Preface

Script with subjects and exercises for graduation in Physics relevant to the courses of the IFSC: FCM0501 (Física I para físicos), FCM0101 (Física I para engenheiros e matemáticos), FFI0405 (Física Geral I para engenheiros e matemáticos), FCM0200 (Física Básica I para engenheiros e matemáticos).

Information and announcements regarding the course will be published on the website:
http://www.ifsc.usp.br/ strontium/ − > Teaching − > FFI0132

The following literature is recommended for preparation and further reading:

Ph.W. Courteille, script on *Optical spectroscopy: A practical course* (2020)

Ph.W. Courteille, script on *Electrodynamics: Electricity, magnetism, and radiation* (2020)

Ph.W. Courteille, script on *Quantum mechanics applied to atomic and molecular physics* (2020)

H.J. Pain, *The Physics of Vibrations and Waves*

Zilio & Bagnato, *Apostila do Curso de Física, Mecânica, calor e ondas*

Part I

Classical Mechanics

Chapter 1

Foundations and mathematical tools

1.1 General considerations on physics

Before starting the course let us make some general comments on physics [1].

1.1.1 Definition of physics

1.1.1.1 Why to study physics?

The best motivation to study physics is certainly the desire to unravel the mysteries of the universe. The desire may be driven by curiosity (where are we coming from and where are we going) or by necessity, to improve our living conditions or to survive critical situations ("we've gonna have to science the shit out of this [Matt Damon]").

Even if, during the studies or practicing research, curiosity is not always satisfied and many questions remain open, physicists are often confronted with fundamental questions.

1.1.1.2 What is the purpose of physics?

- Technology
- Understanding the world, curiosity leading to sometimes unexpected applications
- The reward of the study is a better appreciation of the simplicity, beauty, and harmony of the laws of nature.

1.1.1.3 Theory and reality

Since ancient Greece philosophers and scientists have been wondering about what is out there and how much of it the human mind can grasp. How does our image of the universe connect to reality? How much of reality can we learn through observation?

"Quantum phenomena do not occur in a Hilbert space. They occur in a laboratory [Asher Peres]"

[1] See [961], Cap. 1.

"It doesn't matter how beautiful your theory is, it doesn't matter how smart you are. If it doesn't agree with experiment, it's wrong" [Richard P. Feynman].

1.1.1.4 The scientific method, physics and mathematics

Observation and experimentation as well as abstraction and induction.

- Abstraction of inessential effects
- Physical laws and theories (reduction of a large number of phenomena to a few laws, predictive power)
- Domains of restricted validity (new theories contain the old ones in some limit, even if the basic concepts may differ radically)
- Ancient theories have their right to be (e.g. because of their simplicity, they can be derived from a more general theory following well-defined procedures).

1.1.1.5 Relationship between physics and mathematics

Although mathematics is the most important tool in physics, these two sciences are fundamentally different. According to *Carl Friedrich von Weizsäcker* mathematics is a *structural science* while physics is a *natural science* [1345, 1346]. The mathematical method is deductive. A mathematical theory is good when it is complete and intrinsically without controversy, it cannot be *correct*. It is not more than a tool and does not contain *reality*. For instance, axiomatic geometry remains valid, when the words 'point, straight, plane' are replaced by 'table, cup, chair'. The method of mathematics is deductive.

In contrast, physics is a *natural science*. A physical theory is good when it is *true*, which means that it describes the universe as correctly as possible. The central activity of a physicist is to *measure* [2]. The physicist makes hypotheses that he formulates as theories, but he must verify their correctness experimentally, otherwise the theory is of no use. The physicist already has in his mind an image of how the universe works (which may or may not be correct), and this image guides his intuition in the formulation of new better theories or improved measurement techniques. According to *Karl Popper*, in contrast to pseudo-science and religious beliefs, a physical theory or model must be *falsifiable*, i.e. its correctness must be verifiable through experimentation. It is good practice to incorporate into a scientific model conjectures about its range of validity (e.g. sufficiently low velocities, small masses, or high energies). Within its range of validity the model should be universal, i.e. always and everywhere make correct predictions in the outcome of experiments. A single negative experiment is sufficient to falsify the model. A scientific model must provide recipes allowing for its falsification by experiment or at least allow for them to be formulated. An good example is Einstein's hidden variables assumption. At the beginning the debate appeared as purely metaphysical. Only Bell's proposal how to test the assumption by measurement turned it into a scientific theory, which finally was falsified experimentally. This shows that the whole art of a physicist consists in constructing meaningful

[2] 'Quantum phenomena do not occur in Hilbert space, they occur in laboratory' [A. Peres].

experiments. The biggest task of theory is to allow questions to be asked. Measuring means: asking the *right question*. A right question is a question with possible answers, called *observables*.

1.1.1.6 Relationship between physics and other sciences

- Chemistry and molecular biology

1.1.1.7 Plato, Newton, Leibniz, Kant, Einstein and Bohr

What is first ideas or phenomena? Plato, Newton, Kant and Einstein would perhaps say: ideas. Leibniz and Bohr: phenomena.

However, Plato has a lot say about quantum mechanics, dialectic approach, the part and the whole. Also the cave parabola seems to indicate that Plato would support the relativity of perceptions.

1.1.1.8 Space and time

The discussion of the role of *space* and *time* in physics is best started with the controverse between Newton and Leibniz. Newton imagined space and time as a Cartesian space. Space and time are basically different from all other quantities: They are dimensions, they are the recipient in which all processes occur, To say it with Kant, 'die Gefäße unserer Erkenntnis, unseres Denkens'. *Leibniz* had another vision. He asked what a space with nothing in it might look like, what a time with nothing happening might look like. Space and time are no observables, but rather *distance* between objects or duration between events. They have no physical reality by themselves. They are nothing more than mathematical concepts, dimensions in which things may be displaced and evolve.

Time may be defined through processes which are, to the best of our knowledge, periodic, i.e. repetitive, like the oscillations of a pendulum. But we might also understand time as a measure for the frequency of any events, e.g. collisions between any two atoms in a gas. Then time runs fast if a lot happens, but slowly if nothing happens. Time then goes with the inverse of temperature.

1.1.1.9 Before the big bang

The basic process in modern physics is a collision. Every interaction force is mediated by particles. These particles collide with other particles and exchange energy, momentum and other features. The fundamental nature of the collision process leads us to define time as the inverse of the collision rate.

In this light, the question about the beginning of the universe or what was before the *big bang* might be a silly one, like to ask about the start point of a sphere. If with the density in the early universe the temperature diverges, so does the time. Time steps have to be chosen shorter and shorter as one approaches the big bang, without ever reaching the limit.

This implies that causality is interrupted, there is no point in asking about the before of the universe, may not even its origin.

1.1.1.10 The arrow of time

Aging seems to be a macroscopic phenomenon. It comes into play at the interface between the microscopic and macroscopic world. Classically at the boundary of kinetic theory and thermodynamics, i.e. via the second law of thermodynamics [951]. Modern theories pin it down to decoherence phenomena [1004].

Causality in chaos science: *weak causality*: Same causes have same effects.

strong causality: Similar causes have similar effects.

Not the physical laws are subject to *indeterminism*, but the quantum states cannot be characterized better than permitted by the uncertainty relation.

1.1.2 Structure of physics

1.1.2.1 Orders of magnitude, significant number of digits

The objects of physical science are measurable quantities or *observables*, which (at least in classical physics) correspond to *real* numbers. Even though complex numbers are sometimes used to represent physical quantities, only their real parts are associated with physical reality.

Many physical quantities have wide ranges of possible values (time, distances, ..), and many values are little known (for example, the number of stars in the universe. No physical quantity can be measured with absolute certainty. That is, when presenting the result of measurements, we always need to specify the estimated uncertainty or error. For example, a measurement of a mathematical constant may yield $\pi = 3.14159 \pm 0.00002$. Obviously, it is meaningless to specify a value with a higher precision as the uncertainty or to specify the uncertainty itself by more than 1 (or at most 2) digits. Hence, we always use the same number of *significant digits* for the value and its uncertainty, that is, the same number of digits behind the decimal point. If the quantity depends on several quantities, the significant digit is given by the quantity with the smallest precision.

The uncertainty of a measurement of a quantity m is a complicated issue because, in order to quantify it, in principle we would need a more precise measurement to compare with. However, what we always can do is repeat the measurement N times (if possible varying the conditions) and to calculate the mean value,

$$\bar{m} = \tfrac{1}{N} \sum_k m_k \tag{1.1}$$

of the individual measurement outcomes m_k, as well as the standard deviation,

$$\Delta m = \sqrt{\frac{1}{N-1} \sum_k (m_k - \bar{m})^2} \ . \tag{1.2}$$

The physical quantity is then specified as,

$$m = \bar{m} \pm \Delta m \ . \tag{1.3}$$

This uncertainty grasps *stochastic (or random) errors* due to an imperfect realization of the measurement limiting the *precision*. On the other hand, a conceptual flaw

of the design of the measurement apparatus can lead to deviations, which often are unknown. These are called *systematic errors* and limit the *accuracy* of the apparatus, as illustrated in Fig. 1.1.

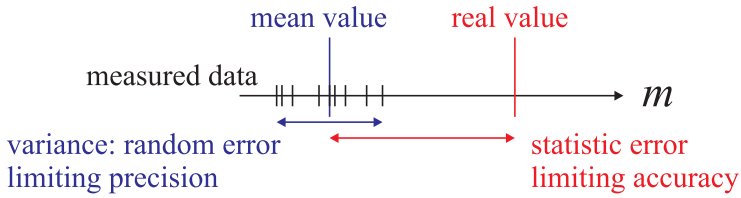

Figure 1.1: Illustration of stochastic and systematic errors in a measurement of a quantity m.

1.1.2.2 Units

Physical quantities *always* consist of a number and a unit forming an inseparable entity. For example, a mass can be specified by the assertion,

$$m = 2\,\mathrm{kg}\ , \tag{1.4}$$

stating that a particular object I have in mind and that I will call henceforward by the name m has a mass of 2 kg. Note that every equation represents an assertion, that is either a *definition* or a *verifiable statement*, which we assume to be true if not otherwise stated. For example, the sentence

$$2\,\mathrm{kg}\cdot 2\,\mathrm{m/s}^2 = 4\,\mathrm{N} \tag{1.5}$$

is a verifiable statement that we find to be correct [3]. In contrast, the statement

$$2\ \cdot 2 = 4\,\mathrm{N} \tag{1.6}$$

is false and the statement

$$2\ \cdot 2 = 4 \tag{1.7}$$

is physically meaningless.

Measuring means determining the numerical value of a physical quantity, but this is only possible with respect to a reference value. For example, distances are compared to the circumference of the Earth, times with the duration of the day. In practice, it is more convenient to choose as reference value the unitary value. For example, we will consider the distance

$$d = 1\,\mathrm{m}\ , \tag{1.8}$$

as our reference distance, which in turn is related to a (previously determined) Earth circumference by a fixed numerical factor of 1:40 000 000. In this sense, measurement always means comparison with a reference that we will call *standard*.

[3] A practical issue of consequently using units is that they allow us to quickly check whether a formula is false. If a formula represented by an equation exhibits different units on both sides, it must obviously be wrong.

1.1.2.3 Linearization of functions, graphical representation

The linearization of exponential, logarithmic and polynomial functions facilitates their graphical representation and the determination of constants,

$$\begin{aligned} y &= ax + b \\ \lg y &= ax + b \quad \Longrightarrow \quad y = 10^{ax+b} = BA^x \\ y &= a \lg x + b \\ \lg y &= a \lg x + b \quad \Longrightarrow \quad y = 10^{a \lg x + b} = Bx^a \end{aligned} \tag{1.9}$$

where we defined $B \equiv 10^b$ and $A \equiv 10^a$. See Fig. 1.2.

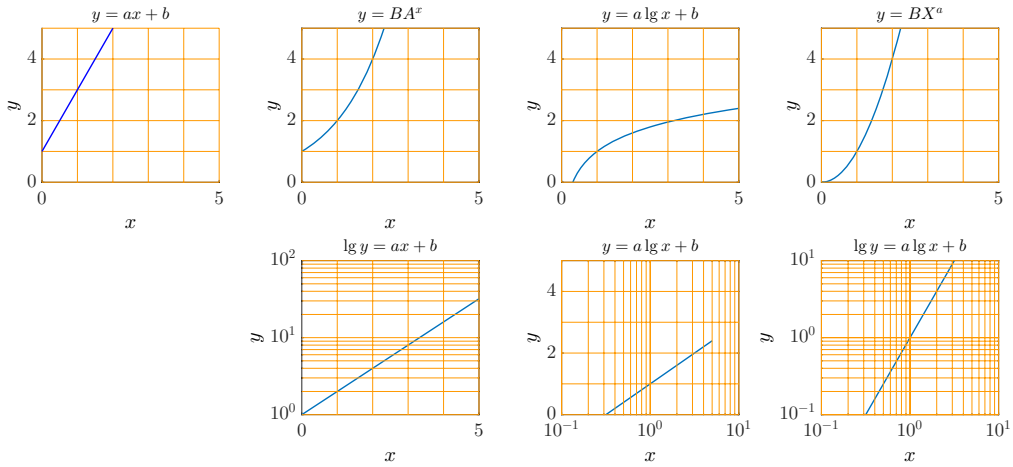

Figure 1.2: Original and linearized curved.

1.1.2.4 Length measurements

- Historical standards $1\,\mathrm{m} = 1\ 650\ 763.73 \lambda_{Kr86}$ and $c = 299\ 792\ 458\,\mathrm{m/s}$.
- Measurement of Eratosthenes 300 AC.

1.1.2.5 Coordinate systems

- Cartesian or polar coordinates for two or three dimensions.
- The latitude is easy to measure ($\lambda = 90° - \angle(norte - zenit)$), but the longitude is difficult (needs very precise clocks).

1.1.2.6 Time measurements

Absolute space and time do not exist. According to the restricted and the general theory of relativity they are interconnected by velocity and they depend on the presence of mass. But even in a more metaphysical sense one may wonder with Gottfried

Leibniz about the meaning of space with nothing inside and of time with nothing happening. Indeed, our practical approach to the measurement of time is based on the observation of recurrent phenomena that we think of being periodic, such as a day on Earth, the dripping of a water pipe, or the oscillation of a pendulum or of an atomic excitation. Assuming the time intervals separating the recurrent phenomena as being all the same, we build a ruler for time which we call clock (see Sec. 36.5).

Historically, the development of ever precise clocks has been motivated by navigation. Indeed, 1 minute of inaccuracy in the clock generates an uncertainty of 28 km in global positioning. And this motivation still prevails nowadays although, meanwhile, atomic clocks have uncertainties of below 10^{-16}.

Apart from periodic processes, time measurement can also be done by exponential processes, such as radioactive decay. This method is commonly used in radioactive dating. Do the Excs. 1.1.3.1 to 1.1.3.5.

1.1.2.7 The international system of units

Not every physical quantity needs to have its own standard. Often it is easier to quantify this quantity by measuring other physical quantities to which it is related in a simple way. For example, instead of measuring a *distance* by comparing it to the Earth circumference it may be easier to measure the *time* needed by a beam of light to cover this distance. In this sense, all physical quantities have been traced back by simple relationships to a small number of so-called *basic units*. Today, seven basic units are officially recognized as such by the international Conférence Générale des Poids et mesures (CGPM): the second (unit symbol 's') as a measure of time, the meter (unit symbol 'm') as a measure of distance, the kilogram (unit symbol 'kg') as a measure of mass, the Ampère (unit symbol 'A') as a measure of electrical current, the Kelvin (unit symbol 'K') as a measure of temperature, the mol (unit symbol 'mol') as a measure of molar mass, and the candela (unit symbol 'cd') as a measure of luminosity [4].

By decision of the 26^e CPGM in 2018 [5], all basic units are related to the most fundamental unit, the second, for which the most precise measurement tools are available. Measurements of all other units are traced back to time measurements using simple relationships and *natural constants* [6]:

[4] Note that, the molar mass and the luminosity are not fundamental in a strict sense, and only appear in the SI-system, because they are convenient for the communities of chemistry and illumination industry. After all, industrial and practical life applications are a main motivation for standardization (see Quantum Science Seminar talk by William Phillips).

[5] SI-Brochure.

[6] So, in a sense, 'time' is the only remaining fundamental quantity.

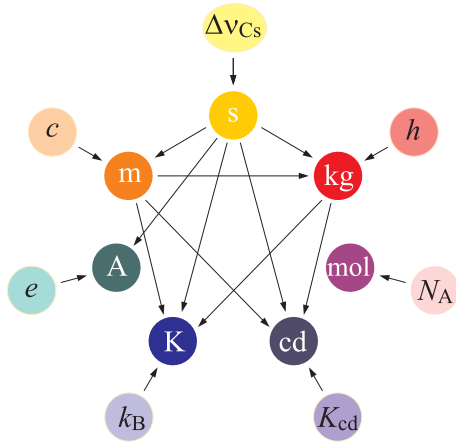

Figure 1.3: SI unit system.

base unit	relationship	definition
time	t	$1\,\mathrm{s} = \frac{9\ 192\ 631\ 770}{\Delta\nu_{Cs}}$
distance	$d = ct$	$1\,\mathrm{m} = \frac{c}{299\ 792\ 458}\,1\,\mathrm{s}$
mass	$m = \frac{h\nu}{c^2}$	$1\,\mathrm{kg} = \frac{(299\ 792\ 458)^2}{c^2}\frac{h}{6.626\ 070\ 15\times10^{-34}}\ \frac{1}{1\,\mathrm{s}}$
electric current	$I = \dot{Q}$	$1\,\mathrm{A} = \frac{e}{1.602\ 176\ 634\times10^{-19}}\ \frac{1}{1\,\mathrm{s}}$
temperature	$T = \frac{h\nu}{k_B}$	$1\,\mathrm{K} = \frac{c^2}{(299\ 792\ 458)^2}\frac{1.308\ 649\times10^{-23}}{k_B}\ 1\,\mathrm{kg}$
molar mass	$T = \frac{mc^2}{k_B}$	$1\,\mathrm{mol} = \frac{6.022\ 140\ 76\times10^{23}}{N_A}$
luminosity		$1\,\mathrm{cd}$

These natural constants are the transition frequency of cesium atoms Δ_{Cs}, the velocity of light c, Planck's constant h, the elementary charge e, Boltzmann's constant k_B, and Avogadro's constant N_A. The natural constants are considered as fixed and exact. Hence, any improved measurement of the velocity of light will not result in a more precise value of c, but in an improved definition of the meter.

1.1.3 Exercises

1.1.3.1 Ex: Mean value and standard deviation

The surface area of a house plant is measured by 10 people finding different values. Determine the mean and standard deviation of the measurement. How many measurements are in the confidence interval, that is, within the standard deviation?

person	measured value [m^2]
1	99.9
2	76
3	96.0
4	100
5	101.2
6	99.9
7	110
8	96.0
9	100.4
10	101.6

Solution: *The average value of the measurements is,*

$$\bar{A} = \frac{1}{10}\sum_{i=1}^{10} A_i = 98.1 \ .$$

The standard deviation is,

$$\bar{\sigma} = \sqrt{\frac{1}{10}\sum_{i=1}^{10}(A_i - \bar{A})} \simeq 8.22 \ .$$

Therefore, all measurements between $98.10 + 8.22 = 106.32$ *and* $98.1 - 8.22 = 89.88$ *fall within the confidence interval.*

1.1.3.2 Ex: Circumference of the Earth

In the 3rd century BC, the Greek Eratosthenes measured the circumference of the Earth by comparing the angles between the sun's rays and the vertical at noon in two different places. In Siena he measured 0° and in Alexandria, which is 785 km north of Siena, he measured 7.2°. What is the circumference he found?

Solution: *With* $s = 785$ *km and* $\theta = 7.2°$ *we find,*

$$\frac{s}{2\pi R} = \frac{\theta}{360°} \ .$$

Hence, $2\pi R = 39250\,\text{km}$.

1.1.3.3 Ex: Radioactive dating with ^{40}K

A chemical analysis of a 1 g rock sample reveals the presence of $m_K = 4.21 \cdot 10^{-2}$ g potassium (^{39}K+^{40}K) and $m_A = 9.02 \cdot 10^{-7}$ g argon (^{40}A). How old is the rock? **Help:** The current relative abundance is 1 atom of ^{40}K for every 8400 atoms of ^{39}K.

Only 12% of ^{40}K desintegrate into ^{40}A, the rest into ^{40}Ca. The decay time of ^{40}K is $t_{1/2} = 1.3 \cdot 10^9$ a.

Solution: *The amounts of potassium and argon correspond to,*

$$N_K = \frac{m_K}{u_K} = \frac{4.21 \cdot 10^{-2}\,\mathrm{g}}{39.1u} = 6.48 \cdot 10^{20}$$
$$N_A = \frac{m_A}{u_A} = \frac{9.02 \cdot 10^{-7}}{39.95u} = 1.36 \cdot 10^{16} \ .$$

Given the relative abundance, the current number of atoms of ^{40}K in the sample is,

$$N_{K40}^{actual} = \frac{N_K}{8400} \ .$$

The number of ^{40}K that disintegrated is,

$$N_{K40}^{desint} = \frac{100 N_A}{12} \ ,$$

and the initial number of ^{40}K number was,

$$N_{K40}^{initial} = N_{K40} + N_{K40}^{desint} \ .$$

So the rock age is,

$$t = t_{1/2} \log_2 \frac{N_{K40}^{initial}}{N_{K40}^{actual}} = 3.5 \cdot 10^9\,\mathrm{a} \ .$$

1.1.3.4 Ex: Paramecia

A biologist analyzes the behavior of a paramecium. Make a position versus time diagram and determine the average speed.

tempo [s]	posição [cm]
0	2
10.5	2.1
12	96.0
23	100
40	101.6

Solution: *The animal covers a distance of* 101.6 cm *in* 40 *seconds. With that we get the average speed,*

$$\bar{v} = \frac{101.6\,\mathrm{m}}{40\,\mathrm{s}} = 2.54\,\mathrm{cm/s} \ .$$

1.1.3.5 Ex: Spirograph

Find the parametrization of the curves produced by a spirograph.

Solution:

1.2 Basics mathematical notions, vector analysis

We will not spend time on mathematical fundamentals, such as notions of vectors and matrices, one-dimensional derivatives and integers, complex numbers, and differential equations. Students who have doubts should try to solve the exercises of Chapter 1 of the Handbook by Zilio and Bagnato.

1.2.1 Scalars, vectors and matrices

1.2.2 Exercises

1.2.2.1 Ex: Vectors

A room has the dimensions $3 \times 4 \times 5\,\mathrm{m}^3$. A fly departs from one of its corners and flies to the diametrically opposite corner. What is the absolute value of the displacement? Could its trajectory be less than this displacement? Choose a convenient coordinate system and express the displacement in vector form.

Solution: *see Zilio & Bagnato, Apostila: Física I: Mecânica, calor e ondas*

1.2.2.2 Ex: Vectors

Consider the vectors $\mathbf{x} = x_1\hat{\mathbf{e}}_1 + x_2\hat{\mathbf{e}}_2 + x_3\hat{\mathbf{e}}_3$ and $\mathbf{y} = y_1\hat{\mathbf{e}}_1 + y_2\hat{\mathbf{e}}_2 + y_3\hat{\mathbf{e}}_3$. Calculate $|\mathbf{x}|$, $\mathbf{x} \cdot \mathbf{y}$ and $\mathbf{x} \times \mathbf{y}$.

Solution:

1.2.2.3 Ex: Vectors

Can we combine two vectors with different absolute values and have a resulting vector with zero length? How about 3 vectors?

Solution: *see Zilio & Bagnato, Apostila: Física I: Mecânica, calor e ondas*

1.2.2.4 Ex: Vectors

Consider a moving body whose position vector is given (in cm) by $\mathbf{r} = 3\hat{\mathbf{e}}_x \cos\omega t + 4\hat{\mathbf{e}}_y \sin\omega t$.
a. Display in a scaled graph $\mathbf{r}$ at a given time t;

b. after a small time interval Δt show the new vector $\mathbf{r}$ on the same graph;
c. calculate the displacement $\Delta\mathbf{s} = \mathbf{r}(t + \Delta t) - \mathbf{r}(t)$ suffered by the body during the interval Δt;
d. calculate $\mathbf{v} = \Delta\mathbf{s}/\Delta t$ and check its orientation for $\omega t = 0,\ \pi/2,\ \pi,\ 3\pi/2$;
e. calculate $\mathbf{r} \cdot \mathbf{v}$ and discuss the result;
f. calculate $\mathbf{r} \times \mathbf{v}$ and discuss the result.

Solution: *see Zilio & Bagnato, Apostila: Física I: Mecânica, calor e ondas*

1.2.2.5 Ex: Vectors

Show that the magnitude of the sum of two vectors $\mathbf{a}$ and $\mathbf{b}$ is always within the limits,

$$||\mathbf{a}| - |\mathbf{b}|| \leq |\mathbf{a} + \mathbf{b}| \leq |\mathbf{a}| + |\mathbf{b}| \ .$$

Solution: *Calculating the square of the terms,*

$$(|\mathbf{a}| - |\mathbf{b}|)^2 \leq (\mathbf{a} + \mathbf{b})^2 \leq (|\mathbf{a}| + |\mathbf{b}|)^2 \ ,$$

we get,

$$-|\mathbf{a}||\mathbf{b}| \leq |\mathbf{a}||\mathbf{b}| \cos\theta \leq |\mathbf{a}||\mathbf{b}| \ .$$

1.2.2.6 Ex: Vector product

Invent a method based on the cross product to calculate the area enclosed by a path delimited by the points $A \to B \to C$....

Solution: *The area is given by,*

$$F = \tfrac{1}{2}(\overrightarrow{AB} \times \overrightarrow{AC} + \overrightarrow{AC} \times \overrightarrow{AD} + \overrightarrow{AB} \times \overrightarrow{AC} + ...) \ .$$

For convex paths, all components are positive. For partially concave paths, some components can be negative.

1.2.2.7 Ex: Matrix multiplication

Determine the products of the following matrices,

$$\begin{pmatrix} 1 & a \\ 0 & 1 \end{pmatrix}\begin{pmatrix} 1 & 0 \\ b & 1 \end{pmatrix} \quad , \quad \begin{pmatrix} 1 & 0 \\ b & 1 \end{pmatrix}\begin{pmatrix} 1 & a \\ 0 & 1 \end{pmatrix} \quad , \quad \begin{pmatrix} 4 & 3 \\ 2 & 2 \\ 7 & -5 \end{pmatrix}\begin{pmatrix} 1 & 2 & 3 & 4 \\ 5 & 6 & 7 & 8 \end{pmatrix} \ .$$

Solution: *trivial*

1.2.2.8 Ex: Matrix multiplication

Consider the matrices A and B and the column vector $\mathbf{x}$ given by,

$$A = \begin{pmatrix} 0 & 1 & 0 \\ 1 & 1 & 0 \\ 0 & 1 & 1 \end{pmatrix} \quad , \quad B = \begin{pmatrix} -1 & -5 & 8 \\ 2 & 1 & 0 \\ 1 & 4 & 6 \end{pmatrix} \quad , \quad \vec{x} = \begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix} \ .$$

a. Calculate the vector $\mathbf{y} = A(B\mathbf{x})$.
b. Show that for arbitrary matrices A and B and vectors $\mathbf{x}$ holds $A(B\mathbf{x}) = (AB)\mathbf{x}$.
c. Let A be an arbitrary matrix with A_{ij} elements. The conjugate matrix of A^t is defined by $(A^t)_{ij} = A_{ji}$; that is, the column indexes i and those of the row j are exchanged. Show,

$$(AB)^t = B^t A^t \ .$$

Solution: *a. We calculate,*

$$\begin{pmatrix} 0 & 1 & 0 \\ 1 & 1 & 0 \\ 0 & 1 & 1 \end{pmatrix} \begin{pmatrix} -1 & -5 & 8 \\ 2 & 1 & 0 \\ 1 & 4 & 6 \end{pmatrix} \begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix} = \begin{pmatrix} 2 \\ 1 \\ 3 \end{pmatrix} \ .$$

b. We calculate,

$$\begin{aligned}
(AB)\mathbf{x} &= \begin{pmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{pmatrix} \begin{pmatrix} b_{11} & b_{12} & b_{13} \\ b_{21} & b_{22} & b_{23} \\ b_{31} & b_{32} & b_{33} \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \\ x_3 \end{pmatrix} \\
&= \begin{pmatrix} a_{11}b_{11} + a_{12}b_{21} + a_{13}b_{31} & a_{11}b_{12} + a_{12}b_{22} + a_{13}b_{32} & a_{11}b_{13} + a_{12}b_{23} + a_{13}b_{33} \\ a_{21}b_{11} + a_{22}b_{21} + a_{23}b_{31} & a_{21}b_{12} + a_{22}b_{22} + a_{23}b_{32} & a_{21}b_{13} + a_{22}b_{23} + a_{23}b_{33} \\ a_{31}b_{11} + a_{32}b_{21} + a_{33}b_{31} & a_{31}b_{12} + a_{32}b_{22} + a_{33}b_{32} & a_{31}b_{13} + a_{32}b_{23} + a_{33}b_{33} \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \\ x_3 \end{pmatrix} \\
&= \begin{pmatrix} (a_{11}b_{11} + a_{12}b_{21} + a_{13}b_{31})\,x_1 + (a_{11}b_{12} + a_{12}b_{22} + a_{13}b_{32})\,x_2 + (a_{11}b_{13} + a_{12}b_{23} + a_{13}b_{33})\,x_3 \\ (a_{21}b_{11} + a_{22}b_{21} + a_{23}b_{31})\,x_1 + (a_{21}b_{12} + a_{22}b_{22} + a_{23}b_{32})\,x_2 + (a_{21}b_{13} + a_{22}b_{23} + a_{23}b_{33})\,x_3 \\ (a_{31}b_{11} + a_{32}b_{21} + a_{33}b_{31})\,x_1 + (a_{31}b_{12} + a_{32}b_{22} + a_{33}b_{32})\,x_2 + (a_{31}b_{13} + a_{32}b_{23} + a_{33}b_{33})\,x_3 \end{pmatrix} \\
&= \begin{pmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{pmatrix} \begin{pmatrix} b_{11}x_1 + b_{12}x_2 + b_{13}x_3 \\ b_{21}x_1 + b_{22}x_2 + b_{23}x_3 \\ b_{31}x_1 + b_{32}x_2 + b_{33}x_3 \end{pmatrix} = A(B\mathbf{x})
\end{aligned}$$

c. We calculate,

$$\begin{aligned}
(AB)^t &= \left[\begin{pmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{pmatrix} \begin{pmatrix} b_{11} & b_{12} & b_{13} \\ b_{21} & b_{22} & b_{23} \\ b_{31} & b_{32} & b_{33} \end{pmatrix} \right]^t \\
&= \begin{pmatrix} a_{11}b_{11} + a_{12}b_{21} + a_{13}b_{31} & a_{11}b_{12} + a_{12}b_{22} + a_{13}b_{32} & a_{11}b_{13} + a_{12}b_{23} + a_{13}b_{33} \\ a_{21}b_{11} + a_{22}b_{21} + a_{23}b_{31} & a_{21}b_{12} + a_{22}b_{22} + a_{23}b_{32} & a_{21}b_{13} + a_{22}b_{23} + a_{23}b_{33} \\ a_{31}b_{11} + a_{32}b_{21} + a_{33}b_{31} & a_{31}b_{12} + a_{32}b_{22} + a_{33}b_{32} & a_{31}b_{13} + a_{32}b_{23} + a_{33}b_{33} \end{pmatrix}^t \\
&= \begin{pmatrix} a_{11}b_{11} + a_{12}b_{21} + a_{13}b_{31} & a_{21}b_{11} + a_{22}b_{21} + a_{23}b_{31} & a_{31}b_{11} + a_{32}b_{21} + a_{33}b_{31} \\ a_{11}b_{12} + a_{12}b_{22} + a_{13}b_{32} & a_{21}b_{12} + a_{22}b_{22} + a_{23}b_{32} & a_{31}b_{12} + a_{32}b_{22} + a_{33}b_{32} \\ a_{11}b_{13} + a_{12}b_{23} + a_{13}b_{33} & a_{21}b_{13} + a_{22}b_{23} + a_{23}b_{33} & a_{31}b_{13} + a_{32}b_{23} + a_{33}b_{33} \end{pmatrix} \\
&= \begin{pmatrix} b_{11} & b_{21} & b_{31} \\ b_{12} & b_{22} & b_{32} \\ b_{13} & b_{23} & b_{33} \end{pmatrix} \begin{pmatrix} a_{11} & a_{21} & a_{31} \\ a_{12} & a_{22} & a_{32} \\ a_{13} & a_{23} & a_{33} \end{pmatrix} \\
&= \begin{pmatrix} b_{11} & b_{12} & b_{13} \\ b_{21} & b_{22} & b_{23} \\ b_{31} & b_{32} & b_{33} \end{pmatrix}^t \begin{pmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{pmatrix}^t = B^t A^t \ .
\end{aligned}$$

1.3 Infinitesimal calculus

Several physical quantities are related by derivatives or integrals.

1.3.1 Derivation

1.3.2 Integration

1.3.3 Exercises

1.3.3.1 Ex: Derivatives

We know that $(\sin x)' = \cos x$ and $(\cos x)' = -\sin x$. Use this notion to calculate:

a. $(\arccos x)'$,
b. $(\arctan x)'$.

Derive by x:

c. $y = (x^3 + 2)\cos x^2$,
d. $y = \dfrac{x^2 + 1}{\sin \ \ln x}$.

Calculate the derivatives of,

e. $f(x) = 5 \ x \ e^{ax} \ \sin x$,
f. $f(t) = \dfrac{a^t}{\sin t}$,
g. $f(z) = \ln \dfrac{1 - z^2}{1 + z^2}$.

Solution: *Deriving by x*

c. $y' = 3x^2 \cos x^2 - 2x\left(x^3 + 2\right)\sin x^2$
d. $y' = \dfrac{2x}{\sin(\ln x)} - \dfrac{x^2 + 1}{\sin^2 \ln x}\dfrac{\cos \ln x}{x}$.

The derivatives are

e. $f(x) = 5e^{ax}\sin x + 5xe^{ax}(\sin x)\, a + 5xe^{ax}\cos x$
f. $f(t) = -a^t \dfrac{\ln a \sin t - \cos t}{-1 + \cos^2 t}$
h. $f(z) = \dfrac{4z}{z^4 - 1}$.

1.3.3.2 Ex: Curves discussion

Consider the parable $y = 2x^2 + x - 3$.
a. Using the concept of the derivative, find the position x_0 that corresponds to the extreme (maximum or minimum);

b. Substitute the value of x_0 in the parabola equation to find the value of y_0;
c. Calculate the squares to find the vertex points x_0 and y_0;
d. Find the points at which the parable crosses the axis x;
e. Sketch the parable (graphic with few details);
f. Using integration, find the area under the parable between the points 1 and 2.

Solution: *see Zilio & Bagnato, Apostila: Física I: Mecânica, calor e ondas*

1.3.3.3 Ex: Integrals

Calculate the following indefinite integrals,

$$\text{a.} \quad \int 3x \; dx \;,$$
$$\text{b.} \quad \int (7x^2 + 4x^3 - 2) \; dx \;,$$

and the definite integrals,

$$\text{c.} \quad \int_0^{\pi} (3\sin x + \cos x) \; dx \;,$$
$$\text{d.} \quad \int_{-1}^{1} (5 + 2x^2) \; dx \;,$$
$$\text{e.} \quad \int_0^{1} e^{2x} \; dx \;,$$
$$\text{f.} \quad \int_0^{\pi/4} \sin x \cos x \; dx \;.$$

Solution: *see Zilio & Bagnato, Apostila: Física I: Mecânica, calor e ondas*

1.3.3.4 Ex: Integrals

Find a suitable substitution to solve the following integrals,

a. $\int dt \;\; \sin(\omega t + \alpha)$ b. $\int dx \; \frac{2x}{\sqrt{1+x^2}}$

c. $\int dx \; x^2 \ln x$ d. $\int_0^{\pi/3} d\phi \; \frac{\sin\phi}{\sqrt{1+\cos\phi}}$

Calculate by partial integration,

e. $\int dx \; (x+2)^2 \ln x$ f. $\int dx \; xe^{-x}$

g. $\int dx \; x^2 \ln x$ h. $\int_0^1 dx \; x\sqrt{1+x}$

Calculate,

i. $\int \frac{dx}{x(\ln x)^3}$ j. $\int dx\ \frac{\sin 2x}{1-\cos 2x}$

Find a serial expansion around the position $x = 0$ for,

k. $\int_0^1 dx\ e^{-x^2}$ l. $\int_0^\pi dx\ \frac{\sin x}{x}$

Solution:

a. $$\int \sin(\omega t + \alpha)dt = -\frac{\cos(\omega t + \alpha)}{\omega}$$

b. $$\int \frac{2x}{\sqrt{1+x^2}}dx = 2\sqrt{(1+x^2)}$$

c. $$\int x^2 \ln x dx = \frac{1}{3}x^3 \ln x - \frac{1}{9}x^3$$

d. $$\int_0^{\pi/3} \frac{\sin\phi}{\sqrt{1+\cos\phi}}d\phi = -2\sqrt{(1+\cos\phi)}\Big|_0^{\pi/3} = \left(2-\sqrt{3}\right)\sqrt{2}$$

e. $$\int (x+2)^2 \ln x dx = \left(\frac{1}{3}x^2 + 2x + 4\right) x\ln x - \left(\frac{1}{9}x^2 + x + 4\right)x$$

f. $$\int xe^{-x}dx = -(x+1)e^{-x}$$

g. $$\int x^2 \ln x dx = \frac{1}{3}x^3 \ln x - \frac{1}{9}x^3$$

h. $$\int_0^1 x\sqrt{1+x}dx = -\frac{2}{3}\left(\sqrt{(1+x)}\right)^3 + \frac{2}{5}\left(\sqrt{(1+x)}\right)^5\Big|_0^1 = \frac{4}{15}(\sqrt{2}+1)$$

i. $$\int \frac{dx}{x(\ln x)^3} = -\frac{1}{2\ln^2 x}$$

j. $$\int \frac{\sin 2x}{1-\cos 2x}dx = \frac{1}{2}\ln(1-\cos 2x)$$

k. $$\int \frac{x}{e^x}dx = -(x+1)e^{-x}$$

l. $$\int_0^1 e^{-x^2}dx = \int_0^1 \sum_{n=0}^{\infty}\frac{(-1)^n x^{2n}}{n!}dx = \sum_{n=0}^{\infty}\frac{(-1)^n}{n!}\frac{x^{2n+1}}{2n+1}\Big|_0^1$$
$$= \sum_{n=0}^{\infty}\frac{(-1)^n}{n!}\frac{1}{2n+1}$$

m. $$\int_0^\pi \frac{\sin\phi}{\phi}d\phi = \int_0^\pi \sum_{n=0}^{\infty}\frac{(-1)^n\phi^{2n}}{(2n+1)!}d\phi = \sum_{n=0}^{\infty}\frac{(-1)^n\phi^{2n+1}}{(2n+1)!(2n+1)}\Big|_0^\pi$$
$$= \sum_{n=0}^{\infty}\frac{(-1)^n\pi^{2n+1}}{(2n+1)!(2n+1)}$$

1.3.3.5 Ex: Numerical integration for pedestrians

Consider the differential equation for the mass-spring system $\ddot{x} = -\omega^2 x$ with $\omega = 2\pi \cdot 1\ \mathrm{s}^{-1}$.
a. Determine the equivalent system of coupled first-order differential equations.
b. Calculate using the Euler procedure the numerical solution of this system for the initial conditions, $x(t = 0) = 1$ m and $v(t = 0) = 0$ for the two time intervals of $\Delta t = 0.1$ s. Compare the result with the exact solution.
c. Repeat the calculation of (b) with four time intervals of $\Delta t = 0.05$ s.
d. Use the second-order Runge-Kutta procedure with two time intervals of $\Delta t = 0.1$ s.

Figure 1.4: Runge-Kutta procedure.

Solution: *a.* $y_1(t) = x(t)$, $y_2(t) = \dot{x}(t) = v(t) \Rightarrow \dot{y}_2(t) = -\omega^2 x(t)$, $\dot{y}_1(t) = y_2(t)$
$f_1(t) = y_2(t)$, $f_2 = -\omega^2 y_1(t)$

b. Euler, $\Delta t = 0.1$

t (s)	*0*	*0.1*	*0.2*
x (m)	*1.0*	*1.0*	*0.605*
v (m/s)	*0.0*	*-3.948*	*-7.896*

c. Euler, $\Delta t = 0.05$

t (s)	*0*	*0.05*	*0.1*	*0.15*	*0.2*
x (m)	*1.0*	*1.0*	*0.901*	*0.704*	*0.418*
v (m/s)	*0.0*	*-1.974*	*-3.948*	*-5.727*	*-7.116*

d. Runge-Kutta of second-order

t (s)	*0*	*0.1*	*0.2*
x (m)	*1.0*	*0.803*	*0.249*
v (m/s)	*0.0*	*-3.948*	*-6.337*

$$y_1(t+h) = y_1(t) + \Delta t \cdot y_2(t) - \tfrac{(\Delta t)^2}{2}\omega^2 y_1(t)$$
$$y_2(t+h) = y_2(t) - \Delta t\omega^2 \cdot y_1(t) - \tfrac{(\Delta t)^2}{2}\omega^2 y_2(t)$$

1.3.3.6 Ex: Taylor series

Expand the function

$$f(x) = \frac{1}{\sqrt{1+x}}$$

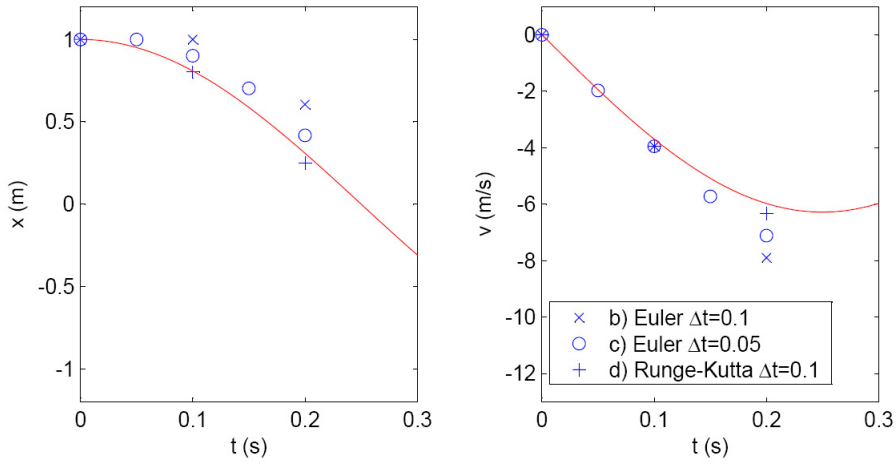

Figure 1.5: Runge-Kutta procedure.

in a Taylor series around the position $x = 0$. To do this, calculate the derivatives at least until third order and try to find the general law indicating how to find the series coefficients. Draw the function and the Taylor approximations.

Solution:

1.3.3.7 Ex: Partial derivatives

Be $r(x_1, x_2, x_3) = \sqrt{x_1^2 + x_2^2 + x_3^2}$. Find the first two partial derivatives and show by explicit calculation, that

$$\text{a.} \quad \frac{\partial^2 r}{\partial x_i \partial x_j} = \frac{\partial^2 r}{\partial x_j \partial x_i} \qquad \text{and} \qquad \text{b.} \quad \sum_{i=1}^{3} \frac{\partial^2}{\partial x_i^2}\left(\frac{1}{r}\right) = 0 \ .$$

Solution: *a. The first derivative is,*

$$\frac{\partial}{\partial x_i} r(x_1, x_2, x_3) = \frac{x_i}{r} \ ,$$

and the second,

$$\frac{\partial^2}{\partial x_i \partial x_j} r(x_1, x_2, x_3) = -\frac{x_i x_j}{r^3} + \delta_{ij} \frac{1}{r} \ .$$

With that, (a) it is already proven.
b. Now,

$$\sum_{i=1}^{3}\frac{\partial^2}{\partial x_i^2}\left(\frac{1}{r}\right)=\sum_{i=1}^{3}\frac{\partial}{\partial x_i}\left(\frac{-1}{r^2}\frac{\partial r}{\partial x_i}\right)=-\sum_{i=1}^{3}\left(\frac{\partial^2}{\partial x_i^2}\frac{1}{r^2}-\frac{2}{r^3}\left(\frac{\partial r}{\partial x_i}\right)^2\right)$$
$$=-\sum_{i=1}^{3}\left(-\frac{x_i^2}{r^5}+\frac{1}{r^3}-\frac{2}{r^3}\left(\frac{x_i}{r}\right)^2\right)$$
$$=-\sum_{i=1}^{3}\left(-3\frac{x_i^2}{r^5}+\frac{1}{r^3}\right)=-\frac{3}{r^3}+\frac{3}{r^5}\sum_{i=1}^{3}(x_i^2)=0\ .$$

1.4 Complex numbers

The imaginary unit is defined as,

$$\boxed{\imath\equiv\sqrt{-1}}\ . \tag{1.10}$$

From this follows a number of arithmetic rules that are studied in the following exercises.

1.4.1 Basic rules

real part, imaginary part, absolute value

1.4.2 The complex plane

the Euler formulae

1.4.3 Complex numbers in physics

1.4.4 Exercises

1.4.4.1 Ex: Complex numbers

Solve the following equations,

$$\frac{z}{1+\imath}-\frac{z}{1-\imath}=1+(z-\bar{z})\sin(\pi+\imath\ln 3)\quad,\quad -2\imath z=\frac{1+\bar{z}}{1+\imath}\ .$$

Calculate the absolute value, the real part and the imaginary part of,

$$\frac{2\imath-1}{\imath-2}\quad,\quad(1+2\imath)^3\quad,\quad\frac{3\imath}{\imath-\sqrt{3}}\ .$$

Solution: *a. We have,*

$$\sin(\pi + \imath \ln 3) = \sin\pi \cosh \ln 3 + \imath \cos\pi \sinh \ln 3 = -\imath \sinh \ln 3$$
$$= -\imath \frac{e^{\ln 3} - e^{-\ln 3}}{2} = -\imath \frac{3 - 1/3}{2} = -\imath \frac{4}{3} \ .$$

On the other side we have,

$$\frac{z}{1+\imath} - \frac{z}{1-\imath} = \frac{z(1-\imath) - z(1+\imath)}{(1-\imath)(1+\imath)} = -\imath z \ .$$

With that and after having entered $z = a + ib$ the equation to solve simplifies to,

$$-\imath a + b = -\imath z = \frac{z}{1+\imath} - \frac{z}{1-\imath}$$
$$= 1 + (z - \bar{z}) \sin(\pi + \imath \ln 3) = 1 + 2\imath b \left(-\imath \frac{4}{3}\right) = 1 + b\frac{8}{3} \ .$$

The comparison of real and imaginary parts gives,

$$a = 0 \qquad \textit{and} \qquad b = -\frac{3}{5} \ .$$

b. Multiplying the equation to solve with $1 + \imath$ gives,

$$-2\imath z + 2z = 1 + \bar{z} \ .$$

Inserting $z = a + \imath b$ gives,

$$2\imath(b - a) + 2(a + b) = 1 + a - \imath b \ .$$

The comparison of real and imaginary parts gives,

$$2(a + b) = 1 + a \qquad \textit{and} \qquad 2(b - a) = -b \ .$$

Solving the system of equations finally gives $a = 3$ and $b = 2$.
c. We have,

$$\left|\frac{2\imath - 1}{\imath - 2}\right| = \frac{2\imath - 1}{\imath - 2}\frac{-2\imath - 1}{-\imath - 2} = 1$$
$$\mathfrak{Re}\ \frac{2\imath - 1}{\imath - 2} = \frac{1}{2}\left(\frac{2\imath - 1}{\imath - 2} + \frac{-2\imath - 1}{-\imath - 2}\right) = \frac{4}{5}$$
$$\mathfrak{Im}\ \frac{2\imath - 1}{\imath - 2} = \frac{1}{2\imath}\left(\frac{2\imath - 1}{\imath - 2} - \frac{-2\imath - 1}{-\imath - 2}\right) = -\frac{3}{5} \ .$$

Also, we get for the absolute value, $|(1+2i)^3| = 5\sqrt{5}$, for the real part, $\mathfrak{Re}\ [(1+2i)^3] = -11$, and for the imaginary part, $\mathfrak{Im}\ [(1+2i)^3] = -2$. Also,

$$\left|\frac{3\imath}{\imath - \sqrt{3}}\right| = \frac{3}{2} \quad , \quad \mathfrak{Re}\ \left[\frac{3\imath}{\imath - \sqrt{3}}\right] = \frac{3}{4} \quad , \quad \mathfrak{Im}\ \left[\frac{3\imath}{\imath - \sqrt{3}}\right] = -\frac{3}{4}\sqrt{3} \ .$$

1.4.4.2 Ex: Complex numbers

Let $z = a + \imath b$ be a complex number. Calculate the real part and the imaginary part of the following expressions: $\sin z$, $z^2 - \bar{z}^2$, $\frac{z+\imath}{\bar{z}-\imath}$.

Solution: *a.*

$$\begin{aligned}\sin z &= \frac{1}{2\imath}(e^{\imath z} - e^{-\imath z}) = \frac{1}{2\imath}\left(e^{\imath(a+\imath b)} - e^{-\imath(a+\imath b)}\right) = \frac{1}{2\imath}\left(e^{\imath a}e^{-b} - e^{-\imath a}e^{b}\right)\\ &= \frac{1}{2\imath}\left(\left[\cos a + \imath \sin a\right]e^{-b} - \left[\cos a - \imath \sin a\right]e^{b}\right)\\ &= \frac{1}{2}\sin a(e^b + e^{-b}) + \frac{\imath}{2}\cos a(e^b - e^{-b}) = \sin a \cosh b + \imath \cos a \sinh b\end{aligned}$$

b.

$$z^2 - \bar{z}^2 = (a+\imath b)^2 - (a-\imath b)^2 = a^2 + 2\imath ab - b^2 - (a^2 - 2\imath ab - b^2) = 4\imath ab$$

c.

$$\frac{z+\imath}{\bar{z}-\imath} = \frac{a+\imath(b+1)}{a-\imath(b+1)} = \frac{a+\imath(b+1)}{a-\imath(b+1)}\frac{a+\imath(b+1)}{a+\imath(b+1)} = \frac{a^2-(b+1)^2}{a^2+(b+1)^2} + \imath\frac{2a(b+1)}{a^2+(b+1)^2}$$

1.4.4.3 Ex: Complex numbers

Solves the following equation by $z \in \mathbb{C}$:

$$-\bar{z} = \frac{1-z}{\imath - 1} + \ln(43)\cdot\sin\left(\frac{\pi}{\imath+1} + \frac{\pi}{\imath-1}\right) - \frac{e^{-\imath\frac{5}{4}\pi}}{\sqrt{2}}\ .$$

Solution: *Complex equation*

$$\begin{aligned}-\bar{z} &= \frac{1-z}{\imath-1} + \ln(43)\cdot\sin\underbrace{\left(\frac{\pi}{\imath+1} + \frac{\pi}{\imath-1}\right)}_{=\frac{2\pi\imath}{-2}} - \frac{e^{-\imath\frac{5}{4}\pi}}{\sqrt{2}}\\ &\Leftrightarrow -\bar{z} = \frac{1-z}{\imath-1} + 0 - \frac{\imath}{\imath-1}\\ &\Leftrightarrow -\bar{z}(\imath-1) = 1 - z - \imath\\ &\Rightarrow -(a-\imath b)(\imath-1) = 1 - (a+\imath b) - \imath\\ &\Leftrightarrow -a\imath - b + a - \imath b = 1 - a - \imath b - \imath\\ &\Leftrightarrow -a\imath - b + 2a = 1 - \imath\\ &\Rightarrow \begin{pmatrix}-b+2a\\ -a\end{pmatrix} = \begin{pmatrix}1\\-1\end{pmatrix}\\ &\Rightarrow a = 1, b = 1 \Rightarrow z = \imath + 1\ .\end{aligned}$$

1.4.4.4 Ex: Complex numbers

Be $z_1 = 4 + 7\imath,\ z_2 = 3 - 9\imath$. Calculate

a. $z_1 + z_2$ e $z_1 - z_2$
b. $z_1 \cdot z_2$
c. z_1^2 e z_2^3
d. $|z_1|$ e $|z_2|$
e. z_1/z_2 .

Now be $z = x + \imath y$. Calculate the real and imaginary part of the expression,

$$\frac{z}{1+2z} \ .$$

Finally, we consider two complex numbers z_1 and z_2. Show that $(z_1 z_2)^* = z_1^* z_2^*$, where z^* is the conjugate complex number of z.

Solution:

1.4.4.5 Ex: Complex numbers

Be

$$z_1 = 1 - \imath\sqrt{3} \quad , \quad z_2 = \frac{1}{2\sqrt{2}} + \imath\frac{\sqrt{2}}{4} \quad , \quad z_3 = -\imath \ ,$$

a. Represent $z_{1,2,3}$ in a polar form $z_{1,2,3} = r_{1,2,3} e^{\imath\phi_{1,2,3}}$.
b. Are the angles $\phi_{1,2,3}$ determined unambiguous? What values are possible?
c. Now, calculate,

$$\sqrt{z_1} \quad , \quad \sqrt[3]{z_2} \quad , \quad \sqrt[4]{z_3} \ .$$

Show how the different possible values of ϕ lead to an ambiguity of the roots.

Solution:

1.5 Differential equations

1.5.1 First order differential equations

The solution is usually an exponential function.

1.5.2 Second order differential equations

Oscillations are processes described by second-order differential equations. We now consider the second-order linear differential equation with constant coefficients:

$$z''(x) + \alpha z'(x) + \beta z(x) = f(x) \ , \tag{1.11}$$

where $z, f : \mathcal{R} \to \mathcal{C}$, com $\alpha, \beta \in \mathcal{C}$.

The homogeneous equation $f \equiv 0$ is always solved by a linear combination of two solutions of the form $z_{1,2}(x) = e^{\lambda_{1,2}x}$ or $z_1(x) = e^{\lambda_1 x}$, $z_2(x) = xe^{\lambda_1 x}$. To show this, we consider two solutions z_1 and z_2 of the homogeneous differential equation, i.e. for $f = 0$, then $z''_{1,2}(x) + \alpha z'_{1,2}(x) + \beta z_{1,2}(x) = 0$. Now we insert the linear combination $Az_1 + Bz_2$ into the differential equation:

$$(Az_1 + Bz_2)'' + \alpha(Az_1 + Bz_2)' + \beta(Az_1 + Bz_2) = 0 \ . \tag{1.12}$$

Arranging,

$$(Az_1'' + \alpha Az_1' + \beta Az_1) + (Bz_2'' + \alpha Bz_2' + \beta Bz_2) = 0 \ . \tag{1.13}$$

The two parentheses must disappear separately. By inserting the ansatz $e^{\lambda x}$ into the homogeneous differential equation, we get,

$$\begin{aligned}(e^{\lambda x})'' + \alpha(e^{\lambda x})' + \beta(e^{\lambda x}) &= 0\\ \lambda^2 e^{\lambda x''} + \lambda\alpha e^{\lambda x} + \beta e^{\lambda x} &= 0\\ \lambda^2 + \lambda\alpha + \beta &= 0 \ .\end{aligned}$$

The characteristic polynomial has two solutions,

$$\lambda_{1,2} = -\frac{\alpha}{2} \pm \sqrt{\frac{\alpha^2}{4} - \beta} \ .$$

Depending on the values of the coefficients α and β the root can be real, zero, or imaginary. For real $\lambda_{1,2}$, the solutions $e^{\lambda x}$ describe an exponential increase or a decay. For zero roots we obtain the aperiodic limit case. For imaginary $\lambda_{1,2}$ we get a vibration.

The inhomogeneous equation, $f \neq 0$, can always be solved by the solutions mentioned above plus a particular solution $z_f(x)$.

1.5.3 Exercises

1.5.3.1 Ex: Exponential law

The value of a coin is divided by two each day. Derive the exponential law allowing to predict the value of the currency at any future date.

Solution: *The value of the currency decreases regularly, which means,*

$$dV = -\alpha dt V(t) \ .$$

This gives,

$$\frac{dV}{V} = -\alpha dt \ ,$$

or

$$V = V_0 e^{-\alpha dt} \ ,$$

with $\alpha = 2d^{-1}$ *and* $\Delta t = 1d$.

1.5.3.2 Ex: First order differential equation

A differential equation of order n is usually an equation between the first n derivatives from a function, the function itself, and its independent variables with the form $F(x, y(x), y'(x), ..., y^{(n)}(x)) = 0$. The initial conditions $(y^{(n-1)}(x_0) = y_0^{(n-1)}, ..., y(x_0) = y_0)$ must be specified to obtain an unambiguous solution. A particular case are first-order equations of the form $y'(x) + f(x)g(y(x)) = 0$ with $y(x_0) = y_0$.
a. Show that the general solution of this equation is given by $\int_{y_0}^{y} \frac{d\tilde{y}}{g(\tilde{y})} = -\int_{x_0}^{x} f(\tilde{x})d\tilde{x}$.
b. Solve the following equations:

$$y'(x) + \cos 2y \cos x = 0 \qquad \text{with} \qquad y(0) = \pi/4$$
$$\log y'(x)x + y + x^2 = 0 \qquad \text{with} \qquad y(\infty) = 0 \ .$$

Does each initial condition make sense?
c. Show that homogeneous linear first-order differential equations $y'(x)+f(x)y(x) = 0$ (with $y(x_0) = y_0$) belong to the class specified above. Find the general solution. $\left(y(x) = y_0 e^{-\int_{x_0}^{x} f(x)dx}\right)$.

Solution: *a. Rephrasing the equation* $y'(x) + f(x)g(y(x)) = 0$

$$\frac{y'}{g(y)} = -f(x)$$
$$\int_{y_0}^{y} \frac{d\tilde{y}}{g(\tilde{y})} = -\int_{x_0}^{x} f(\tilde{x})d\tilde{x} \ .$$

b. Rephrasing the equation $y' + \cos^2 y \cos x = 0$

$$\frac{y'}{\cos^2 y} = -\cos x$$
$$\int_{y_0}^{y} \frac{dy}{\cos^2 y} = -\int_{x_0}^{x} \cos x dx$$
$$\int_{y_0}^{y} \frac{dy}{\cos^2 y} = -\sin x + \sin x_0 \ .$$

Rephrasing the equation $\ln \frac{y'}{x} + y + x^2 = 0$

$$\frac{y'}{x} = e^{-y-x^2}$$
$$\int_{y_0}^{y} \tilde{y} e^{\tilde{y}} d\tilde{y} = \int_{x_0}^{x} \tilde{x} e^{-\tilde{x}^2} d\tilde{x}$$
$$ye^y|_{y_0}^{y} - \int_{y_0}^{y} e^y dy = \frac{1}{2}\int_{x_0^2}^{x^2} e^{-\xi} d\xi$$
$$(1-y)e^y = (1-y_0)e^{y_0} + \frac{1}{2}(e^{-x^2} - e^{-x_0^2}) \ .$$

Inserting the initial conditions $y(\infty) = 0$,

$$y_0 = -\frac{1}{2}e^{-x_0^2 - y_0} - e^{-y_0} + 1 \ ,$$

gives the solution,

$$(1-y)e^y = 1 + \frac{1}{2}e^{-x^2} \ .$$

The right side is always positive. Therefore, only initial conditions $y > 0$ are relevant.
c.

$$\begin{aligned} y'(x) + f(x)y(x) &= 0 \\ \int \frac{dy(x)}{y(x)} &= -\int f(x)dx \\ y &= y_0 e^{-\int f(x)dx} \ . \end{aligned}$$

1.5.3.3 Ex: Bernoulli's differential equation

Consider the equation,

$$y' = ay + by^\alpha \ ,$$

with $a, b \in \mathbb{R}$, $\alpha \neq 0, 1$ and the initial conditions $x_0 = 0$ and $y_0 = \left(\frac{1-b}{a}\right)^{1/(1-\alpha)}$. Find the solution $y(x)$.
Help: Transform the nonlinear differential equation into a first order linear differential equation by the substitution $y = z^{1/(1-\alpha)}$.

Solution: *With the given substitution we obtain,*

$$\frac{1}{1-\alpha} z^{\alpha/(1-\alpha)} z' = a z^{1/(1-\alpha)} + b z^{\alpha/(1-\alpha)} \ .$$

With that follows,

$$\frac{z'}{1-\alpha} = az + b \quad \Rightarrow \quad z' = (az+b)(1-\alpha) \ .$$

Separation of variables,

$$\begin{aligned} \frac{dz}{az+b} = (1-\alpha)dx \quad &\Rightarrow \quad \int_{z_0}^{z} \frac{d\tilde{z}}{a\tilde{z}+b} = (1-\alpha)\int_{x_0}^{x} d\tilde{x} \\ &\Rightarrow \frac{1}{a}\ln(a\tilde{z}+b)\Big|_{z_0}^{z} = (1-\alpha)(x-x_0) \\ &\Rightarrow \ln(az+b) = \ln(az_0+b) + a(1-\alpha)(x-x_0) \ . \end{aligned}$$

Inserting the initial conditions,

$$\ln(az+b) = a(1-\alpha)x \Rightarrow z(x) = \frac{1}{a}\left[e^{a(1-\alpha)x} - b\right] \ .$$

Finally,

$$y(x) = \left\{\frac{1}{a}\left[e^{a(1-\alpha)x} - b\right]\right\}^{1/(1-\alpha)} \ .$$

1.5.3.4 Ex: Ellipse

An ellipse is the set of all points C satisfying the condition $\overline{AC} + \overline{BC} = 2a$, where the two focal points A and B are at a given distance $2e$.
a. Show that this definition is equivalent to the ellipse equation of the form,

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1 \ ,$$

where a and b are the large and small half-axes. How does e depend on a de b?
b. Show that the ellipse equation is given in plane polar coordinates by,

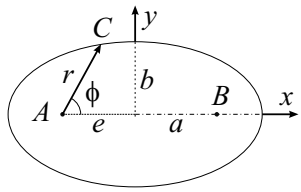

Figure 1.6: Ellipse.

$$r = \frac{P}{1 - \epsilon \cos\phi} \ .$$

Determine the eccentricity ϵ and the parameter P as a function of a and b.

Solution: *a. We have the conditions* $\overline{AC} + \overline{BC} = 2a$, $\overline{AB} = 2e$ *and* $\overline{AC} = r$. *By the Pythagorean theorem we have therefore,*

$$y^2 = \overline{AC}^2 - \left(\tfrac{1}{2}\overline{AB} + x\right)^2 = \overline{BC}^2 - \left(\tfrac{1}{2}\overline{AB} - x\right)^2 \ , \tag{1.14}$$

resp.

$$y^2 = r^2 - (e+x)^2 = (2a - r)^2 - (e - x)^2 \ . \tag{1.15}$$

Solving the second equation (1.15) by r *we obtain,*

$$r = a + e\frac{x}{a} \ . \tag{1.16}$$

Substituting into the first equation (1.15) we obtain,

$$\begin{aligned} y^2 &= \left(a + e\frac{x}{a}\right)^2 - (e+x)^2 \\ &= a^2 - e^2 - x^2 + e^2\frac{x^2}{a^2} \ . \end{aligned} \tag{1.17}$$

For $x = 0$ *holds* $y = b$, *hence,*

$$e^2 = a^2 - b^2 \ . \tag{1.18}$$

Inserting in Eq. (1.17) we finally get the ellipse equation,

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1 \ . \tag{1.19}$$

b. According to the drawing,

$$\begin{aligned} r\sin\phi &= y \\ r\cos\phi &= x + e \ . \end{aligned} \tag{1.20}$$

Inserting into the ellipse equation (1.19) yields,

$$\begin{aligned} \frac{(r\cos\phi - e)^2}{a^2} + \frac{r^2\sin^2\phi}{b^2} &= 1 \\ b^2r^2\cos^2\phi - b^2 2er\cos\phi + b^2e^2 + a^2r^2\sin^2\phi &= a^2b^2 \\ a^2r^2 - 2b^2er\cos\phi - e^2r^2\cos^2\phi &= b^4 \ . \end{aligned} \tag{1.21}$$

Introducing the parameter $P \equiv b^2/a$ and the eccentricity $\epsilon \equiv \sqrt{a^2 - b^2}/a$,

$$r^2 = P^2 + 2P\varepsilon r\cos\phi + \varepsilon^2 r^2\cos^2\phi = (P + \varepsilon r\cos\phi)^2 \ . \tag{1.22}$$

Finally,

$$r = \frac{P}{1 - \varepsilon\cos\phi} \ . \tag{1.23}$$

1.5.3.5 Ex: Binomial- and Poisson distribution

Show that from the binomial distribution,

$$P(n) = \frac{N!}{n!\,(N-n)!}\ p^n\ (1-p)^{N-n} \ .$$

follows the Poisson distribution,

$$P(n) = \frac{\alpha^n}{n!}e^{-\alpha} \qquad \text{with} \quad \alpha \equiv \bar{n} \equiv N\ p \ ,$$

in the limit $p \ll 1$ and $n \ll N$. Use the approximation formulas $\log(1-p) \simeq -p$ and $\frac{N!}{(N-n)!} \simeq N^n$. Can you justify the approximation formulas?

Solution: *The first approximation formula follows the Taylor expansion, the second follows from,*

$$\frac{N!}{(N-n)!} \equiv \prod_{j=0}^{n-1}(N-j) \simeq_{n\ll N} \prod_{j=0}^{n-1} N \equiv N^n \ .$$

Hence, $(1-p)^{N-n} = \exp\left(log(1-p)^{N-n}\right) = \exp(N-n)\log(1-p) \simeq \exp(-N\,p) = \exp(-\alpha)$. For this, $\frac{N!}{(N-n)!}\ p^n \simeq N^n\ p^n = \alpha^n$.

1.5.3.6 Ex: Second order differential equations

Find the general solutions $z(x)$ of the following equations:
a. $7z'' - 2\imath\sqrt{3}z' - 3z = 6$
b. $z'' - 10z' + 9z = 9x$.

Solution: *a. Inserting the ansatz* $z(x) = e^{\lambda x}$ *in the homogeneous differential equation,* $7z'' - 2\imath\sqrt{3}z' - 3z = 0$*, we obtain,*

$$\begin{aligned} 7\lambda^2 e^{\lambda x} - 2\imath\sqrt{3}\lambda e^{\lambda x} - 3e^{\lambda x} &= 0 \\ 7\lambda^2 - 2\imath\sqrt{3}\lambda - 3 &= 0 \ , \end{aligned}$$

and therefore the characteristic polynomial,

$$\lambda_{1,2} = \frac{\imath\sqrt{3}}{7} \pm \sqrt{\frac{-3}{49} + \frac{3}{7}} \ .$$

It is appropriate to search as a particular inhomogeneous solution $z_{inh}(x)$ *of the differential equation* $7z'' - 2\imath\sqrt{3}z' - 3z = 6$ *a function whose first and second derivatives disappear* ($z'' = 0 = z'$)*, that is, a solution of the equation,*

$$-3z_{inh} = 6 \ .$$

We can easily see that

$$z(x) = z_{hmg}(x) + z_{inh}(x) = Ae^{\lambda_1 x} + Be^{\lambda_2 x} - 2$$

solves the inhomogeneous equation.
b. Inserting the ansatz $z(x) = e^{\lambda x}$ *in the homogeneous differential equation,* $z'' - 10z' + 9z = 0$*, we obtain,*

$$\begin{aligned} \lambda^2 e^{\lambda x} - 10\lambda e^{\lambda x} + 9e^{\lambda x} &= 0 \\ \lambda^2 - 10\lambda + 9 &= 0 \ . \end{aligned}$$

and therefore the characteristic polynomial,

$$\lambda_{1,2} = 5 \pm \sqrt{25 - 9} = 1 ou\ 9 \ .$$

As a particular inhomogeneous solution of the differential equation $z'' - 10z' + 9z = 9x$ *we insert a first order polynomial, whose second derivative disappears,* $z_{inh}(x) \equiv x + a$*. Inserting in the differential equation,*

$$\begin{aligned} z''_{inh} - 10z'_{inh} + 9z_{inh} &= 9x \\ -10 + 9(x + a) &= 9x \\ a &= \frac{10}{9} \ . \end{aligned}$$

We can easily see that,

$$z(x) = z_{hmg}(x) + z_{inh}(x) = Ae^{x} + Be^{9x} + x + \frac{10}{9}$$

solves the inhomogeneous equation.

1.5.3.7 Ex: Second order differential equations

Given is a second order linear differential equation with constant coefficients: $z''(x) + \alpha z'(x) + \beta z(x) = f(x)$, where $z,\ f\colon \mathbb{R} \to \mathbb{C}$, $\alpha,\ \beta \in \mathbb{C}$. Show that
a. for the case $f(x) = \gamma x^n$ an ansatz $z_f(x) = \sum_{k=0}^{n} a_k x^k$ solves the inhomogeneous equation, where $\gamma, a_k \in \mathbb{C}$;
b. for the case, that $f(x)$ can be expanded in a Taylor series around the point x_0, the ansatz $z_f(x) = \sum_{k=0}^{\infty} a_k (x - x_0)^k$, $\gamma, a_k \in \mathbb{C}$, solves the inhomogeneous equation. Use linearity and the result of (a).
c. for the case $f(x) = \gamma x^n e^{\delta x}$ an ansatz $z_f(x) = e^{\delta x} \sum_{k=0}^{n} a_k x^k$ solves the inhomogeneous equation, where $\gamma\ ,\ \delta\ ,\ a_k \in \mathbb{C}$.

Solution: *a. Inserting the ansatz in the differential equation we obtain,*

$$\sum_{k=2}^{n} a_k k(k-1) x^{k-2} + \alpha \sum_{k=1}^{n} a_k k x^{k-1} + \beta \sum_{k=0}^{n} a_k x^k = \gamma x^n \ .$$

The terms proportional to x^k must disappear separately, such that the coefficients can be determined iteratively,

$$\begin{aligned} \beta a_n &= \gamma \\ \beta a_{n-1} &= -n\alpha a_n \\ \beta a_k &= -(k+1)\alpha a_{k+1} - (k+2)(k+1) a_{k+2} \ , \end{aligned}$$

for $k = n-2, .., 0$.
b. For each term of the Taylor expansion $\propto x_n$ we can find a solution as done in item (a). Using the linearity it is clear that for the expansion we have as a solution the linear combination of these partial solutions.
c.

1.5.3.8 Ex: Population explosion

Develop a model for population explosion.

Solution: *Discretize,*

$$\begin{aligned} a_k^{60} &= a_{k-1}^{40} - a_{k-1}^{60} \\ a_k^{40} &= a_{k-1}^{20} - a_{k-1}^{40} \\ a_k^{20} &= a_{k-1}^{0} - a_{k-1}^{20} \\ a_k^{0} &= \eta a_k^{20} \ . \end{aligned}$$

Total population,

$$\begin{aligned} \sum_j a_k^j &= \eta a_k^{20} + a_{k-1}^0 - a_{k-1}^{20} + a_{k-1}^{20} - a_{k-1}^{40} + a_{k-1}^{40} - a_{k-1}^{60} \\ &= \eta a_k^{20} + a_{k-1}^0 - a_{k-1}^{60} \ . \end{aligned}$$

Solve numerically

$$\begin{pmatrix} a_k^0 \\ a_k^{20} \\ a_k^{40} \\ a_k^{60} \end{pmatrix} = \begin{pmatrix} \eta & 0 & 0 & 0 \\ 1 & -1 & 0 & 0 \\ 0 & 1 & -1 & 0 \\ 0 & 0 & 1 & -1 \end{pmatrix} \begin{pmatrix} a_{k-1}^0 \\ a_{k-1}^{20} \\ a_{k-1}^{40} \\ a_{k-1}^{60} \end{pmatrix} .$$

1.5.3.9 Ex: Population explosion

Develop a model for the Wuhan virus pandemia.

Solution:

1.6 Vector analysis

1.6.1 Vector algebra

Let us start with a little revision of vector algebra. A vector is a physical quantity composed of a value, a direction and a unit. For example, $\mathbf{v}$ could be the velocity of a body measured in meters per second traveling in northbound direction. Mathematically, vectors form a *vector space*, that is, an algebraic construct characterized by the existence of several operations defined by the following laws.

The addition of vectors is a *commutative* and *associative* operation, that is,

$$\mathbf{a}+\mathbf{b}=\mathbf{b}+\mathbf{a} \quad \text{and} \quad (\mathbf{a}+\mathbf{b})+\mathbf{c}=\mathbf{a}+(\mathbf{b}+\mathbf{c}) \ . \tag{1.24}$$

The multiplication with a scalar is *commutative* and *distributive*,

$$\lambda\mathbf{a}=\mathbf{a}\lambda \quad \text{and} \quad \lambda(\mathbf{a}+\mathbf{b})=\lambda\mathbf{a}+\lambda\mathbf{b} \ . \tag{1.25}$$

The scalar product of two vectors defined by,

$$\boxed{\mathbf{a}\cdot\mathbf{b}\equiv ab\cos\theta} \ , \tag{1.26}$$

where θ is the angle between the two vectors, is *commutative* and *distributive*, but not *associative*,

$$\mathbf{a}\cdot\mathbf{b}=\mathbf{b}\cdot\mathbf{a} \quad \text{and} \quad \mathbf{a}\cdot(\mathbf{b}+\mathbf{c})=\mathbf{a}\cdot\mathbf{b}+\mathbf{a}\cdot\mathbf{c} \quad \text{and} \quad (\mathbf{a}\cdot\mathbf{b})\mathbf{b}\neq\mathbf{a}(\mathbf{b}\cdot\mathbf{c}) \ . \tag{1.27}$$

Finally, the vector product defined by,

$$\boxed{\mathbf{a}\times\mathbf{b}\equiv ab\hat{\mathbf{e}}_n\sin\theta} \ , \tag{1.28}$$

where θ is the angle between the two vectors and $\hat{\mathbf{e}}_n$ a unit vector pointing in the direction perpendicular to $\mathbf{a}$ and $\mathbf{b}$, is *distributive*, but neither *commutative* nor *associative*,

$$\begin{aligned} \mathbf{a}\times\mathbf{b}=-\mathbf{b}\times\mathbf{a}\neq\mathbf{b}\times\mathbf{a} \quad &\text{and} \quad \mathbf{a}\times(\mathbf{b}+\mathbf{c})=\mathbf{a}\times\mathbf{b}+\mathbf{a}\times\mathbf{c} \\ &\text{and} \quad (\mathbf{a}\times\mathbf{b})\times\mathbf{c}\neq\mathbf{a}\times(\mathbf{b}\times\mathbf{c}) \ . \end{aligned} \tag{1.29}$$

Once we have chosen a basis, that is, a set of three linearly independent vectors, we can also express the vectors in terms of their components in this basis. The most common basis is the Cartesian coordinate system characterized by three fixed and orthogonal vectors, $\hat{\mathbf{e}}_x$, $\hat{\mathbf{e}}_y$, and $\hat{\mathbf{e}}_z$, such that each vector can be decomposed as,

$$\mathbf{a} = a_x\hat{\mathbf{e}}_x + a_y\hat{\mathbf{e}}_y + a_z\hat{\mathbf{e}}_z \ . \tag{1.30}$$

In this representation the operations on the vector space defined above read,

$$\begin{aligned} \mathbf{a}+\mathbf{b} &= (a_x+b_x)\hat{\mathbf{e}}_x + (a_y+b_y)\hat{\mathbf{e}}_y + (a_z+b_z)\hat{\mathbf{e}}_z \\ \lambda\mathbf{a} &= \lambda a_x\hat{\mathbf{e}}_x + \lambda a_y\hat{\mathbf{e}}_y + \lambda a_z\hat{\mathbf{e}}_z \\ \mathbf{a}\cdot\mathbf{b} &= a_xb_x + a_yb_y + a_zb_z \\ \mathbf{a}\times\mathbf{b} &= \begin{pmatrix} a_yb_z - a_zb_y \\ a_zb_x - a_xb_z \\ a_xb_y - a_yb_z \end{pmatrix} \ . \end{aligned} \tag{1.31}$$

Combinations of scalar and vector products can be used to calculate other geometric quantities. An example is the *scalar triple product* defined by $\mathbf{a}\cdot(\mathbf{b}\times\mathbf{c})$ and satisfying the following permutation rules,

$$\mathbf{a}\cdot(\mathbf{b}\times\mathbf{c}) = \mathbf{c}\cdot(\mathbf{a}\times\mathbf{b}) = -\mathbf{c}\cdot(\mathbf{b}\times\mathbf{a}) = (\mathbf{a}\times\mathbf{b})\cdot\mathbf{c} \ . \tag{1.32}$$

Its absolute value $|\mathbf{a}\cdot(\mathbf{b}\times\mathbf{c})|$ has the meaning of the volume of the parallelepiped spanned by the three vectors. The *vector triple product* defined by $\mathbf{a}\times(\mathbf{b}\times\mathbf{c})$ can be simplified,

$$\mathbf{a}\times(\mathbf{b}\times\mathbf{c}) = \mathbf{b}(\mathbf{a}\cdot\mathbf{c}) - \mathbf{c}(\mathbf{a}\cdot\mathbf{b}) \ . \tag{1.33}$$

We verify the commutativity and the distributivity of the scalar and vector triple products in Exc. 1.6.3.1, and we train them more in Excs. 1.6.3.2 to 1.6.3.4.

1.6.2 Transformation of vectors

Of course, the definition of the vector as quantity characterized by a magnitude and a direction is unequivocal, for example, the speed $\mathbf{v}$ of a car on a road. Nevertheless, the representation of the vector depends on the orientation of the Cartesian coordinate system, which is totally arbitrary. For example, a vector given by $\mathbf{r} = x\hat{\mathbf{e}}_x + y\hat{\mathbf{e}}_r + z\hat{\mathbf{e}}_z$ in one system will be described by $\mathbf{r} = x'\hat{\mathbf{e}}'_x + y'\hat{\mathbf{e}}'_y + z'\hat{\mathbf{e}}'_z$ in another system.

The behavior of vectors under transformations of coordinate systems is a very important characteristic of physical quantities and of theories governing their dynamics. For example, while classical mechanics is defined by the Galilei transform, relativistic mechanics is defined by the Lorentz transform, and we will see later that electrodynamics is incompatible with the Galilei transform. In Excs. 1.6.3.5 to 1.6.3.12 we practice the calculus with rotation matrices [7].

There are basically two things that can be done with vectors in space: *translations* and *rotations*. Both will be discussed in the following.

[7] Note that the procedure is different from the one used in quantum mechanics, where any transformation needs to be described by unitary operations.

1.6.2.1 Translations

Translations are simply performed by adding a vector to all position vectors,

$$\mathbf{r}' = \mathcal{T}_{tr}\mathbf{r} = \mathbf{r} + \mathbf{a} \ . \tag{1.34}$$

1.6.2.2 Rotations

If the two systems are simply rotated with respect to each other, we have [8],

$$\mathbf{r}' = \begin{pmatrix} x' \\ y' \\ z' \end{pmatrix} = \mathcal{T}_{rt}\mathbf{r} = \begin{pmatrix} R_{xx} & R_{xy} & R_{xz} \\ R_{yx} & R_{yy} & R_{yz} \\ R_{zx} & R_{zy} & R_{zz} \end{pmatrix} \begin{pmatrix} x \\ y \\ z \end{pmatrix} = \mathcal{R}\mathbf{r} \ , \tag{1.35}$$

or [9],

$$\boxed{r'_k = \sum_l R_{kl} r_l} \ . \tag{1.36}$$

Example 1 (*Rotation about the z-axis*): For example, for a rotation around the z-axis by an angle of ϕ we get,

$$\begin{pmatrix} x' \\ y' \\ z' \end{pmatrix} = \begin{pmatrix} \cos\phi & \sin\phi & 0 \\ -\sin\phi & \cos\phi & 0 \\ 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} x \\ y \\ z \end{pmatrix} \ .$$

Rotation matrices $\mathcal{R}$ must satisfy the following requirements:

- The transformation preserves the lengths and orientations of vectors and the angles between vectors. That is, the scalar product satisfies $\mathcal{R}\mathbf{r}_2 \cdot \mathcal{R}\mathbf{r}_2 = \mathbf{r}_1 \cdot \mathbf{r}_2$.
- The transformation is orthogonal, $\mathcal{R}^{-1} = \mathcal{R}^\dagger$, and unitary, $\det \mathcal{R} = 1$.

1.6.3 Exercises

1.6.3.1 Ex: Vector algebra

a. Show that scalar and vector products are distributive.
b. Find out whether the vector product is associative.

Solution: *a. Distributivity of the scalar product,*

$$\mathbf{a} \cdot (\mathbf{b} + \mathbf{c}) = ... = \mathbf{a} \cdot \mathbf{b} + \mathbf{a} \cdot \mathbf{c}$$

Distributivity of the vector product,

$$\mathbf{a} \times (\mathbf{b} + \mathbf{c}) = ... = \mathbf{a} \times \mathbf{b} + \mathbf{a} \times \mathbf{c}$$

[8] By $\mathcal{T}$ we denote operations or prescriptions, while $\mathcal{R}$ is a rotation matrix.
[9] We note here that a tensor of two dimensions transforms like,

$$T'_{kl} = \sum_{l,k} R_{km} R_{ln} T_{mn} \ .$$

b. Associativity of the vector product,

$$\mathbf{a} \times (\mathbf{b} \times \mathbf{c}) = ... = (\mathbf{a} \times \mathbf{b}) \times \mathbf{c} \ .$$

1.6.3.2 Ex: Vector algebra

a. Consider a unit cube with one corner fixed at the origin and generated by the vectors, $\mathbf{a} = (1, 0, 0)$, $\mathbf{b} = (0, 1, 0)$ and $\mathbf{c} = (0, 0, 1)$. Determine the angle between the diagonals passing through the center of the cube.
b. Consider the plane containing the points $\mathbf{a}$, $\mathbf{b}$, and $\mathbf{c}$ giving in (a). Use the vector product to calculate the normal vector of this plane.

Solution: *a. We choose the diagonals* $\mathbf{d}_1 = (1, 1, 1) - (0, 0, 0)$ *and* $\mathbf{d}_2 = (1, 0, 0) - (0, 1, 1)$ *and we get the scalar product,*

$$\mathbf{d}_1 \cdot \mathbf{d}_2 = -1 = d_1 d_2 \cos\theta \ .$$

With $d_1 = d_2 = \sqrt{3}$*, we find* $\theta = 109.47°$*.*
b. We choose two vectors of the plane, $\mathbf{d}_1 = \mathbf{a} - \mathbf{b}$ *and* $\mathbf{d}_2 = \mathbf{a} - \mathbf{c}$ *and we calculate the vector product,*

$$\mathbf{d}_1 \times \mathbf{d}_2 = (\mathbf{a} - \mathbf{b}) \times (\mathbf{a} - \mathbf{c}) = \begin{pmatrix} 1 \\ -1 \\ 0 \end{pmatrix} \times \begin{pmatrix} 1 \\ 0 \\ -1 \end{pmatrix} = \begin{pmatrix} 1 \\ 1 \\ 1 \end{pmatrix} \ .$$

1.6.3.3 Ex: Vector algebra

a. Prove the rule $\mathbf{a} \times (\mathbf{b} \times \mathbf{c}) = \mathbf{b}(\mathbf{a} \cdot \mathbf{c}) - \mathbf{c}(\mathbf{a} \cdot \mathbf{b})$ writing both sides in component form.
b. Prove $\mathbf{a} \times (\mathbf{b} \times \mathbf{c}) + \mathbf{b} \times (\mathbf{c} \times \mathbf{a}) + \mathbf{c} \times (\mathbf{a} \times \mathbf{b})$. Under what conditions holds $\mathbf{a} \times (\mathbf{b} \times \mathbf{c}) = (\mathbf{a} \times \mathbf{b}) \times \mathbf{c}$?

Solution: *a.*
b. Obviously when $\mathbf{a} = \mathbf{c}$*, since,*

$$\mathbf{a} \times (\mathbf{b} \times \mathbf{a}) = -(\mathbf{b} \times \mathbf{a}) \times \mathbf{a} = (\mathbf{a} \times \mathbf{b}) \times \mathbf{a} \ .$$

1.6.3.4 Ex: Vector algebra

a. Two vectors point from the origin to points $\mathbf{r} = (2, 8, 7)$ and $\mathbf{r}' = (4, 6, 8)$. Determine the distance between the points.

Solution: *The distance is,* $|\mathbf{r} - \mathbf{r}'| = \sqrt{(2-4)^2 + (8-6)^2 + (7-8)^2} = 3$.

1.6.3.5 Ex: Rotation of the coordinate system

a. Show that the two-dimensional rotation matrix

$$\begin{pmatrix} \cos\phi & \sin\phi \\ -\sin\phi & \cos\phi \end{pmatrix}$$

preserves the scalar product, that is, $a'_x b'_x + a'_y b'_y = a_x b_x + a_y b_y$.
b. What are the constraints for the elements R_{ij} of the three-dimensional rotation matrix to preserve the length of an arbitrary vector under transformation?

Solution: *a. We have*

$$\begin{aligned} \mathbf{a}' \cdot \mathbf{b}' &= \begin{pmatrix} \cos & \sin \\ -\sin & \cos \end{pmatrix} \begin{pmatrix} a_x \\ a_y \end{pmatrix} \begin{pmatrix} \cos & \sin \\ -\sin & \cos \end{pmatrix} \begin{pmatrix} b_x \\ b_y \end{pmatrix} \\ &= \begin{pmatrix} a_x \cos + a_y \sin \\ -a_x \sin + a_y \cos \end{pmatrix} \begin{pmatrix} b_x \cos + b_y \sin \\ -b_x \sin + b_y \cos \end{pmatrix} = \ldots = a_x b_x + a_y b_y \ . \end{aligned}$$

b. First we consider a two-dimensional matrix. As the condition,

$$a'^2_x + a'^2_y = (R_{xx} a_x + R_{xy} a_y)^2 + (R_{yx} a_x + R_{yy} a_y)^2 = a_x^2 + a_y^2$$

needs to be satisfied for all a_x and a_y, the terms proportional to a_x^2, a_y^2 and $a_x a_y$ must zero separately:

$$\begin{aligned} a_x^2 &\longmapsto R_{xx}^2 + R_{yx}^2 = 1 \\ a_y^2 &\longmapsto R_{xy}^2 + R_{yy}^2 = 1 \\ a_x a_y &\longmapsto R_{xx} R_{xy} + R_{yx} R_{yy} = 0 \ , \end{aligned}$$

what is satisfied by $R_{xx} = R_{yy} = \cos\phi$ and $R_{xy} = -R_{yx} = \sin\phi$. In three dimensions,

$(R_{xx} a_x + R_{xy} a_y + R_{xz} a_z)^2 + (R_{yx} a_x + R_{yy} a_y + R_{yz} a_z)^2 + (R_{zx} a_x + R_{zy} a_y + R_{zz} a_z)^2$
$= a_x^2 + a_y^2 + a_z^2$

gives,

$$\begin{aligned} a_x^2 &\longmapsto R_{xx}^2 + R_{yx}^2 + R_{zx}^2 = 1 = \sum_k R_{kx} \\ a_y^2 &\longmapsto R_{xy}^2 + R_{yy}^2 + R_{zy}^2 = 1 = \sum_k R_{ky} \\ a_z^2 &\longmapsto R_{xz}^2 + R_{yz}^2 + R_{zz}^2 = 1 = \sum_k R_{kz} \\ a_x a_y &\longmapsto R_{xx} R_{xy} + R_{yx} R_{yy} + R_{zx} R_{zy} = 0 = \sum_k R_{kx} R_{ky} \\ a_x a_z &\longmapsto R_{xx} R_{xz} + R_{yx} R_{yz} + R_{zx} R_{zz} = 0 = \sum_k R_{kx} R_{kz} \\ a_y a_z &\longmapsto R_{xy} R_{xz} + R_{yy} R_{yz} + R_{zy} R_{zz} = 0 = \sum_k R_{ky} R_{kz} \ . \end{aligned}$$

1.6.3.6 Ex: Rotation of the coordinate system

Find the matrix describing a rotation of 120° around the axis $\vec{\omega} = (1,1,1)$.

Solution: *Two procedures are possible. The first is to satisfy the conditions for R to be a rotation matrix, as shown in Exc. 1.6.3.5, and impose the additional conditions that $\omega = (1,1,1)$ stays still and that any vector orthogonal to ω, for exemple, $a = (1,-1,0)$ makes a rotation of 120°,*

$$\begin{pmatrix} R_{xx} & R_{xy} & R_{xz} \\ R_{yx} & R_{yy} & R_{yz} \\ R_{zx} & R_{zy} & R_{zz} \end{pmatrix} \begin{pmatrix} 1 \\ 1 \\ 1 \end{pmatrix} = \begin{pmatrix} R_{xx}+R_{xy}+R_{xz} \\ R_{yx}+R_{yy}+R_{yz} \\ R_{zx}+R_{zy}+R_{zz} \end{pmatrix} = \begin{pmatrix} 1 \\ 1 \\ 1 \end{pmatrix} .$$

The second procedure is to rotate the axis $\omega = (1,1,1)$ towards $\hat{\mathbf{e}}_z$ using rotations around the $\hat{\mathbf{e}}_z$ and then $\hat{\mathbf{e}}_y$-axes, to apply the desired rotation of 120°, and finally come back. With MAPLE it is easy to verify that the matrix,

$$M = \begin{pmatrix} \cos(-\phi) & \sin(-\phi) & 0 \\ -\sin(-\phi) & \cos(-\phi) & 0 \\ 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} \cos(-\alpha) & 0 & \sin(-\alpha) \\ 0 & 1 & 0 \\ -\sin(-\alpha) & 0 & \cos(-\alpha) \end{pmatrix} \begin{pmatrix} \cos\beta & \sin\beta & 0 \\ -\sin\beta & \cos\beta & 0 \\ 0 & 1 & \end{pmatrix} \begin{pmatrix} \cos\alpha & 0 & \sin\alpha \\ 0 & 1 & 0 \\ -\sin\alpha & 0 & \cos\alpha \end{pmatrix} \begin{pmatrix} \cos\phi & \sin\phi & 0 \\ -\sin\phi & \cos\phi & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

with $\phi = \frac{\pi}{4}$ and $\alpha = \arctan\frac{1}{\sqrt{2}}$ meets the requirement,

$$\begin{pmatrix} 1 \\ 1 \\ 1 \end{pmatrix} = M \begin{pmatrix} 1 \\ 1 \\ 1 \end{pmatrix} .$$

Calculating the sinus and cosinus of the angles, including the angle $\beta = \frac{2\pi}{3}$,

$$\begin{aligned} &\cos\phi = \cos\tfrac{\pi}{4} = \sqrt{\tfrac{1}{2}} = \sin\phi \\ &\cos\alpha = \cos\arctan\sqrt{\tfrac{1}{2}} = \cos\arcsin\sqrt{\tfrac{1}{3}} = \sqrt{\tfrac{1}{3}} \quad , \quad \sin\alpha = \sqrt{\tfrac{2}{3}} \\ &\cos\beta = \cos\tfrac{2\pi}{3} = -\tfrac{1}{2} \quad , \quad \sin\beta = \tfrac{\sqrt{3}}{2} . \end{aligned}$$

With these angles we find the rotation matrix about an axis ω,

$$M = \begin{pmatrix} \frac{1}{3}+\frac{2}{3}\cos\beta & \frac{1}{3}+\frac{1}{3}\sqrt{3}\sin\beta-\frac{1}{3}\cos\beta & \frac{1}{3}-\frac{1}{3}\sqrt{3}\sin\beta-\frac{1}{3}\cos\beta \\ \frac{1}{3}-\frac{1}{3}\sqrt{3}\sin\beta-\frac{1}{3}\cos\beta & \frac{1}{3}+\frac{2}{3}\cos\beta & \frac{1}{3}+\frac{1}{3}\sqrt{3}\sin\beta-\frac{1}{3}\cos\beta \\ \frac{1}{3}+\frac{1}{3}\sqrt{3}\sin\beta-\frac{1}{3}\cos\beta & \frac{1}{3}-\frac{1}{3}\sqrt{3}\sin\beta-\frac{1}{3}\cos\beta & \frac{1}{3}+\frac{2}{3}\cos\beta \end{pmatrix} = \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 1 & 0 & 0 \end{pmatrix} .$$

A third procedure is to define a coordinate system with z as the axis of rotation, for example,

$$\mathbf{a} = \tfrac{1}{2}(1,-1,0) \quad , \quad \mathbf{b} = \tfrac{1}{6}(1,1,-2) \quad , \quad \omega = \tfrac{1}{3}(1,1,1) ,$$

checking that $\mathbf{a}\times\mathbf{b} = \vec{\omega}$. The transformation matrix between these coordinate systems is,

$$\mathcal{R}_t = \begin{pmatrix} \hat{\mathbf{e}}_x\cdot\mathbf{a} & \hat{\mathbf{e}}_x\cdot\mathbf{b} & \hat{\mathbf{e}}_x\cdot\vec{\omega} \\ \hat{\mathbf{e}}_y\cdot\mathbf{a} & \hat{\mathbf{e}}_y\cdot\mathbf{b} & \hat{\mathbf{e}}_y\cdot\vec{\omega} \\ \hat{\mathbf{e}}_z\cdot\mathbf{a} & \hat{\mathbf{e}}_z\cdot\mathbf{b} & \hat{\mathbf{e}}_z\cdot\vec{\omega} \end{pmatrix} .$$

Now just concatenate these arrays.

1.6.3.7 Ex: Rotation of the coordinate system

Consider the transformation that corresponds to an inversion of the components of the vector $\mathbf{r} \longrightarrow -\mathbf{r}$ and find out, how the vector product and the triple scalar product transform under inversion.

Solution: *The vector product transform as,*

$$(-\mathbf{r}_1) \times (-\mathbf{r}_2) = \mathbf{r}_1 \times \mathbf{r}_2 \ .$$

That is, the resulting vector is not inverted. *Therefore, it is also called* pseudo-vector. *Examples are torque* $\mathbf{r} \times \mathbf{P}$ *and the Lorentz force* $e\mathbf{v} \times \mathbf{B}$. *The triple scalar product becomes,*

$$(-\mathbf{r}_1) \cdot [(-\mathbf{r}_2) \times (-\mathbf{r}_3)] = -\mathbf{r}_1 \cdot (\mathbf{r}_2 \times \mathbf{r}_3) \ .$$

That is, the resulting scalar is inverted. *This is why it is also called* pseudo-scalar.

1.6.3.8 Ex: Rotation matrices

Show that the scalar product $\mathbf{a} \cdot \mathbf{b}$ and the angle α between the two vectors are preserved when we rotate the two vectors by an angle θ around any axis.

Solution: *Treating the two vectors as matrices,* $\mathbf{a} = A$ *and* $\mathbf{b} = B$, *we write the scalar product as,* $\mathbf{a} \cdot \mathbf{b} = A^\dagger B$. *Now, since the rotation matrix must satisfy,* $\mathcal{R}^\dagger = \mathcal{R}^{-1}$,

$$A^\dagger \cdot B = A^\dagger \mathcal{R}^\dagger \mathcal{R} B = (\mathcal{R}A)^\dagger \mathcal{R} B \ .$$

Alternative solution: *We chose the orthonormal base in such a way that an arbitrary* rotation *be described as a rotation around the axis. z:*

$$\mathcal{R} = \begin{pmatrix} \cos\theta & \sin\theta & 0 \\ -\sin\theta & \cos\theta & 0 \\ 0 & 0 & 1 \end{pmatrix} \ .$$

Thereby,

$$\begin{aligned} \mathcal{R}\mathbf{a} \cdot \mathcal{R}\mathbf{b} &= \left[\begin{pmatrix} \cos\theta & \sin\theta & 0 \\ -\sin\theta & \cos\theta & 0 \\ 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} a_1 \\ a_2 \\ a_3 \end{pmatrix} \right]^t \begin{pmatrix} \cos\theta & \sin\theta & 0 \\ -\sin\theta & \cos\theta & 0 \\ 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} b_1 \\ b_2 \\ b_3 \end{pmatrix} \\ &= (a_1 \cos\theta + a_2 \sin\theta)(b_1 \cos\theta + b_2 \sin\theta) \\ &\quad + (-a_1 \sin\theta + a_2 \cos\theta)(-b_1 \sin\theta + b_2 \cos\theta) + a_3 b_3 \\ &= a_1 b_1 + a_2 b_2 + a_3 b_3 = \mathbf{a} \cdot \mathbf{b} \ . \end{aligned}$$

The absolute value is,

$$\begin{aligned} |\mathcal{R}\mathbf{a}| &= \left\| \begin{pmatrix} \cos\theta & \sin\theta & 0 \\ -\sin\theta & \cos\theta & 0 \\ 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} a_1 \\ a_2 \\ a_3 \end{pmatrix} \right\| \\ &= \sqrt{|a_1 \cos\theta + a_2 \sin\theta|^2 + |-a_1 \sin\theta + a_2 \cos\theta|^2 + |a_3|^2} = \sqrt{(a_2^2 + a_1^2 + a_3^2)} = |\mathbf{a}| \ . \end{aligned}$$

The angle should be maintained as,

$$|\mathcal{R}\mathbf{a}|^2 \cos\alpha = \mathcal{R}\mathbf{a}\cdot\mathcal{R}\mathbf{a} = \mathbf{a}\cdot\mathbf{a} = |\mathbf{a}|^2\cos\alpha \ .$$

1.6.3.9 Ex: Rotation matrices

Consider the matrix,

$$\mathcal{R} = \frac{1}{2}\begin{pmatrix} \sqrt{2} & \sqrt{2} & 0 \\ -1 & 1 & \sqrt{2} \\ 1 & -1 & \sqrt{2} \end{pmatrix} \ .$$

a. Show that $\mathcal{R}$ is a rotation matrix.
b. Determine the axis of rotation.
Help: The rotation axis $\mathbf{a}$ stays invariant under rotation: $\mathcal{R}\mathbf{a} = \mathbf{a}$. Use this condition.
c. Determine the rotation angle.
Help: Consider for this a vector that is perpendicular to $\mathbf{a}$.

Solution: *a. Rotation matrices are unitary operations maintaining orientation, i.e.,* $\det\mathcal{R} = +1$ *and* $\mathcal{R}^T\mathcal{R} = 1$,

$$\det\mathcal{R} = \frac{1}{2^3}\det\begin{pmatrix} \sqrt{2} & \sqrt{2} & 0 \\ -1 & 1 & \sqrt{2} \\ 1 & -1 & \sqrt{2} \end{pmatrix} = 1$$

$$\mathcal{R}^T\mathcal{R} = \frac{1}{2^2}\begin{pmatrix} \sqrt{2} & -1 & 1 \\ \sqrt{2} & 1 & -1 \\ 0 & \sqrt{2} & \sqrt{2} \end{pmatrix}\begin{pmatrix} \sqrt{2} & \sqrt{2} & 0 \\ -1 & 1 & \sqrt{2} \\ 1 & -1 & \sqrt{2} \end{pmatrix} = 1 \ .$$

b. We have,

$$\mathcal{R}\mathbf{a} = \frac{1}{2}\begin{pmatrix} \sqrt{2} & \sqrt{2} & 0 \\ -1 & 1 & \sqrt{2} \\ 1 & -1 & \sqrt{2} \end{pmatrix}\begin{pmatrix} x \\ y \\ z \end{pmatrix} = \begin{pmatrix} \frac{1}{2}\sqrt{2}x + \frac{1}{2}\sqrt{2}y \\ -\frac{1}{2}x + \frac{1}{2}y + \frac{1}{2}\sqrt{2}z \\ \frac{1}{2}x - \frac{1}{2}y + \frac{1}{2}\sqrt{2}z \end{pmatrix} = \begin{pmatrix} x \\ y \\ z \end{pmatrix} = \mathbf{a} \ .$$

The resolution of the system of linear equations gives $y = (\sqrt{2}-1)x$ *and* $z = x$. *The axis of rotation, i.e.* the eigenvector of the rotation *is* $\mathbf{a} = \frac{1}{\sqrt{5-2\sqrt{2}}}\begin{pmatrix} 1 \\ \sqrt{2}-1 \\ 1 \end{pmatrix}$.

c. We choose a test vector $\mathbf{b}$ *perpendicular to* $\mathbf{a}$. *E.g.* $\mathbf{b} = \begin{pmatrix} 2 \\ 0 \\ -2 \end{pmatrix}$. *The rotation* $\mathcal{R}$

applied to $\mathbf{b}$ *gives,* $\mathbf{c} = \mathcal{R}\mathbf{b} \begin{pmatrix} \sqrt{2} \\ -1-\sqrt{2} \\ 1-\sqrt{2} \end{pmatrix}$,

$$|\mathbf{c}| = |\mathbf{b}| = \sqrt{8}$$
$$\mathbf{bc} = 4\sqrt{2} - 2 = |\mathbf{b}||\mathbf{c}| \cos\alpha = 8\cos\alpha \ .$$

with that, follow, $\cos\alpha = \frac{1}{\sqrt{2}} - \frac{1}{4} \simeq 0.4571$. *Therefore, the rotation angle is* $\alpha \simeq 62.8°$.

1.6.3.10 Ex: Rotation matrices

A rotation by an angle ϕ around the z-axis is described by the rotation matrix $\mathcal{R}_z(\phi)$ with,

$$\mathcal{R}_z(\phi) = \begin{pmatrix} \cos\phi & \sin\phi & 0 \\ -\sin\phi & \cos\phi & 0 \\ 0 & 0 & 1 \end{pmatrix} \ .$$

a. Show by an explicit calculation that inverse matrix satisfies, $\mathcal{R}_z^{-1}(\phi) = \mathcal{R}_z(-\phi) = \mathcal{R}_z^t(\phi)$.
b. Show, $\mathcal{R}_z(\phi_1)\mathcal{R}_z(\phi_2) = \mathcal{R}_z(\phi_1+\phi_2) = \mathcal{R}_z(\phi_2)\mathcal{R}_z(\phi_1)$.
c. Show, $[\mathcal{R}_z(\phi_1)\mathcal{R}_z(\phi_2)]^t = \mathcal{R}_z^t(\phi_2)\mathcal{R}_z^t(\phi_1)$.

Solution: *a. Rotation matrices are unitary. Therefore, the inverse matrix is equal to the transposed matrix. The transposed matrix is easily obtained by inversion of the sign of the angle* ϕ.
b. This can be done with MAPLE. We find that,

$$\begin{aligned} \mathcal{R}_z(\phi_1)\mathcal{R}z(\phi_2) &= \begin{pmatrix} \cos\phi_1 & \sin\phi_1 & 0 \\ -\sin\phi_1 & \cos\phi_1 & 0 \\ 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} \cos\phi_2 & \sin\phi_2 & 0 \\ -\sin\phi_2 & \cos\phi_2 & 0 \\ 0 & 0 & 1 \end{pmatrix} \\ &= \begin{pmatrix} \cos\phi_1\cos\phi_2 - \sin\phi_1\sin\phi_2 & \cos\phi_1\sin\phi_2 + \sin\phi_1\cos\phi_2 & 0 \\ -\sin\phi_1\cos\phi_2 - \cos\phi_1\sin\phi_2 & \cos\phi_1\cos\phi_2 - \sin\phi_1\sin\phi_2 & 0 \\ 0 & 0 & 1 \end{pmatrix} \\ &= \begin{pmatrix} \cos(\phi_1+\phi_2) & \sin(\phi_1+\phi_2) & 0 \\ -\sin(\phi_1+\phi_2) & \cos(\phi_1+\phi_2) & 0 \\ 0 & 0 & 1 \end{pmatrix} = \mathcal{R}_z(\phi_1+\phi_2) = \mathcal{R}_z(\phi_2)\mathcal{R}_z(\phi_1) \ . \end{aligned}$$

1.6.3.11 Ex: Rotation matrices

a. Be given the basis $(\hat{\mathbf{e}}_x, \hat{\mathbf{e}}_y, \hat{\mathbf{e}}_z)$ in Cartesian coordinates. Determine the transformation matrices for cylindrical basis $(\hat{\mathbf{e}}_\rho, \hat{\mathbf{e}}_\varphi, \hat{\mathbf{e}}_z)$ and the spherical basis $(\hat{\mathbf{e}}_r, \hat{\mathbf{e}}_\theta, \hat{\mathbf{e}}_\varphi)$ and their inverse matrices.

b. For both cases transform the force fields,

$$\mathbf{F}_1 = -\kappa \begin{pmatrix} x \\ y \\ z \end{pmatrix} \qquad \mathbf{F}_2 = \gamma \begin{pmatrix} y \\ -x \\ 0 \end{pmatrix} \qquad \mathbf{F}_3 = \delta \begin{pmatrix} -\frac{xz}{\sqrt{x^2+y^2}} \\ -\frac{y\ z}{\sqrt{x^2+y^2}} \\ \sqrt{x^2+y^2} \end{pmatrix} .$$

c. Show generally that for rotation matrices, the vectors that correspond to the columns of the matrices are mutually orthogonal. The same holds for rows of the matrices. Use the relationship, $A^t A = A A^t = 1$.

Solution: *a. The matrices consisting of the basis vectors are in Cartesian coordinates,*

$$\mathcal{R}_{ka} = \begin{pmatrix} \hat{\mathbf{e}}_x, & \hat{\mathbf{e}}_y, & \hat{\mathbf{e}}_z \end{pmatrix} = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix} ,$$

in cylindrical coordinates,

$$\begin{aligned} \mathbf{r}_{zy} &= \begin{pmatrix} \hat{\mathbf{e}}_\rho, & \hat{\mathbf{e}}_\phi, & \hat{\mathbf{e}}_z \end{pmatrix} \\ &= \begin{pmatrix} \hat{\mathbf{e}}_x \cos\phi + \hat{\mathbf{e}}_y \sin\phi, & -\hat{\mathbf{e}}_x \sin\phi + \hat{\mathbf{e}}_y \cos\phi, & \hat{\mathbf{e}}_z \end{pmatrix} = \begin{pmatrix} \cos\phi & -\sin\phi & 0 \\ \sin\phi & \cos\phi & 0 \\ 0 & 0 & 1 \end{pmatrix} , \end{aligned}$$

and in spherical coordinates,

$$\begin{aligned} \mathcal{R}_{ku} &= \begin{pmatrix} \hat{\mathbf{e}}_r, & \hat{\mathbf{e}}_\theta, & \hat{\mathbf{e}}_\phi \end{pmatrix} \\ &= \begin{pmatrix} \hat{\mathbf{e}}_x \sin\theta\cos\phi + \hat{\mathbf{e}}_y \sin\theta\sin\phi + \hat{\mathbf{e}}_z \cos\theta \\ \hat{\mathbf{e}}_x \cos\theta\cos\phi + \hat{\mathbf{e}}_y \cos\theta\sin\phi - \hat{\mathbf{e}}_z \sin\theta \\ -\hat{\mathbf{e}}_x \sin\theta + \hat{\mathbf{e}}_y \cos\theta \end{pmatrix}^T \\ &= \begin{pmatrix} \sin\theta\cos\phi & \cos\theta\cos\phi & -\sin\theta \\ \sin\theta\sin\phi & \cos\theta\sin\phi & \cos\theta \\ \cos\theta & -\sin\theta & 0 \end{pmatrix} \end{aligned}$$

they are precisely the transformation matrices. Inverse transformations simply follow as transpositions of unitary matrices, $\mathcal{R}^{-1} = \mathcal{R}^T$.
b. Transforming force fields is easy with MAPLE.
c. The condition for a rotation matrix is,

$$1 = \mathcal{R}^T\mathcal{R} = \begin{pmatrix} a & b & c \\ d & f & g \\ h & k & l \end{pmatrix}^T \begin{pmatrix} a & b & c \\ d & f & g \\ h & k & l \end{pmatrix} = \begin{pmatrix} a^2+d^2+h^2 & ab+df+hk & ac+dg+hl \\ ab+df+hk & b^2+f^2+k^2 & bc+fg+kl \\ ac+dg+hl & bc+fg+kl & c^2+g^2+l^2 \end{pmatrix} .$$

That is, equivalent to the requirement, that the column vectors are mutually orthogonal,

$$\begin{pmatrix} a \\ d \\ h \end{pmatrix} \begin{pmatrix} b \\ f \\ k \end{pmatrix} = \begin{pmatrix} a \\ d \\ h \end{pmatrix} \begin{pmatrix} c \\ g \\ l \end{pmatrix} = \begin{pmatrix} b \\ f \\ k \end{pmatrix} \begin{pmatrix} c \\ g \\ l \end{pmatrix} = 0 .$$

1.6.3.12 Ex: Rotation of the coordinate system

Here, we want to rotate a rod around several axes and determine, whether its final orientation depends on the rotation path. We know that the matrix

$$\mathcal{R}_z(\alpha) = \begin{pmatrix} \cos\alpha & \sin\alpha & 0 \\ -\sin\alpha & \cos\alpha & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

describes the transformation of a vector under rotation of the coordinate system by an angle α around the axis z.
a. Show that corresponding rotations around the x-axis, respectively, the y-axis are given by,

$$\mathcal{R}_x(\alpha) = \begin{pmatrix} 1 & 0 & 0 \\ 0 & \cos\alpha & \sin\alpha \\ 0 & -\sin\alpha & \cos\alpha \end{pmatrix} \quad , \quad \mathcal{R}_y(\alpha) = \begin{pmatrix} \cos\alpha & 0 & -\sin\alpha \\ 0 & 1 & 0 \\ \sin\alpha & 0 & \cos\alpha \end{pmatrix} .$$

b. Show that a rotation of the coordinate system around the y-axis by an angle $\alpha = \pi/2$ leads to the same result as a rotation around the z-axis by the angle $\pi/2$ followed by a rotation around x by the angle $\pi/2$ followed by a rotation around z by the angle $3\pi/2$.

Solution: *a. All rotation matrices are unitary,* $\det \mathcal{R}(\alpha) = 1$, $R^{-1}(\alpha) = \mathcal{R}^t(\alpha)$. *The matrix* $\mathcal{R}_x(\alpha)$ *leaves the* x*-component of the vector unchanged, the matrix* $R^y(\alpha)$ *leaves the* y*-component unchanged,*

$$\mathcal{R}_x(\alpha) = \begin{pmatrix} 1 & 0 & 0 \\ 0 & \cos\alpha & \sin\alpha \\ 0 & -\sin\alpha & \cos\alpha \end{pmatrix} \begin{pmatrix} a \\ b \\ c \end{pmatrix} = \begin{pmatrix} a \\ b\cos\alpha + c\sin\alpha \\ -b\sin\alpha + c\cos\alpha \end{pmatrix}$$

$$\mathcal{R}_y(\alpha) = \begin{pmatrix} \cos\alpha & 0 & -\sin\alpha \\ 0 & 1 & 0 \\ \sin\alpha & 0 & \cos\alpha \end{pmatrix} \begin{pmatrix} a \\ b \\ c \end{pmatrix} = \begin{pmatrix} a\cos\alpha - c\sin\alpha \\ b \\ a\sin\alpha + c\cos\alpha \end{pmatrix} .$$

b. We have,

$$\mathcal{R}_z(3\pi/2)\mathcal{R}_x(\pi/2)\mathcal{R}_z(\pi/2) = \begin{pmatrix} 0 & -1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & -1 & 0 \end{pmatrix} \begin{pmatrix} 0 & 1 & 0 \\ -1 & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix}$$
$$= \begin{pmatrix} 0 & 0 & -1 \\ 0 & 1 & 0 \\ 1 & 0 & 0 \end{pmatrix} = \mathcal{R}_y(\pi/2) .$$

Chapter 2

Dynamics of point masses

2.1 Motion of point masses

2.1.1 One-dimensional motion

Among the various movements that we will study, the one-dimensional motion is the simplest, because all vector quantities that describe the motion are parallel. Since the motion occurs in only one dimension, only one coordinate is required to specify the position of a body at each instant of time [1].

2.1.1.1 Velocity

The rate of change of the spatial coordinates of a body is called *velocity*. It can be characterized by specifying the body's position in a time table, as shown below (stroboscopic measurement) or by a graph, as shown in Fig. 2.1.

t [s]	x [m]	v [m/s]
0	0	-
1	0.4	0.4
2	0.6	0.1
3	0.7	0.06
4	0.8	0.07

The velocity averaged over a time interval $[t_1, t_2]$,

$$\bar{v} = \frac{x(t_2) - x(t_1)}{t_2 - t_1} \ , \tag{2.1}$$

is the angular coefficient of the slope connecting the points $(x(t_1), t_1)$ and $(x(t_2), t_2)$ of the curve (see Fig. 2.1).

A motion is called *uniform* when the velocity is constant,

$$x(t) = x_0 + v(t - t_0) \ . \tag{2.2}$$

For non-uniform (e.g. accelerated) motion the instantaneous velocity is calculated via,

$$\boxed{v(t) = \lim_{\Delta t \to 0} \frac{x(t + \Delta t) - x(t)}{\Delta t} \equiv \frac{dx(t)}{dt} \equiv \dot{x}(t)} \ . \tag{2.3}$$

[1] See [Cap. 2, Moyses] [Cap. 2, Zilio & Bagnato].

For example, the function $y(t) = -10\,\mathrm{m/s^2}\cdot t^2 + 5\,\mathrm{m/s}\cdot t + 2\,\mathrm{m}$ parametrizes a trajectory taken by a uniform motion [2].

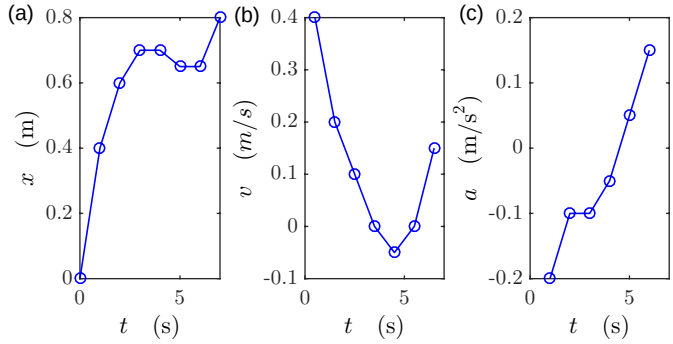

Figure 2.1: Graphical representation of the motion specified in the table. (a) Instantaneous position, (b) velocity, and (c) acceleration.

Inverse problem: Draw a graph $t \mapsto v$ and measure the area underneath:

$$x(t_2) - x(t_1) = \int_{t_1}^{t_2} v(t)dt \ . \tag{2.4}$$

2.1.1.2 Acceleration

The rate of change of the instantaneous velocity of a body is called *acceleration*. Analogous to the velocity it can be characterized by specifying the body's velocity in a time table or a graph.

Acceleration can be progressive or backward, leading to deceleration. The instantaneous acceleration is calculated via,

$$\boxed{a(t) = \lim_{\Delta t \to 0} \frac{v(t+\Delta t) - v(t)}{\Delta t} \equiv \frac{dv(t)}{dt} \equiv \dot{v}(t)} \ . \tag{2.5}$$

Inverse problem: Draw a graph $t \mapsto a$ and measure the area underneath:

$$v(t_2) - v(t_1) = \int_{t_1}^{t_2} a(t)dt \ , \tag{2.6}$$

yielding [3],

$$x(t) = x(t_0) + \int_{t_0}^{t} v(t')dt' = x(t_0) + \int_{t_0}^{t} \left[v(t_0) + \int_{t_0}^{t'} a(t'')dt'' \right] dt' \tag{2.7}$$

$$= x(t_0) + v(t_0)(t - t_0) + \int_{t_0}^{t} \int_{t_0}^{t'} a(t'')dt''dt' \ . \tag{2.8}$$

One-dimensional motion will be studied in Excs. 2.1.4.1 to 2.1.4.11.

[2] Why do we have to write the units?
[3] Galileo.

2.1.2 Motion in two and three dimensions

2.1.2.1 Description in terms of coordinates

Under normal circumstances, space is three-dimensional, and so is the motion of a body through it. Hence, we need three coordinates to specify the position of a body at a given time, and knowing the time-dependence of the three coordinates we can parametrized the body's motion through space. Luckily, specifying a coordinate system we can reduce a bi- or (tri-)dimensional motion into two (three) one-dimensional motions.

That is to say, the physical quantities position, velocity, and force are vector quantities consistent, in fact, of three values. In this sense, they are fundamentally different from scalar quantities, such as time, temperature, or volume [4]. Using the basis,

$$\hat{\mathbf{e}}_x \equiv \begin{pmatrix} 1 \\ 0 \end{pmatrix} \qquad \text{and} \qquad \hat{\mathbf{e}}_y \equiv \begin{pmatrix} 0 \\ 1 \end{pmatrix} \ , \tag{2.9}$$

called *Cartesian basis*, we write the vector velocity,

$$\mathbf{v}(t) = \frac{d\mathbf{r}(t)}{dt} = \dot{x}(t)\hat{\mathbf{e}}_x + \dot{y}(t)\hat{\mathbf{e}}_y = \begin{pmatrix} v_x(t) \\ v_y(t) \end{pmatrix} \ , \tag{2.10}$$

and the vector acceleration,

$$\mathbf{a}(t) = \frac{d\mathbf{v}(t)}{dt} = \dot{v}_x(t)\hat{\mathbf{e}}_x + \dot{v}_y(t)\hat{\mathbf{e}}_y = \begin{pmatrix} a_x(t) \\ a_y(t) \end{pmatrix} \ . \tag{2.11}$$

2.1.2.2 Uniformly accelerated movement by gravitation

The differential equations (2.3) or (2.5) are insufficient to determine the trajectory of a body. We additionally need to specify initial conditions. For a n-dimensional motion, we need $2n$ initial conditions.

Example 2 (*Motion due to terrestrial gravitation*): The acceleration of a body in the Earth's gravitational field is,

$$\mathbf{a}(t) = const = \Big(0, -g\Big) \ . \tag{2.12}$$

With arbitrary initial conditions, $\mathbf{r}(t_0) = \mathbf{r}_0$ and $\mathbf{v}(t_0) = \mathbf{v}_0$ we find,

$$\mathbf{v}(t) = \mathbf{v}_0 + \mathbf{a}(t - t_0) \tag{2.13}$$

and,

$$\mathbf{v}(t) = \mathbf{v}_0 + \mathbf{a}(t - t_0) \qquad \text{and} \qquad \mathbf{r}(t) = \mathbf{r}_0 + \mathbf{v}_0(t - t_0) + \tfrac{1}{2}\mathbf{a}(t - t_0)^2 \ . \tag{2.14}$$

Elimination time in these two equations,

$$y - y_0 = \frac{v_{0y}}{v_{0x}}(x - x_0) + \frac{a}{2}(x - x_0)^2 \ . \tag{2.15}$$

[4] Rules of how to use vectors (length, scalar product, and vector product.

Example 3 (*Motion of a projectile subject to gravity*): We identify the motion as being two-dimensional. Hence, an appropriate choice of the coordinate system allows us to eliminate one coordinate and to restrict to two coordinates that we will call $\hat{\mathbf{e}}_x$ and e_y. We choose the initial conditions as $\mathbf{r}(t_0) = (0, 0)$ and $\mathbf{v}(t_0) = v_0 \begin{pmatrix} \cos\theta \\ \sin\theta \end{pmatrix}$. The equations of motion are then,

$$\mathbf{r}(t) = \begin{pmatrix} v_0 t \cos\theta \\ v_0 t \sin\theta - \frac{1}{2} g t^2 \end{pmatrix} . \tag{2.16}$$

Elimination time in the two equations (2.16),

$$y = x \tan\theta - \frac{g x^2}{2 v_0^2 \cos^2\theta} . \tag{2.17}$$

We my now use this equation to calculate the maximum height and the maximum range of the throw.

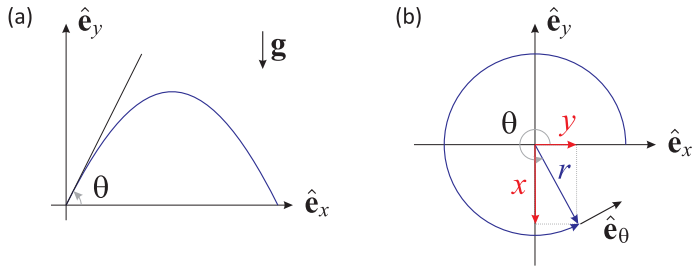

Figure 2.2: (a) Ballistic trajectory in the field of gravity. (b) Circular motion in Cartesian and polar coordinates.

Note that two movements $x(t)$ and $y(t)$ can be coupled by other physical effect, such as via the friction exerted by air.

2.1.2.3 Circular motion and polar coordinates

When we called a movement one, two, or three-dimensional, what we really meant is the number of scalar differential equations needed to describe it. Strictly speaking, however, any movement of a point mass is described by a curve in space, which is a one-dimensional object. Consequently, in the examples 4 and 3 we were able to replace the two differential equations parametrized in time $\{x(t), y(t)\}$ by a single one for $y(x)$ by eliminating time [5].

Sometimes the number of differential equations needed to describe a motion can be reduced without having to eliminate time by a proper choice of the coordinate system, which is better adapted to the symmetry of the motion. Until now we only used Cartesian coordinates (2.9). A nice example for this is the *circular motion*

[5] Note that time is automatically reintroduced in the equations once we calculate velocities by derivating coordinates.

defined by $|\mathbf{r}| = r = const$. Let us define two new coordinates oriented along the instantaneous position and the instantaneous velocity of the body,

$$\boxed{\hat{\mathbf{e}}_r(t) \equiv \frac{\mathbf{r}(t)}{r} \qquad \text{and} \qquad \hat{\mathbf{e}}_\theta(t) \equiv \frac{\mathbf{v}(t)}{v(t)}} \ . \tag{2.18}$$

We note that (for a circular motion) the new coordinates, called *polar coordinates*, are orthogonal but not fixed in space: they rotate along the circle together with the body.

The constancy of the radius $r^2 = x(t)^2 + y(t)^2$, however, implies that we may, choosing the Cartesian coordinate system such as to satisfy the initial condition $x(0) = r$, define two new variables $\{r, \theta(t)\}$ one of which is constant and the other time-dependent, such that,

$$\mathbf{r}(t) = \begin{pmatrix} x(t) \\ y(t) \end{pmatrix} = r \begin{pmatrix} \cos\theta(t) \\ \sin\theta(t) \end{pmatrix} = r\hat{\mathbf{e}}_r(t) \ , \tag{2.19}$$

for the velocity,

$$\mathbf{v}(t) = \frac{d\mathbf{r}(t)}{dt} = \begin{pmatrix} v_x(t) \\ v_y(t) \end{pmatrix} = r \begin{pmatrix} -\dot{\theta}(t)\sin\theta(t) \\ \dot{\theta}(t)\cos\theta(t) \end{pmatrix} = \dot{\theta}(t) \begin{pmatrix} -y(t) \\ x(t) \end{pmatrix} = v(t)\hat{\mathbf{e}}_\theta(t) \ , \tag{2.20}$$

and for the acceleration,

$$\mathbf{a}(t) = \frac{d\mathbf{v}(t)}{dt} = r \begin{pmatrix} -\ddot{\theta}(t)\sin\theta(t) - \dot{\theta}(t)^2\cos\theta(t) \\ \ddot{\theta}(t)\cos\theta(t) - \dot{\theta}(t)^2\sin\theta(t) \end{pmatrix} = -r\dot{\theta}(t)^2\hat{\mathbf{e}}_r + r\ddot{\theta}(t)\hat{\mathbf{e}}_\theta(t) \ . \tag{2.21}$$

That is, the acceleration is composed of a tangential and a normal component,

$$\mathbf{a}(t) \cdot \hat{\mathbf{e}}_\theta(t) = r\ddot{\theta}(t) \qquad \text{and} \qquad \mathbf{a}(t) \cdot \hat{\mathbf{e}}_r = -r\dot{\theta}(t)^2 \ . \tag{2.22}$$

The circular motion is called *uniform* when $|\mathbf{v}| = v = const$. Then, $\ddot{\theta} = 0$ and $\dot{\theta} \equiv \omega = const$, and the above formulas simplify accordingly. Then $\theta = \theta_0 + \omega(t - t_0)$ and, using $\omega \equiv v/r$, we get for the arc traveled by the body,

$$s(t) = r\theta(t) = s_0 + v(t - t_0) \ . \tag{2.23}$$

Motion in one and two dimensions will be studied in Excs. 2.1.4.12 to 2.1.4.12.

2.1.3 Newton's laws

Newton formulated the following fundamental laws of classical mechanics:

i. Principle of inertia (without forces objects move with uniform velocity)

ii. $F = ma$

iii. Reaction principle (actio = reaction)

iv. Forces can be added (corollary)

Their interpretation is that: (i) In the absence of forces linear momentum is conserved; systems not subject to external forces (called *inertial systems*) are equivalent, e.g. there no way to decide an absolute speed from with in a system. (ii) Forces generate a change of linear momentum leading to an acceleration $\sum_k \mathbf{F}_k = m\dot{\mathbf{v}}$.

Newton's laws have a wide range of applications. Formulated for fixed masses, they can nevertheless be generalized to variable masses,

$$\boxed{\mathbf{F} = \dot{\mathbf{p}} = m\dot{\mathbf{v}} + \mathbf{v}\dot{m}} \ . \tag{2.24}$$

2.1.4 Exercises

2.1.4.1 Ex: Overtaking

A car travels at a constant safety distance of 40 m behind a truck (length: 25 m) at 80 km/h . To overtake, he accelerates with $a = 1.3\,\mathrm{m/s^2}$ to $v = 100\,\mathrm{km/h}$. How long is the overtaking time and the path length if the safety distance at the time of reentering the drive lane is 40 m?

Solution: *Be x the location of the car and $z(t) = 80\,\mathrm{km/h}\cdot t$ the location of the truck. Before the overtaking manoeuvre, at the time t_0,*

$$\begin{aligned} x(t_0) - z(t_0) &= -40\,\mathrm{m} \\ \dot{x}(t_0) - \dot{z}(t_0) &= 0 \ . \end{aligned}$$

From then until the time t_1 of reaching the maximum speed $x(t) = 100\,\mathrm{km/h}$ we have,

$$\begin{aligned} \ddot{x}(t) - \ddot{z}(t) &= 1.3\,\mathrm{m/s^2} \\ \dot{x}(t) - \dot{z}(t) &= 1.3\,\mathrm{m/s^2}\cdot(t - t_0) \\ x(t) - z(t) &= 1.3\,\mathrm{m/s^2}\cdot\frac{(t-t_0)^2}{2} - 40\,\mathrm{m} \ . \end{aligned}$$

The maximum speed is reached after the time

$$t_1 - t_0 = \frac{\dot{x}(t_1) - \dot{x}(t_0)}{a} = 4.3\,\mathrm{s}$$

At this time, the distance from the truck is,

$$x(t_1) - z(t_1) = 1.3\,\mathrm{m/s^2}\cdot\frac{(t_1-t_0)^2}{2} - 40\,\mathrm{m} = -28\,\mathrm{m} \ .$$

Now the car is traveling at a constant speed up to the time t_2. It must hold,

$$x(t_2) - z(t_2) = [\dot{x}(t_1) - \dot{z}(t_1)]\cdot(t_2 - t_1) - 28\,\mathrm{m} = 40\,\mathrm{m} + 25\,\mathrm{m} \ .$$

From this we calculate the time $t_2 - t_1 = 16.7\,\mathrm{s}$, hence, in total,

$$t_2 - t_0 = 21\,\mathrm{s}$$

The distance covered is the distance covered by the truck plus the acquired lead,

$$x(t) = 40\,\mathrm{m} + 40\,\mathrm{m} + 25\,\mathrm{m} + 80\,\mathrm{km/h}\cdot 21\,\mathrm{s} = 572\,\mathrm{m} \ .$$

2.1.4.2 Ex: Skater

A roller skater who moves at a constant speed of 10 m/s overtakes a jogger. After 5 minutes she passes a snack bar, where she takes a break for 2 minutes. Then she drives back at the same speed and meets the jogger after another 3 minutes. How fast does the jogger run?

Solution: *First, we calculate the distance traveled by the roller skater to the snack bar:* $s = vt = 10\,\mathrm{m/s} \times 5\,\mathrm{min}$. *She meets the jogger after* $5 + 2 + 3 = 10\,\mathrm{min}$, *when the jogger has traveled* $10\,\mathrm{m/s} \times 5\,\mathrm{min} - 10\,\mathrm{m/s} \times 3\,\mathrm{min} = 1200\,\mathrm{m}$. *The jogger therefore needs* $10\,\mathrm{min}$ *for* $1200\,\mathrm{m}$, *from this follows for his speed* $v = s/t = 1200\,\mathrm{m}\,/600\,\mathrm{s} = 2\,\mathrm{m/s}$.

2.1.4.3 Ex: Thieves

Two bank robbers on the run have to walk $s = 10\,\mathrm{km}$ to the rescue border, but only have one bike without luggage rack. They therefore decide to proceed as follows: Robber A drives 500 m ahead, leaves the bike and continues. Robber B goes up to the bike, sits on, drives past Robber A and continues 500 m. Then he in turn leaves the bike. In this way the robbers take turns up to the border. Assume the robbers are 6 km/h on foot and 20 km/h on bike.
a. Is this a good idea? Are the robbers really faster? If so, calculate the time saved.
b. How often do they have to change?

Solution: *a. Robber B overtakes robber A for the first time after* 1 km. *This is clear for reasons of symmetry (time inversion invariance), but can also be calculated in detail. In order to overcome the* 10 km *they have to make 10 partial trips.*
b. For a partial trip the robbers need the time $t = 500\,\mathrm{m}\left(\frac{1}{v_{rad}} + \frac{1}{v_{fus}}\right) = 0.1083\,\mathrm{h}$. *Hence, for the entire route 1.083 h. This is faster than on foot (*1.666 h*), but slower than by bike (*0.5 h*). All in all, these robbers seem to be smart and should rather earn their living as an mathematician rather than robbing banks.*

2.1.4.4 Ex: One-dimensional movement

A large jet plane must reach a speed of 500 km/h in order to take off, and has an acceleration of $4\,\mathrm{m/s^2}$. How long does it take for the plane to take off and how far does it have to run on the runway?

Solution: *The speed is given by* $v = at$. *Therefore,*

$$t = \frac{v}{a} = \frac{500}{3.6 \cdot 4}\,\mathrm{s} = 33.7\,\mathrm{m} \ .$$

The distance is,

$$x = \frac{a}{2}t^2 = \frac{4}{2} \cdot 33.7^2\,\mathrm{m} = 2270\,\mathrm{m} \ .$$

2.1.4.5 Ex: One-dimensional movement

A particle, initially at rest at the origin, moves for 10 s on a straight line, with increasing acceleration according to the law, $a = bt$, where t is time and $b = 0.5\,\mathrm{m/s^3}$. Plot the velocity v and the position x of the particle as a function of time. What is the analytical expression for $v(t)$?

Solution: *With the initial condition $x_0 = 0$ e $v_0 = 0$, the expressions are,*

$$v(t) = v_0 + \int_0^t a(t_1)dt_1 = \frac{b}{2}t^2$$
$$x(t) = x_0 + \int_0^t v(t_1)dt_1 = \frac{b}{6}t^3 \ .$$

2.1.4.6 Ex: One-dimensional movement

A projectile of mass m is ejected at the initial velocity v_0 vertically from a catapult.
a. Calculate the maximum height that the projectile reaches without considering the air resistance.
b. Now, we consider air resistance given by Stokes' friction law. Write down the equation of motion for this case.
c. Show that the equation of motion is solved by $v = e^{-\gamma t/m}\left(\frac{mg}{\gamma} + v_0\right) - \frac{mg}{\gamma}$.
d. Determine the time t_m when the projectile is at its maximum point from $v(t_m) = 0$.
e. What is the maximum height $s(t_m)$?

Solution: *a. The equation of motion, $ma = -mg$, has the solution, $v = v_0 - gt$. The maximum point, $v = 0$, is reached when $t_m = \frac{v_0}{g}$. So the maximum height is,*

$$s = v_0 t_m - \frac{g}{2}t_m^2 = v_0\frac{v_0}{g} - \frac{g}{2}\left(\frac{v_0}{g}\right)^2 = \frac{v_0^2}{2g} \ .$$

b. With friction we have, $ma = -mg - \gamma v$.
c. To solve this we separate the variables,

$$dt = \frac{-mdv}{mg + \gamma v}$$
$$\Leftrightarrow \quad t = -m\int_{v_0}^{v}\frac{dv}{mg+\gamma v} = -\frac{m}{\gamma}\int_{mg+\gamma v_0}^{mg+\gamma v}\frac{d\zeta}{\zeta} = -\frac{m}{\gamma}\ln\left(\frac{mg+\gamma v}{mg+\gamma v_0}\right) \ .$$

Hence,

$$v = e^{-\gamma t/m}\left(\frac{mg}{\gamma} + v_0\right) - \frac{mg}{\gamma} \simeq \left(1 - \frac{\gamma t}{m}\right)\left(\frac{mg}{\gamma} + v_0\right) - \frac{mg}{\gamma} = v_0 - gt - \frac{\gamma v_0 t}{m} \ .$$

d. Now $v(t_m) = 0$ leads to,

$$t_m = -\frac{m}{\gamma}\ln\frac{1}{1+\gamma v_0/mg} \simeq -\frac{m}{\gamma}\left(-\frac{\gamma v_0}{mg} + \frac{\gamma^2 v_0^2}{2m^2g^2}\right) = \frac{v_0}{g}\left(1 - \frac{\gamma v_0}{mg}\right) \ .$$

e. Finally,

$$\begin{aligned} s(t_m) &= \int_0^{t_m} v dt = -e^{-\gamma t_m/m}\frac{m}{\gamma}\left(\frac{mg}{\gamma}+v_0\right) - \frac{mg}{\gamma}t_m + \frac{m}{\gamma}\left(\frac{mg}{\gamma}+v_0\right) \\ &= -\frac{1}{1+\gamma v_0/mg}\frac{m}{\gamma}\left(\frac{mg}{\gamma}+v_0\right) - \frac{mg}{\gamma}\left(-\frac{m}{\gamma}\ln\frac{1}{1+\gamma v_0/mg}\right) + \frac{m}{\gamma}\left(\frac{mg}{\gamma}+v_0\right) \\ &= \frac{mv_0}{\gamma} + \frac{m^2 g}{\gamma^2}\ln\frac{1}{1+\gamma v_0/mg} \\ &\simeq \frac{mv_0}{\gamma} + \frac{m^2 g}{\gamma^2}\left(-\frac{\gamma v_0}{mg} + \frac{\gamma^2 v_0^2}{2m^2 g^2} - \frac{\gamma^3 v_0^3}{3m^3 g^3}\right) = \frac{v_0^2}{2g}\left(1-\frac{\gamma v_0}{3mg}\right) . \end{aligned}$$

2.1.4.7 Ex: Acceleration

A possible method to measure the acceleration of gravity g is to launch a ball upwards in an evacuated tube and accurately measure the instants t_1 and t_2 of its passage (on its way up and down) across a given height z. Show that:

$$g = \frac{2z}{t_1 t_2} .$$

Solution: *The motion equation is,*

$$s(t) = \frac{g}{2}t^2 + v_0 t .$$

We know two points of the trajectory:

$$\frac{g}{2}t_1^2 + v_0 t_1 = z = \frac{g}{2}t_2^2 + v_0 t_2 .$$

Hence,

$$\begin{aligned} g &= \frac{2z}{t_1^2} - \frac{2v_0}{t_1} \qquad \textit{and} \qquad v_0 = \frac{z}{t_2} - \frac{g}{2}t_2 \\ g &= \frac{2z}{t_1^2} - \frac{2}{t_1}\left(\frac{z}{t_2} - \frac{g}{2}t_2\right) \\ g &= \frac{-2z}{t_1 t_2} . \end{aligned}$$

2.1.4.8 Ex: Acceleration

You want to train to be a juggler, keeping two balls in the air throwing them to a maximum height of 2 m. How often and how fast and how fast do you have to throw

the balls up?

Solution: *The equation of motion is,*

$$s(t) = \frac{g}{2}t^2 + v_0 t \ .$$

We know two points of the trajectory,

$$0 = -\frac{g}{2}t^2 + v_0 t \qquad \textit{and} \qquad y_m = -\frac{g}{2}\left(\frac{t}{2}\right)^2 + v_0\frac{t}{2} \ .$$

Hence,

$$v_0 = \frac{g}{2}t \qquad \textit{and} \qquad y_m = -\frac{g}{2}\left(\frac{t}{2}\right)^2 + \frac{g}{2}t\frac{t}{2} = \frac{g}{8}t^2$$

$$t = \sqrt{\frac{8y_m}{g}} \simeq 1.3\,\mathrm{s} \qquad \textit{and} \qquad v_0 = \frac{g}{2}\sqrt{\frac{8y_m}{g}} = \sqrt{2gy_m} \simeq 6.3\,\mathrm{m/s} \ .$$

With two balls this time has to be divided by 2.

2.1.4.9 Ex: Acceleration

A racing car can be accelerated from 0 to 100 km/h in 4 s. Compare the corresponding mean acceleration with the acceleration of gravity. If the acceleration is constant, how far does the car travel until it reaches 100 km/h?

Solution: *The average acceleration is,*

$$a = \frac{100\,\mathrm{km/h} - 0\,\mathrm{km/h}}{4\,\mathrm{s} - 0\,\mathrm{s}} \simeq 7\,\mathrm{m/s^2} \simeq 0.7g \ .$$

The distance traveled is,

$$s = \frac{a}{2}t^2 \simeq 55.5\,\mathrm{m} \ .$$

2.1.4.10 Ex: Optical cooling

Atoms of a gas (rubidium-87) are irradiated by a laser beam. Each photon transfers the moment $\Delta p = h/\lambda$, where $\lambda = 780\,\mathrm{nm}$ is the wavelength of the light and $h = 6.626 \cdot 10^{-34}\,\mathrm{Js}$. The mass of a rubidium atom is $m = 87 \cdot 1.66 \cdot 10^{-27}\,\mathrm{kg}$. The scattering rate is $\Gamma = 3.8 \cdot 10^7\,\mathrm{s^{-1}}$. What is the acceleration? Compare with the Earth's gravitational acceleration.

Solution: $a = \frac{F}{m} = \frac{1}{m}\frac{d}{dt}p = \frac{1}{m}\Gamma\Delta p \simeq 220000\,\mathrm{m/s^2} \simeq 22600\ g.$

2.1.4.11 Ex: Free fall

A stone falls from a balloon vertically ascending at a speed of $v_0 = 20\,\mathrm{m/s}$.
a. Calculate the speed of the stone after 10 s.
b. Calculate the distance covered by the stone in 10 s.
c. Solve the same problem with a balloon descending at the same speed.

Solution: *Upper signs refer to the ascending balloon and lower signs for the descending.*
a. The speed after 10 s *follows from,*

$$v(t) = -gt \pm v(0)$$

with $v(10\,\mathrm{s}) = -98.1\,\mathrm{m/s} \pm 20\,\mathrm{m/s} = -78.1\,\mathrm{m/s}$, *resp.* $-118.1\,\mathrm{m/s}$.
b. The distance traveled after the position where it left the balloon is,

$$s(t) = -\frac{g}{2}t^2 \pm v(0)t \ ,$$

hence $s(10\,\mathrm{s}) = -9.81 \cdot 50\,\mathrm{m} \pm 200\,\mathrm{m} = -290.5\,\mathrm{m}$ *resp.* $-690.5\,\mathrm{m}$.

2.1.4.12 Ex: Two-dimensional movement

A hose, with the nozzle 1.5 m above ground, is pointed upwards at an angle of 30° with the floor. The water jet hits a flower bed 15 m away.
a. At what velocity does the jet come out of the hose?
b. What is its maximum height.

Solution: *The equations of motion are,*

$$x = v_0 t \cos\alpha \qquad (\textit{and} \qquad y = -\frac{g}{2}t^2 + v_0 t \sin\alpha + y_0 \ .$$

with $\alpha = 30°$, $(t_0, x_0, y_0) = (0, 0, 1.5\,\mathrm{m})$ *and* $(t_1, x_1, y_1) = (t_1, 15\,\mathrm{m}, 0)$. *Substituting* t,

$$\begin{aligned} x_1 &= v_0 t_1 \cos\alpha \\ 0 &= -\frac{g}{2}\left(\frac{x_1}{v_0\cos\alpha}\right)^2 + x_1\tan\alpha + y_0 \\ v_0 &= \frac{x_1}{\cos\alpha}\sqrt{\frac{g}{2}\frac{1}{x_1\tan\alpha + y_0}} \simeq 12\,\mathrm{m/s} \ . \end{aligned}$$

To find the maximum height, we seek the minimum speed,

$$\begin{aligned} 0 = \dot{y} &= -gt_2 + v_0\sin\alpha \\ t_2 &= \frac{v_0}{g}\sin\alpha \\ y_2 &= -\frac{g}{2}t_2^2 + v_0 t_2 \sin\alpha + y_0 = \frac{v_0^2}{2g}\sin^2\alpha + y_0 \simeq 3.3\,\mathrm{m} \ . \end{aligned}$$

2.1.4.13 Ex: Potential

The following force field is given: $\mathbf{F}(\mathbf{r}) = \begin{pmatrix} -2axyz^2 + by^2 \\ -ax^2z^2 + 2bxy \\ -2ax^2yz \end{pmatrix}$. Determine the corresponding potential $V(\mathbf{r})$. Determine the work required to bring a point mass from $\begin{pmatrix} -1 \\ -1 \\ -1 \end{pmatrix}$ to $\begin{pmatrix} 1 \\ 1 \\ 1 \end{pmatrix}$.

Solution: *The potential follows from integrating* $\mathbf{F} = -\nabla\phi$ *in the individual components,*

$$\begin{aligned} -\phi &= -ax^2yz^2 + bxy^2 + A_x(y,z) \\ &= -ax^2yz^2 + bxy^2 + A_y(x,z) \\ &= -ax^2yz^2 + A_z(x,y) \ . \end{aligned}$$

Hence, $A_x(y,z) = A_y(x,z) = A_z(x,y) - bxy^2 \equiv B$*, such that* $\phi = ax^2yz^2 - bxy^2 - B$*. The work is,*

$$\phi(\mathbf{r}_2) - \phi(\mathbf{r}_1) = \left(ax_2^2y_2z_2^2 - bx_2y_2^2 - B\right) - \left(ax_1^2y_1z_1^2 - bx_1y_1^2 - B\right) = 2a - 2b \ .$$

2.1.4.14 Ex: Shot put

A shot put is able to throw a 7.257 kg ball at an initial speed of $v_0 = 15\,\mathrm{m/s}$. What is the maximum range w he can achieve with such a throw? How much further could he throw the ball (at the same initial speed) if it were half as heavy? How much further could he throw the ball if he were on the moon? Note: The lunar attraction is $g_M = 1.62\,\mathrm{m/s^2}$.

Solution: *The ballistic parabola is described by,*

$$\mathbf{r}(t) = \begin{pmatrix} v_0 t\cos\alpha \\ v_0 t\sin\alpha - \frac{g}{2}t^2 \end{pmatrix} \equiv \begin{pmatrix} w \\ 0 \end{pmatrix} \ .$$

The throw range is maximum if $\frac{dw}{d\alpha} = \frac{2v_0^2}{g}\left(\cos^2\alpha - \sin\alpha^2\right) \equiv 0$*, hence, when* $\sin\alpha = \cos\alpha$*, or when* $\alpha = \pi/4$*. So the throw range is* $w = v_0 t_m \cos\alpha = v_0 \frac{2v_0\sin\alpha}{g}\cos\alpha = \frac{v_0^2}{g} = 22.9\,\mathrm{m}$*. The throw distance does not depend on the mass of the ball. On the moon the range would be* $w = 138.9\,\mathrm{m}$*.*

2.1.4.15 Ex: Shot put

In a shot put, a ball with the initial speed $v_0 = 10\,\mathrm{m/s}$ is thrown at a height of $h = 2\,\mathrm{m}$ above ground at an angle of 35°.

a. Calculate the throw distance of the ball.
b. At what speed and at what angle does the ball hit the ground?
c. Calculate the maximum throw height and the time when it is reached?
d. What condition must the throw angle fulfill for maximum throw range? At what angle is the maximum throw range reached in the special case $h = 0\,\mathrm{m}$?

Solution: *a. Equation of motion*

$$\begin{aligned} x &= v_0 t \cos\alpha \\ y &= v_0 t \sin\alpha - \frac{g}{2}t^2 + y_0 \equiv 0 \ . \end{aligned}$$

Boundary condition

$$\begin{aligned} 0 \equiv t_1^2 - \frac{2v_0 t_1}{g}\sin\alpha + \left(\frac{v_0}{g}\sin\alpha\right)^2 - \sqrt{\left(\frac{v_0}{g}\sin\alpha\right)^2 + \frac{2}{g}y_0}^2 \\ t_1 = \frac{v_0}{g}\sin\alpha \pm \sqrt{\left(\frac{v_0}{g}\sin\alpha\right)^2 + \frac{2}{g}y_0} = 1.45\,\mathrm{s} \\ x_1 = v_0 t_1 \cos\alpha = 11.9\,\mathrm{m} \ . \end{aligned}$$

b. Impact,

$$v(t_1) = \sqrt{\dot{x}(t_1)^2 + \dot{y}(t_1)^2} = \sqrt{v_0^2\cos^2\alpha + (v_0\sin\alpha - g t_1)^2} = 11.8\,\mathrm{m/s} \ ,$$

and

$$\alpha = \arctan\frac{\dot{y}(t_1)}{\dot{x}(t_1)} = 56^\circ \ .$$

c. Maximum height

$$\begin{aligned} 0 \equiv \dot{y} &= v_0\sin\alpha - g t_2 \\ t_2 &= \frac{v_0\sin\alpha}{g} = 0.6\,\mathrm{s} \\ y(t_2) &= v_0 t_2 \sin\alpha - \frac{g}{2}t_2^2 + y_0 = 3.7\,\mathrm{m} \ . \end{aligned}$$

d. Starting altitude $y_0 = h$, altitude of impact y. $v_\perp = v_0\sin\alpha$, $v_\parallel = v_0\cos\alpha$.

$$\begin{aligned} \textit{Total time of flight:} \quad & t = \frac{v_\perp + \sqrt{v_\perp^2 + 2g(y_0 - y)}}{g} \\ \textit{Throw range:} \quad & x = v_\parallel \cdot t. \\ \textit{Maximum:} \quad & 0 \equiv \partial_\alpha x = \frac{v_0^2}{g}\partial_\alpha\left(\cos\alpha\sin\alpha + \cos\alpha\sqrt{\sin^2\alpha + \frac{2g}{v_0^2}(y_0 - y)}\right). \end{aligned}$$

Hence,

$$\cos^2\alpha\left(1 + \frac{\sin\alpha}{\sqrt{\sin^2\alpha + \frac{2g(y_0-y)}{v_0^2}}}\right) = \sin^2\alpha\left(1 + \sqrt{\sin^2\alpha + \frac{2g(y_0-y)}{v_0^2}}\right).$$

A special case is obtained for $y_0 - y = 0$:

$$0 = \frac{4v_0^2}{g}(\cos^2\alpha - \frac{1}{2}) \Rightarrow \alpha = \pi/4 \ .$$

2.1.4.16 Ex: Rocket in the homogeneous field of gravitation

A rocket moves in the homogeneous field of gravity vertically upwards. Reactor gas is ejected at a constant rate $\gamma = \left|\frac{dm}{dt}\right| = const$ and with the velocity v_g. Describe the recoil of the rocket exerted by the ejected gas using $\mathbf{F} = \frac{dm}{dt}\mathbf{v}_g$ or exploiting the momentum conservation law for infinitesimal changes of m (occurring with the velocity v_g) and of v_{rocket}.

Solution: *The mass and speed of the rocket depend on time. At each instant, the force*

$$F = \frac{d}{dt}(mv) = \frac{dm}{dt}v_g + m\frac{dv}{dt} = -mg$$

acts on the rocket. By separating the variables

$$v_g \int \frac{dm}{m} + v = -\int g dt \ ,$$

and finally

$$v(t) - v_0 = v_g \ln\frac{m_0}{m(t)} - gt \ .$$

2.2 Kinetic and potential energy

2.2.1 Conservative potentials

Newton's axioms tell us that the reason for acceleration are forces, but they do not explain the origin of the forces. In our daily experience the forces seem to arise either from contact between bodies, i.e. collisions, or from action at a distance, as in the case of gravity or electromagnetism. In the latter case, the force exerted on a body may or may not depend on its position.

Newton realized the existence of a vertical force field called gravity, which appears to be homogeneous, that is, $F(y) = F = mgy$, where $g = 9.81\,\mathrm{m/s^2}$ is called *gravitational acceleration*.

> **Example 4 (*Ball rolling on a slope*):** Throwing a mass into a rising slope, we experimentally notice that the height over ground Δy the mass reaches when coming to rest only depends on its initial velocity but not on the path. We also notice that this height satisfies,
>
> $$\Delta y \propto v^2 \ . \tag{2.25}$$
>
> Furthermore, we measure the proportionality factor to be $1/2g$.

Hence, in the homogeneous field of gravity,

$$F\Delta y = mg\Delta y = \frac{m}{2}v^2 \ . \tag{2.26}$$

We call the quantity on the right-hand side the *kinetic energy* of the mass while moving at a velocity v at ground height. The left-hand side quantity, attributed to the mass having climbed the slope to height Δy and been stopped to zero velocity, is termed *potential energy* of gravitation. Repeating the experiment for various types of slopes with various inclinations which may even vary along the slope, we verify that the final height does not depend on the trajectory of the mass, that we may parametrize as $t \to \mathbf{s}(\mathbf{t})$. That is,

$$\int_{init}^{final} \mathbf{F} \cdot d\mathbf{s} = const = V(y_{final}) - V(y_{init}) \ , \tag{2.27}$$

or for a closed path,

$$\oint \mathbf{F} \cdot d\mathbf{s} = 0 \ . \tag{2.28}$$

Only this fact allows us to attribute the potential energy solely to the mass and not to the force field. We will see later that this is only true for particular force fields (e.g. homogeneous or radial fields) and in the absence of friction. We will call force fields having this property *conservative*. The above integral equation can be cast into a differential version,

$$\boxed{\nabla \times \mathbf{F}(\mathbf{r}) = 0 \qquad \text{such that} \qquad \mathbf{F}(\mathbf{r}) = -\nabla V(\mathbf{r})} \ , \tag{2.29}$$

provided, of course, that such a unique conservative potential exists.

2.2.2 Conservation of energy

2.2.3 Translations and rotations of point masses, Galilei boost

The *Galilei transform* to an inertial system moving with velocity $\mathbf{u}$ is defined by,

$$\begin{aligned} t &\to t' = t \\ \mathbf{x} &\to \mathbf{x}' = \mathbf{x} + \mathbf{u}t \ . \end{aligned} \tag{2.30}$$

2.2.3.1 Galilei invariance

Consider a set of interacting particles, $m\dot{v}_i = -\nabla_{\mathbf{x}_i} \sum_j V_{ij}(|\mathbf{x}_i - \mathbf{x}_j|)$. This equation has obviously a Galilei-invariant form. In contrast, the wave equation $\nabla_r^2\psi - \frac{1}{c^2}\frac{\partial^2\psi}{\partial t^2} = 0$ has not, because,

$$\left.\frac{\partial}{\partial t'}\right|_{r'=const} = \left.\frac{\partial}{\partial t}\right|_{r=const} - \mathbf{u} \cdot \nabla_r \ . \tag{2.31}$$

Do the Exc. 2.2.4.1.

2.2.4 Exercises

2.2.4.1 Ex: Galilei transform

A train runs at a constant speed v_0. Inside the train, from a height h_0 a ball of mass m is released.
a. Calculate the ball's trajectory as seen by an observer traveling on the train.
b. Calculate the ball's trajectory as seen by an observer outside the train.
c. Now, the train is uniformly decelerated from the moment on when the ball is released. Calculate the trajectory of the ball as seen by an observer i. traveling on the train and ii. outside the train.

Solution: *a. The observer on the train finds,*

$$\mathbf{r}_1(t) = (h_0 - \tfrac{g}{2}t^2)\hat{\mathbf{e}}_y \ .$$

b. The outside observer finds,

$$\mathbf{r}_2(t) = (h_0 - \tfrac{g}{2}t^2)\hat{\mathbf{e}}_y + v_0 t\hat{\mathbf{e}}_x \ .$$

c. The deceleration be $a_0 < 0$. The observer on the train finds a horizontal accelerating force,

$$\mathbf{r}_1(t) = (h_0 - \tfrac{g}{2}t^2)\hat{\mathbf{e}}_y + \tfrac{a_0}{2}t^2\hat{\mathbf{e}}_x \ .$$

d. The outside observer finds the same trajectory as before,

$$\mathbf{r}_2(t) = (h_0 - \tfrac{g}{2}t^2)\hat{\mathbf{e}}_y + v_0 t\hat{\mathbf{e}}_x \ .$$

2.2.4.2 Ex: Energy conservation in free fall

Consider the free fall of a mass m from the height h.
a. Write down the kinetic energy and the potential energy of the mass as functions of $z(t)$ respectively $\dot{z}(t)$.
b. Calculate $z(t)$ by integrating the energy conservation law for the initial conditions $\dot{z}(t=0) = 0$. To do this, derive from $\dot{z}(t)$ an equation of the form $\dot{z} = f(z)$ and integrate this equation after separating the variables.

Solution: *a. The potential energy is $E_{pot}(z,\dot{z}) = mgz$, the kinetic energy is $E_{kin}(z,\dot{z}) = \frac{1}{2}m\dot{z}^2$.*
b. The energy is conserved, $E(z,\dot{z}) = \frac{1}{2}m\dot{z}^2 + mgz = const.$ If $z(0) = 0$ and $\dot{z}(0) = 0$, we can let $E = 0$. The equation of motion is $\dot{z} = \sqrt{-2gz}$, where $z < 0$. Now,

$$\frac{dz}{\sqrt{-2gz}} = dt$$

$$\int_{z(0)}^{z(t)} \frac{dz'}{\sqrt{-2gz'}} = \int_0^t dt'$$

$$\frac{1}{\sqrt{2g}}\left[-2\sqrt{-z(t)} + 2\sqrt{-z(0)}\right] = t \ .$$

Finally, we get $z(t) = -\frac{1}{2}gt^2$.

2.2.4.3 Ex: Ski jumping with salto

Two skiers go down a slope on different routes. Calculate the final speed and the arrival time for the two trajectories sketched on the graph by solid and dashed lines.

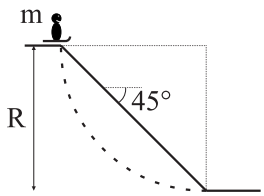

Figure 2.3: Scheme of the ramp.

Solution: *a. We parametrize the trajectory of a body descending a slope of height* h *inclined by an angle* $\theta = \pi/4$ *as,*

$$\mathbf{r}(\xi) = h\begin{pmatrix}1-\xi\\1-\xi\end{pmatrix} \qquad \textit{such that} \qquad \mathbf{v} = -h\dot{\xi}\begin{pmatrix}1\\1\end{pmatrix} \ ,$$

where $\xi \in [0,1]$ *and choosing the origin of the coordinates at the basis of the slope. Energy is conserved,* $\frac{m}{2}v_x^2 + \frac{m}{2}v_y^2 + mgy = mgh$*, with the initial energy* $E_{pot} = mgh$*. We derive,*

$$v^2 = v_x^2 + v_y^2 = 2h^2\dot{\xi}^2 = 2g(h-y) = 2gh\xi$$

That is, we know the speed at each point,

$$v = \sqrt{2gh\xi} \ .$$

The speed does not depend on the trajectory, but only on the height of the slope. But to find $\xi(t)$*, we must solve the differential equation,*

$$\dot{\xi}^2 = \frac{g}{h}\xi$$

or the integral

$$\int_0^\xi \frac{d\xi}{\sqrt{\xi}} = 2\sqrt{\xi} = \sqrt{\frac{g}{h}}t \ .$$

That is, $\xi = \frac{g}{4R}t^2$ *b. We parametrize the trajectory of a body descending a circle segment of* R *as,*

$$\mathbf{r}(\xi) = h\begin{pmatrix}\cos\xi\\1-\sin\xi\end{pmatrix} \qquad \textit{such that} \qquad \vec{v} = -h\dot{\xi}\begin{pmatrix}\sin\xi\\\cos\xi\end{pmatrix} \ ,$$

where $\xi \in [0, \pi/2]$ and choosing the origin of the coordinates at the basis of the circle segment. Energy is conserved, $\frac{m}{2}v_x^2 + \frac{m}{2}v_y^2 + mgy = mgh$, with the initial energy $E_{pot} = mgh$. We derive,

$$v^2 = v_x^2 + v_y^2 = h^2\dot{\xi}^2 = 2g(h-y) = 2gh\sin\xi \ .$$

That is, we know the speed at each point,

$$v = \sqrt{2gh\sin\xi} \ .$$

The speed does not depend on the trajectory, but only on the height of the slope. But to find $\alpha(t)$, we must solve the differential equation,

$$\dot{\xi} = \sqrt{\frac{2g}{h}\sin\xi}$$

or the elliptic integral,

$$\int_0^\xi \frac{d\xi}{\sqrt{\sin\xi}} = \sqrt{\frac{2g}{h}}t \ .$$

c. We parametrize the trajectory of a body descending a parabola defined by,

$$\mathbf{r}(\xi) = h\begin{pmatrix} 1-\xi \\ (1-\xi)^2 \end{pmatrix} \qquad \textit{such that} \qquad \vec{v} = -h\dot{\xi}\begin{pmatrix} 1 \\ 2(1-\xi) \end{pmatrix} \ ,$$

where $\xi \in [0, 1]$ and choosing the origin of the coordinates at the basis of the circle segment. Energy is conserved, $\frac{m}{2}v_x^2 + \frac{m}{2}v_y^2 + mgy = mgh$, with the initial energy $E_{pot} = mgh$. We derive,

$$v^2 = v_x^2 + v_y^2 = h^2\dot{\xi}^2[1 + 4(1-\xi)^2] = 2g(h-y) = 2gh[1-(1-\xi)^2] \ .$$

That is, we know the speed at each point,

$$v = \xi\sqrt{2gh} \ .$$

The speed does not depend on the trajectory, but only on the height of the slope. But to find $\xi(t)$, we must solve the differential equation,

$$\dot{\xi} = \sqrt{\frac{2g}{h}}\sqrt{\frac{1-(1-\xi)^2}{1+4(1-\xi)^2}}$$

or the elliptic integral,

$$\int_0^\xi \sqrt{\frac{1+4(1-\xi)^2}{1-(1-\xi)^2}}d\xi = \sqrt{\frac{2g}{h}}dt \ .$$

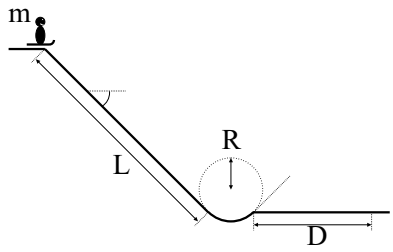

Figure 2.4: Scheme of the ramp.

2.2.4.4 Ex: Ski jumping with salto

A skier with a body weight of 75 kg descends an $L = 50\,\mathrm{m}$ high ski jump with a -100% gradient. At the lower end the ski jump merges into a trough, the curvature of which is described by a circle with radius $R = 10\,\mathrm{m}$. At an inclination of 100%, the trough suddenly merges into a horizontal plane. Friction is neglected. What is the minimum weight the skis must bear before they break? How far does the skier fly over the plane D?

Solution: *On the descent, the skier converts the potential energy* $E_{pot} = mgh = mgL\sin 45^\circ$ *into kinetic energy* $E_{kin} = E_{pot} = \frac{m}{2}\mathbf{v}^2$. *The initial speed when jumping off the trough is thus,*

$$\mathbf{v}(0) = \sqrt{\frac{E_{kin}}{m}} \begin{pmatrix} 1 \\ 1 \end{pmatrix} .$$

The ballistic parabola is given by,

$$\mathbf{x}(t) = \begin{pmatrix} v_{x0}t \\ v_{y0}t - \frac{g}{2}t^2 \end{pmatrix} \equiv \begin{pmatrix} v_{x0}t \\ 0 \end{pmatrix} .$$

Hence,

$$t = \frac{2v_{y0}}{g} ,$$

so the range of the jump is $D = \frac{2v_{x0}v_{y0}}{g} = \frac{2E_{kin}}{mg} = 2h \approx 70.7\,\mathrm{m}$. *The height difference between the position of the take-off and the lowest point of the trough is* $R - R\cos 45^\circ \approx 2.9\,\mathrm{m}$. *That is why the maximum speed of the skier is,*

$$v_m = \sqrt{\frac{2E_{kin}}{m}} = \sqrt{\frac{2mgh'}{m}} = \sqrt{2g\left(L\sin 45^\circ + R - R\cos 45^\circ\right)} .$$

Inside the circular trough at the lowest point of the ski jump the centrifugal force is,

$$F_z = m\omega^2 R = m\frac{v_m^2}{R} .$$

Together with the skier's weight, the skis have to withstand a load of up to,

$$\begin{aligned} m' &= m + \frac{F_z}{g} = m + \frac{mv_m^2}{gR} \\ &= m\left(2 + \frac{2L}{R}\sin 45^\circ - \cos 45^\circ\right) = 8.36\,\mathrm{m} \approx 630\,\mathrm{kg} \ . \end{aligned}$$

2.2.4.5 Ex: Ski jumping with salto

A skier goes down a slide. The work exerted by the gravitational field on the skier is,

$$W = \int_{s_0}^{s_1} \mathbf{F} \cdot d\vec{s} = \int_0^x F_s \sqrt{1 + y''} dx \ .$$

Now we consider three different slides:
a. The slide is described by the function $y(x) = \sqrt{h^2 - x^2}$ with $dy/dx = -x/\sqrt{h^2 - x^2} = -x/y$. We also know,

$$F_s(x) = (-mg\hat{\mathbf{e}}_y) \cdot (-\hat{\mathbf{e}}_\theta) = mg\cos\theta \ .$$

Therefore, we can simplify the integral with $x = h\cos\theta$ and $y = h\sin\theta$,

$$\begin{aligned} W &= mg\cos\theta \int_0^x \frac{xdx}{\sqrt{h^2 - x^2}} = mg\int_0^x \frac{xdx}{y} = -mg\int_h^{\sqrt{h^2-x^2}} dy \\ &= mg(h - \sqrt{h^2 - x^2}) = mg(h - y) = \frac{m}{2}v^2 \ . \end{aligned}$$

b. The slide is described by the function $y(x) = (h - x)^2$ with $dy/dx = -2(h - x)$. We also know,

$$F_s(x) = -mg\sin\theta = -mg\frac{\tan\theta}{\sqrt{1 + \tan^2\theta}} = -mg\frac{y'}{\sqrt{1 + y'^2}} \ .$$

So we can simplify the integral,

$$W = -mg\int_0^x \frac{y'}{\sqrt{1 + y'^2}}\sqrt{1 + y'^2}dx = -mg\int_0^x y'dx = -mg\int_h^y dy = mg(h - y) = \frac{m}{2}v^2 \ .$$

c. The slide is described by the function $y(x) = h - \sqrt{h^2 - (x - h)^2}$. With $dy/dx = \frac{-(x-h)}{\sqrt{h^2-(x-h)^2}}$. We also know,

$$F_s(x) = -mg\sin\theta = -mg\frac{\tan\theta}{\sqrt{1 + \tan^2\theta}} = -mg\frac{y'}{\sqrt{1 + y''}} \ .$$

So we can simplify the integral,

$$W = -mg\int_0^x \frac{y'}{\sqrt{1 + y''}}\sqrt{1 + y'^2}dx = -mg\int_0^x y'dx = -mg\int_h^y dy = mg(h - y) = \frac{m}{2}v^2 \ .$$

Solution:

2.2.4.6 Ex: Looping

A body starts at speed $v_0 = 0$ from point A and slides without friction on a slope (see figure). At point B the slope becomes a circle of radius R.
a. What is the speed at points B and C of the circle?
b. What is the maximum fraction R/h to prevent the body from falling at point B?
c. What is the minimum speed at point B to prevent the body from falling?

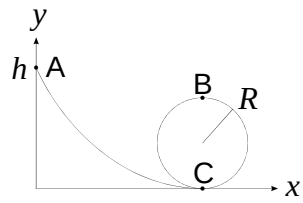

Figure 2.5: Looping.

Solution: *a. Energy conservation* $\frac{m}{2}v_C^2 = mgh$ *yields,*

$$v_C = \sqrt{2gh} \ .$$

Energy conservation $\frac{m}{2}v_B^2 + 2mgR = mgh$ *yields,*

$$v_B = \sqrt{2gh - 4gR} \ .$$

b. The centrifugal force must be greater than the gravitation force, that is, $m\frac{v_B^2}{R} > mg$. *Substitution of* v_B *leads to,*

$$\frac{R}{h} > \frac{2}{5} \ .$$

c. Energy conservation $\frac{m}{2}v_B^2 + 2mgR = \frac{m}{2}v_C^2$ *yields, after resolution by* v_B *and substitution in the condition* $m\frac{v_B^2}{R} > mg$,

$$v_C > \sqrt{5gR} \ .$$

2.2.4.7 Ex: Forces

A body of mass m moves under the influence of three forces:

$$\begin{aligned}
\mathbf{F}_1(\mathbf{r}) &= (\alpha \cos \omega(x+y), -\beta(y+y_0)^2, \gamma(z+z_0)^2) \\
\mathbf{F}_2(\mathbf{r}) &= (\alpha \sin \omega x \sin \omega y, \beta(y-y_0)^2, -\gamma(z-z_0)^2) \\
\mathbf{F}_3(\mathbf{r}) &= (\alpha \cos(\omega x + \pi) \cos \omega y, 3\beta y y_0, \gamma z_0(z_0 - 4z)) \ .
\end{aligned}$$

The body is at $t = 0$ at the point $\mathbf{r}(0)$ with velocity $\mathbf{v}(0)$. What is the absolute value of the body's velocity $|\mathbf{v}(t)|$ after a time t when it is at the point $\mathbf{r}(t)$?

Solution: *The force*

$$\mathbf{F} = \begin{pmatrix} \alpha\cos\omega(x+y) \\ -\beta(y+y_0)^2 \\ \gamma(z+z_0)^2 \end{pmatrix} + \begin{pmatrix} \alpha\sin\omega x\sin\omega y \\ \beta(y-y_0)^2 \\ -\gamma(z-z_0)^2 \end{pmatrix} + \begin{pmatrix} \alpha\cos(\omega x+\pi)\cos\omega y \\ 3\beta y y_0 \\ \gamma z_0(z_0-4z) \end{pmatrix}$$

can be simplified to,

$$\begin{pmatrix} m\ddot{x} \\ m\ddot{y} \\ m\ddot{z} \end{pmatrix} = \begin{pmatrix} 0 \\ -\beta y y_0 \\ \gamma z_0^2 \end{pmatrix} .$$

Then the velocities in x and z-direction are, respectively, $\dot{x} = v_{x0}$ and $\dot{z} = \frac{\gamma z_0^2}{m}t + v_{z0}$. For the y-direction we get a vibration,

$$y = \frac{v_{y0}}{\omega}\sin\omega t + y_0\cos\omega t \quad \textit{with} \quad \omega = \sqrt{\frac{\beta y_0}{m}} ,$$

satisfying the boundary conditions $y(0) = y_0$ and $\dot{y}(0) = v_{y0}$. Finally, the absolute value of the speed is,

$$|\mathbf{v}| = \sqrt{v_x^2 + v_y^2 + v_z^2} = \sqrt{v_{x0}^2 + (v_{y0}\cos\omega t - y_0\omega\sin\omega t)^2 + \left(\frac{\gamma z_0^2}{m}t + v_{z0}\right)^2} .$$

2.2.4.8 Ex: Pushed inclined plane

A 45° wedge is pushed over a table with constant acceleration a. A cuboid of mass m slides on the wedge without friction. At the time $t = 0$ the cuboid is at a height h and, like the cuboid, at rest.
a. Give the acceleration $\mathbf{a}(t)$ and speed $\mathbf{v}(t)$ as a function of time.
b. Give kinetic and potential energy of the cuboid as a function of time. Does energy conservation hold?

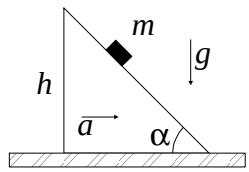

Figure 2.6: Pushed inclined plane.

Solution: *a. The weight $\mathbf{F}_g = -mg\hat{\mathbf{e}}_y$ and the force due to the acceleration of the wedge $\mathbf{F}_a = ma\hat{\mathbf{e}}_x$ act on the cuboid. Let $\hat{\mathbf{e}}_f = \hat{\mathbf{e}}_x\cos\alpha - \hat{\mathbf{e}}_y\sin\alpha$ be the unit vector of the surface of the wedge and $\hat{\mathbf{e}}_n = \hat{\mathbf{e}}_x = \sin\alpha + \hat{\mathbf{e}}_y\cos\alpha$ the normal of the surface. As*

long as the cuboid adheres to the surface of the wedge, we only need to consider the projection of gravity on the surface and the projection of the acceleration of the wedge on the normal,

$$\begin{aligned} m\frac{d^2}{dt^2}\mathbf{r} &= (\mathbf{F}_g \cdot \hat{\mathbf{e}}_f)\hat{\mathbf{e}}_f + (\mathbf{F}_a \cdot \hat{\mathbf{e}}_n)\hat{\mathbf{e}}_n \\ &= [-mg\hat{\mathbf{e}}_y \cdot (\hat{\mathbf{e}}_x \cos\alpha - \hat{\mathbf{e}}_y \sin\alpha)]\,(\hat{\mathbf{e}}_x \cos\alpha - \hat{\mathbf{e}}_y \sin\alpha) + [ma\hat{\mathbf{e}}_x \cdot (\hat{\mathbf{e}}_x \cos\alpha + \hat{\mathbf{e}}_y \sin\alpha)]\,(\hat{\mathbf{e}}_x \cos \\ &= m\begin{pmatrix} g\sin\alpha\cos\alpha + a\cos\alpha\cos\alpha \\ -g\sin\alpha\sin\alpha + a\cos\alpha\sin\alpha \end{pmatrix} \overset{\alpha=45^\circ}{\longrightarrow} \frac{m}{2}\begin{pmatrix} g+a \\ -g+a \end{pmatrix} \\ m\frac{d}{dt}\mathbf{r} &= \frac{m}{2}\begin{pmatrix} g+a \\ -g+a \end{pmatrix} t \\ m\mathbf{r} &= \frac{m}{4}\begin{pmatrix} g+a \\ -g+a \end{pmatrix} t^2 + \begin{pmatrix} 0 \\ h \end{pmatrix} \ . \end{aligned}$$

b. The energy,

$$\begin{aligned} E = T + V &= \frac{m}{2}v^2 + mgy(t) = \frac{m}{2}(\dot{x}(t)^2 + \dot{y}(t)^2) + mg\dot{y}(t) \\ &= \frac{m}{2}\frac{1}{2}(a^2+g^2) + mg\frac{1}{2}\frac{1}{2}(a-g)t^2 + mgh = \frac{m}{4}(a^2+ag)t^2 + mgh \end{aligned}$$

is not conserved,

$$\frac{dE}{dt} = \frac{m}{2}(a^2+ag)t \neq 0$$

for $a \neq 0$.

2.2.4.9 Ex: Bungee jump

An organizer is offering bungee jumps from a bridge of height H. First of all, a student (body length h, mass m) wants to jump upside down from a standing position. The rope (spring constant C) is tied to him exactly in the middle of the body. Help the operator with his calculations.
a. By what length a_0 is the rope stretched when the student is hanging on the rope at rest?
b. How long is the rope to be dimensioned so that the student can just touch the surface of the water flowing under the bridge with his head? Take into account (a) calculated pre-stretch of the rope. (Numerical values: $H = 100\,\mathrm{m}$, $h = 1.90\,\mathrm{m}$, $m = 50\,\mathrm{kg}$, $C = 50\,\mathrm{N/m}$)

Solution: *Let l_0 be the length of the unstretched rope and S the total stretch.*
a. The rope elongation at rest results from $|\mathbf{F}| = Cx$ that is $mg = Ca_0$ yielding,

$$a_0 = \frac{mg}{C} = 9.81\,\mathrm{m} \ .$$

b. The following applies to the lengths $H - \frac{h}{2} = l_0 + a_0 + x$. We seek for $l_0 = H - \frac{h}{2} - (a_0 + x) = H - \frac{h}{2} - s$. s results from the equilibrium between potential energy

and elongation energy of the elastic rope $mgH = \frac{1}{2}Cs^2$. *Hence,*

$$s = \sqrt{\frac{2mgH}{C}} = 44.29\,\mathrm{m} \ .$$

Therefore $l_0 = 54.76\,\mathrm{m}$ *and* $x = s - a_0 = 34.48\,\mathrm{m}$.

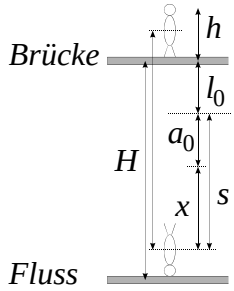

Figure 2.7: Scheme of the arrangement.

2.2.4.10 Ex: Body sliding from a cylinder with friction

A body bound to move with friction on a cylinder of radius R is released at an angle θ_0 with zero velocity.
a. What is the maximum coefficient of static friction μ_e allowed for the body to slide?
b. Once the body starts to slide, the friction is dominated by the dynamic friction coefficient μ_d. What is the work done until the body reaches the horizontal position ($\theta = 0°$)?
c. What is the final velocity?

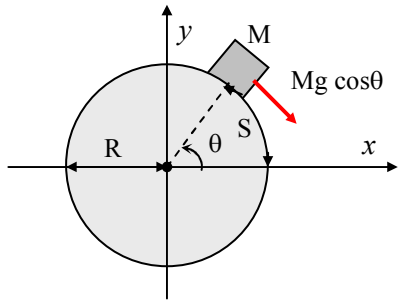

Figure 2.8: Body sliding from a cylinder with friction.

Solution: *a. The tension due to the pressure of the body on the cylinder depends on its position,*

$$\mathbf{N} = mg\sin\theta \ .$$

So the friction force is,

$$\mathbf{F}_{at} = -\mu_e \mathbf{N} = -\mu_e mg \sin\theta \ .$$

To allow the body to slide, we need at least,

$$0 < F_{gr} + F_{at} = mg\cos\theta_0 - \mu_e mg \sin\theta_0 \ .$$

That is, $\mu_e < \cot\theta_0$.
b. In the case of sliding, the work performed is,

$$W = \int_{s_0}^{s_1} (\mathbf{F}_{gr} + F_{at}) d\vec{s} = -\int_{\theta_0}^{0} (mg\cos\theta \mathbf{F}_{gr} - \mu_d mg \sin\theta) R d\theta \ .$$

with $ds = -Rd\theta$. *Hence,*

$$W = -Rmg(-\sin\theta_0 + \mu_d - \mu_d \cos\theta_0) = \frac{m}{2} v^2 \ .$$

c. And from this we get the velocity,

$$v = \sqrt{2Rg(\sin\theta_0 - \mu_d + \mu_d \cos\theta_0)} \ .$$

2.2.4.11 Ex: Bodies sliding down a slope

Two children are descending with an interval of 2 s a 4 m high frictionless slide ending in a horizontal plane. What is the final distance between them?

Solution: *The final velocity of children is,*

$$v = \sqrt{2gh} \ .$$

Therefore, the distance is $d = vt = t\sqrt{2gh} = 17.7\,\mathrm{m}$.

2.2.4.12 Ex: Energy conservation in the harmonic oscillator

Consider a mass of $m = 0.1\,\mathrm{kg}$ that vibrates on a spring with the spring constant $C = 10\,\mathrm{N/m}$. The maximum deflection A around the rest position of the spring is 10 cm.
a. At what frequency does the mass vibrate?
b. Give the potential and the kinetic energy of the mass as a function of the displacement $x(t)$ resp. $\dot{x}(t)$.
c. Derive the equation of motion for the deflection from the energy theorem. The initial condition is chosen so that at time $t = 0$ the mass is at the zero crossing ($x(0) = 0$) and has maximum speed. First help: Integrate using the *variable separation* method. Second help: $\int \frac{dx}{\sqrt{a^2 - x^2}} = \arcsin\frac{x}{a}$.

Solution: *a. The force equation is* $m\ddot{x} = -Cx$. *Hence, the mass vibrates with the frequency* $\omega/2\pi = \frac{1}{2\pi}\sqrt{C/m} \approx 0.16\ s^{-1}$.
b. The potential energy is $E_{pot}(x) = \frac{C}{2}x^2$, *the kinetic energy is* $E_{kin}(\dot{x}) = \frac{1}{2}m\dot{x}^2$.
c. The energy remains constant, $E = \frac{1}{2}m\dot{x}^2 + \frac{C}{2}x^2 = \frac{C}{2}A^2$. *Hence,*

$$\frac{dx}{\sqrt{C/m}\sqrt{A^2 - x^2}} = dt$$
$$\int_{x(0)}^{x(t)} \frac{dx'}{\sqrt{C/m}\sqrt{A^2 - x'^2}} = \int_0^t dt'$$
$$\frac{1}{\sqrt{C/m}} \arcsin \frac{x'}{A}\bigg|_0^{x(t)} = t\ .$$

Finally we get $x = A \sin \sqrt{C/m}t$.

2.2.4.13 Ex: Anharmonic potential

A mass m moves in a potential $V(x)$, which has a minimum at $V(0) = 0$ for $x = 0$ and a first maximum at x_M. At time $t = 0$ the mass is at point $x = 0$. The initial speed is chosen so that, when it reaches the maximum of the potential at x_M its velocity is zero. Calculate for the two cases $V(x) = \alpha x^2 - \beta x^4$ and $V(x) = \lambda(1 - \cos^2 \kappa x)$:
a. the coordinates of the maximum x_M and $V(x_M)$;
b. with the help of the energy conservation law the total energy E;
c. the implicit equation of motion $t = g(x)$ or, if possible, the explicit one $x = f(t)$;
How long does the mass take to reach the point x_M. Justify the result by physical arguments.

Solution: *a. For the first potential there are extrema when* $\frac{d}{dx}V(x) = 2\alpha x - 4\beta x^3 = 0$, *that is,* $x = 0$ *as well as* $x = \pm\sqrt{\frac{\alpha}{2\beta}}$. *Because of* $\frac{d^2}{dx^2}V(x) = 2\alpha - 12\beta x^2$ *there is a minimum at* $x = 0$ *if* $\alpha > 0$. *There are maxima at* $x = \pm\sqrt{\frac{\alpha}{2\beta}}$ *if* $\alpha > 0$. *For the second potential* $\frac{d}{dx}V(x) = 2\lambda \cos \kappa x \sin \kappa x = 0$, *that is, there is a minimum at* $x = 0$. *There are maxima at* $x = \pm\frac{\pi}{2\kappa}$.
b. The energy is for both potentials,

$$E = \frac{m}{2}v^2 + \alpha x^2 - \beta x^4 = \alpha\frac{\alpha}{2\beta} - \beta\frac{\alpha^2}{4\beta^2} = \frac{\alpha^2}{4\beta}$$
$$E = \frac{m}{2}v^2 + \lambda(1 - \cos^2 \kappa x) = \lambda(1 - \cos^2 \kappa x_M) = \lambda\ .$$

c. The equation of motion results from the energy theorem. For the first potential,

$$\begin{aligned}
\dot{x} &= \sqrt{\frac{2\alpha^2}{4m\beta} - \frac{2\alpha}{m}x^2 + \frac{2\beta}{m}x^4} \\
dt &= \sqrt{\frac{4m\beta}{2}}\frac{dx}{\sqrt{\alpha^2 - 4\alpha\beta x^2 + 4\beta^2 x^4}} = \frac{\sqrt{2m\beta}dx}{\alpha - 2\beta x^2} \\
t &= \sqrt{2m\beta}\int \frac{dx}{\alpha - 2\beta x^2} = \frac{1}{\sqrt{2\alpha\beta}}\,arctanh\; x\sqrt{\frac{2\beta}{\alpha}} \\
x &= \sqrt{\frac{\alpha}{2\beta}}\tanh t\sqrt{2\alpha\beta}\ .
\end{aligned}$$

Hence, $t = \frac{1}{\sqrt{2\alpha\beta}}\,arctanh\; x\sqrt{\frac{2\beta}{\alpha}} \overset{x\to x_M}{\longrightarrow} \infty$. *For the second potential,*

$$\begin{aligned}
\dot{x} &= \sqrt{\frac{2\lambda}{m}}\cos\kappa x \\
dt &= \sqrt{\frac{m}{2\lambda}}\frac{dx}{\cos\kappa x} \\
t &= \sqrt{\frac{m}{2\lambda}}\int \frac{dx}{\cos\kappa x} = \sqrt{\frac{m}{2\lambda}}\frac{\ln(1+\sin\kappa x) - \ln(\cos\kappa x)}{\kappa} \\
e^{\sqrt{\frac{2\lambda}{m}}\kappa t} &= \frac{1+\sin\kappa x}{\cos\kappa x} \\
x &= \frac{1}{\kappa}\,\mathrm{arcsin}\tanh\sqrt{\frac{2\lambda\kappa^2}{m}}t\ .
\end{aligned}$$

Hence, $t = \sqrt{\frac{m}{2\lambda}}\frac{\ln 2 - \ln 0}{\kappa} \overset{x\to x_M}{\longrightarrow} \infty$. *In both cases, the mass takes an infinitely long time to reach the maximum. This is because the maximum is an unstable point. If the mass sits up there and* $v = 0$*, it is not accelerated.*

2.2.4.14 Ex: Anharmonic potential

A particle with the mass $m = 1.4 \times 10^{-25}\,\mathrm{kg}$ moves along the positive x-axis. A constant force directed towards the origin of the coordinate system of $B = 10^{-23}\,\mathrm{N}$ and a repulsive force of A/x^2 act on the particle, whereby $A = 10^{-35}\,\mathrm{Nm}^2$.
a. Calculate the potential energy function $V(x)$.
b. Sketch the energy as a function of the location x when the maximum kinetic energy is $T_0 = 10^{-28}\,\mathrm{J}$.
c. Determine the equilibrium position x_0 (force $F(x_0) = 0$) and the turning points (velocity $\dot{x} = 0$).
d. How large is the frequency of small vibrations around x_0?

Solution: *The force is,*

$$F = \frac{A}{x^2} - B\ .$$

The equilibrium position is at $F(x_0) = 0$, *also* $x_0 = \sqrt{A/B} \approx 1\,\mu\text{m}$. *The potential is,*

$$V = \frac{A}{x} + Bx \ .$$

The Taylor expansion around the equilibrium position is,

$$\begin{aligned} V &= V(x_0) + V'(x_0)(x - x_0) + V''(x_0)\frac{(x - x_0)^2}{2!} + ... \\ &\simeq \frac{A}{x_0} + Bx_0 + \left(-\frac{A}{x_0^2} + B\right)(x - x_0) + \frac{A}{x_0^3}(x - x_0)^2 \\ &= const + \frac{A}{x_0^3}\tilde{x}^2 \ . \end{aligned}$$

The frequency of small vibrations is therefore,

$$\omega = \sqrt{\frac{2}{m}\frac{A}{x_0^3}} \approx 2\pi \times 2\,\text{kHz} \ .$$

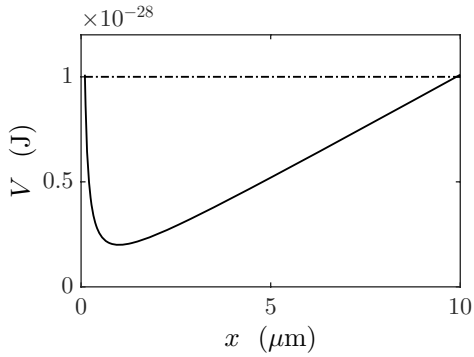

Figure 2.9: Anharmonic potential.

2.2.4.15 Ex: Free flight with friction

A body of mass m starts to fall at time $t = 0$ and point $z = 0$ with the initial velocity $\mathbf{v} = v_0\hat{\mathbf{e}}_z$ in the homogeneous terrestrial field of gravity (the z-axis is directed downwards). Its movement in the atmosphere is subject to Newton's friction force, $\mathbf{F}_R = -\alpha v\mathbf{v}$. We are considering only the movement along the z-axis.
a. What is the equation of motion for the body?
b. How should v_0 be chosen to obtain a movement with constant speed? v
c. Now, let the initial velocity v_0 be zero. Calculate the relationship between the falling distance z and the maximum reached velocity. **Help:** Use the method of separating the variables and, for that, write the equation of motion in the form $dz = f(v)dv$. Use the following result: $\int \frac{x}{a^2 - x^2}dx = -0.5\ln(a^2 - x^2)$.)

d. After which falling distance does the body reach 50 % of the maximum speed?

Solution: *a. The equation of motion is* $m\ddot{z} + \alpha v^2 = mg$.
b. For acceleration to end, we need $\ddot{z} = 0$. *From this follows* $v_0 = \sqrt{\frac{mg}{\alpha}}$.
c. The equation of motion can be written in the form,

$$dt = \frac{mdv}{mg - \alpha v^2}$$

The differential dt *can be replaced by* $v = \frac{dz}{dt}$, *giving,*

$$dz = \frac{mvdv}{mg - \alpha v^2} \ .$$

Hence,

$$z = \frac{m}{\alpha}\int_0^v \frac{vdv}{mg/\alpha - v^2} = -\frac{m}{2\alpha}\ln\left(\frac{mg}{\alpha} - v^2\right)\Big|_0^v = -\frac{m}{2\alpha}\ln\left(1 - \frac{\alpha}{mg}v^2\right) \ .$$

We can also integrate the differential, dt,

$$t = \frac{m}{\alpha}\int_0^v \frac{dv}{mg/\alpha - v^2} = \frac{m}{2\alpha}\ln\pm\frac{mg/\alpha + v}{mg/\alpha - v}\Big|_0^v = \frac{m}{2\alpha}\ln\frac{mg/\alpha + v}{mg/\alpha - v} \ .$$

d. The maximum speed is reached for $z \to \infty$. *The logarithm*

$$z = \infty = -\frac{m}{2\alpha}\ln\left(1 - \frac{\alpha}{mg}v_m^2\right) \ .$$

diverges, when $v_m = \sqrt{\frac{mg}{\alpha}}$. *The body reaches 50 % of its maximum speed at the position,*

$$z = -\frac{m}{2\alpha}\ln\left(1 - \frac{\alpha}{mg}\left(\frac{v_m}{2}\right)^2\right) = -\frac{m}{2\alpha}\ln\left(1 - \frac{1}{4}\right) = \frac{m}{2\alpha}0.2877 \ .$$

2.2.4.16 Ex: Free flight with friction numerically

Here, we want to solve Exc. 2.2.4.15 numerically. A body of mass $m = 1\,\text{kg}$ begins to fall at time $t = 0$ at point $z = 0$ with the initial velocity $\mathbf{v} = v_0\hat{\mathbf{e}}_z$ in the homogeneous gravitational field of the Earth (the z-axis is directed downwards). When moving in the atmosphere, it is subject to Newton's friction force $\mathbf{F}_R = -\alpha v\mathbf{v}$ with $\alpha = 0.01\,\text{kg/m}$. We are considering only the movement along the z-axis.
a. What is the equation of motion for the body?
b. Calculate the trajectory of the body by numerically integrating the equation of motion with the Euler method. Use different starting velocities v_0. Choose v_0 such that, at the beginning, the movement has constant v?

Solution: *a. The equation of motion is* $m\ddot{z} + \alpha v^2 = mg$. *It can be rewritten into the following system of equations:*

$$\dot{v} = -\frac{\alpha}{m}v^2 + g$$
$$\dot{z} = v \ .$$

b. Speed and location are after a small time interval dt,

$$v(t+dt) = v(t) + dt \ \left(g - \frac{\alpha}{m}v(t)^2\right)$$
$$z(t+dt) = z(t) + dt \ v \ .$$

One can now discretize by $t_k \equiv t + kdt$, $z_k \equiv z(t+t_k)$ *and* $v_k \equiv v(t_k)$ *and solve the system of equations iteratively.*

$$v_{k+1} = v_k + dt \ \left(g - \frac{\alpha}{m}v_k^2\right)$$
$$z_{k+1} = z_k + dt \ v_k \ .$$

The movement is constant from the beginning if $v_0 = \sqrt{mg/\alpha} \approx 31.3209$.

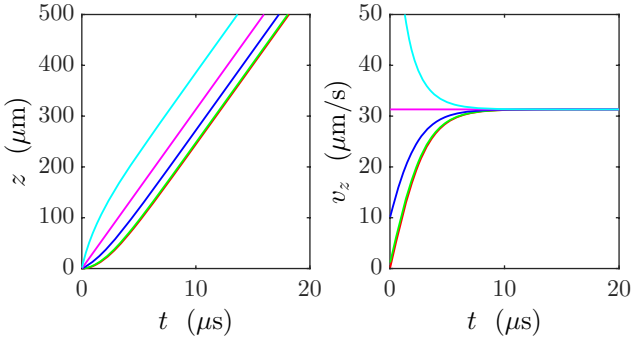

Figure 2.10: Trajectory and speed for a free fall with friction for different initial velocities $v_0 = 0, 1, 10, 31.3209, 100$. Here $dt = 0.02\,\mathrm{s}$.

2.2.4.17 Ex: Parachutist with resistance (Möllemanns Rechenaufgabe)

A skydiver exits his plane in 2000 m. Unfortunately, he forgot to put on his parachute. Suppose that air resistance can be described by Stokes friction with the friction coefficient $k = 0.05\,\mathrm{s}^{-1}$.
a. Calculate the parachutist's maximum speed.
b. What would be the total time T of the skydiver's flight if the friction was negligible?
c. What is the distance between the skydiver and the ground at time T in case the friction is not negligible.

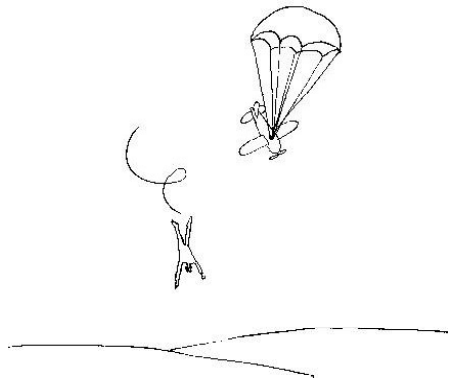

Figure 2.11: Parachutist with resistance.

Solution: *Gravity acts along* $\hat{\mathbf{e}}_z$*. The equation of motion is now,*

$$m\ddot{z} + mk\dot{z} - mg = 0 \ .$$

After separating the variables,

$$dt = \frac{dv}{g - kv} \ .$$

The solution is,

$$t = \int_0^t t dt = \int_0^v \frac{dv}{g - kv} = -\frac{1}{k}\left[\ln(g - kv)\right]_0^v = -\frac{1}{k}\ln\left(\frac{g - kv}{g}\right)$$
$$v = \frac{g}{k}(1 - e^{-kt}) \ .$$

The maximum speed is $v_\infty = \frac{g}{k} \approx \frac{9.81\,\mathrm{m/s^2}}{0.05\,\mathrm{Ns/m}} = 196\,\mathrm{m/s}$*. The flight time without friction follows from* $h = \frac{g}{2}t^2$ *para* $t = \sqrt{\frac{2h}{g}} = 20.2\,\mathrm{s}$*. The falling distance with friction is,*

$$z(T) = \int_0^T v dt = \frac{g}{k}\int_0^T (1 - e^{-kT}) dt = \frac{g}{k}\left[T + \frac{1}{k}e^{-kT}\right]_0^T = \frac{g}{k}\left[T - \frac{1}{k}(1 - e^{-kT})\right] \ .$$

Hence, the rest of the way is $h - z(T) \approx 533\,\mathrm{m}$*. An estimate with Taylor expansion gives,*

$$h - z(T) = \frac{g}{2}t^2 - \frac{g}{k}\left[t - \frac{1}{k}\left(1 - 1 + kt - \frac{1}{2}k^2t^2 + \frac{1}{6}k^3t^3\right)\right] \simeq \frac{g}{6}kt^3 \approx 674\,\mathrm{m/s} \ .$$

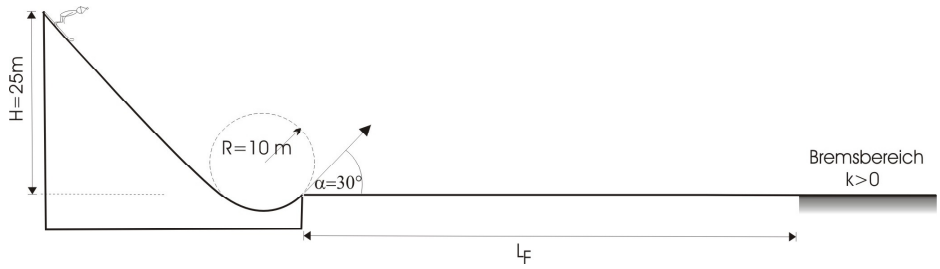

Figure 2.12: Oblique throw with friction.

2.2.4.18 Ex: Oblique throw with friction

You built a ski jumping tower, and now you have to create the associated slope. It consists of an inclined plane and a circular arc with radius $R = 10\,\mathrm{m}$ connected to it. The point of take-off is at ground level, and the tangent to the arc and the surface of the ground enclose an angle of $\alpha = 30°$. The ski ramp is frictionless and there is no friction by air resistance during the flight. Now, the braking area behind the desired flight path L_F, that causes a friction force $F_R = -k \cdot v$, needs to be engineered. The jumper has a mass of $m = 80\,\mathrm{kg}$.
a. At what distance L_F must the braking area begin so that the jumper arrives directly at the braking area for a height of the tower of $H = 25\,\mathrm{m}$?
b. What acceleration does the ski jumper experience in the lowest point of the tower (inside the circular path) in addition to the normal gravitational acceleration?
c. As soon as he arrives at the braking area, the frictional force acts and slows down the jumper. How large must the friction coefficient be chosen so that the ski jumper comes to a standstill in less than 6 s? A residual speed of less than 1 cm/s is defined as a standstill. To do this, set up the differential equation and solve it.

Solution: *a. Starting speed at the time of take-off:* $E_{kin} = E_{pot}$:

$$\frac{1}{2}mv^2 = mgH \Rightarrow v = \sqrt{2gH}$$
$$v_x = v\cos\alpha = \sqrt{2gH}\cos\alpha$$
$$v_x = v\cos\alpha = \sqrt{2gH}\sin\alpha \ .$$

Flight time t_F *until touch-down:*

$$0 = v_y t_F - \frac{1}{2}gt_F^2 \Rightarrow t_F = \frac{2v_y}{g} = \frac{2\sqrt{2gH}\sin\alpha}{g} \ .$$

Flight distance,

$$L_F = v_x \cdot t_F = \sqrt{2gH}\cos\alpha \cdot \frac{2\sqrt{2gH}\sin\alpha}{g} = 4H\sin\alpha\cdot\cos\alpha \simeq 43.3\,\mathrm{m} \ .$$

b. The lowest point is lower than 0 m*:*

$$H' = H + h' \qquad with \qquad h' = R\cdot(1-\cos(30°)) \simeq 1.34\,\mathrm{m} \Rightarrow v = \sqrt{2gH'} \simeq 25.6\,\mathrm{m/s} \ .$$

The centrifugal force at this speed is:

$$m \cdot a = \frac{mv^2}{R} \Rightarrow a = \frac{2gH'}{R} = 2g(H/R + \cos\alpha) \simeq 66\,\mathrm{m/s^2} \simeq 6.7g \ .$$

c. Only $v_x(t=0) \simeq 22.15\,\mathrm{m/s}$ *need to be decelerated.*

$$\dot{v}_x = -\frac{F_R}{m} = -\frac{k}{m}v_x \Leftrightarrow \frac{dv_x}{dt} = -\frac{k}{m}v_x$$

such that,

$$\frac{dv_x}{v_x} = -\frac{k}{m}dt \Rightarrow \int_{v_{x0}}^{v_x} \frac{dv'_x}{v'_x} = -\frac{k}{m}\int_0^t dt' \Rightarrow k = \frac{m}{t}\ln\left(\frac{v_{x0}}{v_x}\right) \ .$$

With $t = 6\,\mathrm{s}$, $v_x = 0.01\,\mathrm{m/s}$ *and* $v_{x0} = v_x(t=0) = 22.15\,\mathrm{m/s}$ *we obtain* $k = 102.7\,\mathrm{kg/s^2}$.

2.2.4.19 Ex: Oblique throw with friction

A soccer ball with a mass of 1 kg is shot at an initial speed v_0. In addition to the force of gravity, the Stokes force acts on the ball $\mathbf{F}_R = -km\mathbf{v}$.
a. Set up the equations of motion.
b. Solve the equations of motion for $x(t)$ and $y(t)$.
c. Show by a Taylor expansion of the solutions $x(t)$ and $y(t)$ that for $\beta \to 0$ follows the solution of the frictionless oblique throw.
d. Give an equation for the flight time T_{max} and determine the range x_{max}.
Note: Note that the general solution of the inhomogeneous differential equation consists of the general solution of the homogeneous and a particular solution of the inhomogeneous differential equation. Determine the constants from the boundary conditions.

Solution: *a. The equation of motion is* $m\ddot{\mathbf{r}} + \beta\dot{\mathbf{r}} - m\mathbf{g} = 0$. *In component notation,*

$$m\ddot{x} + \beta\dot{x} = 0 \qquad \textit{and} \qquad m\ddot{y} + \beta\dot{y} + mg = 0 \ .$$

b. The equation for vertical movement can be solved by separating the variables,

$$dt = \frac{d\dot{y}}{-\beta\dot{y}/m - g}$$

$$t = \frac{m}{-\beta}\int_{\dot{y}_0}^{\dot{y}} \frac{d\dot{y}}{\dot{y} + mg/\beta} = -\frac{m}{\beta}\ln\left(\dot{y} + mg/\beta\right) + \frac{m}{\beta}\ln\left(\dot{y}_0 + mg/\beta\right) = -\frac{m}{\beta}\ln\frac{\dot{y} + mg/\beta}{\dot{y}_0 + mg/\beta}$$

$$\dot{y} = \left(\dot{y}_0 + mg/\beta\right)e^{-\beta t/m} - mg/\beta$$

$$y = \left(\dot{y}_0 + mg/\beta\right)\int_0^t e^{-\beta t/m}dt - \int_0^t mg/\beta dt = \left(\dot{y}_0 + \frac{mg}{\beta}\right)\frac{m}{\beta}\left(1 - e^{-\beta t/m}\right) - \frac{mgt}{\beta} \ .$$

The solution for horizontal movement is analog for $g = 0$,

$$x = \frac{m\dot{x}_0}{\beta}(1 - e^{-\beta t/m}) \ .$$

c. Taylor expansion of $y(t)$ yields,

$$y = \left(\dot{y}_0 + \frac{mg}{\beta}\right)\frac{m}{\beta}\left(1 - 1 + \frac{\beta}{m}t - \frac{\beta^2}{2m^2}t^2 + \frac{\beta^3}{6m^3}t^3 - ...\right) - \frac{mgt}{\beta} \overset{\beta\to 0}{\longrightarrow} \dot{y}_0 t - \frac{g}{2}t^2 \ ,$$

and analogously for x.
d. The flight time follows from,

$$y = 0 = \left(\dot{y}_0 + \frac{mg}{\beta}\right)\frac{m}{\beta}\left(1 - e^{-\beta t_m/m}\right) - \frac{mgt_m}{\beta} \ .$$

The equation cannot be explicitly resolved by t. We can solve it numerically or graphically, or we can develop the exponential function into a Taylor series,

$$\left(\dot{y}_0 + \frac{mg}{\beta}\right)\frac{m}{\beta}\left(1 - \left[1 - \frac{\beta t}{m} + \frac{1}{2}\left(\frac{\beta t_m}{m}\right)^2 - ...\right]\right) = \frac{mgt_m}{\beta}$$

$$t_m \simeq \frac{2}{1 + gm/\beta\dot{y}_0} \ .$$

The reach is then $x_m = x(t_m)$.

2.2.4.20 Ex: Oscillations and static friction

A wooden block vibrates smoothly on a horizontal spring with an oscillation period of $T = 1.2\,\mathrm{s}$. A second block of wood lies on top of the first, the coefficient of static friction between the two blocks being $\mu_H = 0.25$. The static friction is caused by the

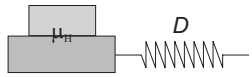

Figure 2.13: Oscillations and static friction.

surface roughness of the two blocks and depends on the mass m of the upper block like $F_H = \mu_H mg$.
a. Will the wooden block slip, if the amplitude of the vibration is 1 cm?
b. Determine the largest allowable vibration amplitude for the wooden block not to slip.

Solution: *The following applies to the period and angular frequency of the harmonic oscillation $T = 2\pi\sqrt{m/D}$ and $\omega_0 = \sqrt{D/m}$,*

$$x(t) = x_0\cos\omega_0 t \quad , \quad \dot{x}(t) = -x_0\omega_0\sin\omega_0 t \quad , \quad \ddot{x}(t) = -x_0\omega_0^2\cos\omega 0t \ .$$

Hence,

$$\ddot{x}_{max} = -x_0\frac{D}{m} = x_0(2\pi/T)^2 \ .$$

a. With $x_0 = 1\,\mathrm{cm}$ we find $\ddot{x}_{max} = 0.274\,\mathrm{m/s^2}$. The static friction is $F_H = \mu_H mg$. In the event of slipping, must apply,

$$F = m\ddot{x} > F_H \qquad \Rightarrow \qquad \ddot{x} > 0.25\cdot g \simeq 2.45\,\mathrm{m/s^2} \equiv a_{crit} \ .$$

Hence, the block does not slip.
b. $x_{max} = a_{crit}(T/(2\pi))^2 = 8.95\,\mathrm{cm}$. *For* $x > 8.95\,\mathrm{cm}$ *the block will slip.*

2.2.4.21 Ex: Stokes' friction

In viscous media (fluids, gases) a velocity-dependent force F_R acts opposite to the movement of a body. For laminar flows, $F_R = Cv$ with a constant C, which in the case of a sphere of radius r has the value $C = 6\pi\eta r$, where η is the viscosity of the medium.
a. Emperor Charlemagne (year 742-814) is upset, because the Saxon Duke Widukind does let himself be subdued. Out of frustration, he threw his golden sphere, symbol of his kingdom (radius $r = 8\,\mathrm{cm}$, density $\rho = 3.19\,\mathrm{g/cm^3}$) into the Rhine. Establish the equation of motion for the sphere in the water and solve it with the initial values $x(t = 0) = 0\,\mathrm{m}$, $v(t = 0) = 0\,\mathrm{m/s}$. How fast does the golden sphere descend to the bottom? Despise buoyancy. The viscosity of water is $\eta_{H_2O} = 1.7 \cdot 10^{-3}\,\mathrm{Ns/m^2}$.
b. If Charlemagne had launched the sphere from the Lorelei rock (height 125 m above the Rhine), how big would the difference in velocity be due to Stokes friction at the moment of impact on the Rhine's surface compared to the frictionless case? Solve the equation of motion of the sphere with the viscosity of the air $\eta_{\mathrm{ar}} = 1.7 \cdot 10^{-5}\,\mathrm{Ns/m^2}$.

Solution: *a. The equation of motion is,*

$$ma = -C_{ag}v - mg \ .$$

Separating the variables,

$$dt = -\frac{mdv}{C_{ag}v + mg} \ .$$

Integrating,

$$t = -\frac{m}{C_{ag}} \ln \frac{C_{ag}v + mg}{C_{ag}v_0 + mg} \ ,$$

or

$$v = \frac{mg}{C_{ag}} e^{-C_{ag}t/m} - \frac{mg}{C_{ag}} \ .$$

With the initial speed $v_0 = 0$ *and the mass* $m = \frac{4\pi}{3} r^3 \rho \simeq 6.8\,\mathrm{kg}$ *we get the maximum speed* $v_{max} = -mg/C_{ag} \simeq 26\,\mathrm{kg/s}$.
b. Without friction the speed of the sphere after a drop of 125 m *would be,*

$$v = \sqrt{2gh} \simeq 50\,\mathrm{m/s} \ .$$

With friction we need to calculate the fall time,

$$0 = \frac{mg}{C_{ar}} \int_0^{t_q} (e^{-C_{ar}t_q/m} - 1)dt = -\frac{m^2 g}{C_{ar}^2} \left(e^{-C_{ar}t_q/m} - \frac{C_{ar}t_q}{m} \right) \ .$$

giving $t_q \simeq ....$ *Now, we can calculate the final speed by,*

$$v = \frac{mg}{C_{ar}} e^{-C_{ar}t_q/m} - \frac{mg}{C_{ar}} \simeq ... \ .$$

2.2.4.22 Ex: Newton's friction

A sports car feels air resistance of the form $F_R = -b \cdot v^2$ as well as a rolling frictional force independent on the velocity F_{rol}. Derive an equation for the power needed to maintain a high velocity v. Assume realistic values for the constants and the sports car's power, and calculate the maximum possible resulting speed. Justify your choice of values!

Solution: *The car's engine must exert an accelerating force F_{mot} to keep the car moving,*

$$ma = F_{mot} - bv^2 - F_{rol} = 0 \ .$$

Let's assume that the car has the power $P = 100\,\mathrm{kW}$. We get,

$$P = F_{mot}v = (bv^2 + F_{rol})v \ .$$

We also assume that air resistance limits the speed to $v_{max} = 300\,\mathrm{km/h}$ disregarding rolling friction. Hence,

$$P \simeq bv_{max}^3 \ ,$$

giving $b \simeq 0.17\,\mathrm{kg\ s/m}$. On the other hand, we can assume that the rolling friction also limits the speed to $v_{max} = 300\,\mathrm{km/h}$ neglecting air resistance. So,

$$P \simeq F_{rol}v_{max} \ ,$$

giving $F_{rol} \simeq 1200\,\mathrm{N}$. We must now solve the second cubic equation.

2.2.4.23 Ex: Mass sliding with friction

What is the energy expenditure for a body of mass m sliding over and decelerated by a horizontal plane with the dynamic friction coefficient μ_d.

Solution: *The friction force is,*

$$F_{at} = -\mu_d N = -\mu_d mg \ .$$

The work is,

$$W = \int_{s_i}^{s_f} F_{at}ds = E_{kin,f} - E_{kin,i}$$
$$-\mu_d mg\Delta s = \frac{m}{2}v^2 - \frac{m}{2}v_0^2 \ .$$

2.2.4.24 Ex: One-dimensional movement

The driver of a train moving with speed v_1, sees, at a distance d ahead of him, a freight train moving in the same direction with speed v_2. He applies the brakes, transmitting the acceleration $-a$ to the train. Show that if: $d > (v_1 - v_2)^2/2a$, there will be no

collision and if $d < (v_1 - v_2)^2/2a$ there will be a collision.

Solution: *The trajectories of the two trains are described by,*

$$x_1 = v_1 t \qquad \text{and} \qquad x_2 = d + v_2 t - \tfrac{a}{2} t^2 \ .$$

The condition for collision, $x_1 = x_2$, requires,

$$\tfrac{a}{2} t^2 + (v_1 - v_2)t - d = 0 \ .$$

That is, the collision occurs at time,

$$t = -\frac{(v_1 - v_2)}{a} \pm \sqrt{\frac{(v_1 - v_2)^2}{a^2} - \frac{2d}{a}} \ .$$

There will be no collision when the root becomes imaginary, that is when $d > (v_1 - v_2)^2/2a$.

2.2.4.25 Ex: One-dimensional movement

Drops of water fall from a shower onto the floor 2 m below. The drops fall at regular intervals and when the first one hits the ground, the fourth is starting to fall. Determine the position of all the drops at the instant when one of them hits the floor.

Solution: *The time for a drop to fall to the ground is given by,*

$$h = \frac{g}{2} \Delta t_4^2 \ .$$

For 4 drops, time is divided by 3. So,

$$y_1 = h - \frac{g}{2}\left(\frac{3\Delta t_4}{3}\right)^2 = h - \frac{9h}{9} = 0\,\text{m} \quad , \quad y_2 = h - \frac{g}{2}\left(\frac{2\Delta t_4}{3}\right)^2 = h - \frac{4h}{9} = \tfrac{10}{9}\,\text{m} \ ,$$

$$y_3 = h - \frac{g}{2}\left(\frac{1\Delta t_4}{3}\right)^2 = h - \frac{h}{9} = \tfrac{16}{9}\,\text{m} \quad , \quad y_4 = h - \frac{g}{2}\left(\frac{0\Delta t_4}{3}\right)^2 = h = 2\,\text{m} \ .$$

2.2.4.26 Ex: One-dimensional movement

The position of a particle that moves along the x-axis depends on time according to the equation: $x = at^2 - bt^3$, x in cm, t in s.
a. At what point is x maximum?
b. What is the speed and at what moment is it zero?
c. What is the acceleration and at what time is it zero?

Solution: *See [1435].*

2.2.4.27 Ex: One-dimensional movement

A plane with speed v_0 lands on an aircraft carrier with negative acceleration $a = -A\sqrt{t}$. What is the minimum required length of the runway?

Solution: *The plane's speed at the end of the runway is given by,*

$$v = v_0 + \int_0^{t_f} a\ dt = v_0 - A\int_0^{t_f} t^{1/2}\ dt = v_0 - A\frac{2}{3}t_f^{3/2} = 0\ .$$

The position is, inserting $t_f = \left(\frac{3v_0}{2A}\right)^{2/3}$,

$$x = \int_0^{t_f} v\ dt = \int_0^{t_f}\left(v_0 - A\frac{2}{3}t^{3/2}\right)\ dt = v_0 t_f - A\frac{2}{3}\frac{2}{5}t_f^{5/2} = \frac{3v_0}{5}\left(\frac{3v_0}{2A}\right)^{2/3}\ .$$

2.2.4.28 Ex: One-dimensional movement

Two bodies are located at the origin of the x-axis when $t = 0\,\mathrm{s}$. Body A has a constant speed of $2\,\mathrm{m/s}$. Body B is initially at rest but subject to a constant acceleration of $1\,\mathrm{m/s^2}$.
a. Represent schematically, in the same graph, the positions of bodies A and B as a function of time.
b. What is the time of collision?
c. What is the position x when the collision will occur?
d. What is the speed of body B at the time of collision?
e. At what time will the velocities of the two bodies be equal?

Solution: *a. The trajectories of the bodies are given by,*

$$x_a = v_a t$$
$$x_b = \frac{a}{2}t^2\ .$$

b. They meet when $x_a = x_b$*, that is, at time* $t_e = \frac{2v_a}{a} = 4\,\mathrm{s}$.
c. The position of the bodies at this time is $x_a(t_e) = v_a t_e = 8\,\mathrm{m}$.
d. The speed of body B is $v_b = at_e = 4\,\mathrm{m/s}$.
e. From the condition $v_a = v_b = at_v$ *we obtain* $t_v = \frac{v_a}{a} = 2\,\mathrm{s}$.

2.2.4.29 Ex: Cylinder rolling without sliding

Consider a cylinder of radius R rolling without sliding on a horizontal plane. The center of mass of the cylinder is accelerated.
a. What is the angular acceleration of the cylinder?
b. What is the rotation angle β of the cylinder as a function of time?

Solution:

2.2.4.30 Ex: Relative velocity of rotating bodies

Two bodies A and B are in uniform circular movements of concentric trajectories with radii r_a and r_b and angular velocities ω_a and ω_b. Determine the relative speed between the two bodies.

Solution:

2.2.4.31 Ex: Acceleration of a sliding body

Determine the acceleration of a body that slides along the thread of a screw with step h and radius R. Disregard friction and consider the body to have started from rest.

Solution:

2.2.4.32 Ex: Ballistics

To launch a ball from ground over a wall of height H located at a distance S (see figure), what is the lowest initial speed with which the ball has to be launched?

Solution:

2.2.4.33 Ex: Ballistics

A bullet is fired from a cannon with speed v_0. Determine the geometric region where the bullet will certainly not hit the ground.

Solution:

2.2.4.34 Ex: Ballistics

An inclined plane forms an angle α with the xy-plane, as shown in the figure. A body is launched with speed v_0, forming an angle with the y-axis. Disregarding friction calculate: x_{max}, z_{max} and the time it takes for the projectile to return to the y-axis.

Solution:

2.2.4.35 Ex: Ballistics

A stone is launched at an initial speed of 20 m/s. Knowing that it stayed for 2 s in the air, calculate:
a. the launch angle (with respect to the horizontal), b. the maximum height reached,
c. the reach,
d. another launch angle for which the stone will have the same range. (In this case

the time will be different from 2 s).

Solution:

2.2.4.36 Ex: Translation with / without friction

A body is moved with speed $v = 5\,\mathrm{m/s}$ over a horizontal plane without friction. Suddenly he encounters another plane (also without friction) inclined by an angle $\theta = 30°$ and having a height of $H = 0.8\,\mathrm{m}$, as shown in the figure.
a. At what distance d from the end of the inclined plane will the body fall?
b. What is the maximum height that the body will reach

Solution:

2.2.4.37 Ex: Collision

A small body is launched from the origin with speed $v_0 = 100/\sqrt{3}\,\mathrm{m/s}$ under an angle $\theta = 60°$ with the horizontal. Another body is launched 1 second later, at the same speed v_0, but horizontally and from a height H, as shown in the figure. Suppose there is a collision between the two bodies and that $g = 10\,\mathrm{m/s^2}$. a. At what time does the collision occur?
b. How high should H be for the collision to occur?
c. What are the x and y coordinates of the collision?

Solution:

2.2.4.38 Ex: Ballistics

A small body is launched from the origin with speed v_0 under an angle θ with the horizontal. Another body is launched with the same speed v_0, but horizontally and from a height H, as shown in the figure. What should be the value of H such that they reach the same point on the x-axis?

Solution:

2.2.4.39 Ex: Ballistics

a. Show that the movement of a projectile launched with v_0 and θ is described by the parabola: $y(x) = \frac{v_{0y}^2}{2g} - \frac{g}{2}\left(\frac{x}{v_{0x}} - \frac{v_{0y}}{g}\right)^2$, with $v_{0x} = v_0\cos\theta$ and $v_{0y} = v_0\sin\theta$.
b. Find the angle α that the trajectory forms with the horizontal for any x ($\tan\alpha = dy/dx$),
c. Find x_{max} corresponding to the top of the trajectory ($\tan\alpha = 0$).
d. Find the reach R by letting $\alpha = \pi - \theta$.

Solution:

2.2.4.40 Ex: Coupled masses

a. Find the angle θ for the left figure so that the system remains at rest. Disregard friction.
b. Find the ratio between the masses M_1 and M_2 such that the system remains at rest in the right figure. Disregard friction.

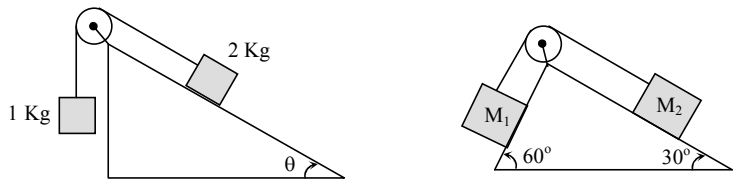

Figure 2.14: Coupled masses.

Solution: *a. Equilibrium,*

$$a_1 = -m_1 g \equiv a_2 = -m_2 g \sin\theta \ .$$

Hence,

$$\theta = \arcsin \frac{m_1}{m_2} = \arcsin \frac{1}{2} = 30^\circ \ .$$

b. Equilibrium

$$a_1 = -m_1 g \sin\theta_1 \equiv a_2 = -m_2 g \sin\theta_2 \ .$$

Hence,

$$\frac{m_2}{m_1} = \frac{\sin\theta_1}{\sin\theta_2} = \frac{1}{\sqrt{3}} \ .$$

2.2.4.41 Ex: Coupled masses

a. Find the acceleration of the 2 kg body shown in the left figure.
b. Find the mass of body A such that the acceleration of body B in the right figure is zero.

Solution: *a. We know that the acceleration of the pulley, $a_{12} = -a_5$, is given by,*

$$a_5 = -g\frac{m_5 - (m_1 + m_2)}{m_5 + (m_1 + m_2)} = -\frac{g}{4} \ .$$

Also,

$$a_2 = (-g + a_5)\frac{m_2 - m_1}{m_1 + m_2} - a_5 = -\frac{g}{6} \ .$$

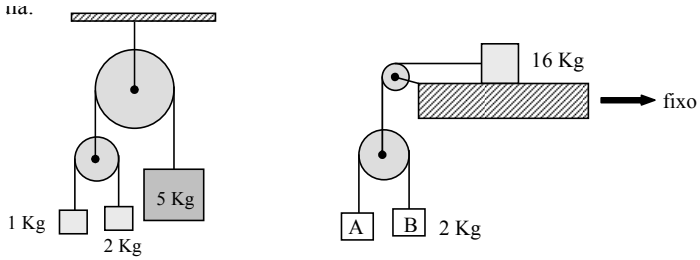

Figure 2.15: Coupled masses.

This does not agree with the template [1435]: $a_2 = \frac{2}{15}g$.
b. We know that the acceleration of the pulley, $a_{AB} = -a_{16}$*, is given by,*

$$(m_A + m_B + m_{16})a_{16} = (m_A + m_B)g \ .$$

Hence,

$$a_{16} = \frac{m_A + m_B}{m_A + m_B + m_{16}}g \ .$$

Also,

$$0 = a_B = (-g + a_{16})\frac{m_B - m_A}{m_B + m_A} - a_{16}$$

or equivalently,

$$-2a_{16} = a_A = (-g + a_{16})\frac{m_A - m_B}{m_B + m_A} - a_{16} \ .$$

Inserting in the equation for a_B *the expression for* a_{16}*, we get*

$$0 = -g\frac{-m_{16}m_A + m_{16}m_B + m_A^2 + 2m_Am_B + m_B^2}{(m_A + m_B + m_{16})(m_A + m_B)}$$

which is only satisfied when the numerator is zero:

$$m_A = \frac{m_{16}}{2} - m_B \pm \sqrt{m_{16}\left(\frac{m_{16}}{4} - 2m_B\right)} = 6\,\text{kg} \ .$$

This does not agree with the template [1435]: $m_A = 4kg$.

2.2.4.42 Ex: Frictionless pulley

A string of length L and linear mass density λ passes through a pulley without friction. It is released from rest, with a length x pending on one side and $L - x$ on the other.
a. determine the acceleration as a function of x;
b. for which situation is the acceleration zero?

Solution: *a. We have,*

$$a = \frac{\int_0^x \lambda ds - \int_0^{L-x} \lambda ds}{\int_0^L \lambda ds}g = \left(\frac{2x}{L} - 1\right)g \ .$$

b. $x = \frac{L}{2}$.

2.2.4.43 Ex: Coupled bodies

In the system shown in the figure, find:
a. the acceleration of the total system and
b. the force on the rope at point A.

Solution:

2.2.4.44 Ex: Coupled bodies

N bodies connected to each other by massless strings are pulled on a ramp by means of a force F. Calculate the tension in the rope connected to the i-th body.

Solution:

2.2.4.45 Ex: Coupled bodies

Consider the conical pendulum shown in the figure, where the string connecting the mass M to point O has no mass.
a. find the angle θ as a function of the velocity of mass M,
b. find the tension in the string at point O.

Solution:

2.2.4.46 Ex: Coupled bodies without friction

A body of mass M is hung by an ideal string over a triangular block of angle θ, as shown in the figure. In the absence of friction between the blocks, we ask what is the maximum acceleration that can be given to the system such that the body M remains in contact with the triangular block. In this case, what is the tension in the rope? If the system is moving at a constant speed, what is the value of the tension in the rope and of the normal?

Solution:

2.3 Friction

Stokes friction $F_{frc} \propto -v$ and *Newton friction* $F_{frc} \propto -v^2$.

2.3.0.1 Ex: Coupled masses with friction

In the system exhibited in the figure body A slides on a surface with a friction coefficient μ. The ropes and pulleys have no mass.
a. find the accelerations of blocks A and B;
b. find the tension in the rope connected to body A.

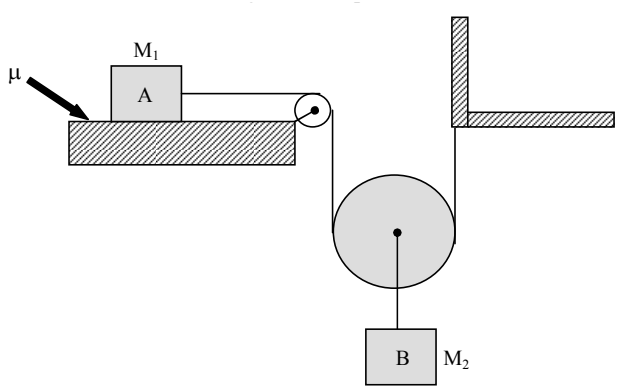

Figure 2.16: Coupled masses with friction.

Solution: *a. We use the energy conservation law:*

$$\frac{M_1}{2}v_1^2 + \frac{M_2}{2}v_2^2 + M_2 g x_2 = -\mu M_1 g x_1 \ ,$$

with the derivative,

$$\frac{M_1}{2}2v_1\dot{v}_1 + \frac{M_2}{2}2v_2\dot{v}_2 + M_2 g\dot{x}_2 = -\mu M_1 g\dot{x}_1 \ .$$

The geometry of the problem shows, that $x_1 = -2x_2$. Therefore,

$$\frac{M_1}{2}2v_1\dot{v}_1 + \frac{M_2}{4}v_1\dot{v}_1 - \frac{M_2}{2}g\dot{x}_1 = -\mu M_1 g\dot{x}_1$$
$$M_1 a_1 + \frac{M_2}{4}a_1 - \frac{M_2}{2}g = -\mu M_1 g \ .$$

Hence,

$$a_1 = 2a_2 = 2g\frac{M_2 - 2\mu M_1}{M_2 + 4M_1} \ .$$

b. The stresses are,

$$T_2 = \frac{1}{2}M_2(g - a_2) = \frac{1}{2}M_2\left(g - g\frac{M_2 - 2\mu M_1}{M_2 + 4M_1}\right) = gM_1M_2\frac{2+\mu}{M_2 + 4M_1}$$
$$T_1 = T_3 = \tfrac{1}{2}T_2 \ .$$

where T_3 is the tension in the rope between the pulleys.
Alternatively, we can establish the equations of motion,

$$\begin{aligned} M_1 a_1 &= -F_{at} + T_1 \\ M_2 a_2 &= M_2 g - T_2 \\ F_{at} &= \mu M g \\ a_1 &= 2a + 2 \ , \end{aligned}$$

This system of equations can be solved by giving the same results.

2.3.0.2 Ex: Inclined plane with and without friction

a. Given the angle θ of an inclined plane without friction, what is the acceleration a_R such that the block of mass m shown in the figure does not slide?
b. If the inclined plane had a friction coefficient μ, what would be the maximum and minimum accelerations such that the block does not slide?

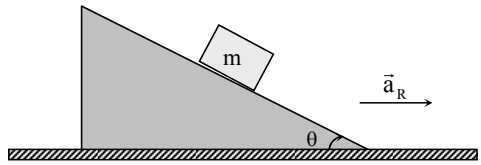

Figure 2.17: Inclined plane.

Solution: *a. Without friction, the projections of the forces on the inclined axis must cancel:*

$$a_R \cos\theta = g \sin\theta \ .$$

In this case, $N = mg\cos\theta$.
b. Along the inclined axis the balance of forces demands,

$$mg\sin\theta - ma_R\cos\theta \mp \mu_e N = 0 \ ,$$

where the upper sign indicates an upward frictional force (case of sliding downward) and the lower sign indicates a downward frictional force (case of sliding upward). In the normal direction to the inclined axis we have,

$$-mg\cos\theta + ma_R\sin\theta + N = 0 \ .$$

Hence,

$$mg\sin\theta - ma_R\cos\theta \mp \mu_e mg\cos\theta \pm \mu_e ma_R\sin\theta = 0 \ ,$$

which gives,

$$a_R = g\frac{\sin\theta \mp \mu_e\cos\theta}{\cos\theta \mp \mu_e\sin\theta} \ .$$

2.3.0.3 Ex: Static friction

a. The system shown in the figure is friction-free. Determine the value of the force F such that body A does not descend or rise.
b. If there were a static friction μ between the surfaces of the blocks, what would be the maximum and minimum values of forces such that body A does not fall or rise?

Solution:

2.3.0.4 Ex: Viscous medium

A body with initial velocity v_0 penetrates a medium that produces a viscous force given by (a) $F = -b\sqrt{v}$ and (b) $F = -cv^2$. Determine the maximum distance that the body penetrates into this medium for both cases.

Solution: *a. The equation of motion,*

$$ma = m\frac{dv}{dt} = -b\sqrt{v} \ ,$$

can be written,

$$v^{-1/2}dv = -\frac{b}{m}dt \ .$$

Integration,

$$\int_{v_0}^{v} v^{-1/2}dv = -\frac{b}{m}\int_0^t dt \ ,$$

gives the velocity,

$$v = \left(v_0^{1/2} - \frac{b}{2m}t\right)^2 \ .$$

The body stops, whenv $= 0$*, isto é* $t_0 = \frac{2m}{b}v_0^{1/2}$*. At this moment, the path taken is,*

$$s_0 = \int_0^{t_0} vdt = v_0 t_0 - v_0^{1/2}\frac{b}{2m}t_0^2 + \frac{b^2}{12m^2}t_0^3 = \frac{2}{3}v_0^{\frac{3}{2}}\frac{m}{b} \ .$$

b. The equation of motion,

$$ma = m\frac{dv}{dt} = -bv^2$$

can be written,

$$v^{-2}dv = -\frac{b}{m}dt \ .$$

Integration,

$$\int_{v_0}^{v} v^{-2}dv = -\frac{b}{m}\int_0^t dt$$

gives the velocity,

$$v = \frac{1}{v_0^{-1} + \frac{b}{m}t} \ .$$

Using the substitution,

$$u = v_0^{-1} + \frac{b}{m}t \qquad with \qquad \frac{du}{dt} = \frac{b}{m} \ .$$

The path taken is,

$$s = \int_0^t \frac{1}{v_0^{-1} + \frac{b}{m}t} dt = \frac{m}{b} \int_{v_0^{-1}}^{v_0^{-1} + \frac{b}{m}t} \frac{du}{u} = \frac{m}{b} \ln\left(1 + v_0 \frac{b}{m}t\right) \ .$$

That is, the body penetrates the medium without limitation.

2.3.0.5 Ex: Inclined plane with friction

The system shown in the figure employs pulleys without mass. Find the acceleration of each block and the tension in the string.

Solution:

2.3.0.6 Ex: Coupled bodies subject to friction

In the system shown in the figure, the block is in contact with the horizontal surface without friction and subject to a force F. There is a static friction μ between this block and block A in such a way that there is no relative movement between the three blocks forming the system. Calculate: (a) The angle, (b) The tension in the string, and (c) the minimum μ.

Solution:

2.3.0.7 Ex: Body subject to friction

A block of mass M rests on a table with a static friction coefficient μ_e. A force F is applied to the block so as to form an angle θ with the horizontal, as shown in the figure. Assuming that the block is always on the verge of sliding,
a. what is the angle θ that allows the applied force to be minimal, and
b. in this case, what will be the value of the force F_{min}?

Solution:

2.3.0.8 Ex: Coupled bodies with friction

A block of mass M_1 is on top of another block of mass M_2, which slides over the floor, as shown in the figure. The static friction between the two blocks is μ_e and the kinetic friction between block 2 and the ground is μ_c. a. Determine the maximum force F that can be applied to block 2 without block 1 sliding over it.

b. If the force is increased such that M_1 starts to slide, and the kinetic friction between the blocks is also μ_c, what will be the acceleration of each mass?

Solution:

2.3.0.9 Ex: Coupled bodies with friction

A block of mass M is located on top of another block of the same mass, on a flat plane inclined by an angle θ, as shown in the figure. The static friction between the two blocks is μ, and between the lower block and the plane it is zero.
a. Determine the maximum force F that can be applied to the upper block without sliding over the lower block.
b. In this case, what will be the acceleration of the total system?

Solution:

2.3.0.10 Ex: Inclined plane with friction

A body of mass m is located on a triangular block of angle θ and mass M, as shown in the figure. There is no friction between the triangular block and the ground, and static friction coefficient between the two blocks is μ.
a. What is the maximum horizontal force F that can be applied to the block m such that it does not slide over the wedge?
b. What is the value of normal in this situation?

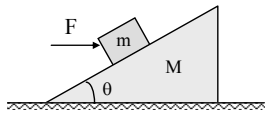

Figure 2.18: Inclined plane.

Solution: *a. We have the following equations. The acceleration of the system is* $(M+m)a = F$*, the friction in the static limit is* $F_{at} = \mu_e N$*, and the mass weight* m *produces a normal tension* N *and a friction force* F_{at}*, such that,*

$$N\cos\theta - F_{at}\sin\theta - mg = 0 \ .$$

The tangential force is

$$F_t = F\cos\theta - mg\sin\theta - F_{at} \ ,$$

and the normal force is,

$$F_n = -F\sin\theta - mg\cos\theta + N \ .$$

Thus, the horizontal acceleration of the mass m *is,*

$$ma = F_t\cos\theta - F_n\sin\theta = (F\cos\theta - mg\sin\theta - F_a)\cos\theta - (-F\sin\theta - mg\cos\theta + N)\sin\theta \ ,$$

which gives,

$$F = \frac{M+m}{M}(\mu_e + \tan\theta)N\cos\theta \ .$$

Solving the equation of balance between weight and friction for N and inserting into the equation above, we finally find,

$$F = mg\frac{M+m}{M}\frac{\tan\theta + \mu_e}{1-\mu_e\tan\theta} \ .$$

b. Solving the first equation for N, we obtain,

$$N = \frac{mg}{\cos\theta - \mu_e\sin\theta} \ .$$

2.3.0.11 Ex: Potential energy

A body is accelerated uniformly from rest until it reaches the speed v_f in time t_f. Show that the instantaneous power delivered to the body is:

$$P(t) = mv_f^2\frac{t}{t_f^2} \ .$$

Solution: *The final speed is,*

$$v_f = at_f \ .$$

With that, we can calculate the instantaneous power:

$$\dot{W} = \frac{d}{dt}\int_0^s Fds = F\frac{d}{dt}s = F\frac{d}{dt}\frac{a}{2}t^2 = Fat = \frac{mv_f^2}{t_f^2}t \ .$$

2.3.0.12 Ex: Body subject to friction

Consider the system sketched in the figure, where the force F is constant and the planes have a dynamic friction coefficient μ. Calculate the total work performed by the forces acting on the system when it moves an infinitesimal distance Δx.

Solution:

2.3.0.13 Ex: Lennard-Jones potential

Consider the Lennard-Jones potential commonly used as the interaction energy between two atoms forming a molecule:

$$U(r) = C\left[\left(\frac{r_0}{r}\right)^{12} - 2\left(\frac{r_0}{r}\right)^{6}\right] \ .$$

a. Draw $U(r)$ as a function of r.
b. Show that the minimum energy (equilibrium position) is at r_0.
c. Find the force between atoms as a function of r.
d. What is the energy required to separate the atoms that form the molecule?

Solution: *b. The derivative of the potential must zero:*

$$0 = \frac{dU(r)}{dr} = C\frac{d}{dr}\left[\left(\frac{r_0}{r}\right)^{12} - 2\left(\frac{r_0}{r}\right)^{6}\right] = C\left[\frac{-12}{r}\left(\frac{r_0}{r}\right)^{12} - 2\frac{-6}{r}\left(\frac{r_0}{r}\right)^{6}\right] .$$

c. The force is,

$$F = -\frac{dU(r)}{dr} = 12C\left[\frac{-1}{r}\left(\frac{r_0}{r}\right)^{12} + \frac{1}{r}\left(\frac{r_0}{r}\right)^{6}\right] .$$

d. The energy is,

$$E_{ion} = \int_{r_0}^{\infty} F dr = U(r_0) - U_\infty = C .$$

2.3.0.14 Ex: Pendulum

A pendulum of mass m and length l is released from the point $\theta = 60°$ from rest, as shown in the figure. Upon reaching the vertical position $\theta = 0°$, the pendulum string encounters a nail fixed at a distance d from the ceiling. Find the minimum distance d for the mass m to rotate around the nail.

Solution:

2.3.0.15 Ex: Body in a circular truss

A body of mass m moves within a vertical circular rail of radius R (see figure). When m is at the lowest position its speed is v_0.
a. What is the minimum value of v_0 such that the body goes through the entire track?
b. If v_0 were 78% of the value determined in (a), the body would go up the rail up the point P, where it will lose contact with the rail. Find the coordinate θ of this point.

Solution:

2.3.0.16 Ex: Body in a potential

A body of mass M, subject to a potential $U(x) = -\cos \pi x$, is released at the origin ($x = 0$) with speed v_0.
a. Sketch the potential in the region $-1 \leq x \leq 1$.
b. Find the force $F(x)$ acting on the body.
c. What is the maximum speed v_0 that can be imparted to the body in such a way

that it is confined to the region $-1 \leq x \leq 1$?

Solution:

2.3.0.17 Ex: Roller coaster with looping

A mass m slides without friction along the roller coaster shown in the figure. The circular part has radius R and the mass departs from rest at point B, at the height h measured with respect to relation to the base of the tracks.
a. What is the kinetic energy of m at the point P?
b. What is the acceleration of m at point P assuming that the mass remains on the track?
c. What is the lowest value of h for m to perform the circular motion?
d. For a value of h greater than this minimum, write down the expression for the normal force exerted by the track on the mass.

Solution:

2.3.0.18 Ex: Body on an inclined plane

A 2 kg body is released on an inclined plane from a point where it elongates by 4 m a spring having the constant spring constant of $k = 100\,\mathrm{N/m}$. The spring is fixed parallel to the plane, inclined by $\theta = 30°$ (see figure).
a. Calculate the maximum compression of the spring assuming that its mass be negligible;
b. Calculate the maximum compression of the spring when the inclined plane exerts friction, the friction coefficient between it and the body being equal to 0.2);
c. In the case (b), what is the height that the body reaches on its way back upward?

Solution:

2.3.0.19 Ex: Bodies climbing a slope

Two bodies propagating at the same speed v on a horizontal plane have a distance of d. After having climbed a high slope h, what will be the distance between them?

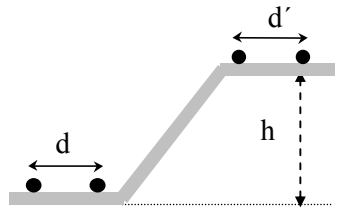

Figure 2.19: Bodies climbing a slope.

Solution: *The velocity of the bodies in the upper plane, v_s, is given by,*

$$\frac{m}{2}v^2 - \frac{m}{2}v_s^2 = mgh \ .$$

As the trajectories of the bodies are the same, we have,

$$d_s = \frac{v_s}{v}d = d\sqrt{1 - \frac{2gh}{v^2}} \ .$$

2.3.1 Exercises

2.4 Many-body systems

2.4.1 Balance of forces

2.4.2 Center-of-mass

2.4.3 Collisions and conservation of linear momentum

2.4.3.1 Binary elastic collisions and molecule formation

Binary collisions between atoms are always *elastic*. To see this, we set up the conservation laws for energy and momentum allowing for an inelastic lost of kinetic energy ΔE:

$$\boxed{\frac{p_{i1}^2}{2m} + \frac{p_{i2}^2}{2m} = \frac{p_{f1}^2}{2m} + \frac{p_{f2}^2}{2m} + \Delta E \quad \text{and} \quad \mathbf{p}_{i1} + \mathbf{p}_{i2} = \mathbf{p}_{f1} + \mathbf{p}_{f2}} \ . \tag{2.32}$$

Without loss of generality we may transform in to the center-of-mass system, where $\mathbf{p}'_{i1} + \mathbf{p}'_{i2} = 0 = \mathbf{p}'_{f1} + \mathbf{p}'_{f2}$. Inserting this into the law of energy conservation,

$$m\Delta E = p'^2_{i1} - p'^2_{f1} \ . \tag{2.33}$$

So, obviously, if no energy can be dissipated, e.g. into internal atomic excitations, the kinetic energy must remain unchanged.

Without loss of generality we may transform into the inertial system, where $\mathbf{p}''_{i2} = 0$. Inserting this into the conservation laws,

$$\frac{p''^2_{i1}}{2m} = \frac{p''^2_{f1}}{2m} + \frac{p''^2_{f2}}{2m} + \Delta E \quad \text{and} \quad \mathbf{p}''_{i1} = \mathbf{p}''_{f1} + \mathbf{p}''_{f2} \ . \tag{2.34}$$

Now substituting $\mathbf{p}_{i1}$ in the energy conservation law,

$$m\Delta E = \mathbf{p}''_{f1} \cdot \mathbf{p}''_{f2} \ . \tag{2.35}$$

So, if no energy can be dissipated, the atoms move in orthogonal directions after the collision.

Can two colliding atoms form a molecule? The laws of energy and momentum conservation require,

$$\frac{\mathbf{p}_1^2}{2m} + \frac{\mathbf{p}_2^2}{2m} = \frac{\mathbf{p}_{12}^2}{m} + \Delta E \qquad \text{and} \qquad \mathbf{p}_1 + \mathbf{p}_2 = \mathbf{p}_{12} \ . \tag{2.36}$$

In the center-of-mass inertial system, we have,

$$2\frac{\mathbf{p}_1''}{2m} = \Delta E \qquad \text{and} \qquad \mathbf{p}_1' + \mathbf{p}_2' = 0 = \mathbf{p}_{12}' \ . \tag{2.37}$$

That is, a molecule can only be formed if the collision is inelastic ($\Delta E \neq 0$), which is only possible if there is an excited internal state having exactly the energy ΔE.

2.4.4 Exercises

2.4.4.1 Ex: Mass hanging at a gallow

The mass M is hanging from a string attached to a vertical mast and attached to a boom, so that the angle becomes $\alpha = 90°$, as indicated in the figure. With $h = 1\,\mathrm{m}$, $l = 1\,\mathrm{m}$ and $m = 1\,\mathrm{kg}$, calculate the tension in the wire.

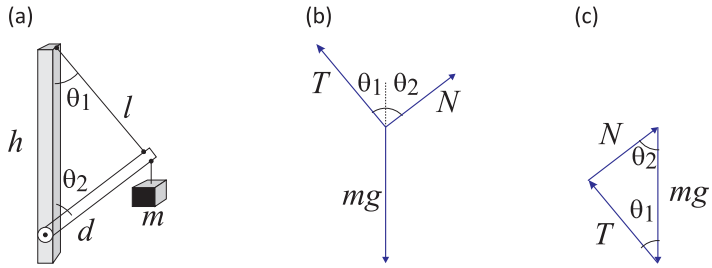

Figure 2.20: (a) Mass hanging at a gallow. (b,c) Alternative force diagrams.

Solution: *The balance of forces requires for the tensions acting on the wire (T) and the boom (N),*

$$0 = T\sin\theta_1 - N\sin\theta_2$$
$$mg = T\cos\theta_1 + N\cos\theta_2 \ .$$

Multiplying the first equation by $\cos\theta_2$ *and the second by* $\sin\theta_2$ *and adding the results,*

$$T = \frac{mg\sin\theta_2}{\sin\theta_2\cos\theta_1 + \sin\theta_1\cos\theta_2} \ .$$

For arbitrary triangles hold the trigonometric relationships,

$$l^2 + h^2 - 2hl\cos\theta_1 = d^2 \qquad \text{and} \qquad d^2 + h^2 - 2hd\cos\theta_2 = l^2 \ .$$

Inserting in the above equation for T we get,

$$T = mg\frac{\sqrt{1-\left(\frac{d^2+h^2-l^2}{2hd}\right))^2}}{\frac{l^2+h^2-d^2}{2hl}\sqrt{1-\left(\frac{d^2+h^2-l^2}{2hd}\right)^2} + \frac{d^2+h^2-l^2}{2hd}\sqrt{1-\left(\frac{l^2+h^2-d^2}{2hl}\right)^2}} = mg\frac{l}{h} = 9.81\,\mathrm{N} \ .$$

2.4.4.2 Ex: Three blocks

Determine the equilibrium situation of the system sketched in the figure.

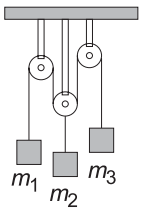

Figure 2.21: Scheme of the system.

Solution: *The solution is,*

$$(m_1 + m_2 + m_3)a = m_1 g \pm m_2 g - m_3 g \ .$$

2.4.4.3 Ex: Balance of forces on the inclined plane

One body with the mass 8 kg and a second body with the mass 10 kg connected by a wire slide without friction each one on an inclined plane. The wire runs without friction over a block, as shown in the diagram.
a. In which direction will the bodies move?
b. Calculate the acceleration of the bodies.
c. Now the two bodies are replaced by other bodies with the masses m_1 and m_2, such that there is no more acceleration, that is, the bodies are at rest. What should the ratio of the mass m_1 and m_2 be?

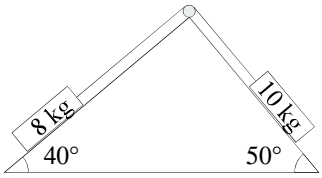

Figure 2.22: Inclined plane.

Solution: *a. The* 10 kg *body pulls the* 8 kg *body over the block.*

b. The forces acting on the bodies m_l and m_r are,

$$(m_l + m_r)a = m_l g \sin\alpha_l - m_r g \sin\alpha_r$$
$$a = g\frac{m_l \sin\alpha_l - m_r \sin\alpha_r}{m_l + m_r} = g\frac{8\sin\left(\pi\frac{40}{180}\right) - 10\sin\left(\pi\frac{50}{180}\right)}{8+10} = 1.37\,\mathrm{m/s^2} \ .$$

c. Equilibrium is reached when,

$$0 = g\frac{m_l \sin\alpha_l - m_r \sin\alpha_r}{m_l + m_r}$$
$$\frac{m_l}{m_r} = \frac{\sin\alpha_r}{\sin\alpha_l} = \frac{\sin\left(\pi\frac{50}{180}\right)}{\sin\left(\pi\frac{40}{180}\right)} \simeq 1.15 \ .$$

2.4.4.4 Ex: Balance of forces on the arc

Two spheres of mass m_1 and $m_2 = 2m_1$ connected by a rope of length L are located on both sides of a wall with a semicircular cross-sectional area (see figure). The diameter of the circular arc is $2R$.

a. At what horizontal distance x from the center of the wall must the spheres be in

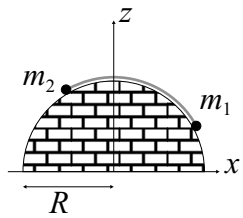

Figure 2.23: Balance of forces on the arc.

order to avoid acceleration? Assume $L = \pi R/2$.

b. Set up the equation of motion.

c. Now assume that the rope is so short that the sine expressions can be replaced by their first-order Taylor expansion. Solve the equation of motion in this approximation. Assume that at $t = 0$ the balls are the same height.

Solution: *a. The forces acting on the spheres are due to gravity $F_k(x) = m_k g \sin\alpha_k$, where the angles α_k are taken with respect to the vertical. With the boundary condition $\alpha_1 + \alpha_2 = \frac{L}{R}$ is the balance equation is,*

$$m_1 g \sin\alpha_1 = m_2 g \sin\alpha_2 \quad \Rightarrow \quad \sin\alpha_1 = \frac{m_2}{m_1}\sin\left(\frac{L}{R} - \alpha_1\right) \quad \Rightarrow \quad \tan\alpha_1 = 2 = \frac{1}{\tan\alpha_2} \ .$$

The angles between the vertical and the locations of the masses are $\alpha_1 = 63.4°$ and $\alpha_2 = 26.6°$. The distances are $x_1 = \cos\alpha_1 = 0.45R$ resp. $x_2 = 0.89R$.

b. The acceleration force is $(m_1+m_2)a(t) = (m_1+m_2)R\ddot{\alpha}_1(t)$. *Hence, the equation of motion is,*

$$(m_1+m_2)R\ddot{\alpha}_1(t) = m_1 g\sin\alpha_1(t) - m_2 g\sin\left(\frac{L}{R}-\alpha_1(t)\right)$$
$$\Rightarrow \quad \ddot{\alpha}_1(t) - \frac{g}{3R}\sin\alpha_1(t) + \frac{2g}{3R}\sin\left(\frac{L}{R}-\alpha_1(t)\right) = 0 \ .$$

c. From the approximate equation of motion, $\ddot{\alpha}_1(t) - \frac{g}{R}\alpha_1(t) = -\frac{2gL}{3R^2}$ *one obtains the characteristic equation with the ansatz,* $\alpha_1 = Ae^{\lambda t} + C$,

$$\lambda^2 Ae^{\lambda t} - \frac{g}{R}\left(Ae^{\lambda t}+C\right) = -\frac{2gL}{3R^2} \ .$$

It follows $C = \frac{2L}{3R}$ *and* $\lambda = \pm\sqrt{\frac{g}{R}}$. *The solution is now,* $\alpha_1 = Ae^{\sqrt{\frac{g}{R}}t} + Be^{-\sqrt{\frac{g}{R}}t} + \frac{2L}{3R}$. *From the initial condition* $\alpha_1(0) = \frac{2L}{3R}$ *follows,*

$$\alpha_1 = 2\sinh\sqrt{\frac{g}{R}} + \frac{2L}{3R} \ .$$

2.4.4.5 Ex: Relative and center of mass coordinates

Consider two mass m_1 and m_2 at the positions $\mathbf{r}_1$ and $\mathbf{r}_2$.
a. Calculate the vector $\mathbf{r}$ of the center of mass and express the vectors $\mathbf{r}_1$ and $\mathbf{r}_2$ as a function of the vector $\mathbf{r}$ and the relative vector $\mathbf{r} \equiv= \mathbf{r}_2 - \mathbf{r}_1$.
b. Show that the vector is on the line connecting the masses m_1 and m_2. (**Help:** Parametrize the direct path from $\mathbf{r}_1$ to $\mathbf{r}_2$ and show, that $\mathbf{r}$ is a point on that path.)
c. Suppose that there are no external forces acting on the two masses and that only the gravitational force between them is present. Also suppose that each mass moves on a circle around the center of mass. Assume equilibrium between the gravitational attraction and the centripetal force for the two masses. Compare with the corresponding equation of motion for the relative coordinate (reduced mass).
d. Consider as an example the two-body system composed of the Earth and the Moon ($m_E = 5.974\times10^{24}\,\mathrm{kg}$, $m_M = 7.35\times10^{22}\,\mathrm{kg}$, $r = 384000\,\mathrm{km}$). What is the distance d from the center of mass of this system from the center of the Earth?
e. What is the error in calculating the period T of a revolution of the Moon around the Earth, when the Earth's movement is neglected, that is, when the origin of the coordinates is identified with the center of the Earth?

Solution: *a. The total momentum is additive. We define the vector of the center of mass* $\mathbf{r}$, *such that* $P = M\dot{\mathbf{r}} = (m_1+m_2)\dot{\mathbf{r}} \equiv m_1\dot{\mathbf{r}}_1 + m_2\dot{\mathbf{r}}_2 = \mathbf{p}_1 + \mathbf{p}_2$. *Then,*

$$\mathbf{r} = \frac{m_1\mathbf{r}_1 + m_2\mathbf{r}_2}{M} \ .$$

With $\mathbf{r} = \mathbf{r}_2 - \mathbf{r}_1$ *the individual coordinates are expressed by,*

$$\mathbf{r}_1 = \mathbf{r} - \frac{m_2}{M}\mathbf{r} \qquad \textit{and} \qquad \mathbf{r}_2 = \mathbf{r} + \frac{m_1}{M}\mathbf{r} \ .$$

b. The connecting line is given by,

$$\mathbf{r}(s) = \mathbf{r}_1 + s(\mathbf{r}_2 - \mathbf{r}_1) \ .$$

For $s = m_2/M$ we obtain,

$$\mathbf{r}(s) = \left(1 - \frac{m_2}{M}\right)\mathbf{r}_1 + \frac{m_2}{M}\mathbf{r}_2 = \frac{m_1}{M}\mathbf{r}_1 + \frac{m_2}{M}\mathbf{r}_2 = \mathbf{r} \ .$$

c. The centripetal force on m_1 respectively m_2 is,

$$m_1\omega^2|\mathbf{r}_1 - \mathbf{r}| = \frac{Gm_1m_2}{r^2} \qquad \textit{resp.} \qquad m_2\omega^2|\mathbf{r}_2 - \mathbf{r}| = \frac{Gm_1m_2}{r^2} \ .$$

After replacing the individual coordinates,

$$\frac{m_1m_2}{M}\omega^2 r = \frac{Gm_1m_2}{r^2} \ .$$

Follows the equation of motion,

$$\dot{\varphi} = \omega^2 = \frac{GM}{r^3} \ .$$

The equation of motion of the relative coordinate is, $\mu\frac{d^2\mathbf{r}}{dt^2} = -\frac{Gm_1m_2}{r^3}\mathbf{r}$, with reduced mass $\mu = m_1m_2/M$. The derivatives of the position vector are,

$$\begin{aligned}
\mathbf{r} &= r\hat{\mathbf{e}}_r(t) = r\hat{\mathbf{e}}_x\cos\varphi(t) + r\hat{\mathbf{e}}_y\sin\varphi(t) \\
\frac{d\mathbf{r}}{dt} &= -r\dot{\varphi}\hat{\mathbf{e}}_x\sin\varphi + r\dot{\varphi}\hat{\mathbf{e}}_y\cos\varphi = -r\dot{\varphi}\hat{\mathbf{e}}_\varphi \\
\frac{d^2\mathbf{r}}{dt^2} &= -r\dot{\varphi}^2\hat{\mathbf{e}}_x\cos\varphi - r\dot{\varphi}^2\hat{\mathbf{e}}_y\sin\varphi - r\ddot{\varphi}\hat{\mathbf{e}}_x\sin\varphi + r\ddot{\varphi}\hat{\mathbf{e}}_y\cos\varphi = -r\dot{\varphi}^2\hat{\mathbf{e}}_r \ .
\end{aligned}$$

So the equation of motion,$\mu r\dot{\varphi}^2 = \frac{Gm_1m_2}{r^2}$ is identical with the one derived above.
d. For the Earth-Moon system, the modulus of the center of mass vector is, according to (a), with $m_1 = m_E$ and $m_2 = m_M$

$$|\mathbf{r} - \mathbf{r}_E| = \frac{m_M}{M}r = \frac{7.35\times10^{22}}{5.974\times10^{24} + 7.35\times10^{22}} \times 384000\,\text{km} = 4667\,\text{km} \ .$$

Thus, it stays within the volume of the Earth.
e. The rotation frequency is, following (c) $\omega = \sqrt{\frac{GM}{r^3}}$. The approximated rotation frequency is given by $m_{2M}\omega_n^2 r = \frac{Gm_Em_M}{r^2}$. Hence, $\omega_n = \sqrt{\frac{Gm_E}{r^3}}$. That is,

$$\frac{\omega_n}{\omega} = \sqrt{\frac{m_E}{M}} = \sqrt{\frac{5.974\times10^{24}}{5.974\times10^{24} + 7.35\times10^{22}}} = 0.9939 \ .$$

The error is 0.6%.

2.4.4.6 Ex: Why Paddy's Not at Work Today (Pat Cooksey)

Identify the movement described in the following song and calculate the total time of the event assuming that each floor is 3 m high, Paddy weighs 70 kg and the pile of bricks 100 kg.

Dear Sir I write this note to inform you of my plight
And at the time of writing I am not a pretty sight
My body is all black and blue, my face a deathly gray
I write this note to tell why Paddy's not at work today

While working on the fourteenth floor, some bricks I had to clear
And to throw them down from off the top seemed quite a good idea
But the gaffer wasn't very pleased, he was an awful sod
He said I had to cart them down the ladder in me hod.

Well clearing all those bricks by hand, it seemed so very slow
So I hoisted up a barrel and secured the rope below
But in my haste to do the job, I was too blind to see
That a barrel full of building bricks is heavier than me.

So when I had untied the rope, the barrel fell like lead
And clinging tightly to the rope I started up instead
I took off like a rocket and to my dismay I found
That half way up I met the bloody barrel coming down.

Well the barrel broke my shoulder as on to the ground it sped
And when I reached the top I banged the pulley with me head
I held on tight, though numb with shock from this almighty blow
And the barrel spilled out half its load fourteen floors below

Now when those building bricks fell from the barrel to the floor
I then outweighed the barrel so I started down once more
I held on tightly to the rope as I flew to the ground
And I landed on those building bricks that were scattered all around.

Now as I lay there on the deck I thought I'd passed the worst
But when the barrel reached the top, that's when the bottom burst
A shower of bricks came down on me, I knew I had no hope
In all of this confusion, I let go the bloody rope.

The barrel being heavier, it started down once more
And landed right on top of me as I lay on the floor
It broke three ribs and my left arm, and I can only say
That I hope you'll understand why Paddy's not at work today.

Solution:

2.4.4.7 Ex: Superposition of forces

A climber wants to climb a mountain. He weighs with all its equipment 90 kg. He has a cable with a tensile strength of 100 kg. For safety reasons, he uses two ropes fixed at a distance of 10 m at the same height of the wall. He pulls upwards in a way to be always at an equal distance from the two fixing points. Will the ropes hold or will he fall? If so, at what point?

Solution: *Be $d = 10\,\mathrm{m}$ the distance from the fixing points and $-h$ the height difference between the fixing point and the climber. The force due to the climber's weight is,*

$$\mathbf{G} = -mg\hat{\mathbf{e}}_y = \mathbf{F}_+ + \mathbf{F}_- \ .$$

On both cables the acting forces are $\mathbf{F}_\pm = x \begin{pmatrix} \mp d/2 \\ -h \\ 0 \end{pmatrix}$. *From this follows* $x = \frac{mg}{2h}$. *The value of the stresses acting on the cables must be less than* $F_{mx} = 100\,\mathrm{kg}$, *so* $F_\pm = \frac{mg}{2h}\sqrt{d^2/4 + h^2} < F_{mx}$. *From this follows,*

$$h > \frac{d/2}{\sqrt{\left(\frac{2F_{mx}}{mg}\right)^2 - 1}} = \frac{10\,\mathrm{m}/2}{\sqrt{\left(\frac{2\cdot 100}{90}\right)^2 - 1}} \simeq 2.5\,\mathrm{m} \ .$$

2.4.4.8 Ex: Mobile sports field

Two athletes play with a heavy medicine ball ($m = 4\,\mathrm{kg}$) on a moving platform without friction. They are at a distance of $L = 10\,\mathrm{m}$. In the middle between them there is an elastic net with spring constant $D = 800\,\mathrm{N/m}$. The left athlete throws the ball at a speed of $v_B = 8\,\mathrm{m/s}$ parallel to the Earth's surface.

a. What is the velocity of the platform together with the athletes (total mass

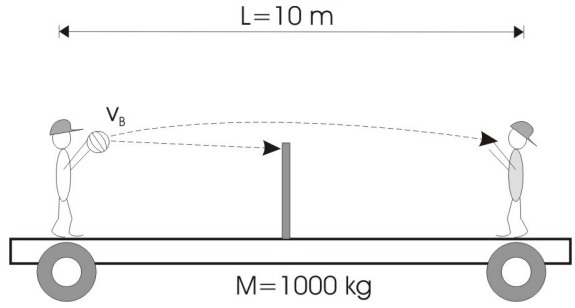

Figure 2.24: Scheme of the system.

$M = 1000\,\mathrm{kg}$), after the moment when the ball leaves the athlete's hand? Suppose the athletes to be firmly connected to the ground.
b. The ball reaches the athlete to the right who catches it. What is the distance covered by the platform?
c. Now, suppose that the ball is blocked by the net. What is the maximum deflection of the net? How is the speed profile of the platform from the moment on when the ball is released?

Solution: *a. Momentum conservation requests,*

$$m \cdot v_B = M \cdot v_W \Leftrightarrow v_W = \frac{m}{M}\, v_B = 3.2\,\mathrm{cm/s}$$

b. Total flight duration $t_w = L/v_R = 1.245\,\mathrm{s}$. *Traveled distance* $L_W = v_W \cdot t_W \simeq \mathrm{cm}$.
c. Relative velocity ball-net $v_R = v_B + v_W = 8.032\,\mathrm{m/s}$. *Energy conservation:*

$$\frac{1}{2} m v_R^2 = \frac{1}{2} D x_{max}^2 \Leftrightarrow x_{max} = \sqrt{\frac{m v_R^2}{D}} \simeq 56.8\,\mathrm{cm}\ .$$

Velocity profile for the platform: Oscillation during half a period $T/2 = \pi\sqrt{m/D}$*:*

$$v_W(t) = \begin{cases} \frac{m}{M} v_B & t < \frac{L/2}{v_R} \simeq 0.62\,\mathrm{s} \\ \frac{m}{M} v_B \cdot (1 - \sin(\sqrt{m/D}t)) & \frac{L/2}{v_R} \simeq 0.62\,\mathrm{s} < t < \frac{L/2}{v_R} + \pi\sqrt{\frac{m}{D}} \simeq 0.94\,\mathrm{s} \\ -\frac{m}{M} v_B & t > \frac{L/2}{v_R} + \pi\sqrt{\frac{m}{D}} \simeq 0.94\,\mathrm{s} \end{cases}$$

2.4.4.9 Ex: Firework ratchet

A firework ratchet is launched vertically up to a height of 50 m (along the z-axis). At the apex of the parabolic trajectory, the ratchet explodes in three parts with masses $m_1 = 200\,\mathrm{g}$, $m_2 = 300\,\mathrm{g}$ and $m_3 = 400\,\mathrm{g}$. The energy liberated by the explosion (200 J) is converted into kinetic energy for the three fragments. Assume that the resulting momenta are on a single horizontal line (along the x-axis). How long after the explosion and at what positions do the fragments hit the ground in the case that the larger fragment receives the same energy than the sum of the energy of the smaller fragments?
How will the results change when the masses m_1 and m_2 stay the same, but the larger fragment has the mass $m_3 = 500\,\mathrm{g}$?

Solution: *Total fall time:* $t = \sqrt{2s/g} = \sqrt{100/9.81}\,\mathrm{s} \simeq 3.2\,\mathrm{s}$.

$$\begin{aligned} &\textit{momentum conservation:} && p_1 + p_2 + p_3 = 0\ , \\ &\textit{energy conservation:} && \frac{p_1^2}{2m_1} + \frac{p_2^2}{2m_2} + \frac{p_3^2}{2m_3} = E_0\ . \end{aligned}$$

With $\frac{p_3^2}{2m_3} = E_0/2 \Rightarrow p_3 = \sqrt{E_0 m_3}$ *follows,*

$$p_1 + p_2 + \sqrt{E_0 m_3} = 0 \Rightarrow p_1 = -(p_2 + \sqrt{E_0 m_3})\ .$$

Now,

$$\Rightarrow \frac{(-\sqrt{E_0 m_3} - p_2)^2}{2m_1} + \frac{p_2^2}{2m_2} = E_0/2 \Rightarrow p_{2\pm} = \pm \frac{\sqrt{E_0 m_2}(\sqrt{m_1}\sqrt{m_1 + m_2 - m_3} \mp \sqrt{m_2 m_3})}{m_1 + m_2} \ .$$

Because of the two possibilities for the sign of p_2 there are two configurations:

	p_1 *(kg·m/s)*	p_2	p_3	v_1 *(m/s)*	v_2	v_3	x_1 *(m)*	x_2	x_3
p_{2+}	*-5.77*	*-3.17*	*8.94*	*-28.8*	*-10.6*	*22.4*	*-92.1*	*-33.8*	*71.4*
p_{2-}	*-1.39*	*-7.56*	*8.94*	*-6.9*	*-25.2*	*22.4*	*-22.1*	*-80.4*	*71.4*

When the largest mass is $m_3 = 500\,\mathrm{g}$, it is equal to the sum of the others. In this case, $v_3 = v_{cm,1+2}$.

2.4.4.10 Ex: Ballistic pendulum

We measure the speed of a bullet by a ballistic pendulum. The pendulum, suspended on a wire (length $L = 2\,\mathrm{m}$, mass $M = 4\,\mathrm{kg}$) is moved due to the collision. Determine from the maximum horizontal displacement ($y = 10\,\mathrm{cm}$) the velocity of the pendulum after the collision and the velocity of the bullet (mass $m = 0.1\,\mathrm{kg}$).

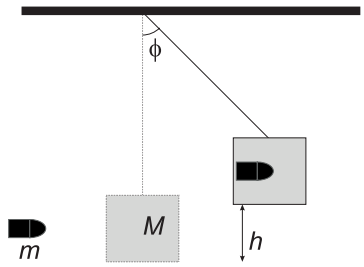

Figure 2.25: Ballistic pendulum.

Solution: *Momentum conservation requires equal linear momenta of the bullet p_{bal} before and of the pendulum p_{pen} after the collision. Therefore,*

$$m v_{bal} = (M + m) v_{pen} \ .$$

On the other hand, kinetic energy is not conserved,

$$T_{bal} = \frac{m}{2} v_{bal}^2 \neq \frac{m^2}{2(M+m)} v_{bal}^2 = \frac{M+m}{2} \frac{m^2}{(M+m)^2} v_{bal}^2 = \frac{M+m}{2} v_{pen}^2 = T_{pen} \ .$$

The energy $\Delta E = T_{bal} - T_{pen} = \frac{mM}{2(M+m)} v_{bal}^2$ must therefore be dissipated. Energy conservation after the collision requires,

$$(M + m) g h = \frac{M+m}{2} v_{pen}^2 \ .$$

Therefore, the velocity of the bullet is,

$$v_{bal} = \frac{M+m}{m} v_{pen} = \frac{M+m}{m}\sqrt{2gh}\ .$$

For the pendulum holds, $y = L\sin\theta$ *e* $h + L\cos\theta = L$*. Solving by* h*, we find,*

$$h = L - L\sqrt{1 - \frac{y^2}{L^2}} \simeq \frac{1}{2L}y^2$$

for small oscillations. Finally,

$$v_{bal} = \frac{M+m}{m} y\sqrt{\frac{g}{L}} \approx 9\,\mathrm{m/s}\ .$$

2.4.4.11 Ex: Central collision in a train station

A wagon of mass m_1 collides elastically with another wagon at rest of mass m_2. What is the relation between the masses m_1 and m_2, if after the collision
a. the wagons have the same velocity in opposite directions,
b. m_2 is three times the velocity of m_1 in the same direction,
c. m_1 is repelled with a third of the initial velocity?

Solution: *a. The condition is,*

$$v_1' = \frac{m_1 - m_2}{m_1 + m_2} v_1 + \frac{2m_2}{m_1 + m_2} \cdot 0 \stackrel{!}{=} -v_2' = -\frac{m_2 - m_1}{m_1 + m_2} \cdot 0 - \frac{2m_1}{m_1 + m_2} v_1$$

hence,

$$\Rightarrow m_1 - m_2 = -2m_1 \Leftrightarrow m_2 = 3m_1$$

b. The condition is,

$$3 \cdot v_1' = 3\frac{m_1 - m_2}{m_1 + m_2} v_1 + \frac{3 \cdot 2m_2}{m_1 + m_2} \cdot 0 \stackrel{!}{=} v_2' = \frac{m_2 - m_1}{m_1 + m_2} \cdot 0 - \frac{2m_1}{m_1 + m_2} v_1$$

hence,

$$\Rightarrow 3(m_1 - m_2) = 2m_1 \Leftrightarrow m_1 = 3m_2$$

c. The condition is,

$$v_1' = \frac{m_1 - m_2}{m_1 + m_2} v_1 + \frac{2m_2}{m_1 + m_2} \cdot 0 \stackrel{!}{=} -\frac{1}{3} v_1'$$

hence,

$$\Rightarrow m_1 - m_2 = -\frac{1}{3}(m_1 + m_2) \Leftrightarrow \frac{4}{3}m_1 = \frac{2}{3}m_2 \Leftrightarrow 2m_1 = m_2$$

2.4.4.12 Ex: (In-) elastic collision

A billiard ball with the speed $\mathbf{v}_{1i} = v_0\hat{\mathbf{e}}_x$ hits a second one initially at rest. Due to the collision the first ball changes the speed to $\mathbf{v}_{1f} = \frac{2v_0}{3}(\hat{\mathbf{e}}_x\cos\theta + \hat{\mathbf{e}}_y\sin\theta)$, where $\theta = 45°$.
a. Determine the speed of the second ball, $\mathbf{v}_{2f}$, after the collision.
b. Calculate the dissipated energy and determine if shock whether elastic or inelastic.

Solution: *a. With the conservation of linear momentum,*

$$\begin{aligned} m\mathbf{v}_{1i} &= m\mathbf{v}_{1f} + m\mathbf{v}_{2f} \\ \Leftrightarrow \quad \begin{pmatrix} v_0 \\ 0 \end{pmatrix} &= \begin{pmatrix} \frac{2v_0}{3}\cos\theta + v_{2fx} \\ \frac{2v_0}{3}\sin\theta + v_{2fy} \end{pmatrix} \\ \Leftrightarrow \mathbf{v}_{2f} = \begin{pmatrix} v_{2fx} \\ v_{2fy} \end{pmatrix} &= v_0 \begin{pmatrix} 1 - \frac{2}{3}\cos\theta \\ \frac{2}{3}\sin\theta \end{pmatrix} = v_0 \begin{pmatrix} 1 - \frac{\sqrt{2}}{3} \\ \frac{\sqrt{2}}{3} \end{pmatrix} . \end{aligned}$$

b. The difference between the kinetic energies before and after shock is,

$$\begin{aligned} E_{diss} = E_i - E_f &= \frac{m}{2}v_{1i}^2 - \frac{m}{2}v_{1f}^2 - \frac{m}{2}v_{2f}^2 = \frac{m}{2}v_0^2\left(1 - \tfrac{2^2}{3^2} - (1 - \tfrac{\sqrt{2}}{3})^2 - (\tfrac{\sqrt{2}}{3})^2\right) \\ &= \frac{6\sqrt{2} - 8}{9}E_i \simeq 0.054E_i > 0 . \end{aligned}$$

The shock is partially inelastic.

2.4.4.13 Ex: Variable mass

A wagon of mass M initially at rest is filled with fuel representing half of its mass. The fuel is now horizontally ejected at a constant rate γ and a constant speed v_c, thus propelling the car in the opposite direction. What is the final speed of the wagon when the fuel is completely consumed?

Solution: *The equation of motion is,*

$$F = \frac{d}{dt}(mv) = m\frac{dv}{dt} + v_c\frac{dm}{dt} = 0 .$$

Separating the variables

$$\int_0^{v_f} dv = -v_c\int_M^{M/2}\frac{dm}{m} ,$$

giving

$$v_f = -v_c\ln\tfrac{1}{2} \simeq 0.7v_c .$$

2.4.4.14 Ex: Mass sliding down a movable wedge

A block of mass m rests on a wedge of mass M and angle θ, which is placed on a horizontal surface. Releasing the system from rest, with the body at a height h, determine the speed of the wedge when the block touches the ground. All surfaces are free from friction.

Solution: *We use the principle of energy and momentum conservation,*

$$mgh = \frac{m}{2}v^2 + \frac{M}{2}V^2 \qquad \textit{and} \qquad 0 = mv_x + MV_x \qquad \textit{and} \qquad \frac{-v_y}{v_x - V_x} = \tan\theta \ .$$

We insert the second and third equation into the first,

$$mgh = \frac{m}{2}v_x^2+\frac{m}{2}v_y^2+\frac{M}{2}V_x^2 = \frac{m}{2}v_x^2+\frac{m}{2}(v_x-V_x)^2\tan^2\theta+\frac{M}{2}V_x^2 = \frac{M^2}{2m}V_x^2+\frac{m}{2}(-\frac{M}{m}V_x-V_x)^2\tan^2\theta+$$

This gives,

$$V_x = \sqrt{\frac{2gh}{\left(1+\frac{M}{m}\right)\frac{M}{m}+(1+\frac{M}{m})^2\tan^2\theta}} = \sqrt{\frac{2gh\cos^2\theta}{\left(1+\frac{M}{m}\right)\left(\frac{M}{m}+\sin^2\theta\right)}} \ .$$

2.4.4.15 Ex: Vertical collision

A body of mass $M = 400\,\mathrm{g}$ is released from rest from a height of $h = 10\,\mathrm{m}$ with respect to the Earth's surface. Simultaneously, a bullet of mass $m = 100\,\mathrm{g}$ is fired vertically from the surface with the speed $v_0 = 10\,\mathrm{m/s}$. Knowing that somewhere in the trajectory the masses collide and merge, we ask how long it takes for the masses to fall from the moment when M is released.

Solution: *The masses meet at the height*

$$Y_1 = Y_0 - \frac{g}{2}t_1^2 \equiv y_1 = v_0 t_1 - \frac{g}{2}t_1^2$$

and time

$$t_1 = \frac{y_0}{v_0} = 1\,\mathrm{s} \ ,$$

yielding

$$\begin{aligned} y_1 &= y_0 - \frac{g y_0^2}{2v_0^2} = 5.1\,\mathrm{m} \\ V_1 &= \dot{Y}_1 = -gt_1 = -g\frac{y_0}{v_0} = -9.8\,\mathrm{m/s} \\ v_1 &= \dot{y}_1 = v_0 - gt_1 = v_0 - g\frac{y_0}{v_0} = 0.2\,\mathrm{m/s} \ . \end{aligned}$$

Momentum conservation requires,

$$MV_1 + mv_1 = (M+m)v_2 \ .$$

So the speed of the combined masses is,

$$v_2 = \frac{MV_1 + mv_1}{M+m} = -7.8\,\mathrm{m/s} \ ,$$

at the height

$$y_2 = y_1 + v_2 t_2 - \frac{g}{2} t_2^2 \equiv 0 \ ,$$

and time

$$t_2 = \frac{v_2}{g} \pm \sqrt{\frac{v_2^2}{g^2} + \frac{2}{g} y_1} = 0.49\,\mathrm{m/s} \ .$$

The total time is,

$$t_{tot} = t + t_2 = 1.49\,\mathrm{m/s} \ .$$

2.4.4.16 Ex: Variable mass

An open freight car weighs 10 tons and is sliding on a frictionless track with a speed of 60 cm/s. Heavy rain suddenly starts and the drops fall vertically with a velocity v_0 with respect to the ground. How fast is the wagon after collecting 500 kg of water?

Solution: *The equation of motion is,*

$$ma = m\frac{dv}{dt} = -\frac{dm}{dt} v \ .$$

Hence,

$$\int_{v_0}^{v_f} \frac{dv}{v} = -\int_{m_0}^{m_f} \frac{dm}{m}$$
$$\ln \frac{v_f}{v_0} = \ln \frac{m_0}{m_f} \ .$$

Finally,

$$v_f = v_0 \frac{m_0}{m_f} = 57.14\,\mathrm{cm/s} \ .$$

2.4.4.17 Ex: Variable mass

An hourglass is placed on a scale plate. Initially ($t = 0$), all the sand is at rest in the upper container of the hourglass. The sand falls into the lower container at a rate $\lambda = -dm/dt$. Prepare a graph of the reading on the scale for $t \geq 0$.

Solution: *The weight of the hourglass only varies when it starts to pour sand and when it ends doing it. In the interval between these moments, the part of the sand that is in free flight does not contribute to the weight, such that the weight is less.*

The graph shows a rapid and linear initial decrease from the initial weight to a lower weight. Then the weight remains constant for a long time until it comes to the point where it increases again linearly to the initial value.
To calculate the stationary reading, that is, $\dot{x}_{scale} = 0$, we write,

$$0 = ma_{scale} = -mg - \dot{m}u_{top} + \dot{m}u_{bottom} - kx \ ,$$

where the coordinate x represents the reading of the scale. The velocity of sand leaving the upper container is $\dot{x}_{top} = 0$ and the velocity of sand entering the lower container is $\dot{x}_{bottom} = gt = \sqrt{2sg}$, where s is the vertical distance between the containers. With this,

$$x = -\frac{m}{k}g - \lambda\sqrt{2sg} \ .$$

2.4.4.18 Ex: Variable mass

A raindrop of initial mass M_0 starts to fall from rest. Assuming that the drop gains mass as it passes through the clouds at a rate proportional to the product of mass by velocity ($dm/dt = Kmv$), calculate the velocity $v(t)$. Neglect air resistance.

Solution: *The equation of motion is,*

$$ma = m\dot{v} = -mg + \dot{m}v = mg + (Kmv)v \ ,$$

or

$$\frac{dv}{dt} = -g + Kv^2 \ .$$

Hence,

$$-\int_0^t dt = \frac{1}{g}\int_0^v \frac{dv}{1 - \frac{K}{g}v^2} \ ,$$

with the solution,

$$-t = \frac{1}{g}\sqrt{\frac{g}{K}}\, artanh\left(\sqrt{\frac{K}{g}}v\right) \ .$$

Finally,

$$v = \sqrt{\frac{g}{K}}\tanh(\sqrt{Kg}t) \ .$$

2.4.4.19 Ex: Variable mass

A toy rocket has a carcass that weighs 100 g and an initial amount of fuel of 400 g. The velocity relative to the rocket with which the fuel comes out is 100 m/s and the rate at which it is burned is 100 m/s. Assuming it takes off from the Earth's surface ($g = 10\,\mathrm{m/s^2}$ constant) with zero initial velocity, what maximum velocity will it

reach?

Solution: *We have the relative velocity of the fuel of the rocket* $u = 100\,\mathrm{m/s}$ *and the fuel expense rate of* $\dot{m} = -100\,\mathrm{g/s}$*, the initial weight* $m = 500\,\mathrm{g}$ *and the final weight* $m_f = 100\,\mathrm{g}$*. The equation of motion is,*

$$ma = m\frac{dv}{dt} = -mg + \dot{m}u \ .$$

The mass varies as $m(t) = m_i - \dot{m}t$ *until it reaches the point* $m(t) = m_f$*, which happens at time* $t = (m_i - m_f)/\dot{m}$*. Thereby,*

$$\int_0^v dv = \int_0^{(m_i-m_f)/\dot{m}} \left(-g + \frac{\dot{m}u}{m_i - \dot{m}t}\right) dt \ .$$

The speed is,

$$\begin{aligned} v &= -g\frac{m_i - m_f}{\dot{m}} + u\dot{m}\int_0^{(m_i-m_f)/\dot{m}} \frac{dt}{m_i - \dot{m}t} = -g\frac{m_i - m_f}{\dot{m}} - u\int_{m_i}^{m_f}\frac{dz}{z} \\ &= -g\frac{m_i - m_f}{\dot{m}} - u\ln\frac{m_f}{m_i} = (-40 + 100)\,\mathrm{m/s}\ln 5 = 120\,\mathrm{m/s} \ . \end{aligned}$$

This is different from the template: $61.6\,\mathrm{m/s}$*, which is false!*

2.4.4.20 Ex: Variable mass

Calculate the power required to lift a rope vertically, initially completely wound on the ground, at a constant speed v_0. The linear mass density of the rope is λ.

Solution: *The length of the raised part of the string grows as* $y = v_0 t$ *until the time* $t_f = L/v_0$*. The power required,*

$$P = F \cdot v_0 = m(t)gv_0 = \lambda L(t)gv_0 = \lambda v_0 t g v_0 \ ,$$

grows linearly until it's maximum at time t_f*,*

$$P = \lambda L g v_0 = Mgv_0 \ .$$

2.4.4.21 Ex: Collision of two masses

Two trolleys with masses m_1 and m_2 and speeds v_1 and v_2 collide elastically (energy is conserved). Knowing that the momentum of the system is preserved during the collision, calculate the speeds of the cars after the crash.

Solution: *Conservation of energy and momentum,*

$$\begin{aligned} \frac{m_1}{2}v_{1i}^2 + \frac{m_2}{2}v_{2i}^2 &= \frac{m_1}{2}v_{1f}^2 + \frac{m_2}{2}v_{2f}^2 \\ m_1 v_{1i} + m_2 v_{2i} &= m_1 v_{1f} + m_2 v_{2f} \ . \end{aligned}$$

Inserting the second in the first equation, thus eliminating v_{2f}, we get,

$$m_1 v_{1i}^2 + m_2 v_{2i}^2 = m_1 v_{1f}^2 + \tfrac{1}{m_2}\left(m_1 v_{1i} + m_2 v_{2i} - m_1 v_{1f}\right)^2 \ ,$$

and

$$0 = \tfrac{m_1}{m_2}(m_1+m_2)v_{1f}^2 - 2\tfrac{m_1}{m_2}(m_1 v_{1i}+m_2 v_{2i})v_{1f} - m_1 v_{1i}^2 - m_2 v_{2i}^2 + \tfrac{1}{m_2}(m_1 v_{1i}+m_2 v_{2i})^2 \ ,$$

and

$$\begin{aligned} 0 &= v_{1f}^2 - 2\frac{m_1 v_{1i} + m_2 v_{2i}}{m_1+m_2} v_{1f} - \frac{m_2(m_1 v_{1i}^2 + m_2 v_{2i}^2)}{m_1(m_1+m_2)} + \frac{(m_1 v_{1i} + m_2 v_{2i})^2}{m_1(m_1+m_2)} \\ &= \left(v_{1f} - \frac{m_1 v_{1i} + m_2 v_{2i}}{m_1+m_2}\right)^2 - \sqrt{\left(\frac{m_1 v_{1i} + m_2 v_{2i}}{m_1+m_2}\right)^2 + \frac{m_2(m_1 v_{1i}^2 + m_2 v_{2i}^2)}{m_1(m_1+m_2)} - \frac{(m_1 v_{1i} + m_2 v_{2i})^2}{m_1(m_1+m_2)}}^2 \\ &= \left(v_{1f} - \frac{m_1 v_{1i} + m_2 v_{2i}}{m_1+m_2}\right)^2 - \left(m_2 \frac{v_{1i} - v_{2i}}{m_1+m_2}\right)^2 \ . \end{aligned}$$

Finally,

$$\begin{aligned} v_{1f} &= \frac{m_1 v_{1i} + m_2 v_{2i} \pm m_2 v_{1i} \mp m_2 v_{2i}}{m_1+m_2} \\ &= v_{1i}, \frac{(m_1 - m_2)\, v_{1i} + 2 m_2 v_{2i}}{m_1+m_2} \ , \end{aligned}$$

and for symmetry reasons,

$$v_{2f} = v_{2i}, \frac{(m_2 - m_1) v_{2i} + 2 m_1 v_{1i}}{m_1+m_2} \ .$$

2.4.4.22 Ex: Collision of two masses

Two balls A and B of different masses collide. A is initially at rest and B has the velocity v. After the shock, B has a speed of $v/2$ and moves perpendicular to the direction of the initial movement. Determine the direction of A's movement after the collision. What is the change in energy due to the collision?

Solution: *Momentum conservation requires,*

$$\begin{pmatrix} m_B v \\ 0 \end{pmatrix} = \begin{pmatrix} m_A v_{Ax} \\ m_A v_{Ay} + m_B \frac{v}{2} \end{pmatrix} \ .$$

Therefore, the direction is given by,

$$\tan\theta_A = \frac{v_{Ax}}{v_{Ay}} = \frac{1}{2} \ .$$

Energy conservation requires,

$$\frac{m_B}{2} v^2 = \frac{m_A}{2} v_A^2 + \frac{m_B}{2}\left(\frac{v}{2}\right)^2 \ .$$

Therefore, energy expenditure is,

$$\Delta E_{kin} = \frac{m_A}{2}(v_{Ax}^2 + v_{Ay}^2) + \frac{m_B}{2}\left(\frac{v}{2}\right)^2 - \frac{m_B}{2}v^2$$
$$= \frac{m_A}{2}\left(\frac{m_B^2}{m_A^2}v^2 + \frac{m_B^2}{4m_A^2}v^2\right) + \frac{m_B}{2}\left(\frac{v}{2}\right)^2 - \frac{m_B}{2}v^2 = -\frac{m_B}{2}v^2\frac{3m_A - 5m_B}{4m_A} \ .$$

2.4.4.23 Ex: Collision of two masses

A bullet of mass m is fired with the velocity v against a ballistic pendulum of mass M. The bullet passes through the pendulum and emerges with the velocity $v/4$.
a. calculate the maximum height of the oscillating pendulum,
b. calculate the energy dissipated when the bullet passes through the pendulum.

Solution: *a. Momentum conservation during the collision,*

$$mv = Mv_M + m\frac{v}{4} \qquad \Longrightarrow \qquad v_M = \frac{3m}{4M}v \ .$$

Energy conservation of the accelerated pendulum,

$$\frac{M}{2}v_M^2 = Mgh \qquad \Longrightarrow \qquad h = \frac{v_M^2}{2g} = \frac{1}{2g}\left(\frac{3m}{4M}v\right)^2 = \frac{9m^2}{32gM^2}v^2 \ .$$

b. Energy conservation during the collision,

$$\frac{m}{2}v^2 = Mgh + \frac{m}{2}\left(\frac{v}{4}\right)^2 + E_{diss}$$
$$\Longrightarrow E_{diss} = \frac{m}{2}v^2 - Mgh - \frac{m}{2}\left(\frac{v}{4}\right)^2 = \frac{15m}{32}v^2 - Mg\frac{9m^2}{32gM^2}v^2 = \left(\frac{15}{16} - \frac{9m}{16M}\right)\frac{m}{2}v^2 \ .$$

Chapter 3

Rotations and dynamics of rigid bodies

So far we have considered the translation dynamics of point masses. Obviously, point masses, unlike extended rigid bodies, cannot rotate.

3.1 Rotation about a fixed axis

Summary of common transformations,

operation	action on position	on momentum
translation	$\mathcal{T}_{tr}\mathbf{r} = \mathbf{r} + \mathbf{a}$	$\mathcal{T}_{tr}\mathbf{p} = \mathbf{p}$
kick	$\mathcal{T}_{kc}\mathbf{r} = \mathbf{r}$	$\mathcal{T}_{kc}\mathbf{p} = \mathbf{p} + m\mathbf{v}$
rotation	$\mathcal{T}_{rt}\mathbf{r} = e^{\vec{\alpha}\times}\mathbf{r}$	$\mathcal{T}_{rt}\mathbf{p} = e^{\vec{\alpha}\times}\mathbf{p}$
Galilei boost	$\mathcal{T}_{G}\mathbf{r} = \mathbf{r} + \mathbf{v}t$	$\mathcal{T}_{G}\mathbf{p} = \mathbf{p} + m\mathbf{v}$
transform to accelerated frame	$\mathcal{T}_{ac}\mathbf{r} = \mathbf{r}$	$\mathcal{T}_{ac}\mathbf{p} = \mathbf{p} + m\mathbf{g}t$
transform to rotating frame	$\mathcal{T}_{ar}\mathbf{r} = e^{\vec{\omega}t\times}\mathbf{r}$	$\mathcal{T}_{ar}\mathbf{p} = e^{\vec{\omega}t\times}\mathbf{p}$

Let us have a closer look at the rotation operator defined by,

$$\boxed{\mathcal{T}_{rt}\mathbf{r} = e^{\vec{\alpha}\times}\mathbf{r}}\ . \tag{3.1}$$

It can be expanded as,

$$\begin{aligned}\mathcal{T}_{rt}\mathbf{r} = \sum_n \frac{(\vec{\alpha}\times)^n}{n!}\mathbf{r} &= \mathbf{r} + \vec{\alpha}\times\mathbf{r} + \tfrac{1}{2}\vec{\alpha}\times(\vec{\alpha}\times\mathbf{r}) + ... \\ &= \hat{\mathbf{e}}_\alpha(\hat{\mathbf{e}}_\alpha\cdot\mathbf{r}) + \hat{\mathbf{e}}_\alpha\times\mathbf{r}\sin\alpha - \hat{\mathbf{e}}_\alpha\times(\hat{\mathbf{e}}_\alpha\times\mathbf{r})\cos\alpha\ .\end{aligned} \tag{3.2}$$

Choosing the rotation angle along Cartesian coordinates, we find matrix representations of the rotations transformations. For, $\vec{\alpha} = \alpha\hat{\mathbf{e}}_x$,

$$\mathcal{T}_{rt}\mathbf{r} = x\hat{\mathbf{e}}_x + (y\hat{\mathbf{e}}_z - z\hat{\mathbf{e}}_y)\sin\alpha + (y\hat{\mathbf{e}}_y + z\hat{\mathbf{e}}_z)\cos\alpha = R_x\mathbf{r} \tag{3.3}$$

$$\text{with}\qquad R_x = \begin{pmatrix}1 & 0 & 0\\ 0 & \cos\alpha & -\sin\alpha\\ 0 & \sin\alpha & \cos\alpha\end{pmatrix}\ ,$$

for, $\vec{\alpha} = \alpha\hat{\mathbf{e}}_y$,

$$\mathcal{T}_{rt}\mathbf{r} = y\hat{\mathbf{e}}_y + (z\hat{\mathbf{e}}_x - x\hat{\mathbf{e}}_z)\sin\alpha + (x\hat{\mathbf{e}}_x + z\hat{\mathbf{e}}_z)\cos\alpha = R_y\mathbf{r} \tag{3.4}$$
$$\text{with} \qquad R_y = \begin{pmatrix} \cos\alpha & 0 & -\sin\alpha \\ 0 & 1 & 0 \\ \sin\alpha & 0 & \cos\alpha \end{pmatrix} ,$$

and for, $\vec{\alpha} = \alpha\hat{\mathbf{e}}_z$,

$$\mathcal{T}_{rt}\mathbf{r} = z\hat{\mathbf{e}}_z + (x\hat{\mathbf{e}}_y - y\hat{\mathbf{e}}_x)\sin\alpha - \hat{\mathbf{e}}_z \times (\hat{\mathbf{e}}_z \times \mathbf{r})\cos\alpha = R_z\mathbf{r} \tag{3.5}$$
$$\text{with} \qquad R_z = \begin{pmatrix} \cos\alpha & -\sin\alpha & 0 \\ \sin\alpha & \cos\alpha & 0 \\ 0 & 0 & 1 \end{pmatrix} .$$

Furthermore, since the vectors $\hat{\mathbf{e}}_\alpha$, $\hat{\mathbf{e}}_\alpha \times \mathbf{p}$, and $\hat{\mathbf{e}}_\alpha \times (\hat{\mathbf{e}}_\alpha \times \mathbf{p})$ in Eq. (3.2) obviously form an orthogonal coordinate system, we find defining $\gamma \equiv \angle(\hat{\mathbf{e}}_\alpha, \mathbf{p})$,

$$\begin{aligned} \mathcal{T}_{rt}(e^{\vec{\alpha}\times}\mathbf{p})^2 &= [\hat{\mathbf{e}}_\alpha(\hat{\mathbf{e}}_\alpha \cdot \mathbf{p}) + \hat{\mathbf{e}}_\alpha \times \mathbf{p}\sin\alpha\hat{\mathbf{e}}_\alpha \times (\hat{\mathbf{e}}_\alpha \times \mathbf{p})\cos\alpha]^2 \\ &= [\hat{\mathbf{e}}_\alpha(\hat{\mathbf{e}}_\alpha \cdot \mathbf{p})]^2 + [\hat{\mathbf{e}}_\alpha \times \mathbf{p}\sin\alpha]^2 + [\hat{\mathbf{e}}_\alpha \times (\hat{\mathbf{e}}_\alpha \times \mathbf{p})\cos\alpha]^2 \\ &= \mathbf{p}^2\cos^2\gamma + \mathbf{p}^2\sin^2\alpha\sin^2\gamma + \mathbf{p}^2\cos^2\alpha\sin^2\gamma = \mathbf{p}^2 , \end{aligned} \tag{3.6}$$

that the kinetic energy and the potential energy in radial potentials is invariant to rotation,

$$\mathcal{T}_{rt}\left(\frac{\mathbf{p}^2}{2m} + V(|\mathbf{r}|)\right) = \frac{\mathbf{p}^2}{2m} + V(|\mathbf{r}|) . \tag{3.7}$$

3.1.1 Transformation into a rotating system

Transformation into a rotating system,

$$\frac{d}{dt}T_{ar}\mathbf{r} = e^{\vec{\omega}t\times}\frac{d}{dt}\mathbf{r} + \left(\frac{d}{dt}e^{\vec{\omega}t\times}\right)\mathbf{r} = \left(\frac{d}{dt} + \vec{\omega}\times\right)T_{ar}\mathbf{r} , \tag{3.8}$$

from which we deduce the rule,

$$\boxed{\left\{\frac{d}{dt}\right\}_{lab} = \left\{\frac{d}{dt}\right\}_{rot} + \vec{\omega}\times} . \tag{3.9}$$

Use this expression to resolve Exc. 3.1.4.1 to 3.1.4.4.

3.1.2 Inertial forces in the rotating system

Coriolis force, .

3.1.3 Inertial forces in the linearly accelerated system

3.1.4 Exercises

3.1.4.1 Ex: Rotating coordinate systems

A body of mass m is thrown horizontally at a velocity v_0 in the x-direction in the homogeneous gravitational field of the Earth. (Gravity towards $-z$). The rotation of the Earth is not taken into account.
a. Give the solution $\mathbf{r}(t)$ of the equation of motion.
b. Transform the solution into a coordinate system that rotates around the z-axis at the angular velocity ω.
c. Set up the equation of motion in the rotating system and show that the transformed path from (b) satisfies it.

Solution: *a. Path,*

$$\mathbf{r}(t) = \begin{pmatrix} v_0 t \\ 0 \\ -\frac{1}{2} g t^2 \end{pmatrix} .$$

b. The rotation is performed by,

$$R_z = \begin{pmatrix} \cos\omega t & \sin\omega t & 0 \\ -\sin\omega t & \cos\omega t & 0 \\ 0 & 0 & 1 \end{pmatrix} ,$$

so that,

$$\mathbf{r}'(t) = R_z \mathbf{r}(t) = \begin{pmatrix} v_0 t \cos\omega t \\ -v_0 t \sin\omega t \\ -\frac{1}{2} g t^2 \end{pmatrix} .$$

c. It must hold,

$$\frac{d^2}{dt^2}\mathbf{r}' = \mathbf{g}' - \vec{\omega} \times (\vec{\omega} \times \mathbf{r}') - 2\vec{\omega} \times \frac{d}{dt}\mathbf{r}' .$$

with $\mathbf{g}' = \mathbf{r} - (g\hat{\mathbf{e}}_z) = -g\hat{\mathbf{e}}_z$ *and* $\vec{\omega} = \omega\hat{\mathbf{e}}_z$. *This is valid because of (calculate with MAPLE),*

$$\frac{d}{dt}\mathbf{r}' = \begin{pmatrix} -\omega v_0 t \sin\omega t + v_0 \cos\omega t \\ -\omega v_0 t \cos\omega t - v_0 \sin\omega t \\ -gt \end{pmatrix}$$

$$\frac{d^2}{dt^2}\mathbf{r}' = \frac{d}{dt}\begin{pmatrix} -\omega^2 v_0 t \cos\omega t - 2\omega v_0 \sin\omega t \\ \omega^2 v_0 t \sin\omega t - 2\omega v_0 \cos\omega t \\ -g \end{pmatrix}$$

$$\vec{\omega} \times (\vec{\omega} \times \mathbf{r}') = \begin{pmatrix} -\omega^2 v_0 t \cos\omega t \\ \omega^2 v_0 t \sin\omega t \\ 0 \end{pmatrix}$$

$$\vec{\omega} \times \frac{d}{dt}\mathbf{r}' = \begin{pmatrix} \omega^2 v_0 t \cos\omega t + \omega v_0 \sin\omega t \\ -\omega^2 v_0 t \sin\omega t + \omega v_0 \cos\omega t \\ 0 \end{pmatrix} .$$

3.1.4.2 Ex: Rotating vulture

Consider two Cartesian coordinate systems that are identical at time $t = 0$. One rotates around the z-axis at a constant angular velocity ω, while the laboratory system is at rest. On the x-axis of this rotating system, a vulture moves from the coordinate origin (at time $t = 0$) at a constant speed v.
a. Calculate the vectors of the vulture's position and velocity in the rotating coordinate system.
b. Calculate the Cartesian coordinates of the vulture in the laboratory system and from this the velocity in the laboratory system.
c. Calculate directly the velocity observed in the laboratory system using the relationship (3.9).

Solution: *a. The location in the rotating coordinate system is* $\mathbf{r}(t) = vt\hat{\mathbf{e}}_{x,rot}$. *The velocity* $\mathbf{v}_R = v\hat{\mathbf{e}}_{x,rot}$.
b. The location in the laboratory system is,

$$\mathbf{r}(t) = vt \begin{pmatrix} \cos\phi \\ \sin\phi \\ 0 \end{pmatrix}$$

with $\phi = \omega t$. *The velocity is,*

$$\dot{\mathbf{r}}(t) = v \begin{pmatrix} \cos\phi \\ \sin\phi \\ 0 \end{pmatrix} + vt\omega \begin{pmatrix} -\sin\phi \\ \cos\phi \\ 0 \end{pmatrix}$$

with $|v| = \sqrt{v^2 + (\omega v t)^2}$.
c. The velocity observed in the laboratory system is,

$$\begin{aligned}\mathbf{v}_{lab} &= v\hat{\mathbf{e}}_r + \vec{\omega} \times r\hat{\mathbf{e}}_r = v\hat{\mathbf{e}}_r + \omega v t \hat{\mathbf{e}}_\phi \\ &= v\hat{\mathbf{e}}_{x,rot} + \omega v t \hat{\mathbf{e}}_{y,rot} = v \begin{pmatrix} \cos\phi \\ \sin\phi \\ 0 \end{pmatrix} + vt\omega \begin{pmatrix} -\sin\phi \\ \cos\phi \\ 0 \end{pmatrix} .\end{aligned}$$

$|v_{lab}|$ *is obviously independent of the chosen basic system.*

3.1.4.3 Ex: Rotating system

Consider a rotating coordinate system, which at time $t = 0$ coincides with the lab system, but rotates relative to the lab system with angular velocity $\omega = 2\pi/T$, $T = 10\,\mathrm{s}$, around the z-axis. In this coordinate system the rotation of a mass point be given by the vector,

$$\mathbf{r}' = \begin{pmatrix} a \\ a \\ 0 \end{pmatrix} .$$

a. Determine the position vector of this point with respect to the laboratory coordinate system.
b. Consider the position vector at time $t = 5\,\mathrm{s}$ and determine its velocity measured in the rotating system and in the laboratory system.

Solution: *a. We have,*

$$\mathbf{r}(t) = \mathcal{R}_z(\omega t)\mathbf{r}' = \begin{pmatrix} \cos\omega t & \sin\omega t & 0 \\ -\sin\omega t & \cos\omega t & 0 \\ 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} a \\ a \\ 0 \end{pmatrix} = \begin{pmatrix} a\cos\omega t + a\sin\omega t \\ -a\sin\omega t + a\cos\omega t \\ 0 \end{pmatrix} .$$

b. We have,

$$\mathbf{r}(5\,\mathrm{s}) = \begin{pmatrix} a\cos 2\pi\frac{t}{T} + a\sin 2\pi\frac{t}{T} \\ -a\sin 2\pi\frac{t}{T} + a\cos 2\pi\frac{t}{T} \\ 0 \end{pmatrix} = \begin{pmatrix} a\cos\pi + a\sin\pi \\ -a\sin\pi + a\cos\pi \\ 0 \end{pmatrix} = \begin{pmatrix} -a \\ -a \\ 0 \end{pmatrix} .$$

And,

$$\mathbf{v}'(t) = \left\{\frac{d\mathbf{r}}{dt}\right\}_{rot} = \begin{pmatrix} -a\omega\sin\omega t + a\omega\cos\omega t \\ -a\omega\cos\omega t - a\omega\sin\omega t \\ 0 \end{pmatrix}$$

$$|\mathbf{v}'(t)| = a\omega\sqrt{(|-\sin\omega t + \cos\omega t|^2 + |-\cos\omega t - \sin\omega t|^2)} = \tfrac{2\pi}{T}\sqrt{2}a = a \cdot 0.89 \;\; 1/\mathrm{s}$$

$$\mathbf{v}(t) = \left\{\frac{d\mathbf{r}}{dt}\right\}_{lab} = \left\{\frac{d\mathbf{r}}{dt}\right\}_{rot} + \vec{\omega} \times \mathbf{r} = a\omega \begin{pmatrix} -\sin\omega t + \cos\omega t - (-\sin\omega t + \cos\omega t) \\ -\cos\omega t - \sin\omega t + (\cos\omega t + \sin\omega t) \\ 0 \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \\ 0 \end{pmatrix}$$

$$\|\mathbf{v}'(t)\| = 0 .$$

3.1.4.4 Ex: Rotating system

Consider two coordinate systems, both with their origin at the center of the Earth and their z-axis parallel to the Earth's rotation axis. The rotating system rotates with the Earth, while the laboratory system is fixed to the solar system. An airplane moves at a constant velocity v relative to the Earth's surface on a direct trajectory from the north pole to the equator, where it arrives after a time $\tau = 12\,\mathrm{h}$. What is the velocity of the plane (as a function of time) seen by the lab system?

Solution: *The transformation from the laboratory to rotating system is described by,*

$$\mathcal{R}_z(\omega t) = \begin{pmatrix} \cos\omega t & \sin\omega t & 0 \\ -\sin\omega t & \cos\omega t & 0 \\ 0 & 0 & 1 \end{pmatrix} ,$$

where $\omega = 2\pi/48$ h. In the rotating system it is parametrized by,

$$\mathbf{r}'(t) = \begin{pmatrix} R\sin\Omega t \\ 0 \\ R\cos\Omega t \end{pmatrix} ,$$

where $\Omega = \frac{1}{2}\pi/12$ h$= \frac{1}{2}\omega$. In the rotating system the speed is,

$$\mathbf{v}'(t) = \frac{d}{dt}\mathbf{r}'(t) = \begin{pmatrix} \Omega R\cos\Omega t \\ 0 \\ -\Omega R\sin\Omega t \end{pmatrix} ,$$

with the absolute value $|\mathbf{v}'(t)| = \Omega R$. In the laboratory system the trajectory is,

$$\mathbf{r}(t) = R^z(-\omega t)\mathbf{r}'(t) = \begin{pmatrix} R\sin\Omega t\cos\omega t \\ R\sin\Omega t\sin\omega t \\ R\cos\Omega t \end{pmatrix}$$

and the speed,

$$\mathbf{v}(t) = \frac{d}{dt}\mathbf{r}(t) = \begin{pmatrix} \Omega R\cos\Omega t\cos\omega t - \omega R\sin\Omega t\sin\omega t \\ \Omega R\cos\Omega t\sin\omega t + \omega R\sin\Omega t\cos\omega t \\ -\Omega R\sin\Omega t \end{pmatrix} .$$

Alternatively we can write,

$$\begin{aligned}\mathbf{v}(t) &= \frac{d}{dt}\mathbf{r}(t)\\ &= \frac{d}{dt}[R^z(-\omega t)\mathbf{r}'(t)]\\ &= R^z(-\omega t)\frac{d}{dt}\mathbf{r}'(t) + \left[\frac{d}{dt}R^z(-\omega t)\right]\mathbf{r}'(t)\\ &= R^z(-\omega t)\frac{d}{dt}\mathbf{r}'(t) + R^z(-\omega t)\left[\vec{\omega}\times\mathbf{r}'(t)\right]\\ &= R^z(-\omega t)\frac{d}{dt}\mathbf{r}'(t) + \vec{\omega}\times R^z(-\omega t)\mathbf{r}'(t)\\ &= R^z(-\omega t)\mathbf{v}'(t) + \vec{\omega}\times\mathbf{r}(t)\ .\end{aligned}$$

We easily check,

$$\begin{aligned}\mathcal{R}_z(-\omega t)\mathbf{v}'(t) + \vec{\omega}\times\mathbf{r}(t) &= \begin{pmatrix}\cos\omega t & -\sin\omega t & 0\\ \sin\omega t & \cos\omega t & 0\\ 0 & 0 & 1\end{pmatrix}\begin{pmatrix}\Omega R\cos\Omega t\\ 0\\ -\Omega R\sin\Omega t\end{pmatrix} + \begin{pmatrix}0\\0\\\omega\end{pmatrix}\times\begin{pmatrix}R\sin\Omega t\cos\omega t\\ R\sin\Omega t\sin\omega t\\ R\cos\Omega t\end{pmatrix}\\ &= \begin{pmatrix}\Omega R\cos\Omega t\cos\omega t - \omega R\sin\Omega t\sin\omega t\\ \Omega R\cos\Omega t\sin\omega t + \omega R\sin\Omega t\cos\omega t\\ -\Omega R\sin\Omega t\end{pmatrix}\ .\end{aligned}$$

The value after 12 h *is* $|\mathbf{v}(t)| = \sqrt{\omega^2R^2\sin^2\Omega t + v_0^2} = \sqrt{\omega^2R^2\sin^2\frac{1}{2}\pi + (\Omega R)^2} = R\sqrt{\omega^2+\Omega^2} = R\sqrt{\omega^2+(\frac{1}{2}\omega)^2} = 6730\,\text{km}\cdot\frac{2\pi}{24\,\text{h}}\sqrt{\frac{5}{4}} = 547\,\text{m/s}$.

3.1.4.5 Ex: Inertial forces

A car travels at a speed $v = 100\,\text{km/h}$ from São Carlos (latitude $\theta = -22°$) to Ribeirão Preto, which is north of São Carlos.
a. Calculate the value of the Coriolis acceleration. In which direction is the car deviated?
b. Calculate the centrifugal force knowing that the radius of the Earth is 6370 km.

Solution: *a. The Coriolis force is*

$$\vec{a}_{Cor} = -2\vec{\omega}\times\mathbf{v} = -2\hat{\mathbf{e}}_\phi\frac{2\pi}{T_{dia}}v\sin\theta = 1.5\cdot10^{-4}g\hat{\mathbf{e}}_\phi\ .$$

Deviation to the left.
b. The centrifugal force is,

$$\vec{a}_{cen} = -2\vec{\omega}\times(\vec{\omega}\times\mathbf{r}) = -2\hat{\mathbf{e}}_\rho\omega^2R\sin(90°-\theta) = 2\hat{\mathbf{e}}_\rho\left(\frac{2\pi}{T_{dia}}\right)^2R\cos\theta = 6.4\cdot10^{-3}\,\text{g}\ .$$

3.1.4.6 Ex: Foucault's pendulum

A pendulum of mass $m = 7\,\mathrm{kg}$ and length $L = 6\,\mathrm{m}$ is deflected by the angle $\beta = 4°$ and then released. The experiment takes place at a latitude of $\Phi = 51°$ north.
a. How strong is the Coriolis force when passing through the rest position?
b. What is the radius of curvature r of the projection of the pendulum's path onto the horizontal base at the rest point?
c. How long is the oscillation period T of a full rotation of the pendulum plane in the lab frame?

Solution: *a. The velocity v_0 of the pendulum at zero crossing is, with the help of the energy conservation law, given by,*

$$\frac{m}{2}v_0^2 = mgl(1-\cos\beta)$$

or

$$v_0 = \sqrt{2gl(1-\cos\beta)}\ .$$

Hence,

$$F_C = 2mv_0\omega' = 2m\sqrt{2gl(1-\cos\beta)}\omega'\ .$$

The effective component ω' of the angular velocity at the location of the latitude Φ is,

$$\omega' = \frac{2\pi}{d^*}\sin\Phi\ ,$$

where $d^* = 86164\,\mathrm{s}$ is the duration of a sidereal day, which is slightly different from $d = 24\cdot 3600\,\mathrm{s} = 86400\,\mathrm{s}$. Therefore follows for the Coriolis force at zero crossing,

$$F_C = \frac{4\pi m}{d^*}\sin\Phi\sqrt{2gl(1-\cos\beta)} \approx 4.25\cdot 10^{-4}\,\mathrm{N}\ .$$

b. The Coriolis force is equal to the centrifugal force of the horizontal movement, i.e.,

$$F_C = 2mv_0\omega' = F_Z = \frac{m}{r}v_0^2\ .$$

From this we calculate the radius of curvature to be,

$$r = \frac{v_0}{2\omega'} = \frac{d^*}{4\pi\sin\Phi}\sqrt{2gl(1-\cos\beta)} \approx 5\,\mathrm{km}\ .$$

c. One gets a full turn for $T = d^*/\sin\Phi \approx 30.8\,\mathrm{h}$.

3.1.4.7 Ex: Earth rotation

a. A car with the mass $m = 1000\,\mathrm{kg}$ stands on the equator of the Earth. What is the total force acting on the car, and in which direction does it point? Assume the Earth to be a sphere with radius $R_{earth} = 6370\,\mathrm{km}$. The angular velocity is $\omega_{earth} = 7.27\cdot 10^{-5}\,\mathrm{s^{-1}}$.
b. Now the car is traveling eastwards at a speed $v = 100\,\mathrm{km/h}$ along the equator. What total force is acting on it, and which direction does this force have?

Figure 3.1: Earth rotation.

c. How fast would the car have to travel eastwards along the equator to lift off the surface of the Earth?

Solution: *a. When the car is stands still, only gravity and centrifugal force act on it,* $\mathbf{F}_g = -mg\hat{\mathbf{e}}_r$ *and*

$$\mathbf{F}_Z = -m\vec{\omega} \times (\vec{\omega} \times \mathbf{r}) = -m[\vec{\omega} \cdot (\vec{\omega} \cdot \mathbf{r}) - \mathbf{r} \cdot (\vec{\omega} \cdot \vec{\omega})] = m\omega^2 r\hat{\mathbf{e}}_r \ .$$

That is, all in all,

$$\mathbf{F}_{ges} = (-mg + m\omega^2 r)\hat{\mathbf{e}}_r \ .$$

b. Now, three forces act along the equator in an eastward direction $\mathbf{F}_g = -mg\hat{\mathbf{e}}_r$, $\mathbf{F}_Z = +m\left(\frac{v^2}{R} + \omega^2 R\right)\hat{\mathbf{e}}_r$, $\mathbf{F}_C = +2m\omega v\hat{\mathbf{e}}_r$. *It should be noted here, that the centrifugal acceleration is increased when traveling in the east direction, since the Earth also rotates in the east direction. So overall,*

$$\mathbf{F}_{ges} = m\left(-g + \frac{v^2}{R} + \omega^2 R + 2\omega v\right)\hat{\mathbf{e}}_r \ .$$

c. For the car to take off, the sum of all forces acting on it must disappear, i.e.,

$$-mg + m\left(\omega^2 R + \frac{v^2}{R}\right) + 2m\omega v = 0 \ .$$

Resolved by the speed v *we get,*

$$v = -R\omega \pm \sqrt{Rg} \ .$$

Hence, $v_{West} = -8.37\,\mathrm{km/s}$ *and* $v_{Ost} = 7.44\,\mathrm{km/s}$.

3.1.4.8 Ex: Spinning top in a horizontal plane

Discuss the spinning top on a horizontal plane. What happens when the plane is inclined?

Solution:

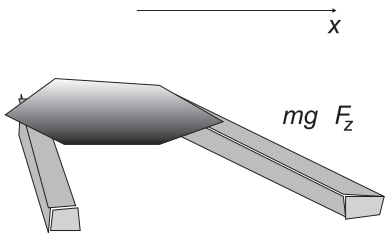

Figure 3.2: Spinning top.

3.1.4.9 Ex: Inertial forces

a. Calculate the correction for the weight of a mass m at rest at the equator due to centrifugal force. Does the centrifugal force modify the falling time for a mass released at a height above the Earth?
b. What are the value and orientation of the Coriolis acceleration acting on a body at the north pole moving with the speed $v = 100\,\mathrm{m/s}$ to the south?
c. Calculate the deviation due to the Coriolis force for a body falling at the equator from a height of $h = 100\,\mathrm{m}$.

Solution: *a. With* $\omega = \frac{2\pi}{1\,\mathrm{d}}$ *we find,*

$$\mathbf{F}_{centr} = -m\vec{\omega} \times (\vec{\omega} \times \mathbf{r}) = m\omega^2 r\hat{\mathbf{e}}_r \ .$$

This gives, $\Delta g = 0.0034\,\mathrm{g}$. *However, the force does not act on free masses.*
b. With $\omega = \frac{2\pi}{1\,\mathrm{d}}$

$$\mathbf{F}_{Cor} = -2m\vec{\omega} \times \mathbf{v} = -2m\omega v\hat{\mathbf{e}}_\phi \ .$$

The force acts towards east and has the value $a_{Cor} = 0.015\,\mathrm{m/s}$.
c. The Coriolis force can be approximated (the deviation from the vertical path is negligible),

$$\mathbf{F}_{Cor} = -2m\vec{\omega} \times \vec{v} \simeq m\vec{a}_{Cor}$$

with $a_{Cor} = 2\omega v_{grv}$. *The fall time and the instantaneous speed are,*

$$t_1 = \sqrt{\frac{2h}{g}} \qquad \textit{and} \qquad v_{grv} = gt \ .$$

So, we get the speed,

$$v_{Cor} = \int_0^t a_{Cor}dt = \int_0^t 2\omega g t dt = 2\omega g\frac{t^2}{2}$$

and the deviation,

$$s_{Cor} = \int_0^{t_1} v_{Cor}dt = \frac{1}{3}\omega g t_1^3 \ .$$

3.1.4.10 Ex: Carousel

A vertical bar rotates around the z-axis at a constant angular velocity ω. A thread of length l is attached to the upper end of the rod, while a mass m is attached to the other end of the thread.
a. Find the tension that acts on the thread.
b. Find the angle between thread and bar in equilibrium.

Solution: *Gravity is* $\mathbf{F}_g = -mg\hat{\mathbf{e}}_z$*, the centrifugal force is* $\mathbf{F}_z = -m\vec{\omega} \times (\vec{\omega} \times \mathbf{r})$ *and the tension of the thread is* $\mathbf{F}_T = -T\sin\phi\hat{\mathbf{e}}_x + T\cos\phi\hat{\mathbf{e}}_z$*. With,*

$$\mathbf{r} = l[\sin\phi\hat{\mathbf{e}}_x + (1-\cos\phi)\hat{\mathbf{e}}_z] \ ,$$

follows,

$$\mathbf{F}_g = m\omega^2 l\sin\phi\hat{\mathbf{e}}_x \ .$$

In equilibrium of forces,

$$0 = -mg\hat{\mathbf{e}}_z + m\omega^2 l\sin\phi\hat{\mathbf{e}}_x - T\sin\phi\hat{\mathbf{e}}_x + T\cos\phi\hat{\mathbf{e}}_z \ .$$

The equations for the components are,

$$m\omega^2 l\sin\phi - T\sin\phi = 0 \qquad \textit{and} \qquad T\cos\phi - mg = 0 \ .$$

One solution to the first equation is $\sin\phi = 0$*, when the centrifugal force vanishes. Otherwise we find,*

$$T = m\omega^2 l \qquad \textit{and} \qquad \cos\phi = \frac{g}{\omega^2 l} \ .$$

3.1.4.11 Ex: Yo-yo

A yo-yo with radius R and thickness D is accelerated in the field of terrestrial attraction.
a. Determine the inertial moments with respect to the yo-yo's symmetry axis and to the instantaneous point of suspension on the string.
b. Calculate the torque and write down the equation for the rotational motion.
c. From the equation of motion, calculate the angular and linear accelerations, the angular and linear velocities, and the angular momentum.

Solution: *a. The mass of the yo-yo is,*

$$M = \int dm = \rho\pi R^2 D \ .$$

The inertial moment with respect to the axis of symmetry is,

$$I_{cm} = \int r^2 dm = \frac{M}{2}R^2 \ .$$

The inertial moment with respect to the suspension point is,

$$I = I_{cm} + MR^2 = \frac{3M}{2}R^2 \ .$$

b. The equation of motion is,

$$\begin{aligned} I\vec{\alpha} = \vec{\tau} &= \mathbf{r} \times \mathbf{F} \\ \Leftrightarrow \quad \frac{3M}{2}R^2\alpha &= RMg \ . \end{aligned}$$

c. So we have,

$$\begin{aligned} \alpha &= \frac{2g}{3R} \quad , \quad a = R\alpha = \frac{2g}{3} \\ \omega &= \int \alpha dt = \frac{2g}{3R}t \quad , \quad v = R\alpha = \frac{2g}{3}t \\ L &= I\omega = \frac{3M}{2}R^2\frac{2g}{3R}t = MgRt = \tau t \ . \end{aligned}$$

Alternatively it is possible to use energy conservation,

$$\begin{aligned} \tfrac{d}{dt}Mgh &= \tfrac{d}{dt}\tfrac{1}{2}I\omega^2 \\ \Rightarrow Mgv &= \tfrac{1}{2}I2\omega\dot{\omega} \\ \Rightarrow MgR &= I\alpha \\ \Rightarrow \frac{2g}{3R} &= \alpha \ . \end{aligned}$$

3.1.4.12 Ex: Deviation to the east

An object is thrown up vertically at the initial speed v_0. Determine the east deflection based on the Earth's rotation as a function of latitude.

Solution: *The coordinate system is placed in the starting point of the movement so that the initial conditions are:* $\mathbf{r}(0) = 0$ *und* $\mathbf{v}(0) = z0\hat{\mathbf{e}}_z$. *z points up, y to the east and x to the south. For the eastward movement we have,*

$$\dot{y} = -2\omega(x\cos\lambda + z\sin\lambda) \ .$$

The southward movement of the body is negligible. Likewise the effect of the eastward deviation on z. We get the movement of free fall,

$$z = \frac{g}{2}t^2 + v_0 t \ .$$

Inserting into the eastward deviation,

$$\dot{y} = -2\omega\left(\frac{g}{2}t^2 + v_0 t\right)\sin\lambda \ .$$

Hence, the eastward deviation points in western direction:

$$y = 2\omega \left(\frac{g}{6} t^3 - \frac{v_0}{2} \right) \sin\lambda \ .$$

3.1.4.13 Ex: Coriolis force

A body falls in free fall at the equator of the Earth from a height of $h = 100\,\mathrm{m}$. At the beginning of the movement ($t = 0$) the body rests at the height h. Air friction is neglected. The centrifugal acceleration is already taken into account in the value of the gravitational acceleration $g = 9.81\,\mathrm{m/s^{-2}}$ relative to the Earth's surface.
a. Set up the equations of motion. Show that the path lies in a plane. What is its spatial location?
b. Solve the differential equations by combining the remaining components of $\mathbf{r}(t)$ into a complex variable $u(t)$. Pay attention to the initial conditions!
c. Give the solution $\mathbf{r}(t)$ and then approximate for small ωt (ω being the angular velocity of the Earth's rotation). Why is this approximation justified?
d. What is the distance from the real point of impact to the point that would be reached without the action of the Coriolis force? In which direction is the body deviated?

Solution: *a. In the Earth-bound system (x to the east, y to the north, z upwards):*

$$\ddot{\mathbf{r}}(t) = \mathbf{g} - 2\vec{\omega} \times \dot{\mathbf{r}}(t) - \vec{\omega} \times (\vec{\omega} \times \mathbf{r}(t)) \qquad \textit{with} \qquad \mathbf{g} = -g\hat{\mathbf{e}}_z \qquad \textit{with} \qquad \vec{\omega} = \omega \hat{\mathbf{e}}_y \ .$$

From the initial condition $\mathbf{r}(0) = h\hat{\mathbf{e}}_z$ and $\dot{\mathbf{r}}(0) = 0$ follows $\hat{\mathbf{e}}_y \cdot \mathbf{r}(t) = 0$. So the movement only takes place in the (x, z) plane.
b. In component notation,

$$\ddot{x} = -2\omega\dot{z} + \omega^2 x \qquad \textit{and} \qquad \ddot{z} = -g + 2\omega\dot{x} + \omega^2 z \ ,$$

where $\omega = \frac{2\pi}{24\,\mathrm{h}} = 7.3 \cdot 10^{-5}\,\mathrm{s^{-1}}$. Via $u(t) = z(t) + \imath x(t)$ with $u(0) = h$ and $\dot{u}(0) = 0$ one gets the complex differential equation,

$$\ddot{u} + 2\imath\omega\dot{u} - \omega^2 u = -g \ ,$$

with the particular solution $u_{part} = g/\omega^2$. The homogeneous ansatz $u_{hom} \sim e^{\lambda t}$ provides the characteristic equation $\lambda^2 + 2\imath\omega\lambda - \omega^2 = 0$ with the solution $\lambda = -\imath\omega$. From this follows,

$$\begin{aligned} u(t) &= g/\omega^2 + (A + Bt)e^{-\imath\omega t} \qquad \textit{and} \qquad \dot{u}(t) &&= [B - \imath\omega(A + Bt)]e^{-\imath\omega t} \\ \Rightarrow \quad A &= h - g/\omega^2 \qquad \textit{and} \qquad B &&= \imath\omega A = \imath\omega(h - g/\omega^2) \ . \end{aligned}$$

Finally,

$$u(t) = g/\omega^2 + (h - g/\omega^2)(1 + \imath\omega t)e^{-\imath\omega t} \ .$$

c. The real components,

$$\begin{aligned} z(t) &= g/\omega^2 + (h - g/\omega^2)[\cos\omega t + \omega t \sin\omega t] \\ x(t) &= (h - g/\omega^2)[-\sin\omega t + \omega t \cos\omega t] \end{aligned}$$

with the expansion of $\omega t \ll 1$*:*

$$\cos\omega t + \omega t \sin\omega t = 1 + \frac{1}{2}\omega^2 t^2 + \mathcal{O}(\omega^4 t^4)$$
$$-\sin\omega t + \omega t \cos\omega t = -\frac{1}{3}\omega^3 t^3 + \mathcal{O}(\omega^5 t^5) \ ,$$

become,

$$z(t) \approx h - \frac{1}{2}gt^2 \qquad \textit{and} \qquad x(t) \approx \frac{1}{3}g\omega t^3$$

d. Drop time T *and deviation* $x(T)$*:*

$$T = \sqrt{\frac{2h}{g}} = 4.5\,\mathrm{s} \qquad \textit{and} \qquad x(T) = \frac{1}{3}g\omega T^3 = 2.2\,\mathrm{cm} \ .$$

Note: *If we omit the terms* $\mathcal{O}(\omega^2)$ *from the equations of motion, the DEq system can be solved trivially.*

3.1.4.14 Ex: Coriolis force

A penguin with the mass m is located directly at the South Pole and begins to slide horizontally at the initial velocity v on the ice. The ice slows him down with the force $\mathbf{F} = -\gamma\mathbf{v}$.
a. Write down the equations of motion in a coordinate system originating at the south pole, which rotates with the Earth.
Note: Place the x-axis in the direction of the penguin's initial velocity and combine the variables x and y to a complex variable $z = x + \imath y$. Neglect the curvature of the Earth. b. Calculate the end position of the penguin on the assumption that the

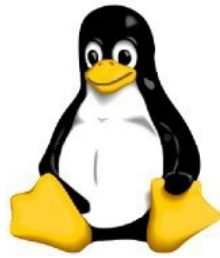

Figure 3.3: Coriolis force.

rotation speed of the earth ω is small enough to neglect quadratic terms $\propto \omega^2$ in the equations of motion or in their solution.

Solution: *a. In the rotating system* $\vec{\omega} = (0, 0, \omega)$ *the equation of motion is,*

$$\ddot{r}' = -\frac{\gamma}{m}\mathbf{r} \ .$$

Hence, in the lab system,

$$\left(\frac{d}{dt}-\vec{\omega}\times\right)\left(\frac{d}{dt}-\vec{\omega}\times\right)\mathbf{r}=-\frac{\gamma}{m}\mathbf{r}\ .$$

From this follows,

$$\mathbf{r}-2\vec{\omega}\times\mathbf{r}+\vec{\omega}\times(\vec{\omega}\times\mathbf{r})=-\frac{\gamma}{m}\mathbf{r}\ .$$

For the x- resp. y-components the equations of motion are,

$$\begin{aligned}\ddot{x}&=-\frac{\gamma}{m}\dot{x}+\omega^2x-2\omega\dot{y}\\ \ddot{y}&=-\frac{\gamma}{m}\dot{y}+\omega^2y+2\omega\dot{x}\ ,\end{aligned}$$

wheres the second and third terms represent centripetal and Coriolis force, $z=x+\imath y$, hence,

$$\begin{aligned}\ddot{z}&=-\tilde{\gamma}\dot{z}+\omega^2z+2\imath\omega\dot{z}\qquad z=Ce^{\lambda t}\\ \lambda^2&=-\tilde{\gamma}\lambda+\omega^2+2\imath\omega\lambda\qquad z=Ae^{\lambda_1 t}+Be^{\lambda_2 t}\\ \lambda_{1,2}&=\frac{-\tilde{\gamma}+2\imath\ \omega\pm\sqrt{\tilde{\gamma}^2-4\imath\tilde{\gamma}\omega}}{2}\ ,\end{aligned}$$

where $\tilde{\gamma}=\gamma/m$. $x=\mathfrak{Re}\ z$ and $y=\mathfrak{Im}\ z$ will be damped sine/cosine.
b. The equation resp. solution will be,

$$\begin{aligned}\ddot{z}&=-\tilde{\gamma}\dot{z}+2\imath\omega\dot{z}\qquad z=Ce^{\lambda t}\\ \lambda^2&=-\tilde{\gamma}\lambda+2\imath\omega\lambda\qquad z=Ae^{\lambda_1 t}+Be^{\lambda_2 t}\\ \lambda_{1,2}&=\frac{-\tilde{\gamma}+2\imath\omega\pm(\tilde{\gamma}-2\imath\omega)}{2}\to\lambda_1=0\quad\lambda_2=-\tilde{\gamma}+2\imath\omega\ .\end{aligned}$$

The initial conditions $z(0)=0$, $\dot{z}(0)=v$ lead to,

$$B=-A=\frac{v}{-\tilde{\gamma}+2\imath\omega}\simeq-v\frac{\tilde{\gamma}+2\imath\omega}{\tilde{\gamma}^2}+O(\omega^2)\ .$$

For large t we have $e^{-\tilde{\gamma}t}\ll 1$ and $z\simeq A=v/\tilde{\gamma}+2\imath v\omega/\tilde{\gamma}$ such that $x(\infty)=mv/\gamma$, $y(\infty)=2mv\ \omega/\gamma$.

3.1.4.15 Ex: Center of mass

You have three rectangular blocks of same heights and depths, but with different lengths and different masses. You want to build an inclined tower with them. Determine experimentally or theoretically how to stack the blocks so that the top block overhangs as much as possible. What is the most favorable order in the case of same masses but different lengths? What is the most advantageous order in the case of same lengths but different masses?

Solution: *Let x_{sj} be the center-of-masses points of the individual blocks. In order for the uppermost block $j = 3$ to remain on the middle block $j = 2$, the following must apply,*

$$\frac{m_3(x_{s3} - x_{s2})}{m_3} < \frac{1}{2}L_2 \ .$$

The following must apply so that the two upper blocks remain on the lower block $j = 1$,

$$\frac{m_2\,(x_{s2} - x_{s1}) + m_3\,(x_{s3} - x_{s1})}{m_2 + m_3} < \frac{1}{2}L_1 \ .$$

Let the origin be fixed by $x_{s1} = 0$. Then by eliminating x_{s2} we get from (1) and (2),

$$x_{s3} < \frac{L_1}{2} + \frac{m_2}{m_2 + m_3}\frac{L_2}{2} \ .$$

So the overhang is,

$$\ddot{u} = x_{s3} + \frac{L_3}{2} < \frac{L_1}{2} + \frac{m_2}{m_2 + m_3}\frac{L_2}{2} + \frac{L_3}{2} \ .$$

In the case of equal lengths,

$$\ddot{u} < L\left(1 + \frac{1}{2}\frac{m_2}{m_2 + m_3}\right) \ ,$$

it makes sense to put the light mass on top of the heavy one, $m_3 < m_2$. In the case of equal masses,

$$\ddot{u} < \frac{L_1}{2} + \frac{L_2}{4} + \frac{L_3}{2} \ ,$$

it makes sense to put the longer block on top of the shorter one, $L_3 > L_2$.

3.1.4.16 Ex: Inclined pyramid

Five identical point masses m are arranged at the corners of an oblique pyramid with the height H and a square base area $F = a^2$, i.e. they are located at $(x, y, z) = (\pm a/2, \pm a/2, 0)$ and $(b, 0, H)$. What is the maximum lateral displacement b of the top of the pyramid so that the pyramid does not tip out of the horizontal xy-plane?

Solution: *The mass of the pyramid is $M = 5m$. The center of gravity vector of a discrete mass distribution is given by,*

$$\mathbf{S} = \frac{\sum m_j \mathbf{r}_j}{\sum m_j} \ .$$

For the given pyramid,

$$\mathbf{S} = \frac{1}{M}\sum_{j=1}^{5} m\mathbf{r}_j = \frac{1}{M}\left(m(H\hat{\mathbf{e}}_z + b\hat{\mathbf{e}}_x) + m\sum_{j=1}^{4}\mathbf{r}_j\right) = \frac{1}{M}m(H\hat{\mathbf{e}}_z + b\hat{\mathbf{e}}_x) = \frac{H\hat{\mathbf{e}}_z + b\hat{\mathbf{e}}_x}{5} \ .$$

Now the axis is tilted from the center of the base to the top of the pyramid by an angle α. It falls over when $\mathbf{S}\hat{\mathbf{e}}_x > \frac{a}{2}$, hence,

$$\frac{H\hat{\mathbf{e}}_z + b\hat{\mathbf{e}}_x}{5}\hat{\mathbf{e}}_x > \frac{a}{2} \ ,$$

hence $b > 2.5a$.

3.1.4.17 Ex: Inclined cone

A rigid cone with a homogeneous mass distribution has the height H and a base area with a radius R. How far can you tilt the cone before it falls over?

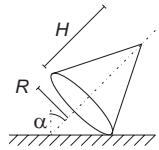

Figure 3.4: Inclined cone.

Solution: *The mass of the cone is,*

$$m = \rho_0 \int_{cone} d^3\mathbf{r} = \rho_0 \int_0^H \int_0^{2\pi} \int_0^{R-Rz/H} \rho d\rho d\phi dz = 2\pi\rho_0 \int_0^H \int_0^{R-Rz/H} \rho d\rho dz$$
$$= 2\pi\rho_0 \int_0^H \frac{(R-Rz/H)^2}{2} dz = 2\pi\rho_0 R^2 \left[\frac{z}{2} - \frac{z^2}{2H} + \frac{z^3}{6h^2}\right]_0^H = \frac{\pi}{3}\rho_0 R^2 H \ .$$

The center of gravity vector of a continuous mass distribution $\rho(\mathbf{r})$ is given by,

$$\mathbf{S} = \frac{\int \rho(\mathbf{r})\mathbf{r}d^3\mathbf{r}}{\int \rho(\mathbf{r})d^3\mathbf{r}} \ .$$

For a homogeneous cone,

$$\mathbf{S} = \frac{\rho_0}{m}\int_{cone} \mathbf{r}d^3\mathbf{r} = \frac{\rho_0}{m}\int_0^H \int_0^{2\pi} \int_0^{R-Rz/H} \begin{pmatrix} \rho\cos\phi \\ \rho\sin\phi \\ z \end{pmatrix} \rho d\rho d\phi dz$$

$$= 2\pi\frac{\rho_0}{m}\int_0^H \begin{pmatrix} 0 \\ 0 \\ z \end{pmatrix} \int_0^{R-Rz/H} \rho d\rho dz = 2\pi\frac{\rho_0}{m}\hat{\mathbf{e}}_z \int_0^H z\frac{(R-Rz/H)^2}{2} dz$$

$$= 2\pi\frac{\rho_0}{m}R^2\hat{\mathbf{e}}_z \left[\frac{z^2}{4} - \frac{2z^3}{6H} + \frac{R^2z^4}{8H^2}\right]_0^H = \frac{\pi}{12}\frac{\rho_0}{m}R^2H^2\hat{\mathbf{e}}_z = \frac{H}{4}\hat{\mathbf{e}}_z \ .$$

Now the cone is tilted by the angle α. It falls over when $S\sin\alpha > R\cos\alpha$, hence,

$$\arctan\alpha > \frac{H}{4R} \ .$$

3.1.4.18 Ex: Angular momentum of the Earth

a. Calculate the angular momentum of the Earth's rotation around its center of mass (mass $M = 5.97 \times 10^{24}\,\mathrm{kg}$, radius $R = 6370\,\mathrm{km}$).
b. Compare this with the angular momentum of the Earth's rotation around the sun (distance between Sun and Earth $D = 150 \times 10^{9}\,\mathrm{km}$).

Solution: *a. The angular momentum is,*

$$\mathbf{L} = I\vec{\omega} \ .$$

With the inertial moment $I = \frac{2}{5}MR^2$ *we obtain,*

$$L = I\omega = \frac{2}{5}MR^2\frac{2\pi}{60\cdot 60\cdot 24\,\mathrm{s}} = 7.0\cdot 10^{33}\,\mathrm{kg\ m^2\,s^{-1}} \ .$$

b. The inertial moment is now $I = MD^2$*. Hence,*

$$L = I\omega = MD^2\frac{2\pi}{60\cdot 60\cdot 24\cdot 365\,\mathrm{s}} = 4.8\cdot 10^{31}\,\mathrm{kg\ m^2\,s^{-1}} \ .$$

3.1.4.19 Ex: Inertial moment

a. Calculate the mass of a cone with homogeneous density (height H and a base radius R).
b. Calculate the cone's inertial moment with respect to the symmetry axis.
c. The cone now rotates with the frequency ω around an axis displaced by a distance R parallel to the symmetry axis. How to calculate the angular momentum?

Solution: *a. The cone mass is,*

$$\begin{aligned} M &= \int dm = \rho\int_0^{2\pi}\int_0^{H}\int_0^{R-zR/H} r dr dz d\phi = 2\pi\rho\int_0^{H}\tfrac{1}{2}\left(R-\frac{R}{H}z\right)^2 dz \\ &= -2\pi\rho\frac{H}{R}\int_R^0 \tfrac{1}{2}\zeta^2 d\zeta = \pi\rho\frac{H}{R}\frac{1}{3}R^3 = \frac{\pi\rho}{3}HR^2 \ . \end{aligned}$$

b. The inertial moment is,

$$\begin{aligned} I_{cm} &= \int dm = \rho\int_0^{2\pi}\int_0^{H}\int_0^{R-zR/H} r^2 r dr dz d\phi = 2\pi\rho\int_0^{H}\tfrac{1}{4}\left(R-\frac{R}{H}z\right)^4 dz \\ &= -2\pi\rho\frac{H}{R}\int_R^0 \tfrac{1}{4}\zeta^4 d\zeta = \frac{\pi}{2}\rho\frac{H}{R}\frac{1}{5}R^5 = \frac{3}{10}MR^2 \ . \end{aligned}$$

c. The angular momentum is,

$$L = I\omega = (I_{cm} + MR^2)\omega = \frac{13}{10}MR^2 \ .$$

3.1.4.20 Ex: Glass of beer

A cylindrical glass of beer (height $H = 18\,\text{cm}$, diameter $D = 6\,\text{cm}$, mass $m_G = 0.5\,\text{kg}$, the bottom is without mass) has, when empty, its center of mass exactly halfway up. Obviously, it is there too, when the glass is filled with beer (density $\rho = 1000\,\text{kg/m}^3$) up to the upper limit. Down to which height h do you have to drink the beer for the center of mass to be at its lowest height?

Solution: *Be h the wanted height of beer. Then the beer mass is,*

$$m_B = \frac{\pi D^2}{4} h\rho \ .$$

The center of mass of the beer is at $h/2$, that of the glass at $H/2$. The total center of mass is at,

$$S = \frac{\frac{H}{2}m_G + \frac{h}{2}m_B}{m_G + m_B} = \frac{\frac{H}{2}m_G + \frac{h}{2}\frac{\pi D^2}{4}h\rho}{m_G + \frac{\pi D^2}{4}h\rho} = \frac{4Hm_G + \pi D^2\rho h^2}{8m_G + 2\pi D^2\rho h} \ .$$

With $dS/dh = 0$ we find,

$$\begin{aligned} 2\pi D^2\rho h\left(8m_G + 2\pi D^2\rho h\right) - \left(4Hm_G + \pi D^2\rho h^2\right)2\pi D^2\rho &= 0 \\ 2\pi^2 D^4\rho^2 h^2 + 16\pi m_G\rho D^2 h - 8\pi m_G\rho D^2 H &= 0 \\ h^2 + \frac{8m_G}{\pi D^2\rho}h - \frac{4m_G}{\pi D^2\rho}H &= 0 \\ h = -\frac{4m_G}{\pi D^2\rho} + \frac{4m_G}{\pi D^2\rho}\sqrt{1 + \frac{\pi D^2\rho H}{4m_G}} &> 0 \ . \end{aligned}$$

Therefore, the height is $h = 7.44\,\text{cm}$.

3.1.4.21 Ex: Inertial moment

Consider a flat symmetrical triangle with surface density σ and corner length a. Fix the coordinate system such that the triangle is given by the corners $A = (0, \frac{a}{2})$, $B = (0, -\frac{a}{2})$ e $C = (\frac{a\sqrt{3}}{2}, 0)$.
a. Calculate the mass of the triangle.
b. Calculate the center of mass.
c. Calculate the inertial moment with respect to an axis normal to the surface through the center of mass of the triangle.

Solution: *a. The mass is,*

$$M = 2\sigma\int_0^{a/2}\int_0^{\sqrt{3}(a/2-y)} dxdy = 2\sigma\int_0^{a/2}\sqrt{3}\left(\tfrac{a}{2} - y\right)dy = 2\sigma\sqrt{3}\left[\tfrac{a}{2}y - \tfrac{1}{2}y^2\right]_0^{a/2} = \sigma\sqrt{3}\frac{a^2}{4} \ .$$

b. The center of mass is given by,

$$x_{cm} = \frac{\int\int \sigma x dxdy}{\int\int \sigma dxdy} = \frac{1}{M} 2\sigma \int_0^{a/2} \int_0^{\sqrt{3}(a/2-y)} x dxdy = \frac{2\sigma}{M} \int_0^{a/2} \tfrac{1}{2}\sqrt{3}^2 \left(\tfrac{a}{2} - y\right)^2 dy$$
$$= \frac{3\sigma}{M} \frac{1}{24} a^3 = \frac{a}{2\sqrt{3}}$$
$$y_{cm} = 0 \ .$$

c. The inertial moment with respect to an axis crossing the origin is,

$$I_0 = \int r^2 dm = 2\sigma \int_0^{a/2} \int_0^{\sqrt{3}(a/2-y)} (x^2+y^2) dxdy = 2\sigma \int_0^{a/2} \left[\tfrac{1}{3}\sqrt{3}^3 (\tfrac{a}{2}-y)^3 + \sqrt{3}(\tfrac{a}{2}-y)y^2\right] dy$$
$$= 2\sigma\sqrt{3} \int_0^{a/2} \left[(\tfrac{a}{2}-y)^3 + (\tfrac{a}{2}-y)y^2\right] dy = \tfrac{2\sigma\sqrt{3}}{48} a^4 = \tfrac{M}{6} a^2 \ .$$

And the inertial moment with respect to an axis crossing the center of mass is,

$$I = I_{cm} + I_0 = M \left(\frac{a}{2\sqrt{3}}\right)^2 + \tfrac{M}{6} a^2 = \frac{M}{4} a^2 \ .$$

3.1.4.22 Ex: Inertial moment

Consider a flat arc segment with surface density σ, radius R, and angle ϕ. Fix the coordinate system at the center of the arc such that the axis of symmetry is x.
a. Calculate the mass of the segment.
b. Calculate the center of mass.
c. Calculate the inertial moment with respect to a normal axis at the surface through the center of mass of the segment.

Solution: *a. The mass is,*

$$M = \sigma \int_{-\phi/2}^{\phi/2} \int_0^R r dr d\phi = \sigma \frac{R^2}{2} \phi \ .$$

b. The center of mass is given by,

$$x_{cm} = \frac{\int\int \sigma x dxdy}{\int\int \sigma dxdy} = \frac{\sigma}{M} \int_{-\phi/2}^{\phi/2} \int_0^R x r dr d\phi = \frac{\sigma}{M} \int_{-\phi/2}^{\phi/2} \int_0^R r^2 \cos\phi dr d\phi = \frac{\sigma}{M} \frac{R^3}{3} \int_{-\phi/2}^{\phi/2} \cos\phi d\phi$$
$$= \frac{2\sigma}{3M} R^3 \sin\frac{\phi}{2} = \frac{4R}{3\phi} \sin\frac{\phi}{2}$$
$$y_{cm} = 0 \ .$$

c. The inertial moment with respect to an axis crossing a corner is,

$$I_0 = \int r^2 dm = \sigma \int_{-\phi/2}^{\phi/2} \int_0^R r^3 dr d\phi = \sigma \frac{R^4}{4} \phi = \frac{M}{2} R^2 \ .$$

And the inertial moment with respect to an axis crossing the center of mass is,

$$I = I_{cm} + I_0 = Mx_{cm}^2 + \frac{M}{2}R^2 = M\left(\frac{4R}{3\phi}\sin\frac{\phi}{2}\right)^2 + \frac{M}{2}R^2 = \frac{M}{2}R^2\left[1 + \frac{32}{9\phi^2}\sin^2\tfrac{\phi}{2}\right] .$$

3.1.4.23 Ex: Inertial tensor

Calculate the moment of inertia of a homogeneous hollow cylinder with mass m, length L, outer radius R, and inner radius r.

Solution: *The mass of the hollow cylinder is,*

$$m = \pi\varrho_0 L(R^2 - r^2) .$$

The inertia tensor is for continuous systems given by,

$$I_{ij} = \int_V \varrho(\mathbf{r})\left[\delta_{ij}\mathbf{r}^2 - x_i x_j\right] dV .$$

So for a hollow cylinder with length L, outer radius R, and inner radius r,

$$\begin{aligned} I_{33} &= \varrho_0 \int_{hollow\ \ cylinder} \left(x^2 + y^2\right) dV = \varrho_0 \int_0^{2\pi}\int_{-L/2}^{L/2}\int_r^R \rho^2 \rho d\rho dz d\phi \\ &= \pi\varrho_0 L\frac{R^4 - r^4}{2} = \frac{m}{2}(R^2 + r^2) . \end{aligned}$$

For I_{11} and I_{22} one gets,

$$\begin{aligned} I_{11} + I_{22} &= \varrho_0 \int_{hollow\ \ cylinder} \left(x^2 + y^2 + 2z^2\right) dV = I_{33} + 2\varrho_0 \int_0^{2\pi}\int_{-L/2}^{L/2}\int_r^R z^2 \rho d\rho dz d\phi \\ &= \frac{m}{2}(R^2 + r^2) + \frac{m}{6}L^2 = 2I_{11} = 2I_{22} . \end{aligned}$$

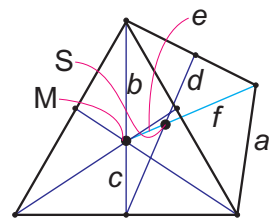
For the non-diagonal elements one gets,

$$I_{i\neq j} = \int_V \rho(\mathbf{r}) x_i x_j dV = \rho\int_{-d/2}^{d/2} x_i x_j dx_i dx_j dx_k = 0 .$$

3.1.4.24 Ex: Inertial tensor

Determine the tensor of inertia for
a. a tetrahedron in which the mass is distributed equally between the corner points in a coordinate system in which the z-axis passes through the center of opposite edges;
b. of the tetrahedron in a coordinate system in which the z-axis passes through one of its corners and through its center of gravity.

Solution:



Tetraeder. If the tetrahedron has the edge length of a, then the distance of the center M of a facet from a corner of the same facet is $b = \frac{a}{2\cos 30^\circ} = a\frac{\sqrt{3}}{3}$. *The distance of the center of a facet to an edge of the same facet is* $c = \frac{a}{2}\tan 30^\circ = a\frac{\sqrt{3}}{6}$. *The distance of the center of gravity of the tetrahedron from the edges is* $d = \frac{1}{2}\sqrt{(b+c)^2 - \frac{a^2}{4}} = a\frac{\sqrt{2}}{4}$. *The distance of the center of gravity to the center of the facets is* $e = \sqrt{d^2 - c^2} = \frac{a}{2\sqrt{6}}$. *The distance of the corners from the center of gravity is* $f = \sqrt{d^2 + \frac{a^2}{4}} = \frac{a}{2}\sqrt{\frac{3}{2}}$, *such that for every corner* α *holds* $\mathbf{r}_\alpha^2 = \frac{3}{8}a^2$.
The inertial tensor is for point-like systems,

$$I_{ij} = \sum_\alpha m_\alpha \left(\delta_{ij}\mathbf{r}_\alpha^2 - x_\alpha^{(i)} x_\alpha^{(j)}\right) = \begin{pmatrix} \sum_\alpha m_\alpha \left(\mathbf{r}_\alpha^2 - x_\alpha^2\right) & -\sum_\alpha m_\alpha x_a y_\alpha & -\sum_\alpha m_\alpha x_a z_\alpha \\ -\sum_\alpha m_\alpha x_a y_\alpha & \sum_\alpha m_\alpha \left(\mathbf{r}_\alpha^2 - y_\alpha^2\right) & -\sum_\alpha m_\alpha y_a z_\alpha \\ -\sum_\alpha m_\alpha x_a z_\alpha & -\sum_\alpha m_\alpha y_a z_\alpha & \sum_\alpha m_\alpha \left(\mathbf{r}_\alpha^2 - z_\alpha^2\right) \end{pmatrix} .$$

a. Placing the coordinate system so that the z-axis cuts two opposite edges in their center and the x-axis runs parallel to one of the edges, then the points of the tetrahedron are at $(\pm a/2, 0, d)$ *and* $(0, \pm a/2, -d)$,

$$I = m\begin{pmatrix} 4\frac{3a^2}{8} - \frac{a^2}{4} - \frac{a^2}{4} - 0 - 0 & 0 & 0 \\ 0 & 4\frac{3a^2}{8} - 0 - 0 - \frac{a^2}{4} - \frac{a^2}{4} & 0 \\ 0 & 0 & 4\frac{3a^2}{8} - \frac{a^2}{8} - \frac{a^2}{8} - \frac{a^2}{8} - \frac{a^2}{8} \end{pmatrix} = ma^2\mathbf{1}_3 .$$

b. Placing the coordinate system so that the z-axis goes through one corner of the tetrahedron and through its center of gravity and the x-axis points towards a second corner, then the points of the tetrahedron at $(0, 0, f)$, $(0, b, -e)$ *and* $(\pm a/2, -c, -e)$,

$$I = m\begin{pmatrix} 4\frac{3a^2}{8} - 0 - 0 - \frac{a^2}{4} - \frac{a^2}{4} & -0 - 0 + \frac{ac}{2} - \frac{ac}{2} & -0 - 0 + \frac{ae}{2} - \frac{ae}{2} \\ -0 - 0 + \frac{ac}{2} - \frac{ac}{2} & 4\frac{3a^2}{8} - 0 - b^2 - c^2 - c^2 & -0 + be - ce + ce \\ -0 - 0 + \frac{ae}{2} - \frac{ae}{2} & -0 + be - ce + ce & 4\frac{3a^2}{8} - f^2 - e^2 - e^2 - e^2 \end{pmatrix} = ma^2\mathbf{1}_3 .$$

One could have come up with it straight away, since the matrix must emerge from that of part (b) by rotation, but the unit matrix is equal into itself when it rotates, $D^t E_3 D = E_3$.

3.1.4.25 Ex: Inertial tensor

Two balls of different radii $R_1 > R_2$ and same homogeneous mass density ρ are welded together at their point of contact. Derive the moment of inertia of each individual sphere (axis of rotation through the center).
a. Where is the center-of-mass of the total system?
b. Calculate the main moments of inertia of the total system with regard to its center of gravity. **Note:** Use Steiner's theorem.

Solution: *It doesn't matter about which axis the ball is rotated; we take the z-axis.*

$$I = \int_{ball} \rho(x^2+y^2)dV = \rho \int_0^R r^2 dr \int_0^\pi \sin\theta d\theta \int_0^{2\pi} d\phi \left(r^2 \sin^2\theta \cos^2\phi + r^2 \sin\theta^2 \sin^2\phi\right)$$
$$= 2\pi\rho \frac{1}{5} R^5 \int_0^\theta d\theta \sin^3\theta = 2\pi\rho \frac{1}{5} R^5 \frac{4}{3} \ .$$

The last integral can be solved by partial integration. So the moment of inertia is, $I = \frac{8}{15}\pi\rho R^5$. *With* $\rho = M/V = M/(\frac{4}{3}\pi R^3)$ *one gets* $I = \frac{2}{5}MR^2$.
a. The center of gravity vector of the system is,

$$\mathbf{S} = \frac{M_1\mathbf{r}_1 + M_2\mathbf{r}_2}{M_1+M_2} \ .$$

The center of gravity is on the connecting line between the individual centers of the spheres. If we now place the coordinate origin in the center of sphere 1 and, for example, the x-axis along the vector connecting the two centers of the spheres, only the x-component of $\mathbf{S} \neq 0$, *namely,*

$$S_x = \frac{M_2}{M_1+M_2}(R_1+R_2) \ .$$

This shows that the center of gravity seen from the center of sphere 1 is at $\frac{M_2}{M_1+M_2}$ *of the connecting line.*
b. Let us rotate the system around an axis $\hat{\omega}$ *that goes through the center of sphere 1. Then the moment of inertia about this axis is calculated according to Steiner's theorem to* $I_\omega = I_\omega^{SP} + Mb^2$. *Note that we are looking for* I_ω^{SP}. *On the other hand, the moment of inertia when rotating around this axis is also equal to the sum of the moment of inertia of ball 1 when rotating around its center plus the moment of inertia of ball 2 when rotating around the axis through ball 1. So:*

$$I_\omega = \frac{2}{5}MR_1^2 + I_{\omega,K_2}$$

We can now calculate again I_{ω,K_2} *using the Steiner theorem:*

$$I_{\omega,K_2} = \frac{2}{5}M_2R_2^2 + M_2(R_1+R_2)^2 \ .$$

Inserting we get,

$$I_\omega = \frac{2}{5}M_1R_1^2 + I_{\omega,K_2} = \frac{2}{5}M_1R_1^2 + \frac{2}{5}M_2R_2^2 + M_2(R_1+R_2)^2$$
$$I_\omega = I_\omega^{SP} + Mb^2 = I_\omega^{SP} + (M_1+M_2)\left(\frac{M_2}{M_1+M_2}(R_1+R_2)\right)^2 \ .$$

This we can now solve by

$$I_\omega^{SP} = I_\omega - (M_1+M_2)b^2 = \frac{2}{5}M_1R_1^2 + \frac{2}{5}M_2R_2^2 + M_2(R_1+R_2)^2 - \frac{M_2}{M_1+M_2}(R_1+R_2)^2$$

The second main moment of inertia is identical to the one just calculated and the third (axis of rotation through both spherical centers) is additively composed of the individual moments of inertia of the spheres for rotations around their centers.

3.1.4.26 Ex: Rolling movement

A cylinder of mass m with radius R rolls over the ski jump shown in the figure, which has a gradient of -173% (i.e. $\tan\alpha = -1.73$). After having left the ski jump at a height of $h = H/2$, he falls in the Earth's gravity field. Compare the flight distance with the case in which the cylinder does not roll, but slides smoothly over the hill.

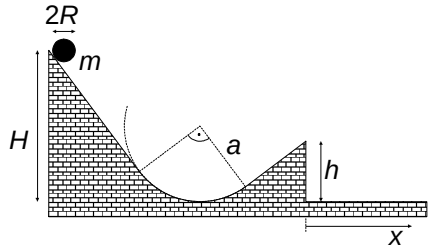


Figure 3.5: Rolling movement.

Solution: *In the event of rolling, the potential energy is converted into kinetic and rotational energy,*

$$\frac{m}{2}v^2 + \frac{I_z}{2}\omega^2 = mg(H-h) \ .$$

With $\omega = v/R$ and $I_z = mR^2/2$ one get at the take-off position $v_0 = \sqrt{\frac{4}{3}g(H-h)}$. The rotational energy is lost.
When sliding, the kinetic energy is greater at the take-off position,

$$\frac{m}{2}v^2 = mg(H-h) \ ,$$

because no rotational energy is generated, so $v_0 = \sqrt{2g(H-h)}$.
The slope angle of the ski jump is at the take-off position $\alpha + 90° = 30°$, such that,

$$\dot{x}_0 = v_0\cos(\alpha+90) = \frac{\sqrt{3}}{2}v_0 \qquad \textit{and} \qquad \dot{y}_0 = v_0\sin(\alpha+90) = \frac{1}{2}v_0 \ .$$

The flight time is given by,

$$y(t) = -\frac{g}{2}t^2 + \dot{y}_0 t + h = 0 \qquad \textit{respectively} \qquad t = \frac{1}{g}\left(\dot{y}_0 + \sqrt{\dot{y}_0^2 + 2gh}\right) \ .$$

The flight distance is then $x(t) = \dot{x}_0 t$. With $\eta = 4/3$ for the rolling motion and $\eta = 2$ for the sliding motion we can write,

$$\begin{aligned}
&x(t) = \dot{x}_0 t \\
&= \sqrt{\eta g(H-h)}\cos(\alpha+90)\tfrac{1}{g}\left(\sqrt{\eta g(H-h)}\sin(\alpha+90°) + \sqrt{\eta g(H-h)\sin(\alpha+90°)^2 + 2gh}\right) \\
&= \sqrt{\eta g\left(H-\frac{H}{2}\right)}\frac{\sqrt{3}}{2}\frac{1}{g}\left(\sqrt{\eta g\left(H-\frac{H}{2}\right)}\frac{1}{2} + \sqrt{\eta g\left(H-\frac{H}{2}\right)\frac{1}{4} + 2g\frac{H}{2}}\right) \\
&= \frac{\sqrt{3}H}{8}\left(\eta + \sqrt{\eta^2+8\eta}\right) \ .
\end{aligned}$$

The ratio is,

$$\frac{x_{roll}(t)}{x_{slide}(t)} = \frac{\frac{4}{3} + \sqrt{\left(\frac{4}{3}\right)^2 + 8 \cdot \frac{4}{3}}}{2 + \sqrt{2^2 + 8 \cdot 2}} = \frac{2}{3}\frac{1+\sqrt{7}}{1+\sqrt{5}} \simeq 0.75 \ .$$

3.1.4.27 Ex: Accelerated rotational movement

A mass $m = 1\,\mathrm{kg}$ is hanging on a light cord, which is wound on a $d = 2\,\mathrm{cm}$ thick wheel with the radius $r = 10\,\mathrm{cm}$. The wheel has a homogeneously distributed mass of $M = 10\,\mathrm{kg}$ and rotates without friction.
a. Determine the tensile force in the cord.
b. Determine the acceleration of the mass.

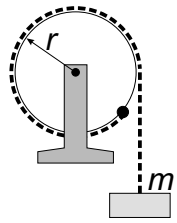

Figure 3.6: Accelerated rotational movement.

Solution: *a. The force of the weight force and the acceleration work to pull the mass m downwards, $m\mathbf{a} = m\mathbf{g} + \mathbf{Z}$. The tensile force in the cord is therefore of an amount $Z = mg - ma$.*
b. The torque is $\mathbf{D} = \frac{d}{dt}\mathbf{L}$. Hence, $\mathbf{r} \times \vec{Z} = I\frac{d}{dt}\vec{\omega}$.
Now we have $Zr = I\dot{\omega} = I\frac{d}{dt}\frac{v}{r} = I\frac{a}{r}$. Hence, $a = \frac{Zr^2}{I}$.
Now $mg - Z = m\frac{Zr^2}{I}$, also $Z = \frac{mg}{1+mr^2/I}$ respectively $a = \frac{mgr^2}{I+mr^2)}$.
The following applies to the wheel (solid cylinder): $I = \frac{1}{2}Mr^2$, thus the acceleration of the mass is $a = \frac{mgr^2}{\frac{1}{2}Mr^2+mr^2} = \frac{2m}{M+2m}g$.
c. Be H the height of the wheel axle, h the initial height of the mass m, $z(t)$ the time-dependent height of the mass.
Conservation of energy requires: $MgH + mgh = MgH + \frac{1}{2}I\omega(t)^2 + mgz(t) + mv^2(t)$.
thus $mg(h - z(t)) = \frac{1}{4}Mr^2\omega^2(t) + \frac{1}{2}mv^2(t)$.
We have $\omega = d\phi(t)/dt$ and $dz/dt = v(t) = rd\phi/dt = r\omega(t)$.
also $mg(h - z) = \frac{1}{4}Mv^2 + \frac{1}{2}mv^2 = \frac{M+2m}{4}\left(\frac{dz}{dt}\right)^2$.
Separation of the variables: $\sqrt{\frac{4mg}{M+2m}}dt = \frac{dz}{\sqrt{h-z}}$.
Integration: $\sqrt{\frac{4mg}{M+2m}}t = \left[-2\sqrt{h-\tilde{z}}\right]_z^h = 2\sqrt{h-z}$, also $z(t) = h - \frac{4mg}{M+2m}t^2 = h - t^2 0.8175\,\mathrm{m/s^2}$ and $a(t) = -\frac{2m}{M+2m}g$.

3.1.4.28 Ex: Hovering dumbbell

A dumbbell rotates at the angular velocity ω around a rotation axis that passes through its center of gravity and forms an angle α with the axis connecting the masses (see figure).
a. Calculate the angular momentum vector of the barbell in the co-rotating coordinate system.
b. How does the angular momentum behave in a non-rotating coordinate system?
c. Calculate the torque that must act so that the angular velocity remains constant.

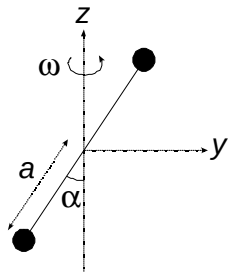

Figure 3.7: Hovering dumbbell.

Solution: *a. The angular momentum vector of the dumbbell in the co-rotating coordinate system is,*

$$\mathbf{L} = I\vec{\omega} = I \begin{pmatrix} 0 \\ 0 \\ \omega \end{pmatrix}$$

$$\mathbf{r}_i = \begin{pmatrix} 0 \\ \pm a \sin\alpha \\ \pm a \cos\alpha \end{pmatrix}$$

$$I_{zx} = 0 \quad , \quad I_{zy} = -2ma^2 \sin\alpha\cos\alpha \quad , \quad I_{zz} = 2ma^2 \sin^2\alpha \ .$$

Hence,

$$\mathbf{L} = \begin{pmatrix} 0 \\ -2ma^2\omega \sin\alpha\cos\alpha \\ 2ma^2\omega \sin^2\alpha \end{pmatrix} \ .$$

b. The angular momentum in a non-rotating coordinate system is,

$$\mathbf{L}_{lab} = \begin{pmatrix} \cos\omega t & -\sin\omega t & 0 \\ \sin\omega t & \cos\omega t & 0 \\ 0 & 0 & 1 \end{pmatrix} \mathbf{L} = 2ma^2\omega \sin\alpha \begin{pmatrix} \cos\alpha \sin\omega t \\ -\cos\alpha\cos\omega t \\ \sin\alpha \end{pmatrix} \ .$$

c. The torque is,

$$\mathbf{N} = \frac{d\mathbf{L}}{dt} = \omega^2 2\omega^2 ma^2 \sin\alpha\cos\alpha \begin{pmatrix} \cos\omega t \\ \sin\omega t \\ 0 \end{pmatrix} .$$

3.1.4.29 Ex: Hovering cross

Four masses of equal weight m are connected to each other in the manner shown by a rigid cross. The mass of the connecting rods is negligible. The cross rotates at a constant angular velocity ω around an axis of rotation that lies in its plane, passes through its center of gravity and forms an angle α with its long axis.
a. Calculate the inertia tensor I of the body in the co-rotating system. b. First

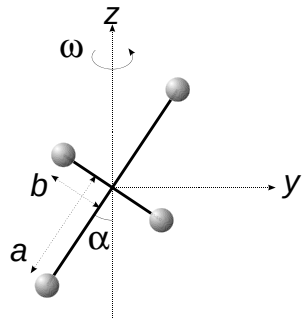

Figure 3.8: Hovering cross.

calculate the angular momentum $\mathbf{L}$ in the co-rotating system using the relationship $\mathbf{L} = I\vec{\omega}$, where $\vec{\omega} = (0, 0, \omega)$ is invariant under rotation around the z-axis. Then transform $\mathbf{L}$ back into the laboratory system.
c. Calculate the torque that must act so that the angular velocity remains constant.

Solution: *a. The angular momentum vector of the dumbbell in the co-rotating coordinate system is,* $\mathbf{L} = I\vec{\omega} = I\omega\hat{\mathbf{e}}_z$. *The masses are at the positions,*

$$\mathbf{r}_{1,2} = \begin{pmatrix} 0 \\ \pm a\sin\alpha \\ \pm a\cos\alpha \end{pmatrix} \qquad \textit{and} \qquad \mathbf{r}_{3,4} = \begin{pmatrix} 0 \\ \mp b\cos\alpha \\ \pm b\sin\alpha \end{pmatrix} .$$

Only the last column of the tensor of inertia is interesting. The components are,

$$\begin{aligned} I_{zx} &= 0 \\ I_{zy} &= -2ma^2 \sin\alpha\cos\alpha - 2mb^2 \sin\alpha\cos\alpha \\ I_{zz} &= 2ma^2 \sin^2\alpha + 2mb^2 \cos\alpha \ . \end{aligned}$$

b. Hence,

$$\mathbf{L} = \begin{pmatrix} 0 \\ -2m\omega \sin\alpha \cos\alpha (a^2 + b^2) \\ 2m\omega (a^2 \sin^2\alpha + b^2 \cos^2\alpha) \end{pmatrix} .$$

The angular momentum in a non-rotating coordinate system is,

$$\mathbf{L}_{lab} = \begin{pmatrix} \cos\omega t & -\sin\omega t & 0 \\ \sin\omega t & \cos\omega t & 0 \\ 0 & 0 & 1 \end{pmatrix} \mathbf{L} = 2m\omega \begin{pmatrix} \sin\alpha\cos\alpha \sin\omega t (a^2 + b^2) \\ -\sin\alpha\cos\alpha\cos\omega t \left(a^2 + b^2\right) \\ a^2 \sin^2\alpha + b^2 \cos^2\alpha \end{pmatrix} .$$

c. The torque is,

$$\mathbf{N} = \frac{d\mathbf{L}}{dt} = 2m\omega^2 \sin\alpha\cos\alpha (a^2 + b^2) \begin{pmatrix} \cos\omega t \\ \sin\omega t \\ 0 \end{pmatrix} .$$

3.1.4.30 Ex: A farmer on a ladder

A farmer of mass $M = 90\,\mathrm{kg}$ harvests apples climbing a ladder (length $L = 10\,\mathrm{m}$, mass $m = 30\,\mathrm{kg}$) leaning at an angle $\phi = 60°$ against a branch relative to the Earth's surface. While harvesting the highest apples at the top, the branch suddenly breaks away. In his fear, the farmer clings to the ladder. The system ladder-farmer now falls down with the ladder base remaining fixed. Neglect the spatial expansion of the farmer. The ladder can be viewed as a one-dimensional rod.
a. Show that the moment of inertia I_{LB} of the ladder-farmer system for a rotation around the ladder base point can be given as $I_{LB} = \left(\frac{m}{3} + M\right) L^2$.
b. At what speed v_1 does the farmer reach the surface of the Earth?
c. At the instant when the branches break, in his shock the farmer drops an apple. At what speed v_2 does the apple reach the surface of the Earth?
d. Would the farmer fall more slowly when letting the ladder go at the moment when the branch breaks?

Solution: *a. The moment of inertia of a bar orthogonal to its length is,*

$$I_L = \int r^2 dm = \int \rho(\mathbf{r}) r^2 d^3 r = \rho_0 \int_0^L r^2 dr = \rho_0 \frac{L^3}{3} = m\frac{L^2}{3} .$$

The farmer is located at a distance L from the pivot. Hence, according to Steiner's theorem, $I_B = ML^2$. Overall,

$$I_{LB} = I_L + I_B = \left(\frac{m}{3} + M\right) L^2 .$$

b. The potential energy of the farmer is $E_{pot,B} = MgL\sin\phi$, the energy of the ladder $E_{pot,L} = \frac{m}{2} gL\sin\phi$ is converted into rotational energy when falling, $E_{rot} = \frac{I}{2}\omega^2$. Hence,

$$\frac{I}{2}\omega^2 = \left(\frac{m}{2} + M\right) gL\sin\phi .$$

Thus,

$$v_1 = \omega L = L\sqrt{\frac{2\,(m/2+M)\,gL\sin\phi}{I}} = \sqrt{\frac{m/2+M}{m/3+M}2gL\sin\phi} =$$

c. The speed follows from equating $E_{pot} = \frac{m_A}{2}L\sin\phi$ *and* $E_{kin} = \frac{m_A}{2}v_2^2$

$$m_A gL\sin\phi = \frac{m_A}{2}v_2^2 \ .$$

Hence,

$$v_2 = \sqrt{2gL\sin\phi} =$$

d. Because of

$$v_1 = \sqrt{\frac{m/2+M}{m/3+M}2gL\sin\phi} > \sqrt{2gL\sin\phi} = v_2$$

it actually falls more slowly.

3.1.4.31 Ex: Angular momentum

A thin bar of length L and mass M is suspended at one end thus forming a physical pendulum.
a. I calculate the inertial moment of the bar.
b. Now, the pendulum is tilted a little. Calculate the torque as a function of the angle of inclination.
c. For very small angles θ holds the approximation $\sin\theta \simeq \theta$. Use this approach to establish the equation of motion.

Solution: *a. Be* $\lambda = M/L$ *the linear mass density of the bar. The inertial moment is,*

$$I = \int r^2 dm = \lambda\int_0^L z^2 dz = \frac{\lambda}{3}L^3 = \frac{M}{3}L^2 \ .$$

b. The torque is,

$$I\ddot{\vec{\theta}} = \tau = \mathbf{L}\times M\mathbf{g} = LMg\sin(180^\circ-\theta) = LMg\sin\theta \ .$$

c. The equation of motion is,

$$\ddot{\theta} \simeq \frac{LMg}{I}\theta = \frac{3g}{L}\theta \ .$$

3.1.4.32 Ex: Accelerated pendulum

A pendulum of length R is suspended in a car which is uniformly accelerated with the acceleration a.
a. Calculate the angle of the pendulum's displacement.

b. Calculate the torque exerted by the accelerating force of the car.
c. What is the torque exerted by the weight in this situation?
d. Calculates the ratio of the torques. Justify the obtained result.

Solution: *a. The angle is given by,*

$$\tan\theta = \frac{a}{g} \ .$$

b. The torque due to the acceleration of the car is,

$$|\vec{\tau}_a| = |\mathbf{r}\times\mathbf{F}| = Rma\sin(90^\circ - \theta) = Rma\cos\theta = Rma\frac{1}{\sqrt{1+\tan\theta^2}} = Rma\frac{1}{\sqrt{1+\frac{a^2}{g^2}}} = Rm\frac{1}{\sqrt{\frac{1}{a^2}+\frac{1}{g^2}}}$$

c. The torque due to the gravitational acceleration is,

$$|\vec{\tau}_g| = |\mathbf{r}\times\mathbf{F}| = Rmg\sin\theta = Rmg\frac{1}{\sqrt{1+1/\tan\theta^2}}$$
$$= Rmg\frac{1}{\sqrt{1+\frac{g^2}{a^2}}} = Rm\frac{1}{\sqrt{\frac{1}{g^2}+\frac{1}{a^2}}} \ .$$

d. The ratio is,

$$\frac{|\vec{\tau}_a|}{|\vec{\tau}_a|} = \frac{Rma\cos\theta}{Rmg\sin\theta} = \frac{a}{g\tan\theta} = 1.$$

That's because the pendulum is in balance.

3.1.4.33 Ex: Rotating disc

A round disk of mass M with radius R is rotatably mounted about a vertical axis passing through its center. A spring of negligible mass with the spring constant κ is attached to the disc tangentially to the edge. The spring, which is initially fully compressed by the length d, represents a launching device for a ball of mass m. The disk rests until the ball is released being ejected horizontally by the spring. Calculate the angular velocity of the disk after the ejection.
Help: Use the angular momentum and energy conservation laws.

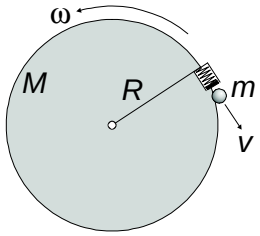

Figure 3.9: Rotating disc.

Solution: *The moment of inertia of the disc is* $I_{disc} = \frac{1}{2}MR^2$. *Conservation of angular momentum requires,* $0 = \mathbf{L}_{disc} + \mathbf{L}_{sphere}$, *hence,*

$$0 = I\vec{\omega} + \mathbf{r} \times \mathbf{p}_{sphere} \ ,$$

resp.

$$p_{sphere} = -\frac{I\omega}{R\sin\alpha} = -\frac{I\omega}{R} \ .$$

Conservation of energy requires $E_{spring} = E_{sphere} + E_{disc}$, *also*

$$\frac{\kappa}{2}d^2 = \frac{1}{2m}p_{sphere}^2 + \frac{I}{2}\omega^2 \ .$$

Substitution of p_{sphere} *yields,*

$$\frac{\kappa}{2}d^2 = \frac{1}{2m}\left(\frac{I\omega}{R}\right)^2 + \frac{I}{2}\omega^2 \ ,$$

and resolved after ω

$$\omega = \sqrt{\frac{\kappa d^2}{I^2/mR^2 + I}} = \frac{2d}{R}\sqrt{\frac{\kappa m}{M^2 + 2mM}} \ .$$

3.1.4.34 Ex: Billiard

A resting billiard ball with radius r is played with a horizontal queue, which gives it an impulse $\Delta p = F\Delta t$. The queue hits the ball at a height h above the table. How does the initial angular velocity ω of the sphere depend on Δp and h? **Help:** The ball rolls without slipping.

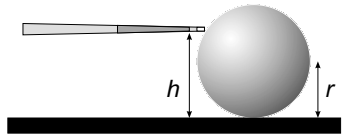

Figure 3.10: Billiard.

Solution: *The moment of inertia of the sphere is* $I_\omega = \frac{2}{5}mr^2$. *The angular momentum is* $\mathbf{L} = \mathbf{r} \times \Delta\mathbf{p} = I_\omega\omega$. *Hence,*

$$\omega = \frac{r\Delta p\sin\phi}{I_\omega} \ ,$$

where $\sin\phi = \frac{h-r}{r}$. *With* $v_0 = \Delta p/m$ *we get,*

$$\omega = \frac{rmv_0}{\frac{2}{5}mr^2}\frac{h-r}{r} = \frac{5}{2}v_0\frac{h-r}{r^2} \ .$$

3.1.4.35 Ex: Rotating and propagating arc

Calculate the angular momentum of an arc (a) rotating around its center of mass, (b) rotating around a peripheral point, and (c) rolling without friction on a surface.

Solution: *a. The inertial moment of the arc is $I_{cm} = MR^2$. The angular momentum of the mass distribution m in the center of mass system (cm) is,*

$$\mathbf{L}_m^{(cm)} = \sum_i \vec{x}_i \times m_i \mathbf{u}_i = \sum_i m_i R u \hat{\mathbf{e}} a_\omega = MR^2 \vec{\omega}_{cm} = I\vec{\omega}_{cm} \ .$$

Considering the same rotation from the point of view of a point O located away from the center of mass,

$$\begin{aligned}\mathbf{L}^{(O)} &= \sum_i \mathbf{r}_i \times m_i \mathbf{v}_i = \sum_i (\mathbf{r}_{cm} + \vec{x}_i) \times m_i (\mathbf{v}_{cm} + \mathbf{u}_i) \\ &= \sum_i m_i \mathbf{r}_{cm} \times \mathbf{v}_{cm} + m_i \mathbf{r}_{cm} \times \mathbf{u}_i + m_i \vec{x}_i \times \mathbf{v}_{cm} + m_i \vec{x}_i \times \mathbf{u}_i \\ &= M\mathbf{r}_{cm} \times \mathbf{v}_{cm} + m_i \mathbf{r}_{cm} \times \mathbf{u}_i + m_i \vec{x}_i \times \mathbf{v}_{cm} + m_i \vec{x}_i \times \mathbf{u}_i = \mathbf{L}_M^{(O)} + 0 + 0 + \mathbf{L}_m^{(cm)} \ ,\end{aligned}$$

with $M = \sum_i m_i$. As the arc does not move its center of mass, $\mathbf{L}_M^{(O)} = 0$, and

$$\mathbf{L}^{(O)} = \mathbf{L}_m^{(cm)} \ .$$

b. Now we assume that the arc moves with angular velocity ω_{cm} around a peripheral point. In the center of mass system the arc still rotates in the same way as in (a) producing an angular momentum $\mathbf{L}_m^{(cm)}$. But in addition the center of mass rotates with the same angular velocity ω_{cm}, producing an angular momentum $\mathbf{r}_{cm} \times \mathbf{p}_{cm}$,

$$\mathbf{L}^{(O)} = \mathbf{r}_{cm} \times \mathbf{p}_{cm} + \mathbf{L}_m^{(cm)} = MRv_{cm}\hat{\mathbf{e}}_\omega + I\vec{\omega}_{cm} = 2MR^2\vec{\omega}_{cm} \ .$$

We would have reached the same conclusion using Steiner's theorem, $I_O = I_{cm} + MR^2$,

$$\mathbf{L}^{(O)} = I_{(O)}\vec{\omega}_{cm} = (I_{cm} + MR^2)\vec{\omega}_{cm} = 2MR^2\vec{\omega}_{cm} \ .$$

c. Now we assume that the arc's center of mass moves with velocity $v_{cm} = R\omega_{cm}$ on a straight line, such that the circumference is in phase with a tangential surface,

$$\mathbf{L}^{(O)} = \mathbf{r}_{cm} \times \vec{p}_{cm} + \mathbf{L}_m^{(cm)} = Mbv_{cm}\hat{\mathbf{e}}_\omega + I\vec{\omega}_{cm} = MR^2\vec{\omega}_{cm} + I\vec{\omega}_{cm} = 2MR^2\vec{\omega}_{cm} \ ,$$

where $b = R$ is the impact parameter. It is interesting that this gives the same result as in (b). This can be understood, because the propagation on the surface can be seen in each infinitesimal instant as a rotation around the support point.

3.2 The rigid body

In mechanics a rigid body is defined as a system of masses whose mutual distances are kept fixed during any motion. The rigid bodies of practical interest are generally

extended over macroscopic volumes and form a (quasi-)continuous mass distribution. The motion of large rigid bodies is more complicated than the motion of a point mass, since in addition to the translational motion, there may be rotations about one or more axes. The dynamics of both types of motion can clearly be separated in rigid bodies.

3.2.1 Translations and rotations: linear and angular momentum

The translational motion of a rigid body of mass M is fully described by the evolution of the coordinates and the velocity of its center-of-mass. In fact, one can assimilate the translation dynamics of the body with the whole mass M being concentrated in the center-of-mass. The total momentum $\mathbf{p}$ of the body is,

$$\mathbf{p} = m\mathbf{v} \ , \tag{3.10}$$

where $\mathbf{v}$ is the velocity of the center-of-mass. The equation that determines the translational dynamics is Newton's second law,

$$\mathbf{F}_{ext} = \frac{d\mathbf{p}}{dt} \ , \tag{3.11}$$

where $\mathbf{F}_{ext}$ is the vectorial sum of external forces acting on the body. When no external forces act, the amount of translational motion of the rigid body is conserved. Similarly, the translational kinetic and the gravitational potential energies of the rigid body can be evaluated by simply considering, respectively, the velocity and height H of the center-of-mass with respect to a reference level of potential energy:

$$E_{kin} = \frac{M}{2}v^2 \qquad \text{and} \qquad E_{grv} = MgH \ . \tag{3.12}$$

The (pure) rotation of a rigid body about its center-of-mass also contains kinetic energy. The quantity representing the amount of rotational motion of a rigid body is the rotational angular momentum. For simplicity, we will assume that the rotation occurs about an axis passing through the center-of-mass of the body, and that the body is symmetric around that axis. In this situation, the angular momentum reads,

$$\mathbf{L} = I\vec{\omega} \ , \tag{3.13}$$

where $\vec{\omega}$ is the angular velocity and I the moment of inertia of the rigid body with respect to the rotation axis. The moment of inertia is obtained by summing for the entire body over the contributions of the products between the elementary mass fragments δm_i and the square of their distances d_i^2 from the rotation axis,

$$I = \sum_i d_i^2 \delta m_i \ . \tag{3.14}$$

For an extensive body of volume V and density ρ, the sum in this equation is expressed as an integral along the infinitesimal mass elements $dm = \rho dV$,

$$I - \int_V d^2 \rho dV \ . \tag{3.15}$$

3.2.2 Rotational energy and moment of inertia

The equation that determines the dynamics of rotation is a consequence of Newton's second law, and results in,

$$\tau_{ext} = \frac{d\mathbf{L}}{dt} \ . \tag{3.16}$$

where τ_{ext} is the vectorial sum over the torques exerted by each external force acting on the body,

$$\tau_{ext} = \sum_i \mathbf{r}_i \times \mathbf{F}_{ext,i} \ . \tag{3.17}$$

In this expression, $\mathbf{r}_i$ is the vector indicating the point of application of the force $\mathbf{F}_{ext,i}$ on the body, measured with respect to the center-of-mass. When the total external torque is zero, the angular momentum of the rigid body is conserved. The kinetic energy associated with the rotation of the rigid body is given by the expression,

$$E_{rot} = \frac{I}{2}\omega^2 \ . \tag{3.18}$$

Example 5 (*Cylinder on a slope*): A cylinder of radius R rolls down a slope of inclination θ. We have $h = z\sin\theta$ and $v = R\omega$. Energy conservation means, $mgh = \frac{m}{2}v^2 + \frac{I}{2}\omega^2$, hence,

$$v = \sqrt{\frac{2gh}{1 + I/mR^2}} \ . \tag{3.19}$$

For a plain cylinder we know $I = \frac{m}{2}R^2$ and for a hollow one we know $I = \frac{m}{2}(R^2+r^2)$. This means, plain cylinders will always reach the same final velocity,

$$v = \sqrt{\frac{4gh}{3}} \ , \tag{3.20}$$

while hollow cylinders will be slower,

$$v = \sqrt{\frac{4gh}{3 + r^2/R^2}} \ . \tag{3.21}$$

3.2.3 Rotation dynamics about a fixed axis

3.2.4 Static equilibrium of a rigid body

3.2.5 Constant acceleration

3.2.6 Exercises

3.2.6.1 Ex: Inertial momentum

Calculate the moment of inertia of a quadrilateral of point masses in relation to the axes shown in the figure.

Solution: *Regarding axis 1 we have,*

$$I_1 = 2\tfrac{a^2}{4}m + 2\tfrac{a^2}{4}2m = \tfrac{3}{2}a^2 m \ .$$

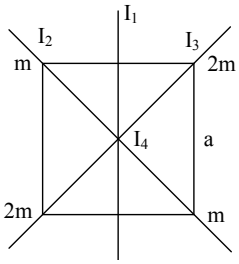

Figure 3.11: Inertial momentum.

Regarding axis 2 we have,

$$I_2 = 2\frac{a^2}{4}2m = 2a^2m \ .$$

Regarding axis 3 we have,

$$I_3 = 2\frac{a^2}{4}m = a^2m \ .$$

Regarding axis 4 we have,

$$I_4 = 2\frac{a^2}{2}m + 2\frac{a^2}{2}2m = 3a^2m \ .$$

3.2.6.2 Ex: Inertial momentum

A disc of radius R and surface mass density σ has a circular hole of radius r at a distance a from the center of the disc. Calculate the moments of inertia with respect to the axes 1, 2 and 3, as shown in the figure.

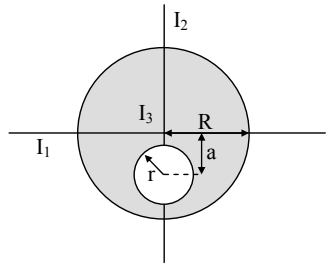

Figure 3.12: Inertial momentum.

Solution: *The moment of inertia of a disk of mass $M = \pi R^2\sigma$ with respect to an axis within the plane through the center of mass is,*

$$I_d = \int \rho^2 dm = \sigma \int_{-R}^{R}\int_{-\sqrt{R^2-z^2}}^{\sqrt{R^2-z^2}} \rho^2 d\rho dz = \sigma \int_{-R}^{R} \frac{\rho^3}{3}\Big|_{-\sqrt{R^2-z^2}}^{\sqrt{R^2-z^2}} dz$$
$$= \frac{2\sigma}{3}\int_{-R}^{R} \sqrt{R^2-z^2}^3 dz = \sigma\frac{\pi}{4}R^4 = M\frac{R^2}{4} \ .$$

So we have with respect to the axis 1,

$$I_1 = M\frac{R^2}{4} - \left(m\frac{r^2}{4} + ma^2\right) \ ,$$

where M is the mass of the disk without a hole and m is the mass that is missing from the hole. Regarding axis 2 we have,

$$I_2 = M\frac{R^2}{4} - m\frac{r^2}{4}.$$

The moment of inertia of the disk with respect to an axis within normal to the plane crossing the center of mass is,

$$I_n = \int \rho^2 dm = \sigma \int_0^{2\pi}\int_0^R \rho^2 \rho d\rho d\phi = 2\pi\sigma \left.\frac{\rho^4}{4}\right|_0^R = M\frac{R^2}{2} \ .$$

Hence, we have with respect to the axis 3,

$$I_3 = M\frac{R^2}{2} - \left(m\frac{r^2}{2} + ma^2\right) \ .$$

3.2.6.3 Ex: Inertial momentum

Calculate the moment of inertia of a sphere of mass M and radius R with respect to an axis passing through the center of mass.

Solution: *As the volume of the sphere is $V = \frac{4}{3}\pi R^3$, we get with $\rho^2 \equiv x^2 + y^2$,*

$$I = \int \rho^2 dm = \frac{M}{V}\int_V \rho^2 d^3r = \frac{M}{V}\int_0^{2\pi}\int_0^R\int_0^{\sqrt{R^2-z^2}} \rho^2 \rho d\rho dz d\phi = \frac{M}{V}\int_0^R \left[\frac{2\pi}{4}\rho^4\right]_0^{\sqrt{R^2-z^2}} dz$$
$$= \frac{M}{V}\frac{2\pi}{4}\int_0^R (R^2 - z^2)dz = \frac{3M}{4\pi R^3}\frac{2\pi}{4}\left[R^2 z - \tfrac{1}{3}z^3\right]_0^R = \frac{2MR^2}{5} \ .$$

3.2.6.4 Ex: Inertial momentum of a slender bar

A thin bar of mass M and length L makes an angle θ with the y-axis, as shown in the figure.
a. Calculate the moment of inertia for rotation about the axis;
b. Calculate the moment of inertia for rotation around an axis parallel to y and passing through the center of mass.

Solution: *a. With the mass distribution $dm = \lambda dl$ we have,*

$$I_a = \int r^2 dm = \lambda \int_0^L (l\sin\theta)^2 dl = \frac{\lambda L^3}{3}\sin^2\theta = \frac{ML^2}{3}\sin^2\theta \ .$$

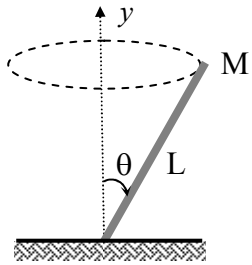

Figure 3.13: Slender bar.

b. We laso have,

$$I_b = I_a - M\left(\frac{L}{2}\sin\theta\right)^2 = \frac{ML^2}{12}\sin^2\theta \ ,$$

or alternatively

$$I_b = \int r^2 dm = \lambda \int_{-L/2}^{L/2} (l\sin\theta)^2 dl = \frac{\lambda}{3} 2\left(\frac{L}{2}\right)^3 \sin^2\theta = \frac{ML^2}{12}\sin^2\theta \ .$$

3.3 Angular momentum

3.3.1 Torque and angular momentum of a particle system

3.3.1.1 Steiner's theorem

The angular momentum I_ω of a rigid body with respect to a rotation axis $\hat{\mathbf{e}}_\omega$ can be divided into $I_\omega = I_\omega^{SP} + Mb^2$. Here, I_ω^{SP} is the inertial moment of the body with respect to the rotation axis $\hat{\mathbf{e}}_{0\omega}$, which is parallel to $\hat{\mathbf{e}}_\omega$ and traverses the center-of-mass of the body, M is the mass of the body, and b is the distance from the rotation axis. This is *Steiner's theorem*.

To demonstrate Steiner's theorem, we consider the vector of a mass point α of the rigid body a first time in the coordinate system, whose origin lies on the axis $\hat{\mathbf{e}}_\omega$, and which we call $\mathbf{r}_\alpha$. A second time we describe this mass point in the coordinate system, whose origin lies in the center-of-mass, and which we call $\mathbf{r}$. The vector of the position of the mass α in the center-of-mass system be described by ρ_α. With this nomenclature,

$$\mathbf{r}_\alpha = \mathbf{r} + \vec{\rho}_\alpha \ .$$

The moment of inertia with respect to the $\hat{\mathbf{e}}_\omega$-axis is then,

$$\begin{aligned} I_\omega &= \sum_\alpha m_\alpha \left(\mathbf{r}_\alpha^2 - (\mathbf{r}_\alpha \cdot \hat{\mathbf{e}}_\omega)\right) \\ &= \sum_\alpha m_\alpha \left[(\mathbf{r} + \vec{\rho}_\alpha)^2 - ((\mathbf{r} + \vec{\rho}_\alpha) \cdot \hat{\mathbf{e}}_\omega)^2\right] \\ &= \sum_\alpha m_\alpha \left[(\mathbf{r}^2 + 2\mathbf{r}\vec{\rho}_\alpha + \vec{\rho}_\alpha^2 - (\mathbf{r} \cdot \hat{\mathbf{e}}_\omega)^2 - 2(\mathbf{r} \cdot \hat{\mathbf{e}}_\omega)(\vec{\rho}_\alpha \cdot \hat{\mathbf{e}}_\omega) - (\vec{\rho}_\alpha \cdot \hat{\mathbf{e}}_\omega)^2\right] \\ &= MR^2 + 0 + \sum_\alpha m_\alpha \vec{\rho}_\alpha^2 - M\,(\mathbf{r} \cdot \hat{\mathbf{e}}_\omega)^2 - 0 - \sum_\alpha m_\alpha\,(\vec{\rho}_\alpha \cdot \hat{\mathbf{e}}_\omega)^2 \\ &= I_\omega^{SP} + Mb^2 \ . \end{aligned}$$

The zeros of the fourth line come from $\sum_\alpha m_\alpha \vec{\rho}_\alpha = 0$, because the left side just corresponds to the center-of-mass vector multiplied with the total mass, but which has in the center-of-mass system the value $\mathbf{r} = 0$.

3.3.2 Rotational work-energy relation

3.3.3 Conservation of angular momentum

Like the conservation law for linear momentum, the conservation law for angular momentum is universal. It holds for a rotational collision,

$$(I_1 + I_2)\omega = I_1\omega_1 + I_2\omega_2 \ . \tag{3.22}$$

On the other side, non-rotational energy is not conserved in a rotational collision, $E_{rot} < E_{rot,1} + E_{rot,2}$, because part of the energy can be dissipated:

$$E_{rot,1} + E_{rot,2} - E_{rot} = \frac{I_1}{2}\omega_1^2 + \frac{I_2}{2}\omega_2^2 - \frac{I_1 + I_2}{2}\omega^2 = \frac{-I_1 I_2}{2(I_1 + I_2)}(\omega_1 - \omega_2)^2 \ . \tag{3.23}$$

3.3.4 Combination of translation and rotation

Example 6 (*Gyroscope*): The angular momentum due to the rotation of a wheel is,

$$\mathbf{L}_\omega = I_\omega^{(cm)}\vec{\omega} \ .$$

for a disk-shaped wheel the inertial moment $I_\omega^{(cm)}$ about an axis of rotation $\vec{\omega}$ crossing the center-of-mass is,

$$I_\omega^{(cm)} = \frac{M}{2}R^2 \ .$$

The force of gravitation,

$$\mathbf{F}_g = m\mathbf{g}$$

produces a torque,

$$\vec{\tau}_g = \mathbf{D} \times \mathbf{F}_g = Dmg\hat{\mathbf{e}}_\phi \sin\theta \ .$$

Initially, the rotation axis of the disk is horizontal $\theta = 0$. Due to the torque the shaft tilts downward thus forcing the angular momentum to shift to $\mathbf{L}_\omega + d\mathbf{L}_\omega$ with the velocity,

$$\tfrac{d\mathbf{L}_\omega}{dt} = \vec{\tau}_g \ .$$

How can the system react to compensate for this change of $\mathbf{L}_\omega$?
The *total angular momentum in the direction* $\mathbf{g}$ *must be conserved*, as there is no external torque in it. Fortunately, there is another possible movement that can generate an angular momentum: the rotation around the point of support O with the angular velocity $\vec{\Omega}$:

$$const = \mathbf{L}_{tot} = \mathbf{L}_\omega + \mathbf{L}_\Omega \qquad \text{or} \qquad \frac{d\mathbf{L}_\omega}{dt} = -\frac{d\mathbf{L}_\Omega}{dt} \ .$$

That is, we have a torque $\vec{\tau}_\Omega = \frac{d\mathbf{L}_\Omega}{dt}$. Hence, $|\tau_\omega| = |\tau_\Omega|$, but since the orientation of $\mathbf{L}_\Omega$ is vertically fixed, the orientation of $\vec{\tau}_\Omega$ is also vertical, which corresponds to an azimuthal force. Thus, instead of an inclination of the rotation axis $\mathbf{L}_\omega$, we get an *azimuthal* shift by an angle,

$$d\vec{\phi} = \frac{d\mathbf{L}_\Omega}{L_\omega \sin\theta} = \frac{d\mathbf{L}_\omega}{L_\omega \sin\theta} = \frac{\vec{\tau}_g dt}{I_\omega^{(cm)} \omega \sin\theta} = \frac{Dm(-\mathbf{g})\sin\theta dt}{I_\omega^{(cm)} \omega \sin\theta} = -\frac{Dm\mathbf{g}dt}{I_\omega^{(cm)}\omega} \ .$$

The frequency of this *precession* movement,

$$\vec{\Omega} = \frac{d\vec{\phi}}{dt} \ ,$$

produces an angular momentum,

$$\mathbf{L}_\Omega = M\mathbf{D} \times \mathbf{v}_\Omega = MD^2\vec{\Omega} = I_\Omega^{(O)}\vec{\Omega} \ .$$

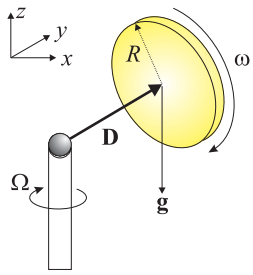

Figure 3.14: Rotating wheel supported on one end of its axis.

Now, the precession modifies the direction of the angular momentum in the plane,

$$\mathbf{L}_\omega = L_\omega \hat{\mathbf{e}}_\phi \ ,$$

with $\hat{\mathbf{e}}_\phi = \hat{\mathbf{e}}_x \cos\Omega t + \hat{\mathbf{e}}_y \sin\Omega t$. Hence,

$$\dot{\mathbf{L}} = L\vec{\Omega} = \vec{\tau}_\omega = L\frac{-Dm\mathbf{g}dt}{I_\omega^{(cm)}\omega} = -Dm\mathbf{g} = \mathbf{D} \times \mathbf{F} \ .$$

Finally, we find a force exactly compensating gravity,

$$\mathbf{F} = -m\mathbf{g} \ .$$

3.3.5 Exercises

3.3.5.1 Ex: Statics of a ladder

A ladder of mass M and length L leans on a frictionless wall and and stands on a floor with friction μ (see figure). Knowing that the angle between the ladder and the wall is 45°, what should be the force on a rope tied in the middle of the stairs so that it does not fall?

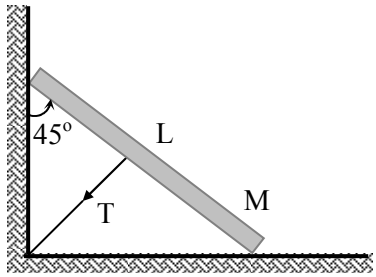

Figure 3.15: Statics of a ladder.

Solution: *The equations of motion are,*

$$\begin{aligned} 0 &= Mg + T\cos\theta - N_2 \\ 0 &= F_{at} + T\sin\theta - N_1 \\ 0 &= \tau_0 + \tau_T - \tau_1 \end{aligned}$$

where $F_{at} = \mu N_2$ *and,*

$$\begin{aligned} \tau_0 &= |\mathbf{r} \times M\mathbf{g}| = \frac{L}{2} Mg \sin(\theta + 90^\circ) \\ \tau_T &= |\mathbf{r} \times \vec{T}| = \frac{L}{2} T \sin\alpha \\ \tau_1 &= |\mathbf{r} \times N_1| = L N_1 \sin(180^\circ - \theta) \ . \end{aligned}$$

For $\theta = 45^\circ$ *we have* $\alpha = 90^\circ$*, and the equations of motion become,*

$$\begin{aligned} 0 &= Mg + \frac{T}{\sqrt{2}} - N_2 \\ 0 &= F_{at} + \frac{T}{\sqrt{2}} - N_1 \\ 0 &= \frac{L}{2}\frac{Mg}{\sqrt{2}} + \frac{L}{2} T - L\frac{N_1}{\sqrt{2}} \ . \end{aligned}$$

Eliminating N_2 and then N_1

$$\begin{aligned} 0 &= Mg + \frac{T}{\sqrt{2}} - \frac{F_{at}}{\mu} = Mg + \frac{T}{\sqrt{2}} - \frac{1}{\mu}\left(N_1 - \frac{T}{\sqrt{2}}\right) \\ &= Mg + \frac{T}{\sqrt{2}} - \frac{1}{\mu}\left(\left[\frac{1}{2}Mg + \frac{1}{\sqrt{2}}T\right] - \frac{T}{\sqrt{2}}\right) = Mg + \frac{T}{\sqrt{2}} - \frac{1}{2\mu}Mg \\ T &= \frac{\mu^{-1} - \sqrt{2}}{\sqrt{2}}Mg \ . \end{aligned}$$

3.3.5.2 Ex: Statics of a ladder

A ladder of mass M and length L leans against wall and stands on the floor (both without friction) such as to form an angle θ with the wall, as shown in the figure. A rope tied at a height of H (parallel to the floor) keeps the ladder at rest. Calculate:
a. the tension in the rope;
b. the maximum height H_{max} at which equilibrium is possible;
c. the angular acceleration at the instant this rope is cut.

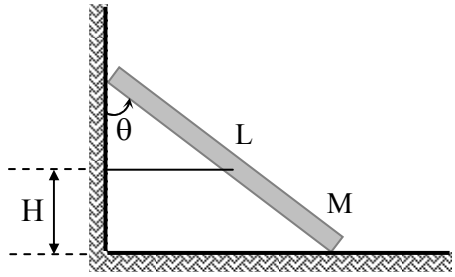

Figure 3.16: Statics of a ladder.

Solution: *a. Since the body is in equilibrium, all forces and all torques must compensate, $\sum \mathbf{F} = 0$ and $\sum \vec{\tau} = 0$. Let $\mathbf{N}_1$ and $\mathbf{N}_2$ be the pressures acting in normal direction on the wall and the floor, respectively. $\mathbf{T}$ is the tension in the string. We place the origin at the support point of the ladder on the wall. We can then express the distance between this point and the point of attachment of the rope by,*

$$x = \frac{L\cos\theta - H}{\cos\theta} \ .$$

We now have,

$$\begin{aligned} N_2 - Mg &= 0 \\ N_1 - T &= 0 \\ LN_2\sin\theta - xT\cos\theta - \tfrac{L}{2}Mg\sin\theta &= 0 \ , \end{aligned}$$

torque around the support point. Replacing the pressures,

$$LMg\sin\theta - (L\cos\theta - H)T - \tfrac{L}{2}Mg\sin\theta = 0$$
$$\Rightarrow T = \frac{1}{2}\frac{LMg\sin\theta}{L\cos\theta - H} \ .$$

b. This depends on the resistance of the rope, because when H rises, approaching $L\cos\theta$, the tension diverges.
c. The angular acceleration if the string is cut, that is if $T = 0$, is given by,

$$I\vec{\alpha} = \sum \vec{\tau} = LN_2\sin\theta - \tfrac{L}{2}Mg\sin\theta \ .$$

with the moment of inertia being $I = ML^2/3$, we have

$$\alpha = \frac{1}{I}\frac{L}{2}Mg\sin\theta = \frac{3}{2}\frac{g\sin\theta}{L} \ .$$

3.3.5.3 Ex: Statics of a ladder

A Λ-shaped ladder of mass $2M$ mass is opened to form an angle θ. What should be the coefficient of static friction with the floor so that it doesn't fall? (see figure).

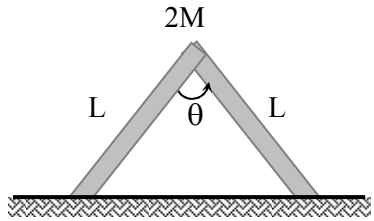

Figure 3.17: Statics of a ladder.

Solution: *Since the body is in equilibrium, all forces and all torques must compensate, $\sum \mathbf{F} = 0$ and $\sum \vec{\tau} = 0$. Instead of considering the ladder as open, since the problem is symmetrical, we can consider half the ladder leaning against a wall at an angle $\theta/2$. Let $\mathbf{N}_1$ and $\mathbf{N}_2$ be the normal pressures on the wall and floor, respectively, and $F_{at} = \mu N_2$ the friction force on the floor. With that we have,*

$$N_2 - Mg = 0$$
$$N_1 - F_{at} = 0$$
$$\tfrac{L}{2}Mg\sin\tfrac{\theta}{2} - LF_{at}\cos\tfrac{\theta}{2} = 0 \ ,$$

because the friction force compensates the pressure on the wall, and the torque exerted by the weight compensates the torque exerted by the friction. Therefore,

$$\mu = \tfrac{1}{2}\tan\tfrac{\theta}{2} \ .$$

3.3.5.4 Ex: Statics of a ladder

A painter of mass M stands at the top of a Λ-shaped ladder of negligible weight (length of each side: L) that rests on an extremely smooth floor M. There is a crossbar at half height that prevents the ladder from opening. The vertex angle is θ. What is the force on the crossbar?

Solution: *Since the body is in equilibrium, all forces and all torques must compensate,* $\sum \mathbf{F} = 0$ *and* $\sum \vec{\tau} = 0$. *Instead of considering the ladder as open, as the problem is symmetrical, we can consider half the ladder leaning against a wall at an angle* $\theta/2$. *Let* $\mathbf{N}_1$ *and* $\mathbf{N}_2$ *be the normal pressures to the wall and floor, respectively. For the system to be in balance, we have*

$$\begin{aligned} N_1 - T &= 0 \\ N_2 - \tfrac{1}{2}Mg &= 0 \\ LN_2 \sin\tfrac{\theta}{2} - \tfrac{L}{2}N_1 \cos\tfrac{\theta}{2} &= 0 \ , \end{aligned}$$

because the pressure on the 'wall' is compensated by the tension in the rope, the weight exerts a pressure on the floor, and the torque due to the weight is compensated by the torque exerted by the rope. So the tension in the crossbar is,

$$T = Mg \tan\tfrac{\theta}{2} \ .$$

3.3.5.5 Ex: Statics of a ladder

A bar of length L and mass M is placed over a hole, as shown in the figure. What must be the friction coefficient for the bar to stay at rest?

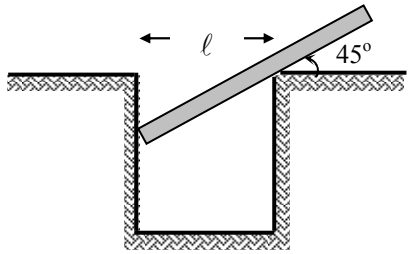

Figure 3.18: Statics of a ladder.

Solution: *In addition to the weight* Mg, *the following forces act on the center of mass: the tension at the right edge of the hole* $T_x = T\sin\theta$ *and* $T_y = T\cos\theta$, *the tension* $N = -T_x$, *and the friction* $F_{at} = \mu N$ *at the left edge of the hole. For The acceleration we write,*

$$0 = Ma = Mg - T_y - F_{at} = Mg - N\cot\theta - \mu N \ .$$

The bar can rotate around the right support point. Two forces act vertically, the weight acts on the center of mass located at a distance $d_1 = \frac{\ell}{\cos\theta} - L$ *from the rotation axis, and the friction acts on the left end of the bar at a distance* $d_2 = \frac{\ell}{\cos\theta}$ *of the rotation axis. This produces a torque:*

$$\begin{aligned} 0 = I\alpha &= |\mathbf{d}_1 \times M\mathbf{g}| + |\mathbf{d}_2 \times \mathbf{F}_{at}| \\ &= \left(\frac{\ell}{\cos\theta} - L\right) Mg\sin\theta - \frac{\ell}{\cos\theta}\mu N\sin\theta = \ell Mg\tan\theta - LMg\sin\theta - \ell\mu N\tan\theta \ . \end{aligned}$$

Solving the equation for the acceleration by N*,*

$$N = \frac{Mg}{\mu + \cot\theta} \ ,$$

and inserting into the equation for the torque we get,

$$0 = \ell Mg\tan\theta - LMg\sin\theta - \ell\mu\tan\theta\frac{Mg}{\mu + \cot\theta} \ ,$$

or solving for μ*,*

$$\mu = \left(\frac{1}{1 - L/\ell\sqrt{2}} - 1\right)^{-1} \ .$$

3.3.5.6 Ex: Torque on a block

On a smooth surface, a cubic block of size L and mass M slides with speed v (see figure). At a certain point, the cube hits a small obstacle. How fast should the velocity v of the block be in order to rotate around this point?

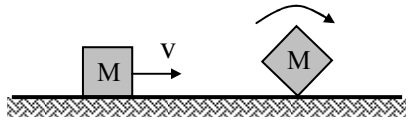

Figure 3.19: Torque on a block.

Solution: *The kinetic energy of the block is given by* $K = \frac{1}{2}Mv^2$ *before the crash. As the movement does not dissipate energy, we have energy conservation. At the instant when the cube is starting to rotate, we have only gravitational potential energy. So* $K = U$*, where* U *is the gravitational potential energy of the cube when it is going to fall to its other side. The difference in the height of the center of mass in the stable and labile position is,*

$$h = \frac{\sqrt{2}}{2}L - \frac{L}{2} = (\sqrt{2} - 1)\frac{L}{2} \ .$$

Hence,

$$\tfrac{1}{2}Mv_0^2 = Mgh = Mg(\sqrt{2}-1)\frac{L}{2}$$
$$\Rightarrow v_0 = \sqrt{Lg(\sqrt{2}-1)}\ .$$

That is, v_0 is the velocity necessary for the rotating cube to stop with the diagonal being vertical. So any velocity $v > v_0$ makes the cube flip over.

3.3.5.7 Ex: Falling rod

At the end of a rod of length L the negligible mass is placed a mass M. The system is released from vertical under the action of gravity. What is the equation that describes the angle $\theta(t)$ (see the figure)?

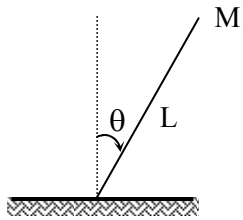

Figure 3.20: Falling rod.

Solution: *The inertial moment of the rod is $I = ML^2$. In the case of friction, the rod falls rotating around the point of the plane, supporting the lower end of the rod. Hence,*

$$I\alpha = |\mathbf{L} \times M\mathbf{g}| = LMg\sin\theta\ ,$$

and finally,

$$\ddot{\theta} = \frac{g}{L}\sin\theta\ .$$

Without friction, the rod rotates around its center of mass. Its acceleration is partially compensated by a stress $N = Mg\sin\theta$ exerted by the plane:

$$Ma = Mg - N\ .$$

Therefore, the angular acceleration is given by,

$$I\alpha = |\mathbf{L} \times M\mathbf{g}| + |\frac{\mathbf{L}}{2} \times \mathbf{N}| = LMg\sin\theta - \frac{L}{2}Mg\sin^2\theta\ .$$

Finally,

$$\ddot{\theta} = \frac{g}{L}\sin\theta - \frac{g}{2L}\sin^2\theta\ ,$$

and the acceleration is,

$$a = g - g\sin\theta\ ,$$

until the point, wave the bar suddenly encounters the plane.

3.3.5.8 Ex: Rotating arc

An arc of radius R, which rotates with angular velocity ω_0, is placed on a rough horizontal surface, as shown in the figure, the speed of its center of mass being zero. Determine the speed of the center of mass after slipping has ceased.

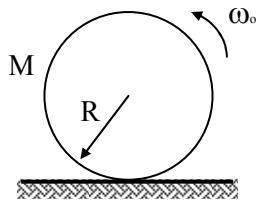

Figure 3.21: Rotating arc.

Solution: *The inertial moment of the arc is $I = MR^2$. The angular momentum at the center of mass before contact is,*

$$\mathbf{L}_{cm,i} = I\vec{\omega}_0 = MR^2\vec{\omega}_0 \ .$$

After contact between the arc and the rough surface, the arc starts to rotate around the contact point. The angular momentum is,

$$\mathbf{L}_f = \mathbf{L}_{cm,f} + \mathbf{r} \times \vec{p}_{cm}$$
$$L_f = \tilde{I}\omega + Rp_{cm}$$

with $\tilde{I} = I + MR^2$. As the bow does not slide, $R\omega = v_{cm}$, and

$$L_f = \tilde{I}\frac{v_{cm}}{R} + MRv_{cm} = 2MR^2\frac{v_{cm}}{R} + MRv_{cm} \ .$$

Since the angular momentum is conserved, $L_f = L_{cm,i}$, we obtain,

$$2MR^2\frac{v_{cm}}{R} + MRv_{cm} = MR^2\omega_0 \ ,$$

and finally,

$$v_{cm} = \frac{1}{3}R\omega_0 \ .$$

3.3.5.9 Ex: Angular momentum

The integral of the torque with respect to time is called the angular momentum. Starting from the relationship $\vec{\tau} = d\mathbf{L}/dt$, show that the impulse is the variation of the angular momentum.

Solution: *We have,*

$$\int_{t_1}^{t_2} \vec{\tau} dt = \int_{t_1}^{t_2} \frac{d\mathbf{L}}{dt} dt = \mathbf{L}(t_2) - \mathbf{L}(t_1) \ .$$

3.3.5.10 Ex: Billiard

A billiard ball initially at rest receives an instant boost from a cue. The cue is kept horizontal at a distance h from the center. The ball leaves with speed v_0 and the final speed is $9v_0/7$. Show that $h = 4R/5$, where R is the radius of the sphere.

Solution: *We divide the problem into three phases. The first (A) refers to the instant when the ball receives the kick, the second (B) refers to the instant immediately after the kick, when the ball acquires the speed v_0 and slides over the table, and the third (C) when the ball, after sliding a certain distance on the table, has speed v and rolls on the table without sliding. The translation movement in (B) is the result of the momentum transfer (ΔP, where P is the linear momentum of the ball) due to the force F applied in (A),*

$$\begin{aligned} \Delta P = P_B - P_A = Mv_0 - 0 = F\Delta t \\ F\Delta t = Mv_0 \ . \end{aligned}$$

The same analysis can be done for the rotation movement of the ball, where L is the angular movement, I is the moment of inertia, and ω_0 is the initial angular velocity of the ball:

$$\begin{aligned} \Delta L = L_B - L_A = I\omega_0 - 0 = \tau\Delta t \\ \frac{2MR^2}{5}\omega_0 = -Fh\Delta t \\ F\Delta t = -\frac{2MR^2}{5h}\omega_0 \ . \end{aligned}$$

The negative sign that appears in the last equation refers to the direction of the torque that the force F exerts on the ball. Equating the two equations for $F\Delta t$,

$$\begin{aligned} Mv_0 = -\frac{2MR^2}{5h}\omega_0 \\ \Longrightarrow \omega_0 = -\frac{5hv_0}{2R^2} \ . \end{aligned}$$

Now let's analyze the translation of the ball from state (B) to state (C):

$$\begin{aligned} \sum F = Ma_x \\ a_x = \frac{F}{M} \ . \end{aligned}$$

Movement from (B) to (C):

$$v_x = v_{x0} + a_x t \ .$$

The v_x speed was given in the statement of the problem:

$$\begin{aligned} \frac{9}{7}v_0 &= v_0 + \frac{F}{M}t \\ \Longrightarrow Ft &= \frac{2}{7}Mv_0 \ . \end{aligned}$$

Now let's analyze the rotation of the ball from state (B) to state (C):

$$\begin{aligned} \sum \tau_z &= I\alpha_z \\ FR &= \frac{2MR^2}{5}\alpha \\ \alpha &= \frac{5F}{2MR} \ . \end{aligned}$$

Rotation from (B) to (C):

$$\begin{aligned} \omega_z &= \omega_{z_0} + \alpha_z t \\ \Longrightarrow \frac{-9v_0}{7R} &= -\frac{5hv_0}{2R^2} + \frac{5F}{2MR}t \\ \Longrightarrow Ft &= Mv_0\left(\frac{h}{R} - \frac{18}{35}\right) \ . \end{aligned}$$

Equating the equations for the quantity Ft we obtain,

$$\frac{2}{7}Mv_0 = Mv_0\left(\frac{h}{R} - \frac{18}{25}\right) \ ,$$

and finally, $h = \frac{4}{5}R$.

3.3.5.11 Ex: Bohr's atom

Niels Bohr postulated that a rotating mechanical system can only have angular momentum with multiple values of a constant $\hbar$, called Planck's constant $\hbar = h/2\pi = 1.054 \times 10^{-34}$ Js, that is: $L = I\omega = n\hbar$, being n a positive integer or zero.
a. Show that with this postulate, the energy of a rotor can only acquire discrete, that is, quantized values.
b. Consider a mass m forced to rotate on a circle of radius R (e.g. hydrogen atom). What are the possible values for the angular velocity considering Bohr's postulate?
c. What kinetic energy values can the atom adopt?

Solution: *a. The possible energies of the quantized rotor are,*

$$E_{rot} = \frac{I}{2}\omega^2 = \frac{1}{2}L\omega = \frac{1}{2}n\hbar\omega \ .$$

b. Inserting the inertial moment of the electron $I = mR^2$ in the rotational energy, we have,

$$\omega = \frac{n\hbar}{mR^2} \ .$$

c. The kinetic energy is,

$$E_{kin} = \frac{m}{2}R^2\omega^2 = \frac{m}{2}R^2\left(\frac{n\hbar}{mR^2}\right)^2 = \frac{1}{2m}\frac{n^2\hbar^2}{R^2} \ .$$

3.3.5.12 Ex: Earth rotation

Many of the great rivers flow into the equatorial region carrying sandy sediments. What effect does this have on the Earth's rotation?

Solution: *They transfer mass to regions further from the Earth's rotation axis and thus increase the moment of inertia. Since rotational energy must be preserved,*

$$\frac{I_1}{2}\omega_1^2 = E_{rot} = \frac{I_2}{2}\omega_2^2 \ ,$$

the frequency of the Earth's rotation decreases.

3.3.5.13 Ex: Cylinder rolling on an inclined plane

A cylinder of mass M and radius R rotates without sliding on a horizontal plane. The speed of the center of mass is v. It encounters a plane with a tilt angle θ in front of it, as shown in the figure.
b. What were the linear and angular momenta when the cylinder meets the inclined plane?
c. How long does the cylinder take to reach the maximum height, and to what height does it rise on the inclined plane?
d. In this position, what was the change in angular momentum?

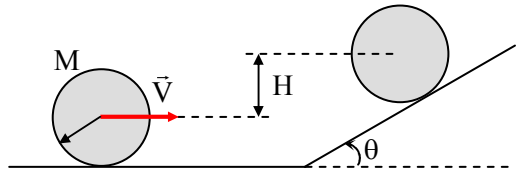

Figure 3.22: Cylinder rolling on an inclined plane.

Solution: *a. We assume the cylinder to meet the inclination as a fully elastic shock.*

In this case, the momenta due to the shock are,

$$\mathbf{I}_p = \int_{t_1}^{t_2} \mathbf{F} dt = \vec{p}_2 - \vec{p}_1 = \begin{pmatrix} mv_0 \\ 0 \end{pmatrix} - \begin{pmatrix} mv_0 \cos\theta \\ mv_0 \sin\theta \end{pmatrix}$$
$$\mathbf{I}_L = \int_{t_1}^{t_2} \vec{\tau} dt = \mathbf{L}_2 - \mathbf{L}_1 = 0 \ .$$

b. The only torque is due to friction. So the equations of motion are,

$$I\vec{\alpha} = \vec{\tau} = \mathbf{r} \times \mathbf{F}_{at}$$
$$Ma_{cm} = Mg\sin\theta - F_{at} \ .$$

Since the cylinder does not slide, $\alpha = \frac{a_{cm}}{R}$, and with the inertial moment, $I = \frac{M}{2}R^2\alpha$, we have,

$$a_{cm} = g\sin\theta - \frac{F_{at}}{M} = g\sin\theta - \frac{I\alpha}{MR} = g\sin\theta - \frac{\frac{M}{2}R^2\alpha}{MR} = g\sin\theta - \frac{1}{2}R\frac{a_{cm}}{R} = \frac{2}{3}g\sin\theta \ .$$

The body comes to a halt, when $0 = v_{cm} = v_0 - a_{cm}t = v_0 - \frac{2}{3}gt\sin\theta$, that is, at the time,

$$t = \frac{3v_0}{2g\sin\theta}$$

at the height,

$$H = s\sin\theta = \left(v_0 t - \frac{a_{cm}}{2}t^2\right)\sin\theta = \frac{3v_0^2}{4g} \ .$$

c. The initial angular momentum was,

$$\mathbf{L} = \mathbf{r}_0 \times \vec{p}_0 + I\vec{\omega}_0$$
$$L = MRv_0 + \frac{M}{2}R^2\omega_0 = \frac{3M}{2}Rv_0$$

and after stopping at the time H is $L = 0$.
d. The dissipated energy is,

$$E_{diss} = E_{pot} - E_{kin} + E_{rot} = MgH - \frac{M}{2}v_0^2 - \frac{M}{2}\omega_0^2 r^2 = -\frac{M}{4}v_0^2 \ .$$

3.3.5.14 Ex: Disc pushed by a mass

A disk of mass M and radius R can move around an axis passing through its center of mass, as shown in the figure. A particle of mass M as well follows a linear path with velocity v_i and impact parameter $d = R/2$ relative to the center-of-mass point. When it hits the disk it undergoes a deflection of 90° and has its velocity changed to $v_f = v_i/2$.
a. What is the angular velocity of the disc after the collision?
b. What is the energy dissipated in the collision?

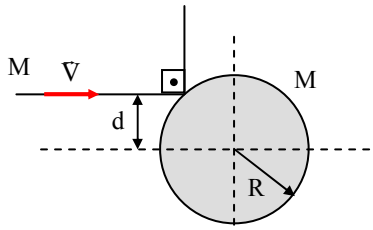

Figure 3.23: Disc pushed by a mass.

Solution: *a. Using the impact parameters $d_i = R/2 = d_f$ and the inertial moment of the disk $I = \frac{M}{2}R^2$ we have the initial angular momentum,*

$$\mathbf{L}_i = \mathbf{r} \times M\mathbf{v}_i = rMv_i\hat{\mathbf{e}}_\theta \sin\phi = Mv_i d_i \hat{\mathbf{e}}_\theta = Mv_i \tfrac{1}{2}R\hat{\mathbf{e}}_\theta \ .$$

In the same way we obtain for the final angular momentum,

$$\mathbf{L}_f = Mv_f d_f \hat{\mathbf{e}}_\theta + I\vec{\omega}_f = \left(Mv_f \tfrac{1}{2}R + \tfrac{M}{2}R^2\omega_f\right)\hat{\mathbf{e}}_\theta \ .$$

The momenta are equal, giving

$$Mv_i \tfrac{1}{2}R = M2v_i\sqrt{3}\tfrac{1}{2}R + \frac{M}{2}R^2\omega_f \ ,$$

and finally,

$$\omega_f = \frac{v_i}{2R} \ .$$

b. The dissipated energy is,

$$E_{diss} = \frac{M}{2}v_f^2 + \frac{I}{2}\omega_f^2 - \frac{M}{2}v_i^2 = \frac{M}{2}\left(\frac{v_i}{2}\right)^2 + \frac{1}{2}\frac{M}{2}R^2\frac{v_i^2}{4R^2} - \frac{M}{2}v_i^2 = -\frac{5}{8}\frac{M}{2}v_i^2 \ .$$

3.3.5.15 Ex: Disc pushed by a mass

A disc of mass $2m$ and radius R rests on an extremely smooth horizontal table. A bullet of mass m, speed v_0 and impact parameter R hits the disc and chokes it (see figure). Calculate:
a. The angular velocity of the system right after the collision;
b. The center-of-mass velocity after the collision;
c. The energy dissipated in the collision.

Solution: *a. Using the inertial moment of the disk $I = mR^2$ we have the initial angular momentum,*

$$\mathbf{L}_i = \mathbf{r} \times m\mathbf{v}_0 = rmv_0\hat{\mathbf{e}}_\theta \sin\phi = mv_0 R\hat{\mathbf{e}}_\theta \ .$$

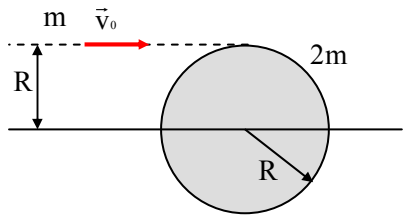

Figure 3.24: Disc pushed by a mass.

The final angular momentum is,

$$\mathbf{L}_j = I\omega\hat{\mathbf{e}}_\theta \ .$$

The moments are equal, giving

$$\omega = \frac{mv_0R}{I} = \frac{v_0}{R} \ .$$

b. The speed of the center of mass after the collision is given by the conservation of linear momentum,

$$\vec{p}_i = mv_0\hat{\mathbf{e}}_x = \vec{p}_f = (2m+m)v_f\hat{\mathbf{e}}_x \ .$$

Hence,

$$v_f = \frac{v_0}{3} \ .$$

c. The energy dissipated in the collision is,

$$E_{diss} = \frac{m}{2}v_f^2 + \frac{I}{2}\omega_f^2 - \frac{2m+m}{2}v_0^2 = \frac{1}{9}\frac{m}{2}v_0^2 + \frac{1}{9}\frac{mR^2}{2}\left(\frac{v_0^2}{R^2}\right) - \frac{m}{2}v_0^2 = \frac{m}{2}v_0^2\frac{-7}{9} \ .$$

3.3.5.16 Ex: Billiard

A billiard ball initially at rest receives an sudden impulse from a cue, which forms an angle with the horizontal, as shown in the figure. The ball leaves with initial velocity v_0 and at the end of the movement it is at rest.
a. Determine the angle θ for this to happen.
b. What is the initial angular velocity of the ball?
c. What is the energy dissipated during the movement?

Solution: *a. The inertial moment of the ball is $I_{cm} = \frac{2}{5}MR^2$. After the momentum, the ball's center of mass has the linear momentum,*

$$p_x = Mv_0 = p\cos\theta \ .$$

As the cue hits the ball at an angle θ, the other component of the impulse generates an angular momentum,

$$L = I_{cm}\omega_0 = Rp_y = RMv_0\sin\theta \ .$$

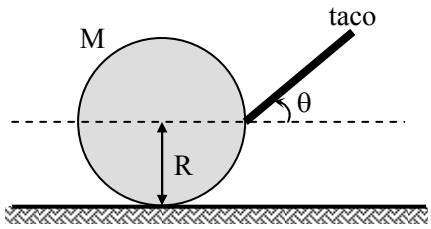

Figure 3.25: Billiard.

Therefore, the initial velocity of the ball is,

$$\omega_0 = \frac{RMv_0 \sin\theta}{I_{cm}} = \frac{5v_0 \sin\theta}{2R} \ .$$

b. Now, we have a movement combining translation and rotation,

$$\begin{aligned} Ma &= -F_{at} \\ I\alpha &= \tau = RF_{at} \ , \end{aligned}$$

where the inertial moment needs to be taken with respect to the instantaneous rotation axis that is in the plane,

$$I = I_{cm} + MR^2 \ .$$

Integrating the equations we get,

$$\begin{aligned} 0 = v &= v_0 + at = v_0 - \frac{F_{at}}{M}t \\ 0 = \omega &= \omega_0 + \alpha t = \omega_0 - \frac{RF_{at}}{I}t \end{aligned}$$

eliminating, $F_{at}t$,

$$\begin{aligned} Mv_0 = \frac{I\omega_0}{R} = \frac{I_{cm} + MR^2}{R}\frac{5v_0 \sin\theta}{2R} = \frac{\frac{2}{5}MR^2 + MR^2}{R}\frac{5v_0 \sin\theta}{2R} = \frac{7M}{2}v_0 \sin\theta \\ \theta = \arcsin\tfrac{2}{7} = 16.6^\circ \ . \end{aligned}$$

c. The energy is totally dissipated,

$$E_{diss} = 0 - \frac{M}{2}v_0^2 - \frac{M}{2}R^2\omega_0^2 \ .$$

3.3.5.17 Ex: Horizontal pendulum with variable length

A particle of mass m is attached to the end of a wire and follows a circular path of radius r on a horizontal table without friction. The wire passes through a hole in the table and the other end is initially fixed. In this situation, the initial radius is r_0 and

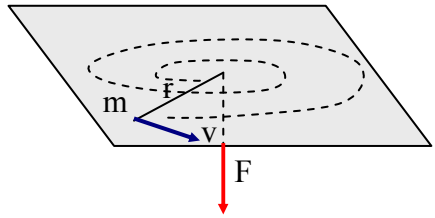

Figure 3.26: Horizontal pendulum with variable length.

the initial angular velocity is ω_0. The wire is then slowly pulled in order to reduce the radius of the circular path, as shown in the figure.
a. How will the angular velocity vary as a function of r?
b. What work has to be done to bring the particle to the radius $r_0/2$?

Solution: *a. The inertial moment is* $I = mr_0^2$. *As the angular momentum is conserved, we have,*

$$L = I\omega = mr^2\omega = mr_0^2\omega_0 = I_0\omega_0 = L_0 \ .$$

Hence,

$$\omega = \frac{r_0^2}{r^2}\omega_0 \ .$$

b. The work is,

$$W = \int \mathbf{F}\cdot d\mathbf{S} = \int_{r_0}^{r_0/2} m\omega^2 r dr = \int_{r_0}^{r_0/2} m\frac{r_0^4}{r^4}\omega_0^2 r dr$$
$$= m\omega_0^2 r_0^4\left(\frac{-1}{2(r_0/2)^2} + \frac{1}{2r_0^2}\right) = \frac{-3m}{2}\omega_0^2\frac{r_0^4}{r_0^2} \ .$$

3.3.5.18 Ex: Cylinder rolling on an inclined plane

Consider a cylinder of mass M and radius R descending an inclined plane of angle θ without sliding. Calculate the acceleration of the center of mass and the friction force acting on the cylinder.

Solution: *We have the equations of motion,*

$$Ma = Mg\sin\theta - F_{at}$$
$$I\alpha = \tau_{at} = RF_{at} \ ,$$

with $I = \frac{M}{2}R^2$. *As the cylinder does not slide, we have,*

$$a = R\alpha \ .$$

Inserting the linear and rotational accelerations,

$$g\sin\theta - \frac{F_{at}}{M} = R\frac{RF_{at}}{I} \ ,$$

giving the friction,

$$F_{at} = \frac{M}{3} g \sin\theta \ .$$

Now we can calculate the acceleration of the center of mass,

$$a = \frac{2}{3} g \sin\theta \ .$$

Calculating the total energy,

$$E = Mgh - \frac{M}{2}v^2 + \frac{M}{2}R^2\omega^2 = -Mg\sin\theta\frac{a}{2}t^2 + M(at)^2 = \frac{1}{9}Mg^2t^2\sin^2\theta \ ,$$

we find that it increases over time, which is strange.
Alternatively, we can consider the movement as a rotation around the support point. Regarding this point, the cylinder's moment of inertia is,

$$I = \frac{M}{2}R^2 + MR^2 \ ,$$

following Steiner's law. Therefore,

$$I\vec{\alpha} = \vec{\tau} = \mathbf{r} \times M\mathbf{g} \ .$$

That is,

$$a = R\alpha = \frac{R}{I}RMg\sin\theta = \frac{2}{3}g\sin\theta \ .$$

3.3.5.19 Ex: Billiard

A billiard ball of mass M and radius R ($I = \frac{2}{5}MR^2$ slides without rotating with speed v_0 on a frictionless table. Suddenly it encounters a part of table with friction and after some time is running without sliding.
a. Calculate the final speed of the ball.
b. What is the energy dissipated in the process?

Solution: *a. We have the equations of motion,*

$$I\alpha = \tau = RF_{at} = R\mu Mg$$
$$Ma = -F_{at} = -\mu Mg \ ,$$

with $I = \frac{2}{5}MR^2$. The speed of the ball will decrease while the angular velocity will increase,

$$v = v_0 + at = v_0 - \mu gt$$
$$\omega = \omega_0 + \alpha t = \frac{R\mu Mg}{I}t = \frac{5\mu g}{2R}t \ ,$$

up to the moment T_e, when the ball does not slide any more, that is,

$$v(t_e) = R\omega(t_e) \ .$$

In this case, we find,

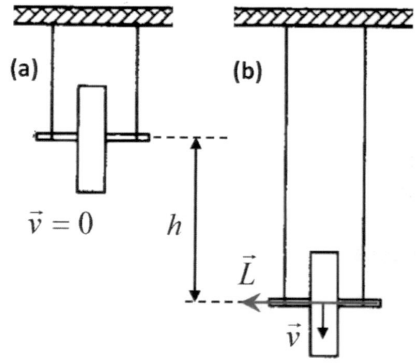
$$t_e = \frac{2v_0}{7\mu g} \qquad \textit{and} \qquad v_e = \frac{5v_0}{7} \ .$$

b. The dissipated energy is,

$$E_{diss} = \frac{m}{2}v_0^2 - \frac{m}{2}v_e^2 - \frac{I}{2}\omega^2 = \frac{M}{2}v_0^2\left(1 - \frac{25}{49} - \frac{2}{5}\right) \approx 0.09\frac{m}{2}v_0^2 \ .$$

3.3.5.20 Ex: Shock and conservation laws

In an experiment Maxwell's wheel was used to determine the moment of inertia I of a body of mass $m = 1490\,\mathrm{g}$. The axis of the body around which it spins during the fall has a radius of $r = 0.6\,\mathrm{cm}$ (the mass of the axis is included in the mass m of the body). See figure below. Measurements of the fall time t_b were made for various heights h, and the data are given in the table below. The moment of inertia I is given by the expression,



$$I = \left(\frac{gt_b^2}{2h} - 1\right) mr^2 \ ,$$

which implies the following relationship between h and t_b,

$$h = \alpha t_b^2 \qquad \text{where} \qquad \alpha = \frac{g}{2}\frac{mr^2}{I + mr^2} \ .$$

a. Using a double logarithmic paper draw the graph $\log h \times \log t_b$. Choose the line that best approximates the data and determine its angular and linear coefficients. From them determine (i) The power law of t_b in the expression $h = \alpha t_b^{\beta}$ and (ii) The value of α and from it the value of I.
b. Using a millimetric paper draw the graph $h \times t_b^2$, and from the slope α determine the value of I again. Compare the results.

h (cm)	t_b (s)
10	1.2
20	1.8
30	2.1
40	2.5
50	2.8
60	3.0
70	3.3
80	3.6
90	3.7

Solution: *a. From the graph we obtain the slope,*

$$\beta = \frac{\lg h_2 - \lg h_1}{\lg t_{b2} - \lg t_{b1}} \approx 2$$

and the linear coefficient,

$$\alpha = 10^{\lg h_3 - \beta \lg t_{b3}} = 6.5\,\mathrm{cm/s^2} \ .$$

With that we calculate,

$$I = mr^2 \left(\frac{g}{2\alpha} - 1\right) = 0.004\,\mathrm{kg\ m^2} \ .$$

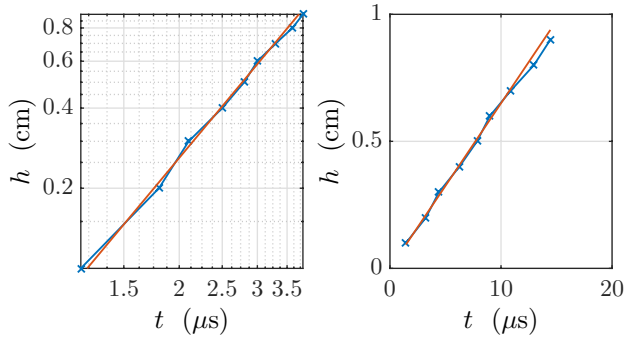


Figure 3.27:

b. From the graph we obtain the slope

$$\alpha = \frac{h_2 - h_1}{t_{b2}^2 - t_{b1}^2} \approx 6.5\,\mathrm{cm/s^2} \ .$$

With that we calculate,

$$I = \frac{g}{2}\frac{mr^2}{\alpha} - mr^2 = 0.004\,\mathrm{kg\ m^2} \ .$$

Chapter 4

Vibrations

Vibrations are periodic processes, that is, processes that repeat themselves after a given time interval. After a time called *period*, the system under consideration returns to the same state in which it was initially. There innumerable examples for periodic processes, such as the motion of a seesaw, oceanic tides, electronic $L-C$ circuits, alternating current or rotations like that of the Earth around the Sun. Thus, vibrations are among the most fundamental processes in all domains of physics. A lecture version of this chapter can be found at (watch talk).

4.1 Free periodic motion

A movement is considered as free, when apart from a *restoring force*, that is a force working to counteract the displacement, there are no other forces accelerating or slowing down the motion.

4.1.1 Clocks

Periodic motions are used to *measure time*. Assuming a given process to be truly periodic, we can inversely *postulate* that the time interval within which this process occurs is constant. This interval is used to define a *unit of time*. For example, the 'day' is defined as the interval that the Earth needs to complete a rotation about its axis. The 'second' is defined as the 86400-th fraction of this period. Taking the second inversely as the base unit, we can define the day as the time interval needed for a periodic process taking 1 s to occur 86400 times. That is, we count the number of times ν that this process occurs within a day and calculate the duration of a day through,

$$\Delta T = \frac{1}{\nu} \, . \tag{4.1}$$

In real life, vibrations are subject to perturbations, just like all physical processes. These perturbations may afflict the periodicity and falsify the measurement of time. For example, the oceanic tides, which depend on the rotation of the moon around the Earth, can influence the Earth's own rotation. One of the challenges of *metrology*, which is the science dealing with issues related to the measurement of time, is to identify processes in nature that are likely to be insensitive to external perturbations. Nowadays, the most stable known periodic processes are vibrations of electrons within atoms. Therefore, the international time is defined by an atomic clock based on

cesium: The 'official' second is the time interval in which the state of an electron oscillates 9192631770 times when the hyperfine structure of a cesium atom is excited by a microwave.

The unit of time is,

$$\text{unit}(T) = \text{s} \ . \tag{4.2}$$

A *frequency* is defined as the number of processes that occur within one second. We use the unit,

$$\text{unit}(\nu) = \text{Hz} \ . \tag{4.3}$$

Often, to simplify mathematical formulas, we will use the derived quantity of the *angular frequency* also called *angular velocity*,

$$\omega \equiv 2\pi\nu \ . \tag{4.4}$$

It has the unit,

$$\text{unit}(\omega) = \text{rad/s} \neq \text{Hz} \ . \tag{4.5}$$

It is important not to use the unit 'Hertz' for angular frequencies in order to avoid confusion.

4.1.2 Periodic trajectories

Many periodic processes are based on repetitive trajectories of particles or bodies. As an example, let us the movement of a body in a box shown in Fig. 4.1. When the body encounters a wall, it is elastically reflected thereby maintaining its velocity but reversing the direction of propagation. Clearly, the velocity is the derivative of the position,

$$v(t) = \dot{x}(t) \ . \tag{4.6}$$

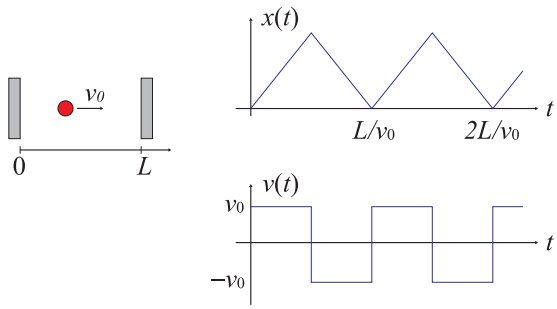

Figure 4.1: Trajectory of a body in a rectangular box. Upper trace: instantaneous position. Lower trace: instantaneous velocity.

To fully describe the trajectory of a body and to identify, when the trajectory repeats, two parameters are needed. Specifying, for example, the time evolution of position $x(t)$ and velocity $v(t)$, we can search for time intervals T after which,

$$x(t_0 + T) = x(t_0) \qquad \text{and} \qquad v(t_0 + T) = v(t_0) \ . \tag{4.7}$$

Obviously, as seen in Fig. 4.1, it is not enough just to look for the time when $x(t_0 + T) = x(t_0)$.

4.1.3 Simple harmonic motion

The simplest motion imaginable is the harmonic oscillation described by,

$$x(t) = A\cos(\omega_0 t - \phi) \ , \tag{4.8}$$

and exhibit in Fig. 4.2. A is the *amplitude* of the motion, such that $2A$ is the distance between the two turning points. $T = 2\pi/\omega_0$ is the oscillation period, since,

$$\cos[\omega_0(t+T) - \phi] = \cos[\omega_0 t + 2\pi - \phi] = \cos[\omega_0 t - \phi] \ . \tag{4.9}$$

ϕ is a *phase shift* describing the time delay $t = \phi/\omega_0$ for the oscillation to reach the turning point.

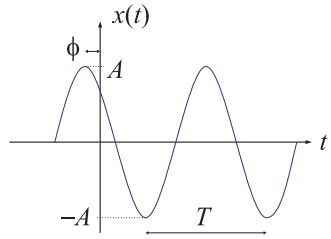

Figure 4.2: Illustration of the cosenus function with the amplitude A, the period T and the phase being negative for this graph $\phi < 0$.

The velocity and acceleration follow from,

$$v(t) = \dot{x}(t) = -\omega_0 A\sin(\omega_0 t - \phi) \qquad \text{and} \qquad a(t) = \dot{v}(t) = -\omega_0^2 A\cos(\omega_0 t - \phi) \ . \tag{4.10}$$

with this we can, using Newton's law, calculate the force necessary to sustain the oscillation of the body,

$$F(t) = ma(t) = -m\omega_0^2 A\cos(\omega_0 t - \phi) = -m\omega_0^2 x(t) \equiv kx(t) \ . \tag{4.11}$$

That is, in the presence of a force, which is proportional to the displacement but with the opposite direction, $F \propto -x$, we expect a sinusoidal solution. The proportionality constant k is called *spring constant*. Obviously the oscillation frequency is independent of amplitude and phase,

$$\omega_0 = \sqrt{k/m} \ . \tag{4.12}$$

Solve Exc. 4.1.10.1 and 4.1.10.2.

Example 7 (*Harmonic vibration*):

- Suspended spring-mass system, pendulums with various masses and lengths of wire, oscilloscope and function generator, water recipient with a floating body.

4.1.4 The spring-mass system

Let us now discuss a possible experimental realization of a sinusoidal vibration. Fig. 4.3 illustrates the spring-mass system consisting of a mass horizontally fixed to a spring. This system has a resting position, which we can set to the point $x = 0$, where no forces act on the mass. When elongated or compressed, the spring exerts a restoring force on the mass working to bring the mass back into its resting position,

$$F_{restore} = -kx \ . \tag{4.13}$$

This so-called *Hooke's law* holds for reasonably small elongations. The spring coefficient k is a characteristic of the spring.

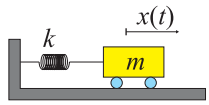

Figure 4.3: Illustration of the spring-mass system.

The oscillation frequency of the spring-mass system is determined by the spring coefficient and the mass, but the phase and the amplitude of the oscillation are parameters, that depend on the way the spring-mass is excited. Knowing the position and velocity of the oscillation at a given time, that is, the initial conditions of the motion, we can determine the amplitude and phase. To see this, we expand the general formula for a sinusoidal oscillation,

$$x(t) = A\cos(\omega_0 t - \phi) = A\cos(\omega_0 t)\cos\phi + A\sin(\omega_0 t)\sin\phi \tag{4.14}$$

and calculate the derivative,

$$v(t) = -A\omega_0\cos\phi\sin(\omega_0 t) + A\omega_0\sin\phi\cos(\omega_0 t) \ . \tag{4.15}$$

With the initial conditions $x(0) = x_0$ and $v(0) = v_0$ we get,

$$A\cos\phi = x_0 \qquad \text{and} \qquad A\omega_0\sin\phi = v_0 \ . \tag{4.16}$$

Hence,

$$x(t) = x_0\cos(\omega_0 t) + \frac{v_0}{\omega_0}\sin(\omega_0 t) \ . \tag{4.17}$$

Solve the Excs. 4.1.10.3, 4.1.10.4, 4.1.10.5, and 4.1.10.6.

4.1.5 Energy conservation

Considerations of *energy conservation* can often help solving mechanical problems. The kinetic energy due to the movement of the mass m is,

$$E_{kin} = \tfrac{m}{2}v^2 \ , \tag{4.18}$$

and the potential energy due to the restoring force is,

$$E_{pot} = -\int_0^x F dx' = -\int_0^x -kx' dx' = \tfrac{k}{2}x^2 \ . \tag{4.19}$$

The total energy must be conserved:

$$E = E_{kin} + E_{pot} = \frac{m}{2}v^2 + \frac{k}{2}x^2 = const \ , \tag{4.20}$$

but is continuously transformed between kinetic energy and potential energy. This is illustrated on the left-hand side of the Fig. 4.4.

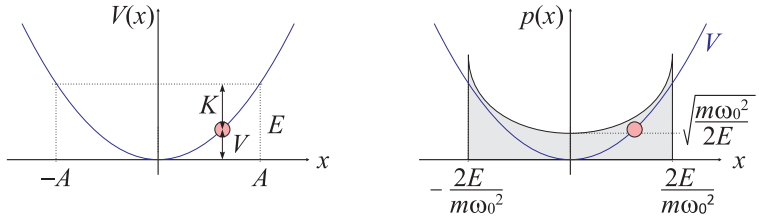

Figure 4.4: (Left) Energy conservation in the spring-mass system showing the kinetic energy K, the potential energy V, and the total energy E. (Right) Probability density of finding the oscillator in position x.

Example 8 (*Probability distribution in the harmonic oscillator*): Let us now use the principle of energy conservation to calculate the probability of finding the oscillating mass next to a given displacement x. For this, we solve the last equation by the velocity,

$$v = \frac{dx}{dt} = \sqrt{\frac{2}{m}E - \frac{k}{m}x^2} = \omega_0\sqrt{\frac{2E}{m\omega_0^2} - x^2} \ , \tag{4.21}$$

or

$$\frac{dx}{\sqrt{\frac{2E}{m\omega_0^2} - x^2}} = \omega_0 dt \ . \tag{4.22}$$

The probability of finding the mass within a given time interval dt is,

$$p(t)dt = \frac{dt}{T} = \frac{\omega_0}{2\pi}dt = \frac{dx}{2\pi\sqrt{\frac{2E}{m\omega_0^2} - x^2}} = \tilde{p}(x)dx \ . \tag{4.23}$$

Hence,

$$\tilde{p}(x) = \frac{1}{2\pi\sqrt{\frac{2E}{m\omega_0^2} - x^2}} \tag{4.24}$$

is the probability density of finding in the mass at the position $x(t)$. Using $\int \frac{dx}{\sqrt{a^2-x^2}} = \arcsin\frac{x}{a}$ with $x_0 = \sqrt{\frac{2E}{m\omega_0^2}}$ we verify,

$$2\int_{-x_0}^{x_0}\tilde{p}(x)dx = \frac{1}{\pi}\left[\arcsin\frac{x}{\sqrt{\frac{2E}{m\omega_0^2}}}\right]_{-x_0}^{x_0} = \frac{2}{\pi}\arcsin\frac{x_0}{\sqrt{\frac{2E}{m\omega_0^2}}} = \frac{2}{\pi}\arcsin 1 = 1 \ . \tag{4.25}$$

The probability density is shown on the right side of Fig. 4.4 [1].

[1] To understand the difference between the probability densities $p(t)$ and $\tilde{p}(x)$ we imagine the following experiments: We divide the period T into equal intervals dt and take a series of photos, all with the same exposure time dt. To understand the meaning of $p(t)$, we throw a random number to choose one of the photos. Each photo has the same probability dt/T to be chosen and, of course, $\int_0^T p(t)dt = 1$. To understand the meaning of $\tilde{p}(x)$, we identify the position of the oscillator in each photo and plot it in a histogram. This histogram is reproduced by $\tilde{p}(x)$.

4.1.6 The spring-mass system with gravity

When a mass is suspended vertically to a spring, as shown on the left-hand side of Fig. 4.5, the gravitational force acts on the mass in addition to the restoring force. This can be expressed by the following balance of forces,

$$ma = -ky - mg \ , \tag{4.26}$$

letting the y-axis be positive in the direction opposite to gravitation. Replacing $\tilde{y}' \equiv y - y_0$ with $y_0 \equiv -\frac{mg}{k}$, we obtain,

$$m\tilde{a} = -k\tilde{y} \ . \tag{4.27}$$

Therefore, the movement is the same as in the absence of gravitation, but around an equilibrium point shifted downward by y_0.

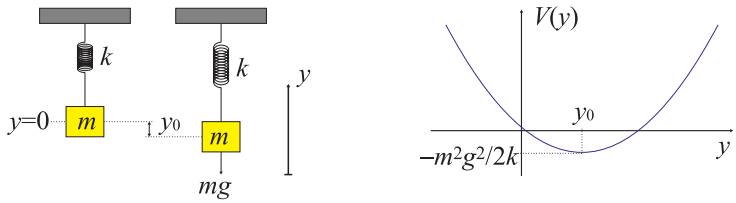

Figure 4.5: Left: Vertical spring-mass system. Right: Conservation of energy in the spring-mass system with gravity.

Energy conservation is now generalized to,

$$E = E_{kin} + E_{mol} + E_{grv} = \tfrac{m}{2}v^2 + \tfrac{k}{2}y^2 + mgy = const \ , \tag{4.28}$$

the potential energy being,

$$\begin{aligned} E_{pot} = E_{mol} + E_{grv} &= \tfrac{k}{2}y^2 + mgy \\ &= \tfrac{k}{2}(y - y_0)^2 + \tfrac{k}{2}2y_0y - \tfrac{k}{2}y_0^2 + mgy = \tfrac{k}{2}(y - y_0)^2 - \frac{m^2g^2}{2k} \ . \end{aligned} \tag{4.29}$$

The right-hand side of Fig. 4.5 illustrates the conservation of energy in the spring-mass system with gravity. See Excs. 4.1.10.7, 4.1.10.8, 4.1.10.9, and 4.1.10.10.

4.1.7 The pendulum

The pendulum is another system which oscillates in the gravitational field. In the following, we will distinguish three different types of pendulums. In the *ideal pendulum* the mass of the oscillating body is all concentrated in one point and the oscillations have small amplitudes. In the *physical pendulum* the mass of the body is distributed over a finite spatial region. And *mathematical pendulum* is a point mass oscillating with a large amplitude and therefore subject to a nonlinear restoring force.

Figure 4.6: Physical pendulum.

4.1.7.1 The ideal pendulum

The *ideal pendulum* is schematized on the left side of Fig. 4.6. As the centrifugal force is compensated for by the traction of the wire supporting the mass, the acceleration force ma is solely due to the perpendicular projection $-mg\sin\theta$ on the wire. For small amplitudes, $\sin\theta \simeq \theta$, such that [2],

$$ma \simeq -mg\theta \ . \tag{4.30}$$

The tangential acceleration is now,

$$a = \dot{v} = \ddot{s} = \frac{d}{dt}\theta L = L\ddot{\theta} \ . \tag{4.31}$$

Thus,

$$\ddot{\theta} + \frac{g}{L}\theta \simeq 0 \ . \tag{4.32}$$

This equation has the same structure as that of the already studied spring-mass system $\ddot{x} + \frac{k}{m}x = 0$. Therefore, we can deduce that the ideal pendulum oscillates with the frequency,

$$\omega_0 = \sqrt{\frac{g}{L}} \ , \tag{4.33}$$

only that the oscillating degree of freedom is an angle rather than a spatial shift. It is interesting to note that the oscillation frequency is independent of the mass. See Exc. 4.1.10.11.

4.1.7.2 The physical pendulum

We consider an irregular body suspended at a point P as schematized on the right-hand side of Fig. 4.6. The center-of-mass be displaced from the suspension point by a distance D. This system represents the *physical pendulum*. Gravitation exerts a torque $\vec{\tau}$ on the center-of-mass,

$$\vec{\tau} = \mathbf{D} \times m\mathbf{g} \qquad \text{with} \qquad \tau = I\ddot{\theta} \ , \tag{4.34}$$

where I is the moment of inertia of the body for rotations about the suspension axis. Like this,

$$I\ddot{\theta} = -Dmg\sin\theta \ . \tag{4.35}$$

[2]The equation of motion can be derived from the Hamiltonian $H = \frac{L_\theta^2}{2ml^2} + mgl\cos\theta$ using $\dot{\theta} = \partial H/\partial \mathbf{L}_\theta$ and $\dot{L_\theta} = -\partial H/\partial\theta$, where L_θ is the angular momentum.

Considering once more small angles, $\sin\theta \simeq \theta$, we obtain,

$$\ddot{\theta} + \omega_0^2 \theta \simeq 0 \qquad \text{with} \qquad \omega_0 \equiv \sqrt{\frac{Dmg}{I}} \ . \tag{4.36}$$

It is worth mentioning that the inertial moment of a body whose mass is concentrated in a point at a distance D from the suspension point follows *Steiner's law*,

$$I = mD^2 \ . \tag{4.37}$$

With this we recover the expression of the ideal pendulum,

$$\omega_0 = \sqrt{\frac{Dmg}{mD^2}} = \sqrt{\frac{g}{D}} \ . \tag{4.38}$$

4.1.7.3 The mathematical pendulum

The equation describing the mathematical pendulum (see Fig. 4.6) has already been derived but, differently from what we did before, here we will not apply the small angle approximation,

$$\ddot{\theta} = -\frac{g}{L}\sin\theta = -\omega_0^2 \sin\theta \ . \tag{4.39}$$

Energy conservation can be formulated as follows:

$$\begin{aligned} 0 = \frac{dE}{dt} &= \frac{d}{dt}(E_{rot} + E_{pot}) = \frac{d}{dt}\frac{I}{2}\dot{\theta}^2 + \frac{d}{dt}mgL(1-\cos\theta) \\ &= \frac{I}{2}2\dot{\theta}\ddot{\theta} + mgL\dot{\theta}\sin\theta \simeq \dot{\theta}(I\ddot{\theta} + mgL\theta) \ . \end{aligned} \tag{4.40}$$

Thus, we obtain the same differential equation,

$$\ddot{\theta} + \frac{mgL}{I}\theta = 0 \ . \tag{4.41}$$

Example 9 (*Simulation of an anharmonic pendulum*): When the anharmonicity is not negligible, it is impossible to solve the differential equation analytically. We must resort to numerical simulations. The simplest procedure is an iteration of the type,

$$\begin{aligned} \theta(t+dt) &= \theta(t) + dt\dot{\theta} = \theta(t) + dt\omega \\ \omega(t+dt) &= \omega(t) + dt\dot{\omega} = \omega(t) - dt\omega_0 \sin\theta \ . \end{aligned}$$

Fig. 4.7(a) shows the temporal dephasing of the oscillation caused by the anharmonicity as compared to the harmonic oscillation. Fig. 4.7(b) shows the orbits $\theta(t) \longmapsto \omega(t)$ in the phase space.

4.1.8 The spring-cylinder system

Another example of an oscillating system is shown in Fig. 4.8. The inertial moment of the cylinder is $I = \frac{M}{2}R^2$. The spring exerts the force,

$$F_{mol} = -kx \ . \tag{4.42}$$

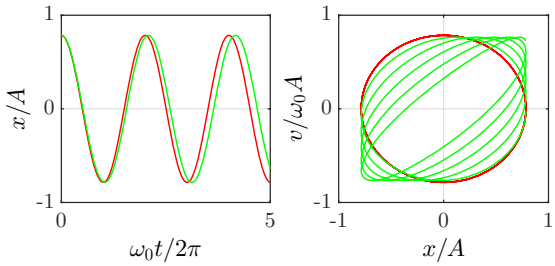

Figure 4.7: (code) Diffusion due to anharmonicities (a) in time and (b) in phase space. The red curves show the harmonic approximation.

Therefore, we have the equations of motion,

$$M\ddot{x} = F_{mol} - F_{at} \qquad (4.43)$$
$$I\ddot{\theta} = -RF_{at} \ .$$

If the wheel does not slip, we can eliminate the friction using $x = R\omega$, and we obtain,

$$I\ddot{\theta} = I\frac{\ddot{x}}{R} = \frac{M}{2}R^2\frac{\ddot{x}}{R} = -RF_{at} = -R(-kx - M\ddot{x}) \ . \qquad (4.44)$$

Resolving by $\ddot{x}$,

$$\ddot{x} + \frac{2k}{3M}x = 0 \ . \qquad (4.45)$$

The frequency is,

$$\omega_0 = \sqrt{\frac{2k}{3M}} \ . \qquad (4.46)$$

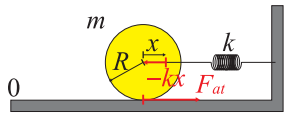

Figure 4.8: The spring-cylinder system.

4.1.9 Two-body oscillation

We now consider the oscillations of two bodies m_1 and m_2 located at the positions x_1 and x_2 and interconnected by a spring k, as shown in Fig. 4.9. The free length, that is, the distance at which the spring exerts no forces on the masses, is ℓ. The forces grow with the stretch $x \equiv x_2 - x_1 - \ell$ of the spring, such that $x > 0$ when the spring is stretched and $x < 0$ when it is compressed. Thereby,

$$m_1\ddot{x}_1 = kx \qquad \text{and} \qquad m_2\ddot{x}_2 = -kx \ . \qquad (4.47)$$

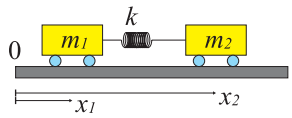

Figure 4.9: Two bodies in relative vibration.

Adding these equations,

$$m_1\ddot{x}_1 + m_2\ddot{x}_2 \equiv (m_1 + m_2)\ddot{x}_{cm} = 0 \ . \tag{4.48}$$

Dividing the equations by the masses and subtracting them,

$$\ddot{x}_1 - \ddot{x}_2 = -k\left(\frac{1}{m_1} + \frac{1}{m_2}\right)x = \ddot{x}_{rel} = -\frac{k}{\mu}x = \omega_0 x \ , \tag{4.49}$$

where $\omega_0^2 = k/\mu$ and $\mu^{-1} \equiv m_1^{-1} + m_2^{-1}$ is called the *reduced mass*. The introduction of the reduced mass turns the oscillator consisting of two bodies equivalent to a system consisting of only one mass and one spring, but with an increased vibration frequency,

$$\omega_\mu = \sqrt{\frac{k}{\mu}} = \sqrt{2\frac{k}{m}} \ . \tag{4.50}$$

This system represents an important model for the description of *molecular vibration*. Note that for $m_1 \longrightarrow \infty$ we restore the known situation of a spring-mass system fixed to a wall.

4.1.10 Exercises

4.1.10.1 Ex: Zenith in São Carlos

Knowing that the latitude of the Sun in the tropics of Capricorn is $\alpha_{trop} = 23°$ calculate at what time of the year the sun is vertical at noon in São Carlos, SP, Brazil.

Solution: *The zenith of the sun oscillates sinusoidally with a period of one year and an amplitude α_{trop}. Hence,*

$$\alpha(t) = \alpha_{trop}\cos\frac{2\pi t}{365\,\mathrm{d}} \ .$$

The sun is vertical in São Carlos ($\alpha_{sc} = 21.92°$) when $\alpha(t) = \alpha_{sc}$, that is,

$$\alpha_{trop}\cos\frac{2\pi t}{365\,\mathrm{d}} = \alpha_{sc} \ .$$

or

$$t = \frac{365\,\mathrm{d}}{2\pi}\arccos\frac{\alpha_{SC}}{\alpha_{WK}} = 17.9\,\mathrm{d} \ .$$

4.1.10.2 Ex: Length of days on Earth

Calculate the length of a day on Earth as a function of the location's longitude ϕ and latitude θ and of the season of the year.

Solution: *We set the z-axis to coincide with the axis of Earth, so that a location on Earth is specified by,*

$$\mathbf{r} = r \begin{pmatrix} \cos\theta\cos\phi \\ \cos\theta\sin\phi \\ \sin\theta \end{pmatrix} ,$$

with $\phi = 2\pi t/24\,\mathrm{h}$, θ, *and* $R = 6370\,\mathrm{km}$. *The coordinate of the Sun is parameterized as,*

$$\mathbf{R} = R \begin{pmatrix} \cos\alpha \\ 0 \\ \sin\alpha \end{pmatrix} ,$$

with $R = 1.59 \cdot 10^9\,\mathrm{km}$ *and the inclination of the Earth's axis,*

$$\alpha = \alpha_0 \sin\tfrac{2\pi t}{365\,\mathrm{d}} ,$$

with $\alpha_0 = 23^\circ$. *The condition* $\mathbf{r}\cdot\mathbf{R} = 0$ *yields,*

$$\Delta t = \frac{24\,\mathrm{h}}{2\pi}\Delta\phi = \frac{24\,\mathrm{h}}{\pi}\arccos(-tan\theta\tan\alpha) .$$

For example, for Quimper located at $\theta = 48^\circ$, *we get on the 21-th of June* $\Delta t = 15\,\mathrm{h}\,45\,\mathrm{min}$ *and on the 21-th of December* $\Delta t = 8\,\mathrm{h}\,15\,\mathrm{min}$. *For Nice located at* $\theta = 43^\circ$, *we get in summer* $\Delta t = 15\,\mathrm{h}\,6\,\mathrm{min}$ *and in winter* $\Delta t = 8\,\mathrm{h}\,53\,\mathrm{min}$.

4.1.10.3 Ex: Swing modes

In the systems shown in the figure there is no friction between the surfaces of the bodies and floor, and the springs have negligible mass. Find the natural oscillation frequencies.

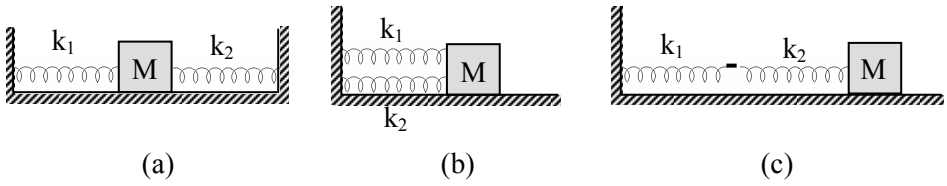

Figure 4.10: Swing modes.

Solution: *a. Be* x_1 *and* x_2 *the independent rest positions of the two springs, such that the independent restorative forces are,*

$$F_1 = -k_1(x - x_1) \qquad and \qquad -F_2 = -k_2(x_2 - x) .$$

The resting position of the springs acting jointly x_0 follows from,

$$0 = F_1 + F_2 = -k_1(x_0 - x_1) - k_2(x_0 - x_2) \ ,$$

giving,

$$x_0 = \frac{k_1 x_1 + k_2 x_2}{k_1 + k_2} \ .$$

The equation of motion is now,

$$M\ddot{x} = F_1 + F_2 = -k_1(x_0 - x_1) - k_2(x_0 - x_2) = -(k_1 + k_2)(x - x_0) \ .$$

Hence,

$$\omega_0 = \sqrt{\frac{k_1 + k_2}{M}} \ .$$

b. The same argument can be used to treat springs in parallel. We have $k = k_1 + k_2$, hence,

$$\omega_0 = \sqrt{\frac{k_1 + k_2}{M}}.$$

c. For springs in series the derivation is more complicated. We call y and y_1, respectively, the current position and the resting position of the connection point between the springs and x and x_2, respectively, the current position and the resting position of the mass. Since the connection point has no mass, we have an equilibrium between the forces exerted by the two springs,

$$0 = F_1 + F_2 = -k_1(y - y_1) + k_2(x - x_2 - y + y_1) \ ,$$

yielding,

$$y - y_1 = \frac{k_2}{k_1 + k_2}(x - x_2) \ .$$

The equation of motion is now,

$$M\ddot{x} = F_M = -F_2 = -k_2(x - x_2 - y + y_1) = -\frac{k_1 k_2}{k_1 + k_2}(x - x_2) \ .$$

Hence, $k = (k_1^{-1} + k_2^{-1})^{-1}$ and,

$$\omega_0 = \sqrt{\frac{(k_1^{-1} + k_2^{-1})^{-1}}{M}} \ .$$

4.1.10.4 Ex: Coupled springs

A mass m is suspended within a horizontal ring of radius $R = 1\,\mathrm{m}$ by three springs with the constants $D_1 = 0.1\,\mathrm{kg/m}$, $D_2 = 0.2\,\mathrm{N/m}$, and $D_3 = 0.3\,\mathrm{N/m}$. The suspension points of the springs on the ring have the same mutual distances. Determine the equilibrium position of the mass assuming that the springs' extensions at rest range is 0.

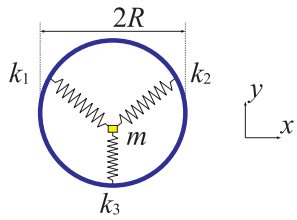

Figure 4.11: Coupled springs.

Solution: *We choose the origin of the coordinate system at the center of the ring and the equilibrium position at* $\mathbf{r}$*. Then the forces are balanced holds* $\mathbf{F}_1 + \mathbf{F}_2 + \mathbf{F}_3 = 0$*. Following the scheme the suspension points are at,*

$$\mathbf{a}_1 = R\begin{pmatrix} -\frac{1}{2}\sqrt{3} \\ \frac{1}{2} \end{pmatrix} \quad , \quad \mathbf{a}_2 = R\begin{pmatrix} \frac{1}{2}\sqrt{3} \\ \frac{1}{2} \end{pmatrix} \quad , \quad \mathbf{a}_3 = R\begin{pmatrix} 0 \\ -1 \end{pmatrix} \ ,$$

where $a_1 = a_2 = a_3$*. Hence,* $-k_1(\mathbf{a}_1 - \mathbf{r}) - k_2(\mathbf{a}_2 - \mathbf{r}) - k_3(\mathbf{a}_3 - \mathbf{r}) = 0$*. Finally we get for the components,*

$$x_0 = \frac{k_1 - k_2}{k_1 + k_2 + k_3}\frac{R}{2}\sqrt{3} \quad , \quad y_0 = \frac{k_1 + k_2 - 2k_3}{k_1 + k_2 + k_3}\frac{R}{2} \ .$$

The equations of motion are, letting the springs be equal, $k_1 = k_2 = k_3$*,*

$$m\ddot{x} = -k\left(x + \tfrac{R}{2}\sqrt{3}\right) - k\left(x - \tfrac{R}{2}\sqrt{3}\right) - kx = -3kx$$
$$m\ddot{y} = -k\left(y - \tfrac{R}{2}\right) - k\left(y - \tfrac{R}{2}\right) - k\left(y + R\right) = -3ky \ .$$

4.1.10.5 Ex: Coupled springs

A mass m is suspended by four springs with the constants k_n, as shown in the figure. Determine the equilibrium position of the mass. Assume the ideal case of ideally compressible springs.

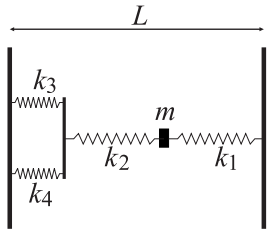

Figure 4.12: Coupled springs.

Solution: *Springs are arbitrarily compressible, i.e., $F_n = -k_n a_n$. Following the scheme, both the mass m and the connecting plate between the springs are in equilibrium, that is, $F_{34} = F_2 = F_1$. Since the springs k_3 and k_4 are mounted in parallel, their total spring constant is additive. Hence we have $(k_3 + k_4)a_3 = k_2 a_2 = k_1 a_1$. Using the condition that the sum of the individual displacements of the spring is $a_1 + a_2 + a_3 = L$, we obtain:*

$$a_1 = \frac{L}{1 + k_1/k_2 + k_1/(k_3 + k_4)} \ .$$

4.1.10.6 Ex: Coupled springs

Calculate the resulting spring constants for the constructions shown in the scheme. Individual springs are arbitrarily compressible with spring constants D_k.

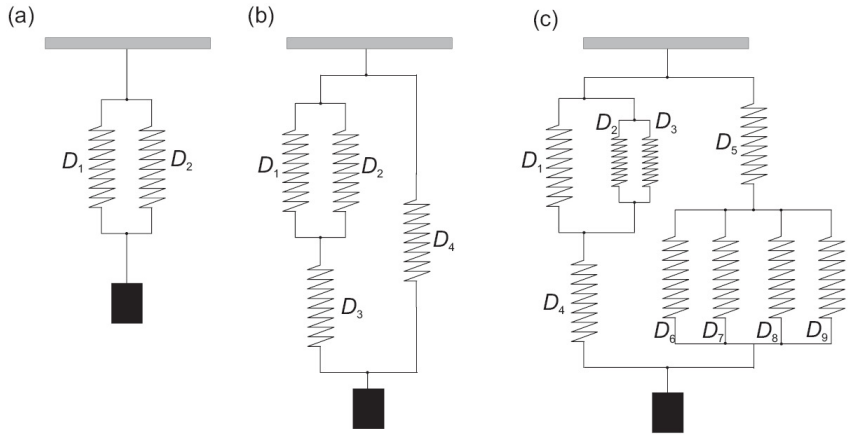

Figure 4.13: Coupled springs.

Solution: *For a spring assembly in series we have the two equations,*

$$mg - D_1 x_1 = 0 \qquad \textit{and} \qquad mg - D_2(x_2 - x_1) = 0 \ .$$

Hence,

$$x_2 = \frac{D_1 + D_2}{D_2} x_1 = \frac{D_1 + D_2}{D_1 D_2} mg \ ,$$

or

$$D_{tot} = \left(\frac{1}{D_1} + \frac{1}{D_2} \right)^{-1} \ .$$

And analogously for a parallel assembly we have the equation

$$mg - D_1 x - D_2 x = 0 \ .$$

Hence,

$$D_{tot} = D_1 + D_2 \ .$$

By applying these rules to the shown assemblies, we get
a. $D = D_1 + D_2$
b. $D = \left(\frac{1}{D_1+D_2} + \frac{1}{D_3}\right)^{-1} + D_4$
c. $D = \left(\frac{1}{D_1+D_2+D_3} + \frac{1}{D_4}\right)^{-1} + \left(\frac{1}{D_5} + \frac{1}{D_6+D_7+D_8+D_9}\right)^{-1}$

4.1.10.7 Ex: Spring-mass system

A body of unknown mass hangs at the end of a spring, which is neither stretched nor compressed, and is released from rest at a certain moment. The body drops a distance y_1 until it rests for the first time after the release. Calculate the period of oscillatory motion.

Solution: *Since the mass is released at rest, it will periodically return to the starting point. By conservation of energy the falling distance is twice the oscillation amplitude, which is equal to the resting position in the gravitational field,*

$$y_1 = 2y_0 = \tfrac{mg}{2k} \ .$$

So the oscillation frequency is,

$$\omega_0 = \sqrt{\frac{k}{m}} = \frac{2g}{y_1} \ .$$

4.1.10.8 Ex: Spring-mass system

A body of $m = 1.5\,\mathrm{kg}$ stretches a spring by $y_0 = 2.8\,\mathrm{cm}$ from its natural length when being at rest. Now, we let it swing at this spring with an amplitude of $y_m = 2.2\,\mathrm{cm}$.
a. Calculate total energy of the system.
b. Calculate the gravitational potential energy at the body's lower turning point.
c. Calculate the potential energy of the spring at the body's lower turning point.
d. What is the maximum kinetic energy of the body (when $U = 0$ is the point where the spring is at equilibrium).

Solution: *a. Since the stretch of the spring corresponds to* $y_0 = -\frac{mg}{k}$*, we can calculate the spring constant,*

$$k = \frac{mg}{-y_0} = 526\,\mathrm{N/m} \ ,$$

and the oscillation frequency is,

$$\omega_0 = \sqrt{\frac{k}{m}} \ .$$

So we can describe the motion by the function,

$$y(t) = y_m \cos \omega_0 t + y_0 \ .$$

The total energy at the upper turning point is,

$$E = E_{mol} + E_{grv} = \frac{k}{2}(y_m + y_0)^2 + mg(y_m + y_0) = -0.079\,\mathrm{J} \ .$$

b. The gravitational potential energy at the lower turning point is

$$E_{grv} = mg(-y_m + y_0) = -0.74\,\mathrm{J} \ .$$

c. The total potential energy at the lower turning point is equal to the total energy (a), because the kinetic energy disappears.
d. The instantaneous velocity being,

$$v(t) = -y_m \omega_0 \sin \omega_0 t \ ,$$

the maximum kinetic energy is,

$$E_{kin} = \frac{m}{2} y_m^2 \omega_0^2 = 0.13\,\mathrm{J} \ .$$

The figure shows the energy conservation using the expressions of the formula (4.28). The red line shows the temporal transformation of kinetic energy, the green line of the spring, the blue of gravitation, the cyan of the potential, and black of the total energy.

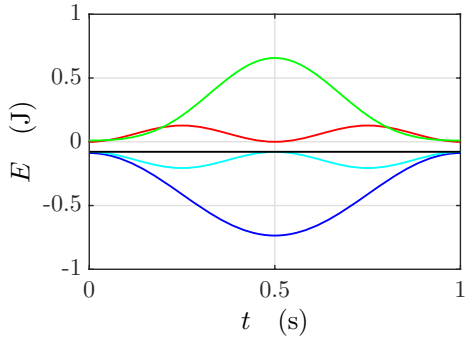

Figure 4.14: Spring-mass system.

4.1.10.9 Ex: U-shaped water tube

Consider a U-shaped tube filled with water. The total length of the water column is L. Exerting pressure on one tube outlet the column is incited to perform oscillations. Calculate the period of the oscillation.

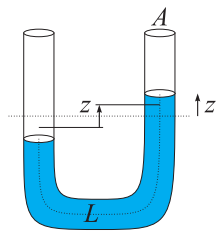

Figure 4.15: U-shaped water tube.

Solution: *If A is the cross section, the total mass of the water is $M = \rho V = \rho AL$, where ρ is the density of water. When the column moves at velocity v, it has kinetic energy,*

$$E_{kin} = \frac{M}{2} v^2 \ .$$

To put the mass $M_z = \rho V_z = \rho Az$ above the resting level of the water, such that the center of mass is a distance z above the low level, we need to provide the work,

$$-W = gM_z z = g\rho Az^2 = E_{pot} \ .$$

Energy conservation requires,

$$E = E_{kin} + E_{pot} = \frac{\rho AL}{2}\dot{z}^2 + g\rho Az^2 = \frac{M}{2}\dot{z}^2 + \frac{2gM}{2L}z^2 = const.$$

Hence, comparing the coefficient of the potential energy with $\frac{M}{2}\omega_0^2$,

$$\omega_0 = \sqrt{\frac{2g}{L}} \ .$$

4.1.10.10 Ex: Buoy in the sea

A hollow cylindrical buoy with cross-sectional area A and mass M floats in the sea so that the axis of symmetry is aligned with gravitation. An albatross of mass m sitting on the buoy waits until time $t = 0$ and takes off. With which frequency and amplitude does the buoy oscillate if friction can be neglected? Derive the equation of motion and the complete solution.

Solution: *The upward buoyant force of the water is,*

$$F_a = \sigma Agz \ ,$$

with the water density $\sigma = 1\,\mathrm{kg/l}$ and the immersion depth of the buoy z. Following Archimedes' law the buoy is at balance at the depth z_0, when $F_a - (M + m)g = 0$, that is, when,

$$-\sigma Az_0 g = (M + m)g \ .$$

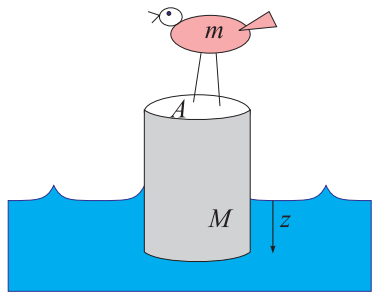

Figure 4.16: Fluctuating buoy.

From this we derive an immersion depth with albatross of $z_0 = \frac{M+m}{\sigma A}$. *When the albatross takes off, the weight decreases and we get an acceleration,* $M\ddot{z} = -\sigma A z g - Mg$ *com* $z(0) = z_0$. *That is, the equation of motion is,*

$$\ddot{z} + \frac{\sigma A g}{M} z = -g \ .$$

Hence, the vibration frequency is $\omega = \sqrt{\frac{\sigma A g}{M}}$. *To make this inhomogeneous differential equation a homogeneous one, we make, as in the case of the spring-mass in the gravitational field, the substitution,* $\tilde{z} = z + \frac{M}{\sigma A}$. *With that we get,*

$$\ddot{\tilde{z}} + \frac{\sigma A g}{M} \tilde{z} = 0 \ .$$

The general solution of this equation is $\tilde{z} = C \sin \omega t + D \cos \omega t$, *such that,*

$$z = C \sin \omega t + D \cos \omega t - \frac{M}{\sigma A} \ .$$

With the known initial conditions we have,

$$\begin{aligned} z(0) = z_0 &= C \sin \omega t + D \cos \omega t - \frac{M}{\sigma A} = D - \frac{M}{\sigma A} \\ \dot{z}(0) = 0 &= \omega C \cos \omega t - \omega D \sin \omega t = \omega C \ , \end{aligned}$$

and we can calculate the vibration amplitude, $D = z_0 + \frac{M}{\sigma A} = -\frac{m}{\sigma A}$. *Hence, the complete solution is,*

$$z = -\frac{m}{\sigma A} \cos \omega t - \frac{M}{\sigma A} \ .$$

4.1.10.11 Ex: Complicated pendulum oscillation

At a distance of $d = 30\,\text{cm}$ below the suspension point of a pendulum with the length $l_1 = 50\,\text{cm}$ there is a fixed pin S on which the wire suspending the pendulum temporarily bends during vibration. How many vibrations does the pendulum perform

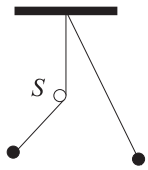

Figure 4.17: Mathematical pendulum.

per minute?

Solution: *We have half vibrations for two different wire lengths, l_1 and $l_2 = l_1 - d$. We know,*

$$\omega_{1,2} = \sqrt{\frac{g}{l_{1,2}}} \qquad \textit{and} \qquad T_{1,2} = \frac{2\pi}{\omega_{1,2}} \ .$$

Thereby,

$$f = \frac{1}{T} = \frac{1}{T_1/2 + T_2/2} = \frac{\sqrt{g}}{\pi(\sqrt{l_1} + \sqrt{l_2})} \approx 51.8\,\mathrm{min}^{-1} \ .$$

4.1.10.12 Ex: Physical pendulum

Calculate the oscillation frequency of a thin bar of mass m and length L suspended at one end.

Solution: *The inertial moment of a thin bar is,*

$$I = \tfrac{1}{3} m L^2 \ .$$

The center-of-mass is in the middle of the bar, $L = 2D$. Hence,

$$\omega_0 = \sqrt{\frac{Dmg}{I}} = \sqrt{\frac{3g}{2L}} \ .$$

4.1.10.13 Ex: Physical pendulum

An irregularly shaped flat body has the mass $m = 3.2\,\mathrm{kg}$ and is hung on a massless rod with adjustable length, which is free to swing in the plane of the body itself. When the rod's length is $L_1 = 1.0\,\mathrm{m}$, the period of the pendulum is $t_1 = 2.6\,\mathrm{s}$. When the rod is shortened to $L_2 = 0.8\,\mathrm{m}$, the period decreases to $t_2 = 2.5\,\mathrm{s}$. What is the period of the oscillation when the length is $L_3 = 0.5\,\mathrm{m}$?

Solution: *Knowing that the period is proportional to the root of the distance between the point of suspension and the center of gravity of the body, $t_k = C\sqrt{L_k}$ with a constant C, we have*

$$t_1 = C\sqrt{\Delta L + L_1} \qquad , \qquad t_2 = C\sqrt{\Delta L + L_2} \ ,$$

where ΔL is the distance between the center of gravity of the body and the attachment point on the rod. With this,

$$C = \sqrt{\frac{t_2^2 - t_1^2}{L_2 - L_1}} \quad , \qquad \Delta L = \frac{t_1^2}{C^2} - L_1 \ ,$$

and

$$t_3 = C\sqrt{\Delta L + L_3} = \sqrt{t_1^2 + (t_2^2 - t_1^2)\frac{L_3 - L_1}{L_2 - L_1}} = 2.34\,\mathrm{s} \ .$$

4.1.10.14 Ex: Physical pendulum

A physical pendulum of mass M consists of a homogeneous cube with the edge length d. As shown in the figure, the pendulum is hung without friction on a horizontal rotation axis.
a. Determine the inertial momentum about the rotation axis using Steiner's theorem.
b. The pendulum now performs small oscillations around its resting position. Determine the angular momentum.
c. Give the equation of motion for small pendulum amplitudes ϕ around its resting position and the oscillation period.

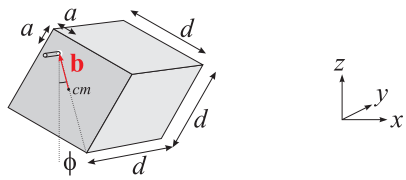

Figure 4.18: Physical pendulum.

Solution: *a. We calculate the tensor of inertia I_{ij} for a coordinate system in the center of the cube:*

$$I_{ij} = \int_V \rho(\mathbf{r}) \left[\delta_{ij} \sum_{\alpha=1}^{3} x_\alpha^2 - x_i x_j \right] dV \ .$$

Hence,

$$\begin{aligned} I_{11} &= \int_V \rho(\vec{r}) \left[x_1^2 + x_2^2 + x_3^2 - x_1 x_1 \right] dV = \rho \int_{-d/2}^{d/2} (x_2^2 + x_3^2) dx_1 dx_2 dx_3 \\ &= \frac{\rho d^5}{6} = \frac{M d^2}{6} = I_{22} = I_{33} \\ I_{\imath \neq j} &= \int_V \rho(\mathbf{r}) x_i x_j dV = \rho \int_{-d/2}^{d/2} x_i x_j dx_i dx_j dx_k = 0 \ . \end{aligned}$$

Thus, I^{CM} adopts the form:

$$I^{CM} = \begin{pmatrix} Md^2/6 & 0 & 0 \\ 0 & Md^2/6 & 0 \\ 0 & 0 & Md^2/6 \end{pmatrix} .$$

Now we nail the cube to the wall. Here, the vertical distance b from the new axis of rotation $\vec{\omega} = \omega\hat{\mathbf{e}}_3$ until the center of mass is given by,

$$\mathbf{b} = \sqrt{2}\left(\frac{d}{2} - a\right)\hat{\mathbf{e}}_b \ .$$

$\hat{\mathbf{e}}_b$ shows from the origin of the new coordinate system (around which the rotation occurs) to the origin of the old coordinate system (the center-of-mass system), $\hat{\mathbf{e}}_b = -\hat{\mathbf{e}}_1 \sin\phi - \hat{\mathbf{e}}_2 \cos\phi$. With Steiner's theorem, $I_\omega = I^{CM}_{\omega_0} + Mb^2$, we get the inertial moment regarding the new rotation axis $I_\omega = 2M\left(\frac{1}{3}d^2 - da + a^2\right)$. The torque is,

$$\mathbf{D} = \frac{\partial}{\partial t}\mathbf{L} = \frac{\partial}{\partial t} I\vec{\omega} = I_\omega \ddot{\phi}\hat{\mathbf{e}}_3 \ .$$

The force of gravitational attraction $F_g = -Mg\hat{e}_2$ cause, when displaced from the rest position, a torque,

$$\mathbf{D} = \mathbf{b} \times \mathbf{F}_g = -b\hat{\mathbf{e}}_b \times Mg\hat{\mathbf{e}}_2 = bMg \sin\phi \hat{\mathbf{e}}_3 \ .$$

Where ϕ is the angle between $\vec{b}$ and the axis $\hat{\mathbf{e}}_2$, that is, the direction of gravitational attraction. Since the torque has to be conserved ($\frac{\partial}{\partial t}\mathbf{L} = 0$), the sum of the torques must be zero,

$$0 = I_\omega \ddot{\phi} + bMg \sin\phi \ .$$

Solving the differential equation for small $\phi(t)$ gives the period T as,

$$T = 2\pi\sqrt{\frac{I_\omega}{bMg}} \ .$$

4.1.10.15 Ex: Physical pendulum on a spiral spring

Consider a beam of mass $m = 1\,\mathrm{kg}$ with the dimensions $(a, b, c) = (3\,\mathrm{cm}, 3\,\mathrm{cm}, 8\,\mathrm{cm})$. The beam is rotatable about an axis through the point A. At point B, at a distance r from point A, the beam is fixed to a spiral spring exerting the retroactive force $\mathbf{F}_R = D\vec{\phi}$ with $D = 100\,\mathrm{N/m}$. Determine the differential equation of motion and solve it. Determine the period of the oscillation.

Solution: *The retroactive force exerts a torque $|\mathbf{M}| = |\mathbf{r} \times \mathbf{F}_R| = rD\phi$. The torque due to the inertia of the mass is $\mathbf{M}_T = I\vec{\omega}$. With that the equation of motion gets,*

$$I\ddot{\phi} + rF_R\phi = 0 \ .$$

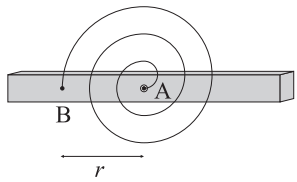

Figure 4.19: Physical pendulum on a spiral spring.

The inertial moment of the beam is,

$$I_\omega = \frac{1}{V}\int_{viga} \varrho(\mathbf{r})(y^2+z^2)d^3r = \frac{\varrho_0}{V}\int_{-c/2}^{c/2}\int_{-b/2}^{b/2}\int_{-a/2}^{a/2}(y^2+z^2)dxdydz$$
$$= \frac{\varrho_0 abc}{12V}(a^2+c^2) = \frac{\varrho_0}{6}(a^2+c^2)\ ,$$

The rest is trivial.

4.1.10.16 Ex: Accelerated pendulum

A simple pendulum of length L is attached to a cart that slides without friction downward an plane inclined by an angle α with respect to the horizontal. Determine the oscillation period of the pendulum on the cart.

Solution: *The force accelerating the car is,*

$$\mathbf{F}_{car} = m\mathbf{a} \qquad with \qquad a = g\sin\alpha\ .$$

The effective force acting on the pendulum suspended inside the cart is,

$$\mathbf{F}_{eff} = m\mathbf{g} - m\mathbf{a} \qquad with \qquad F_{eff} = gm\cos\alpha\ .$$

where $\mathbf{a}$ *is the acceleration of the cart along the plane. Hence, the pendulum's oscillation frequency is,*

$$\omega_0 = \sqrt{\frac{g_{eff}}{L}} = \sqrt{\frac{g\cos\alpha}{L}}\ .$$

4.1.10.17 Ex: Accelerated pendulum

a. A pendulum of length L and mass M is suspended from the roof of a wagon horizontally accelerated with the acceleration a_{ext}. Find the equilibrium position of the pendulum. Determine the oscillation frequency for small oscillations and derive the differential equation of motion for an observer sitting in the wagon. (Note that you cannot assume small displacements, if the acceleration a_{ext} is large.)
b. In the same wagon there is a mass m connected to the front wall by a spring k. Find the equilibrium position of the mass. Determine the oscillation frequency and

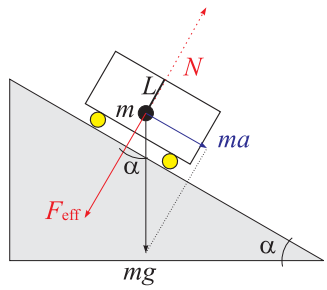

Figure 4.20: Accelerated pendulum.

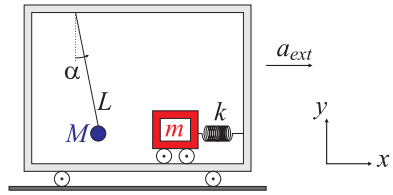

Figure 4.21: Accelerated pendulum.

derive the differential motion equation for an observer sitting in the wagon.

Solution: *a. Effective acceleration is,*

$$a_{ef} = \sqrt{g^2 + a^2} \ .$$

Hence the frequency for small amplitudes is,

$$\omega_0 = \sqrt{\frac{a_{ef}}{L}} = \sqrt{\frac{\sqrt{g^2 + a^2}}{L}} \ .$$

We derive the equation of motion in the sketched Cartesian system, where $x = L\sin\alpha$ *and* $y = -L\cos\alpha$*. Here, Newton's equation* $m\ddot{\vec{x}} = m\vec{g} + m\vec{a}$ *becomes,*

$$mL\begin{pmatrix}\ddot{\alpha}\cos\alpha - \dot{\alpha}^2\sin\alpha \\ \ddot{\alpha}\sin\alpha + \dot{\alpha}^2\cos\alpha\end{pmatrix} = m\begin{pmatrix}\ddot{x} \\ \ddot{y}\end{pmatrix} = mg\sin\alpha\begin{pmatrix}-\cos\alpha \\ -\sin\alpha\end{pmatrix} + \begin{pmatrix}ma \\ 0\end{pmatrix} \ .$$

Calculating $m\ddot{x}\cos\alpha + m\ddot{y}\sin\alpha$ *we find,*

$$\ddot{\alpha} = -\frac{g}{L}\sin\alpha + \frac{a}{L}\cos\alpha \ .$$

To find the oscillation frequency, we need to put this equation into a form $\ddot{\alpha} = -A\sin(\alpha - \phi) = A\cos\phi\sin\alpha - A\sin\phi\cos\alpha$*. By comparison,*

$$A\cos\phi = -\frac{g}{L} \quad , \quad A\sin\phi = -\frac{a}{L} \ ,$$

or

$$A = \sqrt{\frac{g^2 + a^2}{L^2}} \quad , \quad \tan\phi = \frac{a}{g} \ .$$

Hence,

$$\ddot{\alpha} = -\frac{\sqrt{g^2+a^2}}{L}\sin(\alpha - \arctan\tfrac{a}{g}) \simeq -\frac{\sqrt{g^2+a^2}}{L}(\alpha - \arctan\tfrac{a}{g}) \ ,$$

confirming the effective acceleration. Still, we transform to the variable $\tilde{\alpha} \equiv \alpha - \arctan\frac{a}{g}$,

$$\ddot{\tilde{\alpha}} = -\frac{\sqrt{g^2+a^2}}{L}\sin(\tilde{\alpha}) \ .$$

b. The equation $m\mathbf{x} = m\mathbf{g} + m\mathbf{a}$ *becomes,*

$$m\ddot{x} = -kx + ma \ .$$

Substituting $\tilde{x} = x - \frac{ma}{k}$,

$$m\ddot{x} = -k\left(\tilde{x} + \frac{ma}{k}\right) + ma = -k\tilde{x} = m\ddot{\tilde{x}} \ .$$

4.1.10.18 Ex: Oscillation of a rolling cylinder

Consider a cylinder secured by two springs that rotates without sliding, as shown in the figure. Calculate the frequency for small oscillations of the system.

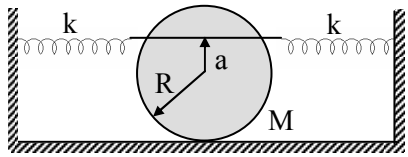

Figure 4.22: Rolling cylinder.

Solution: *The inertial moment is* $I = \frac{M}{2}R^2$. *The springs exert the forces,*

$$F_{mol} = -kx + k(L - x) \ .$$

Hence we have the equations of motion,

$$M\ddot{x} = F_{mol} - F_{at}$$
$$I\ddot{\theta} = I\frac{\ddot{x}}{R} = dF_{mol} - RF_{at} \ .$$

Using $x = R\omega$ *and eliminating the friction, we get,*

$$I\ddot{\theta} = I\frac{\ddot{x}}{R} = \frac{M}{2}R^2\frac{\ddot{x}}{R} = dF - RF_{at} = d[-kx + k(L-x)] - R[-kx + k(L-x) - M\ddot{x}] \ .$$

Solving by $\ddot{x}$,

$$\ddot{x} + \frac{2k}{M}\left(1 + \frac{d}{R}\right)(2x - L) = 0 \ .$$

The frequency is,

$$\omega_0 = \sqrt{\frac{4k}{M}\left(1 - \frac{d}{R}\right)} \ .$$

4.1.10.19 Ex: Rocking chair

Consider a thin rod of mass M and length $2L$ leaning on its center-of-mass, as shown in the figure. It is attached at both ends by springs of constants k. Calculate the angular frequency for small oscillations of the system.

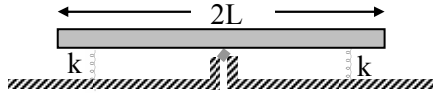

Figure 4.23: Rocking chair.

Solution: *The moment of inertia is $I = \frac{1}{3}ML^2$. The equation of motion is,*

$$I\vec{\alpha} = \vec{\tau} = \mathbf{L} \times \mathbf{F}_{ml} + (-\mathbf{L}) \times \mathbf{F}_{ml} = \mathbf{L} \times (-k\mathbf{x}) + (-\mathbf{L}) \times k\mathbf{x} \ .$$

Hence,

$$\frac{1}{3}MR^2\ddot{\theta} = -2Lkx = -2Lk\ell\theta$$
$$\ddot{\theta} + \frac{6k}{M}\theta = 0$$
$$\omega_0 = \sqrt{\frac{6k}{M}} \ .$$

4.1.10.20 Ex: Rotational oscillation of a disk

Consider a disk of mass M and radius R ($I = \frac{1}{2}MR^2$) that can rotate around the polar axis. A body of mass $m$hangs at an ideal rope that runs through the disk (without slipping) and is attached to a wall by a spring of constant k, as shown in the figure. Calculate the natural oscillation frequency of the system.

Solution: *The angular acceleration of the disc M the inertial moment of which is $I = \frac{M}{2}R^2$, is given by,*

$$\frac{M}{2}R^2\vec{\alpha} = I\vec{\alpha} = \vec{\tau}_m + \vec{\tau}_k = \mathbf{R} \times m\mathbf{g} - \mathbf{R} \times k\mathbf{x} = (Rmg - Rkx)\hat{\mathbf{e}}_\theta \ .$$

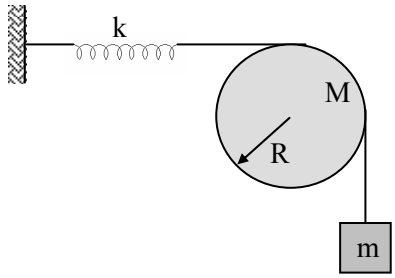

Figure 4.24: Rotational oscillation of a disk.

As the body does not slide, the angle of the disc is linked to the mass displacement, $x = R\theta$. *We get,*

$$\alpha = \ddot{\theta} = \frac{2mg - 2kx}{MR} = \frac{2mg}{MR} + \frac{2k}{M}\theta \ .$$

Substituting $\theta \equiv \tilde{\theta} - \frac{mg}{kR}$*:*

$$\ddot{\tilde{\theta}} = \frac{2mg}{MR} - \frac{2k}{M}\left(\tilde{\theta} - \frac{mg}{kR}\right) = -\frac{2k}{M}\tilde{\theta} \ .$$

That is, we have a harmonic oscillation around the angle $\theta_0 = \frac{mg}{kR}$ *with frequency* $\omega_0 = \sqrt{\frac{2k}{M}}$.

4.1.10.21 Ex: Oscillation of a half cylinder

Consider a massive, homogeneous half-cylinder of mass M and radius R resting on a horizontal surface. If one side of this solid is slightly pushed down and released, it will swing around its equilibrium position. Determine the period of this oscillation.

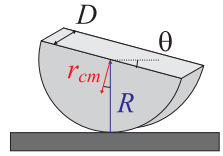

Figure 4.25: Oscillation of a half cylinder.

Solution: *The mass of the half cylinder is,*

$$M = \int dm = \rho_0 \int_0^D \int_0^\pi \int_0^R \rho_0 r dr d\theta dz = \rho_0 \pi D \tfrac{R^2}{2} \ .$$

The moment of inertia about the symmetry axis of the cylinder, if it were complete, would be,

$$I_0 = \int r^2 dm = \rho_0 \int_0^D \int_0^\pi \int_0^R r^2 \rho_0 r dr d\theta dz = \rho_0 \pi D \tfrac{R^4}{4} = MR^2/2 \ .$$

Following Steiner's theorem the moment of inertia with respect to support point of the half-cylinder is,

$$I = I_0 + MR^2 = \tfrac{3}{2}MR^2 \ .$$

We calculate the center-of-mass of a half cylinder lying on its flat side. The definition of the center-of-mass is,

$$\mathbf{r}_{cm} = \frac{1}{M}\int \mathbf{r} dm \ .$$

For symmetry reasons $x_{cm} = 0$. Also,

$$y_{cm} = \frac{\rho_0}{M}\int_0^D \int_0^R \int_{-\sqrt{R^2-y^2}}^{\sqrt{R^2-y^2}} y dx dy dz = \frac{\rho_0 D}{M}\int_0^R 2y\sqrt{R^2-y^2}dy = \frac{\rho_0 D}{M}\int_0^{R^2} \sqrt{R^2-u}du$$
$$= -\frac{2}{3}\frac{\rho_0 D}{M}(R^2-u)^{\frac{3}{2}}\Big|_0^{R^2} = \frac{2}{3}R^3\frac{\rho_0 D}{M} = \frac{4R}{3\pi} \ .$$

Let θ be the angle of oscillation. Seen from the support point the center-of-mass is at,

$$\mathbf{r} = \begin{pmatrix} 0 \\ R \\ 0 \end{pmatrix} - \begin{pmatrix} y_{cm}\sin\theta \\ y_{cm}\cos\theta \\ 0 \end{pmatrix} \ .$$

The equation of motion is,

$$m\ddot{x} = -F_{at}...$$
$$I\ddot{\theta} = \vec{\tau} = \mathbf{r}\times\vec{F} = \begin{pmatrix} -y_{cm}\sin\theta \\ R - y_{cm}\cos\theta \\ 0 \end{pmatrix} \times \begin{pmatrix} 0 \\ -gM \\ 0 \end{pmatrix} = -y_{cm}gM\hat{e}_z\sin\theta$$
$$\ddot{\theta} = -\frac{y_{cm}gM}{I}\sin\theta = -\frac{\frac{4R}{3\pi}gM}{\frac{3}{2}MR^2}\sin\theta = -\frac{8g}{9\pi R}\sin\theta \ .$$

Hence, the period of oscillation is,

$$T = \frac{2\pi}{\omega} = \frac{2\pi}{\sqrt{\frac{8g}{9\pi R}}} = \sqrt{\frac{9\pi^3}{2}}\sqrt{\frac{R}{g}} \approx 7.78\sqrt{R/g} \ .$$

4.1.10.22 Ex: Pendulum coupled to a spring

Consider a simple pendulum of mass m and length L, connected to a spring of constant k, as shown in the figure. Calculate the frequency of the system for small oscillation amplitudes.

Solution: *The inertial moment is $I = ML^2$. The equation of motion is,*

$$I\vec{\alpha} = \vec{\tau} = \vec{L}\times M\vec{g} + \vec{a}\times\vec{F}_{ml} \ .$$

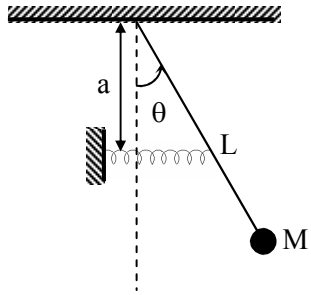

Figure 4.26: Pendulum coupled to a spring.

Hence,

$$ML^2\ddot{\theta} = -LMg\sin\theta - akx = -LMg\sin\theta - aka\theta$$
$$0 = \ddot{\theta} + \frac{g}{L}\sin\theta + \frac{ka^2}{ML^2}\theta \simeq \ddot{\theta} + \left(\frac{g}{L} + \frac{ka^2}{ML^2}\right)\theta$$
$$\omega_0 = \sqrt{\frac{g}{L} + \frac{ka^2}{ML^2}}\ .$$

4.1.10.23 Ex: Pendulum carousel

A mass m is hung by a rope of length l on a carousel with the radius R. The pendulum performs small amplitude oscillations in the direction of the rotation axis of the carousel. How does the period of oscillation depend on the rotation speed of the carousel?

Solution: *The retroactive force is,*

$$F_R = -mg\sin\phi + \frac{mv^2}{R'}\cos\phi\ .$$

We have $v(x) = (R+x)\omega = (R + l\sin\phi)\omega$ *and* $R' = R + x$. *Hece,*

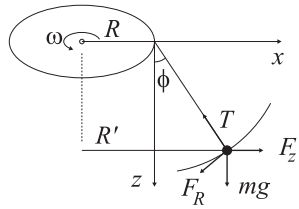

Figure 4.27: Pendulum carousel.

$$F_R = -mg\sin\phi + m\omega^2(R + l\sin\phi)\cos\phi\ .$$

The equation of motion, hence, is,

$$m\ddot{s} = -mg\sin\phi + m\omega^2(R + l\sin\phi)\cos\phi \ .$$

Since $s = l\phi$, $\ddot{s} = l\ddot{\phi}$, *follows* $l\ddot{\phi} = -g\sin\phi + \omega^2(R + l\sin\phi)\cos\phi$ *or,*

$$\ddot{\phi} + \frac{g}{l}\sin\phi - \omega^2\left(\frac{R}{l} + \sin\phi\right)\cos\phi = 0 \ .$$

For small displacements we have, $\cos\phi \approx 1$ *and* $\sin\phi \approx \phi$, *d.h.*

$$\ddot{\phi} + \left(\frac{g}{l} - \omega^2\right) - \omega^2\frac{R}{l} = 0 \ .$$

The solution of the homogeneous differential equation is,

$$\phi_h = \sin\sqrt{\frac{g}{l} - \omega^2}t$$

A particular solution of the inhomogeneous differential equation is,

$$\phi_i = \frac{\omega^2(R/l)}{g/l - \omega^2}$$

The total solution is $\phi = \phi_h + \phi_i$. *The oscillation period is,*

$$T = \frac{2\pi}{\sqrt{g/l - \omega^2}}$$

For large angular velocities, $\omega = \sqrt{g/l}$, *the period of oscillation tends to infinity because the centrifugal force dominates.*

4.2 Superposition of periodic movements

Several movements that we already know can be understood as superpositions of periodic movements in different directions and, possibly, with different phases. Example are the circular or elliptical motion of a planet around the sun or the Lissajous figures. In these cases, the motion must be described by vectors, $\mathbf{r}(t) \equiv (x(t), y(t))$. It is also possible to imagine superpositions of periodic movements in the same degree of freedom. The movement of the membrane of a loudspeaker or musical instruments usually vibrates harmonically, but follows a *superposition* of harmonic oscillations. According to the *superposition principle*, we will take the resultant of several harmonic vibrations as the sum of the individual vibrations.

4.2.1 Rotations and complex notation

We now consider a uniform circular motion. The radius of the circle being R, the motion is completely described by the angle $\theta(t)$ which grows uniformly,

$$\theta = \omega t + \alpha \ . \tag{4.51}$$

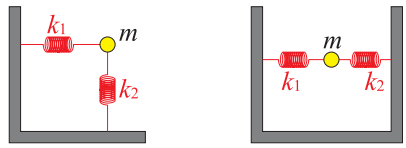

Figure 4.28: Superposition of vibrations in different (left) and equal (right) degrees of freedom.

The projections of the movement in x and y are,

$$x(t) = A\cos\theta \qquad \text{and} \qquad y(t) = A\sin\theta\ . \tag{4.52}$$

Thus, we can affirm $x(t) = y(t + \pi/2)$, that is, the projections have a mutual phase shift of $\pi/2$.

The circular motion can be represented in the complex plane using the imaginary unit $i \equiv \sqrt{-1}$ and Euler's relationship $e^{\imath\theta} = \cos\theta + \imath\sin\theta$, as illustrated in Fig. 4.29.[3,4] With $r = Ae^{\imath\theta}$ we obtain $x = A\mathfrak{Re}\ e^{\imath\theta}$ and $\imath y = A\mathfrak{Im}\ e^{\imath\theta}$ and $r = x + \imath y$.

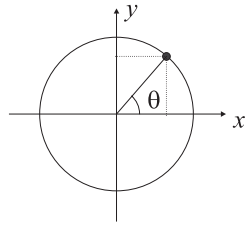

Figure 4.29: Circular motion in the complex plane.

We will use the complex notation extensively, as it greatly facilitates the calculation.

4.2.2 Lissajous figures

Other periodic movements in the two-dimensional plane are possible, when the movements in x and y have different phases or frequencies. These are called *Lissajous figures*.

We consider a body subject to two harmonic movements in orthogonal directions:

$$x(t) = A_x\cos(\omega_x t + \varphi_x) \qquad \text{and} \qquad y(t) = A_y\cos(\omega_y t + \varphi_y)\ . \tag{4.53}$$

When ω_x/ω_y is a rational number, the curve is closed and the motion repeats after equal time periods. The upper charts in Fig. 4.30 show trajectories of the body for $\omega_x/\omega_y = 1/2,\ 1/3$, and $2/3$, letting $A_x = A_y$ and $\varphi_x = \varphi_y$. The lower charts in Fig. 4.30 show trajectories for $\omega_x/\omega_y = 1/2,\ 1/3$, letting $\varphi_x - \varphi_y = 0,\ \pi/4$, and $\pi/2$.

Example 10 (*Lissajous figures*):

[3] The Euler relation can easily be derived by Taylor expansion.

[4] To check your notions on complex numbers do the exercises in Chp. 1 of the Book of A.P. French.

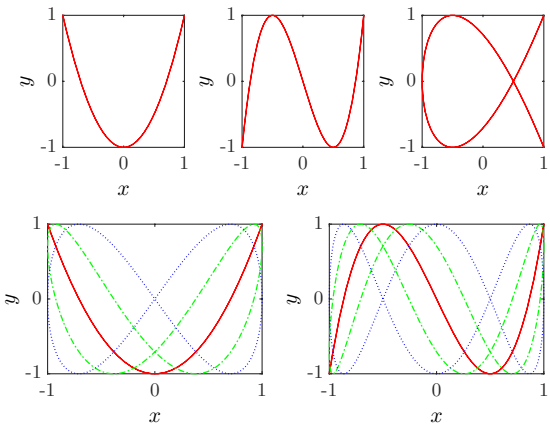

Figure 4.30: (code) Trajectories of a body oscillating with different frequencies in two dimensions.

- Connect two function generators to the two channels of an oscilloscope in x-y.
- MATLAB simulation.

.

4.2.3 Vibrations with equal frequencies superposed in one dimension

Vibratory movements can overlap. The result can be described as a sum,

$$\begin{aligned} x(t) &= x_1(t) + x_2(t) = A_1\cos(\omega t + \alpha_1) + A_2\cos(\omega t + \alpha_2) \\ &= \mathrm{Re}[A_1 e^{\imath(\omega t+\alpha_1)} + A_2 e^{\imath(\omega t+\alpha_2)}] = \mathrm{Re}e^{\imath\omega t}[A_1 e^{\imath\alpha_1} + A_2 e^{\imath\alpha_2}] \ . \end{aligned} \tag{4.54}$$

That is, the new motion is a cosine vibration, $x(t) = A\cos\omega t$, with the phase,

$$\tan\alpha = \frac{\mathrm{Im}\ x(0)}{\mathrm{Re}\ x(0)} = \frac{\mathrm{Im}(A_1 e^{\imath\alpha_1} + A_2 e^{\imath\alpha_2})}{\mathrm{Re}(A_1 e^{\imath\alpha_1} + A_2 e^{\imath\alpha_2})} = \frac{A_1\sin\alpha_1 + A_2\sin\alpha_2}{A_1\cos\alpha_1 + A_2\cos\alpha_2} \ , \tag{4.55}$$

and the amplitude,

$$A = |A_1 e^{\imath\alpha_1} + A_2 e^{\imath\alpha_2}| = \sqrt{A_1^2 + A_2^2 + 2A_1A_2\cos(\alpha_1 - \alpha_2)} \ . \tag{4.56}$$

We consider the case $A_1 = A_2$,

$$\tan\alpha = \frac{\sin\alpha_1 + \sin\alpha_2}{\cos\alpha_1 + \cos\alpha_2} \quad , \quad A = 2A\cos\frac{\alpha_1 - \alpha_2}{2} \ . \tag{4.57}$$

The cases $\alpha_1 = \alpha_2$ or $\alpha_2 = 0$ further simplify the result.

4.2.4 Frequency beat

Vibratory movements with different frequencies can overlap. The result can be described as a sum,

$$x(t) = x_1(t) + x_2(t) = A_1 \cos \omega_1 t + A_2 \cos \omega_2 t = \mathfrak{Re}\left[A_1 e^{\imath\omega_1 t} + A_2 e^{\imath\omega_2 t}\right] . \tag{4.58}$$

Considering the case $A_1 = A_2$ we obtain,

$$\begin{aligned} x(t) &= A\mathfrak{Re}\left[e^{\imath\omega_1 t} + e^{\imath\omega_2 t}\right] \\ &= A\mathfrak{Re}\left[e^{\imath(\omega_1+\omega_2)t/2} e^{\imath(\omega_1-\omega_2)t/2} + e^{\imath(\omega_1+\omega_2)t/2} e^{-\imath(\omega_1-\omega_2)t/2}\right] \\ &= A\mathfrak{Re}\; e^{\imath(\omega_1+\omega_2)t/2} 2\cos\frac{(\omega_1-\omega_2)t}{2} \\ &= 2A\cos\frac{(\omega_1+\omega_2)t}{2}\cos\frac{(\omega_1-\omega_2)t}{2} \; . \end{aligned} \tag{4.59}$$

Example 11 (*Amplitude modulation*): An important example is the amplitude modulation of radiofrequency signals.

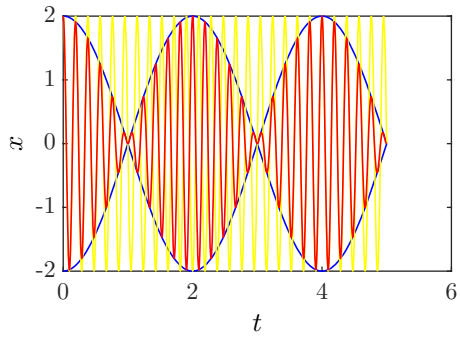

Figure 4.31: (code) Illustration of the beating of two frequencies $\nu_1 = 5.5\,\text{Hz}$ and $\nu_2 = 5\,\text{Hz}$ showing the perceived vibration (red), the vibration with the frequency $(\nu_1 + \nu_2)/2$ (blue), and the vibration with frequency $(\nu_1 - \nu_2)/2$ (yellow).

Example 12 (*Visualization of beat frequencies on an oscilloscope*):

- Connect two function generators to the two channels of an oscilloscope and add the channels.
- MATLAB simulation.
- Modulate one signal by another in a frequency mixer.

.

4.2.5 Amplitude and frequency modulation

Radio frequencies above 300 kHz can easily be emitted and received by antennas, while audio frequencies are below 20 kHz. However, radio frequencies can be used as carriers for audio frequencies. This can be done by modulating the audio signal

on the *amplitude* of the carrier () before sending the carrier frequency. The receiver retrieves the audio signal by demodulating the carrier. Therefore, audio signals can be transmitted by electromagnetic waves. Another technique consists in modulating the *frequency* of these waves (). We will now calculate the spectrum of these two modulations using complex notation and show how to demodulate the encoded audio signals by multiplication with a local oscillator corresponding to the carrier wave.

4.2.5.1 AM

Let ω and Ω be the frequencies of the carrier wave and the modulation, respectively. We can describe the amplitude modulation by,

$$U(t) = (1 + S(t)) \cos \omega t \ . \tag{4.60}$$

After the receiver has registered this signal, we demodulate it by multiplying it with $\cos \omega t$:

$$U(t) \cos \omega t = (1 + S(t)) \cos^2 \omega t = (1 + S(t)) \left(\tfrac{1}{2} + \tfrac{1}{2} \cos 2\omega t\right) \ . \tag{4.61}$$

We purify this signal passing it through a low-pass filter eliminating the rapid oscillations:

$$U(t) \cos \omega t \longrightarrow \tfrac{1}{2}(1 + S(t)) \ . \tag{4.62}$$

We retrieve the original signal $S(t)$.

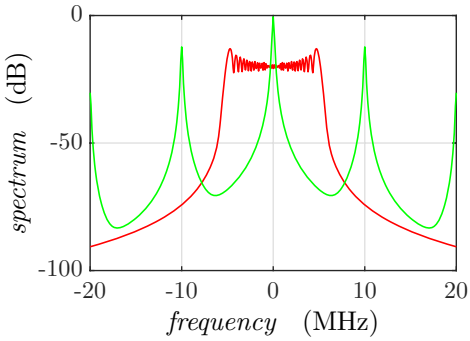

Figure 4.32: (code) Modulation signal.

4.2.5.2 FM

We can describe the frequency modulation by,

$$U(t) = e^{\imath(\omega t + N \sin \Omega t)} = e^{\imath \omega t} \sum_{k=-\infty}^{\infty} \mathcal{J}_k(N) e^{\imath k \Omega t} \ . \tag{4.63}$$

The modulation of the carrier wave generates sidebands. This can be seen by expanding the signal carrying the phase modulation into a Fourier series,

$$e^{\imath \omega t} \sum_{k=-\infty}^{\infty} \mathcal{J}_k(\beta) e^{\imath k \Omega t} \simeq e^{\imath \omega t} + \mathcal{J}_1(N) e^{\imath \omega t + \imath \Omega t} + \mathcal{J}_{-1}(N) e^{\imath \omega t - \imath \Omega t} \tag{4.64}$$

when the *modulation index* N is small. Here, $J_{-k}(N) = (-1)^k J_k(N)$ are the Bessel functions.

The spectrum of a signal with PM modulation consists of discrete lines, called sidebands, whose amplitudes are given by Bessel functions,

$$S(\omega) = \sum_{k=-\infty}^{\infty} |\mathcal{J}_k(N)|^2 \delta(\omega + k\Omega) \ . \tag{4.65}$$

In real systems, the frequency bands have finite widths β due to frequency noise or to the finite resolution of the detectors,

$$S(\omega) = \sum_{k=-\infty}^{\infty} |\mathcal{J}_k(N)|^2 \frac{N^2}{(\omega - k\Omega)^2 + N^2} \ . \tag{4.66}$$

Example 13 (*Frequency spectrum*):

- Modulate the frequency of a VCO.
- Show in the spectrum analyzer the transition to sidebands.

.

4.2.6 Exercises

4.2.6.1 Ex: Amplitude modulation

Consider a carrier wave of $\omega/2\pi = 1$ MHz frequency whose amplitude is modulated by an acoustic signal of $\Omega/2\pi = 1\,\text{kHz}$: $U(t) = A\cos\Omega t\cos\omega t$. To demodulate the signal, multiply the received wave $U(t)$ by the carrier radiofrequency. Interpret the result.

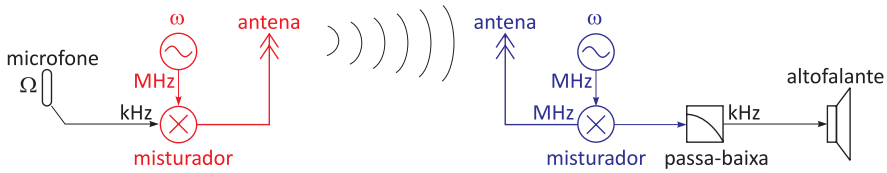

Figure 4.33: Illustration of radiofrequency signal transmission.

Solution: *The demodulated signal is,*

$$S(t)\cos\omega t = A\cos\omega t\cos\Omega t\cos\omega t = \tfrac{1}{4}A\cos[(2\omega - \Omega)t] + \tfrac{1}{4}A\cos[(2\omega + \Omega)t] + \tfrac{1}{2}A\cos\Omega t \ .$$

The first two terms oscillate with high frequency and can be eliminated by a low-pass filter. The third term oscillates precisely with the frequency of the wanted signal Ω.

4.3 Damped and forced vibrations

Frequently, vibrations are exposed to external perturbations. For example, damping forces due to friction exerted by the medium in which vibration takes place work to waste and dissipate the energy of the oscillation and, therefore, to reduce the amplitude of the oscillation. In contrast, periodic forces can pump energy into the oscillator system and excite vibrations.

4.3.1 Damped vibration and friction

Let us first deal with damping by forces named *Stokes friction*, that is, forces which are proportional to the velocity of the oscillating mass and contrary to the direction of motion, $F_{frc} = -bv$, where b is the friction coefficient. With this additional term, the equation of motion is,

$$ma = -bv - kx \ . \tag{4.67}$$

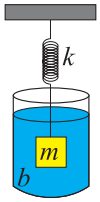

Figure 4.34: Oscillation damped by a viscous medium.

The calculation of the *damped oscillator* can be greatly simplified by the use of complex numbers by making the ansatz,

$$x(t) = Ae^{\lambda t} \ , \tag{4.68}$$

where λ is a complex number. We get,

$$m\lambda^2 + b\lambda + k = 0 \ , \tag{4.69}$$

giving the characteristic equation,

$$\lambda = -\gamma \pm \sqrt{\gamma^2 - \omega_0^2} \ , \tag{4.70}$$

with

$$\omega_0 = \sqrt{\frac{k}{m}} \qquad \text{and} \qquad \gamma = \frac{b}{2m} \ . \tag{4.71}$$

The friction determines the damping behavior. We distinguish three cases discussed in the following sections.

4.3.1.1 Overdamped case

In the overdamped case, for $\omega_0 < \gamma$, there are two real solutions $\lambda = -\gamma \pm \kappa$ with $\kappa \equiv \sqrt{\gamma^2 - \omega_0^2}$ for the characteristic equation, giving,

$$x(t) = e^{-\gamma t}(Ae^{-\kappa t} + Be^{\kappa t}) \ . \tag{4.72}$$

Choosing the initial conditions,

$$\begin{aligned} x_0 = x(0) &= e^{-\gamma t}(Ae^{-\kappa t} + Be^{\kappa t}) = A + B \\ 0 = v(0) &= -A(\gamma+\kappa)e^{-(\gamma+\kappa)t} - B(\gamma-\kappa)e^{-(\gamma-\kappa)t} = -A(\gamma+\kappa) - B(\gamma-\kappa) \ , \end{aligned} \tag{4.73}$$

we determine the amplitudes,

$$A = \frac{x_0}{2}\left(1 - \frac{\gamma}{\kappa}\right) \qquad \text{and} \qquad B = \frac{x_0}{2}\left(1 + \frac{\gamma}{\kappa}\right) \ . \tag{4.74}$$

Finally, the solution is [5],

$$x(t) = x_0 e^{-\gamma t}\left[\cosh \kappa t + \frac{\gamma}{\kappa}\sinh \kappa t\right] \ . \tag{4.75}$$

4.3.1.2 Underdamped case

In the underdamped case, for $\omega_0 > \gamma$, we have two complex solutions $\lambda = -\gamma \pm \imath\omega$ with $\omega \equiv \sqrt{\omega_0^2 - \gamma^2}$, giving,

$$x(t) = e^{-\gamma t}(Ae^{\imath\omega t} + Be^{-\imath\omega t}) \ . \tag{4.76}$$

Choosing the initial conditions,

$$\begin{aligned} x_0 = x(0) &= e^{-\gamma t}(Ae^{\imath\omega t} + Be^{-\imath\omega t}) = A + B \\ 0 = v(0) &= -A(\gamma-\imath\omega)e^{-(\gamma-\imath\omega)t} - B(\gamma+\imath\omega)e^{-(\gamma+\imath\omega)t} = -A(\gamma-\imath\omega) - B(\gamma+\imath\omega) \ , \end{aligned} \tag{4.77}$$

we determine the amplitudes,

$$A = \frac{x_0}{2}\left(1 + \frac{\gamma}{\imath\omega}\right) \qquad \text{and} \qquad B = \frac{x_0}{2}\left(1 - \frac{\gamma}{\imath\omega}\right) \ . \tag{4.78}$$

Finally, the solution is [6],

$$x(t) = x_0 e^{-\gamma t}\left[\cos \omega t + \frac{\gamma}{\omega}\sin \omega t\right] \ . \tag{4.79}$$

[5] Note that for super-strong damping, we have $\kappa \simeq \gamma$ and therefore,

$$x(t) = Ae^{-2\gamma t} + B \ .$$

, This is nothing more than the solution of the equation of motion without restoring force, $ma = -bv$.

[6] Note that, for very weak damping, we have $\gamma \simeq 0$ and $\omega \simeq \omega_0$ and hence,

$$x(t) = Ae^{\imath\omega_0 t} + Be^{-\imath\omega_0 t} \ .$$

This is nothing more than the solution of the frictionless equation of motion, $ma = -kx$.

4.3.1.3 Critically damped case

In the critically damped case, for $\omega_0 = \gamma$, there is only one solution $\lambda = -\gamma$, giving

$$x(t) = Ae^{-\gamma t} \ . \tag{4.80}$$

Since one solution is not sufficient to solve a second order differential equation, we need to look for another linearly independent solution. We can try another ansatz,

$$x(t) = Bte^{\lambda t} \ , \tag{4.81}$$

resulting in the characteristic equation,

$$m(\lambda^2 te^{\lambda t} + 2\lambda e^{\lambda t}) + b(\lambda te^{\lambda t} + e^{\lambda t}) + kte^{\lambda t} = 0 \ . \tag{4.82}$$

The terms in $e^{\lambda t}$ and $te^{\lambda t}$ should disappear separately, giving,

$$2m\lambda + b = 0 \quad \text{and} \quad m\lambda^2 t + b\lambda t + kt = 0 \quad \Longrightarrow \quad \lambda = -\frac{b}{2m} = -\gamma = -\omega_0 \ . \tag{4.83}$$

Finally, the solution is,

$$x(t) = (A + Bt)e^{-\gamma t} \ . \tag{4.84}$$

Choosing the initial conditions,

$$\begin{aligned} x_0 = x(0) &= (A + Bt)e^{-\gamma t} = A \\ 0 = v(0) &= (-\gamma A - \gamma Bt + B)e^{-\gamma t} = -\gamma A + B \ , \end{aligned} \tag{4.85}$$

we determine the amplitudes,

$$A = x_0 \qquad \text{and} \qquad B = \gamma x_0 \ . \tag{4.86}$$

Finally, the solution is,

$$x(t) = x_0(1 + \gamma t)e^{-\gamma t} \ . \tag{4.87}$$

Fig. 4.35 illustrates the damping of the oscillation for various friction rates γ.

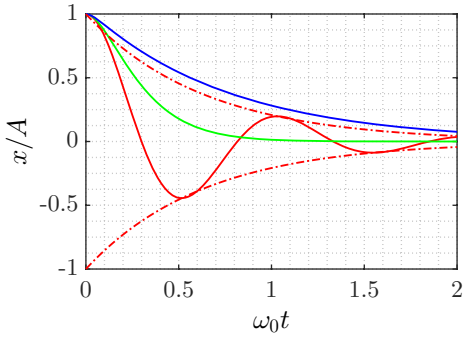

Figure 4.35: (code) Damped oscillation for $\omega_0 = 10\,\mathrm{s}^{-1}$ and $\gamma = 2.5\,\mathrm{s}^{-1}$ (red), $10\,\mathrm{s}^{-1}$ (green), and $25\,\mathrm{s}^{-1}$ (blue).

The critical friction coefficient generates a damped movement without any 'overshoot', since the velocity $\dot{x}(t)$ only disappears for $t = 0$.

4.3.1.4 Quality factor and energy loss

For a harmonic oscillation we establish the balance of energies,

$$\begin{aligned} E &= \frac{m}{2}v^2 + \frac{k}{2}x^2 \\ &= \frac{m}{2}\left(A\imath\omega_0 e^{\imath\omega_0 t} - B\imath\omega_0 e^{-\imath\omega_0 t}\right)^2 + \frac{m}{2}\omega_0^2\left(Ae^{\imath\omega_0 t} + Be^{-\imath\omega_0 t}\right)^2 = 2m\omega_0^2 AB \ . \end{aligned} \tag{4.88}$$

Now, for an underdamped oscillation we replace the amplitudes by $A \to Ae^{-\gamma t}$ and $B \to Be^{-\gamma t}$, such that,

$$E(t) = 2m\omega_0^2 ABe^{-2\gamma t} \ . \tag{4.89}$$

Obviously, the energy is decreasing at the rate 2γ.

We define the *quality factor* as the number of radians that the damped system oscillates before its energy falls to e^{-1},

$$Q = \frac{\omega}{2\gamma} = \frac{\omega m}{b} \simeq \frac{\omega_0 m}{b} \ . \tag{4.90}$$

Comparing the initial energy with the energy remaining after one cycle,

$$\frac{E}{\Delta E} = \frac{E(0)}{E(0) - E(2\pi/\omega)} = \frac{1}{1 - e^{-4\pi\gamma/\omega}} \simeq \frac{\omega}{4\pi\gamma} \ , \tag{4.91}$$

we find that the quantity,

$$\frac{Q}{2\pi} = \frac{E}{\Delta E} \tag{4.92}$$

represents a measure for the energy dissipation.

4.3.2 Forced vibration and resonance

We have seen that a damped oscillator loses its energy over time. To sustain the oscillation, it is necessary to provide energy. The simplest way to do this, is to force the oscillator to oscillate at a frequency ω by applying an external force $F_0 \cos\omega t$. The question now is, what will be the amplitude of the oscillation and its phase with respect to the phase of the applied force. We begin by establishing the equation of motion,

$$ma + bv + m\omega_0^2 x = F_0 \cos\omega t \ . \tag{4.93}$$

The calculation can be greatly simplified by the use of complex numbers. We write the differential equation as,

$$ma + bv + m\omega_0^2 x = F_0 e^{\imath\omega t} \ , \tag{4.94}$$

making the ansatz $x(t) = Ae^{\imath\omega t - \imath\delta}$, yielding

$$-\omega^2 Ae^{\imath\omega t - \imath\delta} m + \imath\omega b Ae^{\imath\omega t - \imath\delta} + m\omega_0^2 Ae^{\imath\omega t - \imath\delta} = F_0 e^{\imath\omega t} \ . \tag{4.95}$$

We rewrite this formula,

$$e^{\imath\delta} = A\frac{m(\omega_0^2 - \omega^2) + \imath b\omega}{F_0} \ . \tag{4.96}$$

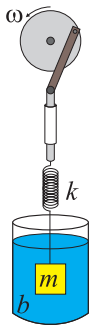

Figure 4.36: Forced oscillation damped by a viscous medium.

Immediately we get the solutions,

$$\tan\delta = \frac{\sin\delta}{\cos\delta} = \frac{\mathfrak{Im}\; e^{\imath\delta}}{\mathrm{Re}e^{\imath\delta}} = \frac{b\omega}{m(\omega_0^2-\omega^2)} \tag{4.97}$$
$$A = \left|Ae^{-\imath\delta}\right| = \left|\frac{F_0}{m(\omega_0^2-\omega^2)+\imath\omega b}\right| = \frac{F_0}{\sqrt{m^2(\omega_0^2-\omega^2)^2+b^2\omega^2}} \ .$$

The frequency response (spectrum) of the oscillator to the periodic excitation is illustrated in Fig. 4.37. We see that, when we increase the friction, we decrease the height and increase the width of the spectrum $|A(\omega)|$. Fig. 4.37(b) shows that, increasing the excitation frequency, the oscillation undergoes a phase shift of π.

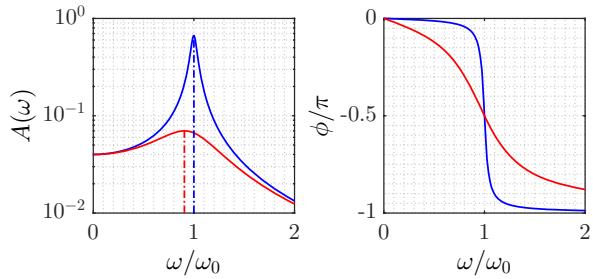

Figure 4.37: (code) Frequency response of the amplitude and phase of the oscillator for a force of $F_0 = 1\,\mathrm{N}$, a mass of $m = 1\,\mathrm{kg}$, a resonance frequency of $\omega_0 = (2\pi)\ 5\,\mathrm{Hz}$, and a friction coefficient of $b = 0.5$ (blue) or $b = 1$ (red).

We now ask, at what excitation frequency ω the oscillator responds with maximum amplitude,

$$0 = \frac{d}{d\omega_m}A(\omega_m) = F_0\omega_m\frac{2m^2\omega_0^2 - 2m^2\omega_m^2 - b^2}{(m^2\omega_0^4 - 2m^2\omega_0^2\omega_m^2 + m^2\omega_m^4 + b^2\omega_m^2)^{\frac{3}{2}}} \ . \tag{4.98}$$

The numerator disappears for,

$$\omega_m = \sqrt{\omega_0^2 - \frac{b^2}{2m^2}} \ , \tag{4.99}$$

and the amplitude becomes,

$$A_m = \frac{F_0}{b\sqrt{\omega_0^2 - \frac{b^2}{4m^2}}} \ . \tag{4.100}$$

4.3.2.1 Quality factor

For weak damping $\gamma \ll \omega_0$ and small detunings, $|\omega - \omega_0| \ll \omega_0$, we can approximate the expression for the spectrum by,

$$A(\omega) \simeq \left| \frac{F_0}{m} \frac{1}{2\omega_0(\omega_0 - \omega) + \imath\omega_0 \frac{b}{m}} \right| = \left| \frac{F_0}{2m\omega_0} \frac{1}{\omega - \omega_0 - \imath\gamma} \right| \ .$$

This function corresponds to a Lorentzian profile with the width FWHM $\Delta\omega = 2\gamma$. The *quality factor* defined in the section discussing the damped oscillator measures the quality of the resonance,

$$Q = \frac{\omega}{2\gamma} = \frac{\omega}{\Delta\omega} \ . \tag{4.101}$$

Example 14 (*Harmonic vibration*):

- Construct a L-C-circuit, excite it by a function generator by making a frequency ramp, and show the resonance on the oscilloscope. It works with a coil of $N = 12$ turns, of length $\ell = 6\,\text{cm}$ and of radius $r = 1.4\,\text{cm}$, giving $L = 1.4\,\mu\text{H}$. We can also set $R = 2.2\,\Omega$ and $C = 100\,\text{nF}$, giving $\omega_0 = 9.4\,\text{MHz}$.

4.3.3 Exercises

4.3.3.1 Ex: Resolution of the damped oscillator equation

Solve the damped oscillator equation for $4km > b^2$ using the ansatz $x(t) = Ae^{-\gamma t}\cos\omega t$.

Solution: *To determine the frequency of the damped oscillation described by this equation, we choose the function,*

$$x(t) = Ae^{-\gamma t}\cos\omega t$$

with the derivatives:

$$v(t) = -\gamma Ae^{-\gamma t}\cos\omega t - \omega Ae^{-\gamma t}\sin\omega t$$
$$a(t) = (\gamma^2 - \omega^2)Ae^{-\gamma t}\cos\omega t + 2\gamma\omega Ae^{-\gamma t}\sin\omega t \ .$$

Entering the differential equation and collecting the cos and sin terms separately:

$$(\gamma^2 - \omega^2) - \gamma\frac{b}{m} + \frac{k}{m} = 0 \qquad \text{and} \qquad 2\gamma\omega - \omega\frac{b}{m} = 0$$
$$\gamma = \frac{b}{2m} \qquad \text{and} \qquad \omega = \sqrt{\gamma^2 - \gamma\frac{b}{m} + \frac{k}{m}} = \sqrt{\omega_0^2 - \frac{b^2}{4m^2}}$$

com $\omega_0 \equiv \sqrt{k/m}$.

4.3.3.2 Ex: Damped oscillation

In a damped oscillation the oscillation period is $T = 1\,\mathrm{s}$. The ratio between two consecutive amplitudes is 2. Despite the large damping, the deviation of the period T_0 compared to the undamped oscillation is small. Calculate the deviation.

Solution: *The oscillation is described by,*

$$x(t) = Ae^{-\gamma t}\cos\omega t \ ,$$

with $\omega = 2\pi/T$. Hence, the condition $x(0) = 2x(T)$ gives,

$$A = 2Ae^{-\gamma T} \qquad or \qquad \gamma = \frac{\ln 2}{T} = 0.6931\,\mathrm{s}^{-1} \ .$$

This gives the frequency of the undamped oscillation,

$$\omega_0 = \sqrt{\omega^2 - \gamma^2} = (2\pi)\ 0.9939\,\mathrm{s}^{-1} \ ,$$

and the deviation,

$$\Delta T = T - T_0 = 2\pi\left(\frac{1}{\omega} - \frac{1}{\omega_0}\right) = 0.0061\,\mathrm{s} \ .$$

4.3.3.3 Ex: Damped physical pendulum

The physical pendulum shown in the figure consists of a disk of mass M and radius R suspended on an axes parallel to the symmetry axis of the disk and passing the edge of the disk.
a. Calculate the inertial momentum of the disk, $I = \int_V r^2 dm$, with respect to the suspension axes.
b. Derive the equation of motion by considering a weak Stokes damping due to friction proportional to the angular velocity and by approximating for small amplitude oscillations.
c. What is the natural oscillation frequency of the pendulum (without friction)? How to calculate the oscillation frequency considering friction?
d. Write down the solution of the equation of motion for the initial situation $\phi(0) = 0$ and $\dot{\phi}(0) = \dot{\phi}_0$.

Solution: *a. The mass of the cylinder is,*

$$M = \int_V \rho_0 dm = \rho_0 \int_0^L \int_0^{2\pi} \int_0^R r dr d\phi dz = \rho_0 \pi R^2 L \ .$$

The moment of inertia for a rotation around the center-of-mass is,

$$I_{cm} = \int_V \rho_0 r^2 dm = \rho_0 \int_0^L \int_0^{2\pi} \int_0^R r^2 r dr d\phi dz = \rho_0 \pi L \frac{R^4}{2} = \frac{M}{2} R^2 \ .$$

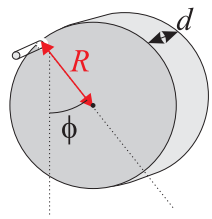

Figure 4.38: Damped physical pendulum.

The moment of inertia for a rotation about the distant axis is,

$$I = I_{cm} + MR^2 = \frac{3M}{2}R^2 \ .$$

b. The equation of motion is,

$$I\alpha = |\vec{R} \times \vec{\tau}| = -MgR\sin\theta - b\dot{\theta} \ ,$$

or, considering small amplitude oscillations,

$$\ddot{\theta} + \frac{2b}{3MR^2}\dot{\theta} + \frac{2g}{3R}\theta = 0 \ .$$

c. The frequency without friction is,

$$\omega_0 = \sqrt{\frac{2g}{3R}} \ ,$$

the damping coefficient is,

$$\gamma = \frac{b}{3MR^2} \ ,$$

and the frequency with friction is,

$$\omega = \sqrt{\omega_0^2 - \gamma^2} = \sqrt{\omega_0^2 - \frac{b^2}{9M^2R^4}} \ .$$

d. Making the ansatz $\phi(t) = e^{-\gamma t}(Ae^{\imath\omega t} + Be^{-\imath\omega t})$, we obtain,

$$\begin{aligned} \phi(0) &= 0 = A + B \\ \dot{\phi}(0) &= \dot{\phi}_0 = (\imath\omega - \gamma)A + (-\imath\omega - \gamma)B \ . \end{aligned}$$

Hence,

$$A = -B = \frac{\dot{\phi}_0}{2\imath\omega} \ ,$$

and finally,

$$\phi(t) = e^{-\gamma t}\left(\frac{\dot{\phi}_0}{2\imath\omega}e^{\imath\omega t} - \frac{\dot{\phi}_0}{2\imath\omega}e^{-\imath\omega t}\right) = \frac{\dot{\phi}_0}{\omega}e^{-\gamma t}\sin\omega t \ .$$

4.3.3.4 Ex: Pendulum with friction

Jane has prepared dinner and Tarzan (80 kg) and Cheeta (40 kg) must return home. The house is in a tree at a height of 10 m, so that both must swing home on a (massless) rope hanging from $l = 100\,\mathrm{m}$ high tree. Tarzan grabs the rope at the height of its center-of-mass $h = 1.2\,\mathrm{m}$ above ground, Cheeta because of its height is smaller at 0.8 m above ground. With what initial speed both need to grab the rope to reach the platform of the house with their feet. Consider Stokes' friction force, $F_R = C \cdot v$ with $C = 4{\cdot}10^{-4}\,\mathrm{Ns/m}$ (Tarzan) respectively, $C = 2{\cdot}10^{-4}\,\mathrm{Ns/m}$ (Cheeta). Why is this force different for the two? Treat the oscillating motion as small displacement. Determine whether the vibration is weakly damped. Do you think Jane will have dinner alone?

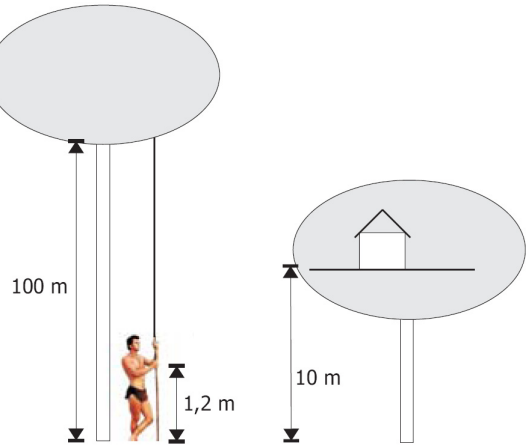

Figure 4.39: Pendulum with friction.

Solution: *The effective length of the rope is* $l = 100\,\mathrm{m} - h$. *Hence,*

$$x = l\phi \qquad \Rightarrow \qquad \dot{x} = l\dot{\phi} \qquad \text{and} \qquad \ddot{x} = l\ddot{\phi}\ .$$

Maximum displacement required for feet to reach the house floor,

$$x_{goal} = \sqrt{(100\,\mathrm{m})^2 - (95\,\mathrm{m})^2} = 31.2\,\mathrm{m}$$
$$\Rightarrow \phi_{goal} = \arctan(31.2\ \mathrm{m}/100\,\mathrm{m}) \simeq 0.3061\ .$$

Since $\sin(0.3061) \simeq 0.3014$, *the assumption of weak damping is justified,*

$$\ddot{\phi} + \frac{C}{m}\dot{\phi} + \frac{g}{l}\sin\phi = 0\ .$$

With the ansatz $\phi(t) = E^{\lambda t}$ *we get the equation,*

$$\lambda = -\frac{C}{2m} \pm \sqrt{\left(\frac{C}{2m}\right)^2 - \frac{g}{l}}\ .$$

Testing the damping force, e.g.,

$$\delta^2 \equiv \frac{C^2}{4m^2} = \frac{4 \cdot 10^{-4}\,\mathrm{Ns/m}}{4 \cdot 80\,\mathrm{kg}} \simeq 3 \cdot 10^{-8}\ \frac{1}{s^2} \ll \frac{g}{l} \simeq 0.1\ \frac{1}{\mathrm{s}^2}$$
$$\lambda_{1,2} = -\delta \pm \imath\sqrt{\frac{g}{l} - \delta^2} = -\delta \pm \imath\omega_1$$

with $\omega_1 = \sqrt{\omega_0^2 - \delta^2}$ *and* $\omega_0 = \sqrt{g}l$. *The general solution for the displacement* $x(t)$ *with the amplitude* A *is,*

$$x(t) = A \cdot e^{-\delta t} \cdot \cos(\omega_1 t + \phi_0)\ .$$

With the boundary condition $x(t=0) = 0$ *we obtain* $\Phi_0 = -\pi/2$ *and,*

$$x(t) = A \cdot e^{-\delta t} \cdot \sin(\omega_1 t)\ .$$

Reaching the required height is conditioned to $x(t = \frac{2\pi}{\omega_1}) = x_{goal}$, *Hence,*

$$A = x_{goal} \cdot e^{2\pi\delta/\omega_1}\ .$$

The required initial speed follows with

$$\dot{x}(t) = -\delta A e^{-\delta t}\sin(\omega_1 t) + \omega_1 A e^{-\delta t}\cos(\omega_1 t)\ ,$$

yielding,

$$\dot{x}(t=0) = \omega_1 A = \omega_1 \cdot x_{goal} \cdot e^{2\pi\frac{\delta}{\omega_1}}\ .$$

Substitution of numerical values for Tarzan and Cheeta gives the following values,

$$\dot{x}_{Tarzan}(t=0) \simeq 9.84\,\mathrm{m/s} \simeq 35.4\,\mathrm{km/h} \qquad \textit{and} \qquad \dot{x}_{Cheeta}(t=0) \simeq 9.81\,\mathrm{m/s} \simeq 35.3\,\mathrm{km/h}\ .$$

Jane should have dinner alone, if they can't reach the speed of athletes like Michael Johnson: 10.35 m/s.

4.3.3.5 Ex: Resolution of the forced oscillator equation

Solve the forced oscillator equation using the ansatz $x(t) = A\cos(\omega t - \delta)$.

Solution: *Inserting the ansatz* $x(t) = A\cos(\omega t - \delta)$ *into the differential equation we get,*

$$-\omega^2 mA\cos(\omega t - \delta) - \omega bA\sin(\omega t - \delta) + m\omega_0^2 A\cos(\omega t - \delta) = F_0\cos\omega t\ .$$

Using the trigonometric rules,

$$\cos(\omega t - \delta) = \cos\omega t\cos\delta + \sin\omega t\sin\delta$$
$$\sin(\omega t - \delta) = \sin\omega t\cos\delta - \cos\omega t\sin\delta$$

we obtain,

$$-\omega^2 mA\left[\cos\omega t\cos\delta+\sin\omega t\sin\delta\right]-\omega bA\left[\sin\omega t\cos\delta-\cos\omega t\sin\delta\right]$$
$$+m\omega_0^2 A\left[\cos\omega t\cos\delta+\sin\omega t\sin\delta\right]=F_0\cos\omega t\ .$$

This equation must be valid for $t=\omega\pi/2$ and for $t=0$. That is, we get two equations,

$$-\omega bA\cos\delta+m\left(\omega_0^2-\omega^2\right)A\sin\delta=0$$
$$\omega bA\sin\delta+m\left(\omega_0^2-\omega^2\right)A\cos\delta=F_0$$

or

$$\tan\delta=\frac{b\omega}{m(\omega_0^2-\omega^2)}$$
$$A=\frac{F_0}{\omega b\sin\delta+m(\omega_0^2-\omega^2)\cos\delta}\ .$$

To solve the second equation we derive the following trigonometric rules

$$\tan\delta=\frac{\sin\delta}{\cos\delta}=\frac{\sin\delta}{\sqrt{1-\sin^2\delta}}=\frac{1}{\sqrt{\frac{1}{\sin^2\delta}-1}}\qquad\Longrightarrow\qquad\sin\delta=\sqrt{\frac{1}{1+\frac{1}{\tan^2\delta}}}$$
$$\tan\delta=\frac{\sin\delta}{\cos\delta}=\frac{\sqrt{1-\cos^2\delta}}{\cos\delta}=\sqrt{\frac{1}{\cos^2\delta}-1}\qquad\Longrightarrow\qquad\cos\delta=\frac{1}{\sqrt{1+\tan^2\delta}}\ .$$

With this we can calculate:

$$A=\frac{F_0}{\omega b\sqrt{\frac{1}{1+\frac{1}{\tan^2 x}}}+m(\omega_0^2-\omega^2)\frac{1}{\sqrt{1+\tan^2\delta}}}$$
$$=\frac{F_0}{\omega b\sqrt{\frac{1}{1+\frac{1}{\left(\frac{b\omega}{m(\omega_0^2-\omega^2)}\right)^2}}}+m(\omega_0^2-\omega^2)\frac{1}{\sqrt{1+\left(\frac{b\omega}{m(\omega_0^2-\omega^2)}\right)^2}}}=\frac{F_0}{\sqrt{m^2(\omega_0^2-\omega^2)^2+b^2\omega^2}}\ .$$

4.3.3.6 Ex: Oscillation with coercive force

On a body of mass m along the x-axis act a force proportional to the displacement $F_h=-\kappa x$ and a Stokes friction force $F_R=-\gamma\dot{x}$. A time-dependent force is switched on at time $t=0$, while the body rests at the position $x=0$. The force increases linearly over time until it suddenly disappears at time $t=T$. Determine the work that the external force has done up this time. Consider the various solutions of the equation of motion resulting from the various combinations of κ and γ.

Solution: *The particular solution can be found by the ansatz $x_p(t)=be^{-t/\tau}$ with $b=\beta\tau^2/(m-\gamma\tau+\kappa\tau^2)$. Depending on whether $\gamma^2-4\kappa m>,=,<0$ we have for a. $\gamma^2-4\kappa m\equiv\Gamma^2>0$*

$$x(t)=e^{-\frac{\gamma t}{2m}}\left(Ae^{-\frac{\Gamma t}{2m}}+Be^{\frac{\Gamma t}{2m}}\right)+\frac{\beta\tau^2 m\ e^{-\frac{t}{\tau}}}{(m-\frac{\gamma\tau}{2})^2-\frac{\Gamma^2\tau^2}{4}}\ ;$$

for b. $\gamma^2 - 4\kappa m = 0$

$$x(t) = e^{-\frac{\gamma t}{2m}}(A + Bt) + \frac{\beta\tau^2 m\, e^{-\frac{t}{\tau}}}{(m - \frac{\gamma\tau}{2})^2} \; ;$$

for c. $\kappa m - \gamma^2 \equiv \Omega^2 > 0$

$$x(t) = e^{-\frac{\gamma t}{2m}}\left(A\cos\frac{\Omega t}{2m} + B\sin\frac{\Omega t}{2m}\right) + \frac{\beta\tau^2 m\, e^{-\frac{t}{\tau}}}{(m - \frac{\gamma\tau}{2})^2 + \frac{\Omega^2\tau^2}{4}} \; .$$

Through the boundary conditions $x(0) = 0$, $\dot{x}(0) = 0$ *we can determine* A, B. *Furthermore, we immediately see that* $x(\infty) = 0$, $\dot{x}(\infty) = 0$ *for all of the above mentioned solutions. Since the work of the two non-conservative forces equals the difference between the kinetic energy and the work for conservative forces, that is,* $A = 0$, *the entire work of* $F(t)$ *has been dissipated by* F_R.

4.3.3.7 Ex: Oscillation with coercive force

You want to measure the friction coefficient γ of a sphere (mass $m = 10\,\text{kg}$, diameter $d = 10\,\text{cm}$) in water. To do this, you let the sphere oscillate on a spring (spring constant $k = 100\,\text{N/m}$) in a water bath exciting the oscillation by a periodic force, $F(t) = F_0\cos\omega t$. By varying the excitation frequency ω until observing the maximum oscillation amplitude, you measure the resonance frequency $\omega_w = 2\pi\cdot 1\,\text{Hz}$. Now, you let the water out of the tub and repeat the measurement finding $\omega_0 = 2\pi\cdot 2\,\text{Hz}$.
a. Determine the resting position of the mass in water and air.
b. Establish the differential equation of motion. Assume that the weight of the sphere in water is reduced by the buoyancy $V\rho_{wat}g$, where V is the volume of the sphere and ρ_{wat} the density of the water.
c. What is the value of γ?

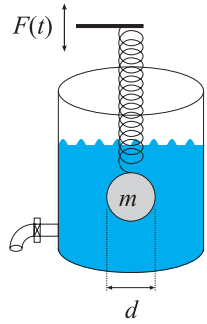

Figure 4.40: Driven pendulum.

Solution: *a. The differential equation is,*

$$m\ddot{x} + \gamma\dot{x} + Dx = mg - V\rho_{was}g + F_0\cos\omega t \; .$$

b. The resting position of the mass in air is $x_l = \frac{mg}{D} \simeq 0.98\,\mathrm{m}$ *and in water* $x_w = z + \frac{m - V\rho_{was}}{D} g \simeq 0.57\,\mathrm{m}$. *This ansatz leads to the known differential equation,*

$$m\ddot{z} + \gamma\dot{z} + Dz = F_0 \cos\omega t \ .$$

c. The resonance frequencies with and without friction are related by,

$$\omega_w = \sqrt{\omega_0^2 - \frac{\gamma^2}{2m^2}} \ .$$

Hence, $\gamma = m\sqrt{2\omega_0^2 - 2\omega_w^2} \simeq 154\,\mathrm{kg/s}$.

4.3.3.8 Ex: Electronic oscillator circuit

The instantaneous current $I(t)$ in an L-R-C-circuit (inductance of a coil, ohmic resistance and capacitance in series) excited by an alternating voltage source $U(t) = U_0 \cos\omega t$ satisfies the following differential equation,

$$L\dot{I} + RI + C^{-1}\int_0^t I dt' = U_0 \sin\omega t \ .$$

a. Derive the equation for the moving charge $\dot{Q} = I$, compare the obtained equation with that of the damped and forced spring-mass oscillator and determine the solution for the current.
b. Determine the resonance frequency ω_0 of the circuit.
c. Determine the quality factor Q of the circuit. How you can increase Q without changing the resonance frequency?

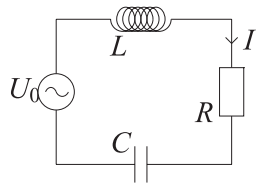

Figure 4.41: Line filter.

Solution: *a. The equation of motion of the damped and forced spring mass system is,*

$$ma + bv + kx = F_0 \cos\omega t \ .$$

The solutions are,

$$\tan\delta = \frac{\sin\delta}{\cos\delta} = \frac{Im\ e^{\imath\delta}}{Re\ e^{\imath\delta}} = \frac{R\omega}{L(\omega_0^2 - \omega^2)}$$
$$A = \left|Ae^{-\imath\delta}\right| = \left|\frac{U_0\omega}{L(\omega_0^2 - \omega^2) + \imath\omega R}\right| = \frac{U_0\omega}{\sqrt{L^2(\omega_0^2 - \omega^2)^2 + R^2\omega^2}} \ .$$

b. The natural frequency is,

$$\omega_0 = \frac{1}{\sqrt{LC}} \ .$$

c. Quality factor can be increased by decreasing strength R,

$$Q = \frac{1}{R}\sqrt{\frac{L}{C}} \ .$$

4.3.3.9 Ex: Electronic oscillator circuit

A voltage $U(t)$ is known to produce in an coil of inductance L the current $I_L = L^{-1}\int_0^{t'} U dt$, in an ohmic resistance R the current $I_R = R^{-1}U$, and in a capacitor of capacitance C the current $I = C\dot{U}$. In the parallel L-R-C circuit shown in the figure, at each instant of time the sum of the currents I_L, I_R and I_C must compensate the current $I_F(t) = I_0 e^{i\omega t}$ supplied by an alternating current source, while the voltage $U(t)$ is the same across all components.
a. Derive the differential equation for the derivative of the voltage $\dot{U}$.
b. What would be the oscillation frequency of the current without source ($I_0 = 0$) and without resistance ($R = \infty$)?
c. What would be the oscillation frequency of the current without source ($I_0 = 0$) but with resistance ($R \neq \infty$)?
d. Doing the ansatz $U(t) = U_0 e^{\imath\omega t + \imath\phi}$ derive the characteristic equation.
e. Use the characteristic equation to calculate the impedance defined by $Z \equiv |U_0/I_0|$ and the phase ϕ of the current oscillation as a function of the frequency ω. Prepare qualitative sketches of functions $Z(\omega)$ and $\phi(\omega)$.

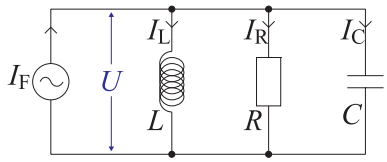

Figure 4.42: Notch filter.

Solution: *a. The equation of motion of the damped and forced system is,*

$$I_L + I_R + I_C = L^{-1}\int_0^{t'} U dt + R^{-1}U + C\dot{U} = I_0 e^{\imath\omega t} = I_F \ ,$$

or

$$L^{-1}U + R^{-1}\dot{U} + C\ddot{U} = \imath\omega I_0 e^{\imath\omega t} \ .$$

b. Without source and without resistance the differential equation would be,

$$\ddot{U} + (LC)^{-1}U = 0 \ .$$

Therefore, the natural frequency would be,

$$\omega_0 = \frac{1}{\sqrt{LC}} \ .$$

c. Without source but with resistance the differential equation would be,

$$\ddot{U} + (RC)^{-1}\dot{U} + (LC)^{-1}U = 0 \ .$$

Therefore, the oscillation frequency would be,

$$\omega_\gamma = \sqrt{\omega_0^2 - \gamma^2} \ ,$$

com $2\gamma \equiv (RC)^{-1}$.
d. Inserting the ansatz $U = U_0 e^{\imath\omega t + \imath\phi}$,

$$L^{-1}U_0 e^{\imath\phi} + \imath\omega R^{-1}U_0 e^{\imath\phi} - \omega^2 C U_0 e^{\imath\phi} = \imath\omega I_0 \ ,$$

or

$$-\omega U_0 + 2i\gamma\omega U_0 + \omega_0^2 U_0 = \imath e^{-\imath\phi}\omega I_0/C \ .$$

e. The solutions are,

$$Z \equiv \frac{U_0}{I_0}e^{\imath\phi} = \frac{\imath\omega}{L^{-1} + \imath\omega R^{-1} - \omega^2 C} = \frac{1}{R^{-1} + \imath[\omega C - 1/(\omega L)]} = \frac{\imath\omega/C}{\omega_0^2 - \omega^2 + 2\imath\gamma\omega} \ ,$$

$$|Z| = \left|\frac{U_0}{I_0}\right| = \frac{1}{\sqrt{R^{-2} + [\omega C - 1/(\omega L)]^2}} = \frac{\omega^2/C}{\sqrt{(\omega^2 - \omega_0^2)^2 + 4\gamma^2\omega^2}}$$

$$\tan\phi = \frac{Im\ Z}{Re\ Z} = \frac{-[\omega C - 1/(\omega L)]}{R^{-1}} = R/(\omega L) - \omega RC = \frac{\omega_0^2 - \omega^2}{2\gamma\omega} \ .$$

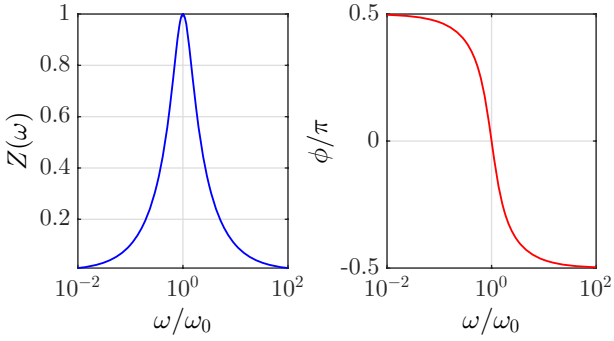

Figure 4.43: Bode diagram of the notch filter.

4.3.3.10 Ex: Lorentz model of light-atom interaction

The Lorentz model describes the interaction of an electron attached to an atom with an incident light beam as a damped oscillator. The electron's binding to the nucleus is taken into account by a restoring force $-\omega_0^2 x$. The decay of the excited state with the rate Γ is the reason for the damping force $-m\Gamma\dot{x}$. And the excitation is produced by the Lorentz force exerted by the electrical component of the light beam, $e\mathcal{E}_0 e^{\imath\omega t}$, where e is the charge of the electron. Establish the differential equation and calculate the amplitude of electron's oscillation as a function of the excitation frequency.

Solution: *The differential equation is,*

$$m\ddot{x} + m\Gamma\dot{x} + m\omega_0^2 x = e\mathcal{E}_0 e^{\imath\omega t} \ .$$

The ansatz $x \equiv x_0 e^{\imath\omega t}$ *leads to the oscillation amplitude,*

$$x_0(\omega) = \left| \frac{e\mathcal{E}_0}{m} \frac{1}{\omega_0^2 - \omega^2 - \imath\Gamma\omega} \right| \ .$$

For small detunings $\delta = \omega - \omega_0 \ll \omega$ *vale*

$$x_0(\omega) \simeq \frac{e\mathcal{E}_0}{m} \left| \frac{1}{2\omega_0(\omega_0 - \omega) + \imath\Gamma\omega_0} \right| = \frac{e\mathcal{E}_0}{m\omega_0} \left| \frac{1}{\delta - \imath\frac{\Gamma}{2}} \right| \ .$$

We also have,

$$\phi(\omega) = \frac{\mathfrak{Im}\ \alpha}{\mathfrak{Re}\ \alpha} = \frac{-\gamma\omega^2}{\omega^2 - \omega_0^2} \xrightarrow{\omega \to \omega_0} \frac{\gamma}{2\Delta} \ .$$

4.3.3.11 Ex: Lorentz model of light-atom interaction

a. Electric fields $\mathcal{E}$ exert on electric charges q the Coulomb force $F = q\mathcal{E}$. Write the differential equation for the undamped motion of an electron (charge $-e$, mass m) harmonically bound to its nucleus under the influence of an alternating electric field, $\mathcal{E} = \mathcal{E}_0 \sin\omega t$.
b. Show that the general solution can be written as,

$$x(t) = \frac{-e\mathcal{E}_0 \sin\omega t}{m(\omega_0^2 - \omega^2)} + A\cos\omega_0 t + B\sin\omega_0 t \ .$$

c. Write the solution in terms of the initial conditions $x(0) = 0 = \dot{x}(0)$.

Solution: *a. The differential equation is,*

$$m\ddot{x} + m\omega_0^2 x = -e\mathcal{E}\sin\omega t \ .$$

b. Entering the solution into the differential equation makes it easy to verify that the solution satisfies the differential equation.
c. Entering the initial conditions,

$$x(0) = A = 0 \qquad , \qquad \dot{x}(0) = \frac{-e\omega\mathcal{E}}{m(\omega_0^2 - \omega^2)} + B\omega_0 = 0 \ .$$

Hence,

$$x(t) = \frac{e\mathcal{E}}{m(\omega_0^2 - \omega^2)} \left(\frac{\omega}{\omega_0} \sin \omega_0 t - \sin \omega t \right) \ .$$

4.4 Coupled oscillations and normal modes

So far we have discussed the behavior of isolated oscillators. Energy losses or gains were described in a bulk way via a coupling to an external reservoir without structure of its own. However, the reservoir often has vibrational degrees of freedom, as well, and can dump (or supply) energy. This usually happens when neighboring oscillators share a rigid, massive, or sturdy medium. The transfer of energy to neighboring oscillators is the key ingredient for any oscillatory propagation of energy called *wave*.

4.4.1 Two coupled oscillators

To discuss the *coupling between oscillators* at the most fundamental level, we consider two ideal and identical pendulums (length L and mass m) coupled by a spring of constant k, as shown in Fig. 4.44. The differential equations of motion for the angles

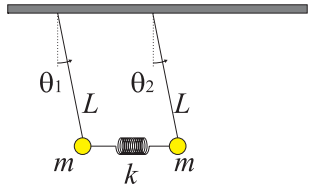

Figure 4.44: Two coupled pendulums.

θ_1 and θ_2 are,

$$\begin{aligned} mL\ddot{\theta}_1 &= -mg \sin\theta_1 - k(x_1 - x_2) \\ mL\ddot{\theta}_2 &= -mg \sin\theta_2 - k(x_2 - x_1) \ , \end{aligned} \tag{4.102}$$

with $x_j = L \sin\theta_j$. For small oscillations we have, therefore,

$$\begin{aligned} \ddot{\theta}_1 &= -\tfrac{g}{L} \sin\theta_1 - \tfrac{k}{m}(\sin\theta_1 - \sin\theta_2) \simeq -(\tfrac{g}{L} + \tfrac{k}{m})\theta_1 + \tfrac{k}{m}\theta_2 \\ \ddot{\theta}_2 &= -\tfrac{g}{L} \sin\theta_2 - \tfrac{k}{m}(\sin\theta_2 - \sin\theta_1) \simeq -(\tfrac{g}{L} + \tfrac{k}{m})\theta_2 + \tfrac{k}{m}\theta_1 \ . \end{aligned} \tag{4.103}$$

We define the normal coordinates of the vibration $\aleph \equiv \frac{1}{\sqrt{2}}(\theta_1 - \theta_2)$ and $\Psi \equiv \frac{1}{\sqrt{2}}(\theta_1 + \theta_2)$. We find the differential equations for $\aleph$ and Ψ by adding and subtracting the equations of motion,

$$\ddot{\theta}_1 + \ddot{\theta}_2 \simeq -\tfrac{g}{L}(\theta_1 + \theta_2) \qquad \text{and} \qquad \ddot{\theta}_1 - \ddot{\theta}_2 \simeq -(\tfrac{g}{L} + \tfrac{2k}{m})(\theta_1 - \theta_2) \ ,$$

or,

$$\ddot{\Psi} + \omega_\Psi^2 \Psi = 0 \qquad \text{and} \qquad \ddot{\aleph} + \omega_\aleph^2 \aleph = 0$$

using the angular frequencies of the vibrational normal modes,

$$\omega_\Psi = \sqrt{\frac{g}{L}} \quad \text{and} \quad \omega_\aleph = \sqrt{\frac{g}{L} + \frac{2k}{m}} \ .$$

4.4.2 Normal modes

Thus, the normal coordinates Ψ and $\aleph$ allow a description of the motion by decoupled linear differential equations. A vibration involving only one *normal coordinate* is called *normal mode*. In this mode all the components participating in the oscillation oscillate at the same frequency.

The importance of the normal modes is they are totally independent, that is, they never exchange energy and they can be pumped separately. Therefore, the total energy of the system can be expressed as the sum of terms containing the squares of the normal coordinates (potential energy) and their first derivatives (kinetic energy). Every independent path by which a system can gain energy is called *degree of freedom* and has an associated normal coordinate. For example, an isolated harmonic oscillator has two degrees of freedom, as it can gain potential or kinetic energy and two normal coordinates, x and v. And the coupled oscillator system,

$$E_\aleph = a\dot{\aleph}^2 + b\aleph^2 \quad \text{and} \quad E_\Psi = a\dot{\Psi}^2 + b\Psi^2 \ , \tag{4.104}$$

has four degrees of freedom.[7]

Every movement of the system can be represented by a superposition of normal modes,

$$\aleph = \tfrac{1}{\sqrt{2}}(\theta_1 - \theta_2) = \aleph_0 \cos(\omega_\aleph t + \phi_\aleph) \quad \text{and} \quad \Psi = \tfrac{1}{\sqrt{2}}(\theta_1 + \theta_2) = \Psi_0 \cos(\omega_\Psi t + \phi_\Psi) \ . \tag{4.105}$$

Choosing $\sqrt{2}A = \aleph_0 = \Psi_0$ and $\phi_\aleph = \phi_\Psi = 0$,

$$\begin{aligned} \theta_1 &= \tfrac{1}{\sqrt{2}}(\Psi + \aleph) = A\cos\omega_\aleph t + A\cos\omega_\Psi t = 2A\cos\tfrac{(\omega_\Psi - \omega_\aleph)t}{2}\cos\tfrac{(\omega_\Psi + \omega_\aleph)t}{2} \\ \theta_2 &= \tfrac{1}{\sqrt{2}}(\Psi - \aleph) = A\cos\omega_\aleph t - A\cos\omega_\Psi t = 2A\sin\tfrac{(\omega_\Psi - \omega_\aleph)t}{2}\sin\tfrac{(\omega_\Psi + \omega_\aleph)t}{2} \ . \end{aligned} \tag{4.106}$$

The oscillation shows the behavior of a frequency beat [8].

Example 15 (*Normal modes*):

- Two pendulums suspended on a movable horizontal bar which, in turn, is suspended by two wires to a rigid ceiling. Show (anti-)symmetric modes and their different exposure to damping of the motion of the bar.

4.4.3 Normal modes in large systems

There are techniques for solving systems many coupled oscillator. Let us consider, for example, a chain of $n = 1, ..., N$ oscillators coupled by springs. We have,

[7] Note that the motion of a single pendulum is a movement in two Cartesian dimensions and therefore would have four degrees of freedom. However, the joint action of gravity and the tension of the wire constrains the movement into one dimension thus freezing two degrees of freedom.

[8] Normal modes are observed in the molecular vibrations of H_2O and CO_2 (see Pain).

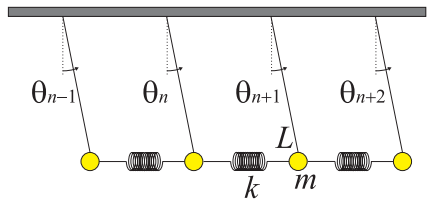

Figure 4.45: Array of coupled pendulums.

$$\ddot{\theta}_n = -\frac{g}{l}\theta_n - \frac{k}{m}(\theta_n - \theta_{n+1}) - \frac{k}{m}(\theta_n - \theta_{n-1}) \ . \tag{4.107}$$

Inserting the ansatz $\theta_n \equiv A_n e^{i\omega t}$, we obtain

$$\omega^2 A_n = \omega_0^2 A_n + \beta^2(A_n - A_{n+1}) + \beta^2(A_n - A_{n-1}) \ , \tag{4.108}$$

using the abbreviations $\omega_0^2 = g/l$ and $\beta^2 = k/m$. Defining the vector $\vec{A} \equiv (\cdots A_n \cdots)$ and the matrix,

$$\hat{M} \equiv \begin{pmatrix} \omega_0^2+\beta^2 & -\beta^2 & & & & & \\ -\beta^2 & \ddots & \ddots & & & & \\ & \ddots & \omega_0^2+2\beta^2 & -\beta^2 & & & \\ & & -\beta^2 & \omega_0^2+2\beta^2 & \ddots & & \\ & & & \ddots & \ddots & -\beta^2 & \\ & & & & -\beta^2 & \omega_0^2+\beta^2 \end{pmatrix} \ , \tag{4.109}$$

we put the characteristic equation into a form called an eigenvalue equation,

$$\hat{M}\vec{A} = \omega^2 \vec{A} \ . \tag{4.110}$$

The matrix $\hat{M}$ is characterized by the fact that it contains on its diagonal the energy of each individual oscillator (that is, $\omega_0^2 + 2\beta^2$ when the oscillator is in the middle of the chain, and $\omega_0^2 + \beta^2$) at the two ends of the chain). On the secondary diagonals (that is, at the positions $M_{n,n\pm1}$) are the coupling energies between two oscillators n and $n \pm 1$. A normal mode of the system corresponds to an *eigenvector* of the matrix $\hat{M}$, and the natural frequency of this mode corresponds to the respective *eigenvalue*.

The equation (4.110) has non-trivial solutions only, when the determinant of the matrix $\hat{M} - \omega^2$ vanishes. The eigenvalues are those ω^2 which satisfy this requirement,

$$\det(\hat{M} - \omega^2 \mathbf{1}) = 0 \ . \tag{4.111}$$

4.4.4 Dissipation in coupled oscillator systems

We now extend the system of two coupled pendulums to include damping. Assuming that the movement of the pendulum is subject to damping,

$$\begin{aligned} \ddot{\theta}_1 &= -\Gamma\dot{\theta}_1 - \tfrac{g}{L}\theta_1 - \tfrac{k}{m}(\theta_1 - \theta_2) \\ \ddot{\theta}_2 &= -\Gamma\dot{\theta}_2 - \tfrac{g}{L}\theta_2 - \tfrac{k}{m}(\theta_2 - \theta_1) \ , \end{aligned} \tag{4.112}$$

giving the collective modes,

$$\begin{aligned} \ddot{\Psi} &= \ddot{\theta}_1 + \ddot{\theta}_2 = -\Gamma\dot{\Psi} - \tfrac{g}{L}\Psi \\ \ddot{\aleph} &= \ddot{\theta}_1 - \ddot{\theta}_2 = -\Gamma\dot{\aleph} - \left(\tfrac{g}{L} + \tfrac{2k}{m}\right)\aleph \ . \end{aligned} \tag{4.113}$$

Assuming that the movement of the spring (not the movement of the pendulums) is subject to damping,

$$\begin{aligned} \ddot{\theta}_1 &= -\tfrac{g}{L}\theta_1 - \tfrac{k}{m}(\theta_1 - \theta_2) - \Gamma(\dot{\theta}_1 - \dot{\theta}_2) \\ \ddot{\theta}_2 &= -\tfrac{g}{L}\theta_2 - \tfrac{k}{m}(\theta_2 - \theta_1) - \Gamma(\dot{\theta}_2 - \dot{\theta}_1) \ , \end{aligned} \tag{4.114}$$

giving the collective modes

$$\begin{aligned} \ddot{\Psi} &= \ddot{\theta}_1 + \ddot{\theta}_2 = -\tfrac{g}{L}\Psi \\ \ddot{\aleph} &= \ddot{\theta}_1 - \ddot{\theta}_2 = -\left(\tfrac{g}{L} + \tfrac{2k}{m}\right)\aleph - 2\Gamma\dot{\aleph} \ . \end{aligned} \tag{4.115}$$

Thus, the anti-symmetric mode Ψ is free from damping, while the symmetric mode $\aleph$ damps out twice as fast. Therefore, Ψ is called the *subradiant* mode and $\aleph$ the *superradiant* mode.

4.4.5 Exercises

4.4.5.1 Ex: Energy of normal modes

Verify that the total energy of a system of two coupled oscillators is equal to the sum of the energies of the normal modes.

Solution: *We have,*

$$\begin{aligned} E_{tot} &= E_{kin,1} + E_{pot,1} + E_{kin,2} + E_{pot,2} + E_{cpl} \\ &= \tfrac{m}{2}v_1^2 + \tfrac{mg}{2L}x_1^2 + \tfrac{m}{2}v_2^2 + \tfrac{mg}{2L}x_2^2 + \tfrac{k}{2}(x_1 - x_2)^2 \\ &= \tfrac{m}{2}(L\dot{\theta}_1)^2 + \tfrac{mg}{2L}(L\theta_1)^2 + \tfrac{m}{2}(L\dot{\theta}_2)^2 + \tfrac{mg}{2L}(L\theta_2)^2 + \tfrac{k}{2}L^2(\theta_1 - \theta_2)^2 \\ &= \tfrac{m}{2}(L\dot{\Psi})^2 + \tfrac{m}{2}gL\Psi^2 + \tfrac{m}{2}(L\dot{\aleph})^2 + \tfrac{m}{2}gL\aleph^2 + kL^2\aleph^2 \\ &= \tfrac{m}{2}(L\dot{\Psi})^2 + \tfrac{m}{2}\omega_\Psi^2(L\Psi)^2 + \tfrac{m}{2}(L\dot{\aleph})^2 + \tfrac{m}{2}\omega_\aleph^2(L\aleph)^2 = E_\Psi + E_\aleph \ . \end{aligned}$$

4.4.5.2 Ex: Normal modes of two spring-coupled masses

Consider two different masses m_1 and m_2 coupled by a spring k.
a. Determine the equation of motion and the characteristic equation for each mass.
b. Write the characteristic equations in matrix form: $\hat{M}\vec{a} = \omega^2\vec{a}$, where $\vec{a} \equiv (a_1, a_2)$ and a_j are the amplitude of the oscillations and calculate the two eigenvalues of the matrix.
c. Calculate the normal modes, that is, the eigenvectors solving the equation $\hat{M}\vec{a} = \omega_k^2\vec{a}$ for each eigenvalue.

d. Derive the differential equations of the center-of-mass motion and the relative motion. Compare the result with the normal modes.

Solution: *a. For a chain of two masses we have,*

$$m_1\ddot{x}_1 = -k(x_1 - x_2) \qquad , \qquad m_2\ddot{x}_2 = -k(x_2 - x_1) \ .$$

Doing the ansatz $x_n = a_n e^{i\omega t}$ *and with the abbreviation* $\omega_j \equiv \frac{k}{m_j}$ *we get the characteristic equations,*

$$-\omega^2 a_1 = -\omega_1^2(a_1 - a_2) \qquad , \qquad -\omega^2 a_2 = -\omega_2^2(a_2 - a_1) \ .$$

b. The matrix form of the characteristic equations is,

$$\begin{pmatrix} \omega_1^2 & -\omega_1^2 \\ -\omega_2^2 & \omega_2^2 \end{pmatrix} \begin{pmatrix} a_1 \\ a_2 \end{pmatrix} = \omega^2 \begin{pmatrix} a_1 \\ a_2 \end{pmatrix} \ .$$

Solving,

$$0 = \det(\hat{M} - \omega^2 \mathbf{1}) = -\omega_1^2\omega^2 - \omega^2\omega_2^2 + \omega^4 = \omega^2(\omega^2 - \omega_1^2 - \omega_2^2) \ ,$$

we get the eigenvalues $\omega = 0$ *and* $\omega = \sqrt{\omega_1^2 + \omega_2^2}$.
c. The first eigenvector is obtained by,

$$\hat{M}\vec{a} = \begin{pmatrix} \omega_1^2 a_1 - \omega_1^2 a_2 \\ -\omega_2^2 a_1 + \omega_2^2 a_2 \end{pmatrix} = 0 \cdot \begin{pmatrix} a_1 \\ a_2 \end{pmatrix} = \omega^2 \vec{a} \ ,$$

which is only possible when $a_1 = a_2$. *For the second eigenvalue,*

$$\hat{M}\vec{a} = \begin{pmatrix} \omega_1^2 a_1 - \omega_1^2 a_2 \\ -\omega_2^2 a_1 + \omega_2^2 a_2 \end{pmatrix} = (\omega_1^2 + \omega_2^2) \begin{pmatrix} a_1 \\ a_2 \end{pmatrix} = \omega^2 \vec{a} \ ,$$

which implies $\omega_1^2 a_2 = -\omega_2^2 a_1$. *Therefore, the normal modes are,*

$$\vec{a} = \begin{pmatrix} 1 \\ 1 \end{pmatrix} \qquad \textit{and} \qquad \vec{a} = \frac{1}{\sqrt{\omega_1^4 + \omega_2^4}} \begin{pmatrix} \omega_1^2 \\ -\omega_2^2 \end{pmatrix} \ .$$

d. The center of mass is at the position $x_{cm} = \frac{m_1 x_1 + m_2 x_2}{m_1 + m_2}$. *We call* $x_{rl} = x_1 - x_2$ *the relative coordinate. The equations are,*

$$\ddot{x}_{cm} = \frac{m_1\ddot{x}_1 + m_2\ddot{x}_2}{m_1 + m_2} = \frac{-k(x_1 - x_2) - k(x_2 - x_1)}{m_1 + m_2} = 0$$

$$\ddot{x}_{rl} = \ddot{x}_1 - \ddot{x}_2 = -\frac{k}{m_1}(x_1 - x_2) + \frac{k}{m_2}(x_2 - x_1) = -\frac{k}{\mu}(x_1 - x_2) = -(\omega_1^2 + \omega_2^2)(x_1 - x_2) \ ,$$

with $\mu^{-1} \equiv m_1^{-1} + m_2^{-1}$. *The first mode corresponds to a translation without vibration, the second to an anti-symmetrical vibration without translation around the center-of-mass. This corresponds to the results obtained by the reduced mass method.*

4.4.5.3 Ex: Spring-coupled chain of masses

Consider a chain of spring-coupled masses.
a. Determine the equation of motion and the characteristic equation for each mass.
b. Calculate the normal modes for a chain consisting of three masses.

Solution: *a. For each mass we have,*

$$m\ddot{x}_n = -k(x_n - x_{n-1}) - k(x_n - x_{n+1}) \ .$$

Making the ansatz $x_n = A_n e^{\imath\omega t}$ *we get the characteristic equation,*

$$-\omega^2 A_n = -\omega_0^2(A_n - A_{n-1}) - \omega_0^2(A_n - A_{n+1}) \ .$$

In matrix notation,

$$\begin{pmatrix} \omega_0^2 & -\omega_0^2 & 0 & 0 & 0 \\ -\omega_0^2 & 2\omega_0^2 & -\omega_0^2 & 0 & 0 \\ 0 & -\omega_0^2 & \ddots & \ddots & 0 \\ 0 & 0 & \ddots & 2\omega_0^2 & -\omega_0^2 \\ 0 & 0 & 0 & -\omega_0^2 & \omega_0^2 \end{pmatrix} \ .$$

b. For a chain of three masses we have,

$$\begin{pmatrix} \omega_0^2 & -\omega_0^2 & 0 \\ -\omega_0^2 & 2\omega_0^2 & -\omega_0^2 \\ 0 & -\omega_0^2 & \omega_0 \end{pmatrix} \ .$$

To find the eigenvalues, we solve,

$$0 = \det[\hat{M} - \lambda\mathbf{1}]] = -3\omega_0^4\lambda + 4\omega_0^2\lambda^2 - \lambda^3 = -\lambda(\lambda - \omega_0)(\lambda - 3\omega_0^2) \ ,$$

giving the eigenvalues, $\lambda = 0$, $\lambda = \omega_0^2$, *and* $\lambda = 3\omega_0^2$. *To find the eigenvectors, we do* $\hat{M}\vec{a} = 0\vec{a}$ *with* $\vec{a} \equiv (a_1, a_2, a_3)$, *yielding,*

$$a_1 = a_2 = a_3 \ ,$$

and therefore the eigenvector,

$$\vec{a} = \frac{1}{\sqrt{3}} \begin{pmatrix} 1 \\ 1 \\ 1 \end{pmatrix} \ .$$

For the second eigenvector, we do $\hat{M}\vec{a} = \omega_0^2\vec{a}$ *yielding,*

$$a_2 = 0 \quad , \quad a_3 = -a_1 \ ,$$

and therefore the eigenvector,

$$\vec{a} = \frac{1}{\sqrt{3}} \begin{pmatrix} 1 \\ 0 \\ -1 \end{pmatrix} \ .$$

For the third eigenvector, we do $\hat{M}\vec{a} = 3\omega_0^2\vec{a}$ *yielding,*

$$a_1 - a_2 = 3a_1 \quad , \quad a_1 - a_2 = 3a_1 \quad , \quad -a_2 + a_3 = 3a_3 \ ,$$

or

$$a_1 = a_3 = -\tfrac{1}{2}a_2 \quad , \quad a_2 = a_2 \ ,$$

and therefore the eigenvector,

$$\vec{a} = \frac{1}{\sqrt{3}}\begin{pmatrix} -\frac{1}{2}a_2 \\ a_2 \\ -\frac{1}{2}a_2 \end{pmatrix} / \frac{a_2}{\sqrt{2}} = \sqrt{\frac{2}{3}}\begin{pmatrix} -\frac{1}{2} \\ 1 \\ -\frac{1}{2} \end{pmatrix} \ .$$

4.4.5.4 Ex: Normal modes of CO_2

We consider the carbon dioxide molecule CO_2, for which we make a spring-mass model with three masses coupled by k springs in a linear chain. Calculate the frequencies of the normal modes and the eigenvectors of the vibrations.

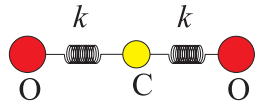

Figure 4.46: Normal modes of CO_2.

Solution: *The differential equations are*

$$\begin{aligned} m_O\ddot{x}_1 &= -k(x_1 - x_2) \\ m_C\ddot{x}_2 &= -k(x_2 - x_1) - k(x_2 - x_3) \\ m_O\ddot{x}_3 &= -k(x_3 - x_2) \ . \end{aligned}$$

With the ansatz $x_n = A_n e^{i\omega t}$ *and the abbreviations* $\omega_O \equiv \sqrt{\frac{k}{m_O}}$ *and* $\omega_C \equiv \sqrt{\frac{k}{m_C}}$ *we get the characteristic equations,*

$$\begin{aligned} \omega^2 A_1 &= \omega_O^2(A_1 - A_2) \\ \omega^2 A_2 &= \omega_C^2(A_2 - A_1) + \omega_C^2(A_2 - A_3) \\ \omega^2 A_3 &= \omega_O^2(A_3 - A_2) \ . \end{aligned}$$

Introducing the matrix and the vector,

$$M \equiv \begin{pmatrix} \omega_O^2 & -\omega_O^2 & 0 \\ -\omega_C^2 & 2\omega_C^2 & -\omega_C^2 \\ 0 & -\omega_O^2 & \omega_O^2 \end{pmatrix} \quad \text{and} \quad \vec{A} \equiv \begin{pmatrix} A_1 \\ A_2 \\ A_3 \end{pmatrix} \ ,$$

the equation takes the form of an eigenvalue equation,

$$M\vec{A} = \omega^2\vec{A} \ .$$

The frequencies of the normal modes are the eigenvalues of the matrix,

$$\begin{aligned} 0 = \det[M - \omega^2 E_3] &= -2\omega_O^2\omega_C^2\omega^2 - \omega_O^4\omega^2 + 2\omega_O^2\omega^4 + 2\omega^4\omega_C^2 - \omega^6 \\ &= -\omega^2(\omega^2 - \omega_O^2 - 2\omega_C^2)(\omega^2 - \omega_O^2) \ . \end{aligned}$$

Entering the eigenvalue $\omega = 0$ in the eigenvalue equation gives,

$$A_1 = A_2 = A_3 \qquad \textit{and hence} \qquad \vec{A} = \begin{pmatrix} 1 \\ 1 \\ 1 \end{pmatrix} \ .$$

Entering the eigenvalue $\omega = \omega_O$ in the eigenvalue equation we get,

$$A_2 = 0 \quad , \quad A_1 = -A_3 \qquad \textit{and hence} \qquad \vec{A} = \begin{pmatrix} 1 \\ 0 \\ -1 \end{pmatrix} \ .$$

Entering the eigenvalue $\omega = \sqrt{\omega_O^2 + 2\omega_C^2}$ in the eigenvalue equation we get,

$$2\omega_C^2 A_1 = -\omega_O^2 A_2 = 2\omega_C^2 A_3 \qquad \textit{and hence} \qquad \vec{A} = \begin{pmatrix} 1 \\ -2\omega_C^2/\omega_O^2 \\ 1 \end{pmatrix} \ .$$

4.4.5.5 Ex: Three coupled pendulums

Determine the frequencies of the oscillation modes of a chain of three spring-coupled pendulums.

Solution: *In the example of three oscillators we have,*

$$\begin{pmatrix} \omega_0^2 + \beta^2 & \beta^2 & 0 \\ \beta^2 & \omega_0^2 + 2\beta^2 & \beta^2 \\ 0 & \beta^2 & \omega_0^2 + \beta^2 \end{pmatrix} \begin{pmatrix} A_1 \\ A_2 \\ A_3 \end{pmatrix} = 0 \ .$$

The matrix eigenvectors and eigenvalues are:

$$\begin{aligned} (1,1,1) \quad & \textit{for} \quad \omega^2 = \omega_0^2 \\ (1,0,-1) \quad & \textit{for} \quad \omega^2 = \omega_0^2 + \beta^2 \\ (1,-2,1) \quad & \textit{for} \quad \omega^2 = \omega_0^2 + 3\beta^2 \ . \end{aligned}$$

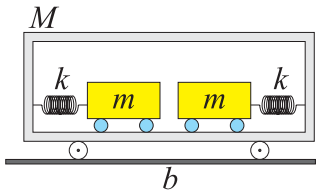

Figure 4.47: Super- and subradiant pendulums.

4.4.5.6 Ex: Super- and subradiance

We consider three carts attached by springs (spring constant k), as shown in the figure. The inner carts have mass m and are subject to damping by friction with the coefficient γ. The outer cart has mass M and friction Γ.
a. Establish the equations of motion of the three carts.
b. Discuss the case $M \to 0$.

Solution: *a. The equations of motion of these three carts are,*

$$\begin{aligned} m\ddot{x}_1 &= -k(x_1 - x_2) - \gamma\dot{x}_1 \\ M\ddot{x}_2 &= -k(x_2 - x_1) - k(x_2 - x_3) - \Gamma\dot{x}_2 \\ m\ddot{x}_3 &= -k(x_3 - x_2) - \gamma\dot{x}_3 \ . \end{aligned}$$

b. Para $M \to 0$,

$$\begin{aligned} m\ddot{x}_1 &= -kx_1 + \tfrac{1}{2}kx_1 + \tfrac{1}{2}kx_3 - \tfrac{1}{2}\Gamma\dot{x}_2 - \gamma\dot{x}_1 \\ kx_2 &= \tfrac{1}{2}kx_1 + \tfrac{1}{2}kx_3 - \tfrac{1}{2}\Gamma\dot{x}_2 \\ m\ddot{x}_3 &= -kx_3 + \tfrac{1}{2}kx_1 + \tfrac{1}{2}kx_3 - \tfrac{1}{2}\Gamma\dot{x}_2 - \gamma\dot{x}_3 \ . \end{aligned}$$

Substituting,

$$\begin{aligned} m\ddot{x}_1 &= -\tfrac{1}{2}k(x_1 - x_3) - \tfrac{1}{2}\Gamma\dot{x}_2 - \gamma\dot{x}_1 \\ m\ddot{x}_3 &= -\tfrac{1}{2}k(x_3 - x_1) - \tfrac{1}{2}\Gamma\dot{x}_2 - \gamma\dot{x}_3 \ . \end{aligned}$$

Considering the normal modes,

$$m\ddot{\Psi} = -\Gamma\dot{x}_2 - \gamma\dot{\Psi} \qquad , \qquad m\ddot{\aleph} = -k\aleph - \gamma\dot{\aleph} \ .$$

Obviously, in the absence of dissipation γ in the movement of the individual oscillators, we have two modes. One of the modes, called Ψ, is subject to dissipation Γ linked to the coupling between the oscillators. This mode is called superradiant, as it delivers its energy quickly to the environment. The other mode, called $\aleph$, is free of dissipation and is therefore called subradiant.

Chapter 5

Waves

While in *vibrating* bodies the motion and the energy are localized in space, *waves* do propagate and carry energy to other places. In fact, waves represent the most important mechanism for transporting and exchanging energy and information. We can understand a wave as a perturbation propagating through an elastic material medium. In some cases, however, e.g. for electromagnetic waves, the propagation of the wave is due to a self-sustained oscillation between two forms of energy (electric and magnetic) without the need of a material medium. Here, is a classification of the most common types of waves: A lecture version of this chapter can be found at

Table 5.1: *Types of waves.*

wave	pulse	sound	sound	surface	light	de Broglie

transform	Galilei	Galilei	Galilei	Galilei	Lorentz	Galilei
wave eq.	Helmholtz	Helmholtz	Helmholtz	Helmholtz	Helmholtz	Schrödinger

(watch talk).

5.1 Propagation of waves

There are several types of wave that we will classify according to the propagation medium and to the polarization, that is, we will distinguish longitudinal and transverse waves. There are media only supporting transverse waves (strings, water surfaces). Others only withstand longitudinal waves (sound in fluid media). Finally, there are media supporting both (sound in solids, electromagnetic waves).

The simplest example of a pulse is a local deformation of a string, as shown in Fig. 5.1. The pulse travels to one end of the string by a motion called *propagation*. The propagation is not conditioned to any transport of mass, but all the particles of the system go back to their original positions after the passage of the pulse. However, there is energy transport along the string, since each of its portions suffers an increase in kinetic and potential energy during the passage of the pulse.

In general, the pulse broadens during propagation, an effect called *dispersion*. To simplify the problem let us, as a first approximation neglect the dispersion and

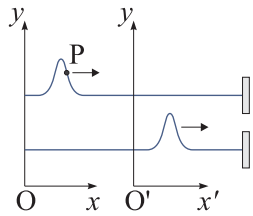

Figure 5.1: Pulse propagation along a rope.

suppose that the pulse does not change its shape,

$$Y(x,t) = f(x - vt) \ , \tag{5.1}$$

where the propagation velocity is positive when the pulse propagates in the direction of the positive x-axis.

The behavior of the pulse at the end of the rope depends on its fixation. Attached to a wall, the reflected pulse has opposite propagation amplitude and direction,

$$Y_{rfl}(x,t) = -f(x + vt) \ . \tag{5.2}$$

Fixed to another rope, the pulse will be partially reflected and partially transmitted.

5.1.1 Transverse waves, propagation of pulses on a rope

Pulses on a rope are examples for transverse waves. The speed at which the pulse propagates on a rope depends essentially on the properties of the string, that is, its mass density μ and the applied tension T, but not on the pulse amplitude. We take a small length element dx of the string with mass $dm = \mu dx$ and consider a pulse traveling with velocity v, as shown in Fig. 5.1.

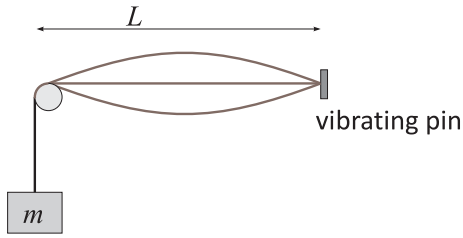

Figure 5.2: Mass element of a rope upon a passage of a pulse.

The vertical force due to the difference of tensions is,

$$F_y = T \sin\theta(x + dx) - T \sin\theta(x) \ . \tag{5.3}$$

Assuming $\theta(x)$ small, such that $\sin\theta(x) \simeq \tan\theta(x) = \frac{dY}{dx}$,

$$F_y = T \left(\frac{dY}{dx}\right)_{x+dx} - T \left(\frac{dY}{dx}\right)_x = T \frac{\partial^2 Y}{\partial x^2} dx \ . \tag{5.4}$$

On the other hand, applying Newton's second law to this string element, we find,

$$F_y = dm\frac{\partial^2 Y}{\partial t^2} \ . \tag{5.5}$$

Thus,

$$\frac{\partial^2 Y}{\partial x^2} = \frac{\mu}{T}\frac{\partial^2 Y}{\partial t^2} \ . \tag{5.6}$$

This equation is called *wave equation* and fully describes the propagation of the pulse on the string. Since $Y = f(x - vt)$ depends on both x and t, the derivatives that appear in the equation are partial, that is, one derives with respect to one variable keeping the other constant. To find the velocity, we write,

$$\frac{\partial^2 Y}{\partial t^2} = \frac{\partial}{\partial t}\left(\frac{\partial x}{\partial t}\frac{\partial Y}{\partial x}\right) = v\frac{\partial}{\partial t}\left(\frac{\partial Y}{\partial x}\right) = v\frac{\partial}{\partial x}\left(\frac{\partial Y}{\partial t}\right) = v\frac{\partial}{\partial x}\left(\frac{\partial x}{\partial t}\frac{\partial Y}{\partial x}\right) = v^2\frac{\partial Y^2}{\partial x^2} \ , \tag{5.7}$$

and compare the second relation with the wave equation, finding,

$$v = \sqrt{\frac{T}{\mu}} \ . \tag{5.8}$$

Example 16 (*Reflection of pulses on a rope*):

- Excite a pulse on a rope fixed to the wall (i) directly or (ii) through a thinner rope.

5.1.2 Longitudinal waves, propagation of sonar pulses in a tube

Acoustic pulses are examples for longitudinal waves. They are due to a process of compression and decompression of a gaseous medium (such as air), liquid or even solid. Let us consider an oscillating piston inside a tube (cross section A) filled with air of mass density ρ_0, as shown in Fig. 5.3. When the piston moves, it causes a local pressure increase. We want to find the velocity v at which the compression travels along the tube.

As shown in Fig. 5.3, the piston causes a negative pressure gradient along the tube giving rise to an unbalanced force which accelerates mass elements of air to the right. To simplify the situation let us assume that the piston is moved with velocity u within a time interval Δt compressing the volume of the tube by a value

$$\Delta V = -Au\Delta t \ . \tag{5.9}$$

During this time, the piston accelerates a mass $m = \rho_0 V$ of air within a volume V given by the propagation velocity v of the pulse along the tube,

$$V = Av\Delta t \ . \tag{5.10}$$

The mass within this volume receives a momentum,

$$F\Delta t = mu \ . \tag{5.11}$$

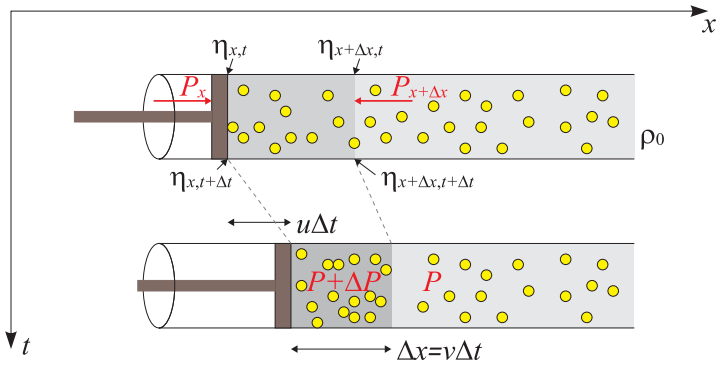

Figure 5.3: Sound waves produced by a swinging piston.

The pressure difference inside and outside the volume V causes a pressure imbalance,

$$F = A\Delta P \ . \tag{5.12}$$

With these relations we can calculate the *compressibility* of the gas,

$$\frac{1}{\kappa} \equiv -\frac{\Delta P}{\Delta V/V} = \frac{F/A}{u/v} = \frac{mu/A\Delta t}{u/v} = \frac{\rho_0 V v}{A\Delta t} = \rho_0 v^2 \ , \tag{5.13}$$

we obtain the propagation velocity of the pulse in the gas,

$$v = \sqrt{\frac{1}{\kappa\rho_0}} \ . \tag{5.14}$$

Thus, the velocity of sound propagation depends critically on the material medium. We have $v_{ar} = 331\,\mathrm{m/s}$, $v_{H_2} = 1286\,\mathrm{m/s}$, $v_{H_2O} = 331\,\mathrm{m/s}$, $v_{rubber} = 54\,\mathrm{m/s}$, and $v_{Al} = 5100\,\mathrm{m/s}$.

To derive the equation of motion, we consider a thin gas element with thickness Δx and mass $m = \rho_0 A\Delta x$ subject to a difference of pressure on both sides of,

$$P_x - P_{x+\Delta x} = -\frac{\partial P_x}{\partial x}\Delta x = -\frac{\partial}{\partial x}(P_0 + \Delta P)\Delta x = -\frac{\partial \Delta P}{\partial x}\Delta x \ , \tag{5.15}$$

where we subtracted the background pressure P_0 assumed to be constant. This pressure difference creates a force $F = A(P_x - P_{x+\Delta x})$ accelerating the gas element following Newton's law, $F = m\ddot{\eta}$, where $\eta(x)$ is the displacement of the element, such that,

$$\frac{\partial \eta}{\partial x} = \frac{\Delta V}{V} \tag{5.16}$$

and the compression (see Fig. 5.3). We therefore obtain,

$$\rho_0 \Delta x \frac{\partial^2 \eta}{\partial t^2} = \frac{F}{A} = -\frac{\partial \Delta P}{\partial x}\Delta x \ . \tag{5.17}$$

Substituting ΔP by the relationship (5.13),

$$\rho_0 \frac{\partial^2 \eta}{\partial t^2} = -\frac{\partial}{\partial x}\left(-\frac{1}{\kappa}\frac{\partial \eta}{\partial x}\right) = \frac{1}{\kappa}\frac{\partial^2 \eta}{\partial x^2} \ , \tag{5.18}$$

which gives the wave equation. Solve Excs. 5.1.7.1, 5.1.7.2, and 5.1.7.3.

5.1.3 Electromagnetic waves

Electromagnetic waves are in several aspects different from mechanical longitudinal or transverse waves. For example, they do not need a propagation medium, but move through the vacuum at an extremely high speed. The speed of light, $c = 299792458\,\mathrm{m/s}$ exactly, is so high, that the laws of classical mechanics are no longer valid, but must be replaced by relativistic laws. And since there is no propagation medium, with respect to vacuum all inertial systems are equivalent, which will have important consequences for the Doppler effect. We will show that the electromagnetic wave equation almost comes out as a corollary of the theory of special relativity.

Electromagnetic waves always arise when a charge changes position. In this way the theory of electromagnetic waves is also a consequence of the theory electromagnetism, which is contained in Maxwell's equations. We will introduce here, without derivation, the wave equation for the electric and magnetic fields.

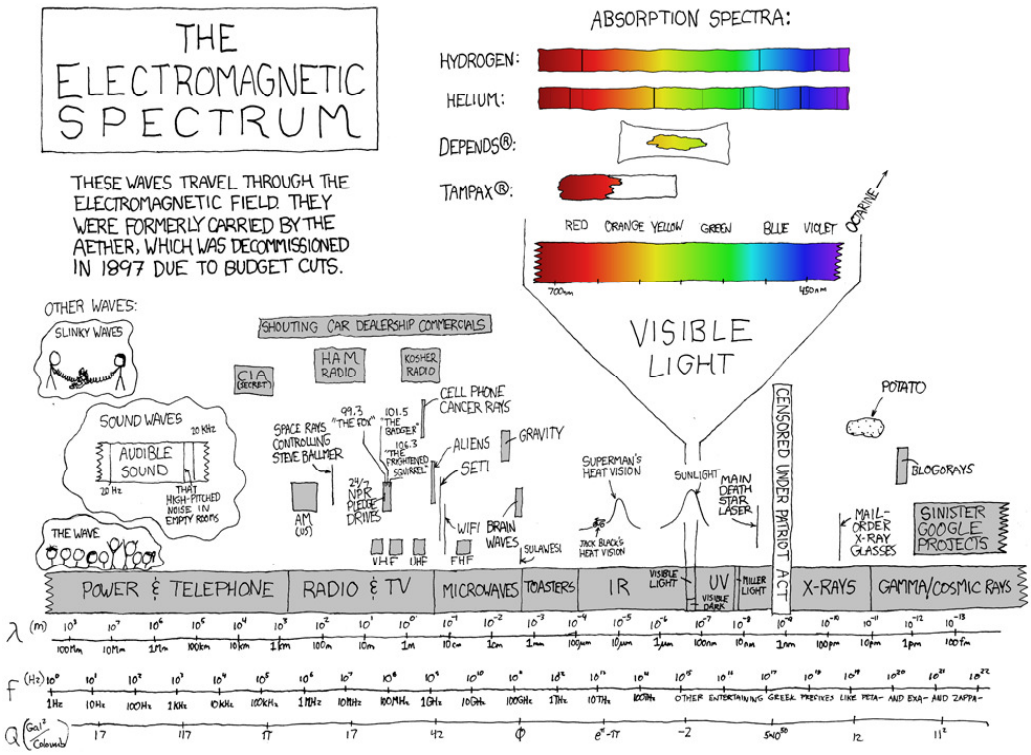

Figure 5.4: The electromagnetic spectrum.

5.1.3.1 Helmholtz equation

We have already seen how the periodic conversion between kinetic and potential energy in a pendulum can propagate in space when the pendulum is coupled to other pendulums attached to each other in a chain, and that this model explains the propagation of a pulse on the string. We also discussed how electrical and magnetic

energy can be interconverted in an electronic L-C-circuit with a capacitor storing electrical energy and an inductance (a coil) storing magnetic energy. The law of electrodynamics describing the transformation of electric field variations into magnetic energy is *Ampère's law*, and the law describing the transformation of magnetic field variations into electric energy is *Faraday's law*,

$$\frac{\partial \vec{\mathcal{E}}}{\partial t} \curvearrowright \vec{\mathcal{B}}(t) \quad , \quad \frac{\partial \vec{\mathcal{B}}}{\partial t} \curvearrowright -\vec{\mathcal{E}}(t) \ . \tag{5.19}$$

Extending the circuit L-C to a chain, it is possible to show that the electromagnetic oscillation propagates along the chain. This model describes well the propagation of electromagnetic energy along a coaxial cable or the propagation of light in free space.

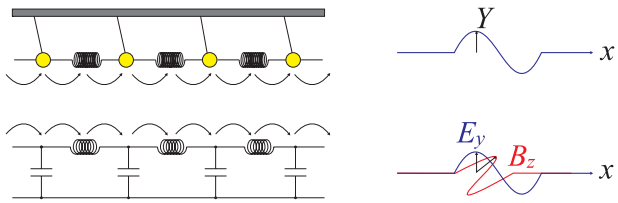

Figure 5.5: Analogy between the propagation of mechanical waves (above) and electromagnetic waves (below).

The *electrical energy* stored in the capacitor and the *magnetic energy* stored in the coil are given by,

$$E_{ele} = \tfrac{\varepsilon_0}{2}|\vec{\mathcal{E}}|^2 \quad , \quad E_{mag} = \tfrac{1}{2\mu_0}|\vec{\mathcal{B}}|^2 \ , \tag{5.20}$$

where the constants $\varepsilon_0 = 8.854 \cdot 10^{-12}\,\mathrm{As/Vm}$ and $\mu_0 = 4\pi \cdot 10^{-7}\,\mathrm{Vs/Am}$ are called *permittivity* and *permeability* of the vacuum. By analogy with the waves on a string, we can write the wave equations (called *Helmholtz equations*) for plane electromagnetic waves propagating along the x-axis,

$$\frac{\partial^2 \mathcal{E}_y}{\partial t^2} = \frac{1}{\varepsilon_0 \mu_0}\frac{\partial^2 \mathcal{E}_y}{\partial x^2} \quad , \quad \frac{\partial^2 \mathcal{B}_z}{\partial t^2} = \frac{1}{\varepsilon_0 \mu_0}\frac{\partial^2 \mathcal{B}_z}{\partial x^2} \ . \tag{5.21}$$

The formal derivation must be made from the *Maxwell equations*, which are the fundamental equations of the theory of electrodynamics. Here, we only note that,

- electromagnetic waves (in free space) are transverse;
- the electric field vector, the magnetic field vector, and the direction of propagation are orthogonal;
- the propagation velocity is the speed of light, because $c^2 = 1/\varepsilon_0\mu_0$.

5.1.3.2 Radiation intensity

In electrodynamic theory the energy flux is calculated by the *Poynting vector*,

$$\vec{S}(\mathbf{r}, t) = \tfrac{1}{\mu_0}\vec{\mathcal{E}}(\mathbf{r}, t) \times \vec{\mathcal{B}}(\mathbf{r}, t) \ . \tag{5.22}$$

The absolute value is the intensity of the light field,

$$I(\mathbf{r}, t) = |\mathbf{S}(\mathbf{r}, t)| \ . \tag{5.23}$$

5.1.4 Harmonic waves

In general, a light field is a superposition of many waves with many different frequencies and polarizations and propagating in many directions. The laser is an exception. Being monochromatic, polarized, directional, and coherent, it is very close to the ideal of an *harmonic wave*, that is, a wave described by the function,

$$Y(x, t) = Y_0 \cos(kx - \omega_0 t) \ , \tag{5.24}$$

where $\omega_0 = 2\pi\nu$ is the angular frequency of the oscillation and $k = 2\pi/\lambda$ the wavevector. By inserting this function into the *wave equation*,

$$\frac{\partial^2 Y}{\partial t^2} = c^2 \frac{\partial Y^2}{\partial x^2} \ , \tag{5.25}$$

where we now call c the propagation velocity of the harmonic wave, we verify the *dispersion relation*,

$$\omega = ck \ . \tag{5.26}$$

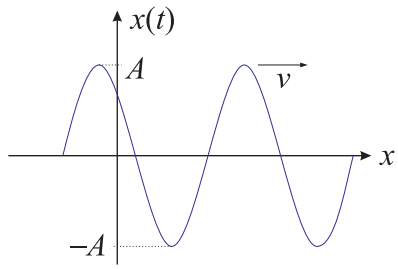

Figure 5.6: Illustration of a harmonic wave.

Often, the propagation velocity is independent of the wavelength, $c(k) = const$. In this case, a wave composed of several waves with different wavevectors k propagates without dispersing, that is, without changing its shape. In other cases, when $c(k) \neq const$, the wave deforms along its path.

5.1.5 Wave packets

Since the wave equation (5.25) is linear, the superposition principle is valid, that is, if Y_1 and Y_2 are solutions, then $\alpha Y_1 + \beta Y_2$ also is. More generally, we can say that, if $A(k)e^{\imath(kx-\omega t)}$ is a solution satisfying the wave equation for any k, then obviously,

$$Y(x, t) = \int_{-\infty}^{\infty} A(k) e^{\imath(kx-\omega t)} dk \ , \tag{5.27}$$

is. This means that the displacement $Y(x)$ and the distribution of amplitudes $A(k)$ are related by Fourier transform, $Y(x,t) = e^{-i\omega t}\mathcal{F}A(k)$.

Assuming a Gaussian distribution of wavevectors characterized by the width [1] Δk, $A(k) = e^{-(k-k_0)^2/2\Delta k^2}$, we obtain as solution for the wave equation,

$$\begin{aligned} Y(x,t) &= \int_{-\infty}^{\infty} e^{-(k-k_0)^2/2\Delta k^2} e^{\imath(kx-\omega t)} dk \qquad (5.28) \\ &= e^{\imath(k_0 x-\omega t)} \int_{-\infty}^{\infty} e^{-q^2/2\Delta k^2} e^{\imath q x} dq = \sqrt{2\pi k} e^{-\Delta k^2 x^2/2} e^{\imath(k_0 x-\omega t)} \ . \end{aligned}$$

This solution of the wave equation describes an *wave packet* with a Gaussian envelope [2], that is, a localized perturbation, as we discussed at the initial example of a pulse propagating on a string. Obviously, other distributions of wavevectors are possible.

Note that the width of the distribution of wavevectors, Δk, and that of the spatial distribution, $\Delta x \equiv 1/\Delta k$ satisfy a relation called *Fourier's theorem*,

$$\Delta x \Delta k = 1 \ , \qquad (5.29)$$

which in quantum mechanics turns into *Heisenberg's uncertainty relation*: The broader a wavevector distribution, the narrower the spatial distribution, and vice versa. In the limit of a sinusoidal wave described by a single wavevector, we expect a infinite spatial extension of the wave.

5.1.6 Dispersion

We consider a superposition of two waves,

$$\begin{aligned} Y_1(x,t) + Y_2(x,t) &= a\cos(k_1 x - \omega_1 t) + a\cos(k_2 x - \omega_2 t) \qquad (5.30) \\ &= 2a\cos\left[\tfrac{(k_1-k_2)x}{2} - \tfrac{(\omega_1-\omega_2)t}{2}\right] \cos\left[\tfrac{(k_1+k_2)x}{2} - \tfrac{(\omega_1+\omega_2)t}{2}\right] \ . \end{aligned}$$

The resulting wave can be regarded as a wave of frequency $\frac{1}{2}(\omega_1+\omega_2)t$ and wavelength $\frac{1}{2}(k_1+k_2)$, whose amplitude is modulated by an envelope of frequency $\frac{1}{2}(\omega_1-\omega_2)t$ and wavelength $\frac{1}{2}(k_1-k_2)x$.

In the absence of dispersion the *phase velocities* of the two waves and the propagation velocity of the envelope, called *group velocity*, are equal,

$$c = \frac{\omega_1}{k_1} = \frac{\omega_2}{k_2} = \frac{\omega_1-\omega_2}{k_1-k_2} = \frac{\Delta\omega}{\Delta k} = v_g \ . \qquad (5.31)$$

[1] Δk is half the *total* Gaussian width at *rms* (root-mean-square) height, that is, at $1/\sqrt{e}$ of the maximum.

[2] The definition of the Fourier transform in one dimension is,

$$Y(x) = \mathcal{F}A(k) \equiv \tfrac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} A(k) e^{\imath kx} dk \ .$$

For the Gaussian function we have,

$$\begin{aligned} Y(x) &= \tfrac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} e^{-ak^2} e^{\imath kx} dk = \tfrac{1}{\sqrt{2\pi}} e^{-x^2/4a} \int_{-\infty}^{\infty} e^{-a(k-ix/2a)^2} dk \\ &= \tfrac{1}{\sqrt{2\pi}} e^{-x^2/4a} \int_{-\infty}^{\infty} e^{-aq^2} dq = \tfrac{1}{\sqrt{2a}} e^{-x^2/4a} \ . \end{aligned}$$

However, the phase velocities of the two harmonic waves can also be different, such that the frequency depends on the wavelength, $\omega = \omega(k)$. In this case, the phase velocity also varies with the wavelength,

$$v_g = \frac{d\omega}{dk} = \frac{d}{dk}(kc) = c + k\frac{dc}{dk} \ . \tag{5.32}$$

Often this variation is not very strong, such that it is possible to expand,

$$\omega(k) = \omega_0 + \left.\frac{d\omega}{dk}\right|_{k_0} \cdot (k-k_0) + \frac{1}{2}\left.\frac{d^2\omega}{dk^2}\right|_{k_0} \cdot (k-k_0)^2 \equiv \omega_0 + v_g(k-k_0) + \beta(k-k_0)^2 \ . \tag{5.33}$$

In general we have, $v_g < c$, a situation that is called *normal dispersion*. But there are examples of *abnormal dispersion*, where $v_g > c$, e.g. close to resonances or with matter waves characterized by a quadratic dispersion relation $\hbar\omega = (\hbar k)^2/2m$.

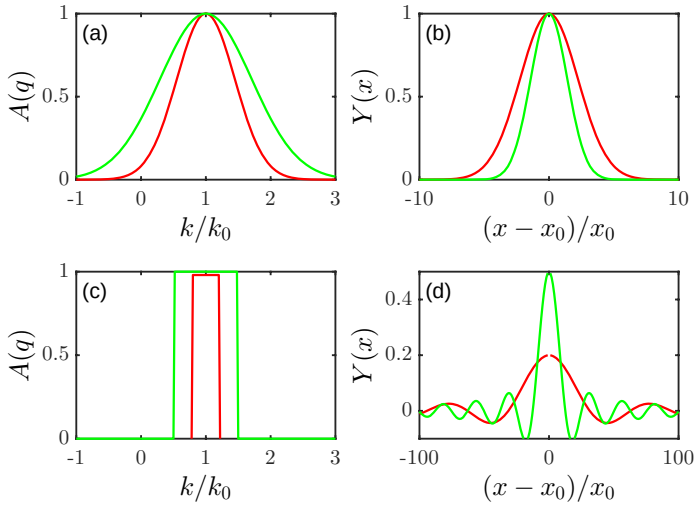

Figure 5.7: (code) Gaussian (upper graphs) and rectangular (lower graphs) distribution of amplitudes in momentum space (left) and in position space (right).

5.1.6.1 Rectangular wave packet with linear dispersion

As an example, we determine the shape of the wavepacket for a rectangular amplitude distribution, $A(k) = A_0\chi_{[k_0-\Delta k/2, k_0+\Delta k/2]}$, subject to linear dispersion (expansion up

to the linear term in Eq. (5.33)). By the Fourier theorem,

$$Y(x,t) = \int_{-\infty}^{\infty} A(k) e^{\imath(kx-\omega t)} dk = A_0 \int_{k_0-\Delta k/2}^{k_0+\Delta k/2} e^{\imath(kx-\omega_0 t + \frac{d\omega}{dk}\big|_{k_0}(k-k_0)t)} dk \tag{5.34}$$

$$= A_0 e^{\imath(k_0 x-\omega_0 t)} \int_{k_0-\Delta k/2}^{k_0+\Delta k/2} e^{\imath(k-k_0)\left(x-\frac{d\omega}{dk}\big|_{k_0} t\right)} dk$$

$$= A_0 e^{\imath(k_0 x-\omega_0 t)} \int_{-\Delta k/2}^{\Delta k/2} e^{\imath k\left(x-\frac{d\omega}{dk}\big|_{k_0} t\right)} dk = A_0 e^{\imath(k_0 x-\omega_0 t)} \int_{-\Delta k/2}^{\Delta k/2} e^{\imath k u} dk$$

$$= A_0 e^{\imath(k_0 x-\omega_0 t)} \frac{e^{\imath\Delta k/2 u} - e^{-i\Delta k/2 u}}{\imath u} = 2A_0 e^{\imath(k_0 x-\omega_0 t)} \frac{\sin\frac{u\Delta k}{2}}{u} \equiv A(x,t) e^{\imath(k_0 x-\omega_0 t)} .$$

With the abbreviation $u \equiv x - \frac{d\omega}{dk}\big|_{k_0} t = x - v_g t$ the interpretation of the group velocity becomes obvious,

$$v_g \equiv \left.\frac{d\omega}{dk}\right|_{k_0} t . \tag{5.35}$$

The envelope has the shape of a 'sinc' function, such that the intensity of the wave is,

$$|Y(x,t)|^2 = A_0 \Delta k \ \mathrm{sinc}\left[\tfrac{\Delta k}{2}(x-v_g t)\right] . \tag{5.36}$$

Obviously, the *wavepacket* is localized in space. It moves at group velocity, but does not diffuse.

5.1.6.2 Dispersion of a Gaussian wave packet subject to quadratic dispersion

Quadratic dispersion leads to a spreading of the wavepackets. We show this at the example of the Gaussian wavepacket $A(k) = e^{-\alpha(k-k_0)^2}$, expanding the dispersion relation (5.33) up to the quadratic term. By the Fourier theorem,

$$Y(x,t) = \int_{-\infty}^{\infty} A(k) e^{\imath(kx-\omega t)} dk = A_0 e^{\imath(k_0 x-\omega_0 t)} \int_{-\infty}^{\infty} e^{\imath(k-k_0)(x-v_g t)-(\alpha+i\beta t)(k-k_0)^2} dk$$

$$= A_0 e^{\imath(k_0 x-\omega_0 t)} \int_{-\infty}^{\infty} e^{\imath k(x-v_g t)-(\alpha+i\beta t)k^2} dk$$

$$\equiv A_0 e^{\imath(k_0 x-\omega_0 t)} \int_{-\infty}^{\infty} e^{\imath k u - v k^2} dk = A_0 \sqrt{\tfrac{\pi}{v}} e^{\imath(k_0 x-\omega_0 t)} e^{-u^2/4v} . \tag{5.37}$$

The absolute square of this solution describes the spatial energy distribution of the wavepacket,

$$|Y(x,t)|^2 = A_0^2 \frac{\pi}{\sqrt{v v^*}} e^{-u^2/4v - u^2/4v^*} = A_0^2 \frac{\pi}{x_0\sqrt{\alpha/2}} e^{-(x-v_g t)^2/x_0^2} , \tag{5.38}$$

with $x_0 \equiv \sqrt{2\alpha}\sqrt{1+\frac{\beta^2}{\alpha^2}t^2}$. Obviously, for long times the pulse spreads out at constant speed. Since the constant α gives the initial width of the pulse, we realize that an initially compressed pulse spreads faster. Therefore, the angular coefficient of the dispersion relation determines the group velocity, while the curvature determines the spreading speed (dispersion).

5.1.7 Exercises

5.1.7.1 Ex: Speed of sound

A person drops a stone from the top of a bridge and hears the sound of the stone hitting the water after $t = 4\,\mathrm{s}$.
a. Estimate the distance between the bridge and the water level, assuming that the propagation time of sound is negligible.
b. Improve the estimate by taking into account the finite speed of sound.

Solution: *a. The height would be* $h = \frac{g}{2}t^2 = 78.48\,\mathrm{m}$.
b. We know $h = \frac{g}{2}t_{cai}^2 = c_{som}(t - t_{cai})$. *Hence,*

$$t_{fall} = -\frac{c_{sound}}{g} \pm \frac{c_{sound}}{g}\sqrt{1 + \frac{2gt}{c_{sound}}} = 3.79\,\mathrm{s} \ ,$$

and $h = 70.55\,\mathrm{m}$.

5.1.7.2 Ex: Distance of a lightning

An approximate method for estimating the distance of a lightning consists in starting to count the seconds when the lightning stroke and stop counting when the thunder arrives. The number of seconds counted divided by 3 gives the distance from the lightning in kilometers. Estimate accuracy of this procedure.

Solution:

5.1.7.3 Ex: Speed of sound

A student in her room listens to the radio broadcasting a nearby football game. She is 1.6 km south of the field. On the radio, the student hears the noise generated by an electromagnetic pulse caused by a lightning strike. Two seconds later she hears the noise of thunder on the radio which was captured by the microphone of the football field. Four seconds after hearing the noise on the radio, she hears the noise of the thunder directly. Where did the lightning strike in relation to the soccer field?

Solution:

5.1.7.4 Ex: Absence of dispersion in sound

Discuss the experimental evidence that leads us to assume that the speed of sound in the audible range must be the same at all wavelengths.

Solution: *If there were dispersion, high and low sounds would be desynchronized (e.g., at a public concert). The noise of explosions noise would be quickly attenuated.*

5.1.7.5 Ex: Optical dispersion

a. While vacuum is strictly dispersionless, the refractive index of air depends on the wavelength of light λ, on temperature T in $^\circ$ C and on the atmospheric pressure P in mbar like,

$$n_s = 1 + 10^{-8}\left(8342.13 + \frac{2406030}{130 - 10^{12}/\lambda^2} + \frac{15997}{38.9 - 10^{12}/\lambda^2}\right)$$
$$n = 1 + (n_s - 1)\frac{0.00185097P}{1 + 0.003661T} \ .$$

Calculate the dispersion of air within range $\lambda_1 = 400\,\text{nm}$ and $\lambda_2 = 800\,\text{nm}$.
b. Using Snell's law,

$$\frac{n_1}{n_2} = \frac{\sin\alpha_2}{\alpha_1} \ ,$$

calculate the angular dispersion $d\alpha_{ar}/d\lambda$ of a beam of light at the interface between vacuum and atmospheric air for $P = 1013\,\text{mbar}$ and $T = 25^\circ$ C around $\lambda = 500\,\text{nm}$.

Solution: *We have,*

$$\frac{d\alpha_{ar}}{d\lambda} = \frac{d}{d\lambda}\arcsin\frac{\sin\alpha_{vac}}{n} = \ .$$

5.1.7.6 Ex: Dispersion near an atomic resonance

Near an atomic resonance ω_0 the refractive index can be approximated by,

$$n = 1 - \frac{\alpha}{\omega^2 - \omega_0^2} \ ,$$

where the polarizability of the gas α is a constant. Calculate the group velocity $v_g(\omega_l)$ of a laser wave packet passing through a gas of these atoms as a function of the laser frequency ω_l. Approximate $|\omega - \omega_0| \ll \omega_0$. Make a qualitative chart of $n(\omega_l)$, $k(\omega_l)$, of the phase velocity $v_f(\omega_l)$, and of the group velocity $v_g(\omega_l)$.

Solution: *Expressing k by ω,*

$$k = \frac{\omega n(\omega)}{c} = \frac{\omega}{c}\left(1 - \frac{\alpha}{\omega^2 - \omega_0^2}\right)$$

we can calculate the phase velocity by,

$$v_f = \frac{c}{n} = \frac{c}{1 - \frac{\alpha}{\omega^2 - \omega_0^2}} \ .$$

we can calculate the group velocity by,

$$v_g = \left.\frac{d\omega}{dk}\right|_{k=k_l} = \frac{1}{\left.\frac{dk}{d\omega}\right|_{\omega=\omega_l}} = \frac{1}{\left.\frac{d}{d\omega}\frac{\omega n(k)}{c}\right|_{\omega=\omega_l}} = \frac{1}{\left.\frac{d}{d\omega}\frac{\omega}{c}\left(1 - \frac{\alpha}{\omega^2-\omega_0^2}\right)\right|_{\omega=\omega_l}}$$
$$= \frac{c}{1 + \alpha\frac{\omega_l^2 + \omega_0^2}{(\omega_l^2 - \omega_0^2)^2}} = \frac{c}{n - (n-1)\frac{2\omega^2}{\omega^2 - \omega_0^2}} \ .$$

For $\omega \simeq \omega_0$ we can approximate,

$$v_g = \frac{c}{1 + \frac{\alpha}{2(\omega_l - \omega_0)^2}} \ .$$

Alternatively, approximating $\omega \simeq \omega_0$ we can calculate,

$$k \simeq \frac{\omega}{c}\left(1 - \frac{\alpha}{2\omega_0(\omega - \omega_0)}\right) \ ,$$

and express ω by k,

$$\omega = \tfrac{1}{2}\left(\omega_0 + \tfrac{\alpha}{2\omega_0} + ck\right) \pm \sqrt{\tfrac{1}{4}\left(\omega_0 + \tfrac{\alpha}{2\omega_0} + ck\right)^2 - ck\omega_0} \ ,$$

giving,

$$v_g = \left.\frac{d\omega}{dk}\right|_{k=k_l} = \tfrac{c}{2} \pm \tfrac{c}{2} \frac{-\omega_0 + \frac{\alpha}{2\omega_0} + ck_l}{\sqrt{\left(\omega_0 + \frac{\alpha}{2\omega_0} + ck_l\right)^2 - 4ck_l\omega_0}} \ .$$

The graph shows the approximation as points in magenta. Similarly, we can show

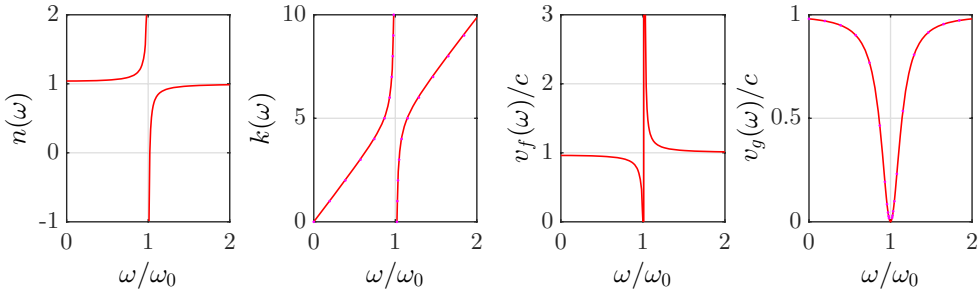

Figure 5.8: Dispersion near an atomic resonance.

that for $n(\omega) = 1 + \frac{\alpha}{1+(\omega-\omega_0)^2/\Gamma^2}$ group velocity is,

$$v_g = \frac{c}{n - (n-1)\frac{2\omega^2(\omega-\omega_0)}{\Gamma^2+(\omega-\omega_0)^2}} \ ,$$

and for $n(\omega) = 1 + \alpha e^{-(\omega-\omega_0)^2/\Gamma^2}$ the group velocity is,

$$v_g = \frac{c}{n - (n-1)\frac{2\omega(\omega-\omega_0)}{\Gamma^2}} \ .$$

5.1.7.7 Ex: Group velocity near a broad transition

The refractive index of a dilute gas (density ρ) of atoms excited by a light beam of frequency ω near a transition (resonant frequency ω_0 and width Γ) can be approximated

by,

$$n = \sqrt{1 - \frac{4\pi\rho\Gamma}{k_0^3(2\Delta + \imath\Gamma)}} \simeq 1 - \frac{2\pi\rho\Gamma}{k_0^3(2\Delta + \imath\Gamma)} \ ,$$

where $ck_0 = \omega_0$ and $\Delta \equiv \omega - \omega_0$. Calculate the group velocity near resonance.

Solution: *The real part is,*

$$n_r = \mathfrak{Re}\ n = 1 - \frac{4\pi\rho\Gamma\Delta}{k_0^3(4\Delta^2 + \Gamma^2)} \ .$$

The group velocity is,

$$v_g = \frac{1}{\frac{dk}{d\omega}\Big|_{\omega=\bar{\omega}}} = \frac{1}{\frac{d}{d\omega}\frac{\omega n(k)}{c}\Big|_{\omega=\bar{\omega}}} = \frac{1}{\frac{d}{d\omega}\left(\frac{\omega}{c} - \frac{\omega}{c}\frac{4\pi\rho\Gamma\Delta}{k_0^3(4\Delta^2+\Gamma^2)}\right)\Big|_{\omega=\bar{\omega}}}$$
$$= \frac{c}{1 - \frac{4\pi\rho\Gamma}{k_0^3}\frac{-4\omega_0(\omega-\omega_0)^2+(2\omega-\omega_0)\Gamma^2}{[4(\omega-\omega_0)^2+\Gamma^2]^2}\Big|_{\omega=\bar{\omega}}} \ .$$

The profile of the group velocity shows two poles.

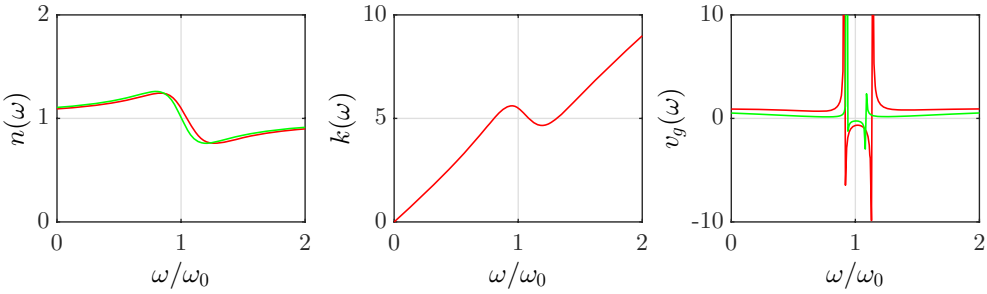

Figure 5.9: Group velocity near a broad transition.

5.1.7.8 Ex: Dispersion in a metal

The dispersion ratio in metals can be approximated by,

$$n^2(\omega) = 1 + \omega_p^2\left(\frac{f_e}{-\omega^2 - \imath\gamma_e\omega} + \sum_j \frac{f_j}{\omega_{0j}^2 - \omega^2 - \imath\gamma_j\omega}\right) \ ,$$

where ω_p is called the plasma frequency and f_e and f_j are constants. Calculate the group velocity $v_g(\omega)$.

Solution:

5.2 The Doppler effect

5.2.1 Sonic Doppler effect

Waves propagate from a source to an listener within an elastic material medium with the propagation velocity v. So far, we assumed the source, the medium, and the listener at rest. The question now is, what happens when one of these three components gets in motion.

5.2.1.1 Source in motion

We imagine a source emitting signals at frequency f_0. Within the time of a period $T = \frac{1}{f_0}$ these pulses travel a distance,

$$\lambda = vT = \frac{v}{f_0} \ , \tag{5.39}$$

within the medium. While the source is at rest, the distance between the pulses is λ. However, when the source moves in the propagation direction of the pulses, a resting listener judges that the pulses are emitted within the medium at reduced distances Δx, as shown in Fig. 5.10,

$$\Delta x = \lambda - u_s T \ . \tag{5.40}$$

A listener now receives the pulses at the increased frequency of,

$$f = \frac{v}{\Delta x} = \frac{v}{\lambda - u_s T} = \frac{v f_0}{v - u_s} = \frac{f_0}{1 - u_s/v} \ . \tag{5.41}$$

This effect is called *sonic Doppler effect*. For small velocities we can expand,

$$f = \frac{f_0}{1 \mp u_s/v} \simeq f_0 \left(1 \pm \frac{u_s}{v}\right) \ , \tag{5.42}$$

where the upper (lower) signals apply, when the source approaches (moves away from) the listener.

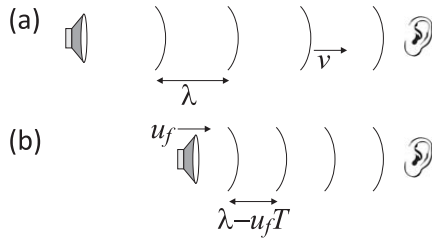

Figure 5.10: Doppler effect due to a motion of the source. In (a) the source is at rest, in (b) it moves toward the listener.

5.2.1.2 Listener in motion

Again, we consider the same source emitting signals at frequency f_0. While the source is at rest, the distance between the pulses is λ. However, when the listener is approaching the source, as shown in Fig. 5.11, pulses are recorded by the listener in a shorter time intervals,

$$T = \frac{\lambda}{v + u_r} = \frac{1}{f} \ . \tag{5.43}$$

That is, the listener measures a larger number of pulses,

$$f = f_0 \left(1 \pm \frac{u_r}{v}\right) \ , \tag{5.44}$$

where the upper (lower) signs apply, when the receiver approaches (moves away from) the source.

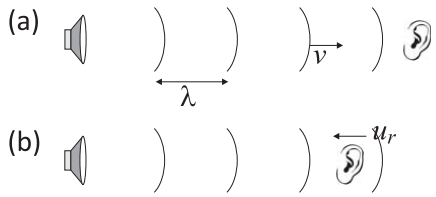

Figure 5.11: Doppler effect due to a motion of the listener. In (a) the listener is at rest, in (b) it moves toward the source.

5.2.1.3 Moving medium

We can combine the two Doppler effects into a single expression,

$$f = f_0 \frac{v^2 - \mathbf{v} \cdot \mathbf{u}_r}{v^2 - \mathbf{v} \cdot \mathbf{u}_s} \ . \tag{5.45}$$

The cases discussed above refer to the source or the listener being in motion *with respect to the medium carrying the wave* considered at rest. If the medium is moving at a velocity u_m, e.g. due to a wind moving the air, the velocities of the source and the listener with respect to the medium are modified, $u_s \to u_s - u_m$ and $u_r \to u_r - u_m$, such that,

$$f = f_0 \frac{1 - (u_r - u_m)/v}{1 - (u_s - u_m)/v} \ . \tag{5.46}$$

The same result is obtained by a transformation of the propagation velocity of the sound, $v \to v + u_m$.

5.2.2 Wave equation under Galilei transformation

The Galilei transformation says, that we obtain the function describing the motion in the system S' simply by substituting $x \to x'$ and $t \to t'$ with [3],

$$\begin{aligned} t' \equiv t \quad &\text{and} \quad x' \equiv x - ut \quad \text{or} \\ t \equiv t' \quad &\text{and} \quad x \equiv x' + ut \ , \end{aligned} \tag{5.47}$$

which implies,

$$v' = \frac{\partial x'}{\partial t'} = \frac{\partial x}{\partial t} - u = v - u \ . \tag{5.48}$$

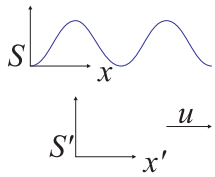

Figure 5.12: Wave in the inertial system S seen by an observer moving at the velocity u in the system S'.

Newton's classical mechanics is *Galilei invariant*, which means that fundamental equations of the type,

$$m\dot{v}_i = -\nabla_{x_i} \sum_j V_{ij}(|x_i - x_j|) \ , \tag{5.49}$$

do not change their form under *Galilei transform*. In contrast, the wave equation is not Galilei invariant. To see this, we consider a wave in the inertial system S being at rest with respect to the propagation medium. The wave is described by $Y(x,t)$ and satisfies the wave equation,

$$\frac{\partial^2 Y(x,t)}{\partial t^2} = c^2 \frac{\partial^2 Y(x,t)}{\partial x^2} \ . \tag{5.50}$$

An observer be in the inertial system S' moving with respect to S with velocity u, such that $x' = x - ut$. The question now is, what is the equation of motion for this wave described by $Y'(x',t')$, that is, we want to check the validity of,

$$\frac{\partial^2 Y'(x',t')}{\partial t'^2} \stackrel{?}{=} c^2 \frac{\partial^2 Y'(x',t')}{\partial x'^2} \ . \tag{5.51}$$

For example, the wave $Y(x,t) = \sin k(x - ct)$ traveling to the right is perceived in the system S', also traveling to the right, as $Y'(x',t') = \sin k[x' - (c-u)t'] = Y(x,t)$. Hence,

$$Y'(x',t') = Y(x,t) \ , \tag{5.52}$$

[3] Note that the Galilei transform,

$$\begin{pmatrix} ct' \\ x' \end{pmatrix} = G \begin{pmatrix} ct \\ x \end{pmatrix} \qquad \text{with} \qquad G \equiv \begin{pmatrix} 1 & 0 \\ -\beta & 1 \end{pmatrix}$$

is unitary because $\det G = 1$.

that is, we expect that the laws valid in S are also valid in S'. We calculate the partial derivatives,

$$\frac{\partial Y'(x',t')}{\partial t'} = \frac{\partial Y(x,t)}{\partial t'} = \frac{\partial t}{\partial t'}\left.\frac{\partial Y(x,t)}{\partial t}\right|_{x=const} + \frac{\partial x}{\partial t'}\left.\frac{\partial Y(x,t)}{\partial x}\right|_{t=const} = \frac{\partial Y(x,t)}{\partial t} + u\frac{\partial Y(x,t)}{\partial x}$$
$$\frac{\partial Y'(x',t')}{\partial x'} = \frac{\partial Y(x,t)}{\partial x'} = \frac{\partial t}{\partial x'}\left.\frac{\partial Y(x,t)}{\partial t}\right|_{x=const} + \frac{\partial x}{\partial x'}\left.\frac{\partial Y(x,t)}{\partial x}\right|_{t=const} = \frac{\partial Y(x,t)}{\partial x} \ . \quad (5.53)$$

Therefore, we come to the conclusion that in the system propagating with the wave, the wave equation is modified,

$$\begin{aligned}\frac{\partial^2 Y'(x',t')}{\partial t'^2} &= \frac{\partial^2 Y(x,t)}{\partial t^2} + 2u\frac{\partial^2 Y(x,t)}{\partial t\partial x} + u^2\frac{\partial^2 Y(x,t)}{\partial x^2} \\ &= c^2\frac{\partial^2 Y(x,t)}{\partial x^2} + 2u\frac{\partial^2 Y(x,t)}{\partial t\partial x} + u^2\frac{\partial^2 Y(x,t)}{\partial x^2} \\ &= (c^2+u^2)\frac{\partial^2 Y(x,t)}{\partial x^2} + 2u\frac{\partial^2 Y(x,t)}{\partial t\partial x} = (c^2-u^2)\frac{\partial^2 Y'(x',t')}{\partial x'^2} + 2u\frac{\partial^2 Y'(x',t')}{\partial t'\partial x'} \ .\end{aligned} \quad (5.54)$$

Only in cases, where the wavefunction can be written as $Y(x,t) = f(x-ct) = f(x'-(c-u)t') = f'(x'-ct') = Y'(x',t')$, do we obtain a wave equation similar to the one of the system S, but with the modified propagation velocity,

$$\begin{aligned}\frac{\partial^2 f'(x'-ct')}{\partial t'^2} &= (c^2-u^2)\frac{\partial^2 f'(x'-ct')}{\partial x'^2} + 2u\frac{\partial^2 f'(x'-ct')}{\partial x'\partial t'} \\ &= (c^2-u^2)\frac{\partial^2 f'(x'-ct')}{\partial x'^2} + 2u\frac{\partial^2 f(x'-(c-u)t')}{\partial x'\partial t'} \\ &= (c^2-u^2)\frac{\partial^2 f'(x'-ct')}{\partial x'^2} - 2u(c-u)\frac{\partial^2 f'(x'-ct')}{\partial x'^2} = (c-u)^2\frac{\partial^2 f'(x'-ct')}{\partial x'^2} \ .\end{aligned} \quad (5.55)$$

The observation that the wave equation is not Galilei-invariant expresses the fact that there is a preferential system for the wave to propagate, which is simply the system in which the propagation medium is at rest. Only in this inertial system will a spherical wave propagate isotropically.

Example 17 (*Wave equation under Galilei transformation*): We now verify the validity of the wave equation in the propagating system S' using the example of a sine wave,

$$\begin{aligned}&(c^2-u^2)\frac{\partial^2 \sin k[x'-(c-u)t']}{\partial x'^2} + 2u\frac{\partial^2 \sin k[x'-(c-u)t']}{\partial x'\partial t'} \\ &= -k^2(c^2-u^2)\sin k[x'-(c-u)t'] + 2uk^2(c-u)\sin k[x'-(c-u)t'] \\ &= -k^2(c-u)^2\sin k[x'-(c-u)t'] = \frac{\partial^2 \sin k[x'-(c-u)t']}{\partial t'^2} \ .\end{aligned}$$

5.2.3 Wave equation under Lorentz transformation

The question now is, how about electromagnetic waves which, as we have already noted and as has been verified by the famous Michelson experiment, survive without any medium. If there is no propagation medium, all inertial systems should be

equivalent and the wave equation should be the same in all systems, as well as the propagation velocity, i.e. the speed of light. These were the consideration of *Henry Poincaré*. To resolve the problem we need another transformation than the one of *Galileo Galilei*. Who found it first was *Hendrik Antoon Lorentz*, however the biggest intellectual challenge was to accept all the consequences that this transformation bears. It was *Albert Einstein* who accepted the challenge and created a new mechanics called *relativistic mechanics*. As the wave equation for electromagnetic waves, called the *Helmholtz equation*, is a direct consequence of Maxwell's theory, it is not surprising that the relativistic theory is not only compatible with the electrodynamic theory, but provides a deeper understanding of it.

We begin by making the ansatz of a general transformation interconnecting the temporal and spatial coordinates by four unknown parameters, γ, $\tilde{\gamma}$, β, and $\tilde{\beta}$,

$$ct = \gamma(ct' + \beta x') \qquad \text{and} \qquad x = \tilde{\gamma}(x' + \tilde{\beta}ct') \; . \tag{5.56}$$

The same calculation made for the Galilei transform now gives the first derivatives,

$$\frac{\partial Y'(x',t')}{c\partial t'} = \frac{\partial Y(x,t)}{c\partial t'} = \frac{\partial t}{\partial t'}\,\frac{\partial Y(x,t)}{c\partial t}\bigg|_{x=const} + \frac{\partial x}{c\partial t'}\,\frac{\partial Y(x,t)}{\partial x}\bigg|_{t=const} = \gamma\frac{\partial Y(x,t)}{c\partial t} + \tilde{\gamma}\tilde{\beta}\frac{\partial Y(x,t)}{\partial x} \tag{5.57}$$

$$\frac{\partial Y'(x',t')}{\partial x'} = \frac{\partial Y(x,t)}{\partial x'} = \frac{\partial ct}{\partial x'}\,\frac{\partial Y(x,t)}{c\partial t}\bigg|_{x=const} + \frac{\partial x}{\partial x'}\,\frac{\partial Y(x,t)}{\partial x}\bigg|_{t=const} = \gamma\beta\frac{\partial Y(x,t)}{c\partial t} + \tilde{\gamma}\frac{\partial Y(x,t)}{\partial x} \; .$$

The second derivatives and the application of the wave equation in the system S give,

$$\begin{aligned}
\frac{\partial^2 Y'(x',t')}{c^2\partial t'^2} &= \gamma^2\frac{\partial^2 Y(x,t)}{c^2\partial t^2} + 2\gamma\tilde{\gamma}\tilde{\beta}\frac{\partial^2 Y(x,t)}{c\partial t\partial x} + (\tilde{\gamma}\tilde{\beta})^2\frac{\partial^2 Y(x,t)}{\partial x^2} \\
&= \gamma^2\frac{\partial^2 Y(x,t)}{\partial x^2} + 2\gamma\tilde{\gamma}\tilde{\beta}\frac{\partial^2 Y(x,t)}{c\partial t\partial x} + (\tilde{\gamma}\tilde{\beta})^2\frac{\partial^2 Y(x,t)}{c^2\partial t^2} \\
&= (\gamma\beta)^2\frac{\partial^2 Y(x,t)}{c^2\partial t^2} + 2\gamma\tilde{\gamma}\beta\frac{\partial^2 Y(x,t)}{c\partial t\partial x} + \tilde{\gamma}^2\frac{\partial^2 Y(x,t)}{\partial x^2} = \frac{\partial^2 Y(x',t')}{\partial x'^2} \; .
\end{aligned} \tag{5.58}$$

That is, the wave equation in the system S' has the same form [4]. Thus, the requirement of invariance of the wave equation allows to affirm,

$$\gamma = \tilde{\gamma} \qquad \text{and} \qquad (\gamma\beta)^2 = (\tilde{\gamma}\tilde{\beta})^2 \qquad \text{and} \qquad \beta = \tilde{\beta} \; . \tag{5.59}$$

In addition, the transformation

$$\begin{pmatrix} ct' \\ x' \end{pmatrix} = L\begin{pmatrix} ct \\ x \end{pmatrix} \qquad \text{with} \qquad L \equiv \begin{pmatrix} \gamma & \gamma\beta \\ \gamma\beta & \gamma \end{pmatrix} \tag{5.60}$$

has to be unitary, that is,

$$1 = \det L = \gamma\tilde{\gamma} - \gamma\tilde{\gamma}\beta\tilde{\beta} = \gamma^2(1-\beta^2) \; , \tag{5.61}$$

[4] Note that the calculus is dramatically simplified using the covariant formalism of 4-dimensional *space-time vectors* introduced by *Hermann Minkowski* and *Gregory Ricci-Curbastro*.

which allows to relate the parameters γ and β by,

$$\gamma = \frac{1}{\sqrt{1-\beta^2}} \ . \tag{5.62}$$

Finally and obviously, we expect to recover the Galilei transform at low velocities,

$$ct = \gamma(ct' + \beta x') \to ct \qquad \text{and} \qquad x = \gamma(x' + \beta ct') \to x + ut \ . \tag{5.63}$$

That is, the limit is obtained by $\gamma \to 1$ and $\gamma\beta c \to u$, such that,

$$\beta = \frac{u}{c} \ . \tag{5.64}$$

such that the *Lorentz transform* from one inertial system S to another system S' is,

$$\begin{aligned} t' &= \gamma\left(t - \tfrac{u}{c^2}x\right) \qquad \text{and} \qquad x' = \gamma(x - ut) \qquad \text{or} \\ t &= \gamma\left(t' + \tfrac{u}{c^2}x'\right) \qquad \text{and} \qquad x = \gamma(x' + ut') \ . \end{aligned} \tag{5.65}$$

5.2.4 Relativistic Doppler effect

We have seen at the example of sonic waves, that the magnitude of the Doppler effect depends on who moves with respect to the medium, whether it is the source or the listener. Electromagnetic waves, however, propagate in empty space, hence there is no material medium or wind. According to Einstein's theory of relativity, there is no absolute motion and the propagation velocity of light is the same for all inertial systems. Therefore, the theory of the sonic Doppler effect can not apply to electromagnetic waves. To deal with the Doppler effect of light, we need to talk a little about time dilation.

5.2.4.1 Dilation of time

We consider a clock flying through the lab S with the velocity v. The clock produces regular time intervals for which we measure in the lab the duration $t_2 - t_1$. The spatio-temporal points are Lorentz-transformed to the system S' in which the clock is at rest by,

$$\begin{pmatrix} ct'_j \\ z'_j \end{pmatrix} = \begin{pmatrix} \gamma ct_j - \gamma\beta z_j \\ -\gamma\beta ct_j + \gamma z_j \end{pmatrix} \ . \tag{5.66}$$

Hence,

$$\begin{aligned} t'_2 - t'_1 &= \gamma t_2 - \gamma\beta\frac{z_2}{c} - \gamma t_1 + \gamma\beta\frac{z_1}{c} \\ &= \gamma t_2 - \beta\left(\frac{z'}{c} + \gamma\beta t_2\right) - \gamma t_1 + \beta\left(\frac{z'}{c} + \gamma\beta t_1\right) = \gamma^{-1}(t_2 - t_1) \ . \end{aligned} \tag{5.67}$$

Consequently, in the lab the time interval seems longer than in the resting system.

Example 18 (*Doppler effect on a moving laser*): Coming back to the Doppler effect we now consider a light source flying through the lab S, for example, a laser operating at a frequency ω', which is well defined by an atomic

transition of the active medium. A spectrometer installed in the same resting system S' as the laser will measure just this frequency. Now we ask ourselves, what frequency would a spectrometer installed in the lab measure. The classical response has been derived for a moving sound source,

$$\omega = \omega' - ku = \omega' - \frac{\omega}{c}u = \frac{\omega'}{1+\frac{u}{c}} \ , \tag{5.68}$$

with $k = \omega/c$. But now, because of time dilation, we need to multiply by γ,

$$\omega = \frac{\gamma^{-1}\omega'}{1+\frac{u}{c}} = \sqrt{\frac{1-\beta}{1+\beta}}\omega' \simeq \omega'\left(1 \pm \frac{u}{c} + \frac{u^2}{2c^2}\right) \ . \tag{5.69}$$

5.2.5 Exercises

5.2.5.1 Ex: Sonic Doppler effect

A speaker hanging from a wire of length $L = 1\,\mathrm{m}$ oscillates with a maximum angle of $\theta_m = 10°$ and emits a sound of $\nu = 440\,\mathrm{Hz}$.
a. What is the frequency of oscillation of the pendulum?
b. What is the energy $E_{cin} + E_{pot}$ of the oscillation?
c. What is the maximum oscillation speed?
d. What are the minimum and maximum frequencies of the sound perceived by a stationary receiver.

Solution: *a. The pendulum's oscillation frequency is,*

$$\omega = \sqrt{\frac{g}{L}} = 2\pi \cdot 0.5\,\mathrm{Hz} \ .$$

b. The energy of the oscillation is,

$$E_{cin} + E_{pot} = \tfrac{m}{2}v^2 + mg(L - L\cos\theta) = \tfrac{m}{2}v_m^2 = mg(L - L\cos\theta_m) = 0.149\,\mathrm{J} \ .$$

c. Therefore, the maximum speed of the speaker is,

$$v_m = \sqrt{2gL(1-\cos\theta_m)} = 54.6\,\mathrm{cm/s} \ .$$

d. The speed of sound being $v_s = 340\,\mathrm{m/s}$, the minimum and maximum sound frequencies are,

$$\nu_r = \nu_f \frac{v_s}{v_s \pm v_m} = 440\,\mathrm{Hz} \ \ \frac{340}{340 \pm 0.3} = 439.3 \ (440.7)\,\mathrm{m/s} \ .$$

5.2.5.2 Ex: Sonic Doppler effect

Two identical speakers uniformly emit sound waves of $f = 680\,\text{Hz}$. The audio power of each speaker is $P = 1\,\text{mW}$. A point P is $r_1 = 2.0\,\text{m}$ away from one device and $r_2 = 3.0\,\text{m}$ from the other.
a. Calculate the intensities I_1 and I_2 of the sound from each speaker separately at the P.
b. If the emission of the speakers were coherent and in phase, what would be the sound intensity in P?
c. If the emission of the speakers were coherent with a phase difference of 180°, what would be the sound intensity in P?
d. If the speaker output were incoherent, what would be the sound intensity in P?

Solution: *a. First speaker (distance r_1):*

$$I_1 = \frac{P}{4\pi r_1^2} = 19.9\,\mu\text{W/m}^2 \ .$$

Second speaker (distance r_2):

$$I_2 = \frac{P}{4\pi r_2^2} = 8.849\,\mu\text{W/m}^2 \ .$$

b. Knowing that the frequency is constant, and that the intensity I is proportional to the square of the amplitude A, it is possible to calculate the intensity when the interference is fully constructive (intensity is maximum) by: $A = C\sqrt{I}$. Since the frequency is constant, C will be the same value at any given point. Adding the amplitudes, we get,

$$\sqrt{I_{max}} = A/C = \sqrt{I_1} + \sqrt{I_2}$$
$$I_{max} = (\sqrt{I_1} + \sqrt{I_2})^2 = 55.3\,\mu\text{W/m}^2 \ .$$

c. Same as for the previous item, however, knowing that in totally destructive interference, the intensity is minimal and its amplitudes are subtracted, we get,

$$\sqrt{I_{min}} = A/C = \sqrt{I_1} - \sqrt{I_2}$$
$$I_{min} = (\sqrt{I_1} - \sqrt{I_2})^2 = 2.21\,\mu\text{W/m}^2 \ .$$

d. Knowing that these are incoherent waves, we just add the intensities:

$$I = I_1 + I_2 = 19.9\,\mu\text{W/m}^2 + 8.849\,\mu\text{W/m}^2 = 28.7\,\mu\text{W/m}^2 \ .$$

5.2.5.3 Ex: Sonic Doppler effect

Suppose that a source of sound and a listener are both at rest, but the medium is moving relative to this frame. Will there be any variation in the frequency heard by

the observer?

Solution: *No, because within the inertial system moving together with the medium the frequency would actually be shifted up (down) when the medium moves in the direction opposite (parallel) to the vector pointing from the source to observer. But this effect is compensated by the opposite effect upon sound reception by the listener, who hears the frequency lower (higher) when the medium moves in the opposite (parallel) direction.*

5.2.5.4 Ex: Sonic Doppler effect

Consider a source that emits waves of frequency f_{fnt} moving at velocity v_{fnt} on the x-axis. Consider an observer moving with velocity v_{obs} also on the x-axis. What will be the frequency perceived by the observer? Call the wave propagation velocity of c.

Solution: *Be x_{fnt} the position of the sound source and $v_{fnt} > 0$ its speed relative to the x-axis. The wavelength produced by the source in a medium is given by,*

$$\lambda_{med} = \lambda_{fnt}\left(1 - \frac{v_{fnt}}{c}\right) = \frac{c}{f_{fnt}}\left(1 - \frac{v_{fnt}}{c}\right) \ ,$$

where $c > 0$ in the region $x > x_{fnt}$ and $c < 0$ in the region $x < x_{fnt}$. Now, an observer in the region $x > x_{fnt}$ that moves with speed v_{obs} relative to the x-axis probes this wavelength with frequency,

$$\begin{aligned} f_{obs} &= \frac{c - v_{obs}}{\lambda_{med}} = \frac{c - v_{obs}}{\frac{c}{f_{fnt}}\left(1 - \frac{v_{fnt}}{c}\right)} = f_{fnt}\frac{1 - \frac{v_{obs}}{c}}{1 - \frac{v_{fnt}}{c}} \\ &\simeq f_{fnt}\left(1 - \frac{v_{obs}}{c}\right)\left(1 + \frac{v_{fnt}}{c}\right) = f_{fnt}\left(1 - \frac{v_{obs} - v_{fnt}}{c} - \frac{v_{obs}v_{fnt}}{c}\right) \\ &\simeq f_{fnt}\left(1 - \frac{v_{obs} - v_{fnt}}{c}\right) \ . \end{aligned}$$

5.2.5.5 Ex: Sonic Doppler effect

Two trains travel on rails in opposite directions at velocities of the same magnitude. One of them is whistling. The whistle frequency perceived by a passenger on the other train ranges from 348 Hz when approaching to 259 Hz when moving away.
a. What is the velocity of the trains.
b. What is the frequency of the whistle.

Solution: *a.* 90 km/h,
b. 300 Hz.

5.2.5.6 Ex: Sonic Doppler effect

On a mountain road, while approaching a vertical wall which the road will surround, a driver is honking his horn. The echo from the wall interferes with the sound of the horn, producing 5 beats per second. Knowing that the frequency of the horn is 200 Hz, what is the speed of the car?

Solution: 15 km/h.

5.2.5.7 Ex: Sonic Doppler effect

A fixed sound source emits a sound of frequency ν_0. The sound is reflected by a fast approaching object (velocity u). The reflected echo returns to the source, where it interferes with the emitted waves giving rise to frequent beats $\Delta\nu$. Show that it is possible to determine the amplitude of the velocity of the moving object $|u|$ as a function of $\Delta\nu$, of ν_0, and of the speed of sound c.

Solution: $|u| = \frac{\nu\Delta\nu}{2\nu_0+\Delta\nu}$.

5.2.5.8 Ex: Sonic Doppler effect

Two cars (1 and 2) drive in opposite directions on a road, with velocities of amplitudes v_1 and v_2. Car 1 travels against the wind, whose velocity is V. At sight of car 2 the driver of car 1 presses his horn, whose frequency is ν_0. The speed of sound in motionless air is c. What is the frequency ν of the horn sound perceived by the driver of car 2? What is the frequency ν' heard by the driver of a car 3 traveling in the same direction as car 1 and at the same speed?

Solution: $\nu = \nu_0 \frac{c-V+v_2}{c-V-v_1}$; $\nu' = \nu_0$.

5.2.5.9 Ex: Sonic Doppler effect

A physicist is molested by a fly orbiting his head. Since he is also a musician, he realizes that the sound of the buzz varies by one pitch. Calculate the speed of the fly.

Solution:

5.2.5.10 Ex: Doppler effect

a. In a storm with wind velocity v a speaker well attached to the ground makes a sound of frequency f_0. How do you calculate the frequency recorded by a microphone taken by the wind and driven away from the speaker at the speed u?
b. Verify your answer in (a) by comparing the three cases (i) $u = 0$, (ii) $u = v$, and (iii) $v = 0$ with the cases of a moving source or receiver.

Solution: *a. In the system where the air is at rest the speaker is moving away with the speed v. Therefore, the frequency that would be perceived by a listener moving along with the wind is,*

$$f_{medium} = \frac{f_0}{1+v/c} \ .$$

In the system where the air is at rest the microphone is moving away in the same direction as the speaker with the speed $u - v < 0$. Hence,

$$f_{micro} = f_{medium}\left(1 - \frac{u-v}{c}\right) = f_0 \frac{1-(u-v)/c}{1+v/c} = f_0\left(1 + \frac{-u/c}{1+v/c}\right) \ .$$

Alternatively, we calculate the Doppler shift first disregarding the wind,

$$f_{rep} = f_0\left(1 - \frac{u}{c}\right) \ ,$$

and transforming to the wind system by, $c \to c+v$, giving the same result,

$$f = f_0\left(1 - \frac{u}{c+v}\right) \ .$$

b. (i) With the microphone fixed to the ground $u = 0$, we observe $f = f_0$.
(ii) In case where the microphone reaches the wind speed, $u = v$, we observe $f = f_0 \frac{1}{1+v/c}$, which is the Doppler effect of a moving source.
(iii) Without wind $v = 0$ but with a microphone velocity u we observe $f = f_0\left(1 - \frac{u}{c}\right)$, which is the Doppler of a moving receiver.

5.2.5.11 Ex: Sonic Doppler effect

A citizen of São Carlos is molested by a Tucano airplane operated by the Academia das Forças Aéreas de Pirassununga. He notices that while the airplane realizes looping on top of his head, the emitted sounds varies by up to an octave. Estimate the airplane's velocity.

Solution: *Assuming for simplicity that the airplane moves with uniform velocity on a straight line passing near by the citizen, we calculate for the maximum and minimum velocities $\pm u_s$ with respect to the observer,*

$$f_0\left(1 + \frac{u_s}{v}\right) = 2f_0\left(1 - \frac{u_s}{v}\right) \ ,$$

from which we obtain $u_s = \frac{v}{3}$ independently of the emitted sound frequency.

5.3 Interference

The superposition of two counterpropagating waves can generate a *standing wave*. In these waves the oscillation amplitude depends on the position, but there is no energy transport.

5.3.1 Standing waves

We consider two waves $Y_\pm(x,t) = A\cos(kx \mp \omega t + \phi)$ propagating in opposite directions. In the case of a string this situation can be realized, e.g. by exciting a wave $Y_-(x,t)$ propagating in $-x$ direction, reflecting it subsequently at the end of the string ($x = 0$), and letting the wave $Y_+(x,t)$ propagate back in x direction,

$$Y(x,t) = Y_-(x,t) + Y_-(x,t) = A\cos(kx + \omega t) \pm A\cos(kx - \omega t) \ . \tag{5.70}$$

The sign of the reflected wave depends on how the end of the string is attached. If the end is fixed, the reflected wave inverts its amplitude. If it is free to move, the amplitude remains unaltered.

Let L be the length of the rope. The boundary conditions can be formulated as follows: When one end is clamped, the oscillation amplitude must be zero at this end,

$$Y(0,t) = 0 \qquad \text{or} \qquad Y(L,t) = 0 \ . \tag{5.71}$$

When one end is loose, the amplitude of oscillation must be maximum,

$$Y(0,t) = A \qquad \text{or} \qquad Y(L,t) = A \ . \tag{5.72}$$

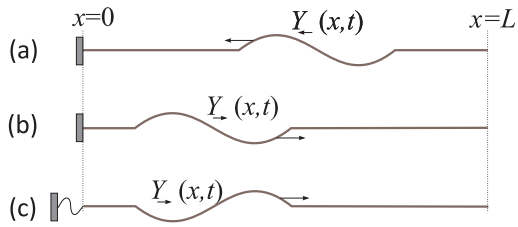

Figure 5.13: Superposition of a left-bound wave (a) with a wave reflected at a clamped end (b) or a loose end (c).

5.3.1.1 Rope with two ends fastened

In case that the two ends of the rope are clamped, we can simplify the superposition (5.70),

$$Y(x,t) = A\cos(kx + \omega t) - A\cos(kx - \omega t) = 2\sin kx \sin \omega t \ . \tag{5.73}$$

The boundary condition, $Y(L,t) = 0$, requires,

$$kL = \frac{2\pi L}{\lambda} = n\pi \ , \tag{5.74}$$

for a natural number n. This means that for a given length L and a given propagation velocity v, we can only excite oscillations satisfying,

$$\lambda = \frac{2L}{n} \qquad \text{and} \qquad \nu = \frac{v}{\lambda} = n\frac{v}{2L} \ . \tag{5.75}$$

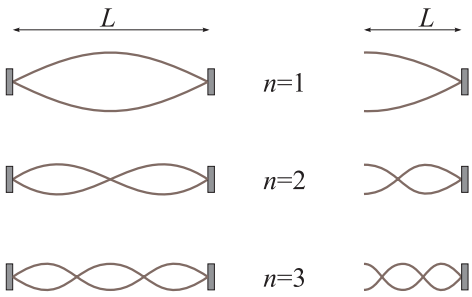

Figure 5.14: Vibration modes of a string fot (left) both ends tight up and (right) for one loose end.

5.3.1.2 Rope with one free end

In case that the end of the string at $x = 0$ is loose, we can simplify the superposition (5.70),

$$Y(x,t) = A\cos(kx + \omega t) + A\cos(kx - \omega t) = 2\cos kx \cos \omega t \ . \tag{5.76}$$

The boundary condition, $Y(L,t) = 0$, requires,

$$\phi = \tfrac{\pi}{2} \qquad \text{and} \qquad kL = \frac{2\pi L}{\lambda} = \left(n - \tfrac{1}{2}\right)\pi \ , \tag{5.77}$$

for a natural number n. This means that for a given length L and a given propagation velocity v, we can only excite oscillations satisfying,

$$\lambda = \frac{2L}{n - \frac{1}{2}} \qquad \text{and} \qquad \nu = \frac{v}{\lambda} = \left(n - \tfrac{1}{2}\right)\frac{v}{2L} \ . \tag{5.78}$$

Example 19 (*Stationary sound wave*):

- Exciting a stationary sound wave in a bottle.
- Exciting a standing sound wave on a guitar string.

5.3.2 Interferometry

5.3.2.1 Phase matching of two laser beams

When phase-matching two plane waves $\mathcal{E}_1 = Ae^{\imath\omega_1 t}$ and $\mathcal{E}_2 = Ae^{\imath\omega_2 t}$ on a photodiode, such that their wavevectors are parallel, the photodiode generates a *beat signal*,

$$I = |E_1 + E_2|^2 = AB[2 + 2\cos(\omega_1 - i\omega_2)t] \ . \tag{5.79}$$

In order to get a high signal contrast, a good phase-matching is important. It is particularly important to adjust the wavevectors to be absolutely parallel. In practice, however, this can be tricky, as the laser beams are frequently not plane waves, but have a finite diameter and radius of curvature.

Example 20 (*Laser interferometry*):

- Construct Michelson and Mach-Zehnder laser interferometers with one mirror mounted on a piezo. Show interference rings.

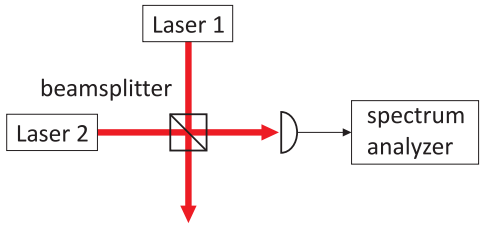

Figure 5.15: Principle of a beat frequency measurement.

5.3.3 Diffraction

According to the Huygens principle, each point P_z within a slit emits a spherical wave reaching a given point P_k of the screen with a phase lag corresponding to the distance, as shown in Fig. 5.16,

$$r_{12} = \overline{P_\eta P_y} = \sqrt{(y-\eta)^2 + z^2} \ . \tag{5.80}$$

Thus, the phase difference between this ray and a ray coming out of the origin (which we place somewhere on the optical axis) is,

$$\phi = k\Delta r_{12} = k(\sqrt{(y-\eta)^2+z^2} - \sqrt{y^2+z^2}) \simeq -\frac{ky\eta}{\sqrt{y^2+z^2}} \simeq -\frac{ky\eta}{z} \equiv q\eta \ , \tag{5.81}$$

with $q = k\sin\alpha = ky/z$. If $A(\eta)$ is the amplitude of the excitation at the point η of the slit, then $B(y) = \frac{1}{z}e^{\imath\phi}$ is the amplitude at point y of the screen. Adding the contributions of all points,

$$B(q) = \sum_z e^{\imath\phi(y,z)} \to \int A(\eta) e^{\imath q\eta} d\eta \ . \tag{5.82}$$

We see that the amplitude distribution on the screen $B(y)$ is nothing more than the Fourier transform of the amplitude distribution $A(\eta)$ within the slit, regardless of the shape of the slit.

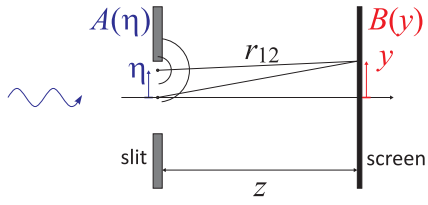

Figure 5.16: Fraunhofer diffraction at the slit.

The theory can be extended to 2D and 3D geometries, for example, a distribution of point-like scatterers within a given volume.

5.3.3.1 Single slit

As an example, we calculate the interference pattern behind a single slit. The Fourier transform of $A(\eta) = \chi_{[-d/2,d/2]}$ is,

$$B(q) = \int_{-d/2}^{d/2} e^{\imath q\eta} d\eta = \left. \frac{e^{\imath q\eta}}{\imath q} \right|_{-d/2}^{d/2} = d \frac{\sin \frac{1}{2} qd}{\frac{1}{2} qd} \ . \tag{5.83}$$

The intensity is $I(q) = c\varepsilon_0 |B(q)|^2$.

5.3.3.2 Diffraction grating

We now calculate the interference pattern behind a diffraction grating with $N = 1000$ infinitely thin slits aligned within one millimeter. The Fourier transform of $A(\eta) = \sum_{n=1}^{N} \chi_{[(n-1)d,(n-1)d+\Delta d]}$ is,

$$\begin{aligned} B(q) = \sum_{n=1}^{N} \int_{(n-1)d}^{(n-1)d+\Delta d} e^{\imath q\eta} d\eta = \frac{e^{\imath q\Delta d} - 1}{\imath q} \sum_{n=1}^{N} e^{\imath (n-1) qd} \\ \simeq \Delta d \sum_{n=0}^{N} e^{\imath nqd} = \Delta d \frac{1 - e^{\imath Nqd}}{1 - e^{\imath qd}} \ , \end{aligned} \tag{5.84}$$

where we approximated for $q\Delta d \ll 1$. For $N \to \infty$ we can approximate further,

$$B(q) = \frac{\Delta d}{1 - e^{\imath qd}} \ . \tag{5.85}$$

This is the *Airy function*, which is zero everywhere except at points where $qd = 2n\pi$. The intensity is,

$$I(q) = c\varepsilon_0 |B(q)|^2 = c\varepsilon_0 \frac{\Delta d^2}{2 - 2\cos qd} = c\varepsilon_0 \left(\frac{\Delta d}{2 \sin \frac{qd}{2}} \right)^2 \ . \tag{5.86}$$

The grating constant is $d = 0.001\,\text{mm}$. The resulting pattern can be interpreted as arising from a regular chain of antennas emitting synchronously. With a large number of point antennas, the chain emits in very well-defined directions. In addition, the direction can be controlled by arranging for a well-defined phase shift between the fields driving neighboring antennas.

5.3.4 Plane and spherical waves

In three dimensions the wave equation takes the form,

$$0 = \Box E \equiv \left(\frac{1}{c^2} \frac{\partial}{\partial t} - \nabla^2 \right) E \ . \tag{5.87}$$

In Cartesian coordinates, this gives,

$$0 = \left(\frac{1}{c^2} \frac{\partial^2}{\partial t^2} - \frac{\partial^2}{\partial x^2} - \frac{\partial^2}{\partial y^2} - \frac{\partial^2}{\partial z^2} \right) E \ . \tag{5.88}$$

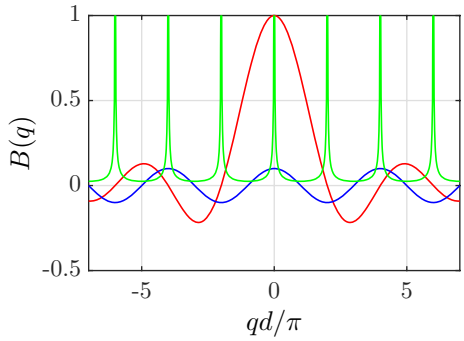

Figure 5.17: (code) Intensity distribution behind a diffraction grating for a single slit (red), a double slit (blue), and an infinite diffraction grating (green).

Plane waves, that is, waves described by the function,

$$Y(\vec{r},t) = Y_0 \sin(\vec{k}\cdot\vec{r} - \omega t) \ , \tag{5.89}$$

satisfy the wave equation if,

$$0 = -\frac{\omega^2}{c^2} + k_x^2 + k_y^2 + k_z^2 = -\frac{\omega}{c^2} + \vec{k}^2 \ . \tag{5.90}$$

5.3.4.1 Spherical waves

Spherical waves, that is, waves described by the function,

$$Y(\mathbf{r},t) = f(r)\sin(kr - \omega t) \ , \tag{5.91}$$

also satisfy the wave equation, provided the function $f(r)$ satisfies certain conditions. To find these conditions we use the representation of the *Laplace operator* in spherical coordinates,

$$\nabla^2 = \frac{1}{r}\frac{\partial^2}{\partial r^2}r + \frac{1}{r^2\sin\theta}\frac{\partial}{\partial\theta}\left(\sin\theta\frac{\partial}{\partial\theta}\right) + \frac{1}{r^2\sin^2\theta}\frac{\partial^2}{\partial\phi^2} \ , \tag{5.92}$$

and insert the ansatz for $Y(\mathbf{r},t)$ into the wave equation. We have on one hand,

$$\frac{1}{c^2}\frac{d^2}{dt^2}(f\sin) = -\frac{\omega^2}{c^2} f\sin \ . \tag{5.93}$$

On the other hand,

$$\begin{aligned}\frac{1}{r}\frac{d^2}{dr^2}(rf\sin) &= \frac{1}{r}\frac{d}{dr}[f\sin + rf'\sin + krf\cos] \\ &= f''\sin + \frac{2f'}{r}\sin - k^2 f\sin + \frac{2k}{r}f\cos + 2kf'\cos \ ,\end{aligned} \tag{5.94}$$

such that,

$$0 = \Box f\sin = -\left(f'' + \frac{2f'}{r}\right)\sin - 2k\left(f' + \frac{f}{r}\right)\cos \ . \tag{5.95}$$

Thus the function f must satisfy the radial differential equation,

$$rf' + f = 0 \ . \tag{5.96}$$

This equation can be easily solved with the result $f(r) = r^{-1}$.

5.3.5 Formation of light beams

We consider monochromatic waves with frequency ω. Other waveforms can be synthesized by superpositions of waves with different frequencies. We also restrict to scalar waves. In fact, electromagnetic light fields are vectorial, however, close to the axis of an optical beam the fields are practically uniformly polarized, and representing the amplitude of the field by a scalar wave is an excellent approximation. The field amplitude $\psi(\mathbf{r}, t)$ is governed by the following scalar wave equation,

$$\nabla^2\psi = \frac{1}{c^2}\frac{\partial^2\psi}{\partial t^2} \ . \tag{5.97}$$

We let ψ be of the form,

$$\psi(\mathbf{r}, t) = A(\mathbf{r})e^{\imath[\phi(\mathbf{r})-\omega t]} \ , \tag{5.98}$$

where A and ϕ are real functions of space. A is the *amplitude*, and the exponent is called the *phase* of the wave. In this form, it is implied that abrupt spatial or temporal variations are contained in the phase. The surface obtained by fixing the phase equal to a constant,

$$\phi(\mathbf{r}) - \omega t = const \tag{5.99}$$

is called *wave front* or *phase front*. The fast motion associated with a wave can be followed through the propagation of a particular wavefront. The interference between two waves is formed by the fronts of the two waves. The speed at which a particular wavefront is moving is called *phase velocity*. Suppose we follow a particular wavefront at the moment t: At time $t + \Delta t$, the phase front will have moved to another surface. A point $\mathbf{r}$ on the original surface will have moved to another point $\mathbf{r} + \Delta\mathbf{r}$ [see Fig. 5.18(a)]:

$$\phi(\mathbf{r} + \Delta\mathbf{r}) - \omega(t + \Delta t) = \phi(\mathbf{r}) - \omega t = const \tag{5.100}$$

Expanding $\phi(\mathbf{r} + \Delta\mathbf{r}) \simeq \phi(\mathbf{r}) + \nabla\phi(\mathbf{r})\Delta\mathbf{r}$, we obtain,

$$\nabla\phi(\mathbf{r})\Delta\mathbf{r} = -\omega t \ . \tag{5.101}$$

$\nabla\phi(\mathbf{r})$ is orthogonal to the phase front and is called the *wavevector*. $\Delta\mathbf{r}$ is smallest in the direction $\nabla\phi$, and the wavefront propagates with the velocity,

$$\frac{|\Delta\mathbf{r}|}{\Delta t} = \frac{\omega}{|\nabla\phi(\mathbf{r})|} \ . \tag{5.102}$$

which is the *phase velocity*. The phase velocity can vary from point to point in space.

Example 21 (*Phase velocity of a superposition of two plane waves*): The superposition of two plane waves with wavevectors $\mathbf{k}_{1,2} = k\hat{\mathbf{e}}_z\cos\theta \pm k\hat{\mathbf{e}}_x\sin\theta$ is described by,

$$\psi(\mathbf{r}, t) = A_0e^{\imath(\mathbf{k}_1\cdot\mathbf{r}-\omega t)} + A_0e^{\imath(\mathbf{k}_2\cdot\mathbf{r}-\omega t)} = 2A_0\cos(kx\sin\theta)e^{\imath(kz\cos\theta-\omega t)} \ . \tag{5.103}$$

The phase front of this wave is a plane with normal vectors pointing along the z-axis, as illustrated in Fig. 5.18(b), and the phase velocity is now $\omega/k\cos\theta = c/\cos\theta > c$.

5.3.5.1 Beam formation by superposition of plane waves

Plane waves extend throughout the space and are uniform in transverse direction, whereas an *optical beam* is confined in transverse direction. However, as we saw in the last example, by superposing two plane waves, a resulting wave can be obtained which varies sinusoidally in transverse direction. By extrapolating this concept to superpositions of many plane waves, it is possible to construct by interference arbitrary transverse amplitude distributions. The propagation of a confined wave is the essence of *diffraction theory*. A particular case is the Gaussian beam. For mathematical simplicity and ease of visualization let us restrict ourselves to waves in two dimensions in the x-z plane. Only in the final phase will we present the complete results for three-dimensional Gaussian beams.

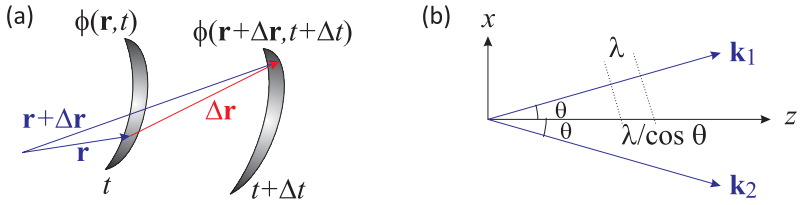

Figure 5.18: Superposition of two plane waves. The phase velocity along the direction z is higher than c, the speed of light, because in one period, the wavefront of each partial wave propagates over a distance λ, but along the z axis over a distance of $\lambda/\cos\theta$.

Before going into detailed calculations, we consider the last example again. The transverse standing wave resulting from the superposition of two plane waves, each one propagating at an angle θ with respect to the z-axis has a spatial frequency $k\sin\theta \simeq k\theta$ for small θ. We now come to a very important property of wave diffraction. Suppose that, in order to confine the wave in transverse direction, we continue adding plane waves, each one propagating at a different small angle θ, so that the amplitude adds constructively within the range $|x| < \Delta x$ and destructively out of it. By the uncertainty principle that results from the Fourier analysis and applies to this case,

$$\Delta(k\theta)\Delta x \gtrsim 1 \ . \tag{5.104}$$

That is, to confine a beam inside a width of Δx, it requires a distribution of plane waves in an angular spreading of at least $\lambda/2\pi\Delta x$. The angular spreading means that the beam will eventually diverge with an angle $\Delta\theta$.

5.3.5.2 Fresnel integrals and beam propagation

Let us now superpose plane waves in a way to form a beam. Each partial wave propagates under some angle θ with respect to the z-axis and has an amplitude

$A(\theta)d\theta$, so that the resulting wave (omitting the harmonic temporal variation) is,

$$\psi(x,z) = \int d\theta A(\theta) e^{\imath kx \sin\theta + \imath kz\cos\theta} \ . \tag{5.105}$$

In the so-called *paraxial approximation*, $A(\theta)$ is significant only within a small angular interval close to zero. This means that, according to Eq. (5.104), the transverse dimension of the beam is large in comparison to the wavelength. Expanding the trigonometric functions up the order θ^2,

$$\psi(x,z) \simeq \int d\theta A(\theta) e^{\imath kx\theta + \imath kz(1-\theta^2/2)} = e^{\imath kz} \int d\theta A(\theta) e^{\imath kx\theta - ikz\theta^2/2} \ . \tag{5.106}$$

This wave can be considered as a plane wave, $e^{\imath kz}$, modulated by the integral of (5.106). The expression (5.106) completely describes the propagation of the wave, provided that the wave is known at some point, say $z = 0$. In fact, at $z = 0$, the expression (5.106) for $\psi_0(x) \equiv \psi(x,0)$ is a Fourier transform, whose inverse yields the angular distribution,

$$A(\theta) = \frac{k}{2\pi} \int d\xi \psi_0(\xi) e^{-\imath k\xi\theta} \ . \tag{5.107}$$

Substitution of $A(\theta)$ back into Eq. (5.106) gives,

$$\psi_z(x) \equiv \psi(x,z) = \frac{k}{2\pi} e^{\imath kz} \int d\theta \int d\xi \psi_0(\xi) e^{\imath(k\theta x - k\theta\xi - kz\theta^2/2)} \ . \tag{5.108}$$

From here on, in order to emphasize the different roles played by the transverse coordinates x and y, we will label the axial position z as an index to the wave function.

We can first integrate over θ via a quadratic extension of the exponent. The result,

$$\frac{k}{2\pi} e^{\imath kz} \int d\theta e^{\imath(k\theta x - k\theta\xi - kz\theta^2/2)} = \sqrt{\frac{k}{2\pi\imath z}} e^{\imath k(z + (x-\xi)^2/2z} \equiv h_z(x-\xi) \ , \tag{5.109}$$

gives us the field at the position z as an integral over ξ of the field in $z = 0$, $\psi_0(\xi)$. The expression (5.109) is called *impulse response*, *kernel*, *propagator*, or *Green's function*, depending on the context. Carry out the integral (5.109) in Exc. 5.3.6.17.

The kernel has very simple physical interpretations: It is the field at point (x,z) generated by a point source with unitary amplitude located in $(\xi,0)$. In the same time, it is a (two-dimensional) spherical wave in a paraxial form. To see this, we write the field of a two-dimensional spherical wave (i.e. a circular wave) with its center in $(\xi,0)$ as,

$$\sqrt{\frac{1}{r}} e^{\imath kr} \ , \tag{5.110}$$

where $r = \sqrt{(x-\xi)^2 + z^2}$. (Instead of $1/r$ as in three dimensions, the amplitude decreases as $\sqrt{1/r}$ in two dimensions.) Near the z-axis, we approximate $r \simeq z + (x-\xi)^2/2z$, and the spherical wave becomes,

$$\sqrt{\frac{1}{z}} e^{\imath k[z + (x-\xi)^2/2z]} \ , \tag{5.111}$$

which is the same expression as $h_z(x-\xi)$ in Eq. (5.109). Note that the quadratic term in $x-\xi$ can become considerable in comparison with the wavelength. Eq. (5.106) now becomes,

$$\boxed{\psi_z(x) = \int h_z(x-\xi)\psi_0(\xi)d\xi = \sqrt{\frac{k}{2\pi\imath z}}e^{\imath kz}\int e^{\imath k(x-\xi)^2/2z}\psi_0(\xi)d\xi} \ . \tag{5.112}$$

We will call this integral the *Fresnel integral*. It is the mathematical expression of the *Huygens principle*: The field in (x,z) is the sum of all spherical waves centered on all previous points $(\xi,0)$ weighed with the respective field amplitude $\psi_0(\xi)$ [1204].

The expressions (5.106) and (5.112) represent two equivalent ways to calculate wave propagation. Eq. (5.106) calculates the wave from the angular distribution of its plane wave components. When the angular distribution is of Hermite-Gaussian type, a Gaussian beam results. In contrast, Eq. (5.112) computes the wave at a point z from the field at an initial point $z=0$. This is the traditional theory of Fresnel diffraction. Here, also a Gaussian beam results when ψ_0 is Hermite-Gaussian.

To deepen our understanding of beam propagation let us introduce the important concept of *near field* and *far field*. By 'near field' we mean a distance z sufficiently small to be allowed to neglect the quadratic term in the exponent of Eq. (5.106),

$$k\theta^2 z \ll 1 \ . \tag{5.113}$$

Then the near field, in zero-order approximation, is precisely the field at $z=0$ multiplied with propagation phase factor $e^{\imath kz}$,

$$\psi_z(x) \simeq e^{\imath kz}\int d\theta A(\theta)e^{\imath kz\theta} = e^{\imath kz}\psi_0(x) \ , \tag{5.114}$$

where the second equation follows from Eq. (5.107). Let us now examine the first-order correction and define 'near' more precisely.

The question is, what is the maximum angle of θ allowed in (5.113)? It is not $\pi/2$, but rather, it is the range of angles over which $A(\theta)$ is significantly different from zero. This angular range $\Delta\theta$ is related to the range of transverse distance Δx via the Fourier transform (5.104), so that,

$$\frac{\pi\Delta x^2}{\lambda} \gg z/2 \ . \tag{5.115}$$

The quantity on the left side, called the *Rayleigh range*, is the demarcation between the near and far field regimes. A simple physical interpretation for this quantity will be given below.

Let us now investigate the 'far field' regime of large z having a closer look at Eq. (5.112). When ψ_0 is confined to Δx, and if z is sufficiently large for the quadratic factor to be,

$$k\xi^2/2z \ll 1 \ , \tag{5.116}$$

or

$$\frac{\pi\Delta x^2}{\lambda} \ll z \ , \tag{5.117}$$

then it can be ignored, and the integral becomes,

$$\psi(x,z) \simeq \sqrt{\frac{k}{\imath 2\pi z}} e^{\imath k(z+x^2/2z)} \int e^{-\imath k x\xi/z} \psi_0(\xi) d\xi \ . \tag{5.118}$$

We see that the amplitude of the far field is given by the amplitude of the Fourier transform of the field at $z = 0$ except for a quadratic phase factor $kx^2/(2z)$ [5]

Let us go back to the near field and calculate the first-order correction. For small $z = \Delta z$, we can expand the exponent in equation (5.106),

$$\begin{aligned} \psi_z(x) &\simeq e^{\imath k\Delta z} \int d\theta A(\theta) \left(1 - \imath k \frac{\theta^2}{2} \Delta z\right) e^{\imath k\theta x} \\ &= e^{\imath k\Delta z} \psi_0(x) - e^{\imath k\Delta z} \frac{\imath k\Delta z}{2} \int d\theta A(\theta) \theta^2 e^{\imath k\theta x} \ . \end{aligned} \tag{5.119}$$

The last integral is,

$$\int d\theta A(\theta) \theta^2 e^{\imath k\theta x} = -\frac{1}{k^2} \frac{\partial^2}{\partial x^2} \int d\theta A(\theta) e^{\imath k\theta x} = -\frac{1}{k^2} \frac{\partial^2 \psi_0(x)}{\partial x^2} \ , \tag{5.120}$$

Such that close to $z = 0$, we get,

$$\psi_z(x) \simeq e^{\imath k\Delta z} \left[\psi(x,0) + \frac{\imath \Delta z}{2k} \frac{\partial^2 \psi(x,0)}{\partial x^2}\right] \ . \tag{5.121}$$

Note that the first-order correction is in quadrature with the zero-order term (5.114) (if ψ_0 is real), which means that the correction is in the phase, not in the amplitude. The second derivative can be seen as a diffusion operator [6], and it is this phase diffusion, which is the cause of phenomenon of *diffraction*.

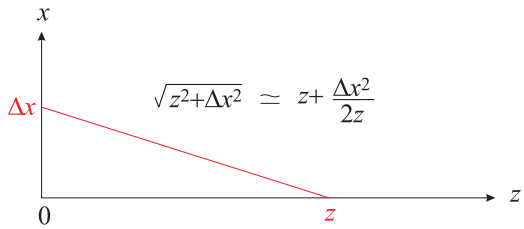

Figure 5.19: Illustration of the Rayleigh range: The distance from $(0,0)$ to $(0,z)$ is z. The distance from $(0,\Delta x)$ to $(0,z)$ is approximately $z + \Delta x^2/(2z)$. The difference is $\Delta x^2/(2z)$. Thus, a wave coming from $(0,0)$ and a wave coming from $(0,\Delta x)$ will acquire a phase difference of $k\Delta x^2/(2z)$ when they reach $(0,z)$. The phase difference is equal to 1 when z equals the Rayleigh range. The phase difference is insignificant in the far field, but significant in the near field.

We can generalize a little more: Suppose we write ψ as a plane wave $e^{\imath kz}$ modulated by a function with slow variation $u(x,z)$,

$$\psi_z(x) \equiv u_z(x) e^{\imath kz} \ , \tag{5.122}$$

[5] In fact, the phase factor can be circumvented by choosing z equal to a focal length f of a lens.

[6] This is because the second derivative of a Gaussian function is negative in the center and positive in the wings, so that when added to the original function, the distribution is reduced in the center and increased in the wings.

then

$$u_{\Delta z}(x) - u_0(x) = \frac{\imath \Delta z}{2k} \frac{\partial^2 u_0(x)}{\partial x^2} \ . \tag{5.123}$$

We derived this relation for a particular point on the z-axis, $z = 0$. However, there is no particular need to choose this point, and the relationship applies to any z. Thus, letting $\Delta z \to 0$, we get,

$$2ik \frac{\partial u}{\partial z} + \frac{\partial^2 u}{\partial x^2} = 0 \ . \tag{5.124}$$

This equation is called *paraxial wave equation*. It is an approximate form of the scalar wave equation and has the same form as the Schrödinger equation for a free particle. The equation can be generalized to three dimensions by a similar derivation:

$$\boxed{2\imath k \frac{\partial u}{\partial z} + \frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} = 0} \ . \tag{5.125}$$

The *Fresnel integral is the solution of the paraxial wave equation* with a boundary condition for ψ at $z = 0$. We will show in Sec. 18.4.3 that a three-dimensional wave can be constructed from two-dimensional waves [1364]. The resulting Fresnel integral in three dimensions is,

$$\boxed{\psi_z(x,y) = \frac{e^{\imath kz}}{\imath \lambda z} \int e^{\imath k(x-\xi)^2/2z} e^{\imath k(y-\eta)^2/2z} \psi_0(\xi,\eta) d\xi d\eta} \ , \tag{5.126}$$

where $\psi_0(x,y)$ is the distribution of the field amplitude at $z = 0$. Note that, as required by energy conservation, in three dimensions the field decays like $1/z$ and not like $\sqrt{1/z}$, as it does in two dimensions. Note also that the pulse response in three dimensions is essentially the product of two two-dimensional pulse responses.

5.3.5.3 Application of Fresnel diffraction theory

The Fresnel diffraction integral, Eq. (5.112), can be applied in various situations illustrating its use and the difference between wave optics and geometric optics. Examples are the diffraction through a slit, the pin-hole camera, the focusing of a thin lens, etc. [1364].

Near-field diffraction (also called *Fresnel diffraction*) and far-field diffraction (also called *Fraunhofer diffraction*) are often distinguished by a quantity called the *Fresnel number*,

$$F \equiv \frac{a^2}{z\lambda} \ , \tag{5.127}$$

where a is the size of the beam (or *aperture*). The near field zone is defined by $F \gtrsim 1$, whereas in the far field zone, $F \ll 1$. For a Gaussian beam, letting $a = \sqrt{\pi} w_0$, we recover the Rayleigh length condition for Fresnel diffraction $z \lesssim z_R$, respectively Fraunhofer diffraction, $z \gg z_R$.

5.3.6 Exercises

5.3.6.1 Ex: Waves on a rope

A string with linear mass density μ is attached at two points distant by $L = 1\,\mathrm{m}$. A mass of $m = 1\,\mathrm{kg}$ is attached to one end of the string that goes over a pulley, as shown in the figure. Excited by a vibrating pin with frequency $f = 1\,\mathrm{kHz}$ the string performs transverse vibrations with the wavelength $\lambda = 2L$.
a. Calculate the sound velocity.
b. Now the mass is replaced by a mass $m' = 4m$. Calculate the new sound velocity.
c. Assuming the sound velocity, how often should the pin excite the string to observe the third oscillation mode (three anti-nodes)?

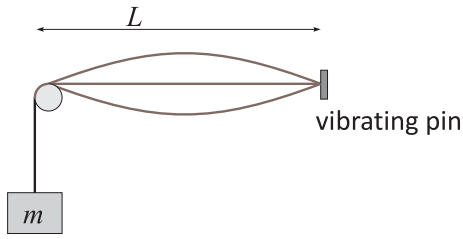

Figure 5.20: Waves on a rope.

Solution: *a. We have,*

$$v = \lambda_n f_n = \frac{2L}{n} f_n \ .$$

Hence, $v_1 = 2Lf_1 = 2\,\mathrm{km/s}$.
b. We have,

$$v' = \sqrt{\frac{m'g}{\mu}} = 2v \ .$$

Hence, $v_1' = 4\,\mathrm{km/s}$.
c. To calculate the new frequency,

$$v' = \lambda_3 f_3 = \frac{2L}{3} f_3 \ .$$

Hence, $f_3 = \frac{3v_1'}{2L} = 6\,\mathrm{kHz}$.

5.3.6.2 Ex: Optical cavity

Optical cavities consist of two light reflecting mirrors. Standing light waves must satisfy the condition that the electric and magnetic fields vanish on the mirror surfaces. What is the frequency difference between two consecutive modes of a of length $L = 10\,\mathrm{cm}$?

Solution: *The free spectral range is,*

$$\delta_{fsr} = \frac{c}{2L} = 1.5\,\mathrm{GHz} \ .$$

5.3.6.3 Ex: Waves on a rope

A string vibrates according to the equation $y(x,t) = 15\sin\frac{\pi x}{4\,\mathrm{cm}}\cos(30\,\mathrm{s}^{-1}\,\pi t)$.
a. What is the velocity of a string element at the position $x = 2\,\mathrm{cm}$ at the instant of time $t = 2\,\mathrm{s}$?
b. What is the propagation speed of this wave?

Solution: *a. In this position there is a node. Therefore,*

$$\dot{y}(x,t) = (-30\pi)15\sin\frac{\pi x}{4}\sin(30\pi t) = 0 \ .$$

b. Since it is a standing wave, it does not propagate.

5.3.6.4 Ex: Violin

The length of a violin string is $L = 50\,\mathrm{cm}$, and its mass is $m = 2.0\,\mathrm{g}$. When it is attached at the ends, the string can emit the a'-pitch ('la') corresponding to 440 Hz. Where should a finger be placed so that the emitted sound is the c"-pitch ('do') at 528 Hz?

Solution: *The mass density is,*

$$\mu = \frac{m}{L} = 4\,\mathrm{g/m} \ .$$

For a given string, the fundamental frequency only depends on its length. Hence, the frequencies 440 Hz *and* 528 Hz*,*

$$f_1 = \frac{1}{2L_1}\sqrt{\frac{T}{\mu}} \quad , \quad f_2 = \frac{1}{2L_2}\sqrt{\frac{T}{\mu}} \ ,$$

are related by,

$$L_2 = L_1\frac{f_1}{f_2} = 20\,\mathrm{cm}\,\frac{440}{528} \ .$$

5.3.6.5 Ex: Sound waves

The air column inside a closed tube, filled with a gas whose characteristic sound velocity is v_s, is excited by a speaker vibrating at the frequency f. Gradually increasing the frequency of the speaker one observes that the tube emits a sound at $f = 440\,\text{Hz}$ and the next time at 660 Hz.
a. What is the length of the tube?
b. What is the speed of sound?

Solution: *a. We have,*

$$v_s = \lambda_n f_n = \frac{2L}{n} f_n = \frac{2L}{n+1} f_{n+1} \ ,$$

with $f_n = 440\,\text{Hz}$ *and* $f_{n+1} = 610\,\text{Hz}$. *Hence,*

$$\Delta f = f_{n+1} - f_n = \frac{n+1}{2L} v_s - \frac{n}{2L} v_s = \frac{v_s}{2L} \ .$$

Finally, $L = \frac{v_s}{2\Delta f} = 1\,\text{m}$.
b. We also know,

$$n = \frac{f_n}{f_{n+1} - f_n} = 2 \ .$$

Hence, $v_s = \lambda_n f_n = \frac{2L}{n} f_n = 440\,\text{m/s}$.

5.3.6.6 Ex: Sound in a bottle

An experimenter blows into a bottle partially filled with water producing a sound of 1000 Hz. After drinking some of the water until the level decreased by 5 cm he is able to produce a sound at 630 Hz. Determine the possible values for the speed of sound knowing that the vibration of the air column inside the bottle should have a node at the end which is in contact with water and an anti-node at the mouth of the bottle. Comparing the result to the known value for the speed of sound in air, what is the excited vibration mode?

Solution: *We know* $c = \lambda_n \nu_n$ *and,*

$$(\tfrac{1}{4} + \tfrac{n}{2})\lambda_n = L_n \ ,$$

for $n = 0, 1, 2, ..,$ *where* L_n *is the height of the air column. Therefore,*

$$c = \frac{2\Delta L}{(n + \frac{1}{2})(\frac{1}{\nu_1} - \frac{1}{\nu_2})} \ .$$

With $n = 0$ *we have* $c = 340\,\text{Hz}$, *what is the known sound velocity. Hence, the fundamental mode is excited.*

5.3.6.7 Ex: Sonic waves in a tube

The figure shows a rod fixed at its center to a vibrator. A disc attached to the end of the rod penetrates a glass tube filled with a gas and where cork dust had been deposited. At the other end of the tube there is a movable piston. When producing longitudinal vibrations at the rod, we note that for certain positions of the movable piston, the cork dust forms a pattern of node and anti-nodes. Knowing for one of the positions of the piston the distance d between the anti-nodes and the frequency f of the vibration, show that the speed of sound in the gas is $v = 2fd$. This is called Kundt's method for determining the speed of sound in a gas.

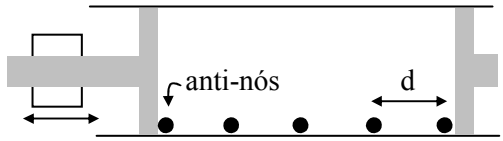

Figure 5.21: Sonic waves in a tube.

Solution:

5.3.6.8 Ex: Sound filter

A tube can act as an acoustic filter discriminating various sound frequencies crossing it from its own frequencies. A car muffler is an application example.
a. Explain how this filter works.
b. Determine the 'cut-off' frequency below which sound is not transmitted.

Solution:

5.3.6.9 Ex: Snell's law

Derive Snell's law from Huygens principle.

Solution:

5.3.6.10 Ex: Surface gravitational waves, capillary waves

Dependence of the propagation velocity on the height of the water column.

Solution:

5.3.6.11 Ex: Propagating standing wave

Consider two propagating waves $\mathcal{E}_\pm(x,t)$ with equal amplitudes and slightly different frequencies $\omega_\pm$ propagating in opposite directions along the x-axis.
a. Show that, approximating $k_+ \simeq k_-$, at each instant of time the interference pattern along the x-axis forms a standing wave.
b. Determine the group velocity of this wave.

Solution: *a. We have,*

$$\begin{aligned}|e^{\imath(k_+x-\omega_+t)} + e^{\imath(-k_-x-\omega_-t)}| &= |e^{\imath\omega_+(x/c-t)} + e^{\imath\omega_-(-x/c-t)}| \\ &= \sqrt{2+2\cos[\omega_+(x/c-t)-\omega_-(-x/c-t)]} \\ &= 2\cos\left[\tfrac{\omega_++\omega_-}{2c}x - \tfrac{\omega_+-\omega_-}{2}t\right] \simeq 2\cos\left[kx - \tfrac{\omega_+-\omega_-}{2}t\right] \ .\end{aligned}$$

In real notation [7] *defining*

$$a+b = k_+x-\omega_+t \quad , \quad a-b = -k_-x-\omega_-t \ ,$$

or

$$a = \tfrac{k_+-k_-}{2}x - \tfrac{\omega_++\omega_-}{2}t \quad , \quad b = \tfrac{k_++k_-}{2}x - \tfrac{\omega_+-\omega_-}{2}t$$

we can write,

$$\begin{aligned}\cos(k_+x-\omega_+t)+\cos(-k_-x-\omega_-t) &= \cos(a+b)+\cos(a-b) = 2\cos a\cos b \\ &= 2\cos\left(\tfrac{k_+-k_-}{2}x - \tfrac{\omega_++\omega_-}{2}t\right)\cos\left(\tfrac{k_++k_-}{2}x - \tfrac{\omega_+-\omega_-}{2}t\right) \\ &\simeq 2\cos\left(\tfrac{k_+-k_-}{2}x - \omega t\right)\cos\left(kx - \tfrac{\omega_+-\omega_-}{2}t\right) \ .\end{aligned}$$

b. Interference produces a standing wave that moves slowly with the group velocity, $v_g = \frac{\omega_1-\omega_2}{k}$.

5.3.6.12 Ex: Mach-Zehnder and Michelson-interferometer

Interferometers are devices that allow the comparison of distances via the propagation time of waves taking different paths. The interferometers outlined in the figures are based on beam splitters that divide and recombine a wave described by $I_n(x,t) = A_n\cos(kx-\omega t)$. Determine the amplitude of the signal at the position of the beam splitter recombining the waves as a function of a variation $\Delta x = 4\pi/k$ of the length of the second interferometer arm.

Solution: *Be* $I_0(0,t) = e^{\imath(kx-\omega t)} = e^{-\imath\omega t}$ *the signal immediately in front of the first beam splitter. Immediately behind it we have two waves* $I_{1,2}(0,t) = 2^{-1/2}e^{\imath(kx-\omega t)} =$

[7] We note,

$$\begin{aligned}|z_1+z_2|^2 = |z_1|^2+|z_2|^2+z_1z_2^*+z_1^*z_2 = x_1^2+y_1^2+x_2^2+y_2^2+2x_1x_2+2y_1y_2 &= (x_1+x_2)^2+(y_1+y_2)^2 \\ &= |\mathrm{Re}z_1+\mathrm{Re}z_2|^2+|\mathrm{Im}z_1+\mathrm{Im}z_2|^2 \ .\end{aligned}$$

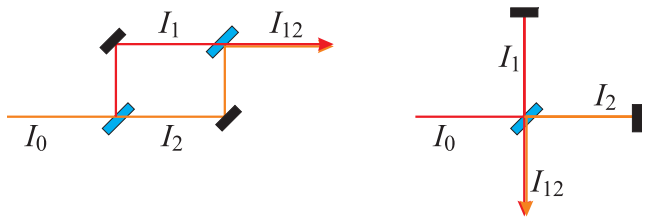

Figure 5.22: Mach-Zehnder and Michelson-interferometer.

$2^{-1/2}e^{-\imath\omega t}$. *With the interferometer arm lengths* $d_{1,2}$ *we have, just in front of the second separator, the signals* $I_{1,2}(d_{1,2},t) = 2^{-1/2}e^{\imath(kd_{1,2}-\omega t)}$. *Immediately behind it we have the recombined wave,*

$$I_s(t) = 2^{-1/2}e^{\imath(kd_1-\omega t)} + 2^{-1/2}e^{\imath(kd_2-\omega t)} = 2^{1/2}\cos k(d_1+d_2)e^{-\imath\omega t} \ .$$

That is, after the second beam splitter the signal oscillates with an amplitude that depends on the length difference of the interferometer arms like $\cos k(d_1+d_2)$.

5.3.6.13 Ex: Multiple interference in optical cavities

An optical beam splitter is a mirror with partial transmission and partial reflection,

$$\mathcal{E}_r(x,t) = \pm r\mathcal{E}_0(x,t) \quad , \quad \mathcal{E}_t(x,t) = t\mathcal{E}_0(x,t) \ .$$

The reflection signal depends on the direction of incidence, because reflection at a denser medium introduces a phase shift of π. Using this rules derive for a set of two mirrors r_1 and r_2 separated by a distance L the field $\mathcal{E}_{cav}$ between the mirrors as a function of the wave vector of the incident field $\mathcal{E}_{in}$. Also calculate the amplitudes of the transmitted and reflected light. Calculate the phase shifts between the transmitted (reflected) light and the incident light. Interpret the results.

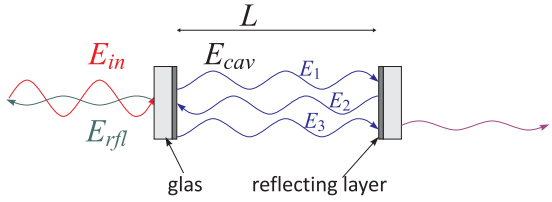

Figure 5.23: Optical cavity.

Solution: *The wave is reflected several times. For the field within the cavity we find, using* $r_j = 1 - t_j$,

$$\mathcal{E}_{cav}(x) = \mathcal{E}_{in}t_1\sum_n\left[(r_1r_2)^n e^{\imath k[2nL+x]} - r_2(r_1r_2)^n e^{\imath k[(2n+2)L-x]}\right] = \mathcal{E}_{in}t_1\frac{e^{\imath kx} - r_2e^{\imath k(2L-x)}}{1-r_1r_2e^{\imath k2L}} \ ,$$

using the Fourier expansion of $(1-s)^{-1} = \sum_n s^n$. *The reflected and transmitted fields are,*

$$\mathcal{E}_{rfl} = r_1 \mathcal{E}_{in} + \mathcal{E}_{in} \sum_{n=0}^{\infty} t_1(-r_2)(r_1 r_2)^n t_1 e^{\imath k 2(n+1)L} = \mathcal{E}_{in}\left(r_1 - \frac{e^{\imath k 2L} t_1^2 r_2}{1 - r_1 r_2 e^{2\imath k L}}\right)$$

$$\mathcal{E}_{trns} = \mathcal{E}_{in} \sum_{n=0}^{\infty} t_1 (r_1 r_2)^n t_2 e^{\imath k(2n+1)L} = \mathcal{E}_{in} \frac{t_1 t_2 e^{\imath k L}}{1 - r_1 r_2 e^{2\imath k L}} \ .$$

The phase shift is calculated by,

$$\phi = \arctan \frac{\mathfrak{Im}\ \mathcal{E}}{\mathfrak{Re}\ \mathcal{E}} \ .$$

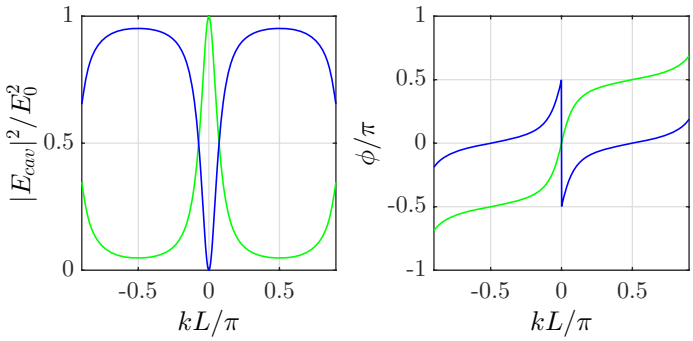

Figure 5.24: Optical cavity.

5.3.6.14 Ex: Double slit

Calculate the interference pattern behind a double slit.

Solution: *The Fourier transform of* $A(z) = \chi_{[-d/2-\Delta d,-d/2]} + \chi_{[d/2,d/2+\Delta d]}$ *is,*

$$\begin{aligned} B(q) &= \int_{-d/2-\Delta d}^{-d/2} e^{\imath q z} dz + \int_{d/2}^{d/2+\Delta d} e^{\imath q z} dz \\ &= \frac{e^{-iqd/2}}{\imath q}(1 - e^{-iq\Delta d}) + \frac{e^{\imath q d/2}}{\imath q}(e^{\imath q \Delta d} - 1) \simeq 2\Delta d \cos \tfrac{1}{2} q d \ . \end{aligned}$$

The intensity is $I(q) = c\varepsilon_0 |B(q)|^2$.

5.3.6.15 Ex: Spherical waves

Show that spherical waves given by $Y(\mathbf{r}, t) = \frac{Y_0}{kr} \sin(kr - \omega t)$ satisfy the 3D wave equation. Use Cartesian coordinates.

Solution: *We proceed in Cartesian coordinates. On one hand, we have,*

$$\frac{1}{c^2}\frac{d^2}{dt^2}\frac{\sin(kr-\omega t)}{kr} = -\frac{\omega^2}{c^2}\frac{\sin}{kr} \ .$$

On the othe hand,

$$\begin{aligned}\frac{d^2}{dx^2}\frac{\sin(kr-\omega t)}{kr} &= \frac{d^2}{dx^2}\frac{\sin(k\sqrt{x^2+y^2+z^2}-\omega t)}{k\sqrt{x^2+y^2+z^2}} \\ &= \frac{k^2r^2x^2\sin -3x^2\sin +r^2\sin -3kx^2r\cos +kr^3\cos}{kr^5} \ ,\end{aligned}$$

such that,

$$\nabla^2\frac{\sin(kr-\omega t)}{kr} = \frac{k^2r^4\sin -3r^2\sin +3r^2\sin -3kr^3\cos +3kr^3\cos}{kr^5} = \frac{k^2\sin}{kr} \ .$$

In spherical coordinates the task is trivial.

5.3.6.16 Ex: Interference in spherical waves

Two spherical waves are generated at positions $\mathbf{r}_\pm = \pm R\hat{\mathbf{e}}_z$. Determine surfaces of destructive interference for these waves.

Solution: *Destructive interference occurs when*

$$\begin{aligned}&\cos[k|\mathbf{r}-\mathbf{r}_+|-\omega t]+\cos[k|\mathbf{r}-\mathbf{r}_-|-\omega t] \\ &\qquad = 2\cos\frac{k|\mathbf{r}-\mathbf{r}_+|+k|\mathbf{r}-\mathbf{r}_-|-2\omega t}{2}\cos\frac{k|\mathbf{r}-\mathbf{r}_+|-k|\mathbf{r}-\mathbf{r}_-|}{2} = 0\end{aligned}$$

at all times. This requires,

$$|\mathbf{r}-\mathbf{r}_+|-|\mathbf{r}-\mathbf{r}_-| = \left(n+\tfrac{1}{2}\right)\lambda \ ,$$

for integer n. This means that for a distant observation point, $r \gg R$,

$$\begin{aligned}\left(n+\tfrac{1}{2}\right)\lambda &= \sqrt{r^2+R^2-2R\mathbf{r}\hat{\mathbf{e}}_z}-\sqrt{r^2+R^2+2R\mathbf{r}\hat{\mathbf{e}}_z} \\ &= r\sqrt{1+\frac{R^2}{r^2}-\frac{2Rz}{r^2}}-r\sqrt{1+\frac{R^2}{r^2}+\frac{2Rz}{r^2}} \simeq -2R\cos\theta \ .\end{aligned}$$

Constructive interference lines are obtained similarly.

5.3.6.17 Ex: Green's function

Calculate the integral Eq. (5.109).

Solution: *We have,*

$$\int d\theta e^{\imath(kx\theta - kx'\theta - kz\theta^2/2)} = \int d\theta e^{\imath k[(x-x')\theta - z\theta^2/2]} = \int d\theta e^{\imath k\left[\frac{(x-x')^2}{2z} - \frac{z}{2}\left(\theta - \frac{x-x'}{z}\right)^2\right]}$$
$$= e^{\imath k\frac{(x-x')^2}{2z}} \int d\theta' e^{-\frac{\imath kz}{2}\theta'^2} = e^{\imath k\frac{(x-x')^2}{2z}} \sqrt{\frac{2}{\imath kz}} \int d\tilde{\theta} e^{-\tilde{\theta}^2} = e^{\imath k\frac{(x-x')^2}{2z}} \sqrt{\frac{2\pi}{\imath kz}} \ .$$

5.4 Fourier analysis

Every periodic function $f(\xi) = f(\xi + 2\pi)$ can be decomposed into a series of harmonic vibrations. This is the *Fourier theorem*,

$$\boxed{f(\xi) = \frac{a_0}{2} + \sum_{n=1}^{\infty}(a_n \cos n\xi + b_n \sin n\xi)} \ . \tag{5.128}$$

To determine the coefficients, we calculate,

$$\int_0^{2\pi} f(\xi)d\xi = \int_0^{2\pi} \left[\frac{a_0}{2} + \sum_{m=1}^{\infty} a_m \cos m\xi + b_m \sin m\xi\right] d\xi = \pi a_0 \tag{5.129}$$
$$\int_0^{2\pi} f(\xi)\cos k\xi d\xi = \int_0^{2\pi} \left[\frac{a_0}{2} + \sum_{m=1}^{\infty} a_m \cos m\xi + b_m \sin m\xi\right] \cos n\xi d\xi = \pi a_n$$
$$\int_0^{2\pi} f(\xi)\sin k\xi d\xi = \int_0^{2\pi} \left[\frac{a_0}{2} + \sum_{m=1}^{\infty} a_m \cos m\xi + b_m \sin m\xi\right] \sin n\xi d\xi = \pi b_n \ ,$$

using the rules,

$$\int_0^{2\pi} \cos n\xi \cos m\xi d\xi = \int_0^{2\pi} \sin n\xi \sin m\xi d\xi = \pi\delta_{n,m} \quad \text{and} \quad \int_0^{2\pi} \cos n\xi \sin m\xi dx = 0 \ . \tag{5.130}$$

We can use these equations to calculate the Fourier expansion. To simplify the calculations, it is useful to consider the symmetry of the periodic function, since if $f(\xi) = f(-\xi)$, we can neglect all the coefficients b_n, and if $f(\xi) = -f(-\xi)$, we can neglect the coefficients b_n [8]

[8] Alternatively we can write the theorem as,

$$f(\xi) = \sum_{n=-\infty}^{\infty} d_n e^{\imath n\xi} \ ,$$

determining the coefficients as,

$$\int_{-\pi}^{\pi} f(\xi)e^{-\imath k\xi}d\xi = \int_{-\pi}^{\pi} f(\xi)e^{-\imath k\xi}d\xi \sum_{n=-\infty}^{\infty} d_n e^{\imath n\xi}d\xi = 2\pi d_n \ ,$$

with,

$$2d_n = a_n - \imath b_n \quad \text{for} \quad n \geq 0 \quad \text{and} \quad 2d_n = a_{-n} + \imath b_{-n} \quad \text{for} \quad n < 0 \ .$$

Example 22 (*Frequency spectrum and low-pass filter*):

- Show the spectrum of a rectangular signal on an oscilloscope and on an spectrum analyzer.
- Show the same spectrum filtered by a low pass filter.

.

5.4.1 Expansion of vibrations

Interpreting $\xi \equiv \omega t$ as time, we can apply the Fourier theorem (5.128) on temporal signals, $S(t) = f(\omega t)$, where ω is the angular frequency,

$$S(t) = f(\omega t) = \frac{a_0}{2} + \sum_{n=1}^{\infty} (a_n \cos n\omega t + b_n \sin n\omega t) \ , \tag{5.131}$$

with,

$$a_0 = \frac{\omega}{\pi} \int_0^{2\pi/\omega} S(t) dt \qquad \text{and} \qquad a_n = \frac{\omega}{\pi} \int_0^{2\pi/\omega} S(t) \cos n\omega t dt \tag{5.132}$$
$$\text{and} \qquad b_n = \frac{\omega}{\pi} \int_0^{2\pi/\omega} S(t) \sin n\omega t dt \ .$$

The representation of the coefficients a_n and b_n as functions of the number n is called *harmonic spectrum*. As we mentioned earlier, the spectrum of a sound is what determines the timbre. The total *harmonic distortion* is defined by,

$$k \equiv \frac{\sum_{n=2}^{\infty} (a_n + b_n)}{\sum_{n=1}^{\infty} (a_n + b_n)} \ . \tag{5.133}$$

Radiofrequency circuits such as HiFi amplifiers are characterized by their transmission fidelity, that is, the absence of harmonic distortion in the amplification of each harmonic coefficient.

5.4.1.1 Expansion of a triangular signal

We consider a *triangular signal* given by [9],

$$S(t) = \begin{cases} \omega t \\ \pi - \omega t \end{cases} \qquad \text{for} \qquad \begin{array}{l} 0 < \omega t < \frac{\pi}{2} \\ \frac{\pi}{2} < \omega t < \pi \end{array} \ . \tag{5.134}$$

We calculate the coefficients, $a_0 = 0$, because the signal is symmetric about the t-axis (it has no offset), and $a_n = 0$, because the signal has the symmetry $S(t) = -S(-t)$. Also,

$$b_n = \frac{2\omega}{\pi} \int_0^{\pi/2\omega} \omega t \sin n\omega t dt + \frac{2\omega}{\pi} \int_{\pi/2\omega}^{\pi/\omega} (\pi - \omega t) \sin n\omega t dt = \frac{4}{\pi} \frac{\sin \frac{1}{2}\pi n}{n^2} \ , \tag{5.135}$$

[9] Note that the function $S(t) = \frac{\pi}{2} - \left(\frac{\pi}{2} - \omega t\right) \frac{\cos \omega t}{|\cos \omega t|}$, which describes the same triangular signal, it is easier to program in numerical softwares.

with the consequence,

$$S(t) = \frac{4}{\pi} \sum_{n=1,3,\ldots} \frac{(-1)^{(n-1)/2}}{n^2} \sin n\omega t \ . \tag{5.136}$$

5.4.2 Theory of harmony

Non-linearities in oscillating systems can excite harmonic frequencies f_n, that is, multiples of the fundamental frequency $f_n = (n+1)f$. These are the components of the Fourier series.

All musical instruments produce harmonics. This is what makes the timbre of the instrument. When we play several notes together, we perceive the octave interval as pleasant. This is, because all the harmonics of a pitch and of its octave coincide.

- harmonic pitch, well-tempered chromatic scale, flat ♭, sharp ♯, ♮, musical clef, tuning fork $f_{a'} = 440\,\mathrm{Hz}$

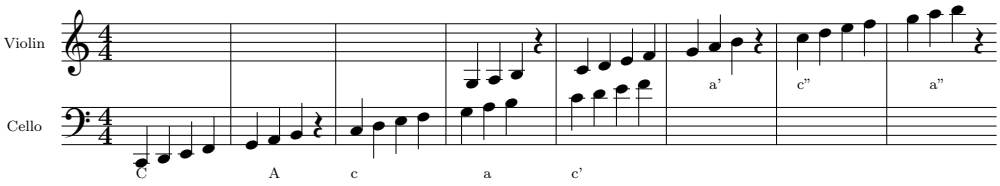

Figure 5.25: (code) Ladder of pitches over 3 octaves. Pitches can be generated in MATLAB. A sample program can be downloaded by clicking on the link.

In the *well-tempered* tonality the interval of a *octave* is divided into 12 intervals,

$$n \in [\mathrm{a}, \mathrm{a\#}, \mathrm{h}, \mathrm{c}, \mathrm{c\#}, \mathrm{d}, \mathrm{d\#}, \mathrm{e}, \mathrm{f}, \mathrm{f\#}, \mathrm{g}, \mathrm{g\#}] \ . \tag{5.137}$$

Defining *normal tuning* as,

$$f_a = 440\,\mathrm{Hz} \ , \tag{5.138}$$

the pitches correspond to the frequencies,

$$f_n = 2^{n/12} f_a \ . \tag{5.139}$$

For example, we calculate the frequency of the 'd',

$$f_d = 2^{-7/12} f_a = 391.9954\,\mathrm{Hz} \ . \tag{5.140}$$

Thus, all notes are logarithmically equidistant:

$$\mathrm{lb}\ f_{n+1} - \mathrm{lb}\ f_n = \mathrm{lb}\ (2^{(n+1)/12} f_{la}) - \mathrm{lb}\ (2^{n/12} f_{la}) = 1 \tag{5.141}$$

$$\frac{f_{n+1}}{f_n} = \frac{2^{(n+1)/12} f_{la}}{2^{n/12} f_{la}} = 2^{1/12} \ . \tag{5.142}$$

Why are there just 12 pitches? Several instruments have more than one resonator emitting sound, e.g. the violoncello has 4 strings, c, g, d', and a'. Each string is detuned by a *quint* from the next string, that is,

$$3f_c = 2f_g \qquad \text{and} \qquad 3f_g = 2f_{d'} \qquad \text{and} \qquad 3f_{d'} = 2f_{a'} \ . \tag{5.143}$$

Each string has its own series of harmonics. The timbre of the instrument appears more pleasant, when the harmonics of the various strings coincide. Let us now check, whether our definition of logarithmically equidistant pitches satisfies this condition,

$$3f_d = 3 \cdot 2^{-7/12} f_a = 2.0023 f_a \neq 2f_a \ . \tag{5.144}$$

Thus, harmonic tuning is not perfect, but quite close to the well-tempered tuning. In Exc. 5.4.6.5 we show that, nevertheless, the discrepancy is able to produce nasty beat notes.

The guitar, which is tuned in *quart*s,

$$4f_c = 3f_{fa} \ , \tag{5.145}$$

has the same problem [10],

$$4f_c = 4 \cdot 2^{-5/12} f_f = 2.9966 f_f \neq 3f_f \ . \tag{5.146}$$

Resolve the Excs. 5.4.6.6, 5.4.6.7 and 5.4.6.8.

5.4.3 Expansion of waves

Interpreting $\xi \equiv kx$ as position, we can apply the Fourier theorem (5.128) to standing waves, $Y(x) = f(kx)$, where $k = 2\pi/k$ is the wavevector.

5.4.4 Normal modes in continuous systems at the example of a string

We will now apply the Fourier expansion to calculate the normal modes of a vibrating string. Depending on which mode of oscillation is excited, the displacement of the string is given by,

$$Y_n(x,t) = (A_n \cos \omega_n t + B_n \sin \omega_n t) \sin \tfrac{\omega_n x}{c} \ , \tag{5.147}$$

where $\omega_n = n\pi c/l$ is the frequency of the *normal mode*. An arbitrary vibration can be decomposed as superpositions of these modes,

$$Y(x,t) = \sum_n Y_n(x,t) \ . \tag{5.148}$$

As an initial condition we assume that the string is at a position $Y(x,0) = Y_0(x)$ with the velocity $V(x,0) = V_0(x)$ at all points. Then,

$$Y_0(x) = \sum_n Y_n(x,0) = \sum_n A_n \sin \tfrac{\omega_n x}{c} \tag{5.149}$$

$$\text{and} \qquad V_0(x) = \sum_n \frac{d}{dt} Y_n(x,0) = \sum_n \omega_n B_n \sin \tfrac{\omega_n x}{c} \ .$$

[10] Include Matlab sound examples here!

We find the amplitudes by calculating the integrals,

$$\frac{2}{l}\int_0^l Y_0(x)\sin\tfrac{\omega_n x}{c}dx = \frac{2}{l}\sum_m A_m\int_0^l \sin\tfrac{m\pi x}{l}\sin\tfrac{n\pi x}{l}dx = A_n \tag{5.150}$$
$$\frac{2}{l}\int_0^l V_0(x)\sin\tfrac{\omega_n x}{c}dx = \frac{2}{l}\int_0^l \sum_m \omega_n B_m \sin\tfrac{m\pi x}{l}\sin\tfrac{n\pi x}{l}dx = \omega_n B_n \ .$$

We now assume that the rope is initially excited by a triangular deformation, that is, we pull the rope in its middle up to a distance d and let go. That is, the initial conditions are given by,

$$V_0(x) = 0 \qquad \text{and} \qquad \frac{\pi}{2d}Y_0(x) = \begin{cases} \frac{\pi x}{l} \\ \frac{\pi(l-x)}{l} \end{cases} \qquad \text{for} \qquad \begin{array}{l} 0 < \frac{\pi x}{l} < \frac{\pi}{2} \\ \frac{\pi}{2} < \frac{\pi x}{l} < \pi \end{array} \ . \tag{5.151}$$

We can compare this function with the triangle function Eq. (5.134) and make the same Fourier expansion as in (5.136),

$$\frac{\pi}{2d}Y_0(x) = \frac{4}{\pi}\sum_{n=1,3,\ldots}\frac{(-1)^{(n-1)/2}}{n^2}\sin\tfrac{n\pi x}{l} \ . \tag{5.152}$$

Comparing this expansion with (5.149), we find $B_n = 0$ and,

$$\sum_m A_m \sin\tfrac{\omega_m x}{c} = Y_0(x) = \frac{2d}{\pi}\frac{4}{\pi}\sum_{n=1,3,\ldots}\frac{(-1)^{(n-1)/2}}{n^2}\sin\tfrac{n\pi x}{l} \ . \tag{5.153}$$

yielding for odd coefficients $m = 1, 3, ..,$

$$A_n = \frac{8d}{n^2\pi^2}(-1)^{(n-1)/2} \ . \tag{5.154}$$

Thus, the vibration of the string is completely described by,

$$Y(x,t) = \frac{8d}{\pi^2}\sum_{n=1,3,\ldots}\frac{(-1)^{(n-1)/2}}{n^2}\cos\omega_n t\sin\tfrac{\omega_n x}{c} \ . \tag{5.155}$$

The energy is the sum of the energies of all normal modes,

$$E = \sum_{n=1,3,\ldots}\frac{m}{4}\omega_n^2 A_n^2 = \sum_{n=1,3,\ldots}\tfrac{m}{4}\left(\frac{n\pi c}{l}\right)^2\left(\frac{8d}{n^2\pi^2}\right)^2 = \sum_{n=1,3,\ldots} m\frac{16d^2c^2}{n^2\pi^2 l^2} = \frac{2md^2c^2}{l^2} \ , \tag{5.156}$$

knowing $\sum_{n=1,3,\ldots}\frac{1}{n^2} = \frac{\pi^2}{8}$.

5.4.5 Waves in crystalline lattices

The sound may propagate in a crystalline lattice, for example a metal or a crystal, by means of longitudinal or transverse vibrations. To understand the propagation of longitudinal vibrations in a monoatomic lattice, we consider the model of a chain of

N masses coupled by springs. The treatment for transverse vibrations is analogous. As we have shown in previous sections, the movement of each mass is described by the differential equation,

$$\ddot{x}_n = \omega_0^2(x_n - x_{n-1}) + \omega_0^2(x_n - x_{n+1}) \ , \tag{5.157}$$

with $n = 1, .., N$. Making the ansatz $x_n = A_n e^{-\imath\omega t}$, we obtain the characteristic equation,

$$\omega^2 A_n = \omega_0^2(A_n - A_{n-1}) + \omega_0^2(A_n - A_{n+1}) \ . \tag{5.158}$$

When we hit one of the oscillators of a linear chain, we excite a wave that propagates along the chain. Therefore, it is reasonable to guess $A_n = Ae^{\imath nka}$ for the displacements of the oscillators, where $a \equiv x_{n+1} - x_n$ is the lattice constant. We obtain,

$$\omega^2 = \omega_0^2(1 - e^{-ika}) + \omega_0^2(1 - e^{\imath ka}) = 2\omega_0^2(1 - \cos ka) = 4\omega_0^2 \sin^2 \frac{ka}{2} \ . \tag{5.159}$$

The dispersion relation is shown in Fig. 5.26. Obviously, in the limit of long waves, $ka \ll 1$, the relation can be approximated by,

$$\omega = 2\omega_0 \left| \sin \frac{ka}{2} \right| \simeq \omega_0 ka \equiv ck \ , \tag{5.160}$$

where c is the propagation velocity of the wave. This relation is linear, thus reproducing the situation of acoustic waves.

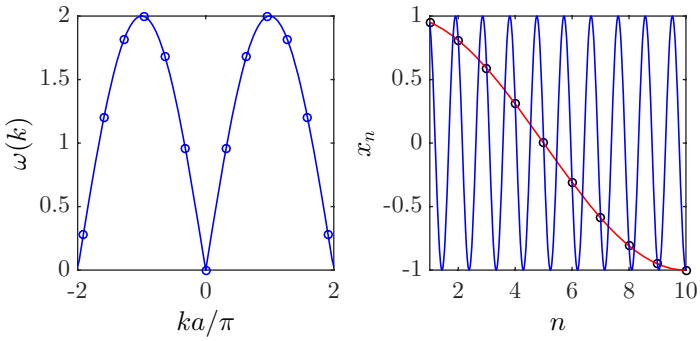

Figure 5.26: (code) Dispersion relation of a one-dimensional crystalline lattice consisting of 20 atoms.

The displacements of individual oscillators are now,

$$x_n(t) = na + Ae^{\imath nka - \imath\omega t} \ . \tag{5.161}$$

We need now to discuss, what are the possible values for k. First, since by adding 2π to the value ka we get the same result, we may concentrate on the region $-\pi < ka < \pi$, called the first *Brillouin zone*. And since the crystal is symmetric (we can reverse the

order of all oscillators), we can assume cyclic boundary conditions, $e^{\imath nka} = e^{\imath(N-n)ka}$, such that $(N-2n)ka/2\pi$ is an arbitrary integer number for any n, for example $n = 0$,

$$k = \frac{2\pi}{Na} \cdot \ell \ , \tag{5.162}$$

for $\ell \in \mathbb{N}$. To stay within the Brillouin zone, we set $\ell = -\frac{N}{2}, .., \frac{N}{2}$. That is, we have N possible values, which corresponds to just half the number of degrees of freedom.

Let us consider particular solutions. In the center of the Brillouin zone, $k = 0$ we have,

$$x_n(t) = na + Ae^{\imath\omega t} \ , \tag{5.163}$$

which corresponds to an in-phase oscillation of all oscillators. On the edge of the Brillouin zone, $k = \pm\pi/a$,

$$x_n(t) = na + A(-1)^n e^{\imath\omega t} \ , \tag{5.164}$$

which corresponds to a movement, where consecutive oscillators oscillate in anti-phase.

5.4.5.1 Waves in diatomic crystalline lattices

Many lattices are diatomic, that is, made of two species of atoms with different masses. For example, the NaCl salt crystal is a lattice alternating Na^+ and Cl^- ions. In analogy with the monoatomic lattice we establish the equations of motion,

$$\begin{aligned} \ddot{x}_n &= -\omega_x^2(x_n - y_{n-1}) - \omega_x^2(x_n - y_n) \\ \ddot{y}_n &= -\omega_y^2(y_n - x_{n+1}) - \omega_y^2(y_n - x_n) \ , \end{aligned} \tag{5.165}$$

with $\omega_{x,y} \equiv \sqrt{k/m_{x,y}}$. Inserting the ansätze $x_n = Ae^{\imath(nka-\omega t)}$ and $y_n = Be^{\imath(nka-\omega t)}$, we find the equations,

$$\begin{aligned} -\omega^2 A &= -\omega_x^2(2A - Be^{-\imath ka} - B) \\ -\omega^2 B &= -\omega_y^2(2B - Ae^{\imath ka} - A) \ , \end{aligned} \tag{5.166}$$

or,

$$\begin{pmatrix} 2\omega_x^2 - \omega^2 & -\omega_x^2(1 + e^{-ika}) \\ -\omega_y^2(1 + e^{\imath ka}) & 2\omega_y^2 - \omega^2 \end{pmatrix} \begin{pmatrix} A \\ B \end{pmatrix} = 0 \ . \tag{5.167}$$

The characteristic equation is,

$$0 = \det \hat{M} = (2\omega_x^2 - \omega^2)(2\omega_y^2 - \omega^2) - \omega_x^2(1 - e^{-\imath ka})\omega_y^2(1 - e^{\imath ka}) \ , \tag{5.168}$$

with the solution,

$$\omega^2 = \omega_x^2 + \omega_y^2 \pm \sqrt{\omega_x^4 + \omega_y^4 + 2\omega_x^2\omega_y^2 \cos ka} \ . \tag{5.169}$$

For $ka \ll 1$ we can approximate,

$$\begin{aligned} \omega^2 &\simeq \omega_x^2 + \omega_y^2 \pm \sqrt{(\omega_x^2 + \omega_y^2)^2 - \omega_x^2\omega_y^2 k^2 a^2} \\ &\simeq 2(\omega_x^2 + \omega_y^2) \quad , \quad \omega_x^2\omega_y^2 k^2 a^2 \ . \end{aligned} \tag{5.170}$$

The first eigenvalue is called the *optical branch* and the second the *acoustic branch*. The optical branch corresponds to an anti-phase motion of the atoms of the species x and y. This motion can be excited by light fields. The acoustic branch corresponds to an in-phase motion of the atoms.

In contrast, for $ka \simeq \pm\pi/a$ we obtain,

$$\omega^2 = \omega_x^2 \quad , \quad \omega_y^2 \ . \tag{5.171}$$

In these solutions either atom x oscillates while y stays at rest, or the opposite.

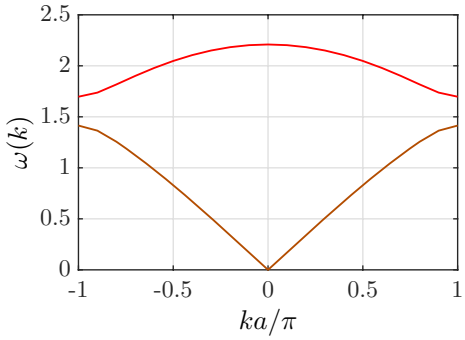

Figure 5.27: (code) Dispersion relation in a one-dimensional lattice showing in blue the optical branch and in green the acoustic branch.

5.4.6 Exercises

5.4.6.1 Ex: Fourier expansion

Expand the function $f(\xi) = \sin^3 \xi$ in a Fourier series.

Solution: *Trigonometric rules allow us to calculate,*

$$f(\xi) = \sin^3 \xi = \tfrac{3}{4} \sin \xi - \tfrac{1}{4} \sin 3\xi \ .$$

But the same result can be obtained by Fourier expansion. For symmetry reasons it is clear that $a_0 = 0 = a_n$. The coefficients,

$$b_n = \frac{1}{\sqrt{\pi}} \int_{-\pi}^{\pi} \sin^3 \xi \sin n\xi d\xi = \frac{12 \sin n\pi}{n^4 - 10n^2 + 9}$$

only do not disappear for $n = 1$ and $n = 3$. The graph on the left of the figure shows the two expansion terms separately, while the graph on the right shows the sum $f(\alpha)$.

5.4.6.2 Ex: Fourier expansion of sea waves

Surface waves on the sea are often better described by the function $f(x,t) = (kx - 2n\pi)^2$ inside the intervals $x \in [(2n-1)\pi/k, (2n+1)\pi/k]$ com $n \in \mathbb{N}$. Expands the

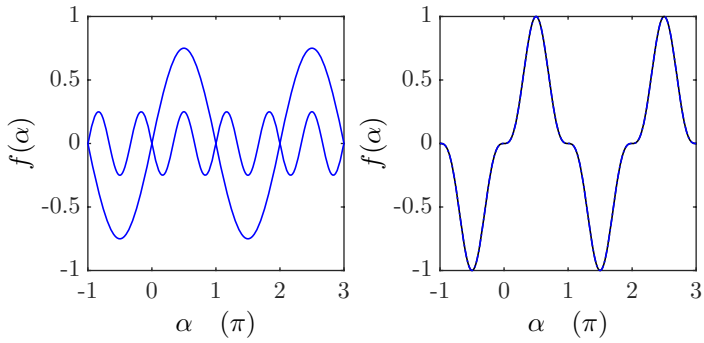

Figure 5.28: (code)

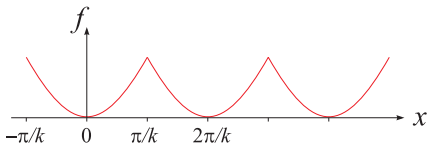

Figure 5.29: (code)

wave in a spatial Fourier series. Use the formula $\int z^2\cos(bz)dz = \frac{1}{b^3}[(b^2z^2-2)\sin bz + 2bz\cos bz]$.

Solution: *The coefficients of expansion are,*

$$a_0 = \frac{1}{\pi}\int_{-\pi}^{\pi} f(x)d(kx) = \frac{1}{\pi}\int_{-\pi}^{\pi}(kx)^2 d(kx) = \frac{u^3}{3\pi}\Big|_{-\pi}^{\pi} = \frac{2\pi^2}{3}$$

$$a_n = \frac{1}{\pi}\int_{-\pi}^{\pi} f(x)\cos nkx d(kx) = \frac{1}{\pi}\int_{-\pi}^{\pi}(kx)^2\cos nkx d(kx)$$

$$= \frac{1}{n^3}[(n^2z^2-2)\sin nz + 2nz\cos nz]\Big|_{-\pi}^{\pi} = \frac{4\cos n\pi}{n^2}$$

$$b_n = \frac{1}{\pi}\int_{-\pi}^{\pi} f(x)\sin nkx d(kx) = 0$$

$$f(x) = \frac{a_0}{2} + \sum_{n=1}^{\infty}(a_n\cos nkx + b_n\sin nkx) = \frac{\pi^2}{3} + 4\sum_{n=1}^{\infty}\frac{(-1)^n}{n^2}\cos nkx\ .$$

Note that the function can be parametrized as $f(x) = (mod(kx-\pi, 2\pi)-\pi)^2$ *for numerical treatment.*

5.4.6.3 Ex: Fourier expansion of a rectified signal

An alternating electric current can be turned into a signal of half-cycles, $f(t) = |\cos\frac{\omega t}{2}|$, by a diode rectifier bridge. Expand this signal into a temporal Fourier series. Use the formula $\int\cos(az)\cos(bz)dz = \frac{\sin[(a-b)z]}{2(a-b)} + \frac{\sin[(a+b)z]}{2(a+b)}$.

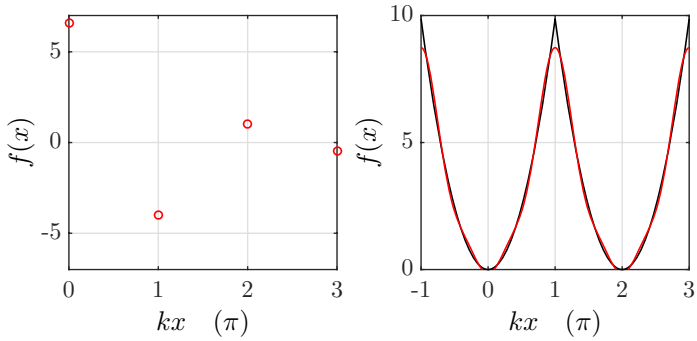

Figure 5.30: (code)

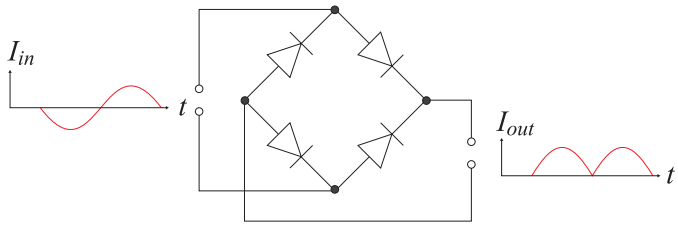

Figure 5.31: Fourier expansion of a rectified signal.

Solution: *The expansion coefficients are,*

$$a_0 = \frac{1}{\pi}\int_{-\pi}^{\pi} f(t)d(\omega t) = \frac{1}{\pi}\int_{-\pi}^{\pi} \cos\tfrac{\omega t}{2} d(\omega t) = \frac{2}{\pi}\int_{-\pi/2}^{\pi/2} \cos u du = \frac{2}{\pi}\sin u\Big|_{-\pi/2}^{\pi/2} = \frac{4}{\pi}$$

$$a_n = \frac{1}{\pi}\int_{-\pi}^{\pi} f(t)\cos\omega t d(\omega t) = \frac{1}{\pi}\int_{-\pi}^{\pi} \cos\tfrac{\omega t}{2}\cos nkt d(\omega t) = \frac{1}{\pi}\int_{-\pi}^{\pi} \cos\tfrac{z}{2}\cos nz dz = -\frac{4}{\pi}\frac{\cos\pi n}{4n^2-1}$$

$$b_n = \frac{1}{\pi}\int_{-\pi}^{\pi} f(t)\sin n\omega t d(\omega t) = 0$$

$$f(x) = \frac{a_0}{2} + \sum_{n=1}^{\infty}(a_n\cos n\omega t + b_n \sin n\omega t) = \frac{2}{\pi} + \frac{4}{\pi}\sum_{n=1}^{\infty}\frac{(-1)^n}{4n^2-1}\cos n\omega t\ .$$

The graph on the left of the figure shows Fourier components, while the graph on the right shows the original function $f(t)$ as well as the expanded function up to third order.

5.4.6.4 Ex: Action of a low pass filter on a spectrum

One method of creating a sinusoidal signal in electronics consist in first creating a rectangular signal via a switching circuit and then pass this signal through a low-pass filter by cutting off the harmonics. Simulate this procedure using the Fourier transform method starting from the rectangular signal $S(t) = \sin\omega t/|\sin\omega t|$ with

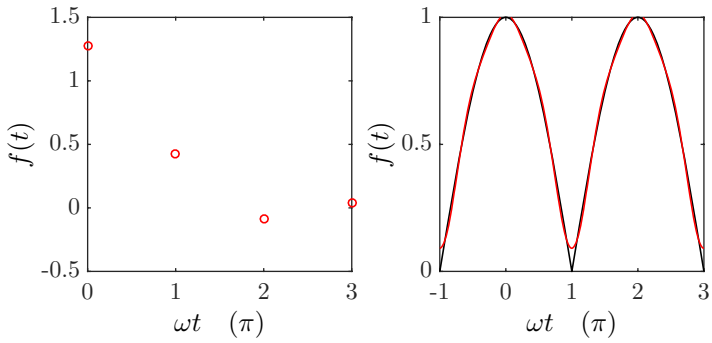

Figure 5.32: (code)

$\omega/2\pi = 1\,\mathrm{kHz}$ and using a low pass filter, such as $F(\omega) = 1/\left(1+(\omega/\omega_g)^2\right)$, where the cut-off frequency is, $\omega_g/2\pi = 1\,\mathrm{kHz}$. Evaluate the harmonic distortion of the rectangular signal and the filtered signal.

Solution: *For the function $S(t)$ we calculate the coefficients,*

$$a_0 = \frac{\omega}{\pi}\int_0^{2\pi/\omega} \frac{\sin\omega t}{|\sin\omega t|}dt = 0 \quad , \quad a_n = \frac{\omega}{\pi}\int_0^{2\pi/\omega} \frac{\sin\omega t}{|\sin\omega t|}\cos n\omega t dt = 0 \quad ,$$

$$b_n = \frac{\omega}{\pi}\int_0^{2\pi/\omega} \frac{\sin\omega t}{|\sin\omega t|}\sin n\omega t dt = \frac{2}{\pi}\int_0^{\pi}\sin n\alpha d\alpha = -\frac{2}{\pi}\frac{\cos\pi n - 1}{n} = \frac{2}{n\pi}[1-(-1)^n] \ ,$$

with the consequence,

$$S(t) = \frac{2}{\pi}\sum_{n=1,3,\ldots}\frac{\sin n\omega t}{n} \ .$$

Graph (a) shows the amplitudes b_n and graph (b) the approximation by the Fourier series to orders 1, 2, and 20 (red). Attenuating the amplitudes as,

$$\tilde{b}_n = \frac{b_n}{1+(n\omega/\omega_g)^2} \ ,$$

we have,

$$S(t) = \frac{2}{\pi}\sum_{n=1,3,\ldots}\frac{1}{n}\frac{\sin n\omega t}{1+(n\omega/\omega_g)^2} \ .$$

Graph (c) shows the amplitudes attenuated by the filter $\tilde{b}_n$ and graph (d) the Fourier series approximation to orders 1, 2 and 20 (red). Obviously, the filtered signal is almost sinusoidal. A higher order filter can improve the result. Calculating the harmonic distortion of the numerically filtered rectangular signal gives $k \approx 0.1466$. For a second order filter of type $1/\left(1+(\omega/\omega_g)^4\right)$, we obtain $k \approx 0.0018$.

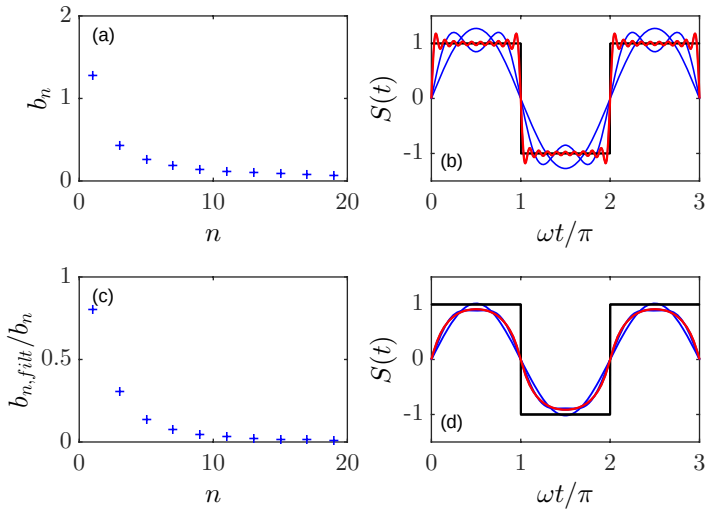

Figure 5.33: (code)

5.4.6.5 Ex: Tuning a violin

What would be the beat frequency between the pitches $3f_{c'}$ and $2f_{g'}$ if the strings were tuned logarithmically equidistant.

Solution: *It would be,*

$$\begin{aligned}\Delta f \equiv 3f_c - 2f_g &= 3\cdot 2^{-9/12} f_a - 2\cdot 2^{-2/12} f_a \\ &= (3\cdot 2^{-9/12} - 2\cdot 2^{-2/12}) f_a = 0.002\ f_a = 0.8858\,\text{Hz}\ ,\end{aligned}$$

which is enough to be nasty.

5.4.6.6 Ex: String instruments

Imagine a string instrument with 12 strings tuned in quints. How far would be the highest string from a harmonic of the lowest one.

Solution: *We find* $2^7 - (3/2)^1 2 \simeq 1.7\,\text{Hz}$.

5.4.6.7 Ex: String instruments

Prepare a list comparing the harmonics up to ninth order in the harmonic and in the tempered scale.

Solution: *The comparison is listed in the following table:*

harmonic scale f_n	*tempered scale* $\tilde{f}_n$	$(f_n - \tilde{f}_n)/f_n$
$1f = 2^0 \cdot f$		0
$2f = 2^1 \cdot 2f$		0
$3f = 2^1 \cdot \frac{3}{2}f$	$\simeq 2^1 \cdot 2^{7/12} \cdot f = 2.9966f$	0.11%
$4f = 2^2 \cdot f$		0
$5f = 2^2 \cdot \frac{5}{4}f$	$\simeq 2^2 \cdot 2^{4/12} \cdot f = 5.0397f$	−0.79%
$6f = 2^2 \cdot \frac{3}{2}f$	$\simeq 2^2 \cdot 2^{7/12} \cdot f = 5.9932f$	0.11%
$7f = 2^2 \cdot \frac{7}{4}f$	$\simeq 2^2 \cdot 2^{10/12} \cdot f = 7.1272f$	−1.82%
$8f = 2^3 \cdot f$		0
$9f = 2^3 \cdot \frac{9}{8}f$	$\simeq 2^3 \cdot 2^{2/12} \cdot f = 8.9797f$	0.23%

5.4.6.8 Ex: Frequency beating of sound waves

To tune a violin a musician first tunes the a-string ('la') at $f_a = 440\,\text{Hz}$ and then plays two neighboring strings, paying attention to the frequency beats. When playing the a- and the e-string ('mi'), the violinist hears a beat frequency of 3 Hz, and he notes that this frequency increases as the tension of the e-string increases. (The e-string is tuned to $f_e = 660\,\text{Hz}$.)
a. Why is there a beat when the two strings are played simultaneously?
b. What is the vibration frequency of the e-string when the beat frequency it generates together with the a-string is 3 Hz?
c. If the tension on the e-string is 80 N for a beat frequency of 3 Hz, what tension corresponds to a perfect tuning of the string?

Solution:

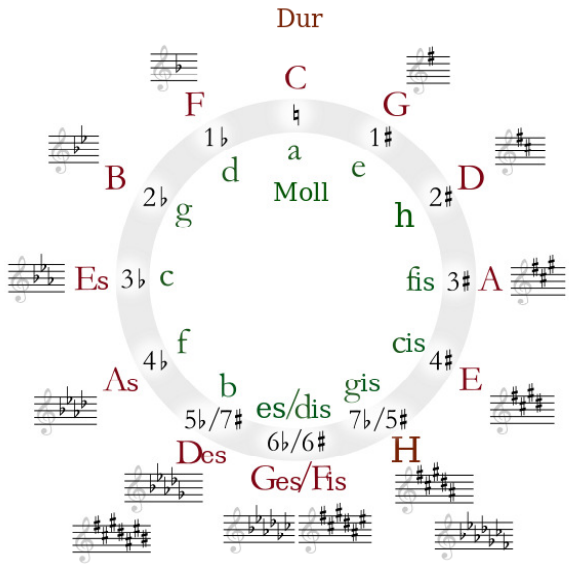

Figure 5.34: Circulo de quintas.

5.4.6.9 Ex: Frequency beating of sound waves

A violinist tries to tune the strings of his instrument.
a. Comparing the a-string ('la') to a tuning fork ($\nu_{dia} = 440\,\text{Hz}$), he hears a beat with the frequency 1 Hz. By increasing the tension on the rope, the beat frequency increases. What was the frequency of the 'a'-string before the tension increased?
b. After having adjusted the a-string the violinist wants to tune the d-string ('re'). He realizes that the second harmonic $3\nu_d$ produces with the first harmonic of the a-string ($2\nu_a$) a beat of 1 Hz. Decreasing the tension of the d-string the beat disappears. What was the initial frequency of the d-string and by what percentage does the violinist need to decrease the tension of the string?

Solution: *a. The beat frequency is,*

$$\tfrac{1}{2}(\nu_{frk} - \nu_a) = \pm 1\,\text{Hz} \ .$$

Since $\nu_a \propto \sqrt{F_T}$ and noting that, by increasing the voltage, an increase in the beat frequency is observed, we conclude $\nu_a > \nu_{frk}$. Hence, $\nu_a = 402\,\text{Hz}$.
b. We know

$$\tfrac{1}{2}(3\nu_d - 2\nu_a) = \pm 1\,\text{Hz} \ .$$

Since by decreasing the tension (and therefore the frequency) of the d-string the harmonic frequencies coincide, we deduce,

$$\nu_d = \tfrac{2}{3}\nu_a + \tfrac{2}{3}\,\text{Hz} = 294\,\text{Hz} \ .$$

After tuning we have $\nu'_d = \frac{2}{3}\nu_a = 293.3\,\text{Hz}$. Hence,

$$\frac{F_T/\mu}{F'_T/\mu} = \left(\frac{\nu_d}{\nu'_d}\right)^2 = \left(\frac{293.3}{294}\right)^2 = 99.6\% \ .$$

5.4.6.10 Ex: Normal modes on a string

A stretched wire of mass m, length L, and tension T is triggered by two sources, one at each end. Both sources have the same frequency ν and amplitude A, but are out of phase by exactly 180° with respect to each other. (At each end there is an anti-node.) What is the lowest possible value of ω consistent with the stationary vibrations of the wire?

Solution: *It is $\lambda = 2L$ and hence,*

$$\omega = 2\pi\frac{c}{\lambda} = 2\pi\frac{\sqrt{T/\mu}}{2L} = 2\pi\frac{\sqrt{TL/m}}{2L} = \pi\sqrt{\frac{T}{Lm}} \ .$$

5.4.6.11 Ex: Normal modes on a string

a. Find the total vibration energy of a wire of length L fixed at both ends and oscillating in its n-th characteristic mode with amplitude A. The tension on the wire is T, and its total mass is M. (**Suggestion:** Consider the integrated kinetic energy at the instant when the wire is straight.)
b. Calculate the total vibration energy of the same wire vibrating in the following superposition of normal modes:

$$Y(x,t) = A_1 \sin \tfrac{\pi x}{L} \cos \omega_1 t + A_3 \sin \tfrac{3\pi x}{L} \cos(\omega_3 t - \tfrac{\pi}{4}) \ .$$

You should be able to verify that it is the sum of the energies of the two modes taken separately.

Solution: *a. The function describing the n-th mode can be written as,*

$$Y(x,t) = \sin \frac{n\pi x}{L} \cos \omega_n t \ .$$

The kinetic energy of each mass element of the wire is,

$$\frac{d}{dt} Y(x,t) = -A_1 \omega_n \sin \frac{n\pi x}{L} \sin \omega_n t \ .$$

At the moments when the rope is stretched, $\omega_n t = \pi/2 + N\pi$, the energy is,

$$\frac{d}{dt} Y(x,t) = -A_1 \omega_n \sin \frac{n\pi x}{L} \ .$$

The spatial integral gives the total energy,

$$E = \int_0^L \frac{m/L}{2} \left(\frac{d}{dt} Y(x,t) \right)^2 dx = A_1^2 \omega_1^2 \frac{m}{2L} \frac{L}{n\pi} \int_0^{n\pi} \sin^2 \xi d\xi = A_1^2 \omega_1^2 \frac{m}{2L} \frac{n\pi}{2} = A_1^2 \frac{m\omega_n^2}{4} \ .$$

With

$$\omega_n = 2\pi \frac{c}{\lambda_n} = 2\pi \frac{\sqrt{T/(m/L)}}{2L/n} = \pi \sqrt{\frac{Tn^2}{mL}} \ ,$$

we have,

$$E = \frac{A_1^2 n^2 \pi^2 T}{4L} \ .$$

b. We consider the stationary wave at time, $t = 0$. At this instant, ...

5.4.6.12 Ex: Normal modes on a string

A wire of length L is attached at both ends under a tension T. The wire is pulled sideways by a distance h from its center, such that the rope adopts a triangular shape, and the it is released.
a. What is the energy of the subsequent oscillations. **Suggestion**: Consider the work that needs to be done against the tension to give the wire its initial deformation, and suppose that the tension remains unchanged upon a slight increase of its length

caused by transverse the displacements.
b. How many times will the triangular shape reappear?

Solution: *a. The work is,*

$$W = \int_0^h F dh' = 2\int_0^h T\sin\alpha dh' = 2T\int_0^h \frac{h'dh'}{\sqrt{h'^2+(L/2)^2}} = LT\int_0^{2h/L} \frac{zdz}{\sqrt{z^2+1}}$$
$$= LT\left(\sqrt{1+\left(\frac{2h}{L}\right)^2}-1\right) \simeq \frac{2h^2T}{L} \ .$$

b. Periodicity is given by the fundamental vibration.

5.4.6.13 Ex: Waves on a rope

A string with linear mass density μ is attached at two points distant from each other by $L = 1\,\text{m}$. A mass $m = 1\,\text{kg}$ is now attached to one end of the rope that goes through a pulley, as shown in the figure. Excited by a vibrating pin with frequency $f = 1\,\text{kHz}$ the string performs transverse vibrations with wavelength $\lambda = 2L$.
a. Calculate the propagation velocity of the wave.
b. At what frequency should the pin excite the rope to observe the third oscillation mode (three anti-nodes)?
c. Now the mass is doubled. Calculate the new speed of sound.
d. How should the mass be chosen to obtain a fundamental mode frequency equal to the frequency of the third mode calculated in (b)?

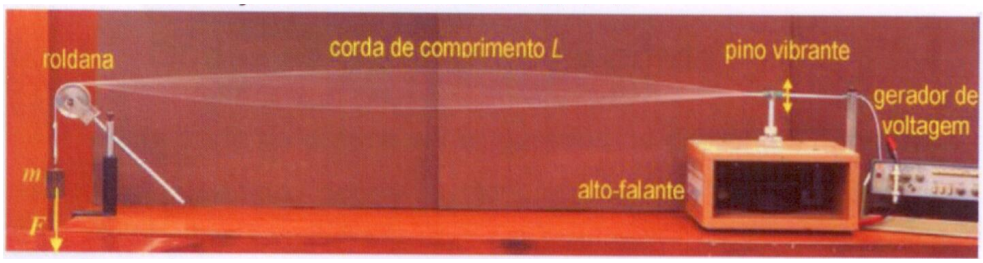

Figure 5.35: Waves on a rope.

Solution: *a. We have,*

$$v = \lambda_n f_n = \frac{2L}{n} f_n \ .$$

Hence, $v_1 = 2Lf_1 = 2\,\text{km/s}$.
b. To calculate the frequency, we let,

$$v' = \lambda_3 f_3 = \frac{2L}{3} f_3 \ .$$

Hence, $f_3 = \frac{3v_1'}{2L} = 3\,\mathrm{kHz}$.
c. We have,

$$v' = \sqrt{\frac{m'g}{\mu}} = \sqrt{2}\sqrt{\frac{mg}{\mu}} = \sqrt{2}v \ .$$

Hence, $v_1' = 2.82\,\mathrm{km/s}$.
d. We have,

$$3 = \frac{v'}{v} = \sqrt{\frac{m'g}{\mu}\frac{\mu}{mg}} = \sqrt{\frac{m'}{m}} \ .$$

Hence, $m' = 9m \approx 9\,\mathrm{kg}$.

5.5 Matter waves

Quantum mechanics tells us that light sometimes behaves like particles and matter like waves. Letting us guide by this analogy we will, in the following, guess the fundamental equations of motion for the propagation of matter waves from a comparison of the respective dispersion relations of light and massive particles.

5.5.1 Dispersion relation and Schrödinger's equation

On one hand, the propagation light is (in the vacuum) is described by the dispersion relation $\omega = ck$ or,

$$\omega^2 - c^2k^2 = 0 \ . \tag{5.172}$$

Since light is a wave it can, in the most general form, be described by a wavepacket, $A(\mathbf{r},t) = \int e^{\imath(\mathbf{k}\cdot\mathbf{r}-\omega t)}a(\mathbf{k})d^3k$. It is easy to verify that the *wave equation*,

$$\frac{\partial^2}{\partial t^2}A - c^2\nabla^2 A = 0 \ , \tag{5.173}$$

reproduces the dispersion relation.

On the other hand, slow massive particles possess the kinetic energy,

$$E = \frac{p^2}{2m} \ . \tag{5.174}$$

With de Broglie's hypothesis that even a massive particle has wavelength, we can try an *ansatz* [11] for a wave equation satisfying the dispersion relation (5.174). From Planck's formula, $E = \hbar\omega$, and the formula of *Louis de Broglie*, $\mathbf{p} = \hbar\mathbf{k}$, describing the particle by a wavepacket not being subject to external forces $\psi(\mathbf{r},t) = \int e^{\imath(\mathbf{k}\cdot\mathbf{r}-\omega t)}\phi(\mathbf{k})d^3k$, it is easy to verify that the differential equation,

$$\imath\hbar\frac{\partial}{\partial t}\psi = \left(-\frac{\hbar^2}{2m}\nabla^2\right)\psi \ , \tag{5.175}$$

[11] Kick, work hypothesis, guess.

reproduces the dispersion relation. If the particle is subject to a potential, its total energy is $E = \mathbf{p}^2/2m + V(\mathbf{r}, t)$. This dispersion relation corresponds to the famous *Schrödinger equation*,

$$\imath\hbar\frac{\partial}{\partial t}\psi = \left(-\frac{\hbar^2}{2m}\Delta + V(r,t)\right)\psi \ . \tag{5.176}$$

Since we accept that light particles and lenses behave like a wave, to calculate their trajectories, we must determine the potential landscape $V(\mathbf{r})$ in which this particle moves before solving the Schrödinger equation. This is the role of *wave mechanics*, which is one of the formulations of quantum mechanics.

5.5.1.1 Scalar waves and vectorial waves

The electromagnetic field is a *vector field*, since $\vec{\mathcal{E}}(\mathbf{r}, t)$ and $\vec{\mathcal{B}}(\mathbf{r}, t)$ are vectors. Therefore, it has a polarization. In contrast, the field of matter $\psi(\mathbf{r}, t)$ is a *scalar field* and therefore does not have the degree of freedom of polarization, in analogy with sound. This has important consequences, for example, the fact that two collinear light fields with orthogonal polarizations do not interfere has no analogue with matter wave fields.

5.5.2 Matter waves

Broglie's formula assigns a wave to each body, The wavelength decreases as the velocity of the particle grows. The necessity to describe a massive particle as a matter wave depends on the relationship between its Broglie wavelength and other characteristic quantities of the system under consideration. If the wavelength is large, we expect typical interference phenomena for waves; if the wavelength is small, the particle will behave like a mass, which is perfectly localized in space and incapable of interfering.

Characteristic features of the system may be, for example, the presence of a narrow slit diffracting the Broglie wave of an atom or an electron passing through it. Another characteristic feature is the average distance between several atoms. In fact, when an atomic gas is so cold, that is, composed of atoms so slow, that the Broglie wavelength of the atoms is longer than the average distance, then the atoms interfere with each other. In the case of bosonic atoms, the interference will be constructive, resulting in a matter wave of gigantic amplitude. This phenomenon is called Bose-Einstein condensation [12].

Before calculating the temperature required for this phenomenon to happen, we need to inform the reader, that the interatomic distance can not be compressed arbitrarily, because below distances of typically $\bar{d} = 1\ \mu$m, the gas tends to form molecules. For the Broglie waves of different atoms to interfere, the wavelength must be longer. The average velocity of the atoms in a gas of temperature T is given by,

$$\frac{m}{2}\bar{v}^2 = \frac{k_B}{2}T \ .$$

Therefore, the temperature of the gas must be,

$$T = \frac{m\bar{v}^2}{k_B} = \frac{\bar{p}^2}{k_B m} = \frac{\hbar^2\bar{k}^2}{k_B m} = \frac{4\pi^2\hbar^2}{k_B m\lambda_{dB}^2} < \frac{h^2}{k_B m d^2} \ .$$

[12] See script on *Quantum mechanics* (2023).

For rubidium atoms of mass $m = 87u$ we calculate $T < 200\,\text{nm}$.

The development of powerful experimental techniques allowed in 1995 the cooling of rubidium gases down to such low temperatures and the experimental realization of Bose-Einstein condensates, that is, matter waves made up of 10^6 atoms. See Exc. 5.5.3.1.

5.5.3 Exercises

5.5.3.1 Ex: Interference in Bose-Einstein condensates

Calculate the periodicity of the interference pattern of two Bose-Einstein condensates supposed to have intrinsic temperatures $T = 0$ interpenetrating at a relative velocity $v = 1\,\text{mm/s}$.

Solution: *The periodicity is* $d = \frac{\lambda_{dB}}{2} = \frac{2\pi}{2k} = \frac{2\pi\hbar}{2mv} = 2.3\,\mu\text{m}$.

Chapter 6

Gravitation

6.1 Planetary orbits

6.1.1 Kopernicus' laws

Nicolaus Copernicus published in 1543 his book *De revolutionibus orbium coelestium* in which he states:

1. The planetary orbit is a circle with epicycles.
2. The Sun is approximately at the center of the orbit.
3. The speed of the planet in the main orbit is constant.

Despite being correct in saying that the planets revolved around the Sun, Copernicus was incorrect in defining their orbits. It was Kepler who correctly defined the orbit of planets as follows:

1. The planetary orbit is not a circle with epicycles, but an ellipse.
2. The Sun is not at the center but at a focal point of the elliptical orbit.
3. Neither the linear speed nor the angular speed of the planet in the orbit is constant, but the area speed is constant.

6.1.2 Kepler's laws

Kepler's laws of planetary motion, published by *Johannes Kepler* between 1609 and 1619, describe the orbits of planets around the Sun:

1. The orbit of a planet is an ellipse with the Sun at one of the two foci.
2. A line segment joining a planet and the Sun sweeps out equal areas during equal intervals of time.
3. The square of a planet's orbital period is proportional to the cube of the length of the semi-major axis of its orbit.

The elliptical orbits of planets were indicated by calculations of the orbit of Mars. From this, Kepler inferred that other bodies in the Solar System, including those farther away from the Sun, also have elliptical orbits. The second law helps to establish

that when a planet is closer to the Sun, it travels faster. The third law expresses that the farther a planet is from the Sun, the slower its orbital speed, and vice versa. *Isaac Newton* showed in 1687 that relationships like Kepler's would apply in the Solar System as a consequence of his own laws of motion and law of universal gravitation. Do the Excs. 6.1.3.1, 6.1.3.2, and 6.1.3.3.

The eccentricity of the orbit of the Earth makes the time from the March equinox to the September equinox, around 186 days, unequal to the time from the September equinox to the March equinox, around 179 days. A diameter would cut the orbit into equal parts, but the plane through the Sun parallel to the equator of the Earth cuts the orbit into two parts with areas in a 186 to 179 ratio, so the eccentricity of the orbit of the Earth is approximately,

$$e \approx \frac{\pi}{4}\frac{186-179}{186+179} \approx 0.015 \ , \tag{6.1}$$

which is close to the correct value (0.016710218). The accuracy of this calculation requires that the two dates chosen be along the elliptical orbit's minor axis and that the midpoints of each half be along the major axis. As the two dates chosen here are equinoxes, this will be correct when perihelion, the date the Earth is closest to the Sun, falls on a solstice. The current perihelion, near January 4, is fairly close to the solstice of December 21 or 22.

6.1.3 Exercises

6.1.3.1 Ex: Kepler orbits

The moon moves in a good approximation on a circular path with radius $R = 384000\,\mathrm{km}$ around the Earth. Assume that the Earth's mass would suddenly decrease.
a. How much would the mass have to decrease so that the moon could escape the Earth?
b. How would the moon's orbit change if the mass decreased by a factor of 3, 2 or 1.5?

Solution: *a. The total energy of the moon rotation is negative,*

$$E = E_{kin} + E_{pot} = \frac{m_{☾}}{2}v_0^2 - \frac{\gamma_N M_{♁} m_{☾}}{r_0} = -\frac{m_{☾}}{2}v_0^2 = -\frac{\gamma_N M_{♁} m_{☾}}{2r_0} \ .$$

After the loss of mass, the Earth has the mass $\tilde{M}_{♁}$ and the moon has the energy,

$$\tilde{E} = \frac{m_{☾}}{2}v_0^2 - \frac{\gamma_N \tilde{M}_{♁} m_{☾}}{r_0} = \frac{\gamma_N (M_{♁}/2 - \tilde{M}_{♁}) m_{☾}}{r_0} \ .$$

In order to escape from Earth, the total energy must be positive. I.e. the mass of the Earth must be reduced to less than half, $M_{♁} > 2\tilde{M}_{♁}$.
b. The path of the moon is described by a conic section,

$$r = \frac{P}{1-\varepsilon\cos\phi} \quad \textit{and} \quad P = \frac{L^2}{\alpha m_{☾}} \quad \textit{and} \quad \varepsilon = \frac{C}{\alpha m} = \sqrt{1 + \frac{2L^2}{\alpha^2 m}(E_{kin}+E_{pot})} \ ,$$

where $\alpha = \gamma_N M_{\sun} m_{\moon}$ and the angular momentum of the moon is $L = m_{\moon}\,\omega r_0^2$. The half parameter and the eccentricity are,

$$P = \frac{\omega^2 r_0^4}{\gamma_N M_{\sun}} = r_0$$
$$\varepsilon = \sqrt{1 + \frac{2L^2}{\alpha^2 m_{\moon}}(E_{kin} + E_{pot})} = \sqrt{1 + \frac{2r_0}{\gamma_N M_{\sun} m_{\moon}}\left(-\frac{\gamma_N M_{\sun} m_{\moon}}{2r_0}\right)} = 0\ .$$

I.e. the moon initially describes a circular orbit. After the mass reduction, the total energy changes,

$$\varepsilon = \sqrt{1 + \frac{2r_0}{\gamma_N M_{\sun} m_{\moon}}\left(\frac{\gamma_N (M_{\sun}/2 - \tilde{M}_{\sun}) m_{\moon}}{r_0}\right)} = \sqrt{2 - \frac{2\tilde{M}_{\sun}}{M_{\sun}}}\ .$$

The eccentricity becomes $\varepsilon = 1$ if the reduced mass is $\tilde{M}_{\sun} = M_{\sun}/2$. The lunar orbit then becomes a parabola. The eccentricity becomes $\varepsilon > 1$ if the mass reduction is larger. The lunar orbit then becomes the hyperbola.

6.1.3.2 Ex: Kepler orbits of missiles

Consider an object of mass $m \ll M_{\earth}$ which is launched at an initial velocity $\mathbf{v}_0$ (at an angle θ relative to the Earth's surface). We neglects any friction.
a. What possible trajectories can the object move on? How does the type of trajectory depend on the conservation parameters?
b. Calculate the maximum speed that the object may have to move on a closed trajectory. Does this speed depend on θ? Does the projectile always fall back to Earth when the path is closed?
c. Neglecting the Earth's rotation calculate the flight distance of the projectile above the Earth's surface for velocities below the above-mentioned limit velocity.
Help: Set the center of the Earth in the focal point of the Kepler orbit.

Solution: *a. The projectile can move on ellipses, parabolas or hyperbolas, depending on the initial velocity. The equation of motion is that of a conic section,*

$$r = \frac{P}{1 - \epsilon\cos\phi}\ ,$$

where $\epsilon = \sqrt{1 + \frac{2l^2}{\alpha^2 m}E}$. The conservation parameters are the total energy $E = \frac{m}{2}v^2 - \frac{\alpha}{r}$ and the angular momentum l. For the projectile to move on a closed path, the eccentricity must be $\epsilon < 1$, i.e. $mv^2/2 < \alpha/r$. Otherwise it moves on hyperbolas or a parabola.
b. The escape speed is when $R_{\earth} = 6370\,\mathrm{km}$ is the Earth's radius and $M_{\earth} = 6\times10^{24}\,\mathrm{kg}$ its mass,

$$v_f = \sqrt{\frac{2\alpha}{mR_{\earth}}} = \sqrt{\frac{2\gamma_N M_{\earth}}{R_{\earth}}} \approx 11.2\,\mathrm{km/s}\ .$$

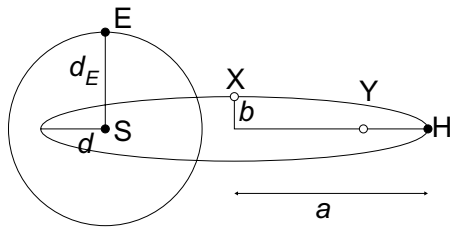
It does not depend on the launch angle θ.
c. According to the sketch, $\theta = 90° - \phi$. Hence, the length of the geodesic $L = \frac{\phi}{2\pi} 2\pi R_{\oplus} = (90° - \theta) R_{\oplus}$.

6.1.3.3 Ex: Halley's Comet

The comet Haley moves like a planet on an elliptical orbit around the sun. Its orbital period is 75 years and the closest distance to the sun is 0.5 AE. (One astronomical unit is the distance from the Earth to the sun, assuming that the orbit of the Earth around the sun is a circular orbit.)
a. Use this information to calculate the value for the major semi-axis a and the minor semi-axis b of the comet's orbit in astronomical units. Use this to determine the eccentricity ε of the orbit.
b. What is the maximum distance of the comet from the sun?
c. Calculate the minimum and maximum speed of the comet on its orbit.

Solution:
We have $T = 75\,\mathrm{a}$, $T_{\oplus} = 1\,\mathrm{a}$, $d = 0.5\,\mathrm{AE}$ and $d_E = 1\,\mathrm{AE} = a_E$.
a. According to Kepler's 3rd law,

$$\frac{T^2}{a^3} = \frac{T_{\oplus}^2}{a_E^3} = \frac{(1\,\mathrm{a})^2}{(1\,\mathrm{AE})^3} = const\ .$$



From this follows

$$a = \sqrt[3]{\frac{(1\,\mathrm{AE})^3}{(1\,\mathrm{a})^2}(75\,\mathrm{a})^2} \simeq 17.78\,\mathrm{AE}\ .$$

From the ellipse construction follows,

$$\begin{aligned} \bar{SX} + \bar{XY} = 2\bar{SX} &= 2a \\ \Rightarrow \bar{SX} &= a = \sqrt{b^2 + (a-d)^2} \\ \Rightarrow b &= \sqrt{a^2 - (a-d)^2} = \sqrt{2ad - d^2} \simeq 4.19\,\mathrm{AE}\ . \end{aligned}$$

b. The maximum distance is at the far end of the major semi-axis,

$$r_{\max} = 2a - d = 35.06\,\mathrm{AE}\ .$$

c. The change in the swept area is,

$$\frac{dA}{dt} = \frac{1}{2}\left|\mathbf{r} \times \frac{d\mathbf{r}}{dt}\right| = \frac{1}{2}|\mathbf{r} \times \mathbf{r}| = \frac{|\mathbf{l}|}{2m} = \frac{A_{ges}}{T} = \frac{\pi ab}{T} = const\ .$$

Since we have at the locations of maximum and minimum distance, or minimum and maximum speed $\mathbf{r} \perp \mathbf{v}$,

$$\frac{dA}{dt} = \frac{1}{2} rv = \frac{\pi ab}{T} = const\ .$$

From which follows,

$$v_{\min} = \frac{2\pi ab}{T r_{\max}} \simeq 0.178 \ \text{AE/a} \qquad \textit{and} \qquad v_{\max} = \frac{2\pi ab}{T r_{\min}} \simeq 12.48 \ \text{AE/a} \ .$$

6.2 Newton's law

Newton's law of *gravity* about the force between two massive bodies,

$$\mathbf{F} = -\nabla V(r) \ . \tag{6.2}$$

can be deduced from a conservative central potential,

$$\boxed{V(r) = \frac{\gamma_N M m}{r}} \ . \tag{6.3}$$

If $M = M_{♁}$ is the mass of the Earth, a test mass m close to the surface ($r_{♁} \approx 6378\,\text{km}$) will be accelerated by,

$$g = \frac{F}{m} = -\frac{\partial}{\partial r}\frac{\gamma_N M_{♁}}{r}\bigg|_{r=R_{♁}} = \frac{\gamma_N M_{♁}}{R_{♁}^2} = 9.81\,\text{m/s}^2 \ . \tag{6.4}$$

with Newton's constant,

$$\boxed{\gamma_N = 6.67 \cdot 10^{-11}\,\text{m}^3/\text{kg s}^2} \ . \tag{6.5}$$

6.2.1 Cosmic velocities

6.2.1.1 First cosmic velocity

The first *cosmic velocity* is defined as the velocity that a body must have in order to circle the center of the Earth on an orbit with the Earth's radius. We calculate this velocity from the condition that the centripetal force be equal to the centrifugal force,

$$\frac{m v_1^2}{r_{♁}} = \gamma_N \frac{m M_{♁}}{r_{♁}^2} \qquad \Rightarrow \qquad v_1 = \sqrt{\frac{\gamma_N M_{♁}}{r_{♁}}} \ , \tag{6.6}$$

yielding $v_1 \approx 7.91\,\text{km/s} = 2.84 \cdot 10^4\,\text{km/h}$. In Exc. 6.2.3.1 we estimate the mass of the milky way galaxy from the velocity of the sun and its distance from the galaxy's center. In Exc. 6.2.3.2 we compare the heights of stationary orbits around the Earth and the moon.

Example 23 (*Angular velocity of a satellite*): Here, we calculate the velocity of a satellite on a circular orbit at a height of 400 km above the Earth's surface,

$$v_1 = \sqrt{\frac{\gamma_N M_{♁}}{r_{♁} + h}} \ ,$$

yielding $v_1 \approx 7.66\,\text{km/s} = 2.76 \cdot 10^4\,\text{km/h}$.

6.2.1.2 Escape velocity

The *escape velocity* or second cosmic velocity is the velocity that a body must have to be able to leave the Earth's gravity field completely. We calculate the second cosmic speed for the Earth from,

$$E_{kin} = \frac{m}{2}v_2^2 = \text{final} - \text{initial energy in the limit final energy } \to 0 \ . \tag{6.7}$$

Hence,

$$E_{kin} = 0 - \left(-\gamma_N \frac{mM_{\text{♁}}}{r_{\text{♁}}}\right) \qquad \Rightarrow \qquad v_2 = \sqrt{\frac{2\gamma_N M_{\text{♁}}}{r_{\text{♁}}}} = v_1\sqrt{2} \ , \tag{6.8}$$

yielding $v_2 \approx 11.2\,\text{km/s} = 4.03 \cdot 10^4\,\text{km/h}$. Apparently, the cosmic velocities v_1 and v_2 are related. In Exc. 6.2.3.3 and 6.2.3.4 we calculate cosmic velocities for, respectively, Earth and the comet Tschurjumow-Gerasimenko.

> **Example 24 (*Escape velocity for a satellite*):** The escape velocity for a satellite that is in a 400 km high orbit above the Earth's surface is $v_2 \approx 10.83\,\text{km/s} = 3.90 \cdot 10^4\,\text{km/h}$.

6.2.2 Deriving Kepler's laws from Newton's laws

6.2.2.1 Kepler's first law

The orbits are ellipses, with focal points F1 and F2 for the first planet and F1 and F3 for the second planet. The Sun is placed at focal point F1. The two shaded sectors A1 and A2 have the same surface area and the time for planet 1 to cover segment A1 is equal to the time to cover segment A2. The total orbit times for planet 1 and planet 2 have a ratio $(a_1/a_2)^{3/2}$.

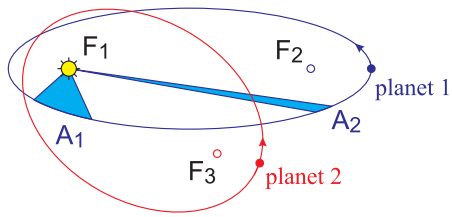


Figure 6.1: Illustration of Kepler's three laws with two planetary orbits.

6.2.2.2 Kepler's second law

The area swept by the planet's trajectory in infinitesimal time steps is,

$$A(t, t+dt) = \tfrac{1}{2}|\mathbf{r}(t) \times \dot{\mathbf{r}}(t)|dt = \tfrac{L}{2m}dt \ .$$

Since central potentials preserve angular momentum,

$$\dot{\mathbf{L}} = \frac{d}{dt}m\mathbf{r} \times \mathbf{p} = m(\dot{\mathbf{r}} \times \dot{\mathbf{r}} + \mathbf{r} \times \ddot{\mathbf{r}}) = m\mathbf{r} \times \ddot{\mathbf{r}} = -\mathbf{r} \times \nabla V(r) = -\mathbf{r} \times \frac{\partial V(r)}{\partial r}\hat{\mathbf{e}}_r = \mathbf{0} \ ,$$

for a given time difference $dt = t_1 - t_0$ the swept area is the same. Angular momentum is a constant of motion, $\dot{\mathbf{L}} = 0$, for central potentials.

6.2.2.3 Kepler's third law

6.2.3 Exercises

6.2.3.1 Ex: Mass of the Milky Way

Estimate the total mass of our galaxy (the milky way) using the parameters of the orbits of the sun (and the solar system) around the center of the galaxy. Assume that the major part of the mass of our galaxy is in the form of a uniform sphere (bulge). The speed of the sun on its way around the center of the galaxy is approximately $v = 250\,\mathrm{km/h}$, the distance of the sun from the center of the galaxy is approximately $r = 28000\,\mathrm{ly}$ (light years). To how many stars like our sun does this correspond to?

Solution: *We use Newton's second law, $F = ma$, with a as centripetal acceleration, $a = v^2/r$, and F as the general law of gravity:*

$$\gamma_N \frac{Mm}{r^2} = m\frac{v^2}{r} \ ,$$

where M is the mass of the galaxy and m is the mass of our sun or the solar system. As a solution we get,

$$M = \frac{rv^2}{\gamma_N} \approx 3 \cdot 10^{41}\,\mathrm{kg} \ .$$

In terms of number of stars like our sun ($M_\odot = 2.0 \cdot 10^{30}\,\mathrm{kg}$) we get about 10^{11} stars.

6.2.3.2 Ex: Gravitation on Earth and Moon

How high are the orbits of 'geo-stationary' and 'lunar-stationary' satellites?

Solution: *The equilibrium position r of 'planeto-stationary' orbits results from,*

$$\frac{mv_1^2}{r} = \gamma_N \frac{mM}{r^2} \qquad \textit{with} \qquad v_1 = \frac{2\pi r}{T} \ ,$$

with T the period for a revolution of the planet around itself. Form this,

$$r = \sqrt[3]{\gamma_N \frac{M}{4\pi^2} T^2} \ .$$

For the Earth with $M = M_\oplus = 5.97 \cdot 10^{24}\,\mathrm{kg}$ and $T = 1\,\mathrm{d}$ we get $r = 42200\,\mathrm{km}$. For the Moon with $M_\leftmoon = 7.35 \cdot 10^{22}\,\mathrm{kg}$ and $T = 27.3\,\mathrm{d}$ we get $r = 88400\,\mathrm{km}$.

6.2.3.3 Ex: Cosmic velocities

a. How long is the orbital period T of a 1 t satellite on a circular orbit at a height of 20 km around the Earth? How long is the orbital period T of the Earth around the sun (the mass of the sun is 3.334×10^5 times larger than that of the Earth)? At what distance from Earth is the orbit of a satellite geostationary?
b. Calculate the escape velocity from Earth (or cosmic speed) for a person weighing 75 kg.

Solution: *a. The satellite is on a stable orbit when the centrifugal force is compensated by gravity,*

$$m\omega^2 r = \frac{\gamma_N M m}{r^2}$$

$$T = \frac{2\pi}{\omega} = 2\pi\sqrt{\frac{r^3}{\gamma_N M}} \ .$$

With $r = 6370\,\mathrm{km} + 20\,\mathrm{km}$, $M = 5.97 \times 10^{24}\,\mathrm{kg}$ *we get* $T = 1.4128\,\mathrm{h}$. *The calculation bill with* $r = 1.496 \times 10^8\,\mathrm{km}$ *and* $M = 1.99 \times 10^{30}\,\mathrm{kg}$ *yields the sidereal year* $T = 365.2364\,\mathrm{d}$. *A geostationary orbit is obtained for* $T = \mathrm{d}$, *hence,*

$$r = (\gamma_N M)^{1/3} \left(\frac{T}{2\pi}\right)^{2/3} \approx 42270\,\mathrm{km} \ .$$

b. The initial kinetic energy compensates for the potential difference, if

$$\frac{m}{2}v^2 = \frac{\gamma_N M m}{r} - \frac{\gamma_N M m}{\infty} \ ,$$

where r *is the earth's radius. So* $v = \sqrt{2\gamma_N M/r} \approx 11.2\,\mathrm{km/s}$.

6.2.3.4 Ex: Tschurjumow-Gerasimenko

The satellite Rosetta of the ESA ($m_{sat} = 3000\,\mathrm{kg}$) was placed on an orbit of the comet Tschurjumow-Gerasimenko (mass $m_{TG} = 3.14 \cdot 10^{12}\,\mathrm{kg}$, diameter $d_{TG} = 4\,\mathrm{km}$).
a. For the satellite to orbit the comet once a terrestrial day, what is the required height of the orbit?
b. What is the escape velocity from the comet's surface?

Solution: *a. Equilibrium between the gravitational force and the centrifugal force requires,*

$$F = \gamma_N \frac{m_{TG} m_{sat}}{h^2} = m_{sat}\omega^2 h \ .$$

Hence,

$$h = \left(\gamma_N \frac{m_{TG}}{\omega^2}\right)^{1/3} = \left(\gamma_N \frac{m_{TG}}{4\pi^2} T^2\right)^{1/3} = 3.4\,\mathrm{km} \ .$$

Thus, the satellite should fly $1.4\,\mathrm{km}$ *above the comet's surface.*
b. The escape velocity is given by,

$$\gamma_N \frac{m_{TG} m}{d_{TG}/2} = \frac{m}{2} v_{esc}^2 \ .$$

Hence,

$$v_{esc} = \sqrt{\frac{4\gamma_N m_{TG}}{d_{TG}}} = 45\,\mathrm{cm/s} \ .$$

6.3 Gravitational potential

For an arbitrary mass distribution $\rho(\mathbf{r})$ the *gravitational potential* acting on a test mass m can be calculated from,

$$\boxed{V(\mathbf{r}) = -\gamma_N m \int_{\mathbb{R}^3} \frac{\rho(\mathbf{r}')}{|\mathbf{r}-\mathbf{r}'|} d^3r'} \ . \tag{6.9}$$

For a point-mass with mass M located at the origin, $\mathbf{r}' = 0$, we parametrize $\rho(\mathbf{r}') = M\delta^3(\mathbf{r}')$, and recover Newton's law,

$$V(\mathbf{r}) = -\gamma_N \frac{Mm}{r} \ . \tag{6.10}$$

The gravitational potential being conservative, trajectories of test masses can simply be derived by solving the equation of motion,

$$\boxed{m\ddot{\mathbf{r}} = -\nabla V(\mathbf{r}) = \gamma_N m \int_{\mathbb{R}^3} \rho(\mathbf{r}') \frac{\mathbf{r}-\mathbf{r}'}{|\mathbf{r}-\mathbf{r}'|^3} d^3r'} \ . \tag{6.11}$$

If in practice analytic solution are beyond reach, numerical procedure are always possible.

Example 25 (*Gravitational potential in- and outside a homogeneous sphere*): In this example we will calculate the gravitational force that a particle of mass m is subjected to when placed inside a homogeneous sphere of radius R at a distance r from its center.
The potential exerted by a mass distribution with the density $\rho(\mathbf{r}')$ on a particle of mass m located at the position $\mathbf{r}$ is,

$$V(\mathbf{r}) = -\int \rho(\mathbf{r}') \frac{\gamma_N m}{|\mathbf{r}-\mathbf{r}'|} d^3r' = -\int_{sphere} \rho_0 \frac{\gamma_N m}{|\mathbf{r}-\mathbf{r}'|} r'^2 \sin\theta' dr' d\theta' d\phi' \ . \tag{6.12}$$

Substituting,

$$\xi \equiv |\mathbf{r}-\mathbf{r}'| = \sqrt{r^2 + r'^2 - 2rr'\cos\theta'} \tag{6.13}$$
$$\frac{d\xi}{d\theta'} = \frac{rr'\sin\theta'}{\xi} \ ,$$

we obtain,

$$V(\mathbf{r}) = -\int_{sphere} \rho_0 \frac{\gamma_N m r'}{r} d\xi dr' d\phi' = \frac{2\pi\rho_0\gamma_N m}{r} \int_0^R \int_{\xi_{\min}}^{\xi_{\max}} r' d\xi dr' \ . \tag{6.14}$$

The integration limits follow from the values adopted by ξ for $\theta = 0$ resp. $\theta = \pi$. For $r \leq R$ we have that r' is always greater than r. Hence, $\xi = r' - r, .., r' + r$. For $R \leq r$ we have that r' is always smaller than r. Hence, $\xi = r - r', .., r' + r$.

$$V(\mathbf{r}) = -\frac{2\pi\rho_0\gamma_N m}{r} \begin{cases} \int_r^R 2rr'dr' + \int_0^r 2r'^2 dr' \\ \int_0^R 2r'^2 dr' \end{cases} \quad \text{for} \quad \begin{cases} r \leq R \\ R \leq r \end{cases} . \tag{6.15}$$

With the sphere's mass,

$$M = \frac{4\pi\rho_0 R^3}{3} , \tag{6.16}$$

the potential becomes,

$$\begin{aligned} V(\mathbf{r}) &= -2\pi\rho_0\gamma_N m \left(R^2 - \frac{1}{3}r^2\right)\theta(R-r) - 2\pi\rho_0\gamma_N m\frac{2R^3}{3r}\theta(r-R) \\ &= -\gamma_N Mm\left(\frac{3}{2R} - \frac{r^2}{2R^3}\right)\theta(R-r) - \gamma_N Mm\frac{1}{r}\theta(r-R) . \end{aligned} \tag{6.17}$$

The force can be calculated using the gradient in spherical coordinates,

$$\begin{aligned} \mathbf{F} &= -\nabla V(\mathbf{r}) = -\hat{\mathbf{e}}_r\frac{\partial}{\partial r}V(\mathbf{r}) \\ &= -\hat{\mathbf{e}}_r\gamma_N Mm\frac{r}{R^3}\theta(R-r) - \hat{\mathbf{e}}_r\gamma_N Mm\frac{1}{r^2}\theta(r-R) . \end{aligned} \tag{6.18}$$

The gravitational acceleration is often specified in units of *Gal* after *Galilei*, where $1\,\text{Gal} \equiv 1\,\text{cm/s}^2$.

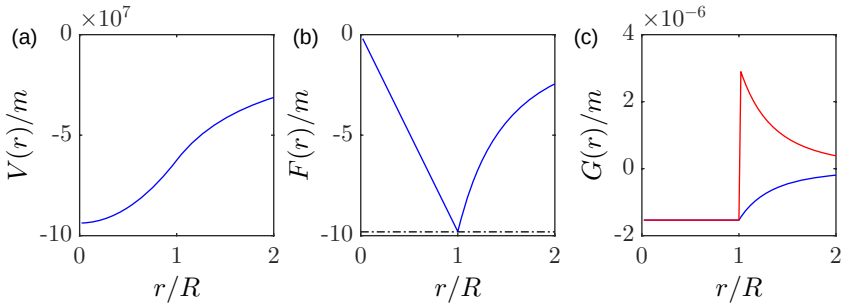

Figure 6.2: (code) Gravity in- and outside of Earth. (a) Gravitational potential, (b) gravitational force, and (c) radial (blue) and transverse (red) gravity gradient.

The above example shows that

1. outside a spherical mass distribution the gravitational potential can simply be replaced by that of a point mass sitting at the center of the mass distribution;
2. the superposition principle,

$$\boxed{V_{\rho_1+\rho_2}(\mathbf{r}) = V_{\rho_1}(\mathbf{r}) + V_{\rho_2}(\mathbf{r})} , \tag{6.19}$$

allows us to described the impact of mass cavities via simple subtraction

In classical mechanics we often describe gravity as a homogenous force field, which can be derived from a potential scaling linearly with the height above normal ground,

$$V(h) = mgh \ . \tag{6.20}$$

Obviously, this is approximation obtained by linearizing the gravitational potential on the Earth's surface. From Newton's law,

$$V(\mathbf{r}) = -\frac{\gamma_N M m}{r} \ , \tag{6.21}$$

using the Taylor expansion:

$$V(\mathbf{r}+\mathbf{h}) = e^{\mathbf{h}\cdot\nabla_\mathbf{r}} V(\mathbf{r}) = \sum_{\nu=0}^{\infty} \frac{(\mathbf{h}\cdot\nabla_\mathbf{r})^\nu}{\nu!} V(\mathbf{r}) = V(\mathbf{r}) + (\mathbf{h}\cdot\nabla_\mathbf{r})V(\mathbf{r}) + \frac{1}{2}(\mathbf{h}\cdot\nabla_\mathbf{r})(\mathbf{h}\cdot\nabla_\mathbf{r})V(\mathbf{r}) \ , \tag{6.22}$$

we get,

$$V(\mathbf{r}+\mathbf{h}) \simeq V(\mathbf{r}) + h\frac{\gamma_N M m}{r^2} = V(\mathbf{r}) + hgm \ . \tag{6.23}$$

In Exc. 6.3.5.1 we derive an expression generalizing Eq. (6.17) to arbitrary isotropic gravitational potentials. In Excs. 6.3.5.2, 6.3.5.3, 6.3.5.4, and 6.3.5.5 we calculate the potentials for other isotropic mass distributions. In Exc. 6.3.5.6 we use the superposition principle to calculate the potential generated by a spherical cavity inside a homogeneous sphere. In Excs. 6.3.5.7, 6.3.5.8, and 6.3.5.9 we calculate potentials generated by non-spherical density distributions. In Excs. 6.3.5.10, 6.3.5.11, and 6.3.5.12 we apply the results derived for the Earth's inner gravitational potential to derive possible trajectories through boreholes traversing the Earth.

6.3.1 Rotation and divergence of gravitational force fields

The rotation and divergence of gravitational force fields are,

$$\begin{aligned} \nabla^2 V(\mathbf{r}) = \nabla\cdot\mathbf{F}(\mathbf{r}) &= -4\pi\gamma_N m\rho(\mathbf{r}) \\ \nabla\times\mathbf{F}(\mathbf{r}) &= 0 \ . \end{aligned} \tag{6.24}$$

The integral formulation of Eq. (6.24) reads,

$$\oint_{\partial V} \mathbf{F}\cdot d\mathbf{S} = -4\pi\gamma_N M m \ , \tag{6.25}$$

with $M = \oint_{\partial V} \rho(\mathbf{r}) d^3r$.

The interpretation of these expressions are:

- The Poisson equation relates the divergence of the force field directly to the density distribution.
- The divergence is nothing else than the diagonal of gravity gradient defined in Sec. 6.3.2.
- For being conservative, gravitational potentials are rotation-free.

- The integral over a closed surface is proportional to the enclosed mass.

The Lagrangian density for Newtonian gravity is,

$$\mathcal{L}(\mathbf{r},t) = -\rho(\mathbf{r},t) - \tfrac{1}{8\pi\gamma_N}[\nabla V(\mathbf{r},t)]^2 \ . \tag{6.26}$$

Applying the Hamitonian principle to this Lagrangian one recovers the Poisson equation for gravity.

6.3.2 Gravity gradients

The *gravity gradient* is a tensor defined as the second derivative of the potential,

$$\boxed{G_{kl}(\mathbf{r}) = G_{lk}(\mathbf{r}) = \frac{\partial g_l(\mathbf{r})}{\partial x_k} = \frac{1}{m}\frac{\partial F_l(\mathbf{r})}{\partial x_k} = -\frac{1}{m}\frac{\partial}{\partial x_k}\frac{\partial V(\mathbf{r})}{\partial x_l}} \ . \tag{6.27}$$

Inserting the potential (6.9) we obtain,

$$\begin{aligned} G_{kl}(\mathbf{r}) &= -\frac{1}{m}\frac{\partial}{\partial x_k}\frac{\partial V(\mathbf{r})}{\partial x_l} = \gamma_N \int_{R^3} \rho(\mathbf{r}')\frac{\partial}{\partial x_k}\frac{\partial}{\partial x_l}\frac{1}{|\mathbf{r}-\mathbf{r}'|}d^3r' \qquad (6.28)\\ &= \gamma_N \int_{R^3} \frac{\rho(\mathbf{r}')}{|\mathbf{r}-\mathbf{r}'|^5}\begin{pmatrix} 3(x-x')^2-(\mathbf{r}-\mathbf{r}')^2 & 3(x-x')(y-y') & 3(x-x')(z-z') \\ 3(x-x')(y-y') & 3(y-y')^2-(\mathbf{r}-\mathbf{r}')^2 & 3(y-y')(z-z') \\ 3(x-x')(z-z') & 3(y-y')(z-z') & 3(z-z')^2-(\mathbf{r}-\mathbf{r}')^2 \end{pmatrix} d^3r' \\ &= \gamma_N \int_{R^3} \frac{\rho(\mathbf{r}')}{|\mathbf{r}-\mathbf{r}'|^3} K_{kl}(\mathbf{r}-\mathbf{r}')d^3r' \ , \end{aligned}$$

defining the kernel,

$$K_{kl}(\mathbf{r}-\mathbf{r}') \equiv \frac{3(x_k-x'_k)(x_l-x'_l)-\delta_{kl}(\mathbf{r}-\mathbf{r}')^2}{|\mathbf{r}-\mathbf{r}'|^2} \ . \tag{6.29}$$

For example, for the gravitational potential generated by a point mass,

$$V(r) = \gamma_N \frac{Mm}{r} = \gamma_N \frac{Mm}{\sqrt{x^2+y^2+z^2}} \ , \tag{6.30}$$

we find,

$$\begin{aligned} G_{kl}(\mathbf{r}) = -\frac{1}{m}\frac{\partial}{\partial x_k}\frac{\partial V(\mathbf{r})}{\partial x_l} &= \frac{\gamma_N M}{r^5}\begin{pmatrix} 3x^2-r^2 & 3xy & 3xz \\ 3xy & 3y^2-r^2 & 3yz \\ 3xz & 3yz & 3z^2-r^2 \end{pmatrix} \qquad (6.31)\\ &= \frac{\gamma_N M}{r^5}(3x_k x_l - r^2\delta_{kl}) \ . \end{aligned}$$

Gravity gradients are often given in units of *Eotvos* after *Eötvös*, where 1 Eotvos = $10^{-9}\,\mathrm{s}^{-2}$. In Exc. 6.3.5.13 we calculate the gravity gradient tensor of Earth (modeled as an idealized sphere) at the north-pole.

Example 26 (*Gravitational curvature in- and outside a homogeneous sphere*): The gravitational potential an force in- and outside a homogeneous sphere have been calculated in the example 25. Using the result we derive the gravity gradient,

$$
\begin{aligned}
G_{kl}(\mathbf{r}) &= -\frac{1}{m}\frac{\partial}{\partial x_k}\frac{\partial}{\partial x_l}V(\mathbf{r}) \qquad (6.32)\\
&= -\frac{\gamma_N M}{R^3}\begin{pmatrix}1&0&0\\0&1&0\\0&0&1\end{pmatrix}\theta(R-r) + \frac{\gamma_N M}{r^5}\begin{pmatrix}3x^2-r^2 & 3xy & 3xz\\ 3xy & 3y^2-r^2 & 3yz\\ 3xz & 3yz & 3z^2-r^2\end{pmatrix}\theta(r-R)\\
&= -\frac{\gamma_N M}{R^3}\delta_{kl}\theta(R-r) - \frac{\gamma_N M}{r^3}\left(\delta_{kl}-\frac{3x_k x_l}{r^2}\right)\theta(r-R)\ .
\end{aligned}
$$

The example 25 revealed that neither the potential nor the force are discontinuous at the sphere's surface. In contrast, the radial component of the curvature $G_{k=l}(r=R)$ is discontinuous at the north pole, while the transverse components $G_{k\neq l}(r=R)$ stay continuous, which is obviously due to the isotropic symmetry of the potential. To see this better, let us move along the symmetry axis setting $\mathbf{r} = r\hat{\mathbf{e}}_z$,

$$
G_{kl}(r\hat{\mathbf{e}}_z) = -\frac{\gamma_N M}{R^3}\begin{pmatrix}1&0&0\\0&1&0\\0&0&1\end{pmatrix}\theta(R-r) - \frac{\gamma_N M}{r^3}\begin{pmatrix}1&0&0\\0&1&0\\0&0&-2\end{pmatrix}\theta(r-R)\ . \qquad (6.33)
$$

Applying this results to Earth, be find inside Earth a constant gravity gradient of $-\gamma_N M_{\oplus}/R_{\oplus}^3 = 1.54\cdot 10^{-6}\,\mathrm{s}^{-2}$.

6.3.2.1 Gravimetry and gravity gradiometry

Gravity-gradiometers measure spatial variations of the gravitational acceleration. Being obtained as second derivatives of the gravitational potential, they are more sensitive to local mass variations, as nearly homogeneous large scale contributions to the acceleration are removed. For this reason, gravity-gradiometers need to be less accurate, provided they are sensitive enough. In Exc. 6.3.5.14 we estimate the sensitivity of modern gravimeters.

Example 27 (*Gravitation in- and outside a massive shell*): The calculations of examples 25 and 26 can be generalized for a homogenous massive shell with density ρ_1, inner radius R_i, and outer radius R_0. In Exc. 6.3.5.2 we show that the gravitational potential is,

$$
\begin{aligned}
V(\mathbf{r}) = -2\pi\rho_1\gamma_N m\,\big[&(R_o^2-R_i^2)\theta(R_i-r) \qquad (6.34)\\
&+\left(R_o^2-\frac{r^2}{3}-\frac{2R_o^3}{3r}\right)\theta(r-R_i)\theta(R_o-r) + \frac{2(R_o^3-R_i^3)}{3r}\theta(r-R_o)\Big]\ ,
\end{aligned}
$$

the gravitational force,

$$
\begin{aligned}
\mathbf{F}(\mathbf{r} = -\nabla V(\mathbf{r}) &= -\hat{\mathbf{e}}_r\frac{\partial}{\partial r}V(\mathbf{r}) \qquad (6.35)\\
&= \hat{\mathbf{e}}_r\frac{4\pi\rho_1\gamma_N m}{3}\left[\left(-r+\frac{R_o^3}{r^2}\right)\theta(r-R_i)\theta(R_o-r) - \frac{R_o^3-R_i^3}{r^2}\theta(r-R_o)\right]\ ,
\end{aligned}
$$

and the gravity gradient,

$$G_{kl}(\mathbf{r}) = -\frac{1}{m}\frac{\partial}{\partial x_k}\frac{\partial}{\partial x_l}V(\mathbf{r}) \tag{6.36}$$
$$= -\frac{4\pi\rho_1\gamma_N}{3}\left[\left(\delta_{kl} - \frac{R_i^3}{r^3}\left(\delta_{kl} - \frac{3x_k x_l}{r^2}\right)\right)\theta(r-R_i)\theta(R_o-r) + \frac{R_o^3 - R_i^3}{r^3}\left(\delta_{kl} - \frac{3x_k x_l}{r^2}\right)\theta(r-R_o)\right] .$$

For $R_i \to 0$ we recover the results of example 26. Particularly along the symmetry axis,

$$G_{zz}(\mathbf{r}) = -\frac{4\pi\rho_1\gamma_N}{3}\left[\left(1 + \frac{2R_i^3}{r^3}\right)\theta(r-R_i)\theta(R_o-r) - 2\frac{R_o^3 - R_i^3}{r^3}\theta(r-R_o)\right] . \tag{6.37}$$

6.3.3 Constants of motion

Trajectories can also be derive exploiting constants of motion. In Excs. 6.3.5.18 to 6.3.5.23 we calculate trajectories of bodies under the influence of gravity.

6.3.4 The virial law

The virial law states,

$$\boxed{\overline{T} = -\overline{\frac{1}{2}\sum_i \mathbf{F}_i\mathbf{r}_i}} . \tag{6.38}$$

For potentials of the form $V(r) = \alpha r^k$ we have,

$$\mathbf{F} = -\nabla V = -k\alpha r^{k-1}\hat{\mathbf{e}}_r . \tag{6.39}$$

Thus $\overline{T}$ and $\overline{V}$ related via,

$$\overline{T} = -\overline{\frac{1}{2}\sum_i \mathbf{F}_i\mathbf{r}_i} = \frac{k}{2}\overline{\sum_i \alpha r_i^{k-1}\hat{\mathbf{e}}_{r_i}\cdot\mathbf{r}_i} = \frac{k}{2}\overline{\sum_i \alpha r_i^k} = \frac{k}{2}\overline{V} . \tag{6.40}$$

In Exc. 6.3.5.24 we apply the virial law to a spring pendulum.

Example 28 (*The virial law for the harmonic potential and for* $1/r$*-potentials*): The special case $k = 2$ yields,

$$V(r) = \alpha r^2 \Rightarrow \overline{T} = \overline{V} , \tag{6.41}$$

and corresponds to a harmonic oscillator with $\alpha = \frac{1}{2}m\omega_0^2$.
The special case $k = -1$ yields,

$$V(r) = \frac{\alpha}{r} \Rightarrow \overline{T} = -\frac{1}{2}\overline{V} , \tag{6.42}$$

and corresponds to a Coulomb potential with $\alpha = \frac{q_1 q_2}{4\pi\epsilon_0}$, respectively a gravitational potential with $\alpha = -\gamma_N Mm$.
In the case of the gravitational potential, for positive total energy, we get,

$$E = \overline{T} + \overline{V} > 0 \qquad \overline{T} = -\tfrac{1}{2}\overline{V} \Rightarrow E = \tfrac{1}{2}\overline{V} > 0 \Rightarrow Mm < 0 . \tag{6.43}$$

Thus,

$$\overline{T} = \frac{1}{2} m \overline{v^2} = -\frac{1}{2}\overline{V} < 0 \Rightarrow m < 0 \tag{6.44}$$

This leads to the demand for negative masses, which is not sensible. The virial theorem can only apply to bound systems with $E < 0$.

6.3.5 Exercises

6.3.5.1 Ex: Arbitrary isotropic mass density distributions

a. Generalize the calculation of gravitational potentials and forces exhibited in example 24 to arbitrary, but isotropic mass density distributions $\rho(\mathbf{r}') = \rho(r')$.
b. Study the case of a sharp edge, $\rho(r') \equiv \rho(r')\theta(R - r')$.
c. Study the case of a homogeneous distribution, $\rho(r') \equiv \rho_0\theta(R - r')$, for a sphere with total mass M.
d. Study the case of a parabolic distribution, $\rho(r') \equiv \rho_0 \left(1 - \frac{r'^2}{R^2}\right) \theta(R - r')$, for a sphere with total mass M.

Solution: *a. The potential is,*

$$\begin{aligned} V(\mathbf{r}) &= -\int_{\mathbb{R}^3} \rho(r') \frac{\gamma_N m}{|\mathbf{r} - \mathbf{r}'|} d^3r' = -\int_{\mathbb{R}^3} \rho(r') \frac{\gamma_N m}{|\mathbf{r} - \mathbf{r}'|} r'^2 \sin\theta' dr' d\theta' d\phi' \\ &= -2\pi\gamma_N m \int_0^\infty \rho(r') r'^2 \int_0^\pi \frac{\sin\theta'}{\sqrt{r^2 + r'^2 - 2rr'\cos\theta'}} d\theta' dr' \ . \end{aligned}$$

The solution of the angular integral is,

$$\begin{aligned} \int_0^\pi \frac{\sin\theta'}{\sqrt{r^2 + r'^2 - 2rr'\cos\theta'}} d\theta' &= \frac{r\left[1 + \text{sign}(r' - r)\right] + r'\left[1 - \text{sign}(r' - r)\right]}{rr'} \\ &= \begin{cases} \frac{2}{r} \\ \frac{2}{r'} \end{cases} \quad for \quad \begin{cases} r' < r \\ r' > r \end{cases} . \end{aligned}$$

With this,

$$V(r) = -4\pi\gamma_N m \left(\int_0^r \rho(r') \frac{r'^2}{r} dr' + \int_r^\infty \rho(r') r' dr' \right) \ ,$$

or,

$$\boxed{V(r) = -4\pi\gamma_N m \left(\int_0^r \rho(r') \left(\frac{r'^2}{r} - r' \right) dr' + \int_0^\infty \rho(r') r' dr' \right)} \ . \tag{6.45}$$

The force follows from, $\mathbf{F}(\mathbf{r}) = -\nabla V(\mathbf{r}) = -\hat{\mathbf{e}}_r \partial_r V(r)$*, yielding,*

$$\boxed{F(r) = -\frac{\partial V(r)}{\partial r} = 4\pi\gamma_N m \frac{\partial}{\partial r} \int_0^r \rho(r') \left(\frac{r'^2}{r} - r' \right) dr'} \ . \tag{6.46}$$

b. Assuming a sharp edge, $\rho(r') \equiv \rho(r')\theta(R - r')$*, such that,*

$$M = 4\pi \int_0^R \rho(r') r'^2 dr' \ ,$$

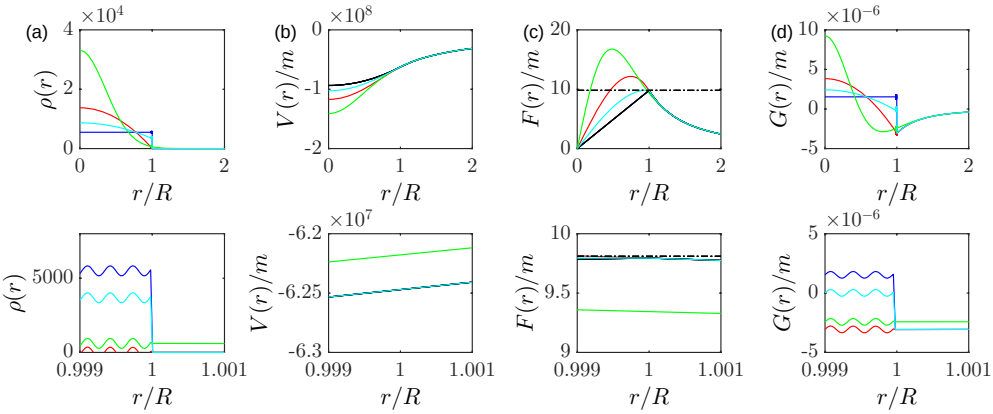

Figure 6.3: (code) (a) Radial density distributions, (b) potentials, (c) forces, and (d) gravity gradients for (blue) a homogeneous sphere, (red) a parabolic density distribution, (green) a Gaussian density distribution, and (cyan) a homogeneous density distribution with a superposed radial density modulation. The mass and the radius of the sphere are taken from Earth.

we get,

$$V(r) = -4\pi\gamma_N m \left(\int_0^r \rho(r')\theta(R-r')\frac{r'^2}{r}dr' + \int_r^\infty \rho(r')\theta(R-r')r'dr' \right)$$
$$= -4\pi\gamma_N m \begin{cases} \int_0^r \rho(r')\frac{r'^2}{r}dr' + \int_r^R \rho(r')r'dr' & for \quad r<R \\ \int_0^R \rho(r')\frac{r'^2}{r}dr' & \quad r>R \end{cases} .$$

The force is now,

$$F(r) = -\frac{\partial V(r)}{\partial r}$$
$$= -4\pi\gamma_N m \begin{cases} \int_0^r \rho(r')r'^2dr' \frac{\partial}{\partial r}\frac{1}{r} + \frac{1}{r}\frac{\partial}{\partial r}\int_0^r \rho(r')r'^2dr' - \rho(r)r & for \quad r<R \\ \int_0^R \rho(r')r'^2dr' \frac{\partial}{\partial r}\frac{1}{r} & \quad r>R \end{cases}$$
$$= -4\pi\gamma_N m \begin{cases} -\frac{1}{r^2}\int_0^r \rho(r')r'^2dr' & for \quad r<R \\ -\frac{1}{r^2}\int_0^R \rho(r')r'^2dr' & \quad r>R \end{cases} .$$

c. Assuming a homogeneous density distribution, $\rho(r') \equiv \rho_0\theta(R-r')$, such that,

$$M = 4\pi\rho_0 \int_0^R r'^2dr' = \frac{4\pi}{3}R^3\rho_0 ,$$

we get,

$$V(r) = -\gamma_N M m \begin{cases} \frac{3}{2R} - \frac{r^2}{2R^3} & for \quad r<R \\ \frac{1}{r} & \quad r>R \end{cases} .$$

The force is now,

$$F(r) = \gamma_N M m \begin{cases} \frac{r}{R^3} & for \quad r<R \\ \frac{1}{r^2} & \quad r>R \end{cases} .$$

d. Assuming a parabolic density distribution, $\rho(r') \equiv \frac{15M}{8\pi R^3}\left(1-\frac{r'^2}{R^2}\right)\theta(R-r')$*, such that,*

$$M = 4\pi\int_0^\infty \rho(r')r'^2dr' = 4\pi\rho_0\int_0^R\left(1-\frac{r'^2}{R^2}\right)r'^2dr' = \frac{8\pi R^3\rho_0}{15}\ ,$$

we get,

$$V(r) = -4\pi\gamma_N m\frac{15M}{8\pi R^3}\begin{cases}\int_0^r\left(1-\frac{r'^2}{R^2}\right)\frac{r'^2}{r}dr' + \int_r^R\left(1-\frac{r'^2}{R^2}\right)r'dr' & for \quad r<R\\ \int_0^R\left(1-\frac{r'^2}{R^2}\right)\frac{r'^2}{r}dr' & \quad r>R\end{cases}$$

$$= -\frac{15\gamma_N Mm}{2R^3}\begin{cases}\int_0^r\left(1-\frac{r'^2}{R^2}\right)\frac{r'^2}{r}dr' + \int_r^R\left(1-\frac{r'^2}{R^2}\right)r'dr' & for \quad r<R\\ \int_0^R\left(1-\frac{r'^2}{R^2}\right)\frac{r'^2}{r}dr' & \quad r>R\end{cases}\ .$$

6.3.5.2 Ex: Gravitational potential of a spherical shell

Consider a spherical shell with an inner radius a and an outer radius b.
a. Calculate the gravitational potential inside the sphere, inside the shell material and outside the sphere. (**Help:** Substitute the distance between the test particle m and a point of the mass distribution and make a case distinction for the integration limits for this distance variable.)
b. Calculate the force on a test particle.
c. Specify now for a massive sphere.
d. Specify for a very thin spherical shell.

Solution: *a. The potential exerted by a mass distribution with density* $\rho(\mathbf{r}')$ *on a particle of mass* m *located at the position* $\mathbf{r}$ *is,*

$$V(\mathbf{r}) = -\int\rho(\mathbf{r}')\frac{\gamma_N m}{|\mathbf{r}-\mathbf{r}'|}d^3\mathbf{r}' = -\int_{shell}\rho_0\frac{\gamma_N m}{|\mathbf{r}-\mathbf{r}'|}r'^2\sin\theta' dr'd\theta'd\phi'\ .$$

Substituting,

$$R \equiv |\mathbf{r}-\mathbf{r}'| = \sqrt{r^2+r'^2-2rr'\cos\theta'}$$
$$\frac{dR}{d\theta'} = \frac{rr'\sin\theta'}{R}\ ,$$

we obtain

$$V(\mathbf{r}) = -\int_{shell}\rho_0\frac{\gamma_N mr'}{r}dRdr'd\phi' = \frac{2\pi\rho_0\gamma_N m}{r}\int_a^b\int_{R_{\min}}^{R_{\max}}r'dRdr'\ .$$

The integration limits follow from the values adopted by R *for* $\theta = 0$ *respectively* $\theta = \pi$*. For* $r \le a$ *we have that* r' *is always larger than* r*. Therefore,* $R = r'-r,..,r'+r$*. For* $b \le r$ *we have that* r' *is always less than* r*. Hence,* $R = r-r',..,r'+r$*.*

$$V(\mathbf{r}) = -\frac{2\pi\rho_0\gamma_N m}{r}\begin{cases}\int_a^b 2rr'dr' & \quad r\le a\\ \int_r^b 2rr'dr' + \int_a^r 2r'^2dr' & for \quad a\le r\le b\\ \int_a^b 2r'^2dr' & \quad b\le r\end{cases}\ .$$

The result is,

$$V(\mathbf{r}) = -2\pi\rho_0\gamma_N m \begin{cases} b^2 - a^2 \\ b^2 - \frac{1}{3}r^2 - \frac{2}{3}\frac{a^3}{r} \\ \frac{2}{3}\frac{b^3-a^3}{r} \end{cases} \quad for \quad \begin{cases} r \le a \\ a \le r \le b \\ b \le r \end{cases} .$$

b. The force follows from,

$$\mathbf{F} = -\nabla V(\mathbf{r}) = \hat{\mathbf{e}}_r \frac{\partial}{\partial r} V(\mathbf{r}) = \hat{\mathbf{e}}_r 2\pi\rho_0\gamma_N m \begin{cases} 0 \\ \frac{2}{3}\frac{a^3}{r^2} - \frac{2}{3}r \\ -\frac{2}{3}\frac{b^3-a^3}{r^2} \end{cases} \quad for \quad \begin{cases} r \le a \\ a \le r \le b \\ b \le r \end{cases} .$$

c. Applying the result for the potential to a massive sphere ($a = 0$ and $M = \rho_0 V = \rho_0 \frac{4\pi b^3}{3}$) we have,

$$V(\mathbf{r}) = -\frac{\gamma_N M m}{r} \begin{cases} \frac{3r}{2b} - \frac{r^3}{2b^3} \\ 1 \end{cases} \quad for \quad \begin{cases} r \le b \\ b \le r \end{cases} .$$

Applying the result for the force to a massive sphere,

$$\mathbf{F} = -\hat{\mathbf{e}}_r \frac{\gamma_N M m}{r^2} \begin{cases} \frac{M_r}{M} \\ 1 \end{cases} \quad for \quad \begin{cases} r \le b \\ b \le r \end{cases} ,$$

where $M_r \equiv 4\pi\rho_0 r^3/3$.
d. We now calculate the potential for a thin shell, $\rho(\mathbf{r}') = \rho_0 = \sigma_0\delta(r' - b)$ and $M = \sigma_0 4\pi b^2$. We have,

$$\begin{aligned} V(\mathbf{r}) &= -\frac{2\pi\rho_0\gamma_N m}{r} \begin{cases} \int_0^b 2rr'dr' \\ \int_0^b 2r'^2 dr' \end{cases} \quad for \quad \begin{cases} r \le b \\ b \le r \end{cases} \\ &= -\frac{2\pi\sigma_0 b^2\gamma_N m}{r} \begin{cases} 2br \\ 2b^2 \end{cases} \quad for \quad \begin{cases} r \le b \\ b \le r \end{cases} \\ &= -\frac{\gamma_N M m}{r} \begin{cases} \frac{r}{b} \\ 1 \end{cases} \quad for \quad \begin{cases} r \le b \\ b \le r \end{cases} . \end{aligned}$$

Applying the result of force to a thin shell,

$$\mathbf{F} = -\hat{\mathbf{e}}_r \frac{\gamma_N M m}{r^2} \begin{cases} 0 \\ 1 \end{cases} \quad for \quad \begin{cases} r \le b \\ b \le r \end{cases} .$$

6.3.5.3 Ex: Two concentric shells

Let us consider two concentric spherical shells of uniform density with masses M_1 and M_2. Calculate the force on a particle of mass m placed (a) inside the inner shell, (b) outside the inner but inside the outer shell, and (c) outside the outer sphere.

Solution:

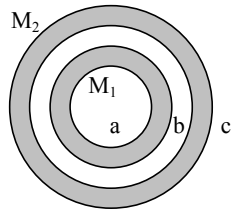

Figure 6.4:

6.3.5.4 Ex: Gravity influenced by a thin surface layer

Model the Earth as a homogeneous sphere of mass density ρ_0 isotropically covered by a $\Delta R = 1\text{m}$ thick homogeneous layer with different density ρ_1. How does the gravitational potential depend on the ratio ρ_1/ρ_0?

Solution: *Understanding Earth as a homogeneous sphere, the gravitational potential, force, and curvature are known. Hence, we may restrict to calculating these fields for a shell of positive or negative mass, whose fields will add to that of the homogeneous Earth. Also, as shown in the example 3, only the radial component of the gravity gradient is discontinuous at density boundaries such as the sphere's surface. Hence, we may concentrate our analysis on this component. The mass of the Earth*

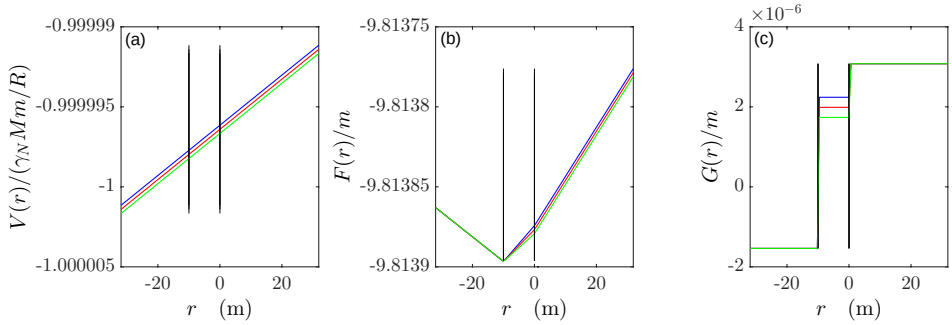

Figure 6.5: (code) Gravity gradient within a thin surface layer.

M without the layer is,

$$M = \frac{4\pi\rho_0 R^3}{3} \ .$$

The potentials generated by the Earth and the outer shell are, respectively, at a location r outside Earth are,

$$V_{\overset{\star}{\circ}}(\mathbf{r}) = -2\pi\rho_0\gamma_N m\frac{2}{3}\frac{R^3}{r}\hat{\mathbf{e}}_r$$
$$V_{\bigcirc}(\mathbf{r}) = -2\pi\rho_1\gamma_N m\frac{2}{3}\frac{(R+\Delta R)^3 - R^3}{r}\hat{\mathbf{e}}_r \ .$$

Adding both,

$$V_{\oplus}(\mathbf{r}) + V_{\bigcirc}(\mathbf{r}) = -\frac{4\pi\gamma_N m}{3}\hat{\mathbf{e}}_r\left(\rho_0\frac{R^3}{r} + \rho_1\frac{(R+\Delta R)^3 - R^3}{r}\right)$$
$$\simeq -\gamma_N M m\frac{\hat{\mathbf{e}}_r}{r}\left(1 + \frac{\rho_1}{\rho_0}\frac{3\Delta R}{R}\right) \ .$$

Setting $r \equiv R + \Delta R$*,*

$$V_{\oplus}(\mathbf{r}) + V_{\bigcirc}(\mathbf{r}) \simeq -\gamma_N M m\frac{\hat{\mathbf{e}}_r}{R+\Delta R}\left(1 + \frac{\rho_1}{\rho_0}\frac{3\Delta R}{R}\right) \ .$$

The dependency on the surface density is,

$$\frac{\partial[V_{\oplus}(\mathbf{r}) + V_{\bigcirc}(\mathbf{r})]}{V_{\oplus}(\mathbf{r})\partial\rho_1}\Delta\rho_1 = -\frac{3\Delta R}{R}\frac{\Delta\rho_1}{\rho_0} \approx \frac{3\cdot 1\,\mathrm{m}}{6378\,\mathrm{km}}\frac{\Delta\rho_1}{\rho_0} \approx -4.7\times 10^{-7}\frac{\Delta\rho_1}{\rho_0} \ .$$

The mean density and gravity gradient of Earth are,

$$\rho_{\oplus} = \frac{3M_{\oplus}}{4\pi R_{\oplus}^3} \approx 5450\,\mathrm{kg/m^3} \qquad \textit{and} \qquad \frac{4\pi\rho_{\oplus}\gamma_N}{3} = \frac{\gamma_N M_{\oplus}}{R_{\oplus}^3} \approx 1.54\cdot 10^{-6}\,\mathrm{s^{-2}} \ .$$

Hence, it seems that, if local gravity is uncertain, this will cause an offset, but the depth-dependence of the gravity gradient should still depend on ρ_1*.*

6.3.5.5 Ex: Gravitational force inside a shell

Show through geometric arguments that a particle of mass m placed inside a spherical shell of uniform mass density is subject to zero force, regardless of the position of the particle. What would happen if the surface mass density was not constant?

Solution: *Using spherical coordinates, we can divide the spherical shell into mass elements* $dm = \sigma R^2\sin\theta d\theta d\phi$*, such that,*

$$\int dm = \int_0^{2\pi}\int_0^{\pi}\sigma R^2\sin\theta' d\theta' d\phi' = 4\pi R^2\sigma = M \ .$$

Each mass element generates a gravitational field at the position $\mathbf{r}$ *within the shell of*

$$\mathbf{g}(\mathbf{r}) = -\frac{\gamma_N M}{r^2}\hat{\mathbf{e}}_r \ .$$

Therefore, for each mass element centered at the position θ', ϕ' *there is an element centered at the opposite position* $\pi-\theta', \pi+\phi'$ *having the same solid angle and exerting a force of equal intensity but opposite direction.*

6.3.5.6 Ex: Gravitational potential of a massive sphere with spherical cavity

A spherical cavity is machined into in a lead sphere of radius R such that its surface touches the outer surface of the massive sphere and passes through the its center. The primitive mass of the lead sphere is M. What will be the force that the sphere with the cavity will exert on a mass m at a distance z from the center of the outer sphere, when the mass and the centers of the sphere and the cavity are aligned?

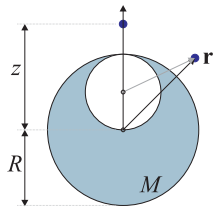

Figure 6.6: Scheme of the problem.

Solution: *The gravitational potential is given by,*

$$V(\mathbf{r}) = -\gamma_N \rho_0 m \int_{constr} \frac{dV'}{|\mathbf{r}-\mathbf{r}'|} = V_{outer-sphere}(\mathbf{r}) - V_{inner-cavity}(\mathbf{r}) \ .$$

Defining the mass of the outer sphere and the mass missing in the inner sphere,

$$M_o = \frac{4\pi}{3}\rho_0 R^3 \quad , \quad M_i = \frac{4\pi}{3}\rho_0 \left(\frac{R}{2}\right)^3 = \frac{M_o}{8} \ ,$$

we get, using the results (6.16),

$$V_{outer-sphere}(\mathbf{r}) = \begin{cases} -\gamma_N \frac{M_o m}{R}\left(\frac{3}{2} - \frac{r^2}{2R^2}\right)\hat{\mathbf{e}}_r & for\ r \le R \\ -\gamma_N \frac{M_o m}{r}\hat{\mathbf{e}}_r & for\ r \ge R \end{cases}$$

$$V_{inner-cavity}(\mathbf{r}) = \begin{cases} -\gamma_N \frac{M_i m}{R/2}\left(\frac{3}{2} - \frac{|\mathbf{r}-\frac{R}{2}\hat{\mathbf{e}}_z|^2}{2(R/2)^2}\right)\hat{\mathbf{e}}_r & for\ |\mathbf{r}-\frac{R}{2}\hat{\mathbf{e}}_z| \le \frac{R}{2} \\ -\gamma_N \frac{M_i m}{|\mathbf{r}-\frac{R}{2}\hat{\mathbf{e}}_z|}\hat{\mathbf{e}}_r & for\ |\mathbf{r}-\frac{R}{2}\hat{\mathbf{e}}_z| \ge \frac{R}{2} \end{cases} .$$

Along the z-axis, $\mathbf{r} = z\hat{\mathbf{e}}_z$*, the formulas simplify to,*

$$V_{outer-sphere}(0,0,z) = \begin{cases} -\gamma_N \frac{M_o m}{2R}\left(3 - \frac{z^2}{R^2}\right)\hat{\mathbf{e}}_z & for\ |z| \le R \\ -\gamma_N \frac{M_o m}{|z|}\hat{\mathbf{e}}_z & for\ |z| \ge R \end{cases}$$

$$V_{inner-cavity}(0,0,z) = \begin{cases} -\gamma_N \frac{M_o m}{8R}\left(3 - \frac{|z-\frac{R}{2}|^2}{(R/2)^2}\right)\hat{\mathbf{e}}_z & for\ |z-\frac{R}{2}| \le \frac{R}{2} \\ -\gamma_N \frac{M_o m}{8|z-\frac{R}{2}|}\hat{\mathbf{e}}_z & for\ |z-\frac{R}{2}| \ge \frac{R}{2} \end{cases} .$$

Particular solutions are found for $z = 0$*,*

$$V(0,0,z=0) = -\gamma_N \frac{5M_o m}{4R}\hat{\mathbf{e}}_z \ .$$

For $z = +R$ we have,

$$V(0,0,z=+R) = -\gamma_N \frac{3M_o m}{4R}\hat{\mathbf{e}}_z \ .$$

For $z = -R$ we have,

$$V(0,0,z=-R) = -\gamma_N \frac{11M_o m}{12R}\hat{\mathbf{e}}_z \ ,$$

and finally for $z \to \pm\infty$,

$$V(0,0,z\to\pm\infty) = -\gamma_N M_o m\hat{\mathbf{e}}_z \left(\frac{1}{|z|} - \frac{1}{8|z-\frac{R}{2}|}\right) \simeq -\gamma_N \frac{7M_o m}{8z}\hat{\mathbf{e}}_z \ .$$

6.3.5.7 Ex: Gravitational potential of a disk

Calculate the potential of a homogeneous thin disc with the surface density $\sigma = M/\pi R^2 = \rho dz$ along the axis of symmetry and the gravitational force it exerts on a mass m.
Help: When integrating over the thickness a of the disk, use the relation: $\int_0^d zf(z')dz' = f(0)dz$.

Solution: *The potential of a mass distribution $\rho(\mathbf{r}')$ acting on a test mass m located at the position $\mathbf{r}$ is,*

$$\begin{aligned} V(\mathbf{r}) &= -\int_{disk} \rho(\mathbf{r}')\frac{\gamma_N m}{|\mathbf{r}-\mathbf{r}'|}d^3\mathbf{r}' \\ &= -\gamma_N m\int_0^a\int_0^R\int_0^{2\pi} \rho_0 \frac{1}{\sqrt{(r-r')^2+(z-z')^2}} r'dr'dz'd\phi' \ . \end{aligned}$$

Now be $\mathbf{r} = z\hat{\mathbf{e}}_z$.

$$\begin{aligned} V(z) &= -2\pi\gamma_N m\rho_0 \int_0^a\int_0^R \frac{1}{\sqrt{r''+(z-z')^2}} r'dr'dz' \\ &= -2\pi\gamma_N m\rho_0 \int_0^a \left(\sqrt{R^2+(z-z')^2} - (z-z')\right)dz' \ . \end{aligned}$$

For a thin disk $\rho(z) \simeq \rho_0 a\delta(z)$,

$$V(z) = -2\pi\gamma_N m\rho_0 a(\sqrt{R^2+z^2} - z) \ .$$

The force is,

$$F = -\frac{d}{dz}V(z) = 2\pi\gamma_N m\rho_0 a\left(\frac{z}{\sqrt{R^2+z^2}} - 1\right) \ .$$

6.3.5.8 Ex: Gravitational force of a ring

Calculate the gravitational force of a ring of linear mass density $\lambda = M/2\pi R = \rho dRdz$ on the symmetry axis.
Help: When integrating on the thickness of the ring, use the relations: $\int_0^{dz} f(z')dz' = f(0)dz$ and $\int_R^{R+dR} f(r')dr' = f(R)dR$.

Solution: *The gravitational potential of a ring around the axis of symmetry* $\hat{\mathbf{e}}_z$ *is,*

$$V(\mathbf{r}) = -\int_{ring} \frac{\gamma_N m}{|\mathbf{r}-\mathbf{r}'|}\rho(\mathbf{r}')dV' = -\gamma_N M \int_{ring} \frac{1}{|\mathbf{r}-\mathbf{r}'|}\rho(\mathbf{r}')r'dr'dz'd\phi'$$
$$= -\gamma_N m\rho RdRdz \int_0^{2\pi} \frac{1}{\left|\begin{pmatrix}x\\y\\z\end{pmatrix} - \begin{pmatrix}R\cos\phi'\\R\sin\phi'\\0\end{pmatrix}\right|} d\phi' \ .$$

For a test mass m *located on the symmetry axis,* $\mathbf{r} = z\hat{\mathbf{e}}_z$*,*

$$V(\mathbf{r}) = -\gamma_N m\lambda R \int_0^{2\pi} \frac{1}{\left|\begin{pmatrix}0\\0\\z\end{pmatrix} - \begin{pmatrix}R\cos\phi'\\R\sin\phi'\\0\end{pmatrix}\right|} d\phi'$$
$$= -\gamma_N m\lambda R \int_0^{2\pi} \frac{1}{\sqrt{R^2\cos^2\phi' + R^2\sin^2\phi' + z^2}} d\phi'$$
$$= -\gamma_N m\lambda R \int_0^{2\pi} \frac{1}{\sqrt{R^2+z^2}} d\phi' = -2\pi\gamma_N m\lambda R \frac{1}{\sqrt{R^2+z^2}} = -\frac{\gamma_N Mm}{\sqrt{R^2+z^2}} \ .$$

The gradient gives the force, $\mathbf{F}(\mathbf{r}) = -\nabla V(\mathbf{r})$*, or,*

$$F_z = -\frac{\partial V}{\partial z} = -\frac{d}{dz}\frac{\gamma_N Mm}{\sqrt{R^2+z^2}} = -\frac{\gamma_N Mm}{s^3}z = -\frac{\gamma_N Mm}{s^2}\cos\alpha \ .$$

6.3.5.9 Ex: Gravitational oscillation through a ring

Consider a heavy ring of mass M and radius R and a particle of mass m placed in its center. What is the frequency for small amplitude oscillations in the direction perpendicular to the plane of the ring?

Solution: *The gravitational potential of a ring around the symmetry axis* $\hat{\mathbf{e}}_z$ *is,*

$$V(\mathbf{r}) = \int_{ring} \frac{\gamma_N m}{|\mathbf{r}-\mathbf{r}'|}\rho(\mathbf{r}')dV' = \gamma_N m \int_{ring} \frac{\lambda\delta(z')\delta(r'-R')}{\left|\begin{pmatrix}x\\y\\z\end{pmatrix} - \begin{pmatrix}r'\cos\phi'\\r'\sin\phi'\\z'\end{pmatrix}\right|} r'dr'd\phi'dz'$$

$$= \gamma_N mR \int_{ring} \frac{\lambda}{\left|\begin{pmatrix}x\\y\\z\end{pmatrix} - \begin{pmatrix}R\cos\phi'\\R\sin\phi'\\0\end{pmatrix}\right|} d\phi' \ .$$

For a test mass m *located on the symmetry axis,* $\mathbf{r} = z\hat{\mathbf{e}}_z$*,*

$$V(\mathbf{r}) = \gamma_N mR \int_{ring} \frac{\lambda}{\left|\begin{pmatrix}0\\0\\z\end{pmatrix} - \begin{pmatrix}R\cos\phi'\\R\sin\phi'\\0\end{pmatrix}\right|} d\phi' = \gamma_N mR \int_{ring} \frac{\lambda}{\sqrt{R^2\cos^2\phi' + R^2\sin^2\phi' + z^2}} d\phi'$$

$$= \gamma_N mR \int_{ring} \frac{\lambda}{\sqrt{R^2+z^2}} d\phi' = 2\pi\gamma_N mR \frac{\lambda}{\sqrt{R^2+z^2}} = \frac{\gamma_N Mm}{\sqrt{R^2+z^2}} \ .$$

The gradient gives force,

$$\mathbf{F}(\mathbf{r}) = -\nabla V(\mathbf{r})$$

$$F_z = -\frac{\partial V}{\partial z} = -\frac{d}{dz}\frac{\gamma_N Mm}{\sqrt{R^2+z^2}} = -\frac{\gamma_N Mm}{s^3} z = m\ddot{z} \ .$$

Therefore, the frequency of small oscillations will be,

$$\omega = \sqrt{\frac{\gamma_N M}{s^3}} \ .$$

6.3.5.10 Ex: Intraplanetary oscillation

A body of mass m is placed at a distance r_0 from the center of a planet of mass M and radius R.
a. Calculate the potential energy for $0 \leq r \leq \infty$. Suppose that the mass density of the planet is uniform and that the mass m can move within it through a tunnel. Consider $V(\infty) = 0$. Calculate the velocity as a function of r for $r < R$ knowing that $V(r_0) = 0$.

Solution: *Within the planet the gravitational force is*

$$F = \frac{\gamma_N Mmr}{R^3} = m\ddot{r} \ .$$

Following Hooke's law the proportionality $F \propto r$ *produces a harmonic movement,*

$$r = r_0 \sin\omega t \qquad , \qquad v = \omega v_0 \cos\omega t \ ,$$

with

$$\omega = \sqrt{\frac{\gamma_N M}{s^3}} \ .$$

6.3.5.11 Ex: Shortcut avoiding the Earth's center

Show that in a tunnel dug through the Earth (not necessarily along a diameter) the movement of an object will be harmonic.

Solution: *Within a massive sphere the gravitational force is,*

$$\mathbf{F} = \frac{\gamma_N M m r}{b^3} \hat{\mathbf{e}}_r \ .$$

Following Hooke's law the proportionality $F \propto r$ produces a harmonic movement.

6.3.5.12 Ex: Shortcut through the Earth

a. Two innovative companies make suggestions on how to get mail to New Zealand as quickly as possible. One company suggests drilling a hole through the Earth, placing the mail in a fireproof box and allowing it to swing through the hole (smoothly) through the center of the Earth so that it can be easily received by the recipient in New Zealand. The other company wants to shoot the mail in a very low orbit of only 1 m above the surface of the Earth at the first cosmic speed (smoothly) to New Zealand, where it should then be caught by a correspondingly soft pillow. Which of these two suggestions (if they were feasible) would get the mail faster to destination?
b. Assume that the well was planned incorrectly and that the hole missed the center of the earth by 100 km. What does the equation of motion look like?
Help: The mass distribution of the earth can be assumed to be homogeneous. Earth rotation and friction effects are neglected.

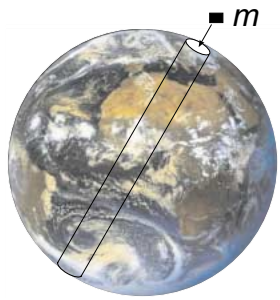

Figure 6.7:

Solution: *a. Let m be the mass of mail. For the first company,*

$$\frac{mv_1^2}{r_{\oplus}} = \gamma_N \frac{mM_{\oplus}}{r_{\oplus}^2} \qquad \Rightarrow \qquad v_1 = \sqrt{\frac{\gamma_N M_{\oplus}}{r_{\oplus}}} \qquad \Rightarrow \qquad t_1 = \frac{\frac{1}{2}U_{\oplus}}{v_1} = \frac{\pi r_{\oplus}}{\sqrt{\frac{\gamma_N M_{\oplus}}{r_{\oplus}}}} \ .$$

Inserting numbers, $v_1 \approx 7.91\,\mathrm{km/s}$. Now,

$$t_1 = \frac{\frac{1}{2} \cdot U_{\oplus}}{v_1} = \frac{\pi r_{\oplus}}{\sqrt{\frac{\gamma_N M_{\oplus}}{r_{\oplus}}}} \ ,$$

yielding, $t_1 \approx 42.3\,\mathrm{min}$.
For the second company: For $r < r_{\oplus}$ the force law applies,

$$F(r) = -\gamma_N \ \frac{Mm}{r_{\oplus}} \ r \ ,$$

thus the force is analogous to that of a spring,

$$F(r) = -Dr \qquad with \qquad D = g \ \frac{M_{\oplus} m}{r_{\oplus}^3} \ .$$

The movement is a harmonic vibration of the frequency,

$$\omega = \sqrt{D/m} = \sqrt{\frac{\gamma_N M_{\oplus}}{R_{\oplus}^3}} \ .$$

Postal delivery corresponds to half an oscillation period,

$$t_2 = \frac{T}{2} = \frac{\pi}{\omega} = \pi r_{Earth} \sqrt{r_{\oplus}/(\gamma_N \cdot M_{\oplus})} \ ,$$

and is just as long as the way taking the orbit.
b. .

6.3.5.13 Ex: Gravity gradient caused by underground cavities

In this exercise we discuss whether gravity gradiometry can identify the presence of underground cavities. We proceed in steps:
a. Assuming a homogeneous density distribution for Earth, calculate the gravity gradient tensor at the north-pole.
b. How does the tensor change in the presence of a point-like mass $M_1 = 10\,\mathrm{tons}$ located at a distance $d = 1\,\mathrm{m}$ in southern direction.
c. Describe the underground cavity by a spherical void centered at 1 m below the north-pole's surface at having a radius such that the missing mass corresponds to 10 tons of Earth material.

Solution: *a. We assume an isotropic mass density distribution for Earth and set the origin in the north-pole. The potential then reads,*

$$V(\mathbf{r}) = \gamma_N M m \left(\frac{3}{2R} - \frac{|\mathbf{r} + R\hat{\mathbf{e}}_z|^2}{2R^3} \right) \theta(-r) + \gamma_N M m \frac{1}{|\mathbf{r} + R\hat{\mathbf{e}}_z|} \theta(r) \ .$$

Since $\mathbf{r} = 0$ *at the north-pole, the gravity gradient is,*

$$\begin{aligned} G(\mathbf{r}) &= \frac{\gamma_N M}{R^3} \begin{pmatrix} -1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & 1 \end{pmatrix} \theta(-r) \\ &\quad + \frac{\gamma_N M}{|\mathbf{r} + R\hat{\mathbf{e}}_z|^5} \begin{pmatrix} 2x^2 - y^2 - (z+R)^2 & 3xy & 3x(z+R) \\ 3xy & 2y^2 - (z+R)^2 - x^2 & 3y(z+R) \\ 3x(z+R) & 3y(z+R) & 2(z+R)^2 - x^2 - y^2 \end{pmatrix} \theta(r) \\ &\longrightarrow \frac{\gamma_N M}{R^3} \begin{pmatrix} -1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & 2 \end{pmatrix} \theta(r) + \frac{\gamma_N M}{R^3} \begin{pmatrix} -1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & 2 \end{pmatrix} \theta(-r) \ , \end{aligned}$$

or,

$$G_{kl}(0) = \frac{\gamma_N M}{R^3} (1 - 3\theta(r)\delta_{kz})\delta_{kl} \ ,$$

with $R = 6378\,\mathrm{km}$.
b. For the additional potential we perform an analogous calculation,

$$\begin{aligned} G_1(\mathbf{r}) &= \frac{\gamma_N M_1}{|\mathbf{r} + d\hat{\mathbf{e}}_x|^5} \begin{pmatrix} 2(x+d)^2 - y^2 - z^2 & 3(x+d)y & 3(x+d)z \\ 3(x+d)y & 2y^2 - z^2 - (x+d)^2 & 3yz \\ 3(x+d)z & 3yz & 2z^2 - (x+d)^2 - y^2 \end{pmatrix} \\ &\longrightarrow \frac{\gamma_N M_1}{d^3} \begin{pmatrix} 2 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & -1 \end{pmatrix} \ , \end{aligned}$$

with $d = 1\,\mathrm{m}$. *A direct comparison shows,*

$$\frac{\gamma_N M}{R^3} \approx 1.5 \cdot 10^{-6}\,\mathrm{s}^{-2} \qquad \textit{and} \qquad \frac{\gamma_N M_1}{d^3} \approx 6.7 \times 10^{-7}\,\mathrm{s}^{-2} \ .$$

That is, a gravity gradiometer which is capable of measuring the inhomogeneity of a 'perfect' Earth is not far from being able to detect inhomogeneities caused by heavy local masses.
c. The absence of mass can be treated in the same way as the presence. That is, we can apply the results of (a) and (b) for a 'negative' mass M_1 *distributed over spherical cavity of radius,*

$$R_1 = \left(\frac{3M_1}{4\pi\rho_{\odot}} \right)^{1/3} = R_{\odot} \left(\frac{M_1}{M_{\odot}} \right)^{1/3} \approx 0.76\,\mathrm{m} \ .$$

6.3.5.14 Ex: Gravity gradient upon horizontal density modulation

A gravimeter and a gravity gradiometer are hovering at a distance z over a flat surface infinitely extended in x and y. The surface has a thickness b and a horizontal density modulation in x-direction: $\rho_1(\mathbf{r}') = \rho_1(x')\theta(b+z')\theta(-z')$. Calculate the gravitational potential, force, and gradients. Consider the particular case of a localized density modulation: $\rho_1(x') = \rho_1\theta(x')\theta(a-x')$.

Solution: *As the mass distribution is infinite, the potential will naturally diverge. On the other hand, the force is finite,*

$$\begin{aligned}\mathbf{F}(\mathbf{r}) &= -\gamma_N \int_{-\infty}^{\infty} \rho_1(x') \int_{-b}^{0}\int_{-\infty}^{\infty} \frac{\mathbf{r}-\mathbf{r}'}{\sqrt{(x-x')^2+y'^2+(z-z')^2}^3} dy'dz'dx' \\ &= -\gamma_N \int_{-\infty}^{\infty} \rho_1(x') \begin{pmatrix} 2\arctan\frac{b+z}{x-x'} - 2\arctan\frac{z}{x-x'} \\ 0 \\ \ln\frac{(x-x')^2+(z+b)^2}{(x-x')^2+z^2} \end{pmatrix} dx' \ .\end{aligned}$$

The gravity gradient is,

$$\begin{aligned}G_{kl}(\mathbf{r}) &= \frac{1}{m}\frac{\partial F_l(\mathbf{r})}{\partial x_k} \\ &= \gamma_N \int \rho_1(x') \int_{-b}^{0}\int_{-\infty}^{\infty} \frac{1}{\sqrt{(x-x')^2+y'^2+(z-z')^2}^5} \times \\ &\quad \times \begin{pmatrix} 2(x-x')^2-y'^2-(z-z')^2 & 0 & 3(x-x')(z-z') \\ 0 & 0 & 0 \\ 3(x-x')(z-z') & 0 & 2(z-z')^2-(x-x')^2-y'^2 \end{pmatrix} dy'dz'dx' \\ &= \gamma_N \int \frac{2b\rho_1(x')}{[(x-x')^2+z^2][(x-x')^2+(z+b)^2]} \begin{pmatrix} (x-x')^2-z(z+b) & 0 & (x-x')(2z+b) \\ 0 & 0 & 0 \\ (x-x')(2z+b) & 0 & -(x-x')^2+z(z+b)^2 \end{pmatrix} dx' \ .\end{aligned}$$

If the gravimeter or the gravity gradiometer are hovering at a small distance $z \ll b$ close to the surface, the force becomes,

$$\mathbf{F}(x,0,0) \xrightarrow{z\ll b} -\gamma_N \int_{-\infty}^{\infty} \rho_1(x') \begin{pmatrix} 2\arctan\frac{b}{x-x'} \\ 0 \\ \ln\left(1+\left(\frac{b}{x-x'}\right)^2\right) \end{pmatrix} dx' \ ,$$

and the gradients,

$$G_{kl}(x,0,0) \xrightarrow{z\ll b} 2\gamma_N b \int_{-\infty}^{\infty} \frac{\rho_1(x')}{(x-x')^2+b^2} dx' \begin{pmatrix} 1 & 0 & \frac{b}{x-x'} \\ 0 & 0 & 0 \\ \frac{b}{x-x'} & 0 & -1 \end{pmatrix} \ .$$

Assuming a limited density fluctuation $\rho_1(x') = \rho_1\theta(x')\theta(a-x')$, the force reads,

$$\mathbf{F}(x,0,0) = -\gamma_N\rho_1 \begin{pmatrix} 2a\arctan\frac{b}{x-a} - 2x\arctan\frac{ab}{x(x-a)+b^2} + b\ln\frac{x^2+b^2}{(x-a)^2+b^2} \\ 0 \\ x\ln\frac{(x^2+b^2)(x-a)^2}{x^2[(x-a)^2+b^2]} + a\ln\left(1+\frac{b^2}{(x-a)^2}\right) + 2b\arctan\frac{ab}{x(x-a)+b^2} \end{pmatrix} \ ,$$

and the gradients (using $\arctan x \pm \arctan y = \arctan \frac{x \pm y}{1 \mp xy}$*),*

$$G_{kl}(x,0,0) = 2\gamma_N \rho_1 \begin{pmatrix} \arctan \frac{ab}{x(x-a)+b^2} & 0 & \frac{1}{2}\ln\frac{(x-a)^2+b^2}{x^2+b^2} - \ln\frac{x-a}{x} \\ 0 & 0 & 0 \\ \frac{1}{2}\ln\frac{(x-a)^2+b^2}{x^2+b^2} - \ln\frac{x-a}{x} & 0 & -\arctan\frac{ab}{x(x-a)+b^2} \end{pmatrix} .$$

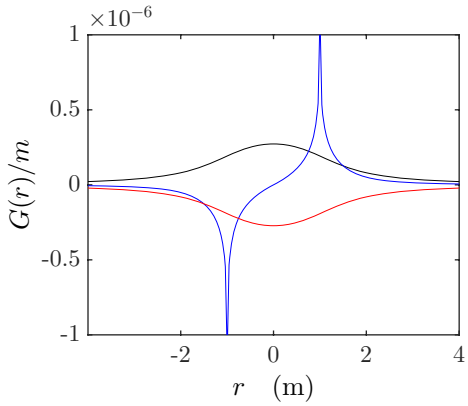

Figure 6.8: (code) Gravity gradients due to a 1 m deep and 1 m large mass of density $\rho_1 = 1300$ kg/cm^3: (black) horizontal gradient upon horizontal displacement G_{xx}, (red) vertical gradient upon vertical displacement G_{zz}, and (blue) horizontal gradient upon vertical displacement G_{xz}, and vice versa.

6.3.5.15 Ex: Gravity gradients

a. Modern commercial gravity gradiometers can measure acceleration gradients on the order of $|\nabla a| \approx 10^{-5}\,\mathrm{s}^{-2}$. Compare with the gravity gradient on the Earth's surface. What is the smallest height difference detectable by a state of the art gradiometer?
b. Calculate the gravity gradient caused by a massive sphere of mass $m_{sphere} = 10\,\mathrm{t}$ at $d = 1\,\mathrm{m}$ distance?
c. The French company μQuans offers atomic quantum gravimeters with guaranteed sensitivities of $50\,\mu\mathrm{Gal}/\sqrt{\mathrm{Hz}}$ at a cycling frequency of 2 Hz. Assuming the Earth as a homogeneous sphere, for how long must the signal be integrated to be able to measure a 1 cm height variation over the Earth's surface.
d. For how long must the signal be integrated to be able to measure a gravity variation caused by a 10 t mass at 1 m distance.

Solution: *a. From Newton's law,*

$$g = \frac{F}{m} = \frac{\gamma_N M_{\odot}}{r^2} ,$$

where $M_{\oplus}$ is the mass of the Earth and r the distance from the center of the Earth. We calculate,

$$\frac{\nabla g}{g} = \frac{\partial g}{g \partial r} \nabla r = \frac{-2\gamma_N M_{\oplus}}{g r^3} \hat{\mathbf{e}}_r = \frac{-2}{r} \hat{\mathbf{e}}_r \ .$$

This yields at the surface of the Earth ($r = R_{\oplus}$),

$$\frac{\partial g}{g \partial R} = \frac{-2}{R_{\oplus}} \approx -3 \cdot 10^{-7}\,\mathrm{m}^{-1} \ ,$$

or,

$$\frac{\partial g}{\partial R} = \frac{-2g}{R_{\oplus}} \approx -3 \cdot 10^{-6}\,\mathrm{s}^{-2} \ .$$

So, with state-of-the-art gravity gradiometers we can measure the variation of g due to height changes of about $3\,\mathrm{m}$.
b. The same calculation as in (a) yields,

$$a_d = \frac{\gamma_N m_{sphere}}{d^2} \ ,$$

and,

$$\frac{\partial a}{\partial d} = \frac{-2\gamma_N m_{sphere}}{d^3} \approx -1.33 \cdot 10^{-6}\,\mathrm{s}^{-2} \ .$$

c. As we have seen, the gravitational acceleration on Earth is,

$$\frac{\partial g}{\partial R} \approx -3 \cdot 10^{-6}\,\mathrm{s}^{-2} = -3\,\mu\mathrm{Gal/cm} \ .$$

with the gravimeter's sensitivity of,

$$s \equiv \Delta g \sqrt{\tau} = \frac{50\,\mu\mathrm{Gal}}{\sqrt{\mathrm{Hz}}} \ ,$$

it should be possible to detect a $\Delta R = 1\,\mathrm{cm}$ elevation in

$$\tau = \left(s \frac{\Delta R}{\Delta g} \frac{1}{\Delta R} \right)^2 = \left(\frac{50\,\mu\mathrm{Gal}}{\sqrt{\mathrm{Hz}}} \ \frac{\mathrm{cm}}{3.1\,\mu\mathrm{Gal}} \ \frac{1}{1\,\mathrm{cm}} \right)^2 \approx 260\,\mathrm{s} = 4.3\,\mathrm{min} \ .$$

d. The same calculations as in (c) yields,

$$\tau = \left(s \frac{\Delta R}{\Delta g} \frac{1}{\Delta R} \right)^2 = \left(\frac{50\,\mu\mathrm{Gal}}{\sqrt{\mathrm{Hz}}} \ \frac{\mathrm{cm}}{1.3\,\mu\mathrm{Gal}} \ \frac{1}{1\,\mathrm{cm}} \right)^2 \approx \left(\frac{50}{1.3} \right)^2 = 24.6\,\mathrm{min} \ .$$

6.3.5.16 Ex: Acceleration of a mass subject to a circular motion in an inhomogeneous force field

Commercial *Gravity Gradient Instruments* (GGI) are based on accelerometers mounted on the border of a disk of radius R rotating at a frequency ω. Let us suppose that the disk's rotation axis is the z-axis and that is located inside an inhomogeneous force

field (e.g. gravity) characterized by its gradient tensor (assumed to be constant over time and over the length scale of R).
a. Calculate the time-dependent acceleration recorded by the accelerometer in radial direction.
b. The voltage signal delivered by the accelerometer is now added to one delivered by a second accelerometer sitting on the opposite side of the disk.
c. Finally, the signals are demodulated at 2ω and time-averaged over a period $2\pi/\omega$.

Solution: *The Taylor expansion of gravitational potential can be written,*

$$\begin{aligned} V(\mathbf{r}+\mathbf{R}) &= \exp(\mathbf{R}\cdot\nabla_{\mathbf{r}})V(\mathbf{R}) = V(\mathbf{r}) + (\mathbf{R}\cdot\nabla_{\mathbf{r}})V(\mathbf{r}) + \tfrac{1}{2}(\mathbf{R}\cdot\nabla_{\mathbf{r}})(\mathbf{R}\cdot\nabla_{\mathbf{r}})V(\mathbf{r}) + ... \\ &= V(\mathbf{r}) + \tfrac{1}{2}\sum_{k=1} R_k \frac{\partial V(\mathbf{r})}{\partial x_k} + \tfrac{1}{2}\sum_{k,l=1} R_k R_l \frac{\partial^2 V(\mathbf{r})}{\partial x_k \partial x_l} + ... \\ &\equiv V(\mathbf{r}) - \tfrac{m}{2}\sum_{k=1} R_k a_k(\mathbf{r}) - \tfrac{m}{2}\sum_{k,l=1} R_k R_l G_{kl}(\mathbf{r}) + ... \ . \end{aligned}$$

a. Describing the trajectory of an accelerometer by,

$$\mathbf{r}+\mathbf{R}(t) = \mathbf{r} + \begin{pmatrix} R\cos\omega t \\ R\sin\omega t \\ 0 \end{pmatrix} \ ,$$

the acceleration sensed by the rotating mass is just given by the centripetal force,

$$\mathbf{a}_{rot}(t) = -\omega^2 \mathbf{R}(t) \ ,$$

exerted by the coercive force imposed by the disk, plus possible stationary external force gradients,

$$\begin{aligned} \mathbf{a}_{grd}(t) = \mathbf{a}_{grd}(\mathbf{r}+\mathbf{R}(t)) &= \begin{pmatrix} a_{x,grd}(x+X(t), y+Y(t), z+Z(t)) \\ a_{y,grd}(x+X(t), y+Y(t), z+Z(t)) \\ a_{z,grd}(x+X(t), y+Y(t), z+Z(t)) \end{pmatrix} \\ &= \begin{pmatrix} a_{x,grd}(\mathbf{r}) + X\left.\frac{\partial a_{x,grd}}{\partial x}\right|_{X=0} + Y\left.\frac{\partial a_{x,grd}}{\partial y}\right|_{Y=0} + Z\left.\frac{\partial a_{x,grd}}{\partial z}\right|_{Z=0} \\ a_{y,grd}(\mathbf{r}) + X\left.\frac{\partial a_{y,grd}}{\partial x}\right|_{X=0} + Y\left.\frac{\partial a_{y,grd}}{\partial y}\right|_{Y=0} + Z\left.\frac{\partial a_{y,grd}}{\partial z}\right|_{Z=0} \\ a_{z,grd}(\mathbf{r}) + X\left.\frac{\partial a_{z,grd}}{\partial x}\right|_{X=0} + Y\left.\frac{\partial a_{z,grd}}{\partial y}\right|_{Y=0} + Z\left.\frac{\partial a_{z,grd}}{\partial z}\right|_{Z=0} \end{pmatrix} \quad with \quad G_{kl} \equiv \left.\frac{\partial a_{k,grd}}{\partial x_l}\right|_{X_l=0} \\ &= \begin{pmatrix} a_{x,grd}(\mathbf{r}) + XG_{xx}(\mathbf{r}) + YG_{xy}(\mathbf{r}) + ZG_{xz}(\mathbf{r}) \\ a_{y,grd}(\mathbf{r}) + XG_{yx}(\mathbf{r}) + YG_{yy}(\mathbf{r}) + ZG_{yz}(\mathbf{r}) \\ a_{z,grd}(\mathbf{r}) + XG_{zx}(\mathbf{r}) + YG_{zy}(\mathbf{r}) + ZG_{zz}(\mathbf{r}) \end{pmatrix} \\ &= \begin{pmatrix} a_{x,grd}(\mathbf{r}) + RG_{xx}(\mathbf{r})\cos\omega t + RG_{xy}(\mathbf{r})\sin\omega t \\ a_{y,grd}(\mathbf{r}) + RG_{yx}(\mathbf{r})\cos\omega t + RG_{yy}(\mathbf{r})\sin\omega t \\ a_{z,grd}(\mathbf{r}) + RG_{zx}(\mathbf{r})\cos\omega t + RG_{zy}(\mathbf{r})\sin\omega t \end{pmatrix} \ . \end{aligned}$$

Now, we assume that the mass be in fact an accelerometer oriented such that it measures only the radial component of the acceleration (simplifying the notation by drop-

ping the $(\mathbf{r})$*-dependence),*

$$\begin{aligned} a_r(t) &= [\mathbf{a}_{rot}(t) + \mathbf{a}_{grd}(t)] \cdot \mathbf{R}(t) \\ &= -\omega^2 R^2 + \begin{pmatrix} a_{x,grd} + RG_{xx}\cos\omega t + RG_{xy}\sin\omega t \\ a_{y,grd} + RG_{yx}\cos\omega t + RG_{yy}\sin\omega t \\ a_{z,grd} + RG_{zx}\cos\omega t + RG_{zy}\sin\omega t \end{pmatrix} \cdot \begin{pmatrix} R\cos\omega t \\ R\sin\omega t \\ 0 \end{pmatrix} \\ &= -\omega^2 R^2 + a_{x,grd} R\cos\omega t + a_{y,grd} R\sin\omega t + \\ &+ \tfrac{1}{2}R^2\left[G_{xx} + G_{yy} + (G_{xx} - G_{yy})\cos 2\omega t + (G_{xy} + G_{yx})\sin 2\omega t\right] \ . \end{aligned}$$

b. Now, we assume that on the opposite side of the disk there is a second accelerometer delivering a signal shifted by $\omega t \longrightarrow \omega t + \pi$*. The sum of both cancels the terms oscillating at* ω*,*

$$a'_r(t) = -2\omega^2 R^2 + R^2\left[G_{xx} + G_{yy} + (G_{xx} - G_{yy})\cos 2\omega t + (G_{xy} + G_{yx})\sin 2\omega t\right] \ .$$

c. The signals are demodulated at 2ω *and time-averaged over a period* $2\pi/\omega$*,*

$$\begin{aligned} &\overline{a'_r(t)\sin 2\omega t} \\ &= \frac{\omega}{2\pi}\int_0^{2\pi/\omega} R^2\left[G_{xx} + G_{yy} + (G_{xx} - G_{yy})\cos 2\omega t + (G_{xy} + G_{yx})\sin 2\omega t\right]\sin 2\omega t dt \\ &= R^2 G_{xy} \\ &\overline{a'_r(t)\cos 2\omega t} \\ &= \frac{\omega}{2\pi}\int_0^{2\pi/\omega} R^2\left[G_{xx} + G_{yy} + (G_{xx} - G_{yy})\cos 2\omega t + (G_{xy} + G_{yx})\sin 2\omega t\right]\cos 2\omega t dt \\ &= \tfrac{1}{2}R^2(G_{xx} - G_{yy}) \ . \end{aligned}$$

The GGI thus delivers the components $G_{xy}(\mathbf{r})$ *and* $G_{xx}(\mathbf{r}) - G_{yy}(\mathbf{r})$ *of the gravity gradient tensor as it is moved through space* $\mathbf{r}$*.*

6.3.5.17 Ex: Angular momentum in spherical coordinates

a. Calculate the acceleration, the angular momentum, and its derivative in spherical coordinates using the result of Exc. 12.3.8.6.
b. Set $\theta = \frac{\pi}{2}$ in all expressions.
c. Derive the equation of motion for a central potential.

Solution: *a. The expressions for position, velocity, and acceleration found in Exc. 12.3.8.6 are,*

$$\begin{aligned} \mathbf{r} &= r\hat{\mathbf{e}}_r \\ \mathbf{v} &= \dot{\mathbf{r}} = \dot{r}\hat{\mathbf{e}}_r + r\dot{\theta}\hat{\mathbf{e}}_\theta + \dot{\phi}r\sin\theta\hat{\mathbf{e}}_\phi \\ \mathbf{a} &= \ddot{\mathbf{r}} = (\ddot{r} - r\dot{\theta}^2 - \dot{\phi}^2 r\sin^2\theta)\hat{\mathbf{e}}_r \\ &\quad + (2\dot{r}\dot{\theta} + r\ddot{\theta} - \dot{\phi}^2 r\sin\theta\cos\theta)\hat{\mathbf{e}}_\theta \\ &\quad + (2\dot{\phi}\dot{r}\sin\theta + 2\dot{\phi}r\dot{\theta}\cos\theta + \ddot{\phi}r\sin\theta)\hat{\mathbf{e}}_\phi \ . \end{aligned}$$

The angular momentum and its derivative follow immediately,

$$\begin{aligned}\mathbf{L} &= \mathbf{r}\times\mathbf{p} = mr(-r\dot\theta\hat{\mathbf{e}}_\phi + \dot\phi r\sin\theta\hat{\mathbf{e}}_\theta)\\ \dot{\mathbf{L}} &= \mathbf{r}\times\dot{\mathbf{p}}\\ &= -mr(2\dot r\dot\theta + r\ddot\theta - \dot\phi^2 r\sin\theta\cos\theta)\hat{\mathbf{e}}_\phi + (2\dot\phi\dot r\sin\theta + 2\dot\phi r\dot\theta\cos\theta + \ddot\phi r\sin\theta)\hat{\mathbf{e}}_\theta\ .\end{aligned}$$

b. With $\theta = \frac{\pi}{2}$ the expressions simplify to,

$$\begin{aligned}\mathbf{r} &= r\hat{\mathbf{e}}_r\\ \mathbf{v} &= \dot r\hat{\mathbf{e}}_r + \dot\phi r\hat{\mathbf{e}}_\phi\\ \mathbf{a} &= (\ddot r - \dot\phi^2 r)\hat{\mathbf{e}}_r + (2\dot\phi\dot r + \ddot\phi r)\hat{\mathbf{e}}_\phi\\ \mathbf{L} &= m\omega r^2\hat{\mathbf{e}}_\theta\\ \dot{\mathbf{L}} &= \mathbf{r}\times\dot{\mathbf{p}} = (2\dot\phi\dot r + \ddot\phi r)\hat{\mathbf{e}}_\theta = (\hat{\mathbf{e}}_\phi\cdot\mathbf{a})\hat{\mathbf{e}}_\theta\ .\end{aligned}$$

c. In a central potential $V(r)$, Newton's law reads,

$$\begin{aligned}m\mathbf{a} &= -\nabla V(r)\\ &= -\left(\hat{\mathbf{e}}_r\frac{\partial}{\partial r} + \hat{\mathbf{e}}_\theta\frac{1}{r}\frac{\partial}{\partial\theta} + \hat{\mathbf{e}}_\phi\frac{1}{r\sin\theta}\frac{\partial}{\partial\phi}\right)V(r) = -\hat{\mathbf{e}}_r\frac{\partial V}{\partial r}\ .\end{aligned}$$

Hence for $\theta = \frac{\pi}{2}$,

$$\begin{aligned}a_r &= \ddot r = -\frac{\partial V}{m\partial r} + \dot\phi^2 r = -\frac{\partial V_{eff}}{m\partial r} \qquad \textit{with} \qquad V_{eff}(r) = V(r) + \frac{m}{2}\omega^2 r^2\\ a_\phi &= \ddot\phi = -\frac{2\dot\phi\dot r}{r} = -\frac{2\omega\dot r}{r}\\ a_\theta &= \ddot\theta = 0\ .\end{aligned}$$

We finally find $\mathbf{L} = m\omega r^2\hat{\mathbf{e}}_\theta$ and $\dot{\mathbf{L}} = 0$.

6.3.5.18 Ex: Scattering at a central force, angular momentum

Consider the scattering of a particle of mass M at an attractive central force field $\mathbf{F}(\mathbf{r}) = -\frac{\alpha}{r^2}\hat{\mathbf{e}}_r$ with $\alpha > 0$. Far from the force center the velocity of the particle is given by v_∞. The asymptotic distance perpendicular to the velocity for very large distances from the force center is called the impact parameter b.
a. Determine the relationship between the impact parameter b and the angular momentum L of the particle.
b. The path of the particle has the shape of a conic section, which in plane polar coordinates can be parametrized by $r = P/(1-\epsilon\cos\phi)$. Find ϵ and P as a function of b, v_∞, M and α. c. Find an expression for $\sin(\theta/2)$. Here, θ is the scattering angle between the asymptotic orbits of the particle, i.e. the paths of the incoming and outgoing particles for large distances from the force center.
d. How does θ for constant v_∞ depend on the impact parameter b? Discuss the special cases $b = 0$ and $b \to \infty$.

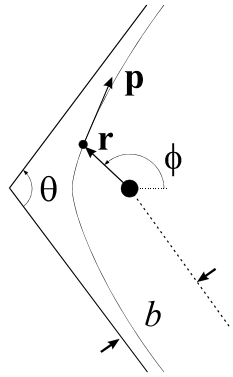

Figure 6.9:

Solution: *a. The angular momentum is in a central potential* $\mathbf{L} = \mathbf{r} \times \mathbf{p} = rp\hat{\mathbf{e}}_z \sin\beta$ *s a constant of motion. For* $t \to -\infty$ *we have* $\beta = \phi$ *and* $r \sin\phi = b$*. So,*

$$\mathbf{L} = mv_\infty b\hat{\mathbf{e}}_z \ .$$

b. The force field is,

$$\mathbf{F} = \dot{\mathbf{p}} = -\nabla V = \nabla\frac{\alpha}{r} = -\frac{\alpha}{r^3}\mathbf{r} \ .$$

We can now show,

$$\begin{aligned}\frac{d}{dt}(\mathbf{p}\times\mathbf{L}) = \dot{\mathbf{p}}\times\mathbf{L} &= -\frac{\alpha}{r^3}\mathbf{r}\times(\mathbf{r}\times\mathbf{p}) \\ &= -\frac{\alpha}{r^3}\left[\mathbf{r}(\mathbf{r}\cdot\mathbf{p}) - \mathbf{p}(\mathbf{r}\cdot\mathbf{r})\right] = m\alpha\left[\frac{\mathbf{v}}{r} - \frac{\mathbf{r}(\mathbf{r}\cdot\mathbf{v})}{r^3}\right] = \frac{d}{dt}m\alpha\frac{\mathbf{r}}{r} \ .\end{aligned}$$

Integration provides a constant of motion, the Lenz vector $\mathbf{C} = m\alpha\frac{\mathbf{r}}{r} - \mathbf{p}\times\mathbf{L}$*,*

$$\begin{aligned}\mathbf{r}\cdot(\mathbf{p}\times\mathbf{L}) &= \alpha\frac{\mathbf{r}}{r} - \mathbf{r}\cdot\mathbf{C} \\ L^2 &= m\alpha r - rC\cos\phi \\ \frac{L^2}{m\alpha - C\cos\phi} = r &= \frac{P}{1-\varepsilon\cos\phi} \ .\end{aligned}$$

So by comparison with the ellipse equation,

$$P = \frac{L^2}{\alpha m} = \frac{b^2v_\infty^2m^2}{\alpha m} \qquad \textit{and} \qquad \varepsilon = \frac{C}{\alpha m} \ .$$

For the absolute value of Lenz's vector C *one gets,*

$$\begin{aligned}C^2 &= m^2\alpha^2 + p^2L^2 - 2m\alpha\cdot\frac{\mathbf{r}}{r}(\mathbf{p}\times\mathbf{L}) = m^2\alpha^2 + p^2L^2 - 2m\alpha L^2\frac{1}{r} \\ &= m^2\alpha^2 + 2mL^2\left(\frac{p^2}{2m} - \frac{\alpha}{r}\right) = m^2\alpha^2 + 2mL^2(E_{kin} + E_{pot}) \\ &= m^2\alpha^2 + m^2L^2v_\infty^2 = m^2\alpha^2 + m^4v_\infty^4b^2 \ ,\end{aligned}$$

since $E = E_{kin} + E_{pot} = \frac{m}{2}v_\infty^2$ *is another constant of motion. In the end,*

$$\varepsilon^2 = 1 + \frac{m^2 v_\infty^4 b^2}{\alpha^2} \ .$$

c. Consider the ellipse equation $r(\phi) = \frac{P}{1-\varepsilon\cos\phi}$ *for* $r \to \pm\infty$,

$$1 - \varepsilon\cos\phi_\infty = 0 \ .$$

It follows,

$$\theta = \phi_{-\infty} + \phi_\infty = 2\arccos\frac{1}{\varepsilon}$$

$$\sin\theta/2 = \sin\arccos\frac{1}{\varepsilon} = \sqrt{1-1/\varepsilon^2} = \sqrt{\frac{\frac{m^2v_\infty^4 b^2}{\alpha^2}}{1+\frac{m^2v_\infty^4 b^2}{\alpha^2}}} = \sqrt{\frac{\kappa^2}{1+\kappa^2}} \ .$$

with the abbreviation $\kappa \equiv \frac{mv_\infty^2 b}{\alpha}$.
d. Given v_∞ *we have that* $\kappa \propto b$. *For the case Fall* $b \to 0$ *we have that* $\theta = 0$, *i.e. the particle is reflected. In the case of* $b \to \infty$, $\theta = \pi$, *i.e. there is no deviation.*

6.3.5.19 Ex: Gravitational force, trajectory

The trajectory of the Kepler problem can be derived from the integral expression:

$$\varphi(r) = \varphi_0 + \int_{r_0}^{r} \frac{l\,dr}{r^2\sqrt{2m(E+\frac{\alpha}{r}) - \frac{l^2}{r^2}}} \ .$$

Here E is the total energy, $\alpha = \gamma_N mM$ and $l = mr^2\dot{\varphi}$. We also introduce the quantities:

$$p = \frac{l^2}{m\alpha} \qquad \text{and} \qquad \varepsilon = \sqrt{1+\frac{2El^2}{m\alpha^2}} \ .$$

a. Convince yourself that, with the substitution $\xi = (p/r - 1)/\varepsilon$, the integral expression can be written in the form:

$$\varphi(r) = \varphi_0 - \int_{\frac{1}{\varepsilon}(\frac{p}{r_0}-1)}^{\frac{1}{\varepsilon}(\frac{p}{r}-1)} \frac{d\xi}{\sqrt{1-\xi^2}} \ .$$

b. Show with the help of energy conservation that the minimum distance from the force center is determined by $r_{\min} = \frac{p}{1+\varepsilon}$ for all values of E.
c. Show that the trajectories for $\varphi_0 = \pi$ and $r = r_{\min}$ are $r(\varphi) = \frac{p}{1-\varepsilon\,\cos\varphi}$, where $\int dx/\sqrt{1-x^2} = \arcsin x$.
d. Confirm that for elliptical trajectories ($0 \le \varepsilon < 1$ and $p = b^2/a^2$ where $a(b)$, the major semi-axis follows Kepler's 3rd law. Use the area theorem.

Solution: *a. The integral can be rewritten with the following substitutions: With* $u = 1/v$ *that is* $\frac{dr}{r^2} = -du$*, we get,*

$$-l \int_{1/r_0}^{1/r} \frac{du}{\sqrt{2mE + 2m\alpha u - l^2 u^2}} \ .$$

With $x = Pu$ *and* $P = l^2/m\alpha$ *we get,*

$$-\int \frac{dx}{\sqrt{2El^2/m\alpha^2 + 2x - x^2}} \ .$$

With $y = x - 1$ *we get,*

$$-\int \frac{dy}{\sqrt{2El^2/m\alpha^2 + 1 - y^2}} \ .$$

With $\xi = y/\epsilon$ *and* $\epsilon = \sqrt{1 + \frac{2El^2}{m\alpha^2}}$ *we get,*

$$-\int \frac{d\xi}{\sqrt{1 - \xi^2}} \ .$$

This results in,

$$\phi = -\int_{\xi_0=(P/r_0-1)/\epsilon}^{\xi=(P/r-1)/\epsilon} \frac{d\xi}{\sqrt{1 - \xi^2}} + \phi_0 \ .$$

b.Energy conservation with $\dot{r} = 0$ *(turning points):*

$$E = \frac{l^2}{2mr^2} - \frac{\alpha}{r} \ ,$$

with $u = 1/r$ *and* $P = l^2/m\alpha$ *follows* $Pu^2 - 2u = 2E/\alpha$*. The solution to this is,*

$$u_{1,2} = \frac{2 \pm \sqrt{4 + 4\frac{2PE}{\alpha}}}{2P} = \frac{1 \pm \varepsilon}{P} \ .$$

The minimum value for r *corresponds to a maximum value of* u*:*

$$\text{for } \varepsilon < 1 \quad , \quad u_{\max} = \frac{1+\varepsilon}{P} \text{ follows } r_{\min} = \frac{P}{1+\varepsilon}$$
$$\text{for } \varepsilon \geq 1 \quad , \quad u_{\max} = \frac{1+\varepsilon}{P} > 0 \text{ follows } r_{\min} = \frac{P}{1+\varepsilon} \ .$$

c. For the integral expression we get $\phi = \arccos\xi + \phi_0 - \arccos\xi_0$*. Insert for* $\phi_0 = \pi$ *the value* $r_0 = r_{\min}$ *and hence* $\xi_0 = \frac{P/r_0-1}{\varepsilon} = 1$*:*

$$\phi = \arccos\xi + \pi - \arccos 1 \ .$$

Follows $\xi = \frac{P/r-1}{\varepsilon} = \cos(\phi - \pi) = -\cos\phi$ *and hence* $r = \frac{P}{1-\varepsilon\cos\phi}$.
d. With the area theorem,

$$\frac{l}{2m} = \frac{\text{total area}}{T} = \frac{\pi ab}{T} \ ,$$

$$\frac{T^2}{a^3} = \frac{4m^2\pi^2 b^2}{l^2 a} \ ,$$

with $P = \frac{b^2}{a} = \frac{l^2}{m\alpha}$

$$\frac{T^2}{a^3} = \frac{4m^2\pi^2 P}{e^2} = \frac{4m\pi^2}{\alpha} = \frac{4\pi^2}{\gamma_N M} = const \ .$$

6.3.5.20 Ex: Central force, trajectory

Consider two masses m_1 and m_2 located at $\mathbf{r}_1$ and $\mathbf{r}_2$. There is an attractive force between them of the amount $F(\mathbf{r}_1, \mathbf{r}_2) = 2\lambda/|\mathbf{r}_1 - \mathbf{r}_2|^3$ ($\lambda > 0$).
a. Specify the angular momentum of the relative motion $\mathbf{l}$ and the energy conservation as a function of $\mathbf{r}$, $\mathbf{p}$ and the reduced mass μ, whereby we may designate by $E > 0$ the total energy of the system.
b. At the time $t = 0$ we let the relative distance of both particles be $r_{\min}$, the relative velocity in the direction of r be zero and $\varphi(r_{\min}) = 0$. Determine the relationship between $r_{\min}$, E, l, λ and μ. Is it possible to eliminate l and λ from the energy conservation law? Calculate the function $r(t)$.
c. Express $\frac{d}{d\varphi} r(\varphi) = \dot{r}/\dot{\varphi}$ as a function of E, l, r and $r_{\min}$ and calculate the trajectory $r(\varphi)$.

Solution: *a. We have,*

$$E = \frac{1}{2}\mu\dot{r}^2 + \frac{l^2}{2\mu r^2} + \frac{\lambda}{r^2} \ .$$

b. From (a) follows with $\dot{r}(r_{\min}) = 0$,

$$\begin{aligned} \frac{\mu}{2}\dot{r}^2 + \frac{l^2}{2\mu r^2} + \frac{\lambda}{r^2} = E = \frac{l^2}{2\mu r_{\min}^2} + \frac{\lambda}{r_{\min}^2} \\ \Rightarrow \frac{l^2}{2\mu} + \lambda = E r_{\min}^2 \\ \Rightarrow E = \frac{\mu}{2}\dot{r}^2 + E\frac{r_{\min}^2}{r^2} \ . \end{aligned}$$

Separation of variables and integration provides,

$$\begin{aligned} \frac{dr}{dt} &= \sqrt{\frac{2E}{\mu}} \frac{1}{r} \sqrt{r^2 - r_{\min}^2} \\ \Rightarrow \int \frac{r dr}{\sqrt{r^2 - r_{\min}^2}} &= \int \sqrt{\frac{2E}{\mu}} dt \\ \Rightarrow r(t) &= \sqrt{r_{\min}^2 + \frac{2E}{\mu} t^2} \ . \end{aligned}$$

c. We have,

$$\frac{dr(\varphi)}{d\varphi} = \frac{\dot{r}}{\dot{\varphi}} = \frac{r^2}{l}\sqrt{2\mu E\left(1 - \frac{r_{\min}^2}{r^2}\right)} \ .$$

Separation of variables and integration provides,

$$\int \frac{dr(\varphi)}{r\sqrt{r^2 - r_{\min}^2}} = \int \frac{\sqrt{2\mu E}}{l} d\varphi$$

$$\Rightarrow -\frac{1}{r_{\min}} \arctan \frac{r_{\min}}{\sqrt{r^2 - r_{\min}^2}} = \frac{\sqrt{2\mu E}}{l}\varphi$$

$$\Rightarrow r = \sqrt{r_{\min}^2 + \frac{r_{\min}^2}{\tan^2\left(\frac{-\sqrt{2\mu E}}{l} r_{\min}\varphi\right)}} = \frac{r_{\min}}{\sin\left(\frac{-\sqrt{2\mu E}}{l} r_{\min}\varphi\right)} = \frac{-r_{\min}}{\sin\left(\varphi\sqrt{1 + \frac{2\mu\lambda}{l^2}}\right)} \ .$$

Hence,

$$r(\varphi) = \frac{r_{\min}}{\cos\Omega\varphi} \ .$$

6.3.5.21 Ex: Ballistic movement

Consider the movement of an intercontinental missile launched at an inclination of θ_0, as shown in the figure, with speed v_0, in the indicated position. Calculate the body's trajectory.

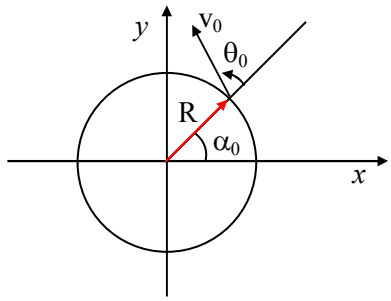

Figure 6.10:

Solution:

6.3.5.22 Ex: Rotation of three bodies

Three identical bodies of mass M are located at the vertices of an equilateral triangle with border length L. How fast should they move, if they all rotate under the influence of mutual gravity, on a circular orbit that circumscribes the triangle always kept

equilateral?

Solution: *With the distance r of each body from the center of origin, the distance between the bodies is $L = 2r\cos\frac{60^\circ}{2} = r\sqrt{3}$. The centripetal force that must act on one of the three masses is,*

$$\mathbf{F}_1 = -\frac{Mv^2}{r}\hat{\mathbf{e}}_r \ .$$

The gravitational force between two bodies is

$$\mathbf{F}_{12} = -\frac{\gamma_N MM}{L^2}\hat{\mathbf{e}}_{12} \ .$$

Equilibrium demands $\mathbf{F}_1 = \mathbf{F}_{12} + \mathbf{F}_{13}$. Hence,

$$-\frac{Mv^2}{r} = -2\frac{\gamma_N MM}{L^2}\cos\tfrac{60^\circ}{2} \ ,$$

Which gives,

$$v = \sqrt{\frac{\gamma_N M}{L}} \ .$$

6.3.5.23 Ex: Rotation of two bodies

Consider two masses m and $2m$ with gravitational attraction. At what angular velocity should they rotate so that the distance d between them is constant?

Solution: *Both masses revolve around the center of mass located at the point,*

$$0 = \mathbf{r}_{cm} = \frac{m\mathbf{r}_m + 2m\mathbf{r}_{2m}}{m+2m} = \frac{1}{3}(\mathbf{r}_m + 2\mathbf{r}_{2m}) \ .$$

Hence, $\mathbf{r}_m = -2\mathbf{r}_{2m}$, or with $d = r_m + r_{2m}$ we have $d = 3r_{2m} = \frac{3}{2}r_m$. Force equilibrium requests,

$$\frac{mv_m^2}{r_m} = \frac{\gamma_N m2m}{d^2} = \frac{2mv_{2m}^2}{r_{2m}} \ ,$$

which gives,

$$\frac{3v_m^2}{2d} = \frac{\gamma_N 2m}{d^2} = \frac{6v_{2m}^2}{d} \ ,$$

and finally,

$$v_m = 2v_{2m} = \sqrt{\frac{4\gamma_N m}{3d}} \ .$$

6.3.5.24 Ex: The virial law

Consider a mathematical spring pendulum with $D = 100\,\mathrm{N/m}$ and an attached mass of $m = 100\,\mathrm{g}$. The average kinetic energy of the pendulum be $\overline{T} = 0.5\,\mathrm{J}$. What is the mean deflection $\overline{x}$ and the mean quadratic deflection $\overline{x^2}$?

Solution: *For $\overline{x}$, integration over a period of oscillation $T = (2\pi\omega_0)^{-1}$ yields,*

$$\overline{x} = \frac{1}{T}\int_0^T A \cdot \sin(2\pi\omega_0 t + \phi) = 0 \ .$$

For $\overline{x^2}$, with $E = \overline{T} + \overline{V}$, we deduce,

$$\overline{T} = \overline{V} = E/2 \qquad \Rightarrow \qquad \frac{1}{2}m\omega_0^2\overline{x^2} = E/2 \qquad \Rightarrow \qquad \overline{x^2} = \frac{E}{m\omega_0^2} = \frac{E}{D} \ ,$$

with $\omega_0 = \sqrt{D/m}$. With $E = 2\overline{T} = 1\,\mathrm{J}$ we get $\overline{x^2} = 0.01\,\mathrm{m}^2$ resp. $\sqrt{\overline{x^2}} = 10\,\mathrm{cm}$. Specifying the mass is not required.

6.4 Outlook on general relativity

The fundamental idea of *general relativity* is the *equivalence* of inert and heavy mass. While special relativity follows from Lorentz invariance, general relativity follows from Lorentz boost invariance, see also Secs. 12.4.3 and 20.5.

Example 29 (*Relativistic correction to Newton's law*): .

6.4.1 Gravitational red-shift

The *gravitational red-shift* $\Delta\omega$ suffered by a clock of mass m can be estimated from (see Sec.36.5.2),

$$\boxed{\hbar\Delta\omega = m\Delta\tfrac{V(\mathbf{r})}{m}} \ , \tag{6.47}$$

where $\Delta V(\mathbf{r})$ is the gravitational potential difference with and without a nearby heavy mass. The mass of the clock is a measure of its pace: $m = E/c^2 = \hbar\omega/c^2$. For instance, on the surface of Earth we get,

$$\hbar\Delta\omega = mg\Delta z = \frac{E}{c^2}g\Delta z = \frac{\hbar\omega}{c^2}g\Delta z \ . \tag{6.48}$$

Hence,

$$\frac{\Delta\omega}{\omega} = \frac{g}{c^2}\Delta z \simeq \Delta z \cdot 10^{-16}\,\mathrm{m}^{-1} \ . \tag{6.49}$$

Chapter 7

Classical mechanics

7.1 The Lagrange formalism

Lagrange function $L = T - V$ with holonomic constraints, $F_i(r_1, r_2, r_3) = A = const$ with $i \in [1, .., e]$,

$$\frac{\delta L}{\delta r_j} + \sum_{i=1}^{e} \lambda_i \frac{\partial F_i}{\partial r_j} = 0 \ . \tag{7.1}$$

with

$$\frac{\delta L}{\delta r_j} \equiv \frac{\partial L}{\partial r_j} - \frac{d}{dt}\frac{\partial L}{\partial \dot{r}_j} \ . \tag{7.2}$$

7.1.1 Exercises

7.1.1.1 Ex: Rigid bodies

Two point masses m and M ($m \neq M$) are connected to the ends of a massless wire of length l, which passes through a hole in a horizontal table; m moves without friction on the table while M does it vertically under the joint action of gravity and tension of the wire (disregard also the friction between the wire and the hole).
a. What initial speed must be given to m in order for M to remain at rest below the table surface?
b. Knowing that the system's Lagrangian is $\mathcal{L} = \frac{1}{2}(m+M)\dot{r}^2 + \frac{1}{2}mr^2\dot{\theta}^2 - Mg(r-l)$, get the equations of motion.
c. Get the conserved quantities and explain the physical meaning of each one.
d. If M were slightly displaced from its vertical position, small oscillations would occur in the system. Calculate the period of these oscillations.

Solution: *a. The balance between centrifugal and gravitational forces requires,*

$$\frac{mv^2}{r} = F_{cp} = T = F_g = Mg \ .$$

Hence,

$$v = \sqrt{\frac{Mgr}{m}} \ .$$

b. Lagrange equations:

$$\frac{\partial \mathcal{L}}{\partial q} = \frac{d}{dt}\frac{\mathcal{L}}{\partial \dot{q}} \ .$$

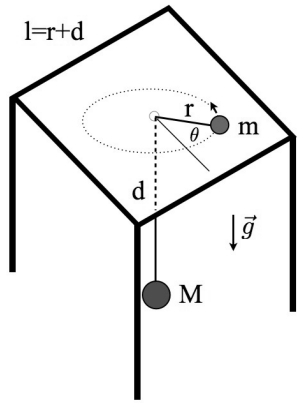

Figure 7.1:

For $q \equiv r$:

$$\frac{\partial \mathcal{L}}{\partial r} = -Mg + mr\dot{\theta}^2 = -Mg + \frac{L^2}{mr^2} = \frac{d}{dt}\frac{\mathcal{L}}{\partial \dot{r}} = (m+M)\ddot{r} \ .$$

where $\mathcal{L} = mr^2\dot{\theta}$ is the angular momentum. For $q \equiv \theta$:

$$\frac{\partial \mathcal{L}}{\partial \theta} = 0 = \frac{d}{dt}\frac{\mathcal{L}}{\partial \dot{\theta}} = \frac{d}{dt}(mr^2\dot{\theta}) \ .$$

In summary, the equations of the movement are:

$$(m+M)\ddot{r} = -Mg + mr\dot{\theta}^2 = -Mg + \frac{L^2}{mr^2}$$
$$\frac{d}{dt}(mr^2\dot{\theta}) = \frac{d}{dt}L = 0 \ .$$

c. Energy,

$$E = T+V = \tfrac{1}{2}(m+M)\dot{r}^2 + \tfrac{1}{2}mr^2\dot{\theta}^2 + Mg(r-l) = \tfrac{1}{2}(m+M)\dot{r}^2 + \frac{L^2}{2mr^2}\dot{\theta}^2 + Mg(r-l) \ .$$

Angular momentum,

$$L = mr^2\dot{\theta} \ .$$

E and L have no explicit dependence on time and are constant.
d. The effective potential is:

$$V_{ef} = Mg(r-l) + \frac{L^2}{2mr^2} \ ,$$

the spring constant is $k = \left.\frac{d^2V_{ef}}{dr^2}\right|_{r_{eq}}$. Calculating the first and second derivatives:

$$\left.\frac{dV_{ef}}{dr}\right|_{r_{eq}} = Mg - \left.\frac{L^2}{mr^3}\right|_{r_{eq}} = 0 \Longrightarrow \ L^2 = Mmgr_{eq}^3$$
$$\left.\frac{d^2V_{ef}}{dr^2}\right|_{r_{eq}} = \left.\frac{3L^2}{mr^4}\right|_{r_{eq}} = \frac{3r_{eq}^3Mmg}{mr_{eq}^4} = \frac{3Mg}{r_{eq}} \ ,$$

we get,

$$T = 2\pi \frac{1}{\sqrt{\frac{h}{M+m}}} = 2\pi \sqrt{\frac{(M+m)r_{eq}}{3Mg}} \ .$$

7.1.1.2 Ex: Trapped particle

A particle of mass m is subject to a one-dimensional potential $V(x) = \frac{1}{2}kx^2 - \frac{k}{4a^2}x^4$, where k and a are positive constants and $-\infty < x < \infty$.
a. Determine the force $F(x)$, obtain the equilibrium points, and determine their nature.
b. Calculate the period of the movement for small oscillations around the stable equilibrium point.
c. Assume that the particle is at rest at the point $x = 0$, and that it receives an impulse that instantly gives it a velocity v oriented in positive x-direction. Discuss what happens in the following cases:
i. $0 < v \leq a\sqrt{k/2m}$,
ii. $v > a\sqrt{k/2m}$.
d. Sketch the system's phase diagram (i.e. $p = m\dot{x}$ vs. x, for $E(x,p) = cte$) for the various types of movement. Indicate clearly the curve that corresponds to the transition between periodic and non-periodic motion, as well as the corresponding energy value.

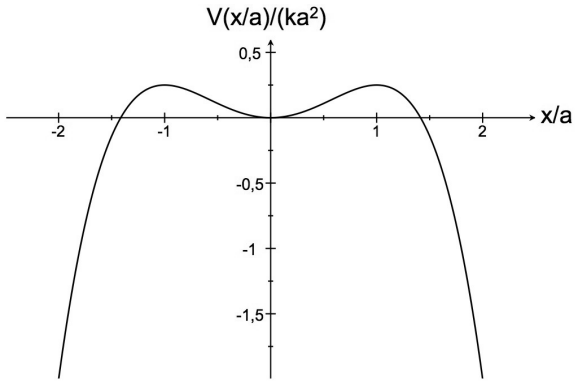

Figure 7.2:

Solution: *a. The force is,*

$$F = -\frac{dV(x)}{dx} = -kx + \frac{k}{a^2}x^3 \ .$$

The equilibrium points are, where the force goes to zero, that is, we have $x = 0$ and $x = \pm a$. As the derivative $D(x) \equiv dF/dx = -k + \frac{k}{a^2}x^2$ is,

$$D(0) < 0 \qquad and \qquad D(\pm a) = 0 \ ,$$

the position $x = 0$ is stable and the points $x = \mp a$ are labile.
b. For small oscillations we can neglect the fourth order of the potential,

$$V(x) \simeq \frac{k}{2}x^2 \ .$$

Hence,

$$\omega = \sqrt{\frac{k}{m}} \ .$$

c. The height of the potential at the points $\pm\alpha$ is,

$$V(\pm a) = \frac{k}{4}a^2 \ .$$

The kinetic energy corresponding to the initial velocity $v_0 = a\sqrt{k/2m}$ is,

$$E_{kin} = \frac{m}{2}v^2 = \frac{m}{2}\frac{ka^2}{2m} = \frac{k}{4}a^2 \ .$$

Therefore, the particle is trapped when $v_0 = a\sqrt{k/2m}$.
d. Phase diagram:

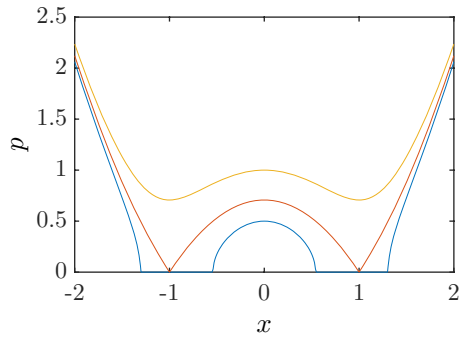

Figure 7.3:

7.1.1.3 Ex: Satellite

An artificial satellite of mass m_1 on an elliptical orbit around the Earth has its maximum and minimum distances from the **surface** of the Earth given by h and H, respectively. It is also known that the maximum approximation occurs over the North Pole. A particle of mass $m_2 = m_1/10$ collides centrally and completely inelastically with the satellite, exactly when it is passing over the North Pole. At the time of the collision, the absolute value of the satellite's speed was v_1 and the particle had the same speed, but in the opposite direction to the satellite. Assume that the Earth is a sphere of uniform density with radius R and mass M; despise air resistance.
a. Obtain the speed v_S of the 'satellite+mass' system after the collision in terms of v_1?

b. Obtain the speed v_1 of the satellite before the collision.
c. Obtain the energy and the angular momentum of the 'satellite+mass' system in terms of quantities that characterize the satellite's movement before the collision (i.e., mass, speed, and position).
d. Obtain the equation for the orbit of the 'satellite+mass' system.

Solution: *a. Moment conservation during the inelastic collision with* $v_2 = -v_1$ *and* $m_2 = m_1/10$

$$(m_1 + m_2)v_S = m_1 v_1 + m_2 v_2$$
$$\Longrightarrow \; v_S = \frac{m_1 - m_2}{m_1 + m_2} v_1 = \frac{0.9}{1.1} v_1 \; .$$

b. Conservation of energy and angular momentum with $r_h = R_T + h$ *and* $r_H = R_T + H$,

$$E \equiv \frac{m_1}{2} v_H^2 - \frac{GM_T m_1}{r_H} = \frac{m_1}{2} v_h^2 - \frac{GM_T m_1}{r_h}$$
$$L \equiv m_1 r_H v_H = m_1 r_h v_h \; .$$

Solving the second equation by v_H *and replacing in the first,*

$$\left(\frac{r_h}{r_H} v_h\right)^2 - \frac{2GM_T}{r_H} = v_h^2 - \frac{2GM_T}{r_h}$$
$$\Longrightarrow \; v_h = \sqrt{\frac{2GM_T r_H}{r_h(r_h + r_H)}} \; .$$

c. Energy at the instant after the collision,

$$E_S = \frac{m_1 + m_2}{2} v_S^2 - \frac{GM_T(m_1 + m_2)}{r_h} = \frac{(m_1 - m_2)^2}{2(m_1 + m_2)} v_1^2 - \frac{GM_T(m_1 + m_2)}{r_h} \; .$$

Angular momentum,

$$\vec{L}_S = (m_1 + m_2)\vec{r}_h \times \vec{v}_S = (m_1 + m_2) r_h \frac{m_1 - m_2}{m_1 + m_2} v_1 \hat{e}_L = (m_1 - m_2) r_h v_1 \hat{e}_L = \tfrac{9}{10}\vec{L} \; ,$$

d. The equation for the orbit is, according to the problem,

$$r(\phi) = \frac{p}{1 + \epsilon \cos\phi} \qquad \textit{where} \qquad p = \frac{L^2}{GM_T m} \qquad \textit{and} \qquad \epsilon = \sqrt{1 + \frac{2EL^2}{(GM_T)^2 m}} \; .$$

Substituting E_S, L_S, *and* m_S *we obtain the orbit equation after the collision. The orbit remains bound* ($E_S < 0$), *i.e. like an ellipse with the center of the Earth in one of the foci.*

7.1.1.4 Ex: Rigid bodies

A simple pendulum consists of a particle of mass m suspended by an inextensible wire of length a and with negligible mass. Its suspension point is connected to a support

that moves horizontally without friction, as shown in the figure. Suppose that the support is small enough and that the pendulum moves only in the vertical plane. Using as generalized coordinates x and θ, where x is the horizontal position of the support and θ the angular displacement of the pendulum, as shown in the figure. The movement of the system is described by the Lagrangian:

$$\mathcal{L} = \frac{m}{2}\dot{x}^2 + \frac{m}{2}\left(a^2\dot{\theta}^2 + 2a\dot{x}\dot{\theta}\cos\theta\right) + mga\cos\theta \ .$$

a. Get the equation of motion for the coordinate θ.
b. Assuming that the angular displacements are small and that the movement of the support is harmonic and described by $x(t) = x_0\cos\omega t$, obtain the general solution $\theta(t)$ of the equation of motion for the coordinate θ.
c. In the case of the previous item, obtain the resonance frequency ω_R.
d. Write down the general solution for $\theta(t)$, when the initial conditions are $\theta(0) = 0$ and $\dot{\theta}(0) = 0$ and the support moves with the frequency $\omega < \omega_R$.

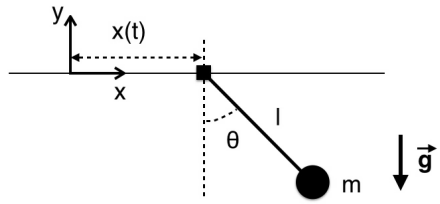

Figure 7.4:

Solution: *a. Inserting $\mathcal{L}$ into the Lagrange equation,*

$$\frac{d}{dt}\frac{\partial\mathcal{L}}{\partial\dot{\theta}} - \frac{\partial\mathcal{L}}{\partial\theta} = 0$$

gives

$$\begin{aligned}
&\frac{d}{dt}\left(ml^2\dot{\theta} + ml\dot{x}\cos\theta\right) - \left(-ml\dot{x}\dot{\theta}\sin\theta - mgl\sin\theta\right) \\
&= ml^2\ddot{\theta} + ml\ddot{x}\cos\theta - ml\dot{x}\dot{\theta}\sin\theta + ml\dot{x}\dot{\theta}\sin\theta + mgl\sin\theta \\
&= ml^2\ddot{\theta} + ml\ddot{x}\cos\theta + mgl\sin\theta = 0 \ ,
\end{aligned}$$

or

$$\ddot{\theta} + \frac{\ddot{x}}{l}\cos\theta + \frac{g}{l}\sin\theta = 0 \ .$$

b. In the limit of small oscillations, $\cos \to 1$ *and* $\sin \to \theta$*. This simplifies the equation of motion to,*

$$\ddot{\theta} + \frac{g}{l}\theta = -\frac{\ddot{x}}{l} \ .$$

Inserting $\ddot{x}(t) = -x_0\omega^2\cos\omega t$ *and defining* $\omega_0 = \sqrt{g/l}$*, we obtain the equation of motion for this particular movement of the support in the limit of small oscillations,*

$$\ddot{\theta} + \omega_0^2\theta = \frac{1}{l}x_0\omega^2\cos\omega t \ ,$$

whose solution is a superposition of the general homogeneous solution (1) with a particular inhomogeneous solution (2):

$$\theta_g(t) = a\cos\omega_0 t + b\sin\omega_0 t \ ,$$
$$\theta_p(t) = A\cos(\omega t + \delta) \ .$$

Inserting the particular solution into a differential equation,

$$A = \frac{x_0\omega^2}{l|\omega_0^2 - \omega^2|} \ ,$$

with the sign + for $\omega < \omega_0$, i.e. $\delta = 0$ and the sign − for $\omega > \omega_0$, i.e. $\delta = -\pi$. (The sign $\pm$ refers to the phase δ, which in this frictionless case is simply '+' when $\omega_0 > \omega$ and '-' when $\omega_0 < \omega$. Finally,

$$\theta(t) = a\cos\omega_0 t + b\sin\omega_0 t \pm \frac{x_0\omega^2}{l|\omega_0^2 - \omega^2|}\cos(\omega t) \ .$$

c. We have,

$$\omega_R = \omega_0 = \sqrt{g/l} \ .$$

d. With the initial condition $\theta(0) = 0$ we have,

$$\alpha + \frac{x_0\omega^2}{l(\omega_0^2 - \omega^2)} = 0 \ ,$$

that is, $\alpha = -\frac{x_0\omega^2}{l(\omega_0^2-\omega^2)}$. Also,

$$\dot\theta(t) = -\frac{x_0\omega^3\sin\omega t}{l(\omega_0^2 - \omega^2)} - \alpha\omega_0\sin\omega_0 t + b\omega_0\cos\omega_0 t \ .$$

that is $b = 0$. Finally,

$$\theta(t) = -\frac{x_0\omega^2}{l(\omega_0^2 - \omega^2)}(\cos\omega_0 t - \cos\omega t) \ .$$

7.1.1.5 Ex: Tritium atom

A tritium atom can be classically described as a nucleus with an electric charge $+e$, composed of a proton and two neutrons, orbited by an electron of charge $-e$ on a circular orbit of radius r_0. In a process known as β-decay, the nucleus of the tritium atom turns into an ionized helium atom, whose nucleus is composed of two protons and one neutron, emitting a pair of particles that quickly escape from the atomic system. As a consequence the electron suddenly perceives a new situation now orbiting a nucleus of charge $+2e$. The nucleus has a mass large enough to be considered at rest.
a. Obtain the energy E_a of the electron orbital before β-decay.
b. Calculate the energy E_d of the electron after the β- decay and get the ratio

$\rho = E_a/E_d$.
c. Determine the total angular momentum of the electron only as a function of r_0 and the electron mass m_e.
d. Calculate the largest and smallest distances between the electron and the nucleus in the new orbit in terms of r_0.

Solution: *a. The orbit is circular:*

$$\frac{mv_0^2}{r_0} = F_{electrostatic} = \frac{e^2}{4\pi\epsilon_0 r_0^2} \ .$$

Introducing $C = mv_0^2 = \frac{e^2}{4\pi\epsilon_0 r_0}$ *and writing the energy* E_a *of the orbit before the decay:*

$$E_a = \frac{mv_0^2}{2} - \frac{e^2}{4\pi\epsilon_0 r_0} = -\tfrac{1}{2}C \ .$$

b. In the instant the decay occurs, the orbital electron has the velocity v_0*, but its potential energy has suddenly changed to* $\frac{-2e^2}{4\pi\epsilon_0 r_0}$*. Hence.*

$$E_b = \frac{mv_0^2}{2} - \frac{2e^2}{4\pi\epsilon_0 r_0} = -\frac{3}{2}\frac{e^2}{4\pi\epsilon_0 r_0} = -\tfrac{3}{2}C \ .$$

So the ratio is,

$$\rho = E_a/E_d = \frac{1}{3} \ .$$

c. The electron orbital angular momentum is also constant: it has the same value as in the instant when the β*-decay occurred. Writing down the energy conservation:*

$$E_d = -\frac{3}{2}\frac{e^2}{4\pi\epsilon_0 r_0} = -\frac{2e^2}{4\pi\epsilon_0 r_0} + \frac{m\dot{r}^2}{2} + \frac{mr^2\dot{\theta}^2}{2} = -2\frac{e^2}{4\pi\epsilon_0 r_0}\frac{r_0}{r} + \frac{m\dot{r}^2}{2} + \frac{L^2\dot{\theta}^2}{2mr^2} \ .$$

Calculating the angular momentum at the instant of the decay in terms of r_0 *and* m*:*

$$L = mr_0 v_0 = mr_0\sqrt{\frac{1}{r}\frac{e^2}{4\pi\epsilon_0 r_0}} = \sqrt{\frac{me^2 r_0}{4\pi\epsilon_0}} \ ,$$

or also

$$\frac{L^2}{2mr^2} = \frac{1}{2mr^2}\frac{me^2}{4\pi\epsilon_0 r_0}r_0^2 = \frac{1}{2}\frac{e^2}{4\pi\epsilon_0 r_0}\frac{r_0^2}{r^2} = \frac{1}{2}C\frac{r_0^2}{r^2} \ .$$

d. For the points of maximum and minimum approximation, $\dot{r} = 0$*, we get,*

$$-\frac{3}{2}C = -2C\frac{r_0}{r} + \frac{1}{2}\frac{r_0^2}{r^2} \ .$$

Hence,

$$\frac{1}{2}\left(\frac{r_0}{r}\right)^2 - 2\frac{r_0}{r} + \frac{3}{2} = 0 \ ,$$

with the roots:

$$\frac{r_0}{r} = 3 \qquad \textit{and} \qquad \frac{r_0}{r} = 1 \ ,$$

and hence,

$$r_{max} = r_0 \qquad \textit{and} \qquad r_{min} = \frac{1}{3}r_0 \ .$$

7.1.1.6 Ex: Pendulum in a wagon

Consider a mathematical pendulum of mass m and length L suspended in a wagon of mass M initially at rest, as shown in the figure. Derive the equations of motion for the pendulum and the wagon including a friction for the movement of the wagon. Approximate for small oscillation amplitudes.

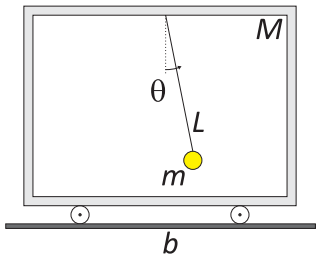

Figure 7.5: Pendulum in a wagon.

Solution: *If X is the position of the wagon, the pendulum position is,*

$$x = L\sin\theta + X \qquad , \qquad y = -L\cos\theta \ .$$

So we have four generalized coordinates, θ, $\dot\theta$, X, and $\dot X$. The kinetic energy of the system is,

$$\begin{aligned} T &= \tfrac{M}{2}\dot X^2 + \tfrac{m}{2}\dot x^2 + \tfrac{m}{2}\dot y^2 \\ &= \tfrac{M}{2}\dot X^2 + \tfrac{m}{2}(\ell\dot\theta\cos\theta + \dot X)^2 + \ell^2\tfrac{m}{2}\dot\theta^2\sin^2\theta \\ &= \tfrac{M}{2}\dot X^2 + \tfrac{m}{2}\ell^2\dot\theta^2 + m\ell\dot X\dot\theta\cos\theta + \tfrac{m}{2}\dot X^2 \ , \end{aligned}$$

and the potential energy,

$$V = mgy = -mg\ell\cos\theta$$

and the Lagrangian $L = T - V$. We calculate,

$$\begin{aligned} \frac{d}{dt}\frac{\partial\mathcal{L}}{\partial\dot\theta} &= \frac{d}{dt}(m\ell^2\dot\theta + m\ell\dot X\cos\theta) = m\ell^2\ddot\theta + m\ell\ddot X\cos\theta - m\ell\dot X\dot\theta\sin\theta \\ \frac{\partial\mathcal{L}}{\partial\theta} &= -m\ell\dot X\dot\theta\sin\theta - mg\ell\sin\theta \\ \frac{d}{dt}\frac{\partial\mathcal{L}}{\partial\dot X} &= \frac{d}{dt}(M\dot X + m\ell\dot\theta\cos\theta + m\dot X) = M\ddot X + m\ell\ddot\theta\cos\theta - m\ell\dot\theta^2\sin\theta + m\ddot X \\ \frac{\partial\mathcal{L}}{\partial X} &= 0 \ . \end{aligned}$$

The Lagrange equations are,

$$\begin{aligned} 0 &= \frac{d}{dt}\frac{\partial\mathcal{L}}{\partial\dot\theta} - \frac{\partial\mathcal{L}}{\partial\theta} = m\ell^2\ddot\theta + m\ell\ddot X\cos\theta + mg\ell\sin\theta \\ 0 &= \frac{d}{dt}\frac{\partial\mathcal{L}}{\partial\dot X} - \frac{\partial\mathcal{L}}{\partial X} = M\ddot X + m\ell\ddot\theta\cos\theta - m\ell\dot\theta^2\sin\theta + m\ddot X - 0 \ . \end{aligned}$$

For small angles,

$$0 = m\ell\ddot{\theta} + m\ddot{X} + mg\theta$$
$$0 = (M+m)\ddot{X} + m\ell\ddot{\theta} - m\ell\dot{\theta}^2\theta \ ,$$

or,

$$\ell\ddot{\theta} = -g\theta - \ddot{X}$$
$$M\ddot{X} = mg\theta + m\ell\dot{\theta}^2\theta \ .$$

The last term corresponds to the centrifugal force and is small for small angles,

$$\ddot{\theta} \simeq -\frac{g}{\ell}\left(1 + \frac{m}{M}\right)\theta \ .$$

7.1.1.7 Ex: Two pendulums in a wagon

Consider two pendulums of mass m and length L suspended inside a wagon of mass M initially at rest, as shown in the figure.
a. Making the approximation for small oscillation amplitudes, derive the equations of motion for each pendulum and for the wagon including a damping due to friction of the moving wagon.
b. Calculate the oscillation frequencies of the collective modes. Which mode is most subject to friction?

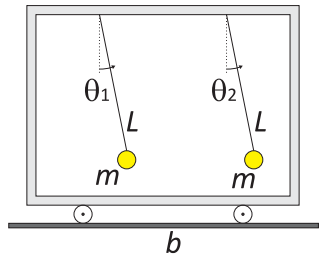

Figure 7.6: Two pendulums in a wagon.

Solution: *a. If X is the position of the wagon, the pendulum positions are,*

$$x_1 = L\sin\theta_1 + X \quad , \quad x_2 = L\sin\theta_2 + X \quad , \quad y_1 = -L\cos\theta_1 \quad , \quad y_2 = -L\cos\theta_2 \ .$$

So we have six generalized coordinates, θ_1, $\dot{\theta}_1$, θ_2, $\dot{\theta}_2$, X and $\dot{X}$. In analogy with the single-pendulum system we calculate,

$$\begin{aligned} T &= \tfrac{M}{2}\dot{X}^2 + \tfrac{m}{2}\dot{x}_1^2 + \tfrac{m}{2}\dot{x}_2^2 + \tfrac{m}{2}\dot{y}_1^2 + \tfrac{m}{2}\dot{y}_2^2 \\ &= \tfrac{M}{2}\dot{X}^2 + \tfrac{m}{2}\ell^2\dot{\theta}_1^2 + m\ell\dot{X}\dot{\theta}_1\cos\theta + \tfrac{m}{2}\ell^2\dot{\theta}_2^2 + m\ell\dot{X}\dot{\theta}_2\cos\theta_2 + m\dot{X}^2 \ , \end{aligned}$$

and the potential energy,

$$V = mgy_1 + mgy_2 = -mg\ell\cos\theta_1 - mg\ell\cos\theta_2$$

and the Lagrangian $\mathcal{L} = T - V$*. We calculate,*

$$\begin{aligned}
\frac{d}{dt}\frac{\partial\mathcal{L}}{\partial\dot\theta_1} &= m\ell^2\ddot\theta_1 + m\ell\ddot X\cos\theta_1 - m\ell\dot X\dot\theta_1\sin\theta_1\\
\frac{\partial\mathcal{L}}{\partial\theta_1} &= -m\ell\dot X\dot\theta\sin\theta_1 - mg\ell\sin\theta_1\\
\frac{d}{dt}\frac{\partial\mathcal{L}}{\partial\dot\theta_2} &= m\ell^2\ddot\theta_2 + m\ell\ddot X\cos\theta_2 - m\ell\dot X\dot\theta_2\sin\theta_2\\
\frac{\partial\mathcal{L}}{\partial\theta_2} &= -m\ell\dot X\dot\theta\sin\theta_2 - mg\ell\sin\theta_2\\
\frac{d}{dt}\frac{\partial\mathcal{L}}{\partial\dot X} &= M\ddot X + m\ell\ddot\theta_1\cos\theta_1 - m\ell\dot\theta_1^2\sin\theta_1 + m\ell\ddot\theta_2\cos\theta_2 - m\ell\dot\theta_2^2\sin\theta_2 + 2m\ddot X\\
\frac{\partial\mathcal{L}}{\partial X} &= 0\ .
\end{aligned}$$

Lagrange's equations become for small angles,

$$\begin{aligned}
0 &= m\ell\ddot\theta_1 + m\ddot X + mg\theta_1\\
0 &= m\ell\ddot\theta_2 + m\ddot X + mg\theta_2\\
0 &= M\ddot X + m\ell\ddot(\theta_1+\theta_2) - m\ell(\dot\theta_1^2\theta_1 + \dot\theta_2^2\theta_2) + 2m\ddot X\ .
\end{aligned}$$

or neglecting non-linear terms,

$$\ddot\Psi = -\frac{g}{\ell}\Psi - \frac{2}{\ell}\ddot X \qquad , \qquad \ddot\aleph = -\frac{g}{\ell}\aleph \qquad , \qquad (M+2m)\ddot X \simeq -m\ell\ddot\Psi\ .$$

or,

$$\ddot\Psi = -\frac{g}{\ell}\left(1+\frac{2m}{M}\right)\Psi \qquad , \qquad \ddot\aleph = -\frac{g}{\ell}\aleph \qquad , \qquad \ddot X = \frac{mg}{M}\Psi\ .$$

b. The frequencies of the normal modes are $\omega = 0$ *for the uniform movement of the entire system,* $\omega = \sqrt{g/\ell}$ *for the oscillation with opposite phases, and* $\omega = \sqrt{\frac{g}{\ell}(1+2m/M)}$ *for the in-phase oscillation.*

7.1.1.8 Ex: Two pendulums in a wagon attached by a spring

Repeat the previous exercise, but now the car is attached to a wall by a spring k.

Solution: *The generalized coordinates and the kinetic energy remain the same, but the potential energy changes to,*

$$V = -mg\ell\cos\theta_1 - mg\ell\cos\theta_2 + \frac{k}{2}X^2\ .$$

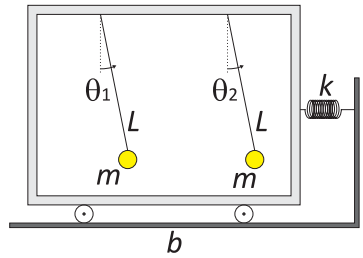

Figure 7.7: Two pendulums in a wagon.

Recalculating the Lagrangian $\mathcal{L} = T - V$ of the car movement,

$$\frac{d}{dt}\frac{\partial \mathcal{L}}{\partial \dot{X}} = M\ddot{X} + m\ell\ddot{\theta}_1\cos\theta_1 - m\ell\dot{\theta}_1^2\sin\theta_1 + m\ell\ddot{\theta}_2\cos\theta_2 - m\ell\dot{\theta}_2^2\sin\theta_2 + 2m\ddot{X}$$
$$\frac{\partial \mathcal{L}}{\partial X} = kX \ .$$

Lagrange's equations become for small angles,

$$0 = m\ell\ddot{\theta}_1 + m\ddot{X} + mg\theta_1$$
$$0 = m\ell\ddot{\theta}_2 + m\ddot{X} + mg\theta_2$$
$$0 = M\ddot{X} + m\ell\ddot{(}\theta_1 + \theta_2) - m\ell(\dot{\theta}_1^2\theta_1 + \dot{\theta}_2^2\theta_2) + 2m\ddot{X} - kX \ .$$

or neglecting non-linear terms,

$$\ddot{\Psi} = -\frac{g}{\ell}\Psi - \frac{2}{\ell}\ddot{X} \quad , \quad \ddot{\aleph} = -\frac{g}{\ell}\aleph \quad , \quad (M+2m)\ddot{X} \simeq -kX - m\ell\ddot{\Psi} \ .$$

or,

$$\ddot{\Psi} = -\frac{g}{\ell}\left(1 + \frac{2m}{M}\right)\Psi + \frac{2k}{M\ell}X \quad , \quad \ddot{\aleph} = -\frac{g}{\ell}\aleph \quad , \quad \ddot{X} = \frac{-k}{M}X + \frac{mg}{M}\Psi \ .$$

7.1.1.9 Ex: Super- and subradiance

We consider two pendulums of mass m and length ℓ suspended on a rod of mass M that itself is suspended to an immobile ceiling by wires of length L, as shown in the figure. Derive the equations for collective modes including damping for small amplitudes.

Solution: *The position of the rod is,*

$$X = L\sin\Theta \quad , \quad Y = -L\cos\Theta \ .$$

The pendulum positions are,

$$x_1 = \ell\sin\theta_1 + L\sin\Theta \quad , \quad y_1 = -\ell\cos\theta_1 - L\cos\Theta$$
$$x_2 = \ell\sin\theta_2 + L\sin\Theta \quad , \quad y_2 = -\ell\cos\theta_2 - L\cos\Theta \ .$$

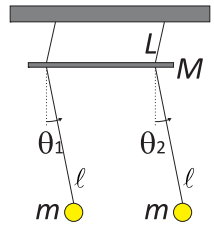

Figure 7.8: Super- and subradiance.

So we have six generalized coordinates, θ_1, $\dot\theta_1$, θ_2, $\dot\theta_2$, Θ e $\dot\Theta$. In analogy with the single-pendulum system we calculate,

$$\begin{aligned}
T &= \tfrac{M}{2}\dot X^2 + \tfrac{M}{2}\dot Y^2 + \tfrac{m}{2}\dot x_1^2 + \tfrac{m}{2}\dot y_1^2 + \tfrac{m}{2}\dot x_2^2 + \tfrac{m}{2}\dot y_2^2 \\
&= \tfrac{3M}{2}L^2\dot\Theta^2 + \tfrac{m}{2}\ell^2\dot\theta_1^2 + mL\ell\dot\theta_1\cos\theta_1\dot\Theta\cos\Theta + mL\ell\dot\theta_1\sin\theta_1\dot\Theta\sin\Theta \\
&\quad + \tfrac{m}{2}\ell^2\dot\theta_2^2 + mL\ell\dot\theta_2\cos\theta_2\dot\Theta\cos\Theta + mL\ell\dot\theta_2\sin\theta_2\dot\Theta\sin\Theta \\
&= \tfrac{3M}{2}L^2\dot\Theta^2 + \tfrac{m}{2}\ell^2\dot\theta_1^2 + mL\ell\dot\theta_1\dot\Theta\cos(\theta_1-\Theta) + \tfrac{m}{2}\ell^2\dot\theta_2^2 + mL\ell\dot\theta_2\dot\Theta\cos(\theta_2-\Theta)\ ,
\end{aligned}$$

and the potential energy,

$$V = mgY + mgy_1 + mgy_2 = -MgL\cos\Theta - mg\ell\cos\theta_1 - mg\ell\cos\theta_2\ .$$

The Lagrangian $\mathcal{L} = T - V$ is,

$$\begin{aligned}
\frac{d}{dt}\frac{\partial\mathcal{L}}{\partial\dot\Theta} &= 3ML^2\ddot\Theta + mL\ell\ddot\theta_1\cos(\theta_1-\Theta) - mL\ell\dot\theta_1(\dot\theta_1-\dot\Theta)\sin(\theta_1-\Theta) \\
&\quad + mL\ell\ddot\theta_2\cos(\theta_2-\Theta) - mL\ell\dot\theta_2(\dot\theta_2-\dot\Theta)\sin(\theta_2-\Theta) \\
\frac{\partial\mathcal{L}}{\partial\Theta} &= mL\ell\dot\theta_1\dot\Theta\sin(\theta_1-\Theta) + mL\ell\dot\theta_2\dot\Theta\sin(\theta_2-\Theta) - MgL\sin\Theta \\
\frac{d}{dt}\frac{\partial\mathcal{L}}{\partial\dot\theta_1} &= m\ell^2\ddot\theta_1 + mL\ell\ddot\Theta\cos(\theta_1-\Theta) - mL\ell\dot\Theta(\dot\theta_1-\dot\Theta)\sin(\theta_1-\Theta) \\
\frac{\partial\mathcal{L}}{\partial\theta_1} &= -mL\ell\dot\theta_1\dot\Theta\sin(\theta_1-\Theta) - mg\ell\sin\theta_1 \\
\frac{d}{dt}\frac{\partial\mathcal{L}}{\partial\dot\theta_2} &= m\ell^2\ddot\theta_2 + mL\ell\ddot\Theta\cos(\theta_2-\Theta) - mL\ell\dot\Theta(\dot\theta_2-\dot\Theta)\sin(\theta_2-\Theta) \\
\frac{\partial\mathcal{L}}{\partial\theta_2} &= -mL\ell\dot\theta_2\dot\Theta\sin(\theta_2-\Theta) - mg\ell\sin\theta_2\ .
\end{aligned}$$

The Lagrange equations are,

$$\begin{aligned}
0 &= 3ML\ddot\Theta + m\ell\ddot\theta_1\cos(\theta_1-\Theta) - m\ell\dot\theta_1^2\sin(\theta_1-\Theta) \\
&\quad + m\ell\ddot\theta_2\cos(\theta_2-\Theta) - m\ell\dot\theta_2^2\sin(\theta_2-\Theta) + Mg\sin\Theta \\
0 &= \ell\ddot\theta_1 + L\ddot\Theta\cos(\theta_1-\Theta) + L\dot\Theta^2\sin(\theta_1-\Theta) + g\sin\theta_1 \\
0 &= \ell\ddot\theta_2 + L\ddot\Theta\cos(\theta_2-\Theta) + L\dot\Theta^2\sin(\theta_2-\Theta) + g\sin\theta_2\ .
\end{aligned}$$

For small angles and neglecting nonlinear terms,

$$\ddot{\Theta} = -\frac{g}{3L}\Theta - \frac{m\ell}{3ML}(\ddot{\theta}_1 + \ddot{\theta}_2) \quad , \quad \ddot{\theta}_1 = -\frac{g}{\ell}\theta_1 - \frac{L}{\ell}\ddot{\Theta} \quad , \quad \ddot{\theta}_2 = -\frac{g}{\ell}\theta_2 - \frac{L}{\ell}\ddot{\Theta} \; .$$

or,

$$\ddot{\Theta} = -\frac{g}{3L}\Theta - \frac{m\ell}{3ML}\ddot{\Psi} \quad , \quad \ddot{\Psi} = -\frac{g}{\ell}\Psi - \frac{2L}{\ell}\ddot{\Theta} \quad , \quad \ddot{\aleph} = -\frac{g}{\ell}\aleph \; ,$$

or,

$$\ddot{\Theta} = -\frac{1}{1-\frac{2m}{3M}}\frac{g}{3L}\Theta - \frac{1}{1-\frac{3M}{2m}}\frac{\ell g}{2L^2}\psi \quad , \quad \ddot{\Psi} = -\frac{1}{1-\frac{2m}{3M}}\frac{g}{L}\psi + \frac{1}{1-\frac{2m}{3M}}\frac{2g}{3\ell}\Theta \quad , \quad \ddot{\aleph} = -\frac{g}{\ell}\aleph \; .$$

Chapter 8

Hydrodynamics

8.1 Foundations

8.1.1 Archimedes' principle, buoyancy

The density of a substance is the quotient between its mass and its volume,

$$\rho \equiv \frac{m}{V} \ . \tag{8.1}$$

Archimedes' principle says that

> A body immersed in a liquid undergoes the action of an upward force, whose absolute value is equal to the weight of the volume of liquid displaced by the body.

Let us consider a liquid, with density ρ, in hydrostatic equilibrium inside a container and highlight a portion of it, with volume V, as shown in Fig. 8.1(a). In order to have hydrostatic equilibrium, it is necessary that the sum over all forces acting on the highlighted volume of liquid be zero. One of these forces is the weight,

$$\mathbf{P} = m\mathbf{g} = \rho V \mathbf{g} \ , \tag{8.2}$$

of the volume V. The other force is the sum $\mathbf{E}$ over all pressure forces that the remaining liquid exerts on the surface of the volume V, Fig. 8.1(b). That is,

$$\mathbf{P} + \mathbf{E} = 0 \ . \tag{8.3}$$

Thus, the force $\mathbf{E}$ which 'pushes' the highlighted portion of liquid, has a magnitude equal to its weight, $E = P = \rho V g$, and is called *buoyancy*.

In case that the highlighted volume V is filled with another body with density ρ' different from that of the liquid ρ, the buoyancy will not change. That is, the buoyancy E will always be the weight of the liquid of density ρ displaced by the body of density ρ' that has been introduced in its interior.

On the other hand, the new weight of the volume is $P' = \rho' m V$. In the case $\rho > \rho'$, the body submerged in the liquid will rise to the surface, since the buoyancy exerted by the liquid will be greater than the weight of the body. Otherwise, when $\rho < \rho'$, the submerged body will sink to the bottom of the container. In both cases, the submerged body will not stay in hydrostatic equilibrium. Resolve the Exc. 8.1.2.1.

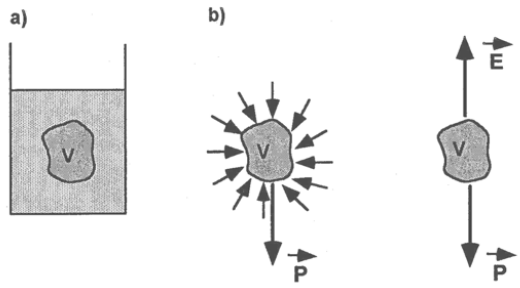

Figure 8.1: Representation of the forces acting on a body submerged in a liquid.

8.1.2 Exercises

8.1.2.1 Ex: Critical buoyancy and Cartesian diver

A balloon is filled at atmospheric pressure with 1 liter of air. An aluminum weight of 1 kg is attached to it. The whole setup is now immersed into water. Calculate the total force acting on the setup as function of the depth of immersion.

Solution: *The buoyancy of the balloon is given by,*

$$B_{bal} = g\rho_{wat}V_{bal} \ ,$$

where the volume of the balloon adjusts to the water pressure at a given depth,

$$pV_{bal} = Nk_BT \ .$$

Assuming a constant water temperature, we find,

$$V_{bal}(z) = \frac{p(0)}{p(z)}V_{bal}(0) \ ,$$

where the underwater pressure is,

$$p(z) = g\rho_{wat}z + p(0) \ .$$

The buoyancy of the aluminum weight is given by,

$$B_{wei} = g\rho_{wat}V_{Al} = m_{wei}g\frac{\rho_{wat}}{\rho_{Al}} \ .$$

It is independent on the depth, because aluminium is incompressible. The total force is now,

$$\begin{aligned} F = B_{bal} + B_{wei} - m_{wei}g &= \frac{g\rho_{wat}}{g\rho_{wat}z + p(0)}p(0)V_{bal}(0) + m_{wei}g\frac{\rho_{wat}}{\rho_{Al}} - m_{wei}g \\ &\simeq \frac{p(0)V_{bal}(0)}{z} - m_{wei}g\left(1 - \frac{\rho_{wat}}{\rho_{Al}}\right) \ , \end{aligned}$$

neglecting the atmospheric pressure $p(0)$. The force balances at $F = 0$ that is

$$z_0 \simeq \frac{p(0)V_{bal}(0)}{m_{wei}g\left(1 - \frac{\rho_{wat}}{\rho_{Al}}\right)} \simeq \frac{p(0)V_{bal}(0)}{m_{wei}g} \ ,$$

neglecting the buoyancy of the weight. Hence,

$$F \simeq p(0)V_{bal}(0)\left(\frac{1}{z} - \frac{1}{z_0}\right) \ .$$

That for z above the critical depth $z_0 \approx 10$ m, the force is directed upward. Else downward.

8.1.2.2 Ex: Buoyancy of a a wooden ball in a liquid

A wooden ball of density m is trapped at depth h in a liquid of density density ρ. Releasing the ball from its position, determine how high above the surface it will float.

Solution:

8.1.2.3 Ex: Buoyancy of oil

Three containers with false bottoms (see figure) were placed in water at the same depth. Filling into the three bottles the same amount of oil, which one of the three bottoms will fall first? Justify!

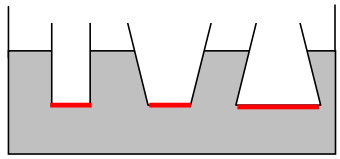

Figure 8.2: Buoyancy of oil.

Solution:

8.1.2.4 Ex: A tank

A lidless rectangular tank, with the dimensions given in the figure, moves with an acceleration a and contains water up to a height of h (when $a = 0$). At what value of the acceleration will the water begin to flow out?

Solution:

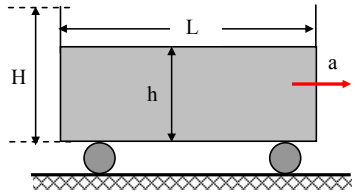

Figure 8.3: Scheme of the tank.

8.1.2.5 Ex: Buoyancy in mercury and water

A cube of a certain material floats in a container containing mercury ($\rho_{Hg} = 13.6\,\mathrm{g/cm^3}$) such that 1/4 of its volume is submerged. Adding enough water to the system to cover the cube ($\rho_{water} = l\,\mathrm{g/cm^3}$), what fraction of its volume will still remain immersed in mercury?

Solution:

8.1.2.6 Ex: Immersion

A board of length L leans on a stone and is partially immersed in water. As the figure shows, a portion of length a is above the support point. Being d is the density of the wood, what portion of the board is submerged?

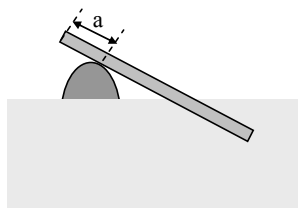

Figure 8.4: Immersion of a stone.

Solution:

8.1.2.7 Ex: Conical container

Milk is placed in a conical container. Over time, occurs at the top the formation of cream, which is less dense. During this process there is no change in volume, that is, h remains constant (see figure). What happens to the pressure at the bottom of the container? Justify your answer.

Solution:

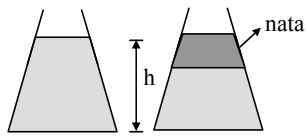

Figure 8.5: Conical container.

8.1.2.8 Ex: Cylindrical can

a. Into a cylindrical can of area A water is poured up to a height of h. Determine the velocity v at which water flows out of a hole of area A located at the bottom. How much water should be added to the can per unit of time such that v is constant?
b. In case that no water is added to the can and the height varies, calculate the flow rate θ as a function of time.

Solution:

8.1.2.9 Ex: Siphon

Via a siphon, water is removed from a container, as shown in the figure. The area of the pipe is constant along its length and the velocity of the surface of the liquid is neglected.
a. What is the water speed at the outlet of the pipe?
b. What is the pressure at the highest point of the siphon?
c. What is the maximum height h at which it is still possible to siphon water?

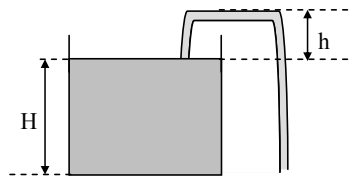

Figure 8.6: Siphon.

Solution:

8.1.2.10 Ex: Water tank

A water tank is mounted on a wagon that can move horizontally without friction (see figure). In the wall of the box there is a hole of area A at a depth H, through which water flows parallel to the horizontal plane. The initial total mass of the system (box, water and wagon) is M_0 and the speed of the water surface is neglected. If the wagon is initially at rest when the hole is opened, what will be the initial acceleration of the

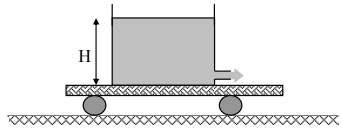

Figure 8.7: Water tank.

system?

Solution:

8.1.2.11 Ex: Water pipe

A water pipe rotates at a speed ω around a vertical axis, as shown in the figure. Calculate the pressure as a function of r, using $P(r = 0) = P_0$.

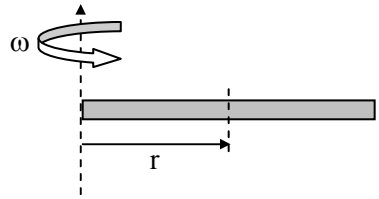

Figure 8.8: Water pipe.

Solution:

8.1.2.12 Ex: Flow meter

A flow meter consists of a conical, vertical glass tube with a metallic sphere of mass m and radius r inside it, as shown in the figure. Calculate the flow of a gas with a given viscosity as a function of the height h. Consider, very small. **Note:** $F_{Stokes} = 6\pi\eta rv$.

Solution:

8.2 Continuity and Navier-Stokes equations

Chapter 9

Thermodynamics and kinetic gas theory

Thermodynamics is a central branch of modern science, and its general laws govern the physical and chemical processes which occur in our world. An important early application of thermodynamics dealt with steam engines (heat engines) in which heat is converted to mechanical energy. Classical thermodynamics was developed in the nineteenth and in the beginning of the twentieth century by Watt, Carnot, Clausius, Joule, von Helmholtz, Lord Kelvin, Nernst, Boltzmann and Gibbs. The so-called First, Second and Third Laws of Thermodynamics were discovered during this period. They set general limits for the conversion of one form of energy, for example heat or chemical energy, to another one, for example mechanical work. One phase in the development of thermodynamics ended with the formulation of statistical thermodynamics by Boltzmann and Gibbs. Statistical thermodynamics is based on the fact that what we experience as heat is actually an outward manifestation of molecular and atomic motion.

Classical thermodynamics has played a dominant role in the development of modern science and technology. In suffers, however, from certain limitations, as it cannot be used for the study of irreversible processes but only for reversible processes and transitions between different states of equilibrium. Many of the most important and interesting processes in nature are irreversible. A good example is provided by living organisms which consume chemical energy in the form of nutrients, perform work and excrete waste as well as give off heat to the surroundings without themselves undergoing changes; they represent what is called a stationary or steady state. The boiling of an egg provides another example, and still another one is, a thermocouple with a cold and a hot junction connected to an electrical measuring instrument.

The first investigator who developed a method for the exact treatment of such problems, for example of the thermocouple, was Onsager. His approach was, however based on assumptions which in principle make it applicable only to systems close to equilibrium. The contribution of Prigogine to thermodynamic theory is his successful extension of it to systems which are far from thermodynamic equilibrium. This is extremely interesting as large differences compared to conditions close to equilibrium had to be expected. Prigogine has demonstrated that a new form of ordered structures can exist under such conditions, and he has given them the name dissipative structures to stress that they only exist in conjunction with their environment.

In the present chapter we will first deal with equilibrium thermodynamics, as well

in the classical as in the quantum regime.

9.1 Equilibrium thermodynamics

9.1.1 Probabilities

Excs. 9.1.5.1 to 9.1.5.8.

9.1.2 Thermal motion

9.1.3 Temperature and Maxwell-Boltzmann distribution

9.1.3.1 Temperature and heat

9.1.3.2 Temperature measurement

Scales of *Celsius*, *Fahrenheit*, and *Kelvin*.

9.1.4 Heat capacity

Heat capacity

9.1.5 Exercises

9.1.5.1 Ex: Probabilities

In a game, 5 ideal dice are rolled.
a. What is the probability that exactly two of these dice show the number one?
b. What is the probability that at least one die shows the number one?

Solution: *a. The probability that exactly two of these dice show the number one is,*

$$P = \binom{5}{2} \frac{1}{6}^2 \left(1 - \frac{1}{6}\right)^{5-2} = \frac{625}{3888} \approx 16\% \ .$$

b. The probability that at least one die shows the number one is,

$$P = 1 - \binom{5}{0} \frac{1}{6}^0 \left(1 - \frac{1}{6}\right)^{5-0} = \frac{4651}{7776} \approx 60\% \ .$$

9.1.5.2 Ex: Probabilities

With what probability have out of
a. 1000 random numbers between 1 and 100 exactly five the value 50;
b. 100 two people on birthday January 1st.

Solution: *a. From the Poisson distribution:*

$$P = \frac{10^n}{n!} e^{-\alpha} = \frac{10^5}{5!} e^{-1000/100} \simeq 0.0378 \ .$$

b. Similarly,

$$P = \frac{10^n}{n!} e^{-\alpha} = \frac{10^2}{2!} e^{-100/365} \simeq 0.0285 \ .$$

9.1.5.3 Ex: Probabilities

What is the probability that you inhale at least one molecule that Julius Caesar exhaled during his last breath (Tu quoque, Brute, fili mi!)? Assume a breathing volume of 3 liters and an atmosphere height of approximately 10 km. Assume the density of the atmosphere is approximately homogeneous.

Solution: *The number of molecules per liter is approximately,*

$$N_L = \frac{pV}{k_B T} \simeq \frac{1013\,\mathrm{hPa} \cdot 10^{-3}\,\mathrm{m}^3}{k_B \cdot 300\,\mathrm{K}} = 2.44 \cdot 10^{22} \ .$$

The number of molecules in the atmosphere is about $N = N_L \cdot V_A/(1\ liter)$, where $V_A \simeq 4\pi R_E^2 h \simeq 1.4 \cdot 10^{44}\,\mathrm{m}^3$. The number of molecules per breath is $A \simeq 8 \cdot 10^{22}$. The probability that no molecule can be found is,

$$P \simeq (1-p)^A = e^{(A \log(1-p))} \simeq e^{(-Ap)} = 1.4 \cdot 10^{-22} \ ,$$

where $p = A/N$ is the probability to find one of Caesar's molecules. Alternatively, the Poisson distribution with $\alpha = A^2/N$ and $n = 0$, $P = e^{-A\ p}$ gives the same result. That means we share each of our breaths with Caesar!

9.1.5.4 Ex: Idiots roulette

A Bavarian, a Swabian and an East Frisian play Russian roulette together, each according to their own rules. The Bavarian inserts two cartridges into the drum of a six-shot revolver, sets the drum in a rapid rotation, aims at his own head and pulls the trigger once. The Swabian puts a cartridge in the revolver and pulls the trigger twice, the East Frisian puts a cartridge in the revolver, pulls the trigger once, turns the drum a second time and pulls the trigger again. What is the chance of survival of the three crazy people?

Solution: *The chance of survival for the Bavarian is $P = \frac{2}{3} = 66\%$, for the Swabian $P = \frac{1}{6} \cdot \frac{1}{6}$, and for the East Frisian $P = \frac{5}{6} \cdot \frac{5}{6} = 69\%$.*

9.1.5.5 Ex: Idiots roulette

A student writes a multiple choice test in physics. It consists of 18 tasks. For each task, only one of the four proposed solutions is correct. Since he does not understand much about the topic, he trusts his luck and checks the possible solutions by chance. What is the probability that the student meets the minimum requirement of 8 correct answers?

Solution: *The probability is,*

$$P = 1 - \sum_{k=0}^{7} \binom{18}{k} \left(\frac{1}{4}\right)^k \left(\frac{3}{4}\right)^{18-k} = 0.057 \ .$$

9.1.5.6 Ex: Probabilities

A slot machine consists of three concentric rings. Each ring is evenly divided into 10 sections and the sections in each ring are continuously labeled with "a" to "j". By pressing the start button, the three rings start to rotate independently. If the luck button is pressed, the rings brake independently of one another and three letters appear side by side in the viewing window. With three ones you win, with two ones there is a free spin.
a. Calculate the probability for one free spin per game.
b. What is the probability of getting exactly 3 free spins in 10 games?
c. What is the probability of winning at least once in 10 games?

Solution: *a. The probability for one "a" is* $p_1 = 0.1$. *The probability to make exactly* m *"a" per game* $W_{3,m} = \binom{3}{m} p_1^k (1-p_1)^{N-k}$. *So the probability for a free spin is,*

$$P_{3,2} = \binom{3}{2} \cdot 0.1^2 \cdot 0.9^1 = 2.7\% \ .$$

b. The probability to find in N *games* k *times exactly two "a" is* $P_{N,k} = \binom{N}{k} W_{3,2}^k (1 - W_{3,2})^{N-k}$. *The probability of getting exactly three free spins in 10 games is thus,*

$$P_{N,k} = \binom{10}{3} 0.027^3 \cdot 0.973^7 = 0.2\% \ .$$

c. The probability for three "a" is $p_3 = 0.1^3 = 0.001$. *So the probability to get in* N *games exactly* k *times this result is* $P_{N,k} = \binom{N}{k} p_3^k (1-p_3)^{N-k}$. *So the probability in* 10 *tries to get* 0 *times this result is,*

$$P_{10,0} = \binom{10}{0} 0.001^0 \cdot 0.999^{10} = 0.999^{10} = 99\% \ .$$

The probability of winning at least once is finally $P_{gewinn} = 1 - P_{10,0} = 1\%$.

9.1.5.7 Ex: Binomial distribution

Two drunks stagger on the x-axis. Starting from the origin, they take a step to the right or to the left with the same probability. The steps take place synchronously, and the steps of both people are the same and constant. Determine the probability that they will meet again after N steps.

Solution: *Let us first consider one drunk. The probability for a step to the left is* $p_l = 0.5$. *If he walks exactly* $N/2$ *steps to the left, it means that he also has to walk* $N/2$ *steps to the right in order to come back. The probability of this is* $P_N(N/2) = \binom{N}{N/2} p_l^{N/2}(1-p_l)^{N-N/2}$.
For two drunks, we can sit in the inertial system of one of them. Then the distance between them either increases by two steps or stays unchanged, both with a probability of 50%. We can therefore take the above solution and replace N *with* $N/2$. *So the solution is,*

$$P_N(N/2) = \binom{2N}{N} p_l^N (1-p_l)^{2N-N} = \frac{(2N)!}{(N!)^2}\frac{1}{2^{2N}} \ .$$

The task can also be solved in the following way. The probability that the drunks change their distance is $p_2 = 0.5$. *The probability that they change their distance* k *times in* N *steps* $P_2 = \binom{N}{k} p_2^k (1-p_2)^{N-k}$. *For each of the routes contained in* P_2 *there are again as many routes back to the original distance of the drunk. The overall probability is* $P_2 \cdot P_2$. *Now, we just have to add up all* k *and get the alternative solution,*

$$P = \frac{1}{2^{2N}} \sum_{k=0}^{N} \binom{N}{k}^2 \ .$$

It turns out that this is identical to the above one, but what remains to be shown!

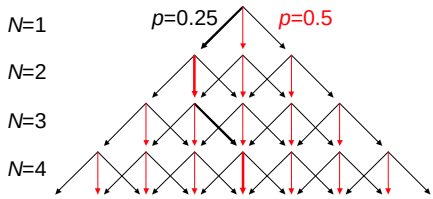

Figure 9.1: Generation of a binomial distribution.

9.1.5.8 Ex: Quantum statistics

n particles are distributed to $N > n$ different cells with the same probability. Calculate the probability:
a. that there is exactly one particle in the first n cells;
b. that there is no cell with more than one particle.
Use the three different assumptions that:
i. the particles are identifiable and arbitrarily many particles can be assigned to each

cell;
ii. the particles are NOT identifiable and arbitrarily many particles can be assigned to each cell;
iii. the particles are NOT identifiable and only a single particle may be assigned to each cell.

Solution: *Be $C(N,n) = N!/(n!(N-n)!)$ the number of different combinations to choose n elements from N, regardless of the order. There are N^n possible cases:*

$$i.\ p_b = \frac{n!}{N^n} \quad , \quad p_a = C(N,n)p_b = \frac{N!}{(N^n(N-n)!)}$$

$$ii.\ p_b = \frac{n!(N-1)!}{(N+n-1)!} \quad , \quad p_a = C(N,n)p_b = \frac{N!(N-1)!}{((N-n)!(N+n-1)!)}$$

$$iii.\ p_a = 1 \quad , \quad p_b = \frac{p_a}{C(N,n)} = \frac{n!(N-n)!}{N!} \ .$$

9.1.5.9 Ex: Velocity distribution

The Maxwellian velocity distribution or Boltzmann distribution of a one-dimensional ideal gas of identical particles of mass m at temperature T is,

$$f(v)dv = \sqrt{\frac{m}{2\pi k_B T}} e^{-mv^2/2k_B T} dv \ .$$

This gives the average kinetic energy for each molecule of $\langle E_{kin} \rangle = \frac{1}{2} k_B T$. According to the equipartition theorem, Maxwell's velocity distribution of a three-dimensional gas is given by $f(v_x)dv_x\ f(v_y)dv_y\ f(v_z)dv_z$.
a. Write down the velocity distribution explicitly and determine the average kinetic energy of a molecule in the three-dimensional gas at temperature T.
Determine the average absolute velocity $\langle v \rangle = \langle |\mathbf{v}| \rangle$ and compare $\langle v \rangle^2$ with $\langle v^2 \rangle$ for the three-dimensional case.
c. What is the number of particles $F(v)dv$ with an absolute velocity $v = |\mathbf{v}|$ in the range v and $v + dv$.
d. Consider a gas made of rubidium atoms ($m = 87 \cdot 1.67 \cdot 10^{-27}\,\mathrm{kg}$) and sketch $F(v)$ for temperatures between 100 K and 300 K.
e. Consider the rubidium gas at room temperature ($T = 300\,\mathrm{K}$). What is the proportion of molecules whose average velocity $\langle v \rangle$ is greater than 1000 m/s?

Solution: *a. The explicit form of the velocity distribution is,*

$$f(v_x)dv_x\ f(v_y)dv_y\ f(v_z)dv_z = \sqrt{\frac{m}{2\pi k_B T}}^3 e^{-m\mathbf{v}^2/2k_B T} d^3\mathbf{v} \ .$$

The mean kinetic energy is,

$$\begin{aligned}
\langle E_3\rangle(|\mathbf{v}|) &= \frac{m}{2}\left\langle \mathbf{v}^2\right\rangle = \int_{-\infty}^{\infty}\frac{m}{2}\mathbf{v}^2 f_3(\mathbf{v})d^3\mathbf{v} \\
&= \int\int\int_{-\infty}^{\infty}\frac{m}{2}\left(v_x^2+v_y^2+v_z^2\right)\left(\frac{m}{2\pi k_BT}\right)^{3/2}\exp\left(-m\frac{v_x^2+v_y^2+v_z^2}{2k_BT}\right)dv_xdv_ydv_z \\
&= \int_0^{2\pi}\int_0^{\pi}\int_0^{\infty}\frac{m}{2}v_r^2\left(\frac{m}{2\pi k_BT}\right)^{3/2}\exp\left(-\frac{mv_r^2}{2k_BT}\right)v_r^2\sin\theta dv_rdv_\theta dv_\phi \\
&= 4\pi\frac{m}{2}\left(\frac{m}{2\pi k_BT}\right)^{3/2}\int_0^{\infty}v_r^4\exp\left(-\frac{mv_r^2}{2k_BT}\right)v_r^2dv_r \\
&= \textit{...(part. integration, surface terms drop out)} \\
&= 4\pi\frac{m}{2}\left(\frac{m}{2\pi k_BT}\right)^{3/2}\frac{3}{8}\sqrt{\pi}\left(\frac{m}{2k_BT}\right)^{-5/2} = \frac{3}{2}k_BT\ .
\end{aligned}$$

Here, one uses,

$$\int_{-\infty}^{\infty}x^ne^{-x^2}dx = \Gamma\left(\tfrac{n+1}{2}\right) = \frac{n-1}{2}\Gamma\left(\tfrac{n-1}{2}\right) \qquad \textit{and} \qquad \Gamma\left(\tfrac{1}{2}\right) = \sqrt{\pi}\ .$$

b. The average absolute velocity is,

$$\begin{aligned}
\langle|\mathbf{v}|\rangle &= \int_{-\infty}^{\infty}vf_3(\mathbf{v})d^3\mathbf{v} \\
&= 4\pi\left(\frac{m}{2\pi k_BT}\right)^{3/2}\int_0^{\infty}v_r\exp\left(-\frac{mv_r^2}{2k_BT}\right)v_r^2dv_r \\
&= \textit{...(part. integration, surface terms drop out)} \\
&= 4\pi\left(\frac{m}{2\pi k_BT}\right)^{3/2}\frac{1}{2}\left(\frac{m}{2k_BT}\right)^{-2} = \sqrt{\frac{8k_BT}{\pi m}}\ .
\end{aligned}$$

Hence,

$$\frac{m}{2}\langle v\rangle^2 = \frac{4}{\pi}k_BT \neq \frac{3}{2}k_BT = \frac{m}{2}\left\langle\vec{v}^2\right\rangle\ .$$

c. The number of particles with absolute velocity in the interval v and $v+dv$ is,

$$F(v)dv = 4\pi v^2 f_3(v)dv\ ,$$

where

$$f_3(v) = \left(\frac{m}{2\pi k_BT}\right)^{3/2}e^{-mv^2/2k_BT}\ .$$

It's easy to verify,

$$\begin{aligned}
\int_0^{\infty}F(v)dv &= 4\pi\left(\frac{m}{2\pi k_BT}\right)^{3/2}\int_0^{\infty}v^2e^{-mv^2/2k_BT}dv \\
&= 4\pi\left(\frac{m}{2\pi k_BT}\right)^{3/2}\left(\frac{2k_BT}{m}\right)^{3/2}\int_0^{\infty}y^2e^{-y^2}dy = 1\ .
\end{aligned}$$

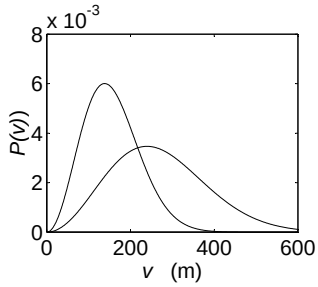

Figure 9.2: Maxwell distribution.

d. Sketch of the distribution function $4\pi v^2 f_3(v)$ *for rubidium atoms:*
e. The definite integral can be traced back by partial integration to,

$$\int_{v_0}^{\infty} F(v)dv = \frac{4}{\sqrt{\pi}} \int_{y_0}^{\infty} y^2 e^{-y^2} dy = \frac{4}{\sqrt{\pi}} \left[-\frac{1}{2} y e^{-y^2} + \frac{1}{4}\sqrt{\pi}\, erf\,(y) \right]_{y_0}^{\infty}$$
$$= 1 - erf\,(y_0) + \frac{2}{\sqrt{\pi}} y_0 e^{-y_0^2} \ .$$

$y_0 = v_0\sqrt{m/2k_BT} \approx 4.18$ *and hence* $\int_{v_0}^{\infty} F(v)dv = 1.251\ 5 \times 10^{-7}$.

9.1.5.10 Ex: Maxwell-Boltzmann distribution

Calculate the number of particles in an ideal homogeneous gas having velocities slower than $2v_{rms}$.

Solution: *With the particle distribution given by,*

$$f(\vec{v}) = \sqrt{\frac{m}{2\pi k_B T}}^3 e^{-m\vec{v}^2/2k_BT} \ ,$$

we can calculate the number of particles,

$$N = 4\pi \int_0^{2v_{rms}} f(v)v^2 dv = \frac{4\pi}{\sqrt{\pi}^3} \int_0^{2v_{rms}} \sqrt{\frac{m}{2k_BT}}^3 e^{-mv^2/2k_BT} v^2 dv = \frac{4}{\sqrt{\pi}} \int_0^{2\zeta_{rms}} e^{-\zeta^2}\zeta^2 d\zeta \ ,$$

using the substitution $\zeta \equiv v\sqrt{m/2k_BT}$. *Since* $v_{rms} = \sqrt{3k_BT/m}$, *we have* $2\zeta_{rms} = \sqrt{6}$. *Using the partial integration rule,* $\int u'v = uv - \int uv'$, *we know,*

$$\int_0^{\sqrt{6}} 1 \cdot e^{-\zeta^2} d\zeta = \zeta \cdot e^{-\zeta^2}\Big|_0^{\sqrt{6}} - \int_0^{\sqrt{6}} \zeta \cdot (-2\zeta) e^{-\zeta^2} d\zeta \ .$$

With this,

$$N = \frac{4}{\sqrt{\pi}} \frac{1}{2} \left[\int_0^{\sqrt{6}} 1 \cdot e^{-\zeta^2} d\zeta - \zeta \cdot e^{-\zeta^2}\Big|_0^{\sqrt{6}} \right] = \frac{4}{\sqrt{\pi}} \frac{1}{2} \left[\int_0^{\sqrt{6}} e^{-\zeta^2} d\zeta - \sqrt{6} e^{-6} \right] = 99.2\% \ .$$

9.1.5.11 Ex: Maxwell-Boltzmann distribution

Using the Maxwell-Boltzmann distribution $f(v)$ and the following formulas, calculate the velocities $\bar{v} \equiv \int_0^\infty v f(v) v^2 dv$ and $v_{rms} \equiv \sqrt{\overline{v^2}}$:

$$\int_0^\infty x^n e^{-x^2} dx = \tfrac{1}{2}\Gamma(\tfrac{n+1}{2}) = \begin{cases} \frac{(2k-1)!!\sqrt{\pi}}{2^{k+1}} & \text{for} \quad n = 2k \\ \frac{k!}{2} & \text{for} \quad n = 2k+1 \end{cases} .$$

Solution:

9.1.5.12 Ex: Mean velocity in a gas

The average velocity of the molecule in an ideal gas is 500 m/s. If the gas maintains the same temperature and the molecular masses are doubled, what will be the new average velocity?

Solution:

9.1.5.13 Ex: Evaporation

a. A three-dimensional homogeneous gas consisting of $N = 10^8$ rubidium atoms (mass $m = 87 \cdot u$) has the temperature $T = 100\,\mu$K. How many atoms are faster on average than $v_1 = 10$ cm/s?
b. Now suppose that all atoms with a velocity $v > v_1$ were suddenly removed. After some time, a new thermal equilibrium is established due to collisions. What is the temperature of the gas now?

Help: Formula for partial integration: $\int y^n e^{-y^2} dy = -\frac{y^{n-1}}{2} e^{-y^2} + \frac{n-1}{2} \int y^{n-2} e^{-y^2} dy$
You can take the value of the error function given by $\text{erf}\,(y_1) \equiv \frac{1}{\sqrt{\pi}} \int_{y_1}^\infty e^{-y^2} dy$ from the sketched curve.

Solution: ***A factor 4 is wrong here, which stems from an originally incorrect normalization of the error function.***
a. The number of particles with absolute velocity $v > v_1 = 10$ cm/s is,

$$N_1 = N \int_{v>v_1} f_3(v) d^3\vec{v} = N \int_0^{2\pi} \int_0^\pi \int_{v_1}^\infty \left(\frac{m}{2\pi k_B T}\right)^{3/2} e^{-mv^2/2k_BT} v^2 \sin\theta dv dv_\theta dv_\phi$$
$$= N 4\pi \left(\frac{m}{2\pi k_B T}\right)^{3/2} \left(\frac{2k_BT}{m}\right)^{3/2} \int_{y_1}^\infty y^2 e^{-y^2} dy ,$$

with $y_1 \equiv v_1\sqrt{m/2k_BT} = 0.10\sqrt{\frac{87\cdot 1.67\cdot 10^{-27}}{2\cdot 1.38\cdot 10^{-23}\cdot 100\cdot 10^{-6}}} \simeq 0.72$. The definite integral can be traced back by partial integration with the definition of the error function (surface

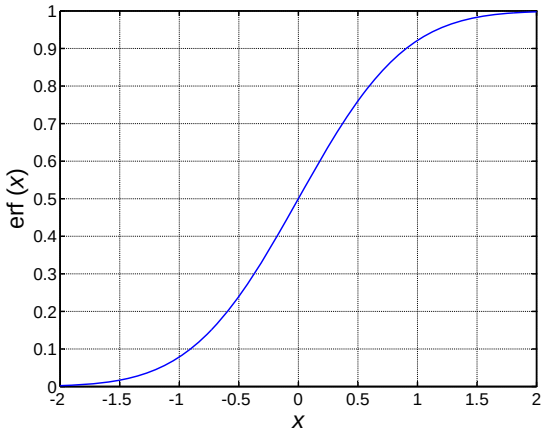

Figure 9.3:

terms are eliminated) to,

$$N_1 = \frac{4N}{\sqrt{\pi}}\int_{y_1}^{\infty} y^2 e^{-y^2} dy = \frac{4N}{\sqrt{\pi}}\left[-\frac{y}{2}e^{-y^2} + \frac{\sqrt{\pi}}{4}\,\mathrm{erf}\,(y)\right]_{y_1}^{\infty}$$
$$= N\left[1 - \mathrm{erf}(y_1) + \frac{2}{\sqrt{\pi}} y_1 e^{-y_1^2}\right] = N\left[1 - \mathrm{erf}(0.72) + \frac{2}{\sqrt{\pi}} 0.72 e^{-0.72^2}\right] \simeq 0.79N \ .$$

b. The total energy is, immediately after removing the fast particles,

$$E = N_1 \int_{v<v_1}^{\infty} \frac{m}{2}\vec{v}^2 f_3(\vec{v}) d^3\vec{v} = N_1 \int_0^{2\pi}\int_0^{\pi}\int_0^{\infty} \frac{m}{2} v^2 \left(\frac{m}{2\pi k_B T}\right)^{3/2} e^{-mv^2/2k_B T} v^2 \sin\theta dv_r dv_\theta dv_\phi$$
$$= N_1 4\pi \frac{m}{2}\left(\frac{m}{2\pi k_B T}\right)^{3/2}\left(\frac{2k_B T}{m}\right)^{5/2}\int_{y_1}^{\infty} y^4 e^{-y^2} dy \ .$$

The definite integral can be traced back by partial integration (surface terms are eliminated) to,

$$E = \frac{4N_1 k_B T}{\sqrt{\pi}}\int_{y_1}^{\infty} y^4 e^{-y^2} dy = \frac{4N_1 k_B T}{\sqrt{\pi}}\left[-\frac{y^3}{2}e^{-y^2}\Big|_{y_1}^{\infty} + \frac{3}{2}\int_{y_1}^{\infty} y^2 e^{-y^2} dy\right]$$
$$= \frac{4N_1 k_B T}{\sqrt{\pi}}\left[\frac{y_1^3}{2}e^{-y_1^2} + \frac{3}{2}\frac{\sqrt{\pi}N_1}{4N}\right] = \frac{4N_1 k_B T}{\sqrt{\pi}}\frac{y_1^3}{2}e^{-y_1^2} + \frac{3N_1^2 k_B T}{2N} \ .$$

After thermalization the kinetic energy is $E_1 = \frac{3N_1}{2}k_B T_1 \equiv E = \frac{4N_1 k_B T}{\sqrt{\pi}}\frac{y_1^3}{2}e^{-y_1^2} + \frac{3N_1^2 k_B T}{2N}$. *From this follows,*

$$T_1 = T\left[\frac{4}{\sqrt{\pi}}\frac{y_1^3}{3}e^{-y_1^2} + \frac{N_1}{N}\right] = T\left[\frac{4}{\sqrt{\pi}}\frac{0.72^3}{3}e^{-0.72^2} + 0.79\right] \simeq 0.96T \ .$$

9.1.5.14 Ex: Trapped gases

The density distribution of a rubidium gas in a three-dimensional harmonic potential can be expressed by,

$$n(\mathbf{r})d^3r = n_0 e^{-U(\mathbf{r})/k_BT} d^3r \ ,$$

where $U(\mathbf{r}) = \frac{m}{2}\omega^2 r^2$. Numerical values: $m = 87 \cdot 1.67 \cdot 10^{-27}$ kg and $\omega = 2\pi \cdot 50$ Hz.
a. Determine the expansion of the gas ($1/e$ width of the distribution) at a given temperature $T = 100$ μK.
b. Determine the maximum density n_0 of the gas when $N = \int n(\mathbf{r})d^3r = 10^8$ is the total number of atoms.
c. The effective volume is defined by $V_{eff} = N/n_0$. How many atoms are in the effective volume?

Solution: *a. The expansion $\bar{r}$ follows with,*

$$\frac{1}{e} = \frac{n(\bar{r})}{n_0} = e^{-m\omega^2\bar{r}^2/2k_BT} \ .$$

With the numerical values $\bar{r} = \sqrt{\frac{2k_BT}{m\omega^2}} = 440$ μm.
b. The maximum density n_0 results from,

$$N = n_0 \int e^{-r^2/\bar{r}^2} d^3r = n_0 \left(\bar{r}\int e^{-x^2}dx\right)^3 = n_0\pi^{3/2}\bar{r}^3 \ .$$

With the numerical values follows $n_0 = \frac{N}{\pi^{3/2}\bar{r}^3} = 2.1 \times 10^{11}$ cm^{-3}.
c. The effective volume is,

$$V_{eff} = \frac{N}{n_0} = \pi^{3/2}\bar{r}^3 \equiv \frac{4\pi}{3}\tilde{r}^3$$
$$\tilde{r} = \bar{r}\sqrt{\pi}\left(\frac{3}{4\pi}\right)^{1/3} \ .$$

So the number of particles is,

$$\begin{aligned} N_{eff} &= \int_{V_{eff}} n(r)d^3r = 4\pi\int_{\tilde{r}} n(r)r^2dr = 4\pi n_0 \int_{\tilde{r}} r^2 e^{-r^2/\bar{r}^2}dr \\ &= 4\pi n_0\left(-\frac{1}{2}\bar{r}^2\tilde{r}e^{-\frac{\tilde{r}^2}{\bar{r}^2}} + \frac{1}{4}\bar{r}^2\bar{r}\sqrt{\pi}\,\mathrm{erf}\left(\frac{\tilde{r}}{\bar{r}}\right)\right) \\ &= N\left(\mathrm{erf}\left(\sqrt{\pi}\left(\frac{3}{4\pi}\right)^{1/3}\right) - \left(\frac{2}{\pi}\right)^{1/3} e^{-\pi\left(\frac{3}{4\pi}\right)^{2/3}}\right) \ . \end{aligned}$$

With the numerical values follows $N = 6.2 \times 10^7$.

9.1.5.15 Ex: Trapped gases

Calculate the internal energy and heat capacity of an ideal gas stored in a harmonic trap and compare the result with a free gas.

Solution: *The normalization condition requires,*

$$\begin{aligned}
1 &= \int\int e^{-\beta\varepsilon-\beta U} d^3\mathbf{k} d^3\mathbf{r} \\
&= \left(\frac{m}{2\pi\hbar}\right)^3 \int\int e^{-\beta\frac{m}{2}v^2-\beta\frac{m}{2}\omega^2 r^2} d^3\mathbf{v} d^3\mathbf{r} \\
&= \left(\frac{m}{2\pi\hbar}\right)^3 \left(\int e^{-\beta\frac{m}{2}v^2} dv \int e^{-\beta\frac{m}{2}\omega^2 r^2} dr\right)^3 \\
&= \left(\frac{m}{2\pi\hbar}\right)^3 \left(\frac{2\pi}{\beta m}\right)^{3/2} \left(\frac{2\pi}{\beta m\omega^2}\right)^{3/2} = \left(\frac{k_B T}{\hbar\omega}\right)^3 .
\end{aligned}$$

The energy is,

$$\begin{aligned}
E(T) &= N\int\int \varepsilon e^{-\beta\varepsilon-\beta U} d^3\mathbf{k} d^3\mathbf{r} \\
&= N\left(\frac{m}{2\pi\hbar}\right)^3 \int\int \frac{m}{2}v^2 e^{-\beta\frac{m}{2}v^2-\beta\frac{m}{2}\omega^2 r^2} d^3\mathbf{v} d^3\mathbf{r} \\
&= N\left(\frac{m}{2\pi\hbar}\right)^3 \int \frac{m}{2}v^2 e^{-\beta\frac{m}{2}v^2} 4\pi v^2 dv \times \left(\int e^{-\beta\frac{m}{2}\omega^2 r^2} dr\right)^3 \\
&= N\left(\frac{m}{2\pi\hbar}\right)^3 4\pi\frac{m}{2}\left(\frac{2}{\beta m}\right)^{5/2} \int u^4 e^{-u^2} du \times \left(\frac{2}{\beta m\omega^2}\right)^{3/2} \left(\int e^{-x^2} dx\right)^3 \\
&= N\left(\frac{m}{2\pi\hbar}\right)^3 4\pi\frac{m}{2}\left(\frac{2}{\beta m}\right)^{5/2} \frac{3}{8}\sqrt{\pi} \times \left(\frac{2}{\beta m\omega^2}\right)^{3/2} \sqrt{\pi}^3 \\
&= \frac{3}{2}Nk_B T\left(\frac{k_B T}{\hbar\omega}\right)^3 = \frac{3}{2}Nk_B T .
\end{aligned}$$

9.1.5.16 Ex: Trapped gases

An ultracold gas made of 10^8 rubidium atoms (mass number 87) is trapped in a three-dimensional potential of the form $U(r) = \frac{m}{2}\omega^2 r^2$ with the oscillation frequencies $\omega/2\pi = 100$ Hz.
a. Assume the spatial distribution function for the atoms to be $n(\mathbf{r}) = n_0 e^{-U(r)/k_B T}$. What is its width at $1/\sqrt{e}$ of the maximum height? How does the width of the distribution function change when the number of atoms is doubled?
b. The trap potential is suddenly switched off. The atoms are robbed of their potential energy, while their kinetic energy leads to the ballistic expansion of the cloud. 20 ms after switching off the trapping potential, a $1/\sqrt{e}$ width of $\bar{r}_a = 0.2$ mm is experimentally measured for the distribution of the expanded atomic cloud. What was the temperature of the atomic cloud in the trap?
Help: Assume that the final size of the atomic cloud is much larger than the size of the trap. Neglect collisions between the atoms.

Solution: *a. The distribution of the atoms in the potential* $U(r) = \frac{m}{2}\omega^2 r^2$ *is,*

$$n(\mathbf{r})d^3r = n_0 e^{-U(r)/k_B T} d^3\mathbf{r} \ .$$

Normalization requires $N = \int n_0 e^{-U(r)/k_B T} d^3r$. *Hence,*

$$n_0 = \frac{N}{\int e^{-U(r)/k_B T} d^3r} = \left(\frac{m\omega^2}{2k_B T}\right)^{3/2} \ .$$

The $1/\sqrt{e}$ *width of the distribution follows from* $n_0/\sqrt{e} = n_0 e^{-U(\bar{r})/k_B T}$ *and reads,*

$$\bar{r} = \sqrt{\frac{k_B T}{m\omega^2}} \ .$$

Obviously, the latitude is independent of the number of atoms.
b. The total energy of the atoms is,

$$E = E_{kin} + E_{pot} = \frac{m}{2}\langle v^2\rangle + \frac{m}{2}\omega^2\langle r^2\rangle \ .$$

After switching off the trap,

$$E = \frac{m}{2}\langle v^2\rangle = \frac{3m}{2}\langle v_x^2\rangle = \frac{3k_B T}{2} \ .$$

After $t = 20$ *ms time-of-flight,*

$$\bar{v}_x = \sqrt{\langle v_x^2\rangle} = \sqrt{\frac{k_B T}{m}} = \frac{\bar{r}_a}{t} \ .$$

Hence,

$$T = \frac{m\bar{r}_a^2}{k_B T^2} \approx 1.05 \ \mu K \ .$$

9.1.5.17 Ex: Heat capacities

The specific heat capacity of air is $c_V = 715\,\mathrm{J\ kg^{-1}\ K^{-1}}$. What is the molar heat capacity? (Air has the relative molecular mass $\mu \approx 29$ and the mass of the H atom is $m_H = 1.67 \cdot 10^{-27}\,\mathrm{kg}$. How many air molecules are there in one kilogram of air?

Solution: *We calculate,*

$$C_V = \frac{\mu c_V}{1000} = 20.735 \ ,$$

and

$$N = N_A \frac{1000}{29} = 6 \cdot 10^{23} \cdot \frac{1000}{29} \ ,$$

or

$$N = \frac{1}{\mu m_H} = 2.06 \cdot 10^{25} \ .$$

9.2 The ideal gas

9.2.1 Equation of state for an ideal gas

The most famous equation of state is based on observations of *Boyle*, *Mariotte* and *Gay-Lussac*:

$$\boxed{pV = Nk_BT} \,. \tag{9.1}$$

9.2.2 Applications of the ideal gas law

The gas thermometer and the barometric formula are examples of the numerous applications of the ideal gas law (see Excs. 9.2.5.1 and 9.2.5.2).

9.2.2.1 The barometric formula

Excs. 9.2.5.3 and 9.2.5.4.

9.2.3 The vacuum

Vacuum pumps

9.2.4 Pressure measurement

9.2.5 Exercises

9.2.5.1 Ex: Gas thermometer

A gas thermometer filled with an ideal gas and working at a constant volume is calibrated on the one hand in dry ice (carbon dioxide in its solid state at a temperature of -80.0° C) and on the other hand in boiling alcohol (78.0° C). At these respective temperatures, the pressure in the gas thermometer is 0.900 bar or 1.635 bar. At absolute zero, the gas in the thermometer is still gaseous, but the pressure has dropped to 0.000 bar.
a. At what $^\circ$ C is the absolute zero?
b. What is the pressure at the freezing point of water and what is it at the boiling point?

Solution: *a. From the ideal gas formula we have,*

$$\begin{aligned} \frac{V}{V_0} &= \frac{T}{T_0}\frac{p_0}{p} \\ \Rightarrow \frac{p_0}{T_0} &= \frac{\Delta p}{\Delta T} = \frac{1.635\,\text{bar} - 0.9\,\text{bar}}{78^\circ\,\text{C} - (-80^\circ\,\text{C})} \approx 4.652 \cdot 10^{-3}\frac{\text{bar}}{^\circ\,\text{C}} \,. \end{aligned}$$

In order to lower the pressure by another 0.9 bar at $T = -80\,$C, the temperature has to be reduced further by $\Delta T = \frac{0.9\ bar}{4.652 \cdot 10^{-3}\frac{\text{bar}}{\text{C}}} = 193.47\ C$. The absolute zero point is therefore at $T = -80^\circ C - 193.47^\circ\,\text{C} = -273.47^\circ\,\text{C} \equiv 0\,\text{K}$.

b. We have,

$$p(0^\circ\,\mathrm{C}) = p(273.47\,\mathrm{K}) = 4.652 \cdot 10^{-3}\frac{\mathrm{bar}}{K} \cdot 273.47\,\mathrm{K} = 1.272\,\mathrm{bar}$$
$$p(100^\circ\,\mathrm{C}) = p(373.47\,\mathrm{K}) = 4.652 \cdot 10^{-3}\frac{\mathrm{bar}}{K} \cdot 373.47\,\mathrm{K} = 1.737\,\mathrm{bar}\ .$$

9.2.5.2 Ex: Gas thermometer

A gas thermometer "a" is connected to a second gas thermometer "b", which is kept in a water bath at a constant temperature. The connecting capillary has a cross-sectional area A and is filled with mercury ($\rho = 13.5$ g/cm^3). At the same temperature T_0 in the two thermometers, the mercury level in both capillaries is the same. Now the gas in thermometer "a" is heated by ΔT. This increases the pressure p_a and thus the volume $V_a \to V_a + \Delta V$. The mercury column is displaced accordingly.
a. What is the relationship between the volume increase ΔV and the temperature increase ΔT in this setup?
b. To simplify, assume that the volumes $V_a = V_b = V_0$ and thus the particle numbers $N_a = N_b = N_0$ are the same. How much has the temperature of the gas in thermometer "a" increased if the following conditions exist in the coupled thermometer: $N_0 = 10^{22}$, $h = 5$ mm, $T_0 = 300$ K, $V_0 = 1000$ cm^3, $A = 1$ cm^2?

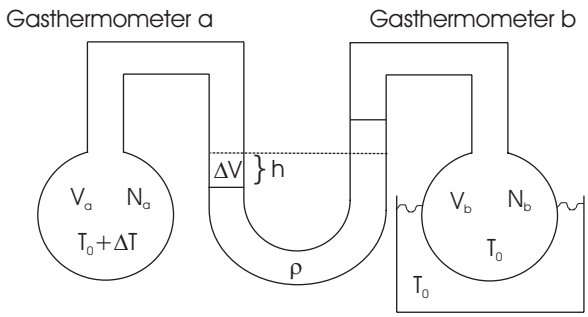

Figure 9.4: Gas thermometer.

Solution: *a. First we consider both thermometers at the same temperature and without displacement of the mercury column:* $p_a = p_b$*, the following also applies* $p_a V_a = T_0 N_a k_B$ *and* $p_b V_b = T_0 N_b k_B \Rightarrow V_a = V_b \frac{N_a}{N_b}$.
Now with increasing temperature in thermometer "a": $T_a \to T_a + \Delta T = T'_a \Rightarrow p'_a T'_a = T'_a N_a k_B \Leftrightarrow p'_a(V_a + \Delta V) = (T_0 + \Delta T) N_a k_B \Rightarrow p'_a = \frac{(T_0+\Delta T) N_a k_B}{V_a + \Delta V}$.
The following applies to thermometer "b": $p'_b(V_b - \Delta V) = T_0 N_b k_B \Rightarrow p'_b = \frac{T_0 N_b k_B}{V_b - \Delta V}$.
In equilibrium, we have, $p'_a = 2\rho g h + p'_b$ *(double height* h *of the mercury column relative to zero displacement):* $\frac{T_+ \Delta T}{V_a + \Delta V} N_a k_B = 2\rho g h + \frac{T_0 N_b k_B}{V_b - \Delta V}$.
The temperature increase will then be $\Delta T = \left(2\rho g h + \frac{T_0 N_b k_B}{V_b - \Delta V}\right) \frac{V_a + \Delta V}{N_a k_B} - T_0$.

b. For $N_a = N_b = N_0$ and $V_a = V_b = V_0$ the equation simplifies to $\Delta T = 2\rho hg\frac{V_0+\Delta V}{N_0 k_B} + \left(\frac{V_0+\Delta V}{V_0-\Delta V} - 1\right) T_0$. For the given values we get $\Delta T \approx 9.9$ K.

9.2.5.3 Ex: Barometric formula

The barometric height formula is usually derived assuming constant temperature. Now suppose that the temperature depends on the height h above the surface of the Earth according to the relationship $T = T_0/(1 + \alpha h)$.
a. Show that the pressure p then must satisfy the following differential equation,

$$\frac{dp}{dh} = -\frac{mg}{k_B T_0}(1 + \alpha h)p \ .$$

b. Find the solution to this differential equation. What is the sign of the constant α? Is the pressure at a fixed height larger or smaller than the value resulting from the height formula at a fixed temperature?

Solution: *a. The additional pressure exerted by the part of the air column within the height difference Δh onto the surface F is,*

$$\Delta p = -\frac{mgN_{\Delta h}}{F} = -\frac{mg\rho\Delta V}{\Delta V/\Delta h} = -mg\frac{N}{V}\Delta h \ .$$

For an ideal gas applies $pV = Nk_BT$. Hence,

$$\Delta p = -mg\frac{p}{\kappa_B T}\Delta h = -mg\frac{p}{\kappa_B T_0}(1 + \alpha h)\Delta h \ .$$

b. By separating the variables,

$$\begin{aligned} \frac{dp}{p} &= -\frac{mg}{k_B T_0}\,(1 + \alpha h)\,dh \\ \ln p - \ln p_0 &= -\frac{mg}{k_B T_0}\left(h + \frac{\alpha}{2}h^2\right) \\ p &= p_0 e^{-\frac{mg}{k_B T_0}\left(h+\frac{\alpha}{2}h^2\right)} \ . \end{aligned}$$

For the temperature to decrease we must have $\alpha > 0$. But then the pressure is lower than estimated with the corresponding barometric height formula at constant temperature.

9.2.5.4 Ex: Barometric formula

The air pressure p at a height h is equal to the weight $m \cdot g$ of the air column, which at this height rests on an (imaginary) horizontal base divided by the base area A of the column ($m = m(h)$: mass of the air column, neglect the curvature of the Earth and the height dependence of the temperature). Therefore, we have for the change dp of the pressure upon a small change of height dh, with the local density $\rho = \rho(h)$:

$$dp = \frac{g\ dm}{A} = \frac{g\rho dV}{A} = -g\rho dh \ . \tag{9.2}$$

Here $dV = -A\ dh$ is the change in volume of the air column (located above the base). The air should be treated approximately as a substance with a uniform molar mass M.
a. Show with the help of the ideal gas equation that Eq. (9.2) can be cast into the form $dp = -k\ \rho\ dh$ under the given conditions with the constant k. Which is the expression for k?
b. So what is the integral relationship $p = p(h)$? At what height h is the air pressure at $T = 273\,\mathrm{K}$ and $M = 29\,\mathrm{g/mol}$ only half the size of $p(0)$?
c. To what fraction is the air pressure on the Mont Blanc (4794 m) and the Mount Everest (8848 m) at $T = 273\,\mathrm{K}$ reduced compared to $p(0)$ at sea level? How big is the pressure difference Δp compared to normal zero on the Tübingen market place ($h = 341\,\mathrm{m}$)?

Solution: *a. We have $dp = -g\ \rho\ dh$. To link the density ρ with the pressure p, we use the relationship valid for the one-component system: $\rho = \frac{mass}{volume} = \frac{mass}{molar\ mass} \cdot \frac{molar\ mass}{volume} = M \cdot c$. In addition, the ideal gas equation provides a link between c and p: $p = RTc$ or $c = p/(RT)$. Using these two relationships,*

$$dp = \frac{gM}{RT} p\ dh = -k\ p\ dh \quad \Leftrightarrow \quad \frac{dp}{dh} = -k\ p\ , \tag{9.3}$$

where $k = \frac{gM}{RT}$. Since the temperature should be constant, k is constant.
b. According to Eq. (9.3) the change in pressure with the height is proportional to the pressure. So we obtain as an integral solution,

$$p = p(0)\ \exp(-k\ h) = p(0)\ \exp\left(-\frac{Mg}{RT} h\right)\ . \tag{9.4}$$

$h = 0$ denotes the height of the sea level. At the half-value $h_{1/2}$, the pressure is only half the size of $p(0)$. According to Eq. (9.3)(a): $\frac{1}{2} = exp(-k \cdot h_{1/2})$. Then $h_{1/2} = \frac{\ln 2}{k} = \ln 2 \frac{RT}{Mg}$. Inserting the specified values we find $h \approx 5500\,\mathrm{m}$. c. From Eq. (9.4),

$$\frac{p}{p(0)} = \exp\left(-\frac{\ln 2}{h_{1/2}} h\right)\ .$$

9.3 Entropy and the second law of thermodynamics

9.3.1 Kinetic theory

Following Maxwell (1859) we will now develop a microscopic theory. Let us consider a cubic box with volume V and surface A with N particles inside. The particles undergo elastic collisions, but they will not interact, as we suppose the *gas to be ideal.*

We also disregard external forces. However, we only consider the x-direction. We divide the particles into i classes of velocities v_i. The momentum transferred when a particle encounters the wall of the box is $\Delta p_{xi} = 2mv_{xi}$. The number of encounters of this wall in a time interval Δt is,

$$\frac{1}{2}\frac{N_i}{V}\ Av_{xi}\Delta t\ . \tag{9.5}$$

The total change of momentum is,

$$I = 2mv_{xi} \times \frac{1}{2}\frac{N_i}{V}\ Av_{xi}\Delta t = \frac{N_i m v_{xi}^2 A\Delta t}{V}\ . \tag{9.6}$$

The pressure is,

$$P_i = \frac{I}{A\Delta t} = \frac{N_i m v_{xi}^2}{V}\ . \tag{9.7}$$

Hence,

$$P = \sum_i P_i = \frac{m}{V}\sum_i N_i m v_{xi}^2 \equiv \frac{m}{V}\bar{v_x^2} = \frac{N}{3V}m\bar{v^2} = \frac{2}{3}N\bar{E_{kin}}\ . \tag{9.8}$$

With the ideal gas law $P = Nk_BT$. (Compare Tipler Cap. 8-1 and see Exc. 9.3.5.1).

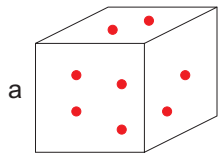

Figure 9.5: Box with N molecules.

9.3.2 Thermal expansion

9.3.3 Heat and work

9.3.4 Heat transport

9.3.5 Exercises

9.3.5.1 Ex: Kinetic pressure

A closed box with end face A and side length L is divided into two equal halves by a movable plate (see figure). Both halves contain one mole of helium under a pressure of p_0. The movable plate is now shifted to the right by the distance x. The shift takes place at constant temperature $T = 20°\text{C}$.
a. Give the volume of the right or left sub-box as a function of x. Give the pressure in the right or left sub-box as a function of x.
b. Calculate the work W that needs to be done to move the plate from $x = 0$ to $x = L/4$. Specify W in joules.

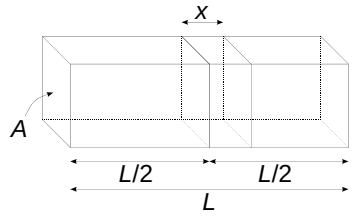

Figure 9.6: Ideal gas in a box.

Solution: *a. For the volumes holds,*

$$V_l = A\left(\frac{L}{2} + x\right) \qquad \textit{and} \qquad V_r = A\left(\frac{L}{2} - x\right) \ .$$

For the pressure we know, $pV = Nk_BT$*, where* N *and* T *are constant. So*

$$p_l = p_0\frac{V_0}{V_l} = p_0\frac{AL/2}{A\,(L/2+x)} = p_0\frac{L}{L+2x} \qquad \textit{and} \qquad V_r = p_0\frac{L}{L-2x} \ .$$

b. The gas on the left exerts the force $F_l = p_lA$ *on the plate in positive* x *direction. The gas on the right* $F_r = -p_rA$*. So the work that has to be done is,*

$$\begin{aligned} W &= -\int_0^{L/4}(F_l + F_r)dx = -A\int_0^{L/4}\left(p_0\frac{L}{L+2x} - p_0\frac{L}{L-2x}\right)dx \\ &= \frac{LAp_0}{2}\ln\frac{4}{3} \ . \end{aligned}$$

Now, we get, $W = p_0V_0\ln\frac{4}{3} = Nk_BT\ln\frac{4}{3} = 1mol{\cdot}6.022{\cdot}10^{23}\ mol^{-1}{\cdot}1.38{\cdot}10^{-23}\ J/K{\cdot}293\ K{\cdot}\ln\frac{4}{3} = 700\ J.$

9.3.5.2 Ex: Bi-metal

Two bars of different materials, with lengths, Young's modules and thermal expansion coefficients given respectively by L_1, L_2, Y_1, Y_2, α_1, and α_2, are pinched between two walls, as shown in the figure. Calculate the distance travelled by the junction point of the bars when the system is heated by an amount ΔT. What is the tension on the bars?

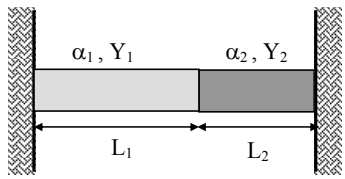

Figure 9.7:

Solution:

9.3.5.3 Ex: Bi-metal

In the sketched construction two thin metal strips with different linear expansion coefficients (aluminium and copper) $\alpha_{Al} = 24 \cdot 10^{-6}$ K^{-1} and $\alpha_{Cu} = 17 \cdot 10^{-6}$ K^{-1} are connected to each other by bars so that they have a fixed distance $d = 1$ mm. When the temperature increases, the two strips expand so that they form circular segments with different radii, as shown in the figure. An angle of the circle segment of $\phi = 1°$ is measured. How big is the temperature increase?

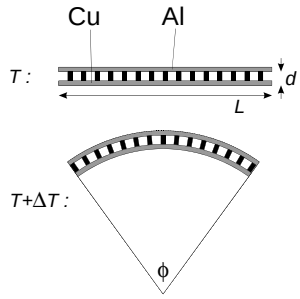

Figure 9.8: Bimetal.

Solution: *For the individual strips holds,*

$$(L + \alpha_{Al}\Delta T L) = \phi(r + d)$$
$$(L + \alpha_{Cu}\Delta T L) = \phi r \ .$$

Therefore,

$$(\alpha_{Al} - \alpha_{Cu})\Delta T L) = \phi d \ .$$

The temperature change is therefore $\Delta T = \frac{\phi d}{L(\alpha_{Al} - \alpha_{Cu})} \approx 25 \ K.$

9.3.5.4 Ex: Linear expansion

The length of a 10 cm long spacer made of quartz glass with linear expansion coefficient $\alpha_1 = -1$ cm/m/°C is to be kept constant by using a spacer made of Invar steel with a linear expansion coefficient $\alpha_1 = 10$ cm/m/°C. How long must the spacer be?

Solution: *Banane.*

9.4 Ideal gas thermodynamics

9.4.1 Heat capacity

9.4.2 Types of expansions

9.4.3 Adiabaticity coefficient

An *adiabatic process* in thermodynamics is a process, in which the system does not exchange heat with the environment. To verify how the pressure and volume of an ideal gas vary during an adiabatic process we need two ingredients. First, the equation of state of an ideal gas, that is,

$$pV = nRT = Nk_BT \ , \tag{9.9}$$

where n is the number of moles of gas, N is the number of molecules of gas, R is the gas constant, and k_B the Boltzmann constant, that is, $Nk_B = nR$ or $R = N_Ak$, where N_A is Avogadro's number. The other ingredient is the *equipartition theorem*, which says that in an ideal gas in equilibrium at temperature T (in Kelvin), the average energy of each molecule per degree of freedom is,

$$\tfrac{1}{2}k_BT \ . \tag{9.10}$$

That is, the total energy of the gas is,

$$U = \tfrac{f}{2}Nk_BT = \tfrac{f}{2}nRT \ , \tag{9.11}$$

where f is the number of degrees of freedom of the gas molecule (accessible at that temperature). In an adiabatic process there is no heat exchange, and therefore energy conservation claims, that the energy variation dU must be equal to the (negative) work dW realized by the gas, that is,

$$dU + dW = 0 \ . \tag{9.12}$$

From (9.11) we have:

$$dU = \tfrac{f}{2}nRdT = -dW = -pdV \ . \tag{9.13}$$

From (9.9) we have:

$$Vdp + pdV = nRdT \ . \tag{9.14}$$

Hence,

$$\tfrac{f}{2}(Vdp + pdV) = -pdV \ , \tag{9.15}$$

yielding,

$$\tfrac{f}{2}Vdp = \left(1 + \tfrac{f}{2}\right)pdV \ . \tag{9.16}$$

Defining,

$$\gamma \equiv \frac{f+2}{f} \ , \tag{9.17}$$

we get,

$$Vdp = -\gamma pdV \ , \tag{9.18}$$

yielding,

$$\frac{dp}{p} = -\gamma \frac{dV}{V} \ , \tag{9.19}$$

yielding,

$$d\ln P = -d\ln V^{\gamma} \ . \tag{9.20}$$

That is,

$$d[\ln(pV^{\gamma})] = 0 \ . \tag{9.21}$$

Hence,

$$pV^{\gamma} = const. \tag{9.22}$$

The heat capacity is defined as the ratio between the absorbed heat and the rise in temperature, i.e.,

$$\Delta Q = C\Delta T \ . \tag{9.23}$$

For a process where the volume is maintained constant the gas does not perform work, and the heat is only used to increase the energy. From (3) we have:

$$\Delta Q = \tfrac{f}{2} \ . \tag{9.24}$$

Therefore, the heat capacity, at constant volume, is,

$$C_V = \tfrac{f}{2} nR \ . \tag{9.25}$$

If the process is done at constant pressure, then the heat is used to change the energy and also to perform work, that is:

$$\Delta Q = \Delta U + \Delta W \ . \tag{9.26}$$

From (1) we have that at constant pressure,

$$p\Delta V = nRT\Delta T \ . \tag{9.27}$$

Hence,

$$\Delta Q = \tfrac{f}{2} nR\Delta T + nR\Delta T = \left(1 + \tfrac{f}{2}\right) \ . \tag{9.28}$$

and

$$C_p = \left(1 + \tfrac{f}{2}\right) nR \ . \tag{9.29}$$

We conclude, then,

$$\frac{C_p}{C_V} = \gamma \qquad \text{and} \qquad C_p - C_V = nR \ . \tag{9.30}$$

Since the specific heat can be obtained from the heat capacity simply by dividing by the mass, the ratio of the specific heat at constant pressure and to the specific heat at constant volume is also equal to the constant γ, that is, $\gamma = c_p/c_V$.

9.4.3.1 The Cléments-Desormes method

The specific heat of solids and liquids is usually measured with samples under atmospheric conditions and without control of the volume of the material. For this reason, these are specific heats measured at constant pressure: c_P. To measure the heat capacity of gases, it is much simpler to work with the gas contained in a rigid recipient, such as a glass bulb with little thermal expansion within the temperature range of the experiment. Then, the measured value is the specific heat at constant volume c_V. The value c_P of a gas is larger than c_V, because in the experiment, at constant pressure, the heat delivered to the material also causes an expansion of the gas, which means that part of that energy has been converted into work and not into an increase the body's thermal energy. The ratio between specific heats at constant pressure and volume, $\gamma = c_p/c_v$, is a value that often appears in the description of thermodynamic processes in gases. This ratio can be measured by isobaric and isochoric processes, respectively measuring c_p and c_v. The first experiment to measure the factor γ in gases was performed in 1819 by *Desormes* and *Clément*. The method consists of applying to a (ideal) gas, a sequence of two processes illustrated in Fig. 9.9: an adiabatic expansion from state (1) to (2), and isochoric heating from (2) to (3). In the initial equilibrium state (1), a certain amount of moles of gas n are at a pressure P_1 above atmospheric pressure with the volume V_1, and a temperature T_1 equal to room temperature. An adiabatic expansion is performed to state (2) with pressure P_2 equal to atmospheric pressure, volume V_2, and temperature T_2 lower than room temperature. Immediately an isochoric heating is carried out toward the state (3), at room temperature, for T_1, and pressure P_3.

To calculate the factor γ of the gas, we consider the relation between P and V in the course of an adiabatic process: $pV^\gamma = const.$. Thus, we can write,

$$p_1 V_1^\gamma = p_2 V_2^\gamma \ . \tag{9.31}$$

From this relation, it is possible to write the factor γ as in Fig. 9.9 for the gas process realized by the Cléments-Desormes experiment: between the initial state (1) and (2) the process is adiabatic. Between (2) and (3) it is isochoric. In order to obtain the result only in terms of pressures and not volumes which, in practice, are more difficult to measure accurately, we can now consider the isochoric process (2) to (3) imposing the condition that states (1) and (3) lie on the same isothermal curve with temperature T_1 (see Exc. 9.4.5.30).

9.4.3.2 Rüchardt's method

Rüchardt's method is discussed in Exc. 9.4.5.20.

9.4.4 Cyclic processes and thermal machines

Thermal machines are based on cyclic processes. Examples are the Carnot cycle, the *Otto cycle*, or the *Diesel cycle*.

9.4.4.1 Carnot cycle

A *Carnot cycle* is an ideal thermodynamic cycle providing, by Carnot's theorem, an upper limit on the efficiency of any classical thermodynamic engine during the

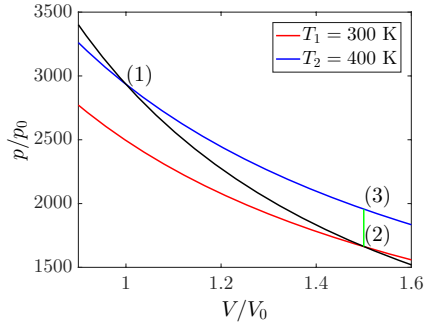

Figure 9.9: Clément-Desormes cyclic process.

conversion of heat into work, or conversely, the efficiency of a refrigeration system in creating a temperature difference through the application of work to the system.

In a Carnot cycle, an engine transfers energy in the form of heat between two thermal reservoirs at temperatures T_{hot} and T_{cold}, and a part of this transferred energy is converted to the work done by the system. The cycle is reversible and hence isentropic. In other words, entropy is conserved; it is only transferred between the thermal reservoirs. When work is applied to the system, heat moves from the cold to hot reservoir, which is exploited in *heat pumps* and *refrigerators*, depending on whether the heat increase of the hot reservoir is exploited or the heat decrease of the cold reservoir. When heat moves from the hot to the cold reservoir, the system applies work to the environment, which can be exploited in *heat engines*.

The work W done by the system or engine to the environment per Carnot cycle depends on the temperatures of the thermal reservoirs and the entropy transferred from the hot reservoir to the system ΔS per cycle such as,

$$W = (T_{hot} - T_{cold})\Delta S = (T_{hot} - T_{cold})\frac{Q_{hot}}{T_{hot}} \ , \tag{9.32}$$

where Q_{hot} is heat transferred from the hot reservoir to the system per cycle.

To calculate the yield of the Carnot cycle (see Fig. 9.10) we ...

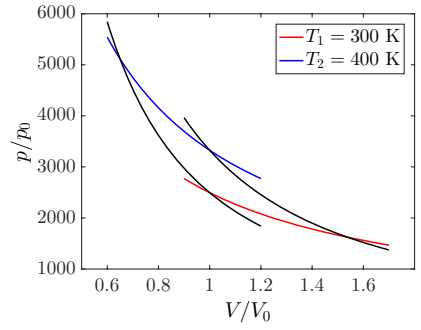

Figure 9.10:

9.4.5 Exercises

9.4.5.1 Ex: Depth gauge

You want to build a depth gauge for diving operations and take advantage of the compressibility of air. To do this, you take a glass cylinder with a movable flask (volume $V = A \cdot x$, footprint A) and a millimeter scale located in the flask. To what water depth h can the device deliver the targeted measuring accuracy of ± 1 m, if the piston position x can be read with an accuracy of ± 1 mm and $x(p_0) = 0.2$ m at the water surface?

Solution: *For $h = 0$ m the pressure is $p = p_0 = 10^5$ Pa and $x = x_0 = 0.2$ m. According to Boyle-Mariotte: $(p_0 + \rho g h) \cdot A \cdot x = p_0 \cdot A \cdot x_0$. $\Rightarrow h = a \cdot \frac{x_0 - x}{x}$ with $a = \frac{p_0}{\rho g} = 10.2$ m. $\Rightarrow \frac{\Delta h}{\Delta x} \approx \frac{\partial h}{\partial x} = -a\frac{x_0}{x^2} < 0$. $\Rightarrow x \approx \sqrt{a x_0 \left|\frac{\Delta x}{\Delta h}\right|}$.*
With $\Delta x = 1$ mm and $\Delta h = 1$ m we get $x = 4.52$ cm and accordingly $h = 35$ m. The device is accurate to a depth of $h = 35$ m to 1 m.

9.4.5.2 Ex: Tramway

A tram with mass $m_B = 12500$ kg brakes from a speed $v = 57.6$ km/h to standstill. What is the temperature of the eight cast iron brake blocks when the mass of each block is 9.0 kg and 60% of the kinetic energy flows into the heating of the blocks?

Solution: *The amount of heat flowing into the brake padsis $Q = 0.6 \cdot 0.5 \cdot m_B v^2 = 960$ kJ. The mass of an Fe atom is 56 u and with the rule of Dulong-Petit follows $c_{Fe} = \frac{24.9}{56}\ \frac{J}{g \cdot K} \approx 0.445\ \frac{J}{g \cdot K}$. The mass of all brake blocks is $M = 8 \cdot 9$ kg= 72 kg, such that we expect a temperature increase of $\Delta T = \frac{Q}{M \cdot c_{Fe}} = \frac{960\ kJ}{72\ kg \cdot 0.445\ \frac{J}{g \cdot K}} \approx 30$ K.*

9.4.5.3 Ex: Heat capacities

a. Two gas containers are brought into thermal contact. They contain gases with the temperatures T_1 and T_2, as well as the heat capacities C_1 and C_2. The thermal capacity of the containers is negligible. What is the temperature of the gases after an equilibrium has been reached?
b. Now consider the temperature equilibrium of three containers, each with 100 g of the gas H_2 at the temperature $T_{H_2} = 10$ C, 50 g of the gas He at the temperature $T_{He} = 15$ C, and 200 g of the gas N_2 at temperature $T_{N_2} = 20$ C. What is the final temperature?

Solution: *a. The temperature is,*

$$T_m = \frac{C_1 T_1 + C_2 T_2}{C_1 + C_2}\ ,$$

because the heat delivered by gas 1 $\Delta Q = C_1(T_1 - t_m) = -C_2(T_2 - T_m)$ must be absorbed by gas 2.

b. The molar heat capacities are $\tilde{C} = N_A \frac{\bar{f}}{2} k_B$*, hence,*

$$\tilde{C}_{H_2} = \tilde{C}_{N_2} = N_A \frac{5}{2} k_B = 20.8\,\mathrm{J/K\ mol} \qquad \textit{and} \qquad \tilde{C}_{He} = N_A \frac{3}{2} k_B = 12.5\,\mathrm{J/K\ mol}\ .$$

The specific heat capacities are $c = \tilde{C}/(m\ N_A)$*, hence,*

$$c_{H_2} = \frac{5}{2}\frac{k_B}{2u} \simeq 10393\,\mathrm{J/K\ kg} \qquad \textit{and} \qquad c_{He} = \frac{3}{2}\frac{k_B}{2u} \simeq 3118\,\mathrm{J/K\ kg}$$
$$\textit{and} \qquad c_{N_2} = \frac{5}{2}\frac{k_B}{14u} \simeq 742\,\mathrm{J/K\ kg}\ .$$

If M *is the total mass of the gases, then the actual heat capacities are* $C = cM$*, hence,*

$$C_{H_2} = 0.1 \cdot 10393\,\mathrm{J/K} \qquad \textit{and} \qquad C_{He} = 0.05 \cdot 3118\,\mathrm{J/K} \qquad \textit{and} \qquad C_{N_2} = 0.2 \cdot 742\,\mathrm{J/K}\ .$$

The temperature is finally,

$$T_m = \frac{C_{H_2} T_{H_2} + C_{He} T_{He} + C_{N_2} T_{N_2}}{C_{H_2} + C_{He} + C_{N_2}} = 11.7\,\mathrm{C}\ .$$

9.4.5.4 Ex: Calorimetry

a. A calorimeter initially contains a volume of $V_1 = 100$ ml of water in thermal equilibrium with the calorimeter at temperature $T_1 = 15°\mathrm{C}$. Now we add a volume $V_2 = 100$ ml of water at temperature $T_2 = 40°\mathrm{C}$. After reaching thermal equilibrium again, the temperature becomes $T_f = 25°\mathrm{C}$. What is the thermal capacity of the calorimeter?
b. Starting from the final condition of the previous item, we add to the calorimeter a metallic body with mass $m_3 = 80$ kg and temperature $T_3 = 90°\mathrm{C}$. After reaching thermal equilibrium again, the temperature becomes $T_{ff} = 35°\mathrm{C}$. What is the specific heat of the body?

Solution: *a. The thermal capacity of the calorimeter is,*

$$C = m_2 c_a \frac{T_2 - T_f}{T_f - T_1} - m_1 c_a = 100\ g{\cdot}1\ cal/g\ ^\circ C{\cdot}\frac{40-25}{25-15} - 100\ g{\cdot}1\ cal/g\ ^\circ C = 50\ cal/^\circ C\,.$$

b. The specific heat of the body is,

$$c_3 = \frac{(m_1+m_2)c_a + C}{m_3}\frac{T_{ff} - T_f}{T_3 - T_{ff}} = \frac{200\ g \cdot 1\ cal/g\ ^\circ C + 50\ cal/^\circ C}{80\ g}\frac{35-25}{90-35} = 0.5682\ cal/g\ ^\circ C\,.$$

9.4.5.5 Ex: Calorimeter for mixtures

The specific heat capacity of platinum c_{Pt} is to be measured with a mixing calorimeter. For this purpose, a platinum body is heated to 100 °C and then thrown into water of 20 °C. To simplify the evaluation, the mass of the water is chosen to be that of the platinum body. The heat absorption of the calorimeter body should be neglected. The specific heat capacity of water is $c_{\mathrm{H_2O}} = 4.19$ J/(g K), the relative atomic mass of platinum is $m_{\mathrm{Pt}} = 195$ u, the linear expansion coefficient $\alpha = 9.0 \cdot 10^{-6}$ K^{-1}.
a. The mixing temperature is 22.41 °C. What value follows for c_{Pt}?
b. What is the value for c_{Pt} when applying the Dulong-Petit rule?
c. The platinum body and the water have the same mass. What is the ratio of the number of platinum atoms to the number of water molecules?
d. How many degrees does the platinum body have to be heated to increase its volume by 1 %?

Solution: *a. We have,*

$$\Delta Q = m_{H_2O} c_{H_2O} \Delta T_{H_2O} + m_{Pt} c_{Pt} \Delta T_{Pt} = 0 \ .$$

The following also applies $m_{H_2O} = m_{Pt}$. Then follows,

$$\Rightarrow c_{Pt} = -c_{H2_O} \frac{\Delta T_{H_2O}}{\Delta T_{Pt}} \ .$$

With $T_{H_2O} = 2.41$ K, $T_{Pt} = -77.59$ K and $c_{H_2O} = 4.19$ J/(g·K) we get $c_{Pt} = 0.130$ J/(g·K).
b. Dulong-Petit: $C_{mol} = 24.9$ J/mol·K $\Rightarrow c_{Pt} = \frac{24.9}{195} \frac{J}{g \cdot K} \approx 0.128 \frac{J}{g \cdot K}$
c. Mass of a H_2O-molecule: $m_{H_2O} = 18$ u, mass of a platinum atom: $m_{Pt} = 195$ u, $N_{H_2O} \cdot m_{H_2O} = M_{H_2O} = M_{Pt} = N_{Pt} \cdot m_{Pt} \Rightarrow \frac{N_{Pt}}{N_{H_2O}} = \frac{18}{195} \approx \frac{0.092}{1}$
d. $L' = (1 + \alpha \cdot \Delta T)L \Rightarrow V' = L'^3 = (1 + \alpha \cdot \Delta T)^3 L^3 = (1 + \alpha \cdot \Delta T)^3 V = 1,01 \cdot V$ $\Rightarrow \Delta T = \frac{\sqrt[3]{1.01} - 1}{\alpha} \approx 370$ K.

9.4.5.6 Ex: Calorimeter for mixtures

The equation of state of an ideal gas $pV = Nk_BT$ applies and the energy is given as $E = C_V T$.
a. Show that for the entropy change of an ideal gas from state A with temperature T_A and volume V_A to state B with temperature T_B and volume V_B holds: $\Delta S = C_V \log(T_B/T_A) + Nk_B \log(V_B/V_A)$.
b. Two insulated containers with the same volume $V = 10$ cm^3, the same pressure $p = 1$ bar and the same temperature $T = 100°$ C are filled with nitrogen and oxygen, respectively. Determine the change in entropy when connecting the containers so that the gases can mix.

Solution: *a. The 1st law of thermodynamics states $\delta Q = dE - \delta W = C_V dT + pdV$. With that and with the ideal gas equation $p = Nk_B \frac{T}{V}$ on gets,*

$$dS = \frac{\delta Q}{T} = \frac{C_V dT + pdV}{T} = C_V \frac{dT}{T} + Nk_B \frac{dV}{V} \ .$$

Hence, we get the entropy change

$$\Delta S = S_B - S_A = \int_{S_A}^{S_B} dS = C_V \int_{T_A}^{T_B} \frac{dT}{T} + Nk_B \int_{V_A}^{V_B} \frac{dV}{V} = C_V \ln \frac{T_B}{T_A} + Nk_B \ln \frac{V_B}{V_A} \ .$$

b. The ideal gas equation $\frac{pV}{T} = Nk_B$ *tells us that with identical pressure, volume and temperature the particle numbers must also be identical, i.e.* $N = N_{O_2} = N_{N_2}$*. Since both gases are diatomic,* $E_{O_2} = E_{N_2} = \frac{f}{2} Nk_B T = C_V T$ *with* $5 = f = f_{O_2} = f_{N_2}$ *degrees of freedom, i.e. the internal energies are identical as are the specific heats. Now if the gases mix, we have,*

$$\Delta Q = 0 = \Delta W \Rightarrow \Delta E = 0 \ ,$$

since the thermal insulation of the containers impedes any exchange of thermal energy with the surroundings. Likewise, no work is done by simply bringing the containers together and removing the partition. The internal energies of the two gases are also the same, so that the two gas components also do not exchange energy. On the other hand, $\Delta E = 0$ *means that the temperature does not change,* $T = constant = T_A = T_B$*. Each of the two gas components* O_2 *and* N_2 *sees its volume doubled,* $V_A \equiv V \to 2V \equiv V_B$*. So with equation (3)*

$$\Delta S_{O_2} = \Delta S_{N_2} = C_V \ln \frac{T_B}{T_A} + Nk_B \ln \frac{V_B}{V_A} = Nk_B \ln 2 \ .$$

Finally, $\Delta S = \Delta S_{O_2} + \Delta S_{N_2} = Nk_B 2 \ln 2$*.*
Note: *The formula (3) respectively (4) apply provided that the particle number* N *of the ideal gas under consideration is maintained constant. If* N *were also to change, the formula receives an additional term that takes this change in particle number into account. Assuming that in subtask (b) the two gases are identical, then the simple addition of the individual entropy change leads to a wrong result. Because of the indistinguishability,* $\Delta S = 0$*, since the probability to find a particle before and after does not change. One could consider the entropy change if the gas is first in* V *with particle number* N *and then in* $2V$ *with particle number* $2N$*. But that would require the extended formula.*

9.4.5.7 Ex: Partial pressures

A closed cylindrical reservoir with the base area $S = 10$ cm^2 is kept at a constant temperature $T = 27°$C. It is divided in two volumes by an airtight mobile disk with the mass $m = 10$ kg. The upper volume V_{O_2} contains $\eta_{O_2} = 1$ mol of oxygen, the lower volume V_{N_2} contains the same amount of nitrogen. Due to its weight the disc finds an equilibrium position when the lower volume is $V_{N_2} = 10$ l.
a. What are the masses m_{O_2} and m_{N_2} of the gases?
b. What are the pressures P_{O_2} and P_{N_2}?
c. What is the upper volume V_{O_2}?
d. What are the densities n_{O_2} and n_{N_2}?
e. Now the disc has a hole, so that the gases can mix and the disc falls to the bottom of the reservoir. What is the final pressure of the mixture?

Solution: *a. The numbers of particles in the gases are equal,*

$$N_{O_2} = \eta_{O_2} N_A = \eta_{N_2} N_A = N_{N_2} = N \ .$$

Therefore, the masses are,

$$m_{O_2} = N \cdot 16u = 16 \ g \qquad and \qquad m_{N_2} = N \cdot 14u = 14 \ g \ .$$

b. The disc presses on the lower volume with the pressure mg/S. The pressures on the volumes are therefore related by $p_{O_2} + \frac{mg}{S} = p_{N_2}$. The pressure in the lower volume is,

$$P_{N_2} = \frac{N k_B T}{V_{N_2}} = 2.5 \ bar \ .$$

The pressure in the upper volume is,

$$P_{O_2} = P_{N_2} - \frac{mg}{S} = 1.5 \ bar \ .$$

c. Now we can calculate the upper volume

$$V_{O_2} = \frac{N k_B T}{P_{O_2}} = 16.5 \ l \ .$$

d. The densities are

$$n_{O_2} = \frac{N}{V_{O_2}} = \frac{P_{O_2}}{k_B T} = 6.0 \cdot 10^{25} \ m^{-3} \qquad and \qquad n_{N_2} = \frac{N}{V_{N_2}} = \frac{P_{N_2}}{k_B T} = 3.6 \cdot 10^{25} \ m^{-3} \ .$$

e. The total pressure is the sum of the partial pressures, $P = P_{O_2} + P_{N_2}$. Knowing the total volume of the reservoir, $\tilde{V} = V_{O_2} + V_{N_2}$ and the ideal gas law we have,

$$\tilde{P} = \tilde{P}_{O_2} + \tilde{P}_{N_2} = \frac{N k_B T}{\tilde{V}} + \frac{N k_B T}{\tilde{V}} = \frac{2 N k_B T}{V_{O_2} + V_{N_2}} = 1.9 \ bar \ .$$

9.4.5.8 Ex: Ideal gas

A diver is at a water depth of h_0 and breathes air from a compressed air bottle. When exhaling, he creates (spherical) air bubbles with the volume V_0. Assume that the surface water temperature is T_1 and decreases evenly to a depth of h_0 by an amount of temperature α per meter.
a. Assume a constant water density ρ and calculate the pressure p depending on the water depth at an atmospheric pressure p_1. b. Calculate the volume of the bubbles as a function of water depth. How big is the volume just below the water surface? Why is it important for the diver to exhale continuously as he ascends?
Numerical values: Water depth $h_0 = 40$ m, $V_0 = 1$ cm^3, $T_1 = 20°$C, $\alpha = 0.2°$C/m, $\rho = 1$ kg/l, and $p_1 = 1013$ hPa.

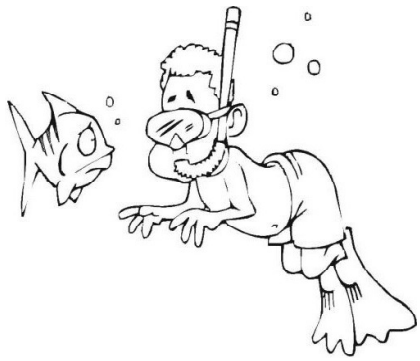

Figure 9.11: Ideal gas in a box.

Solution: *a. The pressure in a water column of depth is h,*

$$p = p_0 + \frac{mg}{A} = p_0 + \frac{\rho V g}{A} = p_0 + \frac{\rho A h g}{A} = p_0 + \rho h g \ .$$

b. The temperature is,

$$T = T_0 - \alpha h \ .$$

According to the ideal gas law, $pV = Nk_BT$, we get,

$$V(h) = \frac{p_{40}V_{40}}{Nk_BT_{40}}\frac{Nk_BT(h)}{p(h)} = V_{40}\frac{p_{40}}{p}\frac{T}{T_{40}} = V_{40}\frac{p_0 + \rho h_{40} g}{p_0 + \rho h g}\frac{T_0 - \alpha h}{T_0 - \alpha h_{40}} \approx V_{40}\frac{h_{40}}{h}\frac{T_0 - \alpha h}{T_0 - \alpha h_{40}} \ .$$

The result is $V_1/V_0 \simeq 5$. The air in the lungs expands. If the diver does not exhale, the alveoli may burst.

9.4.5.9 Ex: Simple model for a solid

Consider a system of N atomic particles at a temperature T. The individual atoms can only be in one of two states. Either in state "0" at the energy $\epsilon_0 = 0$ or in state "1" at energy $\epsilon_1 = \epsilon$. Apart from this energy ϵ_i, the atoms have no kinetic or other energies.
a. Determine the probability w_i that a certain atom is in state i. Note: The distribution is a Boltzmann distribution. How should the normalization be chosen?
b. Determine the statistical mean $\bar{\epsilon}$ for the energy of an atom. What is the expression for the total energy E of N atoms? Which values result for $k_BT = \epsilon$?
c. Calculate the population probability w_j to find a certain atom at the energy ϵ if for temperatures satisfy: $k_BT_j = 0.1 \cdot j \cdot \epsilon$ für $j = 1, 2, 3, 4$. Also calculate the energy E_j of the entire system at these temperatures.
d. Find an expression for the heat capacity c of this N atom system. Note: For this system, the total energy is identical to the thermal energy.
e. Calculate the heat capacities c_j especially for the temperatures T_j from subtask (a). What does this result have to do with 'freezing degrees of freedom'?

Solution: *a. The probability of finding a certain atom in state i is*

$$w_0 = \frac{1}{1+e^{-\epsilon/k_BT}} \qquad \textit{and} \qquad w_0 = \frac{e^{-\epsilon/k_BT}}{1+e^{-\epsilon/k_BT}} \ .$$

b. The statistical mean is,

$$\bar{\epsilon} = 0w_0 + \epsilon w_1 = \epsilon \frac{e^{-\epsilon/k_BT}}{1+e^{-\epsilon/k_BT}} = \epsilon \frac{e^{-1}}{1+e^{-1}} = 027\epsilon \ .$$

The total energy is,

$$E = N\bar{\epsilon} \ .$$

c. The occupation probabilities for the different temperatures are $w_1 = 0.000045$, $w_2 = 0.0067$, $w_3 = 0.03445$, *and* $w_4 = 0.0758$.
d. The heat capacity is,

$$C = \frac{dE}{dT} = N\epsilon \frac{dw_1}{dT} = N\epsilon \frac{de^{-\epsilon/k_BT}}{dT} \frac{d}{dx}\frac{x}{1+x} = Nk_B \frac{\epsilon^2}{(k_BT)^2} \frac{e^{-\epsilon/k_BT}}{(1+e^{-\epsilon/k_BT})^2} \ .$$

e. The associated heat capacities are $C/NK_B = 0.0045$,

$$E = N\bar{\epsilon} \ .$$

Beware: *The model is nonsensical for* $k_BT > \epsilon/2$. *Then several levels are required.*

9.4.5.10 Ex: 1. law of thermodynamics

In a thermally insulated container there is one mole of air at the temperature $T = 400$ K. Now, it is reversibly compressed, doing the work $W = 1.987$ cal. Calculate the ratio V_f/V_i between the final and initial volume. Assume that the air behaves like an ideal gas and that the container itself does not absorb heat from the air.

Solution: *Conversion to Joule:* $1\ cal = 4.187\ J$. *The differential work is for adiabatic processes* $dW = -pdV$. *With the ideal gas equation,* $pV = \nu RT$, *we can substitute the pressure,* $dW = -\frac{\nu RT}{V}dV$, *or,*

$$W = -\nu RT \int \frac{dV}{V} = -\nu RT(\ln V_f - \ln V_i) = -\nu RT \ln \frac{V_f}{V_i} \ .$$

So We get,

$$\frac{V_f}{V_i} = e^{-W/\nu N_A k_B T} \simeq 0.9977 \ .$$

9.4.5.11 Ex: Energy of air

Calculate the kinetic energy as well as the average molecular velocity in 1 kg of air (main components N_2, O_2) at $T = 300$ K. Help: $E_{kin} = Q = m \cdot c \cdot T$; specific heat $c = f/2 \cdot R$.

Solution: $Q = 2.13 \cdot 10^5\ J$ *and* $v = 505.6\ m/s$

9.4.5.12 Ex: Gas compression

Calculate the temperature change resulting from *adiabatic* compression of an ideal gas of volume $V(T_1)$ to $V(T_2) = V(T_1)/10$.
Compare this with the temperature change through an analog *isobaric* compression of an equally ideal gas. **Note:** $\kappa = c_p/c_v = 1.4$ (for air), $T_1 = 293$ K.

Solution: *The following applies to adiabatic compression,* $p_1 V_1^\kappa = p_2 V_2^\kappa$. *Hence,*

$$\Delta T = T_2 - T_1 = \frac{p_2 V_2}{N k_B} - T_1 = \frac{p_1 V_1}{N k_B} \frac{V_1^{\kappa-1}}{V_2^{\kappa-1}} - T_1 = T_1 10^{\kappa-1} - T_1 = \left(10^{1.4-1} - 1\right) \cdot 293\ K \simeq 442.98\ K\,.$$

Mistake!!!??? The expected result is $\Delta T_{adiabatisch} = +460\ K$.
The following applies to isobaric compression $\frac{V_1}{T_1} = \frac{V_2}{T_2}$. *Hence,*

$$\Delta T = T_2 - T_1 = \frac{V_2}{V_1} T_1 - T_1 = \left(\frac{V_2}{V_1} - 1\right) T_1 = \left(\frac{1}{10} - 1\right) \cdot 293\ K \simeq -263.7\ K\,.$$

9.4.5.13 Ex: Gas compression

An oxygen bottle with the volume $V_2 = 40$ l contains a filling ex works that would have the volume $V_1 = 6$ m^3 at atmospheric pressure $p_1 = 101$ kPa. The bottle, which has been emptied to atmospheric pressure, is refilled at a constant temperature of $T_1 = 18°$C. What mechanical work W must be added to the gas to compress it isothermally from p_1 to the filling pressure?

Solution: *The particle number* $N = \frac{pV}{k_B T}$ *is constant, because* pV *is constant. The work follows from* $\delta W = pdV$,

$$W = \int_{V_1}^{V_2} p dV = \int_{V_1}^{V_2} \frac{N k_B T \cdot dV}{V} = p_1 V_1 \int_{V_1}^{V_2} \frac{dV}{V} = p_1 V_1 \left(\ln V_2 - \ln V_1\right)$$
$$= 101000 \cdot 6 \cdot \ln \frac{0.04}{6}\ J = -3.036\ MJ\,.$$

9.4.5.14 Ex: Gas expansion

1 kmol of nitrogen under normal conditions ($p_0 = 1.01 \cdot 10^5$ Pa, $T = 0°$C) adiabatically expands from V_1 to $V_2 = 5 \cdot V_1$. Calculate the change in the internal energy of the gas and the amount of work the gas does as it expands.

Solution: *The adiabatic coefficient is,*

$$\kappa = \frac{c_p}{c_V} = \frac{\tilde{f}+1}{\tilde{f}} = \frac{3.5}{2.5} = 1.4 \ .$$

Adiabatic expansion means,

$$pV^\kappa = \frac{Nk_BTV^\kappa}{V} = const \ .$$

So because of $dU = pdV = -\delta W$ the work is,

$$\begin{aligned}
\Delta W &= \int_{V_1}^{V_2} \frac{Nk_BT}{V}\frac{V^\kappa}{V^\kappa}dV = \frac{Nk_BT}{V}V^\kappa \int_{V_1}^{V_2}\frac{dV}{V^\kappa} \\
&= Nk_BTV^{\kappa-1}\left(\frac{-1}{(\kappa-1)V_2^{\kappa-1}} - \frac{-1}{(\kappa-1)V_1^{\kappa-1}}\right) \\
&= \frac{Nk_BT_1}{\kappa-1}\left(1-\frac{1}{5^{\kappa-1}}\right) = \frac{1\ kmol\cdot N_Ak_B\cdot 273.15\ K}{\kappa-1}\left(1-\frac{1}{5^{\kappa-1}}\right) \\
&= \frac{1000\cdot 8.31\cdot 273.15}{0.4}\left(1-\frac{1}{5^{0.4}}\right)\ J = 2.7\,\text{MJ} \ .
\end{aligned}$$

The change in internal energy is therefore $dU = -2.7$ MJ.

9.4.5.15 Ex: 1. law of thermodynamics

In a thermally insulated container B there are n mol of an ideal gas and a body K with the heat capacity C. Specify the relationship between pressure p and volume V, whereby the change in V is carried out so slowly that the following always applies to body and gas: $T_K = T_G$.
Note: Body and gas exchange heat. Assume that the container itself does not take heat from the gas or the body.

Solution: *Because the gas only gives away heat to the body, the 1st law gives for an infinitesimal variation of the state of the gas:*

$$dU = nC_V dT = \delta Q|_{\text{G}} - pdV \qquad \delta Q|_{\text{G}} = -\delta Q|_{\text{K}} = -CdT \ .$$

It follows,

$$dT = -\frac{p}{C+nC_V}(p\ dV) \ .$$

In addition, by differentiating the equation of state,

$$dT = \frac{1}{nR}(p\ dV + V\ dp) \ .$$

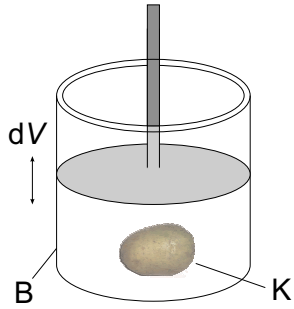

Figure 9.12: Potato.

Equating the results gives,

$$(\kappa+1)pdV+\kappa V dp=0\ , \qquad \kappa=\frac{C_V+C/n}{R}\ .$$

Now we integrate

$$p\ V^{\tilde{\gamma}}=\text{const.} \qquad \tilde{\gamma}=1+\frac{1}{\kappa}=\frac{C_p+C/n}{C_V+C/n}\ .$$

9.4.5.16 Ex: 1. law of thermodynamics

In a thermally insulated container there is one mole of air at temperature $T = 400$ K. It is compressed very slowly (reversibly) while doing the work $W = 1.987$ cal on it. Calculate the behavior of the ratio V_f/V_i between the end and start volume. Assume that the air behaves like an ideal gas and that the container itself does not absorb heat from the air.

Solution: *Conversion to Joule: 1 cal=4.187 J. The differential work for adiabatic processes is $dW = -pdV$. With the ideal gas equation, $pV = \nu RT$, we can substitute the pressure, $dW = -\frac{\nu RT}{V}dV$. Or*

$$W=-\nu RT\int\frac{dV}{V}=-\nu RT(\ln V_f-\ln V_i)=-\nu RT\ln\frac{V_f}{V_i}\ .$$

So we get,

$$\frac{V_f}{V_i}=e^{-W/\nu N_A k_B T}\approx 0.9977\ .$$

9.4.5.17 Ex: 1. law of thermodynamics

A container with 1 mol helium and a container of the same size with 1 mol nitrogen are both heated with the same heating power $W = 10$ W.

a. Calculate how long it takes to warm up the containers from $T_1 = 20°\text{C}$ to $T_2 = 100°\text{C}$, if the thermal capacity of the container is 10 J/K.
b. How long does it take to warm up to 1000°C assuming that the vibrational degrees freedom of N_2 molecules can be excited above 500°C? Neglect heat loss.

Solution: *The thermal energy of a mole is* $Q = \frac{f}{2}RT$.
a. For helium, $f = 3 \Rightarrow Q = \frac{3}{3}RT$. *The heating energy is then* $W = 10 \cdot t\ J = \frac{3}{2}R(100-20)\ K + 10\ J/K \cdot 80\ K$, *where the last term takes into account the heating of the container. With* $R = 8.3\ J(K{\cdot}mol)$ *follows,*

$$t = \frac{120 \cdot 8.31 + 800}{10}\ s = 180\ s = 3\ min\ .$$

For N_2 *molecules above* $T = 300\ K$ *holds,* $f = 5$*:* $t = \frac{200 \cdot 8.31 + 800}{10}\ s = 246\ s = 4.1\ min.$
b. The heating to 1000° C lasts for helium,

$$t = \frac{980 \cdot 3R/2 + 9800}{10}\ s \approx 2200\ s \approx 37\ min\ .$$

For N_2 *between 20-500° we got* $f = 5$, *for* $T > 500°$ *we got* $f = 7$.
Hence,

$$t = \frac{480 \cdot 8.31 \cdot 5/2 + 500R \cdot 7/2 + 9800}{10}\ s = 3431\ s = 57.2\ min\ .$$

9.4.5.18 Ex: 2. law of thermodynamics

A thermally insulated container with a total volume of 10 l is separated into two equal parts by a disc. In each part there are 10 mol of an ideal atomic gas. In one part the gas has the temperature $T_1 = 300$ K, in the other the temperature $T_2 = 400$ K. Calculate the change in the total entropy of the system ΔS in the event that:
a. the disc does not insulate heat;
b. a small hole opens in the disc through which the gases can mix slowly and which at the end closes again;
c. the disc is suddenly removed and then put back in after some time without any work being done.
In all three cases there we wait for equilibrium to establish.

Solution: *In general, we have,*

$$dS = \frac{\delta Q}{T} = C_p \frac{dT}{T}\ .$$

Hence, for finite processes $i \to f$ *we get,*

$$\Delta S = \int C_p \frac{dT}{T} = C_p \ln \frac{T_f}{T_i}\ .$$

For the given example the initial and final states are the same in all three cases. The entropy change in the overall system is the sum of the changes for the two subsystems, the volumes of which do not change. The final temperature $(T_1 + T_2)/2$ *is:*

$$\Delta S_T = \Delta S_1 + \Delta S_2 = \frac{3}{2} N k_B \left(\log \frac{T_1 + T_2}{2T_1} + \log \frac{T_1 + T_2}{2T_2} \right) = 0.06 \ cal/K \ .$$

9.4.5.19 Ex: 2. law of thermodynamics

A heat engine works between two heat sources with temperatures $T_2 > T_1$. If we take away the heat $\mathcal{Q}$ from the second heat source, what is the maximum and minimum work $\mathcal{L}_{\mathcal{M}}$ and $\mathcal{L}_{\Updownarrow}$ that the heating machine can do? What could the corresponding processes look like?

Solution:

9.4.5.20 Ex: Rüchardt's calorimetric method

A mono-atomic ideal gas with the adiabatic coefficient $\kappa = 1.4$ is in a thermally insulated bottle with a long neck. The total volume of the bottle and the neck is $V_0 = 10$ l. At the beginning there is atmospheric pressure. A thermally insulating ball with mass $m = 20$ g is now inserted into the neck (precision tube with a diameter of $d = 16$ mm), which hermetically seals the bottle to the outside. The ball can move smoothly.
a. Determine the equilibrium position of the ball. What is the pressure and volume in the part of the bottle sealed by the ball?
b. The ball is now pushed down slightly from the equilibrium position and then released. With what period τ does the ball vibrate.
Help: Relate the instantaneous pressure p in the bottle to small volume changes ΔV and linearize the expression using a Taylor expansion.

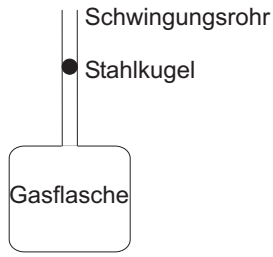

Figure 9.13:

Solution: *a. In equilibrium* $F_{atmos} + mg = F_{pressure}$ *applies. With the pipe cross*

section $A = \frac{1}{4}\pi d^2 = 201\ mm^3$, the pressure exerted on the air volume under the sphere is $p_1 = p_0 + \frac{mg}{A} = 1023\ hPa$. The volume results from the adiabatic equation,

$$p_1 V_1^\kappa = p_0 V_0^\kappa \ ,$$

giving $V_1 = V_0 \left(\frac{p_0}{p_1}\right)^{1/\kappa} = 9.93\ l$. Hence, the equilibrium position $\Delta x = \frac{V_0 - V_1}{A} = 0.35\ m$ below the top of the tube.
b. In Rüchardt's experimental set-up, adiabatic changes in the state of a given gas volume are caused by rapid alternation of compression and expansion by dropping a steel ball into a precision tube above the gas volume, so that it then carries out harmonic vibrations on the gas cushion. Again, the weight and buoyancy act on the ball,

$$F = ma(t) = F_{atmos} + mg - F_{druck} = p_0 A + mg - (p_1 - \Delta p)A = A\Delta p \ .$$

Again, we get for the adiabatic compression, $pV^\kappa = p_1 V_1^\kappa$. Hence, the instantaneous pressure is,

$$p = \frac{p_1 V_1^\kappa}{(V_1 + \Delta V)^\kappa} \simeq p_1 V_1^\kappa \left(\frac{1}{V_1^\kappa} - \frac{\kappa}{V_1^{\kappa+1}}\Delta V\right) = p_1 - \frac{\kappa p_1}{V_1}\Delta V = p_1 + \Delta p \ .$$

By inserting $\Delta V = A\Delta x$ we get from the force equation,

$$ma = A\Delta p = -A\frac{\kappa p_1}{V_1}\Delta V = -A\frac{\kappa p_1}{V_1}A\Delta x$$

the vibration equation,

$$\Delta\ddot{x} + \kappa\frac{p_1 A^2}{mV_1}\cdot\Delta x = 0 \ .$$

The period of the oscillation is $\tau = 2\pi/\omega$ with $\omega = \sqrt{\frac{A^2\kappa p_1}{mV_1}} = 2\pi\cdot 0.86\ Hz$.

9.4.5.21 Ex: Specific heat

The specific heat for an isobaric transformation is defined as $C_p = R + C_V$. A mass of $m = 10$ g of nitrogen is heated at constant pressure $p = 2$ atm and an initial temperature of $T_a = 20°$ C until its volume increases by 20%. Calculate the initial volume V, the final temperature T_e, and the heat supplied Q.

Solution: *$m_{N_2} = 10\ g$ then $N_{N_2} = m_{N_2}/28u$ and $T_a = 20°C$ and $p = 2\ atm = 2\cdot 0.981\ bar$*
a. We get,

$$V_a = \frac{N_{N_2} k_B T_a}{p} = \frac{m_{N_2} k_B T_a}{p28u} = 0.0044\ m^3 = 4.4\ l \ .$$

b. The ideal gas law holds at the beginning and at the end,

$$pV_a = N_{N_2} k_B T_a$$
$$pV_e = N_{N_2} k_B T_e \ .$$

We know, $V_e = 1.2V_a$, so the end temperature is $T_e = 1.2T_a = 1.2{\cdot}293.15^\circ C = 78.63^\circ C$.
c. The heat supplied is,

$$\begin{aligned}\delta Q &= C_V dT + pdV \\ &= C_p dT = N_{N_2} k_B \left(\frac{\tilde{f}}{2} + 1\right) dT \ .\end{aligned}$$

With 3 translational and 2 rotational degrees of freedom $\tilde{f} = 5$, so $\delta Q = 3.5 N_{N_2} k_B dT = 208\ J$.

9.4.5.22 Ex: Specific heat

Calculate the specific heat per mol of an ideal gas for a reversible process according to the law $pV^k =$ constant with $k \in \mathbb{R}$. Can such specific heat be negative? Justify the result.

Solution: *It is not necessary to consider exactly one mole of an ideal gas. We may simply replace the particle number N with the particle number N_A in a mol. We consider an ideal gas with N particles. From the ideal gas equation $\frac{pV}{T} = Nk_B$ and the process with $pV^k = const$ follows,*

$$Nk_B = \frac{pV}{T} = pV^k \frac{V^{1-k}}{T} = const \frac{V^{1-k}}{T} \ .$$

Hence, $\frac{V^{1-k}}{T} = const$.
For the case $k = 1$ this results in $T = const$, i.e. the process is carried out isothermally. Here, the definition of the specific heat $C \equiv \frac{\delta Q}{dT} = \frac{\Delta Q}{\Delta T}$ is meaningless.
Let us now consider the case $k \neq 1$. From $\frac{V^{1-k}}{T} = const$ we get,

$$\frac{V}{T^{1/(1-k)}} \equiv c_0 = \ const \ .$$

Hence, $V = c_0 T^{1/(1-k)}$, which leads us to the following derivation,

$$\frac{dV}{dT} = c_0 \frac{1}{1-k} T^{1/(1-k)-1} \ .$$

The 1st law of thermodynamics $\delta Q = dE - \delta W = C_V dT + pdV$ leads us to the specific heat using equation (2),

$$C = \frac{\delta Q}{dT} = C_V + p\frac{dV}{dT} = C_V + pc_0 \frac{1}{1-k} T^{1/(1-k)-1} = C_V + \frac{1}{1-k}\frac{pV}{T} = C_V + \frac{1}{1-k} Nk_B \ .$$

At the penultimate equal sign, we replaced the constant c_0 with equation (1), and we used the ideal gas equation for the last equal sign. For processes according to the law $pV^k = const$, the specific heat $C \equiv C(k)$ is given by,

$$C \equiv C(k) = C_V + \frac{1}{1-k} Nk_B = Nk_B \left(\frac{f}{2} + \frac{1}{1-k}\right) \ ,$$

as a function of the real number $k \neq 1$ of the process, whereby we used $C_V = \frac{f}{2} N k_B$ (with $f = 3, 5, ...$). We saw above that the specific heat cannot be defined for the isothermal process (with $k = 1$). In fact, it is not even a sensible quantity in the borderline process $k \to 1$, because

$$\lim_{k \searrow 1} \frac{1}{1-k} = -\infty \quad , \quad \lim_{k \nearrow 1} \frac{1}{1-k} = +\infty \ .$$

The specific heat can also become negative: We find exactly,

$$\begin{aligned} &C \equiv C(k) < 0 \quad \textit{for} \quad 1 < k < 2/f + 1 \ , \\ &C \equiv C(k) = 0 \quad \textit{for} \quad k = 2/f + 1 \ , \\ &C \equiv C(k) > 0 \quad \textit{for} \quad k > 2/f + 1 \quad \textit{or} \quad k < 1 \ . \end{aligned}$$

9.4.5.23 Ex: Expansion of a gas

One mole of a simple ideal gas, defined by $u = cRT$, $pv = RT$, is contained in a container of initial volume v_0 and pressure p_0. The gas expands from that initial state to the state corresponding to a final volume $2v_0$, through several different processes. Determine the work W done by the gas and the heat Q received by the gas for each of these processes. Final answers should be given only in terms of (v_0, p_0) and the constant c.
a. Free expansion: also determine the temperature variation ΔT.
b. Isentropic expansion: also obtain the final pressure p_f, using the fact that in this process for an ideal gas $pv^\gamma = constant$, where $\gamma = (c+1)/c$.
c. Isobaric quasi-static expansion.
d. Isothermal quasi-static expansion.
Formulas of thermodynamics:

$$\begin{aligned} \Delta u &= Q - W \\ W &= \int p dV \\ dU &= TdS - pdV + \mu dN \\ \beta &\equiv \frac{1}{k_B T} \\ Z &\equiv e^{-\beta F} = \sum_n e^{-\beta E_n} \\ P_n &= e^{-\beta E_n}/Z \\ U &\equiv \langle E_n \rangle = \sum_n E_n P_n \\ f &= u - TS \ . \end{aligned}$$

Solution: *a. For free expansion, we know* $Q = W = 0$. *Therefore,*

$$\Delta u = cR\Delta T = 0 \ ,$$

with the result, $\Delta T = 0$.
b. This process being isentropic, we have $p_f v_f^\gamma = p_i v_i^\gamma$. *Hence,*

$$p_f = p_i(v_i/v_f)^{1+1/c} = p_0(1/2)^{1+1/c} \ .$$

Since an isentropic process is also quasi-static adiabatic, $Q = 0$, *and*

$$W = -\Delta u = -(u_f - u_i) = -cR(T_f - T_i) = -(cp_f v_f - cp_i v_i) = -cp_0 v_0[(\tfrac{1}{2})^{1/c} - 1] \ .$$

Alternative solution: *Starting from* $p(v) = p_0(v_0/v)^{1+1/c}$, *we obtain,*

$$W = \int_{v_i=v_0}^{v_f=v_0} p(v)dv = -[cp_0 v_0 \tfrac{v_0}{v}^{1/c}]_{v_0}^{2v_0} = -cp_0 v_0[\left(\tfrac{1}{2}\right)^{1/c} - 1] \ .$$

c. We know $W = \int_{v_i=v_0}^{v_f=2v_0} p_0 dv = p_0 v_0$. *With that, we derive,*

$$\begin{aligned} Q = \Delta u + W = \Delta u + p_0\Delta v = u_f - u_i + p_0(v_f - v_i) = cR(T_f - T_i) + p_0(v_f - v_i) \\ = cp_0(v_f - v_i) + p_0(v_f - v_i) = (c+1)p_0(v_f - v_i) = (c+1)p_0 v_0 \ . \end{aligned}$$

d. We have $RT_0 = p_0 v_0 = const$ *throughout the isothermal process. Now,*

$$p(v) = RT_0/v = p_0 v_0/v$$

$$W = \int_{v_i=v_0}^{v_f=2v_0} p(v)dv = p_0 v_0[\ln v]_{v_0}^{2v_0} = p_0 v_0 \ln 2 \ .$$

With $\Delta u = cR\Delta T = Q - W = 0$ *we obtain* $Q = W = p_0 v_0 \ln 2$.

9.4.5.24 Ex: Calorimeter

a. A calorimeter initially contains 100 ml of water in thermal equilibrium with the calorimeter at a temperature of $T_1 = 20°$. Now, an amount of 150 ml of water with the temperature $T_2 = 70°$ is added. After reaching thermal equilibrium again, the temperature becomes $T_f = 45°$. Knowing the specific heat of water, $c_a = 4.186$ J/gK, calculate the thermal capacity of the calorimeter.
b. Now we put into the same calorimeter (filled with 250 ml of water at temperature $T_f = 45°$) additionally a metallic body with the mass $m_3 = 200$ g and temperature $T_3 = 50°$. After reaching thermal equilibrium again, the temperature becomes $T_{ff} = 41°$. Calculate specific heat of the body.

Solution: *a. The thermal capacity of the calorimeter is,*

$$C = m_2 c_a \frac{T_2 - T_f}{T_f - T_1} - m_1 c_a = \left(150 \cdot 4.186 \cdot \frac{70 - 40}{40 - 20} - 100 \cdot 4.186\right) \ J/K = 209 \ J/K \ .$$

b. The specific heat of the body is,

$$c_3 = \frac{[(m_1 + m_2)c_a + C](T_{ff} - T_f)}{m_3(T_3 - T_{ff})} = \frac{[250 \cdot 4.186 + 209](41 - 40)}{200 \cdot (50 - 41)} = 0.698 \ J/gK \ .$$

9.4.5.25 Ex: Measurement of latent heat upon water condensation

A calorimeter with thermal capacity $C = 209$ J/K initially contains 250 ml of water in thermal equilibrium at a temperature of $T_1 = 20°$. Now, an amount of 40 ml of water vapor is added. After reaching thermal equilibrium again, the temperature is $T_f = 92°$. Calculate the latent heat of water condensation.

Solution: *The latent heat of water condensation isfound to be,*

$$L_c = \frac{(m_1 c_a + C)(T_1 - T_f)}{m_2} + c_a(T_c - T_f) = \frac{(250 \cdot 4.186 + 209)(20 - 92)}{40} + 4.186 \cdot (100 - 92)$$
$$= -2226 \ J/g \ .$$

9.4.5.26 Ex: Latent heat in a sauna

A Finnish sauna is heated to 90°C. To increase the thermal conductivity of the air, you put 1 liter of water at a temperature of 20°C in the oven container, where the water is evaporated. How does the temperature of the sauna evolve?

Solution:

9.4.5.27 Ex: Adiabatic expansion

a. During the adiabatic expansion of a gas the pressure P and the volume V of the gas satisfy the relationship $PV^\gamma = \alpha$, where α is a constant, and γ is the factor of the gas that gives the ratio between the specific heats at constant pressure and volume, i.e. $\gamma = c_P/c_V$. A gas was placed in a cylinder with a movable (frictionless) plunger completely insulated from the external environment. The assembly makes it possible to measure the volume and pressure of the gas during its expansion and the experimental values obtained are given in the table below.
a. From the values in the table below, and using the least squares method, determine the gas factor and the constant α. (**Hint:** to obtain a linear relationship, take $x = \log V$ and $y = \log P$.).
b. Determine, through the method of least squares, the uncertainties in the values obtained for γ and α.
c. Using a log×log paper, prepare a graph P×V and determine the values of γ and α. Compare with the results obtained by the least squares method.
Notes: When displaying the values of γ and α, be sure to indicate the units in which they are expressed.
Display the values of S_x, S_y, S_{x2} and S_{xy} used in the least squares method calculations.

V (litros)	P (atm)
40	1.20
41	1.16
43	1.10
44	1.05
46	0.98
47	0.96
49	0.90
50	0.87

Solution: *a. We initially calculate,*

V *(litros)*	P *(atm)*	$\lg V$ *(ltr)*	$\lg P$ *(atm)*
40	*1.20*	*1.6021*	*0.0792*
41	*1.16*	*1.6128*	*0.0645*
43	*1.10*	*1.6335*	*0.0414*
44	*1.05*	*1.6435*	*0.0212*
46	*0.98*	*1.6628*	*-0.0088*
47	*0.96*	*1.6721*	*-0.0177*
49	*0.90*	*1.6902*	*-0.0458*
50	*0.87*	*1.6990*	*-0.0605*

With $x \equiv \lg V$ *e* $y \equiv \lg P$*, we get,*

$$y = ax + b = -\gamma x + \lg \alpha \ .$$

We calculate $N = 8$ *and,*

$$S_x = \sum_{i=1}^{N} x_i = 13.2158 \quad , \quad S_y = \sum_{i=1}^{N} y_i = 0.0735$$

$$S_{x^2} = \sum_{i=1}^{N} x_i^2 = 21.8408 \quad , \quad S_{xy} = \sum_{i=1}^{N} x_i y_i = 0.1089$$

$$D = N S_{x^2} - S_x^2 = 0.0691$$

$$a = \frac{N S_{xy} - S_x S_y}{D} = -1.4441 \quad , \quad b = \frac{S_y S_{x^2} - S_{xy} S_x}{D} = 2.3949$$

$$\Delta y = \sqrt{\frac{\sum_{i=1}^{N} (a x_i + b - y_i)^2)}{N-2}} = 0.0955$$

$$\Delta a = \Delta y \sqrt{\frac{N}{D}} = 1.0281 \quad , \quad \Delta b = \Delta y \sqrt{\frac{S_{x^2}}{D}} = 1.6987 \ .$$

With that we find,

$$\gamma = -a = 1.44 \quad , \quad \alpha = 10^b = 248$$

$$\Delta\gamma = \Delta a = 1.03 \quad , \quad \Delta\alpha = 10^b \ln 10 \Delta b = 971 \ .$$

Consider a set of N *pairs of experimental data* (x_i, y_i)*, where the values* x_i *are*

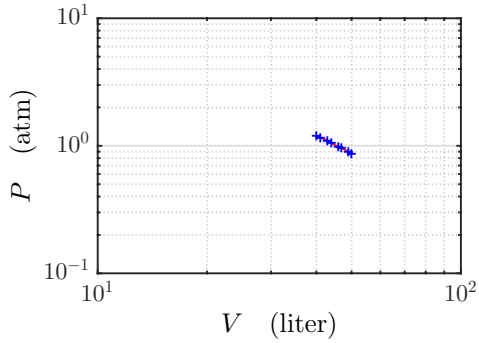

Figure 9.14: Adiabatic expansion.

assigned to the independent variable and y_i to the dependent variable. Assuming that the relationship $y(x)$ is considered as linear, i.e.,

$$y = ax + b \ .$$

the least squares method provides the values for the slope a and the linear term b for the line that best approximates the experimental data. The expressions of the line coefficients and their respective uncertainties are:

$$a = \frac{NS_{xy} - S_x S_y}{D} \quad , \quad \Delta a = \Delta y \sqrt{\frac{N}{D}}$$
$$b = \frac{S_y S_{x^2} - S_{xy} S_x}{D} \quad , \quad \Delta b = \Delta y \sqrt{\frac{S_{x^2}}{D}} \ ,$$

where,

$$S_x = \sum_{i=1}^{N} x_i \quad , \quad S_y = \sum_{i=1}^{N} y_i$$
$$S_{x^2} = \sum_{i=1}^{N} x_i^2 \quad , \quad S_{xy} = \sum_{i=1}^{N} x_i y_i$$

and

$$\Delta y = \sqrt{\frac{\sum_{i=1}^{N} (ax_i + b - y_i)^2)}{N-2}} \quad , \quad D = NS_{x^2} - S_x^2 \ .$$

9.4.5.28 Ex: Adiabatic expansion

A diatomic gas is initially maintained at a pressure of $P_i = 4000$ hPa in a piston of volume $V_i = 1$ l at temperature $T_i = 100°$C. Now the gas pressure forces the piston to move until it reaches half the pressure. Considering the expansion as an adiabatic

process
a. calculate the number of moles η inside the piston;
b. calculate the thermal capacity at constant volume C_V of the gas;
c. calculate thermal capacity at constant pressure C_P;
d. calculate the adiabatic coefficient γ;
e. calculate the final volume of the piston;
f. calculate the final temperature of the gas;
g. calculate the work done by the gas on the piston.
h. Now, the gas cools down gradually while the piston is held fix. Calculate the pressure P_r when the temperature reached $T_r = 20°\text{C}$.

Solution: *a. We have* $\eta = \frac{P_i V_i}{RT_i} = \frac{4\cdot 10^5 \cdot 10^{-3}}{8.31\cdot 293.15}\ mol = 0.16\ mol$;
b. As the gas is diatomic, $C_V = \frac{5}{2}\eta R = 3.4\ J/K$.
c. Similarly, $C_P = \frac{7}{2}\eta R = 4.8\ J/K$.
d. The adiabatic coefficient is, $\gamma = \frac{7}{5} = 1.4$.
e. For adiabatic expansion, $PV^\gamma = const$. *Hence,*

$$V_f = V_i \left(\frac{P_i}{P_f}\right)^\gamma = 10^{-3}\ m^3 \cdot 2^{1.4} = 2.6\ l.$$

f. The final temperature is,

$$T_f = \frac{P_f V_f}{\eta R} = \frac{2\cdot 10^5 \cdot 2.6\cdot 10^{-3}}{8.31\cdot 0.16} = 117.8°\,C\ .$$

g. The work is,

$$\delta W = dE_{int} = C_V dT = \frac{5}{2}\eta R(T_f - T_i) = \frac{5}{2}\cdot 0.16\cdot 8.31\cdot (117.8 - 20) = 325\ J\ .$$

h. The pressure is,

$$P_r = \frac{\eta R T_r}{V_f} = \frac{0.16\cdot 8.31\cdot 293.15}{2.6\cdot 10^{-3}} = 1500\ hPa\ .$$

9.4.5.29 Ex: Cyclic process

A and B be two states of an ideal gas with the same temperature T, but different pressures and volumes. Show explicitly that $\Delta Q/T$ remains the same, regardless of whether we go from A to B via a reversible isothermal process or first with a reversible isobaric process and then with a reversible isochoric process.

Solution: *We denote by* P_A *and* V_A *the pressure and volume of state A, analogously* p_B *and* V_B *of state B. Since both states have the same temperature* $T_A = T_B = T_0$, *it follows from the ideal gas equation that,*

$$p_A V_A = N k_B T_0 = p_B V_B \Rightarrow \frac{p_B}{p_A} = \frac{V_A}{V_B}\ .$$

Isothermal process: *Since* $T = T_0 = const$, *we get* $\Delta E = 0$. *With the 1st law of thermodynamics* $\delta Q = -\delta W = pdV$. *Use the ideal gas equation,* $p = N k_B \frac{T}{V}$ *brings*

us to,,

$$dS = \frac{\delta Q}{T} = \frac{pdV}{T} = Nk_B \frac{dV}{V} \ ,$$

Hence,

$$\Delta S_{it} = \int_{S_A}^{S_B} dS = Nk_B \int_{V_A}^{V_B} \frac{dV}{V} = Nk_B \ln \frac{V_B}{V_A} \ .$$

The index "it" at the entropy change ΔS_{it} means "isothermal". Analogously below, the index "ib" means "isobar" and "ic" means "isochor".
***Isobaric + isochoric process**: $(p_A, V_A) \stackrel{isobar}{\longrightarrow} (p_A, V_B) \stackrel{isochor}{\longrightarrow} (p_B, V_B)$. Here, the temperature changes in each of the two processes T.*
First the isobaric process $(p_A, V_A) \stackrel{isobar}{\longrightarrow} (p_A, V_B)$. The ideal gas equation provides,

$$T = \frac{p_A}{Nk_B} V \Rightarrow dT = \frac{p_A}{Nk_B} dV \ .$$

Replacing dT in the 1st law, $\delta Q = dE - \delta W = C_V dT + p_A dV$, and T in $dS = \frac{\Delta Q}{T}$, we get the relation,

$$dS = \frac{\delta Q}{T} = \frac{1}{T}(C_V dT + p_A dV) = (C_V + Nk_B)\frac{dV}{V} \ .$$

Hence,

$$\Delta S_{ib} = (C_V + Nk_B) \int_{V_A}^{V_B} \frac{dV}{V} = (C_V + Nk_B) \ln \frac{V_B}{V_A} \ .$$

Now the following isochore process control: $(p_A, V_B) \stackrel{isochor}{\longrightarrow} (p_B, V_B)$. The ideal gas equation provides,

$$T = \frac{V_B}{Nk_B} p \Rightarrow dT = \frac{V_B}{Nk_B} dp \ .$$

Because of $\Delta V = 0$ the 1st law is reduced to $\delta Q = dE = C_V dT$. Hence,

$$dS = \frac{\delta Q}{T} = C_V \frac{dT}{T} = C_V \frac{dp}{p} \ .$$

This leads to,

$$\Delta S_{ic} = C_V \int_{p_B}^{p_A} \frac{dp}{p} = C_V \ln \frac{p_B}{pA} = -C_V \ln \frac{V_B}{V_A} \ ,$$

where we used equation (3) for the last equal sign. Overall, we get the entropy change,

$$\Delta S_{ib+ic} = \Delta S_{ib} + \Delta S_{ic} = Nk_B \ln \frac{V_B}{V_A} = \Delta S_{it} \ ,$$

which corresponds to the change in entropy deduced for the isothermal process ΔS_{it} [see equation (4)].

9.4.5.30 Ex: Clément-Desormes cyclic process

An ideal gas with N atoms and the heat capacities $C_V = \frac{3}{2}Nk_B$ and $C_p = \frac{5}{2}Nk_B$ goes through the cycle shown in the figure: First an isotherm from "1" to "2", then an isobar from "2" to "3" and finally an isochore from "3" to "1". For the starting point "1", the temperature T_1 and the volume V_1 are known, for "2" V_2 is given.
a. Calculate the work done and the heat input for all three steps of the cycle.
b. Calculate the efficiency η of the process as a function of V_1 and V_2 respectively T_1 and T_3. Calculate the total changes of internal energy and entropy (see Fig. 9.9).

Solution: *a. For the different ways we get,*

$$
\begin{aligned}
1 \to 2: \quad & \Delta Q = \Delta A = \int_{V_1}^{V_2} p \, dV = Nk_B T_1 \log \frac{V_2}{V_1} \\
2 \to 3: \quad & \Delta Q = \frac{5}{2} N \; k_B \Delta T = -\frac{5}{2} Nk_B T_1 \left(1 - \frac{V_1}{V_2}\right) \; , \\
& \Delta A = p_2 \Delta V = -Nk_B T_1 \left(1 - \frac{V_1}{V_2}\right) \\
3 \to 1: \quad & \Delta Q = \frac{3}{2} N \; k_B \Delta T = \frac{3}{2} Nk_B T_1 \left(1 - \frac{V_1}{V_2}\right) \; , \\
& \Delta A = 0 \; .
\end{aligned}
$$

b. We get,

$$
\begin{aligned}
\eta &= \frac{A_{1\to2} + A_{2\to3}}{Q_{1\to2} + Q_{3\to1}} = \frac{Q_{1\to2} + Q_{2\to3} + Q_{3\to1}}{Q_{1\to2} + Q_{3\to1}} = 1 + \frac{Q_{2\to3}}{Q_{1\to2} + Q_{3\to1}} \\
&= 1 - \frac{5(V_2 - V_1)}{2V_2 \log \frac{V_2}{V_1} + 3(V_2 - V_1)} = \frac{2V_2 \log \frac{V_2}{V_1} - 2(V_2 - V_1)}{2V_2 \log \frac{V_2}{V_1} + 3(V_2 - V_1)} \\
&= 1 - \frac{5(T_1 - T_3)}{2T_1 \log \frac{T_1}{T_3} + 3(T_1 - T_3)} = \frac{2T_1 \log \frac{T_1}{T_3} - 2(T_1 - T_3)}{2T_1 \log \frac{T_1}{T_3} + 3(T_1 - T_3)} \\
\Delta S &= \Delta E = 0 \; .
\end{aligned}
$$

9.4.5.31 Ex: Cyclic process

An ideal gas with N atoms and the heat capacities $C_V = \frac{3}{2}Nk_B$ and $C_p = \frac{5}{2}Nk_B$ goes through the cycle shown in the figure. For the starting point 1 its pressure p_1, volume V_1, and thus also the temperature T_1 are known.
a. Calculate p_2, T_2, p_3 and T_3, if $V_2 = V_3 = 3V_1$.
b. For all 3 steps of the cycle, calculate the work done on the gas ΔW, the heat supplied ΔQ, and the internal energy ΔE, as well as the change in entropy ΔS.

Solution: *a. For the isothermal process* $1 \to 2$ *we know* $p_1 V_1 = p_2 V_2 = 3p_2 V_1$. *Hence,*

$$
p_2 = p_1/3 \qquad \textit{and} \qquad T_2 = T_1 \; .
$$

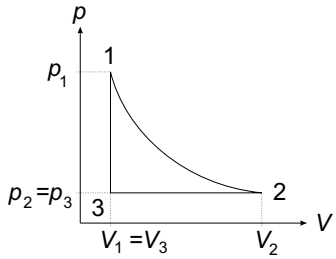

Figure 9.15:

For the adiabatic process $3 \to 1$ *we know* $p_1V_1^\kappa = p_3V_3^\kappa = p_3V_1^\kappa \cdot 3^{5/3}$ *with* $\kappa \equiv C_p/C_V = 5/3$. *Hence,*

$$p_3 = p_1/3^{5/3} \ .$$

Furthermore, $p_3V_3/p_1V_1 = T_3/T_1$. *Hence,*

$$T_3 = \frac{p_1 3V_1}{3^{5/3}p_1V_1}T_1 = \frac{3}{3^{5/3}}T_1 \ .$$

b. For the isothermal process $1 \to 2$ *we know* $\Delta E = \Delta Q + \Delta W = 0$. *Hence,*

$$\Delta W = -\int pdV = -\int_{V_1}^{V_2} Nk_BT_1\frac{dV}{V} = -Nk_BT_1 \ln\frac{V_2}{V_1} = -Nk_BT_1 \ln 3 \ .$$

Thus, the heat is $\Delta Q = -\Delta W$ *and the entropy* $\Delta S = \frac{1}{T_1}\Delta Q = Nk_B \ln 3$.
For the isochoric process $2 \to 3$ *we know* $\Delta W = 0$ *and hence* $\Delta Q = \Delta E = C_V\Delta T = \frac{3}{2}Nk_B(T_3 - T_1) = -\frac{3}{2}Nk_BT_1(1 - 3^{-2/3})$. *Hence,*

$$\Delta S = \int \frac{\delta Q}{T} = C_V\int_{T_1}^{T_3}\frac{dT}{T} = \frac{3}{2}Nk_B \ln\frac{T_3}{T_1} = \frac{3}{2}Nk_B \ln\frac{1}{3^{2/3}} = -Nk_N \ln 3 = \Delta S_{1-2} \ .$$

For the adiabatic process $3 \to 1$ *we know* $\Delta Q = 0 = \Delta S$. *Hence* $\Delta E = \Delta W = C_V(T_1 - T_3) = \frac{3}{2}Nk_BT(1 - 3^{-2/3})$.

9.4.5.32 Ex: Cyclic process

In a heat power machine (illustrated in Fig. 9.16), the working gas (helium) is sealed off in a cylinder by a movable piston. The gas is alternately heated and cooled from the outside. The piston moves back and forth periodically and drives a shaft. The initial state is: $p = 0.2 \cdot 10^6$ Pa, $V = 150\,\mathrm{cm}^3$, $T = 300$ K.
a. Calculate the mass of the enclosed helium and the adiabaticity coefficient.
b. During a complete work cycle, the gas undergoes the following changes in its state:
$1 \to 2$ isochoric heating to 600 K,
$2 \to 3$ isothermal expansion to twice the volume,
$3 \to 4$ isochoric cooling to the initial temperature,
$4 \to 1$ isothermal compression to initial volume.

Calculate the respective pressures and illustrate the cyclic process in a $p-V$ diagram.
c. Calculate the total mechanical work.
d. Calculate the efficiency η of the engine as a ratio of the amount of useful work to the total amount of work.

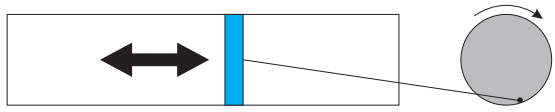

Figure 9.16: Heat power engine

Solution: *a. The mass of helium is $m_{He} = 4u$. Hence, the enclosed mass is,*

$$m = N m_{He} = \frac{pV}{k_B T} m_{He} = x\,\mathrm{kg} \ .$$

The adiabaticity coefficient for the one-atomic gas is,

$$\gamma = \frac{f+1}{f} = 4/3 \ .$$

b. The pressures are... Fig. 9.17 shows the cyclic process.
c. $\Delta W = 20.8$ J.
d. $\eta = 24\%$.

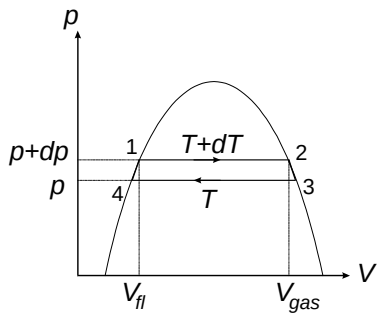

Figure 9.17: Cyclic process of a heat power engine.

9.4.5.33 Ex: Cyclic process

An engine, whose four work steps consist of two isothermal and two isochoric processes, runs at a speed of $N = 500\ \mathrm{min}^{-1}$. There is $\nu = 0.5$ mol of an ideal, monoatomic gas in the volume of the engine. The parameters for the individually labeled working steps are $T_1 = 50°\mathrm{C}$, $p_1 = 2.0$ bar, and $p_2 = 5.0$ bar.
a. Determine the volumes $V_1 = V_2$ and $V_3 = V_4$, the pressure p_4, and the temperature T_2.

b. What efficiency η does the cycle have?
c. How high is the net power P of the engine?

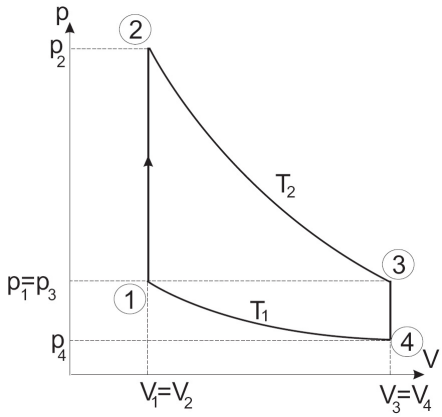

Figure 9.18:

Solution: *a.* $V_1 = 6.7\ dm^3$, $V_3 = 16.75\ dm^3$, $T_2 = 807\ K$, $p_4 = 0.8\ bar$.
b. The efficiency is, $\eta = 0.6 = 60\ \%$.
c. To calculate the engine power $P = \frac{\Delta W_{ges}}{t}$ *we need the work done in the compression and the decompression phase respectively* $W_2 = \nu R T_2 \ln \frac{V_1}{V_3} = -3074\ J$ *respectively* $W_1 = \nu R T_1 \ln \frac{V_3}{V_1} = 1230\ J$. $W_{ges} = W_1 + W_2 = 1817\ J \Rightarrow P = \frac{1843\ J}{0.12\ s} = 15.4\ kJ$.

9.4.5.34 Ex: Particle collisions with a container

How many particle collisions Z does a wall surface $A = 1\ \mathrm{dm}^2$ experience in $\Delta t = 1$ s at $T = 298$ K and $p = 1$ bar through the particles of an ideal gas, if $\langle |v_x| \rangle$, the mean value of the particle velocity in the x direction, has the value 330 m/s?
Hint: Imagine a cuboid box in an xyz coordinate system and assume the wall surface of interest as one of the cuboid surfaces perpendicular to the x-axis. The width of the box is Δx, so its volume is $V = A \cdot \Delta x$. There is a simple relationship for the mean number $\langle \nu_x \rangle$ of impacts that a single particle does exert on the wall within a time Δt depending on Δx, Δt and $\langle |v_x| \rangle$. To get Z you have to consider that the gas contains N particles.

Solution: *Between the impacts on the right wall, the particle has to cross the box once in both directions. The distance covered is* $2\Delta x$. *The average number* $\langle \nu_x \rangle$ *of the impacts that a single particle exerts on the wall results from the average distance* $\langle |v_x| > \cdot \Delta t$ *covered within the time interval* Δt *divided by this distance* $2\Delta x$*:*

$$\langle \nu_x \rangle = \frac{\Delta t \cdot \langle |v_x| >}{2\Delta x} \ .$$

The average number Z of impacts on the wall caused by N particles is therefore,

$$Z = N \cdot \langle \nu_x \rangle = \frac{N\ \Delta t \cdot \langle |v_x| \rangle}{2\Delta x}\ .$$

With $\Delta x = V/A$ and $V = \frac{N\ k_B\ T}{p}$ follows,

$$Z = \frac{\Delta t \cdot < |v_x| > \cdot A \cdot p}{2k_B T} = \frac{10^5\ Nm^{-2} \cdot 1\ s \cdot 330\ ms^{-1} \cdot 0.01\ m^2}{2 \cdot 1.38 \cdot 10^{-23} Nm \cdot K^{-1} \cdot 298\ K} \approx 4 \cdot 10^{25}\ .$$

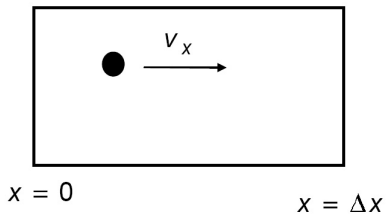

Figure 9.19:

9.4.5.35 Ex: Entropy changes

a. What entropy increase results when 200 g of (liquid) water at 0°C and 200 g water at 90°C are mixed at constant pressure in a heat-insulated recipient? The molar heat c_p of the water should be 75.5 J/(mol K) regardless of the temperature.
b. 1 dm^3 helium at $p_0 = 1$ bar and $T_0 = 0$°C are heated to the temperature $T = 500$ K. How big is the change in entropy upon isochoric and isobaric heating?

Solution: *a. Since S is a state variable, it does not matter which way the temperature equilibration takes place. Because of the path-independence of the entropy one can imagine the mixing process such that the two water portions are brought from their respective initial temperatures to the end temperature as homogeneous phases "1" and "2". The differential entropy change of the individual phases is given by $dS = C_p\ d\ln T$. So we get,*

$$\Delta S = \Delta S_1 + \Delta S_2 = C_P \int_{T_{1,0}}^{T_m} d\ln T + C_P \int_{T_{2,0}}^{T_m} d\ln T = C_P \ln \frac{T_m^2}{T_{1,0} T_{2,0}}\ .$$

From this, $\Delta S \approx 17.0\ J/K$, where $C_p = \nu \cdot c_p = 11.111\ mol \cdot 75.5\ J/(mol\ K)$ and $T_m = 45°\,C = 319\ K$.
b. The entropy change upon isobaric heating from $T_0 = 273\ K$ to $T_1 = 500\ K$ is,

$$\Delta S_{isobar} = \nu \left(C_V \ln \frac{T_1}{T_0} + R \ln \frac{V_1}{V_0} \right)\ ,$$

where $\nu = 1/22.4$ is the molar fraction. Because of $V_1/V_0 = T_1/T_0$ for $p =$const and with $C_P = R + C_V$ we get:

$\Delta S_{isobar} = \nu C_p \ln \frac{T_1}{T_0}$ *with* $C_p = 21$ *J/(K·mol). From this* $\Delta S_{isobar} = \frac{21}{22.4} \ln \frac{500}{273} = 0.58$ *J/K.*
Isochoric heating: $\Delta S_{isochor} = \nu C_v \ln \frac{T_1}{T_0}$ *with* $C_v = 12.7$ *J/(K mol)*$= 0.34$ *J/K.*

9.4.5.36 Ex: Material parameters

The compressibility κ, the thermal expansion coefficient α, and the stress coefficient β are important material parameters. In the case of a single substance system, they are defined by,

$$\kappa = -\frac{1}{V}\left.\frac{\partial V}{\partial p}\right|_{n,T} \qquad \alpha = \frac{1}{V}\left.\frac{\partial V}{\partial T}\right|_{n,p} \qquad \beta = \frac{1}{p}\left.\frac{\partial p}{\partial T}\right|_{n,V} .$$

Here n is the number of moles.
a. Show that these relationships can be rewritten, using the molar volume v, to,

$$\kappa = -\frac{1}{v}\left.\frac{\partial v}{\partial p}\right|_{T} \qquad \alpha = \frac{1}{v}\left.\frac{\partial v}{\partial T}\right|_{p} \qquad \beta = \frac{1}{p}\left.\frac{\partial p}{\partial T}\right|_{v} .$$

b. Use the total differential of $V = V(T, p, n)$ to show that, in general,

$$\beta = \frac{\alpha}{\kappa p} .$$

c. Calculate κ, α and β for an ideal gas as functions of p and T. Show that the relationship from (b) is also fulfilled.

Solution: *a. Relationship between volume* V *and molar volume* v*:* $V = n\ v$.

$$\kappa = -\frac{1}{V}\left.\frac{\partial V}{\partial p}\right|_{n,T} = -\frac{1}{n\ v}\left.\frac{\partial (n\ v)}{\partial p}\right|_{n,T} = -\frac{1}{n\ v} n \left.\frac{\partial v}{\partial p}\right|_{n,T} = -\frac{1}{v}\left.\frac{\partial v}{\partial p}\right|_{n,T} .$$

Analogously for α*. For* $p = p(T, v)$*:*

$$dp = \left.\frac{\partial p}{\partial T}\right|_{v} dT + \left.\frac{\partial p}{\partial v}\right|_{T} dv .$$

Constant v *can be achieved by keeping* V *and* n *constant. So:*

$$\left.\frac{\partial p}{\partial T}\right|_{v} = \left.\frac{\partial p}{\partial T}\right|_{n,V} .$$

From this follows (as requested):

$$\beta = \frac{1}{p}\left.\frac{\partial p}{\partial T}\right|_{n,V} = \frac{1}{p}\left.\frac{\partial p}{\partial T}\right|_{v} .$$

b. Total differential of V*:*

$$dV = \frac{\partial V}{\partial T} dT + \frac{\partial V}{\partial p} dp + \frac{\partial V}{\partial n} dn$$

can be rewritten with α and κ:

$$dV = V\ \alpha\ dT - V\ \kappa\ dp + \frac{\partial V}{\partial n} dn\ .$$

If V and n are constant,

$$0 = V(\alpha\ dT - \kappa\ dp)$$

with $dp = \left.\frac{\partial p}{\partial T}\right|_{n,V} dT$. Hence:

$$0 = V\left[\alpha - \kappa\ \left.\frac{\partial p}{\partial T}\right|_{n,V}\right]\ dT\ .$$

At $V, dT \neq 0$ follows,

$$\alpha - \kappa\ \left.\frac{\partial p}{\partial T}\right|_{n,V} = 0\ .$$

This leads to the wanted relationship.
c. With $v = R\ T/p$ follows,

$$\kappa = -\frac{1}{v}\left.\frac{\partial v}{\partial p}\right|_T = -\frac{p}{RT}\left(R\ T\frac{-1}{p^2}\right) = \frac{1}{p}$$
$$\alpha = \frac{1}{v}\left.\frac{\partial v}{\partial T}\right|_p = \frac{p}{R\ T}\frac{R}{p} = \frac{1}{T}$$
$$\beta = \frac{1}{p}\left.\frac{\partial p}{\partial T}\right|_v = \frac{v}{R\ T}\frac{R}{v} = \frac{1}{T}\ .$$

9.4.5.37 Ex: A lake in winter

How long does it take at an air temperature of $-6°$C to form a 4 cm thick layer of ice on the surface of a lake (thermal conductivity of ice: $\kappa = 1.7 \cdot 10^{-2}$ J/(s cm K); density of ice: $\rho = 0.92$ g/cm^3; amount of heat that must be dissipated to form 1 g of ice: 335 J)
Note: First consider a layer of ice of thickness z, and then think about how much heat has to be dissipated from the lake in order to to form additional layer of thickness dz.

Solution: *Consider a layer of ice of thickness z. To form the next layer of ice of thickness dz, heat must be transported outside through the initial layer. The amount of heat that must be dissipated to form an additional layer of thickness dz and area A is,*

$$dQ_1 = Q_0 \cdot dM = Q_0 \cdot \rho \cdot A \cdot dz$$

with $Q_0 = 335$ J. The amount of heat that can be dissipated in time dt through the layer of ice z is,

$$dQ_2 = -\frac{\kappa\ A\ \Delta T}{z} \cdot dt\ .$$

The ice forms at $T = 0°C \Rightarrow \Delta T = -6\ K$. dQ_1 *and* dQ_2 *must be the same,*

$$\Rightarrow Q_0\ \rho\ A\ dz = -\frac{\kappa\ A\ \Delta T}{z} \Leftrightarrow dt = -\frac{Q_0\ \rho}{\kappa\ \Delta T} z\ dz\ .$$

Integration on both sides yields,

$$\int_0^t dt' = -\frac{Q_0\ \rho}{\kappa\ \Delta T} \int_0^d z\ dz\ ,$$

hence,

$$\Rightarrow t = -\frac{Q_0\ \rho}{\kappa\ \Delta T} \cdot \frac{d^2}{2} \Rightarrow \frac{335\ J/g \cdot 0.92\ g/cm^3}{1.7 \cdot 10^{-2} J/(s{\cdot}cm{\cdot}K) \cdot 6\ K} \cdot \frac{1}{2} \cdot 16\ cm^2 \approx 2.417{\cdot}10^4\ s \approx 6h\,43min\,.$$

9.4.5.38 Ex: Clausius-Clapeyron relationship

Show that the *Clausius-Clapeyron* equation,

$$\frac{dp}{dT} = \frac{L}{T(V_{gas} - V_{fl})}$$

can also be derived via a cycle analogous to Carnot's cycle. The working fluid is an evaporating liquid, and the efficiency of this fictitious machine is dT/T, because the temperature difference between the two isotherms is dT. From the heat Q used in the evaporation and the work done $\oint pdV$, which are related on one hand to the latent heat L and on the other to the volume difference of V_{fl} and V_{gas}, results the rise in vapor pressure dp/dt.

Solution: *We know,* $W = \int pdV \approx dp(V_{gas} - V_{fl})$, $\frac{W}{Q} = \eta = \frac{dT}{T}$, *and* $Q \equiv L$. *From this follows,* $\frac{dp}{dT} = \frac{L}{T(V_{gas} - V_{fl})}$.

9.4.5.39 Ex: Hydrogen concentration in a metal

The concentration of hydrogen c_H, which is dissolved in a metal in the form of H atoms, depends on the pressure p of the H_2 gas around the metal. Determine the relationship between concentration and pressure!
Hint: In equilibrium the chemical reaction $H_2 = 2H$ is determined by $\mu_{H_2} = 2\mu_H$, where $\mu_{H_2} = k_B T \ln p + \chi_{H_2}(T)$. Consult the textbooks to find a suitable ansatz for the chemical potential of a substance (and thus also for atomic hydrogen) in dilute solution.

Solution: *The relation* $\mu_{H_2} = k_B T \ln p + \chi_{H_2}$, *in a solid corresponds to* $p_H \hat{=} c_H$. *Furthermore,* $\mu_H = k_B T \ln c_H + \chi_H$. *In equilibrium be* $\mu_{H_2} = 2\mu_H$, *follows,*

$$\frac{1}{2} \ln p + \frac{\chi_{H_2}}{2k_B T} = \ln c_H + \frac{\chi_H}{k_B T}\ ,$$

follows,

$$c_H = p^{1/2} e^{(\chi_{H_2} - 2\chi_H)/2k_B T} \ .$$

9.4.5.40 Ex: Heat power engine and heat pump

Consider a heat power engine and a heat pump based on the Carnot cycle. Calculate the efficiency and the generated, respectively, consumed power ad a function of the temperature difference between the hot and the cold bath.

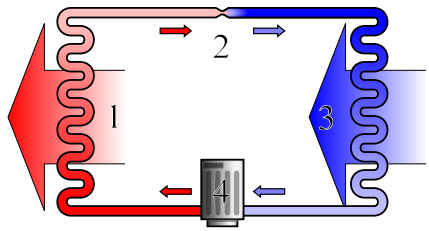

Figure 9.20: Principle of a heat pump.

Solution:

9.4.5.41 Ex: Heat capacity

When drilling a brass block of 500 g ($c = 0.1$ cal/g°C), a power of 300 W is provided for 2 minutes. What is the temperature rise of the block if 75% of the heat generated warms it up? What happens to the remaining 25%?

Solution:

9.4.5.42 Ex: Specific heat

Suppose the specific heat of a body varies with temperature according to the expression $c = A + BT^2$, where A and B are constant and T given in °C. Compare the average value of c between $T = 0$ and $T = T_1$ with its value at $T_1/2$.

Solution:

9.4.5.43 Ex: Thermal expansion

Consider a solid body with momentum of inertia I. Show that due to a small temperature variation ΔT, this momentum varies by $\Delta I = 2\alpha \Delta T$, where α is the linear expansion coefficient. With this result, calculate how much the period of a physical

pendulum varies when subject to a temperature variation ΔT.

Solution:

9.4.5.44 Ex: Thermal conduction

Show that the thermal current in a substance of conductivity K located between the surfaces of two concentric spheres is given by:

$$\frac{dQ}{dt} = H = (T_1 - T_2)\frac{4\pi k r_1 r_2}{r_2 - r_1} \ ,$$

where r_1 and r_2 are respectively the radii of the inner and outer surfaces and $T_1 > T_2$.

Solution:

9.4.5.45 Ex: Thermal work

A thermodynamic system is brought from an initial state A to another B and then brought back to A via the point C, as illustrated in the diagram in the figure. Calculate the work done by the system to complete the entire cycle.

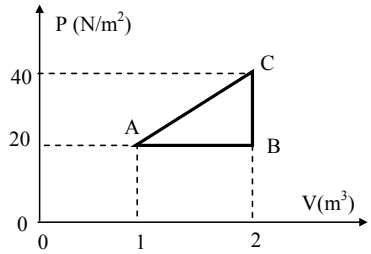

Figure 9.21:

Solution:

9.4.5.46 Ex: Thermal expansion

A bar with thermal expansion coefficient α and Young's modulus Y $\left(\frac{F}{A} = Y\frac{\Delta L}{L}\right)$ is stuck between two walls, as shown in the figure. Calculate the stress in the bar when the temperature is increased by ΔT.

Solution:

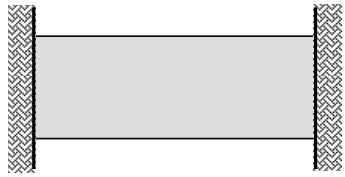

Figure 9.22:

9.4.5.47 Ex: Latent heat

How much heat is needed to transform 1 g of ice at $-10°$C ($c_{gelo} = 0.55$ cal/g°C, $L_f = 80$ cal/g) in a vapor at 100°C ($L_V = 540$ cal/g)?

Solution:

9.4.5.48 Ex: Heat capacity

A metal bar ($C = 0.2$ cal/g°C) at 100°C is placed on a large block of ice at 0°C. What is the mass of the bar if, when the system reaches thermal equilibrium, 500 g of ice have melted?

Solution:

9.4.5.49 Ex: Latent heat

An ice block is placed at $-20°$C in an airtight container together with 200 g of water vapor at 100°C. If the mass of the ice is 500 g, what will be the final temperature of the system?

Solution:

9.4.5.50 Ex: Thermal conduction

Find the temperature gradient and thermal current in a bar of conductivity K, length L and irregular cross section, as shown in the figure.

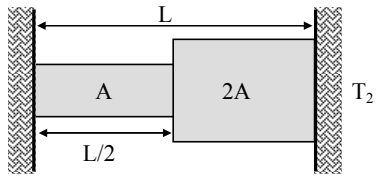

Figure 9.23:

Solution:

9.4.5.51 Ex: Volumetric expansion of an ideal gas

Calculate the volumetric expansion coefficient of an ideal gas at constant pressure.

Solution:

9.4.5.52 Ex: Adiabatic expansion

Calculate the volumetric expansion coefficient of an ideal gas during an adiabatic expansion.

Solution:

9.4.5.53 Ex: Compressibility of an ideal gas

Calculate the compressibility $\left(\kappa = \frac{1}{V}\frac{dV}{dP}\right)_T$ of an ideal gas.

Solution:

9.4.5.54 Ex: Adiabatic expansion

An ideal gas, initially at pressure P_1 and volume V_1, expands adiabatically to pressure P_2 and volume V_2. Show that the work done is $W = (P_1V_1 - P_2V_2)/(\gamma - 1)$, where $\gamma = C_p/C_V$.

Solution:

9.4.5.55 Ex: The Otto cycle

Calculate the yield ($\eta = W/Q$, Q_1 =heat received by the system) of the Otto cycle (see figure).

Solution:

9.4.5.56 Ex: Specific heat at constant volume / pressure

Explain why the specific heat at constant volume is less than the specific heat at constant pressure.

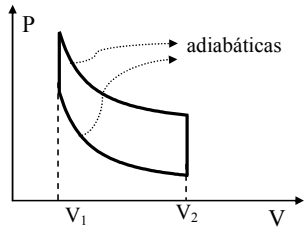

Figure 9.24:

Solution:

9.4.5.57 Ex: Adiabatic coefficient

Show that for a diatomic gas $\gamma = \frac{C_p}{C_V} = \frac{7}{5}$.

Solution:

9.4.5.58 Ex: Thermal cycle

Consider the thermal cycle shown in the figure.
a. Calculate the heat supplied to the system in the isothermal branch $1 \to 2$,
b. Calculate the work in the isobaric branch $2 \to 3$ and
c. Calculate the heat supplied to the system in the isochoric branch $3 \to 1$.

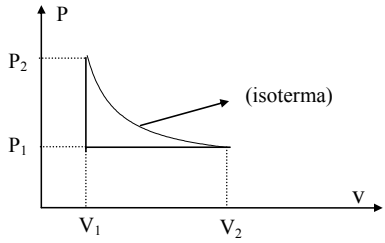

Figure 9.25:

Solution:

9.5 Free energy and enthalpy

9.5.1 Equation of state of the real gas

In reality interparticle interactions increase the effective pressure and the finite size of the molecules reduces the effective volume. In the van der Waals model the ideal gas equation is generalized to,

$$(p + p^*)(V - V^*) = Nk_BT \ , \tag{9.33}$$

with $p^* \propto (N/N_A)^2/V^2$ and V^*. Real gases are studied in Excs. 9.5.5.1 to 9.5.5.4.

9.5.1.1 Joule-Thompson process

In thermodynamics, the *Joule-Thompson effect* describes the temperature change of a real gas or liquid (as differentiated from an ideal gas) when it is forced through a valve or porous plug while keeping it insulated so that no heat is exchanged with the environment (see Exc. 9.5.5.5).

9.5.2 Phase transitions

9.5.2.1 Liquid-gas phase transition

9.5.3 Solutions

9.5.4 Osmotic pressure

9.5.5 Exercises

9.5.5.1 Ex: Real gas

Here we study a *real gas*. The state equation for a real gas according to van der Waals is,

$$\left(p + \frac{a}{V^2}\right)(V - b) = Nk_BT \ .$$

a. Why is the critical point for the liquid-gas phase transition defined by to the conditions,

$$\frac{dp}{dV} = \frac{d^2p}{dV^2} = 0 \ ?$$

b. Show that the temperature of the critical point T_c and the volume of the system at the critical point V_c are linked to the material constants a and b by the relationships:

$$k_BT_c = \frac{8a}{27Nb} \qquad \text{and} \qquad V_c = 3b \ .$$

c.How to calculate the pressure at the critical point as a function of a and b?
d. For CO_2 the values $a = 3.6 \cdot 10^{-6}$ bar m^6 mol^{-2} and $b = 4.3 \cdot 10^{-5}$ m^3 mol^{-1} are suitable parameters of the van der Waals equation. Consider a mole of CO_2 and calculate the values for the critical point V_c, T_c and p_c.

Solution: *a. The critical point corresponds to a saddle point in the pV-diagram.*
b. We have,

$$\begin{aligned} p(V) &= \frac{Nk_BT}{V-b} - \frac{a}{V^2} \\ \frac{dp}{dV} &= -\frac{Nk_BT}{(V-b)^2} + \frac{2a}{V^3} \\ \frac{d^2p}{dV^2} &= \frac{2Nk_BT}{(V-b)^3} - \frac{6a}{V^4} \ . \end{aligned}$$

Inserting the specified relations between T_c and V_c and the material constants yields, for the second and third equations,

$$\begin{aligned} \frac{dp}{dV} &= -\frac{8aN}{27Nb4b^2} + \frac{2a}{27b^3} = 0 \\ \frac{d^2p}{dV^2} &= \frac{2N8a}{27b8b^3} - \frac{6a}{81b^4} = 0 \ . \end{aligned}$$

c. The pressure is at the critical point is,

$$p = \frac{N8a}{27Nb2b} - \frac{a}{9b^2} = \frac{a}{27b^2} \ .$$

d. The values for T_c and p_c are,

$$\begin{aligned} V_c &= 3 \cdot 4.3 \cdot 10^{-5} \ m^3 mol^{-1} \cdot 1 \ mol = 12.9 \cdot 10^{-5} \ m^3 \\ T_c &= \frac{8 \cdot 3.6 \cdot 10^{-6}}{27 N_A k_B \cdot 4.3 \cdot 10^{-5}} \cdot 10^5 \ J \ m^{-3} = 298.5 \ K \\ p_c &= \frac{3.6 \cdot 10^{-5}}{27 \cdot 4.3^2 \cdot 10^{-10}} \ bar = 72.1 \ bar \ . \end{aligned}$$

9.5.5.2 Ex: Real gas

One mole of a real gas satisfies the Dieterici equation of state (an alternative to the van der Waals equation),

$$pe^{\alpha/(N_A k_B TV)}(V-\beta) = N_A k_B T \ ,$$

where are α and β parameters.
a. In what units α and β have to be specified? What sign do you expect for each parameter?
b. Express the parameters of the critical point T_c and V_c by α and β.
c. What arises for $p_c V_c / N_A k_B T_c$?

Solution:

9.5.5.3 Ex: Real gas

The pressure p of a dense gas behaves as a function of temperature T and molar volume v according to the following state equation,

$$p = \frac{RT}{v} - \frac{a}{v^2} \ ,$$

where a is a positive constant and R is the universal gas constant.
a. Use the identity,

$$\left(\frac{\partial u}{\partial v}\right)_T = T\left(\frac{\partial p}{\partial T}\right)_v - p$$

to determine the molar energy u as a function of v.
b. Assuming that $c_v = (\partial u/\partial T)_v$ be constant and equal to c, find u as a function of T and v.
c. In a free gas expansion, does the temperature rise or fall? Take into account that in a free expansion u remains invariant and v grows. Determine ΔT for a small variation Δv of the molar volume.
d. Demonstrate the identity in item (a).

Solution: *a. From the equation of state we obtain,*

$$\frac{\partial p}{\partial T} = \frac{R}{v}$$

which, replaced in the identity, gives,

$$\frac{\partial u}{\partial v} = T\frac{R}{v} - p = \frac{a}{v^2} \ .$$

Integrating,

$$u = -\frac{a}{v} + K(T)$$

where $K(T)$ depends only on T.
b. Differentiating the above expression

$$c_v = \frac{\partial u}{\partial T} = K'(T) = c \ .$$

Integrating $K(T) = cT + K_0$. Hence,

$$u = -\frac{a}{v} + cT + K_0 \ .$$

c. As u is constant, the expression above says that, if v grows then T decreases. Keeping u constant, the expression above says that,

$$c\frac{dT}{dv} = \frac{a}{v^2} \ .$$

Hence,

$$\Delta T = \frac{dT}{dv}\Delta v = \frac{a}{cv^2}\Delta v \ .$$

d. From $du = Tds - pdv$ we get,

$$\left(\frac{\partial u}{\partial v}\right)_T = T\left(\frac{\partial s}{\partial v}\right)_T - p \ .$$

Using the Maxwell relation,

$$\left(\frac{\partial s}{\partial v}\right)_T = \left(\frac{\partial p}{\partial T}\right)_v$$

we obtain the identity.

9.5.5.4 Ex: Isothermal expansion

Calculate the work done during isothermal expansion from V_1 to V_2 of a real gas.

Solution:

9.5.5.5 Ex: Joule-Thomson process

Here we study the *Joule-Thomson effect*. A gas is forced under constant pressure p_1 from a container B1 through a porous partition into a container B2 with constant pressure $p_2 < p_1$. The constancy of the pressures in the containers is ensured by increasing or decreasing their volumes. Finally, it is assumed that the gas is adiabatically isolated from the environment and therefore only exchanges with it energy in the form of work.
a. Show that the enthalpy H remains constant in both recipients during this process.
b. Show that,

$$\left(\frac{\partial T}{\partial p}\right)_H = \frac{1}{C_p}\left(T\frac{\partial V}{\partial T}_p - V\right)$$

and calculate $\left(\frac{\partial T}{\partial p}\right)_H$ explicitly for an ideal gas.
c. For a real gas, the so-called inversion curve $p(T)$ defined by $\left(\frac{\partial T}{\partial p}\right)_H$ is obtained in the pT-plane. Physically interpret the areas above and below this curve. Calculate the inversion curve for the van der Waals gas using the thermal equation of state for real gases.
d. Discuss the behavior of entropy in this process.

Solution:

9.6 Canonical formulation of thermodynamics

The state of stationary thermodynamic systems may ne expressed by equations of state interrelating thermodynamic potentials:

$$f(x_1, ..x_q) = 0 \ . \tag{9.34}$$

The most current *thermodynamic variables* in a *grand canonical ensemble* are the temperature T, the entropy S, the pressure $-P$, the volume V, the particle number N, and the chemical potential μ. The pressure and volume may be replaced by other mechanical variables.

9.6.1 The laws of thermodynamics

There are four fundamental truths in thermodynamics:

- 0. The zeroth law affirms that two systems each one in thermal equilibrium with a third are in equilibrium themselves.
- 1. The first law states that the total energy is conserved $dU = \delta Q + dW$.
- 2. The second law states that heat flows from hot to cold places, i.e. the entropy of closed systems goes always increasing, $dS \geq 0$.
- 3. The third law that for $T \to 0$, the entropy difference between systems connected by a reversible process vanishes, $dS \to 0$. This last law has its origins in quantum mechanics.

9.6.2 Thermodynamic potentials

The main thermodynamic potentials are the total energy E, the heat W, the Helmholtz free energy F, the Gibbs free energy G, the free enthalpy H, and the grand potential W:

$$\boxed{\begin{array}{lll} E = TS - PV + \mu N & \text{and} & dE = TdS - PdV + \mu dN \\ H = TS + \mu N & \text{and} & dH = TdS + VdP + \mu dN \\ F = -PV + \mu N & \text{and} & dF = -SdT - PdV + \mu dN \\ W = PV & \text{and} & dW = -SdT - PdV - Nd\mu \\ G = \mu N & \text{and} & dG = -SdT + VdP - Nd\mu \\ Q = H & \text{and} & dQ = TdS \end{array}} \tag{9.35}$$

From that follow the conditional derivatives of the thermodynamic potentials and other quantities, like the *heat capacity*:

$$\begin{aligned} C_V &= \left(\frac{\partial E}{\partial T}\right)_{N,V} = T\left(\frac{\partial S}{\partial T}\right)_{\mu,V} \\ C_P &= \left(\frac{\partial E}{\partial T}\right)_{N,P} . \end{aligned} \tag{9.36}$$

Therefore, all thermodynamic quantities may be calculated from a few basic formulae:

$$TS(T) = E - \sum\nolimits_j k_B T \ln\left[1 - \exp(-\beta E_j)\right] . \tag{9.37}$$

9.6.3 Exercises

9.6.3.1 Ex: Legendre transform

Legendre transform.

Solution:

9.7 Thermodynamic phase transitions

9.7.1 The balance of transitions

The equilibrium of a chemical reaction may be on the left or right side.

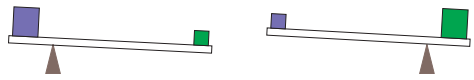

Figure 9.26: The equilibrium of a chemical reaction may be on the left or right side.

9.7.2 Solid-liquid-vapor

In the case of the *liquid-vapor transition* the two phases are only quantitatively distinct, but have the same symmetry. Therefore, a discontinuity of the thermodynamic potentials is required to reveal the phase transition.

In the case of the *solid-liquid transition* the two phases are qualitatively distinct due to different symmetries. We do not need a discontinuity to distinguish the phases. Landau's theory holds for this class of transitions. It establishes a relationship between symmetry considerations and physical characteristics by introducing the notion of the *order parameter* and *free energy*.

9.7.3 Classification of phase transitions

The old *Ehrenfest classification* [641] calls a phase transition of n^{th} order if the derivative $\partial^n \mu / \partial T^n$ is discontinuous. Thus BEC of a trapped ideal gas is a first-order phase transition, because the chemical potential suddenly changes its slope at T_c.

The modern *Landau classification* distinguishes two types of phase transitions in homogeneous systems: First-order phase transitions exhibit a discontinuity in the order parameter, while for continuous phase transitions the order parameter does not make jumps.

First order phase transitions are characterized by 1. equilibrium between phases (liquid-gas, liquid-solid), 2. discontinuous entropy, therefore latent heat, 3. at least one derivative of a thermodynamic potential is discontinuous. **The two phases coexist at the transition point.** E.g. at $T = 0°C$ in a closed system water and ice coexist.

Continuous phase transitions are characterized by 1. no equilibrium, 2. no latent heat, but often discontinuous heat capacity, 3. first order derivatives are all continuous, but second order is discontinuous. **There is no phase coexistence at the critical point**. E.g. at $T = T_c$ there no condensate; only below T_c.

9.7.3.1 Bose-Einstein condensation

Is the observed phase transition in trapped gases really Bose-Einstein condensation? A homogeneous gas has strong fluctuations near T_c that can heavily be influenced by interactions, which could result in phase domains. In contrast, a trapped gas is quite robust near T_c due to the modification of the density of states for small energies by the trapping potential, which make the interaction less important (see stabilization of attractive gases). However, T_c is not precisely defined and far from T_c interactions become very important (Thomas-Fermi limit).

The dynamics of phase transition is rules by a competition between internal energy which tries to minimize itself and entropy which tries to maximize itself. Here are a few examples.

9.8 Quantum statistics

9.8.1 Maxwell-Boltzmann, Bose-Einstein and Fermi-Dirac distribution

9.8.1.1 Black-body radiation

The Bose-Einstein and the Fermi-Dirac distribution both have many applications in quantum mechanics, e.g. for the explanation of the blackbody radiation, the heat capacity of metals, the laser, the Bose-Einstein condensation, and much more. In fact, these distributions must be used whenever quantum statistical effects are important. Here, we will only focus on two examples, one for each type of distribution: We will discuss the blackbody radiation using the Bose-Einstein distribution and an ideal ultra-cold trapped fermion gas with the Fermi-Dirac distribution.

9.8.1.2 Ultra-cold ideal fermion gas

To address this problem, before we study the effects of quantum statistics, we begin by identifying the geometric constraints. Many properties can be understood by calculating the density-of-states $g(\epsilon)$ defined by,

$$\int g(\epsilon)d\epsilon = \frac{1}{(2\pi)^3}\int d^3\mathbf{x}d^3\mathbf{k} = \frac{(2m)^{3/2}}{(2\pi)^2\hbar^3}\int d^3\mathbf{x}d\epsilon\sqrt{\epsilon - U(\mathbf{r})}\ . \tag{9.38}$$

For example, for a box, $U(\mathbf{x}) = -U_0\chi(|\mathbf{x}| > a)$, we get $g(\epsilon) = ...$ For a harmonic oscillator, $U(\mathbf{x}) = \frac{m}{2}\omega^2|\mathbf{x}|^2$, we get $g(\epsilon) = \epsilon^2/2\hbar^2\omega^2$.

Now, the Fermi-Dirac distribution,

$$N = \int \frac{g(\epsilon)}{e^{\beta(\epsilon-\mu)}+1}\ . \tag{9.39}$$

gives the chemical potential.

We can now calculate all thermodynamic potentials, e.g.,

$$E = \frac{\int \epsilon g(\epsilon) f_{FD}(\epsilon)}{\int g(\epsilon) f_{FD}(\epsilon)} \ . \tag{9.40}$$

Same for BEC.

9.8.2 Bose-Einstein condensation

Start calculating the density of states on a box potential, $\rho(\epsilon)d\epsilon = \frac{4\pi V}{h^3}(2m^3)^{1/2}\epsilon^{1/2}d\epsilon$, N and E are

$$\begin{aligned} N &= \int_0^\infty f_{BE}\rho d\epsilon = V\lambda_{th}^{-3} g_{3/2}(e^{-\mu}) \\ E &= \int_0^\infty \epsilon f_{BE}\rho d\epsilon = V\lambda_{th}^{-3}\frac{3k_BT}{2} g_{5/2}(e^{-\mu}) \\ &= \frac{3}{2}k_BT\left(1 - 2^{-5/2}n\lambda_{th}^3\right) + \dots \ , \end{aligned} \tag{9.41}$$

where $\lambda_{th} = \sqrt{2\pi\hbar^2/mk_BT}$ is the *thermal de Broglie wavelength*. Bose gases have a lower pressure then classically predicted.

9.8.3 Fermi degeneracy

A completely analogous treatment to the Bose-gas yield for the case of fermion

$$E = \frac{3}{2}k_BTN\left(1 + 2^{-5/2}n\lambda_{th}^3\right) + \dots \ . \tag{9.42}$$

Bosonic ^{4}He has a very different behavior than fermionic ^{3}He. It stays gaseous at very low temperatures and becomes a Fermi gas before becoming fluid. Fermi gases have a higher pressure then classically predicted.

Electrons in a solid are characterized by a high density and a low mass. Hence, $n\lambda_{th}^3 \approx 10^3$. The interelectronic repulsion is canceled by atomic attraction, so that they may be considered an ideal gas. For the density of states we get the same formula as for bosons in a box multiplied with the factor 2 to account for the spin degree of freedom. Thus, from

$$N = \int_0^{E_F} \rho f_{FD} d\epsilon \ , \tag{9.43}$$

we derive the Fermi energy $E_F = \frac{h^2}{8m}(3N/\pi V)(2/3)$. The free electron gas is deep in the Fermi regime, the classical statistics may only be used at temperatures above $T > 10^5$ K. Hence the energy is temperature-independent and the heat capacity vanishes, *i.e.* the electron gas does not contribute to the heat capacity of a metal. It is only at very low temperatures of a few K, when the heat capacity of the atomic lattice drops due to the underlying bosonic statistics, that the electrons contribute.

Now, make the metallic box potential having a finite depth. An electron can then leave the metal, if it surmounts the *exit work* $W = -V_{min} - E_F \simeq 10$ eV, which is the

difference between the potential depth and the Fermi energy. At high temperatures, the tail of the Fermi-Dirac distribution can leak into the unbound regime, which gives rise to *thermoionic emission*. This feature explains the existence of *contact potentials*: Metals with different W and E_F brought into contact exchange charges until their Fermi level is at same height.

9.8.3.1 Phase space quantization

If *phase space* was not quantized, the cells' size could be chosen so small that they admit at most one particle. Then quantum statistics would not apply, the system would be classical.

9.8.4 Microcanonical ensembles

To obtain the partition function in the *microcanonical ensemble*, we proceed as follows. Bosons have anti-symmetric wavefunctions, Fermions have symmetric ones. Boltzmann particles (called boltzons here for simplicity) have all wavefunctions as eigenfunctions. In the limit of high temperatures all particles behave like boltzons. Discretize the one-particle energies in small cells labeled i of constant energy e_i. Let n_i be their number and g_i their degeneracy. For bosons, each level g_k can hold arbitrarily many of the n_i particles:

$$W_{\{n_i\}} = \prod_i \binom{n_i + g_i - 1}{n_i} \,. \tag{9.44}$$

For boltzons, each level g_k can hold ni particles:

$$W_{\{n_i\}} = \prod_i \frac{g_i^{n_i}}{n_i!} \,. \tag{9.45}$$

For fermions, each level g_k can hold at most one of the n_i particles:

$$W_{\{n_i\}} = \prod_i \binom{g_i}{n_i} \,. \tag{9.46}$$

Using the Laguerre variation principle with $W_{\{n_i\}} = \max\{W_{\{n_i\}}\}$ one can show:

$$\bar{n}_{n_i} = \frac{g_i}{z^{-1}\exp(\beta e_i) + a} \,, \tag{9.47}$$

where $a = +1$ for fermions, $a = -1$ for bosons, and $a = 0$ for boltzons. z and b follow from the boundary conditions:

$$N = \sum_i n_i \qquad \text{and} \qquad E = \sum_i e_i \,. \tag{9.48}$$

From $W_{\{n_i\}}$ the thermodynamic potentials can be calculated. E.g. the entropy reads $S = k_B \ln W_{\{n_i\}} = \sum_i n_i \ln(g_i/\bar{n}_i - a) - a g_i \ln(1 - a\bar{n}_i/g_i)\}$.

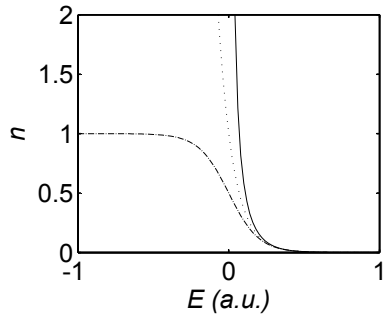

Figure 9.27: Quantum statistic weight for fermions (dash-dotted line), bosons (solid line) and boltzons (dotted line).

9.8.5 Detailed balance

Quantum statistical (anti-)symmetrization of the wavefunction of a cold system leads to Bose-enhancement(Pauli blocking). Take a state $\Psi = \psi_\alpha(1)\psi_\beta(2)$ and symmetrize it to $\Psi s, a = 2^{-1/2}[\psi_\alpha(1)\psi_\beta(2) \pm \psi_\alpha(2)\psi_\beta(1)]$. Now assume the single particle wavefunction overlap, $\alpha = \beta$, then $|\Psi|^2 = (s+1)\ |\psi_\alpha(1)|^2|\psi_\beta(2)|^2$, where $s = 0$ for boltzons, $s = 1$ for bosons, and $s = -1$ for fermions. Generalized to arbitrary numbers of particles we state: *If n bosons(fermions) are in state Ψ, the probability for another bosons(fermions) to joint this state is $1 \pm n$ times the probability without quantum statistics.*

An alternative intuitive derivation of the quantum statistical distribution function is based on the postulate of *detailed balance*, claiming that *equality of the rates $W_{12\to34}$ for two particles to change their states and the rate for the inverse process $W_{34\to12}$ is a sufficient condition for thermal equilibrium*,

$$\begin{aligned} W_{12\to34} &= |M_{12,34}|^2 n_1 n_2 (1+sn_3)(1+sn_4) \\ W_{34\to12} &= |M_{12,34}|^2 n_3 n_4 (1+sn_1)(1+sn_2)\ . \end{aligned} \tag{9.49}$$

Hence,

$$\frac{n_1}{1+sn_1} + \frac{n_2}{1+sn_2} = \frac{n_3}{1+sn_3} + \frac{n_4}{1+sn_4}\ . \tag{9.50}$$

Energy conservation requires

$$E_1 + E_2 = E_3 + E_4\ . \tag{9.51}$$

For a macrocanonic ensemble in thermal equilibrium

$$f(E_i) = n_i\ . \tag{9.52}$$

To satisfy Eqs. (9.50) and (9.51) f must have the functional form

$$f(E_i) = \frac{1}{e^{\beta(E_i-\mu)} \mp s}\ . \tag{9.53}$$

The Bose-Einstein distribution follows directly from the assumption of stimulated emission *bosonic stimulation*.

The Maxwell velocity distribution in a gas in a special application of the Boltzmann distribution.

9.8.6 Canonical ensembles

In order to calculate the density of states, state equation, mean values in the grand *canonical ensemble*, we start from the partition sum (upper signs for fermions and lower signs for bosons):

$$Tr\rho = \prod_{\mathbf{p}} \left(1 + ze^{-\beta e_p}\right)^{\pm 1} \quad . \tag{9.54}$$

Internal energy with fixed volume is proportional to the pressure. For large systems (thermodynamic limit) the sum may be replaced by an integral $\sum_{\mathbf{p}} \overset{N\to\infty}{\longrightarrow} V/h^3 \int d^3\mathbf{p}$, and the integral may be expressed by the Riemann zeta-function (see Sec. (??)). The terms in {} brackets only hold for Bosons, because the integral diverges otherwise. The thermodynamic potentials are

$$\begin{aligned}
n_{\mathbf{p}} &= -\frac{1}{\beta}\frac{\partial}{\partial e_{\mathbf{p}}} \ln Tr\rho = \frac{z\exp(-\beta e_{\mathbf{p}})}{1 \pm z\exp(-\beta e_{\mathbf{p}})} \qquad (9.55)\\
\frac{PV}{k_BT} &= \ln Tr\rho = \sum_{\mathbf{p}} \ln\left(1 \pm z\exp(-\beta e_{\mathbf{p}})\right) \overset{N\to\infty}{\longrightarrow} \frac{V}{\lambda_{dB}^3} g_{5/2}^{(\pm)}(z) - \{N\ln(1-z)\}\\
N &= z\frac{\partial}{\partial z}\ln Tr\rho = \sum_{\mathbf{p}} n_{\mathbf{p}} \overset{N\to\infty}{\longrightarrow} \frac{V}{\lambda_{dB}^3} g_{3/2}^{(\pm)}(z) + \{\frac{N}{1-z}\} \qquad \text{gives the chemical potential}\\
\frac{E}{N} &= -\frac{\partial}{\partial\beta}\ln Tr\rho = \sum_{\mathbf{p}} n_{\mathbf{p}} e_{\mathbf{p}} \overset{N\to\infty}{\longrightarrow} \frac{3k_BTV}{2\lambda_{dB}^3} g_{5/2}^{(\pm)}(z) \approx \frac{3PV}{2}\\
\frac{S}{k_BN} &= \ln Tr\rho = \beta E - N\ln z \overset{N\to\infty}{\longrightarrow} \frac{5V}{2\lambda_{dB}^3} g_{5/2}^{(\pm)}(z) - \{\ln z\} \overset{T\to 0}{\longrightarrow} 0\\
\frac{C_V}{k_BN} &= \left(\frac{\partial E}{\partial\left(k_BT\right)}\right)_{N,V} \overset{N\to\infty}{\longrightarrow} \frac{15V}{4\lambda_{dB}^3} g_{5/2}^{(\pm)}(z) - \left\{\frac{9Ng_{3/2}^{(\pm)}(z)}{4g_{1/2}^{(\pm)}(z)}\right\} \overset{T\to 0}{\longrightarrow} 0\\
\frac{G}{Nk_BT} &= \ln z \ .
\end{aligned}$$

The Bose-Einstein phase transition occurs at some critical temperature T_c. At high temperature $T > T_c$ the ground state population vanishes. At low temperature $T < T_c$, we have to substitute in the above equations z by 1. Since $g_{3/2}$ is limited for $z = 0..1$ the population bilance must be equilibrated by an additional term describing the ground state population:

$$\begin{aligned}
\frac{N}{V} &= \left\{\begin{array}{ll} \frac{g_{3/2}^{(\pm)}(1)}{\lambda_{dB}^3} + \frac{N_0}{V} & \text{for} \quad T \le T_c \\ \frac{g_{3/2}^{(\pm)}(z)}{\lambda_{dB}^3} & \text{for} \quad T \ge T_c \end{array}\right\} \qquad (9.56)\\
\frac{P}{k_BT} &= \left\{\begin{array}{ll} \frac{g_{5/2}^{(\pm)}(1)}{\lambda_{dB}^3} & \text{for} \quad T \le T_c \\ \frac{g_{5/2}^{(\pm)}(z)}{\lambda_{dB}^3} & \text{for} \quad T \ge T_c \end{array}\right\}
\end{aligned}$$

State equation in the Bose-gas phase:

$$\frac{P}{k_BT} = \frac{N}{V}\frac{g_{5/2}^{(\pm)}(z)}{g_{3/2}^{(\pm)}(z)} \ . \tag{9.57}$$

In the classical limit and we get the ideal gas equation:

$$\frac{P}{k_B T} = \frac{N}{V} \ . \tag{9.58}$$

The state equation in the Bose-condensat phase follows directly from equation (II.2.3):

$$\frac{N_0}{N} = 1 - \left(\frac{T}{T_c}\right)^{3/2} \ . \tag{9.59}$$

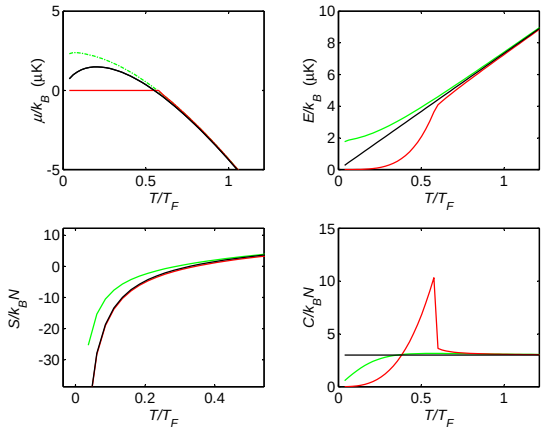

Figure 9.28: Thermodynamic potentials for fermion, bosons and boltzons.

9.8.6.1 Micro- and macrocanonical Bose-condensates

The question which *canonical ensemble* is the correct assumption depends on the experimental situation. The question is particularly interesting in the context of Bose-Einstein condensation: Here it is related to the question which state better describes a BEC: A Fock or a Glauber state.

The condensates experimentally produced in alkali gases consisted of relatively small atom numbers between 1000 to 10^7, so that the validity of the thermodynamic approximation and the use of the density of states approach has been questioned [551]. Also, the decision whether to use the grand canonical, the canonical or the micro-canonical ensemble for calculating the thermodynamic quantities noticeably influences the results. Herzog and Olshanii [615] have shown that for small atom numbers on the order of 100 the canonical and grand canonical statistics lead to predictions on the condensed fraction that differ by up to 10%. On the other hand, they give the same results if the particle numbers are large. Which canonical statistics is more appropriate is not a trivial question and depends on the experimental setup and in particular on the time scale of the measurements. If we look at the sample for short times, the number of condensed atoms will be fixed, and we can assume a canonical ensemble. For longer times, however, the atom number may be an equilibrium parameter depending on the contact of the sample with a reservoir, and the grand canonical statistics is better suited.

9.8.7 Photons

9.8.7.1 Blackbody radiation

The chemical potential is the equilibrium parameter for the particle number. Since, photons are massless and can be created or annihilated in the vacuum, the chemical potential must vanish $\mu = 0$. The Boson number is determined in the case of photons by other thermodynamic quantities like temperature or volume. Blackbody radiation is independent of the walls if the volume is sufficiently large, and only depends on the temperature T. We can therefore freely fix the boundary conditions, f.e.

$$\mathbf{k} = 2\pi/L \cdot \mathbf{n} \qquad \text{where} \qquad n_x, n_y, n_z \in N \ . \tag{9.60}$$

Allowed momentum on a sphere:

$$V/(2\pi)^3 \cdot 4\pi k^2 dk \ . \tag{9.61}$$

For larger volumes:

$$\begin{aligned}
&\sum\nolimits_{\mathbf{p}} \longrightarrow \frac{V}{h^3}\int d^3\mathbf{p} && (9.62)\\
&Z = \frac{1}{1-e^{-\beta\hbar\omega}} \\
&Tr\rho = \sum\nolimits_{\mathbf{k},\kappa} \exp(-\beta E_{\{\mathbf{k},\kappa\}}) = \prod\nolimits_{\mathbf{k},\kappa} \frac{1}{1-e^{-\beta\hbar\omega}} \\
&\langle n_{\mathbf{k}}\rangle = -\frac{1}{\beta}\frac{\partial}{\partial\hbar\omega}\ln Tr\rho = \frac{2}{e^{\beta\hbar\omega}-1} \qquad \text{for the two polarizations} \\
&\rho = \sum\nolimits_n |n\rangle\langle\rho\rangle\langle n| = \sum_n |n\rangle \frac{\langle n\rangle}{(1+\langle n\rangle)^{n+1}}\langle n| = \\
&E = -\frac{\partial}{\partial\beta}\ln Tr\rho = \sum\nolimits_{\mathbf{k},\kappa} \hbar\omega\langle n_{\mathbf{k}}\rangle = 3PV \ .
\end{aligned}$$

9.8.8 Statistical density

There are three possible ensembles that deal with a system of colliding particles depending on the specific boundary conditions. In the microcanonical ensemble

$$\rho_{mn} = \left\{ \begin{matrix} C\cdot\delta_{mn} & \text{for} & E < E_n < E+\Delta & \text{and} & H|\psi_n\rangle = E|\psi_n\rangle \\ & & 0 \quad \text{else} & & \end{matrix} \right\} \ . \tag{9.63}$$

It follows:

$$\rho = \sum_{E<E_n<E+\Delta} |\psi_n\rangle\langle\psi_n| \ . \tag{9.64}$$

Connected to the thermodynamics via $S(E,V) = k_B \log Tr\rho$. After that in almost complete analogy to classical mechanics. In the canonical ensemble, the temperature is an equilibrium parameter.

$$\rho_{mn} = \delta_{mn}\exp(-\beta E_n) \qquad \text{com} \qquad \beta = 1/k_B T \ . \tag{9.65}$$

It follows:

$$1\rho = \exp(-\beta H) \sum_n |\psi_n\rangle\langle\psi_n| \ . \tag{9.66}$$

In the grand canonical ensemble, the temperature and chemical potential are equilibrium parameters.

$$1\rho_{mn} = \exp(-\beta E_n - \mu N) \ . \tag{9.67}$$

It follows:

$$1\rho = \exp(-\beta H - \mu N) \qquad \text{com} \qquad [H, N] = 0 \ . \tag{9.68}$$

9.8.8.1 Calculating thermodynamic systems

The density operator depends on $\varrho = \varrho(\mathbf{1})$ for a microcanonical ensemble, $\varrho = \varrho(\mathbf{1}, E)$ for a canonical ensemble, $\varrho = \varrho(\mathbf{1}, E, N)$ for a grand canonical ensemble, $\varrho = \varrho(\mathbf{1}, E, N, V)$ for a macrocanonical ensemble. The variables on which the density operator does not depend, $\langle\mathbf{1}\rangle, \langle E\rangle, \langle N\rangle, \langle V\rangle$, are fixed for the system,

$$\delta\left(S + k_B\left[(\ln Z - 1)\langle\mathbf{1}\rangle - \beta\langle E\rangle + \beta\mu\langle N\rangle - \beta p\langle V\rangle\right]\right) = 0 \ . \tag{9.69}$$

The thermodynamic quantities follow from equations like

$$dS_{rev} = k_B\beta(\beta dE - \mu dN + pdV) \leq 0 \ . \tag{9.70}$$

Other thermodynamic potentials may be defined via Legendre transformations.

How to calculate thermodynamical systems? Chose the ensemble that applies to the problem, $\varrho = e^{-\beta\cdots}/Z$ and the respective potential P with its thermodynamic relation. Express the dynamic variables a_i via the state sum $Z = \text{Tr } e^{-\beta\cdots}$ and the natural variables n_i by $a_i = (\partial P/\partial n_i)_{a_k, a_l}$. Now express the other potentials via the state sum and the natural variables by $P' = P + a_i n_i$. Express the second derivatives and all other thermodynamic quantities by Z and n_i. Calculate the state sum explicitly, and finally substitute Z everywhere.

9.8.9 Heat capacity measurement

According to the theory of an ideal Bose gas trapped in a harmonic potential the temperature dependence of the heat capacity at the threshold to condensation can easily be obtained as follows. The condensed fraction determines the chemical potential through:

$$N = N_0 + \left(\frac{k_B T}{\hbar\omega}\right)^3 g_3(z) \ , \tag{9.71}$$

where $z(T) = \exp(\mu/k_B T)$ for a grand canonical ensemble and g_n denotes the Riemann zeta function. The condensed fraction vanishes above the critical temperature, the chemical potential vanishes below the critical temperature. $(k_B T/\hbar\omega)^3 = 2\pi(a_{trap}/\lambda_{dB})^3$ denotes the normalized volume of a phase space cell. Knowing $z(T)$ from equation (9.71), we can calculate the total energy, the heat capacity and all the other thermodynamic potentials:

$$C_N = 12 k_B \left(\frac{k_B T}{\hbar\omega}\right)^3 g_4(z) - 9 k_B N \frac{g_3(z)}{g_2(z)} \ . \tag{9.72}$$

The considerable interest in the measurement of thermodynamic quantities of a BEC is motivated by its departure from ideal gas behavior (equations (??) and (9.72)). Indeed, the abrupt discontinuous change in the heat capacity at the phase transition to BEC, expected for ideal gases, is smeared out by atomic collisions [72]. Deviations due to atomic interactions and the finite number of particles [551] should even show up in the temperature dependent measurement of the condensed fraction as it is done by simple time-of-flight analysis. But experimental uncertainties until now prohibited a quantitative investigation [580]. A measurement of the release energy has been performed in Ref. [417].

A possible approach is the in-situ analysis of the cloud's shape while it is trapped. The shape of its condensed fraction reveals its chemical potential which in turn determines the excitation energies and populations of the thermal part of the gas [380].

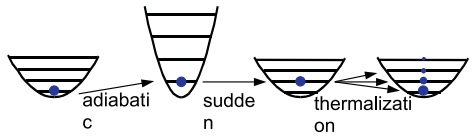

Figure 9.29: Population variation during a slow adiabatic compression followed by a sudden non-adiabatic decompression.

The basic idea consists of applying an adiabatic change followed by a sudden change in the curvature of the trapping potential (Fig. 9.29) in such a way, that the particle number remains constant, the temperature changes in a controllable and predictable way, but the populations are redistributed over the excited energy levels. We take pictures of the trapped cloud just before and after the trap manipulation and analyze them to extract the energy change. The heat capacity can then directly be calculated according to its definition:

$$C_N = \left(\frac{\partial U}{\partial T}\right)_N \quad . \tag{9.73}$$

In the following, we will discuss the steps in more detail. During the slow adiabatic compression the temperature of the trapped cloud will gradually increase like $T' = T\omega'/\omega$, but the population distribution of the energy levels will not. This can be seen from the phase space density, $r = g_3(z)$, that should remain unchanged under adiabatic variations of the trapping potential. In contrast, the sudden switching from ω' back to w will first create a population imbalance (that can even be an inversion). Elastic collisions between the atoms then will rethermalize the sample at the same temperature T. We calibrate the temperature change to the amount of compression and evaluate the heatcapacity:

$$C_N \approx \frac{U' - U}{T' - T} = \frac{1}{T}\frac{U' - U}{\omega'/\omega - 1} \quad . \tag{9.74}$$

The adiabatic compression should be slow, the sudden switching should be fast compared to the trap secular frequencies. The shape of a partially condensed gas is determined by the geometry of the trapping potential ω_r, ω_z, the number of condensed

atoms N_0 and the equilibrium temperature T. One way to measure the energy distribution is to fit the recorded shape of a trapped cloud with calculated wavefunctions for the ground and excited states:

$$n(\mathbf{r}) = |\psi_0(\mathbf{r})|^2 + \sum_j N_j |\psi_j(\mathbf{r})|^2 \ . \tag{9.75}$$

The sum of the particle distribution functions N_j gives the total atom number, the sum of the energy eigenvalues belonging to the wavefunction weigthed with the population distribution (that depends on the temperature) gives the total energy:

$$N = \sum_j N_j \qquad , \qquad U = \sum_j N_j E_j \ . \tag{9.76}$$

The fitting procedure using equation ((??)) consists of several steps. We assume the validity of the two-gas model [380] stating, that the shape of the condensed cloud is (almost) not affected by the thermal cloud. Knowing the condensed atom number, we can solve the Gross-Pitaevski equation and calculate the chemical potential of the trapped cloud. We employ the method of steepest descent [320]

$$\left[-\frac{\hbar^2}{2m}\Delta + V_{trp}(\mathbf{r}) + g|\psi_0(\mathbf{r})|^2 \right] \psi_0(\mathbf{r}) = \mu \psi_0(\mathbf{r}) \ . \tag{9.77}$$

Within this two-gas model, we can now consider the thermal atoms to be moving in an effective potential, that consists of the trapping potential modified by the presence of the condensate $V_{eff}(\mathbf{r}) = V_{trap}(\mathbf{r}) + g|\psi_0(\mathbf{r})|^2$. We can therefore set up and solve a Schrödinger equation eigenvalue problem:

$$\left[-\frac{\hbar^2}{2m}\Delta + V_{eff}(\mathbf{r}) \right]_j \psi_j(\mathbf{r}) = E_j \psi_j(\mathbf{r}) \ . \tag{9.78}$$

As soon as we found the eigenvalues E_j and the eigenfunctions ψ_j, we can determine the population distribution N_j by fitting the measured shape of the total cloud to equation (9.75) and calculate the total energy according to equation (9.76) and the heat capacity according to equation (9.72). Of course, the fitting is only precise if few excited states are populated.

This procedure requires a high resolution power of the imaging system, since typical wavefunction sizes ($N \gg 100000$, $(\nu_{ax}\nu_{rad}^2)^{1/3} \gg 80$ Hz) are on the order of a few 10 mm. In our actual setup the resolution would be diffraction limited to 6mm. We plan to drastically increase the resolution by placing an achromat inside the vacuum chamber close to the atomic cloud. This should allow us to resolve the shapes of the condensed and thermal clouds. Furthermore, we need to set up a nondestructive dispersive imaging system as has been demonstrated by [34].

Experimentally, it is easier to perform Time-Of-Flight (TOF) measurements where the cloud is allowed to freely expand until the spatial distribution of the cloud becomes negligible compared to the expanded velocity distribution. Of course this method is destructive and therefore the adiabatic-sudden change in the trapping potential, meant to calibrate the temperature scale and maintain a fix atom number during the measurement, makes no sense anymore.

The informations about the cloud that follow immediately from TOF measurements are the following: The total number of atoms N is extracted from a calibrated measurement of the integrated counts of missing photons in the probe beam shadow. Since the thermal part and the condensed part are well separated in the expanded cloud we can separately determine the number of condensed atoms N_c. Finally, we can fit the temperature T from the thermal cloud in the far wings, where to a good approximation, the equipartition theorem guaranties a Gaussian distribution:

$$n(E) = \frac{1}{\exp((E-\mu)/k_B T) - 1} \approx (N - N_0) \exp\left(\frac{-p^2}{2m}\right) . \tag{9.79}$$

With these data we can plot the condensed fraction N_c/N versus the reduced temperature $T/T_c(N)$, where $k_B T_c = \hbar\omega \left(N/g_3(1)\right)^{1/3}$ [301] and compare with theory [580]. But the data contain some more information, because we know the absolute value of the condensed atom number N_c. This enables us to calculate the chemical potential by numerically solving the Gross-Pitaevski equation (9.77). Then we can calculate the quasi-particle excitation spectrum according to equation (9.78). Assuming thermal equilibrium we know:

$$N_j = \frac{1}{\exp((E_j - \mu)/k_B T) - 1} , \tag{9.80}$$

and are able to calculate the total energy and the heat capacity from equation (9.75). It is obvious that this method requires much more input from theory and can barely be considered an experimental test of the thermodynamics of ideal gases. For that reason, we opt for the first method.

9.8.9.1 Adiabatic compression

Adiabaticity of a process means reversibility, while tha atom number is unchanged $N = const$ and, hence, constant entropy $S - const$. This implies an unchanged population distribution $n_j = const$ and $\beta\varepsilon_j/T = const$ also we get $\beta\mu, \beta U = const$. Furthermore, the phase space density keeps unchanged $\rho = const$. The process of adiabatically compressing a harmonic trap therefore changes the temperature like $T' = T\omega'/\omega$. This is valid above and below the transition point. The measure is repeated twice: With and without adiabatic-sudden variation. The heat capacity then follows from equation...

9.9 Out-of-equilibrium thermodynamics

9.9.1 Boltzmann's transport equation

Until now we have only treated systems in thermal equilibrium. However many systems are not stable, they drift or oscillate. Even if they are stable, this stability is sometimes only ensured by a continuous feeding with external energy or entropy, which is balanced by some dissipation mechanism. Non-equilibrium systems are difficult to treat.

9.9.1.1 H-theorem

Boltzmann's *H-theorem* is concerned with the tendency of non-equilibrium systems to return to equilibrium. The basic idea is that the fundamental process in gases are collisions. They introduce randomness into the evolution, which breaks the time-reversal symmetry. Other processes may have similar effects. The main point is that a very precisely defined input channel couples to a continuum of output channels, so that the equilibrium lies on the side of the larger mode volume (see Fig. (??)).

9.9.2 Stoßzahlansatz

Consider a gas with velocity distribution f. The *Boltzmann Stoßzahlansatz* reads,

$$\frac{\partial f}{\partial t} = \mathbf{v}\frac{\partial f}{\partial \mathbf{x}} + \left(\frac{\partial f}{\partial t}\right)_{coll} . \tag{9.81}$$

A general rate equation for may write,

$$\frac{d\varrho}{dt} = \frac{\partial \varrho}{\partial t} + \mathbf{v}\nabla_r + \mathbf{a}\nabla_v = R^+ - R^- . \tag{9.82}$$

For constant entropy increase $dS/dt \geq 0$, we get,

$$\frac{d\varrho}{dt} = \sum_{z'} \left(W_{zz'}\varrho_{z'} - W_{z'z}\varrho_z\right) . \tag{9.83}$$

And finally follows the *Boltzmann transport equation*,

$$\frac{d\varrho}{dt} = \int |\mathbf{v}-\mathbf{v}'|\sigma(\mathbf{v},\mathbf{v}'\to\mathbf{u},\mathbf{u}')\left[\varrho(t,\mathbf{r},\mathbf{u})\varrho(t,\mathbf{r},\mathbf{u}') - \varrho(t,\mathbf{r},\mathbf{v})\varrho(t,\mathbf{r},\mathbf{v}')\right] d^3\mathbf{v}'d^3\mathbf{u}d^3\mathbf{u}' , \tag{9.84}$$

which holds for binary collisions disregarding inner degrees of freedom, container walls, molecular chaos, and so on. For a free gas consisting of a single particle species, $dS/dt = 0$, the Liouville equation holds,

$$\frac{d\varrho}{dt} = 0 , \tag{9.85}$$

which yields,

$$\varrho(t,\mathbf{r},\mathbf{u}) = C(t,\mathbf{r})\exp\frac{\left[\mathbf{v}-\mathbf{v}_0(t,\mathbf{r})\right]^2}{-A(t,\mathbf{r})} , \tag{9.86}$$

and from which follows the *Maxwell-Boltzmann distribution*,

$$\varrho(\mathbf{v}) = \left(\frac{3}{2\pi\Delta v^2}\right)^{3/2}\exp -\frac{3[\mathbf{v}-\langle\mathbf{v}\rangle]^2}{2\Delta v^2} . \tag{9.87}$$

9.9.2.1 H quantity and entropy

From the Boltzmann Stoßzahlansatz is it possible to find for the quantity,

$$H \equiv \int f\ \ln f\ d^3\mathbf{p} , \tag{9.88}$$

the inequality,

$$\frac{dH}{dt} \leq 0 \ . \tag{9.89}$$

The equality holds for equilibrium.

It can be shown,

$$S = -k_B H \ . \tag{9.90}$$

Therefore the H quantity is nothing else than the entropy. Due to the derivation from the Stoßzahlansatz, this equation gives a definition of entropy for non-equilibrium systems.

9.9.2.2 Entropy problem

The H theorem is not generally true as is clear from *Loschmidt's reversibility paradox*. This illustrates a certain contradiction between classical mechanics and thermodynamics. Consider the diffusion of a drop of ink in a glass of water. From the point of view of mechanics the process is deterministic, thus our knowledge of the state of the system stays constant, (information) entropy must be constant as well, which is contradicted by thermodynamics.

The solution lies in the unprecisely known initial conditions, in particular in quantum systems due to the Heisenberg uncertainty. The H theorem only makes sense if it is understood in terms of its statistical nature: For equilibrium systems the most probable state is the one with maximum entropy. For non-equilibrium systems we have an overwhelming probability for an increasing entropy, but a decrease is not excluded.

9.9.3 H theorem and Fokker-Planck equation

An H theorem can be derived from *Fokker-Planck equations* [1200]. The H quantity is then the non-equilibrium analog to the Helmholtz free energy,

$$F = U - TS \tag{9.91}$$

$$H = U/D - S \ . \tag{9.92}$$

9.9.4 Irreversibility

Thermodynamics separates into two regimes: Of a *reversible process* and an *irreversible process*. Reversible processes are those, whose trajectories in parameter space can be reverse by inverting the signs of heat exchange Q, mass exchange m and work W. For systems in equilibrium, phase transitions are in general reversible by appropriately tuning some control parameter. For systems far from equilibrium, irreversible *temporal phase transition* may occur. However this classification is phenomenological and insufficient to make the connection to mechanics, in contrast to equilibrium thermodynamics which has been traced back to statistical physics.

For equilibrium statistical mechanics it is the interaction among the degrees of freedom which permits to approach equilibrium. This view coincides with modern views of the role of decoherence. The final (steady) state exhibits no macroscopic dynamics and is in a situation called *detailed balance*. In contrast a flux of energy or

matter may result in the emergence of *spatial patterns* of *rhythmic phenomena*. The transition to ordered structures requires a instabilities, i.e. a critical distance from equilibrium and nonlinear kinetics.

For any change of the state of a system the entropy behaves like,

$$dS = d_e S + d_i S \ , \tag{9.93}$$

where $d_e S$ is the entropy exchange with the external world and $d_i S \geq 0$ the internal *entropy production*. This shows that the entropy of a system can be lowered if $d_e S < 0$. The thermodynamics of irreversible processes exhibits linear and nonlinear phenomena. For small (linear) deviations from equilibrium the steady state of a system is characterized by a *minimum entropy production*. This is however *not* generally the case far from equilibrium. This rule is analogous to the change of internal energy,

$$dU = dQ + dW \ , \tag{9.94}$$

where dQ denotes the heat exchanged with the external world and dW the reversible work applied to the system.

9.9.4.1 Application to the Kuramoto model

According to Prigogine the transition to a dissipative structure is governed by a thermodynamic stability criterion involving excess entropy production. The excess entropy is the amount of dissipation introduced by the disturbance causing the instability. From the above it becomes clear how it is possible that CARL creates order, i.e. lowers entropy: the dissipative force constitutes a large entropy reservoir to which the system may deliver excess entropy.

For Bénard structures and surface waves there is no intrinsic length scale on which the order is expected. In contrast CARL bunching occurs on the order of an optical wavelength. The microsystems are the atoms, the macrosystem is the light.

At first glance the *Kuramoto model* produces order without apparent dissipative force: Universally coupled pendulum exhibit synchronization, i.e., the entropy of the system is reduced. Since the dynamics is deterministic and thus reversible, one would expect no entropy production or reduction. This is however incorrect, the Kuramoto model inherently contains assumptions, which are equivalent to dissipation. This is seen from the derivation of the equations governing weakly coupled pendulum. In fact the Kuramoto does not describe coupled *pendulum* but *pendulum clocks*, i.e. limit cycle oscillations sustained by an external force.

A thermodynamic treatment of the Kuramoto model establishing a link between the Prigogine and Haken point of view is given by Shiino [1200]. The non-equilibrium phase transition can also be of first-order.

[S.W. Koch, 'Dynamics of first-order phase transitions in equilibrium and nonequilibrium systems.', Springer, Lecture Notes in Physics]

9.9.5 Dissipative structures and synergetics

9.9.5.1 Prigogine's approach

Consider a system that exits far from thermodynamic equilibrium (see thermodynamics), hence efficiently dissipates the heat generated to sustain it, and has the capacity

of changing to higher levels of orderliness (see self-organization). According to Prigogine, systems contain subsystems that continuously fluctuate. At times a single fluctuation or a combination of them may become so magnified by possible feedback, that it shatters the preexisting organization. At such revolutionary moments or "bifurcation points", it is impossible to determine in advance whether the system will disintegrate into "chaos" or leap to a new, more differentiated, higher level of "order". The latter case defines the *dissipative structure* so termed because they need more energy to sustain them than the simpler structures they replace and are limited in growth by the amount of heat they are able to disperse [1057].

Quite generally it is possible in principle to distinguish between two types of structures: equilibrium structures, which can exist as isolated systems (for example crystals), and dissipative structures, which can only exist in symbiosis with their surroundings. Dissipative structures display two types of behaviour: close to equilibrium their order tends to be destroyed but far from equilibrium order can be maintained and new structures be formed.

The probability for order to arise from disorder is infinitesimal according to the laws of chance. The formation of ordered, dissipative systems demonstrates, however, that it is possible to create order from disorder. The description of these structures have led to many fundamental discoveries and applications in diverse fields of human endeavour, not only in chemistry. In the last few years applications in biology have been dominating but the theory of dissipative structures has also been used to describe phenomena in social systems [1250, 950].

9.9.5.2 Minimum entropy production

Far from equilibrium nonlinear effects in the rate equations get important. This implies the possibility of multiple solutions, each one with different regions of stability. Transitions from one solution to another occur as phase transitions. In the linear regime with one thermodynamic force held fixed (e.g. temperature gradients) the stable state is a steady-state with *minimum entropy production* and it is *unique*. We say the state lies on the thermodynamic branch. Moving away from the linear regime the thermodynamic branch gets unstable. A *linear stability analysis* can tell when the system gets unstable, but it cannot predict where the system is going to go. At some point a non-equilibrium phase transition occurs often accompanied by dramatic macroscopic changes. The new state is characterized by an order parameter. Even if the boundary condition is held fixed and the steady state in the linear regime is homogeneous, the new state can exhibit oscillations in space and time. The symmetry is broken. The new state has more structure (less symmetry). This requires a steady flow of matter or energy, i.e. entropy production to maintain it.

In my words, Prigogine has in mind that a pumped system develops internal invisible coherence. At some point it has to release it (what entropy/coherence) in a kind of temporal phase transition, where the system has two choices: either turn into chaos or develop a higher order. The state of higher order (or lower symmetry) is called dissipative structure.

9.9.5.3 Criticism

Ilya Prigogine coined the phrase *dissipative structures* as a name for the patterns which self-organize in far-from-equilibrium dissipative systems. Dissipation inspires the wrath of the moralist and the envy of most others; for the physicist, however, it is merely faintly depressing. We call something dissipative if it looses energy to waste-heat. (Technically: if volume in the phase space is not conserved.) The famous Second Law of Thermodynamics amounts to saying that, if something is isolated from the rest of the world, it will dissipate all the free energy it has. Equivalently, it maximizes its entropy. Thermal equilibrium is the state of maximum entropy.

If something is (in a well-defined sense) near thermal equilibrium, one can show that its behavior is governed by linear differential equations (hence the name 'linear thermodynamics' for the appropriate body of theory), and that left to itself it will approach equilibrium exponentially (hence the somewhat more common name 'irreversible thermodynamics'). Here we are guided, not by the entropy, but by 'entropy production', the rate of increase in entropy. Since, once we reach equilibrium, the entropy cannot increase (by definition), the entropy production at equilibrium is zero, and the entropy production is always decreasing (the 'principle of minimum entropy production').

In general, however, things are not well-isolated from the rest of the world. If energy arrives from the outside as quickly as it is dissipated, even bodies in the linear regime can be kept away from equilibrium. (Hence various creationist arguments about the Second Law are worthless: neither living things nor the Earth are well-isolated from the rest of the universe, as may be observed every day at sunrise.) Thus dissipation, and why dissipative systems are not necessarily dull as dish-water. So you can have structures in dissipative systems, and there's no reason not to call them "dissipative structures", though it's not obvious that there are many interesting generalizations about them.

"Far-from-equilibrium" means that your system is so far from its thermal equilibrium that the linear laws I mentioned a moment ago no longer apply; non-linear terms become important. The only general rule about the solution to non-linear differential equations is that there are no general rules; hence the interest in the subject. (Cf. Chaos and non-linear dynamics.) This is not good news, of course, if what you want to do is extend thermodynamics to the far-from-equilibrium case. But, one might suppose, matters are not totally hopeless; we aren't talking about just any arbitrary system of equations, but the particular ones important in thermodynamics; perhaps there is some general principle (like those of maximum entropy, or minimum entropy production) which can guide us to solutions. What Prigogine claims to have done is to have found, if not another extremum principle, then at least an inequality (a "universal evolution criterion"), and to have used it to work out the theory of dissipative structures, according to which patterns are supposed to form when the uniform, uninteresting 'thermodynamic branch' of the system becomes unstable. The math for all this is analogous to that of equilibrium phase transitions with 'broken symmetry', where, again, a uniform state becomes unstable, forcing the system into a patterned, coherent one to minimize free energy. Even without Prigogine's claims that this theory is Very Significant to biology and social science, even without the philosophical and cultural importance he claims for it, this would be very interesting, and the big question is whether he's right, i.e. whether and to what the theory applies.

The authors compare symmetry-breaking in thermodynamic equilibrium systems (leading to phase change) and in systems far from equilibrium (leading to dissipative structures). They conclude that the only similarity between the two is their ability to lead to the emergent property of spatial variation from a homogeneous background. There is a well-developed theory for the equilibrium case involving the order parameter concept, which leads to a strong correlation of the order parameter over macroscopic distances in the broken symmetry phase (as exists, for example, in a ferromagnetic domain). This correlation endows the structure with a self-scaled stability, rigidity, autonomy or permanence. In contrast, the authors assert that there is no developed theory of dissipative structures (despite claims to the contrary) and that perhaps there are no stable dissipative structures at all! Symmetry-breaking effects such as vortices and convection cells in fluids — effects that result from dynamic instability bifurcations — are considered to be unstable and transitory, rather than stable dissipative structures. Thus, the authors do not believe that speculation about dissipative structures and their broken symmetries can, at present, be relevant to questions of the origin and persistence of life.

Prigogine and his school have made a series of attempts to build an analogy between these dissipative far-from-equilibrium systems which form patterns and the Landau free energy and its dependence on the order parameter, which leads to the important properties of equilibrium broken symmetry systems. The attempt is to generalize the principle of maximum entropy production, which holds near equilibrium in steady-state dissipative systems, and to find some kind of dissipation function whose extremum determines the state. As far as we can see, in the few cases in which this idea can be given concrete meaning, it is simply incorrect [773]. In any case, it is clearly out of context in relation to the observed chaotic behavior of real dissipative systems.

9.9.5.4 Haken's approach

The *synergetics* is the theory of cooperation, i.e. the theory of the behavior of coupled systems and in particular of *self-organization* [571].

Equilibrium phase transitions (liquid-solid, ferromagnetic, BEC,...) occur by temperature reduction. The less symmetric (or broken) phase, i.e. the phase with more structure is at lower temperature. This is not generally the case, e.g. living systems tend to die at low temperatures. (The universe will die the 'Kältetod' [Boltzmann, Helmholtz, Clausius]. Did the big bang really have lower entropy, than the today's universe?) Such systems are characterised by a steady flow of energy or matter.

The dynamic systems exhibit transition from disorder to order *analogous* to phase transitions. Those temporal transitions can be understood in the following way. Any system has fluctuations. By continuously emitting small subsystems (fluctuations) out of its equilibrium, the system probes the range of possible motional states it can possibly adopt. If the current state of the system is not stable, a fluctuation may trigger a collective instability. More and more subsystems are slaved into the collective motion. If several instabilities occur simultaneously, often only the fittest survives. This is called *mode competition* (see superradiance) and often leads to *symmetry breaking*. A mode is called *order parameter* if it slaves subsystems.

Eventually the driven system may find to a dynamically stable state (see Paul-

traps). Too strong thermodynamic forcing may lead to *turbulence* or *deterministic chaos*.

Note that one may influence which modes survives by external forces. Furthermore, one may speed up the instability by the application of noise (see *stochastic resonance*).

9.9.5.5 Feedback principle

According to Dawson [332] the state of macroscopic systems made of coupled microscopic subsystems subjected to noise not only is the statistical manifestation of the interacting subsystems as suggested by Boltzmann, but also prescribes the environment felt by the subsystem. This provides a positive feedback: Random perturbation of the microsystems are compensated for and the macrosystem exhibits a coherent self-regulated behaviour. However in special circumstances microscopic fluctuations can become amplified by collective action and become important on a macroscopic scale, then termed *critical phenomena*. The distinction between macro- and microsystems breaks down, if the macrosystem gets intrinsically stochastic itself. The role of critical phenomena is ideally studied with bistable systems. It is reminiscent to *stochastic resonance*s.

Feedback is an essential ingredient. It leads to a cyclic causality. Examples are the problem of the hen and the egg, and the self-generated CARL wave. It is very similar to *Darwinism*, the cyclic recurrence of randomness and necessity, of fluctuation and competition, of mutation and selection.

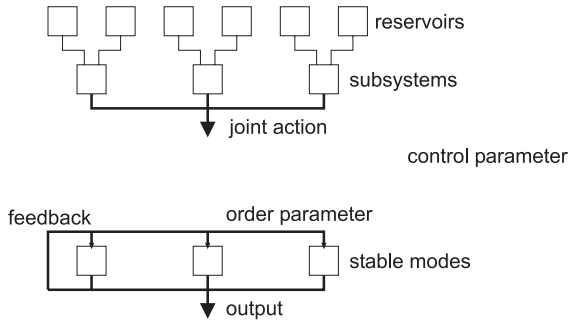

Figure 9.30: Principle of synergetics.

9.9.5.6 Comparison to Prigogine

Prigogine correctly identifies the role of fluctuations.

However he does not rely on feedback. He rather tries to find universal rules based on entropy, i.e. the principle of minimum excess entropy production. Synergetics goes beyond dissipative structures.

9.9.5.7 Example: Bénard instability

Examples range from physical instabilities, autocatalytic chemical reactions to biological, evolutionary, social and economic systems.

The most well-known dissipative structure is perhaps the so-called *Bénard instability*. This is formed when a layer of liquid is heated from below. At a given temperature heat conduction starts to occur predominantly through convection, and it can be observed that regularly spaced, *convection* cells are formed in the layer of liquid. This structure is wholly dependent on the supply of heat and disappears when this ceases. The form of the structures may vary from vertical rolls (distorted to hexagons due to surface tension in the liquid) to concentric rings or spirals. This depends on the exact form of the thermodynamic force, i.e. of the heat gradients.

9.9.5.8 Example: Surface waves

Waves are typically associated with perturbations that propagate in a system and transfer the energy of the system. Wave dynamics is possible both in conservative and dissipative (active) systems. Physical models of nonlinear waves are derived to simplify a complicated system of primary equations in a number of approximations. The same equations at the leading order describe main effects such as nonlinearity, dispersion, diffraction, diffusion, damping and driven forces, and resonances that determine wave propagation.

Oceanic waves generated by wind can reach anomalous high amplitudes in 10-20 meters. Such a giant *surface wave* are called a *freak wave* or *rogue wave*. They are formed as a result of a nonlinear interaction of multiple spectral components of the wave perturbations that propagate with different group velocities. The physical model for freak waves is based in the weak amplitude approximation on the *nonlinear Schrödinger equation* (NLS)

Refs: [http://dmpeli.math.mcmaster.ca/ResearchProjects/ResearchPage4.html].

9.9.5.9 Example: Faraday crispations in fluids

The undulation of the free surface of a viscous fluid in container under vertical vibration is known as *Faraday crispation*. The forced surface waves, which form many interesting *spatio-temporal dissipative structures*, oscillate at a frequency half the forcing frequency. In presence of large dissipation in a thin layer of viscous fluid, the surface crispation may be synchronous with forcing [432, 122, 434, 759, 936, 243].

9.9.5.10 Example: Predator-prey model

The Lotka-Volterra or *predator-prey model* is an example for a temporal oscillation. The populations of predators and prey interdepend via

$$\begin{aligned} \dot{N}_{py} &= \varepsilon_{py} N_{py} - \gamma_{pr} N_{pd} N_{py} \\ \dot{N}_{pd} &= -\varepsilon_{pd} N_{pd} + \gamma_{pd} N_{py} N_{pd} \ . \end{aligned} \tag{9.95}$$

9.9.5.11 Example: Physiology

Kelso's experiment of finger waved in parallel driven by a metronom. Passed a certain critical frequency the fingers are waves in the antiparallel mode. The transition is a phase transition. Amputierte Tausendfüssler spontaneously change their motion

pattern: to insect-like for 6 legs left, dog-like for 4 legs left. The movement is not controlled/programmed by brain, but self-organised via Rückenmark.

The brain exhibits self-organization on many different levels. Firing neurons synchronize, synapses tentatively establish new connections which are only confirmed and reinforced if frequently used. The brain thus resembles much more a dynamically moving system than a computer. Cognition and understanding seems to work like self-organization. Perception is an external control parameter which is only received and processed if it fits into an existing frame. If it doesn't it may still trigger a new idea, a though fluctuation, which can change the state of mind to a new one, if the new state appears to be more consistent or satisfying. The idea takes on the role as order parameter, the brain cell is slaved.

9.9.5.12 Example: Social systems

Static systems are often more unstable than dynamic systems if subject to external forcing. E.g. democracies which are based on an institutionalised permanent revolution can be more robust than dictatures.

9.9.5.13 Example: Laser

The laser is an open system far from equilibrium, because it is coupled to systems with different temperatures. The inversion corresponds to $T < 0$. On the other hand the the emitted photons coupled to ambient atoms at temperatures $T \ll \hbar\omega/k_B$, i.e. $T \approx 0$. Nevertheless, Haken has shown that the laser exhibits all features of a standard equilibrium phase transition.

In particular the equations describing a homogeneously broadened, unidirectional, single mode ring laser are mathematically equivalent to those describing the Bénard instability.

The conversion from a low quality microscopic form of energy (heat, chemical affinity) to a high quality macroscopic form (electricity, work) requires energy itself.

9.9.5.14 Example: CARL

Is a self-organizing system by feedback. As compared to biological systems or even Bénard instabilities, CARL is **very simple**. CARL is **of course** nonlinear: every degrees of freedom is a nonlinear function of the others.

9.9.5.15 Example: Vortex patterns

However there is another example for phase transitions in BECs: The transition from one vortex pattern to another has been classified as a first-order phase transition. But it seems to me that this is rather a non-equilibrium phase transition. I think, *vortex pattern* are *dissipative structures*. They decay by losing the vortices one by one due to relaxation into thermal excitations. On the other hand, vortex pattern are formed by a dissipative force: stirring up a condensate. In fact, an irreversible process is necessary to form a vortex: The BEC is excited by stirring (Dalibard's method) and *decays* into the vortex state. The is perhaps not true even for Cornells method, where the vortex is formed by engineering of the BEC phase.

Vortex pattern are unstable, they have a limited lifetime. It might however be possible to stabilize them have a continuous stirring. This would be a true dissipative structure: A stirring force relying on friction on one hand, diffusion by thermal decay on the other.

9.9.6 Friction and diffusion

Friction and diffusion arise from coupling to a reservoir. Friction comes from coupling to a 0-temperature reservoir, diffusion to a reservoir at finite temperature. For example the decay of a cavity (friction) can be described by coupling to the external vacuum. However if the vacuum contains blackbody radiation, $T > 0$, photons may be coupled in which leads to diffusion.

9.9.7 Non-equilibrium quantum phase transitions

It might be interesting to look out for nonequilibrium quantum phase transitions. However, those are difficults to imagine. Mott-transitions are clearly in some kind of equilibrium (not really a thermal one). They are reversible via a control parameter. They do not require the feeding with energy or entropy, i.e. heating. Clearly, entropy is and must remain zero at $T = 0$.

9.9.8 Fluctuation-dissipation theorem

In statistical physics, the *fluctuation-dissipation theorem* is derived from the assumption that the response of a system in thermodynamic equilibrium to a small external perturbation is the same as its response to a spontaneous fluctuation. There is therefore a direct relation between the fluctuation properties of the thermodynamic system and its linear response properties.

For example, Einstein in his 1905 paper on Brownian motion noted that the same random forces which cause the erratic motion of a particle in Brownian motion would also cause drag if the particle were pulled through the fluid. In other words, the fluctuation of the particle at rest has the same origin as the dissipative frictional force one must do work against, if one tries to perturb the system in a particular direction. From this observation he was able to use statistical mechanics to derive a previously unexpected connection, the Einstein-Smoluchowski relation: $D = \mu k_B T$, linking the diffusion constant D and the mobility of the particles μ (i.e. the ratio of the particle's terminal drift velocity to an applied force, $\mu = vd/F$).

The fluctuation-dissipation theorem can be used to give an explicit relationship between molecular dynamics at thermal equilibrium, and the macroscopic response that is observed in a dynamic measurement. It thus allows molecular scale models (microscopic models) to be used quantitatively to predict material properties in the context of linear response theory.

The essence of fluctuation-dissipation theorem is that it relates equilibrium fluctuations to out-of-equilibrium quantities, like noise power is related to resistance. The theorem is based on fields that are weak relative to the potential of molecular interaction so that rates of relaxation are not affected by the applied field. 'Out-of-equilibrium' in the above sentence should be understood as close to equilibrium or stationary states.

9.9.9 Long-range interactions

Having been pioneered in astrophysics (e.g. in the formation of coherent structures like galaxies and stars), long-range interactions also play a role in plasma physics, hydrodynamics (e.g. jets, vortices like the gulf stream or the Jupiter vortex), systems with dipolar interactions, cold and ultracold gases, clusters and even in some nuclear systems. Today the most promising systems to experimentally study long-range interactions are atomic gases with electromagnetic interactions. However, those are mostly quantum systems. And one is still far from discerning which properties are genuinely ascribable to long-range interactions (whether fundamental or effective).

Systems with *long-range interaction* can behave very differently from systems with *short-range interaction*. The most prominent features are ensemble inequivalence and negative specific heat.[1] The dynamical aspects of the approach of long-range interacting systems to equilibrium is not yet well understood. The statistical physics has to learn in this domain. In particular, if the interacting particles are microscopic objects with quantized degrees of freedom or quantum statistical constraints.

A short-range interacting system is always [229]

- additive, i.e. the total energy of two parts of a system is $E_1 + E_2$, because the interaction energy between the parts E_{12} is negligibly small (is decreases like the surface-to-volume ratio like $N^{2-\alpha/3}$ for an interaction potential $V(R) \propto R^{-\alpha}$);
- having *extensive thermodynamical potentials* (e.g. energy, free energy, entropy, Gibbs free energy,...), i.e. for given values of the *intensive thermodynamical parameters* (e.g. n, T, p,...) they are proportional to N;
- rapid to find to equilibrium (non-equilibrium states are unstable);
- homogeneous at equilibrium (in the absence of external fields).
- having equivalent micro- and macrocanonical ensembles (i.e. the same values for the thermodynamic potentials are calculated for both situations).

In contrast a long-range interacting system

- is not additive;
- has extensive thermodynamical potentials;
- has non-equilibrium situations lasting for macroscopic times (the metastable states represent local extrema of thermodynamic potentials, the evolution towards other non-equilibrium states is driven by mean-field fluctuations);
- is inhomogeneous at all scales;
- exhibits strange concepts like negative specific heat $C = (\partial E/\partial T) < 0$;
- has non-equivalent micro- and macrocanonical ensembles (probably, one has to pick the appropriate ensemble depending on the experimental condition, i.e. isolated system or system held at a fixed temperature);

[1] A specific statistical ensemble is obtained by keeping two out of four (for a 1 component gas) thermodynamic parameters fixed (p, V, T, N).

- exhibits ergodicity breaking;
- shows non-equilibrium phase transitions.

Interaction potentials are short-range if $\int_{R_0}^{\infty} V(\vec{R}) d^3\vec{R} < \infty$. Alternatively, interaction potentials are short-range if there exist constants $C > 0$ and $R_0 > 0$ for which, $|V(\mathbf{r})| = C/|\mathbf{r}|^{\alpha}$ for all $|\mathbf{r}| > R_0$, where $\alpha > 3d$ and d is the dimensionality of the system. The main long-range forces of interest are gravitation and electro-magnetic forces, e.g. Coulomb repulsion and radiation pressure.

$\alpha < 3$ $E_{12} \propto N^{2-\alpha/3}$
$\alpha = 3$ $E_{12} \propto N \ln N$
$3 < \alpha < 4$ $E_{12} \propto N^{2-\alpha/3}$
$\alpha = 4$ $E_{12} \propto N^{2/3} \ln N$
$4 < \alpha$ $E_{12} \propto N^{2/3}$

One distinguishes between continuous and lattice systems.
Long-range interaction is a prerequisite of CARL and self-organization.

9.9.9.1 Negative specific heat

In macrocanonical ensembles the specific heat does not get negative, only in microcanonical ensembles, i.e. in systems isolated from heat baths.

Self-gravitating systems can have *negative specific heat*. According to the virial theorem the energy of such a system is $0 > E = Ekin + E_{pot} = -E_{kin} = \frac{m}{2}\langle v^2 \rangle = \frac{3}{2} k_B T$. For a gravitationally bound two-body system this is easy to see (see Aufgabensammlung zu Integrierter Kurs Physik I, "Keplerbahnen"). Hence, increasing T reduces E. Negative specific heat is usually connected to astrophysical long-range interactions, like self-gravitating clouds, and applies more to equilibrium situations. There is probably no chance of seeing it with CARL. The molasses CARL is best described by a macrocanonical ensemble, since the atoms are not isolated, but connected to a heat bath. The system is completely described by a set of Langevin equations [**?**].

9.9.9.2 Small systems

A short-range interacting *small system* can exhibit similar features as long-range interaction systems, in particular *non-additivity* [**?**]. A small system is defined by the fact, that the range of its interaction is similar to the system's size. As an example one may consider an ultracold atomic gas near a Feshbach resonance. The power law of the interaction potential does not change, but the scattering length can be as large as the atomic cloud.

Chapter 10

Structure of matter

10.1 High energy physics

10.1.1 Nuclear models

There is a new force coming into play, which act between nucleons. Nuclear models are complicated, several models are used to explain the various features. The energy scale is MeV, hence at room temperature the nuclei are in their ground state. However inside stars or in the history of the universe, excited states play an important role.

α scattering reveals deviation from the Coulombian law for collision parameters below 10 fm, indicates the typical size of a nucleus. The nuclear force which helds together the nucleons is short ranged (2 fm), its energy about 10 times larger than the Coulomb repulsion at typical internucleon distances. The force is charge independent, but depends on the nuclear spin. The Yukawa potential is,

$$V(r) = -g^2 \frac{e^{-r/r_0}}{r} \ , \tag{10.1}$$

with $r_0 = \hbar m_\pi c$

The hyperfine structure in atomic spectra tells the total nuclear spin, which is on the order $\mu \simeq \mu_K \equiv \pi\hbar e/2m_p$. The angular moment μ can be parallel or anti-parallel to the spin I. All nucleons have spin 1/2. If $A = N + Z$ is even/odd, I is integer/half-integer.

Neutrons can be detected by sending them onto a parafine sheet, from which they expel protons into a Geiger counter.

Irregularities in the hyperfine structure (deviations from the Landé interval rule) point to non-spherical nuclear charge distributions giving rise a quadrupole moment.

While α scattering reveals the nuclear mass density, electron scattering tells the electric charge distribution (like in an electron microscope). The first minimum of the diffraction pattern $\theta \simeq \lambda/r$ follows from the electron de Broglie wavelength and the charge radius. Such study confirm the following empirical formula for the charge density

$$\rho(r) = \frac{\rho(0)}{1 + e^{(r-a)/b}} \ , \tag{10.2}$$

where $a \approx A^{1/3} \times 1.07\,\text{fm}$ and $b \approx 0.55\,\text{fm}$. This shows that $\rho(r)$ is flat in the center and has a radius $r_{1/2} \propto A^{1/3}$. The mass and the charge densities are related by $Z\rho_m(r) \simeq A\rho(r)$.

10.1.1.1 Mass defect

The atomic mass unit is $u \equiv 12^{-1} m(^{12}\mathrm{C})$. Deviation of measured atomic masses from integer $m(X)/u$ is due to isotope mixtures. Nuclear reactions $a + A \to B + b$ (e.g. $\alpha + {}^{14}\mathrm{N} \to {}^{17}\mathrm{O} + p$) conserve relativistic energy,

$$K_a + m_a c^2 + m_A c^2 = K_B + m_B c^2 + K_b + m_b c^2 \ . \tag{10.3}$$

The Q value of the reaction is $Q = K_B - K_b - K_a = (m_a + m_A - m_B - m_b)c^2$. Measure the kinetic energies K_b and K_a, express K_B via the scattering angle θ using momentum conservation.

The mass of a nucleus is less than the sum of its components. The difference is the nuclear binding energy or defect mass $\Delta m(X) = \Delta E/c^2 = Z m_p + N m_n - m(X)$. Hence, a neutron capture (if it is possible) liberates electromagnetic energy. The defect mass per nucleon rapidly increases from H to Ca and then slowly drops for higher nuclear masses. The behavior is explained by the Weizsäcker droplet model. According to this the absolute nuclear ground state is around Ca ($Z = 40$), and all other nuclei are metastable, i.e. would ultimately decay into Ca is a proper mechanism was at hand.

For example, the energy balance for nuclear fission converting ${}^{238}\mathrm{U} \to {}^{119}\mathrm{X}$ is $2 \times 119 \times 8.5\,\mathrm{MeV} - 238 \times 7.6\,\mathrm{MeV} = 210\,\mathrm{MeV}$, which goes into kinetic, i.e. thermal energy. Similar considerations hold for fusion and radioactive decay processes. Another example is the capture of a neutron by ${}^{235}\mathrm{U}$, which liberates $m({}^{235}\mathrm{U}) + m_p - m({}^{236}\mathrm{U}) = 6.6\,\mathrm{MeV}$. This energy excites nuclear shape oscillations, which may then induce a fission process. In contrast, for ${}^{238}\mathrm{U}$ the liberated energy is only 5 MeV, which is not enough to excite an oscillation, so that the fission process is inhibited.

10.1.1.2 Droplet nuclear model

The droplet model compares the nucleus with a drop of an incompressible liquid: The density is constant as well as the exit work for evaporation, i.e. the binding energy per nucleon. The analogy is expressed in the following semi-empirical defect mass formula. The mass difference of the nucleus and the sum of its components $B(Z,N) = N m_n + Z m_p - m_{nucl}$ is according to *Weizsäcker's droplet model* approximately,

$$B(Z,A) = 14.1A - 13A^{2/3} - 0.595\frac{Z^2}{A^{1/3}} - 19\frac{(Z-N)^2}{A} + 33.5\frac{1}{A^{3/4}} \times \begin{cases} -1 \text{ for uneven } Z,N \\ 1 \text{ for even } Z,N \\ 0 \text{ else} \end{cases} \tag{10.4}$$

The first (volume) term expressed the constance of B/A, i.e. the nucleus matter is distributed rather homogeneously. The second (surface) term corrects, i.e. lowers the binding energy for anisotropies near the surface of the nucleus. The third (Coulomb) term describes the fact that Coulomb repulsion tends to lower the density of the protons, which reduces their contribution to the binding energy. The forth (symmetry) term accounts for the observation that light nuclei with $Z \simeq N$ have larger binding energies.

For heavy nuclei $N \gtrsim Z$. This is because of Coulomb repulsion more neutrons are necessary to dilute protons than neutrons. The fifth (pairing) term expresses

the tendency of the nucleons to pair with other nucleons of the same species. The maximum of $B(Z, A)$ traces stable regimes in the isotope table.

10.1.1.3 Fermi gas model

Assuming that the nucleons move independently in a square well potential made out of the mean-field of the nucleons, we obtain Weisskopf's Fermi gas model. The Fermi energy of the ground state nuclei is estimated via $A = \int_0^{E_F} \rho(E)n(E)dE$. The potential depth is simply $B + E_F$. In this model it becomes clear, why $Z \simeq N$ is energetically favorable, or when Coulomb repulsion increases the level spacing $N \gtrsim Z$.

10.1.1.4 Shell model and collective model

The binding energy exhibits more feature not explained by the droplet model, such as the existence of magical numbers for A around which the binding energy is particularly high: 2,8,10,... This suggests the existence of a shell structure. The formal approach, somewhat analogous to the Hartree treatment of the electron shell of the atoms, is to set up multiparticle Schrödinger equation and to solve by self-consistently adjustment of the potential shape and the excitation levels. In this picture, the magical number are due to a shell structure, where the energies of the shells are interchanges, because they are shifted by strong nuclear spin-orbit interactions.

The model can also predict to some extend the nuclear spins, which predominantly result from jj coupling. In contrast to the electron shell, where Coulomb repulsion favors $\uparrow\uparrow\uparrow$ states according Hund's rule, in nuclei the Coulomb attraction favors $\uparrow\downarrow$ pairing.

The shell model treats individual nucleons, while the droplet model describes collective effects. There are models trying to include collective effects in the shell model by allowing for anisotropic mean-field potentials. Collective motion of nucleons will then lead to time-dependent shape distortions of $V(\mathbf{r})$. E.g. a nucleon with a large orbital momentum moving around the nuclear surface like a protuberance drags other nucleons thus forming a collective tide wave. Such models can quantitatively explain nuclear quadrupole moments and collective rotations and vibrations. See the analogy to the nonlinear Schrödinger equation in collective oscillations in gaseous Bose-condensates.

The optical model is another generalization of the shell model.

10.1.2 Radioactive decay

10.1.2.1 α-decay

Nuclei can mutate via fission, fusion or radioactive α, β or γ-decay. The α-decay consists in the emission of ${}^4He$ particles. The nuclei resulting from α-decay can decay themselves, and so on until a stable isotope is reached. Hence, there are 4 possible decay families, whose fathers are long-lived ($T_{1/2} \approx 10^{10}$ a) radioactive isotopes: $4n \rightarrow^{233} Th$, $4n + 1 \rightarrow^{237} Np$, $4n + 2 \rightarrow^{238} U$, and $4n + 3 \rightarrow^{235} U$. The released energy $\Delta E = m(Z, A) - m(Z - 2, A - 4) - m(\alpha)$ is mainly Coulombian, since the sum of the volume terms is nearly unchanged. It can be determined by measuring the kinetic energy of the α particles.

The potential seen by an α particle has an attractive square well shape inside the nucleus surrounded by a Coulombian repulsive barrier. In a nucleus which is excited into a shape resonance, an α particle may tunnel through this barrier with a rate R, $dN = -NRdt$. The half decay lifetime is $T_{1/2} = \ln 2/R$.

A decay family in a dynamic equilibrium is characterized by $N_k R_k = N_l R_l$, which is found by solving coupled differential equations in steady-state. This allows for some amount of natural abundance even of very short-lived isotopes ($T_{1/2} \approx 1\,\mu s$).

Fathers of a decay family have low decay energies, which makes them stable. For $Z < 80$ the nuclei are stable anyway. In contrast to other small particles, ^4He has a strong defect mass per nucleon. This makes it favorable to emit α particles. However, other heavier particles can be emitted, as in the fission process. The heavier the particles the more Coulomb energy can be released, which makes fission processes take over beyond $A > 100$.

The product of nuclear reactions generally end up in excited states.

Note the tendency to liberate low-quality (kinetic/thermal) energy having high entropy.

Radioactive α-decay families would always maintain the same $Z - N$, which is unfavorable for heavy nuclei. The β-decay converts protons into neutrons (and vice versa) by the emission or capture of electrons or positrons. Note that this decay does not lead to a change of the decay family. The β-decay is directed into the directions toward the stability region $N \gtrsim Z$. Thus an α-decay is often followed by an electron emission or a positron capture to reduce Z and increase N. The energy balance is $\Delta E = m(Z, A) - m(Z \pm 1, A) \pm m_e$.

10.1.2.2 β-decay

β-emission yields a continuous spectrum. Since the electron takes all the kinetic energy, the nucleus being to heavy, one could expect a single narrow peak in the spectrum. Furthermore, angular momentum is not conserved by the creation of an electron. This led Pauli to postulate the existence of (anti-)neutrinos in reactions like $^A X^Z \rightarrow^A X^{Z+1} + e^- + \bar{\nu}_e$. The neutrino spin is 1/2 and it has no charge. The neutrino mass is 0, in order to allow for the electron taking all the decay energy.

Gamov-Teller selection rules for β-decay: $\Delta i = 0$ and conserved parity. The β-decay results from a new force, the weak interaction. Its range is so short that neutrinos traverse stars without interactions. Nevertheless, neutrinos have been detected via the process $\bar{\nu} +^1 \mathrm{H} \rightarrow n + \bar{e}$, where the positrons can be detected in scintillation chambers, because they also sense the electro-magnetic interaction.

Wu observed that nuclei with aligned dipolar magnetic moments preferentially emit β-radiation into one direction, the one with clockwise heliticity, i.e. the process is not invariant under mirroring (three mirrors make a parity transformation). This implies that the weak interaction does not conserve parity. The spin of a neutrino is $\mathbf{L}_\nu \uparrow\downarrow \mathbf{k}$ and for an anti-neutrino $\mathbf{L}_{\bar{\nu}} \uparrow\uparrow \mathbf{k}$, hence there is a $\mathbf{L}_\nu \mathbf{k}$ interaction. The weak interaction is the only one to be sensitive to heliticity.

A *well-defined heliticity requires vanishing rest mass*, i.e. light velocity for the particles. Otherwise an inertial system could be found, where the momentum $\mathbf{k}$ is inverted and thus, for a given angular momentum, the helicitity.

10.1.2.3 γ-decay

Subsequently to nuclear reactions (β-decay, n-capture,...) excited nuclear states with typically $E > 10^{-2}$ can be populated. Those may decay via emission of γ-radiation thus yielding excitation spectra, which are probed via electrons produced by photo-effect, Compton scattering or pair-production. In contrast to the optical regime, where M1 radiation is suppressed by $(v/c)^2 \simeq 10^{-4}$ and E2 radiation by $(a_B/\lambda)^2 \simeq 10^{-6}$, multipolar transitions are more likely especially at high γ energies. Collisional deexcitation is inhibit by the Coulomb barrier surrounding the nuclei. The selection rules are $|I_f - I_i| \leq L \leq I_f + I_i$ and $\Delta P = (-1)^L$ for electric and $(-1)^{L+1}$ for magnetic radiation. $\Delta I = 0$ is forbidden, because photons carry away 1 unit of angular momentum.

10.1.2.4 Nuclear conversion

γ-decay can be accompanied by emission of groups of monoenergetic electrons. This occurs if the γ-photon is reabsorbed by electrons of the inner shells (K, L, M,...) of the atomic electrons. The rate for this process adds up to the normal γ-decay, $R_\gamma + (\alpha_K + \alpha_L + ..)R_\gamma$.

Mössbauer effect (see Sec. 38.3.3).

10.1.3 Nuclear reactions

10.1.3.1 Nuclear conversion

Until we considered spontaneous nuclear decay. Now let us discuss nuclear reactions. The balance of an equilibrated nuclear reaction tells the masses of the participating nuclei. Any reaction must conserve the following quantities: Relativistic energies, momentum, angular momentum, charge, parity (if the weak force is not involved) and the baryon number.

The p-capture is a process, which can be studied in particle accelerators. If a p has sufficient energy to cross the Coulomb barrier, its de Broglie wave is larger than the range of the nuclear force, but smaller than the size of the nucleus. If it collides with a nucleon, it may loose sufficient energy to be reflected from the potential walls. It then collides again with other nucleons, until the energy is uniformly distributed, so that for no single nucleon the energy is sufficient to escape. However, fluctuations may impart sufficient energy to individual nucleons. Preferentially neutrons, which do not sense the Coulomb barrier may then evaporate. The remaining excitation is dissipate via γ-emission. p-capture followed by n-emission ($d +^A \mathrm{X} \rightarrow^A \mathrm{Y} + \alpha$ or $p +^A \mathrm{X} \rightarrow^A \mathrm{Y} + n$) in nuclear power plants often generates β-active isotope, which are precious side-products used for radioactive tracing, etc..

The differential cross section $d\sigma/d\Omega$ is Coulombian at low scattering angles θ. At large θ, where the nuclear potential comes into play, interference effects result in an oscillatory behavior of $(d\sigma/d\Omega)(\theta)$.

The *shape resonances* are due to constructive interference of incident and reflected de Broglie waves. How about Feshbach resonances?

n scattering can probe resonances of composite nuclei. The resonances are described by the *Breit-Wigner formula* for the total cross-section, which holds for every

damped oscillation,

$$\sigma_r(E) = \frac{\lambda^2}{4\pi} \frac{\Gamma_n \Gamma_r}{(E - E_i)^2 + \Gamma^2/4} \ll \pi r_{nucl}^2 \ . \tag{10.5}$$

This is similar to the optical cross section, where $\lambda^2/2\pi \ll \pi a_B^2$.

10.1.3.2 Fission

Hahn and Strassman discovered that the reaction $n + {}^{238}\mathrm{U} \to \mathrm{X} + \mathrm{Y} + n + n + .. + \Delta E$ liberates 200 MeV plus 2 or 3 neutrons, which is 10^6 times more than for a chemical reaction. In this process as long as the products X and Y are closer than the radius of the target nucleus, the energy increases with their distance, because the surface increases. Triggered by collective vibrations leading to shape oscillations the products may eventually separate. From this point on the surface terms are constant, but the products are strongly accelerated by Coulomb repulsion. I.e. the fission slightly increases the surface energy, but strongly minimizes the Coulomb energy. Since for the target $N \gtrsim Z$, 2 or 3 neutrons must be reemitted ($\approx$ MeV) to approach the $N \simeq Z$ regime for the products.

The lifetime for spontaneous fission is 10^{16} a, but it can be induced by slow n. To moderate the neutrons graphite (^{12}C) or heavy water (D_2O) is used, or light water (H_2O) in combination with enriched ^{235}U. The moderation increases the de Broglie wavelength of the neutrons and thus the cross section for capture. In practice, it is tuned such that exactly 1 out of the 2 to 3 emitted neutrons is captured to induce the next fission. The reaction products are decelerated by reactor materials, which heat up and drive gas turbines.

Fast breeder reactors are based on the process $n + {}^{238}\mathrm{U} \to {}^{239}\mathrm{U} \to {}^{239}\mathrm{Pu} + 2e^-$. The product ^{239}Pu now fissions upon n capture similar to ^{235}U.

10.1.3.3 Fusion

While fission is driven by the desire to reduce Coulomb energy, fusion reduces surface energy. The problem is that the collision partners must override the Coulomb barrier at 1 MeV ($= 10^{10}$ K). In the sun the rate for this becomes noticeable above $T > 10^8$ K. Fusion reactors must compensate their limited resources by more efficient rates, i.e. higher temperatures $T > 10^9$ K.

Fusion is the basic process in the creation of all elements up to Fe. All starts with the *big bang*, a kind of neutron star, where the following processes were in equilibrium

$$\begin{aligned} n &\to p + e + \bar{\nu} \\ \bar{\nu} + p &\to p + \bar{e} \\ p + n &\to p + n + \gamma \\ e + \bar{e} &\to \gamma + \gamma \\ \gamma &\to e + \bar{e} \ . \end{aligned} \tag{10.6}$$

Doppler recoil expands this soup, until it gets transparent for the γ, which subsist today as the 3 K blackbody radiation. Now starts the He-cycle producing the 10%

helium in the actual universe,

$$\begin{aligned} p + n &\to \mathrm{D} + \gamma \\ \mathrm{D} + \mathrm{D} &\to^3 \mathrm{He} + n \\ \mathrm{D} + \mathrm{D} &\to \mathrm{D} + p \\ \mathrm{D} + p &\to^4 \mathrm{He} + n \ . \end{aligned} \tag{10.7}$$

The 90% hydrogen are formed through β-decay of n.

Mass fluctuations now trigger agglomerations, where the temperature rises to $T > 10^5\,\mathrm{K}$, forming a proton electron plasma. Beyond $T > 10^7\,\mathrm{K}$ fusion sets in in the *pp*-cycle,

$$\begin{aligned} p + p &\to \mathrm{D} + \bar{e} + \nu + 0.42\,\mathrm{MeV} \\ p + D &\to^3 \mathrm{He} + \gamma + 0.55\,\mathrm{MeV} \\ {}^3\mathrm{He} + {}^3\mathrm{He} &\to^4 \mathrm{He} + p + p + 12.9\,\mathrm{MeV} \ . \end{aligned} \tag{10.8}$$

If the star heats up to $T > 10^8$ K, the carbon-cycle

$$\begin{aligned} {}^4\mathrm{He} + {}^4\mathrm{He} &\to^8 \mathrm{Be} \\ {}^4\mathrm{He} + {}^8\mathrm{Be} &\to^{12} \mathrm{C} \end{aligned} \tag{10.9}$$

become likely, the second one by a collision resonance-enhanced three-body collision. Once enough carbon has been produced, it catalyses the formation of N and O.

Note that our sun has not yet reached the carbon-cycle. All heavier elements in our solar system are remainders from a previous generation of stars. As the star contracts, more Ne and Mg is formed. At $T > 10^9\,\mathrm{K}$ the Coulomb barrier to the formation of Fe can be overruled. But convection between the elements formed in the core and the outer region, in which the *pp*-cycle is still active is needed to form Na. Elements beyond $A > 60$ cannot be formed by fusion. However, together with n-capture and β-decay elements can be formed up to ^{209}Bi. Beyond this n-capture only induces rapid α-decay.

When the hydrogen has been used up, thermal motion cannot counterbalance gravitation. The sun collapses in a few seconds (e.g. in a supernova) expelling an enormous flux of n. This flux may be high enough to allow for the simultaneous capture of several n circumventing the α-decay and thus creating the heavier elements observed in our solar system.

10.1.4 Elementary particles

10.1.4.1 Fundamental forces

At the surface of a nucleus the relative strength of the 4 fundamental forces is $F_{nucl}/F_{elmg}/F_{weak}/F_{grav} = 1 : 10^{-2} : 10^{-12} : 10^{-40}$. The range of the forces is $r_{grav} = r_{elmg} = \infty$, $r_{weak} \ll r_{nucl} \approx 1$ fm. The range is inversely proportional to the mass of the exchange particles (gravitons, photons, pi-mesons and vector bosons).

Transitions emitting photons must occur between states having different angular momentum, because *there are no oscillating monopoles; this is the reason why photons*

must carry away 1 unit of angular momentum. For analogous reasons, gravitons must carry away 2 units of angular momentum, because the *absence of negative gravitational mass renders gravitational dipole oscillations impossible.*

The nuclear force is spin-dependent. This is seen by the fact that the deuteron has as only one bound state a ${}^3S_1$ spin state, while the ${}^1S_0$ is unbound.

conserved quantity	nuclear force	el.mg. force	weak force	gravity
energy	+	+	+	
momentum	+	+	+	
angular momentum	+	+	+	
charge	+	+	+	
# leptons (e and μ)	+	+	+	
# baryons	+	+	+	
isospin **I**	+	−	−	
isospin I_z	+	+	−	
strangeness	+	+	−	
parity (P)	+	+	−	
charge conjugation (C)	+	+	−	
time reversal (T)	+	+	x	
intensity	1	10^{-2}	10^{-12}	10^{-40}
exchange particle	π	γ	?	graviton
mass (MeV)	140	0	$> 10^4$	0
spin	0		1	2
range (fm)	1	∞	$< 10^{-17}$	∞
sign	both	+ or −	?	+

Time reversal symmetry and charge conjugation (i.e. particle antiparticle transformation) are broken by the weak interaction in the (rare) $\mathrm{K_0\bar{K}_0}$ decay, but the CPT symmetry is conserved.

Note that the Schrödinger equation breaks time-reversal symmetry, but its absolute value does not.

10.1.4.2 Mesons

The nuclear force is known to saturate. This suggests that (while it vanishes at distances $r_0 > 2\,\mathrm{fm}$) the nuclear potential is repulsive at short distances $r_0 < 0.5$ fm. Thus every nucleon only interacts with a limited number of neighbors. The nuclear force can be understood as been transmitted by virtual particles, called mesons, carrying momentum. According to Yukawa every nucleon constantly emits and reabsorbes mesons for a short time satisfying $\Delta E \Delta t \sim \hbar$. Within this time the meson could maximally reach a distance $r_0 = c\Delta t = \hbar c/\Delta E = \hbar/m_\pi c$, which is the range of the interaction and the Compton wavelength of the π meson ($m_\pi = 140\,\mathrm{MeV}$). In the presence of another nucleon within this reach, the meson can be reabsorbed by that one. The transferred momentum is largest, when the mesons carry large kinetic energies, which is close to the nuclei.

This is similar to the Coulomb force being mediated by the exchange of virtual photons by electric charges in a second-quantized theory. The range of the Coulomb interaction is infinite, because the photons have no rest mass. I.e. photons with small energies ω can be encountered at very large distances. However, the transferred momentum is largest, when the photons have high energies capable of imparting large recoils, which is close to the charge.

Mesons can be liberated from virtual to real during a collision; they are observed in cosmic rays.

Mesons interconvert protons and neutrons,

$$\begin{aligned} p &\leftrightarrow n + \pi_+ \\ p &\leftrightarrow p + \pi_0 \\ p &\leftrightarrow p + \pi_- \\ n &\leftrightarrow n + \pi_0 \ . \end{aligned} \tag{10.10}$$

They can carry charge, have an intrinsically negative parity and are instable $\pi^0 \rightarrow \gamma + \gamma$ and $\pi^+ \rightarrow \mu^+ + \nu_\mu$.

Mesons are like all exchange particles bosons. They cannot be fermions because the number of fermions is conserved.

Protons *and neutrons* have a charge distribution that can be probed by electron scattering. This is why also the neutron has an electric dipole moment.

10.1.4.3 Muons

Muons are quasi heavy electrons and decay via $\mu^- \rightarrow e^- + \bar{\nu_e} + \nu_\mu$.

Every fermion has its anti-particle. The number of fermions-antifermions is conserved, in particular the lepton numbers and baryon numbers are constant: $\sum L_e = const$, $\sum L_\mu = const$, and $\sum B = const$, where $L_{e^-} = L_{\nu_e} = 1 = -L_{e^+} = -L_{\bar{\nu}_e}$.

10.1.4.4 The particle zoo

Generations of leptons, neutrinos, quarks

$$\begin{bmatrix} e & u \\ \nu_e & d \end{bmatrix} \quad , \quad \begin{bmatrix} \mu & s \\ \nu_\mu & c \end{bmatrix} \quad , \quad \begin{bmatrix} \tau & t \\ \nu_\tau & b \end{bmatrix} \tag{10.11}$$

and their antiparticles.

The quarks do not exist alone, but as *hadrons*, i.e. either antiquark pairs called *mesons* or quark triplets called *baryons*. The most common ones are the π-mesons ($\pi^0 = u\bar{u}?$, $\pi^\pm = u\bar{d}$), the proton ($p = uud$) and the neutron ($p = udd$). The up quark has the charge 2/3, the down quark -1/3.

10.2 Solid state physics

10.2.1 Models for electrons in crystals

10.2.1.1 Types of solids

In contrast to a gas, which in most cases consists of isolated particles, the interparticle interaction plays a dominant role in crystals. Solids, or more specifically crystals, are

classified according to the predominant type of binding. 1. Molecular binding is responsible for the solidification of binary gases like O_2. Here, fluctuating dipole moments inducing dipole moments in neighboring molecules lead to van der Waals attractive forces on the order of $E_{bind} \simeq 10^{-2}\,\mathrm{eV}$ going like r^{-7}. 2. Ionic binding gives rise to periodic structures alternating positive and negative charges, as in NaCl. 3. Covalent binding is directional. This directionality determines the crystalline structure, such as in graphite and diamonds. In those three binding types there are no free electrons and hence no conductance. However, covalently bound crystals can sometimes be semiconductors or transparent. 4. Metallic binding is a limit of covalent binding, in which the valence electrons, which shared by all atoms, overrule the repulsion between the ions. The ionic lattice is immersed in a gas of free electrons. The ions have filled shells and are spherically symmetric. The electrons can easily absorb light, which makes the crystal opaque. The type of binding is studied via X-ray diffraction, via the dielectric properties, etc..

10.2.1.2 Band model

The number of orbitals in the isolated atoms forming the crystal gives the number of states available to the free electron gas. The exchange interaction of the fermionic electrons lifts the degenerescence (generalization of the H_2 molecule) and gives rise to a band structure. The electronic localization determines the width of the band: very delocalized electrons move in large bands. The interatomic distance also influences the band width. The closer the atoms the stronger the interaction, the larger the bands.

Bands connecting to different orbital may finally overlap. Note that the m_l degeneracy is lifted because spherical symmetry is broken by the crystal $[E(3s) \neq E(3p)]$.

10.2.1.3 Electrical conductance

Electrons can only move in presence of a sufficient number of unpopulated states, even under the influence of an external force. If no states are available the crystals becomes isolating. Overlapping filled and empty bands reserve many states and allow for good conductance.

If the Fermi energy E_F lies between a completely filled conducting band and an empty valence band. The crystal is isolating. However, at $T > 0$, if the forbidden band is narrow as in the case of semiconductors (for Si $\Delta E \simeq 1\,\mathrm{eV}$), the gap may be bridged by thermal excitations.

The electrons collide with crystal impurities, defects and phonons. While the velocity of the electrons is about $\bar{v} \simeq 10^7$ cm/s, the short mean free path λ limits the drift velocity to $v_d \simeq 10^{-2}\,\mathrm{cm/s}$. The Lorentz force eE/m accelerates the electrons between successive collisions occurring at a rate $\bar{v}/\lambda$, such that

$$\frac{j}{ne} = v_d = \frac{eE}{m} \times \frac{\lambda}{\bar{v}} \ , \tag{10.12}$$

where j is the current density and ne the charge density. The fact that $\bar{v}$ and λ do not depends on the electric field is known as Ohm's law. The mobility $\mu \equiv v_d/E$ allows to write the electrical conductance as

$$\rho^{-1} = n_- e_- \mu_- + n_+ e_+ \mu_+ \ . \tag{10.13}$$

The value and sign of the Hall coefficient $1/ne$ can be measured by the Hall effect. It is positive if the conductance occurs primarily through holes and negative if it occurs through electrons.

10.2.1.4 Electron gas model

In this model the electrons move in a square well potential, a mean-field approach accounts globally for the periodic lattice of ions and the influence of all other electrons. The density of states and the electron density are the same as for blackbody radiation

$$\rho(\epsilon)d\epsilon = \frac{V(2m^3)^{1/2}}{\pi^2\hbar^3}\sqrt{\epsilon}d\epsilon \ , \tag{10.14}$$
$$n(\epsilon)\rho(\epsilon)d\epsilon = \frac{1}{e^{(\epsilon-\epsilon_F)/k_BT}+1}\rho(\epsilon)d\epsilon \ .$$

The maximum energy at $T = 0$ can be estimated from the quantized energy levels of a square well potential filled with N^2 electrons,

$$E_{max} = \frac{\hbar^2\pi^2}{2mL^2}N^2 = \frac{\hbar^2\pi^2}{2ma^2} \ , \tag{10.15}$$

where a is the lattice constant. This confirms that the width of the bands depends on the interatomic spacing, but not on the number of ions. The electron gas model is good for large overlap of the bands. In the presence of isolated bands $\rho(\epsilon)$ gets more complicated. In particular, if a band edge is reached while filling the potential well with states, $n(\epsilon)\rho(\epsilon)$ reaches a maximum before in drops down to zero.

10.2.1.5 Electrons in a periodic potential

The Bloch model assumes $\psi(x) = u_k(x)e^{\imath kx}$ with $u_k(x) = u_k(x+a)$. The Kronig-Penney model approximates the lattice potential by a periodic array of square well potentials. Bands open at the edges of Brillouin zones thus forming forbidden gaps. The dispersion relation for free particles $E = \hbar\omega = \hbar^2k^2/2m$ with $v = d\omega/dk$ plus a Lorentz force $d\epsilon = e|\mathcal{E}|dx$ yields

$$m^* = \frac{dv}{dt} = e|\mathcal{E}| \tag{10.16}$$
$$\frac{1}{m^*} = \frac{d^2\omega}{dk^2} \ ,$$

For free particles $m_e = m^*$. Without friction the acceleration is constant and, in a lattice m^* goes through apole at the edges of the Brillouin zones due to Bragg reflection. Note that *the momentum beyond π/a, which cannot be given to the electron is transferred to the lattice.* Note also that the density of states goes with the effective mass and is $\propto \rho$. m^* is a material constant (for Fe $m^* \simeq 10m_e$, thus Fe is a poor conductor). ???

10.2.1.6 Semiconductors

There is an intrinsic temperature-dependent conductivity (for Si $\rho(600\,\mathrm{K})/\rho(300\,\mathrm{K}) \approx 10^9$). Extrinsic conductivity can be induced by photoexcitation or doping. E.g. Ar/Ga

in a Ge crystal has one weakly bound electron more/less than required to fit into the lattice. This generates discrete energy levels slightly below the conducting/above the valence band, $min(E_c) - E_n, E_p - max(E_v) \simeq 0.01\,\text{eV}$.

The Fermi energy E_F is the energy, where half of the electrons are below that. In an isolator is between $max(E_v)$ and $min(E_c)$. In the presence of doping E_F is shifted by the additional amount of electrons/holes toward E_n, E_p. If n and p-doped materials are combined, electrons drift from the n to the p region, such as to minimize energy and obtain a uniform E_F across the hole crystal.

Thermally excited electrons may drift and recombine with holes. The junction is maintained by a steady flux in a dynamic equilibrium. An external voltage can higher/lower the barrier, because the potential drops mostly near the junction, where the resistance is highest. In this case the thermal current is not equilibrated, the diode either blocks or opens. The electrons move to try to rectify E_F.

A transistor is a series of junctions in *npn* of *pnp* configuration. The base-emitter current can be used to switch a collector-emitter current by injecting electrons. A tunnel diode acts like a normal diode except that when the bands come closer together within the junction (at low voltages in conduction polarization), electrons may pass by tunneling from the conducting into the valence band. This flow gradually stops when E_F is leveled (for zero voltage). Tunneling currents react much faster than thermal drift currents.

10.2.2 Kondo effect

Magnetic ions dilutely distributed in a non-magnetic metallic crystal can increase resistance at low temperatures. This is due to an exchange interaction between the dipole moments of the 'impurity' ions and the conducting electrons giving rise to an additional scattering mechanism. The magnetization of the e^- in the vicinity of an ion is known as *Friedel interaction* or *RKKY interaction* (Rutherford-Kittel-Kasuya-Yosida) interaction. The effect is known as *Kondo effect*. A similar effect is observed for quantum dots: a spin-entanglement of the electron trapped in the dot with the conducting electrons give rise to an exchange interaction with increases resistance.

10.3 Plasmas

10.3.1 Debye length

Consider a mixture of charges + and −, that is, a *plasma*. Energy seeks to be minimized by local compensation of charge imbalance. However, thermal motion spoils perfect homogeneity. That is, if on the one hand, looking at large scales, the environment seems neutral and homogeneous, at small scales there may be charge imbalances producing potential sites with exponentially decreasing ranges,

$$\frac{1}{\lambda_D} = \frac{1}{\lambda_{D-}} + \frac{1}{\lambda_{D+}} = \frac{ne^2}{\varepsilon_0}\left(\frac{1}{k_B T_+} + \frac{1}{k_B T_-}\right) . \tag{10.17}$$

The *Debye length* naturally enters the thermodynamic description of large systems of mobile charges. We consider a system of 2 different species of charges $q_\pm$ and $n_\pm(\mathbf{r})$ at locations $\mathbf{r}$. According to the so-called *primitive model*, these charges

are distributed in a continuous medium characterized only by its relative static permittivity, ε_r. This distribution of charges through the medium generates an electric potential $\Phi(\mathbf{r})$ that satisfies the *Poisson equation*:

$$\varepsilon\nabla^2\Phi(\mathbf{r}) = -q_+n_+(\mathbf{r}) - q_-n_-(\mathbf{r}) - \rho_E(\mathbf{r}) \ , \tag{10.18}$$

where $\varepsilon \equiv \varepsilon_r\varepsilon_0$, ε_0 is the dielectric constant, and ρ_E is the charge density outside the medium (logically, not spatially).

The mobile charges do not only generate $\Phi(\mathbf{r})$, but also are moved according to the associated Coulomb force, $-q_\pm\nabla\Phi(\mathbf{r})$. Assuming the system to be in thermodynamic equilibrium with a heat reservoir at an absolute temperature T, the concentrations of discrete charges, $n_\pm(\mathbf{r})$, can be considered as thermodynamic averages (ensemble average) and the associated electrical potential as a thermodynamic mean field. With these assumptions, the concentration of species j is described by the Boltzmann distribution,

$$n_\pm(\mathbf{r}) = n_\pm^0 e^{-q_\pm\Phi(\mathbf{r})/k_BT} \ , \tag{10.19}$$

where n_j^0 is the mean field concentration of the charge species j.

Identifying the instantaneous concentrations and the potentials in the Poisson equation with their mean-field counterparts in the Boltzmann distribution, we obtain the Poisson-Boltzmann equation:

$$\varepsilon\nabla^2\Phi(\mathbf{r}) = -q_+n_+^0 e^{-q_+\Phi(\mathbf{r})/k_BT} - q_-n_-^0 e^{-q_-\Phi(\mathbf{r})/k_BT} - \rho_E(\mathbf{r}) \ . \tag{10.20}$$

Solutions of this nonlinear equation are known for simple systems. Solutions for more general systems can be obtained in the high-temperature (or low-coupling) limit, $q_j\Phi(\mathbf{r}) \ll k_BT$, by Taylor expansion of the exponential,

$$e^{-q_\pm\Phi(\mathbf{r})/k_BT} \approx 1 - \frac{q_\pm\Phi(\mathbf{r})}{k_BT} \ . \tag{10.21}$$

This approximation gives the linearized Poisson-Boltzmann equation,

$$\varepsilon\nabla^2\Phi(\mathbf{r}) = \left(\frac{n_+^0q_+^2}{k_BT} + \frac{n_-^0q_-^2}{k_BT}\right)\Phi(\mathbf{r}) - n_+^0q_+ - n_-^0q_- - \rho_e(\mathbf{r}) \tag{10.22}$$

also known as *Debye-Hückel equation*. The second term on the right side disappears for electrically neutral systems. The term in parentheses divided by ε, has the unit $1/\mathrm{m}^2$. By a dimensional analysis, it leads to a definition of a characteristic length scale,

$$\lambda_D = \left(\frac{\varepsilon k_BT}{n_+^0q_+^2 + n_-^0q_-^2}\right)^{1/2} \tag{10.23}$$

usually called *Debye-Hückel length*. Being the only characteristic length scale of the Debye-Hückel equation, λ_D defines the scale of variations in the potential and the concentrations of the charged species. All charged species contribute to the Debye-Hückel length in the same manner regardless of the charge signal. For an electrically neutral system, the Poisson equation is,

$$\nabla^2\Phi(\mathbf{r}) = \lambda_D^{-2}\Phi(\mathbf{r}) - \frac{\rho_e(\mathbf{r})}{\varepsilon} \ . \tag{10.24}$$

To illustrate the Debye shielding, the potential produced by an external point-like charge $\rho_e = Q\delta(\mathbf{r})$ is,

$$\Phi(\mathbf{r}) = \frac{Q}{4\pi\varepsilon r} e^{-r/\lambda_D} \ . \tag{10.25}$$

The bare Coulomb potential is exponentially shielded by the medium over a distance corresponding to the Debye length.

The length of Debye-Hückel can be expressed in terms of the length of Bjerrum λ_B as,

$$\lambda_D = \left(4\pi\lambda_B \sum_{j=1}^{N} n_j^0 \, z_j^2 \right)^{-1/2} \ , \tag{10.26}$$

where $z_j = q_j/e$.

10.3.1.1 Typical values

In plasmas in space, where the electron density is small, the Debye's length can reach macroscopic values.

system	density n_e (m^{-3})	electronic temperature T(K)	magnetic field B(T)	Debye length λ_D(m)
solar core	10^{32}	10^7	–	10^{-11}
Tokamak	10^{20}	10^8	10	10^{-4}
gas discharge	10^{16}	10^4	–	10^{-4}
ionosphere	10^{12}	10^3	10^{-5}	10^{-3}
magnetosphere	10^7	10^7	10^{-8}	10^2
solar wind	10^6	10^5	10^{-9}	10
interstellar medium	10^5	10^4	10^{-10}	10
intergalactic medium	1	10^6	–	10^5

10.3.1.2 Length of Debye in a plasma

In a plasma, the background medium may be treated as the vacuum ($\varepsilon_r = 1$), and the length of Debye is,

$$\lambda_D = \sqrt{\frac{\varepsilon_0 k_B/q_e^2}{n_e/T_e + \sum_j z_j^2 n_j/T_j}} \ , \tag{10.27}$$

where $T_\pm$ are the temperatures of the electrons and ions, n_- is the density of the electrons and n_+ that of the atomic species j, with positive ionic charge $z_+ q_e$. The ion term is often neglected, giving,

$$\lambda_D = \sqrt{\frac{\varepsilon_0 k_B T_e}{n_e q_e^2}} \ , \tag{10.28}$$

although this is valid only, when the mobility of ions is negligible on the time scale of the process.

Appendices to 'Classical Mechanics'

11.1 Constants and units in classical physics

11.1.1 Constants

11.1.1.1 Mathematical constants

π constant	$\pi = 3.1415..$
Euler constant	$e = 2.71828..$

11.1.1.2 Constants of the SI unit system

These numbers of the special adjustment CODATA 2019 were proposed as *exact* values.

frequency of the hyperfine transition of Cs	$\nu = 9\ 192\ 631\ 770\,\mathrm{Hz}$
velocity of light	$c = 299\ 792\ 458\,\mathrm{m/s}$
Planck's constant	$h = 6.626\ 070\ 15 \cdot 10^{-34}\,\mathrm{Js}$
electronic charge	$e = 1.602\ 176\ 634 \times 10^{-19}\,\mathrm{C}$
Boltzmann's constant	$k_B = 1.380\ 649 \times 10^{-23}\,\mathrm{J/K}$
Avogadro's constant	$N_A = 6.022\ 14076 \times 10^{23}\,\mathrm{mol^{-1}}$
Luminous efficiency	$K_{cd} = 683\,\mathrm{lm}$

11.1.1.3 Derived constants

fine-structure constant	$\alpha = e^2/4\pi\varepsilon_0\hbar c \approx 1/137$
vacuum permittivity	$\varepsilon_0 = 1/\mu_0 c^2 = 8.8542 \times 10^{-12}\,\mathrm{As/Vm}$
vacuum permeability	$\mu_0 = 10^{-7}\,\mathrm{Vs/Am}$
Faraday's constant	$F = 96485.309\,\mathrm{C/mol}$
atomic mass unit	$u_A = 1/N_A \times 1\mathrm{g/mol} = 1.6605402 \times 10^{-27}\,\mathrm{kg}$
gas constant	$R = N_A k_B = 8.314510\,\mathrm{L/mol\ K}$
Bohr radius	$a_B = \alpha/4\pi R_\infty = 0.529 \times 10^{-10}\,\mathrm{m}$
Bohr magneton	$\mu_B = e\hbar/2m_e = 9.27 \times 10^{-24}\,\mathrm{J/T}$
classical electron radius	$r_e = \alpha^2 a_B$
Rydberg constant	$R_\infty = m_e c\alpha^2/2h = 13.7\,\mathrm{eV}$
Compton wavelength	$\lambda_C = h/m_e c$
Thomson cross section	$\sigma_e = (8\pi/3)r_e^2$
gravitational constant	$\gamma = 6.67259 \times 10^{-11}\,\mathrm{m^3 kg^{-1} s^{-2}}$

11.1.1.4 Particle constants

electron mass	$m_e = 9.1096 \times 10^{-12}\,\mathrm{kg}$
g-factor of the electron	$g = 2.002\ 319\ 304\ 386$
muon mass	$m_\mu = 105.658389\,\mathrm{MeV}$
proton mass	$m_p = 938.27231\,\mathrm{MeV}$
g-factor of the proton	$g = 5.5858$
neutron mass	$m_p = 939.56563\,\mathrm{MeV}$
g-factor of the neutron	$g = -3.8261$
deuteron mass	$m_d = 1875.61339\,\mathrm{MeV}$

11.1.1.5 Astronomical constants

earth mass	$m_{♁} = 5.9736 \times 10^{24}\,\mathrm{kg}$
earth radius	$R_{♁} = 6370\,\mathrm{km}$
earth gravity	$g_{♁} = 9.80665\,\mathrm{m/s}$
lunar mass	$m_{☾} = 7.348 \times 10^{22}\,\mathrm{kg}$
lunar radius	$R_{☾} = 1740\,\mathrm{km}$
lunar gravity	$g_{☾} = 1.62\,\mathrm{m/s}$
distance earth-moon	$d_{ES} = 384000\,\mathrm{km}$
sun massa	$m_{☼} = 1.99 \times 10^{30}\,\mathrm{kg}$
sun radius	$R_{☼} = 695300\,\mathrm{km}$
sun gravity	$g_{☼} = 273\,\mathrm{m/s}$
distance earth-sun	$d_{ES} = 1.496 \times 10^{8}\,\mathrm{km}$
sinodic day	$d_{syn} = 24\,\mathrm{h}$
sideric day	$d_{syn} = 23.9345\,\mathrm{h} = 23\,\mathrm{h}\,56\,\mathrm{min}\,4\,\mathrm{s}$
sinodic month	$mon_{syn} = 29.530590\,\mathrm{d}$
sideric month	$mon_{sid} = 27.321666\,\mathrm{d}$
sideric year	$a_{syn} = 365.256365\,\mathrm{h} = 365\,\mathrm{d}\,6\,\mathrm{h}\,9\,\mathrm{min}\,10\,\mathrm{s}$
lunar day	$d_{lunar} = 24.8412\,\mathrm{h}$
$\frac{1}{mon_{sid}}$	$= \frac{1}{a_{sid}} + \frac{1}{mon_{syn}}$
$\frac{1}{d_{sid}}$	$= \frac{1}{a_{sid}} + \frac{1}{d_{syn}}$
$\frac{1}{d_{sid}}$	$= \frac{1}{mon_{sid}} + \frac{1}{d_{lunar}}$

11.1.2 Units

charge	Q	basic unit
current	I	A=C/s
voltage	U	V=N/As
polarizability	α_{pol}	$\mathrm{Asm^2/V}$
susceptibility	χ	1
dipolar moment	1 Debye	$= 10^{-27}/2.998\ \mathrm{Cm} = 10^{-19}/c\ \mathrm{Cm^2/s} = 39.36\ ea_B$

11.2 Quantities and formulas in classical mechanics

time	t	basic unit
position	$\mathbf{r}$	basic unit
velocity	$\mathbf{v}$	$\mathbf{v} = \dot{\mathbf{r}}$
acceleration	$\mathbf{a}$	$\mathbf{a} = \dot{\mathbf{v}}$
mass	m	basic unit
linear momentum	$\mathbf{p}$	$\mathbf{p} = m\mathbf{v}$
force	$\mathbf{F}$	$\mathbf{F} = \dot{\mathbf{p}} = m\mathbf{a}$
kinetic energy	E_{kin}	$E_{kin} = \frac{m}{2}v^2$
angle	$\vec{\phi}$	basic unit
angular velocity	$\vec{\omega}$	$\vec{\omega} = \dot{\mathbf{r}}$
angular acceleration	$\vec{\alpha}$	$\vec{\alpha} = \dot{\vec{\omega}}$
inertial moment (continuous density)	I	$I = \int r_\perp^2 dm = \int_V \rho(\mathbf{r})[\mathbf{r}^2 - (\mathbf{r} \cdot \hat{\mathbf{e}}_\omega)]dV$
inertial moment (discrete density)	I	$I = \sum_i m_i r_i^2$
angular momentum	$\mathbf{L}$	$\mathbf{L} = I\vec{\omega} = \mathbf{r} \times \mathbf{p}$
torque	$\vec{\tau}$	$\vec{\tau} = \dot{\mathbf{L}} = I\vec{\alpha} = \mathbf{r} \times \mathbf{F}$
rotational energy	E_{rot}	$E_{rot} = \frac{m}{2}\omega^2 r^2$
potential energy	E_{pot}	$E_{pot}^{grav} = mgh$, $E_{pot}^{sprng} = \frac{k}{2}x^2$
work	W	$W = \int_{s_1}^{s_2} \mathbf{F} \cdot d\mathbf{s}$
power	P	$P = \dot{W}$

11.2.1 Particular forces

gravitation	$F_{grav} = mg$
Hooke's for elastic spring	$F_{mola} = -k\Delta x$
friction	$F_{at} = -\mu N$
Stokes' friction	$F_{fr} = -\gamma v$
Newton's friction	$F_{fr} = -\gamma v^2$

11.2.2 Inertial momentum

Steiner's theorem	$I_{\omega_2} = I_{\omega_1} + md^2$, where d is the distance between parallel axes
theorem of perpendicular axes	$I_z = I_x + I_y$ para $\rho(\mathbf{r}) = \delta(z)\sigma(x,y)$

11.2.3 Inertial forces due to transitions to translated and rotated systems

transformation to an accelerated frame	$\mathbf{F}_{Gal} = -m\mathbf{a}$
centrifugal force	$\mathbf{F}_{cf} = -m\vec{\omega} \times (\vec{\omega} \times \mathbf{r})$
Coriolis force	$\mathbf{F}_{Cor} = -2m\vec{\omega} \times \mathbf{v}$

11.2.4 Conservation laws

energy conservation	$\sum_k E_{kin}^{(ini)} + \sum_k E_{pot}^{(ini)} = \sum_k E_{kin}^{(fin)} + \sum_k E_{pot}^{(fin)}$
linear momentum conservation	$\sum_k \mathbf{p}_k^{(ini)} = \sum_k \mathbf{p}_k^{(fin)}$
angular momentum conservation	$\sum_k \mathbf{L}_k^{(ini)} = \sum_k \mathbf{L}_k^{(fin)}$
definition of the center-of-mass	$\mathbf{r}_{cm} \equiv \frac{\sum_k m_k \mathbf{r}_k}{\sum_k m_k}$

11.2.5 Rigid bodies, minimum required number of equations of motion

1. estimate number of moving masses	m_1, m_2, ...
2. identify possible movement (degree of freedom) for every mass	$v_{1x}, v_{2x}, ...$ $v_{1y}, v_{2y}, ...$ $v_{1z}, v_{2z}, ...$ $\omega_1, \omega_2, ...$
3. write down for every degree of freedom an equation of motion	$m\dot{v}_{kl} = \sum_j F_j$ $I\dot{\omega}_k = \sum_j \tau_j$

11.2.6 Gravitational laws

Newton's law	$\mathbf{F}(\mathbf{r}) = -\frac{GMm}{\lvert\mathbf{R}-\mathbf{r}\rvert^2}\hat{\mathbf{e}}_{Rr} = -\nabla V(\mathbf{r})$
gravitational potential	$V(\mathbf{r}) = -\int \frac{Gm}{\lvert\mathbf{r}-\mathbf{r}'\rvert^2}\rho(\mathbf{r}')dV'$

11.2.7 Volume elements

cartesian coordinates	$dV = dxdydz$
cylindrical coordinates	$dV = \rho d\rho d\phi dz$
spherical coordinates	$dV = r^2 \sin\theta dr d\theta d\phi$

11.2.8 Oscillations $ma + bv + kx = F_0 \cos\omega t$

dissipative motion	$k = 0,\ F_0 = 0$	$x(t) = Ae^{-\gamma t},\ \gamma = \frac{b}{2m}$
harmonic oscillation	$b = 0,\ F_0 = 0$	$x(t) = A\cos(\omega_0 t + \delta),\ \omega_0 = \sqrt{\frac{k}{m}}$
damped oscillation	$F_0 = 0$	$x(t) = Ae^{-\gamma t}\cos(\omega t + \delta),\ \omega = \sqrt{\omega_0^2 - \gamma^2}$
forced oscillation		$x(t) = A\cos(\omega t + \delta)\ ,\ A = \frac{F_0}{\sqrt{m^2(\omega_0^2-\omega^2)^2+b^2\omega^2}}\ ,$ $\tan\delta = \frac{b\omega}{m(\omega_0^2-\omega^2)}$

11.3 Probability distributions

The *binomial distribution* is defined by,

$$B_k^{(n)} = \binom{n}{k} p^k (1-p)^{n-k}\ . \tag{11.1}$$

The *Poisson distribution* is defined by,

$$P_k = \frac{\lambda^k}{k!} e^{-\lambda}\ , \tag{11.2}$$

for large n and small p, we get $B_k^{(n)} \simeq P_k$ with $\lambda = np$.

11.3.1 Some useful formulae

If the limits of two functions tend to 0, $\lim_{t\to t_0} f(t) = 0 = \lim_{t\to t_0} g(t)$ a rule called *l'Hôpital's rule* goes like,

$$\lim_{t\to t_0} \frac{f(t)}{g(t)} = \lim_{t\to t_0} \frac{f'(t)}{g'(t)}\ . \tag{11.3}$$

Part II

Electrodynamics

Chapter 12

Foundations and mathematical tools

The electrodynamic force is one of the four fundamental forces, together with gravitation, the strong nuclear force, and the weak nuclear force. It is a long-range force ($F \propto r^{-2}$) in the same way as gravitation, but unlike nuclear forces, which are short-ranged. Unlike gravitation, it can be attractive or repulsive. The experimentally

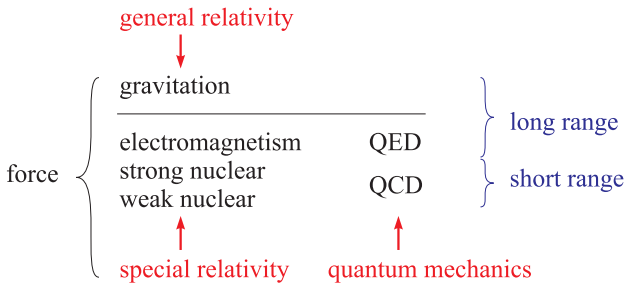

Figure 12.1: The four known fundamental forces.

observed fact, that two spatially separated bodies can exert mutual forces (beyond gravitation), is not explained within classical mechanics. It is necessary to introduce a new degree of freedom called *electric charge* which, to take account of the existence of attractive and repulsive forces, must exist in two different types called positive or negative charges. *Identical charges repel each other, different charges attract each other.* Other observations suggest that the charge is a *conserved and quantized* quantity.

Electrodynamics is an *field theory*, that is, it can describe all electric or magnetic phenomena observed in the following way: Every charge gives rise to a force field, called field electric $\vec{\mathcal{E}}$, which accelerates other charges. But other experimental observations suggest the existence of another force field, called the magnetic field $\vec{\mathcal{B}}$, whose existence is necessary to understand forces only acting on moving charges. That is, the electric and magnetic fields are introduced to explain the forces named after Coulomb and Lorentz,

$$\mathbf{F} = q\vec{\mathcal{E}} + \mathbf{v} \times \vec{\mathcal{B}} \, . \tag{12.1}$$

Thus, fields are quantities distributed in space, which in addition can vary in time,

$$\mathbf{F} = \mathbf{F}(\mathbf{r}, t) \, . \tag{12.2}$$

The concept of a field represents a powerful mathematical tool for describing forces, which are the only observable magnitudes of electromagnetism. That is, we have no sense to *see* the electricity. We can only infer their existence from the observation of forces. On the other hand, the formulation of electrodynamics via vectorial force fields, can be replaced by a description via potentials, which are either scalar or vectorial fields. In many circumstances, potentials facilitate the resolution of electrodynamic problems, but it is important to keep in mind, that potentials are not directly observable.

Maxwell's electrodynamics has a very deep relationship to Einstein's theory of special relativity, such that each theory is conditioned to the validity of the other. The relativistic formulation allows to distill the symmetry inherent to electrodynamics in a highly aesthetic way.

In view of the fundamental role played by scalar and vector fields in electrodynamics, we will start this course the basic mathematical notions of field theory, that is, differential and integral calculus with fields in Cartesian or curvilinear coordinates. We will also have to review basic notions of complex numbers and the Dirac distribution.

12.1 Differential calculus

12.1.1 Scalar and vector fields

The most basic application of vectors is the designation of positions in space, $\mathbf{r} = x\hat{\mathbf{e}}_x + y\hat{\mathbf{e}}_y + z\hat{\mathbf{e}}_z$. But other physical quantities may also depend on the position where they are measured. In case the quantity varying with position is a scalar, $\Phi = \Phi(\mathbf{r})$, we speak of *scalar field*. An example for a scalar field is the temperature distribution across a room. In the case the quantity is a vector, $\mathbf{A} = \mathbf{A}(\mathbf{r})$, we speak of *vector field*. Light propagating through space is an example for a vector field.

A position is generally defined with respect to the center of the coordinate system, called the origin, such that the distance from the center is given by,

$$r \equiv \sqrt{\mathbf{r}\cdot\mathbf{r}} = \sqrt{x^2+y^2+z^2}\ , \tag{12.3}$$

with $\hat{\mathbf{e}}_r$ being a unit vector pointing in the direction of $\mathbf{r}$. In electrodynamics we will often deal with quantities (fields) that depend on the distance between a source located at a position $\mathbf{r}'$ and a detector placed at a position $\mathbf{r}$, such as $\Phi(R) = \Phi(\mathbf{r}-\mathbf{r}')$,

$$\hat{\mathbf{e}}_R = \frac{(x-x')\hat{\mathbf{e}}_x + (y-y')\hat{\mathbf{e}}_y + (z-z')\hat{\mathbf{e}}_z}{\sqrt{(x-x')^2+(y-y')^2+(z-z')^2}}\ . \tag{12.4}$$

12.1.2 The gradient

The derivative of a one-dimensional function $\Phi(x)$ measures, how fast the function changes when we move the position x. That is, when we change x by an amount dx, Φ changes by an amount $d\Phi$ given by,

$$d\Phi = \left(\frac{d\Phi}{dx}\right) dx\ . \tag{12.5}$$

Of course it gets trickier, when Φ is a field depending on three coordinates, because we need to specify in which direction we are changing the position. We have,

$$d\Phi = \left(\frac{\partial\Phi}{\partial x}\right) dx + \left(\frac{\partial\Phi}{\partial y}\right) dy + \left(\frac{\partial\Phi}{\partial z}\right) dz \ . \tag{12.6}$$

This equation resembles the scalar product because,

$$d\Phi = \left(\hat{\mathbf{e}}_x \frac{\partial\Phi}{\partial x} + \hat{\mathbf{e}}_y \frac{\partial\Phi}{\partial y} + \hat{\mathbf{e}}_z \frac{\partial\Phi}{\partial z}\right) \cdot (dx\hat{\mathbf{e}}_x + dy\hat{\mathbf{e}}_y + dz\hat{\mathbf{e}}_z) \equiv \nabla\Phi \cdot d\mathbf{r} \ , \tag{12.7}$$

where we defined a new operator called *nabla*,

$$\nabla \equiv \begin{pmatrix} \partial/\partial x \\ \partial/\partial y \\ \partial/\partial z \end{pmatrix} \ . \tag{12.8}$$

The three-dimensional derivative $\nabla\Phi$ is called the *gradient* of the scalar field Φ,

$$\nabla\Phi(\mathbf{r}) = \hat{\mathbf{e}}_x \frac{\partial\Phi}{\partial x} + \hat{\mathbf{e}}_y \frac{\partial\Phi}{\partial y} + \hat{\mathbf{e}}_z \frac{\partial\Phi}{\partial z} \ , \tag{12.9}$$

and it measures the variation of the value of the field from Φ to $\Phi + d\Phi$, when we move the vector by an infinitesimal amount between two points $\mathbf{r}$ and $\mathbf{r} + d\mathbf{r}$.

We understand the geometric interpretation of the gradient through its formulation as a scalar product:

$$d\Phi = \nabla\Phi \cdot d\mathbf{r} = |\nabla\Phi| \cdot |d\mathbf{r}| \cos\theta \ , \tag{12.10}$$

where θ is the angle between the gradient and the infinitesimal displacement. Now, we fix a *magnitude* of the displacement $|d\mathbf{r}|$ and look for the direction θ in which the variation $d\Phi$ is maximum. Obviously, we find the direction $\theta = 0$, that is, when the gradient points in the same direction as the predefined displacement.

> *The gradient of a scalar field $\Phi(\mathbf{r})$ calculated at a point $\mathbf{r}$ indicates the direction of the greatest field variation from this point, and its absolute value is a measure for the variation.*

The concept of the gradient is easy to understand in a two-dimensional landscape: Imagine being on the slope of a mountain. Depending on the direction in which you are heading and the duration of the journey $d\mathbf{r}$, you will gain or lose a certain amount of potential energy $d\Phi$, which you can calculate by the scalar product $\nabla\Phi \cdot d\mathbf{r}$. If the direction chosen is that indicated by the gradient, you will lose (or gain) a maximum of potential energy. If you choose to go in a direction perpendicular to the gradient, that is, along an equipotential line, the potential energy remains unchanged. This is illustrated in Fig. 12.2.

Let us consider the example of a parabolic field, $\Phi(\mathbf{r}) = -r^2$:

$$\nabla(-r^2) = \begin{pmatrix} -2x \\ -2y \\ -2z \end{pmatrix} = -2\mathbf{r} \ . \tag{12.11}$$

We find that at all points of space the variation is faster in radial direction.

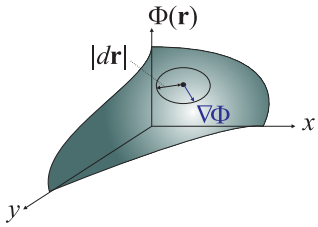

Figure 12.2: The gradient indicates the direction of the largest field variation Φ.

Although the operator ∇ has the shape of a vector, it has no meaning by itself. In fact, it is a *vector operator*, that is, a mathematical *prescription* telling us what to do with the scalar field on which it acts. Nevertheless, it assimilates all the properties of a vector. (We will see in quantum mechanics, that this is more than a coincidence.) Thus, in a way similar as done for the gradient of scalar fields, we can try to apply the ∇ operator on vector fields using the definitions of the scalar and vector products,

$$\text{grad } \Phi(\mathbf{r}) \equiv \nabla\Phi(\mathbf{r}) \quad \text{and} \quad \text{div } \mathbf{A}(\mathbf{r}) \equiv \nabla \cdot \mathbf{A}(\mathbf{r}) \quad \text{and} \quad \text{rot } \mathbf{A}(\mathbf{r}) \equiv \nabla \times \mathbf{A}(\mathbf{r}) \ . \tag{12.12}$$

We practice the calculation with the ∇ operator in the Excs. 12.1.7.1 to 12.1.7.3.

12.1.3 The divergence

Let us now analyze the possible meaning of the expression $\nabla \cdot \mathbf{A}$ called *divergence*. It is easy to show,

$$\nabla \cdot \mathbf{A}(\mathbf{r}) = \frac{\partial A_x}{\partial x} + \frac{\partial A_y}{\partial y} + \frac{\partial A_z}{\partial z} \ . \tag{12.13}$$

Obviously the divergence is a scalar field calculated from a vector field.

> *The divergence measures how much a vector field* $\mathbf{A}(\mathbf{r})$ *spreads out starting from a point* $\mathbf{r}$*. For a given infinitesimal volume it measures the difference between the number of incoming and outgoing field lines.*

Exposed to a field with divergence, an extended distribution of masses will start to concentrate (spread out) in case of a drain (source). The field lines trace the masses trajectories.

> **Example 30 (*Divergence of a radial field*):** We consider the example of the radial field, $\mathbf{A}(\mathbf{r}) = \mathbf{r}$:
>
> $$\nabla \cdot \mathbf{r} = \frac{\partial x}{\partial x} + \frac{\partial y}{\partial y} + \frac{\partial z}{\partial z} = 3 \ . \tag{12.14}$$

12.1.4 The rotation

Let us now examine the possible meaning of the expression $\nabla \times \mathbf{A}$ called *rotation*. It is easy to show,

$$\nabla\times\mathbf{A}(\mathbf{r}) = \begin{vmatrix} \hat{\mathbf{e}}_x & \hat{\mathbf{e}}_y & \hat{\mathbf{e}}_z \\ \partial_x & \partial_y & \partial_z \\ A_x & A_y & A_z \end{vmatrix} = \hat{\mathbf{e}}_x \left(\frac{\partial A_z}{\partial y} - \frac{\partial A_y}{\partial z} \right) + \hat{\mathbf{e}}_y \left(\frac{\partial A_x}{\partial z} - \frac{\partial A_z}{\partial x} \right) + \hat{\mathbf{e}}_z \left(\frac{\partial A_y}{\partial x} - \frac{\partial A_x}{\partial y} \right) . \tag{12.15}$$

Obviously the rotation is a vector field calculated from another vector field.

> *The rotation measures how many of the field lines of a vector field* $\mathbf{A}(\mathbf{r})$ *passing through an infinitesimal volume, return into it.*

Exposed to a field with rotation, an extended distribution of masses will start spinning in closed orbits.

We consider the examples shown in Fig. 12.3. The properties of divergence and rotation are complementary. There are fields exhibiting only one of the properties, or both, or none of them. In cases where there is rotation, it is problematic to specify equipotential lines: Either, the field lines are not orthogonal to the equipotential lines, or they come back.

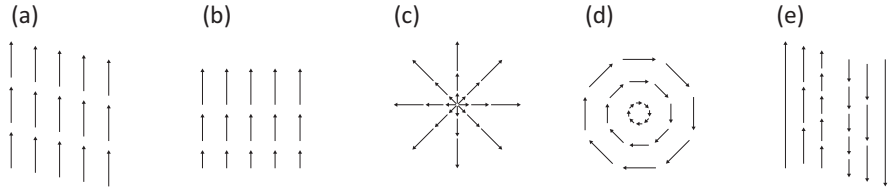

Figure 12.3: (a) Field without divergence, (b) with constant divergence, (c) with radial divergence, (d) with rotation, and (e) with rotation.

Example 31 (*Rotation of a radial field*): We consider the example of a radial field, $\mathbf{A}(\mathbf{r}) = -y\hat{\mathbf{e}}_x + x\hat{\mathbf{e}}_y$:

$$\nabla \times \mathbf{A} = \begin{pmatrix} 0 - \partial_z x \\ \partial_z(-y) - 0 \\ \partial_x x - \partial_y(-y) \end{pmatrix} = 2\hat{\mathbf{e}}_z \ . \tag{12.16}$$

We practice the calculation with divergence and rotation in the Excs. 12.1.7.4 to 12.1.7.7.

12.1.5 Taylor expansion of scalar and vector fields

We know well the Taylor expansion of functions of one variable:

$$\Phi(x+h) = \exp(h\tfrac{d}{dx})\Phi(x) = \sum_{\nu=0}^{\infty} \tfrac{1}{\nu!}(h\tfrac{d}{dx})^\nu \Phi(x) = \Phi(x) + h\Phi'(x) + \tfrac{h}{2}\Phi''(x) + \dots \ . \tag{12.17}$$

The generalization of the expansion to a scalar field, which depends on a vector, is,

$$\Phi(\mathbf{r}+\mathbf{h}) = \exp(\mathbf{h}\cdot\nabla_{\mathbf{r}})\Phi(\mathbf{r}) = \sum_{\nu=0}^{\infty}\frac{1}{\nu!}(\mathbf{h}\cdot\nabla_{\mathbf{r}})^{\nu}\Phi(\mathbf{r}) \tag{12.18}$$
$$= \Phi(\mathbf{r}) + (\mathbf{h}\cdot\nabla_{\mathbf{r}})\Phi(\mathbf{r}) + \tfrac{1}{2}(\mathbf{h}\cdot\nabla_{\mathbf{r}})(\mathbf{h}\cdot\nabla_{\mathbf{r}})\Phi(\mathbf{r}) + \dots\ .$$

We see that the operator $\nabla_{\mathbf{r}}$ generates a translation. We study the Taylor expansion of scalar fields in Exc. 12.1.7.8.

The generalization of the gradient of a vector field is the Jacobian,

$$\mathbf{A} = \begin{pmatrix} A_1 \\ \vdots \\ A_n \end{pmatrix} \qquad \Longrightarrow \qquad J[\mathbf{A}] = \begin{pmatrix} \frac{\partial A_1}{\partial x_1} & \dots & \frac{\partial A_1}{\partial x_n} \\ \vdots & \ddots & \vdots \\ \frac{\partial A_n}{\partial x_1} & \dots & \frac{\partial A_n}{\partial x_n} \end{pmatrix} . \tag{12.19}$$

Therefore, the generalization of the expansion to a vector field is,

$$\mathbf{A}(\mathbf{r}+\mathbf{h}) = \exp(\mathbf{h}\cdot\nabla_{\mathbf{r}})\mathbf{A}(\mathbf{r}) = \mathbf{A}(\mathbf{r}) + \begin{pmatrix} (\mathbf{h}\cdot\nabla_{\mathbf{r}})A_1 \\ \vdots \\ (\mathbf{h}\cdot\nabla_{\mathbf{r}})A_n \end{pmatrix} + \dots \tag{12.20}$$
$$= \mathbf{A}(\mathbf{r}) + \begin{pmatrix} h_1\frac{\partial F_1}{\partial x_1} + \dots + h_n\frac{\partial F_1}{\partial x_n} \\ \vdots \\ h_1\frac{\partial F_n}{\partial x_1} + \dots + h_n\frac{\partial F_n}{\partial x_n} \end{pmatrix} + \dots = \mathbf{A}(\mathbf{r}) + J[\mathbf{A}]\mathbf{h} + \dots\ .$$

12.1.6 Rules for calculation with derivatives

In total there are four possible ways of defining products involving scalar and vector fields, $\Phi\Psi$, $\Phi\mathbf{A}$, $\mathbf{A}\cdot\mathbf{B}$, and $\mathbf{A}\times\mathbf{B}$, and six product rules to calculate the following expressions,

$$\nabla(\Phi\Psi) \quad , \quad \nabla(\mathbf{A}\cdot\mathbf{B}) \quad , \quad \nabla\cdot(\Phi\mathbf{A}) \quad , \quad \nabla\cdot(\mathbf{A}\times\mathbf{B}) \quad , \quad \nabla\times(\Phi\mathbf{A}) \quad , \quad \nabla\times(\mathbf{A}\times\mathbf{B})\ . \tag{12.21}$$

Second derivatives can also be defined in six different combinations,

$$\nabla\cdot(\nabla\phi) \quad , \quad \nabla\times(\nabla\phi) \quad , \quad \nabla(\nabla\cdot\mathbf{A}) \quad , \quad \nabla\cdot(\nabla\times\mathbf{A}) \quad , \quad \nabla\times(\nabla\times\mathbf{A})\ . \tag{12.22}$$

As these rules are used frequently, we summarized them in Secs. 21.6.1 and 21.6.2.

The rules can be derived componentwise from scalar product rules. Very useful tools for this are the *Kronecker symbol* and the *Levi-Civita tensor*. Let us consider a Cartesian coordinate system $i = 1, 2, 3$. The coordinates in this system are x_i and the derivatives $\partial_i \equiv \frac{\partial}{\partial x_i}$. The Kronecker symbol is defined by,

$$\delta_{mn} = \begin{cases} 1 & \text{for } m = n \\ 0 & \text{else} \end{cases} . \tag{12.23}$$

The Levi-Civita tensor is defined by,

$$\epsilon_{kmn} = \begin{cases} 1 & \text{when } (kmn) \text{ is an even permutation of } (123) \\ -1 & \text{when } (kmn) \text{ is an odd permutation of } (123) \\ 0 & \text{when at least two indices are identical} \end{cases} . \tag{12.24}$$

Adopting Einstein's summing convention, we automatically take the sum of an expression over all indexes appearing twice. For example, the scalar product can be written,

$$\mathbf{A} \cdot \mathbf{B} = \sum_i A_i B_i \equiv A_i B_i \ . \tag{12.25}$$

For the vector product we obtain,

$$(\mathbf{A} \times \mathbf{B})_k \equiv \epsilon_{kmn} A_m B_n \ . \tag{12.26}$$

Other examples will be discussed in the Excs. 12.1.7.9 to 12.1.7.11.

12.1.7 Exercises

12.1.7.1 Ex: Differential operators

Find the gradients of the following scalar fields:
a. $\Phi(\mathbf{r}) = x^2 + y^3 + z^4$,
b. $\Phi(\mathbf{r}) = x^2 y^3 z^4$,
c. $\Phi(\mathbf{r}) = e^x \sin y \ln z$.

Solution: *a.* $\nabla\Phi(\mathbf{r}) = 2x\hat{\mathbf{e}}_x + 3y^2\hat{\mathbf{e}}_y + 4z^3\hat{\mathbf{e}}_z$,
b. $\nabla\Phi(\mathbf{r}) = 2xy^3z^4\hat{\mathbf{e}}_x + 3x^2y^2z^4\hat{\mathbf{e}}_y + 4x^2y^3z^3\hat{\mathbf{e}}_z$,
c. $\nabla\Phi(\mathbf{r}) = e^x \sin y \ln z \hat{\mathbf{e}}_x + e^x \cos y \ln z \hat{\mathbf{e}}_y + \frac{e^x \sin y}{z}\hat{\mathbf{e}}_z$.

12.1.7.2 Ex: 2D landscape

A 2D landscape is parametrized by $h(x, y) = 10(2xy - 3x^2 - 4y^2 - 18x + 28y + 12)$.
a. Where is mountain top?
b. What is its height?

Solution: *a. The gradient is,*

$$\nabla h(x, y) = \begin{pmatrix} 20y - 60x - 180 \\ 20x - 80y + 280 \end{pmatrix} = 0 \ ,$$

yielding $x = -2$ *and* $y = 3$.
b. The height is,

$$h(-2, 3) = 720 \ .$$

12.1.7.3 Ex: Differential operators

Calculate $\nabla_{\mathbf{r}'}|\mathbf{r}-\mathbf{r}'|^n$.

Solution: *With*

$$\begin{aligned}\frac{\partial}{\partial x'}&[(x-x')^2+(y-y')^2+(z-z)^2]^{n/2}\\ &=\frac{n}{2}[(x-x')^2+(y-y')^2+(z-z')^2]^{n/2-1}2(x-x')(-1)\\ &=-n|\mathbf{r}-\mathbf{r}'|^{n-2}(x-x')\ .\end{aligned}$$

With this,

$$\nabla(\mathbf{r}-\mathbf{r}')^n=-n|\mathbf{r}-\mathbf{r}'|^{n-2}(\mathbf{r}-\mathbf{r}')\ .$$

12.1.7.4 Ex: Differential operators

Calculate the divergence and the rotation of the vector field $\mathbf{A}=e^{-x^2y}\hat{\mathbf{e}}_x+\frac{z}{1+y^2}\hat{\mathbf{e}}_y+x\hat{\mathbf{e}}_z$ at the position $(0,1,1)$.

Solution: *With Maple*

$$\nabla\cdot\mathbf{A}=-2xye^{-x^2y}-2\frac{z}{(1+y^2)^2}y\ .$$

At the given point the divergence is $\nabla\cdot\mathbf{A}(0,1,1)=-0.5$. *In addition we find,*

$$\nabla\times\mathbf{A}=\begin{pmatrix}-\frac{1}{1+y^2}\\ -1\\ x^2e^{-x^2y}\end{pmatrix}\ .$$

At the given point the rotation is $\nabla\times\mathbf{A}(0,1,1)=(-\frac{1}{2},-1,0)$.

12.1.7.5 Ex: Sources and vertices

a. Determine the divergence and the rotation of the vector field $\mathbf{A}=A_x\hat{\mathbf{e}}_x+A_y\hat{\mathbf{e}}_y+A_z\hat{\mathbf{e}}_z$.
b. Calculate for the following fields the sources and vortices:

$$\begin{aligned}\mathbf{A}_1&=-y\hat{\mathbf{e}}_x+x\hat{\mathbf{e}}_y \quad,\quad \mathbf{A}_2=+y\hat{\mathbf{e}}_x+x\hat{\mathbf{e}}_y\ ,\\ \mathbf{A}_3&=+x\hat{\mathbf{e}}_x+y\hat{\mathbf{e}}_y \quad,\quad \mathbf{A}_4=+x\hat{\mathbf{e}}_x+x\hat{\mathbf{e}}_y\ .\end{aligned}$$

c. Make a graphic illustration of the fields and give a geometric interpretation of div and rot.

Solution: *a. Easy.*
b. The solutions are:

$$\begin{aligned}
\nabla \cdot \mathbf{A}_1 = 0 \quad &, \quad \nabla \times \mathbf{A}_1 = 2\hat{\mathbf{e}}_z \ , \\
\nabla \cdot \mathbf{A}_2 = 0 \quad &, \quad \nabla \times \mathbf{A}_2 = 0 \ , \\
\nabla \cdot \mathbf{A}_3 = 2 \quad &, \quad \nabla \times \mathbf{A}_3 = 0 \ , \\
\nabla \cdot \mathbf{A}_4 = 1 \quad &, \quad \nabla \times \mathbf{A}_4 = \hat{\mathbf{e}}_z \ .
\end{aligned}$$

c. Graphical illustration:

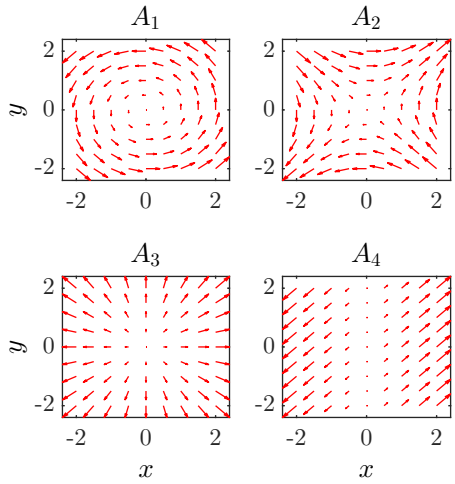

Figure 12.4: Illustration of Sources and vertices.

12.1.7.6 Ex: Sources and vertices

Calculate the divergence $\nabla \cdot \frac{\mathbf{r}}{r^3}$.

Solution: *With*

$$\frac{\partial}{\partial x}\frac{x}{(x^2+y^2+z^2)^{3/2}} = -\frac{2x^2-y^2-z^2}{(x^2+y^2+z^2)^{5/2}} \ ,$$

we obtain,

$$\nabla \cdot \frac{r}{r^3} = -\frac{2x^2-y^2-z^2}{r^5} - \frac{2y^2-z^2-x^2}{r^5} - \frac{2z^2-x^2-y^2}{r^5} = 0 \ .$$

12.1.7.7 Ex: Chain rule for functions of vector field

Apply the chain rule to the gradient of a scalar function of a vector field: $\nabla\phi(\mathbf{E}(\mathbf{r}))$. Use the rule to calculate $\nabla\sqrt{a\mathbf{r}^2}$.

Solution: *By components we have,*

$$\frac{d\phi(E_x,E_y,E_z)}{dx} = \frac{\partial\phi}{\partial E_x}\frac{\partial E_x}{\partial x} + \frac{\partial\phi}{\partial E_y}\frac{\partial E_y}{\partial x} + \frac{\partial\phi}{\partial E_z}\frac{\partial E_z}{\partial x} = \nabla_E\phi\cdot\frac{\partial}{\partial x}\mathbf{E} \ .$$

Hence,

$$\nabla\phi(\mathbf{E}(\mathbf{r})) = \sum_k \frac{\partial\phi}{\partial E_k}\nabla E_k \ .$$

For the given function,

$$\nabla\sqrt{a\mathbf{r}^2} = \sum_k \frac{\partial\sqrt{a\mathbf{r}^2}}{\partial(ax_k^2)}\nabla(ax_k^2) = \sum_k \frac{1}{2\sqrt{a\mathbf{r}^2}}2ax_k\hat{\mathbf{e}}_k = \sqrt{a}\hat{\mathbf{e}}_r \ .$$

12.1.7.8 Ex: Taylor expansion in 3D

Consider the function,

$$f(\mathbf{x}) = \frac{1}{|\mathbf{d}-\mathbf{x}|} \ .$$

Calculate the Taylor expansion in x of this function in Cartesian coordinates at the position $x = 0$ (in all three spatial coordinates) up to second-order.

Solution: *In general we have,*

$$f(\mathbf{x}) = f|_{\mathbf{x}=0} + \left.\frac{\partial f}{\partial x_i}\right|_{\mathbf{x}=0} x_i + \frac{1}{2}\left.\frac{\partial^2 f}{\partial x_i x_j}\right|_{\mathbf{x}=0} x_i x_j + O(|\mathbf{x}|^3) \ ,$$

where we add over equal indices.
In 0. order,

$$f|_{\mathbf{x}=0} = \frac{1}{|\mathbf{d}|} \ .$$

In 1. order,

$$\left[\frac{\partial}{\partial x_i}[(d_1-x_1)^2+(d_2-x_2)^2+(d_3-x_3)^2]^{-1/2}\right]_{\mathbf{x}=0}$$
$$= \left[\frac{d_i-x_i}{[(d_1-x_1)^2+(d_2-x_2)^2+(d_3-x_3)^2]^{3/2}}\right]_{\mathbf{x}=0} = \frac{d_i}{|\mathbf{d}|^3} \ .$$

So we get in first order,

$$\left.\frac{\partial f}{\partial x_i}\right|_{\mathbf{x}=0} x_i = \frac{\mathbf{d}\cdot\mathbf{x}}{|\mathbf{d}|^3} \ .$$

In 2. order for $i \neq j$,

$$\left[\frac{\partial}{\partial x_j}\frac{d_i-x_i}{|\mathbf{d}-\mathbf{x}|^3}\right]_{\mathbf{x}=0} = \left[\frac{\frac{\partial(d_i-x_i)}{\partial x_j}|\mathbf{d}-\mathbf{x}|^3 - (d_i-x_i)\frac{\partial}{\partial x_j}|\mathbf{d}-\mathbf{x}|^3}{|\mathbf{d}-\mathbf{x}|^6}\right]_{\mathbf{x}=0}$$
$$= \left[\frac{3(d_i-x_i)(d_j-x_j)}{|\mathbf{d}-\mathbf{x}|^5}\right]_{\mathbf{x}=0} = 3\frac{d_i d_j}{|\mathbf{d}|^5} \ .$$

In 2. order for $i = j$,

$$\left[\frac{\frac{\partial(d_i-x_i)}{\partial x_i}|\mathbf{d}-\mathbf{x}|^3-(d_i-x_i)\frac{\partial}{\partial x_i}|\mathbf{d}-\mathbf{x}|^3}{|\mathbf{d}-\mathbf{x}|^6}\right]_{\mathbf{x}=0} = \left[\frac{-|\mathbf{d}-\mathbf{x}|^3+(d_i-x_i)3(d_i-x_i)|\mathbf{d}-\mathbf{x}|}{|\mathbf{d}-\mathbf{x}|^6}\right]_{\mathbf{x}=0}$$
$$= \frac{1}{|\mathbf{d}|^5}(3d_i^2-|\mathbf{d}|^2) \ .$$

So we get in second order,

$$\frac{1}{2}\frac{\partial^2 f}{\partial x_i x_j}\Big|_{\mathbf{x}=0} x_i x_j = \frac{3}{2}\frac{d_i d_j}{|\mathbf{d}|^5}x_i x_j + \frac{3}{2}\frac{d_i^2}{|\mathbf{d}|^5}x_i^2 - \frac{1}{2}\frac{1}{|\mathbf{d}|^3}x_i^2 = \frac{3}{2|\mathbf{d}|^5}\sum_{i,j} d_i d_j x_i x_j - \frac{1}{2|\mathbf{d}|^3}\sum_i x_i^2 \ .$$

12.1.7.9 Ex: Levi-Civita tensor

Prove the following relationships for the Kronecker symbol and the Levi-Civita tensor by distinguishing the cases in the indices,
a. $\epsilon_{ijk}\delta_{ij} = 0$,
b. $\epsilon_{ijk}\epsilon_{ijk} = 6$,
d. $\epsilon_{ijk}\epsilon_{imn} = \delta_{jm}\delta_{kn} - \delta_{jn}\delta_{km}$,
c. $\epsilon_{ijk}\epsilon_{ijn} = 2\delta_{kn}$.

Solution: *a. We sum over i and j. Therefore, we can rename these indexes. Now, $\delta_{ij}$is obviously symmetric about permutation, but ϵ_{ijk} is antisymmetric. With that we get,*

$$\begin{aligned} \epsilon_{ijk}\delta_{ij} &= \epsilon_{jik}\delta_{ji} && \text{(rename)} \\ &= -\epsilon_{ijk}\delta_{ij} && \text{(symmetries)} \\ &= 0 \ . \end{aligned}$$

Here we must take into account that $\delta_{jj} = \sum_j \delta_{jj} = 3$.
b. This immediately follows from (b), letting $i = l$ and summing over i.
c. Summing over the i index, which appears twice. j, k, l, m they are fixed indices. Due to tensor properties ϵ the only terms they don't zero are for $j \neq k \neq i$ as well as $l \neq m \neq i$. Therefore, only one i can contribute from the sum and, in addition, it has to be $j = l$ and $k = m$ or $j = m$ and $k = l$. In the first case we get $+1$, in the second (since we must exchange l and m) -1. With this, we immediately prove the statement.
d. Using the result (c) we have,

$$\epsilon_{ijk}\epsilon_{ljk} = \epsilon_{kij}\epsilon_{klj} = \delta_{il}\delta_{jj} - \delta_{ij}\delta jl = 3\delta_{il} - 1\delta_{il} = 2\delta_{il} \ .$$

12.1.7.10 Ex: Levi-Civita tensor

Let the vectors $\mathbf{A}$, $\mathbf{B}$, $\mathbf{C}$, and $\mathbf{D} \in \mathbb{R}^3$ be given. Using the Kronecker Symbol and the Levi-Civita Tensor
a. show $\{\mathbf{A} \times \mathbf{B}\}_i = \epsilon_{ijk} A_j B_k$;
b. prove the relationship, $(\mathbf{A} \times \mathbf{B}) \cdot \mathbf{C} = (\mathbf{B} \times \mathbf{C}) \cdot \mathbf{A} = (\mathbf{C} \times \mathbf{A}) \cdot \mathbf{B}$; c. Using the formulas of (b) derive the following rules of calculation:

i. $(\mathbf{A} \times \mathbf{B})^2 = \mathbf{A}^2\mathbf{B}^2 - (\mathbf{A} \cdot \mathbf{B})^2$
ii. $(\mathbf{A} \times \mathbf{B}) \cdot (\mathbf{C} \times \mathbf{D}) = (\mathbf{A} \cdot \mathbf{C})(\mathbf{B} \cdot \mathbf{D}) - (\mathbf{A} \cdot \mathbf{D})(\mathbf{B} \cdot \mathbf{C})$;

d. prove that:

i. $(\mathbf{A} \times \mathbf{B}) \cdot [(\mathbf{B} \times \mathbf{C}) \times (\mathbf{C} \times \mathbf{A})] = [\mathbf{A} \cdot (\mathbf{B} \times \mathbf{C})]^2$
ii. $\mathbf{A} \times (\mathbf{B} \times \mathbf{C}) + \mathbf{B} \times (\mathbf{C} \times \mathbf{A}) + \mathbf{C} \times (\mathbf{A} \times \mathbf{B}) = 0$.

Solution: *a. Since the indices j and k appear twice, we take the sum applying the Einstein convention. Without restricting generality we choose, $i = 1$. Due to the properties of the ϵ-tensor we get non-zeroing terms just for $j = 2$ and $k = 3$ as well as for $j = 3$ and $k = 2$. In the first case, we have an even permutation of $1, 2, 3$, in the second an odd. We get immediately,*

$$\{\mathbf{A} \times \mathbf{B}\}_1 = A_2 B_3 - A_3 B_2 \ .$$

Analogously we get,

$$\{\mathbf{A} \times \mathbf{B}\}_2 = A_3 B_1 - A_1 B_3$$
$$\{\mathbf{A} \times \mathbf{B}\}_3 = A_1 B_2 - A_2 B_1 \ .$$

b. We have,

$$\epsilon_{ijk} A_j B_k C_i = \epsilon_{jki} B_k C_i A_j = \epsilon_{kij} C_i A_j B_k \ .$$

c.i. Vide (c.ii).
c.ii. We have,

$$\epsilon_{ijk} A_i B_j \epsilon_{lmk} C_l D_m = A_i B_j C_l D_m (\delta_{il}\delta_{jm} - \delta_{im}\delta_{jl}) = A_i C_i B_j D_j - A_i D_i B_j C_j \ .$$

d.i. We have,

$$\epsilon_{ijk} A_i B_j \epsilon_{lmh} B_l C_m \epsilon_{npq} C_n A_p \epsilon_{hqk} = \epsilon_{lmh}\epsilon_{npq}(\delta_{ih}\delta_{jq} - \delta_{iq}\delta_{jh}) A_i B_j B_l C_m C_n A_p \ .$$

We have,

$$= \epsilon_{lmi} B_l C_m A_i \epsilon_{npj} C_n A_p B_j - \epsilon_{npi} A_i C_n A_p \epsilon_{lmj} B_l C_m B_j = \epsilon_{lmi} B_l C_m A_i \epsilon_{npj} C_n A_p B_j \ .$$

d.ii. We have,

$$\epsilon_{ijk}\epsilon_{lmj}(A_i B_l C_m + B_i C_l A_m + C_i A_l B_m) = (\delta_{lk}\delta_{mi} - \delta_{li}\delta_{mk})(A_i B_l C_m + B_i C_l A_m + C_i A_l B_m) = 0 \ .$$

12.1.7.11 Ex: Levi-Civita tensor and vector tautologies

Be Ψ and Φ scalar fields and $\mathbf{A}$, $\mathbf{B}$, $\mathbf{C}$, and $\mathbf{D}$ vector fields. Show the following identities with the help of the Kronecker symbol.:
a. $\mathbf{A}\cdot(\mathbf{B}\times\mathbf{C})=\mathbf{B}\cdot(\mathbf{C}\times\mathbf{A})$,
b. $(\mathbf{A}\times\mathbf{B})\cdot(\mathbf{C}\times\mathbf{D})=(\mathbf{A}\cdot\mathbf{C})(\mathbf{B}\cdot\mathbf{D})-(\mathbf{B}\cdot\mathbf{C})(\mathbf{A}\cdot\mathbf{D})$,
c. $(\mathbf{A}\times\mathbf{B})\times(\mathbf{C}\times\mathbf{D})=((\mathbf{A}\times\mathbf{B})\cdot\mathbf{D})\mathbf{C}-((\mathbf{A}\times\mathbf{B})\cdot\mathbf{C})\mathbf{D}$,
d. $\nabla(\Phi\Psi)=\Phi\nabla\Psi+\Psi\nabla\Phi$,
e. $\nabla\times(\Phi\mathbf{A})=(\nabla\Phi)\times\mathbf{A}+\Phi\nabla\times\mathbf{A}$,
f. $\nabla\times(\mathbf{A}\times\mathbf{B})=(\mathbf{B}\cdot\nabla)\mathbf{A}-(\mathbf{A}\cdot\nabla)\mathbf{B}+\mathbf{A}(\nabla\cdot\mathbf{B})-\mathbf{B}(\nabla\cdot\mathbf{A})$,
g. $\nabla(\mathbf{A}\cdot\mathbf{B})=\mathbf{A}\times(\nabla\times\mathbf{B})+\mathbf{B}\times(\nabla\times\mathbf{A})+(\mathbf{A}\cdot\nabla)\mathbf{B}+(\mathbf{B}\cdot\nabla)\mathbf{A}$,
h. $\nabla\cdot(\nabla\Phi)=\Delta\Phi$,
i. $\mathbf{A}\cdot(\nabla\Phi)=(\mathbf{A}\cdot\nabla)\Phi$,
j. $\mathbf{A}\times(\nabla\Phi)=(\mathbf{A}\times\nabla)\Phi$.
k. $\nabla\cdot(\mathbf{A}\times\mathbf{B})=\mathbf{B}\cdot(\nabla\times\mathbf{A})-\mathbf{A}\cdot(\nabla\times\mathbf{B})$,
l. $\nabla(\Psi\mathbf{A})=\mathbf{A}\cdot\nabla\Psi+\Psi\nabla\cdot\mathbf{A}$,
m. $\nabla\cdot(\Psi\nabla\Psi)=\Psi\Delta\Psi+(\nabla\Psi)^2$
n. $\nabla\cdot(\mathbf{A}\times\mathbf{B})=\mathbf{B}\cdot(\nabla\times\mathbf{A})-\mathbf{A}\cdot(\nabla\times\mathbf{B})$,
o. $\nabla\cdot(\nabla\times\mathbf{A})=0$,
p. $\nabla\times(\nabla\Phi)=0$,
q. $\nabla\times(\nabla\times\mathbf{A})=\nabla(\nabla\cdot\mathbf{A})-\nabla^2\mathbf{A}$.

Solution: *a. We have,*

$$\mathbf{A}\cdot(\mathbf{B}\times\mathbf{C})=...=\mathbf{B}\cdot(\mathbf{C}\times\mathbf{A})$$

b. We have,

$$\begin{aligned}(\mathbf{A}\times\mathbf{B})\cdot(\mathbf{C}\times\mathbf{D})&=(\mathbf{A}\times\mathbf{B})_i(\mathbf{C}\times\mathbf{D})_i\\&=\epsilon_{ijk}\epsilon_{ilm}A_jB_kC_lD_m\\&=(\delta_{jl}\delta_{km}-\delta_{jm}\delta_{kl})A_jB_kC_lD_m\\&=A_jC_jB_kD_k-A_jD_jB_kC_k=(\mathbf{A}\cdot\mathbf{C})(\mathbf{B}\cdot\mathbf{D})-(\mathbf{A}\cdot\mathbf{D})(\mathbf{B}\cdot\mathbf{C})\ .\end{aligned}$$

c. We have,

$$\begin{aligned}\{(\mathbf{A}\times\mathbf{B})\times(\mathbf{C}\times\mathbf{D})\}_i&=\epsilon_{ijk}(\mathbf{A}\times\mathbf{B})_j(\mathbf{C}\times\mathbf{D})_k\\&=\epsilon_{ijk}\epsilon_{jlm}\epsilon_{krs}A_lB_mC_rD_s=\epsilon_{kij}\epsilon_{krs}\epsilon_{jlm}A_lB_mC_rD_s\\&=(\delta_{ir}\delta_{js}-\delta_{is}\delta_{jr})\epsilon_{jlm}A_lB_mC_rD_s\\&=C_iD_j\epsilon_{jlm}A_lB_m-D_iC_j\epsilon_{jlm}A_lB_m\\&=C_i(\mathbf{D}\cdot(\mathbf{A}\times\mathbf{B}))-D_i(\mathbf{C}\cdot(\mathbf{A}\times\mathbf{B}))\\&=C_i(\mathbf{A}\cdot(\mathbf{B}\times\mathbf{D}))-D_i(\mathbf{A}\cdot(\mathbf{B}\times\mathbf{C}))\ ,\end{aligned}$$

where we use in the last line the cyclic permutativity of the triple product.
d. We have,

$$\nabla(\Phi\Psi)=...=\Phi\nabla\Psi+\Psi\nabla\Phi\ .$$

e. We have,

$$\nabla\times(\Phi\mathbf{A})=...=(\nabla\phi)\times\mathbf{A}+\Phi\nabla\times\mathbf{A}\ .$$

f. Here we have,

$$\begin{aligned}\{\nabla\times(\mathbf{A}\times\mathbf{B})\}_i &= \epsilon_{ijk}\partial_j(\mathbf{A}\times\mathbf{B})_k = \epsilon_{ijk}\epsilon_{klm}\partial_j A_l B_m \\ &= (\delta_{il}\delta_{jm}-\delta_{im}\delta_{lj})\partial_j A_l B_m \qquad (T15b)\\ &= \partial_j A_i B_j - \partial_j A_j B_i \\ &= B_j(\partial_j A_i) + A_i(\partial_j B_j) - B_i(\partial_j A_j) - A_j(\partial_j B_i) \\ &= \{\mathbf{A}(\nabla\cdot\mathbf{B}) - \mathbf{B}(\nabla\cdot\mathbf{A}) + (\mathbf{B}\cdot\nabla)\mathbf{A} - (\mathbf{A}\cdot\nabla)\mathbf{B}\}_i \ .\end{aligned}$$

g. We have,

$$\nabla(\mathbf{A}\cdot\mathbf{B}) = ... = \mathbf{A}\times(\nabla\times\mathbf{B}) + \mathbf{B}\times(\nabla\times\mathbf{A}) + (\mathbf{A}\cdot\nabla)\mathbf{B} + (\mathbf{B}\cdot\nabla)\mathbf{A} \ .$$

h. We have,

$$\nabla\cdot(\nabla\Phi) = ... = \Delta\Phi \ .$$

i. We have,

$$\mathbf{A}\cdot(\nabla\Phi) = ... = (\mathbf{A}\cdot\nabla)\Phi \ .$$

j. We have,

$$\mathbf{A}\times(\nabla\Phi) = ... = (\mathbf{A}\times\nabla)\Phi \ .$$

k. We get,

$$\begin{aligned}\nabla\cdot(\mathbf{A}\times\mathbf{B}) &= \epsilon_{ijk}\partial_i A_j B_k = \epsilon_{ijk}(B_k(\partial_i A_j) + A_j(\partial_i B_k)) \\ &= B_k\epsilon_{kij}\partial_i A_j - A_j\epsilon_{jik}\partial_i B_k \\ &= \mathbf{B}\cdot(\nabla\times\mathbf{A}) - \mathbf{A}\cdot(\nabla\times\mathbf{B}) \ .\end{aligned}$$

l. We have,

$$\nabla\cdot(\Psi\mathbf{A}) = \partial_k(\Psi\mathbf{A})_k = \partial_k\Psi A_k = \Psi\partial_k A_k + A_k\partial_k\Psi = \Psi(\nabla\cdot\mathbf{A}) + \mathbf{A}\cdot(\nabla\Psi) \ .$$

m.

n. We have,

$$\begin{aligned}\nabla\cdot(\mathbf{A}\times\mathbf{B}) &= \partial_k(\mathbf{A}\times\mathbf{B})_k = \partial_k\varepsilon_{kmn}a_m b_n = \varepsilon_{nkm}b_n\partial_k a_m - a_m\varepsilon_{mkn}\partial_k b_n \\ &= b_n(\nabla\times\mathbf{A})_n - a_m(\nabla\times\mathbf{B})_m = \mathbf{B}(\nabla\times\mathbf{A}) - \mathbf{A}(\nabla\times\mathbf{B}) \ .\end{aligned}$$

o. We obtain consecutively,

$$\begin{aligned}\nabla\cdot(\nabla\times\mathbf{A}) &= \partial_i\epsilon_{ijk}\partial_j A_k = \epsilon_{ijk}\partial_i\partial_j A_k \\ &= \epsilon_{jik}\partial_j\partial_i A_k && \text{(rename)}\\ &= -\epsilon_{ijk}\partial_i\partial_j A_k && \text{(symmetry)}\\ &= 0 \ .\end{aligned}$$

where we used in the penultimate line, that we can exchange partial derivatives.
p. Here we obtain,

$$\begin{aligned}\{\nabla\times(\nabla\Phi)\}_i &= \epsilon_{ijk}\partial_j\partial_k\Phi \\ &= \epsilon_{ikj}\partial_k\partial_j\Phi && \text{(rename)}\\ &= -\epsilon_{ijk}\partial_j\partial_k\Phi && \text{(symmetry)}\\ &= 0 \ ,\end{aligned}$$

where we once again use the interchangeability of partial derivatives.
q. Vale

$$\begin{aligned}\{\nabla\times(\nabla\times\mathbf{A})\}_i &= \epsilon_{ijk}\partial_j\{\nabla\times\mathbf{A}\}_k\\ &= \epsilon_{ijk}\epsilon_{klm}\partial_j\partial_l A_m\\ &= (\delta_{il}\delta_{jm}-\delta_{im}\delta_{jl})\partial_j\partial_l A_m \qquad (Exc.\ 12.1.7.10(b))\\ &= \partial_i\partial_j A_j-\partial_j\partial_j A_i\\ &= (\nabla)_i(\nabla\cdot\mathbf{A})-\nabla^2 A_i\ .\end{aligned}$$

What was to prove.

12.2 Integral calculus

Three types of integrals are often used in electrodynamics, the *path integral*, the *surface integral*, and the *volume integral*.

12.2.1 Path integral

The path integral is defined on a trajectory $\mathcal{C}(\mathbf{a},\mathbf{b})$ through a (scalar or vector) field linking a start point $\mathbf{a}$ to an end point $\mathbf{b}$. While following the path point by point, incrementing the infinitesimal displacement vector $d\mathbf{l}$ (see Fig. 12.5), we evaluate the local value and the direction of the field, multiply it with $d\mathbf{l}$, and sum it up,

$$\int_{\mathcal{C}(\mathbf{a},\mathbf{b})}\Phi d\mathbf{l}\quad,\quad\int_{\mathcal{C}(\mathbf{a},\mathbf{b})}\mathbf{A}\cdot d\mathbf{l}\ . \tag{12.27}$$

Note that in case of a vector field, the integral is taken over the scalar product between the local field vector and the path element. The work exerted by a force field, $W\equiv\int\mathbf{F}\cdot\mathbf{l}$ is an example. For a path through a field crossing all force lines under right angle, the path integral zeroes, meaning that no work is accumulated.

Depending on the properties of the field, the integral may only depend on the points $\mathbf{a}$ and $\mathbf{b}$ and not on the path $\mathcal{C}$ chosen to go from one to the other. In this case, we say that the vector field is *conservative*, but this is not always the case. Choosing $\mathbf{a}=\mathbf{b}$ we get a closed path, which can be thought of as delimiting a surface in 3D space. We use the notation,

$$\oint_{\partial\mathcal{S}}\mathbf{A}\cdot d\mathbf{l}\ , \tag{12.28}$$

where the symbol ∂S suggests, that the path goes along the edge of the surface S.

In practice, it is often useful to find a parametrization $\mathbf{l}(t)$ for the path with a parameter (e.g. time) defined over $t\in[0,1]$. It allows us to calculate explicitly,

$$\int_{\mathcal{C}(\mathbf{a},\mathbf{b})}\nabla\Phi\cdot d\mathbf{l}=\int_0^1\nabla\Phi(\mathbf{r})\cdot\frac{d\mathbf{l}(t)}{dt}dt\ . \tag{12.29}$$

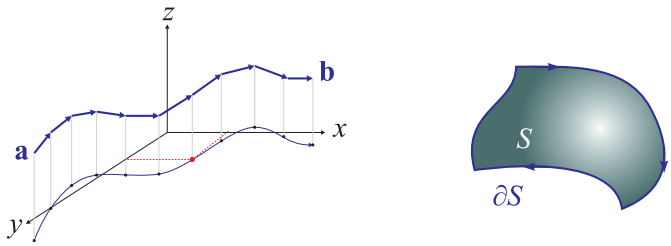

Figure 12.5: Integrating along a path in three-dimensional space.

Example 32 (*Path integral*): As an example, we will calculate the integral along the path parametrized by $\mathbf{l}(t) = \hat{\mathbf{e}}_x \cos t + \hat{\mathbf{e}}_y \sin t$, which is a unit circle around the origin, inside the field $\mathbf{A}(\mathbf{r}) = -y\hat{\mathbf{e}}_x + x\hat{\mathbf{e}}_y$:

$$\oint \mathbf{A} \cdot d\mathbf{l} = \int_0^{2\pi} (-y\hat{\mathbf{e}}_x + x\hat{\mathbf{e}}_y) \cdot \frac{dl}{dt} dt \tag{12.30}$$
$$= \int_0^{2\pi} (-\hat{\mathbf{e}}_x \sin t + \hat{\mathbf{e}}_y \cos t) \left(\hat{\mathbf{e}}_x \frac{d\cos t}{dt} + \hat{\mathbf{e}}_y \frac{d\sin t}{dt} \right) dt = \int_0^{2\pi} (\sin^2 t + \cos^2 t) dt = 2\pi \ .$$

We calculate other examples of path integrals in the Excs. 12.2.7.1 to 12.2.7.4.

12.2.2 Surface integral

The surface integral is defined on a surface $\mathcal{S}$, which can be folded in three-dimensional space. The surface is parceled into infinitesimal areas $d\mathbf{S}$, the local value and the direction of the field are evaluated, multiplied with $d\mathbf{S}$, and summed up,

$$\int_{\mathcal{S}} \Phi d\mathbf{S} \quad , \quad \int_{\mathcal{S}} \mathbf{A} \cdot d\mathbf{S} \ . \tag{12.31}$$

The vector of the area $d\mathbf{S}$ is the local normal vector. In case of the vector field, the integral is taken over the scalar product between the field and the local area. The flux, that is the field lines crossing a surface, $\Psi \equiv \int \mathbf{E} \cdot d\mathbf{S}$ it is an example. The normal vector of the surface of a volume is usually taken as pointing *out of the volume*. For example, a surface element of the x-y plane can be written $d\mathbf{S} = \hat{\mathbf{e}}_z dxdy$ in Cartesian coordinates. For curved surfaces or in curvilinear coordinates the expression will be more complicated.

Often we consider closed surfaces, which can be considered as delimiting a volume in 3D space. We use the notation,

$$\oint_{\partial\mathcal{V}} \mathbf{A} \cdot d\mathbf{S} \ , \tag{12.32}$$

where the symbol $\partial\mathcal{V}$ suggests that the surface encloses the volume $\mathcal{V}$.

Example 33 (*Flow of a field*): As an example, we calculate the field flux

$\mathbf{A} = -y\hat{\mathbf{e}}_x + x^2 y\hat{\mathbf{e}}_y$ through the unit cube:

$$\begin{aligned}\oint_{cubo} \mathbf{A}\cdot dS &= \int_{-1}^{1}\int_{-1}^{1} \mathbf{A}|_{z=1}\hat{\mathbf{e}}_z dxdy + \int_{-1}^{1}\int_{-1}^{1} \mathbf{A}|_{z=-1}(-\hat{\mathbf{e}}_z) dxdy + \int_{-1}^{1}\int_{-1}^{1} \mathbf{A}|_{x=1}\hat{\mathbf{e}}_x dydz \\ &+ \int_{-1}^{1}\int_{-1}^{1} \mathbf{A}|_{x=-1} dydz + \int_{-1}^{1}\int_{-1}^{1} \mathbf{A}|_{y=1}\hat{\mathbf{e}}_y dzdx + \int_{-1}^{1}\int_{-1}^{1} \mathbf{A}|_{y=-1}(-\hat{\mathbf{e}}_y) dzdx \\ &= 0 + 0 + \int_{-1}^{1}\int_{-1}^{1} (-y) dydz + \int_{-1}^{1}\int_{-1}^{1} y dydz + \int_{-1}^{1}\int_{-1}^{1} x^2 dzdx + \int_{-1}^{1}\int_{-1}^{1} x^2 dzdx \\ &= \frac{8}{3}\ . \end{aligned} \tag{12.33}$$

We calculate other examples of surface integrals in Excs. 12.2.7.5 to 12.2.7.8.

12.2.3 Volume integral

The volume integral defined by,

$$\int_{\mathcal{V}} \Phi dV \quad , \quad \int_{\mathcal{V}} \mathbf{A} dV\ . \tag{12.34}$$

In the case of a vector field, we simply write: $\hat{\mathbf{e}}_x \int A_x dV + \hat{\mathbf{e}}_y \int A_y dV + \hat{\mathbf{e}}_z \int A_z dV$.

Example 34 (*Integral de volume*): As an example, we calculate the mass of a cube with homogeneous density ρ_0:

$$m = \int_{-a/2}^{a/2}\int_{-a/2}^{a/2}\int_{-a/2}^{a/2} \rho_0 dxdydz = a^3\rho_0\ . \tag{12.35}$$

We calculate another example of a volume integral in Exc. 12.2.7.9.

12.2.4 Fundamental theorem for gradients

The fundamental theorem of infinitesimal calculus says,

$$\int_{f_a}^{f_b} df = \int_a^b F(x)dx = f(b) - f(a) \qquad \text{or} \qquad df = F(x)dx\ , \tag{12.36}$$

for $F(x) = \frac{df}{dx}$. That is, derivation and integration are inverse operations.

Now in vector analysis, as explained above, we know three different types of derivatives. For each one we need to formulate the fundamental theorem in a specific way. For gradients,

$$\boxed{\int_{\mathcal{C}(\mathbf{a},\mathbf{b})} \nabla\Phi\cdot d\mathbf{l} = \Phi(\mathbf{b}) - \Phi(\mathbf{a})} \qquad \text{or} \qquad d\Phi = \nabla\Phi\cdot d\mathbf{l}\ . \tag{12.37}$$

Since the right-hand side does not depend on the path $\mathcal{C}$, the integral of the gradient can not either. As a consequence,

$$\boxed{\oint_{\mathcal{C}} \nabla\Phi\cdot d\mathbf{l} = 0}\ . \tag{12.38}$$

The geometric interpretation of the fundamental theorem for gradients is simple: Climbing a mountain following a path step by step and gaining at each step the potential energy $d\Phi = \nabla\Phi dx$, we accumulate between the end and the start point of the path the energy $\Phi(\mathbf{b}) - \Phi(\mathbf{a})$. Path independence is an inherent property of gradients.

Example 35 (*Fundamental theorem for gradients*): Let us consider the following example. To travel inside the potential $\Phi(\mathbf{r}) = xy^2$ between the points $\mathbf{r}_1 = (0,0,0)$ and $\mathbf{r}_2 = (2,1,0)$, we can choose between several paths, f.ex. $\mathbf{l}_1(t) = \hat{\mathbf{e}}_x 2t + \hat{\mathbf{e}}_y t$ or $\mathbf{l}_2(t) = \hat{\mathbf{e}}_x 2t + \hat{\mathbf{e}}_y t^2$ with $t \in [0,1]$. In both cases we gain the same potential energy $\Phi(\mathbf{r}_2) - \Phi(\mathbf{r}_1) = 2$:

$$\int_{\mathcal{C}(\mathbf{r}_1,\mathbf{r}_2)} \nabla\Phi \cdot d\mathbf{l}_1 = \int_0^1 (\hat{\mathbf{e}}_x y^2 + \hat{\mathbf{e}}_y 2xy) \cdot (\hat{\mathbf{e}}_x 2 + \hat{\mathbf{e}}_y) dt = \int_0^1 (2t^2 + 4t^2) dt = 2 \tag{12.39}$$

$$\int_{\mathcal{C}(\mathbf{r}_1,\mathbf{r}_2)} \nabla\Phi \cdot d\mathbf{l}_2 = \int_0^1 (\hat{\mathbf{e}}_x y^2 + \hat{\mathbf{e}}_y 2xy) \cdot (\hat{\mathbf{e}}_x 2 + \hat{\mathbf{e}}_y 2t) dt = \int_0^1 (2t^4 + 8t^4) dt = 2 \; .$$

An example for the application of the fundamental theorem for gradients is discussed in Exc. 12.2.7.10.

12.2.5 Stokes' theorem

Stokes' theorem allows us *to convert a surface integral into a path integral* provided the field to be integrated can be expressed as a rotation,

$$\boxed{\int_{\mathcal{S}} (\nabla \times \mathbf{A}) \cdot d\mathbf{S} = \oint_{\partial\mathcal{S}} \mathbf{A} \cdot d\mathbf{l}} \; . \tag{12.40}$$

To find a geometric interpretation we remember that the rotation measures the *twist* of a field $\mathbf{A}$. The integral over the rotation within a given surface (or, more precisely, the flux of the rotation through this surface) measures the total amount of vorticity. A rotating region is like a *kitchen beater* stirring the surface of an incompressible liquid: The more beaters are in the area, the more the liquid will be moved along the edges of the area. Instead of measuring the number of beaters (left-hand side of the theorem (12.40)), we can also walk along the edge of the area and measure the flux along the rim (right-hand side of the theorem (12.40)).

An interesting consequence of Stokes' theorem is that the path integral is independent of the shape of the surface. That is, if the field to be integrated can be expressed bin terms of a rotation, we can deform the surface (without touching the edge) without changing the twist of the field,

$$\boxed{\oint_{\mathcal{S}} (\nabla \times \mathbf{A}) \cdot d\mathbf{S} = 0} \; . \tag{12.41}$$

This is analogous to the corollary obtained for gradients (12.38).

Example 36 (*Teorema de Stokes*): Consider the following example. A field be given by, $\mathbf{A} = -y\hat{\mathbf{e}}_x + x\hat{\mathbf{e}}_y$, such that $\nabla \times \mathbf{A} = 2\hat{\mathbf{e}}_z$. The surface be a disk of

radius R enclosed by a circular path parametrized by, $\mathbf{l} = \begin{pmatrix} R\cos\omega t \\ R\sin\omega t \\ 0 \end{pmatrix}$. Then,

$$\oint_{circle} \mathbf{A}\cdot dl = \int_0^{2\pi} \mathbf{A}\cdot \dot{l}dt = \int_0^{2\pi/\omega} \begin{pmatrix} -y \\ x \\ 0 \end{pmatrix} \cdot \begin{pmatrix} -R\omega\sin\omega t \\ R\omega\cos\omega t \\ 0 \end{pmatrix} dt = 2\pi R^2$$

$$\int_{disk} (\nabla\times\mathbf{A})\cdot dS = \int_{disk} \begin{pmatrix} 0 \\ 0 \\ 2 \end{pmatrix} \hat{\mathbf{e}}_z d\mathbf{A} = 2\int_{disk} dA = 2\pi R^2 \ .$$

In the Excs. 12.2.7.11 and 12.2.7.12 we show applications of Stokes' theorem.

12.2.6 Gauß' theorem

Gauß theorem allows us *to convert a volume integral into a surface integral* provided the field to be integrated can be expressed by a divergence,

$$\boxed{\int_{\mathcal{V}} (\nabla\cdot\mathbf{A})\cdot dV = \oint_{\partial\mathcal{V}} \mathbf{A}\cdot d\mathbf{S}} \ . \tag{12.42}$$

To find a geometric interpretation we remember that the divergence measures the *expansion* force of the field $\mathbf{A}$. The integral over the divergence within a given volume measures the total amount of expansion. A divergent region with is like a tap releasing an incompressible liquid: The more taps are in the volume, the more liquid will be expelled by the edges of the volume. Instead of measuring the number of taps (left-hand side of the theorem (12.42)), we can also bypass the volume by measuring the flux through the surface (right-hand side of the theorem (12.42)).

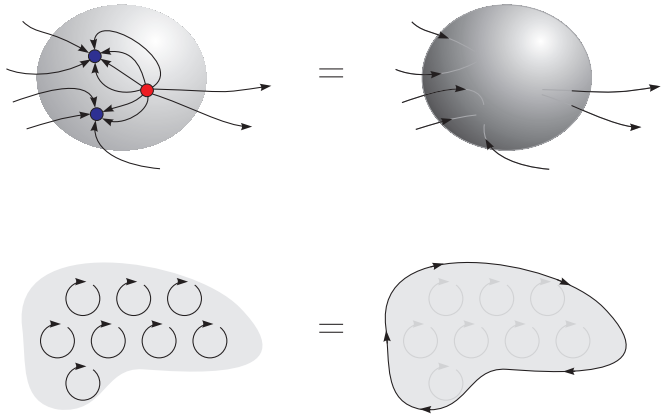

Figure 12.6: Illustration of the theorems of Gauß (above) and Stokes (below).

Example 37 (*Gauß theorem*): Consider the following example. A field be given by, $\mathbf{A} = \mathbf{r}$, such that $\nabla \cdot \mathbf{A} = 3$. The volume be a sphere of radius R enclosed by a surface. So:

$$\oint_{sphericalsurface} \mathbf{A} \cdot d\mathbf{S} = \int_{sphericalsurface} \mathbf{r} \cdot \hat{\mathbf{e}}_r dS = rr^2 \int_0^{2\pi} \int_0^{\pi} \sin\theta d\theta d\phi = 4\pi R^3$$

$$\int_{sphere} (\nabla \cdot A) dV = \int_{sphere} 3dV = 3\frac{4\pi}{3} R^3 = 4\pi R^3 \ .$$

In the Excs. 12.2.7.13 to 12.2.7.16 we show applications of Gauß' theorem.

The theorems of Stokes and Gauß are often used in the context of cylindrical or spherical coordinates. Therefore, we will postpone the presentation of further examples, until we have discussed curvilinear coordinates.

12.2.7 Exercises

12.2.7.1 Ex: Path integral and work

Be the field electric $\mathbf{A}(\mathbf{r}) = E_0 z \hat{\mathbf{e}}_z$ be given. A charge $+q$ be shifted on a straight line from the point $(0,0,0)$ to the point $(1,1,1)$.
a. Write down parametrization for the trajectory.
b. Calculate the work spent on this charge explicitly along the path integral $W = q \int \mathbf{E}(\mathbf{r}) \cdot d\mathbf{r}$.
c. Calculate the work via the potential ϕ.

Solution: *a. One possible parametrization is,*

$$\mathbf{x}(t) = \begin{pmatrix} t \\ t \\ t \end{pmatrix} \qquad with \qquad t \in [0,1] \ .$$

b. The line integral within this parametrization is given by:

$$W = qE_0 \int_0^1 \begin{pmatrix} 0 \\ 0 \\ z(t) \end{pmatrix} \cdot \begin{pmatrix} t \\ t \\ t \end{pmatrix} dt = qE_0 \int_0^1 t dt = \frac{1}{2} qE_0 \ .$$

c. A potential, which corresponds to the field $\mathbf{E}(\mathbf{r})$*, is given by,*

$$\phi(\mathbf{r}) = -\frac{E_0}{2} z^2 \qquad since \qquad -\nabla\phi(\mathbf{r}) = -\begin{pmatrix} d/dx \\ d/dy \\ d/dz \end{pmatrix} \phi(\mathbf{r}) = E_0 z \hat{\mathbf{e}}_z \ .$$

The work is given by,

$$W = -q\phi(\mathbf{r} = (1,1,1)) + q\phi(\mathbf{r} = (0,0,0)) = \frac{1}{2} qE_0 \ .$$

12.2.7.2 Ex: Path integral and work

Consider a field $\mathbf{E}$ depending on z in the following way $\mathbf{E} = E_0 z\hat{\mathbf{e}}_z$. A charge q is moved on a spiral-shaped trajectory $\mathbf{r}(t)$ with radius R,

$$\mathbf{r}(t) = \begin{pmatrix} R\cos t \\ R\sin t \\ \frac{h}{6\pi}t \end{pmatrix}$$

between $z = 0$ until $z = h$. Make a scheme of $\mathbf{r}(t)$. Calculate work made on the charge explicitly via a path integral $W = q\int \mathbf{E}\cdot d\mathbf{r}$. How can we calculate work more easily?

Solution: *Explicitly,*

$$W = q\int \mathbf{E}\cdot d\mathbf{r} = q\int_0^{6\pi} E_0\frac{h}{6\pi}t\hat{\mathbf{e}}_z \begin{pmatrix} 0 \\ 0 \\ h/6\pi \end{pmatrix} dt = \frac{1}{2}qE_0h_2 \ .$$

A integral sobre o potential $\phi = -\frac{E_0}{2}z_2$,

$$W = q(\phi(1) - \phi(2)) = q\left(+\frac{E_0}{2}h_2\right) \ .$$

12.2.7.3 Ex: Path integral and work

Calculate the path integral in the field $\Phi = x^2\hat{\mathbf{e}}_x + 2yz\hat{\mathbf{e}}_y + y^2\hat{\mathbf{e}}_z$ from the origin to the point $(1,1,1)$ on three different paths:
a. For the path $(0,0,0) \longrightarrow (1,0,0) \longrightarrow (1,1,0) \longrightarrow (1,1,1)$;
b. for the path $(0,0,0) \longrightarrow (0,0,1) \longrightarrow (0,1,1) \longrightarrow (1,1,1)$;
c. and on a straight line.

Solution:

12.2.7.4 Ex: Curve parametrization

The movement of a mass point is given in Cartesian coordinates by the vector $\mathbf{r}(t) = (\rho\cos\phi(t), \rho\sin\phi(t), z_0)$ with $\rho = vt$ and $\phi = \omega t + \phi_0$. What is the geometric figure dashed by the movement? Express the speed $\dot{\mathbf{r}}(t)$ and the acceleration $\ddot{\mathbf{r}}(t)$ in Cartesian coordinates. Calculate $|\mathbf{r}(t)|^2$, $|\dot{\mathbf{r}}(t)|^2$,$\mathbf{r}(t)\cdot\ddot{\mathbf{r}}(t)$ and $\mathbf{r}(t)\times\dot{\mathbf{r}}(t)$.

Solution: *We have,*

$$\mathbf{r}(t) = \begin{pmatrix} vt\cos(\omega t + \phi_0) \\ vt\sin(\omega t + \phi_0) \\ z_0 \end{pmatrix} \ ,$$

from which follows,

$$\dot{\mathbf{r}}(t) = v \begin{pmatrix} \cos(\omega t + \phi_0) - \omega t \sin(\omega t + \phi_0) \\ \sin(\omega t + \phi_0) + \omega t \cos(\omega t + \phi_0) \\ 0 \end{pmatrix} ,$$

and

$$\ddot{\mathbf{r}}(t) = v\omega \begin{pmatrix} -2\sin(\omega t + \phi_0) - \omega t \cos(\omega t + \phi_0) \\ 2\cos(\omega t + \phi_0) - \omega t \sin(\omega t + \phi_0) \\ 0 \end{pmatrix} .$$

We also calculate the scalar products,

$$|\mathbf{r}(t)|^2 = v^2 t^2 + z_0^2 \qquad \textit{and} \qquad |\dot{\mathbf{r}}(t)|^2 = v^2\omega^2 t^2 + v^2 ,$$

as well as,

$$\mathbf{r}(t) \cdot \ddot{\mathbf{r}}(t) = v^2 t \qquad \textit{and} \qquad \mathbf{r}(t) \times \dot{\mathbf{r}}(t) = v \begin{pmatrix} -z_0 \sin(\omega t + \phi_0) + z_0 \omega t \cos(\omega t + \phi_0) \\ z_0 \cos(\omega t + \phi_0) - z_0 \omega t \sin(\omega t + \phi_0) \\ v\omega t^2 \end{pmatrix} .$$

12.2.7.5 Ex: Surface integrals

Given be the vector field $\mathbf{A} = zy\hat{\mathbf{e}}_x + y^3 \sin^2 x \hat{\mathbf{e}}_y + xy^2 e^z \hat{\mathbf{e}}_z$. Calculate the integrals $\int \mathbf{A} \cdot d\mathbf{F}$ over the triangle $(0,0,0) \to (0,3,0) \to (0,0,3) \to (0,0,0)$, and over the rectangle $(2,2,0) \to (2,4,0) \to (4,4,0) \to (4,2,0) \to (2,2,0)$.

Solution: *The unit vector of the square points into $\hat{\mathbf{e}}_z$-direction, so with the help of MAPLE,*

$$\int \mathbf{A} \cdot d\mathbf{F} = \int_2^4 dx \int_2^4 dy \; xy^2 = 112 .$$

The unit vector of the triangle points into $\hat{\mathbf{e}}_x$-direction, hence,

$$\int \mathbf{A} \cdot d\mathbf{F} = \int_0^3 dz \int_0^{3-z} dy \; yz = \int_0^3 dz \; \frac{(3-z)^2 z}{2} = \frac{27}{8} .$$

12.2.7.6 Ex: Surface integrals

Calculate the integral over a closed surface
a. of the field $\mathbf{A} = \mathbf{r}$ over the cube $0 \le x \le 1$, $0 \le y \le 1$, $0 \le z \le 1$ e
b. of the field $\mathbf{A} = \rho \mathbf{E}_\rho$ over the radial surface of the cylinder $0 \le z \le 1$, $0 \le \rho \le 1$.

Solution: *a. Surface integral of the cube,*

$$\oint_{cube} \mathbf{r}\cdot d\mathbf{S} = \oint_{cube} \begin{pmatrix} x \\ y \\ z \end{pmatrix} \begin{pmatrix} dS_x \\ dS_y \\ dS_z \end{pmatrix} = \int_0^1 xdydz\Big|_{x=0}^{x=1} + \int_0^1 ydzdx\Big|_{x=0}^{x=1} + \int_0^1 zdxdy\Big|_{x=0}^{x=1}$$
$$= 3\int_0^1 1dy \int_0^1 1dz = 3 \ .$$

b. Parametrization of the cylinder with radius $\rho = R$

$$\mathbf{F} = \left\{ \mathbf{r} = \begin{pmatrix} R\cos\phi \\ R\sin\phi \\ z \end{pmatrix} \right\} \quad , \quad z = [0,1] \quad , \quad \phi = [0, 2\pi] \ .$$

Two linearly independent vectors in directions tangential to the surface are,

$$d\mathbf{F}_z = \frac{\partial \mathbf{r}}{\partial z} dz = \hat{\mathbf{e}}_z dz \qquad \textit{and} \qquad d\mathbf{F}_\phi = \frac{\partial \mathbf{r}}{\partial \phi} d\phi = R\hat{\mathbf{e}}_\phi d\phi \ .$$

With this the area element becomes,

$$d\mathbf{F} = d\mathbf{F}_\phi \times d\mathbf{S}_z = R\hat{\mathbf{e}}_\phi d\phi \times \hat{\mathbf{e}}_z dz = R\hat{\mathbf{e}}_\rho d\phi dz \ .$$

The surface integral of the cylinder is now,

$$\oint_{cylinder} \rho\hat{\mathbf{e}}_\rho d\mathbf{S} = \oint_{cylinder} \rho\hat{\mathbf{e}}_\rho R\hat{\mathbf{e}}_\rho d\phi dz = 2\pi R^2 = 2\pi \ .$$

Alternatively, we can express the divergence in cylindrical coordinates,

$$\nabla\mathbf{v} = \frac{1}{\rho}\frac{\partial}{\partial\rho}(\rho v_\rho) + \frac{1}{\rho}\frac{\partial}{\partial\phi} v_\phi + \frac{\partial}{\partial z} v_z$$

and use Gauß's theorem,

$$\oint_{cylinder} \rho\hat{\mathbf{e}}_\rho d\mathbf{F} = \int \nabla(\rho\hat{\mathbf{e}}_\rho) dV = \int \frac{1}{\rho}\frac{\partial}{\partial\rho}(\rho\rho) d\phi\rho d\rho dz = \int 2\rho d\phi d\rho dz = 2\pi \int 2\rho d\rho = 2\pi \ .$$

12.2.7.7 Ex: Surface integrals

Calculate for the vector field $\mathbf{A}(\mathbf{r}) = c\mathbf{r}$ with c =constant the surface integral

$$I = \int_F \mathbf{A}(\mathbf{r}) \times d\mathbf{S}$$

a. over the surface of a sphere (radius R, center in the origin of coordinates)
b. over the surface of a cylinder (radius R, length L).

Solution: *a. To the surface of the sphere holds* $d\mathbf{F} = R^2 \sin\theta d\theta d\phi \mathbf{E}_r$. *Also, holds* $\mathbf{A} = c\mathbf{r}$ *and hence* $\mathbf{A} \times d\mathbf{F} \sim \mathbf{E}_r \times \mathbf{E}_r = 0$. *Thus,* $I = 0$.
b. For the radial surface of the cylinder $d\mathbf{F} = Rd\varphi dz\mathbf{E}_\rho$. *For the axial surfaces,*

$$F_\pm = \{\mathbf{r} = (\rho\cos\varphi, \rho\sin\varphi, \pm L/2), \text{ where } 0 \le \rho \le R, \text{ and } 0 \le \varphi \le 2\pi\} \ .$$

So here we have,

$$\begin{aligned} d\mathbf{F} &= \left(\frac{\partial \mathbf{r}}{\partial \rho} \times \frac{\partial \mathbf{r}}{\partial \varphi}\right) d\rho d\varphi \\ &= (\cos\varphi, \sin\varphi, 0) \times (-\rho\sin\varphi, \rho\cos\varphi, 0) d\rho d\varphi \\ &= \rho d\rho d\phi \mathbf{E}_z \end{aligned}$$

Following a general convention the normal vector of closed surfaces $d\mathbf{F}$ *points outside. We get,*

$$\begin{aligned} I &= \int_F \mathbf{A} \times d\mathbf{F} = c \int_F (\rho\mathbf{E}_\rho + z\mathbf{E}_z) \times d\mathbf{F} \\ &= c \int_{S_{rad}} Rd\varphi dz(\rho\mathbf{E}_\rho + z\mathbf{E}_z) \times \mathbf{E}_\rho + c \int_{S_{ax}+L/2} d\rho d\varphi\rho(\rho\mathbf{E}_\rho + z\mathbf{E}_z) \times \mathbf{E}_z \\ &\quad - c \int_{S_{ax}-L/2} d\rho d\varphi\rho(\rho\mathbf{E}_\rho + z\mathbf{E}_z) \times \mathbf{E}_z \\ &= cR \int_0^{2\pi} d\varphi \int_{-L/2}^{L/2} dz z\mathbf{E}_\varphi + c \int_0^R d\rho \int_0^{2\pi} d\varphi\rho^2(-\mathbf{E}_\varphi) - c \int_0^R d\rho \int_0^{2\pi} d\varphi\rho^2(-\mathbf{E}_\varphi) \ . \end{aligned}$$

Only that now,

$$\int_0^{2\pi} d\varphi \mathbf{E}_\varphi = \int_0^{2\pi} d\varphi(-\sin\varphi, \cos\varphi, 0) = 0 \ .$$

So here we also get, $I = 0$.

12.2.7.8 Ex: Surface integrals

Prove the relationship:

$$t_{ij} \equiv \int_{O(a)} d\mathbf{f} x_i x_j = \frac{4\pi}{3} a^4 \delta_{ij} \ ,$$

where $i, j = 1, 2, 3$, $x_1 = x$, $x_2 = y$, $x_3 = z$, and the integral has to be calculated on the surface of a sphere with radius a.

Solution: *The area element on the sphere's surface is* $d\mathbf{f} = a^2 d\phi d\theta \sin\theta$. *Also, on the surface of the sphere we have* $x = a\sin\theta\cos\phi$, $y = a\sin\theta\sin\phi$ *and* $z = a\cos\theta$. *With*

$$\int_0^{2\pi} d\phi \sin\phi = \int_0^{2\pi} d\phi \cos\phi = \int_0^{2\pi} d\phi \sin\phi\cos\phi = 0 \ ,$$

we get immediately that the integral zeroes for $i \neq j$. *For* $i = j = 1$ *we obtain,*

$$\begin{aligned} t_{11} &= a^4 \int_0^{2\pi} d\phi \cos^2\phi \int_0^{\pi} d\theta \sin^3\theta \\ &= \pi a^4 \int_{-1}^{+1} dx(1-x^2) = \frac{4\pi}{3}a^4 \ . \end{aligned}$$

In the same way for $i = j = 2$,

$$t_{22} = a^4 \int_0^{2\pi} d\phi \sin^2\phi \int_0^{\pi} d\theta \sin^3\theta = \frac{4\pi}{3}a^4 \ .$$

Finally, for $i = j = 3$

$$t_{33} = 2\pi a^4 \int_{-1}^{+1} dx x^2 = \frac{4\pi}{3}a^4 \ .$$

This was the statement.

12.2.7.9 Ex: Volume integrals

Calculate the volume integral of the function $\Phi = z^2$ over the tetrahedron with the corners in $(0,0,0)$, $(1,0,0)$, $(0,1,0)$, and $(0,0,1)$.

Solution:

12.2.7.10 Ex: Fundamental theorem for gradients

What is the energy gain within the potential $\Phi(\mathbf{r}) = \Phi_0 \frac{\sin kr}{kr}$ along a path keeping a constant distance from the origin.

Solution: *Obviously it's 0.*

12.2.7.11 Ex: Stokes integral theorem

Calculate for following field,

$$\mathbf{A}(\mathbf{r}) = \begin{pmatrix} yz \\ azx \\ xy \end{pmatrix}$$

using Stokes' law the path integral $\oint \mathbf{A} \cdot \mathbf{r}$ for an integration along a circle with radius R around the z-axis at the position $z = h$.

Solution: *The path integral is,*

$$\int_{\partial S} \mathbf{A} \cdot \mathbf{r} = \int_S (\nabla \times \mathbf{A}) \cdot d\mathbf{F} = \int_0^{2\pi} \int_0^R \rho \begin{pmatrix} \partial_y xy - \partial_z axz \\ \partial_z yz - \partial_x xy \\ \partial_x axz - \partial_y yz \end{pmatrix} \hat{\mathbf{e}}_z d\rho d\varphi$$

$$= \int_0^{2\pi} \int_0^R \rho(az - z) d\rho d\varphi = \int_0^{2\pi} (a-1)(\tfrac{1}{2} z R^2) d\varphi = 2\pi(a-1)\tfrac{1}{2} z R^2 \underbrace{=}_{h=z} \tfrac{a-1}{\pi} h R^2 \ .$$

12.2.7.12 Ex: Stokes integral theorem

Calculate the integral $\oint_{\mathcal{C}} x(\hat{\mathbf{e}}_x + \hat{\mathbf{e}}_y)\ d\mathbf{r}$, where $\mathcal{C}$ be the unit circle in the x-y-plane.

Solution: *We have,*

$$\oint_{circumference} x(\hat{\mathbf{e}}_x + \hat{\mathbf{e}}_y)\ d\mathbf{r} = \int_{\mathcal{S}} rot\ x(\hat{\mathbf{e}}_x + \hat{\mathbf{e}}_y)\ d\mathbf{S} = \int_{\mathcal{C}} \hat{\mathbf{e}}_z d\mathbf{S} = \pi \ .$$

12.2.7.13 Ex: Gauß integral theorem

Calculate the flux of the vector field $\mathbf{A}(\mathbf{r}) = \mathbf{r}$ through a sphere with radius R
a. by the surface integral and
b. with the help of Gauß's theorem for the volume integral over the divergence.

Solution: *The surface integral is,*

$$\oint_{\partial V} \mathbf{A} \cdot d\mathbf{F} = \oint_{\partial V} \mathbf{r} \left(\hat{\mathbf{e}}_r - \frac{1}{r} \frac{\partial r}{\partial \theta} \hat{\mathbf{e}}_\theta - \frac{1}{r} \frac{1}{\sin\theta} \frac{\partial r}{\partial \phi} \hat{\mathbf{e}}_\phi \right) r^2 \sin\theta d\theta d\phi = \oint r^3 \sin\theta d\theta d\phi = 4\pi R^3 \ .$$

The volume integral is,

$$\int_V \nabla \cdot \mathbf{A} dV = \int_V 3 dV = 4\pi R^3 \ .$$

12.2.7.14 Ex: Gauß integral theorem

Let F be the surface of an arbitrary volume V. Determine for $\mathbf{A}(x_1, x_2, x_3) = (ax_1, bx_2, cx_3)$ the validity of the relationship,

$$\oint_F d\mathbf{F} \cdot \mathbf{A} = (a+b+c)V \ .$$

Solution: *Vale, pois de* $\nabla \cdot \mathbf{A} = a+b+c$ *segue* $\oint_F d\mathbf{F} \cdot \mathbf{A} = \int_V \nabla \cdot \mathbf{A} = (a+b+c)V$.

12.2.7.15 Ex: Gauß integral theorem

Be a a scalar field and $\mathbf{B}$ a vector field. Show,

$$\int_V d^3\mathbf{r}\ \mathbf{B} \cdot \nabla a = \int_{O(V)} a\mathbf{B}\ \cdot\ d\mathbf{F} - \int_V d^3\mathbf{r}\ a\nabla \cdot \mathbf{B} \ .$$

Solution: *Using the Gauß theorem and the chain rule we obtain for an arbitrary volume* V *and its surface* $O(V)$*:*

$$\int_{O(V)} a\mathbf{B}\ \cdot d\mathbf{F} = \int_V d^3\mathbf{r}\ \nabla \cdot\ (a\mathbf{B}) = \int_V (\mathbf{B} \cdot \nabla a + a\nabla \cdot \mathbf{B})\, d^3\mathbf{r}$$

From this follows immediately,

$$\int_V d^3\mathbf{r}\ \mathbf{B} \cdot \nabla a = \int_{O(V)} a\mathbf{B} \cdot d\mathbf{F} - \int_V d^3\mathbf{r}\ a\nabla \cdot \mathbf{B} \ .$$

12.2.7.16 Ex: Gauß integral theorem

Calculate the integral $\oint_{\mathcal{C}} x(\hat{\mathbf{e}}_x + \hat{\mathbf{e}}_y) \cdot d\mathbf{r}$ about a unitary circular path $\mathcal{C}$ along the equator and the integral $\oint_{\mathcal{F}} x(\hat{\mathbf{e}}_x + \hat{\mathbf{e}}_y) \cdot d\mathbf{F}$, where $\mathcal{F}$ be the surface of a unit sphere.

Solution: *Using Gauß law,*

$$\oint_{surface} x(\hat{\mathbf{e}}_x + \hat{\mathbf{e}}_y)\ d\mathbf{F} = \int_{volume} div\ x(\hat{\mathbf{e}}_x + \hat{\mathbf{e}}_y)\ dV = \int_{surface} dV = \frac{4\pi}{3} \ .$$

Using Stokes Law,

$$\oint_{circumference} x(\hat{\mathbf{e}}_x + \hat{\mathbf{e}}_y)\ d\mathbf{r} = \int_{area} rot\ x(\hat{\mathbf{e}}_x + \hat{\mathbf{e}}_y)\ d\mathbf{F} = \int_F \hat{\mathbf{e}}_z d\mathbf{F} = \pi \ .$$

12.3 Curvilinear coordinates

The most commonly used coordinate systems are Cartesian, cylindrical and spherical. Cylindrical coordinates are expressed in terms of Cartesian coordinates by,

$$\begin{pmatrix} x \\ y \\ z \end{pmatrix} = \begin{pmatrix} \rho\cos\phi \\ \rho\sin\phi \\ z \end{pmatrix} \quad . \tag{12.43}$$

And spherical coordinates are expressed in terms of Cartesian coordinates by,

$$\begin{pmatrix} x \\ y \\ z \end{pmatrix} = \begin{pmatrix} r\sin\theta\cos\phi \\ r\sin\theta\sin\phi \\ r\cos\theta \end{pmatrix} \quad . \tag{12.44}$$

The task now is to express the differential elements (that is, line, surface and volume elements), as well as differential operators (that is, the gradient, divergent and rotation) and the Laplacian in term of curvilinear coordinates.

Let us first consider the general case. The transformation from a Cartesian coordinate system (x, y, z) into a general, curvilinear system (u, v, w) is given by,

$$\mathbf{r} \equiv \begin{pmatrix} x(u,v,w) \\ y(u,v,w) \\ z(u,v,w) \end{pmatrix} \quad . \tag{12.45}$$

The change $d_u\mathbf{r}$ resulting from a small variation du is then $d_u\mathbf{r} = \frac{\partial \mathbf{r}}{\partial u}du$ and occurs in the direction of the new unit vector $\hat{\mathbf{e}}_u$. The unit vectors of the new system, therefore, can be written as,

$$\hat{\mathbf{e}}_u = U(u,v,w)\frac{\partial \mathbf{r}}{\partial u} \quad , \quad \hat{\mathbf{e}}_v = V(u,v,w)\frac{\partial \mathbf{r}}{\partial v} \quad , \quad \hat{\mathbf{e}}_w = W(u,v,w)\frac{\partial \mathbf{r}}{\partial w} \ , \tag{12.46}$$

where

$$U = \left|\frac{\partial \mathbf{r}}{\partial u}\right|^{-1} \quad , \quad V = \left|\frac{\partial \mathbf{r}}{\partial v}\right|^{-1} \quad , \quad W = \left|\frac{\partial \mathbf{r}}{\partial w}\right|^{-1} \quad . \tag{12.47}$$

In the Excs. 12.3.8.1 we study transformations into cylindrical and spherical coordinates.

12.3.1 Differential elements in curvilinear coordinates

In the following we restrict ourselves to orthogonal coordinates, where the unit vectors are perpendicular. In this case, the total differential $d\mathbf{r}$ has the form,

$$d\mathbf{r} = \frac{\partial \mathbf{r}}{\partial u}du + \frac{\partial \mathbf{r}}{\partial v}dv + \frac{\partial \mathbf{r}}{\partial w}dw = \hat{\mathbf{e}}_u\frac{du}{U} + \hat{\mathbf{e}}_v\frac{dv}{V} + \hat{\mathbf{e}}_w\frac{dw}{W} \ , \tag{12.48}$$

and has the length,

$$|d\mathbf{r}|^2 = \left(\frac{du}{U}\right)^2 + \left(\frac{dv}{V}\right)^2 + \left(\frac{dw}{W}\right)^2 \ . \tag{12.49}$$

The volume element is,

$$d\tau = ds_u ds_v ds_w \ . \tag{12.50}$$

12.3.2 Gradient in curvilinear coordinates

We can now express the gradient of a scalar field Φ in orthogonal curvilinear coordinates,

$$\text{grad } \Phi = \nabla\Phi = f_u \hat{\mathbf{e}}_u + f_v \hat{\mathbf{e}}_v + f_w \hat{\mathbf{e}}_w \ , \tag{12.51}$$

where the f_i are functions which have yet to be determined. To this end we compare the coefficients of the expressions,

$$d\Phi = \frac{\partial\Phi}{\partial u}du + \frac{\partial\Phi}{\partial v}dv + \frac{\partial\Phi}{\partial w}dw \ , \tag{12.52}$$

and, inserting (12.48) and (12.51),

$$d\Phi = d\mathbf{r}\cdot\nabla\Phi = \frac{f_u}{U}du + \frac{f_v}{V}dv + \frac{f_w}{W}dw \ . \tag{12.53}$$

We obtain,

$$\nabla\Phi = \left(U\frac{\partial\Phi}{\partial u}\right)\hat{\mathbf{e}}_u + \left(V\frac{\partial\Phi}{\partial v}\right)\hat{\mathbf{e}}_v + \left(W\frac{\partial\Phi}{\partial w}\right)\hat{\mathbf{e}}_w \ . \tag{12.54}$$

12.3.3 Divergence in curvilinear coordinates

Now we will show how to express the divergence of a vector field $\mathbf{A}$ in orthogonal curvilinear coordinates,

$$\text{div } \mathbf{A} = \nabla\cdot\mathbf{A} \ . \tag{12.55}$$

The derivation is a bit complicated. We begin by expressing the unit vectors $\hat{\mathbf{e}}_u$, $\hat{\mathbf{e}}_v$, and $\hat{\mathbf{e}}_w$ by the gradients ∇u, ∇v, and ∇w, using the expression for the gradient (12.54),

$$\nabla u = U\hat{\mathbf{e}}_u \quad , \quad \nabla v = V\hat{\mathbf{e}}_v \quad , \quad \nabla w = W\hat{\mathbf{e}}_w \ . \tag{12.56}$$

We now express each unit vector as the vector product of two of these gradients,

$$\begin{aligned} \nabla u\times\nabla v &= UV\ \hat{\mathbf{e}}_u\times\hat{\mathbf{e}}_v = UV\hat{\mathbf{e}}_w \\ \nabla v\times\nabla w &= VW\ \hat{\mathbf{e}}_v\times\hat{\mathbf{e}}_w = VW\hat{\mathbf{e}}_u \\ \nabla w\times\nabla u &= WU\ \hat{\mathbf{e}}_w\times\hat{\mathbf{e}}_u = WU\hat{\mathbf{e}}_v \ . \end{aligned} \tag{12.57}$$

After that we write $\mathbf{A} = a_u\hat{\mathbf{e}}_u + a_v\hat{\mathbf{e}}_v + a_w\hat{\mathbf{e}}_w$ and start considering the first term of the divergence:

$$\begin{aligned}
&\nabla\cdot(a_u\hat{\mathbf{e}}_u) = \nabla\cdot\left(\frac{a_u}{VW}\nabla v\times\nabla w\right) \qquad (12.58)\\
&= (\nabla v\times\nabla w)\cdot\nabla\left(\frac{a_u}{VW}\right) + \frac{a_u}{VW}\nabla\cdot(\nabla v\times\nabla w) \quad \text{using} \quad \nabla\cdot(\alpha\mathbf{A}) = \mathbf{A}\cdot(\nabla\alpha) + \alpha(\nabla\cdot\mathbf{A})\\
&= VW\hat{\mathbf{e}}_u\cdot\left[\hat{\mathbf{e}}_u U\frac{\partial}{\partial u}\left(\frac{a_u}{VW}\right) + \hat{\mathbf{e}}_v V\frac{\partial}{\partial v}\left(\frac{a_v}{VW}\right) + \hat{\mathbf{e}}_w W\frac{\partial}{\partial w}\left(\frac{a_w}{VW}\right)\right]\\
&\quad + \frac{a_u}{VW}\left[\nabla w\cdot(\nabla\times\nabla v) - \nabla v\cdot(\nabla\times\nabla w)\right] \quad \text{using} \quad \nabla\cdot(\mathbf{A}\times\mathbf{B}) = \mathbf{B}\cdot(\nabla\times\mathbf{A}) - \mathbf{A}\cdot(\nabla\times\mathbf{B})\\
&= UVW\frac{\partial}{\partial u}\left(\frac{a_u}{VW}\right) \quad \text{using} \quad \nabla\times(\nabla\alpha) = 0\ .
\end{aligned}$$

Similarly we can show,

$$\nabla\cdot(a_v\hat{\mathbf{e}}_v) = UVW\frac{\partial}{\partial v}\left(\frac{a_v}{UW}\right) \qquad \text{and} \qquad \nabla\cdot(a_w\hat{\mathbf{e}}_w) = UVW\frac{\partial}{\partial w}\left(\frac{a_w}{UV}\right)\ . \qquad (12.59)$$

With this we finally get,

$$\nabla\cdot\mathbf{A} = UVW\left[\frac{\partial}{\partial u}\left(\frac{a_u}{VW}\right) + \frac{\partial}{\partial v}\left(\frac{a_v}{UW}\right) + \frac{\partial}{\partial w}\left(\frac{a_w}{UV}\right)\right]\ . \qquad (12.60)$$

12.3.4 Rotation in curvilinear coordinates

Now we will show how to express the rotation of a vector field $\mathbf{A}$ in orthogonal curvilinear coordinates,

$$\text{rot}\ \mathbf{A} = \nabla\times\mathbf{A}\ . \qquad (12.61)$$

We write again, $\mathbf{A} = a_u\hat{\mathbf{e}}_u + a_v\hat{\mathbf{e}}_v + a_w\hat{\mathbf{e}}_w$ and start considering the first term of the rotation:

$$\begin{aligned}
&\nabla\times(a_u\hat{\mathbf{e}}_u) = \nabla\times\left(\frac{a_u}{U}\nabla u\right) \quad \text{using} \quad (12.56) \qquad (12.62)\\
&= \left(\nabla\frac{a_u}{U}\right)\times\nabla u + \frac{a_u}{U}(\nabla\times\nabla u) \quad \text{using} \quad \nabla\times(\alpha\mathbf{A}) = (\nabla\alpha)\times\mathbf{A} + \alpha(\nabla\times\mathbf{A})\\
&= U\left(\nabla\frac{a_u}{U}\right)\times\hat{\mathbf{e}}_u \quad \text{and} \quad \nabla\times(\nabla\alpha) = 0 \quad \text{using} \quad (12.56)\\
&= U\left[\hat{\mathbf{e}}_u U\frac{\partial}{\partial u}\left(\frac{a_u}{U}\right) + \hat{\mathbf{e}}_v V\frac{\partial}{\partial v}\left(\frac{a_u}{U}\right) + \hat{\mathbf{e}}_w W\frac{\partial}{\partial w}\left(\frac{a_u}{U}\right)\right]\times\hat{\mathbf{e}}_u\\
&= U\left[\hat{\mathbf{e}}_v W\frac{\partial}{\partial w}\left(\frac{a_u}{U}\right) - \hat{\mathbf{e}}_w V\frac{\partial}{\partial v}\left(\frac{a_u}{U}\right)\right]\\
&= UVW\left[\hat{\mathbf{e}}_v\frac{1}{V}\frac{\partial}{\partial w}\left(\frac{a_u}{U}\right) - \hat{\mathbf{e}}_w\frac{1}{W}\frac{\partial}{\partial v}\left(\frac{a_u}{U}\right)\right]\ .
\end{aligned}$$

Similarly we can show,

$$\begin{aligned}
\nabla\times(a_v\hat{\mathbf{e}}_v) &= UVW\left[\hat{\mathbf{e}}_w\frac{1}{W}\frac{\partial}{\partial u}\left(\frac{a_v}{V}\right) - \hat{\mathbf{e}}_u\frac{1}{U}\frac{\partial}{\partial w}\left(\frac{a_v}{V}\right)\right] \qquad (12.63)\\
\nabla\times(a_w\hat{\mathbf{e}}_w) &= UVW\left[\hat{\mathbf{e}}_u\frac{1}{U}\frac{\partial}{\partial v}\left(\frac{a_w}{W}\right) - \hat{\mathbf{e}}_v\frac{1}{V}\frac{\partial}{\partial u}\left(\frac{a_w}{W}\right)\right]\ .
\end{aligned}$$

With this we finally obtain,

$$\nabla \times \mathbf{A} = \hat{\mathbf{e}}_u VW \left[\frac{\partial}{\partial v} \left(\frac{a_w}{W} \right) - \frac{\partial}{\partial w} \left(\frac{a_v}{V} \right) \right] + \hat{\mathbf{e}}_v UW \left[\frac{\partial}{\partial w} \left(\frac{a_u}{U} \right) - \frac{\partial}{\partial u} \left(\frac{a_w}{w} \right) \right] + \hat{\mathbf{e}}_w UV \left[\frac{\partial}{\partial u} \left(\frac{a_v}{V} \right) - \frac{\partial}{\partial v} \left(\frac{a_u}{U} \right) \right] , \tag{12.64}$$

or, written as a determinant,

$$\nabla \times \mathbf{A} = UVW \det \begin{pmatrix} \frac{\hat{\mathbf{e}}_u}{U} & \frac{\hat{\mathbf{e}}_v}{V} & \frac{\hat{\mathbf{e}}_w}{W} \\ \frac{\partial}{\partial u} & \frac{\partial}{\partial v} & \frac{\partial}{\partial w} \\ \frac{a_u}{U} & \frac{a_v}{V} & \frac{a_w}{W} \end{pmatrix} . \tag{12.65}$$

12.3.5 Cylindrical coordinates

Let us now identify the general coordinates u, v, and w with the cylindrical coordinates ρ, θ, and ϕ defined in Eq. (12.43). In Exc. 12.3.8.2 we calculate for the line element,

$$d\mathbf{r} = d\rho \hat{\mathbf{e}}_\rho + \rho d\phi e_\phi + dz \hat{\mathbf{e}}_z , \tag{12.66}$$

the distance element,

$$|d\mathbf{r}|^2 = (d\rho)^2 + (\rho d\phi)^2 + (dz)^2 , \tag{12.67}$$

the surface element given by $z = z(\rho, \phi)$,

$$d\mathbf{s} = \left(-\frac{\partial z}{\partial \rho} \hat{\mathbf{e}}_\rho - \frac{1}{\rho} \frac{\partial z}{\partial \phi} \hat{\mathbf{e}}_\phi + \hat{\mathbf{e}}_z \right) \rho d\rho d\phi , \tag{12.68}$$

and the volume element,

$$d\tau = r dz \phi dr . \tag{12.69}$$

In the Excs. 12.3.8.3 to 12.3.8.5 we calculate, respectively, the gradient,

$$\nabla \Phi = \hat{\mathbf{e}}_\rho \frac{\partial \Phi}{\partial \rho} + \hat{\mathbf{e}}_\phi \frac{1}{\rho} \frac{\partial \Phi}{\partial \phi} + \hat{\mathbf{e}}_z \frac{\partial \Phi}{\partial z} , \tag{12.70}$$

the divergence,

$$\nabla \cdot \mathbf{A} = \frac{1}{\rho} \frac{\partial}{\partial \rho} [\rho \, a_\rho] + \frac{1}{\rho} \frac{\partial}{\partial \phi} [a_\phi] + \frac{\partial}{\partial z} [a_z] , \tag{12.71}$$

the rotation,

$$\nabla \times \mathbf{A} = \hat{\mathbf{e}}_\rho \frac{1}{\rho} \left[\frac{\partial a_z}{\partial \phi} - \rho \frac{\partial a_\phi}{\partial z} \right] + \hat{\mathbf{e}}_\phi \left[\frac{\partial a_\rho}{\partial z} - \frac{\partial a_z}{\partial \rho} \right] + \hat{\mathbf{e}}_z \frac{1}{\rho} \left[\frac{\partial}{\partial \rho} (\rho a_\phi) - \frac{\partial a_\rho}{\partial \phi} \right] \tag{12.72}$$

and the Laplace operator,

$$\Delta \Phi \equiv \nabla \cdot (\nabla \Phi) = \frac{1}{\rho} \frac{\partial}{\partial \rho} \left(\rho \frac{\partial \Phi}{\partial \rho} \right) + \frac{1}{\rho^2} \frac{\partial^2 \Phi}{\partial \phi^2} + \frac{\partial^2 \Phi}{\partial z^2} . \tag{12.73}$$

in cylindrical coordinates.

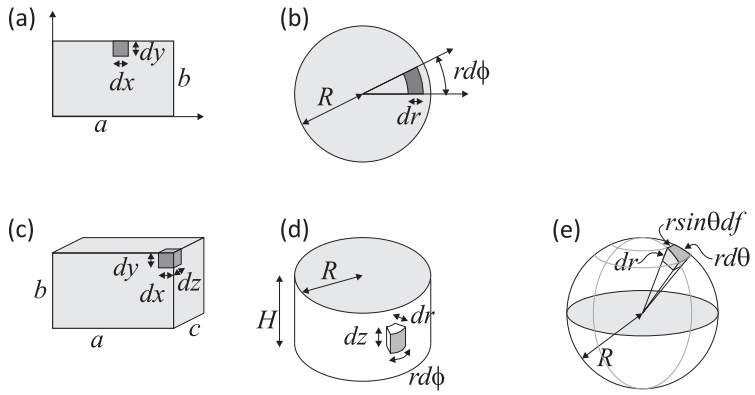

Figure 12.7: Illustration of Cartesian, polar, cylindrical and spherical coordinates.

12.3.6 Spherical coordinates

Let us now identify the general coordinates u, v, and w with the spherical coordinates r, θ, and ϕ defined in Eq. (12.44). In Exc. 12.3.8.2 we calculate for the line element,

$$d\mathbf{r} = dr\hat{\mathbf{e}}_r + rd\theta e_\theta + r\sin\theta d\phi\hat{\mathbf{e}}_\phi \ , \tag{12.74}$$

the distance element,

$$|d\mathbf{r}|^2 = (dr)^2 + (rd\theta)^2 + (r\sin\theta d\phi)^2 \ , \tag{12.75}$$

the surface element given by $r = r(\theta, \phi)$,

$$d\mathbf{s} = \left(\hat{\mathbf{e}}_r - \frac{1}{r}\frac{\partial r}{\partial\theta}\hat{\mathbf{e}}_\theta - \frac{1}{r}\frac{1}{\sin\theta}\frac{\partial r}{\partial\phi}\hat{\mathbf{e}}_\phi\right) r^2\sin\theta d\theta d\phi \ , \tag{12.76}$$

and the volume element,

$$d\tau = ds_u ds_v ds_w = r^2\sin\theta d\theta d\phi dr \ . \tag{12.77}$$

In the Excs. 12.3.8.3 to 12.3.8.5 we calculate, respectively, the gradient,

$$\nabla\Phi = \hat{\mathbf{e}}_r\ \frac{\partial\Phi}{\partial r} + \hat{\mathbf{e}}_\theta\ \frac{1}{r}\ \frac{\partial\Phi}{\partial\theta} + \hat{\mathbf{e}}_\phi\ \frac{1}{r\sin\phi}\ \frac{\partial\Phi}{\partial\phi} \ , \tag{12.78}$$

the divergence,

$$\nabla\cdot\mathbf{A} = \frac{1}{r^2}\frac{\partial}{\partial r}[r^2 a_r] + \frac{1}{r\sin\theta}\frac{\partial}{\partial\theta}[\sin\theta\ a_\theta] + \frac{1}{r\sin\theta}\frac{\partial}{\partial\phi}[a_\phi] \ , \tag{12.79}$$

the rotation,

$$\nabla\times\mathbf{A} = \hat{\mathbf{e}}_r\ \frac{1}{r\sin\theta}\left[\frac{\partial}{\partial\theta}(\sin\theta a_\phi) - \frac{\partial}{\partial\phi}(a_\theta)\right] + \hat{\mathbf{e}}_\theta\ \frac{1}{r\sin\theta}\left[\frac{\partial}{\partial\phi}(a_r) - \sin\theta\frac{\partial}{\partial r}(ra_\phi)\right] + \hat{\mathbf{e}}_\phi\ \frac{1}{r}\left[\frac{\partial}{\partial r}(ra_\theta) - \frac{\partial}{\partial\theta}(a_r)\right] \tag{12.80}$$

and the Laplace operator,

$$\Delta\Phi \equiv \nabla\cdot(\nabla\Phi) = \frac{1}{r^2}\frac{\partial}{\partial r}\left(r^2\frac{\partial\Phi}{\partial r}\right) + \frac{1}{r^2\sin\theta}\frac{\partial}{\partial\theta}\left(\sin\theta\frac{\partial\Phi}{\partial\theta}\right) + \frac{1}{r^2\sin^2\theta}\frac{\partial^2\Phi}{\partial\phi^2}\ , \quad (12.81)$$

in spherical coordinates. We note that the radial part of the Laplace operator can also be written,

$$\frac{1}{r}\frac{\partial^2}{\partial r^2}(r\Phi)\ . \quad (12.82)$$

12.3.7 Differential operators for tensor fields

Until now, we restricted to scalar and vector fields, that is spatially dependent physical quantities such as the temperature or the magnetic field distribution in a room. Some quantities, however, need to be given as matrices or even higher-dimensional objects, for example, gravity gradients or the susceptibility of a crystal. These objects are called tensors. With the definition,

$$\hat{\mathbf{e}}_k \otimes \hat{\mathbf{e}}_l = \hat{\mathbf{e}}_k\hat{\mathbf{e}}_l^\intercal \quad (12.83)$$

we can express a scalar, vector, and second-order tensor as,

$$\Phi \quad , \quad \mathbf{A} = A_k\hat{\mathbf{e}}_k \quad , \quad \mathcal{G} = G_{kl}\hat{\mathbf{e}}_k\otimes\hat{\mathbf{e}}_l\ . \quad (12.84)$$

For instance, in Cartesian coordinates a second-order tensor reads,

$$\mathcal{G} = G_{xx}\hat{\mathbf{e}}_x\hat{\mathbf{e}}_x^\intercal + G_{xy}\hat{\mathbf{e}}_x\hat{\mathbf{e}}_y^\intercal + G_{yx}\hat{\mathbf{e}}_y\hat{\mathbf{e}}_x^\intercal + G_{yy}\hat{\mathbf{e}}_y\hat{\mathbf{e}}_y^\intercal = \begin{pmatrix} G_{xx} & G_{xy}\\ G_{xy} & G_{yy}\end{pmatrix}\ . \quad (12.85)$$

If a tensor $\mathcal{T} = \Phi(\mathbf{r}), \mathbf{A}(\mathbf{r}), \mathcal{G}(\mathbf{r})$ varies in space, we can apply differential operators to it. The gradient $\nabla\mathcal{T}(\mathbf{r})$ of a tensor field in the direction of an arbitrary constant vector $\mathbf{x}$ is defined as,

$$\boxed{\mathbf{x}\cdot\nabla\mathcal{T} = \lim_{\alpha\to 0}\frac{d}{d\alpha}\mathcal{T}(\mathbf{r}+\alpha\mathbf{x})}\ . \quad (12.86)$$

The gradient of a tensor field of order n is a tensor field of order $n+1$. In Cartesian coordinates, $\mathbf{x} = x\hat{\mathbf{e}}_x + y\hat{\mathbf{e}}_y + z\hat{\mathbf{e}}_z$,

$$\nabla\Phi = \hat{\mathbf{e}}_k\frac{\partial}{\partial x_k}\Phi \equiv \Phi_{,k}\hat{\mathbf{e}}_k = \begin{pmatrix}\partial_x\Phi\\ \partial_y\Phi\end{pmatrix} \quad (12.87)$$

$$\nabla\mathbf{A} = \hat{\mathbf{e}}_k\frac{\partial}{\partial x_k}\otimes A_l\hat{\mathbf{e}}_l \equiv A_{,kl}\hat{\mathbf{e}}_k\otimes\hat{\mathbf{e}}_l = \begin{pmatrix}\partial_x A_x & \partial_y A_x\\ \partial_x A_y & \partial_y A_y\end{pmatrix}$$

$$\nabla\mathcal{G} = \hat{\mathbf{e}}_k\frac{\partial}{\partial x_k}\otimes G_{lm}\hat{\mathbf{e}}_l\otimes\hat{\mathbf{e}}_m \equiv G_{,klm}\hat{\mathbf{e}}_k\otimes\hat{\mathbf{e}}_l\otimes\hat{\mathbf{e}}_m = \begin{pmatrix}\partial_x\\ \partial_y\end{pmatrix}\begin{pmatrix}G_{xx} & G_{xy}\\ G_{xy} & G_{yy}\end{pmatrix}\ .$$

The divergence of a tensor field $\mathcal{T}(\mathbf{r})$ is defined using the recursive relation,

$$\begin{aligned}(\nabla\cdot\mathbf{A})\cdot\mathbf{x} &= \text{Tr}\,(\nabla\mathbf{A}) \\ (\nabla\cdot\mathcal{G})\cdot\mathbf{x} &= \nabla\cdot(\mathbf{x}\cdot\mathcal{G}^{\intercal})\ .\end{aligned} \tag{12.88}$$

In Cartesian coordinates the divergence is,

$$\begin{aligned}\nabla\cdot\mathbf{A} &= \hat{\mathbf{e}}_k\frac{\partial}{\partial x_k}\cdot A_l\hat{\mathbf{e}}_l = \frac{\partial A_k}{\partial x_k}\equiv A_{k,k} \\ \nabla\cdot\mathcal{G} &= \hat{\mathbf{e}}_k\frac{\partial}{\partial x_k}\cdot G_{lm}\hat{\mathbf{e}}_l\otimes\hat{\mathbf{e}}_m = \frac{\partial G_{lk}}{\partial x_k}\otimes\hat{\mathbf{e}}_l\equiv G_{lk,k}\hat{\mathbf{e}}_l\ .\end{aligned} \tag{12.89}$$

The curl of an order $n>1$ tensor field $\mathcal{T}(\mathbf{r})$ is also defined using the recursive relation,

$$\begin{aligned}(\nabla\times\mathbf{A})\cdot\mathbf{x} &= \nabla\cdot(\mathbf{A}\times\mathbf{c}) \\ (\nabla\times\mathcal{G})\cdot\mathbf{x} &= \nabla\times(\mathbf{x}\cdot\mathcal{G}^{\intercal})\ ,\end{aligned} \tag{12.90}$$

where c is an arbitrary constant vector. In Cartesian coordinates the divergence the rotation is,

$$\begin{aligned}\nabla\times\mathbf{A} &= \epsilon_{klm}\hat{\mathbf{e}}_k\partial_l A_m \\ \nabla\times\mathcal{G} &= \epsilon_{klm}\hat{\mathbf{e}}_m\otimes\hat{\mathbf{e}}_n\partial_k G_{nl}\ .\end{aligned} \tag{12.91}$$

12.3.8 Exercises

12.3.8.1 Ex: Spherical and cylindrical coordinates

a. Express the cylindrical coordinates ρ, φ, z in terms of the Cartesian ones x, y, z.
b. Express the spherical coordinates r, θ, φ in terms of the Cartesian ones x, y, z.

Solution: *a. We have,*

$$\begin{aligned}r &= \sqrt{x^2+y^2+z^2} \\ \varphi &= \arccos\frac{z}{r} \\ z &= z\ .\end{aligned}$$

b. We have,

$$\begin{aligned}r &= \sqrt{x^2+y^2+z^2} \\ \theta &= \arccos\frac{z}{r} = \arcsin\frac{\sqrt{x^2+y^2}}{r} \\ \varphi &= \arccos\frac{x}{r\sin\theta} = \arccos\frac{x}{\sqrt{x^2+y^2}}\ .\end{aligned}$$

12.3.8.2 Ex: Differential elements in curvilinear coordinates

We have seen in class that the transformation from a Cartesian coordinate system (x, y, z) to another curvilinear and orthogonal system (u, v, w) is given by $\mathbf{r} \equiv (x(u, v, w), y(u, v, w), z(u, v, w))$. Now consider the spherical polar coordinates $\mathbf{r} \equiv (x(r, \theta, \phi), y(r, \theta, \phi), z(r, \theta, \phi)$ defined in class.
a. Calculate the functions U_r, V_θ, W_ϕ defined by,

$$U_r = \left|\frac{\partial \mathbf{r}}{\partial r}\right|^{-1} \quad , \quad V_\theta = \left|\frac{\partial \mathbf{r}}{\partial \theta}\right|^{-1} \quad , \quad W_\phi = \left|\frac{\partial \mathbf{r}}{\partial \phi}\right|^{-1} \ .$$

b. Determine the Cartesian coordinates of the new unit vectors $\hat{\mathbf{e}}_r$, $\hat{\mathbf{e}}_\theta$, $\hat{\mathbf{e}}_\phi$, draw the position of these vectors at a point $\mathbf{r}_0$, and check the orthogonality of the unit vectors. Express the Cartesian unit vectors by the spherical ones.
c. Determine the total differential $d\mathbf{r}$, the line element $(ds)^2 = |d\mathbf{r}|^2$, and the volume element $d\tau = ds_u ds_v ds_w$ in terms of the new coordinates.
d. Repeat steps (a)-(c) for planar polar coordinates.

Solution: *a. We have,*

$$\begin{aligned}
\frac{\partial \mathbf{r}}{\partial r} &= \sin\theta\cos\phi\hat{\mathbf{e}}_x + \sin\theta\sin\phi\hat{\mathbf{e}}_y + \cos\theta\hat{\mathbf{e}}_z \\
\frac{\partial \mathbf{r}}{\partial \theta} &= r\cos\theta\cos\phi\hat{\mathbf{e}}_x + r\cos\theta\sin\phi\hat{\mathbf{e}}_y - r\sin\theta\hat{\mathbf{e}}_z \\
\frac{\partial \mathbf{r}}{\partial \phi} &= -r\sin\theta\sin\phi\hat{\mathbf{e}}_x + r\sin\theta\cos\phi\hat{\mathbf{e}}_y \ .
\end{aligned}$$

From this follows,

$$\begin{aligned}
\frac{1}{U_r} &= \left|\frac{\partial \mathbf{r}}{\partial r}\right| = \sqrt{\sin^2\theta(\cos^2\phi + \sin^2\phi) + \cos^2\theta} = 1 \\
\frac{1}{V_\theta} &= \left|\frac{\partial \mathbf{r}}{\partial \theta}\right| = r\sqrt{\cos^2\theta(\cos^2\phi + \sin^2\phi) + \sin^2\theta} = r \\
\frac{1}{W_\phi} &= \left|\frac{\partial \mathbf{r}}{\partial \phi}\right| = r\sqrt{\sin^2\theta(\cos^2\phi + \sin^2\phi)} = r\sin\theta \ .
\end{aligned}$$

So we have, $U_r = 1$, $V_\theta = \frac{1}{r}$ *and* $W_\phi = \frac{1}{r\sin\theta}$.
b. The unit vectors are,

$$\begin{aligned}
\hat{\mathbf{e}}_r &= U_r\frac{\partial \mathbf{r}}{\partial r} = \hat{\mathbf{e}}_x\sin\theta\cos\phi + \hat{\mathbf{e}}_y\sin\theta\sin\phi + \hat{\mathbf{e}}_z\cos\theta \\
\hat{\mathbf{e}}_\theta &= V_\theta\frac{\partial \mathbf{r}}{\partial \theta} = \hat{\mathbf{e}}_x\cos\theta\cos\phi + \hat{\mathbf{e}}_y\cos\theta\sin\phi - \hat{\mathbf{e}}_z\sin\theta \\
\hat{\mathbf{e}}_\phi &= W_\phi\frac{\partial \mathbf{r}}{\partial \phi} = -\hat{\mathbf{e}}_x\sin\phi + \hat{\mathbf{e}}_y\cos\phi \ .
\end{aligned}$$

It is easy to see that all three unit vectors are orthogonal. Reversing the system of equations, we get,

$$\begin{aligned}\hat{\mathbf{e}}_x &= \hat{\mathbf{e}}_r \sin\theta\cos\phi + \hat{\mathbf{e}}_\theta \cos\theta\cos\phi - \hat{\mathbf{e}}_\phi \sin\phi \\ \hat{\mathbf{e}}_y &= \hat{\mathbf{e}}_r \sin\theta\sin\phi + \hat{\mathbf{e}}_\theta \cos\theta\sin\phi + \hat{\mathbf{e}}_\phi \cos\phi \\ \hat{\mathbf{e}}_z &= \hat{\mathbf{e}}_r \cos\theta - \hat{\mathbf{e}}_\theta \sin\theta \ .\end{aligned}$$

c. The total differential $d\mathbf{r}$ *has the form,*

$$d\mathbf{r} = \hat{\mathbf{e}}_r \frac{dr}{U_r} + \hat{\mathbf{e}}_\theta d\theta V_\theta + \hat{\mathbf{e}}_w \frac{dw}{W_\phi} \ .$$

This makes it easy to show,

$$\begin{aligned}(ds)^2 = |d\mathbf{r}|^2 &= \left(\frac{du}{U}\right)^2 + \left(\frac{dv}{V}\right)^2 + \left(\frac{dw}{W}\right)^2 \\ &= (ds_u)^2 + (ds_v)^2 + (ds_w)^2 \\ &= (dr)^2 + (rd\theta)^2 + (r\sin\theta d\phi)^2 \ .\end{aligned}$$

Now,

$$d\tau = ds_u ds_v ds_w = r^2 \sin\theta d\theta d\phi dr \ .$$

d. This is easy.

12.3.8.3 Ex: Spherical and cylindrical coordinates

Calculate $\nabla\Phi$, $\nabla\cdot\mathbf{A}$, $\nabla\times\mathbf{A}$ and $\Delta\Phi = \nabla\cdot(\nabla\Phi)$
a. in spherical coordinates $(r,\ \theta,\ \phi)$.
b. in cylindrical coordinates $(\rho,\ \phi,\ z)$.

Solution: *a. With Exc. 12.3.8.2(a) segue* $U_r = 1$, $V_\theta = \frac{1}{r}$ *and* $W_\phi = \frac{1}{r\sin\theta}$. *With the results obtained in for arbitrary coordinates we get consecutively:*

$$\nabla\Phi = \hat{\mathbf{e}}_r \ \frac{\partial\Phi}{\partial r} + \hat{\mathbf{e}}_\theta \ \frac{1}{r} \ \frac{\partial\Phi}{\partial\theta} + \hat{\mathbf{e}}_\phi \ \frac{1}{r\sin\phi} \ \frac{\partial\Phi}{\partial\phi} \ ,$$

and

$$\begin{aligned}\nabla\cdot\mathbf{A} &= \frac{1}{r^2\sin\theta}\left(\frac{\partial\Phi}{\partial r}[r^2\sin\theta\ a_r] + \frac{\partial\Phi}{\partial\theta}[r\sin\theta\ a_\theta] + \frac{\partial\Phi}{\partial\phi}[r\ a_\phi\right]) \\ &= \frac{1}{r^2}\frac{\partial\Phi}{\partial r}[r^2 a_r] + \frac{1}{r\sin\theta}\frac{\partial\Phi}{\partial\theta}[\sin\theta\ a_\theta] + \frac{1}{r\sin\theta}\frac{\partial\Phi}{\partial\phi}[a_\phi] \ ,\end{aligned}$$

and also,

$$\nabla\times\mathbf{A} = \frac{1}{r^2\sin\theta} \ \det\begin{pmatrix} \hat{\mathbf{e}}_r & r\hat{\mathbf{e}}_\theta & r\sin\theta\hat{\mathbf{e}}_\phi \\ \frac{\partial}{\partial r} & \frac{\partial}{\partial\theta} & \frac{\partial}{\partial\phi} \\ a_r & ra_\theta & r\sin\theta a_\phi \end{pmatrix} \ ,$$

respectively,

$$\nabla\times\mathbf{A}=\hat{\mathbf{e}}_r\ \frac{1}{r\sin\theta}\left[\frac{\partial\Phi}{\partial\theta}(\sin\theta a_\phi)-\frac{\partial\Phi}{\partial\phi}(a_\theta)\right]+\hat{\mathbf{e}}_\theta\ \frac{1}{r\sin\theta}\left[\frac{\partial\Phi}{\partial\phi}(a_r)-\sin\theta\frac{\partial\Phi}{\partial r}(ra_\phi)\right]$$
$$+\hat{\mathbf{e}}_\phi\ \frac{1}{r}\left[\frac{\partial\Phi}{\partial r}(ra_\theta)-\frac{\partial\Phi}{\partial\theta}(a_r)\right]\ .$$

With the expression for $\nabla\Phi$ *we get immediately,*

$$(\nabla\Phi)_r=\frac{\partial\Phi}{\partial r}\qquad,\qquad(\nabla\Phi)_\theta=\frac{1}{r}\frac{\partial\Phi}{\partial\theta}\qquad,\qquad(\nabla\Phi)_\phi=\frac{1}{r\sin\theta}\frac{\partial\Phi}{\partial\phi}\ ,$$

and

$$\nabla\cdot(\nabla\Phi)=\frac{1}{r^2}\frac{\partial}{\partial r}\left(r^2\frac{\partial\Phi}{\partial r}\right)+\frac{1}{r^2\sin\theta}\frac{\partial}{\partial\theta}\left(\sin\theta\frac{\partial\Phi}{\partial\theta}\right)+\frac{1}{r^2\sin^2\theta}\frac{\partial^2\Phi}{\partial\phi^2}\equiv\Delta\Phi\ .$$

b. The cylindrical coordinates are given by,

$$\mathbf{r}=(x,\ y,\ z)=(\rho\cos\phi,\ \rho\sin\phi,\ z)\ ,$$

From this follows,

$$\frac{\partial\mathbf{r}}{\partial\rho}=\cos\phi\ \hat{\mathbf{e}}_x+\sin\phi\ \hat{\mathbf{e}}_y$$
$$\frac{\partial\mathbf{r}}{\partial\phi}=-\rho\sin\phi\ \hat{\mathbf{e}}_x+\rho\cos\phi\ \hat{\mathbf{e}}_y$$
$$\frac{\partial\mathbf{r}}{\partial z}=\hat{\mathbf{e}}_z\ ,$$

and also,

$${U_\rho}^{-1}=\left|\frac{\partial\mathbf{r}}{\partial\rho}\right|=\sqrt{\cos^2\phi+\sin^2\phi}=1$$
$${V_\phi}^{-1}=\left|\frac{\partial\mathbf{r}}{\partial\phi}\right|=\rho$$
$${W_z}^{-1}=\left|\frac{\partial\mathbf{r}}{\partial z}\right|=1\ .$$

With that we get consecutively,

$$\nabla\Phi=\hat{\mathbf{e}}_\rho\ \frac{\partial\Phi}{\partial\rho}+\hat{\mathbf{e}}_\phi\ \frac{1}{\rho}\ \frac{\partial\Phi}{\partial\phi}+\hat{\mathbf{e}}_z\ \frac{\partial\Phi}{\partial z}\ ,$$

and

$$\nabla\cdot\mathbf{A}=\frac{1}{\rho}\frac{\partial}{\partial\rho}[\rho\ a_\rho]+\frac{1}{\rho}\frac{\partial}{\partial\phi}[a_\phi]+\frac{\partial}{\partial z}[a_z]\ ,$$

and also,

$$\nabla\times\mathbf{A}=\frac{1}{\rho}\ \det\begin{pmatrix}\hat{\mathbf{e}}_\rho & \rho\hat{\mathbf{e}}_\phi & \hat{\mathbf{e}}_z\\ \frac{\partial}{\partial\rho} & \frac{\partial}{\partial\phi} & \frac{\partial}{\partial z}\\ a_\rho & \rho a_\phi & a_z\end{pmatrix}\ ,$$

respectively,

$$\nabla \times \mathbf{A} \;= \hat{\mathbf{e}}_\rho \; \frac{1}{\rho}\left[\frac{\partial a_z}{\partial \phi} - \rho \frac{\partial a_\phi}{\partial z}\right] + \hat{\mathbf{e}}_\phi \; \left[\frac{\partial a_\rho}{\partial z} - \frac{\partial a_z}{\partial \rho}\right] + \hat{\mathbf{e}}_z \; \frac{1}{\rho}\left[\frac{\partial}{\partial \rho}(\rho a_\phi) - \frac{\partial a_\rho}{\partial \phi}\right] \;,$$

and finally,

$$\Delta\Phi = \nabla \cdot (\nabla\Phi) = \frac{1}{\rho}\frac{\partial}{\partial \rho}\left(\rho \frac{\partial \Phi}{\partial \rho}\right) + \frac{1}{\rho^2}\frac{\partial^2 \Phi}{\partial \phi^2} + \frac{\partial^2 \Phi}{\partial z^2} \;.$$

12.3.8.4 Ex: Divergence in curvilinear coordinates

Calculate the divergence of the force field $\mathbf{F}(\mathbf{r}) = \begin{pmatrix} x^2 y \\ 2yz \\ x+z \end{pmatrix}$ (a) in Cartesian and (b) cylindrical coordinates and compare the results.

Solution: *a. In Cartesian coordinates we have* $\nabla \cdot \mathbf{F}(\mathbf{r}) = 2xy + 2z + 1$.
b. The transformation to cylindrical coordinates is defined by

$$\mathbf{r} = \begin{pmatrix} \rho\cos\phi \\ \rho\sin\phi \\ z \end{pmatrix} \;,$$

respectively,

$$\begin{aligned}
\hat{\mathbf{e}}_\rho &\equiv \frac{\partial \mathbf{r}}{\partial r} = \hat{\mathbf{e}}_x \cos\phi + \hat{\mathbf{e}}_y \sin\phi \\
\hat{\mathbf{e}}_\phi &\equiv \frac{1}{r}\frac{\partial \mathbf{r}}{\partial \phi} = -\hat{\mathbf{e}}_x \sin\phi + \hat{\mathbf{e}}_y \cos\phi \\
\hat{\mathbf{e}}_z &\equiv \frac{\partial \mathbf{r}}{\partial z} = \hat{\mathbf{e}}_\rho \times \hat{\mathbf{e}}_\phi \;,
\end{aligned}$$

hence,

$$\begin{aligned}
\hat{\mathbf{e}}_x &= \hat{\mathbf{e}}_\rho \cos\phi - \hat{\mathbf{e}}_\phi \sin\phi \\
\hat{\mathbf{e}}_y &= \hat{\mathbf{e}}_\phi \cos\phi + \hat{\mathbf{e}}_\rho \sin\phi \;.
\end{aligned}$$

The vector field is in cylindrical coordinates,

$$\begin{aligned}
\mathbf{F} &= x^2 y \hat{\mathbf{e}}_x + 2yz\hat{\mathbf{e}}_y + (x+z)\hat{\mathbf{e}}_z \\
&= \hat{\mathbf{e}}_x \rho^3 \cos^2\phi \sin\phi + \hat{\mathbf{e}}_y 2\rho z \sin\phi + \hat{\mathbf{e}}_z(\rho\cos\phi + z) \\
&= (\hat{\mathbf{e}}_\rho \cos\phi - \hat{\mathbf{e}}_\phi \sin\phi)\rho^3 \cos^2\phi \sin\phi + (\hat{\mathbf{e}}_\phi \cos\phi + \hat{\mathbf{e}}_\rho \sin\phi) 2\rho z \sin\phi + \hat{\mathbf{e}}_z(\rho\cos\phi + z) \\
&= \hat{\mathbf{e}}_\rho(\rho^3 \cos^3\phi \sin\phi + 2\rho z \sin^2\phi) + \hat{\mathbf{e}}_\phi(2\rho z \sin\phi\cos\phi - \rho^3 \cos^2\phi \sin^2\phi) + \hat{\mathbf{e}}_z(\rho\cos\phi + z) \;.
\end{aligned}$$

The divergence now is,

$$\nabla\cdot\mathbf{F} = \frac{1}{\rho}\frac{\partial}{\partial\rho}(\rho F_\rho) + \frac{1}{\rho}\frac{\partial}{\partial\phi}F_\phi + \frac{\partial}{\partial z}F_z$$
$$= \frac{1}{\rho}\frac{\partial}{\partial\rho}(\rho^4\cos^3\phi\sin\phi + 2\rho^2 z\sin^2\phi) + \frac{1}{\rho}\frac{\partial}{\partial\phi}(2\rho z\sin\phi\cos\phi - \rho^3\cos^2\phi\sin^2\phi) + \frac{\partial}{\partial z}(\rho\cos\phi + z)$$
$$= (4\rho^2\cos^3\phi\sin\phi + 4z\sin^2\phi) + \left(2z\cos^2\phi - 2z\sin^2\phi + 2\rho^2\cos\phi\sin^3\phi - 2\rho^2\cos^3\phi\sin\phi\right) + 1$$
$$= \frac{4x^3y}{\rho^2} + \frac{4zy^2}{\rho^2} + \frac{2zx^2}{\rho^2} - \frac{2zy^2}{\rho^2} + \frac{2\rho^2xy^3}{\rho^4} - \frac{2\rho^2x^3y}{\rho^4} + 1 = 2xy + 2z + 1\ ,$$

with $\rho^2 = x^2 + y^2$.

12.3.8.5 Ex: Differential operators in curvilinear coordinates

In Cartesian coordinates the differential line element has the form $d\mathbf{r} = \hat{\mathbf{e}}_x dx + \hat{\mathbf{e}}_y dy + \hat{\mathbf{e}}_z dz$ and in arbitrary orthogonal coordinates $d\mathbf{r} = \hat{\mathbf{e}}_1 h_1 dq_1 + \hat{\mathbf{e}}_2 h_2 dq_2 + \hat{\mathbf{e}}_3 h_3 dq_3$ with $\hat{\mathbf{e}}_i = \frac{\partial\mathbf{r}}{\partial q_i}\cdot\left|\frac{\partial\mathbf{r}}{\partial q_i}\right|^{-1}$ and $h_i = \left|\frac{\partial\mathbf{r}}{\partial q_i}\right|$. For spherical coordinates (r,ϕ,θ) we find $h_r = 1, h_\phi = r\sin\theta, h_\theta = r$; for cylindrical coordinates (ρ,ϕ,z) we find $h_\rho = 1, h_\phi = \rho, h_z = 1$.
a. The gradient has the general form,

$$\nabla_i\Phi(\mathbf{r}) = \frac{1}{h_i}\frac{\partial}{\partial q_i}\Phi(\mathbf{r})\ .$$

Determine the gradient in spherical and cylindrical coordinates.
b. The divergence of a vector field $\mathbf{A}$ has the general form,

$$\nabla\cdot\mathbf{A}(\mathbf{r}) = \frac{1}{h_1h_2h_3}\left[\frac{\partial}{\partial q_1}(A_1h_2h_3) + \frac{\partial}{\partial q_2}(A_2h_1h_3) + \frac{\partial}{\partial q_3}(A_3h_1h_2)\right]\ .$$

Determine $\nabla\cdot\mathbf{A}$ in spherical and cylindrical coordinates.
c. Use the results of (a) and (b) to determine the Laplace operator

$$\Delta = \nabla\cdot\nabla$$

in spherical coordinates.

Solution: *For spherical coordinates the coefficients* h_i *are determined from* $\mathbf{r} = \begin{pmatrix} r\sin\theta\cos\phi \\ r\cos\theta\cos\phi \\ r\sin\phi \end{pmatrix}$ *and for cylindrical coordinates from* $\mathbf{r} = \begin{pmatrix} \rho\cos\phi \\ \rho\sin\phi \\ z \end{pmatrix}$.
Gradient in cylindrical coordinates,

$$\nabla\Psi(\rho,\phi,z) = \frac{\partial}{\partial\rho}\Psi(\rho,\phi,z)\hat{\mathbf{e}}_\rho + \frac{1}{\rho}\frac{\partial}{\partial\phi}\Psi(\rho,\phi,z)\hat{\mathbf{e}}_\phi + \frac{\partial}{\partial z}\Psi(\rho,\phi,z)\hat{\mathbf{e}}_z\ .$$

Gradient in spherical coordinates

$$\nabla\Psi(r,\theta,\phi) = \frac{\partial}{\partial r}\Psi(r,\theta,\phi)\hat{\mathbf{e}}_r + \frac{1}{r}\frac{\partial}{\partial\theta}\Psi(r,\theta,\phi)\hat{\mathbf{e}}_\theta + \frac{1}{r\sin\theta}\frac{\partial}{\partial\phi}\Psi(r,\theta,\phi)\hat{\mathbf{e}}_\phi\ .$$

Divergence in cylindrical coordinates,

$$\nabla \cdot \mathbf{A} = \frac{1}{\rho}\frac{\partial}{\partial \rho}(\rho A_\rho) + \frac{1}{\rho}\frac{\partial}{\partial \phi}A_\phi + \frac{\partial}{\partial z}A_z \ .$$

Divergence in spherical coordinate,

$$\nabla \cdot \mathbf{A} = \frac{1}{r^2}\frac{\partial}{\partial r}(r^2 A_r) + \frac{1}{r\sin\theta}\frac{\partial}{\partial \theta}(\sin\theta A_\theta) + \frac{1}{r\sin\theta}\frac{\partial}{\partial \phi}A_\phi \ .$$

Laplace operator in cylindrical coordinates,

$$\Delta = \frac{1}{\rho}\frac{\partial}{\partial \rho}\left(\rho\frac{\partial}{\partial \rho}\right) + \frac{1}{\rho^2}\frac{\partial^2}{\partial \phi^2} + \frac{\partial^2}{\partial z^2} \ .$$

Laplace operator in spherical coordinate,

$$\Delta = \frac{1}{r}\frac{\partial^2}{\partial r^2}r + \frac{1}{r^2\sin\theta}\frac{\partial}{\partial \theta}\left(\sin\theta\frac{\partial}{\partial \theta}\right) + \frac{1}{r^2\sin^2\theta}\frac{\partial^2}{\partial \phi^2} \ .$$

12.3.8.6 Ex: Acceleration in spherical coordinates

In spherical coordinates the velocity vector has the following form,

$$\mathbf{v} = \frac{d\mathbf{r}}{dt} = \dot{r}\hat{\mathbf{e}}_r + r\dot{\theta}\hat{\mathbf{e}}_\theta + \dot{\phi}r\sin\theta\hat{\mathbf{e}}_\phi \ .$$

Calculate the acceleration vector in spherical coordinates. Respect the fact that the basis vectors must also be derived by time.

Solution: *The derivatives of the basis vectors are,*

$$\frac{d}{dt}\hat{\mathbf{e}}_r = \frac{d}{dt}\begin{pmatrix}\sin\theta\cos\phi\\ \sin\theta\sin\phi\\ \cos\theta\end{pmatrix} = \begin{pmatrix}\dot{\theta}\cos\theta\cos\phi - \dot{\phi}\sin\theta\sin\phi\\ \dot{\theta}\cos\theta\sin\phi + \dot{\phi}\sin\theta\cos\phi\\ -\dot{\theta}\sin\theta\end{pmatrix} = \dot{\theta}\hat{\mathbf{e}}_\theta + \dot{\phi}\sin\theta\hat{\mathbf{e}}_\phi$$

$$\frac{d}{dt}\hat{\mathbf{e}}_\theta = \frac{d}{dt}\begin{pmatrix}\cos\theta\cos\phi\\ \cos\theta\sin\phi\\ -\sin\theta\end{pmatrix} = \begin{pmatrix}-\dot{\theta}\sin\theta\cos\phi - \dot{\phi}\cos\theta\sin\phi\\ -\dot{\theta}\sin\theta\sin\phi + \dot{\phi}\cos\theta\cos\phi\\ -\dot{\theta}\cos\theta\end{pmatrix} = -\dot{\theta}\hat{\mathbf{e}}_r + \dot{\phi}\cos\theta\hat{\mathbf{e}}_\phi$$

$$\frac{d}{dt}\hat{\mathbf{e}}_\phi = \frac{d}{dt}\begin{pmatrix}-\sin\phi\\ \cos\phi\\ 0\end{pmatrix} = \begin{pmatrix}-\dot{\phi}\cos\phi\\ -\dot{\phi}\sin\phi\\ 0\end{pmatrix} = -\dot{\phi}\sin\theta\hat{\mathbf{e}}_r - \dot{\phi}\cos\theta\hat{\mathbf{e}}_\theta \ .$$

Hence,

$$\begin{aligned}\mathbf{a} &= \frac{d\mathbf{v}}{dt} = \frac{d^2\mathbf{r}}{dt^2} = \ddot{\mathbf{r}} \\ &= \ddot{r}\hat{\mathbf{e}}_r + \dot{r}\dot{\hat{\mathbf{e}}}_r + \dot{r}\dot{\theta}\hat{\mathbf{e}}_\theta + r\ddot{\theta}\hat{\mathbf{e}}_\theta + r\dot{\theta}\dot{\hat{\mathbf{e}}}_\theta + \ddot{\phi}r\sin\theta\hat{\mathbf{e}}_\phi + \dot{\phi}\dot{r}\sin\theta\hat{\mathbf{e}}_\phi + \dot{\phi}r\dot{\theta}\cos\theta\hat{\mathbf{e}}_\phi + \dot{\phi}r\sin\theta\dot{\hat{\mathbf{e}}}_\phi \ .\end{aligned}$$

Inserting $\dot{\hat{\mathbf{e}}}_r$, $\dot{\hat{\mathbf{e}}}_\theta$ *and* $\dot{\hat{\mathbf{e}}}_\phi$ *gives,*

$$\begin{aligned}\mathbf{a} = &\left(\ddot{r} - r\dot{\theta}^2 - \dot{\phi}^2 r\sin^2\theta\right)\hat{\mathbf{e}}_r \\ &+ \left(2\dot{r}\dot{\theta} + r\ddot{\theta} - \dot{\phi}^2 r\sin\theta\cos\theta\right)\hat{\mathbf{e}}_\theta \\ &+ \left(2\dot{\phi}\dot{r}\sin\theta + 2\dot{\phi}r\dot{\theta}\cos\theta + \ddot{\phi}r\sin\theta\right)\hat{\mathbf{e}}_\phi \ .\end{aligned}$$

12.3.8.7 Ex: Volume element in curvilinear coordinates

a. Calculate the surface of a rectangle with width a and height b in Cartesian coordinates.
b. Calculate the surface of a disk of radius R in polar coordinates.
c. Calculate the volume of a cuboid with dimensions a, b, c in Cartesian coordinates.
d. Calculate the volume of a cylinder with the radius R and height H in cylindrical coordinates.
e. Calculate the volume a sphere with the radius R in spherical coordinates.

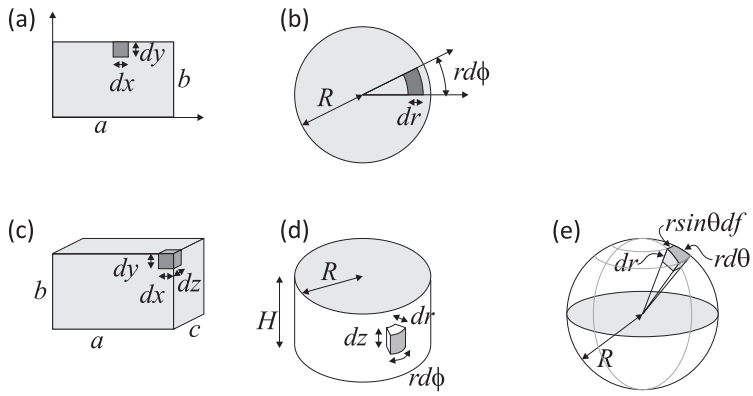

Figure 12.8: Curvilinear coordinates.

Solution: *a. The surface element is,*

$$dS = dxdy \ .$$

With this we calculate the surface of the rectangle,

$$S = \int_{rectangulo} dS = \int_0^a \left(\int_0^b dy\right) dx = \int_0^a dx \int_0^b dy = ab \ .$$

b. The surface element is,

$$dS = rd\phi dr \ .$$

With this we calculate the disk surface,

$$S = \int_{disco} dS = \int_0^R \left(\int_0^{2\pi} r d\phi \right) dr = \int_0^{2\pi} d\phi \int_0^R r dr = 2\pi \frac{R^2}{2} = \pi R^2 \ .$$

c. The volume element is,

$$dV = dxdydz \ .$$

d. The volume element is,

$$dV = rd\phi drdz \ .$$

With this we calculate the cylinder volume,

$$\begin{aligned} V = \int_{cylinder} dV &= \int_0^H \left(\int_0^R \left(\int_0^{2\pi} r d\phi \right) dr \right) dz \\ &= \int_0^{2\pi} d\phi \int_0^R r dr \int_0^H dz = 2\pi \frac{R^2}{2} H = \pi R^2 H \ . \end{aligned}$$

e. The volume element is

$$dV = r^2 \sin\theta d\phi d\theta dr \ .$$

With this we calculate the cylinder volume,

$$\begin{aligned} V = \int_{sphere} dV &= \int_0^\pi \left(\int_0^R \left(\int_0^{2\pi} r \sin\theta d\phi \right) dr \right) r d\theta \\ &= \int_0^{2\pi} d\phi \int_0^R r^2 dr \int_0^\pi \sin\theta d\theta = 2\pi \frac{R^3}{3} 2 = \frac{4\pi}{3} R^3 \ . \end{aligned}$$

12.3.8.8 Ex: Spherical volume

The volume of a body is given by the following formula:

$$V = \int_V 1 \ dV \ .$$

a. Calculate the volume of a 3D-sphere in spherical coordinates.
By the Gauß integral law we can establish a relationship between the volume of the sphere and its surface. (**Help:** For which vector field $\mathbf{A}$ holds: $\nabla \cdot \mathbf{A} = 1$?)
b. Now calculate the volume of the sphere in this sense. You may assume that the surface of the sphere is known.
c. Similarly to the above formula, derive a general relationship between the volume of an n-dimensional hypersphere and its $(n-1)$-dimensional hypersurface. **Help:** Gauß's law holds in arbitrary dimensions with the n-dimensional operator nabla-operator defined by, $\nabla = (\partial/\partial x_1, \ldots, \partial/\partial x_n)$.

Solution: *a. The volume of the sphere is,*

$$V = \int_{sphere} r^2 \sin\theta dr d\theta d\phi = \frac{4\pi}{3} R^3 \ .$$

b. By the law of Gauß,

$$V = \int_{sphere} 1\ dV = \frac{1}{3}\int_V div\ \mathbf{r}\ dV = \frac{1}{3}\oint_{surfaceofsphere} \mathbf{r}d\mathbf{S}$$
$$= \frac{R}{3}\oint_{surfaceofsphere} R^2 d\theta d\phi = \frac{R}{3}\cdot 4\pi R^2\ .$$

c. In n dimensions,

$$V = \int_{hypersphere} 1\ dV = \frac{1}{n}\int_V div\mathbf{r}\ dV = \frac{1}{n}\oint_{surfaceofhypersphere} \mathbf{r}d\mathbf{S}$$
$$= \frac{R}{n}\oint_{surfaceofhypersphere} R^2 d\theta d\phi = \frac{R}{n}\cdot \partial V\ .$$

It i interesting that for $n \to \infty$ the volume of the unitary sphere tends to 0.

12.3.8.9 Ex: Spherical volume

The density distribution of a gas be given by $n(\mathbf{r}) = C^2 - \frac{x^2}{r_0^2} - \frac{y^2}{r_0^2} - \frac{z^2}{r_0^2}$. Determine the constant C in such a way that the density $n(\mathbf{r})$ is normalized to the number of atoms in the gas, i.e., $\int_{\mathcal{V}} n(\mathbf{r})d^3\mathbf{r} = N$, where $\mathcal{V}$ is the volume within which the density is positive, $n(\mathbf{r}) \geq 0$.

Solution: *The volume integral is,*

$$\int_{\mathcal{V}} n(\mathbf{r})d^3\mathbf{r} = \int_{\mathcal{V}} \left(C^2 - \frac{r^2}{r_0^2}\right) d^3\mathbf{r} = 4\pi \int_0^{Cr_0} \left(C^2 - \frac{r^2}{r_0^2}\right) r^2 dr$$
$$= 4\pi \left[\frac{C^2 r^3}{3} - \frac{r^5}{5r_0^2}\right]_0^{Cr_0} = \frac{8\pi C^5 r_0^3}{15} \equiv N\ .$$

With this we get the constant,

$$C = \left(\frac{15N}{8\pi r_0^3}\right)^{1/5}\ .$$

12.3.8.10 Ex: Spherical and cylindrical volume

a. Integrate a circular surface with radius R in Cartesian coordinates and then in polar coordinates.
b. The density distribution of a trapped atomic gas is described by $n(\mathbf{r}) = n_0 e^{-r^2/\bar{r}^2}$, where $n_0 = 10^{13}\,\mathrm{cm}^{-1}$ is the maximum density and $\bar{r} = 100\,\mu\mathrm{m}$ a measure for the extent of the distribution. Calculate the number of atoms $N = \int_{\mathbb{R}^3} n(\mathbf{r})d^3\mathbf{r}$, integrating over Cartesian coordinates and then over polar coordinates.
c. Calculate the density of a homogeneous cylinder of mass 10 kg and length 20 cm by

integrating over its volume..
d. The density distribution of a trapped atomic gas is described by $n(\rho,z) = \max\left\{0, n_0 \cdot \left(1 - \frac{\rho^2}{\rho_m^2} - \frac{z^2}{z_m^2}\right)\right\}$, where $n_0 = 10^{13}\,\mathrm{cm}^{-3}$ is the maximum density and $z_m = 2\rho_m = 100\,\mu\mathrm{m}$ a measure for the extent of the distribution. Calculate the number of atoms by integrating over cylindrical coordinates.

Solution: *a. The surface of the circle is,*

$$S = \int_{circle} d^2r = \int \int_{-\sqrt{R^2-y^2}}^{\sqrt{R^2-y^2}} dxdy = \int 2\sqrt{R^2-y^2}dy = y\sqrt{R^2-y^2} + R^2 \arcsin\frac{y}{R}\Big|_{-R}^{R} = R^2\pi$$

$$S = \int_{circle} d^2r = \int_0^{2\pi}\int_0^R rdrd\phi = 2\pi\frac{R^2}{2} = \pi R^2 \ .$$

b. The number of atoms is,

$$N = \int_{\mathbb{R}^3} n(r)dxdydz = n_0\left(\int_{-\infty}^{\infty} e^{-x^2/\bar{r}^2}dx\right)^3 = n_0\left(\bar{r}\sqrt{\pi}\right)^3$$

$$N = \int_{\mathbb{R}^3} n(r)dr = \int_0^{2\pi}\int_0^{\theta}\int_0^{\infty} n(r)r^2\sin\theta drd\theta d\phi = 4\pi n_0\int_0^{\infty} e^{-r^2/\bar{r}^2}r^2dr$$

$$= 4\pi n_0\left(-\frac{1}{2}\bar{r}^2e^{-r^2/\bar{r}^2}r\Big|_0^{\infty} - \int_0^{\infty} -\frac{1}{2}e^{-r^2/\bar{r}^2}\bar{r}^2dr\right) = \pi n_0\bar{r}^3\sqrt{\pi} \ .$$

Hence, we have $N = 55.7\cdot 10^6$ atoms.
c. The mass is,

$$m = \int_{\mathbb{R}^3}\rho(\vec{r})d^3r = \int_0^h\int_0^{2\pi}\int_0^R \rho_0 rdrd\phi dz = \rho_0\pi h\frac{R^2}{2} = \rho_0 V \ .$$

So the density is, $\rho_0 = \frac{m}{\pi R^2 h} \simeq 6.4\,\mathrm{kg/l}$.
d. The number of atoms is,

$$N = \int_{\mathbb{R}^3} n(\rho,z)d^3r = n_0\int_{n(r)\geq 0}\left(1 - \frac{\rho^2}{\bar{\rho}^2} - \frac{z^2}{\bar{z}^2}\right)\rho d\rho d\phi dz$$

$$= 2\pi n_0\int_{n(r)\geq 0}\left[\frac{\rho^2}{2} - \frac{\rho^4}{4\bar{\rho}^2} - \frac{z^2\rho^2}{2\bar{z}^2}\right]_0^{\bar{\rho}\sqrt{1-z^2/\bar{z}^2}} dz = 2\pi n_0\frac{\bar{\rho}^2}{4}\int_{-\bar{z}}^{\bar{z}}\left(1 - \frac{z^2}{\bar{z}^2}\right)^2 dz$$

$$= 2\pi n_0\frac{\bar{\rho}^2}{4}\left[\frac{1}{5a^4}z^5 - \frac{2}{3}\frac{z^3}{a^2} + z\right]_{-\bar{z}}^{\bar{z}} = 2\pi n_0\frac{\bar{\rho}^2}{4}\frac{16}{15}a = \frac{8\pi}{15}n_0\bar{z}\bar{\rho}^2 \ .$$

Hence, we have $N = 4.2\cdot 10^6$ atoms.

12.3.8.11 Ex: Cylindrical volume

Consider a material (gas or liquid) whose mass density $\rho(\mathbf{r})$ depends on the z-coordinate as follows: $\rho(\mathbf{r}) = \rho_0(1-\alpha z)$. This material is filled into a cylinder (radius R and height c) until the total mass in the cylinder is M. The cylinder stands

in a circular area above the xy in $z = 0$.
a. Calculate the density parameter ρ_0.
b. Calculate vector of center of mass $\mathbf{r}_s$ of the material in the cylinder.
c. Now fill the same material inside a sphere of radius R instead of the cylinder. What are the results in this case if $\alpha = 0.1$ /m, $R = 1$ m, and $M = 10$ kg.
d. A cake of mass M, height h and radius R be cut into fourth equal pieces. Calculate the center of mass of a piece. Calculate the center of mass of the rest of the cake when a piece is taken.

Solution: *a. The total mass integrated over the cylinder is,*

$$M = \int_{cylinder} \rho(\vec{r}) d^3r = \int_0^R \int_0^{2\pi} \int_0^{z_0} \rho_0(1-\alpha z) r dr d\phi dz = \rho_0 2\pi \frac{R^2}{2}\left(z_0 - \frac{\alpha}{2} z_0^2\right) .$$

Therefore, the density parameter is,

$$\rho_0 = \frac{M}{\left(z_0 - \frac{\alpha}{2} z_0^2\right)\pi R^2} = \frac{M}{V}\frac{1}{1-\frac{\alpha}{2}z_0} .$$

b. The center of mass vector is defined by,

$$\vec{r}_s = \frac{1}{M}\int_{cylinder} \vec{r}\rho(\vec{r}) d^3r = (0, 0, z_s) .$$

Hence,

$$z_s = \frac{1}{M}\int_0^R \int_0^{2\pi} \int_0^{z_0} \rho_0 z(1-\alpha z) r dr d\phi dz = \frac{\rho_0}{M}\pi R^2 \left(z_0^2 - \frac{\alpha}{3} z_0^3\right) = z_0 \frac{1-\frac{\alpha}{3}z_0}{1-\frac{\alpha}{2}z_0} .$$

c. For a sphere we calculate in the same way,

$$\begin{aligned} M &= \int_{sphere} \rho(\vec{r}) d^3r = \int_0^{z_0} \int_0^{\sqrt{R^2-(R-z)^2}} \int_0^{2\pi} \rho_0(1-\alpha z) r dr d\phi dz \\ &= 2\pi\rho_0 \int_0^{z_0} \int_0^{\sqrt{R^2-(R-z)^2}} r dr (1-\alpha z) dz = 2\pi\rho_0 \int_0^{z_0} \frac{\sqrt{R^2-(R-z)^2}^2}{2}(1-\alpha z) dz \\ &= 2\pi\rho_0 \int_0^{z_0} \left(\alpha\frac{z^3}{2} - \frac{z^2}{2} - \alpha R z^2 + Rz\right) dz = \pi\rho_0 z_0^2 \left(\frac{\alpha z_0^2}{4} - \frac{z_0}{3} - \frac{2\alpha R z_0}{3} + R\right) . \end{aligned}$$

We easily verify that $\lim_{\alpha\to 0, z_0 \to 2R} M = \frac{4\pi}{3} R^3 \rho_0$. *he center of mass is,*

$$\begin{aligned} \vec{r}_s &= \int_{sphere} \vec{r}\rho(\vec{r}) d^3r = (0, 0, z_s) \\ z_s &= \frac{1}{M}\int_0^{z_0} \int_0^{\sqrt{R^2-(R-z)^2}} \int_0^{2\pi} z\rho_0(1-\alpha z) r dr d\phi dz = \frac{2\pi\rho_0}{M}\int_0^{z_0} \int_0^{\sqrt{R^2-(R-z)^2}} z(1-\alpha z) r dr dz \\ &= \frac{2\pi\rho_0}{M}\int_0^{z_0} \frac{\sqrt{R^2-(R-z)^2}^2}{2} z(1-\alpha z) dz = \frac{2\pi\rho_0}{M}\int_0^{z_0} \left(\alpha\frac{z^4}{2} - \frac{z^3}{2} - \alpha R z^3 + Rz^2\right) dz \\ &= \frac{\pi\rho_0 z^3}{M}\left(\frac{\alpha z_0^2}{5} - \frac{z_0}{4} - \frac{\alpha R z_0}{2} + \frac{2R}{3}\right) = z_0 \frac{\alpha z_0^2/5 - z_0/4 - \alpha R z_0/2 + 2R/3}{\alpha z_0^2/4 - z_0/3 - 2\alpha R z_0/3 + R} . \end{aligned}$$

Once again we can check, $\lim_{\alpha\to 0, z_0\to 2R} z_s = R$.
d. The center of mass of a cake segment is,

$$\vec{r}_s = \frac{\int_{segment}\vec{r}d^3r}{V} = \frac{\int_0^{\phi_0}\int_0^R\int_0^h \vec{r}rdrd\phi dz}{\int_0^{\phi_0}\int_0^R\int_0^h rdrd\phi dz} = \frac{1}{\phi_0 R^2 h/2}\int_0^{\phi_0}\int_0^R\int_0^h \begin{pmatrix} r\cos\phi \\ r\sin\phi \\ z \end{pmatrix} rdrd\phi dz$$

$$= \frac{2}{\phi_0 R^2 h}\begin{pmatrix} \int_0^{\phi_0}\int_0^R\int_0^h r^2\cos\phi drd\phi dz \\ \int_0^{\phi_0}\int_0^R\int_0^h r^2\sin\phi drd\phi dz \\ \int_0^{\phi_0}\int_0^R\int_0^h zrdrd\phi dz \end{pmatrix} = \frac{2}{\phi_0 R^2 h}\begin{pmatrix} \frac{R^3}{3}h\int_0^{\phi_0}\cos\phi d\phi \\ \frac{R^3}{3}h\int_0^{\phi_0}\sin\phi d\phi \\ \frac{R^2h^2}{4}\int_0^{\phi_0} d\phi \end{pmatrix} = \begin{pmatrix} -\frac{2R}{3\phi_0}\sin\phi_0 \\ \frac{2R}{3\phi_0}(\cos\phi_0 - 1) \\ \frac{h}{2} \end{pmatrix} .$$

Since $\int \vec{O}d^3r = V\vec{O}$, *we can without loss of generality place the origin of the coordinate system in the center of the cake.*

12.3.8.12 Ex: Vector potential in curvilinear coordinates

Be given a constant field $\mathbf{B}$ oriented in z-direction. What is the vector potential $\mathbf{A}$ in (a) spherical coordinates, (b) cylindrical coordinates, and (c) Cartesian coordinates? For case (c) also consider the gauge transformation $\mathbf{A}' = \mathbf{A} + \nabla\lambda$ with $\lambda = \pm Bxy/2$.

Solution: *With Stokes' theorem,*

$$\int_F \mathbf{B}\cdot d\mathbf{S} = \int_F (\nabla\times\mathbf{A})\cdot d\mathbf{S} = \int_{R(F)} \mathbf{A}\cdot d\mathbf{S} .$$

Since

$$\mathbf{B} = B\hat{\mathbf{e}}_z ,$$

We chose as integration area a circle with radius ρ *in a plane perpendicular to the* z*-direction at a distance* z *from the origin of our coordinate system. The integration area and the origin then form a cone with the length of the side edges* r *and the half opening angle of the cone* θ.
a. In spherical coordinates $\rho = r\sin\theta$ *is then,*

$$B\pi r^2\sin^2\theta = A_\phi 2\pi r\sin\theta ,$$

that is,

$$\mathbf{A} = A_\phi\hat{\mathbf{e}}_\phi = \frac{B}{2}r\sin\theta\hat{\mathbf{e}}_\phi .$$

b. In cylindrical coordinates we get immediately,

$$B\pi\rho^2 = A_\phi 2\pi\rho ,$$

that is,

$$\mathbf{A} = A_\phi\hat{\mathbf{e}}_\phi = \frac{B}{2}\rho\hat{\mathbf{e}}_\phi .$$

c. For Cartesian coordinates we use the result of (b) with $\rho^2 = x^2 + y^2$ *and insert* $\hat{\mathbf{e}}_\phi$*:*

$$\mathbf{A} = \frac{B}{2}\sqrt{x^2+y^2}\hat{\mathbf{e}}_\phi = \frac{B}{2}\sqrt{x^2+y^2}(-\hat{\mathbf{e}}_x \sin\phi + \hat{\mathbf{e}}_y \cos\phi) = \frac{B}{2}(-y\hat{\mathbf{e}}_x + x\hat{\mathbf{e}}_y) = \frac{B}{2}(-y, x, 0) \ .$$

We now consider the gauge transformation,

$$\mathbf{A}' = \mathbf{A} + \nabla\lambda \ .$$

For

$$\lambda \equiv +\frac{B}{2}xy \ .$$

we obtain,

$$\mathbf{A}' = \frac{B}{2}(-y\hat{\mathbf{e}}_x + x\hat{\mathbf{e}}_y) + \hat{\mathbf{e}}_x\frac{\partial\lambda}{\partial x} + \hat{\mathbf{e}}_y\frac{\partial\lambda}{\partial y} = Bx\hat{\mathbf{e}}_y \ .$$

For

$$\lambda \equiv -\frac{B}{2}xy \ .$$

we get in the same way,

$$\mathbf{A}' = \frac{B}{2}(-y\hat{\mathbf{e}}_x + x\hat{\mathbf{e}}_y) + \hat{\mathbf{e}}_x\frac{\partial\lambda}{\partial x} + \hat{\mathbf{e}}_y\frac{\partial\lambda}{\partial y} = -By\hat{\mathbf{e}}_x \ .$$

12.3.8.13 Ex: Gauß' theorem in curvilinear coordinates

a. Check Gauß' theorem for function $\mathbf{A} = r^2\hat{\mathbf{e}}_r$ using the volume of a sphere of radius R.
b. Do the same for the function $\mathbf{B} = r^{-2}\hat{\mathbf{e}}_r$ and discuss the result.

Solution:

12.3.8.14 Ex: Gauß' theorem in curvilinear coordinates

Calculate the divergence of the function,

$$\mathbf{A} = r\hat{\mathbf{e}}_r \cos\theta + r\hat{\mathbf{e}}_\theta \sin\theta + r\hat{\mathbf{e}}_\varphi \sin\theta\cos\varphi \ .$$

Verify Gauß's theorem for this function using the volume of an inverted semisphere of radius R lying in the x-y-plane.

Solution:

12.3.8.15 Ex: Gauß' theorem in curvilinear coordinates

Calculate the gradient and Laplacian of the function $T = r(\cos\theta + \sin\theta\cos\varphi)$. Check the Laplacian by converting T into Cartesian coordinates. Verify Gauß's theorem using the path $l_1(t) = 2\hat{\mathbf{e}}_x \cos\pi t + 2\hat{\mathbf{e}}_y \sin\pi t$ for $t \in [0, 0.5]$ followed by $l_2(t) = 2\hat{\mathbf{e}}_y \sin\pi t - 2\hat{\mathbf{e}}_z \cos\pi t$ para $t \in [0.5, 1]$.

Solution:

12.3.8.16 Ex: Gauß' theorem in curvilinear coordinates

a. Find the divergence of the function,

$$\mathbf{A} = \rho\hat{\mathbf{e}}_\rho(2 + \sin^2\varphi) + \rho\hat{\mathbf{e}}_\varphi \sin\varphi\cos\varphi + 3z\hat{\mathbf{e}}_z \ .$$

b. Verify Gauß' theorem for this function using a quadrant of cylinder with radius $R = 2$ and height $h = 5$.
c. Find the rotation of $\mathbf{A}$.

Solution:

12.4 Differential geometry in curved space

In previous sections we mainly concentrated on orthogonal coordinate systems, such as Cartesian, cylindrical, or spherical. In cases one has to use non-orthogonal systems the formalism needs to be generalized. For this purpose it is necessary to introduce some new concepts and notations.

Repeat expressions in index formalism *Einstein's sum rule*, $a^n a_n = \sum_a^n a_n$,

$$\boxed{ds^2 = g_{mn} dx^m dx^n} \ . \tag{12.92}$$

12.4.1 Co- and contravariant tensors

A *contravariant* vector or tangent vector (often abbreviated simply as vector, such as a direction vector or velocity vector) has components that contra-vary with a change of basis to compensate. That is, the matrix that transforms the vector components must be the inverse of the matrix that transforms the basis vectors. Examples of contravariant vectors include the position of an object relative to an observer, or any derivative of position with respect to time, including velocity and acceleration. Contravariant components are denoted with upper indices as in,

$$\mathbf{v} = v^i \mathbf{e}_i \ . \tag{12.93}$$

A *covariant* vector or cotangent vector has components that co-vary with a change of basis. That is, the components must be transformed by the same matrix as the

change of basis matrix. Examples of covariant vectors generally appear when taking a gradient of a function. Covariant components are denoted with lower indices as in,

$$\mathbf{w} = w_i \mathbf{e}^i \ . \tag{12.94}$$

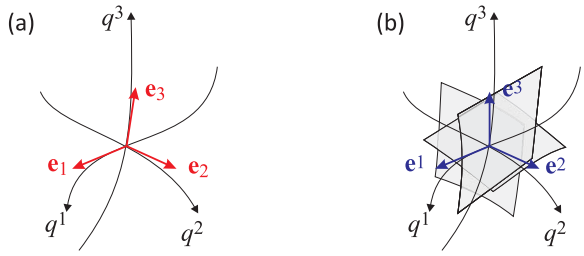

Figure 12.9: (a) Covariant and (b) contravariant basis.

12.4.2 Jacobian for coordinate transformations

The *Jacobian* of a vector field $\mathbf{F}$ is a matrix defined by,

$$\mathbf{J} \equiv \frac{\partial(F_1, .., F_m)}{\partial(x_1, .., x_n)} \equiv \left(\frac{\partial F_m}{\partial x_n} \right) \equiv (J^m_{\ n}) \ . \tag{12.95}$$

We may understand a curvilinear coordinate system $\{x^\mu\}$ as a vector field in Cartesian space $\{x'^\nu\}$,

$$x^\mu = x^\mu(x'^1, .., x'^\nu, .., x'^m) \tag{12.96}$$

for $\mu = 1, .., m$. The Jacobian of this field represents a tool used to transform between the coordinate systems by taking the rate of change of each component of an old basis with respect to each component of a new basis and expressing them as coefficients that make up an old basis. Do the Excs. 12.4.4.2 and 12.4.4.3,

$$\boxed{J^i_{\ j} \equiv \frac{\partial^i x}{\partial x'^j}} \ . \tag{12.97}$$

Example 38 (*Jacobian for polar coordinates*): For example, the Jacobian matrix that transforms polar coordinates to Cartesian coordinates in 2 dimensions is given by,

$$J^i_{\ j} = \begin{pmatrix} \partial_r x & \partial_\theta x \\ \partial_r y & \partial_\theta y \end{pmatrix} = \begin{pmatrix} \cos\theta & r\sin\theta \\ \sin\theta & r\cos\theta \end{pmatrix} \ . \tag{12.98}$$

The components of Cartesian basis vectors can now be written as a linear combination of these coefficients and their corresponding polar bases,

$$\begin{aligned} \hat{\mathbf{e}}_x &= \frac{\partial x}{\partial r}\hat{\mathbf{e}}_r + \frac{\partial x}{\partial \theta}\hat{\mathbf{e}}_\theta = \hat{\mathbf{e}}_r \cos\theta - \hat{\mathbf{e}}_\theta r \sin\theta \\ \hat{\mathbf{e}}_y &= \frac{\partial y}{\partial r}\hat{\mathbf{e}}_r + \frac{\partial y}{\partial \theta}\hat{\mathbf{e}}_\theta = \hat{\mathbf{e}}_r \sin\theta + \hat{\mathbf{e}}_\theta r \cos\theta \ . \end{aligned} \tag{12.99}$$

In the case of relating the Jacobian to the *metric* tensor, the Jacobian can be used to transform the components of one metric to another via the following method,

$$g'_{ij} = \frac{\partial}{\partial x'^i}\frac{\partial}{\partial x'^j} = \left(\frac{\partial x^a}{\partial x'^i}\frac{\partial}{\partial x^a}\right)\left(\frac{\partial x^b}{\partial x'^i}\frac{\partial}{\partial x^b}\right) = \frac{\partial x^a}{\partial x'^i}\frac{\partial x^b}{\partial x'^i}\left(\frac{\partial}{\partial x^a}\frac{\partial}{\partial x^b}\right) = J^a{}_i J^b{}_j g_{ab} \ . \tag{12.100}$$

Knowing this, taking the determinant of the metric g_{ij} requires taking the determinant of the Jacobian matrices and g_{ab} as well,

$$\det g'_{ij} = (\det J^a{}_i)(\det J^b{}_j)(\det g_{ab}) \ . \tag{12.101}$$

Since both Jacobian terms are part of the same matrix and are just written using different indices to differentiate between the components of the old basis,

$$(\det J^a{}_i)(\det J^b{}_j) = (\det J)^2 \ . \tag{12.102}$$

In the case of our old basis being written in Cartesian coordinates,

$$\det g_{ab} = \det \mathbb{I} = 1 \ . \tag{12.103}$$

Therefore the equation of our new transformed metric g_{ij}, simplifies to,

$$\det g_{ij} = (\det J)^2 \quad \Longrightarrow \quad \det J = \sqrt{\det g_{ij}} \ . \tag{12.104}$$

It can be shown that,

$$\frac{d}{dt}\frac{\partial(u,v)}{\partial(x,y)} \equiv \frac{\partial(\frac{d}{dt}u, v)}{\partial(x,y)} + \frac{\partial(u, \frac{d}{dt}v)}{\partial(x,y)} \ . \tag{12.105}$$

The *Hessian* is a square matrix of second-order partial derivatives of a scalar field.

12.4.3 Metric and geodesic equation in Euclidean space

For an arbitrary curvilinear coordinate system u^i we define tangent vectors forming a basis,

$$\mathbf{e}_i = \frac{\partial}{\partial u^i} = \partial_i \ , \tag{12.106}$$

the metric tensor is,

$$g_{ij} \equiv \mathbf{e}_i \cdot \mathbf{e}_j \ . \tag{12.107}$$

See also Secs. 6.4 and 20.5.

12.4.3.1 Metric in spherical coordinates

For spherical coordinates,

$$\mathbf{r} = \begin{pmatrix} x \\ y \\ z \end{pmatrix} = \begin{pmatrix} r\sin\theta\cos\phi \\ r\sin\theta\sin\phi \\ r\cos\theta \end{pmatrix} \quad , \quad \begin{pmatrix} r \\ \theta \\ \phi \end{pmatrix} = \begin{pmatrix} \sqrt{x^2+y^2+z^2} \\ \arccos\frac{z}{\sqrt{x^2+y^2+z^2}} \\ \arctan\frac{y}{x} \end{pmatrix} \ , \tag{12.108}$$

the tangent vectors are,

$$\begin{aligned}
\mathbf{e}_r &= \frac{\partial \mathbf{r}}{\partial r} = \hat{\mathbf{e}}_x \sin\theta\cos\phi + \hat{\mathbf{e}}_y \sin\theta\sin\phi + \hat{\mathbf{e}}_z \cos\theta = \hat{\mathbf{e}}_r \\
\mathbf{e}_\theta &= \frac{\partial \mathbf{r}}{\partial \theta} = r\hat{\mathbf{e}}_x \cos\theta\cos\phi + r\hat{\mathbf{e}}_y \cos\theta\sin\phi - r\hat{\mathbf{e}}_z \sin\theta = r\hat{\mathbf{e}}_\theta \\
\mathbf{e}_\phi &= \frac{\partial \mathbf{r}}{\partial \phi} = -r\sin\theta\hat{\mathbf{e}}_x \sin\phi + r\sin\theta\hat{\mathbf{e}}_y \cos\phi = r\sin\theta\hat{\mathbf{e}}_\phi \ .
\end{aligned} \tag{12.109}$$

Note that, in contrast to the basis vectors $\hat{\mathbf{e}}_i$ the tangent vectors $\mathbf{e}_i$ are not normalized. The spherical metric is,

$$g_{ij} = \frac{\partial x_a}{\partial u^i}\frac{\partial x^a}{\partial u^j} = \begin{pmatrix} \mathbf{e}_r\cdot\mathbf{e}_r & \mathbf{e}_r\cdot\mathbf{e}_\theta & \mathbf{e}_r\cdot\mathbf{e}_\phi \\ \mathbf{e}_\theta\cdot\mathbf{e}_r & \mathbf{e}_\theta\cdot\mathbf{e}_\theta & \mathbf{e}_\theta\cdot\mathbf{e}_\phi \\ \mathbf{e}_\phi\cdot\mathbf{e}_r & \mathbf{e}_\phi\cdot\mathbf{e}_\theta & \mathbf{e}_\phi\cdot\mathbf{e}_\phi \end{pmatrix} = \begin{pmatrix} 1 & 0 & 0 \\ 0 & r^2 & 0 \\ 0 & 0 & r^2\sin^2\theta \end{pmatrix} ,$$

with $x_a = x, y, z$, $u^i = r, \theta, \phi$, and the contra-variant spherical metric being,

$$g^{ij} = \frac{\partial u^i}{\partial x_a}\frac{\partial u^j}{\partial x^a} = \begin{pmatrix} 1 & 0 & 0 \\ 0 & r^{-2} & 0 \\ 0 & 0 & r^{-2}\sin^{-2}\theta \end{pmatrix} . \tag{12.110}$$

we obtain the contra-variant tangent vectors,

$$\begin{aligned}
\mathbf{e}^r &= g^{rr}\mathbf{e}_r = \hat{\mathbf{e}}_x \sin\theta\cos\phi + \hat{\mathbf{e}}_y \sin\theta\sin\phi + \hat{\mathbf{e}}_z \cos\theta = \hat{\mathbf{e}}_r \\
\mathbf{e}^\theta &= g^{\theta\theta}\mathbf{e}_\theta = \frac{1}{r}\hat{\mathbf{e}}_x \cos\theta\cos\phi + \frac{1}{r}\hat{\mathbf{e}}_y \cos\theta\sin\phi - \frac{1}{r}\hat{\mathbf{e}}_z \sin\theta = \frac{1}{r}\hat{\mathbf{e}}_\theta \\
\mathbf{e}^\phi &= g^{\phi\phi}\mathbf{e}_\phi = -\frac{1}{r\sin\theta}\hat{\mathbf{e}}_x \sin\phi + \frac{1}{r\sin\theta}\hat{\mathbf{e}}_y \cos\phi = \frac{1}{r\sin\theta}\hat{\mathbf{e}}_\phi \ .
\end{aligned} \tag{12.111}$$

The diagonal shape of the metrics are comes from the fact that spherical coordinates are orthogonal. In the example 39 we discuss the metric of an non-orthogonal coordinate system.

Example 39 (*Metric in elliptical coordinates*): In contrast to polar, cylindrical, or spherical coordinates, elliptical coordinates given by,

$$\mathbf{r} = \begin{pmatrix} x \\ y \end{pmatrix} = \begin{pmatrix} ar\cos\phi \\ br\sin\phi \end{pmatrix} \quad , \quad \begin{pmatrix} r \\ \phi \end{pmatrix} = \begin{pmatrix} \sqrt{(\frac{x}{a})^2 + (\frac{y}{b})^2} \\ \arctan\frac{ay}{bx} \end{pmatrix} , \tag{12.112}$$

are not orthogonal. The tangent vectors are,

$$\begin{aligned}
\mathbf{e}_r &= \frac{\partial \mathbf{r}}{\partial r} = \hat{\mathbf{e}}_x a\cos\phi + \hat{\mathbf{e}}_y b\sin\phi \\
\mathbf{e}_\phi &= \frac{\partial \mathbf{r}}{\partial \phi} = -\hat{\mathbf{e}}_x ar\sin\phi + \hat{\mathbf{e}}_y br\cos\phi \ .
\end{aligned} \tag{12.113}$$

Note that, in contrast to the basis vectors $\hat{\mathbf{e}}_i$ the tangent vectors $\mathbf{e}_i$ are not normalized. The elliptical metric is,

$$g_{ij} = \frac{\partial x_a}{\partial u^i}\frac{\partial x^a}{\partial u^j} = \begin{pmatrix} \mathbf{e}_r \cdot \mathbf{e}_r & \mathbf{e}_r \cdot \mathbf{e}_\phi \\ \mathbf{e}_\phi \cdot \mathbf{e}_r & \mathbf{e}_\phi \cdot \mathbf{e}_\phi \end{pmatrix} = \begin{pmatrix} a^2\cos^2\phi + b^2\sin^2\phi & (b^2-a^2)r\sin\phi\cos\phi \\ (b^2-a^2)r\sin\phi\cos\phi & (a^2\sin^2\phi + b^2\cos^2\phi)r^2 \end{pmatrix} ,$$

with $x_a = x, y$, $u^i = r, \phi$, and the contra-variant elliptical metric being,

$$g^{ij} = \frac{\partial u^i}{\partial x_a}\frac{\partial u^j}{\partial x^a} = \frac{1}{a^2b^2r^2}\begin{pmatrix} a^2r^2\sin^2\phi + b^2r^2\cos^2\phi & (a^2-b^2)r\sin\phi\cos\phi \\ (a^2-b^2)r\sin\phi\cos\phi & a^2\cos^2\phi + b^2\sin^2\phi) \end{pmatrix} . \tag{12.114}$$

we obtain the cotangent vectors,

$$\begin{aligned} \mathbf{e}^r &= g^{ri}\mathbf{e}_i = g^{rr}\mathbf{e}_r + g^{r\phi}\mathbf{e}_\phi = \hat{\mathbf{e}}_x a^{-1}\cos\phi + \hat{\mathbf{e}}_y b^{-1}\sin\phi \qquad (12.115) \\ \mathbf{e}^\phi &= g^{\phi i}\mathbf{e}_i = g^{\phi r}\mathbf{e}_r + g^{\phi\phi}\mathbf{e}_\phi = -\hat{\mathbf{e}}_x a^{-1}r^{-1}\sin\phi + \hat{\mathbf{e}}_y b^{-1}r^{-1}\cos\phi . \end{aligned}$$

The fact that the metric is not diagonal is due to the elliptical coordinates not being orthogonal. One verifies,

$$\mathbf{e}^r \cdot \mathbf{e}_\phi = 0 = \mathbf{e}_r \cdot \mathbf{e}^\phi \quad , \quad \mathbf{e}^r \cdot \mathbf{e}_r = 1 = \mathbf{e}_\phi \cdot \mathbf{e}^\phi . \tag{12.116}$$

Interestingly, while neither the tangent nor the cotangent vectors are orthogonal, they are mutually orthogonal.

12.4.3.2 Christoffel symbols

The Christoffel symbols are defined by,

$$\Gamma^k_{\ ij} \equiv \frac{\partial \mathbf{e}_i}{\partial x^j}\cdot\mathbf{e}^k . \tag{12.117}$$

They yields for spherical coordinates with $j = r, \theta, \phi$,

$$\Gamma^a_{\ ir} = \begin{pmatrix} 0 & 0 & 0 \\ 0 & r^{-1} & 0 \\ 0 & 0 & r^{-1} \end{pmatrix} \quad , \quad \Gamma^a_{\ i\theta} = \begin{pmatrix} 0 & -r & 0 \\ r^{-1} & 0 & 0 \\ 0 & 0 & -\tan\theta \end{pmatrix} \tag{12.118}$$

$$\Gamma^a_{\ i\phi} = \begin{pmatrix} 0 & 0 & -r\cos^2\theta \\ 0 & r^{-1} & \sin\theta\cos\theta \\ r^{-1} & -\tan\theta & 0 \end{pmatrix} .$$

Do the Exc. 12.4.4.4.

12.4.3.3 Geodesic equation

In differential geometry the *geodesic equation* is a curve representing in some sense the shortest path between two points in a surface, or more generally in a Riemannian manifold. It is a generalization of the notion of a 'straight line'. The geodesic line is obtained by solving the differential equation,

$$\frac{d^2x^k}{ds^2} + \Gamma^k_{\ ab}\frac{dx^a}{ds}\frac{dx^b}{ds} = 0 . \tag{12.119}$$

12.4.4 Exercises

12.4.4.1 Ex: Tensors of rank n

Be given $\mathbf{F} = \mathbf{E} + \imath\mathbf{B}$ and $\mathbf{F}^* = \mathbf{E} - \imath\mathbf{B}$. Identify (in this order) the scalar $\mathbf{F}^* \cdot \mathbf{F}/(8\pi)$, teh vector $\mathbf{F}^* \times \mathbf{F}/(8\pi\imath)$, and the dyade (tensor) $(\mathbf{F}^* \cdot \mathbf{F} + \mathbf{F} \cdot \mathbf{F}^*)/(8\pi)$. What happens to these quantities if we exchange $\mathbf{F}$ for $e^{-\imath\phi}\mathbf{F}$, where ϕ is supposed constant?

Solution: *We get first,*

$$\frac{1}{8\pi}\mathbf{F}^* \cdot \mathbf{F} = \frac{1}{8\pi}(\mathbf{E} - \imath\mathbf{B}) \cdot (\mathbf{E} + \imath\mathbf{B}) = \frac{1}{8\pi}(\mathbf{E}^2 + \mathbf{B}^2) = U \ .$$

Then,

$$\frac{1}{8\pi\imath}\mathbf{F}^* \times \mathbf{F} = \frac{1}{8\pi\imath}(\mathbf{E} - \imath\mathbf{B}) \times (\mathbf{E} + \imath\mathbf{B}) = \frac{1}{4\pi}(\mathbf{E} \times \mathbf{B}) = \frac{1}{c}\mathbf{S} \ .$$

Finally,

$$\begin{aligned}\frac{1}{8\pi}(\mathbf{F}^* \cdot \mathbf{F} + \mathbf{F} \cdot \mathbf{F}^*) &= \frac{1}{8\pi}\left[(\mathbf{E} - \imath\mathbf{B}) \cdot (\mathbf{E} + \imath\mathbf{B}) + (\mathbf{E} + \imath\mathbf{B}) \cdot (\mathbf{E} - i\mathbf{B})\right] \\ &= \frac{1}{8\pi}\left[\mathbf{E} \cdot \mathbf{E} + \imath\mathbf{B} \cdot \mathbf{E} - \imath\mathbf{E} \cdot \mathbf{B} + \mathbf{B} \cdot \mathbf{B} + \mathbf{E} \cdot \mathbf{E} - \imath\mathbf{B} \cdot \mathbf{E} + \imath\mathbf{E} \cdot \mathbf{B} + \mathbf{B} \cdot \mathbf{B}\right] \\ &= \frac{1}{4\pi}(\mathbf{E} \cdot \mathbf{E} + \mathbf{B} \cdot \mathbf{B}) = \overleftrightarrow{T} + U \overleftrightarrow{\mathbf{1}} \ .\end{aligned}$$

Exchanging,

$$\mathbf{F} \to e^{-\imath\phi}\mathbf{F} \qquad \textit{hence} \qquad \mathbf{F}^* \to e^{+\imath\phi}\mathbf{F}^* \ .$$

and we see immediately that all three expressions above are invariant about this transformation.

12.4.4.2 Ex: Jacobian for transformation into curvilinear coordinates

a. Calculate the Jacobian of the transformation from cylindrical coordinates (ρ, z, φ) to Cartesian coordinates (x, y, z).
b. Calculate the Jacobian of the transformation from spherical coordinates (r, θ, φ) to Cartesian coordinates (x, y, z).

Solution: *a. The Jacobian is given by the function* $\mathbf{F} = \mathbf{r}$ *with the components,*

$$\begin{aligned} x &= \rho\cos\varphi \\ y &= \rho\sin\varphi \\ z &= z \ . \end{aligned}$$

The Jacobian of this function is,

$$\mathbf{J}_\mathbf{F}(r, z, \varphi) = \begin{pmatrix} \frac{\partial x}{\partial \rho} & \frac{\partial x}{\partial z} & \frac{\partial x}{\partial \varphi} \\ \frac{\partial y}{\partial \rho} & \frac{\partial y}{\partial z} & \frac{\partial y}{\partial \varphi} \\ \frac{\partial z}{\partial \rho} & \frac{\partial z}{\partial z} & \frac{\partial z}{\partial \varphi} \end{pmatrix} = \begin{pmatrix} \cos\varphi & 0 & -\rho\sin\varphi \\ \sin\varphi & 0 & \rho\cos\varphi \\ 0 & 1 & 0 \end{pmatrix} \ .$$

The determinant is $-\rho$. As an example, the volume element can be expressed as $dV = dxdydz = \rho dr dz d\varphi$. However, this determinant varies with the coordinates.
b. The Jacobian is given by the function $\mathbf{F} = \mathbf{r}$ with the components,

$$\begin{aligned} x &= r\sin\theta\cos\varphi \\ y &= r\sin\theta\sin\varphi \\ z &= r\cos\theta \ . \end{aligned}$$

The Jacobian of this function is,

$$\mathbf{J}_{\mathbf{F}}(r,\theta,\varphi) = \begin{pmatrix} \frac{\partial x}{\partial r} & \frac{\partial x}{\partial \theta} & \frac{\partial x}{\partial \varphi} \\ \frac{\partial y}{\partial r} & \frac{\partial y}{\partial \theta} & \frac{\partial y}{\partial \varphi} \\ \frac{\partial z}{\partial r} & \frac{\partial z}{\partial \theta} & \frac{\partial z}{\partial \varphi} \end{pmatrix} = \begin{pmatrix} \sin\theta\cos\varphi & r\cos\theta\cos\varphi & -r\sin\theta\sin\varphi \\ \sin\theta\sin\varphi & r\cos\theta\sin\varphi & -r\sin\theta\cos\varphi \\ \cos\theta & -r\sin\theta & 0 \end{pmatrix} \ .$$

The determinant is $r^2\sin\theta$. As an example, the volume element can be expressed as $dV = dxdydz = r^2\sin\theta dr d\theta d\varphi$. However, this determinant varies with the coordinates.

12.4.4.3 Ex: Jacobian for Galilei and Lorentz transform

Determine the Jacobean of the Galilei transformation,

$$ct' = ct \quad \text{and} \quad x' = x \quad \text{and} \quad y' = y \quad \text{and} \quad z' = z - \tfrac{u}{c}ct \ ,$$

and the Lorentz transformation,

$$ct' = \gamma(ct - \tfrac{u}{c}x) \quad \text{and} \quad x' = x \quad \text{and} \quad y' = y \quad \text{and} \quad z' = \gamma(z - \tfrac{u}{c}z) \ .$$

Solution: *We have,*

$$G_{\mu\nu} = \frac{\partial x'_\mu}{\partial x_\nu} = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ -\frac{u}{c} & 0 & 0 & 1 \end{pmatrix} \quad , \quad \Lambda_{\mu\nu} = \frac{\partial x'_\mu}{\partial x_\nu} = \begin{pmatrix} \gamma & 0 & 0 & -\frac{u}{c}\gamma \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ -\frac{u}{c}\gamma & 0 & 0 & \gamma \end{pmatrix} \ .$$

12.4.4.4 Ex: Christoffel symbols for two-dimensional polar coordinates

Derive the Christoffel symbols for two-dimensional polar coordinates.

Solution: *Polar coordinates are defined by,*

$$\begin{pmatrix} x \\ y \end{pmatrix} = \begin{pmatrix} r\cos\varphi \\ r\sin\varphi \end{pmatrix} \quad , \quad \begin{pmatrix} r \\ \varphi \end{pmatrix} = \begin{pmatrix} \sqrt{x^2+y^2} \\ \arctan\frac{y}{x} \end{pmatrix} \ .$$

From the definition of the Christoffel symbols,

$$\Gamma^m{}_{ab} = \frac{\partial x^m}{\partial u^k}\frac{\partial^2 u^k}{\partial x^a \partial x^b} \ ,$$

we get explicitly,

$$\Gamma^a{}_{br} = \begin{pmatrix} \Gamma^r{}_{rr} & \Gamma^r{}_{\varphi r} \\ \Gamma^\varphi{}_{rr} & \Gamma^\varphi{}_{\varphi r} \end{pmatrix} = \begin{pmatrix} \frac{\partial r}{\partial x}\frac{\partial^2 x}{\partial r^2} + \frac{\partial r}{\partial y}\frac{\partial^2 y}{\partial r^2} & \frac{\partial r}{\partial x}\frac{\partial^2 x}{\partial \varphi \partial r} + \frac{\partial r}{\partial y}\frac{\partial^2 y}{\partial \varphi \partial r} \\ \frac{\partial \varphi}{\partial x}\frac{\partial^2 x}{\partial r^2} + \frac{\partial \varphi}{\partial y}\frac{\partial^2 y}{\partial r^2} & \frac{\partial \varphi}{\partial x}\frac{\partial^2 x}{\partial \varphi \partial r} + \frac{\partial \varphi}{\partial y}\frac{\partial^2 y}{\partial \varphi \partial r} \end{pmatrix} = \begin{pmatrix} 0 & 0 \\ 0 & 0 \end{pmatrix}$$

$$\Gamma^a{}_{b\varphi} = \begin{pmatrix} \Gamma^r{}_{r\varphi} & \Gamma^r{}_{\varphi\varphi} \\ \Gamma^\varphi{}_{r\varphi} & \Gamma^\varphi{}_{\varphi\varphi} \end{pmatrix} = \begin{pmatrix} \frac{\partial r}{\partial x}\frac{\partial^2 x}{\partial r \partial \varphi} + \frac{\partial r}{\partial y}\frac{\partial^2 y}{\partial r \partial \varphi} & \frac{\partial r}{\partial x}\frac{\partial^2 x}{\partial \varphi^2} + \frac{\partial r}{\partial y}\frac{\partial^2 y}{\partial \varphi^2} \\ \frac{\partial \varphi}{\partial x}\frac{\partial^2 x}{\partial r \partial \varphi} + \frac{\partial \varphi}{\partial y}\frac{\partial^2 y}{\partial r \partial \varphi} & \frac{\partial \varphi}{\partial x}\frac{\partial^2 x}{\partial \varphi^2} + \frac{\partial \varphi}{\partial y}\frac{\partial^2 y}{\partial \varphi^2} \end{pmatrix} = \begin{pmatrix} 0 & -r \\ 0 & 0 \end{pmatrix} \ .$$

12.4.4.5 Ex: Distorted polar coordinates

a. Study the coordinate system,

$$\mathbf{r} = \begin{pmatrix} x \\ y \end{pmatrix} = \begin{pmatrix} f(r)\cos\phi \\ g(r)\sin\phi \end{pmatrix}$$

for arbitrary radial functions $f(r)$ and $g(r)$.
b. Consider the particular cases (i) $f = g$ and (ii) $f = ar$ and $g = br$.

Solution: *a. The tangent vectors are,*

$$\mathbf{e}_r = \frac{\partial \mathbf{r}}{\partial r} = \hat{\mathbf{e}}_x f'(r)\cos\phi + \hat{\mathbf{e}}_y g'(r)\sin\phi$$
$$\mathbf{e}_\phi = \frac{\partial \mathbf{r}}{\partial \phi} = -\hat{\mathbf{e}}_x f(r)\sin\phi + \hat{\mathbf{e}}_y g(r)\cos\phi \ ,$$

and the metric,

$$g_{ij} = \begin{pmatrix} f'(r)^2\cos^2\phi + g'(r)^2\sin^2\phi & [g(r)g'(r) - f(r)f'(r)]\sin\phi\cos\phi \\ [g(r)g'(r) - f(r)f'(r)]\sin\phi\cos\phi & f(r)^2\sin^2\phi + g(r)^2\cos^2\phi \end{pmatrix} \ .$$

The determinant of the metric is,

$$\det g_{ij} = \left[f'(r)g(r)\cos^2\phi + f(r)g'(r)\sin^2\phi\right]^2$$

and the inverse metric,

$$g^{ij} = g_{ij}^{-1} = \frac{1}{\det g_{ij}}\begin{pmatrix} f'(r)^2\sin^2\phi + g'(r)^2\cos^2\phi & [f(r)f'(r) - g(r)g'(r)]\sin\phi\cos\phi \\ [f(r)f'(r) - g(r)g'(r)]\sin\phi\cos\phi & f(r)^2\cos^2\phi + g(r)^2\sin^2\phi \end{pmatrix} \ .$$

b. For the case $f = g$ this simplifies to,

$$g_{ij} = \begin{pmatrix} f'(r)^2 & 0 \\ 0 & f(r)^2 \end{pmatrix} \quad , \quad g^{ij} = \begin{pmatrix} f(r)^2 & 0 \\ 0 & f'(r)^2 \end{pmatrix} ,$$

and for the case, $f = ar$ and $g = br$ to,

$$g_{ij} = \begin{pmatrix} a^2\cos^2\phi + b^2\sin^2\phi & (b^2-a^2)r\sin\phi\cos\phi \\ (b^2-a^2)r\sin\phi\cos\phi & (a^2\sin^2\phi + b^2\cos^2\phi)r^2 \end{pmatrix}$$
$$g^{ij} = \begin{pmatrix} a^{-2}\cos^2\phi + b^{-2}\sin^2\phi & (b^{-2}-a^{-2})r^{-1}\sin\phi\cos\phi \\ (b^{-2}-a^{-2})r^{-1}\sin\phi\cos\phi & (a^{-2}\sin^2\phi + b^{-2}\cos^2\phi)r^{-2} \end{pmatrix} .$$

12.4.4.6 Ex: Metric for ellipsoidal coordinates

Generalize the metric for ellipsoidal coordinates.

Solution: *For ellipsoidal coordinates,*

$$\mathbf{r} = \begin{pmatrix} x \\ y \\ z \end{pmatrix} = \begin{pmatrix} ar\sin\theta\cos\phi \\ br\sin\theta\sin\phi \\ cr\cos\theta \end{pmatrix} \quad , \quad \begin{pmatrix} r \\ \theta \\ \phi \end{pmatrix} = \begin{pmatrix} \sqrt{\left(\frac{x}{a}\right)^2 + \left(\frac{y}{b}\right)^2 + \left(\frac{z}{c}\right)^2} \\ \arccos \frac{z/c}{\sqrt{(x/a)^2+(y/b)^2+(z/c)^2}} \\ \arctan \frac{ay}{bx} \end{pmatrix} ,$$

the tangent vectors are,

$$\mathbf{e}_r = \frac{\partial \mathbf{r}}{\partial r} = a\hat{\mathbf{e}}_x \sin\theta\cos\phi + b\hat{\mathbf{e}}_y \sin\theta\sin\phi + c\hat{\mathbf{e}}_z\cos\theta$$
$$\mathbf{e}_\theta = \frac{\partial \mathbf{r}}{\partial \theta} = ar\hat{\mathbf{e}}_x \cos\theta\cos\phi + br\hat{\mathbf{e}}_y \cos\theta\sin\phi - cr\hat{\mathbf{e}}_z\sin\theta$$
$$\mathbf{e}_\phi = \frac{\partial \mathbf{r}}{\partial \phi} = -ar\hat{\mathbf{e}}_x \sin\theta\sin\phi + br\hat{\mathbf{e}}_y \sin\theta\cos\phi \ .$$

Note that, in contrast to the basis vectors $\hat{\mathbf{e}}_i$ the tangent vectors $\mathbf{e}_i$ are not normalized. The ellipsoidal metric is,

$$g_{ij} = \frac{\partial x_a}{\partial u^i}\frac{\partial x^a}{\partial u^j} = \begin{pmatrix} \mathbf{e}_r\cdot\mathbf{e}_r & \mathbf{e}_r\cdot\mathbf{e}_\theta & \mathbf{e}_r\cdot\mathbf{e}_\phi \\ \mathbf{e}_\theta\cdot\mathbf{e}_r & \mathbf{e}_\theta\cdot\mathbf{e}_\theta & \mathbf{e}_\theta\cdot\mathbf{e}_\phi \\ \mathbf{e}_\phi\cdot\mathbf{e}_r & \mathbf{e}_\phi\cdot\mathbf{e}_\theta & \mathbf{e}_\phi\cdot\mathbf{e}_\phi \end{pmatrix}$$
$$= \begin{pmatrix} B_\phi\sin^2\theta + c^2\cos^2\theta & (B_\phi - c^2)r\sin\theta\cos\theta & C_\phi r\sin^2\theta \\ (B_\phi - c^2)r\sin\theta\cos\theta & (B_\phi\cos^2\theta + c^2\sin^2\theta)r^2 & C_\phi r^2\sin\theta\cos\theta \\ C_\phi r\sin^2\theta & C_\phi r^2\sin\theta\cos\theta & A_\phi r^2\sin^2\theta \end{pmatrix} ,$$

with $x_a = x, y, z$, $\xi^i = r, \theta, \phi$ *and with the abbreviations* $A_\phi \equiv a^2 \sin^2\phi + b^2 \cos^2\phi$, $B_\phi \equiv a^2 \cos^2\phi + b^2 \sin^2\phi$, *and* $C_\phi \equiv (b^2 - a^2)\sin\phi\cos\phi$. *The determinant is,*

$$\det g_{ij} = a^2 b^2 c^2 r^4 \sin^2\theta \ .$$

The contra-variant ellipsoidal metric being,

$$g^{ij} = g_{ij}^{-1} = \frac{\partial \xi^i}{\partial x_a}\frac{\partial \xi^j}{\partial x^a}$$

$$= \frac{1}{a^2 b^2 c^2 r^2}\begin{pmatrix} (a^2 b^2 \cos^2\theta + A_\phi c^2 \sin^2\theta) r^2 & (-a^2 b^2 + A_\phi c^2) r \sin\theta\cos\theta & -C_\phi c^2 r \\ (-a^2 b^2 + A_\phi c^2) r \sin\theta\cos\theta & a^2 b^2 \sin^2\theta + A_\phi c^2 \cos^2\theta & -C_\phi c^2 \cot\theta \\ -C_\phi c^2 r & -C_\phi c^2 \cot\theta & \frac{B_\phi c^2}{\sin^2\theta} \end{pmatrix} .$$

we obtain the contra-variant tangent vectors,

$$\begin{aligned} \mathbf{e}^r &= g^{ri}\mathbf{e}_i = \frac{\hat{\mathbf{e}}_x \sin\theta\cos\phi}{a} + \frac{\hat{\mathbf{e}}_y \sin\theta\sin\phi}{b} + \frac{\hat{\mathbf{e}}_z \cos\theta}{c} \\ \mathbf{e}^\theta &= g^{\theta i}\mathbf{e}_i = \frac{\hat{\mathbf{e}}_x \cos\theta\cos\phi}{ar} + \frac{\hat{\mathbf{e}}_y \cos\theta\sin\phi}{br} - \frac{\hat{\mathbf{e}}_z \sin\theta}{cr} \\ \mathbf{e}^\phi &= g^{\phi i}\mathbf{e}_i = -\frac{\hat{\mathbf{e}}_x \sin\phi}{ar\sin\theta} + \frac{\hat{\mathbf{e}}_y \cos\phi}{br\sin\theta} \ . \end{aligned}$$

One verifies,

$$\mathbf{e}^i \cdot \mathbf{e}_j = \delta_{ij} \qquad , \qquad \mathbf{e}^i \cdot \mathbf{e}^j \neq 0, 1 \ ,$$

for $i, j = r, \theta, \phi$.

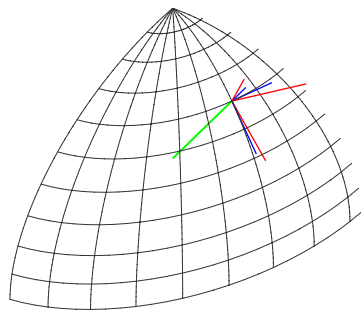

Figure 12.10: (code) Tangent and cotangent coordinates on an ellipsoid.

12.5 Dirac's δ-function

Calculating the divergence of the vector field $\mathbf{A} = \mathbf{r}/r^3$ in spherical coordinates [1],

$$\nabla \cdot \mathbf{A} = \frac{1}{r^2}\frac{\partial}{\partial r}\left(r^2 \frac{1}{r^2}\right) = 0 \ , \tag{12.120}$$

[1] Or in Cartesian coordinates: $\nabla \cdot \mathbf{A} = \frac{\partial}{\partial r^3}\frac{x}{r^3} + \frac{\partial}{\partial r^3}\frac{y}{r^3} + \frac{\partial}{\partial r^3}\frac{z}{r^3} = \frac{3r^3 - 3x^2 r}{r^6} + ... = 0.$

we expect,

$$\int_{sphere} \nabla \cdot \mathbf{A} dV = 0 \ . \tag{12.121}$$

This is surprising, because intuition tells us to expect a huge divergence near the origin. The problem is that the field $\mathbf{A}$ diverges at the origin, which calls for a modification of the expression for the gradient. Gauß' law gives us an indication since, according to this law, the result (12.121) should be equal to the surface integral,

$$\oint_{\partial\ sphere} \mathbf{A} \cdot d\mathbf{S} = \int_0^{2\pi} \int_0^{\pi} \frac{\hat{\mathbf{e}}_r}{R^2} \cdot (R^2 \sin\theta d\theta d\phi \hat{\mathbf{e}}_r) = 4\pi \ . \tag{12.122}$$

As the integral (12.121) contains a divergence within the volume of integration, we conclude that the integral (12.122), which has no divergence within the integration surface is more reliable. Therefore, we look for a function δ satisfying,

$$\int_{sphere} \nabla \cdot \mathbf{A}(\mathbf{r}) dV = \int_{sphere} 4\pi\delta(\mathbf{r}) dV = 4\pi \ , \tag{12.123}$$

that is, a function having the property of killing integrals.

12.5.1 The Dirac function in 1 dimension

In one dimension the *Dirac function* is defined by,

$$\boxed{\delta(x) \equiv \begin{cases} 0 & \text{for} \quad x \neq 0 \\ \infty & \text{for} \quad x = 0 \end{cases}} \ , \tag{12.124}$$

such that,

$$\int_{-\infty}^{\infty} \delta(x) dx = 1 \ . \tag{12.125}$$

The Dirac function can be expressed as the limit of a series of continuous functions,

$$\begin{aligned} \delta(x) &= \lim_{n\to\infty} \frac{n}{\pi} \frac{1}{1+n^2x^2} \\ \delta(x) &= \lim_{n\to\infty} \frac{n}{\pi} \left(\frac{\sin nx}{nx}\right)^2 \\ \delta(x) &= \lim_{n\to\infty} \frac{1}{\pi} \frac{\sin nx}{x} = \lim_{n\to\infty} \frac{1}{2\pi} \int_{-n}^{+n} e^{\imath kx} dk \ . \end{aligned} \tag{12.126}$$

We also note that the Dirac function is even, $\delta(-x) = \delta(x)$, non-linear, $\delta(ax) = \delta(x)/|a|$, and can be interpreted as the derivative of the *Heavyside function*,

$$\int_{-\infty}^{x} \delta(x') dx' = \Theta(x) \qquad \text{or} \qquad \frac{d\Theta}{dx} = \delta(x) \ . \tag{12.127}$$

We will train the calculus with the Dirac function in Excs. 12.5.4.1 to 12.5.4.3.

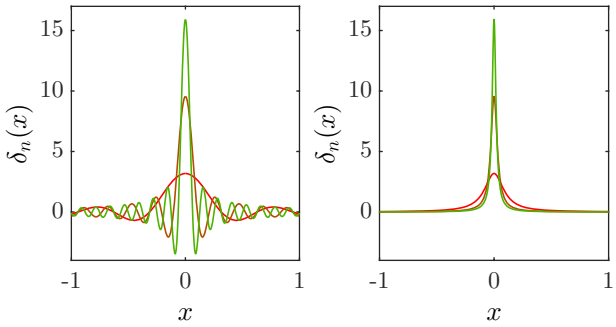

Figure 12.11: (code) Illustration of the function $\frac{1}{\pi}\frac{\sin nx}{x}$ (left) and of the function $\frac{1}{\pi}\frac{n}{1+n^2x^2}$ (right) for various $n \to \infty$.

When the argument of a Dirac function is itself a function $f(x)$, the Dirac is evaluated at each zero-passage of f,

$$\boxed{\int_a^b dx\ g(x)\delta(f(x)) = \int_a^b dx\ g(x)\sum_i \frac{\delta(x-x_i)}{|f'(x_i)|}}\ , \tag{12.128}$$

where $f'(x_i) \neq 0$. We will apply this theorem in Exc. 12.5.4.4.

12.5.2 The Dirac function in 2 and 3 dimensions

In more dimensions the δ-function is often used to parametrize points, paths, or surfaces within a volume. For example, a point charge Q at the position $\mathbf{a}$ can be described by the three-dimensional density distribution,

$$\rho(\mathbf{r}) = Q\delta^3(\mathbf{r}-\mathbf{a}) = Q\delta(x-a_x)\delta(y-a_y)\delta(z-a_z)\ , \tag{12.129}$$

a current I in a circular loop with radius R within the $z=0$ plane generates a current density,

$$\mathbf{j} = I\delta(r-R)\delta(z)\hat{\mathbf{e}}_\phi\ , \tag{12.130}$$

called a *current yarn*. Similarly, a two-dimensional arrangement of charges σ homogeneously distributed over the surface of a sphere with radius R can be described by the three-dimensional density distribution,

$$\rho(\mathbf{r}) = \sigma\delta(r-R)\ . \tag{12.131}$$

Such parametrizations are useful, because they can be applied in fundamental laws of electromagnetism (see Exc. 12.5.4.5).

Example 40 (*Parametrization of a current distribution*): As an example we calculate the current I produced by the distribution (12.130) crossing a rectangular area around the point $\mathbf{r} = R\hat{\mathbf{e}}_x$,

$$\int_{area}\mathbf{j}\cdot d\mathbf{A} = I\int_{R-\Delta x}^{R+\Delta x}\int_{-\Delta z}^{\Delta z}\delta(r-R)\delta(z)\hat{\mathbf{e}}_y d\mathbf{A} = I\int_{r-\Delta x}^{r+\Delta x}\delta(x-R)dx = I\ .$$

Example 41 (*Parametrization of a charge distribution*): In another example we calculate the total charge Q produced by the distribution (12.131),

$$\int_{volume} \rho(\mathbf{r}) dV = \sigma \int_0^{2\pi} \int_0^{\pi} \int_0^{\infty} \delta(r-R) r^2 \sin\theta d\theta d\phi dr = \sigma 4\pi R^2 = Q \ .$$

Example 42 (*Dirac function in Coulomb's Law*): In a third example we show that the field of a point charge, $\varrho(\mathbf{r}) = Q\delta(x)\delta(y)\delta(z)$, can be obtained from Coulomb's law,

$$\vec{\mathcal{E}} = \int \frac{\varrho(\mathbf{r}')}{4\pi\varepsilon_0} \frac{\mathbf{r}-\mathbf{r}'}{|\mathbf{r}-\mathbf{r}'|^3} dV' = \frac{Q}{4\pi\varepsilon_0} \frac{\mathbf{r}}{r^3} \ .$$

12.5.3 Analytical signals

In signal processing theory, an *analytic signal* is a complex-valued function without negative frequency components. The real and imaginary parts of an analytic signal are mutually related by a *Hilbert transform*. Conversely, the analytic representation of a real-valued function is an analytic signal, which comprises the original function and its Hilbert transform. This representation facilitates many mathematical manipulations. The basic idea is that the negative frequency components of the Fourier transform (or spectrum) of a real function are superfluous due to the Hermitian symmetry of such a spectrum. These negative-frequency components can be discarded without loss of information, as long as we are willing to deal with a complex function. This makes certain attributes of the function more accessible, particularly for application in radiofrequency manipulation techniques.

While the manipulated function has no negative frequency components (that is, it is still analytic), the inverse conversion from complex to real is just a matter of discarding the imaginary part. The analytical representation is a generalization of the *phasor* concept: while the phasor is restricted to time-invariant amplitudes, phases and frequencies, the analytic signal allows for temporally variable parameters.

12.5.3.1 Transfer function generating an analytical signal

We consider a real function $s(t)$ with its Fourier transform $S(f)$. Then the transformed function exhibits a Hermitian symmetry about the point $f = 0$, since,

$$S(-f) = S(f)^* \ , \tag{12.132}$$

The function,

$$S_a(f) \equiv \begin{cases} 2S(f) & \text{for } f > 0 \\ S(f) & \text{for } f = 0 \\ 0 & \text{for } f < 0 \end{cases} = S(f) + \text{sgn}(f) S(f) \ , \tag{12.133}$$

where $\mathrm{sgn}(f)$ calculates the sign of f, only contains the non-negative components of $S(f)$. This operation is reversible due to the Hermitian symmetry of $S(f)$:

$$S(f) = \begin{cases} \frac{1}{2}S_a(f) & \text{para } f > 0 \\ S_a(f) & \text{para } f = 0 \\ \frac{1}{2}S_a(-f)^* & \text{para } f < 0 \end{cases} = \tfrac{1}{2}[S_a(f) + S_a(-f)^*] \ . \tag{12.134}$$

The analytical signal of $s(t)$ is the inverse Fourier transform of $S_a(f)$,

$$\begin{aligned} s_a(t) &\equiv \mathcal{F}^{-1}[S_a(f)] = \mathcal{F}^{-1}[S(f) + \mathrm{sgn}(f) \cdot S(f)] \\ &= \mathcal{F}^{-1}[S(f)] + \mathcal{F}^{-1}[\mathrm{sgn}(f)] \star \mathcal{F}^{-1}[S(f)] = s(t) + \imath \left[\tfrac{1}{\pi t} \star s(t)\right] = s(t) + \imath\hat{s}(t) \ , \end{aligned} \tag{12.135}$$

where $\star$ denotes the convolution.

$$\boxed{\hat{s}(t) \equiv \mathcal{H}[s(t)] \equiv \tfrac{1}{\pi t} \star s(t) = \tfrac{1}{\pi}\mathcal{P}\int_{-\infty}^{\infty} \frac{s(\tau)}{t-\tau} d\tau} \ , \tag{12.136}$$

with $\mathcal{P}$ denoting Cauchy's principal value, is the definition of the *Hilbert transform* of $s(t)$ [2].

Example 43 (*Analytical signal of the cosine function*): We consider the signal $s(t) = \cos\omega t$, where $\omega > 0$. Now

$$\begin{aligned} \hat{s}(t) &= \cos(\omega t - \tfrac{\pi}{2}) = \sin\omega t \ , \\ s_a(t) &= s(t) + \imath\hat{s}(t) = \cos\omega t + \imath \sin\omega t = e^{\imath\omega t} \ . \end{aligned}$$

In general, the analytical representation of a simple sinusoidal function is obtained by expressing it in terms of complex exponentials, discarding the negative frequency components, and doubling the positive frequency components, as in the example $s(t) = \cos(\omega t + \theta) = \frac{1}{2}(e^{\imath(\omega t+\theta)} + e^{-\imath(\omega t+\theta)})$. Here, we get directly from Euler's formula,

$$s_a(t) = \begin{cases} e^{\imath(\omega t+\theta)} &= e^{\imath|\omega|t}e^{\imath\theta} & \text{if } \omega > 0 \\ e^{-\imath(\omega t+\theta)} &= e^{\imath|\omega|t}e^{-\imath\theta} & \text{if } \omega < 0 \end{cases} \ .$$

The analytical representation of a sum of sinusoidal functions is the sum of the analytical representations of the individual sinuses.

We note that it is not forbidden to compute $s_a(t)$ for a complex $s(t)$. But this representation may be irreversible, since the original spectrum is usually not symmetric. Therefore, with the exception of the case $s(t) = e^{-\imath\omega t}$ with $\omega > 0$, where,

$$\begin{aligned} \hat{s}(t) &= \imath e^{-\imath\omega t} \\ s_a(t) &= e^{-\imath\omega t} + \imath^2 e^{-\imath\omega t} = e^{-\imath\omega t} - e^{-\imath\omega t} = 0 \ , \end{aligned} \tag{12.137}$$

[2] Also holds,

$$\begin{aligned} \hat{s}(t) &= -\tfrac{1}{\pi}\lim_{\epsilon\to 0}\int_{\epsilon}^{\infty} \frac{s(t+\tau) - s(t-\tau)}{\tau} d\tau \\ \mathcal{H}(\mathcal{H}(s))(t) &= -s(t) \ . \end{aligned}$$

we assume real $s(t)$.

We also note that, since $s(t) = \mathfrak{Re}\,[s_a(t)]$, we can retrieve the negative-frequency components simply by discarding $\mathfrak{Im}\,[s_a(t)]$, which may seem counterintuitive. On the other hand, the conjugate complex part $s_a^*(t)$ contains only the negative-frequency components. Therefore, $s(t) = \mathfrak{Re}\,[s_a^*(t)]$ retrieves the suppressed positive frequency components. In Exc. 12.5.4.7 we calculate the intensity of an electromagnetic wave.

12.5.3.2 Envelope and instantaneous phase

An analytical signal can also be expressed in polar coordinates,

$$s_a(t) = |s_a(t)|e^{\imath\phi(t)} \ , \tag{12.138}$$

in terms of an instantaneous amplitude or *envelope* $|s_a(t)|$ varying with time and an instantaneous phase angle $\phi(t) \equiv \arg[s_a(t)]$. In Fig. 12.12 the blue curve shows $s(t)$ and the red curve shows $|s_a(t)|$.

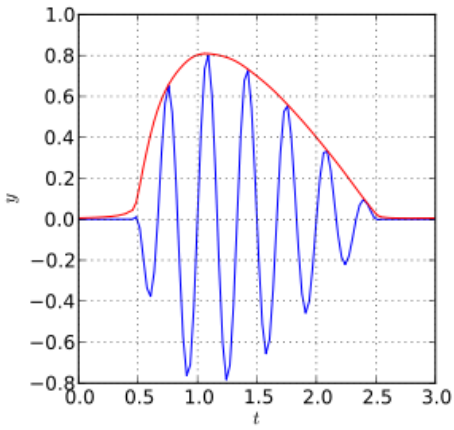

Figure 12.12: Illustration of a function (blue) and the magnitude of its analytical representation (red).

The time derivative of the unwrapped instantaneous phase is the instantaneous angular frequency,

$$\omega(t) \equiv \frac{d\phi(t)}{dt} \ . \tag{12.139}$$

The instantaneous amplitude and the instantaneous phase and frequency are used in some applications to measure and detect local characteristics of the signal or to describe the demodulation of a modulated signal. Polar coordinates conveniently separate amplitude and phase modulation effects.

Analytical signals are often frequency-shifted (down-converted) to 0 Hz, which can create negative (non-symmetric) frequency components:

$$s'_a(t) \equiv s_a(t)e^{-\imath\omega_0 t} = s_m(t)e^{\imath(\phi(t)-\omega_0 t)} \ , \tag{12.140}$$

where ω_0 is an arbitrary reference angular frequency. The function $s'_a(t)$ is called *complex envelope* or 'baseband'. The complex envelope is not unique, but determined

by the choice of ω_0. This concept is often used to deal with band-pass signals. When $s(t)$ is a modulated signal, ω_0 is conveniently chosen as the carrier frequency.

12.5.4 Exercises

12.5.4.1 Ex: Dirac's δ function

a. Calculate $\int_0^\pi d\theta \ \sin^3\theta \ \delta(\cos\theta - \cos\frac{\pi}{3})$.
b. Now, be $\mathbf{r}_0$ a fixed three-dimensional vector with Cartesian coordinates x_0, y_0, and z_0. For the three-dimensional δ-function holds,

$$\int_V f(\mathbf{r})\delta(\mathbf{r}-\mathbf{r}_0)d^3r = \begin{cases} f(\mathbf{r}_0) & \text{if } \mathbf{r}_0 \text{ is within the volume } V \\ 0 & \text{else} \end{cases} .$$

In Cartesian coordinates, $\delta^{(3)}(\mathbf{r}-\mathbf{r}_0) \equiv \delta(x-x_0)\delta(y-y_0)\delta(z-z_0)$. Express $\delta^{(3)}(\mathbf{r}-\mathbf{r}_0)$ in cylindrical coordinates (ρ,φ,z) as a product of three one-dimensional functions δ in $\rho-\rho_0$, $\varphi-\varphi_0$, and $z-z_0$.

Solution: *a. Here, $g(\theta) = \cos\theta - \cos\frac{\pi}{3}$. This function goes through zero within the interval $[0,\pi]$ at position $\theta_1 = \pi/3$. Now, $g'(\theta) = -\sin\theta$ and hence $g'(\theta_1) = -\sin\theta_1$. Consequently, we get,*

$$\int_0^\pi d\theta \sin^3\theta\delta(\cos\theta - \cos\tfrac{\pi}{3}) = \int_0^\pi d\theta \frac{\sin^3\theta}{|\sin\theta_1|}\delta(\theta - \tfrac{\pi}{3}) = \sin^2\theta_1 = \frac{3}{4} .$$

b. In cylindrical coordinates the volume element is, $d^3\mathbf{r} = \rho d\rho d\varphi dz$. We also have, $\mathbf{r} = (x = \rho\cos\varphi\ , y = \rho\sin\varphi\ , z)$ and $\mathbf{r}_0 = (x_0 = \rho_0\cos\varphi_0\ , y_0 = \rho_0\sin\varphi_0\ , z_0)$ Making the ansatz,

$$\delta^{(3)}(\mathbf{r}-\mathbf{r}_0) = f(\rho,\varphi,z)\delta(\rho-\rho_0)\delta(\varphi-\varphi_0)\delta(z-z_0) \ ,$$

we get immediately, (for $\mathbf{r}_0$ in V)

$$\begin{aligned} 1 = \int_V d^3\mathbf{r}\delta^{(3)}(\mathbf{r}-\mathbf{r}_0) &= \int_V d\rho\rho d\varphi dz f(\rho,\varphi,z)\delta(\rho-\rho_0)\delta(\varphi-\varphi_0)\delta(z-z_0) \\ &= \rho_0 f(\rho_0,\varphi_0,z_0) \end{aligned}$$

and hence, $f(\rho_0,\varphi_0,z_0) = \rho_0^{-1}$ respectively,

$$\delta^{(3)}(\mathbf{r}-\mathbf{r}_0) = \frac{1}{\rho_0}\delta(\rho-\rho_0)\delta(\varphi-\varphi_0)\delta(z-z_0) .$$

12.5.4.2 Ex: Dirac's δ function

Calculate the following expressions:
a. $\int_{-1}^{+1} \delta(x)[f(x) - f(0)]\ dx$,
b. $\int_{-1}^{3}(x^3 - x)\sin\left(\frac{\pi}{4}x\right)\delta(x-2)\ dx$,

c. $\int_0^{2\pi} \sin x \ \delta(\cos x) dx$,
d. $\int_{\mathbb{R}^3} \delta(r-R) d^3\mathbf{r}$,
e. $\int_{\mathbb{R}^3} \delta(r-R)\delta(z) d^3\mathbf{r}$,
f. $\int_{-\infty}^{\infty} \left(\frac{d}{dx}\delta(x)\right) f(x) dx$ por integration parcial,
g. $\int_{-\infty}^{\infty} \left(\frac{d^n}{dx^n}\delta(x)\right) f(x) dx$.

Solution: *The solutions are: a.* $\int_{-1}^{+1} \delta(x)[f(x) - f(0)] \ dx = 0$,
b. $\int_{-1}^{3} (x^3 - x) \sin\left(\frac{\pi}{4}x\right) \delta(x-2) \ dx = 6$,
c. $\int_0^{2\pi} \sin x \ \delta(\cos x) dx = \int_0^{2\pi} \sin x \left(\frac{\delta(x-\pi/2)}{1} + \frac{\delta(x-3\pi/2)}{1}\right) dx = 0$,
d. $\int_{\mathbb{R}^3} \delta(r-R) d^3\mathbf{r} = 4\pi R^2$,
e. $\int_{\mathbb{R}^3} \delta(r-R)\delta(z) d^3\mathbf{r} = 2\pi R$,
f. $\int_{-\infty}^{\infty} \left(\frac{d}{dx}\delta(x)\right) f(x) dx = \delta(x) f(x)|_{-\infty}^{\infty} - \int \delta(x) \left(\frac{d}{dx} f(x)\right) dx = -f'(0)$,
g. $\int_{-\infty}^{\infty} \left(\frac{d^n}{dx^n}\delta(x)\right) f(x) dx = (-1)^n f^{(n)}(0)$.

12.5.4.3 Ex: Dirac's δ function

Show,

$$\int_{-\infty}^{\infty} 1 \cdot \hat{f}(k) dk = \int_{-\infty}^{\infty} \hat{1}(x) f(x) dx = 2\pi f(0) \ ,$$

where $\hat{f}(k) \equiv \int_{-\infty}^{\infty} e^{-\imath kx} dx$ is the Fourier transform and $f(x) \equiv \int_{-\infty}^{\infty} e^{\imath kx} dk$ the inverse transform. Also show,

$$\hat{1} = 2\pi\delta(x) \ .$$

Help: $1 = e^{\imath k 0}$.

Solution: *We have,*

$$\int_{-\infty}^{\infty} 1 \cdot \hat{f}(k) dk = \int_{-\infty}^{\infty} \hat{f}(k) e^{ik0} dk = 2\pi f(0) \ ,$$

with the definition of inverse Fourier transformation. We also have,

$$\begin{aligned} \int_{-\infty}^{\infty} 1 \cdot \hat{f}(k) dk &= \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} f(x) e^{-ikx} dx \cdot 1 dk \\ &= \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} 1(k) e^{-ikx} dk f(x) dx = \int_{-\infty}^{\infty} \hat{1}(x) f(x) dx \ . \end{aligned}$$

Comparing these two results,

$$\int_{-\infty}^{\infty} \left(\frac{1}{2\pi}\hat{1}(x)\right) f(x) dx = f(0) \qquad \textit{that is} \qquad \frac{1}{2\pi}\hat{1}(x) = \delta(x) \ .$$

12.5.4.4 Ex: Dirac's δ function

The following properties are, among others, characteristics for Dirac's δ-function,

$$\int_a^b f(x)\delta(x-c)\,dx = \begin{cases} f(c) & \text{if } c \in [a,b] \\ 0 & \text{else} \end{cases} .$$

Being $g(x)$ a function with simple zero passages x_n, that is, $g(x_n) = 0$ and $g'(x_n) \neq 0$, we have

$$\delta(g(x)) = \sum_n \frac{1}{|g'(x_n)|}\delta(x - x_n) .$$

Use these relationships to solve the following integrals,
a. $\int_{-2}^{5} dx\ (x^2 - 5x + 6)\ \delta(x-3)$.
b. $\int_{-\infty}^{\infty} dx\ x^2\ \delta(x^2 - 3x + 2)$.

Solution: *a. 0*
b. We have,

$$\int_{-\infty}^{\infty} dx\ x^2\ \delta(x^2-3x+2) = \int_{-\infty}^{\infty} dx\ x^2\ \left(\frac{\delta(x-1)}{|2x-3|_{x=1}} + \frac{\delta(x-2)}{|2x-3|_{x=2}}\right) = 5 .$$

12.5.4.5 Ex: Dirac's δ function

Demonstrate the following property of the δ-function:

$$\delta(\omega_1 - \omega)\delta(\omega_2 - \omega) = \frac{\delta(\omega_1 - \omega) + \delta(\omega_2 - \omega)}{|\omega_1 - \omega_2|} .$$

Solution:

12.5.4.6 Ex: Parametrization of currents

Parametrize the current density $\mathbf{j}(\mathbf{r}')$ of a current loop
a. in Cartesian coordinates and
b. in spherical coordinates.

Solution: *a. In Cartesian coordinates we make ansatz,* $\mathbf{j}(\mathbf{r}') = \alpha\delta(z')\delta(\rho' - R)\hat{\mathbf{e}}_\phi$. *The normalization condition requires that the integral of* $\mathbf{j}$ *across the surface in the* $y = 0$ *plane for* $x > 0$ *be,*

$$I = \int_{\mathcal{S}} \mathbf{j}(\mathbf{r}') \cdot d\mathbf{S}' = \int_{-\infty}^{\infty}\int_0^{\infty} \alpha\delta(z')\delta(\rho' - R)d\rho' dz' = \alpha ,$$

such that,

$$\mathbf{j}(\mathbf{r}') = I\delta(z')\delta(\rho' - R)\hat{\mathbf{e}}_\phi$$

b. In spherical coordinates we make ansatz, $\mathbf{j}(\mathbf{r}') = \alpha\delta(\theta')\delta(r'-R)\hat{\mathbf{e}}_\phi$. *The normalization condition requires that the integral of* $\mathbf{j}$ *across the surface in the* $y = 0$ *plane for* $x > 0$ *be,*

$$I = \int_{\mathcal{S}} \mathbf{j}(\mathbf{r}') \cdot d\mathbf{S}' = \int_0^\pi \int_0^\infty \alpha\delta(\theta')\delta(r'-R)r'dr'd\theta' = \alpha R \ ,$$

such that,

$$\mathbf{j}(\mathbf{r}') = \frac{I}{R}\delta(\theta')\delta(r'-R)\hat{\mathbf{e}}_\phi \ .$$

Note that for a function $g(x)$ *with simple zero crossings,* $g(x_n) = 0$ *but* $g'(x_n) \neq 0$, *we get* $\delta(g(x)) = \sum_n \frac{1}{|g'(x_n)|}\delta(x - x_n)$. *In our example,*

$$\delta(\cos\theta) = \frac{\delta(\theta - \frac{\pi}{2})}{|-\sin\frac{\pi}{2}|} = \delta(\theta - \tfrac{\pi}{2}) \ .$$

12.5.4.7 Ex: Intensity of an electromagnetic wave

Calculate the intensity of the electromagnetic wave given by (a) $\vec{\mathcal{E}}(\mathbf{r},t) = \vec{\mathcal{E}}_0\cos(kz - \omega t)$ and (b) $\vec{\mathcal{E}}(\mathbf{r},t) = \vec{\mathcal{E}}_0 e^{\imath kz - \imath\omega t}$. Discuss!

Solution: *The magnetic field of the wave is,*

$$\vec{\mathcal{B}} = \tfrac{\mathbf{k}}{\omega} \times \vec{\mathcal{E}}_0\cos(kz - \omega t) \qquad or \qquad \vec{\mathcal{B}} = \tfrac{\mathbf{k}}{\omega} \times \vec{\mathcal{E}}_0 e^{\imath kz - \imath\omega t} \ .$$

With this we calculate the Poynting vector,

$$\mathbf{S} = \vec{\mathcal{E}} \times \vec{\mathcal{B}} = \tfrac{\mathbf{k}}{\omega}\mathcal{E}_0^2\cos^2(kz - \omega t) \qquad or \qquad \mathbf{S} = \tfrac{\mathbf{k}}{\omega}\mathcal{E}_0^2 e^{2\imath kz - 2\imath\omega t} \ .$$

The intensity is now,

$$I = |\mathbf{S}|^2 = \tfrac{1}{c}\mathcal{E}_0^2\cos^2(kz - \omega t) \qquad or \qquad I = \tfrac{1}{c}\mathcal{E}_0^2 \ .$$

The results are different.

Chapter 13

Electrostatics

We have already seen that all electromagnetic phenomena are due to charges, that these charges are quantized and conserved, and that the superposition principle holds for electromagnetic forces. In principle, it should be possible to explain all electromagnetic phenomena by calculation the forces exerted by every charge on every other charge for arbitrary charge distributions. In reality however, the situation is much more complex, because the forces not only depend on the position of the charges, but also on their speed and acceleration. In addition, any information on the actual state of a charge is only transmitted at the finite speed of light, which gives rise to retardation effects.

To simplify the problem we will initially only consider immobile charges. The theory dealing with immobile electric charges is named *electrostatics*. Its fundamental task of electrostatics resides in calculating the force exerted by spatial distributions of charges.

13.1 The electric charge and the Coulomb force

13.1.1 Quantization and conservation of the charge

We know that ordinary matter consists of electrically neutral atoms. An atom, consists of a heavy nucleus and a shell of very light-weighted electrons. The nucleus, in turn, is made up of a number of protons and neutrons. Each proton carries a positive elementary charge $Q = +e$, that is, the charge is quantized in units of e. For an atom to be neutral, the number of electrons (with negative charge $-e$) in the shell must be equal to the number of atoms.

Macroscopic bodies are usually neutral, but that does not mean that positive and negative charges are annihilated. What they can do, is to bunch by equal numbers within restricted regions of space. Then, the forces exerted by the positive and negative charges of a specific region on other far-away charges compensate each other. This effect is called shielding.

Nevertheless, it is possible, exerting work, to separate positive and negative charges, to generate polarizations in dielectric materials or currents in conducting metals, and to perform experiments with electrically charged macroscopic objects.

13.1.2 Coulomb's law

To begin with, we consider a single point charge Q at the position $\mathbf{r}'$ exerting a force on another charge located in $\mathbf{r}$. The so-called *Coulomb force* is,

$$\mathbf{F}_C = \frac{Qq}{4\pi\varepsilon_0}\frac{\mathbf{r}-\mathbf{r}'}{|\mathbf{r}-\mathbf{r}'|^3} \ , \tag{13.1}$$

where ε_0 is a constant called the permittivity of free space. The Coulomb force decreases quadratically with the distance and is directed along the straight line connecting the two charges. Note that the force can be attractive (for $Qq < 0$) or repulsive (for $Qq > 0$). See the Excs. 13.1.3.1 to 13.1.3.22.

According to the *superposition principle* the force acting on the charge is not influenced by the possible existence of other forces, for example, exerted by other charges Q_k located in other positions $\mathbf{r}_k$,

$$\mathbf{F} = \mathbf{F}_1 + \mathbf{F}_2 + ... = \sum_k \frac{Q_k q}{4\pi\varepsilon_0}\frac{\mathbf{r}-\mathbf{r}_k}{|\mathbf{r}-\mathbf{r}_k|^3} \ . \tag{13.2}$$

Introducing an abbreviation,

$$\vec{\mathcal{E}} = \sum_k \frac{Q_k}{4\pi\varepsilon_0}\frac{\mathbf{r}-\mathbf{r}_k}{|\mathbf{r}-\mathbf{r}_k|^3} \ , \tag{13.3}$$

called the *electric field*, we can express the Coulomb force as,

$$\boxed{\mathbf{F}_C = q\vec{\mathcal{E}}} \ . \tag{13.4}$$

Using the Dirac function we can parametrize the distribution of charges by,

$$\varrho(\mathbf{r}) = \sum_k Q_k \delta^3(\mathbf{r}-\mathbf{r}_k) \ . \tag{13.5}$$

The charge of a single electron is small, and often many charges are involved in electrical phenomena. Thus, the discrete character of the charge does not appear, and the charge distribution appears as a smooth distribution of *charge density*, such that,

$$\int_{\mathbb{R}} \varrho(\mathbf{r}')dV' = \int_{\mathbb{R}} \sum_k Q_k \delta^3(\mathbf{r}'-\mathbf{r}_k)dV' = \sum_k Q_k \ . \tag{13.6}$$

With this (fluid model) approximation,

$$\sum_k Q_k ... \longrightarrow \int dV' \varrho(\mathbf{r}') ... \ , \tag{13.7}$$

the *Coulomb law* can be written,

$$\boxed{\vec{\mathcal{E}} = \int \frac{\varrho(\mathbf{r}')}{4\pi\varepsilon_0}\frac{\mathbf{r}-\mathbf{r}'}{|\mathbf{r}-\mathbf{r}'|^3}dV'} \ , \tag{13.8}$$

since by inserting the discrete distribution (13.5) we recover Coulomb's law (13.3).

It is also possible to define from ϱ a two-dimensional *surface charge density* σ or a one-dimensional *linear charge density* λ using the Dirac function. For example, the surface charge density on a spherical shell,

$$\varrho(\mathbf{r}) = \sigma(\theta, \phi)\delta(r - R) \ , \tag{13.9}$$

or the linear charge density on a ring,

$$\varrho(\mathbf{r}) = \lambda(\phi)\delta(r - R)\delta(z) \ . \tag{13.10}$$

Substituting ϱ of the Coulomb law with these expressions, we reduce the dimensionality of the integral. We will study problems related to charge distributions in the Excs. 13.2.4.1 to 13.2.4.12.

13.1.3 Exercises

13.1.3.1 Ex: • Coulomb force

A point charge of $-2.0\,\mu\text{C}$ and a point charge of $4.0\,\mu\text{C}$ are separated by a distance L. Where should a third point charge be placed in order for the electrostatic force on this third charge to be zero?

Solution: ***Gabarite:*** *At a distance equal of* $0.41L$ *from the charge* $-2.0\,\mu\text{C}$ *on side opposite side to the charge* $4.0\,\mu\text{C}$.
The forces must compensate each other, $\mathbf{F}_{13} + \mathbf{F}_{23} = 0$, *giving,*

$$\frac{1}{4\pi\varepsilon_0}\frac{q_1 q_3}{(L+x)^2} = \frac{1}{4\pi\varepsilon_0}\frac{q_2 q_3}{x^2} \ .$$

For $q_1 = 2q_2$ *we get the equation,*

$$x^2 - 2Lx - L^2 = 0 \ ,$$

with the solution,

$$x = L(1 \pm \sqrt{2}) \ .$$

Only the positive sign produces a force minimum, the negative sign corresponds to a maximum.

13.1.3.2 Ex: • Coulomb force

A point particle with a charge of $-1.0\,\mu\text{C}$ is located at the origin; a second point particle with a charge of $2.0\,\mu\text{C}$ is located at $x = 0$, $y = 0.1\,\text{m}$; and a third point particle with a charge of $4.0\,\mu\text{C}$ is located at $x = 0.2\,\text{m}$, $y = 0$. Determine the electrostatic force on each of the three particles.

Solution: *We have,*

$$\mathbf{F}_1 = (0.9\,\text{N})\hat{\mathbf{e}}_x + (1.8\,\text{N})\hat{\mathbf{e}}_y \ ,$$
$$\mathbf{F}_2 = (-1.3\,\text{N})\hat{\mathbf{e}}_x - (1.2\,\text{N})\hat{\mathbf{e}}_y \ , \mathbf{F}_3 = (0.4\,\text{N})\hat{\mathbf{e}}_x - (6.4\,\text{N})\hat{\mathbf{e}}_y \ .$$

13.1.3.3 Ex: • Coulomb force

A point charge of $-5.0\,\mu\text{C}$ is located at $x = 4.0\,\text{m}$, $y = -2.0\,\text{m}$, and a second point charge of $12.0\,\mu\text{C}$ is located at $x = 1.0\,\text{m}$, $y = 2.0\,\text{m}$.
a. Determine the absolute value, the direction and the orientation of the electric field in $x = -1.0\,\text{m}$, $y = 0$.
b. Calculate the absolute value, the direction and the orientation of the electric force acting on an electron placed in the electric field at $x = -1.0\,\text{m}$, $y = 0$.

Solution: *a. We have* $13\,\text{kN/C}$ *at* $230°$.
b. We have $2.1 \cdot 10^{-15}\,\text{N}$ *at* $51°$.

13.1.3.4 Ex: Coulomb force

Imagine an electron near the Earth's surface. At what point should we place a second electron in order for the electrostatic force between the electrons to compensate the gravitational force acting on the first electron?

Solution: *The gravitational force will be compensated by the Coulomb force when* $F_G = m_e g = \frac{1}{4\pi\varepsilon_0}\frac{e^2}{r^2} = F_C$. *Hence,*

$$r = \sqrt{\frac{e^2}{4\pi\varepsilon_0\, m_e g}} = 5\,\text{m} \ .$$

13.1.3.5 Ex: Coulomb force

Three positive point charges Q_1, Q_2, and Q_3 are placed at the corners of an equilateral triangle with the edge length $L = 10\,\text{cm}$. Calculate the value and direction of the force acting on an electron located in the center of the triangle.

Solution: *Following the Coulomb law we have,*

$$\sum_j \mathbf{F}_j = \sum_j \frac{1}{4\pi\varepsilon_0}\frac{Q_j e}{|\mathbf{r}_0 - \mathbf{r}_j|^2}\frac{\mathbf{r}_0 - \mathbf{r}_j}{|\mathbf{r}_0 - \mathbf{r}_j|} \ .$$

Placing the origin in the center, $\mathbf{r}_0 = 0$, *we get,*

$$r_1 = r_2 = r_3 \equiv r \ .$$

Defining h *as the shortest distance between the center and the edges,*

$$\left(\frac{L}{2}\right)^2 + h^2 = r^2 \qquad \textit{and} \qquad (r+h)^2 + \left(\frac{L}{2}\right)^2 = L^2 \ .$$

Solving the second equation by L *and replacing* r *using the first equation,*

$$r + h = \frac{\sqrt{3}}{2}L \qquad \textit{and} \qquad \sqrt{\left(\frac{L}{2}\right)^2 + h^2} + h = \frac{\sqrt{3}}{2}L \ .$$

Solving by h and r,

$$h = \frac{L}{2\sqrt{3}} \qquad \textit{and} \qquad r = \left(\frac{\sqrt{3}L}{2} - \frac{L}{2\sqrt{3}}\right) = \frac{L}{\sqrt{3}} \ .$$

Hence,

$$\begin{aligned}
\mathbf{r}_1 &= -\frac{L}{2}\hat{\mathbf{e}}_x - h\hat{\mathbf{e}}_y = -\frac{L}{2}\hat{\mathbf{e}}_x - \frac{L}{2\sqrt{3}}\hat{\mathbf{e}}_y \ , \\
\mathbf{r}_2 &= \frac{L}{2}\hat{\mathbf{e}}_x - h\hat{\mathbf{e}}_y = \frac{L}{2}\hat{\mathbf{e}}_x - \frac{L}{2\sqrt{3}}\hat{\mathbf{e}}_y \ , \\
\mathbf{r}_3 &= r\hat{\mathbf{e}}_y = \frac{L}{\sqrt{3}}\hat{\mathbf{e}}_y \ .
\end{aligned}$$

Finally,

$$\mathbf{F} = \mathbf{F}_1 + \mathbf{F}_2 + \mathbf{F}_3 = \frac{1}{4\pi\varepsilon_0}\frac{e}{r^3}(Q_1\mathbf{r}_1 + Q_2\mathbf{r}_2 + Q_3\mathbf{r}_3) = \frac{1}{4\pi\varepsilon_0}\frac{3}{2L^2}e\begin{pmatrix} -\sqrt{3}Q_1 + \sqrt{3}Q_2 \\ -Q_1 - Q_2 + 2Q_3 \\ 0 \end{pmatrix} \ .$$

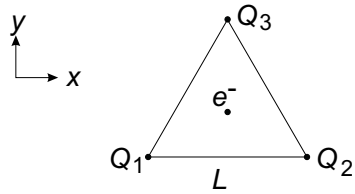

Figure 13.1: Coulomb force.

13.1.3.6 Ex: • Coulomb force

Two particles carrying equal charges q are placed at a mutual distance of $r = 3\,\mathrm{mm}$ and then released. The acceleration of the first particle after having been released is $a_1 = 7\,\mathrm{m/s^2}$, and the acceleration of the second particle is $a_2 = 2\,\mathrm{m/s^2}$. The mass of the first particle is $m_1 = 6 \cdot 10^{-7}\,\mathrm{kg}$.
a. What is the mass of the second particle?
b. What is the charge of the particles?

Solution: *a. The Coulomb force acting on both particles is $F_C = \frac{1}{4\pi\varepsilon_0}\frac{q_1 q_2}{r^2}$, $q_1 = q_2 = q$. Soon after releasing, we have*

$$m_1 a_1 = \frac{1}{4\pi\varepsilon_0}\frac{q}{r^2} = -m_2 a_2 \ .$$

Hence, $m_2 = -m_1 a_1/a_2 = 2.1 \cdot 10^{-6}\,\mathrm{kg}$.
b. In addition, we calculate,

$$q = \sqrt{4\pi\varepsilon_0 r^2 m_1 a_1} = 6.5 \cdot 10^{-11}\,\mathrm{C} = 4 \cdot 10^8\ e\ .$$

13.1.3.7 Ex: • Coulomb force

A small ball of graphite (mass $m = 1\,\mathrm{kg}$) suspended on a wire is touched by an electrically charged plastic stick and picks up 1% of its charge. The result is that the ball is displaced by an angle of 30°, while the stick is held in place at the former position of the ball. The distance between the center of the ball and the end of the stick is 10 cm.
a. Calculate the force exerted by the wire on the ball?
b. Assume that the charge on the stick is fully concentrated at its end. What are the charges on the ball and on the stick?

Solution:

13.1.3.8 Ex: • Acceleration of charges

An electron has an initial velocity of $v_0 = 2 \cdot 10^6\,\mathrm{m/s}$ in $+x$-direction. It enters a region of uniform electric field $\vec{\mathcal{E}} = (300\,\mathrm{N/C})\ \hat{\mathbf{e}}_x$.
a. Determine the acceleration of the electron.
b. How long does it take for the electron to travel a distance of $s = 10.0\,\mathrm{cm}$ along the x-axis towards $+x$ in the region that has field.
c. At what angle and in what direction does the motion of the electron deflect as it travels 10.0 cm in x-direction?

Solution: *a. The acceleration is,*

$$a = \frac{F}{m_e} = \frac{-e\mathcal{E}}{m_e} = -5.28 \cdot 10^{13}\,\mathrm{m/s^2}\ .$$

b. Instantaneous speed is,

$$v = v_0 - at\ .$$

With this we get the traveled distance,

$$s = \int_0^t v dt = v_0 t - \tfrac{a}{2} t^2\ .$$

Hence, the time is,

$$t = \frac{v_0}{a} \pm \sqrt{\frac{v_0^2}{a^2} - \frac{2s}{a}} = 50\,\mathrm{ns}\ .$$

c. The angle is calculated by,

$$\theta = \tan \tfrac{\Delta y}{\Delta x} = 33.4^\circ\ .$$

in $-y$-direction.

13.1.3.9 Ex: • Acceleration of charges

A charged particle of 2.0 g is released from rest in a region that has a uniform electric field, $\vec{\mathcal{E}} = (300\,\mathrm{kN/C})\hat{\mathbf{e}}_x$. After traveling a distance of 0.5 m in this region, the particle has a kinetic energy of 0.12 J. Determine the particle's charge.

Solution: *Putting the formulas together,*

$$v = at \qquad and \qquad s = \tfrac{a}{2}t^2 \ ,$$

we obtain,

$$s = \tfrac{v^2}{2a} \ .$$

The acceleration is,

$$a = \tfrac{F}{m} = \tfrac{qE}{m} \ ,$$

such that the kinetic energy gets,

$$E_{cin} = \tfrac{m}{2}v^2 = \tfrac{m}{2}2as = sqE \ .$$

Finally we get,

$$q = \frac{E_{cin}}{sE} = 800\,\mu\mathrm{C} \ .$$

13.1.3.10 Ex: Charged copper coins

The positive proton charge and the negative electron charge have the same absolute value. Assume that the absolute values would have a relative difference of only 0.0001%. Consider copper coins with $3 \cdot 10^{22}$ atoms. What would be the repulsive force of two coins 1 m apart?
Help: A neutral copper atom contains 29 protons and the same amount of electrons.

Solution: *Each coin has the charge $Q = 29 \cdot 3 \cdot 10^{22} \cdot 0.0001\% \cdot e = 0.14\,\mathrm{C}$. The copper coins repel each other with the electrostatic force,*

$$F_C = \frac{1}{4\pi\varepsilon_0}\frac{Q^2}{r^2} = 1.7 \cdot 10^8\,\mathrm{N} \ .$$

13.1.3.11 Ex: • Weight of the electron

A metal sphere is charged with $Q = +1\,\mu\mathrm{C}$. Determine whether the mass of the sphere increases or decreases due to the charging and calculate the value?

Solution: *Since the sphere is positively charged, the electrons must exit the sphere. Therefore, the sphere loses mass. An electron has the charge* $e = 1.6 \cdot 10^{-19}\,\mathrm{C}$ *and its mass* $m_e = 9.1 \cdot 10^{-31}\,\mathrm{kg}$. *The loss of mass is therefore* $\delta m = \frac{m_e Q}{e} = 5.7 \cdot 10^{-18}\,\mathrm{kg}$, *which is little.*

13.1.3.12 Ex: The hydrogen atom

In the hydrogen atom the typical distance between the positively charged proton and the negatively charged electron is $d \sim 5 \cdot 10^{-11}\,\mathrm{m}$.
a. Calculate the Coulomb force.
b. Compare this force with the gravitational force between the two particles.
c. What should be the speed of the electron around the nucleus to compensate for the gravitational attraction by the centrifugal force?

Solution: *a. Coulomb's force is,*

$$F_C = \frac{1}{4\pi\varepsilon_0}\frac{q_1 q_2}{r^2} = 9.2 \cdot 10^{-8}\,\mathrm{N}\ .$$

b. The gravitational force is,

$$\frac{F_G}{F_C} = \frac{-G\frac{m_1 m_2}{r^2}}{\frac{1}{4\pi\varepsilon_0}\frac{q_1 q_2}{r^2}} = -4\pi\varepsilon_0 G\frac{m_1 m_2}{q_1 q_2} = 4.5 \cdot 10^{-40}\ .$$

Therefore, the ratio is independent of the distance and in addition very small.
c. The balance of forces requires,

$$F_C = \frac{1}{4\pi\varepsilon_0}\frac{q_1 q_2}{r^2} = \frac{mv^2}{r} = F_Z\ ,$$

such that,

$$v = \sqrt{\frac{1}{4\pi\varepsilon_0}\frac{q_1 q_2}{mr}} = 2.25 \cdot 10^6\,\mathrm{m/s} \approx \frac{1}{133}\ c\ .$$

Comment: The ratio of this speed to the speed of light is approximately equal to the fine-structure constant $\alpha \approx \frac{1}{137}$.

13.1.3.13 Ex: Exercise of understanding

Two metallic spheres are placed at a distance d from each other and respectively charged with $+Q$ and $-2Q$.
a. Do spheres attract or repel each other?
b. What happens if we let the spheres contact each other and then put them at the same distance d. How much does the force change?

Solution: *a. Initially, the spheres attract each other, because they are loaded with opposite charges.*
b. When the spheres touch, the charge can flow and will spread evenly over the two

spheres. Therefore, each sphere will have the same charge $-Q/2$, and the spheres will repel each other. While initially the spheres attracted each other with a force proportional to $2Q^2$, now they repel each other with a force proportional to $Q^2/4$. That is, the absolute value of the force decreased by a factor of 8.

13.1.3.14 Ex: • Charged sphere on a spring

A ball with the m is suspended on a spring with the spring constant f.
a. What will be the displacement of the ball due to its weight? What will be the frequency of oscillation?
b. Now the ball is loaded with the charge Q and a second ball with the same charge is approached from below the first ball. Derive the relationship between the position of the first ball z_1 and the position of the second z_2. The position $z_1 = 0$ is the resting position of the spring, that is, the position that the spring would have without suspended mass. CAUTION: you'll get a third order equation in z_1, don't try to solve it!
c. For which position z_2 of the second ball does the first ball stay at the resting position of the spring, that is, for which z_2 do we find $z_1 = 0$ to be solution? Are there any other solutions? What are your interpretations?
d. What is the frequency of oscillation under these conditions, when ball 1 is only slightly displaced around $z_1 = 0$? Use the approximation $\frac{1}{(a-x)^2} \approx \frac{1}{a^2} + \frac{2}{a^3}x$, which holds for $x \ll a$.

Solution: *a. Displacement:*

$$mg = fz_1 \rightarrow z_1 = \frac{mg}{f} \ .$$

Oscillation frequency: in the displaced position z_1 holds:

$$m\ddot{z}_1 = -fz_1 \ .$$

With the ansatz $z_1 = \cos(\omega t)$ follows $\omega = \sqrt{f/m}$. b. Setting the sum of all forces equal to zero:

$$mg - fz_1 - \frac{1}{4\pi\varepsilon_0}\frac{Q^2}{(z_2 - z_1)^2} = 0$$

$$-fz_1^3 + z_1^2(2fz_2 + mg) + z1(-2mgz_2 - fz_2^2) + mgz_2^2 - \frac{1}{4\pi\varepsilon_0}Q^2 = 0 \ .$$

There is a solution $z_1 = 0$, when the constant term disappears, that is, for,

$$mgz_2^2 - \frac{1}{4\pi\varepsilon_0}Q^2 = 0$$

$$z_2 = \frac{Q}{\sqrt{4\pi\varepsilon_0 mg}} \ .$$

We are left with a second order equation. This can have two real solutions, but only one is physically significant: the one where the first ball is below the second. Here, the

spring tries to bounce the first ball upwards, which is prevented by Coulomb's repulsion force exerted by the second ball.
c. The force in the equilibrium position is, with the approximation $z_1 \ll z_2$

$$F(z_1,z_2) \approx mg - fz_1 - \frac{1}{4\pi\varepsilon_0}Q^2(\frac{1}{z_2^2}+\frac{2}{z_2^3}z_1) = mg - \frac{Q^2}{4\pi\varepsilon_0 z_2^2} - (f - \frac{2Q^2}{4\pi\varepsilon_0 z_2^3})z_1$$
$$= mg - \frac{Q^2}{4\pi\varepsilon_0}\frac{4\pi\varepsilon_0 mg}{Q^2} - (f - \frac{2Q^2}{4\pi\varepsilon_0}\frac{(4\pi\varepsilon_0 mg)^{3/2}}{Q^3})z_1 = -(f - \frac{2\sqrt{4\pi\varepsilon_0(mg)^3}}{Q})z_1 \ .$$

Therefore, the new oscillation frequency is,

$$\omega = \sqrt{\frac{1}{m}\left(f - \frac{2\sqrt{4\pi\varepsilon_0(mg)^3}}{Q}\right)} \ .$$

That is, the frequency is less than before.

13.1.3.15 Ex: Stability of a charge distribution

The charge distributions shown in the figure are given. All positive and negative charges have the same absolute value.
a. Determine whether one of these distributions is stable? What happens in different cases?
b. Is it possible to choose the absolute values of the charges in such a way as to make the configurations stable?

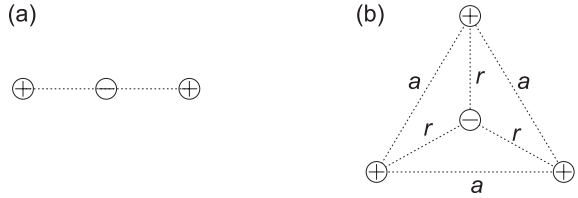

Figure 13.2: Geometry of charge distribution.

Solution: *a. As Coulomb's force falls quadratically with distance and since unequal charges are at twice the distance of equal charges, the two positively charged balls will approach the negative and collide.*
b. Considering the energies we have,$a = \sqrt{3}r$:

$$E = 3 \times \frac{1}{4\pi\varepsilon_0}(2\frac{Q^2}{a} - \frac{Q^2}{r}) = 3 \times \frac{1}{4\pi\varepsilon_0}(2\frac{Q^2}{\sqrt{3}r} - \frac{Q^2}{r}) = 3 \times \frac{Q^2}{4\pi\varepsilon_0 r}(\frac{2}{\sqrt{3}} - 1) \ .$$

Since $\frac{2}{\sqrt{3}} - 1 > 0$, holds $F = -\frac{dE}{dr} > 0$, and so the positive charges will move away from the negative ones.
a. We call the negative charge $-Q_1$ and the two positive charges Q_2,

$$\frac{Q_1 Q_2}{r^2} = \frac{Q_2 Q_2}{(2r)^2} \qquad \textit{such that} \qquad \frac{Q_1}{Q_2} = \frac{1}{4} \ .$$

The outer charges must be four times greater than the inner charges for the force to zero at all distances, that is, to be at equilibrium. However, this equilibrium is unstable, as a small deviation from the correct charges is sufficient to let the system collapse or explode.
b. Analogically with the energy:

$$\frac{Q_1 Q_2}{r} = \frac{2Q_2 Q_2}{\sqrt{3}r} \qquad \textit{such that} \qquad \frac{Q_1}{Q_2} = \frac{2}{\sqrt{3}} \ .$$

The problem here is, that the charge ratio should be irrational. This is not possible because of the charge quantization.

13.1.3.16 Ex: Stability of a charge distribution

Three balls with mass m and each charged with the charge Q are placed in a parabolic bowl. This can be described as a surface in space, where the coordinate z of the surface is given by $z = z(x, y) = A(x^2 + y^2)$. Gravitation shows into $-\hat{\mathbf{e}}_z$ direction. What is the distance the balls adopt, when we set as an additional condition, that all charges are at the same height?

Solution: *The gravitational potential energy is,*

$$W_{gr} = \sum_{k=1}^{3} mgz_k = 3mgz_1 \ .$$

The balls have the same reciprocal distance a_{12} and r_1 from the center of the bowl: $a_{12} = r_1\sqrt{3} = \sqrt{3\,(x_1^2 + y_1^2)}$. Hence,

$$W_{gr} = 3mgA\left(x_1^2 + y_1^2\right) = mgAa_{12}^2 \ .$$

The electrostatic energy is,

$$W_{el} = \frac{1}{2}\sum_{\substack{k,j=1 \\ k\neq j}}^{3} \frac{1}{4\pi\varepsilon_0}\frac{Q^2}{|\mathbf{r}_k - \mathbf{r}_j|} = \frac{1}{2}\frac{1}{4\pi\varepsilon_0}\frac{Q^2}{a_{12}} 3(3-1) = \frac{3}{4\pi\varepsilon_0}\frac{Q^2}{a_{12}} \ .$$

From the minimization condition,

$$0 = \frac{d}{da_{12}}\left(W_{gr} + W_{el}\right) = \frac{d}{da_{12}}\left(mgAa_{12}^2 + \frac{3}{4\pi\varepsilon_0}\frac{Q^2}{a_{12}}\right) = \frac{d}{da_{12}}\left(2mgAa_{12} - \frac{3}{4\pi\varepsilon_0}\frac{Q^2}{a_{12}^2}\right)$$

we have,

$$a_{12} = \left(\frac{3}{8\pi\varepsilon_0}\frac{Q^2}{mgA}\right)^{1/3} \ .$$

The energy then becomes,

$$W_{gr} + W_{el} = \frac{3}{4\pi\varepsilon_0}\frac{Q^2}{a_{12}} + mgAa_{12}^2 = \frac{3}{4\pi\varepsilon_0}\frac{Q^2}{\left(\frac{3}{4\pi\varepsilon_0}\frac{Q^2}{mgA}\right)^{1/3}} + mgA\left(\frac{3}{4\pi\varepsilon_0}\frac{Q^2}{mgA}\right)^{2/3}$$

$$a_{12} = \left(\frac{3}{4\pi\varepsilon_0}\frac{Q^2}{mgA}\right)^{1/3}$$

$$W_{gr} + W_{el} = \left(\frac{3mgAQ^2}{4\pi\varepsilon_0}\right)^{4/3} .$$

Comment: *It is not obvious whether there are other configurations with a charge in the center that would have less energy. Alternatively, we could suspend three balls loaded on a spring.*

13.1.3.17 Ex: Ions in a harmonic potential

Two ions with the positive charge $+e$ are confined to an isotropic harmonic potential. Each ion has the potential energy $U = \frac{1}{2}m\omega^2 r^2$, where r is the distance from the center of the potential. The ions are at rest, only consider two dimensions.
a. What is the distance of the two ions from the center?
b. Calculate the distance for three identical ions.

Solution: *a. The force exerted by the harmonic potential on an ion is,*

$$-\frac{dU}{dr} = -m\omega^2 r .$$

This force must be equalized with the Coulomb force:

$$m\omega^2 r = \frac{1}{4\pi\varepsilon_0}\frac{Q^2}{(2r)^2} \qquad \text{such that} \qquad r = \left(\frac{1}{4\pi\varepsilon_0}\frac{Q^2}{4m\omega^2}\right)^{1/3} .$$

b. With three ions, we must consider that the ions minimize energy by placing themselves in a symmetrical triangle. So the distance between two ions is $a = \sqrt{3}r$. The total energy of the three ions is,

$$E = 3 \times \left(\frac{1}{4\pi\varepsilon_0}\frac{Q^2}{a} + \frac{1}{2}m\omega^2 r^2\right) = \frac{\sqrt{3}}{4\pi\varepsilon_0}\frac{Q^2}{r} + \frac{3}{2}m\omega^2 r^2 .$$

The force is given by,

$$F = -\frac{dE}{dr} = \frac{\sqrt{3}}{4\pi\varepsilon_0}\frac{Q^2}{r^2} - 3m\omega^2 r .$$

From the equilibrium condition, $F = 0$, follows:

$$r = \left(\frac{1}{4\pi\varepsilon_0}\frac{Q^2}{\sqrt{3}m\omega^2}\right)^{1/3} .$$

13.1.3.18 Ex: Spheres on a wire

Two identical spheres with mass $m = 0.1\,\mathrm{kg}$ are suspended at the same point of a ceiling by a 1 m long wire and have the same charge. What is the value of the charge if the two centers of the spheres are 4 cm apart. Use the approximation $\sin\alpha \approx \tan\alpha \approx \alpha$ for small angles α.

Solution: *Each of the two spheres is displaced by* $d = 2\,\mathrm{cm}$ *from the center. The displacement angle is in first order,* $\alpha = d/l$ *with* $l = 1\,\mathrm{m}$ *the wire length. By this displacement the ball is lifted (in first approximation) by a value of* $h = \alpha d$*, hence we have* $h = \frac{d^2}{l}$*. The potential energy of the two balls, therefore, is* $E_{pot} = 2mgh = \frac{2mgd^2}{l}$*. This energy must be matched with the Coulomb potential:*

$$\frac{2mgd^2}{l} = \frac{1}{4\pi\varepsilon_0}\frac{Q^2}{d} \qquad \textit{such that} \qquad Q = \sqrt{\frac{8\pi\varepsilon_0 mgd^3}{l}}\ .$$

Inserting the values we get, $Q = 42\,\mathrm{nC}$.

13.1.3.19 Ex: Oscilloscope

We consider a simple model of an oscilloscope. Inside the device is a Braun tube, inside which electrons are accelerated by a voltage U to a speed v. Then, the electrons fly through the plates of a capacitor and are deflected by the electric field E of the capacitor. (In a real oscilloscope there are two capacitors: one for horizontal deviation and one for vertical.) Behind the capacitor, the electrons fly to a screen, where they produce a bright spot.
a. Calculate the electron velocity v for an accelerating voltage of $U = 1\,\mathrm{kV}$. (Do not consider relativistic effects!)
b. The capacitor has a length of $l = 5$ cm and a distance from the plates of $d = 2\,\mathrm{cm}$. What is the maximum allowable voltage $U_{\max}$ at the capacitor to prevent electrons from hitting one of the capacitor plates? (Electrons enter the capacitor in the center between the plates.)
c. What should be the distance between the plates and the screen (which is 10 cm wide), so that with maximum voltage $U_{\max}$ the entire area of the screen is used?
Comment: Disregard capacitor edge effects!

Solution:

13.1.3.20 Ex: • Electron between charged plates

Between two parallel horizontal plates there is a homogeneous electric field $|\vec{\mathcal{E}}| = 2\cdot 10^3\,\mathrm{N/C}$. The lower plate is charged with a positive charge, the upper plate with a negative, such that the field is oriented upwards. The length of the plates is $L = 10\,\mathrm{cm}$, their distance $d = 2\,\mathrm{cm}$. From the left edge of the bottom plate an electron is shot at an initial velocity $|v_0| = 6\cdot 10^6\,\mathrm{m/s}$ under an angle 45° into the space between the plates.
a. When will the electron hit one of the plates?

b. Which plate is eventually hit and at what horizontal distance from the firing point?

Solution: *a. The electron in the homogeneous field is accelerated downward by the Coulomb force, $m\ddot{y} = -e\mathcal{E}$. The gravitational force is many orders of magnitude weaker. The electron trajectory is given by,*

$$x = v_0 t \cos\alpha \qquad \text{and} \qquad y = -\frac{eE}{2m}t^2 + v_0 t \sin\alpha \ .$$

The electron reaches its maximum height when $\dot{y} = 0$, that is,

$$t_m = \frac{mv_0 \sin\alpha}{e\mathcal{E}} = 12\,\text{ns} \ .$$

At this moment it has reached the height,

$$y_m = -\frac{e\mathcal{E}}{2m}t_m^2 + v_0 t_m \sin\alpha = \frac{mv_0^2 \sin^2\alpha}{2e\mathcal{E}} = 25.7\,\text{cm}$$

and the distance,

$$x_m = v_0 t_m \cos\alpha = 51.1\,\text{cm} \ .$$

That is, at most only the top plate can be reached.
b. The height of the upper plate is reached, when $y = d = -\frac{eE}{2m}t_d^2 + v_0 t_d \sin\alpha$. From this follows,

$$t_d = \frac{mv_0 \sin\alpha}{e\mathcal{E}} \pm \sqrt{\left(\frac{mv_0 \sin\alpha}{eE}\right)^2 - \frac{2md}{e\mathcal{E}}} = 6.4\ ns \quad or \quad 17.7\ ns \ .$$

At the previous instant the distance is $x_d = v_0 t_d = 23.8\,\text{cm}$, that is, the electron can escape.

13.1.3.21 Ex: • The Coulomb-Kepler problem

We consider two particles charged with charges Q_1 and Q_2 and masses $m = m_1 = m_2$ which, for simplicity, can only move along the $\hat{\mathbf{e}}_z$-axis and are subject to mutual Coulomb forces.
a. Derive the differential equations for the positions z_1 and z_2 of the two particles. Reduce the number of variables of the problem by introducing the difference variable $z = z_2 - z_1$ and establish the differential equation for z.
b. The differential equation obtained has the same shape as that of the Kepler problem in mechanics, which, however, is not defined along an axis but on a plane. What are the solutions to Kepler's problem? What important physical quantity does not appear to constrain the freedom of movement to one axis? What would be the impact of this constraint on the solutions to Kepler's problem? What is the additional degree of freedom in the Coulomb-Kepler problem as compared to the Kepler problem?
c. Kepler's differential equation is not easy to solve. Even so, we can learn something by looking at the phase space diagram. For this, we consider two identical particles $Q = Q_1 = Q_2$ and $m = m_1 = m_2$, placed at a distance z_0. What is going to happen?

How will the velocities v_1 and v_2 of the two particles behave with respect to each other? Derive a relationship between the distance z and the velocity v of one of the particles (energy conservation). What is the value of the velocity for $z \to \infty$? Prepare a phase space diagram in (z, v) for three different distances z_0.

Solution: *a. We have,*

$$m\ddot{z}_1(t) = -\frac{Q_1 Q_2}{(z_2(t) - z_1(t))^2} \qquad \textit{and} \qquad m\ddot{z}_2(t) = \frac{Q_1 Q_2}{(z_2(t) - z_1(t))^2} \ ,$$

and with $z = z_2 - z_1$ taking the difference of the two differential equations follows,

$$m\ddot{z}(t) = 2\frac{Q_1 Q_2}{z^2} \ .$$

b. The solutions to Kepler's problem are described by Kepler's three laws. These are,

- *The orbits are ellipses, the center of gravity is in one of the focus of the ellipse.*
- *During same time intervals, a beam sweeps through equal areas.*
- *The squares of the orbital periods of two objects behave like the cubes of the large semi-axes.*

In Kepler's problem, the angular momentum is an important parameter, since it neutralizes attractive gravity, and thus stabilizes the orbit. In just one dimension the angular momentum is zero, therefore, two bodies attract each other without stopping. In the Coulomb-Kepler problem we have the additional freedom, that the force can be repulsive.
c. The two particles will move away from each other without limit. From momentum conservation $mv_1(t) + mv_2(t) = 0$ follows $v_1(t) = -v_2(t)$. Therefore, it is sufficient to analyze only one of the two velocities.
The total energy of the system consists of the potential energy and the kinetic energy of both particles:

$$\begin{aligned} E &= U + T \\ U &= \frac{1}{4\pi\varepsilon_0}\frac{Q^2}{z} \\ T &= \frac{1}{2}mv_1^2 + \frac{1}{2}mv_2^2 = mv^2 \ . \end{aligned}$$

The energy is fixed by the initial conditions $z(0) = z_0$ and $v(0) = 0$:

$$E = \frac{1}{4\pi\varepsilon_0}\frac{Q^2}{z_0} \ .$$

Inserting we get,

$$\frac{1}{4\pi\varepsilon_0}\frac{Q^2}{z_0} = \frac{1}{4\pi\varepsilon_0}\frac{Q^2}{z} + mv^2 \qquad \textit{such that} \qquad v = \sqrt{\frac{1}{4\pi\varepsilon_0 m}\left(\frac{1}{z_0} - \frac{1}{z}\right)} \ .$$

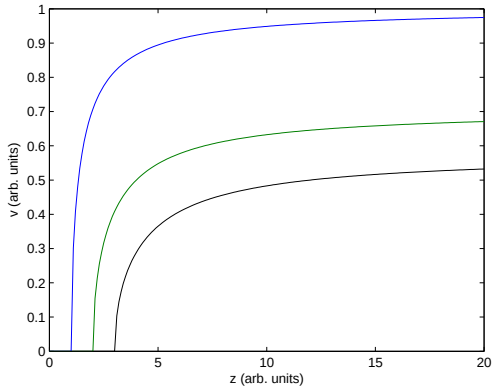

Figure 13.3: Coulomb-Kepler problem.

In the limiting case $z \to \infty$ we get,

$$v_\infty = \sqrt{\frac{1}{4\pi\varepsilon_0 m z_0}} \ .$$

13.1.3.22 Ex: Particle spinning around a charged wire

An infinitely long line uniformly charged with negative charge, has a charge density of λ and is located on the z-axis. A small positively charged particle has mass m and a charge q and is on circular orbit of radius R in the xy-plane centered on the charge line.
a. Deduce an expression for the velocity of the particle.
b. Obtain an expression for the period of the particle's orbit.

Solution: *The field is*

$$\mathcal{E}_r = \frac{1}{2\pi\varepsilon_0}\frac{\lambda}{r} \ .$$

Therefore, force is,

$$F_r = q\mathcal{E}_r = q\frac{1}{2\pi\varepsilon_0}\frac{\lambda}{r} = F_{centr} = m\frac{v^2}{r} \ .$$

With that we get the velocity,

$$v = \sqrt{\frac{1}{2\pi\varepsilon_0}\frac{\lambda q}{m}} \ ,$$

and the period of revolution,

$$T = \frac{2\pi}{\omega} = \frac{2\pi}{v/r} = 2\pi r\sqrt{\frac{2\pi\varepsilon_0 m}{\lambda q}} \ .$$

13.2 Properties of the electric field

In principle the fundamental problem of electrostatics is solved by Coulomb's law. In practice however, the calculation of the electric field generated by a charge distribution can be complicated. On the other hand, electrostatic problems often exhibit symmetries, which allow for their resolution by other techniques avoiding the integrals of Coulomb's law.

13.2.1 Field lines and the electric flux

When we calculate the electric vector field for a charge distribution on a matrix of points in space, we get diagrams like the one shown in Fig. 13.4. The arrows represent, through the lengths of the vectors, the value of the field and, through the orientation of the vector, the direction of the force exerted by the field. The diagram suggests to connect the arrows thus forming lines called *field lines*. These lines are nothing more than the trajectories taken by test charges placed inside the field [1]. Field lines can never intersect (otherwise the direction of force acting on a test charge would be ambiguous) and can never begin or end in free space. They always start from a positive charge and end up in a negative charge.

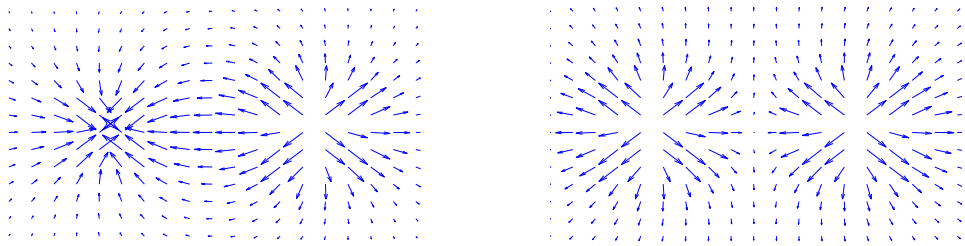

Figure 13.4: Field lines of two equal charges (right) and two opposed charges (left).

The *electric flux* is a measure for the density of field lines crossing a surface. As we have already said, the field line density corresponds to the amplitude of the electric field $\vec{\mathcal{E}}$. The normal vector of the surface $\mathbf{S}$ being locally perpendicular to the plane, we must calculate the flux by taking the integral of the scalar product,

$$\boxed{\Psi_E \equiv \int_{\mathcal{S}} \vec{\mathcal{E}} \cdot d\mathbf{S}} \,. \tag{13.11}$$

Then, instead of illustrating the amplitude of a field through the length of the arrows representing the force exerted on a charge, $\vec{\mathcal{E}} \propto \mathbf{F}$, we can illustrate the amplitude through the local density of lines field, $\vec{\mathcal{E}} \propto \Psi_E$.

The concept of the flux allows us to quantitatively formulate the statement, that field lines can not start or end in free space, but always come out (or penetrate) into charges. For this, we calculate the flux through a sphere around an electric charge q

[1] Note, that the representation by lines (instead of vectors) misses the information about the local field strength. However, this information is still encoded in the local density of the field lines.

located at the origin using Coulomb's law:

$$\oint_{spherical\ surface} \vec{\mathcal{E}} \cdot d\mathbf{S} = \oint_{spherical\ surface} \frac{1}{4\pi\varepsilon_0} \frac{q}{|\mathbf{r}|^2} \hat{\mathbf{e}}_\mathbf{r} \cdot r^2 \sin\theta d\theta d\phi \hat{\mathbf{e}}_\mathbf{r} = \frac{q}{\varepsilon_0} \ . \quad (13.12)$$

With the superposition principle we can generalize this result to arbitrary distributions of charges Q. The so-called *Gauß' law*, or Maxwell's third equation,

$$\boxed{\oint_{\partial\mathcal{V}} \vec{\mathcal{E}} \cdot d\mathbf{S} = \frac{Q}{\varepsilon_0}} \ , \quad (13.13)$$

states, that the number of field lines entering a charge-free volume $\mathcal{V}$ through a closed surface $\partial\mathcal{V}$ must equal the number of lines leaving it. The law also states that *there exist electric charges* acting as sources or drains of field lines. We will resolve flux problems in the Excs. 13.2.4.13 to 13.2.4.29.

13.2.2 Divergence of the electric field and Gauß' law

Gauß' integral theorem (12.42) allows us to rewrite Gauß' law (13.13). On the one hand, we have,

$$\oint_{\partial\mathcal{V}} \vec{\mathcal{E}} \cdot d\mathbf{S} = \int_\mathcal{V} \nabla \cdot \vec{\mathcal{E}} dV \ , \quad (13.14)$$

on the other hand, we can express the total charge inside the volume $\mathcal{V}$ as a sum over the charge distribution,

$$Q = \int_\mathcal{V} \varrho(\mathbf{r}) dV \ . \quad (13.15)$$

comparing the integrands, we obtain the differential form of Gauß' law or Maxwell's third equation:

$$\boxed{\nabla \cdot \vec{\mathcal{E}} = \frac{\varrho}{\varepsilon_0}} \ . \quad (13.16)$$

The Gauß law can also be derived directly from the general Coulomb law: We calculate the divergence of the field of formula (13.8),

$$\begin{aligned} \nabla \cdot \vec{\mathcal{E}} &= \nabla_\mathbf{r} \cdot \int \frac{\varrho(\mathbf{r}')}{4\pi\varepsilon_0} \frac{\mathbf{r}-\mathbf{r}'}{|\mathbf{r}-\mathbf{r}'|^3} dV' = \frac{1}{4\pi\varepsilon_0} \int \varrho(\mathbf{r}') \nabla_\mathbf{r} \cdot \frac{\mathbf{r}-\mathbf{r}'}{|\mathbf{r}-\mathbf{r}'|^3} dV' \quad (13.17) \\ &= \frac{1}{4\pi\varepsilon_0} \int \varrho(\mathbf{r}') 4\pi\delta^3(\mathbf{r}-\mathbf{r}') dV' = \frac{\varrho(\mathbf{r})}{\varepsilon_0} \ . \end{aligned}$$

In the integral form, Gauß' law is very useful for calculating electric fields particularly in situations with a high degree of symmetry. Let us discuss some examples in the following.

Example 44 (*Electric field outside a charged sphere*): We consider a sphere with radius R carrying the total charge Q. Gauß' law says,

$$\oint_{\partial\mathcal{V}} \vec{\mathcal{E}} \cdot d\mathbf{S} = \frac{Q}{\varepsilon_0} \ ,$$

where we choose as volume a sphere with radius $r > R$. At first glance, this does not seem to help much because the field, in which we are interested, is under the integral. But we can explore the symmetry of the system to simplify the integral, since $\vec{\mathcal{E}} = \mathcal{E}\hat{\mathbf{e}}_r$ and $\mathrm{d}\mathbf{S} = dS\hat{\mathbf{e}}_r$, such that we can write the integral,

$$\int_0^{\pi}\int_0^{2\pi} \mathcal{E}r^2 \sin\theta d\theta d\phi = 4\pi r^2 \mathcal{E} = \frac{Q}{\varepsilon_0} \ .$$

Hence,

$$\vec{\mathcal{E}} = \frac{Q}{4\pi\varepsilon_0 r^2}\hat{\mathbf{e}}_r \ .$$

This is precisely Coulomb's law. It is interesting to note that the field does not depend on the distribution ϱ of the charge within the volume. Of course, to take advantage of the symmetry of the system, it is important to choose the adequate volume.

Example 45 (*Box containing an interface*): Let us now give another example of the utility of Gauß' law. We are interested in the electric field generated by an infinitely extended plane carrying a homogeneous surface charge density σ. By symmetry, the $\vec{\mathcal{E}}$-field must cross the plane perpendicularly and have opposite directions above and below the plane. We now imagine a rectangular pill box enclosing a small area of the plane, so that two surfaces of the box (with area S) are parallel to the plane. Inside the box we find the charge,

$$Q = \varepsilon_0 \oint_{\mathcal{S}_{box}} \vec{\mathcal{E}} \cdot d\mathbf{S} = \varepsilon_0 \int_{\mathcal{S}_{upper}} \mathcal{E}dS + \varepsilon_0 \int_{\mathcal{S}_{lower}} \mathcal{E}dS = 2S\mathcal{E} \ .$$

On the other hand, $Q = \int_{\mathcal{V}_{box}} \varrho dV = \sigma S$. Hence,

$$\vec{\mathcal{E}} = \frac{\sigma}{2\varepsilon_0}\hat{\mathbf{n}} \ .$$

It may seem strange that the electric field does not depend on the distance from the plane, but this is due to the fact that the plane is supposed infinite, which is an unrealistic concept. For a limited surface we expect field components not being perpendicular to the interface, which come from the edges of the surface.

13.2.3 Rotation of the electric field and Stokes' law

Stokes' integral theorem (12.40) allows us to rewrite Maxwell's fourth equation(13.23). From

$$\boxed{\oint_{\partial\mathcal{S}} \vec{\mathcal{E}} \cdot d\mathbf{r} = 0} = \int_{\mathcal{S}} (\nabla \times \vec{\mathcal{E}}) \cdot d\mathbf{S} \ , \tag{13.18}$$

we obtain the differential form of Maxwell's second equation:

$$\boxed{\nabla \times \vec{\mathcal{E}} = 0} \ . \tag{13.19}$$

The second Maxwell equation (applied to electrostatics) can also be derived directly from the general Coulomb law: We calculate the rotation of the field of formula (13.3),

$$\nabla \times \vec{\mathcal{E}} = \nabla_{\mathbf{r}} \times \int \frac{\varrho(\mathbf{r}')}{4\pi\varepsilon_0} \frac{\mathbf{r}-\mathbf{r}'}{|\mathbf{r}-\mathbf{r}'|^3} dV' = \frac{1}{4\pi\varepsilon_0} \int \varrho(\mathbf{r}') \nabla_{\mathbf{r}} \times \frac{\mathbf{r}-\mathbf{r}'}{|\mathbf{r}-\mathbf{r}'|^3} dV' = 0 \ . \tag{13.20}$$

The fact that the rotation of any electrostatic field must vanish is a severe constraint. For example, there is no charge distribution leading to a field of the form $\vec{\mathcal{E}} = y\hat{\mathbf{e}}_x$.

A direct consequence of this law is that we can introduce the concept of the potential. This is fundamental, because electrodynamics can be fully formulated in terms of scalar potentials. We will devote the whole next section to electric potentials.

13.2.4 Exercises

13.2.4.1 Ex: Use of Dirac's function in Coulomb's law

Show how the following Coulomb law formulas for one-, two- and three-dimensional density distributions,

$$\vec{\mathcal{E}}(\mathbf{r}) = \frac{1}{4\pi\varepsilon_0}\int_V \frac{\mathbf{r}-\mathbf{r}'}{|\mathbf{r}-\mathbf{r}'|^3}\rho(\mathbf{r}')dV'$$
$$\vec{\mathcal{E}}(\mathbf{r}) = \frac{1}{4\pi\varepsilon_0}\int_A \frac{\mathbf{r}-\mathbf{r}'}{|\mathbf{r}-\mathbf{r}'|^3}\sigma(\mathbf{r}')dA'$$
$$\vec{\mathcal{E}}(\mathbf{r}) = \frac{1}{4\pi\varepsilon_0}\int_C \frac{\mathbf{r}-\mathbf{r}'}{|\mathbf{r}-\mathbf{r}'|^3}\lambda(\mathbf{r}')dC'$$

are linked using Dirac's δ-function, defined by,

$$\delta(x) = \left\{ \begin{array}{ll} \infty & \text{for } x = 0 \\ 0 & \text{for } x \neq 0 \end{array} \right\} \quad \text{such that} \quad \int f(x)\delta(x-a)dx = f(a)\infty\frac{1}{\infty} = f(a)\ .$$

Use the examples of a. A linear charge distribution along the x-axis, given by $\rho(\mathbf{r}') = \lambda(x')\delta(y')\delta(z')$, and b. a surface charge distribution in the $z = 0$ plane, given by$\rho(\mathbf{r}') = \sigma(x', y')\delta(z')$.

Solution: *a. We have*

$$\vec{\mathcal{E}}(\mathbf{r}) = \frac{1}{4\pi\varepsilon_0}\int_V \frac{\mathbf{r}-\mathbf{r}'}{|\mathbf{r}-\mathbf{r}'|^3}\rho(\mathbf{r}')dV' = \frac{1}{4\pi\varepsilon_0}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\frac{\mathbf{r}-\mathbf{r}'}{|\mathbf{r}-\mathbf{r}'|^3}\lambda(x')\delta(y')\delta(z')dx'dy'dz'$$
$$= \frac{1}{4\pi\varepsilon_0}\int_{-\infty}^{\infty}\frac{\mathbf{r}-\mathbf{r}'}{|\mathbf{r}-\mathbf{r}'|^3}\lambda(x')dx' = \frac{1}{4\pi\varepsilon_0}\int_{-\infty}^{\infty}\frac{\mathbf{r}-x'\hat{\mathbf{e}}_x}{|\mathbf{r}-x'\hat{\mathbf{e}}_x|^3}\lambda(x')dx'\ .$$

b. We have

$$\vec{\mathcal{E}}(\mathbf{r}) = \frac{1}{4\pi\varepsilon_0}\int_V \frac{\mathbf{r}-\mathbf{r}'}{|\mathbf{r}-\mathbf{r}'|^3}\rho(\mathbf{r}')dV' = \frac{1}{4\pi\varepsilon_0}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\frac{\mathbf{r}-\mathbf{r}'}{|\mathbf{r}-\mathbf{r}'|^3}\sigma(x', y')\delta(z')dx'dy'dz'$$
$$= \frac{1}{4\pi\varepsilon_0}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\frac{\mathbf{r}-\mathbf{r}'}{|\mathbf{r}-\mathbf{r}'|^3}\sigma(x', y')dx'dy'$$
$$= \frac{1}{4\pi\varepsilon_0}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\frac{\mathbf{r}-x'\hat{\mathbf{e}}_x-y'\hat{\mathbf{e}}_y}{|\mathbf{r}-x'\hat{\mathbf{e}}_x-y'\hat{\mathbf{e}}_y|^3}\sigma(x', y')dx'dy'\ .$$

13.2.4.2 Ex: Electric field generated by a linear charge distribution

Calculate the electric field generated by a linear charge distribution. Analyze the field in a remote region.

Solution: *We put the charge distribution $\lambda(x) = Q/L$ along the x-axis and the observation point at $x = 0$. Following Coulomb's law we have,*

$$\vec{\mathcal{E}}(\mathbf{r}) = \frac{1}{4\pi\varepsilon_0}\int_{x_1}^{x_2} \frac{\begin{pmatrix} x \\ y \end{pmatrix} - \begin{pmatrix} x' \\ y' \end{pmatrix}}{\sqrt{(x-x')^2+(y-y')^2}^3}\lambda(x')dx' = \lambda\int_{x_1}^{x_2} \frac{\begin{pmatrix} 0 \\ y \end{pmatrix} - \begin{pmatrix} x' \\ 0 \end{pmatrix}}{\sqrt{x'^2+y^2}^3}dx' \ .$$

Using

$$\int \frac{zdz}{\sqrt{z^2+a^2}^3} = -\frac{1}{\sqrt{z^2+a^2}} \qquad \text{and} \qquad \int \frac{dz}{\sqrt{z^2+a^2}^3} = \frac{z}{a^2\sqrt{z^2+a^2}} \ ,$$

we obtain,

$$\mathcal{E}_x(r) = \frac{\lambda}{4\pi\varepsilon_0}\int_{x_1}^{x_2} \frac{-x'}{\sqrt{x'^2+y^2}^3}dx' = \frac{\lambda}{4\pi\varepsilon_0}\frac{\sqrt{x_1^2+y^2}-\sqrt{x_2^2+y^2}}{\sqrt{x_2^2+y^2}\sqrt{x_1^2+y^2}} = \frac{\lambda}{4\pi\varepsilon_0}\left(\frac{1}{r_2}-\frac{1}{r_1}\right)$$

$$\mathcal{E}_y(r) = \frac{\lambda}{4\pi\varepsilon_0}\int_{x_1}^{x_2} \frac{y}{\sqrt{x'^2+y^2}^3}dx' = \frac{\lambda}{4\pi\varepsilon_0}\frac{x_2\sqrt{x_1^2+y^2}-x_1\sqrt{x_2^2+y^2}}{\sqrt{x_2^2+y^2}y\sqrt{x_1^2+y^2}} = \frac{\lambda}{4\pi\varepsilon_0}\left(\frac{x_2}{yr_2}-\frac{x_1}{yr_1}\right) \ .$$

with the abbreviations $r_k \equiv \sqrt{x_k^2+y^2}$. At long distances along the axis x, $x_1, x_2 \gg L$, we get $\mathcal{E}_y(x) = 0$ for symmetry reasons and

$$\mathcal{E}_x(x) = \frac{\lambda}{4\pi\varepsilon_0}\left(\frac{1}{x_2}-\frac{1}{x_1}\right) = \frac{Q}{4\pi\varepsilon_0 L}\frac{-L}{x_1(x_1+L)} \simeq \frac{-Q}{4\pi\varepsilon_0 x_1^2} \ .$$

At long distances along the y-axis, that is, $y \gg L$, we get $\mathcal{E}_x(x) = 0$ and,

$$\begin{aligned}\mathcal{E}_y(x) &= \frac{\lambda}{4\pi\varepsilon_0}\frac{(x_1+L)\sqrt{x_1^2+y^2}-x_1\sqrt{(x_1+L)^2+y^2}}{\sqrt{x_1^2+y^2}y\sqrt{(x_1+L)^2+y^2}} \\ &\simeq \frac{\lambda}{4\pi\varepsilon_0}\frac{(x_1+L)\sqrt{y^2}-x_1\sqrt{y^2}}{\sqrt{y^2}y\sqrt{y^2}} = \frac{Q}{4\pi\varepsilon_0}\frac{L}{y^2} \ .\end{aligned}$$

For an infinite charge distribution, $x_2 = -x_1 \gg y$,

$$\mathcal{E}_y(x) = \frac{\lambda}{4\pi\varepsilon_0}\frac{x_2\sqrt{x_1^2+y^2}-x_1\sqrt{x_2^2+y^2}}{\sqrt{x_1^2+y^2}y\sqrt{x_2^2+y^2}} = \frac{\lambda}{4\pi\varepsilon_0}\frac{2x_2}{y\sqrt{x_2^2+y^2}} \simeq \frac{\lambda}{2\pi\varepsilon_0}\frac{1}{y} \ .$$

13.2.4.3 Ex: Electric field produced by a charged disc

a. Calculate the electric field along the symmetry axis generated by a thin disk of radius R evenly charged with the charge Q.
b. Discuss the limit $R \to \infty$ assuming that the surface charge density is kept constant.

Solution: *a. The electric field produced by a charged disc is,*

$$\vec{\mathcal{E}}(\mathbf{r}) = \frac{1}{4\pi\varepsilon_0}\int_{disco}\frac{\mathbf{r}-\mathbf{r}'}{|\mathbf{r}-\mathbf{r}'|^3}\rho(\mathbf{r}')r'dr'd\phi'dz'$$

$$= \frac{Q}{4\pi\varepsilon_0\pi R^2}\int_{disco}\frac{\begin{pmatrix}x\\y\\z\end{pmatrix}-\begin{pmatrix}R\cos\phi'\\R\sin\phi'\\0\end{pmatrix}}{\sqrt{(x-r'\cos\phi')^2+(y-r'\sin\phi')^2+z^2}^3}r'dr'd\phi' \ .$$

On the symmetry axis we have $\mathcal{E}_x(z) = \mathcal{E}_y(z) = 0$ *e*

$$\mathcal{E}_z(z) = \frac{Q}{4\pi\varepsilon_0\pi R^2}\int_{disco}\frac{z}{\sqrt{r'^2\cos^2\phi'+r'^2\sin^2\phi'+z^2}^3}r'dr'd\phi'$$

$$= \frac{Q}{4\pi\varepsilon_0\pi R^2}2\pi z\int_0^R\frac{r'}{\sqrt{r'^2+z^2}^3}dr' = \frac{Q}{4\pi\varepsilon_0\pi R^2}2\pi z\int_{z^2}^{R^2+z^2}\frac{u^{-3/2}}{2}du$$

$$= \frac{Q}{4\pi\varepsilon_0\pi R^2}2\pi z\left.\frac{-1}{\sqrt{r'^2+z^2}}\right|_0^R = \frac{Q}{2\pi\varepsilon_0 R^2}\left(\frac{-z}{\sqrt{R^2+z^2}}+\frac{z}{|z|}\right) \ ,$$

with $\int\frac{udu}{\sqrt{u^2+z^2}^3} = -\frac{1}{\sqrt{u^2+z^2}}$.
b. Considering a disk with infinite extension, $R \longrightarrow \infty$*, but with constant charge surface density,* $\sigma \equiv Q/\pi R^2 = const$*, we obtain,*

$$E_z(z) = \frac{\sigma}{2\varepsilon_0}\frac{z}{|z|} \ .$$

That is, the electric field is uniform and opposite on both sides of the disk.

13.2.4.4 Ex: Electric field produced by a spherical layer

A charge q is deposited on a solid conducting sphere of radius R.
a. Parametrize the charge distribution $\rho(\mathbf{r})$.
b. Determine the surface charge density σ on the sphere's surface.
c. Using the Gauß law, $\oint_{\partial V}\vec{\mathcal{E}}(\mathbf{r})\cdot d\mathbf{a} = \frac{Q}{\varepsilon_0}$, calculate the electric field inside and outside the sphere.
d. Using the Coulomb law, $\vec{\mathcal{E}}(\mathbf{r}) = \frac{1}{4\pi\varepsilon_0}\int_A\frac{\mathbf{r}-\mathbf{r}'}{|\mathbf{r}-\mathbf{r}'|^3}\sigma(\mathbf{r}')dA'$ in spherical coordinates,

$$\mathbf{r}' = \begin{pmatrix}R\sin\theta'\cos\phi'\\R\sin\theta'\sin\phi'\\R\sin\theta'\end{pmatrix} \qquad \text{and} \qquad dA' = R^2\sin\theta'd\theta d\phi' \ ,$$

calculate the electric field $E_z(z)$ along the z-axis in- and outside the sphere. Help:

$$\int_{-R}^{R} \frac{z-z'}{\sqrt{z^2-2zz'+R^2}^3} dz' = \begin{cases} \frac{-2R}{z^2} & z < -R \\ 0 & \text{for } -R < z < R \\ \frac{2R}{z^2} & R < z \end{cases} .$$

Solution: *a. The charge density is given by a δ-function: $\rho(\mathbf{r}) = C \cdot \delta^{(3)}(r-R)$, where the constant C must be determined by integration over the entire space. Integrating the density, we hope to obtain the total charge:*

$$\int_V \rho(\mathbf{r}) = C \int_V \delta^{(3)}(r-R) \equiv Q \ .$$

On the other hand, the integral over the δ-function reproduces the total surface:

$$\int_{\partial V} \delta^{(3)}(r-R) = 4\pi R^2 \ .$$

Hence, $C = \frac{Q}{4\pi R^2} = \sigma$ is the surface charge density.
b. The charge will be deposited on the outer surface of the sphere. Thus, the surface charge density is,

$$\sigma = \frac{Q}{4\pi R^2} \ .$$

c. Using the Gauß law,

$$\oint_{\partial V} \vec{\mathcal{E}}(\mathbf{r}) \cdot d\mathbf{a} = E_r 4\pi r^2 = \frac{Q_{inside}}{\varepsilon_0} \ ,$$

we find

$$\vec{\mathcal{E}}(\mathbf{r}) = 0 \ \ for \ \ r < R \ \ and \ \ \vec{\mathcal{E}}(\mathbf{r}) = \frac{Q}{4\pi\varepsilon_0 r^2}\hat{\mathbf{e}}_r \ \ for \ \ r > R \ ,$$

what exactly is Coulomb's law.
d. On the surface σ is constant. Hence,

$$\begin{aligned} \vec{\mathcal{E}}(\mathbf{r}) &= \frac{\sigma}{4\pi\varepsilon_0} \int_A \frac{\mathbf{r}-\mathbf{r}'}{|\mathbf{r}-\mathbf{r}'|^3} dA' = \frac{\sigma}{4\pi\varepsilon_0} \int_A \frac{\mathbf{r}-R\hat{\mathbf{e}}'_r}{|\mathbf{r}-\mathbf{r}'|^3} R^2 \sin\theta' d\theta' d\phi' \\ &= \frac{\sigma R^2}{4\pi\varepsilon_0} \int_A \frac{\begin{pmatrix} 0 \\ 0 \\ z \end{pmatrix} - R \begin{pmatrix} \sin\theta'\cos\phi' \\ \sin\theta'\sin\phi' \\ \cos\theta' \end{pmatrix}}{\sqrt{(x-x')^2+(y-y')^2+(z-z')^2}^3} \sin\theta' d\theta' d\phi' \ . \end{aligned}$$

For the component E_z along the z-axis we have

$$\begin{aligned}\mathcal{E}_z(z) &= \frac{\sigma R^2}{4\pi\varepsilon_0}\int_0^{\pi}\int_0^{2\pi}\frac{z - R\cos\theta'}{\sqrt{(R\sin\theta'\cos\phi')^2 + (R\sin\theta'\sin\phi')^2 + (z - R\cos\theta')^2}^3}\sin\theta' d\theta' d\phi' \\ &= \frac{\sigma R^2}{4\pi\varepsilon_0}2\pi\int_0^{\pi}\frac{z - R\cos\theta'}{\sqrt{(R\sin\theta')^2 + (z - R\cos\theta')^2}^3}\sin\theta' d\theta' \\ &= \frac{Q}{8\pi\varepsilon_0}\int_{-1}^{1}\frac{z - R\cos\theta'}{\sqrt{z^2 - 2Rz\cos\theta' + R^2}^3}d\cos\theta' = \frac{Q}{8\pi\varepsilon_0 R}\int_{-R}^{R}\frac{z - z'}{\sqrt{z^2 - 2zz' + R^2}^3}dz' \ .\end{aligned}$$

Using the formula for calculating the integral, we find,

$$\mathcal{E}_z(z) = \frac{Q}{4\pi\varepsilon_0 z^2}\cdot\begin{cases}-1 & z < -R \\ 0 \quad for & -R < z < R \\ 1 & R < z\end{cases}.$$

13.2.4.5 Ex: Field of a homogeneously charged sphere

Calculate with the Gauß law the electric field of a homogeneously charged sphere (charge Q, radius R)
a. for $r < R$ and
b. for $r \geq R$.

Solution: *For reasons of symmetry the electric field $\vec{\mathcal{E}}$ produced by the charge must show radially outward and the absolute value E can only depend on r. The charge density of the sphere is $\rho(\mathbf{r}) = \rho_0 = \frac{Q}{4\pi R^3/3}$ for $r \leq R$, else $\rho(\mathbf{r}) = 0$. Following the Gauß law we have $\int_{\partial\ subsphere}\vec{\mathcal{E}}\cdot d\mathbf{S} = \frac{1}{\varepsilon_0}\int_{subsphere}\rho(\mathbf{r})d^3r$. Hence, for $r < R$*

$$4\pi r^2\mathcal{E}_r = \frac{\rho_0}{\varepsilon_0}\int_{subsphere} r^2\sin\theta dr d\theta d\phi = \frac{4\pi\rho_0}{3}r^3 \ ,$$

and finally,

$$\mathcal{E}_r = \frac{Q}{4\pi\varepsilon_0 R^3}r \ .$$

For $r \geq R$ we have,

$$4\pi r^2\mathcal{E}_r = \frac{\rho_0}{\varepsilon_0}\int_{sphere} r^2\sin\theta dr d\theta d\phi = \frac{4\pi\rho_0}{3}R^3 \ ,$$

and finally,

$$\mathcal{E}_r = \frac{Q}{4\pi\varepsilon_0 r^2} \ .$$

13.2.4.6 Ex: Field of a charge distribution with spherical symmetry

The electric field generated by a spherically symmetric charge distribution $\rho(r)$ can be given in the form,

$$\vec{\mathcal{E}}(\mathbf{r}) = \frac{\mathbf{r}}{r^3}\, 4\pi \int_0^r dr'\; r'^{\,2}\, \rho(r')\ ,$$

where the origin is in the center of the sphere and $r = |\mathbf{r}|$.
a. Show that $\mathrm{div}\vec{\mathcal{E}} = 4\pi\ \rho$ and $\mathrm{rot}\vec{\mathcal{E}} = 0$.
b. Calculate the field for a sphere of radius R, which is homogeneously charged in the entire volume with the total charge Q.
c. Resolve (b) for a homogeneously charged hollow concentric sphere with inner radius R_i, outer radius R_a and full load Q.
d. Resolve (c) for the case, that the center of the hollow spherical part is displaced by a vector $\mathbf{d}$ with respect to the center of the spherical surface.
Help: The electric field is an additive quantity.

Solution: *a. We have*

$$\nabla\cdot\vec{\mathcal{E}} = \vec{\nabla}\cdot\left[\frac{4\pi}{r^2}\int_0^r dr'\; r'^{\,2}\rho(r')\right]\hat{\mathbf{e}}_r = \frac{1}{r^2}\frac{\partial}{\partial r}\left[r^2\frac{4\pi}{r^2}\int_0^r dr'\; r'^{\,2}\rho(r')\right]$$
$$= \frac{4\pi}{r^2}\frac{\partial}{\partial r}\int_0^r dr'\; r'^{\,2}\rho(r') = \frac{4\pi}{r^2}r^2\rho(r) = 4\pi\rho(r)\ .$$

Vale $\vec{\mathcal{E}} = \hat{\mathbf{e}}_r E_r \equiv \nabla g(r)$. *From this follows immediately,*

$$\vec{\nabla}\times\vec{\mathcal{E}} = \vec{\nabla}\times(\vec{\nabla}g) \equiv 0\ .$$

b. We have,

$$\rho(r) = \begin{cases} \frac{Q}{4\pi R^3/3} & \textit{para } r \le R \\ 0 & \textit{else} \end{cases}\ .$$

Hence,

$$\int_0^r dr'\; r'^2\rho(r') = \begin{cases} \frac{Q}{4\pi R^3/3}\frac{r^3}{3} & \textit{for } r \le R \\ \frac{Q}{4\pi R^3/3}\frac{R^3}{3} & \textit{for } r > R \end{cases}$$

e por isso,

$$\vec{\mathcal{E}}(r) = \hat{\mathbf{e}}_r Q \begin{cases} \frac{r}{R^3} & \textit{for } r \le R \\ \frac{1}{r^2} & \textit{for } r > R \end{cases}\ .$$

c. We have

$$\rho(r) = \begin{cases} 0 & \textit{para } r < R_i \\ \frac{Q}{4\pi(R_a^3 - R_i^3)/3} & \textit{for } R_i \le r \le R_a \\ 0 & \textit{for } r > R_a \end{cases}\ .$$

Hence,

$$\int_0^r dr'\; r'^2\rho(r') = \frac{Q}{4\pi(R_a^3 - R_i^3)/3}\begin{cases} 0 & \textit{for } r < R_i \\ (r^3 - R_i^3)/3 & \textit{para } R_i \le r \le R_a \\ (R_a^3 - R_i^3)/3 & \textit{for } r > R_a \end{cases}$$

and therefore,

$$\vec{\mathcal{E}}(r) = \hat{\mathbf{e}}_r\, Q \begin{cases} 0 & for r < R_i \\ \frac{r^3 - R_i^3}{R_a^3 - R_i^3}\frac{1}{r^2} & for\ R_i \le r \le R_a \\ \frac{1}{r^2} & for\ r > R_a \end{cases} .$$

In the outer region, therefore, we have the same behavior as in (b). Here the field only depends on the total evenly distributed charge Q.
d. We want to place the origin in the center of a large solid *sphere. An arbitrary point* $\mathbf{r}$ *on the surface of the sphere has the vector relative to the center of the small* hollow *sphere* $\mathbf{r}' = \mathbf{r} - \mathbf{d}$. *We let the charge density be,*

$$\rho_1 = \frac{Q}{\frac{4\pi}{3}(R_a^3 - R_i^3)}$$

and use that

$$\vec{\mathcal{E}} = \vec{\mathcal{E}}_{solid\ sphere} - \vec{\mathcal{E}}_{hollow\ sphere} .$$

Now,

$$\vec{\mathcal{E}}_{solid\ sphere} = \frac{\mathbf{r}}{r}\frac{4\pi}{3}\rho_1 \begin{cases} r & for\ r \le R_a \\ \frac{R_a^3}{r^2} & for\ r > R_a \end{cases}$$

and

$$\vec{\mathcal{E}}_{hollow\ sphere} = \frac{\mathbf{r}'}{r'}\frac{4\pi}{3}\rho_1 \begin{cases} r' & for\ r' \le R_i \\ \frac{R_i^3}{r'^2} & for r' > R_i \end{cases} .$$

From this follows immediately,

$$\vec{\mathcal{E}}(\mathbf{r}) = \frac{4\pi}{3}\rho_1 \begin{cases} \mathbf{d} & inside\ the\ hollow\ sphere \\ \mathbf{r} - \frac{\mathbf{r}-\mathbf{d}}{|\mathbf{r}-\mathbf{d}|^3}R_i^3 & within\ the\ shell \\ \frac{\mathbf{r}}{r^3}R_a^3 - \frac{\mathbf{r}-\mathbf{d}}{|\mathbf{r}-\mathbf{d}|^3}R_i^3 & outside \end{cases} .$$

13.2.4.7 Ex: Field of a charge distribution with spherical symmetry

A sphere of radius R is in a vacuum. It is made of a material with a constant permittivity ε and carries the charge q in its center.
a. Calculate the field the electrostatic field $\vec{\mathcal{E}}$ inside and outside the sphere.
b. Calculate the electrostatic potential Φ in the entire space.

Solution:

13.2.4.8 Ex: Charge distribution

We consider the charge density $\rho(\mathbf{r}) = cr\int_0^R dr'\delta(r'-r)$, where $r = |\mathbf{r}|$, $R > 0$ and $c = const$. The total charge be Q.
a. Make a scheme of the function $\rho(\mathbf{r})$. What is the relationship between the constant

c and the total charge Q?
b. Start by showing that the electric field created by a spherically symmetric charge distribution ρ can be written as $\vec{\mathcal{E}}(\mathbf{r}) = \frac{\mathbf{r}}{r^3}\int_0^r dr' r'^2 \frac{1}{\varepsilon_0}\rho(r')$. Here, $\mathbf{r}$ is the vector starting from the origin at the center of symmetry and reaching the surface. Determine the absolute value and direction of the electric field $\vec{\mathcal{E}}(\mathbf{r})$ for $|\mathbf{r}| < R$ and $|\mathbf{r}| > R$ for the given charge distribution. Make a scheme of the profile $|\vec{\mathcal{E}}(\mathbf{r})|$.

Solution: *a. The charge is,*

$$\begin{aligned} Q &= \int \rho(\mathbf{r}) d^3r = 4\pi \int_0^\infty r^2 \rho(r) dr = 4\pi c \int_0^\infty dr\ r^3 \int_0^R dr' \delta(r'-r) \\ &= 4\pi c \int_0^R dr\ r^3 = 4\pi c \frac{R^4}{4} = \pi c R^4 \\ &\Longrightarrow c = \frac{Q}{\pi R^4} \ . \end{aligned}$$

The charge distribution therefore increases linearly with the pitch c between $r = 0$ and $r = R$ and drops to zero for $r > R$.
b. For $\rho(\mathbf{r}) = \rho(r)$ the expression $\vec{\mathcal{E}} = E_r \frac{\mathbf{r}}{r}$ is the volume integral of a sphere with radius r, where the center of the sphere is the center of symmetry,

$$\int_V div\ \vec{\mathcal{E}} d^3r' = \int_V \frac{1}{\varepsilon_0}\rho d^3r' = \frac{4\pi}{\varepsilon_0}\int_0^r \rho(r') r'^2 dr' \ .$$

With Gauß

$$\int_V div\ \vec{\mathcal{E}} d^3r' = \int_{\partial V} \vec{\mathcal{E}} d^2\mathbf{f} = 4\pi r^2 \mathcal{E}_r(r) \ .$$

Follows

$$\begin{aligned} \vec{\mathcal{E}}(\mathbf{r}) &= \frac{1}{\varepsilon_0}\frac{\mathbf{r}}{r^3}\int_0^r dr' r'' \rho(r') = \frac{c}{\varepsilon_0}\frac{\mathbf{r}}{r^3}\int_0^r dr' r''' r' \int_0^R dr'' \delta(r'') - r') \\ &= \begin{cases} \frac{c}{\varepsilon_0}\frac{\mathbf{r}}{r^3}\int_0^r dr' r''' = \frac{Q}{4\pi\varepsilon_0}\hat{\mathbf{e}}_r \frac{r^2}{R^4} & for \quad r \le R \\ \frac{c}{\varepsilon_0}\frac{\mathbf{r}}{r^3}\int_0^R dr' r''' = \frac{Q}{4\pi\varepsilon_0}\hat{\mathbf{e}}_r \frac{1}{r^2} & for \quad r > R \end{cases} . \end{aligned}$$

The amplitude $\mathcal{E}_r$ of the electric field increases between $r = 0$ and R quadratically and then falls as $1/r^2$.

13.2.4.9 Ex: Charge distribution

A thin, square and conductive sheet has $d = 5.0$ m long edges and a charge of $Q = 80\,\mu C$. Assume that the load is evenly distributed on the faces of the sheet.
a. Determine the charge density on each face of the sheet and the electric field in the vicinity of one face.
b. The sheet is placed to the right of an infinite, non-conductive plane charged with the charge density $\sigma_{inf} = 2.0\ \mu C/m^2$, with the faces of the sheet parallel to the plane. Determine the electric field on each face of the sheet and determine the charge density

on each face.

Solution: *a. The charge densities on each side of the sheet are,*

$$\sigma_{esq} = \sigma_{dir} = \frac{Q}{2A} = 1.6\,\mu\text{C/m}^2 \ .$$

With that, we get the fields close to the surfaces,

$$\mathcal{E}_{esq} = -\frac{\sigma_{esq}}{\varepsilon_0} = -181\,\text{kN/C} \qquad \textit{and} \qquad \mathcal{E}_{dir} = \frac{\sigma_{dir}}{\varepsilon_0} = 181\,\text{kN/C} \ .$$

b. The field generated by the infinite plane on its right side is,

$$\mathcal{E}_{inf} = \frac{\sigma_{inf}}{2\varepsilon_0} = 113\,\text{kN/C} \ .$$

Therefore, the total fields on both sides of the sheet are,

$$\mathcal{E}_{esq,x} = \mathcal{E}_{esq} + \mathcal{E}_{inf} = -68\,\text{kN/C} \qquad \textit{and} \qquad \mathcal{E}_{dir,x} = \mathcal{E}_{dir} + \mathcal{E}_{inf} = 294\,\text{kN/C} \ .$$

As the sheet is conductive, the charge densities rearrange themselves like

$$\sigma_{esq,x} = \varepsilon_0 E_{esq,x} = 0.6\,\mu\text{C/m}^2 \qquad \textit{and} \qquad \sigma_{dir,x} = \varepsilon_0 E_{dir,x} = 2.6\,\mu\text{C/m}^2 \ .$$

13.2.4.10 Ex: Charge distribution

A large, flat, non-conductive and non-uniformly charged surface is placed along the $x = 0$ plane. At the origin, the charge density is $\sigma = 3.1\,\mu\text{C/m}^2$. At a short distance from the surface in the positive direction of the x-axis, the x-component of the electric field is $\mathcal{E}_{dir} = 4.65 \cdot 10^5\,\text{N/C}$. What is the value of $\mathcal{E}_x$ a short distance from the surface in the negative direction of the axis x.

Solution: *The discontinuity of the normal of the electric field has to be,*

$$\Delta E_n = \frac{\sigma}{\varepsilon_0} \ .$$

Hence, the field on the left is

$$E_{esq} = E_{dir} - \frac{\sigma}{\varepsilon_0} = -115\,\text{kN/C} \ .$$

The inequality of the fields on the left and right sides comes from the superposition of another electric field due to the uneven distribution of charge on the surface.

13.2.4.11 Ex: Charge distribution

An infinite flat non-conductive blade with surface charge density $\sigma_1 = +3.0\,\mu\text{C/m}^2$ is located in the $y_0 = -0.6\,\text{m}$ plane. A second infinite flat blade with surface charge density of $\sigma_2 = -2.0\,\mu\text{C/m}^2$ is located in the $x_0 = 1.0\,\text{m}$ plane. Finally, a thin

non-conductive spherical shell with radius $R = 1.0\,\mathrm{m}$ and its center in the $z_0 = 0$ plane at the intersection of the two charged blades, has a surface charge density of $\sigma_3 = -3.0\,\mu\mathrm{C/m}^2$. Determine the magnitude, direction, and orientation of the electric field along the x-axis and
a. $x_1 = 0.4\,\mathrm{m}$ and
b. $x_2 = 2.5\,\mathrm{m}$.

Solution: *a. The fields produced by σ_n are,*

$$\vec{\mathcal{E}}_1 = \frac{\sigma_1}{2\varepsilon_0}\frac{y-y_0}{|y-y_0|}\hat{\mathbf{e}}_y \quad , \quad \vec{\mathcal{E}}_2 = \frac{\sigma_2}{2\varepsilon_0}\frac{x-x_0}{|x-x_0|}\hat{\mathbf{e}}_x \quad ,$$
$$\vec{\mathcal{E}}_3 = 0 \;\; for \;\; r < R \;\; and \;\; \frac{\sigma_3 4\pi R^2}{4\pi\varepsilon_0}\frac{1}{r}\hat{\mathbf{e}}_r \;\; for \;\; r > R \;,$$

where $r^2 \equiv (x-x_0)^2 + (y-y_0)^2 + (z-z_0)^2$. The total field is,

$$\vec{\mathcal{E}} = \vec{\mathcal{E}}_1 + \vec{\mathcal{E}}_2 + \vec{\mathcal{E}}_3 \;.$$

We verify that the observation point $\mathbf{r}_1 = (x_1, 0, 0)$ is within the sphere σ_3, $r_1 < R$. Hence,

$$\vec{\mathcal{E}} = \frac{\sigma_1}{2\varepsilon_0}\hat{\mathbf{e}}_y + \frac{\sigma_2}{2\varepsilon_0}(-\hat{\mathbf{e}}_x) + 0 \;,$$

giving $E = \frac{\sqrt{\sigma_1^2+\sigma_2^2}}{2\varepsilon_0} = 204\ kN/C$ and $\theta = \frac{\sigma_1}{\sigma_2} = 56.3°$.
b. We verify that the observation point $\mathbf{r}_2 = (x_2, 0, 0)$ is outside the sphere σ_3, $r_2 > R$. Hence,

$$\vec{\mathcal{E}} = \frac{\sigma_1}{2\varepsilon_0}\hat{\mathbf{e}}_y + \frac{\sigma_2}{2\varepsilon_0}(+\hat{\mathbf{e}}_x) + \frac{\sigma_3}{\varepsilon_0}\frac{R^2}{r_1^2}\hat{\mathbf{e}}_x \;,$$

giving $E = \frac{\sqrt{\sigma_1^2+(\sigma_2+\frac{2R^2}{r_1^2})^2}}{2\varepsilon_0} = 263\ kN/C$ and $\theta = \frac{\sigma_1}{\sigma_2+\frac{2R^2}{r_1}} = 153°$.

13.2.4.12 Ex: Charged sphere

A solid non-conducting sphere with radius $R = 1.0\,\mathrm{cm}$ carries a uniform volumetric charge density. The magnitude of the electric field at a distance $r = 2.0\,\mathrm{cm}$ from the center of the sphere is $\mathcal{E}_r = 1.88 \cdot 10^3\,\mathrm{N/C}$.
a. What is the volumetric charge density of the sphere?
b. Determine the magnitude of the electric field at a distance $d = 5.0\,\mathrm{cm}$ from the center of the sphere.

Solution: *a. Using the Gauß law,*

$$\mathcal{E}_r = \frac{1}{4\pi\varepsilon_0}\frac{Q_{inside}}{r^2} \;,$$

we obtain,

$$Q_{inside} = 4\pi\varepsilon_0 r^2 E_r \;.$$

The density follows from,

$$\rho = \frac{Q_{inside}}{\frac{4\pi}{3}R^3} = \frac{3\varepsilon_0 r^2 \mathcal{E}_r}{R^3} = 2.0\ \mu C\ .$$

b. The electric field at this distance is,

$$\mathcal{E}_d = \frac{1}{4\pi\varepsilon_0}\frac{Q_{inside}}{d^2} = 301.3\,\mathrm{N/C}\ .$$

Gabarite: *a.* $2.0\,\mu\mathrm{C/m^3}$. *b.* $470\,\mathrm{N/C}$.

13.2.4.13 Ex: Electrical flow

A point charge Q is placed in the center of a hypothetical ball with radius R, which on one side is cut at a height h. What is the flow of electric field $\vec{\mathcal{E}}$ through the plane of the cut A illustrated in the figure?

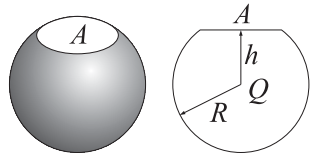

Figure 13.5: Scheme.

Solution: *The electric field is given by,*

$$\vec{\mathcal{E}}(\mathbf{r}) = \frac{1}{4\pi\varepsilon_0}\frac{Q}{r^2}\hat{\mathbf{e}}_r\ .$$

As in a central field without divergence or rotation the flow must be preserved, we can consider instead of the flow through the cut A, a flow through the spherical cap. The flow of the electric field is therefore,

$$\begin{aligned}\Phi &= \int_A \vec{\mathcal{E}}(\mathbf{r}')\cdot d\mathbf{S}' = \int_{\mathcal{S}} \frac{1}{4\pi\varepsilon_0}\frac{Q}{r^2}\hat{\mathbf{e}}_r\cdot d\mathbf{S} = \int_A \frac{1}{4\pi\varepsilon_0}\frac{Q}{R^2}R^2\sin\theta d\theta d\phi \\ &= 2\pi\frac{Q}{4\pi\varepsilon_0}\cos\theta|_{\arccos(h/R)}^{0} = \frac{Q}{2\varepsilon_0}\left(1-\frac{h}{R}\right)\ .\end{aligned}$$

13.2.4.14 Ex: Electrical flow

The cube shown in the figure has an edge length of $d = 1.4\,\mathrm{m}$ and is located inside an electric field.
a. Calculate the electrical flux through the right surface of the cube for an electric field given by $\vec{\mathcal{E}} = -3\,\mathrm{V/m}\cdot\hat{\mathbf{e}}_x + 4\,\mathrm{V/m}\cdot\hat{\mathbf{e}}_z$. What is the total flux across the entire

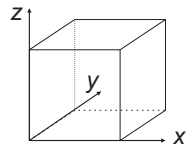

Figure 13.6: Scheme.

surface of the cube?
b. Calculate the total flux across the entire surface of the cube for the electric field $\vec{\mathcal{E}} = -4\,\mathrm{V/m}^2 \cdot \hat{\mathbf{e}}_x + (6\,\mathrm{V/m} + 3\,\mathrm{V/m}^2 \cdot y)\hat{\mathbf{e}}_y$. What charge is contained in the cube?

Solution:

13.2.4.15 Ex: Electrical flow

Calculate the electric field flux $\vec{\mathcal{E}}(\mathbf{r}) = \mathcal{E}_0\hat{\mathbf{e}}_z$ through the semi-sphere with radius R shown in the figure.

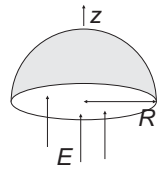

Figure 13.7: Scheme.

Solution: *The surface element in spherical coordinates is,*

$$d\mathbf{a} = R^2 \sin\theta d\theta d\phi \hat{\mathbf{e}}_r \qquad with \qquad \hat{\mathbf{e}}_r = \begin{pmatrix} \sin\theta\cos\phi \\ \sin\theta\sin\phi \\ \cos\theta \end{pmatrix} .$$

The electric field on the surface of the sphere is,

$$\vec{\mathcal{E}} = \mathcal{E}_0 \begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix} .$$

The flux through the semi-sphere is therefore,

$$\Psi = R^2 \int_0^{\pi/2} d\theta \sin\theta \int_0^{2\pi} d\phi \mathcal{E}_0 \begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix} \cdot \begin{pmatrix} \sin\theta\cos\phi \\ \sin\theta\sin\phi \\ \cos\theta \end{pmatrix} = 2\pi\mathcal{E}_0 R^2 \int_0^{\pi/2} d\theta \sin\theta\cos\theta = \pi\mathcal{E}_0 R^2 .$$

Smart solution: *As the field is homogeneous, the flux* $\int \vec{\mathcal{E}} \cdot d\mathbf{a} = \int E_0 \hat{\mathbf{e}}_z \cdot d\mathbf{a}$ *through the area of the semi-sphere is equal to the flux through a circular surface with the same radius:*

$$\int_{semi-sphere} \vec{\mathcal{E}} \cdot d\mathbf{a} = \int_{circle} \mathcal{E}_0 \hat{\mathbf{e}}_z \cdot \hat{\mathbf{e}}_z dA = \mathcal{E}_0 \pi R^2 \ .$$

13.2.4.16 Ex: Electrical flow

Calculate the flow of the vector field with cylindrical symmetry $\vec{\mathcal{E}}(\mathbf{r}) = \mathcal{E}_0 \hat{\mathbf{e}}_\rho$ through the half cylindrical surface shown in the figure with radius R and length L.

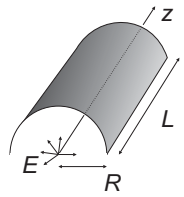

Figure 13.8: Scheme.

Solution: *The surface element is in cylindrical coordinates,*

$$d\mathbf{S} = Rd\phi\hat{\mathbf{e}}_\rho \qquad with \qquad \hat{\mathbf{e}}_\rho = \begin{pmatrix} \cos\phi \\ \sin\phi \\ 0 \end{pmatrix} \ .$$

The flux through the cylinder surface is given by the following expression:

$$\Psi = \int \vec{\mathcal{E}}(\mathbf{r}) \cdot d\mathbf{S} = \int_{\mathcal{S}} E_0 \hat{\mathbf{e}}_\rho \hat{\mathbf{e}}_\rho df = E_0 \pi RL \ .$$

13.2.4.17 Ex: Electric field of a charged sheet

An infinitely extended non-conductive sheet carries a charge with a surface density of $0.1\,\mu C/m^2$ on either side. What is the distance of the equipotential surfaces for a potential difference of 50 V?

Solution: *With* $\rho(\mathbf{r}) = \sigma_0 \delta(z)$ *vale,*

$$\int \mathcal{E}\ df = \oint_{\partial V} \vec{\mathcal{E}}\ d\mathbf{S} = \frac{1}{\varepsilon_0} \int \rho dV = \frac{\sigma_0}{\varepsilon_0} \int dS \ .$$

Follows $\mathcal{E} = \sigma/\varepsilon_0$. *With* $\mathcal{E} = U/d$ *follows* $d = \varepsilon_0 U/\sigma = 4.4\,\text{mm}$.

13.2.4.18 Ex: Electric field between charged planes

Consider two thin, non-conductive planes with infinite length perpendicular to the x-axis and crossing this axis at the positions x_1 and x_2 with $x_1 < x_2$. The planes are uniformly charged with charge densities σ_2. Calculate the electric fields in the three regions $x < x_1$ and $x_1 < x < x_2$ and $x_2 < x$. Discuss the particular cases $\sigma_2 = \sigma_1$ and $\sigma_2 = -\sigma_1$.

Solution: *The fields are,*

$$\mathcal{E}_{esq} = -\frac{\sigma_1}{2\varepsilon_0} - \frac{\sigma_2}{2\varepsilon_0} \quad , \quad \mathcal{E}_{med} = +\frac{\sigma_1}{2\varepsilon_0} - \frac{\sigma_2}{2\varepsilon_0} \quad , \quad \mathcal{E}_{dir} = +\frac{\sigma_1}{2\varepsilon_0} + \frac{\sigma_2}{2\varepsilon_0} \ .$$

For $\sigma_2 = -\sigma_1$, we obtain $\mathcal{E}_{esq} = \mathcal{E}_{dir} = 0$ and $\mathcal{E}_{med} = \sigma_1/\varepsilon_0$.
For $\sigma_2 = \sigma_1$, we obtain $\mathcal{E}_{med} = 0$ and $\mathcal{E}_{esq} = \mathcal{E}_{dir} = \sigma_1/\varepsilon_0$.

13.2.4.19 Ex: Electric field of a photocopier

The electric field just above the surface of the electrically charged drum of a photocopier has the absolute value $2.3 \cdot 10^5\,\mathrm{N/C}$. The drum has a length of 42 cm and a diameter of 12 cm.
a. What is the charge density on the surface supposed conductive?
b. What is the total charge on the drum?
c. Decreasing the drum to 8 cm in order to build a more compact photocopier, the field on the surface must remain the same. What should the charge be in this case?

Solution: *a. For an infinitesimal volume element including a part of the drum's surface we can express the surface density of charges as $\sigma = \varepsilon_0 \mathcal{E} = 2 \cdot 10^{-6}\,\mathrm{C/m^2}$.*
b. For the whole cylinder,

$$\oint_{cylindersurface} \vec{\mathcal{E}}\, d\mathbf{S} = \mathcal{E} \cdot 2\pi RL = \frac{Q}{\varepsilon_0} \ .$$

Follows $Q = \varepsilon_0 E \cdot 2\pi RL = 6.4 \cdot 10^{-7}\,\mathrm{C}$.
c. The charge on the smaller drum should be 12/8=1.5 times less.

13.2.4.20 Ex: Geiger counter

A Geiger-Müller meter consists essentially of a metal tube filled with gas (inner radius r_a) with a thin wire inside (radius r_i). A high voltage is applied between the two. The meter serves, for example, to detect charged particles, which produce pairs of electrons and ions from the gas, which are then extracted by an applied voltage and detected as an electrical signal.
a. Calculate the potential $\phi(r)$, where $\phi(r_a) = 0$ and $\phi(r_i) = U = 1000\,\mathrm{V}$.
b. Be $r_i = 15\,\mu\mathrm{m}$, $r_a = 1\,\mathrm{cm}$. Calculate the strength of the field at the tube's surface.
c. The average free path in the gas is $L = 3\,\mu\mathrm{m}$. At what distance R_I from the wire does an avalanche form, that is, an electron stopped due to a collision is accelerated over a distance L up to the ionization energy $E_I = 5\,\mathrm{eV}$ and, thus, can generate

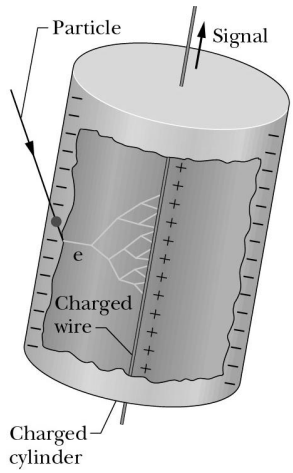

Figure 13.9: Geiger counter.

another electron-ion pair in the subsequent collision?

Solution: *a. The flux through the curved surface of a cylinder with radius r surrounding the wire follows Gauß' law:*

$$\int_{\partial V} \vec{\mathcal{E}} \cdot d\mathbf{S} = \frac{1}{\varepsilon_0} \int_V \rho dV \ .$$

and with that $\mathcal{E} = \frac{Q}{2\pi\varepsilon_0 lr}$ with the charge Q within a segment of the wire of length l. The potential continues follows from the integration of $\vec{\mathcal{E}} = -\vec{\nabla}\Phi$,

$$\Phi = -\int \mathcal{E} dr + C = -\int \frac{Q}{2\pi\varepsilon_0 lr} dr + C = -\frac{Q}{2\pi\varepsilon_0 l} \ln r + C \ .$$

With the boundary condition $\Phi(\mathbf{r})|_{r=r_a} = -\frac{Q}{2\pi\varepsilon_0 l} \ln r_a + C = 0$ segue $\Phi(\mathbf{r}) = \frac{Q}{2\pi\varepsilon_0 l} (\ln r_a - \ln r_i)$. With the boundary condition $\Phi(\mathbf{r})|_{r=r_i} = \frac{Q}{2\pi\varepsilon_0 l}(\ln r_a - \ln r) = U$ segue,

$$\Phi(r) = U \frac{\ln(r_a/r)}{\ln(r_a/r_i)} \ .$$

b. With that we get the field strength on the wire surface,

$$\mathcal{E}(r_i) = \frac{Q}{2\pi\varepsilon_0 l r_i} = \frac{1}{r_i} \frac{U}{\ln \frac{r_a}{r_i}} = 7.2 \cdot 10^4 \, \mathrm{V/cm} \ .$$

c. Avalanches happen at the position R_I,

$$E_I = e\Phi(R_I) - e\Phi(R_I - L) = \frac{eQ}{2\pi\varepsilon_0 l} \ln \frac{R_I - L}{R_I} = eU \frac{\ln \frac{R_I - L}{R_I}}{\ln \frac{r_a}{r_I}} \ .$$

From this,

$$R_I = \frac{L}{1 + \left(\frac{r_a}{r_I}\right)^{E_I/eU}} = 1.5 \, \mathrm{mm} \ .$$

13.2.4.21 Ex: Electrical flow

A thin, non-conductive uniformly charged spherical shell with radius R, has a total positive charge equal to Q. A small piece is removed from the surface.
a. What are the absolute value, the direction and the orientation of the electric field at the center of the void?
b. The piece is placed back into the void. Determine the electrical force exerted on the piece.
c. Using the strength of the force, calculate the electrostatic pressure that tends to expand the sphere.

Solution: *a. The total charge is,*

$$\begin{aligned}\int_{esfer}\rho(\mathbf{r}')dV' &= \int_0^{\pi}\int_0^{2\pi}\int_0^{\infty}\frac{Q}{4\pi R^2}\delta(r'-R)r'^2dr'\sin\theta'd\theta'd\phi' \\ &= 4\pi\int_0^{\infty}\frac{Q}{4\pi R^2}\delta(r'-R)r'^2dr' = Q\ .\end{aligned}$$

The electric field is,

$$\begin{aligned}\vec{\mathcal{E}}(\mathbf{r}) &= \frac{1}{4\pi\varepsilon_0}\int_{sphere}\frac{\mathbf{r}-\mathbf{r}'}{|\mathbf{r}-\mathbf{r}'|^3}\rho(\mathbf{r}')dV' \\ &= \frac{1}{4\pi\varepsilon_0}\int_{d\theta}^{\pi}\int_0^{2\pi}\int_0^{\infty}\frac{\mathbf{r}-\mathbf{r}'}{|\mathbf{r}-\mathbf{r}'|^3}\frac{Q}{4\pi R^2}\delta(r'-R)r'^2dr'\sin\theta'd\theta'd\phi'\ .\end{aligned}$$

At the observation point $\mathbf{r}\equiv R\hat{\mathbf{e}}_z$

$$\vec{\mathcal{E}}(\mathbf{r}) = \frac{1}{4\pi\varepsilon_0}\frac{Q}{4\pi R^2}\int_{d\theta}^{\pi}\int_0^{2\pi}\int_0^{\infty}\frac{R\hat{\mathbf{e}}_z-\mathbf{r}'}{\sqrt{x'^2+y'^2+(R-z')^2}^3}\delta(r'-R)r'^2\sin\theta'd\theta'd\phi'\ ,$$

that is,

$$\begin{aligned}\mathcal{E}_z(R\hat{\mathbf{e}}_z) &= \frac{1}{4\pi\varepsilon_0}\frac{Q}{4\pi R^2}\int_{d\theta}^{\pi}\int_0^{2\pi}\frac{R-R\cos\theta'}{R^3\sqrt{\sin^2\theta'\cos^2\phi'+\sin^2\theta'\sin^2\phi'+(1-\cos\theta')^2}^3}R^2\sin\theta'd\theta'd\phi' \\ &= \frac{1}{4\pi\varepsilon_0}\frac{Q}{4\pi R^2}2\pi\int_{d\theta}^{\pi}\frac{1-\cos\theta'}{\sqrt{\sin^2\theta'+(1-\cos\theta')^2}^3}\sin\theta'd\theta' \\ &= \frac{1}{4\pi\varepsilon_0}\frac{Q}{4\pi R^2}2\pi\int_{d\theta}^{\pi}\frac{\sin\theta'd\theta'}{\sqrt{8}\sqrt{1-\cos\theta'}} = \frac{1}{4\pi\varepsilon_0}\frac{Q}{4\pi R^2}2\pi\left(1-\frac{1}{\sqrt{2}}\sqrt{1-\cos d\theta}\right) \\ &= \frac{1}{4\pi\varepsilon_0}\frac{Q}{2R^2}\left(1-\sin\tfrac{d\theta}{2}\right)\simeq\frac{1}{4\pi\varepsilon_0}\frac{Q}{2R^2}\ .\end{aligned}$$

The force is,

$$\mathbf{F} = Q_{void}\vec{\mathcal{E}} = \frac{\pi a^2Q}{4\pi R^2}E_z\hat{\mathbf{e}}_z = \frac{\pi a^2Q}{4\pi R^2}\frac{1}{4\pi\varepsilon_0}\frac{Q}{2R^2}\hat{\mathbf{e}}_z = \frac{a^2Q^2}{32\pi\varepsilon_0R^4}\hat{\mathbf{e}}_z\ .$$

Alternatively we can subtract the field above the entire sphere $\mathcal{E}_r$ from the field of a disk with radius a at a height h above the disk:

$$\begin{aligned}\mathcal{E}_{sphere} - \mathcal{E}_{disc} &= \frac{1}{4\pi\varepsilon_0}\frac{Q}{R^2} - \frac{\sigma}{2\varepsilon_0}\left(1 - \frac{h}{\sqrt{a^2+h^2}}\right) \\ &= \frac{1}{4\pi\varepsilon_0}\frac{Q}{R^2} - \frac{1}{2\varepsilon_0}\frac{Q}{4\pi R^2}\left(1 - \sin\tfrac{d\theta}{2}\right) \simeq \frac{Q}{8\pi\varepsilon_0 R^2} \ .\end{aligned}$$

Gabarite: *a.* $E = \frac{Q}{8\pi\varepsilon_0 R^2}$, *radially outward. b.* $F = \frac{Q^2 a^2}{32\pi\varepsilon_0 R^4}$, *radially outward. c.* $P = \frac{Q^2}{32\pi^2\varepsilon_0 R^4}$.

13.2.4.22 Ex: Flow through a cone

An imaginary straight circular cone with base angle θ and base radius R is in a charge-free region exposed to a uniform electric field $\vec{\mathcal{E}}$ (the field lines are vertical to the cone axis). What is the ratio between the number of field lines per unit area entering the base and the number of lines per unit area entering the cone's conical surface. Use Gauß's law in your answer.

Solution: *An element of the cone surface is,*

$$dS = \rho d\phi \frac{dz}{\sin\theta} = \left(R - \frac{z}{\tan\theta}\right) d\phi \frac{dz}{\sin\theta} \ .$$

The total surface of the cone is,

$$\begin{aligned}S_{cone} &= \int_0^{2\pi}\int_0^{R\tan\theta}\left(R - \frac{z}{\tan\theta}\right) d\phi\frac{dz}{\sin\theta} = \frac{2\pi}{\sin\theta}\int_0^{R\tan\theta}\left(R - \frac{z}{\tan\theta}\right) dz \\ &= 2\pi\frac{\tan\theta}{\sin\theta}\frac{R^2}{2} = \frac{\pi R^2}{\cos\theta} = \frac{S_{base}}{\cos\theta} \ .\end{aligned}$$

Since the number of field lines crossing S_{base} and S_{cone} is the same, but the areas are different, the number of lines per unit area is $\cos\theta$ times less for S_{cone}.

13.2.4.23 Ex: Flow of a field

Consider the rectangle with the corners,

$$\begin{pmatrix} x_i \\ y_i \\ z_i \end{pmatrix} = \begin{pmatrix} b \\ \frac{a}{\sqrt{2}} \\ 0 \end{pmatrix}, \begin{pmatrix} 0 \\ \frac{a}{\sqrt{2}} \\ 0 \end{pmatrix}, \begin{pmatrix} 0 \\ 0 \\ \frac{a}{\sqrt{2}} \end{pmatrix}, \begin{pmatrix} b \\ 0 \\ \frac{a}{\sqrt{2}} \end{pmatrix}$$

and calculate the flux integral of the field $\mathbf{A}(\mathbf{r})$ through the area $\mathbf{F}$ of the rectangle,

$$\mathbf{A}(\mathbf{r}) = \begin{pmatrix} y^2 \\ 2xy \\ 3z^2 - x^2 \end{pmatrix} \ .$$

Solution: *The solution is,*

$$\int \mathbf{A} \cdot d\mathbf{F} = ab\sqrt{2}\ (\frac{1}{2}a^2 - \frac{1}{3}b^2 + \frac{1}{2\sqrt{2}}ba)$$

.

13.2.4.24 Ex: Flow of a vector field

Calculate the flux of the vector field $\mathbf{A}(\mathbf{r})$ across the surface of a sphere of radius R around the origin of the coordinate system for
a.

$$\mathbf{A}(\mathbf{r}) = 3\frac{\mathbf{r}}{\mathbf{r}^2}\ .$$

b.

$$\mathbf{A}(\mathbf{r}) = \begin{pmatrix} 3z - 2y \\ x + 5z \\ y + x \end{pmatrix}\ .$$

Solution: *We have* $d\mathbf{F} = R^2\ \sin\theta\ d\theta\ d\phi\ \hat{\mathbf{e}}_r$.
a. Hence, $\mathbf{A}(\mathbf{r}) \cdot d\mathbf{F} = 3R\sin\theta d\theta d\phi$ *and therefore,*

$$\int\ \mathbf{A}(\mathbf{r}) \cdot d\mathbf{F} = 12\pi\ R\ .$$

b. Now,

$$\mathbf{A}(\mathbf{r}) = \begin{pmatrix} R(3\cos\theta - 2\sin\theta\sin\phi) \\ R(\sin\theta\cos\phi + 5\cos\theta) \\ R\sin\theta(\sin\phi + \cos\phi) \end{pmatrix}$$

and hence,

$$\mathbf{A}(\mathbf{r}) \cdot d\mathbf{F} = R^3\ (\cos\theta\sin^2\theta(4\cos\phi + 6\sin\phi) - \sin^3\theta\cos\phi\sin\phi)d\theta d\phi\ .$$

Now,

$$\int_0^{2\pi} d\phi \sin\phi = \int_0^{2\pi} d\phi\cos\phi = 0\ ,$$

as well as,

$$\int_0^{2\pi} d\phi \sin\phi\cos\phi = \int_{-1}^{+1} dx\ x = 0\ .$$

Hence follows immediately,

$$\int\ \mathbf{A}(\mathbf{r}) \cdot d\mathbf{F} = 0\ .$$

Alternatively: We immediately see that $\nabla \cdot \mathbf{A} = 0$. *With Gauß' theorem the same result immediately follows.*

13.2.4.25 Ex: Van de Graaff generator

The spherical shell (radius R) of a Van de Graaf generator must be charged until a potential difference of $10^6\,\mathrm{V}$. What should be the minimum diameter of the sphere to avoid lightning discharge?
Help: The field for disruptive discharge in air is $3 \cdot 10^6\,\mathrm{V/m}$.

Solution: *From the Gauß law,*

$$\mathcal{E}_r = \frac{Q}{4\pi\varepsilon_0 r^2} \qquad \textit{and} \qquad \Phi = -\frac{Q}{4\pi\varepsilon_0 r} \ .$$

The potential difference regarding ∞ is,

$$V = \frac{Q}{4\pi\varepsilon_0 R} \ .$$

The electric field on the surface is,

$$R_r = \frac{Q}{4\pi\varepsilon_0 R^2} = \frac{V}{R} \ .$$

from this follows,

$$R = \frac{V}{\mathcal{E}} > \frac{V}{E_{disrp}} = \frac{10^6}{3 \cdot 10^6}\,\mathrm{m} = 33\,\mathrm{cm} \ .$$

13.2.4.26 Ex: Van de Graaff accelerator

Protons are released from rest in a Van de Graaff accelerator system. The protons are initially located at a position where the electrical potential has a value of $5.0\,\mathrm{MV}$, and then, they travel through vacuum to a region where the potential is zero.
a. Determine the final velocity of these electrons.
b. Determine the magnitude of the accelerating electric field if the potential changes uniformly over a distance of $2\,\mathrm{m}$.

Solution: *a.* $3.09 \cdot 10^7\,\mathrm{m/s}$.
b. $2.5\,\mathrm{MV/m}$.

13.2.4.27 Ex: Faraday cage

Show that in a space confined by a grounded surface the electric field must disappear.

Solution: *By the second fundamental law of electrostatics $\nabla \cdot \vec{\mathcal{E}} = \rho/\varepsilon_0$ with $\rho = 0$ and with the field $\vec{\mathcal{E}} = -\nabla\Phi$, follows the Poisson equation,*

$$\Delta\Phi = 0 \ .$$

According to the boundary condition, the surface is at a given potential:

$$\Phi|_{\partial V} = \Phi_0 = const \ .$$

Obviously, $\Phi(\mathbf{r}) \equiv \Phi_0$ *it is a solution. This solution is unequivocal, such that the field is,*

$$\vec{\mathcal{E}} = \nabla \cdot \Phi = 0 \ .$$

13.2.4.28 Ex: Waveguide

The figure shows a portion of the cross section of an infinitely long concentric cable. The inner conductor has a linear charge density of 6 nC/m and the outer conductor has no net charge.
a. Determine the electric field for all values of R, where R is the distance perpendicular to the common axis in the cylindrical system.
b. What are the surface charge densities on the surfaces inside and outside the outer conductor?

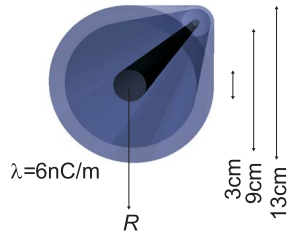

Figure 13.10: Waveguide.

Solution: *a. We imagine an axial cylindrical volume of radius* r *and length* d*. The radial electric field is given by Gauß' law,*

$$\mathcal{E}_R A = \mathcal{E}_R 2\pi d R = \frac{q}{\varepsilon_0} = \frac{\lambda d}{\varepsilon_0} \ .$$

Hence, $E_R = \frac{\lambda}{2\pi\varepsilon_0 R}$*. As the charge goes to the surface of the inner cylinder, we have,*

$$\mathcal{E}_R = 0 \text{ for } R < R_{int} \text{ and } \mathcal{E}_R = \frac{\lambda}{2\pi\varepsilon_0 R} = \frac{1}{R} 107.85\,\mathrm{Nm/C} \text{ for } R_{int} < R < R_{extint}$$

$$\mathcal{E}_R = 0 \text{ for } R_{extint} < R < R_{ext} \text{ and } \mathcal{E}_R = \frac{\lambda_2}{2\pi\varepsilon_0 R} = \frac{1}{R} 107.85\,\mathrm{Nm/C} \text{ for } R < R_{ext} \ .$$

b. With $d\lambda = q = 2\pi r_{int} d\sigma$ *we have,*

$$\sigma_{extint} = \frac{\lambda}{2\pi R_{extint}} = -21.2\,\mathrm{nC/m^2} \text{ and } \sigma_{ext} = \frac{\lambda}{2\pi R_{ext}} = 14.7\,\mathrm{nC/m^2} \ .$$

13.2.4.29 Ex: Fundamental equations of electrostatics

a. Gives the fundamental electrostatic equations in integral and differential form.
b. Gives the fundamental equation in terms of the electrostatic potential.

Solution: *a. In the differential form:*

$$div\ \vec{\mathcal{E}} = \frac{\rho(\mathbf{r})}{\varepsilon_0} \qquad and \qquad rot\ \vec{\mathcal{E}} = 0\ .$$

Using the Gauß', respectively, Stokes theorem we obtain the integral form:

$$\oint_{\partial V} \vec{\mathcal{E}} \cdot d\mathbf{S} = \frac{Q}{\varepsilon_0} \qquad and \qquad \oint_{\partial \mathcal{S}} \vec{\mathcal{E}} \cdot d\mathbf{r} = 0\ .$$

b. For a given charge distribution rho(r) we have:

$$\Phi(\mathbf{r}) = \frac{1}{4\pi\varepsilon_0} \int_V d^3r \frac{\varrho(\mathbf{r}')}{|\mathbf{r} - \mathbf{r}'|}\ .$$

13.3 The scalar electrical potential

We already noted that the electric field generates a force that can accelerate a charge Q along a field line. Therefore, the electric field contains a potential energy which it can convert into kinetic energy by exerting work, $W = \int \mathbf{F} \cdot \mathbf{r} = Q \int \vec{\mathcal{E}} \cdot \mathbf{r}$. The quantity [2],

$$\boxed{\Phi_{\mathbf{a},\mathbf{b}} \equiv \int_{\mathcal{C}_{\mathbf{a},\mathbf{b}}} \vec{\mathcal{E}} \cdot d\mathbf{r}} \tag{13.21}$$

is called the difference of *electric potential* between the points $\mathbf{a}$ and $\mathbf{b}$ connected by a path $\mathcal{C}_{\mathbf{a},\mathbf{b}}$.

Stokes' law (13.18) allows us to state, that the potential difference (13.21) does not depend on the path chosen, because for two different paths $\mathcal{C}$ and $\mathcal{C}'$ between the points $\mathbf{a}$ and $\mathbf{b}$ we have,

$$\int_{\mathcal{C}(\mathbf{a},\mathbf{b})} \vec{\mathcal{E}} \cdot d\mathbf{r} - \int_{\mathcal{C}'(\mathbf{a},\mathbf{b})} \vec{\mathcal{E}} \cdot d\mathbf{r} = 0\ . \tag{13.22}$$

Consequently, the potential defined between a reference point $\mathcal{O}$ and any observation point $\mathbf{r}$ is unambiguous,

$$\Phi(\mathbf{r}) = -\int_{\mathcal{O}}^{\mathbf{r}} \vec{\mathcal{E}} \cdot d\mathbf{r}\ , \tag{13.23}$$

and the potential difference between two points $\mathbf{a}$ and $\mathbf{b}$ is well defined,

$$\Phi(\mathbf{b}) - \Phi(\mathbf{a}) = -\int_{\mathbf{a}}^{\mathbf{b}} \vec{\mathcal{E}} \cdot d\mathbf{r}\ . \tag{13.24}$$

[2] We note that the electric potential is linked to potential energy, but is not the same.

The fundamental theorem for gradients, on the other hand, says that,

$$\Phi(\mathbf{b}) - \Phi(\mathbf{a}) = \int_{\mathbf{a}}^{\mathbf{b}} (\nabla\Phi) \cdot d\mathbf{r} \ . \tag{13.25}$$

These results being valid for any choice of points $\mathbf{a}$ and $\mathbf{b}$, we conclude by comparing these two equations,

$$\boxed{\vec{\mathcal{E}} = -\nabla\Phi} \ . \tag{13.26}$$

Example 46 (*Potential of a point charge*): For an electric field generated by an electric charge e located at the origin we can easily calculate the integral along a path $\mathcal{C}$ between two points a and b using Coulomb's law:

$$\begin{aligned}\int_{\mathcal{C}} \vec{\mathcal{E}} \cdot d\mathbf{r} &= \int_{\mathbf{a}}^{\mathbf{b}} \frac{1}{4\pi\varepsilon_0} \frac{e}{|\mathbf{r}|^2} \hat{\mathbf{e}}_{\mathbf{r}} \cdot (\hat{\mathbf{e}}_{\mathbf{r}} dr + \hat{\mathbf{e}}_\theta r d\theta + \hat{\mathbf{e}}_\phi r \sin\theta d\phi) \\ &= \frac{1}{4\pi\varepsilon_0} \int_{\mathbf{a}}^{\mathbf{b}} \frac{e}{r^2} dr = \frac{1}{4\pi\varepsilon_0} \left(\frac{e}{r_a} - \frac{e}{r_b} \right) \ .\end{aligned}$$

With the superposition principle we can generalize this result for distributions of arbitrary charges Q.

Some comments are appropriate at this point:

- The formulation by the potential (a scalar field) instead of the vector electric field is more compact. It summarized the Coulomb (13.8) law along with the constraint (13.19).
- The reference point $\mathcal{O}$ is arbitrary. Exchanging this reference point by another $\mathcal{O}'$ only adds a global constant to the potential,

$$\Phi'(\mathbf{r}) = -\int_{\mathcal{O}'}^{\mathbf{r}} \vec{\mathcal{E}} \cdot d\mathbf{r} = -\int_{\mathcal{O}'}^{\mathcal{O}} \vec{\mathcal{E}} \cdot d\mathbf{r} - \int_{\mathcal{O}}^{\mathbf{r}} \vec{\mathcal{E}} \cdot d\mathbf{r} = K + \Phi(\mathbf{r}) \ , \tag{13.27}$$

  but does not affect neither the difference of two potentials,

$$\Phi'(\mathbf{b}) - \Phi'(\mathbf{a}) = \Phi(\mathbf{b}) - \Phi(\mathbf{a}) \ , \tag{13.28}$$

  nor the electric field,

$$\nabla\Phi' = \nabla\Phi \ . \tag{13.29}$$

  We conclude that the potential is not a real quantity, but a mathematical trick to simplify our life [3]. Generally, the reference point is placed at infinity, $\mathcal{O} = \infty$, fixing the free choice of the global constant by,

$$\Phi(\infty) \equiv 0 \ . \tag{13.30}$$

- In the same way as the electric field, the electric potential also obeys the superposition principle.

[3] We shall see later that this conclusion must be reviewed in quantum mechanics in the context of the Aharonov-Bohm effect.

13.3.1 The equations of Laplace and Poisson

We already learned the two equations defining the electrostatic field (13.19) and (13.16), that is, $\nabla \times \vec{\mathcal{E}} = 0$ and $\nabla \cdot \vec{\mathcal{E}} = \varrho/\varepsilon_0$. Let us now rewrite these equations for the electric potential,

$$\nabla \times (\nabla \Phi) = 0 \quad , \quad \nabla \cdot \nabla \Phi = \Delta \Phi = -\varrho/\varepsilon_0 \ . \tag{13.31}$$

Thus, the formulation by the potential (13.21) automatically satisfies the requirement (13.22), that the rotation must disappear.

On the other side, we have a second-order differential equation called the *Poisson equation*. In regions with no charge, this equation turns into a *Laplace equation*,

$$\Delta \Phi = 0 \ . \tag{13.32}$$

13.3.2 Potential generated by localized charge distributions

The Poisson equation allows us to reconstruct a charge distribution once its potential is known. However, we usually want to do the opposite. Let us start with a point charge, located at the origin, the potential of which is,

$$\Phi(\mathbf{r}) = -\int \vec{\mathcal{E}} \cdot d\mathbf{r}' = \frac{-1}{4\pi\varepsilon_0} \int \frac{Q}{r'^2} dr' = \frac{1}{4\pi\varepsilon_0} \frac{Q}{r'} \Big|_{\infty}^{\mathbf{r}} = \frac{1}{4\pi\varepsilon_0} \frac{Q}{r} \ . \tag{13.33}$$

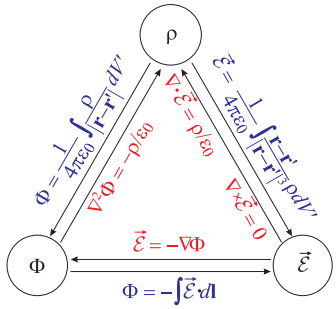

Figure 13.11: The fundamental laws of electrostatics relate the three fundamental quantities, the charge distribution ϱ, the electric field $\vec{\mathcal{E}}$, and the electric potential Φ.

According to the superposition principle, for a discrete distribution of charges Q_k located at the positions $\mathbf{r}_k$,

$$\Phi(\mathbf{r}) = \frac{1}{4\pi\varepsilon_0} \sum_k \frac{Q_k}{|\mathbf{r} - \mathbf{r}_k|} \ . \tag{13.34}$$

Finally, for a continuous distribution $\varrho(\mathbf{r}')$, we obtain the fundamental solution of the electrostatic problem,

$$\boxed{\Phi(\mathbf{r}) = \frac{1}{4\pi\varepsilon_0} \int \frac{dQ'}{|\mathbf{r} - \mathbf{r}'|} = \frac{1}{4\pi\varepsilon_0} \int \frac{\varrho(\mathbf{r}')}{|\mathbf{r} - \mathbf{r}'|} d^3r'} \ . \tag{13.35}$$

From this equation we can derive the Coulomb law (13.8).

Low-dimensional distributions can be treated by suitable parametrization, as in the examples (13.9) and (13.10).

13.3.3 Electrostatic boundary conditions

We have already noticed that the electric field always suffers a discontinuity when passing through a surface charge distribution. To study this, we consider a charged interface traversed by an external electric field $\vec{\mathcal{E}}_{ext}$. Now, we make two thought experiments: (1) We envision a rectangular pill box enclosing a small part of the interface, as shown in Fig. 13.12. The height ϵ of the box is so small that the flux through the sides of the box can be neglected. With this,

$$\oint \vec{\mathcal{E}} \cdot d\mathbf{S} = \tfrac{1}{\varepsilon_0} Q = \tfrac{1}{\varepsilon_0} \sigma S \ , \tag{13.36}$$

where $\vec{\mathcal{E}}$ is the total electric field (that is, the sum of the field generated by the surface charge and field $\vec{\mathcal{E}}_{ext}$). A is the surface of the box. This gives,

$$\mathcal{E}^{\perp}_{top} - \mathcal{E}^{\perp}_{bottom} = \tfrac{1}{\varepsilon_0} \sigma \ . \tag{13.37}$$

(2) We imagine a rectangular surface perpendicular to the interface and cutting through the interface. As shown in Fig. 13.12, the height ϵ of the surface is so small that the potential difference along the vertical branches can be neglected. With this,

$$\oint \vec{\mathcal{E}} \cdot d\mathbf{l} = \int \vec{\mathcal{E}}_{top} \cdot d\mathbf{l} + \int \vec{\mathcal{E}}_{bottom} \cdot d\mathbf{l} = (\vec{\mathcal{E}}_{top} - \vec{\mathcal{E}}_{bottom}) \cdot \mathbf{l} = 0 \ , \tag{13.38}$$

where l is the length of the surface. This gives,

$$\vec{\mathcal{E}}^{\parallel}_{top} = \vec{\mathcal{E}}^{\parallel}_{bottom} \ . \tag{13.39}$$

That is, when traversing a charged interface, only the part of the electric field which is perpendicular to the interface suffers a discontinuity. This simply reflects the fact that the charge generates its own electric field, which is perpendicular to the interface and superposes to the external field.

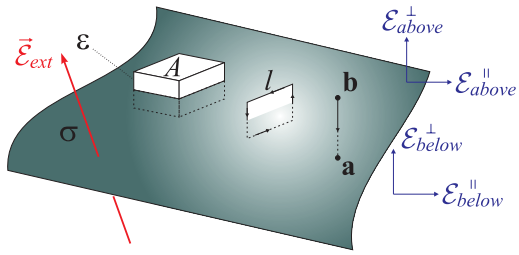

Figure 13.12: Surface S around a box-shaped volume enclosing a small part of the interface, path l around a small area cutting through the interface, and potential difference between two points **a** and **b**.

The potential, on the other hand, is continuous, since the integral between a point **a** above the interface and a point **b** below is,

$$\int_{\mathbf{b}}^{\mathbf{a}} \vec{\mathcal{E}} \cdot d\mathbf{l} = \Phi(\mathbf{b}) - \Phi(\mathbf{a}) \overset{\mathbf{a}\to\mathbf{b}}{\longrightarrow} 0 \ . \tag{13.40}$$

We study the electrostatic boundary conditions in Exc. 13.3.4.18.

13.3.4 Exercises

13.3.4.1 Ex: Earnshaw theorem

Show that the electrostatic potential in free space does not exhibit a maximum. **Comment:** This is why it is not possible to confine charged particles in electrostatic fields.

Solution: *For a charged particle to remain in a stable equilibrium, the force acting on the particle must be repulsive in every direction of space, that is, all field lines must be directed towards the equilibrium point. This is only possible when the divergence of this field is less than zero, that is, this point acts as a sink. However, this is prohibited in free space (that is, inthe absence of charges) by Gauß's law:*

$$\nabla \cdot \mathbf{F} = \nabla \cdot (\nabla \Phi) = \Delta \Phi = 0 \ .$$

An electrostatic force that can be derived from a potential $\Phi(\mathbf{r})$ is always non-divergent, that is, it has neither minimums nor maximums but, at best, saddle points.

13.3.4.2 Ex: Electrical potential between point charges

A point particle with a charge equal to $+2\,\mu$C is fixed at the origin.
a. hat is the electrical potential V at a point 4 m from the origin, considering that $V = 0$ at infinity?
b. How much work must be done to bring a second point charge with a charge of $+3\,\mu$C from infinity to a distance of 4.0 m from the first charge?

Solution: *a.* 4.49 kV
b. 13.5 J

13.3.4.3 Ex: Electrical potential between point charges

Three identical point particles with charge q are located at the corners of an equilateral triangle that is circumscribed in a circle of radius a contained in the plane $z = 0$ and centered at the origin. The values of q and a are $+3.0\,\mu$C and 60 cm, respectively. (Consider that, far from all charges, the potential is zero.)
a. What is the electrical potential at the origin?
b. What is the electrical potential at the point of the z-axis being at $z = a$?
c. How would your responses to the parts (a) and (b) change if the charges q were larger? Explain your answer.

Solution: *a.* 135 kV.
b. 95.3 kV.
c. Since the two field points are equidistant from all points in the circle, the responses to the parts (a) and (b) do not change.

13.3.4.4 Ex: Electrical potential between point charges

Two identical positively charged point particles are fixed to the x-axis at $x = +a$ and $x = -a$.
a. Write down an expression for the electrical potential $V(x)$ as a function of x for all points on the x-axis.
b. Draw $V(x)$ versus x for all points on the x-axis.

Solution: *a.* $V(x) = \frac{1}{4\pi\varepsilon_0}\left(\frac{1}{|x-a|} + \frac{1}{|x+a|}\right)$.

13.3.4.5 Ex: Electrical potential between point charges

The electric field on the x-axis due to a fixed point charge at the origin is given by $\vec{\mathcal{E}} = (b/x^2)\hat{\mathbf{e}}_x$, where $b = 6.0\,\text{kV}\cdot\text{m}$ and $x \neq 0$.
a. Determine the amplitude and sign of the point charge.
b. Determine the potential difference between the points on the x-axis at $x = 1\,\text{m}$ and $x = 2\,\text{m}$. Which of these points is at a higher potential?

Solution: *a.* +668 nC.
b. 3.0 kV. *The point at* $x = 2\,\text{m}$ *is at the highest potential.*

13.3.4.6 Ex: Dielectric disruption of air

Determine the maximum surface charge density σ_{max} that can exist on the surface of any conductor before dielectric discharge in the air occurs.

Solution: $\approx 3 \cdot 10^{-5}\,\text{C/m}^2$.

13.3.4.7 Ex: Potential energy of a charged sphere

a. How much charge is on the surface of an isolated spherical conductor that has a radius of $R = 10.0\,\text{cm}$ and is charged with 2.0 kV?
b. What is the electrostatic potential energy of this conductor? (Consider that the potential is zero far from the sphere.)

Solution: *a.* 22.3 nC,
b. 22.3 μJ.

13.3.4.8 Ex: Energy of a particle in a potential

Four point charges are attached to the vertices of a square centered on the origin. The length of each side of the square is $2a$. The charges are located as follows: $+q$ is in $(-a, +a)$, $+2q$ is in $(+a, +a)$, $-3q$ is in $(+a, -a)$, and $+6q$ is in $(-a, -a)$. A fifth particle with mass m and charge $+q$ is placed at the origin and released from rest. Determine its velocity when it is far from the origin.

Solution: $v = q\sqrt{\frac{6\sqrt{2k}}{ma}} = 2.91q\sqrt{\frac{k}{ma}}$.

13.3.4.9 Ex: Energy of a particle in a potential

Two metallic spheres have radii of 10 cm each. The centers of the two spheres are separated by 50 cm. The spheres are initially neutral, but a charge Q is transferred from one sphere to another, creating a potential difference between them of 100 V. A proton is released from rest at the surface of the positively charged sphere and travels to the negatively charged sphere.
a. What is the kinetic energy once it reaches the negatively charged sphere?
b. At what velocity does it collide with the sphere?

Solution: *a. As the potential difference ΔV is known, it is sufficient to calculate,*

$$U = e\Delta V = 100\,\text{eV} \ .$$

b. With the mass of the proton $m_p = 1.672{\cdot}10^{-27}\,\text{kg}$ and the kinetic energy $U = \frac{m_p}{2}v^2$, we calculate,

$$v = \sqrt{\frac{2U}{m_p}} = 1.38 \cdot 10^5\,\text{m/s} \ .$$

13.3.4.10 Ex: Potential of connected spheres

A spherical conductor of radius R_1 is charged with $V_i = 20\,\text{kV}$. When it is connected through a very thin and long conductive wire to a second very distant spherical conductor, its potential drops to $V_f = 12\,\text{kV}$. What is the radius of the second sphere?

Solution: *We have*

$$V_i = \frac{1}{4\pi\varepsilon_0}\frac{Q}{R_1} \quad , \quad V_f = \frac{1}{4\pi\varepsilon_0}\frac{Q_1}{R_1} = \frac{1}{4\pi\varepsilon_0}\frac{Q_2}{R_2} \quad , \quad Q_1 + Q_2 = Q \ .$$

Solving

$$R_2 = R_1\frac{Q_2}{Q_1} = R_1\frac{Q - Q_1}{Q_1} = R_1\frac{V_i - V_f}{V_f} = R_1\frac{2}{3} \ .$$

13.3.4.11 Ex: Potential of a charged disk

Along the central axis of a uniformly loaded disc, at a point 0.6 m away from the center of the disc, the potential is 80 V and the field intensity is 80 V/m. At a distance of 1.5 m, the potential is 40 V and the electric field strength is 23.5 V/m. (Consider that the potential is very far from the disk). Determine the total charge of the disk.

Solution: 7.1 nC.

13.3.4.12 Ex: Potential of spherical shells

Two conductive concentric spherical shells have equal charges with opposite signs. The inner shell has an external radius a and the charge $+q$; the outer shell has an internal radius b and the charge $-q$. Determine the potential difference $V_a - V_b$ between the shells.

Solution: $V_a - V_b = \frac{q}{4\pi\varepsilon_0}\left(\frac{1}{a} - \frac{1}{b}\right)$.

13.3.4.13 Ex: Electrical potential of a disk

A disk of radius R has a surface charge distribution given by $\sigma = \sigma_0 r^2/R^2$, where σ_0 is a constant and R is the distance from the center of the disk.
a. Determine the total charge on the disk.
b. Find the expression for the electrical potential at a distance z from the center of the disk along the axis that passes through the center of the disk and is perpendicular to its plane.

Solution: *a.* $Q = \frac{1}{2}\pi\sigma_0 R^2$,
b. $V = \frac{\sigma_0}{6\varepsilon_0 R^2}[(R^2 - 2z^2)\sqrt{z^2 + R^2} + 2z^3]$.

13.3.4.14 Ex: Electrical potential of a rod

A stick of length L has a total charge Q evenly distributed along its length. The stick is placed along the x-axis with its center at the origin.
a. What is the electrical potential as a function of the position along the x-axis for $x > L/2$?
b. Show that for $x \gg L/2$, your result reduces to that due to a point charge Q.

Solution: *a.* $V(x) = \frac{Q}{4\pi\varepsilon_0 L}\ln\frac{x+L/2}{x-L/2}$.

13.3.4.15 Ex: Potential of a thin disk

Calculate the electrical potential of a thin disc homogeneously charged with the charge Q along the symmetry axis.

Solution: *The potential that a charge distribution $\varrho(\mathbf{r}')$ exerts on a test charge q located at the position $\mathbf{r}$ is,*

$$\begin{aligned} V(\mathbf{r}) &= -\int_{disc} \frac{1}{4\pi\varepsilon_0}\rho(\mathbf{r}')\frac{q}{|\mathbf{r}-\mathbf{r}'|}d^3r' \\ &= -\frac{q}{4\pi\varepsilon_0}\int_{-a}^{a}\int_0^R\int_0^{2\pi}\rho(z')\frac{1}{\sqrt{(r-r')^2+(z-z')^2}}r'dr'dz'd\phi' \ . \end{aligned}$$

Now let $\mathbf{r} = z\hat{\mathbf{e}}_z$.

$$\begin{aligned} V(z) &= -2\pi\frac{q}{4\pi\varepsilon_0}\int_{-a}^{a}\int_0^R\rho(z')\frac{1}{\sqrt{r'^2+(z-z')^2}}r'dr'dz' \\ &= -2\pi\frac{q}{4\pi\varepsilon_0}\int_{-a}^{a}\rho(z')(\sqrt{R^2+(z-z')^2}-(z-z'))dz' \ . \end{aligned}$$

for a thin disc $\rho(z) \simeq \rho_0\Delta a\delta(z)$

$$\begin{aligned} V(z) &= -2\pi\frac{q}{4\pi\varepsilon_0}\int_{-a}^{a}\rho_0(\sqrt{R^2+(z-z')^2}-(z-z'))\delta(z)\Delta a dz' \\ &= \frac{-q\rho_0}{2\varepsilon_0}[\sqrt{R^2+z^2}-z]\Delta a \ . \end{aligned}$$

The forçe is,

$$F = -\frac{d}{dz}V(z) = 2\pi\frac{q}{4\pi\varepsilon_0}\rho_0\Delta a\left(\frac{z}{\sqrt{R^2+z^2}}-1\right) \ .$$

13.3.4.16 Ex: Electrical potential of four wires

Consider four wires oriented parallel to the z-direction, as shown in the figure. The wires are charged with the charge per unit length q/L.
a. Calculate the electrical potential as a function of x and y.
b. Expand the potential around $x = 0$ and $y = 0$ ($|x|, |y| \ll a$) up to second order. What is the shape of the potential at this point?

Solution: *a. The electrostatic potential is given by* $\Phi(\mathbf{r}) = \frac{1}{4\pi\varepsilon_0}\int\frac{\rho(\mathbf{r}')}{|\mathbf{r}-\mathbf{r}'|}d^3r'$ *with the distribution of* $\rho(\mathbf{r}') = -q\delta(x'-a)\delta(y') + q\delta(x')\delta(y'-a) - q\delta(x'+a)\delta(y') +$

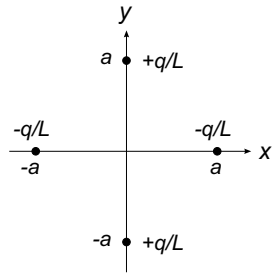

Figure 13.13: Four wires.

$q\delta(x')\delta(y'+a)$. With that, the integral becomes,

$$\begin{aligned}\Phi(\mathbf{r}) &= \frac{q}{4\pi\varepsilon_0}\int\left[\frac{-1}{\sqrt{(x-a)^2+y^2+(z-z')^2}}+\frac{1}{\sqrt{x^2+(y-a)^2+(z-z')^2}}\right.\\ &\left.+\frac{-1}{\sqrt{(x+a)^2+y^2+(z-z')^2}}+\frac{1}{\sqrt{x^2+(y+a)^2+(z-z')^2}}\right]dz'\\ &= \frac{q}{4\pi\varepsilon_0}\ln\frac{\left(z'-z+\sqrt{x^2+(y-a)^2+(z-z')^2}\right)\left(z'-z+\sqrt{x^2+(y+a)^2+(z-z')^2}\right)}{\left(z'-z+\sqrt{(x-a)^2+y^2+(z-z')^2}\right)\left(z'-z+\sqrt{(x+a)^2+y^2+(z-z')^2}\right)}\Bigg|_{-\infty}^{\infty}\\ &= \frac{q}{8\pi\varepsilon_0}\ln\frac{[x^2+(y-a)^2][x^2+(y+a)^2]}{[(x-a)^2+y^2][(x+a)^2+y^2]}\ .\end{aligned}$$

And now??? Alternative solution:
a. We first consider a conductor. The flux through the cylindrical cap with radius r around the wire follows from the Gauß law, $\int_{\partial V}\vec{\mathcal{E}}\cdot\vec{n}d\vec{f}=\frac{1}{\varepsilon_0}\int_V\rho dV$ hence $\mathcal{E}l2\pi r=\frac{1}{\varepsilon_0}Q$, with Q the charge on apiece of wire of length l . With the definition of linear charge density $q=Q/l$ follows: $\mathcal{E}=\frac{2q}{4\pi\varepsilon_0 r}$. For the potential ϕ ($\vec{\mathcal{E}}=-\vec{\nabla}\phi$) we integrate the field and obtain: $\phi=-\frac{2q}{4\pi\varepsilon_0}\ln r$. With four conductors we add the potentials:

$$\begin{aligned}\Phi(\mathbf{r}) &= -\frac{2q}{4\pi\varepsilon_0}\left[-\ln\sqrt{(x-a)^2+y^2}+\ln\sqrt{x^2+(y-a)^2}-\ln\sqrt{(x+a)^2+y^2}+\ln\sqrt{x^2+(y+a)^2}\right]\\ &= \frac{q}{4\pi\varepsilon_0}\ln\frac{[x^2+(y-a)^2][x^2+(y+a)^2]}{[(x-a)^2+y^2][(x+a)^2+y^2]}\ .\end{aligned}$$

b. The expansion up to second order is formally, $\phi(\mathbf{r})=\phi(\mathbf{0})+(\mathbf{r}\nabla)\phi(\mathbf{0})+\frac{1}{2!}(\mathbf{r}\nabla)^2\phi(\mathbf{0})+$ .... We easily get the zero order,

$$\Phi(\mathbf{0})=\frac{q}{4\pi\varepsilon_0}\ln\frac{a^2a^2}{a^2a^2}=0\ .$$

Auxiliary calculation for the first order,

$$\left(x\frac{d}{dx'}+y\frac{d}{dy'}\right)\ln\left[(x'-a)^2+(y'-b)^2\right]=\frac{2x(x'-a)+2y(y'-b)}{(x'-a)^2+(y'-b)^2}\xrightarrow{x',y'=0}\frac{-2ax-2by}{a^2+b^2}$$

With that we get for the first order,

$$(\mathbf{r}\cdot\nabla)\Phi(\mathbf{0}) = \frac{q}{4\pi\varepsilon_0}\left[\frac{-2ay}{a^2}+\frac{2ay}{a^2}-\frac{-2ax}{a^2}-\frac{2ax}{a^2}\right] = 0\ .$$

Auxiliary calculation for the second order,

$$\left(x^2\frac{d^2}{dx''}+2xy\frac{d^2}{dx'dy'}+y^2\frac{d^2}{dy''}\right)\ln[(x'-a)^2+(y'-b)^2]$$
$$= -2x^2\frac{(x'-a)^2-(y'-b)^2}{[(x'-a)^2+(y'-b)^2]^2}-8xy\frac{(x'-a)(y'-b)}{[(x'-a)^2+(y'-b)^2]^2}-2y^2\frac{-(x'-a)^2+(y'-b)^2}{[(x'-a)^2+(y'-b)^2]^2}$$
$$\xrightarrow{x',y'=0}\frac{-2(x^2-y^2)(a^2-b^2)-8xyab}{(a^2+b^2)^2}\ .$$

With that we get for the second order,

$$\frac{1}{2!}(\mathbf{r}\cdot\nabla)^2\phi(\mathbf{0}) = \frac{q}{8\pi\varepsilon_0}\left[\frac{2(x^2-y^2)a^2}{a^4}+\frac{2(x^2-y^2)a^2}{a^4}-\frac{-2(x^2-y^2)a^2}{a^4}-\frac{-2(x^2-y^2)a^2}{a^4}\right]$$
$$= \frac{q}{\pi\varepsilon_0 a^2}(x^2-y^2)\ .$$

Therefore, we obtain a saddle potential.

13.3.4.17 Ex: Stokes law

Consider a thin straight wire of infinite length uniformly charged with linear charge density λ.
a. Parametrize the linear load density using the δ-function.
b. Using Gauss' law, calculate the electric field.
c. Calculate the path integral $\int\vec{\mathcal{E}}\cdot d\mathbf{s}$ for the path parametrized by $\mathbf{s}(t)=\rho(\hat{\mathbf{e}}_x\cos t+\hat{\mathbf{e}}_y\sin t)$ with $t\in[0,2\pi]$.
d. From the electric field obtained in (b) calculate $\nabla\times\vec{\mathcal{E}}$ in Cartesian or cylindrical coordinates.
Help: $\nabla\times\mathbf{S}=\hat{\mathbf{e}}_\rho\ \frac{1}{\rho}\left[\frac{\partial S_z}{\partial\phi}-\rho\frac{\partial S_\phi}{\partial z}\right]+\hat{\mathbf{e}}_\phi\ \left[\frac{\partial S_\rho}{\partial z}-\frac{\partial S_z}{\partial\rho}\right]+\hat{\mathbf{e}}_z\ \frac{1}{\rho}\left[\frac{\partial}{\partial\rho}(\rho S_\phi)-\frac{\partial S_\rho}{\partial\phi}\right]$.

Solution: *a. The linear charge density is,*

$$\varrho(\mathbf{r}) = \lambda\delta(x)\delta(y)\ .$$

b. Gauss' law requires,

$$2\pi\mathcal{E}_\rho\rho\int_{-\infty}^{\infty}dz = \int_0^{2\pi}\int_{-\infty}^{\infty}E_\rho\rho d\phi dz = \oint\vec{\mathcal{E}}\cdot d\mathbf{S} = \int_{\mathbb{R}}\nabla\cdot\vec{\mathcal{E}}dV = \frac{1}{\varepsilon_0}\int\varrho(\mathbf{r})dV$$
$$= \frac{1}{\varepsilon_0}\int_{-\infty}^{\infty}\delta\lambda(x)\delta(y)dV = \frac{1}{\varepsilon_0}\lambda\int_{-\infty}^{\infty}dz\ .$$

Therefore, the electric field is,

$$\vec{\mathcal{E}}_\rho = \frac{\lambda}{2\pi\varepsilon_0\rho}\hat{\mathbf{e}}_\rho = \frac{\lambda}{2\pi\varepsilon_0}\frac{\hat{\mathbf{e}}_x\cos\phi+\hat{\mathbf{e}}_y\sin\phi}{\sqrt{x^2+y^2}}\ .$$

c. The integral yields,

$$\oint \vec{\mathcal{E}} \cdot d\mathbf{s} = \int_0^{2\pi} \frac{\lambda}{2\pi\varepsilon_0\rho} \hat{\mathbf{e}}_\rho \cdot \rho \hat{\mathbf{e}}_\phi d\phi = 0 \ .$$

d. Thus, satisfying Maxwell's law, we obtain in Cartesian coordinates,

$$\nabla \times \vec{\mathcal{E}} = \begin{pmatrix} \partial_y \mathcal{E}_z - \partial_z \mathcal{E}_y \\ \partial_z \mathcal{E}_x - \partial_x \mathcal{E}_z \\ \partial_x \mathcal{E}_y - \partial_y \mathcal{E}_x \end{pmatrix} = \frac{\lambda}{2\pi\varepsilon_0} \begin{pmatrix} 0 \\ 0 \\ \frac{\partial}{\partial x} \frac{\sin\phi}{\sqrt{x^2+y^2}} - \frac{\partial}{\partial y} \frac{\cos\phi}{\sqrt{x^2+y^2}} \end{pmatrix}$$

$$= \frac{\lambda}{2\pi\varepsilon_0} \begin{pmatrix} 0 \\ 0 \\ -\frac{x\sin\phi}{(x^2+y^2)^{\frac{3}{2}}} + \frac{y\cos\phi}{(x^2+y^2)^{\frac{3}{2}}} \end{pmatrix} = \frac{\lambda}{2\pi\varepsilon_0} \begin{pmatrix} 0 \\ 0 \\ -\frac{xy\sin\phi}{\rho^4} + \frac{yx\cos\phi}{\rho^4} \end{pmatrix} = 0 \ .$$

Alternatively, we calculate in spherical coordinates,

$$\nabla \times \vec{\mathcal{E}} = \hat{\mathbf{e}}_\rho \ \frac{1}{\rho} \left[\frac{\partial \mathcal{E}_z}{\partial \phi} - \rho \frac{\partial \mathcal{E}_\phi}{\partial z} \right] = 0 \ .$$

13.3.4.18 Ex: Surface of a conductor

Consider an arbitrary macroscopic conductor whose surface is closed and smooth. Starting from Gauss's law and the electrostatic rotation of the electric field:
a. calculate the electric field inside the conductor;
b. obtain the normal component of the electric field on the outer surface of the conductor in terms of the surface charge density;
c. obtain the tangential component of the electric field on the outer surface of the conductor.

Solution: *a. The electrical charges in the conductor will repel mutually and go to its surface. Tracing a Gaussian surface just below the conductor's surface we see that, in electrostatic equilibrium, there are no charges inside the conductor, such that,*

$$\nabla \cdot \vec{\mathcal{E}} = \rho/\varepsilon_0 = 0 \implies \int_V (\nabla \cdot \vec{\mathcal{E}}) dV = \int_S (\vec{\mathcal{E}} \cdot \hat{n}) dA = \mathcal{E} A \implies \vec{\mathcal{E}} = 0$$

inside the conductor.
b. Consider a Gaussian surface in the shape of a cylinder of infinitesimal height with the top face being outside and the bottom face inside the surface:

$$\nabla \cdot \vec{\mathcal{E}} = \rho/\varepsilon_0 \implies \int_V (\nabla \cdot \vec{\mathcal{E}}) dV = \int_V (\rho/\varepsilon_0) dV \implies \int_S (\vec{\mathcal{E}} \cdot \hat{n}) dA = \int_S (\sigma/\varepsilon_0) dA \implies \vec{\mathcal{E}} \cdot \hat{n} = \sigma/\varepsilon_0 \ ,$$

which is the normal component of the electric field in the vicinity of the surface.
c. Consider a closed, rectangular path γ with infinitesimal height h with one of the

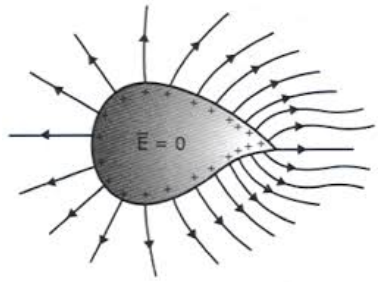

Figure 13.14: Surface of a conductor.

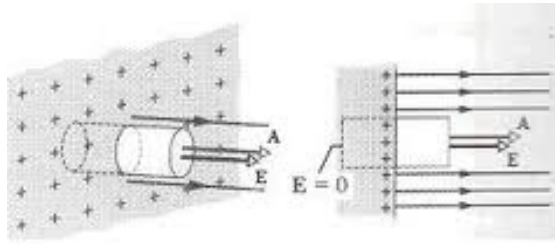

Figure 13.15: Surface of a conductor.

longer path sections L outside and the other inside the surface:

$$\nabla\times\vec{\mathcal{E}}=0 \implies \int_S(\nabla\times\vec{\mathcal{E}})\cdot(\hat{t}\times\hat{n})dA=\oint_\gamma \vec{\mathcal{E}}\cdot d\vec{l}=0 \implies \mathcal{E}_t L+\mathcal{E}_n h-0L-\mathcal{E}_n h=0 \implies \mathcal{E}_t=0\,,$$

which is the tangential component of the electric field in the vicinity of the surface.

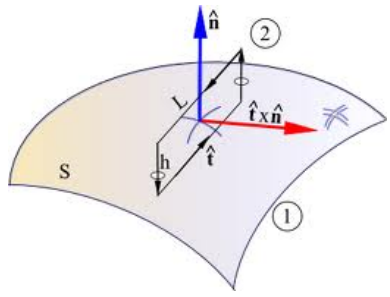

Figure 13.16: Surface of a conductor.

13.4 Electrostatic energy

We calculate the work required to move a test charge q between two points $\mathbf{a}$ and $\mathbf{b}$ within the potential created by a charge distribution,

$$W = -\int_{\mathbf{a}}^{\mathbf{b}} \mathbf{F} \cdot d\mathbf{r} = -q \int_{\mathbf{a}}^{\mathbf{b}} \vec{\mathcal{E}} \cdot d\mathbf{r} = q[\Phi(\mathbf{b}) - \Phi(\mathbf{a})] \ . \tag{13.41}$$

Since the work does not depend on the path, we call the potential *conservative*. Taking the test charge from the reference point to infinity,

$$W = q[\Phi(\mathbf{b}) - \Phi(\infty)] = q\Phi(\mathbf{b}) \ . \tag{13.42}$$

In this sense, the potential is nothing more than the energy per unit of charge q required to take a particle from infinity to a point $\mathbf{r}$.

13.4.1 Energy of a charge distribution

The next question is, what energy is needed to put together a distribution of charges taking them one by one from infinity to predefined points. Every charge Q_k uses an amount of work W_k, only the first charge does not, $W_1 = 0$. Using the abbreviation,

$$W_{k,m} \equiv \frac{1}{4\pi\varepsilon_0} \frac{Q_k Q_m}{|\mathbf{r}_k - \mathbf{r}_m|} \ , \tag{13.43}$$

the work is easily calculated for the second charge, $W_2 = W_{1,2}$. For the third and fourth charge we need *additionally* the amounts of work,

$$W_3 = W_{1,3} + W_{2,3} \qquad \text{and} \qquad W_4 = W_{1,4} + W_{2,4} + W_{3,4} \ . \tag{13.44}$$

The general rule is obvious: For N charges we need in *total* to provide the work,

$$W = \sum_{k=1}^{N} W_k = \sum_{k=1}^{N} \sum_{\substack{m=1 \\ m<k}}^{N} W_{k,m} = \frac{1}{2} \sum_{k=1}^{N} \sum_{\substack{m=1 \\ m\neq k}}^{N} W_{k,m} \ . \tag{13.45}$$

Explicitly, calling Φ the potential created by all charges minus the charge Q_k,

$$\Phi(\mathbf{r}_k) \equiv \sum_{\substack{m=1 \\ m\neq k}}^{N} \frac{1}{4\pi\varepsilon_0} \frac{Q_m}{|\mathbf{r}_k - \mathbf{r}_m|} \ , \tag{13.46}$$

we can write the energy as,

$$W = \tfrac{1}{2} \sum_k Q_k \Phi(\mathbf{r}_k) \ . \tag{13.47}$$

For continuous distributions, this equation turns into,

$$W = \tfrac{1}{2} \int \Phi dQ = \tfrac{1}{2} \int \varrho \Phi dV \ . \tag{13.48}$$

13.4.2 Energy density of an electrostatic field

The energy of a continuous charge distribution can be rewritten using Gauß' law,

$$W = \tfrac{\varepsilon_0}{2} \int (\nabla \cdot \vec{\mathcal{E}}) \Phi dV \ . \tag{13.49}$$

Integration by parts allows transferring the derivative of $\vec{\mathcal{E}}$ to Φ,

$$W = \tfrac{\varepsilon_0}{2} \left[\oint_{\partial \mathcal{V}} \Phi \vec{\mathcal{E}} \cdot d\mathbf{S} - \int_{\mathcal{V}} \vec{\mathcal{E}} \cdot (\nabla \Phi) dV \right] \ . \tag{13.50}$$

The surface integral can be neglected, because we can choose the integration volume arbitrarily large $\mathcal{V}$. Expressing the gradient by the field,

$$W = \tfrac{\varepsilon_0}{2} \int_{\mathcal{V}} \vec{\mathcal{E}}^2 dV = \tfrac{\varepsilon_0}{2} \int_{\mathcal{V}} u dV \ , \tag{13.51}$$

introducing the *energy density*,

$$\boxed{u \equiv \tfrac{\varepsilon_0}{2} \vec{\mathcal{E}}^2} \ . \tag{13.52}$$

Example 47 (*Electrostatic energy of a charged spherical layer*): As an example we calculate the electrostatic energy of a spherical shell of radius R uniformly charged with the total charge Q. Using the formula (13.48) we obtain,

$$W = \frac{1}{2} \int \varrho \Phi dV = \frac{1}{2} \int \frac{Q}{4\pi R^2} \delta(r-R) \Phi R^2 \sin\theta d\theta d\phi dr = \frac{Q}{2} \Phi(R) = \frac{Q}{2} \frac{1}{4\pi\varepsilon_0} \frac{Q}{R} = \frac{Q^2}{8\pi\varepsilon_0} \frac{1}{R} \ .$$

Alternatively, we calculate by the formula (13.51),

$$W = \frac{\varepsilon_0}{2} \int_{\mathbb{R}^3} \vec{\mathcal{E}}^2 dV = \frac{\varepsilon_0}{2} \int_{r \geq R} \left(\frac{1}{4\pi\varepsilon_0} \frac{Q}{R^2} \right)^2 R^2 \sin\theta d\theta d\phi dr = \frac{Q^2}{8\pi\varepsilon_0} \int_R^\infty \frac{1}{R^2} dr = \frac{Q^2}{8\pi\varepsilon_0} \frac{1}{R} \ .$$

1. Comparing the expressions for the electrostatic energy (13.47) and (13.51) [4] we perceive an inconsistency, since the second only allows positive energies, while the former allows positive and negative energies, for example, in the case of two charges with opposed signs aiming to attract each other.

   In fact, both equations are correct, but they describe slightly different situations. Equation (13.47) does not take into account of the work necessary to create these elementary point charges in the first place. In fact, equation (13.51) indicates that the energy of a point charge diverges,

   $$W = \frac{\varepsilon_0}{2} \frac{1}{(4\pi\varepsilon_0)^2} \int_{\mathbb{R}^3} \left(\frac{e}{r^2} \right)^2 r^2 \sin\theta dr d\theta d\phi = \frac{e^2}{8\pi\varepsilon_0} \int_0^\infty \frac{1}{r^2} r^2 \sin\theta dr d\theta d\phi \to \infty \ .$$

   The equation (13.51) is more complete in the sense that it gives the total energy stored in the charge configuration, but the (13.47) is more appropriate when working with point charges, because we then prefer to ignore the part needed

[4] Or equivalently (13.48), which also can not be negative.

for the construction of the electrons. Anyway, we do not know how to create or dismount electrons.

The inconsistency enters the derivation, when we make the transition between the Eqs. (13.47) and (13.48). In the first equation, $\Phi(\mathbf{r}_i)$ represents the potential due to all the other charges except q_i, while in the second $\Phi(\mathbf{r})$ is the total potential. For continuous distributions there is no difference, since the amount of charge at any mathematical point $\mathbf{r}$ is negligible, and its contribution to the potential is zero.

In practice, the divergence does not appear because, when we use Eq. (13.51), generally we consider smooth distributions of charges and not point-like charges.

2. The energy is stored in the entire electrostatic field, that is, we need to integrate over the entire space $\mathbb{R}^3$.

3. The superposition principle is not valid for electrostatic energy, since it is quadratic in the fields, $\int(\vec{\mathcal{E}}_1 + \vec{\mathcal{E}}_2)^2 dV \neq \int(\vec{\mathcal{E}}_1^2 + \vec{\mathcal{E}}_2^2)dV$.

13.4.3 Dielectrics and conductors

In an *insulating* material, such as rubber or glass, all electrons are attached to individual atoms. They can be displaced inside the atom by an external electric field, which creates a polarization of the atom. But they do not move away from the atom. In contrast, in a *conducting* material, such that a metal, one or more electrons per atom can move freely.

What are the characteristics of an ideal conductor?

1. $\vec{\mathcal{E}} = 0$ **inside a conductor.** The electric field inside a conductor must vanish, otherwise there would be forces on the charges working to rearrange them until the forces (and the motion of charges) compensate. In the presence of an external electric field, the charges arrange themselves in such a way as to generate their own field designed to compensate the external field.

2. $\varrho = 0$ **inside a conductor.** Since there is no electric field, Gauß' law prevents residual charges in the interior, since $\varrho = \nabla \cdot \vec{\mathcal{E}}/\varepsilon_0$.

3. **All residual charge is on the surface,** simply because it can not be inside.

4. **Conductor as an equipotential.** As there is no electric field, Stokes' law prevents different potentials because $\Phi(\mathbf{b}) - \Phi(\mathbf{a}) = -\int_{\mathbf{a}}^{\mathbf{b}} \vec{\mathcal{E}} \cdot d\mathbf{r} = 0$.

5. $\vec{\mathcal{E}}$ **is perpendicular to the surface near the surface.** Otherwise, the electric field components parallel to the surface would create forces to rearrange the residual charges until the parallel components disappear. Consequently, electric field lines always meet a conductor orthogonally to the surface $\vec{\mathcal{E}} \perp \partial V$.

13.4.4 Induction of charges (influence)

When we place a charge in front of a neutral conductor we measure an attraction force. The reason is that free charges of the conductor with opposite sign are attracted, while

charges with the same sign are repelled [5]. Now, since the charges with opposite sign are closer to the charge in front than those with the same sign, the attractive force will dominate the repulsive force (see Fig. 13.17 left).

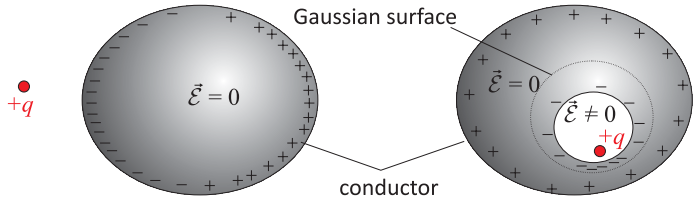

Figure 13.17: Electrostatic induction.

The electric field inside a conductor must vanish, but this only holds for the conductor's bulk material and not necessarily for dielectric impurities or cavities enclosed by the conductor. For example, in the case where there is a charge $+q$ inside a enclosed cavity [see Fig. 13.17(right)], the electric field inside the cavity is clearly nonzero. However, since it must vanish within the conductor, Gauß' law requires that within a volume enclosed by a Gaussian surface, the total charge must be zero. Choosing this Gaussian surface very close to the cavity, we find that a surface charge must have formed at the edges of the cavity, compensating for the charge $+q$ inside the cavity. This charge can only come from the outer surface, which is now charged with the opposite charge, as well. In this way *the charge $+q$ becomes visible from the outside of the conductor.*

The electric field inside a cavity without charges enclosed by a conductor must be zero, because without charges, the field lines could only traverse the cavity. However, the entrance and exit points between the cavity and the conductor are on the same potential, and have no surface charge. This is the principle of *Faraday's cage*, where people inside a conductive cage are shielded and thus protected from electrical phenomena like lightning discharges.

The migration of free excess charges in conductors to the surface is also called *skin effect*: The potential inside the metal the same everywhere, and the electric field disappears $\vec{\mathcal{E}} = 0$.

Example 48 (*Conductors with enclosed cavities*): Two cavities with radii a and b are excavated from a neutral conducting sphere of radius R. In the center of each cavity there be charges, q_a and q_b, respectively.

- The charges on the surfaces of the cavities σ_a and σ_b must be organized such as to shield the charges $q_{a,b}$ in order to prevent the formation of an electric field inside the conductor. If the charges are at the centers of the spheres we simply obtain, $\sigma_a = \frac{q_a}{4\pi a^2}$ and $\sigma_b = \frac{q_b}{4\pi b^2}$. The charges used for shielding are missing from the conductor and must be compensated for by charges of opposite sign. The only place where these opposite charges can accumulate is the outer surface of the conductor. Thus, we have the surface charge $\sigma_R = \frac{-q_a - q_b}{4\pi R^2}$.

[5] That is, the charges in the conductor rearrange to compensate for the electric field created by the charge in front until the total field inside the conductor has vanished.

- The field outside the driver is consequently, $\vec{\mathcal{E}} = \frac{q_a+q_b}{4\pi\varepsilon_0}\frac{\mathbf{r}}{r^3}$, where $\mathbf{r}$ is the point of observation with respect to the center of the conductor.
- Inside each cavity the electric field is determined by Gauß' law, $\vec{\mathcal{E}} = \frac{q_{a,b}}{4\pi\varepsilon_0}\frac{r}{r^3}$, where $\mathbf{r}$ is the observation point respect to the center of the cavity. Note that the surface charge $\sigma_{a,b}$ does not influence the field.
- Since the charges $q_{a,b}$ do not feel external fields, they are not subject to forces.
- Putting a third charge q_c near the conductor, the charge distribution σ_R would change in order to compensate the field within the conductor. Thus, the other quantities determined in (a)-(d) would not change. *The conductor effectively decouples all processes occurring on disconnected surfaces.*

13.4.5 Electrostatic pressure

What is the force exerted by an applied electric field $\vec{\mathcal{E}}_{ext}$ on a charged conductive surface? We know that the surface charge causes a discontinuity of the electric field, so that we need to calculate the force on a surface element dS as the average of the forces acting from above and from below,

$$d\mathbf{F} = dS\frac{\sigma}{2}(\vec{\mathcal{E}}_{top} + \vec{\mathcal{E}}_{bottom}) = \vec{\mathcal{P}}dS \ , \tag{13.53}$$

where $\vec{\mathcal{P}}$ is the *electrostatic pressure* (see Fig. 13.18).

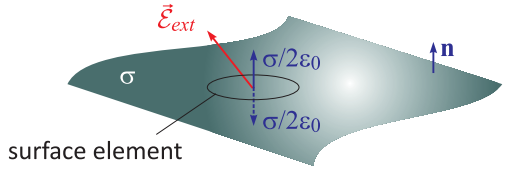

Figure 13.18: Electrostatic pressure exerted by a field $\vec{\mathcal{E}}_{ext}$ on a charged surface element.

In the case of a thin surface, we have,

$$\vec{\mathcal{E}}_{top} = \vec{\mathcal{E}}_{ext} + \frac{\sigma}{2\varepsilon_0}\hat{\mathbf{n}} \quad , \quad \vec{\mathcal{E}}_{bottom} = \vec{\mathcal{E}}_{ext} - \frac{\sigma}{2\varepsilon_0}\hat{\mathbf{n}} \ , \tag{13.54}$$

such that the pressure is,

$$\vec{\mathcal{P}} = \sigma\vec{\mathcal{E}}_{ext} \ . \tag{13.55}$$

In the case of a charged surface of a massive conductor without external field,

$$\vec{\mathcal{E}}_{outside} = \frac{\sigma}{\varepsilon_0}\hat{\mathbf{n}} \quad , \quad \vec{\mathcal{E}}_{inside} = 0 \ , \tag{13.56}$$

such that the pressure is,

$$\vec{\mathcal{P}} = \frac{\sigma}{2}\frac{\sigma}{2\varepsilon_0}\hat{\mathbf{n}} = \frac{\varepsilon_0}{2}\mathcal{E}^2_{outside}\hat{\mathbf{n}} \ . \tag{13.57}$$

That is, even without external field a charged conductor suffers a force trying to push it into the field created by itself, regardless of the sign of the charge. It is interesting to note that this force goes with the square of σ and of $\vec{\mathcal{E}}_{outside}$.

13.4.6 Exercises

13.4.6.1 Ex: Motion of two charges

Two particles with masses m_1 and m_2 and charges $Q_1 > 0$ and $Q_2 > 0$ are placed at a mutual distance d_0 and can move freely in space.
a. What will happen to the particles qualitatively? Which relation holds at all times for the velocities v_1 and v_2 of the two particles?
b. Calculate the velocities of the two particles as a function of their distance and plot the functions $v_1(d)$, respectively $v_2(d)$ (phase space diagrams). What are the velocities reached in the limit $d \to \infty$?

Solution: *a. The charges repel each other. Here, momentum conservation holds,* $m_1 v_1 = -m_2 v_2$.
b. The equation of motion for the distance follows from Coulomb's law, $m_1 \dot{v}_1 = \frac{1}{4\pi\varepsilon_0}\frac{Q_1 Q_2}{|r_1 - r_2|^2} = -m_2 \dot{v}_2$.

$$\ddot{d} = \dot{v}_1 - \dot{v}_2 = \frac{1}{4\pi\varepsilon_0}\left(\frac{1}{m_1} + \frac{1}{m_2}\right)\frac{Q_1 Q_2}{d^2} \ .$$

b. The total energy of the system is composed of the potential energy and the kinetic energy of the two particles:

$$\begin{aligned} E &= T + U \ , \\ U &= \frac{1}{4\pi\varepsilon_0}\frac{Q_1 Q_2}{d} \ , \\ T &= \frac{m_1}{2}v_1^2 + \frac{m_2}{2}v_2^2 \ . \end{aligned}$$

The energy is fixed by the initial conditions $d(0) = d_0$ *and* $v(0) = 0$*:*

$$E = \frac{1}{4\pi\varepsilon_0}\frac{Q_1 Q_2}{d_0} \ .$$

Inserting,

$$\begin{aligned} \frac{m_1}{2}v_1^2 + \frac{m_2}{2}v_2^2 + \frac{1}{4\pi\varepsilon_0}\frac{Q_1 Q_2}{d} &= \frac{1}{4\pi\varepsilon_0}\frac{Q_1 Q_2}{d_0} \\ \Longrightarrow v_1^2\left(\frac{m_1}{2} + \frac{m_1^2}{2m_2}\right) = v_2^2\left(\frac{m_2^2}{2m_1} + \frac{m_2}{2}\right) &= \frac{Q_1 Q_2}{4\pi\varepsilon_0}\left(\frac{1}{d_0} - \frac{1}{d}\right) \\ \Longrightarrow v_k = \sqrt{\frac{Q_1 Q_2}{2\pi\varepsilon_0 m_k^2\left(\frac{1}{m_1} + \frac{1}{m_2}\right)}\left(\frac{1}{d_0} - \frac{1}{d}\right)} \ . \end{aligned}$$

over large distances d

$$v_k \to \frac{1}{m_k}\sqrt{\frac{Q_1 Q_2}{2\pi\varepsilon_0\left(\frac{1}{m_1} + \frac{1}{m_2}\right)}\frac{1}{d_0}} \ .$$

13.4.6.2 Ex: Paul trap

We consider four parallel wires oriented along the z-direction and forming a quadrupolar configuration in the xy-plane, as shown in the figure. The wires are charged with $\pm q$ per unit of length l. Calculate the electrical potential as a function of x and y in the center between the wires and expand around $x = 0$ and $y = 0$ ($|x|, |y| \ll a$) up to second order. What is the shape of the potential at this position? Do you think it is possible to trap a charged particle in this potential?

Solution:

13.4.6.3 Ex: Energy of the electron

Supposing that the charge is homogeneously distributed over a sphere, calculate the *classical electron radius*.

Solution: *We assume that the charge is evenly distributed inside a sphere of radius r_e, $e = \varrho\frac{4\pi}{3}r_e^3$. We try two equivalent calculations:*
a. Using Gauss' law we get for the electric field,

$$\mathcal{E}_{r<r_e} = \frac{\varrho}{3\varepsilon_0}r = \frac{e}{4\pi\varepsilon_0}\frac{r}{r_e^3} \quad , \quad \mathcal{E}_{r>r_e} = \frac{\varrho}{3\varepsilon_0}\frac{r_e^3}{r^2} = \frac{e}{4\pi\varepsilon_0}\frac{1}{r^2} \ .$$

With that, the energy becomes,

$$\mathcal{E}_{ele} = \frac{\varepsilon_0}{2}\int_V |\mathcal{E}_r|^2 dV = \frac{\varepsilon_0}{2}4\pi\int_0^{r_e}\left(\frac{e}{4\pi\varepsilon_0}\frac{r}{r_e^3}\right)^2 r^2 dr + \frac{\varepsilon_0}{2}4\pi\int_{r_e}^{\infty}\left(\frac{e}{4\pi\varepsilon_0}\frac{1}{r^2}\right)^2 r^2 dr = \frac{e^2}{4\pi\varepsilon_0}\frac{3}{5r_e} \ .$$

b. Knowing that the electric field within the homogeneous charge distribution grows linearly with the distance from the origin, we do the following ansatz for the potential, $\Phi(r) = ar^2 + b$. The coefficients are calibrated using the known solutions for the potential and the field on the surface::

$$\Phi(r = r_e) = ar_e^2 + b = \frac{e}{4\pi\varepsilon_0}\frac{1}{r_e} \quad \Longrightarrow \quad b = \frac{e}{4\pi\varepsilon_0}\frac{1}{r_e} - ar_e^2$$
$$\mathcal{E}(r = r_e) = -\frac{d}{dr}\Phi(r_e) = -2ar_e = \frac{e}{4\pi\varepsilon_0}\frac{1}{r_e^2} \quad \Longrightarrow \quad a = -\frac{e}{8\pi\varepsilon_0}\frac{1}{r_e^3} \ .$$

Finally,

$$\Phi(r) = -\frac{e}{8\pi\varepsilon_0}\frac{1}{r_e^3}r^2 + \frac{e}{4\pi\varepsilon_0}\frac{1}{r_e} - ar_e^2 = \frac{e}{4\pi\varepsilon_0 r_e}\left(\frac{3}{2} - \frac{R^2}{2r_e^2}\right) \ .$$

13.4.6.4 Ex: Radius of the electron

a. Try to calculate the electrostatic energy of the field of an electron via,

$$E_F = \int_{\mathbb{R}^3}\frac{\varepsilon_0}{2}\vec{\mathcal{E}}^2(\mathbf{r})\ d^3r$$

What problem appears in the calculation of the radial part of the integral $\int dr$, if the lower limit of integration goes to $r_0 \to 0$?
b. This problem is known as *self-energy divergence*. It is possible to work around this problem, leaving the limits out and choosing the classic electron radius r_0 as the integration limit. The energy E_F of the electric field is then identified with half the energy $E = \frac{1}{2}m_e c^2$ of the electron rest mass m_e. Calculate the classic electron radius!

Solution: *a. We have*

$$\vec{\mathcal{E}} = \frac{1}{4\pi\varepsilon_0}\frac{q}{r^2}\hat{\mathbf{e}}_r \ .$$

With that,

$$E_F = \frac{4\pi\varepsilon_0}{2}\lim_{r_0\to 0}\int_{r_0}^{\infty}\vec{\mathcal{E}}^2(r)r^2dr = \frac{1}{2}\frac{1}{4\pi\varepsilon_0}\lim_{r_0\to 0}\int_{r_0}^{\infty}\frac{q^2}{r^2}dr = \lim_{r_0\to 0}\frac{1}{2}\frac{q^2}{4\pi\varepsilon_0}\frac{1}{r_0} \to \infty \ .$$

b. Equalizing we obtain,

$$\frac{1}{2}\frac{q^2}{4\pi\varepsilon_0}\frac{1}{r_0} = \frac{1}{2}m_e c^2 \ ,$$

and from this,

$$r_0 = \frac{q^2}{4\pi\varepsilon_0 m_e c^2} = 2.82\,\text{fm} \ .$$

13.4.6.5 Ex: Electrostatic energy

a. Write the potential energy of a charge q in an external field $\vec{\mathcal{E}} = -\vec{\nabla}\Phi$?
b. What is the value of the electrostatic energy of N point charges?
c. What is the value of the energy of a charge distribution in the electric field $\vec{\mathcal{E}}(\mathbf{r})$?
d. What are the boundary conditions for the $\vec{\mathcal{E}}$-field on a conductor's surface?
e. Draw the electric field of a point charge q located in front of a metallic plane. What is the induced charge? What is the value of the force on the charge q?

Solution: *a. Electrostatic energy* $W = q\Phi$.
b. Electrostatic energy $W = \frac{1}{2}\sum_{i,k=1;i\neq k}^{N}\frac{q_i q_k}{4\pi\varepsilon_0|\mathbf{r}_i-\mathbf{r}_k|}$.
c. Electrostatic energy $W = \frac{\varepsilon_0}{2}\int d^3r|\vec{\mathcal{E}}(\mathbf{r})|^2$.
d. Boundary conditions on the conductor surface $\vec{\mathcal{E}}_{condutor} = 0$, $\vec{\mathcal{E}}_t = 0$, $\hat{n}\cdot\vec{\mathcal{E}} = \frac{\sigma}{\varepsilon_0}$.
e. The induced charge is $-q$, *the force is,*

$$\mathbf{F} = -\nabla\phi = -\nabla\frac{1}{4\pi\varepsilon}\frac{-q}{|\mathbf{r}+\mathbf{d}|} = \nabla\frac{q}{4\pi\varepsilon}\frac{\mathbf{r}+\mathbf{d}}{|\mathbf{r}+\mathbf{d}|^3}\bigg|_{\mathbf{r}=\mathbf{d}} = \frac{1}{4\pi\varepsilon}\frac{q}{(2d)^2} \ .$$

13.4.6.6 Ex: Electrostatic energy

What is the electrostatic energy of
a. four equal charges Q located at the corners of a tetrahedron with the edge length

d?
b. a dielectric sphere with radius R homogeneously charged with the charge Q? To do this, calculate the electric field inside and outside the sphere using Gauß' law.

Solution: *a. The energy of a charge distribution is,*

$$W = \frac{1}{2}\sum_{\substack{i,k=1\\ i\neq j}}^{N} \frac{1}{4\pi\varepsilon_0}\frac{q_i q_k}{|\mathbf{r}_i - \mathbf{r}_k|} \ .$$

In the equilateral tetrahedron all charges are equidistant, so that,

$$W = \frac{1}{2}\sum_{\substack{i,k=1\\ i\neq j}}^{4} \frac{1}{4\pi\varepsilon_0}\frac{Q^2}{d} = \frac{1}{2}\frac{1}{4\pi\varepsilon_0}\frac{Q^2}{d}4(4-1) = \frac{3}{2\pi\varepsilon_0}\frac{Q^2}{d} \ .$$

b. The energy of a homogeneously charged sphere with radius R follows from,

$$W = \frac{\varepsilon_0}{2}\int_V \vec{\mathcal{E}}^2(\mathbf{r})d^3r = \frac{\varepsilon_0}{2}\int_V \mathcal{E}^2(r)r^2\sin\theta d\theta d\phi dr \ .$$

For reasons of symmetry the electric field must be radial, $\vec{\mathcal{E}}(\mathbf{r}) = E(r)\hat{\mathbf{e}}_r$. The electric field at distance r from the origin follows from the charge inside a sphere having the same radius,

$$Q(r) = \varepsilon_0\int \nabla\vec{\mathcal{E}}\cdot(r')d^3r' = \varepsilon_0\oint \mathcal{E}(r)r^2\sin\theta d\theta d\phi = \varepsilon_0 E(r)4\pi r^2 \ .$$

The field inside and outside the charge distribution is,

$$\mathcal{E}_{in}(r) = \frac{1}{4\pi\varepsilon_0}\frac{Q(r)}{r^2} = \frac{1}{4\pi\varepsilon_0}\frac{Qr}{R^3} \qquad \textit{resp.} \qquad \mathcal{E}_{out}(r) = \frac{1}{4\pi\varepsilon_0}Q\frac{1}{r^2} = \frac{1}{4\pi\varepsilon_0}\frac{Q}{r^2} \ .$$

With that we get the same energy,

$$\begin{aligned} W &= \frac{\varepsilon_0}{2}\int E_{in}^2(r)r^2\sin\theta d\theta d\phi dr + \frac{\varepsilon_0}{2}\int_V E_{out}^2(r)r^2\sin\theta d\theta d\phi dr \\ &= \frac{\varepsilon_0}{2}4\pi\left[\int_{r\le R}\left(\frac{1}{4\pi\varepsilon_0}\frac{Qr}{R^3}\right)^2 r^2dr + \int\left(\frac{1}{4\pi\varepsilon_0}\frac{Q}{r^2}\right)^2 r^2dr\right] \\ &= \frac{1}{2}\frac{Q^2}{4\pi\varepsilon_0}\left(\frac{r^5}{5R^6}\Big|_0^R + \frac{-1}{r}\Big|_R^\infty\right) = \frac{3Q^2}{20\pi\varepsilon_0 R} \ . \end{aligned}$$

13.4.6.7 Ex: Electrostatic energy

a. Eight point charges q are placed in the corners of a cube with the edge length l. Calculate the electrostatic energy of this configuration.

b. A balloon with radius R is charged homogeneously with the charge Q. What is the value of electrostatic energy? What is the force required to inflate the balloon even more, neglecting the elastic force of the balloon?

Solution: *We have for the potential energy of N point charges in their own field:*

$$W_{tot} = \frac{1}{2} \sum_{i,k=1;k\neq i}^{N} \frac{q_i q_k}{4\pi\varepsilon_0 |\mathbf{r}_i - \mathbf{r}_k|} \ .$$

The potential energy of a charge in the given configuration is,

$$W = 3W_{distance\ l} + 3W_{distance\ \sqrt{2}l} + W_{distance\ \sqrt{3}l} = \frac{q^2}{4\pi\varepsilon_0 2}\left(\frac{3}{l} + \frac{3}{\sqrt{2}l} + \frac{1}{\sqrt{3}l}\right)$$
$$= \frac{q^2}{8\pi\varepsilon_0 l}\left(3 + \frac{3}{\sqrt{2}} + \frac{1}{\sqrt{3}}\right) \ .$$

So we get W_{tot}

$$W_{tot} = 8W = \frac{q^2}{\pi\varepsilon_0 l}\left(\frac{3}{l} + \frac{3}{\sqrt{2}l} + \frac{1}{\sqrt{3}l}\right) \approx \frac{5.7q^2}{\pi\varepsilon_0 l} \ .$$

b. With Gauß follows $\mathcal{E} = \frac{Q}{4\pi\varepsilon_0}\frac{1}{r^2}$ for $r > R$ and $\mathcal{E} = 0$ for $r \leq R$. The energy is,

$$E_F = \int dV \frac{\varepsilon_0}{2}\vec{\mathcal{E}}^2(r)dr = 4\pi\frac{\varepsilon_0}{2}\int_0^\infty r^2\mathcal{E}(r)dr = 4\pi\frac{\varepsilon_0}{2}\frac{Q^2}{(4\pi\varepsilon_0)^2}\int_0^\infty r^{-2}dr$$
$$= \frac{Q^2}{8\pi\varepsilon_0}\int_R^\infty r^{-2}dr = \frac{Q^2}{8\pi\varepsilon_0}R^{-1} \ .$$

To increase the radius of the air balloon we must change the energy by $\mathbf{F} = -\nabla E_F$ follows:

$$F = -\frac{d}{dR}E_F = \frac{Q^2}{8\pi\varepsilon_0}\frac{1}{R^2} \ .$$

The force is positive. The air balloon tries to inflate itself!

13.4.6.8 Ex: Charge separation

Two conducting neutral spheres are in contact and attached to insulating rods on a large wooden table. A positively charged stick is brought close to the surface of one of the spheres on the side opposite the point of contact with the other sphere.
a. Describe the charges induced in the two conductive spheres and discuss the charge distribution in both.
b. The two spheres are separated and then the charged stick is taken away. Then, the spheres are separated by a great distance. Discuss the charge distributions on the spheres after they are separated.

Solution: *a. When approaching the positively charged stick, a negative charge is*

induced to the sphere being close to the stick, leaving the more distant sphere positively charged.
b. After separating the spheres and then moving the stick away, the induced charges are evenly distributed in each of the spheres.

13.5 Treatment of boundary conditions and the uniqueness theorem

In practice, the solution of an electrostatic problem, that is, the resolution of the Poisson equation, can be hampered by boundary conditions. For example, charges in front of conducting surfaces induce a redistribution of charges in the conductor which modifies the electric field. The field is unequivocally determined by the charge and the boundary conditions. In this section we will discuss the method of image charges, which is a heuristic model, and the mathematical treatment of boundary conditions.

13.5.1 The method of images charges

One way to simulate boundary conditions is to 'invent' imaginary charges and distribute them in a way that the total field automatically satisfies these boundary conditions. This is usually only helpful when the boundary conditions exhibit a high degree of symmetry. This is the method of the so-called *image charge*s.

The simplest case is that of the point charge Q at a distance d in front of a conductive and grounded plane. By induction the charge will cause a redistribution of charges on the surface of the conductor in such a way, that the field lines cross the surface of the conductor at right angles. But the same boundary conditions can be satisfied by replacing the conductive plane with a second imaginary charge with opposite sign at the position of the image of the first charge regarding the plane as a mirror. From the point of view of the electric field the two configurations are equivalent, but the field is much easier to calculate for a charge and its image using Coulomb's law. See Excs. 13.5.6.1, 13.5.6.2, 13.5.6.3, 13.5.6.4, and 13.5.6.5.

Example 49 (*Induced surface charge*): In the case of the point charge in front of a conducting plane, which is the simplest case imaginable, the boundary conditions are,

$$\Phi(x,y,0)=0 \quad , \quad \Phi(|\mathbf{r}|\gg d)=0 \ ,$$

the potential is,

$$\Phi(\mathbf{r})=\frac{1}{4\pi\varepsilon_0}\left(\frac{Q}{\sqrt{x^2+y^2+(z-d)^2}}+\frac{-Q}{\sqrt{x^2+y^2+(z+d)^2}}\right) \ ,$$

and the field is,

$$\vec{\mathcal{E}}=-\nabla\Phi=\frac{-Q}{4\pi\varepsilon_0}\left(\frac{-1}{\sqrt{x^2+y^2+(z-d)^2}^3}(\hat{\mathbf{e}}_z-\mathbf{r})+\frac{1}{\sqrt{x^2+y^2+(z+d)^2}^3}(\hat{\mathbf{e}}_z+\mathbf{r})\right) .$$

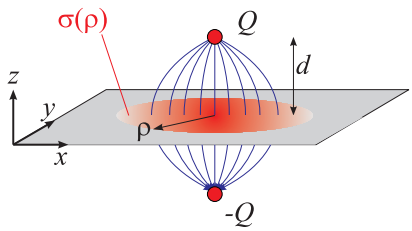

Figure 13.19: Point charge in front of a conductive plane.

We can now calculate the charge distribution on the surface. Gauß' law says,

$$\int_{box} \vec{\mathcal{E}} \cdot d\mathbf{S} = \frac{Q}{\varepsilon_0} = \frac{1}{\varepsilon_0} \int \varrho(\mathbf{r}) dV = \frac{1}{\varepsilon_0} \int \sigma(x,y)\delta(z) dV = \frac{1}{\varepsilon_0} \int \sigma(x,y) dA \ .$$

Therefore, on the surface,

$$\hat{\mathbf{e}}_z \cdot \vec{\mathcal{E}}(x,y,z=0) = \frac{\sigma(x,y)}{\varepsilon_0} \ .$$

Resolving by the charge density,

$$\sigma(x,y) = \varepsilon_0 \hat{\mathbf{e}}_z \cdot \vec{\mathcal{E}}(x,y,z=0) = \frac{-Q}{4\pi} \frac{2}{\sqrt{x^2+y^2+d^2}^3} \ .$$

Also, we can verify that the total surface charge is, $Q_s = -Q$.

13.5.2 Formal solution of the electrostatic problem

The solution of the Laplace equation will, in general, depend on boundary conditions imposed by the geometry of the system. For example, a charge in free space will generate another field than a charge above a conductive surface. The two most common boundary conditions are named after *Dirichlet* and *von Neumann*. The Dirichlet condition fixes the value of the potential on a geometry of surfaces enclosing a volume, $\Phi|_{\partial\mathcal{V}} = \Phi_0$, while the von Neumann condition fixes the value of the potential gradient, $\nabla\Phi|_{\partial\mathcal{V}} = \vec{\mathcal{E}}_0$. Let us discuss these conditions in the following.

Using the following four relationships,

$$\begin{aligned}
&\text{(i)} \quad \nabla^2 \tfrac{1}{4\pi|\mathbf{r}-\mathbf{r}'|} = -\delta(\mathbf{r}-\mathbf{r}') \\
&\text{(ii)} \quad \nabla\cdot(\phi\mathbf{F}) = \phi(\nabla\cdot\mathbf{F}) + (\nabla\phi)\cdot\mathbf{F} \\
&\text{(iii)} \quad \int_{\mathcal{V}} \nabla\cdot\mathbf{F} dV' = \int_{\partial V} \mathbf{F}\cdot d\mathbf{S}' \\
&\text{(iv)} \quad \nabla^2\Phi = -\tfrac{\varrho}{\varepsilon_0} \ ,
\end{aligned} \tag{13.58}$$

we now solve the Poisson equation,

$$\Phi(\mathbf{r}) = \int_{\mathcal{V}} \Phi(\mathbf{r}')\delta(\mathbf{r}-\mathbf{r}')dV' = \tfrac{-1}{4\pi}\int_{\mathcal{V}} \underbrace{\Phi(\mathbf{r}')}_{\phi}\nabla\cdot\underbrace{\left(\nabla\tfrac{1}{|\mathbf{r}-\mathbf{r}'|}\right)}_{\mathbf{F}}dV' \qquad \text{with (i)} \qquad (13.59)$$

$$= \tfrac{1}{4\pi}\int_{\mathcal{V}} \underbrace{\nabla\Phi(\mathbf{r}')}_{\mathbf{F}}\cdot\nabla\underbrace{\tfrac{1}{|\mathbf{r}-\mathbf{r}'|}}_{\phi}dV' - \tfrac{1}{4\pi}\int_{\mathcal{V}}\nabla\cdot\left(\Phi(\mathbf{r}')\nabla\tfrac{1}{|\mathbf{r}-\mathbf{r}'|}\right)dV' \qquad \text{with (ii)}$$

$$= -\tfrac{1}{4\pi}\int_{\mathcal{V}}\tfrac{1}{|\mathbf{r}-\mathbf{r}'|}\nabla\cdot\nabla\Phi(\mathbf{r}')dV' + \tfrac{1}{4\pi}\int_{\mathcal{V}}\nabla\cdot\left(\tfrac{1}{|\mathbf{r}-\mathbf{r}'|}\nabla\Phi(\mathbf{r}')\right)dV' - \tfrac{1}{4\pi}\int_{\mathcal{V}}\nabla\cdot\left(\Phi(\mathbf{r}')\nabla\tfrac{1}{|\mathbf{r}-\mathbf{r}'|}\right)dV' .$$

Finally, using relations (iii and iv), we obtain the final result,

$$\boxed{\Phi(\mathbf{r}) = \tfrac{1}{4\pi\varepsilon_0}\int_{\mathcal{V}}\tfrac{\varrho(\mathbf{r}')}{|\mathbf{r}-\mathbf{r}'|}dV' + \tfrac{1}{4\pi}\oint_{\partial\mathcal{V}}\left(\Phi(\mathbf{r}')\nabla'\tfrac{1}{|\mathbf{r}-\mathbf{r}'|} - \tfrac{1}{|\mathbf{r}-\mathbf{r}'|}\nabla'\Phi(\mathbf{r}')\right)\cdot d\mathbf{S}'}\ , \qquad (13.60)$$

which is an integral version of the Poisson equation. For volumes going to infinity, where the potential disappears, the surface integrals can be neglected, and we get the familiar form of Coulomb's law. For finite volumes, boundary conditions on surfaces can dramatically influence the potential.

Example 50 (*Consistency of Green's relationship*): Obviously, by imposing boundary conditions that coincide with equipotential surfaces of the field created by the charge distribution, the surface terms vanish. Choosing as an example a point charge placed at the origin, $\varrho(\mathbf{r}') = Q\delta^3(\mathbf{r}')$, and inserting its potential,

$$\Phi(\mathbf{r} = R\hat{\mathbf{e}}_r) = \frac{Q}{4\pi\varepsilon_0}\frac{1}{R} = \frac{Q}{4\pi\varepsilon_0}\left.\frac{1}{|\mathbf{r}-\mathbf{r}'|}\right|_{\mathbf{r}\in\partial\mathcal{V}} . \qquad (13.61)$$

in the relationship (13.60), we find that the surface integrals cancel out.

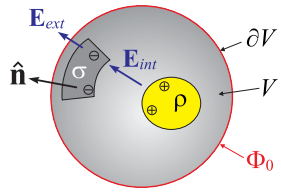

Figure 13.20: Illustration of boundary conditions.

The surface term can be interpreted in terms of a surface charge density, because we know that the normal electric field is discontinuous when crossing a charged sur-

face [6]:

$$\frac{\sigma(\mathbf{r}')}{\varepsilon_0} = -\nabla'\Phi(\mathbf{r}') \cdot \hat{\mathbf{n}} \ . \tag{13.62}$$

We consider the example of a charge distribution, $\varrho(\mathbf{r}')$, surrounded by a surface on which the potential is zero, $\Phi(\mathbf{r}')|_{\partial\mathcal{V}'} = 0$, such that the first surface term of the relation (13.60) fades away. Inserting the expression (13.62) in the second surface term, the relation becomes,

$$\Phi(\mathbf{r}) = \frac{1}{4\pi\varepsilon_0}\int_{\mathcal{V}} \frac{\varrho(\mathbf{r}')}{|\mathbf{r}-\mathbf{a}|} + \frac{1}{4\pi\varepsilon_0}\oint_{\partial\mathcal{V}} \frac{\sigma(\mathbf{r}')}{|\mathbf{r}-\mathbf{r}'|} dS' \ . \tag{13.63}$$

The interpretation of this modified Coulomb law is, that the charge induces a density distribution of surface charges σ within the conducting plane which modifies the electric potential, such that the boundary condition is satisfied.

13.5.3 Green's Function

The function $\frac{1}{4\pi|\mathbf{r}-\mathbf{r}'|}$ not the only one to satisfy the condition (13.58)(i). In fact, there is an entire class of functions called Green functions defined by,

$$\nabla^2 G(\mathbf{r},\mathbf{r}') \equiv -\delta(\mathbf{r}-\mathbf{r}') \ . \tag{13.64}$$

Obviously, for these functions the formula derived in (13.59) will be generalized,

$$\boxed{\Phi(\mathbf{r}) = \tfrac{1}{\varepsilon_0}\int_{\mathcal{V}} \varrho(\mathbf{r}')G(\mathbf{r},\mathbf{r}')dV' + \oint_{\partial\mathcal{V}} (\Phi(\mathbf{r}')\nabla G(\mathbf{r},\mathbf{r}') - G(\mathbf{r},\mathbf{r}')\nabla\Phi(\mathbf{r}')) \cdot d\mathbf{S}'} \ . \tag{13.65}$$

The advantage of the Green function is, that we have the freedom to add any function F,

$$G(\mathbf{r},\mathbf{r}') = \frac{1}{4\pi|\mathbf{r}-\mathbf{r}'|} + F(\mathbf{r},\mathbf{r}') \tag{13.66}$$

satisfying the Laplace equation,

$$\nabla^2 F(\mathbf{r},\mathbf{r}') = 0 \ , \tag{13.67}$$

and the Green function (13.66) will still satisfy the definition (13.64). In particular, we can choose the function F in a way to eliminate one of the two surface integrals in Eq. (13.65) and to obtain an expression only involving Dirichlet's or von Neumann's boundary conditions.

[6] We can derive this considering a thin disk located within the x-y plane and homogeneously charged with the charge density σ_0,

$$\Phi(z\hat{\mathbf{e}}_z) = \frac{1}{4\pi\varepsilon_0}\int_{disco} \frac{\sigma(\mathbf{r}')}{|z\hat{\mathbf{e}}_z - \mathbf{r}'|} dA' = \frac{\sigma_0}{2\varepsilon_0}\int_0^R \frac{1}{\sqrt{r'^2+z^2}} r'dr' = \frac{\sigma_0}{2\varepsilon_0}[\sqrt{R^2+z^2} - z] \ ,$$

and therefore,

$$E_z = -\frac{d\Phi(z\hat{\mathbf{e}}_z)}{dz} = -\frac{\sigma_0}{2\varepsilon_0}\left(\frac{z}{\sqrt{R^2+z^2}} - 1\right) \overset{z\ll R}{\longrightarrow} \frac{\sigma_0}{2\varepsilon_0} \ .$$

13.5.4 Poisson equation with Dirichlet's boundary conditions

The first *uniqueness theorem* proclaims,

> *The solution of the Poisson (or Laplace) equation in a volume $\mathcal{V}$ is uniquely determined, if Φ is specified on the surface of the volume $\partial\mathcal{V}$.*

To prove this theorem, let us specify that the potential adopts the (not necessarily constant) value Φ_0 on the surface and consider two possible solutions of the Laplace equation, Φ_1 and Φ_2. The difference $\Phi_3 \equiv \Phi_1 - \Phi_2$ disappears on the surface, $\Phi_3|_{\partial\mathcal{V}} = 0$, and must also satisfy the Laplace equation: $\nabla^2\Phi_3 = 0$. Now, since the Laplace equation does not allow local maxima or minima [7], Φ_3 must be zero throughout space (see Fig. 13.21 left).

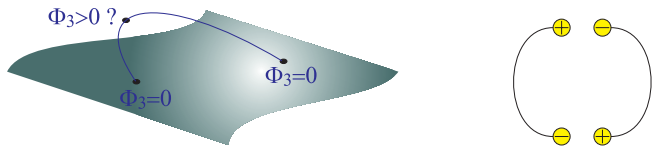

Figure 13.21: Illustration of the uniqueness theorems.

We consider as an example a finite volume V without charges, $\varrho = 0$, surrounded by a conducting border ∂V maintained at a fixed potential, $\Phi(\mathbf{r} \in \partial\mathcal{V}) = \Phi_0 = const.$ This is a typical situation realized, for example, in conductive materials such as metals. Therefore, $\Delta\Phi = 0$ within the volume. A possible trivial solution of the Laplace equation is, $\Phi(\mathbf{r}) = \Phi_0$. The uniqueness theorem now tells us that this is the *unique* solution.

To implement this theorem we choose the following boundary conditions,

$$G_D(\mathbf{r}, \mathbf{r}'_{\in\partial\mathcal{V}}) = 0 \ , \tag{13.68}$$

such that the relationship (13.64) becomes,

$$\boxed{\Phi(\mathbf{r}) = \tfrac{1}{\varepsilon_0}\int_{\mathcal{V}} \varrho(\mathbf{r}')G_D(\mathbf{r},\mathbf{r}')dV' + \oint_{\partial\mathcal{V}} \Phi(\mathbf{r}')\nabla' G_D(\mathbf{r},\mathbf{r}')\cdot d\mathbf{S}'} \ . \tag{13.69}$$

Do the Excs. 13.5.6.7, 13.5.6.8, 13.5.6.9, and 13.5.6.10.

13.5.5 Poisson equation with von Neumann's boundary conditions

The second uniqueness theorem proclaims,

> *In a volume $\mathcal{V}$ surrounded by conductors and containing a specified charge density ϱ, the electric field is uniquely determined by the total charge of each conductor.*

[7] For in a hypothetical maximum (minimum) we would have $\nabla^2\Phi_3 < 0$ (> 0).

To prove this theorem, we will consider a sample of conductors i each one carrying the charge Q_i. Assuming that there are two solutions for the electric field between the conductors, $\vec{\mathcal{E}}_1$ and $\vec{\mathcal{E}}_2$, each of these fields must satisfy, $\nabla \cdot \vec{\mathcal{E}}_1 = \nabla \cdot \vec{\mathcal{E}}_2 = Q_i$. The difference $\vec{\mathcal{E}}_3 \equiv \vec{\mathcal{E}}_1 - \vec{\mathcal{E}}_2$ must also satisfy Gauss' law $\nabla \cdot \vec{\mathcal{E}}_3 = 0$. Hence, $\vec{\mathcal{E}}_3$ must be vanish throughout the space (see Fig. 13.21 right) [8].

In the case of von Neumann boundary conditions we choose,

$$\nabla' G_N(\mathbf{r}, \mathbf{r}'_{\in \partial\mathcal{V}}) = -\tfrac{\hat{\mathbf{n}}}{S} \ , \tag{13.70}$$

because we must satisfy the definition (13.60),

$$-1 = \int_{\mathcal{V}} \nabla'^2 G_N(\mathbf{r}, \mathbf{r}') dV' = \oint_{\partial\mathcal{V}} \nabla' G_N(\mathbf{r}, \mathbf{r}') \cdot d\mathbf{S} = \oint_{\partial\mathcal{V}} \tfrac{-\hat{\mathbf{n}}}{S} \cdot d\mathbf{S} \tag{13.71}$$

such that,

$$\boxed{\Phi(\mathbf{r}) = \tfrac{1}{\varepsilon_0} \int_{\mathcal{V}} \varrho(\mathbf{r}') G_N(\mathbf{r}, \mathbf{r}') dV' - \tfrac{1}{A} \oint_{\partial\mathcal{V}} \Phi(\mathbf{r}') dA' - \oint_{\partial\mathcal{V}} G_N(\mathbf{r}, \mathbf{r}') \nabla' \Phi(\mathbf{r}') \cdot d\mathbf{S}'} \ . \tag{13.72}$$

The first surface term is simply the average of the potential over the area of the surface.

13.5.6 Exercises

13.5.6.1 Ex: Mirror charge

A long, thin wire is suspended along the y-direction at a distance $z = d$ parallel to a grounded metal plate located in the $z = 0$-plane. The surface of the wire carries the charge Q/l per unit length.
a. Draw a scheme of the electric field in the semi-space $z > 0$. **Help:** Use the principle of image charges!
b. Calculate the profile of the electric field near the surface of the plate.
c. What is the surface density $\sigma(x, y)$ of charges on the plate surface.
d. What is the charge induced in the plate per unit length in y-direction?
Comment: A similar problem occurs for conductors on printed circuits. The metal plate corresponds to the copper coating on the backside of the circuit board.

Solution: *a. Analogously to a point charge in front of a metallic plate we now expect a mirror wire with the charge $-Q$ in the distance $-d$ from the surface.*
b. The absolute value of the field generated by the wire is at the position $z = +d$,

$$\mathcal{E}_{wire} = \frac{Q}{2\pi\varepsilon_0 l} \frac{1}{\rho} = \frac{Q}{2\pi\varepsilon_0 l} \frac{1}{\sqrt{x^2 + (z-d)^2}}$$

(towards radially away from the wire). Analogously, for the mirror wire at the position $z = -d$,

$$\mathcal{E}_{mirror} = \frac{-Q}{2\pi\varepsilon_0 l} \frac{1}{\sqrt{x^2 + (z+d)^2}} \ .$$

[8] We present here a slightly simplified argumentation. See [545] for a more complete proof.

On the plate surface the field is parallel to $\hat{\mathbf{e}}_z$*. The* x *and* z*-components of the* E *field on the plate surface at the position* $z = 0$ *are,*

$$\mathcal{E}_{wire,x} = |\mathcal{E}_{wire,x}| \sin\phi = |\mathcal{E}_{wire,x}| \frac{x}{\sqrt{x^2+d^2}} = \frac{Q}{2\pi\varepsilon_0 l} \frac{1}{\sqrt{x^2+d^2}} \frac{x}{\sqrt{x^2+d^2}} = \frac{Q}{2\pi\varepsilon_0 l} \frac{x}{x^2+d^2}$$

and

$$\mathcal{E}_{wire,z} = -|\mathcal{E}_{wire,x}| \cos\phi = -|\mathcal{E}_{wire,x}| \frac{d}{\sqrt{x^2+d^2}} = \frac{-Q}{2\pi\varepsilon_0 l} \frac{1}{\sqrt{x^2+d^2}} \frac{d}{\sqrt{x^2+d^2}} = \frac{-Q}{2\pi\varepsilon_0 l} \frac{d}{x^2+d^2} \ .$$

for the mirror wire we have analogously,

$$\mathcal{E}_{wire,x} = \frac{-Q}{2\pi\varepsilon_0 l} \frac{x}{x^2+d^2}$$

and

$$\mathcal{E}_{wire,z} = \frac{-Q}{2\pi\varepsilon_0 l} \frac{d}{x^2+d^2} \ .$$

This means that the x*-component disappears and (for* $z > 0$*),*

$$\mathcal{E}_z = 2\mathcal{E}_{wire,z} = \frac{-Q}{\pi\varepsilon_0 l} \frac{d}{x^2+d^2} \ .$$

c. We use $\rho(x,y,z) = \sigma(x,y)\delta(z)$*. Furthermore, div* $\vec{\mathcal{E}} = \frac{\partial \mathcal{E}_z}{\partial z}$*, because all other components disappear on the surface. Now we place a small box (area* dA *parallel to the surface) such that a piece of the surface is inside. Now,*

$$\frac{1}{\varepsilon_0} \int \varrho(x,y,z) dV = \frac{1}{\varepsilon_0} \int \sigma(x,y) dA \ .$$

Furthermore,

$$\frac{1}{\varepsilon_0} \int_V \varrho dV = \oint_{\partial box} \vec{\mathcal{E}} \cdot d\mathbf{S} = \mathcal{E}_{z,z>0} dS \ .$$

From this follows,

$$\sigma(x,y) = \varepsilon_0 \mathcal{E}_{z,z>0} = -\frac{Qd}{\pi l} \frac{1}{x^2+d^2} \ .$$

d. Integrating over the length l *in* y*-direction and over all values of* x *gives,*

$$Q_{plate} = \int_0^l dy \int_{-\infty}^{\infty} dx \left(\frac{-Qd}{\pi l} \frac{1}{x^2+d^2} \right) = \frac{-Qdl}{\pi l} \int_{-\infty}^{\infty} dx \frac{1}{x^2+d^2} = \frac{-Qdl}{\pi} \frac{1}{d} \arctan\frac{x}{d} \Big|_{-\infty}^{\infty} = -Q \ .$$

13.5.6.2 Ex: Mirror charge

Consider the scheme, illustrated in the figure, of a point charge $+q$ in front of a corner of a grounded wall.
a. Determine the positions and values of the image charges.
b. Calculate the electrostatic potential $\Phi(\mathbf{r})$ in the upper right quadrant.

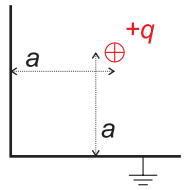

Figure 13.22: Mirror charge.

Solution: *a. There are three image charges,*

$$-q, \begin{pmatrix} -a \\ a \\ 0 \end{pmatrix} \quad , \quad +q, \begin{pmatrix} -a \\ -a \\ 0 \end{pmatrix} \quad , \quad -q, \begin{pmatrix} a \\ -a \\ 0 \end{pmatrix} .$$

b. So we have for $\mathbf{r}$ *in the upper right quadrant:*

$$\Phi(\mathbf{r}) = \frac{q}{4\pi\varepsilon_0}\left[-\frac{1}{\sqrt{(x+a)^2+(y-a)^2+z^2}} + \frac{1}{\sqrt{(x+a)^2+(y+a)^2+z^2}} - \frac{1}{\sqrt{(x-a)^2+(y+a)^2+z^2}} + \frac{1}{\sqrt{(x-a)^2+(y-a)^2+z^2}}\right] .$$

Proof: $\Phi(\mathbf{r}) = 0$ *para* $x = 0$ *ou* $y = 0$.

13.5.6.3 Ex: Mirror charge

Inside a grounded hollow metallic sphere with the inner radius a be a charge $+Q$ at the position $\mathbf{r}_1 = (0, 0, z_1)$. Determine the charge Q' and the position $\mathbf{r}_2$ of an image charge with which it is possible to describe the potential $\Phi(\mathbf{r})$ of the original charge distribution using only the system consisting of the charge and the image charge. Determine $\Phi(\mathbf{r})$.
Help: The position $\mathbf{r}_2$ and the charge Q' are not unambiguously determined. Choose $\mathbf{r}_1 = (0, 0, z_1)$ and $z_2/a = a/z_1$.

Solution: *The boundary condition is* $\Phi(|\mathbf{r}| = a) = 0$. *We now place a charge* Q' *for symmetry reasons at the point* z_2*:*

$$4\pi\varepsilon_0\Phi(\mathbf{r}) = \frac{Q}{|\mathbf{r} - z_1\hat{\mathbf{e}}_z|} + \frac{Q'}{|\mathbf{r} - z_2\hat{\mathbf{e}}_z|}$$

with $\mathbf{r} = r\hat{\mathbf{e}}_r$ *follows from the condition*

$$4\pi\varepsilon_0\Phi(\mathbf{r} = a\hat{\mathbf{e}}_r) = \frac{Q/a}{|\hat{\mathbf{e}}_r - z_1\hat{\mathbf{e}}_z/a|} + \frac{Q'/a}{|\hat{\mathbf{e}}_r - z_2\hat{\mathbf{e}}_z/a|} \equiv 0 .$$

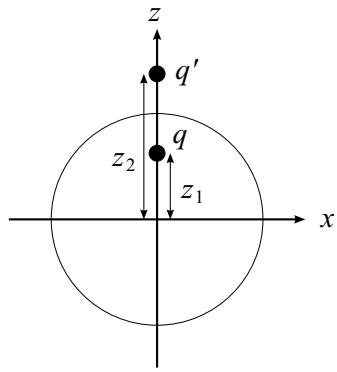

Figure 13.23: Mirror charge.

This is satisfied when

$$Q\sqrt{a^2+z_2^2-az_2\hat{\mathbf{e}}_r\cdot\hat{\mathbf{e}}_z}=-Q'\sqrt{a^2+z_1^2-az_1\hat{\mathbf{e}}_r\cdot\hat{\mathbf{e}}_z}\ .$$

The square gives,

$$Q^2(a^2+z_2^2-az_2\hat{\mathbf{e}}_r\cdot\hat{\mathbf{e}}_z)=Q'^2(a^2+z_1^2-az_1\hat{\mathbf{e}}_r\cdot\hat{\mathbf{e}}_z)Q'Q<0\ .$$

Since this should be satisfied for all angles $\theta=\arccos(\hat{\mathbf{e}}_r\cdot\hat{\mathbf{e}}_z)$,

$$Q^2(-az_2\hat{\mathbf{e}}_r\cdot\hat{\mathbf{e}}_z)=Q''(-az_1\hat{\mathbf{e}}_r\cdot\hat{\mathbf{e}}_z)\qquad\textit{and}\qquad Q^2(a^2+z_2^2)=Q''(a^2+z_1^2)\ ,$$

resp.

$$\frac{Q^2}{Q''}=\frac{z_1}{z_2}=\frac{a^2+z_1^2}{a^2+z_2^2}\ .$$

The second equation gives,

$$z_1a^2+z_1z_2^2-a^2z_2-z_1^2z_2=0\ ,$$

which yields $z_1=a^2/z_2$. *With that we substitute* z_1 *in the first equation,*

$$Q'=\pm Q\frac{z_2}{a}\qquad\textit{and}\qquad Q'Q<0\ .$$

We get a trivial solution for $z_2=z_1$ *and* $Q=-Q'$.

13.5.6.4 Ex: Mirror charge

A conductive surface in the (x,y)-plane has a protrusion in the form of a semi-sphere with radius R. The center of the sphere is in the plane and at the origin of the coordinates. On the symmetry axis $\hat{\mathbf{e}}_z$ at a distance $d>R$ from the plane there is a point charge Q. Determine with the image charge method the potential $\Phi(\mathbf{r})$ and the force $\mathbf{F}$ on the charge Q.

a. To make the surface of the semisphere an equipotential surface ($\Phi \equiv 0$) we need a mirror charge Q_1 on the z-axis at a distance z_1 from the origin. Determine Q_1 and z_1.
b. For the (x, y)-plane to become an equipotential surface as well, we need two more image charges Q_2 and Q_3. Determine the value and position of these charges.
c. With the values and positions of the charges determine: The electrostatic potential $\Phi(\mathbf{r})$ at an arbitrary point $\mathbf{r}$ above the conductive surface, the force $\mathbf{F}$ on the charge Q and its direction (repulsive or attractive).

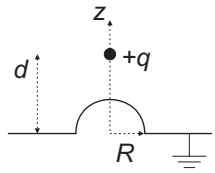

Figure 13.24: Mirror charge.

Solution: *a. The potential must satisfy the boundary condition,*

$$\Phi(\mathbf{r})|_{\mathbf{r}\in spheresurface} = \frac{1}{4\pi\varepsilon_0}\left[\frac{Q}{|\mathbf{r}-z_0\hat{\mathbf{e}}_z|}+\frac{Q_1}{|\mathbf{r}-z_1\hat{\mathbf{e}}_z|}\right]_{\mathbf{r}\in spheresurface} = 0\ .$$

This can be met in a non-trivial way by $z_1 = R^2/z_0$ and $q_1 = -qR/z_0$, since

$$\left[\frac{Q}{|\mathbf{r}-z_0\hat{\mathbf{e}}_z|}+\frac{-qR/z_0}{|\mathbf{r}-\frac{R^2}{z_0}\hat{\mathbf{e}}_z|}\right]_{\mathbf{r}\in spheresurface} = \frac{Q}{\sqrt{X^2+Y^2+(Z-z_0)^2}} - \frac{QR/z_0}{\sqrt{X^2+Y^2+\left(Z-\frac{R^2}{z_0}\right)^2}}$$

$$= \frac{Q}{\sqrt{R^2-2Zz_0+z_0^2}} - \frac{QR}{\sqrt{z_0^2X^2+z_0^2Y^2+z_0^2Z^2-2z_0ZR^2+R^4}} = 0\ .$$

b. The two additional charges must reflect the charges Q and Q_1 in the (x, y)-plane: $z_2 = -z_0$ and $Q_2 = -Q$ and $z_3 = -z_1$ and $Q_3 = -Q_1$.
c. With that we have a complete expression for the potential,

$$\Phi(\mathbf{r}) = \frac{1}{4\pi\varepsilon_0}\sum_{k=0}^{3}\frac{Q_k}{|\mathbf{r}-z_k\hat{\mathbf{e}}_z|} = \frac{Q}{4\pi\varepsilon_0}\left(\frac{1}{|\mathbf{r}-z_0\hat{\mathbf{e}}_z|}-\frac{1}{|\mathbf{r}+z_0\hat{\mathbf{e}}_z|}+\frac{\frac{R}{z_0}}{|\mathbf{r}+\frac{R^2}{z_0}\hat{\mathbf{e}}_z|}-\frac{\frac{R}{z_0}}{|\mathbf{r}-\frac{R^2}{z_0}\hat{\mathbf{e}}_z|}\right)\ .$$

The force acting on the charge follows from the gradient of the field of the three image charges at the position of Q,

$$\mathbf{F}(\mathbf{r}=z_0\hat{\mathbf{e}}_z) = -\nabla\frac{1}{4\pi\varepsilon_0}\sum_{k=1}^{3}\frac{Q_k}{|\mathbf{r}-z_k\hat{\mathbf{e}}_z|}$$

$$= \frac{-Q}{4\pi\varepsilon_0}\hat{\mathbf{e}}_z\left(-\frac{2z_0}{|z_0\hat{\mathbf{e}}_z+z_0\hat{\mathbf{e}}_z|^3}+\frac{\frac{R}{z_0}(z_0+\frac{R^2}{z_0})}{|z_0\hat{\mathbf{e}}_z+\frac{R^2}{z_0}\hat{\mathbf{e}}_z|^3}-\frac{\frac{R}{z_0}(z_0-\frac{R^2}{z_0})}{|z_0\hat{\mathbf{e}}_z-\frac{R^2}{z_0}\hat{\mathbf{e}}_z|^3}\right)$$

$$= \frac{-Q}{4\pi\varepsilon_0}\left(-\frac{1}{4z_0^2}+\frac{Rz_0}{(z_0^2+R^2)^2}-\frac{Rz_0}{(z_0^2-R^2)^2}\right) = \frac{Q}{4\pi\varepsilon_0}\left(\frac{1}{4z_0^2}+\frac{4R^3z_0^3}{(z_0^4-R^4)^2}\right) > 0\ .$$

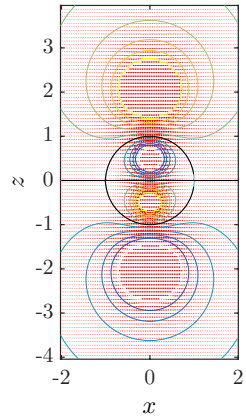

Figure 13.25: Mirror charge.

Therefore, the force is attractive.

13.5.6.5 Ex: Mirror charge

Consider a hollow conducting sphere with radius R whose center is at the origin. At the position with the vector $\mathbf{a}$ ($|\mathbf{a}| > R$) be a point charge q.
a. The sphere is grounded (that is, $\Phi = 0$ at the edge of the hollow sphere). Calculate the potential outside the sphere using the image charge method.
b. Calculate the charge induced on the surface of the sphere.
c. What changes when the sphere is not grounded, but neutral?

Solution:

13.5.6.6 Ex: Point charges in front of a conductor

Consider a point charge Q located at a distance d in front of an infinitely extended conductive plane.
a. Find the parametrization $\varrho(\mathbf{r})$ of the volume charge distribution for the charge and its image.
b. Calculate the potential from the distribution $\varrho(\mathbf{r})$.
c. Calculate the electric field from the distribution $\varrho(\mathbf{r})$.
d. Calculate the surface charge distribution $\sigma(\rho)$ induced in the conductor using Gauss' law.
e. Calculate the potential $\Phi(z)$ along the z-axis from Coulomb's law using the surface charge distribution $\sigma(\rho)$.
f. Compare the result obtained in (e) with the potential produced by the image charge calculated in (b).
Help:: $\int \frac{1}{\sqrt{u^2+a^2}^3} \frac{1}{\sqrt{u^2+b^2}} u du = \frac{1}{a^2-b^2} \sqrt{\frac{u^2+b^2}{u^2+a^2}}$

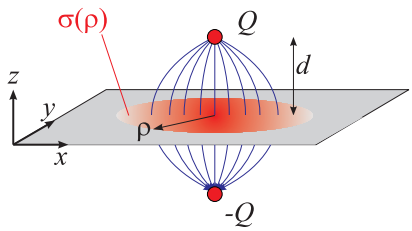

Figure 13.26: Mirror charge.

Solution: *a. We invent a second charge on the other side of the conductive plane, such that the volume charge distribution is,*

$$\varrho(\mathbf{r}) = Q[\delta^3(\mathbf{r} - d\hat{\mathbf{e}}_z) - \delta^3(\mathbf{r} + d\hat{\mathbf{e}}_z)] \ .$$

b. The potential becomes,

$$\begin{aligned}\Phi(\mathbf{r}) &= \frac{1}{4\pi\varepsilon_0}\int_{\mathcal{V}} \frac{\varrho(\mathbf{r}')dV'}{|\mathbf{r}-\mathbf{r}'|} = \frac{1}{4\pi\varepsilon_0}\int_{\mathcal{V}} \frac{Q\left[\delta^3(\mathbf{r} - d\hat{\mathbf{e}}_z) - \delta^3(\mathbf{r} + d\hat{\mathbf{e}}_z)\right]}{|\mathbf{r}-\mathbf{r}'|}dV' \\ &= \frac{1}{4\pi\varepsilon_0}\left(\frac{Q}{|\mathbf{r} - d\hat{\mathbf{e}}_z|} - \frac{Q}{|\mathbf{r} + d\hat{\mathbf{e}}_z|}\right) \ .\end{aligned}$$

c. The field becomes,

$$\vec{\mathcal{E}}(\mathbf{r}) = \frac{1}{4\pi\varepsilon_0}\int_{\mathcal{V}} \frac{\mathbf{r}-\mathbf{r}'}{|\mathbf{r}-\mathbf{r}'|^3}\varrho(\mathbf{r}')dV' = \frac{Q}{4\pi\varepsilon_0}\left(\frac{\mathbf{r} - d\hat{\mathbf{e}}_z}{|\mathbf{r} - d\hat{\mathbf{e}}_z|^3} - \frac{\mathbf{r} + d\hat{\mathbf{e}}_z}{|\mathbf{r} + d\hat{\mathbf{e}}_z|^3}\right) \ .$$

d. With Gauss' law we calculate,

$$\begin{aligned}\frac{1}{\varepsilon_0}\int_0^{2\pi}\int_0^{\infty}\sigma(\rho)\rho d\rho d\phi = \frac{Q}{\varepsilon_0} &= \int_{\mathcal{V}} \nabla\cdot\vec{\mathcal{E}}(\mathbf{r})dV = \oint_{\partial\mathcal{V}} \vec{\mathcal{E}}(\mathbf{r})\cdot d\mathbf{S} \\ &= \frac{Q}{4\pi\varepsilon_0}\int_0^{2\pi}\int_0^{\infty}\left(\frac{\rho\hat{\mathbf{e}}_\rho\cdot\hat{\mathbf{e}}_z - d}{|\rho\hat{\mathbf{e}}_\rho - d\hat{\mathbf{e}}_z|^3} - \frac{\rho\hat{\mathbf{e}}_\rho\cdot\hat{\mathbf{e}}_z + d}{|\rho\hat{\mathbf{e}}_\rho + d\hat{\mathbf{e}}_z|^3}\right)\rho d\rho d\phi \\ &= \frac{Q}{4\pi\varepsilon_0}\int_0^{2\pi}\int_0^{\infty}\left(\frac{-d}{\sqrt{\rho^2+d^2}^3} - \frac{d}{\sqrt{\rho^2+d^2}^3}\right)\rho d\rho d\phi \ ,\end{aligned}$$

such that,

$$\sigma(\rho) = \frac{-2dQ}{4\pi\sqrt{\rho^2+d^2}^3} \ .$$

e. The potential produced by the distribution of surface charge is, for $z \geq 0$,

$$\begin{aligned}\Phi_+(z) &= \frac{1}{4\pi\varepsilon_0}\oint_{\partial V}\frac{\sigma(\mathbf{r}')}{|\mathbf{r}-\mathbf{r}'|}dA' = \frac{1}{4\pi\varepsilon_0}\int_0^{2\pi}\int_0^{\infty}\frac{1}{|z\hat{\mathbf{e}}_z - \mathbf{r}'|}\frac{-2dQ}{4\pi\sqrt{\rho'^2+d^2}^3}\rho' d\rho' d\phi' \\ &= \frac{1}{4\pi\varepsilon_0}\frac{-2dQ}{4\pi}2\pi\int_0^{\infty}\frac{1}{\sqrt{z^2+\rho'^2}}\frac{1}{\sqrt{\rho'^2+d^2}^3}\rho' d\rho' = -\frac{Q}{4\pi\varepsilon_0}\frac{1}{d+z} \ ,\end{aligned}$$

using the given integral formula.
f. From the result obtained in (b) we find the same result for the potential produced by the image load along the z-axis,

$$\Phi(z) = -\frac{1}{4\pi\varepsilon_0}\frac{Q}{|z\hat{\mathbf{e}}_z + d\hat{\mathbf{e}}_z|} = -\frac{1}{4\pi\varepsilon_0}\frac{Q}{|z+d|} \ .$$

13.5.6.7 Ex: Dirichlet boundary conditions by the Green method

Here we want to analyze the problem of a potential in the semi-space defined by $z \geq 0$ with Dirichlet boundary conditions in the $z = 0$-plane and at infinity.
a. Determine the corresponding Greens function.
b. The potential has in the $z = 0$-plane within a circle of radius a the fixed value Φ_0. Outside this circle and on the same plane the potential is $\Phi = 0$. Derive the integral expression for the potential at a point in the upper semi-space with the cylindrical coordinates (ρ, ϕ, z).
c. Now show that the potential along an axis perpendicularly traversing the center of the circle is given by $\Phi(z) = \Phi_0(1 - z/\sqrt{a^2 + z^2})$.

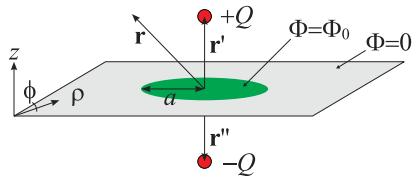

Figure 13.27: Green's function.

Solution: *a. Be* $\mathbf{r} = (x, y, z) = (\rho\cos\varphi, \rho\sin\varphi, z)$ *the position vector of an arbitrary point in the upper semi-space. For the establishment of the Green function, we consider a test charge* $q = +1$ *at a point in the upper semi-space given by the vector* $\mathbf{r}' = (\rho'\cos\varphi', \rho'\sin\varphi', z')$*, together with the corresponding image charge* $q = -1$ *at the* $\mathbf{r}'' = (\rho'\cos\varphi', \rho'\sin\varphi', -z')$ *of the lower semi-space. In this case,*

$$G(\mathbf{r}, \mathbf{r}') = \frac{1}{4\pi|\mathbf{r} - \mathbf{r}'|} - \frac{1}{4\pi|\mathbf{r} - \mathbf{r}''|}$$
$$= \frac{1}{4\pi\sqrt{\rho^2 + \rho'^2 - 2\rho\rho'\cos(\varphi - \varphi') + (z - z')^2}} - \frac{1}{4\pi\sqrt{\rho^2 + \rho'^{\,2} - 2\rho\rho'\cos(\varphi - \varphi') + (z + z')^2}} \ .$$

b. For the Dirichlet boundary problem,

$$\Phi(\mathbf{r}) = -\int_F \Phi(\rho', \varphi', 0)\left(-\frac{\partial G}{\partial z'}\right)_{z'=0} \rho' d\rho' d\varphi'$$
$$= \frac{1}{2\pi}\int_F d\varphi' d\rho' \rho' \Phi(\rho', \varphi', 0)\frac{z}{(\rho^2 + \rho'^2 - 2\rho\rho'\cos(\varphi - \varphi') + z^2)^{3/2}} \ .$$

From this follows,

$$\Phi(\rho,\varphi,z)=\frac{1}{2\pi}\int_0^{2\pi}d\varphi'\int_0^a d\rho'\rho'\frac{\Phi_0 z}{(\rho^2+\rho'^{\,2}-2\rho\rho'\cos(\varphi-\varphi')+z^2)^{3/2}}\ .$$

c. Now we let $\rho=0$ (z-axis). Then,

$$\Phi(0,\varphi,z)=\frac{1}{2\pi}\int_0^{2\pi}d\varphi'\int_0^a d\rho'\rho'\frac{\Phi_0 z}{(\rho'^{\,2}+z^2)^{3/2}}=\Phi_0 z\int_0^a\frac{d\rho'\rho'}{(\rho'^{\,2}+z^2)^{3/2}}$$
$$=\Phi_0 z\left[\frac{-1}{\sqrt{\rho'^{\,2}+z^2}}\right]_{\rho'=0}^{\rho'=a}=\Phi_0 z\left[\frac{1}{z}-\frac{1}{\sqrt{z^2+a^2}}\right]=\Phi_0\left[1-\frac{z}{\sqrt{z^2+a^2}}\right]\ .$$

13.5.6.8 Ex: Conductor plates with mirror charges by the Green method

We consider two flat conductive plates (infinitely extended) with the mutual distance L. Exactly in the middle between the plates there is a point charge $+q$. Use the method of an infinite series of mirror images to calculate the potential between the plates and the force on a plate.

Solution: *We place the z-axis perpendicular to the two conductive plates and through the charge $+q$. At the position of the charge we set $z=0$. The mirror charges must then adopt at $\pm L$ the value $-q$, at $\pm 2L$ the value $+q$, etc. With that, we get for the Green's function (and therefore for the potential),*

$$G=\Phi(x,y,z)=\sum_{m=-\infty}^{m=+\infty}\frac{(-)^m}{\sqrt{x^2+y^2+(z-mL)^2}}$$

The Coulomb force on the right plate is then equal to the sum of the forces exerted by the real charge and the image charges on the left side ($z<0$) on the mirror charges on the right side. For $z\le 0$ we have charges $q(-)^n$ at $z=-Ln$ for $n=0,1,2,....$ For $z>0$ $q(-)^m$ at $z=+Lm$ for $m=1,2,3,....$ For the force between n-th left charge and all the right charges m then holds,

$$F_n=q(-)^n\sum_{m=1}^{\infty}\frac{q(-)^m}{[L(m+n)]^2}$$

With that we get,

$$F=\sum_{n=0}^{\infty}F_n=\sum_{n=0}^{\infty}\sum_{m=1}^{\infty}\frac{q^2(-)^{n+m}}{L^2(m+n)^2}=\frac{q^2}{L^2}\sum_{s=1}^{\infty}\sum_{m=1}^{s}\frac{(-)^s}{s^2}=\frac{q^2}{L^2}\sum_{s=1}^{\infty}\frac{(-)^s}{s}=\frac{q^2}{L^2}\ln 2\ .$$

13.5.6.9 Ex: Hollow sphere by the Green method

We consider an infinitely thin conductive hollow sphere with radius a. In spherical coordinates, the potential on the surface of the sphere is given by $\Phi(a,\theta,\phi)=\Phi_0\cos\theta$.
a. Calculate, using the Green function for the sphere, the potential and the field inside the sphere on the z-axis.
b. Show that $\Phi(r,\theta,\phi)=\Phi_0(r/a)\cos\theta$ is the solution for the interior of the sphere and that $\vec{\mathcal{E}}(\mathbf{r})=-(\Phi_0/a)\hat{\mathbf{e}}_z$.

Solution: *a. Green's function inside the sphere is*

$$G(\mathbf{r},\mathbf{r}')=\frac{1}{4\pi|\mathbf{r}-\mathbf{r}'|}-\frac{a}{4\pi r'|\mathbf{r}-\frac{a^2}{r'^2}\mathbf{r}'|}\ .$$

Letting $\mathbf{r}$ *point in* z*-direction we get,*

$$G=\frac{1}{4\pi\sqrt{r^2+r'^2-2rr'\cos\vartheta'}}-\frac{1}{4\pi\sqrt{\frac{r^2r'^{\ 2}}{a^2}+a^2-2rr'\cos\vartheta'}}\ .$$

So, inside the sphere on the z*-axis,*

$$\Phi_\pm(\mathbf{r})=\pm\int_F\Phi(\mathbf{r}')\frac{\partial G(\mathbf{r},\mathbf{r}')}{\partial r'}\,df'\ .$$

On the other hand,

$$\left.\frac{\partial G(\mathbf{r},\mathbf{r}')}{\partial r'}\right|_{r'=a}=\frac{r^2-a^2}{a\sqrt{r^2+a^2-2ra\cos\vartheta'}^3}\ ,$$

where the $\pm$ *index indicates* r *going to* $\pm z$*. With that we get,*

$$\begin{aligned}\Phi_\pm&=\pm\frac{1}{4\pi}\int_F V_0\cos\vartheta'\frac{r^2-a^2}{a\sqrt{r^2+a^2-2ra\cos\vartheta'}^3}a^2\sin\vartheta'd\vartheta'd\varphi'\\&=\pm\frac{V_0}{2}a(a^2-r^2)\int_{-1}^{+1}\frac{xdx}{(r^2+a^2-2arx)^{3/2}}=\pm\frac{V_0}{2}a(a^2-r^2)\left[\frac{1}{r^2a^2}\frac{-rax+a^2+r^2}{\sqrt{r^2+a^2-2rax}}\right]_{-1}^{+1}\\&=\pm\frac{(a^2-r^2)V_0}{2r^2a}\left[\frac{-ra+a^2+r^2}{a-r}-\frac{ra+a^2+r^2}{a+r}\right]=\pm\frac{r}{a}V_0\ .\end{aligned}$$

Here it is important to have, in both cases, positive roots (for this reason we chose $a-r$ *and not* $r-a$*, which would give the solution in outer space). Since* $\Phi=V_0\cos\vartheta$ *is given, we have that the sign* $+$ *holds for* $\vartheta=0$*, and the sign* $-$ *for* $\vartheta=\pi$*.*
b. We let,

$$\Phi(\mathbf{r})=\frac{V_0}{a}r\cos\vartheta\ ,$$

and hence,

$$\vec{\mathcal{E}}(\mathbf{r})=-\frac{V_0}{a}\hat{\mathbf{e}}_z\ .$$

Here we use the Laplace operator in spherical coordinates. So on the surface of the spheres holds,

$$\Delta\Phi = \frac{1}{r^2}\frac{\partial}{\partial r}\left(r^2\frac{\partial\Phi}{\partial r}\right) + \frac{1}{r^2\sin\vartheta}\frac{\partial}{\partial\vartheta}\left(\sin\vartheta\frac{\partial\Phi}{\partial\vartheta}\right) = \frac{\frac{2V_0}{a}\cos\vartheta}{r} - \frac{\frac{2V_0}{a}\cos\vartheta}{r} = 0 \ .$$

Using the gradient in spherical coordinates and replacing the corresponding unit vectors by Cartesian ones, we obtain immediately,

$$\vec{\mathcal{E}}(\mathbf{r}) = -\frac{V_0}{a}\hat{\mathbf{e}}_z \ .$$

13.5.6.10 Ex: Unambiguity of the solution of the contour problem

Show that with the Dirichlet boundary condition $\Phi(\mathbf{r}) = \Phi_0(\mathbf{r})|_{\in\partial V}$ or the von Neumann boundary condition $\frac{\partial\Phi}{\partial n}\big|_{\partial V} = -\frac{\sigma}{\varepsilon_0}$ within the region of the volume V the potential Φ is unambiguously determined by the Poisson equation $\Delta\Phi = -\frac{1}{\varepsilon_0}\rho(\mathbf{r})$and a constant.

Solution: *Be $\Phi_1(\mathbf{r})$ and $\Phi_2(\mathbf{r})$ solutions of the Poisson equation with*

$$\Phi_1(\mathbf{r}) \equiv \Phi_2(\mathbf{r}) \qquad on \qquad \partial V \ ,$$

respectively

$$\frac{\partial\Phi_1}{\partial n} \equiv \frac{\partial\Phi_2}{\partial n} \qquad on \qquad \partial V \ .$$

For the potential $\Psi(\mathbf{r}) = \Phi_1(\mathbf{r}) - \Phi_2(\mathbf{r})$ then holds $\Delta\Psi \equiv 0$ with

$$\Psi|_{\partial V} \equiv 0 \qquad resp. \qquad \frac{\partial\Psi}{\partial n}\bigg|_{\partial V} \ .$$

We consider,

$$\int_V \nabla(\Psi\nabla\Psi)d^3r = \int_V \Psi\Delta\Psi d^3r + \int_V (\nabla\Psi)\cdot(\nabla\Psi)d^3r = \int_V (\nabla\Psi)\cdot(\nabla\Psi)d^3r \ ,$$

and, with the Gauß theorem,

$$\int_V \nabla(\Psi\nabla\Psi)d^3r = \oint_{\partial V} \Psi(\nabla\Psi)\cdot d\mathbf{F} = 0 \ ,$$

because according to the boundary condition, on the border $\Psi = 0$ (Dirichlet) respectively $\nabla\Psi\cdot d\mathbf{F} = 0$ (von Neumann). But since $(\nabla\Psi)^2 \geq 0$, necessarily everywhere $(\nabla\Psi) = 0$, that is, Ψ must be constant. For the Dirichlet boundary condition, the constant must disappear, because $\Psi|_{\partial V} = 0$, that is,

$$\Phi_1 = \Phi_2 \ .$$

For von Neumann's boundary condition,

$$\Phi_1 = \Phi_2 + const \ .$$

13.6 Solution of the Laplace equation in situations of high symmetry

The Poisson (or Laplace) equation is a second order partial differential equation, which depends on three spatial coordinates. Many situations are characterized by symmetries, which allow us to disregard some spatial dimensions and dramatically simplify the mathematical problem. In the following, we will discuss situations of Cartesian, cylindrical and spherical symmetry.

13.6.1 Variable separation in Cartesian coordinates

In situations where the symmetry of the problem suggests a separation of the Cartesian variables, we can make the ansatz,

$$\Phi(\mathbf{r}) = X(x)Y(y)Z(z) \ . \tag{13.73}$$

In Cartesian coordinates the Laplace equation is written,

$$\left[\frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} + \frac{\partial^2}{\partial z^2}\right]\Phi = 0 \ . \tag{13.74}$$

Inserting the ansatz into the Laplace equation and dividing by Φ,

$$\frac{1}{X}\frac{\partial^2 X}{\partial x^2} + \frac{1}{Y}\frac{\partial^2 Y}{\partial y^2} + \frac{1}{Z}\frac{\partial^2 Z}{\partial z^2} = 0 \ . \tag{13.75}$$

The three terms are functions of different variables and must therefore be constant independently and separately,

$$\frac{1}{X}\frac{\partial^2 X}{\partial x^2} = C_1 \quad , \quad \frac{1}{Y}\frac{\partial^2 Y}{\partial y^2} = C_2 \quad , \quad \frac{1}{Z}\frac{\partial^2 Z}{\partial z^2} = C_3 = -C_1 - C_2 \ . \tag{13.76}$$

The advantage of this procedure is that, the differential equations for the three spatial coordinates being decoupled, we can be solve them separately. In the best case, the field is homogeneous in one of the coordinates, which reduces the dimensionality of the problem.

Example 51 (*Field of a grounded board*): For example, to calculate the field of a plate held at a fixed potential Φ_0 and being infinitely extended in the x-y-plane, we can let $X'(x) = Y'(y) = 0$ and solve the equation,

$$\frac{\partial^2 Z}{\partial z^2} = 0 \ , \tag{13.77}$$

which gives, $\Phi(\mathbf{r}) = Z(z) = Cz + \Phi_0$ and $\vec{\mathcal{E}} = C\hat{\mathbf{e}}_z$. The constants C and Φ_0 must be specified by additional boundary conditions. See Exc. 13.6.4.1.

13.6.2 Variable separation in cylindrical coordinates

In situations where the symmetry of the problem suggests a possible separation of cylindrical variables, we can try the ansatz,

$$\Phi(\mathbf{r}) = R(r)F(\phi)Z(z) \ . \tag{13.78}$$

In cylindrical coordinates the Laplace equation is written,

$$\left[\frac{1}{\rho}\frac{\partial}{\partial\rho}\left(\rho\frac{\partial}{\partial\rho}\right) + \frac{1}{\rho^2}\frac{\partial^2}{\partial\phi^2} + \frac{\partial^2}{\partial z^2}\right]\Phi = 0 \ . \tag{13.79}$$

Inserting the ansatz into the Laplace equation and dividing by Φ,

$$\frac{1}{R\rho}\frac{\partial}{\partial\rho}\left(\rho\frac{\partial R}{\partial\rho}\right) + \frac{1}{F}\frac{\partial^2 F}{\partial\phi^2} + \frac{1}{Z}\frac{\partial^2 Z}{\partial z^2} = 0 \ . \tag{13.80}$$

The three terms are functions of different variables and must therefore be constant separately,

$$\frac{1}{R\rho}\frac{\partial}{\partial\rho}\left(\rho\frac{\partial R}{\partial\rho}\right) = C_1 \quad , \quad \frac{1}{F}\frac{\partial^2 F}{\partial\phi^2} = C_2 \quad , \quad \frac{1}{Z}\frac{\partial^2 Z}{\partial z^2} = C_3 = -C_1 - C_2 \ . \tag{13.81}$$

Example 52 (*Field of a straight wire*): Many geometries have cylindrical symmetry, such that the equations in θ and z become trivial. For example, to calculate the field of a straight and infinite wire maintained at a fixed potential, it is enough to solve a radial differential equation,

$$\frac{\partial}{\partial\rho}\left(\rho\frac{\partial R}{\partial\rho}\right) = 0 \ ,$$

which gives, $\Phi(\mathbf{r}) = R(\rho) = C\ln\rho + \Phi_0$ and $\vec{\mathcal{E}} = C\hat{\mathbf{e}}_\rho/\rho$. The constants C and Φ_0 must be specified by additional boundary conditions.

13.6.3 Variable separation in spherical coordinates

In situations where the symmetry of the problem suggests a possible separation of the spherical variables, we can try the make ansatz,

$$\Phi(\mathbf{r}) = R(r)T(\theta)F(\phi) \ . \tag{13.82}$$

In spherical coordinates the Laplace equation is written,

$$\left[\frac{1}{r^2}\frac{\partial}{\partial r}\left(r^2\frac{\partial}{\partial r}\right) + \frac{1}{r^2\sin\theta}\frac{\partial}{\partial\theta}\left(\sin\theta\frac{\partial}{\partial\theta}\right) + \frac{1}{r^2\sin^2\theta}\frac{\partial^2}{\partial\phi^2}\right]\Phi = 0 \ . \tag{13.83}$$

Inserting the ansatz into the Laplace equation and dividing by Φ,

$$\frac{1}{R}\frac{\partial}{\partial r}\left(r^2\frac{\partial R}{\partial r}\right) + \frac{1}{T\sin\theta}\frac{\partial}{\partial\theta}\left(\sin\theta\frac{\partial T}{\partial\theta}\right) + \frac{1}{Fr^2\sin^2\theta}\frac{\partial^2 F}{\partial\phi^2} = 0 \ . \tag{13.84}$$

The three terms are functions of different variables and must therefore be constant separately,

$$\frac{1}{R}\frac{\partial}{\partial r}\left(r^2\frac{\partial R}{\partial r}\right) = C_1 \quad , \quad \frac{1}{T\sin\theta}\frac{\partial}{\partial\theta}\left(\sin\theta\frac{\partial T}{\partial\theta}\right) = \ell(\ell+1) \tag{13.85}$$
$$\frac{1}{Fr^2\sin^2\theta}\frac{\partial^2 F}{\partial\phi^2} = m = -C_1 - \ell(\ell+1) \ .$$

Example 53 (*Sphere with fixed potential*): Many geometries have spherical symmetry, such that the equations in θ and ϕ become trivial. For example, to calculate the field of a sphere held at a fixed potential, we only have to solve a radial differential equation,

$$\frac{1}{R}\frac{\partial}{\partial r}\left(r^2\frac{\partial R}{\partial r}\right) = 0 \ ,$$

which gives, $\Phi(\mathbf{r}) = R(r) = -C/r + \Phi_0$ and $\vec{\mathcal{E}} = C\hat{\mathbf{e}}_r/r^2$. The constants C and Φ_0 must be specified by additional boundary conditions.

In case of *only azimuthal* symmetry, we have $m = 0$ and $C_1 = -\ell(\ell+1)$. The solutions of the radial equation are simple,

$$R(r) = A_\ell r^\ell + \frac{B_\ell}{r^{\ell+1}} \ . \tag{13.86}$$

The solutions of the angular equation are called *Legendre polynomials*,

$$T(\theta) = P_\ell(\cos\theta) \ . \tag{13.87}$$

They can be derived from the *Rodrigues formula*,

$$P_\ell(z) = \frac{1}{2^\ell \ell!}\left(\frac{d}{dz}\right)^\ell (z^2-1)^\ell \ . \tag{13.88}$$

The first polynomials are,

$$P_0(z) = 1 \quad , \quad P_1(z) = z \quad , \quad P_2(z) = \tfrac{1}{2}(3z^2-1) \quad , \quad P_3(z) = \tfrac{1}{2}(5z^3-3z) \ . \tag{13.89}$$

All in all we get,

$$\boxed{\Phi(\mathbf{r}) = \sum_{\ell=0}^{\infty}\left(A_\ell r^\ell + \frac{B_\ell}{r^{\ell+1}}\right)P_\ell(\cos\theta)} \ . \tag{13.90}$$

Example 54 (*Charged spherical layer*): In this example we consider a spherical shell carrying a surface charge described by $\sigma(\theta)$. The regions $r \le R$ and $r \ge R$ are treated separately. The ansatz (13.90) can not diverge, neither within the sphere where we must let $B_\ell = 0$, nor outside the sphere where we have to let $A_\ell = 0$. On the surface even the potential has to be continuous, such that

$$0 = [\Phi_\ge - \Phi_\le]_{r=R} = \sum_{\ell=0}^{\infty}\frac{B_l}{R^{\ell+1}}P_\ell(\cos\theta) - \sum_{\ell=0}^{\infty}A_\ell R^\ell P_\ell(\cos\theta) \ ,$$

resulting in $B_\ell = A_\ell R^{2\ell+1}$. On the other hand, the electric field is discontinuous,

$$-\frac{\sigma(\theta)}{\varepsilon_0} = \left[\frac{\partial\Phi_>}{\partial r} - \frac{\partial\Phi_<}{\partial r}\right]_{r=R} = \sum_{\ell=0}^{\infty}(2\ell+1)A_\ell R^{\ell-1}P_\ell(\cos\theta) \ .$$

The coefficients are,

$$A_\ell = \frac{1}{2\varepsilon_0 R^{\ell-1}}\int_0^\pi \sigma(\theta)P_\ell(\cos\theta)\sin\theta d\theta \ ,$$

which can be verified from the orthogonality relation,

$$\int_{-1}^{1} P_\ell(z)P_{\ell'}(z)dz = \frac{2\delta_{\ell,\ell'}}{2\ell+1} \ .$$

Particularly for the case $\sigma(\theta) = \sigma_0\cos\theta = \sigma_0 P_1(\cos\theta)$ we obtain,

$$A_\ell = \frac{\sigma_0}{2\varepsilon_0 R^{\ell-1}}\int_0^\pi P_1(z)P_l(z)dz = \frac{\sigma_0}{2\varepsilon_0 R^{\ell-1}}\frac{2}{2\ell+1}\delta_{\ell,1} = \frac{\sigma_0}{3\varepsilon_0}\delta_{\ell,1} \ .$$

Finally,

$$\Phi(\mathbf{r}) = \begin{cases} \frac{\sigma_0}{3\varepsilon_0} r\cos\theta = \frac{\sigma_0}{3\varepsilon_0}\mathbf{r}\cdot\hat{\mathbf{e}}_z & \text{for } \ r \le R \\ \frac{\sigma_0 R^3}{3\varepsilon_0}\frac{1}{r^2}\cos\theta = \frac{\sigma_0 R^3}{3\varepsilon_0}\frac{\mathbf{r}\cdot\hat{\mathbf{e}}_z}{r^3} & \text{for } \ r \ge R \end{cases} \ .$$

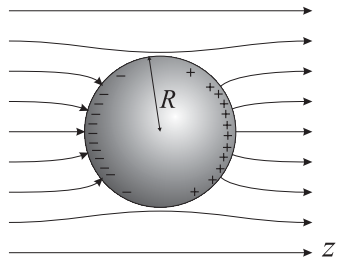

Figure 13.28: Distortion of a homogeneous field by a metallic sphere.

13.6.4 Exercises

13.6.4.1 Ex: Variable separation

Calculate the potential within an infinite rectangular waveguide in the z-direction by solving the Laplace equation using the variable separation method.

Solution: *After separating the variables,* $\Phi(\mathbf{r}) = X(x)Y(y)Z(z)$*, the Laplace equation in Cartesian coordinates becomes,*

$$\frac{1}{X}\frac{\partial^2 X}{\partial x^2} = k^2 \quad , \quad \frac{1}{Y}\frac{\partial^2 Y}{\partial y^2} = -k^2 \quad , \quad \frac{1}{Z}\frac{\partial^2 Z}{\partial z^2} = 0 \ .$$

This gives,

$$X(x) = Ae^{kx} + Be^{-kx} \quad , \quad Y(y) = C\sin ky + D\cos ky \quad , \quad Z(z) = Ez + F \ ,$$

where the amplitudes are fixed by the boundary conditions imposed by the waveguide, for example,

$$\Phi(x,y,z\to\infty)=0 \quad , \quad \Phi(x,y=0,z)=\Phi(x,y=b,z)=0 \quad , \quad \Phi(x=a,y,z)=\Phi(x=-a,y,z)$$

Satisfying the first two conditions,

$$\Phi = 2A\cosh\frac{n\pi x}{b}\sin\frac{n\pi y}{b} \ .$$

To satisfy the third condition we construct a linear combination,

$$\Phi = \sum_{n=1}^{\infty} 2A\cosh\frac{n\pi x}{b}\sin\frac{n\pi y}{b} \ ,$$

postulating,

$$\Phi(a,y,z) = \sum_{n=1}^{\infty} 2A\cosh\frac{n\pi a}{b}\sin\frac{n\pi y}{b} \equiv \Phi_0 \ .$$

It is possible to show by comparison with the Fourier expansion,

$$\Phi(x,y,z) = \frac{4\Phi_0}{\pi}\sum_{n=1,3,5,..}\frac{1}{n}\frac{\cosh n\pi x/b}{\cosh n\pi a/b}\sin\frac{n\pi y}{b} \ .$$

13.6.4.2 Ex: Field of a sphere with a hole

On the surface of a hollow sphere of radius R, from which a cap defined by the opening angle $\theta=\alpha$ was cut out at the north pole, there is a homogeneously distributed surface charge density $Q/4\pi R^2$.
a. Show that the potential within the volume of the sphere can be written in the form,

$$\Phi(r,\theta,\phi) = \frac{Q}{2}\sum_{\ell=0}^{\infty}\frac{1}{2\ell+1}\left[P_{\ell+1}(\cos\alpha)-P_{\ell-1}(\cos\alpha)\right]\ \frac{r^\ell}{R^{\ell+1}}\ P_\ell(\cos\theta)$$

where for $\ell=0$ we have to let $P_{\ell-1}(\cos\alpha)=-1$. What is the shape of the potential outside the hollow sphere?
b. Determine the absolute value and the direction of the electric field at the origin.
c. What potential do we get for $\alpha\to 0$?
Help: Use the following relation for the surface charge density:

$$-\frac{\sigma}{\varepsilon_0} = \left[\frac{\partial\Phi_>}{\partial r}-\frac{\partial\Phi_<}{\partial r}\right]_{r=R} \ ,$$

where the indices $<$ resp. $>$ hold for regions inside resp. outside the sphere. For the integration, the following recursion relation is useful,

$$P_l(x) = \frac{1}{2\ell+1}\left(\frac{dP_{\ell+1}(x)}{dx}-\frac{dP_{\ell-1}(x)}{dx}\right)$$

that holds for $\ell > 0$.

Solution: *a. The solutions inside and outside the hollow sphere must join together in a continuous manner at $r = R$. Therefore, the following Ansätze are valid,*

$$\Phi_>(r,\theta) = \sum_{\ell=0}^{\infty} A_\ell \left(\frac{R}{r}\right)^{\ell+1} P_\ell(\cos\theta) \quad , \quad \Phi_<(r,\theta) = \sum_{\ell=0}^{\infty} A_\ell \left(\frac{r}{R}\right)^{\ell} P_\ell(\cos\theta) \ .$$

Given the surface charge density,

$$\sigma(\cos\theta) = \begin{cases} \frac{Q}{4\pi R^2} & \text{when } \cos\theta < \cos\alpha \\ 0 & \text{else} \end{cases} \ .$$

Now we have Gauß' law,

$$\frac{\sigma}{\varepsilon_0} = \left[\frac{\partial\Phi_<}{\partial r} - \frac{\partial\Phi_>}{\partial r}\right]_{r=R} = \frac{1}{R}\sum_{\ell=0}^{\infty}(2\ell+1)A_\ell P_\ell(\cos\theta) \ .$$

Using the orthogonality of the Legendre polynomials, $(2\ell+1)\int_{-1}^{1} dx P_\ell(x)P_{\ell'}(x) = 2\delta_{\ell,\ell'}$, and the abbreviation $x = \cos\theta$ we apply the operation $\int_{-1}^{1} dx P_{\ell'}(x)...$ to both sides of the last equation,

$$\frac{1}{\varepsilon_0}\int_{-1}^{+1} dx\sigma(x)P_{\ell'}(x) = \frac{Q}{4\pi\varepsilon_0 R^2}\int_{-1}^{\cos\alpha} dx P_{\ell'}(x) = \frac{1}{R}\sum_{\ell=0}^{\infty}(2\ell+1)A_\ell \int_{-1}^{+1} dx P_\ell(x)P_{\ell'}(x) = \frac{2}{R}A_{\ell'} \ .$$

Therefore, we have for the expansion coefficients with the given relationship,

$$\begin{aligned} A_\ell &= \frac{Q}{8\pi\varepsilon_0 R}\int_{-1}^{\cos\alpha} dx P_\ell(x) = \frac{Q}{8\pi\varepsilon_0 R}\frac{1}{2\ell+1}\left[P_{\ell+1}(x) - P_{\ell-1}(x)\right]_{-1}^{\cos\alpha} \\ &= \frac{Q}{8\pi\varepsilon_0 R}\frac{1}{2\ell+1}\left(P_{\ell+1}(\cos\alpha) - P_{\ell-1}(\cos\alpha)\right) \ , \end{aligned}$$

at least for $\ell \neq 0$. But for $\ell = 0$ the integral is trivial: $\int_{-1}^{\cos\alpha} dx P_\ell(x) = \cos\alpha + 1 = P_1(\cos\alpha) - P_{-1}(\cos\alpha)$ with the definition of the problem. Insertion into our original Ansätze immediately gives the potential inside and outside the hollow sphere.
b. We have,

$$\vec{\mathcal{E}} = -\nabla\Phi = -\hat{\mathbf{e}}_r\frac{\partial\Phi}{\partial r} - \hat{\mathbf{e}}_\theta\frac{1}{r}\frac{\partial\Phi}{\partial\theta} + 0 = -\hat{\mathbf{e}}_r\frac{\partial\Phi}{\partial r} + \hat{\mathbf{e}}_\theta\frac{\sin\theta}{r}\frac{\partial\Phi}{\partial\cos\theta} \ .$$

Therefore, we have inside,

$$\vec{\mathcal{E}} = \frac{Q}{8\pi\varepsilon_0}\sum_{\ell=0}^{\infty}\frac{P_{\ell+1}(\cos\alpha) - P_{\ell-1}(\cos\alpha)}{2\ell+1}\frac{r^{\ell-1}}{R^{\ell+1}}\left[-\hat{\mathbf{e}}_r\ell P_\ell(\cos\theta) + \hat{\mathbf{e}}_\theta\sin\theta\frac{dP_\ell(x)}{dx}\right] \ .$$

For $r \to 0$ all terms with the exception of $\ell = 1$ disappear. We therefore have

$$\vec{\mathcal{E}}(\mathbf{r}=0) = \frac{Q}{6R^2}(P_2(\cos\alpha) - P_0(\cos\alpha))(-\hat{\mathbf{e}}_r\cos\theta + \hat{\mathbf{e}}_\theta\sin\theta) \ .$$

Now, $\hat{\mathbf{e}}_r \cos\theta - \hat{\mathbf{e}}_\theta \sin\theta = \hat{\mathbf{e}}_z$, $P_2(\cos\alpha) = (3\cos^2\alpha - 1)/2$ *and* $P_0(\cos\alpha) = 1$. *With that, we get for the electric field at the origin,*

$$\vec{\mathcal{E}}(\mathbf{r}=0) = -\frac{Q}{6R^2}\hat{\mathbf{e}}_z(\frac{3}{2}\cos^2\alpha - \frac{3}{2}) = \frac{Q}{4R^2}\sin^2\alpha\hat{\mathbf{e}}_z \ .$$

c. For $\alpha = 0$ *we have* $\cos\alpha = 1$ *and* $P_\ell(\cos\alpha) = P_\ell(1) = 1$. *With that, in our formulas for the potential, only the terms* $\ell = 0$ *survive:*

$$\Phi_<(\mathbf{r}) = \frac{Q}{4\pi\varepsilon_0 R} \quad , \quad \Phi_>(\mathbf{r}) = \frac{Q}{4\pi\varepsilon_0 r} \ .$$

This is the known result for a closed spherical layer.

13.7 Multipolar expansion

The basic idea of *multipolar expansion* is the approximate description of the potential generated by an arbitrary distribution of charges localized within a volume $\mathcal{V}$. The larger the distance between the observation point and the charge distribution in comparison to the extent of the volume $\mathcal{V}$, the more the potential looks like that of a point charge. The smaller the distance, the more terms (multipole moments) must be taken into account, $\Phi(\mathbf{r}) = \sum_k \Phi_k(\mathbf{r})$. High multipolar orders decay faster (like r^{-k}) with the distance between the observation point and the volume where the charge is concentrated.

We have already seen how to do the Taylor expansion of scalar fields in the formula (12.17) [9]. Here, we want to expand in terms of r^{-1}. We start by expanding the function,

$$\frac{1}{|\mathbf{r}-\mathbf{r}'|} = \frac{1}{r}\sum_{\ell=0}^{\infty}\left(\frac{r'}{r}\right)^\ell P_\ell(\cos\theta') \ , \tag{13.91}$$

where θ' is the angle between $\mathbf{r}$ and $\mathbf{r}'$. Inserting the expansion into Coulomb's law (13.35),

$$\Phi(\mathbf{r}) = \frac{1}{4\pi\varepsilon_0}\int\frac{\varrho(\mathbf{r}')}{|\mathbf{r}-\mathbf{r}'|}d^3r' = \frac{1}{4\pi\varepsilon_0}\sum_{\ell=0}^{\infty}\frac{1}{r^{\ell+1}}\int\varrho(\mathbf{r}')r'^\ell P_\ell(\cos\theta')d^3r' \ . \tag{13.92}$$

Example 55 (*Multipolar expansion by Legendre polynomials*): To discuss the multipolar expansion of the function $\frac{1}{|\mathbf{r}-\mathbf{r}'|}$ we chose the axis $\hat{\mathbf{r}}$ as the symmetry axis, as shown in Fig. 13.29, because in this coordinate system the function has azimuthal symmetry in the variable $\mathbf{r}'$. Therefore, we can apply the solution of the Laplace equation in spherical coordinates derived above,

$$\Phi(\mathbf{r}') = \sum_{\ell=0}^{\infty}\left(A_\ell r'^\ell + \frac{B_\ell}{r'^{\ell+1}}\right)P_\ell(\cos\theta') \ .$$

[9] Using the following property of the Legendre polynomials,

$$\frac{1}{\sqrt{1+\eta(\eta-2z)}} = \sum_\ell \eta^\ell P_\ell(z) \ ,$$

where the left side is called the generating function of the polynomials.

We consider two cases: In a first case in which $r' < r$, for the solution $\Phi(\mathbf{r}')$ to converge, we need to guarantee $B_\ell = 0$ such that,

$$\frac{1}{|\mathbf{r} - \mathbf{r}'|} = \sum_{\ell=0}^{\infty} A_\ell(r) r'^\ell P_\ell(\cos\theta') \ .$$

In the second case in which case $r' > r$, we need to ensure $A_\ell = 0$, such that,

$$\frac{1}{|\mathbf{r} - \mathbf{r}'|} = \sum_{\ell=0}^{\infty} \frac{B_\ell(r)}{r'^{\ell+1}} P_\ell(\cos\theta') \ ,$$

The coefficients $A_\ell(\mathbf{r})$ and $B_\ell(\mathbf{r})$ can not depend on $\mathbf{r}'$. Let us now have a closer look at this second case and rename the variables $\mathbf{r} \leftrightarrow \mathbf{r}'$:

$$\frac{1}{|\mathbf{r}' - \mathbf{r}|} = \sum_{\ell=0}^{\infty} \frac{B_\ell(r')}{r^{\ell+1}} P_\ell(\cos\theta) \ .$$

Comparing this to the first case and using $\theta = -\theta'$ we find,

$$A_\ell(r) r^{\ell+1} = \frac{B_\ell(r')}{r'^\ell} = const = C \ .$$

Hence,

$$\frac{1}{|\mathbf{r} - \mathbf{r}'|} = \sum_{\ell=0}^{\infty} C \frac{r'^\ell}{r^{\ell+1}} P_\ell(\cos\theta') \ .$$

The constant C can be calibrated considering a particular case, for example $\mathbf{r} \parallel \mathbf{r}'$ and $r \gg r'$. In this case, since $P_\ell(1) = 1$, the multipolar expansion,

$$\frac{1}{|\mathbf{r} - \mathbf{r}'|} = \frac{1}{|r - r'|} = \sum_{\ell=0}^{\infty} C \frac{r'^\ell}{r^{\ell+1}} \ ,$$

is nothing more than a Taylor expansion around the point $r - r' \simeq r$.

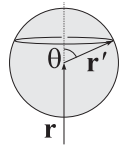

Figure 13.29: In the coordinate system $\hat{\mathbf{r}} = \hat{\mathbf{e}}_z$ the function $|\mathbf{r} - \mathbf{r}'|^{-1}$ has azimuthal symmetry.

13.7.1 The monopole

For $n = 0$ the contribution of the *monopole moment* Q to the potential is,

$$\boxed{\Phi_0(\mathbf{r}) = \frac{Q}{4\pi\varepsilon_0} \frac{1}{r}} \quad \text{where} \quad \boxed{Q = \int_{\mathcal{V}} d^3r' \ \varrho(\mathbf{r}')} \tag{13.93}$$

is just the electric charge.

13.7.2 The dipole

For $n = 1$ the contribution of the *electric dipole moment* $\mathbf{d}$ to the potential follows immediately from formula (13.91),

$$\begin{aligned}\Phi_1(r) &= \tfrac{1}{4\pi\varepsilon_0}\tfrac{1}{r^2}\int \varrho(\mathbf{r}')r' P_1(\cos\theta')d^3r' \\ &= \tfrac{1}{4\pi\varepsilon_0}\tfrac{1}{r^3}\int \varrho(\mathbf{r}')rr'\cos\theta' d^3r' = \tfrac{1}{4\pi\varepsilon_0}\tfrac{\mathbf{r}}{r^3}\cdot\int \varrho(\mathbf{r}')\mathbf{r}' d^3r' \ .\end{aligned}$$

We obtain,

$$\boxed{\Phi_1(\mathbf{r}) = \frac{1}{4\pi\varepsilon_0}\sum_k d_k\frac{x_k}{r^3}} \quad \text{where} \quad \boxed{\mathbf{d} = \int_{\mathcal{V}} d^3r' \ \mathbf{r}'\varrho(\mathbf{r}')} \ . \tag{13.94}$$

13.7.3 The quadrupole

For $n = 2$ the contribution of the *electric quadrupole moment* $q_{i,j}$ to the potential follows immediately from the formula(13.91),

$$\begin{aligned}\Phi_2(r) &= \tfrac{1}{4\pi\varepsilon_0}\tfrac{1}{r^3}\int \varrho(\mathbf{r}')r'^2 P_2(\cos\theta')d^3r' = \tfrac{1}{4\pi\varepsilon_0}\tfrac{1}{r^3}\int \varrho(\mathbf{r}')r'^2\tfrac{3\cos^2\theta'-1}{2}d^3r' \\ &= \tfrac{1}{4\pi\varepsilon_0}\tfrac{1}{2r^5}\int \varrho(\mathbf{r}')(3(\mathbf{r}\cdot\mathbf{r}')^2 - r^2r'^2)d^3r' \\ &= \tfrac{1}{4\pi\varepsilon_0}\tfrac{1}{2r^5}\sum_{k,m}\int \varrho(\mathbf{r}')(3x_kx'_kx_mx'_m - x_kx_mr'^2\delta_{k,m})d^3r' \ .\end{aligned}$$

We obtain,

$$\boxed{\Phi_2(\mathbf{r}) = \frac{1}{4\pi\varepsilon_0}\frac{1}{2}\sum_{k,m} q_{k,m}\frac{x_kx_m}{r^5}} \quad \text{where} \quad \boxed{q_{k,m} = \int_{\mathcal{V}} d^3r' \ (3x'_kx'_m - r'^2\delta_{k,m})\varrho(\mathbf{r}')} \ . \tag{13.95}$$

Example 56 (*Multipole moments of a dipole*): As an example, we consider the simplest dipole, which consists of two charges e and $-e$ separated by a fixed distance a, which we choose parallel to the z-axis. The monopolar moment is,

$$Q = \int d^3r' \ [e\delta(\tfrac{a}{2}\hat{\mathbf{e}}_z - \mathbf{r}') - e\delta(\tfrac{a}{2}\hat{\mathbf{e}}_z + \mathbf{r}')] = 0 \ ,$$

as expected. The dipole moment is,

$$\mathbf{d} = \int d^3r' \ \mathbf{r}'[e\delta(\tfrac{a}{2}\hat{\mathbf{e}}_z - \mathbf{r}') - e\delta(\tfrac{a}{2}\hat{\mathbf{e}}_z + \mathbf{r}')] = ea\begin{pmatrix}0\\0\\1\end{pmatrix} \ ,$$

and the quadrupolar moment is,

$$q_{k,m} = \int d^3r' \ (3x'_k x'_m - r'^2\delta_{km})[e\delta(\tfrac{a}{2}\hat{\mathbf{e}}_z - \mathbf{r}') - e\delta(\tfrac{a}{2}\hat{\mathbf{e}}_z + \mathbf{r}')]$$
$$= \frac{ea^2}{4}\begin{pmatrix} -1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & 2 \end{pmatrix} - \frac{ea^2}{4}\begin{pmatrix} -1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & 2 \end{pmatrix} = 0 \ .$$

See the Excs. 13.7.5.1 to 13.7.5.10.

Example 57 (*The electric dipole*): The gradient of the potential of a dipole is,

$$\vec{\mathcal{E}}_1 = -\nabla\frac{\mathbf{r}\cdot\mathbf{d}}{4\pi\varepsilon_0 r^3} = \frac{-1}{4\pi\varepsilon_0}\hat{\mathbf{e}}_x\frac{\partial}{\partial x}\frac{xd_x + yd_y + zd_z}{(x^2+y^2+z^2)^{3/2}} + ...$$
$$= \frac{-1}{4\pi\varepsilon_0}\hat{\mathbf{e}}_x\frac{d_x(x^2+y^2+z^2)^{3/2} - (xd_x + yd_y + zd_z)3x(x^2+y^2+z^2)^{1/2}}{(x^2+y^2+z^2)^3} + ...$$
$$= \frac{-1}{4\pi\varepsilon_0}\hat{\mathbf{e}}_x\frac{d_x r^2 - \mathbf{r}\cdot\mathbf{d}3x}{r^5} + ... = \frac{1}{4\pi\varepsilon_0}\frac{3(\hat{\mathbf{e}}_r\cdot\mathbf{d})\hat{\mathbf{e}}_r - \mathbf{d}}{r^3} \ .$$

13.7.4 Expansion into Cartesian coordinates

The multipolar expansion can also be done in Cartesian coordinates by a Taylor series of the Green function [10]. To take this into account, we evaluate the function $G(\mathbf{r},\mathbf{r}') = G(\mathbf{r}-\mathbf{r}')$ around the distance $\mathbf{r}-\mathbf{r}' \simeq \mathbf{r}$,

$$G(\mathbf{r}-\mathbf{r}') = \sum_k \frac{1}{k!}(\mathbf{r}'\cdot\nabla)^k G(\mathbf{r}) = G(\mathbf{r}) + \sum_{k=1} x'_k\frac{\partial}{\partial x_k}G(\mathbf{r}) + \frac{1}{2!}\left(\sum_{k=1}^{3} x'_k\frac{\partial}{\partial x_k}\right)^2 G(\mathbf{r}) + ... \tag{13.96}$$
$$= G(\mathbf{r}) + \sum_{k=1} x'_k\frac{\partial}{\partial x_k}G(\mathbf{r}) + \frac{1}{2!}\sum_{k,m=1}^{3} x'_k x'_m\frac{\partial^2}{\partial x_k\partial x_m}G(\mathbf{r}) + ...$$
$$= G(\mathbf{r}) + \sum_{k=1} x'_k\frac{\partial}{\partial x_k}G(\mathbf{r}) + \frac{1}{6}\sum_{k,m=1}^{3}(3x'_k x'_m - r'^2\delta_{k,m})\frac{\partial^2}{\partial x_k\partial x_m}G(\mathbf{r}) + ...$$

The last transformation is valid if the function G satisfies the Laplace equation, $\nabla^2 G = 0$.

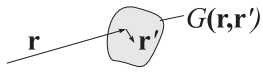

Figure 13.30: Taylor expansion of the Green function around the point $\mathbf{r}-\mathbf{r}' \simeq \mathbf{r}$.

[10] We can imagine the Green function as the potential created by a point-charge distribution, $\varrho(\mathbf{r}') = Q\delta(\mathbf{r}-\mathbf{a})$, since $\Phi(\mathbf{r}) = \int G(\mathbf{r}-\mathbf{r}')\varrho(\mathbf{r}')dV' = QG(\mathbf{r}'-\mathbf{a})$. That is, the multipolar terms come into play due to a small stretching of the charge distribution around the point $\mathbf{r}' = \mathbf{a}$

Example 58 (*Cartesian multipolar expansion*): As an example, we expand the Coulomb potential, $G(\mathbf{r}-\mathbf{r}') = \frac{1}{|\mathbf{r}-\mathbf{r}'|}$. The first derivatives,

$$\frac{\partial}{\partial x_k}\frac{1}{|\mathbf{r}-\mathbf{r}'|} = \frac{x_k - x_k'}{|\mathbf{r}-\mathbf{r}'|^3} \ ,$$

and the second derivatives,

$$\frac{\partial^2}{\partial x_k \partial x_m}\frac{1}{|\mathbf{r}-\mathbf{r}'|} = \frac{3(x_k-x_k')^2 - (\mathbf{r}-\mathbf{r}')^2\delta_{k,m}}{|\mathbf{r}-\mathbf{r}'|^5} \ ,$$

allow us to calculate,

$$\frac{1}{|\mathbf{r}-\mathbf{r}'|} = \frac{1}{r} + \frac{\mathbf{r}\cdot\mathbf{r}'}{r^3} + \frac{1}{6}\sum_{k,m=1}^{3}\frac{3x_kx_m - r^2\delta_{k,m}}{r^5}(3x_k'x_m' - r'^2\delta_{k,m}) \ .$$

The octupolar term of the multipole expansion of the Coulomb potential is,

$$\frac{1}{3!}(\mathbf{r}'\cdot\nabla)^3\frac{1}{r'} = \frac{1}{6}\sum_{k,m,n=1}^{3} x_k'x_m'x_n'\frac{-15x_kx_mx_n + 3r''(x_k\delta_{mn} + x_m\delta_{kn} + x_n\delta_{mk})}{r^7} \ .$$

Inserting this into Coulomb's Law,

$$\Phi(\mathbf{r}) = \frac{1}{4\pi\varepsilon_0}\int\frac{\varrho(\mathbf{r}')}{|\mathbf{r}-\mathbf{r}'|}dV' = \frac{1}{4\pi\varepsilon_0}\left(\frac{1}{r}Q + \frac{\mathbf{r}}{r^3}\cdot\mathbf{d} + \frac{1}{6}\sum_{k,m=1}^{3}\frac{3x_kx_m - r^2\delta_{k,m}}{r^5}q_{k,m} + ...\right) \ ,$$

with the definitions of the multipole moments.

13.7.5 Exercises

13.7.5.1 Ex: Multipoles

A point charge $+2Q$ is at the position $(0,0,a)$ and another charge $+1Q$ at the position $(0,0,-a)$. Calculate a. The monopolar, b. the dipolar, and c. the quadrupolar contribution of the multipolar expansion.

Solution: *a. The charge distribution is parametrized by* $\rho(\mathbf{r}) = 2Q\delta(x)\delta(y)\delta(z-a) + Q\delta(x)\delta(y)\delta(z+a)$. *So, the monopolar moment is,*

$$Q = \int\rho(\mathbf{r})d^3r = 3Q \ .$$

b. The dipole moment is,

$$\begin{aligned}\mathbf{d} &= \int\mathbf{r}\rho(\mathbf{r})d^3r = 2Q\int\mathbf{r}\delta(x)\delta(y)\delta(z-a)d^3r + Q\int\mathbf{r}\delta(x)\delta(y)\delta(z+a)d^3r \\ &= 2Qa\hat{\mathbf{e}}_z + Q(-a)\hat{\mathbf{e}}_z = Qa\hat{\mathbf{e}}_z \ .\end{aligned}$$

c. The quadrupole moment is $q_{ij} = \int\left(3x_ix_j - r^2\delta_{ij}\right)\rho(\mathbf{r})d^3r$. *In particular,*

$$\begin{aligned}q_{11} = q_{22} &= 2Q\int(3x^2-r^2)\delta(x)\delta(y)\delta(z-a)d^3r + Q\int(3x^2-r^2)\delta(x)\delta(y)\delta(z+a)d^3r \\ &= -3Qa^2 \ , \\ q_{33} &= 2Q\int(3z^2-r^2)\delta(x)\delta(y)\delta(z-a)d^3r + Q\int(3z^2-r^2)\delta(x)\delta(y)\delta(z+a)d^3r = 6Qa^2 \ , \\ q_{12} &= 0 \ .\end{aligned}$$

13.7.5.2 Ex: Di- and quadrupolar momenta of spherical charge distributions

Do spherically symmetrical load distributions have dipole or quadrupolar moments? Justify!

Solution: *Spherically symmetrical distributions appear, outside the volume by which they are confined, as point charges and, therefore, can be completely described by the monopolar moment, that is, they have neither dipole nor quadrupolar moment.*

13.7.5.3 Ex: Electric dipole

An electrical dipole consists of two charges of the value $q = 1.5\,\mathrm{nC}$ distant by $a = 6\,\mu\mathrm{m}$.
a. What is the dipole moment?
b. Calculate the dipole potential along the $\hat{\mathbf{e}}_z$ axis of symmetry and in the xy-plane.
c. The dipole is in an $1100\,\mathrm{N/C}$ electric field. What is the difference in potential energies comparing parallel and antiparallel orientations of the dipole.

Solution: *a. With* $\rho(\mathbf{r}) = q\delta(\mathbf{r} - \mathbf{a}/2) - q\delta(\mathbf{r} + \mathbf{a}/2)$ *the charge is,*

$$Q = \int \rho(\mathbf{r}) d^3r = 0 \ .$$

The dipole moment is,

$$\mathbf{a} = \int \mathbf{r}\rho(\mathbf{r}) d^3r = q\mathbf{a} = 9 \cdot 10^{-15}\,\mathrm{Cm} \ .$$

b. The potential is,

$$\Phi(\mathbf{r}) = \frac{1}{4\pi\varepsilon_0} \frac{q}{|\mathbf{r} - \mathbf{a}/2|} - \frac{1}{4\pi\varepsilon_0} \frac{q}{|\mathbf{r} + \mathbf{a}/2|} \ .$$

Along the z-axis we have for $z \notin [-d/2, d/2]$

$$\Phi(0,0,z) = \frac{\pm q}{4\pi\varepsilon_0} \left(\frac{1}{z - a/2} - \frac{1}{z + a/2} \right) = \frac{\pm q}{4\pi\varepsilon_0} \frac{a}{z^2 - a^2/4} \ .$$

Along the z-axis we have for $z \in [-d/2, d/2]$

$$\Phi(0,0,z) = \frac{-q}{4\pi\varepsilon_0} \left(\frac{1}{a/2 - z} - \frac{1}{\sqrt{z + a/2}} \right) = \frac{q}{4\pi\varepsilon_0} \frac{2z}{z^2 - a^2/4} \ .$$

In the x-y-plane we have,

$$\Phi(x,y,0) = \frac{q}{4\pi\varepsilon_0} \left(\frac{1}{\sqrt{x^2 + y^2 + a^2/4}} - \frac{1}{\sqrt{x^2 + y^2 + a^2/4}} \right) = 0 \ .$$

c. The energy of the dipole in the electric field is,

$$E_\pm = -\mathbf{d}\cdot\vec{\mathcal{E}}_\pm = \mp aE \ .$$

With that, the energy difference is $E_+ - E_- = 2aE = 1.8\cdot 10^{-11}\,\mathrm{Cm}$.

13.7.5.4 Ex: Electric dipole

An electric dipole with the moment $\mathbf{d}$ is at the position $\mathbf{r}$. At the origin of the coordinate system there is a point charge e.
a. Calculate the potential energy of the dipole.
b. Calculate the force acting on the dipole.
c. Calculate the force acting on the charge. Is Newton's axiom of mechanics valid: 'actio = reactio'?

Solution: *a. The potential energy of the dipole* $\mathbf{d} = q\mathbf{a}$ *can be calculated from the charge of the dipole in the field of the electron,*

$$\begin{aligned} E_{d,pot} &= \tfrac{1}{2}\int d^3r'\ \rho_d(\mathbf{r}')\Phi_e(\mathbf{r}') = \frac{1}{4\pi\varepsilon_0}\frac{1}{2}\int d^3r'\ \left(q\delta^3(\mathbf{a}/2) - q\delta^3(-\mathbf{a}/2)\right)\frac{e}{|\mathbf{r}'|} \\ &= \frac{1}{4\pi\varepsilon_0}\frac{q}{2}\left(\frac{e}{|\mathbf{a}/2|} - \frac{e}{|-\mathbf{a}/2|}\right) = 0 \ , \end{aligned}$$

or from the charge of the electron e *in the field of the dipole,*

$$\begin{aligned} E_{e,pot} &= \frac{1}{2}\int d^3r'\ \rho_e(\mathbf{r}')\Phi_d(\mathbf{r}') = \frac{1}{4\pi\varepsilon_0}\frac{1}{2}\int d^3r'\ e\delta^3(\mathbf{r})\left(\frac{q}{|\mathbf{r}'-\mathbf{a}/2|} - \frac{q}{|\mathbf{r}'+\mathbf{a}/2|}\right) \\ &= \frac{1}{4\pi\varepsilon_0}\frac{e}{2}\left(\frac{q}{|\mathbf{a}/2|} - \frac{q}{|\mathbf{a}/2|}\right) = 0 \ . \end{aligned}$$

b. The force acting on the dipole follows from $\mathbf{F}_d = -\nabla_{\mathbf{r}} E_{d,pot}|_{\mathbf{r}=0}$, *where*

$$\begin{aligned} E_{d,pot}(\mathbf{r}) &= \frac{1}{2}\int d^3r'\ \rho_d(\mathbf{r}')\Phi_{e,\mathbf{r}}(\mathbf{r}') = \frac{1}{4\pi\varepsilon_0}\frac{1}{2}\int d^3r'\ \left(q\delta^3(\mathbf{r}'-\mathbf{a}/2) - q\delta^3(\mathbf{r}'+\mathbf{a}/2)\right)\frac{e}{|\mathbf{r}'-\mathbf{r}|} \\ &= \frac{1}{4\pi\varepsilon_0}\frac{q}{2}\left(\frac{e}{|\mathbf{a}/2-\mathbf{r}|} - \frac{e}{|-\mathbf{a}/2-\mathbf{r}|}\right) \ . \end{aligned}$$

With this,

$$\mathbf{F}_d = -\frac{1}{4\pi\varepsilon_0}\frac{q}{2}\nabla_{\mathbf{r}}\left[\frac{e}{|\mathbf{a}/2-\mathbf{r}|} - \frac{e}{|-\mathbf{a}/2-\mathbf{r}|}\right]_{\mathbf{r}=0} = \frac{1}{4\pi\varepsilon_0}\frac{q}{2}\left(\frac{e\mathbf{a}/2}{|\mathbf{a}/2|^3} + \frac{e\mathbf{a}/2}{|\mathbf{a}/2|^3}\right) = \frac{1}{\pi\varepsilon_0}\frac{eq}{d^2}\hat{\mathbf{e}}_d \ .$$

c. The force acting on the dipole follows from $\mathbf{F}_e = -\nabla_{\mathbf{r}} E_{e,pot}|_{\mathbf{r}=0}$, *where*

$$\begin{aligned} E_{e,pot}(\mathbf{r}) &= \frac{1}{2}\int d^3r'\ \rho_e(\mathbf{r}')\Phi_{d,\mathbf{r}'}(\mathbf{r}') = \frac{1}{4\pi\varepsilon_0}\frac{1}{2}\int d^3r'\ e\delta^3(\mathbf{r}'+\mathbf{r})\left(\frac{q}{|\mathbf{r}'-\mathbf{a}/2|} - \frac{q}{|\mathbf{r}'+\mathbf{a}/2|}\right) \\ &= \frac{1}{4\pi\varepsilon_0}\frac{e}{2}\left(\frac{q}{|-\mathbf{r}-\mathbf{a}/2|} - \frac{q}{|-\mathbf{r}+\mathbf{a}/2|}\right) \ . \end{aligned}$$

With this,

$$\mathbf{F}_e = -\frac{1}{4\pi\varepsilon_0}\frac{e}{2}\nabla_{\mathbf{r}}\left[\frac{q}{|-\mathbf{r}-\mathbf{a}/2|} - \frac{q}{|-\mathbf{r}+\mathbf{a}/2|}\right]_{\mathbf{r}=0} = \frac{1}{4\pi\varepsilon_0}\frac{e}{2}\left(-\frac{q\mathbf{a}/2}{|\mathbf{a}/2|^3} + \frac{-q\mathbf{a}/2}{|\mathbf{a}/2|^3}\right) = \frac{-1}{\pi\varepsilon_0}\frac{eq}{d^2}\hat{\mathbf{e}}_d \ .$$

Hence, the principle 'actio = reactio' is valid, $\mathbf{F}_d = -\mathbf{F}_e$.

13.7.5.5 Ex: Electric dipole in a field

What is the force acting on an electric dipole $\mathbf{d} = ea \cdot \hat{\mathbf{e}}_r$ at a point $\mathbf{r}$ being aligned along the field lines of an external field produced by a sphere with radius R homogeneously charged with a charge Q?

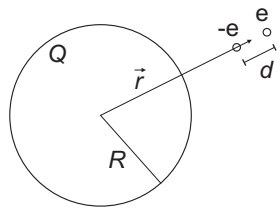

Figure 13.31: Electric dipole in a field.

Solution: *Following Gauß's law,* $\int_{\partial\mathcal{V}} \vec{\mathcal{E}}(\mathbf{r}) \cdot d\mathbf{A} = \frac{1}{\varepsilon_0}\int_{\mathcal{V}} \varrho(\mathbf{r}) d^3r$ *outside the sphere,*

$$\int_{\partial\mathcal{V}} \mathcal{E} dA = \mathcal{E} 4\pi r^2 = \int_{\partial\mathcal{V}} \mathcal{E} dA = \frac{1}{\varepsilon_0} Q$$

and with that,

$$\vec{\mathcal{E}} = \frac{Q}{4\pi\varepsilon_0 r^2}\hat{\mathbf{e}}_r \ .$$

The force now is,

$$\mathbf{F} = e\vec{\mathcal{E}}(\mathbf{r}-\mathbf{a}/2) + e\vec{\mathcal{E}}(\mathbf{r}+\mathbf{a}/2) = \frac{Qe}{4\pi\varepsilon_0}\hat{\mathbf{e}}_r\left(\frac{1}{(r-a/2)^2} - \frac{1}{(r+a/2)^2}\right) \ .$$

for small $d \ll r$ *we can approximate as follows,*

$$\mathbf{F} = \frac{Qe}{4\pi\varepsilon_0}\hat{\mathbf{e}}_r\frac{(r+a/2)^2-(r-a/2)^2}{(r-a/2)^2(r+a/2)^2} \simeq \frac{Qe}{4\pi\varepsilon_0}\hat{\mathbf{e}}_r\frac{2ar}{r^4} \ .$$

This result also follows for small dipolar moments approximating the interaction energy by,

$$W = -\mathbf{d}\cdot\vec{\mathcal{E}} = -ea\hat{\mathbf{e}}_r \cdot \frac{Q}{4\pi\varepsilon_0 r^2}\hat{\mathbf{e}}_r = -\frac{Qea}{4\pi\varepsilon_0 r^2}$$

where we assume, that $\vec{\mathcal{E}}(\mathbf{r}+\mathbf{a}/2) \simeq \vec{\mathcal{E}}(\mathbf{r}-\mathbf{a}/2)$. *The force is finally,*

$$\mathbf{F} = -\nabla W = -\frac{Qea}{2\pi\varepsilon_0 r^3}\hat{\mathbf{e}}_r \ .$$

13.7.5.6 Ex: Electric dipole in a field

Consider a molecule that consists of two rigidly bound masses $m_1 = m_2 = 10^{-25}\,\mathrm{kg}$ at a distance of $a = 10^{-12}\,\mathrm{m}$ and with charges $+e$ resp. $-e$.
a. Calculate the electric dipole moment $\mathbf{d} = d \cdot \hat{\mathbf{e}}_x$ of this charge distribution.
b. Now the molecule is put into rotation by a homogeneous electric field $\vec{\mathcal{E}} = \hat{\mathbf{e}}_z \cdot 100\,\mathrm{V/m}$. Calculate the rotation speed of the molecule as a function of the angle between the dipole moment and the electric field.
Help: The sum of the kinetic and electrostatic energies is conserved during the rotation.

Solution: *a. The dipole moment is,*

$$\mathbf{d} = ea\hat{\mathbf{e}}_x = 1.6 \cdot 10^{-31}\,\mathrm{Cm}\ \ \hat{\mathbf{e}}_x.$$

A homogeneous electric field placed in $\hat{\mathbf{e}}_z$ *direction produces a torque,*

$$\vec{\mathcal{D}} = \left(\mathbf{r} + \frac{\mathbf{a}}{2}\right) \times e\vec{\mathcal{E}} - \left(\mathbf{r} - \frac{\mathbf{a}}{2}\right) \times e\vec{\mathcal{E}} = ea\hat{\mathbf{e}}_x \times \mathcal{E}\hat{\mathbf{e}}_z = -ea\mathcal{E}\hat{\mathbf{e}}_y\ .$$

b. The energy of the dipole in the electric field is,

$$W = -\mathbf{d} \cdot \vec{\mathcal{E}} = -d\mathcal{E}\cos\phi\ .$$

The kinetic energy is,

$$T = \frac{m}{2}v_1^2 + \frac{m}{2}v_2^2 = mv_1^2\ ,$$

since $|v_1| = |v_2|$. *With the angular velocity,*

$$\omega_1 = \frac{v_1}{a/2}$$

the kinetic energy becomes,

$$T = mv_1^2 = m\left(\frac{\omega_1 a}{2}\right)^2\ .$$

At the beginning ($t = 0$) *the electrostatic energy disappears because,* $\phi(0) = 90°$, *and the kinetic energy disappears, because* $v_k(0) = 0$,

$$T(0) + W(0) = 0 = m\left(\frac{\omega_1 a}{2}\right)^2 - d\mathcal{E}\cos\phi\ .$$

Hence,

$$\omega_1^2 = 4\frac{d\mathcal{E}\cos\phi}{ma^2}\ .$$

13.7.5.7 Ex: Dipolar field in two dimensions

Consider two infinitely long parallel conductors with distance d carrying the linear charge density $+\lambda$ resp. $-\lambda$ (charge $\pm Q$ per length l of the conductor). Using the Gauß theorem, first calculate the electric field and the electric potential of one conductor. Then calculate the potential of both conductors by overlapping the individual potentials as a function of the distance r and the angle α (see Fig. 13.32). **Note:** Choose as integration volume a cylinder with length l and radius r along the symmetry axis around the wire. Determine the asymptotic behavior for $r \gg d/2$ and for $r \ll d/2$. To do this, do a Taylor expansion of the expression using: $\ln \frac{1+\epsilon}{1-\epsilon} \approx -2\epsilon + O(\epsilon^3)$. Write the result as a function of the dipole moment $\mathbf{p}$, where $p = |\mathbf{p}| = \lambda d$ is positive and indicates the direction of the dipole moment vector showing from the positive conductor to the negative.

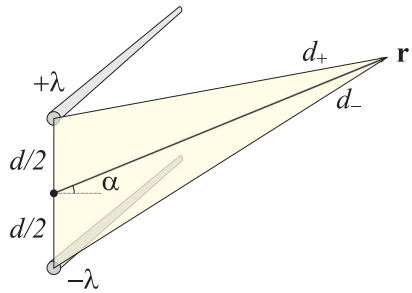

Figure 13.32: Dipolar field.

Solution: *With Gauß' integral theorem,* $\oint_{\partial\mathcal{V}} \vec{\mathcal{E}} \cdot \vec{n} dA = 4\pi \int_{\mathcal{V}} \rho dV$ *follows* $\mathcal{E} l 2\pi r = 4\pi Q$*, with the charge* Q *on a piece of wire of length* l*. With the definition of the linear charge density* $\lambda = Q/l$ *follows,* $\mathcal{E} = \frac{2\lambda}{r}$*. For the potential* Φ *(*$\vec{\mathcal{E}} = -\nabla\Phi$*) we integrate the field and obtain,*

$$\Phi = -2\lambda \ln(r) \ .$$

With two conductors we add the potentials: $\Phi = -2\lambda(\ln(d_+) - \ln(d_-)) = -\lambda \ln \frac{d_+^2}{d_-^2}$*. For* d_+ *and* d_- *we obtain:*

$$d_+^2 = r^2 + a^2 - 2ar\sin\alpha, \qquad \text{and} \qquad d_+^2 = r^2 + a^2 + 2ar\sin\alpha \ ,$$

where we let $a = d/2$*. Therefore, the potential of the two conductors is:*

$$\Phi = -\lambda \ln\left(\frac{1 + \frac{a^2}{r^2} - 2\frac{a}{r}\sin\alpha}{1 + \frac{a^2}{r^2} + 2\frac{a}{r}\sin\alpha}\right) = -\lambda \ln\left(\frac{1 + \frac{r^2}{a^2} - 2\frac{r}{a}\sin\alpha}{1 + \frac{r^2}{a^2} + 2\frac{r}{a}\sin\alpha}\right) \ .$$

For short distances $r/a \ll 1$ *we take the second expression and, neglecting the terms with* r^2/a^2*, we get,*

$$\Phi = 4\lambda \frac{r}{a}\sin\alpha \ .$$

For long distances $r/a \gg 1$ *we take the first term and get analogously,*

$$\Phi = 4\lambda \frac{a}{r}\sin\alpha \ .$$

With $\sin\alpha = -\frac{\mathbf{pr}}{pr}$ *follows for short distances* $\Phi = -2\frac{\mathbf{p}\cdot\mathbf{r}}{a^2}$ *and for long distances* $\Phi = -2\frac{\mathbf{p}\cdot\mathbf{r}}{r^2}$.

13.7.5.8 Ex: Dipolar and quadrupolar fields

Let us consider a system of three point charges aligned to the z-axis. At the positions $z = \pm a$ we have charges $+Q$, at the position $z = 0$ the charge $-2Q$.
a. Determine the charge distribution in terms of the δ-function in Cartesian coordinates.
b. Calculate the electrostatic potential $\Phi(\mathbf{r})$ of this charge distribution and approximate for long distances $|\mathbf{r}| \gg a$. (**Help:** Write the denominators that appear as $\frac{1}{|\mathbf{r}\pm\mathbf{a}|} = \frac{1}{r}\frac{1}{\sqrt{1+x}}$ with $x \equiv \frac{a^2\pm 2\mathbf{a}\cdot\mathbf{r}}{r^2}$ and expand up to second order in a.)
c. Calculate the monopolar moment and the Cartesian components of the dipolar moment and the quadrupolar tensor.
d. Calculate the monopolar, dipolar, and quadrupolar potentials and show that the results coincides with the expansion (b).
e. Now rotate the coordinate system around the x-axis by an angle of 45°. What are the new values for multipolar moments? (**Help:** The quadrupolar tensor is transformed with the rotation matrix λ as $q'_{il} = \lambda_{il} q_{lm} \lambda^{\dagger}_{mj}$).

Solution: *a. The density of charges is,*

$$\varrho(\mathbf{r}) = Q\delta(x)\delta(y)(\delta(z-a) + \delta(z+a) - 2\delta(z)) \ .$$

b. We define the vector $\mathbf{a} \equiv a\hat{\mathbf{e}}_z$. *In this case, we have for the potential at an arbitrary point* $\mathbf{r}$,

$$\Phi(\mathbf{r}) = \frac{1}{4\pi\varepsilon_0}\left(\frac{Q}{|\mathbf{r}-\mathbf{a}|} + \frac{Q}{|\mathbf{r}+\mathbf{a}|} - \frac{2Q}{|\mathbf{r}|}\right) \ .$$

Using the Taylor expansion,

$$\tfrac{1}{\sqrt{1+x}} = 1 - \tfrac{1}{2}x + \tfrac{3}{8}x^2 - \ldots$$

we approximate up to the second order terms in a/r *and we get,*

$$\frac{1}{|\mathbf{r}\pm\mathbf{a}|} = \frac{1}{\sqrt{r^2 + a^2 \pm 2\mathbf{a}\cdot\mathbf{r}}} = \frac{1}{r}\frac{1}{\sqrt{1 + \frac{a^2\pm 2\mathbf{a}\cdot\mathbf{r}}{r^2}}} = \frac{1}{r}\left(1 \mp \frac{\mathbf{a}\cdot\mathbf{r}}{r^2} - \frac{a^2}{2r^2} + \frac{3}{2}\frac{(\mathbf{a}\cdot\mathbf{r})^2}{r^4}\right) + \ldots$$

Follows for the potential,

$$\Phi(\mathbf{r}) \simeq \frac{Q}{4\pi\varepsilon_0}\left(-\frac{2}{r} + \frac{2}{r} + \frac{\mathbf{a}\cdot\mathbf{r}}{r^3} - \frac{\mathbf{a}\cdot\mathbf{r}}{r^3} - \frac{a^2}{r^3} + 3\frac{(\mathbf{a}\cdot\mathbf{r})^2}{r^5}\right) = \frac{Q}{4\pi\varepsilon_0}\left(\frac{3(\mathbf{a}\cdot\mathbf{r})^2}{r^5} - \frac{a^2}{r^3}\right) \ .$$

c. The monopolar moment of this charge distribution is equal to the total charge and therefore obviously equal to 0,

$$Q_{tot} = \int_{\mathbb{R}} \varrho(\mathbf{r}')dV' = 0 \ .$$

For the dipole moment we need to integrate $\rho(\mathbf{r})\mathbf{r}$. The x and y-components of the vector obviously give 0. Now, we consider the z-component. Here we get $Q(a-a-2\cdot 0)=0$,

$$\mathbf{d}=\int_{\mathbb{R}}\mathbf{r}'\varrho(\mathbf{r}')dV'=0\ .$$

Finally, we consider the quadrupolar moment using the general formula,

$$q_{ij}=\int_{\mathbb{R}}(3x_ix_j-r^2\delta_{ij})\varrho(\mathbf{r}')dV'\ .$$

For $i\neq j$ we see immediately, $q_{ij}=0$. For $i=j$ and $i=1$ holds,

$$q_{11}=\int_{\mathbb{R}}(2x^2-y^2-z^2)\varrho(\mathbf{r}')dV'=-2Qa^2$$

in the same way,

$$q_{22}=\int_{\mathbb{R}}(2y^2-x^2-z^2)\varrho(\mathbf{r}')dV'=-2Qa^2$$

and finally,

$$q_{33}=\int_{\mathbb{R}}(2z^2-x^2-y^2)\varrho(\mathbf{r}')dV'=+4Qa^2$$

Hence,

$$(q_{ij})=2Qa^2\begin{pmatrix}-1&0&0\\0&-1&0\\0&0&2\end{pmatrix}\ .$$

d. For the potential follows,

$$\begin{aligned}\Phi(\mathbf{r})&=\tfrac{1}{4\pi\varepsilon_0 r}\sum_i Q_i+\tfrac{1}{4\pi\varepsilon_0 r^3}\sum_i d_ir_i+\tfrac{1}{2}\tfrac{1}{4\pi\varepsilon_0 r^5}\sum_{ij}q_{ij}x_ix_j+\ldots\\&\simeq 0+0+\tfrac{1}{8\pi\varepsilon_0 r^5}2Qa^2(-x^2-y^2+2z^2)=\tfrac{1}{4\pi\varepsilon_0}\tfrac{Qa^2}{r^5}(3z^2-r^2)\ .\end{aligned}$$

e. The matrix describing a rotation around the x-axis is,

$$\begin{pmatrix}x'\\y'\\z'\end{pmatrix}=\begin{pmatrix}1&0&0\\0&\frac{1}{\sqrt{2}}&\frac{1}{\sqrt{2}}\\0&-\frac{1}{\sqrt{2}}&\frac{1}{\sqrt{2}}\end{pmatrix}\begin{pmatrix}x\\y\\z\end{pmatrix}\ ,$$

resp. in a compressed version, $x_i'=\sum_j\lambda_{ij}x_j$. The monopolar moment transforms like a scalar and, therefore, remains unchanged. The dipole moment is like a vector but, as all components in the previous coordinate system are 0, also in the rotated system there is no dipole moment. We need to calculate the quadrupolar tensor. We use now, that λ is an orthogonal transformation, ($det\lambda=1$, $\lambda^{-1}=\lambda^T$), and write,

$$q_{ij}'=\int d^3r'(3x_i'x_j'-r'^2\delta_{ij})=\sum_{lm}\lambda_{il}\lambda_{jm}\int d^3r'(3x_lx_m-r^2\delta_{lm})=\sum_{lm}\lambda_{il}q_{lm}(\lambda^T)_{mj}\ ,$$

where we use that $d^3r' = d^3r$. Inserting the matrix above gives immediately,

$$q' = \begin{pmatrix} 1 & 0 & 0 \\ 0 & \frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}} \\ 0 & -\frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}} \end{pmatrix} \begin{pmatrix} -2Qa^2 & 0 & 0 \\ 0 & -2Qa^2 & 0 \\ 0 & 0 & 4Qa^2 \end{pmatrix} \begin{pmatrix} 1 & 0 & 0 \\ 0 & \frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}} \\ 0 & -\frac{1}{\sqrt{2}} & \frac{1}{\sqrt{2}} \end{pmatrix} = \begin{pmatrix} -2aQ^2 & 0 & 0 \\ 0 & -Qa^2 & 3Qa^2 \\ 0 & 3Qa^2 & 3Qa^2 \end{pmatrix} .$$

13.7.5.9 Ex: Multipoles

The two charge distributions shown in the graph are given.
a. Calculate for both cases first the electrical potential Φ for the distances $r = 2a$, $r = 10a$, and $r = 100a$ for the angles $\alpha = 0°$, $\alpha = 45°$, and $\alpha = 90°$, respectively.
b. The results must now be compared with those of the quadrupolar expansion. What are the monopolar, dipolar and quadrupolar moments for these two geometries? Calculate the monopolar, dipolar and quadrupolar contributions of the electrical potential for the same positions as above. Compare these values with those calculated exactly and identify the dominant contributions.

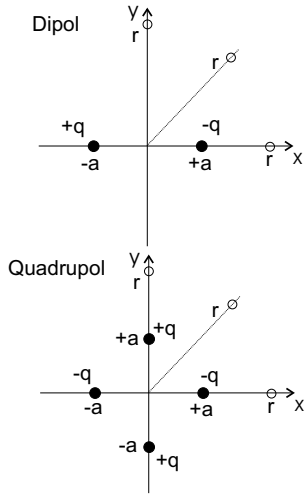

Figure 13.33: Multipoles.

Solution: *We first consider only the superior charge distribution. The potential is,*

$$\Phi = \frac{1}{4\pi\varepsilon_0} \frac{-q}{|\mathbf{r} - \vec{a}|} + \frac{1}{4\pi\varepsilon_0} \frac{q}{|\mathbf{r} + \vec{a}|} .$$

In the given positions with $\alpha = 0°$ we have,

$$\Phi|_{r=na,\alpha=0} = \Phi(na, 0, 0) = \frac{1}{4\pi\varepsilon_0} \frac{-q}{\sqrt{(na-a)^2}} + \frac{1}{4\pi\varepsilon_0} \frac{q}{\sqrt{(na+a)^2}} = \frac{-2q}{4\pi\varepsilon_0 a} \frac{1}{n^2-1}$$

$$\Phi|_{r=2a,\alpha=0} = \frac{-q}{4\pi\varepsilon_0 a} \frac{2}{3} \quad , \quad \Phi|_{r=10a,\alpha=0} = \frac{-q}{4\pi\varepsilon_0 a} \frac{2}{99} \quad , \quad \Phi|_{r=100a,\alpha=0} = \frac{-q}{4\pi\varepsilon_0 a} \frac{2}{9999}$$

with $\alpha = 45^\circ$

$$\Phi|_{r=na,\alpha=45^\circ} = \Phi\left(\frac{na}{\sqrt{2}}, \frac{na}{\sqrt{2}}, 0\right) = \sum_{\pm} \frac{1}{4\pi\varepsilon_0} \frac{\mp q}{\sqrt{(\frac{na}{\sqrt{2}} \mp a)^2 + (\frac{na}{\sqrt{2}})^2}} = \sum_{\pm} \frac{1}{4\pi\varepsilon_0 a} \frac{\mp q}{\sqrt{n^2 \mp \sqrt{2}n + 1}}$$

$$\Phi|_{r=2a,\alpha=0} = \frac{-q}{4\pi\varepsilon_0 a} \cdot 0.32 \quad , \quad \Phi|_{r=10a,\alpha=0} = \frac{-q}{4\pi\varepsilon_0 a} \cdot 0.014 \quad , \quad \Phi|_{r=100a,\alpha=0} = \frac{-q}{4\pi\varepsilon_0 a} \cdot 0.00014$$

with $\alpha = 90^\circ$

$$\Phi|_{r=na,\alpha=90^\circ} = \Phi(0, na, 0) = \frac{1}{4\pi\varepsilon_0} \frac{-q}{\sqrt{(-a)^2 + (na)^2}} + \frac{1}{4\pi\varepsilon_0} \frac{q}{\sqrt{(a)^2 + (na)^2}} = 0 \ .$$

b. With the charge density $\rho(\mathbf{r}) = q[\delta(\mathbf{r}+\vec{a}) - \delta(\mathbf{r}-\vec{a})]$ *the monopolar moment becomes,*

$$Q = \int \rho(\mathbf{r}')d^3r' = q - q = 0 \ .$$

The monopolar part of the potential then is,

$$\Phi_0(\mathbf{r}) = \frac{Q}{4\pi\varepsilon_0} = 0 \ .$$

The dipole moment is,

$$\mathbf{d} = \int \mathbf{r}'\rho(\mathbf{r}')d^3r' = q \int \mathbf{r}'[\delta(\mathbf{r}' + \vec{a}) - \delta(\mathbf{r}' - \vec{a})]d^3r' = -2q\vec{a} \ .$$

The dipolar part of the potential is then,

$$\Phi_1(\mathbf{r}) = \frac{1}{4\pi\varepsilon_0} \frac{\mathbf{r} \cdot \vec{d}}{r^3} = \frac{-2q}{4\pi\varepsilon_0} \frac{\mathbf{r} \cdot \vec{a}}{r^3}.$$

In the given positions with $\alpha = 0^\circ$ *we have,*

$$\Phi_1|_{r=na,\alpha=0} = \frac{-2q}{4\pi\varepsilon_0} \frac{na^2}{(na)^3} = \frac{-q}{4\pi\varepsilon_0 a} \frac{2}{n^2}$$

$$\Phi_1|_{r=2a,\alpha=0} = \frac{-q}{4\pi\varepsilon_0 a} \frac{2}{4} \quad , \quad \Phi_1|_{r=10a,\alpha=0} = \frac{-q}{4\pi\varepsilon_0 a} \frac{2}{100} \quad , \quad \Phi_1|_{r=100a,\alpha=0} = \frac{-q}{4\pi\varepsilon_0 a} \frac{2}{10000}$$

with $\alpha = 45^\circ$

$$\Phi_1|_{r=na,\alpha=45^\circ} = \frac{-2q}{4\pi\varepsilon_0} \frac{(na/\sqrt{2})a}{(na)^3} = \frac{-q}{4\pi\varepsilon_0 a} \frac{\sqrt{2}}{n^2}$$

$$\Phi_1|_{r=2a,\alpha=45^\circ} = \frac{-q \cdot 0.35}{4\pi\varepsilon_0 a} \quad , \quad \Phi_1|_{r=10a,\alpha=0} = \frac{-q \cdot 0.014}{4\pi\varepsilon_0 a} \quad , \quad \Phi_1|_{r=100a,\alpha=0} = \frac{-q \cdot 0.00014}{4\pi\varepsilon_0 a}$$

with $\alpha = 90^\circ$

$$\Phi_1|_{r=na,\alpha=90^\circ} = 0 \ .$$

The quadrupolar moment is,

$$Q_{ij} = \int \rho(\mathbf{r}')[3x'_I x'_j - r''\delta_{ij}]d^3r'$$

$$Q_{11} = \int \rho(\mathbf{r}')[3x''_1 - x''_1 - x''_2]d^3r' = 0 = Q_{22}$$

$$Q_{12} = \int \rho(\mathbf{r}')[3x'_1 x'_2 - x''_1 - x''_2]d^3r' = 0 = Q_{21} \ .$$

The quadrupolar part of the potential then is,

$$\Phi_2(\mathbf{r}) = \frac{1}{4\pi\varepsilon_0}\frac{1}{2}\sum_{ij} Q_{ij}\frac{x_I x_j}{r^5} = 0 \ .$$

Now we consider the distribution of the inferior charges.

13.7.5.10 Ex: Multipoles

Four point charges $+e$ and $-e$ are located at the Cartesian coordinates $(x, y, z) = (0, d, 0), (0, -d, 0), (0, 0, d), (0, 0, -d)$ and four other charges $-e$ at the points $(-d, 0, 0)$, $(-\frac{d}{2}, 0, 0)$, and $(d, 0, 0)$. Calculate the monopolar moment and the Cartesian components of the dipolar and quadrupolar moment of this charge distribution.

Solution:

13.7.5.11 Ex: Multipolar moments of a charge distribution

An ideal hollow sphere with radius R_0 has the surface charge density $\sigma(r, \theta, \phi) = \sigma_0 \cos\theta$ with σ_0 =const. Calculate:
a. The multipolar moments of this charge distribution.
b. The electrostatic potential outside the sphere.

Solution: *a. We have,*

$$\sigma(R_0, \theta, \phi) = \sigma_0 \cos\theta \qquad resp. \qquad \rho(r, \theta, \phi) = \sigma_0 \cos\theta \ \delta(r - R_0) \ .$$

Because of,

$$Y_{10}(\theta, \phi) = \sqrt{\frac{3}{4\pi}}\cos\theta \qquad vale \qquad \rho(r, \theta, \phi) = \sigma_0\delta(r - R_0)\sqrt{\frac{4\pi}{3}}\ Y_{10}(\theta) \ .$$

From this follows

$$\begin{aligned} q_{lm} &\equiv \int_0^{R_0+\epsilon} dr' \int_{(4\pi)} d\Omega' (r')^{l+2} \rho(r', \theta', \phi') Y^*_{lm}(\theta', \phi') \\ &= \sigma_0 \sqrt{\frac{4\pi}{3}} R_0^{l+2} \int_{(4\pi)} d\Omega' Y_{10}(\theta') Y^*_{lm}(\theta', \phi') \\ &= \sigma_0 \sqrt{\frac{4\pi}{3}} R_0^3 \delta_{l1}\delta_{m0} \ . \end{aligned}$$

Therefore, there is only the dipole moment. Defining it as always,

$$P \equiv \sqrt{\frac{4\pi}{3}} q_{10}.$$

we get immediately,

$$P = \left(\frac{4\pi}{3}R_0^3\right)\sigma_0 = V_{sphere}\sigma_0 \ .$$

b. Outside the sphere,

$$\Phi(r,\theta,\phi) = \sum_{l=0}^{\infty}\sum_{m=-l}^{+l} \frac{4\pi}{2l+1}\, q_{lm}\, \frac{Y_{lm}}{r^{l+1}} = \frac{4\pi}{3} R_0^3\, \sigma_0 \sqrt{\frac{4\pi}{3}}\, \frac{Y_{10}(\theta)}{r^2}$$
$$= \frac{4\pi}{3} R_0^3\, \sigma_0\, \frac{\cos\theta}{r^2} = P\, \frac{\cos\theta}{r^2}\ .$$

13.7.5.12 Ex: Multipolar moment of an atomic nucleus

A simple model of a deformed atomic nucleus is a body homogeneously charged with the full charge Ze and being delimited by the quadrupolar surface $R(\theta) = R_0(a(\beta) + \beta Y_{20}(\theta))$. We now assume that the absolute value of the deformation parameter β is very small with respect to 1. For the average radius it is $R_0 = 1.2\ A^{1/3}$ [fm], where A is the number of nucleons present.
a. Visualize the shape of the nucleus.
b. Determine $a(\beta)$ up to second order in β from the request, that the core volume is always $V = 4\pi R_0^3/3$.
c. Calculate the multipolar moments Q_{lm} up to the octupolar term and up to the linear terms in β. Are there any multipolar moments that zero exactly?
d. Calculate also the electrostatic potential also up to linear terms in β.

Solution: *a. We have*

$$Y_{20} = \frac{1}{2}\sqrt{\frac{5}{4\pi}}(3\cos^2\theta - 1)\ .$$

Hence, $Y_{20} = 0$, when $\cos\theta = \pm\frac{1}{\sqrt{3}}$, that is, $\theta \approx 55°$. Depending on whether $\beta > 0$ or $\beta < 0$ we obtain the schemes shown in Fig. 13.34.

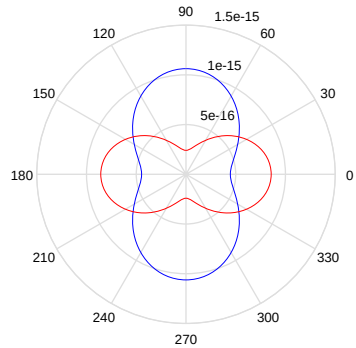

Figure 13.34: Shapes of an atomic nucleus for $\beta > 0$ (blue) and $\beta < 0$ (red).

b. The request reads,

$$V = \frac{4\pi}{3}R_0^3 = \text{const} = \int d\Omega \int_0^{R(\theta)} r^2 dr$$

$$= \int d\Omega \frac{1}{3}R^3(\theta) = \frac{R_0^3}{3}\int d\Omega(a^3 + 3a^2\beta Y_{20} + 3a\beta^2 Y_{20}^2 + O(\beta^3)) = \frac{4\pi}{3}R_0^3(a^3 + \frac{3a\beta^2}{4\pi}) \ .$$

With this we obtain,

$$a = \left(1 - \frac{3\beta^2 a}{4\pi}\right)^{1/3} = 1 - \frac{\beta^2}{4\pi}a + ... \ .$$

resp.

$$a = \frac{1}{1 + \frac{\beta^2}{4\pi}} = 1 - \frac{\beta^2}{4\pi} + ... \ .$$

c. In general we get,

$$q_{lm} = \int_V \rho(\mathbf{r}')(r')^{l+2}Y_{lm}^*(\theta', \phi')dr'd\Omega' \ .$$

Due to the independence on ϕ follows immediately, that all multipolar moments with $m \neq 0$ should disappear. Now,

$$\rho = \frac{3Ze}{4\pi R_0^3} \ .$$

With that, follows for q_{00},

$$q_{00} = \frac{3Ze}{4\pi R_0^3}\int_V \frac{1}{\sqrt{4\pi}}\int d\Omega \int_0^{R(\theta)} drr^2 = \frac{Ze}{\sqrt{4\pi}} \ .$$

With that the monopolar moment becomes,

$$Q_0 \equiv \sqrt{4\pi}q_{00} = Ze \ .$$

In the same way,

$$q_10 = \frac{3Ze}{4\pi R_0^3}\frac{R_0^4}{4}\int d\Omega \left(1 - \frac{\beta^2}{4\pi} + \beta Y_20\right)^4 Y_{10}^* = 0 \ ,$$

since Y_{20} (and hence its powers Y_{20}^k) is an even function of $\cos\theta$, while Y_{10} contains the argument $\cos\theta$ linearly. For the dipole moment follows from that,

$$P \equiv \sqrt{\frac{4\pi}{3}}q_{10} = 0 \ .$$

Furthermore,

$$q_{20} = \frac{3Ze}{4\pi R_0^3}\frac{R_0^5}{5}\int d\Omega(1 + 5\beta Y_{20} + O(\beta^2))Y_{20} = \frac{3Ze}{4\pi}R_0^2\beta \ .$$

resp. for the quadrupolar moment often found in nuclear physics,

$$Q_{20} \equiv \sqrt{\frac{16\pi}{5}} q_{20} = \frac{3Ze}{\sqrt{5\pi}} R_0^2 \beta \ .$$

The octupolar moment $q_{30}$is, on the other hand, equal to 0, since Y_30 is again an odd function in $\cos\theta$.
d. Generally speaking,

$$\Phi(\mathbf{r}) = \sum_{l=0}^{\infty} \sum_{m=-l}^{+l} \frac{4\pi}{2l+1} q_{lm} \frac{Y_{lm}}{r^{l+1}} \ .$$

For our case we get ($m = 0$),

$$\Phi(\mathbf{r}) = \sum_{l=0}^{\infty} q_{l0} \frac{Y_{l0}}{r^{l+1}} = 4\pi q_{00} \frac{1}{\sqrt{4\pi}} \frac{1}{r} + \frac{4\pi}{5} q_{20} \frac{Y_{20}}{r^3} + ... = \frac{Ze}{r} + \frac{3Ze}{5} R_0^2 \beta \frac{Y_{20}}{r^3} \ .$$

13.7.5.13 Ex: Dipole-dipole interaction

a. Consider an electric dipole with dipole moment $\mathbf{d}$. Show that the electric field of the dipole is given by:

$$\vec{\mathcal{E}}(\mathbf{r} = r\hat{\mathbf{e}}_r) = -\frac{1}{4\pi\varepsilon_0} \frac{\mathbf{d} - 3\hat{\mathbf{e}}_r(\hat{\mathbf{e}}_r \cdot \mathbf{d})}{r^3} \ .$$

You may use the expression for a dipole potential.
b. Use this result to calculate the interaction energy U_{12} of two equal dipoles located at a distance d from one another for the dipole configurations shown in the scheme.
Help: To calculate the interaction energy $U_{12}(\mathbf{a})$ between the two dipoles we con-

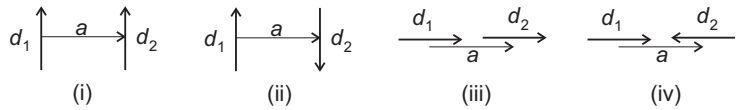

Figure 13.35: Dipole-dipole interaction.

sider the energy of dipole 1 in the electric field of dipole 2. So, $U_{12}(\mathbf{a}) = -\mathbf{d}_1 \vec{\mathcal{E}}_2$. In which configurations do the dipoles attract, in which do they repel each other?
c. A current research area deals with cold dipolar molecules, for example, RbLi molecules having a permanent dipole electrical moment of $d_{RbLi} = 4.3$ Debye. What should be the atomic density n, where $n = a^{-3}$, in order to obtain a dipolar interaction U_0 at least as large as the thermal energy of the molecules? Ultra-cold molecular gases typically have a temperature around 10^{-6} K.

Solution: *The potential of a dipole is,*

$$\Phi(\mathbf{r}) = \frac{1}{4\pi\varepsilon_0} \frac{\mathbf{d} \cdot \mathbf{r}}{r^3} \ .$$

The electric field is given by $\vec{\mathcal{E}} = -\nabla\Phi$. *Derivating,*

$$\begin{aligned}\nabla\Phi &= \frac{-1}{4\pi\varepsilon_0}\left[\frac{(d_x,d_y,d_z)}{r^3} - \frac{3}{2}\frac{\mathbf{d}\cdot\mathbf{r}}{r^5}(2x,2y,2z)\right] \\ &= \frac{-1}{4\pi\varepsilon_0}\left[\frac{\mathbf{d}}{r^3} - 3\frac{\mathbf{d}\cdot\mathbf{r}}{r^5}\mathbf{r}\right] = \frac{-1}{4\pi\varepsilon_0}\frac{\mathbf{d}-3(\mathbf{d}\cdot\hat{\mathbf{e}}_r)\hat{\mathbf{e}}_r}{r^3} \ .\end{aligned}$$

The interaction energy is:

$$-\mathbf{d}_1\cdot\vec{\mathcal{E}}_2 = -\mathbf{d}_1\ \frac{-1}{4\pi\varepsilon_0}\ \frac{\mathbf{d}_2-3(\mathbf{d}_2\cdot\hat{\mathbf{e}}_r)\hat{\mathbf{e}}_r}{a^3} = \frac{-1}{4\pi\varepsilon_0 a^3}\left(\mathbf{d}_1\cdot\mathbf{d}_2 - 3(\mathbf{d}_1\cdot\hat{\mathbf{e}}_r)(\mathbf{d}_2\cdot\hat{\mathbf{e}}_r)\right) \ .$$

Extracting the absolute value of the dipole moment: $\mathbf{d}_i = d\hat{d}_1$*:*

$$U_{12} = \frac{d^2}{4\pi\varepsilon_0 a^3}\left(\hat{d}_1\cdot\hat{d}_2 - 3(\hat{d}_1\cdot\hat{\mathbf{e}}_r)(\hat{d}_2\cdot\hat{\mathbf{e}}_r)\right) \ .$$

b. We define $U_0 \equiv \frac{d^2}{4\pi\varepsilon_0 a^3}$*, so we get for the various configurations:*
i. $U_{12} = U_0(1-3(0)\cdot(0) = U_0 > 0$ *this is repulsive*
ii. $U_{12} = U_0(-1-3(0)\cdot(0) = -U_0 < 0$ *this is attractive*
iii. $U_{12} = U_0(1-3(1)\cdot(1) = -2U_0 < 0$ *this is attractive*
iv. $U_{12} = U_0(-1-3(1)\cdot(-1) = 2U_0 > 0$ *this is repulsive*
c. One Debye corresponds to $3.3\cdot10^{-33}\,\mathrm{cm}$*. Therefore, the RbLi molecule has the dipole moment* $14.2\cdot10^{-33}\,\mathrm{Cm}$*. We get the density from,*

$$\frac{d^2}{4\pi\varepsilon_0 a^3} = k_B T \qquad \textit{and hence} \qquad n = \frac{k_B T 4\pi\varepsilon_0}{d^2} = 7.6\cdot10^{24}\,\mathrm{m^{-3}} \ .$$

13.7.5.14 Ex: Photoelectric effect

During the process described by the photoelectric effect, ultraviolet light can be used to electrically charge a piece of metal.
a. If this light strikes a bar of conductive material electrons, and are ejected with sufficient energy to escape from the surface of the metal, after how much time will the metal have accumulated a charge of $+1.5\,\mathrm{nC}$ if $1.0\cdot10^6$ electrons are ejected per second?
b. If $1.3\,\mathrm{eV}$ is required to eject an electron from the surface, what is the power of the light beam? (Consider the process to be 100% efficient.)

Solution: *a. It will take*

$$\frac{1.5\,\mathrm{nC}}{e\cdot1.0\cdot10^6\,\mathrm{s^{-1}}} = 2.6\,\mathrm{h} \ .$$

b. The required power is

$$1.3\,\mathrm{V}\cdot e\cdot1.0\cdot10^6\,\mathrm{s^{-1}} = 2.1\cdot10^{-13}\,\mathrm{W} \ .$$

13.7.5.15 Ex: Polonium and the use of the Green function

The radioactive metal Polonium (Po), discovered by Marie and Pierre Curie in 1898, crystallizes in a simple cubic lattice (each atom has six neighbors on a regular grid). The nucleus contains 84 protons and the diameter of the atom is approximately $3 \cdot 10^{-8}$ cm. Calculate the distribution of the potential within a primitive cell of a Po crystal traversed by a constant current. Suppose the following model for the crystal: Atomic nuclei (radius $\sim 9 \cdot 10^{-13}$ cm) are at positions $\mathbf{x}'_{\lambda\mu\nu} = (\lambda a + a/2, \mu a + a/2, \nu a + a/2)$ for $\lambda, \mu\nu = 0, \pm 1, \pm 2, ...$, and will be treated as point charges. The electronic shell of a Po atom is represented by charges induced in a grounded conducting cube of size a, in the middle of which is located the positively charged nucleus inducing these charges. Proceed as follows:
a. Start showing that,

$$G(\mathbf{r}, \mathbf{r}') = \frac{32}{\pi a} \sum_{l,m,n=1}^{\infty} \frac{1}{l^2+m^2+n^2} \sin\frac{l\pi x}{a} \sin\frac{l\pi x'}{a} \sin\frac{m\pi y}{a} \sin\frac{m\pi y'}{a} \sin\frac{n\pi z}{a} \sin\frac{n\pi z'}{a} \ ,$$

is the Green function for the Dirichlet contour problem of a cube with edge length a.
b. Calculate the potential in the atom at the position $(a/2, a/2, a/2)$, where we assume for the interior of the cube a charge $\rho(x', y', z') = q\delta(x' - a/2)\delta(y' - a/2)\delta(z' - a/2)$ and that the potential on the six surfaces of the cube adopts the following values: $\Phi(\mathbf{r}') = 0$ on the surface $x' = 0$, $\Phi(\mathbf{r}') = V_0$ on the surface $x' = a$, and $\Phi(\mathbf{r}') = V_0 x'/a$ on the other 4 surfaces $y' = 0,\ y' = a,\ z' = 0,\ z' = a$.
c. Reformulate the term describing the contribution of the surface to the potential using that for $0 < x < \pi$ holds: $1 = (4/\pi)(\sin x + (1/3)\sin 3x + (1/5)\sin 5x + ...)$ and $x = 2(\sin x - (1/2)\sin 2x + (1/3)\sin 3x - (1/4)\sin 4x + ...)$.

Solution: *a. We need to show:*
(i) $G(\mathbf{r}, \mathbf{r}') = G(\mathbf{r}', \mathbf{r})$
(ii) $G(\mathbf{r}, \mathbf{r}' \in$ *peripherical surface*$) = 0$
(iii) $\Delta G(\mathbf{r}, \mathbf{r}') = -4\pi\delta^{(3)}(\mathbf{r} - \mathbf{r}')$
(i) and (ii) they are trivially satisfied. For (iii) we calculate:

$$\begin{aligned}
&\Delta G(\mathbf{r}, \mathbf{r}') \\
&= \frac{32}{\pi a} \sum_{l,m,n=1}^{\infty} \frac{1}{l^2+m^2+n^2} \sin\frac{l\pi x}{a} \sin\frac{l\pi x'}{a} \sin\frac{m\pi y}{a} \sin\frac{m\pi y'}{a} \sin\frac{n\pi z}{a} \sin\frac{n\pi z'}{a} \cdot \frac{\pi^2}{a^2}(-l^2 - m^2 - n^2) \\
&= -4\pi \left(\sqrt{\frac{2}{a}}\right)^6 \sum_{l,m,n=1}^{\infty} \frac{1}{l^2+m^2+n^2} \sin\frac{l\pi x}{a} \sin\frac{l\pi x'}{a} \sin\frac{m\pi y}{a} \sin\frac{m\pi y'}{a} \sin\frac{n\pi z}{a} \sin\frac{n\pi z'}{a} \ .
\end{aligned}$$

Now holds the completeness relation,

$$\sum_{l=1}^{\infty} \sqrt{\frac{2}{a}} \sin\left(\frac{l\pi x}{a}\right) \sin\left(\frac{l\pi x'}{a}\right) = \delta(x - x') \ ,$$

yielding the statement (iii).
b. Vale,

$$\begin{aligned}\Phi(x,y,z) = &\int_V \rho(x',y',z')G(\mathbf{r},\mathbf{r}')dx'dy'dz' \\ &- \frac{1}{4\pi}\int_0^a dy'\int_0^a dz'\Phi(x'=0)\frac{\partial G}{\partial x'}|_{x'=0} - \frac{1}{4\pi}\int_0^a dy'\int_0^a dz'\Phi(x'=a)\frac{\partial G}{\partial x'}|_{x'=a} \\ &- \frac{1}{4\pi}\int_0^a dx'\int_0^a dz'\Phi(y'=0)\frac{\partial G}{\partial y'}|_{y'=0} - \frac{1}{4\pi}\int_0^a dx'\int_0^a dz'\Phi(y'=a)\frac{\partial G}{\partial y'}|_{y'=a} \\ &- \frac{1}{4\pi}\int_0^a dx'\int_0^a dy'\Phi(z'=0)\frac{\partial G}{\partial z'}|_{z'=0} - \frac{1}{4\pi}\int_0^a dx'\int_0^a dy'\Phi(z'=a)\frac{\partial G}{\partial z'}|_{z'=a} \ .\end{aligned}$$

The volume integral gives, after inserting the charge density,

$$\frac{32q}{\pi a}\sum_{l,m,n=1}^{\infty}\frac{(-)^{l+m+n}\sin\left(\frac{(2l+1)\pi x}{a}\right)\sin\left(\frac{(2m+1)\pi y}{a}\right)\sin\left(\frac{(2n+1)\pi z}{a}\right)}{(2l+1)^2+(2m+1)^2+(2n+1)^2} \ .$$

For the surface term we get,

$$\frac{8V_0}{\pi^3}\sum_{l,m,n=1}^{\infty}(-)^{l+1}\frac{(1-(-)^n)(1-(-)^m)}{lmn}\sin\left(\frac{l\pi x}{a}\right)\sin\left(\frac{m\pi y}{a}\right)\sin\left(\frac{n\pi z}{a}\right) \ .$$

With $x=y=z=a/2$ we get from this the desired result.
c. We obtain for the surface term Φ_2, by applying the given formulas on l,m,n inside the cube:

$$\Phi_2(\mathbf{r}) = V_0\frac{x}{a} \ .$$

This is the profile of a potential due to the influence of the constant current toward the negative x-direction, which overlaps with the potential of the crystal.

13.7.5.16 Ex: Electrostatic potential of a hollow sphere via Green function

On the surface of a hollow sphere with radius b without charge there be a certain potential $V(\theta,\phi) = V_0[P_2(\cos\theta) + \alpha P_3(\cos\theta)]$. Calculate the electrostatic potential $\Phi(\mathbf{r})$ inside the sphere.
Help: Green's function for the interior space between two concentric spheres with radii a and b ($a<b$) is,

$$G(\mathbf{r},\mathbf{r}') = \sum_{l=0}^{\infty}\frac{4\pi}{2l+1}\left[1-\left(\frac{a}{b}\right)^{2l+1}\right]\left[r_<^l - \frac{a^{2l+1}}{r_<^{l+1}}\right]\left[\frac{1}{r_>^{l+1}} - \frac{r_>^l}{b^{2l+1}}\right]\sum_{m=-l}^{+l}Y_{lm}(\Omega)Y_{lm}^*(\Omega') \ .$$

where $r_< \equiv \min(|\mathbf{r}|, |\mathbf{r}'|)$ and $r_> \equiv \max(|\mathbf{r}|, |\mathbf{r}'|)$. We also know, $Y_{l0}(\theta, \phi) = \sqrt{(2l+1)/4\pi} P_l(\cos\theta)$.

Solution: *We consider the Green function as given. For the space of a single sphere we set $a = 0$. Hence,*

$$G(\mathbf{r}, \mathbf{r}') = \sum_{l=0}^{\infty} \frac{4\pi}{2l+1} r_<^l \left[\frac{1}{r_>^{l+1}} - \frac{r_>^l}{b^{2l+1}} \right] \sum_{m=-l}^{+l} Y_{lm}(\Omega) Y_{lm}^*(\Omega') \ .$$

The hollow sphere is uncharged. So for all $\mathbf{r}$ in the sphere volume V_K, holds,

$$\int_{V_K} G(\mathbf{r}, \mathbf{r}') \rho(\mathbf{r}') d^3 r' = 0 \ .$$

and therefore,

$$\Phi(\mathbf{r}) = -\frac{1}{4\pi} \int_{O_K} V(\Omega') \left(\frac{\partial G(\mathbf{r}, \mathbf{r}')}{\partial r'} \right)_{r'=b} b^2 d\Omega' \ .$$

where O_K denotes the surface of the sphere. For this surface obviously holds $|\mathbf{r}'| = r_>$ and $|\mathbf{r}| = r_<$, and so we have within the sphere

$$\begin{aligned} \Phi(\mathbf{r}) &= -\frac{1}{4\pi} \int_{(4\pi)} V(\Omega') \sum_{l=0}^{\infty} \frac{4\pi}{2l+1} r^l \left(-\frac{l+1}{b^{l+2}} - \frac{l b^{l-1}}{b^{2l+1}} \right) \sum_{m=-l}^{+l} Y_{lm}(\Omega) Y_{lm}^*(\Omega') b^2 d\Omega' \\ &= \sum_{l=0}^{\infty} \left(\frac{r}{b} \right)^l \sum_{m=-l}^{+l} Y_{lm}(\Omega) \int_{(4\pi)} V(\Omega') Y_{lm}^*(\Omega') d\Omega' \end{aligned}$$

Now,

$$V(\Omega') = V_0 \left(P_2(\cos\theta) + \alpha P_3(\cos\theta) \right) = V_0 \sqrt{4\pi} \left(\frac{Y_{20}(\theta)}{\sqrt{5}} + \frac{\alpha Y_{30}(\theta)}{\sqrt{7}} \right) \ .$$

Using the orthonormality of spherical harmonics,

$$\begin{aligned} \Phi(\mathbf{r}) &= V_0 \sqrt{4\pi} \left[\left(\frac{r}{b} \right)^2 \frac{Y_{20}(\theta)}{\sqrt{5}} + \left(\frac{r}{b} \right)^3 \frac{\alpha Y_{30}(\theta)}{\sqrt{7}} \right] \\ &= V_0 \left(\frac{r}{b} \right)^2 \left[P_2(\cos\theta) + \alpha \left(\frac{r}{b} \right) P_2(\cos\theta) \right] \ . \end{aligned}$$

Chapter 14

Electrical properties of matter

There are many types of materials, such as solids, liquids, gases, metals, wood or glass, all of which respond differently to applied electric fields. However, most materials can at least roughly be classified into two categories: In materials called *dielectrics* (or insulators) the electrons are strongly bound to the atoms, while in *metals* there are free electrons. Some materials, such as semiconductors, have particular properties, which do not fit into these categories.

Under the influence of electric (or magnetic) forces the electrons can be displaced within a macroscopic body, thus producing a polarization, when the electrons are bound, or a current, when the electrons are free.

14.1 Polarization of dielectrics

Let us first discuss dielectrics. The elementary blocks (molecules) of dielectric materials can react in various ways to applied electric fields, For example, they can be insensitive to electric fields or behave like *permanent dipoles*. Permanent dipoles exist independently of the application of an external field, but generally (without external field) they have random and disorderly orientations. Under the influence of an external field the dipoles will try to reorient themselves, which is called *orientation polarization*.

It is also possible that a material does not have intrinsic dipole moments, but *develops* dipole moments under the action of an external field. In this case we speak of *induced dipoles*. Induced dipoles are formed in the presence of a field displacing bound positive and negative charges in molecules against each other, thus producing a *translation polarization*.

14.1.1 Energy of permanent dipoles

Polar molecules exhibit permanent electric moments. Water is an example or salt Na^+Cl^-. The reason is that halogens, which have a much higher electro-affinity than alkalines, and try to steal electrons from their partner and monopolize the electronic cloud.

The potential energy of a dipole depends on its orientation with respect to the electric field. Using the parametrization $\varrho(\mathbf{r}') = Q[\delta^3(\mathbf{r}' - \frac{\mathbf{a}}{2}) - \delta^3(\mathbf{r}' + \frac{\mathbf{a}}{2})]$, we find

for the interaction energy with a homogeneous field given by $\Phi(\mathbf{r}') = -\mathcal{E}_0 z'$,

$$H_{int} = \int \varrho(\mathbf{r}')\Phi(\mathbf{r}')dV = -Q\mathcal{E}_0 a_z = -\mathbf{d}\cdot\vec{\mathcal{E}}\ . \tag{14.1}$$

Hence [1],

$$\boxed{H_{int} = -\mathbf{d}\cdot\vec{\mathcal{E}}}\ . \tag{14.2}$$

The energy is minimal when $\mathbf{d} \parallel \vec{\mathcal{E}}$.

To calculate the interaction energy between two dipoles $\mathbf{d}_1$ and $\mathbf{d}_2$ we calculate the energy of $\mathbf{d}_1$ within the field created by $\mathbf{d}_2$ (which has been derived in the example 57),

$$H_{int} = -\mathbf{d}_1\cdot\vec{\mathcal{E}}_2 = -\mathbf{d}_1\cdot\frac{1}{4\pi\varepsilon_0}\frac{3(\hat{\mathbf{e}}_r\cdot\mathbf{d}_2)\hat{\mathbf{e}}_r - \mathbf{d}_2}{r^3} = \frac{1}{4\pi\varepsilon_0}\frac{\mathbf{d}_1\cdot\mathbf{d}_2 - 3(\mathbf{d}_1\cdot\hat{\mathbf{e}}_r)(\mathbf{d}_2\cdot\hat{\mathbf{e}}_r)}{r^3}\ . \tag{14.3}$$

14.1.1.1 Alignment of permanent dipoles

In a homogeneous field the force on an (neutral) electric dipole $\mathbf{d} = Q\mathbf{a}$ vanishes, since $\mathbf{F} = Q\vec{\mathcal{E}} + (-Q)\vec{\mathcal{E}} = 0$. However, there will be a torque because,

$$\vec{\tau} = \frac{\mathbf{a}}{2}\times Q\vec{\mathcal{E}} + \frac{-\mathbf{a}}{2}\times(-Q)\vec{\mathcal{E}} = \mathbf{d}\times\vec{\mathcal{E}}\ . \tag{14.4}$$

This means that a freely moving molecule will rotate about its mass center, as illustrated in Fig. 14.1, until (in the presence of dissipation) it finds the orientation with the lowest energy. In this orientation the molecule is aligned to the applied field. See Exc. 14.1.7.1.

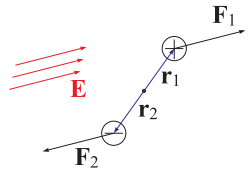

Figure 14.1: Torque on a dipole exerted by an electric field.

In a *non-homogeneous* field, the forces on the charges $\pm Q$ do not compensate [2], $\mathbf{F} = Q\vec{\mathcal{E}}_+ - Q\vec{\mathcal{E}}_- = Q(\mathbf{a}\cdot\nabla)\vec{\mathcal{E}}$. Hence,

$$\boxed{\mathbf{F} = (\mathbf{d}\cdot\nabla)\vec{\mathcal{E}}}\ . \tag{14.5}$$

Placed in front of a conductive surface a dipole feels the forces exerted by the charge of its own image. In Exc. 14.1.7.2 we calculate the torque exerted by a conducting surface on a dipole.

[1] We can also calculate the energy of a dipole in an electric field by the work required to rotate it away from its rest position, $H_{int} = \int\vec{\tau}\cdot d\theta = \int \mathbf{d}\times\vec{\mathcal{E}}d\theta = \int_0^\theta dE\sin\theta d\theta = -dE\cos\theta$.

[2] We note that the force that a field exerts on a dipole can be calculated as a gradient of the interaction energy: $\mathbf{F} = -\nabla H_{int} = \nabla(\mathbf{d}\cdot\vec{\mathcal{E}}) = (\mathbf{d}\cdot\nabla)\vec{\mathcal{E}} + (\vec{\mathcal{E}}\cdot\nabla)\mathbf{d} + (\mathbf{d}\times\nabla)\times\vec{\mathcal{E}} + (\vec{\mathcal{E}}\times\nabla)\times\mathbf{d} = (\mathbf{d}\cdot\nabla)\vec{\mathcal{E}}$.

14.1.2 Induction of dipoles in dielectrics

A priori, neutral non-polar atoms and molecules should not react to applied electric fields. However, the fact that atoms are composed of positive charge distributions (concentrated in a heavy nucleus) and negative ones (concentrated in a light-weighed electron shell), permits a more or less important displacement of these charge distributions with respect to the center-of-mass. Consequently, an electric field *polarizes the atom* and induces an electric dipole moment whose magnitude is approximately proportional to the field,

$$\boxed{\mathbf{d} = \alpha_{pol}\vec{\mathcal{E}}} \ , \tag{14.6}$$

where the constant α_{pol} is called *polarizability*.

> **Example 59 (*Polarizability of a primitive atom*):** In a primitive model we envision an atom as a point-like nucleus carrying the charge $+Q$ surrounded by a uniformly charged electron sphere with radius a carrying the inverse charge $-Q$. In the presence of an external field $\vec{\mathcal{E}}$ the nucleus will be slightly shifted by a distance $\epsilon/2$ to one side and the electron sphere by a distance $-\epsilon/2$ to the opposite side. The polarized atom is in equilibrium, when the field created by the induced dipole $\mathcal{E}_{dp}$ (calculated in Exc. 13.2.4.5) equalizes the external field, i.e.,
>
> $$\mathcal{E}_{dp} = \frac{1}{4\pi\varepsilon_0}\frac{Q\epsilon}{a^3} = \mathcal{E} \ .$$
>
> Hence,
>
> $$\frac{\alpha_{pol}}{4\pi\varepsilon_0} = \frac{d}{4\pi\varepsilon_0\mathcal{E}} = a^3 \approx 0.15 \cdot 10^{-30}\,\mathrm{m}^3 \ ,$$
>
> using for $a = a_B$ the Bohr radius. Despite the simplicity of the model, this results represents a good approximation. A slightly better model is discussed in Exc. 14.1.7.3.

The values for the atomic polarizability range from $\alpha_{pol}/4\pi\varepsilon_0 = 0.205 \cdot 10^{-30}\,\mathrm{m}^3$ for helium to $59.6 \cdot 10^{-30}\,\mathrm{m}^3$ for cesium. This shows that it is far more difficult to polarize atoms with closed electron shells (like noble gases) than atoms with isolated valence electron (such as alkaline atoms). Molecules may react in a more complicated way to the applied fields necessitating an interpretation of the polarizability α_{pol} in terms of a tensor represented by a matrix.

14.1.2.1 Energy of induced dipoles

We now calculate the energy of a polarizable molecule inside an external electric field. We expect two contributions: The first one is the energy W_{ind} stored in the field created by the separation of charges under the action of the external field. The second contribution is the energy H_{int} due to the interaction of the induced dipole with the external field.

W_{ind} is calculated by the work spent on separating the charges. Let e be the valence charge bound to the molecule. The force between this charge and the molecule is described, in first approximation, by a harmonic oscillator with the spring constant k. Inside the electric field, the charge feels the force $e\vec{\mathcal{E}}$, but at the same time the force of the 'molecular spring' goes in the opposite direction. In equilibrium,

$$-k\mathbf{a} + e\vec{\mathcal{E}} = 0 \ . \tag{14.7}$$

To induce this dipole, the electric field must do the work,

$$W_{ind} = \tfrac{1}{2}ka^2 = \tfrac{1}{2}e\mathcal{E}a \ . \tag{14.8}$$

Defining the induced dipole as $\mathbf{d}_{ind} \equiv Ze\mathbf{d}$, we obtain:

$$W_{ind} = \tfrac{1}{2}\mathbf{d}_i \cdot \vec{\mathcal{E}} \ . \tag{14.9}$$

Since the energy of a dipole in an external electric field is, $H_{int} = -\mathbf{d}_i \cdot \vec{\mathcal{E}}$, for the induced dipole we obtain the total energy,

$$H_{tot} = H_{int} + W_{ind} = -\tfrac{1}{2}\mathbf{d}_i \cdot \vec{\mathcal{E}} \ . \tag{14.10}$$

The energy value is less than in the case of a permanent dipole (14.5), since part of the energy had to be spent on creating the dipole in the first place. Expressing the dipole moment by the polarizability (14.6),

$$\boxed{H_{tot} = -\frac{\alpha_{pol}}{2}\vec{\mathcal{E}}^2} \ . \tag{14.11}$$

14.1.3 Macroscopic polarization

With these results we can now describe, what happens to a dielectric material placed in an electric field: If the substance consists of neutral atoms (or non-polar molecules), the field will induce in each particle a small dipole moment pointing in the direction of the field. If the substance consists of polar molecules, each permanent dipole will try to orientate itself along the field [3].

Note that both mechanisms produce the same result: a multitude of small dipoles aligned along the applied field. The sum of the microscopic moments gives rise to a macroscopic *polarization* defined by the sum over all dipole moments,

$$\vec{\mathcal{P}} = \frac{N\mathbf{d}}{V} \ . \tag{14.12}$$

In reality, the two types of polarization are not always well separated, and there are cases where both contribute. Nevertheless, it is usually much easier to rotate a molecule (rotational energy) than to stretch it (vibrational energy). In some (ferro-electric) materials it is possible to freeze the polarization.

14.1.4 Electrostatic field on a polarized or dielectric medium

In this section we will describe the electric field inside a polarized medium forgetting the physical cause of the polarization $\vec{\mathcal{P}}$. The field produced by the polarization (not the external field) can be calculated by the sum of the fields produced by the individual dipoles,

$$\Phi(\mathbf{r}) = \frac{1}{4\pi\varepsilon_0}\sum_k \frac{\mathbf{d}_k \cdot (\mathbf{r}-\mathbf{r}_k)}{|\mathbf{r}-\mathbf{r}_k|^3} \longrightarrow \frac{1}{4\pi\varepsilon_0}\int_{\mathcal{V}} dV' \frac{\vec{\mathcal{P}}(\mathbf{r}')\cdot(\mathbf{r}-\mathbf{r}')}{|\mathbf{r}-\mathbf{r}'|^3} \ , \tag{14.13}$$

[3] Note that thermal motion, particularly at high temperatures, competes with this process, such that the alignment will never be perfect.

introducing the dipole moment distribution $\vec{\mathcal{P}}(\mathbf{r}')$ by $\mathbf{d}_k \to \vec{\mathcal{P}} dV'$. We can rewrite the integral in the form,

$$\Phi(\mathbf{r}) = \frac{1}{4\pi\varepsilon_0}\int_{\mathcal{V}} \vec{\mathcal{P}}(\mathbf{r}')\cdot\nabla'\frac{1}{|\mathbf{r}-\mathbf{r}'|}dV' = \frac{1}{4\pi\varepsilon_0}\left[\int_{\mathcal{V}}\nabla'\cdot\frac{\vec{\mathcal{P}}(\mathbf{r}')}{|\mathbf{r}-\mathbf{r}'|}dV' - \int_{\mathcal{V}}\frac{1}{|\mathbf{r}-\mathbf{r}'|}\nabla'\vec{\mathcal{P}}(\mathbf{r}')dV'\right]$$
$$= \frac{1}{4\pi\varepsilon_0}\oint_{\partial\mathcal{V}}\frac{\vec{\mathcal{P}}(\mathbf{r}')}{|\mathbf{r}-\mathbf{r}'|}dS' - \frac{1}{4\pi\varepsilon_0}\int_{\mathcal{V}}\frac{1}{|\mathbf{r}-\mathbf{r}'|}\nabla'\cdot\vec{\mathcal{P}}(\mathbf{r}')dV' \ . \tag{14.14}$$

Defining,

$$\boxed{\sigma_b \equiv \vec{\mathcal{P}}\cdot\mathbf{n}_S} \quad \text{and} \quad \boxed{\varrho_b \equiv -\nabla\cdot\vec{\mathcal{P}}}\ , \tag{14.15}$$

we obtain

$$\Phi(\mathbf{r}) = \frac{1}{4\pi\varepsilon_0}\oint_{\partial\mathcal{V}}\frac{\sigma_b}{|\mathbf{r}-\mathbf{r}'|}dS' - \frac{1}{4\pi\varepsilon_0}\int_{\mathcal{V}}\frac{\varrho_b}{|\mathbf{r}-\mathbf{r}'|}dV' \ . \tag{14.16}$$

The meaning of this result is that the potential (and therefore the field) of a polarized object is the same as the one produced by a volume distribution ϱ_b plus a surface charge distribution σ_b. The index b indicates the fact that we consider here 'bound charges' (i.e. localized charges). Instead of integrating the field contributions of all individual infinitesimal dipoles, as in Eq. (14.13), we can try to find these bound charges, and then calculate the fields they produce, as we already did in the previous chapter.

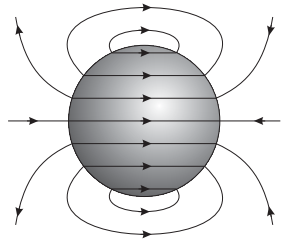

Figure 14.2: Distortion of polarization.

Example 60 (*Microscopic theory of induced dipoles*): As an example we calculate the electric field produced by a homogeneous polarization within a sphere. While the volume charge is zero (otherwise $\vec{\mathcal{P}}$ could not be uniform), the surface charge is $\sigma_b = \vec{\mathcal{P}}\cdot\mathbf{n}_S = \mathcal{P}\cos\theta$. This charge distribution generates a potential which, applying the result derived in example 54, we can write,

$$\Phi(r,\theta) = \begin{cases} \frac{\mathcal{P}}{3\varepsilon_0} r\cos\theta = \frac{1}{4\pi\varepsilon_0}\frac{\mathbf{d}\cdot\mathbf{r}}{R^3} & \text{for} \quad r \le R \\ \frac{\mathcal{P}}{3\varepsilon_0}\frac{R^3}{r^2}\cos\theta = \frac{1}{4\pi\varepsilon_0}\frac{\mathbf{d}\cdot\mathbf{r}}{r^3} & \text{for} \quad r \ge R \end{cases},$$

with $\mathbf{d} = \frac{4\pi}{3}R^3\vec{\mathcal{P}}$. The potential produces a field, which is uniform within the sphere,

$$\vec{\mathcal{E}} = -\nabla\Phi = \begin{cases} -\frac{\mathcal{P}}{3\varepsilon_0}\hat{\mathbf{e}}_z\frac{\partial\Phi}{\partial z} = -\frac{\vec{\mathcal{P}}}{3\varepsilon_0} & \text{for} \quad r \le R \\ \frac{\mathcal{P}}{3\varepsilon_0}\frac{R^3}{r^2}\cos\theta = \frac{1}{4\pi\varepsilon_0}\frac{3(\hat{\mathbf{e}}_r\cdot\mathbf{d})\hat{\mathbf{e}}_r - \mathbf{d}}{r^3} & \text{for} \quad r \ge R \end{cases}.$$

The physical interpretation of the surface charge produced by a uniform polarization is simply a displacement of all the electrons of the body with respect to the positively charged nuclei. Since the electrons remain attached to the nuclei, the volume charge inside the sphere remains neutral. However, the edges of the body accumulate negative charge on one side and positive charge on the other.

14.1.5 Electric displacement

In the previous section we found that the phenomenon of polarization can be understood as being due to a volume charge $\varrho_b = -\nabla \cdot \vec{\mathcal{P}}$ inside the dielectric and a surface charge on the surface of the body $\sigma_b = \vec{\mathcal{P}} \cdot \mathbf{n}_S$. However, many materials have dielectric characteristics and at the same time conductive characteristics, which do not result from a polarization and which we take into account via a distribution of free charges, ϱ_f, the index f indicating 'free charges'.

14.1.5.1 Gauß' Law in dielectric media

Gauß's law can now be generalized for arbitrary media,

$$\varepsilon_0 \nabla \cdot \vec{\mathcal{E}} = \varrho = \varrho_b + \varrho_f = -\nabla \cdot \vec{\mathcal{P}} + \varrho_f \ , \tag{14.17}$$

where $\vec{\mathcal{E}}$ is the total electric field. Defining a new field called the *electric displacement*,

$$\boxed{\vec{\mathcal{D}} \equiv \varepsilon_0 \vec{\mathcal{E}} + \vec{\mathcal{P}}} \ , \tag{14.18}$$

we can now write,

$$\nabla \cdot \vec{\mathcal{D}} = \varrho_f \ . \tag{14.19}$$

The electric displacement is that part of the electric field, which comes only from free charges (which is the part useful for generating currents). We can also define the *electric susceptibility* χ_ε via,

$$\vec{\mathcal{P}} = \varepsilon_0 \chi_\varepsilon \vec{\mathcal{E}} \ , \tag{14.20}$$

or the *permittivity* ε via,

$$\vec{\mathcal{D}} = \varepsilon \vec{\mathcal{E}} = \varepsilon_0 (1 + \chi_\varepsilon) \vec{\mathcal{E}} \ . \tag{14.21}$$

Note that the rotation of the polarization *does not necessarily vanish*, since the susceptibility may depend on position, $\chi_\varepsilon = \chi_\varepsilon(\mathbf{r})$,

$$\nabla \times \vec{\mathcal{D}} = \varepsilon_0 (\nabla \times \vec{\mathcal{E}}) + \nabla \times \vec{\mathcal{P}} = \nabla \times (\varepsilon_0 \chi_\varepsilon \vec{\mathcal{E}}) \neq 0 \ . \tag{14.22}$$

Therefore, $\vec{\mathcal{D}}$ generally can not be derived from a potential, and Coulomb's law is not valid for $\vec{\mathcal{D}}$.

14.1.5.2 Boundary conditions involving dielectrics

The integral version of Gauß's law, $\oint \vec{\mathcal{D}} \cdot d\mathbf{S} = Q_f$, allows us to determine the behavior of the electric displacement near interfaces,

$$\mathcal{D}^\perp_{top} - \mathcal{D}^\perp_{bottom} = \sigma_f \ . \tag{14.23}$$

On the other hand, Stokes' law $\nabla \times \vec{\mathcal{D}} = \varepsilon_0 \nabla \times \vec{\mathcal{E}} + \nabla \times \vec{\mathcal{P}} = \nabla \times \vec{\mathcal{P}}$ yields,

$$\vec{\mathcal{D}}^{\parallel}_{top} - \vec{\mathcal{D}}^{\parallel}_{bottom} = \vec{\mathcal{P}}^{\parallel}_{top} - \vec{\mathcal{P}}^{\parallel}_{bottom} \ . \tag{14.24}$$

This is in contrast to the behavior of the electric $\vec{\mathcal{E}}$ field at interfaces described by Eqs. (13.37) and (13.39).

14.1.6 Electrical susceptibility and permittivity

14.1.6.1 Linear dielectrics

In many materials, as long as the applied electric field is not too strong, the polarization is proportional to the field, $\vec{\mathcal{P}} \propto \vec{\mathcal{E}}$, that is, the electric susceptibility depends on the material's microscopic properties and external factors such as temperature, but not on the applied field, $\chi_\varepsilon \neq \chi_\varepsilon(\vec{\mathcal{E}})$. Hence, linear media can be characterized by a constant,

$$\varepsilon_r \equiv \frac{\varepsilon}{\varepsilon_0} \ , \tag{14.25}$$

called *relative permittivity*.

In *non-linear* media, in contrast, the susceptibility $\chi_\varepsilon(\vec{\mathcal{E}})$ depend on the strength of the electric field. Often the polarization can be expanded in orders of the electric field,

$$\vec{\mathcal{P}}(\vec{\mathcal{E}}) = \varepsilon^{(1)}\vec{\mathcal{E}} + \varepsilon^{(2)}\vec{\mathcal{E}}^2 + \varepsilon^{(3)}\vec{\mathcal{E}}^3 + \dots \ . \tag{14.26}$$

In *anisotropic* materials the situation gets more complicated, because the susceptibility and the permittivity must be understood as tensors,

$$\mathcal{P}_k(\vec{\mathcal{E}}) = \sum_m \varepsilon^{(1)}_{km}\mathcal{E}_m + \sum_{ml} \varepsilon^{(2)}_{kml}\mathcal{E}_m\mathcal{E}_l + \sum_{mlj} \varepsilon^{(3)}_{kmlj}\mathcal{E}_m\mathcal{E}_l\mathcal{E}_j + \dots \ . \tag{14.27}$$

Example 61 (*Microscopic theory of induced dipoles*): We know that an *external electric field* $\vec{\mathcal{E}}_{ext}$ applied to a linear purely dielectric medium generates a *macroscopic polarization* proportional to the field,

$$\vec{\mathcal{P}} = \chi_\varepsilon \varepsilon_0 \vec{\mathcal{E}}_{ext} \ .$$

On the other hand, if the material consists of atoms (or non-polar molecules), the *microscopic dipole moment* induced in each atom is proportional to the *local field*,

$$\mathbf{d}_{ind} = \alpha_{pol}\vec{\mathcal{E}}_{loc} \ .$$

Here, $\vec{\mathcal{E}}_{loc}$ is the *total field* due to the applied field $\vec{\mathcal{E}}_{ext}$ plus the field $\vec{\mathcal{E}}_{self}$ generated by the polarization of the other atoms which are around. The question now is, what is the relationship between the atomic polarizability α_{pol} (characterizing the sample from a microscopic point of view) and the susceptibility χ_e (characterizing the sample from a macroscopic point of view)?

To begin with we consider low densities, in which case it is a good approximation to suppose that the atom does not feel the polarization of its neighbors, that is $\vec{\mathcal{E}}_{loc} \simeq \vec{\mathcal{E}}_{ext}$. We already noticed in Eq. (??) that the polarization is nothing more than the sum over all the dipole moments induced by the local electric field, such that, comparing the last two relations, a first trial would be to affirm,

$$\chi_\varepsilon = \frac{N}{V}\frac{\alpha_{pol}}{\varepsilon_0} \ .$$

But for dense gases, there will be a correction, and the local field will be a superposition of the external field and the field generated by the surrounding dipoles, $\vec{\mathcal{E}}_{loc} = \vec{\mathcal{E}}_{ext} + \vec{\mathcal{E}}_{self}$. To estimate this field, we imagine a single dipole located inside a sphere. The polarization of the surrounding medium is modeled by a surface charge density with the value $\sigma_b \equiv -\mathcal{P}\cos\theta$. The electric field produced by this charge distribution was calculated in example 60: $\vec{\mathcal{E}}_{self} = \vec{\mathcal{P}}/3\varepsilon_0$. With this we calculate,

$$\chi_\varepsilon = \frac{\mathcal{P}}{\varepsilon_0 \mathcal{E}_{ext}} = \frac{\mathcal{P}}{\varepsilon_0(\mathcal{E}_{loc} - \mathcal{E}_{self})} = \frac{\mathcal{P}}{\varepsilon_0(\frac{p_{ind}}{\alpha_{pol}} - \frac{\mathcal{P}}{3\varepsilon_0})} = \frac{N\alpha_{pol}/\varepsilon_0 V}{1 - N\alpha_{pol}/3\varepsilon_0 V} \ . \tag{14.28}$$

This equation is known as *Clausius-Mossotti formula*. The difference between the denominator and 1, called *Lorentz-Lorenz shift*, comes from the energy displacements of the atoms due to the dipole-dipole interactions. At low densities we recover the linear relation. In terms of the relative permittivity we can also write,

$$\frac{\alpha_{pol}}{\varepsilon_0} = \frac{3V}{N}\frac{\varepsilon_r - 1}{\varepsilon_r + 2} \ .$$

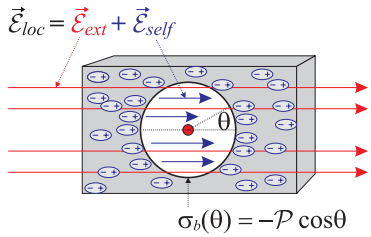

Figure 14.3: The local field $\vec{\mathcal{E}}_{loc}$ is the sum of the external field $\vec{\mathcal{E}}_{ext}$ and the field generated by the polarization $\vec{\mathcal{E}}_{self}$.

14.1.7 Exercises

14.1.7.1 Ex: Torque on dipoles

Calculate the torque on a dipole in front of a conducting surface.

Solution: *The coordinates of the charges of the dipole and its image are,*

$$\mathbf{r}_\pm = \pm\frac{\mathbf{d}}{2} \quad , \quad \mathbf{x}_\pm = -2a\hat{\mathbf{e}}_z \mp \left[\frac{\mathbf{d}}{2} - (\hat{\mathbf{e}}_z \cdot \mathbf{d})\hat{\mathbf{e}}_z\right] \ .$$

With this we calculate the vector products,

$$\mathbf{r}_+ \times \mathbf{x}_\pm = -\mathbf{r}_- \times \mathbf{x}_\pm = (-2a \pm \hat{\mathbf{e}}_z \cdot \mathbf{d})\frac{\mathbf{d}}{2} \times \hat{\mathbf{e}}_z = -\left(a \mp \frac{d}{2}\cos\theta\right) d\sin\theta\hat{\mathbf{e}}_x \ .$$

O torque agora é,

$$
\begin{aligned}
\vec{\tau} &= \mathbf{r}_+ \times Q\vec{\mathcal{E}}(\mathbf{r}_+) + \mathbf{r}_- \times (-Q)\vec{\mathcal{E}}(\mathbf{r}_-) \\
&= \frac{Q^2}{4\pi\varepsilon_0}\left[\mathbf{r}_+ \times \left(\frac{\mathbf{r}_+ - \mathbf{x}_+}{|\mathbf{r}_+ - \mathbf{x}_+|^3} - \frac{\mathbf{r}_+ - \mathbf{x}_-}{|\mathbf{r}_+ - \mathbf{x}_-|^3}\right) - \mathbf{r}_- \times \left(\frac{-\mathbf{r}_+ - \mathbf{x}_+}{|-\mathbf{r}_+ - \mathbf{x}_+|^3} - \frac{-\mathbf{r}_+ - \mathbf{x}_-}{|-\mathbf{r}_+ - \mathbf{x}_-|^3}\right)\right] \\
&= \frac{Q^2}{4\pi\varepsilon_0}\left[\frac{\mathbf{r}_+ \times \mathbf{x}_+}{|\mathbf{d} + (2a - (\hat{\mathbf{e}}_z \cdot \mathbf{d}))\hat{\mathbf{e}}_z|^3} - \frac{\mathbf{r}_+ \times \mathbf{x}_-}{|2a + (\hat{\mathbf{e}}_z \cdot \mathbf{d})|^3} + \frac{\mathbf{r}_+ \times \mathbf{x}_+}{|2a - (\hat{\mathbf{e}}_z \cdot \mathbf{d})|^3} - \frac{\mathbf{r}_+ \times \mathbf{x}_-}{|-\mathbf{d} + (2a + (\hat{\mathbf{e}}_z \cdot \mathbf{d}))\hat{\mathbf{e}}_z|^3}\right] \\
&= \frac{Q^2}{4\pi\varepsilon_0}\left[\frac{-a - \frac{d}{2}\cos\theta}{\sqrt{4a^2 + d^2\sin^2\theta}^3} + \frac{a - \frac{d}{2}\cos\theta}{\sqrt{4a^2 + d^2 + 4ad\cos\theta}^3} + \frac{-a - \frac{d}{2}\cos\theta}{\sqrt{4a^2 + d^2 - 4ad\cos\theta}^3} + \frac{-a + \frac{d}{2}\cos\theta}{\sqrt{4a^2 + d^2\sin^2\theta}^3}\right] d\,s \\
&\simeq \frac{Q^2}{4\pi\varepsilon_0}\left[\frac{a + \frac{z}{2}}{\sqrt{4a^2 + 4az}^3} + \frac{-a + \frac{z}{2}}{\sqrt{4a^2 - 4az}^3} + \frac{-z}{\sqrt{4a^2}^3}\right] d\sin\theta\hat{\mathbf{e}}_x \simeq -\frac{Q^2}{4\pi\varepsilon_0}\frac{3d^2\sin\theta\cos\theta}{8a^3}\hat{\mathbf{e}}_x \ .
\end{aligned}
$$

Assuming $d \ll a$ we disregarded, in the last line, the terms $\propto d^2$ and expanded in

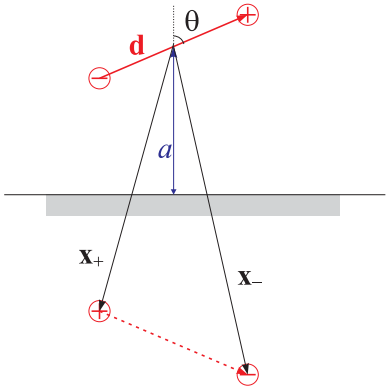

Figure 14.4: Dipoles.

terms of $z \equiv \cos\theta$. In particular, when the dipole is perpendicular to the surface ($\theta \simeq 0$),

$$\vec{\tau}_{perp} = -\frac{Q^2}{4\pi\varepsilon_0}\frac{3d^2}{8a^3}\hat{\mathbf{e}}_x\theta \ .$$

That is, in this position it is in a stable position, because when θ increases ($\theta > 0°$), it receives a torque pushing it backwards. On the other hand, when the dipole is parallel to the surface ($\theta' \equiv \theta - 90° \simeq 0$), we have,

$$\vec{\tau}_{para} \simeq \frac{Q^2}{4\pi\varepsilon_0}\frac{3d^2}{8a^3}\hat{\mathbf{e}}_x\theta' \ .$$

That is, it stays in a labile equilibrium, because when θ' increases ($\theta' > 0°$), it gets a torque pushing it forward.

14.1.7.2 Ex: Torque on dipoles

Consider the configuration of two dipoles shown in the figure and calculate the reciprocal torques.

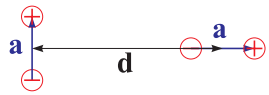

Figure 14.5: Dipoles.

Solution: *a. We put the first dipole in the origin,* $\mathbf{r}_\pm = \pm\frac{d}{2}\hat{\mathbf{e}}_z$*, such that the second is at the coordinates* $\mathbf{x}_\pm = (a+\frac{d}{2})\hat{\mathbf{e}}_x$*. The electric field* $\vec{\mathcal{E}}_\pm$ *generated by the second dipole at the position of the first is,*

$$\vec{\mathcal{E}}(\mathbf{r}_+) = \frac{Q}{4\pi\varepsilon_0}\frac{\frac{d}{2}\hat{\mathbf{e}}_z - (a+\frac{d}{2})\hat{\mathbf{e}}_x}{|\frac{d}{2}\hat{\mathbf{e}}_z - (a+\frac{d}{2})\hat{\mathbf{e}}_x|^3} - \frac{Q}{4\pi\varepsilon_0}\frac{\frac{d}{2}\hat{\mathbf{e}}_z - (a-\frac{d}{2})\hat{\mathbf{e}}_x}{|\frac{d}{2}\hat{\mathbf{e}}_z - (a-\frac{d}{2})\hat{\mathbf{e}}_x|^3}$$
$$\vec{\mathcal{E}}(\mathbf{r}_-) = \frac{Q}{4\pi\varepsilon_0}\frac{-\frac{d}{2}\hat{\mathbf{e}}_z - (a+\frac{d}{2})\hat{\mathbf{e}}_x}{|-\frac{d}{2}\hat{\mathbf{e}}_z - (a+\frac{d}{2})\hat{\mathbf{e}}_x|^3} - \frac{Q}{4\pi\varepsilon_0}\frac{-\frac{d}{2}\hat{\mathbf{e}}_z - (a-\frac{d}{2})\hat{\mathbf{e}}_x}{|-\frac{d}{2}\hat{\mathbf{e}}_z - (a-\frac{d}{2})\hat{\mathbf{e}}_x|^3} \ .$$

The torque now is,

$$\begin{aligned}
\vec{\tau} &= \tfrac{d}{2}\hat{\mathbf{e}}_z \times Q\vec{\mathcal{E}}(\mathbf{r}_+) + (-\tfrac{d}{2}\hat{\mathbf{e}}_z)\times(-Q)\vec{\mathcal{E}}(\mathbf{r}_-) = \frac{Q^2}{4\pi\varepsilon_0}\frac{d}{2}\hat{\mathbf{e}}_z \\
&\times\left(\frac{\frac{d}{2}\hat{\mathbf{e}}_z - (a+\frac{d}{2})\hat{\mathbf{e}}_x}{|\frac{d}{2}\hat{\mathbf{e}}_z - (a+\frac{d}{2})\hat{\mathbf{e}}_x|^3} - \frac{\frac{d}{2}\hat{\mathbf{e}}_z - (a-\frac{d}{2})\hat{\mathbf{e}}_x}{|\frac{d}{2}\hat{\mathbf{e}}_z - (a-\frac{d}{2})\hat{\mathbf{e}}_x|^3} + \frac{-\frac{d}{2}\hat{\mathbf{e}}_z - (a+\frac{d}{2})\hat{\mathbf{e}}_x}{|-\frac{d}{2}\hat{\mathbf{e}}_z - (a+\frac{d}{2})\hat{\mathbf{e}}_x|^3} - \frac{-\frac{d}{2}\hat{\mathbf{e}}_z - (a-\frac{d}{2})\hat{\mathbf{e}}_x}{|-\frac{d}{2}\hat{\mathbf{e}}_z - (a-\frac{d}{2})e_x|^3}\right) \\
&= -\frac{Q^2}{4\pi\varepsilon_0}\frac{d}{2}\left(\frac{a+\frac{d}{2}}{\sqrt{\left(\frac{d}{2}\right)^2+\left(a+\frac{d}{2}\right)^2}^3} - \frac{a-\frac{d}{2}}{\sqrt{\left(\frac{d}{2}\right)^2+\left(a-\frac{d}{2}\right)^2}^3} + \frac{a+\frac{d}{2}}{\sqrt{\left(\frac{d}{2}\right)^2+\left(a+\frac{d}{2}\right)^2}^3} - \frac{a-\frac{d}{2}}{\sqrt{\left(\frac{d}{2}\right)^2+\left(a-\frac{d}{2}\right)^2}^3}\right) \\
&= -\frac{Q^2}{4\pi\varepsilon_0}\frac{d}{2}\left(\frac{2a+d}{\sqrt{\left(\frac{d}{2}\right)^2+\left(a+\frac{d}{2}\right)^2}^3} - \frac{2a-d}{\sqrt{\left(\frac{d}{2}\right)^2+\left(a-\frac{d}{2}\right)^2}^3}\right)\hat{\mathbf{e}}_y \\
&\simeq -\frac{Q^2}{4\pi\varepsilon_0}\frac{d}{2}\left(\frac{2a+d}{a^3} - \frac{2a-d}{a^3}\right)\hat{\mathbf{e}}_y = -\frac{Q^2}{4\pi\varepsilon_0}\frac{d^2}{a^3}\hat{\mathbf{e}}_y \ .
\end{aligned}$$

That is, there exists a torque.
b. Now we put the second dipole at the origin, $\mathbf{r}_\pm = \pm\frac{d}{2}\hat{\mathbf{e}}_z$*, such that the second is at the coordinates ...*

14.1.7.3 Ex: Polarizability of hydrogen

In quantum mechanics we find for the electronic charge distribution in a hydrogen atom,

$$\varrho(r) = \frac{Q}{\pi a_B^3}e^{-2r/a_B} \ .$$

Calculate the polarizability.

Solution: *The electric field of the electronic shell is given by Gauss's law,*

$$\oint \vec{\mathcal{E}}_{ele}\cdot d\mathbf{S} = 4\pi r^2 \mathcal{E}_{ele}(r)$$
$$= \int \frac{\varrho(\mathbf{r}')}{\varepsilon_0} dV' = \frac{1}{\varepsilon_0}\int \frac{Q}{\pi a_B^3} e^{-2r'/a_B} 4\pi r'^2 dr' = \frac{Q}{\varepsilon_0}\left[1 - \left(1 + \frac{2r}{a_B} + \frac{2r^2}{a_B^2}\right) e^{-2r/a_B}\right]$$
$$\simeq \frac{Q}{\varepsilon_0}\left[\frac{4r^3}{3a_B^3} - \frac{2r^4}{a_B^4} + ...\right] .$$

Applying an outer field along the z-axis, in equilibrium position,

$$\frac{Q}{3\pi\varepsilon_0 a_B^3}\mathbf{r} \simeq \vec{\mathcal{E}}_{ele} = \vec{\mathcal{E}}_{ext} = \mathcal{E}_{ext}\hat{\mathbf{e}}_z ,$$

yielding,

$$\mathbf{r} = \frac{3\pi\varepsilon_0 a_B^3}{Q}\mathcal{E}_{ext}\hat{\mathbf{e}}_z .$$

The dipole moment of the electron shell being shifted away from the nucleus is,

$$\mathbf{d} = \int \left[Q\delta^3(\mathbf{r}' - \tfrac{z}{2}\hat{\mathbf{e}}_z) - \varrho(\mathbf{r}' + \tfrac{z}{2}\hat{\mathbf{e}}_z)\right]\mathbf{r}' dV' = \int \left[Q\delta^3(\mathbf{r}' - z\hat{\mathbf{e}}_z) - \varrho(\mathbf{r}')\right](\mathbf{r}' - \tfrac{z}{2}\hat{\mathbf{e}}_z)dV'$$
$$= Q\tfrac{z}{2}\hat{\mathbf{e}}_z - \frac{Q}{\pi a_B^3}\int e^{-2r'/a_B}\mathbf{r}' dV' + \frac{Q}{\pi a_B^3}\tfrac{z}{2}\hat{\mathbf{e}}_z \int e^{-2r'/a_B} dV'$$
$$= Q\tfrac{z}{2}\hat{\mathbf{e}}_z - 0 + \frac{Q}{\pi}\tfrac{z}{2}\hat{\mathbf{e}}_z 4\pi \int_0^\infty u^2 e^{-2u} du = Qz\hat{\mathbf{e}}_z .$$

Finally, the polarizability is,

$$\frac{\alpha_{pol}}{4\pi\varepsilon_0} = \frac{d}{4\pi\varepsilon_0\mathcal{E}_{ext}} = \frac{Qz}{4\pi\varepsilon_0\mathcal{E}_{ext}} = \frac{3}{4}a_B^3 .$$

Alternatively:

$$4\pi r^2\mathcal{E}_{ele}(r) = \frac{Q}{\pi\varepsilon_0 a_B^3}4\pi\int_0^r e^{-2r'/a_B} r'^2 dr' \simeq \frac{Q}{\pi\varepsilon_0 a_B^3}4\pi\int_0^r r'^2 dr' = \frac{Q}{\varepsilon_0 a_B^3}\frac{4r^3}{3} \tag{14.29}$$

gives the same result.

14.1.7.4 Ex: Susceptibility

One liter of water is evaporated in $10\,\mathrm{m}^3$ of dry air at room temperature $T = 300\,\mathrm{K}$.
a. Calculate the dipolar density n of the air. Assume that only the dipolar moments of the evaporated molecules contribute.
b. Determine the susceptibility χ_ε of the air. Use the relation $\mathcal{P} = \varepsilon_0\chi_\varepsilon\mathcal{E}$, as well as Curie's law for the polarization $\mathcal{P}$.

Solution: *a. The number of molecules in* $1\,\mathrm{l} = 1\,\mathrm{kg} = m_0$ *of water, with the molecular mass being* $m_{H_2O} = 18u = 18 \cdot 1.66 \cdot 10^{-27}\,\mathrm{kg}$*, is,*

$$N = \frac{m_0}{m_{H_2O}} = 3.35 \cdot 10^{25} \ .$$

the dipolar density is:

$$n = \frac{N}{V} = 3.35 \cdot 24\,\mathrm{m}^{-3} \ .$$

b. The definition of χ_e *is given by:* $\mathcal{P} = \varepsilon_0 \chi_0 \mathcal{E}$*. With Curie's law:*

$$\vec{\mathcal{P}} = \frac{1}{3} n \frac{\mathbf{d} \cdot \vec{\mathcal{E}}}{k_B T} \mathbf{d} = \frac{1}{3} n \frac{d^2 \mathcal{E}}{k_B T} \hat{\mathbf{e}}_d$$

to d *parallel to* $\mathcal{E}$*. Equalizing,*

$$\varepsilon_0 \chi_0 = \frac{1}{3} n \frac{d^2}{k_B T} = 1.17 \cdot (-3) \ .$$

14.2 Influence of charges and capacitance

We now assume that we have two separate conductors, one carrying the charge $+Q$ and the other $-Q$. Since the potential of each conductor is the same at each point of its body, we can specify a potential difference, called *voltage*, between them,

$$U \equiv \Phi_+ - \Phi_- = -\int_{(-)}^{(+)} \vec{\mathcal{E}} \cdot d\mathbf{l} \ , \tag{14.30}$$

which does not depend on the distribution of the charges throughout the conductors. However, we know from Coulomb's law that the electric field is proportional to the charge Q and from the above equation, also the voltage. The proportionality factor is called *capacitance*,

$$C \equiv \frac{Q}{U} \ . \tag{14.31}$$

14.2.1 Capacitors and storage of electric energy

A device capable of storing charges is called *capacitor*.

> **Example 62 (*Plate capacitor*):** The simplest geometry for a capacitor are two parallel conducting plates (area S) maintained at a distance d. The surface charge distribution $\sigma = Q/S$ produces a field $\mathcal{E} = \sigma/\varepsilon_0$ and a potential difference $U = \mathcal{E}d$, such that,
>
> $$C = \varepsilon_0 \frac{S}{d} \ . \tag{14.32}$$

To charge a capacitor we must bring electrons from the positive side to the negative side of the capacitor. For a single electron, this requires the work

$$\Delta W_e = \int_0^d \mathbf{F} \cdot d\mathbf{r} = ed|\vec{\mathcal{E}}| = eU \ .$$

For a small amount of charge dq,

$$\Delta W_e = \int U \ dQ = \int_0^Q \frac{Q}{C} dQ = \frac{Q^2}{2C} = \frac{1}{2} CU^2 \ .$$

Resolve the Excs. 14.2.2.1-14.2.2.10.

14.2.1.1 Capacitors with dielectrics

In the presence of a dielectric the capacitance increases, $C = \varepsilon_r C_{vac}$. Thus, the field energy also increases by a factor of ε_r.

We consider a capacitor filled with a linear dielectric and charged with the free charge ϱ_f, which generates a voltage U between the electrodes. We want to know the work needed to add a little bit more charge $\delta\varrho_f$ to the volume element dV,

$$\delta W = \int U \ \delta\varrho_f dV \ . \tag{14.33}$$

Now, with Eq. (14.19) we write $\varrho_f = \nabla \cdot \vec{\mathcal{D}}$ and $\delta\varrho_f = \nabla \cdot \delta\vec{\mathcal{D}}$, such that,

$$\delta W = \int_{\mathcal{V}} U \nabla \cdot \delta\vec{\mathcal{D}} dV = \int_{\partial\mathcal{V}} U \ \delta\vec{\mathcal{D}} \cdot d\mathbf{S} - \int_{\mathcal{V}} \delta\vec{\mathcal{D}} \cdot \nabla U dV = \int_{\mathcal{V}} \delta\vec{\mathcal{D}} \cdot \vec{\mathcal{E}} dV \ . \tag{14.34}$$

For a linear dielectric, $\vec{\mathcal{D}} = \varepsilon\vec{\mathcal{E}}$, such that, $\vec{\mathcal{E}} \cdot \delta\vec{\mathcal{D}} = \vec{\mathcal{E}}\varepsilon \cdot \delta\vec{\mathcal{E}} = \frac{1}{2}\delta(\varepsilon E^2) = \frac{1}{2}\delta(\vec{\mathcal{D}} \cdot \vec{\mathcal{E}})$, giving,

$$\delta W = \tfrac{1}{2} \int \delta(\vec{\mathcal{D}} \cdot \vec{\mathcal{E}}) dV \ . \tag{14.35}$$

Finally, to charge the capacitor completely,

$$W = \int \delta W = \tfrac{1}{2} \int \vec{\mathcal{D}} \cdot \vec{\mathcal{E}} = \int u dV \ , \tag{14.36}$$

with the energy density,

$$\boxed{u = \frac{1}{2} \vec{\mathcal{E}} \cdot \vec{\mathcal{D}}} \ . \tag{14.37}$$

Do the Excs. 14.2.2.11-14.2.2.18.

> **Example 63 (*Forces on dielectrics*):** Dielectrics in electric fields are subjected to forces due to the polarization induced in the medium. Let us consider the example of a plate capacitor inside which we insert a dielectric. In the scheme shown in Fig. 14.6 the electric field homogeneously traverses the capacitor and also the dielectric body, such that the forces should disappear. On the other hand, on its edges the dielectric distorts the field, such that forces become possible.

The easiest way to calculate these forces is via the potential energy gradient, $\mathbf{F} = -\nabla W$. If the dielectric body is free to move in x-direction, we have,

$$\mathbf{F} = -\frac{dW}{dx} = -\frac{d}{dx}\frac{Q^2}{2C} = -\frac{d}{dx}\frac{CU^2}{2} \ .$$

We use the first expression, in case the charge on the capacitor is kept constant, and the second, when the voltage on the capacitor is kept constant. Gradually inserting the dielectric, a part of the volume of the capacitor will be empty and another part will be filled with the dielectric medium:

$$C = C_{vac}\frac{x}{a} + C_{vac}\varepsilon_r\frac{a-x}{a} \ .$$

Keeping the charge constant, we get,

$$\mathbf{F} = \frac{Q^2}{2C^2}\frac{dC}{dx} = -\frac{d}{dx}\frac{Q^2}{2(C_{vac}\frac{x}{a} + C_{vac}\varepsilon_r\frac{a-x}{a})} = \frac{Q^2}{2C_{vac}}\frac{-a\chi_\varepsilon}{(a - x\chi_\varepsilon)^2} \ .$$

Since the force is negative, the dielectric is drawn into the capacitor.
The situation is different when we keep the voltage constant, for example, by connecting the capacitor to a battery. In this case we need to use the second expression. However, we must take into account the work UdQ that the battery must do to increase the charge on the capacitor in order to maintain the voltage constant while we increase the capacity via $C_{vac} \to C$,

$$dW = -Fdx + UdQ \ .$$

Hence,

$$F = -\frac{dW}{dx} + U\frac{dQ}{dx} = -\frac{U^2}{2}\frac{dC}{dx} + U^2\frac{dC}{dx} = \frac{Q^2}{2C^2}\frac{dC}{dx} \ ,$$

and we get the same result as in the case where we kept the charge constant.

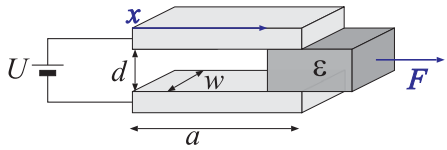

Figure 14.6: Force on the dielectric between the plates of a capacitor.

14.2.1.2 Capacitor circuits

For parallel circuits $C_{tot} = C_1 + C_2$, for circuits in series $C_{tot}^{-1} = C_1^{-1} + C_2^{-1}$. Do the Excs. 14.2.2.19-14.2.2.27.

14.2.2 Exercises

14.2.2.1 Ex: Capacitors

Be given two isolated conductors carrying equal charges but with opposite signs $\pm Q$. The capacity of this configuration is the ratio between the absolute value of the charge of one conductor and the absolute value of the potential difference between the two

conductors. Using Gauß' law calculate the capacity of
a. 2 large parallel plates with area A being at a short distance d;
b. 2 concentric cylindrical conductors (without surfaces at the ends of the cylinders) with radii ρ_1 and ρ_2.
c. 2 concentric spherical surfaces with radii r_1 and r_2.
Help: Choose integration volumes that fits the symmetry of your system.

Solution: *a. Choosing a volume enclosing one of the plates and using Gauß' law:*

$$\frac{Q}{\varepsilon_0} = \int_{\partial V} \vec{\mathcal{E}} \cdot d\mathbf{S} = \int_{\partial V} \mathcal{E}_z \; dxdy = \mathcal{E}_z S \; .$$

The potential difference is,

$$\Phi_1 - \Phi_2 = \int_{plane1}^{plane2} \vec{\mathcal{E}} \cdot d\mathbf{s} = \int_{z_1}^{z_2} \frac{Q}{\varepsilon_0 S} dz = \frac{Q}{\varepsilon_0 A} d \; .$$

Therefore, the capacity is,

$$C = \frac{Q}{|\Phi_1 - \Phi_2|} = \varepsilon_0 \frac{S}{d} \; .$$

b. Choosing a volume enclosing the inner cylinder and using Gauß' law:

$$\frac{Q}{\varepsilon_0} = \int_{\partial V} \vec{\mathcal{E}} \cdot d\mathbf{S} = \int_{\partial V} \mathcal{E}_\rho \; \rho d\phi dz = \mathcal{E}_\rho 2\pi\rho L \; .$$

The potential difference is,

$$\Phi_1 - \Phi_2 = \int_{cilint}^{cilext} \vec{\mathcal{E}} \cdot d\mathbf{l} = \int_{\rho_1}^{\rho_2} \frac{Q}{2\pi\varepsilon_0 L} \frac{1}{\rho} d\rho = \frac{1}{2} \frac{Q}{\pi\varepsilon_0 L} \ln \frac{\rho_2}{\rho_1} \; .$$

Therefore, the capacity is,

$$C = \frac{Q}{|\Phi_1 - \Phi_2|} = \frac{2\pi\varepsilon_0 L}{\ln \rho_2 - \ln \rho_1} \; .$$

c. Choosing a volume enclosing the inner sphere and using Gauß' law:

$$\frac{Q}{\varepsilon_0} = \int_{\partial V} \vec{\mathcal{E}}_\rho \cdot d\mathbf{S} = \int_{\partial V} \mathcal{E}_r \; r^2 \sin\theta d\theta d\phi = \mathcal{E}_r r^2 4\pi \; .$$

The potential difference is,

$$\phi_1 - \phi_2 = \int_{esfint}^{esfext} \vec{\mathcal{E}} \cdot d\mathbf{s} = \int_{r_1}^{r_2} \frac{Q}{4\pi\varepsilon_0 r^2} dr = -\frac{Q}{4\pi\varepsilon_0} \frac{r_1 - r_2}{r_2 r_1} \; .$$

Therefore, the capacity is,

$$C = \frac{Q}{|\phi_1 - \phi_2|} = \frac{4\pi\varepsilon_0 r_2 r_1}{r_2 - r_1} \; .$$

14.2.2.2 Ex: Capacitance of a mercury drop

The capacity of a spherical drop of mercury with radius R is given by $C = 4\pi\varepsilon_0$. Now, two of these drops merge. What is the capacity of this larger drop?

Solution: *The capacity of this larger drop ...*

14.2.2.3 Ex: Charged plates

Consider a thin, very extended metal plate, $d^2 \ll A$, with area A and thickness d carrying the charge Q. Calculate the charge distribution (surface charge density) and the electric field on both sides of the plate neglecting edge effects. How do the charge distribution and the electric field change, when we have two plates instead of one with thickness d at a distance l, one being charged with the charge Q and the other with $-Q$.

Solution:

14.2.2.4 Ex: Plate capacitor

A capacitor is made of two flat metal plates with the surfaces $1\,\mathrm{m}^2$. What should be the distance of the plates to give the capacitor a capacity of $1\,\mathrm{F}$? Is it possible to build such a capacitor?

Solution: *a. From the relationship* $C = \varepsilon_0 \frac{A}{d}$ *It follows that the distance between the plates should be less than* $d = \varepsilon_0 \frac{A}{C} < 8.9\,\mathrm{pm}$*, which is smaller than the atomic radius and therefore impossible.*

14.2.2.5 Ex: Cylindrical capacitor

A cylindrical capacitor is made of two infinitesimally thin coaxial cylindrical surfaces with radii R_1 and R_2. For simplicity, assume that the cylinders are infinitely extended in z-direction. The charge per unit length on the inner cylinder is $+Q/l$, on the outer cylinder $-Q/l$. Calculate the electric field $\vec{\mathcal{E}}(r)$ as a function of the distance r from the symmetry axis for $r \leq R_1$, $R_1 < r < R_2$, and $r \geq R_2$.
Help: Use the symmetry of the problem and Gauß' law.

Solution: *From Gauß' law,* $\int_V \nabla \cdot \vec{\mathcal{E}} d^3\mathbf{r} = \oint_{\partial V} \vec{\mathcal{E}} \cdot d\mathbf{S}$ *together with* $\nabla \cdot \vec{\mathcal{E}} = \varrho/\varepsilon_0$ *gives,*

$$\int_V \varrho d^3\mathbf{r} = \varepsilon_0 \oint_{\partial V} \vec{\mathcal{E}} \cdot d\mathbf{A} \ .$$

Because of the cylindrical symmetry we only need to consider the radial component of the field. We integrate on a cylinder with radius r*. For* $r < R_1$ *we get,*

$$\mathcal{E}_{r<R_1} = 0 \ .$$

for $R_1 < r < R_2$ *we get* $\int_{V_r} \varrho d^3\mathbf{r} = \pi r^2 \varrho L = \frac{Q}{l} L$ *and* $\oint_{\partial V} \vec{\mathcal{E}} \cdot d\mathbf{S} = \mathcal{E}_r \cdot 2\pi r L$. *From this follows,* $\frac{Q}{l} L = \varepsilon_0 \mathcal{E}_r 2\pi r L$, *and finally,*

$$\mathcal{E}_{R_1<r<R_2} = \frac{Q}{2\pi\varepsilon_0 l} \frac{1}{r} \ .$$

for $R_2 < r$ *we get* $Q = 0$, *hence,*

$$\mathcal{E}_{R_2<r} = 0 \ .$$

14.2.2.6 Ex: Cylindrical capacitor (T7)

Two concentric infinitely thin hollow conductive cylinders with radii a and b ($a < b$) and length l are charged with charges $+q$ resp. $-Q$. l is much larger than b, such that border effects are negligible. For symmetry reasons, the electric field can only have one radial component.
a. Write down the charge distribution $\varrho(\mathbf{r})$ in cylindrical coordinates (r, ϕ, z) with the help of the δ-function.
b. Calculate the electric field $\vec{\mathcal{E}}(r, \phi, z)$ in the whole space ($r < a,\ a < r < b,\ b < r$). Use for this the fundamental equations of electrostatics and $\nabla \cdot \vec{\mathcal{E}} = \frac{1}{r} \frac{d}{dr}(eE_r)$. Alternatively, this part can be resolved using Gauß' law.
c. Calculate the potential difference $|\Phi(r = b) - \Phi(r = a)|$ between the two surface of the cylinders. To do this, calculate the line integral $\int \vec{\mathcal{E}} \cdot d\mathbf{r}$ along a suitable path.
d. The capacity C of the device is defined by the absolute value of the ratio between the charge on one cylinder and the potential difference between the cylinders. Calculate the capacity of this 'cylindrical capacitor'.

Solution: *a. We have,*

$$\varrho(r, \phi, z) = \frac{q}{2\pi a l} \delta(r - a) - \frac{q}{2\pi b l} \delta(r - b) \ .$$

Proof:

$$\int\limits_{cil.int} d^3 r \varrho = 2\pi l \int\limits_{a-\varepsilon}^{a+\varepsilon} dr r \varrho = 2\pi a l \frac{q}{2\pi a l} = q \ .$$

b. Using Gauß' faw:

$$\int\limits_{sup.\ cyl.} \vec{\mathcal{E}} \cdot d\vec{f} = 2\pi r l E_r = \int\limits_{vol.\ cyl.} d^3\mathbf{r}\ \nabla \cdot \vec{\mathcal{E}} = 4\pi Q \ ,$$

where Q *is the total charge inside the integration volume. Follows,*

$$\mathcal{E}_r = 0 \qquad for \qquad r < a \qquad and \qquad r > b$$

$$\mathcal{E}_r = \frac{2q}{l} \frac{1}{r} \qquad for \qquad a < r < b \ .$$

Alternatively with Gauß' law,

$$\nabla \cdot \vec{\mathcal{E}} = \frac{1}{r}\frac{d}{dr}(r\mathcal{E}_r) = 4\pi\varrho \ ,$$

and hence,

$$r\mathcal{E}_r|_0^r = 4\pi \int_0^r dr' r' \varrho = \frac{2q}{l}\frac{1}{r} \qquad for \qquad a < r < b \ ,$$

and 0 else.
c. We have,

$$\Delta\Phi = \int_{cyl.int}^{cyl.ext} \vec{\mathcal{E}} \cdot d\mathbf{r} = \int_a^b dr \frac{2q}{lr} = \frac{2q}{l}\ln(\frac{b}{a}) \ .$$

d. We have,

$$C = \frac{q}{\Delta\Phi} = \frac{l}{2}\frac{1}{\ln(\frac{b}{a})} \ .$$

14.2.2.7 Ex: Spherical capacitor

Consider a homogeneously charged ball with radius R_1 and an infinitely thin spherical homogeneously charged shell with radius R_2. The ball has the full charge $+Q$, the shell $-Q$. Calculate the electric field $\vec{\mathcal{E}}(r)$ for $r \leq R_1$, $R_1 < r < R_2$ and $r \geq R_2$.
Help: Use the fact that $\vec{\mathcal{E}}$ must be, for symmetry reasons, radially symmetrical, and depends on the charge density via $\nabla \cdot \vec{\mathcal{E}}(r) = \varrho(r)/\varepsilon_0$. Also use Gauß' law.

Solution: *From the ansatz:*

$$\vec{\mathcal{E}}(\mathbf{r}) = \mathcal{E}(r)\hat{\mathbf{e}}_r \qquad and \qquad d\mathbf{S} = r^2 \sin\theta \ d\theta \ d\phi \ \hat{\mathbf{e}}_r \ .$$

with Gauß:

$$\int_{\partial V} \vec{\mathcal{E}}(\mathbf{r}) \cdot d\mathbf{S} = \frac{1}{\varepsilon_0} \ q(V) \ .$$

For the case $r \leq R_1$:

$$\int \vec{\mathcal{E}} \cdot d\mathbf{S} = \int_{\theta=0}^{\pi}\int_{\phi=0}^{2\pi} \mathcal{E}(r) r^2 \sin\theta d\theta d\phi = 4\pi r^2 E(r) \equiv \frac{1}{\varepsilon_0}Q(r)$$

$Q(r) = \phi V(r)$ *with* $\phi = \frac{Q}{4/3\pi R_1^3}$ *homogeneous charge density, hence* $Q(r) = Q\frac{r^3}{R_1^3}$, *hence* $\mathcal{E}(r) = \frac{Q}{4\pi\varepsilon_0 R_1^3} r$.
For the case $R_1 < r < R_2$:

$$Q(r) = +Q$$

with Gauß $\rightsquigarrow 4\pi r^2 \mathcal{E}(r) = \frac{Q}{\varepsilon_0}$, *hence* $\mathcal{E}(r) = \frac{Q}{4\pi\varepsilon_0}\frac{1}{r^2}$.
For the case $r \leq R_2$:

$$Q = +Q + (-Q) = 0$$

Hence, $\mathcal{E}(r) = 0$.

14.2.2.8 Ex: Thunderstorm

The cloud of a thunderstorm with $17\,\mathrm{km}^2$ of total area floats at a height of $900\,\mathrm{m}$ above the Earth's surface and forms with it a plate capacitor.
a. Calculate the capacity of this plate capacitor (the area to be considered on Earth is equal to that of the cloud).
b. What is the maximum charge of the thundercloud before the capacitor discharges? (The discharge electric field in air is $10^4\,\mathrm{V/cm}$).
c. The capacitor is totally discharged by a lightning, once the critical field strength is reached. What is the current flowing to Earth if the lightning's duration is $1\,\mathrm{ms}$?
d. What power does this correspond to? For how long a power station with a power of $2000\,\mathrm{MW}$ needs to work to produce the energy released by lightning?

Solution:

14.2.2.9 Ex: Spherical capacitor

A spherical capacitor consists of two concentric conducting spheres of radii R_1 and R_2, with $R_1 < R_2$. The inner sphere has a charge $+Q$ and the outer sphere has a charge $-Q$.
a. Calculate the absolute value of the electric field and the energy density as a function of r, where r is the radial distance from the center of the spheres for any r.
b. Determine the capacitance C of the capacitor.
c. Calculate the energy associated with the electric field integrated over a spherical shell of radius r, thickness dr, and volume $4\pi r^2 dr$ located between the conductors. Integrate the obtained expression to find the total energy between the conductors. Give your answer in terms of the charge Q and the capacitance C.

Solution: *a. We have*

$$\vec{\mathcal{E}}(\mathbf{r}) = \mathcal{E}(r)\hat{e}_r \qquad \textit{and} \qquad d\mathbf{F} = r^2 \sin\theta \; d\theta \; d\phi \; \hat{e}_r \; .$$

Gauß' law requires

$$\int_{\partial V} \vec{\mathcal{E}}(\mathbf{r}) \cdot d\mathbf{F} = \frac{1}{\varepsilon_0} \; q(V) \; .$$

That is:

$$\int \vec{\mathcal{E}} d\mathbf{F} = \int_{\theta=0}^{\pi} \int_{\phi=0}^{2\pi} \mathcal{E}(r) r^2 \sin\theta d\theta d\phi = 4\pi r^2 \mathcal{E}(r) \equiv \frac{1}{\varepsilon_0} Q(r) \; ,$$

where $Q(r)$ is the charge concentrated within a sphere with radius r. For $r \leq R_1$, as there is no charge inside the inner sphere, we have,

$$\mathcal{E}(r) = 0 \; .$$

Between the spheres we have

$$\mathcal{E}(r) = \frac{Q}{4\pi\varepsilon_0^2} \; .$$

Outside the outer sphere we have,

$$\mathcal{E}(r) = 0 \ ,$$

because the opposite charges of the spheres compensate. The energy density is,

$$u(r) = \frac{1}{2}\vec{\mathcal{D}} \cdot \vec{\mathcal{E}} = \frac{\varepsilon_0}{2}\mathcal{E}^2 = \frac{Q^2}{32\pi^2\varepsilon_0 r^4} \ .$$

b. The voltage between the spheres is,

$$\Delta V = -\int_{R_1}^{R_2} \mathcal{E}(r)dr = -\frac{Q}{4\pi\varepsilon_0}\int_{R_1}^{R_2}\frac{1}{r^2}dr = \frac{Q}{4\pi\varepsilon_0}\left(\frac{1}{R_2} - \frac{1}{R_1}\right) \ .$$

The capacitance is,

$$C = \frac{Q}{\Delta V} = \frac{4\pi\varepsilon_0}{\frac{1}{R_1} - \frac{1}{R_2}} \ .$$

c. The energy inside a thin layer is given by,

$$\begin{aligned} U &= \int_V u(r)d^3r = \int_0^{2\pi}\int_0^{\pi}\int_r^{r+dr}\frac{Q^2}{32\pi^2\varepsilon_0 r^4}r^2\sin\theta d\phi d\theta dr \\ &= \frac{Q^2}{32\pi^2\varepsilon_0}4\pi\int_r^{r+dr}\frac{1}{r^2}dr = \frac{Q^2}{8\pi\varepsilon_0}\frac{dr}{r} \ . \end{aligned}$$

The total energy between the spheres is,

$$\begin{aligned} U &= \int_V u(r)d^3r = \int_0^{2\pi}\int_0^{\pi}\int_{R_1}^{R_2}\frac{Q^2}{32\pi^2\varepsilon_0 r^4}r^2\sin\theta d\phi d\theta dr \\ &= \frac{Q^2}{32\pi^2\varepsilon_0}4\pi\int_{R_1}^{R_2}\frac{1}{r^2}dr = \frac{Q^2}{8\pi\varepsilon_0}\left.\frac{-1}{r}\right|_{R_1}^{R_2} = \frac{Q^2}{8\pi\varepsilon_0}\left[\frac{1}{R_1} - \frac{1}{R_2}\right] \ . \end{aligned}$$

14.2.2.10 Ex: Lightning rod

The absorption of lightning by a lightning rod can be described by the following model (outlined in the figure): The (x, y) plane of a Cartesian coordinate system divides a half space with the conductivity κ (the soil of the Earth, $z < 0$) from a space with conductivity 0 (air, $z > 0$). In the center of the coordinates is an extremely conductive semispherical electrode connected with the lightning rod of diameter d. Current I can cross the semisphere and enter the conducting half space. For symmetry reasons, the current density may only depend on the distance r from the origin of the coordinates and must be oriented radially: $\mathbf{j} = j_r(r)\hat{\mathbf{e}}_r$. All of the following questions refer to points in the conductive semi-space outside the electrode.
a. Calculate the current density $\mathbf{j}$ as a function of the current amplitude I and the distance r from the source. **Help:** The current flowing from the electrode to the conducting half space must also exit the semisphere K.

b. Determine the electric field $\vec{\mathcal{E}}(\mathbf{r})$.
c. Determine the electrical voltage $U(x, s)$ between two points on the positive x-axis, having the coordinates x and $x + s$, respectively.
d. Determine the voltage U_{tot} for $x = d/2$ and $s \to \infty$. What ohmic resistance can be attributed to the conducting half space?

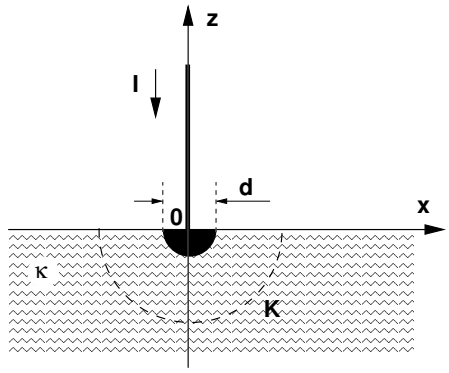

Figure 14.7:

Solution:

14.2.2.11 Ex: Plate capacitor (H13)

An ideal plate capacitor consists of two parallel plates at a distance d. One of the plates, defined by the corners $(0, 0, 0)$, $(a, 0, 0)$, $(a, b, 0)$, and $(0, b, 0)$), be charged with the charge $-Q$, the other plate, defined by the corners $(0, 0, d)$, $(a, 0, d)$, (a, b, d) and $(0, b, d)$, has the charge $+Q$. A part of the intermediate space (up to the surface between the points $(x, 0, 0)$, $(x, b, 0)$, (x, b, d), and $(x, 0, d)$) be filled with a homogeneous dielectric with the dielectric constant ε; the rest of the space between the plates is empty. We assume that a and b are very large, such that border effects can be neglected.
a. Calculate the electric field $\vec{\mathcal{E}}$ and the dielectric displacement $\vec{\mathcal{D}}$ between the plates.
Help: Use $\nabla \times \vec{\mathcal{E}} = 0$ and $\nabla \cdot \vec{\mathcal{D}} = \varrho$. Use surface charge densities.
b. Calculate the energy of the electrostatic field W of this device.
c. What force $F = -dW/dx$ acts on the dielectric for an infinitesimal displacement dx?

Solution: *a. We want to neglect edge effects. The dielectric displacement in the region of the dielectric is given by,*

$$\vec{\mathcal{D}}_1 = \varepsilon \vec{\mathcal{E}}_1 \ .$$

in the remaining region (without dielectric) between the plates by,

$$\vec{\mathcal{D}}_2 = \varepsilon_0 \vec{\mathcal{E}}_2$$

Of course, all of these fields only have the z-component. Now we have,

$$\nabla \times \vec{\mathcal{E}} = 0 \ .$$

Hence, $\mathcal{E}_z$ cannot depend on x nor on y and must be continuous on the boundary surface of the dielectric (in the following, we no longer place the index 'z' to simplify the notation):

$$\mathcal{E}_1 \equiv \mathcal{E}_2 \equiv \mathcal{E} \ .$$

Now we have in the dielectric,

$$\mathcal{D}_1 = \varepsilon \mathcal{E}$$

in the free space between the plates,

$$\mathcal{D}_2 = \varepsilon_0 \mathcal{E}$$

and everywhere,

$$\nabla \cdot \vec{\mathcal{D}} = \varrho \ .$$

Hence,

$$\mathcal{D}_1 = \sigma_1 \qquad \textit{and} \qquad \mathcal{D}_2 = \sigma_2 \ ,$$

where σ_1 resp. σ_2 represent the densities of surface charges. With that we get the full charge,

$$Q = \sigma_1 \ A_1 + \sigma_2 \ A_2 = D_1 A_1 + D_2 A_2 = \mathcal{E}(\varepsilon A_1 + \varepsilon_0 A_2) = \mathcal{E} b(\varepsilon x + \varepsilon_0 a - \varepsilon_0 x) = \mathcal{E} b(\varepsilon_0 a + (\varepsilon - \varepsilon_0)x) \ .$$

resp. for the electric field,

$$\mathcal{E} = \frac{Q}{b(\varepsilon_0 a + [\varepsilon - \varepsilon_0]x)} \ .$$

b. Follows immediately,

$$W = \frac{1}{2} \int d\tau \ \vec{\mathcal{E}} \cdot \vec{\mathcal{D}} = \frac{1}{2}[\mathcal{E}\mathcal{D}_1 A_1 d + \mathcal{E}\mathcal{D}_2 A_2 d] = \frac{1}{2} E^2 d[\varepsilon A_1 + A_2]$$
$$= \frac{1}{2}\mathcal{E}^2 db[\varepsilon_0 a + (\varepsilon - \varepsilon_0)x] = \frac{1}{2} \frac{Q^2 d}{b[\varepsilon_0 a + (\varepsilon - \varepsilon_0)x]} \ .$$

c. The force follows with,

$$F = -\frac{dW}{dx} = \frac{1}{2} \frac{dQ^2(\varepsilon - \varepsilon_0)}{b[a + (\varepsilon - \varepsilon_0)x]^2} \ \geq \ 0 \ .$$

It is oriented in $+x$-direction. The dielectric is therefore dragged to the capacitor.

14.2.2.12 Ex: Spherical capacitor with dielectric (H14)

Two concentric conducting spheres with radii a and b ($a < b$) carry the charges $\pm Q$. Half of the space between the spheres is filled by a dielectric $\varepsilon = const.$
a. Determine the electric field at all points between the spheres.
b. Calculate the surface charge distribution on the inner sphere.
c. Calculate the polarization charge density induced on the surface of the dielectric

at $r = a$.

Solution: *We denote the region between the spheres without dielectric by I, the one with dielectric by I. Without dielectric we have in the intermediate region, $\Phi(r) = \alpha/r + c$. Since the field within the dielectric is also radial, we can use this ansatz in this region as well.*
a. Integration gives immediately,

$$\mathcal{D}_r(r) = \begin{cases} \frac{\alpha}{r^2} & ED\ I\ e \\ \frac{\varepsilon\alpha}{r^2} & ED\ II \end{cases} .$$

The constant α can be determined by Gauß' law:

$$\int\limits_S dS\ \hat{\mathbf{e}}_r \cdot \vec{\mathcal{D}} = 4\pi Q\ ,$$

where Q is the enclosed charge. With that we get,

$$Q = \frac{1}{4\pi}\int\limits_S dS \frac{\alpha}{r^2} + \frac{1}{4\pi}\int\limits_S dS \frac{\varepsilon\alpha}{r^2} = \frac{\varepsilon+1}{2}\alpha\ ,$$

since the integration over the area in both cases gives the same value $4\pi r^2/2$. From this follows for $a < r < b$,

$$\vec{\mathcal{E}}(\mathbf{r}) = \frac{2Q}{\varepsilon+1}\frac{1}{r^2}\hat{\mathbf{e}}_r\ .$$

b. Inside and outside the inner spherical layer we have, $\vec{\mathcal{D}} = 0$, on the surface $\mathcal{D}_r(r = a) = 4\pi\sigma$. Therefore,

$$\sigma = \begin{cases} \frac{1}{\varepsilon+1}\frac{Q}{2\pi a^2} & ED\ I \\ \frac{\varepsilon}{\varepsilon+1}\frac{Q}{2\pi a^2} & ED\ II \end{cases} .$$

c. We have $\mathcal{D}_r = \mathcal{E}_r + 4\pi\sigma_{pol}$. Hence, $\sigma_{pol} = (\mathcal{D}_r - \mathcal{E}_r)/(4\pi) = (\varepsilon - 1)\mathcal{E}_r/4\pi$. Hence,

$$\sigma_{pol} = \begin{cases} 0 & ED\ I \\ \frac{\varepsilon-1}{\varepsilon+1}\frac{Q}{2\pi a^2} & ED\ II \end{cases} .$$

14.2.2.13 Ex: Potential of a charged sphere (T10)

A sphere of radius R be in the vacuum. It consists of a material with the dielectricity constant $\varepsilon = const$ and carries in its center the charge q. Calculate the potential in full space.

Solution: *As there is no surface charge ($\sigma = 0$), a normal component of $\vec{\mathcal{D}}$ is continuous. For $r < R$ we have $\vec{\mathcal{E}}_i = \mathcal{D}_i(r)\vec{\mathcal{E}}_r$. Hence,*

$$\int\limits_{\mathcal{V}(\nabla)} d^3\mathbf{r}\ \nabla \cdot \vec{\mathcal{D}}_i = \int\limits_{O(V(r))} d\mathbf{S} \cdot \vec{\mathcal{D}}_i = \int\limits_{V(r)} d^3\mathbf{r}\ 4\pi\varrho = 4\pi q\ .$$

Integration gives immediately,

$$4\pi r^2 \ \varepsilon \ \mathcal{D}_i(r) = 4\pi q \ ,$$

and hence,

$$\mathcal{D}_i(r) = \frac{q}{\varepsilon r^2} \qquad \textit{well as, obviously} \qquad \mathcal{D}_a(r) = \frac{q}{r^2} \ ,$$

where the index a indicates the region $r > a$. The potential outside the sphere is obviously,

$$\Phi_a(r) = \frac{q}{r} \ .$$

Inside we have,

$$\Phi_i(r) = \frac{q}{R} - \int_R^r \frac{q}{\varepsilon r'^2} dr = \frac{q}{\varepsilon r} + \frac{q}{R}\frac{\varepsilon - 1}{\varepsilon} \ .$$

14.2.2.14 Ex: Plate capacitor with dielectric

We consider two parallel electrodes with area A and distance d (see figure). Calculate the force on the upper electrode in the x-direction, once for constant voltage V_0 and once for constant charge Q for the following two cases:
a. The electrodes are inside a dielectric liquid with permittivity ε;
b. a fixed dielectric with permittivity ε is introduced between capacitor plates. In the residual gap there is no dielectric medium.

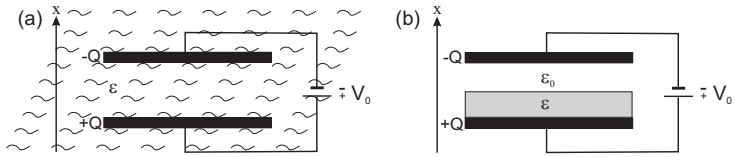

Figure 14.8: Plate capacitor.

Solution: *a. The power of the plate capacitor is (when $Q_1 = -Q_2$)*

$$W = \frac{1}{2}CU^2 = -\frac{1}{2}\frac{Q^2}{C}$$

with $C = \varepsilon_0 \varepsilon \frac{A}{x}$. Now, we have,

$$\mathbf{F}_U = -\nabla W|_{U=const} = -\frac{d}{dx}\frac{1}{2}CU^2 = \frac{1}{2}\varepsilon_0 \varepsilon \frac{A}{x^2}U^2$$

as well as,

$$\mathbf{F}_Q = -\nabla W|_{Q=const} = \frac{d}{dx}\frac{1}{2}\frac{Q^2}{C} = \frac{1}{2}\frac{1}{\varepsilon_0 \varepsilon A}Q^2$$

that is, the force is attractive.
b. As in (a) but with the total capacity of two capacitors in series:

$$C = \frac{1}{\frac{1}{\varepsilon_0 \frac{A}{x-s}} + \frac{1}{\varepsilon_0 \varepsilon \frac{A}{s}}}$$

where x is the distance and s the thickness of the dielectric. Now we have,

$$\mathbf{F}_U = -\frac{d}{dx}\frac{U^2}{2}\frac{1}{\frac{x-s}{\varepsilon_0 A} + \frac{s}{\varepsilon_0 \varepsilon A}} CU^2 = \frac{\varepsilon_0 \varepsilon A U^2}{2}\frac{1}{(\varepsilon(x-s)+s)^2}$$

as well as,

$$\mathbf{F}_Q = \frac{d}{dx}\frac{Q^2}{2}\left(\frac{x-s}{\varepsilon_0 A} + \frac{s}{\varepsilon_0 \varepsilon A}\right) = \frac{Q^2}{2\varepsilon_0 A} \ .$$

14.2.2.15 Ex: Plate capacitor with dielectric

The plate capacitor shown in the figure has a plate surface of $A = 115\,\mathrm{cm}^2$ and a plate distance of $d = 1.24\,\mathrm{cm}$. Between the plates we have the potential difference $U_0 = 85.5\,\mathrm{V}$ produced by a battery. Now, the battery is removed and a dielectric $b = 0.78\,\mathrm{cm}$ thick plate with dielectric constant $\varepsilon = 2.61$ is inserted, as shown in the figure. First calculate
a. capacitance without dielectric and
b. the free charge on the capacitor plates.
c. Now, the dielectric is inserted. Calculate the electric field in the voids and within the dielectric, as well as
d. the potential difference between the plates.
e. What is the capacitance with dielectric?
f. Now assume that the battery remains connected to the capacitor while the dielectric is inserted into the space between the plates. Calculate now the capacitance,
g. the charge on the capacitor plates, and
h. the electric field in the void and inside the dielectric.

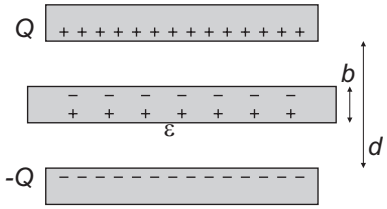

Figure 14.9: Plate capacitor.

Solution: *a. The capacity is,*

$$C = \varepsilon_0 \frac{A}{d} = 8.2\,\mathrm{pF} \ .$$

b. The free charge follows from,

$$Q = CU_0 = 8.2\,\mathrm{pF}\cdot 85.5\,\mathrm{V} = 7\cdot 10^{-10}\,\mathrm{C}\ .$$

c. The electric field in the spaces is,

$$\mathcal{E}_f = \frac{Q}{\varepsilon_0 A} = \frac{7\cdot 10^{-10}\,\mathrm{C}}{\varepsilon_0\cdot 115\,\mathrm{cm}^2} = 68.75\,\mathrm{V/cm}\ .$$

and in the dielectric,

$$E_\varepsilon = \frac{\mathcal{E}_f}{\varepsilon} = \frac{71.25\,\mathrm{V/cm}}{2.61} = 26.34\,\mathrm{V/cm}\ .$$

d. After insertion of the dielectric the potential difference is,

$$U_\varepsilon = \phi_2 - \phi_1 = \int \vec{\mathcal{E}}\cdot d\vec{s} = \mathcal{E}_f(d-b) + \mathcal{E}_\varepsilon b = 71.25\,\mathrm{V/cm}\cdot 0.46\,\mathrm{cm} + 27.30\,\mathrm{V/cm}\cdot 0.78\,\mathrm{cm} = 52.9\,\mathrm{V}\ .$$

e. The capacitance in the dielectric is,

$$C_d = \left(\frac{1}{\varepsilon_0\frac{2A}{(d-b)}} + \frac{1}{\varepsilon_0\varepsilon\frac{A}{b}} + \frac{1}{\varepsilon_0\frac{2A}{(d-b)}}\right)^{-1} = 10.9\,\mathrm{pF}\ .$$

f. If the dielectric is inserted while the battery is connected, the capacity obviously remains unchanged.
g. However, the charge on the capacitor plates is,

$$Q' = C_d U_0 = 10.9\,\mathrm{pF}\cdot 85.5\,\mathrm{V} = 9.3\cdot 10^{-10}\,\mathrm{C}\ .$$

h. The electric field in the empty spaces is,

$$\mathcal{E}_f = \frac{Q'}{\varepsilon_0 A} = \frac{9.3\cdot 10^{-10}\,\mathrm{C}}{\varepsilon_0\cdot 115\,\mathrm{cm}^2} = 91.43\,\mathrm{V/cm}\ .$$

and in the dielectric,

$$\mathcal{E}_\varepsilon = \frac{E_f}{\varepsilon} = \frac{71.25\,\mathrm{V/cm}}{2.61} = 35.03\,\mathrm{V/cm}\ .$$

14.2.2.16 Ex: Plate capacitor with dielectric

Consider a quadratic plate capacitor with edge length l and plate distance d.
a. What is the capacity of the empty capacitor? What is the electrostatic energy when the plates are charged with the charges kept fixed $+Q$ and $-Q$?
b. A dielectric with thickness d, width $L > l$, and dielectric constant ε is now inserted from the side. What is the electrostatic energy as a function of penetration depth x for $0 < x < l$?
c. What is the force acting on the dielectric with function of x for $0 < x < l$?

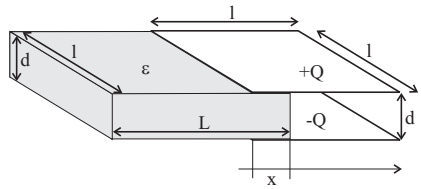

Figure 14.10: Plate capacitor.

Solution: *a. The capacity and energy of the empty capacitor are,*

$$C = \varepsilon_0 \frac{l^2}{d} \ ,$$
$$W = \frac{Q^2}{2C} = \frac{dQ^2}{2\varepsilon_0 l^2} \ .$$

b. Inserting the dielectric we change the capacity and the energy,

$$C_\varepsilon(x) = \varepsilon_0 \frac{l(l-x)}{d} + \varepsilon\varepsilon_0 \frac{lx}{d} = \frac{\varepsilon_0 l}{d}(l + x\varepsilon - x) \ ,$$
$$W = \frac{Q^2}{2C_\varepsilon(x)} = \frac{dQ^2}{2\varepsilon_0 l(l + x\varepsilon - x)} \ .$$

c. On the dielectric acts a force in x-direction,

$$F_x = -\nabla_x W = -\frac{d}{dx}\frac{dQ^2}{2\varepsilon_0 l(l + x\varepsilon - x)} = -\frac{dQ^2}{2\varepsilon_0 l(\varepsilon - 1)} \frac{1}{\left(\frac{l}{\varepsilon - 1} + x\right)^2} \ .$$

14.2.2.17 Ex: Plate capacitor with dielectric

At a plate capacitor consisting of two parallel metal plates of area $0.5\,\mathrm{m}^2$ and distant by $d = 10\,\mathrm{cm}$, there be a voltage of $U_0 = 1000\,\mathrm{V}$.
a. What are the values for the capacitance of the capacity C, the electrical field E between plates, and the charge surface density σ on the plates?
b. A quarter of the capacitor volume is now filled with a dielectric ($\varepsilon = 5$), as shown in the diagram. What is now the capacitance C_g?
Help: We may construct an equivalent circuit diagram by inserting imaginary capacitor plates along equipotential surfaces.

Solution: *a. In a vacuum we have:*

$$C = \varepsilon_0 \frac{A}{d} = 4.43 \cdot 10^{-11} \qquad \textit{and} \qquad \mathcal{E} = \frac{U}{d} = 10^4\,\mathrm{V/m}$$

The surface density of the charge on the capacitor plates is,

$$\sigma = \frac{Q}{A} = \frac{CU}{A} = \varepsilon_0 \frac{U}{d} = \varepsilon_0 \mathcal{E} = 8.85 \cdot 10^{-8}\,\mathrm{C/m}^2 \ .$$

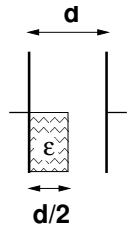

Figure 14.11: Plate capacitor.

b. The equivalent circuit becomes a parallel circuit of the upper half of the capacitor C_1 with the circuit in series of the dielectric quarter C_2 and the empty quarter in the lower half of the capacitor:

$$C_1 = \varepsilon_0 \frac{A/2}{d} = \frac{C}{2} \qquad \textit{and} \qquad C_2 = \varepsilon_0 \varepsilon \frac{A/2}{d/2} = \varepsilon C \qquad \textit{and} \qquad C_3 = \varepsilon_0 \frac{A/2}{d/2} = C \ .$$

With that we get the full capacitance,

$$C_g = C_1 + \frac{C_2 C_3}{C_2 + C_3} = \frac{C}{2} \frac{\varepsilon C}{1+\varepsilon} = \frac{4}{3} C = 5.91 \cdot 10^{-11}\,\mathrm{F} \ .$$

14.2.2.18 Ex: Water capacitor

Consider a plate capacitor (plate distance $d = 20\,\mathrm{cm}$, plate surface area $A = 400\,\mathrm{cm}^2$), which can be half filled with water (dielectric constant $\varepsilon_w = 80.3$). We apply a voltage of $U = 240\,\mathrm{V}$.
a. Calculate the capacitance of the capacitor for the following cases:
i. No water.
ii. The water is perpendicular to the plates..
iii. The water is parallel to the plates.
b. Calculate the charges on the plates for these three cases.
c. Compare the electric field energy of the cases (i) and (iii). From what source does the energy difference come from when the capacitor is filled with water?

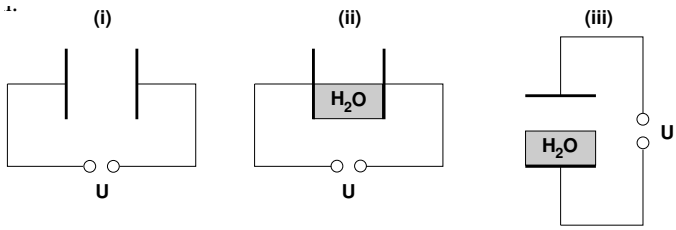

Figure 14.12: Capacitor.

Solution:

14.2.2.19 Ex: Capacitor circuit

The capacitance of the capacitors in the schematic circuit are $C_1 = 10\,\mu\text{F}$, $C_2 = 5\,\mu\text{F}$ and $C_3 = 4\,\mu\text{F}$. The voltage is $U = 100\,\text{V}$.
a. Calculate the total capacitance.
b. Determine for each capacitor the value of the charge, voltage, and stored energy.

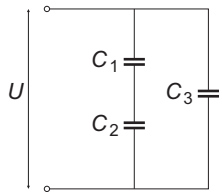

Figure 14.13: Capacitor.

Solution: *a. The total capacitance is,*

$$C = \left(\frac{1}{C_1} + \frac{1}{C_2}\right)^{-1} + C_3 = 7.3\,\mu\text{F} \ .$$

b. From the relationships $U_1 + U_2 = U$ *and* $C_1U_1 = Q_1 = Q_2 = C_2U_2$ *follows,*

$$U_1 = \frac{C_2U}{C_1 + C_2} = 33.3\,\text{V} \qquad \textit{and} \qquad U_2 = \frac{C_1U}{C_1 + C_2} = 66.6\,\text{V} \ .$$

Furthermore,

$$Q_1 = Q_2 = \frac{C_1C_2U}{C_1 + C_2} = (C - C_3)U = 333\,\mu\text{C} \qquad \textit{and} \qquad Q_3 = C_3U = 400\,\mu\text{C} \ ,$$

which shows that $Q = Q_1 + Q_3 = CU = 733\,\text{C}$. *With* $W = \frac{1}{2}CU^2$, *the potential energies are,*

$$W_1 = 5.5\,\text{mJ} \quad , \quad W_2 = 11.1\,\text{mJ} \quad , \quad W_3 = 20\,\text{mJ} \ .$$

The sum of the energies is $W_1 + W_2 + W_3 = \frac{1}{2}CU^2$.

14.2.2.20 Ex: Capacitor circuit

Calculate the total capacitance of the circuits shown in the figure.
a. between the points P1 and P3,
b. between the points P1 and P2.

Solution: *a. Between* P_1 *and* P_3 *the total capacity is:*

$$C_{13} = C + C + \frac{1}{\frac{1}{C} + \frac{1}{C+C}} = \frac{8}{3}C \ .$$

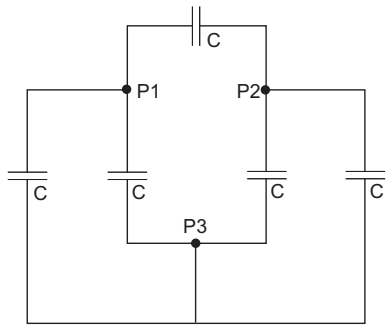

Figure 14.14: Capacitor circuit.

b. Between P_1 and P_2 the total capacity is:

$$C_{12} = C + \frac{1}{\frac{1}{C+C} + \frac{1}{C+C}} = 2C \ .$$

14.2.2.21 Ex: Capacitor circuit

Calculate the total capacitance of the circuits shown in the figure.

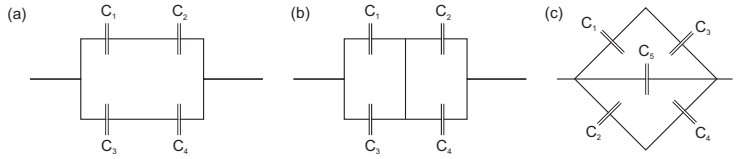

Figure 14.15: Capacitor circuit.

Solution: *a. In circuit in-series the capacities are added reciprocally, in-parallel they are added normally.*

$$C_{tot} = \frac{C_1 C_2}{C_1 + C_2} + \frac{C_3 C_4}{C_3 + C_4} \ .$$

b. Redrawing the circuit we realize that we are dealing with two parallel circuits of capacitors C_1 and C_3, resp., C_2 and C_4 put in series,

$$C_{tot} = \frac{(C_1 + C_3)(C_2 + C_4)}{C_1 + C_3 + C_2 + C_4} \ .$$

c. Redrawing the circuit we realize that the capacitors in series, C_2 and C_4, are paralleled to C_5 and the in-series capacitors C_1 and C_3,

$$C_{tot} = \frac{C_2 C_4}{C_2 + C_4} + C_5 + \frac{C_1 C_3}{C_1 + C_3} \ .$$

14.2.2.22 Ex: Energy in combinations of capacitors

a. Two identical capacitors are connected in parallel. This combination is then connected to the terminals of a battery. How does the total energy stored in the parallel combination of these two capacitors compare to the total energy stored if only one of the capacitors were connected to the terminals of the same battery?
b. Two identical discharged capacitors are connected in series. This combination is then connected to the terminals of a battery. How does the total energy stored in the in-series combination of these two capacitors compare to the total energy stored if only one of the capacitors were connected to the terminals of the same battery?

Solution: *a.* $U_{paralelo} = 2U_{unico}$.
b. $U_{serie} = \frac{1}{2}U_{unico}$

14.2.2.23 Ex: Plate capacitor

An air-filled plate capacitor consists of plates of $2.0\,\mathrm{m}^2$ area separated by 1 mm and is charged with 100 V.
a. What is the electric field between the plates?
b. What is the electrical energy density between the plates?
c. Determine the total energy by multiplying the response to part (b) with the volume between the plates.
d. Determine the capacitance of this arrangement.
e. Calculate the total energy using $U = \frac{1}{2}CV^2$ and compare your answer with the result of part (c).

Solution: *a.* $100\,\mathrm{kV/m}$.
b. $44.3\,\mathrm{mJ/m}^3$.
c. $88.5\,\mu\mathrm{J}$.
d. $17.7\,\mathrm{nF}$.
e. $88.5\,\mu\mathrm{J}$

14.2.2.24 Ex: Combination of capacitors

A $10.0\,\mu\mathrm{F}$ capacitor and a $20.0\,\mu\mathrm{F}$ capacitor are connected in parallel to the terminals of a 6.0 V battery.
a. What is the equivalent capacitance of this combination?
b. What is the potential difference in each capacitor?
c. Determine the charge on each capacitor.
d. Determine the energy stored in each capacitor.

Solution: *a.* $30.0\,\mu\mathrm{F}$.
b. 6.0 V.
c. $Q_{10} = 60\,\mu\mathrm{C}$, $Q_{20} = 120.0\,\mu\mathrm{C}$.
d. $U_{10} = 180\,\mu\mathrm{J}$, $U_{20} = 360\,\mu\mathrm{J}$.

14.2.2.25 Ex: Infinite series of capacitors

What is the equivalent capacitance (in terms of C, which is the capacitance of one of the capacitors) of the infinite chain shown in the figure.

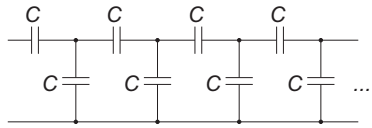

Figure 14.16: Capacitor circuit.

Solution: *The capacitance C_k between the vertical capacitors of one mesh is related to the capacitance C_{k-1} of the previous mesh by,*

$$C_k = C + (C_{k-1} \parallel C) = C + \frac{1}{\frac{1}{C} + \frac{1}{C_{k-1}}} \ .$$

For an infinite succession we can put $C_k = C_{k-1}$, which gives,

$$C_k^2 - CC_k - C^2 = 0 \ ,$$

with the solution,

$$C_k = \frac{C}{2}(1 \pm \sqrt{5}) \ .$$

Therefore, the equivalent capacitance is $C_{eq} = \frac{C}{2}(1 + \sqrt{5})$.

14.2.2.26 Ex: Reconnecting capacitors

A 100 pF capacitor and a 400 pF capacitor are both charged at 2.0 kV. They are then disconnected from the voltage source and connected together, positive plate to positive plate and negative plate to negative plate.
a. Determine the resulting potential difference at each capacitor.
b. Determine the dissipated energy when the connection is made.

Solution: *a.* $V_{100} = V_{400} = 1.2\,\text{kV}$.
b. 640 μJ.

14.2.2.27 Ex: Reconnecting capacitors

A 1.2 μF capacitor is charged at 30 V. After charging the capacitor is disconnected from the voltage source and is connected to the terminals of a second capacitor that had previously been discharged. The final voltage on the 1.2 μF capacitor is 10 V.
a. What is the capacitance of the second capacitor?
b. How much energy was dissipated when the connection was made?

Solution: *a.* 2.4 μF.
b. 0.4 mJ.

14.3 Conduction of current and resistance

To charge a capacitor we need to carry charges to its electrodes. By permitting a displacement of charges we escape, in this section, for the first time from the premises of electrostatics and introduce the concept of a *current* as being due to a movement of charges within a conductor. For now, let us not raise the question, how this current will act on other charges or currents, this subject being discussed in the next chapter.

14.3.1 Motion of charges in dielectrics and conductors

In electrostatics the *electromotive force* accelerating a charge Q is the Coulomb force, $\mathbf{F} = Q\vec{\mathcal{E}}$. Interpreting the current as the sum of the motions v_k of all charges $\sum_k \frac{N_k}{V} Q_k$ within a volume V, we introduce the *current density* in a way analogous to the charge density,

$$\mathbf{j}(\mathbf{r}) = \sum_k \tfrac{N_k Q_k}{V} \mathbf{v}_k \longrightarrow \varrho(\mathbf{r}) \mathbf{v}_{med}(\mathbf{r}) \ , \tag{14.38}$$

where the average is calculated over a small volume. The flow of charges in and out of the volume satisfies the *continuity equation*,

$$\boxed{\nabla \cdot \mathbf{j} + \partial_t \varrho = 0} \ . \tag{14.39}$$

To interpret this equation we consider a volume $\mathcal{V}$ and calculate the flow of charges through the surface of the volume,

$$I \equiv \oint_{\partial \mathcal{V}} \mathbf{j} d\mathbf{S} = \int_{\mathcal{V}} \nabla \cdot \mathbf{j} dV = \int_{\mathcal{V}} \dot{\varrho} dV = \dot{Q} \ . \tag{14.40}$$

That is, the charges passing through the surface must accumulate within the volume. The charge flow I is called *current*.

14.3.2 Ohm's law, stationary currents in continuous media

In the case of free charges inside a conductor, we empirically observe that the electromotive force leads to a stationary current. Obviously, this current depends on the electric field,

$$\mathbf{j} = \mathbf{j}(\vec{\mathcal{E}}) \ , \tag{14.41}$$

despising the magnetic force, which is usually weak. Moreover, we find empirically that the current is often proportional to the field,

$$\boxed{\mathbf{j} = \varsigma \vec{\mathcal{E}}} \ . \tag{14.42}$$

with the *conductivity* ς. This observation is called *Ohm's law*.

We said earlier that $\vec{\mathcal{E}} = 0$ inside a conductor for electrostatic situations, $\mathbf{j} = 0$. This remains valid for perfect conductors, $\vec{\mathcal{E}} = \mathbf{j}/\varsigma = 0$, even when current is flowing.

14.3.2.1 Microscopic view of conduction

Ohm's law may seem surprising, since the current arising from charges accelerated by a potential difference, we would expect that the flow of charges (i.e. the current) should grow in time as the velocity of the charges increases. But in fact, the accelerated electrons often collide with the atoms of the conducting material and are decelerated by the electromotive force $F = m_e a$ or redirected. Moreover, at finite temperature, the thermal velocity of the electrons is very high,

$$v_{term} = \sqrt{\frac{2k_B T}{3m_e}} \approx 6700\,\mathrm{m/s} \ , \tag{14.43}$$

so that the average velocity is constant. The time between two collisions of an electron can be related to its mean free path λ by,

$$t = \frac{\lambda}{v_{term}} \ . \tag{14.44}$$

Now, the average velocity is,

$$v_{med} = \frac{1}{t}\int_0^t v(t')dt' = \frac{at}{2} \ . \tag{14.45}$$

Finally, with n_a molecules per unit volume, each one providing N free electrons, the current density is,

$$\mathbf{j} = n_a N Q \mathbf{v}_{med} = n_a N q \frac{t}{2m_e}\mathbf{F} = n_a N Q \frac{\lambda}{2m_e v_{term}}\mathbf{F} = \frac{n_a N Q^2 \lambda}{2m_e v_{term}}\vec{\mathcal{E}} \ . \tag{14.46}$$

That is, the conductivity can be estimated as,

$$\varsigma = \frac{n_a N Q^2 \lambda}{2m_e v_{term}} \ . \tag{14.47}$$

The *resistivity* is

$$\rho \equiv \frac{1}{\varsigma} \ . \tag{14.48}$$

We note that the resistivity depends on the temperature, $\rho \propto T^{1/2}$.

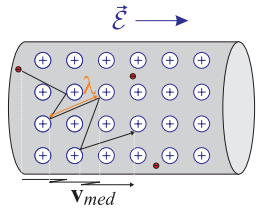

Figure 14.17: Microscopic view of the current.

Example 64 (*Estimation of the average velocity of electrons in a conductor*): Based on Eq. (14.38) we now want to estimate the average propagation velocity of electrons in a copper wire (radius $R = 1\,\text{mm}$) carrying a current of $I = 1\,\text{A}$. With the density of copper of $\rho_m = 8920\,\text{kg/m}^3$, its atomic mass $m_a = 63.5u$ and $N = 1$ valence electron per atom we estimate,

$$v_{med} = \frac{I}{n_a N e \pi R^2} = \frac{Iu}{m_a e \pi R^2} \simeq 8.5\,\text{cm/h} \ .$$

14.3.2.2 Resistors and energy consumption

Let us consider the conductor with the most common geometry: a metallic wire with the shape of a cylinder with cross section S and length L. Applying an electric field, we get,

$$I = \mathbf{j} \cdot \mathbf{S} = \varsigma \vec{\mathcal{E}} \cdot \mathbf{S} = \frac{\varsigma S}{L} U \ , \tag{14.49}$$

where $R = l/\varsigma A$ is called *resistance*. In this form the Ohm's law adopts the following form,

$$\boxed{U = RI} \ . \tag{14.50}$$

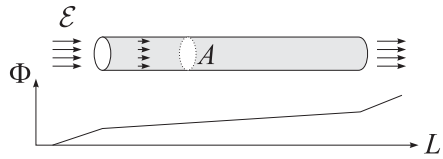

Figure 14.18: Concept of resistance.

A consequence of the frequent collisions of the electrons with the atoms is, that the conductor heats up. The power wasted on a resistance R is,

$$P = VI = RI^2 \ . \tag{14.51}$$

14.3.2.3 Resistor circuits

For parallel circuits $R_{tot}^{-1} = R_1^{-1} + R_2^{-1}$, for circuits in series $R_{tot} = R_1 + R_2$.

14.3.3 Exercises

14.3.3.1 Ex: The α-particle

A beam of α-particles ($q = +2e$), which move with constant kinetic energy $E = 20\,\text{MeV}$, corresponds to a current of $I = 0.25\,\mu\text{A}$. The beam is directed perpendicular to a flat surface.
a. How many α-particles hit the surface in $t = 3\,\text{s}$?
b. How many α-particles are at each instant of time within a $s = 20\,\text{cm}$ long beam segment?

c. What potential difference does an α-particle have to travel to be accelerated from rest to an energy of 20 MeV?

Solution: *a. The number is* $N = It/q = 2.3 \cdot 10^{12}$.
b. The velocity is $v = \sqrt{2E/m} = 3.1 \cdot 10^7$ m/s *for* $m = 4u$. *The time that the particles need to travel the distance is* $t_a = s/v = 6.4$ ns. *Hence, there are* $N_a = It_a/q = 5000$ *particles in this segment.*
c. To reach this energy, a particle must travel the potential difference $U = E/e = 20$ MV.

14.3.3.2 Ex: Electric power

A potential difference of 120 V powers a heater whose resistance is 1 Ω when it is hot.
a. At what rate does this device transform electricity into heat?
b. What is the electricity consumption bill for $t = 5$ h of operation with a price for electricity of $S = 5$ ct/kWh?

Solution: *a. The rate is* $\frac{dE}{dt} = P = \frac{U^2}{R} = 1$ kJ/s.
b. The cost is $K = t\ P\ S = 25.7$ ct.

14.3.3.3 Ex: Ohm's Law and electric Power

By how many degrees does a copper conductor of 100 m in length and 1.2 mm^2 in diameter heat up, when it is traversed for 1 hour by a current of 6 A? Assume the heat is not dissipated and use the following data: specific resistivity: $\rho = 0.02\,\Omega\text{mm}^2/\text{m}$; density: $\rho_{\text{Cu}} = 8.93\,\text{kg/dm}^3$; specific heat capacity: $c_{\text{Cu}} = 389.4\,\text{J/kg K}$.

Solution: *Conductor resistance:*

$$R = \rho\frac{l}{A} = 0.02\ \frac{\Omega\text{mm}^2}{\text{m}}\ .$$

Power spent:

$$P = U\,I = RI^2 = 60\,\text{W}\ .$$

Joule heat produced in 1 h*:*

$$Q = Pt = 216000\,\text{J}\ .$$

Mass of the wire:

$$m_{Cu} = \rho_{Cu}\,V = \rho_{Cu}\,A\,l = 1.0716\,\text{kg}\ .$$

Heating of the wire:

$$Q = c_{Cu}m_{Cu}\Delta T \Rightarrow \Delta T = \frac{Q}{c_{Cu}m_{Cu}} = 518\,\text{K}\ .$$

14.3.3.4 Ex: Continuity equation and conserved quantities

The continuity equation,

$$\dot{\rho} + \nabla \cdot (\vec{v}\rho) = 0 \ ,$$

appears in various areas of physics and describes, for example, the conservation of matter, charge or probability.
a. Explain, based on Gauß' law, the relationship between the continuity equation and charge conservation.
b. Consider a simple mechanical example: A 10 l gas bottle is opened letting gas escape. Determine with the help of the continuity equation after how many minutes half of the gas is gone, if the gas exits at a constant velocity of $v = 1\,\mathrm{m/s}$ and the outlet valve has a cross-sectional area of $A = 10\,\mathrm{mm}^2$?

Solution: *a. Charge conservation requires,*

$$\frac{dQ}{dt} = \int dV \frac{\partial \rho}{\partial t} = -\int dV \nabla \cdot \mathbf{v}\rho = -\int d\mathbf{S} \cdot \mathbf{v}\rho \ .$$

The integral form of the continuity equation holds for any volume V. If within this volume the mass, charge or probability changes, a corresponding quantity must flow across the surface of the volume. This is precisely the conservation.
b. Continuity equation,

$$\frac{dM}{dt} = \int dV \frac{\partial \rho}{\partial t} = -\int dV \nabla \cdot \vec{v}\rho = -\int d\mathbf{S} \cdot \mathbf{v}\rho = -Sv\rho = -Sv\frac{M}{V} \ .$$

Ansatz for the differential equation,

$$M(t) = M_0 e^{-Avt/V} \ .$$

If half of the gas escaped by the time T, then

$$\frac{M(T)}{M_0} = e^{-AvT/V} = \frac{1}{2} \ .$$

Hence,

$$T = \ln 2 \frac{V}{Av} = 690\,\mathrm{s} \ .$$

14.3.3.5 Ex: Drift of electrons in a conducting wire

A gold wire has a circular cross section of 0.1 mm diameter. The ends of this wire are connected to the terminals of a 1.5 V battery. If the wire length is 7.5 cm, how long does it take on average for two electrons leaving the negative terminal of the battery to reach the positive terminal? Consider a resistivity of gold of $2.44 \cdot 10^{-8}\,\Omega\mathrm{m}$.

Solution: 0.86 s.

14.4 The electric circuit

Within a (ideal) conductor potential differences vanish everywhere $\Delta\Phi = 0$, regardless of the conductor's length or shape. In a stationary situations, that is, in the presence of static electric fields, the free electrons of the conductor self-organize their spatial distribution (if necessary by creating local charge imbalances) in order to satisfy this condition. As soon as the condition is satisfied, the movement of charges, necessary for their spatial reorganization, comes to an end.

To sustain a stationary current we need to recycle the electrons, that is, waste the electrons accumulated on the side, where the conductor is connected to the positive potential and provide new electrons on the side, where the conductor is connected to the negative potential. In other words, we need to *close* the circuit by an source-drain device for electrons, called *voltage source* or *current source* depending on the properties of the device.

In addition to the source, there is a wide variety of electronic components capable of manipulating the potential or the current in different ways, such as resistors, capacitors, inductors or transistors. In a circuit, these components are interconnected by conductive wires assumed to be ideal in the sense that they a potential without losses from one component to another.

14.4.1 Kirchhoff's rules

Electrical circuits can be more complicated and consist of several branches. The *mesh rule*,

$$\sum_k U_k = 0 \tag{14.52}$$

and the *node rule*,

$$\sum_k I_k = 0 \ , \tag{14.53}$$

govern the behavior of the potentials and currents in any circuit and serve to analyze its properties.

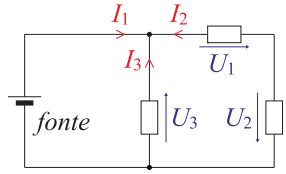

Figure 14.19: Illustration of Kirchhoff mesh and node rules.

Example 65 (*R-C circuit in series*): In addition to the voltage source we got to know two types of elements which can locally influence the voltage or the current: the capacitor and the resistor. The simplest imaginable electrical circuit containing these two components is the *R-C* circuit shown in Fig. 14.20. This circuit can be treated by Kirchhoff's laws,

$$0 = U_F + U_C + U_R \qquad \text{and} \qquad I_F = I_C = I_R \ . \tag{14.54}$$

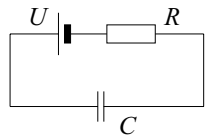

Figure 14.20: Illustration of a R-C-circuit.

Since the current is the same at each point of the circuit, we get the differential equation,

$$0 = U_F + \frac{Q}{C} + RI = U_F + \tfrac{1}{C}\int_0^t I dt' + RI \ , \tag{14.55}$$

which can quickly be solved by imposing the condition that the charge of the capacitor is initially zero,

$$I(t) = I_0(1 - e^{-t/RC}) \ . \tag{14.56}$$

14.4.2 Measuring instruments

Instruments for voltage and current measurement are discussed in the applied undergraduates courses, and we will not repeat this here.

14.4.3 Exercises

14.4.3.1 Ex: Motor starter issues

The starter of a car runs too slow. The mechanic has to decide which part is defective: the motor, the power cord, or the battery. According to the manufacturer's technical instructions, the internal resistance of the $U_0 = 12\,\mathrm{V}$ battery should not exceed $R_{bat} < 0.02\,\Omega$, resistance of the motor must not exceed $R_{mot} < 0.2\,\Omega$, and the resistance of the power cord must not exceed $R_{cab} < 0.04\,\Omega$. Examining the starter motor the mechanic finds a potential difference of 11.4 V at the battery, 3 V in the cable, and a current of 50 A in the starter circuit. Which element of the starter is defective?

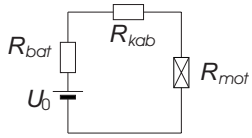

Figure 14.21: Motor starter circuit.

Solution: *The voltage measured on the battery is,*

$$U_{bat} = U_0 - R_{bat}I = (R_{cab} + R_{mot})I \ .$$

That is, the current that must flow is,

$$I = \frac{U_0}{R_{bat} + R_{cab} + R_{mot}} = \frac{12}{0.02 + 0.04 + 0.2} = 46.2\,\Omega \ .$$

The measured resistances are,

$$R'_{bat} = \frac{U_0 - U'_{bat}}{I'} = \frac{12 - 11.4}{50} = 0.012\,\Omega$$
$$R'_{cab} = \frac{U'_{cab}}{I'} = \frac{3\,\mathrm{V}}{50\,\mathrm{A}} = 0.06\,\Omega$$
$$R'_{mot} = \frac{U'_{bat}}{I'} - R'_{cab} = \frac{11.4\,\mathrm{V}}{50\,\mathrm{A}} - 0.06\,\Omega = 0.17\,\Omega \ .$$

Therefore, the cables are defective.

14.4.3.2 Ex: Solar cell

A solar cell generates a voltage of 0.1 V at a resistive load of 500 Ω, but only a voltage of 0.15 V at a resistive load of 1000 Ω. Consider the cell as a *real* voltage source with an internal resistance.
a. What are the internal resistance and unloaded voltage of the cell?
b. Calculate the efficiencies obtained with the two mentioned loads.

Solution: *a. We know,*

$$U_0 - R_i I_1 = R_1 I_1 = U_1 \qquad \textit{and} \qquad U_0 - R_i I_2 = R_2 I_2 = U_2 \ .$$

Hence,

$$U_0 - R_i \frac{U_1}{R_1} = U_1 \qquad \textit{and} \qquad U_0 - R_i \frac{U_2}{R_2} = U_2$$

We obtain,

$$R_i = \frac{U_1 - U_2}{\frac{U_2}{R_2} - \frac{U_1}{R_1}} = 1000\,\Omega \qquad \textit{and} \qquad U_0 = U_1 + \frac{U_1 - U_2}{\frac{U_2}{R_2} - \frac{U_1}{R_1}} \frac{U_1}{R_1} = 0.3\,\mathrm{V}$$

b. Efficiency is defined by,

$$\eta = \frac{P_c}{P_i + P_c} = \frac{R_{1,2} I_{1,2}^2}{R_i I_{1,2}^2 + R_{1,2} I_{1,2}^2} = \frac{R_{1,2}}{R_i + R_{1,2}} \ .$$

Hence, $\eta_1 = 1/3$ and $\eta_2 = 1/2$.

14.4.3.3 Ex: Current and voltage measurement

Circuit (a) shows an arrangement with an amperemeter with internal resistance R_A and a voltmeter with internal resistance R_U to measure resistance R. The value of the resistance follows from $R = U_V/I_R$, where U_V is the value indicated by the voltmeter and I_R the current through the resistance. A part of the current I_A measured by the amperemeter, however, flows through the voltmeter, such that the ratio U_V/I_A of the measured values only indicates an apparent resistance, which we will call R'.
a. How are the true resistance R and the apparent resistance R' interconnected

through the internal resistance R_V voltmeter? How should the internal resistance of the voltmeter be chosen to guarantee that $R' \to R$?
b. With the circuit (b) it is also possible to measure a resistance with an amperemeter and a voltmeter, and also in this case the ratio between the measured values gives only an apparent resistance. How can we determine the true resistance R in this circuit, and how should the internal resistance R_A of the amperemeter be chosen?

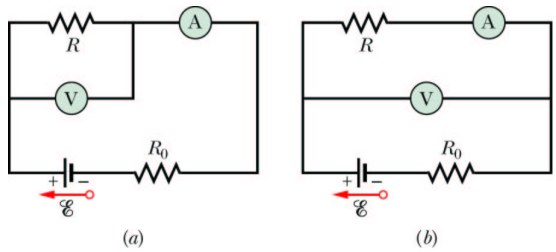

Figure 14.22: Current and voltage measurement.

Solution: *a. With* $U_V = RI_R$, $U_V = R'I_A$, $U_V = R_V I_V$ *and* $I_A = I_R + I_V$ *we have,*

$$R = \frac{U_V}{I_A - I_V} = \frac{U_V}{I_A - \frac{U_V}{R_V}} = \frac{1}{\frac{1}{R'} - \frac{1}{R_V}} \ .$$

For $R_V \to \infty$ *we have* $R' \to R$.
b. With $U_R = RI_A$, $U_V = R'I_A$, $U_A = R_A I_A$ *and* $U_V = U_R + U_A$ *we have,*

$$R = \frac{U_V - U_A}{I_A} = \frac{R'I_A - U_A}{I_A} = R' - R_A \ .$$

For $R_A \to 0$ *for* $R' \to R$.

14.4.3.4 Ex: Real current source

a. How should the internal resistance of a current source R_i be specified in order to obtain a current as independent as possible from the consuming load?
b. You want to run 40 A through an electric coil. The coil has the ohmic resistance of $R = 1\,\Omega$. What should be the internal resistance of the current source in order for a 10% increase in resistance not to change the current by more than 0.1%?

Solution: *a. The current that runs is* $I = U_0/(R_i + R)$. *To prevent that* R *has an influence, we need to let* $R_i \gg R$.
b. We imagine the source as a circuit in series with an ideal voltage source U_0 *and an internal resistance* R_i,

$$U_0 = (R_i + R)I \qquad \text{and} \qquad U_0 = (R_i + R')I' \ ,$$

with $R' = 1.1R$ *and* $I' = 0.99I$ *follows,*

$$R_i = -\frac{RI - R'I'}{I - I'} = -R\frac{1 - \frac{R'I'}{RI}}{1 - \frac{I'}{I}} = 98.9R \ .$$

14.4.3.5 Ex: Real voltage source

A battery can be understood as a real voltage source, consisting of an ideal voltage source U_0 and an internal resistance R_i. The voltage supplied by the battery depends on the consuming load. Which current flows through the resistor R and which voltage U_{out} does the battery supply? How must the resistive load be chosen to maximize the power spent at the ohmic resistor?

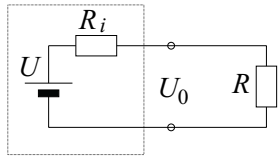

Figure 14.23: Battery.

Solution: *The current through R is,*

$$U_0 = R_{ges} I = (R_i + R) I \quad \Rightarrow \quad I = \frac{U_0}{R_i + R} \ .$$

With Kirchhoff's law:

$$-U_0 + U_R + U_i = -U_0 + RI + R_i I = 0 \quad \Rightarrow \quad I = \frac{U_0}{R_i + R} \ .$$

The voltage U_{out} at the battery is,

$$U_{out} = RI = U_0 \frac{R}{R + R_i} \ .$$

The resistance of the load for which the ohmic power at R is maximum (power matching):

$$P = U_{out} I = U_0 \ \frac{R}{R + R_i} \frac{U_0}{R + R_i} = U_0^2 \ \frac{R}{(R + R_i)^2} \ .$$

Deriving,

$$\frac{dP}{dR} = U_0^2 \ \frac{(R + R_i)^2 - R2(R + R_i)}{(R + R_i)^4} = U_0^2 \ \frac{R^2 + 2RR_i + R_i^2 - 2R^2 - 2RR_i}{(R + R_i)^4}$$
$$= U_0^2 \ \frac{R_i^2 - R^2}{(R + R_i)^4} = 0 \quad \Rightarrow \quad R = R_i \ .$$

Second derivative:

$$\frac{d^2 P}{dR^2} = U_0^2 \ \frac{-2R(R + R_i)^4 - (R_i^2 - R^2)4(R + R_i)^3}{(R + R_i)^8} = U_0^2 \ \frac{-32R^5 - 0}{(2R)^8} = -\frac{U_0^2}{8R^3} < 0$$

for $R_i = R$. Therefore, the power is maximum for $R = R_i$.

14.4.3.6 Ex: Battery circuit

Two batteries 1 and 2 (voltages $U_1 = 2\,\mathrm{V}$ and $U_2 = 0.5\,\mathrm{V}$) and three resistors $R_1 = R_2 = R_3 = 1\,\Omega$ are connected as shown in the figure.
a. What currents flow through the resistors R_1, R_2, and R_3?
b. What is the voltage drop between points A and B?

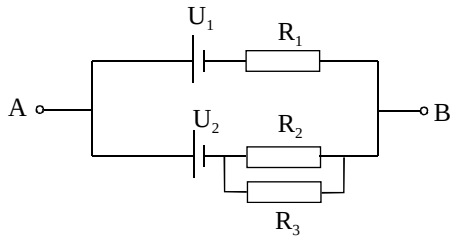

Figure 14.24: Battery circuit.

Solution:

14.4.3.7 Ex: Circuit with battery

Three batteries ($U_1 = 20\,\mathrm{V}$, $U_2 = 5\,\mathrm{V}$, $U_3 = 20\,\mathrm{V}$) each with a finite internal resistance of $0.1\,\Omega$ are connected in parallel. In series with this circuit two resistors are connected ($R_1 = 100\,\Omega$, $R_2 = 200\,\Omega$) (see scheme). What is the electrical voltage at R_1 and R_2?

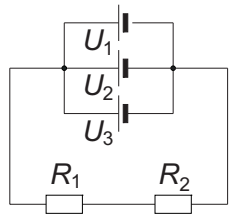

Figure 14.25: Battery circuit.

Solution: *We can imagine each individual battery as being composed by an ideal voltage source U_k and an internal resistance R_{ik}. So the voltage U_k measured at the parallel circuit corresponds to the voltage drop between points a and b: $U_k = U_2 + R_{i2}I_{i2}$. In addition, we have $2I_{i1} = I_{i2}$, since the node law gives at the point the current $I_{i1} + I_{i3} = I_{i2}$ and, for symmetry reasons, also holds $I_{i3} = I_{i1}$. Moreover, the mesh*

law gives,

$$\begin{aligned} -U_1 + R_{i1}I_{i1} + R_{i2}I_{i2} + U_2 = 0 & \\ \Longrightarrow -U_1 + R_{i1}\frac{I_{i2}}{2} + R_{i2}I_{i2} + U_2 = 0 & \\ \Longrightarrow I_{i2}\left(\frac{R_{i1}}{2} + R_{i2}\right) = U_1 - U_2 & \\ \Longrightarrow I_{i2} = 2\frac{U_1 - U_2}{3R_{i2}} \ , & \end{aligned}$$

since $R_{i1} = R_{i2}$. *With that follows* $U_k = U_2 + R_{i2}2\frac{U_1-U_2}{3R_{i2}} = 2U_1 - \frac{1}{3}U_2 = \frac{115}{3}\,\mathrm{V}$. *For the circuit in series we have* $U_k = U_{R1} + U_{R2}$ *and* $\frac{U_{R1}}{U_{R2}} = \frac{R_1}{R_2}$. *Finally,*

$$U_{R1} = \frac{1}{3}\frac{115}{3}\,\mathrm{V} \qquad \textit{and} \qquad U_{R1} = \frac{2}{3}\frac{115}{3}\,\mathrm{V} \ .$$

14.4.3.8 Ex: Kirchhoff's rules

The current circuit shown in the figure consists of voltage sources, $U_1 = 20\,\mathrm{V}$ and $U_2 = 10\,\mathrm{V}$ and resistors, $R_1 = 150\,\Omega$, $R_2 = R_3 = R_5 = 100\,\Omega$, and $R_4 = 50\,\Omega$. What is the current measured by the Ampèremeter A?

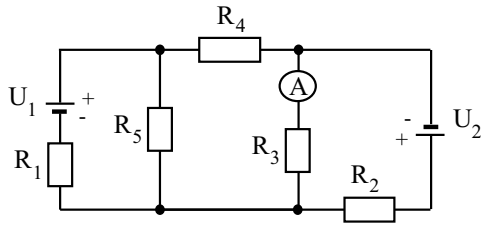

Figure 14.26: Circuits.

Solution:

14.4.3.9 Ex: Kirchhoff's rules

Be given $R_1 = 1\,\Omega$, $R_2 = 2\,\Omega$, as well as $\varepsilon_1 = 2\,\mathrm{V}$ and $\varepsilon_2 = \varepsilon_3 = 4\,\mathrm{V}$.
a. Show that Kirchhoff's node rule for steady currents is a consequence of the continuity equation $\oint \vec{j}d\vec{A} = \frac{dq}{dt}$.
b. Calculate the currents across the three ideal batteries in the circuit shown in figure.
c. Calculate the potential difference between points a and b.

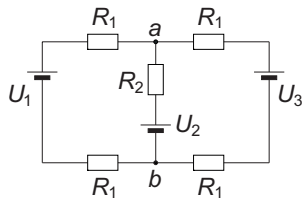

Figure 14.27: Circuits.

Solution: *a. For steady currents we may request:* $\frac{dq}{dt} = 0$. *When several currents parameterized by* $\mathbf{j}_k(\mathbf{r})d\vec{A}_k = I_k$ *combining, follows,*

$$\oint \mathbf{j} d\mathbf{A} = \sum_k I_k = 0 \ .$$

b. We start writing Kirchhoff rules for both nodes and both meshes (node b is redundant):

$$\begin{aligned} -U_1 + R_1 I_1 + R_2 I_2 + U_2 + R_1 I_1 = 0 \\ -U_3 + R_1 I_3 + R_2 I_2 + U_2 + R_1 I_3 = 0 \\ I_1 + I_3 - I_2 = 0 \ . \end{aligned}$$

Eliminating the third equation,

$$\begin{aligned} (2R_1 + R_2)\, I_1 + R_2 I_3 + U_2 - U_1 = 0 \\ R_2 I_1 + (2R_1 + R_2)\, I_3 + U_2 - U_3 = 0 \ . \end{aligned}$$

Solving for I_1 *and* I_3

$$\begin{aligned} I_3 &= -\frac{1}{4} \frac{R_2 U_1 + 2R_1 U_2 - (2R_1 + R_2)\, U_3}{R_1\,(R_1 + R_2)} \\ I_1 &= \frac{1}{4} \frac{(2R_1 + R_2)\, U_1 - 2R_1 U_2 - R_2 U_3}{R_1\,(R_1 + R_2)} \\ I_2 &= \frac{1}{2} \frac{U_1 - 2U_2 + U_3}{R_1 + R_2} \ . \end{aligned}$$

Hence, the currents are $I_1 = -2/3\,\mathrm{A}$, $I_3 = 1/3\,\mathrm{A}$ *and* $I_2 = -1/3\,\mathrm{A}$.
c. The potential difference is,

$$U_{ab} = R_2 I_2 + U_2 = \frac{1}{2} \frac{R_2 U_1 + 2R_1 U_2 + R_2 U_3}{R_1 + R_2} \ .$$

Hence, $U_{ab} = 10/3\,\mathrm{V}$.

14.4.3.10 Ex: Kirchhoff's rules

Consider the following circuit fed by a battery of voltage V. Using Kirchhoff's laws calculate the voltages and currents at the points $P1$ and $P2$. What is the total resistance of this circuit?

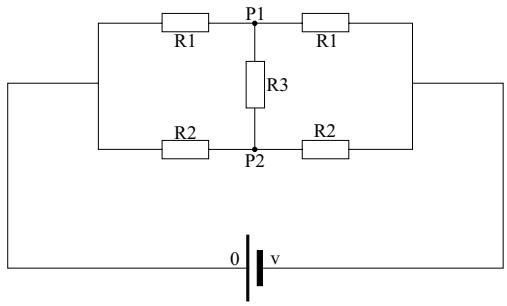

Figure 14.28: Circuits.

Solution: *Applying Kirchhoff's first law to the current at nodes,*

$$\begin{aligned} \textit{(i for the node P1)} \quad & I_{1,l} - I_{1,r} - I_3 = 0 \quad \Rightarrow \quad I_{1,r} = I_{1,l} - I_3 \\ \textit{(ii for the node P2)} \quad & I_{2,l} - I_{2,r} + I_3 = 0 \quad \Rightarrow \quad I_{2,r} = I_{2,l} + I_3 \end{aligned}$$

Applying Kirchhoff's second law to the meshes,

$$\begin{aligned} \textit{(iii for the upper left mesh)} \quad & U_{1,l} + U_3 - U_{2,l} = I_{1,l}R_1 + I_3R_3 - I_{2,l}R_2 = 0 \\ \textit{(iv for the upper right mesh)} \quad & U_{1,r} - U_{2,r} - U_3 = I_{1,r}R_1 - I_{2,r}R_2 - I_3R_3 = 0 \\ \textit{(v for lower mesh)} \quad & U_{2,l} + U_{2,r} - |V| = I_{2,l}R_2 + I_{2,r}R_2 - |V| = 0 \ . \end{aligned}$$

Inserting (i) and (ii) into (iv) we obtain,

$$\textit{(iv')} \quad I_{1,l}R_1 - I_3R_1 - I_{2,l}R_2 - I_3R_2 - I_3R_3 = 0 \ .$$

Subtracting (iii)-(iv') we get,

$$I_3R_1 + I_3R_2 + 2I_3R_3 = R_1 + R_2 + 2R_3)I_3 = 0 \quad \Rightarrow \quad I_3 = 0 \ .$$

Thus, it follows from (i) and (ii),

$$I_{1,r} = I_{1,l} = I_1 \quad \textit{and} \quad I_{2,r} = I_{2,l} = I_2 \ ,$$

and with (v),

$$2I_2R_2 = |V| \quad \Rightarrow \quad I_2 = \frac{|V|}{2R_2}$$

and with (iii):

$$I_1R_1 = I_2R_2 \quad \Rightarrow \quad I_1 = I_2\frac{R_2}{R_1} = \frac{|V|}{2R_1} \ .$$

Using Ohm's law we find the voltages at the resistances,

$$U_{1,l} = U_{1,r} = R_1I_1 = \frac{|V|}{2} \quad \textit{and} \quad U_{2,l} = U_{2,r} = R_2I_2 = \frac{|V|}{2} \ .$$

The voltage at points P1 and P2 is $V/2$, i.e. there is no current I_3 flowing. That is, we have the case of a balanced bridge circuit.

To calculate the total circuit resistance we consider two possibilities of equivalent circuits:
a. Points P1 and P2 staying at the same potential can be short-circuited, giving,

$$R_{ges} = \left(\frac{1}{R_1} + \frac{1}{R_2}\right)^{-1} + \left(\frac{1}{R_1} + \frac{1}{R_2}\right)^{-1} = 2\left(\frac{R_2 + R_1}{R_1 R_2}\right)^{-1} = \frac{2\,R_1\,R_2}{R_1 + R_2}\ .$$

b. Since the current $I_3 = 0$, points P1 and P2 can be separated, giving,

$$R_{ges} = \left(\frac{1}{R_1 + R_1} + \frac{1}{R_2 + R_2}\right)^{-1} = \left(\frac{R_2 + R_1}{2R_1 R_2}\right)^{-1} = \frac{2\ R_1\ R_2}{R_1 + R_2}\ .$$

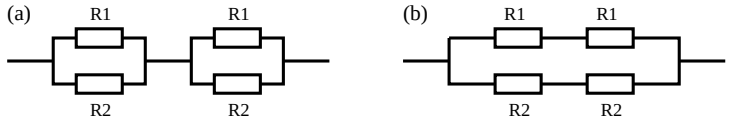

Figure 14.29: Circuits.

14.4.3.11 Ex: Combination of resistors

You have a maximum of 5 resistors of $100\,\Omega$ each. With these try to build circuits having the total resistance of a. $R = 25\,\Omega$, b. $R = 66.\bar{6}\,\Omega$, c. $R = 120\,\Omega$.

Solution: *a. 4 parallel resistors,* $\frac{1}{R_{ges}} = \frac{1}{R} + \frac{1}{R} + \frac{1}{R} + \frac{1}{R} = \frac{4}{R} \ \Rightarrow\ R_{ges} = \frac{R}{4} = 25\,\Omega$
b. 3 resistors, $\frac{1}{R_{ges}} = \frac{1}{R+R} + \frac{1}{R} = \frac{3}{2R} \ \Rightarrow\ R_{ges} = \frac{2}{3}R = 66,\bar{6}\,\Omega$
c. 5 resistors, $\frac{1}{R_{ges}} = \frac{1}{R+R+R} + \frac{1}{R+R} = \frac{5}{6R} \ \Rightarrow\ R_{ges} = \frac{6}{5}R = 120\,\Omega$

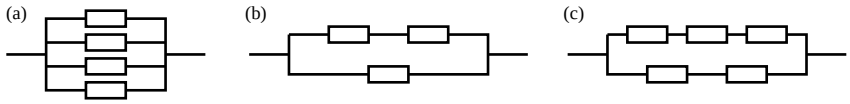

Figure 14.30: Resistors circuits.

14.4.3.12 Ex: Circuit with capacitors and resistors

In the circuit shown in the figure be $R_1 = 600\,\Omega$, $R_2 = 200\,\Omega$, $R_3 = 300\,\Omega$, $C = 20\,\mu\text{F}$, and $U = 12\,\text{V}$.
a. Calculate the voltages measured at the individual resistors and the capacitor as well as the total current I_{ges} when the capacitor is fully charged (stationary case).
b. At time $t = 0$ the switch S is opened. After which time the capacitor voltage drops

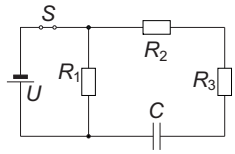

Figure 14.31: Circuits.

to 10 mV?

Solution: *a. When the capacitor is fully charged, no current flows through the resistors R_2 and R_3. The total voltage of* 12 V *drops at the capacitor and the resistor R_1. Through the resistor R_1 goes the current $I = U/R_1 = 20\,\mathrm{mA}$.*
b. When the switch is opened, the capacitor discharges through the circuit in series of all three resistors. Therefore,

$$(R_1 + R_2 + R_3)I = (R_1 + R_2 + R_3)\dot{Q} = U = Q/C \ ,$$

resp.

$$U = U_0 e^{-t/(R_1+R_2+R_3)C} \ .$$

14.4.3.13 Ex: Circuits with resistors and capacitors

Consider the circuit shown in the figure with the following values, $R_1 = R_3 = 100\,\Omega$, $R_2 = R_4 = 200\,\Omega$, $C_1 = C_2 = 10\,\mu\mathrm{F}$, and $U_0 = 20\,\mathrm{V}$.
a. Calculate equivalent resistance and the equivalent capacity of the circuit.
b. At time $t = 0$ the switch S is closed. Find the differential equation for the voltage $U(t)$ at the capacitor C_1 and solve it. When does the voltage drop to $1/e$ of its maximum value?
c. Determine the evolution of the amplitude of the resistor current R_3.

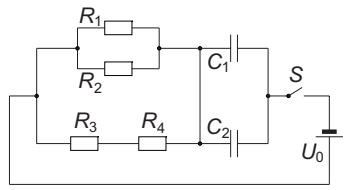

Figure 14.32: Circuits.

Solution: *a. Equivalent resistance,*

$$R_{eq} = \left(\frac{1}{R_1} + \frac{1}{R_2} + \frac{1}{R_3 + R_4}\right)^{-1} \approx 54.5\,\Omega \ .$$

Equivalent capacity,

$$C_{eq} = C_1 + C_2 = 20\,\mu\text{F} \ .$$

b. The mesh rule gives $U_0 = R_{ers}I(t) + U(t)$*, since the voltage in* C_1 *is the same as that in* C_2*. From this follows,*

$$U_0 = R_{eq}\frac{dQ}{dt} + U(t) = R_{ers}C_{ers}\frac{dU(t)}{dt} + U(t) \equiv \frac{1}{M}\frac{dU(t)}{dt} + U(t) \ .$$

Hence, we get the differential equation,

$$\frac{dU(t)}{dt} = MU_0 - MU(t) \ .$$

The solution is obviously, $U(t) = U_0(1 - e^{-Mt})$*. The value* $1/e$ *is reached when* $t = -\frac{1}{M}\ln(1 - 1/e) \approx 0.5\,\text{ms}$*.*
c. With $I(t) = \frac{1}{R_{tot}}[U_0 - U(t)]$ *and the nodes rule,* $I(t) = I_{34} + I_{12}$*, and the mesh rule,* $I_{34}(R_3 + R_4) - I_{12}(R_1 \parallel R_2) = 0$ *, we obtain,*

$$I_1(t) = \frac{R_1 \parallel R_2}{(R_1 \parallel R_2) + R_3 + R_4}I(t) = \frac{R_1 \parallel R_2}{(R_1 \parallel R_2) + R_3 + R_4}U_0 e^{-Mt} \ .$$

14.4.3.14 Ex: Circuits with resistors and capacitors

Calculate the total resistances and capacitances of the following circuits.
Help for (e): Consider the capacitor as a set of capacitors with/without dielectric in series and in parallel.

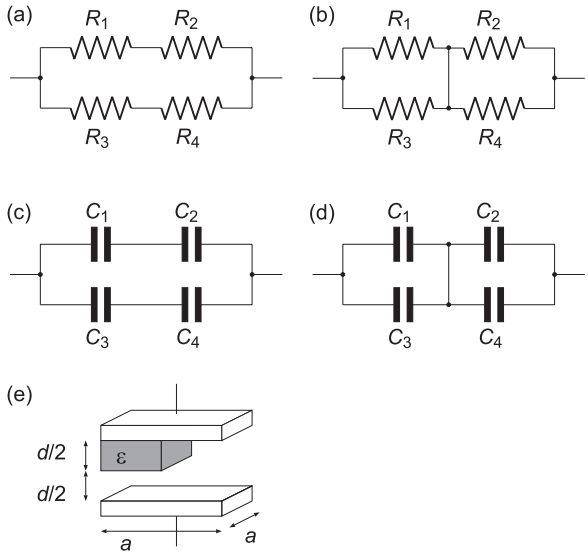

Figure 14.33: Circuits.

Solution: *a.*

$$R = \frac{1}{\frac{1}{R_1+R_2} + \frac{1}{R_3+R_4}} \ .$$

b.

$$R = \frac{1}{\frac{1}{R_1} + \frac{1}{R_2}} + \frac{1}{\frac{1}{R_3} + \frac{1}{R_4}} \ .$$

c.

$$R = \frac{1}{\frac{1}{C_1} + \frac{1}{C_2}} + \frac{1}{\frac{1}{C_3} + \frac{1}{C_4}} \ .$$

d.

$$R = \frac{1}{\frac{1}{C_1+C_2} + \frac{1}{C_3+C_4}} \ .$$

e.

$$C = \varepsilon_0 \frac{a^2/2}{d} + \frac{1}{\frac{1}{\varepsilon_0 \varepsilon \frac{a^2/2}{d}}} + \frac{1}{\varepsilon_0 \frac{a^2/2}{d}} = \varepsilon_0 \frac{a^2}{2d} \frac{2+\varepsilon}{1+\varepsilon} \ .$$

14.4.3.15 Ex: Charging a capacitor

The circuit shown in Fig. 14.20 consists of a voltage source U, a resistance R, and a capacity C. Initially be $U = 0$. From the time $t = 0$ on the voltage source shall give the constant value $U = U_0$. Calculate the time evolution of the current I in the circuit as well as the time evolution of the voltages at the capacitor and at the resistance.
Help: Begin by establishing the differential equation for the current I.

Solution: *Before turning on the source we have $U_0 = U_R = U_C = 0$. Immediately after turning on we have $U_0 = U_R + U_C$. With the current across the resistance $I = U_R/R$ and the capacitor charge $Q_c = CU_C$ we get,*

$$U_0 = RI + \frac{Q}{C} \ .$$

With $I = \dot{Q}_C$ follows,

$$\dot{U}_0 = R\dot{I} + \frac{I}{C} = 0 \ .$$

Finally,

$$\dot{I} = -\frac{1}{RC} I \ ,$$

with the solution $I(t) = I_0 e^{-t/\tau}$ with $\tau = RC$. At time $t = 0$ the capacitor is discharged, so $U_C = 0$. Hence, $U_0 = U_R(t = 0) = RI(t = 0)$ and $I_0 = U_0/R$, hence,

$$I(t) = \frac{U_0}{R} e^{-t/\tau} \ .$$

The resistor voltage drops exponentially, $U(t) = RI(t) = U_0 e^{-t/\tau}$. For the capacitor voltage we have,

$$\dot{U}_C = \frac{I}{C} = \frac{U_0}{RC} e^{-t/\tau}$$
$$\Longrightarrow U_C = \frac{Q}{C} = -\tau \frac{U_0}{RC} e^{-t/\tau} + const = -U_0 e^{-t/\tau} + const \ .$$

At time $t = 0$ holds $U_C = 0$ and with that $const = U_0$, hence U_C goes exponentially from 0 to U_0: $U_C = U_0(1 - e^{-t/\tau}$.

14.4.3.16 Ex: R-C circuit

Consider the electrical circuit shown in the figure with the ideal voltage sources U_k, the resistors R_k, and the capacitor C. Initially the switch C_1 is open.
a. Calculate the charge Q_0 on the capacitor after a long time.
b. Now, the switch is closed. Using Kirchhoff's laws, express the charge on the capacitor as a function of the current I_C across the capacitor and the parameters shown in the figure.
c. Based on the result obtained in (b), calculate the time evolution of the capacitor charge.
d. Indicate the values for $t = 0$ and $t \to \infty$.
e. Discuss the cases (i) $U_2 = U_1$ and (ii) $U_2 = -U_1$.

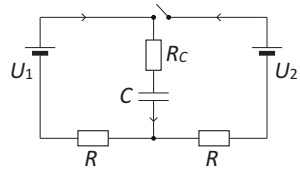

Figure 14.34: Circuits.

Solution: *a. Kirchhoff's node rule for the left mesh gives:*

$$U_1 - \frac{Q_0}{C} - R_C I - RI = 0 \ .$$

In steady state no current is flowing, $I = 0$. Hence,

$$Q_0 = CU_1 \ .$$

b. Now we have two connected meshes. We start writing Kirchhoff's rules for both nodes and both meshes (node b is redundant):

$$U_1 - \frac{Q}{C} - R_C I_C - RI_1 = 0$$
$$U_2 - \frac{Q}{C} - R_C I_C - RI_2 = 0$$
$$I_1 + I_2 - I_C = 0 \ .$$

Adding the first and second equation and replacing the third,

$$0 = U_1 + U_2 - 2\frac{Q}{C} - 2R_C I_C - R(I_1 + I_2) = U_1 + U_2 - 2\frac{Q}{C} - 2R_C I_C - RI_C \ .$$

c. Solving for I_C,

$$\begin{aligned}
(2R_C + R)\frac{dQ}{dt} + 2\frac{Q}{C} &= U_1 + U_2 \\
\tfrac{C}{2}(2R_C + R)\frac{dQ}{\frac{C}{2}(U_1 + U_2) - Q} &= dt \\
-\tfrac{C}{2}(2R_C + R)\ln[\tfrac{C}{2}(U_1 + U_2) - Q]\big|_{Q_0}^{Q(t)} &= t \\
Q(t) &= \tfrac{C}{2}(U_1 + U_2) - [\tfrac{C}{2}(U_1 + U_2) - Q_0]e^{-2t/C(2R_C+R)} \ .
\end{aligned}$$

Substituting $Q_0 = CU_1$, we obtain,

$$Q(t) = \tfrac{C}{2}(U_1 + U_2) + \tfrac{C}{2}(U_1 - U_2)e^{-2t/C(2R_C+R)} \ .$$

d. We have $Q(t = 0) = CU_1$ and $Q(t \to \infty) = \frac{C}{2}(U_1 + U_2)$.
e. For (i) $U_2 = U_1$

$$Q(t) = CU_1 = const \ ,$$

and for (ii) $U_2 = -U_1$

$$Q(t) = CU_1 e^{-2t/C(2R_C+R)} \ .$$

14.4.3.17 Ex: Internal resistance of a battery

A 5 V power supply has an internal resistance of 50 Ω. What is the smallest resistor that can be taken in series with the power source so that the potential drop in the resistor is larger than 4.5 V?

Solution: 0.45 kΩ.

14.4.3.18 Ex: Circuit with two batteries

In the circuit shown in the figure, the batteries have negligible internal resistances. Determine
a. the current in each branch of the circuit
b. the potential difference between the points a and b, and
c. the power supplied by each battery.

Solution: *a. $I_{4\Omega} = 0.667$ A, $I_{3\Omega} = 0.889$ A and $I_{6\Omega} = 1.56$ A.*
b. $V_{ab} = 9.88$ V,
c. $P_{esq} = 8.0$ W, $P_{dir} = 10.7$ W.

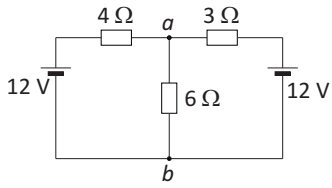

Figure 14.35: Circuits.

14.4.3.19 Ex: Circuit with three batteries

For the circuit shown in the figure, determine the potential difference between the points a and b.

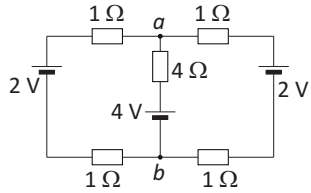

Figure 14.36: Circuits.

Solution: $V_a - V_b = 2.4\,\mathrm{V}$.

14.4.3.20 Ex: Real voltmeter

The voltmeter shown in the figure can be modeled as an *ideal* voltmeter (a voltmeter that has an infinite internal resistance) in parallel with a $10\,\mathrm{M\Omega}$ resistor. Calculate the voltmeter reading when
a. $R = 1.0\,\mathrm{k\Omega}$,
b. $R = 10.0\,\mathrm{k\Omega}$,
c. $R = 1.0\,\mathrm{M\Omega}$,
d. $R = 10.0\,\mathrm{M\Omega}$,
e. $R = 100.0\,\mathrm{M\Omega}$.
f. What is the largest possible value of R if the measured voltage should be within 10% of the *true* voltage (i.e. the voltage drop at R without placing the voltmeter)?

Solution: *a.* $3.33\,\mathrm{V}$,
b. $3.33\,\mathrm{V}$,
c. $3.13\,\mathrm{V}$,
d. $2.00\,\mathrm{V}$,
e. $0.435\,\mathrm{V}$,
f. $R_{max} = 1.67\,\mathrm{M\Omega}$.

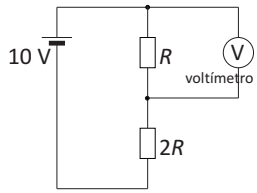

Figure 14.37: Voltmeter.

14.4.3.21 Ex: Circuit with battery and capacitor

The switch shown in the figure is closed after having been open for a long time.
a. What is the initial value of battery current right after the switch S has been closed?
b. What is the battery current a long time after the key has been closed?
c. What are the charges on the capacitor plates a long time after the switch has been closed?
d. Now, the switch S is opened again. What are the charges on the capacitor plates a long time after the switch has been reopened?

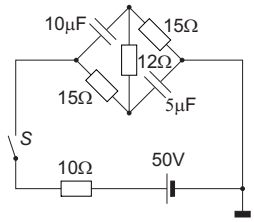

Figure 14.38: Circuits.

Solution: *a.* .

14.4.3.22 Ex: Circuit with battery and capacitor

In the circuit shown in the figure, the capacitor has a capacitance of 2.5 μF and the resistor has a resistance of 0.5 MΩ. Before the switch is closed, the potential drop in capacitor is 12 V, as shown in the figure. The switch S is closed at $t = 0$.
a. What is the current immediately after the switch has been closed?
b. At what instant of time t is the voltage on the capacitor 24 V?

Solution: *a.* 48.0 μA.
b. 0.866 s.

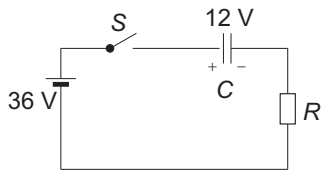

Figure 14.39: Circuits.

14.4.3.23 Ex: Three-phase current

Three-phase current is generated by three potential differences with respect to ground described by,

$$U_n(t) = U_0 \sin(\omega t + n\tfrac{2\pi}{3}) \ ,$$

where $n = 1, 2, 3$ labels the three phases. Assuming $U_0 = 127\,\mathrm{V}$.
a. What is the period-averaged voltage of each phase with respect to ground?
b. What is the period-averaged voltage difference between two phases?
c. What is the amplitude of the voltage difference between two phases?
d. Derive the time-dependent expressions for all currents labeled in Fig. 14.40(a).

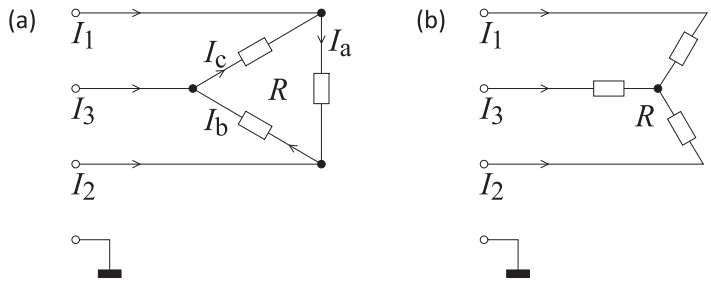

Figure 14.40: (a) Star connection, (b) triangular connection.

Solution: *a. The period-averaged voltage of each phase is,*

$$\bar{U}_n = \sqrt{\frac{\omega}{2\pi}\int_0^{2\pi/\omega} U_n^2(t)dt} = U_0\sqrt{\frac{\omega}{2\pi}\int_0^{2\pi/\omega} \sin^2(\omega t + n\tfrac{2\pi}{3})dt} = \frac{U_0}{\sqrt{2}} \ .$$

b. The period-averaged voltage difference between two phases is,

$$\bar{U}_d = U_0\sqrt{\frac{\omega}{4\pi}\int_0^{4\pi/\omega} \left[\sin(\omega t + \tfrac{2\pi}{3}) - \sin\omega t\right]^2 dt} = \sqrt{\tfrac{3}{2}}U_0 = \sqrt{3}\bar{U}_n \ .$$

c. The voltage difference between two phases is,

$$U(t) = U_0\left[\sin(\omega t + \tfrac{2\pi}{3}) - \sin\omega t\right] = U_0\left(\tfrac{\sqrt{3}}{2}\cos\omega t - \tfrac{3}{2}\sin\omega t\right) = U_0\sqrt{3}\sin(\omega t + \tfrac{5\pi}{6}) \ .$$

Hence, $U_{d0} = \sqrt{3}U_0 = 220\,\mathrm{V}$. *d. Kirchhoff's node rule yields,*

$$I_1 = I_a - I_c \quad , \quad I_2 = I_b - I_a \quad , \quad I_3 = I_c - I_b \ .$$

Resulting in $I_1 + I_2 + I_3 = 0$. *We also know from Kirchhoff's mesh rule,*

$$U_{12} = R_a I_a \quad , \quad U_{23} = R_b I_b \quad , \quad U_{31} = R_c I_c$$

with $U_{mn} = U_m - U_n$. *Hence,*

$$\begin{aligned} I_1 &= \frac{U_{12}}{R_a} - \frac{U_{31}}{R_c} = \frac{U_1 - U_2}{R_a} - \frac{U_3 - U_1}{R_c} \\ &= U_0 \left[\left(\frac{1}{R_a} + \frac{1}{R_c} \right) \sin\left(\omega t + \tfrac{2\pi}{3}\right) - \frac{1}{R_a} \sin\left(\omega t + \tfrac{4\pi}{3}\right) - \frac{1}{R_c} \sin\left(\omega t + \tfrac{6\pi}{3}\right) \right] \end{aligned}$$

etc.. Furthermore,

$$I_a = \frac{U_{12}}{R_a} = \frac{U_1 - U_2}{R_a} = \frac{U_0}{R_a} \left[\sin\left(\omega t + \tfrac{2\pi}{3}\right) - \sin\left(\omega t + \tfrac{4\pi}{3}\right) \right] = \frac{U_0}{R_a} \sqrt{3} \sin\left(\omega t + \tfrac{9\pi}{6}\right)$$

etc..

Chapter 15

Magnetostatics

Magnetostatics is the theory dealing with stationary currents, the fundamental problem being the calculation of the force exerted by spatial current distributions. Since a current is always due to displacement of charges, it is obviously not stationary in the strict sense. On the other hand, if the charge is transported in such a way that every charge leaving a volume element is immediately replaced by another equivalent charge, the integral over the volume element yields a stationary charge distribution.

15.1 Electric current and the Lorentz force

In the previous chapter we have shown that charges can travel through electric conductors, thus producing currents. We observe experimentally that electrically neutral conductors can exert reciprocal forces. For example, passing currents through two parallel, almost infinitely long thin wires, we find that they attract (repel) each other when their directions are (anti-)parallel. We also observe that a compass needle is deflected near a current-carrying conductor in directions describing concentric circles around the conductor. If the compass needle traces the field lines of a yet unknown field, the force attracting (or repelling) two currents DOES NOT point in the direction of the field lines. These observations show the presence of another phenomenon and another force not explained by Coulomb's law (see Fig. 15.1).

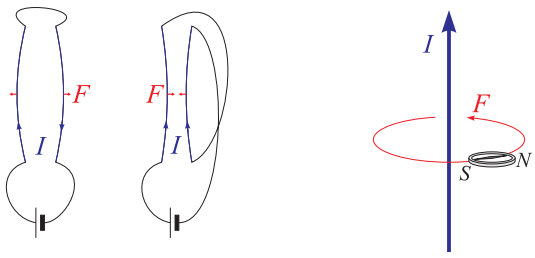

Figure 15.1: Mutual force between two conductors carrying antiparallel and parallel currents. Torque exerted by a current on a compass.

Apparently, the new force is not oriented in the direction of the current I, nor in the direction of the lines described by the compass needle, but perpendicular to the two. To describe this fact, we postulate the existence of a field $\vec{\mathcal{B}}$ called *magnetic*

field, such that the force is described by the vector product,

$$\mathbf{F}_L = I\mathbf{l} \times \vec{\mathcal{B}} \,, \tag{15.1}$$

where $\mathbf{l}$ is an element of the current path. This force is called *Lorentz force*. Note, that this force behaves like a pseudo-vector(see Exc. 1.6.3.7).

In order to analyze this phenomenon from the microscopic point of view, we put forward the hypothesis that the observed force has to do with the *motion* of the charges constituting the current within the postulated magnetic field. We have already introduced in the previous chapter the notion of the *current*, and we connected the current density with the propagation velocity of charges in the Eqs. (14.38) and (14.46),

$$\mathbf{j}(\mathbf{r}') = \varrho(\mathbf{r}')\mathbf{v}' \,. \tag{15.2}$$

With this we get,

$$\begin{aligned} \mathbf{F}_L &= I \int_{\mathcal{C}} d\mathbf{l}' \times \vec{\mathcal{B}} = I \int_{\mathcal{C}} \hat{\mathbf{e}}'_j \times \vec{\mathcal{B}} dl' \\ &= \int_{\mathcal{V}} I\delta^2(\mathbf{r}'_\perp - \mathbf{l}_\perp)\hat{\mathbf{e}}'_j \times \vec{\mathcal{B}} dV' = \int_{\mathcal{V}} \mathbf{j}(\mathbf{r}') \times \vec{\mathcal{B}} dV' = \int_{\mathcal{V}} \varrho(\mathbf{r}')\mathbf{v}' \times \vec{\mathcal{B}}(\mathbf{r}') dV' \,, \end{aligned} \tag{15.3}$$

where we simplified the notation $\mathbf{j}(\mathbf{r}') = I\delta^2(\mathbf{r}'_\perp - \mathbf{l}_\perp)\hat{\mathbf{e}}'_j = I\delta(\hat{\mathbf{e}}_1 \cdot \mathbf{r}' - \hat{\mathbf{e}}_1 \cdot \mathbf{l})\delta(\hat{\mathbf{e}}_2 \cdot \mathbf{r}' - \hat{\mathbf{e}}_2 \cdot \mathbf{l})\hat{\mathbf{e}}'_j$, where $\hat{\mathbf{e}}_{1,2}$ and $\hat{\mathbf{e}}'_j$ are all mutually orthogonal. We conclude,

$$\boxed{\mathbf{F}_L = Q\mathbf{v} \times \vec{\mathcal{B}}} \,. \tag{15.4}$$

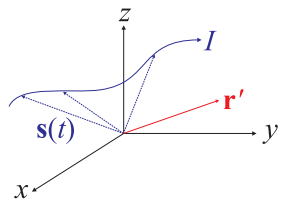

Figure 15.2: Parametrization of a yarn of current using the following recipe: For each point in space $\mathbf{r}' \in \mathbb{R}$ check that this point is also in $\mathbf{r}' \in \mathcal{C}$, that is, whether there exists a t such that $\mathbf{r}' = \mathbf{l}(t)$. At this point determine the direction of the path, $\hat{\mathbf{e}}'_j = d\mathbf{l}/|d\mathbf{l}|$, find two orthogonal unit vectors $\hat{\mathbf{e}}_{1,2}$ and apply the Dirac distribution to these dimensions.

Example 66 (*Cyclotron and synchrotron motion*): A consequence of the fact that, according to (15.4), the force on moving charges is always perpendicular to their velocity is, that their trajectory in a homogeneous magnetic field are *circular*. The centrifugal force compensates for the Lorentz force when,

$$F_L = Qv\mathcal{B} = m\frac{v^2}{R} = F_{cf} \,,$$

which allows to determine the radius R of the circle [1].

This fact is used in particle accelerators called *cyclotrons*, where beams of

[1] This behavior can be observed by injecting a charged particles into a homogeneous magnetic field. Collimated electron beams can be created by an electrode device called the *Wehnelt's cylinder* used in cathode ray tubes called *Braun's tube*.

charged particles are accelerated in by electric fields and deflected by homogeneous magnetic fields located between the regions of acceleration.

An important consequence of the particular form of the Lorentz force is the fact that *magnetic forces do not work*,

$$W_{mg} = \int_{\mathcal{C}} \mathbf{F} \cdot d\mathbf{l} = 0 \ .$$

The direction of motion of a charge can be changed by magnetic fields, but not the absolute value of its velocity. This may seem surprising, as we know that magnets can exert forces of iron bodies.

Example 67 (*Work exerted by magnetic fields*): We consider a conductive wire loop carrying current and being partially immersed in a homogeneous magnetic field, as shown in Fig. 15.3. The device is in equilibrium, when,

$$F = Ia\mathcal{B} = mg \ .$$

When the current exceeds the value $mg/a\mathcal{B}$, a vertical force lifting the device is observed, such that the device gains potential energy,

$$W = Fh \ ,$$

where h is the acquired height. However, the vertical motion corresponds to a current $I\hat{\mathbf{e}}_z$, which creates a force contrary to the current I, such that the battery feeding the wire loop needs to work to maintain the current. The magnetic field only reorients the force into a direction having a parallel component to the horizontal part of the wire loop, thus allowing the battery to work against this force. We shall discuss this from another point of view in context of the Lenz-Faraday law.

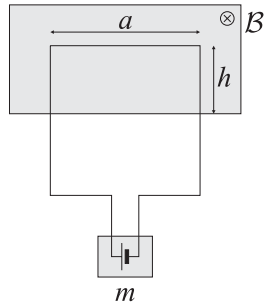

Figure 15.3: Hypothetical device to make the magnetic field work.

15.1.1 The Hall effect

As an example we consider the *Hall effect*: As shown in Fig. 15.4, a current flows to the right through a rectangular rod made of conductive material in the presence of a perpendicular uniform magnetic field $\vec{\mathcal{B}}$. If the mobile charges are positive, they will

be deflected by the magnetic field in downward direction. This deflection results in an accumulation of charges on the upper and lower boundaries of the rod which, in turn, generates an electric Coulomb force counteracting the magnetic force. A balance is reached when the two forces compensate:

$$F_C = Q\mathcal{E} = Q\frac{U_H}{w} = Qv_{med}\mathcal{B} = F_L \ . \tag{15.5}$$

The difference of the electric potentials on the upper and lower boundaries is called *Hall voltage*. The average velocity of the charges can be estimated from Eq. (14.46),

$$v_{med} = \frac{j}{n_a NQ} \ , \tag{15.6}$$

where n_a is the volumetric density of molecules of the rod material, each molecule providing N free electrons. Now, using the dimensions of the rod outlined in Fig. 15.4, we calculate the Hall voltage,

$$U_H = v_{med}\mathcal{B}w = \frac{j}{n_a NQ}\mathcal{B}w = \frac{I\mathcal{B}}{d\ n_a NQ} = A_H\frac{I\mathcal{B}}{d} \ , \tag{15.7}$$

where $A_H = 1/n_a NQ$ is a constant which depends on the rod material.

If the mobile charges were negative, the Hall voltage would change its sign. This fact can be used to identify the sign of free charges in unknown current conductors. Resolve the Excs. 15.1.3.1-15.1.3.13.

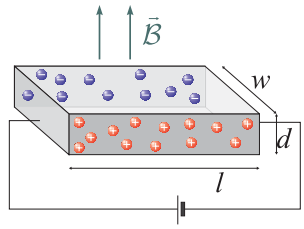

Figure 15.4: Illustration of the Hall Effect.

15.1.2 Biot-Savart's law

In the same way as we parametrize charge distributions (linear, superficial and volumetric) in electrostatics,

$$\sum_k (..)Q_k \longrightarrow \int_{\mathcal{C}} (..)\lambda dl \sim \int_{\mathcal{S}} (..)\sigma dS \sim \int_{\mathcal{V}} (..)\varrho dV \ , \tag{15.8}$$

we can parametrize current distributions (linear, superficial and volumetric) in magnetostatics,

$$\sum_k (..)Q_k\mathbf{v}_k \longrightarrow \int_{\mathcal{C}} (..)\mathbf{I}dl \sim \int_{\mathcal{S}} (..)\vec{\kappa}dS \sim \int_{\mathcal{V}} (..)\mathbf{j}dV \ . \tag{15.9}$$

In electrostatics we had the condition $\dot{\varrho} = 0$, which implies, via the continuity equation (14.39),

$$\nabla \cdot \mathbf{j} = 0 \ . \tag{15.10}$$

In magnetostatics we furthermore demand that $\dot{\mathbf{j}} = 0$.

The equivalent of Coulomb's law in magnetostatics is the Biot-Savart law,

$$\boxed{\vec{\mathcal{B}}(\mathbf{r}) = \frac{\mu_0}{4\pi}\int_{\mathcal{C}} \frac{\mathbf{I}(\mathbf{r}')\times(\mathbf{r}-\mathbf{r}')}{|\mathbf{r}-\mathbf{r}'|^3}dl' = \frac{\mu_0 I}{4\pi}\int_{\mathcal{C}} \frac{d\mathbf{l}'\times(\mathbf{r}-\mathbf{r}')}{|\mathbf{r}-\mathbf{r}'|^3} = \frac{\mu_0}{4\pi}\int_{\mathcal{V}} \mathbf{j}(\mathbf{r}')\times\frac{\mathbf{r}-\mathbf{r}'}{|\mathbf{r}-\mathbf{r}'|^3}dV'} \ . \tag{15.11}$$

Analogously to the way in which we apply Coulomb's law to electrostatics to calculate the electric field produced by charge distributions, we can apply the Biot-Savart's law in magnetostatics to calculate the magnetic field produced by currents.

Example 68 (*Magnetic field of a straight current wire*): We consider an infinitely long and thin wire oriented along the z-axis carrying a current I parametrized by $\mathbf{j}(\mathbf{r}') = \hat{\mathbf{e}}_z I\delta(x')\delta(y')$. Using $\mathbf{r} = \rho\hat{\mathbf{e}}_\rho + z\hat{\mathbf{e}}_z$ and $\mathbf{r}' = z'\hat{\mathbf{e}}_z$ we calculate,

$$\begin{aligned}\vec{\mathcal{B}}(\mathbf{r}) &= \frac{\mu_0 I}{4\pi}\int_{-\infty}^{\infty} dz' \frac{\hat{\mathbf{e}}_z\times(\mathbf{r}-\mathbf{r}')}{|\mathbf{r}-\mathbf{r}'|^3} = \frac{\mu_0 I}{4\pi}\hat{\mathbf{e}}_z\times\rho\hat{\mathbf{e}}_\rho\int_{-\infty}^{\infty}\frac{dz'}{\sqrt{\rho^2+(z-z')^2}^3} \\ &= \frac{\mu_0 I}{4\pi}\hat{\mathbf{e}}_z\times\rho\hat{\mathbf{e}}_\rho\left[\frac{z'}{\rho^2}(\rho^2+z'^2)^{-\frac{1}{2}}\right]_{-\infty}^{\infty} = \frac{\mu_0 I}{4\pi}\hat{\mathbf{e}}_z\times\rho\hat{\mathbf{e}}_\rho\frac{2}{\rho^2} = \frac{\mu_0 I}{2\pi\rho}\hat{\mathbf{e}}_\phi \ .\end{aligned}$$

With this we can now calculate the force exerted by this current on another current I_2 flowing in parallel direction but at a distance ρ:

$$\mathbf{F} = I_2 l\hat{\mathbf{e}}_z\times\vec{\mathcal{B}} = \frac{\mu_0 I I_2 l}{2\pi\rho}(-\hat{\mathbf{e}}_\rho) \ .$$

So the force is attractive.

Example 69 (*Magnetic field of a loop of circular current*): We consider a circular current parametrized by $\mathbf{j}(\mathbf{r}') = \hat{\mathbf{e}}_\phi I\delta(z)\delta(\rho-R)$. Following the Biot-Savart law the generated magnetic field is,

$$\vec{\mathcal{B}}(\mathbf{r}) = \frac{\mu_0}{4\pi}\int_{\mathcal{V}}\frac{\mathbf{j}(\mathbf{r}')\times(\mathbf{r}-\mathbf{r}')}{|\mathbf{r}-\mathbf{r}'|^3}dV' = \frac{\mu_0 I}{4\pi}\oint_{\mathcal{C}}\frac{\hat{\mathbf{e}}_{\phi'}\times(\mathbf{r}-R\hat{\mathbf{e}}_{r'})}{|\mathbf{r}-R\hat{\mathbf{e}}_{r'}|^3}Rd\phi' \ .$$

On the symmetry axis $\mathbf{r} = z\hat{\mathbf{e}}_z$ we get,

$$\begin{aligned}\vec{\mathcal{B}}(z\hat{\mathbf{e}}_z) &= \frac{\mu_0 IR}{4\pi}\oint_{\mathcal{C}}\frac{\hat{\mathbf{e}}_{\phi'}\times(z\hat{\mathbf{e}}_z - R\hat{\mathbf{e}}_{r'})}{\sqrt{R^2\cos^2\phi' + R^2\sin^2\phi' + z^2}^3}d\phi' \\ &= \frac{\mu_0 IR}{4\pi}\oint_{\mathcal{C}}\frac{z\hat{\mathbf{e}}_r + R\hat{\mathbf{e}}_z}{\sqrt{R^2+z^2}^3}d\phi' = \frac{\mu_0 IR^2}{2\sqrt{R^2+z^2}^3}\hat{\mathbf{e}}_z \ ,\end{aligned}$$

where the integral containing the term $z\hat{\mathbf{e}}_r$ vanishes by symmetry.

Resolve the Excs. 15.1.3.14-15.1.3.15.

15.1.3 Exercises

15.1.3.1 Ex: Force on a current conductor

A piece wire having the shape of a semicircle (radius R) congruent to the xy-plane at $z = 0$ is immersed in a homogeneous magnetic $\vec{\mathcal{B}}$-field oriented along $\hat{\mathbf{e}}_z$, as shown in the scheme. Through the wire runs a current I. Calculate the force on the loop and compare it to the force on a piece of straight wire oriented along the y-axis with length $2R$. The current in this wire runs along $\hat{\mathbf{e}}_y$.

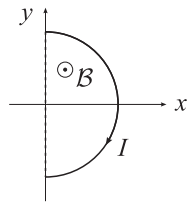

Figure 15.5: Wires.

Solution: *For a small piece of wire holds,*

$$d\mathbf{F} = Id\mathbf{l} \times \vec{\mathcal{B}} \ .$$

The force shows into radial direction and has the absolute value,

$$dF = Idl\mathcal{B} = I\mathcal{B}Rd\phi \ .$$

The component parallel to y is,

$$F_y = \int_{-\pi/2}^{\pi/2} dF \sin\phi = 0 \ .$$

The component parallel to x is,

$$F_x = I\mathcal{B}R \int_{-\pi/2}^{\pi/2} d\phi \cos\phi = 2I\mathcal{B}R \ .$$

This is equal but in opposite direction to the force acting on the piece of wire with length $2R$ toward y (the force on the entire loop is 0, as expected).

15.1.3.2 Ex: Lorentz force

In a wooden cylinder of mass $m = 0.25\,\mathrm{kg}$ and length $L = 10\,\mathrm{cm}$ is wound a 10 turns coil of conducting wire such that the axis of the cylinder is within the plane of the coil. The cylinder is (not slipping) on an plane inclined by $\alpha = 30°$ with respect to the horizontal, so that the plane of the coil is parallel to the inclined plane. The whole setup is subject to a homogeneous vertical magnetic field with the absolute

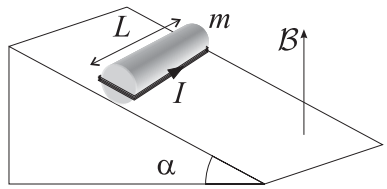

Figure 15.6: Lorentz force.

value $\mathcal{B} = 0.5\,\mathrm{T}$. What should be the minimum current through the coil to prevent the coil from rotating around its center of mass?

Solution: *The weight* $\mathbf{F}_g = -mg\hat{\mathbf{e}}_z$ *exerts a torque around the support point A of the cylinder in the inclined plane. Imagining the cylinder as a mass point concentrated at its center C, we find a torque acting on it,*

$$\vec{\tau}_g = \mathbf{r}_g \times \mathbf{F}_g \ ,$$

where $\mathbf{r}_g = R(\hat{\mathbf{e}}_x \sin\alpha + \hat{\mathbf{e}}_z \cos\alpha)$ *is the vector from A to C and R is the radius of the cylinder. Therefore,*

$$\vec{\tau}_g = -mg\mathbf{r}_g \times \hat{\mathbf{e}}_z = Rmg\hat{\mathbf{e}}_y \sin\alpha \ .$$

The Lorentz forces acting on the front side and the back side of the conductive loop, $\mathbf{F}_\pm = \pm NI\ \mathbf{L} \times \vec{\mathcal{B}} = \pm NILB\hat{\mathbf{e}}_x$*, cause torques,*

$$\vec{\tau}_\pm = \mathbf{r}_\pm \times \mathbf{F}_\pm \ ,$$

where $\mathbf{r}_\pm = \mathbf{r}_g \pm R(\hat{\mathbf{e}}_x \cos\alpha - \hat{\mathbf{e}}_z \sin\alpha) = R(\hat{\mathbf{e}}_x \sin\alpha \pm \hat{\mathbf{e}}_x \cos\alpha + \hat{\mathbf{e}}_z \cos\alpha \mp \hat{\mathbf{e}}_z \sin\alpha)$ *are the vectors of A to the points, where the Lorentz force acts. Therefore,*

$$\begin{aligned}\vec{\tau}_l &= \vec{\tau}_+ + \vec{\tau}_- = NILB(\mathbf{r}_+ - \mathbf{r}_-) \times \hat{\mathbf{e}}_x \\ &= RNILB\hat{\mathbf{e}}_z \times \hat{\mathbf{e}}_x\,[(\cos\alpha - \sin\alpha) - (\cos\alpha + \sin\alpha)] = -R2NILB\hat{\mathbf{e}}_y \sin\alpha \ .\end{aligned}$$

Alternatively, we calculate from magnetic moment, $\mathbf{m} = 2RLNI\hat{\mathbf{e}}_g$*, the torque,*

$$\vec{\tau}_l = \mathbf{m} \times \vec{\mathcal{B}} = -2RLNI\mathcal{B}\sin\alpha \ .$$

To prevent the cylinder from moving, we need $\vec{\mathcal{M}}_g + \vec{\mathcal{M}}_l = 0$*, which means that the current is independent of the slope,*

$$I = \frac{mg}{2NL\mathcal{B}} \ .$$

The current is $I = 2.45\,\mathrm{A}$*.*

15.1.3.3 Ex: Magnetic field mass spectrometer

A spectrometer is used to separate doubly ionized uranium ions of mass $3.92\times10^{-25}\,\mathrm{kg}$ from other similar isotopes. The ions are first accelerated by a potential difference of

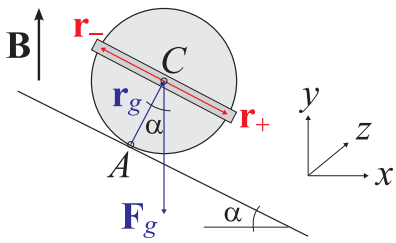

Figure 15.7: Lorentz force.

100 kV and then enter a homogeneous magnetic field, where they are deviated into a circular orbit of radius 1 m. After having covered an angle of 180°, they enter through a 1 mm wide and 1 cm high slit and are accumulated in a collector.
a. Determine the magnetic field of the mass spectrometer from the energy balance of the (individual) ions.
b. The device should be able to separate 100 mg of the desired ions per hour. What should be the intensity of the ionic flux in the beam?
c. What heat is produced in the collector in one hour?

Solution:

15.1.3.4 Ex: Mass spectrometer

In a mass spectrometer, a $^{24}Mg^{+}$ ion has a mass of $3.983 \cdot 10^{-26}$ kg and is accelerated by a potential difference of 2.5 kV. It then enters a region, where it is deflected by a magnetic field of 557 G.
Determine the radius of curvature of the orbits of the ion.
b. What is the difference between the radii of the orbits of the ions ^{26}Mg and ^{24}Mg? Consider a ratio between the masses of 26 : 24.

Solution: *a.* 63.3 cm.
b. 2.58 cm.

15.1.3.5 Ex: Magnetron

A magnetron consists of a diode tube, an anode shaped like a circular cylinder with radius $R_A =$ cm in the center of which the cathode filament is coaxially located. On the glass tube of this diode is a wound cylindrical coil whose axis coincides with the anode. The coil is long enough that the magnetic field along the cathode can be considered homogeneous. The electrons emitted from the cathode wire simultaneously are subject to the electric field between cathode and anode, $U = 1000$ V and the magnetic field $\mathcal{B} = 0.533 \cdot 10^{-2}$ T. The latter has been adjusted so that the electrons barely do not reach the anode. The whole apparatus is basically a velocity filter for electrons and thus a compact version of J.J. Thomson's e/m experiment (1987). From the equation of motion of an electron in the tube, determine the ratio e/m.

Solution:

15.1.3.6 Ex: Conductive copper strips

A copper strip of length $l = 2\,\text{cm}$, width $b = 1\,\text{cm}$, and thickness $d = 150\,\mu\text{m}$ lies within a homogeneous magnetic field $\vec{\mathcal{B}}$ of value $0.65\,\text{T}$, oriented perpendicular to the flat side of the strip. The concentration of free charges in copper is 8.47×10^{28} electrons/m^3. What is the potential difference V across the width of the tape, if it is traversed by a current of $I = 23\,\text{A}$?

Solution: *The Hall voltage is,*

$$U_{Hall} = bE_H = b\frac{1}{en}\frac{I}{bd}\mathcal{B} = \frac{1}{en}\frac{I}{d}\mathcal{B} \simeq 7.3\,\mu\text{V} \quad .$$

15.1.3.7 Ex: Lorentz force

A firm, horizontal, 25 cm long linear wire has a mass of 5 g and is connected to an emf-source via light and flexible wires. A magnetic field of 1.33 T is horizontal and perpendicular to the wire. Determine the current needed for the wire to float, that is, when the wire is released from rest, it remains at rest.

Solution: 1.5 A.

15.1.3.8 Ex: Lorentz force

A current carrying wire is bent in a closed semicircle of radius R in the xy-plane. The wire is inside a uniform magnetic field oriented in $+z$-direction, as shown in the figure. Verify that the force exerted on the ring is zero.

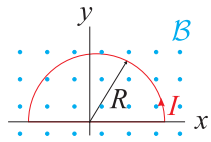

Figure 15.8: Lorentz force.

Solution:

15.1.3.9 Ex: Coulomb and Lorentz force

Two equal point charges are, at some instant of time, located at $(0,0,0)$ and $(0,b,0)$. Both are moving with velocity v in $+x$-direction (consider $v \ll c$). Determine the ratio between the magnitude of the magnetic force and the magnitude of the electric force at each charge.

Solution: *The first charge generates a magnetic field at the position of the second charge which, following the Biot-Savart law, is,*

$$\vec{\mathcal{B}}(\mathbf{b}) = \frac{\mu_0}{4\pi}\frac{q\mathbf{v}\times\mathbf{b}}{b^2} \ .$$

That is,

$$\mathcal{B} = \frac{\mu_0 qv}{4\pi b^2} \ .$$

This produces the Lorentz force,

$$F_L = qv\mathcal{B} = \frac{\mu_0 q^2 v^2}{4\pi b^2} \ .$$

The Coulomb force following Coulomb's law is,

$$F_C = \frac{1}{4\pi\varepsilon_0}\frac{q^2}{b^2} \ .$$

Hence,

$$\frac{F_L}{F_C} = \varepsilon_0\mu_0 c^2 \ .$$

15.1.3.10 Ex: Penning trap

In Penning traps, charged particles move under the influence of a homogeneous magnetic field $\vec{\mathcal{B}} = \mathcal{B}_h\hat{\mathbf{e}}_z$ and a quadrupolar electric field $\vec{\mathcal{E}} = \mathcal{E}_q(\rho\hat{\mathbf{e}}_\rho - 2z\hat{\mathbf{e}}_z)$. On which orbits do the particle move?
Help: Consider the axial and radial movements separately. For the radial motion consider two cases:
1. The influence of the electric field is negligible,
2. centripetal force is negligible.

Solution: *Lorentz force,*

$$\begin{aligned}\mathbf{F} &= Q\vec{\mathcal{E}} + Q\mathbf{v}\times\vec{\mathcal{B}} \\ &= Q\mathcal{E}_q(\rho\hat{\mathbf{e}}_\rho - 2z\hat{\mathbf{e}}_z) + Q\mathbf{v}\times\mathcal{B}_h\hat{\mathbf{e}}_z \\ &= Q\mathcal{E}_q\begin{pmatrix} x \\ y \\ 2z \end{pmatrix} + Q\mathcal{B}_h\begin{pmatrix} v_y \\ -v_x \\ 0 \ . \end{pmatrix}\end{aligned}$$

The linear restoring force in axial direction $F_z = -Q\mathcal{E}_q 2z$ *generates a harmonic oscillation,* $z = z_0 \cos\omega t + \frac{v_0}{\omega}\sin\omega t$ *with the oscillation frequency,*

$$\omega_h = \sqrt{\frac{q}{m} 2\mathcal{E}_q} \ .$$

For the radial motion, we get,

$$m\ddot{x} = Q\mathcal{E}_q x + Q\mathcal{B}_h v_y \qquad \textit{and} \qquad m\ddot{y} = Q\mathcal{E}_q y - Q\mathcal{B}_h v_x \ .$$

Despising the electric field,

$$m\ddot{x} = Q\mathcal{B}_h v_y \qquad \textit{and} \qquad m\ddot{y} = Q\mathcal{B}_h v_x \ .$$

Taking the square gives, $m\ddot{r} = Q\mathcal{B}_h v$ *resp.* $m\omega^2 r = Q\mathcal{B}_h \omega r$*. The particle rotates in the equatorial plane with the cyclotron frequency,*

$$\omega_c = \frac{Q\mathcal{B}_h}{m} \ .$$

Neglecting inertia,

$$0 = Q\mathcal{E}_q x + Q\mathcal{B}_h v_y \qquad \textit{and} \qquad 0 = Q\mathcal{E}_q y - Q\mathcal{B}_h v_x \ .$$

Taking the square gives, $\mathcal{E}_q r = \mathcal{B}_h v$ *resp.* $\mathcal{E}_q r = \mathcal{B}_h \omega r$*. The particle rotates in the equatorial plane with the magnetron frequency of,*

$$\omega_m = \sqrt{\frac{\mathcal{E}_q}{\mathcal{B}_h}} \ .$$

15.1.3.11 Ex: Magnetic trap near a current wire

An infinitely long conducting wire (radius R, axis in z-direction at position $x = y = 0$) carries the current I.
a. Calculate the magnetic field inside and outside the wire.
b. Now a homogeneous magnetic field is added, $\vec{\mathcal{B}}_{apl} = \mathcal{B}_0 \hat{\mathbf{e}}_x$. Calculate the absolute value of the total magnetic field $|\vec{\mathcal{B}}_{tot}|$ inside and outside of wire.
c. Where inside and outside the wire do appear points where $|\vec{\mathcal{B}}_{tot}|$ vanishes? What conditions for the parameters I, R, and $\mathcal{B}_0$ must be met for such points to exist?

Solution: *a. The magnetic field produced by the current is outside the wire,*

$$\vec{\mathcal{B}}_{fio} = \frac{\mu_0 I}{2\pi\rho}\hat{\mathbf{e}}_\phi = \frac{\mu_0 I}{2\pi\rho^2}\begin{pmatrix} -y \\ x \\ 0 \end{pmatrix}$$

and inside,

$$\vec{\mathcal{B}}_{fio} = \frac{\mu_0 I}{2\pi R^2}\rho\hat{\mathbf{e}}_\phi = \frac{\mu_0 I}{2\pi R^2}\begin{pmatrix} -y \\ x \\ 0 \end{pmatrix}$$

b. Total field is outside the wire,

$$|\vec{\mathcal{B}}_{tot}| = \left|\mathcal{B}_0\hat{\mathbf{e}}_x + \frac{\mu_0 I}{2\pi\rho}\hat{\mathbf{e}}_\phi\right| = \left|\left(\mathcal{B}_0 - \frac{\mu_0 I}{2\pi\rho^2}y\right)\hat{\mathbf{e}}_x + \frac{\mu_0 I}{2\pi\rho^2}x\hat{\mathbf{e}}_y\right| = \sqrt{\left(B_0 - \frac{\mu_0 I}{2\pi\rho^2}y\right)^2 + \left(\frac{\mu_0 I}{2\pi\rho^2}x\right)^2}\,.$$

and inside,

$$|\vec{\mathcal{B}}_{tot}| = \left|\mathcal{B}_0\hat{\mathbf{e}}_x + \frac{\mu_0 I}{2\pi R^2}\hat{\mathbf{e}}_\phi\right| = \left|\left(\mathcal{B}_0 - \frac{\mu_0 I}{2\pi R^2}y\right)\hat{\mathbf{e}}_x + \frac{\mu_0 I}{2\pi R^2}x\hat{\mathbf{e}}_y\right| = \sqrt{\left(\mathcal{B}_0 - \frac{\mu_0 I}{2\pi R^2}y\right)^2 + \left(\frac{\mu_0 I}{2\pi R^2}x\right)^2}\,.$$

c. The point outside the wire, where the absolute value vanishes, follows with,

$$\left(\mathcal{B}_0 - \frac{\mu_0 I}{2\pi\rho^2}y\right)^2 + \left(\frac{\mu_0 I}{2\pi\rho^2}x\right)^2 = 0$$

and is at,

$$x = 0 \qquad \textit{and} \qquad \rho = y = \frac{\mu_0 I}{2\pi\mathcal{B}_0}\ .$$

For such points to stay outside the wire, $\rho > R$, we need $\frac{\mu_0 I}{2\pi\mathcal{B}_0} > R$.
The point inside the wire, where the absolute value vanishes, follows with,

$$\left(\mathcal{B}_0 - \frac{\mu_0 I}{2\pi R^2}y\right)^2 + \left(\frac{\mu_0 I}{2\pi R^2}x\right)^2 = 0\ ,$$

and is at,

$$x = 0 \qquad \textit{and} \qquad \rho = y = \frac{2\pi\mathcal{B}_0 R^2}{\mu_0 I}\ .$$

For such points to stay inside the wire, $\rho < R$, we again need $\frac{\mu_0 I}{2\pi\mathcal{B}_0} > R$. That is, once the condition is met, the zero points appear in pairs outside and inside the wire.

15.1.3.12 Ex: Charge in homogeneous fields

A charge e moves in vacuum under the influence of homogeneous fields $\vec{\mathcal{E}}$ and $\vec{\mathcal{B}}$. Suppose that $\vec{\mathcal{E}}\cdot\vec{\mathcal{B}} = 0$ and $\mathbf{v}\cdot\vec{\mathcal{B}} = 0$. At what speed does the charge move without acceleration? What is the absolute value of its speed if $|\vec{\mathcal{E}}| = |\vec{\mathcal{B}}|$?

Solution: *By hypothesis, the electric field $\vec{\mathcal{E}}$ as well as the speed of the charge $\mathbf{v}$ are perpendicular to the magnetic induction. The total force on the charge is,*

$$\mathbf{F} = e\vec{\mathcal{E}} + \frac{e}{c}\mathbf{v}\times\vec{\mathcal{B}}\ .$$

Without acceleration, due to Newton's law, this force must disappear:

$$e\vec{\mathcal{E}} + \frac{e}{c}\mathbf{v} \times \vec{\mathcal{B}} = 0 \ .$$

But that means, that $\vec{\mathcal{E}}$ *and* $\mathbf{v} \times \vec{\mathcal{B}}$ *must be parallel. From this it follows that the velocity must also be perpendicular to the electric field. Since,*

$$\mathbf{v} \cdot \vec{\mathcal{E}} = \mathbf{v} \cdot \vec{\mathcal{B}} = 0 \ .$$

we can write,

$$\mathbf{v} = \lambda \vec{\mathcal{E}} \times \vec{\mathcal{B}} \ .$$

where λ *is a constant. Inserting into the force equation gives,*

$$e\vec{\mathcal{E}} + \frac{e}{c}\lambda(\vec{\mathcal{E}} \times \vec{\mathcal{B}}) \times \vec{\mathcal{B}} = 0 \ .$$

But now we have,

$$(\vec{\mathcal{E}} \times \vec{\mathcal{B}}) \times \vec{\mathcal{B}} = \vec{\mathcal{B}}(\vec{\mathcal{E}} \cdot \vec{\mathcal{B}}) - \vec{\mathcal{E}}(\vec{\mathcal{B}} \cdot \vec{\mathcal{B}}) \ .$$

Since $\vec{\mathcal{E}} \cdot \vec{\mathcal{B}} = 0$ *by hypotheses, immediately follows,*

$$e\vec{\mathcal{E}} - \frac{e}{c}\lambda \mathcal{B}^2 \vec{\mathcal{E}} = 0 \ .$$

where we introduced $\mathcal{B} \equiv |\vec{\mathcal{B}}|$*. With this relationship follows,*

$$\lambda = \frac{c}{\mathcal{B}^2} \ .$$

resp.

$$\mathbf{v} = \frac{c}{\mathcal{B}^2}\vec{\mathcal{E}} \times \vec{\mathcal{B}} \ .$$

For $|\vec{\mathcal{E}}| = |\vec{\mathcal{B}}|$ *we obtain* ($\vec{\mathcal{E}} \cdot \vec{\mathcal{B}} = 0$) $|\vec{\mathcal{E}} \times \vec{\mathcal{B}}| = \mathcal{B}^2$*, and therefore for this particular case,*

$$|\mathbf{v}| = c \ .$$

15.1.3.13 Ex: Rain accelerated by the Earth's magnetic field

Analyze the following train propulsion concept. The train shall be propelled by the magnetic force of the vertical component of the Earth's magnetic field acting on the current-carrying axes of the train. The value of the vertical component of the Earth's magnetic field is 10 μT, the axes have a length of 3 m. The current is fed by the rails and flows from one rail through the conducting wheels and axles to the other rail.
a. What must be the amplitude of the current to generate the modest force of 10 kN on an axis?
b. What is the rate of electric energy loss due to heat production?

Solution: *a. Lorentz's force is* $\mathbf{F} = I\mathbf{l} \times \vec{\mathcal{B}}$*. Therefore, the required current is,*

$$I = \frac{F}{lB} = 333 \cdot 10^6 \,\mathrm{A} \ .$$

b. ???

15.1.3.14 Ex: Biot-Savart law

We consider an infinitely long and thin wire oriented along the z-axis and concentrically embraced by a hollow conductor with radius R and negligible wall thickness. Through the conductor flows the current I_0 and through the wire the current I_1.
a. Calculate based on the Biot-Savart law the magnetic field produced by the inner wire at a distance d from the z-axis.
b. Calculate the force exerted by the magnetic field of the inner wire on a surface element of the current conductor.
c. What is the resulting pressure with $I_1 = -I_0 = 10$ A, $R = 1$ mm?
Help:

$$\int_a^b (c^2 + x^2)^{-\frac{3}{2}} dx = \left[\frac{x}{c^2}(c^2 + x^2)^{-\frac{1}{2}}\right]_a^b$$

Solution: *a. Magnetic field*

$$\vec{\mathcal{B}}(\mathbf{r}) = \frac{\mu_0 I_1}{4\pi} \int_{-\infty}^{\infty} dz' \frac{\hat{\mathbf{e}}_z \times (\mathbf{r} - \mathbf{r}')}{|\mathbf{r} - \mathbf{r}'|^3} \ .$$

With $\mathbf{r} = \mathbf{d} + z\hat{\mathbf{e}}_z$ *and* $\vec{r'} = z'\hat{\mathbf{e}}_z$

$$\begin{aligned}
\vec{\mathcal{B}}(\mathbf{r}) &= \frac{\mu_0 I_1}{4\pi} \hat{\mathbf{e}}_z \times \mathbf{d} \int_{-\infty}^{\infty} dz' (\mathbf{d}^2 + (z - z')^2)^{-3/2} \\
&= \frac{\mu_0 I_1}{4\pi} \hat{\mathbf{e}}_z \times \mathbf{d} \left[\frac{z'}{d^2}(d^2 + z'^2)^{-\frac{1}{2}}\right]_{-\infty}^{\infty} \\
&= \frac{\mu_0 I_1}{4\pi} \hat{\mathbf{e}}_z \times \mathbf{d} \frac{2}{d^2} = \frac{\mu_0 I_1}{2\pi d} \hat{\mathbf{e}}_\phi \ .
\end{aligned}$$

b. Force

$$\begin{aligned}
d\mathbf{F} &= dI_0 dl \hat{\mathbf{e}}_z \times \vec{\mathcal{B}} = -\frac{I_0 d\phi}{2\pi} dl \frac{\mu_0 I_1}{2\pi R} \hat{\mathbf{e}}_\rho \\
&= -\frac{\mu_0 I_0 I_1}{(2\pi R)^2} d\mathbf{S} \ .
\end{aligned}$$

c. Pressure

$$P = \frac{dF}{dA} = -\frac{\mu_0 I_0 I_1}{(2\pi R)^2} \approx 3.183\,\text{Pa} \ .$$

15.1.3.15 Ex: Biot-Savart law

We consider an infinitely long hollow conductor running along the z-axis with finite wall thickness with inner radius $R - \epsilon$ and outer radius $R + \epsilon$. The current density j_0 within the hollow conductor is constant and the total current is I_0.
a. Calculate j_0 from I_0, ϵ, and R.

b. Calculate, based on Ampere's law, the magnetic field produced by the hollow conductor at a distance ρ from the z-axis for $R-\epsilon<\rho<R+\epsilon$.
c. Calculate the resulting force on a volume element of the current-carrying conductor.
d. Integrate the radial force and calculate the limit $\epsilon \to 0$.
e. What is the resulting pressure in $I_0 = 10$ A, $R = 1$ mm? Does the force act inward or outward?

Solution: *a. Current density,*

$$I_0 = j_0\pi[(R+\epsilon)^2-(R-\epsilon)^2] = 4\pi R\epsilon j_0$$
$$j_0 = \frac{I_0}{4\pi R\epsilon}\ .$$

b. Total current within a cylinder of radius ρ,

$$I(\rho) = \pi\left(\rho^2-(R-\epsilon)^2\right)j_0\ .$$

With Ampere's law and making use of the axial symmetry follows for the magnetic field,

$$\vec{\mathcal{B}}(\rho) = \frac{\mu_0}{2\pi\rho}I(\rho)\hat{\mathbf{e}}_\phi = \frac{\mu_0 j_0}{2\rho}\left(\rho^2-(R-\epsilon)^2\right)\hat{\mathbf{e}}_\phi\ .$$

c. Force on the volume element,

$$\begin{aligned} d\vec{F} &= j_0\rho\, d\phi\, d\rho\, dz\, \hat{\mathbf{e}}_z\times\vec{\mathcal{B}}(\rho)\\ &= j_0\rho\, d\phi\, d\rho\, dz\, \hat{\mathbf{e}}_z\times\hat{\mathbf{e}}_\phi\frac{\mu_0 j_0}{2\rho}\left(\rho^2-(R-\epsilon)^2\right)\\ &= -\frac{j_0^2\mu_0}{2}\, d\phi\, d\rho\, dz\, \hat{\mathbf{e}}_\rho\left(\rho^2-(R-\epsilon)^2\right)\ . \end{aligned}$$

d. Integrated force,

$$\int_{R-\epsilon}^{R+\epsilon}(\rho^2-(R-\epsilon)^2)d\rho = \left[\frac{1}{3}\rho^3-\rho(R-\epsilon)^2\right]_{R-\epsilon}^{R+\epsilon}$$
$$= 4R\epsilon^2-\frac{4}{3}\epsilon^3\to 4R\epsilon^2\ .$$

The radially integrated force on a surface element in the limes $\epsilon\to 0$ is,

$$d\vec{F}_A = -2j_0^2\mu_0 R\epsilon^2\, d\phi\, dz\, \hat{\mathbf{e}}_\rho = -2j_0^2\mu_0\epsilon^2 d\mathbf{S} = -\frac{\mu_0 I_0^2}{8\pi^2R^2}d\mathbf{S}\ .$$

e. Pressure,

$$P = -\frac{\mu_0 I_0^2}{8\pi^2R^2}\approx -1.592\,\text{Pa}\ .$$

The force acts inwards, because currents following the same direction attract each other.

15.1.3.16 Ex: Magnetic field of the Earth

The Earth's magnetic field is approximately 0.6 G at the magnetic poles and points vertically downwards at the magnetic pole of the northern hemisphere. If the magnetic field were due to an electric current circulating on a ring with a radius equal to Earth's inner iron core (approximately 1300 km),
a. what would be the required amplitude of the current?
b. What orientation would the current need to have, the same as Earth's rotational motion or the opposite? Justify.

Solution: *a.* 15.5 GA
b. As the Earth's magnetic field points downward at the north pole, the application of the right-hand rule tells us that the current is opposite to the Earth's rotation.

15.1.3.17 Ex: Biot-Savart law

Consider the following device: A current I runs through two identical infinitely thin rings with radius R. The common center of the two rings is at the origin of the coordinates. One ring lies in the xy-plane and the other on the xz-plane.
a. Parametrize the current density $\mathbf{j}$ in spherical coordinates.
b. Show that the $\vec{\mathcal{B}}$ field resulting from this device at source is given by:

$$\vec{\mathcal{B}}(\mathbf{0}) = -\frac{\mu_0 I}{2}\frac{1}{R}\hat{\mathbf{e}}_z - \frac{\mu_0 I}{2}\frac{1}{R}\hat{\mathbf{e}}_y \ .$$

Help: A δ-function in spherical coordinates for the r variable must be multiplied by $\frac{1}{r}$; a δ-function in spherical coordinates for the ϕ variable must be multiplied by $\frac{\pi}{2}$.

Solution: *a. Current density in spherical coordinates:*

$$\mathbf{j} = I\left[\tfrac{1}{r}\delta(r-R)\delta(\theta-\tfrac{\pi}{2})\hat{\mathbf{e}}_\phi + \tfrac{1}{r}\delta(r-R)\frac{\pi}{2}\delta(\phi)\hat{\mathbf{e}}_\phi - \tfrac{1}{r}\delta(r-R)\tfrac{\pi}{2}\delta(\phi-\pi)\hat{\mathbf{e}}_\phi\right] \ .$$

b. Following the law of Biot-Savart:

$$
\begin{aligned}
\vec{\mathcal{B}}(\mathbf{r}) &= \frac{\mu_0}{4\pi}\int_{V'} \nabla \times \frac{\mathbf{j}(\mathbf{r}')}{|\mathbf{r}-\mathbf{r}'|}dV' = \frac{\mu_0}{4\pi}\int_{V'} \frac{(\mathbf{r}-\mathbf{r}')\times \mathbf{j}(\mathbf{r}')}{|\mathbf{r}-\mathbf{r}'|^3}dV' \\
&= \frac{\mu_0}{4\pi}\left[\int_{V'} dV' \frac{\pi}{2}\frac{1}{r'}\delta(r'-R)\delta(\theta'-\tfrac{\pi}{2})\frac{(\mathbf{r}-\mathbf{r}')\times \hat{\mathbf{e}}_\phi}{|\mathbf{r}-\mathbf{r}'|^3} + \int_{V'} dV' \frac{\pi}{2}\frac{1}{r'}\delta(r'-R)\delta(\phi')\frac{(\mathbf{r}-\mathbf{r}')\times \hat{\mathbf{e}}_\theta}{|\mathbf{r}-\mathbf{r}'|^3}\right. \\
&\quad \left. - \int_{V'} dV' \frac{\pi}{2}\frac{1}{r'}\delta(r'-R)\delta(\phi'-\pi)\frac{(\mathbf{r}-\mathbf{r}')\times \hat{\mathbf{e}}_\theta}{|\mathbf{r}-\mathbf{r}'|^3}\right] \\
&= \frac{\mu_0}{4\pi}\left[\int_{V'} dV' \frac{1}{r'}\delta(r'-R)\delta(\theta'-\tfrac{\pi}{2})\frac{\left[\begin{pmatrix}0\\0\\0\end{pmatrix} - \begin{pmatrix}r'\sin\theta'\cos\phi'\\ r'\sin\theta'\sin\phi'\\ r'\cos\theta'\end{pmatrix}\right]\times\begin{pmatrix}-\sin\phi'\\ \cos\phi'\\ 0\end{pmatrix}}{\left|\begin{pmatrix}0\\0\\0\end{pmatrix} - \begin{pmatrix}r'\sin\theta'\cos\phi'\\ r'\sin\theta'\sin\phi'\\ r'\cos\theta'\end{pmatrix}\right|^3}\right. \\
&\quad + \int_{V'} dV' \frac{\pi}{2}\frac{1}{r'}\delta(r'-R)\delta(\phi')\frac{\left[\begin{pmatrix}0\\0\\0\end{pmatrix} - \begin{pmatrix}r'\sin\theta'\cos\phi'\\ r'\sin\theta'\sin\phi'\\ r'\cos\theta'\end{pmatrix}\right]\times\begin{pmatrix}\cos\theta'\cos\phi'\\ \cos\theta'\sin\phi'\\ -\sin\theta'\end{pmatrix}}{\left|\begin{pmatrix}0\\0\\0\end{pmatrix} - \begin{pmatrix}r'\sin\theta'\cos\phi'\\ r'\sin\theta'\sin\phi'\\ r'\cos\theta'\end{pmatrix}\right|^3} \\
&\quad \left. - \int_{V'} dV' \frac{\pi}{2}\frac{1}{r'}\delta(r'-R)\delta(\phi'-\pi)\frac{\left[\begin{pmatrix}0\\0\\0\end{pmatrix} - \begin{pmatrix}r'\sin\theta'\cos\phi'\\ r'\sin\theta'\sin\phi'\\ r'\cos\theta'\end{pmatrix}\right]\times\begin{pmatrix}\cos\theta'\cos\phi'\\ \cos\theta'\sin\phi'\\ -\sin\theta'\end{pmatrix}}{\left|\begin{pmatrix}0\\0\\0\end{pmatrix} - \begin{pmatrix}r'\sin\theta'\cos\phi'\\ r'\sin\theta'\sin\phi'\\ r'\cos\theta'\end{pmatrix}\right|^3}\right] .
\end{aligned}
$$

In the next step we transform the volume element into spherical coordinates and evaluate the δ-function:

$$\begin{aligned}
\vec{\mathcal{B}}(\mathbf{r}) &= \frac{\mu_0}{4\pi}\Big[\int_0^{2\pi} R^2 \sin\left(\theta' = \frac{\pi}{2}\right)\frac{1}{R}d\phi' \frac{\begin{pmatrix}-R\cos\phi'\\-R\sin\phi'\\0\end{pmatrix}\times\begin{pmatrix}-\sin\phi'\\\cos\phi'\\0\end{pmatrix}}{\left[\sqrt{R^2\cos\phi'+R^2\sin\phi'}\right]^3} + \int_0^{\pi} R^2\sin(\theta')\frac{\pi}{2}\frac{1}{R}d\theta' \frac{\begin{pmatrix}-R\sin\theta'\\0\\-R\cos\theta'\end{pmatrix}\times\begin{pmatrix}\cos\theta'\\0\\-\sin\theta'\end{pmatrix}}{\left[\sqrt{R^2\cos\theta'+R^2\sin\theta'}\right]^3} \\
&\quad - \int_0^{\pi} R^2\sin(\theta')\frac{\pi}{2}\frac{1}{R}d\theta' \frac{\begin{pmatrix}+R\sin\theta'\\0\\-R\cos\theta'\end{pmatrix}\times\begin{pmatrix}-\cos\theta'\\0\\-\sin\theta'\end{pmatrix}}{\left[\sqrt{R^2\cos\theta'+R^2\sin\theta'}\right]^3}\Big] \\
&= \frac{\mu_0}{4\pi}R\Big[\int_0^{2\pi} d\phi' \frac{\begin{pmatrix}0\\0\\-R\cos^2\phi'-R\sin^2\phi'\end{pmatrix}}{R^3} + \int_0^{\pi}\frac{\pi}{2}d\phi' \frac{\begin{pmatrix}0\\-R\cos^2\theta'-R\sin^2\theta'\\0\end{pmatrix}}{R^3} - \int_0^{\pi}\frac{\pi}{2}d\phi' \frac{\begin{pmatrix}0\\+R\cos^2\theta'+R\sin^2\theta'\\0\end{pmatrix}}{R^3}\Big] \\
&= \frac{\mu_0}{4\pi}R\Big[2\pi\frac{R}{R^3}(-\hat{\mathbf{e}}_z) + 2\frac{\pi}{2}\frac{R}{R^3}(-\hat{\mathbf{e}}_y) - 2\frac{\pi}{2}\frac{R}{R^3}(\hat{\mathbf{e}}_y)\Big] .
\end{aligned}$$

15.2 Properties of the magnetic field

15.2.1 Field lines and magnetic flux

The *magnetic flux* is introduced in the same way as the electric flux,

$$\boxed{\Psi_M \equiv \int_{\mathcal{S}} \vec{\mathcal{B}}\cdot d\mathbf{S}} \; . \tag{15.12}$$

Resolve the Exc. 15.2.4.1.

15.2.2 Divergence of the magnetic field and Gauß's law

Let us compute the divergence of a magnetic field given by Biot-Savart's law [2],

$$\nabla_r\cdot\vec{\mathcal{B}} = \frac{\mu_0}{4\pi}\int_{\mathcal{V}}[\nabla_r\times\mathbf{j}(\mathbf{r}')]\cdot\frac{\mathbf{r}-\mathbf{r}'}{|\mathbf{r}-\mathbf{r}'|^3}dV' - \frac{\mu_0}{4\pi}\int_{\mathcal{V}}\mathbf{j}(\mathbf{r}')\cdot\left[\nabla_r\times\frac{\mathbf{r}-\mathbf{r}'}{|\mathbf{r}-\mathbf{r}'|^3}\right]dV' = 0 \; , \tag{15.13}$$

since, as we have already shown, the rotation of a Coulombian field is zero. Therefore,

$$\boxed{\nabla\cdot\vec{\mathcal{B}} = 0} \; . \tag{15.14}$$

With Gauß' law we can derive the integral version of this statement,

$$\boxed{\oint_{\partial\mathcal{V}}\vec{\mathcal{B}}\cdot d\mathbf{S} = 0} \; . \tag{15.15}$$

Comparing this equation with the corresponding electrostatic equation (13.13), we deduce the following interpretation: The total magnetic flux Ψ_M across a closed surface

[2] Using the rule $\nabla\cdot(\vec{\mathcal{E}}\times\vec{\mathcal{B}}) = (\nabla\times\vec{\mathcal{E}})\cdot\vec{\mathcal{B}} - \vec{\mathcal{E}}\cdot(\nabla\times\vec{\mathcal{B}})$.

must vanish and can not be changed by *hypothetical magnetic charges*, i.e. *magnetic charges do not exist*!

A direct consequence of this law is that we can introduce the concept of the vector potential, which is fundamental in the sense that it allows us to formulate electrodynamics completely in terms of potentials. We will dedicate the whole next section to magnetic potentials.

15.2.3 Rotation of the magnetic field and Ampère's law

Let us now calculate the rotation of the magnetic field given by Biot-Savart's law [3],

$$\nabla_r \times \vec{\mathcal{B}} = \frac{\mu_0}{4\pi}\int_{\mathcal{V}} -[\mathbf{j}(\mathbf{r}')\cdot\nabla_r]\frac{\mathbf{r}-\mathbf{r}'}{|\mathbf{r}-\mathbf{r}'|^3}dV' + \frac{\mu_0}{4\pi}\int_{\mathcal{V}}\mathbf{j}(\mathbf{r}')\left(\nabla_r\cdot\frac{\mathbf{r}-\mathbf{r}'}{|\mathbf{r}-\mathbf{r}'|^3}\right)dV' \tag{15.16}$$

$$= \frac{\mu_0}{4\pi}\int_{\mathcal{V}}[\mathbf{j}(\mathbf{r}')\cdot\nabla_{r'}]\frac{\mathbf{r}-\mathbf{r}'}{|\mathbf{r}-\mathbf{r}'|^3}dV' + \frac{\mu_0}{4\pi}\int_{\mathcal{V}}\mathbf{j}(\mathbf{r}')4\pi\delta(\mathbf{r}-\mathbf{r}')dV'$$

$$= \frac{\mu_0}{4\pi}\int_{\mathcal{V}}[\mathbf{j}(\mathbf{r}')\cdot\nabla_{r'}]\frac{\mathbf{r}-\mathbf{r}'}{|\mathbf{r}-\mathbf{r}'|^3}dV' + \mu_0\mathbf{j}(\mathbf{r})\ . \tag{15.17}$$

Considering the x-component,

$$(\nabla_r\times\vec{\mathcal{B}})_x = \frac{\mu_0}{4\pi}\int_{\mathcal{V}}\mathbf{j}(\mathbf{r}')\cdot\nabla_{r'}\frac{x-x'}{|\mathbf{r}-\mathbf{r}'|^3} + \mu_0 j_x(\mathbf{r})$$

$$= -\frac{\mu_0}{4\pi}\oint_{\partial\mathcal{V}}\mathbf{j}(\mathbf{r}')\frac{x-x'}{|\mathbf{r}-\mathbf{r}'|^3}d\mathbf{S}' + \frac{\mu_0}{4\pi}\int_{\mathcal{V}}\frac{x-x'}{|\mathbf{r}-\mathbf{r}'|^3}\nabla_{r'}\cdot\mathbf{j}(\mathbf{r}')dV' + \mu_0 j_x(\mathbf{r})\ .$$

The surface integral vanishes when the volume goes to infinity. On the other hand, $\nabla\cdot\mathbf{j} = -\dot{\varrho} = 0$. With this, we obtain,

$$\boxed{\nabla\times\vec{\mathcal{B}} = \mu_0\mathbf{j}}\ . \tag{15.18}$$

The results (15.14) and (15.18) represent parts of Maxwell's first and fourth equations. The equation (15.18) is also called *Ampère's law*. The integral version can be obtained from Stokes' law,

$$\boxed{\oint_{\mathcal{C}}\vec{\mathcal{B}}\cdot d\mathbf{l} = \mu_0 I}\ . \tag{15.19}$$

The interpretation of Ampere's law is, that *every current produces a rotational magnetic field*, that is, a field with closed field lines. Measuring the magnetic field along an closed path we can evaluate the current passing through the surface delimited by the path.

Ampère's law has many applications. Let's discuss some in the next.

Example 70 (*Magnetic field of a straight current-carrying wire*): Let us re-evaluate the example 68 using Ampere's law,

$$\oint\vec{\mathcal{B}}\cdot d\mathbf{l} = B\int_0^{2\pi}\rho d\phi = \mathcal{B}2\pi\rho = \mu_0 I\ .$$

[3] Using the rule $\nabla\times(\vec{\mathcal{E}}\times\vec{\mathcal{B}}) = (\vec{\mathcal{B}}\cdot\nabla)\vec{\mathcal{E}} - (\vec{\mathcal{E}}\cdot\nabla)\vec{\mathcal{B}} + \vec{\mathcal{E}}(\nabla\cdot\vec{\mathcal{B}}) - \vec{\mathcal{B}}(\nabla\cdot\vec{\mathcal{E}})$.

Hence,

$$\mathcal{B} = \frac{\mu_0 I}{2\pi\rho} \ .$$

Example 71 (*Ampère's law*): We can use Ampère's law to show that a locally uniform magnetic field, such as the one shown in Fig. 15.9, is impossible. Let us have a look at the rectangular curve shown by the dashed lines. With the chosen geometry, the curve does not include current,

$$\mu_0 I = 0 \ .$$

On the other hand, the magnetic field accumulated along the curve is,

$$\oint_C \vec{\mathcal{B}} \cdot d\mathbf{l} \neq 0 \ .$$

This is a contradiction. Thus, this example shows that, in the absence of currents, any magnetic field is conservative. We could then define a scalar potential whose gradient would be the magnetic field, but this potential must be *simply connected*, i.e. not be traversed by currents, which limits the practical use of such a potential.

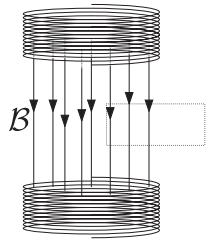

Figure 15.9: Impossibility of a localized homogeneous magnetic field.

Example 72 (*Field of a solenoid*): A solenoid is a very long coil (the distance between two consecutive turns is much smaller than the radius and the total length l of the coil) carrying a current I (see diagram in Fig. 15.10). Ampère's law can be used to easily calculate the magnetic field inside a solenoid composed of N turns,

$$\mathcal{B}dl = \oint_C \vec{\mathcal{B}} \cdot d\mathbf{r} = \mu_0 I \ dN \ .$$

Hence,

$$\mathcal{B} = \mu_0 I \frac{dN}{dl} \ .$$

Resolve the Excs. 15.2.4.2 to 15.2.4.9. In the Excs. 15.2.4.10 to 15.2.4.12 we apply the Biot-Savart law to *Helmholtz coils* and *anti- Helmholtz coils*.

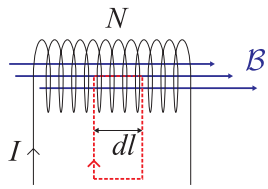

Figure 15.10: Scheme of a solenoid with loop density dN/dl.

15.2.4 Exercises

15.2.4.1 Ex: Magnetic flux

A long solenoid has n turns per unit length, radius R_1, and carries a current I. A circular coil with radius R_2 and N turns is coaxial to the solenoid and is equidistant from its ends.
a. Determine the magnetic flux through the coil if $R_2 < R_1$.
b. Determine the magnetic flux through the coil if $R_2 > R_1$.

Solution: *a.* $\phi_m = \mu_0 n I N \pi R_1^2$.
b. $\phi_m = \mu_0 n I N \pi R_2^2$.

15.2.4.2 Ex: Magnetic field of a conducting ring and Ampère's law

A ring-shaped conducting loop lies in the yz-plane; the loop's symmetry axis is the x-axis. It is traversed by a current I generating on the axis the field $\mathcal{B}_x = \frac{1}{2}\mu_0 I R^2 (x^2+R^2)^{-3/2}$.
a. Calculate the line integral $\int \vec{\mathcal{B}} \cdot d\mathbf{s}$ along the x-axis between $x = -L$ and $x = +L$.
b. Show that for $L \to \infty$ the line integral converges to $\mu_0 I$.
Help: This result can also be obtained with Ampère's law, when we close the integration path through a semicircle with radius L, for which holds $\mathcal{B} \simeq 0$, when L is very large.

Solution: *The line integral is,*

$$\int \vec{\mathcal{B}} \cdot d\mathbf{s} = \frac{\mu_0 I}{2} \int_{-L}^{L} \frac{R^2 \hat{\mathbf{e}}_x}{(x^2+R^2)^{3/2}} \cdot d\mathbf{s} = \frac{\mu_0 I}{2} \int_{-L}^{L} \frac{R^2}{(x^2+R^2)^{3/2}} dx$$
$$= \frac{\mu_0 I}{2} \frac{x}{\sqrt{(x^2+R^2)}}\Bigg|_{-L}^{L} = \frac{\mu_0 I}{2} \frac{2L}{\sqrt{L^2+R^2}} \ .$$

For large distances L,

$$\int \vec{\mathcal{B}} \cdot d\mathbf{s} \longrightarrow \mu_0 I \ .$$

For very large L we can close the integration path,

$$\lim_{L\to\infty} \int \vec{\mathcal{B}} \cdot d\mathbf{s} \simeq \oint \vec{\mathcal{B}} \cdot d\mathbf{s} = \mu_0 I \ ,$$

and obtain Ampere's law.

15.2.4.3 Ex: Biot-Savart's and Ampère's laws

a. Calculate the magnetic field generated by a constant current I on a straight conductor piece of length L.
b. Show that for an infinitely long conductor the Biot-Savart law becomes Ampere's law.

Solution: *a. Following the Biot-Savart,*

$$\vec{\mathcal{B}}(\mathbf{r}) = \frac{\mu_0}{4\pi}\int_{V'}\frac{(\mathbf{r}-\mathbf{r}')\times\mathbf{j}(\mathbf{r}')}{|\mathbf{r}-\mathbf{r}'|^3}d^3\mathbf{r}' \ .$$

With the current wire $\mathbf{j}(\mathbf{r}) = I\hat{\mathbf{e}}_z\delta(x)\delta(y)\theta(-L/2<z<L/2)$ *follows,*

$$\vec{\mathcal{B}}(\mathbf{r}) = \frac{\mu_0 I}{4\pi}(y\hat{\mathbf{e}}_x - x\hat{\mathbf{e}}_y)\int\frac{1}{\sqrt{\rho^2+(z-z')^2}^3}dz' = \frac{\mu_0 I}{4\pi}(y\hat{\mathbf{e}}_x - x\hat{\mathbf{e}}_y)\left.\frac{z'-z}{\rho^2\sqrt{\rho^2+(z-z')^2}}\right|_{-L/2}^{L/2}$$

$$= \frac{\mu_0 I}{4\pi}\frac{y\hat{\mathbf{e}}_x - x\hat{\mathbf{e}}_y}{\rho^2}\left[\frac{L/2-z}{\sqrt{\rho^2+(z-L/2)^2}} + \frac{L/2+z}{\sqrt{\rho^2+(z+L/2)^2}}\right] \ .$$

For long conductor pieces $L\to\infty$,

$$\vec{\mathcal{B}}(\mathbf{r}) \longrightarrow \frac{\mu_0 I}{2\pi}\frac{y\hat{\mathbf{e}}_x - x\hat{\mathbf{e}}_y}{\rho^2} \ .$$

The absolute value is now, $|\vec{\mathcal{B}}(\mathbf{r})| = \frac{\mu_0 I}{2\pi\rho}$. *The magnetic field follows as rotation from the potential vector,* $\vec{\mathcal{B}}(\mathbf{r}) = \nabla\times\mathbf{A}(\mathbf{r}) = \nabla\times\frac{-\mu_0 I}{4\pi}\frac{\hat{\mathbf{e}}_z}{\rho^2}$.

15.2.4.4 Ex: Solenoid

a. To determine the number of turns of a solenoid with diameter $D = 4\,\mathrm{cm}$ and length $L = 10\,\mathrm{cm}$, an experimenter passes a current $I = 1\,\mathrm{A}$ through the coil. He measures the magnetic field $\mathcal{B} = 10\,\mathrm{mT}$. How many windings are there?
b. To confirm it measures the diameter of the copper wire ($d = 1\,\mathrm{mm}$) and ohmic resistance finding $R = 2\,\Omega$. On the internet he finds the resistivity of copper $\rho = 1.7\cdot 10^{-8}\,\Omega\mathrm{m}$.

Solution: *a. The field is*

$$\mathcal{B}(\rho) = \mu_0\frac{N}{L}I \ .$$

Hence, $N = 796$.
b. The resistance is,

$$R = \rho\frac{L}{A} = \rho\frac{N2\pi(D/2)}{\pi(d/2)^2} = 2\ \Omega \ .$$

Hence, $N = 735$.

15.2.4.5 Ex: Toroidal coil

A coil with N turns is arranged in a toroidal form with rotational symmetry around z-axis and has its center at the origin of the coordinates. The coil is densely wound and traversed by a current I (see scheme).
a. Calculate the $\hat{\mathbf{e}}_\phi$-component of the $\vec{\mathcal{B}}$-field for $z = 0$ (xy-plane) as a function of distance ρ from the origin.
b. Determine the $\hat{\mathbf{e}}_\phi$-component of the $\vec{\mathcal{B}}$-field in the entire *inner* space outside the toroid. Draw the $\hat{\mathbf{e}}_\phi$ component as a function of ρ.
c. What should be the value of b, so that $\mathcal{B}_\phi$ is constant within the toroid with an accuracy of $\alpha = 1\%$, when $a = 1\,\text{cm}$? [That is: $\mathcal{B}_\phi(b-a) - \mathcal{B}_\phi(b+a) < \alpha \cdot \mathcal{B}_\phi(b)$]

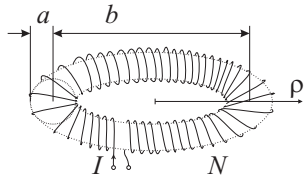

Figure 15.11: Toroidal coil.

Solution: *a. Following Stokes' law:*

$$\oint_C \vec{\mathcal{B}} d\mathbf{s} = N\mu_0 \int \mathbf{j}(\mathbf{r}) d\mathbf{f}$$
$$\mathcal{B}_\phi 2\pi\rho = N\mu_0 I$$
$$\Rightarrow B_\phi = \frac{N\mu_0 I}{2\pi\rho} \qquad para \qquad (b-a) \le \rho \le (b+a)\ ,$$

where the path C is chosen on a circle around the symmetry axis.
b. Outside the torus we have $\mathcal{B}_\phi = 0$ in the entire space. Scheme of the $\mathcal{B}_\phi$-component: $\frac{1}{\rho}$: hyperbolic cut between $b-a$ and $b+a$.
c. $a = 0.01$ m and we need: $\mathcal{B}_\phi(b-a) - \mathcal{B}_\phi(b+a) < \alpha\mathcal{B}_\phi(b)$, hence,

$$\frac{N\mu_0 I}{2\pi}\left(\frac{1}{b-a} - \frac{1}{b+a}\right) < 0.01\frac{N\mu_0 I}{2\pi}\frac{1}{b}$$
$$\frac{1}{b-a} - \frac{1}{b+a} < \alpha\frac{1}{b}$$
$$\Rightarrow 0 < b^2 - \frac{2ab}{\alpha} - a^2$$
$$\Rightarrow b > 200.005\,\text{cm}\ .$$

15.2.4.6 Ex: Toroidal coil

A toroidal coil tightly wound with 1000 turns has an inner radius of 1.0 cm, an outer radius of 2.0 cm, carries a current of 1.5 A. The torus is centered at the origin with

the centers of the individual turns in the $z = 0$ plane. What is the intensity of the magnetic field in the $z = 0$ plane a distance of (a) 1.1 cm and (b) 1.5 cm away from the origin?

Solution: *a.* $\mathcal{B}(1.1\,\mathrm{cm}) = 27.3\,\mathrm{mT}$.
b. $\mathcal{B}(1.5\,\mathrm{cm}) = 20.0\,\mathrm{mT}$

15.2.4.7 Ex: Inhomogeneous current density

The current density on a straight wire of infinite length with the radius R grows linearly from the center outward, $\mathbf{j}(r) = j_0 r\hat{\mathbf{e}}_z$, where $\hat{\mathbf{e}}_z$ shows in the direction of the wire and the total current going through the wire is I.
a. Calculate j_0 as a function of I.
b. Calculate, using Ampere's law, the magnetic field inside and outside the wire.
c. Make a graph of the normalized magnetic field, $\mathcal{B}(r)/\mathcal{B}_R$, versus r/R, where $\mathcal{B}_R \equiv \mu_0 I/2\pi R$.

Solution: *a. The integral of the current density over the surface shall give the total current:*

$$\int_0^{2\pi} r d\phi \int_0^R j_0 r dr = \frac{2\pi}{3} j_0 R^3 = I \ .$$

Hence, $j_0 = \frac{3}{2\pi}\frac{I}{R^3}$.
b. Using Ampère's law we calculate for $r < R$*:*

$$\oint \vec{\mathcal{B}} d\mathbf{l} = 2\pi r \mathcal{B}(r) = \mu_0 \int \mathbf{j} \cdot d\mathbf{S}$$
$$= \mu_0 \frac{3}{2\pi}\frac{I}{R^3} \int_0^{2\pi} r' d\phi \int_0^r r' dr = \mu_0 \frac{3}{2\pi}\frac{I}{R^3} 2\pi \frac{r^3}{3} = \mu_0 I \frac{r^3}{R^3} \ .$$

Hence,

$$\mathcal{B}(r) = \frac{\mu_0}{2\pi} I \frac{r^2}{R^3} \ .$$

In the case $r > R$*, we find again* $\mathcal{B}(r) = \frac{\mu_0}{2\pi}\frac{I}{r}$.
c. The normalized magnetic field starts growing quadratically up to the edge of the conductor, $\frac{\mathcal{B}(r)}{\mathcal{B}_R} = \frac{r^2}{R^2}$*, where it adopts the value* 1*. Then it falls off like,* $\frac{\mathcal{B}(r)}{\mathcal{B}_R} = \frac{R}{r}$.

15.2.4.8 Ex: Magnetic field in a coaxial cable

A coaxial cable consists of an inner conductor with radius R_1 and a cylindrical outer conductor with inner radius R_2 and outer radius R_3. In both conductors flows the same current I in opposite directions. The current densities in each conductor are homogeneous.
a. Calculate the current densities in each conductor.

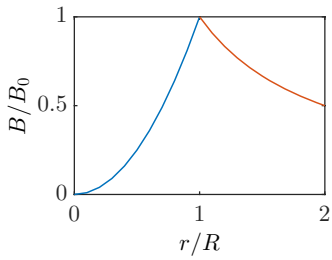

Figure 15.12: Magnetic field.

b. Calculate the magnetic field $\mathcal{B}(r)$ for $r \leq R_1$,
c. for $R_1 \leq r \leq R_2$,
d. for $R_2 \leq r \leq R_3$,
e. for $R_3 \leq r$.

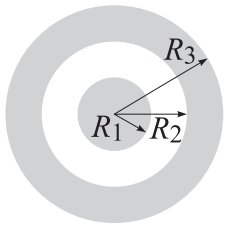

Figure 15.13: Magnetic field in a coaxial cable.

Solution: *a. Current densities in the inner and outer conductors are given by,*

$$j_i = \frac{I}{\pi R_1^2} \qquad \text{and} \qquad j_e = \frac{I}{\pi(R_3^2 - R_2^2)} \ .$$

b. With $\oint \vec{\mathcal{B}} \cdot d\mathbf{l} = \mu_0 \int \mathbf{j} \cdot d\mathbf{S}$ *segue para* $r \leq R_1$,

$$2\pi r \mathcal{B}_b(r) = \mu_0 j_i \pi r^2 = \mu_0 I \frac{r^2}{R_1^2}$$
$$\mathcal{B}_b(r) = \frac{\mu_0 I}{2\pi R_1^2} r \ .$$

c. For $R_1 \leq r \leq R_2$ *we get,*

$$2\pi r \mathcal{B}_c(r) = \mu_0 j_i \pi R_1^2 = \mu_0 I$$
$$\mathcal{B}_c(r) = \frac{\mu_0 I}{2\pi r} \ .$$

d. For $R_2 \leq r \leq R_3$ we get,

$$2\pi r\mathcal{B}_d(r) = \mu_0 j_i \pi R_1^2 - \mu_0 j_a \pi (r^2 - R_2^2) = \mu_0 I - \mu_0 I \frac{r^2 - R_2^2}{R_3^2 - R_2^2}$$
$$B(r)_d = \frac{\mu_0 I}{2\pi r}\left(1 - \frac{r^2 - R_2^2}{R_3^2 - R_2^2}\right) .$$

e. For $R_3 \leq r$ we get,

$$2\pi r\mathcal{B}_e(r) = \mu_0 j_i \pi R^2 - \mu_0 j_e \pi (R_3^2 - R_2^2) = 0$$
$$\mathcal{B}_e(r) = 0 .$$

Note that the magnetic field is continuous at the interfaces: $\mathcal{B}_b(R_1) = \mathcal{B}_c(R_1)$, $\mathcal{B}_c(R_2) = \mathcal{B}_d(R_2)$, and $\mathcal{B}_d(R_3) = \mathcal{B}_e(R_3)$.

15.2.4.9 Ex: Magnetic field of a current conductor

In a straight, infinitely long conductor with circular cross-sectional area with radius R runs a current I with a uniform current density distribution. How are the magnetic induction field lines $\vec{\mathcal{B}}$?
a. Calculate $\vec{\mathcal{B}}$ inside and outside the conductor.
b. Prepare a scheme of the profile $\mathcal{B}(r) \equiv |\vec{\mathcal{B}}(r)|$, where r be the distance from the symmetry axis of the conductor in a direction perpendicular to it.

Solution: *In Cartesian coordinates $\mathbf{j} = (0, 0, I/(\pi R^2))$. For symmetry reasons the $\vec{\mathcal{B}}$-field lines follow circles in the planes perpendicular to the conductor symmetry axis.*
a. We have $\nabla \times \vec{\mathcal{B}} = 4\pi\mathbf{j}/c$. We now integrate over a circular area S with radius r in a plane perpendicular to the symmetry axis of the conductor. The symmetry axis crosses the center of the area,

$$\int_{\mathcal{S}} (\nabla \times \vec{\mathcal{B}}) \cdot d\mathbf{S} = \frac{4\pi}{c} \int_{\mathcal{S}} \mathbf{j} \cdot d\mathbf{S}$$
$$= \frac{4\pi}{c} \frac{I}{\pi R^2} \begin{cases} \pi r^2 & ser \leq R \\ \pi R^2 & ser > R \end{cases} .$$

On the other hand, Stokes's law shows,

$$\int_{\mathcal{S}} (\nabla \times \vec{\mathcal{B}}) \cdot d\mathbf{S} = \int_{\partial\mathcal{S}} \vec{\mathcal{B}} \cdot d\mathbf{S} = 2\pi r B(r)$$

This gives,

$$\mathcal{B}(r) = \frac{2I}{c} \begin{cases} \frac{r}{R^2} & ser \leq R \\ \frac{1}{r} ser > R . \end{cases}$$

b. Is trivial.

15.2.4.10 Ex: Helmholtz and anti-Helmholtz coils

a. Show that the magnetic field of a round current loop conductor with radius R on the symmetry axis is given by,

$$\vec{\mathcal{B}}(z) = -\frac{\mu_0 I}{2}\frac{R^2}{\sqrt{R^2+z^2}^3}\hat{\mathbf{e}}_z \ .$$

b. Now consider two identical parallel loops placed on the symmetry axis with distance $d = R$. The loops are traversed by currents of equal amplitude. What is the behavior of the magnetic field on the symmetry axis for (i) equal directions of currents (ii) opposite directions? Choosing as the origin the center between the two coils, expands the magnetic field to second order in a Taylor series around the origin.

Solution: *a. The current density can be parametrized by* $\mathbf{j}(\mathbf{r}) = I\delta(\rho - R)\delta(z)\hat{\mathbf{e}}_\phi$. *The vector potential is,*

$$\mathbf{A}(\mathbf{r}) = \frac{\mu_0}{4\pi}\int \frac{\mathbf{j}(\mathbf{r}')}{|\mathbf{r}-\mathbf{r}'|}d^3r' \ .$$

Following the Biot-Savart law the magnetic field is,

$$\begin{aligned}
\vec{\mathcal{B}}(\mathbf{r}) &= \frac{\mu_0}{4\pi}\int \nabla\times\frac{\mathbf{j}(\mathbf{r}')}{|\mathbf{r}-\mathbf{r}'|}d^3r' = \frac{\mu_0}{4\pi}\int d^3\mathbf{r}'\frac{(\mathbf{r}-\mathbf{r}')\times\mathbf{j}(\mathbf{r}')}{|\mathbf{r}-\mathbf{r}'|^3} \\
&= \frac{\mu_0 I}{4\pi}\int \rho' d\rho' d\phi' dz' \frac{\delta(\rho'-R)\delta(z')(\mathbf{r}-\mathbf{r}')\times\hat{\mathbf{e}}_{\phi'}}{|\mathbf{r}-\mathbf{r}'|^3} \\
&= \frac{\mu_0 I}{4\pi}\int \rho' d\rho' d\phi' dz' \frac{\delta(\rho'-R)\delta(z')\begin{pmatrix}\rho\cos\phi-\rho'\cos\phi'\\ \rho\sin\phi-\rho'\sin\phi'\\ z-z'\end{pmatrix}\times\begin{pmatrix}-\sin\phi'\\ \cos\phi'\\ 0\end{pmatrix}}{\sqrt{(\rho\cos\phi-\rho'\cos\phi')^2+(\rho\sin\phi-\rho'\sin\phi')^2+(z-z')^2}^3} \\
&= \frac{\mu_0 I}{4\pi}\int Rd\phi' \frac{\begin{pmatrix}-z\cos\phi'\\ -z\sin\phi'\\ (\rho\cos\phi-R\cos\phi')\cos\phi'+(\rho\sin\phi-R\sin\phi')\sin\phi'\end{pmatrix}}{\sqrt{(\rho\cos\phi-R\cos\phi')^2+(\rho\sin\phi-R\sin\phi')^2+z^2}^3} \ .
\end{aligned}$$

Along the axis $\rho = 0$,

$$\begin{aligned}
\vec{\mathcal{B}}(z) &= \frac{\mu_0 I}{4\pi}\int Rd\phi' \frac{1}{\sqrt{R^2+z^2}^3}\begin{pmatrix}-z\cos\phi'\\ -z\sin\phi'\\ -R\end{pmatrix} = \frac{\mu_0 I}{4\pi}2\pi R\frac{1}{\sqrt{R^2+z^2}^3}\begin{pmatrix}0\\ 0\\ -R\end{pmatrix} \\
&= -\frac{\mu_0 I}{2}\frac{R^2}{\sqrt{R^2+z^2}^3}\hat{\mathbf{e}}_z = -\frac{\mu_0 I}{2}\frac{R^2}{\sqrt{R^2+z^2}^3}\hat{\mathbf{e}}_z \ .
\end{aligned}$$

b. For two conductive loops distant by $d = R$,

$$\vec{\mathcal{B}}_t(z) = \vec{\mathcal{B}}(z-R/2)\pm\vec{\mathcal{B}}(z+R/2) = -\frac{\mu_0 I}{2}\hat{\mathbf{e}}_z\left(\frac{R^2}{\sqrt{R^2+(z-R/2)^2}^3}\pm\frac{R^2}{\sqrt{R^2+(z+R/2)^2}^3}\right) \ .$$

A Taylor expansion for identical, respectively, opposite currents gives,

$$\vec{\mathcal{B}}_{t+}(z) = -\frac{8}{5\sqrt{5}}\frac{\mu_0 I\hat{\mathbf{e}}_z}{R}[1+O(z^3)]$$
$$\vec{\mathcal{B}}_{t-}(z) = -\frac{48}{25\sqrt{5}}\frac{\mu_0 I\hat{\mathbf{e}}_z}{R^2}[z+O(z^3)]\ .$$

Alternatively, the formula can be derived from the magnetic field of a current element,

$$d\vec{\mathcal{B}} = \frac{\mu_0 I}{4\pi}\frac{d\mathbf{l}\times(\mathbf{r}-\mathbf{r}')}{|\mathbf{r}-\mathbf{r}'|^3}$$
$$d\mathcal{B}_z = d\mathcal{B}\sin\alpha = d\mathcal{B}\frac{R}{\sqrt{R^2+z^2}}$$
$$\mathcal{B}_z = \frac{\mu_0 I}{4\pi}\oint\frac{\left|d\vec{l}\times(\mathbf{r}-\mathbf{r}')\right|}{|\mathbf{r}-\mathbf{r}'|^3}\frac{R}{\sqrt{R^2+z^2}} = \frac{\mu_0 I}{4\pi}2\pi R\frac{R}{\sqrt{R^2+z^2}^3} = \frac{\mu_0 I}{2}\frac{R^2}{\sqrt{R^2+z^2}^3}\ .$$

15.2.4.11 Ex: Helmholtz coils

Two identical circular coils of radius R and negligible thickness are mounted with their axes coinciding with the z-axis, as shown in the figure below. Their centers are separated by a distance d, with the midpoint P coinciding with the origin of the z-axis. The coils carry electric currents of the same intensity I, and both counterclockwise.
a. Use the Biot-Savart law to show that the magnetic field $\mathcal{B}(z)$ along the z-axis is,

$$\vec{\mathcal{B}}_{t+}(z) = -\frac{\mu_0 I}{2}\hat{\mathbf{e}}_z\left(\frac{R^2}{\sqrt{R^2+(z-R/2)^2}^3}\pm\frac{R^2}{\sqrt{R^2+(z+R/2)^2}^3}\right)\ .$$

b. Assuming that the spacing d is equal to the radius R of the coils, show that at point P the following equalities are valid: $d\mathcal{B}/dz = 0$ and $d^2\mathcal{B}/dz^2 = 0$.
c. Looking at the graphs below, which curve describes the magnetic field along the z-axis in the configuration of item (b)? Justify!
d. Assuming that the current in the upper coil is reversed, calculate the new value of the magnetic field at point P.

Solution: *a. The magnetic field generated at a position* $\mathbf{r}$ *by a current element* $d\mathbf{l}$ *located at position* $\mathbf{r}'$ *is,*

$$d\vec{\mathcal{B}}(\mathbf{r}) = \frac{\mu_0 I}{4\pi}\frac{d\vec{l}\times(\mathbf{r}-\mathbf{r}')}{|\mathbf{r}-\mathbf{r}'|^3}\ .$$

Considering a circular coil located in the xz*-plane and integrating with* $\mathbf{r} = (0,0,z)$ *and* $\mathbf{r}' = R(\cos\phi,\sin\phi,0)$ *and* $d\vec{\ell} = Rd\phi(\sin\phi,-\cos\phi,0)$*,*

$$\mathcal{B}_z = \frac{\mu_0 I}{4\pi}\oint\frac{(d\vec{l}\times(\mathbf{r}-\mathbf{r}'))_z}{|\mathbf{r}-\mathbf{r}'|^3} = \frac{\mu_0 I}{4\pi}\int_0^{2\pi}\frac{-R^2 d\phi}{|\mathbf{r}-\mathbf{r}'|^3} = \frac{\mu_0 I}{2}\frac{R^2}{\sqrt{R^2+z^2}^3}\ .$$

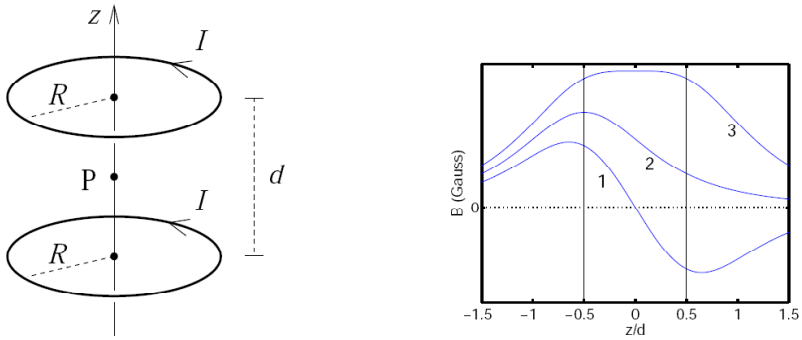

Figure 15.14: (code) Geometry and magnetic field amplitude of a pair of Helmholtz coils.

Now, for two coils distant by $d = R$,

$$\vec{\mathcal{B}}_t(z) = \vec{\mathcal{B}}(z-R/2) \pm \vec{\mathcal{B}}(z+R/2) = -\frac{\mu_0 I}{2}\hat{\mathbf{e}}_z \left(\frac{R^2}{\sqrt{R^2+(z-R/2)^2}^3} \pm \frac{R^2}{\sqrt{R^2+(z+R/2)^2}^3} \right) .$$

b. Taylor expansion for equal and opposite current directions,

$$\vec{\mathcal{B}}_{t+}(z) = -\frac{8}{5\sqrt{5}}\frac{\mu_0 I \hat{\mathbf{e}}_z}{R}[1+O(z^3)]$$
$$\vec{\mathcal{B}}_{t-}(z) = -\frac{48}{25\sqrt{5}}\frac{\mu_0 I \hat{\mathbf{e}}_z}{R^2}[z+O(z^3)] .$$

It is obvious that for equal directions the first and second derivatives of the field disappear.
c. Curve (3) corresponds to the Helmholtz configuration, since this curve satisfies $d\mathcal{B}/dz = 0 = d^2\mathcal{B}/dz^2$ in the center. Curve (1) describes the anti-Helmholtz configuration, since this curve is linear in the center.
d. The magnetic field at point P for anti-Helmholtz configuration is 0 according to the formula obtained in item (a) or in the Taylor expansion in item (b).

15.2.4.12 Ex: Helmholtz coils

A pair of identical coils, each with a radius of 30 cm, is separated by a distance equal to their radii. Called Helmholtz coils, they are coaxial and carry equal currents oriented such that their axial fields point into the same z-direction. A feature of Helmholtz coils is, that the resulting magnetic field in the region between the coils is quite uniform. Assume that the current in each one is 15 A and that there are 250 turns for each coil. Using a spreadsheet, calculate and plot the magnetic field along the z-axis for $-30\,\text{cm} < z < +30\,\text{cm}$. Within which z-range does the field vary by less than 20%?

Solution: *See the figure.*

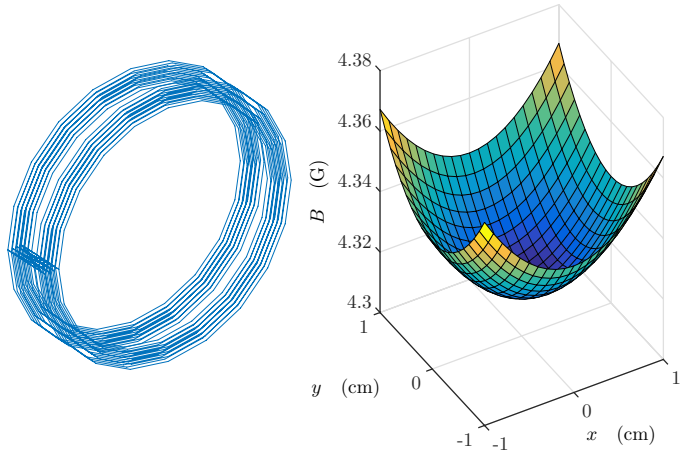

Figure 15.15: Numerical integration of the Biot-Savart law.

15.3 The magnetic vector potential

The fact that the divergence of the magnetic field vanishes, $\nabla \cdot \vec{\mathcal{B}} = 0$, allows us to introduce a vector field $\mathbf{A}$ called *vector potential* of which the magnetic field is the rotation,

$$\boxed{\vec{\mathcal{B}} = \nabla \times \mathbf{A}} \, . \tag{15.20}$$

15.3.1 The Laplace and Poisson equations

Ampère's law says,

$$\mu_0 \mathbf{j} = \nabla \times \vec{\mathcal{B}} = \nabla \times (\nabla \times \mathbf{A}) = \nabla(\nabla \cdot \mathbf{A}) - \nabla^2 \mathbf{A} \, . \tag{15.21}$$

Note that, just as we can add a constant to the electrostatic potential without changing the electric field, we have the freedom to add to the vector potential the *gradient of a scalar field*,

$$\nabla \times \mathbf{A} = \nabla \times (\mathbf{A} + \nabla \chi) \, , \tag{15.22}$$

since the rotation of a gradient always vanishes. This freedom allows us to impose other conditions on this scalar field $\chi(\mathbf{r})$. One of them is called the *Coulomb gauge*,

$$\boxed{\nabla \cdot \mathbf{A} \equiv 0} \, . \tag{15.23}$$

To show that it is always possible to choose a function χ such, that the potential vector $\mathbf{A} + \nabla\chi$ satisfies the condition (15.23) and at the same time produces the same magnetic field (15.22), we just insert this potential into Eq. (15.23) and find a formal solution of the following Poisson equation,

$$\nabla^2 \chi = -\nabla \cdot \mathbf{A} \, . \tag{15.24}$$

is simply the Coulomb potential [see (13.33)],

$$\chi(\mathbf{r}) = \frac{1}{4\pi}\int_{\mathcal{V}} \frac{\nabla_{r'}\cdot\mathbf{A}(\mathbf{r}')}{|\mathbf{r}-\mathbf{r}'|}dV' \ , \tag{15.25}$$

supposing that $\nabla\cdot\mathbf{A} \overset{r\to\infty}{\longrightarrow} 0$.

Within the Coulomb gauge the Eq. (15.21) also adopts the simple form of a Poisson equation,

$$\boxed{\nabla^2\mathbf{A} = -\mu_0\mathbf{j}} \ , \tag{15.26}$$

which we can solve,

$$\boxed{\mathbf{A}(\mathbf{r}) = \frac{\mu_0}{4\pi}\int \frac{\mathbf{j}(\mathbf{r}')}{|\mathbf{r}-\mathbf{r}'|}d^3\mathbf{r}'} \ . \tag{15.27}$$

This relationship is the equivalent of the electrostatic potential (13.35). We verify that we recover Biot-Savart's law (15.8) via,

$$\nabla_r\times\mathbf{A}(\mathbf{r}) = \frac{\mu_0}{4\pi}\int_{\mathcal{V}}\mathbf{j}(\mathbf{r}')\times\frac{|\mathbf{r}-\mathbf{r}'|}{|\mathbf{r}-\mathbf{r}'|^3}dV' \ . \tag{15.28}$$

Example 73 (*Vector potential of a one-dimensional current*): As an example we consider a one-dimensional current, $\mathbf{j}(\mathbf{r}') = I\delta^2(\mathbf{r}'-\mathbf{s}_\perp)\hat{\mathbf{e}}'_j$,

$$\mathbf{A}(\mathbf{r}) = \frac{\mu_0 I}{4\pi}\int_{\mathcal{C}}\frac{d\mathbf{s}'}{|\mathbf{r}-\mathbf{r}'|} \qquad \text{and} \qquad \vec{\mathcal{B}}(\mathbf{r}) = \frac{\mu_0 I}{4\pi}\int_{\mathcal{C}}\frac{d\mathbf{s}'\times|\mathbf{r}-\mathbf{r}'|}{|\mathbf{r}-\mathbf{r}'|^3} \ .$$

For a current element oriented along the z-axis,

$$\mathbf{A}(\mathbf{r}) = \frac{\mu_0 I}{4\pi}\int_0^a \frac{\hat{\mathbf{e}}_z dz'}{\sqrt{\rho^2+(z-z')^2}} = \frac{\mu_0 I}{4\pi}\hat{\mathbf{e}}_z \ln\frac{-(z-a)+\sqrt{r^2+(z-a)^2}}{-z+\sqrt{r^2+z^2}} \ .$$

The scheme 15.16 summarizes the fundamental laws of magnetostatics.

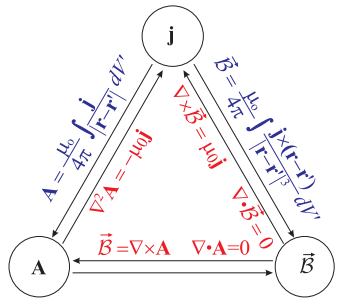

Figure 15.16: Organization chart for the fundamental laws of magnetostatics. Note, that there is no simple expression to calculate $\mathbf{A}$ from $\vec{\mathcal{B}}$.

15.3.2 Magnetostatic boundary conditions

In order to find the magnetostatic boundary conditions imposed by current-carrying interfaces, we proceed in the same way as in the electrostatic case. First, we consider a 'pill box', as schematized in Fig. 15.17. From

$$\oint \vec{\mathcal{B}} \cdot d\mathbf{S} = 0 \ , \tag{15.29}$$

we find for the component of the magnetic field perpendicular to the interface,

$$\mathcal{B}^{\perp}_{top} = \mathcal{B}^{\perp}_{down} \ . \tag{15.30}$$

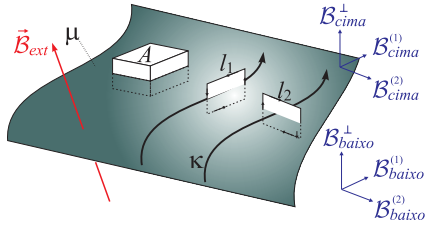

Figure 15.17: Illustration of the pillbox-shaped volume delimited by the surface A cutting through a small part of the interface. Also shown are paths on the interface being perpendicular (l_1) or parallel (l_2) to the surface current κ.

We now consider a closed loop in the plane defined by the magnetic field and perpendicular to the current. From

$$\oint \vec{\mathcal{B}} \cdot d\mathbf{l}_2 = (\mathcal{B}^{(2)}_{top} - \mathcal{B}^{(2)}_{bottom}) l_2 = \mu_0 I = \mu_0 \kappa l_2 \ , \tag{15.31}$$

where we defined $\kappa \equiv I/l_2$ as the surface current density, that is, the current dI flowing through a ribbon of width dl_2 sticking to the interface. We find,

$$\mathcal{B}^{(2)}_{top} - \mathcal{B}^{(2)}_{bottom} = \mu_0 \kappa \ . \tag{15.32}$$

Thus, the component of $\vec{\mathcal{B}}$ parallel to the surface but perpendicular to the current is discontinuous by a value $\mu_0 \kappa$.

Similarly, a closed loop in the direction parallel to the current shows that the parallel component of $\vec{\mathcal{B}}$ is continuous,

$$\oint \vec{\mathcal{B}} \cdot d\mathbf{l}_1 = (\mathcal{B}^{(1)}_{top} - \mathcal{B}^{(1)}_{bottom}) l_1 = 0 \ . \tag{15.33}$$

In summary,

$$\vec{\mathcal{B}}_{top} - \vec{\mathcal{B}}_{bottom} = \vec{\mathcal{B}}^{\parallel}_{top} - \vec{\mathcal{B}}^{\parallel}_{bottom} = \mu_0 \vec{\kappa} \times \hat{\mathbf{n}} \ . \tag{15.34}$$

In the same way as the scalar potential in electrostatics, the potential vector remains continuous through the interface,

$$\mathbf{A}_{top} = \mathbf{A}_{bottom} \ , \tag{15.35}$$

because $\nabla \cdot \mathbf{A} = 0$ ensures that the normal component is continuous and,

$$\oint \mathbf{A} \cdot d\mathbf{l} = \int \nabla \times \mathbf{A} \cdot d\mathbf{S} = \int \vec{\mathcal{B}} \cdot d\mathbf{S} = \Psi_M \ , \tag{15.36}$$

means that the tangential components are continuous (the flux through an Amperian loop of negligible thickness vanishes). On the other hand, the derivative of $\mathbf{A}$ inherits the discontinuity of $\vec{\mathcal{B}}$:

$$\frac{\partial \mathbf{A}_{top}}{\partial n} - \frac{\partial \mathbf{A}_{bottom}}{\partial n} = -\mu_0 \vec{\kappa} \ , \tag{15.37}$$

where n is the coordinate perpendicular to the surface.

Example 74 (*Proof of the discontinuity of the derivative of the vector potential*): To prove the statement (15.37) we consider a surface current in the direction $\vec{\kappa} = \kappa \hat{\mathbf{e}}_x$ within an interface located in the x-y-plane. So,

$$\vec{\mathcal{B}}_{top} - \vec{\mathcal{B}}_{bottom} = \begin{pmatrix} 0 \\ \mu_0 \kappa \\ 0 \end{pmatrix} = \begin{pmatrix} \partial_y A^{(z)}_{top} - \partial_z A^{(y)}_{top} \\ \partial_z A^{(x)}_{top} - \partial_x A^{(z)}_{top} \\ \partial_x A^{(y)}_{top} - \partial_y A^{(x)}_{top} \end{pmatrix} - \begin{pmatrix} \partial_y A^{(z)}_{bottom} - \partial_z A^{(y)}_{bottom} \\ \partial_z A^{(x)}_{bottom} - \partial_x A^{(z)}_{bottom} \\ \partial_x A^{(y)}_{bottom} - \partial_y A^{(x)}_{bottom} \end{pmatrix} \ .$$

Now,

$$0 = \partial_y A^{(z)}_{top} - \partial_y A^{(z)}_{bottom} = \partial_z A^{(y)}_{top} - \partial_z A^{(y)}_{bottom} = \partial_x A^{(y)}_{top} - \partial_x A^{(y)}_{bottom} = \partial_y A^{(x)}_{top} - \partial_y A^{(x)}_{bottom}$$
$$\mu_0 \kappa_x = \partial_z A^{(x)}_{top} - \partial_z A^{(x)}_{bottom} - \partial_x A^{(z)}_{top} + \partial_x A^{(z)}_{bottom} \ .$$

Assuming a uniform field, only the derivative in z can contribute, such that,

$$\mu_0 \kappa_x = \partial_z A^{(x)}_{top} - \partial_z A^{(x)}_{bottom} \ .$$

15.3.3 Exercises

15.3.3.1 Ex: Vector potential and electric field of a rotating charged sphere

On the surface of a hollow sphere with radius R be evenly distributed the charge Q. The sphere rotates at constant angular velocity $\vec{\omega}$ around one of its diameters.
a. Determine the current density generated by the motion $\mathbf{j}(\mathbf{r})$.
b. Derive the components of the potential vector $\mathbf{A}(\mathbf{r})$ and the magnetic field $\vec{\mathcal{B}}(\mathbf{r})$.

Solution: *a. The charge density is,*

$$\rho(\mathbf{r}) = \frac{Q}{4\pi R^2} \delta(r - R) \ ,$$

giving the current density,

$$\mathbf{j}(\mathbf{r}) = \rho(\mathbf{r}) \mathbf{v}(\mathbf{r}) = \rho(\mathbf{r}) [\vec{\omega} \times \mathbf{r}]$$

Now, we have at the surface,

$$\mathbf{r} = R\hat{\mathbf{e}}_r = R(\sin\theta\cos\phi, \sin\theta\sin\phi, \cos\theta) \ .$$

With $\vec{\omega} = \omega\hat{\mathbf{e}}_z = \omega(0,0,1)$ *we obtain,*

$$\hat{\mathbf{e}}_z \times \hat{\mathbf{e}}_r = (-\sin\theta\sin\phi, \sin\theta\cos\phi, 0) = \sin\theta(-\sin\phi, \cos\phi, 0) = \sin\theta\hat{\mathbf{e}}_\phi$$

and therefore the current density,

$$\mathbf{j}(\mathbf{r}) = \frac{Q\omega}{4\pi R}\sin\theta\delta(r-R)\hat{\mathbf{e}}_\phi$$

b. For the potential vector we have,

$$\mathbf{A}(\mathbf{r}) = \frac{\mu_0}{4\pi}\int \frac{\mathbf{j}(\mathbf{r}')}{|\mathbf{r}-\mathbf{r}'|}d^3r' = \frac{Q}{(4\pi)^2R^2}\vec{\omega}\times\int d^3\mathbf{r}\ '\delta(r'-R)\frac{\mathbf{r}'}{|\mathbf{r}-\mathbf{r}'|} \ .$$

For the integration we let $\mathbf{r}$ *go towards* z *(in this case, the direction of* $\vec{\omega}$ *is no longer the* z*-axis). Now we have,* $|\mathbf{r}-\mathbf{r}'| = \sqrt{r^2+r'^2-2rr'\cos\theta'}$ *and* $\mathbf{r}' = r'(\sin\theta'\cos\phi', \sin\theta'\sin\phi', \cos\theta'$ *A integration over* ϕ' *then gives for the* x *and* y *components the value 0. Denoting* $\cos'$ *by* u' *and replacing* $\hat{\mathbf{e}}_z$*, we get again, after integration for* $\hat{\mathbf{e}}_r$*,*

$$\begin{aligned}\mathbf{A}(\mathbf{r}) &= \frac{2\pi Q}{(4\pi)^2R^2}(\vec{\omega}\times\hat{\mathbf{e}}_r)\int r'^3\delta(r'-R)\int_{-1}^{+1}\frac{u'du'}{\sqrt{r^2+r'^2-2rr'u'}}dr' \\ &= \frac{\mu_0 QR}{8\pi}(\vec{\omega}\times\hat{\mathbf{e}}_r)\int_{-1}^{+1}\frac{u'du'}{\sqrt{r^2+R^2-2rRu'}} \ .\end{aligned}$$

The integral can be resolved by partial integration,

$$\begin{aligned}I &= \int_{-1}^{+1}\frac{u'du'}{\sqrt{r^2+R^2-2rRu'}} = -\frac{1}{rR}\left[u'\sqrt{r^2+R^2-2rRu'}\right]_{-1}^{+1} + \frac{1}{rR}\int_{-1}^{+1}\sqrt{r^2+R^2-2rRu'} \\ &= -\frac{1}{rR}(|r-R|+|r+R|) + \frac{1}{rR}\left[-\frac{2}{3}\frac{1}{2rR}(r^2+R^2-2rRu')^{3/2}\right]_{-1}^{+1} \\ &= -\frac{1}{rR}(|r-R|+|r+R|) - \frac{1}{3r^2R^2}(|r-R|^3-|r+R|^3) \ .\end{aligned}$$

For $r > R$ *we get from this* $I = \frac{2R}{3r^2}$*, while for* $r < R$ *we find* $I = \frac{2r}{3R^2}$*. With this we get for the potential vector,*

$$\mathbf{A}(\mathbf{r}) = \frac{\mu_0 QR}{12\pi}(\vec{\omega}\times\hat{\mathbf{e}}_r)\begin{cases}\frac{r}{R^2} & if \ \ r<R \\ \frac{R}{r^2} & se \ \ r>R\end{cases} = \frac{\mu_0 QR}{12\pi}\omega\sin\theta\hat{\mathbf{e}}_\phi\begin{cases}\frac{r}{R^2} & if \ \ r<R \\ \frac{R}{r^2} & se \ \ r>R\end{cases}$$

where we use again that $\vec{\omega} = \omega\hat{\mathbf{e}}_z$ *and* $\hat{\mathbf{e}}_z\times\hat{\mathbf{e}}_r = \sin\theta\hat{\mathbf{e}}_\phi$*. Obviously,* $\mathbf{A}$ *has only the component* ϕ*.*

b. Now the magnetic induction is $\vec{\mathcal{B}} = \nabla\times\mathbf{A}$*. Using the rotation in spherical coordinates (12.80), we get immediately,*

$$\vec{\mathcal{B}} = \hat{\mathbf{e}}_r\left[\frac{1}{r\sin\theta}\frac{\partial A_\phi\sin\theta}{\partial\theta}\right] - \hat{\mathbf{e}}_\theta\left[\frac{1}{r}A_\phi + \frac{\partial A_\phi}{\partial r}\right] = \frac{\mu_0 Q\omega}{6\pi R}\begin{cases}(\hat{\mathbf{e}}_r\cos\theta - \hat{\mathbf{e}}_\theta\sin\theta) & if \ \ r<R \\ \frac{R^3}{r^3}(\hat{\mathbf{e}}_r\cos\theta + \frac{1}{2}\hat{\mathbf{e}}_\theta\sin\theta) & if \ \ r>R\end{cases}$$

With $\hat{\mathbf{e}}_r\cos\theta - \hat{\mathbf{e}}_\theta\sin\theta = \hat{\mathbf{e}}_z$ *we find that, curiously, the magnetic field is homogeneous within the layer.*

15.3.3.2 Ex: Magnetic field of a rotating spherical layer with spherical harmonics

Calculate the vector potential, magnetic field and magnetization of a charged rotating spherical layer using spherical harmonics.

Solution: *We can express the current density in Cartesian coordinates,*

$$\begin{aligned} j_x &= -v_\phi \sin\phi = -\tfrac{e\omega}{4\pi r_e}\delta(r-r_e)\sin\theta\sin\phi \\ j_y &= +v_\phi \cos\phi = +\tfrac{e\omega}{4\pi r_e}\delta(r-r_e)\sin\theta\cos\phi \\ j_z &= 0 \ . \end{aligned}$$

Now we have,

$$\begin{aligned} Y_{1\pm1}(\theta,\phi) &= \mp\sqrt{\tfrac{3}{8\pi}}\sin\theta(\cos\phi \pm i\sin\phi) \\ Y_{11}+Y_{1-1} &= -2\imath\sqrt{\tfrac{3}{8\pi}}\sin\theta\sin\phi \\ Y_{11}-Y_{1-1} &= -2\sqrt{\tfrac{3}{8\pi}}\sin\theta\cos\phi \ , \end{aligned}$$

that is,

$$\begin{aligned} j_x &= \frac{e\omega}{4\pi r_e}\delta(r-r_e)\left(+\frac{1}{2i}\sqrt{\tfrac{8\pi}{3}}\right)(Y_{11}+Y_{1-1}) \\ j_y &= \frac{e\omega}{4\pi r_e}\delta(r-r_e)\left(-\frac{1}{2}\sqrt{\tfrac{8\pi}{3}}\right)(Y_{11}-Y_{1-1}) \ . \end{aligned}$$

Now we have,

$$\mathbf{A} = \frac{1}{c}\int d\tau' \frac{\mathbf{j}(\mathbf{r}')}{|\mathbf{r}-\mathbf{r}'|}$$

and also,

$$\frac{1}{|\mathbf{r}-\mathbf{r}'|} = \sum_{lm}\frac{4\pi}{2l+1}\frac{r_<^l}{r_>^{l+1}}{Y_{lm}}^*(\theta',\phi')Y_{lm}(\theta,\phi) \ .$$

The current density is limited to the surface of the sphere. For the calculation of the vector potential in outer space we obtain, $r_< = r'$ and $r_> = r$. With that we get,

$$\begin{aligned} \begin{pmatrix} A_x \\ A_y \end{pmatrix} &= \begin{pmatrix} \frac{1}{2i}\sqrt{\frac{8\pi}{3}} \\ -\frac{1}{2}\sqrt{\frac{8\pi}{3}} \end{pmatrix} \frac{e\omega}{4\pi r_e c}\sum_{lm}\frac{4\pi}{2l+1}Y_{lm}(\theta,\phi)\cdot\int\delta(r'-r_e){r'}^{l+2}Y_{lm}^*(\theta',\phi')\begin{pmatrix} Y_{11}+Y_{1-1} \\ Y_{11}-Y_{1-1} \end{pmatrix}dr'd\Omega' \\ &= \frac{e\omega}{3c}\left(\frac{r}{r_e}\right)^2 \begin{matrix} \frac{1}{2i}\sqrt{\frac{8\pi}{3}}(Y_{11}+Y_{1-1}) \\ -\frac{1}{2}\sqrt{\frac{8\pi}{3}}(Y_{11}-Y_{1-1}) \end{matrix} \ . \end{aligned}$$

So,

$$\begin{aligned} A_x &= -\frac{e\omega}{3c}\left(\frac{r_e}{r}\right)^2\sin\theta\sin\phi \\ A_y &= +\frac{e\omega}{3c}\left(\frac{r_e}{r}\right)^2\sin\theta\cos\phi \\ A_z &= 0 \end{aligned}$$

that is,

$$\mathbf{A} = A_\phi \hat{\mathbf{e}}_\phi \qquad with \qquad A_\phi = \frac{e\omega}{3c}\left(\frac{r_e}{r}\right)^2 \sin\theta \ .$$

Now we have $\vec{\mathcal{B}} = \nabla \times \mathbf{A}$. *We get immediately,*

$$\begin{aligned}
\mathcal{B}_r &= \frac{1}{r\sin\theta}\left[\frac{\partial}{\partial\theta}(\sin\theta A_\phi)\right] = \frac{e\omega r_e^2}{3cr^3} 2\cos\theta \\
\mathcal{B}_\theta &= -\frac{1}{r}\left[\frac{\partial}{\partial r}(r A_\phi)\right] = \frac{e\omega r_e^2}{3cr^3}\sin\theta \\
\mathcal{B}_\phi &= 0 \ .
\end{aligned}$$

Comparing with Exc. 15.4.2.19(d) we get,

$$\vec{\mathcal{M}} = \frac{e\omega r_e^2}{3c}\hat{\mathbf{e}}_z = \frac{e\omega r_e^2}{3c}\left(\cos\theta\hat{\mathbf{e}}_r - \sin\theta\hat{\mathbf{e}}_\phi\right) \ .$$

15.3.3.3 Ex: Conducting thin loops

Consider a circular conducting loop with radius R. The wire of the loop is infinitely thin (δ-function). Through the loop flows a continuous current I.
a. What is the expression for current density $\mathbf{j}(\mathbf{r})$? Express the result in spherical coordinates considering that the integral of the current over a surface perpendicular to the wire must give I.
b. Calculate the magnetic dipolar moment of this current loop,

$$\mathbf{m} = \frac{1}{2}\int [\mathbf{r}\times\mathbf{j}(\mathbf{r})] d^3r \ .$$

c. For large distances from a localized current distribution, the potential vector $\mathbf{A}$ is dominated by the dipolar contribution,

$$\mathbf{A}(\mathbf{r}) = \frac{\mathbf{m}\times\mathbf{r}}{r^3} \ .$$

What are, in this approximation, the values of the potential vector $\mathbf{A}$ and the magnetic field $\vec{\mathcal{B}}$ for the conducting loop?

Solution: *a. The useful parametrization is* $\mathbf{j}(\mathbf{r},t) = I\hat{\mathbf{e}}_z\delta(z)\delta(\rho - R)$.
b. We use the definition,

$$\mathbf{m} = \tfrac{1}{2}\int \mathbf{r}'\times\mathbf{j}(\mathbf{r}',t)d^3r' = \tfrac{1}{2}\int \mathbf{r}'\times I\hat{\mathbf{e}}_\phi\delta(z')\delta(\rho'-R)\rho' d\rho' dz' d\phi' = \tfrac{1}{2}I2\pi R\mathbf{R}\times\hat{\mathbf{e}}_\phi = I\pi R^2\hat{\mathbf{e}}_z \ .$$

c. Inserting into the expression for potential vector,

$$\mathbf{A}(\mathbf{r}) = \frac{I\pi R^2\hat{\mathbf{e}}_z\times\mathbf{r}}{r^3} = \frac{I\pi R^2}{r^2}\hat{\mathbf{e}}_\phi \ .$$

Using the relation with the magnetic field and the expression for the rotation in spherical coordinates (12.80),

$$\vec{\mathcal{E}}(\mathbf{r}) = \nabla \times \mathbf{A} = \hat{\mathbf{e}}_r \frac{1}{r\sin\theta}\frac{\partial}{\partial\theta}(\sin\theta A_\phi) - \hat{\mathbf{e}}_\theta \frac{1}{r}\frac{\partial}{\partial r}(rA_\phi)$$
$$= I\pi R^2 \left[\hat{\mathbf{e}}_r \frac{1}{r\sin\theta}\frac{1}{r^2}\frac{\partial \sin\theta}{\partial\theta} - \hat{\mathbf{e}}_\theta \frac{1}{r}\frac{\partial}{\partial r}\frac{1}{r}\right] = \frac{I\pi R^2}{r^3}(\hat{\mathbf{e}}_\theta - \hat{\mathbf{e}}_r \cot\theta) \ .$$

15.3.3.4 Ex: Conducting thin loops

Consider a system of N different conducting loops (use δ-functions) through which runs a current I_j $(j = 1, \ldots, N)$. The magnetic flux through the j-th loop is then given by,

$$\Phi_j = \sum_{m=1}^{N} \int_{F_j} \vec{\mathcal{B}}_m \cdot d\mathbf{S} \ ,$$

where the integral must be taken over the area enclosed by the current loops j and $\vec{\mathcal{B}}_m$ is the part of the magnetic field due to the j-th loop.
a. Show,

$$\Phi_j = c \sum_{m=1}^{N} L_{jm} I_m$$

with the induction coefficient,

$$L_{jm} = \frac{\frac{1}{c^2}\int_j \int_m d\mathbf{r}_j \cdot d\mathbf{r}_m}{|\mathbf{r}_j - \mathbf{r}_m|} \ ,$$

where the integrals are taken over the loops j and m.
b. Also show that the magnetic field energy of the loop system is given by,

$$W = \frac{1}{2}\sum_{j,m} L_{jm} I_j I_m \ .$$

Solution:

15.3.3.5 Ex: Conducting thin loops

A conducting loop made of two semicircles (see diagram) with radii $r_i = 0.3\,\mathrm{m}$ and $r_a = 0.5\,\mathrm{m}$ carries a current $I = 1.5\,\mathrm{A}$.
a. Calculate the magnetic moment $\vec{\mu}$ of the conducting loop.
b. The conducting loop is now traversed by a $\mathcal{B}$-field of amplitude $\mathcal{B} = 0.3\,\mathrm{T}$. Calculate the resulting torque $\mathbf{m}$ on the loop, when the $\mathcal{B}$-field is directed (i) toward z, (ii) toward x, and (iii) orthogonal to the plane of the scheme.

Solution:

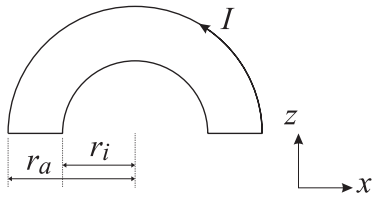

Figure 15.18: Loop.

15.3.3.6 Ex: Gauge transformation

Be given the potential vector,

$$\mathbf{A}(\mathbf{r}) = \frac{1}{y^2+z^2+a^2}\begin{pmatrix}0\\ z\\ -y\end{pmatrix} .$$

Discusses the corresponding magnetic field $\vec{\mathcal{B}} = \nabla \times \mathbf{A}$.
a. Show that the potential

$$\mathbf{A}'(\mathbf{r}) = \frac{1}{y^2+z^2+a^2}\begin{pmatrix}0\\ y+z\\ z-y\end{pmatrix}$$

gives the same magnetic field as the potential $\mathbf{A}(\mathbf{x})$.
b. Show:

$$\mathbf{A}'(\mathbf{r}) = \mathbf{A}(\mathbf{r}) - \nabla\alpha(\mathbf{r})$$

and determine $\alpha(\mathbf{r})$.

Solution: *It is easy to verify that,*

$$\vec{\mathcal{B}}(\mathbf{r}) = -\frac{2a^2}{(y^2+z^2+a^2)^2}\hat{\mathbf{e}}_z ,$$

for both potentials $\mathbf{A}(\mathbf{r})$ *and* $\mathbf{A}'(\mathbf{r})$. *The function* $\alpha(\mathbf{r})$ *is obtained by the relation:*

$$\mathbf{A}'(\mathbf{r}) - \mathbf{A}(\mathbf{x}) = \frac{1}{y^2+z^2+a^2}\begin{pmatrix}0\\ y\\ z\end{pmatrix} = \frac{1}{2}\nabla\ln(y^2+z^2+a^2) ,$$

and hence,

$$\alpha(\mathbf{r}) = -\frac{1}{2}\ln(y^2+z^2+a^2).$$

15.3.3.7 Ex: Coulomb gauge

Be given the vector potential,

$$\mathbf{A}(x,y,z) = \frac{(x+y)\hat{\mathbf{e}}_x + (-x+y)\hat{\mathbf{e}}_y}{\sqrt{x^2+y^2}} \ .$$

Find a gauge transformation $\alpha(x,y,z)$, where $\mathbf{A} \to \mathbf{A}' = \mathbf{A} - \nabla\alpha$, such that transformed vector potential satisfies the Coulomb gauge.
Help: The Laplace operator in cylindrical coordinates has the form,

$$\Delta = \frac{1}{\rho}\frac{\partial}{\partial\rho}\left(\rho\frac{\partial}{\partial\rho}\right) + \frac{\partial^2}{\partial z^2} + \frac{1}{\rho^2}\frac{\partial^2}{\partial\phi^2} \ .$$

where $\rho^2 = x^2 + y^2$.

Solution: *In the Coulomb gauge,* $\nabla \cdot \mathbf{A}' = 0$*; it implies* $\Delta\alpha = \nabla \cdot \mathbf{A}$*. From the given expression for the potential vector* $\mathbf{A}$ *we get,*

$$\nabla \cdot \mathbf{A} = \frac{2}{\sqrt{x^2+y^2}} \ .$$

The function α *is the solution to the differential equation.:*

$$\Delta\alpha(x,y,z) = \frac{2}{\sqrt{x^2+y^2}} \ .$$

The easiest is to solve this equation in cylindrical coordinates. With $\rho = \sqrt{x^2+y^2}$*, we have:*

$$\frac{\partial}{\partial\rho}\left(\rho\frac{\partial}{\partial\rho}\alpha\right) = 2 \ .$$

(We already used the fact that the function α *does not depend on* z, ϕ*). The solution is straightforward,* $\alpha = 2\rho$*; in Cartesian coordinates,* $\alpha = 2\sqrt{x^2+y^2}$*.*

15.3.3.8 Ex: Vector potential of a homogeneous field

We consider a homogeneous magnetic field in z-direction,

$$\vec{\mathcal{B}} = \mathcal{B}\hat{\mathbf{e}}_z \ .$$

Invent a potential vector $\mathbf{A}$, such that $\vec{\mathcal{B}} = \text{rot } \mathbf{A}$. How does the potential vector look like in the Coulomb gauge (that is, under the condition: div $\mathbf{A} = 0$).

Solution: *The potential vector,*

$$\mathbf{A} = \tfrac{1}{2}\vec{\mathcal{B}} \times \mathbf{r} = \tfrac{\mathcal{B}}{2}(-y\hat{\mathbf{e}}_x + x\hat{\mathbf{e}}_y)$$

gives the magnetic field,

$$\vec{\mathcal{B}} = \nabla \times \mathbf{A} = \tfrac{\mathcal{B}}{2}\nabla \times (-y\hat{\mathbf{e}}_x + x\hat{\mathbf{e}}_y) = \tfrac{\mathcal{B}}{2}\begin{pmatrix} \partial_y 0 - \partial_z x \\ \partial_z(-y) - \partial_x 0 \\ \partial_x x - \partial_y(-y) \end{pmatrix} = \mathcal{B}\hat{\mathbf{e}}_z \ .$$

15.4 Multipolar expansion

Using the expansion (13.91) we can expand the vector potential in the same way as we did with the electrostatic potential in formula (13.92),

$$\mathbf{A}(\mathbf{r}) = \frac{\mu_0 I}{4\pi} \oint \frac{1}{|\mathbf{r}-\mathbf{r}'|} d\mathbf{l}' = \frac{\mu_0 I}{4\pi} \sum_{\ell=0}^{\infty} \frac{1}{r^{\ell+1}} \oint r'^{\ell} P_\ell(\cos\theta') d\mathbf{l}' \ . \tag{15.38}$$

Explicitly,

$$\mathbf{A}(\mathbf{r}) = \frac{\mu_0 I}{4\pi} \left[\frac{1}{r} \oint d\mathbf{l}' + \frac{1}{r^2} \oint r' \cos\theta' d\mathbf{l}' + \frac{1}{r^3} \oint r'^2 (\tfrac{3}{2}\cos^2\theta' - \tfrac{1}{2}) d\mathbf{l}' + ... \right] \ . \tag{15.39}$$

15.4.1 Multipolar magnetic moments

Since there are no magnetic monopoles, the first term of the multipolar expansion will be $\oint d\mathbf{l}' = 0$. The next term is the dipole term,

$$\mathbf{A}_{dip} = \frac{\mu_0 I}{4\pi r^2} \oint \hat{\mathbf{r}} \cdot \mathbf{r}' d\mathbf{l}' \ . \tag{15.40}$$

Doing the calculation,

$$\begin{aligned} \mathbf{c} \cdot \oint \hat{\mathbf{r}} \cdot \mathbf{r}' d\mathbf{l}' = \oint \mathbf{c}(\hat{\mathbf{r}} \cdot \mathbf{r}') \cdot d\mathbf{l}' = \int \nabla_{r'} \times [\mathbf{c}(\hat{\mathbf{r}} \cdot \mathbf{r}')] \cdot d\mathbf{S}' \qquad (15.41) \\ = -\int [\mathbf{c} \times \nabla_{r'}(\hat{\mathbf{r}} \cdot \mathbf{r}')] \cdot d\mathbf{S}' = -(\mathbf{c} \times \hat{\mathbf{r}}) \cdot \int d\mathbf{S}' = -\mathbf{c} \cdot \left(\hat{\mathbf{r}} \times \int d\mathbf{S}' \right) \ , \end{aligned}$$

for arbitrary constants $\mathbf{c}$, we find,

$$\boxed{\mathbf{A}_{dip} = -\frac{\mu_0 I}{4\pi r^2} \hat{\mathbf{r}} \times \int d\mathbf{S}' = \frac{\mu_0}{4\pi} \frac{\mathbf{m} \times \hat{\mathbf{r}}}{r^2}} \quad \text{where} \quad \boxed{\mathbf{m} \equiv I \int d\mathbf{S}} \tag{15.42}$$

is the *magnetic dipole moment*.

> **Example 75 (*Magnetic moment of a current loop*):** The magnetic moment of a conductive coil of radius R lying in the x-y-plane and traversed by a current is calculated by,
>
> $$\mathbf{m} = I \int d\mathbf{S} = I\pi R^2 \hat{\mathbf{e}}_z \ .$$

We will show in Exc. 15.4.2.1 how the magnetic dipole moment of a current loop can also be calculated from a suitable parametrization via the definition,

$$\boxed{\mathbf{m} = \tfrac{1}{2} \int \mathbf{r}' \times \mathbf{j}(\mathbf{r}', t) d^3 r'} \ . \tag{15.43}$$

15.4.2 Exercises

15.4.2.1 Ex: Magnetic moment

Calculate the torque on a rectangular coil with N loops placed in a homogeneous magnetic field, as shown in the figure.

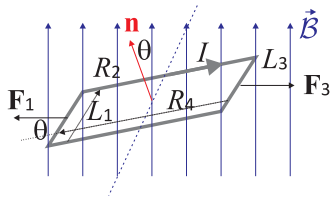

Figure 15.19: Magnetic moment.

Solution:

15.4.2.2 Ex: Magnetic moment

a. Determine the magnetic moment of a circular conducting loop with radius R carrying a current I_1. The loop is in the xy-plane.
b. Now two outer segments of the circle are deformed at a distance a at right angles to the direction $-\hat{\mathbf{e}}_z$. What is the magnetic moment of the new configuration.
c. Now consider an infinitely long current line I_2 at a distance d from the origin and oriented in z-direction. What is the torque acting on the configurations in (a) and (b).

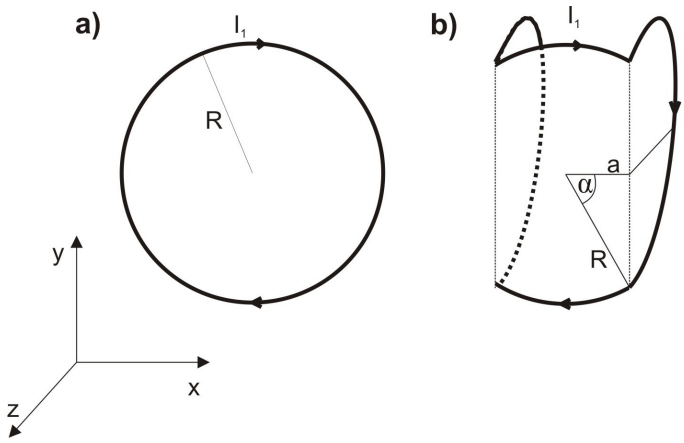

Figure 15.20: Magnetic moment.

Solution: *a.* $\mathbf{m}_1 = I_1\mathbf{F} = -\pi r^2 I_1 \hat{\mathbf{e}}_z$

b. The magnetic moment of the deformed segments is exactly opposite. Therefore, only the magnetic moment of the area in the plane x-y is relevant. The inner area has the value: $F = r^2(\pi - 2\alpha - \sin 2\alpha)$ *with* α *in rad. Hence,* $\mathbf{m}_2 = I_1\mathbf{F} = -r^2(\pi - 2\alpha - \sin 2\alpha)I_1\hat{\mathbf{e}}_z$.
c. The magnetic field of an infinitely long wire is given by:

$$\mathcal{B}(r) = \mu_0 I_2/2\pi r \Rightarrow \mathcal{B}(d) = \mu_0 I_2/2\pi d \ .$$

In the questions (a) and (b): $\mathbf{d}_{1,2} = \mathbf{m}_{1,2} \times \vec{\mathcal{B}}$.

15.4.2.3 Ex: Magnetic moment of a cube

A conductor carries the current $I = 6\,\mathrm{A}$ along the path shown in the figure, which runs through 8 of the 12 corners of the cube whose length is $L = 10\,\mathrm{cm}$.
a. Calculate dipole magnetic moment along the way.
b. Calculate the magnetic induction $\vec{\mathcal{B}}$ at the points $(x, y, z) = (0, 5\,\mathrm{m}, 0)$ and $(x, y, z) = (5\,\mathrm{m}, 0, 0)$.

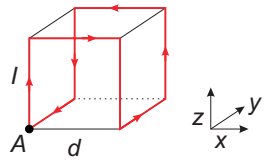

Figure 15.21: Magnetic moment.

Solution: *a. Explicitly the magnetic moment follows from the definition,*

$$\mathbf{m} = \tfrac{1}{2}\int \mathbf{r}' \times \mathbf{j}(\mathbf{r}')d^3\mathbf{r}' \ .$$

Hence,

$$
\begin{aligned}
\mathbf{m} &= \frac{1}{2}\int \mathbf{r}'\times\hat{\mathbf{e}}_z\delta(x')\delta(y')d^3\mathbf{r}' + \frac{1}{2}\int \mathbf{r}'\times\hat{\mathbf{e}}_x\delta(y')\delta(z'-L)d^3\mathbf{r}' - \frac{1}{2}\int \mathbf{r}'\times\hat{\mathbf{e}}_z\delta(x'-L)\delta(y')d^3\mathbf{r}' \\
&+ \frac{1}{2}\int \mathbf{r}'\times\hat{\mathbf{e}}_y\delta(x'-L)\delta(z')d^3\mathbf{r}' + \frac{1}{2}\int \mathbf{r}'\times\hat{\mathbf{e}}_z\delta(x'-L)\delta(y'-L)d^3\mathbf{r}' - \frac{1}{2}\int \mathbf{r}'\times\hat{\mathbf{e}}_x\delta(y'-L)\delta(z'-L)d^3\mathbf{r}' \\
&- \frac{1}{2}\int \mathbf{r}'\times\hat{\mathbf{e}}_z\delta(x')\delta(y'-L)d^3\mathbf{r}' - \frac{1}{2}\int \mathbf{r}'\times\hat{\mathbf{e}}_y\delta(x')\delta(z')d^3\mathbf{r}' \\
&= \frac{1}{2}\int_0^L \begin{pmatrix} y' \\ -x' \\ 0 \end{pmatrix}\delta(x')\delta(y')d^3\mathbf{r}' + \frac{1}{2}\int_0^L \begin{pmatrix} 0 \\ z' \\ -y' \end{pmatrix}\delta(y')\delta(z'-L)d^3\mathbf{r}' - \frac{1}{2}\int_0^L \begin{pmatrix} y' \\ -x' \\ 0 \end{pmatrix}\delta(x'-L)\delta(y')d^3\mathbf{r}' \\
&+ \frac{1}{2}\int \begin{pmatrix} -z' \\ 0 \\ x' \end{pmatrix}\delta(x'-L)\delta(z')d^3\mathbf{r}' + \frac{1}{2}\int \begin{pmatrix} y' \\ -x' \\ 0 \end{pmatrix}\delta(x'-L)\delta(y'-L)d^3\mathbf{r}' - \frac{1}{2}\int \begin{pmatrix} 0 \\ z' \\ -y' \end{pmatrix}\delta(y'-L)\delta(z'-L)d^3\mathbf{r}' \\
&- \frac{1}{2}\int \begin{pmatrix} y' \\ -x' \\ 0 \end{pmatrix}\delta(x')\delta(y'-L)d^3\mathbf{r}' - \frac{1}{2}\int \begin{pmatrix} -z' \\ 0 \\ x' \end{pmatrix}\delta(x')\delta(z')d^3\mathbf{r}' \\
&= \frac{1}{2}\int_0^L \begin{pmatrix} 0 \\ 0 \\ 0 \end{pmatrix}dz' + \frac{1}{2}\int_0^L \begin{pmatrix} 0 \\ L \\ 0 \end{pmatrix}dx' - \frac{1}{2}\int_0^L \begin{pmatrix} 0 \\ -L \\ 0 \end{pmatrix}dx' \\
&+ \frac{1}{2}\int_0^L \begin{pmatrix} 0 \\ 0 \\ L \end{pmatrix}dy' + \frac{1}{2}\int_0^L \begin{pmatrix} L \\ -L \\ 0 \end{pmatrix}dz' - \frac{1}{2}\int_0^L \begin{pmatrix} 0 \\ L \\ -L \end{pmatrix}dx' \\
&- \frac{1}{2}\int_0^L \begin{pmatrix} L \\ 0 \\ 0 \end{pmatrix}dz' - \frac{1}{2}\int_0^L \begin{pmatrix} 0 \\ 0 \\ 0 \end{pmatrix}dy' \\
&= \frac{L^2}{2}\left(\mathbf{0} + \hat{\mathbf{e}}_y + \hat{\mathbf{e}}_y + \hat{\mathbf{e}}_z + (\hat{\mathbf{e}}_x - \hat{\mathbf{e}}_y) - (\hat{\mathbf{e}}_y - \hat{\mathbf{e}}_z) - \hat{\mathbf{e}}_x - \vec{0}\right) = L^2\hat{\mathbf{e}}_z \ .
\end{aligned}
$$

Alternatively, the path can be decomposed into three flat loops. Their magnetic moments are additive,

$$\mathbf{m} = \mathbf{m}_{x=0,y,z} + \mathbf{m}_{x,y,z=L} + \mathbf{m}_{x=L,y,z} = -L^2\hat{\mathbf{e}}_x + L^2\hat{\mathbf{e}}_z + L^2\hat{\mathbf{e}}_x = L^2\hat{\mathbf{e}}_z \ .$$

15.4.2.4 Ex: Magnetic moment of thin circular disk

Consider a very thin disk with radius R, homogeneously charged with the charge Q, and spinning around the z-axis with angular velocity ω.
a. Parametrize the charge and current distributions.
b. Calculate the magnetic moment.

Solution: *a. The charge distribution is,*

$$\rho(\mathbf{r}) = \frac{Q}{\pi R^2}\delta(z) \qquad para \qquad r \le R \ .$$

The current distribution is,

$$\mathbf{j}(\mathbf{r}) = \rho(\mathbf{r})\vec{v}(\mathbf{r}) = \rho(\mathbf{r})\vec{\omega}\times\mathbf{r} = \frac{Q}{\pi R^2}\delta(z)\omega r\hat{\mathbf{e}}_\phi \qquad for \qquad r \le R \ .$$

b. With this we get the magnetic moment,

$$\vec{m} = \frac{1}{2}\int_V \mathbf{r}\times\mathbf{j}(\mathbf{r})\; d^3\mathbf{r} = \frac{1}{2}\frac{Q}{\pi R^2}\omega\int_V \delta(z) r^2 \hat{\mathbf{e}}_r \times \hat{\mathbf{e}}_\phi \; d^3\mathbf{r}$$
$$= \frac{1}{2}\frac{Q}{\pi R^2}\omega\hat{\mathbf{e}}_z \int_0^{2\pi}\int_0^R r^2 \; r dr d\phi = \frac{1}{2}\frac{Q}{\pi R^2}\omega\hat{\mathbf{e}}_z 2\pi\frac{R^4}{4} = \frac{1}{4}QR^2\omega\hat{\mathbf{e}}_z \; .$$

15.4.2.5 Ex: Magnetic compass

A topographer uses a magnetic compass while standing 6.1 m under a high voltage line on which flows a current of 100 A. The horizontal component of the Earth's magnetic field at this place is 20 μT. How large is the magnetic field due to the current at the position of the compass? Will the magnetic field disturb the compass noticeably?

Solution: *The magnetic field of the conductor at the distance r follows from* $\oint \vec{\mathcal{B}}\cdot d\vec{s} = \mu_0 I$*, giving,*

$$\mathcal{B}(r) = \frac{\mu_0 I}{2\pi r} \simeq 3.3\,\mu\mathrm{T} \; .$$

This is not negligible compared to the magnetic field of the Earth.

15.4.2.6 Ex: Torque of a magnetic needle

A magnetic needle has a dipolar magnetic moment $\mu = 10^{-2}\,\mathrm{Am}^2$. Calculate the torque on the needle due to the horizontal component of the Earth's magnetic field at the equator ($\mathcal{B}_H = 4\cdot 10^{-5}\,\mathrm{T}$), if the magnetic north pole of the needle points in northeastern direction.

Solution: *The torque of a magnetic needle is,*

$$\mathbf{d} = \mathbf{m}\times\vec{\mathcal{B}}_H = -m\sin\phi\cdot\mathcal{B}_H\hat{\mathbf{e}}_z = -10^{-2}\,\mathrm{Am}^2\cdot 0.71\cdot 4\cdot 10^{-5}\,\mathrm{T}\cdot\hat{\mathbf{e}}_z = 2.8\cdot 10^{-7}\,\mathrm{Nm}\cdot\hat{\mathbf{e}}_z \; .$$

15.4.2.7 Ex: Curved conductive circuit

A rectangular conducting loop is deformed in the middle of the edges (length a) to form a right angle. The conducting loop is traversed by a current I. Calculate the dipolar magnetic moment $\mathbf{m}$ of this configuration. Give the absolute value and orientation of $\mathbf{m}$.
Help: Use the overlapping principle and replace the above geometry with an overlap of two conductive loops.

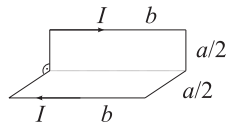

Figure 15.22: Curved conductive circuit.

Solution: *We consider two conductive loops, closed by the dashed line in the figure. For the loop in the xy-plane,*

$$\mathbf{m}_{xy} = \frac{Iab}{2}\hat{\mathbf{e}}_z \ .$$

For the loop in the xz-plane,

$$\mathbf{m}_{xz} = \frac{Iab}{2}\hat{\mathbf{e}}_x \ .$$

In total,

$$\mathbf{m} = \mathbf{m}_{xy} + \mathbf{m}_{xz} = \frac{Iab}{2}(\hat{\mathbf{e}}_z + \hat{\mathbf{e}}_x) \ .$$

The direction of the magnetic momentum is the diagonal in the xz-plane. The absolute value is,

$$m = \frac{Iab}{\sqrt{2}} \ .$$

15.4.2.8 Ex: Magnetic dipole

A magnetic dipole $\vec{\mu} = \mu\hat{\mathbf{e}}_z$ is at origin of the coordinate system and has the value $\mu = 1\,\mathrm{esu}\cdot\mathrm{cm}$. This dipole generates a magnetic field of the form,

$$\vec{\mathcal{B}}(\mathbf{r}) = \frac{3\mathbf{r}(\vec{\mu}\cdot\mathbf{r}) - r^2\vec{\mu}}{r^5} \ .$$

a. At what distance from the origin does the absolute value of $\vec{\mathcal{B}}$ take the value $1\,\mathrm{esu/cm}^2$ going (i) in z-direction, (ii) in x-direction, and (iii) in a diagonal direction with in the xz-plane?
b. Which direction does $\vec{\mathcal{B}}$ point in these three cases?

Solution: *The evaluation of the given formula immediately yields,*

$$\begin{aligned} r^3\mathcal{B}_x &= \mu 3\cos\theta\sin\theta\cos\phi \\ r^3\mathcal{B}_y &= \mu 3\cos\theta\sin\theta\sin\phi \\ r^3\mathcal{B}_z &= \mu(3\cos^2\theta - 1) \ . \end{aligned}$$

For $y = 0$ we obviously have $\phi = 0$ and hence $\sin\phi = 0$ and $\cos\phi = 1$.
a. Thus we get (for $y = 0$),

$$r^3|\vec{\mathcal{B}}| = \mu\sqrt{9\cos^2\theta\sin^2\theta + (3\cos^2\theta - 1)^2} \ .$$

In the direction of the z-axis [case (i)] we have $\theta = 0$, in the direction of the x-axis [case (ii)] we have $\theta = 90°$, and in the diagonal direction [case (iii)] we have $\theta = 45°$. Therefore,

$$(i) \quad r^3|\vec{\mathcal{B}}| = 2\mu \quad , \quad (ii) \quad r^3|\vec{\mathcal{B}}| = \mu \quad , \quad (iii) \quad r^3|\vec{\mathcal{B}}| = \tfrac{\sqrt{10}}{2}\mu \ .$$

For $\mu/|\vec{\mathcal{B}}| = 1\,\mathrm{cm}^3$, giving,

$$(i) \quad r = 2^{1/3}\,\mathrm{cm} \quad , \quad (ii) \quad r = 1\,\mathrm{cm} \quad , \quad (iii) \quad r = (\tfrac{\sqrt{10}}{2})^{1/3}\,\mathrm{cm} \ .$$

b. For the orientations of $\vec{\mathcal{B}}$ in all three cases follows,

$$(i) \quad +\hat{\mathbf{e}}_z \quad , \quad (ii) \quad -\hat{\mathbf{e}}_z \quad , \quad (iii) \quad \tfrac{3}{2}\hat{\mathbf{e}}_x + \tfrac{1}{2}\hat{\mathbf{e}}_z \ .$$

15.4.2.9 Ex: Fields of electric and magnetic point dipoles

a. Calculate the field of an electric dipole taking care to remove the divergence in the center of origin by calculating the field averaged over a sphere and comparing it with known results.
b. Repeat the procedure of (b) for a magnetic dipole.

Solution: *The scalar electrostatic potential and field of an electric dipole at the origin are given by,*

$$\begin{aligned}
\mathbf{\Phi}_{dip}(\mathbf{r}) &= \frac{1}{4\pi\varepsilon_0}\frac{p\cos\theta}{r^2} = \frac{1}{4\pi\varepsilon_0}\frac{\mathbf{p}\cdot\hat{\mathbf{e}}_r}{r^2} \\
\vec{\mathcal{E}}_{dip}(\mathbf{r}) &= -\nabla\Phi_{dip} = \frac{p}{4\pi\varepsilon_0 r^3}(2\hat{\mathbf{e}}_r\cos\theta + \hat{\mathbf{e}}_\theta\sin\theta) = \frac{1}{4\pi\varepsilon_0 r^3}[3(\mathbf{p}\cdot\hat{\mathbf{e}}_r)\hat{\mathbf{e}}_r - \mathbf{p}] \ ,
\end{aligned}$$

where $\mathbf{p}$ is the electric dipole moment. This term appears as the second term in the multipolar expansion of any electrostatic potential $\Phi(\mathbf{r})$. If the source of $\Phi(\mathbf{r})$ is a dipole, this term is the only term that does not go to zero in the multipolar expansion of $\Phi(\mathbf{r})$. The average field is, by symmetry, oriented in z-direction. Hence, using $\hat{\mathbf{e}}_z\cdot\hat{\mathbf{e}}_r = \cos\theta$ and $\hat{\mathbf{e}}_z\cdot\hat{\mathbf{e}}_\theta = -\sin\theta$,

$$\begin{aligned}
\bar{\vec{\mathcal{E}}} &= \frac{\int_0^R\int_0^\pi\int_0^{2\pi}(\vec{\mathcal{E}}_{dip}\cdot\hat{\mathbf{e}}_z)\hat{\mathbf{e}}_z r^2\sin\theta d\theta dr d\phi}{\int_0^R\int_0^\pi\int_0^{2\pi} r^2\sin\theta d\theta dr d\phi} \\
&= \frac{3\mu_0}{8\pi R^3}\hat{\mathbf{e}}_z\int_0^R\frac{1}{r}dr\int_0^\pi(2\cos^2\theta - \sin^2\theta)\sin\theta d\theta = \frac{3\mu_0}{8\pi R^3}\hat{\mathbf{e}}_z\ \infty\cdot 0 \ .
\end{aligned}$$

If we integrate over any lower limit $\epsilon > 0$ out to R, the problem goes away and the integral is a well-behaved zero, $0\cdot\int_\epsilon^R\frac{1}{r}dr = 0$. We know however that average field of a charge distribution within a sphere is,

$$\bar{\vec{\mathcal{E}}} = -\frac{\mathbf{p}}{4\pi\varepsilon_0 R^3} = \frac{-\frac{\mathbf{p}}{3\varepsilon_0}\int_{\mathbb{R}^3}\delta^3(\mathbf{r})d^3r}{\frac{4\pi}{3}R^3} \ .$$

We may thus write (although it is not really correct),

$$\boxed{\vec{\mathcal{E}}_{dip}(\mathbf{r}) = \frac{1}{4\pi\varepsilon_0 r^3}[3(\mathbf{p}\cdot\hat{\mathbf{e}}_r)\hat{\mathbf{e}}_r - \mathbf{p}] - \frac{\mathbf{p}}{3\varepsilon_0}\delta^3(\mathbf{r})} \ ,$$

understanding that the first term doesn't apply at $r = 0$.
b. The vector potential and field of a magnetic dipoles are given by,

$$\mathbf{A}_{dip}(\mathbf{r}) = \frac{\mu_0}{4\pi}\frac{m\sin\theta}{r^2}\hat{\mathbf{e}}_\theta = \frac{\mu_0}{4\pi}\frac{\mathbf{m}\times\hat{\mathbf{e}}_r}{r^2}$$
$$\vec{\mathcal{B}}_{dip}(\mathbf{r}) = \nabla\times\mathbf{A}_{dip} = \frac{\mu_0 m}{4\pi r^3}(2\hat{\mathbf{e}}_r\cos\theta + \hat{\mathbf{e}}_\theta\sin\theta) = \frac{\mu_0 m}{4\pi r^3}[3(\mathbf{m}\cdot\hat{\mathbf{e}}_r)\hat{\mathbf{e}}_r - \mathbf{m}] \ ,$$

where $\mathbf{r}$ is the vector between the position of the dipole to the position where the field is measured. It is exactly the field of a point-like dipole, just the dipolar term in the multipole expansion of an arbitrary field, and roughly the field of an arbitrary dipolar configuration at long distance. The average is, by symmetry, in the z-direction. Hence, using $\hat{\mathbf{e}}_z\cdot\hat{\mathbf{e}}_r = \cos\theta$ and $\hat{\mathbf{e}}_z\cdot\hat{\mathbf{e}}_\theta = -\sin\theta$,

$$\bar{\vec{\mathcal{B}}} = \frac{\int_0^R\int_0^\pi\int_0^{2\pi}(\vec{\mathcal{B}}_{dip}\cdot\hat{\mathbf{e}}_z)\hat{\mathbf{e}}_z r^2\sin\theta d\theta dr d\phi}{\int_0^R\int_0^\pi\int_0^{2\pi} r^2\sin\theta d\theta dr d\phi}$$
$$= \frac{3\mu_0}{8\pi R^3}\hat{\mathbf{e}}_z\int_0^R\frac{1}{r}dr\int_0^\pi(2\cos^2\theta - \sin^2\theta)\sin\theta d\theta = \frac{3\mu_0}{8\pi R^3}\hat{\mathbf{e}}_z\ \infty\cdot 0 \ .$$

If we integrate over any lower limit $\epsilon > 0$ out to R, the problem goes away and the integral is a well-behaved zero, $0\cdot\int_\epsilon^R\frac{1}{r}dr = 0$. We know however that average field of a charge distribution within a sphere is,

$$\bar{\vec{\mathcal{B}}} = \frac{2\mu_0\mathbf{m}}{4\pi R^3} = \frac{\frac{2}{3}\mu_0\mathbf{m}\int_{R^3}\delta^3(\mathbf{r})d^3r}{\frac{4\pi}{3}R^3} \ .$$

We may thus write (although it is not really correct),

$$\boxed{\vec{\mathcal{B}}_{dip}(\mathbf{r}) = \frac{\mu_0 m}{4\pi r^3}[3(\mathbf{m}\cdot\hat{\mathbf{e}}_r)\hat{\mathbf{e}}_r - \mathbf{m}] + \frac{2}{3}\mu_0\mathbf{m}\delta^3(\mathbf{r})} \ ,$$

understanding that the first term doesn't apply at $r = 0$.
In cylindrical coordinates the distant field of a magnetic dipole is given by,

$$\mathcal{B}(m, r, \lambda) = \frac{\mu_0}{4\pi}\frac{m}{r^3}\sqrt{1 + 3\sin^2\lambda} \ ,$$

where r is the distance from the center, λ is the magnetic latitude (equal to $0^\circ - \theta$, where θ is measured from the dipole axis. We convert to cylindrical coordinates using $r^2 = z^2 + \rho^2$ and $\lambda = \arcsin\frac{z}{\sqrt{z^2+\rho^2}}$, where ρ is the perpendicular distance from the z-axis. So,

$$\mathcal{B}(\rho, z) = \frac{\mu_0 m}{4\pi(z^2+\rho^2)^{3/2}}\sqrt{1 + \frac{3z^2}{z^2+\rho^2}} \ .$$

15.4.2.10 Ex: Magnetic dipole moment of a rectangular conducting loop

A (ideal) rectangular conducting loop with edge lengths a and b carries a current I.
a. Give the current density distribution $\mathbf{j}$.
b. Calculate the corresponding dipolar magnetic moment $\vec{\mathcal{M}}$.

Solution: *a. We place the conducting loop symmetrically around the origin within the xy-plane. The current density distribution is then,*

$$\mathbf{j}(\mathbf{r}) = I\delta(z)\left[(\delta(x-\tfrac{a}{2})-\delta(x+\tfrac{a}{2}))\Theta(\tfrac{b}{2}-|y|)\hat{\mathbf{e}}_y-(\delta(y-\tfrac{b}{2})-\delta(x+\tfrac{b}{2}))\Theta(\tfrac{a}{2}-|x|)\hat{\mathbf{e}}_x\right] .$$

b. We have,

$$\begin{aligned}\mathbf{r}\times\mathbf{j}(\mathbf{r}) = I\delta(z)\big[&(\delta(x-\tfrac{a}{2})-\delta(x+\tfrac{a}{2}))\Theta(\tfrac{b}{2}-|y|)x\hat{\mathbf{e}}_z+(\delta(y-\tfrac{b}{2})-\delta(y+\tfrac{b}{2}))\Theta(\tfrac{a}{2}-|x|)y\hat{\mathbf{e}}_z\\ &-(\delta(x-\tfrac{a}{2})-\delta(x+\tfrac{a}{2}))\Theta(\tfrac{b}{2}-|y|)z\hat{\mathbf{e}}_x-(\delta(y-\tfrac{b}{2})-\delta(y+\tfrac{b}{2}))\Theta(\tfrac{a}{2}-|x|)z\hat{\mathbf{e}}_y\big] .\end{aligned}$$

We use now that,

$$\int dy\Theta(\tfrac{b}{2}-|y|) = \int_{-b/2}^{+b/2} dy = b .$$

and we immediately get,

$$\vec{\mathcal{M}} = \frac{1}{2c}\int d^3\mathbf{r}'\ (\mathbf{r}'\times\mathbf{j}(\mathbf{r}')) = \frac{Iab}{c}\hat{\mathbf{e}}_z .$$

15.4.2.11 Ex: Dipolar magnetic moment of a rectangular loop

The rectangular conducting loop of Exc. 15.4.2.10 is deformed in the middle of the edges (length a) to form a right angle (see figure). It is traversed by a current I. Calculate the dipolar magnetic moment of this geometry.

Solution: *We first want to solve the exercise 'by hand'. For the current density distribution holds,*

$$\begin{aligned}\mathbf{j}(\mathbf{r}) = I\big\{&\delta(z)\delta(x-\tfrac{a}{2}\Theta(\tfrac{b}{2}-|y|)\hat{\mathbf{e}}_y-\delta(x)\delta(z-\tfrac{a}{2})\Theta(\tfrac{b}{2}-|y|)\hat{\mathbf{e}}_y\\ &-\delta(z)(\delta(y-\tfrac{b}{2})-\delta(y+\tfrac{b}{2}))\Theta(\tfrac{a}{2}-x)\Theta(x)\hat{\mathbf{e}}_x+\delta(x)(\delta(y-\tfrac{b}{2})-\delta(y+\tfrac{b}{2}))\Theta(\tfrac{a}{2}-z)\Theta(z)\hat{\mathbf{e}}_z\big\} .\end{aligned}$$

This gives,

$$\begin{aligned}\mathbf{r}\times\mathbf{j}(\mathbf{r}) = I\ \big\{&\delta(z)\delta(x-\frac{a}{2})\Theta(\tfrac{b}{2}-|y|)(x\hat{\mathbf{e}}_z-z\hat{\mathbf{e}}_x)-\delta(x)\delta(z-\tfrac{a}{2})\Theta(\tfrac{b}{2}-|y|)(x\hat{\mathbf{e}}_z-z\hat{\mathbf{e}}_x)\\ &\delta(z)(\delta(y-\tfrac{b}{2})-\delta(y+\tfrac{b}{2}))\Theta(\tfrac{a}{2}-x)\Theta(x)(z\hat{\mathbf{e}}_y-y\hat{\mathbf{e}}_z)\\ &+\delta(x)(\delta(y-\tfrac{b}{2})-\delta(y+\tfrac{b}{2}))\Theta(\tfrac{a}{2}-z)\Theta(z)(y\hat{\mathbf{e}}_x-x\hat{\mathbf{e}}_y)\big\} .\end{aligned}$$

Integration provides immediately,

$$\vec{\mathcal{M}} = \frac{I}{2c}\left(\frac{ba}{2}\hat{\mathbf{e}}_z\ +\ \frac{ba}{2}\hat{\mathbf{e}}_x+\frac{ba}{2}\hat{\mathbf{e}}_z\ +\ \frac{ba}{2}\hat{\mathbf{e}}_x\right) = \frac{Iab}{2c}(\hat{\mathbf{e}}_z+\hat{\mathbf{e}}_x) .$$

However, we can solve the exercise much more elegantly by letting the same current I run in the directions $+z$ and $-z$, as well. The total current then disappears. Now, we are considering two independent rectangular loops (edge lengths b and $a/2$). Exc. ?? then provides for the loop in the xy-plane,

$$\vec{\mathcal{M}}_{xy} = \frac{Iab}{2c}\hat{\mathbf{e}}_z \ .$$

and for the loop in the yz-plane,

$$\vec{\mathcal{M}}_{yz} = \frac{Iab}{2c}\hat{\mathbf{e}}_x \ .$$

therefore,

$$\vec{\mathcal{M}} = \vec{\mathcal{M}}_{xy} + \vec{\mathcal{M}}_{yz} = \frac{Iab}{2c}(\hat{\mathbf{e}}_z + \hat{\mathbf{e}}_x) \ .$$

15.4.2.12 Ex: Force on the walls of a hollow cylinder

Consider an infinitely long cylindrical shell of radius a in which flows a current. The magnetic force on this hollow cylinder is such that it tries to compress the cylinder. To counteract this force, we can fill the inside of the cylinder with a gas of pressure P. What is the pressure required to balance the magnetic force?

Solution: *We let the current flow in $+z$-direction and choose cylindrical coordinates. So,*

$$\mathbf{j} = \frac{I}{2\pi a}\delta(\rho - a)\hat{\mathbf{e}}_z \ .$$

With the Ampère's law we have,

$$\nabla \times \vec{\mathcal{B}} = \mu_0 \mathbf{j} = \mu_0 \frac{I}{2\pi a}\delta(\rho - a)\hat{\mathbf{e}}_z \ .$$

As the integration area we chose a circular area perpendicular to the symmetry axis of the cylinder with radius ρ and centered at the origin. Application of Stokes's law then gives for $\rho \geq a$,

$$2\pi\rho\mathcal{B}(\rho) = \mu_0 I \ .$$

that is,

$$\vec{\mathcal{B}} = \frac{\mu_0 I}{2\pi\rho}\hat{\mathbf{e}}_\phi \ ,$$

while inside the cylinder the magnetic field obviously zeroes. Now, we calculate the force acting on an infinitesimal area $\Delta S = \rho\Delta\phi\Delta z$ of the conductor by,

$$\begin{aligned}\mathbf{F} &= \int_{\Delta\mathcal{V}} \mathbf{j} \times \vec{\mathcal{B}} dV = \frac{I}{2\pi a}\frac{\mu_0 I}{2\pi}\int_{\Delta\mathcal{V}} \frac{\delta(\rho - a)}{\rho}\hat{\mathbf{e}}_z \times \hat{\mathbf{e}}_\phi \rho d\rho dz d\phi \\ &= \frac{\mu_0 I^2}{4\pi^2 a}\int_0^{\Delta z}\int_0^{\Delta\phi}(-\hat{\mathbf{e}}_\rho)dzd\phi = -\frac{\mu_0 I^2}{4\pi^2 a}\Delta z\Delta\phi\hat{\mathbf{e}}_\rho \ .\end{aligned}$$

Obviously, the direction of the force depends on where we choose the integration volume. To compensate for the force, we need gas exerting the opposite pressure,

$$P = \frac{F}{a\Delta\phi\Delta z} = \frac{\mu_0 I^2}{4\pi^2 a^2} \ .$$

15.4.2.13 Ex: Infinitely dense coil

A coil with N 'infinitely dense' windings carries a current I. It forms with respect to the z-axis a torus with rotational symmetry with an inner radius $b-a$ and an outer radius $b+a$. The figure shows the cross-sectional area of a cut in the plane perpendicular to the xy-plane.
a. Calculate by exploiting the symmetric geometry of this device in cylindrical coordinates (ρ, ϕ, z) a ϕ-component of the magnetic $\vec{\mathcal{B}}$-field in the xy-plane (that is, for $z = 0$) as a function of the distance ρ from the origin of the coordinate system. **Help:** Use Stokes' law.
b. What is the value of the ϕ-component of $\vec{\mathcal{B}}$ in the entire space *outside* of the torus (that is, also for $z \neq 0$).
c. Draw the profile of $\mathcal{B}_\phi(\rho)$ in the $z = 0$ plane as a function of ρ.
d. Let $a = 1$ cm. What should be the value of b in first approximation, so that $\mathcal{B}_\phi$ in the torus is constant within 1%? **Help:** $(1 \pm \epsilon)^{-1} \ \approx \ 1 \mp \epsilon$.

Solution: *a. Because of the symmetry of the device, $\vec{\mathcal{B}}$ is independent of the angle ϕ. We chose as integration area a circular area in the xy ($z = 0$) plane centered at the origin and having the radius ρ. Thus the area element is, $d\mathbf{S} \ \sim \ \hat{\mathbf{e}}_z$ and the border element is $d\mathbf{l} \ \sim \ \hat{\mathbf{e}}_\phi$. With Stokes' law we get for $\mathcal{B}_\phi(\rho)$ in the $z = 0$ plane,*

$$\int\limits_{\mathcal{S}(\rho)} (\nabla \times \vec{\mathcal{B}}) \cdot d\mathbf{S} = \int\limits_{\partial\mathcal{S}(\rho)} \vec{\mathcal{B}} \cdot d\mathbf{l} = 2\pi\rho\mathcal{B}_\phi(\rho) = \frac{4\pi}{c} \int\limits_{\mathcal{S}(\rho)} \mathbf{j} \cdot d\mathbf{l} \ .$$

With that we get,

$$\begin{aligned}
&\text{Für } 0 < \rho < b-a \ : \qquad 2\pi\rho\mathcal{B}_\phi(\rho) = 0 \\
&\text{Für } b-a \leq \rho < b+a \ : \qquad 2\pi\rho\mathcal{B}_\phi(\rho) = \frac{4\pi}{c} \ NI \\
&\text{Für } b+a \leq \rho < \infty \ : \qquad 2\pi\rho\mathcal{B}_\phi(\rho) = \frac{4\pi}{c} \ (NI - NI) = 0 \ .
\end{aligned}$$

b. Outside the torus $\mathcal{B}_\phi$ is zero everywhere, because each circular area symmetrically centered around the z-axis and parallel to the xy-plane with $\rho < b-a$ or $\rho > b+a$ is always traversed by the total current $\int_{\mathcal{S}(\rho)} \mathbf{j} \cdot d\mathbf{S} = 0$.
c. Following part (a) the field $\mathcal{B}_\phi(\rho)$ zeroes for $\rho < b-a$ and $\rho > b+a$. At $\rho = b-a$ it adopts the value $\frac{2NI}{c(b-a)}$ and then drops proportionally $(\frac{1}{\rho})$ down to the value $\frac{2NI}{c(b+a)}$ at $\rho = b+a$.
d. An approximately constant magnetic field in the toroid can be, based on part (c),

only obtained for the case $b \gg a$. We need,

$$\frac{1}{b-a} - \frac{1}{b+a} \approx \frac{1}{100(b+a)} \qquad \textit{resp.} \qquad \frac{1}{1-\frac{a}{b}} - \frac{1}{1+\frac{a}{b}} \approx \frac{1}{100(1+\frac{a}{b})} \ .$$

From this follows in first approximation,

$$1 + \frac{a}{b} - 1 + \frac{a}{b} \approx \frac{1}{100} \qquad \textit{hence} \qquad b \approx 200a \ .$$

For $a = 1\,\mathrm{cm}$, therefore we need $b = 2\,\mathrm{m}$.

15.4.2.14 Ex: Magnetic field in a cylindrical hollow space

Parallel to the axis of an infinitely long massive conducting cylinder of radius a at a distance d from it, there is a hollow cylindrical space of radius b ($d + b < a$). The current density within this perforated metal cylinder is homogeneous and oriented parallel to the symmetry axis. Using Ampère's law and the linear superposition principle, determine the absolute value and orientation of the magnetic field inside the hollow space.

Solution: *To start with we use the known solution for the solid cylinder, replacing the (constant) current density $I/(\pi a^2)$ with j and noting that $\vec{\mathcal{B}}$ only has the ϕ-component. In addition, we focus on the region $r < a$,*

$$\vec{\mathcal{B}}_a = B_a(r)\hat{\mathbf{e}}_\phi = \frac{2\pi j}{c} r\hat{\mathbf{e}}_\phi$$

Now we use $\hat{\mathbf{e}}_\phi = -\sin\phi\hat{\mathbf{e}}_x + \cos\phi\hat{\mathbf{e}}_y$ and $\theta = 90°$. with this,

$$\vec{\mathcal{B}}_a = \frac{2\pi j}{c}(-y\hat{\mathbf{e}}_x + x\hat{\mathbf{e}}_y)$$

In the same way we get for the field of a solid cylinder with radius b, whose center is, as indicated, displaced by d along the x-axis in its interior region,

$$\vec{\mathcal{B}}_b = \frac{2\pi j}{c}(-y\hat{\mathbf{e}}_x + (x-d)\hat{\mathbf{e}}_y)$$

For the field inside and outside the cavity we get simply by subtraction,

$$\vec{\mathcal{B}}_{int} = \frac{2\pi j}{c} d\hat{\mathbf{e}}_y$$

resp., letting the total current be $I = \pi(a^2 - b^2)j$,

$$\vec{\mathcal{B}}_{int} = \frac{2Id}{(a^2-b^2)c}\hat{\mathbf{e}}_y \ .$$

Inside the cavity the field is therefore constant and oriented toward y. It disappears for $d = 0$, i.e. when the empty space is centered.

15.4.2.15 Ex: Torque of a conducting cylinder

Determine the torque (per unit length) felt by a massive conducting cylinder of radius R that slowly rotates with constant angular velocity ω inside a homogeneous $\vec{\mathcal{B}}$-field around its symmetry axis. $\vec{\mathcal{B}}$ be oriented orthogonal to the axis of the cylinder.

Solution: *We place the axis of the cylinder (same as the rotation axis) in direction* 3 *and the $\vec{\mathcal{B}}$-field in direction* 2*. For the torque per unit length l we get,*

$$\frac{\vec{\tau}}{l} = \frac{1}{c} \int\limits_{V(l=1)} d^3\mathbf{r}\mathbf{r} \times (\mathbf{j} \times \vec{\mathcal{B}}) \ .$$

where $V(l=1)$ is the volume of the cylinder with unit length. Denoting the conductivity by σ, the current is given by,

$$\mathbf{j} = \sigma \vec{\mathcal{E}}' = \sigma \left(\frac{\vec{v}}{c} \times \vec{\mathcal{B}} \right) \ .$$

where $\vec{\mathcal{E}}'$ is the induced field in the coordinate system rotating together with the cylinder. Now we use $\mathbf{v} = \vec{\omega} \times \mathbf{r}$ and let $\mathbf{r}$ be within the xy-plane (because we want to determine the torque per unit length). We obtain,

$$\mathbf{j} = \frac{\sigma\omega\mathcal{B}}{c} \left[(\hat{\mathbf{e}}_3 \times \mathbf{r}) \times \hat{\mathbf{e}}_2 \right] = -\frac{\sigma\omega\mathcal{B}}{c} y\hat{\mathbf{e}}_3 \ .$$

Follows,

$$\mathbf{j} \times \vec{\mathcal{B}} = -\frac{\sigma\omega\mathcal{B}^2}{c} y\hat{\mathbf{e}}_3 \times \hat{\mathbf{e}}_2 = \frac{\sigma\omega\mathcal{B}^2}{c} y\hat{\mathbf{e}}_1 \ .$$

as well as,

$$\mathbf{r} \times (\mathbf{j} \times \vec{\mathcal{B}}) = \frac{\sigma\omega\mathcal{B}}{c} y(x\hat{\mathbf{e}}_1 + y\hat{\mathbf{e}}_2) \times \hat{\mathbf{e}}_1 = -\frac{\sigma\omega\mathcal{B}^2}{c} y^2\hat{\mathbf{e}}_3 \ .$$

In cylindrical coordinates we have $y^2 = r^2 \sin^2\phi$ and hence,

$$\frac{\vec{\tau}}{l} = -\frac{\sigma\omega\mathcal{B}^2}{c^2} \int\limits_0^R dr r^3 \int\limits_0^{2\pi} d\phi \sin^2\phi \hat{\mathbf{e}}_3 = -\frac{\pi\sigma\omega\mathcal{B}^2 a^4}{4c^2} \hat{\mathbf{e}}_3 \ .$$

15.4.2.16 Ex: Rotating rings

Consider two 'infinitely thin' concentric rings with radii a and b ($a < b$). The rings are in the xy-plane and their common center is at the origin. On the inner ring there is a homogeneously distributed charge $+q$ (that is, the linear charge density is constant), and the outer ring carries the homogeneously distributed charge $-q$.
a. Write down the charge density $\rho(\mathbf{r}) = \rho(r, \phi, z)$ in cylindrical coordinates.
b. Now the entire device rotates with constant angular velocity ω around the symmetry axis z. Determine the resulting current density $\mathbf{j}(\mathbf{r}) = \mathbf{j}(r, \phi, z)$ in cylindrical

coordinates, as well.
c. What are the Cartesian components of current density $\mathbf{j}$?
d. Calculate the magnetic dipole moment $\mathbf{m}$ of the rotating device.

Solution: *We do the following ansatz* $\rho(\mathbf{r}) = C\delta(z)\delta(r-a) - C\delta(z)\delta(r-b)$. *The normalization is* $q = \int \rho(\mathbf{r})dV$. *a. In cylindrical coordinates the current density is,*

$$\rho(r,\phi,z) = \frac{q}{2\pi}\delta(z)\left[\frac{1}{a}\delta(r-a) - \frac{1}{b}\delta(r-b)\right] \ .$$

b. $\mathbf{v}(r,\phi,z) = r\omega\hat{\mathbf{e}}_\phi$ *and therefore, (since* $Id\mathbf{l} = Qd\mathbf{v}$, *such that* $I = Qr\omega$*),*

$$\mathbf{j}(r,\phi,z) = \frac{q\omega}{2\pi}\delta(z)[\delta(r-a) - \delta(r-b)]\hat{\mathbf{e}}_\phi \ .$$

c. With this we get for the Cartesian coordinates,

$$\begin{aligned} j_x &= -\frac{q\omega}{2\pi}\delta(z)[\delta(r-a) - \delta(r-b)]\sin\phi \\ j_y &= +\frac{q\omega}{2\pi}\delta(z)[\delta(r-a) - \delta(r-b)]\cos\phi \\ j_z &= 0 \ . \end{aligned}$$

d. We have,

$$\mathbf{r}\times\mathbf{j} = \det\begin{pmatrix} \hat{\mathbf{e}}_x & \hat{\mathbf{e}}_y & \hat{\mathbf{e}}_z \\ x & y & z \\ j_x & j_y & 0 \end{pmatrix} = -zj_y\hat{\mathbf{e}}_x + zj_x\hat{\mathbf{e}}_y + (xj_y - yj_x)\hat{\mathbf{e}}_z \ .$$

Hence,

$$\mathbf{m} = \frac{1}{2}\frac{q\omega}{2\pi}\int_0^{2\pi}d\phi'\int_0^\infty dr'r'\int_{-\infty}^\infty dz'\delta(z')[\delta(r'-a)-\delta(r'-b)]\cdot \\ \cdot\left[-z'\cos\phi'\hat{\mathbf{e}}_x - z'\sin\phi'\hat{\mathbf{e}}_y + (r'\cos^2\phi' + r'\sin^2\phi')\hat{\mathbf{e}}_z\right] = \frac{q\omega}{2}[a^2-b^2]\hat{\mathbf{e}}_z \ .$$

d. Alternatively,

$$\mathbf{r}\times\mathbf{j} = (r\hat{\mathbf{e}}_r + z\hat{\mathbf{e}}_z)\times\mathbf{j} = \hat{\mathbf{e}}_z rj = \frac{q\omega}{2\pi}(a\delta(r-a) - b\delta(r-b))\delta(z) \ .$$

Hence,

$$\mathbf{m} = \frac{1}{2}\int_V \mathbf{r}'\times\mathbf{j}(\mathbf{r}')d^3\mathbf{r}' = \frac{1}{2}\frac{q\omega}{2\pi}2\pi\hat{\mathbf{e}}_z\left[\int a\delta(r-a)rdr - \int b\delta(r-b)rdr\right] = \frac{q\omega}{2}\hat{\mathbf{e}}_z(a^2-b^2) \ .$$

15.4.2.17 Ex: Magnetic field inside a current tube

A thin hollow conducting tube is traversed by a current along its symmetry axis. The current is homogeneously distributed. Calculate the magnetic field inside and outside
a. from Ampère's law,
b. from the Biot-Savart law.

Solution: *To find the parametrization for the current density* $\mathbf{j}(\mathbf{r}')$ *we consider the normalization condition,*

$$I = \int_S \mathbf{j}(\mathbf{r}') \cdot d\mathbf{S}' = \eta \int_S I\delta(\rho' - R)\hat{\mathbf{e}}_z \cdot d\mathbf{S}' = \eta I \int_S \delta(\rho' - R)\rho' d\rho' d\phi' = \eta I 2\pi R \ ,$$

giving $\eta = \frac{1}{2\pi R}$*, such that,*

$$\mathbf{j}(\mathbf{r}') = \frac{I}{2\pi R}\delta(\rho' - R)\hat{\mathbf{e}}_z \ .$$

The potential vector is now,

$$\begin{aligned}
\mathbf{A}(\mathbf{r}) &= \frac{\mu_0}{4\pi}\int \frac{\mathbf{j}(\mathbf{r}')dV'}{|\mathbf{r} - \mathbf{r}'|} = \frac{\mu_0}{4\pi}\frac{I}{2\pi R}\int \frac{\delta(\rho' - R)\hat{\mathbf{e}}_z}{|\mathbf{r} - \rho'\hat{\mathbf{e}}_{\rho'} - z'\hat{\mathbf{e}}_z|}\rho' d\rho' d\phi' dz' \\
&= \frac{\mu_0}{4\pi}\frac{I}{2\pi R}\int \frac{\delta(\rho' - R)\hat{\mathbf{e}}_z}{\sqrt{(\rho\cos\phi - \rho'\cos\phi')^2 + (\rho\sin\phi - \rho'\sin\phi')^2 + (z - z')^2}}\rho' d\rho' d\phi' dz' \\
&= \frac{\mu_0 I}{8\pi^2}\hat{\mathbf{e}}_z \int \frac{1}{\sqrt{\rho^2 + R^2 - 2R\rho\cos(\phi + \phi') + (z - z')^2}} d\phi' dz' \ ,
\end{aligned}$$

as the result cannot depend on z *nor on* ϕ*, we can set* $z = 0$ *and* $\phi = 0$*,*

$$\mathbf{A}(\mathbf{r}) = \frac{\mu_0 I}{8\pi^2}\hat{\mathbf{e}}_z \int_0^{2\pi}\int_{-\infty}^{\infty} \frac{1}{\sqrt{\rho^2 + R^2 - 2R\rho\cos\phi' + z'^2}} dz' d\phi' = ???$$

Maybe the magnetic field is easier to calculate,

$$\begin{aligned}
\vec{\mathcal{B}}(\mathbf{r}) &= \frac{\mu_0}{4\pi}\int \frac{\mathbf{j}(\mathbf{r}') \times (\mathbf{r} - \mathbf{r}')dV'}{|\mathbf{r} - \mathbf{r}'|^3} \\
&= \frac{\mu_0}{4\pi}\frac{I}{2\pi R}\int \frac{\delta(\rho' - R)\hat{\mathbf{e}}_z \times (\mathbf{r} - \mathbf{r}')}{\sqrt{(\rho\cos\phi - \rho'\cos\phi')^2 + (\rho\sin\phi - \rho'\sin\phi')^2 + (z - z')^2}^3}\rho' d\rho' d\phi' dz' \\
&= \frac{\mu_0 I}{8\pi^2}\int \frac{\rho\hat{\mathbf{e}}_\phi - \rho'\hat{\mathbf{e}}_{\phi'}}{\sqrt{\rho^2 + R^2 - 2R\rho\cos(\phi + \phi') + (z - z')^2}^3} d\phi' dz' \ .
\end{aligned}$$

Since the result cannot depend on z *nor on* ϕ*, we can set* $z = 0$ *and* $\phi = 0$*. For this choice the* x*-component vanishes,*

$$\mathcal{B}_x(\mathbf{r}) = \frac{\mu_0 I}{8\pi^2}\int_{-\infty}^{\infty}\int_0^{2\pi} \frac{R\sin\phi'}{\sqrt{\rho^2 + R^2 - 2R\rho\cos\phi' + z'^2}^3} d\phi' dz' = 0$$

and the y*-component*

$$\mathcal{B}_y(\mathbf{r}) = \frac{\mu_0 I}{8\pi^2}\int_{-\infty}^{\infty}\int_0^{2\pi} \frac{\rho - R\cos\phi'}{\sqrt{\rho^2 + R^2 - 2R\rho\cos\phi' + z'^2}^3} d\phi' dz' = ???$$

15.4.2.18 Ex: Magnetic induction in a hollow conductor

A conductor (ideal and infinitely thin) be on the z-axis and carries a current I flowing in $+z$-direction. This conductor is enclosed by a conductive hollow cylinder with radius R, within which a homogeneously distributed total current I runs in the opposite direction $-z$ (coaxial cable). Calculate the magnetic induction inside and outside this device.

Solution: *In cylindrical coordinates we have,*

$$\mathbf{j}(\mathbf{r}) = \left[\frac{I}{\rho}\delta(\rho)\delta(\phi) - \frac{I}{2\pi R}\delta(\rho - R)\right]\hat{\mathbf{e}}_z \ .$$

We now use for the integration a circular area with radius ρ in $+z$-direction. So, $d\vec{f} = \rho' d\rho' d\phi' \hat{\mathbf{e}}_z$ and hence,

$$\int\limits_{F(\rho)} (\nabla \times \vec{\mathcal{B}}) \cdot d\mathbf{f} = \frac{4\pi}{c} \int\limits_{F(\rho} \mathbf{j} \cdot d\mathbf{f} = \frac{4\pi}{c} I \begin{cases} 1 & for \rho < R \\ 0 & else \end{cases}$$
$$= \int\limits_{R(\rho} \vec{\mathcal{B}} \cdot d\vec{s} = 2\pi\rho\mathcal{B}(\rho)$$

With that we immediately get,

$$\vec{\mathcal{B}} = \frac{2I}{c\rho} \begin{cases} 1 & for \rho < R \\ 0 & else \end{cases} \ .$$

15.4.2.19 Ex: Current ring

A (ideal) current ring in the xy-plane with radius a and centered at the origin is traversed by a current I. In spherical coordinates the current density is given by,

$$\mathbf{j}(\mathbf{r}) = \mathbf{j}(r, \theta, \phi) = \frac{I}{a}\delta(\cos\theta)\delta(r - a)\hat{\mathbf{e}}_\phi \ .$$

For $|\mathbf{r}| \gg a$ the corresponding potential then has the form,

$$\mathbf{A}(\mathbf{r}) = \mathbf{A}(r, \theta, \phi) = \frac{I\pi a^2}{cr^2} \sin\theta \hat{\mathbf{e}}_\phi \ .$$

and for magnetic field holds,

$$\vec{\mathcal{B}}(\mathbf{r}) = \vec{\mathcal{B}}(r, \theta, \phi) = \frac{I\pi a^2}{cr^3} \left(2\cos\theta \hat{\mathbf{e}}_r + \sin\theta \hat{\mathbf{e}}_\theta\right) \ .$$

where $\hat{\mathbf{e}}_r$, $\hat{\mathbf{e}}_\theta$, and $\hat{\mathbf{e}}_\phi$ are the unit vectors in r, θ, and ϕ-direction.
a. Calculate the Cartesian components of $\mathbf{j}(\mathbf{r})$.

b. Calculate the Cartesian components of the dipolar magnetic moment $\vec{\mathcal{M}}$ using the formula,

$$\vec{\mathcal{M}} = \frac{1}{2c}\int d^3r'(\mathbf{r}' \times \mathbf{j}(\mathbf{r}')) \ .$$

c. What are the components of $\vec{\mathcal{M}}$ in r, θ, and ϕ-direction.
d. Show with the help of (c) that the magnetic field at a point $\mathbf{r}$ of the arbitrary surface can be written,

$$\vec{\mathcal{B}}(\mathbf{r}) = \frac{3\hat{\mathbf{e}}_r(\vec{\mathcal{M}}\cdot\hat{\mathbf{e}}_r) - \vec{\mathcal{M}}}{r^3} \ .$$

e. Calculate the Cartesian components of magnetic field and check, with the help of (b), that also in Cartesian coordinates holds,

$$\vec{\mathcal{B}}(\mathbf{r}) = \frac{3\mathbf{r}(\vec{\mathcal{M}}\cdot\mathbf{r}) - r^2\vec{\mathcal{M}}}{r^5} \ .$$

Solution: *a. We have,*

$$\begin{aligned}
\hat{\mathbf{e}}_r &= \sin\theta\cos\phi\hat{\mathbf{e}}_x + \sin\theta\sin\phi\hat{\mathbf{e}}_y + \cos\theta\hat{\mathbf{e}}_z \\
\hat{\mathbf{e}}_\theta &= \cos\theta\cos\phi\hat{\mathbf{e}}_x + \cos\theta\sin\phi\hat{\mathbf{e}}_y - \sin\theta\hat{\mathbf{e}}_z \\
\hat{\mathbf{e}}_\phi &= -\sin\phi\hat{\mathbf{e}}_x + \cos\phi\hat{\mathbf{e}}_y \ .
\end{aligned}$$

From this follows,

$$\mathbf{j}(\mathbf{r}) = j_x(r,\theta,\phi)\hat{\mathbf{e}}_x + j_y(r,\theta,\phi)\hat{\mathbf{e}}_y = \frac{I}{a}\delta(r-a)\delta(cos\theta)\begin{pmatrix} -\sin\phi \\ \cos\phi \\ 0 \end{pmatrix} \ .$$

b. With the result of (a) we get,

$$\mathbf{r}\times\mathbf{j}(\mathbf{r}) = \det\begin{pmatrix} \hat{\mathbf{e}}_x & \hat{\mathbf{e}}_y & \hat{\mathbf{e}}_z \\ x & y & z \\ j_x & j_y & 0 \end{pmatrix} = -zj_y\hat{\mathbf{e}}_x + zj_x\hat{\mathbf{e}}_y + (xj_y - yj_x)\hat{\mathbf{e}}_z \ .$$

Now,

$$x = r\sin\theta\cos\phi, \quad y = r\sin\theta\sin\phi \qquad \textit{and} \qquad z = r\cos\theta \ ,$$

and therefore we get,

$$\begin{aligned}
\mathbf{r}\times\mathbf{j}(\mathbf{r}) = -\frac{I}{a}\delta(r-a)\delta(\cos\theta)r[&\cos\theta\cos\phi\hat{\mathbf{e}}_x + \cos\theta\sin\phi\hat{\mathbf{e}}_y \\
&- (\sin\theta\cos^2\phi + \sin\theta\sin^2\phi)\hat{\mathbf{e}}_z] \ .
\end{aligned}$$

that is,

$$\mathbf{r}\times\mathbf{j}(\mathbf{r}) = -\frac{I}{a}\delta(r-a)\delta(\cos\theta)r[\cos\theta\cos\phi\hat{\mathbf{e}}_x + \cos\theta\sin\phi\hat{\mathbf{e}}_y - \sin\theta\hat{\mathbf{e}}_z] \ .$$

With that we get,

$$\begin{aligned}\vec{\mathcal{M}} &= \frac{1}{2c}\int d^3\mathbf{r}'\mathbf{r}'\times\mathbf{j}(\mathbf{r}') \\ &= -\frac{I}{2ac}\int dr'd(\cos\theta')d\phi' {r'}^3\delta(\cos\theta')\delta(r'-a)[\cos\theta'\cos\phi'\hat{\mathbf{e}}_x+\cos\theta'\sin\phi'\hat{\mathbf{e}}_y-\sin\theta'\hat{\mathbf{e}}_z]\ .\end{aligned}$$

Due to $\delta(\cos\theta')$ only the last term survives, and we get,

$$\vec{\mathcal{M}} = \frac{Ia^2\pi}{c}\hat{\mathbf{e}}_z\ .$$

c. Here we need to express Cartesian unit vectors by spherical coordinates. A simple calculation [see (a)] gives,

$$\begin{aligned}\hat{\mathbf{e}}_x &= \cos\phi\sin\theta\hat{\mathbf{e}}_r+\cos\phi\cos\theta\hat{\mathbf{e}}_\theta-\sin\phi\hat{\mathbf{e}}_\phi \\ \hat{\mathbf{e}}_y &= \sin\phi\sin\theta\hat{\mathbf{e}}_r+\sin\phi\cos\theta\hat{\mathbf{e}}_\theta+\cos\phi\hat{\mathbf{e}}_\phi \\ \hat{\mathbf{e}}_z &= \cos\theta\hat{\mathbf{e}}_r-\sin\theta\hat{\mathbf{e}}_\theta\ .\end{aligned}$$

With that we get immediately,

$$\mathcal{M}_r = \frac{Ia^2\pi}{c}\cos\theta \quad , \quad \mathcal{M}_\theta = -\frac{Ia^2\pi}{c}\sin\theta \quad , \quad \mathcal{M}_\phi = 0\ .$$

d. We obtain,

$$\frac{3\hat{\mathbf{e}}_r(\vec{\mathcal{M}}\cdot\hat{\mathbf{e}}_r)-\vec{\mathcal{M}}}{r^3} = \frac{Ia^2\pi}{cr^3}(3\cos\theta\hat{\mathbf{e}}_r-\cos\theta\hat{\mathbf{e}}_r+\sin\theta\hat{\mathbf{e}}_\theta) = \frac{Ia^2\pi}{cr^3}[2\cos\theta\hat{\mathbf{e}}_r+\sin\theta\hat{\mathbf{e}}_\theta] = \vec{\mathcal{B}}(\mathbf{r})\ .$$

e. With part (c) follows,

$$\begin{aligned}2\cos\theta\hat{\mathbf{e}}_r+\sin\theta\hat{\mathbf{e}}_\theta &= 2\cos\theta\sin\theta\cos\phi\hat{\mathbf{e}}_x+2\cos\theta\sin\theta\sin\phi\hat{\mathbf{e}}_y+2\cos^2\theta\hat{\mathbf{e}}_z \\ &\quad+\sin\theta\cos\theta\cos\phi\hat{\mathbf{e}}_x+\sin\theta\cos\theta\sin\phi\hat{\mathbf{e}}_y-\sin^2\theta\hat{\mathbf{e}}_z \\ &= 3\sin\theta\cos\theta\cos\phi\hat{\mathbf{e}}_x+3\sin\theta\cos\theta\sin\phi\hat{\mathbf{e}}_y+(3\cos^2\theta-1)\hat{\mathbf{e}}_z\ .\end{aligned}$$

Therefore, we get,

$$\vec{\mathcal{B}} = \frac{3Ia^2\pi}{cr^3}\begin{pmatrix}\cos\theta\sin\theta\cos\phi\\ \cos\theta\sin\theta\sin\phi\\ \cos^2\theta-\frac{1}{3}\end{pmatrix}\ .$$

With

$$\mathcal{M}_x = \mathcal{M}_y = 0 \quad , \quad \mathcal{M}_z = \frac{Ia^2\pi}{c}\ ,$$

follows immediately,

$$\begin{aligned}\frac{3\mathbf{r}(\vec{\mathcal{M}}\cdot\mathbf{r})}{r^5}-\frac{\vec{\mathcal{M}}}{r^3} &= \frac{Ia^2\pi}{cr^3}\left[\frac{3\mathbf{r}z}{r^2}-\hat{\mathbf{e}}_z\right] \\ &= \frac{Ia^2\pi}{cr^3}\left[\frac{3xz}{r^2}\hat{\mathbf{e}}_x+\frac{3yz}{r^2}\hat{\mathbf{e}}_y+\frac{3z^2}{r^2}\hat{\mathbf{e}}_z-\hat{\mathbf{e}}_z\right] \\ &= \frac{Ia^2\pi}{cr^3}\left[3\cos\theta\sin\theta\cos\phi\hat{\mathbf{e}}_x+3\cos\theta\sin\theta\sin\phi\hat{\mathbf{e}}_y+(3\cos^2\theta-1)\hat{\mathbf{e}}_z\right] = \vec{\mathcal{B}}(\mathbf{r})\ .\end{aligned}$$

15.4.2.20 Ex: Magnetic field of a long coil

Determine the magnetic $\vec{\mathcal{H}}$-field inside a very long current-carrying coil. The number of turns is n, the length of the coil l, its radius a, and the amplitude of the current I. How does the magnetic field change, if the coil has an iron core with the permeability μ?

Solution: *We place the symmetry axis of the coil on the x-axis and choose as integration path a rectangle in the xz-plane defined by the points.* $(0,0,0)$, $(s,0,0)$, $(s,0,b)$, *and (0,0,b). Here we choose $b > a$ so big that $\vec{\mathcal{H}}$ will vanish there. With that, we get immediately, by applying Stokes' law,*

$$\int_{\mathcal{S}} (\nabla \times \vec{\mathcal{H}}(\mathbf{r})) \cdot d\mathbf{S} = \int_{\partial\mathcal{S}} \vec{\mathcal{H}}(\mathbf{r}) \cdot d\mathbf{r} = \frac{4\pi}{c} \int_{\mathcal{S}} \mathbf{j}(\mathbf{r}) \cdot d\mathbf{S} = \mathcal{H}s = \frac{4\pi}{c} \frac{n}{l} sI \ .$$

Inserting the iron core into the coil changes the magnetic $\vec{\mathcal{B}}$-field, but not the $\vec{\mathcal{H}}$-field inside the coil. So we get for the interior,

$$\mathcal{H} = \frac{4\pi}{c} \frac{n}{l} I \qquad , \qquad \mathcal{B} = \mu \frac{4\pi}{c} \frac{n}{l} I \ .$$

15.4.2.21 Ex: Shielded dipolar field

The magnetic field of a dipole is shielded by a hollow sphere (inner radius a, outer radius b) made of a material with permeability μ. The dipole $\vec{\mathcal{P}}_M$ is in the center of the sphere and points towards z.
a. Show that the magnetic field $\vec{\mathcal{H}}$ in the entire space can be written as the negative gradient of a potential $\Phi_M(\mathbf{r})$.
b. Show that this magnetic potential satisfies the Laplace equation in whole space, $\triangle \Phi_M(\mathbf{r}) = 0$.
c. To solve this Laplace equation, do the following ansatz of variable separation,

$$\Phi_M^{(i)}(r, \theta\phi) = \sum_{l=0}^{\infty} \sum_{m=-l}^{+l} \frac{4\pi}{2l+1} \left[\beta_{lm}^{(i)} r^l + \gamma_{lm}^{(i)} \frac{1}{r^{l+1}} \right] Y_{lm}(\theta, \phi) \ .$$

where the $\beta_{lm}^{(i)}$ and $\gamma_{lm}^{(i)}$ be constant and $i = I, II, II$ denote the different regions $(I : 0 \leq r < a \ , II : a \leq r \leq b \ , III : b < r)$. What are the consequences for $\beta_{lm}^{(i)}$ and $\gamma_{lm}^{(i)}$ due to the fact that Φ_M
i. is, in the origin, the potential of a pure dipolar field $\vec{\mathcal{P}}_M$?
ii. is cylindrically symmetrical about the z-axis?
iii. disappears at infinity?
d. At the interfaces between the different regions the normal component of the magnetic $\vec{\mathcal{B}}$-field and the tangential component of the $\vec{\mathcal{H}}$-field are discontinuous. Use these conditions to establish a system of equations for the coefficients $\beta_{lm}^{(i)}$ and $\gamma_{lm}^{(i)}$, using

$\text{grad}_r \Phi_M = \frac{\partial \Phi_M}{\partial r}$, $\text{grad}_\theta \Phi_M = \frac{1}{r}\frac{\partial \Phi_M}{\partial \theta}$, $\frac{\partial Y_{10}}{\partial \theta} = \sqrt{\frac{2l+1}{4\pi}} P_l^1(\cos\theta)$, as well as the orthogonality relations $\int d\Omega Y_{l0}^*(\Omega) Y_{l'0}(\Omega) = \delta_{ll'}$ and $\int_{-1}^{+1} dx P_l^1(x) P_{l'}^1(x) = \delta_{ll'} \frac{2}{2l+1} \frac{(l+1)!}{(l-1)!}$.
e. Solve the equation system first for the case $l \neq 1$.
f. Solve the system of equations for $l = 1$.
g. What does the magnetic field look like outside the sphere for $\mu \gg 1$?

Solution: *a. For the current density holds in the entire space,*

$$\mathbf{j}(\mathbf{r}) = 0 \ .$$

From this immediately follows,

$$\nabla \times \vec{\mathcal{H}} = \frac{4\pi}{c}\mathbf{j} = 0 \ .$$

Therefore we have,

$$\vec{\mathcal{H}} = -\nabla \Phi_M(\mathbf{r}) \ .$$

b. Since

$$\nabla \cdot \vec{\mathcal{B}} = 0 \qquad \textit{and} \qquad \vec{\mathcal{B}} = \mu \vec{H} \ .$$

and with (a) we get in the entire space,

$$\nabla \cdot \vec{\mathcal{H}} = -\nabla \cdot \nabla \Phi_M = 0 \ .$$

hence the Laplace equation,

$$\triangle \Phi_M = 0 \ .$$

c. We separated the variables,

$$\Phi_M^{(i)} r, \theta\phi) = \sum_{l=0}^{\infty} \sum_{m=-l}^{+l} \frac{4\pi}{2l+1} \left[\beta_{lm}^{(i)} r^l + \gamma_{lm}^{(i)} \frac{1}{r^{l+1}} \right] Y_{lm}(\theta, \phi) \ .$$

(1) For $r \to 0$ we have a pure dipolar field towards z:

$$\Phi_{Dipol} = \frac{4\pi}{3} q_{10} \frac{Y_{10}}{r^2} = \sqrt{\frac{4\pi}{3}} P_M \frac{Y_{10}}{r^2} \ .$$

From this follows,

$$\gamma_{lm}^{(I)} = \sqrt{\frac{3}{4\pi}} P_M \delta_{l1} \delta_{m0} \ .$$

(2) Because of the cylindrical symmetry of the problem, Φ_M cannot depend on the angle ϕ. From this follows for all three regions ($i = I, II, III$),

$$\beta_{lm}^{(i)} = \beta_l^{(i)} \delta_{m0}$$
$$\gamma_{lm}^{(i)} = \gamma_l^{(i)} \delta_{m0} \ .$$

(3) $\vec{\mathcal{H}}$ must disappear in the infinite. So we normalize our potential in such a way that Φ_M disappears (becomes constant) at infinity. This means that for all l,

$$\beta_l^{(III)} = 0 \ .$$

d. Be $a_\pm \equiv a \pm \epsilon$ *and* $b_\pm \equiv b \pm \epsilon$. *The continuity of the normal component of* $\vec{\mathcal{B}}$ *provides the boundary conditions,*

$$\begin{aligned}(\nabla\Phi_M(a_-,\theta))_r &= \mu(\nabla\Phi_M(a_+,\theta))_r \\ \mu(\nabla\Phi_M(b_-,\theta))_r &= (\nabla\Phi_M(b_+,\theta))_r \ .\end{aligned}$$

the one of the tangential component of $\vec{\mathcal{H}}$ *provides,*

$$\begin{aligned}(\nabla\Phi_M(a_-,\theta))_\theta &= (\nabla\Phi_M(a_+,\theta))_\theta \\ (\nabla\Phi_M(b_-,\theta))_\theta &= (\nabla\Phi_M(b_+,\theta))_\theta \ .\end{aligned}$$

If we now use,

$$(\nabla\Phi_M)_r = \frac{\partial\Phi_M}{\partial r} \qquad \textit{and} \qquad (\nabla\Phi_M)_\theta = \frac{1}{r}\frac{\partial\Phi_M}{\partial\theta} \ .$$

as well as,

$$\frac{\partial Y_{10}}{\partial\theta} = \sqrt{\frac{2l+1}{4\pi}}P_l^1(\cos\theta) \ .$$

we get consecutively,

$$\begin{aligned}
\sum_l \frac{4\pi}{2l+1}Y_{l0}\left[\beta_l^{(I)}la^{l-1} - \gamma_l^{(I)}\frac{l+1}{a^{l+2}}\delta_{l1}\right] &= \mu\sum_l \frac{4\pi}{2l+1}Y_{l0}\left[\beta_l^{(II)}la^{l-1} - \gamma_l^{(II)}\frac{l+1}{a^{l+2}}\right] \\
\mu\sum_l \frac{4\pi}{2l+1}Y_{l0}\left[\beta_l^{(II)}lb^{l-1} - \gamma_l^{(II)}\frac{l+1}{b^{l+2}}\right] &= -\sum_l \frac{4\pi}{2l+1}Y_{l0}\gamma_l^{(III)}\frac{l+1}{b^{l+2}} \\
\sum_l \sqrt{\frac{4\pi}{2l+1}}P_l^1\left[\beta_l^{(I)}a^l + \frac{\gamma_l^{(I)}}{a^{l+1}}\delta_{l1}\right] &= \sum_l \sqrt{\frac{4\pi}{2l+1}}P_l^1\left[\beta_l^{(II)}a^l + \frac{\gamma_l^{(II)}}{a^{l+1}}\right] \\
\sum_l \sqrt{\frac{4\pi}{2l+1}}P_l^1\left[\beta_l^{(II)}b^l + \frac{\gamma_l^{(II)}}{b^{l+1}}\right] &= \sum_l \sqrt{\frac{4\pi}{2l+1}}P_l^1\frac{\gamma_l^{(III)}}{b^{l+1}} \ .
\end{aligned}$$

We now multiply the first two equations with Y_{l0}^* *(*l *is fixed) and integrate over* Ω*; we multiply the last two equations with* P_l^1 *and we integrate over* $x = \cos\theta$. *This gives, exploiting the given orthogonalaty relations, the following system of equations,*

$$\begin{pmatrix} la^{l-1} & -\mu la^{l-1} & \mu\frac{l+1}{a^{l+2}} & 0 \\ 0 & \mu lb^{l-1} & -\mu\frac{l+1}{b^{l+2}} & \frac{l+1}{b^{l+2}} \\ a^l & -a^l & -\frac{1}{a^{l+1}} & 0 \\ 0 & b^l & \frac{1}{b^{l+1}} & -\frac{1}{b^{l+1}} \end{pmatrix}\begin{pmatrix} \beta_l^{(I)} \\ \beta_l^{(II)} \\ \gamma_l^{(II)} \\ \gamma_l^{(III)} \end{pmatrix} = \begin{pmatrix} \gamma_l^{(I)}\frac{l+1}{a^{l+2}}\delta_{l1} \\ 0 \\ -\gamma_l^{(I)}\frac{1}{a^{l+1}}\delta_{l1} \\ 0 \end{pmatrix} \ .$$

e. For $l \neq 1$ the above system of equations is homogeneous. The determinant of the matrix of coefficients is,

$$
\begin{aligned}
\det A \equiv \det & \begin{pmatrix} la^{l-1} & -\mu l a^{l-1} & \mu\frac{l+1}{a^{l+2}}0 & \\ 0 & \mu l b^{l-1} & -\mu\frac{l+1}{b^{l+2}} & \frac{l+1}{b^{l+2}} \\ a^l & -a^l & -\frac{1}{a^{l+1}} & 0 \\ 0 & b^l & \frac{1}{b^{l+1}} & -\frac{1}{b^{l+1}} \end{pmatrix} \\
= \det & \begin{pmatrix} la^{l-1} & (1-\mu) l a^{l-1} & \mu\frac{l+1}{a^{l+2}}0 & \\ 0 & \mu l b^{l-1} & (1-\mu)\frac{l+1}{b^{l+2}} & \frac{l+1}{b^{l+2}} \\ a^l & 0 & -\frac{1}{a^{l+1}} & 0 \\ 0 & b^l & 0 & -\frac{1}{b^{l+1}} \end{pmatrix} \\
= la^{l-1} \det & \begin{pmatrix} \mu l b^{l-1} & (1-\mu)\frac{l+1}{b^{l+2}} & \frac{l+1}{b^{l+2}} \\ 0 & -\frac{1}{a^{l+1}} & 0 \\ b^l & 0 & -\frac{1}{b^{l+1}} \end{pmatrix} + a^l \det \begin{pmatrix} (1-\mu) l a^{l-1} & \mu\frac{l+1}{a^{l+2}} & 0 \\ \mu l b^{l-1} & (1-\mu)\frac{l+1}{b^{l+2}} & \frac{l+1}{b1 l+2} \\ b^l & 0 & -\frac{1}{b^{l+1}} \end{pmatrix} \\
= la^{l-1} & \left[\frac{\mu l b^{l-1}}{a^{l+1} b^{l+1}} + \frac{(l+1) b^l}{a^{l+1} b^{l+2}} \right] \\
& + a^l \left[-(1-\mu)^2 \frac{l(l+1) a^{l-1}}{b^{l+1} b^{l+2}} + \frac{\mu (l+1)^2 b^l}{a^{l+2} b^{l+2}} + \frac{\mu^2 l (l+1) b^{l-1}}{a^{l+2} b^{l+1}} \right] \\
= \frac{a^{2l-1}}{b^2} & \left[\frac{\mu l^2}{a^{2l+1}} + \frac{l(l+1)}{a^{2l+1}} - (1-\mu)^2 \frac{l(l+1)}{b^{2l+1}} + \frac{\mu (l+1)^2}{a^{2l+1}} + \frac{\mu^2 l (l+1)}{a^{2l+1}} \right] \\
= \frac{a^{2l-1}}{b^2} & \left[(1-\mu)^2 \left\{ \frac{1}{a^{2l+1}} - \frac{1}{b^{2l+1}} \right\} + \mu \frac{(2l+1)^2}{a^{2l+1}} \right] .
\end{aligned}
$$

where we have used that

$$l^2 + (l+1)^2 + 2l(l+1) = 4l^2 + 4l + 1 = (2l+1)^2 .$$

Now $0 < a < b$ and $\mu \geq 1$. So we always have,

$$\det A > 0 .$$

and therefore for $l \neq 1$ only exist trivial solutions,

$$\beta_l^{(I)} = \beta_l^{(II)} = \gamma_l^{(II)} = \gamma_l^{(III)} = 0 .$$

Since moreover for $l \neq 1$ we know,

$$\beta_l^{(III)} = \gamma_l^{(I)} = 0 .$$

we get as a result that the magnetic potential has only a $l = 1$ (dipolar) component.
f. For $l = 1$ we have the following system of equations (for simplicity, we suppress the

index $l = 1$ in the following),

$$\begin{aligned}
\beta^{(I)} - \mu\beta^{(II)} + \frac{2\mu}{a^3}\gamma^{(II)} &= \frac{2}{a^3}\gamma^{(I)} \\
\mu\beta^{(II)} - \frac{2\mu}{b^3}\gamma^{(II)} + \frac{2}{b^3}\gamma^{(III)} &= 0 \\
a\beta^{(I)} - a\beta^{(II)} - \frac{1}{a^2}\gamma^{(II)} &= -\frac{1}{a^2}\gamma^{(I)} \\
b\beta^{(II)} + \frac{1}{b^2}\gamma^{(II)} - \frac{1}{b^2}\gamma^{(III)} &= 0 \ .
\end{aligned}$$

We now multiply the last of these equations with $2/b$ and add it to the second, which gives,

$$(2+\mu)\beta^{(II)} - \frac{2(\mu-1)}{b^3}\gamma^{(II)} = 0 \ .$$

resp.

$$\gamma^{(II)} = \frac{b^3(\mu+2)}{2(\mu-1)}\beta^{(II)} \ .$$

We now divide the third equation by a and subtract it from the first, which gives,

$$-(\mu-1)\beta^{(II)} + \frac{1}{a^3}(2\mu+1)\gamma^{(II)} = \frac{3}{a^3}\gamma^{(I)} \ .$$

Hence,

$$-(\mu-1)\beta^{(II)} + \frac{1}{a^3}(2\mu+1)\frac{b^3(\mu+2)}{2(\mu-1)}\beta^{(II)} = \frac{3}{a^3}\gamma^{(I)} \ .$$

and therefore,

$$\beta^{(II)}\left(\frac{b^3(2\mu+1)(\mu+2) - 2a^3(\mu-1)^2}{2(\mu-1)}\right) = 3\gamma^{(I)} \ .$$

Therefore we get,

$$\begin{aligned}
\beta^{(II)} &= \frac{6(\mu-1)\gamma^{(I)}}{b^3(2\mu+1)(\mu+2) - 2a^3(\mu-1)^2} \\
\gamma^{(II)} &= \frac{3b^3(\mu+2)\gamma^{(I)}}{b^3(2\mu+1)(\mu+2) - 2a^3(\mu-1)^2} \\
\gamma^{(III)} &= \frac{9b^3\mu\gamma^{(I)}}{b^3(2\mu+1)(\mu+2) - 2a^3(\mu-1)^2} \\
\beta^{(I)} &= -\frac{2(\mu-1)(\mu+2)\left[\frac{b^3}{a^3} - 1\right]\gamma^{(I)}}{b^3(2\mu+1)(\mu+2) - 2a^3(\mu-1)^2} \ .
\end{aligned}$$

Moreover, we had,

$$\beta^{(III)} \equiv 0 \qquad \textit{and} \qquad \gamma^{(I)} = \sqrt{\frac{3}{4\pi}}P_M \ .$$

The result can be verified by letting $\mu = 1$. In this case,

$$\beta^{(I)} = \beta^{(II)} = \beta^{(III)} \qquad \text{and} \qquad \gamma^{(II)} = \gamma^{(III)} = \gamma^{(I)} = \sqrt{\frac{3}{4\pi}} P_M \ ,$$

giving the dipolar field in vacuum.
g. In region III we have,

$$\beta^{(III)} = 0 \qquad ; \qquad \gamma^{(III)} = \frac{9}{2}\gamma^{(I)} \frac{1}{\frac{(2\mu+1)(\mu+2)}{2\mu} - \frac{a^3}{b^3}\frac{(\mu-1)^2}{\mu}} \ .$$

Para $\mu \gg 1$ segue,

$$\gamma^{(III)} \sim \frac{9}{2}\gamma^{(I)} \frac{1}{1 - \frac{a^3}{b^3}} \frac{1}{\mu} \ .$$

Chapter 16

Magnetic properties of matter

The most common manifestations of magnetism are certainly magnets, compass needles, and the Earth's magnetic field, and it is not obvious how they are related to the magnetic fields produced by currents, discussed in the previous chapter. Nevertheless, all magnetic phenomena are ultimately due to currents, even if they are microscopic, for example, electrons orbiting atomic nuclei or spinning around their own axis. From the macroscopic point of view we can treat these circular currents as magnetic dipoles. Generally, the dipoles of a medium have random orientations, such that the generated magnetic fields cancel out. However, when we apply a *external* magnetic field, the dipoles can realign and *magnetize* the medium.

16.1 Magnetization

There are several macroscopic manifestations of microscopic dipole moments known as para-, dia-, and ferromagnetism. We will discuss these in the following sections.

16.1.1 Energy of permanent dipoles and paramagnetism

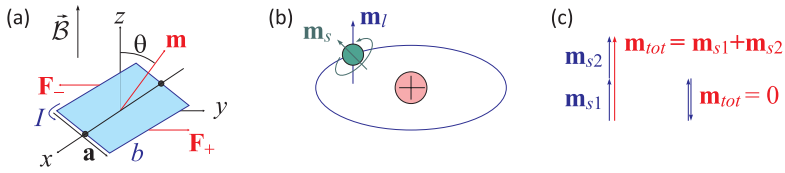

Figure 16.1: (a) Illustration of the torque exerted by a magnetic field on a magnetic dipole. (b) An electron spinning around a nucleus may have orbital and intrinsic angular momentum. (c) Dipole moments are added as vectors.

We consider current loops of rectangular shape [1]. In the case of the geometry shown in Fig. 16.1(a) the Lorentz forces acting on the wire sections a being parallel to the z-y-plane compensate each other, because the forces and the points on which they act are all on a straight line. On the other side, the forces acting on the wire sections b,

$$\mathbf{F}_{\pm} = \pm I\mathbf{b} \times \vec{\mathcal{B}} = \pm Ib\mathcal{B}\hat{\mathbf{e}}_y \ , \tag{16.1}$$

[1] Arbitrary shapes can be constructed by two-dimensional arrays of rectangular loops.

both contribute to create a torque,

$$\vec{\tau} = \tfrac{\mathbf{a}}{2} \times \mathbf{F}_+ + \tfrac{-\mathbf{a}}{2} - \times \mathbf{F}_- = I\mathcal{B}b\mathbf{a} \times \hat{\mathbf{e}}_y = Iab\mathcal{B}\hat{\mathbf{e}}_x \sin\theta \ , \tag{16.2}$$

With the definition of the magnetic moment (15.42) we find,

$$\boxed{\vec{\tau} = \mathbf{m} \times \vec{\mathcal{B}}} \ . \tag{16.3}$$

We can also calculate the energy of a dipole in a magnetic field by the work required to rotate it out of its equilibrium position,

$$H_{int} = \int_0^\theta \vec{\tau} \cdot d\theta = \int_0^\theta \mathbf{m} \times \vec{\mathcal{B}} d\theta = \int_0^\theta m\mathcal{B} \sin\theta d\theta = -m\mathcal{B}\cos\theta \ , \tag{16.4}$$

such that,

$$\boxed{H_{int} = -\mathbf{m} \cdot \vec{\mathcal{B}}} \ . \tag{16.5}$$

The formula (16.3) holds for homogeneous magnetic fields or, alternatively, for almost point-like dipoles in inhomogeneous fields. It represents the magnetic equivalent of the torque on electric dipoles (14.4). The torque is oriented so as to align the dipole moment to the direction of the magnetic field. This mechanism is used to explain the phenomenon of paramagnetism [see Fig. 16.3(a)].

In atomic physics we learn that electrons bound to atoms may have, besides an orbital angular momentum due to the planetary motion around the atomic nucleus, an *intrinsic angular momentum* called *spin* as if the electron were a small electrically charged sphere rotating about its own axis [see illustration of Fig. 16.1(b)]. The spins of the various electrons in the electron layer of an atom generally couple to form a total dipole moment, which then interacts with external magnetic fields. This is called *Zeeman effect*. The spins may pair and add up or compensate pairwise such as to zero the magnetic dipole moment of the atom [see illustration of Fig. 16.1(c)]. Note that a strong external magnetic field can break the angular momentum coupling and interact with the electron spins separately. This is called *Paschen-Back effect*.

The phenomenon of *paramagnetism* is observed in materials whose molecules have permanent magnetic dipole moments, that is, in chemical elements with unpaired valence electrons. It is not observed in noble gases, covalent crystals, etc..

Unlike the torque, the *force exerted by a homogeneous field* on a dipole vanishes,

$$\mathbf{F} = I \oint d\mathbf{l} \times \vec{\mathcal{B}} = I \left(\oint d\mathbf{l} \right) \times \vec{\mathcal{B}} = 0 \ . \tag{16.6}$$

For inhomogeneous fields we need to calculate the force from the energy gradient as,

$$\mathbf{F} = -\nabla H_{int} = \nabla(\mathbf{m} \cdot \vec{\mathcal{B}}) = \mathbf{m} \times (\nabla \times \vec{\mathcal{B}}) + (\mathbf{m} \cdot \nabla)\vec{\mathcal{B}} = (\mathbf{m} \cdot \nabla)\vec{\mathcal{B}} \ . \tag{16.7}$$

This formula can be obtained by Taylor expansion of the magnetic field (see Exc. 16.1.7.1).

16.1.2 Impact of magnetic fields on electronic orbits and diamagnetism

A magnetic field can have another effect on the motion of electrons. Let us consider an electron rotating on a circular orbit of radius R. If the motion of the electron is

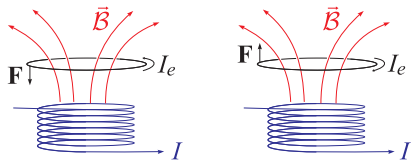

Figure 16.2: Illustration of the force exerted by an inhomogeneous magnetic field on a magnetic dipole: A dipole oriented in the same direction as the magnetic field will be drawn to the field maximum, if it is oriented anti-parallel, it is repelled from the field maximum.

fast, it will generate a current,

$$I = \frac{-e}{T} = \frac{-ev}{2\pi R} \ , \tag{16.8}$$

creating a dipole moment,

$$\mathbf{m} = I\mathbf{A} = \frac{-e}{T}\pi R^2 \hat{\mathbf{e}}_z = \frac{-e}{2} vR\hat{\mathbf{e}}_z \ . \tag{16.9}$$

Now, the orbit of the electron can be, for example, an atomic orbital or a trajectory of a free electron in a conductor. The magnetism of a free electron gas in a metal is treated by the theory of *Landau diamagnetism*. This theory considers the trajectories of electrons as being curved by the Lorentz force which, because of the rule of Lenz, generates a field contrary to the applied magnetic field. That is, the magnetic flux is expelled from the material. Hence, in inhomogeneous magnetic fields, diamagnetic materials are repelled from high field regions [2].

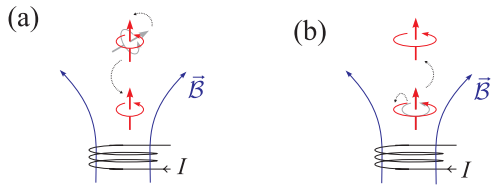

Figure 16.3: Classical interpretation of paramagnetism (a) and diamagnetism (b): In paramagnetic materials the permanent dipoles reorient in the direction of the external field. Exposed to inhomogeneous fields, the dipoles are thus attracted to field maxima. In diamagnetism, currents are forced into circular orbits, and the so-formed dipoles are oriented in a direction opposite the external external. Exposed to inhomogeneous fields, the dipoles are thus repelled from the field maxima.

The case of electronic orbitals in atoms is treated by the theory of *Langevin diamagnetism*. In this theory we consider Bohr orbitals of electrons bound to a nucleus by the Coulomb force. In the presence of an external magnetic field the dipole feels a torque, but in addition, the field has the effect of accelerating or decelerating the electron depending on its orientation. To estimate this effect we consider the equilibrium condition for an electronic orbit,

$$\mathbf{F}_C = \frac{1}{4\pi\varepsilon_0}\frac{e^2}{R^2} = m_e\frac{v^2}{R} = \mathbf{F}_{centrifugal} \ . \tag{16.10}$$

[2]Note that some metals may be weakly paramagnetic due to an effect called *Pauli paramagnetism*.

Adding a magnetic field oriented along the rotation axis [3],

$$\mathbf{F}_C + \mathbf{F}_L = \frac{1}{4\pi\varepsilon_0}\frac{e^2}{R^2} + ev'\Delta\mathcal{B} = m_e\frac{v'^2}{R} = \mathbf{F}_{centrifugal} \ . \tag{16.11}$$

Subtracting these equations,

$$ev'\Delta\mathcal{B} = \frac{m_e}{R}(v'^2 - v^2) = \frac{m_e}{R}(v' - v)(v' + v) \simeq \frac{2m_e}{R}v'\Delta v \ , \tag{16.12}$$

such that,

$$\Delta v = \frac{eR\Delta\mathcal{B}}{2m_e} \ . \tag{16.13}$$

The acceleration of the electron, when we switch on the magnetic field, increases the value of the dipole moment because, with the formula (16.9),

$$\Delta\mathbf{m} = \frac{-e}{2}\Delta v R\hat{\mathbf{e}}_z = -\frac{e^2R^2}{4m_e}\Delta\vec{\mathcal{B}} \ . \tag{16.14}$$

But the ***variation*** is *always contrary to the direction of the magnetic field*, even if the dipole moment was initially aligned to the field [see Fig. 16.3(b)] [4]. Therefore, the dipole is repelled by an inhomogeneous magnetic field. Note that changing the sign of the charge does not affect $\Delta\mathbf{m}$.

Diamagnetism is a property of all materials, but is often hidden by the presence of permanent magnetic moments. Therefore, to observe diamagnetism, one must choose materials with no permanent magnetic moment, such as atoms with completely filled electron shells. Many amorphous materials (such as wood, glass, rubber, etc.) and many metals as diamagnets.

It is worth mentioning that the magnetic behavior of a macroscopic body is not necessarily the same as the one of its elementary components. For example, metallic sodium is diamagnetic, while gaseous sodium is paramagnetic.

paramagnetism	diamagnetism
atoms with unpaired e^-	atoms with paired e^-
$\mathbf{m}$ robust and independent of $\vec{\mathcal{B}}$	$\mathbf{m}$ weak and $\mathbf{m} \propto \vec{\mathcal{B}}$
$\vec{\mathcal{M}} \parallel \vec{\mathcal{B}} \curvearrowright$ attractive force	$\vec{\mathcal{M}} \parallel -\vec{\mathcal{B}} \curvearrowright$ repulsive force
$\mu > 1 \curvearrowright \chi > 0$	$\mu < 1 \curvearrowright \chi < 0$

It is also important to note that essential aspects of *para- and atomic diamagnetism are quantum*. That is, quantitative theories must be formulated within quantum mechanics. A classical theory can only give an qualitative picture of the effect.

[3] In Exc. 16.1.7.2 we have shown, that the radius of the electronic orbit does not change under the influence of an external magnetic field.

[4] If the charge distribution is spherically symmetric, we can assume $\langle x^2\rangle = \langle y^2\rangle = \langle z^2\rangle = \frac{1}{3}\langle r^2\rangle$, where $\langle r^2\rangle$ is the average distance between the electron and the nucleus. Therefore, $\langle R^2\rangle = \langle x^2\rangle + \langle y^2\rangle = \frac{2}{3}\langle r^2\rangle$. If N is the number of atoms per unit volume, we have $\chi = \frac{\mu_0 Nm}{\mathcal{B}} = -\frac{\mu_0 NZe^2}{6m}\langle r^2\rangle$.

16.1.3 Macroscopic magnetization

In the presence of a magnetic field, matter becomes magnetized, that is, the atomic or molecular dipoles align in a particular direction. We have already discussed two possible mechanisms causing this reorientation, the para- and the diamagnetism. Regardless of the mechanism we measure the degree of alignment by the vector quantity,

$$\vec{\mathcal{M}} = \frac{N\mathbf{m}}{V} \tag{16.15}$$

called *magnetization*. It plays the same role as the polarization in electrostatics. In the following section we will calculate for a given magnetization $\vec{\mathcal{M}}$ the field that it produces.

In most materials diamagnetism and paramagnetism are very weak effects and can only be detected by sensitive measurements and strong magnetic fields. In *non-ferromagnetic* materials, the weakness of the magnetization allows us to neglect the magnetic field produced by magnetization. In contrast, in iron, nickel or cobalt the forces are between 10^4 and 10^5 greater.

16.1.4 Magnetostatic field of a magnetized material

We consider a sample of magnetic dipoles. According to the formula (15.42), the vector potential is given by,

$$\mathbf{A}(\mathbf{r}) = \frac{\mu_0}{4\pi}\sum_k \frac{\mathbf{m}\times(\mathbf{r}-\mathbf{r}')}{|\mathbf{r}-\mathbf{r}'|^3} \longrightarrow \frac{\mu_0}{4\pi}\int_{\mathcal{V}} dV' \frac{\vec{\mathcal{M}}\times(\mathbf{r}-\mathbf{r}')}{|\mathbf{r}-\mathbf{r}'|^3}\ , \tag{16.16}$$

where we introduced the dipole moment distribution $\vec{\mathcal{M}}(\mathbf{r}')$ via $\mathbf{m}_k \to \vec{\mathcal{M}}dV'$. As in the electrostatic case, we can rewrite the integral in the form,

$$\begin{aligned}\mathbf{A}(\mathbf{r}) &= \frac{\mu_0}{4\pi}\int_{\mathcal{V}} \vec{\mathcal{M}}(\mathbf{r}')\times\nabla'\frac{1}{|\mathbf{r}-\mathbf{r}'|}dV' \\ &= \frac{\mu_0}{4\pi}\left[-\int_{\mathcal{V}}\nabla'\times\frac{\vec{\mathcal{M}}(\mathbf{r}')}{|\mathbf{r}-\mathbf{r}'|}dV' + \int_{\mathcal{V}}\frac{1}{|\mathbf{r}-\mathbf{r}'|}\nabla'\times\vec{\mathcal{M}}(\mathbf{r}')dV'\right] \\ &= \frac{\mu_0}{4\pi}\oint_{\partial\mathcal{V}}\frac{\vec{\mathcal{M}}(\mathbf{r}')\times d\mathbf{S}'}{|\mathbf{r}-\mathbf{r}'|} + \frac{\mu_0}{4\pi}\int_{\mathcal{V}}\frac{1}{|\mathbf{r}-\mathbf{r}'|}\nabla'\times\vec{\mathcal{M}}(\mathbf{r}')dV'\ .\end{aligned} \tag{16.17}$$

Comparing these terms with the formula (15.27), we find that the first term looks like the potential of a surface current, while the second term looks like the potential of a volume current. Defining,

$$\boxed{\vec{\kappa}_b \equiv \vec{\mathcal{M}}\times\mathbf{n}_S} \quad \text{and} \quad \boxed{\mathbf{j}_b \equiv \nabla\times\vec{\mathcal{M}}}\ , \tag{16.18}$$

we obtain,

$$\mathbf{A}(\mathbf{r}) = \frac{\mu_0}{4\pi}\oint_{\partial\mathcal{V}}\frac{\vec{\kappa}_b}{|\mathbf{r}-\mathbf{r}'|}dS' + \frac{\mu_0}{4\pi}\int_{\mathcal{V}}\frac{\mathbf{j}_b}{|\mathbf{r}-\mathbf{r}'|}dV'\ . \tag{16.19}$$

The meaning of this result is that the potential (and therefore the field) of a magnetized object is the same as the one produced by a volume current distribution

$\mathbf{j}_b$ plus a surface current distribution $\vec{\kappa}_b$. Instead of integrating the contributions of all individual infinitesimal dipoles, as in Eq. (16.17), we can try to find these bound currents, and then calculate the fields they produce, as we did in the previous chapter.

16.1.5 The H-field

In the previous section we found that the phenomenon of magnetization of a body can be understood as being due to *localized currents* inside the material, $\mathbf{j}_b = \nabla \times \vec{\mathcal{M}}$, and on the surface of the body, $\vec{\kappa}_b = \vec{\mathcal{M}} \times \hat{n}_S$. The magnetization field is the magnetic field produced by these currents. In addition, there are obviously *free currents*, such as those generated by the motion of free electrons in a metal.

16.1.5.1 Ampère's law in magnetized materials

Ampère's law can now be generalized for arbitrary media,

$$\tfrac{1}{\mu_0} \nabla \times \vec{\mathcal{B}} = \mathbf{j} = \mathbf{j}_b + \mathbf{j}_f = \nabla \times \vec{\mathcal{M}} + \mathbf{j}_f \ , \tag{16.20}$$

where $\vec{\mathcal{B}}$ is the total magnetic field. Defining a new field $\vec{\mathcal{H}}$, sometimes called *magnetic excitation*,

$$\boxed{\vec{\mathcal{H}} \equiv \mu_0^{-1} \vec{\mathcal{B}} - \vec{\mathcal{M}}} \ , \tag{16.21}$$

we can now write,

$$\nabla \times \vec{\mathcal{H}} = \mathbf{j}_f \ . \tag{16.22}$$

The field $\vec{\mathcal{H}}$ is that part of the magnetic field, which comes only from free currents. We can also define the *magnetic susceptibility* χ_μ via [5],

$$\vec{\mathcal{M}} = \chi_\mu \vec{\mathcal{H}} \ , \tag{16.23}$$

or the *permeability* μ via,

$$\vec{\mathcal{B}} = \mu \vec{\mathcal{H}} = \mu_0 (1 + \chi_\mu) \vec{\mathcal{H}} \ . \tag{16.24}$$

Note, that the divergence of the *magnetization does not necessarily vanish*, since the susceptibility may depend on position, $\chi_\mu = \chi_\mu(\mathbf{r})$,

$$\nabla \cdot \vec{\mathcal{H}} = \mu_0^{-1} \nabla \cdot \vec{\mathcal{B}} - \nabla \cdot \vec{\mathcal{M}} = -\nabla \cdot (\chi_\mu \vec{\mathcal{H}}) \neq 0 \ . \tag{16.25}$$

Hence, $\vec{\mathcal{H}}$ generally can not be derived from a vector potential, and Biot-Savart's law is not valid for $\vec{\mathcal{H}}$. In anisotropic materials the susceptibility and the permeability must be understood as tensors.

[5] Note, that this definition is not symmetric with that of the electric susceptibility (14.20).

16.1.5.2 Boundary conditions involving magnetic materials

The integral version of Eq. (16.25), $\oint \vec{\mathcal{H}} \cdot d\mathbf{S} = -\oint \vec{\mathcal{M}} \cdot d\mathbf{S}$, allows us to determine the behavior of the magnetic excitation near interfaces,

$$H^{\perp}_{top} - H^{\perp}_{bottom} = -M^{\perp}_{top} + M^{\perp}_{bottom} \ . \tag{16.26}$$

On the other hand Ampère's law, $\nabla \times \vec{\mathcal{H}} = \mathbf{j}_f$, yields,

$$\vec{\mathcal{H}}^{\parallel}_{top} - \vec{\mathcal{H}}^{\parallel}_{bottom} = \vec{\kappa}_f \times \hat{\mathbf{n}} \ . \tag{16.27}$$

This is in contrast to the behavior of the magnetic $\vec{\mathcal{B}}$ field at interfaces described by Eqs. (15.30), (15.32), and (15.34). Do the Excs. 16.1.7.7 to 16.1.7.9.

16.1.6 Magnetic susceptibility and permeability

Materials respond to applied magnetic fields $\vec{\mathcal{H}}$ generating a magnetization $\vec{\mathcal{M}}$, such that the total magnetic field is $\vec{\mathcal{B}} = \mu_0 \vec{\mathcal{H}} + \mu_0 \vec{\mathcal{M}}$. The behavior of a material depends on the value of its susceptibility. In vacuum $\chi_\mu = 0$, for typical diamagnets $\chi_\mu \lesssim 0$, for superconductors $\chi_\mu = -1$, for paramagnets $\chi_\mu \gtrsim 0$, and for ferromagnets $\chi_\mu \gg 1$.

Typical values are listed in the following table:

material	$\chi_\mu[10^{-5}]$	type of magnetism
superconductor	-10^5	dia-
carbon	-2.1	Langevin dia-
copper	-1	Landau dia-
water	-0.9	Langevin dia-
hydrogen	-0.00022	Langevin dia-
oxygen (gas)	0.2	para-
sodium (metal)	0.7	Pauli para-
magnesium	1.2	Pauli para-
lithium	1.4	Pauli para-
cesium	5.1	Pauli para-
platinum	28	
oxygen(liquid)	390	
gadolinium	48000	ferro-
iron		ferro-

16.1.6.1 Linear media

In many materials, as long as the applied magnetic field is not too strong, the magnetization is proportional to the field, $\vec{\mathcal{M}} \propto \vec{\mathcal{B}}$, i.e. the magnetic susceptibility depends

on the material's microscopic properties and external factors, such as temperature, but not on the applied field, $\chi_\mu \neq \chi_\mu(\vec{\mathcal{B}})$. Hence, linear media can be characterized by a constant,

$$\mu_r \equiv \frac{\mu}{\mu_0} \ , \tag{16.28}$$

called *relative permeability*.

16.1.6.2 The role of temperature in paramagnetism

Experiments show, that in inhomogeneous magnetic fields, paramagnetic materials are attracted toward high field regions, but with a force that decreases with temperature. This is understood by the Zeeman effect: The dipole moment can only adopt a few possible (quantized) values corresponding to levels of well-defined positive or negative energy (called Zeeman sub-levels). At high temperature all Zeeman sub-levels are equally populated, such that the total force cancels. At low temperature the populations are distributed according to Boltzmann's law, $n_k/n_l = e^{-(E_k-E_l)/k_BT}$, that is, the lower levels (which are precisely the *high-field seekers*) dominate.

Example 76 (*Paramagnetism of hot samples*): As an example, we consider atoms with two possible orientations for the permanent magnetic moment, $\mathbf{m} \cdot \vec{\mathcal{B}} = \pm m\mathcal{B}$. The magnetization produced by $n = n_+ + n_-$ atoms is then $\vec{\mathcal{M}} = n_+\mathbf{m}_+ + n_-\mathbf{m}_-$. The two orientations are populated according to Boltzmann's law $n_+/n_- = e^{-2m\mathcal{B}/k_BT}$, such that,

$$\frac{\vec{\mathcal{M}}}{n} = \frac{e^{m\mathcal{B}/k_BT} - e^{-m\mathcal{B}/k_BT}}{e^{m\mathcal{B}/k_BT} + e^{-m\mathcal{B}/k_BT}}\mathbf{m} \simeq \frac{m\mathcal{B}}{k_BT}\mathbf{m} \ .$$

For weak fields, we obtain the *Curie law*,

$$\chi_\mu = \frac{M}{H} \simeq \frac{nm^2\mathcal{B}}{k_BTH} \simeq \frac{\mu_0 nm^2}{k_BT} \sim T^{-1} \ .$$

For strong fields, the magnetization saturates. Assuming $m \simeq \mu_B$ (see Exc. 16.1.7.4), we estimate for a metal with $n \approx 10^{22}\,\mathrm{cm}^{-3}$ at room temperature, $\chi_\mu \approx 2.6 \times 10^{-4}$ [6].

16.1.6.3 Ferromagnetism

In a linear medium the alignment of the magnetic dipoles is maintained by the application of an external field. There are, however, magnetic materials that do not depend on applied fields. This phenomenon of 'frozen' magnetization is called *ferromagnetism*. As in the case of paramagnetism, ferromagnets develop dipoles associated with the spins of unpaired electrons, but in addition, the dipoles strongly interact with

[6] In metals free electrons contribute to paramagnetism. In metals the Curie law does not apply, but χ is found to be almost constant. The reason is, that the Boltzmann distribution is inappropriate for electrons, so we need to use the Fermi-Dirac distribution. The energy distribution $\rho(\epsilon)n_{FD}(\epsilon)$ of the electrons depends on the orientation of their spin with respect to the applied magnetic field: electrons with (anti-)parallel spin see their energy increased (reduced). To maintain a uniform E_F, electrons with parallel spin will flip it to antiparallel spin, such that the entire system is slightly *high-field seeking*. This is called *Pauli paramagnetism*. This effect always competes with diamagnetism, which involves all electrons and has opposite sign.

each other and, for reasons that can only be understood within a quantum theory, like to orient themselves in parallel [7].

The correlation is so strong that within regions called *Weiss domains* almost 100% of the dipoles are aligned. On the other hand, a block of ferromagnetic material consists of many spatially separated domains, each domain having a magnetization pointing in a random direction, such that the block as a whole does not exhibit macroscopic magnetization. Inside a Weiss domain the magnetization is so strong that even a strong external magnetic field can not influence the alignment. On the other hand, at the boundaries between Weiss domains the alignment is not well defined, such that the external field can exert a torque $\tau = \mathbf{m} \times \vec{\mathcal{B}}$ shifting the boundaries in a way to favor those domains, which are already aligned. For a sufficiently strong field one domain will prevail and the ferromagnetic material saturate.

Experiments show that the alignment is not fully reversible, that is, not all Weiss domains return to their initial orientation (before the external magnetic field was applied). Consequently, the material remains permanently magnetized. This effect is called *remanescence*.

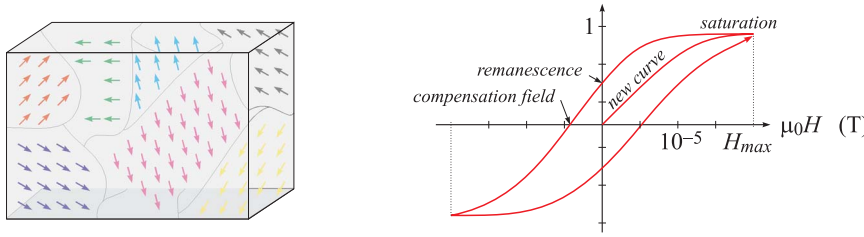

Figure 16.4: Hysteresis curve of magnetization. To allow for a comparison of the scales we plot in real units (Tesla) the applied field ($\vec{\mathcal{H}} \propto I$ in the case of a solenoid) versus the obtained field ($\vec{\mathcal{B}} \simeq \vec{\mathcal{M}}$).

To compensate for remanescence, it is necessary to apply a *compensation field* oriented in the opposite direction (see Fig. 16.4) [8] Beyond the compensation field we observe saturation in the opposite direction. Finally, returning to the initial situation, we draw a curve called *hysteresis curve*, which indicates that magnetization does not only depend on the applied magnetic field, but also on the 'history' of applied fields. Fig. 16.4 shows how an applied field can be dramatically amplified by ferromagnetism.

As already discussed, temperature tends to randomize the alignment of atomic dipoles. At low temperature the heat will not be sufficient to misalign the dipoles within the Weiss domains. But interestingly, beyond a well-defined temperature (the *Curie temperature* of iron is 770 C), the iron undergoes an abrupt phase transition to a paramagnetic state.

[7] The survival of domains in thermal reservoirs can not be understood by classical interactions between dipoles, but we need to contemplate band structure models. In particular, the $3d$ orbital bands provide electrons to the ferromagnetic elements Fe, Co, Ni. These bands are so close that the exchange interaction influences the orientation of spins in neighboring bands, which induces correlations between the spins of neighboring atoms.

[8] In practice, to demagnetize an iron block, we apply an alternating voltage gradually reducing its amplitude.

Note, that there are also antiferromagnetic materials (MnO_2), where neighboring atoms have antiparallel spins.

Example 77 (*Microscopic theory of induced dipoles*): The permittivity and relative permeability of a dense gas can be connected to the microscopic quantities through the *Clausius-Mossotti formula*,

$$\varepsilon_r = \frac{1+\frac{2}{3}\frac{N}{V}\alpha_{pol,e}}{1-\frac{1}{3}\frac{N}{V}\alpha_{pol,e}} \quad , \quad \mu_r = \frac{1+\frac{2}{3}\frac{N}{V}\alpha_{pol,m}}{1-\frac{1}{3}\frac{N}{V}\alpha_{pol,m}} \ , \tag{16.29}$$

that is, to the susceptibilities,

$$\chi_\varepsilon = \varepsilon_r - 1 = \frac{\frac{N}{V}\alpha_{pol,e}}{1-\frac{1}{3}\frac{N}{V}\alpha_{pol,e}} \quad , \quad \chi_\mu = \mu_r - 1 = \frac{\frac{N}{V}\alpha_{pol,m}}{1-\frac{1}{3}\frac{N}{V}\alpha_{pol,m}} \ , \tag{16.30}$$

where the induced electric and magnetic polarizabilities are,

$$\alpha_{pol,e} = \frac{2d_{fi}}{|\vec{\mathcal{E}}_p|}\rho_{if} \quad , \quad \alpha_{pol,m} = \frac{2m_{fi}}{|\vec{\mathcal{B}}_p|}\rho_{if} \ . \tag{16.31}$$

d_{fi} and m_{fi} are the dipole moments for electric and magnetic transitions and ρ_{if} the coherences excited in these transitions, which can be calculated from the Bloch equations. The relative strength between magnetic and electrical transitions is,

$$\frac{2\mu_B}{cea_B} = \alpha \ . \tag{16.32}$$

16.1.7 Exercises

16.1.7.1 Ex: Dipole in an inhomogeneous field

Derive the formula for the force on a dipole in an inhomogeneous field.

Solution: *An inhomogeneous magnetic field can be approximated by,*

$$\vec{\mathcal{B}}(\mathbf{r}) = \vec{\mathcal{B}}(\mathbf{r}') + [(\mathbf{r}-\mathbf{r}')\cdot\nabla']\vec{\mathcal{B}}(\mathbf{r}') \ .$$

We need to show,

$$\mathbf{F} = I\oint d\mathbf{l}\times[(\mathbf{r}\cdot\nabla')\vec{\mathcal{B}}(\mathbf{r}')] = ... = (\mathbf{m}\cdot\nabla)\vec{\mathcal{B}} \ .$$

We know,

$$\oint(\mathbf{c}\cdot\mathbf{r})d\mathbf{l} = \mathbf{S}\times\mathbf{c} \ ,$$

where

$$\mathbf{S} = \int_{\mathcal{S}} d\mathbf{S} = \frac{1}{2}\oint \mathbf{r}\times d\mathbf{l} \ .$$

Thereby,

$$(\mathbf{S}\times\mathbf{c})_k = \epsilon_{kgj}S_g c_j = \oint c_m r_m dl_k \ .$$

Now using

$$\epsilon_{ikn}\epsilon_{kgj} = \epsilon_{ikn}\epsilon_{jkg} = \delta_{ij}\delta_{ng} - \delta_{ig}\delta_{nj} \ ,$$

we calculate,

$$F_i = I\epsilon_{ikn}(\oint r_m dl_k)[\nabla'_m \mathcal{B}_n(\mathbf{r}')] = I\epsilon_{ikn}\epsilon_{kgj}S_g[\nabla'_j \mathcal{B}_n(\mathbf{r}')] = (\delta_{ij}\delta_{ng} - \delta_{ig}\delta_{nj})m_g[\nabla'_j \mathcal{B}_n(\mathbf{r}')]$$
$$= m_n[\nabla'_i \mathcal{B}_n(\mathbf{r}')] - m_i[\nabla'_n \mathcal{B}_n(\mathbf{r}')] = m_n[\nabla'_i \mathcal{B}_n(\mathbf{r}')] - m_i(\nabla' \cdot \vec{\mathcal{B}}) = m_n[\nabla'_i \mathcal{B}_n(\mathbf{r}')] \ .$$

16.1.7.2 Ex: Langevin diamagnetism

An electron circulates around its atomic nucleus on an orbit of radius R.
a. Calculate the magnetic dipole moment generated by this movement as a function of velocity.
b. Now a weak magnetic field $\vec{\mathcal{B}}$ is slowly turned on perpendicular to the orbital plane. Calculate the increase of the electron's velocity due to the electric field induced by turning on the magnetic field using Faraday's law.
c. Show that the increase in kinetic energy, ΔE_{kin}, corresponds to the interaction energy between the electronic dipole moment and the magnetic field.
d. Does the turning on of the magnetic field change the radius of the electronic orbit? Justify your answer!

Solution: *a. The current corresponding to the motion being $I = -e/T$, we obtain,*

$$\mathbf{m} = I\mathbf{S} = -\frac{ev}{2\pi R}\pi R^2 \hat{\mathbf{n}} = -\frac{e}{2}\mathbf{R} \times \mathbf{v} \ .$$

b. We assume that the magnetic field ranges from 0 to $\mathcal{B}$ within a period of time t. This variation produces a rotation of an electric field given by $\nabla \times \vec{\mathcal{E}} = \partial_t \vec{\mathcal{B}}$. With Stokes law,

$$\oint_{\partial \mathcal{S}} \vec{\mathcal{E}} \cdot d\mathbf{l} = \int_{\mathcal{S}} \nabla \times \vec{\mathcal{E}} \cdot d\mathbf{S} = -\frac{\partial}{\partial t}\int_{\mathcal{S}} \vec{\mathcal{B}} \cdot d\mathbf{S} \ ,$$

or $\mathcal{E} 2\pi R = \pi R^2 \dot{\mathcal{B}}$. Thus, the variation of the electron velocity is,

$$\Delta v = \int_0^t \frac{F}{m_e} dt = \int_0^t \frac{-e\mathcal{E}}{m_e} dt = \int_0^t \frac{-eR\dot{\mathcal{B}}}{2m_e} dt = \frac{-eR}{2m_e}\int_0^{\mathcal{B}} d\mathcal{B} = \frac{-eR}{2m_e}\mathcal{B} \ .$$

(This is the same formula derived from Langevin's discussion of diamagnetism under the premise that the radius of the orbit is constant.)
c. The increase in kinetic energy is,

$$\Delta E_{kin} = \frac{m_e}{2}(v+\Delta v)^2 - \frac{m_e}{2}v^2 \simeq m_e v \Delta v = m_e\left(-\frac{2|\mathbf{m}|}{eR}\right)\frac{-eR}{2m_e}\mathcal{B} = -\mathbf{m}\cdot\vec{\mathcal{B}} = \Delta E_{zee} \ .$$

d. The fact that all energy added goes to kinetic energy and nothing is left for the Coulomb energy shows, that the assumption of a fixed radius used in the discussion of Langevin's diamagnetism is justified.

16.1.7.3 Ex: Magnetic susceptibility

By molecular magnetism it is possible to lift any objects in a sufficiently strong magnetic field. Estimate the magnetic field $|\vec{\mathcal{B}}|$ and the field gradient $\nabla|\vec{\mathcal{B}}|^2$ (one may estimate $\nabla|\vec{\mathcal{B}}|^2 = 2|\vec{\mathcal{B}}|\nabla|\vec{\mathcal{B}}| \simeq |\vec{\mathcal{B}}|^2/l$ with $l \simeq 10\,\mathrm{cm}$ as the typical length for such strong magnetic fields), needed to lift a frog. Water is predominantly diamagnetic with $\chi_\mu \simeq -0.9 \cdot 10^{-5}$ is the magnetic susceptibility of water.

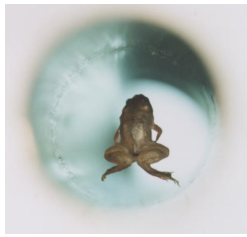

Figure 16.5: Magnetic susceptibility.

Solution: *The condition for frog levitation is,*

$$\mathbf{F}_{lev} = (\sum\nolimits_k \mathbf{m}_k \cdot \nabla)\vec{\mathcal{B}} > m_{frog} g = \mathbf{F}_{peso} \ ,$$

taking the sum over all diamagnetic moments of the frog,

$$\sum_k \mathbf{m}_k = \vec{\mathcal{M}} V = \chi_\mu \vec{\mathcal{H}} V = \frac{\chi_\mu}{\mu} \vec{\mathcal{B}} V \ .$$

For the vertical axis we get,

$$F_{lev} = \frac{\chi_\mu}{\mu} \mathcal{B} V \frac{d\mathcal{B}}{dz} > m_{frog} g = \rho_{water} V g \ ,$$

giving the necessary condition for diamagnetic levitation,

$$\mathcal{B}\frac{d\mathcal{B}}{dz} = \mu_0 \rho \frac{g}{\chi_m u} \ ,$$

Water levitates at $\mathcal{B}\frac{d\mathcal{B}}{dz} \approx 1370\,\mathrm{T}^2/\mathrm{m}$. *To levitate a frog, however, we need very strong magnetic fields of the order of* $\mathcal{B} = \sqrt{l\mu_0\rho\frac{g}{\chi_m u}} \approx 12\,\mathrm{T}$.

16.1.7.4 Ex: Larmor precession of a Bohr atom in a magnetic field

As a model of the Larmor precession, consider the Bohr's atom model: An electron flying on circular orbits around a proton. Only certain discrete orbits with the radii $r_n = n^2 a_B$, where $a_B = 4\pi\varepsilon_0 \frac{\hbar^2}{m_e e^2}$, are allowed. The movement of the electron on these orbits is not accompanied by radiative emission.
a. Calculate the velocity of the electron in its ground state $n = 1$ and compare the

result with the speed of light in vacuum c.
b. What is the orbital momentum $\mathbf{L}$ of the electron in a hydrogen atom in this state?
c. Relate the magnetic moment $\mathbf{m}_L$ due to the circular current generated by the electron to the orbital momentum $\mathbf{L}$.
d. Placed in a magnetic field of $\mathcal{B} = 1\,\mathrm{T}$ the atom suffers a torque, which creates a precession of the angular momentum vector $\mathbf{L}$ around the direction of the $\vec{\mathcal{B}}$-field. Determine the frequency of this Larmor precession from $\omega_L = \dot{L}/(L\sin\theta)$, where θ is the angle between $\mathbf{m}_L$ and $\vec{\mathcal{B}}$. ($\hbar = 1.034 \cdot 10^{-34}\,\mathrm{Js}$, $e = 1.602 \cdot 10^{-19}\,\mathrm{C}$, $\varepsilon_0 = 8.854 \cdot 10^{-8}\,\mathrm{As/Vm}$.

Solution: *a. In the ground state the equilibrium of the electron orbit is given by,*

$$F_C = \frac{1}{4\pi\varepsilon_0}\frac{e^2}{a_B^2} = m_e\frac{v^2}{a_B} = F_{centrifug}\ .$$

Therefore, the velocity is,

$$v = \sqrt{\frac{1}{4\pi\varepsilon_0}\frac{e^2}{m_e a_B}} = \frac{e^2}{4\pi\varepsilon_0\hbar} = 2.2\cdot 10^6\,\mathrm{m/s} = \alpha c\ .$$

b. The orbital momentum is,

$$\mathbf{L} = \mathbf{r}\times\mathbf{p} = m_e a_B v\hat{\mathbf{L}} = m_e 4\pi\varepsilon_0\frac{\hbar^2}{m_e e^2}\frac{e^2}{4\pi\varepsilon_0\hbar}\hat{\mathbf{L}} = \hbar\hat{\mathbf{L}}\ .$$

c. The rotation of the electron on its orbit produces a current, $I = -ev/2\pi R$, which produces a magnetic moment,

$$\mathbf{m}_L = I\mathbf{A} = \frac{-eva_B\hat{\mathbf{L}}}{2} = \frac{-e}{2m_e}\mathbf{L}\ .$$

d. We have, $dL = L\sin\theta\cdot\omega_L dt$. Thus, the frequency of Larmor is,

$$\omega_L = \frac{\dot{L}}{L\sin\theta} = \frac{\tau}{L\sin\theta} = \frac{m_L\mathcal{B}\sin\theta}{L\sin\theta} = \frac{m_L\mathcal{B}}{L} = \frac{-e}{2m_e}\mathcal{B}\ .$$

Note, that,

$$\mu_B = \frac{e\hbar}{2m_e}$$

It's called Bohr's magneton.

16.1.7.5 Ex: H-field of a cylindrical current wire

A cylindrical wire with radius a and permeability μ is traversed by a constant current density $\mathbf{j}$.
a. Calculate the absolute values and the directions of the $\vec{\mathcal{H}}$ and $\vec{\mathcal{B}}$-fields in- and outside the wire using Stokes law.
b. The electric field $\vec{\mathcal{E}}$ within the wire and the current $\mathbf{j}$ are connected by Ohm's law

$\mathbf{j} = \sigma\vec{\mathcal{E}}$, where σ is the electrical conductivity. What is the value and direction of the Poynting vector $\mathbf{s}$ on the wire surface?
c. Calculate the total energy flow across the surface of a piece of wire of length L. Show that the energy flow corresponds exactly to the power converted, in this piece of wire, to ohmic heat.
Help: The energy conservation law of electrodynamics is given by: $-\frac{\partial u}{\partial t} = \nabla\cdot\mathbf{s}+\mathbf{j}\cdot\vec{\mathcal{E}}$, where $u = \frac{1}{2}(\vec{\mathcal{E}}\cdot\vec{\mathcal{D}} + \vec{\mathcal{B}}\cdot\vec{\mathcal{H}})$ is the total energy density, $\mathbf{s} = \vec{\mathcal{E}}\times\vec{\mathcal{H}}$ the flow of energy, and $\mathbf{j}\cdot\vec{\mathcal{E}}$ the work done by the field on the electric current density.

Solution: *a. Assuming an isotropic wire medium we know $\vec{\mathcal{B}} = \mu\vec{\mathcal{H}}$ inside the wire and $\vec{\mathcal{B}} = \mu_0\vec{\mathcal{H}}$ outside, which means that both fields are parallel everywhere and that there is a magnetization inside the wire $\vec{\mathcal{M}} = (\mu_0^{-1} - \mu^{-1})\vec{\mathcal{B}}$. The wire of length L carries a current I generated by a voltage U. Hence, the electric field inside the wire is,*

$$\vec{\mathcal{E}} = \frac{U}{L}\hat{\mathbf{e}}_z \ .$$

Imagining an Ampèrian loop inside and outside the wire we find, using the Ampère-Maxwell equation,

$$\oint \mathcal{H}\cdot d\mathbf{r} = 2\pi r\mathcal{B}(r) = \int \nabla\times\vec{\mathcal{H}}\cdot d\mathbf{S} = \int \mathbf{j}\cdot d\mathbf{S} = \begin{cases} I\frac{r^3}{R^3} & for \ \ r < R \\ I & for \ \ r > R \end{cases} .$$

Hence,

$$\vec{\mathcal{H}}(\mathbf{r}) = \begin{cases} \frac{I}{2\pi}\frac{r^2}{R^3}\hat{\mathbf{e}}_\phi & for \ \ r < R \\ \frac{I}{2\pi}\frac{1}{r}\hat{\mathbf{e}}_\phi & for \ \ r > R \end{cases} ,$$

and we see that the parallel component of the $\vec{\mathcal{H}}$-field is continuous at the wire surface, but this cannot be the case for $\vec{\mathcal{B}}$, which will have a discontinuity corresponding to the magnetization.
b. The Poynting vector

$$\mathbf{s} = \vec{\mathcal{E}}\times\vec{\mathcal{H}} = \frac{U}{L}\hat{\mathbf{e}}_z \times \frac{\mu}{2\pi}I\frac{r^2}{R^3}\hat{\mathbf{e}}_\phi = \begin{cases} -\frac{U}{L}\frac{\mu I}{2\pi}\frac{r^2}{R^3}\hat{\mathbf{e}}_\rho & for \ \ r < R \\ -\frac{U}{L}\frac{\mu I}{2\pi}\frac{1}{r}\hat{\mathbf{e}}_\rho & for \ \ r > R \end{cases}$$

is perpendicular to the wire surface.
c. The total energy flow across the surface is,

$$\int \mathbf{s}\cdot d\mathbf{S} = s(2\pi aL) = UI = R_{heat} \ .$$

16.1.7.6 Ex: Ferromagnetism

a. Make a scheme of the dependence of the magnetization $\mathcal{M}$ of a ferromagnetic material on the magnetic 'excitation' $\mathcal{H}$ with the initial condition $\mathcal{M} = \mathcal{H} = 0$ and

letting $\mathcal{H}(t)$ cycle through $0 \to \mathcal{H}_{max} \to -\mathcal{H}_{max} \to \mathcal{H}_{max}$. Indicate the remaining magnetization in the scheme.
b. How does the magnetization of a ferromagnet change when we heat it up above the Curie temperature T_C? How does the magnetic susceptibility behave in this case χ_m?
c. It explains the order of the atomic magnetic moments in ferro-, antiferro- and ferrimagnets and its influence on their magnetization.

Solution: *a. The 'virgin curve' shows the magnetization of an initially non-magnetized ferromagnet, when it is exposed to an external magnetic excitation field rising from 0 to $\mathcal{H}_{max}$.*
b. When heat above T_C, the ferromagnetic order is lost, and the ferromagnet becomes a paramagnet. The magnetic susceptibility behaves at temperatures $T > T_C$ as $\chi_m \propto 1/(T - T_C)$.
c. Within ordered areas (Weiss domains) for ferromagnets all magnetic dipolar moments are equal and oriented in parallel. For antiferromagnets the magnetic dipole moments are also equal, but oriented antiparallel. For ferrimagnets the magnetic dipolar moments of neighboring atoms are different and antiparallel. The resulting magnetization is large for ferromagnets, lower for ferrimagnet and zero for antiferromagnet (see Fig. 16.4).

16.1.7.7 Ex: Rectangular toroidal coil

A circular coil is made of a core with rectangular cross-sectional area, $A = h(r_2 - r_1)$, on which two coils are densely wound on top of each other, one with the number of turns N_1 and the other with N_2. Establishes a relationship for the mutual inductance L of the two coils.
Help: To calculate the mutual inductance, invoke the flux equation for the case that the coil N_1 is traversed by the current I_1, that is, $\oint \mathcal{H} \cdot d\mathbf{s} = N_1 I_1$ and calculate the induced flux Φ.

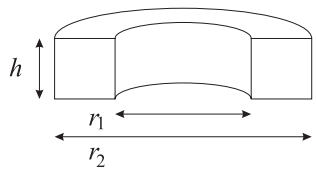

Figure 16.6: Rectangular toroidal coil.

Solution: *The first coil produces a magnetic flux,*

$$\Phi = \frac{L_1}{N_1} I_1 \ .$$

This flux produces in the second coil the current,

$$I_2 = \frac{N_2}{L_2}\Phi = \frac{N_2}{N_1}\frac{L_1}{L_2} I_1 \ .$$

16.1.7.8 Ex: Toroidal coil

Consider a toroidal coil with the average radius R, which consists of N turns carrying the current I. The coil is filled with an iron core of permeability μ.
a. Calculate the amplitude of the fields $\mathcal{H}$ and $\mathcal{B}$ inside the coil.
b. Now consider a core with an air gap d with $d \ll R$ interrupting the torus. Calculate once again the fields $\mathcal{H}$ and $\mathcal{B}$ within the slot.

Solution: *a. Let the coil be in the xy-plane. With the Ampère's law,*

$$\oint \vec{\mathcal{H}} \cdot d\mathbf{l} = 2\pi R\mathcal{H} = \int \mathbf{j} \cdot d\mathbf{S} = NI \ .$$

With this follows,

$$\mathcal{H} = \frac{NI}{2\pi R} \qquad \textit{and} \qquad \mathcal{B} = \mu\mu_0\mathcal{H} = \mu\mu_0\frac{NI}{2\pi R} \ .$$

b. At the transition between iron and air the normal component of $\vec{\mathcal{B}}$ and the parallel component of $\vec{\mathcal{H}}$ are continuous. Therefore, since in our geometry ($d \ll R$) the fields $\vec{\mathcal{B}}$ and $\vec{\mathcal{H}}$ are approximately uniform, we only have normal components, such that: $\mathcal{B}_{Fe} = \mathcal{B}_{ar}$ and $\mu\mathcal{H}_{Fe} = \mathcal{H}_{ar}$. Now, we have,

$$\oint \vec{\mathcal{H}} \cdot d\mathbf{l} = (2\pi R - d)\mathcal{H}_{Fe} + d\mathcal{H}_{ar} = (2\pi R - d)\frac{\mathcal{H}_{ar}}{\mu} + d\mathcal{H}_{ar} = \int \mathbf{j} \cdot d\mathbf{S} = NI \ .$$

Hence,

$$\mathcal{H}_{ar} = \frac{NI\mu}{2\pi R - d + \mu d} \ ,$$

and

$$\mathcal{B}_{ar} = \mu_0\mathcal{H}_{ar} = \frac{NI\mu\mu_0}{2\pi R + (\mu - 1)d} \ .$$

For a very narrow gap with $\mu \simeq 2000$ we get a big amplification of the field:

$$\mathcal{B}_{ar} \simeq \frac{NI\mu\mu_0}{2\pi R} \ .$$

16.1.7.9 Ex: Toroidal coil

A slotted steel ring has the dimensions: $b = 20\,\text{mm}$, $r = 80\,\text{mm}$, $a = 15\,\text{mm}$, and $d = 1\,\text{mm}$ (see the figure).
a. Calculate, first without air gap, for a magnetic flux density $\mathcal{B}$ the total magnetic flux Ψ_M and the corresponding $\mathcal{H}$ field. What is the amount of current I required generate this flux in a coil of N turns?

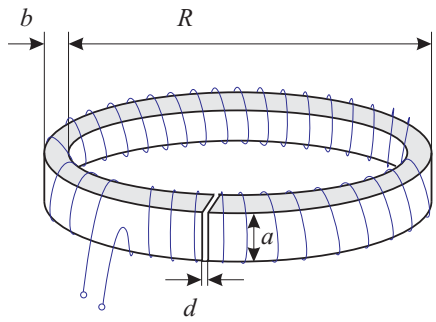

Figure 16.7: Toroidal coil.

b. How must $\mathcal{H}$ and I be modified, if the ring is interrupted by a 1 mm wide air gap, to reach the same flux? Use $\mathcal{B} = 1.2\,\mathrm{T}$, $N = 300$, $\mu_r = 650$.

Solution: *a. The magnetic field of a long coil is* $\mathcal{H} = \mathcal{B}/\mu_0\mu_r$ *and is related to the current by* $\mathcal{H} = NI/l$. *It follows for the current,*

$$I = \frac{l\mathcal{B}}{\mu_0\mu_r N} = \frac{2\pi r\mathcal{B}}{\mu_0\mu_r N} \simeq 1.5385\,\mathrm{A} \ .$$

The flux is,

$$\Phi = \int \vec{\mathcal{B}} \cdot d\mathbf{S} = \mathcal{B}S \simeq 3.6 \cdot 10^{-4}\,\mathrm{Vs} \ .$$

b. The magnetic fields in the core and the slot are,

$$\mathcal{H}_{fe} = \frac{\mathcal{B}}{\mu_0\mu_r} \simeq 1470 \qquad \textit{and} \qquad \mathcal{H}_{ar} = \frac{\mathcal{B}}{\mu_0} \simeq 955\ 000\,\mathrm{A/m} \ .$$

The current is,

$$I = \frac{1}{N}\int \vec{\mathcal{H}} \cdot d\mathbf{l} = \frac{\mathcal{H}_{fe}}{N}(2\pi r - \Delta s) + \frac{\mathcal{H}_{ar}}{N}\Delta s \simeq 4.72\,\mathrm{A} \ .$$

16.2 Induction of currents and inductance

We have already seen that the fundamental cause of current $\mathbf{j}$ is a motion of charges Q [see Eq. (14.38)]. To incite charges to move we need a force,

$$\boxed{\mathbf{j} = \varsigma\frac{\mathbf{F}}{Q}} \ , \tag{16.33}$$

where ς is a proportionality factor called *conductivity* and $\mathbf{F}$ is the Coulomb-Lorentz force, such that,

$$\boxed{\mathbf{j} = \varsigma(\vec{\mathcal{E}} + \mathbf{v} \times \vec{\mathcal{B}})} \ . \tag{16.34}$$

The first part, $\mathbf{j} = \varsigma\vec{\mathcal{E}}$, is Ohm's law already discussed in Sec. 14.3. Now, in addition to taking into account the Coulomb force acting on electrons traveling in conductors, let us also consider the Lorentz force.

16.2.1 The electromotive force

When we consider a closed electric circuit with a current source and a consumer, knowing the slow average velocity of the electrons carrying the current (see Exc. 14.3.3.3), it is not immediately obvious why the current starts to flow simultaneously in all parts of the circuit. The explanation is that if this were not the case, charges would accumulate in parts of the circuit creating local imbalances. The consequence of this would be the creation of electric fields working to eliminate the imbalances. These fields $\vec{\mathcal{E}}$ are superposed to the electromotive force $\mathbf{f}_0$ exerted by the current source. If the source has an internal resistance, as schematized in Fig. 16.8(a), part of the electromotive force $\mathbf{f}_i$ is spent on it,

$$\mathbf{f}_i = \mathbf{f}_0 + \vec{\mathcal{E}} \ . \tag{16.35}$$

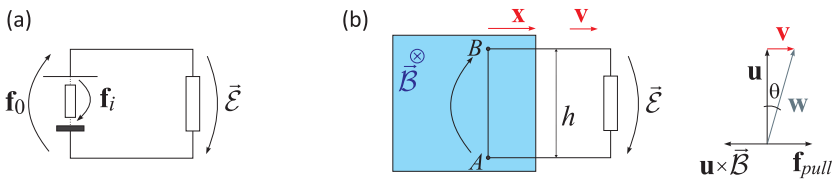

Figure 16.8: (a) Illustration of the electromotive force $\mathbf{f}_0$ exerted by an arbitrary voltage source, the force $\mathbf{f}_i$ spent on the internal resistance of the source, and the electrostatic force $\vec{\mathcal{E}}$ on the circuit. (b) Electromotive force $\mathbf{f}_0$ generated by the motion of a part of the circuit inside a magnetic field.

In the case of an ideal source, $\mathbf{f}_i = 0$, the path integral along the circuit,

$$\mathcal{E} \equiv \int_+^- \mathbf{f}_0 \cdot d\mathbf{l} = -\int_+^- \vec{\mathcal{E}} \cdot d\mathbf{l} = U \ , \tag{16.36}$$

yields exactly the voltage.

The electromotive force can be caused by batteries, photocells, generators, etc. In the case of a generator, the electromotive force is the Lorentz force acting on the free charges of a conductor moved within an applied magnetic field. Let us consider the setup schematized in Fig. 16.8(b). When the part of the conductor between the points A and B (length h) is moved to the right with velocity $\mathbf{v}$ within the magnetic field $\vec{\mathcal{B}}$, positive charges are accelerated upwards, as in the case of the Hall effect. We obtain an electromotive force,

$$\mathcal{E} \equiv \oint \mathbf{f}_L \cdot d\mathbf{l} = hv\mathcal{B} \ , \tag{16.37}$$

which acts as a source of voltage. Of course, it is not the magnetic field which does the work through the Lorentz force, but the person pushing the conductor: Calling

u the velocity along the conductor acquired by the accelerated charges, this velocity creates inside the magnetic field an electromotive force $\mathbf{u} \times \vec{\mathcal{B}}$ against the motion of the conductor exerting per unit of charge the work,

$$\int \mathbf{f}_{pull} \cdot d\mathbf{l}_w = -\int (\mathbf{u} \times \vec{\mathcal{B}}) \cdot d\mathbf{l}_w = \int u\mathcal{B}\hat{\mathbf{e}}_x \cdot d\mathbf{l}_w \tag{16.38}$$
$$= \int_0^h \frac{v}{\tan\theta} \mathcal{B}\cos(90^\circ - \theta)\frac{dh}{\cos\theta} = hv\mathcal{B} = \mathcal{E} \ .$$

We find that the work exerted per unit of charge exactly compensates the electromotive force.

Applying the definition of the magnetic flux (15.12), to the situation illustrated in Fig. 16.8(b),

$$\Psi_M = \int \vec{\mathcal{B}} \cdot d\mathbf{S} = \mathcal{B}hx \ , \tag{16.39}$$

we can reshape the Eq. (16.37),

$$h\mathcal{B}v = -h\mathcal{B}\dot{x} = \boxed{-\frac{d\Psi_M}{dt} = \mathcal{E}} \ . \tag{16.40}$$

Hence, the temporal variation of the magnetic flux induces a *counteracting* electromotive force. This is known as *Lenz's rule*.

16.2.2 The Faraday-Lenz law

In a series of experiments *Michael Faraday* demonstrated that the relationship (16.40) can be generalized to any geometry of the circuit immersed in a magnetic field, to any velocity of the motion, and even to time-varying geometries. The applications of this effect are innumerable, see Exc. 16.2.3.1 to 16.2.3.23. Relating the electromotive force on one side to the generation of a voltage (16.36), $\mathcal{E} = \oint \vec{\mathcal{E}} \cdot d\mathbf{l}$, and on the other side to the variation of the flux (16.40), $\mathcal{E} = -\frac{d\Psi_M}{dt}$, we can write,

$$\boxed{\oint \vec{\mathcal{E}} \cdot d\mathbf{l} = -\frac{\partial}{\partial t}\int \vec{\mathcal{B}} \cdot d\mathbf{S}} \ . \tag{16.41}$$

In the differential version we get,

$$\boxed{\nabla \times \vec{\mathcal{E}} = -\frac{\partial \vec{\mathcal{B}}}{\partial t}} \ . \tag{16.42}$$

Note that, without temporal variations of the magnetic field, we recover electrostatics, $\nabla \times \vec{\mathcal{E}} = 0$.

16.2.2.1 Mutual inductance

Here, we consider two loops of arbitrary shapes. The first loop carries the current I_1 and produces a magnetic field, which we can calculate, for example, by Biot-Savart's law,

$$\vec{\mathcal{B}}_1 = \frac{\mu_0 I_1}{4\pi} \oint \frac{d\mathbf{l}_1 \times (\mathbf{r} - \mathbf{r}')}{|\mathbf{r} - \mathbf{r}'|^3} \ . \tag{16.43}$$

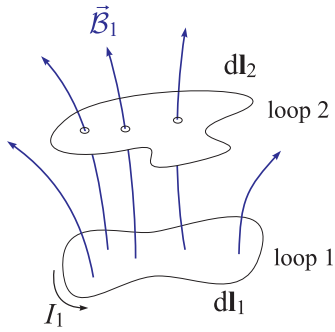

Figure 16.9: Indução.

The part of the magnetic flux passing through the second loop is,

$$\Psi_{M2} = \int \vec{\mathcal{B}}_1 \cdot d\mathbf{S}_2 \equiv M_{21} I_1 \ , \tag{16.44}$$

where M_{21} is a constant that depends only on the geometry of the two loops. It is called *mutual inductance* and can be expressed as,

$$\begin{aligned} M_{21} &= \frac{1}{I_1} \int \nabla \times \mathbf{A}_1 \cdot d\mathbf{S}_2 = \frac{1}{I_1} \oint \mathbf{A}_1 \cdot d\mathbf{l}_2 \\ &= \frac{1}{I_1} \oint \left(\frac{\mu_0 I_1}{4\pi} \oint \frac{d\mathbf{l}_1}{|\mathbf{r} - \mathbf{r}'|} \right) \cdot d\mathbf{l}_2 = \frac{\mu_0}{4\pi} \oint \oint \frac{d\mathbf{l}_1 \cdot d\mathbf{l}_2}{|\mathbf{r} - \mathbf{r}'|} \ . \end{aligned} \tag{16.45}$$

The symmetry of this formula suggests,

$$M_{21} = M_{12} = M \ . \tag{16.46}$$

We can drop the indices and call both constants M. The conclusion of this is that, regardless of the shapes and positions of the loops, the flux through loop 2 when we throw a current I into the loop 1 is identical to the flux through 1 when we throw the same current I into 2,

$$I_1 = I_2 = I \Longrightarrow \int \vec{\mathcal{B}}_1 \cdot d\mathbf{S}_2 = \int \vec{\mathcal{B}}_2 \cdot d\mathbf{S}_1 \ . \tag{16.47}$$

Example 78 (*Dynamo*): We consider a rotating coil set in motion by a crank inside a magnetic field, as shown in the figure. The voltage wasted by the resistor is,

$$U = \oint \vec{\mathcal{E}} \cdot d\mathbf{l} = -\frac{d}{dt} \Psi_M = -\frac{d}{dt} \int \vec{\mathcal{B}} \cdot d\mathbf{A} = -\frac{d}{dt} \mathcal{B} A \cos \omega t = \omega \mathcal{B} A \sin \omega t \ .$$

16.2.2.2 Self-inductance

The magnetic flux produced by the current in loop 1 not only traverses the second loop, but also the first loop itself. Therefore, any variation of the flux will also induce an electromotive force in this loop 1,

$$\Psi_{M1} = M_{11} I_1 \equiv L I_1 \ , \tag{16.48}$$

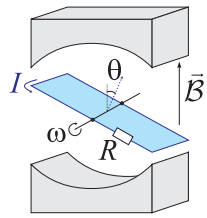

Figure 16.10: Schematic of a generator of alternating voltage (or dynamo).

where the constant L is called *self-inductance*. With the law of Lenz-Faraday,

$$\mathcal{E} = -\frac{d\Psi_M}{dt} = -L\dot{I} \ . \tag{16.49}$$

Example 79 (*Self-inductance of a solenoid*): Consider the solenoid shown in Fig. 16.11. With the formula of the example 72 we calculate the magnetic flux,

$$\Psi_M = \int \vec{\mathcal{B}} \cdot d\mathbf{A} = \mu I \frac{N}{l} \ N\pi R^2 \ .$$

Comparing with the formula (16.48), we find self-inductance,

$$L = \mu \frac{N^2}{l} \ \pi R^2$$

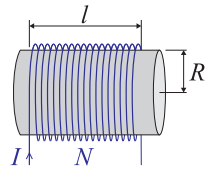

Figure 16.11: Scheme of a solenoid characterized by a self-inductance L.

16.2.3 Exercises

16.2.3.1 Ex: Application of the Faraday-Lenz law

The current in a coil characterized by the inductance $L = 1\,\text{mH}$ is linearly reduced in one second from 1 A to 0. Calculate the induced voltage.

Solution: *The induced voltage is,*

$$U_L = -L\dot{I} = 1\,\text{mV} \ .$$

16.2.3.2 Ex: Breathing charge distribution

A radially symmetric charge distribution varies over time as $\lambda(t)$ in a 'breathing oscillation',

$$\varrho(\mathbf{r},t) = \varrho_0\lambda(t)\frac{1}{r^2}e^{-a\lambda(t)r} \ ,$$

where $\varrho_0 = const.$ and $a = const.$
a. What is the value of the total charge?
b. Calculate the current density $\mathbf{j}(\mathbf{r},t)$, which corresponds to $\varrho(\mathbf{r},t)$ from the continuity equation.
c. Determine $\vec{\mathcal{E}}(\mathbf{r},t)$ from the ansatz $\vec{\mathcal{E}}(\mathbf{r},t) = \mathcal{E}(r,t)\frac{\mathbf{r}}{r}$ (radial symmetry).
d. Calculate the corresponding magnetic field $\vec{\mathcal{B}}$.
e. Show that the solutions for $\vec{\mathcal{E}}$ and $\vec{\mathcal{B}}$ satisfy Maxwell's equations.

Solution: *a. The total charge is,*

$$Q = \int_{\mathbf{V}} \varrho(\mathbf{r},t)dV = 4\pi\varrho_0\lambda(t)\int_0^\infty \frac{1}{r^2}e^{-a\lambda(t)r}r^2dr = 4\pi\varrho_0\lambda(t)\left[\frac{e^{-a\lambda(t)r}}{-a\lambda(t)}\right]_0^\infty = \frac{4\pi\varrho_0}{a} \ .$$

b. From the continuity equation we calculate,

$$\begin{aligned} 4\pi r^2 j_r &= \oint_{\partial\mathcal{V}} \mathbf{j}\cdot d\mathbf{S} = -\partial_t\int_{\mathcal{V}}\varrho dV = -4\pi\varrho_0\partial_t\lambda(t)\int_0^r e^{-a\lambda(t)r'}dr' \\ &= \frac{4\pi\varrho_0}{a}\partial_t[e^{-a\lambda(t)r}-1] = -4\pi\varrho_0 r\dot{\lambda}(t)e^{-a\lambda(t)r} \ , \end{aligned}$$

giving,

$$j_r = -\frac{\varrho_0\dot{\lambda}(t)}{r}e^{-a\lambda(t)r} \ .$$

c. From the Gauß law,

$$4\pi r^2\mathcal{E}_r = \oint_{\partial\mathcal{V}}\vec{\mathcal{E}}\cdot d\mathbf{S} = \int_{\mathcal{V}}\frac{\varrho}{\varepsilon_0}dV = \frac{1}{\varepsilon_0}4\pi\varrho_0\lambda(t)\left[\frac{e^{-a\lambda(t)r}}{-a\lambda(t)}\right]_0^r = \frac{4\pi\varrho_0}{\varepsilon_0 a}(1-e^{-a\lambda(t)r}) \ ,$$

giving,

$$\mathcal{E}_r = \frac{\varrho_0}{\varepsilon_0 a r^2}(1-e^{-a\lambda(t)r}) \ .$$

d. The magnetic field is zero, because by symmetry it could only be radial. However, the rotational radial field is zero, $\nabla\times\vec{\mathcal{B}} = 0$. As the divergent also zeroes, $\nabla\cdot\vec{\mathcal{B}} = 0$, we conclude $\vec{\mathcal{B}} = 0$.
e. Maxwell's first equation then gets,

$$\nabla\times\vec{\mathcal{B}} = \mu_0\mathbf{j} + \varepsilon_0\mu_0\partial_t\vec{\mathcal{E}} = 0 \ ,$$

what we verified with the results of (b) and (c).

16.2.3.3 Ex: Law of induction

a. Explain the concept of magnetic flux across an area F. How does magnetic flux depend on the choice of surface?
b. What is the form of Faraday's induction law? What are the experimental observations underlying this law?
c. What is the physical content of Lenz's law?
d. What is Maxwell's displacement current? Give a physical justification for this current.
e. Write down Maxwell's equations.
f. What is the motivation for introducing the electromagnetic potentials Φ and $\mathbf{A}$?
g. What is the allowed gauge transformation for electromagnetic potentials?
h. What is the meaning of the Lorentz gauge? What advantages does it offer?
i. Formulate the energy conservation law of electrodynamics.
j. What is the physical meaning of the Poynting vector?

Solution: *a. The magnetic flux is* $\Psi = \int_F \vec{\mathcal{B}} \cdot d\mathbf{S}$. *For a given field* $\vec{\mathcal{B}}$ *the flux across two different surfaces with the same edge is the same.*
b. $U_{ind} = \oint \vec{\mathcal{E}} \cdot d\mathbf{S} = -d\Psi/dt$. *Temporally varying magnetic fields induce voltages in conductive loops.*
c. The voltage induced by a variable magnetic field generates a current and therefore a magnetic field oriented opposite to the variation of the original magnetic field.
d. A temporal variation of the electric displacement field $\partial\vec{\mathcal{D}}/\partial t$ *can be interpreted via a displacement current. This is the only way current can be transported through a capacitor, once there is no charge flow possible between the plates.*
e. rot $\vec{\mathcal{H}} = \dot{\vec{\mathcal{D}}} + \mathbf{j}$, *rot* $\vec{\mathcal{E}} = -\dot{\vec{\mathcal{B}}}$, *div* $\vec{\mathcal{D}} = \rho$, *and div* $\vec{\mathcal{B}} = 0$.
f. The potentials are introduced by $\vec{\mathcal{B}} = \nabla \times \mathbf{A} = 0$ *and* $\vec{\mathcal{E}} = -\nabla\Phi - d\mathbf{A}/dt$.
g. Allowed is $\mathbf{A}' = \mathbf{A} + \nabla\Lambda$ *and* $\Phi' = \Phi - d\Lambda/dt$.
h. With $\nabla \cdot \mathbf{A}'/\mu_0 + \varepsilon_0 d\Phi/dt = 0$ *follows* $-\Delta\Phi + \mu_0\varepsilon_0\ddot{\Phi} = \rho/\varepsilon_0$ *and* $-\Delta\mathbf{A} + \mu_0\varepsilon_0\ddot{\mathbf{A}} = \mu_0\mathbf{j}$.
i. $du/dt = \nabla \cdot \mathbf{S} + \mathbf{j} \cdot \vec{\mathcal{E}}$ *with* $u = \frac{1}{2}(\vec{\mathcal{E}} \cdot \vec{\mathcal{D}} + \vec{\mathcal{B}} \cdot \vec{\mathcal{H}})$.
j. The Poynting vector describes the flow of energy: $\mathbf{S} = \vec{\mathcal{E}} \times \vec{\mathcal{H}}$.

16.2.3.4 Ex: Induction and Lorentz force

Two parallel metal rods are tilted by an angle φ with respect to the ground (see diagram). Between the rods a third movable rod of mass m and length L placed at right angles glides without friction. A homogeneous magnetic field $\vec{\mathcal{B}}$ crosses perpendicularly the plane defined by the three rods. The parallel rods are connected at the top end by a capacitor C, such that a closed current circuit is formed together with the transverse rod.
a. Set up the equation of motion for the transverse rod.
b. Determine the solution $x(t)$ of the equation of motion for the initial condition $x(0) = v(0) = 0$.

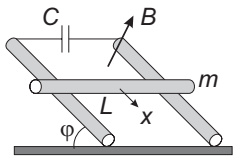

Figure 16.12: Induction.

Solution: *a. The equation of motion is,*

$$m\ddot{x} = mg\sin\varphi + BIL \ .$$

By definition,

$$I = -\frac{dq}{dt}$$

and

$$q = CU_{ind} = C(-\frac{d\Phi}{dt}) = -C\mathcal{B}\frac{dS}{dt} = -C\mathcal{B}L\frac{dx}{dt} \ .$$

Now we get,

$$m\ddot{x} = mg\sin\varphi + C\mathcal{B}^2L^2\ddot{x}$$

or

$$\ddot{x} = \frac{mg\sin\varphi}{m - C\mathcal{B}^2L^2} \ .$$

b. The trivial solution of the differential equation is,

$$x(t) = \frac{mg\sin\varphi}{m - C\mathcal{B}^2L^2}t^2 \ .$$

16.2.3.5 Ex: Magnetic flux and induction

Consider the conductive ring of radius l and negligible electrical resistance shown in the figure. Perpendicular to the plane of the ring there is a homogeneous magnetic field $\vec{\mathcal{B}}$. A rod 2 rotates with angular frequency ω. Calculate the current I across the resistance R of another resting rod 1.

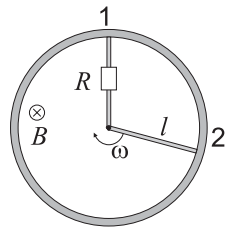

Figure 16.13: Induction.

Solution: *The voltage induced by the decrease of the left area is,*

$$U_{ind,e} = -\frac{d\Phi}{dt} = -\frac{\vec{\mathcal{B}} \cdot \Delta \mathbf{S}_e}{\Delta t} \ ,$$

where

$$\Delta S_e = \frac{l(ld\phi)}{2}\hat{\mathbf{e}}_z \ ,$$

with $d\phi$ the angle of variation of the rotary motion. Therefore, the induced voltage is,

$$U_{ind,e} = -\frac{\mathcal{B}l^2}{2}\frac{d\phi}{dt} = -\frac{-\mathcal{B}\omega l^2}{2} \ .$$

At the same time, the right area grows by an area,

$$\Delta S_d \hat{\mathbf{e}}_z = -\Delta S_e(-\hat{\mathbf{e}}_z) \ .$$

inducing a voltage,

$$U_{ind,d} = \frac{\mathcal{B}\omega l^2}{2} \ .$$

Hence, the two voltages produce a current going through the resistor,

$$I = -\frac{|U_{ind,e}|}{R} - \frac{|U_{ind,d}|}{R} = \frac{\omega \mathcal{B} l^2}{R} \ .$$

The directions of the currents must be the same, since following Lenz's law, I_e must generate a magnetic field supporting the diminishing flux in the area S_e and I_d must generate a field preventing the increasing flux in the area S_d. Alternatively we calculate:

$$\mathcal{E} = \int \vec{\mathcal{E}} \cdot d\mathbf{l} = \tfrac{1}{q}\int \mathbf{F} \cdot d\mathbf{l} = \int_0^l \mathbf{v}_{tot} \times \vec{\mathcal{B}} d\mathbf{l} = \int_0^l (-\omega l \hat{\mathbf{e}}_\phi - v_i \hat{\mathbf{e}}_\rho) \times \vec{\mathcal{B}} d\mathbf{l} = \frac{\omega l^2 B}{2} - v_i \mathcal{B} l \hat{\mathbf{e}}_\phi \ .$$

16.2.3.6 Ex: Induction

Consider the conductive loop at right angle shown in the figure. There is a homogeneous magnetic field given by,

$$\vec{\mathcal{B}}(\mathbf{r}) = \mathcal{B}_0 \hat{e}_y \ .$$

The conductive loop rotates around the bending axis (z-axis) with constant angular frequency.ω.
a. What is the voltage induced in the loop as a function of time?
b. Calculate the time average of the induced voltage.

Solution: *a. We calculate the flux Φ as a function of the rotation angle ϕ by separately considering the areas A_1 and A_2 defined by the two parts of the loop. The*

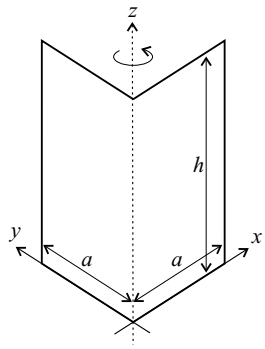

Figure 16.14: Induction.

flux through the area A_1 is $\Phi_1 = \mathcal{B}_0 \cdot h \cdot a \cdot \cos\phi$, and the flux through the area A_2 is $\Phi_2 = B_0 \cdot h \cdot a \cdot \sin\phi$. So the total flux is,

$$\Phi_{tot} = \Phi_1 + \Phi_2 \ .$$

The derivative of the total flux is,

$$\frac{d}{dt}(\mathcal{B}_0 ha(\cos\phi + \sin\phi)) = \mathcal{B}_0 ha(-\dot{\phi}\sin\phi + \dot{\phi}\cos\phi) \ ,$$

and with $\phi = \omega t$ resp. $\omega = \dot{\phi}$ follows,

$$\dot{\Phi}_{tot} = \mathcal{B}_0 ha\omega[\cos(\omega t) - \sin(\omega t)] = \mathcal{B}_0 ha\sqrt{2}\sin(\tfrac{\pi}{4} - \omega t) \ .$$

The induced voltage now follows via,

$$U_{ind} = -\dot{\Phi}_{tot} = -\omega\mathcal{B}_0 ha\sqrt{2}\cos(\tfrac{\pi}{4} - \omega t) \ .$$

b. Also,

$$\int_0^{2\pi/\omega} dt[\cos(\omega t) - \sin(\omega t)] = 0 \to \bar{U}_{ind} = 0 \ .$$

16.2.3.7 Ex: Induction

A circular ring with radius R rotates with constant angular velocity ω around a diameter. Perpendicular to the rotation axis there is a magnetic field $\vec{\mathcal{B}}$.
a. Calculate the voltage induced in the ring as a function of time.
b. The ring consists of a metallic wire with conductivity σ. What current $I(t)$ flows through the ring, assuming the current is evenly distributed across the cross section of the wire?

Solution: *We call $\hat{\mathbf{e}}_n$ the normal vector perpendicular to the area spanned by the*

wire. So the surface element is, $d\mathbf{S} = dS\hat{\mathbf{e}}_n$*, and for the angle* $\phi(t)$ *that the* $\vec{\mathcal{B}}$*-field forms with* $\hat{\mathbf{e}}_n$*, holds* $\phi(t) = \omega(t - t_0)$*.*
a. For the induced voltage,

$$U_{ind} = -\frac{\partial}{\partial t}\Phi(t) \ ,$$

and

$$\Phi(t) = \int\limits_{circular\ area} d\mathbf{F} \cdot \vec{\mathcal{B}} = \int\limits_{circular\ area} df\hat{\mathbf{e}}_n \cdot \vec{\mathcal{B}}$$
$$= \mathcal{B}\cos[\omega(t - t_0)] \int\limits_{circular\ area} df = \mathcal{B}\pi R^2 \cos[\omega(t - t_0)]$$

hence,

$$U_{ind} = \mathcal{B}\pi R^2 \omega \sin[\omega(t - t_0)] \ .$$

b. For the conductive ring holds,

$$U_{ind} = \int\limits_{circularborder} \vec{\mathcal{E}} \cdot d\mathbf{r} = \frac{1}{\sigma} \int\limits_{circular\ border} \mathbf{j} \cdot d\mathbf{r} = \frac{I}{\sigma A} \int\limits_{circular\ border} dr = \frac{2\pi R}{\sigma A} I \ .$$

From this, and using (a) follows immediately,

$$I(t) = \frac{1}{2}\sigma \mathcal{B} A R \omega \sin[\omega(t - t_0)] \ .$$

16.2.3.8 Ex: Induction

An equidistant triangle-shaped conductive loop (edge length S) in the xy-plane is 'immersed' with constant velocity $\mathbf{v} = v\hat{\mathbf{e}}_x$ starting at the tip into a homogeneous magnetic field $\vec{\mathcal{B}} = \mathcal{B}\hat{\mathbf{e}}_z$ ($\mathcal{B}$ is constant) (see diagram) until being completely inside the magnetic field.
a. Calculate the maximum voltage induced in the loop.
b. Make a scheme of the time evolution of the induced voltage.

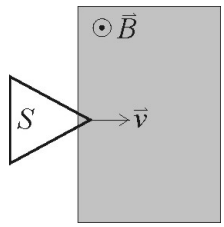

Figure 16.15: Induction.

Solution: *Calculation of the induced voltage,*

$$U_{ind} = \oint \vec{\mathcal{E}} \cdot d\mathbf{l} = \int (\nabla \times \vec{\mathcal{E}}) \cdot d\mathbf{S} = -\frac{d}{dt} \int \vec{\mathcal{B}} \cdot d\mathbf{S} = -\frac{d\Psi}{dt} \ .$$

Hence,

$$\Psi(t) = \int_A \vec{\mathcal{B}} \cdot d\mathbf{f} = \mathcal{B} \int_A df = \mathcal{B}A(t) \ ,$$

since $\vec{\mathcal{B}} \| d\mathbf{S}$ *and* $\mathcal{B} = const.$ *Now,*

$$A(t) = \frac{1}{2} s(t) v(t) = \frac{1}{\sqrt{3}} v^2 t^2$$

since $h^2 + \frac{s^2}{4} = s^2$ *resp.* $h(t) = \frac{\sqrt{3}}{2} s(t) = vt$. *With that we get for the flux and the induced voltage,*

$$\Psi(t) = \frac{1}{\sqrt{3}} \mathcal{B} v^2 t^2 \qquad \textit{and} \qquad U_{ind}(t) = -\frac{2}{\sqrt{3}} \mathcal{B} v^2 t \ .$$

The maximum voltage is finally,

$$U_{ind}^{\max} = U_{ind}(t = T)$$

with $T = \frac{H}{v} = \frac{\sqrt{3}}{2v} s$.

16.2.3.9 Ex: Induction

A rectangular conducting loop with height $2a$ and width $2b$ rotates with angular velocity ω around the z-axis. At time $t = 0$ the conducting loop is in the xz-plane. In addition, the loop is exposed to the inhomogeneous time-varying magnetic field $\vec{\mathcal{B}}(\mathbf{r}, t) = \mathcal{B}_0 t z^2 \hat{\mathbf{e}}_x$.
a. Show, $\nabla \cdot \vec{\mathcal{B}}(\mathbf{r}, t) = 0$.
b. Calculate the magnetic flux $\Psi(\mathbf{r}, t) = \int \vec{\mathcal{B}} \cdot d\mathbf{F}$ through the rotating loop as a function of time.
c. What is the value of the voltage $U_{ind}(t)$ induced in the loop as a function of time?

Solution: *a. Obvious.*
b. The normal vector of the area is time-dependent $d\mathbf{S} = \hat{\mathbf{e}}_x dS \sin\omega t + \hat{\mathbf{e}}_y dS \cos\omega t$. *Therefore, the magnetic flux is,*

$$\begin{aligned} \Phi(\mathbf{r}, t) &= \int \vec{\mathcal{B}} \cdot d\mathbf{S} = \int \mathcal{B}_0 t z^2 \hat{\mathbf{e}}_x \cdot (\hat{\mathbf{e}}_x dx \sin\omega t + \hat{\mathbf{e}}_y dy \cos\omega t) \ dz \\ &= \mathcal{B}_0 t \sin\omega t \int_{-a}^{a} \int_{-b}^{b} z^2 \ dxdz = \mathcal{B}_0 t \sin\omega t \, [x]_{-b}^{b} \left[\frac{z^3}{3}\right]_{-a}^{a} = \frac{4a^3 b}{3} \mathcal{B}_0 t \sin\omega t \ . \end{aligned}$$

c. The induced voltage is,

$$U_{ind}(t) = -\dot{\Psi}(t) = -\frac{4}{3} b a^3 \mathcal{B}_0 [\sin\omega t + \omega t \cos\omega t] \ .$$

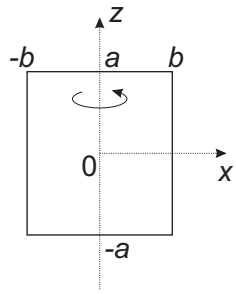

Figure 16.16: Induction.

16.2.3.10 Ex: Induction in a coil

Calculate the magnetic $\mathcal{B}$-field in the middle and at the end of a coil of length $L = 1\,\mathrm{m}$. The number of turns is $N = 2000$, the radius $r = 2\,\mathrm{cm}$, and the current through the coil $I = 5\,\mathrm{A}$. To do this first calculate, using the Biot-Savart law, the magnetic field $\mathcal{B}_1(0,0,z)$ of a single circular conductor with radius r located at a point z_1 of the coil's symmetry axis. Use the formula obtained for $\mathcal{B}_1$ to describe the magnetic field generated by a coil element dz.

Solution: *The magnetic field of a conductive loop about its symmetry axis has already been calculated,*

$$\vec{\mathcal{B}}_{loop}(z) = \frac{\mu_0 I}{2}\frac{r^2}{\sqrt{r^2+z^2}^3}\hat{\mathbf{e}}_z \ .$$

For the whole coil holds,

$$\begin{aligned}
\vec{\mathcal{B}}(z) &= \sum_{n=1}^{2000}\frac{\mu_0 I}{2}\frac{r^2}{\sqrt{r^2+(z-nL/N)^2}^3}\hat{\mathbf{e}}_z = \frac{\mu_0 NI}{L}\frac{r^2}{2}\hat{\mathbf{e}}_z\int_0^L\frac{1}{\sqrt{r^2+(z-z')^2}^3}dz' \\
&= \frac{\mu_0 NI}{L}\frac{r^2}{2}\hat{\mathbf{e}}_z\frac{\sqrt{r^2+z^2}(L-z)+z\sqrt{r^2+(z-L)^2}}{r^2\sqrt{r^2+z^2}\sqrt{r^2+(z-L)^2}} \\
&= \frac{\mu_0 NI}{2L}\hat{\mathbf{e}}_z\frac{\sqrt{r^2+z^2}(L-z)+z\sqrt{r^2+(z-L)^2}}{\sqrt{r^2+z^2}\sqrt{r^2+(z-L)^2}} \ .
\end{aligned}$$

At the given positions we have,

$$\begin{aligned}
\vec{\mathcal{B}}(L/2) &= \mu_0 NI\hat{\mathbf{e}}_z\frac{1}{\sqrt{4r^2+L^2}} \simeq \mu_0 NI\hat{\mathbf{e}}_z\frac{1}{L} \ , \\
\vec{\mathcal{B}}(0) &= \mu_0 NI\hat{\mathbf{e}}_z\frac{1}{2\sqrt{r^2+L^2}} \simeq \mu_0 NI\hat{\mathbf{e}}_z\frac{1}{2L} \ .
\end{aligned}$$

16.2.3.11 Ex: Induction in a rectangular mesh

A rectangular conducting loop has the length a and the width b. In the same plane defined by the loop, parallel to a distance d is a straight conductor traversed by a

current I, as shown in the figure.
a. Calculate the magnetic field produced by the current.
b. Calculate the flux through the loop.
c. Calculate the self-inductance imposed on the current circuit by the existence of the loop.
d. Linearize the expression of self-inductance for $b/d \ll 1$.

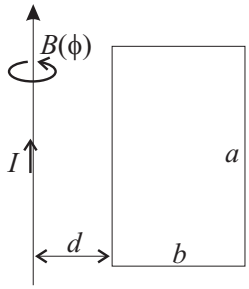

Figure 16.17: Induction.

Solution: *a. By the law of Ampère,* $2\pi\rho\mathcal{B}_\rho = \oint \vec{\mathcal{B}} \cdot \mathbf{l} = \mu_0 I$*, we find,*

$$\vec{\mathcal{B}} = \frac{\mu_0 I}{2\pi\rho}\hat{\mathbf{e}}_\phi \ .$$

b. The flux is,

$$\Psi_M = \int \vec{\mathcal{B}} \cdot d\mathbf{S} = \int_d^{d+b} \int_0^a \frac{\mu_0 I}{2\pi\rho}\hat{\mathbf{e}}_\phi \cdot \hat{\mathbf{e}}_\phi dz d\rho = \frac{\mu_0 I a}{2\pi} \ln\left(1 + \frac{b}{d}\right) \ .$$

c. The self-inductance L *is defined by,*

$$U_{ind} = -L\dot{I} \ .$$

On the other hand, the voltage induced in the loop, U_{ind}*, depends on the magnetic flux* Ψ_M *through Faraday's induction law,*

$$\dot{\Psi}_M = -U_{ind} \ .$$

The variable varying in time is the current $I \equiv I(t)$*, which leads to a temporal variation of the flux* $\Phi \equiv \Phi(t)$*. Comparing the two equations we get,*

$$L = \frac{\mu_0}{2\pi} a \ln\left(1 + \frac{b}{d}\right) \ .$$

d. With the linearization $\ln(1+x) \approx x$ *(truncation of the Taylor expansion for* $|x| \ll 1$ *very small) we get,*

$$L = \frac{\mu_0}{2\pi}\frac{ab}{d} \ .$$

16.2.3.12 Ex: Falling rod

A metal rod of $L = 1\,\mathrm{m}$ length falls in the gravitational field of the Earth. At time $t = 0$ the initial velocity is 0. The rod is oriented parallel to the ground. Perpendicular to the rod and parallel to the ground there is a magnetic field $\vec{\mathcal{B}}$ with the absolute value $2 \cdot 10^{-5}\,\mathrm{T}$.
a. What voltage is induced between the ends of the rod as a function of the distance traveled h?
b. What value is obtained for the voltage after a fall of 5 m?

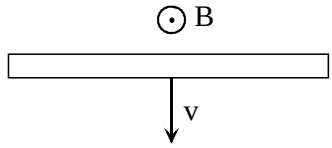

Figure 16.18: Induction.

Solution: *a. Following Faraday's law we have,*

$$U_{ind} = \oint_C \vec{\mathcal{E}} \cdot d\vec{\ell} = -\frac{d}{dt} \int \vec{\mathcal{B}} \cdot d\mathbf{S} = -\frac{d}{dt}[\mathcal{B}L(x_0 + \frac{g}{2}t^2)] = \mathcal{B}Lgt = \mathcal{B}L\sqrt{2gh}\ .$$

Alternatively, we consider the rod as a Hall probe. The condition for an equilibrium of charges,

$$F_C = q\mathcal{E} = q\frac{U_{ind}}{L} = qgt\mathcal{B} = qv\mathcal{B} = F_L\ .$$

Hence we get the same result.
b. Entering the distance of 5 m*, we get,*

$$U_{ind} = \mathcal{B}L\sqrt{2gh} \approx 1.98 \cdot 10^{-4}\,\mathrm{V}\ .$$

16.2.3.13 Ex: Sliding rod

We consider two parallel metal rails (distance $d = 10\,\mathrm{cm}$) inclined by an angle ϕ with respect to the ground. Between the rails slides a frictionless rod (mass $M = 100$ g). At a right angle to the plane defined by the rails there is a homogeneous magnetic field $\mathcal{B}$ (amplitude: $0.1\,\mathrm{T}$). We sent a current of $I = 9.8\,\mathrm{A}$ through the rails and through the rod. What is the maximum allowable value of ϕ necessary to let the rod move upward along the rails?

Solution: *With Ampère we know $d\mathbf{F} = Id\mathbf{l} \times \vec{\mathcal{B}}$. Therefore, the force on the moving rod is given by $F_I = Id\mathcal{B}$; it goes in the direction of the rails. It should point upward, but for this, either $\vec{\mathcal{B}}$ or I must be opposite.*
In z-direction downward acts the force of the weight $F_G = Mg$, which has a component $-Mg\sin\phi$ along the rails. In order for the transverse rod to slide up, we need

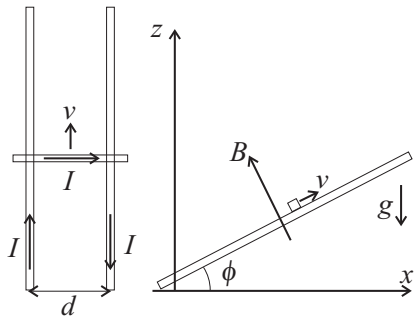

Figure 16.19: Sliding rod.

$Id\mathcal{B} > Mg\sin\phi$, that is, $\phi < \arcsin(Id\mathcal{B}/Mg) \approx 5.6°$.

16.2.3.14 Ex: Conductive ring in oscillating magnetic field

A circular conductive loop (inductance L, resistance R) is traversed by an oscillating magnetic flux, $\Psi = \Psi_0 e^{\imath\omega t}$.
a. Calculate the amplitude of the current in the conductor as well as its phase relative to Ψ.
b. What is the average power dissipated in the conductor? Also discuss the limiting cases $\omega \to 0$ and $\omega \to \infty$.
Help: Start setting up an equivalent circuit incorporating a voltage source, a resistance, and an inductance.

Solution: *a. The equivalent circuit consist of a voltage source U, a resistance R, and an inductance L in series. The induced voltage $U_{ind} = -\dot{\Psi} = -\imath\omega\Psi_0 e^{\imath\omega t}$ corresponds to the voltage source U. With this we have $U = (R + \imath\omega L)I$ or $I = \frac{U}{R+\imath\omega L} = \frac{-\imath\omega\Phi_0}{R+\imath\omega L} e^{\imath\omega t} = I_0 e^{\imath\omega t}$. Holds,*

$$I_0 = \frac{-\imath\omega}{R + \imath\omega L}\Psi_0 = \frac{-\imath\omega(R - \imath\omega L)}{R^2 + \omega^2 L^2}\Psi_0 = \frac{\omega^2 L - \imath\omega R}{R^2 + \omega^2 L^2}\Psi_0 \ ,$$

with the absolute value,

$$|I_0| = \sqrt{I_0 I_0^*} = \frac{-\imath\omega\Psi_0}{R + \imath\omega L} = \frac{\omega\Psi_0}{\sqrt{R^2 + \omega^2 L^2}}$$

and the phase,

$$\delta = \arctan\frac{-\omega R\Psi_0}{\omega^2 L\Psi_0} = \arctan\frac{-R}{\omega L} \ .$$

b. The power is,

$$P = UI^* = -\imath\omega\Phi_0\frac{\imath\omega\Psi_0}{R - \imath\omega L} = \frac{\omega^2\Psi_0^2 R + \imath\omega^3\Psi_0^2 L}{R^2 + \omega^2 L^2} = P_W + \imath P_B \ .$$

The average active power is,

$$\overline{P_W} = \frac{\Psi_0^2}{2}\frac{R\omega^2}{R^2+\omega^2 L^2} \ .$$

In the limiting case $\omega \to 0$ *we have* $\overline{P_W} \to 0$. *In the limiting case* $\omega \to \infty$ *we have* $\overline{P_W} \to \frac{\Psi_0^2}{2}\frac{R}{L^2}$.

16.2.3.15 Ex: Self-inductance of a current loop

Calculate the self-inductance of a current loop.

Solution: *The current density can be parametrized as* $\mathbf{j}(\mathbf{r}) = I\delta(\rho - R)\delta(z)\hat{\mathbf{e}}_\phi$. *The potential vector is,*

$$\mathbf{A}(\mathbf{r}) = \frac{\mu_0}{4\pi}\int \frac{\mathbf{j}(\mathbf{r}')}{|\mathbf{r}-\mathbf{r}'|}d^3\mathbf{r}' \ .$$

According to Biot-Savart law the magnetic field is,

$$\begin{aligned}
\vec{\mathcal{B}}(\mathbf{r}) &= \frac{\mu_0}{4\pi}\int \nabla \times \frac{\mathbf{j}(\mathbf{r}')}{|\mathbf{r}-\mathbf{r}'|}d^3\mathbf{r}' = \frac{\mu_0}{4\pi}\int d^3\mathbf{r}'\frac{(\mathbf{r}-\mathbf{r}')\times\mathbf{j}(\mathbf{r}')}{|\mathbf{r}-\mathbf{r}'|^3} \\
&= \frac{\mu_0 I}{4\pi}\int \rho' d\rho' d\phi' dz' \frac{\delta(\rho'-R)\delta(z')(\mathbf{r}-\mathbf{r}')\times\hat{\mathbf{e}}_{\phi'}}{|\mathbf{r}-\mathbf{r}'|^3} \\
&= \frac{\mu_0 I}{4\pi}\int \rho' d\rho' d\phi 1 dz' \frac{\delta(\rho'-R)\delta(z')\begin{pmatrix}\rho\cos\phi-\rho'\cos\phi'\\ \rho\sin\phi-\rho'\sin\phi'\\ z-z'\end{pmatrix}\times\begin{pmatrix}-\sin\phi'\\ \cos\phi'\\ 0\end{pmatrix}}{\sqrt{(\rho\cos\phi-\rho'\cos\phi')^2+(\rho\sin\phi-\rho'\sin\phi')^2+(z-z')^2}^3} \\
&= \frac{\mu_0 I}{4\pi}\int Rd\phi' \frac{\begin{pmatrix}-z\cos\phi'\\ -z\sin\phi'\\ (\rho\cos\phi-R\cos\phi')\cos\phi'+(\rho\sin\phi-R\sin\phi')\sin\phi'\end{pmatrix}}{\sqrt{(\rho\cos\phi-R\cos\phi')^2+(\rho\sin\phi-R\sin\phi')^2+z^2}^3} \ .
\end{aligned}$$

The field through $z = 0$ *plane is,*

$$\begin{aligned}
\mathcal{B}_z(x,y) &= \frac{\mu_0 IR}{4\pi}\int_0^{2\pi} d\phi' \frac{(\rho\cos\phi-R\cos\phi')\cos\phi'+(\rho\sin\phi-R\sin\phi')\sin\phi'}{\sqrt{(\rho\cos\phi-R\cos\phi')^2+(\rho\sin\phi-R\sin\phi')^2}^3} \\
&= \frac{\mu_0 IR}{4\pi}\int_0^{2\pi} d\phi' \frac{\rho\cos\phi\cos\phi'+\rho\sin\phi\sin\phi'-R}{\sqrt{\rho^2+R^2-2\rho R\cos\phi\cos\phi'-2\rho R\sin\phi\sin\phi'}^3} \\
&= \frac{\mu_0 IR}{4\pi}\int_0^{2\pi} d\phi' \frac{\rho\cos(\phi-\phi')-R}{\sqrt{\rho^2+R^2-2\rho R\cos(\phi-\phi')}^3} \\
&= \frac{\mu_0 IR}{4\pi}\int_0^{2\pi} d\alpha \frac{\rho\cos\alpha-R}{\sqrt{\rho^2+R^2-2\rho R\cos\alpha}^3} \ ,
\end{aligned}$$

and the flux through the $z = 0$ plane is,

$$\begin{aligned}
\Psi &= \int_A \mathcal{B}_z(x,y)dA = \frac{\mu_0 IR}{4\pi}\int_0^{2\pi} d\phi \int_0^R \rho d\rho \int_0^{2\pi} d\alpha \frac{\rho\cos\alpha - R}{\sqrt{\rho^2+R^2-2\rho R\cos\alpha}^3} \\
&= \frac{\mu_0 IR}{4\pi} 2\pi \int_0^R \rho d\rho \int_0^{2\pi} d\alpha \frac{\rho\cos\alpha - R}{\sqrt{\rho^2+R^2-2\rho R\cos\alpha}^3} = \frac{\mu_0 IR}{4\pi} 2\pi \int_0^{2\pi} d\alpha \int_0^1 \zeta d\zeta \frac{\zeta\cos\alpha - 1}{\sqrt{\zeta^2+1-2\zeta\cos\alpha}^3} \\
&= \frac{\mu_0 IR}{4\pi} 2\pi \int_0^{2\pi} d\alpha \frac{-2\cos\alpha + \left(\cos\alpha \ln(-\cos\alpha + 1 + \sqrt{2-2\cos\alpha})\right)\sqrt{2-2\cos\alpha} + 1 - (\cos\alpha \ln(-\cos\alpha +}{\sqrt{2-2\cos\alpha}} \\
&= \frac{\mu_0 IR}{4\pi} 2\pi \int_0^{2\pi} d\alpha \frac{-2\cos\alpha + \left(\cos\alpha \ln\left(-\cos\alpha + 1 + 2\sin\frac{\alpha}{2}\right)\right) 2\sin\frac{\alpha}{2} + 1 - (\cos\alpha \ln(-\cos\alpha + 1))2\sin\frac{\alpha}{2}}{2\sin\frac{\alpha}{2}} \\
&= \frac{\mu_0 IR}{4\pi} 2\pi 4 = 2\mu_0 IR \ .
\end{aligned}$$

Finally, self-inductivity becomes,

$$L = \frac{\Phi}{I} = 2\mu_0 R \ .$$

When there are N windings, we have,

$$L_N = N^2 L \ .$$

16.2.3.16 Ex: Potentials

Be given are scalar potential and vector potential:

$$\Phi(\mathbf{r},t) = b\frac{\mathbf{r}\hat{\mathbf{e}}_z}{r^3}e^{\imath\omega t} \qquad \text{and} \qquad A(\mathbf{r},t) = \imath k b \frac{e^{\imath kr}}{r^3} e^{\imath\omega t}\hat{\mathbf{e}}_z \ ,$$

where $\omega = ck$ and $r = |\mathbf{r}|$. Calculate the corresponding electric field $\vec{\mathcal{E}}(\mathbf{r},t)$ and the magnetic field $\vec{\mathcal{B}}(\mathbf{r},t)$.

Solution: *With the given potentials,*

$$\nabla\phi = be^{\imath\omega t}\nabla\frac{z}{r^3} = be^{\imath\omega t}\begin{pmatrix} \frac{d}{dx}\frac{z}{(x^2+y^2+z^2)^{3/2}} \\ \frac{d}{dy}\frac{z}{(x^2+y^2+z^2)^{3/2}} \\ \frac{d}{dz}\frac{z}{(x^2+y^2+z^2)^{3/2}} \end{pmatrix} = \frac{be^{\imath\omega t}}{r^5}\begin{pmatrix} -3xz \\ -3yz \\ r^2-3z^2 \end{pmatrix} \ ,$$

and

$$\frac{\partial}{\partial t}\mathbf{A} = \frac{\partial}{\partial t}\imath k b e^{\imath\omega t}\frac{e^{\imath kr}}{r}\hat{\mathbf{e}}_z = -k\omega b e^{\imath\omega t}\frac{e^{\imath kr}}{r}\hat{\mathbf{e}}_z \ .$$

With this the $\vec{\mathcal{E}}$-field becomes,

$$\vec{\mathcal{E}} = -\nabla\phi - \frac{\partial\mathbf{A}}{\partial t} = -\frac{be^{\imath\omega t}}{r^5}\begin{pmatrix} -3xz \\ -3yz \\ r^2-3z^2 \end{pmatrix} + k\omega b e^{\imath\omega t}\frac{e^{\imath kr}}{r}\hat{\mathbf{e}}_z = be^{\imath\omega t}\begin{pmatrix} \frac{3xz}{r^5} \\ \frac{3yz}{r^5} \\ \frac{3z^2-r^2}{r^5} + k\omega\frac{e^{\imath kr}}{r} \end{pmatrix} \ .$$

The $\vec{\mathcal{B}}$-field becomes,

$$\vec{\mathcal{B}} = \nabla \times \mathbf{A} = \nabla \times \begin{pmatrix} 0 \\ 0 \\ \imath k b \frac{e^{\imath kr}}{r^3} e^{\imath \omega t} \end{pmatrix} = e^{\imath \omega t} b k (kr + 3\imath) \frac{e^{\imath kr}}{r^5} \begin{pmatrix} -y \\ x \\ 0 \end{pmatrix} .$$

16.2.3.17 Ex: Motion-induced electromotive force

In the figure a conductive rod of mass m and negligible resistance is free to slide without friction along two parallel rails that have negligible resistances, are separated by a distance ℓ, and connected by a resistance R. The rails are attached to a long plane inclined by an angle θ from the horizontal. There is a magnetic field pointing upwards as shown.
a. Show that there is a retarding force directed upward on the inclined plane given by $F = (\mathcal{B}^2 \ell^2 v \cos^2\theta)/R$.
b. Show that the terminal velocity of the stick is $v_t = mgR \sin\theta/(\mathcal{B}^2 \ell^2 \cos^2\theta)$.

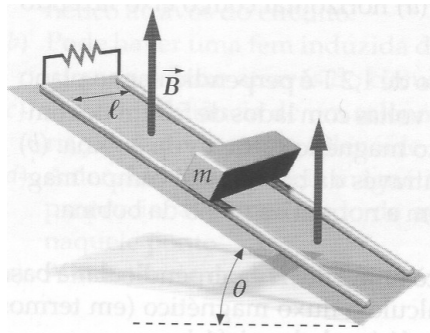

Figure 16.20: Motion-induced electromotive force.

Solution: *a. The induced voltage is,*

$$U_{ind} = -\dot{\Psi} = -\vec{\mathcal{B}} \cdot \dot{\mathbf{A}} = -\mathcal{B} \frac{d}{dt}(\ell v t \cos\theta) = -\mathcal{B} \ell v \cos\theta \ ,$$

creating a current,

$$I = \frac{U_{ind}}{R} \ ,$$

creating a Lorentz force,

$$F_L = I \ell \mathcal{B} = -\frac{\mathcal{B} \ell v \cos\theta}{R} \ell \mathcal{B} \ .$$

The projection of the force onto the plane of the rails is,

$$F_\theta = F_L \cos\theta = -\frac{\mathcal{B}^2 \ell^2 v \cos^2\theta}{R} \ .$$

b. This force is in equilibrium with the gravitational acceleration force, $F_g = mg\sin\theta$*, when,*

$$-\frac{\mathcal{B}^2\ell^2 v_t\cos^2\theta}{R} = mg\sin\theta \ ,$$

giving the final velocity,

$$v_t = \frac{mgR\sin\theta}{\mathcal{B}^2\ell^2\cos^2\theta} \ .$$

16.2.3.18 Ex: Induction

An insulated wire with resistance of $18.0\,\Omega/\mathrm{m}$ and length of $9.0\,\mathrm{m}$ will be used to build a resistor. First the wire is bent in half and doubled, and then the double wire is wound into a cylindrical shape (see figure) to create a $25\,\mathrm{cm}$ long, $2.0\,\mathrm{cm}$ diameter helix. Determine the resistance and inductance of this twisted wire resistor.

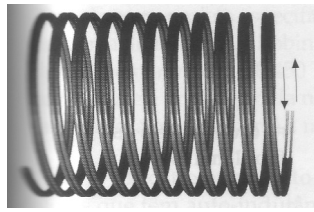

Figure 16.21: Induction.

Solution: $L = 0,\ R = 162\,\Omega.$

16.2.3.19 Ex: R-L-circuit

In the circuit shown in the figure the inductor has negligible internal resistance, and the switch S has been left open for a long time. Now, the switch is closed.
a. Determine the current in the battery, the current in the $100\,\Omega$ resistor, and the current in the inductance immediately after the switch has been closed.
b. Determine the current in the battery, the current in the $100\,\Omega$ resistor, and the current in the inductance a long time after the switch has been closed.
c. After being closed for a long time, the key is now opened again. Determine the current in the battery, the current in the $100\,\Omega$ resistor, and the current in the inductance immediately after the switch has been opened.
d. Determine the current in the battery, the current in the $100\,\Omega$ resistor, and the current in the inductance a long time after the key has been reopened.

Solution: *a. Immediately after the switch has been closed the inductor has an infinite resistance such that all current flows through the* $100\,\Omega$*,*

$$I_L = 0 \qquad \textit{and} \qquad I_R = \frac{U}{R_{100}+R_{10}} = \frac{10}{110}\,\mathrm{A} \ .$$

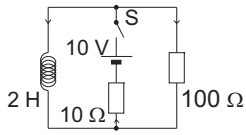

Figure 16.22: Circuit.

b. A long time after the key has been closed the inductor has zero resistance such that all current flows through the inductance,

$$I_R = 0 \qquad and \qquad I_L = \frac{U}{R_{10}} = 1\,\mathrm{A}\ .$$

c. Immediately after the switch has been opened the inductance produces an induced voltage trying to preserve the magnetic field, i.e. the current. This is only possible if the current is deviated to the $100\,\Omega$ *resistor,*

$$I_L = I_R = \frac{U}{R_{10}} = 1\,\mathrm{A}\ .$$

d. A long time after the switch has been reopened all magnetostatic energy stored in the inductance is spent in the resistor, and the current disappears,

$$I_R = 0 \qquad and \qquad I_L = 0\ .$$

16.2.3.20 Ex: Low pass filter

The circuit shown in the figure is an example of a *low-pass filter*. (Consider that the output is connected to a load that conducts negligible current.)
a. If the input voltage is given by $V_{in} = V_{in,pico}\cos\omega t$, shows that the output voltage is $V_{out} = V_L\cos(\omega t - \phi)$, where $V_L = V_{in,pico}/\sqrt{1+(\omega RC)^{-2}}$.
b. Discuss the trend in the limiting cases $\omega \to 0$ and $\omega \to \infty$.

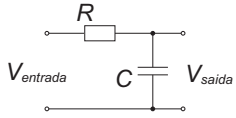

Figure 16.23: Low pass filter.

Solution: *a. We have,*

$$V_{out} = V_{in}\frac{\frac{1}{iC\omega}}{R+\frac{1}{iC\omega}}\ .$$

With this,

$$|V_{out}| = |V_{in}|\sqrt{\frac{1}{1+(\omega RC)^2}}\ .$$

b. For $\omega \to 0$ *we get,*

$$V_{out} = V_{in} \ ,$$

and for $\omega \to \infty$ *we get,*

$$V_{out} = 0 \ .$$

Gabartite: *b.* $V_L \overset{\to 0}{\longrightarrow} V_{in,pico}$ *and* $V_L \overset{\to \infty}{\longrightarrow} 0$.

16.2.3.21 Ex: Notch filter

The circuit shown in the figure is a *cutoff filter*. (Consider that the output is connected to a load carrying a negligible current.)
a. Show that the cutoff filter rejects signals in a frequency band centered in $\omega = 1/\sqrt{LC}$.
How does the width of the rejected frequency band depend on R?

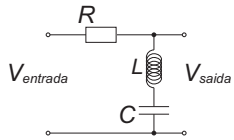

Figure 16.24: Notch filter.

Solution: *a. We have,*

$$V_{saida} = V_{ent} \frac{iL\omega + \frac{1}{iC\omega}}{R + iL\omega + \frac{1}{iC\omega}} \ .$$

With this,

$$|V_{saida}| = |V_{ent}| \frac{L\omega - \frac{1}{C\omega}}{\sqrt{R^2 + \left(L\omega - \frac{1}{C\omega}\right)^2}} \ .$$

b. $\Delta\omega = \frac{R}{L}$.

16.2.3.22 Ex: Effective power

Show that the expression $P_{med} = R\mathcal{E}_{rms}^2/Z^2$ provides the correct result for a circuit containing only one ideal *ac*-generator and
a. one resistor R,
b. one capacitor C and
c. one inductance L. In the given expression, P_{med} is the average power supplied by the generator, $\mathcal{E}_{rms}$ is the average quadratic value of the emf-generator.

Solution: *We have,*

$$P_{med} = \frac{1}{T} \int_0^T UIdt = \ .$$

16.2.3.23 Ex: *R*-*L*-*C*-circuit

In the circuit shown in the figure the ideal generator produces a voltage of 115 V when operated at 60 Hz. What is the *rms*-voltage between the points
a. A and B, b. B and C, c. C and D, d. A and C, and e. B and D?

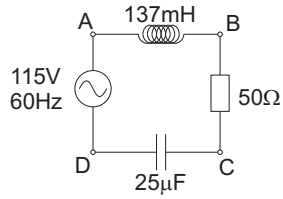

Figure 16.25: Circuit.

Solution: *a.* 80 V, *b.* 78 V, *c.* 170 V, *d.* 110 V, *e.* 180 V.

16.3 Magnetostatic energy

To calculate the magnetostatic energy stored in a magnetic field we will proceed as follows: We will look for a general expression guessed by analogy with the electrostatic energy, $W = \frac{1}{2}\int \varrho\Phi dV$, and show that, applied to a current-carrying loop, this expression gives the correct result. The analogous formula is,

$$W = \tfrac{1}{2}\int \mathbf{j}\cdot\mathbf{A}dV \ . \tag{16.50}$$

16.3.1 Energy density of a magnetostatic field

The energy of a current distribution can be rewritten using Ampere's law,

$$W = \tfrac{1}{2\mu_0}\int (\nabla\times\vec{\mathcal{B}})\cdot\mathbf{A}dV \ . \tag{16.51}$$

Integration by parts allows transferring the derivative from $\vec{\mathcal{B}}$ to $\mathbf{A}$,

$$W = \tfrac{1}{2\mu_0}\left[-\oint(\mathbf{A}\times\vec{\mathcal{B}})\cdot d\mathbf{S} + \int \vec{\mathcal{B}}\cdot(\nabla\times\mathbf{A})dV\right] \ . \tag{16.52}$$

The surface integral can be neglected because we can choose the integration volume $\mathcal{V}$ to be arbitrarily large. Expressing the rotation by the field,

$$W = \tfrac{1}{2\mu_0}\int \vec{\mathcal{B}}^2 dV = \tfrac{1}{2\mu_0}\int u dV \ , \tag{16.53}$$

and introducing the *energy density*,

$$\boxed{u \equiv \frac{1}{2\mu_0}\vec{\mathcal{B}}^2} \ . \tag{16.54}$$

It may seem strange, that we need energy to build up a magnetic field which in turn can not exert work. On the other hand, to create this magnetic field, we have to ramp it up from zero which, according to Faraday's law induces an electric field. This field, in turn, can work. Initially there is no $\vec{\mathcal{E}}$ and at the end of the process there is no $\vec{\mathcal{E}}$ neither; but in between, while $\vec{\mathcal{B}}$ is being constructed, there is. The work has to be exerted against the $\vec{\mathcal{E}}$-field.

16.3.2 Inductors and storage of magnetostatic energy

Using the magnetostatic energy formula,

$$W = \frac{1}{2}\int \mathbf{j}\cdot\mathbf{A}dV = \frac{1}{2}\oint \mathbf{I}\cdot\mathbf{A}dl = \frac{I}{2}\oint \mathbf{A}\cdot d\mathbf{l} = \frac{I}{2}\int (\nabla\times\mathbf{A})\cdot d\mathbf{S} = \frac{I}{2}\int \vec{\mathcal{B}}\cdot d\mathbf{S} = \frac{I}{2}\Psi_M \ . \tag{16.55}$$

Finally, considering a coil and using the formula (16.48),

$$\boxed{W = \frac{1}{2}LI^2} \ , \tag{16.56}$$

which corresponds to the power,

$$\frac{dW}{dt} = -\mathcal{E}I = LI\frac{dI}{dt} \ . \tag{16.57}$$

16.3.3 Exercises

16.3.3.1 Ex: Switching processes

Consider the RL-circuit show in the figure, where the ohmic resistor $R = R(t)$ varies over time. Let τ be the length of the switching-on process starting at time $t = 0$. The resistance be,

$$R(t) = \begin{cases} \infty & \text{for } t < 0 \\ R_0\tau/t & \text{for } 0 \le t \le \tau \\ R_0 \text{for } \tau \le t \end{cases} \ .$$

a. Set up for the time intervals $t \in [0, \tau]$ and $t \in [\tau, \infty]$ separate differential equations for the current $I(t)$.
b. Solve the differential equations (using a simple ansatz or a method of variable separation) and connect the solutions continuously at $t = \tau$. What is the condition for fast or slow switching?

Solution: *a. The differential equation to solve* $L\dot{I}(t) + R(t)I(t) = U$ *becomes for* $0 \le t \le \tau$

$$L\dot{I}_<(t) + \frac{R_0\tau}{t}I_<(t) = U \ .$$

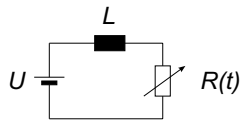

Figure 16.26: Circuit.

For $t \geq \tau$ the equation is,

$$L\dot{I}_>(t) + R_0 I_>(t) = U \ .$$

b. For $0 \leq t \leq \tau$ with the ansatz $I_<(t) = \alpha t$ we obtain $\alpha = \frac{U}{L+R_0\tau}$, hence,

$$I_<(t) = \frac{U}{L + R_0\tau} t \ .$$

For $t \geq \tau$ with the ansatz $I_>(t) = \beta e^{-\kappa t} + \gamma$ we obtain $-\kappa L\beta e^{-\kappa t} + R_0\left(\beta e^{-\kappa t} + \gamma\right) = U$, hence,

$$\gamma = \frac{U}{R_0} \qquad \text{and} \qquad \kappa = \frac{R_0}{L} \ ,$$

and finally,

$$I_>(t) = \beta e^{-\frac{R_0}{L}t} + \frac{U}{R_0} \ .$$

The continuity of the current requires $I_<(\tau) = I_>(\tau)$, which means,

$$\beta = -e^{\frac{R_0}{L}\tau}\left(\frac{U}{R_0} - \frac{U}{L + R_0\tau}\tau\right) \ .$$

With this,

$$I_>(t) = \frac{U}{R_0}\left(1 - \frac{L/R_0}{L/R_0 + \tau} e^{-\frac{R_0}{L}(t-\tau)}\right) \ .$$

The final value U/R_0 is reached exponentially. The temporal constant of the switching is L/R_0. For $\tau \ll L/R_0$ the switching is fast $I(\tau) \ll U/R_0$. For $\tau \gg L/R_0$ it is slow $I(\tau) \approx U/R_0$.

16.3.3.2 Ex: Current density of a rotating charge

The surface of a hollow sphere with radius R carries a uniformly distributed charge Q. The sphere rotates with the constant angular velocity ω around one of its diameters.
a. Determine the current density $\mathbf{j}(\mathbf{r})$ generated by this movement.
b. Calculate the magnetic moment produced by $\mathbf{j}$.
c. Derive the components of the potential vector $\mathbf{A}(\mathbf{r})$ and the magnetic field $\vec{\mathcal{B}}(\mathbf{r})$.

Solution: *The charge density is, $\rho(\mathbf{r}) = \frac{Q}{4\pi R^2}\delta(r - R)$. The current density is $\mathbf{j}(\mathbf{r}) = \rho(\mathbf{r})\mathbf{v}(\mathbf{r}) = \rho(\mathbf{r})(\vec{\omega} \times \mathbf{r})$. In the coordinate system defined by $\vec{\omega} = \omega\hat{\mathbf{e}}_z = \omega(0, 0, 1)$ the surface normal is given by $\mathbf{r} = R\hat{\mathbf{e}}_r = R(\sin\theta\cos\phi, \sin\theta\sin\phi, \cos\theta)$. With that we get, $\hat{\mathbf{e}}_z \times \hat{\mathbf{e}}_r = \sin\theta\hat{\mathbf{e}}_\phi$ and finally the current density,*

$$\mathbf{j}(\mathbf{r}) = \frac{Q\omega}{4\pi R}\sin\theta\delta(r - R)\hat{\mathbf{e}}_\phi \ .$$

16.3.3.3 Ex: Train track

The two iron rails of a toy train have a thickness of $d = 5\,\text{mm}$ and a reciprocal distance of $a = 50\,\text{mm}$ They are connected by a metal rod of mass $m = 0.5\,\text{g}$, which is movable without friction in a direction perpendicular to the rails. A current applied to the rails, which also runs through the metal rod, causes the rod to accelerate along the rails.
a. Calculate the magnetic field between the two rails, if through them runs the same current I but in inverse directions. Neglect inhomogeneities at the ends of the rails and the magnetic field generated by the current passing through the rod.
b. How strong is the force accelerating the rod along the rails?
c. What current would be needed to accelerate the rod over a distance of $l = 5\,\text{m}$, up to a speed of $10\,\text{m/s}$? Ignore all friction effects.

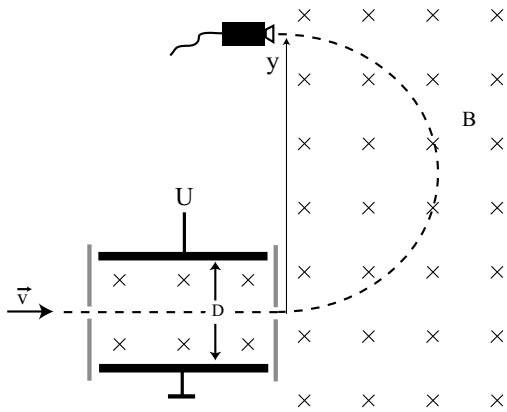

Figure 16.27: Circuit.

Solution:

16.3.3.4 Ex: Mass spectrometer

A mass spectrometer consists, as shown in the figure, of a plate capacitor with $D = 5\,\text{mm}$ distance between the electrodes, placed within a magnetic field $\mathcal{B} = 0.4\,\text{T}$ with homogeneous amplitude. A mixture of isotopes of carbon ion $^{12}C^{+}$ and $^{14}C^{+}$ penetrates the capacitor through a circular slot. After transit through the capacitor the ions move in the magnetic field on a semicircular path and are counted by a detector, whose distance y from the slot can be varied.
a. What voltage should be applied to the plates of the capacitor to ensure that only ions with the velocity $v = 10^5\,\text{m/s}$ can exit the capacitor through the second slot?
b. At what distances y can the two isotopes be detected respectively?

Solution:

16.3.3.5 Ex: Transformer

Consider two similar coils with number of turns N_1 and N_2 connected by an iron yoke. In the first coil we apply a time-varying voltage U_1. Therefore, in this coil (called primary) runs a current I_1, producing a magnetic flux Ψ, which is transmitted entirely through the iron yoke to the second (second) coil. Here, a voltage U_2 is induced.
a. Calculate the ratio U_2/U_1 as a function of the number of turns. What is the behavior of the phase between U_1 and U_2.
b. What are the phases of the currents I_1 and I_2 running through the coils with respect to phases of the voltages? What is the consequence for the average power in the coils?

Solution: *a. The voltage in the primary coil U_1 belongs to a flux through the coil induced by $U_1 = -N_1\dot{\Psi}_1$. Since the entire flux also flows through the second coil, we have $\Psi_2 = \Psi_1$. For the voltage in the second coil we have analogously: $U_2 = -N_2\dot{\Psi}_2$. Hence,*

$$U_2 = -N_2\dot{\Psi}_2 = -N_2\dot{\Psi}_1 = \frac{N_2}{N_1}U_1 \ .$$

The ratio between voltages, therefore, is equal to the ratio of the number of turns. Both voltages oscillate synchronously with the same phase.
b. The currents are proportional to the magnetic fields that, in turn, are proportional to the magnetic flux:

$$I_{1,2} \propto \mathcal{B}_{1,2} \propto \Psi_{1,2} = \Psi \ .$$

Due to,

$$\dot{\Psi} \propto U_{1,2} \propto \cos\omega t$$

we have after integration,

$$I_{1,2} \propto \Psi \propto \sin\omega t \ .$$

For the power $P = UI$ we get,

$$P \propto \sin\omega t \cos\omega t \ .$$

In the time average (integration of P over a period of oscillation) the oscillatory part cancels out in P, so we have $\bar{P} = 0$.
*b. **Presence of a consumer on the secondary side:** We have for the primary and the secondary mesh,*

$$\begin{aligned} U_{01}e^{i\omega t} &= L_1\dot{I}_1 + M\dot{I}_2 \\ -RI_2 &= L_2\dot{I}_2 + M\dot{I}_1 \ . \end{aligned}$$

Eliminating I_1 gives us a differential equation for I_2:

$$\dot{I}_2 + \frac{L_1 R}{L_1L_2 - M^2}I_2 = -\frac{MU_{01}e^{i\omega t}}{L_1L_2 - M^2} \ ,$$

that can be solved by the ansatz $I_2 = I_{02}e^{\imath\omega t+\imath\phi}$*, giving,*

$$\imath\omega I_{02}e^{\imath\phi} + \frac{L_1R}{L_1L_2 - M^2}I_{02}e^{\imath\phi} = -\frac{MU_{01}}{L_1L_2 - M^2} \ .$$

$$I_{02}e^{\imath\phi} = -\frac{MU_{01}}{(L_1L_2 - M^2)\left(\imath\omega + \frac{L_1R}{L_1L_2-M^2}\right)} \ .$$

The absolute value and phase of the current, therefore, are:

$$I_{02} = \left|-\frac{MU_{01}}{(L_1L_2 - M^2)\left(i\omega + \frac{L_1R}{L_1L_2-M^2}\right)}\right| = \frac{MU_{01}}{(L_1L_2 - M^2)}\sqrt{\omega^2 + \left(\frac{L_1R}{L_1L_2 - M^2}\right)^2}$$

$$\tan\phi = \frac{\mathfrak{Im}\ \left(\imath\omega + \frac{L_1R}{L_1L_2-M^2}\right)^{-1}}{\mathfrak{Re}\ \left(\imath\omega + \frac{L_1R}{L_1L_2-M^2}\right)^{-1}} = \frac{-\omega(L_1L_2 - M^2)}{L_1R} \ .$$

16.3.3.6 Ex: Resonant L-R-C-circuit

Consider an excited LRC serial circuit. The components of the oscillating circuit have the values $R = 5\,\Omega$, $C = 10\,\mu\text{F}$, $L = 1\,\text{H}$, and $U = 30\,\text{V}$.
a. At what excitation frequency ω_a does the amplitude of the current have its maximum value? Give the value of the current?
b. At what angular frequencies ω_{a1} and ω_{a2} does the amplitude of the current have exactly half the maximum value? What is therefore the FWHM width of the resonance curve for this oscillating circuit? Show that the width of the resonance curve is given by,

$$\frac{\omega_{a1} - \omega_{a2}}{\omega_a} = R\sqrt{\frac{3C}{L}} \ .$$

c. Make a scheme of some resonance curves for various values of R.

Solution: ***Error, because*** α ***also depends on*** ω***:*** *a. After transient oscillations the current is given by,*

$$I_s(t) = |A|e^{\imath(\omega t+\phi)}$$

with

$$A = -\frac{\alpha}{\omega^2 - \omega_0^2 - i2\beta\omega}$$

where

$$|A| = \frac{\alpha}{\sqrt{(\omega^2 - \omega_0^2)^2 + 4\beta^2\omega^2}} \qquad \textit{and} \qquad \tan\phi = \frac{\mathfrak{Im}\ A}{\mathfrak{Re}\ A} = \frac{2\beta\omega}{\omega^2 - \omega_0^2} \ .$$

Here, we have,

$$\omega_0^2 = \frac{1}{LC} \qquad \textit{and} \qquad 2\beta = \frac{R}{L} \qquad \textit{and} \qquad \alpha = \frac{U_0\omega}{L} \ .$$

The amplitude $|A|$ is maximum when,

$$0 = \frac{d|A|}{d\omega} = \frac{d}{d\omega}\frac{\alpha}{\sqrt{(\omega^2-\omega_0^2)^2+4\beta^2\omega^2}} = 2\alpha\omega\frac{-\omega^2+\omega_0^2-2\beta^2}{\sqrt{(\omega^2-\omega_0^2)^2+4\beta^2\omega^2}^3} \ ,$$

which means,

$$\omega_a = \sqrt{\omega_0^2-2\beta^2} = \sqrt{\frac{1}{LC}-\frac{R^2}{2L^2}} \ .$$

With the given values we get, $\omega_a = 2\pi\cdot 50.326\,\mathrm{Hz}$, during $\omega_0 = 2\pi\cdot 50.329\,\mathrm{Hz}$. The amplitude of the current here is,

$$|A| = \frac{\alpha}{\sqrt{4\beta^4+4\beta^2(\omega_0^2-2\beta^2)}} = \frac{\alpha}{2\beta\omega_0} = \frac{U_0\omega_a}{L}\frac{L}{R}\frac{1}{\omega_0} \simeq \frac{U_0}{R} \ .$$

With the given values we get, $|A| = 6\,\mathrm{A}$.
b. From $\frac{|A(\omega_a)|}{2} = |A(\omega_{a1})|$ we obtain,

$$\begin{aligned}\frac{1}{2\sqrt{4\beta^4+4\beta^2(\omega_0^2-2\beta^2)}} &= \frac{1}{\sqrt{(\omega_{a1}^2-\omega_0^2)^2+4\beta^2\omega_{a1}^2}} \\ &\Longrightarrow \omega_{a1}^4+(4\beta^2-2\omega_0^2)\omega_{a1}^2 = 16\beta^2\omega_0^2-16\beta^4-\omega_0^4 \\ &\Longrightarrow \omega_{a1}^2 = \omega_0^2-2\beta^2\pm 2\sqrt{3\beta^2(\omega_0^2-\beta^2)} \simeq \omega_0^2\pm 2\beta\omega_0\sqrt{3} \ .\end{aligned}$$

With the given values we get, $\omega_{a1} = 2\pi\cdot 51.41\,\mathrm{Hz}$ and $\omega_{a1} = 2\pi\cdot 49.22\,\mathrm{Hz}$. For $\omega_0 \gg \beta$ follows,

$$\begin{aligned}&\omega_{a1}^2 \simeq \omega_0^2 \pm 2\beta\omega_0\sqrt{3} \\ &\Longrightarrow \frac{\omega_{a1}-\omega_{a2}}{\omega_0} = \frac{1}{\omega_0}\frac{\omega_{a1}^2-\omega_{a2}^2}{\omega_{a1}+\omega_{a2}} \simeq \frac{4\beta\omega_0\sqrt{3}}{2\omega_0^2} = \frac{2\beta\sqrt{3}}{\omega_0} = \frac{R\sqrt{3CL}}{L} = R\sqrt{\frac{3C}{L}} \ .\end{aligned}$$

Correction:
a. After the transient process the current is given by,

$$I_s(t) = |A|e^{\imath(\omega t+\phi)}$$

which

$$A = -\frac{U_0}{L}\frac{\omega}{\omega^2-\omega_0^2-i2\beta\omega} \ ,$$

where

$$|A| = \frac{U_0}{L}\frac{\omega}{\sqrt{(\omega^2-\omega_0^2)^2+4\beta^2\omega^2}} \qquad \textit{and} \qquad \tan\phi = \frac{\mathfrak{Im}\ A}{\mathfrak{Re}\ A} = \frac{2\beta\omega}{\omega^2-\omega_0^2} \ .$$

Here, we have,

$$\omega_0^2 = \frac{1}{LC} \qquad \textit{and} \qquad 2\beta = \frac{R}{L} \qquad \textit{and} \qquad \alpha = \frac{U_0\omega}{L} \ .$$

The amplitude $|A|$ is maximum when,

$$0 = \frac{d|A|}{d\omega} = \frac{U_0}{L}\frac{d}{d\omega}\frac{\omega}{\sqrt{(\omega^2-\omega_0^2)^2+4\beta^2\omega^2}} = \frac{U_0}{L}\frac{-\omega^4+\omega_0^4}{\sqrt{(\omega^2-\omega_0^2)^2+4\beta^2\omega^2}^3} \ ,$$

which means,

$$\omega_a = \omega_0 = \sqrt{\frac{1}{LC}} \ .$$

With the given values we get, $\omega_a = 2\pi \cdot 50.326\,\mathrm{Hz}$. The amplitude of the current here is,

$$|A| = \frac{U_0}{L}\frac{\omega}{\sqrt{(\omega^2-\omega_0^2)^2+4\beta^2\omega^2}} = \frac{U_0}{L}\frac{1}{2\beta} = \frac{U_0}{L}\frac{L}{R} \simeq \frac{U_0}{R} \ .$$

With the given values we get, $|A| = 6\,\mathrm{A}$.
b. From $\frac{|A(\omega_a)|}{2} = |A(\omega_{a1})|$ we obtain for $\omega_0 \gg \beta$

$$\begin{aligned}\frac{\omega_a}{2\sqrt{(\omega_a^2-\omega_0^2)^2+4\beta^2\omega_a^2}} &= \frac{\omega_h}{\sqrt{(\omega_h^2-\omega_0^2)^2+4\beta^2\omega_h^2}} \\ &\Longrightarrow \sqrt{(\omega_h^2-\omega_0^2)^2+4\beta^2\omega_h^2} = 4\beta\omega_h \\ &\Longrightarrow \omega_h^2 = (\omega_0^2+6\beta^2) \pm \sqrt{(\omega_0^2+3\beta^2)12\beta^2} \simeq \omega_0^2 \pm \sqrt{12}\beta\omega_0 \ .\end{aligned}$$

With the given values we get, $\omega_{a1} = 2\pi \cdot 51.41\,\mathrm{Hz}$ and $\omega_{a1} = 2\pi \cdot 49.22\,\mathrm{Hz}$. Follows,

$$\frac{\omega_{a1}-\omega_{a2}}{\omega_0} = \frac{1}{\omega_0}\frac{\omega_{a1}^2-\omega_{a2}^2}{\omega_{a1}+\omega_{a2}} \simeq \frac{4\beta\omega_0\sqrt{3}}{2\omega_0^2} = \frac{2\beta\sqrt{3}}{\omega_0} = \frac{R\sqrt{3CL}}{L} = R\sqrt{\frac{3C}{L}} \ .$$

16.3.3.7 Ex: Inductive circuit

Consider the circuit shown in the figure, which consists of a coil L, a voltage source U, and an ohmic resistor $R = 100\,\Omega$. The coil is a long solenoid with 50 turns per cm and an inductance of 200 mH. For times $t < 0$ there is no current flow through the solenoid. At time $t = 0$, the voltage is suddenly increased from 0 to 10 V. How long does it take the magnetic field in the solenoid to reach the value $\pi \cdot 10^{-4}\,\mathrm{T}$?

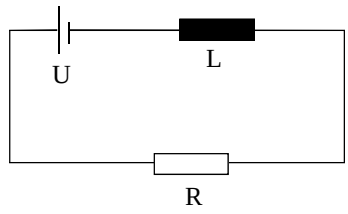

Figure 16.28: Circuit.

Solution: *By Kirchhoff laws,*

$$U(t) = L\dot{I} + RI \ .$$

The homogeneous differential equation is,

$$\frac{dI}{I} = -\frac{R}{L}dt$$

The general solution of the inhomogeneous differential equation is $I(t) = I_0 e^{-Rt/L} + I_{inh}$ *with* $I_{inh} = U_0/R$. *With the initial condition* $I(0) = 0$ *follows* $I_0 = -U_0/R$. *The induced voltage, therefore, is* $U_{ind}(t) = -L\dot{I} = U_0 e^{-Rt/L}$ *and the current after switching on is,*

$$I(t) = \frac{U_0}{R}(1 - e^{-Rt/L}) \ .$$

The magnetic field in the long coil is now,

$$\mathcal{B}_z(t) = \mu_0 \frac{N}{l} I(t) = \mu_0 \frac{N}{l}\frac{U_0}{R}\left(1 - e^{-Rt/L}\right) \ .$$

The given value for the field is reached after a time,

$$t = -\frac{L}{R}\ln\left(1 - \frac{lR\mathcal{B}_z}{\mu_0 N U_0}\right) \simeq 1.39\,\text{ms} \ .$$

16.3.3.8 Ex: Inductive circuit

Consider the circuit shown in the figure, which consists of a coil L, a voltage source $U_0 = 10\,\text{V}$, and three ohmic resistors $R = 100\,\Omega$. The coil is a long solenoid with 50 turns per cm and an inductance of 200 mH. Initially, the switch is open for a long time. Then at time $t = 0$, it is closed.
a. What is the initial value of the magnetic field in the solenoid while the switch is still open?
b. Using Kirchhoff's laws, derive the formula describing the temporal evolution of the field after the switch has been closed.
c. Determine the field for long times after the switch has been closed.

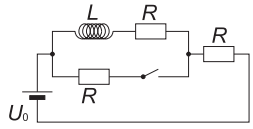

Figure 16.29: Circuit.

Solution: *a. While the switch is open, current only flows through the branch of the solenoid. We have by Kirchhoff's laws,*

$$U_0 = L\dot{I} + RI + RI = 2RI \ ,$$

because at long times, $\dot{I} = 0$. Therefore, the current is,

$$I = \frac{U_0}{2R} \ ,$$

giving $I = 50\,\mathrm{mA}$. The field of the solenoid is now,

$$\mathcal{B} = \mu_0 \frac{N}{\ell} I = \mu_0 \frac{N}{\ell} \frac{U_0}{2R} \ ,$$

giving $\mathcal{B} = 3.14 \cdot 10^{-4}\,\mathrm{T}$.
b. After the switch is closed, the current flows in both branches. We have by Kirchhoff's laws,

$$U_0 = L\dot{I}_L + RI_L + RI \quad , \quad U_0 = RI_R + RI \quad , \quad I = I_L + I_R \ .$$

Eliminating I

$$U_0 = L\dot{I}_L + RI_L + R(I_L + I_R) \quad , \quad U_0 = RI_R + R(I_L + I_R) \ ,$$

and eliminating I_R,

$$U_0 = L\dot{I}_L + RI_L + RI_L + \tfrac{1}{2}(U_0 - RI_L) = L\dot{I}_L + \tfrac{3}{2}RI_L + \tfrac{1}{2}U_0 = 2L\dot{I}_L + 3RI_L \ .$$

We get the differential equation,

$$\int_{I_0}^{I} \frac{dI_L}{I_L - U_0/3R} = -\frac{3R}{2L} \int_0^t dt \ ,$$

with the solution,

$$\ln\left(I_L - \frac{U_0}{3R}\right)\Big|_{I_0}^{I} = -\frac{3R}{2L}t \ .$$

Finally,

$$I_L(t) = \frac{2U_0}{3R} + \left(I_0 - \frac{2U_0}{3R}\right) e^{-3Rt/2L} = \frac{2U_0}{3R} - \frac{U_0}{6R} e^{-3Rt/2L} \ .$$

The magnetic field in the solenoid is now,

$$\mathcal{B}(t) = \mu_0 \frac{N}{\ell} I(t) = \mu_0 \frac{N}{\ell} \frac{U_0}{3R} \left(1 + \frac{1}{2}\right) e^{-3Rt/2L} \ .$$

c. For long times we get,

$$\mathcal{B}(t) = \mu_0 \frac{N}{\ell} \frac{U_0}{3R} \ ,$$

giving $\mathcal{B}(\infty) = 2.09 \cdot 10^{-4}\,\mathrm{V/m}$.

16.3.3.9 Ex: Conductive circular rings

Consider two infinitely thin conducting rings. They are concentric with radii a and b ($a < b$) and arranged in the xy-plane with a common center at the coordinate origin. The inner ring carries a homogeneously distributed charge $+q$ (that is, with linear constant charge density), the outer ring carries the homogeneously distributed charge $-q$.
a. First, write the charge density $\rho(\mathbf{r}) = \rho(r, \phi, z)$ in cylindrical coordinates. Now, let the inner ring rotate with the constant angular velocity ω about the symmetry axis (that is, the z-axis). Write the resulting current density also in cylindrical coordinates. **Help:** $\mathbf{j}(\mathbf{r}) = \rho(\mathbf{r}) \cdot \mathbf{v}(\mathbf{r})$ where $\mathbf{v}(\mathbf{r})$ is the velocity at the position $\mathbf{r}$. b. Determine by an explicit calculation the dipolar magnetic moment $\mathbf{m} = \frac{1}{2} \int d^3r \; \mathbf{r} \times \mathbf{j}(\mathbf{r})$ of the rotating ring.

Solution:

16.4 Alternating current

16.4.1 Electromagnetic oscillations

We have already met the plate capacitor as the most basic device for storing electrostatic energy in an (homogeneous) electric field. Similarly, the solenoid is the most basic device for storing magnetostatic energy in a (homogeneous) magnetic field. Placing a solenoid with inductance L and a capacitor with capacitance C in an electric circuit we find that electric energy can be converted into magnetic energy (and vice versa) in an analogous way as potential energy can be converted into kinetic energy (and vice versa) in a mass-spring system. This can generate (electromagnetic) oscillations.

Example 80 (*Oscillating circuits*): Let us first consider a circuit with a coil and a capacitor connected in series. Kirchhoff's law of meshes requires, $U_{ind} = U_C$, which gives,

$$-L\frac{dI}{dt} = \frac{Q}{C}$$

or

$$L\ddot{I} + C^{-1}I = 0 \; .$$

We now consider a circuit with a battery, a switch, a coil, and a resistor in series. Kirchhoff's law of meshes requires, $U_0 = -U_{ind} + U_R = L\dot{I} + RI$, which gives,

$$\frac{dI}{I - U_0/R} = -\frac{R}{L}dt$$

with the solution

$$I(t) = \frac{U_0}{R} + \left(I_0 - \frac{U_0}{R}\right) e^{-Rt/L} \; ,$$

where we choose the initial current $I_0 = 0$.

16.4.2 Alternating current circuits

To discuss alternating voltages, we consider the circuit shown in Fig. 16.30 fed by a voltage source, $U(t) = U_0 e^{\imath\omega t}$. To simplify the mathematical expressions we adopt a complex notation. The objective is to calculate the current for the various types of consumers Z that we already got to know. In the case of an ohmic resistance we have,

$$I = \frac{U_0}{R} e^{\imath\omega t} = \frac{U}{R} \ . \tag{16.58}$$

Hence,

$$Z = \frac{U}{I} = R \ . \tag{16.59}$$

In the case of a capacitance we have,

$$I = \dot{Q} = C U_0 \frac{d}{dt} e^{\imath\omega t} = \imath\omega C U \ . \tag{16.60}$$

Hence,

$$Z = \frac{U}{I} = \frac{1}{\imath\omega C} \ . \tag{16.61}$$

In the case of an inductance we have,

$$I = \int_0^t L U_0 e^{\imath\omega t} dt = \frac{U}{\imath\omega L} \ . \tag{16.62}$$

Hence,

$$Z = \frac{U}{I} = \imath\omega L \ . \tag{16.63}$$

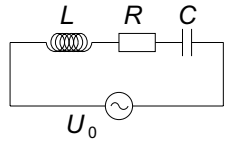

Figure 16.30: *L-R-C* circuit powered by an alternating voltage.

These results can be interpreted graphically (plotting Im U versus Re U) or analytically substituting $\imath = e^{\imath\pi/2}$. For the above three cases we obtain,

$$R = \frac{U_0 e^{\imath\omega t}}{I_0 e^{\imath\omega t + \pi/2}} \quad , \quad L\omega = \frac{U_0 e^{\imath\omega t}}{I_0 e^{\imath\omega t + \imath\pi/2}} \quad , \quad \frac{1}{C\omega} = \frac{U_0 e^{\imath\omega t}}{I_0 e^{\imath\omega t - \imath\pi/2}} \ . \tag{16.64}$$

This means that in the case of an inductance or capacitance, the voltage is not in phase with the current but has, respectively, an advance or a delay of 90°.

In cases of combinations of resistors and reactants the expression to calculate this phase shift becomes more complicated and may vary with the frequency imposed by the alternating source. Let us see how to calculate it at the example of the *L-R-C* circuit in series, writing in the same way as before,

$$Z = \frac{U}{I} = \imath L\omega + R + \frac{1}{\imath C\omega} = |Z| e^{\imath\phi} \ . \tag{16.65}$$

Hence,

$$|Z| = ZZ^* = \sqrt{R^2 + \left(L\omega - \frac{1}{\imath C\omega}\right)^2} \qquad \text{and} \qquad \tan\phi = \frac{\sin\phi}{\cos\phi} = \frac{L\omega - \frac{1}{C\omega}}{R} \ . \quad (16.66)$$

A resonance is met when $\omega = 1/\sqrt{LC}$. Other combinations of components are treated in the same way.

16.4.3 Exercises

16.4.3.1 Ex: High-pass filter

The circuits shown in the figure are called (a) first-order and (b) second-order high-pass filter. Calculate for both cases the ratio of output voltage U_a and input voltage U_e. Suppose that $U_e(t) = U_e \cos\omega t$ and $U_a(t) = U_a \cos(\omega t + \phi)$. Plot the result as a function of frequency on a logarithmic graph with the y-axis $\log(U_a/U_e)$ and the x-axis $\log\omega$. (This graph is called 'Bode diagram'.) What is the phase shift ϕ as a function of frequency?

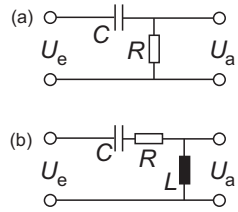

Figure 16.31: High pass.

Solution: *a. First order high-pass filter: We start with the (complex) impedance Z,*

$$Z = \frac{1}{\imath\omega C} + R \ .$$

With this we calculate the current I,

$$I(t) = \frac{U_e}{Z} = \frac{U_0 e^{\imath\omega t}}{1/\imath C\omega + R} \ .$$

The output voltage U_a equals the voltage drop at this impedance.,

$$U_a(t) = U_R = RI(t) = \frac{U_0 e^{\imath\omega t}}{1/\imath CR\omega + 1} = U_0 \frac{\frac{1}{\imath CR\omega} - 1}{\left(\frac{1}{\imath CR\omega}\right)^2 + 1} e^{\imath\omega t}$$
$$= U_0 \frac{\omega CR}{\sqrt{1 + (\omega CR)^2}} e^{\imath[\omega t + \arctan(\omega CR)]} = \tilde{U}_0(\omega) e^{\imath[\omega t + \phi]} \ .$$

b. Second order high-pass filter: Same procedure as above, the output voltage is measured in the coil,

$$Z = \frac{1}{\imath\omega C} + R + \imath L\omega \ .$$

Current,

$$I(t) = \frac{U_e}{Z} = \frac{U_0 e^{\imath\omega t}}{\frac{1}{\imath C\omega} + R + \imath\omega L}$$

Voltage,

$$\begin{aligned} U_a(t) = U_L = -L\dot{I}(t) = \frac{\imath\omega L U_0 e^{\imath\omega t}}{\frac{1}{\imath C\omega} + R + \imath\omega L} = U_0 \frac{1}{-\frac{1}{LC\omega^2} + \frac{R}{\imath\omega L} + 1} e^{\imath\omega t} \\ = U_0 \frac{1 - \frac{1}{LC\omega^2} - \frac{R}{\imath\omega L}}{\left(1 - \frac{1}{LC\omega^2}\right)^2 + \left(\frac{R}{\omega L}\right)^2} e^{\imath\omega t} = \frac{U_0 e^{\imath\left[\omega t + \arctan\left(\frac{R}{\omega L - 1/\omega C}\right)\right]}}{\sqrt{\left(1 - \frac{1}{LC\omega^2}\right)^2 + \left(\frac{R}{\omega L}\right)^2}} \ . \end{aligned}$$

16.4.3.2 Ex: Band and notch filter

The circuits shown in the figure are called (a) bandpass and (b) notch filter. Calculate

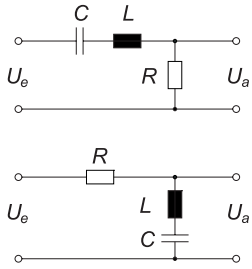

Figure 16.32: Filter.

for both cases the output voltage $U_a(t)$ under the condition that the input voltage is a sinusoidal oscillation, $U_e(t) = U_0 \cos\omega t$. Draw the amplitude of the output voltages as a function of frequency.
a. How do the amplitudes behave in the resonant case?
b. Discuss the limiting cases (i) $L \to 0$ resp., (ii) $C \to \infty$ based on transfer functions.

Solution: *a. For the bandpass filter we have the impedance, resistance, and phase shift,*

$$\begin{aligned} Z(\omega) &= \frac{U_a(\omega)}{U_e(\omega)} = \frac{R}{R + \imath L\omega + \frac{1}{\imath C\omega}} = \frac{R^2 - \imath\left(LR\omega - \frac{R}{C\omega}\right)}{R^2 + \left(L\omega - \frac{1}{C\omega}\right)^2} \\ |Z(\omega)|^2 &= \frac{R^2}{R^2 + \left(L\omega - \frac{1}{C\omega}\right)^2} \\ \phi(\omega) &= \arctan\frac{\mathfrak{Im}\ Z(\omega)}{\mathfrak{Re}\ Z(\omega)} = -\frac{1}{R}\left(L\omega - \frac{1}{C\omega}\right) \ . \end{aligned}$$

In resonance, $|U_a| = |U_e|$.
b. For the notch filter we have the impedance, resistance, and phase shift,

$$Z(\omega) = \frac{U_a(\omega)}{U_e(\omega)} = \frac{\imath L\omega + \frac{1}{\imath C\omega}}{R + \imath L\omega + \frac{1}{\imath C\omega}} = \frac{\left(L\omega - \frac{1}{C\omega}\right)^2 + \imath\left(LR\omega - \frac{R}{C\omega}\right)}{R^2 + \left(L\omega - \frac{1}{C\omega}\right)^2}$$

$$|Z(\omega)|^2 = \frac{\left(L\omega - \frac{1}{C\omega}\right)^2}{R^2 + \left(L\omega - \frac{1}{C\omega}\right)^2}$$

$$\phi(\omega) = \arctan \frac{\mathfrak{Im}\ Z(\omega)}{\mathfrak{Re}\ Z(\omega)} = \frac{R}{L\omega - \frac{1}{C\omega}} \ .$$

In resonance, $|U_a| = 0$.
c. Cases (a.i) and (b.ii) make high-pass filters, cases (a.ii) and (b.i) make low-pass filters.

16.4.3.3 Ex: Coaxial cable

A coaxial cable consists of a cylindrical conductor of radius a and a thin cylindrical waveguide of radius $b > a$. Between the conductors there is a voltage difference of U, and inside them flow currents in opposite directions I. Calculate the Poynting vector in the empty space and the power carried through the cable.
Help: Calculate the electric field between the conductors using Gauß' law and the magnetic field between the conductors using Ampere law.

Solution: *The z-axis is chosen as the rotational symmetry axis of the coaxial cable.*
Calculations of the $\vec{\mathcal{E}}$-field: *Over the inner cable is distributed the charge Q per length L. As always, because of symmetry reasons, the absolute value of the $\vec{\mathcal{E}}$ field only depends on the distance $\rho = \sqrt{x^2 + y^2}$ from the z-axis of the cylinder. Including the direction we have therefore,*

$$\vec{\mathcal{E}} = \mathcal{E}_\rho \hat{\mathbf{e}}_\rho(\mathbf{r})$$

for all $\mathbf{r} = (x, y, z) \in \mathbb{R}^3$ with $\rho \neq 0$. We now consider a cylindrical volume Z_ρ of length L and radius $a \leq \rho < b$, with the z-axis as the axis of rotational symmetry. Now with the law of Gauß and div $\vec{\mathcal{E}} = \rho/\varepsilon_0$, we get,

$$\frac{Q}{\varepsilon_0} = \int_{\partial Z_\rho} \vec{\mathcal{E}} \cdot d\mathbf{F} = 2\pi\rho L \mathcal{E}_\rho \ .$$

Hence, $\mathcal{E}_\rho = \frac{Q}{2\pi\varepsilon_0 L\rho}$ for all the $\rho \in [a, b[$. This leads to the potential,

$$\Phi(\mathbf{r}) \equiv \Phi(\rho) = -\frac{Q}{2\pi\varepsilon_0 L} \ln \rho \ ,$$

for all $\rho \in [a, b]$. (Note that the potential must be continuous, that is, it can be continued to the point $\rho = b$.) The voltage U between the inner and outer conductor is given by the potential difference,

$$U = \Phi(a) - \Phi(b) = \frac{Q}{2\pi\varepsilon_0 L} \ln(b/a) \ .$$

Follows,

$$Q = \frac{2\pi\varepsilon_0 LU}{\ln(b/a)} \ .$$

Inserting the last expression in the formula for $\mathcal{E}_\rho$*, we obtain,*

$$\mathcal{E}_\rho = \frac{U}{\ln(b/a)\rho} \ ,$$

for all $\rho \in [a, b]$*.*

Calculations of the* $\vec{\mathcal{B}}$*-field: *In the inner cable the direction of positive current is chosen to be the* z*-direction. For symmetry reasons the absolute value of the* B*-field only depends on the distance* $\rho = \sqrt{x^2 + y^2}$ *from the* z*-axis of the cylinder, that is,*

$$\vec{\mathcal{B}}(\mathbf{r}) = \mathcal{B}_\rho \hat{\mathbf{e}}_\phi(\mathbf{r})$$

for all $\mathbf{r} = (x, y, z) \in \mathbb{R}^3$ *without the* z*-axis. We consider the area of a disk* K_ρ *with radius* $\rho > 0$ *and the* z*-axis as the axis of symmetry. Then, using Ampere's law,*

$$2\pi\rho\mathcal{B}_\rho = \int_{\partial K_\rho} \vec{\mathcal{B}} \cdot d\mathbf{S} = \mu_0 I(K_\rho) = \mu_0 I$$

for $a \leq \rho < b$ *and* $2\pi\rho B_\rho = 0$ *else. Here,* $I(K_\rho)$ *means the entire current going through the disk* K_ρ*. Hence,*

$$\mathcal{B}_\rho = \frac{\mu_0 I}{2\pi\rho}$$

for $\rho \in [a, b[$*.*

Calculation of the Poynting vector = Energy flow: *We have* $\hat{\mathbf{e}}_\rho(\mathbf{r}) \times \hat{\mathbf{e}}_\phi(\mathbf{r}) = \hat{\mathbf{e}}_z$ *para cada ponto* $\mathbf{r} \in \mathbb{R}$ *except on the* z*-axis, where* $\hat{\mathbf{e}}_\rho$ *and* $\hat{\mathbf{e}}_\phi$ *are not defined. With that, the Poynting vector gets,*

$$\mathbf{S}(\mathbf{r}) = \frac{1}{\mu_0}\vec{\mathcal{E}}(\mathbf{r}) \times \vec{\mathcal{B}}(\mathbf{r}) = \frac{1}{\mu_0} E_\rho \mathcal{B}_\rho \hat{\mathbf{e}}_z = \hat{\mathbf{e}}_z \frac{IU}{2\pi \ln(b/a)\rho^2}$$

for $\rho \in [a, b[$ *and* $\mathbf{S} = 0$ *else, for each point of space* $\mathbf{r} \in \mathbb{R}^3$ *which is not on the* z*-axis. As a result, energy flow only occurs in the space between the inner conductor and the outer conductor, in the direction along the coaxial cable.*

16.4.3.4 Ex: *ac*-resistance

Calculate the work performed by an alternating current $I = I_0 \sin \omega t$ on a conductor with ohmic resistance R over a time period T. Make a scheme of the evolution in a diagram power versus time.

Solution:

16.4.3.5 Ex: *ac*-motor

An alternating voltage motor provides with an alternating voltage of $U = 220\,\mathrm{V}$ at $f = 50\,\mathrm{Hz}$ with the power $P = UI\cos\phi = 2.2\,\mathrm{kW}$. The power factor of the engine is $\cos\phi = 0.6$ and the efficiency $\eta = P_{out}/P_{in} = 0.89$.
a. What current does the motor receive?
b. Which capacitor must be connected in parallel to the terminals of the motor in order to increase the power factor to a value of $\cos\phi = 0.9$? Sketch the current pointer in the $U - I$-plane.

Solution:

16.4.3.6 Ex: Displacement current

a. Explain the significance of the continuity equation,

$$\oint \mathbf{j} \cdot d\mathbf{S} + \frac{d}{dt}\int \rho dV = 0\ .$$

b. Consider an enclosed area $S_1 + S_2$, because here the continuity equation has the form,

$$\oint \mathbf{j} \cdot d\mathbf{S} - \frac{d}{dt}\int \vec{\mathcal{D}} \cdot d\vec{\mathcal{D}}V = 0\ .$$

Show that holds,

$$\oint_C \vec{\mathcal{H}} \cdot d\mathbf{l} = \int_{S_2} \frac{d}{dt}\int \vec{\mathcal{D}} \cdot d\mathbf{S}\ .$$

Help: No field lines penetrate through the area S_1, and no current flows through the area S_2.

Solution:

16.4.3.7 Ex: Resonant *LC*-circuit

The capacitor of an undamped oscillating electromagnetic circuit has the capacity $C = 22$ nF. The eigenfrequency of the circuit is $f_0 = 5735\,\mathrm{Hz}$. At time $t = 0$ the capacitor has its maximum charge: $Q_0 = 0.33\,\mu\mathrm{C}$.
a. Derive for the undamped oscillating circuit the differential equation for $Q(t)$ from the energy conservation law and determine the solution. Write down the equation for eigenfrequency f.
b. Calculate inductance of the coil.
c. Set up equations for the energy content of the coil and and the capacitor as a function of time t.
d. Calculate the instant of time t_2, at which the energy content of the coil is, for the second time, half the energy content of the capacitor.

Solution: *a. The total energy is,* $E_G = E_C(t) + E_L(t) = \frac{1}{2}CU_C^2(t) + \frac{1}{2}LI_L^2(t)$. *With this follows,*

$$\begin{aligned} 0 = \frac{d}{dt}E_G &= CU_C(t)\dot{U}_C(t) + LI_L(t)\dot{I}_C(t) \\ 0 &= \frac{1}{C}Q(t)\dot{Q}(t) + L\dot{Q}(t)\ddot{Q}(t) \\ 0 &= \ddot{Q}(t) + LCQ(t) \ . \end{aligned}$$

The trial of a possible solution $Q(t) = Q_0 \sin(\omega t + \phi)$ *leads us, with* $Q(0) = Q_0$ *to* $\phi = \pi/2$ *and,*

$$f = \frac{1}{2\pi\sqrt{LC}} \ .$$

b. With this the inductance of the coil becomes,

$$L = \frac{1}{4\pi^2 C f} = 35\,\mathrm{mH} \ .$$

c. Energy of the capacitor,

$$E_C(t) = \frac{1}{2}\frac{Q^2}{C} = \frac{1}{2}\frac{Q_0^2\cos^2\omega t}{C} \ .$$

Energy of the coil,

$$E_L(t) = \frac{1}{2}LI^2(t) = \frac{1}{2}\omega^2 L Q_0^2 \sin^2\omega t \ .$$

d. From,

$$\begin{aligned} 2 = \frac{E_C(t)}{E_L(t)} &= \frac{\frac{1}{2}\frac{Q_0^2}{C}\cos^2\omega t}{\frac{1}{2}\omega^2 Q_0^2 \sin^2\omega t} = \frac{1}{\omega^2 C\tan^2\omega t} \\ t &= \frac{1}{\omega}\arctan\frac{1}{\sqrt{2C}\omega} \ . \end{aligned}$$

follows $\Delta t =$.

16.4.3.8 Ex: Resonant *LRC*-circuit

The oscillating *LRC*-circuit shown in 16.30 is excited by the alternating voltage source $U(t) = U_0 \cos\omega t$.
a. Calculate the total impedance Z as a function of ω and prepare graphs of the amplitude response $|Z(\omega)|$ and the phase response $\phi(\omega) = \arctan\frac{\Im\mathfrak{m}\ Z(\omega)}{\Re\mathfrak{e}\ Z(\omega)}$.
b. Establish the differential equation for the current. Start by solving the homogeneous differential equation and then the inhomogeneous one.

Solution: *a. Total impedance and square of absolute value are,*

$$\begin{aligned} Z(\omega) &= \imath\omega L + R + \frac{1}{\imath C\omega} \\ &= R + \imath\left(\omega L - \frac{1}{C\omega}\right) \\ |Z|^2 &= R^2 + (\omega L)^2 + \left(\frac{1}{\omega C}\right)^2 - \frac{2L}{C} \ . \end{aligned}$$

b. $U(T)$ defines a voltage. The coil, resistance and capacitor are opposite. The differential equation, therefore, is,

$$\begin{aligned} U_0 e^{\imath\Omega t} &= U_L + U_R + U_C \\ &= L\dot{I} + RI + \frac{Q}{C} \ . \end{aligned}$$

Drifting once again with $\dot{Q} = I$, we obtain,

$$\frac{U_0\imath\Omega}{L} e^{\imath\Omega t} = \ddot{I} + \frac{R}{L}\dot{I} + \frac{1}{CL} I \ .$$

With the respective definitions for the damping term and the eigenfrequency, the equation is equivalent to that of the harmonic, damped and forced pendulum:

$$\alpha e^{\imath\Omega t} = \ddot{I} + 2\beta\dot{I} + \omega_0^2 I \ .$$

With the trial solution for the homogeneous differential equation $I(t) = I_0 e^{\lambda t}$ we get the characteristic equation,

$$0 = \lambda^2 + 2\beta\lambda + \omega_0^2$$

hence, $\lambda_{1,2} = -\beta \pm \imath\sqrt{\omega_0^2 - \beta^2} \equiv -\beta \pm \imath\omega$. That is, the homogeneous general form is,

$$I_a(t) = e^{-\beta t}\left(B_1 e^{\imath\omega t} + B_2 e^{-\imath\omega t}\right) \ .$$

This solution decays exponentially with the damping constant $\beta = R/2L$. In the general solution, which represents the sum of this homogeneous solution and a particular solution, the homogeneous contribution may be neglected after a characteristic transient phase,

$$I(t) = I_a(t) + I_s(t)$$

with $I_a(t) \to 0$ for $t \gg \beta^{-1}$. We are now looking for another particular solution. The ansatz $I_s(t) = Ae^{\imath\Omega t}$ in the initial equation gives,

$$\alpha = A\left(-\Omega^2 + \imath 2\beta\Omega + \omega_0^2\right) \ .$$

Since A is complex the solution can also be written,

$$A = -\frac{\alpha}{\Omega^2 - \omega_0^2 - \imath 2\beta\Omega} = -\alpha\frac{\Omega^2 - \omega_0^2 + \imath 2\beta\Omega}{\left(\Omega^2 - \omega_0^2\right)^2 + 4\beta^2\Omega^2} = |A|e^{\imath\phi}$$

with

$$|A| = \frac{\alpha}{\sqrt{(\Omega^2 - \omega_0^2)^2 + 4\beta^2\Omega^2}} \qquad \textit{and} \qquad \tan\phi = \frac{\mathfrak{Im}\ A}{\mathfrak{Re}\ A} = \frac{2\beta\Omega}{\Omega^2 - \omega_0^2} \ .$$

Hence, we have the particular solution,

$$I_s(t) = |A|e^{\imath(\Omega t+\phi)} \ .$$

16.4.3.9 Ex: Resonant LRC-circuit

The components of an RLC-circuit (see 16.30) have the values $R = 5\ \Omega$, $C = 10\,\mu\text{F}$, $L = 1\,\text{H}$, and $U = 30\,\text{V}$.
a. At what angular frequency ω_a does the current amplitude have its maximum value? What is the corresponding current?
b. At what angular frequencies ω_{a1} and ω_{a2} does the amplitude of the current have half the maximum value? What is the relative half-width of the resonance curve for this resonant circuit?
c. Show with the help of the formulas of (b) that the relative half-width of each resonance curve is given by,

$$\frac{\Delta_a}{\omega} = R\sqrt{\frac{3C}{L}} \ ,$$

where Δ_a is the width of the resonance profile at half the maximum amplitude.
d. Prepare schemes of the resonance profile for various values of R. When is the current circuit predominantly capacitive and when inductive?
e. Show that the damping term $e^{-Rt/2L}$ (containing L but not C!) can be written in a more symmetrical form in L and C as follows,

$$e^{-\pi R\frac{t}{T}\sqrt{\frac{C}{L}}} \ .$$

Here, T is the period of oscillation when we neglect resistance. What is the SI-unit of the term $\sqrt{C/L}$?
f. Show, based on the result (e), that the condition for a smaller relative energy loss per oscillation cycle is: $R \ll \sqrt{L/C}$.

Solution:

16.4.3.10 Ex: Resonant LRC-circuit

Consider a dampened oscillating RLC-circuit. The charge $\bar{q}$ on the capacitor is described by the differential equation,

$$L\frac{d^2\bar{q}}{dt^2} + R\frac{d\bar{q}}{dt} + \frac{1}{C}\bar{q} = 0 \ .$$

a. Use the ansatz $\bar{q} = q_0 e^{\imath\omega t}$ and show that,

$$\omega_{1,2} = \imath\frac{R}{2L} \pm \omega' \qquad \text{where} \qquad \omega' = \omega_0\sqrt{1 - \frac{R^2C}{4L}}$$

with $\omega_0 = 1/\sqrt{LC}$ solves the differential equation.
b. Since this is a second order differential equation, we need two boundary conditions to determine the general solution of the form,

$$\bar{q}(t) = a\bar{q}_1(t) + b\bar{q}(t) \qquad \text{with} \qquad \bar{q}_{1,2} = \bar{q}_0 e^{-\frac{R}{2L}t} e^{\pm \imath\omega' t} \ .$$

Use the conditions $\bar{q}(0) = 0$ and $\dot{\bar{q}}(0) = I_0$ and determine the coefficients a and b. What is the solution for the charge $\bar{q}(t)$ in this case, and for the current $I(t) = \dot{\bar{q}}(t)$?
c. Sketch the evolution of the charge and the current on the capacitor for the following set of parameters and interpret the curves. What is the respective duration T of an oscillation period? Give for each of the following parameter sets the respective general solution before entering the values:
i. $I_0 = 1\,\text{mA}$, $R = 10\,\Omega$, $L = 1\,\text{mH}$, $C = 0.1\,\mu\text{F}$
ii. $I_0 = 1\,\text{mA}$, $R = 200\,\Omega$, $L = 1\,\text{mH}$, $C = 0.1\,\mu\text{F}$
iii. $I_0 = 1\,\text{mA}$, $R = 500\,\Omega$, $L = 1\,\text{mH}$, $C = 0.1\,\mu\text{F}$

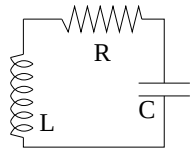

Figure 16.33: Resonant LRC-circuit.

Solution:

16.4.3.11 Ex: Magnetized sphere

We consider a sphere with radius R magnetized such that, inside the sphere, the magnetic field density is given by $\vec{\mathcal{B}} = \mathcal{B}_0 \hat{\mathbf{e}}_z$. The outer space is empty, that is, there are no currents, such that rot $\vec{\mathcal{B}} = 0$ and div $\vec{\mathcal{B}} = 0$. Therefore, we can let for the outer space,

$$\vec{\mathcal{B}} = -\text{grad}\Psi \quad \text{and} \quad \Psi(r, \vartheta, \varphi) = \sum_{l=0}^{\infty} \alpha_l \frac{P_l(\cos\vartheta)}{r^{l+1}} \ ,$$

with P_l the Legendre polynomials and r, ϑ and φ the usual spherical coordinates. Consider the boundary conditions for $\mathcal{B}_r$, $\mathcal{B}_\theta$ as well as for $\mathcal{H}_r$ and $\mathcal{H}_\theta$ at the transition between the inner and outer space of the sphere. Determine from this the expansion coefficients α_l as well as the magnetization $\vec{\mathcal{M}}$ inside the sphere. With this we finally get the magnetic field density $\vec{\mathcal{B}}$ magnetic $\vec{\mathcal{H}}$-field in the inner and outer space.

Solution:

16.4.3.12 Ex: Magnetic dipole moving through a conductive loop

What is the current signal produced by a ^{87}Rb Bose-Einstein condensate with its spin being polarized in the state $|F, m_F\rangle = |2, 2\rangle$ when it falls through a SQUID? Assume

that the SQUID has the diameter $2a = 3\,\mathrm{cm}$, the condensate consists of $N = 100000$ atoms and has a constant velocity of $v_z = 10\,\mathrm{cm/s}$.

Solution: *In the specified state each atom has a dipolar magnetic moment $\mu = \mu_B$. This moment creates, at the point $\mathbf{r} = (x, y, z)$, a magnetic field,*

$$\vec{\mathcal{B}} = \frac{\mu_0}{4\pi r^5} \begin{pmatrix} 3xz \\ 3yz \\ 3z^2 - r^2 \end{pmatrix} .$$

The magnetic flux through the SQUID enclosing an area $\mathbf{A} = \pi a^2 \mathbf{n}$ in the $x = y = 0$ plane then is,

$$\Psi = \int_A \vec{\mathcal{B}} \cdot \hat{\mathbf{e}}_n dF = \int_0^a 2\pi\rho \mathcal{B}_z d\rho = \frac{\mu_0}{2} \int_0^a \frac{3z^2 - r^2}{r^5} \rho d\rho = \frac{\mu_0}{2} \frac{a^2}{(a^2 + z^2)^{3/2}} .$$

For a point dipole we can suppose, $z = \dot{z}t$. The induced current in the SQUID is now,

$$U_{ind}(t) = -\dot{\Psi} = \frac{3a^2\mu_0}{2} \frac{z\dot{z}}{(a^2 + z^2)^{5/2}} .$$

With the specified numerical values we get voltages on the order of $10^{-17}\,\mathrm{V}$ and currents in the SQUID of the order of pA.

16.4.3.13 Ex: Electric current and magnetism

a. How are current and current density defined? What is a 'current line'?
b. What conditions should charge and current densities meet in magnetostatics?
c. How is the magnetic field $\vec{\mathcal{B}}$ defined empirically?
d. Writes the general form of Ampère's law. How is Ampère's law expressed in the case of two parallel conductors carrying currents I_1 and I_2?
e. What does the Ampère's law say?
f. What is the magnetic moment of an arbitrary, flat, closed current circuit?
g. What are the force and thye torque on a magnetic dipole in an external field $\vec{\mathcal{B}}(\mathbf{r})$.
h. Explain the term 'magnetization current density'.
i. What are the macroscopic equations of the magnetostatic field?
j. What is diamagnetism and paramagnetism? What differentiates these two phenomena? What is ferromagnetism?

Solution: *a. The current is defined by $I = \dot{Q}$; the current density is $\mathbf{j} = I/A$; a current wire is an idealization of current flow to 1 dimension.*
b. The current and current density must satisfy the continuity equation $\frac{\partial \rho}{\partial t} = \nabla \cdot \mathbf{j} = 0$.
c. Empirically the magnetic field $\vec{\mathcal{B}}$ is defined by Lorentz forces acting on currents. Currents are the cause of the field, but simultaneously subject to their action.
d. Ampère's law on forces is $d\mathbf{A} = Id\mathbf{l} \times \vec{\mathcal{B}}$. In the case of two parallel conductors with currents I_1 and I_2 the law predicts a force of mutual attraction.

e. Ampère's law on fluxes $\oint \vec{\mathcal{B}} \cdot d\mathbf{s} = \mu_0 I$ *says, that magnetic field lines are always closed (unlike electrostatic ones). Magnetic fields have no start or end points. Currents produce closed field lines around them. Here, the line integral over the magnetic field density on the edge of a surface is proportional to the total current crossing this surface.*
f. The magnetic moment of an arbitrary, flat and closed current circuit is, $\mathbf{m} = \frac{1}{2}\int \mathbf{r}' \times \mathbf{j}(\mathbf{r}')d^3r' = \frac{1}{2}\oint_{\partial\mathcal{S}} \mathbf{r}' \times d\mathbf{l} = I\int_F d\mathbf{A} = I\mathbf{A}$.
g. The force on a magnetic dipole in an external field is $\mathbf{F} = -\nabla U$ *with* $U = -\mathbf{m}\cdot\vec{\mathcal{B}}$. *The torque is,* $\vec{\mathcal{D}} = \mathbf{m} \times \vec{\mathcal{B}}$.
h. In matter with magnetization (density of magnetic dipoles) $\vec{\mathcal{M}}$ *the magnetization current density* $\mathbf{m} = \nabla \times \vec{\mathcal{M}}$ *adds to the macroscopic current density.*
i. The macroscopic field equations of magnetostatics are, $\text{rot}\,\vec{\mathcal{B}} = \mu_0\mathbf{j}$ *and* $\text{div}\,\vec{\mathcal{B}} = 0$ *respectively, with Stokes and Gauß laws,* $\int_s \vec{\mathcal{B}}\cdot d\mathbf{r} = \mu_0\int \mathbf{j}\cdot d\mathbf{A} = I$ *and* $\oint_f \vec{\mathcal{B}}\cdot d\mathbf{A} = 0$.
j. Diamagnetism is generated by induced dipoles. In the material, due to an applied magnetic field, an opposite magnetization is formed. Diamagnetic bodies are repelled by a permanent magnet in the direction opposite to the field gradient. Paramagnetism is generated by permanent dipoles located within the material. Paramagnetic bodies are attracted to a magnet. For diamagnetism, $\chi_m < 0$, *for paramagnetism,* $\chi_m > 0$. *In the case of ferromagnetism, the permanent dipole moments align within the so-called Weiß domains and therefore amplify.*

16.4.3.14 Ex: Electro-motor

Consider the electromotor of the scheme. Two pairs of Helmholtz coils aligned along the x- and y-axes are powered by alternating currents, $I_x(t) = I_0\cos\omega t$ and $I_y(t) = I_0\sin\omega t$, respectively. In the field there is a rotating rectangular coil traversed by a constant current I. The inertial moment of the coil is $\mathcal{I}$.
a. Show that the field in the center is given by $\mathcal{B}_x(0) = \frac{-8}{5\sqrt{5}}\frac{\mu_0 I_x \hat{\mathbf{e}}_x}{R}$.
b. Describes the temporal behavior of the magnetic field.
c. Relate the torque with the angular acceleration of the coil.
d. Calculate the instantaneous torque acting on the coil.
e. Suppose that the coil initially rotates with an angular velocity Ω such that, $\theta(t) = \theta_0 + \Omega t$. How you should choose Ω and the initial angle θ_0 to ensure an always positive torque? **Help:** $\sin\alpha\cos\beta + \cos\alpha\sin\beta = \sin(\alpha+\beta)$
f. Calculate the voltage induced in the coil. **Help:** $\sin\alpha\sin\beta + \cos\alpha\cos\beta = \cos(\alpha-\beta)$
g. Suppose the coil has an ohmic resistance ...

Solution: *a.*
b. The coils generate a rotating magnetic field, $\vec{\mathcal{B}}(t) = \mathcal{B}_0(\hat{\mathbf{e}}_x\cos\omega t + \hat{\mathbf{e}}_y\sin\omega t)$.
c. The torque is,

$$\vec{\tau} = \mathcal{I}\ddot{\theta}\ .$$

d. The Lorentz force is,

$$\mathbf{F}(t) = I\mathbf{l}\times\vec{\mathcal{B}}(t) = I\mathcal{B}_0(\mathbf{l}\times\hat{\mathbf{e}}_x\cos\omega t + \mathbf{l}\times\hat{\mathbf{e}}_y\sin\omega t) = Il\mathcal{B}_0(-\hat{\mathbf{e}}_y\cos\omega t + \hat{\mathbf{e}}_x\sin\omega t)\ .$$

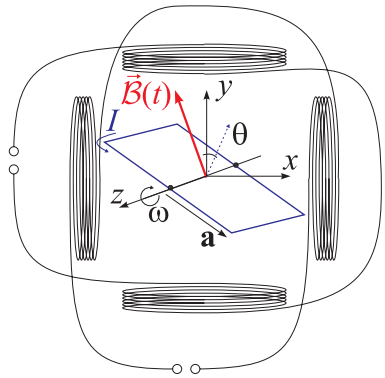

Figure 16.34: Electro-motor.

we write the vector, $\mathbf{a} = a[\hat{\mathbf{e}}_x \cos(\theta - 90^\circ) + \hat{\mathbf{e}}_y \sin(\theta - 90^\circ)] = a\hat{\mathbf{e}}_x \sin\theta - a\hat{\mathbf{e}}_y \cos\theta$. *With this the torque becomes,*

$$\begin{aligned}\vec{\tau} = \mathbf{a} \times \mathbf{F}(t) &= aIlB_0(\hat{\mathbf{e}}_x \sin\theta - \hat{\mathbf{e}}_y \cos\theta) \times (-\hat{\mathbf{e}}_y \cos\omega t + \hat{\mathbf{e}}_x \sin\omega t) \\ &= aIlB_0\hat{\mathbf{e}}_z(-\sin\theta\cos\omega t + \cos\theta\sin\omega t) = \sin(\omega t - \theta)\ .\end{aligned}$$

e. The initial angle should be,

$$\sin[\omega t - (\Omega t + \theta_0)] = -\sin\theta_0 > 0\ .$$

That is, we need $\Omega = \Omega$ *and* $\theta_0 \in [-180^\circ, 0]$.
f. Expressing the surface as $\mathbf{A} = la(-\hat{\mathbf{e}}_x \sin\theta + \hat{\mathbf{e}}_y \cos\theta)$, *the induced voltage is,*

$$\begin{aligned}U_{ind} = -\frac{d}{dt}\vec{\mathcal{B}} \cdot \mathbf{A} &= -la\mathcal{B}_0 \frac{d}{dt}(\hat{\mathbf{e}}_x \cos\omega t + \hat{\mathbf{e}}_y \sin\omega t) \cdot (-\hat{\mathbf{e}}_x \sin\theta + \hat{\mathbf{e}}_y \cos\theta) \\ &= -la\mathcal{B}_0(-\hat{\mathbf{e}}_x \sin\omega t + \hat{\mathbf{e}}_y \cos\omega t) \cdot (-\hat{\mathbf{e}}_x \sin\theta + \hat{\mathbf{e}}_y \cos\theta) \\ &= -la\mathcal{B}_0(\sin\omega t \sin\theta + \cos\omega t \cos\theta) \\ &= \cos(\omega t - \theta) = \cos\theta_0\ .\end{aligned}$$

g.

16.4.3.15 Ex: Magnetism

A given magnetic material is composed of N non-interacting atoms, whose magnetic moments μ can point in three possible directions, as shown in the figure, μx, μy, and $-\mu x$. The system is in thermal equilibrium at temperature T and subject to a uniform magnetic field oriented along the y-direction, $\vec{\mathcal{H}} = \mathcal{H}\hat{\mathbf{e}}_y$, so the energy levels corresponding to a single atom are $\varepsilon_0 = -\mu\mathcal{H}$, $\varepsilon_1 = 0$, and $\varepsilon_2 = 0$.
a. Get the canonical partition function z for one atom, the canonical partition function Z of the system, and the Helmholtz free energy f per atom.
b. Determine the mean energy $u \equiv \langle\varepsilon_n\rangle$ and the entropy s/k_B per atom.
c. Get magnetization per atom $\mathbf{m} \equiv \langle\vec{\mu}_n\rangle = m_x\hat{x} + m_y\hat{y}$.

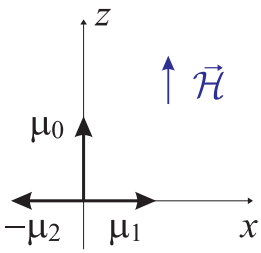

Figure 16.35:

d. Verify that the isothermal susceptibility $\chi_T \equiv (\partial m_y/\partial \mathcal{H})_T \propto 1/T$ at zero field obeys Curie's law of paramagnetism, $\chi_T(\mathcal{H} \to 0) \propto 1/T$.

Solution: *a. We have* $\varepsilon_0 = -\mu\mathcal{H}$ *and* $\varepsilon_1 = \varepsilon_2 = 0$. *Now,*

$$z = \sum_{n=0}^{2} e^{-\beta\varepsilon_n} = e^{\beta\mu\mathcal{H}} + 2$$
$$Z = \sum_{n} e^{-\beta E_n} = z^N = (e^{\beta\mu\mathcal{H}} + 2)^N$$
$$f = -\tfrac{1}{\beta}\ln z = -\frac{1}{\beta}\ln(e^{\beta\mu\mathcal{H}} + 2)\ .$$

b. Firstly,

$$u \equiv \langle\varepsilon_n\rangle = \sum_{n=0}^{2}\frac{\varepsilon_n e^{-\beta\varepsilon_n}}{z} = -\tfrac{1}{z}\sum_{n=0}^{2}\frac{\partial e^{-\beta\varepsilon_n}}{\partial\beta} = -\frac{1}{z}\frac{\partial z}{\partial\beta} = -\frac{\partial\ln z}{\partial\beta} = -\frac{\mu\mathcal{H}e^{\beta\mu\mathcal{H}}}{e^{\beta\mu\mathcal{H}}+2}\ .$$

From the definition $f = u - Ts$, *we get,*

$$\frac{s}{k_B} = \beta(u-f) = -\frac{\beta\mu\mathcal{H}e^{\beta\mu\mathcal{H}}}{e^{\beta\mu\mathcal{H}}-2} + \ln(e^{\beta\mu\mathcal{H}}+2)\ .$$

c. We have,

$$m = \langle\mu_n\rangle = \tfrac{1}{z}\sum_{n=0}^{2}\mu_n e^{-\beta\varepsilon_n} = \tfrac{1}{z}(\mu\hat{y}e^{\beta\mu\mathcal{H}} + \mu\hat{x} - \mu\hat{x}) = \frac{\mu\hat{y}e^{\beta\mu\mathcal{H}}}{e^{\beta\mu\mathcal{H}}+2}\ .$$

d. We already know $m_y = \mu/(1+2e^{-\beta\mu\mathcal{H}})$. *Thereby,*

$$\chi_T \equiv \left(\frac{\partial m_y}{\partial\mathcal{H}}\right)_T = \frac{2\beta\mu^2 e^{-\beta\mu\mathcal{H}}}{(1+2e^{-\beta\mu\mathcal{H}})^2}\ .$$

Thereby, $\chi_T(\mathcal{H}\to 0) = \frac{2}{9}\beta\nu^2 = \frac{2}{9}\mu^2/k_BT$.
Alternative solution:
Expanding

$$m_y = \tfrac{1}{3}\frac{\mu}{(1-\frac{2}{3}\beta\mu\mathcal{H})} + O(\beta\mu\mathcal{H})^2 = \tfrac{1}{3}(1+\tfrac{2}{3}\beta\mu\mathcal{H}) + O(\beta\mu\mathcal{H})^2\ .$$

Now,

$$\chi_T \equiv \left.\frac{\partial m_y}{\partial \mathcal{H}}\right|_T = \tfrac{2}{9}\beta\mu^2 + O(\beta\mu\mathcal{H}) \ ,$$

and

$$\chi_T(\mathcal{H} \to 0) = \tfrac{2}{9}\beta\mu^2 = \tfrac{2}{9}\mu^2 k_B T \ .$$

Chapter 17

Maxwell's equations

In the first part of the course, we derived the laws of electromagnetism from experimental observations related to the Coulomb force on electric charges and the Lorentz force on electric currents. We have found that these forces can be understood by introducing electric fields $\vec{\mathcal{E}}$ and magnetic fields $\vec{\mathcal{B}}$, to which the laws of electromagnetism apply. These laws were all known before Maxwell. These are,

$$\begin{aligned}
\nabla \times \vec{\mathcal{B}} &= \mu_0 \mathbf{j} && \textit{Ampère's law} \text{ leading to } \textit{Biot-Savart's law} \\
\nabla \times \vec{\mathcal{E}} &= -\partial_t \vec{\mathcal{B}} && \textit{Faraday's law} \\
\nabla \cdot \vec{\mathcal{E}} &= \varepsilon_0^{-1} \varrho && \textit{Gauß' law} \text{ leading to } \textit{Poisson's law} \text{ and } \textit{Coulomb's law} \\
\nabla \cdot \vec{\mathcal{B}} &= 0 && \text{absence of magnetic monopoles}
\end{aligned} \tag{17.1}$$

As we will show shortly, well-behaved vector fields are entirely defined by their divergences and rotations, so that we can expect that the set of laws (17.1) be complete, that is, it should be able to describe all electromagnetic phenomena.

However, by comparing the laws of Faraday and Ampère, we perceive an inconsistency: taking the divergences of the rotations, we expect them to zero:

$$\begin{aligned}
0 = \nabla \cdot (\nabla \times \vec{\mathcal{E}}) &= \nabla \cdot \left(-\frac{\partial \vec{\mathcal{B}}}{\partial t} \right) = -\frac{\partial}{\partial t} (\nabla \cdot \vec{\mathcal{B}}) \\
0 = \nabla \cdot (\nabla \times \vec{\mathcal{B}}) &= \mu_0 (\nabla \cdot \mathbf{j}) = -\mu_0 \frac{\partial \varrho}{\partial t} \neq 0 \ ,
\end{aligned} \tag{17.2}$$

where the last step makes use of the continuity equation (14.39). For temporal variations of the charge distribution the second equation can not be correct.

Maxwell's idea for solving the problem was to simply subtract from Ampère's law the term that prevents the second equation (17.2) from zeroing. With

$$\boxed{\nabla \times \vec{\mathcal{B}} = \mu_0 \mathbf{j} + \varepsilon_0 \mu_0 \frac{\partial \vec{\mathcal{E}}}{\partial t}} \ , \tag{17.3}$$

we verify,

$$\nabla \cdot (\nabla \times \vec{\mathcal{B}}) = \mu_0 \nabla \cdot \mathbf{j} + \varepsilon_0 \mu_0 \frac{\partial \nabla \cdot \vec{\mathcal{E}}}{\partial t} = \mu_0 \left(\nabla \cdot \mathbf{j} + \frac{\partial \varrho}{\partial t} \right) = 0 \ , \tag{17.4}$$

where, once more, we used the continuity equation. The Eq. (17.3) could be called *Maxwell's law* and the surface integral of the additional term,

$$\varepsilon_0 \frac{\partial}{\partial t} \oint_{\mathcal{S}} \vec{\mathcal{E}} \cdot d\mathbf{S} \equiv \oint_{\mathcal{S}} \mathbf{j}_d \cdot d\mathbf{S} = I_d \ . \tag{17.5}$$

is named *displacement current*. We will study consequences of this law in the Excs. 17.1.5.1 and 17.1.5.2.

Example 81 (*Necessity of a displacement current*): We consider the circuit shown in Fig. 17.1. On the one hand, the current passing through the Ampèrian loop must be independent of the shape of the enclosed area,

$$I = \int_{\mathcal{S}} \mathbf{j} \cdot d\mathbf{S} = \tfrac{1}{\mu_0} \oint_{\partial\mathcal{S}} \vec{\mathcal{B}} \cdot d\mathbf{l} \ .$$

On the other hand, we know that the current can not cross the capacitor and must accumulate on one of the electrodes.
The problem is solved by identifying the electric field, which is developing due to the accumulated charge,

$$\frac{\partial Q}{\partial t} = \varepsilon_0 \frac{\partial}{\partial t} \int_{\mathcal{V}} \nabla \cdot \vec{\mathcal{E}} dV = \varepsilon_0 \frac{\partial}{\partial t} \int_{\partial\mathcal{V}} \vec{\mathcal{E}} \cdot d\mathbf{S} \equiv I_d \ ,$$

with a *displacement current* I_d.

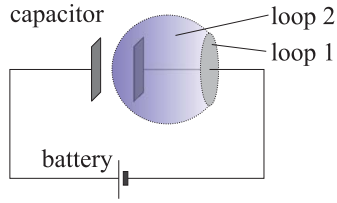

Figure 17.1: Necessity for a displacement current: The magnetic field at the edge of the loops 1 and 2 can not depend on the shape of the chosen surface.

17.1 The fundamental laws of electrodynamics

With these results we can finally summarize the *Maxwell equations* as,

$$\boxed{\begin{array}{lrcl} \text{(i)} & \nabla \times \vec{\mathcal{B}} - \varepsilon_0 \mu_0 \partial_t \vec{\mathcal{E}} & = & \mu_0 \mathbf{j} \\ \text{(ii)} & \nabla \times \vec{\mathcal{E}} + \partial_t \vec{\mathcal{B}} & = & 0 \\ \text{(iii)} & \nabla \cdot \vec{\mathcal{E}} & = & \varepsilon_0^{-1} \varrho \\ \text{(iv)} & \nabla \cdot \vec{\mathcal{B}} & = & 0 \end{array}} \ . \tag{17.6}$$

These equations form the complete basis of the electrodynamical theory initially motivated by the empirical observation of forces acting on features of matter identified

as *charges* and *currents*, that is, the electric (Coulomb) force and magnetic (Lorentz) force,

$$\mathbf{F}_{Lor} = Q(\vec{\mathcal{E}} + \mathbf{v} \times \vec{\mathcal{B}}) \ , \tag{17.7}$$

where $\vec{\mathcal{E}}$ is a *polar vector* ($\vec{\mathcal{E}} = -\vec{\mathcal{E}}_{mirrored}$) [1] and $\vec{\mathcal{B}}$ is an *axial vector* ($\vec{\mathcal{B}} = \vec{\mathcal{B}}_{mirrored}$). The electric field $\vec{\mathcal{E}}$ and the magnetic field $\vec{\mathcal{B}}$ and their field equations were 'invented' to explain the Coulomb-Lorentz force. They are only observable through their action on charged particles. According to the *Helmholtz theorem* discussed in the next section, arbitrary (but well-behaved) field vectors are fully defined by their divergence and rotation properties. That is exactly what Maxwell's equations do with the electric and magnetic fields.

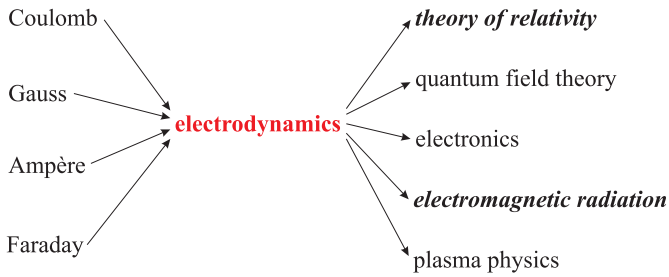

Figure 17.2: Construction and application of the theory of electrodynamics.

Once we know the fundamental laws of electromagnetism [2], we can reverse the reasoning by placing them as postulates and deriving the observable phenomena from them. This will be the procedure of this second part of the course of electromagnetism.

Example 82 (*Derivation of electro- and magnetostatics from Maxwell's equations*): For static systems we can let $\dot{\mathbf{E}} = \dot{\mathbf{B}} = 0$. In particular for the electrostatic case, we ignore currents, $\mathbf{j} = 0$, and for the magnetostatic case we ignore charges, $\varrho = 0$. Maxwell's equations then simplify considerably and can often be replaced by the Poisson equations,

$$-\nabla \cdot \vec{\mathcal{E}} = \nabla \cdot (\nabla\Phi) = \nabla^2\Phi = -\varepsilon_0^{-1}\varrho$$
$$-\nabla \times \vec{\mathcal{B}} = -\nabla \times (\nabla \times \mathbf{A}) = \nabla^2\mathbf{A} - \nabla(\cancelto{0}{\nabla \cdot \mathbf{A}}) = -\mathbf{j} \ ,$$

where the divergence of $\mathbf{A}$ is set to zero in the Coulomb gauge.

We will apply Maxwell's equations to solve the Excs. 17.1.5.3 to Excs. 17.1.5.5. In the Excs. 17.1.5.6, 17.1.5.7, and 17.1.5.8 we study implications of a supposed existence of *magnetic charges* or *magnetic monopoles*.

[1] Mirroring means inversion of the dynamic quantities $\mathbf{v} \to -\mathbf{v}$, $\mathbf{F}_{Lor} \to -\mathbf{F}_{Lor}$. Examples for polar vectors are $\mathbf{r}$, $\mathbf{p}$, $\vec{\mathcal{E}}$. Examples for axial vectors are $\mathbf{L}$, ω, $\vec{\mathcal{B}}$. We have for axial vectors $\mathbf{a}_i$ and polar vectors $\mathbf{p}_i$, the following relations,

$$\mathbf{a}_1 \times \mathbf{a}_2 = \mathbf{a}_3 \quad , \quad \mathbf{p}_1 \times \mathbf{p}_2 = \mathbf{a}_3 \quad , \quad \mathbf{p}_1 \times \mathbf{a}_2 = \mathbf{p}_3 \ .$$

[2] We note, that Maxwell's laws can be deduced from more fundamental principles, including the conservation laws for energy, momentum, angular momentum, and charge and the relativistic Lorentz transform.

17.1.1 Helmholtz's theorem

The *Helmholtz theorem* says that, knowing the divergence and the rotation of an unknown vector field $\mathbf{F}$, we can reconstruct this field under the condition that the divergence and the rotation disappear sufficiently fast in the infinity [3] and that $|\mathbf{F}|$ disappears at least as fast as $1/r^2$. That is, knowing the scalar field,

$$D(\mathbf{r}) \equiv \nabla \cdot \mathbf{F}(\mathbf{r}) \tag{17.8}$$

and the vectorial field,

$$\mathbf{C}(\mathbf{r}) \equiv \nabla \times \mathbf{F}(\mathbf{r}) \ , \tag{17.9}$$

the field $\mathbf{F}$ is completely defined. Note that obviously, $\nabla \cdot \mathbf{C} = 0$.

To prove this, we show that,

$$\mathbf{F} = -\nabla\Phi + \nabla \times \mathbf{A} \ , \tag{17.10}$$

where

$$\Phi(\mathbf{r}) \equiv \frac{1}{4\pi}\int_{\mathbb{R}^3} \frac{D(\mathbf{r}')}{|\mathbf{r}-\mathbf{r}'|}dV' \qquad \text{and} \qquad \mathbf{A}(\mathbf{r}) \equiv \frac{1}{4\pi}\int_{\mathbb{R}^3} \frac{\mathbf{C}(\mathbf{r}')}{|\mathbf{r}-\mathbf{r}'|}dV' \ , \tag{17.11}$$

meets the requirements (17.8) and (17.9). The divergence is,

$$\begin{aligned} \nabla_{\mathbf{r}} \cdot \mathbf{F} &= -\nabla^2_{\mathbf{r}}\Phi + \cancelto{0}{\nabla_{\mathbf{r}} \cdot \nabla_{\mathbf{r}} \times \mathbf{A}} \\ &= -\frac{1}{4\pi}\int D(\mathbf{r}')\nabla^2_{\mathbf{r}}\left(\frac{1}{|\mathbf{r}-\mathbf{r}'|}\right)dV' = \int D(\mathbf{r}')\delta^3(\mathbf{r}-\mathbf{r}')dV' = D(\mathbf{r}) \ . \end{aligned} \tag{17.12}$$

We verify,

$$\begin{aligned} 4\pi\nabla_{\mathbf{r}} \cdot \mathbf{A} &= \int \mathbf{C}(\mathbf{r}') \cdot \nabla_{\mathbf{r}} \frac{1}{|\mathbf{r}-\mathbf{r}'|}dV' = -\int \mathbf{C}(\mathbf{r}') \cdot \nabla_{\mathbf{r}'} \frac{1}{|\mathbf{r}-\mathbf{r}'|}dV' \\ &= -\int \frac{1}{|\mathbf{r}-\mathbf{r}'|} \cancelto{\nabla \cdot \nabla \times \mathbf{F} = 0}{\nabla_{\mathbf{r}'} \cdot \mathbf{C}(\mathbf{r}')}dV' - \oint \frac{1}{|\mathbf{r}-\mathbf{r}'|}\mathbf{C}(\mathbf{r}') \cdot d\mathbf{S}' \longrightarrow 0 \ , \end{aligned} \tag{17.13}$$

because the surface integral can be arbitrarily reduced by choosing very distant surfaces $\mathbf{r}' \to \infty$. Finally, the rotation is,

$$\begin{aligned} \nabla_{\mathbf{r}} \times \mathbf{F} &= \cancelto{0}{-\nabla_{\mathbf{r}} \times \nabla_{\mathbf{r}}\Phi} + \nabla_{\mathbf{r}} \times \nabla_{\mathbf{r}} \times \mathbf{A} = -\nabla^2_{\mathbf{r}}\mathbf{A} + \nabla_{\mathbf{r}}(\cancelto{0}{\nabla_{\mathbf{r}} \cdot \mathbf{A}}) \\ &= -\frac{1}{4\pi}\int \mathbf{C}(\mathbf{r}')\nabla^2_{\mathbf{r}}\left(\frac{1}{|\mathbf{r}-\mathbf{r}'|}\right)dV' = \int \mathbf{C}(\mathbf{r}')\delta^3(\mathbf{r}-\mathbf{r}')dV' = \mathbf{C}(\mathbf{r}) \ , \end{aligned} \tag{17.14}$$

using rules of vector analysis summarized in (21.111).

17.1.2 Potentials in electrodynamics

In electrodynamics, two fields are required to describe the Coulomb and Lorentz forces, the electric and the magnetic field. With Helmholtz's theorem we can now

[3] Faster than $1/r$ in order to guarantee that the integrals (17.8) and (17.9) converge.

declare that four equations are necessary and sufficient to completely characterize these fields through the following rotations and divergences,

$$\text{rot}\,\vec{\mathcal{B}} = \ldots \quad , \quad \text{rot}\,\vec{\mathcal{E}} = \ldots \quad , \quad \text{div}\,\vec{\mathcal{E}} = \ldots \quad , \quad \text{div}\,\vec{\mathcal{B}} = \ldots \,. \tag{17.15}$$

These equations are precisely those of Maxwell. In addition, the derivation of the preceding section showed that

> *each vector field which disappears fast enough at long distances can be expressed as the sum of the gradient of a scalar function and rotation of a vector function,*

since,

$$\mathbf{F} = -\nabla\Phi + \nabla\times\mathbf{A} = -\nabla\frac{1}{4\pi}\int_{\mathbb{R}^3}\frac{D(\mathbf{r}')}{|\mathbf{r}-\mathbf{r}'|}dV' + \nabla\times\frac{1}{4\pi}\int_{\mathbb{R}^3}\frac{\mathbf{C}(\mathbf{r}')}{|\mathbf{r}-\mathbf{r}'|}dV' \,. \tag{17.16}$$

The functions Φ and $\mathbf{A}$ are called *scalar potential* and *vector potential*, respectively.

Irrotational fields, that is, fields without vortices are conservative and can be expressed by the gradient of a scalar field,

$$\nabla\times\mathbf{F} = 0 \quad \Longleftrightarrow \quad \mathbf{A} = 0 \quad \Longleftrightarrow \quad \mathbf{F} = -\nabla\Phi \quad \Longleftrightarrow \quad \oint \mathbf{F}\cdot d\mathbf{l} = 0 \,. \tag{17.17}$$

Example 83 (*Potentials in electrostatics*): Electrostatics is an example for an irrotational field, since Maxwell's electrostatic equations are precisely, $\nabla\times\vec{\mathcal{E}} = 0$ and $\nabla\cdot\vec{\mathcal{E}} = D = \varrho/\varepsilon_0$. Therefore, there is an electric potential Φ, such that $-\nabla\Phi = \vec{\mathcal{E}}$.

Fields without divergences, that is, without sources or sinks, can be expressed by the rotation of a vector field,

$$\nabla\cdot\mathbf{F} = 0 \quad \Longleftrightarrow \quad \Phi = 0 \quad \Longleftrightarrow \quad \mathbf{F} = \nabla\times\mathbf{A} \quad \Longleftrightarrow \quad \oint \mathbf{F}\cdot d\mathbf{S} = 0 \,. \tag{17.18}$$

Example 84 (*Potentials in magnetostatics*): Magnetostatics is an example for a field without divergences, since Maxwell's magnetostatic equations are precisely, $\nabla\times\vec{\mathcal{B}} = \mathbf{C} = \mu_0\mathbf{j}$ and $\nabla\cdot\vec{\mathcal{B}} = 0$. Therefore, there is a vector potential $\mathbf{A}$, such that $\nabla\times\mathbf{A} = \vec{\mathcal{B}}$.

We will train the calculation with potentials in Excs. 17.1.5.9 and 17.1.5.10.

17.1.3 The macroscopic Maxwell equations

Electric and magnetic fields and electromagnetic waves survive in vacuum. Maxwell's equations (17.6) are formulated for this environment. On the other hand, we saw in the first part of the course, that charges (14.17) and currents (16.20) that are free or localized in a medium generate a polarization and a magnetization of the medium which can influence the fields.

In this section, we will repeat the derivation of the equations (14.18), respectively, (16.21) in a more stringent way from a microscopic model of matter. We suppose

matter to be made of molecules, each one being constructed from atoms composed of positively charged nuclei orbited by negatively charged electrons. On each of these elementary particles considered as point-like, the electromagnetic field diverges. But doing this statement, we are talking about microscopic electromagnetic fields, which can not be measured by macroscopic probes which, are composed of atoms themselves. We can not directly measure microscopic quantities with a macroscopic apparatus.

According to the model of matter already formulated by Democritus 300 years before Christ, we suppose the space between the elementary particles to be empty, such that we can assume the validity of Maxwell's equations for vacuum in a *microscopic environment*, that is, we believe in the equations (17.6) for the fields $\vec{\mathcal{E}}_{mic}$ and $\vec{\mathcal{B}}_{mic}$, where the subscript *mic* indicates the presence of localized or moving point-like charges. A macroscopic measurement apparatus will always deliver an effective mean value, averaged in space and time, of electromagnetic quantities. We will show in the following [659] how, via spatial averaging of Maxwell's microscopic equations, it is possible to deduce Maxwell's macroscopic equations taking account of polarization and magnetization (14.18), respectively, (16.21).

We obtain the spatial average by smearing out the microscopic quantities within a characteristic volume defined by a spherically symmetric function $f(r)$, chosen to cancel out exponentially at sufficiently large distances [4]. The reach of this function must be adapted to the resolution of the macroscopic device. For example, the resolution limit for devices based on optics will limit the reach of the function $f(r)$ to some 100 nm [5]. The spatial average of the electromagnetic quantities $\vec{\mathcal{E}}_{mic}(\mathbf{r},t)$, $\vec{\mathcal{B}}_{mic}(\mathbf{r},t)$, $\varrho_{mic}(\mathbf{r},t)$, and $\mathbf{j}_{mic}(\mathbf{r},t)$ is then,

$$\langle X_{mic}(\mathbf{r},t)\rangle \equiv \int_{\mathbb{R}^3} d^3\mathbf{r}' f(\mathbf{r}') X_{mic}(\mathbf{r}-\mathbf{r}',t)\ . \tag{17.19}$$

The macroscopic fields are defined as the averages of the respective microscopic fields:

$$\vec{\mathcal{E}}(\mathbf{r},t) \equiv \langle \vec{\mathcal{E}}_{mic}(\mathbf{r},t)\rangle \qquad \text{and} \qquad \vec{\mathcal{B}}(\mathbf{r},t) \equiv \langle \vec{\mathcal{B}}_{mic}(\mathbf{r},t)\rangle\ , \tag{17.20}$$

where macroscopic quantities do not have the subscript *mic*.

Now, taking the averages of the microscopic Maxwell equations, we obtain,

$$\begin{array}{lrcl}
\text{(i)} & \langle \nabla\times\vec{\mathcal{B}}_{mic}(\mathbf{r},t)\rangle - \varepsilon_0\mu_0\left\langle \frac{\partial\vec{\mathcal{E}}_{mic}(\mathbf{r},t)}{\partial t}\right\rangle &=& \mu_0\langle \mathbf{j}_{mic}(\mathbf{r},t)\rangle \\
\text{(ii)} & \langle \nabla\times\vec{\mathcal{E}}_{mic}(\mathbf{r},t)\rangle + \left\langle \frac{\partial\vec{\mathcal{B}}_{mic}(\mathbf{r},t)}{\partial t}\right\rangle &=& 0 \\
\text{(iii)} & \langle \nabla\cdot\vec{\mathcal{E}}_{mic}(\mathbf{r},t)\rangle &=& \frac{1}{\varepsilon_0}\langle \varrho_{mic}(\mathbf{r},t)\rangle \\
\text{(iv)} & \langle \nabla\cdot\vec{\mathcal{B}}_{mic}(\mathbf{r},t)\rangle &=& 0
\end{array}\ . \tag{17.21}$$

However,

$$\begin{aligned}
\langle \nabla\cdot\vec{\mathcal{E}}_{mic}(\mathbf{r},t)\rangle &= \nabla\cdot\langle\vec{\mathcal{E}}_{mic}(\mathbf{r},t)\rangle = \nabla\cdot\vec{\mathcal{E}}(\mathbf{r},t) \\
\langle \nabla\times\vec{\mathcal{E}}_{mic}(\mathbf{r},t)\rangle &= \nabla\times\langle\vec{\mathcal{E}}_{mic}(\mathbf{r},t)\rangle = \nabla\times\vec{\mathcal{E}}(\mathbf{r},t)\ ,
\end{aligned} \tag{17.22}$$

[4] An example for a normalized smoothing function is $f(\mathbf{r}') \equiv (a/\pi)^{3/2}e^{-ar'^2}$, as it satisfies $\int_{\mathbb{R}^3} f(\mathbf{r}')d^3r' = 1$.

[5] In contrast, X-rays with a resolution of about 10 nm allow for an analysis of the microscopic structure of matter.

and analogously for $\vec{\mathcal{B}}_{mic}$, since ∇ acts only on $\mathbf{r}$ and not on the integration variable $\mathbf{r}'$. On the other hand, the partial time-derivative also does not act on $\mathbf{r}$ nor on $\mathbf{r}'$,

$$\left\langle \frac{\partial \vec{\mathcal{E}}_{mic}(\mathbf{r},t)}{\partial t} \right\rangle = \frac{\partial}{\partial t}\langle \vec{\mathcal{E}}_{mic}(\mathbf{r},t)\rangle = \frac{\partial \vec{\mathcal{E}}(\mathbf{r},t)}{\partial t} \ , \tag{17.23}$$

and analogously for $\vec{\mathcal{B}}_{mic}$. Thus, we already deduced the two homogeneous macroscopic Maxwell equations (ii) and (iv), and the set of equations (17.21) simplifies to:

$$\begin{aligned}
&\text{(i)} && \nabla\times\vec{\mathcal{B}}(\mathbf{r},t) - \varepsilon_0\mu_0\partial_t\vec{\mathcal{E}}(\mathbf{r},t) &&= \mu\langle \mathbf{j}_{mic}(\mathbf{r},t)\rangle \\
&\text{(ii)} && \nabla\times\vec{\mathcal{E}}(\mathbf{r},t) + \partial_t\vec{\mathcal{B}}(\mathbf{r},t) &&= 0 \\
&\text{(iii)} && \nabla\cdot\vec{\mathcal{E}}(\mathbf{r},t) &&= \tfrac{1}{\varepsilon_0}\langle \varrho_{mic}(\mathbf{r},t)\rangle \\
&\text{(iv)} && \nabla\cdot\vec{\mathcal{B}}(\mathbf{r},t) &&= 0
\end{aligned} \ , \tag{17.24}$$

but we still need to calculate $\langle \varrho_{mic}(\mathbf{r},t)\rangle$ and $\langle \mathbf{j}_{mic}(\mathbf{r},t)\rangle$.

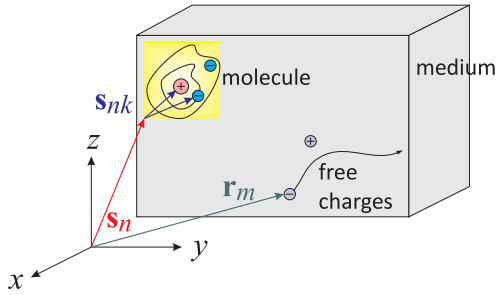

Figure 17.3: Charges localized in molecules and free charges.

To do so we imagine that, as illustrated in Fig. 17.3, there are N charges in each molecule of the material and, for simplicity, we also assume the material to be a pure substance, that is to say, composed of identical molecules. Be $\vec{\mathcal{S}}_n$ the position of the n-th molecule, measured from an arbitrary origin of the coordinate system. Thus, the k-th charge q_{kn} of the n-th molecule is at the point $\vec{\mathcal{S}}_{kn}$, with respect to the position vector of the molecule $\vec{\mathcal{S}}_n$. This means that, with respect to the origin of the coordinate system, the position of the charge q_{kn} is given by $\vec{\mathcal{S}}_{kn} + \vec{\mathcal{S}}_n$. We will also allow for free charges, q_m, at positions $\mathbf{r}_m$. As all the charges can move, all their positions $\mathbf{r}_m(t)$, $\vec{\mathcal{S}}_n(t)$, and $\vec{\mathcal{S}}_{kn}(t)$ must be considered as functions of time.

First, we will calculate the charge density,

$$\varrho_{mic}(\mathbf{r},t) = \sum_m q_m\delta^{(3)}(\mathbf{r}-\mathbf{r}_m) + \sum_{n,k} q_{kn}\delta^{(3)}(\mathbf{r}-\vec{\mathcal{S}}_{kn}-\vec{\mathcal{S}}_n) \ , \tag{17.25}$$

and using the definition of the spatial average (17.19),

$$\langle \varrho_{mic}(\mathbf{r},t)\rangle = \sum_m q_m f(\mathbf{r}-\mathbf{r}_m) \ (\to \varrho(\mathbf{r},t)) + \sum_{n,k} q_{kn} f(\mathbf{r}-\vec{\mathcal{S}}_{kn}-\vec{\mathcal{S}}_n) \ , \tag{17.26}$$

where we recall, that the first term represents the macroscopic density of free charges $\varrho(\mathbf{r},t)$. Typically, $|\vec{\mathcal{S}}_{kn}|$ is on the order of some Angströms only, and therefore the 'smoothing' function $f(\mathbf{r}-\vec{\mathcal{S}}_{kn}-\vec{\mathcal{S}}_n)$ does not appreciably differ from $f(\mathbf{r}-\vec{\mathcal{S}}_n)$, such that we can approximate:

$$f(\mathbf{r}-\vec{\mathcal{S}}_{kn}-\vec{\mathcal{S}}_n) \simeq f(\mathbf{r}-\vec{\mathcal{S}}_n) - \vec{\mathcal{S}}_{kn}\cdot\nabla f(\mathbf{r}-\vec{\mathcal{S}}_n) + \tfrac{1}{2}(\vec{\mathcal{S}}_{kn}\cdot\nabla)^2 f(\mathbf{r}-\vec{\mathcal{S}}_n)\ , \quad (17.27)$$

and, with this approximation, obtain,

$$\begin{aligned}\langle\varrho_{mic}(\mathbf{r},t)\rangle &\simeq \varrho(\mathbf{r},t) + \sum_{n,k} q_{kn} f(\mathbf{r}-\vec{\mathcal{S}}_n) - \sum_{n,k} q_{kn}\vec{\mathcal{S}}_{kn}\cdot\nabla f(\mathbf{r}-\vec{\mathcal{S}}_n) \\ &\quad + \sum_{n,k} q_{kn}\tfrac{1}{2}(\vec{\mathcal{S}}_{kn}\cdot\nabla)^2 f(\mathbf{r}-\vec{\mathcal{S}}_n) \\ &= \varrho(\mathbf{r},t) + \cancelto{0}{\sum_{n,k} q_{kn}} f(\mathbf{r}-\vec{\mathcal{S}}_n) - \nabla\cdot\sum_n\left(\sum_k q_{kn}\vec{\mathcal{S}}_{kn}\right) f(\mathbf{r}-\vec{\mathcal{S}}_n) \\ &\quad + \tfrac{1}{6}\sum_n \nabla\cdot\left[\left(3\cancelto{0}{\sum_k q_{kn}\vec{\mathcal{S}}_{kn}\vec{\mathcal{S}}_{kn}}\right)\cdot\nabla f(\mathbf{r}-\vec{\mathcal{S}}_n)\right] \\ &= \varrho(\mathbf{r},t) - \nabla\cdot\sum_n \mathbf{d}_n f(\mathbf{r}-\vec{\mathcal{S}}_n)\ .\end{aligned} \quad (17.28)$$

In the last line we assumed that each molecule is neutral,

$$\sum_k q_{kn} = 0\ , \quad (17.29)$$

we use the definition of the electric dipole moment of the n-th molecule,

$$\mathbf{d}_n = \sum_k q_{kn}\vec{\mathcal{S}}_{kn}\ , \quad (17.30)$$

and we suppose, to simplify our calculations below, that the electric quadrupole momentum of the n-th molecule,

$$\overleftrightarrow{Q}_n \equiv 3\sum_k q_{kn}\vec{\mathcal{S}}_{kn}\vec{\mathcal{S}}_{kn} \stackrel{!}{=} \overleftrightarrow{0}\ , \quad (17.31)$$

is zero, that is, that the molecules of the material have zero electric quadrupolar momentum. As shown in the discussion of the relationship (??), the polarization of a medium is the sum of the individual instantaneous dipole moments of each molecule,

$$\vec{\mathcal{P}}_{mic}(\mathbf{r},t) = \sum_n \mathbf{d}_n\delta^{(3)}(\mathbf{r}-\vec{\mathcal{S}}_n)\ , \quad (17.32)$$

With these observations, we conclude that,

$$\langle\vec{\mathcal{P}}_{mic}(\mathbf{r},t)\rangle = \sum_n \mathbf{d}_n f(\mathbf{r}-\vec{\mathcal{S}}_n)\ , \quad (17.33)$$

and, identifying this quantity in the expression (17.28), we get,

$$\langle \varrho_{mic}(\mathbf{r},t)\rangle \simeq \varrho(\mathbf{r},t) - \nabla\cdot\vec{\mathcal{P}}(\mathbf{r},t)\ , \tag{17.34}$$

where we introduced the abbreviation, $\vec{\mathcal{P}}(\mathbf{r},t) \equiv \langle \vec{\mathcal{P}}_{mic}(\mathbf{r},t)\rangle$, analogously to the electrostatic case. The macroscopic Gauß law (17.21)(iii) becomes then,

$$\nabla\cdot\vec{\mathcal{E}}(\mathbf{r},t) = \tfrac{1}{\varepsilon_0}[\varrho(\mathbf{r},t) - \nabla\cdot\vec{\mathcal{P}}(\mathbf{r},t)]\ , \tag{17.35}$$

that is,

$$\nabla\cdot\vec{\mathcal{D}}(\mathbf{r},t) = \varrho(\mathbf{r},t)\ , \tag{17.36}$$

where we defined the field of *electric displacement* as,

$$\boxed{\vec{\mathcal{D}}(\mathbf{r},t) \equiv \varepsilon_0\vec{\mathcal{E}}(\mathbf{r},t) + \vec{\mathcal{P}}(\mathbf{r},t)}\ . \tag{17.37}$$

Let us now calculate, $\langle \mathbf{j}_{mic}(\mathbf{r},t)\rangle$. From the very definition of the microscopic current we have,

$$\mathbf{j}_{mic}(\mathbf{r},t) \equiv \varrho_{mic}(\mathbf{r},t)\mathbf{v}_{mic}(\mathbf{r},t)\ , \tag{17.38}$$

where $\mathbf{v}_{mic}(\mathbf{r},t)$ is the velocity field of the charges of the material medium. By inserting the expression (17.25) for the charge density,

$$\begin{aligned}\mathbf{j}_{mic}(\mathbf{r},t) &= \sum_m q_m\delta^{(3)}(\mathbf{r}-\mathbf{r}_m)\mathbf{v}_{mic}(\mathbf{r},t) + \sum_{n,k} q_{kn}\delta^{(3)}(\mathbf{r}-\vec{\mathcal{S}}_{kn}-\vec{\mathcal{S}}_n)\mathbf{v}_{mic}(\mathbf{r},t) \\ &= \sum_m q_m\dot{\mathbf{r}}_m\delta^{(3)}(\mathbf{r}-\mathbf{r}_m) + \sum_{n,k} q_{kn}(\dot{\mathbf{s}}_{kn}+\dot{\mathbf{s}}_n)\delta^{(3)}(\mathbf{r}-\vec{\mathcal{S}}_{kn}-\vec{\mathcal{S}}_n)\ ,\end{aligned} \tag{17.39}$$

where the field of charge velocities calculated exactly at the location of the m-th charge gives the value of its velocity,

$$\delta^{(3)}(\mathbf{r}-\mathbf{x})\mathbf{v}_{mic}(\mathbf{r},t) = \delta^{(3)}(\mathbf{r}-\mathbf{x})\dot{\mathbf{x}}\ .$$

We can now evaluate the average (17.19),

$$\langle \mathbf{j}_{mic}(\mathbf{r},t)\rangle = \sum_m q_m\dot{\mathbf{r}}_m f(\mathbf{r}-\mathbf{r}_m) \longrightarrow \mathbf{j}(\mathbf{r},t) + \sum_{n,k} q_{kn}(\dot{\mathbf{s}}_{kn}+\dot{\mathbf{s}}_n)f(\mathbf{r}-\vec{\mathcal{S}}_{kn}-\vec{\mathcal{S}}_n)\ , \tag{17.40}$$

where we recall, that the first term represents the macroscopic density of free current $\mathbf{j}(\mathbf{r},t)$. Approximating again,

$$f(\mathbf{r}-\vec{\mathcal{S}}_{kn}-\vec{\mathcal{S}}_n) \simeq f(\mathbf{r}-\vec{\mathcal{S}}_n) - \vec{\mathcal{S}}_{kn}\cdot\nabla f(\mathbf{r}-\vec{\mathcal{S}}_n)\ , \tag{17.41}$$

and, with this approximation, we obtain,

$$\langle \mathbf{j}_{mic}(\mathbf{r},t)\rangle \simeq \mathbf{j}(\mathbf{r},t) + \sum_{n,k} q_{kn}(\dot{\mathbf{s}}_{kn}+\dot{\mathbf{s}}_n)f(\mathbf{r}-\vec{\mathcal{S}}_n) - \sum_{k,n} q_{kn}(\dot{\mathbf{s}}_{kn}+\dot{\mathbf{s}}_n)\vec{\mathcal{S}}_{kn}\cdot\nabla f(\mathbf{r}-\vec{\mathcal{S}}_n)\ . \tag{17.42}$$

As we are now working to obtain the macroscopic Ampère-Maxwell equation, we need to let appear in the above results the rotation of the magnetization, in addition to the time derivative of the polarization. Recalling that the magnetic dipole moment of the n-th molecule $\vec{\mu}_n$ is defined by equation (15.43) as,

$$\vec{\mu}_n \equiv \tfrac{1}{2}\sum_k q_{kn}\vec{\mathcal{S}}_{kn}\times\dot{\mathbf{s}}_{kn}\ , \tag{17.43}$$

based on the relationship (16.15), we can write magnetization as the sum of the instantaneous magnetic dipole moments of every molecule,

$$\vec{\mathcal{M}}_{mic}(\mathbf{r},t) = \sum_n \vec{\mu}_n \delta^{(3)}(\mathbf{r}-\vec{\mathcal{S}}_n)\ , \tag{17.44}$$

Thus, we want to identify, in the expression for $\langle \mathbf{j}_{mic}(\mathbf{r},t)\rangle$, the rotation of $\langle\vec{\mathcal{M}}_{mic}(\mathbf{r},t)\rangle$:

$$\begin{aligned}\nabla\times\langle\vec{\mathcal{M}}_{mic}(\mathbf{r},t)\rangle &= \nabla\times\sum_n\vec{\mu}_n f(\mathbf{r}-\vec{\mathcal{S}}_n) = -\sum_n\vec{\mu}_n\times\nabla f(\mathbf{r}-\vec{\mathcal{S}}_n) \\ &= -\tfrac{1}{2}\sum_{n,k} q_{kn}(\vec{\mathcal{S}}_{kn}\times\dot{\mathbf{s}}_{kn})\times\nabla f(\mathbf{r}-\vec{\mathcal{S}}_n) \\ &= -\tfrac{1}{2}\sum_{n,k} q_{kn}\dot{\mathbf{s}}_{kn}[\vec{\mathcal{S}}_{kn}\cdot\nabla f(\mathbf{r}-\vec{\mathcal{S}}_n)] + \tfrac{1}{2}\sum_{n,k} q_{kn}\vec{\mathcal{S}}_{kn}[\dot{\mathbf{s}}_{kn}\cdot\nabla f(\mathbf{r}-\vec{\mathcal{S}}_n)]\ ,\end{aligned} \tag{17.45}$$

using the BAC-CAB rule (21.110)(v), and continuing,

$$\begin{aligned}\nabla\times\langle\vec{\mathcal{M}}_{mic}(\mathbf{r},t)\rangle &= -\sum_{n,k} q_{kn}\dot{\mathbf{s}}_{kn}\vec{\mathcal{S}}_{kn}\cdot\nabla f(\mathbf{r}-\vec{\mathcal{S}}_n) + \tfrac{1}{2}\sum_n\left[\sum_k q_{kn}\frac{d}{dt}(\vec{\mathcal{S}}_{kn}\vec{\mathcal{S}}_{kn})\right]\cdot\nabla f(\mathbf{r}-\vec{\mathcal{S}}_n) \\ &= -\sum_{n,k} q_{kn}\dot{\mathbf{s}}_{kn}\vec{\mathcal{S}}_{kn}\cdot\nabla f(\mathbf{r}-\vec{\mathcal{S}}_n) + \tfrac{1}{6}\sum_n\left[\frac{d}{dt}\left(3\sum_k q_{kn}\vec{\mathcal{S}}_{kn}\vec{\mathcal{S}}_{kn}\right)^{0}\right]\cdot\nabla f(\mathbf{r}-\vec{\mathcal{S}}_n)\ .\end{aligned} \tag{17.46}$$

The second term is zero again because, as in (17.31), we are assuming that $\overleftrightarrow{Q}_n \overset{!}{=} \overleftrightarrow{0}$. Continuing the calculation (17.42),

$$\begin{aligned}\langle\mathbf{j}_{mic}(\mathbf{r},t)\rangle = \mathbf{j}(\mathbf{r},t) &+ \sum_{n,k} q_{kn}\dot{\mathbf{s}}_{kn} f(\mathbf{r}-\vec{\mathcal{S}}_n) + \sum_{n,k} q_{kn}^{\ 0}\dot{\mathbf{s}}_n f(\mathbf{r}-\vec{\mathcal{S}}_n) \\ &+ \nabla\times\langle\vec{\mathcal{M}}_{mic}(\mathbf{r},t)\rangle - \sum_{n,k} q_{kn}\dot{\mathbf{s}}_n\vec{\mathcal{S}}_{kn}\cdot\nabla f(\mathbf{r}-\vec{\mathcal{S}}_n)\ .\end{aligned} \tag{17.47}$$

The third term disappears, because again we are assuming that the total charge of every molecule is zero, $\sum_k q_{kn} = 0$. The partial temporal derivative of the polarization is given by the expression (17.33),

$$\begin{aligned}\frac{\partial\vec{\mathcal{P}}(\mathbf{r},t)}{\partial t} &= \frac{\partial}{\partial t}\sum_{n,k} q_{kn}\vec{\mathcal{S}}_{kn} f(\mathbf{r}-\vec{\mathcal{S}}_n) = \sum_{n,k} q_{kn}\frac{\partial\vec{\mathcal{S}}_{kn}}{\partial t} f(\mathbf{r}-\vec{\mathcal{S}}_n) + \sum_{n,k} q_{kn}\vec{\mathcal{S}}_{kn}\frac{\partial}{\partial t} f(\mathbf{r}-\vec{\mathcal{S}}_n) \\ &= \sum_{n,k} q_{kn}\dot{\mathbf{s}}_{kn} f(\mathbf{r}-\vec{\mathcal{S}}_n) - \sum_{n,k} q_{kn}\vec{\mathcal{S}}_{kn}\dot{\mathbf{s}}_n\cdot\nabla f(\mathbf{r}-\vec{\mathcal{S}}_n)\ .\end{aligned} \tag{17.48}$$

We can use this result to replace the second term in equation (17.47),

$$\langle \mathbf{j}_{mic}(\mathbf{r},t)\rangle \simeq \mathbf{j}(\mathbf{r},t) + \nabla\times\langle\vec{\mathcal{M}}_{mic}(\mathbf{r},t)\rangle + \frac{\partial\vec{\mathcal{P}}(\mathbf{r},t)}{\partial t} + \sum_{n,k} q_{kn}[\vec{\mathcal{S}}_{kn}\dot{\mathbf{s}}_n\cdot\nabla f(\mathbf{r}-\vec{\mathcal{S}}_n) - \dot{\mathbf{s}}_n\vec{\mathcal{S}}_{kn}\cdot\nabla f(\mathbf{r}-\vec{\mathcal{S}}_n)] \ . \tag{17.49}$$

Note, that the last term of this expression is identical to (17.45) with the difference, that the electronic velocities $\dot{\mathbf{s}}_{kn}$ of that expression or now replaced by the molecular velocities $\dot{\mathbf{s}}_n$.

Now let us suppose that the material itself is not in motion, so that the (averaged absolute) velocities of the molecules, $\dot{\mathbf{s}}_n$, are much smaller than the (averaged absolute) velocities of the charges in every molecule, $\dot{\mathbf{s}}_{kn}$. With this, we can neglect the last term of the above equation in comparison to the first,

$$\mu_0\langle \mathbf{j}_{mic}(\mathbf{r},t)\rangle \simeq \mu_0\mathbf{j}(\mathbf{r},t) + \mu_0\frac{\partial\vec{\mathcal{P}}(\mathbf{r},t)}{\partial t} + \mu_0\nabla\times\langle\vec{\mathcal{M}}_{mic}(\mathbf{r},t)\rangle \ . \tag{17.50}$$

The Ampère-Maxwell equation, then reads in its spatial average (17.21)(i),

$$\begin{aligned}\nabla\times\vec{\mathcal{B}}(\mathbf{r},t) &= \mu_0\langle\mathbf{j}_{mic}(\mathbf{r},t)\rangle + \varepsilon_0\mu_0\left\langle\frac{\partial\vec{\mathcal{E}}_{mic}(\mathbf{r},t)}{\partial t}\right\rangle \\ &= \mu_0\mathbf{j}(\mathbf{r},t) + \mu_0\frac{\partial\vec{\mathcal{P}}(\mathbf{r},t)}{\partial t} + \mu_0\nabla\times\langle\vec{\mathcal{M}}_{mic}(\mathbf{r},t)\rangle + \varepsilon_0\mu_0\frac{\partial\vec{\mathcal{E}}(\mathbf{r},t)}{\partial t} \ ,\end{aligned} \tag{17.51}$$

or,

$$\nabla\times[\vec{\mathcal{B}}(\mathbf{r},t) - \mu_0\nabla\times\langle\vec{\mathcal{M}}_{mic}(\mathbf{r},t)\rangle] = \mu_0\mathbf{j}(\mathbf{r},t) + \mu_0\frac{\partial}{\partial t}[\varepsilon\vec{\mathcal{E}}(\mathbf{r},t) + \vec{\mathcal{P}}(\mathbf{r},t)] \ , \tag{17.52}$$

Introducing the abbreviation,

$$\vec{\mathcal{M}}(\mathbf{r},t) \equiv \langle\vec{\mathcal{M}}_{mic}(\mathbf{r},t)\rangle \ , \tag{17.53}$$

defining *magnetic excitation* field,

$$\boxed{\vec{\mathcal{H}}(\mathbf{r},t) \equiv \tfrac{1}{\mu_0}\vec{\mathcal{B}}(\mathbf{r},t) - \vec{\mathcal{M}}(\mathbf{r},t)} \ , \tag{17.54}$$

and recognizing the electric displacement field, $\vec{\mathcal{D}}(\mathbf{r},t) = \varepsilon_0\vec{\mathcal{E}}(\mathbf{r},t) + \vec{\mathcal{P}}(\mathbf{r},t)$, we obtain,

$$\nabla\times\vec{\mathcal{H}}(\mathbf{r},t) = \frac{\partial\vec{\mathcal{D}}(\mathbf{r},t)}{\partial t} + \mathbf{j}(\mathbf{r},t) \ , \tag{17.55}$$

which is the macroscopic Ampère-Maxwell equation.

The above derivations show that $\vec{\mathcal{P}}$ and $\vec{\mathcal{M}}$ do not exist as exact physical quantities in the microscopic sense. They are artifacts of a process of smearing out the microscopic charges and currents over smooth macroscopic distributions, with the aim of facilitating the calculation with macroscopic quantities.

17.1.4 The fundamental laws in polarizable and magnetizable materials

The derivations made in the previous chapter led to Maxwell's macroscopic equations, which correspond to the Maxwell equations for vacuum complemented by material equations characterizing the medium. In short,

$$\boxed{\begin{array}{lrcl} \text{(i)} & \nabla \times \vec{\mathcal{H}} & = & \partial_t \vec{\mathcal{D}} + \mathbf{j} \\ \text{(ii)} & \nabla \times \vec{\mathcal{E}} & = & -\partial_t \vec{\mathcal{B}} \\ \text{(iii)} & \nabla \cdot \vec{\mathcal{D}} & = & \varrho \\ \text{(iv)} & \nabla \cdot \vec{\mathcal{B}} & = & 0 \end{array}} \; . \tag{17.56}$$

The fields are related by the macroscopic *polarization* and *magnetization*,

$$\vec{\mathcal{P}} = \vec{\mathcal{D}} - \varepsilon_0 \vec{\mathcal{E}} \quad \text{and} \quad \vec{\mathcal{M}} = \mu_0^{-1} \vec{\mathcal{B}} - \vec{\mathcal{H}} \; . \tag{17.57}$$

For a given free charge density distribution $\varrho(\mathbf{r}, t)$ and a free current density distribution $\mathbf{j}(\mathbf{r}, t)$, the above six equations (17.56) and (17.57) define the six components of the fields unambiguously. In vacuum $\varepsilon_0 \vec{\mathcal{E}} = \vec{\mathcal{D}}$ and $\mu_0^{-1} \vec{\mathcal{B}} = \vec{\mathcal{H}}$ Maxwell's equations simplify. In material media, however, the secondary quantities $\vec{\mathcal{D}}$ and $\vec{\mathcal{H}}$ are not equal to the fields.

Depending on its structure, a medium may have (or not) bound or free charges and currents, responding in a specific way to applied electric and magnetic fields and giving rise to a wide variety of features. For example, a medium is *non-conductive* when, even in the presence of electric fields applied to the medium, there is no flux of current. A medium is *linear* when the polarization and the magnetization depend linearly on the electric and magnetic fields, respectively. A medium is *homogeneous* when the susceptibilities do not vary across the medium. When the directions of induced polarization and magnetization are parallel, respectively, to the electric and magnetic fields, the medium is said to be *isotropic*, otherwise it is said to be *anisotropic*.

Depending on the type of material and its properties the equations do sometimes simplify. For example, we have for a

medium	condition
dielectric	$\vec{\mathcal{D}} = \varepsilon\vec{\mathcal{E}}$, $\vec{\mathcal{P}} = \chi_\varepsilon\varepsilon_0\vec{\mathcal{E}}$, $\varepsilon = 1 + \chi_\varepsilon$
non-linear dielectric	$\vec{\mathcal{D}} = \vec{\mathcal{D}}(\vec{\mathcal{E}}) \nsim \vec{\mathcal{E}}$
dia- and paramagnetic	$\vec{\mathcal{B}} = \mu\vec{\mathcal{H}}$, $\vec{\mathcal{M}} = \chi_\mu\vec{\mathcal{H}}$, $\mu = 1 + \chi_\mu$
non-linear magnetic	$\vec{\mathcal{B}} = \vec{\mathcal{B}}(\vec{\mathcal{H}}) \nsim \vec{\mathcal{B}}$
neutral	$\rho = 0$
isolating	$\mathbf{j} = 0$
ohmic	$\mathbf{j} = \sigma\vec{\mathcal{E}}$
non ohmic	$\mathbf{j} = \mathbf{j}(\vec{\mathcal{E}}) \nsim \vec{\mathcal{E}}$

The material equations define the material constants, that is, the *permittivity* ε, the *permeability* μ, and the *conductivity* σ. These quantities are scalar for isotropic media and tensors for anisotropic media. Resolve the Exc. 17.1.5.11.

17.1.5 Exercises

17.1.5.1 Ex: Displacement current

Consider a straight big conducting wire of radius a with a small transverse gap of width $w \ll a$ carrying a constant current I. Find the magnetic field in the gap for distances of the symmetry axis $r < a$ as a function of the current.

Solution: *The two surfaces on either side of the gap act as a plate capacitor as the charges build up on these surfaces. Consequently, the electric field between the plates increases, which generates a magnetic field. Neglecting boundary effects at the edges of the plates, the temporal variation of the electric field between the plates is,*

$$\frac{\partial\mathcal{E}}{\partial t} = \frac{\partial}{\partial t}\frac{\sigma}{\varepsilon_0} = \frac{\partial}{\partial t}\frac{Q}{\pi a^2\varepsilon_0} = \frac{I}{\pi a^2\varepsilon_0} \ .$$

Taking a circular path of radius r between the plates (there is no current here, so that $\mathbf{j} = 0$), we have,

$$2\pi r\mathcal{B} = \oint_{\partial\mathcal{S}} \vec{\mathcal{B}}\cdot d\mathbf{l} = \int_{\mathcal{S}} \nabla\times\vec{\mathcal{B}}\cdot d\mathbf{S} = \varepsilon_0\mu_0\int_{\mathcal{S}} \frac{\partial\vec{\mathcal{E}}}{\partial t}\cdot d\mathbf{S} = \varepsilon_0\mu_0\int_{\mathcal{S}} \frac{I}{\pi a^2\varepsilon_0}dS = \varepsilon_0\mu_0\frac{I}{\pi a^2\varepsilon_0}\pi r^2 \ .$$

Hence,

$$\vec{\mathcal{B}} = \mu_0\frac{Ir}{2\pi a^2}\hat{\mathbf{e}}_\phi \ ,$$

by symmetry and using the right hand rule, and taking the z-direction as showing from the positive plate towards the negative plate.

17.1.5.2 Ex: Plate capacitor

A disk-shaped plate capacitor with radius R, distance d, and $\varepsilon = 1$ is charged by a constant current I.
a. Calculate from the continuity equation, neglecting edge effects, the temporal variation of the charges on the plates $q(t)$, respectively, $-q(t)$.
b. Calculate the temporal variation of the electric field between the plates and Maxwell's displacement current density.
c. Calculate the magnetic field $\vec{\mathcal{B}}$ between the plates along a circular path Γ inside ($\rho < R$) and outside ($\rho > R$) the capacitor.
d. Show that the $\vec{\mathcal{B}}$-field between the plates is, for $\rho > R$, equal to the $\vec{\mathcal{B}}$-field produced by the charging current I around the conductors feeding the capacitor.

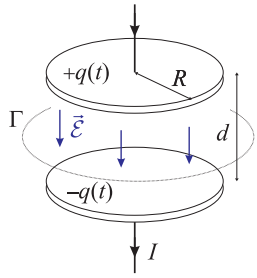

Figure 17.4: Plate capacitor.

Solution: *a. The surface integral over a closed area S surrounding the upper plate of the capacitor is,*

$$\oint \mathbf{j} \cdot d\mathbf{S} = -I \ .$$

With the law of Gauß and the continuity equation,

$$\oint \mathbf{j} \cdot d\mathbf{S} = \int_V \nabla \cdot \mathbf{j} dV = -\frac{\partial}{\partial t} \int \rho dV = -\frac{\partial}{\partial t} q(t) \ .$$

Follows,

$$q(t) = It + q(0) \ .$$

b. Maxwell's third equation,

$$\nabla \cdot \vec{\mathcal{D}} = \rho \ ,$$

where $\vec{\mathcal{D}} = \varepsilon_0 \vec{\mathcal{E}} \equiv -\varepsilon_0 \mathcal{E} \hat{\mathbf{e}}_z$ without dielectric. Thereby,

$$\oint \vec{\mathcal{D}} \cdot d\mathbf{S} = \mathcal{D} \pi R^2 = q \ .$$

Hence, $\varepsilon_0 \dot{\mathcal{E}} = \dot{\mathcal{D}} = \frac{\dot{q}(t)}{\pi R^2}$. According to (17.5) Maxwell's displacement current density is defined as,

$$\mathbf{j}_d \equiv \varepsilon_0 \frac{\partial \vec{\mathcal{E}}}{\partial t} = -\frac{\dot{q}}{\pi R^2} \hat{\mathbf{e}}_z = -\frac{I}{\pi R^2} \hat{\mathbf{e}}_z \ .$$

c. Between the plates we have no free charges, $\mathbf{j} = 0$. *The line integral along the circle* Γ *between the capacitor plates around the z-axis is,*

$$\oint_\Gamma \vec{\mathcal{B}} \cdot d\mathbf{l} = \mu_0 \int \mathbf{j}_d \cdot d\mathbf{S} \ .$$

For a radius of the circle less than the radius of the plates, $\rho < R$, *we have* $\mathcal{B}_\rho 2\pi\rho = \mu_0 \left(-\frac{I}{\pi R^2}\right) \hat{\mathbf{e}}_z \cdot \hat{\mathbf{e}}_z \pi\rho^2$. *Hence,*

$$\vec{\mathcal{B}}_\rho = -\frac{\mu_0 I}{2\pi R^2}\rho\hat{\mathbf{e}}_\phi \ .$$

For $\rho > R$, *we have* $\mathcal{B}_\rho 2\pi\rho = -\mu_0 \frac{I}{\pi R^2}\pi R^2$. *Hence,*

$$\vec{\mathcal{B}}_\rho = -\frac{\mu_0 I}{2\pi\rho}\hat{\mathbf{e}}_\phi \ .$$

d. Above the capacitor the field $\mathcal{B}_\rho$ *is, due to* $\mathbf{j}_{displ} = 0$,

$$\oint \vec{\mathcal{B}} \cdot d\mathbf{S} = \mu_0 \int \mathbf{j} \cdot d\mathbf{S}$$

Hence, $\mathcal{B}2\pi\rho = -\mu_0 I$, *that is,*

$$\vec{\mathcal{B}}_\rho = -\frac{\mu_0 I}{2\pi\rho}\hat{\mathbf{e}}_\phi \ .$$

17.1.5.3 Ex: Maxwell's equations for a particular charge and current density distribution

Determine the charge and current density distributions producing the fields,

$$\vec{\mathcal{E}}(\mathbf{r}, t) = -\frac{1}{4\pi\varepsilon_0}\frac{q}{r^2}\Theta(vt - r)\hat{\mathbf{e}}_r \qquad \text{and} \qquad \vec{\mathcal{B}}(\mathbf{r}, t) = 0 \ ,$$

where Θ is the Heavyside function and v is a constant. Show that the fields satisfy all Maxwell equations. Describe the physical situation producing these fields.

Solution: *It is easy to show,*

$$\nabla \cdot \vec{\mathcal{B}} = \nabla \times \vec{\mathcal{B}} = \nabla \times \vec{\mathcal{E}} = 0 \ ,$$

because the electric field is radial. The third Maxwell equation gives,

$$\begin{aligned}
\varrho &= \varepsilon_0 \nabla \cdot \vec{\mathcal{E}} = -\frac{q}{4\pi}\nabla \cdot \frac{\Theta(vt - r)\hat{\mathbf{e}}_r}{r^2} \\
&= -\frac{q}{4\pi}\left(\Theta(vt - r)\nabla \cdot \frac{\hat{\mathbf{e}}_r}{r^2} + \frac{\hat{\mathbf{e}}_r}{r^2} \cdot \nabla\Theta(vt - r)\right) \\
&= -\frac{q}{4\pi}\left(\Theta(vt - r)4\pi\delta^3(\mathbf{r}) + \frac{\hat{\mathbf{e}}_r}{r^2} \cdot [-\delta(vt - r)\hat{\mathbf{e}}_r]\right) \\
&= -\frac{q}{4\pi}\left(4\pi\delta^3(\mathbf{r}) + \frac{\hat{\mathbf{e}}_r}{r^2} \cdot [-\delta(vt - r)\hat{\mathbf{e}}_r]\right) = -q\delta^3(\mathbf{r}) + \frac{q}{4\pi r^2}\delta(vt - r) \ .
\end{aligned}$$

Also, we obtain from Maxwell's first equation,

$$\mathbf{j} = -\varepsilon_0 \frac{\partial \vec{\mathcal{E}}}{\partial t} = \frac{qv}{4\pi r^2}\delta(vt-r)\hat{\mathbf{e}}_r \ .$$

With the temporal variation of the charge density,

$$\frac{\partial \varrho}{\partial t} = \frac{q}{4\pi r^2}\frac{\partial \delta^3(ct-r)}{\partial t} \ ,$$

and the divergence of the current density,

$$\begin{aligned}\nabla\cdot\mathbf{j}(\mathbf{r},t) &= \frac{qv}{4\pi r^2}\delta(vt-r)\nabla\cdot\frac{\mathbf{r}}{r^3} + \frac{qv}{4\pi r^2}\nabla\delta(vt-r) \\ &= \frac{qv}{4\pi r^2}\cancelto{0}{\delta(vt-r)(-4\pi)\delta^3(\mathbf{r})} - \frac{qv}{4\pi r^2}\frac{\partial\delta^3(vt-r)}{\partial r} \ ,\end{aligned}$$

we see that the continuity equation is satisfied. The situation corresponds to a point charge $+q$ at the origin and a spherical shell charge distribution (with the total charge $-q$) expanding with velocity v). The electric field inside the shell is entirely due to the charge at the origin, and the field outside the sphere is zero, since the total enclosed charge is zero. Only the expanding sphere contributes to the current density.

17.1.5.4 Ex: Atomic diamagnetism

An electron (charge q) orbits a nucleus (charge Q) at a distance r, the centripetal acceleration being provided by the Coulomb attraction. Now, a small magnetic field $d\mathcal{B}$ is slowly ramped up, perpendicular to the plane of the orbit. Show that the increase of the kinetic energy, dT, transferred to the electron via the induced electric field, is exactly the one necessary to keep the circular motion on the original radius r. (This allows us, in the discussion of *diamagnetism*, to assume a fixed electron radius.)

Solution: *The atom is stable if,*

$$\frac{mv^2}{r} = \frac{Qq}{4\pi\varepsilon_0 r^2} \ .$$

In the presence of a magnetic field the force balance is modified by the Lorentz force,

$$\frac{mv_1^2}{r} = \frac{Qq}{4\pi\varepsilon_0 r^2} - qv_1 d\mathcal{B} \ .$$

That is, we observe a variation of the kinetic energy which, assuming that the radius stays unchanged, is given by,

$$dT = \tfrac{m}{2}v_1^2 - \tfrac{m}{2}v^2 = -\tfrac{1}{2}qrvd\mathcal{B} \ .$$

This may seem surprising knowing that magnetic fields do not work. The solution is that the increase of the kinetic energy must come from the electric field induced by the temporal variation of the magnetic field,

$$\pi r^2\frac{\partial\mathcal{B}}{\partial t} = \int\frac{\partial\vec{\mathcal{B}}}{\partial t}\cdot d\mathbf{S} = -\int_{\mathcal{S}}\nabla\times\vec{\mathcal{E}}d\mathbf{S} = -\oint_{\partial\mathcal{S}}\vec{\mathcal{E}}\cdot d\mathbf{l} = -2\pi r\mathcal{E} \ .$$

The force on the electron is now a Coulomb force,

$$\mathbf{F}_E = q\mathcal{E}\hat{\mathbf{e}}_\phi = -\frac{qr}{2}\frac{\partial \mathcal{B}}{\partial t}\hat{\mathbf{e}}_\phi \ .$$

Therefore, the kinetic energy varies by,

$$dT = F_E dl = -\frac{qr}{2}\frac{\partial \mathcal{B}}{\partial t}dl = -\frac{qr}{2}\frac{\partial \mathcal{B}}{\partial t}vdt = -\frac{qr}{2}vd\mathcal{B} \ ,$$

which corresponds to the value determined above by assuming an invariable radius [6].

17.1.5.5 Ex: Variable charge with constant current

Suppose that $\mathbf{j}(\mathbf{r})$ is constant over time, but not $\varrho(\mathbf{r}, t)$. Such conditions can prevail, for example, during the charging process of a capacitor.
a. Show that the charge density at any point is a linear function of time: $\varrho(\mathbf{r}, t) = \varrho(\mathbf{r}, 0) + \dot{\varrho}(\mathbf{r}, 0)t$.
b. Despite the fact that this configuration is not electrostatic or magnetostatic, both the Coulomb law and the Biot-Savart law remain valid, since they satisfy Maxwell's equations. Show in particular that,

$$\vec{\mathcal{B}}(\mathbf{r}) = \frac{\mu_0}{4\pi}\int \frac{\mathbf{j}(\mathbf{r}') \times \hat{\mathbf{e}}_R}{R^2} d^3r'$$

with $R \equiv |\mathbf{r} - \mathbf{r}'|$ obeys Ampère's law including Maxwell's displacement term.

Solution: *a. From the continuity equation,*

$$\dot{\varrho}(\mathbf{r}, t) = -\nabla \cdot \mathbf{j}(\mathbf{r}) = const = \dot{\varrho}(\mathbf{r}, 0)$$

we check,

$$\varrho(\mathbf{r}, t) - \varrho(\mathbf{r}, 0) = \dot{\varrho}(\mathbf{r}, 0)\int_0^t d\tau = \dot{\varrho}(\mathbf{r}, 0)t \ .$$

b. Inserting the given magnetic field into the first Maxwell equation we calculate, using the rule $\nabla \times (\mathbf{A} \times \mathbf{B}) = (\mathbf{B} \cdot \nabla)\mathbf{A} - (\mathbf{A} \cdot \nabla)\mathbf{B} + \mathbf{A}(\nabla \cdot \mathbf{B}) - \mathbf{B}(\nabla \cdot \mathbf{A})$,

$$\begin{aligned}\nabla \times \vec{\mathcal{B}}(\mathbf{r}) &= \frac{\mu_0}{4\pi}\int \nabla \times \frac{\mathbf{j}(\mathbf{r}') \times \hat{\mathbf{e}}_R}{R^2} d^3r' = \frac{\mu_0}{4\pi}\int \left(- [\mathbf{j}(\mathbf{r}') \cdot \nabla] \frac{\hat{\mathbf{e}}_R}{R^2} + \mathbf{j}(\mathbf{r}') \left[\nabla \cdot \frac{\hat{\mathbf{e}}_R}{R^2}\right]\right) d^3r' \\ &= -\frac{\mu_0}{4\pi}\int [\mathbf{j}(\mathbf{r}') \cdot \nabla'] \frac{\hat{\mathbf{e}}_R}{R^2} d^3r' + \frac{\mu_0}{4\pi}\int \mathbf{j}(\mathbf{r}') 4\pi\delta^3(\mathbf{r}) d^3r' \ ,\end{aligned}$$

[6] We note that in quantum mechanics, we also calculate the Zeeman effect assuming in first order, that the electronic orbitals $|n\rangle$ remain unchanged, $E^{(1)} = \langle n|\hat{H}^{(1)}|n\rangle$.

where in the second line we replaced ∇ with ∇'. Now, we consider the coordinate x,

$$\begin{aligned}\left[\nabla\times\vec{\mathcal{B}}(\mathbf{r})\right]_x &= -\frac{\mu_0}{4\pi}\int\left[\mathbf{j}(\mathbf{r}')\cdot\nabla'\right]\frac{x-x'}{R^3}d^3r' + \mu_0 j_x(\mathbf{r}) \\ &= -\frac{\mu_0}{4\pi}\int\left\{\nabla'\cdot\left[\mathbf{j}(\mathbf{r}')\frac{x-x'}{R^3}\right] - \frac{x-x'}{R^3}\nabla'\cdot\mathbf{j}(\mathbf{r}')\right\}d^3r' + \mu_0 j_x(\mathbf{r}) \\ &= -\frac{\mu_0}{4\pi}\oint\mathbf{j}(\mathbf{r}')\frac{x-x'}{R^3}\cdot d\mathbf{S}' + \frac{\mu_0}{4\pi}\int\frac{x-x'}{R^3}(-\dot{\varrho})d^3r' + \mu_0 j_x(\mathbf{r}) \\ &= -\frac{\mu_0}{4\pi}\frac{d}{dt}\int\frac{x-x'}{R^3}\varrho d^3r' + \mu_0 j_x(\mathbf{r}) = -\frac{\mu_0}{4\pi}\frac{d}{dt}4\pi\varepsilon_0\mathcal{E}_x + \mu_0 j_x(\mathbf{r})\ ,\end{aligned}$$

neglecting surface terms. Hence,

$$\begin{aligned}\nabla\times\vec{\mathcal{B}} &= \nabla\times\frac{\mu_0}{4\pi}\int\frac{\mathbf{j}(\mathbf{r}')\times\hat{\mathbf{e}}_R}{R^2}d^3r' \\ &= \mu_0\varepsilon_0\frac{d}{dt}\frac{1}{4\pi\varepsilon_0}\int\frac{\varrho(\mathbf{r}',t)\hat{\mathbf{e}}_R}{R^2}d^3r' + \mu_0\mathbf{j}(\mathbf{r}) = \mu_0\varepsilon_0\frac{d\vec{\mathcal{E}}}{dt} + \mu_0\mathbf{j}(\mathbf{r})\ .\end{aligned}$$

17.1.5.6 Ex: Force on magnetic monopoles

In free space Maxwell's equations are perfectly symmetric under the operation $\vec{\mathcal{E}}\to\vec{\mathcal{B}}\to-\varepsilon_0\mu_0\vec{\mathcal{E}}$. But the existence of charges and electric currents breaks this symmetry. The introduction of 'magnetic charges' and 'magnetic currents' would restore the symmetry, but they were never observed [7]. In this exercise we assume the existence of a 'Coulomb law' for 'magnetic charges' q_m,

$$\mathbf{F} = \frac{\mu_0}{4\pi}\frac{q_{m_1}q_{m_2}}{|\mathbf{r}-\mathbf{r}'|^3}(\mathbf{r}-\mathbf{r}')\ .$$

a. Find the force law for a magnetic charge moving with velocity $\mathbf{v}$ through electric and magnetic fields $\vec{\mathcal{E}}$ and $\vec{\mathcal{B}}$ [1097].
b. One of the methods used to search for magnetic monopoles in laboratory [227] consists of passing them through a wire loop with the self-inductance L. What current would be induced in the circuit by the passage of a magnetic monopole?

Solution: *a. It is sufficient to look at the symmetry of Maxwell's equations to find,*

$$\mathbf{F} = q_m\vec{\mathcal{B}} - \frac{q_m}{c^2}\mathbf{v}\times\vec{\mathcal{E}}\ .$$

b. One of the experiments trying to discover magnetic monopoles [227] consisted of a superconducting ring (i.e. without resistance) with a magnet aligned to attract the monopoles (if they exist) through the ring. Assuming that a single 'magnetic charge' q_m produces a Coulomb magnetic field,

$$\vec{\mathcal{B}} = \frac{\mu_0}{4\pi}\frac{q_m}{r^2}\hat{\mathbf{e}}_r\ ,$$

[7] Dirac showed that the existence of magnetic charges would explain the quantization of charge.

we can estimate the flux through the ring (radius b) upon passage of the monopole along the symmetry axis. Let v be the velocity of the monopole. We place the origin in the center of the ring and choose z as the axis of symmetry. We must integrate the magnetic field over the disk-shaped area enclosed by the ring to obtain the flux,

$$\Phi_m = \int_{disco} \vec{\mathcal{B}} \cdot d\mathbf{a} \ .$$

When the monopole is at position $d\hat{\mathbf{e}}_z$, the magnetic field observed at a point on the disk with distance ρ from the z-axis is,

$$\vec{\mathcal{B}} = \frac{\mu_0}{4\pi} \frac{q_m}{|\rho\hat{\mathbf{e}}_\rho - d\hat{\mathbf{e}}_z|^2} (\rho\hat{\mathbf{e}}_\rho - d\hat{\mathbf{e}}_z) \ .$$

The surface element is,

$$d\mathbf{a} = \hat{\mathbf{e}}_z \rho d\rho d\phi \ ,$$

such that the flux is,

$$\begin{aligned} \Phi_m &= \frac{\mu_0 q_m}{4\pi} \int_0^{2\pi} \int_0^b \frac{\rho\hat{\mathbf{e}}_\rho - d\hat{\mathbf{e}}_z}{d^2+\rho^2} \cdot \hat{\mathbf{e}}_z \rho d\rho d\phi \\ &= \frac{\mu_0 q_m d}{2} \int_0^b \frac{\rho d\rho}{\sqrt{d^2+\rho^2}^3} = \frac{\mu_0 q_m}{2} \left(1 - \frac{d}{\sqrt{d^2+b^2}}\right) \ . \end{aligned}$$

We take $t = 0$ as the time when the monopole crosses the plane of the ring, so that $d = -vt$ and $\vec{\mathcal{B}} \cdot d\mathbf{a} > 0$ for $t < 0$ and $d = +vt$ and $\vec{\mathcal{B}} \cdot d\mathbf{a} < 0$ for $t > 0$. Hence,

$$\Phi_m = \frac{\mu_0 q_m}{2} \left(1 - 2\Theta(t) + \frac{vt}{\sqrt{(vt)^2+b^2}}\right) \ .$$

Now, we consider the generalized Maxwell equation for magnetic monopoles,

$$\nabla \times \vec{\mathcal{E}} = -\frac{\partial \vec{\mathcal{B}}}{\partial t} - \mu_0 \mathbf{j}_m \ ,$$

where $\mathbf{j}_m$ is the density of 'magnetic current'. Applying Stokes' theorem, we integrate the electric field along the ring and the terms on the right-hand side over the area enclosed by the ring,

$$U \equiv \oint_{anel} \vec{\mathcal{E}} \cdot d\mathbf{l} = -\frac{\partial \Phi_m}{\partial t} - \mu_0 \int_{disco} \mathbf{j}_m \cdot d\mathbf{a} \equiv -\frac{\partial \Phi_m}{\partial t} - \mu_0 I_{m,enc} \ ,$$

where U is the retro-induced electromotive force, which can be written in terms of the self-inductance L of the ring:

$$U = -L\frac{dI(t)}{dt} \ ,$$

and $I_{m,enc}$ is the magnetic current flowing through the ring. Considering that we have only a single monopole to make the 'magnetic current', we write it as a δ-function:

$$I_{m,enc} = q_m \delta(t) \ .$$

That is, there is a current consisting of a single 'magnetic charge' passing through the area enclosed by the ring only at time $t = 0$. Since the δ-function is the derivative of the Heaviside Θ-function, we can integrate Faraday's law to obtain,

$$LI(t) = \int_{-\infty}^{t} \mu_0 I_{m,enc} dt' + \Phi_m(t) = \mu_0 q_m \Theta(t) + \Phi_m(t) \ .$$

With this,

$$I(t) = \frac{\mu_0 q_m}{L}\Theta(t) + \frac{\mu_0 q_m}{2L}\left(1 - 2\Theta(t) + \frac{vt}{\sqrt{(vt)^2 + b^2}}\right) = \frac{\mu_0 q_m}{2L}\left(1 + \frac{vt}{\sqrt{(vt)^2 + b^2}}\right) \ .$$

For $t \to -\infty$ we have $I \to 0$, while for $t \to \infty$ we have $I \to \mu_0 q_m / L$. This means, that when monopole is approaching but still distant, there is no induced current. The current increases, when the monopole is closer, but since the superconducting ring has no resistance, the generated current never dissipates and tends to a finite value when the monopole moves away on the other side of the ring.

17.1.5.7 Ex: Duality transform

a. In the case of existing magnetic charges and currents, Maxwell's equations would take the form,

$$\begin{aligned}
&\text{(i)} && \nabla \times \vec{\mathcal{B}} - \varepsilon_0 \mu_0 \partial_t \vec{\mathcal{E}} = \mu_0 \mathbf{j}_e \\
&\text{(ii)} && \nabla \times \vec{\mathcal{E}} + \partial_t \vec{\mathcal{B}} = -\mu_0 \mathbf{j}_m \\
&\text{(iii)} && \nabla \cdot \vec{\mathcal{E}} = \varepsilon_0^{-1} \varrho_e \\
&\text{(iv)} && \nabla \cdot \vec{\mathcal{B}} = \mu_0 \varrho_m \ .
\end{aligned}$$

Show that these equations are invariant under the *duality transform* given by,

$$\begin{pmatrix} \vec{\mathcal{E}}' \\ c\vec{\mathcal{B}}' \end{pmatrix} = \begin{pmatrix} \cos\alpha & \sin\alpha \\ -\sin\alpha & \cos\alpha \end{pmatrix} \begin{pmatrix} \vec{\mathcal{E}} \\ c\vec{\mathcal{B}} \end{pmatrix} \quad , \quad \begin{pmatrix} cq_e' \\ q_m' \end{pmatrix} = \begin{pmatrix} \cos\alpha & \sin\alpha \\ -\sin\alpha & \cos\alpha \end{pmatrix} \begin{pmatrix} cq_e \\ q_m \end{pmatrix} \ ,$$

where α is an arbitrary rotation angle in the $\mathcal{E}$-$\mathcal{B}$ space. Densities of charges and currents transform in the same way as q_e and q_m. This means, in particular, that if you would know the fields produced by an electric charge configuration, you could immediately (using $\alpha = 90°$) deduce the fields produced by a corresponding arrangement of the magnetic charge.

b. Show that the force law derived in Exc. 17.1.5.6,

$$\mathbf{F} = q_e(\vec{\mathcal{E}} + \mathbf{v} \times \vec{\mathcal{B}}) + q_m(\vec{\mathcal{B}} - \tfrac{1}{c^2}\mathbf{v} \times \vec{\mathcal{E}})$$

is also invariant under duality transformation.

Solution: *a. Inserting the transformation into the given extended Maxwell equations,*

$$\begin{aligned}
\nabla \times \left(\vec{\mathcal{B}}\cos\alpha - \tfrac{1}{c}\vec{\mathcal{E}}\sin\alpha\right) - \varepsilon_0\mu_0\frac{\partial\left(\vec{\mathcal{E}}\cos\alpha + c\vec{\mathcal{B}}\sin\alpha\right)}{\partial t} &= \mu_0\left(\mathbf{j}_e\cos\alpha + \tfrac{1}{c}\mathbf{j}_m\sin\alpha\right)\\
\nabla \times \left(\vec{\mathcal{E}}\cos\alpha + c\vec{\mathcal{B}}\sin\alpha\right) - \frac{\partial\left(\vec{\mathcal{B}}\cos\alpha - \frac{1}{c}\vec{\mathcal{E}}\sin\alpha\right)}{\partial t} &= -\mu_0\left(\mathbf{j}_m\cos\alpha - c\mathbf{j}_e\sin\alpha\right)\\
\nabla\cdot\left(\vec{\mathcal{E}}\cos\alpha + c\vec{\mathcal{B}}\sin\alpha\right) &= \frac{\varrho_e\cos\alpha + \frac{1}{c}\varrho_m\sin\alpha}{\varepsilon_0}\\
\nabla\cdot\left(\vec{\mathcal{B}}\cos\alpha - \tfrac{1}{c}\vec{\mathcal{E}}\sin\alpha\right) &= \mu_0\left(\varrho_m\cos\alpha - c\varrho_e\sin\alpha\right)\ .
\end{aligned}$$

Obviously, the terms in cos *and* sin *satisfy the Maxwell equations separately.*
b. Inserting the transformation into given expression for the Lorentz force,

$$\begin{aligned}
\mathbf{F} &= \left(q_e\cos\alpha + \tfrac{q_m}{c}\sin\alpha\right)\left[\vec{\mathcal{E}}\cos\alpha + c\vec{\mathcal{B}}\sin\alpha + \mathbf{v}\times\left(\vec{\mathcal{B}}\cos\alpha - \tfrac{1}{c}\vec{\mathcal{E}}\sin\alpha\right)\right]\\
&\quad + \left(q_m\cos\alpha - cq_e\sin\alpha\right)\left[\vec{\mathcal{B}}\cos\alpha - \tfrac{1}{c}\vec{\mathcal{E}}\sin\alpha - \tfrac{1}{c^2}\mathbf{v}\times\left(\vec{\mathcal{E}}\cos\alpha + c\vec{\mathcal{B}}\sin\alpha\right)\right]\\
&= q_e(\vec{\mathcal{E}} + \mathbf{v}\times\vec{\mathcal{B}})\cos^2\alpha + \left[q_e\left(c\vec{\mathcal{B}} - \tfrac{1}{c}\mathbf{v}\times\vec{\mathcal{E}}\right) + \tfrac{q_m}{c}\left(\vec{\mathcal{E}} + \mathbf{v}\times\vec{\mathcal{B}}\right)\right]\cos\alpha\sin\alpha\\
&\quad + q_m\left(\vec{\mathcal{B}} - \tfrac{1}{c^2}\mathbf{v}\times\vec{\mathcal{E}}\right)\sin^2\alpha + q_m\left(\vec{\mathcal{B}} - \tfrac{1}{c^2}\mathbf{v}\times\vec{\mathcal{E}}\right)\cos^2\alpha\\
&\quad + \left[-q_e\left(c\vec{\mathcal{B}} - \tfrac{1}{c}\mathbf{v}\times\vec{\mathcal{E}}\right) - \tfrac{q_m}{c}(\vec{\mathcal{E}} + \mathbf{v}\times\vec{\mathcal{B}})\right]\cos\alpha\sin\alpha\\
&\quad + q_e(\vec{\mathcal{E}} + \mathbf{v}\times\vec{\mathcal{B}})\sin^2\alpha\\
&= q_e(\vec{\mathcal{E}} + \mathbf{v}\times\vec{\mathcal{B}}) + q_m\left(\vec{\mathcal{B}} - \tfrac{1}{c^2}\mathbf{v}\times\vec{\mathcal{E}}\right)\ .
\end{aligned}$$

17.1.5.8 Ex: Quantization of magnetic monopoles

a. Show that the vector potential,

$$\mathbf{A} = \frac{g(1-\cos\theta)}{r\sin\theta}\hat{\mathbf{e}}_\phi$$

produces a Coulomb-type magnetic field [1053].
b. Calculate the magnetic flux across the solid angle delimited by the polar angle θ.
c. Calculate the vector potential $\mathbf{A}'$ obtained by a gauge transformation with the gauge field $\chi = 2g\phi$.
d. Now consider the vector potential defined by $\mathbf{A}'' \equiv \mathbf{A}$ for $\theta \leq \frac{\pi}{2}$ and $\mathbf{A}'' \equiv \mathbf{A}'$ for $\theta \geq \frac{\pi}{2}$. This potential has no more singularity. Derive, from the condition that the transformation $U_{cl} = e^{-\imath e\chi/\hbar}$ be unique, the value of the magnetic charge.

Solution: *a. With the rotation operator expressed in spherical coordinates we easily*

calculate,

$$\begin{aligned}\vec{\mathcal{B}}_{mon} &= \nabla\times\mathbf{A}\\ &= \frac{\hat{\mathbf{e}}_r}{r\sin\theta}\left[\frac{\partial}{\partial\theta}(\sin\theta a_\phi)-\frac{\partial}{\partial\phi}(a_\theta)\right]+\frac{\hat{\mathbf{e}}_\theta}{r\sin\theta}\left[\frac{\partial}{\partial\phi}(a_r)-\sin\theta\frac{\partial}{\partial r}(ra_\phi)\right]\\ &\quad+\frac{\hat{\mathbf{e}}_\phi}{r}\left[\frac{\partial}{\partial r}(ra_\theta)-\frac{\partial}{\partial\theta}(a_r)\right]=\frac{g}{r^2}\hat{\mathbf{e}}_r\ .\end{aligned}$$

b. The flux is,

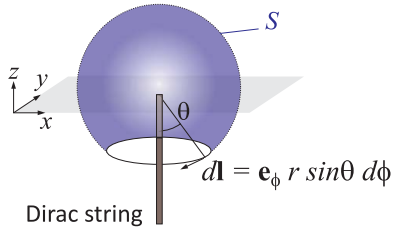

Figure 17.5: Magnetic monopole.

$$\begin{aligned}\Phi_m &= \int_0^{2\pi}\int_0^{\theta}\vec{\mathcal{B}}_{mon}\cdot d\mathbf{S}=\oint\mathbf{A}\cdot d\mathbf{l}=\oint\frac{g(1-\cos\theta)}{r\sin\theta}\hat{\mathbf{e}}_\phi\cdot d\mathbf{l}\\ &=\oint\frac{g(1-\cos\theta)}{r\sin\theta}r\sin\theta d\phi=2\pi g(1-\cos\theta)\ .\end{aligned}$$

However, we must look more carefully at this result, because for $\theta\to\pi$ we obtain $\Phi_m=4\pi g$. But that can not be right, since the integration path converges to 0. The singular line $4\pi g\Theta(-z)\delta(x)\delta(y)\hat{\mathbf{e}}_z$ is called the Dirac string. We can correct by subtracting the singularity,

$$\nabla\times\mathbf{A}_{Dir}=\nabla\times\mathbf{A}-4\pi g\Theta(-z)\delta(x)\delta(y)\hat{\mathbf{e}}_z=\frac{g}{r^2}\hat{\mathbf{e}}_r-4\pi g\Theta(-z)\delta(x)\delta(y)\hat{\mathbf{e}}_z\ ,$$

such that,

$$\Phi_m=\int\nabla\times\mathbf{A}_{Dir}\cdot d\mathbf{S}=\begin{cases}2\pi g(1-\cos\theta) & for\ \theta<\pi\\ 0 & for\ \theta=\pi\end{cases}\ .$$

c. The gradient in spherical coordinates is,

$$\nabla\chi=\hat{\mathbf{e}}_r\frac{\partial\chi}{\partial r}+\hat{\mathbf{e}}_\theta\frac{1}{r}\frac{\partial\chi}{\partial\theta}+\hat{\mathbf{e}}_\phi\frac{1}{r\sin\theta}\frac{\partial\chi}{\partial\phi}=\frac{2g}{r\sin\theta}\hat{\mathbf{e}}_\phi\ ,$$

such that the new vector potential is,

$$\mathbf{A}'=\mathbf{A}-\nabla\chi=-\frac{g(1+\cos\theta)}{r\sin\theta}\hat{\mathbf{e}}_\phi\ .$$

d. For the transformation to be unequivocal, we need,

$$e^{-\imath e\chi(\phi=0)/\hbar}=e^0=e^{-\imath e2g2\pi/\hbar}=e^{-\imath e\chi(\phi=2\pi)/\hbar}\ .$$

That is,

$$n = \frac{2eg}{\hbar} = 0, \pm 1, \pm 2, \ldots \ .$$

17.1.5.9 Ex: Green's identities

Be ϕ and ψ two continuously differentiable functions and V a volume with the border ∂V. Show with the help of Gauß' theorem,

a.

$$\int\limits_{\mathcal{V}} \left[\phi \nabla^2 \psi + (\nabla\phi)\cdot(\nabla\psi)\right] \ dV = \int\limits_{\partial\mathcal{V}} \phi(\nabla\psi) \ d\mathbf{S} \ ,$$

b.

$$\int\limits_{\mathcal{V}} \left[\phi \nabla^2 \psi - \psi \nabla^2 \phi\right] \ dV = \int\limits_{\partial\mathcal{V}} \left[\phi \nabla\psi - \psi\nabla\phi\right] \ d\mathbf{S} \ .$$

Solution: *a. Green's first identity is solved by Gauß' theorem and the chain rule:*

$$\int\limits_{\partial\mathcal{V}} \phi(\nabla\psi) \ d\mathbf{S} = \int\limits_{\mathcal{V}} \nabla\cdot\left[\phi(\nabla\psi)\right] \ dV = \int\limits_{\mathcal{V}} \left[\phi\nabla^2\psi + (\nabla\phi)\cdot(\nabla\psi)\right] \ dV \ .$$

b. Green's second identity follows from the first:

$$\int\limits_{\mathcal{V}} \left[\phi \nabla^2 \psi + (\nabla\phi)\cdot(\nabla\psi)\right] \ dV = \int\limits_{\partial\mathcal{V}} \phi(\nabla\psi) \ d\mathbf{S}$$

$$\int\limits_{\mathcal{V}} \left[\psi \nabla^2 \phi + (\nabla\psi)\cdot(\nabla\phi)\right] \ dV = \int\limits_{\partial\mathcal{V}} \psi(\nabla\phi) \ d\mathbf{S} \ .$$

Subtracting the second equation from the first, we obtain the second Green identity.

17.1.5.10 Ex: Decomposition of vector fields

Be $\mathbf{F}(\mathbf{r},t)$ an arbitrary vector field defined on $\mathbb{R}$, which tends (along with its derivatives) to zero in sufficiently high order, when $|\mathbf{r}| \to \infty$. This field can be decomposed into a sum of a longitudinal and a transverse component, $\mathbf{F} = \mathbf{F}_l + \mathbf{F}_t$ with $\nabla\times\mathbf{F}_l = 0$ and $\nabla\cdot\mathbf{F}_t = 0$.

a. Prove,

$$\mathbf{F}_l(\mathbf{r},t) = -\frac{1}{4\pi}\nabla\int\frac{\nabla'\cdot\mathbf{F}(\mathbf{r}',t)}{|\mathbf{r}-\mathbf{r}'|}d^3r' \quad \text{and} \quad \mathbf{F}_t(\mathbf{r},t) = +\frac{1}{4\pi}\nabla\times\nabla\times\int\frac{\mathbf{F}(\mathbf{r}',t)}{|\mathbf{r}-\mathbf{r}'|}d^3r' \ .$$

Help: Begin showing that,

$$\mathbf{F}(\mathbf{r},t) = -\frac{1}{4\pi}\triangle\int\frac{\mathbf{F}(\mathbf{r}',t)}{|\mathbf{r}-\mathbf{r}'|}d^3r'$$

and use the vector identity,

$$\nabla \times \nabla \times \mathbf{A} = \nabla(\nabla \cdot \mathbf{A}) - \triangle \mathbf{A} \ .$$

b. Show that the vector field $\mathbf{F}(\mathbf{r})$ is unequivocally given by its sources, $\nabla \cdot \mathbf{F}(\mathbf{r})$, and vertices, $\nabla \times \mathbf{F}(\mathbf{r})$.

Solution: *We have,*

$$\begin{aligned} \triangle_{\mathbf{r}} \int d^3\mathbf{r}' \frac{\mathbf{F}(\mathbf{r}',t)}{|\mathbf{r}-\mathbf{r}'|} &= \int d^3r' \mathbf{F}(\mathbf{r}',t) \triangle_{\mathbf{r}} \frac{1}{|\mathbf{r}-\mathbf{r}'|} \\ &= \int d^3r' \mathbf{F}(\mathbf{r}',t)[-4\pi\delta(\mathbf{r}-\mathbf{r}')] = -4\pi\mathbf{F}(\mathbf{r},t) \ , \end{aligned}$$

and hence,

$$\mathbf{F}(\mathbf{r},t) = -\frac{1}{4\pi} \triangle \int d^3r' \frac{\mathbf{F}(\mathbf{r}',t)}{|\mathbf{r}-\mathbf{r}'|} \qquad (*) \ .$$

Now, $\triangle \mathbf{A} = \nabla(\nabla \cdot \mathbf{A}) - \nabla \times \nabla \times \mathbf{A}$ *and hence,*

$$\triangle \int d^3\mathbf{r}' \frac{\mathbf{F}(\mathbf{r}',t)}{|\mathbf{r}-\mathbf{r}'|} = \nabla \left(\nabla \cdot \int d^3r' \frac{\mathbf{F}(\mathbf{r}',t)}{|\mathbf{r}-\mathbf{r}'|} \right) - \nabla \times \left(\nabla \times \int d^3r' \frac{\mathbf{F}(\mathbf{r}',t)}{|\mathbf{r}-\mathbf{r}'|} \right) \ .$$

For the first term we obtain by partial integration,

$$\begin{aligned} \nabla \cdot \int d^3r' \frac{\mathbf{F}(\mathbf{r}',t)}{|\mathbf{r}-\mathbf{r}'|} &= + \int d^3r' \mathbf{F}(\mathbf{r}',t) \cdot \nabla_{\mathbf{r}'} \frac{1}{|\mathbf{r}-\mathbf{r}'|} \\ &= - \int d^3r' \mathbf{F}(\mathbf{r}',t) \cdot \nabla_{\mathbf{r}'} \frac{1}{|\mathbf{r}-\mathbf{r}'|} \\ &= + \int d^3r' \frac{1}{|\mathbf{r}-\mathbf{r}'|} \nabla_{\mathbf{r}'} \cdot \mathbf{F}(\mathbf{r}',t) \ . \end{aligned}$$

With $(*)$ *follows,*

$$\mathbf{F}(\mathbf{r},t) = -\frac{1}{4\pi} \nabla_{\mathbf{r}} \left(\int d^3r' \frac{\nabla_{\mathbf{r}'} \cdot \mathbf{F}(\mathbf{r}',t)}{|\mathbf{r}-\mathbf{r}'|} \right) = +\frac{1}{4\pi} \nabla_{\mathbf{r}} \times \left(\nabla_{\mathbf{r}} \int d^3r' \frac{\mathbf{F}(\mathbf{r}',t)}{|\mathbf{r}-\mathbf{r}'|} \right) \ .$$

The rotation of a gradient disappears, as well as the divergent of a rotation. Therefore,

$$\begin{aligned} \mathbf{F}_l(\mathbf{r},t) &= -\frac{1}{4\pi} \nabla \int d^3r' \frac{\nabla' \cdot \mathbf{F}(\mathbf{r}',t)}{|\mathbf{r}-\mathbf{r}'|} \qquad \textit{with} \qquad \nabla \times \mathbf{F}_l = 0 \\ \mathbf{F}_t(\mathbf{r},t) &= +\frac{1}{4\pi} \nabla \times \nabla \int d^3r' \frac{\mathbf{F}(\mathbf{r}',t)}{|\mathbf{r}-\mathbf{r}'|} \qquad \textit{with} \qquad \nabla \cdot \mathbf{F}_t = 0 \ , \end{aligned}$$

and obviously holds,

$$\mathbf{F} = \mathbf{F}_l + \mathbf{F}_t \ .$$

17.1.5.11 Ex: Conductivity of seawater

Sea water has at the frequency $v = 4 \cdot 10^8\,\mathrm{Hz}$ the permittivity $\varepsilon = 81\varepsilon_0$, the permeability $\mu = \mu_0$, and the resistivity $\rho = 0.23\,\Omega\mathrm{m}$. What is the ratio between the conduction current and the displacement current? **Help:** Consider a parallel-plate capacitor immersed in seawater and driven by a voltage $V_0\cos(2\pi\nu t)$.

Solution: *The conduction current density is,*

$$j_{cond} = \frac{\mathcal{E}}{\rho} = \frac{dV_0\cos(2\pi\nu t)}{\rho}\ .$$

The displacement current density is,

$$j_{disp} = \frac{\partial D}{\partial t} = \frac{\partial \varepsilon d V_0\cos(2\pi\nu t)}{\partial t} = -2\pi\nu\varepsilon d V_0\sin(2\pi\nu t)\ .$$

The ratio of their amplitudes is,

$$\frac{j_{cond}}{j_{disp}} = -\frac{dV_0}{2\pi\nu\varepsilon d V_0\rho} = \frac{1}{2\pi\nu\varepsilon\rho} \approx 2.4\ .$$

17.2 Conservation laws in electromagnetism

The importance of *conservation laws* and *symmetries* lies in their universal validity and their independence of a particular theory (mechanics, electrodynamics, ..). They often allow the derivation of laws, which are specific for a theory and of equations of motion for particular systems. For example, in classical mechanics, we can derive Newtonian axioms from the conservation of linear momentum, and in electrodynamics, as we shall see later, we can derive Maxwell's equations from the principles of Lorentz invariance, gauge invariance, and electric charge conservation, as expressed by the continuity equation. The question which we will elucidate in the following sections will be that of the validity of other mechanical conservation laws in electrodynamics, that is, the laws of energy, linear momentum, and angular momentum conservation.

In the context of preparing the deductions, let us defined some important quanti-

ties [8],

$$\begin{array}{lll} \text{(i)} & u = \frac{1}{2}(\vec{\mathcal{E}}\cdot\vec{\mathcal{D}} + \vec{\mathcal{B}}\cdot\vec{\mathcal{H}}) & \textit{energy density} \\ \text{(ii)} & \vec{\mathcal{S}} = \vec{\mathcal{E}}\times\vec{\mathcal{H}} & \textit{energy flux} \text{ or } \textit{Poynting vector} \\ \text{(iii)} & \mathbf{f} = \varrho\vec{\mathcal{E}} + \mathbf{j}\times\vec{\mathcal{B}} & \textit{Lorentz force density} \\ \text{(iv)} & \vec{\wp}^A = \varepsilon_0\mu_0\vec{\mathcal{S}} = \frac{1}{c^2}\vec{\mathcal{E}}\times\vec{\mathcal{H}} & \textit{Abraham momentum density} \\ \text{(iv)} & \vec{\wp}^M = \vec{\mathcal{D}}\times\vec{\mathcal{B}} & \textit{Minkowski momentum density} \\ \text{(v)} & \vec{\ell} = \mathbf{r}\times\vec{\wp} & \textit{angular momentum density} \\ \text{(vi)} & \overleftrightarrow{\mathbf{T}} = \vec{\mathcal{D}}\otimes\vec{\mathcal{E}} + \vec{\mathcal{H}}\otimes\vec{\mathcal{B}} - \frac{1}{2}u\mathbb{I} & \textit{Maxwell stress tensor}\,. \end{array} \tag{17.58}$$

All fields are time-dependent. From Maxwell's equations we derive the *electrodynamical continuity equation*, the *Poynting theorem*, and the conservation of linear and angular momentum. Resolve the Exc. 17.2.5.1.

17.2.1 Charge conservation and continuity equation

Calculating the divergence of Maxwell's first equation and using the third,

$$\nabla\cdot(\nabla\times\vec{\mathcal{H}}) = \partial_t\nabla\cdot\vec{\mathcal{D}} + \nabla\cdot\mathbf{j} = \boxed{\partial_t\varrho + \nabla\cdot\mathbf{j} = 0}\,. \tag{17.59}$$

This law describes *charge conservation* in electrodynamics.

17.2.2 Energy conservation and Poynting's theorem

The time derivative of the energy density (17.58)(i) is,

$$\partial_t u = \tfrac{1}{2}(\vec{\mathcal{E}}\cdot\partial_t\vec{\mathcal{D}} + \vec{\mathcal{D}}\cdot\partial_t\vec{\mathcal{E}} + \vec{\mathcal{B}}\cdot\partial_t\vec{\mathcal{H}} + \vec{\mathcal{H}}\cdot\partial_t\vec{\mathcal{B}}) = \vec{\mathcal{E}}\cdot\partial_t\vec{\mathcal{D}} + \vec{\mathcal{H}}\cdot\partial_t\vec{\mathcal{B}}\,, \tag{17.60}$$

supposing $\vec{\mathcal{D}} = \varepsilon\vec{\mathcal{E}}$ and $\vec{\mathcal{H}} = \vec{\mathcal{B}}/\mu$ with time- and space-independent $\varepsilon, \mu = const.$ The divergence of the Poynting vector is,

$$\nabla\cdot\vec{\mathcal{S}} = \nabla\cdot(\vec{\mathcal{E}}\times\vec{\mathcal{H}}) = \vec{\mathcal{H}}\cdot(\nabla\times\vec{\mathcal{E}}) - \vec{\mathcal{E}}\cdot(\nabla\times\vec{\mathcal{H}}) = -\vec{\mathcal{H}}\cdot\partial_t\vec{\mathcal{B}} - \vec{\mathcal{E}}\cdot(\partial_t\vec{\mathcal{D}} + \mathbf{j})\,. \tag{17.61}$$

With this we immediately see,

$$\boxed{\partial_t u + \nabla\cdot\vec{\mathcal{S}} = -\mathbf{j}\cdot\vec{\mathcal{E}}}\,. \tag{17.62}$$

To better understand this theorem, we calculate the work exerted by the Coulomb-Lorentz force per unit time on a test charge q,

$$\frac{dW}{dt} = \frac{d}{dt}\int_{\mathcal{C}}\mathbf{F}\cdot d\mathbf{l} = \frac{d}{dt}\int q(\vec{\mathcal{E}} + \cancelto{0}{\mathbf{v}\times\vec{\mathcal{B}}})\cdot\mathbf{v}dt = q\mathbf{v}\cdot\vec{\mathcal{E}}\,. \tag{17.63}$$

[8] The question of the correct expression for the momentum density is difficult and will be dealt with later.

The current generated by the charge can be derived from the parametrization $\mathbf{j}(\mathbf{r}) = q\mathbf{v}\delta^3(\mathbf{r}-\mathbf{r}')$. Thus, we derive the *Poynting theorem*,

$$\frac{dW}{dt} = \int_{\mathcal{V}} \vec{\mathcal{E}}\cdot\mathbf{j}dV = -\frac{d}{dt}\int_{\mathcal{V}} udV - \int_{\mathcal{V}} \nabla\cdot\vec{\mathcal{S}}dV = -\frac{dU_{erg}}{dt} - \oint_{\partial\mathcal{V}} \vec{\mathcal{S}}\cdot d\mathbf{S}\ . \quad (17.64)$$

This theorem postulates *energy conservation*. That is, the electromagnetic energy U_{erg} within a volume $\mathcal{V}$ can only change 1. by diffusion out of the volume via a flux $\int \vec{\mathcal{S}}\cdot d\mathbf{S}$ of the Poynting vector, or 2. when mechanical work W is done on the volume or when the electromagnetic energy in the volume is dissipated into other forms of energy, for example heat. We apply the Poynting theorem to a current-carrying wire in Exc. 17.2.5.2.

Example 85 (*Derivation of Ohm's law by the Poynting vector*): The current flux through a wire exerts *work*, because the wire heats up. We calculate the energy transferred to the wire per unit time via the Poynting vector. The electric field (assumed to be uniform) along the wire (length L and radius a) is,

$$\mathcal{E} = \frac{U}{L}\ ,$$

where U is the voltage between the ends of the wire. The magnetic field at the surface of the wire is,

$$\mathcal{B} = \frac{\mu_0 I}{2\pi a}\ .$$

Therefore, the absolute value of the Poynting vector is,

$$s = \frac{1}{\mu_0}\mathcal{E}\mathcal{B} = \frac{UI}{2\pi aL}\ .$$

pointing into the wire, $\vec{\mathcal{S}} \propto -\hat{\mathbf{e}}_r$. The energy per unit of time passing through the surface of the wire is therefore,

$$\int \vec{\mathcal{S}}\cdot d\mathbf{S} = s(2\pi aL) = UI\ ,$$

confirming previously obtained results. As the fields are stationary, the electromagnetic energy does not vary with time, neither, $\partial_t U_{erg} = 0$.

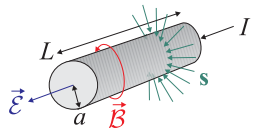

Figure 17.6: Energy flux into the wire causes heating.

17.2.3 Conservation of linear momentum and Maxwell's stress tensor

The interaction between two charges is described by the Coulomb-Lorentz force. However, when these charges accelerate each other mutually, they generate non-stationary

fields, so that the force laws of Coulomb and Biot-Savart do not apply. We will see later, how to generalize these laws.

Nevertheless, at first glance, the Coulomb force seems compatible with the third Newton law: *actio = reactio*, but not with the Lorentz force.

Example 86 (*Linear momentum of the electromagnetic field*): To see this, we consider two charged particles with trajectories,

$$\mathbf{l}_1(t) = vt\hat{\mathbf{e}}_y \quad , \quad \mathbf{l}_2(t) = vt\hat{\mathbf{e}}_x \ .$$

Charge 1 produces a field $\vec{\mathcal{B}}_1$ at the position of charge 2 and vice versa. At time $t = 0$, when they collide, the forces become orthogonal:

$$\mathbf{F}_{12} = q\mathbf{v}_2 \times \vec{\mathcal{B}}_1 \perp q\mathbf{v}_1 \times \vec{\mathcal{B}}_2 = \mathbf{F}_{21} \ .$$

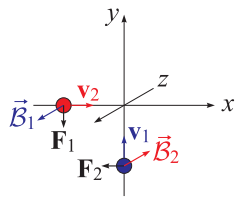

Figure 17.7: The Lorentz forces exerted by approaching charges are mutually orthogonal.

Obviously, in electrodynamics, the Lorentz force flagrantly violates Newton's third law in way to raise questions about the validity of momentum conservation. The solution is that in electrodynamics, *the electromagnetic field itself may lose or gain momentum* and should be included in the formulation of a law of momentum conservation. Moreover, the field does not move instantaneously, but propagates at the speed of light and is subject to retardation effects. The law *actio = reactio* postulates the existence of forces acting at a distance that, as we nowadays know, do not exist [9]. We shall return to this problem in the discussion of the relativistic Lorentz transformation.

17.2.3.1 Maxwell's tress tensor

We now consider the Lorentz force density, which we will try to express totally in terms of fields, eliminating the charge and current densities [898],

$$\mathbf{f} = \varrho\vec{\mathcal{E}} + \mathbf{j} \times \vec{\mathcal{B}} = \vec{\mathcal{E}}(\nabla \cdot \vec{\mathcal{D}}) + \left(\nabla \times \vec{\mathcal{H}} - \frac{\partial \vec{\mathcal{D}}}{\partial t}\right) \times \vec{\mathcal{B}} \ . \tag{17.65}$$

We reformulate the last term,

$$-\frac{\partial \vec{\mathcal{D}}}{\partial t} \times \vec{\mathcal{B}} = \vec{\mathcal{D}} \times \frac{\partial \vec{\mathcal{B}}}{\partial t} - \frac{\partial}{\partial t}(\vec{\mathcal{D}} \times \vec{\mathcal{B}}) = -\vec{\mathcal{D}} \times (\nabla \times \vec{\mathcal{E}}) - \frac{\partial}{\partial t}(\vec{\mathcal{D}} \times \vec{\mathcal{B}}) \ . \tag{17.66}$$

[9] One of the important changes of paradigm in the history of physics is from interaction at a distance to local interaction. Newton was a supporter of non-local interaction for gravity. Ironically he argued against waves in favor of particles for light. Today the opinion thinks the other way round: Particles are mediators of local interactions, while only waves can mediate non-local features.

Knowing $\vec{\mathcal{H}}(\nabla \cdot \vec{\mathcal{B}}) = 0$, we can add this term to the force without cost,

$$\mathbf{f} = \vec{\mathcal{E}}(\nabla \cdot \vec{\mathcal{D}}) - \vec{\mathcal{D}} \times (\nabla \times \vec{\mathcal{E}}) + \vec{\mathcal{H}}(\nabla \cdot \vec{\mathcal{B}}) - \vec{\mathcal{B}} \times (\nabla \times \vec{\mathcal{H}}) - \frac{\partial}{\partial t}(\vec{\mathcal{D}} \times \vec{\mathcal{B}}) \ . \tag{17.67}$$

We use the rule from vector analysis,

$$\begin{aligned} \nabla(\vec{\mathcal{E}} \cdot \vec{\mathcal{D}}) &= \vec{\mathcal{E}} \times (\nabla \times \vec{\mathcal{D}}) + \vec{\mathcal{D}} \times (\nabla \times \vec{\mathcal{E}}) + (\vec{\mathcal{E}} \cdot \nabla)\vec{\mathcal{D}} + (\vec{\mathcal{D}} \cdot \nabla)\vec{\mathcal{E}} \\ &= 2\vec{\mathcal{D}} \times (\nabla \times \vec{\mathcal{E}}) + 2(\vec{\mathcal{E}} \cdot \nabla)\vec{\mathcal{D}} \ , \end{aligned} \tag{17.68}$$

and analogously for $\vec{\mathcal{B}} \cdot \vec{\mathcal{H}}$. The second equation holds, because for $\vec{\mathcal{D}} = \varepsilon\vec{\mathcal{E}}$ with $\varepsilon = const$, we can arbitrarily exchange the order of products between $\vec{\mathcal{D}}$ and $\vec{\mathcal{E}}$. We also assume $\mu = const$, which allows us to exchange the order of products between $\vec{\mathcal{H}}$ and $\vec{\mathcal{B}}$. We use the rule (17.68) to replace the terms with vector products in equation (17.67),

$$\begin{aligned} \mathbf{f} &= \vec{\mathcal{E}}(\nabla \cdot \vec{\mathcal{D}}) - \tfrac{1}{2}\nabla(\vec{\mathcal{E}} \cdot \vec{\mathcal{D}}) + (\vec{\mathcal{E}} \cdot \nabla)\vec{\mathcal{D}} \\ &+ \vec{\mathcal{H}}(\nabla \cdot \vec{\mathcal{B}}) - \tfrac{1}{2}\nabla(\vec{\mathcal{H}} \cdot \vec{\mathcal{B}}) + (\vec{\mathcal{H}} \cdot \nabla)\vec{\mathcal{B}} - \partial_t \vec{\mathcal{D}} \times \vec{\mathcal{B}} \ . \end{aligned} \tag{17.69}$$

The last term is nothing more than the time derivative of the *Minkowski momentum density* of the electromagnetic field defined in (17.58), $\vec{\wp}^M \equiv \vec{\mathcal{D}} \times \vec{\mathcal{B}}$, which still awaits interpretation.

Now we introduce the *Maxwell stress tensor* (in Minkowski's form) by [10],

$$\boxed{T^M_{ij} \equiv \mathcal{D}_i\mathcal{E}_j + \mathcal{H}_i\mathcal{B}_j - \tfrac{\delta_{ij}}{2}(\vec{\mathcal{E}} \cdot \vec{\mathcal{D}} + \vec{\mathcal{H}} \cdot \vec{\mathcal{B}})} \ . \tag{17.70}$$

Defining the divergent of a matrix, we obtain using Einstein's sum convention,

$$\begin{aligned} (\nabla \cdot \overleftrightarrow{\mathbf{T}})_j \equiv (\partial_i T_{ij})_j &= \Big(\partial_i(\mathcal{D}_i\mathcal{E}_j) + \partial_i(\mathcal{H}_i\mathcal{B}_j) - \partial_i \tfrac{\delta_{ij}}{2}(\vec{\mathcal{E}} \cdot \vec{\mathcal{D}} + \vec{\mathcal{H}} \cdot \vec{\mathcal{B}})\Big)_j \\ &= \Big(\mathcal{E}_j\nabla \cdot \vec{\mathcal{D}} + \vec{\mathcal{D}} \cdot \nabla\mathcal{E}_j + \mathcal{B}_j\nabla \cdot \vec{\mathcal{H}} + \vec{\mathcal{H}} \cdot \nabla\mathcal{B}_j - \tfrac{1}{2}\partial_j(\vec{\mathcal{E}} \cdot \vec{\mathcal{D}} + \vec{\mathcal{H}} \cdot \vec{\mathcal{B}})\Big)_j \ . \end{aligned} \tag{17.71}$$

These terms coincide with those of the equation (17.69) except for the last one. Now, we can reshape the Lorentz force,

$$\boxed{-\partial_t\vec{\wp}^M + \nabla \cdot \overleftrightarrow{\mathbf{T}} = \mathbf{f}} \ . \tag{17.72}$$

The mechanical force acting on a volume $\mathcal{V}$,

$$\mathbf{F} = \oint_{\partial\mathcal{V}} \overleftrightarrow{\mathbf{T}} \cdot d\mathbf{S} - \frac{d}{dt}\int_{\mathcal{V}} \vec{\wp}^M dV \ , \tag{17.73}$$

can be expressed by a momentum flux escaping the volume plus a 'stress' acting on its surface in every direction. The diagonal components T_{ii} represent 'pressures' and the non-diagonal 'shear stresses'. In static situations only the stress results in forces.

[10] In matrix notation,

$$\nabla \cdot \overleftrightarrow{T} = \begin{pmatrix} \frac{d}{dx} & \frac{d}{dy} & \frac{d}{dz} \end{pmatrix} \begin{pmatrix} T_{xx} & T_{xy} & T_{xz} \\ T_{yx} & T_{yy} & T_{xz} \\ T_{zx} & T_{zy} & T_{zz} \end{pmatrix} \ .$$

Example 87 (*Force on a charged body*): As an example of application of the stress tensor we calculate the force exerted by a solid uniformly charged (charge Q) sphere of radius R on its own upper part. The volume of the upper hemisphere is enclosed by two surfaces: one hemispheric surface and a flat one. In Cartesian coordinates,

$$\hat{\mathbf{e}}_r = \hat{\mathbf{e}}_x \sin\theta\cos\phi + \hat{\mathbf{e}}_y \sin\theta\sin\phi + \hat{\mathbf{e}}_z \cos\theta \ ,$$

for the hemispherical surface, we write the electric field and the surface element as,

$$\vec{\mathcal{E}} = \frac{1}{4\pi\varepsilon_0}\frac{Q}{R^2}\hat{\mathbf{e}}_r \qquad \text{and} \qquad d\mathbf{a} = \hat{\mathbf{e}}_r R^2 \sin\theta d\theta d\phi \ .$$

We calculate the stress tensor,

$$\begin{aligned}\overleftrightarrow{\mathbf{T}} &= \varepsilon_0 \begin{pmatrix} \mathcal{E}_x^2 - \frac{1}{2}\mathcal{E}^2 & \mathcal{E}_x\mathcal{E}_y & \mathcal{E}_x\mathcal{E}_z \\ \mathcal{E}_x\mathcal{E}_y & \mathcal{E}_y^2 - \frac{1}{2}\mathcal{E}^2 & \mathcal{E}_y\mathcal{E}_z \\ \mathcal{E}_x\mathcal{E}_z & \mathcal{E}_y\mathcal{E}_z & \mathcal{E}_z^2 - \frac{1}{2}\mathcal{E}^2 \end{pmatrix} \\ &= \varepsilon_0 \left(\frac{1}{4\pi\varepsilon_0}\frac{Q}{R^2}\right)^2 \begin{pmatrix} \sin^2\theta\cos^2\phi - \frac{1}{2} & \sin^2\theta\cos\phi\sin\phi & \cos\theta\sin\theta\cos\phi \\ \sin^2\theta\cos\phi\sin\phi & \sin^2\theta\sin^2\phi - \frac{1}{2} & \cos\theta\sin\theta\sin\phi \\ \cos\theta\sin\theta\cos\phi & \cos\theta\sin\theta\sin\phi & \cos^2\theta - \frac{1}{2} \end{pmatrix} \ .\end{aligned}$$

The integral of the tensor over the surface can be evaluated by Maple,

$$\int \overleftrightarrow{\mathbf{T}} d\mathbf{a} = \int_0^{2\pi}\int_0^{\pi/2} \overleftrightarrow{\mathbf{T}}\hat{\mathbf{e}}_r R^2 \sin\theta d\theta d\phi = \frac{Q^2}{32\pi\varepsilon_0 R^2}\hat{\mathbf{e}}_z \ .$$

For the flat surface we write,

$$\vec{\mathcal{E}} = \frac{1}{4\pi\varepsilon_0}\frac{Q}{R^3} r\hat{\mathbf{e}}_r \qquad \text{and} \qquad d\mathbf{a} = -\hat{\mathbf{e}}_z r dr d\phi \ .$$

Now we calculate with $\theta = \pi/2$,

$$\overleftrightarrow{\mathbf{T}} = \varepsilon_0 \frac{1}{(4\pi\varepsilon_0)^2}\frac{Q^2}{R^6} \begin{pmatrix} r^2\cos^2\phi - \frac{1}{2} & r^2\cos\phi\sin\phi & 0 \\ r^2\cos\phi\sin\phi & r^2\sin^2\phi - \frac{1}{2} & 0 \\ 0 & 0 & -\frac{1}{2}r^2 \end{pmatrix} \ .$$

The integral over the surface gives,

$$\int \overleftrightarrow{\mathbf{T}} d\mathbf{a} = -\int_0^{2\pi}\int_0^{R} \overleftrightarrow{\mathbf{T}}\hat{\mathbf{e}}_z r dr d\phi = \frac{Q^2}{64\pi\varepsilon_0 R^2}\hat{\mathbf{e}}_z \ .$$

Combining the results we obtain the force by the equation (17.73),

$$\mathbf{F} = \oint_{\text{hemisphere}} \overleftrightarrow{\mathbf{T}} d\mathbf{a} = \frac{3Q^2}{64\pi\varepsilon_0 R^2}\hat{\mathbf{e}}_z \ .$$

The result of this example demonstrates, how we can reduce the calculation of a force acting on a volume to an integral over the surface enclosing the volume. We will calculate other examples in Excs. 17.2.5.3 to 17.2.5.6.

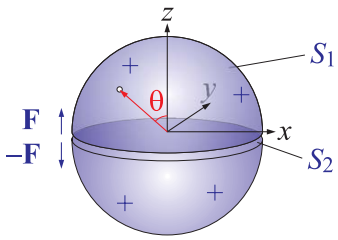

Figure 17.8: Electrostatic forces inside a charged sphere.

17.2.3.2 Conservation of linear momentum

According to Newton's second law, $\mathbf{F} = \partial_t \mathbf{p}_{mec}$ or $\mathbf{f} = \partial_t \vec{\wp}_{mec}$, the Lorentz force produces a variation of the *mechanical momentum*. In addition, there is a momentum $\mathbf{p}^M = \int_\mathcal{V} \vec{\wp}^M dV$, which must be attributed to the *electromagnetic field*, since it only exists in the presence of both electric and magnetic fields. $\mathbf{p}_{mec}$ and $\mathbf{p}^M$ can be interconverted, as in the example of the photonic recoil received by an atom upon an absorption process. But the sum of the mechanical momentum and the momentum of the field can only change through the term $\nabla \cdot \overleftrightarrow{\mathbf{T}}$. This is the law of *linear momentum conservation*. Evidently, $-\overleftrightarrow{\mathbf{T}}$ is the momentum flux density, playing a role similar to the one of the current density $\mathbf{j}$ in the continuity equation or of the energy flux density $\vec{\mathcal{S}}$ in Poynting's theorem. $-T_{ij}$ is the momentum per unit area and time in the direction i passing a surface oriented in j-direction.

We note two very different roles of the Poynting vector: In the energy conservation equation $\vec{\mathcal{S}}$ is the energy per unit area and time carried by electromagnetic fields, while in the momentum conservation equation, $\vec{\wp}^M = \varepsilon_0 \mu_0 \vec{\mathcal{S}}$ is the momentum per unit volume stored in these fields. Similarly, $\overleftrightarrow{\mathbf{T}}$ plays two roles: $\overleftrightarrow{\mathbf{T}}$ is the electromagnetic stress (i.e. a force per unit area or pressure) acting on a surface, while $-\overleftrightarrow{\mathbf{T}}$ describes the momentum flux (momentum current density) carried by these fields.

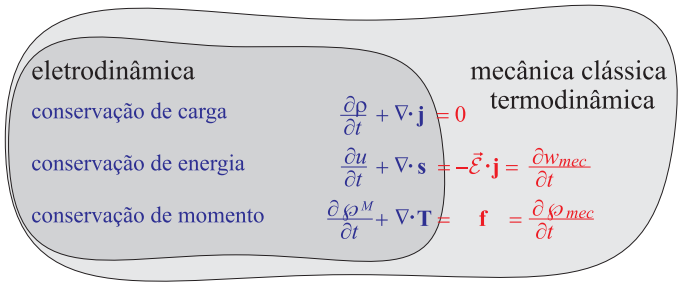

Figure 17.9: The laws of energy and momentum conservation connect the theories of electrodynamics with classical mechanics and thermodynamics.

Forces exerted by (non-radiating) fields on particles can be interpreted as being due to a scattering of 'virtual particles'. For example, the electrostatic force between charged particles and the magnetostatic force between magnetic dipoles are caused

by an exchange of virtual photons. These photons carry momentum that is transferred via recoil in a scattering event. Since the photon has no mass, the electric (respectively, magnetic) potential has infinite range.

The photonic concept can be extended to electromagnetic fields, as demonstrated by *Max Planck* in his discussion of the blackbody radiation. The spontaneous emission of a photon during the decay of an excited atom, postulated by *Albert Einstein*, is forbidden in 'classical' quantum mechanics, and requires quantization of the electromagnetic field for its explanation. The quantized energy packets, called (real) photons, also carry momentum, which can be transferred to bodies absorbing the radiation. The fact that light beams can exert forces is nowadays commonly exploited in techniques for cooling atomic gases. This process is called *radiation pressure* and will be discussed in the next chapter.

Example 88 (*The Abraham-Minkowski dilemma*): The expression $\vec{\wp}^A = \frac{1}{c^2}\vec{\mathcal{E}} \times \vec{\mathcal{H}}$ for the momentum flux in dielectric media was proposed by Abraham in 1909, but it is not obvious that this expression is correct. In fact, in the same year 1909 Minkowski proposed the expression $\vec{\wp}^M = \vec{\mathcal{D}} \times \vec{\mathcal{B}}$, and until today this *Abraham-Minkowski dilemma* is not satisfactorily solved [98, 1358]. See also (watch talk).

In an (over-)simplified way, we may illustrate the dilemma by the fact that even the correct expression for the photonic momentum within a dielectric is unknown. For, knowing that the phase velocity is reduced in a dielectric medium, $c \to c/n$, we could derive from the kinetic momentum in vacuum, $p = m\frac{c}{n}$, where the mass follows from Einstein's formula, $m = \frac{\hbar\omega}{c^2}$. That is, the photonic momentum within a dielectric medium should be,

$$p = \frac{\hbar\omega}{nc} \ .$$

This is Abraham's conclusion, which emphasizes the corpuscular aspect of the photon. On the other side, starting with de Broglie's expression, $p = \frac{\hbar}{\lambda}$, using the dispersion relation, $\lambda = \frac{c}{n\nu}$, we would conclude that the photonic momentum within a dielectric medium must be,

$$p = \frac{n\hbar\omega}{c} \ ,$$

which is Minkowski's result emphasizing the undulating features of the photon. In fact, the dilemma arises because, a priori, it is not clear whether the correct expression for the momentum carried by an electromagnetic wave is,

$$\vec{\wp}^A = \tfrac{1}{c^2}\mathbf{S} = \tfrac{1}{c^2}\vec{\mathcal{E}} \times \vec{\mathcal{H}} \qquad \text{or} \qquad \vec{\wp}^M = \vec{\mathcal{D}} \times \vec{\mathcal{B}} \ .$$

In vacuum there is no difference, but in the case of a plane wave inside a dielectric medium, $\vec{\mathcal{E}}(\mathbf{r},t) = \mathcal{E}_0\hat{\mathbf{e}}_x \cos\omega(t - \frac{n}{c}z)$ and $\vec{\mathcal{B}}(\mathbf{r},t) = \frac{n}{c}\hat{\mathbf{e}}_z \times \vec{\mathcal{E}}(\mathbf{r},t)$, we calculate,

$$\begin{aligned}
\wp^A &\equiv \tfrac{1}{c^2}\overline{\vec{\mathcal{E}} \times \vec{\mathcal{H}}} = \tfrac{1}{\mu_0 c^2}\overline{\vec{\mathcal{E}} \times \vec{\mathcal{B}}} = \tfrac{1}{\mu_0 c^2}\mathcal{E}_0^2\hat{\mathbf{e}}_z\tfrac{n}{c}\overline{\cos^2\omega(t - \tfrac{n}{c}z)} \\
&= \tfrac{1}{\mu_0 c^2}\mathcal{E}_0^2\hat{\mathbf{e}}_z\tfrac{n}{c}\tfrac{1}{2} = \tfrac{1}{\varepsilon_0\mu_0 c^2} - \hat{\mathbf{e}}_z\tfrac{u}{nc} = \hat{\mathbf{e}}_z\tfrac{u}{nc} \\
\wp^M &\equiv \overline{\vec{\mathcal{D}} \times \vec{\mathcal{B}}} = \varepsilon_0\overline{\vec{\mathcal{E}} \times \vec{\mathcal{B}}} = \varepsilon_0\mu_0 c^2\vec{\wp}^A = n^2\vec{\wp}^A \ .
\end{aligned}$$

17.2.4 Conservation of angular momentum of the electromagnetic field

The *angular momentum conservation* (17.58) is also ruled by Maxwell's equations. But its derivation is complicated [545, 659] and will not be reproduced here. In Exc. 17.2.5.7 we calculate the angular momentum stored in a static combination of electric and magnetic fields. In Exc. 17.2.5.8 we calculate the torque acting on charges due to a temporal variation of electromagnetic fields. Finally, in Exc. 17.2.5.9 we try classical discussion of the intrinsic angular momentum (spin) of the electron.

Example 89 (*Angular momentum of electromagnetic fields*): Imagine a very long solenoid with radius R, n windings per unit length, and carrying the current I. Coaxially to the solenoid there are two long cylindrical layers of length d. The first one, of radius a, lies inside the solenoid and carries a charge $+Q$ evenly distributed over the surface; the other one, of radius b, is outside the solenoid and carries the charge $-Q$, as shown in Fig. 17.10. We suppose $d \gg b$. When the current in the solenoid is gradually reduced, the cylinders begin to rotate. The question is, where does the angular momentum come from?

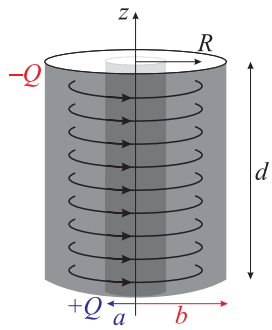

Figure 17.10: Device with a solenoid and charged cylinders illustrating the conservation of angular momentum.

Let us first calculate the angular momentum stored in the electric and magnetic field before we started to reduce the current. In the region between the cylinders, $a < \rho < b$, we had the electric field $\vec{\mathcal{E}} = \frac{Q}{2\pi\varepsilon_0 d}\frac{\hat{\mathbf{e}}_\rho}{\rho}$, and in the inner region of the solenoid, $\rho < R$, the magnetic field, $\vec{\mathcal{B}} = \mu_0 nI\hat{\mathbf{e}}_z$. Therefore, in the region $a < \rho < R$, the momentum density (17.58) was,

$$\vec{\wp} = \varepsilon_0 \vec{\mathcal{E}} \times \vec{\mathcal{B}} = -\frac{\mu_0 QnI}{2\pi\rho d}\hat{\mathbf{e}}_\phi$$

The angular momentum density,

$$\vec{\ell} = \mathbf{r} \times \vec{\wp} = -\frac{\mu_0 nIQ}{2\pi d}\hat{\mathbf{e}}_z \ ,$$

was constant, which facilitates the calculation of the total orbital angular momentum,

$$\mathbf{L} = \int \vec{\ell} dV = \vec{\ell}\pi(R^2 - a^2)d = -\tfrac{1}{2}\mu_0 nIQ(R^2 - a^2)\hat{\mathbf{e}}_z \ .$$

Apparently, the existence of an orbital angular momentum is conditioned to the presence of both, a charge and a current.
Now, when the current is turned off, the variation of the magnetic field induces a circumferential electric field, given by Faraday's law:

$$\vec{\mathcal{E}} = -\tfrac{1}{2}\mu_0 n \frac{dI}{dt}\hat{\mathbf{e}}_\phi \begin{cases} \rho & \text{for} \quad \rho < R \\ \frac{R^2}{\rho} & \text{for} \quad \rho > R \end{cases} .$$

The Coulomb force exerted by the electric field on the charged outer cylinder produces a torque on the cylinder,

$$\mathbf{N}_b = \mathbf{r} \times (-Q\vec{\mathcal{E}}) = \tfrac{1}{2}\mu_0 n Q R^2 \frac{dI}{dt}\hat{\mathbf{e}}_z ,$$

so that it receives the angular momentum,

$$\mathbf{L}_b = \int_0^\infty \mathbf{N}_b dt = \tfrac{1}{2}\mu_0 n Q R^2 \hat{\mathbf{e}}_z \int_I^0 \frac{dI}{dt} dt = -\tfrac{1}{2}\mu_0 n I Q R^2 \hat{\mathbf{e}}_z .$$

In the same way, we obtain for the inner cylinder,

$$\mathbf{N}_a = -\tfrac{1}{2}\mu_0 n Q a^2 \frac{dI}{dt}\hat{\mathbf{e}}_z \quad , \quad \mathbf{L}_a = \tfrac{1}{2}\mu_0 n I Q a^2 \hat{\mathbf{e}}_z .$$

Hence, we verify that $\mathbf{L} = \mathbf{L}_a + \mathbf{L}_b$. The angular momentum lost by the fields is precisely equal to the angular momentum acquired by the cylinders, that is, the total angular momentum is conserved.

17.2.5 Exercises

17.2.5.1 Ex: Poynting vector for free charges and currents

Write down the Poynting vector and the momentum density for the case, that there are only free *charges and currents*.

Solution: *We suppose,* $\varrho = \varrho_l$ *and* $\mathbf{j} = \mathbf{j}_l$. *We then deduce that the polarization is* $-\nabla \cdot \vec{\mathcal{P}} = \varrho_b = 0$ *and the magnetization* $\nabla \times \vec{\mathcal{M}} = \mathbf{j}_b$. *Hence,*

$$\vec{\mathcal{S}} = \vec{\mathcal{E}} \times \vec{\mathcal{H}} = \tfrac{1}{\mu_0}\vec{\mathcal{E}} \times \vec{\mathcal{B}} ,$$

and

$$\wp = \vec{\mathcal{D}} \times \vec{\mathcal{B}} = \varepsilon_0 \vec{\mathcal{E}} \times \vec{\mathcal{B}} .$$

17.2.5.2 Ex: Energy flux in a current-carrying wire

A cylindrical wire with radius a and permeability μ is traversed by a constant current density $\mathbf{j}$. The electric field $\vec{\mathcal{E}}$ inside the wire and the current density $\mathbf{j}$ are connected by Ohm's law $\mathbf{j} = \varsigma\vec{\mathcal{E}}$, where ς is the electrical conductivity.
a. What absolute value and which direction does the Poynting vector $\vec{\mathcal{S}}$ have in the wire and on the wire surface?
b. Calculate the total energy flux running through the surface of a piece of wire of

length l. Show that this flux of energy is precisely the power dissipated within this piece for the production of ohmic heat.
Help: The law of energy conservation in electrodynamics is given by $-\frac{du}{dt} = \nabla\vec{\mathcal{S}} + \mathbf{j}\cdot\vec{\mathcal{E}}$, where $u = \frac{1}{2}(\vec{\mathcal{E}}\cdot\vec{\mathcal{D}} + \vec{\mathcal{B}}\cdot\vec{\mathcal{H}})$ is the total energy density, $\vec{\mathcal{S}} = \vec{\mathcal{E}}\times\vec{\mathcal{H}}$ the energy flux and $\mathbf{j}\cdot\vec{\mathcal{E}}$ the work exerted on the electric current density.

Solution: *a. We calculate,*

$$2\pi\rho\mathcal{H} = \oint \vec{\mathcal{H}}\cdot d\mathbf{l} = I = j\pi\rho^2 = \int \mathbf{j}\cdot d\mathbf{S} \ .$$

We replace $\vec{\mathcal{E}} = \frac{1}{\varsigma}\mathbf{j}$ *and* $\vec{\mathcal{H}} = \frac{j}{2}\rho\hat{\mathbf{e}}_\phi$ *in the Poynting vector,*

$$\vec{\mathcal{S}} = \vec{\mathcal{E}}\times\vec{\mathcal{H}} = \tfrac{1}{\varsigma}\mathbf{j}\times\tfrac{j}{2}\rho\hat{\mathbf{e}}_\phi = -\tfrac{1}{2\varsigma}j^2\rho\hat{\mathbf{e}}_z\times\hat{\mathbf{e}}_\phi = -\tfrac{1}{2\varsigma}j^2\rho\hat{\mathbf{e}}_\rho \ .$$

$\vec{\mathcal{S}}$ points in radial direction towards the interior of the cylinder, energy flows from the outside into the cylinder. On the surface the Poynting vector is,

$$\vec{\mathcal{S}} = -\tfrac{1}{2\varsigma}j^2 a\hat{\mathbf{e}}_r \ .$$

b. The energy flow from outside to the inside of the wire is (note, that $\vec{\mathcal{S}}$ and $d\mathbf{S}$ have opposite signs),

$$\int_{cyl.surf} \vec{\mathcal{S}}\cdot d\mathbf{S} = -s\ 2\pi al = -\tfrac{1}{2\varsigma}j^2 a\ 2\pi al \ .$$

The ohmic power is,

$$\int \mathbf{j}\cdot\vec{\mathcal{E}}\ dV = \frac{j^2}{\varsigma}\pi a^2 l \ .$$

The time dependence of the energy density disappears, since $\vec{\mathcal{E}}$ and $\vec{\mathcal{H}}$ are constants,

$$\int_{wire.piece} \frac{du}{dt} dV = 0 \ .$$

Hence,

$$\int_{wire.piece} \nabla\cdot\vec{\mathcal{S}}\ dV = \int_{cyl.surf} \vec{\mathcal{S}}\cdot d\mathbf{S} = -\int_{wire.piece} \mathbf{j}\cdot\vec{\mathcal{E}}\ dV = 0 \ ,$$

as calculated above.

17.2.5.3 Ex: Intrinsic force in a rotating charged shell via Maxwell's tensor

Calculate the attractive magnetic force between the north and south hemispheres of a uniformly charged spherical shell (radius R and surface charge density Q) rotating with the angular velocity ω. Use the result of Exc. 15.3.3.1 (clicking on the title).

Solution: *We use the result of Exc. 15.3.3.1,*

$$\vec{\mathcal{B}} = \frac{\mu_0 Q\omega}{6\pi R}\begin{cases}\hat{\mathbf{e}}_z & for \;\; r<R \\ \frac{R^3}{r^3}(\hat{\mathbf{e}}_r\cos\theta + \frac{1}{2}\hat{\mathbf{e}}_\theta \sin\theta) & for \;\; r>R\end{cases} .$$

We chose an arbitrary volume enclosing the northern hemisphere. Choosing this very large volume, we only need to integrate the stress tensor in the equatorial plane ($\theta = \pi/2$, $\hat{\mathbf{e}}_\theta = -\hat{\mathbf{e}}_z$),

$$d\mathbf{a} = -\hat{\mathbf{e}}_z r dr d\phi \ ,$$

where the magnetic field is,

$$\vec{\mathcal{B}} = \frac{\mu_0 Q\omega}{6\pi R}\hat{\mathbf{e}}_z\begin{cases}1 & for \;\; r<R \\ -\frac{R^3}{2r^3} & for \;\; r>R\end{cases} .$$

We calculate the stress tensor by,

$$\overleftrightarrow{\mathbf{T}} = \frac{1}{\mu_0}\begin{pmatrix}\mathcal{B}_x^2 - \frac{1}{2}\mathcal{B}^2 & \mathcal{B}_x\mathcal{B}_y & \mathcal{B}_x\mathcal{B}_z \\ \mathcal{B}_x\mathcal{B}_y & \mathcal{B}_y^2 - \frac{1}{2}\mathcal{B}^2 & \mathcal{B}_y\mathcal{B}_z \\ \mathcal{B}_x\mathcal{B}_z & \mathcal{B}_y\mathcal{B}_z & \mathcal{B}_z^2 - \frac{1}{2}\mathcal{B}^2\end{pmatrix} = \frac{1}{2\mu_0}\mathcal{B}_z^2\begin{pmatrix}-1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & 1\end{pmatrix}$$

$$= \frac{1}{2\mu_0}\left(\frac{\mu_0 Q\omega}{6\pi R}\right)^2\begin{pmatrix}-1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & 1\end{pmatrix}\begin{cases}1 & for \;\; r<R \\ \frac{R^6}{4r^6} & for \;\; r>R\end{cases} .$$

The force on the upper equatorial plane is,

$$F_z = \int T_{zz}^{r<R}\hat{\mathbf{e}}_z\cdot\hat{\mathbf{e}}_z da + \int T_{zz}^{r>R}\hat{\mathbf{e}}_z\cdot\hat{\mathbf{e}}_z da$$
$$= \left(\frac{\mu_0 Q\omega}{6\pi R}\right)^2\frac{1}{2\mu_0}\int_0^R\int_0^{2\pi} r dr d\phi + \left(\frac{\mu_0 Q\omega}{6\pi R}\right)^2\frac{1}{2\mu_0}\int_R^\infty\int_0^{2\pi}\frac{R^6}{4r^6} r dr d\phi = \frac{\mu_0 Q^2\omega^2}{64\pi} .$$

17.2.5.4 Ex: Coulomb force via Maxwell's tensor

Consider two equal (or opposite) point charges q, separated by distance $2a$. Construct the plane which is equidistant from the two charges. Determine the mutual force between the charges.

Solution: *The electric field,*

$$\vec{\mathcal{E}} = \frac{1}{4\pi\varepsilon_0}\frac{Q}{|\mathbf{r}-\mathbf{a}|^3}(\mathbf{r}-\mathbf{a}) \pm \frac{1}{4\pi\varepsilon_0}\frac{Q}{|\mathbf{r}+\mathbf{a}|^3}(\mathbf{r}+\mathbf{a})$$

lies in the symmetry plane,

$$\vec{\mathcal{E}}_{plane} = \frac{1}{4\pi\varepsilon_0}\frac{Q}{\sqrt{\rho^2+a^2}^3}[(\mathbf{r}-\mathbf{a}) \pm (\mathbf{r}+\mathbf{a})] \ ,$$

with $\rho^2 \equiv x^2 + y^2$. *With this, Maxwell's stress tensor,*

$$\overleftrightarrow{\mathbf{T}}_{\pm,plane} = \varepsilon_0 \begin{pmatrix} -\frac{1}{2}\mathcal{E}_z^2 & 0 & 0 \\ 0 & -\frac{1}{2}\mathcal{E}_z^2 & 0 \\ 0 & 0 & \frac{1}{2}\mathcal{E}_z^2 \end{pmatrix}$$

lies in the plane in the case of equal (or opposite) charges,

$$\overleftrightarrow{\mathbf{T}}_{-,plane} = \frac{1}{32\pi^2\varepsilon_0}\frac{Q^2 4a^2}{(\rho^2+a^2)^3}\begin{pmatrix} -1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

$$\textit{and} \quad \overleftrightarrow{\mathbf{T}}_{+,plane} = \frac{1}{32\pi^2\varepsilon_0}\frac{Q^2 4\rho^2}{(\rho^2+a^2)^3}\begin{pmatrix} -1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & 1 \end{pmatrix} \ .$$

With the surface element in the plane $d\mathbf{a} = \hat{\mathbf{e}}_z r dr d\phi$, *the force follows as the integral of the tensor,*

$$\int \overleftrightarrow{\mathbf{T}}_{\pm,plane} d\mathbf{a} = \int_0^{2\pi}\int_0^{\infty} \overleftrightarrow{\mathbf{T}}_{-,plane}\hat{\mathbf{e}}_z \rho d\rho d\phi$$

for the case of equal (or opposite) charges,

$$\int \overleftrightarrow{\mathbf{T}}_{-,plane} d\mathbf{a} = \int_0^{2\pi}\int_0^{\infty} \frac{1}{32\pi^2\varepsilon_0}\frac{Q^2 4a^2}{(\rho^2+a^2)^3}\hat{\mathbf{e}}_z \rho d\rho d\phi = \frac{1}{4\pi\varepsilon_0}\frac{Q^2}{(2a)^2}\hat{\mathbf{e}}_z$$

$$\int \overleftrightarrow{\mathbf{T}}_{+,plane} d\mathbf{a} = \int_0^{2\pi}\int_0^{\infty} \frac{1}{32\pi^2\varepsilon_0}\frac{Q^2 4\rho^2}{(\rho^2+a^2)^3}\hat{\mathbf{e}}_z \rho d\rho d\phi = \frac{1}{4\pi\varepsilon_0}\frac{Q^2}{(2a)^2}\hat{\mathbf{e}}_z \ .$$

17.2.5.5 Ex: Force on a current distribution in a magnetic field

The force felt by a current distribution $\mathbf{j}(\mathbf{r})$ in an external magnetic field is,

$$\mathbf{F} = \int_{\mathcal{V}} d^3r' \mathbf{j}(\mathbf{r}') \times \vec{\mathcal{B}}(\mathbf{r}') \ .$$

Show that this force can also be written as an integral over the surface $\mathcal{S} \equiv \partial\mathcal{V}$ enclosing the volume $\mathcal{V}$:

$$F_j = \oint_{\mathcal{S}} \sum_{i=1}^{3} dS_i \ T_{ij} \qquad \text{with} \qquad T_{ij} = \tfrac{1}{\mu_0}\left(\mathcal{B}_i\mathcal{B}_j - \tfrac{1}{2}\mathcal{B}^2\delta_{ij}\right) \ .$$

Solution: *We have,*

$$\mathbf{F} = \int\limits_{\mathcal{V}} d^3\mathbf{r}'\mathbf{j}(\mathbf{r}') \times \vec{\mathcal{B}}(\mathbf{r}') = \tfrac{1}{\mu_0}\int\limits_{\mathcal{V}} d^3\mathbf{r}'(\nabla\times\vec{\mathcal{B}})\times\vec{\mathcal{B}}\ .$$

and hence,

$$F_i = \tfrac{1}{\mu_0}\int\limits_{\mathcal{V}} d^3\mathbf{r}'\left\{(\nabla\times\vec{\mathcal{B}})\times\vec{\mathcal{B}}\right\}_i\ .$$

Now,

$$\begin{aligned}\left\{(\nabla\times\vec{\mathcal{B}})\times\vec{\mathcal{B}}\right\}_i &= \epsilon_{ijk}(\nabla\times\vec{\mathcal{B}})_j\mathcal{B}_k \\ &= \epsilon_{ijk}\epsilon_{jmn}(\partial_m\mathcal{B}_n)\mathcal{B}_k = -\epsilon_{ikj}\epsilon_{mnj}(\partial_m\mathcal{B}_n)\mathcal{B}_k \\ &= -(\delta_{im}\delta_{kn}-\delta_{in}\delta_{km})(\partial_m\mathcal{B}_n)\mathcal{B}_k \\ &= (\partial_k\mathcal{B}_i)\mathcal{B}_k - (\partial_i\mathcal{B}_k)\mathcal{B}_k\ .\end{aligned}$$

We now use,

$$\mathcal{B}_k(\partial_k\mathcal{B}_i) = \partial_k(\mathcal{B}_i\mathcal{B}_k) - \mathcal{B}_i(\partial_k\mathcal{B}_k) = \partial_k(\mathcal{B}_i\mathcal{B}_k)\ .$$

since $\nabla\cdot\vec{\mathcal{B}} = 0$*, as well as,*

$$\mathcal{B}_k(\partial_i\mathcal{B}_k) = \tfrac{1}{2}\partial_i(\mathcal{B}_k\mathcal{B}_k) = \tfrac{1}{2}\partial_i\mathcal{B}^2\ .$$

Hence,

$$\left\{(\nabla\times\vec{\mathcal{B}})\times\vec{\mathcal{B}}\right\}_i = \frac{\partial}{\partial x_k}\left(\mathcal{B}_i\mathcal{B}_k - \tfrac{1}{2}\delta_{ik}\mathcal{B}^2\right) = \mu_0\frac{\partial}{\partial x_k}T_{ki}\ .$$

This is the divergence of a vector field (k indexes). Applying Gauß' law immediately follows the statement.

17.2.5.6 Ex: Force on the plates of a capacitor

Consider an infinite parallel-plate capacitor, with the lower plate (at $z = -d/2$) carrying the charge density $-\sigma$ and the upper plate (at $z = +d/2$) carrying the charge density σ. Determine the stress tensor in the region between the plates.

Solution: *The electric field is,*

$$\mathcal{E}_z = \frac{\sigma}{\varepsilon_0}\ .$$

Therefore, the stress tensor is,

$$\overleftrightarrow{\mathbf{T}} = \varepsilon_0\begin{pmatrix}-\frac{1}{2}\mathcal{E}_z^2 & 0 & 0\\ 0 & -\frac{1}{2}\mathcal{E}_z^2 & 0\\ 0 & 0 & \frac{1}{2}\mathcal{E}_z^2\end{pmatrix} = \frac{\sigma^2}{2\varepsilon_0}\begin{pmatrix}-1 & 0 & 0\\ 0 & -1 & 0\\ 0 & 0 & 1\end{pmatrix}\ .$$

So the pressure is,

$$\mathbf{P} = \frac{\mathbf{F}}{A} = -T_{zz}\hat{\mathbf{e}}_z = -\frac{\sigma^2}{2\varepsilon_0}\hat{\mathbf{e}}_z \ .$$

This force corresponds to a momentum flux per unit area and per unit time, crossing the x-y-plane. On the plates this momentum is absorbed, and the plates recoil (unless there is some non-electric force holding them in position).

17.2.5.7 Ex: Angular momentum of an electromagnetic field

Assuming the existence of an electric charge q_e and a magnetic monopole q_m, calculate the total angular momentum stored in the fields,

$$\vec{\mathcal{E}} = \frac{q_e}{4\pi\varepsilon_0}\frac{\hat{\mathbf{e}}_r}{R^2} \qquad \text{and} \qquad \vec{\mathcal{B}} = \frac{\mu_0 q_m}{4\pi}\frac{\hat{\mathbf{e}}_r}{R^2} \ ,$$

when the two charges are separated by a distance d.

Solution: *We place the origin at the position of the electric charge, such that the magnetic charge is at the position* $\mathbf{d} = d\hat{\mathbf{e}}_z$*. Then,*

$$\begin{aligned}\mathbf{L} &= \int \varepsilon_0 \mathbf{r} \times (\vec{\mathcal{E}} \times \vec{\mathcal{B}}) d^3r = \int \varepsilon_0 \mathbf{r} \times \left(\frac{q_e}{4\pi\varepsilon_0}\frac{\mathbf{r}}{r^3} \times \frac{\mu_0 q_m}{4\pi}\frac{\mathbf{r} - d\hat{\mathbf{e}}_z}{|\mathbf{r} - d\hat{\mathbf{e}}_z|^3} \right) d^3r \\ &= \frac{\mu_0 q_e q_m}{(4\pi)^2} \int \frac{\mathbf{r} \times (\mathbf{r} \times d\hat{\mathbf{e}}_z)}{r^3 |\mathbf{r} - d\hat{\mathbf{e}}_z|^3} d^3r \ .\end{aligned}$$

Using,

$$\begin{aligned}\mathbf{r} \times (\mathbf{r} \times d\hat{\mathbf{e}}_z) &= \mathbf{r}(\mathbf{r} \cdot d\hat{\mathbf{e}}_z) - d\hat{\mathbf{e}}_z(\mathbf{r} \cdot \mathbf{r}) \\ &= dr^2(\hat{\mathbf{e}}_r \cos\theta - \hat{\mathbf{e}}_z) \\ &= dr^2(\sin\theta\cos\theta\cos\phi\hat{\mathbf{e}}_x + \sin\theta\cos\theta\sin\phi\hat{\mathbf{e}}_y + \cos^2\theta\hat{\mathbf{e}}_z - \hat{\mathbf{e}}_z) \\ &= dr(\sin\theta\cos\theta\cos\phi\hat{\mathbf{e}}_x + \sin\theta\cos\theta\sin\phi\hat{\mathbf{e}}_y - \sin^2\theta\hat{\mathbf{e}}_z) \ ,\end{aligned}$$

we conclude the calculation,

$$\begin{aligned}\mathbf{L} &= \frac{\mu_0 q_e q_m}{(4\pi)^2} \int \frac{dr^2(\cancelto{0}{\sin\theta\cos\theta\cos\phi\hat{\mathbf{e}}_x} + \cancelto{0}{\sin\theta\cos\theta\sin\phi\hat{\mathbf{e}}_y} - \sin^2\theta\hat{\mathbf{e}}_z)}{r^3|\mathbf{r} - d\hat{\mathbf{e}}_z|^3} r^2\sin\theta d\theta d\phi dr \\ &= -\frac{\mu_0 q_e q_m}{(4\pi)^2} 2\pi d\hat{\mathbf{e}}_z \int_0^\pi \int_0^\infty \frac{r\sin^3\theta}{\sqrt{r^2 + d^2 - 2rd\cos\theta}^3} dr d\theta \\ &= -\frac{\mu_0 q_e q_m}{(4\pi)^2} 2\pi d\hat{\mathbf{e}}_z \left(\frac{2}{d}\right) = -\frac{\mu_0 q_e q_m}{4\pi}\hat{\mathbf{e}}_z \ .\end{aligned}$$

17.2.5.8 Ex: Torque on a demagnetized or discharged iron sphere

We imagine an iron sphere of radius R carrying a charge Q and a uniform magnetization $\vec{\mathcal{M}} = \mathcal{M}\hat{\mathbf{e}}_z$. The sphere is initially at rest.
a. Calculate the angular momentum stored in the electromagnetic fields.
b. Suppose the sphere is gradually (and uniformly) demagnetized (perhaps by heating it beyond the Curie point). Use Faraday's law to determine the induced electric field and find the torque that this field exerts on the sphere. Calculate the total angular momentum transferred to the sphere during demagnetization.
c. Suppose that, instead of demagnetizing the sphere, we discharge it by connecting the north pole of the sphere via a wire to Earth. Suppose that the current flows on the surface in such a way, that the charge density remains uniform. Use the Lorentz force law to determine the torque on the sphere and calculate the total angular momentum given to the sphere during the discharge. (The magnetic field is discontinuous on the surface ... does this matter?)

Solution: *a. We start from the known magnetic field of a uniformly magnetized iron sphere,*

$$\vec{\mathcal{B}} = \begin{cases} \frac{2}{3}\mu_0\mathcal{M}\hat{\mathbf{e}}_z = \frac{2}{3}\mu_0\mathcal{M}(\hat{\mathbf{e}}_r\cos\theta - \hat{\mathbf{e}}_\theta\sin\theta) & for \;\; r < R \\ \frac{\mu_0\mathcal{M}R^3}{3r^3}(2\hat{\mathbf{e}}_r\cos\theta + \hat{\mathbf{e}}_\theta\sin\theta) & for \;\; r > R \end{cases} .$$

The electric field is,

$$\vec{\mathcal{E}} = \begin{cases} 0 & for \;\; r < R \\ \frac{Q}{4\pi\varepsilon_0 r^2} & for \;\; r > R \end{cases} .$$

The linear momentum density is then,

$$\vec{\wp} = \varepsilon_0\vec{\mathcal{E}}\times\vec{\mathcal{B}} = \frac{\mu_0\mathcal{M}QR^3}{12\pi r^5}\hat{\mathbf{e}}_\phi\sin\theta \;,$$

for $r > R$, such that the angular momentum density is,

$$\ell = \mathbf{r}\times\vec{\wp} = -\frac{\mu_0\mathcal{M}QR^3}{12\pi r^4}\hat{\mathbf{e}}_\theta\sin\theta \;.$$

The total angular momentum is,

$$\mathbf{L} = -\frac{\mu_0\mathcal{M}QR^3}{12\pi}\int_R^\infty\int_0^\pi\int_0^{2\pi}\hat{\mathbf{e}}_\theta\frac{\sin\theta}{r^4}r^2 dr\sin\theta d\theta d\phi \;.$$

Since the unit vector $\hat{\mathbf{e}}_\theta$ varies in space, we must express it in spherical coordinates,

$$\hat{\mathbf{e}}_\theta = \hat{\mathbf{e}}_x\cos\theta\cos\phi + \cos\theta\sin\phi - \hat{\mathbf{e}}_z\sin\theta \;.$$

The integrals over ϕ vanish, such that,

$$\mathbf{L} = -\frac{\mu_0\mathcal{M}QR^3}{12\pi}2\pi\hat{\mathbf{e}}_z\int_R^\infty\hat{\mathbf{e}}_\theta\frac{dr}{r^2}\int_0^\pi\sin^3\theta d\theta = \tfrac{2}{9}\mu_0\mathcal{M}QR^2\hat{\mathbf{e}}_z \;.$$

b. Now the magnetic field is turned off, which, according to Faraday's law, generates a rotational electric field,

$$\oint \vec{\mathcal{E}} \cdot \mathbf{l} = -\frac{d\Phi}{dt} = \int \frac{\partial \vec{\mathcal{B}}}{\partial t} \cdot d\mathbf{a} \ .$$

Choosing as the integration path a circle on the surface of the sphere perpendicular to the symmetry axis, we get the radius $R \in \theta$ for the circle as a function of z. Then the last relation gives,

$$\mathcal{E} 2\pi R \sin\theta = -\pi (R \sin\theta) \frac{\partial \mathcal{B}}{\partial t} \ ,$$

that is,

$$\vec{\mathcal{E}} = -\frac{R \sin\theta}{2} \frac{\partial B}{\partial t} \hat{\mathbf{e}}_\phi \ .$$

Now, we imagine the circle as a circular ribbon with circumference $2\pi R \sin\theta$ and width $Rd\theta$. With the surface charge density $\sigma = Q/4\pi R^2$ we find the charge on this ribbon,

$$dq = \frac{Q}{4\pi R^2} (2\pi R \sin\theta) R d\theta = \tfrac{1}{2} Q \sin\theta d\theta \ .$$

The force on this ribbon is,

$$d\mathbf{F} = \vec{\mathcal{E}} dq = -\frac{1}{4} RQ \sin^2\theta d\theta \frac{\partial \mathcal{B}}{\partial t} \hat{\mathbf{e}}_\phi \ ,$$

and the torque,

$$d\mathbf{N} = \mathbf{r} \times d\mathbf{F} = -(R \sin\theta) \frac{1}{4} RQ \sin^2\theta d\theta \frac{\partial \mathcal{B}}{\partial t} \hat{\mathbf{e}}_z = -\frac{R^2 Q \sin^3\theta)}{4} d\theta \frac{\partial \mathcal{B}}{\partial t} \hat{\mathbf{e}}_z \ .$$

The total torque on the sphere is,

$$\mathbf{N} = \int_0^\pi d\mathbf{N}(\theta) = -\frac{QR^2}{3} \frac{\partial \mathcal{B}}{\partial t} \hat{\mathbf{e}}_z \ .$$

We obtain the final angular momentum by integrating the torque over time,

$$\mathbf{L} = -\frac{QR^2}{3} \hat{\mathbf{e}}_z \int_0^\infty \frac{\partial \mathcal{B}}{\partial t} dt = \tfrac{2}{9} \mu_0 \mathcal{M} Q R^2 \hat{\mathbf{e}}_z \ ,$$

which agrees with the angular momentum initially stored in the fields.
c. Now the charge is removed in a way as to let the charge density be always uniform. The drainage current inside the field of the magnetization will generate a force. To calculate the current we consider the same ribbon of item (b). The current $I(\theta)$ passing through a ribbon located at the position θ should be composed of the drainage current passing through the lower ribbon $I(\theta + d\theta)$ and the draining of the ribbon itself,

$$I(\theta) = I(\theta + d\theta) + \frac{\partial \sigma}{\partial t} (2\pi R \sin\theta)(R d\theta) \ ,$$

that is,

$$\frac{dI}{d\theta} = -\frac{\partial \sigma}{\partial t} 2\pi R^2 \sin\theta \ ,$$

with the solution,

$$I(\theta) = \frac{\partial\sigma}{\partial t} 2\pi R^2 \cos\theta + \alpha \ .$$

The integration constant α can be determined by the boundary condition, $I(\pi) = 0$,

$$I(\theta) = \frac{\partial\sigma}{\partial t} 2\pi R^2 (1 + \cos\theta) \ .$$

For the discharging process we can make a capacitor model,

$$\sigma(t) = \sigma(0) e^{-t/\tau} = \frac{Q}{4\pi R^2} e^{-t/\tau} \ .$$

Now we can calculate the Lorentz force on a ribbon,

$$\begin{aligned} d\mathbf{F} &= I(\theta)(Rd\theta)\hat{\mathbf{e}}_\theta \times \vec{\mathcal{B}} = \frac{\partial\sigma}{\partial t} 2\pi R^2 (1+\cos\theta)(Rd\theta)\hat{\mathbf{e}}_\theta \times \tfrac{2}{3}\mu_0 \mathcal{M}(\hat{\mathbf{e}}_r \cos\theta - \hat{\mathbf{e}}_\theta \sin\theta) \\ &= -\frac{1}{\tau}\frac{Q}{4\pi R^2} e^{-t/\tau} 2\pi R^2 (1+\cos\theta)(Rd\theta)\tfrac{2}{3}\mu_0 \mathcal{M}\cos\theta(-\hat{\mathbf{e}}_\phi) \ . \end{aligned}$$

The torque on the ribbon is,

$$d\mathbf{N} = \mathbf{r} \times d\mathbf{F} = \frac{\mu_0 \mathcal{M} Q R^2}{3\tau} e^{-t/\tau} \hat{\mathbf{e}}_z \sin\theta\cos\theta(1+\cos\theta) \ .$$

The total torque, therefore, is,

$$\mathbf{N} = \int_0^\pi d\mathbf{F} = \frac{2\mu_0 \mathcal{M} Q R^2}{9\tau} e^{-t/\tau} \hat{\mathbf{e}}_z \ .$$

Finally, we integrate over time,

$$\mathbf{L} = \int_0^\infty \mathbf{N} = \tfrac{2}{9}\mu_0 \mathcal{M} Q R^2 \hat{\mathbf{e}}_z \ .$$

The discontinuity of the magnetic field does not matter, since the angular momentum is stored in the zone outside the sphere, where the fields superpose.

17.2.5.9 Ex: Magnetic moment of the electron

In relativistic quantum mechanics the magnetic moment of the electron has the value,

$$\mu = g\mu_B \frac{1}{2} = \frac{e\hbar}{2mc} = 9.28 \cdot 10^{-25} \text{ T m}^3 \ .$$

This exercise aims to show that the classical interpretation of this magnetic moment, as being due to a rotating charge distribution, leads to intrinsic contradictions. Let us regard the electron as a sphere of mass m_e with radius r_e carrying the charge e homogeneously distributed over its surface. It rotates around its z-axis with the angular velocity ω. Classically, the movement of the surface charge causes a magnetic moment.
a. Calculate the total energy contained in the electromagnetic fields.

b. Calculate the total angular momentum contained in the fields.
c. According to Einstein's formula, $W_{ED} = m_e c^2$, the energy in the fields must contribute to the mass of the electron. Lorentz and other scientists have speculated that the entire mass of the electron could be understood in this way. Suppose, furthermore, that the rotational angular momentum (spin) of the electron is entirely attributable to the electromagnetic fields: $L_{ED} = \hbar/2$. From these two premisses, determine the radius and the angular velocity of the electron, as well as the product ωr_e. Does this classical model make sense?
d. Determine the magnetic moment of the rotating electron.

Solution: *a. The electric field produced by a spherical surface charge density,*

$$\rho(\mathbf{r}) = \frac{e}{4\pi r_e^2}\delta(r - r_e) \ ,$$

has already been calculated in other exercises, e.g. 13.2.4.4,

$$\vec{\mathcal{E}}(r) = \begin{cases} 0 \quad for \quad r < r_e \\ \frac{e}{4\pi\varepsilon_0 r^2}\hat{\mathbf{e}}_r \quad for \quad r > r_e \end{cases} \ .$$

For the electrostatic energy we obtain, then,

$$W_e = \frac{\varepsilon_0}{2}\int \mathcal{E}^2 dV = \frac{e^2}{32\pi^2\varepsilon_0^2}4\pi\int_{r>r_e} dr\frac{1}{r^2} = \frac{e^2}{8\pi\varepsilon_0 r_e} \ .$$

The magnetic field produced by a surface current distribution,

$$\mathbf{j}(\mathbf{r}) = j_\phi\hat{\mathbf{e}}_\phi = \rho(\mathbf{r})v_\phi\hat{\mathbf{e}}_\phi = \frac{e}{4\pi r_e}\delta(r - r_e)\omega\sin\theta\hat{\mathbf{e}}_\phi \ ,$$

was also calculated in other exercises, e.g. 15.3.3.1,

$$\vec{\mathcal{B}}(r) = \frac{\mu_0 e\omega}{6\pi r_e}\begin{cases} \hat{\mathbf{e}}_z \quad for \quad r < r_e \\ \frac{r_e^2}{r^3}(\hat{\mathbf{e}}_r\cos\theta + \frac{1}{2}\hat{\mathbf{e}}_\theta\sin\theta) \quad for \quad r > r_e \end{cases} \ .$$

For the magnetostatic energy we obtain, then,

$$\begin{aligned} W_m &= \frac{1}{2\mu_0}\int \mathcal{B}^2 dV \\ &= \frac{1}{2\mu_0}\left[\int_{r<r_e}\left(\frac{\mu_0 e\omega}{6\pi R}\right)^2 d^3r + \int_{r>r_e}\left(\frac{1}{4\pi\varepsilon_0}\right)^2\left(\frac{e\omega r_e^2}{3cr^3}\right)^2(4\cos^2 y + \sin^2 y)\sin y dy d\phi\right] \\ &= \frac{1}{2\mu_0}\frac{4\pi R^3}{3}\left(\frac{\mu_0 e\omega}{6\pi R}\right)^2 + \left(\frac{1}{4\pi\varepsilon_0}\right)^2\frac{1}{2\mu_0}\left(\frac{e\omega r_e^2}{3c}\right)^2\int_a^\infty \frac{1}{r^6}r^2 dr\int_0^{2\pi} d\phi\int_0^\pi(4\cos^2 y + \sin^2 y)\sin y dy \\ &= \frac{\mu_0 e^2\omega^2 r_e c^2}{54\pi} + \frac{1}{2\mu_0}\left(\frac{e\omega r_e^2}{3c}\right)^2\frac{1}{3r_e^3}2\pi 4\left(\frac{1}{4\pi\varepsilon_0}\right)^2 = \frac{\mu_0 e^2\omega^2 r_e c^2}{36\pi} \ . \end{aligned}$$

b. Only in the outer region the momentum density does not vanish ,

$$\vec{\wp} = \varepsilon_0\vec{\mathcal{E}}\times\vec{\mathcal{B}} = \varepsilon_0\frac{e}{4\pi\varepsilon_0 r^2}\hat{\mathbf{e}}_r \times \frac{\mu_0 e\omega}{6\pi r_e}\frac{r_e^2}{r^3}\frac{\hat{\mathbf{e}}_\theta}{2}\sin\theta = \frac{\mu_0 e^2\omega r_e^2}{48\pi^2}\frac{\sin\theta}{r^5}\hat{\mathbf{e}}_\phi \ ,$$

and the angular momentum density,

$$\vec{\ell} = \mathbf{r} \times \vec{\wp} = -\frac{\mu_0 e^2 \omega r_e}{48\pi^2} \frac{\sin\theta}{r^4} \hat{\mathbf{e}}_\theta \ .$$

The total angular momentum of the field is obtained by inserting $\hat{\mathbf{e}}_\theta = \hat{\mathbf{e}}_x \cos\theta\cos\phi + \hat{\mathbf{e}}_y \cos\theta \sin\phi - \hat{\mathbf{e}}_z \sin\theta$,

$$\mathbf{L}_{ED} = -\frac{\mu_0 e^2 \omega r_e^2}{48\pi^2} \int_{r>r_e} \frac{\sin\theta}{r^4} \hat{\mathbf{e}}_\theta d^3 r = \frac{\mu_0 e^2 \omega r_e^2}{24\pi} \hat{\mathbf{e}}_z \int_{r_e}^{\infty} \int_0^\pi \frac{\sin^3\theta}{r^2} d\theta dr = \frac{\mu_0 e^2 \omega r_e}{18\pi} \hat{\mathbf{e}}_z \ .$$

c. Equalizing the energy of the electromagnetic field with the rest mass of the electron, $m_e c^2$, *and the angular momentum with* $\frac{1}{2}\hbar$, *we obtain,*

$$\frac{e^2}{8\pi\varepsilon_0 r_e} + \frac{\mu_0 e^2 \omega^2 r_e c^2}{36\pi} = m_e c^2 \qquad , \qquad \frac{\mu_0 e^2 \omega r_e}{18\pi} = \frac{\hbar}{2} \ .$$

Resolving by r_e *and* ω,

$$r_e = \frac{1}{8} \frac{18\hbar^2\pi^2\varepsilon_0 + e^4\mu_0}{m_e \pi e^2} = \frac{9\pi\varepsilon_0\hbar^2}{4me^2} + \frac{e^2}{8\pi\varepsilon_0 m_e c^2} \approx 2.98 \cdot 10^{-11}\,\mathrm{m} + 1.41 \cdot 10^{-15}\,\mathrm{m} \ ,$$

and

$$\omega = 72 \frac{\hbar\pi^2 m_e c^2 \varepsilon_0}{18\hbar^2\pi^2\varepsilon_0 + e^4\mu_0} \approx 3.105 \cdot 10^{21}\,\mathrm{s}^{-1} \ .$$

This gives a ridiculously high orbital velocity in the equatorial plane,

$$\omega r_e = 9.246 \cdot 10^{10}\,\mathrm{m/s} \ .$$

d. Using $-\hat{\mathbf{e}}_r \times \hat{\mathbf{e}}_\phi = \hat{\mathbf{e}}_\theta = \hat{\mathbf{e}}_x \cos\theta\cos\phi + \hat{\mathbf{e}}_y \cos\theta\sin\phi - \hat{\mathbf{e}}_z \sin\theta$ *we calculate,*

$$\begin{aligned}
\vec{\mathcal{M}}_e &= \tfrac{1}{2} \int \mathbf{r}' \times \mathbf{j}(\mathbf{r}', t) d^3 r' = \frac{1}{2} \int \mathbf{r}' \times \frac{e\omega}{4\pi\varepsilon_0} \delta(r' - r_e) \sin\theta' \hat{\mathbf{e}}'_\phi d^3 r' \\
&= \frac{1}{2} \frac{e\omega}{4\pi\varepsilon_0} \int_0^{2\pi} \int_0^\pi \int_0^\infty \delta(r' - r_e) \sin\theta' \hat{\mathbf{e}}_{r'} \times \hat{\mathbf{e}}_{\phi'} r'^3 \sin\theta' d\theta' dr' d\phi' \\
&= -\frac{1}{2} \frac{e\omega}{4\pi\varepsilon_0} \int_0^{2\pi} \int_0^\pi \int_0^\infty \delta(r' - r_e) \sin\theta' (\hat{\mathbf{e}}_x \cos\theta' \cos\phi' + \hat{\mathbf{e}}_y \cos\theta' \sin\phi' - \hat{\mathbf{e}}_z \sin\theta') r'^3 \sin\theta' d\theta' dr' d\phi' \\
&= \frac{\hat{\mathbf{e}}_z}{2} \frac{e\omega}{4\pi\varepsilon_0} \frac{r_e^4}{4} \int_0^\pi \sin^3\theta' d\theta' = \frac{e\omega r_e^4}{24\pi\varepsilon_0} \hat{\mathbf{e}}_z \approx 3.7 \cdot 10^{-12}\,\mathrm{T\ m^3} \ .
\end{aligned}$$

We note, that the classical electron radius is defined by,

$$r_{cl} = \frac{e^2}{4\pi\varepsilon_0 m_e c^2} \ .$$

17.3 Potential formulation of electrodynamics

17.3.1 The vector and the scalar potential

All quantities involved in Maxwell's equations for vacuum, the fields $\vec{\mathcal{E}}(\mathbf{r},t)$ and $\vec{\mathcal{B}}(\mathbf{r},t)$ as well as charge ($\rho(\mathbf{r},t)$) and current ($\mathbf{j}(\mathbf{r},t)$) distributions they depend on space and time. Knowing that the divergence of a field is zero everywhere, $\nabla\cdot\vec{\mathcal{B}}=0$, we conclude that this field must be the rotation of another field. That is, there is a vector field $\mathbf{A}(\mathbf{r},t)$, such that,

$$\vec{\mathcal{B}}(\mathbf{r},t)=\nabla\times\mathbf{A}(\mathbf{r},t)\ . \tag{17.74}$$

Substituting the so-called *vector potential* $\mathbf{A}(\mathbf{r},t)$ in Faraday's law, $\nabla\times\vec{\mathcal{E}}=-\frac{\partial\vec{\mathcal{B}}}{\partial t}$, we obtain,

$$\nabla\times\vec{\mathcal{E}}=-\frac{\partial}{\partial t}(\nabla\times\mathbf{A})=-\nabla\times\frac{\partial\mathbf{A}}{\partial t}\ . \tag{17.75}$$

Hence,

$$\nabla\times\left(\vec{\mathcal{E}}+\frac{\partial\mathbf{A}}{\partial t}\right)=0\ . \tag{17.76}$$

Now, since the rotational field within the parentheses is null everywhere, it follows that there exists a scalar field $\Phi(\mathbf{r},t)$, called *scalar potential*, such that,

$$\vec{\mathcal{E}}+\frac{\partial\mathbf{A}}{\partial t}=-\nabla\Phi\ . \tag{17.77}$$

The minus sign in front of the gradient of $\Phi(\mathbf{r},t)$, is introduced to recover the electrostatic case when $\mathbf{A}(\mathbf{r},t)$ does not depend on time. In summary, if we know the vector and scalar potentials, we can calculate the fields $\vec{\mathcal{E}}(\mathbf{r},t)$ and $\vec{\mathcal{B}}(\mathbf{r},t)$ following the prescription expressed by the equations:

$$\boxed{\vec{\mathcal{E}}(\mathbf{r},t)=-\nabla\Phi(\mathbf{r},t)-\frac{\partial\mathbf{A}(\mathbf{r},t)}{\partial t}\qquad\text{and}\qquad\vec{\mathcal{B}}(\mathbf{r},t)=\nabla\times\mathbf{A}(\mathbf{r},t)}\ . \tag{17.78}$$

17.3.2 Gauge transformation

Substituting the expression for the electric field by the vector and scalar potentials in Gauß' law, $\nabla\cdot\vec{\mathcal{E}}=\frac{\varrho}{\varepsilon_0}$,

$$\frac{\varrho}{\varepsilon_0}=\nabla\cdot\left(-\nabla\Phi-\frac{\partial\mathbf{A}}{\partial t}\right)=-\nabla^2\Phi-\frac{\partial\nabla\cdot\mathbf{A}}{\partial t}\ . \tag{17.79}$$

Replacing the fields $\vec{\mathcal{E}}(\mathbf{r},t)$ and $\vec{\mathcal{B}}(\mathbf{r},t)$ by the potentials defined in (17.78), within the law of Ampère-Maxwell, $\nabla\times\vec{\mathcal{B}}=\mu_0\mathbf{j}+\varepsilon_0\mu_0\frac{\partial\vec{\mathcal{E}}}{\partial t}$, we obtain,

$$\nabla\times(\nabla\times\mathbf{A})=\nabla(\nabla\cdot\mathbf{A})-\nabla^2\mathbf{A}=\mu_0\mathbf{j}-\frac{1}{c^2}\frac{\partial}{\partial t}\left(-\nabla\Phi-\frac{\partial\mathbf{A}}{\partial t}\right)\ . \tag{17.80}$$

that is,

$$\nabla^2\mathbf{A}-\frac{1}{c^2}\frac{\partial\mathbf{A}^2}{\partial t^2}-\nabla\left(\nabla\cdot\mathbf{A}+\frac{1}{c^2}\frac{\partial\Phi}{\partial t}\right)=-\mu_0\mathbf{j}\ . \tag{17.81}$$

The coupled differential equations (17.79) and (17.81) allow us, in principle, to derive a set of potentials Φ and $\mathbf{A}$, generated by a charge and current distribution ϱ and $\mathbf{j}$, from which the fields $\vec{\mathcal{E}}$ and $\vec{\mathcal{B}}$ can be calculated. However, these *potentials are not unique*. To see this, let us suppose new potentials,

$$\Phi_1 \equiv \Phi - \frac{\partial \chi}{\partial t} \qquad \text{and} \qquad \mathbf{A}_1 \equiv \mathbf{A} + \nabla\chi \; . \tag{17.82}$$

Obviously, these potentials produce the same fields, since,

$$\vec{\mathcal{B}}_1 = \nabla \times (\mathbf{A} + \nabla\chi) = \vec{\mathcal{B}} \; , \tag{17.83}$$

using the expressions (17.78) and,

$$\vec{\mathcal{E}}_1 = -\nabla\left(\Phi - \frac{\partial\chi}{\partial t}\right) - \frac{\partial}{\partial t}(\mathbf{A} + \nabla\chi) = -\nabla\Phi - \frac{\partial}{\partial t}\mathbf{A} = \vec{\mathcal{E}} \; . \tag{17.84}$$

Thus, it is clear that the fields are the same for an infinite number of different potentials, provided they follow from each other by a so-called *gauge transform*,

$$\boxed{\mathbf{A} \longrightarrow \mathbf{A} + \nabla\chi \qquad \text{and} \qquad \Phi \longrightarrow \Phi - \partial_t\chi} \; . \tag{17.85}$$

This *gauge invariance* leaves the observable fields $\vec{\mathcal{E}}$ and $\vec{\mathcal{B}}$ invariant.

The freedom of choosing an appropriate gauge field can be employed to simplify the set of equations (17.79) and (17.81) for particular problems, as we will discuss in the following sections.

17.3.2.1 Lorentz gauge

We note that if the expression within the brackets of Eq. (17.81) were zero,

$$\boxed{\nabla \cdot \mathbf{A} + \frac{1}{c^2}\frac{\partial\Phi}{\partial t} \stackrel{!}{=} 0} \tag{17.86}$$

we would have from the equations (17.79) and (17.81) 'wave' type equations for the potentials,

$$\nabla^2\Phi - \frac{1}{c^2}\frac{\partial^2\Phi}{\partial t^2} = -\frac{\varrho}{\varepsilon_0} \qquad \text{and} \qquad \nabla^2\mathbf{A} - \frac{1}{c^2}\frac{\partial^2\mathbf{A}}{\partial t^2} = -\mu_0\mathbf{j} \; . \tag{17.87}$$

To analyze the viability of the expression (17.86), we apply a gauge transformation,

$$\nabla \cdot (\mathbf{A} + \nabla\chi) + \frac{1}{c^2}\frac{\partial(\Phi - \partial_t\chi)}{\partial t} = \nabla^2\chi - \frac{1}{c^2}\frac{\partial^2\chi}{\partial t^2} = 0 \; . \tag{17.88}$$

Hence, imposing the additional condition (17.86) is legal, because it can always be satisfied by a simple gauge transformation with a field χ satisfying the wave equation (17.88).

The equation (17.86) is known as the *Lorentz gauge*. We emphasize that *it is not necessary to postulate the equation*, but it is always possible to find a scalar function χ,

which allows the use of new potentials, giving the same $\vec{\mathcal{E}}$ and $\vec{\mathcal{B}}$ fields and satisfying this equation [11].

Introducing the notation of the *d'Alembert operator*,

$$\Box \equiv \nabla^2 - \varepsilon_0\mu_0 \frac{\partial^2}{\partial t^2} \ , \tag{17.89}$$

the wave equations (17.87) become,

$$\Box\Phi = -\varepsilon_0^{-1}\varrho \qquad \text{and} \qquad \Box\mathbf{A} = -\mu_0\mathbf{j} \ . \tag{17.90}$$

They generalize the electro- and magnetostatic equations (17.6) to include temporal variations simply by replacing the Laplacian with a d'Alembertian. The democratic treatment of Φ and $\mathbf{A}$ by a Poisson-like equation in four space-time dimensions is particularly interesting in the context of special relativity. We study examples of the Lorentz gauge in Excs. 15.3.3.6 to 15.3.3.8 and 17.3.8.1 to 17.3.8.7.

17.3.2.2 Coulomb gauge, transverse and longitudinal currents

Another condition that can be applied to the potentials in order to simplify the differential equations (17.86) and (17.88) consists in setting,

$$\boxed{\nabla\cdot\mathbf{A} \stackrel{!}{=} 0} \ . \tag{17.91}$$

This is called the *Coulomb gauge*. With this condition we obtain from (17.79) the *Poisson equation* as well as an equation for the vector potential,

$$\begin{aligned} -\nabla^2\Phi &= \frac{\varrho}{\varepsilon_0} \\ -\nabla^2\mathbf{A} + \frac{1}{c^2}\left(\frac{\partial^2\mathbf{A}}{\partial t^2} + \frac{\partial}{\partial t}\nabla\Phi\right) &= \mu_0\mathbf{j} \ . \end{aligned} \tag{17.92}$$

These two equations determine the vector and scalar potentials if the current and charge density distributions are specified [12]. The first Eq. (17.92) is solved by *Coulomb's law*, letting $\Phi(\infty) = 0$,

$$\Phi(\mathbf{r},t) = \frac{1}{4\pi\varepsilon_0}\int \frac{\varrho(\mathbf{r}',t)}{|\mathbf{r}-\mathbf{r}'|}d^3r' \ . \tag{17.93}$$

It is important to be aware that, unlike in electrostatics, we need to know also $\mathbf{A}(\mathbf{r},t)$ to be able to calculate the field $\vec{\mathcal{E}}(\mathbf{r},t)$ through the formula (17.78).

It may seem strange that the scalar potential in Coulomb's gauge is determined by the instantaneous charge distribution: Moving an electron at a point $\mathbf{r}'$, the potential at a distant point, $\Phi(\mathbf{r})$, immediately captures this change, not being limited by the speed limit for the transmission of information postulated by special relativity. The explanation is, that Φ is not an observable physical quantity. To infer a change of ϱ, we must measure $\vec{\mathcal{E}}$, which depends on $\mathbf{A}$ as well. Somehow it is encoded into the

[11] E.g. choosing χ such that $\nabla\chi = -\mathbf{A}$ and $c^{-1}\partial_t\chi = \phi$.

[12] The determination still leaves the freedom to add fields satisfying $\nabla^2\Theta = 0$.

Coulomb gauge that, while $\Phi(\mathbf{r})$ instantly reflects all variations of $\varrho(\mathbf{r}')$, the vector potential depends in a much more complicated way on these variations, such that the combination $-\nabla\Phi - \partial\mathbf{A}/\partial t$ only responds to the variations after a long enough time for information to arrive.

The advantage of the Coulomb gauge is that the scalar potential is simple to calculate. The disadvantage is that, in addition to the non-causal appearance of Φ, it is particularly difficult to calculate $\mathbf{A}$: The differential equation for $\mathbf{A}$ in the Coulomb gauge is (17.81).

In order to obtain an equation involving only the vector field and the current density, we use Helmholtz's theorem to write the current density as the sum of *transverse* and *longitudinal* components,

$$\mathbf{j} = \mathbf{j}_T + \mathbf{j}_L \ , \tag{17.94}$$

where the terms 'transverse' and 'longitudinal' are defined by the following two conditions,

$$\boxed{\nabla \cdot \mathbf{j}_T = 0 \qquad \text{and} \qquad \nabla \times \mathbf{j}_L = 0} \ . \tag{17.95}$$

Calculating the rotation of the second equation (17.92) we see that the term containing the gradient of the scalar potential vanishes. Hence,

$$-\nabla^2\mathbf{A} + \frac{1}{c^2}\frac{\partial^2\mathbf{A}}{\partial t^2} = \mu_0\mathbf{j}_T \ , \tag{17.96}$$

which shows that the transverse component of $\mathbf{j}$ is fully associated only with the vector potential. Now, substituting this result into the second equation (17.92) we are left with,

$$\varepsilon_0\frac{\partial}{\partial t}\nabla\Phi = \mathbf{j}_L \ . \tag{17.97}$$

That is, the longitudinal component of $\mathbf{j}$ is fully associated to the scalar potential. The solution of Eq. (17.96) requires some preparation and will be given in the following sections.

17.3.3 Green's function

A useful tool for solving Laplace equations, such as derived in Eq. (17.87) or (17.96), is the *Green's function*. The dynamics of physical systems are often described by differential equations of the type,

$$\mathcal{L}u(\mathbf{r}) = \varrho(\mathbf{r}) \ , \tag{17.98}$$

where $\mathcal{L} = \mathcal{L}(\mathbf{r})$ is a linear *differential operator*. While this operator has a very generic form, the behavior of a particular system depends on the choice of the function ϱ. The Laplace equation, where $\mathcal{L}(\mathbf{r}) \equiv \nabla^2$ and ϱ is a particular charge distribution is an example.

One method of solving this differential equation is to first solve the following equation,

$$\mathcal{L}\mathcal{G}(\mathbf{r}, \mathbf{x}) = \delta^3(\mathbf{r} - \mathbf{x}) \ , \tag{17.99}$$

where $\mathcal{G}(\mathbf{r}, \mathbf{x})$ is called the Green function of the operator. In general, the Green function is not unique. However, in practice, some combination of symmetry, boundary conditions and/or other externally imposed criteria can make the Green function unique.

Green functions are useful tools for solving wave and diffusion equations. In quantum mechanics, the Green function of the Hamiltonian is intrinsically connected to the concept of density of states. If the operator is invariant under translations, that is, if $\mathcal{L}$ has constant coefficients with respect to $\mathbf{r}$, then the Green function can be taken as the convolution [13],

$$\mathcal{G}(\mathbf{r}, \mathbf{x}) = \mathcal{G}(\mathbf{r} - \mathbf{x}) \ . \tag{17.100}$$

If such a function $\mathcal{G}$ can be found for the operator $\mathcal{L}$, then multiplying Eq. (17.99) for the Green function by $\varrho(\mathbf{x})$, and then integrating by the variable $\mathbf{x}$, we obtain:

$$\int \mathcal{L}\mathcal{G}(\mathbf{r}, \mathbf{x})\varrho(\mathbf{x})d^3x = \int \delta^3(\mathbf{r} - \mathbf{x})\varrho(\mathbf{x})d^3x = \varrho(\mathbf{r}) = \mathcal{L}u(\mathbf{r}) \ , \tag{17.101}$$

comparing the result with the Eq. (17.98). As we assume, that the operator $\mathcal{L} = \mathcal{L}(\mathbf{r})$ is linear and acts only on the variable $\mathbf{r}$ (and not on the integration variable $\mathbf{x}$), we can put $\mathcal{L}$ out of the integral on the right side. We conclude,

$$u(\mathbf{r}) = \int \mathcal{G}(\mathbf{r}, \mathbf{x})\varrho(\mathbf{x})d^3x \ . \tag{17.102}$$

Hence, we can obtain the function $u(\mathbf{r})$ from the Green function $\mathcal{G}(\mathbf{r}, \mathbf{x})$, determined by Eq. (17.99), and the source term $\varrho(\mathbf{x})$.

The Green function, also called the fundamental solution associated with the operator $\mathcal{L}$, can be considered as the inversion of $\mathcal{L} \equiv \mathcal{G}^{-1}$. Not every operator $\mathcal{L}$ admits a Green function. In practice, not only calculating the Green function can be difficult for a particular operator, but also evaluating the integral in Eq. (17.102). In Exc. 17.3.8.8 we will get to know a Green function of the wave equation.

Example 90 (*Solving the Laplace equation by Green's method*): The Laplace equation is,

$$\nabla^2\Phi(\mathbf{r}) = -\varepsilon_0^{-1}\varrho(\mathbf{r}) \ .$$

The Green function,

$$\mathcal{G}(\mathbf{r}, \mathbf{r}') = \mathcal{G}(\mathbf{r} - \mathbf{r}') = -\frac{1}{4\pi|\mathbf{r} - \mathbf{r}'|} \ ,$$

resolves the Poisson equation,

$$\nabla^2\mathcal{G}(\mathbf{r} - \mathbf{r}') = \delta^3(\mathbf{r} - \mathbf{r}') \ .$$

Therefore, the solution of the Laplace equation is,

$$\Phi(\mathbf{r}) = \frac{1}{4\pi\varepsilon_0}\int \frac{\varrho(\mathbf{r}')d^3r'}{|\mathbf{r} - \mathbf{r}'|} \ .$$

To solve the wave equations (17.90), we need to find the Green function for a spatio-temporal differential operator $\mathcal{L}(\mathbf{r}, t) = \Box$. We will do this in the example 91, but for now, in the following section, we will adopt more empirical arguments.

[13] In this case, the Green function is the same as the *pulse response* in the theory of time-independent linear systems.

17.3.4 Retarded potentials of continuous charge distributions

In the Lorentz gauge Φ and $\mathbf{A}$ satisfy the inhomogeneous wave equations (17.90) incorporating a 'source' term. We will use in the following exclusively the Lorentz gauge within which the entire electrodynamics comes down to solving (17.90).

But before that, let us take a look at the static situation, where the equations (17.90) reduce to Poisson equations,

$$\nabla^2\Phi = -\varepsilon_0^{-1}\varrho \qquad \text{and} \qquad \nabla^2\mathbf{A} = -\mu_0\mathbf{j}\ , \tag{17.103}$$

with the known solutions,

$$\Phi(\mathbf{r}) = \frac{1}{4\pi\varepsilon_0}\int \frac{\varrho(\mathbf{r}')}{|\mathbf{r}-\mathbf{r}'|}d^3r' \qquad \text{and} \qquad \mathbf{A}(\mathbf{r}) = \frac{\mu_0}{4\pi}\int \frac{\mathbf{j}(\mathbf{r}')}{|\mathbf{r}-\mathbf{r}'|}d^3r'\ . \tag{17.104}$$

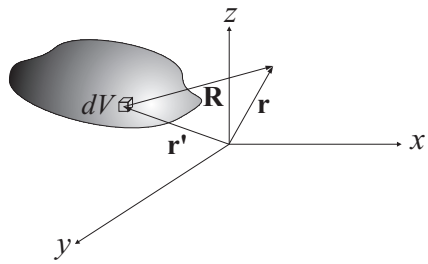

Figure 17.11: Geometry of source and the observation point.

In the dynamic case, the charge confined in the volume dV' (see Fig. 17.11) can move, but for the information on this movement to reach the point of observation $\mathbf{r}$ it takes a time determined by the propagation velocity of the light: $|\mathbf{r}-\mathbf{r}'|/c$. Introducing the distance R between the position of the charge and the observation point and the time retardation t_r by,

$$\mathbf{R} \equiv \mathbf{r}-\mathbf{r}' \qquad \text{and} \qquad t_r \equiv t - \tfrac{R}{c}\ , \tag{17.105}$$

we expect the following generalization of the equation (17.104),

$$\boxed{\Phi(\mathbf{r},t) = \frac{1}{4\pi\varepsilon_0}\int \frac{\varrho(\mathbf{r}',t_r)}{R}d^3r' \qquad \text{and} \qquad \mathbf{A}(\mathbf{r}) = \frac{\mu_0}{4\pi}\int \frac{\mathbf{j}(\mathbf{r}',t_r)}{R}d^3r'}\ , \tag{17.106}$$

called *retarded potential*.

The argument given above seems reasonable, but does not represent a stringent derivation, which will be given in the following. In fact, the same argument applied to the fields $\vec{\mathcal{E}}$ and $\vec{\mathcal{B}}$ would give false results, as we shall see later.

To verify the correctness of the assertion (17.106) we can simply show that it satisfies the wave equation (17.90) and the Lorentz gauge (17.89). However, this is not trivial, since the integral expressions depend on $\mathbf{r}$ explicitly (via the distance R

in the denominator) and implicitly (via the retarded time t_d). Here, we present the calculation for the scalar potential,

$$\begin{aligned}\nabla_r\Phi(\mathbf{r}) &= \frac{1}{4\pi\varepsilon_0}\int \nabla_r \frac{\varrho(\mathbf{r}', t-\frac{|\mathbf{r}-\mathbf{r}'|}{c})}{|\mathbf{r}-\mathbf{r}'|} d^3r' \qquad (17.107)\\ &= \frac{1}{4\pi\varepsilon_0}\int \left[\frac{1}{R}\nabla_r\varrho + \varrho\nabla_r\frac{1}{R}\right] d^3r' = \frac{1}{4\pi\varepsilon_0}\int \left[\frac{1}{R}\frac{-\dot\varrho}{c}\frac{\mathbf{R}}{R} + \varrho\frac{-\mathbf{R}}{R^3}\right] d^3r' \ .\end{aligned}$$

The divergence of the gradient,

$$\begin{aligned}\nabla_r^2\Phi(\mathbf{r}) &= \frac{1}{4\pi\varepsilon_0}\int \left[\frac{-\dot\varrho}{c}\left(\nabla_r\cdot\frac{\mathbf{R}}{R^2}\right) - \frac{\mathbf{R}}{R^2}\cdot\left(\frac{\nabla_r\dot\varrho}{c}\right) - (\nabla_r\varrho)\cdot\frac{\mathbf{R}}{R^3} - \varrho\left(\nabla_r\cdot\frac{\mathbf{R}}{R^3}\right)\right] d^3r'\\ &= \frac{1}{4\pi\varepsilon_0}\int \left[\cancel{\frac{-\dot\varrho}{c}\frac{1}{R^2}} - \frac{\mathbf{R}}{R^2}\cdot\left(\frac{-\ddot\varrho\mathbf{R}}{c^2R}\right) - \cancel{\left(\frac{-\dot\varrho\mathbf{R}}{cR}\right)\cdot\frac{\mathbf{R}}{R^3}} - \varrho 4\pi\delta^3(\mathbf{R})\right] d^3r'\\ &= \frac{1}{4\pi\varepsilon_0}\int \left[\frac{\ddot\varrho}{c^2R} - 4\pi\varrho\delta^3(\mathbf{R})\right] d^3r' = \frac{1}{c^2}\frac{\partial^2\Phi}{\partial t^2} - \frac{\varrho(\mathbf{r},t)}{\varepsilon_0}\ , \qquad (17.108)\end{aligned}$$

where we replaced in the last line the integral of $\ddot\varrho/c^2R$ by the expression (17.106), reproduces the wave equation. In Exc. 17.3.8.9 we verify that the retarded potentials (17.106) satisfy the Lorentz gauge.

It is interesting to note that the same calculation can be made for advanced times, where the potential would be affected by a *future* movement of the charge, $t_a = t + \frac{R}{c}$. But this would violate causality.

Example 91 (*Resolution of the wave equation by the Greens function*): We showed in the previous section that in the Lorentz gauge, given the sources ϱ and $\mathbf{j}$, all we have to do to find the scalar and vector potentials is to solve wave type differential equations (17.87),

$$\nabla^2\psi(\mathbf{r},t) - \frac{1}{c^2}\frac{\partial^2\psi(\mathbf{r},t)}{\partial t^2} = f(\mathbf{r},t)\ ,$$

where ψ is a variable to denote the fields Φ or $\mathbf{A}$ and f to denote the sources ϱ or $\mathbf{j}$. First, we want to find a particular solution of this equation. To this end, we use the Green function $\mathcal{G}(\mathbf{r},t,\mathbf{r}',t')$, which by definition satisfies,

$$\boxed{\nabla^2\mathcal{G}(\mathbf{r},t,\mathbf{r}',t') - \frac{1}{c^2}\frac{\partial^2}{\partial t^2}\mathcal{G}(\mathbf{r},t,\mathbf{r}',t') = \delta^{(3)}(\mathbf{r}-\mathbf{r}')\delta(t-t')}\ .$$

We can perform the Fourier transform with respect to the variable t and obtain,

$$\nabla^2 g(\mathbf{r},\omega,\mathbf{r}',t') + \frac{\omega^2}{c^2}g(\mathbf{r},\omega,\mathbf{r}',t') = \delta^{(3)}(\mathbf{r}-\mathbf{r}')\frac{e^{\imath\omega t'}}{2\pi}\ ,$$

where we used the integral representation of the Dirac delta function, i.e.,

$$\delta(t-t') = \frac{1}{2\pi}\int_{-\infty}^{\infty} e^{-\imath\omega(t-t')}d\omega$$

and we defined,

$$\mathcal{G}(\mathbf{r},t,\mathbf{r}',t') \equiv \int_{-\infty}^{\infty} e^{-\imath\omega t} g(\mathbf{r},\omega,\mathbf{r}',t')d\omega\ .$$

As we will explain later, instead of solving the above differential equation, we will modify it:

$$\nabla^2 g_\eta(\mathbf{r},\omega,\mathbf{r}',t') + (k_0+\imath\eta)^2 g_\eta(\mathbf{r},\omega,\mathbf{r}',t') = \delta^{(3)}(\mathbf{r}-\mathbf{r}')\frac{e^{\imath\omega t'}}{2\pi} \ ,$$

with $k_0 \equiv \omega/c$ assuming positive and negative values for ω: We can now take the Fourier transform with respect to the variable $\mathbf{r}$ and obtain,

$$-k^2 \bar{g}_\eta(\mathbf{k},\omega,\mathbf{r}',t') + (k_0+\imath\eta)^2 \bar{g}_\eta(\mathbf{k},\omega,\mathbf{r}',t') = \frac{e^{-\imath\mathbf{k}\cdot\mathbf{r}'+\imath\omega t'}}{(2\pi)^4} \ ,$$

where we used,

$$\delta^{(3)}(\mathbf{r}-\mathbf{r}') = \frac{1}{(2\pi)^3}\int_{\mathbb{R}^3} e^{\imath\mathbf{k}\cdot(\mathbf{r}-\mathbf{r}')} d^3k \ ,$$

and defined,

$$g_\eta(\mathbf{r},\omega,\mathbf{r}',t') \equiv \int e^{\imath\mathbf{k}\cdot\mathbf{r}} \bar{g}_\eta(\mathbf{k},\omega,\mathbf{r}',t') d^3k \ .$$

Hence,

$$\bar{g}_\eta(\mathbf{k},\omega,\mathbf{r}',t') = \frac{e^{-\imath\mathbf{k}\cdot\mathbf{r}'+\imath\omega t'}}{(2\pi)^4[-k^2+(k_0+\imath\eta)^2]} \ ,$$

and therefore,

$$g_\eta(\mathbf{r},\omega,\mathbf{r}',t') = \int \frac{e^{-\imath\mathbf{k}\cdot(\mathbf{r}-\mathbf{r}')+\imath\omega t'}}{(2\pi)^4[-k^2+(k_0+\imath\eta)^2]} d^3k \ .$$

Note that, if we had not modified the original equation (i.e. set $\eta = 0$), the integral above would not converge, and we could not find a Green function by the present method. Now, however, the Green function is,

$$\mathcal{G}_\eta(\mathbf{r}-\mathbf{r}',t-t') = \int_{-\infty}^{\infty} e^{-\imath\omega t} g_\eta(\mathbf{r},\omega,\mathbf{r}',t') d\omega = \int d^3k \int_{-\infty}^{\infty} d\omega \frac{e^{\imath\mathbf{k}\cdot(\mathbf{r}-\mathbf{r}')-\imath\omega(t-t')}}{(2\pi)^4[-k^2+(k_0+\imath\eta)^2]} \ ,$$

or yet,

$$\mathcal{G}_\eta(\mathbf{r},t) = \int d^3k \int_{-\infty}^{\infty} \frac{d\omega\ e^{\imath\mathbf{k}\cdot\mathbf{r}-\imath\omega t}}{(2\pi)^4[-k^2+(k_0+\imath\eta)^2]} = \frac{1}{(2\pi)^4}\int_{-\infty}^{\infty} d\omega e^{-\imath\omega t} \int \frac{d^3k\ e^{\imath\mathbf{k}\cdot\mathbf{r}}}{[k^2-(k_0+\imath\eta)^2]} \ .$$

In polar coordinates, choosing the orientation of the $\mathbf{k}$-vector space such that k_z is parallel to the vector $\mathbf{r}$,

$$\begin{aligned}
\int d^3k \frac{e^{\imath\mathbf{k}\cdot\mathbf{r}}}{[k^2-(k_0+\imath\eta)^2]} &= \int_0^\infty k^2 dk \frac{1}{[k^2-(k_0+\imath\eta)^2]} \int_0^{2\pi} d\phi_k \int_0^\pi d\theta_k \sin\theta_k e^{\imath\mathbf{k}\cdot\mathbf{r}} \\
&= \int_0^\infty dk \frac{k^2}{[k^2-(k_0+\imath\eta)^2]} \int_0^{2\pi} d\phi_k \int_0^\pi d\theta_k \sin\theta_k e^{\imath kr\cos\theta_k} \\
&= \int_0^\infty dk \frac{2\pi k^2}{[k^2-(k_0+\imath\eta)^2]} \int_{-1}^1 du e^{\imath kru} \\
&= \frac{2\pi}{\imath r}\int_0^\infty dk \frac{k}{[k^2-(k_0+\imath\eta)^2]}(e^{\imath kr}-e^{-\imath kr}) \ ,
\end{aligned}$$

where we used the substitution $u \equiv \cos\theta_k$. Since,

$$\int_0^\infty dk \frac{ke^{-\imath kr}}{[k^2-(k_0+\imath\eta)^2]} = -\int_{-\infty}^0 dk \frac{ke^{\imath kr}}{[k^2-(k_0+\imath\eta)^2]} \ ,$$

we can write,

$$\int d^3k \frac{e^{\imath \mathbf{k}\cdot\mathbf{r}}}{[k^2-(k_0+\imath\eta)^2]} = \frac{2\pi}{\imath r}\int_{-\infty}^{\infty} dk \frac{ke^{\imath kr}}{[k^2-(k_0+\imath\eta)^2]} \ .$$

The poles of this integral are given by,

$$Z_\pm = \pm(k_0+\imath\eta) \ .$$

We consider the integral in the complex plane:

$$\oint_C \frac{Ze^{\imath rZ}}{(Z-Z_+)(Z-Z_-)}dZ \ ,$$

where the contour is closed over the upper complex half-plane. When $\eta \to 0^+$ [see Fig. 17.12(a)], we get,

$$\oint_C \frac{Ze^{\imath rZ}}{(Z-Z_+)(Z-Z_-)}dZ = 2\pi\imath\frac{Z_+e^{\imath rZ_+}}{Z-Z_+} = \imath\pi e^{\imath k_0 r} \ .$$

When $\eta \to 0^-$ [see Fig. 17.12(b)], we get,

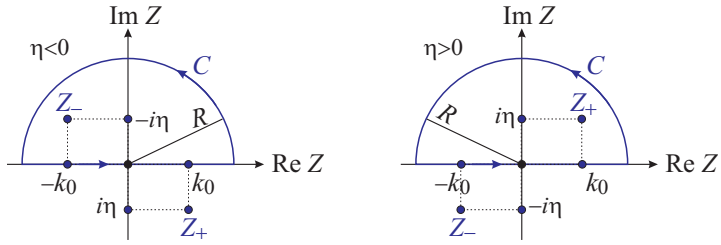

Figure 17.12: Illustration of the integration path.

$$\oint_C \frac{Ze^{\imath rZ}}{(Z-Z_+)(Z-Z_-)}dZ = \imath\pi e^{-\imath k_0 r} \ .$$

But, with the closed contour over the upper complex half-plane,

$$\int_{-\infty}^{\infty} dk \frac{ke^{\imath kr}}{[k^2-(k_0+\imath\eta)^2]} = \oint_C \frac{Ze^{\imath rZ}}{(Z-Z_+)(Z-Z_-)}dZ = \imath\pi e^{\pm\imath k_0 r} \ .$$

With these results, we can conclude that,

$$\int d^3k \frac{e^{\imath \mathbf{k}\cdot\mathbf{r}}}{[k^2-(k_0+\imath\eta)^2]} = \frac{2\pi^2}{r}e^{\pm\imath k_0 r} \ ,$$

and hence,

$$\mathcal{G}_\pm(\mathbf{r},t) = -\frac{1}{(2\pi)^4}\int_{-\infty}^{\infty} d\omega e^{-\imath\omega t}\frac{2\pi^2}{r}e^{\pm\imath k_0 r} = -\frac{1}{8\pi^2 r}\int_{-\infty}^{\infty} d\omega e^{-\imath\omega(t\mp\frac{r}{c})} = -\frac{1}{4\pi r}\delta(t\mp\tfrac{r}{c}) \ .$$

Thus, we also have,

$$\mathcal{G}_\pm(\mathbf{r}-\mathbf{r}',t-t') = -\frac{1}{4\pi}\frac{1}{|\mathbf{r}-\mathbf{r}'|}\delta(t-t'\mp\tfrac{|\mathbf{r}-\mathbf{r}'|}{c}) \ .$$

There are, therefore, two possible solutions to the problem:

$$\psi(\mathbf{r},t) = \int d^3r' \int_{-\infty}^{\infty} dt' \mathcal{G}_{\pm}(\mathbf{r}-\mathbf{r}', t-t') f(\mathbf{r}', t')$$
$$= -\frac{1}{4\pi} \int \frac{d^3r'}{|\mathbf{r}-\mathbf{r}'|} \int_{-\infty}^{\infty} dt' \delta(t' - t \pm \tfrac{|\mathbf{r}-\mathbf{r}'|}{c}) f(\mathbf{r}', t') = -\frac{1}{4\pi} \int d^3r' \frac{f(\mathbf{r}', t \mp \frac{|\mathbf{r}-\mathbf{r}'|}{c})}{|\mathbf{r}-\mathbf{r}'|} \,.$$

In this case, we will use retarded rather than advanced solutions, i.e.,

$$\Phi(\mathbf{r},t) = \frac{1}{4\pi\varepsilon_0} \int \frac{\varrho(\mathbf{r}', t - \frac{|\mathbf{r}-\mathbf{r}'|}{c})}{|\mathbf{r}-\mathbf{r}'|} d^3\mathbf{r}' \quad \text{and} \quad \mathbf{A}(\mathbf{r},t) = \frac{\mu_0}{4\pi} \int \frac{\mathbf{j}(\mathbf{r}', t - \frac{|\mathbf{r}-\mathbf{r}'|}{c})}{|\mathbf{r}-\mathbf{r}'|} d^3\mathbf{r}' \,.$$

17.3.5 Retarded fields in electrodynamics and Jefimenko's equations

From the retarded potentials (17.106) we can determine the fields through equations (17.78),

$$\vec{\mathcal{E}}(\mathbf{r},t) = -\nabla_r \Phi - \frac{\partial \mathbf{A}}{\partial t} = -\frac{1}{4\pi\varepsilon_0} \int \left[\frac{1}{R} \frac{-\dot{\varrho}}{c} \frac{\mathbf{R}}{R} + \varrho \frac{-\mathbf{R}}{R^3} \right] d^3r' - \frac{\mu_0}{4\pi} \int \frac{\dot{\mathbf{j}}(\mathbf{r}', t_r)}{R} d^3r' \,,$$

using the result (17.107). With $c^2 = 1/\varepsilon_0\mu_0$ we obtain the time-dependent generalization of Coulomb's law,

$$\boxed{\vec{\mathcal{E}}(\mathbf{r},t) = \frac{1}{4\pi\varepsilon_0} \int \left[\frac{\varrho(\mathbf{r}', t_r)}{R^2} \hat{\mathbf{e}}_R + \frac{\dot{\varrho}(\mathbf{r}', t_r)}{cR} \hat{\mathbf{e}}_R - \frac{\dot{\mathbf{j}}(\mathbf{r}', t_r)}{c^2 R} \right] d^3r'} \,. \tag{17.109}$$

In static situations the second and third term cancel, $\varrho(\mathbf{r}', t') = \varrho(\mathbf{r}')$ becomes independent of time, and we recover the electrostatic Coulomb law.

We now calculate the magnetic field via the rotation,

$$\vec{\mathcal{B}}(\mathbf{r},t) = \nabla_r \times \mathbf{A} = \frac{\mu_0}{4\pi} \int \left[\frac{1}{R} (\nabla_r \times \mathbf{j}) - \mathbf{j} \times \nabla_r \left(\frac{1}{R} \right) \right] d^3r' \,. \tag{17.110}$$

With,

$$[\nabla_r \times \mathbf{j}(\mathbf{r}', t - \tfrac{R}{c})]_x = \frac{\partial j_z}{\partial y} - \frac{\partial j_y}{\partial z} = \dot{j}_z \frac{\partial t_r}{\partial y} - \dot{j}_y \frac{\partial t_r}{\partial z} \tag{17.111}$$
$$= -\frac{1}{c} \left(\dot{j}_z \frac{\partial R}{\partial y} - \dot{j}_y \frac{\partial R}{\partial z} \right) = \left[\frac{1}{c} \dot{\mathbf{j}} \times \nabla_r R \right]_x = \left[\frac{1}{c} \dot{\mathbf{j}} \times \frac{\mathbf{R}}{R} \right]_x \,.$$

Thus, the time-dependent generalization of the Biot-Savart law is,

$$\boxed{\vec{\mathcal{B}}(\mathbf{r},t) = \frac{\mu_0}{4\pi} \int \left[\frac{\mathbf{j}(\mathbf{r}', t_r)}{R^2} + \frac{\dot{\mathbf{j}}(\mathbf{r}', t_r)}{cR} \right] \times \frac{\mathbf{R}}{R} d^3r'} \,. \tag{17.112}$$

The equations (17.109) and (17.112) are the (causal) solutions of Maxwell's equations published by *Jefimenko* in 1966. In practice, these equations are of limited

utility, since it is usually easier to calculate the retarded potentials, instead of going directly to the fields. However, they provide the satisfying sensation of a closed theory. We note that the simple replacement of the times t by t_r made for the potentials in (17.106) does not apply to the fields, as it would only produce the first terms of Jefimenko's expressions.

In the Excs. 17.3.8.10 and 17.3.8.11 we evaluate the fields for slow current variations.

17.3.6 The Liénard-Wiechert potentials

The goal now is to calculate the retarded electromagnetic potentials produced by a moving point charge q along a predefined path $\mathbf{w}(t)$. The presence of the charge at a time t_r at a point $\mathbf{w}(t_r)$, called the *retarded position* of this trajectory, has an impact on an arbitrary point of space $\mathbf{r}$ at a time t given by,

$$t = t_r + \frac{|\mathbf{r}-\mathbf{w}(t_r)|}{c} \ . \tag{17.113}$$

At a given instant of time t, the potentials $\Phi(\mathbf{r},t)$ and $\mathbf{A}(\mathbf{r},t)$ evaluated at the point

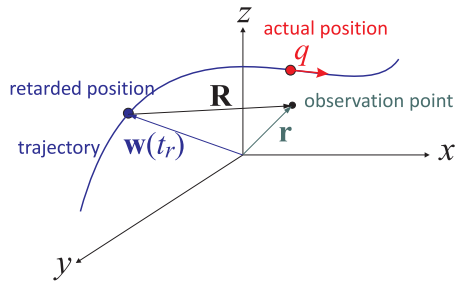

Figure 17.13: Retardation of potentials.

$\mathbf{r}$ *depend only on a single point* of the trajectory $\mathbf{w}(t_r)$ occupied by the charge in the past. The equation (17.106) now allows you to calculate the potentials. For a given trajectory $\mathbf{w}(t')$ the charge and current densities are parametrized by,

$$\boxed{\varrho(\mathbf{r}',t') = q\delta^3(\mathbf{r}'-\mathbf{w}(t')) \qquad \text{and} \qquad \mathbf{j}(\mathbf{r}',t') = \mathbf{v}\varrho(\mathbf{r}',t')} \ . \tag{17.114}$$

However, we need the density at the retarded time t_r [14],

$$\varrho(\mathbf{r}',t_r) = q\int \delta^3(\mathbf{r}'-\mathbf{w}(t'))\delta(t'-t_r)dt' \ . \tag{17.115}$$

We obtain,

$$\begin{aligned}\Phi(\mathbf{r},t) = \frac{q}{4\pi\varepsilon_0}\int\frac{\varrho(\mathbf{r}',t_r)}{|\mathbf{r}-\mathbf{r}'|}d^3r' &= \frac{q}{4\pi\varepsilon_0}\int\int\frac{\delta^3(\mathbf{r}'-\mathbf{w}(t'))}{|\mathbf{r}-\mathbf{r}'|}\delta(t'-t_r)d^3r'dt' \\ &= \frac{q}{4\pi\varepsilon_0}\int\frac{1}{|\mathbf{r}-\mathbf{w}(t')|}\delta(t'-(t-\tfrac{|\mathbf{r}-\mathbf{w}(t')|}{c}))dt' \ ,\end{aligned} \tag{17.116}$$

[14] Can not simply replace $t' \to t_r$ in the argument of $\mathbf{w}(t')$, because t_r implicitly depends on $\mathbf{w}(t')$ via the expression (17.113).

where spatial integration replaced $\mathbf{r}' = \mathbf{w}(t')$.

To evaluate a function $\delta(g(x))$ which depends on another function $g(x)$, we make the substitution,

$$u \equiv g(x) \qquad \text{with} \qquad du = \tfrac{dg}{dx} dx \ , \tag{17.117}$$

such that,

$$\int \delta(g(x))dx = \int \frac{\delta(u)}{|dg/dx|} du = \frac{1}{\left|\frac{dg(x_0)}{dx}\right|} \ , \tag{17.118}$$

where x_0 is defined by $u = g(x_0) = 0$. Applied to our problem, we identify,

$$u = g(t') = t' - \left(t - \tfrac{|\mathbf{r}-\mathbf{w}(t')|}{c}\right) = t' - t_r \ . \tag{17.119}$$

That is, the time when $u = g(t') = 0$ is simply $t' = t_r$. Now, the time derivative is,

$$\frac{dg}{dt'} = 1 + \frac{1}{c}\frac{d}{dt'}|\mathbf{r} - \mathbf{w}(t')| = 1 - \frac{\mathbf{v}(t')}{c} \cdot \frac{\mathbf{r} - \mathbf{w}(t')}{|\mathbf{r} - \mathbf{w}(t')|} \ , \tag{17.120}$$

with $\mathbf{v} \equiv \dot{\mathbf{w}}$. With this, the expression (17.116) becomes,

$$\Phi = \frac{q}{4\pi\varepsilon_0} \int \frac{1}{|\mathbf{r} - \mathbf{w}(t')|} \frac{\delta(u)}{\left|\frac{dg}{dt'}\right|} du = \frac{q}{4\pi\varepsilon_0} \frac{1}{|\mathbf{r} - \mathbf{w}(t_r)|} \frac{1}{|1 - \frac{\mathbf{v}(t_r)}{c} \cdot \frac{\mathbf{r}-\mathbf{w}(t_r)}{|\mathbf{r}-\mathbf{w}(t_r)|}|} \ , \tag{17.121}$$

where the application of the $\delta(u)$ function comes down to replacing t' by t_r. Finally, recalling the abbreviation $\mathbf{R} \equiv \mathbf{r} - \mathbf{w}(t_r)$,

$$\boxed{\Phi(\mathbf{r},t) = \frac{1}{4\pi\varepsilon_0} \frac{qc}{Rc - \mathbf{R}\cdot\mathbf{v}}} \qquad \text{and} \qquad \boxed{\mathbf{A}(\mathbf{r},t) = \frac{\mu_0}{4\pi} \frac{qc\mathbf{v}}{Rc - \mathbf{R}\cdot\mathbf{v}} = \frac{\mathbf{v}}{c^2}\Phi(\mathbf{r},t)} \ , \tag{17.122}$$

where the vector potential is obtained in an analogous way. These are the so-called *Liénard-Wiechert potentials* [15]. In Exc. 17.3.8.12 we calculate the potentials of a point charge in uniform motion.

17.3.7 The fields of a moving point charge

Fields produced by a moving point charge are calculated from the potentials (17.122) using (17.78). The calculation is complicated, because we must evaluate both, distance and speed,

$$\mathbf{R} = \mathbf{r} - \mathbf{w}(t_r) \qquad \text{and} \qquad \mathbf{v} = \dot{\mathbf{w}}(t_r) \tag{17.123}$$

at the retarded time, which is implicitly defined by the equation,

$$R = |\mathbf{r} - \mathbf{w}(t_r)| = c(t - t_r) \ . \tag{17.124}$$

We start with the gradient of the scalar potential (17.122),

$$\nabla\Phi = \frac{qc}{4\pi\varepsilon_0} \frac{-1}{(Rc - \mathbf{R}\cdot\mathbf{v})^2} \nabla(Rc - \mathbf{R}\cdot\mathbf{v}) \ , \tag{17.125}$$

[15] We get the same result from the argument, that light needs a finite time to cross the volume of the charge distribution $d^3r' = dV'$, such that the volume appears stretched at the time instant t_r, $dV' \longrightarrow \frac{dV'}{1-\hat{\mathbf{e}}_r\cdot\mathbf{v}/c}$.

and evaluate both terms separately. Using (17.124) we find,

$$\nabla(Rc) = -c^2 \nabla t_r \ , \tag{17.126}$$

where we leave the calculation of the gradient of retarded time for later. Also, using the rule (21.111)(ix), we find,

$$\nabla(\mathbf{R}\cdot\mathbf{v}) = (\mathbf{R}\cdot\nabla)\mathbf{v} + (\mathbf{v}\cdot\nabla)\mathbf{R} + \mathbf{R}\times(\nabla\times\mathbf{v}) + \mathbf{v}\times(\nabla\times\mathbf{R}) \ . \tag{17.127}$$

The first term of this expression gives,

$$(\mathbf{R}\cdot\nabla)\mathbf{v}(t_r) = R_x\frac{\partial t_r}{\partial x}\frac{d\mathbf{v}}{dt_r} + R_y\frac{\partial t_r}{\partial y}\frac{d\mathbf{v}}{dt_r} + R_z\frac{\partial t_r}{\partial z}\frac{d\mathbf{v}}{dt_r} = \mathbf{a}(\mathbf{R}\cdot\nabla t_r) \ , \tag{17.128}$$

where $\mathbf{a} \equiv \dot{\mathbf{v}}$ is the acceleration at the retarded time. The second term is,

$$(\mathbf{v}\cdot\nabla)\mathbf{R} = (\mathbf{v}\cdot\nabla)\mathbf{r} - (\mathbf{v}\cdot\nabla)\mathbf{w} = \mathbf{v} - \mathbf{v}(\mathbf{v}\cdot\nabla t_r) \ . \tag{17.129}$$

Now, using,

$$\nabla\times\mathbf{v} = \left(\frac{\partial t_r}{\partial y}\frac{dv_z}{dt_r} - \frac{\partial t_r}{\partial z}\frac{dv_y}{dt_r}\right)\hat{\mathbf{e}}_x + ... = -\mathbf{a}\times\nabla t_r \ , \tag{17.130}$$

the third term becomes,

$$\mathbf{R}\times(\nabla\times\mathbf{v}) = -\mathbf{R}\times(\mathbf{a}\times\nabla t_r) \ . \tag{17.131}$$

Finally, using,

$$\nabla\times\mathbf{R} = \cancelto{0}{\nabla\times\mathbf{r}} - \nabla\times\mathbf{w} = \mathbf{v}\times\nabla t_r \ , \tag{17.132}$$

the fourth term is,

$$\mathbf{v}\times(\nabla\times\mathbf{R}) = \mathbf{v}\times(\mathbf{v}\times\nabla t_r) \ . \tag{17.133}$$

With these results the expression (17.127) becomes,

$$\begin{aligned}\nabla(\mathbf{R}\cdot\mathbf{v}) &= \mathbf{a}(\mathbf{R}\cdot\nabla t_r) + \mathbf{v} - \mathbf{v}(\mathbf{v}\cdot\nabla t_r) - \mathbf{R}\times(\mathbf{a}\times\nabla t_r) + \mathbf{v}\times(\mathbf{v}\times\nabla t_r) \\ &= \mathbf{v} + (\mathbf{R}\cdot\mathbf{a} - v^2)\nabla t_r \ ,\end{aligned} \tag{17.134}$$

using in the last step the rule $\mathbf{A}\times(\mathbf{B}\times\mathbf{C}) = \mathbf{B}(\mathbf{A}\cdot\mathbf{C}) - \mathbf{C}(\mathbf{A}\cdot\mathbf{B})$. Now, we calculate ∇t_r,

$$\begin{aligned}\nabla t_r &= -\tfrac{1}{c}\nabla R = -\tfrac{1}{c}\nabla\sqrt{\mathbf{R}\cdot\mathbf{R}} = -\frac{1}{2c\sqrt{\mathbf{R}\cdot\mathbf{R}}}\nabla(\mathbf{R}\cdot\mathbf{R}) \\ &= -\frac{1}{cR}[(\mathbf{R}\cdot\nabla)\mathbf{R} \ + \ \mathbf{R}\times(\nabla\times\mathbf{R})] \\ &= -\frac{1}{cR}[(\mathbf{R}\cdot\nabla)\mathbf{r} - (\mathbf{R}\cdot\nabla)\mathbf{w} \ + \ \mathbf{R}\times(\nabla\times\mathbf{R})] \\ &= -\frac{1}{cR}[\mathbf{R} - \mathbf{v}(\mathbf{R}\cdot\nabla t_r) \ + \ \mathbf{R}\times(\mathbf{v}\times\nabla t_r)] = -\frac{1}{cR}[\mathbf{R} - (\mathbf{R}\cdot\mathbf{v})\nabla t_r)] \ .\end{aligned} \tag{17.135}$$

To get $(\mathbf{R}\cdot\nabla)\mathbf{w}$ we did a calculation similar to (17.128) and $\nabla\times\mathbf{R}$ was already calculated in (17.132). Solving the result (17.135) by ∇t_r,

$$\nabla t_r = -\frac{\mathbf{R}}{cR - \mathbf{R}\cdot\mathbf{v}} \ . \tag{17.136}$$

Finally, the gradient of the scalar potential (17.125) is,

$$\nabla\Phi = \frac{1}{4\pi\varepsilon_0}\frac{qc}{(cR-\mathbf{R}\cdot\mathbf{v})^3}\left[(cR-\mathbf{R}\cdot\mathbf{v})\mathbf{v}-(c^2-v^2+\mathbf{R}\cdot\mathbf{a})\mathbf{R}\right] . \tag{17.137}$$

A similar calculation for the temporal derivative of the vector potential gives the result,

$$\frac{\partial\mathbf{A}}{\partial t} = \frac{1}{4\pi\varepsilon_0}\frac{qc}{(cR-\mathbf{R}\cdot\mathbf{v})^3}\left[(cR-\mathbf{R}\cdot\mathbf{v})(-\mathbf{v}+\frac{R}{c}\mathbf{a})+\frac{R}{c}(c^2-v^2+\mathbf{R}\cdot\mathbf{a})\mathbf{v}\right] . \tag{17.138}$$

The rotation of the vector potential yields,

$$\begin{aligned}\nabla\times\mathbf{A} &= \frac{1}{c^2}\nabla\times(\Phi\mathbf{v}) = \frac{1}{c^2}[\Phi(\nabla\times\mathbf{v})-\mathbf{v}(\nabla\Phi)] \\ &= -\frac{1}{c}\frac{q}{4\pi\varepsilon_0}\frac{1}{(\mathbf{R}\cdot\mathbf{u})^3}\mathbf{R}\times[(c^2-v^2)\mathbf{v}+(\mathbf{R}\cdot\mathbf{a})\mathbf{v}+(\mathbf{R}\cdot\mathbf{u})\mathbf{a}] ,\end{aligned} \tag{17.139}$$

using the expressions (17.130) and (17.137) and introducing the abbreviation $\mathbf{u} \equiv c\hat{\mathbf{e}}_R - \mathbf{v}$.

Combining these results with equations (17.78), we find the fields,

$$\boxed{\vec{\mathcal{E}}(\mathbf{r},t) = \frac{q}{4\pi\varepsilon_0}\frac{R}{(\mathbf{R}\cdot\mathbf{u})^3}[(c^2-v^2)\mathbf{u}+\mathbf{R}\times(\mathbf{u}\times\mathbf{a})]} , \tag{17.140}$$

and,

$$\boxed{\vec{\mathcal{B}}(\mathbf{r},t) = \tfrac{1}{c}\hat{\mathbf{e}}_R\times\vec{\mathcal{E}}(\mathbf{r},t)} . \tag{17.141}$$

Obviously, the magnetic field of a point charge is always perpendicular to the electric field and to the vector of the retarded point. The first term in $\vec{\mathcal{E}}$ (involving $(c^2-v^2)\cdot\mathbf{u}$) falls off like $1/R^2$. If the velocity $\mathbf{v}$ and the acceleration $\mathbf{a}$ were zero, this term survives and reduces to the old electrostatic result (13.3). For this reason, this term is called the generalized Coulomb field. The second term (involving $\mathbf{R}\times(\mathbf{u}\times\mathbf{a})$) falls off like $1/R$ and thus becomes dominant at large distances. As we will see in Sec. 19.4, this is the term responsible for electromagnetic radiation.

Knowing the fields generated by the moving charge q we can, by the laws of the *Coulomb force* and the *Lorentz force*, determine the force acting on a test particle Q located at $\mathbf{r}$ and moving with velocity $\mathbf{V}$,

$$\begin{aligned}\mathbf{F}(\mathbf{r},t) = \frac{qQ}{4\pi\varepsilon_0}\frac{R}{(\mathbf{R}\cdot\mathbf{u})^3}\Big\{&[(c^2-v^2)\mathbf{u}+\mathbf{R}\times(\mathbf{u}\times\mathbf{a})] \\ &+\frac{\mathbf{V}}{c}\times\left[\hat{\mathbf{e}}_R\times[(c^2-v^2)\mathbf{u}+\mathbf{R}\times(\mathbf{u}\times\mathbf{a})]\right]\Big\} ,\end{aligned} \tag{17.142}$$

where $\mathbf{r}$, $\mathbf{u}$, $\mathbf{v}$, and $\mathbf{a}$ are all evaluated at the retarded time. The entire classical electrodynamics is contained in this equation because, since the charge is quantized, we can apply the superposition principle and calculate the impact of any charge distribution on a test particle Q. However, in view of the complexity of (17.142), the necessary effort seems huge. The scheme 17.14 summarizes the fundamental laws of electrodynamics.

Resolve the Excs. 17.3.8.13 to 17.3.8.16.

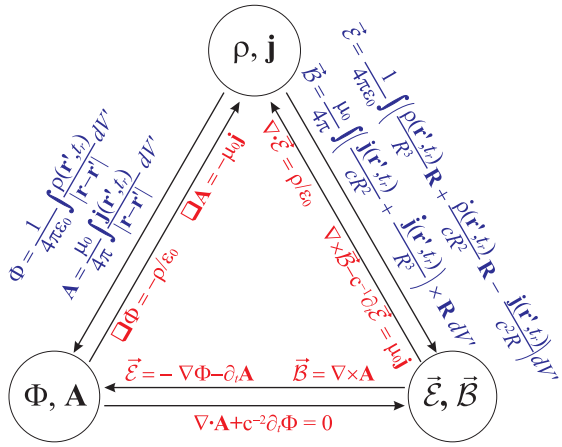

Figure 17.14: Organization chart of the fundamental laws of electrodynamics. Compare with the corresponding charts in electrostatics Fig. 13.11 and magnetostatics Fig. 15.16.

Example 92 (*Electric and magnetic fields generated by a uniformly moving charge*): Letting $\mathbf{a} = 0$ in (17.140),

$$\vec{\mathcal{E}}(\mathbf{r},t) = \frac{q}{4\pi\varepsilon_0}\frac{R}{(\mathbf{R}\cdot\mathbf{u})^3}(c^2-v^2)\mathbf{u}\ ,$$

we can express the position of the charge at the retarded time by its constant velocity, $\dot{\mathbf{w}} = \mathbf{v}$. We calculate using the definition of $\mathbf{u}$,

$$R\mathbf{u} = c\mathbf{R} - R\mathbf{v} = c\mathbf{R} - R\dot{\mathbf{w}} = c(\mathbf{r}-\mathbf{v}t_r) - c(t-t_r)\mathbf{v} = c(\mathbf{r}-\mathbf{v}t)\ .$$

The square of the relationship $|\mathbf{r}-\mathbf{v}t_r| = c(t-t_r)$ resolved by t_r gives,

$$t_r = \frac{(c^2t - \mathbf{r}\cdot\mathbf{v}) \pm \sqrt{(c^2t-\mathbf{r}\cdot\mathbf{v})^2 + (c^2-v^2)(r^2-c^2t^2)}}{c^2-v^2}\ ,$$

where we only consider the sign $-$. With this we calculate,

$$\begin{aligned}\mathbf{R}\cdot\mathbf{u} &= Rc - \mathbf{R}\cdot\mathbf{v} = c^2(t-t_r) - (\mathbf{r}-\mathbf{v}t_r)\cdot\mathbf{v} = c^2t - \mathbf{r}\cdot\mathbf{v} - (c^2-v^2)t_r\\ &= \sqrt{(c^2t-\mathbf{r}\cdot\mathbf{v})^2 + (c^2-v^2)(r^2-c^2t^2)}\\ &= \sqrt{(c^2-v^2)(\mathbf{r}-\mathbf{v}t)^2 + [(\mathbf{r}-\mathbf{v}t)\cdot\mathbf{v}]^2}\\ &= \sqrt{(c^2-v^2)d^2 + (\mathbf{d}\cdot\mathbf{v})^2} = d\sqrt{c^2-v^2+v^2\cos^2\theta} = dc\sqrt{1-\tfrac{v^2}{c^2}\sin^2\theta}\ ,\end{aligned}$$

where the abbreviation $\mathbf{d} \equiv \mathbf{r} - \mathbf{v}t$ is the vector between $\mathbf{r}$ and the *actual position* of the particle and θ is the angle between $\mathbf{d}$ and $\mathbf{v}$. Then,

$$\vec{\mathcal{E}}(\mathbf{r},t) = \frac{q}{4\pi\varepsilon_0}\frac{1-v^2/c^2}{(1-\frac{v^2}{c^2}\sin^2\theta)^{3/2}}\frac{\hat{\mathbf{e}}_d}{d^2}\ .$$

Note that $\vec{\mathcal{E}}$ points along the distance $\mathbf{d}$. This is an extraordinary coincidence; after all, the 'message' came from the retarded position. Because of the $\sin^2\theta$ in the denominator, the field of a charge moving fast is flattened like a pancake

in the direction perpendicular to the motion (see Fig. 17.15). In the forward and backward directions $\vec{\mathcal{E}}$ is reduced by a factor $(1-v^2/c^2)$ with respect to the field of a charge at rest; in the perpendicular direction is amplified by a factor $1/\sqrt{1-v^2/c^2}$.
To get $\vec{\mathcal{B}}$ we calculate,

$$\hat{\mathbf{e}}_R = \frac{\mathbf{r}-\mathbf{v}t_r}{R} = \frac{(\mathbf{r}-\mathbf{v}t)+(t-t_r)\mathbf{v}}{R} = \frac{\mathbf{d}}{R}+\frac{\mathbf{v}}{c}\ ,$$

and hence,

$$\vec{\mathcal{B}} = \tfrac{1}{c}(\hat{\mathbf{e}}_R \times \vec{\mathcal{E}}) = \tfrac{1}{c^2}(\mathbf{v}\times\vec{\mathcal{E}})\ .$$

The $\vec{\mathcal{B}}$-field lines form circles around the charge, as shown in Fig. 17.15. At low velocities, $v \ll c$,

$$\vec{\mathcal{E}}(\mathbf{r},t) = \frac{q}{4\pi\varepsilon_0}\frac{\mathbf{d}}{d^2} \quad , \quad \vec{\mathcal{B}} = \frac{\mu_0 q}{4\pi}\frac{\mathbf{v}\times\hat{\mathbf{e}}_d}{d^2}\ .$$

we recover the laws of Coulomb and Biot-Savart for point charges.

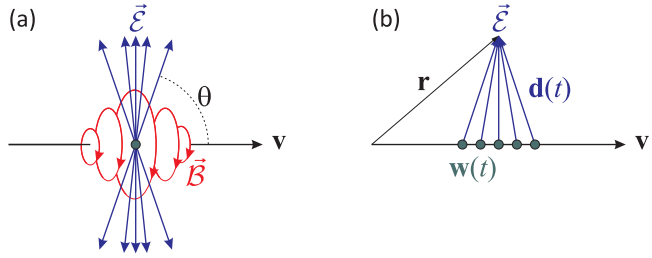

Figure 17.15: (a) Electric and magnetic field generated by of a point charge in uniform motion. (b) Electric field seen from an observation point $\mathbf{r}$ fixed in space.

17.3.8 Exercises

17.3.8.1 Ex: Potentials, fields and the Lorentz gauge

Consider a scalar field and a vector field of the form,

$$\Phi(\mathbf{r},t) = cd\frac{\mathbf{r}\cdot\hat{\mathbf{e}}_z}{r^3}e^{\imath\omega t} \quad \text{and} \quad \mathbf{A}(\mathbf{r},t) = \imath kd\frac{e^{\imath kr}}{r}e^{\imath\omega t}\,\hat{\mathbf{e}}_z\ .$$

where $k=\omega/c$.
a. Calculate the corresponding fields $\vec{\mathcal{B}}$ and $\vec{\mathcal{E}}$.
b. Show that for small r the given potentials satisfy the Lorentz gauge.

Solution: *a. We have for the $\vec{\mathcal{B}}$-field,*

$$\vec{\mathcal{B}} = \nabla\times\mathbf{A} = \begin{pmatrix} \partial_y A_z \\ -\partial_x A_z \\ 0 \end{pmatrix}\ .$$

Now,

$$\partial_i\left(\frac{e^{\imath kr}}{r}\right)=\frac{\imath kre^{\imath kr}\partial_i r-e^{\imath kr}\partial_i r}{r^2}=\frac{e^{\imath kr}}{r}\left(\imath k\frac{x_i}{r}-\frac{x_i}{r^2}\right)\ .$$

Hence,

$$\vec{\mathcal{B}}=\imath kd\frac{e^{\imath kr}}{r}\left(\imath k-\frac{1}{r}\right)e^{\imath\omega t}\begin{pmatrix}y/r\\-x/r\\0\end{pmatrix}=-k^2de^{\imath\omega t}\frac{e^{\imath kr}}{r}\left(1-\frac{1}{\imath kr}\right)(\hat{\mathbf{e}}_r\times\hat{\mathbf{e}}_z)\ .$$

For the $\vec{\mathcal{E}}$-field we have,

$$\vec{\mathcal{E}}=-\nabla\Phi-\frac{1}{c}\frac{\partial\mathbf{A}}{\partial t}=-\nabla\Phi-k^2d\frac{e^{\imath kr}}{r}e^{\imath\omega t}\hat{\mathbf{e}}_z\ .$$

Now,

$$\partial_i\left(\frac{z}{r^3}\right)=\frac{\delta_{iz}}{r^3}-\frac{3zx_i}{r^5}\ .$$

Hence,

$$-\nabla\Phi=-cde^{\imath\omega t}\nabla\frac{z}{r^3}=cde^{\imath\omega t}\frac{3\mathbf{r}(\mathbf{r}\cdot\hat{\mathbf{e}}_z)-r^2\hat{\mathbf{e}}_z}{r^5}\ .$$

and so,

$$\vec{\mathcal{E}}=de^{\imath\omega t}\left[c\frac{3(\mathbf{r}\cdot\hat{\mathbf{e}}_z)\mathbf{r}}{r^5}-\hat{\mathbf{e}}_z\left(c\frac{1}{r^3}-k^2\frac{e^{\imath kr}}{r}\right)\right]\ .$$

b. We have,

$$\nabla\cdot\mathbf{A}=\partial_zA_z=\imath kde^{\imath\omega t}\partial_z\frac{e^{\imath kr}}{r}=-k^2de^{\imath\omega t}\frac{e^{\imath kr}}{r}\left(1-\frac{1}{\imath kr}\right)\frac{z}{r}\ .$$

and

$$\frac{1}{c^2}\frac{\partial\Phi}{\partial t}=\frac{d}{c}\frac{\mathbf{r}\cdot\hat{\mathbf{e}}_z}{r^3}\imath\omega e^{\imath\omega t}=\imath kde^{\imath\omega t}\ \frac{z}{r^3}\ .$$

For small r now holds $e^{\imath kr}\simeq 1$ and the term $1/r^3$ dominates. For this case,

$$\nabla\cdot\mathbf{A}=-\imath kde^{\imath\omega t}\frac{z}{r^3}\ .$$

With this, the Lorentz gauge is satisfied.

17.3.8.2 Ex: Fields, potentials, and the gauge transformation

Find the charge and current distributions producing the following potential,

$$\Phi(\mathbf{r},t)=0\qquad\text{and}\qquad\mathbf{A}(\mathbf{r},t)=\frac{\mu_0k}{4c}(ct-|x|)^2\hat{\mathbf{e}}_z\ \Theta(|x|-ct)\ ,$$

where $k = const.$

Solution: *We calculate the fields,*

$$\vec{\mathcal{E}} = -\nabla\Phi - \frac{\partial \mathbf{A}}{\partial t} = -\frac{\mu_0 k}{2}(ct - |x|)\hat{\mathbf{e}}_z\Theta(ct - |x|) \ ,$$

and

$$\vec{\mathcal{B}} = \nabla \times \mathbf{A} = \frac{\mu_0 k}{4c}\Theta(ct-|x|)\hat{\mathbf{e}}_y\frac{\partial}{\partial x}(ct-|x|)^2 = \frac{\mu_0 k}{4c}\Theta(ct-|x|)\vec{\mathcal{E}}_y 2(ct-|x|)[1-2\Theta(x)] \ .$$

With this we calculate the charge densities,

$$\varrho = \varepsilon_0 \nabla \cdot \vec{\mathcal{E}} = -\varepsilon_0 \frac{\mu_0 k}{2}\Theta(ct - |x|)\frac{\partial}{\partial z}(ct - |x|) = 0 \ ,$$

and the current densities,

$$\begin{aligned}
\mathbf{j} &= \tfrac{1}{\mu_0}\nabla \times \vec{\mathcal{B}} - \varepsilon_0 \frac{\partial \vec{\mathcal{E}}}{\partial t} \\
&= \frac{1}{\mu_0}\frac{\mu_0 k}{4c} 2\Theta(ct - |x|)[1 - 2\Theta(x)]\hat{\mathbf{e}}_z \frac{\partial}{\partial x}(ct - |x|) + \frac{\varepsilon_0\mu_0 ck}{2}\hat{\mathbf{e}}_z\Theta(ct - |x|) \\
&= -\frac{1}{\mu_0}\hat{\mathbf{e}}_z\frac{\mu_0 k}{2c}\Theta(ct - |x|)[1 - 2\Theta(x)]^2 + \frac{\varepsilon_0\mu_0 ck}{2}\hat{\mathbf{e}}_z\Theta(ct - |x|) = 0 \ .
\end{aligned}$$

Of course, here we have a uniform surface current flowing in z-direction on the $x = 0$-plane. It starts at $t = 0$ and increases proportionally with t. Notice that the perturbation travels (in both directions) at the speed of light: for points $|x| > ct$ the perturbation (the notice that the current is now flowing) has not yet arrived, hence, the fields must be zero.

17.3.8.3 Ex: Fields derived from potentials

Show that the differential equations for Φ and $\mathbf{A}$ can be written in a more symmetric form as,

$$\Box\Phi + \frac{\partial L}{\partial t} = -\frac{\varrho}{\varepsilon_0} \qquad \text{and} \qquad \Box\mathbf{A} - \nabla L = -\mu_0\mathbf{j} \ ,$$

where $L \equiv \nabla \cdot \mathbf{A} + \varepsilon_0\mu_0\frac{\partial\Phi}{\partial t}$.

Solution: *We calculate,*

$$\begin{aligned}
\Box\Phi + \frac{\partial L}{\partial t} &= \nabla^2\Phi - \varepsilon_0\mu_0\frac{\partial^2\Phi}{\partial t^2} + \frac{\partial}{\partial t}\left(\nabla \cdot \mathbf{A} + \varepsilon_0\mu_0\frac{\partial\Phi}{\partial t}\right) \\
&= \nabla^2\Phi + \frac{\partial}{\partial t}\nabla \cdot \mathbf{A} = \nabla \cdot \left(\nabla\Phi + \frac{\partial \mathbf{A}}{\partial t}\right) = -\nabla \cdot \vec{\mathcal{E}} = -\frac{\varrho}{\varepsilon_0} \ ,
\end{aligned}$$

and,

$$\begin{aligned}\Box\mathbf{A} - \nabla L &= \nabla^2\mathbf{A} - \varepsilon_0\mu_0\frac{\partial^2\mathbf{A}}{\partial t^2} - \nabla\left(\nabla\cdot\mathbf{A} + \varepsilon_0\mu_0\frac{\partial\Phi}{\partial t}\right)\\ &= \nabla^2\mathbf{A} - \nabla(\nabla\cdot\mathbf{A}) - \varepsilon_0\mu_0\frac{\partial^2\mathbf{A}}{\partial t^2} - \varepsilon_0\mu_0\frac{\partial\nabla\Phi}{\partial t}\\ &= -\nabla\times(\nabla\times\mathbf{A}) - \varepsilon_0\mu_0\frac{\partial^2\mathbf{A}}{\partial t^2} - \varepsilon_0\mu_0\frac{\partial\nabla\Phi}{\partial t} = -\nabla\times\vec{\mathcal{B}} + \varepsilon_0\mu_0\frac{\partial\vec{\mathcal{E}}}{\partial t} = -\mu_0\mathbf{j}\ .\end{aligned}$$

17.3.8.4 Ex: Fields derived from potentials

a. Find the fields and the charge and current distributions corresponding to,

$$\Phi(\mathbf{r},t) = 0 \qquad \text{and} \qquad \mathbf{A}(\mathbf{r},t) = -\frac{1}{4\pi\varepsilon_0}\frac{qt}{r^2}\hat{\mathbf{e}}_r\ .$$

b. Use the gauge function $\chi = -\frac{1}{4\pi\varepsilon_0}\frac{qt}{r}$ to transform the potentials in (a), and comment the result.
c. Check whether the potentials are in the Lorentz or in the Coulomb gauge.

Solution: *a. We find with the relationships (17.78),*

$$\vec{\mathcal{E}} = -\nabla\Phi - \frac{\partial\mathbf{A}}{\partial t} = \frac{1}{4\pi\varepsilon_0}\frac{q}{r^2}\hat{\mathbf{e}}_r\ ,$$

and,

$$\vec{\mathcal{B}} = \nabla\times\mathbf{A} = 0\ .$$

b. The transformed potentials are,

$$\begin{aligned}\Phi' &= \Phi - \frac{\partial\chi}{\partial t} = 0 + \frac{\partial}{\partial t}\frac{qt}{4\pi\varepsilon_0 r} = \frac{q}{4\pi\varepsilon_0 r}\\ \mathbf{A}' &= \mathbf{A} + \nabla\chi = -\frac{qt}{4\pi\varepsilon_0 r^2}\hat{\mathbf{e}}_r - \nabla\frac{qt}{4\pi\varepsilon_0 r} = -\frac{qt}{4\pi\varepsilon_0 r^2}\hat{\mathbf{e}}_r - \frac{qt}{4\pi\varepsilon_0}\frac{-\mathbf{r}}{r^3} = 0\ .\end{aligned}$$

Thus, we see that this is a Colombian potential.
c. For the original potentials we find,

$$\frac{\partial\Phi}{\partial t} = \frac{\partial}{\partial t}0 = 0 \qquad \textit{and} \qquad \nabla\cdot\mathbf{A} = -\nabla\cdot\left(\frac{1}{4\pi\varepsilon_0}\frac{qt}{r^2}\hat{\mathbf{e}}_r\right) = -\frac{qt}{\varepsilon_0}\delta^{(3)}\mathbf{r}\ ,$$

such that they are neither in the Lorentz nor in the Coulomb gauge. For the transformed potentials we find,

$$\frac{\partial\Phi'}{\partial t} = \frac{\partial}{\partial t}\frac{q}{4\pi\varepsilon_0 r} = 0 \qquad \textit{and} \qquad \nabla\cdot\mathbf{A}' = \nabla\cdot\mathbf{0} = 0\ ,$$

such that they satisfy simultaneously both gauges.

17.3.8.5 Ex: Fields derived from potentials

a. Suppose $\Phi = 0$ and $\mathbf{A} = A_0 \sin(kx - \omega t)\hat{\mathbf{e}}_y$, where A_0, ω, and k are constants. Find $\vec{\mathcal{E}}$ and $\vec{\mathcal{B}}$, and verify, that they satisfy Maxwell's equations in vacuum. What conditions should be imposed to ω and k?
b. Check whether the potentials are in the Lorentz or in the Coulomb gauge.

Solution: *We find with the relationships (17.78),*

$$\vec{\mathcal{E}} = -\nabla\Phi - \frac{\partial \mathbf{A}}{\partial t} = \omega A_0 \cos(kx - \omega t)\hat{\mathbf{e}}_y \ ,$$

and,

$$\vec{\mathcal{B}} = \nabla \times \mathbf{A} = kA_0 \cos(kx - \omega t)\hat{\mathbf{e}}_z \ .$$

We calculate,

$$\nabla \times \vec{\mathcal{E}} = -\omega k A_0 \sin(kx - \omega t)\hat{\mathbf{e}}_z = -\frac{\partial \vec{\mathcal{B}}}{\partial t}$$
$$\nabla \times \vec{\mathcal{B}} = k^2 A_0 \sin(kx - \omega t)\hat{\mathbf{e}}_y = \frac{k^2}{\omega^2}\frac{\partial \vec{\mathcal{E}}}{\partial t}$$
$$\nabla \cdot \vec{\mathcal{E}} = 0 = \nabla \cdot \vec{\mathcal{B}} \ .$$

The condition to satisfy Maxwell's law (second equation) is,

$$\frac{k^2}{\omega^2} = \varepsilon_0 \mu_0 = \frac{1}{c^2} \ .$$

b. For the potentials we find,

$$\frac{\partial \Phi}{\partial t} = \frac{\partial}{\partial t} 0 = 0 \qquad \textit{and} \qquad \nabla \cdot \mathbf{A} = \nabla \cdot A_0 \sin(kx - \omega t)\hat{\mathbf{e}}_y = 0 \ ,$$

such that they satisfy simultaneously both gauges.

17.3.8.6 Ex: Other gauges

Check the viability of a gauge defined by $\Phi \equiv 0$ and a gauge defined by $\mathbf{A} \equiv 0$.

Solution: *Allowed gauges χ transform the potentials as,*

$$\mathbf{A}' = \mathbf{A} + \nabla\chi \qquad \textit{and} \qquad \Phi' = \Phi - c^{-1}\partial_t \chi \ .$$

Choosing $\partial_t \chi = c\Phi$ we can design a scalar potential $\Phi' = 0$ yielding the electric and magnetic fields,

$$\vec{\mathcal{E}} = -\frac{\partial \mathbf{A}'}{\partial t} - \cancelto{0}{\nabla\Phi'} = -\frac{\partial(\mathbf{A} + \nabla\chi)}{\partial t} = -\frac{\partial \mathbf{A}}{\partial t} - c\Phi$$
$$\vec{\mathcal{B}} = \nabla \times \mathbf{A}' = \nabla \times (\mathbf{A} + \cancelto{0}{\nabla\chi}) = \nabla \times \mathbf{A} \ .$$

On the other hand, the choice $\mathbf{A} = -\nabla\chi$ does not produce a magnetic field because $\vec{\mathcal{B}} = -\nabla \times (\nabla\chi) = 0$.

17.3.8.7 Ex: Coulomb gauge

a. Show that the vector potential can be expressed by the magnetic field as,

$$\mathbf{A}(\mathbf{r},t) = \nabla \times \int \frac{\vec{\mathcal{B}}(\mathbf{r}',t)}{4\pi|\mathbf{r}-\mathbf{r}'|} d^3r' \ .$$

Show that, given by this expression, the potential vector satisfies the Coulomb gauge.
b. Show that for uniform and constant magnetic fields,

$$\mathbf{A}(\mathbf{r},t) = -\tfrac{1}{2}\mathbf{r} \times \vec{\mathcal{B}} \ .$$

Why can't you use the formula in (a) to solve the problem?

Solution: *a. The ∇ operator does not act on the integration coordinate $\mathbf{r}'$. Therefore, the vector potential can be written,*

$$\mathbf{A}(\mathbf{r},t) = \nabla \times \int \frac{\vec{\mathcal{B}}(\mathbf{r}',t)}{4\pi R} d^3r' = \int \left(\nabla \frac{1}{4\pi R}\right) \times \vec{\mathcal{B}}(\mathbf{r}',t) d^3r' = -\int \frac{\mathbf{r}}{4\pi R^3} \times \vec{\mathcal{B}}(\mathbf{r}',t) d^3r' \ .$$

With this, the rotation becomes,

$$\begin{aligned}
\nabla \times \mathbf{A}(\mathbf{r},t) &= -\int \nabla \times \left[\frac{\mathbf{r}}{4\pi R^3} \times \vec{\mathcal{B}}(\mathbf{r}',t)\right] d^3r' \\
&= \frac{1}{4\pi} \int \left[\vec{\mathcal{B}}(\mathbf{r}',t)\left(\nabla \cdot \frac{\mathbf{r}}{R^3}\right) - \left(\vec{\mathcal{B}}(\mathbf{r}',t) \cdot \nabla\right) \frac{\mathbf{r}}{R^3}\right] d^3r' \\
&= \frac{1}{4\pi} \int \vec{\mathcal{B}}(\mathbf{r}',t) 4\pi\delta(\mathbf{r}) d^3r' + \frac{1}{4\pi} \int \left[\nabla\left(\frac{\mathbf{r}}{R^3} \cdot \vec{\mathcal{B}}(\mathbf{r}',t)\right) - \vec{\mathcal{B}}(\mathbf{r}',t) \times \cancelto{0}{\left(\nabla \times \frac{\mathbf{r}}{R^3}\right)}\right] d^3r' \\
&= \vec{\mathcal{B}}(\mathbf{r},t) + \frac{1}{4\pi} \oint \frac{\mathbf{r}}{R^3} \cdot \vec{\mathcal{B}}(\mathbf{r}',t) d\mathbf{S}' = \vec{\mathcal{B}}(\mathbf{r},t) \ .
\end{aligned}$$

The vector potential satisfies the Coulomb gauge, since its divergence is,

$$\nabla \cdot \mathbf{A}(\mathbf{r},t) = \cancelto{0}{\nabla \cdot \nabla \times} \int \frac{\vec{\mathcal{B}}(\mathbf{r}',t)}{4\pi R} d^3r' = 0 \ .$$

b. For uniform magnetic fields,

$$\nabla \times \mathbf{A}(\mathbf{r},t) = \nabla \times \left(-\tfrac{1}{2}\mathbf{r} \times \vec{\mathcal{B}}\right) = -\tfrac{1}{2}\left(\vec{\mathcal{B}} \cdot \nabla\right)\mathbf{r} + \tfrac{1}{2}\vec{\mathcal{B}}(\nabla \cdot \mathbf{r}) = -\tfrac{1}{2}\vec{\mathcal{B}} + \tfrac{3}{2}\vec{\mathcal{B}} = \vec{\mathcal{B}} \ .$$

The vector potential satisfies the Coulomb gauge, since,

$$\nabla \cdot \mathbf{A}(\mathbf{r},t) = -\nabla \cdot \tfrac{1}{2}(\mathbf{r} \times \vec{\mathcal{B}}) = -\tfrac{1}{2}(\nabla \times \mathbf{r}) \cdot \vec{\mathcal{B}} + \tfrac{1}{2}\mathbf{r} \cdot (\nabla \times \vec{\mathcal{B}}) = 0 \ .$$

To solve the problem, we also could try to use formula in (a) inserting $\vec{\mathcal{B}}(\mathbf{r}',t) = \vec{\mathcal{B}}$. However, the integral diverges at $\mathbf{r}' = \mathbf{r}$.

17.3.8.8 Ex: Green function

Show that $G(\mathbf{r},\mathbf{r}') = \frac{e^{\imath k|\mathbf{r}-\mathbf{r}'|}}{4\pi|\mathbf{r}-\mathbf{r}'|}$ is the Green function of the operator $\mathcal{L} = \nabla^2 + k^2$.

Solution: *We calculate,*

$$\nabla_r^2 \frac{e^{\imath k|\mathbf{r}-\mathbf{r}'|}}{4\pi|\mathbf{r}-\mathbf{r}'|} = \nabla_R^2 \frac{e^{\imath kR}}{4\pi R} = \frac{1}{R^2}\frac{\partial}{\partial R}\left(R^2 \frac{\partial}{\partial R}\frac{e^{\imath kR}}{4\pi R}\right) = -k^2\frac{e^{\imath kR}}{4\pi R} = -k^2\frac{e^{\imath k|\mathbf{r}-\mathbf{r}'|}}{4\pi|\mathbf{r}-\mathbf{r}'|}$$

.

17.3.8.9 Ex: Gauge of retarded potentials

Confirm, that retarded potentials (17.106) are in the Lorentz gauge.

Solution: *From the retarded potentials,*

$$\Phi(\mathbf{r},t) = \frac{1}{4\pi\varepsilon_0}\int \frac{\varrho(\mathbf{r}',t_r)}{R}d^3r' \qquad \textit{and} \qquad \mathbf{A}(\mathbf{r},t) = \frac{\mu_0}{4\pi}\int \frac{\mathbf{j}(\mathbf{r}',t_r)}{R}d^3r'$$

we calculate the derivatives,

$$\frac{d}{dt}\Phi(\mathbf{r},t) = \frac{1}{4\pi\varepsilon_0}\int \frac{\dot{\varrho}(\mathbf{r}',t_r)}{R}d^3r' \qquad \textit{and} \qquad \nabla\cdot\mathbf{A}(\mathbf{r},t) = \frac{\mu_0}{4\pi}\int \nabla\cdot\frac{\mathbf{j}(\mathbf{r}',t_r)}{R}d^3r' \ .$$

To evaluate the divergence of the vector potential we first calculate,

$$\nabla\cdot\frac{\mathbf{j}}{R} - \frac{1}{R}\nabla\cdot\mathbf{j} = \mathbf{j}\cdot\nabla\frac{1}{R} = -\mathbf{j}\cdot\nabla'\frac{1}{R} = -\nabla'\cdot\frac{\mathbf{j}(\mathbf{r}',t-R/c)}{R} + \frac{1}{R}\nabla'\cdot\mathbf{j} \ .$$

We now calculate the divergence of the current,

$$\nabla'\cdot\mathbf{j}(\mathbf{r}',t-R/c) = \frac{\partial\mathbf{j}}{\partial\mathbf{r}'} + \frac{\partial\mathbf{j}}{\partial t_r}\cdot\nabla' t_r = \frac{\partial\mathbf{j}}{\partial\mathbf{r}'} - \frac{\partial\mathbf{j}}{\partial t_r}\cdot\nabla t_r = \frac{\partial\mathbf{j}}{\partial\mathbf{r}'} - \nabla\cdot\mathbf{j}(\mathbf{r}',t-R/c) \ ,$$

where we defined the explicit spatial derivative, $\frac{\partial\mathbf{j}}{\partial\mathbf{r}'}$. *We conclude,*

$$\begin{aligned}
\nabla\cdot\mathbf{A}(\mathbf{r},t) &= \frac{\mu_0}{4\pi}\int \nabla\cdot\frac{\mathbf{j}(\mathbf{r}',t_r)}{R}d^3r' \\
&= \frac{\mu_0}{4\pi}\int\left[-\nabla'\cdot\frac{\mathbf{j}(\mathbf{r}',t-R/c)}{R} + \frac{1}{R}\nabla'\cdot\mathbf{j} + \frac{1}{R}\nabla\cdot\mathbf{j}\right]d^3r' \\
&= \frac{\mu_0}{4\pi}\cancelto{0}{\oint\frac{\mathbf{j}(\mathbf{r}',t-R/c)}{R}\cdot d\mathbf{S}} + \frac{\mu_0}{4\pi}\int\frac{1}{R}\cancelto{-\dot{\varrho}}{\frac{\partial\mathbf{j}}{\partial\mathbf{r}'}}d^3r' = -\varepsilon_0\mu_0\frac{d}{dt}\Phi(\mathbf{r},t) \ .
\end{aligned}$$

17.3.8.10 Ex: Jefimenko with constant current

Suppose that $\mathbf{j}(\mathbf{r})$ is constant in time, such that $\varrho(\mathbf{r},t) = \varrho(\mathbf{r},0) + \dot{\varrho}(\mathbf{r},0)t$. Demonstrate the validity of Coulomb's law with the charge density evaluated at the *non-retarded* time.

Solution: *Jefimenko's expression for the electric field is,*

$$\begin{aligned}\vec{\mathcal{E}}(\mathbf{r},t) &= \frac{1}{4\pi\varepsilon_0}\int\left[\frac{\varrho(\mathbf{r}',t_r)}{R^2}\hat{\mathbf{e}}_r + \frac{\dot{\varrho}(\mathbf{r}',t_r)}{cR}\hat{\mathbf{e}}_r - \frac{\cancelto{0}{\dot{\mathbf{j}}(\mathbf{r}',t_r)}}{c^2R}\right]d^3r' \\ &= \frac{1}{4\pi\varepsilon_0}\int\frac{\varrho(\mathbf{r}',t_r) + \frac{R}{c}\dot{\varrho}(\mathbf{r}',t_r)}{R^2}\hat{\mathbf{e}}_r d^3r' \ .\end{aligned}$$

Now,

$$\varrho(\mathbf{r}',t_r) + \tfrac{R}{c}\dot{\varrho}(\mathbf{r}',t_r) = \left[\varrho(\mathbf{r}',0) + \dot{\varrho}(\mathbf{r}',0)(t - \tfrac{R}{c})\right] + \tfrac{R}{c}\dot{\varrho}(\mathbf{r}',0) = \varrho(\mathbf{r}',t) \ .$$

17.3.8.11 Ex: Jefimenko with slowly varying current

Suppose a current density varying sufficiently slowly so that we can ignore all higher derivatives of the Taylor expansion $\mathbf{j}(\mathbf{r},t_r) = \mathbf{j}(\mathbf{r},t) + (t_r - t)\dot{\mathbf{j}}(\mathbf{r},t_r) + ...$ Demonstrate the validity of the Biot-Savart law with the charge density evaluated at the *non-retarded* time. This means that the quasi-static approximation is much better than could have expected.

Solution: *Jefimenko's expression for the magnetic field is,*

$$\vec{\mathcal{B}}(\mathbf{r},t) = \frac{\mu_0}{4\pi}\int\left[\frac{\mathbf{j}(\mathbf{r}',t_r)}{R^2} + \frac{\dot{\mathbf{j}}(\mathbf{r}',t_r)}{cR}\right]\times\hat{\mathbf{e}}_r d^3r' = \frac{\mu_0}{4\pi}\int\frac{\mathbf{j}(\mathbf{r}',t_r) + \frac{R}{c}\dot{\mathbf{j}}(\mathbf{r}',t_r)}{R^2}\times\hat{\mathbf{e}}_r d^3r' \ .$$

Now,

$$\mathbf{j}(\mathbf{r}',t_r) + \tfrac{R}{c}\dot{\mathbf{j}}(\mathbf{r}',t_r) = \mathbf{j}(\mathbf{r}',t) \ .$$

This looks like an adiabaticity condition: either *the variation is slow,* or *nearby.*

17.3.8.12 Ex: Potentials of a point charge in uniform motion

a. Calculate the potentials (17.122) produced by the uniform motion, $w(t) = \mathbf{v}t$, of a charge q.
b. Verify that these potentials satisfy the Lorentz gauge.

Solution: *a. For this, we need to express the retarded time given by* $|\mathbf{r} - \mathbf{v}t_r| = c(t - t_r)$*, that is,*

$$r^2 - 2\mathbf{r}\cdot\mathbf{v}t_r + v^2t_r^2 = c^2(t^2 - 2tt_r + t_r^2) \ .$$

Resolving by t_r,

$$t_r = \frac{c^2t - \mathbf{r}\cdot\mathbf{v} \pm \sqrt{(c^2t-\mathbf{r}\cdot\mathbf{v})^2 + (c^2-v^2)(r^2-c^2t^2)}}{c^2-v^2} \ .$$

As this formula, for the case $\mathbf{v}=0$, simplifies to $t_r = t \pm \frac{r}{c}$, we can eliminate the positive sign. Now we calculate,

$$\begin{aligned}\mathcal{D} \equiv Rc - \mathbf{R}\cdot\mathbf{v} &= c(t-t_r)c - (\mathbf{r}-\mathbf{v}t_r)\cdot\mathbf{v} \\ &= c^2t - \mathbf{r}\cdot\mathbf{v} - (c^2-v^2)t_r = \sqrt{(c^2t-\mathbf{r}\cdot\mathbf{v})^2 + (c^2-v^2)(r^2-c^2t^2)} \ ,\end{aligned}$$

where we replaced t_r in the last step. Therefore,

$$\boxed{\Phi(\mathbf{r},t) = \frac{1}{4\pi\varepsilon_0}\frac{qc}{\mathcal{D}} \qquad \textit{and} \qquad \mathbf{A}(\mathbf{r},t) = \frac{\mu_0}{4\pi}\frac{qc\mathbf{v}}{\mathcal{D}}} \ .$$

Using the substitution $\mathbf{r} = \mathbf{r} - \mathbf{v}t$ and the angle θ between $\mathbf{r}$ and $\mathbf{v}$ we can simplify the expressions. We calculate $\mathbf{r}\cdot\mathbf{v} = v^2t + Rv\cos\theta$ and $r^2 = R^2 + v^2t^2 + 2Rvt\cos\theta$. Thereby,

$$\begin{aligned}\mathcal{D} &= \sqrt{(c^2t-\mathbf{r}\cdot\mathbf{v})^2 + (c^2-v^2)(r^2-c^2t^2)} \\ &= \sqrt{(c^2t - v^2t - Rv\cos\theta)^2 + (c^2-v^2)(R^2+v^2t^2+2Rvt\cos\theta - c^2t^2)} \\ &= R\sqrt{1 - v^2\sin^2\theta/c^2} \ .\end{aligned}$$

Finally,

$$\boxed{\Phi(\mathbf{r},t) = \frac{1}{4\pi\varepsilon_0}\frac{q}{R\sqrt{1-\beta^2\sin^2\theta}} \qquad \textit{and} \qquad \mathbf{A}(\mathbf{r},t) = \frac{\mu_0}{4\pi}\frac{q\mathbf{v}}{R\sqrt{1-\beta^2\sin^2\theta}}} \ .$$

Of course, for low velocities, we recover the laws of Coulomb and Biot-Savart.
b. The potentials of a point charge passing through the origin at time $t=0$ are,

$$\Phi(\mathbf{r},t) = \frac{1}{4\pi\varepsilon_0}\frac{qc}{\sqrt{(c^2t-\mathbf{r}\cdot\mathbf{v})^2 + (c^2-v^2)(r^2-c^2t^2)}} \qquad , \qquad \mathbf{A}(\mathbf{r},t) = \varepsilon_0\mu_0\mathbf{v}\Phi(\mathbf{r},t) \ .$$

We calculate the time derivative of the scalar potential,

$$\begin{aligned}\frac{\partial\mathbf{\Phi}}{\partial t} &= \frac{qc}{4\pi\varepsilon_0}\frac{-1}{2\sqrt{(c^2t-\mathbf{r}\cdot\mathbf{v})^2 + (c^2-v^2)(r^2-c^2t^2)}^3}\frac{d}{dt}\left[(c^2t-\mathbf{r}\cdot\mathbf{v})^2 + (c^2-v^2)(r^2-c^2t^2)\right] \\ &= \frac{qc^3}{4\pi\varepsilon_0}\frac{\mathbf{r}\cdot\mathbf{v} - tv^2}{\sqrt{(c^2t-\mathbf{r}\cdot\mathbf{v})^2 + (c^2-v^2)(r^2-c^2t^2)}^3} \ ,\end{aligned}$$

and the divergence of the vector potential,

$$\begin{aligned}\nabla\cdot\mathbf{A} &= \frac{\mu_0qc}{4\pi}\mathbf{v}\cdot\nabla\frac{1}{\sqrt{(c^2t-\mathbf{r}\cdot\mathbf{v})^2 + (c^2-v^2)(r^2-c^2t^2)}} \\ &= -\frac{\mu_0qc}{4\pi}v_x\frac{-v_x(c^2t-\mathbf{r}\cdot\mathbf{v}) + (c^2-v^2)x}{\sqrt{(c^2t - xv_x - yv_y - zv_z)^2 + (c^2-v^2)(x^2+y^2+z^2-c^2t^2)}^3} + \ldots \\ &= -\frac{\mu_0qc^3}{4\pi}\frac{-v^2t + \mathbf{r}\cdot\mathbf{v}}{\sqrt{(c^2t-\mathbf{r}\cdot\mathbf{v})^2 + (c^2-v^2)(r^2-c^2t^2)}^3} \ .\end{aligned}$$

17.3.8.13 Ex: Liénard-Wiechert potentials for a rotating charge

A particle of charge q moves circularly with constant angular velocity ω in the center of the x-y-plane. At time $t = 0$ the charge is at the position $(a, 0)$. Find the Liénard-Wiechert potentials for the points of the z-axis.

Solution: *We parametrize the position and the velocity of the motion by,*

$$\mathbf{w}(t) = a\hat{\mathbf{e}}_x \cos\omega t + a\hat{\mathbf{e}}_y \sin\omega t \qquad \textit{and} \qquad \mathbf{v}(t) = \dot{\mathbf{w}} = -a\omega\hat{\mathbf{e}}_x \sin\omega t + a\omega\hat{\mathbf{e}}_y \cos\omega t \ .$$

For the observation point $\mathbf{r} = z\hat{\mathbf{e}}_z$ *the retarded time,*

$$t_r = t - \frac{|\mathbf{r} - \mathbf{w}(t)|}{c} = t - \frac{\sqrt{z^2 + a^2}}{c}$$

is independent of the position of the charge. Thus, the potentials are,

$$\Phi(\mathbf{r}, t) = \frac{1}{4\pi\varepsilon_0} \frac{qc}{Rc - \cancelto{0}{\mathbf{R}\cdot\mathbf{v}}} = \frac{1}{4\pi\varepsilon_0} \frac{q}{\sqrt{z^2 + a^2}} \qquad \textit{and} \qquad \mathbf{A}(\mathbf{r}, t) = \frac{\mathbf{v}}{c^2}\Phi(\mathbf{r}, t) \ .$$

17.3.8.14 Ex: Point charge moving on a straight line

Assume that a point charge q is constrained to move along the x-axis. Calculate the fields at points on the axis in front of and behind the charge.

Solution: *The fields generated by a fast moving charge are given by,*

$$\vec{\mathcal{E}}(\mathbf{r}, t) = \frac{q}{4\pi\varepsilon_0} \frac{R}{(\mathbf{r}\cdot\mathbf{u})^3}[(c^2 - v^2)\mathbf{u} + \mathbf{r} \times (\mathbf{u} \times \mathbf{a})] \qquad \textit{and} \qquad \vec{\mathcal{B}}(\mathbf{r}, t) = \frac{1}{c}\mathbf{r} \times \vec{\mathcal{E}}(\mathbf{r}, t) \ .$$

The confinement of the charge on the x-axis results in,

$$\mathbf{w}(t_r) = w(t_r)\hat{\mathbf{e}}_x \quad , \quad \mathbf{v}(t_r) = v(t_r)\hat{\mathbf{e}}_x \quad , \quad \mathbf{a}(t_r) = a(t_r)\hat{\mathbf{e}}_x \quad , \quad \mathbf{u}(t_r) \equiv c\hat{\mathbf{e}}_r - \mathbf{v} = c\hat{\mathbf{e}}_r - v\hat{\mathbf{e}}_x \ .$$

The observer be also on the x-axis, $\mathbf{r} = r\hat{\mathbf{e}}_x$*, in front of the charge,*

$$\mathbf{R} = \mathbf{r} - \mathbf{w}(t_r) = (r - w)\hat{\mathbf{e}}_x = R\hat{\mathbf{e}}_x \qquad \textit{with} \qquad r > w \ .$$

With this, we deduce,

$$\hat{\mathbf{e}}_r = \hat{\mathbf{e}}_x \qquad , \qquad \mathbf{u}(t_r) = (c - v)\hat{\mathbf{e}}_x \qquad , \qquad \mathbf{u} \times \mathbf{a} = 0 \ .$$

Under these conditions, the fields simplify to,

$$\vec{\mathcal{E}}(\mathbf{r}, t) = \frac{q}{4\pi\varepsilon_0} \frac{R}{(\mathbf{r}\cdot\mathbf{u})^3}(c^2 - v^2)\mathbf{u} = \frac{q}{4\pi\varepsilon_0} \frac{c + v}{c - v} \frac{\hat{\mathbf{e}}_x}{R^2} \qquad \textit{and} \qquad \vec{\mathcal{B}}(\mathbf{r}, t) = \frac{1}{c}\mathbf{r} \times \vec{\mathcal{E}}(\mathbf{r}, t) = 0 \ .$$

When is the charge behind, $r < w$, we must replace $v \to -v$ in the equations. Alternatively, we may use the Liénard-Wiechert potentials (17.122),

$$\Phi = \frac{1}{4\pi\varepsilon_0} \frac{qc}{Rc - \mathbf{R}\cdot\mathbf{v}} \qquad , \qquad \mathbf{A} = \frac{\mathbf{v}}{c^2}\Phi \ .$$

For a motion on a straight line, $\mathbf{r} = r\hat{\mathbf{e}}_x$, $\mathbf{v} = v\hat{\mathbf{e}}_x$, $\mathbf{R} = R\hat{\mathbf{e}}_x$, *we simplify,*

$$\Phi = \frac{1}{4\pi\varepsilon_0}\frac{qc}{R(c-v)} \quad , \quad \mathbf{A} = \frac{1}{4\pi\varepsilon_0}\frac{qv\hat{\mathbf{e}}_x}{cR(c-v)} \ .$$

Using (17.136), we calculate the derivatives of R,

$$\nabla R = -c\nabla t_r = -c\frac{-\mathbf{R}}{cR - \mathbf{R}\cdot\mathbf{v}} = \frac{c}{c-v}\hat{\mathbf{e}}_x$$
$$\frac{\partial R}{\partial t} = \frac{\partial(r - vt_r)}{\partial t} = -v\frac{\partial t_r}{\partial t} = -v\frac{\partial(t - \frac{R}{c})}{\partial t} = -v\left(1 - \frac{\partial R}{\partial ct}\right) = \frac{-v}{1-\frac{v}{c}} \ ,$$

using $R = r - vt_r$ *and* $t_r = t - \frac{R}{c}$. *This yields the derivatives of the potentials,*

$$\nabla\Phi = \frac{qc}{4\pi\varepsilon_0(c-v)}\nabla\frac{1}{R} = \frac{qc}{4\pi\varepsilon_0(c-v)}\frac{-1}{R^2}\nabla R = \frac{-qc^2}{4\pi\varepsilon_0 R^2(c-v)^2}\hat{\mathbf{e}}_x \ ,$$

using,

$$\frac{\partial\mathbf{A}}{\partial t} = \frac{1}{4\pi\varepsilon_0}\frac{qv\hat{\mathbf{e}}_x}{c(c-v)}\frac{\partial}{\partial t}\frac{1}{R} = \frac{1}{4\pi\varepsilon_0}\frac{qv\hat{\mathbf{e}}_x}{c(c-v)}\frac{-1}{R^2}\frac{\partial}{\partial t}R = \frac{1}{4\pi\varepsilon_0}\frac{qv^2}{R^2(c-v)^2}\hat{\mathbf{e}}_x \ .$$

Finally,

$$\vec{\mathcal{E}} = -\nabla\Phi - \frac{\partial\mathbf{A}}{\partial t} = \frac{q(c+v)\hat{\mathbf{e}}_x}{4\pi\varepsilon_0 R^2(c-v)} \ .$$

17.3.8.15 Ex: Charge on a hyperbolic motion

Determine the Liénard-Wiechert potentials for a charge on a hyperbolic motion, i.e. $\mathbf{w}(t) = \hat{\mathbf{e}}_x\sqrt{b^2 + c^2t^2}$.

Solution: *The motion corresponds to a reflection of a charge coming from and going back to* $+\infty$ *with the velocity,*

$$\mathbf{v}(t) = \frac{d\mathbf{w}}{dt} = \frac{c^2t\hat{\mathbf{e}}_x}{\sqrt{b^2 + c^2t^2}} \ .$$

We derive the retarded time from,

$$|\mathbf{r} - \mathbf{w}(t_r)| = c(t - t_r) \ .$$

We are only considering observation points on the axis $\mathbf{r} = x\hat{\mathbf{e}}_x$ *to the right side of the charge, that is for* $x > w$. *Then,*

$$x - \sqrt{b^2 + c^2t_r^2} = c(t - t_r) \ ,$$

that is,

$$t_r = \frac{b^2 - (x - ct)^2}{2c(x - ct)} \ .$$

Note that for $t = 0$ and when $x \to \infty$ we have $t_r \to \infty$, which makes sense, since further on the x-axis we place the observer, further we must go to the past to get a signal of the charge. We can substitute this in the trajectory of the charge,

$$\mathbf{w}(t_r) = \hat{\mathbf{e}}_x\sqrt{b^2 + c^2t_r^2} = \hat{\mathbf{e}}_x\sqrt{\frac{1}{4}\frac{(x^2 - 2xct + c^2t^2 + b^2)^2}{(ct - x)^2}} = \pm\hat{\mathbf{e}}_x\frac{(x - ct)^2 + b^2}{2(ct - x)} \ .$$

To determine the correct signal, we consider the point $t = 0$, where $\mathbf{w}(t_r)$ must be positive. We see that we should choose the negative sign,

$$\mathbf{r} = \mathbf{r} - \mathbf{w}(t_r) = \hat{\mathbf{e}}_x(x - \frac{(x - ct)^2 + b^2}{2(x - ct)}) = \frac{\hat{\mathbf{e}}_x}{2}\frac{x^2 - c^2t^2 - b^2}{x - ct} \ .$$

The velocity at the retarded time is,

$$\mathbf{v}(t_r) = \frac{c^2t_r\hat{\mathbf{e}}_x}{\sqrt{b^2 + c^2t_r^2}} = \frac{c^2}{\sqrt{b^2 + c^2\left(\frac{b^2-(x-ct)^2}{2c(x-ct)}\right)^2}}\left(\frac{b^2 - (x - ct)^2}{2c(x - ct)}\right)\hat{\mathbf{e}}_x = \pm c\frac{b^2 - (x - ct)^2}{(x - ct)^2 + b^2}\hat{\mathbf{e}}_x \ .$$

To determine the correct sign, we consider the point $t = 0$. For large x, the signal from the charge comes at a distant past, while it was moving toward the origin. Then we must have a negative velocity using the negative sign. Finally, we were able to calculate the potential,

$$\begin{aligned}\Phi(\mathbf{r}, t) &= \frac{1}{4\pi\varepsilon_0}\frac{qc}{Rc - \mathbf{r}\cdot\mathbf{v}} = \frac{1}{4\pi\varepsilon_0}\frac{qc}{\frac{c}{2}\frac{x^2-c^2t^2-b^2}{x-ct} - \frac{x^2-c^2t^2-b^2}{2(x-ct)}c\frac{b^2-(x-ct)^2}{(x-ct)^2+b^2}} \\ &= \frac{q}{4\pi\varepsilon_0}\frac{(x - ct)^2 + b^2}{(x - ct)(x^2 - c^2t^2 - b^2)} \ .\end{aligned}$$

17.3.8.16 Ex: Actio=reactio with the Lorentz force

Suppose that two charges in uniform motion, the first one along the x-axis and the second along the y-axis, are at the origin at time $t = 0$. Calculate the reciprocal Coulomb-Lorentz forces.

Solution: *The force exerted by a charge q in accelerated motion on another test charge Q with instantaneous velocity $\mathbf{V}$ has been derived in (17.142) and in example 92. If the source charge q is not accelerated, the expression simplifies to,*

$$\begin{aligned}\mathbf{F}(\mathbf{r}, t) &= \frac{qQ}{4\pi\varepsilon_0}\frac{(c^2 - v^2)R}{(\mathbf{R}\cdot\mathbf{u})^3}\left\{\mathbf{u} + \frac{\mathbf{V}}{c}\times(\hat{\mathbf{e}}_R\times\mathbf{u})\right\} \\ &= \frac{qQ}{4\pi\varepsilon_0}\frac{1 - \beta^2}{d^2\sqrt{1 - \beta^2\sin^2\theta}^3}\left\{\hat{\mathbf{e}}_d + \frac{\mathbf{V}}{c}\times\left(\frac{\mathbf{v}}{c}\times\hat{\mathbf{e}}_d\right)\right\} \ ,\end{aligned}$$

with the abbreviations $\mathbf{u} \equiv c\hat{\mathbf{e}}_R - \mathbf{v}$, the distance between the position of the test charge and the retarded *position of the source charge, $\mathbf{R} \equiv \mathbf{r} - \mathbf{w}(t_r)$, and the distance*

between the position of the test charge and the actual *position of the source charge,* $\mathbf{d} \equiv \mathbf{r} - \mathbf{w}(t)$.
Now consider the following situation: The test charge Q, located at position $\mathbf{r}$ where the fields and the Coulomb-Lorentz force have to be evaluated, moves along the x-axis, such that $\mathbf{r} = Vt\hat{\mathbf{e}}_x$ and $\mathbf{V} = V\hat{\mathbf{e}}_x$. The charge q producing the field moves uniformly along the y-axis, such that $\mathbf{a} = 0$ and $\mathbf{v} = v\hat{\mathbf{e}}_y$ and $\mathbf{w}(t) = vt\hat{\mathbf{e}}_y$. Then,

$$\mathbf{d} = Vt\hat{\mathbf{e}}_x - vt\hat{\mathbf{e}}_y \qquad \text{and} \qquad \hat{\mathbf{e}}_d = \frac{Vt\hat{\mathbf{e}}_x - vt\hat{\mathbf{e}}_y}{|Vt\hat{\mathbf{e}}_x - vt\hat{\mathbf{e}}_y|} = \frac{V\hat{\mathbf{e}}_x - v\hat{\mathbf{e}}_y}{\sqrt{V^2+v^2}} \ .$$

With that, the force is,

$$\begin{aligned}\mathbf{F}(x,t) &= \frac{qQ}{4\pi\varepsilon_0}\frac{1-\beta^2}{d^2\sqrt{1-\beta^2\sin^2\theta}^3}\left\{\frac{V\hat{\mathbf{e}}_x - v\hat{\mathbf{e}}_y}{\sqrt{V^2+v^2}} + \frac{V\hat{\mathbf{e}}_x}{c}\times\left(\frac{v\hat{\mathbf{e}}_y}{c}\times\frac{V\hat{\mathbf{e}}_x - v\hat{\mathbf{e}}_y}{\sqrt{V^2+v^2}}\right)\right\} \\ &= \frac{qQ}{4\pi\varepsilon_0}\frac{1-\beta^2}{t^2\sqrt{1-\beta^2\sin^2\theta}^3\sqrt{V^2+v^2}^3}\left\{V\hat{\mathbf{e}}_x - v\hat{\mathbf{e}}_y + \frac{vV^2}{c^2}\hat{\mathbf{e}}_y\right\} \ .\end{aligned}$$

Assuming equal velocities, $v = V$,

$$\mathbf{F}(x,t) = \frac{qQ}{4\pi\varepsilon_0}\frac{1-\beta^2}{t^2\sqrt{1-\beta^2\sin^2\theta}^3\sqrt{2}^3}\{\hat{\mathbf{e}}_x - (1-\beta^2)\hat{\mathbf{e}}_y\} \ .$$

Assuming low velocities,

$$\mathbf{F}(x,t) = \frac{qQ}{4\pi\varepsilon_0}\frac{1}{t^2\sqrt{V^2+v^2}^3}\{V\hat{\mathbf{e}}_x - v\hat{\mathbf{e}}_y\} \ .$$

Chapter 18

Electromagnetic waves

The phenomenon of waves is usually introduced in undergraduate Physics courses. We already discussed that, unlike classical longitudinal or transverse waves, *electromagnetic waves* do not require a propagation medium, but move through the vacuum with the speed of light. And we showed that the wave equation is form-invariant to the Lorentz, but not to the Galilei transform [1].

The electromagnetic waves are generated when charges change their positions. Therefore, the theory of electromagnetic waves is also a consequence of electrodynamic theory, which is summarized in the *Maxwell equations*. In this chapter we will consider these equations as given and deduce from them the properties of electromagnetic waves.

18.1 Wave propagation

By *wave* we mean the propagation of a perturbation $f(\mathbf{r},t)$, which can be a scalar or vector quantity. When it propagates in one dimension, the wave is described by the *wave equation*,

$$\frac{\partial^2 f}{\partial z^2} = \frac{1}{v^2}\frac{\partial^2 f}{\partial t^2} \ , \tag{18.1}$$

where v is the propagation velocity of the wave. The most common waveform is the sine wave,

$$f(z,t) = A\cos(kz-\omega t+\delta) = \mathfrak{Re}\ [\tilde{A}e^{\imath(kz-\omega t)}] = \mathfrak{Re}\ \tilde{f}(z,t) \ , \tag{18.2}$$

in complex notation (often ornamented by a tilde) introducing the complex amplitude $\tilde{A} \equiv Ae^{\imath\delta}$. The wave equation satisfies the superposition principle allowing for the expansion of any wave type according to,

$$\tilde{f}(z,t) = \int_{-\infty}^{\infty} \tilde{A}(k)e^{\imath(kz-\omega t)}dk \ . \tag{18.3}$$

We will show in Exc. 18.1.8.1, that all functions satisfying $f(z,t) = g(z \pm vt)$ automatically obey the wave equation. The most general solution of the wave equation is given by,

$$f(z,t) = g_1(z-vt) + g_2(z+vt) \ . \tag{18.4}$$

We show this in the following example directly generalizing to three dimensions.

[1] See script on *Vibrations and waves* (2020), Sec. 2.2.3.

Example 93 (*General solution of the wave equation*): The three-dimensional wave equation is,

$$\frac{1}{c^2}\frac{\partial^2 f}{\partial t^2} - \nabla^2 f = 0 \ .$$

Using for the Dirac function the representation, $\delta^{(3)}(\mathbf{r}-\mathbf{r}') = \frac{1}{(2\pi)^3}\int d^3k e^{\imath \mathbf{k}\cdot(\mathbf{r}-\mathbf{r}')}$, we can write,

$$\begin{aligned} f(\mathbf{r},t) &= \int_{V_\infty} d^3r' \delta^{(3)}(\mathbf{r}-\mathbf{r}') f(\mathbf{r}',t) \\ &= \int d^3k e^{\imath \mathbf{k}\cdot\mathbf{r}} \int_{V_\infty} d^3r' \tfrac{e^{-\imath \mathbf{k}\cdot\mathbf{r}'}}{(2\pi)^3} f(\mathbf{r}',t) = \int d^3k e^{\imath \mathbf{k}\cdot\mathbf{r}} A(\mathbf{k},t) \ , \end{aligned}$$

where $A(\mathbf{k},t) \equiv \int_{V_\infty} d^3r' \frac{1}{(2\pi)^3} e^{-\imath \mathbf{k}\cdot\mathbf{r}'} f(\mathbf{r}',t)$ is the Fourier transform of f. Applying the operator $\nabla^2 - \frac{1}{c^2}\frac{\partial^2}{\partial t^2}$ to the expression for f gives,

$$\begin{aligned} 0 = \frac{1}{c^2}\frac{\partial^2 f}{\partial t^2} - \nabla^2 f &= \frac{1}{c^2}\int d^3k e^{\imath \mathbf{k}\cdot\mathbf{r}} \frac{\partial^2 A(\mathbf{k},t)}{\partial t^2} - \int d^3k A(\mathbf{k},t) \nabla^2 e^{\imath \mathbf{k}\cdot\mathbf{r}} \\ &= \int d^3k e^{\imath \mathbf{k}\cdot\mathbf{r}} \left[\frac{1}{c^2}\frac{\partial^2 A(\mathbf{k},t)}{\partial t^2} + k^2 A(\mathbf{k},t) \right] \ . \end{aligned}$$

Hence,

$$\frac{1}{c^2}\frac{\partial^2 A(\mathbf{k},t)}{\partial t^2} + k^2 A(\mathbf{k},t) = 0 \ .$$

The general solution of this equation can be written as,

$$A(\mathbf{k},t) = a(\mathbf{k}) e^{\imath kct} + b(\mathbf{k}) e^{-\imath kct} \ ,$$

where $a(\mathbf{k})$ and $b(\mathbf{k})$ are arbitrary functions of $\mathbf{k}$. Thus, the general solution for f is given by,

$$f(\mathbf{r},t) = \int a(\mathbf{k}) e^{\imath \mathbf{k}\cdot\mathbf{r} + \imath kct} d^3k + \int b(\mathbf{k}) e^{\imath \mathbf{k}\cdot\mathbf{r} - \imath kct} d^3k \ .$$

Since f is a real quantity, $f(\mathbf{r},t)^* = f(\mathbf{r},t)$, we must have,

$$a(-\mathbf{k})^* = b(\mathbf{k}) \ ,$$

and,

$$f(\mathbf{r},t) = \mathfrak{Re} \left[\int 2b(\mathbf{k}) e^{\imath \mathbf{k}\cdot\mathbf{r} - \imath kct} d^3k \right] \ .$$

The scalar functions $e^{\imath \mathbf{k}\cdot\mathbf{r} - \imath kct}$ satisfy the wave equation for all $\mathbf{k}$.

Waves of vector quantities must be characterized by a *polarization vector* $\hat{\epsilon} \equiv \mathbf{b}/b$. Therefore, we define,

$$\vec{\mathcal{E}} = \mathfrak{Re}\ \vec{\tilde{\mathcal{E}}} \qquad \text{with} \qquad \vec{\tilde{\mathcal{E}}}(\mathbf{r},t) = \hat{\epsilon}\mathcal{E}_0 e^{\imath \mathbf{k}\cdot\mathbf{r} - \imath kct} \ , \tag{18.5}$$

where $\mathcal{E}_0$ is real and $\omega \equiv kc$, as the vector functions forming the functional basis for the fields. These functions represent plane waves, because on a wavefront, the value of $\vec{\tilde{\mathcal{E}}}(\mathbf{r},t)$ is fixed, and this occurs only when $e^{\imath \mathbf{k}\cdot\mathbf{r} - \imath kct}$ is constant [2].

[2] We shall see later that, when a wave passes through zones with different propagation velocities v, the amplitude $\mathbf{A}$ and the polarization $\hat{\epsilon}$ may change. However, any change must be such that $\tilde{\mathbf{F}}(z_0,t)$ and the derivative $\tilde{\mathbf{F}}'(z_0,t)$ are continuous at the transition point z_0.

To calculate the magnetic field from the complex representation of the electric field, we write first,

$$\vec{\mathcal{B}} = \mathfrak{Re}\ \vec{\tilde{\mathcal{B}}} \qquad \text{with} \qquad \vec{\tilde{\mathcal{B}}}(\mathbf{r},t) = \hat{\epsilon}'\mathcal{B}_0 e^{\imath\mathbf{k}'\cdot\mathbf{r}-\imath k' ct}\ , \tag{18.6}$$

where $\vec{\tilde{\mathcal{B}}}$ is the magnetic plane wave, since both $\vec{\tilde{\mathcal{E}}}$ as well as $\vec{\tilde{\mathcal{B}}}$ satisfy the same wave equation. With Maxwell's equations in the absence of sources, it is obvious that,

$$\mathbf{k} = \mathbf{k}'\ , \tag{18.7}$$

because the equations that couple $\vec{\tilde{\mathcal{E}}}$ and $\vec{\tilde{\mathcal{B}}}$ must be satisfied at every point of space and at every instant of time.

18.1.1 Helmholtz's equation

Electromagnetic waves differ from classical longitudinal or transverse waves in several aspects. For example, they do not require a propagation medium, but move through the vacuum at extremely high speed. Being exactly $c = 299792458$ m/s the speed of light is so high, that the laws of classical mechanics are no longer valid. And because there is no propagation medium, in vacuum all inertial systems are equivalent, and this will have important consequences for the Doppler effect. We will show that the electromagnetic wave equation almost comes out as a corollary of the theory of special relativity.

We have shown in Sec. 5.1 how the periodic conversion between kinetic and potential energy in a pendulum can propagate in space, when the pendulum is coupled to other pendulums hung in an array, and that this model explains the propagation of a pulse along a string. We also discussed, how electric and magnetic energy can be interconverted in an electronic *L-C* circuit constiting of a capacitor (storing electrical energy) and an inductance (a coil storing magnetic energy). The law of electrodynamics describing the transformation of electric field variations into magnetic energy is *Ampère's law*, and the law describing the transformation of magnetic field variations into electric energy is *Faraday's law*,

$$\frac{\partial\vec{\mathcal{E}}}{\partial t} \curvearrowright \vec{\mathcal{B}}(t) \qquad , \qquad \frac{\partial\vec{\mathcal{B}}}{\partial t} \curvearrowright -\vec{\mathcal{E}}(t)\ . \tag{18.8}$$

Extending the *L-C* circuit to an array, it is possible to show that the electromagnetic oscillation propagates along the array. This model describes well the propagation of electromagnetic energy along a coaxial cable or the propagation of light in free space.

The *electrical energy* stored in the capacitor and the *magnetic energy* stored in the coil are given by,

$$E_{ele} = \tfrac{\varepsilon_0}{2}|\vec{\mathcal{E}}|^2 \qquad , \qquad E_{mag} = \tfrac{1}{2\mu_0}|\vec{\mathcal{B}}|^2\ , \tag{18.9}$$

where the constants $\varepsilon_0 = 8.854\cdot 10^{-12}$ As/Vm and $\mu_0 = 4\pi\cdot 10^{-7}$ Vs/Am are called *vacuum permittivity* and *vacuum permeability*. The constant $Z_0 \equiv \sqrt{\mu_0/\varepsilon_0}$ is called *vacuum impedance*.

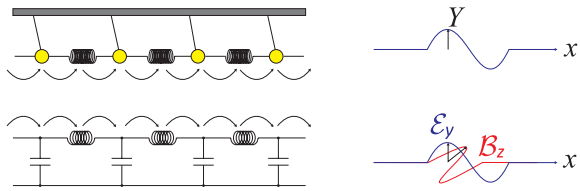

Figure 18.1: Analogy between propagation of mechanical waves (above) and electromagnetic waves (below).

From Maxwell's equations in free space,

$$\nabla \times \vec{\mathcal{B}} - \varepsilon_0 \mu_0 \partial_t \vec{\mathcal{E}} = 0 \qquad \text{and} \qquad \nabla \times \vec{\mathcal{E}} + \partial_t \vec{\mathcal{B}} = 0 \ , \tag{18.10}$$

deriving the first and inserting this into the second, and using the fact that the divergences vanish,

$$\frac{1}{c^2}\frac{\partial^2 \vec{\mathcal{E}}}{\partial t^2} = \frac{1}{\varepsilon_0 \mu_0 c^2}\frac{\partial}{\partial t}\nabla \times \vec{\mathcal{B}} = -\nabla \times (\nabla \times \vec{\mathcal{E}}) = -\nabla(\nabla \cdot \vec{\mathcal{E}}) + \nabla^2 \vec{\mathcal{E}} = \nabla^2 \vec{\mathcal{E}} \tag{18.11}$$

$$\frac{1}{c^2}\frac{\partial^2 \vec{\mathcal{B}}}{\partial t^2} = -\frac{1}{c^2}\frac{\partial}{\partial t}\nabla \times \vec{\mathcal{E}} = -\frac{1}{\varepsilon_0 \mu_0 c^2}\nabla \times (\nabla \times \vec{\mathcal{B}}) = -\nabla(\nabla \cdot \vec{\mathcal{B}}) + \nabla^2 \vec{\mathcal{B}} = \nabla^2 \vec{\mathcal{B}} \ .$$

These are the homogeneous *Helmholtz equations*. We will check in Exc. 18.1.8.2, that

- electromagnetic waves (in free space) are transverse;
- the amplitude of the electric field, the magnetic field, and the direction of propagation are orthogonal;
- the propagation velocity is the speed of light, because $c^2 = 1/\varepsilon_0 \mu_0$.

18.1.2 The polarization of light

A consequence of the requirement, $\nabla \cdot \vec{\mathcal{E}} = 0 = \nabla \cdot \vec{\mathcal{B}}$, following from Maxwell's equations in vacuum is, that the electromagnetic waves are transverse with orthogonal electric and magnetic fields. This is easy to see in the case of plane wave:

$$0 = \nabla \cdot \vec{\mathcal{E}} = \vec{\mathcal{E}}_0 \cdot \nabla e^{\imath(\mathbf{k}\cdot\mathbf{r}-\omega t)} = \imath \vec{\mathcal{E}}_0 \cdot \mathbf{k} e^{\imath(\mathbf{k}\cdot\mathbf{r}-\omega t)} \ , \tag{18.12}$$

and analogously for $\vec{\mathcal{B}}$. We conclude,

$$\boxed{\mathbf{k} \cdot \vec{\mathcal{E}} = 0 = \mathbf{k} \cdot \vec{\mathcal{B}}} \ . \tag{18.13}$$

In addition, from Faraday's law,

$$\vec{\mathcal{B}}_0 \ \imath\omega e^{\imath(\mathbf{k}\cdot\mathbf{r}-\omega t)} = -\frac{\partial \vec{\mathcal{B}}}{\partial t} = \nabla \times \vec{\mathcal{E}} = -\vec{\mathcal{E}}_0 \times \nabla e^{\imath(\mathbf{k}\cdot\mathbf{r}-\omega t)} = -\vec{\mathcal{E}}_0 \times \imath \mathbf{k} e^{\imath(\mathbf{k}\cdot\mathbf{r}-\omega t)} \ . \tag{18.14}$$

together with an analogous result obtained from Ampère-Maxwell's law, we can summarize,

$$\boxed{\vec{\mathcal{B}} = \tfrac{\mathbf{k}}{\omega} \times \vec{\mathcal{E}} \qquad \text{and} \qquad \vec{\mathcal{E}} = -\tfrac{c^2 \mathbf{k}}{\omega} \times \vec{\mathcal{B}}} \ . \tag{18.15}$$

We conclude that the fields $\vec{\mathcal{E}}$ and $\vec{\mathcal{B}}$ and the propagation wavevector are all mutually orthogonal for waves in free space. In the Excs. 18.1.8.3 and 18.1.8.4 we study the polarization of light.

Example 94 (*Circular polarization*): Let us study the example of polarized light,

$$\vec{\tilde{\mathcal{E}}} = (\mathcal{E}_x \hat{\mathbf{e}}_x + \imath \mathcal{E}_y \hat{\mathbf{e}}_y) e^{\imath k_z z - \imath \omega t} \ .$$

If $\mathcal{E}_x = \mathcal{E}_y$, we have circular polarization. If $\mathcal{E}_x \neq \mathcal{E}_y$, the polarization is said to be elliptical. The reason is easily seen by taking the real part of the plane wave:

$$\vec{\mathcal{E}} = \mathfrak{Re}\ \vec{\tilde{\mathcal{E}}} = \mathcal{E}_x \hat{\mathbf{e}}_x \cos(k_z z - \omega t) - \mathcal{E}_y \hat{\mathbf{e}}_y \sin(k_z z - \omega t) \ .$$

In the plane defined by $z = z_0$, with z_0 constant, the electric field vector describes an ellipse as time passes; the ellipse is a circle if $\mathcal{E}_x = \mathcal{E}_y$.
Other polarizations are possible in free space although sometimes a bit more difficult to realize in practice, for example, radial polarization,

$$\vec{\tilde{\mathcal{E}}} = \mathcal{E}_0 \hat{\mathbf{e}}_r e^{\imath k_z z - \imath \omega t} \qquad \text{and} \qquad \vec{\tilde{\mathcal{B}}} = \mathcal{B}_0 \hat{\mathbf{e}}_\theta e^{\imath k_z z - \imath \omega t} \ .$$

18.1.2.1 Polarization optics

A laser generally has a well-defined polarization, for example, linear or circular. The polarizations can be transformed into each other through *birefringent optical elements*, such as birefringent waveplates, Fresnel rhombs, or electro-optical modulators. Superpositions of different polarizations can be separated with polarizing *beam splitters*.

It is important to distinguish between the *polarization*, which is always specified in relation to a fixed coordinate system, and *helicity*, i.e. the rotation direction of the polarization vector with respect to the propagation direction of the light beam. The polarization of a beam propagating in z-direction can easily be expressed by a vector of complex amplitude,

$$\vec{\mathcal{E}}(\mathbf{r}, t) = \begin{pmatrix} a \\ b \\ 0 \end{pmatrix} e^{\imath \mathbf{k}\cdot\mathbf{r} - \imath\omega t} = \begin{pmatrix} 1 \\ e^{-\imath\phi}|b|/|a| \\ 0 \end{pmatrix} |a| e^{\imath \mathbf{k}\cdot\mathbf{r} - \imath\omega t} \ . \tag{18.16}$$

The angle $\phi = \arctan \frac{\mathfrak{Im}\ ab^*}{\mathfrak{Re}\ ab^*}$ determines the polarization of the light beam. The polarization is linear for $\phi = 0$ and circular for $\phi = \pi/2$. $|b|/|a|$ then gives the degree of ellipticity. A device rotating the (linear) polarization of a light beam (e.g. a sugar solution) is described by the so-called *Jones matrix* (we restrict ourselves to the xy-plane orthogonal to the propagation direction),

$$M_{rotator}(\phi) = \begin{pmatrix} \cos\phi & \sin\phi \\ -\sin\phi & \cos\phi \end{pmatrix} \ , \tag{18.17}$$

where ϕ is the angle of rotation. For birefringent half-waveplates the rotation angle is independent on the propagation direction. In devices called *Faraday rotators*, in

contrast, the sign of the rotation angle depends on the propagation direction of the laser beam,

$$M_{Faraday}(\phi) = \begin{pmatrix} \cos\phi & \mathbf{k}\cdot\hat{\mathbf{e}}_z \sin\phi \\ -\mathbf{k}\cdot\hat{\mathbf{e}}_z \sin\phi & \cos\phi \end{pmatrix} , \tag{18.18}$$

A *polarizer* projects the polarization to a specific axis. In case of a polarizer aligned to the x-axis the Jones matrix is,

$$M_{polarizer} = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix} , \tag{18.19}$$

while for an arbitrary axis given by the angle ϕ, it is,

$$M_{polarizer}(\phi) = \begin{pmatrix} \cos\phi & \sin\phi \\ -\sin\phi & \cos\phi \end{pmatrix} \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix} \begin{pmatrix} \cos\phi & \sin\phi \\ -\sin\phi & \cos\phi \end{pmatrix}^{-1} . \tag{18.20}$$

A birefringent crystal acts only on one of the two optical axes. Assuming that only the y-axis is optically active, its Jones's matrix is,

$$M_{\theta\text{-waveplate}} = \begin{pmatrix} 1 & 0 \\ 0 & e^{\imath\theta} \end{pmatrix} . \tag{18.21}$$

For $\theta = 2\pi/n$ we obtain a so-called λ/n-*waveplate*. When we rotate the waveplate (and therefore the optically active about the inactive axis) by an angle ϕ, the Jones matrix becomes [3],

$$\begin{aligned} M_{\theta\text{-waveplate}}(\phi) &= \begin{pmatrix} \cos\phi & \sin\phi \\ -\sin\phi & \cos\phi \end{pmatrix} \begin{pmatrix} 1 & 0 \\ 0 & e^{\imath\theta} \end{pmatrix} \begin{pmatrix} \cos\phi & \sin\phi \\ -\sin\phi & \cos\phi \end{pmatrix}^{-1} \\ &= \begin{pmatrix} \cos^2\phi + e^{\imath\theta}\sin^2\phi & -\sin\phi\cos\phi + e^{\imath\theta}\sin\phi\cos\phi \\ -\sin\phi\cos\phi + e^{\imath\theta}\sin\phi\cos\phi & \sin^2\phi + e^{\imath\theta}\cos^2\phi \end{pmatrix} . \end{aligned} \tag{18.22}$$

We use in most cases $\lambda/4$-waveplates,

$$M_{\lambda/4}(\phi) = \begin{pmatrix} \cos^2\phi + \imath\sin^2\phi & (-1+\imath)\sin\phi\cos\phi \\ (-1+\imath)\sin\phi\cos\phi & \sin^2\phi + \imath\cos^2\phi \end{pmatrix} \tag{18.23}$$

or $\lambda/2$-waveplates,

$$M_{\lambda/2}(\phi) = \begin{pmatrix} \cos 2\phi & -\sin 2\phi \\ -\sin 2\phi & -\cos 2\phi \end{pmatrix} . \tag{18.24}$$

Note that interestingly $M_{\lambda/2}(\phi)^2 = \mathbb{I}$.

[3] See script on *Optical spectroscopy* (2020), Sec. 2.3.1.

Example 95 (*Generating circular polarization*): We can use $\lambda/4$-waveplates to create, from linearly polarized light, circularly polarized light. Choosing an angle $\theta = 45^\circ$ we get from (18.23),

$$M_{\lambda/4}(\pm\pi/4)\begin{pmatrix}1\\0\end{pmatrix} = \begin{pmatrix}\frac{1}{2}+\frac{1}{2}\imath & \mp\frac{1}{2}\pm\frac{1}{2}\imath\\ \mp\frac{1}{2}\pm\frac{1}{2}\imath & \frac{1}{2}+\frac{1}{2}\imath\end{pmatrix}\begin{pmatrix}1\\0\end{pmatrix} = \frac{e^{\imath\pi/4}}{\sqrt{2}}\begin{pmatrix}1\\\pm\imath\end{pmatrix} .$$

Example 96 (*Polarization behavior of upon reflection from a mirror*): A light beam reflected from a mirror under normal incidence does not changes its polarization vector, but only its wavevector. This can be interpreted as conservation of the angular momentum of light upon reflection. One consequence of this is, that $\sigma^\pm$ light turns into $\sigma^\pm$ light upon reflection.

Example 97 (*Action of birefringent waveplates as a function of propagation direction*): The Jones matrices for λ/n-waveplates *do not depend* on the propagation direction, simply because the wavevector does not appear in the expressions. That is, the polarization $\hat{\epsilon} = \hat{\mathbf{e}}_x$ of a beam propagating towards $\pm k\hat{\mathbf{e}}_z$ is transformed by a $M_{\lambda/4}(\pi/4)$ waveplate into σ^+-polarized light regardless of the propagation direction. A consequence of this is that a beam traversing the waveplate $M_{\lambda/4}(\pi/4)$ twice in the round-trip (e.g. being reflected by a mirror) will undergo a rotation of amplitude by 90°,

$$M_{\lambda/4}(\tfrac{\pi}{2})\begin{pmatrix}1\\0\end{pmatrix} = \begin{pmatrix}\imath\\0\end{pmatrix}$$
$$M_{\lambda/4}(\tfrac{\pi}{4})M_{\lambda/4}(\tfrac{\pi}{4}) = \begin{pmatrix}0 & -1\\-1 & 0\end{pmatrix} .$$

This feature is often used to separate counterpropagating light fields via a polarizing beamsplitter.
On the other hand, for $\lambda/2$-waveplates, it is easy to check the following results,

$$M_{\lambda/2}(\tfrac{\pi}{4})\begin{pmatrix}1\\0\end{pmatrix} = \begin{pmatrix}0\\-1\end{pmatrix}$$
$$M_{\lambda/2}(\tfrac{\pi}{8})\begin{pmatrix}1\\0\end{pmatrix} = \tfrac{1}{\sqrt{2}}\begin{pmatrix}1\\-1\end{pmatrix} .$$

In addition, for any ϕ,

$$M_{\lambda/2}(\phi)M_{\lambda/2}(\phi) = \begin{pmatrix}1 & 0\\0 & 1\end{pmatrix} .$$

Thus, the double passage through a $\lambda/2$-waveplate cancels its effect.

18.1.3 The energy density and flow in plane waves

The energy densities stored in the electric field and the magnetic field are given by,

$$u_{ele} = \tfrac{\varepsilon_0}{2}|\vec{\mathcal{E}}|^2 \quad , \quad u_{mag} = \tfrac{1}{2\mu_0}|\vec{\mathcal{B}}|^2 \ . \tag{18.25}$$

In the case of a monochromatic wave parametrized by $\vec{\mathcal{E}}(\mathbf{r},t) = \vec{\mathcal{E}}_0\cos(\mathbf{k}\cdot\mathbf{r}-\omega t)$ the calculus (18.15) shows that $|\vec{\mathcal{B}}| = \frac{k}{\omega}|\vec{\mathcal{E}}| = \frac{1}{c}|\vec{\mathcal{E}}|$, such that the average energy density is,

$$\langle u(\mathbf{r})\rangle = \left\langle |\varepsilon_0\vec{\mathcal{E}}_0\cos(\mathbf{k}\cdot\mathbf{r}-\omega t)|^2 \right\rangle = \tfrac{1}{2}\varepsilon_0|\vec{\mathcal{E}}_0|^2 = \tfrac{1}{2\mu_0}|\vec{\mathcal{B}}_0|^2 \ , \tag{18.26}$$

consistent with the expressions (17.58). When the wave propagates, it carries with it this amount of energy. The energy flux density is calculated by the *Poynting vector*,

$$\langle\vec{\mathcal{S}}(\mathbf{r})\rangle = \tfrac{1}{\mu_0}\left\langle \vec{\mathcal{E}}(\mathbf{r},t)\times\vec{\mathcal{B}}(\mathbf{r},t)\right\rangle = \tfrac{1}{2}c\varepsilon_0|\vec{\mathcal{E}}_0|^2\hat{\mathbf{e}}_k \ . \tag{18.27}$$

The absolute value is the *intensity* of the light field,

$$\langle I(\mathbf{r},t)\rangle = \langle|\vec{\mathcal{S}}(\mathbf{r},t)|\rangle \ . \tag{18.28}$$

In addition, a radiation field can have linear momentum. In vacuum, the momentum is connected to the Poynting vector,

$$\langle\wp\rangle = \left\langle c\varepsilon_0|\vec{\mathcal{E}}(\mathbf{r},t)|^2\hat{\mathbf{e}}_k\right\rangle = c\varepsilon_0|\vec{\mathcal{E}}_0|^2\hat{\mathbf{e}}_k \ . \tag{18.29}$$

but in dielectric media things are different, as we will see later. The *momentum density* is responsible for the *radiation pressure*. When light hits the surface A of a perfect absorber, it transfers, during the time interval Δt, the momentum $\Delta\mathbf{p} = \langle\wp\rangle Ac\Delta t$ to the body. Thus, the pressure is,

$$P = \frac{1}{A}\frac{\Delta p}{\Delta t} = \frac{\varepsilon_0\mathcal{E}_0^2}{2} = \frac{I}{c} \ . \tag{18.30}$$

Note that for a perfect reflector the pressure is doubled.

In Exc. 18.1.8.5 we show a trick how to quickly calculate the temporal average of expressions containing products of oscillating field. We solve problems about the radiative pressure in Excs. 18.1.8.6 to 18.1.8.8. In the Excs. 18.1.8.10 to 18.1.8.12 we calculate u and $\vec{\mathcal{S}}$ for various types of waves.

18.1.3.1 Spherical waves

Other wave geometries are possible (see Exc. 18.1.8.13). For example, it is easy to show that spherical scalar fields of the type $\Phi(\mathbf{r},t) = \Phi_0\frac{e^{\imath(kr-\omega t)}}{r}$ and spherical vector fields of the type $\mathbf{A}(\mathbf{r},t) = \mathbf{A}_0\frac{e^{\imath(kr-\omega t)}}{r}$ satisfy the wave equation,

$$\begin{aligned} 0 &= \nabla^2\Phi - \frac{1}{c^2}\frac{\partial^2\Phi}{\partial t^2} \\ &= \frac{1}{r^2}\frac{\partial}{\partial r}\left(r^2\frac{\partial\Phi}{\partial r}\right) + \cancel{\frac{1}{r^2\sin\theta}\frac{\partial}{\partial\theta}\left(\sin\theta\frac{\partial\Phi}{\partial\theta}\right)}^{0} + \cancel{\frac{1}{r^2\sin^2\theta}\frac{\partial^2\Phi}{\partial\phi^2}}^{0} - \frac{1}{c^2}\frac{\partial^2\Phi}{\partial t^2} \\ &= -k^2\Phi + \frac{\omega^2}{c^2}\Phi \ . \end{aligned} \tag{18.31}$$

This also applies to electric and magnetic fields,

$$\vec{\mathcal{E}}(\mathbf{r},t) \stackrel{?}{=} \vec{\mathcal{E}}_0 \frac{e^{\imath(kr-\omega t)}}{r} \qquad \text{and} \qquad \vec{\mathcal{B}}(\mathbf{r},t) \stackrel{?}{=} \vec{\mathcal{B}}_0 \frac{e^{\imath(kr-\omega t)}}{r} \ . \tag{18.32}$$

But it does not mean that these fields obey Maxwell's equations. In fact, the simplest possible spherical wave corresponds a the dipole radiation, which will be discussed in the next chapter. We will find in Exc. 19.1.6.3 that the expressions for electric dipole radiation satisfy Maxwell's equations and in Exc. 18.1.8.14, that the expressions (18.32) do not satisfy them. In Excs. 18.1.8.15 and 18.1.8.16 we will deepen this discussion.

18.1.4 Slowly varying envelope approximation

The slowly varying envelope approximation [42] (SVEA) is the assumption that the envelope of a forward-traveling wave pulse varies slowly in time and space compared to a period or wavelength. This requires the spectrum of the signal to be narrow-banded. The SVEA is often used because the resulting equations are in many cases easier to solve than the original equations, reducing the order of all (or some) of the highest-order partial derivatives. But the validity of the assumptions which are made need to be justified.

For example, consider the electromagnetic wave equation:

$$\nabla^2 \mathcal{E} - \mu_0 \varepsilon_0 \frac{\partial^2 \mathcal{E}}{\partial t^2} = 0 \ . \tag{18.33}$$

If k_0 and ω_0 are the wave number and angular frequency of the (characteristic) carrier wave for the signal $\mathcal{E}(\mathbf{r},t)$, the following representation is useful:

$$\mathcal{E}(\mathbf{r},t) = \mathfrak{Re}\left[\mathcal{E}_0(\mathbf{r},t) e^{\imath(\mathbf{k}_0\cdot\mathbf{r}-\omega_0 t)}\right] \ . \tag{18.34}$$

In the SVEA it is assumed that the complex amplitude $\mathcal{E}_0(\mathbf{r},t)$ only varies slowly with $\mathbf{r}$ and t. This inherently implies that $\mathcal{E}_0(\mathbf{r},t)$ represents waves propagating forward, predominantly in the $\mathbf{k}_0$ direction. As a result of the slow variation of $\mathcal{E}_0(\mathbf{r},t)$, when taking derivatives, the highest-order derivatives may be neglected [220]:

$$|\nabla^2 \mathcal{E}_0| \ll |\mathbf{k}_0 \cdot \nabla \mathcal{E}_0| \qquad \text{and} \qquad \left|\frac{\partial^2 \mathcal{E}_0}{\partial t^2}\right| \ll \left|\omega_0 \frac{\partial \mathcal{E}_0}{\partial t}\right| \ . \tag{18.35}$$

Consequently, the wave equation is approximated in the SVEA as,
