V\right]\sum_k|\chi_k\rangle|\phi_k\rangle = E\sum_k|\chi_k\rangle|\phi_k\rangle\ ,$$

where V contains all Coulomb interactions. Using that

$$\nabla_R^2|\chi_k\rangle|\phi_k\rangle = (\nabla^2|\chi_k\rangle)|\phi_k\rangle + |\chi_k\rangle(\nabla^2|\phi_k\rangle) + 2|\nabla\chi_k\rangle\cdot\nabla|\phi_k\rangle$$

in the Schrödinger equation

$$\sum_i\left[-\frac{1}{2\mu_{AB}}\left(|\phi_i\rangle\nabla_R^2|\chi_i\rangle + |\chi_i\rangle\nabla_R^2|\phi_i\rangle + 2\nabla_R|\phi_i\rangle.\nabla_R|\chi_i\rangle\right)\right]$$
$$-\sum_k\left[\frac{1}{2M}\left(\sum_{i,j}\nabla_i\cdot\nabla_j|\phi_k\rangle\right)|\chi_k\rangle + \frac{1}{2}|\chi_k\rangle\sum_i\nabla_i^2|\phi_k\rangle - V|\phi_k\rangle|\chi_k\rangle\right] = E\sum_k|\phi_k\rangle|\chi_k\rangle$$

multiplying with $|\phi_n\rangle$ and considering that the base is orthonormal,

$$\sum_i\left[-\frac{1}{2\mu_{AB}}\left(\langle\phi_n|\phi_i\rangle\nabla_R^2|\chi_i\rangle + |\chi_i\rangle\langle\phi_n|\nabla_R^2|\phi_i\rangle + 2\langle\phi_n|\nabla_R|\phi_i\rangle.\nabla_R|\chi_i\rangle\right)\right]$$
$$-\sum_k\left[\frac{1}{2M}\left(\sum_{i,j}\langle\phi_n|\nabla_i\cdot\nabla_j|\phi_k\rangle\right)|\chi_k\rangle + \frac{1}{2}|\chi_k\rangle\sum_i\langle\phi_n|\nabla_i^2|\phi_k\rangle - \langle\phi_n|V|\phi_k\rangle|\chi_k\rangle\right] = E\sum_k\langle\phi_n|\phi_k\rangle|$$
$$\sum_i\left[-\frac{1}{2\mu_{AB}}\left(\nabla_R^2|\chi_i\rangle + |\chi_i\rangle\langle\phi_n|\nabla_R^2|\phi_i\rangle + 2\langle\phi_n|\nabla_R|\phi_i\rangle\cdot\nabla_R|\chi_i\rangle\right)\right]$$
$$-\sum_k\left[\frac{1}{2M}\left(\sum_{i,j}\langle\phi_n|\nabla_i.\nabla_j|\phi_k\rangle\right)|\chi_k\rangle + \frac{1}{2}|\chi_k\rangle\sum_i\langle\phi_n|\nabla_i^2|\phi_k\rangle - \langle\phi_n|V|\phi_k\rangle|\chi_k\rangle\right] = E\sum_k|\chi_k\rangle\ .$$

Hence, since, $\langle\phi_n|\phi_i\rangle = \delta_{ni}$

$$\left\{\sum_k\left[-\frac{1}{2\mu_{AB}}\left(\nabla_R^2 + \langle\phi_k|\nabla_R^2|\phi_k\rangle + 2\langle\phi_k|\nabla_R|\phi_k\rangle.\nabla_R|\right)\right]\right.$$
$$\left.-\sum_k\left[\frac{1}{2M}\left(\sum_{i,j}\langle\phi_i|\nabla_i.\nabla_j|\phi_k\rangle\right) + \frac{1}{2}\sum_i\langle\phi_i|\nabla_i^2|\phi_k\rangle - \langle\phi_i|V|\phi_k\rangle|\right]\right\}|\chi_k\rangle = E\sum_k|\chi_k\rangle\ .$$

d. In the Born-Oppenheimer approximation, the electrons do not influence the kinetic energy of the nuclei and the Hamiltonian becomes completely separable into one part due to the nuclei and another part due to the electrons. In the Born-Huang approximation the wavefunction of the nuclei depends on the wavefunctions of the electrons, which results in a system of coupled equations, but which contains information about the kinetic energy of the nuclei and how the electrons modify that energy. Although more complicated to solve than the equations obtained under the Born-Oppenheimer approximation, the Born-Huang approximation is the starting point for systems that require an approximation that takes into account non-adiabatic effects.

32.1.6.3 Ex: Classical model of the covalent bond

Calculate the energies of the ground state and the last bound state of the potential $V_n = -\frac{C}{r^n}$ for any n.

Solution:

32.1.6.4 Ex: Homonuclear collision

We consider the example of homonuclear collisions of ^{85}Rb atoms. For ground state collisions in the channel $^3\Sigma_+$, $|f = 2, m_f = -2\rangle$, the long-range part of the potential is fixed by $C_6 = 4550$, $C_8 = 550600$, and $C_{10} = 7.67 \times 10^7$ [300, 1108], where $R_m = 9.8a_B$, $D_m = 0.13$, and $B_m = 1/2.5a_B$. The potentials can be merged at a given distance $R_t = 27.6a_B$. Prepare a plot of potential.

Solution: *In atomic units: The green curve shows the short-range Morse potential, the blue curve shows the long-range potential, and the black curve the combined potential around the distance R_t, that is, at very large distances.*

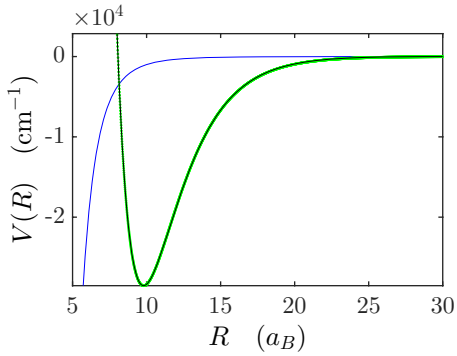

Figure 32.9: Short range potential.

32.2 Rovibrational structure of molecular potentials

The separation of the motion of the nuclei from the electronic dynamics made in the Born-Oppenheimer approximation led to equations (32.6) and (32.7). In a preceding section we analyzed in detail the equation (32.6) with the objective of understanding the phenomenon of molecular binding.

In the following section we will analyze the equation (32.7), which determines the motion of the nuclei. By separating the radii and angular parts of the motion, we will discover vibrational and rotational states.

32.2.1 The radial and angular equations

The interaction between two identical atoms is described by the following Hamiltonian, where $M_r = (M_a^{-1} + M_b^{-1})^{-1} = M/2$ is the *reduced mass* of the nuclei,

$$\hat{H} = \frac{\mathbf{P}^2}{2M_r} + V_{mol}(R) \qquad \text{with} \qquad V_{mol}(R) = \frac{e^2}{4\pi\epsilon_0 R} + V_{BO}(R) \ . \tag{32.36}$$

The interaction potential V_{mol} is composed of a repulsive internuclear Coulomb force and a Born-Oppenheimer adiabatic potential due to the interaction of the electrons with each other and with the two nuclei [4]. The kinetic energy is that of the relative motion (the center-of-mass motion has already been separated in Sec. 32.1.2, such that this inertial system is free of translational kinetic energy). In spherical coordinates,

$$\frac{\mathbf{P}^2}{2M_r}\phi(\mathbf{R}) = -\frac{\hbar^2}{2M_r}\left[\frac{1}{R}\frac{\partial^2}{\partial R^2}[R\phi(\mathbf{R})] + \frac{1}{R^2}\frac{\hat{\mathbf{L}}^2}{\hbar^2}\phi(\mathbf{R})\right] \ . \tag{32.37}$$

The wavefunction can be separated into an angular part and a radial part, $\phi(\mathbf{R}) = \mathcal{R}_v(R)Y_{\ell m}(\theta,\phi)$. The angular part, which was discussed in Sec. 25.1.3, describes a *rigid rotation* of the homonuclear atoms around their center-of-mass with the rotation energy,

$$\boxed{V_\ell(R) = \frac{\mathbf{L}^2}{2M_r R^2} = \frac{\hbar^2\ell(\ell+1)}{2M_r R^2}} \ , \tag{32.38}$$

also called *centrifugal barrier*. The radial part is ruled by,

$$\boxed{\left[-\frac{\hbar^2}{2M_r}\frac{\partial^2}{\partial R^2} + V_\ell(R) + V_{BO}(R)\right] u_v(R) = E u_v(R)} \ , \tag{32.39}$$

where $u_v(R) = r\mathcal{R}_v(R)$ is the radial wavefunction of nuclear motion. The interatomic potential causes a motion of *vibration*. The vibrational states of the adiabatic potential are quantized and characterized by a well-defined vibrational energy. We will discuss the ro-vibrational structure in the following sections.

32.2.1.1 Rotational and vibrational bands

Molecules have much more degrees of freedom than atoms. For example, the atoms of a molecular dimer may vibrate inside the mutual interaction potential. In the center-of-mass system we can imagine these vibrations as oscillations of an atom with reduced mass and quantized energy. The molecule can rotate and have a momentum of inertia. These degrees of freedom contribute energies to the molecule's Hamiltonian, either directly or through interactions with other degrees of freedom. Therefore, molecular spectra are characterized by a much greater complexity.

However, the energy regimes of the strongest excitations are quite different. A typical range for binding energies (depth of the interatomic potential) is $\Delta E_p \simeq$

[4] We note here that at great distances other forces called *van der Waals forces* dominate the interatomic interaction. These will be discussed in Sec. 32.3.

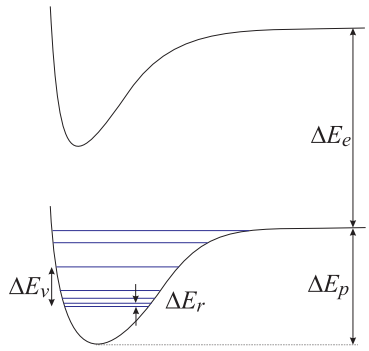

Figure 32.10: Molecular energy scales.

20..200 THz (0.1..1 eV) [5]. Electronic excitations occur in the regime $\Delta E_e \simeq 100..1000$ THz (1..10 eV). The spacing between vibrational excitations typically is $E_{v+1} - E_v \simeq$ THz (0.01 eV). Finally, the rotational excitations are on the scale of $E_{\ell+1} - E_\ell \simeq 100$ MHz (10^{-6} eV). Since at room temperature (a gas of molecules in thermal equilibrium at $T = 300$ K) the energy is on a scale of 2.5×10^{-2} eV, the degree of freedom of the electronic excitation is frozen, while a wide distribution of vibrational and rotational states can be excited (e.g. by intermolecular collisions). The large difference of scales facilitates their separation and, therefore, the identification of the origin of the observed states in experimental measurements.

32.2.2 Vibrational molecular states

The potential energy of a molecule grows when the nuclei are displaced from their equilibrium positions. When the displacement, $x \equiv R - R_e$ is small, we can expand the potential energy,

$$V_{mol}(x) = V_{mol}(0) + \frac{dV_{mol}(0)}{dx} x + \frac{1}{2} \frac{d^2 V_{mol}(0)}{dx^2} x^2 + .. \ . \tag{32.40}$$

The equilibrium energy is not of interest here, and the first derivative disappears in equilibrium. Therefore,

$$V_{mol}(x) \simeq \tfrac{1}{2} k^2 x^2 \qquad \text{with} \qquad k \equiv \frac{d^2 V_{mol}(0)}{dx^2} \ . \tag{32.41}$$

Using the effective mass we can write the Hamiltonian,

$$\hat{H}_{mol} = -\frac{\hbar^2}{2m_1} \frac{d^2}{dx_1^2} - \frac{\hbar^2}{2m_2} \frac{d^2}{dx_2^2} + \tfrac{1}{2} k x^2 = -\frac{\hbar^2}{2M_r} \frac{d^2}{dx^2} + \tfrac{1}{2} k x^2 \ . \tag{32.42}$$

The energy spectrum of this degree of freedom, therefore, is

$$\boxed{E_v = \hbar\omega(v + \tfrac{1}{2})} \ . \tag{32.43}$$

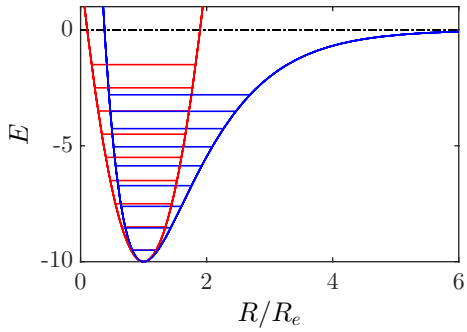

Figure 32.11: (code) Many potentials are approximately harmonic at the center such as, for instance, the Morse potential (blue). The red curve shows the approximate harmonic potential.

with $\omega = \sqrt{k/M_r}$. That is, at the bottom of deep potentials, the energy levels are equidistant.

32.2.2.1 Anharmonic vibrations in the Morse potential

For larger displacements we can no longer despise the anharmonic terms in the Taylor expansion. A better approximation is the *Morse potential*. This potential (blue in Fig. 32.11), unlike the harmonic potential (red in Fig. 32.11), is characterized by an asymptote for large interatomic distances. Therefore, it is often used as an analytical approximation to molecular potentials,

$$\boxed{V_{morse} = D_e(1 - e^{-a(R-R_e)})^2} \ , \tag{32.44}$$

where r is the interatomic distance, r_e the equilibrium bond distance, D_e the depth of the potential measuring from the *dissociation limit*, and a a parameter controlling the range of the potential. At the bottom of the potential we can make the harmonic approximation, $V_{morse}(R) \simeq \frac{k}{2}(R - R_e)^2$ with $k = 2a^2 D_e$. Rewriting the potential in the form,

$$\tilde{V}(R) \equiv V(R) - D_e = D_e(e^{-2a(R-R_e)} - 2e^{-a(R-R_e)}) \ , \tag{32.45}$$

we see, that it is a combination of a short-range repulsive potential and long-range attractive potential (similar to the Lennard-Jones's potential).

The calculation of the energy spectrum of this potential is more difficult [317],

$$E_v = \hbar\omega(v + 1/2) - \hbar\omega\chi_e(v + 1/2)^2 - D_e, \tag{32.46}$$

with $\omega\chi_e \equiv \frac{\hbar a^2}{2M_r}$ and $\omega \equiv \sqrt{k/M_r}$, but the availability of an analytical expression is interesting for the calibration of numerical methods. The second term of the expression (32.46), which is proportional to the anharmonicity constant χ_e, becomes dominant at high excitations. The potential is finite with a dissociation energy of,

$$D_0 = D_e - E_0 \ . \tag{32.47}$$

[5]Electronically excited states (that is, one of the valence electrons moves to an excited orbital) are more weakly bound, because the electrons are not in the most binding orbital.

The number of vibrational states is limited $v = 0, 1, .., v_{max}$. With $E < 0$, we find,

$$v_{max} < \tfrac{1}{x_e} - \tfrac{1}{2} \ . \tag{32.48}$$

Example 188 (*Morse potential*): To solve the Schrödinger equation

$$\left(-\frac{\hbar^2}{2m}\frac{\partial^2}{\partial R^2} + V(R) \right) \Psi(v) = E_v \Psi(v) \ ,$$

it is convenient to introduce new variables,

$$x \equiv aR \quad , \quad \lambda \equiv \frac{\sqrt{2mD_e}}{a\hbar} \quad , \quad \varepsilon_v \equiv \frac{2m}{a^2\hbar^2} E_v \ ,$$

such that,

$$\left(-\frac{\partial^2}{\partial x^2} + V(x) \right) \Psi_n(x) = \varepsilon_n \Psi_n(x) \quad \text{with} \quad V(x) = \lambda^2 \left(e^{-2(x-x_e)} - 2e^{-(x-x_e)} \right) \ .$$

The eigenvalues and eigenfunctions are [317]:

$$\varepsilon_n = 1 - \tfrac{1}{\lambda^2}\left(\lambda - n - \tfrac{1}{2}\right)^2 = \tfrac{2}{\lambda}(n+\tfrac{1}{2})^2 - \tfrac{1}{\lambda^2}(n+\tfrac{1}{2})^2 \quad \text{and} \quad \Psi_n(z) = N_n z^{\lambda-n-\frac{1}{2}} e^{-\frac{1}{2}z} L_n^{(2\lambda-2n-1)}(z) \ ,$$

where $z = 2\lambda e^{-(x-x_e)}$ e $N_n = \left[\frac{n!(2\lambda-2n-1)}{\Gamma(2\lambda-n)} \right]^{\frac{1}{2}}$ and,

$$L_n^{(\alpha)}(z) = \frac{z^{-\alpha}e^z}{n!}\frac{d^n}{dz^n}\left(z^{n+\alpha}e^{-z}\right) = \frac{\Gamma(\alpha+n+1)/\Gamma(\alpha+1)}{\Gamma(n+1)}\ {}_1F_1(-n, \alpha+1, z) \ ,$$

is the generalized Laguerre polynomial. The matrix elements of the spatial operator $\hat{x}$ are (assuming $m > n$ and $N = \lambda - \frac{1}{2}$),

$$\langle \Psi_m | x | \Psi_n \rangle = \frac{2(-1)^{m-n+1}}{(m-n)(2N-n-m)} \sqrt{\frac{(N-n)(N-m)\Gamma(2N-m+1)m!}{\Gamma(2N-n+1)n!}} \ .$$

In the original variables the eigenenergies are:

$$E_v = \hbar\omega(v+1/2) - \frac{[\hbar\omega(v+1/2)]^2}{4D_e} \ ,$$

where v is the vibrational quantum number and $\omega = a\sqrt{\frac{2D_e}{m}}$. The energy difference between adjacent levels decreases with v,

$$E_{v+1} - E_v = \hbar\omega - (\hbar\omega)^2 \frac{v+1}{2D_e} \ .$$

This fact describes well the vibrational structure of non-rotating molecules. However, the equation fails above some value of $v > v_{max}$, where $E_{v_{max}+1} - E_{v_{max}}$ is zero or negative,

$$v_{max} = \frac{2D_e - \hbar\omega}{\hbar\omega} \ .$$

This failure is due to the finite number v_{max} of bound states in the Morse potential. For energies above v_{max} all energies are possible, and the equation for E_v is no longer valid.

32.2.2.2 Vibrational selection rules

Electromagnetic fields of the type $E1$, e.g., black body radiation, can induce transitions between vibrational states and redistribute their populations such as to establish a thermal equilibrium. However, as the stronger transitions are induced by dipole migrations of charges, we need to analyze in more detail the selection rules imposed on the dipole moment $\langle f|\mathbf{d}|i\rangle$.

The states which are relevant for vibrational transitions are specified by $|\epsilon, v\rangle$, where ϵ denotes the electronic state of the molecule, since the vibrational spectrum depends on the electronic structure. The *Born-Oppenheimer approximation* allows us to consider the slow vibrations separately from the dynamics of the electrons. The time scale for electronic transitions is $1/\Delta E_e = 10^{-16}\,\mathrm{s}^{-1}$, and for a nuclear vibration it is $1/\Delta E_v = 10^{-13}\,\mathrm{s}^{-1}$. For each internuclear distance the electrons form an adapted stationary state, minimizing their energy for that distance. This is equivalent to the formation of an adiabatic interaction potential between the nuclei on which the nuclei can vibrate. To find out which vibrational transitions are possible, we need to calculate the matrix,

$$\langle \epsilon', v'|\hat{\mathbf{d}}|\epsilon, v\rangle = \langle v'|\hat{\mathbf{d}}_\epsilon|v\rangle \ . \tag{32.49}$$

The dipole moment, $\mathbf{d}_\epsilon = \langle\epsilon|\hat{\mathbf{d}}|\epsilon\rangle$, of the molecule depends on the distance of the nuclei, since the electronic orbitals $|\epsilon\rangle$ depend on distance. Therefore, we can expand,

$$\hat{\mathbf{d}} = \hat{\mathbf{d}}_0 + \frac{d\hat{\mathbf{d}}_0}{dx}\hat{x} + \frac{1}{2}\frac{d^2\hat{\mathbf{d}}_0}{dx^2}\hat{x}^2 + .. \ . \tag{32.50}$$

Therefore, the transition matrix is,

$$\langle \epsilon', v'|\hat{\mathbf{d}}|\epsilon, v\rangle = \hat{\mathbf{d}}_0\delta_{v,v'} + \frac{d\hat{\mathbf{d}}_0}{dx}\langle v'|\hat{x}|v\rangle + \frac{d^2\hat{\mathbf{d}}_0}{dx^2}\langle v'|\hat{x}^2|v\rangle + .. \ . \tag{32.51}$$

The first term disappears, that is, transitions can only occur, when the dipole moment varies with the distance. Therefore, *homonuclear dimers do not undergo vibrational transitions.*

For heteronuclear molecules with electronic charges that do not depend on the interatomic distance, the dipole moment varies linearly with small displacements. In this case, we only need the second term of the expansion. Within the harmonic approximation, the position operator can be expressed by, $\hat{x} \propto \hat{a} + \hat{a}^\dagger$. Therefore, only transitions $\Delta v = \pm 1$ are possible. However, due to anharmonicities, higher order terms, $\hat{x}^n \propto (\hat{a} + \hat{a}^\dagger)^n$ become influential, and transitions with $\Delta v = \pm 2, \pm 3, ..$ become possible.

Thus, in anharmonic potentials, the vibrational selection rules are replaced by the concept the overlapping wavefunctions called *Franck-Condon factor*.

Raman spectroscopy is a very useful tool to analyze ro-vibrational spectra. In this method, inelastic Raman scattering gives rise to Stokes and anti-Stokes lines in the spectrum at frequencies corresponding to $\Delta v = \pm 1, \pm 2$. The ground state spectrum is asymmetric, because of the absence of the lower state. In homonuclear dimers, the nuclear spins have a major impact on the Raman spectra. Parity considerations show that there can only be odd or even lines.

32.2.3 The Franck-Condon principle

The intensity of molecular transitions are, qualitatively, described by the *Franck-Condon principle*, whose *classical* formulation goes as follows:

> *The jump of an electron in a molecular transition occurs during a very small time compared to the time scale of the nuclear motion, so that immediately after the jump, the nuclei remain practically at the same positions and at the same velocities as before the jump* [614].

For this reason, the transitions are drawn vertically in the scheme of potentials shown in Fig. 32.12(right). To yield considerable rates, transitions must occur when the nuclear velocities in the two coupled states are similar, which is the case at the classical turning points. At these points, the wavefunctions are maximal [6].

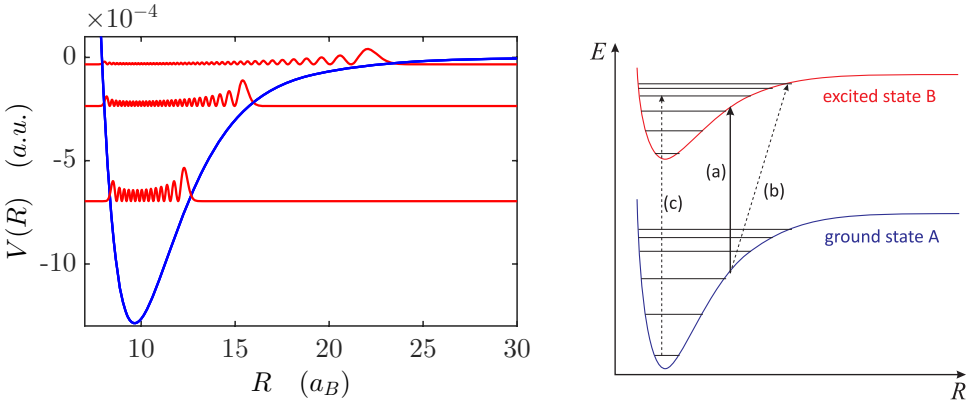

Figure 32.12: (Left, code) Molecular wavefunctions in a potential for three different vibrational states. (Right) Pictorial representation of the classical statement of the Franck-Condon principle. Transition (a) has high intensity (or probability), because here both, the position and the relative velocity of the nuclei do not change. Transitions (b) and (c) are unlikely, because they necessitate either a change in the position of the nuclei (case b) or in velocity (case c).

With this Franck-Condon principle, we can determine which are the strongest transitions between vibrational levels of a molecule, as represented in Fig. 32.12(left). In particular, we are interested in transitions between vibrational levels of different electronic states.

The exact transition probabilities are calculated via the square module of the *transition dipole moment* (TDM). The TDM is an out-of-diagonal matrix element of the electric dipole operator $\mathbf{M}$, given by:

$$\mathbf{M}_{AB} = \langle \Psi^{(A)} | \hat{\mathbf{M}} | \Psi^{(B)} \rangle \ , \tag{32.52}$$

being $|\Psi^{(A)}\rangle$ and $|\Psi^{(B)}\rangle$ two molecular states.

[6] Note that the presence of a hyperfine structure can modify the selection rules.

Still within the Born-Oppenheimer approximation, we can split the dipole moment operator into two terms, a nuclear and an electronic term, according to:

$$\hat{\mathbf{M}}(\mathbf{r},\mathbf{R}) = \hat{\mathbf{M}}_e(\mathbf{r},\mathbf{R}) + \hat{\mathbf{M}}_n(\mathbf{R}) \ . \tag{32.53}$$

Thus, the TDM is:

$$\begin{aligned}\mathbf{M}_{AB} &= \int \Psi^{(A)*}\hat{\mathbf{M}}\Psi^{(B)}dRdr \qquad (32.54)\\ &= \int \hat{\mathbf{M}}_e\psi_e^{(A)*}\ \psi_e^{(B)}\ \psi_n^{(A)*}\ \psi_n^{(B)}dRdr + \int \hat{\mathbf{M}}_n\psi_n^{(A)*}\ \psi_n^{(B)} \int \psi_e^{(A)*}\ \psi_e^{(B)}drdR \ .\end{aligned}$$

Since the electronic wavefunctions of different states are orthogonal, it follows that $\int \psi_e^{(A)*}\psi_e^{(B)}dr = 0$, canceling the second term.

Looking at the first term, we note that the electronic dipole moment $\hat{\mathbf{M}}_e(\mathbf{r},\mathbf{R})$ also depends on the nuclear coordinates as a parameter. The quantum formulation of the Franck-Condon principle consists in stating that, in a *molecular state, the electronic dipole moment varies little with the nuclear coordinates.* Thus, along with the condition of the Born-Oppenheimer approximation, we can split the first TDM term into electronic and nuclear integrals:

$$\mathbf{M}_{AB} = \int \hat{\mathbf{M}}_e\psi_e^{(A)*}\ \psi_e^{(B)}\ dr \int \psi_n^{(A)*}\ \psi_n^{(B)}dR \ . \tag{32.55}$$

Thus, we have a comparative expression for the transition probability given by:

$$P_{AB} \propto |\mathbf{M}_{AB}|^2 = \left|\int \hat{\mathbf{M}}_e\psi_e^{(A)*}\ \psi_e^{(B)}\ dr\right|^2 \left|\int \psi_n^{(A)*}\ \psi_n^{(B)}dR\right|^2 \ . \tag{32.56}$$

The second factor in equation (32.56) is called *Franck-Condon factor*. When we study the transitions between two electronic states, this factor compares the intensities of the transitions between distinct pairs of vibrational levels.

Example 189 (*Ultracold molecules*): Ultracold molecules have been proposed for a variety of applications, such as ultra high resolution spectroscopy [867], test of fundamental laws of physics [350, 1159], quantum computation [349] and others[236]. Most of these applications, however, require that the molecular sample be in a single quantum state. This is an experimental challenge, since molecules have more degrees of freedom than atoms, such as rotation and vibration.

To create a sample of molecules trapped in the ground state of vibration, a possible method is to first produce the molecules from ultracold atoms using a process called *photo association*, and then pump these molecules to the vibrational ground state.

Photoassociation consists in the excitation of a pair of free atoms to the bound state of an excited electronic potential by the absorption of a photon. The pair then decays by spontaneous emission either back to the state of two free atoms (which is not desirable), or to a bound state of the fundamental electronic potential. For Rb_2 molecules, photoassociation is efficient at certain frequencies

[875], with the $A^1\Sigma_u^+$ potential as the excited state (see Fig. 32.13).
Soon after being formed, the molecules are usually in levels of high vibrational energy (around $\nu \approx 80$), because these levels connect best (high Franck-Condon overlap) to the excited state. The transfer of population to the fundamental state of vibration is done by 'optical pumping'.
Vibrational cooling via optical pumping can be done by irradiating a broad frequency band of light that excites transitions to vibrational levels of the excited nuclear potential. These excited states are chosen such that their Franck-Condon overlap with the ground states of lower vibrational energy is larger. As a consequence, a molecule sent to an excited state returns with higher probability to a level of lower vibrational energy. The absorption and emission cycles are repeated, until the molecules reach the fundamental vibrational state.

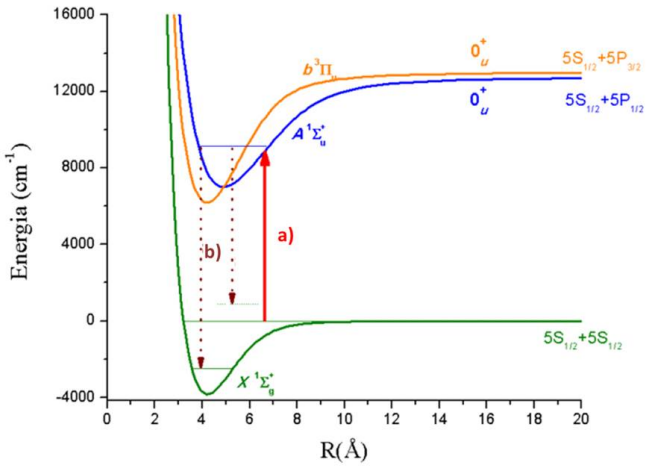

Figure 32.13: Photoassociation scheme to form Rb_2 molecules. In process (a), a pair of free atoms absorbs a photon of the incident radiation, forming a bound state in the excited potential. Then, in (b), the newly formed molecule decays by spontaneous emission to a bound state of the fundamental potential, or it can return to a state of two free atoms.

32.2.4 Rotational progression

Until now we neglected the centrifugal energy (32.38),

$$V_\ell(R) = \frac{\mathbf{L}^2}{2M_r R^2} = \frac{\hbar^2 \ell(\ell+1)}{2M_r R^2} \ . \tag{32.57}$$

As we shall now see, this energy creates a substructure of the vibrational levels.

The moments of inertia in the three axes of space are,

$$I_{qq} = \sum_i m_i r_i^2(q) \ . \tag{32.58}$$

The kinetic energy of the rotation is,

$$E_{rot} = \tfrac{1}{2}\sum_{q=1,2,3} m_q \mathbf{v}_q^2 = \tfrac{1}{2}\sum_{q=1,2,3} I_{qq}\omega_q^2 = \frac{L_x^2}{2I_{xx}} + \frac{L_y^2}{2I_{yy}} + \frac{L_z^2}{2I_{zz}} \ , \tag{32.59}$$

with the angular momentum $L_q = I_{qq}\omega_q$.

Many molecules have a symmetry axis, such that there are two different moments of inertia, $I_\perp \equiv I_{xx} = I_{yy}$ and $I_\parallel \equiv I_{zz}$. Interpreting angular momenta as quantum operators,

$$\hat{H} = \frac{\hat{\mathbf{L}}^2}{2I_\perp} + \left(\frac{1}{2I_\parallel} - \frac{1}{2I_\perp}\right)\hat{L}_z^2 \ . \tag{32.60}$$

We must first consider the rotation of the molecule relative to the symmetry axis of the molecule. Forgetting external fields we calculate the energy of the molecule associated with the observables $\hat{\mathbf{L}}^2$ with the quantum number ℓ and $\hat{\mathbf{L}}_z$ with the quantum number K. We find the eigenvalues,

$$E(\ell, K, M_\ell) = \frac{\hbar^2\ell(\ell+1)}{2I_\perp} + \left(\frac{1}{2I_\parallel} - \frac{1}{2I_\perp}\right)\hbar^2K^2 = B\ell(\ell+1) + (A-B)K^2 \ , \tag{32.61}$$

with $\ell = 0, 1, .., \ K = -\ell, .., \ell$, and $M_\ell = -\ell, .., \ell$ and introducing the *rotational constants*, $A \equiv \hbar^2/2I_\parallel$ and $B \equiv \hbar^2/2I_\perp$. We then analyze this equation in the context of applying an external field that defines both, the direction $\hat{\mathbf{e}}'_z$ in the laboratory as well as the projection of the angular motion $\hat{\mathbf{L}}^2$ on this direction, m_ℓ. That is, we have two axes, the internuclear axis $\hat{\mathbf{e}}_z$ and the rotation axis of the molecule $\hat{\mathbf{e}}'_z$.

Each level $|\ell, m_\ell\rangle$ is $2(2\ell+1)$ times degenerate, because $K = -\ell, .., \ell$ and K can be positive or negative. Each level ℓ contains $2\ell+1$ states. Note that for spherical molecules, $A = B$, and the degree of freedom K disappears. In Exc. 32.2.6.2 we calculate the rotational spectrum of a homonuclear diatomic molecule.

The rotational constant can be approximated by,

$$E_{rot} = \frac{\hbar^2\ell(\ell+1)}{2M_r\langle R^2\rangle} \ , \tag{32.62}$$

where $\sqrt{\langle R^2\rangle}$ is the expectation value for the outer turning point of the vibrational level. As an example, the rotational constant for the vibrational state of $^{87}Rb_2$ which is 5.9 cm^{-1} below the dissociation limit is $B_v = \nu_{rot}^{\ell=1} - \nu_{rot}^{\ell=0} = 81$ MHz. To be more precise, we would need to calculate $\langle R^2\rangle_v = \langle\psi_v|R^2|\psi_v\rangle$.

Transitions between vibrational levels occur together with rotational transitions $\Delta\ell = \pm 1$. Therefore, the frequencies of transitions depend on the rotational constant B_v, which depends on the vibrational state. The energies of the molecule are,

$$E_{v,\ell} = \hbar\omega(v+1/2) - \hbar\omega x_e(v+1/2)^2 + .. + hcB_v\ell(\ell+1) - hcD_v\ell^2(\ell+1)^2 + .. \ . \tag{32.63}$$

Under the influence of a rapid rotation, the atoms of the molecule are subjected to centrifugal force and, hence, are further away from each other [7].

Since at ambient temperatures many rotational levels are populated, we experimentally observe many lines known as P-branch, when $\Delta\ell = -1$, as Q-branch, when $\Delta\ell = 0$, and as R-branch, when $\Delta\ell = 1$. See Exc. 32.2.6.3.

[7] See [60], p.326

32.2.4.1 Rotational selection rules

For transitions between electronic states, the selection rules are $\Delta r = 0, \pm 1$. Rotational transitions can occur between levels $\Delta r = \pm 1$. $\Delta r = 0$ is not allowed, because it violates the conservation of parity. Note also that the nuclear isotope influences the ro-vibrational levels via the reduced mass.

We consider a linear molecule in the state $|\epsilon, \ell, M_\ell\rangle$, where ϵ denotes the electronic and vibrational state of the molecule. To find out which transitions are possible, we need to calculate the matrix,

$$\langle \epsilon', \ell', M'_\ell | \mathbf{d} | \epsilon, \ell, M_\ell \rangle = \langle \ell', M'_\ell | \mathbf{d}_\epsilon | \ell, M_\ell \rangle \ , \tag{32.64}$$

with $\mathbf{d}_\epsilon = \langle \epsilon | \mathbf{d} | \epsilon \rangle$. Here, we apply the *Born-Oppenheimer approximation*, which allows us to separate the dynamics of the electrons and also the vibrations of the molecule, because these movements are so fast, that they are always in a steady state, adiabatically following the slow movement of the rotation.

The selection rules can now be derived from the *Wigner-Eckart theorem*,

$$\frac{\langle \ell', M'_\ell | \mathbf{d}_\epsilon | \ell, M_\ell \rangle|^2}{|\langle \ell' \parallel \mathbf{d}_\epsilon \parallel \ell, M_\ell \rangle|^2} = \frac{1}{2\ell' + 1} \begin{pmatrix} \ell & 1 & \ell' \\ m_\ell & \kappa & -m'_\ell \end{pmatrix} \ . \tag{32.65}$$

We find $\Delta\ell = 1$ e $\Delta M_\ell = 0, \pm 1$. See Exc. 32.2.6.4.

32.2.5 Computation of vibrational states

32.2.5.1 Localization energy

One consequence of Heisenberg's uncertainty relation is that a certain *localization energy* is always required to localize a particle. As an example, we consider the attractive potential,

$$V = -\frac{C}{R^z \alpha} \ . \tag{32.66}$$

The space available for the particle is limited between the classical turning point, which for a given energy is $r_t = \left(\frac{C}{|E|}\right)^{1/\alpha}$. The momentum corresponding to this energy is $k_t = \left(\frac{2m|E|}{\hbar^2}\right)^{1/2}$. Heisenberg's uncertainty relation requires $k_t r_t > 2$, that is, at least half of the wavelength must fit within the potential (between 0 and r_t) at the height of the bound state. Therefore,

$$|E|^{1-2/\alpha} > \frac{2\hbar^2}{mC^{2/\alpha}} \ . \tag{32.67}$$

For a Coulomb potential, with $\alpha = 1$ and $C = e^2/4\pi\varepsilon_0$, we obtain the energy of the ground state of the hydrogen atom,

$$E > E_1 = -\frac{e^2}{4\pi\varepsilon_0 2a_B} \ , \tag{32.68}$$

but there is no state higher than all others. That is, all energies $E_n = E_1/n^2$ exist.

For $\alpha = 2$, we do not get a condition for the energy. For the Casimir-Polder potential, $\alpha = 3$, we obtain,

$$E < -\frac{8\hbar^6}{m^3 C^2} \ . \tag{32.69}$$

This means that, in contrast to the Coulomb potential, the *binding energy* must be *lower* than a certain limit.

32.2.5.2 The LeRoy-Bernstein method

The *LeRoy-Bernstein method* allows us to estimate the highest bound levels. It only applies near the dissociation limit, where the semi-classical formula of quantization is valid,

$$v + \frac{1}{2} = \sqrt{\frac{8M_r}{\hbar^2}} \int_0^{R_1} dR \sqrt{E(v) - V(R)} \ . \tag{32.70}$$

Inserting the potential

$$V(R) = D_e - \frac{C}{R^n} \ , \tag{32.71}$$

we get

$$E(v^*) = D_e - \left(\frac{(n-2)\Gamma\left(1+\frac{1}{n}\right)}{2\Gamma\left(\frac{1}{2}+\frac{1}{n}\right)} (v^* + v_D) \right)^{\frac{2n}{n-2}} \left(\frac{h^{2n}}{(2\pi M_r)^n C^2} \right)^{\frac{1}{n-2}} \ , \tag{32.72}$$

where v^* is a number counting the vibrational levels from the top to the bottom starting at the dissociation limit.

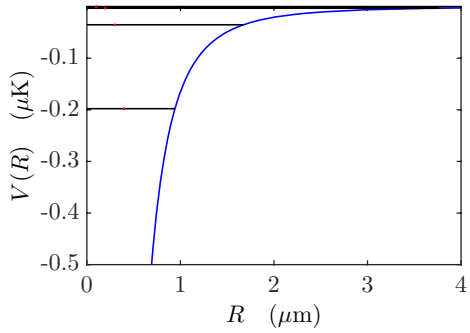

Figure 32.14: (code) Highest vibrational states obtained by the LeRoy-Bernstein method.

32.2.5.3 Open channels

For a given interatomic potential $V(R)$, neglecting the spin structure [690], the relative wavefunction of a two-atom system satisfies the Schrödinger equation,

$$\left[-\tfrac{1}{2\mu}\Delta + V(R) \right] \psi(\mathbf{R}) = E\psi(\mathbf{R}) \ . \tag{32.73}$$

Separating the radial and angular contributions, $\psi(\mathbf{R}) \equiv Y(\vartheta, \varphi) f(R)/R$, we obtain,

$$\left[-\frac{1}{2\mu} \frac{\partial^2}{\partial R^2} + V(R) + \frac{l(l+1)}{2\mu R^2} \right] f(R) = E f(R) \ . \tag{32.74}$$

Now, we introduce the local wavevector, $k(R) = \sqrt{2\mu[E - V(R)] - l(l+1)/R^2}$ and write,

$$f'' = -k^2 f \ . \tag{32.75}$$

This differential equation can be solved numerically [see Fig. 32.15(a)].

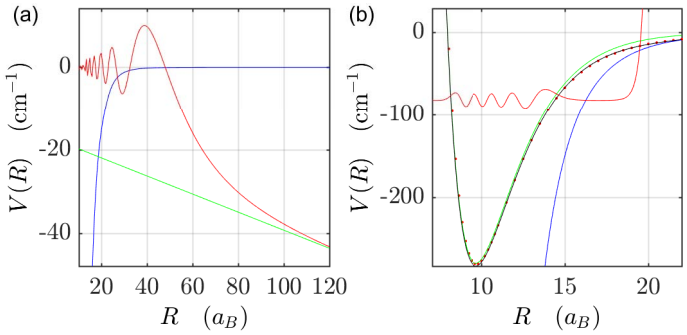

Figure 32.15: (code) (a) Numerical computation of the relative wavefunction for a low energy collision, $E \gtrsim 0$ and $\ell = 0$. The blue curve shows the interatomic Li-Rb potential (a)$^3\Sigma$, the red curve illustrates the relative Broglie wavefunction of the molecule. The asymptote of this extrapolated wavefunction (green curve) cuts the abscissa at $a_s = -120 a_B$, which is just the scattering length for collisions in this channel. (b) Numerical computation of the wavefunction for a vibrational state. The potential is an interpolation (black) between a short-range Morse potential (green), and a long range potential (blue). The red curve illustrates the relative wavefunction for the ninth vibrational state (counting from ground state).

32.2.5.4 Bound states

For bound states, we must simultaneously satisfy the eigenvalue problem. We can, for example, guess an eigenvalue E, calculate the associated wavefunction $f(R)$, check whether it diverges for $R \to \infty$, and vary E until $f(R)$ no longer diverges. Fig. 32.15(b) shows the wavefunction of a vibrational state obtained by solving the Schrödinger equation and adjusting the energy until the function stops diverging in the classically forbidden range.

32.2.5.5 The Fourier grid method

Another, extremely rapid, numerical method for determining the spectrum of vibrational states of a potential, is the *Fourier grid method*. It is based on the discretization of the Hamiltonian along the interatomic potential. We write the Hamiltonian as,

$$H\psi(R) = [T(R) + V(R)]\psi(R) = E\psi(R) \ , \tag{32.76}$$

and put it in a matrix form using the set of functions of the basis $\phi_i(R_j) = \delta(R_i - R_j)$ with $i = 1, .., N$, where $R_i = R_0 + i(R_N - R_0)/N$. This problem has N eigenvalues E_i. The Fourier grid method now evaluates the kinetic energy at each point in the grid. We insert the local terms $H_{ii} = H(R_i)$ and the non-local terms $H_{ij} = H(R_i, R_j)$ into the Hamiltonian, as well as the potential energies $V_{ij} = V(R_i)\delta_{ij}$. The kinetic energy is the inverse Fourier transform from momentum space of $T_{rs} = T(k_r)\delta_{rs} = (k_r^2/2\mu)\delta_{rs}$ and becomes [884, 847, 395],

$$H_{ij} = \frac{\pi^2}{4\mu(R_N - R_1)^2}(-1)^{i-j}\left(\frac{1}{\sin^2\frac{\pi(i-j)}{2N}} - \frac{1}{\sin^2\frac{\pi(i+j)}{2N}}\right) \quad \text{for} \quad i \neq j \tag{32.77}$$

$$H_{ij} = \frac{\pi^2}{4\mu(R_N - R_1)^2}\left(\frac{2N^2+1}{3} - \frac{1}{\sin^2\frac{\pi i}{2N}}\right) + V(R_i) \quad \text{for} \quad i = j \ .$$

To improve the wavefunction, we can interpolate,

$$\psi(q) = \sum\nolimits_{j=1}^{n} \psi(q_j)\ \mathrm{sinc}\frac{\pi(q - q_j)}{\Delta q} \ . \tag{32.78}$$

The method can be extended to coupled channels $\sigma = A, B$ via,

$$H_{\{i\sigma\}\{j\tau\}} = T_{ij}\delta_{\sigma\tau} + V_{\sigma\tau}(R_i)\delta_{ij} \ . \tag{32.79}$$

The Hamiltonian has the general form,

$$H = \begin{pmatrix} T & 0 \\ 0 & T \end{pmatrix} + \begin{pmatrix} V_A & 0 \\ 0 & V_B \end{pmatrix} + \begin{pmatrix} W_{AA} & W_{AB} \\ W_{AB} & W_{BB} \end{pmatrix} \ , \tag{32.80}$$

where all matrices V_k and W_k are diagonal [8].

32.2.6 Exercises

32.2.6.1 Ex: Transitions between vibrational states

Calculate the dipole moment between two arbitrary vibrational states of (a) a harmonic potential and (b) a Morse potential.

Solution:

32.2.6.2 Ex: Rotational spectrum of diatomic molecules

Calculate the rotational spectrum for a diatomic molecule from the result (32.59).

Solution: *We consider a diatomic molecule with R the distance between atoms and the symmetry axis $\hat{\mathbf{e}}_z$. The moments of inertia are then,*

$$I_{xx} = I_{yy} = M_r R^2 \quad , \quad I_{zz} = 0 \ ,$$

[8] Note that the Fourier grid method can be improved by using a grid with spacings adjusted to the potential gradient [739, 1304, 804].

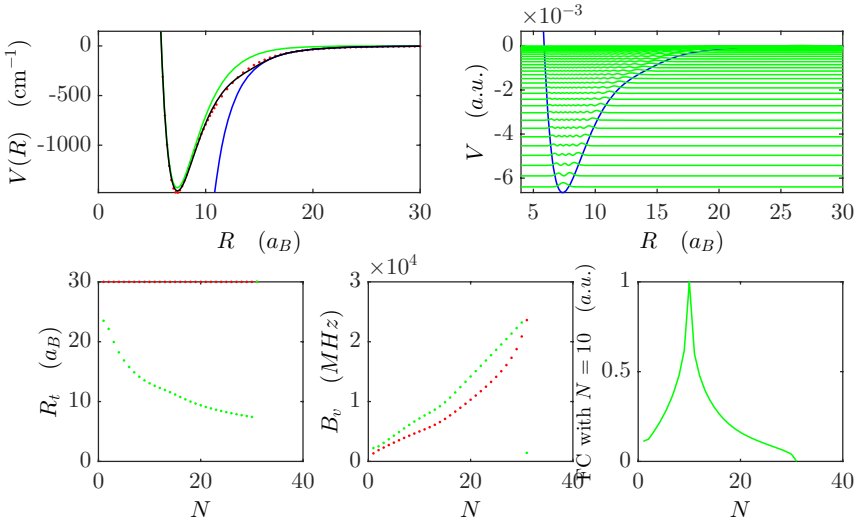

Figure 32.16: (code) Numerical computation of the wavefunction using the Fourier grid method at example of the interatomic potential Li-Rb $(1)^1\Pi$. (a) Short range Morse potential (green), long range (blue), interpolation (black) and [743]. (b) Vibrational wavefunctions, (c) external turning point (red) and center of mass (green), (d) rotational progression, and (e) Franck-Condon overlap with the tenth vibrational state.

where $\mu^{-1} \equiv M_1^{-1} + M_2^{-1}$. *The moment* I_{zz} *disappears because the spatial extent of atoms is negligible. For this case,*

$$A = \frac{\hbar}{4\pi c I_{\|}} = \infty \qquad \textit{and} \qquad B = \frac{\hbar}{4\pi c M_r R^2} \ .$$

This means that the excitations of rotations about the symmetry axis are inaccessible and frozen to the ground state $K = 0$. *Hence,*

$$E(J, M_J) = \frac{\hbar^2}{2M_r R^2} J(J+1) \ .$$

32.2.6.3 Ex: Ro-vibrational spectrum

Determine the frequency spectra of ro-vibrational transitions for the branches P, Q, and R.

Solution:

32.2.6.4 Ex: Rotational spectrum

Determine the rules and the spectrum of rotational transitions for a spherical molecule.

Solution:

32.3 Van der Waals forces and spin coupling

The individual atoms have a complex substructure due to the angular momenta of the electronic motion, its spins and the nuclear spin. All of these angular momenta can interact, couple and generate new energy terms, which need to be taken into account when calculating the various potentials of interatomic interaction,

$$\hat{H} = \frac{\mathbf{P}^2}{2M_r} + V_{coulomb}(R) + \sum_{k=1,2} \left(V_{hfs}^{(k)} + V_{zeeman}^{(k)} \right) + V_{dipole,spin-spin}(R) + V_{dipole,spin-orbit}(R) \; . \tag{32.81}$$

The Coulomb interaction for interacting alkaline gases can be expressed as:

$$V_{coulomb}(R) = V_{coulomb}^{S=0} \mathcal{P}_{S=0} + V_{coulomb}^{S=1} \mathcal{P}_{S=1} \; . \tag{32.82}$$

The projectors $\mathcal{P}_{S=0,1}$ will be required to expand the Hilbert space for the degrees of freedom of the spins.

The *van der Waals forces* include all intermolecular forces. These are long-range forces that occur between permanent and induced atomic dipoles $\sim 1/r^6$ [9]

32.3.1 Analytical models for short and long-range potentials

In general, the potentials are estimated by ab initio Hartree-Fock calculations. A short-range potential, or *Morse potential*, can be approximated by,

$$V_{morse} = D_m \left(\left[1 - e^{-B_m (R - R_m)} \right]^2 - 1 \right) \; . \tag{32.83}$$

Here, B_m is the width of the minimum, R_m the position of the minimum, D_m the length. A long-range potential can be written,

$$V_{vdw}(R) = D_e - \frac{C_6}{R^6} - \frac{C_8}{R^8} - \frac{C_{10}}{R^{10}} \; . \tag{32.84}$$

D_e is the energy of dissociation. The *van der Waals coefficients* C_k, which determine the potential shape at large distances, can be calculated using other methods with higher precision. To obtain a closed formula, the short and long range parts can be joined by,

$$V = V_{morse} F + V_{vdw}(1 - F) \; , \tag{32.85}$$

where $F \equiv e^{-(R/R_t)^{10}}$.

[9] They also occur, in a pure form, in optical resonators such as in the *Casimir effect*. Since the lowest frequency in a cavity is $\omega = \sqrt{2}\pi c/L$, the zero point energies inside and outside the cavity are different. This causes an attractive force between the cavity mirrors $\sim 1/r^3, 1/r^4$.

The situation is different for collisions of identical atoms in excited states, which has a much larger range because of the resonant interaction between dipoles. In this case, an additional *Movre-Pichler potential* dominated by a coefficient C_3 arises,

$$V^e_{vdw} = V^e_{movre} + V^e_{dispersion} \ . \tag{32.86}$$

In contrast, excited state collisions of different species are purely short ranged.

32.3.2 Spin coupling in dimers, molecular quantum numbers

We consider two interacting alkaline atoms, each being described by a set of quantum numbers of internal angular momenta, they couple their spins:

$$\begin{aligned}
\mathbf{l}_i & \quad \text{angular momentum of the individual atom} \\
\mathbf{s}_i & \quad \text{electronic spin} \\
\mathbf{i}_i & \quad \text{nuclear spin} \\
\mathbf{l}_i + \mathbf{s}_i = \mathbf{j}_i & \quad \text{total electronic angular momentum} \\
\mathbf{j}_i + \mathbf{i}_i = \mathbf{f}_i & \quad \text{total angular momentum .}
\end{aligned} \tag{32.87}$$

When the atoms approach each other, at intermediate distances, they couple their spins:

$$\begin{aligned}
\ell \perp \hat{\mathbf{e}}_z & \quad \text{molecular rotation} \\
\mathbf{\Lambda} \equiv |M_L| \hat{\mathbf{e}}_z & \quad \text{projection of } \mathbf{L} \text{ onto the interatomic } \hat{\mathbf{e}}_z \\
\mathbf{\Sigma} \equiv M_S \hat{\mathbf{e}}_z & \quad \text{projection of } \mathbf{S} \text{ onto the interatomic } \hat{\mathbf{e}}_z \\
\mathbf{\Omega} \equiv \mathbf{\Lambda} + \mathbf{\Sigma} & \quad \text{projection of } \mathbf{L} + \mathbf{S} \text{ onto the interatomic } \hat{\mathbf{e}}_z \ .
\end{aligned} \tag{32.88}$$

At short distances, they form a molecular dimer described by the quantum numbers:

$$\begin{aligned}
\mathbf{L} = \mathbf{l}_1 + \mathbf{l}_2 & \quad \text{total electronic angular momentum} \\
\mathbf{S} = \mathbf{s}_1 + \mathbf{s}_2 & \quad \text{electronic spin} \\
\mathbf{I} = \mathbf{i}_1 + \mathbf{i}_2 & \quad \text{nuclear spin} \\
\mathbf{f} = \mathbf{f}_1 + \mathbf{f}_2 & \quad \text{total angular momentum or } (\mathbf{L}, \mathbf{S})\mathbf{k} + \mathbf{I} \\
\mathbf{J} = \mathbf{\Omega} + \ell & \\
\mathbf{F} = \mathbf{f} + \ell & \ .
\end{aligned} \tag{32.89}$$

The quantum numbers couple like,

$$\begin{array}{ccccccccccccc}
\mathbf{l}_1 & + & \mathbf{l}_2 & = & \mathbf{L} & \xrightarrow{\hat{\mathbf{e}}_z} & \mathbf{\Lambda} & & & & & & \\
+ & & + & & + & & + & & & & & & \\
\mathbf{s}_1 & + & \mathbf{s}_2 & = & \mathbf{S} & \xrightarrow{\hat{\mathbf{e}}_z} & \mathbf{\Sigma} & & & & & & \\
= & & = & & = & & = & & & & & & \\
\mathbf{j}_1 & + & \mathbf{j}_2 & = & \mathbf{j} & \xrightarrow{\hat{\mathbf{e}}_z} & \mathbf{\Omega} & + & \ell & = & \mathbf{J} \\
+ & & + & & + & & & & & & + \\
\mathbf{i}_1 & + & \mathbf{i}_2 & = & \mathbf{I} & & & & & & \mathbf{I} \\
= & & = & & = & & & & & & = \\
\mathbf{f}_1 & + & \mathbf{f}_2 & = & \mathbf{f} & & & + & \ell & = & \mathbf{F}
\end{array} \tag{32.90}$$

Obviously, the atomic angular momentum is no longer a conserved quantity, but its projection onto the interatomic molecular axis is. The various possibilities how **L**, **S**, and **j** are projected onto the internuclear axis or directly couple to the rotational angular momentum ℓ are handled by Hund's cases (a) to (e). The spin coupling is described by $\{9j\}$-symbols, as discussed below.

32.3.3 Hund's coupling cases

The coupling force between atomic spins depends on the distance between the atoms. Due to the variety of spins appearing in atoms, there are many possibilities how they can couple. These were classified by Hund into five cases.

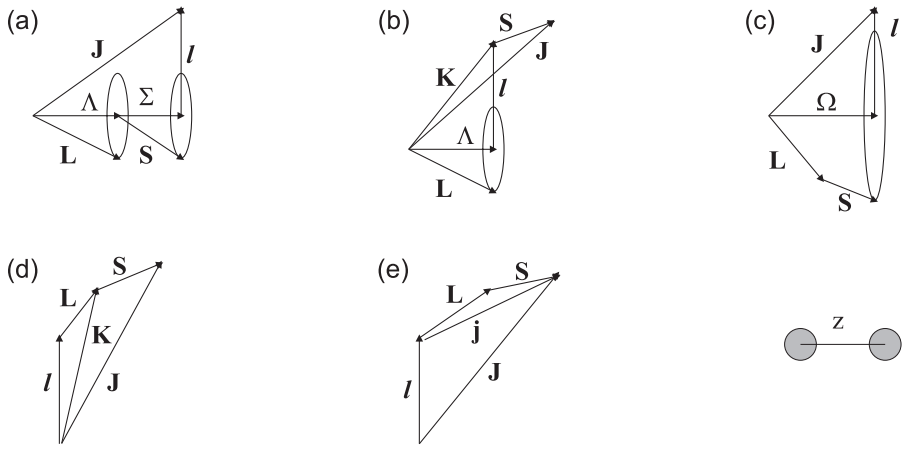

Figure 32.17: Hund's coupling cases.

32.3.3.1 Hund's case (a)

The molecular interaction is so strong that **L** and **S** couple to the z-axis instead of coupling to each other. This case is analogous to the Paschen-Back effect,

$$\begin{aligned} &\mathbf{L} \to \mathbf{\Lambda} \qquad \text{and} \qquad \mathbf{S} \to \mathbf{\Sigma} \\ &((\mathbf{\Lambda}, \mathbf{\Sigma})\mathbf{\Omega}, \ell)\mathbf{J} \ . \end{aligned} \tag{32.91}$$

A common notation is to label the states $\mathbf{\Lambda} = \mathbf{\Sigma}, \mathbf{\Pi}, \mathbf{\Delta}, ...$ That is, in the symbol $X(^{2S+1}\Lambda_\Omega)^{\pm}_{\sigma}$, where $\sigma = g, u$ is the inversion symmetry, $X, A, B, ..$ and $a, b, ..$ are the singlet and triplet series starting from the lowest energy levels. An alternative notation is to assign labels ordered by energy $X = (1), (2), ...$ Finally, $\pm$ is the symmetry upon reflection. For example, $X^1\Sigma_g^+$.

32.3.3.2 Hund's case (b)

L is projected onto the z-axis before coupling to ℓ. The resulting angular momentum afterward directly couples to **S**.

$$\begin{aligned} \mathbf{L} &\rightarrow \mathbf{\Lambda} \\ ((\mathbf{L},\ell)\mathbf{k},\mathbf{S})\mathbf{J} &. \end{aligned} \tag{32.92}$$

32.3.3.3 Hund's case (c)

L and **S** couple together instead of projecting themselves onto the z-axis. This case is analogous to the Zeeman effect,

$$\begin{aligned} (\mathbf{L},\mathbf{S})\mathbf{j} &\rightarrow \mathbf{\Omega} \\ (\mathbf{\Omega},\ell)\mathbf{J} &. \end{aligned} \tag{32.93}$$

A common notation is to label the states by $\mathbf{\Omega} = 0, 1, 2, ...$ That is, in the symbol $X(\Omega)_s^{\pm}$, the letter $X = 1, 2, ..$ is a label ordered by energy. For example $2(0_g^-)$.

32.3.3.4 Hund's case (d)

L is not projected on the z- axis, but directly couples to the rotational angular momentum. The resulting angular momentum afterward only couples to the **S**

$$((\mathbf{L},\ell)\mathbf{k},)\mathbf{J} \; . \tag{32.94}$$

32.3.3.5 Hund's case (e)

L and **S** mutually couple as in the case (c), but are not projected on the z-axis, but couple directly with ℓ, which is quantized,

$$((\mathbf{L},\mathbf{S})\mathbf{j},\ell)\mathbf{J} \; . \tag{32.95}$$

32.3.4 Molecular hyperfine struture

The scattering length in specific channels can be expressed via singlet and triplet scattering lengths,

$$a_{|f_1,m_{f1}\rangle+|f_2,m_{f2}\rangle} = P_{S=0}a_s + P_{S=1}a_t \; . \tag{32.96}$$

The projectors are $P_S = |\langle S|(f_1 f_2)f\rangle|$. According to [213, 889] the recoupling from the uncoupled hyperfine representation into the short range representation is given by,

$$\langle Sm_S \; Im_I \; \ell' m_{\ell'}|f_1 m_{f1} \; f_2 m_{f2} \; \ell m_\ell\rangle = \delta_{\ell\ell'}\delta_{m_\ell m'_\ell} \sum_{f,m_f} \langle Sm_S \; Im_I|fm_f\rangle\langle f_1 m_{f1} \; f_2 m_{f2}|fm_f\rangle \times$$

$$\times \begin{Bmatrix} s_1 & s_2 & S \\ i_1 & i_2 & I \\ f_1 & f_2 & f \end{Bmatrix} \sqrt{\hat{S}\hat{I}\hat{f}_1\hat{f}_2} \left(\frac{1-(1-\delta_{f_1 f_2})(-1)^{S+I+\ell}}{\sqrt{2-\delta_{f_1 f_2}}} \right) \; . \tag{32.97}$$

The last bracket is dropped for unsymmetrized recoupling. We will study examples of spin recoupling in the ground state channels in Exc. 32.3.5.1, 32.3.5.2, and 32.3.5.3.

32.3.5 Exercises

32.3.5.1 Ex: Spin recoupling of identical ^{87}Rb ground state channels

a. Unravel the molecular hyperfine structure of identical ^{87}Rb ground state channels.
b. Project the collisional channels $|f_1 m_{f1}\ f_2 m_{f2}\rangle = |1\,-1\ 1\,-1\rangle$ and $|22\ 22\rangle$ on the singlet and triplet potentials, $S = 0, 1$.

Solution: *a. With hyperfine structure we get for ^{87}Rb: According to Fig. 32.18 the*

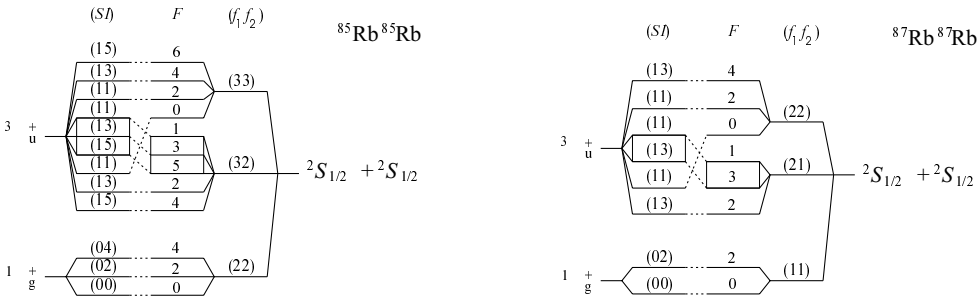

Figure 32.18: Hyperfine recoupling scheme.

levels $f = 1, 3, 4$ have pure triplet character, while $f = 0, 2$ have singlet admixtures. In the presence of hyperfine structure the potential curves split further. Collisions may occur on several levels simultaneously.
We test the recoupling procedure on ^{87}Rb, for which the following projectors are known [296]: $a_{|2,2\rangle+|2,2\rangle} = 0a_s + 1a_t$ and $a_{|1,-1\rangle+|1,-1\rangle} = \frac{3}{16}a_S + \frac{13}{16}a_t$. Now considering atoms with nuclear spin $i_1 = i_2 = 3/2$ in their electronic ground states, $s_1 = s_2 = 1/2$, colliding in identical channels, $f_1 = f_2$ and $m_{f1} = m_{f2}$,

$$\langle S m_S\ I m_I | f_1 m_{f1}\ f_1 m_{f1}\rangle = \sum_f \begin{pmatrix} S & I & f \\ m_S & 2m_{f1} - m_S & -2m_{f1} \end{pmatrix} \times$$
$$\times \begin{pmatrix} f_1 & f_1 & f \\ m_{f1} & m_{f1} & -2m_{f1} \end{pmatrix} \begin{Bmatrix} \frac{1}{2} & \frac{1}{2} & S \\ \frac{3}{2} & \frac{3}{2} & I \\ f_1 & f_1 & f \end{Bmatrix} \hat{f}_1 \sqrt{\hat{S}\hat{I}}\ ,$$

where we used $m_f = m_{f1} + m_{f2} = m_S + m_I$ and the fact that the sum of the lower row of a Clebsch-Gordan must be zero.
b. In the following, we calculate projections of the collisional channels $|f_1 m_{f1}\ f_2 m_{f2}\rangle = |1\,-1\ 1\,-1\rangle$ and $|22\ 22\rangle$ on the singlet and triplet potentials, $S = 0, 1$, separately. For this it suffices to calculate the above projections for various sets of $I = |i_1 - i_2|..i_1 + i_2$ and $m_I = -I..I$. The number $m_S = \min(\max(m_f - m_I, -S), S)$ is fixed by the previous ones. And the sum runs over $f = \max(|f_1 - f_2|, |I - S|)..\min(f_1 + f_2, I + S)$. Doing so, we obtain in the singlet channel (here $f = I$),

$$\langle 0 m_S\ I m_I | 22\ 22\rangle = 0\ ,$$

which gives $P_{S=0} = 0$, *and*

$$\langle 0 m_S \; I m_I | 1 - 1 \; 1 - 1 \rangle = \langle 00 \; 2 - 2 1 - 1 \; 1 - 1 \rangle = \tfrac{1}{4}\sqrt{3} \; ,$$

which gives $P_{S=0} = 3/16$. *Similarly, for the triplet states,* $S = 1$,

$$\langle 1 m_S \; I m_I | 22 \; 22 \rangle = \langle 11 \; 33 | 22 \; 22 \rangle = 1 \; ,$$

which gives $P_{1=0} = 1$, *and*

$$\langle 1 m_S \; I m_I | 1 - 1 \; 1 - 1 \rangle = \begin{cases} \langle 1 + 1 \; 3 - 3 | 1 - 1 \; 1 - 1 \rangle = 0.75 \\ \langle 1 + 0 \; 3 - 2 | 1 - 1 \; 1 - 1 \rangle = -0.4330 \\ \langle 1 - 1 \; 1 - 1 | 1 - 1 \; 1 - 1 \rangle = -0.1581 \\ \langle 1 - 1 \; 3 - 1 | 1 - 1 \; 1 - 1 \rangle = 0.1936 \end{cases} ,$$

which gives $P_{S=1} = \sum_{I,m_I} |\langle 1 m_S \; I m_I | 1 - 1 \; 1 - 1 \rangle|^2 = 13/16$.

32.3.5.2 Ex: Spin recoupling of ^{6}Li^{87}Rb ground state channels

a. Unravel the molecular hyperfine structure of ^{6}Li^{87}Rb ground state channels.
b. Project the collisional channels on short range potentials.

Solution: *As a second example consider* ^{6}*Li* ^{87}*Rb collisions. Apparently the coupling is diagonal in* f, *neglecting spin-spin interactions,*

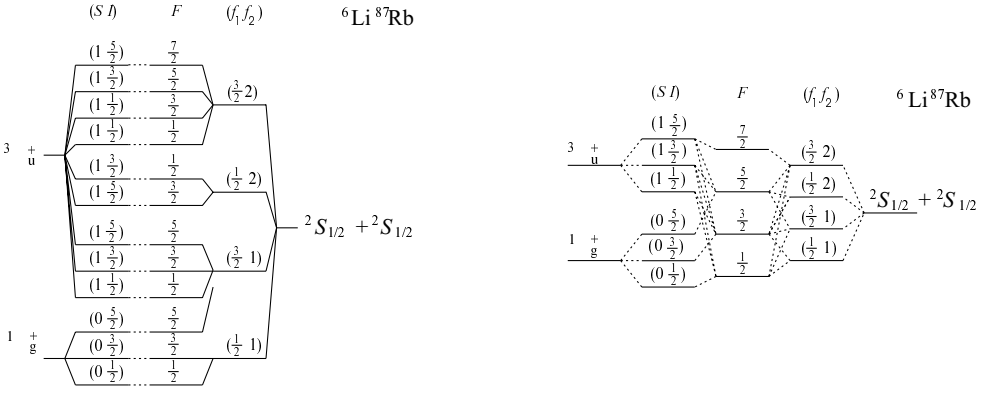

Figure 32.19: Hyperfine recoupling for heteronuclear collisions.

$$\begin{array}{c} (f_6 f_{87}) f \longrightarrow \\ (SI) f \downarrow \\ (0, \tfrac{1}{2})\tfrac{1}{2} \; (1, \tfrac{1}{2})\tfrac{1}{2} \; (1, \tfrac{3}{2})\tfrac{1}{2} \\ (0, \tfrac{3}{2})\tfrac{3}{2} \; (1, \tfrac{1}{2})\tfrac{3}{2} \; (1, \tfrac{3}{2})\tfrac{3}{2} \; (1, \tfrac{5}{2})\tfrac{3}{2} \\ (0, \tfrac{5}{2})\tfrac{5}{2} \; (1, \tfrac{3}{2})\tfrac{5}{2} \; (1, \tfrac{5}{2})\tfrac{5}{2} \\ (1, \tfrac{5}{2})\tfrac{7}{2} \end{array} \quad \begin{array}{ccccc} \tfrac{1}{2},1)\tfrac{1}{2} & (\tfrac{3}{2},1)\tfrac{1}{2} & (\tfrac{3}{2},2)\tfrac{1}{2} & & \\ & 3 \times 3 & & & \\ \tfrac{1}{2},1)\tfrac{3}{2} & (\tfrac{3}{2},1)\tfrac{3}{2} & (\tfrac{1}{2},2)\tfrac{3}{2} & (\tfrac{3}{2},2)\tfrac{3}{2} & \\ & & 4 \times 4 & & \\ & (\tfrac{3}{2},1)\tfrac{5}{2} & (\tfrac{1}{2},2)\tfrac{5}{2} & (\tfrac{3}{2},2)\tfrac{5}{2} & \\ & & & 3 \times 3 & \\ & & & & (\tfrac{3}{2},2)\tfrac{7}{2} \\ & & & & 1 \times 1 \end{array}$$

We start again from the general expression, but now insert the Li (label 1) and Rb (label 2) data,

$$\langle S m_S\ I m_I | f_1 m_{f1}\ f_2 m_{f2}\rangle = \sum_f \begin{pmatrix} S & I & f \\ m_S & m_I & -m_{f1}-m_{f2}\end{pmatrix} \times$$
$$\times \begin{pmatrix} f_1 & f_2 & f \\ m_{f1} & m_{f2} & -m_{f1}-m_{f2}\end{pmatrix} \begin{Bmatrix} \frac{1}{2} & \frac{1}{2} & S \\ 1 & \frac{3}{2} & I \\ f_1 & f_2 & f\end{Bmatrix} \sqrt{\hat{S}\hat{I}\hat{f}_1\hat{f}_2}\ .$$

b. Setting $S=0=m_S$, we get for the various channels,

$$\langle 00\ I m_I | \tfrac{3}{2}\tfrac{3}{2}\ 22\rangle = 0$$

which gives $P_{S=0}=0$, and

$$\langle 00\ I m_I | \tfrac{1}{2}-\tfrac{1}{2}\ 1-1\rangle = \langle 00\ \tfrac{3}{2}-\tfrac{3}{2} | \tfrac{1}{2}-\tfrac{1}{2}\ 1-1\rangle = 0.4564$$

which gives $P_{S=0}=0.2083$. Setting $S=1$, we get,

$$\langle 1 m_S\ I m_I | \tfrac{3}{2}\tfrac{3}{2}\ 22\rangle = \langle 11\ \tfrac{5}{2}\tfrac{5}{2} | \tfrac{3}{2}\tfrac{3}{2}\ 22\rangle = 1\ ,$$

and

$$\langle 1 m_S\ I m_I | \tfrac{1}{2}-\tfrac{1}{2}\ 1-1\rangle = \begin{cases} \langle 1+1\ \frac{5}{2}-\frac{5}{2} | \frac{1}{2}-\frac{1}{2}\ 1-1\rangle = \sqrt{\frac{1}{2}} \\ \langle 1+0\ \frac{5}{2}-\frac{3}{2} | \frac{1}{2}-\frac{1}{2}\ 1-1\rangle = -\sqrt{\frac{1}{5}} \\ \langle 1+0\ \frac{3}{2}-\frac{3}{2} | \frac{1}{2}-\frac{1}{2}\ 1-1\rangle = -0.0913 \\ \langle 1-1\ \frac{5}{2}-\frac{1}{2} | \frac{1}{2}-\frac{1}{2}\ 1-1\rangle = \sqrt{\frac{1}{20}} \\ \langle 1-1\ \frac{3}{2}-\frac{1}{2} | \frac{1}{2}-\frac{1}{2}\ 1-1\rangle = 0.0745 \\ \langle 1-1\ \frac{1}{2}-\frac{1}{2} | \frac{1}{2}-\frac{1}{2}\ 1-1\rangle = -\frac{1}{6} \end{cases},$$

which gives $P_{S=1}=\sum_{I,m_I} |\langle 1 m_S\ I m_I | \frac{1}{2}-\frac{1}{2}\ 1-1\rangle|^2 = 0.7917$.

32.3.5.3 Ex: Hyperfine structure of ^{6}Li^{23}Na and ^{6}Li^{87}Rb

a. Unravel the molecular hyperfine structure of ^{6}Li^{23}Na and ^{6}Li^{87}Rb bound state.
b. How about the open channels?

Solution: *a. The rank of the whole matrix follows from the following table:*

$\langle \vert V \vert S, m_S, i_6, m_6, i_{87}, m_{87}\rangle$	$(0,0)(1,-1..1)(\frac{3}{2},-\frac{3}{2}..\frac{3}{2})$	$(1,-1..1)(1,-1..1)(\frac{3}{2},-\frac{3}{2}..\frac{3}{2})$
$(0,0)(1,-1..1)(\frac{3}{2},-\frac{3}{2}..\frac{3}{2})$	12×12	
$(1,-1..1)(1,-1..1)(\frac{3}{2},-\frac{3}{2}..\frac{3}{2})$		36×36

For example, $^6Li^{87}Rb$ collisions in $S=1$ produce the curves in Fig. 32.20 [1242] using the tabulated values for i_k, $a_{hf,k}$ and g_k [43].

We consider ^6Li and the ground state $|1/2, \mp 1/2\rangle$ and ^{23}Na in $|1, \mp 1\rangle$. For the combined open channel we simply use the Breit-Rabi formula. According to [1242] using $S = 1$, $i_6 = 1$ and $i_{23} = 3/2$, $a_{hf,6} = 152.1368$ MHz and $a_{hf,23} = 885.8131$ MHz, and furthermore $E_B = -5550$ MHz. With $g_S = 2.000...$, $g_6 = -0.000447$ and $g_{23} = -0.000804$. The results can simply transferred to ^{87}Rb, in the same set of

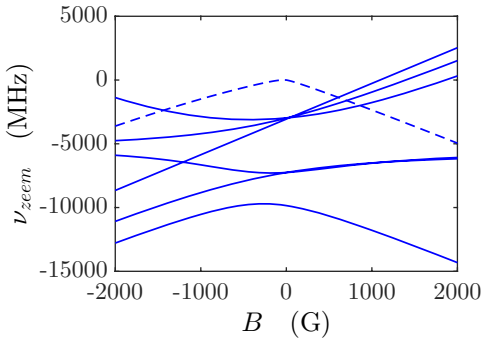

Figure 32.20: (code) Ground state level shift in a magnetic field for LiRb collisions. The binding energy is fitted to $E_B = -5550$ MHz. The dotted line denotes the open channel. Only those states with $m_f = m_{f1} + m_{f2} = -3/2$ are shown for $B < 0$ and $m_f = 3/2$ for $B > 0$.

quantum numbers, but with a different hf splitting, $a_{hf,87} = 3417.3413$ MHz, a different nuclear g-factor, $g_{87} = -0.000995$, and obviously a different orbital energy E_B. Note that the $(i_1, i_2)I$ coupling easily breaks up in a magnetic field. The magnetic field dependence of bound states is thus primarily determined by the total electronic spin. Singlet states $S = 0$ do not shift, triplet states $S = 1$ split up into three hyperfine multiplets [1242].
b. The total energy of a Zeeman-shifted open channel is just the sum of the Zeeman-shifted energy of the individual colliding atoms.

Chapter 33

Collisions

Until now, we mostly restricted our studies to individual atoms or molecules. In practice, however, we investigate atomic or molecular gases by spectroscopic methods. The constituents of thermal gases are constantly in motion. They are subject to Doppler-shifts of their spectral lines and they collide with each other. Colliding atoms often get so close, that the electronic orbitals affect each other, which leads to distortions of the interaction potentials, spectral lineshifts and modifications of the interatomic forces. These are the topics to be addressed in the present chapter.

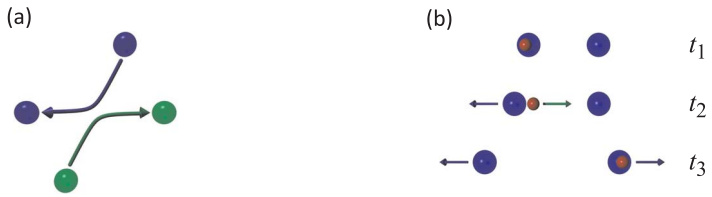

Figure 33.1: Atoms may interact via exchange of (a) virtual photons or (b) real photons.

33.1 Motion of interacting neutral atoms

The following sections, devoted to the relative motion of two neutral atoms, are adapted from J. Walraven's excellent lectures on *Quantum Gases* available at [1355]. The atoms are presumed to move slowly, typically at large separation, and to interact pair wise through a potential of the Van der Waals type. The term slowly refers to,

$$k_{therm} r_0 \ll 1 \qquad \text{where} \qquad \lambda_{therm} = \frac{2\pi}{k_{therm}} = \sqrt{\frac{2\pi\hbar^2}{m k_B T}} \tag{33.1}$$

is the *thermal de Broglie wavelength* and r_0 the range of the interaction potential. As the Van der Waals interaction gives rise to elastic collisions, the total energy of the relative motion is conserved in time. As the potential energy vanishes at large interatomic separation the total energy is usually expressed in the form $E = \hbar^2 k^2 / 2m_r$. This implies that also the wavenumbers for the relative motion before and after the collision must be the same and shows that, far from the potential center, the collision can only affect the phase of the wavefunction - not its wavelength. Apparently, the appearance of a shift in phase relative to the free atomic motion

provides the key to the quantum mechanical description of elastic collisions. This being said, we postpone the discussion of the actual collisional behavior to Sec. 33.2. First we prepare ourselves for this discussion by analyzing the stationary states for the motion in the presence of an interaction potential.

An important simplifying factor in the description of ultracold collisions is the emergence of universal behavior in the relative motion of the atoms. The latter applies to low-energy collisional states as well as to weakly bound states. Universal means in this context that, asymptotically (for $r \gg r_0$), the wavefunctions become independent of the details of the interaction potential but can be characterized in terms of a few parameters, each representing some characteristic length scale of the collisional system. In other words, very different short-range physics can give rise to the same scattering behavior. From a theory point of view this universality has the enormous advantage that the essential features of ultracold collisions can be described with the aid of simple model potentials for which analytical solutions can be obtained.

In our analysis of the collisional motion three characteristic length scales will appear, the interaction range r_0 the scattering length a and the effective range r_e, each expressing a different aspect of the interaction. The range r_0 is the distance beyond which the interaction may be neglected even for $k \to 0$. The second characteristic length, the s-wave scattering length a, acts as an effective hard-sphere diameter. It is a measure for the interaction strength and determines the collision cross section in the limit $k \to 0$ as will be elaborated on in Sec. 33.2. The third characteristic length, the effective range re expresses how the potential affects the energy dependence of the cross section and determines when the $k \to 0$ limit is reached.

The s-wave scattering length is the central parameter for the theoretical description of bosonic quantum gases. It determines both the thermodynamic and the collisional properties of these gases. In single-component fermionic gases the s-wave scattering length plays no role because the wavefunction for the relative motion of the atoms has to be antisymmetric. In two-component fermionic gases this restriction is absent for collisions between atoms of different components. As a consequence, in these systems the inter-component s-wave scattering length determines the collision related properties - for instance the thermalization rate.

In Sec. 33.1.1 we show how the phase shift appears as a result of interatomic interaction in the wavefunction for the relative motion of two atoms. For free particles the phase shift is zero. An integral expression for the phase shift is derived. In Sec. 33.1.2 and beyond we specialize to the case of low-energy collisions ($kr_0 \ll 1$). The basic phenomenology is introduced and analyzed for simple model potentials like the hard-sphere (Sec. 33.1.2) and the spherical well (Sec. 33.1.3), where the existence of a short range is manifest. For the discussion of arbitrarily shaped potentials, we refer to the script [1355].

33.1.1 The collisional phase shift

33.1.1.1 Schrödinger equation

The starting point for the description of the relative motion of two atoms at energy E is the Schrödinger equation (25.33),

$$\left[\frac{1}{2m_r}\left(p_r^2+\frac{\mathbf{L}^2}{r^2}\right)+V(r)\right]\psi(r,\vartheta,\varphi)=E\psi(r,\vartheta,\varphi)\ . \tag{33.2}$$

Here m_r is the reduced mass of the atom pair and $V(r)$ the interaction potential. As discussed in Sec. 25.1.3 the eigenfunctions $\psi(r,\vartheta,\varphi)$ can be separated in a radial and a angular part, $\psi = R_\ell(r)Y_{\ell m}(\vartheta,\varphi)$, where the functions $Y_{\ell m}$ are spherical harmonics and the functions $R_\ell(r)$ satisfy the radial wave equation,

$$\left[\frac{\hbar^2}{2m_r}\left(-\frac{d^2}{dr^2}-\frac{2}{r}\frac{d}{dr}+\frac{\ell(\ell+1)}{r^2}\right)+V(r)\right]R_\ell(r)=ER_\ell(r)\ . \tag{33.3}$$

By the separation procedure the angular momentum term is replaced by a repulsive effective potential,

$$V_{rot}(r)=\frac{\hbar^2\ell(\ell+1)}{2m_r r^2}\ , \tag{33.4}$$

representing the rotational energy of the atom pair at a given distance and for a given rotational quantum number ℓ. In combination with an attractive interaction it gives rise to a centrifugal barrier for the radial motion of the atoms. This is illustrated in Fig. 33.2 for the example of hydrogen.

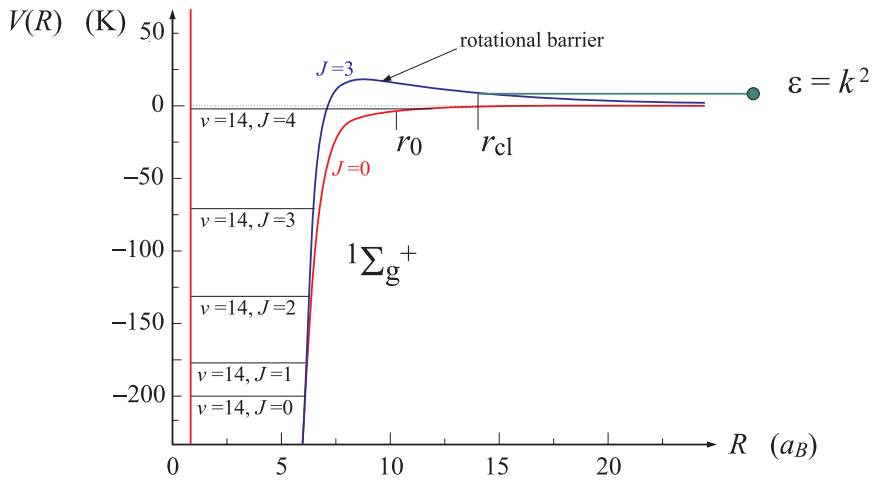

Figure 33.2: Example showing the high-lying bound states near the continuum of the singlet potential $^1\Sigma_g^+$ (the bonding potential) of the hydrogen molecule; v and J are the vibrational and rotational quantum numbers, respectively. The dashed line shows the effect of the $J = 3$ centrifugal barrier. The presence of a rotational barrier gives rise to an exponential suppression of the radial wavefunction for $r < r_{tp}$ and is negligible at distances where the interaction becomes noticeable $r \ll r_0$.

To analyze the radial wave equation we introduce reduced energies,

$$\varepsilon = \frac{2m_r E}{\hbar^2} = \begin{cases} k^2 & \text{for } k > 0 \\ -\kappa^2 & \text{for } k < 0 \end{cases} \quad \text{and} \quad \tilde{V}(r) = \frac{2m_r V(r)}{\hbar^2} \ , \tag{33.5}$$

choosing k and κ as real positive number. This puts Eq. (33.3) in the form,

$$\boxed{R_\ell'' + \frac{2}{r} R_\ell' + \left[\varepsilon - \tilde{V}(r) - \frac{\ell(\ell+1)}{r^2}\right] R_\ell = 0} \ . \tag{33.6}$$

With the substitution $u_\ell(r) = rR_\ell(r)$ it reduces to a 1D Schrödinger equation,

$$\boxed{u_\ell'' + \left[\varepsilon - \tilde{V}(r) - \frac{\ell(\ell+1)}{r^2}\right] u_\ell = 0} \ . \tag{33.7}$$

33.1.1.2 Low-energy limit: the s-wave regime

For two atoms with relative angular momentum $\ell > 0$ there exists a distance r_{tp}, called the classical turning point, below which the rotational energy exceeds the total energy E,

$$k^2 = \frac{\ell(\ell+1)}{r_{tp}^2} \ . \tag{33.8}$$

This is illustrated in Fig. 33.2. In the classically inaccessible region of space ($r < r_{tp}$) the radial wavefunction is exponentially suppressed [1]. Combining Eq. (33.8) with the condition (33.1) we obtain the inequality,

$$kr_0 = \sqrt{\ell(\ell+1)}\frac{r_0}{r_{tp}} \ll 1 \ , \tag{33.9}$$

which implies that, for $\ell \neq 0$, the classical turning point is found at a distance much larger than the range r_0 of the interaction. As the range r_0 defines the distance beyond which the potential can be neglected, this inequality shows that the radial motion is not affected by the presence of the potential $V(r)$ in the radial wave equation. The notable exception is the case $\ell = 0$, where the barrier is absent and the potential gives rise to a substantial distortion of the radial waves. In other words, for $kr_0 \ll 1$ phase shifts (i.e. scattering) can *only arise from collisions with zero angular momentum.* The range of collision energies where the inequalities (33.9) are valid is called the s-wave regime.

33.1.1.3 Free particle motion

We first have a look at the case of free particles or particles in a homogeneous potential, $V(r) = V_0$. By introducing the dimensionless variable $\varrho = kr$, where $k \equiv \sqrt{2m(E - V_0)/\hbar^2}$, the radial wave equation (33.6) can be rewritten in the form of the spherical Bessel differential equation,

$$R_\ell'' + \frac{2}{\varrho} R_\ell' + \left[1 - \frac{\ell(\ell+1)}{\varrho^2}\right] R_\ell = 0 \ . \tag{33.10}$$

[1] At this point we exclude tunneling through the barrier and the occurrence of shape resonances.

Here, the derivatives are with respect to the new variable.

The general solution of Eq. (33.10) for angular momentum ℓ is a linear combination of two particular solutions, one regular with amplitude A_ℓ, the spherical Bessel function $j_\ell(\varrho)$, and one irregular with amplitude B_ℓ, the spherical Neumann function $n_\ell(\varrho)$:

$$\boxed{R_\ell(\varrho) = A_\ell j_\ell(\varrho) + B_\ell n_\ell(\varrho) = c_\ell[\cos\eta_\ell\ j_\ell(\varrho) + \sin\eta_\ell\ n_\ell(\varrho)]}\ , \tag{33.11}$$

where the new parameters c_ℓ and η_ℓ, defined by

$$A_\ell \equiv c_\ell \cos\eta_\ell \qquad \text{and} \qquad B_\ell \equiv c_\ell \sin\eta_\ell\ , \tag{33.12}$$

represent the amplitude c_ℓ and the asymptotic phase η_ℓ of the wavefunction. Note that this equation is singular in the origin except for the case of vanishing phase shifts. Therefore, in the case of free particles we require $\eta_\ell = 0$ for all angular momentum values ℓ. This implies that the general solution reduces to the regular one,

$$R_\ell(\varrho) = c_\ell \cos\eta_\ell\ j_\ell(\varrho)\ . \tag{33.13}$$

33.1.1.4 Significance of the phase shifts

To investigate the effect of a short-range interaction potential $V(r)$ we return to the radial wave equation (33.6). As the potential is of short range it may be neglected for $r \gg r_0$ and the general solutions coincide with those of the spherical Bessel equation,

$$R_\ell(k,r) \underset{r\gg r_0}{\longrightarrow} c_\ell[\cos\eta_\ell\ j_\ell(kr) + \sin\eta_\ell\ n_\ell(kr)]\ . \tag{33.14}$$

For $r \gg 1/k$ the spherical Bessel and Neumann functions assume their asymptotic form and we find,

$$\begin{aligned} R_\ell(k,r) &\underset{kr\to\infty}{\longrightarrow} \frac{c_\ell}{kr}[\cos\eta_\ell \sin(kr - \tfrac{1}{2}\ell\pi) + \sin\eta_\ell \cos(kr - \tfrac{1}{2}\ell\pi)] \\ &= \frac{c_\ell}{kr}\sin(kr + \eta_\ell - \tfrac{1}{2}\ell\pi)\ . \end{aligned} \tag{33.15}$$

where we introduced a the constant η_ℓ representing the asymptotic phase shift. For a given value of k this phase shift fixes the general solution of the radial wavefunction $R_\ell(k,r)$ up to an ℓ dependent normalization constant c_ℓ. Note that in view of the k dependence of the phase shift, R_ℓ is a function of k and r rather than a function of the product kr. Whereas in the case of free particles the phase shifts must all vanish, in the presence of the interaction they provide the proper asymptotic form of the distorted waves. The non-zero asymptotic phase shift is the signature of the interaction at short distance; the motion becomes free-particle like (undistorted) only at large distance from the scattering center. In elastic scattering the relative energy $\hbar^2k^2/2m$ is conserved; hence, asymptotically also k and the de Broglie wavelength. This leaves only the asymptotic phase of the wave to be affected.

Example 190 (*Scattering matrix*): Rewriting Eq. (33.15) in complex notation,

$$R_\ell(k,r) \underset{r\to\infty}{\simeq} \frac{c_\ell}{2k} i \left[e^{-i\eta_\ell} \frac{e^{-i(kr-\frac{1}{2}\ell\pi)}}{r} - e^{i\eta_\ell} \frac{e^{i(kr-\frac{1}{2}\ell\pi)}}{r} \right]\ , \tag{33.16}$$

we see that for $r \to \infty$ the stationary solution $R_\ell(k,r)$ can be regarded as an 'incoming' spherical wave interfering with an 'outgoing' spherical wave. It is convention to choose the phase of the normalization constant such that the phase of the incoming wave is zero,

$$R_\ell(k,r) \underset{r\to\infty}{\simeq} \frac{c'_\ell}{2k} i \left[\frac{e^{-ikr}}{r} - e^{-i\ell\pi} e^{2i\eta_\ell} \frac{e^{ikr}}{r} \right] , \tag{33.17}$$

Apart from the sign, the ratio of the phase factors of the outgoing over the incoming wave is,

$$\mathcal{S}_\ell = e^{2i\eta_\ell} . \tag{33.18}$$

This quantity is called the scattering matrix ($\mathcal{S}$ matrix) or, better, the l-wave contribution to the $\mathcal{S}$ matrix. Being unitary it does not suffer from the divergences of the ratio $B_\ell/A_\ell = \tan\eta_\ell$. In the present context the name scattering matrix is a bit heavy because we only have a single matrix element (1×1 matrix). The term matrix finds its origin in the description of scattering of particles with an internal degree of freedom (like spin), for which the phase factor is replaced by a unitary matrix.

33.1.2 Hard-sphere potentials

We now turn to analytical solutions for model potentials in the limit of low energy. We first consider the case of two hard spheres of equal size. These can approach each other to a minimum distance equal to their diameter a. For $r \le a$ the radial wave function vanishes, $R_\ell(r) = 0$: Outside the hard sphere we have free atoms, $V(r) = 0$, with relative wave number $k = [2m_r E/\hbar^2]^{1/2}$. Thus, for $r \le a$ the general solution for the radial wave functions of angular momentum ℓ is given by the free atom expression (33.11), which asymptotically this takes the form (33.15) of a phase-shifted spherical Bessel function,

$$R_\ell(k,r) = c_\ell[\cos\eta_\ell\ j_\ell(kr) + \sin\eta_\ell\ n_\ell(kr)] \underset{r\to0}{\simeq} \frac{c_\ell}{kr} \sin(kr + \eta_\ell - \tfrac{1}{2}\ell\pi) . \tag{33.19}$$

To determine the phase shift we require as a boundary condition that $R_\ell(k,r)$ vanishes at the surface of the hard sphere (see Fig. 33.3),

$$\cos\eta_\ell\ j_\ell(ka) + \sin\eta_\ell\ n_\ell(ka) = 0 . \tag{33.20}$$

Hence, the phase shift follows from the expression,

$$\tan\eta_\ell = \frac{j_\ell(ka)}{n_\ell(ka)} . \tag{33.21}$$

This expression allows to derive asymptotic expressions (for $ka \ll 1$ and for $ka \gg 1$) for the radial wave function (33.19), as will be shown in Exc. 33.1.5.1.

33.1.2.1 s-wave phase shifts for hard spheres

For the case $\ell = 0$, inserting the analytical expressions for the Bessel and von Neumann function, (33.19) becomes without approximation,

$$R_0(k,r) = \frac{c_0}{kr}(\cos\eta_0 \sin kr + \sin\eta_0 \cos kr) = \frac{c_0}{kr} \sin(kr + \eta_0) . \tag{33.22}$$

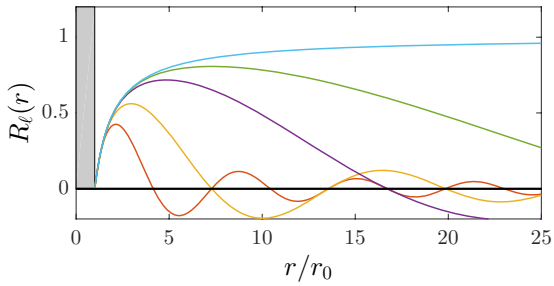

Figure 33.3: (code) Radial wavefunctions ($\ell = 0$) for various values of k (down to the $k \to 0$ limit) in the case of a hard sphere potential. The boundary condition is fixed by the requirement that the wavefunction vanishes at the edge of the hard sphere, $R_0(ka) = 0$.

The phase shift follows from the boundary condition $R_0(k, a) = 0$, which can be written in the form,

$$\cos\eta_0 \sin ka + \sin\eta_0 \cos ka = 0 \ . \tag{33.23}$$

Hence, the phase shift is

$$\eta_0 = -ka \ . \tag{33.24}$$

With this expression Eq. (33.22) reduces to

$$R_0(k, r) = \frac{c_0}{kr} \sin[k(r - a)] \ . \tag{33.25}$$

This expression is exact for any value of k, as announced above. The linear k dependence of η_0 simply expresses its definition in which the shift of the wave (by a) is compared to the de Broglie wavelength λ_{dB}, $\eta_0 = -2\pi a/\lambda_{dB}$. As a consequence the phase shift vanishes for $k \to 0$,

$$\lim_{k\to 0} \eta_0(k) = 0 \ . \tag{33.26}$$

This result is obvious when comparing the finite shift a to the diverging wavelength λ_{therm}. Interestingly, in the limit $k \to 0$ the expression (33.25) becomes k independent,

$$R_0(r) \underset{k\to 0}{\sim} 1 - \frac{a}{r} \qquad \text{for} \qquad a \le r \ll 1/k \ . \tag{33.27}$$

This important result is illustrated in Fig. 33.3. In the limit $k \to 0$ the wavefunction is essentially constant throughout space (up to a distance $1/k \to \infty$ at which it starts to oscillate), except for a small region of radius a around the potential center.

33.1.3 Spherical wells with a flat bottom

The second model potential to consider is the spherical well of range r_0 sketched in Fig. 33.4,

$$\tilde{V}(r) = \begin{cases} 2m_r V_0/\hbar^2 = \tilde{V}_0 = -\kappa_0^2 & \text{for } r \le r_0 \\ 0 & \text{for } r > r_0 \end{cases} \ . \tag{33.28}$$

Here $|U_0| = \kappa_0^2$ is called the well depth (κ_0 is chosen to be real and positive, $\kappa_0 > 0$). The energy of the continuum states is given by $\varepsilon = k^2$. In analogy, the energy of the bound states is written as,

$$\varepsilon_b = -\kappa^2 \ . \tag{33.29}$$

We now have to solve the radial wave equation (33.6) with the spherical well potential (33.28). Since the potential is constant inside the well ($r \leq r_0$) the wavefunction has to be free-particle like with the wave number given by,

$$K_+ = \sqrt{2m_r(E - V_0)/\hbar^2} = \sqrt{\kappa_0^2 + k^2} \ . \tag{33.30}$$

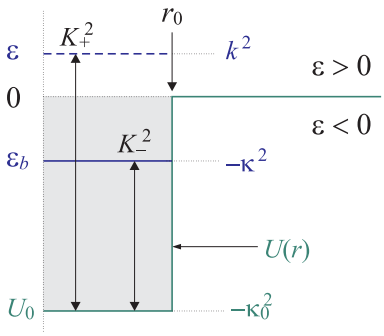
As the wavefunction has to be regular in the origin, inside the well it is given by,

$$R_\ell(r) = C_\ell j_\ell(K_+ r) \quad \text{for } r \leq r_0 \ , \tag{33.31}$$

where C_ℓ is a normalization constant. This expression holds for $E > V_0$ (both $E > 0$ and $E \leq 0$).

Outside the well ($r > r_0$) we have for $E > 0$ free atoms, $\tilde{V}(r) = 0$, with relative wavevector $k = [2m_r E/\hbar^2]^{1/2}$. Thus, for $r > r_0$ the general solution for the radial wave functions of angular momentum ℓ is given by the free atom expression (33.11),

$$R_\ell(k, r) = c_\ell[\cos\eta_\ell \ j_\ell(kr) + \sin\eta_\ell \ n_\ell(kr)] \quad \text{for } r > r_0 \ . \tag{33.32}$$



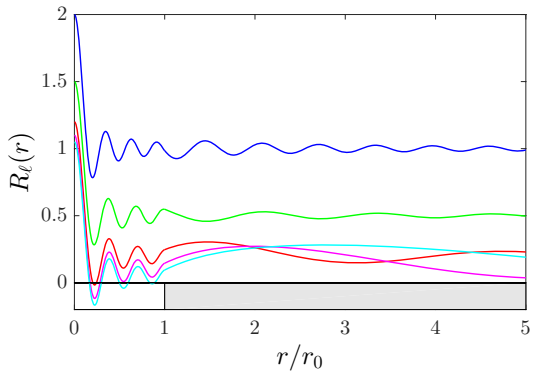


Figure 33.4: (code) (Left) Scheme of the flat bottom potential. (Right) (a) Radial wavefunctions for square wells: (a) continuum state ($\varepsilon = k^2 > 0$); (b) Zero energy state ($\varepsilon = k^2 = 0$) in the presence of an asymptotically bound level ($\varepsilon = -\kappa^2 = 0$); (c) bound state ($\varepsilon = -\kappa^2 < 0$). Note the continuity of $R_0(r)$ and $R_0'(r)$ at $r = r_0$. The wavefunctions are not normalized and are shifted relative to each other only for reasons of visibility.

The full solution [see Fig. 33.4(a)] is obtained by the continuity conditions for $R_\ell(r)$ and $R_\ell'(r)$ at the boundary $r = r_0$. These imply continuity of the logarithmic derivative with respect to r,

$$K_+ \frac{j_\ell'(\varrho_i)}{j_\ell(\varrho_i)} = \left.\frac{R_\ell'(r)}{R_\ell(r)}\right|_{r=r_0} = k \frac{\cos\eta_\ell \ j_\ell'(\varrho_e) + \sin\eta_\ell \ n_\ell'(\varrho_e)}{\cos\eta_\ell \ j_\ell(\varrho_e) + \sin\eta_\ell \ n_\ell(\varrho_e)} \ , \tag{33.33}$$

where we defined the abbreviations $\varrho_i \equiv K_+ r_0$ and $\varrho_e \equiv k r_0$. This ratio suffices to determine η_ℓ independently of the normalization constants C_ℓ and c_ℓ. Once the phase shift is known, the relation between C_ℓ and c_ℓ follows from the continuity condition for $R_\ell(r)$. Furthermore, it shows that the asymptotic phase shift η_ℓ can take any (real) value depending on the depth of the well. In view of the importance of the $\mathcal{S}$ matrix in scattering theory Sec. 33.2, it is advantageous to determine $e^{2i\eta_\ell}$ rather than η_ℓ itself. Expressing $\sin\eta_\ell$ and $\cos\eta_\ell$ in terms of $e^{i\eta_\ell}$ and $e^{-i\eta_\ell}$ Eq. (33.33) becomes,

$$K_+ \partial_\varrho \ln j_\ell(\varrho_i) = k \frac{e^{2i\eta_\ell} h_\ell^{(2)\prime}(\varrho_e) + h_\ell^{(1)\prime}(\varrho_e)}{e^{2i\eta_\ell} h_\ell^{(2)}(\varrho_e) + h_\ell^{(1)}(\varrho_e)} \ , \tag{33.34}$$

with the definition of the Hankel functions of the first and second kind: $h_\ell^{(1,2)} \equiv j_\ell \pm i n_\ell$. Solving for $e^{2i\eta_\ell}$ this leads to the following expression for the ℓ-wave contribution to the $\mathcal{S}$ matrix,

$$\boxed{e^{2i\eta_\ell} = -\frac{h_\ell^{(1)}(\varrho_e)}{h_\ell^{(2)}(\varrho_e)} \frac{K_+ \partial_\varrho \ln j_\ell(\varrho_i) - k \partial_\varrho \ln h_\ell^{(1)}(\varrho_e)}{K_+ \partial_\varrho \ln j_\ell(\varrho_i) - k \partial_\varrho \ln h_\ell^{(2)}(\varrho_e)}} \ , \tag{33.35}$$

where the expression $\partial_\varrho \ln$ stands for the logarithmic derivative. This expression may look a bit heavy, but is valuable as it represents the exact result for arbitrary ℓ. In Exc. 33.1.5.2 we simplify this formula for $\ell = 0$. As the formula (33.35) lacks transparency from the physical point of view, we analyze in the coming sections the case $\ell = 0$ directly discussing the radial wavefunctions u_ℓ.

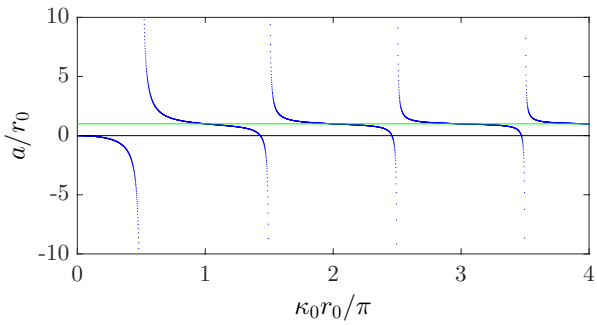

Figure 33.5: (code) The s-wave scattering length a normalized on r_0 as a function of the depth of a spherical square potential well (blue curve). Note that, typically, $a \simeq r_0$ (green line), except near the resonances at $\kappa_0 r_0 = (n + \frac{1}{2})\pi$ being an integer.

33.1.3.1 s-wave scattering ($E > 0$)

The analysis of spherical well potentials becomes particularly simple for the case $\ell = 0$. Let us first consider the case $E > 0$, for which the radial wave equation can be written as a 1D-Schrödinger equation (33.7) of the form,

$$u_0'' + [k^2 - \tilde{V}(r)] u_0 = 0 \ . \tag{33.36}$$

The solution is,

$$u_0(kr) = \begin{cases} C_0 \sin(K_+ r) & \text{for } r \leq r_0 \\ c_0 \sin(kr + \eta_0) & \text{for } r > r_0 \end{cases} . \tag{33.37}$$

To determine $\eta_0(k)$ it is sufficient to apply the boundary condition for continuity of the logarithmic derivative at the edge of the well,

$$\left.\frac{u_0'}{u_0}\right|_{r=r_0} = K_+ \cot K_+ r_0 = k \cot(kr_0 + \eta_0) . \tag{33.38}$$

Note that this expression coincides with the general result given by Eq. (33.33) for the case $\ell = 0$; i.e. the boundary condition of continuity for u_0'/u_0 coincides with that for R_0'/R_0, as we know from a calculation left to Exc. 33.1.5.3. Furthermore, for a vanishing potential ($\kappa_0 \to 0$) we have $K_+ \to k$ and the boundary condition properly yields a zero phase shift ($\eta_0 = 0$).

At this point we introduce the effective hard-sphere diameter $a(k)$ to describe, in analogy with Eq. (33.24), the behavior of the phase shift,

$$\eta_0(k) \equiv -ka(k) . \tag{33.39}$$

By this procedure we extract the linear k dependence as well as the negative sign from the phase shift. This is a good idea because the linear k-dependence does not arise from the potential but simply from the definition of the phase in which, as discussed earlier, the shift of the wave is compared to the de Broglie wavelength. In the limit $k \to 0$, we have $K_+ r_0 \to \kappa_0 r_0$ and with the definition,

$$a \equiv \lim_{k\to 0} a(k) = -\lim_{k\to 0} \eta(k)/k \tag{33.40}$$

the boundary condition (33.38) becomes,

$$\left.\frac{u_0'}{u_0}\right|_{r=r_0} = \kappa_0 \cot \kappa r_0 = \frac{1}{r_0 - a} . \tag{33.41}$$

Solving for a we find,

$$a = r_0 \left(1 - \frac{\tan\gamma}{\gamma}\right) , \tag{33.42}$$

where the dimensionless positive quantity,

$$\gamma \equiv \kappa_0 r_0 \tag{33.43}$$

is called the well parameter. As shown in Fig. 33.5, the value of a can be positive, negative or zero depending on the value of γ. Therefore, rather than using the pictorial term effective hard-sphere diameter the name scattering length is used for a. Next to the range, the scattering length represents the second characteristic length that can be associated with the interaction potential. As the name suggest, it is a measure for the scattering behavior of atoms, and we elaborate on this in Sec. 33.2. Also, in Sec. ?? we will show that a is also a measure for the effective strength of the interaction.

Fig. 33.5 and Eq. (33.42) show that a is typically a quantity of the size of r_0, although for $\gamma = \tan\gamma$ it is zero and for $\gamma = (\nu + \frac{1}{2})\pi$, with ν being an integer,

it diverges. The latter condition points to a resonance phenomenon occurring when (with increasing γ) a new bound level enters the potential well. For the square well potential the scattering length is mostly positive; it is negative in the regions with $\gamma < \tan\gamma$, which become narrower for increasing γ. This unlikely occurrence of negative a is atypical for the general case; e.g. for Van der Waals potentials the probability to find a negative scattering length is 25% .

For $r \geq r_0$ the radial wavefunction corresponding to Eq. (33.37) is of the form,

$$R_0(k,r) = \frac{c_0}{kr}\sin[kr - ka(k)] \ . \tag{33.44}$$

Recalling the definitions (33.39) and (33.40) we find that for $k \to 0$ this radial wavefunction becomes k-independent,

$$R_0(r) \underset{k\to 0}{\sim} 1 - \frac{a}{r} \qquad \text{for} \qquad r_0 < r \ll \frac{1}{k} \ . \tag{33.45}$$

The latter two expressions for the radial wavefunction have the same formal appearance as the hard sphere results (33.25) and (33.27). However, whereas the diameter of the hard-sphere has a fixed value, the scattering length for the well depends on γ. As shown in Fig. 33.6, for positive scattering length the s-wave has a characteristic node at $r = a$; for negative scattering length this becomes a virtual node.

Importantly, because Eq. (33.45) reaches the asymptotic value 1 only for distances $r \gg a$, the use of this equation in the modeling of dilute gases is only justified if a is much smaller than the interparticle spacing,

$$na^3 \ll 1 \ . \tag{33.46}$$

Otherwise, the interaction with neighboring atoms will distort the relative motion of the colliding pair. This violates the binary scattering approximation on which Eq. (33.45) is based. The dimensionless quantity na^3 is called the gas parameter. When its value is small, the gas is called nearly ideal or weakly interacting [2].

33.1.3.2 Bound s-levels ($E \leq 0$)

Let us turn to the case $E \leq 0$. We shall show that the divergences of the scattering length obtained by analyzing the continuum states ($E > 0$) result from the appearance of the next bound s-level when increasing the well parameter. The 1D Schrödinger equation takes the form,

$$u_0'' + [-\kappa^2 - \tilde{V}(r)]u_0(r) = 0 \ . \tag{33.47}$$

where $\varepsilon = -\kappa^2$ is the discrete energy eigenvalue of a bound state with $\ell = 0$. The solutions are of the type (see Fig. 33.30),

$$u_0(k,r) = \begin{cases} C_0 \sin K_- r & \text{for } r \leq r_0 \\ c_0 e^{-\kappa r} & \text{for } r \leq r_0 \end{cases} \tag{33.48}$$

[2] Note that weakly interacting does not mean that that the potential is 'shallow'. Any gas can be made weakly interacting by making the density sufficiently small.

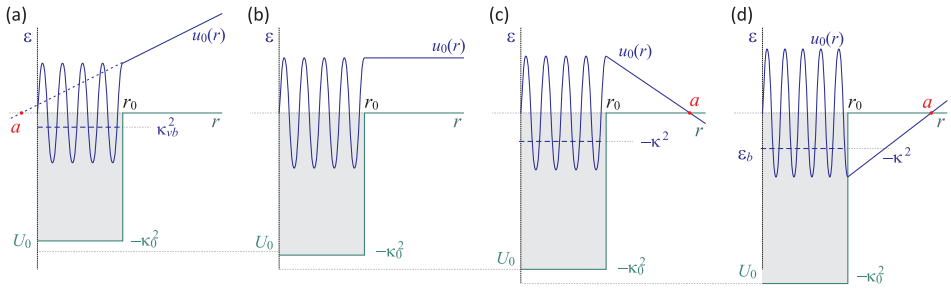

Figure 33.6: Reduced radial wavefunctions $u_0(r)$ for continuum states ($\varepsilon > 0$) in the $k \to 0$ limit for increasing well depth near the threshold value $\kappa_0 r_0 = (n + \frac{1}{2})\pi$: (a) presence of an almost bound state ($a < 0$); (b) presence of zero-energy resonance ($\kappa_{vb} = 0$, $a \to \pm\infty$); (c) presence of a weakly bound state ($a > 0$); (d) deeper binding of the least bound state. For $r > r_0$ the wavefunction is given by $u_0(r) = c_0(r - a)$; hence, the value of a is given by the intercept with the horizontal axis. This gives rise to a characteristic node at $r = a$, which is *real* for $a > 0$ (just as for hard spheres of diameter a), but *virtual* for $a < 0$. The wavefunctions are not normalized.

where $\kappa > 0$ because the bound state wavefunction has to be normalized. The bound state energy is obtained by requiring the continuity of the logarithmic derivative when connecting the inner part of the wavefunction to the outer part,

$$\left.\frac{u_0'(r)}{u_0(r)}\right|_{r=r_0} = K_- \cot K_- r_0 = -\kappa \ , \tag{33.49}$$

where $\kappa > 0$ and

$$K_- = [2m_r(E - V_0)/\hbar^2]^{1/2} = (\kappa_0^2 - \kappa^2)^{1/2} \ . \tag{33.50}$$

With decreasing γ, the least bound level disappears in the limit $\kappa \to 0$, $K_- \to \kappa_0$. In this limit Eq. (33.49) reduces to,

$$\left.\frac{u_0'(r)}{u_0(r)}\right|_{r=r_0} = \kappa_0 \cot \kappa_0 r_0 \underset{\kappa\to 0}{=} 0 \ , \tag{33.51}$$

Increasing from zero the vibrational levels appear sequentially for

$$\gamma = (v + \tfrac{1}{2})\pi \ , \tag{33.52}$$

where $v = 0, 1, .., r_{max}$ is the vibrational quantum number. This shows that a minimum well parameter ($\gamma = \pi/2$) is required to bind the first state [3]. For the least-bound level, v_{max}, we have,

$$(v_{max} + \tfrac{1}{2})\pi = \text{Int } (\tfrac{\gamma}{\pi} - \tfrac{1}{2}) \tag{33.53}$$

and the total number of bound s levels follows with,

$$N_b = v_{max} + 1 = \text{Int } (\tfrac{\gamma}{\pi} + \tfrac{1}{2}) \ . \tag{33.54}$$

[3]This conclusion cannot be extended to lower dimensions; in two dimensions bound states appear for arbitrarily shallow potentials.

The relation between κ and v for a given vibrational level depends on the ratio κ/K_- and is given by

$$\cot K_- r_0 = -\frac{\kappa}{K_-} \ . \tag{33.55}$$

Note that this relation corresponds to $K_- r_0 \simeq (v_{max} + \frac{1}{2})\pi$ for the least-bound state

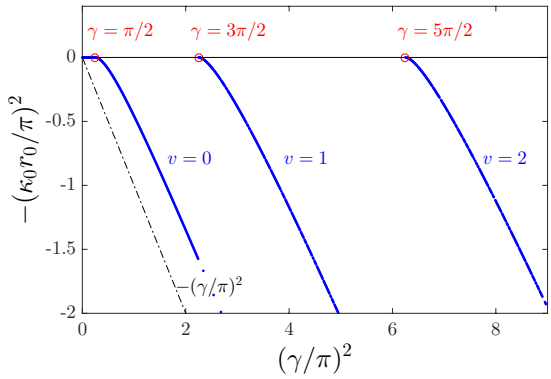

Figure 33.7: (code) Appearance and increase of binding of the first three bound levels for increasing well depth. The quadratic dependence near threshold is universal (i.e. independent of the well shape). The full crossover curve is obtained by numerical solution of Eq. (33.49) and corresponds to a $\pi/2$ phase shift of $K_+ r_0$ near threshold. The dashed line shows the increase in well depth.

$(\kappa/K- \ll 1)$ and to $K_- r_0 \simeq (v_{max} + 1)\pi$ for deeply bound levels $(K_-/\kappa \ll 1)$, as is illustrated in Fig. 33.8(a).

33.1.3.3 Weakly bound s-level: halo states

For weakly bound s levels $(0 < \kappa r_0 \ll 1)$ we have $K_- \to \kappa_0$ and Eq. (33.49) may be approximated by

$$\left.\frac{u_0'(r)}{u_0(r)}\right|_{r=r_0} = \kappa_0 \cot \kappa_0 r_0 = -\kappa \ , \tag{33.56}$$

Furthermore, we recall that in the presence of a weakly bound s-level the scattering length is large and positive, $a \gg r_0$. From Eq. (33.41) we recall that for $k \to 0$ the logarithmic derivative also satisfies the relation

$$\left.\frac{u_0'(r)}{u_0(r)}\right|_{r=r_0} = \kappa_0 \cot \kappa_0 r_0 = \frac{1}{r_0 - a} \simeq -\frac{1}{a} \ , \tag{33.57}$$

Interestingly, for $a \gg r_0$ the logarithmic derivative of the continuum states becomes independent of r_0 and κ_0; i.e. it becomes independent of the shape of the potential well. As we shall see it only depends on the well parameter γ and not on the well shape. This points to a universal limiting shape of the wavefunction for large scattering length. As is sketched in Fig. 33.8(b), for decreasing κ the least-bound state turns into a halo state; i.e. for $\kappa r_0 \ll 1$ most of the probability of the bound state is found in the classically inaccessible region outside the potential well, thus surrounding the

potential center like a halo. This behavior holds for arbitrary short-range potentials.

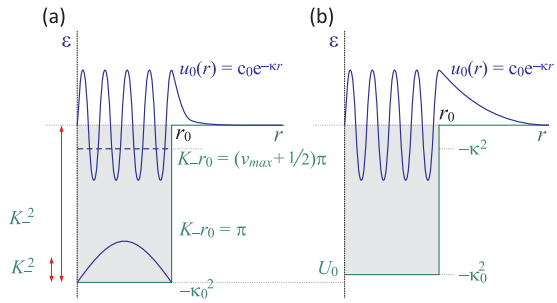

Figure 33.8: Bound states oscillate inside the well and decay exponentially outside the well: (a) the boundary condition depends on the ratio κ/K_-; (b) a slight reduction of the well depth can turn the least bound state into a halo state.

With Eqs. (33.56) and (33.57) we have obtained two expressions for $\kappa_0 \cot \kappa_0 r_0$ and arrive at the conclusion that in the presence of a weakly bound state the scattering length is given by,

$$a \underset{\kappa \to 0}{\simeq} 1/\kappa \ . \tag{33.58}$$

This expression reveals the tight relation between the binding energy of the least-bound state, given by Eq. (33.29), and the scattering length,

$$\boxed{E_b = -\frac{\hbar^2 \kappa^2}{2m_r} \underset{\kappa \to 0}{\longrightarrow} -\frac{\hbar^2}{2m_r a^2}} \ . \tag{33.59}$$

33.1.3.4 *s*-wave resonances in the continuum: The Breit-Wigner formula

To obtain the k-dependence of the phase shift for large but otherwise arbitrary well parameter ($\gamma \gg 1$) we rewrite the boundary condition (33.38) in the form,

$$\eta_0(k) = -kr_0 + \arctan \frac{kr_0}{K_+ r_0 \cot K_+ r_0} \equiv \eta_{bg} + \eta_{res} \ . \tag{33.60}$$

The first term of (33.60) is called the *background contribution* to the phase shift and the second term the *s*-wave *resonance contribution*. Note that the background contribution shows the same phase development as we found in Sec. 33.1.2 for hard spheres. The phase development of the resonance contribution is shown in Fig. 33.9(a) for the case of a large well parameter slightly detuned from the threshold value (at $\gamma = 31.5\pi \approx 98.960169$) such that the scattering length is negative ($\Delta_\gamma = -0.5$). For potentials with $\gamma \gg 1$ the argument of the arctangent is predominantly small, $kr_0/|K_+ r_0 \cot K_+ r_0| \ll 1$, because

$$K_+ r_0 = \kappa_0 r_0 (1 + k^2/\kappa_0^2)^{1/2} > \gamma \gg 1 \ . \tag{33.61}$$

However, the argument of the arctangent diverges when $\cot K_+ r_0$ passes through zero; i.e. for

$$K_+ r_0 = (\tilde{v} + \tfrac{1}{2})\pi \ , \tag{33.62}$$

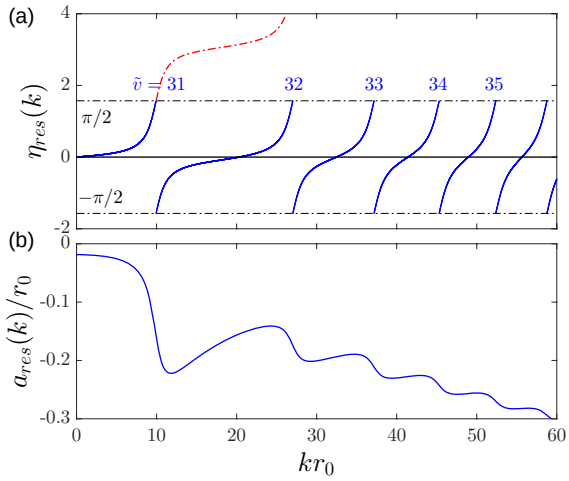

Figure 33.9: (code) (a) Resonance contribution to the s-wave phase shift $\eta_0(k)$ for a large well parameter slightly detuned from the threshold value (at $\gamma = 31.5\pi$), such that the scattering length is negative ($\Delta\gamma = -0.5$): The linear shift of the background contribution is not included in the plot. Note that the π phase jumps arise from the modulo-π representation of the arctangent and do not represent an observable phenomenon; the physical phase increases monotonically and equals $\eta_{res} = \frac{1}{2}$ (modulo π) at the center of the resonances; (b) contribution of the resonances to the effective hard sphere diameter $a(k) = -\eta_0(k)/k$. As (in this example) the lowest resonance is not close to threshold the resonant enhancement is small, $|a_{res}(k)| = r_0 \ll 1$.

where $\tilde{v}$ is an integer called the resonance index. This divergence is observed as a small resonant enhancement of $a(k)$, as shown in Fig. 33.9(b). The physical phase is a continuous function of k, which changes by π when sweeping across the resonance. Because the arctangent remains finite for $\cot K_+ r_0 = 0$ also the resonant phase shift remains finite, having the value $\eta_{res}(k) = \frac{1}{2}\pi$ (modulo π) at the center of each resonance.

In the remainder of this section we shall analyze the width and separation of the s-wave resonances for the case $\gamma \gg 1$. Since $K_+ \geq \kappa_0 \geq K_-$, we have,

$$\tilde{v} \geq \tfrac{\gamma}{\pi} - \tfrac{1}{2} \geq v_{max} \ , \tag{33.63}$$

which shows that for $\gamma \gg 1$ the value of $\tilde{v}$ is large ($\tilde{v}_{min} \geq \tilde{v}_{max} \gg 1$). Hence, the resonance numbering starts where the numbering of bound states ends. To discuss the resonances we denote the wavevectors k and K_+ at resonance by k_{res} and $K_{res} \equiv \sqrt{\kappa_0^2 + k_{res}^2}$, respectively. The resonance energies $\varepsilon_{res} = k_{res}^2$ satisfy the condition,

$$\varepsilon_{res} = K_{res}^2 - \kappa_0^2 = (\tilde{v} + \tfrac{1}{2})\pi(\tfrac{\pi}{r_0})^2 - \kappa_0^2 \geq 0 \ . \tag{33.64}$$

The exceptional case for which the equal sign applies ($\tilde{v} = v_{max}$) corresponds to a resonant bound state ($\kappa = 0$) and the resonance is called a resonance at threshold or zero-energy resonance ($k_{res} = 0$).

Let us first analyze s-wave resonances for large well parameters ($\tilde{v} = v_{max}$) and far from threshold, ($\kappa = 0$). The energy spacing between two subsequent resonances

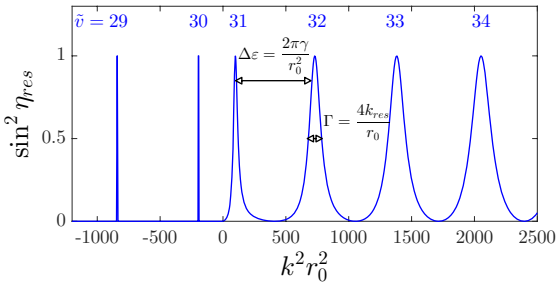

Figure 33.10: (code) (a) Transition from bound states to Breit-Wigner s-wave resonances plotted for $\Delta\gamma = -0.5$ with respect to the threshold at $\gamma = 31.5\pi$ (same conditions as Fig. 33.9). The bound states are indicated as zero-width spikes at energies $\varepsilon = -\kappa^2$, with κ following from Eq. (33.49). For $\varepsilon > 0$ the plot is based on Eqs. (33.60). The width of the resonances increases with the square root of the energy. Note that the band of energies typical for the quantum gases ($kr_0 \ll 1$) corresponds to a narrow zone, unresolved on the energy scale of the plot.

is,

$$\Delta\varepsilon_{res} = \varepsilon_{res}^{(\tilde{v}+1)} - \varepsilon_{res}^{(\tilde{v})} = 2(\tilde{v}+1)\tfrac{\pi^2}{r_0^2} \simeq \tfrac{2\pi\gamma}{r_0^2} \ . \tag{33.65}$$

To analyze a given resonance we expand $K_+ \cot K_+ r_0$ about the point of zero crossing. For this purpose we introduce the notation,

$$K_+ = \sqrt{\kappa_0^2 + (k_{res}+\delta k)^2} = K_{res} + \frac{\delta k\ k_{res}}{K_{res}} \ , \tag{33.66}$$

where $\delta k = k - k_{res}$ is called the detuning from resonance. Thus, restricting ourselves to the low-energy (but not zero energy) s-wave resonances ($1 < k_{res}r_0 \ll K_{res}r_0 \simeq \gamma$), we may approximate $K_+ \cot K_+ r_0 \simeq K_{res} \cot K_+ r_0$. Expanding $\cot K_+ r_0$ about the zero crossing at $K_+ r_0 = (\tilde{v}+1/2)\pi$ and retaining only the linear term we obtain (see Problem 3.4),

$$K_{res} \cot K_+ r_0 = -\delta k\ k_{res} r_0 \ . \tag{33.67}$$

Hence, the diverging argument of the arctangent becomes,

$$\tan\eta_{res} = \frac{k}{K_+ \cot K_+ r_0} \simeq -\frac{1}{\delta k\ r_0} = \frac{-(k+k_{res})}{(k^2-k_{res}^2)r_0} \simeq \frac{-2k_{res}/r_0}{\varepsilon-\varepsilon_0} \ . \tag{33.68}$$

The expansion (33.66) is valid over the full range of the resonant change in phase provided the following condition holds,

$$\delta k\ r_0 \ll \frac{K_{res}}{k_{res}} \simeq \tfrac{\gamma}{k_{res}r_0} \ , \tag{33.69}$$

which is satisfied for the lowest resonances as long as the well parameter is sufficiently large ($\gamma \gg k_{res}r_0$). As long as $\delta k \ll k_{res}$ we may further approximate $k \simeq k_{res}$. With these approximations and after restoring the dimensions, Eq. (33.68) can be written as a function of the energy $E = \hbar^2 2k^2/2m_r$,

$$\tan\eta_{res} = \frac{k}{K_+ \cot K_+ r_0} \simeq \frac{-\Gamma^2}{\varepsilon-\varepsilon_{res}} \ , \tag{33.70}$$

where

$$\Gamma/2 = 2k_{res}/r_0 \tag{33.71}$$

is called the spectral width of the resonance. Comparing the expressions for Γ and ΔE_{res} we find that for given r_0 the width Γ is independent of γ, whereas the resonance spacing is proportional to γ . Thus, only for sufficiently large well parameters ($\gamma \gg 1$) the spectral width becomes smaller than the resonance spacing,

$$\Gamma \ll \Delta\varepsilon_{res} \Longleftrightarrow k_{res} r_0 \ll \pi\gamma \ . \tag{33.72}$$

Knowing the tangent of η_{res}, we readily obtain the sine and Eq. (33.70) is replaced by the *Breit-Wigner formula*,

$$\sin^2 \eta_{res} = \frac{(\Gamma/2)^2}{(\varepsilon - \varepsilon_0)^2 + (\Gamma/2)^2} \ . \tag{33.73}$$

For optical resonances this energy dependence is known as the Lorentz lineshape. Note that Γ corresponds to the full-width-at-half-maximum (FWHM) of this line shape. The lowest energy resonances are plotted in Fig. 33.10 along with the highest-energy bound states.

The resonance near threshold (almost bound level) deserves special attention, as this type of resonance is the only one that can play an important role within the band of energies relevant for the quantum gases ($kr_0 \ll 1$). Fig. 33.10 shows that near the threshold (at $\gamma = 31.5\pi$) the resonance narrows down and becomes asymmetric, which means that the Breit-Wigner lineshape is lost. Using Eq. (33.54) we calculate $\tilde{v} = 31$. The narrow line is reminiscent of a bound level but the scattering length is negative (see Fig. 33.10). Under these conditions the wavefunction has a virtual node at $r = -|a|$ (see Fig. 33.30). Accordingly, the level is called a virtual level and the wavefunction is said to represent a virtual bound state. In analogy with the bound states its energy is written as $\varepsilon = \kappa_{res}^2$, where κ is to be defined later.

33.1.4 Other types of potentials

33.1.4.1 Zero-range potentials

An important model potential is obtained by considering a spherical well in the zero-range limit $r_0 \to 0$. As illustrated in Fig.33.11, it is possible to construct a zero-range well in such a way that the long-range properties of the wavefunction are unaffected; i.e. the scattering length a and the binding energy $\varepsilon = -\kappa^2$ of the least-bound state remain unchanged.

For $E < 0$ this can be demonstrated with the aid of the boundary condition (33.49),

$$-\kappa = K_- \cot K_- r_0 \ . \tag{33.74}$$

Reducing the radius r_0 the value of the binding energy $\varepsilon = -\kappa^2$, can be conserved by increasing κ_0. In the limit $r_0 \to 0$ the well depth should diverge in accordance with,

$$-\frac{\kappa}{K_-} = \cot K_- r_0 \to 0 \ . \tag{33.75}$$

This condition is satisfied for $K_- r_0 \simeq \pi/2$. To elucidate this point we consider the least-bound level with vibrational quantum number $v = v_{max}$, for which $K_- r_0 =$

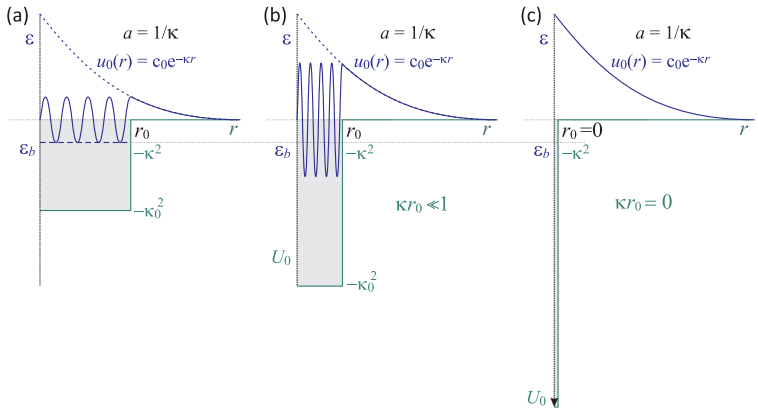

Figure 33.11: Wavefunctions corresponding to the same binding energy ($\varepsilon = -\kappa^2$) plotted for three different values of r_0. Outside r_0 the wavefunctions fall off exponentially, always with the same decay exponent κ; this is the essence of the Bethe-Peierls boundary condition. The dashed lines show the extrapolation for $r \to 0$. (a) reference case; (b) for $\kappa r_0 \ll 1$ most of the probability density of a bound state is found outside the well (halo state); (c) for zero-range potentials ($\kappa r_0 = 0$) the oscillating part of the wavefunction is compressed into a delta function and only the decaying exponent remains (universal limit). Note that these wavefunctions do not share the same normalization.

$(v_{max} + 1/2)\pi$. Reducing r_0 by a factor of 2 the wavenumber K_- has to be doubled to conserve the number of nodes in the wavefunction (i.e. to conserve v_{max}). This means that the kinetic energy inside the well has to increases by a factor 4. Since for the least-bound level we have $K_- r_0 \simeq \gamma$, it means that in this case the binding energy can be conserved at effectively constant well parameter. Obviously, the freedom to conserve (for decreasing r_0) the binding energy of one of the levels can only be used once. It does not hold for the other levels because the level separation diverges with κ_0. In the zero range limit the potential only supports a single bound state and the wavefunction of that state is given by,

$$R_0(r) = c_0 \frac{e^{-\kappa r}}{r} \qquad \text{for} \qquad r > 0 \ , \tag{33.76}$$

and with $\kappa > 0$. Unit normalization, $\int r^2 R_0^2(r) dr = 1$, is obtained for $c_0 = \sqrt{2\kappa}$. For $E > 0$ we can arrive at the same conclusion. The boundary condition for $k \to 0$ and given value of r_0 is given by Eq. (33.41), which we write in the form,

$$\frac{1}{r_0 - a} = \kappa_0 \cot \kappa_0 r_0 \ . \tag{33.77}$$

Reducing the radius r_0, the scattering length a can be conserved by increasing κ_0. In the limit $r_0 \to 0$ the well depth should diverge in accordance with,

$$-\frac{1}{\kappa_0 a} = \cot \kappa_0 r_0 \to 0 \ . \tag{33.78}$$

This is again satisfied for $\kappa_0 r_0 \simeq \pi/2$. In the zero-range limit the radial wavefunction

for $k \to 0$ is given by,

$$R_0(k,r) = \frac{1}{kr}\sin[k(r-a)] \qquad \text{for} \qquad r > 0 \ , \tag{33.79}$$

which implies $R_0(k,r) \simeq 1 - a/r$ for $0 < r \ll 1/k$.

33.1.4.2 Bethe-Peierls boundary condition

Note that Eq. (33.76) is the solution for $E < 0$ of the 1D-Schrödinger equation in the zero-range approximation,

$$u_0'' - \kappa^2 u_0 \qquad \text{for} \qquad r > 0 \ , \tag{33.80}$$

under the boundary condition,

$$\left.\frac{u_0'}{u_0}\right|_{r\to 0} = -\kappa \ . \tag{33.81}$$

The latter relation is called the *Bethe-Peierls boundary condition* and was first used to describe the deuteron, the weakly bound state of a proton with a neutron [**?**]. It shows that for weakly bound states the wavefunction has the universal form of a halo state, which only depends on the binding energy, $\varepsilon_0 = -\kappa^2$ (see Fig. 33.11).

For $E > 0$ the 1D-Schrödinger equation in the zero-range approximation is given by,

$$u_0' + k^2 u_0 = 0 \qquad \text{for} \qquad r > 0 \ . \tag{33.82}$$

The general solution is $u_0(k,r) = c_0 \sin[kr + \eta_0]$. Using the Bethe-Peierls boundary condition we obtain,

$$k \cot \eta_0(k) = -\kappa \ , \tag{33.83}$$

which yields after substituting $\eta_0(k \to 0) \simeq -ka$ the universal relation between the scattering length and the binding energy in the presence of a weakly bound s-level, $\varepsilon_0 = -\kappa^2 = -1/a^2$.

33.1.4.3 Power-law potentials

The general results obtained in the previous sections presumed the existence of a finite range of interaction, r_0. Thus far this presumption was based only on the heuristic argument presented in Sec. **??**. To derive a proper criterion for the existence of a finite range and to determine its value r_0 we have to analyze the asymptotic behavior of the interatomic interaction [929]. For this purpose we consider potentials of the power-law type,

$$V(r) = -\frac{C_s}{r^s} \ , \tag{33.84}$$

where $C_s = V_0 r_c^s$ is the power-law coefficient, with $V_0 \equiv |V(r_c)| \equiv \hbar^2\kappa_c^2/2m_r$ the well depth. These power-law potentials are important from the general physics point of view, because they capture major features of interparticle interactions.

For power-law potentials, the radial wave equation (33.6) takes the form,

$$R_\ell'' + \frac{2}{r}R_\ell' + \left[k^2 + \frac{\kappa_c^2 r_c^s}{r^s} - \frac{\ell(\ell+1)}{r^2}\right] = 0 \ . \tag{33.85}$$

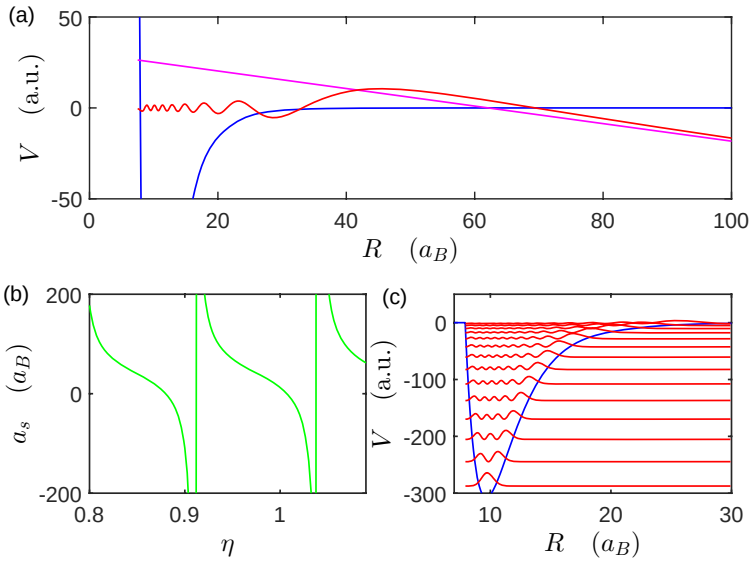

Figure 33.12: (code) Dependence of the scattering length on the potential depth.

Because this equation can be solved analytically in the limit $k \to 0$ it is ideally suited to analyze the conditions under which the potential $V(r)$ may be neglected and thus to determine r_0. To solve Eq. (33.85) we look for a clever substitution of the variable r and the function $R_\ell(r)$ to optimally exploit the known r dependence of the potential in order to bring the differential equation in a well-known form. To leave exibility in the transformation we search for functions of the type,

$$G_\ell(x) = r^{-\nu} R_\ell(r) \ , \tag{33.86}$$

where the power ν is to be selected in a later stage.

33.1.4.4 Computation of the scattering length

The scattering length depends on the *binding energy* E_v of weakly bound states. If a is positive and much greater than the range of the potential, then [542, 465] (33.59),

$$E_v = -\frac{\hbar^2}{2m_r a^2} \ . \tag{33.87}$$

More precisely, for a potential behaving at long range as,

$$V = -\frac{C_6}{R^6} \ , \tag{33.88}$$

we get,

$$E_v = -[(v_D - v)H(m_r, C_6)]^{-1/3} \ , \tag{33.89}$$

where v_D is the vibrational quantum number at the dissociation limit and H a constant. Also,

$$a = \frac{\Gamma(3/4)}{2\sqrt{2}\Gamma(5/4)} \left(\frac{2\mu C_6}{\hbar^2}\right)^{1/4} \left[1 - \tan \pi(v_D + \tfrac{1}{2})\right] \ . \tag{33.90}$$

33.1.4.5 Second method

It yields for $\gamma = \alpha, \beta$,

$$\tfrac{d^2}{dR^2}\varepsilon_\gamma(R) = 2m_r V(R)\varepsilon_\gamma(R) \ . \tag{33.91}$$

Successive approaches start with $\varepsilon_\alpha^{(0)} = R$ and $\varepsilon_\beta^{(0)} = 1$ and get superior orders via,

$$\tfrac{d^2}{dR^2}\varepsilon_\gamma^{(k+1)}(R) = 2m_r V(R)\varepsilon_\gamma^{(k)}(R) \ . \tag{33.92}$$

We define $\delta_\gamma^{(k)} \equiv \varepsilon_\gamma^{(k)} - \varepsilon_\gamma^{(k-1)}$ starting with $\delta_\gamma^{(0)} = \varepsilon_\gamma^{(0)}$, such that,

$$\tfrac{d^2}{dR^2}\delta_\gamma^{(k+1)}(R) = 2m_r V(R)\delta_\gamma^{(k)}(R) \ . \tag{33.93}$$

$\delta_\alpha(R \to \infty) = \delta_\beta(R \to \infty) = 0$. Since $\varepsilon_\alpha = \lim_{k\to\infty} \varepsilon_\alpha^{(k)}$, the wavefunction is thus obtained from,

$$U(R) = \alpha(1 + \delta_\alpha^{(1)} + \delta_\alpha^{(2)} + ..) + \beta(R + \delta_\beta^{(1)} + \delta_\beta^{(2)} + ..) \ . \tag{33.94}$$

This long-range expression must match the short-range value at a certain point R_0:

$$\begin{aligned} U(R_0) &= \alpha\varepsilon_\alpha(R_0) + \beta\varepsilon_\beta(R_0) \ . \\ U'(R_0) &= \alpha\tfrac{d}{dR}\varepsilon_\alpha(R_0) + \beta\tfrac{d}{dR}\varepsilon_\beta(R_0) \end{aligned} \tag{33.95}$$

and

$$a = -\frac{\beta}{\alpha} = \frac{U(R_0)\frac{d}{dR}\varepsilon_\alpha(R_0) - U'(R)\varepsilon_\alpha(R_0)}{U(R_0)\frac{d}{dR}\varepsilon_\beta(R_0) - U'(R)\varepsilon_\beta(R_0)} = \frac{\frac{d}{dR}\frac{\varepsilon_\alpha(R_0)}{U(R_0)}}{\frac{d}{dR}\frac{\varepsilon_\beta(R_0)}{U(R_0)}} \ . \tag{33.96}$$

Let us consider a specific potential,

$$\begin{aligned} V(R) &= \frac{1}{2}BR^{m_r}e^{-\eta R} - \left(\frac{C_6}{R^6} + \frac{C_8}{R^8} + \frac{C_{10}}{R^{10}}\right) f_c(R) \\ f_c(R) &= \theta(R_c - R)e^{-(R_c/R-1)^2} + \theta(R - R_c) \ . \end{aligned} \tag{33.97}$$

At very long range we have $V(R) \simeq -\frac{C_6}{R^6}$, such that,

$$\begin{aligned} \delta_\gamma^{(k+1)} &= \int_0^R 2m_r V\delta_\gamma^{(k+1)}dR = \delta_\gamma^{(k)}(\infty) - \int_R^\infty -\frac{2m_r C_6}{R^6}\delta_\gamma^{(k)}dR \\ &= 2m_r C_6 \int_R^\infty \frac{\delta_\gamma^{(k)}}{R^6}dR \ . \end{aligned} \tag{33.98}$$

In particular,

$$\begin{aligned} \delta_\alpha^{(1)} &= 2m_r C_6 \frac{-1}{4R^4} \quad , \quad \delta_\alpha^{(2)} = (2m_r C_6)^2 \frac{-1}{4\cdot 9R^9} \\ \delta_\beta^{(1)} &= 2m_r C_6 \frac{1}{5R^5} \quad , \quad \delta_\beta^{(2)} = (2m_r C_6)^2 \frac{1}{5\cdot 10R^{10}} \ . \end{aligned} \tag{33.99}$$

33.1.4.6 Third method

To estimate the scattering length for a particular interaction consult [844, **?**, 989]. Following [844] we write the Schrödinger equation in atomic units as,

$$\frac{d^2U}{dR^2} = 2m_r V(R)U(R) \ . \tag{33.100}$$

The ansatz $U(R) = \alpha\varepsilon_\alpha(R) + \beta\varepsilon_\beta(R)$ with $\varepsilon_\alpha(R \to \infty) = R$ and $\varepsilon_\beta(R \to \infty) = 1$ shows that $a = -\beta/\alpha$ is the desired scattering length.

33.1.4.7 Fourth method

The equation for the accumulated phase follows from the Schrödinger equation,

$$\begin{aligned} \phi(r_0) &\equiv \int_\infty^{r_0} k(r)dr \\ k^2(r) &= \frac{2m_r}{\hbar^2}\sqrt{E - V(r) - \frac{\hbar^2 l(l+1)}{2m_r r^2}} \ . \end{aligned} \tag{33.101}$$

According to [989] we start resolving,

$$\frac{d}{dR}\delta_{k,0}(R) = -k^{-1}V(R)\sin^2[kR + \delta_{k,0}(R)] \ . \tag{33.102}$$

33.1.4.8 Pseudo potentials

As in the low-energy limit ($k \to 0$) the scattering properties only depend on the asymptotic phase shift it is a good idea to search for the simplest mathematical form that generates this asymptotic behavior. The situation is similar to the case of electrostatics, where a spherically symmetric charge distribution generates the same far field as a properly chosen point charge in its center. Not surprisingly, the suitable mathematical form is a point interaction. It is known as the pseudo potential and serves as an important theoretical Ansatz at the two-body level for the description of interacting many-body systems [436, 641]. The existence of such pseudo potentials is not surprising in view of the zero-range square well solutions discussed in Sec. 33.6.2.

As the pseudo potential cannot be obtained at the level of the radial wave equation, we return to the full 3D Schrödinger equation for a pair of free atoms,

$$(\nabla^2 + k^2)\psi_k(r) = 0 \ , \tag{33.103}$$

where $k = \sqrt{2m_r E/\hbar^2}$ is the wavenumber for the relative motion. Restricting ourselves to s-wave collisions we derived earlier the solution of this equation as being given by $\psi_k(r) = \frac{c_0}{kr}\sin kr$. However, we are now looking a solution of the type (33.37), which includes a phase shift η_0,

$$\psi_k(r) = \frac{c_0}{kr}\sin(kr + \eta_0) \ . \tag{33.104}$$

Inserting this expression into the wave equation (33.103) we encounter the problem that the solution is irregular in the origin when $\eta_0 \neq 0$. Apparently, we need to complement the wave equation by a (pseudo-)potential to remove this problem.

Our claim is now that the operator,

$$-\frac{4\pi}{k\cot\eta_0}\delta^3(\mathbf{r})\frac{\partial}{\partial r}r \tag{33.105}$$

is the wanted s-wave *pseudo potential* $\tilde{V}(r)$. That is, the wave equation,

$$\boxed{\left(\nabla^2+k^2+\frac{4\pi}{k\cot\eta_0}\delta^3(\mathbf{r})\frac{\partial}{\partial r}r\right)\psi_k(r)=0} \tag{33.106}$$

lets the phase-shifted wavefunction (33.104) be regular at the origin.

The presence of the delta function makes the pseudo-potential act as a boundary condition at $r=0$,

$$\begin{aligned}\frac{4\pi\delta^3(\mathbf{r})}{k\cot\eta_0}\left[\frac{\partial}{\partial r}r\psi_k(r)\right]_{r=r_0} &= 4\pi\delta^3(\mathbf{r})\frac{c_0}{k}\sin\eta_0 \\ &= -4\pi\delta^3(\mathbf{r})\frac{c_0}{k}\sin(ka) \underset{k\to0}{\simeq} -4\pi a c_0\delta^3(\mathbf{r})\ ,\end{aligned} \tag{33.107}$$

where we used the expression for the s-wave phase shift, $\eta_0=-ka$. This is the alternative boundary condition we were looking for. Substituting this into Eq. (33.106) we obtain the inhomogeneous equation

$$(\nabla^2+k^2)\psi_k(r) \underset{k\to0}{\simeq} -4\pi a c_0\delta^3(\mathbf{r})\ . \tag{33.108}$$

This inhomogeneous equation has the solution (33.104), as demonstrated in Exc. 33.1.5.4.

For functions $f(\mathbf{r})$ with regular behavior in the origin we have [4],

$$\left[\frac{\partial}{\partial r}rf(\mathbf{r})\right]_{r=0} = f(\mathbf{0})+r\left[\frac{\partial}{\partial r}f(\mathbf{r})\right]_{r=0} = f(\mathbf{0})\ , \tag{33.109}$$

and the pseudo potential takes the form of a delta function potential [5],

$$\tilde{V}(r) = -\frac{4\pi}{k\cot\eta_0}\delta^3(\mathbf{r}) \underset{k\to0}{\simeq} 4\pi a\delta^3(\mathbf{r})\ , \tag{33.110}$$

or, equivalently, restoring the dimensions,

$$\boxed{V(r)=\frac{g}{2}\delta^3(\mathbf{r}) \qquad \text{with} \qquad g=\frac{4\pi\hbar^2}{m_r}}\ . \tag{33.111}$$

[4] Note that the wavefunction ψ_k is irregular,

$$\delta^3(\mathbf{r})\frac{\partial}{\partial r}[r\psi_k(r)] = \delta^3(\mathbf{r})\frac{\partial}{\partial r}\left(r\frac{c_0\sin(kr+\eta_0)}{kr}\right) = \delta^3(\mathbf{r})c_0\cos[k(r-a)] \underset{k\to0}{=} c_0\delta^3(\mathbf{r})\ .$$

On the other hand,

$$\delta^3(\mathbf{r})\frac{\partial}{\partial r}[r\psi_k(r)] = \delta^3(\mathbf{r})\frac{c_0\sin(kr+\eta_0)}{kr} = \delta^3(\mathbf{r})\frac{c_0\sin[k(r-a)]}{kr} \underset{k\to0}{=} c_0\delta^{(3)}(\mathbf{r})[1-\tfrac{a}{r}]\ .$$

[5] Note that the dependence on the relative position vector $\mathbf{r}$ rather than its modulus r is purely formal as the delta function restricts the integration to only zero-length vectors. This notation is used to indicate that normalization involves a 3-dimensional integration, $\int\delta^3(\mathbf{r})d^3r$. Pseudo potentials do not carry physical significance but are mathematical constructions that can chosen such that they provide wavefunctions with the proper phase shift.

This expression, for $na^3 \ll 1$ valid in the zero energy limit, is convenient for calculating the interaction energy, as will be shown in Sec. ??.

33.1.4.9 Coupling of potentials

When molecular potentials cross and couple via collisions, via radiative coupling, or via a Feshbach resonance (cf. Sec. 33.4.2), new adiabatic potentials are formed. These are obtained as the r-dependent eigenvalues of the coupling Hamiltonian,

$$\hat{H}_{cpl} = \begin{pmatrix} V_1(R) & \Omega \\ \Omega & V_2(R) \end{pmatrix} . \tag{33.112}$$

Such calculations are known as *coupled channels* calculations.

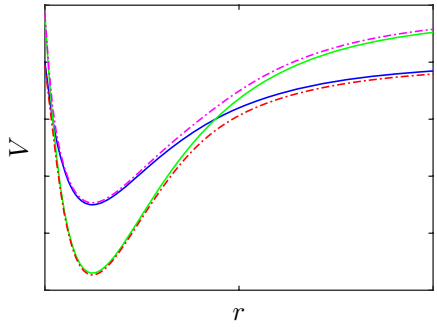

Figure 33.13: (code) The coupling of molecular potentials (solid lines) generates new adiabatic potentials (dash-dotted lines).

33.1.5 Exercises

33.1.5.1 Ex: Asymptotic radial function for hard-sphere potentials

Using asymptotic expressions for the Bessel and von Neumann functions derive the radial function $R_\ell(k,r)$ for the two limiting cases $ka \ll 1$ and $ka \gg 1$.

Solution: *i. For $ka \ll 1$ the phase shift can be written as,*

$$\tan\eta_\ell \underset{k\to 0}{\simeq} -\frac{2\ell+1}{[(2\ell+1)!!]^2}(ka)^{2\ell+1} \underset{k\to 0}{\simeq} \eta_\ell \ ,$$

and the radial wavefunction becomes,

$$R_\ell(k,r) \underset{r\to\infty}{\simeq} \frac{c_\ell}{kr}\sin\left(kr - \frac{2\ell+1}{[(2\ell+1)!!]^2}(ka)^{2\ell+1} - \tfrac{1}{2}\ell\pi\right) \ .$$

In particular, for s-waves we find

$$R_0(k,r) \underset{r\to\infty}{\simeq} \frac{c_\ell}{kr}\sin[k(r-a)] \ .$$

ii. For $ka \gg 1$ we find,

$$\tan\eta_\ell \underset{k\to\infty}{\simeq} -\tan(ka - \tfrac{1}{2}\ell\pi) \Longrightarrow \eta_\ell \underset{k\to\infty}{\simeq} -ka + \tfrac{1}{2}\ell\pi \ ,$$

and for the radial wavefunction,

$$R_\ell(k,r) \underset{r\to 0}{\simeq} \frac{c_\ell}{kr}\sin[k(r-a)] \ .$$

Note that this expression is independent of ℓ; i.e. for large k all wavefunctions are shifted by the diameter of the hard sphere. This is only the case for hard-sphere potentials.

33.1.5.2 Ex: s-wave collision on flat bottom potentials

Simplify the scattering matrix (33.35) for the collisional flat bottom potential for the case of s-wave collisions.

Solution: *We start from the expression (33.35) specifying $\ell = 0$,*

$$e^{2i\eta_0} = -\frac{h_0^{(1)}(\varrho_e)}{h_0^{(2)}(\varrho_e)}\frac{K_+\partial_\varrho \ln j_0(\varrho_i) - k\partial_\varrho \ln h_0^{(1)}(\varrho_e)}{K_+\partial_\varrho \ln j_0(\varrho_i) - k\partial_\varrho \ln h_0^{(2)}(\varrho_e)} \ ,$$

Coming from inside the potential we have at the boundary $\varrho_i = K_+ r_0$,

$$j_0(\varrho_i) = \frac{\sin\varrho_i}{\varrho_i} \qquad \Longrightarrow \qquad \partial_\varrho \ln j_0(\varrho_i) = \frac{j_0'(\varrho_i)}{j_0(\varrho_i)} = \cot\varrho_i - \frac{1}{\varrho_i} \ .$$

Coming from outside the potential we have at the boundary $\varrho_e = kr_0$,

$$n_0(\varrho_e) = -\frac{\cos\varrho_e}{\varrho_e} \qquad \Longrightarrow \qquad h_0^{(1)}(\varrho_e) = j_0(\varrho_e) + in_0(\varrho_e) = -\frac{ie^{i\varrho_e}}{\varrho_e}$$

$$\Longrightarrow \qquad h_0'^{(1)}(\varrho_e) = \frac{i+\varrho_e}{\varrho_e^2}e^{i\varrho_e} \qquad \Longrightarrow \qquad \partial_\varrho \ln h_0^{(1)}(\varrho_e) = -\frac{1-i\varrho_e}{\varrho_e}$$

$$\Longrightarrow \qquad \frac{h_0^{(1)}(\varrho_e)}{h_0^{(2)}(\varrho_e)} = -e^{2i\varrho_e} \ .$$

With this, the S matrix becomes,

$$e^{2i\eta_0} = e^{2i\varrho_e}\frac{K_+\left(\cot\varrho_i - \frac{1}{\varrho_i}\right) + k\frac{1-i\varrho_e}{\varrho_e}}{K_+\left(\cot\varrho_i - \frac{1}{\varrho_i}\right) + k\frac{1+i\varrho_e}{\varrho_e}} = e^{2ikr_0}\frac{K_+\cot K_+r_0 - ik}{K_+\cot K_+r_0 + ik}$$

$$\Longrightarrow \qquad \eta_0 = kr_0 + \frac{1}{2i}\ln\frac{K_+ - ik\tan K_+r_0}{K_+ + ik\tan K_+r_0} = kr_0 - \arctan\frac{k\tan K_+r_0}{K_+} \ ,$$

using $\arctan x = \frac{i}{2}\ln\frac{1-ix}{1+ix}$.
Alternatively, we may derive the same results from the continuity condition for the radial wavefunction $u_0(r)$, which reads,

$$K_+\frac{\cos\varrho_i}{\sin\varrho_i} = \frac{u_0'(r_0)}{u_0(r_0)} = k\frac{\cos\eta_0\cos\varrho_e + \sin\eta_0\sin\varrho_e}{\cos\eta_0\sin\varrho_e - \sin\eta_0\cos\varrho_e} \ ,$$

which can also be written as,

$$K_+ \cot \varrho_i = k \cot(\varrho_e - \eta_0) \ ,$$

or

$$\eta_0 = kr_0 - \arctan \frac{k \tan K_+ r_0}{K_+} \ .$$

With the definition of the scattering length we get,

$$\frac{\eta_0}{k} = r_0 - \frac{1}{k} \arctan \frac{k \tan(\sqrt{k^2 + \kappa_{0+}^2} r_0)}{\sqrt{k^2 + \kappa_0^2}} \underset{k \to 0}{\longrightarrow} r_0 - \frac{\tan \kappa_0 r_0}{\kappa_0} \equiv a \ .$$

33.1.5.3 Ex: Equivalence of boundary conditions

Show that the radial wavefunction R_ℓ and u_ℓ satisfy equivalent boundary conditions at the surface of the spherical box potential.

Solution: *The goal is to show that the following two boundary conditions are equivalent,*

$$\lim_{r \nearrow r_0} \frac{R'_\ell(r)}{R_\ell(r)} = \lim_{r \searrow r_0} \frac{R'_\ell(r)}{R_\ell(r)} \Longleftrightarrow \lim_{r \nearrow r_0} \frac{u'_\ell(r)}{u_\ell(r)} = \lim_{r \searrow r_0} \frac{u'_\ell(r)}{u_\ell(r)} \ .$$

This can be seen from,

$$\frac{u'_\ell(r)}{u_\ell(r)} = \frac{rR'_\ell(r) + R_\ell(r)}{rR_\ell(r)} = \frac{R'_\ell(r)}{R_\ell(r)} + \frac{1}{r} \ .$$

33.1.5.4 Ex: Derivation of a linear expansion

Derive the linear expansion (33.67).

Solution: *We calculate the linear expansion of* $K_{res} \cot K_+ r_0$ *near the zero crossing at* $K_+ r_0 = (\tilde{v}+1/2)\pi$*, where* $\cot K_+ r_0 = 0$*: This follows from the derivative evaluated at* $K_+ r_0 = (\tilde{v} + 1/2)\pi$*:*

$$\left. \frac{dK_{res} \cot K_+ r_0}{d\delta k} \right|_{K_+ r_0 = (\tilde{v}+1/2)\pi} = \left. -\frac{k_{res} r_0|^2}{\sin} K_+ r_0| \right|_{K_+ r_0 = (\tilde{v}+1/2)\pi} == -k_{res} r_0 \ .$$

Multiplying the derivative with δk *we obtain the desired result.*

33.1.5.5 Ex: Pseudo-potential for s-wave scattering

Verify the equation $(\nabla^2 + k^2)\psi_k(r) = 4\pi\delta^3(\mathbf{r})\frac{1}{k}\sin\eta_0$ by direct substitution of the solution (33.104) setting $c_0 = 1$.

Solution: *Integrating (33.108) by over a small sphere V of radius ϵ about the origin we have,*

$$\int_V (\nabla^2 + k^2)\frac{1}{kr}\sin(kr + \eta_0)d^3r = -\frac{4\pi}{k}\sin\eta_0 \ .$$

Here we used $\int_V \delta^3(\mathbf{r})d^3r$ for an arbitrarily small sphere about the origin. The second term on the l.h.s. of the last equation vanishes,

$$4\pi k \lim_{\epsilon\to 0}\int_0^\epsilon r\sin(kr + \eta_0)dr = 4\pi k\sin\eta_0 \lim_{\epsilon\to 0}\epsilon = 0 \ .$$

The first term follows with the divergence theorem (Gauss theorem),

$$\begin{aligned}\lim_{\epsilon\to 0}\int_V \nabla^2\frac{1}{kr}\sin(kr + \eta_0)d^3r &= \lim_{\epsilon\to 0}\oint_{\mathcal{S}} d\mathbf{S}\cdot\nabla\frac{1}{kr}\sin(kr + \eta_0) \\ &= \lim_{\epsilon\to 0} 4\pi\epsilon^2\left(\frac{1}{\epsilon}\cos(kr + \eta_0) - \frac{1}{k\epsilon^2}\sin(kr + \eta_0)\right) = -\frac{4\pi}{k}\sin\eta_0 \ .\end{aligned}$$

33.2 Scattering theory

In this chapter we discuss scattering by time independent potentials satisfying $rV(r \to \infty) \to 0$, that is short-range potentials. Such a potential may have attractive regions supporting bound states with energy $E < 0$. Here, however, we only consider states $E > 0$. Since the potential is supposed independent of time, $\partial_t\hat{H} = 0$, we will focus on time-independent problems,

$$\hat{H}\psi_{\mathbf{k}}(\mathbf{r}) = E_k\psi_{\mathbf{k}}(\mathbf{r}) \ , \tag{33.113}$$

with $\hat{H} = p^2/2m + V(\mathbf{r})$ and $E_{\mathbf{k}} = \hbar^2k^2/2m$. The boundary conditions are given by the scattering geometry in such a way that at long distances the wavefunction behaves as (see Fig. 33.14),

$$\psi_{\mathbf{k}}(\mathbf{r}) \sim e^{i\mathbf{k}\cdot\mathbf{r}} + f_k(\Omega)\frac{e^{ik_sr}}{r} \ . \tag{33.114}$$

For elastic scattering processes we have $k_s = k$. The *scattering amplitude* $f_k(\Omega)$ depends on the energy E_k and on the scattering solid angle. Experimentally, we scatter individual particles described by wave packets. Since the scattering theory is linear, we can describe the packets by superpositions of stationary solutions $\psi_{\mathbf{k}}$ [6].

[6] Note that $\mathbf{k}$ is not a quantum number, since $\psi_{\mathbf{k}}$ contains momentum components $\neq \mathbf{k}$.

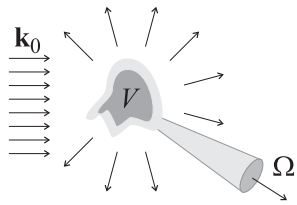

Figure 33.14: Scattering of incident light (wavevector $\mathbf{k}_0$) by a potential V.

33.2.1 Lippmann-Schwinger equation

In order to consider the example of two particles involved in a collision we may go into the center-of-mass system (using reduced masses), fix the origin of the coordinate system on one of the particles, and analyze the trajectory of the second particle inside the interaction potential.

The scattering theory is based on *Green's method*, which we already know from electrostatics. So, let us start of a brief reminder of the use of the *Green's function* as a method to solve electrostatic problems.

Example 191 (*Green's method in electrostatics*): From Maxwell's third equation we obtain,

$$\nabla^2\phi(\mathbf{r}) = -\varepsilon_0^{-1}\rho(\mathbf{r}) \ .$$

Being defined by,

$$\nabla^2 G(\mathbf{r}) = \delta^3(\mathbf{r}) \ ,$$

the Green function is,

$$G(\mathbf{r}) = \frac{-1}{4\pi}\frac{1}{|\mathbf{r}|} \ .$$

With this, we find the solution of the Maxwell equation,

$$\phi(\mathbf{r}) = \left(-G \star \varepsilon_0^{-1}\rho(\mathbf{r})\right)(\mathbf{r}) = -\frac{1}{\varepsilon_0}\int_V \rho(\mathbf{r}_0)G(\mathbf{r}-\mathbf{r}_0)d^3\mathbf{r}_0 = \frac{1}{4\pi\varepsilon_0}\int_V \frac{\rho(\mathbf{x})}{|\mathbf{r}-\mathbf{x}|}d^3\mathbf{x} \ ,$$

known as *Poisson's law*.

33.2.1.1 Green's method in quantum mechanics

Green's method can be used to solve Schrödinger's equation with the boundary condition (33.114). We start from the reduced stationary Schrödinger equation (33.113) [1298],

$$(\Delta + k^2)\psi_{\mathbf{k}}(\mathbf{r}) = \tfrac{2m}{\hbar^2}V(\mathbf{r})\psi_{\mathbf{k}}(\mathbf{r}) \ . \tag{33.115}$$

This equation is not a common eigenvalue problem, since any energy E_k generates a solution. The equation (33.115) is a partial inhomogeneous differential equation with the left side describing free propagation and the right side describing a source that depends on the solution. Such differential equations are usually solved using Green's functions. We choose a point source and we solve,

$$(\Delta + k^2)G(\mathbf{r}, k) = \delta^3(\mathbf{r}) \ , \tag{33.116}$$

along with the boundary conditions. The solution takes the form [151],

$$G(\mathbf{r},k) = -\frac{1}{4\pi}\frac{e^{ik|\mathbf{r}|}}{|\mathbf{r}|} \ , \tag{33.117}$$

such that,

$$\boxed{\psi_{\mathbf{k}}(\mathbf{r}) = e^{i\mathbf{k}\cdot\mathbf{r}} + \left(G \star \tfrac{2m}{\hbar^2} V\psi_{\mathbf{k}}\right)(\mathbf{r}) = e^{i\mathbf{k}\cdot\mathbf{r}} + \tfrac{2m}{\hbar^2}\int_V d^3\mathbf{r}' G(\mathbf{r}-\mathbf{r}',k)V(\mathbf{r}')\psi_{\mathbf{k}}(\mathbf{r}')} \ . \tag{33.118}$$

The equation (33.118) is called *Lippmann-Schwinger equation*. Of course, this equation does not solve, but only reformulate the problem taking into account the boundary conditions. It is more appropriate for an implementation of approximations. See Exc. 33.2.7.1 and 33.2.7.2.

Now let us consider the far field, $r \to \infty$, to verify the asymptotic behavior and find an expression for $f_k(\Omega)$ as a function of $V(\mathbf{r})$. For $r \to \infty$ we can approximate

$$k|\mathbf{r}-\mathbf{r}'| = kr\sqrt{(\hat{\mathbf{e}}_r - \mathbf{r}'/r)^2} = kr\sqrt{1 - 2\hat{\mathbf{e}}_r\cdot\mathbf{r}'/r + (r'/r)^2} \simeq kr - \mathbf{k}'\cdot\mathbf{r}' \simeq kr \ , \tag{33.119}$$

with $\mathbf{k}' \equiv k\hat{\mathbf{e}}_r$. With this the Lippmann-Schwinger equation (33.118) becomes,

$$\begin{aligned}\psi(\mathbf{r}) &\to e^{i\mathbf{k}\cdot\mathbf{r}} - \frac{2m}{\hbar^2}\int_V \frac{1}{4\pi}\frac{e^{ik|\mathbf{r}-\mathbf{r}'|}}{|\mathbf{r}-\mathbf{r}'|}V(\mathbf{r}')\psi(\mathbf{r}')d^3\mathbf{r}' \qquad (33.120)\\ &= e^{i\mathbf{k}\cdot\mathbf{r}} - \frac{2m}{4\pi\hbar^2}\frac{e^{ikr}}{kr}\int_V e^{-i\mathbf{k}'\cdot\mathbf{r}'}V(\mathbf{r}')\psi(\mathbf{r}')d^3\mathbf{r}' \equiv \psi_{in} + f_k(\Omega)\frac{e^{ikr}}{r} \ ,\end{aligned}$$

giving, in comparison with the expression (33.114), the *scattering amplitude*,

$$f_k(\Omega) = \frac{2m}{4\pi\hbar^2}\int_V e^{-i\mathbf{k}'\cdot\mathbf{r}'}V(\mathbf{r}')\psi(\mathbf{r}')d^3\mathbf{r}' \ . \tag{33.121}$$

Starting from the wavefunctions $\psi_{in} \equiv e^{i\mathbf{k}\cdot\mathbf{r}}$ and $\psi_s \equiv f_k(\Omega)e^{ikr}/r$ we can calculate the current densities,

$$\begin{aligned}\mathbf{J}_{in} &= \frac{\hbar}{2mi}(\psi_{in}^\dagger\nabla\psi_{in} - c.c.) = \frac{\hbar\mathbf{k}}{m} \qquad (33.122)\\ \mathbf{J}_s &= \frac{\hbar}{2mi}(\psi_s^\dagger\partial_r\psi_s - c.c.)\hat{\mathbf{e}}_r = \frac{\hbar\mathbf{k}'}{m}\frac{1}{r^2}|f_k(\Omega)|^2 + \mathcal{O}(r^{-3}) \ .\end{aligned}$$

The number $dI(\Omega)$ of particles scattered per second into the solid angle $d\Omega$ is simply $dI(\Omega) = |\mathbf{J}_s|r^2 d\Omega$. With this we can calculate the *differential effective cross section* defined by the ratio between $dI(\Omega)$ and the number $|\mathbf{J}_{in}|$ of incident particles per second,

$$\boxed{\frac{d\sigma}{d\Omega} \equiv \frac{dI(\Omega)}{|\mathbf{J}_{in}|d\Omega} = |f_k(\Omega)|^2} \ . \tag{33.123}$$

Finally we define the *total effective cross section*,

$$\sigma = \int d\Omega |f_k(\Omega)|^2 \ . \tag{33.124}$$

33.2.2 Wave packets

We now let a *wave packet* defined at a time $t = t_0$,

$$\psi(\mathbf{r}, t_0) = \int \frac{d^3k}{(2\pi)^3} a_{\mathbf{k}} e^{i\mathbf{k}\cdot\mathbf{r}} \ , \tag{33.125}$$

impinge on a scattering potential. The amplitude $a_{\mathbf{k}}$ be concentrated around $\mathbf{k}_0$, such that the wave packet approaches the scatterer with the velocity $\mathbf{v}_0 = \hbar\mathbf{k}_0/m$. The time evolution of the wavefunction $\psi(\mathbf{r}, t)$ determines the signal measured by a detector at a later time $t = t_0$. Our task is to determine $\psi(\mathbf{r}, t > t_0)$. The scattered states $\psi_{\mathbf{k}}$ solving the Schrödinger equation (33.113) are complete in the space of the extended wavefunctions, and we can write the temporal evolution as,

$$\psi(\mathbf{r}, t) = \int \frac{d^3k}{(2\pi)^3} A_{\mathbf{k}} \psi_{\mathbf{k}}(\mathbf{r}) e^{-iE_k(t-t_0)/\hbar} \ . \tag{33.126}$$

At time t_0 the results (33.125) and (33.126) must match. To verify this, we write (33.125) replacing the plane wave $e^{i\mathbf{k}\cdot\mathbf{r}}$ using the Lippmann-Schwinger equation (33.118) with Green's function (33.117), and then we compare the coefficients,

$$\psi(\mathbf{r}, t_0) = \int \frac{d^3k}{(2\pi)^3} a_{\mathbf{k}} \left[\psi_{\mathbf{k}}(\mathbf{r}) + \frac{m}{2\pi\hbar^2} \int d^3r' \frac{e^{ik|\mathbf{r}-\mathbf{r}'|}}{|\mathbf{r}-\mathbf{r}'|} V(\mathbf{r}') \psi_{\mathbf{k}}(\mathbf{r}') \right] \ . \tag{33.127}$$

The scattering process is illustrated in Fig. 33.15. To simplify the calculation of

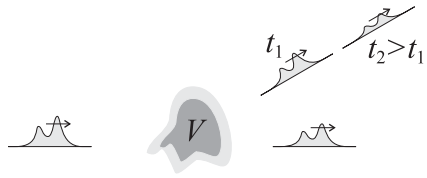

Figure 33.15: Scattering of wave packet at a potential.

the second term in this equation, we assume that $\psi_{\mathbf{k}}$ is smooth, that is, there are no resonances, such that we can approximate, $\psi_{\mathbf{k}} \simeq \psi_{\mathbf{k}_0}$. With $k \simeq \mathbf{k}\cdot\hat{\mathbf{e}}_{k_0}$ we obtain,

$$\begin{aligned} \int \frac{d^3k}{(2\pi)^3} a_{\mathbf{k}} e^{ik|\mathbf{r}-\mathbf{r}'|} \psi_{\mathbf{k}}(\mathbf{r}') &= \int \frac{d^3k}{(2\pi)^3} a_{\mathbf{k}} e^{i\mathbf{k}\cdot(\hat{\mathbf{e}}_{k_0}|\mathbf{r}-\mathbf{r}'|)} \psi_{\mathbf{k}_0}(\mathbf{r}') \\ &\overset{(33.125)}{=} \psi(\hat{\mathbf{e}}_{k_0}|\mathbf{r}-\mathbf{r}'|, t_0) \psi_{\mathbf{k}_0}(\mathbf{r}') \ . \end{aligned} \tag{33.128}$$

Here, $\psi(\hat{\mathbf{e}}_{k_0}|\mathbf{r}-\mathbf{r}'|, t_0)$ is the incident wave package evaluated to the right, where by definition it is $\simeq 0$. The expression (33.127) therefore has the form,

$$\psi(\mathbf{r}, t_0) = \int \frac{d^3k}{(2\pi)^3} a_{\mathbf{k}} \psi_{\mathbf{k}}(\mathbf{r}) \ , \tag{33.129}$$

and a comparison of the coefficients with (33.126) gives, $A_{\mathbf{k}} = a_{\mathbf{k}}$. Finally, we evaluate $\psi(\mathbf{r}, t)$ at the time of detection $t > t_0$ to understand, that the above stationary analysis

is actually physically correct. According to (33.126) we have,

$$\psi(\mathbf{r},t) = \int \frac{d^3k}{(2\pi)^3} A_{\mathbf{k}} \psi_{\mathbf{k}}(\mathbf{r}) e^{-iE_k(t-t_0)/\hbar} \tag{33.130}$$
$$\overset{(33.120)(33.125)}{\simeq} \psi_0(\mathbf{r},t) + \int \frac{d^3k}{(2\pi)^3} a_{\mathbf{k}} \frac{e^{ikr}}{r} f_k(\Omega) e^{-iE_k(t-t_0)/\hbar} \ .$$

Hence, $\psi_0(\mathbf{r},t)$ describes the evolution of the wave packet without scatterer,

$$\psi_0(\mathbf{r},t) = \underbrace{\int \frac{d^3k}{(2\pi)^3} a_{\mathbf{k}} e^{i\mathbf{k}\cdot\mathbf{r}}}_{\psi(\mathbf{r},t_0)} e^{-iE_k(t-t_0)/\hbar} \ . \tag{33.131}$$

If f_k it's smooth around $\mathbf{k} = \mathbf{k}_0$, which allows us to place this amplitude ($f_k \simeq f_{k_0}$) in front of the integral, and with $k \simeq \mathbf{k}\cdot\hat{\mathbf{k}}_0$ we obtain,

$$\psi(\mathbf{r},t) \overset{t \text{ large}}{\Longrightarrow} \underbrace{\psi_0(\mathbf{r},t)}_{\text{packet not scattered}} + \underbrace{\frac{f_{k_0}(\Omega)}{r} \psi_0(\hat{k}_0 r, t)}_{\text{packet scattered}} \ . \tag{33.132}$$

The scattering process is illustrated in Fig. 33.15: According to the last equation the scattering process involves the superposition of the non-scattered packet and a packet scattered in the direction Ω. The latter involves the amplitude $\Psi_0(\hat{k}_0 r, t)$ of a packet propagating in forward direction, which only needs to be evaluated at the right time and distance. This packet will then be multiplied with the amplitude describing the angular dependency f_{k_0}; the angle, therefore, only appears through this amplitude and not in the wavefunction ψ_0. In two situations the above analysis can not be applied :

- when V is long-ranged, f.ex., $V = 1/r$,
- when the incident energy E_k is resonant.

33.2.3 Born approximation

The Lippmann-Schwinger equation suggests the following perturbative iteration called *Born series* [151],

$$\begin{aligned} \psi(\mathbf{r}) &= \psi_i(\mathbf{r}) + \left(G \star \tfrac{2m}{\hbar^2} V\psi\right)(\mathbf{r}) \\ &= \psi_i(\mathbf{r}) + \tfrac{2m}{\hbar^2}(G \star V\psi_i)(\mathbf{r}) + \left(\tfrac{2m}{\hbar^2}\right)^2 [G \star V(G \star V\psi_i)](\mathbf{r}) \\ &= \psi_i(\mathbf{r}) + \tfrac{2m}{\hbar^2} \int_V G(\mathbf{r}-\mathbf{r}')V(\mathbf{r}')\psi_i(\mathbf{r}')d^3\mathbf{r}' \\ &\quad + \left(\tfrac{2m}{\hbar^2}\right)^2 \int_V G(\mathbf{r}-\mathbf{r}')V(\mathbf{r}')G(\mathbf{r}-\mathbf{r}'')V(\mathbf{r}'')\psi_i(\mathbf{r}'')d^3\mathbf{r}'d^3\mathbf{r}'' \ . \end{aligned} \tag{33.133}$$

In the so-called *Born approximation* we consider only the first perturbation order, and inserting a plane wave, $\psi_i(\mathbf{r}) = e^{ikz}/(2\pi)^{3/2}$, we obtain,

$$\psi(\mathbf{r}) = \frac{e^{ikz}}{(2\pi)^{3/2}} - \frac{m}{(2\pi)^{3/2} 2\pi\hbar^2} \int_V \frac{e^{ik|\mathbf{r}-\mathbf{r}'|}}{|\mathbf{r}-\mathbf{r}'|} V(\mathbf{r}') e^{ikz'} d^3\mathbf{r}' \ . \tag{33.134}$$

The asymptotic behavior $r \gg r'$, it follows with (33.119) using $z' = \mathbf{r}' \cdot \hat{\mathbf{e}}_z$ and defining $\mathbf{k}_s = k\hat{\mathbf{e}}_r$ e $\mathbf{k}_i = k\hat{\mathbf{e}}_z$,

$$\begin{aligned}\psi(\mathbf{r}) &\simeq \frac{e^{ikz}}{(2\pi)^{3/2}} - \frac{m}{(2\pi)^{3/2}2\pi\hbar^2}\int_V \frac{e^{ik\left(r-\mathbf{r}\cdot\mathbf{r}'/r\right)}}{r} V(\mathbf{r}')e^{i\mathbf{k}\cdot\mathbf{r}'}d^3\mathbf{r}' \\ &= \frac{e^{ikz}}{(2\pi)^{3/2}} + \frac{m}{(2\pi)^{3/2}2\pi\hbar^2}\frac{e^{ikr}}{r}\int_V V(\mathbf{r}')e^{i(\mathbf{k}_i-\mathbf{k}_s)\cdot\mathbf{r}'}d^3\mathbf{r}' \\ &\equiv \frac{1}{(2\pi)^{3/2}}\left(e^{ikz} + \frac{e^{ikr}}{r}f(k_i,k_s)\right) ,\end{aligned} \tag{33.135}$$

with

$$\boxed{f(k_i,k_s) \equiv \frac{m}{2\pi\hbar^2}\int_V V(\mathbf{r}')e^{i(\mathbf{k}_i-\mathbf{k}_s)\cdot\mathbf{r}'}d^3\mathbf{r}' = -\frac{m}{2\pi\hbar^2}\langle k_s|\tilde{V}|k_i\rangle} .$$

33.2.4 Spherical potentials

For spherically symmetric scattering potentials, $V(\mathbf{r}) = V(r)$, the Hamiltonian $\hat{H} = p^2/2m + V(r)$ commutes with the rotation operators $U_{\vec{\omega}} = e^{-i\vec{\omega}\cdot\mathbf{L}/\hbar}$ around any axis $\hat{\mathbf{e}}_{\vec{\omega}}$. Therefore, we can separate the angular problem and decompose the scattering problem following the irreducible representations of the rotation group. This *partial wave* decomposition can be written,

$$\psi_{\mathbf{k}}(\mathbf{r}) = \sum_{\ell=0}^{\infty}(2\ell+1)i^\ell P_\ell(\cos\theta)R_l(r) , \tag{33.136}$$

where the factor $(2\ell+1)i^\ell$ is a convention facilitating the calculation later on. By inserting this separation ansatz for the radial and angular variables into the stationary Schrödinger equation (33.113), we obtain the radial Schrödinger equation,

$$\left[\frac{\partial^2}{\partial r^2} - \frac{\ell(\ell+1)}{r^2} + k^2\right] rR_\ell(r) = \frac{2m}{\hbar^2}V(r)rR_\ell(r) , \tag{33.137}$$

where $\psi_{\mathbf{k}}$ must satisfy the boundary conditions (33.114). Fortunately, we can also expand the incident wave by partial waves [7],

$$e^{ikz} = e^{ir\cos\theta} = \sum_{\ell=0}^{\infty}(2\ell+1)i^\ell j_\ell(kr)P_\ell(\cos\theta) . \tag{33.138}$$

We now use the result (33.138) to find the boundary conditions for the radial waves R_ℓ. In the infinity we have $rV(r) \overset{r\to\infty}{\longrightarrow} 0$. For this reason,

$$R_\ell(r) \overset{r\to\infty}{\longrightarrow} \alpha_\ell[h_\ell^{(2)}(kr) + s_\ell h_\ell^{(1)}(kr)] , \tag{33.139}$$

[7] For the more general case of arbitrary vectors $\mathbf{k}$ e $\mathbf{r}$, we use the addition theorem for $Y_{\ell m}$ and express $P_\ell(\cos\theta)$ by spherical functions,

$$e^{i\mathbf{k}\cdot\mathbf{r}} = 4\pi\sum_{\ell=0}^{\infty}\sum_{m=-\ell}^{\ell} i^\ell j_\ell(kr)Y^*_{\ell m}(\Omega_{\mathbf{k}})Y_{\ell m}(\Omega_{\mathbf{r}}) .$$

where the Hankel functions $h_\ell^{(1,2)}(kr) \sim e^{\pm i(\rho-(\ell+1)\pi/2)}$ describe, respectively, incident ($h_\ell^{(2)}$) and outgoing ($h_\ell^{(1)}$) spherical waves.

To determine the coefficients α_ℓ and s_ℓ we note first that, without potential, $V(r) = 0$, the solution of the radial equation (33.137) is known,

$$R_\ell(r) = j_\ell(kr) = \tfrac{1}{2}[h_\ell^{(2)}(kr) + h_\ell^{(1)}(kr)] \ , \tag{33.140}$$

such that $\alpha_\ell = \frac{1}{2}$ and $s_\ell = 1$. For $V(r) \neq 0$ the incident wave $h_\ell^{(2)}$ is the same, but not the incident $h_\ell^{(1)}$, which results in $s_\ell \neq 1$. However, particle number conservation requires that the number of particles entering the potential is equal to the number of particles coming out. That is, the total radial flow must be,

$$0 = j_r^\ell(r) = \frac{\hbar}{2im}[R_\ell^* \partial_r R_\ell - R_\ell \partial_r R_\ell^*] = \frac{\hbar}{4mkr^2}[|s_\ell|^2 - 1] \ , \tag{33.141}$$

approximating $2R_\ell \simeq \frac{e^{-i(kr+w_\ell}}{kr} + s_\ell \frac{e^{i(kr+w_\ell}}{kr}$. Hence, $|s_\ell| = 1$, that is,

$$s_\ell = e^{2i\delta_\ell(k)} \ , \tag{33.142}$$

where $\delta_\ell(k)$ is the *scattering phase*. The scattering phase determines the solution of the scattering problem, because it fixes the scattering amplitude: Evaluating the solution (33.136) in the asymptotic limit by the formula (33.138),

$$\begin{aligned} \psi_{\mathbf{k}}(\mathbf{r}) &\sim \tfrac{1}{2}\sum_{\ell=0}^{\infty}(2\ell+1)i^\ell P_\ell(\cos\theta)[h_\ell^{(2)}(kr) + e^{2i\delta_\ell} h_\ell^{(1)}(kr)] \qquad (33.143) \\ &= e^{i\mathbf{k}\cdot\mathbf{r}} + \tfrac{1}{2}\sum_{\ell=0}^{\infty}(2\ell+1)i^\ell P_\ell(\cos\theta)[e^{2i\delta_\ell} - 1]h_\ell^{(1)}(kr) = e^{i\mathbf{k}\cdot\mathbf{r}} + f_k(\theta)\frac{e^{ikr}}{r} \ , \end{aligned}$$

we obtain the scattering amplitude in the form [8]

$$\boxed{f_k(\theta) = \tfrac{1}{k}\sum_\ell (2\ell+1)P_\ell(\cos\theta)e^{i\delta_\ell}\sin\delta_\ell} \ . \tag{33.144}$$

We call

$$\frac{e^{2i\delta_\ell} - 1}{2ik} = \frac{e^{i\delta_\ell}\sin\delta_\ell}{k} \equiv f_\ell \tag{33.145}$$

the *amplitude of the partial wave* [1363, 186].

33.2.5 Scattering phase and length

In summary, we can, within the Born approximation, express the collisional state of any type of particles by isotropic potentials,

$$\psi(\mathbf{r}) \sim e^{i\mathbf{k}\cdot\mathbf{r}} + \frac{e^{ikr}}{r} f_k(\Omega) \ . \tag{33.146}$$

[8] Com $h_\ell^{(1)} \sim (-i)^{\ell+1}\frac{e^{ikr}}{kr}$.

The scattering cross section can be written,

$$\sigma = \int d\Omega |f_{\mathbf{k}}(\Omega)|^2 = \tfrac{1}{k^2} \int d\Omega \Big| \sum_\ell (2\ell+1) P_\ell(\cos\theta) \sin\delta_\ell \Big|^2 \tag{33.147}$$
$$= \frac{4\pi}{k^2} \sum_\ell (2\ell+1) \sin^2\delta_\ell = 4\pi \sum_\ell (2\ell+1) |f_\ell|^2 \ .$$

The quantity

$$\boxed{\sigma_\ell = \frac{4\pi}{k^2}(2\ell+1)\sin^2\delta_\ell = \frac{4\pi}{k^2}(2\ell+1)|f_\ell|^2} \tag{33.148}$$

is called *effective partial cross section*. Obviously, $\sigma_\ell \leq \frac{4\pi}{k^2}(2\ell+1)$ holds. The phase shift $e^{2i\delta_\ell}$ has a simple physical interpretation: We consider the function,

$$e^{i\delta_\ell} j_\ell(kr+\delta_\ell) = \tfrac{e^{i\delta_\ell}}{2}[h_\ell^{(2)}(kr+\delta_\ell) + h_\ell^{(1)}(kr+\delta_\ell)] \tag{33.149}$$
$$\sim \frac{e^{i\delta_\ell}}{2}\left[\frac{(-i)^\ell e^{i(kr+\delta_\ell)}}{kr+\delta_\ell} + \frac{(+i)^\ell e^{-i(kr+\delta_\ell)}}{kr+\delta_\ell}\right] \overset{kr\gg\delta_\ell}{\longrightarrow} \tfrac{1}{2}[h_\ell^{(2)} + e^{2i\delta_\ell} h_\ell^{(1)}] \sim R_\ell \ .$$

Now comparing the case $V = 0$ giving $R_\ell(r) = j_\ell(kr)$ with the case $V \neq 0$ giving $R_\ell(r) \sim e^{i\delta_\ell} j_\ell(kr+\delta_\ell)$, we notice that a positive displacement, $\delta_\ell > 0$, pulls the wavefunction into the potential, while a negative displacement, $\delta_\ell < 0$, pushes the wavefunction out, as illustrated in Fig. 33.16.

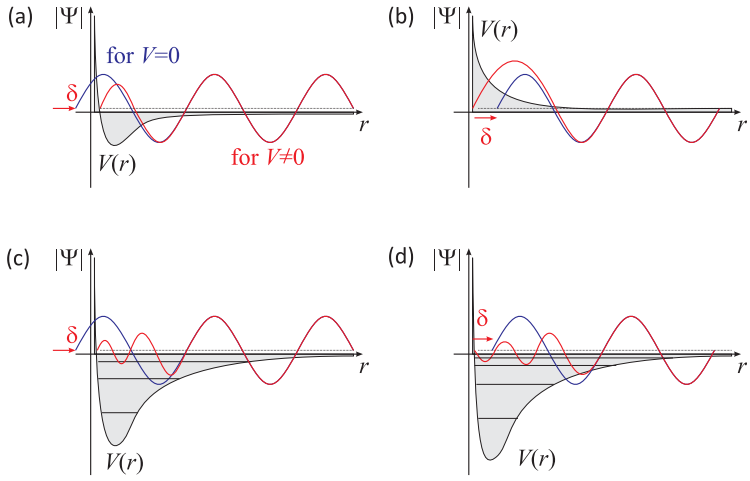

Figure 33.16: Phase shift $\delta_\ell(k)$ of the scattered wavefunction. (a) An attractive potential increases the kinetic energy and the wavefunction oscillates faster, which causes a positive phase shift and a negative scattering length. (b) A repulsive potential slows down the wavefunction oscillation and produces a positive scattering length. (c,d) In an attractive potential deep enough to support vibrational states, the wavefunction performs several oscillations. The sign of the scattering length then depends on the distance of the last bound state to the continuum.

33.2.6 Optical theorem

Consider the amplitude for forward scattering $f(0)$ by writing its imaginary part as,

$$\text{Im } f(0) = \tfrac{1}{k}\sum_k (2\ell+1)P_\ell(\cos\theta)\sin^2\delta_\ell\big|_{\theta=0} = \tfrac{1}{k}\sum_k (2\ell+1)\sin^2\delta_\ell \equiv \frac{k}{4\pi}\sigma\ . \quad (33.150)$$

With this we obtain the *optical theorem*,

$$\boxed{\sigma = \tfrac{4\pi}{k}\text{Im } f(0)}\ . \quad (33.151)$$

The deeper meaning of the optical theorem is the conservation of particle number: The flux of scattered particles, $(\hbar k/m)\sigma = I_{sct}$, must be extracted from the incident flux I_0 by scattering, and therefore, is missing in the forward direction. It is the interference of the scattered wave with the incident wave, which diminishes the non-scattered wave and therefore creates a shadow of the scatterer in the forward direction. The particles missing in the shadow of the scatterer are precisely those that have been scattered. This is the message of the optical theorem, which is always valid in the absence of possible (inelastic) processes leading to trapping or a transformation of the particles.

33.2.6.1 Born approximation for the scattering phase

The scattering problem can be considered as solved when we know the scattering amplitude $f_k(\theta)$, since this quantity gives us the flux measured by the detector. Now, $f_k(\theta)$ is known, when we know the scattering phases $\delta_{\ell,k}$. These are, in general,

determined by integrating the radial equation (33.137). Here, we expect that only angular momenta $\ell < kR_0$ (R_0 is the range of potential) produce significant phase shifts. Particles with larger angular momenta have collision parameters $b \sim \ell/k$ out of the potential reach. We notice that partial s-waves are always scattered, whereas partial p-waves (or higher) are only weakly scattered when the energy is weak, $E < \hbar^2/2mR_0^2$. In these cases an approximate calculation of δ_ℓ is sufficient: We insert (33.136) and $e^{ikz} = \sum_\ell \frac{1}{2}\sqrt{4\pi(2\ell+1)}\int_{-1}^{1} dz P_\ell(z)e^{ikz}$ into (33.121) and integration over Ω' yields,

$$\begin{aligned} f_k(\theta) &= \frac{2m}{4\pi\hbar^2}\int_V e^{-i\mathbf{k}'\cdot\mathbf{r}'}V(\mathbf{r}')\psi(\mathbf{r}')d^3\mathbf{r}' \\ &= -\tfrac{2m}{\hbar^2}\sum_{\ell=0}^{\infty}(2\ell+1)P_\ell(\cos\theta)\int_0^\infty dr\ r^2V(r)j_\ell(kr)R_\ell(r)\ . \end{aligned} \tag{33.152}$$

Comparing this formula with (33.144) we find,

$$e^{i\delta_\ell}\sin\delta_\ell = -\tfrac{2mk}{\hbar^2}\int_0^\infty dr\ r^2V(r)j_\ell(kr)R_\ell(r) \overset{R_\ell\simeq j_\ell}{\simeq} -\tfrac{2mk}{\hbar^2}\int_0^\infty dr\ r^2V(r)j_\ell^2(kr)\ . \tag{33.153}$$

The result (33.153) is the Born approximation for the scattering phase $\delta_\ell(k)$. Note that $R_\ell \simeq j_\ell$ is not a good approximation, in ranges where V is large and R_ℓ strongly suppressed (f.ex., inside hard cores). For ℓ large we have $j_\ell \sim r^\ell$, and $\delta\ell$ is small for a limited potential $V(r)$.

33.2.6.2 Analyticity of $s_\ell(E)$

We consider a short-range potential that disappears at $r > R_0$. The radial solution out of the reach of the potential will then be given by,

$$R_\ell(r) = \tfrac{1}{2}[h_\ell^{(2)}(kr) + s_\ell h_\ell^{(1)}(kr)]\ , \tag{33.154}$$

while for $r < R_0$ the solution R_ℓ must be found by integrating the radial equation (33.137). The scattering phase s_ℓ must be chosen in a way that R_ℓ and $\partial_r R_\ell$ be continuous at R_0. The normalization factor vanishes in the logarithmic derivative, such that,

$$\gamma_\ell \equiv \partial_r \ln R_\ell|_{R_0^-} = \left.\frac{1}{R_\ell}\frac{\partial R_\ell}{\partial r}\right|_{R_0^-} = \left.\frac{\partial_r h_\ell^{(2)} + s_\ell\partial_r h_\ell^{(1)}}{h_\ell^{(2)} + s_\ell h_\ell^{(1)}}\right|_{R_0^+}\ . \tag{33.155}$$

Now [9]

$$s_\ell - 1 = \left.\frac{2(\partial_r - \gamma_\ell)j_\ell}{(\gamma_\ell - \partial_r)h_\ell^{(1)}}\right|_{R_0} \tag{33.156}$$

or with $s_\ell - 1 = \frac{2i}{\cot\delta_\ell - i}$ expressing δ_ℓ by γ_ℓ,

$$\cot\delta_\ell = \left.\frac{(\partial_r - \gamma_\ell)n_\ell}{(\partial_r - \gamma_\ell)j_\ell}\right|_{R_0}\ . \tag{33.157}$$

[9] We have for the spherical Hankel functions: $h_\ell^{(1,2)}(x) = j_\ell(x) \pm iy_\ell(x)$.

The partial effective cross section is,

$$\sigma_\ell = \frac{4\pi}{k^2}(2\ell+1)\sin^2\delta_\ell = \frac{4\pi}{k^2}\frac{2\ell+1}{1+\cot^2\delta_\ell} \ . \tag{33.158}$$

Analyzing the expressions for $s_\ell(\cot\delta_\ell)$ and $\sigma_\ell(\cot\delta_\ell)$ we find that

- for $\cos\delta_\ell = i$ the scattering phase s_ℓ has a pole and $\sigma_\ell \to \infty$;
- for $\cos\delta_\ell = 0$ the scattering phase is $s_\ell - 1$ and $\sigma_\ell = 4\pi(2\ell+1)/k^2$ is maximal.

The poles of s_ℓ are just the bound states: A bound state asymptotically satisfies $R_\ell(r) \sim h_\ell^{(1)}(i\kappa r) \propto e^{-\kappa r}$ with the binding energy $E_B = -\hbar^2\kappa^2/2m$. The condition of continuity is given by,

$$\gamma_\ell = \left.\frac{\partial_r h_\ell^{(1)}}{h_\ell^{(1)}}\right|_{R_0} \ , \tag{33.159}$$

and the insertion into the general continuity condition (33.157) gives,

$$\cot\delta_\ell = \frac{h_\ell^{(1)}\partial_r n_\ell - n_\ell\partial_r h_\ell^{(1)}}{h_\ell^{(1)}\partial_r j_\ell - j_\ell\partial_r h_\ell^{(1)}} = i \ . \tag{33.160}$$

In the same way the zero crossings of $\cot\delta_\ell$ correspond precisely to the scattering resonances. To see this, we expand around a resonance,

$$\cot\delta_\ell(E) \simeq \cot\delta_\ell(E_r) - \frac{1}{\sin^2\delta_\ell}\left.\frac{d\delta_\ell}{dE}\right|_{E_r}(E-E_r) = -\left.\frac{d\delta_\ell}{dE}\right|_{E_r}(E-E_r) \equiv -\frac{2}{\Gamma_r}(E-E_r) \ , \tag{33.161}$$

defining the width $\Gamma_r = \left.\frac{2}{\partial_E\delta_\ell}\right|_{E_r}$ of the resonance peak in the effective section σ_ℓ in the form,

$$\sigma_\ell = \frac{4\pi}{k^2}(2\ell+1)\frac{(\Gamma_r/2)^2}{(E-E_r)^2+(\Gamma_r/2)^2} \ . \tag{33.162}$$

See Fig. 33.17,

$$s_\ell - 1 = \frac{-i\Gamma_r}{E-(E_r - i\gamma_r/2)} \ . \tag{33.163}$$

The scattering phase δ_ℓ increases by π. The value $\delta_\ell(E=0)$ gives the number of bound states, $\delta_\ell(0) = n^\ell_{\text{ligado}}\pi$.

33.2.7 Exercises

33.2.7.1 Ex: Green's method

Show that, knowing the solution of (33.116), that is, knowing the Green function, we can write the solution of the scattering problem (33.115) as,

$$\psi_{\mathbf{k}}(\mathbf{r}) = e^{i\mathbf{k}\cdot\mathbf{r}} + \tfrac{2m}{\hbar^2}\int d^3\mathbf{r}' G(\mathbf{r}-\mathbf{r}',k)V(\mathbf{r}')\psi_{\mathbf{k}}(\mathbf{r}) \ .$$

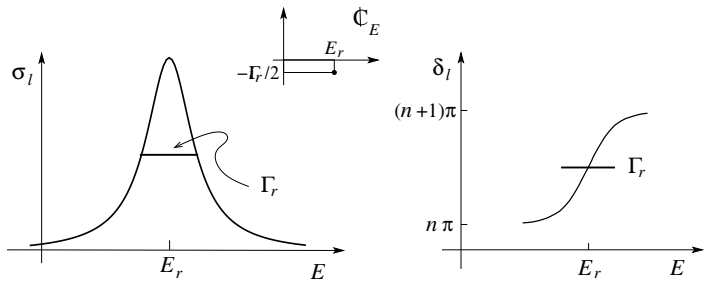

Figure 33.17: Peak of the resonance of width Γ_r: (Left) effective cross section $\sigma_\ell(E)$, (right) scattering phase $\delta_\ell(E)$, and (center) scheme of the position of the pole in the complex energy plane E.

Solution: *The solution of the homogeneous equation is just the incident wave and the solution of the inhomogeneous equation is the scattered wave. To show that this integral equation is equivalent to the problem (33.115) we define the free Hamiltonian* $\hat{H}_0 \equiv p^2/2m$ *and we apply the operator* $(E_k - \hat{H}_0)$ *to the integral equation:*

$$(E_k - \hat{H}_0)\psi_{\mathbf{k}}(\mathbf{r}) = (E_k - \hat{H}_0)e^{i\mathbf{k}\cdot\mathbf{r}} + \tfrac{2m}{\hbar^2}\int d^3r'(E_k - \hat{H}_0)G(\mathbf{r}-\mathbf{r}',k)V(\mathbf{r}')\psi_{\mathbf{k}}(\mathbf{r})$$
$$= \int d^3r'\delta^3(\mathbf{r}-\mathbf{r}',k)V(\mathbf{r}')\psi_{\mathbf{k}}(\mathbf{r}) = V(\mathbf{r})\psi_{\mathbf{k}}(\mathbf{r}) \ .$$

33.2.7.2 Ex: Green's function

Calculate the Green function of the equation (33.116).

Solution: *We make a Fourier transform of this equation,*

$$\int d^3r e^{-i\mathbf{q}\cdot\mathbf{r}}(E - \hat{H}_0)G(\mathbf{q},k) = \int d^3\mathbf{r} e^{-i\mathbf{q}\cdot\mathbf{r}}\tfrac{\hbar^2}{2m}\delta(\mathbf{r})$$
$$\left(E - \tfrac{\hbar^2 q^2}{2m}\right)G(\mathbf{q},k) = \tfrac{\hbar^2}{2m}$$
$$G(\mathbf{q},k) = \frac{\hbar^2}{2m(E-\hbar^2q^2/2m)} = \frac{1}{2mE/\hbar^2 - q^2} \ .$$

Transforming back,

$$G(\mathbf{r},k) = \frac{1}{(2\pi)^3}\int d^3\mathbf{q}\frac{e^{i\mathbf{q}\cdot\mathbf{r}}}{2mE/\hbar^2-q^2} = \frac{1}{(2\pi)^2}\int_0^\infty\int_0^\pi \frac{e^{iqr\cos\theta}}{2mE/\hbar^2-q^2}q^2\sin\theta d\theta dq$$
$$= \frac{1}{(2\pi)^2}\int_0^\infty \frac{q^2}{2mE/\hbar^2-q^2}\int_1^{-1}e^{iqrz}dzdq = \frac{-1}{(2\pi)^2}\int_0^\infty\frac{q^2}{2mE/\hbar^2-q^2}\frac{e^{iqr}-e^{-iqr}}{iqr}dq$$
$$= \frac{-1}{ir(2\pi)^2}\int_{-\infty}^{\infty}\frac{qe^{iqr}}{2mE/\hbar^2-q^2}dq \ .$$

This integral can be solved by the theorem of the residue,

$$G(\mathbf{r},k) = -\frac{e^{\sqrt{2mE}r/\hbar}}{4\pi r} \ .$$

33.2.7.3 Ex: Rutherford scattering

Consider the scattering of a particle of charge Q by a static charge distribution $\rho(\mathbf{r}) = \rho_0 e^{-\alpha r}$ totaling the charge Q'. Derive from (33.136) the formula (22.10) describing the Rutherford scattering.

Solution: *We consider the scattering of a particle of charge Q by a static charge distribution $\int \rho(\mathbf{r}')d^3r' = Q'$,*

$$\begin{aligned} Q' &= \int \rho_0 e^{-\alpha r} d^3r = 4\pi\rho_0 \int_0^\infty r^2 e^{-\alpha r} dr \\ &= -4\pi\rho_0 \left(\frac{r^2}{\alpha} + \frac{2r}{\alpha^2} + \frac{2}{\alpha^3}\right) e^{-\alpha r}\Big|_0^\infty = \frac{8\pi\rho_0}{\alpha^3} \ . \end{aligned}$$

Gauss' law requires, $\nabla^2 V = -4\pi\rho(\mathbf{r})$. Introducing the Fourier transform of the charge distribution,

$$\tilde{\rho}(\mathbf{q}) = \int d^3r e^{-i\mathbf{q}\cdot\mathbf{r}} \rho(\mathbf{r}) \equiv Q' F(\mathbf{q}) \ ,$$

where we defined the form factor $F(\mathbf{q})$ [10]. Thus the Fourier transform of Gauss's law is,

$$\mathbf{q}^2 \tilde{V}(\mathbf{q}) = 4\pi Q Q' F(\mathbf{q}) \ .$$

We calculate [1298],

$$\begin{aligned} \tilde{\rho}(\mathbf{q}) &= \int d^3r \rho_0 e^{-\alpha r} e^{-i\mathbf{q}\cdot\mathbf{r}} = 2\pi \int r^2 dr d(\cos\theta) \rho_0 e^{-\alpha r} e^{-iqr\cos\theta} = 2\pi \int r^2 dr \rho_0 e^{-\alpha r} \frac{e^{-iqr} - e^{iqr}}{-iqr} \\ &= \frac{2\pi}{iq}\rho_0 \int r dr e^{-\alpha r} e^{iqr} + c.c. = \frac{2\pi\rho_0}{iq}\left(-\frac{\partial}{\partial\alpha}\right)\int dr e^{i(q+i\alpha)r} + c.c. \\ &= \frac{2\pi\rho_0}{q}\left(-\frac{\partial}{\partial\alpha}\right)\left\{\frac{1}{q+i\alpha} + c.c.\right\} = 4\pi\rho_0\left(-\frac{\partial}{\partial\alpha}\right)\frac{1}{q^2+\alpha^2} = \frac{8\pi\rho_0\alpha}{(q^2+\alpha^2)^2} \ . \end{aligned}$$

Therefore,

$$F(\mathbf{q}) = \frac{\tilde{\rho}(\mathbf{q})}{\tilde{\rho}(0)} = \left(\frac{\alpha^2}{q^2+\alpha^2}\right)^2 \ .$$

Inserting into the equations (33.136) and (33.124) we obtain the effective differential section in the Born approximation,

$$\frac{d\sigma}{d\Omega} = \frac{4m^2Q^2Q'^2}{(\hbar^2q^2)^2}|F(\mathbf{q})|^2 \ .$$

[10] Always holds $F(0) = 1$

This shows that we can use measurements of effective cross sections to determine form factors and therefore charge distributions.
Particularly for the case $\alpha \to \infty$, when the density distribution describes a point potential by the form factor $F(\mathbf{q}) = 1$, we get the effective differential cross section,

$$\frac{d\sigma}{d\Omega} = \frac{4m^2Q^2Q'^2}{(\hbar^2q^2)^2} = \frac{4m^2Q^2Q'^2}{(\mathbf{p}' - \mathbf{p})^4} = \frac{m^2Q^2Q'^2}{4p^4 \sin^4 \frac{\theta}{2}} ,$$

since $\mathbf{p} \cdot \mathbf{p}' = p^2 \cos\theta$. This is Rutherford's famous scattering formula. It holds not only within the Born approximation, but follows from an exact quantum or classical derivation.

33.2.7.4 Ex: Scattering length for hard-core potentials

Calculate the scattering length for a spherical box barrier and a spherical box potential as a function of potential depth (see also Excs. 25.1.5.4 and 25.1.5.5 and [1354]).

Solution: *Do first for $V = 0$ introduce dephasing for $V \neq 0$, $R_\ell(r) = \frac{1}{2}\left[h_\ell^{(1)}(kr) + S_\ell h_\ell^{(2)}(kr)\right]$. Schrödinger $\psi = \frac{u}{r}$, $\frac{\partial^2 u}{\partial r^2} \equiv 0$ yields for $r \to 0$ $u(r) = c(r - a_s)$ and for $r \to \infty$ yields $u(r) = c' \sin(kr + \delta_0)$. Hence, $\delta_0 = -ka_s$ hard sphere.*

33.3 Cold atomic collisions

Modern techniques developed in the area of atomic optics allow to cool atomic gases to temperatures well below 1 μK. We use the expansions $j_\ell \sim x^\ell/(2\ell+1)!!$ and $n_\ell \sim (2\ell-1)!!/x^{\ell+1}$ in the equation (33.157), and obtain for $kR_0 \ll 1$,

$$\cos\delta_\ell \simeq \frac{2\ell+1)!!(2\ell-1)!!}{(kR_0)^{2\ell+1}} \frac{\ell + 1 + R_0\alpha_\ell(E)}{\ell - R_0\alpha_\ell(E)} . \tag{33.164}$$

A coarse approximation leads to

$$\cos\delta_\ell = \frac{\cos\delta_\ell}{\sin\delta_\ell} \overset{\delta_\ell \ll 1}{\simeq} \frac{1}{\sin\delta_\ell} \simeq \frac{1}{(R_0k)^{2\ell+1}} , \tag{33.165}$$

that is,

$$\sin\delta_\ell \simeq (R_0k)^{2\ell+1} . \tag{33.166}$$

In other words, the scattering phases decrease rapidly, in the regime of cold collisions, with increasing ℓ, and $\ell = 0$ type collisions dominate,

$$k\cot\delta_0 \overset{\alpha_\ell(E) \simeq \alpha_\ell(0)}{\simeq} -\frac{1 + R_0\alpha_0(0)}{R_0^2\alpha_\ell(E)} . \tag{33.167}$$

The s-wave *scattering length* defined by,

$$a_s \equiv \frac{R_0^2\alpha_\ell(E)}{1 + R_0\alpha_0(0)} = \frac{\sin\delta_0}{k} \tag{33.168}$$

then it is the only relevant parameter of the collision. For $R_0\alpha_0 \gg 1$ we find $a \simeq R_0$. For example, for a hard sphere we have $R_\ell(R_0) = 0$, $\alpha_\ell = \infty$, $a = R_0 > 0$ and $\cot\delta_0 = -1/kR_0$. For small kR_0 we obtain $\delta_0 \simeq -kR_0 < 0$, which corresponds to a negative phase shift for the repulsive potential, as expected. The effective cross section is,

$$\boxed{\sigma_0 = \frac{4\pi}{k^2}\frac{1}{1+\cot^2\delta_0} \simeq \frac{4\pi}{k^2+1/a_s^2}} \; . \tag{33.169}$$

In comparison to the effective cross section for higher angular momenta, $\sigma_\ell \propto \frac{\sin^2\delta_\ell}{k^2}$ behaves like,

$$\sigma_\ell \propto R_0^2(R_0k)^{4\ell} \to 0 \; . \tag{33.170}$$

In contrast, we find that the scattering at low energies has an s-wave character, σ being dominated by σ_0,

$$\sigma(E=0) = 4\pi a_s^2 \; . \tag{33.171}$$

For a hard sphere ($a = R_0$) we find an effective cross section *four times larger* than classically expected ($\sigma_{cl} = \pi R_0^2$).

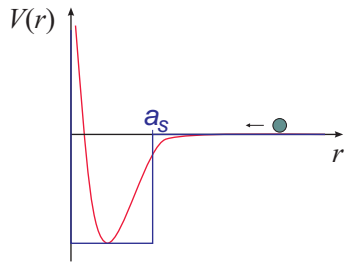

Figure 33.18: The cold collision can be described by a hard core potential.

In summary, for kinetic energies below the centrifugal barrier, only s-wave collisions are significant. The higher-order partial waves are *frozen* behind the centrifugal barrier. That is, the energy of cold collisions is not enough to excite a rotational motion, not even the one with the lowest rotational energy allowed by quantum mechanics. Such a collision is called *cold collision* or *s-wave collision*.

The relative wavefunction tends asymptotically to $\psi(R) \overset{R\to\infty}{\longrightarrow} k_{dB}^{-1}\sin\left[k_{dB}(R-a)\right] \overset{T\to 0}{\longrightarrow} R-a$. This means that for temperatures so low that the length of the Broglie wave of the relative motion is much longer than the potential range $k_{dB}^{-1} \gg R_{turning}$, the scattering becomes independent of temperature, and the scattering length a becomes well defined [11]

Generally, a repulsive interaction potential corresponds to a positive scattering length and an attractive potential to a negative one. However, if the attractive potential supports bound states, the value of the scattering length depends on the energy of the last bound state with respect to the dissociation threshold [1354, 1355].

[11] At temperatures at which the trajectory of atoms is described by de Broglie waves the only difference between an atom before and after an elastic collision is the phase shift δ_0 of this wave.

33.3.1 Collision cross section, unitarity regime

Note that the scattering length a may have a value quite different from r_e, especially in the presence of a Feshbach resonance. The meaning of *universality*, $|a| \gg r_e$, is that short-range properties play no role in the dynamics.

At low temperatures, $kr_e \to 0$, we have the equation (33.169). In contrast, in the *unitarity limit*, $k \to \infty$, but $r_e \to 0$, we have,

$$\sigma = \frac{8\pi}{k^2} \ , \tag{33.172}$$

and the cross section becomes independent of atomic particularities. What the equation (33.169) says is, that the maximum attainable cross-section is limited to the smallest of the values $8\pi a$ and $8\pi/k$. Even though $a(B)$ can be increased to divergent values near a Feshbach resonance, for finite collision energies it will never exceed an effective value $a_{eff} = 1/\sqrt{a^2 + 1/k^2}$. For a thermal gas, $k = \hbar^{-1}\sqrt{2\pi m k_B T}$, while for a pure condensate $k = 2\pi/L$, where L is the size of the condensate. Therefore, the effective scattering length can not exceed the size of the condensate. Unitarity also means that the kinetic energy exceeds the binding energy, $k_B T \equiv \frac{\hbar^2 k^2}{2m} \leq \frac{\hbar^2}{2ma^2}$.

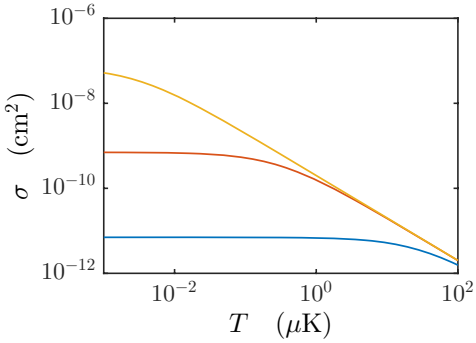

Figure 33.19: (code) Temperature dependence of the collision cross section for various scattering lengths. For higher scattering lengths, the unitarity limit is reached at lower temperatures.

The collision rate depends on the density, temperature and collisional cross section [711],

$$\begin{aligned} \gamma_{coll.peak} &= \sqrt{2}\sigma_{elast}\bar{v}n_0 \ , \\ \gamma_{coll.aver} &= \gamma_{coll.peak}/2\sqrt{2} \ . \end{aligned} \tag{33.173}$$

Note that at the unitary limit, as $\bar{v} \propto \sqrt{T}$, we have that $\sigma_{elas} \propto T$ and $n_0 \propto \bar{r}^{-3} \propto T^{-3/2}$, such that the collision rate is independent of temperature.

At low temperatures, $k \to 0$, the delocalization of the colliding particles is greater than its short-range structure. This is the *Wigner threshold law* [1374, 1363]. For elastic collisions of neutral ground state atoms, the cross section (33.169) becomes temperature-independent. Thus, the rate coefficient decreases as $\langle\sigma\bar{v}\rangle \propto \sqrt{T}$, while the collision rate increases as $\langle\sigma\bar{v}n_0\rangle \propto T^{-1}$.

For inelastic collisions, $\sigma \propto T^{-1}$. For three-body collisions see [424].

33.3.2 Collisions between identical particles

We consider collisions of two identical particles. Separating the center-of-mass coordinates, $\mathbf{R} = \mathbf{r}_1 + \mathbf{r}_2$, from the relative ones, $\mathbf{r} = \mathbf{r}_1 - \mathbf{r}_2$, we see that $\mathbf{R}$ is symmetric and $\mathbf{r}$ antisymmetric in $\mathbf{r}_1$ and $\mathbf{r}_2$. We separate the wavefunction into orbital and spin parts,

$$\Psi(x_1, x_2) = e^{i\mathbf{P}\cdot\mathbf{R}}\psi(\mathbf{r})\chi(s_1, s_2) \ . \tag{33.174}$$

For indistinguishable particles the result of the scattering has the asymptotic form,

$$\psi(\mathbf{r}) \sim e^{i\mathbf{k}\cdot\mathbf{r}} + f(\theta)\frac{e^{ikr}}{r} \ . \tag{33.175}$$

33.3.2.1 Spin 0 bosons

For bosons with spin 0 we have $\chi = 1$ and, because of the symmetry of Ψ, holds $\psi(\mathbf{r}) = \psi(-\mathbf{r})$. Consequently, we must symmetrize the result of the scattering. We make use of the fact that the exchange of particles via $\mathbf{r} \to -\mathbf{r}$ in polar coordinates corresponds to the transformation $\theta \to \pi - \theta$, $r \to r$,

$$\psi \sim (e^{i\mathbf{k}\cdot\mathbf{r}} + e^{-i\mathbf{k}\cdot\mathbf{r}}) + [f(\theta) + f(\pi - \theta)]\frac{e^{ikr}}{r} \ . \tag{33.176}$$

For the effective differential cross section we obtain,

$$\frac{d\sigma}{d\Omega} = |f(\theta) + f(\pi - \theta)|^2 = |f(\theta)|^2 + |f(\pi - \theta)|^2 + 2\mathfrak{Re}\ [f^*(\theta)f(\pi - \theta)] \ . \tag{33.177}$$

The first two terms are classical. The third (interference) term appears because of quantum statistics. The angles showing up in (33.177) are illustrated in Fig. 33.20. For bosons, the interference terms double the cross section as compared to the classical case, when $\theta = \pi/2$,

$$\boxed{\frac{d\sigma}{d\Omega} = 4|f(\tfrac{\pi}{2})|^2} \ . \tag{33.178}$$

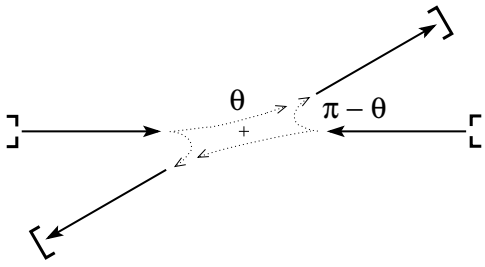

Figure 33.20: The symmetrization of the collision wavefunction produces two paths with angles θ and $\pi - \theta$, which must be added coherently.

For the isotropic potential $V(r)$ we use the partial wave representation,

$$f(\theta) = \sum_\ell i^\ell f_\ell P_\ell(\cos\theta) \ . \tag{33.179}$$

With $P_\ell(\cos\theta) = (-1)^\ell P_\ell(\pi - \cos\theta)$ we get,

$$f(\theta) - f(\pi - \cos\theta) = 2\sum_{\ell\text{par}} i^\ell f_\ell P_\ell(\cos\theta) \ , \tag{33.180}$$

and we find that only *even angular momenta* appear [12]

33.3.2.2 Spin 1/2 fermions

In the case of fermions with spin $\frac{1}{2}$ two situations are possible [13]:

1. The singlet spin state $\chi_s = \frac{1}{\sqrt{2}}[(|\uparrow\downarrow\rangle - |\downarrow\uparrow\rangle]$ is antisymmetric and, consequently, the orbital part,
$$\psi(\mathbf{r}) = \psi(-\mathbf{r}) \tag{33.181}$$
must be symmetric. The cross section is the same as for spin 0 bosons,
$$\left.\frac{d\sigma}{d\Omega}\right|_s = |f(\theta) + f(\pi - \theta)|^2 \ . \tag{33.182}$$

2. The triplet spin states,
$$\chi_s = \begin{cases} |\uparrow\uparrow\rangle \\ \frac{1}{\sqrt{2}}(|\uparrow\downarrow\rangle + |\downarrow\uparrow\rangle) \\ |\downarrow\downarrow\rangle \end{cases} \tag{33.183}$$
require an antisymmetric orbital wavefunction, $\psi(\mathbf{r}) = -\psi(-\mathbf{r})$, and we obtain a scattering amplitude, $f(\theta) \to f(\theta) - f(\pi - \theta)$, which only contains *odd angular momenta* ℓ. With this, the cross section becomes,
$$\left.\frac{d\sigma}{\Omega}\right|_t = |f(\theta) - f(\pi - \theta)|^2 \overset{\theta=\pi/2}{=} 0 \ , \tag{33.184}$$
Note that polarized fermions only scatter in channels of odd angular momenta: cold bosonic atoms show a *contact potential* due to s-wave collisions (33.180)), polarized fermionic atoms only interact weakly in the p-channel. In the case of a statistically mixed ensemble of non-polarized fermions we have a the weighted average,
$$\frac{d\sigma}{d\Omega} = \frac{3}{4}\left.\frac{d\sigma}{\Omega}\right|_t + \frac{1}{4}\left.\frac{d\sigma}{\Omega}\right|_s = |f(\theta)|^2 + |f(\pi - \theta)|^2 - \mathfrak{Re}\,[f^*(\theta) f(\pi - \theta)] \ . \tag{33.185}$$

33.3.2.3 Molecular spectra

Here we consider rotational spectra of low energies $E_{rot} = \hbar^2\ell(\ell+1)/2\Theta \ll E_{eletronico} \sim eV$. In slow time scales we can consider the electronic shell to be rigid. We look at two examples of molecules with bosonic and fermionic nuclei:

[12] For ℓ odd the Legendre polynomial changes sign, and the contributions vanish.

[13] This is analogous to the case of helium, where the spatial function of the state $2s^2\uparrow\uparrow$ is always antisymmetric, but for the $2s\uparrow 2p\uparrow$ exist symmetric spatial orbitals.

- Molecules $(C^{12})_2$: the nuclei are 0-spin bosons, so only collisions with even ℓ are allowed.
- Molecules H_2: the nuclei are spin-$\frac{1}{2}$ fermions, so we have for a spin wavefunction,

$$\chi = \chi_s : \ell = \text{even, para-hydrogen}, \chi = \chi_t : \ell = \text{odd, ortho-hydrogen.} \quad (33.186)$$

The transformation of ortho-hydrogen into para-hydrogen is difficult (the nuclei being well shielded), such that we observe two types of gases with,

$$E_{rot,para} = 0, \frac{3}{\Theta}, \frac{10}{\Theta}, \frac{21}{\Theta}, ... E_{rot,orto} = \frac{1}{\Theta}, \frac{6}{\Theta}, \frac{15}{\Theta}, \dots . \quad (33.187)$$

33.3.3 Collisions between hot atoms

Angular moments with $\ell \leq kR_0$ should contribute a lot to σ, since the collision parameter is inside R_0. For a hard sphere we have $\alpha_\ell = \infty$ and $\cot \delta_\ell = n_\ell(kR_0)/j_\ell(kR_0)$. With the asymptotic expressions of j_ℓ and n_ℓ we obtain $\cot \delta_\ell \sim -\cot(kR_0 - \ell\pi/2)$, that is, $\delta_\sim - kR_0 + \ell\pi/2$ $(+\pi)$. With these scattering phases we can calculate the scattering cross section,

$$\sigma \simeq \tfrac{4\pi}{k^2} \sum_{\ell=0}^{kR_0} (2\ell+1) \sin^2 \delta_\ell \quad (33.188)$$

$$\simeq \tfrac{4\pi}{k^2} \sum_{\ell=0}^{kR_0} (\ell+1) \cos^2[kR_0 - (\ell+1)\pi/2] + \ell \sin^2(kR_0 - \ell\pi/2)$$

$$= \tfrac{4\pi}{k^2} \sum_{\ell=0}^{kR_0} \ell(\cos^2 + \sin^2) = \tfrac{4\pi}{k^2} \frac{kR_0(kR_0+1)}{2} = 2\pi R_0^2 , \quad (33.189)$$

which is the double of the classical value.

33.3.4 Photoassociation during ultracold collisions

Ultra-cold collisions are an interesting example of how light can control the result of inelastic or reactive collisions. Here we discuss as a specific example the *photoassociation*, which illustrates the utility of the dressed states pictures. The upper panel of Fig. 33.22 shows schematic curves of (bare) potentials relevant to our discussion. Two atoms in the ground state form a relatively shallow molecular ground state characterized by electrostatic dispersion

$$V_1(r) = -\frac{C_6}{R^6} . \quad (33.190)$$

or long-range *van der Waals potential*. Two other molecular states arise from the interaction of an excited atom with the ground state atom. The predominant term of the interaction is the potential of resonant dipole-dipole interactions,

$$V_{2,3}(r) = - \mp \frac{C_3}{R^3} . \quad (33.191)$$
